Results: Glomerular Gd-IgA1 deposition was detected in all cases of IgAN (n=17/17) and IgAV-N (n=6/6), and in patients with immunocomplex-mediated glomerulonephritis, including lupus nephritis (n=9/9), membranoproliferative glomerulonephritis (n=3/4), and membranous nephropathy (n=1/1). However, Gd-IgA1 was negative in patients with non-immune related glomerular diseases with IgA deposition, including idiopathic nephrotic syndrome (n=6/6), oligomeganephropenia (n=2/2), Alport syndrome (n=1/1), dense deposit disease (n=1/1), and crescentic glomerulonephritis (n=1/1). Both IgA and Gd-IgA1 were negative in patients with idiopathic nephrotic syndrome (n=5/5), membranoproliferative glomerulonephritis, membranous nephropathy, oligomeganephropenia, Alport syndrome, C3 glomerulonephritis, poststreptococcal acute glomerulonephritis, and hemolytic urmic syndrome (n=1/1 each).

Conclusions: Gd-IgA1 positivity in patients with IgAN and IgAV-N was consistent with previous reportings. However, Gd-IgA1 was also positive in patients with IgA-positive immunocomplex-mediated glomerulonephritis. KM55 may have the potential to distinguish incidental IgA deposition in pediatric cases. We speculate that Gd-IgA1 may be involved in the pathogenesis of these immune-related diseases, or KM55 may recognize IgA-related immunocomplex non-specifically.

PO1846
Urinary Exosomal MicroRNAs Are Potential Diagnostic and Prognostic Biomarkers in IgA Nephropathy Patients
Kyungohan Jeong, Jin Sug Kim, Hyeon Seok Hwang, Ji Yoon Kong, Shinyaegong Kang, Ji Ra Yang, Yun Kim, Ju Young Moon, Sanghee Lim. Division of Nephrology, Department of Internal Medicine, College of Medicine, Kyung Hee University, Seoul, Republic of Korea.

Background: Micro-RNAs (miRNAs) are small non-coding RNA molecules which regulate disease pathophysiology by modulating target gene expression. miRNAs are derived from tissues and biofluids such as serum, saliva, and urine. Recently, emerging evidence suggests urinary exosomal miRNAs as non-invasive biomarkers of various kidney diseases. However, few studies investigated clinical relevance of miRNA in IgA nephropathy (IgAN). In this study, we evaluated urinary exosomal miRNA expression and analyzed its clinical significance in patients with IgAN.

Methods: Urine samples were collected from 93 patients with biopsy-proven IgAN and 14 normal controls. We identified mRNA differential expression of renal tissue between IgAN and normal subjects in the gene expression omnibus database, and selected 884 glomerular and 67 tubulointerstitial genes through meta-analysis. We then used the miRtarBase, TargetScan, micorRNA database to predict potential miRNA targets. Finally, 11 urinary exosomal miRNAs were selected. We observed urinary exosomal expression of miRNAs and analyzed their diagnostic and prognostic accuracy for IgAN.

Results: The expression of miR-16-5p, miR-26b-3p, miR-29a-3p, miR-29c-3p, miR-126-3p, miR-199a-3p, miR-615-3p, and miR-29b-3p were significantly upregulated in IgAN patients as compared with normal controls. miR-16-5p, miR-26b-3p, miR-29a-3p, miR-29c-3p, miR-126-3p, miR-199a-3p, and miR-29b-3p have good diagnostic accuracy for IgAN (area under curve of receiver operating characteristic curve > 0.8). Baseline renal function significantly correlated with miR-16-5p, miR-29a-3p, miR-199a-3p, miR-199b-5p, miR-335-3p, and miR-615-3p. During follow-up period, 43 (46.2%) IgAN patients experienced adverse renal outcomes defined as a greater than 25% reduction in estimated glomerular filtration rate (eGFR), decline in eGFR category from the value determined at the time of renal biopsy, or start renal replacement therapy. miR-16-5p, miR-29a-3p, miR-199a-3p, and miR-335-3p were independently associated with increased risk of adverse renal outcomes.

Conclusions: Urinary exosomal miRNAs might be potential non-invasive biomarkers for diagnosis and prediction of disease progression of IgAN. Further studies are needed to clarify our results and ascertain the underlying mechanisms.

PO1847
Urinary Sediments Could Differentiate the Endocapillary Proliferative Lupus Nephritis and Endocapillary Proliferative IgA Nephropathy
Mo Yuan, Ying Tan. Institute of Nephrology, Peking University, Beijing, China.

Background: The role of manual urine sediment examination in the diagnosis and prognostication of endocapillary proliferative glomerulonephritis remains to be elucidated. This study aims to investigate the differences of urinary sediment findings between lupus nephritis and IgA nephropathy with endocapillary proliferative glomerulonephritis and further evaluated associations of leukocyturia with disease activity, pathological features and prognosis.

Methods: The urinary sediments of 126 patients, including 92 patients with lupus nephritis and 34 patients with IgA nephropathy with a renal biopsy-proven endocapillary proliferative glomerulonephritis were examined in the morning before renal biopsy according to a standardized method. The urinary elements investigated including various cells, casts and crystals. The associations of the level of leukocyturia and disease activity, pathological features and prognosis were further analyzed.

Results: In the patients with endocapillary proliferative glomerulonephritis, normal to mild leukocyturia (<12 HPF), and moderate to severe leukocyturia (>12 HPF) were found in 52(41.27%) and 74 (58.73%) patients, respectively. The proportion of moderate to severe leukocyturia, the frequency of urinary white blood cells casts and waxy casts were significantly higher in endocapillary proliferative lupus nephritis patients compared with endocapillary proliferative IgA nephropathy patients (P<0.001, P=0.020, P=0.010, respectively). In the proliferative lupus nephritis group, the levels of leukocyturia was significantly correlated with serum creatinine (r=0.288, P=0.005), eGFR (r=−0.284, P=0.006), serum C3 (r=−0.275, P=0.009), SLEDAI scores (r=0.383, P<0.001) and glomerular leukocyte infiltration (r=0.285, P=0.002). A multivariate analysis showed that leukocyturia was identified as an independent risk factor for renal outcome in proliferative lupus nephritis (HR: 1.456, 95% CI: 1.083-1.957, P=0.013) but not in IgA nephropathy (HR: 1.069, 95% CI: 0.404-2.312, P=0.866).

Conclusions: Urinary sediments of the endocapillary proliferative lupus nephritis and endocapillary proliferative IgA nephropathy differed in many aspects. Leukocyturia and endocapillary proliferative IgA nephropathy with endocapillary proliferative glomerulonephritis differed in many aspects. Leukocyturia was identified as an independent risk factor for renal outcome in proliferative lupus nephritis.
A Single-Center Retrospective Study of Thrombotic Microangiopathy

Miguel Obrador, Joan S. Carter, Senthil Sukumar, Vedat O. Yildiz, Clarissa A. Cassol, Sergey V. Brodsky, Tibor Nadasy, Spero R. Cataland, Samir V. Parikh, The Ohio State University Wexner Medical Center, Columbus, OH.

Background: Thrombotic microangiopathies (TMAs) are a rare group of clotting disorders of various origin, including infectious, idiopathic, autoimmune or drug-induced. This group shares common clinical manifestations that include low red blood cell and platelet counts. Although the disease is rare but treatable if clinician is aware about its manifestations. To increase the awareness and understand the disease better we conducted a retrospective study to characterize and assess TMAs in our institution

Methods: An observational retrospective study of patients with a diagnosis of TMA at Westchester Medical Center in the past 5 years was conducted. Data was collected from electronic medical records. Demographic, clinical and therapeutic variables were extracted, tabulated and analyzed

Results: A total of 43 patients with a diagnosis of TMA were identified and included in the study. The cohort had a mean age of 39.9 years; 20 were male and 23 females. As shown in Table 1. Thrombotic thrombocytopenia purpura (TTP) (n=14, 32%), systemic lupus erythematosus (SLE) (n=5, 11.6%), and hemolytic uremic syndrome (HUS) (n=5, 11.6%) are the most common etiologies. Other identifiable etiologies were atypical HUS (9%), use of calcineurin inhibitors (9%), acute myeloid leukemia (4.6%). About 6.9% cases didn’t have any identifiable cause (6.9%). Patients with TTP had a mean age of 48 years, mean platelet count of 17 k/mm3, and most were female (71%). Fifty-seven percent had hematuria, 21% proteinuria and 85% had schistocytes in the blood smear.

Conclusions: Most common cause of Thrombotic Microangiopathies is TTP which is what we found in our institution. It is essential to aware about the manifestation of this disease since early recognition and prompt treatment is the key for better outcome

Does Kidney Histology Predict Renal Response or Complement Status in Atypical Hemolytic Uremic Syndrome?

Jessamyn S. Carter, Senthil Sukumar, Vedat O. Yildiz, Clarissa A. Cassol, Sergey V. Brodsky, Tibor Nadasy, Spero R. Cataland, Samir V. Parikh, The Ohio State University Wexner Medical Center, Columbus, OH.

Background: Atypical Hemolytic Uremic Syndrome (aHUS) is diagnosed based on clinical evidence of microangiopathic hemolytic anemia, thrombocytopenia and renal failure and histologic evidence of thrombotic microangiopathy (TMA). However, these characteristics are not specific and cannot differentiate aHUS from other causes. Whether specific histologic lesions of TMA can predict complement mutation status (CM +/-), guide treatment, or predict renal outcomes has not been explored. Here, we evaluate the potential of using kidney histology to predict CM status and renal response in aHUS.

Methods: A retrospective analysis of aHUS patients (N=35) who achieved a hematologic response after treatment with anti-C5 therapy was conducted. Clinical and demographic data were recorded and two blinded Nephropathologists scored native kidney biopsy findings independently. Seventeen histologic lesions of TMA were scored.

Results: In this cohort, 13/29 (45%) were CM+. Of the 17 histologic variables studied, only glomerular intracapillary fibrin differentiated CM+ from CM- (P<0.05), suggesting that histologic features were also similar between patients who achieved renal response (RR) and non-responders (NR). Although not statistically significant, NR had a higher percentage of global glomerulosclerosis (38 vs 16%, P=0.07) and concentric fibros intimal thickening (onion skinning) (70% vs 29%, P=0.08) compared to RR.

Conclusions: Glomerular intracapillary fibrin was the only histologic variable different in CM+ versus CM- TMA. When present, this variable may suggest patients with TMA will be CM-. Percentage of glomerulosclerosis and presence of fibros intimal thickening was higher in NR compared to RR but this did not reach statistical significance. A larger study is needed to determine the value of these features in predicting complement mutation status and renal response in aHUS.

PO1851

Comparative Efficacy of Ravaluzumab and Eculizumab in the Treatment of Atypical Hemolytic Uremic Syndrome: An Indirect Comparison Using Clinical Trial Data

Eric Rondeau,1 Anthony J. Hatswell,2 Spero R. Cataland,3 Peter Chen,4 Nicholas Freeman,5 Karl-Johan Myren,6 Asa Lommele,7 Yan Wang,8 Kevin Deighton,9 Emma Knowles,9 Neil S. Sheerin,9 Ioannis Tomazos,9 1Hospital Tenon, APHP and Sorbonne Université, Paris, France; 2Delta Hat Clinical Trial Data, London, United Kingdom; 3Newcastle University, Newcastle, United Kingdom; 4Ohio State University, Columbus, OH; 5Alexion Pharmaceuticals Inc., Boston, MA; 6University College London, London, United Kingdom; 7Newcastle University, Newcastle, United Kingdom.

Background: Atypical hemolytic uremic syndrome (aHUS) is a rare disease that can cause organ damage or death if not suitably treated. Eculizumab (EUC), a C5 inhibitor, was approved, to treat aHUS in 2011. Ravaluzumab (RAV), approved in 2019, was engineered from EUC to reduce dosing frequency (every 8 weeks [for patients weighing ≥ 20 kg] vs 1 week, respectively) and minimise treatment burden. Both drugs have established safety and efficacy via pivotal single armed studies. We indirectly compared the efficacy of RA V vs ECU using clinical trial data.

Methods: Patient-level data from a pivotal RAV trial (NCT02949128) and pivotal EUC trials (NCT00844428, NCT01194973) for adults with aHUS without kidney transplant were used. Propensity scores were calculated based on baseline characteristics of the ECU trials (NCT00844428, NCT01194973) for adults with aHUS without kidney transplant or acute dialysis program who showed neurologic damage. The mean cost per patient-year changed from 319,931 to 150,878 euros from the pre- to post-MDT period. The number of patients-dialysis or in kidney transplant program (KTx) and the milligrams of Eculizumab used at the pre-MDT implementation.

Results: After balancing patient characteristics between study groups, no significant differences were seen between outcomes for ECU and RAV at 26 weeks.

Conclusions: After balancing patient characteristics between study groups, no significant differences were seen between outcomes for ECU and RAV at 26 weeks.
C3 Inhibition with Pegcetacoplan Targets the Underlying Disease Process of C3 Glomerulopathy (C3G) and Improves Proteinuria

C3 Glomerulonephritis Associated with Monoclonal Gammopathy: A Process of C3 Glomerulopathy (C3G) and Improves Proteinuria

PO1854

The Prognostic Value of Chronic Histopathological Lesions in Monoclonal Immunoglobulin Deposition Disease: A Clinicopathological Analysis of Patients from a Single Institution

Zixuan Zhang, Wenling Ye, Xuemei Li. Peking Union Medical College Hospital, Dongcheng-qi, China.

Background: Kidney is the most common involved organ in monoclonal immunoglobulin deposition disease (MIDD), which could lead to end stage renal disease (ESRD). Few studies have evaluated the association between the irreversible chronic histopathologic lesions and clinical features, and its prognostic value in renal outcomes in MIDD.

Methods: A series of 20 patients with MIDD and 20 patients with renal AL amyloidosis proven by renal biopsy between January 2001 and December 2018 were reviewed retrospectively. The degree of chronic changes including glomerulosclerosis, interstitial fibrosis, and arteriosclerosis were semiquantitatively scored and the overall chronic lesions were also graded based on the grading system proposed in 2017. The association between histopathological lesion and clinical manifestations, and the correlation with risk of progression to ESRD were investigated.

Results: MIDD patients presented more significantly overt ischemia-related global glomerulosclerosis and a more severe tendency of interstitial fibrosis(Figure 1). The significantly higher extent of overall chronic changes was also seen in MIDD compared with AL amyloidosis, which was independently correlated with worse baseline estimated glomerular filtration rate (β coefficient (95% CI): -4.618(-8.238 to -0.999), P=0.017). And the overt interstitial fibrosis predicted the increased risk of developing ESRD in MIDD.

Conclusions: The extent of chronic changes provide information both about baseline manifestation and renal survival. Carefully grading and evaluating the chronic changes in MIDD may help guiding the treatment and accessing the renal outcomes.

Figure 1. Comparison of overt histopathological lesions between AL and MIDD at kidney biopsy

PO1855

Development of Atypical Hemolytic Uremic Syndrome in a Patient with Complement 3 Glomerulonephritis

Ravi V. Patel, Gauri Bhutani, Tripti Singh. University of Wisconsin-Madison, Madison, WI.

Introduction: Uncontrolled hyperactivity of alternative complement pathway has been implicated in development of two distinct pathological processes, namely C3 glomerulonephritis (C3GN) and atypical hemolytic uremic syndrome (aHUS). Here we present a unique case which initially started as C3GN on kidney biopsy and progressed to aHUS.

Case Description: 68-year-old female presented with progressive weakness and palpitations over a month. She denied any fever, chills, dysuria, chest pain, dyspepsia or abdominal pain. Her past medical history was significant for hypertension and coronary artery disease, with no family history of end stage renal disease. On admission, her medications included hydrochlorothiazide for hypertension, levothyroxine for hypothyroidism and intermittent steroids for gouty arthritis. On exam, her vital signs revealed tachycardia with heart rate 119 beats/min and hypotension with blood pressure 97/59 mmHg. Exam was significant for dry mucosa and irregular heart rate. Initial laboratory evaluation was significant for acute kidney injury (AKI), with creatinine (Cr) of 2.6 (baseline Cr of 1.2). Urinalysis demonstrated 21-50 RBC/hpf and urine protein/Cr of 12.5 g/g. A renal biopsy was performed which showed endocapillary proliferation with dominant staining for C3 in the mesangium and along the capillary wall, consistent with C3GN. The patient was started on prednisone 60 mg daily.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Hemodialysis was initiated for uremic symptoms. Complement function test was consistent with ongoing complement dysregulation at C3 convertase level and C5 convertase level without the presence of autoantibodies towards complement proteins. 2 months after her kidney biopsy, she developed worsening anemia and thrombocytopenia, elevated lactate dehydrogenase and undetectable haptoglobin. Direct coombs test was negative, peripheral smear showed schistocytes, ADAMTS13 level was 65%, consistent with diagnosis of atypical hemolytic uremic syndrome. Patient was started on Eculizumab therapy with stabilization of hemoglobin and platelets but remains dialysis dependent.

**Discussion:** In our growing understanding of alternative complement pathway, it is thought that dysregulation at fluid state is associated with C3GN, while solid state dysregulation is associated with widespread endothelial injury leading to aHUS. Our patient developed both pathologies, suggests further research is needed in understanding the details of complement system.

**PO1856**

**Acute Renal Failure from Thrombotic Microangiopathy: Is IgA Vasculitis to Blame?**

Dipal Patel.

Yale University School of Medicine, New Haven, CT.

**Introduction:** Thrombotic microangiopathy (TMA) has been associated with several cases of IgA nephropathy. In most cases the clinical significance of the TMA is uncertain. We describe a case of acute renal failure in a patient with systemic IgA vasculitis, who was found to have severe renal-limited TMA treated with eculizumab for the possibility of underlying complement dysregulation.

**Case Description:** A 34 year old male presented with abdominal pain and bloody bowel movements, and was found to have extensive duodenitis. Infectious testing of stools was negative, though he later tested positive for H. pylori. While hospitalized he developed acute kidney failure, with creatinine rising from 1.5 to 11.7 within four days. Urine sediment demonstrated granular casts consistent with acute tubular injury, though he also had white cell casts for which acute interstitial nephritis was considered. Blood counts were normal on admission, but he developed anemia and thrombocytopenia with mildly positive markers of hemolysis (haptoglobin 25, LDH 269, no schistocytes). Serum complements were profoundly low (C3 33, C4 9). A kidney biopsy revealed severe TMA. Given the rapidity of progression to renal failure requiring dialysis, he was started on eculizumab for a presumed atypical hemolytic uremic syndrome (aHUS). Since he did not have evidence of active hemolysis, he was not started on plasmapheresis. Kidney biopsy demonstrated proliferation and expansion of the mesangium with IgA deposition. Endoscopy was later performed with biopsy consistent with systemic IgA vasculitis, for which he was started on steroids. Abdominal symptoms improved and he was discharged home. He continues on eculizumab with normalization in complements, but without improvement in renal function.

**Discussion:** There have been case reports of complement factor dysregulation resulting in both IgA vasculitis and TMA. Given the extent and acuteness of renal failure in this case, we treated our patient with eculizumab for presumed aHUS.

**PO1857**

**Proliferative Glomerulonephritis with Monoclonal IgG Deposits (PGNMID): A Report of Two Cases Managed with Renin-Angiotensin-Soldosterone System (RAAS) Inhibition Alone**

Marianna Vyunnyk, Maria V. DeVita, Jordan L. Rosenstock. Lenox Hill Hospital, New York, NY.

**Introduction:** PGNMID is a relatively rare disorder with monoclonal immunoglobulins (Ig) deposition in glomeruli that resembles immune complex glomerulonephritis (GN), after exclusion of other related disorders such as amyloidosis and cryoglobulinemia. The pathogenesis and management of PGNMID remains uncertain, especially if no systemic clonal disorder is found, which is frequently the case. Some groups have recommended anti-plasma cell or anti-B cell therapy in most if not all cases, even if a clone is not identified. We present two cases of PGNMID that were managed with RAAS blockade alone and whose renal disease remained stable over 6 and 10 years of follow up.

**Case Description:** Two cases were identified who had prolonged follow up with PGNMID and no immunosuppressive treatment. Charts were reviewed retrospectively and data collected from time of biopsy until most recent follow up. Case 1 is a 25 year old obese black woman with recent onset of hypertension who presented with serum creatinine (sCr) 1.4mg/dl. Urinalysis (UA) showed 1+ protein and no blood. 24hr urine protein was 296mg. Renal biopsy (done as she had positive antiphospholipid antibodies) revealed PGNMID (IgG kappa) with diffuse mesangial proliferation and focal sclerosing GN with focal fibrous crescents. There was no evidence of thrombotic microangiopathy. Serum and urine immunofixation (IF) were negative for monoclonal protein. Bone marrow biopsy was unremarkable. The patient was treated with angiotensin-receptor blocker (ARB) without immunosuppressive therapy. Six years later the most recent sCr was 1.5mg/dl and urine protein-creatinine ratio (PCR) was 1100mg/g. Case 2 is a 41 year old white woman who presented with sCr 0.6mg/dl. UA had 3+ protein and no blood. 24hr urine protein was 2.3g. Renal biopsy showed PGNMID (IgG kappa) with mesangial and endocapillary proliferation. Serum and urine IF were negative for monoclonal proteins. Bone marrow biopsy was not done. The patient was treated with an angiotensin-converting enzyme inhibitor (ACEI) alone. After ten years of follow up, her sCr was 0.7mg/dl, and urine PCR was 0.2mg/g.

**Discussion:** We report 2 cases of PGNMID with stable renal function and proteinuria after 6 and 10 years of RAAS therapy alone. This suggests that not all patients with PGNMID may require immunosuppression.

**PO1858**

**Use of Proneur-Treated Paraffin Immunofluorescence to Unmask a Reclusive Glomerular Disease**

Phuong Truong,1 Anna Ilaha,1 Rama Nadella,1 Diana Mahbod,1 Christopher P. Larsen,2 Irfan Agha.1 Dallas Renal Group, Dallas, TX; ‘Arkana Laboratories, Little Rock, AR.

**Introduction:** Interpretation of renal biopsy depends on light, IF and electron microscopy. Direct IF on unfixed frozen tissue sometimes fails to pick up immunoglobulins. Treatment of paraffin embedded formalin-fixed tissue with pronase renders such Igs more amenable to detection. We present a case of a young woman where use of this “unmasking” technique allowed the correct diagnosis to be made.

**Case Description:** A 24 YO WF presented to our Gn Clinic with intermittent edema, IF and electron microscopy. Direct IF on unfixed tissue sometimes fails to pick up immunoglobulins. Treatment of paraffin embedded formalin-fixed tissue with pronase renders such Igs more amenable to detection. We present a case of a young woman where use of this “unmasking” technique allowed the correct diagnosis to be made.

**Discussion:** A 24 YO WF presented to our GN Clinic with intermittent edema, proteinuria and hematuria noticed about a year ago. Her creatinine was 1.5 mg/dl. Urine P/C ratio was 1.8 g/g. Her ANA was 1:320 but the rest of the antibody panel was negative. C3 and C4 were normal. Lupus Anticoagulant, beta 2 GPI, antiphospholipid IgG and IgM were positive. Screens for paraproteins and relevant viruses were negative. Renal Biopsy: 20/31 glomeruli were globally sclerotic. Intact glomeruli showed mesangial proliferation and hypercellularity. IF showed C3+ but all other stains were negative. IF on pronase digested, paraffin embedded tissue stained IgG, C3 and kappa with no lambda. Stain for SAP was positive. EM showed numerous mesangial deposits, some sub-epithelial but no sub-endothelial deposits. Based on above, she was diagnosed with Membranous like glomerulopathy with masked IgG-kappa deposits. Her age, race, gender, Ab profile as well as biopsy findings all supported the diagnosis. She was started on immunosuppression therapy to attempt salvage of renal function and delay progression.

**Discussion:** Refinedment in IF techniques has expanded our diagnostic ability and mechanistic understanding of glomerular disease. Use of paraffin embedded tissue for IF after pronase treatment helps discover Ig deposits not picked up by traditional IF. This can prove critical in correctly diagnosing glomerular disease, as exemplified in this case. This patient could have been misdiagnosed as C3 glomerulopathy based on traditional IF. Unmasking IgG-kappa deposits allowed us to correctly diagnose her with a rare disease, MGNMID. This technique expands our ability to correctly diagnose glomerular disease and should be applied routinely.

**PO1859**

**Fibrillary Glomerulonephritis: A Case Series with Clinical Features and Outcomes**

Reza Zonozi,1 Karen A. Laliberte,1 Jillian Rosenthal,1 Noah Huizenga,2 Sarah Dowst,1 Anushya Jeyabalani,1 Frank B. Cortazar,2 John Niles,2 Massachusetts General Hospital, Boston, MA; ‘New York Nephrology Vasculitis and Glomerular Center, Albany, NY.

**Background:** Fibrillary glomerulonephritis (FGN) is a rare cause of chronic glomerulonephritis with a poor prognosis. We evaluated a series of patients with FGN, most of whom were treated with rituximab, low-dose cyclophosphamide, and prednisone (RCP).

**Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.**

578
Methods: Patients were included if they had FGN treated at Massachusetts General Hospital between 2008-2020 with a minimum of six months of follow up. The primary outcome was achievement of remission, defined as serum creatinine that remained stable, improved or increased <25% of the original value after treatment, and a 50% reduction in proteinuria at the end of follow up.

Results: We identified 11 consecutive patients with FGN. ANCA-associated vasculitis (n = 3), rheumatoid arthritis (n = 1), chronic hepatitis C (n = 1), and monoclonal B lymphocytosis (n = 1) were concurrently present. At the start of therapy, the median (IQR) serum creatinine, GFR, and proteinuria was 2.31 mg/dL (1.25 – 4.69), 30 mL/minute/1.73 m² (11 – 68), and 6.68 g/L (5.5 – 8.4), respectively. Of the 31 patients, 10 were treated with RCP, and one patient with rituximab monotherapy. The median (IQR) follow-up was 2.6 years (2.0 – 3.9). Seven of 11 patients achieved remission. Of the 4 patients who did not achieve remission, one received pre-emptive transplantation, two initiated hemodialysis, and one had >25% rise in serum creatinine not reaching ESRD. Five serious adverse events occurred over 33 patient years.

Conclusions: Remission was achieved in most patients with FGN treated with rituximab, low-dose cyclophosphamide, and prednisone. Larger studies evaluating this regimen are warranted.

POI1860
An Atypical Case of Fibrillary Glomerulonephritis
Jessica M. Greco,1 Asish Thakkar,1 Clarissa A. Cassol,1 Anjali A. Sato,2 Salem Almanzi,3 Arkan Laboratories, Little Rock, AR; 1The Ohio State University Wexner Medical Center, Columbus, OH; 3Veterans Health Administration, Columbus, OH.

Introduction: Fibrillary glomerulonephritis (FGN) is a rare glomerular disease associated with multiple disease associations such as hepatitis C, malignancy, and dysproteinemia. Despite these known associations, little is known about the interaction between FGN and other comorbidities. We present a case of FGN that presented years after successful eradication of hepatitis C virus infection treated with DAAs with SVR for years referred to nephrology clinic for evaluation of CKD and nephritic syndrome. She also reported pain and a purpuric papular rash on her legs. Labs showed hypocomplementemia and high levels of RF. Cryo was suspected, but repeated testing of serum cryoglobulins was negative. Renal biopsy showed membranoproliferative GN with endocapillary hypercellularity and endocapillary “cryo-plugs” by LM, and IgM dominant with kappa greater than lambda capillary loop and mesangial staining by IF, and subendothelial and mesangial deposits by EM. These findings suggest cryo GN. Patient was treated with a prednisone taper and rituximab.

Case Description: Our patient is a 49-year-old Filipino female, hypertensive, diagnosed case of Immune Complex-Mediated Glomerulonephritis presenting with elevated blood pressure and nephrotic-range proteinuria. Initial adjustment of her anti-hypertensive regimen controlled her blood pressure. Subsequently, she developed resistant hypertension and increasing proteinuria. Creatinine increased to 2.1 mg/dL from a baseline of 1 mg/dL in 12 months. A second renal biopsy was done showing globally widespread podocyte foot process effacement and mesangial fibrillary deposits measuring 13 mm in mean diameter suggestive of Fibrillary Glomerulonephritis. Patient was worked up for an underlying malignancy, autoimmune disease and infectious causes but none turned out positive. At this time, proteinuria has increased to 7596.05 grams from 1622.08 grams with a creatinine clearance of 39.80 ml/min/1.73 m². After discussing with the patient, she was given Rituximab as four weekly doses of 375 mg/m² intravenously. After five months, there was significant reduction in proteinuria at 373 mg/m² intravenously. Further rash, there was significant reduction in proteinuria at 1734.32 grams with stable creatinine clearance of 31.99 ml/min/1.73 m².

Discussion: In general, FGN prognosis is poor and majority of patients progress to ESRD. Treatment options are currently limited and conclusions regarding immunosuppressive therapy cannot be drawn from limited published data. Rituximab may offer benefit particularly in patients with relatively normal baseline renal function.
Renal Biopsy. Cryoglobulinemic Glomerulonephritis

PO1863
Clinico-Biological Characteristics and Treatment of Hepatitis B Virus-Related Mixed Cryoglobulinaemia: Current Clinical Evidence

Introduction: Hepatitis B virus (HBV)-related mixed cryoglobulinaemia (MC) was considered to be a rare disease, presented as mild clinical symptoms just like purpura to severe organ damage such as glomerulonephritis. We aimed to clarify the clinico-biological characteristics and treatment of HBV-related MC.

Methods: We reported a case of HBV-related MC, enrolled 41 HBV-related MC cases from literature, and summarized demographic, clinical, laboratory, treatment group, patients in remission and refractory were compared. Kidney involvement, death and time to death were included for survival analysis.

Results: Of the 42 HBV-related MC, Mean age was 53±14 years, and 47.6% patients were male. Extraglomerular clinical manifestations mainly included cutaneous lesions, kidney involvement, peripheral neuropathy, arterial involvement, which accounted for 78.6%, 54.8%, 35.7%, 19.0%, respectively. 87.1% (27/31) patients had low serum C4, and 92.6% (25/27) patients’ rheumatoid factors (RF) were positive. Renal pathology showed membranous proliferative glomerulonephritis, the capillary lumen disclosed hyaline thrombi and electron microscope found microtubular substructure. 36 (85.7%) patients received antiviral therapy. Corticosteroids were used in 22 (52.4%) patients, immunosuppressive agents were given to 13 (31.0%) patients, and plasma exchange (PE) were used in 9 (21.4%) patients. At the end of follow-up, 52.4% (22/42) patients were in remission, 47.6% (20/42) patients had refractory disease, and 11.9% (5/42) patients died. The patients who had cutaneous necrosis, peripheral neuropathy and kidney involvement had correlation with overall survival (log rank $P=0.034$).

Conclusions: Extraglomerular clinical manifestations of HBV-related MC were varied. Anti-HBV treatment, corticosteroids, immunosuppressive agents and PE were useful for some patients. The patients with kidney involvement may be related to poor prognosis.

PO1864
Membranoproliferative Glomerulonephritis (MPGN) Associated with Epstein Barr Virus (EBV)

Introduction: Immune complex-mediated MPGN has been commonly associated with viral infections including Hepatitis B, C, HIV and Hantavirus. We present a rare case of EBV associated MPGN successfully treated conservatively.

Case Description: A 19-year-old female, previously healthy, presented with fatigue, sore throat and periorbital swelling for 3 weeks. Vitals were stable on presentation. Her EBV IgM and IgG serologies were positive while CMV was negative. UA showed proteinuria (>300mg/dl) and microscopic hematuria. Albumin was 2.9 g/dl. Spot urine protein to creatinine ratio was 2.6g/g. Urine sediment was bland. SCr was 0.72 mg/dl. Extensive serological work up was negative. Renal biopsy showed mesangial hypercellularity, double contours of capillary loops with intramembranous, subendothelial and subepithelial immune type electron dense deposits. Immunofluorescence revealed segmental globular to coarsely granular staining in the glomerular capillary walls for IgG (3+), IgA (1+), IgM (3+), kappa (2+), lambda (3+), C3 (1-2+), C1q (3+), and C4 (1+). Mesangial regions showed segmental granular staining for IgG (1+), kappa (1+), lambda (1+) and C4 (1+). She was treated with furosemide 20mg daily as needed for swelling and linsinopril 5mg daily. Her symptoms resolved within 2 weeks of initiating treatment. She self-discontinued her medications after 4 months. On 6 month follow up, she remained asymptomatic and urine protein was undetectable.

Discussion: Infectious Mononucleosis (IM) is caused by EBV. EBV primarily infects human B cells via the CD21 receptor and may infect renal tissue since the CD21 molecule has been detected in proximal tubular cells of kidneys. Further, acute EBV infection may cause immune-mediated response with deposition of immune complexes and subsequent glomerulopathy. Renal involvement is reported with 3-16% cases of acute IM. Common renal lesions include acute tubulointerstitial nephritis, membranous nephropathy, minimal change disease and vasculitic lesions. MPGN is a rare presentation of EBV and should be considered in patients with IM and proteinuria. Previous case reports have suggested that nephritic syndrome in patients with an acute EBV infection is usually self-limiting. Our case report also suggests that MPGN associated with EBV may have a relatively benign course.

PO1865
Infection-Related Glomerulonephritis Mimicking Lupus Nephritis

Rasha Alawieh, Anjali A. Satoskar, Isabelle Ayoob. The Ohio State University Wexner Medical Center, Columbus, OH.

Introduction: Differentiating infection vs auto-immune related GN is crucial in order to avoid inadvertent immunosuppressive therapy that can be harmful and even lead to fatal consequences. This case illustrates the dilemma of medical management in lupus like-GN.

Case Description: A 66 year old man with mitral valve prolapse, was found to have elevated creatinine of 3.59 mg/dl from a baseline of 1 mg/dl. He complained of leg rash and dark urine. His rash was symmetric and non blanchable petechiae. Urine sediment showed 20 dysmorphic RBC per high-power field and RBC casts. Urine protein/creatinine ratio was 1.35 g/g. Serum creatinine peaked at 14.0 mg/dl. Hemodialysis was begun. Further testing was significant for pancytopenia, low complements (C3 was 40 mg/dl, C4 10 mg/dl) and positive MPO-ANCA. Kidney biopsy was performed (Fig 1). On light microscopy 2 glomeruli were globally sclerotic. One glomerulus showed crescentic and necrotizing lesion. There was diffuse ATN. Some tubules showed red blood cell casts. Interstitial inflammation was mild. Direct IF showed a full house pattern with bright IgG, IgM, kappa, lambda, C1q, C3 and mild to moderate IgA staining. EM identified few mesangial and subendothelial deposits with a single subepithelial hump. During his hospitalization, streptococcus bacteremia was documented. Echo showed mitral valve vegetation. In setting of bacterial endocarditis, the Biopsy is consistent with infection related glomerulonephritis (IRGN).

Discussion: Crescents as well as ANCA positivity have been described in IRGN. However a full-house immunostaining pattern is not typical of IRGN and has never been reported in IRGN. Instead, this is typical of lupus-like GN. The patient didn’t have positive ANA, however he developed pancytopenia and hypocomplementemia which can be manifestations of both SLE even at an old age as well as infection. The dilemma is that auto-immune mediated GN warrants immunosuppressive therapy which is contraindicated in IRGN. Our patient received penicillin and underwent mitral valve replacement His kidney function gradually improved and dialysis was discontinued after 4 months.

PO1866
Hypocomplementemic Urticarial Vasculitis: Interstitial Nephritis with New Microtubular Deposits and Successful Response to Rituximab

Adam Dossaji, Spencer Hodgins, Daniel L. Landry, Giovanna M. Crisi, Sara A. Pawlak, Gregory L. Braden. Baystate Medical Center, Springfield, MA.

Introduction: HUV is caused by antibodies to C1q complement and has many features of systemic lupus and cryoglobulinemia. Different patterns of GN often occur such as the mesangial GN, MPGN or membranous GN but interstitial nephritis has never been described.

Case Description: A 57 year old female in 2007 developed recurrent hives, and asymptomatic leukocytoclastic vasculitis on skin biopsy & 5 g proteinuria with RBC casts. C1q complement was 2 mg/dl, C3 20 mg/dl, C4 6 mg/dl & C1q antibody was 35 mg/ml (NL=10). All other serology and cryos were negative. Serum creatinine was 0.6mg/dL.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Glomerular Diseases: Clinical, Outcomes, and Trials - 1
Poster

Her 1st renal biopsy showed mesangial proliferative GN with +3 IF for IgG, IgA, C1q & C3, subendothelial, subintimal, subperitubular, subepithelial, and focal location of subintimal inflammation. Parallel microtubular structures, 25 nm wide with hollow cores, were present in interstitial capillaries and hilar arterioles but not in the glomeruli. Tubular basement membranes & peritubular capillaries were +3 positive for IgG & C1q with granular, subendothelial & subperitubular deposits. Tubulointerstitial fibrosis & chronic inflammation were minimal. She had 4 weekly doses of Rituximab 375 mg/m^2; she rapidly went into remission within 2 months which was sustained for 6 years. HU flared in 2016 with new onset nephrotic syndrome, hives, angioedema, COPD & AKI. Serum creatinine was 2.2 mg/dl & urine total protein/creatinine ratio was 4.2 g/mmol. C1q was 4 mg/dL, C3 33 mg/dL, C4 4 mg/dL & C1q antibody > 100 mg/mL. A 2nd renal biopsy showed diffuse endocapillary proliferation with membranous GN similar to lupus Class IV & V & interstitial inflammation. IF was +3 for IgG, IgA, C1q and kappa and lambda in the same locations as biopsy 1. Tubular basement membranes & peritubular capillaries were positive for IgG & C1q. Peritubular capillaries had 25 nm hollow microtubule structures as before. Rituximab was initiated at 375 mg/m^2 for 4 doses. It induced a complete renal remission after 3 months with a serum creatinine of 0.6 mg/dl & urine total protein of 210 mg.

Discussion: We conclude: In addition to glomerulonephritis HUV can cause interstitial nephritis with +1IF for IgG & C1q. HUV causes unique microtubular structures in the interstitium but not the glomeruli. Rituximab rapidly induces clinical renal remission in HUV.

UAB867
Unusual Aggregation of Different Glomerulopathies in a Family Resolved by Genetic Testing

Vahalan S. Keskinayan, Reeti Kumar, Rashheed A. Gbadegesin. Duke University, Durham, NC.

Introduction: Glomerulonephritis (GN) is a major cause of chronic kidney disease (CKD) in children. The conventional approach to diagnosis of GN includes clinical evaluation and in most cases kidney biopsy to make a definitive diagnosis. However, in many cases, clinical presentations of different GNs can be indistinguishable leading to uncertainty in diagnosis and management even after renal biopsy. In this report we identify a family with clinical diagnoses of post infectious glomerulonephritis (PIGN) and IgA nephropathy in a parent and two children. Renal biopsies were inconclusive and we were only able to make all the diagnoses in each of the family members after genetic testing and reverse phenotyping.

Case Description: A previously healthy 7 year old male presented to the emergency department with hematuria, fever, and sore throat. Apart from being obese, his physical examination was unremarkable. Laboratory studies were remarkable for microscopic hematuria and non-nephrotic range proteinuria. C3/C4 complements, ASO, anti-DNase b, anti-ssDNA, ANCA, and anti-GBM titers were all normal. A presumptive diagnosis of PIGN was made. However, he had persistent hematuria and proteinuria over the next 10 months. Further history at follow up revealed a history of IgA nephropathy in his mother and CKD of unclear etiology in his maternal grandfather. Renal biopsy was initially reported to be consistent with IgA nephropathy. However, because of the family history we carried out genetic testing and identified a rare hemizygous variant [c.3437G>A (p.Gly1146Glu)] in the gene COL4A5 of his brother and mother.

Discussion: This case highlights the utility of genetic testing and reverse phenotyping in resolving clinical diagnosis in families with unusual presentations of different glomerulopathies. We propose that clustering of different glomerular disease phenotypes in a family should be an indication for genetic testing.

UAB868
Unusual Case of Histiocytic Glomerulopathy in the Setting of Sarcoma-toid Malignancy

Faris Al faris, Majid Al-Ahmad, Llwellyn A. Foulke, Mauricio Monroy, Kelly H. Beers. Albany Medical Center, Albany, NY.

Introduction: We present a case of histiocytic glomerulopathy and pauci-immune ANCA negative glomerulonephritis (GN) in the setting of sarcomatoid malignancy.

Case Description: An 83-year-old female presented to our hospital for evaluation of abdominal pain. Her vital signs were normal and her physical exam was only significant for mid-abdominal tenderness on palpation. Aortic angiography revealed occlusion of the superior mesenteric artery, celiac artery and left renal artery, in addition to a mass engulfing the celiac artery. She later developed acute kidney injury (AKI) with creatinine rising to 1.5mg/dl from baseline of 1.2mg/dl. Work up revealed bland urine sediment and 24-hour proteinuria. Although c-AKNI is a rare and aggressive cause of AKI with 10% of the cases being ANCA-negative. Few case reports linked ANCA-negative pauci-immune GN to non-small cell lung cancer. To our knowledge this is the first case of histiocytic glomerulopathy, ANCA-negative pauci-immune GN and arthritis in the setting of sarcomatoid malignancy.

PO1869
Bilateral Renal Infarctions: A Perplexing Presentation of Polyarteritis Nodosa

Alissa Lee, Matthew Foy. Louisiana State University Health Sciences Center, Baton Rouge, LA.

Introduction: Classic polyarteritis nodosa (c-PAN) is an autoimmune necrotizing vasculitis with predilection for medium-sized vessels. Although c-PAN can be associated with renal involvement, acute renal failure or extensive renal infarctions are exceedingly uncommon. We report a rare case of c-PAN manifested by bilateral renal infarctions on initial clinical presentation.

Case Description: A 40 year old man with no known medical issues presented to the emergency department with encephalopathy in the setting of one month of reported myalgia, fevers, chills, night sweats, and unintentional ten lb. weight loss. Upon physical examination, his vitals were 95.1°F, 101 beats/min, 145/101 mmHg, with no evidence of trauma or skin abnormalities. His lab results were notable for Cr 1.83 mg/dL, AST 116 mm/hr, and he had transient worsening of his Cr (2.96 mg/dL) and Hbg (6.7 g/dL). CT/CTA revealed bilateral renal infarctions with perinephric and retroperitoneal hematomas, right renal artery aneurysm, thrombosis of one of three left renal arteries, and splenic hematoma, while MRI demonstrated a small parietal hematoma and thoracic intrathoracic epidural hemorrhage. He was initiated on monthly cyclophosphamide and prednisone. One month later, he had symptomatic resolution and a Cr of 1.89 mg/dL.

Discussion: Given his fulfillment of five American College of Rheumatology (ACR) criteria, he was diagnosed with c-PAN as a constellation of clinical findings can be used, and biopsy results are not always necessary, especially given the risk of hemorrhage. Although it is a rare condition, it is important to remain cognizant and consider c-PAN in the differential due to its significant implications and the importance of timely treatment.

Right Renal Artery Aneurysm and Renal Infarctions

PO1870
Clinical Predictors of Response to Rituximab in the Nephrotic Syndrome Study Network (NEPTUNE) Cohort

Daniella Levy Eroz, 1,2 Kevin E. Meyers, 1,2 Jarcy Zee, 1 Abigail R. Smith, 3
1Division of Nephrology, Children’s Hospital of Philadelphia, Philadelphia, PA; 2University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 3Arbor Research Collaborative for Health, Ann Arbor, MI.

Background: Rituximab, an anti CD20 monoclonal antibody, is one of the alternative medications offered to children and adults with Nephrotic syndrome. Despite the growing knowledge regarding this medication, there are still concerns regarding long-term safety that need to be considered prior to initiation of therapy. Given these risks there is a need to identify characteristics of patients who will respond best to rituximab therapy.

Methods: We identified all patients who received rituximab within NEPTUNE, a prospective study of adults and children with glomerular disease enrolled at the time of first biopsy or at initial presentation. Remission was defined as UPC<0.3 mg/mg
after rituximab initiation. Kaplan-Meier plots and log-rank tests were used to compare the probability of response among various levels of demographic and clinical variables.

**Results:** Of 734 patients enrolled in NEPTUNE, 57 (34 adult, 23 pediatric) received rituximab after enrollment and were eligible for analysis. In the adult cohort, average age at initiation was 45.8 (SD−15.4), majority were male (79%) and white (88%) and diagnosed with membranous nephropathy (MN) (74%). In the pediatric cohort, most had Minimal change disease (MCD) disease on biopsy or nephrotic syndrome not specified (not biopsied) (NSNS) (83%), mean age was 6.96 yrs (SD−4.25), 57% were male, and 74% were white. Remission was achieved in 18 (53%) adults and children 19 (83%) respectively, with a median time to remission of 25.4 months and 4.8 months respectively. Probability of achieving remission was higher in patients with MCD/NSNS compared to MN (p<0.001, Figure). Among patients with MCD/NSNS, probability of remission was higher in <6 yrs vs. ≥6 yrs and adults (p=0.036).

**Conclusions:** Rituximab response rate in patients with MCD/NSNS were higher and quicker than in those with MN. Young children with MCD/MSNS had the highest rates of response. Future work is now targeted at identifying additional biomarkers (specifically lymphocyte profile) to predict response to rituximab.

**Tobacco Exposure in the Nephrotic Syndrome Study Network (NEPTUNE)**

Linda Wang, Kevin E. Meyers, Christine B. Sethna. NEPTUNE Cardiovascular Working Group 1The Children’s Hospital of Philadelphia, Philadelphia, PA; 2Cohen Children’s Medical Center, Queens, NY.

**Background:** Tobacco exposure is associated with cardiovascular disease (CVD) risk and chronic kidney disease (CKD) progression. Risks of tobacco exposure in proteinuric glomerulopathies are not known. The objectives were to describe the prevalence of tobacco exposure and determine the longitudinal associations between tobacco exposure and CVD risk factors and kidney outcomes in adults and children with proteinuric glomerulopathies in NEPTUNE.

**Methods:** Tobacco exposure was self-reported at study enrollment as non-smoker, active smoker, past smoker and passive smoker. Baseline characteristics were compared by t-test, ANOVA and chi square. Using adjusted generalized estimating equations and time-varying Cox survival analysis, tobacco exposure was analyzed for association with blood pressure (BP), lipids, urine protein/creatinine ratio (UPCR), glomerular filtration rate (eGFR), complete remission (UPCR <0.3), kidney failure (eGFR <15 or Kidney Replacement Therapy [KRT]) and CKD progression (40% eGFR decline and eGFR <90, or KRT).

**Results:** Included were 371 adults (45.9±16.0 yrs; 60.6% M; 23.0% black, eGFR 66.4 [IQR 42, 91]) and 192 children (9.9±5.0 yrs; 57.3% M; 39.4% black, eGFR 93.1 [IQR 78.1,114]) with median 45 (IQR 27,55) months of follow up. Among adults, there were 14.6% active smokers, 29.1% past smokers and 4.9% passive smokers. In children, percentages were 0.5%, 1.6%, and 16.7%, respectively. In adults, there were significant differences in age, sex, race, and employment among groups. In children, non-smokers were significantly older than passive smokers (10.1±4.9 vs. 8.0±4.9, p≤0.01). Tobacco exposure was associated with greater total cholesterol in adults and UPCR in children in adjusted models (Table).

**Conclusions:** In NEPTUNE, tobacco exposure was associated with higher levels of cholesterol in adults and proteinuria in children.

**Funding:** NIDDK Support

**Validating a Computable Phenotype for Nephrotic Syndrome in Children and Adults Using PCORnet Data**

Andrea L. Olives1, Dorotha Marchel1, Cheryl L. Tran1, Isabella Ayoub2, Salem Almanani2, Jessica M. Greco1, Michelle Denburg3, Debbie S. Gipson1, Laura H. Marian1. 1University of Michigan Medical School, Ann Arbor, MI; 2The Ohio State University Wexner Medical Center, Columbus, OH; 3The Children’s Hospital of Philadelphia, Philadelphia, PA; 4Mayo Clinic Minnesota, Rochester, MN.

**Background:** Primary nephrotic syndromes (pNS) are rare diseases which can be a barrier to adequate sample size for observational patient-oriented research. A computable phenotype may be powerful in identifying patients with these diseases for research while leveraging data from millions of patients in the PCORNet Common Data Model (CDM).

**Methods:** A comprehensive algorithm of ICD-9 and ICD-10 codes indicative of pNS was developed based on prior work in the University of Michigan Health System. Cases of pNS were defined as subjects that were seen for at least one encounter with more than 1 NS code, and did not have codes for diabetes mellitus, systemic lupus erythematosus, or amyloidosis. Non-cases were individuals not meeting case criteria who were seen in the same calendar year and within 2 years of age of a case. The algorithm was executed on the PCORnet CDM at 3 institutions from Jan 1, 2009 to Jan 1, 2018, where a random selection of 50 cases and 50 non-cases were reviewed by a nephrologist, for a total of 150 cases and 150 non-cases reviewed. The classification accuracy (sensitivity, specificity, positive and negative predictive value, F1 score) of the computable phenotype was determined.

**Results:** The algorithm identified a total of 2,708 patients with NS from 4,305,092 distinct patients in the CDM at all sites. For all sites, the sensitivity, specificity, PPV, and NPV of the algorithm were 99.1%, 81.0%, 76.7%, and 99.3%, respectively. The accuracy of the algorithm was 88.0% with an F1 score of 86.5%. The most common cause of false positive classification was secondary FSGS (27%), followed by class V lupus nephritis (9.3%).

**Conclusions:** While prior computable phenotypes for glomerular diseases have used IMC and SNOMed codes, this computable phenotype had good classification in identifying both children and adults with pNS utilizing only ICD-9 and ICD-10 codes, which are universally available. This may facilitate future screening and enrollment for research, however further refinements to the algorithm or addition of natural language processing may help better distinguish primary and secondary FSGS.

**Family History of Diabetes Is Associated with Progression of Kidney Disease: The CureGN and CRIC studies**

Francesca Zanoni, 1Miguel Verbistsky, 1Maddalena Marasà, 1Joshua D. Bundy, 2Afshin Parsa, 3Krzysztof Kiryluk, 1Harold I. Feldman, 3Ali G. Ghazikian, 1

1Columbia University Irving Medical Center, New York, NY; 2National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; 3Tulane University, New Orleans, LA; 4University of Pennsylvania, Philadelphia, PA.

**Background:** Family history (FHx) of complex traits may reflect shared genetic/environmental risk. We studied associations of FHx with presentation patterns, comorbidities and renal disease progression in a prospective cohort of primary GN and one of non-GN chronic kidney disease(CKD).

**Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only**

*Underline represents presenting author.*
Methods: The Cure Glomerulopathy Network (CureGN) is a prospective multi-center study of patients (N=2474, median age 29 years) with biopsy-proven GN. Associations of self-reported FHs of diabetes (DM), cancer (C), clotting disorders (CD), and autoimmune diseases (AD) with eGFR and comorbidities prevalence were studied with multivariable regression models. We investigated associations of FHs and end-stage renal disease (ESRD)/50%eGFR decline (ESRD/50%eGFR) with multivariate Cox models. The Chronic Renal Insufficiency Cohort (CRIC) Study, a multi-center prospective study of 3939 adult (median age 59 years) CKD patients, was used for replication.

Results: FHs of DM predicted lower eGFR at diagnosis (p=0.002) in CureGN. Figure 1 summarizes associations of FHs of complex traits with comorbidities in CureGN. FHs of DM was associated with higher odds of DM (OR 1.56, 95%CI 1.16-2.09, p=0.003) in the subgroup of CRIC with no DM at baseline. After adjustment for relevant covariates, FHs of DM was associated with higher risk of the composite outcome of ESRD/50%eGFR reduction in both CureGN (HR 1.43, 95%CI 1.06-1.94, p=0.02) and CRIC (HR 1.15, 95%CI 1.01-1.31, p=0.038).

Conclusions: FHs of complex traits are associated with specific comorbidities. FHs of DM identifies patients with lower eGFR and disease progression. In conclusion, FHs could be an additional parameter for risk stratification and management of CKD.

Funding: NIDDK Support

PO1875
Fractional Excretion of Total Protein in Nephrotic Syndrome
Hideaki Kuno, Go Kanzaki, Takaya Sasaki, Yusuke Okabayashi, Kotaro Haruhara, Kentaro Koike, Nobuo Tsuibo, Takashi Yokoo. The jikei university school of medicine, Minato-ku, Japan.

Background: Lower estimated glomerular filtration rate (eGFR) and higher proteinuria are the most sensitive predictor of the development of progressive renal insufficiency in various glomerular diseases. Fractional excretion of total protein (FETP) calculated by dividing the total protein clearance by the creatinine clearance is tightly associated with both proteinuria and GFR. However, few studies have analyzed in glomerular diseases the FETP to evaluate their relationship with renal function and histologic lesions. This study aimed to evaluate the relationship between FETP and the clinical features and histologic lesions and to assess whether FETP predicts outcome in nephrotic syndrome (NS).

Methods: Subjects who exhibited NS with a histological diagnosis were retrospectively analyzed at the Jikei University School of Medicine Hospital, Tokyo, Japan, during biopsy performed between 2002 and 2018. We analyzed 24-h urinary protein excretion, FETP, and other clinicopathological findings at kidney biopsy. The FETP was determined by the standard clearance technique based on 24-h urine collection: FETP = (urinary total protein / serum total protein) / (urinary creatinine / serum creatinine) × 100.

Results: A total of 113 subjects with NS were identified (Age 53.7 ± 17.3 [mean ± SD] years old; Male 71.7%, eGFR 57.6 ± 27.7 mL/min/1.73m²; urinary protein excretion 7.02 ± 3.67 g/day; minimal change nephrotic syndrome [n = 41]; focal segmental glomerulosclerosis [n = 10]; membranous nephropathy [n = 36]; diabetic nephropathy [n = 26]; FETP was significantly associated with eGFR (p = 0.05), urinary protein excretion (p = 0.58, P < 0.01), interstitial fibrosis and tubular atrophy (p = 0.24, P < 0.05), and glomerulosclerosis (p = 0.24, P < 0.05). Interestingly, patients with diabetic nephropathy showed the highest level of FETP with the poor renal outcome, while membranous nephropathy revealed the lowest level of FETP.

Conclusions: These results suggest that FETP would be a useful marker combining the two predictors of the decline of renal function in NS showing increased glomerular protein permeability and decreased glomerular filtration function.

PO1876
Prediction of Morphological Lesions Using Various Glomerular Filtration Rate Equations in Patients with Primary Glomerulonephritis

Background: Glomerular filtration rate (GFR) is generally accepted best overall index of kidney function. However, it remains controversial to use GFR as a marker of morphological lesions. Aim. To assess GFR equations as a predictor of chronic morphological lesions in patients with glomerulonephritis (GN).

Methods: 100 patients [48 female, age Me 39 (27; 54) years] with biopsy proven primary GN were included in the study (9%− minimal change disease, 28%− focal segmental glomerulosclerosis, 26%− membranous nephropathy, 37%− IgA nephropathy). Serum creatinine was measured by enzymatic, serum cystatin C - immunoturbidimetric methods. GFR was estimated using creatinine clearance (Ccr), MDRD, CKD-EPICr, CKD-EPICysC, full age spectrum (FASsCr) equations. Glomerulosclerosis (GS) was assessed quantitatively, tubulo-interstitial fibrosis (TIF), tubular atrophy (TA) - semi-quantitatively (0-lesions absent; 1-mild focal lesions; 2-moderate lesions; 3-diffuse lesions). All patients were separated consistently in two groups according to the degree of each morphological lesion: "mild" (GS<25% or TIF/TA<1−), “severe” (GS≥25% or TIF/TA≥2−3).

Results: Independently of estimating equation, GFR positively correlated (p<0.001) with GS, TIF, TA and was higher in patients with "mild" GS, TIF and TA (p<0.001). Based on the results of ROC-analysis patients were separated (p=0.001) in two groups using all equations according to the degree of morphological lesions ("mild" or “severe” GS, TIF and TA). Using comparison of AUC we found the significant difference between Ccr and CKD-EPICr, CKD-EPICysC, CKD-EPICrCysC, between MDRD and CKD-EPICr, CKD-EPICysC equations in prediction of TIF, between CKD-EPICrCysC and FASsCr* in prediction of GS and no difference for all equations in prediction of TA (Fig 1).

Conclusions: Independently of estimating equation, GFR is a good marker of morphological lesions in patients with primary GN. Our data shows that CKD-EPI equations, especially CKD-EPICysC, provide the highest diagnostic value in prediction GS and TIF.

**Fluid Overload and Markers of Cardiovascular Damage in Severe Nephrotic Syndrome**

Aleksandra Rymarz, Anna Matyjeck, Stanislaw Niemczyk. **Military Institute of Medicine,** Warsaw, Poland, Warsaw, Poland.

**Background:** The purpose of the study was to evaluate the dimension of body water compartments and markers of cardiovascular damage in patients with severe nephrotic syndrome (SNS) defined as nephrotic range proteinuria and hypalbuminaemia ≤ 2.5 g/dl. Methods: 40 patients with SNS and eGFR >30 ml/min/1.73m² formed the study group (SNSG) and 40 healthy volunteers without SNS matched according to age, sex, height, body mass, kidney function formed the control group (CG). Body water compartments were assessed using Body Composition Monitor, Fresenius Medical Care. For statistical analysis Spearman’s correlation coefficients, chi² or Mann-Whitney U tests were used (Statistica v 13.1).

**Results:** SNSG included 28 males and 12 females, the mean daily proteinuria was 10.5±5.0 g. The groups are described in the table. In SNSG significantly higher fluid retention was associated with the increase in ECW and the decrease in ICW whereas TBW was the same in both groups. Such constellation can indicate intracellular dehydration which was not described so far. OH, which is a derivative of ECW, correlated with markers of cardiovascular damage and can be important for patients with resistant SNS and influence their prognosis.

**Clinical characteristic of the study groups**

**Glomerular Filtration Barrier Dysfunction in an RNA Virus-Induced Glomerulopathy: The Similarities with Findings of Common Nephrotic Syndromes**

Florian Källble, 1 Christoph Eckert, 1 Christian Morath, 1 Jochen Reiser, 1 Martin G. Zeier, 1 Ellen Krautkrämer, 1 Heidelberg University Hospital, Heidelberg, Germany; 2 Rush University Medical Center, Chicago, IL.

**Background:** Virally induced kidney dysfunction is highlighted by the alarming incidence of SARS-CoV-2 associated acute renal disease including nephrotic syndrome (NS). Plasma levels of soluble urinokase plasminogen activator receptor (suPAR) are elevated in COVID patients and provide prognostic insights. SuPAR is also involved in podocyte injury, kidney diseases such as focal segmental glomerulosclerosis (FSGS) in which podocytes effacement/injury is a common feature. Hantavirus-induced hemorrhagic fever with renal syndrome (HFRS) represents another RNA virus-induced disease with acute kidney injury and NS. The exact pathophysiology of proteinuria is, however, unclear. We hypothesized that hantavirus infection results in podocyte injury and a dysfuntional glomerular filtration barrier (GFB), similar to findings in common NS.

**Methods:** Renal biopsy specimens were analyzed by light and electron microscopy. Urinary neprin and suPAR concentrations were measured in 26 patients with HFRS and 18 healthy controls.

**Results:** Hantavirus patients showed significantly increased urinary neprin, immunoglobulin G (IgG), α1-microglobulin (α1-MG) and suPAR concentrations compared to healthy controls. Furthermore, neprin and IgG levels were significantly higher in patients with severe than with mild proteinuria. Differences in α1-MG levels, however, disappeared after normalization to urinary creatinine. Urinary neprin levels as a marker for podocyte damage correlated strongly with biomarkers of non-selective glomerular proteinuria. Interestingly, suPAR correlated significantly with urinary neprin, IgG and α1-MG levels, suggesting suPAR as a potential pathophysiological mediator in GFB dysfunction in response to RNA virus infection. The main finding in microscopy analyses was a focal foot process effacement. Proteinuria and kidney dysfunction recovered autonomously in all patients.

**Conclusion:** Hantavirus infection causes a podocyte injury leading to GFB dysfunction. A better understanding of transient virally induced proteinuria syndromes and their often self-limiting disease character may generate new therapeutic approaches for NS.

**PO1879**

**Nephrotic Syndrome from the Age of 65 Years: Epidemiological, Clinical, and Renal Biopsy Data**

Luanara R. Soares, Jose Mariano S. Pantoja, Lecticia Jorge, Viktoria Woronik, Cristiane B. Dias. **Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.**

**Background:** This study aims to evaluate epidemiological, clinical, and renal biopsy data of patients aged 65 or over with nephrotic syndrome, admitted in a University Hospital.

**Methods:** Retrospective cohort study of renal biopsies performed from 2012 to 2017, considering the age 65 years or over, with diagnosis of nephrotic syndrome, under follow-up at the Nephrology Department of the Hospital das Clinicas of the University of Sao Paulo.

**Results:** In these period 103 renal biopsies were performed in patients aged 65 or over, 45 (43.68%) of them were indicated by the diagnosis of nephrotic syndrome. These 45 patients had mean age of 70.60±5.24 years old, 60% male, laboratory data at diagnosis were median serum creatinine of 2.02±1.53 mg/dl, hemoglobin of 11.34±4.11 g/dl, serum albumin of 2.23±0.83 g/dl and proteinuria of 6.9±4.64 g/day. Only minor complications of renal biopsy were observed and occurred in 6.6% of cases. The most frequent histological lesion was Membranous Nephropathy in 13 cases (28.88%), followed by Membranoproliferative Glomerulonephritis in 9 cases (20%), Focal Segmental Glomerulosclerosis (FSGS) in 8 (17.77%) highlighting that 4 patients had the Collapsing Form, Minimal Change Disease (MCD) occurred in 7 cases (15.55%) and the remaining 8 had others glomerular diseases. In Table 1 has the comparison between patients data according the glomerular disease. [Table]

**Clinical Characteristics, Treatment Patterns, and Outcomes of Children and Adults with Biopsy-Proven Minimal Change Disease from the Cure Glomerulonephropathy Network Study (CureGN)**

Dhruvit P. Chen, 1 Margaret Helmuth, 2 Rasheed A. Ghabadeseng, 3 Amy K. Mottil, 3 Debbie S. Gipson, 4 Katherine Twombley. 5 The Cure Glomerulonephropathy Network Study (CureGN) University of North Carolina, Chapel Hill, NC; 1 Research Collaborative for Health, Ann Arbor, MI; 2 Duke University Hospital, Durham, NC; 3 University of Michigan Mott Children’s Hospital, Ann Arbor, MI; 4 Medical University of South Carolina, Charleston, SC.

**Background:** The age of Minimal Change Disease (MCD) onset spans all ages. We analyzed the CureGN multi-center observational cohort study to elucidate differences in natural history and treatment patterns by age of MCD onset.

**Methods:** 567 participants enrolled within 5 years from kidney biopsy were available. Continuous variables were described as median [25,75 percentile] [IQR]. Univariate comparisons were performed using chi-square tests and Wilcoxon rank-sum tests for categorical and continuous variables, respectively. eGFR was winsorized to 120 or over, 45 (43.68%) of them were nephrotic syndrome, under follow-up at the Nephrology Department of the Hospital das Clinicas of the University of Sao Paulo.

**Results:** Comparisons of age group are shown in the table. There were modest differences in the racial/ethnic composition and weight. Severity of proteinuria was similar at disease onset [6.1 vs 6.5, p-value=0.5] but higher in adults at biopsy (6.6 vs. 3.4, p-value<0.001). At biopsy, eGFR was higher in children than adults (127.7 vs 88.6, p-value=0.001), and were more likely to have received immunosuppression prior to biopsy (58% vs. 18%, p-value<0.001). Compared to children, adults were more likely to report a history of HTN (29% vs 43%, p-value=0.001). Children were more likely to have frequently relapsing/steroid dependent disease than adults (51% vs. 29%, p-value<0.001) and higher steroid resistant disease than adults (17% vs. 12%, p-value<0.001). Over a median of 29.1 months follow up, ESKD occurred in 13 (2%) participants.

**Conclusion:** Significant sociodemographic and clinical differences exist between adult-onset versus pediatric onset MCD at the time of biopsy. These differences are most apparent in race/ethnic differences in renal and biopsy practices relative to symptom onset.

Clinical Characteristics of Acute Glomerulonephritis with Presentation of Nephrotic Syndrome at Onset in Children

Huiping Ge, Qiongjing Yuan, Xiangcheng Xiao. Xiangya Hospital Central South University, Changsha, China.

Background: Acute glomerulonephritis (AGN) is a common disease in children, which placed a huge burden on developing countries. Prognosis of it may not always good. However, the clinical characteristics of AGN with nephrotic syndrome (NS) at onset has not fully clarified.

Methods: 113 cases were analyzed retrospectively. Clinical data, pathological results and prognosis between AGN with NS (AGN-NS) and AGN without NS (AGN-no-NS) were compared.

Results: 20 (17.7%) of 113 patients were AGN-NS. The patients with AGN-NS were more likely to have hypertension (55.0% vs. 25.8%) and acute kidney injury (AKI) (50% vs. 17.2%). The AKI was significantly related to the manifestation of AGN-NS in children (OR=3.812, P=0.040). Compared with the AGN-no-NS, the immunosuppressive treatments were more common in AGN-NS. A severer pathological grade was significantly related to the lower C3 fraction, estimated glomerular filtration rate (eGFR) and AKI, but not the performance of AGN-NS. There was no difference in prognosis between two groups.

Conclusions: The AKI was significantly associated with AGN-NS. The prognosis of AGN-NS and AGN-no-NS in our study was almost good. Given the fact that AGN-NS patients more likely to use the immunosuppressive therapy, the long-term outcome of AGN-NS is worth a further research.

PO1882

Estimation of Childhood Nephrotic Syndrome Incidence: Data from the Atlanta Metropolitan Statistical Area and Meta-Analysis of Worldwide Cases

Jackson Londero,1,2 Larry A. Greenbaum,1,2 Evan Anderson,1,2 Laura Plantinga,1,2 Courtney Mecracken,1,2 Scott Gillespie,1 Chia-Shi Wang.1,2

1Emory University School of Medicine, Atlanta, GA; 2Children’s Healthcare of Atlanta, Atlanta, GA.

Background: There is limited epidemiological data on childhood idiopathic nephrotic syndrome (NS) in the United States. We estimated contemporary childhood NS incidence estimates in a racially and ethnically diverse U.S. population, and performed a meta-analysis of published reports to examine differences by race and ethnicity and changes over time.

Methods: Children 1-17 years-old diagnosed with NS in the Atlanta MSA between 1/1/2013 and 12/31/2018 were identified by chart review using practice data from the only pediatric nephrology practice in the region. Annual incidence rates were calculated by dividing the number of cases by population data provided by the Georgia Department of Public Health. We also performed a literature review for published childhood NS incidence and calculated pooled incidence estimates using random-effects regression models. Incidence estimates by race and ethnicity were compared by calculating pooled estimates within each subgroup and testing for significant heterogeneity between subgroup estimates. We also reviewed U.S. incidence over time comparing pooled incidence estimates before and after 1984.

Results: 175 children aged 1-17y were diagnosed with NS between 2013-2018 in the Atlanta MSA. Incidence by race and ethnicity from the Atlanta MSA and meta-analysis demonstrated highest incidence in Asian children, followed by those of African descent, Hispanics and Caucasians (Table 1). Incidence in the U.S. was stable over time.

Conclusions: Risk for childhood NS development differs by race and ethnicity without changes over time. Future studies need to evaluate the underlying genetic and environmental factors associated with NS incidence.

PO1883

Steroid Treatment for the First Episode of Childhood Nephrotic Syndrome

Comparison of the 8- and 12-Week Regimen Using an Individual Patient Data Meta-Analysis

Anne M. Schievens,1 Nyijke Tenening,1 Eiske Dorrestein,1 Nicholas Webb,1,2 Michiel F. Schreuder,1 Radboudumc, Nijmegen, Netherlands; 2Erasmus MC, Rotterdam, Netherlands; 3Royal Manchester Children’s Hospital, Manchester, United Kingdom; 4Health Innovation Manchester, Manchester, United Kingdom; 5Universitair Medisch Centrum Utrecht, Utrecht, Netherlands.

Background: Steroids are the cornerstone of the treatment of childhood nephrotic syndrome. The optimal duration for the first episode remains a matter of debate. The aim of this study is to determine whether the 8 weeks ISKDC regimen (prednisolone 4 weeks 60mg/m² daily, 4 weeks 40mg/m² on alternate days) is equally effective as the 12 weeks APN regimen (prednisolone 6 weeks 60mg/m² daily, 6 weeks 40mg/m² on alternate days).

Methods: An individual patient data (IPD) meta-analysis of randomized controlled trials reporting on prednisolone treatment for a first episode of childhood nephrotic syndrome was conducted. European trials investigating the ISKDC and/or APN steroid regimen were selected. Statistical models were adjusted for relevant covariates.

Results: Four trials included European patient cohorts treated according to the ISKDC and/or APN steroid regimen. IPD of two trials were available (PREDNOS, UK, 2019, n=109 and Nephrotic Syndrome trial, the Netherlands, 2013, n=62). Baseline characteristics did not significantly differ between the two treatment groups, with the exception of ethnicity. A significant difference was found in the time to first relapse after cessation of steroid treatment between the 8 and 12 weeks treatment group (p=0.04). The incidence of frequent relapsing nephrotic syndrome (FRNS) was similar in the two groups (p=0.75). Importantly, a significant difference was found in the incidence of steroid dependent nephrotic syndrome (44% [8 weeks] vs 24% [12 weeks], p=0.01). Overall, relapse rate ratios were 51% higher in the 8 weeks group compared to the 12 weeks group (p<0.01). Finally, children below 4 years of age seem to have a significantly lower survival time to first relapse and time to FRNS compared to children of 4 years and older (p=0.02 and p=0.003).

Conclusions: The results of this IPD meta-analysis suggest that the 8 weeks regimen for a first episode of nephrotic syndrome is not equally effective as the 12 weeks steroid regimen. Although high less steroids for the first episode would be the most effective method to reduce steroid toxicity in the short term, these results suggest patients treated with a 12 week steroid regimen may have a less complicated disease course.

PO1884

Targeted B-Cell Depletion with Rituximab in Adult Relapsing Minimal Change Disease

Background: Case series suggest use of rituximab is effective in treating adults with relapsing Minimal Change Disease (MCD). We previously reported rituximab to increase time in remission, however, the majority of patients did have further relapses. We thus studied the efficacy of retreatment with rituximab on B cell repletion 2 years to prevent relapse.

Methods: Adult patients with recurrent MCD relapses were identified and treated with rituximab and monitored for lymphocyte depletion (total B-lymphocyte <10x) with pre-emptive re-dosing after reconstitution was observed.

Results: 16 patients (8 female, 8 male) started B cell targeted maintenance rituximab for 10 years. At start of the maintenance period, 14/16 were on immunosuppression, tacrolimus (7) steroids (3), or both (4), stopped at a mean of 6.4 months (range 2-16 months). 15/16 patients re-dosed after reconstitution was observed. 1/16 received 6 monthly rituximab, without waiting for lymphocyte reconstitution, due to a history of rapidly relapsing disease. 3/16 achieved lymphocyte depletion post rituximab. 3/16 relapsed during the 2 year treatment period, 1/3 was B cell deplete at relapse, 2/3 were B cell replete at relapse having been deplete on their previous blood test. As of May 2020, 10/16, have completed 2 years treatment, with a mean follow up post treatment of 6.6 months (range 1 to 13). Of these 3/10 have subsequently relapsed at mean time of
3.3 months (range 1-5), 2/3 were B cell replete at relapse. Rituximab was generally well tolerated, with no significant hypogammaglobulinemia or hospital admissions observed.

Conclusions: Targeting B cell depletion with rituximab is effective in maintaining remission of MCD. However, relapse can occur rapidly post repletion of lymphocytes, so frequent monitoring of lymphocyte subsets is required to ensure early retreatment upon relapse. An alternative strategy, maybe pre-emptive rituximab dosing at fixed intervals. Even after 2 years of maintenance therapy, B cell repletion is still associated with relapse. Further work is needed to compare maintenance strategies and to determine the optimal length of time of maintenance rituximab.

PO1885
Belimumab for the Treatment of Frequently Relapsing Nephrotic Syndrome: The BELNEPH Study

Background: A pathogenic role of B cells in pediatric idiopathic nephrotic syndrome (INS) has been suggested by the therapeutic efficacy of B-cell depletion, which however can impair immune memory. Belimumab treatment affects B-cell survival and differentiation but preserves the established immune memory. Its efficacy has been proven in other immune-mediated diseases, such as systemic lupus erythematosus and membranous nephropathy.

Methods: In this open-label, prospective, single-arm study, 5 children with frequently-relapsing INS who were on alternate-day prednisone only were enrolled. Belimumab was administered at 10 mg/kg i.v. on day 0, 14, 28 and then every 4 weeks for up to 12 months. Concomitant prednisone treatment was gradually tapered up to recommended dose levels. Safety, efficacy and laboratory blood and urine parameters were monitored for the duration of the study.

Results: Four patients completed the primary endpoint (6 months) and 2 patients completed the study. Infusions were well tolerated. One patient experienced a pulmonary infection which required hospitalization 2.3 months after the first infusion. Four patients experienced a first relapse within 6 months (1.9, 2.5, 2.6, 3.3 months after starting treatment) and 1 patient 8.1 months from first infusion. Three patients discontinued the study due to the frequency of relapses (a2) after 5.2, 9.2, 9.6 months, respectively, and were started on another steroid-sparing agent. The study was discontinued due to apparent lack of effect in 1 child. CDR19 B cells decreased during the follow-up, with a nadir at 6 months (8.6% of lymphocytes vs 19.1% at baseline, p<0.01). Naïve B cells started to significantly decrease after 1 month (7.7% vs 12.4% at baseline, p<0.05) and continued to decline during the follow-up. In contrast, no significant impact was observed on memory B cells, which became the most representative B-cell subset already at month 1 (43.5% of B cells vs 27.3% at baseline, p<0.01), with an initial shift toward a switched memory B cells, which became the most representative B-cell subset already at 1 month.

Conclusions: A reduction in B-cell count in healthy subjects. The objectives were to characterize safety, tolerability, PK profile, and safety in healthy subjects. GFB-887 exhibits dose-dependent reduction in urinary Rac1, with an initial shift toward a switched memory B cells, which became the most representative B-cell subset already at 1 month.

Funding: Private Foundation Support

PO1886
GFB-887, a TRPC5 Inhibitor, Is Safe and Well Tolerated and Engages the TRPC5-Rac1 pathway. The safety and efficacy of GFB-887 is summarized as Ratio of Means (ROM) between baseline and follow-up measurements, or change from baseline in healthy subjects.

Methods: This is a phase 1, double-blinded, randomized, placebo-controlled, study in healthy subjects. Subjects were randomized to either GFB-887 or placebo (8:2) in 5, 20, 40, 80,160, 320, and 900 mg SAC cohorts. Each subject received a single dose, had 24-hour urine collection pre and post-dose, and followed for 28 days post-dose.

Results: 70 healthy subjects (median age 43 years, 86% male, 56% Caucasians, 42% African Americans) were dosed with GFB-887. The most common adverse event (AE) was headache. All AEs were mild and non-serious. There were no clinically significant changes in ECGs, vital signs or laboratory results. Blood pressure was modestly and asymptotically reduced at the highest doses. Cmax and AUC of GFB-887 increased with higher doses in a less than dose proportionally manner through 900mg. Urinary Rac1 was significantly reduced from baseline with increasing doses of GFB-887.

Conclusions: The PK profiles of GFB-887 were well tolerated with a favorable PK profile in healthy subjects. GFB-887 exhibits dose-dependent reduction in urinary Rac1, a regulator of podocyte cytoskeleton structure and motility, indicating that GFB-887 engages and inhibits the TRPC5-Rac1 pathway. The safety and efficacy of GFB-887 is currently being evaluated in patients with FSGS, MCD, and DN (NCT04387448).

PO1887
Phase 1 Study of N-Acetylmannosamine (ManNAc) for Glomerular Disease

Background: ManNAc is an uncharged monosaccharide and precursor of N-acetylgalactosaminic acid (NeuAc, sialic acid). It provides anionic charges to proteins, including those constituting the glomerular filtration barrier. Glomerular hyposialylation is common in nephrotic diseases and may contribute to podocyte foot process effacement and increased protein permeability. ManNAc showed benefit in nephrotic mouse models.

Methods: We performed a phase 1 study to evaluate the safety, tolerability, and pharmacokinetics of single and multiple doses of ManNAc in nephrotic subjects (NCT02639260). Seven subjects were enrolled, 6 with focal segmental glomerulosclerosis and 1 with membranous nephropathy. Urine protein/creatinine ratio was 1.3 to 9.9 g/l g.

Results: We evaluated the safety and efficacy of ManNAc in patients with focal segmental glomerulosclerosis (FSGS) and membranous nephropathy. All patients showed a reduction in proteinuria. Two patients (1 with FSGS and 1 with membranous nephropathy) had a ≥50% reduction in proteinuria. Two patients (1 with FSGS and 1 with membranous nephropathy) had a 24-48% reduction in proteinuria. There were no serious adverse events. The most common AEs were nausea, vomiting, and rash.

Conclusions: Oral ManNAc was safe and well tolerated in nephrotic disease subjects. ManNAc supplementation showed a trend towards proteinuria reduction, possibly linked to the degree of glomerular hyposialylation. A phase 2 study is planned to include assessment of longer-term pharmacokinetics, efficacy and safety.

PO1888
Efficacy and Safety of ACE Inhibitor and ARB Therapies in Primary FSGS and Nephrotic Syndrome: A Systematic Review and Meta-Analysis
Kirk N. Campbell,1 Natali Pennese,2 Andrea Zaffalon,2 Barbara Magalhaes,2 Marina Faiella,2 Dawn J. Caster,1 Jai Radhakrishnan,3 Vladimir Tesar,4 Howard Trachtman.4 Mt Sinai School of Medicine, New York, NY; 1LetticePoint Consulting, Geneva, Switzerland; 2University of Louisville School of Medicine, Louisville, KY; 3Columbia University Medical Center, New York, NY; 4Charles University, General University Hospital, Prague, Czechia; 5NYU School of Medicine, NYU Langone Medical Center, New York, NY.

Background: Use of ACEi and/or ARBs (RASi) as conservative management to control proteinuria in primary and genetic focal segmental glomerulosclerosis (FSGS) following guideline recommendations based on other proteinuria-related kidney diseases. There is lack of consensus about the efficacy and safety of RASi therapies in primary and genetic FSGS, thus this systematic review aims to assess the benefits and risks of RASi therapies on renal outcomes in these patients.

Methods: English-language studies were searched in MEDLINE, Embase and Cochrane Central Register of Controlled Trials, from inception to April 2019. Cohort studies assessing efficacy (response to treatment and indicators of renal function) and safety outcomes in primary and genetic FSGS were selected. Study results were summarized as Ratio of Means (ROM) between baseline and follow-up measurements, or as Hazard Ratio (HR) using random effects models.

Results: We selected 30 studies of which only 5 were controlled trials. Only 8 assessed RASi as monotherapy while the rest studied them in combination with other drugs, mainly immunosuppressants (IS). On average, a 32% reduction on proteinuria (ROM-0.68; 95% CI: 0.47-0.98) and no change on CrCl (ROM=0.95; 95% CI: 0.77-1.16) from baseline to variable follow-up periods was observed in patients treated with RASi therapy alone. A reduction of 72% in proteinuria was observed when RASi were combined with other drugs, mainly IS (ROM-0.24, 95% CI: 0.08-0.55). Published data did not allow to evaluate the eGFR ROM between follow-up and baseline and the

Efficacy and Safety of Immunosuppressive Therapy in Primary FSGS: A Systematic Review and Meta-Analysis

Dawn J. Caster, Barbara Magalhaes, Natali Pennese, Andrea Zaffalon, Marma Fatella, Kirk N. Campbell, Raji Radhakrishnan, Vladimir Tesar, Howard Trachtman, University of Louisville School of Medicine, Louisville, KY; 2 LatticePoint Consulting, Geneva, Switzerland; 3 Icahn School of Medicine at Mount Sinai, New York, NY; 4 Columbia University Medical Center, New York, NY; 5 Charles University, General University Hospital, Prague, Czechia; 6 NYU School of Medicine, NYU Langone Medical Center, New York, NY.

Background: Focal segmental glomerulosclerosis (FSGS) is a rare condition which can lead to decline in renal function and progression to ESRD. Immunosuppressants (IS) are often used to treat primary FSGS. However, their efficacy and safety is not clearly established. The aim of this work was to provide evidence on the current knowledge on the clinical effectiveness and safety of IS in the treatment of primary FSGS.

Methods: MEDLINE, EMBASE and Cochrane Central Register of Controlled Trials were searched for English-language studies on primary FSGS from inception to 2019. Clinical outcomes of IS were changes from baseline to follow-up, proteinuria and renal function (eGFR or CrCl) and survival (ESRD, renal failure, doubling of creatinine, or author reported). When possible, study results were summarized using random effects models as Ratio of Means (ROM) between follow-up and baseline measurements as Hazard Ratio (HR).

Results: We included 100 articles. Substantial heterogeneity was observed in patient baseline characteristics and study design. Most studies assessed treatment with corticosteroids alone or combined with other drugs, mainly other IS. On average, patients treated with IS showed a reduction of proteinuria (14 studies, ROM=0.34, 95% CI 0.25-0.46). Pooled studies showed a lower CrCl at the end of the follow-up compared to baseline (ROM=0.77; 95% CI 0.71-0.83). In contrast, eGFR measurements suggested no change from baseline to follow-up (16 studies, ROM=0.92; 95% CI 0.84-1.01). IS treatment had an uncertain effect on reducing the risk of reaching ESRD (HR=0.79; 95% CI 0.45-1.39) and renal endpoint (HR=0.80; 95% CI 0.66-0.96) and moderately reported in <5 studies.

Conclusions: This systematic literature review supports that patients treated with IS have on average, a reduction in proteinuria between baseline and varying follow-up periods. Reported changes from baseline to follow-up in CrCl and eGFR are contrasting and effect of IS on renal survival is uncertain. However, due to lack of properly controlled studies, it is hard to attribute how much of these outcomes are due to IS treatment effect, stressing the low certainty evidence currently available in the literature and the need for better designed studies to reliably assess the effect of IS on primary FSGS patients.

Cellular Senescence Is Associated with Faster Progression of Renal Disease in Adults with Focal Segmental Glomerulosclerosis: A 6-Year Prospective Cohort Study

Benjamin M. Forster, Robert Nee, Stephen W. Olson, Walter Reed National Military Medical Center, Bethesda, MD.

Background: Focal Segmental Glomerulosclerosis (FSGS) is a glomerular disease defined by pathognomonic histopathology but is caused by multiple mechanisms of disease, not all of which have been fully elucidated. Therefore, the reported renal prognosis, treatment strategies, and treatment response has varied significantly in previous small case series. We sought to analyze long term renal survival and associated risk factors in the largest cohort over the longest period of follow up described to date.

Methods: We performed a retrospective cohort study on all previous and current active duty military with biopsy proven FSGS. Potential cases were identified through a query of the military electronic medical record for International Classification of Diseases codes 9 and 10 codes (581.1, 582.1, and N04) and then confirmed by comprehensive chart review. Extensive data collection was performed and then analyzed using STATA 16.

Results: We identified 348 patients with biopsy proven FSGS with a mean follow up of 9.5 years. The majority were black, male, and under 40 years old. Progression to end stage kidney disease (ESKD) was 14%, 25%, and 35% at 5 years, 10 years, and 15 years after diagnosis, respectively. More patients with nephrotic range proteinuria progressed to ESKD (20%, 31%, and 49% at 5, 10, and 15 year follow up, respectively) than non-nephrotic range proteinuria (13%, 20%, and 31% at 5, 10, and 15 year follow up, respectively), and no significant proteinuria (6%, 14%, and 23% at 5, 10, and 15 year follow up, respectively) p=0.04. Overall progression to stage 3 chronic kidney disease (CKD3) was 32%, 40% and 50% at 5, 10, and 15 years after diagnosis, respectively. Full renography at initial treatment was associated with a substantial reduction in progression to ESKD (2%, 4%, and 7% at 5, 10, and 15 years follow up, respectively) compared to partial remission (12%, 21%, and 30%) and no remission (27%, 45%, 63%), p<0.001.

Conclusions: We present the largest cohort of biopsy proven FSGS cases over the longest follow up period to date. Approximately one third of all FSGS patients develop ESKD and one half developed CKD3 within 15 years. Proteinuria significantly increased the risk of progression to ESKD. Achieving a full or partial remission after initial treatment significantly decreased the risk of progression to ESKD.

Clinicopathologic Characterization of Focal and Segmental Glomerulosclerosis in a Dominican Republic Sample
Eliana Dina-Batlle,1 Limber I. Rojas,2 Mirtha C. Almanzar, Hector A. Pantaleon,1 José J. Sánchez.1 Hospital Metropolitano de Santiago, Santiago, Dominican Republic; 2Hospital General de la Plaza de la Salud, Santo Domingo, Dominican Republic; 3Pontificia Universidad Catolica Madre y Maestra, Santiago de los Caballeros, Dominican Republic.

Background: There are limited recent epidemiological and clinicopathological behavior reports on FSGS in the Caribbean population. The aim is to identify clinical characteristic, epidemiological trend and treatment response of patients with diagnosed FSGS and their different variants in a Dominican Republic sample.

Methods: Cross-sectional study of performed transcutaneous native kidney biopsy taken in an interval date from years 2018-2019 of two separate nephrology consult from Dominican Republic. Diagnosed FSGS biopsy reports available and biochemical laboratories (creatinine, BUN, 24h Proteinuria, cholesterol, triglycerides, hematuria) within the date of biopsy were analyzed. Histopathological analysis of foot process effacement (FPE) degree reported and nephrotic syndrome (NS) presentation was correlated to primary or secondary cause of FSGS. Also, description of FSGS variants and response to the different treatments imposed in the time of data collection, overlapping comorbidities and serology were taken in notice.

Results: 49 biopsies were analyzed with FSGS. NS variant was the most common (72%), tip lesion (6%) and collapsing (6%), with no reported perihilar or cellular variants and (4%) reported as unsampled biopsy of FSGS. Biopsy with diffuse FPE (>90%) 24 presented with nephrotic syndrome and 8 did not (p=0.01). Remission in biopsy with described diffuse foot process effacement (DFPE) with unidentified cause 32% had complete remission (CR) (serum albumin >3.5g/dl or <300 mg/24h protein), 16% had partial CR (serum albumin =3.5 to <4.5g/dl) and 52% did not remitted at 6 months period (p=0.92). Steroids and calcineurin inhibitors treatment were significantly associated with CR in FSGS with DFPE with unidentified cause (p=0.029, p=0.014 respectively).

Conclusions: Biopsies analyzed in a 2 year period presented NOS as the most common variant while perihilar or cellular variants were not reported. In the sample studied the degree of FPE was associated to NS presentation. The use of steroids and calcineurin inhibitors in suitable patients is significantly associated with remission of disease. The FPE degree, clinical manifestations of patients and history represent the best tools for correct diagnose and treatment.

Differentialiating Focal and Segmental Glomerulosclerosis
Afonso Santos,1 Ana Lima,1 Ana Gaspar,1 Ana C. Brás,1 Pedro Pereira Campos,2 Rita Theias Manso,3 Karina Soto.1 Nephrology Department, Hospital Professor Doutor Fernando Fonseca EPE, Lisboa, Portugal; 2Pathology Department, Hospital Professor Doutor Fernando Fonseca EPE, Lisboa, Portugal.

Background: FSGS is a histological pattern of kidney injury associated to broad causes and pathogenesis. FSGS can be primary, genetic or secondary to other conditions. Differentiating these subclasses is crucial for management and prognosis, but there is no general consensus, since the diagnosis is not always straightforward. This study aimed to identify FSGS histological diagnosis and clinical and histological criteria comparing outcomes.

Methods: In a retrospective analysis of 359 kidney biopsies we identified patients with diagnosis of FSGS histological diagnosis and secondary FSGS were identified based on clinical and histological data. Genetic FSGS was considered if they present at least one of the following: a nephrotic syndrome (NS) resistant to corticosteroids;b)NS with normal albuminuria;c)NS with focal foot process effacement or diffuse-nephrotic proteinuria with diffuse foot process effacement. Each group was divided in immunosuppression treatment (IST) or only supportive treatment (ST) groups. Renal and survival outcomes were assessed.

Results: Among 66 FSGS patients, 65% were males, 71% non-black, 74% had HTN, 26% diabetes; median eGFR 26.5mL/min/1.73m2 (IQG 15.3-48.8), 24h-UProtein 4.4g (IQG 2.5-7.6). Globally, 38% (n=25) progressed to ESKD and mean time to RRT was longer in IST group (p=0.37). According to the applied criteria 52% (n=34) were classified as having secondary FSGS, 23% (n=15) primary and 25% (n=17) as genetic FSGS. Among primary FSGS patients 40% received IST. In ST group 25% progressed to ESKD in a median time to RRT of 24 months (SD±21.7) vs 13% in 66mo (SD±33.3) in IST group. Among secondary FSGS, 17.6% received IST. Of them, 50% developed ESKD in 31.7mo (IQQ SD±28.6) vs ST group with 46% progression to ESKD in 12mo (SD±28.7). From the genetic group 59% were in IST group and 30% progressed to ESKD in 12mo (SD±27.1) vs ST group with 29% ESKD in 42mo (SD±27.1).

Conclusions: FSGS etiology is not straightforward in most patients. Since IST can be inappropriate and potentially harmful in some FSGS subclasses, it is crucial to identify patients with these conditions to the different treatments imposed in the time of data collection, overlapping comorbidities and serology were taken in notice.

Results: Among 66 FSGS patients, 65% were males, 71% non-black, 74% had HTN, 26% diabetes; median eGFR 26.5mL/min/1.73m2 (IQG 15.3-48.8), 24h-UProtein 4.4g (IQG 2.5-7.6). Globally, 38% (n=25) progressed to ESKD and mean time to RRT was longer in IST group (p=0.37). According to the applied criteria 52% (n=34) were classified as having secondary FSGS, 23% (n=15) primary and 25% (n=17) as genetic FSGS. Among primary FSGS patients 40% received IST. In ST group 25% progressed to ESKD in a median time to RRT of 24 months (SD±21.7) vs 13% in 66mo (SD±33.3) in IST group. Among secondary FSGS, 17.6% received IST. Of them, 50% developed ESKD in 31.7mo (IQQ SD±28.6) vs ST group with 46% progression to ESKD in 12mo (SD±28.7). The Dual Endothelin/Angiotensin II Receptor (ET, R/AT, R) Antagonist Sarspantien Slows Renal Disease, Improves Lifespan, and Attenuates Hearing Loss in Alport Mice: Comparison with Losartan and Atrasentan

Dominic F. Cosgrove,1 Brianna M. Dufek,1 Duane C. Delimont,1 Daniel M. Meehan,2 Gina C. Samuelson,1 Jared Hartsoek,2 Grady Phillips,2 Ruth Gill,2 James Hasson,3 Celia P. Jenkinskin,1 Radko Komers,1 MichaelAnne Grattan,1 1Boys Town National Research Hospital, Omaha, NE; 2Washington University, St. Louis, MO; 3Retrophin, Inc., San Diego, CA.

Background: In Alport syndrome (AS), ET, R activation is important in renal and inner ear pathologies. Previously, sparsentan (SP) was shown to prevent increases in proteinuria, glomerulosclerosis, and glomerular basement membrane dysmorphology in AS mice. Here we compare the effect of SP, the AT R antagonist losartan (LS), and the ET R antagonist atrasentan (ATR) on lifespan and proteinuria, and of SP and LS on hearing loss and inner ear pathology.

Methods: Wild type (WT) and AS mice were gavaged daily with vehicle (V), 60 or 120 mg/kg of SP (SP60, SP120), LS (20 mg/kg; 3-4 W) or LS (10 mg/kg from 4 W), or ATR (7.5 mg/kg females or 10 mg/kg males) in the drinking water. Two studies were conducted: early intervention for hearing from 3-8.75 W (V, SP120 and LS), and for lifespan with treatment from 3 W (V or 4 W, SP60, SP120, LS or ATR). Urinary protein/creatinine ratio (UP/C) was assessed weekly. The auditory brainstem response (ABR) was used to assess hearing ability and sensitivity to noise at 8.75-7.5 W. The cochleae were preserved and strial pathology determined by transmission electron microscopy.

Results: SP120 significantly (P<0.05) increased median lifespan compared to any other group (Figure 1). At 8 W, only SP120 significantly (P<0.05) attenuated the increase in UP/C compared to V (UP/C:mg/ml mean±SD: 47±16 V; 12±18 ATR; 42±18 ATAR; 51±16 SP60; 20±32 SP120). UP/C at 11 W in SP120 mice was significantly attenuated (P<0.05) vs. LS mice. SP120 significantly improved post-noise ABR thresholds at 16 kHz vs. V mice (P<0.05). LS had no effect. Dysmorphology of the stria vascularis was noted in LS treated mice, but not in SP120 mice.

Conclusions: SP120 in AS mice extended lifespan beyond that of mice treated with SP60, LS, or ATR and attenuated noise-induced hearing loss compared to LS. Sarspantien may therefore offer a novel, dual-therapeutic approach in AS by reducing both renal injury and hearing loss.

Long-Term Outcomes of Tacrolimus Treatment for Idiopathic Membranous Nephropathy

Ajikateri K. Nikolopoulou,1 Sarah Gleeson,1 Rakesh Dattani,1 Marie B. Condon,1 Tom Cairns,1 Jeremy B. Levy,1 Liz Lightstone,2 Stephen P. McAdoo,1 Frederick W. Tam,1 Charles D. Pusey,1 Megan Griffith,1 1Imperial College Healthcare NHS Trust, London, United Kingdom; 2Imperial College London Faculty of Medicine, London, United Kingdom.

Background: Tacrolimus (TAC) is effective for the treatment of membranous nephropathy (MN). Methods: Retrospective study of longterm outcomes of 111 patients (pts) with MN treated with TAC from January 2000 to June 2018. Results: Demographics/table 1. Treatment: 91/111 TAC monotherapy, 20/111 dual therapy with mycophenolate + TAC. All pretreated with ACEi/ARB. Median follow up (FU) 68 months (IQR 33-115). 93/111 pts (84%) reached Partial Remission (pCR) reduction by 50% and <300mg/mmol at 5.1 months (median, IQR 2-11), 76/111 (69%) also reached Complete Remission (cPCR). 3/111 pts (6%) had proteinuria, 3/111 pts (6%) had no proteinuria, 1/111 pts (1%) had a rapid reduction of immunosuppression. 28/48 were retreated with TAC and all achieved remission, 15/84 treated with RTX, remission in 11/15. 3/84 treated with TAC and steroids. Only 4 achieved remission, all in the RTX group. 2 lost to FU. 48/83 (51%) of pts that achieved remission relapsed after 22 months (14-34) (Figure 1) following withdrawal of TAC. cPCR rate (37 patients) had urinary protein excretion less than 3.5 grams per day, and one (3%) had no proteinuria. To evaluate renal biopsy specimens, light microscopy was performed in all cases, fluorescence microscopy in 36 cases and electron microscopy (EM) in 28 cases. 14 patients (38%) were diagnosed with primary MN, 22 patients (59%) with secondary MN, and one patient (3%) with de novo MN post-transplantation. Secondary MN were due to lupus erythematosus (27%), mixed connective tissue disease (14%), Sjögren’s syndrome (3%), hepatitis B (11%), b-cellulitis use (3%), and grafted versus host disease (GHVD) after peripheral blood stem cell transplantation (3%). Mean and median follow-up period was 14.9 and 12.0 years, respectively. At the end of follow-up, only two patients out of the 37 patients reached end-stage renal disease, and 33 patients (89%) observed serum creatinine level lower than 1.5 mg/dL. 21 patients achieved complete remission (CR). Among 27 cases who underwent EM, cases with subendothelial deposits had smaller CR rate (3/11 cases) than those without subendothelial deposits (12/16 cases), which was statistically significant (χ²=6.01, p=0.014). The CR rates of cases with mesangial deposits (12/21 cases) and those without mesangial deposits (3/6) was not significantly different (χ²=0.096, p=0.76).

Conclusions: The diagnosis of renal function was fairly good in patients with MN in the age under 50 years old. Cases with coexisting subendothelial deposits showed lower CR rate than the rest.

A Target Antibody-Based Approach to the Classification of Membranous Nephropathy

Shane A. Bobat,1 Shahrazad Tehranian,1 Sanjeev Sethi,1 Mariam P. Alexander,1 Samih H. Nasr,1 Julie A. Vrana,1 Samar M. Said,1 Callen D. Giesen,1 John C. Lieske,1 Fernando C. Fervenza,1 An S. De Vriese.1 1Mayo Clinic Minnesota, Rochester, MN; 2AZ Sint-Jan Brugge-Oostende, VE, Brugge, Belgium.

Background: Primary membranous nephropathy (MN) is caused by circulating auto-antibodies against podocyte surface antigens, identified as M-type-phospholipase–A2-receptor (PLA2R) in 70-80% and thrombospondin-type-1-domain-containing-7A (THSD7A) in 2-5% of patients. Secondary MN occurs in the context of malignancy, autoimmune disease, infection, paraproteinemia or medication. Some patients with PLA2R-associated MN have a current or previously diagnosed associated condition, but it remains statistically significant (χ²=6.01, p=0.014). A few THSD7A-associated MN cases have a strong etiologic link with active malignancy, while in others malignancy appears coincidental. Exostosin 1/exostosin 2 (EXT1/EXT2) are recently discovered target antigens in patients with MN, the majority of whom have autoimmune disease. These recent findings blur the traditional distinction between primary and secondary-containing MN.

Methods: To describe the phenotypes of PLA2R-, THSD7A- and EXT1/EXT2-associated MN, 201 adult patients with biopsy-proven MN were classified using serology, immunostaining and mass spectrometry. Clinical, biochemical and follow-up data were examined for associated disease and its relationship with MN.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

589
Results: PL-2R-associated MN (n=161) occurred predominantly in middle-aged women, with a peak at 40-50 years. Only 1 case of PL-2R-associated MN was identified, with a concomitant malignancy. EX1/EX2-associated MN (n=8) was identified in younger females and was strongly linked with active autoimmunity. The majority of patients who were negative for all three target antigens (n=70) presented with associated disease, mainly malignancy and autoimmunity.

Conclusions: In conclusion, the historical primary-secondary dichotomy has substantial limitations when applied to MN. We propose a terminology combining the target antigen involved in pathogenesis and the associated clinical diseases in order to classify MN and guide clinical decision making.

Non-invasive Diagnosis of Primary Membranous Nephropathy Using Anti-PLA2R A2 Receptor (PLA2R) Antibodies: A Validation Study
Shane A. Bobart,1 Shahrazad Tehranian,1 Cristina Andrades Gómez,2 Sanjeev Sethi,1 Callen D. Gissen,1 John C. Lieske,1 An S. De Vries,2 Fernando C. Fervenza,3 Mayo Clinic Minnesota, Rochester, MN; 3Hospital Universitario Virgen del Rocio, Sevilla, Spain; 4AZ Sint-Jan Brugge-Oostende AV, Brugge, Belgium.

Background: Kidney biopsy is the current gold standard to diagnose membranous nephropathy (MN). Approximately 70-80% of patients with primary MN have circulating anti-PLA2R antibodies, which could provide an alternative diagnostic test to kidney biopsy. We performed a multi-center validation study of two ELISA tests to establish its value as a diagnostic test in MN.

Methods: We retrospectively analyzed 1112 unique Mayo Clinic patients with positive serum anti-PLA2R antibody tests by both ELISA and IFA between July 2018 and April 2020. The test results were compared with the histopathological diagnosis of MN.

Results: A total of 1522 anti-PLA2R antibody tests were ordered in 1112 unique patients, yielding 128 positive results. We excluded previously reported patients (n=33), renal transplant recipients (n=5), no biopsy available (n=18), and pediatric cases (n=2). In all 70 remaining patients, the primary biopsy diagnosis was MN. Associated disease was identified in 28 cases (autoimmunity = 10, malignancy = 6, NSAID = 4, Hepatitis = 3, and unknown = 9). A total of 28 patients were classified into the anti-PLA2R antibody positive group by both ELISA and IFA.

Conclusions: We established that anti-PLA2R antibodies are predictive of membranous nephropathy (MN) and may be used as a non-invasive alternative to kidney biopsy.

PO1903
Concurrent Anti-Glomerular Basement Membrane Nephritis and Membranous Nephropathy
Syeda B. Ahmad,1 Dominick Santoriello, Pietro A. Canetta, Andrew S. Bombach,2 Vivette D. D’Agati,1 Glen S. Markowitz, Woon Ahn,1 Jai Radhakrishnan,1 Gerald B. Appel.1 Columbia University Irving Medical Center, New York, NY.

Background: Anti-GBM nephritis is an uncommon entity with a rapidly progressive course. The concurrent occurrence of anti-GBM nephritis with membranous nephropathy (MN) is rare and poorly understood. We report a single center case series of this dual glomerulopathy with emphasis on presenting features, course, and outcome.

Methods: A total of 12 cases of combined anti-GBM nephritis and MN were identified from the archives of the Columbia Renal Pathology Laboratory over the past 18 years. Presenting clinical, histopathologic and laboratory data with follow up were obtained by chart review.

Results: The cohort of 12 cases included 7 men and 5 women with age range 18-81 years. The most common presenting feature was AKI (mean creatinine 9.3 mg/dl), with one patient having pulmonary symptoms. Positive anti-GBM serology was available at presentation for 11 cases, 5 with titters >100 AU/mL, and all were ANCA negative. Of those tested the majority were PL-2R negative. Patients were predominantly Caucasian (N = 9). All patients required hemodialysis (HD) at presentation, and two patients, a 19-year-old woman and an 81-year-old woman had renal recovery with the later having a stable creatinine of 2.0 mg/dl 11 months later. Treatment regimens included the following: cyclophosphamide, plasmapheresis, and prednisone (N=9); cyclophosphamide and granulocyte colony stimulating factor (N=2) and corticosteroids alone (N=1). The mean follow up time was 36 months after presentation from sepsis. Analysis of the 12 renal biopsies showed combined linear and granular staining of GBMs for IgG, with crescents involving 23-100% of glomeruli, and fibrinoid necrosis involving 15-100%. The two patients who recovered renal function had total crescents (82% crescents, and 23%, respectively) and less fibrinoid necrosis (15% and 31%) compared to the subgroup without recovery respectively, on kidney biopsy.

Conclusions: Combined anti-GBM and MN is a rare entity presenting with severe AKI and HD. Renal recovery is uncommon. High percentage of crescents are consistent with poor outcomes. Treatment and course are dominated by anti-GBM nephritis. The MN component is predominantly PL-2R negative, and further studies into pathogenesis are needed.

PO1904
Recurrent Membranous Post Transplantation: Histopathology, Treatment, and Outcomes
Sarah Gleeson,1 Akikateri K. Nikolopoulou,2,3,11 Meghan Griffith,1,2 Marina Loucaidou,4 Michelle Willcombe,5,6 Candice A. Roufosse,7,8 Imperial NHS Healthcare Trust, London, United Kingdom; Imperial College London Faculty of Medicine, London, United Kingdom.

Background: Membranous nephropathy(MN) recurs in 30-45% of transplants. Reported recurrence rates are higher in centres that perform surveillance biopsies. Optimal treatment is unknown. We examined recurrent MN in our cohort in terms of their histopathology, treatment and outcomes.

Methods: Patients with MN as the cause of their ESRF who were later transplanted were identified from an in-house database. Further data was collected from the electronic health record.

Results: 36 patients with a diagnosis of MN were transplanted. Mean follow up was 6.4 ± 4.2 years. 41.6% had a rejection episode (mean time from transplant 0.42 ± 0.15 years). Overall there was 22% graft loss (mean time 6.5 ± 3.7 years), 11% deaths (8.6 ± 2.3 years from transplant) and 6% deaths with functioning grafts (mean time 6.9 ± 2.3 years). Mean eGFR at 3 months and 1 year were 48.1 ± 18.5 and 48.1±14.5 ml/min. 30/36 patients had at least one biopsy following transplantation. Of those whose biopsies did not show recurrence, the mean time to the most recent biopsy was 2.9 ± 2.7 years (range 0.02-9.3) 8/36 patients (22%) had recurrent MN, 7 detected on indication biopsy and 1 on surveillance biopsy. The mean time to recurrence was 1.9 ± 1.1 years (range 0.09-4.46 years). Granular C4d staining of the capillary wall was detected in 6/8 biopsies prompting immunofluorescence and electron microscopy, leading to the diagnosis of recurrent MN. Histological anti-PLA2R staining was positive in 3/8 biopsies. 2/8 patients had donor specific antibodies. In the 4 patients with clinically significant proteinuria rituximab was used to treat with a complete or partial response in all patients (mean time 22.5±16 months (range 4-43.8 months). There are no significant differences in rejection, graft loss, death or death with functioning graft between those with recurrence and those without recurrence in our cohort.

Conclusions: Recurrent MN was frequent but not associated with increased alloagraft failure in our programme, with the use of rituximab in selected cases. Granular C4d in the glomeruli in transplant patients with MN could prompt further investigation with immunofluorescence and electron microscopy to look for recurrent disease.
Secondary Polycythemia Associated with Membranous Nephropathy
Ramakrishna Thotakura,1 Suman Siddanreddy,2 Sruhti Kanuru,4 Aditya Kadiyala,1,2 University of Arkansas for Medical Sciences, Little Rock, AR;3 Baptist Health, Little Rock, AR;4 University of Maryland Medical System Corporation, Baltimore, MD. 1Central Arkansas Veterans Healthcare System; John L McClellan Memorial Veterans Hospital, Little Rock, AR.

Introduction: Polycythemia has been recognized as a common occurrence in certain renal diseases such as cystic diseases of the kidney, renal cancer, tuberous sclerosis and hydropnephrosis. However, polycythemia in association with membranous nephropathy has rarely been reported. Here we report a case of secondary polycythemia from membranous nephropathy. Although the mechanism of this phenomenon is unclear, decreased effective circulating volume leading to hypoxemia and thereby polycythemia seems to be the most likely explanation.

Case Description: 37-year old white male with Hypertension, OSA using CPAP, tobacco use was admitted with 40-lb weight gain and anasarca. 24-hour urine collection revealed 17-gram protein excretion with serum albumin of 1.1 and marked hyperlipidemia. Kidney biopsy revealed membranous nephropathy. Staining for PLA2R and THSD7a were negative within the glomerular deposits. Evaluation for secondary causes of membranous nephropathy was negative for ANA, RPR/ rhythm antibodies, Hepatitis, HIV, ANCA, Anti-GBM Ab and normal C3,C4 levels. CT of thorax was negative for overt malignancy or hepatoplenomegaly. Patient’s hemoglobin ranged between 16.5 – 18.5 g/dl (hct 52-60%). Serum erythropoietin level was 12.3 IU/L (Normal 5-30 IU/L) with corresponding hemoglobin of 18.2 g/dl. JAK2 exon12, V617F mutations were negative. Hematology evaluation concluded that primary polycythemia is unlikely. Patient received 2 doses of 1 Gm Rituximab given 4 weeks apart. Patient was placed on Apixaban for prophylactic anticoagulation. Follow up labs to evaluate response to therapy are currently pending. It is yet to be seen if polycythemia resolves with remission of membranous nephropathy.

Discussion: Polycythemia is seldom seen in patients with membranous nephropathy. We postulated that hypoxia induced by decreased renal perfusion is the main trigger for polycythemia. However, it is puzzling as to why more patients with membranous nephropathy are not polycythemic. This leads us to believe that there might be some unique processes leading to polycythemia in membranous nephropathy, as in this patient, which probably contribute to these polycythemic patients. Certainly, further enhancements to this research need to be considered in these patients.

Membranous Nephropathy Preceding the Recurrence of Thymoma
Perola Lamba,1,2 David L. Epstein,1,3 Weill Cornell Medicine, New York, NY; 2Rogosin Institute, New York, NY.

Introduction: Membranous nephropathy secondary to neoplastic processes is a recognized phenomenon, and it may be the first finding that leads to the diagnosis of the underlying malignancy. Here we describe a case of secondary MN in a patient with a history of recurrent thymoma that led to a prompt evaluation for malignancy, which did not appear on PET imaging until a few months later.

Case Description: We describe the case of a 62 year old man with myasthenia gravis (on IVIG), history of thymoma with recurrence in 2017 and March 2019 requiring multiple surgeries and adjuvant chemoradiation. There was no evidence of disease in 2018. In November 2019, he presented with worsening anasarca and a myasthenic flare, for which he was treated with steroids, Rituximab and plasma exchange. A kidney biopsy was performed and consistent with recurrent thymoma. He was then referred to Metabolic Stone Center. In February 2020, he presented with marked oedema and heavy proteinuria a kidney biopsy was performed for the possibility of membranous nephropathy. Kidney biopsy revealed a mixed membranous and membranoproliferative glomerulopathy. Investigations: creatinine 44umol/L (55-110), albumin 7g/L (35-50), urine PCR 1456mg/mmol (Normal <50mg/mmol), renal biopsy demonstrated MCD. He was treated with steroids. In order to search for possible secondary causes of membranous nephropathy, this case presentation suggests that hypoxemia and immunosuppression may be the optimal imaging for undiagnosed malignancy or recurrent malignancy in this setting.

Discussion: There have only been 4 previous reports of de novo MCD in pregnancy all of whom were treated with steroids. In our patient who presented early in pregnancy with marked oedema and heavy proteinuria a kidney biopsy was performed. Kidney biopsy should be performed when the benefit of obtaining a diagnosis outweighs the risks of the procedure. In pregnancy the risks are increased (7% versus 1% outside pregnancy). Polycythemia during the 1st trimester is safest. Corticosteroids are often used to treat MCD outside pregnancy. Prednisone is safe in pregnancy as the fetal dose is minimal. However, there were maternal complications including gestational diabetes and weight gain. The recent MinTac trial of prednisone and tacrolimus in patients with MCD found no difference in remission rates at 8, 16 or 26 weeks and no difference in relapse rates. We achieved partial remission in this heavily nephrotic patient with use of tacrolimus alone and rituximab. Anticoagulation, which was started in the first trimester, was maintained on rivaroxaban which was compatible with the GI bleed. We believe tacrolimus is a valuable option for treatment of MCD in pregnancy.

A New Approach to De Novo Minimal Change Disease in Pregnancy
Sarah Gleeson,1 Filipa Cardoso,1 Liz Lightstone,1,2 Tom Cairns.1 Imperial Healthcare NHS Trust, London, United Kingdom; 2Imperial College London Faculty of Medicine, London, United Kingdom.

Introduction: Although proteinuria in pregnancy is common and usually due to preeclampsia, nephrotic range proteinuria especially in early pregnancy, warrants investigation and treatment. We present the first case of minimal change disease (MCD) presenting in pregnancy, treated successfully with tacrolimus.

Case Description: A previously well 20 year old G1P0, presented at 9 weeks gestation with 3 weeks of oedema and shortness of breath. Examination revealed marked oedema. Investigations: creatinine 44umol/L (55-110), albumin 1g/L (35-50), urine PCR 1456mg/mmol (Normal <50mg/mmol). A PET scan confirmed a via renal malignancy. A renal biopsy was performed which demonstrated MCD. She was started on tacrolimus in addition to enoxaparin, furosemide and aspirin. At 12 weeks she had melena with a haematoglobin drop. There was no active bleeding on endoscopy and she had no further episodes in pregnancy. She was managed by serial transfusions and joint renal-obstetric management. The patient subsequently delivered a healthy baby, which was born at term. She was then maintained on tacrolimus alone (levels 5-8ug/L). Her albumin rose and PCR fell throughout pregnancy. By 34 weeks her albumin was 28g/L and uPCR was 128 mg/mmol. Fetal growth was normal on serial growth scans. She did not develop preeclampsia. Labour was induced at 39 weeks and she had a normal vaginal delivery of a 3194g healthy baby.

Discussion: There have only been 4 previous reports of de novo MCD in pregnancy all of whom were treated with steroids. In our patient who presented early in pregnancy with marked oedema and heavy proteinuria a kidney biopsy was performed. Kidney biopsy should be performed when the benefit of obtaining a diagnosis outweighs the risks of the procedure. In pregnancy the risks are increased (7% versus 1% outside pregnancy). Polycythemia is seldom seen in patients with membranous nephropathy. Although the mechanism of this phenomenon is unclear, decreased effective circulating volume leading to hypoxemia and thereby polycythemia seems to be the most likely explanation.

Prevention of TP-Induced Nephrotic Syndrome (NS) in Pregnancy
Greco.1 Baystate Medical Center Renal Fellowship Baystate Medical Center; Springfield, MA; 2University of Massachusetts Medical School, Worcester, MA.

Introduction: Cystinuria, a rare inherited metabolic disorder characterized by defective proximal tubule cysteine transport, manifests predominantly in childhood or young adulthood with renal colic and recurrent nephrolithiasis, often requiring urologic intervention. Insoluble cystine in the urine precipitates into hexagonal crystals that can coalesce into larger, recurrent calculi, with associated higher risk of chronic kidney disease. Prevention of stone formation is the primary goal, using conservative non-pharmacologic approaches and if unsuccessful then pharmacologic. Since its approval in 1986, thiazide (TP), a thiol compound that forms a soluble mixed disulfide, has been used to increase urine cystine solubility. Adverse effects of TP include hypokalemia, cutaneous and mucosal. Reports of TP-induced nephrotic syndrome (NS) are rare, especially due to minimal change disease (MCD).

Case Description: A 19-year-old male with cystinuria and bilateral nephrolithiasis requiring extensive urologic interventions was on TP 300 mg bid for 6 months, when he presented to the Emergency Department with foamy urine, decreased urine output and anasarca. Labs showed elevated urine protein/creatinine ratio 9.2 (uPCR), low serum albumin 1.6 mg/dl and elevated cholesterol. ANA, ANCA, anti-GBM, HBV, HCV, HIV, C3, C4, and cryoglobulins were negative. Renal biopsy demonstrated MCD. He was not treated with steroids. TP was discontinued and uPCR 2 months later was 0.21 and albumin 2.3, with complete resolution of symptoms. He was referred to Metabolic Stone Center to discuss alternative treatment options.

Discussion: Only 31 cases of TP-induced NS have been reported to date, the majority membranous glomerulonephritis (GN), fewer cases of mesangiproliferative or membranoproliferative GN and only two cases of MCD. Although the exact mechanism is unclear, TP is speculated to play an antigenic role interfering with podocyte function. TP induced NS is not necessarily dose-dependent, with no relationship between mean daily dose and prevalence. The highest prevalence occurs in the first six months and is self-limiting. However, treatment with TP should be limited upon cessation of TP, without need for immunosuppressives. Clinicians should be aware of the rare but severe occurrence of NS due to TP. A weekly dipstick for protein may help in early detection.

Recent Nephrotic Syndrome in Podocyte Infolding Glomerulopathy: Remission with Rituximab
Spencer Hodgens,1,2 Barbara A. Greco.1,2 Baystate Medical Center Renal Fellowship Baystate Medical Center; Springfield, MA; 1University of Massachusetts Medical School, Worcester, MA.

Introduction: Podocyte infolding glomerulopathy (PIG) is a recently recognized entity. The seminal paper showed that it is associated with autoimmune disorders and is often responsive to corticosteroids (CS). We present a case of PIG with recurrent nephrotic syndrome (NS) who is maintaining remission on Rituximab off of CS.
Case Description: A 61-year-old woman with type II diabetes mellitus, inflammatory bowel disease (IBD), and uveitis presented in 2009 with proteinuria. Kidney biopsy was read as focal segmental glomerulosclerosis (FSGS). She was treated with angiotensin converting enzyme inhibitor (ACE-I) and prednisone, and proteinuria remitted. In 2012, an increase in proteinuria prompted repeat biopsy resulting in a diagnosis of membranous glomerulonephritis. Anti-PLA2R was negative. ACE-I and prednisone were continued and proteinuria remitted. In 2014, she developed nephrotic syndrome (NS). Repeat biopsy was read as showing FSGS. Prednisone 1 mg/kg/day induced remission. When prednisone was tapered, NS flared. She did not remit with high dose prednisone and at 8 weeks developed acute kidney injury (AKI). Tacrolimus was added and proteinuria and creatinine (Cr) improved. Steroids were tapered over several months. On Humira for IBD and tacrolimus (level 11 µg/dL), NS and AKI flared 1 year later with urine protein:creatinine (UP/C) of 2 and Cr 2.1 mg/dL. Prednisone was restarted. Intravenous cyclophosphamide was started, steroids were tapered, and Humira was discontinued. Within 5 weeks, proteinuria worsened (UP/C 29) and cr rose to 4 mg/dL. Renal biopsy demonstrated foot process invagination yielding a diagnosis of PIG. At trial of cyclosporine was stopped at 1 week due to drug intolerance. Mycophenolate mofetil (MMF) in combination with prednisone and tacrolimus was started. MMF caused severe diarrhea. In September of 2019, 4 weekly treatments of rituximab were administered. Proteinuria remitted and creatinine improved to 1 mg/dL. She remains in remission off of steroids and on lower dose tacrolimus now for 11 months.

Discussion: This case is the first to describe the effectiveness of Rituxan as rescue and maintenance therapy following failure of other IS regimens in a patient with recurrent NS due to PIG. Rituxan should be considered in refractory cases of PIG to induce and maintain remission and allow for steroid sparing.

PO1910 Glomerular Tip Lesion FSGS: A Rare Case of Nephrotic Syndrome in African Americans

Andrew A. Moses, Syed A. Husain, Woon Ahn. Columbia University Irving Medical Center, New York, NY.

Introduction: Nephrotic syndrome caused by focal segmental glomerular sclerosis (FSGS) in African Americans is known to have a poor prognosis and frequent treatment failure. Tip variant FSGS connotes good prognosis, usually responsive to calcineurin inhibitor (CNI) and steroid. We present a case of CNI resistant tip lesion FSGS requiring plasma exchange (PLEX) and rituximab.

Case Description: A 25-year-old African-American male, initially presenting to our outpatient clinic for edema associated with proteinuria. He had a past medical history of seizure disorder controlled with zonisamide. He trialed hydrochlorothiazide and furosemide without success. His urine showed nephrotic range proteinuria with 6g/g creatinine on spot urine. Outpatient workup was unremarkable, and was managed with enalapril and torsemide. He eventually had worsening edema and shortness of breath, prompting ED visit. Biopsy was performed which showed FSGS, tip variant. He was discharged on cyclosporine and increased diuretics. Cyclosporine caused gastrointestinal upset, and so patient switched to tacrolimus. He again had increasing swelling, and was admitted to hospital. He was found to have acute kidney injury, and 10g/g creatinine despite therapeutic tacrolimus levels. Patient trialed stress dose steroids but serum creatinine rose to 4.44. He started PLEX for 10 treatments, and then transitioned to rituximab. During treatment with PLEX patient creatinine quickly downtrended, and after second dose of rituximab as an outpatient he was back to baseline. He lost 30 kg with resolution of his edema. Patient then tapered off steroids, and will continue on rituximab alone.

Discussion: Glomerular tip lesion is more common in European Americans and associated with a favorable outcome compared to other subtypes of FSGS. Resistance to one immunosuppressive treatment is not always associated with resistance to other treatment modalities. PLEX and rituximab should be considered in glomerular tip lesion in African Americans.

PO1911 Utility of Immunofluorescent Intensity of IgG3 and Phospholipase A2 Receptor-to-IgG4 Ratio to Presume the Prognosis of Patients with Membranous Nephropathy

Takatsugu Iwashita, Kaori Takayama, Maiko Yamasaki, Mai Aoyagi, Taisuke Shimizu, Hajime Hasegawa. Department of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawsago, Japan.

Background: Membranous nephropathy (MN) is likely to show the long-term course and is a frequent glomerulonephritis in the elderly. For this reason, effective use of immunosuppressive drugs in a short period of time is desirable. In this study, we aimed to investigate the factors that could predict treatment responsiveness, using the treatment outcome in a short period of time, and retrospectively analyzed patients with MN in our hospital.

Methods: We included 66 patients who underwent renal biopsy and were diagnosed with MN in our hospital between April 2009 and December 2017. The percentage reduction in proteinuria one month after initiation of steroids, immunosuppressants, and ARBs was set to the endpoint. Intensity of immunofluorescent staining (IF) was scored according to the criteria of Japanese Society of Nephrology. Hematuria was quantified by 7-grade scoring of RBC numbers in high powered microscopic field.

Results: The intensity of IF (IgG subclass, PLA2R, THSD7A) was numerically evaluated and used for the analysis. The mean age of the patients included in the analysis was 66.4±11.7 years and baseline cGFR 63.9±18.7 ml/min, baseline urine protein was 7.05±5.45 g/gCr. Multiple parameters in high responder (HR, n=39) that resulted in less than 50% of urine protein after one month and low responder (LR, n=27) that remained proteinuria more than 50% were compared. Baseline urine protein and scored baseline hematuria were both higher in HR group (urine protein: 6.95 in HR vs 3.86 g/gCr in LR, p=0.003; hematuria: 1.0 in HR vs 0.0 in LR, p=0.036), but there was no difference in baseline cGFR (70.5 in HR vs 60.4 ml/min in LR, p=0.087). The mean dose of prednisone was also not different between the two groups (18.6 in HR vs 14.0 mg/day in LR, p=0.451). In IF, significant differences were observed between the two groups in the scored staining intensity of IgG3 and the staining intensity ratio of PLA2R to IgG4 (PLA2R-to-IgG4 intensity ratio;PGIR) were both lower in HR group (IgG3: 0.9 in HR vs 0.0 in LR, p=0.049; PIGR: 0.58 in HR vs 1.00 in LR, p=0.029).

Conclusions: From the result of the present examination, staining intensity of IgG3 and intensity ratio of PLA2R to IgG4 might be helpful to predict better therapeutic responsiveness in addition to the baseline proteinuria and hematuria.

PO1912 Graves Disease and Nephrotic Syndrome

Sajid Mahmood, Alaleh Mazhari, Nicholas Emanuelle, David J. Leehey. Loyola University Health System, Maywood, IL.

Introduction: Disorders of the thyroid and kidney may co-exist. Isolated case reports of Graves’ disease associated with various glomerular diseases, including membranous nephropathy, membranoproliferative GN, fibrillary GN, and minimal change disease have been published. A patient with membranous nephropathy and Graves’ disease who had improvement but not resolution of proteinuria after treatment with radioactive iodine has been described (Sasaki et al. CEN Case Rep. 2014; 3(1): 90-93). We report a case of nephrotic syndrome associated with Graves’ disease which completely resolved after treatment with radioactive iodine.

Case Description: A 33-year-old healthy female was seen for evaluation of proteinuria discovered during a routine life insurance evaluation. BP was normal, and she had trace-1+ lower extremity edema. Urinalysis showed 3+ protein, 1 red blood cell and 1 white blood cell per high power field. Urinary albumin/creatinine ratio was 4010 mg/g. Serum albumin was 2.7 g/dL. Renal function was normal. Tests for histoplasmin B and C, HIV, RPR, ANA, C3, C4, cryoglobulins, immunofixation, and free light chains were normal. Renal biopsy was planned but the patient missed the biopsy date. Subsequently she returned to clinic complaining of neck swelling. Exam revealed tachycardia, palpable goiter, 1+ pedal edema, no tremor. She reported heat intolerance, occasional diarrhea, insomnia, diaphoresis, and weight loss for the past month. A thyroid panel showed TSH <0.01 UU/mL (0.40-4.60 UU/mL), free T3 <2000 pg/dL (230-420), and free T4 10.6 ng/dL (8.5-1.7). TSH receptor and thyroid peroxidase antibodies were present. The patient was treated with methimazole and tapering steroids. She refused thyroid surgery and ultimately underwent two sessions of radioactive iodine treatment. After this treatment, nephrotic syndrome went into complete remission (Figure).

Discussion: Although relatively uncommon, Graves’ disease needs to be considered as a reversible cause of nephrotic syndrome.
TREATMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS WITH OR WITHOUT NEPHRITIS WITH THE IMMUNOPROTEASOME INHIBITOR KZR-616: INITIAL RESULTS OF THE MISSION STUDY

Mary K. Farmer,1 Samir V. Parikh,2 Richard Furie,3 Christopher Kirk,1 Ken Harvey,4 Darrin Bomba. 1Kezar Life Sciences, Inc, South San Francisco, CA; 2The Ohio State University, Columbus, OH; 3Northwell Health, Great Neck, NY.

Background: Immunoproteasome inhibition demonstrated therapeutic potential in preclinical models of systemic lupus erythematosus (SLE) and lupus nephritis (LN). KZR-616 is a first-in-class selective immunoproteasome inhibitor, which has been safe and well tolerated in early clinical trials. One hundred subjects across 2 healthy volunteer studies, with dosing of KZR-616 up to 75mg SC, achieved target levels of immunoproteasome inhibition at doses ≥30mg. Here we report safety, tolerability and exploratory efficacy data from the Phase 1b portion of MISSION (KZR-616-002; NCT: NCT03393013), a clinical trial in which KZR-616 was administered to patients with active SLE with or without LN.

Methods: In this open-label dose-escalation study, SLE patients (per SLICC classification criteria) with SLEDAI ≥4 despite stable background therapy received KZR-616 at doses of 45mg (Cohort 1), 60mg (Cohort 2), or 60mg following a step-up dose (Cohort 2a, 2b, 2c) SC weekly through Week 13 (W13) with 12 weeks of follow-up.

Results: To date, 39 patients with SLE, including 2 patients with active proliferative LN, have enrolled in MISSION. The majority of TEAEs have been mild or moderate with injection site reactions the most common TEAE. Tolerability has improved with an initial step-up dosing regime, subsequent doses and the introduction of a lyophilized formulation. To date, no patients have discontinued from cohorts after implementation of these protocol modifications. Multiple measures of disease activity improved from Baseline to W13 and persisted through W25; no patients worsened over 13 weeks. KZR-616 administration resulted in improvements in multiple serologic markers as well as reduced expression of inflammatory gene expression modules. Both patients with biopsy-proven active proliferative LN had reductions in proteinuria.

Conclusions: KZR-616 has been safe and tolerated at a target dose of 60mg weekly. Step-up dosing, use of select pre-medications, and/or introduction of a lyophilized preparation have increased its tolerability. The administration of KZR-616 resulted in improvements across multiple disease activity measures as well as serologic markers, including improvement in proteinuria in patients with active proliferative LN. MISSION is an on-going study now focused on patients with LN.

RITUXIMAB AS MAINTENANCE THERAPY IN LUPUS NEPHRITIS

Anushya Jeyabalan, Jillian Rosenthal, Reza Zonozi, Noah Huizenga, Karen A. Laliberte, John Niles. Massachusetts General Hospital, Boston, MA.

Background: Rituximab (RTX) has been shown to be effective in refractory lupus nephritis (LN) in some studies. Minimal literature exists on using RTX as maintenance therapy for LN.

Methods: We performed a retrospective review of 21 patients (pts) with biopsy-proven LN who received RTX. We analyzed clinical data at baseline (pre-RTX) and up to 36 months (mo) of follow-up.

Results: Of 21 pts, 7 received RTX as part of first-line treatment, 7 for refractory LN and 7 for relapsing LN. All continued RTX (1gm q4-6 mo) as maintenance therapy, 15/21 (71%) pts were on RTX monotherapy (excluding prednisone and plaquenil) at 12 mo, 14/16 (88%) at 24 mo, and 13/13 (100%) at 36 mo. At 12 mo, 16/21 (76%) achieved complete or partial remission. Median UPCR (g/g) decreased from 2.95 at baseline to 0.61 at 12 mo, 0.42 at 24 mo and 0.21 at 36 mo. 16/21 (76%) pts were on prednisone ≤5mg/day at 12 mo, 13/16 (81%) at 24 mo, and 10/13 (77%) at 36 mo. Over 36 mo, 2 pts had LN relapses while on RTX alone, and later progressed to ESRD. 2 pts developed hypogammaglobulinemia.

Conclusions: RTX monotherapy appears promising as maintenance therapy in LN. Given favorable renal outcomes and steroid-sparing effect, larger studies studying this effect may be warranted.
POI196

A Multicenter Double-Blinded Preclinical Randomized Controlled Trial (pRCT) on Jak1/2 Inhibition in Lupus Nephritis

Yutian Lei,1 Bettina Schenthr,6 Reinhard E. Völ,7 Conxita Jacobs Cachá,4 Maria Jose Soler,1 Maria Dolores Sanchez-Nino,1 Alberto Ortiz,1 Roman D. Bülow,2 Peter Boor,2 Hans J. Anders.2 Division of Nephrology, Department of Medicine IV, University Hospital, LMU Munich, Munich, Germany; 2Institute of Pathology and Department of Nephrology, RWTH University of Aachen, Aachen, Germany; 3IIS-Fundación Jiménez Diaz, School of Medicine, Universidad Autónoma de Madrid, Fundación Renal Iñigo Alvarez de Toledo-IRSN and REDINREN, Madrid, Spain; 4Nephrology Department, Hospital Universitari Vall d’Hebron, Universitat Autònoma de Barcelona, Nephrology Research Group, Vall d’Hebron Research Institute (VHIR) and REDINREN, Barcelona, Spain; 5Division of Nephrology, Department of Medicine IV, University Hospital, LMU Munich, Munich, Germany; 6Department of Pathology and Department of Nephrology, RWTH University of Aachen, Aachen, Germany.

Background: We conducted the first multicenter double-blinded pRCT in the field of nephrology and tested the Jak1/2 inhibitor baricitinib in experimental lupus nephritis.

Methods: We conducted a pRCT at two Spanish and two German academic sites. One site included MRL/lpr mice from their own breeding colony and the other sites included an intent to treat (ITT) population of 266 control and 268 VCS 23.7 mg/BID patients. Here we report key integrated data of interest including renal response, defined as: ● UPCR ≤ 0.5 mg/g Cr ● eGFR ≥ 60 mL/min ● No decline > 20% from baseline ● ≤ 10 mg prednisone 8 weeks prior to endpoint measurement ● No rescue medications

Results: RR at one year was 43.7% for VCS vs 23.3% for control (OR 2.67, 95% CI: 1.21, 5.45; p < 0.011), in a phase II analysis, we noted a 57% increase in RR for VCS compared to control patients. In the phase III clinical trial in patients with active lupus nephritis (LN), patients treated with 23.7 mg voclosporin bid in combination with MMF, achieved renal response rates of 40.8% vs. 22.5% for the control arm (OR 2.65; p < 0.001). The dose of voclosporin (VCS) was adjusted in response to decreases in eGFR. The objective of the present analysis was to evaluate the potential added value for therapeutic drug monitoring (TDM) in the LN patient population.

Methods: Pharmacokinetic (PK) data was analyzed from patients with LN treated with VCS. Based on a population PK model, the influence of various covariates on the disposition of voclosporin was evaluated. Calcineurin inhibition (CNI) was estimated using concentration data in the LN population and previously measured inhibition. Obtained exposure were put into perspective of renal response and the established safety margin.

Results: Sex, body weight, race, age, serum albumin, total bilirubin and eGFR demonstrated no significant or clinically relevant effect on the PK parameters. VCS has linear PK, and the goodness-of-fit plots (Figure 1 a–b) indicate that the model adequately describes observed and predicted concentrations of VCS. A strong correlation between VCS concentration and calcineurin inhibition is observed. VCS inhibits calcineurin in a dose-dependent manner up to maximum of 64 mg bid. In healthy subjects, a 96 mg bid dose was considered to be the upper limit of tolerability though did not present any safety concerns. At the 4-fold lower therapeutic dose of 23.7 mg bid, CNI was estimated to be 15.7% at Cmax and 58.1% at Cinf. In a quartile exposure analysis, no relationship with the odds ratio for renal response was observed and favored VCS in all quartiles.

Conclusions: At a therapeutic dose of 23.7 mg bid, sex, body weight, race, age, serum albumin, total bilirubin and eGFR demonstrated no clinically relevant effect on VCS PK parameters. The linear PK profile of VCS allows the use of a pharmacodynamic approach instead of a pharmacokinetic approach, in which the dose of VCS is adjusted in response to decreases in eGFR. These data suggest that TDM is unlikely to be of added benefit to patient management.

POI197

Management of Lupus Nephritis (LN) with Voclosporin: An Update from a Pooled Analysis of 534 Patients

Brad H. Rovin,1 Samir V. Parikh,1 Robert B. Huizinga,2 Neil Solomon,2 Simrat Randhawa,2 1The Ohio State University Wexner Medical Center, Columbus, OH; 2Aurinia Pharmaceuticals Inc, Victoria, BC, Canada.

Background: Voclosporin (VCS) is a novel calcineurin inhibitor (CNI) with a favorable metabolic profile and a consistent, predictable dose response potentially eliminating the need for therapeutic drug monitoring. VCS significantly improved renal response (RR) in patients with LN in two pivotal trials. Compared to MMF (target dose 2g/day) and prednisone (rapid taper), the addition of VCS 23.7 mg bid increased renal response by 25% in the Phase 2 AURA-LV (OR: 3.21; 95% CI: 1.68, 6.13; p < 0.001) and 18% in the Phase 3 AURA (OR: 2.65; 95% CI: 1.64, 4.27; p < 0.001) studies at one year. To provide more information on VCS treatment effect we analyzed an integrated data set from AURA-LV and AURA.

Methods: The two pivotal trials were of similar design, conducted in comparable patient populations and defined similar key outcome measures. The integrated data set included an intent to treat (ITT) population of 266 control and 268 VCS 23.7 mg/BID patients. Here we report key integrated data of interest including renal response, defined as: ● UPCR ≤ 0.5 mg/g Cr ● eGFR ≥ 60 mL/min ● No decline > 20% from baseline ● ≤ 10 mg prednisone 8 weeks prior to endpoint measurement ● No rescue medications.

Results: RR at one year was 43.7% for VCS vs 23.3% for control (OR 2.76, 95% CI: 1.88, 4.05; p < 0.0001), and at 6 months (VCS 31%; control 20%); (OR: 2.01; 95% CI: 1.34, 3.01; p = 0.0008). In addition, 1-year RR for Hispanic patients was 37.9% in VCS vs 22.5% in control (OR 2.65; p < 0.001). In the phase III clinical trial in patients with active lupus nephritis (LN), patients treated with 23.7 mg voclosporin bid in combination with MMF, achieved renal response rates of 40.8% vs. 22.5% for the control arm (OR 2.65; p < 0.001).

Conclusions: This integrated analysis provides further support to the efficacy of VCS seen in both AURA-LV and AURA including in Hispanic patients, a high-risk LN patient population. Furthermore, VCS’ expected impact on mean eGFR as a CNI was mild over the course of one year.

**PO1919**
Clinical Outcomes in Lupus Nephritis by Renal Response Status: A Retrospective Analysis of the Hopkins Lupus Cohort

Michelle Petri,1 Qingfong Fu,2 Yulia Green,3 Anuradha Madan,4 Daniel W. Goldman,1 Selin Cooper-Blenkinsopp.1 Johns Hopkins University School of Medicine, Baltimore, MD; 1GlaxoSmithKline, Upper Providence, PA; 2GlaxoSmithKline, Uxbridge, United Kingdom; 3GlaxoSmithKline, Collegeville, PA; 4GlaxoSmithKline, Stevenage, United Kingdom.

Background: A retrospective analysis of the Hopkins Lupus Cohort (a prospective, longitudinal study of patients [pts] with systemic lupus erythematosus) reported that renal response (complete/partial/none) at 24 months post-diagnosis of lupus nephritis (LN) predicts long-term renal survival.1 Here, we compare long-term renal survival and chronic renal insufficiency-free survival in pts with and without a renal response (RR) to standard LN therapy, as defined by primary endpoint in the Phase 3 BLISS-LN study (GSK Study BEL114054; NCT01639339).

Methods: This retrospective analysis (GSK Study 213039) of the Hopkins Lupus Cohort included pts with biopsy-proven class III, IV, or V LN. Endpoints were: long-term renal survival (no end-stage renal disease [ESRD] and/or mortality) and long-term chronic renal insufficiency-free survival by RR status at 24 months post-biopsy, both assessed by Kaplan–Meier plots with log-rank test and Cox proportional hazards regression.

Results: 173 pts with LN were included, 91.3% were female and mean (SD) age at biopsy was 36.2 (11.8) years. At 24 months post-biopsy, 114 (65.9%) pts achieved RR. Pts with RR at 24 months were less likely to experience an ESRD/mortality event and chronic renal insufficiency (Figure), even after adjusting for covariates (HR [95% CI] 0.33 [0.13, 0.87], p=0.0255; and HR [95% CI] 0.26 [0.14, 0.47], p<0.0001, respectively).

**Funding:** Other NIH Support - The Hopkins Lupus Cohort is funded by NIH grant R01-AR069752, Commercial Support - GSK.

**Figure:** Survival analysis of renal survival and chronic renal insufficiency-free survival by renal response at 24 months.

**PO1920**
Predictors of Doubling of Serum Creatinine at the Time of Biopsy in a Lupus Nephritis Cohort

Jaime (James) A. Vondenberg, Saeed K. Shafi. University of New Mexico, Albuquerque, NM.

Background: Lupus nephritis is associated with significant morbidity and it is imperative to study the factors associated with renal survival. We study the determinants of doubling of serum creatinine in a predominantly Hispanic cohort.

Methods: We identified patients with biopsy-proven lupus nephritis from the biopsy registry that comprises of biopsies performed between 2002-2016. Demographic, clinical, and biochemical variables were obtained from the registry and electronic medical records. We studied the factors associated with the doubling of creatinine by performing univariate and multivariate proportional hazard analysis. All significant associations (p <0.05) were studied in a multivariate Cox regression model. Patients were censored upon death or the last follow-up.

Results: Out of 62 patients with biopsy-proven lupus nephritis, 53 (85.5%) were female. Whites, Hispanics, and Native Americans comprised 35.5, 30.6, and 16.1% of the cohort, respectively while 56% of the participants identified ethnically as Hispanic. Mean biopsy age, serum creatinine, and spot urine Protein/Creatinine were 34.5 (SD 15.3) years, 1.34 (SD 0.83) mg/dl, and 4.2 (SD 4.3) g/g, respectively. Class IV (48.4%) and III (16.1%) were the most prevalent lupus classes. Median (IQR) follow-up was 474.5 (1170) days. On multivariable analysis, higher age at biopsy was associated with decreased risk of doubling of serum creatinine (Figure 1). A higher spot urine Protein/Creatinine and C4 level at the time of biopsy were associated with increased risk of doubling of serum Cr.5

Conclusions: Previous studies have shown that biochemical markers at the time of kidney biopsy are a poor prognostic marker of renal outcomes in lupus nephritis. In this study, demographic, biochemical, and histological markers failed to predict doubling of serum creatinine. The age and the level of proteinuria at the time of kidney biopsy were associated with doubling of serum creatinine.

Lupus-Related Renal Disease Increases Inpatient Mortality: Analysis of the National Inpatient Sample

Ehizogbe Edigin,1 Precious Eceason,1 Augustine Manadan,1,2 University of Benin Teaching Hospital, Benin City, Nigeria; 1John H. Stroger Hospital of Cook County, Chicago, IL; 2Rush University Medical Center, Chicago, IL.

Background: The aim of this study is to analyze the difference in outcomes of Systemic Lupus Erythematosus (SLE) with and without lupus-related renal disease. The primary outcome was inpatient mortality, while secondary outcomes were hospital length of stay (LOS) and total hospital charges.

Methods: Data were abstracted from the National Inpatient Sample (NIS) 2016 and 2017 Database. NIS is the largest inpatient admission database in the USA. The NIS was searched for adult SLE hospitalizations with and without lupus-related renal disease as principal or secondary diagnosis using ICD-10 codes. Multivariate logistic and linear regression analysis was used to test for confounders for the primary and secondary outcomes respectively. STATA software was used to analyze the data.

Results: There were over 71 million discharges included in the combined 2016 and 2017 NIS database. 355,740 hospitalizations were for adult patients, who had either a principal or secondary ICD-10 code for SLE: 51,875 (14.6%) and 303,865 (85.4%) of these hospitalizations were for SLE with and without lupus-related renal disease respectively. 7,060 adult SLE hospitalizations (2%) resulted in inpatient mortality. 1,110 (2.14%) of the deaths occurred in SLE with lupus-related renal disease vs 5950 (1.96%) without lupus-related renal disease (P=0.228). The adjusted odds ratio (AOR) for inpatient mortality for SLE with lupus-related renal disease compared to those without lupus-related renal disease was 1.38 (95% CI 1.17-1.63, P<0.0001). SLE with lupus-related renal disease hospitalizations had a mean increase in adjusted LOS of 1.14 days (95% CI 0.95-1.34, P<0.0001) compared to SLE without lupus-related renal disease.

Conclusions: Hospitalizations for SLE with lupus-related renal disease have increased inpatient mortality, LOS, and total hospital charges compared to those without lupus-related renal disease. SLE patients with lupus-related renal disease require a multidisciplinary approach involving the rheumatologist and nephrologist to optimize outcomes.

Analysis of Characteristics and Risk Factors of Sepsis in Patients with Lupus Nephritis

Zhenjlan Xu,1 Meisheng Liang,2 Anping Xu.1 1Sun Yat-sen Memorial Hospital of Sun Yat-sen University, Guangzhou, China; 2The People's Hospital of Guangxi Zhuang Autonomous Region, Nanning, China.

Background: Patients with lupus nephritis are at high risk of infection due to intrinsic immune dysregulation and treatment with glucocorticoids and immunosuppressants. Infection is a common complication in patients with lupus nephritis and is a major determinant of in-hospital mortality. Sepsis are the most frequent causes of infection-related mortality. In this research, we study the clinical characteristics and related risk factors of sepsis in patients with lupus nephritis according to a retrospective analysis.

Methods: A retrospective study was carried out for 322 hospitalized patients with lupus nephritis in Sun Yat-Sen Memorial Hospital from 2010 to 2019. The infected group consisted of 140 patients (The infected patients were subdivided into septic group and non-septic group according to the sepsis criteria) while the non-infected group consisted of 182 patients without infection. Baseline data including sex, age, disease duration, hospitalization duration, associated organ involvement, use of glucocorticoid and immunosuppressants.

Results: Compared to the non-infected group, longer hospitalization duration (14 vs. 30 days, P<0.05), pulsed methylprednisolone treatment within 1 month (29.7% vs. 15.5%, P<0.05), cyclophosphamide (22.9% vs. 14.3%, P<0.05), and calcineurin inhibitors (18.6% vs. 10.4%, P<0.05), and higher dose of oral corticosteroid (15 vs. 10mg, P<0.05)can be seen in the infected group (P<0.05). Compared to the non-septic group, higher proportion of patients with elevation of blood pressure (84% vs. 78%, P=0.05), while higher level of serum creatinine (134.0 vs. 88.0μmol/L, P<0.05), C reactive protein (43.8 vs. 32.3mg/L, P<0.05)and erythrocyte sedimentation rate (60.0 vs. 45.5mm/h, P<0.05) can be seen in the septic group. Multivariate Logistic regression analysis revealed that male and pulsed methylprednisolone treatment within 1 month were independent risk factors of sepsis in patients with lupus nephritis (P<0.05).

Conclusions: Male and pulse methylprednisolone treatment within 1 month were independently associated with sepsis in patients with lupus nephritis.

An Evaluation of Costs Associated with Overall and Renal-Specific Organ Damage in Patients with Systemic Lupus Erythematosus in the United States

Christopher F. Bell,1 Juliana Meyers,2 Mayank Ajmera,2 Benjamin Wu,3 Joan Von Feldt,3 GlaxoSmithKline, Research Triangle, NC; RTI Health Solutions, Research Triangle Park, NC; GlaxoSmithKline, Philadelphia, PA.

Background: Systemic lupus erythematosus (SLE) is a chronic, multisystem, inflammatory, autoimmune disease affecting multiple organ systems, and characterized by fluctuating disease activity (flares). The combination of flares and SLE treatment can lead to progression of end-organ damage and death. The costs associated with SLE are substantial and are driven by frequent hospitalizations, use of glucocorticoids and immunosuppressants.

Methods: This retrospective analysis (GSK Study 208380) used the IQVIA PharMetrics Plus Database to identify patients with SLE and OD during 01/01/09–06/30/18. Patients with OD were identified using International Classification of Diseases (ICD)-9/10 codes derived from the Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index. Inclusion criteria: ICHD II classification; >18 years of age; continuous enrollment 12 months both pre and post index (index: date of first observed OD medical claim; a1 inpatient IP or a3 outpatient OP claims within 6 months for an OD diagnosis code a1 IP or a2 OP claims separated by ≥30 days for SLE (ICD-9: 710.0 or ICD-10: M32.X) prior to the index date. Patients with renal-specific OD at index were noted. Patient characteristics were identified in the 12-month pre-index period and all-cause healthcare costs (2018 US$) were reported in the 12-month pre- and post-index periods. Results were analyzed with descriptive statistics.

Results: A total of 8952 patients met OD criteria and 486 (5.4%) had renal-specific OD. Patients were 92% female, mean (standard deviation [SD]) age was 46.4 (12.2) years, and mean (SD) Charlson Comorbidity Index was 2.0 (1.1). Mean (SD) all-cause healthcare costs increased from $15,746 ($20,637) to $26,998 ($57,082) in pre- versus post-index periods, respectively. In patients with renal-specific OD, mean (SD) all-cause healthcare costs increased from $16,131 ($22,914) to $36,905 ($72,188) in pre- versus post-index periods, respectively.

Conclusions: In patients with SLE and OD, annual costs increased after OD diagnosis. A similar increase in annual costs was observed for patients with renal-specific OD at index. Greenwood DM and Urowitz MB. Lupus. 1999;8:632–7.

Characteristics of Lupus Nephritis in a Cross-Sectional Study of Hispanic and Native American Patients in New Mexico

Jame (James) A. Vondenberg, Saeed K. Shaifi. University of New Mexico, Albuquerque, NM.

Background: In patients with lupus, nephritis develops in ~50% of patients, and is associated with significant morbidity. Therefore, it is important to characterize the demographic and biochemical variables associated with lupus nephritis. In this cross-sectional study comprised of many Hispanics and Native Americans, we investigate the demographic and biochemical variables at the time of lupus nephritis diagnosis.

Methods: We identified 62 patients with lupus nephritis from the University of New Mexico kidney biopsy registry that contains biopsies from 2002-2016. Demographics, comorbidities, outcomes, therapies, and laboratory data typically followed in lupus patients (complements, spot urine protein/creatinine (Pr/Cr) ratio, urine RBCs, serologies, etc) were collected from the registry and medical charts.

Results: 62 patients were included, 53 females and 9 males. White, Hispanic, and Native American races accounted for 35.5%, 30.6%, and 16.1% of the cohort, while 56.6% of patients identified ethnically as Hispanic. 3 patients had no labs. Overall mean age at the time of renal biopsy was 34.5 (SD 15.3) years old. Laboratory data among ethnicities is shown in Figure 1. Class IV was the most common classification in the whole cohort (48.5%), for Hispanics (56.7%), and Non-Hispanics (30%). Antibody status was similar among all ethnicities: ANA positive (95%, 80% titer >1,800), anti-dsDNA positivity (73%), anti-Smith positive (52%), and SS-A positive (50%). The most common comorbidities were hypertension (n=46) and depression (n=16). For induction therapy, Hispanics patients received lower dose cyclophosphamide (24.5% vs. 75.5%, P=0.02) and mycophenolate mofetil (MMP) (38% vs. 61%), Non-Hispanics received mycophenolate mofetil (MMP) (38% vs. 61%). For maintenance therapy, both Hispanics (37%) and Non-Hispanics (35%) most often received MMP. 7 patients progressed to ESKD, by ethnicity: Hispanic and 2 Unavailable (1 African American).

Conclusions: We found similar baseline characteristics and lupus nephritis outcomes among Hispanic and Native American patients in New Mexico. Conditions (e.g. hypertension and depression) were more common among Hispanic patients.

PO1925

The ISN/RPS 2016 Classification Predicts Renal Prognosis in Patients with First-Onset Class III/IV Lupus Nephritis

Asaka Hachiya1, Munetoshi Karasawa,1 Takahiro Imaizumi,2,1 Noritoshi Kato,1 Takayuki Katsuno,1 Takuji Ishimoto,1 Tomoki Kosugi,1 Naotake Tsuobi,1 Shoichi Maruyama.1 1Department of Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan; 2Center for Advanced Medicine and Clinical Research, Nagoya University Hospital, Nagoya, Japan; Department of Nephrology and Rheumatology, Aichi Medical University, Nagamura, Japan; 3Department of Nephrology, Fujita Health University Graduate School of Medicine, Toyoaka, Japan.

Background: Lupus nephritis (LN) is a life-threatening complication of systemic lupus erythematosus. The 2003 pathological classification of LN by the International Society of Nephrology/Renal Pathology Society (ISN/RPS) was revised in 2016; it quantitatively evaluates the interstitium in addition to the glomeruli. To date, the clinical usefulness of the 2016 classification has not been fully evaluated.

Methods: We performed a prospective multicenter cohort study and investigated the utility of the 2016 classification—including the activity index (AI), chronicity index (CI), and each pathological component to predict CR or renal function decline defined as >10 ml/min/1.73m2 in estimated glomerular filtration rate (eGFR) decline in serum creatinine and urine protein at 2 years from the time of diagnosis. The primary endpoint was renal failure to achieve CR (adjusted hazard ratios (HR) [95% confident interval (CI)]: 0.75 [0.64–0.88], 0.39 [0.25–0.61], respectively). Similarly, higher CI and higher interstitial fibrosis and lower hyaline deposit scores were associated with failure to achieve CR (adjusted hazard ratios (HR) [95% confidence interval (CI)]: 0.75 [0.64–0.88], 0.39 [0.25–0.61], respectively). Higher CI and higher interstitial fibrosis and lower hyaline deposit scores were associated with renal function decline (adjusted HR [95%CI]: 1.24 [1.01–1.53], 2.66 [1.43–4.93], 0.45 [0.21–0.97], respectively).

Conclusions: We demonstrated the utility of CI and AI of assessing interstitial regions in predicting renal prognosis. The 2016 classification can predict the clinical outcomes more precisely than the 2003 classification.

Resolution of Immune Deposits in the Glomeruli of Patients with Lupus Nephritis (LN)

Ana Malvar,1 Valeria G. Alberton,2 Karina Fayolle,2 rocio A. Jones,2 Pedro J. Davila Terreros,2 Bruno J. Lococo,2 Brad H. Rovin,1 1The Ohio State University, Columbus, OH; 2Hospital Fernandez, Buenos Aires, Argentina.

Background: Patients with proliferative LN have severe glomerular immune injury that resolves over time with treatment. The extent of resolution has been assessed by the histologic activity index (AI) but patients who have had a repeat kidney biopsy during maintenance immunosuppression, and many patients do achieve an AI=0, so-called histologic remission. The fate of glomerular immune complexes in treated LN patients has not yet been characterized. This study examined the immunofluorescence (IF) patterns in biopsies obtained during LN therapy.

Methods: A cohort of Hispanic LN patients (n=89) was studied. All patients had biopsy-proven (Bx1) proliferative (Class III, IVaV) LN, and were treated with corticosteroids plus cyclophosphamide or MMF for 6 months and then switched to MMF for maintenance therapy. After a median of 42 (range 30-52) months patients had a second protocol biopsy (Bx2) to determine if they had achieved histologic remission (AI=0) or had persistent histologic activity (AI>0). Kidney biopsies were evaluated by standard IF microscopy (IgG, IgA, IgM, C3, C4q), and semi-quantitatively graded on a scale of 0-3 (not present;bright).

Results: cyclophosphamide (48%). These patients had a median serum creatinine of 0.7 mg/dl (0.5-2.2) and proteinuria of 0.2 g/dl (0.0-8.0). The 26 patients who had persistent histologic activity at Bx2 had a median AI of 2 (1-6), serum creatinine of 0.75 mg/dl (0.6-1.1), and proteinuria of 0.2 g/dl (0.1-0.9) and about half had been treated with MMF. No residual AI was present in 30% of patients with an AI of 0, but was present in all patients who had an AI>1. IF for IgG became negative in 46% of patients with an AI=0 between Bx1 and Bx2, but in only 7.7% of patients with AI>1 (P=0.005). Similarly, IF for C3 became negative in 84% of patients with AI=0, compared to 31% of patients with AI>1(P=0.0001). After a median of 23 months (11-39) 7 patients who had been in histologic remission suffered an LN flare. None of these patients had complete resolution of IF on Bx2. In contrast, no patient with an AI=0 and an absence of IF on Bx has had an LN flare during a follow-up of 3.5 years.

Conclusions: About one third of patients with LN can achieve histologic and immunologic kidney remission. These patients appear to have an outstanding long-term kidney prognosis.

Vasculopathy Associated with Lupus Nephritis (Severity and Outcomes)

Marcial Torres, Muhammad Alqudsi, Juan Carlos Q. Velez, Muner Mohammed. Ochsner Clinic Foundation, Ochsner Health System, New Orleans, LA.

Background: Lupus nephritis (LN) is common in patients with systemic lupus erythematosus. Classification, prognosis, and treatment considerations of LN relies mainly on kidney biopsy features. Although few observational studies showed LN with vasculopathy has more severe course, literature reviews are scarce and mostly from Asian populations. The goal of the study was to shed more light on severity and response to Immunosuppression (IS) therapy in this subgroup of LN.

Methods: This was a single center retrospective chart review of LN patients from 2010-2019. Inclusion criteria were adults with native kidney biopsy proven LN documented in chart. Patients with systemic thrombocytic microangiopathy (TMA) or possible secondary cause of renal TMA (other than SLE) were excluded. Two groups were identified for comparison, LN without vasculopathy (WV) and LN with vasculopathy (WV). Vasculopathy was defined from kidney biopsy as vascular sclerosis (at least moderate), vascular immunoglobulins deposits, vasculitis, or TMA. Creatinine (Cr), albumin (Alb), urine protein-creatinine ratio (UPCR), stage-end renal disease (ESRD) and treatment regimens were compared, p-values are calculated by Mann Whitney, chi square and ANOVA of repeated measures.

Results: There were 431 patients with LN, 65 patients qualified for the study, patients with LN-WOV (n=38), and LN-WV (n=27). Racial demographics: 49=black (75%), 14=white (21%), 1=Hispanic, 1=Asian. Females 57 (88%). Median age 37 years. Average follow-up 3.5 years. Induction IS regimen for LN-WOV was mycophenolate (75%),14=white (21%), 1=Hispanic, 1=Asian. Females 57 (88%). Median age 37 years. Average follow-up 3.5 years. Induction IS regimen for LN-WOV was mycophenolate mofetil (MMF) in 52%, Cyclophosphamide (CYC) in 11%, and Rituximab (RTX) in 15%. In LN-WV induction IS regimen was MMF in 52%, and CYC in 23%. At baseline, mean values of serum creatinine (Cr), uric acid (UA), and UPCR were similar in LN-WOV and LN-WV were similar (p = 0.38, 0.53, 0.53, respectively). At 6 and 12 months of follow-up, mean values of Cr, Alb, and UPCR remained similar (p = 0.59, 0.49, and 0.64 for 6 months, and 0.34, 0.41, 0.53 for 12 months). No difference was found in ESRD events (7% (18%) in LN-WOV and 10% in LN-WV, p=0.86.

Conclusions: In our cohort, both groups of LN-WOv and LN-WV showed no statistical difference in the severity of presentation, nor in response to IS therapy assessed at 6 and 12 months follow-up of Cr, Alb, and UPCR, and ESRD. Hence, LN-WV was not associated with ominous outcomes or more resistance to IS.
known to rarely occur in lupus. This phenomenon has not been previously described. We speculate that this hypocytic holocellulosis is the result of a novel target of autoimmunity in lupus affecting renal tubular transport.

Outcomes of Lupus-Related Glomerular and Tubulointerstitial Disease: Analysis of the National Inpatient Sample

**Funding:** Emory University W Eugene EHIZOGIE Analysis of the National Inpatient Sample

**Background:** The study aims to compare the differences in outcomes of hospitalizations for Systemic Lupus Erythematosus (SLE) with glomerular and tubulointerstitial disease as principal or secondary diagnosis using ICD-10 codes. The analysis was done using STATA. Multivariable logistic and linear regression analysis was used accordingly to adjust for confounders for the outcomes.

**Results:** There were combined 71 million discharges included in the 2016 and 2017 NIS database. 51,875 hospitalizations were for adult patients, who had either a principal or secondary ICD-10 code for SLE with lupus-related renal disease. 51,525 (99.3%) and 350 (0.7%) of these hospitalizations were for SLE with lupus-related glomerular and tubulointerstitial disease respectively. The mean age for SLE with lupus-related glomerular disease was 40.6 vs 44.2 years for lupus-related tubulointerstitial disease (P=0.084). 7,060 adult SLE hospitalizations resulted in inpatient mortality, 1,110 (2.14%) of the deaths occurred in SLE with lupus-related glomerular disease. The number of deaths for lupus-related tubulointerstitial disease was less than 10, hence it was omitted during the analysis by STATA. SLE with lupus-related glomerular disease had similar LOS (6.8 vs 6.7 days, p=0.865) and total hospital charges ($79,718 vs $83,006, p=0.961) compared to those with tubulointerstitial disease.

**Conclusions:** SLE with glomerular disease makes up the vast majority of SLE with lupus-related renal hospitalization. Almost all the in-hospital deaths of SLE patients with lupus-related renal disease occurred in SLE with glomerular disease. LOS and total hospital charges were similar between hospitalizations for SLE with lupus-related glomerular and tubulointerstitial diseases.

**POI1931**

Lupus Podocytopathy Systematic Review

**Funding:** Other NIH Support - University of Texas Southwestern O’Brien Grant 5P30DK07928-13

**Background:** Patients with lupus, can present with a renal lesion distinct from the ones described by the ISN/RPS classification of lupus nephritis called lupus podocytopathy. Lupus podocytopathy has been described as minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) in patients with SLE with or without membranous involvement but without proliferative or membranous lupus nephritis features. We have gathered the available data on lupus podocytopathy and analyzed it to provide a comprehensive report in this review.

**Methods:** We searched electronic databases including pubmed and google scholar, using keywords related to lupus podocytopathy and synonyms and treatment from inception to December 2019. Articles retrieved were screened for relevance, including reference list of retrieved. We included cohort studies, case series, and retrospective studies. Individual case reports were excluded.

**Results:** The search identified 8 studies, of which 6 were included with a total of 107 patients. The patients were predominantly female (88%). The average age was 35 years. Studies done outside of China had predominantly African-American patients 72.5%. The average serum creatinine was 2.06 mg/dl. The average proteinuria was 6.5 g/day. Four studies reported monotherapy corticosteroids, and three studies reported varied treatments. The average follow up was 3.7 years. Complete remission was reported to be 67% from 3 studies. Four studies reported relapse rate of patients, and it accounted to 72.5% of patients.

**Conclusions:** Our study is the first systematic review of lupus podocytopathy. The strength of this study is the merger of data from known studies in lupus podocytopathy. Lupus podocytopathy has been described as minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) in patients with SLE with or without membranous involvement but without proliferative or membranous lupus nephritis features. We have gathered the available data on lupus podocytopathy and analyzed it to provide a comprehensive report in this review.
PO1934
Cost-Effectiveness of Maintenance Therapy with Azathioprine vs. Rituximab (Tailored or Fixed-Schedule) in Adults with Generalized ANCA Vasculitis in Colombia
Kateir Contreras, Viviana Orozco Ortiz, Eduardo J. Puche Carrascal, Paola García, Camilo A. Gonzalez, Patricia Rodrigo, Diego Rosselli. Hospital Universitario San Ignacio, Bogota, Colombia.

Background: Azathioprine has been the drug of choice for maintenance therapy in patients with generalized ANCA vasculitis. However, recent studies show that rituximab, a high-cost biological agent, which can be administered in two different schedules, might be more effective, so it is necessary to know the cost-effectiveness. Our goal was to compare the cost-effectiveness of the 3 maintenance schemes: standard therapy with azathioprine; fixed-dose rituximab and rituximab tailored according to CD19 lymphocyte level and ANCA titres, from the perspective of the Colombian healthcare system.

Methods: We designed a 5-year annual cycle Markov model with the following stages: remission, minor relapse, major relapse and death. Transition probabilities were obtained from a systematic review of the literature (Scopus and Pubmed). Following national guidelines for economic studies, costs, in 2018, USD = 2.956 Colombian pesos (COP), were estimated based on national drug registries, and official tariff manuals for procedures and other resources. Main outcome was quality-adjusted life years (QALY), using lupus nephropathy as a proxy; values were obtained from Tufts CEA Registry and validated by local expert panel through a modified Delphi technique. Cost-effectiveness threshold was three-times per capita GDP (USD 17253). Discount rate was 5%. Univariate and probabilistic sensitivity analyses were performed.

Results: Overall discounted 5-years costs were USD 1356 for azathioprine; USD 4750 for tailored rituximab and USD 6162 for fixed rituximab. QALY gains were 2.94, 3.63 and 3.64, respectively. Both tailored and fixed rituximab were cost-effective (cost per QALY gained: USD 4.919 and USD 6.865 respectively), but tailored dosing was preferable due to its lower cost. Sensitivity analyses did not modify these results significantly.

Conclusions: To our knowledge this is the first economic evaluation that compares azathioprine with tailored and fixed rituximab regimens as a vasculitis maintenance treatment in adults with ANCA generalized. Due to its lower effectiveness azathioprine should not be the first line of treatment. Tailored rituximab should be a better option than fixed schedule due to its lower cost with similar effectiveness.

PO1935
Use of Subcutaneous IgG to Treat Hypogammaglobulinemia in ANCA-Associated Vasculitis
Sam Kant, Antoine Azar, Eric J. Gapud, Duvuru Geetha. Johns Hopkins University School of Medicine, Baltimore, MD.

Background: Intravenous immunoglobulin (IVIG) has been used to treat ANCA vasculitis (AAV) patients with recurrent infections as a result of hypogammaglobulinemia induced by glucocorticoid treatments such as immunoglobulin (SCIG) has a better safety and tolerability profile. We characterized the clinical features, treatment and outcomes of AAV patients treated with SCIG).

Methods: We conducted a retrospective chart analysis of 187 patients in our AAV database to identify patients with recurrent infections and hypogammaglobulinemia subsequently treated with SCIG. Patient demographics, clinical characteristics, treatment and immunological parameters were assessed.

Results: Of the 187 patients identified with AAV, 6 were treated with SCIG. All were Caucasian, PR3 positive and majority (n=4) were females. All patients had pulmonary involvement, and regimens of cyclophosphamide (CYC) and/or rituximab (RTX) were employed for induction and remission. Ig levels (IgG, IgM, IgA) were reduced in all patients. CD19/CD20 B cells were depleted, and CD3/CD4 and NK cells were preserved in all patients. The majority of patients (n=4) experienced recurrent URIs. 3 had shingles in addition to other infections(table 1). All patients had no discernible IgG antibody response to pneumococcal vaccine. Mean duration between first rituximab administration and initiation of SCIG was 6.4 years. Four patients continued to receive RTX every 6 to 12 months while 2 patients remained in remission off RTX for over 2 yrs. IgG levels normalized and none of the patients had recurrence of infections after initiation of SCIG.

PO1936
Glucocorticoid Maintenance Therapy and Severe Infectious Complications in ANCA-Associated Vasculitis
Claudius Speer, Christian Nussbag, Florian Käble, Christian Morath, Martin G. Zeier, Raoul Bergner, Matthias Schaier.1 University of Heidelberg, Heidelberg, Germany; 2Clinical Center Ludwigshafen, Ludwigshafen, Germany.

Background: Although treatment and outcomes in anti-neutrophil cytoplasmic autoantibody associated vasculitis (AAV) have been improved over the last decades, intensified immunosuppressive burden is concurrently associated with life-threatening adverse effects which are the main cause of death during the first year after disease onset. Our study evaluates the impact of cyclophosphamide (CYC) induction dose and glucocorticoid maintenance dose and duration on patient outcomes with an emphasis on infectious complications.

Methods: A total of 130 AAV patients from two different German Vasculitis Centers diagnosed between 2004 and 2019 treated with CYC for induction therapy and glucocorticoids a mycophenolate mofetil or azathioprine for maintenance therapy were included in this study. We evaluated the impact of CYC dose for induction therapy and glucocorticoid dose and treatment duration for maintenance therapy on time to relapse, kidney function, infectious complications, irreversible physical damage and mortality. Patients were separated into four groups: <3g versus ≥3g cumulative CYC dose and <7.5mg after 6 months versus ≥7.5mg glucocorticoids after 6 months.

Results: The baseline demographic and disease characteristics were comparable between groups. Cumulative CYC dose had no impact on relapse rate, kidney function, infectious complications or mortality. Patients receiving ≥7.5mg glucocorticoids after 6 months had an increased rate of infectious episodes per patient (0.6 vs. 1.7; p=0.001). Urinary tract infection (p=0.007), pneumonia (p=0.003) as well as opportunistic pneumonia (p=0.022) and sepsis (p=0.008) appeared more frequently. Especially pneumonia during the first 24 months after disease onset (hazard ratio, 3.0 [95% confidence interval (CI), 1.5–6.1]) led to more death by infections (p=0.034). Patients ≥65 years with ≥7.5mg glucocorticoids after 6 months were at particular risk for infectious complications. Glucocorticoid maintenance therapy had no impact on relapse rate or kidney function after the last follow-up.

Conclusions: An extended glucocorticoid maintenance therapy may induce severe infectious complications leading to an increased frequency of death by infection, has no effect on time to relapse and should therefore be critically revised throughout the aftercare of AAV patients.

PO1937
Country Differences Exist in the Treatment of ANCA-Associated Vasculitis (AAV), but High-Dose and Prolonged Glucocorticoid Use Is Observed Across Europe
Peter A. Rutherford, Dieter K. Goette. Vifor Pharma Ltd, Glauchburg, Switzerland.

Background: European AAV guidelines recommend remission induction therapy with combination of high dose glucocorticoids (GC) and rituximab (RTX) or cyclophosphamide (CYC) and maintenance therapy with either RTX or azathioprine (AZA). This retrospective study examined the pattern of prescribing, including the use of GCs, across Europe in AAV patients managed in routine clinical practice.

Methods: 1478 AAV patients managed by 493 physicians in France, Germany, Italy, Spain and UK who completed induction therapy for organ or life threatening AAV (49%
incidence and 51% relapsing) and initiated maintenance therapy between 2014-16 were studied. Data were collected at the time maintenance was determined to begin by the physician and then after 6, 12, 18 and 36 months.

**Results:** AAV type varied with more GPA in Germany (52%) and UK (56%) compared to France (47%), Italy (47%) and Spain (40%). Proportion of patients with severe progressive disease varied – 41% in Italy to 48% France. Induction therapy varied with lowest use of IV GC and rituximab (RTX) and highest cyclophosphamide (CYC) use in the UK. Maintenance was defined by clinicians as approximately 6 months following treatment start and GCs were used similarly across all countries with less RTX and less GC use in UK and more AZA in Germany and UK. At 36 months prescribing patterns were similar and a variable proportion of patients (13% Germany to 30% France) stopped therapy but with approximately 25% patients not in full remission.

**Conclusions:** AAV treatment prescribing patterns vary across Europe particularly RTX, driven by economic as well as case mix differences. GC use is high across all countries with high GC use (including IV at induction) and prolonged use over 36 months being common. Sustained remission rates could be improved and there is need for more targeted therapies to reduce reliance on GCs.

**Validation of a Clinical-Pathologic Renal Risk Score in ANCA-Associated Glomerulonephritis: The US Experience**

Sam Kant,1 Silke R. Brix,2 Francesca Costigliolo,1 Paride Fenaroli,1 Avi Z. Rosenberg,1 Duvuru Geetha,1 Johns Hopkins University School of Medicine, Baltimore, MD; 2Manchester Royal Infirmary, Manchester, United Kingdom

**Background:** The prognostication of renal disease in the setting of ANCA associated vasculitis (AAV) continues to pose a significant clinical challenge given lack of validated clinical and pathologic correlates. A risk score has been developed by a German consortium (Brix et al Kidney International 2018), to stratify risk of AAV related renal disease progression to ESKD. We applied this risk score in our cohort of AAV patients to ascertain its reproducibility.

**Methods:** A single center retrospective cohort study was performed reviewing 148 renal biopsies of patients with AAV GN. Data for score calculation was available of 119 patients with a median follow up of 58 months (IQR 28 – 97 months). Three parameters were used in the risk prediction score: (1) # of normal glomeruli (N0 >25%, N1 10-25%, N2 <10%), (2) tubular atrophy and interstitial fibrosis (T0 <25%, T1 >25%) and (3) eGFR at the time of diagnosis (G0 >15, G1 <15). A weighted assignment of points to each parameter was as follows: N1 [4], N2 [6], T1 [2], G1[3], and the resulting aggregate risk score used to classify predicted ESRD risk was low (0), intermediate (2 to 7), or high (8 to 11 points).

**Results:** In the cohort of 148 patients, median age was 67 years and mean eGFR at diagnosis was 27.7. Seventy-six were MPO, 57 were PR3 positive and 15 were ANCA negative. With regards to risk stratification, 34 were in low risk category, 59 in the medium risk category and 26 patients in the high-risk category. Overall, 23 patients (15.3%) progressed to ESKD with 2 (5.9%), 11 (18.6%), 10 (38.5%) in low, medium and high risk groups, respectively. A Kaplan-Meier survival curve (Figure1) demonstrates worsening of renal survival across the risk groups (p=0.0035).

**Conclusions:** This AAV renal risk score was able to reliably predict risk for progression to ESKD. A further analysis revalidating cut-offs and risk score points would likely refine the score improving its prediction accuracy.

**PO1939**

**Clinical Features and Outcomes of Anti-Neutrophil Cytoplasmic Autoantibody-Associated Vasculitis in Chinese Elderly and Very Elderly Patients**

Ting Meng, Departments of Nephrology, Xiangya Hospital Central South University, Xiangya Hospital Central South University, Changsha, China.

**Background:** Anti-neutrophil cytoplasmic autoantibody-associated vasculitis (AAV) is predominantly a disease of the elderly, and the incidence increases with age. However, there are few data focusing on the clinical features in elderly-onset AAV, especially in very elderly-onset AAV in China. The aim of this study was to explore whether elderly-onset AAV shows any specific clinical features and outcomes in Chinese patients.

**Methods:** We performed a retrospective study in Xiangya Hospital, a mixed tertiary medical center in south China. A total of 177 patients presenting with AAV were included between January 1, 2010 and December 31, 2017. Patients were divided into younger group (age<65 years) and older group (age65 years) which was sub-divided into elderly group (age 65-74 years) and very elderly group (age75 years).

**Results:** We found patients in the very elderly group had more chest and cardiovascular involvement (P=0.033 and P=0.017). Older AAV patients had less renal involvement and lower serum C4 level (P<0.013 and P<0.003). Very elderly AAV patients had lower platelet counts. Patients in the younger group had a higher level of BVAS among three groups (P<0.05 younger group vs. very elderly group; P<0.05 younger group vs. elderly group). There were no significantly difference in the proportion of ISRD patients among the three groups (P=0.473). Patients in the very elderly group had the poorest patient survival (P=0.002).

**Conclusions:** Older AAV patients had less renal involvement, lower serum C4 level and BVAS. The very elderly group got the most chest and cardiovascular involvement and had lower platelet counts. Older age is associated with higher mortality in AAV patients.

**Funding:** Government Support - Non-U.S.
Validation of the Renal Risk Score for ANCA-Associated Glomerulonephritis in a National Irish Cohort
Jennifer Scott,1 Silke R. Brix,2 Laura M. Slattery,1 Michelle Clincke,1 Mark A. Little,1 Trinity Health Kidney Centre, Trinity College Dublin, Ireland; 1Trinity Health Kidney Centre, Dublin, Ireland; 2The University of Manchester, Manchester, United Kingdom.

Background: Histopathological examination is currently the gold standard for diagnosis of ANCA-associated glomerulonephritis (AAV GN). However, the commonly used Benedir score is inconsistent at predicting renal outcomes across different cohorts. Furthermore, treatment related morbidity remains a major problem. Brix et al. recently published a clinicopathologic score to predict End-Stage Disease Kidney (ESKD), using 3 parameters to stratify patients into 3 risk groups. Parameters include: percentage normal glomeruli (N0 >25% = 0, N1 10% – 4, N2 >10% = 6), percentage tubular atrophy and interstitial fibrosis (TO ≤25% = 0, T1 >25% = 2), and estimated glomerular filtration rate at the time of diagnosis (G0 >15 ml/min/1.73 m2 = 0, G1 ≤15 ml/min/1.73 m2 = 3). The ultimate aim is to use this to personalise treatment, enabling the optimal balance of toxic immunosuppression for every patient.

Methods: The Rare Kidney Disease (R KD) registry is an Irish national longitudinal, multi-centre, cohort study which includes 567 AAV patients, to date, diagnosed using the European Medicines Agency Algorithm (1990-2019). Patients with Granulomatosis with polyangiitis (Wegener’s) (n=13), microscopic polyangiitis (n=1), with biopsy proven AAV GN and positive PR3 or MPO serology were included in our validation of the renal risk score.

Results: 248 patients, of whom 43 (17.3%) developed ESKD and 35 (14.1%) died, over a median follow up of 32 months (interquartile range, IQR 5.9-99 months), were identified. Outcome data and histology were available for 205 patients. Forty-five patients were in the lowest risk group (group 1) - (2.4%) of which developed ESKD. Eight (8.6%) of the 93 patients in the middle risk group (group 2) reached ESKD. Sixty-seven patients were in the highest risk group (group 3) and 44 (66%) of these patients reached ESKD. Kaplan Meier survival analysis demonstrated a difference in renal outcome between the 3 risk groups (p <0.0001).

Conclusions: The proposed renal risk score accurately predicts ESKD in patients with AAV GN, in our national Irish cohort. The next step is to further refine the predictive cut-off values for the 3 clinicopathologic parameters using a regression tree analysis.

Hypocomplementemia Is Associated with More Severe Renal Disease and Worse Renal Outcomes in Patients with ANCA-Associated Vasculitis: A Retrospective Cohort Study
Aglaia Chalkia,1 Konstantinos Thomas,2 Panagiota E. Giannou,1 Zoe Alexakou,1 Athanasia Kapota,1 Christina Tsalapaki,1 Dimitrios Vassiliopoulos,2 Dimitrios I. Petras.1 1Nephrology Department Hippokration General Hospital, Athens, Greece; 2Joint Rheumatology Program, 1st and 2nd School of Medicine - Clinical Immunology - Rheumatology Unit, 2nd Department of Medicine, Athens, Greece.

Background: The complement system has been recently proposed to play an important role in the pathogenesis of ANCA associated vasculitides (AAV). Real life data assessing its predictive role in renal outcomes is limited. In this study, we evaluated the value of serum and kidney deposited C3 in predicting renal outcomes in patients with AAV.

Methods: In this retrospective study, patients with AAV were categorized according to their baseline serum C3 levels as hypo- or normo-complementemic and to those with positive or negative kidney biopsy immunofluorescence (IF) for C3. Clinical, serologic, treatment and histopathologic characteristics, as well as prognosis between the 2 groups were compared.

Results: Forty-seven patients (51% men) were enrolled with a mean age at diagnosis of 65 years and were followed up for a median period of 56 months. At baseline, 23% (11/47) of the patients were hypocomplementemic (C3 <75 mg/dL). These patients were older (74 vs. 65 years, p=0.013), had higher creatinine levels (4.9 vs. 2.2 mg/dL, p=0.006), were more often hemodialysis dependent (64% vs. 19%, p<0.009) and progressed more often to ESRD (55% vs. 11%, p=0.01) compared to normo-complementemic patients (n=36). On multivariate analysis, serum Cr at diagnosis (HR=16.8, 95%CI: 1.354-208.62, p=0.028) and low serum C3 (HR=2.492; 95% CI: 0.537-11.567, p=0.044) were independent predictors for ESRD. Among 25 patients with kidney biopsy data, those with positive IF staining for C3 (56%, n=14) had more often a mixed histological pattern (72% vs. 27%, p=0.033), low serum C3 levels (42% vs. 18%, p=0.001) and serious infections during follow-up (57% vs. 18%, p=0.047) compared to those with negative (n=11) IF staining.

Conclusions: The subgroup of patients with AAV and low C3 levels at diagnosis (23%) have more severe renal disease and outcomes (ESRD) compared to patients with normal C3 levels. This should be taken into account in therapeutic and monitoring strategies.

Clinical Features and Treatment Outcomes of Patients with Paucl- Immune Vasculitis with and Without a Medical History of Autoimmune Disease
Sophia Lionaki,1 Smaragdi Marinaki,1 Sofia Fragioukidi,1 Emmanuel Kalaitzakis,1 Petros Kalogeropoulos,1 Georgios Lippis,2 Athanasia Tsiofouas,3 Ioannis Boletis.1 1Nephrology, Laiko Hospital, Athens, Greece; 2Pathology, Laiko Hospital, Athens, Greece; 3Pathophysiology department, Laiko Hospital, Athens, Greece.

Background: A proportion of patients with pauci-immune vasculitis (PIV) report a past medical history (PMH) of other autoimmune disorder prior to the diagnosis of vasculitis. The purpose of this study was to identify the differences, if any, between patients with PIV with or without a PMH of other autoimmune disease prior to the onset of vasculitis.

Methods: Among 304 patients with biopsy proven PIV at any site, detailed information regarding their PMH was available in 235 patients (77.3%). Of these, 60 (25.5%) reported a PMH of other autoimmune disorder including Sjogren syndrome, Crohn’s disease, autoimmune thyroiditis, psoriasis, rheumatoid arthritis, and scleroderm. Results: The clinical characteristics and outcomes of the two groups are displayed in [table 1].

Conclusions: Patients with a PMH of other autoimmune disorder prior to the diagnosis of PIV were predominantly PMPO-ANCA positive, had less impaired kidney function at presentation and a low lower probability of relapse after achieving remission, compared to patients without a PMH of autoimmunity.

Low Serum C3 at Diagnosis of Paucl-Immune Glomerulonephritis Is Associated with More Advanced Kidney Impairment and Worst Renal Prognosis
Sophia Lionaki,1 Smaragdi Marinaki,1 Emmanuel Kalaitzakis,1 Sofia Fragioukidi,1 Petros Kalogeropoulos,1 Georgios Lippis,2 Athanasia Tsiofouas,3 Ioannis Boletis.1 1Nephrology, Laiko Hospital, Athens, Greece; 2Pathology, Laiko Hospital, Athens, Greece; 3Pathophysiology, Laiko Hospital, Athens, Greece.

Background: Recent evidence supports the notion that complement activation plays a critical role in puacl-immune (PI) vasculitits pathogenesis. The aim of this study was to investigate if the clinical, serological and laboratory characteristics and treatment outcomes of patients with PI glomerulonephritis (GN) with low serum complement levels at diagnosis differ from those of patients with complement values within the normal range.

Methods: In a retrospective design we studied patients with biopsy proven PIGN with available serum complement measurements at diagnosis, or during a relapse, prior to initiation of immunosuppressive therapy. All patients were tested for antineutrophil cytoplasmic antibodies (ANCA) at presentation. Fisher’s exact tests and Wilcoxon rank sum tests were used to compare the characteristics by serum C3.

Results: Of 96 patients included in the study, 22 (23.9%) had low serum C3 at diagnosis. Comparison of clinical, serological and laboratory characteristics and outcomes between the two groups is shown in [table 1].

Conclusions: Almost one quarter of patients with biopsy proven PIGN had low serum C3 at diagnosis in this cohort. These patients had more advanced renal impairment, required acute dialysis more frequently and were more likely to end up in end-stage kidney disease compared to patients with serum C3 within the normal range.
PO1944

Serum and Urinary Metabolites Discriminate Disease Activity in ANCA-Associated Glomerulonephritis
Sam Kant, Anne Le, Nabeel Attarwala, Duvuru Geetha. Johns Hopkins University School of Medicine, Baltimore, MD.

Background: Relapse of disease and treatment related morbidity due to lack of a reliable biomarker for disease activity continue to be a significant issue in patients with ANCA associated vasculitis (AAV). Renal biopsy is currently gold standard for reliable detection of active disease. Metabolomics have been used to successfully discern disease activity in a number of autoimmune diseases. We sought to investigate the use of serum and urinary metabolomics to discriminate disease activity in ANCA associated GN.

Methods: Ten patients with AAV renal disease had serum and urine supernatant sample collections during active and remission phases of disease. Active renal disease was defined by presence of hematuria >5 RBC/hpf, urinary RBC casts or an increase in serum creatinine >30% or < in eGFR by 25% or biopsy proven GN. The samples were then subjected to targeted metabolomics data acquisition using a Thermo scientific Q Exactive Plus Orbitrap Mass Spectrometer Plus with a Vanquish UPLC at our metabolomics facility.

Results: The mean age in this cohort was 61 years, with 6 patients each being male and Caucasian. Nine patients had biopsy proven renal disease, with clinical diagnosis in one. Mean BVAS and mean GFR was 17 and 28 respectively. Intensities of urinary citrate and iso-citrate are significantly higher in the remission group compared to the active group (Fig 1A). Similar trend of higher citrate and iso-citrate intensities present in serum of patients in remission versus active disease (Fig 1B). There was a disproportionately high intensity difference in citrate and iso-citrate levels in serum and urine samples compared to other metabolites of the TCA cycle implying involvement of additional metabolic pathways.

Conclusions: This study indicates that serum and urinary citrate and iso-citrate may be utilized to monitor disease activity in AAV and emerge as an alternative to kidney biopsy.

PO1945

Renal Involvement in Granulomatosis with Polyangiitis Does Not Increase Inpatient Mortality Compared with No Renal Involvement
Phirzige Edgini, Precious Eseacon, Augustine Manadan.1,2 John H Stroger Hospital of Cook County, Chicago, IL, 1University of Benin Teaching Hospital, Benin City, Nigeria; 2Rush University Medical Center, Chicago, IL.

Background: The aim of this study was to analyze the difference in outcomes of Granulomatosis with polyangiitis (GPA) with and without renal involvement. The primary outcome was inpatient mortality, while secondary outcomes were hospital length of stay (LOS) and total hospital charges.

Methods: Data were abstracted from the National Inpatient Sample (NIS) 2016 and 2017 Database. NIS is the largest inpatient admission database in the United States. The NIS was searched for adult GPA hospitalizations with and without renal involvement as the principal or secondary diagnosis using ICD-10 codes. Multivariate logistic and linear regression analysis was used to adjust for confounders for the primary and secondary outcomes respectively. STATA software was used to analyze the data.

Results: There were 71 million discharges included in the combined 2016 and 2017 NIS database. 23,670 hospitalizations were for adult patients, who had either a principal or secondary ICD-10 code for GPA. 8,265 (34.92%) and 15,405 (65.08%) of these hospitalizations were for GPA with renal and without renal involvement respectively. Inpatient mortality occurred in 3,104 (5.10%) GPA patients (5.14% ± 0.25) vs 558 (3.8%) without renal involvement (p=0.0287). The adjusted odds ratio (AOR) of inpatient mortality for GPA with renal compared to without renal involvement was 1.14 (95% CI 0.84-1.56, p=0.406). GPA with renal involvement hospitalizations had a mean increase in adjusted mean LOS of 1.36 days (95% CI 0.82-1.91, p=0.0001) compared to GPA without renal involvement. GPA with renal involvement hospitalizations had an increased in adjusted total hospital charges of $18,723 compared to GPA without renal involvement (95% CI 9,595-27,852, p=0.0001).

Conclusions: There is no statistically significant difference in inpatient mortality for hospitalizations of GPA with and without renal involvement. However, LOS and total hospital charges in GPA with renal involvement are greater than those without renal involvement. Hence GPA with renal involvement has a greater burden to the healthcare system compared to without renal involvement.

PO1946

Immunological Indexes Both in Renal and Serum Were Associated with Relapse and Patient Outcome in Chinese Patients with Myeloperoxidase-ANCA-Associated Glomerulonephritis
Wei Lin, Zhong Yong. Department of Nephrology, Xiguang Hospital, Central South University, China, Changsha, China.

Background: Rapidly progressive glomerulonephritis (RPGN) caused by antineutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV) are typically characterized by few or no immune deposits in glomerular which was defined as pauci-immune glomerulonephritis (GN). Immune complex (IC) deposits in glomerulus and absence of an immune induced also have been reported and/or by the presence of anti-GBM antibodies with AAV in China are positive for anti-myeloperoxidase (MPO), which more frequently had renal involvement and developed RPGN. Therefore, it is necessary to assess serum immunological indexes and the IC deposits in renal in MPO-ANCA-associated GN.

Methods: Clinical and immunological characteristic of AAV in China are positive for anti-myeloperoxidase (MPO) were retrospectively analyzed. Results: Patients with low sC3 (<790 mU/l) and low sC4 (<100 mU/l) at diagnosis showed poorer renal survival compared to patients with normal value (p=0.003, 0.011). Furthermore, among patients of low sC3 at diagnosis, the cases with persistent low sC3 showed obviously worse renal survival than those whose sC3 recovered to normal after treatment (p<0.001). There are 41%(40/97) patients showed positive IF findings (a2- on a 0 to 4+ scale) for at least one Ig or complement component. In our study, the patients with IC deposits showed higher level of serum creatinine (p=0.01) and lower platelet counts (p=0.009), sC3 level (p=0.013) than patients with pauci-IC deposition at diagnosis. We also found IgG deposits related to worse renal outcome than the negative cases (p=0.047). What’s more, complement C1q deposits displayed significant poorer patient survival than the cases without C1q deposits (p=0.001).

Conclusions: Patients with a persistent low sC3 showed poorer renal prognosis than the patients whose sC3 level return to normal after a period of treatment, which was confirmed that both initial and continuously low sC3 can act as predictive indicators for renal outcome. IgG and complement C1q deposits associated with poorer renal and patient outcome, which can help to judge the prognosis of MPO-ANCA-associated GN to some extent.

PO1947

Rituximab vs. Cyclophosphamide in the Treatment of Anti-GBM Crescentic Glomerulonephritis: An Observational Study
Ajay Jaryal, Sanjay Vikrant, Indira Gandhi Medical College, Shimla, India.

Background: Anti-glomerular basement membrane (GBM) crescentic glomerulonephritis (CGN) is a rare disease affecting kidneys and/or lungs. At present most of the evidence for its treatment is with use of plasmapheresis (PP), high dose steroids (HDS) and cyclophosphamide (CYC). The use of Rituximab (Rtx) in addition to PP and HDS is only anecdotal. Herein, we are describing our experience with the use of both regimens.

Methods: A retrospective analysis of all the patients with anti GBM CGN admitted in our hospital from September 2018 to November 2019 was done. Anti GBM CGN was diagnosed on the basis of ≥50% crescents on kidney biopsy and immunofluorescence showing ≥1 mg/L IgG deposition along GBM and/or by the presence of anti GBM antibodies.

Results: 11 patients were admitted with anti GBM CGN, during this period (15 months). Kidney biopsy was done in 10 patients and in one anti GBM GN was diagnosed on the basis of raised anti GBM antibody titres. There were 8 females and three males (age range 37-72 years). The mean serum creatinine was 8.69mg/dl. Out of 11 patients 2 refused for treatment and 2 were lost to follow up. 3 out of 7 patients had diffuse alveolar hemorrhage (DAH) and in all it succeeded renal involvement (one had diagnosis of usual interstitial pneumonia for 1 year). 4 out of 11 patients had concomitant urinary tract infection. 5 out of 7 (71.42%) were ANCA positive, 2 out 11 had type 2 diabetes mellitus, 5 out of 11 were oligoanuric and 7/11 (63.6%) were dialysis requiring at presentation. PP was given on alternate days. Both the patients who refused for treatment died on follow up. Among remaining 7 patients 5 had received PP+HDS + CYC and 2 had received PP+HDS+Rtx. In CYC group 4 out (all 4 were dialysis dependent and 3 were oligoanuric) out of 5 patients died whereas in Rtx group both the patients survived (one was dialysis dependent and oligoanuric).
Impact of Race on Hospitalization Outcomes for Goodpasture Syndrome in the United States

Methods: The National Inpatient Sample database was used to identify hospitalized patients with a principal diagnosis of Goodpasture’s syndrome from 2003-2014. Goodpasture’s syndrome patients were grouped based on their race. The differences in hospital treatments and outcomes between Caucasian, African American, and Hispanic Goodpasture’s syndrome patients were assessed using logistic regression analysis.

Results: 964 patients were hospitalized with a primarily diagnosis of Goodpasture’s syndrome. Of these, 786 were included in the analysis: 622 (65%) were Caucasian, 73 (8%) were African American, and 91 (9%) were Hispanic. The need for mechanical ventilation, non-invasive ventilation support, and renal replacement therapy in African Americans was greater than Caucasians. There was no significant difference in organ failure, sepsis, and in-hospital mortality between African Americans and Caucasians. In contrast, Hispanics had higher in-hospital mortality than Caucasians but similar risk of organ failure and sepsis.

Conclusions: African American and Hispanic populations account for 8% and 9% of hospitalizations for Goodpasture’s syndrome, respectively. While there is no significant difference in in-hospital mortality between African Americans and Caucasians, Hispanics with Goodpasture’s syndrome carry a higher in-hospital mortality compared to Caucasians.

Overlap Syndrome of Antineutrophil Cytoplasmic Antibody-Associated Vasculitis and IgG4-Related Disease: Distinct Clinicopathologic Clues for Precise Diagnosis

Methods: A case of a 67-year-old man in our hospital who exhibited the characteristics of both AA V and IgG4-RD was performed on PUBMED database from 1976 until January 2020.

Results: Mild hematuria with rapid progressive renal failure of the patient was observed while renal biopsy revealed pauci-immune crescentic glomerulonephritis, the overlap syndrome of AA V and IgG4-RD was performed on PUBMED database from 1976 until January 2020.

Conclusions: Both antineutrophil cytoplasmatic antibody (ANCA)-associated vasculitis (AAV) and IgG4-related disease (IgG4-RD) are multi-system inflammatory disorders. The coexistence of both diseases presents the possibility of a new overlap syndrome which leads to different treatment and outcome. In this study, the symptomatic and pathological concurrence of AAV and IgG4-RD is investigated to explore the possibility and clinicopathologic clues to the diagnosis of this overlapped syndrome.

PO1950

Anti-IL-5 Therapy in Eosinophilic Granulomatosis with Polyangiitis (EGPA): An 18-Month Follow-Up Study of a Steroid-Sparing Therapeutic Approach

Methods: The aim of our study was to analyze the outcome for EGPA patients who received 100mg s/c of MEPO monthly for 18 months and beyond. This retrospective, descriptive study analyzed 13 patients with EGPA, who received 100mg s/c of MEPO therapy monthly. Time points of assessment included MEPO commencement [M0] and ≥ 18 months [M18].

Results: This study demonstrates that anti-IL-5 therapy serves as a favorable model for steroid minimization in EGPA, with an overall 50% reduction in steroid dosage. Additional reduction in conventional immunosuppressants was also observed in 3 patients. ANCA positive serology normalized in all four patients. Well tolerated, it demonstrated considerable clinical benefit, with 12 patients [92.3%] continuing anti-IL5 therapy beyond 18 months. Renal function was preserved. One patient had MEPO switched to Rituximab to treat both EGPA and new onset rheumatoid arthritis. Three patients were switched to alternative anti-IL5 therapies, benralizumab (3x2) and Reslizumab (x1).

Conclusions: The relapsing nature of EGPA places a potential dependency of therapy on steroids, underscoring the importance of targeted pathway specific biologics to minimize steroid exposure, prevent tissue damage and ensure early response to therapy. This was a 50% reduction in steroid dosage in this study, with preserved renal function.

Pauic-Immune Lupus Nephritis: A Case Report

Introduction: Systemic lupus erythematosus (SLE) is an autoimmune disease with multisystem involvement, and Lupus nephritis (LN) typically shows immune deposits on biopsy. Pauic-immune LN is a rare entity.

Case Description: A 35 year old female presented with pedal edema, reduced urine output & yellowish discoloration of eyes since 20 days. No vomiting, dyspnea, joint pains, rashes, or hematuria. She had similar episodes in 2011 and 2013 & was given blood transfusion and oral steroids. She is a hypertensive for 10 years and diabetic for 2 years. She had 2 normal vaginal deliveries with no obstetric complications. On examination was normal. She had severe anemia, renal failure, positive ANA, dsDNA and direct Coombs test, with normal complements. There was no evidence of antiphospholipid syndrome, SLE with Antinuclear hemolytic anemia (AHLA) and probable lupus nephritis (LN) was diagnosed. Steroid pulse was started with stabilization of renal function and hemoglobin. Renal biopsy showed necroinflammatory crescentic glomerulonephritis with no endocapillary proliferation. Immunofluorescence did not show any immune deposits. A diagnosis of pauci immune LN was made, and was started on cyclophosphamide. She had partial renal recovery with creatinine of 1.5 mg/dl, no hematuria, no hemoysis.

Pulmonary Renal Connection: A Case of ANCA Vasculitis and Atypical Anti-GBM Antibody Associated with Vaping
Josephine Abraham, Laith Al-Rabadi, Monica P. Revelo Penafiel, Martin C. Gregory. University Of Utah University of Utah Hospital, Salt Lake City, UT.

Introduction: The use of e cigarettes and vaping is linked to the development of lung injury (EVAI). We present a case of ANCA (antineutrophil cytoplasmic antibody) vasculitis with atypical Anti GBM (glomerular basement membrane antibody) in a patient with EVAI.

Case Description: A 17 year old male with a history of vaping presented with acute respiratory failure requiring mechanical ventilation. CT chest revealed diffuse bilateral consolidation. Evaluation for infection was negative. Nephrology was consulted for acute renal failure. Urine analysis was notable for hematuria and proteinuria. Urine microscopy identified dysmorphic erythrocytes. Renal biopsy showed pauci immune crescentic glomerulonephritis (panel A). ANCA with MPO (myeloperoxidase) specificity and Anti GBM antibody were positive. He was treated with methylprednisolone, therapeutic plasma exchange and oral cyclophosphamide initially and subsequently Rituximab. Four months later his creatinine was 1.2 mg/dL, improved from a peak level of 7.5mg/dL with plasma exchange and oral cyclophosphamide.

Discussion: Anti GBM disease had been associated with alveolar injury from exposure to hydrocarbons or smoking. The presence of the erythrocyte casts and positive anti GBM antibody in patients with vaping associated lung injury raises the possibility exposure to hydrocarbons or smoking. The presence of the erythrocyte casts and positive anti GBM antibody in patients with vaping associated lung injury raises the possibility exposure to hydrocarbons or smoking. The presence of the erythrocyte casts and positive anti GBM antibody in patients with vaping associated lung injury raises the possibility exposure to hydrocarbons or smoking.

PO1954

Isolated ANCA Renal Arteritis
Ishah Shah,1 Nidia C. Messias,2 Muhammad A. Siddiqui,1 Sara Combs,1 J Pedro Teixeira,1 1University of New Mexico Health Sciences Center, Albuquerque, NM; 2Arkana Laboratories, Little Rock, AR

Introduction: Vasculitis associated with antineutrophil cytoplasmic antibodies (ANCA) usually causes acute kidney injury (AKI) through crescentic glomerulonephritis (GN). Renal ANCA arteritis without GN is often accompanied by prominent interstitial nephritis (IN). We present a case of AKI due to ANCA renal arteritis without significant GN or IN.

Case Description: An 84-year-old woman with hypertension, chronic kidney disease [baseline creatinine (Cr) 1.6 mg/dL], and prior right nephrectomy for renal cell carcinoma presented with nausea and anorexia. She was admitted the prior month for pyleonephritis and AKI and discharged to a rehab facility. On return, her serum Cr was 4.9. She was readmitted and started on hemodialysis. Urine microscopy was consistent with acute tubular injury (ATI), but also showed non-glomerular hematuria which persisted on several UAs. Urine protein was 2.1 mg/dL. Both p-ANCA (1:1280) and MPO (>8 AU) were strongly positive. She was given IV corticosteroids and renal biopsy was obtained [Figure]. She was evaluated by rheumatology and felt to have renal-limited disease. She was treated with plasma exchange followed by rituximab, but a week later she opted to stop dialysis and transition to comfort measures and she died 2 days later.

Discussion: Most patients with AKI from ANCA-associated vasculitis will have GN, often crescentic. Extraglomerular features on biopsy of ANCA disease are common and include IN and arteritis/arteriolitis, but often parallel the activity of glomerular disease. Prior case reports of ANCA renal disease without GN have featured prominent IN with or without arteritis/arteriolitis. This case of marked necrotizing arteritis, minimal IN, and absent GN represents a rare phenotype of ANCA renal disease.

PO1953

Sabotaged: Hydralazine-Induced ANCA Glomerulonephritis
Larissa Kruger gomes, Esilida Sula Karreci, Krishna A. Agarwal, Ruth Schuman, Jeffrey H. William, Stewart H. Lecker, Isaac E. Stillman. Beth Israel Deaconess Medical Center, Boston, MA.

Introduction: While usually well known to cause SLE-like syndrome, hydralazine (HZ) can also be involved in a different clinical scenario with ANCA vasculitis.

Case Description: 77y/o woman with hypertension and COPD presents with 2 days of hemoptysis and hematuria, requiring urgent intubation. CT scan reveals multifocal infiltrates and bronchoscopy shows diffuse alveolar hemorrhage. Labs showed Hb of 6.8 and Cr of 1.7. Dysmorphic RBCs were seen in the urine sediment and proteinuria at 1.2g/dL. Given concern for anti-GBM, she received IgG methylprednisolone and plasma exchange. ANA 1:1280 with MPO-ANCA levels >8.0 U, along with positive anti-histone and SCL-70 antibodies, but with negative anti-GBM and ds-DNA. Kidney biopsy showed pauci-immune crescentic GN with trace staining for IgA, IgM, C3, kappa and lambda. As she had been on HZ, the diagnosis of HZ-induced ANCA-associated vasculitis was made. Offending agent was held and cyclophosphamide was started. After 2 months, kidney function returned to baseline, with resolution of proteinuria and hematuria.

Discussion: In patients with HAV unusually high titer of MPO are present and can be used to differentiate drug-associated and spontaneous cases. A minority of patients can also present with other positive antibodies, such as ds-DNA, anti-histone, or Scl-70. As HZ can also cause SLE-like pattern of injury, it can be difficult to obtain a diagnosis based on serologies alone; biopsy is essential for diagnosis and prognosis. The treatment of HAV involves not only removing the inciting agent, but also further immunosuppression, as HZ is thought to lead to increased expression of MPO and PR3 breaking neutrophils tolerance and leading to auto-antibody formation. When choosing a treatment strategy, guidelines for spontaneous ANCA should be followed, in this particular case, as she had severe lung involvement, cyclophosphamide was chosen.

Rare Case of Silicosis-Induced Pauci-Immune Glomerulonephritis
Sandheep Venkataraman, Matthew Ray, James F. Dylewski. University of Colorado, Denver, CO.

Introduction: Pauci-immune glomerulonephritis(GN) caused by ANCA was first described in 1982. Most cases are idiopathic, however, ANCA vasculitis may induced due to certain exposures. Here we report a case of ANCA vasculitis associated with pulmonary silicosis.

Case Description: A 37-year-old man with no prior history presented with anorexia, weight loss, fatigue, and arthralgias for 6 months. He was employed as a sandblaster, stonecutter, and as a mason. On initial exam he was found to have dactylitis and Raynaud’s phenomenon. His presenting creatinine(Cr) was 2.9 mg/dL with urinalysis showing 3+ blood and 1.2 gm proteinuria. Renal ultrasound demonstrated enlarged kidneys bilaterally. Notable serologies were ANA positive 1:1280, p-ANCA positive 1:2560, C3 77 mg/dL, C4 6 mg/dL, and MPO at 78 AU/ml. CT Chest revealed innumerable pulmonary nodules, extensive fibrosis, and mediastinal lymph nodes with eggshell calcifications. Infectious workup was negative. Transbronchial biopsy demonstrated collection of histiocytes containing black pigment without granulomas. Kidney biopsy showed necrotizing crescentic GN, with marked interstitial inflammation and focal intralobular vessel infiltrates. IF and EM was negative, consistent with pauci-immune ANCA vasculitis. Given his history and presentation, he was diagnosed with silica-induced ANCA vasculitis. He was treated with 3 days of IV methylprednisolone, followed by a rapid prednisone taper. He also received IV Rituximab 1 gm on days 0 and 14, plus IV cyclophosphamide 500 mg every 2 weeks for 6 doses starting on day 0. The patient responded well with Cr improving to 1.0 and decreased proteinuria. Unfortunately he relapsed 3 months after last rituximab dose.

Discussion: Silica exposure is most often associated with pulmonary disease but there have been case reports of RPGN associated with it too. The majority of these patients were MPO positive. T-cell dysregulation and endothelial damage from PMNL have been case reports of RPGN associated with it too. The majority of these patients were MPO positive. T-cell dysregulation and endothelial damage from PMNL.

ANCA-Negative Small-Vessel Vasculitis with IgG4-Positive Plasma Cell Infiltration: A Case Report and Literature Review
Hui Peng Ge, Cuifang Li, Qiongjing Yuan. Xiangya Hospital Central South University, Changsha, China.

Introduction: Although the histopathology was critically important for differential diagnosis between AAV and IgG4-RD, overlapping morphologies and clinical manifestations put the clinicians in a dilemma of diagnosis sometimes. Here, we described a case of ANCA negative PICG with IgG4-positive plasma cell infiltration.

Case Description: A 60-year-old man patient presented with cough for 3 months and progressive renal impairment for 8 days. He had elevated serum IgG4 level with absence of anti-neutrophil cytoplasmic antibodies (ANCA). Lung CT as shown in Figure 1. Renal biopsy showed severe tubulointerstitial nephritis (TIN) with extensive infiltration of IgG4-positive plasma cells, suggesting a diagnosis of IgG4-related kidney disease(Figure 2). However, the identification of necrotizing glomerulonephritis and crescents forming and the absence of storiform fibrosis and obliterative phlebitis led to a diagnosis of ANCA negative renal small-vessel vasculitis. The condition was improved by using corticosteroids and cyclophosphamide at beginning.

Discussion: ANCA negative cannot exclude the diagnosis of AAV. The elevated serum IgG4 and/or abundant IgG4-positive cell infiltration can act as one of the manifestations in AAV. ANCA-negative pauci-immune crescentic glomerulonephritis (PICG) might represent an independent disease entity from ANCA positive PICG. Besides, IgG4-related disease (IgG4-RD) is an exclusive diagnosis and needs to be differentiated from vasculitis and other diseases. It is suggested that ANCA-negative PICG with elevated serum IgG4 and/or abundant IgG4-positive cell need to be further studied.

Figure 1. Lung CT in different periods.

Figure 2. Histological findings of the kidney.

PO1957

Adalimumab-Associated Pauci-Immune Glomerulonephritis: Coincidence or Causation Effect?
Nirav N. Patel, Emma Spangler, Pavan Annamuraju. Johnston Memorial Hospital, Abingdon, VA.

Introduction: Adalimumab is a TNF-blocker used in the treatment of hidradenitis suppurativa (HS). Infections, lupus-like syndrome, and lymphoma are known safety concerns with TNF-blockers. We report a rare case of adalimumab associated pauci-immune crescentic GN (PICGN) in a patient with HS.

Case Description: A 19-yr-old male with a history of HS on adalimumab for 6 months was seen on 4/1/20 with a fever of 103°F, cough & epistaxis for 2 weeks. CT sinuses showed polypos and sinusitis. He was treated with antibiotics for sinusitis. CT chest, nasal PCR for COVID-19, blood, and urine cultures were negative. By hospital day 8, he remained febrile and developed AKI [Creatinine (Cr) 9 mg/dl; baseline of 0.8 mg/dl]. Physical exam showed chronic scarred skin lesions on the chest and axilla with no signs of infection or rash. Hematuria and microalbuminuria were noted. Ultrasound showed renomegaly. Inflammatory markers were high (CRP 254 mg/L, Ferritin 1059 ng/mL). PR3-ANCA antibody was positive 530 IU/mL. A renal biopsy confirmed PICGN (Fig 1). Bone marrow biopsy showed no evidence of hemophagocytosis. The patient was treated with pulse doses of steroids and rituximab and plasma exchange (peak cr 6.4 mg/dl). On a 3-week follow up creatinine improved to 1.8 mg/dl suggesting a favorable outcome. The patient never required dialysis.

Discussion: AKI, microscopic hematuria, and proteinuria can be seen in a febrile illness. However, epistaxis and renomegaly prompted us to check for ANCA serology. To our knowledge, this is the first case of adalimumab associated PICGN in a patient with HS. Interestingly, our patient is much younger compared to previously reported cases (mean 51.4 years). It is possible that adalimumab may be unrelated to the vasculitis; however, due to a strong temporal association, it was felt to be the culprit agent. Nephrologists must be aware of the renal side effects of this class of drugs.
A Case of C-ANCA Associated Retropertioneal Fibrosis and Periarthritis
Vinay Srinivasan. Darling Downs Health Service, QLD Australia Darling Downs Hospital and Health Service, Toowoomba, QLD, Australia.

Introduction: Granulomatosis with Polyangiitis (GPA) is a type of small vessel vasculitis that has prevalence rate of 25-160 cases per million population, and a incidence rate of 0.5 cases per 100,000 population per year. Clinical features of the disease involve the respiratory and renal systems. However, large vessels such as the Aorta and retropertioneal tissue are rarely involved.

Case Description: We present the case of a middle-aged male who presented with an obstructive nephropathy in which abdominal CT revealed a soft tissue mass encompassing the Aorta and Inferior Vena Cava causing obstruction of the Left ureter. Despite ursodiol stenting, serum creatinine failed to improve. Furthermore urinary analasyst demonstrated an active urinary sediment; hemoproteinuria. Serum c-ANCA and PR-3 antigen titres were positive. Renal biopsy was performed and confirmed pauci-immune vasculitis. The patient was induced with pulse immunosuppressives and cyclophosphamide and as part of his maintenance treatment received prednisolone and oral cyclophosphamide. On follow up, partial remission has been achieved with his serum creatinine returning to baseline level and proteinuria reduced, though erythrocytes are still evident. Repeat abdominal imaging has revealed a reduction in the size of the soft tissue mass with treatment.

Discussion: Biopsy proven vasculitis has been shown in patients with retropertioneal fibrosis. Few case reports and series have described this association, inferring a pathogenic role of ANCA in the development of retropertioneal fibrosis. Moreover it has been suggested that retro peritoneal fibrosis may be an early clinical manifestation of ANCA associated vasculitides. Consequently, ANCA associated vasculitis should be considered in the differential diagnosis of any patient who has Retropertioneal fibrosis and an active urinary sediment

A Rare Case of ANCA-Negative Pauci-Immune Crescentic Glomerulonephritis in an Elderly Woman
Oscar A. Garcia Valencien, Eduardo Edelman Saul, Yanezy Olivera Arencibia, Marte A. Sosa. University of Miami / Jackson Memorial Hospital, Miami, FL.

Introduction: Acute kidney injury is usually multifactorial with a broad differential diagnosis. Of those, rapidly progressive glomerulonephritis (RPGN) requires special attention as it represents a true diagnostic and therapeutic emergency that can lead to irreversible kidney failure.

Case Description: A 92-year-old female with a history of Chronic Kidney Disease Stage III, Diabetes Mellitus type II, hypertension, and recurrent deep vein thrombosis sent to the ER for evaluation of rapidly worsening kidney function sent on outpatient laboratories for assessment of poor oral intake and fatigue for 2 weeks. On arrival, BP was 133/49mmHg, HR 70bp, temperature 36.9°C, RR 17 rpm and SO2 of 99%. Mental status was at baseline and physical exam was unremarkable. Laboratory data were remarkable for serum creatinine of 10.55 mg/dl from baseline of 1.8 mg/dl, potassium level of 6 mEq/L and bicarbonate of 17 mEq/L. Urinalysis showed proteinuria (3+), hematuria (344 RBCs/hpf) and leukocytosis (68 WBC/hpf). Urine protein creatinine ratio of 2.4. No acute EKG changes. Renal ultrasound demonstrated increased bilateral renal size with an increased medulla from 3.5cm-1.5cm. CT-Abdominal/Pelvis showed bilateral pleural effusions and groundglass nodularity within the right middle and lower lobes. Kidney biopsy showed linear GBM staining for IgG4, with glomerular necrosis, crescents, and unusually prominent endocapillary proliferation (Figure). Treatment included diuretics, antibiotics, IV methylprednisolone, oral cyclophosphamide, and 8 plasma exchanges over 11 days. Serum anti-GBM was undetectable after 2 days. He progressed to dialysis-requiring ESRD over the next 6 weeks: a repeat kidney biopsy showed persistent crescentic GN with endocapillary proliferation and strong linear IgG4 staining, despite repeatedly negative serum anti-GBM.

Discussion: This case highlights complexities in the pathogenesis and diagnosis of anti-GBM disease. RPGN was likely triggered by parainfluenza infection, a rarely associated diagnosis. Low anti-GBM antibody levels were likely explained by the poor sensitivity of ELISA to detect IgG4. Finally, prominent endocapillary proliferation is characteristic of “atypical anti-GBM disease”, yet serum anti-GBM was positive in this case.

Seronegative Anti-GBM: A Spectrum of Disease
Alisa Illescas, Michael B. Kuperman, Sara Combs, J Pedro Teixeira.

Introduction: Glomerulonephritis (GN) due to anti-GBM disease is usually associated with detectable antibodies against the NC1 domain of the type IV collagen α3 chain [NC1-α3 (IV)], but a subset of seronegative atypical GN disease has been described with no lung involvement, non-crescentic GN on biopsy, and indolent course. We present a case of anti-GBM disease that is neither typical nor atypical.

Case Description: A 56-year-old woman with hypertension and obesity underwent renal biopsy after routine labs showed rise in creatinine (Cr) above baseline of 1.5 mg/dl 6 months prior and hemoproteinuria on UA. The results [Figure] prompted transfer to our center. On admit, she noted mild chronic dyspea but denied cough or hemoptysis. She had mild hypertension (146/80) and trace edema. Cr had risen to 4.5, urine protein was 3.4 g/g Cr, and chest x-ray was clear. She was started on IV corticosteroids and plasma exchange (PLEX). Anti-GBM IgG [multiplex bead assay, ARUP], drawn prior to PLEX, was negative (4 AU/mL, upper limit normal 19). She was treated with IV cyclophosphamide and 7 PLEX sessions over 2 weeks and her Cr stabilized at 3.5. She avoided dialysis and was discharged on prednisone with plans to continue monthly cyclophosphamide.

Discussion: Our patient exhibited an intermediate phenotype of anti-GBM disease with crescentic GN, subacute Cr rise, no lung involvement, and negative serology. Modern assays for anti-GBM antibody have a sensitivity of 94-100%. However, negative serology is also seen in rare cases of anti-GBM GN due to antibodies against epitopes of the GBM other than NC1-α3 (IV). Our case illustrates that a negative anti-GBM antibody does not exclude anti-GBM disease which is ultimately a pathologic diagnosis. It also suggests a spectrum exists between classic and atypical anti-GBM disease, but favorable outcome is possible regardless with biopsy-directed therapy.

3) protein by UA; negative/normol C3, C4, ANA, anti-dsDNA, ANCA; viral respiratory PCR positive for parainfluenza; serum anti-GBM 15µ/ml (nl <10µ/ml). CT Thorax showed bilateral pleural effusions and groundglass nodularity within the right middle and lower lobes. Kidney biopsy showed linear GBM staining for IgG4, with glomerular necrosis, crescents, and unusually prominent endocapillary proliferation (Figure).

Treatment included diuretics, antibiotics, IV methylprednisolone, oral cyclophosphamide, and 8 plasma exchanges over 11 days. Serum anti-GBM was undetectable after 2 days.

He progressed to dialysis-requiring ESRD over the next 6 weeks: a repeat kidney biopsy showed persistent crescentic GN with endocapillary proliferation and strong linear IgG4 staining, despite repeatedly negative serum anti-GBM.

Discussion: This case highlights complexities in the pathogenesis and diagnosis of anti-GBM disease. RPGN was likely triggered by parainfluenza infection, a rarely associated diagnosis. Low anti-GBM antibody levels were likely explained by the poor sensitivity of ELISA to detect IgG4. Finally, prominent endocapillary proliferation is characteristic of “atypical anti-GBM disease”, yet serum anti-GBM was positive in this case.

Discussion: Our patient exhibited an intermediate phenotype of anti-GBM disease with crescentic GN, subacute Cr rise, no lung involvement, and negative serology. Modern assays for anti-GBM antibody have a sensitivity of 94-100%. However, negative serology is also seen in rare cases of anti-GBM GN due to antibodies against epitopes of the GBM other than NC1-α3 (IV). Our case illustrates that a negative anti-GBM antibody does not exclude anti-GBM disease which is ultimately a pathologic diagnosis. It also suggests a spectrum exists between classic and atypical anti-GBM disease, but favorable outcome is possible regardless with biopsy-directed therapy.

A Case of Lupus Podocytopathy (LP) with Focal Segmental Glomerulosclerosis (FSGS): Is It Time to Add LP to the Next Revision of the Classification of Lupus Nephritis?

Introduction: Lupus podocytopathy is not included in the commonly used International Society of Nephrology/Renal Pathology Society (ISN/RPS) classification of Lupus Nephritis (LN). It has been reported in literature for the last 20 years. LP can have pathologic transition with variable outcomes. We describe a case of LP with FSGS in a young male patient with subsequent relapse.

Case Description: 25 year old male with past history of lupus without nephritis and chronic immune-mediated thrombocytopenia presented with generalized fatigue. Physical exam revealed diffuse rash and vital signs were within normal limits. Relevant laboratory findings included platelet count of 21000/µl, acute kidney injury with creatinine (Cr) of 1.6 mg/dl (baseline Cr of 0.8 to 1.1 mg/dl), spot urine protein creatinine ratio of 43.3 g, 24 hour urine protein of 4.1 g. Low Cr and C4, hemoglobin of 9.6 g/dl and WBC count of 3.6/µl. Serology was positive for ANA, dsDNA and SAA indicating active lupus flare. Left kidney biopsy showed mild mesangial expansion, no endocapillary proliferation and subtotal (<80%) podocyte foot process effacement. No subendothelial or subepithelial deposits were seen. He was treated with pulse dose steroids followed by oral steroids and serum Cr came back to baseline. Subsequently he was treated with mycophenolate mofetil 2 g/day. At 2 weeks, proteinuria came down to 1.8 g/day and by 12 weeks he achieved remission. However at 6 months, he had urine protein of 8.9 g in 24 hours with increase in Cr to 2.4 from 1.6, suggesting relapse.

Discussion: The presence of minimal or no capillary wall immune deposits with or without mesangial proliferation and effacement of podocyte foot processes in the setting of nephritic range proteinuria is collectively termed as LP. LP must be considered in almost half of all patients diagnosed with Systemic Lupus Erythematosus (SLE). While nephrotic syndrome (NS) in these patients is usually due to type IV/V Lupus Nephritis (LN), it may in rare instances occur secondary to minimal change disease (MCD), a pathologic transition with variable outcomes. We describe a case of LP extending this distinct entity in the classification of lupus nephritis.

Oliglciguat Protects Renal Function and Podocytes in In Vivo and In Vitro Models of Podocytopathies

Emmanuel S. Buys,1 Ehestham Ariz,2 Suzana Marusic,1 Deepak Nihalani,2 1Cyolvern, Cambridge, MA; 2Medical University of South Carolina, Charleston, SC; Hook Laboratories, Lawrence, MA.

Background: The nitric oxide (NO) receptor soluble guanylate cyclase (sGC) is a signal-transduction enzyme producing the secondary messenger cGMP. Impaired NO-cGMP signaling is associated with renal dysfunction. sGC stimulators molecules that enhance NO-mediated cGMP signaling, improve renal function in animal models of cardiac injury.

Methods: We studied the renoprotective effects of oliglciguat, a clinical-stage sGC stimulator, by studying in vitro and in vivo models of glomerular injury.

Results: In an acute focal segmental glomerulosclerosis (FSGS) model of glomerular injury induced by nephrotoxic serum (NTS), treatment with oliglciguat attenuated proteinuria and kidney pathology when compared to vehicle-treated mice. Additionally, oliglciguat treatment prevented NTS-induced mislocalization of the slit diaphragm proteins synaptopodin and nephrin. Ultrastructural analysis by transmission electron microscopy revealed that podocyte foot process morphology was preserved in mice treated with oliglciguat. To further assess the protective effect of sGC stimulation on podocytes, human podocytes injured by exposure to protonsulfate (PS) were treated with oliglciguat. Oliglciguat treatment restored PS-induced damage of podocyte actin cytoskeleton organization and the localization of podocyte cell membrane proteins. The genetic MRL/MpJ-Fas+/+ mouse model of systemic lupus erythematosus (SLE), disease progression, assessed by increased serum creatinine, was reversed in mice treated with the positive control cyclophosphamide or with oliglciguat than in vehicle-treated mice. Fewer kidney lesions (interstitial infiltrates, tubular atrophy, tubular epithelial vacuolation, tubular and interstitial lesions, and glomerular lesions) were observed in mice treated with cyclophosphamide or oliglciguat than in vehicle-treated mice. In contrast to cyclophosphamide, oliglciguat treatment did not result in leukenopins, reduction in spleen weight, or lower anti-dsDNA antibody in serum, suggesting that oliglciguat did not impact the auto-immune aspect of SLE.

Conclusions: In summary, oliglciguat, an orally bioavailable sGC stimulator, exhibits significant renoprotective effects in nonclinical models and warrants further evaluation for the treatment of FSGS, other podocytopathies, or nephropathies associated with diseases such as sickle cell disease.

Minimal Change Disease in Systemic Lupus Erythematosus: An Infrequent Variant

Ehsun Naem, Paul S. Kellerman, Saima Mansur. Beaumont Health, Royal Oak, MI.

Introduction: Lupus Nephritis (LN) is thought to complicate the disease course of almost half of all patients diagnosed with Systemic Lupus Erythematosus (SLE). While nephrotic syndrome (NS) in these patients is usually due to type IV/V Lupus Nephritis (LN), it may in rare instances occur secondary to minimal change disease (MCD), a phenomenon known as Lupus Podocytopathy (LP). We report a case of a young female with LP with concomitant Acute Tubular Necrosis (ATN).

Case Description: 40 year old female, known case of SLE (not on maintenance immunosuppression) and Hypertension presented with bright red blood per rectum and dyspnea for 2 weeks. Review of systems was pertinent for generalized swelling and facial rash. On initial assessment, she was hypertensive and physical exam revealed facial rash and vital signs were within normal limits. Relevant laboratory findings included platelet count of 21000/µl, acute kidney injury with creatinine (Cr) of 1.6 mg/dl, spot urine protein creatinine ratio of 43.3 g, 24 hour urine protein of 4.1 g. Low Cr and C4, hemoglobin of 9.6 g/dl and WBC count of 3.6/µl. Serology was positive for ANA, dsDNA and SSA indicating active lupus flare. Left kidney biopsy showed mild mesangial expansion, no endocapillary proliferation and subtotal (<80%) podocyte foot process effacement. No subendothelial or subepithelial deposits were seen. He was treated with pulse dose steroids followed by oral steroids and serum Cr came back to baseline. Subsequently he was treated with mycophenolate mofetil 2 g/day. At 2 weeks, proteinuria came down to 1.8 g/day and by 12 weeks he achieved remission. However at 6 months, he had urine protein of 8.9 g in 24 hours with increase in Cr to 2.4 from 1.6, suggesting relapse.

Discussion: The presence of minimal or no capillary wall immune deposits with or without mesangial proliferation and effacement of podocyte foot processes in the setting of nephritic range proteinuria is collectively termed as LP. LP must be considered in almost half of all patients diagnosed with Systemic Lupus Erythematosus (SLE). While nephrotic syndrome (NS) in these patients is usually due to type IV/V Lupus Nephritis (LN), it may in rare instances occur secondary to minimal change disease (MCD), a phenomenon known as Lupus Podocytopathy (LP). We report a case of a young female with LP with concomitant Acute Tubular Necrosis (ATN).

Case Description: 40 year old female, known case of SLE (not on maintenance immunosuppression) and Hypertension presented with bright red blood per rectum and dyspnea for 2 weeks. Review of systems was pertinent for generalized swelling and facial rash. On initial assessment, she was hypertensive and physical exam revealed facial swelling, discoid rashes and 2+ lower Extremity edema bilaterally. Workup revealed Normocytic Anemia, Acute Kidney injury, Hyperkalemia and Metabolic Acidosis. Urine studies showed nephrotic-range proteinuria and hematuria but were negative for casts. Free K/L ratio was high at 2.32 and C3 levels low at 42 mg/dl. Ultrasound guided kidney biopsy showed mild thickening of GBM and dilated tubules with diminished brush borders in the absence of crescentic changes. Electron Microscopy noted diffuse fusion of foot processes, along with rare intramembranous deposits. Immunofluorescence revealed a full house staining pattern within the Mesangium and the patient was diagnosed with Lupus Podocytopathy with concurrent LN Type 1. Substantial reduction in proteinuria was noted with a brief course of Prednisone.

Discussion: Our patient with SLE presented with NS and AKI, features typical of membranous/proliferative LN. Interestingly, her biopsy findings provided little evidence of endocapillary proliferation or sub-epithelial IC deposits and were more consistent with MCD as suggestive of Lupus podocytopathy. LP is rare to the extent that it does not form part of the official WHO classification for LN and has only been described a handful of times in prior literature, mostly in the form of case reports. However, given its prognostic implications, LP remains an important consideration in the evaluation of NS in SLE patients. While patients with Type IV/V LN require aggressive immunosuppressive therapy, patients with LP frequently respond well to steroids alone and have a much slower progression of disease.

A Novel In Vivo Approach to Capture the Podocyte Foot Process Proteome
Lori L. O’Brien, Gary F. Gerlach. University of North Carolina at Chapel Hill, Chapel Hill, NC.

Background: Podocytes are an extraordinary cell of the kidney filtration system with their tentacle-like foot processes flowing out from each cell body and interdigitating with neighboring processes. Proper kidney function relies on these cells and the complex architecture created by the interdigitating processes. They are the most critical component of the glomerular filter. Podocytes are injured and their integrity is compromised in the majority of kidney diseases leading to progressive proteinuria. However, we know little about the full complement of proteins localized to the foot process and how they change with disease.

Methods: We have developed a novel genetic mouse model capable of generating a spatially restricted, real-time, in vivo proteome. Recently, proximity labeling techniques have been developed to provide snapshots of spatially localized proteomes. The BioID method utilizes a promiscuous bacterial biotin ligase flexibly linked to a target protein of interest to biotinylate proteins within the vicinity. We have adapted this approach to identify the podocyte foot process proteome. Using podocin as a handle, we have modified the Nphs2 (podocin) locus to link the mutated, promiscuous BirA biotin ligase to podocin (Nphs2BioID). A flexible, 13x linker allows for a generous proximity around podocin, thereby capturing the broad proteome of the podocyte foot process.

Results: We have obtained viable Nphs2BioID/+ animals. Utilizing immunostaining, we have confirmed the proper expression and localization of the podocin-BioID. The HA-tagged biotin ligase appended to podocin colocализed with podocin and other foot process proteins. To test it’s functionality, we injected biotin dialy for 7 days. This produced an increase of biotinylated proteins in Nphs2BioID/+ podocytes versus wild type biotin injected controls or uninjected Nphs2+/+ mice. We have affinity purified the biotinylated proteins from glomerular isolations and are currently performing proteomic analyses.

Conclusions: We have generated the first of it’s kind in vivo mouse model to specifically identify the spatially localized proteome of the podocyte foot process. Our proteomics results will provide unprecedented insights into the make-up of this highly specialized and critical structure.

Soluble RARRES1 Induces Apoptosis of Podocytes to Promote Progression of Kidney Disease
Anquin Chen,1,2 Ye Feng,2 Yu Li,1 Chengguo Wei,1 Tianjun Guan,1 Kyung Lee,1 John C. He1. 1Division of Nephrology, Zhongshan Hospital, Xiamen University, Xiamen, China; 2Division of Nephrology, Department of Medicine, Icahn School of Medicine at Mount Sinai, NY, NY.

Background: Podocyte loss is a major event leading to the progression of focal segmental glomerulosclerosis (FSGS) and diabetic nephropathy (DN). Here, we found that retinoic acid receptor responder protein 1 (RARRES1) contributes to the podocyte loss in FSGS and DN.

Methods: We determined the role of RARRES1 in human and mouse with FSGS and DN. We investigated the mechanisms of RARRES1 in cultured human podocytes.

Results: The expression of RARRES1 increased in the glomeruli of patients with FSGS and DN and correlated with eGFR. Single-cell RNA-sequencing of the kidney showed that RARRES1 expressed highly in podocytes. Immunostaining confirmed that podocyte expression of RARRES1 increased in patients with DN and FSGS as compared to MCD. RARRES1 expression was strongly induced by TNF-α in cultured human podocytes. RNA-sequencing of podocytes with RARRES1 overexpression revealed genes enriched in apoptosis. RARRES1 was cleaved into a soluble RARRES1 and the cleavage site was mapped at the aa70. Overexpression of wild RARRES1 or adding soluble RARRES1 in cultured human podocytes induced apoptosis, while overexpression of RARRES1 cleavage mutant lost the apoptotic effect. Further, we showed that soluble RARRES1 underwent endocytosis to interact with intracellular RIOK1, leading to the activation of p53 and apoptosis in podocytes. In vivo, podocyte-specific overexpression of RARRES1 resulted in marked glomerular injury and albuminuria in mice, while the overexpression of RARRES1 cleavage mutant had no renal phenotype. Finally, knockdown of RARRES1 in podocytes ameliorated kidney injury in mice with adriamycin-induced nephropathy.

Conclusions: We demonstrate a new role and mechanism of RARRES1 in regulation of podocyte apoptosis in glomerular disease, as summarized in the Figure. TNFα induces expression of RARRES1, which is cleaved, then undergoes endocytosis to interact with intracellular RIOK1, leading to the activation of p53 and apoptosis. High RARRES1 expression promotes the progression of FSGS and DKD.

The Glomerulus-on-a-Chip as a System to Unravel Novel Membrane Attack Complex (MAC)-Independent Role of Complement in Membraneous Nephropathy
Stefano Da Sacco,1 Astigik Petrosyan,1 Susan Hartzell,1 Valentina Villani,1 Charmi Dedhia,1 Andrea Angeletti,2 Joaquin Manrique,3 Roger E. De Filippo,3 Laura Pe2, Paolo Cravedi,4 Children’s Hospital of Los Angeles, Los Angeles, CA; 2Division of Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Primary membranous nephropathy (MN) is a leading cause of nephrotic syndrome in adults worldwide due to the deposition of anti-podocyte-antibodies against in the glomerular subepithelial space. While complement deposition is thought to play a crucial pathogenic role, the exact effector mechanism of complement in MN is unclear due to the lack of in vitro and in vivo systems that recapitulate human disease. We have developed a novel glomerulus-on-a-chip system (GOAC) using human primary podocytes and human glomerular endothelial cells (GEC) in combination with OrganoPlates and assessed the functional response to human MN serum and the role of MAC deposition and C3a/C3aR1 signaling in MN pathogenesis.

Methods: Glomerulus chips were cultured with serum from anti-PLA2R + MN patients or healthy individuals. Functional response was assessed by albumin permeability assay to evaluate selectivity-permeability. Role of MAC and C3a/C3aR1 signaling pathway in glomerular filtration barrier damage was assessed by immunofluorescence and functional analysis while mechanisms of action were explored by PCR arrays, Western Blotting and immunostaining. Results were confirmed in vitro using podocytes on which C3aR1 was silenced and in vivo using a C3aR1 KO mouse model.

Results: Following exposure to sera from MN patients, we have confirmed deposition of human IgG on podocytes and formation of MAC complex, accompanied by albumin leakage. GOAC supplemented with C3aR1 antagonists as well as GOAC using podocytes in which C3aR1 was silenced were able to prevent glomerular filtration damage on the GOAC kidney confirmed by rescue of permeability efficiency, while inhibition of MAC formation by protein S (an inhibitor of MAC formation) did not significantly reduce GOAC permeability.

Conclusions: We have successfully developed a glomerulus-on-a-chip system that closely mimics the GFB structure and provides a powerful tool for studying renal regenerative and disease mechanisms in proteinuric diseases. Using this model, we showed that C3a/C3aR signaling plays a dominant role in complement-mediated MN pathogenesis.

PO1969
Dach1 Is Essential for Maintaining Normal Podocytes
Keiko Tanaka, Taiji Matsuoka. Department of Basic Medicine, Tokai University School of Medicine, Isehara, Japan.

Background: Dach1 is a transcription factor, determining cell fates in various organs. Dach1 polymorphism has been reported to be associated with nephrotic syndrome and chronic kidney diseases. We previously found that Dach1 was highly expressed in normal podocytes and rapidly disappeared after induction of podocyte injury, similarly to WT1. We, therefore, aimed to elucidate the function of Dach1 in normal podocytes in vivo.

Methods: Podocyte-specific Dach1-knockout (KO) mice were generated by mating Dach1lox/lox mice with Nphs1-Cre or Nphs2-CreERT2 mice. Podocyte injury was evaluated by urinary analysis (SDS-PAGE) and histology. In addition, we analyzed primary cultured podocytes of Dach1 overexpressing knock-in transgenic (KI) mice (n=9), in which Dach1 is expressed under the control of Rosa26 promoter.

Results: Although the efficiency of Cre-mediated recombination was not high, all of the congenital Dach1/KO mice (n=20, more than 4 weeks old) presented abnormal albuminuria. Seven out of the 11 (63%) mice histologically analyzed showed focal segmental glomerulosclerosis. Injured podocytes lacked Dach1 staining, whereas intact podocytes retained Dach1. When Dach1 KO was induced in adult mice, the mice showed abnormal albuminuria within two weeks. Immunostaining revealed that podocytes lacking Dach1 causes leakage of albumin, while retaining WT1 protein. Since endogenous Dach1

expression in podocytes is very high compared with transgenic expression of Dach1 driven by the Rosa26 promoter, we analyzed primary cultured podocytes, in which endogenous Dach1 was downregulated. Dach1 mRNA was 3.8-fold higher (p < 0.0007) in Dach1-KI podocytes than in control podocytes. We previously found that Dpp4 is one of the candidate target genes of Dach1 by knockdown experiments. Dpp4 mRNA in Dach1-KI podocytes was found to be increased (1.5-fold, p < 0.0002).

Conclusions: These results indicate that Dach1 is important in maintaining normal podocyte integrity, and Dach1 gene deficiency induces podocyte injury.

Dysregulated Dynein-Mediated Vesicle Traffic: Is a New Mechanism of FSGS
Hua Sun,1,2 Martin R. Pollak,1,2 Beth Israel Deaconess Medical Center, Boston, MA; 1Boston Children’s Hospital, Boston, MA; 1Harvard Medical School, Boston, MA.

Background: Focal segmental glomerulosclerosis (FSGS) is a deteriorating kidney disease with poor prognosis. The lack of understanding of its mechanism has hindered the development of treatment. Mutations in IN2 cause FSGS characterized by a podocytopathy with mismatched slit diaphragm (SD) protein critical for the integrity of the glomerular filtration barrier (GBF). This feature has been found in FSGS of other etiologies, making IN2 related podocytopathy a good model to dissect the disturbed vesicle trafficking in podocytopenias prone to FSGS. By yeast two hybridization screening we identified the interaction of IN2 with Dynl1, a dynem component. We hypothesized that IN2 regulates dynein mediated vesicle trafficking, which shuttles endocytosed protein to proteolytic system. This interaction could be disrupted by pathogenic mutations in IN2, suggesting dysregulation of dynein mediated trafficking is an underlying mechanism in focal segmental glomerulosclerosis disease.

Methods: The IN2-Dynl1 interaction was confirmed by yeast mating and CO-IP. The dysregulated dynein mediated trafficking of nephrin was investigated in cultured podocytes by fluorescent based and surface biotinylation based assays, and time-lapse imaging in vitro; and was also observed in the purinergic aminonucleotide induced nephrinopathy (PAN) of IN2 transgenic mice with knockin (KI) of R218Q, a pathogenic mutant that disrupts IN2-Dynl1 interaction.

Results: 1. We demonstrated that IN2 limited dynein mediated retrograde trafficking of nephrin by binding to and sequestering Dynl1, a component essential for the integrity of dynein. 2. R218Q KI podocytes illustrated an impaired recycling of nephrin with enhanced recruitment of dynein components, which could be rescued by targeting dynein transport pathway using Cilobrevin D (Dynein inhibitor), dominant negative Dynactin 1, siRNA for Dynl1 or overexpression of wildtype IN2 (to sequester Dynl1). 3. PAN of R218Q KI mice was characterized by increased recruitment of Dynl1 to nephrin, correlated to increased ubiquitination and decreased surface nephrin, suggesting an enhanced dynein trafficking pathway underlies the impaired functional trafficking of nephrin, disintegrity of SDs and malfunction of the GBF.

Conclusions: Recognition of the dysregulated dynein mediated trafficking of SD protein has enlightened a new understanding and therapeutic targets for IN2 related podocytopathy and FSGS.

Podocyte Cell Cycle Activation During CKD Progression
Laura Perin,1,2 Camille H. Nicolas Frank,3 Roger E. De Filippo,2 Kevin V. Lembly,1,2 Children’s Hospital of Los Angeles, Los Angeles, CA; 1University of Southern California, Los Angeles, CA.

Background: Podocytes, quiescent cells, seem not capable of regeneration to compensate for their loss during CKD progression. Their only adaptive response to injury is their detachment from the basal membrane and cell death. The cell cycle phases modulate this “mitotic catastrophe”. The cell cycle phases are not known. To study the cell cycle in CKD, we used an Alport Syndrome (AS) mouse model characterized by podocyte loss, combined with the Fucci technology which allow the identification of the cell cycle phases using fluorescent reporters: red for G1/S, green for S/G2/M.

Methods: We established a mouse model where Fucci proteins are under the control of Nphs2 gene (podocytes specific) and crossed these mice with AS mice to generate AS-Pod-Fucci mouse. Using flow cytometry, we isolated and evaluated podocytes in different cell cycle phases in WT (wild type and female) and AS-Pod-Fucci mice (hemizygote males; heterozygote, Ht females) and perform proteomics in NPHS2-Cre; Z/EG mice. Using flow cytometry, we isolated and evaluated podocytes in different cell cycle phases (G1, S, G2/M) and performed proteomics in NPHS2-Cre; Z/EG mice.

Results: 1. We demonstrated that INF2 limited dynein mediated retrograde trafficking of nephrin by binding to and sequestering Dynl1, a component essential for the integrity of dynein. 2. R218Q KI podocytes illustrated an impaired recycling of nephrin with enhanced recruitment of dynein components, which could be rescued by targeting dynein transport pathway using Cilobrevin D (Dynein inhibitor), dominant negative Dynactin 1, siRNA for Dynl1 or overexpression of wildtype IN2 (to sequester Dynl1). 3. PAN of R218Q KI mice was characterized by increased recruitment of Dynl1 to nephrin, correlated to increased ubiquitination and decreased surface nephrin, suggesting an enhanced dynein trafficking pathway underlies the impaired functional trafficking of nephrin, disintegrity of SDs and malfunction of the GBF.

Conclusions: Recognition of the dysregulated dynein mediated trafficking of SD protein has enlightened a new understanding and therapeutic targets for IN2 related podocytopathy and FSGS.

RNA Sequencing and ATAC-Seq Reveal Gene Profiles in Injured Podocytes in Mice, and Podocyte-Specific Hypoxia Inducible Factor 2a Deletion Protects from Adriamycin-Induced Podocyte Injury
Xiaoyun Liu,1 H. William Vlcek,1,2 Disneyland Children’s Hospital, Orange, CA; 1University of California, Irvine, CA; 1National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.

Background: Roles for hypoxia-inducible factor (HIF) in kidney diseases have been controversial. Upregulation of HIF expression is believed to be protective in kidney from acute injury, while we and others showed that HIF aggravates chronic fibrosis. In podocytes, deletion of VEGFR caused progressive glomerular damage, prevented by overexpression of hypoxia inducible factor 2a. Here, using podocyte-specific HIF-2α deletion mice, we tested effects of HIF-2α deletion on gene profiles in injured podocytes.

Methods: HIF-2αCre or HIF-2αCre mice were crossed with either Nphs1-2 or Z-Cre mice. HIF-2αCre; Nphs1-2 or Z-Cre mice were further crossed with Z/E.G mice that express GFP only in cells where Cre is active. At 8 weeks old, the mice were given Adriamycin (12 mg/kg). After two weeks later, urine and serum were harvested. Creatinine and albumin levels in urine and serum, and blood urea nitrogen levels in serum were measured with ELISA kits. Podocytes were isolated from HIF-2αCre; Z/E.G mice by flow sorting and RNAseq analysis. The sequencing was performed by single cell RNAseq and the sequencing data was analyzed using star algorithm.

Results: HIF-2αCre; Nphs1-2Cre showed preservation of foot process morphologies and functions, and significantly less proteinuria compared to the WT littermates after being subjected to Adriamycin, while HIF-1αCre; Nphs1-2Cre mice developed a similar degree of proteinuria to that of WT. HIF-1 or 2Cre; Nphs1-2Cre mice showed little GFP expression in podocytes, suggesting that weak penetrance of Nphs1-2Cre led to minimal functional effects. This group was therefore not further evaluated. Podocytes isolated from HIF-2αCre; Z/E.G mice were subjected to RNAseq and ATACseq analysis. In RNAseq, Ndufa12 was among the dysregulated genes. In ATACseq, SMPDL3b was among the highly silenced genes. In vivo, podocyte specific induction of SMPDL3b is sufficient to protect from TNF induced podocyte injury.

Conclusions: Our results identify a new role of SMPDL3b in the uptake of fatty acids, the accumulation of TAGs, EEs and the formation of LDs. Further experiments to understand the exact mechanism by which SMPDL3b expression contributes to the progression of podocyte damage in FSGS are underway.

Sphingomyelin Phosphodiesterase-like 3B (SMPDL3b) Affects Podocyte Lipid Metabolism and Lipid Droplets Formation
Shanroop Kumar Mallera,1 Alia Mitrofanova,1 Xiaochen Liu,1 Lorenza Macrìna,1,2 Devang M. Patel,1 Gloria Michelle Ducasa,1 H. William Vlcek,1,2 Disneyland Children’s Hospital of Los Angeles, Los Angeles, CA; 1Children’s Hospital of Los Angeles, Los Angeles, CA; 1University of Southern California, Los Angeles, CA.

Background: Lipid droplets (LDs) play an important role in many biological processes and LD size and number have been linked to several diseases such type 2 diabetes, heart disease, and non-alcoholic fatty liver disease. LD are mainly composed of triglycerides and cholesterol. We previously demonstrated that the accumulation of LDs occurs in glomeruli of experimental models of diabetic kidney disease (DKD), focal segmental glomerulosclerosis (FSGS) and Alport syndrome, and that lipid accumulation in podocytes is one of the factors contributing to disease progression and may be linked to glomerulosclerosis expression. We further demonstrated that glomerulosclerosis expression of sphingomyelin phosphodiesterase like 3b (SMPDL3b), a glycosylphosphatidylinositol (GPI) anchored protein primarily localized at plasma membrane (PM), affects the function of podocytes in FSGS and diabetic kidney disease (DKD). With this study, we aimed at exploring the role of SMPDL3b in fatty acid uptake and in the formation of LDs ultimately contributing to podocyte damage.

Methods: Fatty acid uptake assay, Lipid droplets isolation, Western blotting, Mass spectrometry, Lipolysis, TNF IV injections.

Results: We demonstrate that decreased SMPDL3b expression (sSMPDL3b) in podocytes is associated with increased FATP protein expression, fatty acid uptake and an increased number of LDs. The number of LDs was decreased in podocytes with increased SMPDL3b expression (sSMPDL3b OE). Similarly, TAGs and CE contents were increased in sSMPDL3b when compared to control podocytes. Finally, we demonstrated that the first time that SMPDL3b is present in isolated LDs suggesting a possible role for SMPDL3b in the formation of LDs and in lipolysis. In vitro, podocyte specific induction of SMPDL3b is sufficient to protect from TNF induced podocyte injury.

Conclusions: Our results identify a new role of SMPDL3b in the uptake of fatty acids, the accumulation of TAGs, EEs and the formation of LDs. Further experiments to understand the exact mechanism by which SMPDL3b expression contributes to the progression of podocyte damage in FSGS are underway.

Shroom3-FYN Regulates Podometrics via LKB1-AMPK Signaling
Khadija Bangl, John M. Basgen, Qisheng Lin, Arun Cumpelik, Lewis Kaufman, Marina Planoutene, Barbara T. Murphy, John C. He, Madhav C. Menon. Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Previously, we showed Shroom3–FYN interaction regulated podocyte cytoskeleton via FYN activation. Intriguingly, globally Shroom3 knockdown mice (CAGS-TG/Shr3 Kd) displayed reduction in glomerular volume-VGlom, podocyte & endothelial fraction of VGlom without podocytopenia [1a].
Methods: To examine mechanism of podometrics regulation by Sh3r, we used Shr3 & FYN Kd human podocytes (hPodo) to study cell protein content & growth regulatory pathways; performed unilateral nephrectomy examining VGlom hypertrophy in remnant kidneys.
Results: At day-7, CAGS-TG mice showed restricted VGlom hypertrophy with reduced expansion of PodoVGlom vs NTGs [1b]. We observed reduced hPodo volume (FSC), Protein:DNA ratios (n=3; P<0.01) & inhibited ribosomal biogenesis (18S RNA) in vitro & in vivo suggesting reduced protein synthesis and FYN to be downstream of Shr3 in regulating hPodo size. Notably, we observed increased AMPK activation, increased p-ULK1 & autophagy (high p-ULK1 and LC3II levels) downstream of AMPK, in vivo studies revealed that Shr3 rats chronically treated with BRL53257 exhibited augmented blood pressure (MAP was 179 ± 15 mmHg vs. 151 ± 11 mmHg), nephromia, albuminuria, and elevation in podocyte calcium in BRL53257 treated Dahl SS rats.
Conclusions: Stimulation of kappa-ORs, but not mG-ORs or delta-ORs, mediated calcium influx in podocytes through activation of TRPC6 channels in rat and human kidney. The effect of BRL53257 was completely abolished when we used the 0 mM calcium media or when SAR7334 (a TRPC6 channel inhibitor) was applied. Triggering the kappa-OR/ TRPC6 pathway induced podocyte cell shape changes via actin cytoskeleton remodeling. In vivo studies revealed that SS rats chronically treated with BRL53257 exhibited significant blood pressure increase (MAP was 179 ± 15 mmHg vs. 151 ± 11 mmHg), nephromia, albuminuria, and elevation in podocyte calcium in BRL53257 treated Dahl SS rats.

PO1975
The Role of Opioid Receptor Signaling in Podocyes and Renal Damage in Dahl Salt-Sensitive Rats
Duria Golosova,1 Oleg Palynin,2 Vladislav Levenchenko,3 Christine A. Klemens,4 Ashraf El-Meanawy,5 Alexander Staruchsenko.6 Medical College of Wisconsin Department of Physiology, Milwaukee, WI; 4Medical College of Wisconsin Department of Medicine, Milwaukee, WI.

Background: The rise in opioid use underscores the urgent need to better understand the direct and indirect effects of opioids on renal function, especially in patients with chronic kidney disease (CKD) or hypertension. The extensive use of opioids is strongly correlated with poor cardiovascular outcomes. We hypothesize that stimulation of opioid receptors (ORs) elevates increased cardiac level in podocytes leading to kidney damage and progression of hypertension.
Methods: Freshly isolated glomeruli from Dahl salt-sensitive (SS) rats, human kidneys and immortalized human podocytes were used to elucidate the contribution of specific ORs to podocyte calcium flux. Calcium response in the podocytes was analyzed via ratiometric confocal fluorescent microscopy. For chronic studies Dahl SS rats were on a 0.4% (LS) or 8% (HS) NaCl diet for 14 days with or without a daily intravenous bolus infusion of BRL53257, a potent and selective kappa-OR agonist.
Results: Stimulation of kappa-ORs, but not mG-ORs or delta-ORs, mediated calcium influx in podocytes through activation of TRPC6 channels in rat and human kidney. The effect of BRL53257 was completely abolished when we used the 0 mM calcium media or when SAR7334 (a TRPC6 channel inhibitor) was applied. Triggering the kappa-OR/TRPC6 pathway induced podocyte cell shape changes via actin cytoskeleton remodeling. In vivo studies revealed that SS rats chronically treated with BRL53257 exhibited increased blood pressure (MAP was 179 ± 15 mmHg vs. 151 ± 11 mmHg), nephromia, albuminuria, and elevation in podocyte calcium in BRL53257 treated Dahl SS rats.
Conclusions: Stimulation of kappa-ORs modulates calcium influx in podocytes via TRPC6 channels. The opiate-induced increase in the calcium flux in podocytes is expected to contribute to podocytopathy, proteinuria, kidney injury and progression of salt-induced hypertension. These findings are important to advance our knowledge of the pathogenesis of the development of CKD and hypertension in the context of pain management.

Knockout of the Neonatal Fc Receptor (FcRn) Alters Lysosomal Function in Podocytes
Judith Blaine,1 Madeline D. Ng,1 Pantipa Tonsawam2, Linda Lewis,1 James F. Dylewski.1 University of Colorado Denver School of Medicine, Aurora, CO; 2Khon Kaen University, Khon Kaen, Thailand.

Background: FcRn is a trafficking protein that diverts monomeric IgG from the lysosome but sorts multimeric IgG and immune complexes (ICs) to the lysosome for processing. FcRn is required in dendritic cells to traffic ICs to the lysosome for proteolytic processing and presentation on MHC II. Podocytes express FcRn and previous work had proposed that podocytes can act as antigen presenting cells. Here we show that cultured podocytes are weak antigen presenting cells (APCs) and that knockout (KO) of FcRn in podocytes does not alter podocyte response to an immune stimulus but does result in significant downregulation of lysosomal function.

Methods: Cultured wild type (WT) and FcRn KO podocytes were treated with interferon gamma (IFNγ) to simulate proinflammatory conditions. MHC II and costimulatory marker expression was assessed by flow cytometry. Antigen presentation was evaluated by examining T cells response when WT or FcRn KO podocytes were treated with ICs and used as APCs. Lysosomal size and cellular location in WT and FcRn KO podocytes were examined using confocal microscopy. WT or FcRn KO podocytes were treated with ICs and colocalization of lysosomes and ICs was quantitated. RNA-seq was used to examine lysosomal pathways.

Results: Both WT and FcRn KO podocytes upregulated MHC II after treatment with IFNγ but there was no difference in expression levels between WT and KO. There was no change in CD80 expression between WT and KO after treatment with IFNγ. CD86 and ICOSL expression levels in WT and FcRn KO were minimal at baseline and after treatment with IFNγ. When used as APCs, WT podocytes induced a very modest amount of IL-2 production by T cells (a marker of T cell activation) whereas KO podocytes induced no response. After treatment with ICs, lysosomes in WT podocytes were significantly larger and were more clustered around the nucleus, indicative of lysosomal activation. In contrast, after IC treatment lysosomes in the KO were smaller and more peripherally located. Treatment with ICs also resulted in significantly greater colocalization between lysosomes and ICs in WT versus FcRn KO podocytes, demonstrating that ICs were not directed to the lysosome in the KO. RNA-seq showed significant downregulation of lysosomal pathways in KO podocytes compared to WT after treatment with ICs.

Conclusions: FcRn KO in podocytes alters lysosomal trafficking and function.

PO1977
Apolipoprotein M as a Biomarker of Glomerular Lipotoxicity in Nephrotic Syndrome
Yelena R. Drexler, Judith T. Molina David, Sandra M. Merscher, Alessia Fornoni. University of Miami Katz Family Division of Nephrology and Hypertension, Miami, FL.

Background: Dysregulation of intrarenal metabolic pathways involved in cholesterol efflux is implicated in lipid-induced podocyte injury in glomerular diseases. Among several genes that are involved in cholesterol efflux, we recently reported a significant downregulation of glomerular apolipoprotein M (APOM) expression in patients with FSGS. HDL-associated APOM facilitates reverse cholesterol transport and is the carrier for the bioactive sphingolipid sphingosine-1-phosphate (S1P). Mutations in S1P lyase, the enzyme responsible for S1P degradation, cause a familial form of FSGS. We hypothesize that glomerular APOM deficiency is a surrogate biomarker for lipid-induced kidney injury in NS.

Methods: Patients with FSGS, MN, and MCD enrolled in NEPTUNE, a multi-center international cohort study of children and adults with NS, who received 1 g/g at baseline were selected for analysis. RNA expression data were obtained from the

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster - Publication Only

610
glomerular compartment isolated from kidney biopsies and compared with living kidney donor controls. Plasma and urinary APOM levels were measured by ELISA using baseline samples. Linear regression analysis was used to correlate glomerular APOM expression with plasma and urinary levels of APOM and to correlate glomerular APOM expression and plasma and urinary APOM levels with eGFR at baseline.

Results: Among 84 patients, 68% were male, mean age was 40 years, mean baseline eGFR was 80.6 mL/min/1.73m², and mean uPCR was 4.9 g/g. Glomerular APOM expression was decreased in patients with NS compared to healthy controls (p <0.001), irrespective of histologic diagnosis. APOM expression was positively correlated with plasma and urinary APOM levels in the NS cohort (R² = 0.089, p = 0.003) and in the FSGS subgroup (R² = 0.189, p = 0.0218). Decreased APOM expression (p = 0.005) and decreased plasma APOM (p = 0.031) were associated with a lower eGFR at baseline. After adjustment for age, sex, and race, each unit decrease in APOM expression was associated with a 9.83 mL/min/1.73m² (95% CI, 3.72 to 15.93, p = 0.002) lower eGFR at baseline.

Conclusions: Glomerular APOM deficiency and decreased plasma APOM levels were associated with decreased kidney function at baseline in the NS cohort. These findings identify APOM as a potential biomarker of lipid-induced kidney injury in NS.

The Sensitivity of Podocytes to ATP in Vivo Is Distinctly Lower than the Sensitivity of Glomerular Endothelial and Proximal Tubular Cells

Julia B.1,2,3 Bernhard Schnermer,1 Thomas Benzing,2 Matthias Hackl,1
1Department II of Internal Medicine and Center for Molecular Medicine Cologne, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany; 2CECAD, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany.

Background: ATP signaling is involved in a plethora of pathways, involving damage signaling. Cell culture models as well as experiments on isolated glomeruli indicate that podocytes respond to ATP with a calcium transient. To date a direct effect of ATP on podocyte calcium signaling has not been described.

Methods: In this study mice expressing GCaMP3 in podocytes (Pod.cre), proximal tubular cells (Pax8.cre) or endothelial cells (Tie2.cre) underwent multiphoton in vivo imaging of the kidney. Mice were anesthetized, an arterial catheter was placed into the right common carotid artery and the aorta and the left kidney was exteriorized. The vasculature was labelled with a 70-kDa dextrane. Different doses of ATP were injected as a bolus via the catheter and dose-dependent calcium transients were monitored.

Results: Our data indicates that even doses of 5 mg/kg ATP did not induce calcium transients in podocytes. ATP transients were observed via a carotid artery catheter, while robust activation of calcium signaling was induced in endothelial and proximal tubular cells with 0.5 mg/kg ATP. Further increasing the ATP dose by injection via an abdominal aortic catheter resulted in a calcium transient in podocytes.

Conclusions: In contrast to endothelial cells and proximal tubular cells, podocytes show a low sensitivity to ATP-mediated calcium signaling. We therefore hypothesize, that the low sensitivity ATP of podocytes is a protection mechanism to avoid calcium signals from filtered ATP.

Cytomegalovirus Viremia-Associated Collapsing FSGS in an Immunosuppressed Systemic Lupus Erythematosus Patient

Emily Daniel,1 Dominick Saporito,2, Andrew S. Bornhack, Hilda E. Fernandez,3 Columbia University Irving Medical Center, New York, NY.

Introduction: Maintaining a broad differential in evaluating AKI in SLE patients with a history of lupus nephritis (LN) is important. We describe a patient with SLE and AKI progressing to dialysis dependence due to collapsing FSGS in the setting of CMV infection. The high CMV viral load and robust response to antiviral therapy argue that the lesion was not representing a high risk APLD. The development of collapsing FSGS is commonly due to a “second hit” on a high risk APLD genetic background, in our case from elevated interferon levels in the setting of CMV viremia. APLD has been implicated in collapsing FSGS due to CMV viremia in African American DDRT recipients, demonstrating the role of genetic testing in African American patients. Our case demonstrates an infectious trigger rather than autoimmune cause of renal failure in an immunosuppressed patient with SLE.

Transcriptional Reprogramming by WT1 Mediates a Repair Response During Podocyte Injury in Mice and Human Kidney Organoids

Sandra S. Etou,1 Younsook L. Jung,2 Tomoya Miyoshi,3 Ken Hiratsuka,3 Ryuji Morizane,3 Peter Park,3 Jordan A. Kreidberg,1 Boston Children’s Hospital, Boston, MA; 2Harvard Medical School, Boston, MA; 3Massachusetts General Hospital, Boston, MA.

Background: We previously identified WT1 as one of the most upstream transcription factors regulating gene expression in podocytes, binding nearly all genes known to be crucial for maintenance of the glomerular filtration barrier. Here, we focus on understanding WT1 transcriptional mechanism in response to injury.

Methods: We used Adriaycin (ADR)-induced podocyte injury as a model for human Focal Segmental Glomerulosclerosis in mice and human kidney organoids, and a conditional WT1 inactivated mouse model to decipher the transcriptional mechanism through which WT1 regulates podocyte gene expression during injury, using transcriptomic approaches.

Results: After injury, we observed a transient increased expression of podocyte genes in mice and human kidney organoids. Transcriptomics analyses of podocytes isolated from mTeto-Nphs2cre mice during the course of injury revealed a transient increase in the expression of crucial podocyte genes, including Nphs2. Synpo and many others, reflecting a reparative response during the early stages of injury. ChIP-seq analyses demonstrated that WT1 binds nearly 50% of known genes in podocytes, and the vast majority of genes whose expression changes during the response to injury. We identified de novo binding of WT1 that were only bound during the course of injury, and the expression of novel WT1 target genes. It appears that WT1 increases gene expression during injury through both the acquisition of novel binding sites, and increasing its binding intensity at sites already occupied by WT1. Mechanistically, motifs present in the promoters of other podocyte-specific transcription factors were highly enriched at sites where WT1 binding increased after injury. Since the DNA binding transition of transcription factors is modulated by chromatin accessibility, we used FACS-isolated podocytes to study epigenetic reprogramming. Both ADR-mediated podocyte injury or inducible podocyte specific inactivation of WT1 resulted in the conversion of active to repressive histone marks at WT1-bound sites.

Conclusions: These results demonstrate that target gene binding of WT1 is highly dynamic in response to injury. WT1 directs the epigenetic regulation of gene expression, maintaining active chromatin marks at bound genes, that change to repressive marks in the absence of WT1.

Atypical Cyscapse 3-Dependent Death Process in Podocytes

Kazuyoshi Yamamoto,1 Masahiro Okabe,1 Takashi Yokoo,2 Taiji Matsusaka,2
1The Jikei University School of Medicine, Tokyo, Japan; 2Tokai University School of Medicine, Isehara, Japan.

Background: Apatosis of podocytes has been widely reported in many in vitro studies, however, definitive apoptosis has been rarely documented in vivo podocytes. To elucidate this discrepancy, we analyzed dying process in podocytes in vitro and in vivo. We previously demonstrated that, in vivo, podocytes can die through a classical apoptosis pathway, while in vitro both classical and necroptosis pathways are involved in podocyte death. Here we report the first in vivo evidence that podocytes can die dependently on caspase 3.

Results: In in vitro studies, administration of LMB2 caused leakage of co-introduced ECFP in podocytes. To elucidate this discrepancy, we analyzed dying process in podocytes in vitro and in vivo. We previously demonstrated that, in vivo, podocytes can die through a classical apoptosis pathway, while in vitro both classical and necroptosis pathways are involved in podocyte death. Here we report the first in vivo evidence that podocytes can die dependently on caspase 3.

Conclusions: In vivo studies, administration of LMB2 caused leakage of co-introduced ECFP in podocytes. To elucidate this discrepancy, we analyzed dying process in podocytes in vitro and in vivo. We previously demonstrated that, in vivo, podocytes can die through a classical apoptosis pathway, while in vitro both classical and necroptosis pathways are involved in podocyte death. Here we report the first in vivo evidence that podocytes can die dependently on caspase 3.
Systematic In Silico Exploration of the Kidney Rho-GTPase System Regulation in CKD

Matthew Lawrence, Anna Buvall. AstraZeneca R&D, Gothenburg, Sweden.

**Background:** It has become evident that dysregulation of the Rho-GTPase system would result in rearrangement of the actin cytoskeleton in the podocyte with resulting foot process effacement, a hallmark for glomerular diseases. To build further understanding how this dysregulation in disease states occurs in CKD, we performed a systematic mining of kidney transcriptomics data to generate a full-face picture and insights on complex interplay between the members of the large family of Rho-GTPases and their regulatory proteins, the Guanine Nucleotide Exchange Factors (GEFs) and the GTPase-activating proteins (GAPs).

**Methods:** A comprehensive list of 143 genes was compiled including the members of the three gene families according to HUGO Gene Nomenclature Committee (HGNIC). Publicly available human transcriptomics data from healthy and CKD kidneys (microarray and RNA-seq, bulk-tissue and single-cell) were used for interrogation of gene expression patterns, including presence of detectable expression, its abundance, cell type specificity, modulation in disease, and co-expression structure. WGCNA and Cytoscape were used to correspondingly generate and visualize the gene co-expression network.

**Results:** All but one (142/143) genes were detectable in the human kidney, with 121 having robust levels >1TPM. The majority of genes were broadly expressed across the different tissues outside the kidney, however expression of several GEF and GAP members showed specific kidney enrichment. A number of GEFs and GAPs were modulated in CKD patient kidneys as compared to controls, predominantly with tendency for up-regulation and negative correlation with renal function, reflecting first time activation in potentially pathophysiological or compensatory disease mechanisms. Hierarchical clustering of pairwise correlation values and WGCNA module analyses identified clusters of closely express genes that may implicate functional similarities.

**Conclusions:** To our knowledge, this is the first systematic evaluation of the Rho-GTPase, GEFs and GAPs kidney expression in the CKD context. Elucidation of the molecular interplay provides systems-level understanding and mechanistic insights that can lead to new biological hypotheses and therapeutic targets.

**Funding:** Commercial Support - Both authors are AstraZeneca employees

Bag as a Potential Mechanoprotector in Podocytes

Ingo Plagmann, Markus M. Rinschen, Jan C. Degenhardt, David Unnersjö-Jess, Sybille Kohler, Bernhard Scherner, Thomas Benzing.

**Department II of Internal Medicine and Center for Molecular Medicine, University of Cologne, Cologne, Germany; 2Department of Cardiology and Center for Molecular Medicine, University of Cologne, Cologne, Germany; 3The Scripps Research Institute, La Jolla, CA; 4The University of Edinburgh Centre for Discovery Brain Sciences, Edinburgh, United Kingdom.

**Background:** Podocyte loss is a hallmark of glomerular diseases leading to glomerulosclerosis and progression of kidney disease. Sitting on the outside of the glomerular tuft podocytes have to withstand extensive mechanical stress due to perfusion and filtration. Hyperfiltration and hyperperfusion e.g. in disease states cause podocyte detachment when overwhelming their mechanoprotective capacity, which start a vicious cycle of mounting strain on the remaining podocytes. Bag3 is an important mechanoprotector in many mechanical strained tissues and by inducing chaperone-assisted autophagy (CASA) maintains the proteostasis of e.g. Filamin and Synaptopodin indispensable for podocyte biology. Additionally Bag3 insufficiency renders susceptibility to diabetic nephropathy in a mouse model. These findings point toward Bag3 as a candidate for mechanical stress protection in podocytes.

**Methods:** Using immunofluorescence, super-resolution-microscopy and mass-spectrometry we examined glomeruli and podocytes for Bag3/CASA expression and characterized the CASA-complex composition in podocytes by immunoprecipitation. The influence of mechanical clues was examined by stiff matrices and cyclic stretch. The role of Bag3 in vivo is being evaluated in different mouse lines (Bag3.F209L mutation, a conditional knockout, fusion-protein).

**Results:** In the glomerulus the Bag3 and the entire CASA-complex is enriched in podocytes in mass-spectrometry. Bag3 staining localizes to the slit diaphragm protein nephrin in superresolution microscopy. Importantly the co-chaperone Bag3 shows interactions with essential actin cytoskeleton regulators like RhoA, Arpc2 and Dynamin2 as effectors for Bag3 in co-immunoprecipitation. The expression of Bag3 and the CASA-complex in podocytes is regulated by mechanical clues. Knockdown of the Bag3 homologue starvin in drosophila nephrocytes displays a mild filtration disturbance. The dominant-negative Bag3.F209L mutation causes a mild proteinuria in a whole-body overexpression model.

**Conclusions:** The data further emphasize the role of Bag3 and chaperone-assisted-selective-autophagy in podocyte mechanoprotection and maintenance of podocyte cytoskeleton architecture. Currently undergoing characterization of podocyte specific Bag3/CASA models and the influence of disease models will further help to understand the role of Bag3 at the kidney filtration barrier.

Hepatocyte Growth Factor-Factor-Activated Induction of NEPHRIN and NEPH1 Serves as a Novel Mechanism for Recovery of Podocytes from Injury

1Medical University of South Carolina, Charleston, SC; 2Augsburg University, Augusta, GA; 3University of Virginia, Charlottesville, VA; 4University of Baltimore, Baltimore, MD.

**Background:** Podocytes (podo.) and their slit diaphragm(SD) are critical components of glomerular filtration barrier, whose dysfunction leads to ESRD (end stage renal disease). Treating ESRD remains a global challenge due to our poor understanding of the mechanisms that participate in recovery of podo. from injury. Glomerular injuries commonly induce podo. cell death and loss of SD, which is a modified tight junction and is formed through a trans-interaction between the extracellular domains of NEPHRIN and NEPH1 that maintain its structural integrity. Here, we present a novel concept showing that apart from structural organization, NEPHRIN and NEPH1 constitute a receptor-based function, and can be activated in a ligand-induced fashion.

**Methods:** Proteomics, SPR, Immunofluorescence

**Results:** The ability of NEPHRIN and NEPH1 to interact with tyrosine phosphatase SHP-2 in a phosphorylation (phos.) dependent manner prompted us to investigate whether ligands that induce PTPN11 stimulation also induced activation of NEPHRIN and NEPH1. Ligands screening identified HGF as a prominent inducer of both NEPHRIN and NEPH1 phos. To further establish HGF as a ligand, we used baculovirus system to generate validated NEPHRIN and NEPH1 proteins and confirmed not only a direct interaction between HGF and the extracellular domains of NEPHRIN and NEPH1, but also, the ligand-induced phos. of these proteins. In addition to their ligand-induced activation, we demonstrate that SHP-2 can directly dephos. these proteins, thus presenting for the first time evidence of SHP-2 in co-immunoprecipitation. The expression of Bag3 and the CASA-complex in podocytes is regulated by mechanical clues. Knockdown of the Bag3 homologue starvin in drosophila nephrocytes displays a mild filtration disturbance. The dominant-negative Bag3.F209L mutation causes a mild proteinuria in a whole-body overexpression model.

**Conclusions:** The data further emphasize the role of Bag3 and chaperone-assisted-selective-autophagy in podocyte mechanoprotection and maintenance of podocyte cytoskeleton architecture. Currently undergoing characterization of podocyte specific Bag3/CASA models and the influence of disease models will further help to understand the role of Bag3 at the kidney filtration barrier.

Knockout of the Neonatal Fc Receptor in Podocytes Ameliorates Nephritis by Reducing Glomerular Apoptosis

Judith Blaine, James F. Dylewski, Linda Lewis, Pantipa Tonsawan.

1University of Colorado, Aurora, CO; 2Khon Kaen University, Khon Kaen, Thailand.

**Background:** There are few targeted treatments for immune mediated kidney diseases which can result in progressive renal failure. Podocytes express the neonatal Fc receptor (FcRn), a trafficking receptor that transports immunoglobulin G (IgG) to the lysosome. In dendritic cells FcRn mediated trafficking of ICs to the lysosome is required for antigen processing and presentation on MHC II. We have found that podocyte specific knockout (KO) of FcRn ameliorates nephrotic syndrome (NTS) nephritis but that this protection occurs via a non-immune mediated mechanism. Here we show that KO of FcRn in podocytes results in a significant reduction in apoptosis both in vitro and in vivo after an immune challenge

**Methods:** Wild type (WT) and FcRn KO podocytes were cultured in the presence or absence of ICs. The intrinsic and extrinsic apoptotic pathways were assessed by Western blot and ELISA. RNA-seq was performed to evaluate changes in apoptotic pathways. NTS nephritis was induced in control and podocyte specific FcRn KO (podFcRn KO) mice. Glomerulosclerosis and crescent formation were quantitated on PAS sections. Flow cytometry was used to measure renal CD4+, CD8+ or FoxP3+ T cells. Glomerular apoptosis was assessed using the TUNEL assay.

**Results:** In vitro, after treatment with ICs, FcRn KO podocytes expressed significantly less caspase-3 and caspase-9 (intrinsisc pathway caspases) and caspase-3 activity was significantly decreased in KO podocytes compared to WT. There was no difference in caspase-8 expression (a marker of extrinsic apoptosis) between WT and KO podocytes. RNA-seq analysis demonstrated significant downregulation of intrinsisc apoptotic pathways in FcRn KO podocytes compared to WT. In vivo, after induction of nephrotic serum nephritis, there was no change in renal CD4+, CD8+ or FoxP3+ T cells in WT and KO mice. However, in FcRn KO mice significantly reduced glomerulosclerosis and crescent formation. Podocyte-specific KO of FcRn also resulted in a significant reduction in the number of apoptotic cells within the glomerulus.

**Conclusions:** KO of FcRn reduces apoptosis via the intrinsic pathway in cultured podocytes after an immune challenge and ameliorates immune-mediated nephritis in vivo by reducing glomerular apoptosis.

The African APOL1 E150 SNP and Cell Surface Expression Are Required for Kidney Risk-Variant (G1/G2)-Mediated Cytotoxicity in Podocytes

Background: Apolipoprotein L1 (APOL1) variants G1 and G2 protect against trypanosome infection, but homozygosity greatly increases the risk of chronic kidney diseases, purportedly by acting as surface cation channels in kidney podocytes. “Wild-type” APOL1-G0 exhibits various single nucleotide polymorphisms (SNPs), most commonly haplotype E150K, M228I and R255K (“KIK”, where the Reference Sequence is “EMR”), whereas G1 and G2 are only found in a single African haplotype background (“EIK”), also seen in some G0 Africans. Lannon et al (Kidney Int. 96: 1303) recently documented that differential cytotoxicity of APOL1-G1 and G2 variants versus G0 in HEK-293 cells depended on the haplotype. However, HEK-293 cells are unusually sensitive to APOL1, and podocytes are a more relevant cell type. Furthermore, only the small fraction of APOL1 that is transported to the cell surface (from its major expression in the electron transport chain (ETC)) requires the African (E150) G1 and G2 cytotoxicity required for APOL1 G1 and G2 to exert cytotoxicity. Non-toxic E150 G0 at equal surface expression levels; K150 G0, G1 and G2 were not toxic. E150 APOL1 were measured by FACS and Western blotting at increasing doxycycline levels.

Methods: We generated podocytes stably expressing APOL1 G0, G1 or G2 under a doxycycline-inducible promoter and compared the effect of the African E150 (EIK) vs K150 (KIK) SNPs on cytotoxicity (by the Cyto-Tox Glo assay). Surface and total APOL1 were measured by FACS and Western blotting at increasing doxycycline levels. Blood was used to prevent APOL1 transport to the cell surface.

Results: Cell surface APOL1 levels increased in a doxycycline dose-dependent manner, but only the E150 G1 and G2 variants caused toxicity to podocytes as compared to E150 G0 at equal surface expression levels; K150 G0, G1 and G2 were not toxic. E150 G1 and G2 cytotoxicity was dose-dependent and required exit of APOL1 from the ER.

Conclusions: Using a physiologically relevant podocyte cell line, we confirmed that the African haplotype (EIK) is required for APOL1 G1 and G2 to exert cytotoxicity. Non-natural KIK versions were not toxic. Additionally, APOL1 G0 was not toxic in either the KIK or EIK background. Furthermore, African (E150) G1 and G2 cytotoxicity required ER exit, supporting the surface cation channel hypothesis. Our data thus suggest two potential therapeutic avenues for APOL1 nephropathies.

Glomerular Heterogeneity and Modulation of miR-93: The Role of Extracellular Vesicles

Laura Perin,1,2 Charmi Dedhia,1 Paola Aguiari,1 Roger E. De Filippo,1 Sargin Sedrakyan,1,2 Children’s Hospital of Los Angeles, Los Angeles, CA; 1University of Southern California, Los Angeles, CA.

Background: Modulation of miRNA in podocytes and glomerular endothelial cells (GEC) has been associated with development of renal diseases. miR-93 is a potent regulator of pathways responsible for glomerular damage, like VEGF, TGFβ and Mek2. We have evidence that miR-93 is altered in the glomeruli of mice with X-linked Alport syndrome (AS), carrying the Col4a5 mutation, and in glomeruli of AS patients. Here, we investigated the role of miR-93 in mesangial cells, podocytes and GEC from WT and AS mice. We also used extracellular vesicles (EVs) derived from human amniotic fluid stem cells (hAFSC) to assess their disease modifying activity in vitro and in vivo by regulation of miR-93.

Methods: miR-93 expression was evaluated by qRT-PCR in mesangial cells, podocytes and GEC sorted from glomeruli of male and female WT (C57BL6/J), and homozygous and heterozygous AS (Col4a5−/−) mice at different stages of disease (2m, 3.5m and 5.5m) and in biopsies of AS patients. Modulation of miR-93 by hEVs was evaluated in vitro and EV therapeutic effect was evaluated in vivo by RNA-seq and survival.

Results: miR-93 expression is different between male and female mice along disease progression. In AS males miR-93 level was significantly lower in GEC, but not in podocytes or mesangial cells vs WT cells. miR-93 expression was downregulated also in AS patients. Expression of WT in panmucin amionucleoside damaged podocytes, and expression of fibronectin and VEGF in damaged GEC was restored by miR-93 hEV cargo transfer. In vivo, hEVs showed therapeutic effect by ameliorating the level of proteinuria and survival.

GDC-0879 Rescues Lipid Peroxidation and Podocyte Dysfunction in Coenzyme Q-Deficient Kidney Disease

Eriene-Heidi Sidhom,1,2 Choai Kim,1,2 Maria Ailimova,2 May Theng Tong,1 Julian R. Avila-Pacheco,1 Andrew J. Watts,1,2 Catherine A. Vernon,1,2 Jamie L. Marshall,1 Astrid Weiss,1 Jillian Shaw,1 Anna Greka,1,2 Harvard Medical School, Boston, MA; 2Boston Children’s Hospital, MA; Brigham and Women’s Hospital, Boston, MA; 3Columbia University Irving Medical Center, New York, NY.

Background: Mutations affecting mitochondrial coenzyme Q (CoQ) biosynthesis lead to kidney failure due to selective loss of essential cells of the kidney filtered called podocytes. Curiously, neighboring tubular epithelial cells are spared early in disease, despite their higher mitochondrial content. We therefore sought to illuminate new, cell-specific roles for CoQ, independent of its role in the electron transport chain (ETC).

Methods: Here we use CoQ deficiency caused by a monogenic disorder due to PDS2 mutations as a model system with which to investigate the cell-specific mechanisms of disease. The resolution afforded by single nucleus RNA sequencing revealed podocyte-specific disease pathways in homozygous kid/kid (kidney disease) mice, the result of a spontaneous missense mutation in Pds2 (V117M, Pds2M117V). We combine single nucleus transcriptomics with in vitro metabolomics and transcriptomics analyses to better understand the metabolic perturbations within this disease.

Results: Single nucleus RNA sequencing from kidneys of Pds2M117V mice, characterized by nephric syndrome and CoQ deficiency in all cells, identified a podocyte-specific perturbation of the Braf/Mapk pathway. Treatment with GDC-0879, a Braf/Mapk-targeting compound ameliorated kidney disease in Pds2M117V mice. In vitro, mechanistic studies demonstrated that depleted podocytes revealed a previously unknown perturbation in PUFAPUFA metabolism leading to lipid peroxidation. Ablation PUFAPUFA metabolism was confirmed in vivo, where the abundance of Gpx4, an enzyme that protects cells from lipid peroxidation, was elevated in disease and restored after treatment with GDC-0879. We demonstrate broader human disease relevance of these findings by uncovering patterns of Gpx4 and Braf/Mapk pathway gene expression in tissue from patients with several kidney diseases.

Conclusions: Our studies reveal ETC-independent roles for Coq in podocyte injury and point to Braf/Mapk as a conserved, podocyte-specific pathway for the treatment of kidney diseases.

Noncanonical PAR-1 Signalling Leads to Profibrotic Effects in Podocytes in Response to Steroid-Resistant Nephrotic Syndrome Disease Plasma

Musleeha Chesor, Jack P. Tuffin, Carl J. May, Gavin I. Welsh, Moin Saleem. Bristol Renal University of Bristol, Bristol, United Kingdom.

Background: Post-transplant recurrence of steroid-resistant nephrotic syndrome (SRNS) is thought to be due to the presence of an unknown “circulating factor”, the identity of which has so far remained elusive. Our previous works suggest a role for protease-activated receptor-1 (PAR-1) involving an unknown circulating protease leading to increased podocyte motility. We have now further elaborated the signalling pathways downstream of PAR-1, which suggests pro-fibrotic activation in podocytes.

Methods: Conditionally immortalised human podocytes (ciPods) were treated with PAR-1 agonist peptide or post-transplant SRNS relapse plasma. Signalling pathways downstream of PAR-1, which promotes pro-fibrotic activation in podocytes were assessed. Furthermore, par-1 knockdown podocytes revealed a previously unknown perturbation in PUFA metabolism leading to lipid peroxidation. Ablation PUFA metabolism was confirmed in vivo, where the abundance of Gpx4, an enzyme that protects cells from lipid peroxidation, was elevated in disease and restored after treatment with GDC-0879. We demonstrate broader human disease relevance of these findings by uncovering patterns of Gpx4 and Braf/Mapk pathway gene expression in tissue from patients with several kidney diseases.

Conclusions: Our studies reveal ETC-independent roles for Coq in podocyte injury and point to Braf/Mapk as a conserved, podocyte-specific pathway for the treatment of kidney diseases.

TRPC6 is a Key Mediator of a PAR1 Activation Pathway in Podocytes That Is Responsible for FSGS

Carl I. Mag, Musleeha Chesor, Gavin I. Welsh, Moin Saleem. University of Bristol, Bristol, United Kingdom.

Background: There is good evidence for the role of a circulating factor in the pathogenesis of idiopathic nephrotic syndrome (NS). We have previously presented our work hypothesising the role of circulating plasma proteases. An active form of the protease activated receptor, PAR-1 expressed in the podocytes of SV129 mice (PAR-1acs) led to proteinuria, sclerosis and death at 42 days. It was found that the signalling

Underline represents presenting author.
response to PAR-1 agonist treatment of podocytes in vitro was also present in the kidney IHC sections from the PAR-1 KO, mouse, and in human podocytes treated with post-transplant recurrence plasma. This response includes the phosphorylation of VASP, JNK and Pakxillin. We hypothesised that the downstream response to PAR-1 signalling involves activation of TRPC6.  

Conclusions: Conditionally immortalised human WT podocytes and TRPC6 KO mouse podocytes were treated with a PAR-1 agonist (15 μM PAR-3931-Pi Peptides International). The PAR-1 KO mouse was crossed with a TRPC6 KO on a C57 Bl6 background to develop the NPHS2 Cre PAR-1 KO, TRPC6 KO mouse. Biopsy tissue was obtained via the UK Nephrotic Syndrome Study, Nephros, housed within the UK Renal Rare Disease Registry, RadDaR.  

Results: We present data confirming activation of the same signalling pathways in vitro in podocytes treated with a PAR-1 agonist, and in vivo in our NPHS2 Cre PAR-1 KO, mouse. TRPC6 activation in human nephropathy biopsies nVASP and JNK signaling is significantly higher in FSGS and Minimal Change Disease biopsies when compared to IgA nephropathy biopsies. TRPC6 is a calcium channel that can be activated at the slit diaphragm and can signal to the actin cytoskeleton. TRPC6 Knock Out (TK6KO) podocytes showed an altered response to PAR-1 agonist treatment. There was no phosphorylation of VASP and only brief phosphorylation of JNK and no phosphorylation of Pakxillin. When we crossed a TK6KO mouse with our NPHS2 Cre PAR-1 Active mouse we saw significantly increased survival from a median of 40 days in the NPHS2 Cre PAR-1 Active mouse to 60 days when TK6KO is knocked out.  

Conclusions: We have identified a common signalling response to PAR-1 activation in podocytes in vitro and in vivo, including in human disease. We identified TRPC6 as being a key player in the response, suggesting a unique role of this ion channel in mediating circulating factor disease, and a direct therapeutic target.

A Novel Insulin Sensitizer Targeting Nuclear Receptor PPARy Provides Beneficial Effects in a Glomerular Disease Model  

Galen Rusk, Amanda P. Waller, Bryce A. Kerlin, Francisco R. Neves, Shing-Au Chow, Beverly J. Swift, Wexner Research Institute at Nationwide Children’s Hospital, Columbus, OH; The Ohio State University, Columbus, OH; Universidade de Brasilia, Brasilia, Brazil.  

Background: Thiazolidinediones (TZDs) are nuclear receptor peroxisome proliferator-activated receptor γ (PPARγ) agonists traditionally used to treat type II diabetes由于 their insulin-sensitizing effects. These have recently been demonstrated to be beneficial in protecting podocytes and reducing proteinuria in glomerular disease. Since these FDA-approved drugs are associated with adverse effects such as weight gain, edema, bone loss and increased risk for heart failure, we hypothesized that disparate beneficial vs. adverse molecular activities of PPARγ can be modulated. We determined if GQ-16, a novel insulin sensitizer and partial PPARγ agonist, which de-phosphorylates PPARγ at Ser273 like other TZDs, provides therapeutic advantage in glomerulonephritis mice.  

Methods: The studies were approved by the Institutional Animal Care and Use Committee at Nationwide Children’s Hospital. Proteinuria was induced in male Wistar rats by single intravenous puromycin amino-nucleoside (PAN) injection, while the control group received saline. PAN-injected rats received sham vehicle, pioglitazone (Pio) or GQ-16 by oral gavage daily (n = 7/group). The rats were weighed daily, and urine samples were collected and analyzed for proteinuria. Plasma with sodium citrate and corn trypsin inhibitor was collected from the inferior vena cava. Endogenous thrombin potential was determined by thrombin generation assay.  

Results: PAN induced robust proteinuria (P=0.009) on Day 11 and Pio reduced PAN-induced proteinuria significantly with 63.3% mean reduction (P=0.038). Interestingly, GQ-16 reduced proteinuria even further by 81.2% (P=0.008), and these were comparable to the control (n=7) study. Increased levels of proteinuria was associated with heart failure (P=0.066). Furthermore, proteinuria reduction correlated with correction of disease associated hyper-coagulopathy. GQ-16 improved PAN-induced hyper-coagulopathy as measured by improved endogenous thrombin potential and peak thrombin. No significant differences in body weights were observed in treatment vs. PAN groups.  

Conclusions: GQ-16, a novel insulin sensitizer and partial PPARγ agonist, shows better efficacy profile in an experimental glomerular disease model than Pio, a traditional TZD with full PPARγ agonist activity.

Tropomyosin Isomers Play a Role in Healthy and Injured Kidney Podocytes  

Dina Hammoud, Jeffrey H. Minet, Hanli Suleiman, Washington University in Saint Louis School of Medicine, Saint Louis, MO.  

Background: The podocytes are a group of glomerular diseases that affect the kidney’s ability to filter the blood, and often lead to kidney failure. Healthy podocytes cover the glomerular capillaries with thousands of extensions called foot processes that interdigitate with one another and maintain their elaborate cell shape by tightly regulating their actin cytoskeleton. Podocytes respond to insults in a typical fashion by reducing their footprint effacement (PFE), a dramatic shift in podocyte morphology and the disappearance of the intricate foot processes. Tropomyosins (Tpm) are coiled-coil dimers that form co-polymers along actin filaments and change the filaments’ biological properties. Over 40 different Tpm isoforms have been identified as the gene products of 4 genes: Tmga1, Tmga2, Tmga3, Tmga4. Tpm expression varies in different locations and cell types and the change of type of actin cables assembled in those locations. We hypothesize that podocyte shape is controlled by a specific set of Tpm isoforms that regulate actin cytoskeleton than the injured and/or their counterparts, with the most significant changes occurring in Tpm 1.7 & Tpm 3.4. PheBio data also showed an interesting novel Tpm-related gene product only in injured glomeruli. We isolated RNA from WT and AdrN glomeruli and compared them to primary podocytes taken from podocyte-specific translating-ribosome-ribosum-deactivation (TRAP) mice. This study allowed us to purify podocyte mRNA for RNaseq, away from that in other glomerular cell types. Comparing the isolated RNA from WT-TRAP & AdrN-TRAP mice, we are able to identify the podocyte-specific Tpm isoforms that are associated with injury.  

Conclusions: This study suggests roles for tropomyosin isoforms changes in regulating podocyte shape in health and injury conditions.

PO1993  

IRE1α Is Essential for Podocyte Proteinosis and Mitochondrial Health  

José R. Navarro-Betancourt, Joan Papillon, Julie Guillemette, Takao Iwawaki, Andrey V. Cybulsky, McGill University, Montreal, QC, Canada; Kanazawa Medical University, Kahoku-gun, Japan.  

Background: Glomerular epithelial cell (GEC)/podocyte proteinosis is disrupted in glomerular diseases. To maintain proteinosis, the endoplasmic reticulum (ER) orchestrates the unfolded protein response (UPR), which includes upregulation of chaperones and clearance of misfolded proteins via autophagy. Insulin requiring enzyme-α (IRE1α) resides in the ER and is a transducer of the UPR. This study characterizes the mechanisms by which IRE1α regulates proteinosis in GECs.  

Methods: Mice with podocyte-specific deletion of IRE1α (IRE1α KO) were produced by breeding IRE1α flox/flox mice with mice expressing podocy-cre recombinase. Nephrosis was induced with a single injection of adriamycin (ADR). GECs were cultured from glomeruli of IRE1α KO flox/flox mice and IRE1α KO was deleted by transfection of Cre recombinase. Cellular oxygen consumption rate (OCR) was quantified using the Seahorse mitochondrial stress test. Mitochondria were visualized using MitoTracker Red CMXROS or MitoTracker Green FM.  

Results: Podocyte-specific IRE1α KO mice had greater ADR-induced albuminuria compared to control littermates. ADR increased expression of ER chaperones in glomeruli of control mice, but this upregulation was impaired in IRE1α KO mice. Autophagy reduction was blunted in ADR-treated IRE1α KO animals, evidenced by reduced LC3-II and increased p62 levels, compared to treated controls. Electron microscopy showed prominent swelling of the ER and mitochondrial injury in podocytes of ADR-treated IRE1α KO mice. In cultured GECs incubated with tunicamycin (TM), deletion of IRE1α or chemical inhibition of the IRE1α RNase with 4μC8 attenuated upregulation of ER chaperones and LC3 lipidation compared to control. LC3 transcription and total LC3 protein levels were also reduced in TM-treated IRE1α KO GECs. Compared to control, IRE1α KO GECs showed decreased maximal and ATP-linked OCR. Mitochondrial membrane potential was lower in IRE1α KO GECs, which may contribute, while total mitochondrial mass was similar in both groups. Inhibition of IRE1α signaling increased ER stress-induced apoptosis.  

Conclusions: Stress-induced chaperone production, autophagy and mitochondrial function are compromised by IRE1α KO. IRE1α KO is pathogenic in glomerular disease associated with podocyte injury and ER stress.

PO1994  

Studying the Pathogenesis of Congenital Nephrotic Syndrome Using NPHS2 Mutant Kidney Organoids  

Aude Dorison, Sara E. Howden, Thomas A. Forbes, Irene Ghobrial, Melissa H. Little.  

Kidney Development, Disease and Regeneration, Murdoch Children's Research Institute, Melbourne, VIC, Australia; Department of Anatomy & Neuroscience, The University of Melbourne, Melbourne, VIC, Australia; Department of Nephrology, Royal Children's Hospital, Melbourne, VIC, Australia; Department of Paediatrics, The University of Melbourne, Melbourne, VIC, Australia.  

Background: Nephrotic syndrome (NS) is one of the most common forms of renal disease in children. NPHS2 mutations are the most common cause of congenital NS with missense NPHS2 mutations reported to result in misfolding and mislocalization of the encoded slit-diaphragm protein, Podocin. Such studies overexpressed mutant protein in cell cultures, with limited podocyte and mouse cell line GECs. This may not capture the consequences of the mutant protein. Here we generated NPHS2 mutant iPSC-derived kidney organoids as a model to dissect the pathogenic process.  

Methods: We have simultaneously reprogrammed and CRISPR/Cas9 gene edited a control human fibroblast line, generating 3 iPSC lines containing mutations of the endogenous NPHS2 locus as well as a control wild type (WT) line. These include the sequence variants c274G>T, c353C>T and c303G>A leading to the protein changes G92C, P118L and R168H respectively. Control and mutant lines were used to generate Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only  

Underline represents presenting author.
kidney organoids containing all nephron segments. Podocin localization was assessed by confocal microscopy and Western blotting.

Results: Podocin protein was evident in the glomeruli of all organoids, however all mutant lines revealed a marked reduction of the Podocin protein. While the G92C mutant protein co-localised with Nphrin at the plasma membrane, the R168H mutant protein failed to show any perinuclear staining suggestive of Golgi retention, together with peripheral co-localisation with the early endosome marker EEA1. Interestingly, the R168H mutant was previously predicted to mislocalise in the endoplasmic reticulum (ER). The P118L mutant was previously predicted to accumulate in the ER and present a trafficking defect from the ER to the Golgi apparatus.

Conclusions: Differences in mutant podocin protein localisation in previous reports and our kidney organoids highlight the need for a more appropriate model to study the pathobiology of NPHS2 mutations. These organoids will allow us to explore approaches to rescue individual Podocin defects, ultimately guiding the development of therapeutic strategies for such patients.

OASIS in Podocytes Promoted Tubular Injury by Suppressing PRKCI Expression

Yasunori Miyake,1 Masanori Obana,1 Ayaha Yamamoto,2 Takeo Harada,1 Takafumi Nakae,3 Shunsuke Noda,1 Sayuri Mitsuoka,1 Koki Tanaka,1 Shota Tanaka,1 Makiko Maeda,3 Kazunori Imaizumi,2 Katsuhiko Asanuma,1 Yasushi Fuji1.1 Osaka University, Suita, Japan; 2Hiroshima Daigaku, Higashihiroshima, Japan; 3Chiba Daigaku Daigakuin Igaku Kenkyuin, Chiba, Japan.

Background: Old astrocyte specifically induced substance (OASIS), a transcription factor, plays important roles in physiological and pathophysiological processes, such as bone formation. Previously, we found that OASIS is expressed in podocytes in murine kidney. However, the pathophysiological roles of OASIS in podocytes remains unknown. The aim of this study is to investigate the functional roles of OASIS in podocytes in the development of kidney diseases.

Methods: The expression of OASIS protein was investigated in glomeruli of murine kidney and cultured mouse podocytes cell line after lipopolysaccharide (LPS) treatment. To examine the roles of OASIS in podocytes in kidney injury, podocyte-specific OASIS knockout (OASIS CKO) mice were generated and subjected to LPS. Twenty-four hours after LPS treatment, serum creatinine and urinary albumin ratio were measured. Podocytes injury was assessed by electron microscope analysis and tubular injury was analyzed by PAS staining and by measuring LCN2 mRNA expression. To explore the secretory molecules downstream of OASIS, DNA microarray analysis was performed using podocytes with lentiviral overexpression of OASIS. In order to examine the effects of the downstream molecule of OASIS on proximal tubule cells, HK-2 cells were cultured.

Results: LPS treatment increased OASIS expression in glomeruli of murine kidney and in cultured podocytes. Podocyte-specific OASIS deletion suppressed LPS-induced serum creatinine (Cr) level (Cr (mg/dl) : control-LPS=1.0±0.2, OASIS CKO-LPS=0.75±0.16, n=8-10, p<0.05), but did not influence albuminuria and podocyte injury. Surprisingly, on the other hand, OASIS CKO mice were protected from LPS-mediated tubular injury. DNA microarray analysis using OASIS-overexpressed podocytes revealed that PRKCI was negatively regulated by OASIS in podocytes. Finally, we found that recombinant LPS-suppressed LPS-induced LCN2 mRNA expression in HK-2 cells in a dose-dependent manner.

Conclusions: Suppression of OASIS in podocytes attenuated LPS-induced tubular injury in part by increased PRKCI secretion. Targeting OASIS-PRKCI signaling in podocytes could be therapeutic value in kidney diseases.

PO1996

The Renal Risk Variants of Apolipoprotein L-1 Lead to an Influx of Sodium and Calcium That Drive Cytotoxicity

Joseph A. Giuvinazzo,1 Russell P. Thomson,1 Naiyia Khalizova,1 Patrick J. Zager,2 Ryan Schreiner,3 Jayne Rapel.1 Hunter College, New York, NY; 2Weill Cornell Medicine, New York, NY.

Background: Apolipoprotein L-1 (APOL1) is an innate immunity gene that protects against protozoan parasites. Recently evolved variants, G1 and G2, provide increased immunity against African trypanosomes while increasing the risk of chronic kidney disease. There is little consensus on how these renal risk variants (RRVs) lead to cell death. We report that the earliest event in RRV-mediated cytotoxicity is localization to the plasma membrane, followed by cation flux driven by Ca2+ and Na+. Because many of the proposed models of RRV cytotoxicity and kidney disease can be activated by an influx of cations Ca2+ and Na+, we propose that the cytosolic cation channels at the cell surface are the upstream even that links them together. Our data suggests that targeting RRV channel activity represents a promising avenue for drug development.

PO1997

Cloning of an IgG Autoantibody Specific for Phospholipase A2 Receptor (PLA2R) Using IgG-Producing Cells from a Patient with Membranous Nephropathy

Zhi qiang Huang,1 Rodney G. King,1 Barbara Knoppova,1 Colin Reily,1 Qi Bian,1 Stacy D. Hall,1 David J. Saltan,1 Laurence H. Beck,2 Bruce A. Julian,1 Jan Novak,1 university of alabama at birmingham, Birmingham, AL; 2Boston University Medical Center, Boston, MA.

Background: Primary membranous nephropathy (MN) is a common autoimmune kidney disease, in which 70% of patients exhibit circulating autoantibodies to one or more conformational epitopes in PLA2R. Anti-B cell therapies have proved effective to decrease autoantibody production and limit further development of the glomerular subepithelial immune deposits of PLA2R and IgG. However, better characterization of anti-PLA2R autoantibodies is needed.

Methods: We used Epstein-Barr virus (EBV)-immortalized B cells isolated from peripheral blood from an anti-PLA2R seropositive MN patient to develop a protocol for the cloning and expression of recombinant IgG (rIgG) specific for PLA2R. A terminally His-tagged fragment consisting of the first 5 domains of human PLA2R was expressed in E. coli. The B cells were transfected with rIgG expression plasmids by transfection or infection and secreted rIgG was isolated from cell supernatant media by incubation with biotin labeled reagents (recombinant PLA2R or IgG-specific antibody) and streptavidin-conjugated magnetic beads. A FITC-conjugated N-terminal PLA2R peptide was used to isolate B cells with antigen-specific B-cell receptor (membrane IgG) by FACS. Variable segments of IgG heavy (VH) and light (VL) chains were cloned through a single-cell workflow that allowed expression of rIgG for follow-up screening using an in-house ELISA to assess IgG binding to human PLA2R. Sera from anti-PLA2R seropositive MN patients and healthy controls served as positive and negative controls, respectively.

Results: Starting with 1.105 EBV-immortalized cells, we first isolated 3.6x106 cells with membrane IgG specifically reactive with non-reduced PLA2R. This subpopulation was next stained with FITC-conjugated PLA2R peptide and the corresponding VH and VL of IgG were cloned using our single-cell workflow. We expressed the cloned VH and VL in Es rIgG in Expi293 cell system. ELISA confirmed that the rIgG bound PLA2R.

Conclusions: This is the first report of cloning a PLA2R-specific IgG autoantibody from a patient with MN. These approaches can be used for further characterization of the molecular mechanisms of autoimmunity and epitope spreading in MN.

Pharmacologic Blockade of the Natriuretic Peptide Clearance Receptor Ameliorates Glomerular Disease in an Animal Model of FSGS

Leonardo Yang,1 Yingpu Tan,1 Andrew Buckley,2 Robert S. Furne2.1 Duke University, Durham, NC; 2Durham VA Medical Center, Durham, NC.

Background: Glomerular podocytes play a key role in glomerular disease processes. Accumulating evidence suggests that cGMP signaling has podocyte protective effects in kidney diseases (J Am Soc Nephrol 28: 260, 2017). cGMP is produced by nitric oxide and by natriuretic peptides (NPs). NPs are the predominant source of cGMP generation in podocytes. NPs stimulate cGMP production by binding to NP receptors (NPRs). NPRA and NPRB stimulate cGMP generation. In contrast, NPRC binds and degrades NPs. Podocytes express all three NPRs (NPRA, NPRB, and NPRC). We hypothesized that blockade of NPRC would enhance local NP levels, promote cGMP signaling in podocytes and ameliorate glomerular injury.

Methods: We blocked clearance of NPs by NPRC using the pharmacologic agent ANP (4-23), which specifically binds NPRC without binding NPRA or NPRB. For the experiments, we used a mouse transgenic (TG) model of focal segmental glomerulosclerosis (FSGS) created in our laboratory (J Clin Invest 125:1913, 2015). These TG mice express constitutively active Gαq-subunit specifically in podocytes. In these animals, treatment with a single dose of the podocyte toxin puromycin aminonucleoside (PAN) causes robust albuminuria in TG mice, but only mild disease in non-TG animals.

Results: PAN induced heavy proteinuria in vehicle-treated TG mice at day 14 (1426 ± 144) vs. 49 ± 19 [baseline] ug/mg creatinine; P = 0.003. The increase in albuminuria at day 14 was significantly reduced by treatment with ANP(4-23) (1426 ± 25 [vehicle] vs. 383 ± 157 [ANP(4-23)]/ug/mg creatinine; P = 0.003). Treatment with ANP(4-23) also tended to reduce the number of mice with glomerular injury (83% [vehicle] vs. 58% [ANP(4-23)]; P = 0.1). ANP(4-23) also reduced proteinuria in TG mice treated with PAN (129 ± 3 [vehicle] vs. 127 ± 3 [ANP(4-23)]) mm Hg; P = NS. Urinary cGMP excretion tended to be higher in ANP(4-23) treated mice (6.7 ± 1.0 ng/mg creatinine) compared to mice treated with vehicle (4.9 ± 1.0 ng/mg creatinine), but this difference was not statistically significant.

Underline represents presenting author.
Conclusions: These data suggest that: 1. Pharmacologic blockade NPRC may be a useful target for treatment of proteinuric kidney disease, and 2. Treatment outcomes might be improved by optimizing blockade of the NPRC to more effectively inhibit clearance of NPs from the circulation.

Mitochondrial Damage in FSGS due to ANLN Mutation
Brandon M. Lane,1,2 Guanghong Wu,1 Megan Chryst-Stangle,1 Gentzon Hall,1,2 Rasheed A. Ghadgesin.1,2 Department of Pediatrics, Duke University School of Medicine, Durham, NC; 3Duke Molecular Physiology Institute, Durham, NC; 4Department of Medicine, Duke University School of Medicine, Durham, NC.

Background: We previously identified ANLN R431C as a cause of focal segmental glomerulosclerosis (FSGS). In addition to defects in actin bundling, targeted evaluation of this variant in cultured human podocytes identified disruption of AKT/mTOR signaling as a cause of ER stress and reduced podocyte viability. Creation of the orthologous R431C point mutation in mice confirmed the increased podocyte ER stress and identified mitochondrial damage as another possible feature of disease. To gain an unbiased view of the molecular mechanisms driving ANLN R431C induced disease, we used transcriptomic analysis and automated live cell imaging to interrogate cultured human podocytes.

Methods: Conditionally immortalized human podocytes overexpressing wildtype ANLN or the R431C variant were evaluated by mRNA-Seq and smRNA-Seq analysis to identify differentially expressed genes and microRNAs, as well as the molecular pathways involved. Potential therapeutic strategies were examined by evaluating cultured podocyte cellular and organelle-specific viability using automated live cell imaging.

Results: The top differentially expressed genes encode molecules that interact with previously identified pathological mechanisms including F-actin bundling (SYNP2L) and AKT/mTOR signaling (ANLN R431C), with mTOR signaling identified as a pathway likely to be affected by ANLN R431C. A common feature of the top differentially expressed gene and microRNA candidates is the potential to regulate mitochondrial viability. When evaluated for changes in mitochondrial membrane potential, expressed gene and microRNA candidates is the potential to regulate mitochondrial likely to be affected by

and AKT/mTOR signaling (ANLN R431C). A common feature of the top differentially expressed gene and microRNA candidates is the potential to regulate mitochondrial viability. When evaluated for changes in mitochondrial membrane potential, ANLN R431C podocytes displayed increased susceptibility to mitochondrial damage that could be rescued by treatment with AKT/mTOR pathway inhibitors. Additionally, compounds targeting improved mitochondrial viability through increased bioenergetic function (AP(39), reduced oxidative stress (MitoQ, MitoTEMPO) and prevention of pore opening (Olesoxime) could all rescue the increased susceptibility to apoptosis in ANLN R431C podocytes.

Conclusions: Unbiased transcriptomic analysis confirmed that ANLN R431C disrupts AKT/mTOR signaling and actin cytoskeletal dynamics, resulting in increased ER stress and mitochondrial damage that reduce podocyte viability. Targeting various aspects of mitochondrial regulation may present viable alternative treatment strategies for FSGS due to defects in ANLN gene.

PO2000
Prothrombin Modulates Podocyte Health and Function During Glomerular Proteinuria
Amanda P. Weller,1 Katelyn Wolfgang,1 Tasha K. Wilkie,1 Sagar Bhayana,1 Kyoko K. Kishi,2 William E. Smoyer,1 Bryce A. Kerlin,1,2 Abigail Werner Research Institute at Nationwide Children’s Hospital, Columbus, OH; The Ohio State University College of Medicine, Columbus, OH.

Background: Ongoing podocyte injury is a known critical determinant of glomerular disease progression. Recent research suggests thrombin exerts biotrope podocyte injury, however, pharmacologic manipulation may cause both on- and off-target effects. Thus, the purpose of this study was to directly examine the effects of thrombin on glomerular proteinuria by manipulating its zymogen precursor, prothrombin (PT). We hypothesized that circulating PT would directly modulate both podocyte function and in situ survival in a rat model of nephrotic syndrome.

Methods: Puromycin aminonucleoside (PAN)-induced proteinuria was treated with: 1) PT antisense oligonucleotide to induce hypoprothrombinemia (LoPT), 2) Serial i.v. PT infusions to sustain hyperprothrombinemia (HiPT), or 3) sham (PT only) controls (Con; n=12/group). Group samples and citrated plasma were collected at day 10 post-PAN. PT plasma activity was measured by chromogenic kit. Glomeruli were isolated from the kidneys, dissociated into single-cell suspension and analyzed by flow cytometry following immunofluorescent antibody and TUNEL staining.

Results: Circulating plasma PT levels (Figure A) modulated proteinuria (B) such that it was significantly decreased in LoPT and increased in HiPT, compared to Con. LoPT also decreased in situ podocyte death (C), while HiPT increased in situ podocyte death, and resulted in fewer podocytes per glomerulus (D).

Conclusions: In conclusion, prothrombin modulates podocyte function (proteinuria) and survival (death and numbers) in the PAN model of glomerular proteinuria. Future studies should work to determine the prothrombinase mechanism that enables thrombin formation and signaling in the glomerulus and evaluate its potential as a novel therapy to target slow glomerular disease progression toward chronic kidney disease.

PO2001
Exosomal Long Non-Coding RNA-G21551 as a Potential Predictive Biomarker for Segmental Sclerosis Change in IgA Nephropathy
Qianqian Han,1 Jiajia Li, Xiaona Wei, Peifen Liang, Qiongqiong Yang. Sun Yat-Sen University Sun Yat-Sen Memorial Hospital, Guangzhou, China.

Background: Segmental sclerosis (S) is an independent pathological predictor for renal progression in IgAN patients, and is closely related to proteinuria. However, there is less invasive biomarker for pathological S change. We investigate the difference in expression profiles of exosomal long non-coding RNAs (lncRNAs) in plasma from IgAN patients compared with their healthy first-degree relatives, then explore the possible lncRNA associated with S.

Methods: To isolate exosomes from the plasma of both IgAN patients and their healthy first-degree relatives. High-throughput RNA sequencing and real-time quantitative polymerase chain reaction (qRT-PCR) was used to validate lncRNA expression profiles. Target lncRNAs were selected by bioinformatics analysis. The relationship between target lncRNA and S was analyzed by Spearman correlation. ROC curve evaluated the area under curve (AUC) of the target lncRNA for diagnosis S and its predictive sensitivity and specificity.

Results: 18 pairs of IgAN patients and their healthy first-degree relatives were enrolled in this study. The mean age was 29.7±6.6 years and urinary protein was 1.00±2.00 (g/24h) in these IgAN patients. LncRNA-G21551 was significantly down-regulated in IgAN patients. The predicted target genes of lncRNA-G21551 are FCGRs, which encode family of Fc gamma receptors (FcγRs). S was observed in 12 IgAN patients (66.7%) and was positively correlated with lncRNA-G21551 relative expression (r=0.545, P=0.019), but had no correlation with proteinuria, blood pressure, mesangial hypercellularity(M), endocapillary proliferation(E), tubulointerstitial fibrosis (T) and crescent(C). The relative expression (fold change) of lncRNA-G21551 was significantly higher in S group than in S0 group (11.26(9.79,20.38) vs 7.04(1.39,11.00), P<0.025). The AUC of lncRNA-G21551 to predict S change was 0.81(95% confidence interval, 0.62~1.00) with a sensitivity of 83.3% and a specificity of 83.3% when a cutoff value of 9.58 was used for lncRNA-G21551 relative expression (Fold Change). In addition, patients with higher lncRNA-G21551 relative expression had more severe podocyte injury.

Conclusions: Exosomal lncRNA-G21551 was down-regulated in IgAN patients, but positively correlated with S change. Exosomal lncRNA-G21551 may be a potential independent predictor for S lesion in IgAN patients.

PO2002
Analysis of the Relationship Between Proteasome and Autophagy in Podocytes Using Podocyte-Specific Proteasome Impairment Mice
Shinichi Makino,1 Hiroyuki Yamada,1 Ika N. Kadariswantiningsih,1 Maulana A. Empita,1 Motoko Yanagita,1 Katsuhiko Shinichi N. Kadariswantiningsih,1 Takanori Ito,1,2 Motoharu Yokota,1,2 Masahiko Kubo,1,2 Takami Hamada,1,2 Chika Daigaku Daigaiku Ikugu Kenkyuu Igakubu, Chiba, Japan; 3Kyoto Daigaku Igaku Kenkyuin Igakubu, Chiba, Japan.

Background: Ubiquitin-proteasome system and autophagy-lysosome system are major intracellular protein degradation machinery. The relationship of these systems in podocyte has not well been understood.

Methods: In this study, we generated podocyte-specific proteasome impaired mice (Rpt3pdKO) by deletion of Rpt3, which is essential for construction of 26S proteasome, using Cre-loxP system. Albuminuria and number of sclerotic glomeruli increased in the Rpt3pdKO mice compared with Rpt3control mice. Oxidative stress and podocytes apoptosis were related to podocyte injury. To evaluated autophagic activity, LC3 dots

Functionally Resolving WT1 Variants of Uncertain Significance in Nephrotic Syndrome
Jennifer Lai Yee,1 Xiaoian Jia,1 V. Vega-Warner,1 Matt G. Sampson,2 Jacob O. Kitzman,3 1University of Michigan, Ann Arbor, MI; 2Boston Children’s Hospital, Boston, MA.

Background: Patients with Mendelian forms of nephrotic syndrome (NS) are likely to progress to end stage kidney disease. Because of the increased availability and promise to guide clinical decision, genetic screening among affected patients is proliferating. However, accurate attribution of pathogenicity to rare variants found during genetic screening remains challenging. WT1 is the second most common gene causing Mendelian NS. Therefore, this project aims to develop a model system to test the transcriptional activity of WT1 variants, as a first step towards high-throughput functional analysis to comprehensively classify variants in this key NS gene.

Methods: Wild-type and several bona fide pathogenic WT1 variants were tested for transcriptional activity in a standard dual-luciferase assay. Several cell lines including HeLa, HEK293, and HK2, were co-transfected with variant or wild-type WT1 and an NPHS1 promoter luciferase vector. Furthermore, potential WT1 target genes specific to HEK293 cells were identified by analyzing differential gene expression in RNA-Seq data of WT1 over-expressing HEK293 cells, in order to identify additional WT1-responsive promoters for use as WT1 activity reporters.

Results: Overexpression of wild-type WT1 in HeLa cells and HEK cells increased expression of luciferase under the NPHS1 promoter by ~2-fold relative to trimmed WT1. The luciferase activity of bona fide pathogenic WT1 variants was also significantly lower than the wild-type WT1 and bona fide benign WT1 variants (P<0.05). Overexpression of wild-type WT1 in HEK293 resulted in upregulation (log2 fold change>0.4, adjusted p<0.05) of IGFIR, EGFIR, TGFβ2. These candidates are being developed as WT1-responsive reporters.

Conclusions: Previous reports suggested NPHS1 promoter reporters as a model system to investigate WT1 functionality. However, the transcriptional effect of WT1 was substantially underexposed. Future work is required to establish a robust WT1 reporter in upcoming studies.

PO2004
Sources of Variability in Podocyte Foot Process Width Measurements and Approaches to Mitigation
Molly Geraghty,1 Morgan P. Thompson,1 Donal Gorman,2 Hui Chen,1 Kondala R. Atkuri,2 Stephen Berardi,2 J. B. Copley,2 Joel M. Henderson,1 1Boston Medical Center; 2Boston, MA; 3Pfizer Inc, New York, NY.

Background: Podocyte foot process (FP) morphology is used in the research setting to quantify podocyte injury and has the potential to be leveraged for diagnostic use. However, the impact of pre-analytic and analytic variables on these measurements are not well understood. We sought to identify these sources of variability and develop a robust method for podocyte foot process width (FPW) measurement within different kidney diseases.

Methods: We examined the impact of operator bias and sample size on FPW measurement in electron micrographs from nephropathies (N) and podocytopathy (P) cases, including primary focal segmental glomerulosclerosis (FSGS) and minimal change disease (MCD), and other glomerular lesions affecting the podocyte. FPW was measured for each individual FP between the midpoints of flanking filtration slits and the geometric mean of all FPW measurements was reported by image. We found that identification of filtration slits was subjective, but interoperator variability was mitigated through use of standardized morphologic criteria, operator training, adjudication of ambiguous features, and a mapping process that eliminated duplicate measurements in adjacent images. These methods reduced interoperator variability in FPW, averaged by image, from 12% to 7%.

Results: Preliminary analysis suggests that, in addition to the expected larger FPW mean in MCD cases vs. Nx cases, there is also larger FPW variability in MCD cases. Related analysis shows ~125 FPW measurements within each of 2 glomeruli (~250 total) in FSGS as the same precision as ~100 FPW measurements in each of 10 glomeruli (~1,000 total) in a MCD case. We also found that intraglomerular variability among 3 glomeruli in each of 2 cases (1 Nx, 1 MCD) ranged from 29% to 46% (Geometric CV), whereas interglomerular variability was only 12% (Geometric CV). Notably, these results were highly reproducible among the Nephrology data set. The study of a larger sample size and different kidney diseases is needed to confirm these findings.

Conclusions: Sources of variability in FPW measurements include operator variability, analytic variability, and interglomerular variability. Future studies in a larger sample size and different kidney diseases could further refine these findings.

PO2005
Glucomerular Transcriptomic Analysis of Glucocorticoid- and Pioglitazone-Treated Nephrotic Syndrome
Sagar Bhavaya, Shhipra Agrawal, Melinda A. Chanley, Amanda P. Waller, Katelyn Wolfgang, Saranga Wijeratne, James Fitch, Bryce A. Kerlin, William E. Smoyer. Nationwide Children’s Hospital, Columbus, OH.

Background: Nephrotic Syndrome (NS) is among the most common glomerular diseases in children. Glucocorticoids (GC) are the primary treatment for NS, but 15-20% of children have or develop steroid resistant NS, creating an unmet need for novel therapeutics. Thiazolidinediones (TZDs) such as pioglitazone (PIO) have been shown to slow diabetic nephropathy progression, and to reduce proteinuria in animal models of NS. Since both GC and PIO act via binding to nuclear receptors we hypothesized that the reported similar degrees of proteinuria reduction by GC and PIO are driven via common molecular pathways.

Methods: We performed transcriptome analyses on glomeruli isolated from GC- and PIO-treated rats 11 days after induction of NS with PAN (n=4/group).

Results: Principal component analyses revealed distinct transcriptional profiles between GC vs. PAN-treated rats, with 319 and 126 differentially up- and down-regulated genes in PAN respectively, which were largely reversed by both GC and PIO. Ingenuity pathway analyses (IPA) combined with drug-target interaction network analyses and gene set enrichment analyses identified 29 glomerular genes that were commonly regulated by GC, PIO, and their respective nuclear receptors (NRECI and PPARγ). Gene ontology annotation revealed these 29 genes to be involved in: ECM modification, plasma membrane dynamics, DNA damage/repair, transcription factor binding, lipid metabolism, and cytoskeletal organization. Gene segregation into their cells of origin using reported high-confidence cell-type transcriptional signatures revealed most dysregulation and restoration of gene expression within podocytes, with moderate changes within mesangial cells and minimal changes within endothelial cells. IPA-based disease and toxicity algorithms developed from these cell-specific data also revealed enhanced cytoskeletal organization and improved cell viability after both GC and PIO vs. PAN.

Conclusions: GC and PIO treatment reduced proteinuria similarly in NS, but by inducing alterations in both distinct and overlapping glomerular gene sets. Notably, informatics analyses of overlapping genes identified ECM proteins, as potential novel targets for future therapies for NS, distinct from current immunosuppressive approaches.

Novel Podocyte Protective Compounds Identified Using Ultra-Miniaturized High-Content Screening (HCS) Assays
Manuel Noben,1 Daniil Qavi,1 Shreyaa Khanna,1 Ha Won Lee,1 Mehetem M. Alfittas,1 Jochen Reiser,1 Susanne Heynen-Genel,2 Vinetc Gupta.1 1 Rush University Medical Center, Chicago, IL; 2 Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA.

Background: Podocytes are specialized epithelial cells which are part of the filtration barrier in the kidney. Podocyte dysfunction is part of kidney pathologies hallmarked by proteinuria. Using a high-content imaging based assay, we have shown that podocytes can be used to identify novel therapeutic compounds.

Methods: Differentiated mouse podocytes were seeded on collagen-I coated multi-well plates. After 10-14 days of differentiation, cells were exposed to puromycin aminonucleoside (PAN, podocyte injury inducing agent), with compounds from the screening library or newly identified targets, or DMSO as control, for 48 hours. After, cells were fixed with 4% paraformaldehyde and permeabilized with 0.1% Triton X-100. Cells were labeled with cytoplasmic stain HCS CellMask Green, and actin fibers were detected by using labeled phalloidin. Cell images were taken with using Opera High-Content Imaging (HCS) System. Columbus software was used to quantify morphology properties such as roundness, as well as the overall F-actin signal. We utilized commercial libraries containing >50k unique compounds to identify podocyte protective hits.

Results: Using PAN as a podocyte damaging agent, we noticed marked reduction in F-actin fiber numbers and intensity, and increased roundness in podocytes. Screening of a library of chemical compounds identified >25 hits which had favorable profiles.

Conclusions: Using our optimized podocytes high-throughput screening assay in 1536-well plates, we have identified a number of highly novel compounds. Further mechanistic studies provide new insights about podocyte pathways that can be therapeutically targeted.

PO2007
The Role for FNBP1L in Podocytes
Qiaoli Tang, Lu Ren, Hui Song, Zhang Sipan, Zheng Tang, Shaolin Shi. Jining Hospital National Clinical Research Center of Kidney Diseases, Jining General Hospital of Jining Military Command Research Institute of Nephrology, Jining, China.

Background: Podocytes exhibit a complex cellular morphology characterized by the formation of foot processes. The normal structure of podocytes depends on their unique cytoskeleton, which is composed of subunit components and actin monomers. The rate limiting step in actin polymerization is the interaction between actin monomers and the barbed end of actin filaments. The podocyte may be the rate limiting step in actin polymerization. There are two distinct nucleotides for actin nucleation in podocytes, Arp2/3 complex and formin, which mediate branch and linear actin filament formations, respectively. We previously identified hundreds of genes expressed in every single podocyte, which were potential podocyte essential genes. Of them, FNBP1L is known to be involved in Arp2/3 complex and formin activity in nuclear, supporting FNBP1L’s essentiality for podocytes. Here, we test this hypothesis.

Methods: Cultured podocytes were used for this study. FNBP1L was knocked down by siRNA, and immunostaining, immunoblotting, qPCR, wound healing assay, and immunoprecipitation were performed to test FNBP1L’s essentiality and mechanism.

Results: FNBP1L was specifically expressed in podocytes in glomeruli, and its expression was decreased in purinycin aminonucleosides-treated in podocytes, where FNBP1L was knocked down, we found that the expression of WT1, SYNO and CD2AP was decreased; that the migratory capability was impaired; that F-actin stress fibers were reduced and disorganized; and that focal adhesion number was decreased while their size increased as shown by p-FAK staining. Mechanistically, FNBP1L regulated Arp2/3 complex and IN2 (a formin) actin nucleation activities. Co-IP and IF showed that FNBP1L colocalized and interacted with CDC42 and N-WASP to facilitate interaction of N-WASP with Arp2/3 complex, thereby increasing the activity of Arp2/3 complex in actin nucleation involved with IN2 and affected its localization in cytoplasm and its actin nucleation. Consistently, the reduction of FNBP1L impaired the interaction between N-WASP and Arp2/3 complex and mis-localized IN2 in the cytoplasm.

Conclusions: FNBP1L may regulate branch and linear actin filament podocytes by regulating Arp2/3 complex and IN2 actin nucleation activities in podocytes, thereby maintaining podocyte normal structure and function. Reduction of FNBP1L expression is involved in podocyte injury and targeting FNBP1L may represent a novel therapeutic approach for podocyte injury.

Role of ATE1 in Radiation-Induced Nephrotoxicity
Anis Ahmad,1 Cameron Bader,2 Saba Ansari,1 Jumana Afaghani,1 Sandra M. Merscher,1 Alessia Fornoni,1 Yousef Zeidman,2 Robert B. Levy,1 Brian Marples.1 Radiation Oncology, Department of Radiation Oncology, University of Miami, Miller School of Medicine, Miami, FL; 2Department of Radiation Oncology, Anatomy, Cell Biology, and Physiology, American University of Beirut School of Medicine, Beirut, Lebanon; 3Peggy and Harold Katz Family Drug Discovery Center and Division of Nephrology, Department of Medicine, University of Miami, Miami, FL; 4Department of Nephrology, University at Buffalo School of Medicine and Dental, Dentistry, Rochester, NY; 5Department of Microbiology and Immunology, Miller School of Medicine, University of Miami, Miami, FL.

Background: Arginylation increases arginine availability for Arg1 and other enzymes. However, the effect of radiation therapy (RT) on arginylation is not known. This study investigated the impact of RT on arginylation in nephrotoxicity.

Methods: Human podocytes were irradiated with 4 Gy, and preced by rituximab mAb (100 μg/mL) or IgG (100 μg/mL) treatment, 30 min before RT. Additionally, 8-6-week-old C57BL/6 male and female mice were submitted to either (i) 1x14Gy bilateral kidney-only RT (ii) unilateral total body irradiation (TBI 10.5Gy) and rescued by strain-donor hematopoietic stem cell transplantation (HSCT) or (iii) left untreated (sham control). Functional, histopathological, and biochemical changes were studied at baseline and 10 weeks post RT.

Results: In podocytes, RT (4Gy) produced time-dependent downregulation of ezrin (30%) and ATE1 (50%) and a significant increase in apoptosis at 4h (p<0.001). Rituximab pretreatment protected against ezrin relocalization and ATE1 downregulation and podocyte apoptosis. In C57BL/6 mice, RT significantly decreased glomerular surface area and increased mesangial expansion scores in 14Gy and TBI animals compared to controls (p<0.05). Similarly, both RT schedules resulted in significant increases in renal fibrosis (p<0.01), serum BUN (p<0.01), and serum creatinine levels (p<0.01). Western blot analysis showed downregulation of ATE1 in the kidney cortex: 67.7±9.6% (14Gy); 69.3±13.3% (TBI) compared to control. Similarly, IHC data showed a decrease in ATE1 expression in glomeruli after 14Gy (30%) and TBI (70%) compared to control. Podocyte nuclei number in the kidney cortex, also decreased significantly after both RT treatments. TEM showed that both RT schedules resulted in significant increases in GBM thickness when compared to control (p<0.001). Foot process width also increased significantly in 14Gy and TBI animals compared to controls (p<0.001).

Conclusions: Our study demonstrates that rituximab pretreatment protects from ATE1 downregulation and confers radioprotective effects in cultured podocytes. ATE1 may be an important therapeutic target for radiation-induced kidney injuries in HSCT patients.

PO2009
Podocyte Inflowing Glomerulopathy: New Disease or Pattern of Injury?
Sri Vibhavari Guntupalli, Suzanne G. Martin. Saint Vincent Hospital, Worcester, MA.

Introduction: Occasional podocyte inflowing is reported in membranous nephropathy, but global and diffuse inflowing is rare. Whether this is a new disease entity or a pattern of podocyte inflowing may influence therapy.

Case Description: 52-yr-old female with hypertension developed lower extremity edema, pleuritic chest pain and dyspnea. CT chest showed bilateral pulmonary emboli. Creatinine was 0.92 mg/dL, cholesterol 239 mg/dL, albumin 3.2 g/dL, urine protein:Cr ratio 32.647 mg/gCr. Renal biopsy showed immune complex deposition in a membranous pattern, and subepithelial deposits with targeted microvascular substructures, suggesting a podocyte inflowing glomerulopathy (PIG) [Fig.1 Electron microscopy showing PIG]. Immune deposits were dominantly reactive for IgG4, and also for other IgG subclasses, C3, IgM, and kappa and lambda light chains. Deposits were reactive for PL2AR. Serum PL2AR antibody and other serologies were negative. He was anticoagulated and treated for 6 months with the modified Ponticelli protocol. Creatinine remains normal, but hypoalbuminemia and proteinuria (190mg – 1.2g/p) persist 8 months after starting treatment.

Discussion: In 1985, Dales and Wallace [1] described massive deposits of spherical organelles in the subepithelial space of glomerular capillary walls in a patient with membranous nephropathy. In 2008, Joh et al [2] studied 25 Japanese patients with microspheres and microtubular structures associated with podocyte inflowing, conferring the term “podocyte inflowing glomerulopathy.” Rare cases are reported in India, Latin America and South Africa. It is unclear whether PIG is a subtype of membranous nephropathy or a distinct glomerular lesion. Identification of PIG associated with vesicoureteral reflux, myeloma, and autoimmune diseases, and the absence of immune complexes in many biopsies, suggest a distinct type of podocyte injury. Ultimately, the pathophysiology of PIG is not well understood. Response to therapy and prognosis are not well-defined. This patient was treated with the modified Ponticelli protocol, given findings of membranous nephropathy, with a reduction in proteinuria but not full remission. This may represent a partial response to therapy or may imply that podocyte inflowing glomerulopathy is a separate disease entity not responsive to immunosuppression.

PO2010
CVD Remodels Skeletal Muscle Metabolism Toward Carbohydrate Oxidation
Keith G. Avin,1,2 Neal X. Chen,2 Shruthi Sriyinivasan,3 Meghan C. Hughes,3 Thomas Oconnell,2 Robert L. Bacalla,2 Christopher G. Perry,2 Sharon M. Moe,1 Indiana University Purdue University at Indianapolis, Indianapolis, IN; 2Indiana University School of Medicine, Indianapolis, IN; 3York University, Toronto, ON, Canada.

Background: Skeletal muscle health progressively declines from chronic kidney disease (CKD). To test the hypothesis that exercise mitigates abnormal muscle metabolism in CKD, we utilized high-resolution mitochondrial respiration and metabolomics techniques for indices of skeletal muscle carbohydrate and fat metabolism in a progressive CKD rat model.

Methods: Animals. 1) Cy/+ (CKD) rats, 2) CKD + wheel running, and 3) normal littermates (NL) (N=12/g). Running wheel was accessible 24 h/day 25-35 weeks of age; normal diet, food and water. We used CKD rats, representing CKD, whose chronic kidney disease was maintained by 6/0 Polyethylene glycol-6000 injection to one kidney. Normal mice served as controls. In 1985, Dales and Wallace [1] described massive deposits of spherical organelles in the subepithelial space of glomerular capillary walls in a patient with membranous nephropathy. In 2008, Joh et al [2] studied 25 Japanese patients with microspheres and microtubular structures associated with podocyte inflowing, conferring the term “podocyte inflowing glomerulopathy.” Rare cases are reported in India, Latin America and South Africa. It is unclear whether PIG is a subtype of membranous nephropathy or a distinct glomerular lesion. Identification of PIG associated with vesicoureteral reflux, myeloma, and autoimmune diseases, and the absence of immune complexes in many biopsies, suggest a distinct type of podocyte injury. Ultimately, the pathophysiology of PIG is not well understood. Response to therapy and prognosis are not well-defined. This patient was treated with the modified Ponticelli protocol, given findings of membranous nephropathy, with a reduction in proteinuria but not full remission. This may represent a partial response to therapy or may imply that podocyte inflowing glomerulopathy is a separate disease entity not responsive to immunosuppression.

Conclusions: These intriguing results indicate CKD impairs skeletal muscle mitochondrial oxidative capacity despite increased pyruvate oxidation. In addition, the metabolomics data suggests impaired fatty acid oxidation that worsened with wheel running due to low carnitine levels. These results suggest dual alterations in response to mild exercise in CKD: 1- impaired fatty acid oxidation from deficient carnitine; 2- enhanced pyruvate oxidation consistent with lower lactate production. These cellular metabolic reprogramming events suggests that skeletal muscle may shift away from fatty acid metabolism towards carbohydrates which may explain why patients with CKD do not experience the usual benefit of exercise.

Podocyte-Derived Testican 2 Promotes In Vitro Glomerular Angiogenesis
Donghai Wen,1 Debby Ngo,1 Benjamin D. Humphreys,2 Martin R. Pollak,3 Robert Gerzsten,3 James G. Wilson,3 Eugene P. Rhee,3 1Massachusetts General Hospital, Boston, MA; 2Washington University in Saint Louis, Saint Louis, MO; 3Beth Israel Deaconess Medical Center, Boston, MA.

Background: In addition to their fundamental role in clearance, the kidneys release select molecules into the circulation, but whether any of these anabolic functions provides insight on kidney function is unknown.

Methods: Using aptamer-based proteomics, we characterized arterial (A) to renal venous (V) gradients for >1,300 proteins in 22 human individuals who underwent invasive sampling. To localize testican-2, immunohistochemistry, immunofluorescence, immunogold electron microscopy and single cell RNA sequencing in human kidney tissue were used. Functional effects of testican-2 were tested on cultured primary human glomerular endothelial cells (HGEC).

Results: Although most of the proteins that changed significantly decreased from A to V, consistent with renal clearance, several were found to increase, the most significant of which was testican-2 (V/A = 1.40, P = 1.5 x 10^-9). Imaging and single cell RNA sequencing demonstrated testican-2 expression in human podocytes. Testican-2 promoted angiogenesis and migration in cultured HGEC, but not proliferation. Further, testican-2 upregulated MMP-2/MMP-9 activity in the culture media of HGEC.

Conclusions: Testican-2 is a circulating protein that is synthesized in the human podocyte. Testican-2 promotes angiogenesis in cultured HGEC, which may be mediated by upregulating MMP-2/MMP-9 activity and increased endothelial cell migration.

PO2012
Mitochondrial Quality Control Mechanisms in Renal Cortex During the Normoalbuminuric Stage of Diabetes Mellitus
Nasihito Ishii,1 Pamela K. Carmine,2 Yoshifumi Kurosaki,1 Akemi Imoto,1 Hideki Ikenaga,2 Masanori Yokoba,1 Takafumi Ichikawa,1 Tsuneo Takenaka,3 Masato Katagiri.1 1Kisatu University, Sagamihara, Japan; 2University of Nebraska Medical Center, Omaha, NE; 3International University of Health & Welfare, Minatoku, Japan; 4Seikai, Tochigi, Japan.

Background: Oxidative stress during the normoalbuminuric stage of type 1 diabetes mellitus (DM) damages renal cortical mitochondria. Because accumulation of damaged mitochondria can contribute to renal dysfunction, we aimed to determine if oxidative stress in DM triggered 1) mitochondrial fission or fusion, 2) increased fatty acid metabolism, and 3) mitophagy as quality control mechanisms.

Methods: Rats receiving i.p. injection of streptozotocin (STZ, 65 mg/kg) or vehicle (Sham) were either left untreated or treated with telmisartan (TLM, an angiotensin receptor blocker; 10 mg/kg/d). Two weeks later, blood glucose levels (BG), blood pressure (BP), glomerular filtration rate, and urinary excretion of albumin and N-acetyl-β-D-glucosaminidase (NAG) were measured. The oxidative stress marker, 3-nitrotyrosine (3-NT), was detected by HPLC. Fission-, fusion-, and mitophagy-related proteins were quantified by Western blot. Levels of acylcarnitine, which transports fatty acids into mitochondria via SLC25A10 (3-NT), was detected by HPLC. Fission-, fusion-, and mitophagy-related proteins were quantified by Western blot. Levels of acylcarnitine, which transports fatty acids into mitochondria via SLC25A10, and the expression of muscle atrophy related genes (quantitative-PCR).

Results: In mice treated with vehicle, exercise tolerance was deteriorated and gastrocnemius muscle wet weight was decreased compared to the control group. Intriguingly, IS administration also reduced a cross-sectional area of fast twitch myofiber and protein levels of fast twitch myosin heavy chain. Also, IS treatment tended to upregulated miRNA expression of muscle atrophy related genes (quantitative-PCR).

Conclusions: IS induces direct sarcopenic effect on mouse skeletal muscle and predominantly decreases on fast-twitch muscle fibers. In the future, we will further investigate the molecular mechanism of uremic toxin induced sarcopenia.

PO2013
Indoxyl Sulfate Modulates Expression of Myosin Heavy Chain Isoforms and induces Sarcopenic Phenotype in Mouse
Takaki Higashihara, Hiroshi Nishi, Koji Takemura, Masao Nangaku. Division of Nephrology and Endocrinology, Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Japan.

Background: In patients with chronic kidney disease, sarcopenia is frequently associated with decreased renal function and correlates with increased morbidity and mortality. However, the molecular mechanism to underlie uremic sarcopenia is not fully elucidated yet. We hypothesized that the accumulation of uremic toxin might have a direct negative effect on skeletal muscle, and investigated the mechanism of indoxyl sulfate (IS) induced toxicity on mouse skeletal muscle.

Methods: We conducted the in vivo experiments using C57BL/6 mice. After unilateral nephrectomy, vehicle (PBS) or high dose IS was intraperitoneally administered daily for 1 week, and evaluated exercise tolerance (treadmill fatigue test and four limbs grip test), skeletal muscle wet weight, cross-sectional area, and protein levels of myosin heavy chain.

Results: We confirmed the in vivo experiments using C57BL/6 mice. After unilateral nephrectomy, vehicle (PBS) or high dose IS was intraperitoneally administered daily for 1 week, and evaluated exercise tolerance (treadmill fatigue test and four limbs grip test), skeletal muscle wet weight, cross-sectional area, and protein levels of myosin heavy chain.

Conclusions: IS induced sarcopenic effect on mouse skeletal muscle and predominantly decreases on fast-twitch muscle fibers. In the future, we will further investigate the molecular mechanism of uremic toxin induced sarcopenia.

PO2014
Lnc-Gm43360 Regulates TCMK-1 Seneescence by the miR-141/Sirt1 Pathway
Jie Li, Hongli Jiang, Lei Chen. The First Affiliated Hospital of Xi’an Jiaotong University, Xi’an, China.

Background: Aging is a complex process, which will lead to the gradual decline of physiological functions of all organs. The kidney, which is a metabolically active organ, is extremely susceptible to aging, but the mechanism of kidney aging is not clear. Long-chain non-coding RNA (lncRNA) is an non-coding RNA consisting of 200 nucleotides, which play an important role in kidney fibrosis and diabetic nephropathy, but there is no study on kidney senescence.

Methods: Detection of lnc-Gm43360 expression by qRT-PCR. Transfection with lnc-Gm43360 siRNA and overexpressed plasmid to measure the miR-141 and Sirt1 expression by qRT-PCR, and the p53, p21 and p16 expression by western blot, and SA-β-gal expression. Transfection with miR-141 mimic and inhibitor to measure Sirt1 expression by qRT-PCR, and p53, p21 and p16 expression by western blot, and SA-β-gal expression.

Results: Lnc-Gm43360 expression in 24-month-mouse lower than 3-month-mouse kidney tissue. The induction of Lnc-Gm43360 expression significantly increases miR-141 expression, decrease Sirt1 expression on both the mRNA and protein level, and induces the SA-β-gal expression. miR-141 mimic and inhibitor decrease and increase Sirt1 expression. Lnc-Gm43360 negatively regulates miR-141 expression and positively negatively regulate Sirt1 expression at both the mRNA and protein level. The function of Lnc-Gm43360 in regulating Sirt1 expression depends on modulating miR-141 expression.

Conclusions: Lnc-Gm43360 can induce TCMK-1 seneescence by miR-141-Sirt1 pathway.

PO2015
Modified Lipoproteins Modulate Renal Lymphatic Vessel Vasodynamics via NKCC1 on Lymphatic Endothelial Cells
Jianyong Zhong, Jing Liu, Elaine L. Shelton, Eric J. Delprie, Huiyang Chung, Valentina Kon. Vanderbilt University Medical Center, Nashville, TN.

Background: In addition to its pivotal role in chloride transporting epithelia, the sodium-potassium–chloride cotransporter 1 (NKCC1) is increasingly recognized as a key modulator of vascular tone. We previously documented NKCC1 expression in renal lymphatic endothelial cells (LECs) of rats and cultured human LECs. Ex vivo we showed that blocking NKCC1 by furosemide caused a dose-dependent dilatation in renal lymphatic vessels, decreased amplitude, and decreased frequency of spontaneous contractions. Since lymphatic vessels clear interstitial lipids and kidney injury increases lipid peroxidation products including isolevuglandins (IsoLG) which modify lipoproteins (apoAI), we examined the role of IsoLG-modified apoAI can affect renal lymphatic vessel contractility through NKCC1.

Methods: Purumycin nephrotoxicity (PN) was induced in Sprague Dawley rats, while non-injected rats served as controls (Cont). Renal lymphatic vessels were isolated and mounted in a perfusion chamber to assess vasoreactivity. The effects of apoAI or IsoLG-apoAI on the NKCC1 signaling pathway were assessed in LECs.

Results: PAN rats had significantly higher renal lymph flow which contained significantly more IsoLG vs Cont. Ex vivo studies showed renal collecting lymphatic vessel diameters from PAN were more dilated than Cont. Immunoreactive revealed NKCC1 expression on LECs that was more prominent in PAN renal lymphatic vessels vs Cont.

**Progranulin Deficiency Exacerbates High-Fat Diet-Induced Inflammation in Kidney**

Maki Murakoshi, Tomohito Gohda, Yusuke Suzuki. *Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan.*

**Background:** Progranulin (PGRN) has been reported to bind to tumor necrosis factor (TNF) receptor (TNFR) and inhibit TNFα signals. Conversely, PGRN is a ‘bad’ adipokine that can contribute to insulin resistance in some metabolic diseases. We evaluated the effect of augmentation of TNFα signals by PGRN deficiency on the progression of kidney injury in high-fat diet-induced obesity model mice.

**Methods:** Eight-week-old PGRN knockout (KO) mice and their wild-type (WT) mice were fed a standard diet or high-fat diet (HFD) for 12 weeks. Mouse proximal tubule (mProx24) cells knocked down with PGRN siRNA were treated with TNFα stimulation.

**Results:** The body weight and albuminuria were significantly increased in WT-HFD group compared with WT-standard diet (SD) group. The body weight of KO-HFD group was significantly decreased compared with WT-HFD group. However, albuminuria and the expression of renal inflammatory markers including TNFα in KO-HFD group were increased than those in WT-HFD group. On the other hand, the WT-HFD mice showed vacuolar changes in the proximal tubule, but KO-HFD mice did not. Immuno-histochemical analysis showed that vacuolar membranes were clearly positive for a lysosomal marker, LAMP-1, suggesting impairment in lysosomal function. The expression of mglalin which plays a critical role in the reabsorption of protein in proximal tubules was found to be decreased in KO mice compared with WT mice, and also reduced in mProx24 stimulated with TNFα.

**Conclusions:** PGRN deficient exacerbated renal inflammation caused by high-fat diet, while the results also showed improvement in tubular vacuolation. Anti-inflammatory treatment with PGRN for kidney diseases should be considered based on the opposing function of PGRN.

**Diet Has a Stronger Impact on the Gut Microbiota Than Kidney Function in Rats with Moderate CKD**

Amabel Biruete,1 Tzu-Wen L. Cross,2 Stephen R. Lindemann,3 Kelly Swanson,3 Neal X. Chen,3 Sharon M. Moc.1 *Indiana University School of Medicine, Indianapolis, IN; Purdue University, West Lafayette, IN; University of Illinois at Urbana-Champaign, Urbana, IL.*

**Background:** Diet and CKD have been shown to alter the gut microbiota. However, whether diet or kidney function plays a stronger role in the gut microbiota in moderate CKD is not well established. We assessed the effects of two diets on the gut microbiota in rats with moderate CKD.

**Methods:** C57BL/10 (C57) and normal (Norm) littermates (NL) consumed an autoclaved grain-based diet containing 7.5% phosphorus (0.3% phytate-bound) and 3.5% crude fiber from birth. At 17-wk-old, half of the animals were maintained on the same diet (Grain) and the other half switched to a semi-purified casein-based diet containing 0.7% phosphorus (0% phytate-bound, 0.6% phosphate additives) and 5% non-fermentable cellulose (Casein) until 28-wk-old (n=10 rats/group). DNA was extracted from cecal and fecal samples collected at euthanasia, the V4 region of the 16S RNA gene was sequenced via Illumina MiSeq, and data were analyzed using QIIME2 and LEfSe.

**Results:** Intestinal microbial α-diversity, or diversity within a sample, was significantly greater in rats fed the grain diet compared to casein diet regardless of kidney function. Diet and kidney function both had significant impacts on microbial β-diversity (diversity between samples), but diet explained a larger portion of the observed variability (27%) than kidney function (11.5%). Consumption of the grain-based diet increased many genera with short-chain fatty acid (SCFA) producing capacity, including *Bifidobacterium, Ruminococcus, Roseburia,* and *Prevotella* than the casein diet. Whereas the casein diet drove greater *Bacteroides* abundance that can metabolize tryptophan to indoles, which may exacerbate the formation of uramic toxins. Notably, the casein diet led to a greater abundance of *Bifidobacterium* in NL rats and greater *Allotriorchis* in CKD. Both of these taxa have been shown to be linked to reduced progression of inflammatory bowel disease. Additionally, CKD rats fed the casein diet had a higher relative abundance of *Akkermansia,* which has been shown to be greater in fiber-free or low fiber interventions, as it may degrade the mucus layer.

**Conclusions:** In rats with moderate CKD, diet had a stronger effect on diversity and gut microbial taxonomic differences than kidney function. Particularly, those fed the grain-based diet had higher bacterial genera known to produce SCFA.

**PO2018**

**Effect of High Fiber or Probiotics-Enriched Diets on Kidney Injury in Mice Model of Bilateral Ischemia Reperfusion**

Shirin Pourashfar, Nabin Poudel, Nataliya Skrynnyk, Junlan Yao, Mark D. Okusa. *University of Virginia Health System, Charlottesville, VA.*

**Background:** Changes in dietary intake have a significant effect on the incidence and development of chronic kidney disease (CKD). The progressive decline in kidney function during CKD can lead to increased systemic chronic inflammation and worsening of kidney injury. Fibers and probiotics are used by gastrointestinal bacteria to produce metabolites with anti-inflammatory activities. The objective of our study was to investigate the role of fiber and probiotics in ameliorating kidney injury using bilateral ischemia reperfusion (IR) surgery as a CKD model in mice.

**Methods:** Thirty-six C57BL/6J wild type, male mice were purchased from the Jackson Laboratory (Bar Harbor, ME, USA). After co-housing for a week, they were then isolated and randomly assigned to a diet: normal chow (C; control), high fiber (HF; modified AIN-93G with increased Hi-Maize Corn), and probiotics (P; AIN-93G with added *Bifidobacteria* spp.). After 14 days, mice underwent sham surgery (5 per group) or IR surgery (7 per group) and then received assigned diet for 28 days. Blood and fecal samples were collected both before surgery and after surgery. Mice were euthanized after 42 days to collect kidneys, small intestine, colon, fecal, and blood samples. Measurements of plasma creatinine, markers of kidney injury, and tissue staining were performed. Fecal samples were further processed to assess diversity of gut microbiota. Two-way ANOVA with Tukey’s multiple comparisons was used for statistical analysis.

**Results:** On each diet, the IR increased serum creatinine compared to sham (p<0.05). However, both HF and P showed the best protection against kidney injury, compared to C (p<0.05). The histology sections in control group appeared to be more fibrotic compared to the other two groups. The sequencing of 16s rRNA gene was completed and is currently being used to assess the composition and diversity of gut microbiota in each group.

**Conclusions:** Supplementation with fiber or probiotics may reduce kidney injury after ischemia. Additional studies to identify specific changes in metabolites driving this protection are needed.

**Funding:** Other NIH Support - T32 DK072922

Dietary Fat Intake and Mortality Across Kidney Function in a Nationally Representative Cohort

Kamyar Kohantebash,1 Yoko Yoneda,2 Dietz,3 Madhumita Narasimhan1,2, Sankar D. Navaneethan,3 Ying Chen4, Amanda H. Anderson1, Laura M. Demler1, Harold I. Feldman1, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 2University of Illinois at Chicago College of Medicine, Chicago, IL; 3Johns Hopkins University, Baltimore, MD; 4Baylor College of Medicine, Houston, TX; 5Tulane University School of Medicine, New Orleans, LA; 6Tulane University, New Orleans, LA; 7University of Michigan, Ann Arbor, MI; 8University of California San Diego School of Medicine, San Diego, CA; 9Wayne State University School of Medicine, Detroit, MI.

Background: In the general population, lower dietary intake of saturated fatty acids (SFA) and higher intake of polyunsaturated fatty acids (PUFA) are associated with greater survival. However, the optimal amount and type of dietary fat intake in patients with kidney disease is unknown. We assessed the relationship between dietary fat intake and mortality in a cohort of US adults with and without kidney disease.

Methods: In the general population, lower dietary intake of saturated fatty acids (SFA) and higher intake of polyunsaturated fatty acids (PUFA) are associated with greater survival. However, the optimal amount and type of dietary fat intake in patients with kidney disease is unknown. We assessed the relationship between dietary fat intake and mortality in a cohort of US adults with and without kidney disease.

Results: Among 37,155 participants who met eligibility criteria, 7% (N=2,677) had kidney dysfunction. In participants with normal kidney function, those with the highest tertile of SFA intake had higher mortality risk compared to their counterparts (HRs (95%CI) 1.21 (1.04, 1.41) and 1.13 (0.97, 1.31), respectively; however, PUFA was not associated with mortality. In participants with kidney dysfunction, SFA intake was associated with a higher mortality risk and trended towards higher mortality, respectively: HRs (95%CI) 1.21 (1.04, 1.41) and 1.13 (0.97, 1.31), respectively; however, PUFA was not associated with survival. In participants with and without kidney dysfunction, MUFA intake was not associated with mortality.

Conclusions: Higher dietary SFA intake was associated with a higher mortality in US adults with and without kidney dysfunction, whereas higher PUFA intake was associated with greater survival in those with preserved kidney function only. Further studies are needed to elucidate mechanisms behind the association of dietary fat intake with mortality.

PO2021

Predictors of Healthy Behavior Engagement in CKD

Sarah J. Schrauben,1 Jesse Y. Hsu,1 Julie A. Wright Nunes,1 Ana C. Ricardo,2 Michael J. Fischer,3 Raquel C. Greer,3 Cheryl A. Anderson,4 Madhumita J. Mohanty,2 Sankar D. Navaneethan,3 Jing Chen4, Amanda H. Anderson1, Laura M. Demler1, Harold I. Feldman1, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 2University of Illinois at Chicago College of Medicine, Chicago, IL; 3Johns Hopkins University, Baltimore, MD; 4Baylor College of Medicine, Houston, TX; 5Tulane University School of Medicine, New Orleans, LA; 6Tulane University, New Orleans, LA; 7University of Michigan, Ann Arbor, MI; 8University of California San Diego School of Medicine, San Diego, CA; 9Wayne State University School of Medicine, Detroit, MI.

Background: Guidelines for chronic kidney disease (CKD) management recommend healthy behaviors to mitigate disease progression, but behavior engagement is low. Identifying predictors of behavior engagement could inform strategies to increase healthy behaviors.

Methods: Using data from the Chronic Renal Insufficiency Cohort Study, potential predictors of behavior engagement included demographics, clinical and psychosocial factors, and behaviors at baseline. We dichotomized behaviors (recommended vs. not): smoking (no vs. current), body mass index (BMI <18.5 or ≥30 kg/m2), physical activity (>150 vs <150 minutes/week), diet (score of ≥2 vs 0-1), and hemoglobin A1c (<7 vs ≥7) if diabetes. Relationships between predictors and behaviors at 2 years were estimated by multinomial adjusted logistic regression models.

Results: Among 5,209 participants at baseline, mean age was 60 years, mean eGFR was 48 ml/min/m2, and 51% had diabetes. In multivariable analyses, baseline behaviors were most strongly associated with behaviors at 2 years. Higher SF-12 physical component scores, which relate to better physical function and pain control, associated with recommended behaviors at 2 years. In models that did not adjust for baseline behaviors, no smoking was associated with older age, female sex, and non-White race, but the other behavior associations were not notably changed.

Conclusions: Interventions to increase healthy behavior engagement should be implemented and tested to evaluate whether they improve physical function and pain control, and possibly mitigate CKD progression.

Impact of Participation in Food Assistance Programs Among NHANES Dialysis Patients from 2001-2016

Hannah Chen, Lea Borgi. Brigham and Women’s Hospital, Boston, MA.

Background: Food insecurity and malnutrition are recognized risk factors for poor outcomes and mortality among end-stage renal disease (ESRD) patients on dialysis. However, little is known about the effect(s) of participation in food assistance programs such as Supplemental Nutrition Assistance Program (SNAP) on outcomes among dialysis patients.

Methods: This is a cross-sectional analysis of dialysis patients in the National Health and Nutrition Examination Survey (NHANES) cohorts from 2001-2016. Food assistance program participation was self-reported as part of the NHANES interview. Differences in baseline characteristics were determined through null hypothesis testing. Logistic and linear regressions were used to examine the association between food assistance program participation and outcomes including hospitalizations and albumin as
a marker of nutrition status. The analyses were adjusted for demographics, BMI, diabetes, hypertension, and hyperlipidemia.

Results: A total of 156 dialysis patients were analyzed across all NHANES cohorts. Dialysis patients receiving food assistance were more likely to be younger, female, and obese (p<0.05). Food assistance participants had significantly larger household size, but lower income and lower levels of post-secondary education (p<0.05). These patients also reported significantly higher daily sugar intake. Dialysis patients receiving food assistance were significantly more likely to report very low food security and less likely to report full food security. Specifically, they reported more concerns regarding food running out, food not lasting, and not being able to afford balanced meals. Approximately 30% of dialysis patients report food insecurity but do not participate in food assistance programs. When adjusted to be representative of the non-institutionalized U.S. population, there was a non-significant trend towards increased hospitalization among dialysis patients on food assistance programs (OR 1.73 [95% CI: 0.42-7.12]). There was a non-significant negative correlation between food assistance program participation and serum.

Conclusions: Food assistance programs are not widely used among dialysis patients, even when patients report food insecurity. Food assistance program participation among dialysis patients did not significantly impact hospitalizations and serum albumin.

Tanushree Banerjee,1 Deidra C. Crews,2 Charles E. McCulloch,1 Nilka Rios Burrows,2 Karen R. Siegel,3 Rajiv Saran,4 Yuo Han,5 Neil R. Powe.1
1University of California San Francisco, San Francisco, CA; 2Johns Hopkins University, Baltimore, MD; 3Centers for Disease Control and Prevention, Atlanta, GA; 4University of Michigan, Ann Arbor, MI.

Background: Food insecurity has been associated with CKD and its progression. Trends in food insecurity among adults with CKD have not been well characterized in the US population, particularly across racial/ethnic groups.

Methods: Data from NHANES from 2003-2016 were used to estimate the prevalence of food insecurity among individuals with CKD (defined by albuminuria or eGFR 15-59 ml/min/1.73 m2) overall and by racial/ethnic group. We included individuals aged 20 years and with a household income≤400% of the federal poverty level (n=3180). Food insecurity was defined as ≥3 yes responses on the 18-item questionnaire. Racial/ethnic groups were defined as non-Hispanic white (NHW) and non-NHW. Survey years were collapsed into time periods 2003-2006, 2007-2010, and 2011-2016. Prevalence rates were estimated after standardization to the 2010 age population distribution from the US Census.

Results: Overall prevalence of food insecurity in adults with CKD was 19.9%. During the period, the age-standardized prevalence rate of food insecurity increased from 5.7% to 32.8% among NHW and from 23.2% to 35.8% among non-NHW (p-trend=0.001). After adjusting for age, sex, education level, and annual household income, non-NHW had a significantly higher prevalence of food insecurity compared to NHW in 2007-2010 but not in 2003-2006 or 2011-2016 (Figure).

Conclusions: From 2003 to 2016, food insecurity among both NHW and non-NHW increased significantly among non-NHW compared to NHW during 2007-2010. One potential explanation may be the US economic recession during that period. Targeted interventions such as medically tailored meals for individuals with CKD and poverty may not in 2003-2006 or 2011-2016 (Figure).

PO2024 Approach to Nutritional Protein Intake in Hemodialysis Patients with Hyperphosphatemia: Associations with Mortality in the DOPPS
Suguru Yamamoto,2 Brian Biber,3 Hiroata Komada,3 Hiroki Kitabayashi,3 Takanozu Nomura,4 Alexi Cases,3 Christian Combe,3 Ronald L. Pisoni,1 Bruce M. Robinson,5 Masafumi Fukagawa.2 Arbor Research Collaborative for Health, Ann Arbor, MI; 3Nephrology, Graduate School of Medical and Dental Sciences, Niigata, Japan; 4Kyowa Kirin Co., Ltd., Tokyo, Japan; 5Tokai University School of Medicine, Isehara, Japan; 6Universitat de Barcelona, Barcelona, Spain; 7Université de Bordeaux, Bordeaux, France.

Background: Pt’s undergoing hemodialysis (HD) have poorer nutritional status than the general population, and worse nutritional status is associated with poor outcomes. Hyperphosphatemia is common in HD pts due to abnormal mineral and bone metabolism. Nephrologists manage hyperphosphatemia by prescribing phosphate binders and/or promoting dietary protein restriction; the latter may, however, adversely affect nutritional status. We address the hypothesis that, even in the presence of hyperphosphatemia, liberalizing dietary protein leads to better outcomes.

Methods: The analysis includes 11,628 HD pts in 12 countries in DOPPS phase 4 (2009-2011), from 254 facilities where the medical director reported facility practices. The primary exposure variable was response to the following question: “For pts with s. albumin 3.0 g/dl and phosphate 6.0 mg/dl, do you typically recommend to (A) increase or (B) not change/descrease dietary protein intake?” The primary outcome was all-cause mortality, analyzed by Cox regression. Linear regression was used to model associations between the exposure and intermediate nutrition markers. Models were adjusted for country, case-mix, and lab values.

Results: In the case scenario, 91% of medical directors in N. America recommended to increase protein intake compared to 58% in Europe (range=16-83% in 7 countries) and 56% in Japan. Advice to increase dietary protein intake was associated with 0.33 mg/dl higher s. creatinine levels (95% CI: 0.08-0.57) while clinically meaningful associations were not observed for s. albumin and phosphorus. Advice to increase dietary protein intake was weakly associated with lower mortality-HR (95% CI)=0.89 (0.77-1.03). The association with survival was stronger in pts with age ≥70 yrs and for those without diabetes (p=0.08 and 0.20 for interaction).

Conclusions: In this large international cohort study, the medical director’s preference to recommend increase in dietary protein intake for HD pts with low albumin and high phosphorus levels was most common in N. America and associated with higher s. creatinine levels and potentially lower all-cause mortality. Further research into the possible benefits of protein intake liberalization for HD pts, even in the presence of hyperphosphatemia, is warranted.

**PO2026**

Mediterranean Diet and the Risk of CKD: A Systematic Review and Meta-Analysis

Panupong Hansrivitit,1 Sharad Oli,1 Resha Khanal,1 Nasrollah Ghahramani,2 Charan P Tongpaprom,3 Wisit Charuhasinprasert,4 1UPTH, Prinmit, Harrisburg, PA; 2Pouw State College of Medicine, Hershey, PA; 3Mayo Clinic Minnesota, Rochester, MN; 4University of Mississippi Medical Center, Jackson, MS; 5Maimonides Medical Center, Brooklyn, NY

**Background:** Mediterranean diet has been shown to be associated with lower risk for cardiovascular disease. However, its association with chronic kidney disease (CKD) remains inconclusive as the results were not consistent among population-based studies. Thus, this study aims to assess the association between Mediterranean diet adherence and CKD prevention.

**Methods:** Ovid MEDLINE, EMBASE, and the Cochrane Library were searched from database inception to March 2020 without language restrictions. We included studies describing the risk for CKD in community-dwelling subjects ≥ 18 years of age. CKD was defined by eGFR < 60 mL/min/1.73m². Mediterranean diet adherence was assessed by standardized food frequency questionnaires. Meta-analysis and meta-regression analysis were used to evaluate the risk of CKD and the association between clinical factors and incidence of CKD, respectively.

**Results:** Of 168 citations, a total of ten (n = 19,151) and five studies (n = 9,099) were included in the systematic review and meta-analysis, respectively. Only studies adopting Mediterranean Diet Scale (MDS) were included in the meta-analysis. The mean score was 4.0 ± 0.1 points. The mean age was 53.1 ± 8.2 years. The mean eGFR was 77.3 ± 29.6 mL/min/1.73m². The average total daily energy intake was 1,989.4 ± 258.8 kilocalories per day. Up to 50.4% were male, 7.1% were black, and 14.9% had a history of diabetes mellitus. With the mean follow-up duration of 11.5 ± 9.5 years, the pooled adjusted odds ratio (OR) for CKD was 0.897 (95% CI, 0.865-0.930; I² = 9.5 years; p = 0.001). There was no significant association between age, black race, eGFR, and total daily energy intake vs. CKD incidence. The incidence of CKD was 0.028 events per person-year (95% CI, 0.012-0.044).

**Conclusions:** Mediterranean diet adherence was assessed by a 1-point increase of MDS was associated with 10% lower risk of CKD. However, this only applies to healthy individuals without a history of pre-existing CKD, whether Mediterranean diet adherence slows CKD progression is to be discovered.

**PO2027**

Attitudes Toward Plant-Based Eating (PBE), Self-Reported Habits, and Relationship to BMI and Blood Pressure in a Population of Inner-City CKD/ESKD Patients

Ahmad Saleh, Kingsley Cruickshank, Takisha Morancy, Iqra Nadeem, Mariana Markell. SUNY Downstate Health Sciences University, Brooklyn, NY.

**Background:** The benefits of a PBE dietary pattern are well described, yet there is scarcity in the literature on the attitudes of CKD/ESKD patients regarding PBE as well as their self-reported habits.

**Methods:** A face-to-face survey was conducted in a random convenience sample patients from CKD clinic (15), Transplant clinic (12), and the Dialysis Unit (4). Pts were asked to answer questions assessing their attitudes and understanding of PBE using a 5-point Likert scale, and to rate their daily vegetable intake. There was no difference noted in answers among the clinics so all data were analyzed together. All comparisons are by t-test unless noted.

**Results:** Mean age was 54.7±1.7 yrs. There were 16 (53%) men and 14 (47%) women, with 25 Black (81%), 12 people (40%) had an income < $20K, with 10 (33%) between $20K and $40K. 30 (103%) were employed, 64.5% (20) were interested in learning more about PBE; 35% had never heard of it. 227% reported consuming animal protein 1-3x/d or more. 20 (57%) reported consuming plant-based foods less <1/d or never. Pts who did not eat plant-based foods had a higher BMI than those who consumed plants 30.9±3.5 vs 29.1±1.86, p<0.05 (30.9±3.5 vs 26.9±1.86, p<0.05 and 77.9±3.5 vs 66.3±4.1, p=0.019). 46.4% thought it would be difficult to find things to eat at restaurants, 51.7% thought it would be difficult to buy food or groceries on a budget; 46.4% thought they could not get all the protein they need from plant-based foods without eating animal meat or products; 40.7% thought it would be hard to get all the vitamins and nutrients but 63.1% thought it would be easy to find recipes that taste good if they followed PBE.

**Conclusions:** In our population: 1. The majority of pts were interested in learning about plant-based diet but ate few to no vegetables on a daily basis. 2. Possible obstacles to introducing PBE in this populations are misconceptions including the difficulty of affording food, getting enough protein and finding something to eat when eating out, believed by almost half of those surveyed. 3. Intensive educational programs targeted towards our population should be developed as pts who ate more vegetables had lower BMI and both systolic and diastolic BP and in general PBE has been shown beneficial for pts with CKD/ESKD.

Higher Estimation of Dietary Phosphorus Content with More Plant-Based Protein in Hemodialysis Patients Across Race/Ethnicity Using 3-Day Food Records with Interviews

Amanda R. Tortorici,1 Connie Rhee,1 Amy S. You,1 Elani Streja,1 Keith C. Norris,2 Kamyar Kalantar-Zadeh,1 1University of California Irvine, Orange, CA; 2University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.

**Background:** Dietary phosphorus (P) restrictions are commonly recommended based on the estimated phosphorus (P) content of foods, not accounting for P type or its absorbability. Whereas plant-based diets have important benefits, they are traditionally not recommended to dialysis patients given perceived higher P content in plant vs. animal-based proteins, although P is less absorbable in plant foods. We examined dietary differences across race/ethnicity in a group of hemodialysis (HD) patients from several dialysis centers in Southern California.

**Methods:** The self-administered 3-day diet diary with face-to-face interview was conducted by a trained dietitian among 80 in-center HD patients, and the data were entered into a diet software (Nutrition Data System for Research), and dietary components of the individuals and subgroups were obtained.

**Results:** Patients were 57±15 years and included 25% Blacks, 36% Hispanics and 18% non-Hispanic Whites. Table shows dietary data across race/ethnicity. [Figure] Shows the association of the phosphorus-to-protein ratio with the percentage of plant protein, correlation coefficient r was 0.58 (p<0.001) for all including 0.28, 0.61 and 0.38 for Blacks, Hispanics and Whites, respectively.

**Conclusions:** Whereas estimated dietary potassium was not substantially different across race/ethnicity or different plant- vs. animal based protein proportions, dietary phosphorus content analyses may not account for varying phosphorus bioavailability across sources, which may lead to incorrect assumptions that higher plant-based protein for dialysis patients is associated with more phosphorus burden.

**Funding:** NIDDK Support

Benefits of Home-Delivered, Low-Sodium Meals in Hemodialysis Patients

Luis M. Perez, Hsin-Yu Fang, Brett Burrows, Alexis King, Sadia anjum Ashrafi, Kenneth R. Wilund. Renal and Cardiovascular Research Laboratory University of Illinois at Urbana-Champaign, Urbana, IL.

**Background:** Patients undergoing maintenance hemodialysis (HD) therapy are routinely counseled to reduce dietary sodium intake to reduce sodium retention, volume overload (VO), and hypertension. Unfortunately, low-sodium trials in HD are sparse and mostly indicate that dietary education and behavioral counseling alone are ineffective in reducing sodium intake. The purpose of this study is to determine if 4-weeks of a low-sodium home delivered meals intervention will reduce interdialytic weight gain (IDWG) and subsequent VO and hypertension in patients undergoing HD when compared to 4-weeks of a usual diet.

**Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only**
Methods: We recruited 20 subjects (55±12 years, BMI 40.7±16.6 kg/m², 45% male, 65% NA, 70% DM, 50% CVF) from a HD clinic in central IL. Participants followed a usual-control diet for the first 4 weeks. PurFoods, LLC prepared and shipped 3 low-sodium kidney meals (<700 mg sodium, potassium, and phosphorus each) per day to patients in the following 4 weeks. We collected monthly IDWG, bioelectrical impedance, standardized blood pressure, 3 days (HD, non-HD, and weekend day) of dietary recalls, and blood at baseline (0M), after a usual diet (1M), and post-intervention meals (2M).

Results: Home-meal delivery significantly reduced both dietary sodium intake, IDWG, BP, and VO in HD patients. It will be important to determine if these changes can be sustained long-term with additional counseling and in larger sample sizes. The long-term benefits and cost-effectiveness of this approach also needs to be evaluated.

Changes in Volume-Related Parameters

PO2030

Performance of GLIM for Nutritional Assessment of Hemodialysis Patients: Comparison with Subjective Global Assessment (SGA) and Malnutrition-Inflammation Score (MIS)

Carla M. Avesani,1 Alice Sabattino,4 Alessandro Guerra,2 Juan J. Carrero,3 Giovanni maria Rossi,1 Peter Stenvinkel,1 Enrico Fiaccadori,4 Bengt Lindholm,1 Karolinska institutet Department of Clinical Sciences Intervention and Technology, Huddinge, Sweden; 2Università degli Studi di Genova, Genova, Italy; 3Karolinska Institutet, Stockholm, Sweden; 4Parma University Hospital, Parma, Italy.

Background: There is a need for methods to identify and monitor malnutrition in maintenance hemodialysis (MHD) patients. We assessed GLIM (Global Leadership Initiative on Malnutrition) performance and evaluated agreement and survival prediction of GLIM vs. SGA and MIS in MHD pts.

Methods: We investigated two cohorts, MHD Italy (121 adult pts from Italy; 67% men, BMI 25±4 kg/m² and MHD Brazil (169 elderly [age 60±7] yrs) pts from Brazil; 71% men, 66% men, BMI 25±4 kg/m²), followed for 40 (27; 46) and 17 (12; 31) months (median and 25%; 65%), respectively. GLIM comprises: 1. Screening and 2. Confirming malnutrition by phenotypic and etiologic criteria. For 1., presence of >1 criteria from protein energy wasting definition was used. Pts at risk were re-tested with GLIM's phenotypic criteria: non-volitional weight loss or low BMI (<20 kg/m², <70y, or <22 kg/m² if ≥70y) and reduced muscle mass (MAMC<90%). As dialysis is a catabolic procedure, all pts were positive for the etiologic criteria. For SGA and MIS, a score ≥5 and ≥8 was considered for malnutrition, respectively.

Results: Malnutrition was present in 38.8% by GLIM, 25.6% by SGA and 29.7% by MIS in the MHDItaly cohort, and in 47.9% by GLIM, 59.8% by SGA and 49.7% by MIS in the MHDBrazil cohort. Cohen’s kappa coefficient (k) showed only “fair” agreement between GLIM and SGA and MIS respectively (Table). Cox regression analysis adjusted for gender and age showed that in the MHDItaly cohort, only pts malnourished by MIS had higher risk for mortality (HR=2.42; 95% CI:1.28 to 4.59; P=0.007) while in the MHDBrazil cohort, pts malnourished by GLIM (HR=2.09; 95% CI:1.1.3 to 3.86; P=0.02), SGA (HR=1.96; 95% CI 1.01 to 3.79; P=0.04) and MIS (HR=2.24; 95% CI 1.20 to 4.16; P=0.01) had higher risk for mortality.

Conclusions: In MHD pts, GLIM showed low agreement with SGA and MIS, raising question on its validity and usefulness in renal care. Only malnutrition by MIS predicted mortality risk in MHDItaly cohort, but in the MHDBrazil cohort, malnutrition by all three methods predicted higher mortality risk.

PO2031

Dietary Fiber Intake, Cardiovascular Risk Factors, and Kidney Function: A Mediation Analysis

Background: Higher fiber intake may be associated with higher eGFR but the mechanisms underlying this association are poorly understood. Considering that higher fiber intake is linked to improved cardiovascular (CV) risk factors, we hypothesize that the effect of fiber intake on eGFR could be mediated by these CV factors.

Methods: CARTaGENE is a population survey of healthy adults. We used multiple linear regression to study the association between fiber intake and eGFR while adjusting for confounding factors, including age, sex, diabetes, hypertension, dyslipidemia, body mass index (BMI), smoking, prior CV disease, physical activity and caloric intake. We assessed whether CV risk factors lie in the causal pathway between fiber intake and eGFR through mediation analyses.

Results: We included 9,854 of the CARTaGENE participants with a completed food questionnaire (mean age: 53 years, 56% males). The main comorbidities were hypertension (25%), diabetes (8%) and cardiovascular disease (7%). The median daily fiber intake was 17.2g (IQR 10.7-23.7) and the mean eGFR was 87.3±14.6 mL/min 1.73 m². After adjustment for the above factors, fiber intake was associated with higher eGFR and serum HDL levels, and lower BMI, glycated hemoglobin and triglyceride levels (Table). Other risk factors were found to be non-significant. The mediation analysis demonstrated that only 10% of the effect of fiber intake on eGFR was mediated through BMI and triglyceride levels.

Conclusions: Higher dietary fiber intake is associated with higher eGFR and better control of certain cardiovascular risk factors. While the association between fiber intake and kidney function may be marginally mediated by healthy weight and triglyceride levels, further studies are needed to understand the mechanisms underlying this association.

Association between dietary fiber intake and clinical variables.

PO2032

Interplay Between Dietary Phosphorus and Protein Intake with Mortality in a Prospective Hemodialysis Cohort

Amanda R. Tortorici,1 Yoko Narusaki, Amy S. You,1 Keith C. Norris,2 Elani Strieja,3 René Amiel Peralta,3 Gabriella Fiaccadori,4 Bengt Stenvinkel,1 Andrea C. Daza Aguilar,1 Ria Arora,1 Robin H. Lo,1 Tracy Nakata,1 Danh V. Nguyen,1 Kamyar Kalantar-Zadeh,1 Connie Rhce,1 1University of California Irvine, Irvine, CA; 2University of California Los Angeles, Los Angeles, CA.

Background: Current dietary recommendations for dialysis patients suggest that high phosphorus (P) diets may be associated with negative outcomes such as increased serum P and death. However, caution must be practiced to ensure dietary P intake is not compromised at the expense of dietary protein intake. We hypothesized that higher concentrations of dietary P intake is associated with higher mortality among a diverse cohort of hemodialysis (HD) patients.

Methods: Among 415 patients from the prospective multi-center Malnutrition, Diet, and Renal Disparities in Kidney Disease Study, we conducted standardized collection of dialysis and treatment characteristics every six months starting in 2011. We examined the association of quartiles of dietary P scaled to 1000 kcal (mg/ kcal), as measured by food frequency questionnaires, with all-cause mortality using Cox models adjusted for expanded case-mix+laboratory+nutrition covariates. To model the association between continuous daily dietary P intake scaled to protein (mg/g) and mortality, we conducted analyses in which dietary P/protein intake was examined as a restricted cubic spline.

Results: In baseline analyses, patients in the lowest quartile of dietary P scaled to 1000 kcal had increased mortality risk compared to those in the highest quartile: adjusted HR (95%CI) 1.80 (1.05, 3.09). In analyses examining the association between continuous dietary P/protein (mg/g) intake and mortality using a cubic spline, we observed that there was a monotonic decrease in death risk with higher dietary P/protein intake.

Conclusion: Contrary to current practice, we found that lower intakes of dietary P scaled to protein and caloric intake were each associated with higher mortality risk. National nutrient databases indicate that foods with lower vs. higher P/protein ratios tend to be from animal proteins vs. plant proteins and dairy. Further studies are needed to clarify the relationship between sources of dietary P intake and mortality in HD patients.

Protein Supplements and Proteinuria: A Case-Control Study in Military Candidates

Sofia H. Marques,1,2 Alberto Freitas,3 Hospital Militar Polo Porto, Porto, Portugal; 2Hospital de Braga, Braga, Portugal; 3Faculty of Medicine of the University of Porto, Porto, Portugal.

Background: Man has long wanted to improve both image and physical performance using supplements some of which include proteins. Low protein diets are recommended by guidelines to attenuate the progression of chronic kidney disease. In healthy individuals, however, protein intake does not seem a risk factor. This study assessed whether protein supplements could cause proteinuria in a healthy population.

Methods: We performed a case-control study at the Military Hospital of Oporto including 1541 military academy candidates who had urinalysis in 2017. Among them, 102 (6.6%) had proteinuria (dipstick test +/++) and these were compared to a random sample of 106 non-proteinuric candidates. Telephone interviews collected data on comorbidities, exercise, smoke, alcohol habits, drugs, supplements, height and weight. Protein supplements were accessed as risk factors for proteinuria using the Pearson Chi-square test.

Results: Answers were obtained from 49 cases and 52 controls. Of these 101 candidates, 88 were males, had a median age of 19 and mean body mass index of 24.1±2.4kg/m2. Most (97%) exercised for a mean weekly time of 6±3.7h: 40% practiced only resistance training; the rest both resistance and strength. Half used supplements at some point in time and 32 were current users. All used protein powder, mainly whey protein. Additional supplements (mostly amino acids) were used by 13. The weekly powder intake ranged from 3 to 14 scopes (20.3±31.0 scope). No significant association was found between the use of protein supplements and proteinuria (p=0.51). Similarly, no difference was found in creatinine, urea or other laboratory parameters. Supplements were significantly used more by those who practiced strength, as compared with resistance-training subjects.

Conclusions: One third of Portuguese military candidates used protein supplements. Increased use was noted in strength training most likely due to peer pressure. Proteinuria was found in 6.6%, similar to screenings in other healthy populations. No relation was found between protein supplements and proteinuria which could mean that the kidneys of healthy individuals are capable of dealing with a higher metabolic strain after increasing protein loads. However we acknowledge that proteinuria as a marker of disease has limitations and that the cumulative evidence and exposure time of protein supplements was not considered and may be relevant.

PO2034

Continuous Intradialytic Amino Acid Infusion from the Start of Dialysis Is Better to Avoid Catabolism under the High-Volume Pre-Dilution Online Hemodiafiltration

Motoko Hyodo,1 Yukie Kitajima,1 Kenichi Kokubo,1 Toru Motoko,2 Department of Clinical Engineering, Eijin Clinic, Hiratsuka, Japan; 1Tokyo University of Technology School of Health Sciences, Setagaya, Japan; 1Allied Health Science, Kitasato University, Sagamihara, Japan; 2Dialysis Center, Eijin Clinic, Hiratsuka, Japan.

Background: Amino acid infusion during dialysis is useful for improving nutritional status (Clin Nephrol 3:234, 1975). Usually, amino acid is infused 60 to 90 minutes before the end of dialysis, but it is reported that continuous administration from the start of dialysis is better (Kidney Int 21: 500, 1982). Moreover, these effects are unclear in high-volume pre-dilution on-line HDF (HVPO-HDF). The optimal administration method of amino acid infusion during the HVPO-HDF was analyzed.

Methods: The subjects were 10 patients receiving HVPO-HDF (7 males, 4 diabetics, median age 77.2±5.5 years). We compared the pre- and post-dialysis plasma amino acid levels and the total amino acids amount in the waste fluid when the amino acids infusion was performed from the start of dialysis (Group A) and from 1 hour before the end of dialysis (Group B). The treatment time is 4 hours. The mean blood flow rate was 200 ml/min. The dialysate flow rate was 600 ml/min. The replacement fluid flow rate was 400 ml/min and total replacement fluid volume was 90 ml. Hemodialyzer FX-21M Nipro (Nipro Ltd) was used.

Results: In pre-dialysis plasma levels of total amino acid (TAA), Group A and Group B showed the same level (247±267 mmol/ml and 262±319 mmol/ml, respectively). In the essential amino acid (EAA) and non-essential amino acid (NEAA), similar results were obtained (827±145 mmol/ml and 847±99 mmol/ml of EAA, 1644±216 mmol/ml and 1120±193 mmol/ml of NEAA, respectively). Moreover, the losses of amino acids were also similar (99.1±13 mg and 880±1204 mg of TAA, 84±58 and 4544±453 mg of EAA, 402±644 mg and 432±862 mg of NEAA, respectively). In Group A, post-dialysis plasma levels of amino acids were significantly lower than in Group B (206±630 mmol/ml and 382±636 mmol/ml of TAA, 94±193 mmol/ml and 22±439 mmol/ml of EAA, 1120±193 mmol/ml and 1577±260 mmol/ml of NEAA, respectively, p < 0.01).

Conclusions: The result of high post-dialysis plasma levels despite the same loss of amino acids suggests more catabolism from muscle to blood in Group B. The continuous intradialytic amino acid infusion is better to avoid catabolism under HVPO-HDF.
yet attenuated relationship was observed among A2 patients. Odds of faster UACR slope was higher only in patients with LDL ≤ 160 mg/dL and with index UACR≥300 mg/g. For A3 patients, there was no association between LDL level and UACR slope.

Conclusions: Among patients with baseline UACR < 300 mg/g, both low and very high LDL were associated with higher odds of having fast UACR change. Yet, among those with higher albuminuria, the relationship with LDL and UACR change was null. More studies are needed to delve into the mechanism between LDL and CKD progression in order to further manage patients kidney health.

PO2038

The Combination of Malnutrition Inflammation and Limitations in Functional Status Is Associated with a Very High Risk of Mortality in Hemodialysis Patients: Results from the DOPPS
Marcelo Lopez,1 Eiichiro Kanda,2 Brian Bieber,1 Kazuhiko Tsuuryu,2 Hidetomi Hirakata,3 Angelo Karaboyas,1 Stefan H. Jacobsson,4 Ingridan Dasgupta,5 Bruce M. Robinson,1 Roberto Pecorillo-Filho,1 DOPPS,1 Arbor Research Collaborative for Health, Ann Arbor, MI; 2Kawasaki Ika Daigaku, Kurashiki, Japan; 3Nara-ken, Nara, Japan; 4Fukuoka Renal Clinic, Fukuoka, Japan; 5Karolinska Institutet, Stockholm, Sweden; 6University of Warwick Warwick Medical School, Coventry, United Kingdom.

Background: The malnutrition-inflammation-complex (MIC) is a risk factor for mortality and lower quality of life in hemodialysis (HD) patients. The identification of MIC and its risk factors, which include the limited ability to perform functional status (FS), is key to improve the patient experience on HD. Our study investigates the association of MIC and FS combinations with mortality in HD patients.

Methods: We analyzed data from a cohort of 5465 HD patients from Australia, France, Germany, Italy, Japan, New Zealand, Spain, Sweden, and United Kingdom, enrolled in the Dialysis Outcomes and Practice Patterns Study phases 4 (2009-2011) and 5 (2012-2015). MIC syndrome was defined as low serum albumin (<3.8 g/dL) and high serum C-reactive protein (>3mg/L in Japan; >10 mg/L elsewhere). Poor functional status was defined as the sum of scores from the self-reported limitations in the Katz Index of Independence in Activities of Daily Living (0 to 5) and the Lawton-Brony Instrumental Activities of Daily Living Scale (score ranges from 0 to 8) less than 11. We investigated the association between combinations of MIC (+/+), FS and FS (low/high) with death, using Cox proportional hazards models adjusted for possible confounders including patient demographics, comorbidity history, catheter use, serum creatinine, phosphorus levels, WBC count, hemoglobin level, and time on dialysis therapy.

Results: The prevalence of different combinations were: MIC-/HD FS 57%, MIC-/ Low FS 24%, MIC+/HD FS 9%, and MIC+/Low FS 10%. Patients with MIC+/HD FS were younger, better nourished, and had lower prevalence of comorbidities. Compared to the reference group, the hazard ratios [HR (95% CI)] for all-cause mortality were 1.56 (1.24-1.98) for MIC-/ low FS, 1.75 (1.32-2.32) for MIC+/ HD FS, and 2.97 (2.31-3.82) for MIC+/ low FS groups. The adjusted HRs for infection-related mortality were 1.57 (0.91, 2.71) for MIC-/low FS, 1.67 (0.84, 3.31) for MIC+/HD FS, and 5.45 (3.15, 9.45) for MIC+/low FS groups.

Conclusions: The combination of MIC and low FS is a strong predictor of mortality, and infectious mortality in particular, in HD patients. Identification of patients with MIC and FS.

PO2039

High-Amylose Resistant Starch (RS) Cookies Supplementation Does Not Decrease Trimethylamine N-Oxide (TMAO) Plasma Level in Hemodialysis (HD) Patients
Denise Mafra,1 Julie ann Kemp,1 Henrique F. Santos,1 Hugo E. de Jesus,1 Marta Espigalho,1 Bruna Paiva,1 Bengt Lindholm,2 Peter Bergman,2 Peter Stenvinkel.1 1Federal University Fluminense, Rio de Janeiro, Brazil; 2Karolinska Institutet, Stockholm, Sweden.

Background: TMAO is generated from dietary nutrients by the gut bacteriome and it is associated with cardiovascular mortality in HD patients. Thus, to reduce its generation, nutritional strategies have been proposed. The aim of this study was to analyze the TMAO levels and potential changes in TMAO-associated bacterial taxa in HD patients after RS supplementation.

Methods: This is a randomized, double-blind, placebo-controlled trial with HD patients that were allocated to RS or placebo group to receive alternately 9 cookies/d (dialysis days) and 1 sachet/d (non-dialysis days) containing 16g/d of RS (Hi-Maize 260, Ingredion®) or manioc flour as the placebo, during 4 weeks. Plasma TMAO, choline, and betaine levels were measured with LC-MS/MS. Fecal bacteriome composition was evaluated by high-throughput sequencing of 16S ribosomal RNA gene V1–V3 region, followed by a search for TMAO-associated taxa.

Results: Thirty-one participants finished the study, 15 in RS group (53.3 %); 56.0 ± 7.5 yrs; 50.0 ± 36.6 months on HD and BMI 26.1 ± 5.0 kg/m² and 16 in the placebo group (31.2 %); 53.5 ± 11.4 yrs; 44.3 ± 26.4 months on HD and BMI 26.6 ± 5.2 kg/m². After four weeks of supplementation no significant changes in TMAO, choline and betaine plasma levels were observed (Table 1). Notably, after the RS supplementation, TMA-producing bacterial taxa such as Ruminococcus torques group [0.026 (0.023 - 0.04) vs. 0.017 (0.017 - 0.02), p = 0.06] and Streptococcus had decreased the relative abundance, while Prevotellaceae family and Enterococcus increased their relative abundance in placebo group. However, the differences did not reach statistical significance. Additionally, the relative abundance of TMA-producing bacterial taxa was low in both groups.

Conclusions: RS supplementation did not influence TMAO plasma levels nor fecal taxa potentially linked to TMAO in HD patients, suggesting that RS did not modify the composition of gut bacteriome that convert its precursors into TMAO.

**Public Health Effects of Sterilized, Used Hemodialyzers for Water Purification in Rural Ghana**

Jommander, Bagah; Boehm; Grisch; G. Raimann,3 Philip K. Nahr,1 Seth Johnson,1,2 Linda L. Donald,1 Harrison K. Matti,1 Maria E. Ferris,1 Mathieu Lamolle,1 Hongbin Zhang,3 Friedrich K. Port,1 Nathan W. Levin,1 Easywater for everyone, Accra, Ghana; 2Department of Field Epidemiology and Applied Biostatistics, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana; 3Health Service, Ada, Ghana; 4Arbor Research Collaborative for Health, Ann Arbor, MI; 5Graduate School of Public Health and Health Policy, New York City, NY; 6Renal Research Institute, New York, NY; 7University of North Carolina System, Chapel Hill, NC; 8Water for Everyone, Geneva, Switzerland.

**Background:** Consumption of contaminated water is a risk factor for infectious diarrhea and according to estimates of the World Health Organization the remains the most often reported cause of death in children and the elderly. Our organization “Easy Water for Everyone (EW/E)” uses a membrane filtration device with repurposed hemodialyzers and we have previously reported remarkable public health effects (Raimann for EWE, SciRep 2020). Here we report the impact our project had on the incidence of diarrhea in two villages in rural Ghana.

**Methods:** This prospective study was conducted with approval from Ghana Health Service and involved the quantification of self-reported diarrhea 4 months before and after implementation of a membrane filtration device in a school and a primary healthcare center. Using a mixed-effects generalized linear model, the odds of developing diarrhea in presence of the membrane device were estimated. We additionally tested the association of age on the estimate, and conducted a subset analyses in those younger than 15 years old. Analyses were conducted in R version 4.0 and odds ratios (OR) reported as OR (95% CI).

**Results:** We studied 927 villagers (55% female, 43% <15 yrs and 33% >50yrs) and the incidence rate of diarrhea was 0.30 per subject month per village-month before and 0.26 after implementation of the device. We found a statistically significant association between the device and incidence of diarrhea [OR 0.79 (0.67 to 0.95)] with significantly higher odds of diarrhea in the younger [OR 1.32 (1.07 to 1.63)] and the elderly [OR 1.45 (1.06 to 1.99)].

**Conclusions:** Our study supports provision of clean drinking water as means to prevent diarrhea and its possible adverse sequelae such as acute kidney injury (AKI). Additionally, we conclude the youngest and the eldest in the population are at highest risk of diarrhea.

**Development and Validation of a Multifrequency Bioimpedance Spectroscopy Equation to Predict Appendicular Skeletal Muscle Mass in Hemodialysis Patients**

Ting-yun Lin, Taipeh Tzu Chi Hospital, Taipei, Taiwan.

**Background:** Sarcopenia is prevalent and associated with poor outcomes in patients with chronic kidney disease (CKD). Although bioimpedance analysis is accepted by major consensus statements as an alternative for muscle mass assessment, it can be affected by hydration status in CKD patients. The Body Composition Monitor (BCM), a multifrequency bioimpedance spectroscopy device, has been widely used to assess body composition and dry weight in hemodialysis patients because it can distinguish normally hydrated lean tissues from overly hydrated tissues. Therefore, our study aimed to develop and validate an equation for obtaining appendicular skeletal muscle mass (ASM) from BCM using dual-energy X-ray absorptiometry (DXA) as the reference among hemodialysis patients.

**Methods:** A total of 322 consecutive body composition measurements with BCM and DXA in 263 hemodialysis patients were randomly divided at a ratio of 2:1 into development and validation groups. Stepwise multiple regression modeling was applied to develop the ASM prediction equation. Tests for agreement included mean differences and Bland-Altman plots. We evaluated the model as a diagnostic tool for sarcopenia using cutoffs of ASM defined by the Asian Working Group for Sarcopenia (AWGS). We further explored the association between ASM predicted by the BCM equation and all-cause mortality in two independent cohorts: one with 326 stage 3–5 CKD patients and one with 629 hemodialysis patients.

**Results:** BCM yielded the following equation: ASM (kg) = −1.838 + 0.395 × total body water (L) + 0.105 × body weight (kg) + 1.213 × male sex – 0.026 × age (years) (R² = 0.914, standard error of estimate = 1.35 kg). In the validation group, Bland-Altman analysis showed no significant bias of 0.098 kg and limits of agreement ±2.440 kg. Using the AWGS criteria, the model was found to have a sensitivity of 94.1%, a specificity of 98.8%, a positive predictive value of 84.2%, and a negative predictive value of 99.6% for the diagnosis of sarcopenia. Low ASM predicted by the BCM equation was associated with significantly worse overall survival among CKD patients but not hemodialysis patients.

**Conclusions:** The new BCM equation provides a feasible and valid option for assessing ASM in hemodialysis patients. Its utility in clinical practice requires further research.

**PO2042**

**Indoxyz Sulfate Reduces the Inducibility of NLRP3 Inflammation in Hemodialysis Patients**

Li-chun Ho,1,2 Chang Min-Yu,1,3 Yi-che Lee,1,3 Hsi-Hao Wang,1,3 Ching-fang Wu,2 Shih-Yuan Hung,1,4 I-Shou University, School of Medicine, Kaoshing City, Taiwan; 1E-Da Hospital, Department of General Medicine, Yanchao, Taiwan; 2E-Da Hospital, Division of Nephrology, Department of Internal Medicine, Yanchao, Taiwan.

**Background:** The NLRP3 inflammasome is a cellular component of innate immunity responsible for the maturation of interleukin-1β (IL-1β). Studies have shown that the basal activity of the NLRP3 inflammasome is increased in the immune cells of hemodialysis (HD) patients, but the inducibility of the NLRP3 inflammasome upon canonical stimulation has not been studied.

**Methods:** Peripheral blood mononuclear cells (PBMCs) isolated from 13 HD patients and 18 volunteers without a history of chronic kidney disease (CKD) were treated with a combination of lipopolysaccharide (LPS) and nigericin to induce NLRP3 inflammasome activation. Likewise, THP-1 monocytic cell-derived macrophages, with or without indoxyz sulfate (IS) pretreatment, underwent the canonical NLRP3 inflammasome stimulus as well. The activity of the inflammasome was determined by immunoblot analysis.

**Results:** Despite the high plasma levels of IL-1β in HD patients, caspase-1 and IL-1β in the PBMCs of HD patients remained predominantly immature and were not stimulated in response to the canonical stimulus. Further investigations showed that while IS treatment alone facilitated the secretion of IL-1β from THP-1-derived macrophages, IS pretreatment reduced the inducibility of NLRP3 inflammasome in response to LPS and nigericin, characterized by the low mature rate of caspase-1. The PBMCs derived from the HD patients and the macrophages exposed to IS both had low expression levels of NLRP3 inflammasome components, suggesting insufficient supplies of inflammasome machinery.

**Conclusions:** The low stimulation response of the NLRP3 inflammasome attributed to indoxyz sulfate probably contributes to a breach of the immune defense system, which may explain the high infection risk in HD patients.

**Prevalence and Risk Factors of High-Altitude Hyperuricemia in the Bai Ethnic Group**

Chenni Gao, Xiaonong Chen. Shanghai Jiao Tong University Medical School Affiliated Ruijin Hospital Department of Nephrology, Shanghai, China.

**Background:** The Bai ethnic group is one of the 55 minorities in the People's Republic of China. Hyperuricemia is not rare among this ethnic partly due to the chronic exposure to high altitude. However, the prevalence of hyperuricemia in the Bai ethnic group remains unclear.

**Methods:** We collected retrospectively the demographic characteristics and laboratory measurements of 1393 Bai ethnic adults undergoing annual medical examination during Jan 2019 to Dec 2019 in the People's Hospital of Jianchuan County (average altitude 2300m), Yunnan Province. We investigated the prevalence of hyperuricemia as well as its clinical features and risk factors.

**Results:** Of the 1393 participants enrolled in the study, the prevalence of hyperuricemia was 24.8%, and the prevalence was significantly higher in male (53.2% vs men vs. 11.0% in women, P<0.001). The prevalence of hyperuricemia increased from 9.2% among participants aged 30-40 years to 30.1% among participants aged 50 years and older. Also, the prevalence elevated from 17.2% among participants with normal body mass index (BMI) to 35.5% among those who were overweight/obese. Interestingly, we found a positive correlation between hemoglobin level (Hb) and serum uric acid (β=2.19, P<0.01). Logistic regression analysis revealed main risk factors for hyperuricemia in the Bai ethnic group included age, sex, BMI, systolic blood pressure (SBP) and Hb.

**Conclusions:** Hyperuricemia is common in the Bai ethnic group. Besides traditional risk factors such as age, sex and BMI, polythecemia secondary to chronic exposure to high altitude may also contribute to the hyperuricemia.
PO2044
Changes in the Gut Microbiota After a Controlled Feeding Study in Individuals with CKD and Healthy Controls

Annabel Biruta,1 Gretchen Wise,2 Tzu-Wen L. Cross,2 Riya Thakkar,2 Stephen R. Lindemann,2 Elizabeth Stremka,3 Ranjani N. Moomth,1 Kelly Swanson,2 Sharon M. Moe,1 Kathleen M. Hill Gallant.1 1Indiana University School of Medicine, Indianapolis, IN; 2Purdue University, West Lafayette, IN; 3University of Illinois System, Urbana, IL.

Background: Diet has been shown to alter the gut microbiota composition and function. However, controlled diet studies assessing the gut microbiota in CKD patients are limited. We assessed the differences in the gut microbiota composition before and after a week of controlled meals in patients with moderate-to-advanced CKD and healthy adults.

Methods: In a secondary analysis, we studied patients with CKD (n=7, eGFR 29.5±55mL/min/1.73m2) vs. controls (n=7) matched for sex, age, and race. Participants ate a diet controlled for macronutrients (protein 0.8g/kg/d), fiber (25g/d), P (1500mg/d), Ca (1400mg/d), K (3500mg/d), and Na (2400mg/d) for 1 week. Fecal samples were obtained before and after the dietary intervention. Fecal DNA was extracted and used to amplify the V4 region of the 16S rRNA gene. Sequencing was performed via Illumina MiSeq platform and analyzed using QIIME2 and LEfSe.

Results: The Gut microbial diversity did not differ between patients with CKD or controls and was not affected due to the dietary intervention. At baseline, control individuals had a higher relative abundance of Blautia and an unclassified genus within Coriobacteriaceae, while CKD patients had a higher relative abundance of Lachnobacterium. After receiving a week of controlled meals, CKD patients had a higher relative abundance of Anaerostilbos and Clostridium, while controls had a higher relative abundance of Parabacteroides and Sutterella. Comparing data before and after dietary treatment within groups, CKD individuals had a lower relative abundance of Lachnobacterium and higher Bacteroides and Holdemansia. Meanwhile, healthy controls had a lower relative abundance of unclassified Mogibacteriaceae, and a higher relative abundance of Anaerostilbos, Parabacteroides and Sutterella.

Conclusions: While there were no major changes in microbial diversity, healthy controls and CKD patients responded differently to a week of controlled meals.

PO2045
Mitochondrial Dysfunction and Uremic Toxins from Gut Microbiota in CKD Patients: Is There a Link?

Denise Mastra,1 Bruna Paiva,1 Drillery V. Reis,1 Karla thais R. Teixeira,1 Laís G. Moreira,1 Estelina S. Capistrano,1 Ludmila F. Cardozo,1 Lia S. Nakao,2 Jessyca S. Brito,1 1Federal University Fluminense, Rio de Janeiro, Brazil; 2Universidade Federal do Parana, Curitiba, Brazil.

Background: Dysbiosis in patients with chronic kidney disease (CKD) is associated with increased production of uremic toxins, such as indoxyl sulfate (IS), p-cresyl sulfate (p-CS) and indole-3-acetic acid (IAA), which are linked to oxidative stress and may be related to mitochondrial dysfunction with alterations in peroxisome proliferator activated gamma receptor coactivator 1 alpha (PGC-1α), respiratory nuclear factor 1 (NRF-1) and mitochondrial transcription factor (TFAM). The aim of this study was to verify possible associations between metabolites produced by gut microbiota and genes related to mitochondrial function (PGC-1α, NRF-1, TFAM) in CKD patients.

Methods: This was a cross-sectional, observational study, involving 46 patients with CKD: 20 patients on hemodialysis (HD) (12 men, 44.2 ± 8.9 years) and 26 non-dialysis patients (8 men, 57.6 ± 6.2 years, GFR 25.0 ± 13.0 mL/min), selected by non-probabilistic sampling of convenience. Plasma levels of IS, p-CS and IAA were assessed by high-performance liquid chromatography (HPLC). The analysis of the gene expression of PGC1-α, NRF-1 and TFAM were performed by real time Polymerase Chain Reaction (RT-PCR) in peripheral blood mononuclear cells (PBMCs). For statistical analysis, software R, version 3.5.0 (R Core Team, Vienna, Austria) was used and the results were expressed as mean ± standard deviation, with a significance level of p <0.05.

Results: As expected, the levels of uremic toxins were higher in HD patients than in non-dialysis patients [IS: 31.1 ± 14.3 mg/L vs 2.9 ± 1.7 mg/L (p <0.001); p-CS: 53.4 ± 34.6 mg/L vs 14.6 ± 10.8 mg/L (p <0.001)]; IAA: 2560.1 ± 1379.6 ug/L vs 1050.4 ± 984.8 ug/L). There was no significant difference in the mitochondrial parameters between PGC1α and NRF1 between the groups of patients. In the HD group was observed a positive linear correlation between TFAM and p-CS (r = 0.978, p <0.001); as well as between PGC1α and NRF1 (r = 0.8, p = 0.006). However, in both groups there was no correlation between mitochondrial genes and uremic toxins.

Conclusions: The uremic toxins levels were significantly higher in HD patients; however, we did not find any correlations with the parameters of mitochondrial function analyzed.

PO2046
Dysbiosis of Gut Microbiota in Adult Idiopathic Membranous Nephropathy with Nephrotic Syndrome

Jian Zhang. Division of Nephrology, Department of medicine, Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.

Background: Gut bacterial microbiota is altered in patients with chronic kidney disease (CKD) and those on dialysis. However, it is not yet clear what bacterial composition changes occur in patients with idiopathic nephrotic syndrome. We present in this report the changes in gut bacterial microbiota in idiopathic nephrotic syndrome patients with membranous nephropathy.

Methods: A total of 156 individuals were recruited for this study. Of these, 80 were CKD3–5 stage patients without nephrotic syndrome, 48 patients had idiopathic nephrotic syndrome and pathological diagnosis of membranous nephropathy, and 30 were age- and sex-matched healthy controls. The gut microbiome composition was analyzed using a 16S ribosomal RNA gene-based sequencing protocol.

Results: The results indicated that the nephrotic syndrome (NS) patients had a significantly different alpha and beta diversity compared with the CKD3–5 group and healthy controls (p < 0.01). At the phylum level, the NS patients showed increased Fusobacteria and Proteobacteria but reduced Firmicutes when compared with the healthy controls. At the genus level, Megamonas, Megaplasma, Akkermansia, and the butyrate-producing bacteria Lachnospira, Roseburia, and Fusobacteria were more abundant in the controls (LDA score > 3) than the CKD3–5 and NS patients. Compared with the healthy controls, we found that Parabacteroides was increased in CKD3–5 and NS patients. In addition, Oscilispora and Ruminococcus were more abundant in CKD patients than in the other two groups (LDA score > 3). At the genus level, ten bacterial taxa were more prevalent in the healthy controls. Providencia and Myrobiotes were more prevalent in NS patients.

Conclusions: Our findings highlight that, NS patients had a significantly different alpha and beta diversity and decreased gut microbiota-derived short-chain fatty acids, such as butyrate. However, large-scale prospective studies should be performed to identify the cause and effect factors of these changes in the microbiota in NS patients.

PO2047
The Alter of Gut Microbiota in Dialysis Patients and Its Influence on the Prognosis for ESRD Patients

Jian Zhang, Dan Luo, Huaixia Xiong, Hui-qun Li. Department of Nephrology, the Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.

Background: Previous studies have found that alteration in gut microbiota occurred in end-stage renal disease (ESRD) patients with or without dialysis, and are associated with complications such as inflammation and cardiovascular events. However, it has not been clarified whether gut microbiota are influenced by dialysis intervention in ESRD patients.

Methods: The fcal samples of 73 ESRD patients were collected, including 33 pre-dialysis ESRD patients, 19 peritoneal dialysis (PD) patients, and 21 hemodialysis (HD) patients; 19 healthy fecal samples were also collected as control in this study. The 16S rRNA sequencing and the bioinformatics was used to analyze the the composition and function of gut microbiota. The clinical outcomes of the patients were tracked from April 2017 to the end of May 2020.

Results: Compared with the pre-dialysis patients, Bacteroides decreased significantly in HD patients. At the genus level, a total of 14 genera showed differences between patients before and after dialysis. Pre-dialysis patients have a increased abundance of Parabacteroides, Prevotella and Oscillibacter, and the decreased abundance of Lachnospira, Klebsiella, Akkermansia and Roseburia. HD could repair the abnormal changes of these flora in pre-dialysis patients. We could not found any bacteria difference function between PD and pre-dialysis patients in phylum and genus level. The PICRUSt analysis showed that PD and HD could change the signal transduction and metabolic pathways of ESRD patients. It was found that Bacteroidetes and SMB53 were associated with the occurrence of cardiovascular events. Blautia, Faecalibacterium, and Veillonella were associated with peritonitis in PD patients.

Conclusions: Our results suggested that compared with healthy control, the composition and function of gut microbiota of pre-dialysis patients were changed, HD could restored the relative abundance of beneficial bacteria and reduced some potential pathogenic bacteria. Some gut microbiota were associated with prognosis in all of ESRD patients and peritonitis in PD patients.

Effect of Intradialytic Oral Nutritional Supplementation with and Without Exercise on the Skeletal Muscle Quantity and Quality of Adult Hemodialysis Patients
Geovana Martin-Alemály,1 L. M. Pérez-Navarro,2 Angeles Espinosa-Cuevas,2 Gloria G. García Villalobos,1 Elba O. Medina,1 Miguel Ángel Reyes Caldeñas,1 Rafael Varela-Oritz1Hospital General de México, Dr. Eduardo Liceaga, Ciudad de México, Mexico; 2National Institute of Medical Science and Nutrition Salvador Zubirán, Ciudad de México, Mexico.

Background: The muscle mass (MM) is one of the major tissues affected by the chronic kidney disease. Patients undergoing chronic hemodialysis (HD) have loss of MM due to many factors. Intradialytic oral nutritional supplementation (ONS) and exercise (EX) have been shown to improve the amount and quality of MM and physical function (PF).

Methods: Patients were randomized in two different groups: 1) ONS and 2) EX + ONS. Patient’s realized 30 minutes of aerobic EX using static bicycles and 30 minutes of resistance EX using Thera-band Bands. Quantity and quality of MM were measured with anthropometrics and computed tomography (CT). PF was measured by short physical performance battery (SPPB), six-minute walk test (6 MWT) and handgrip strength (HGS).

Results: Twenty-three patients conclude the study. Both groups improved their weight (ONS: baseline, 53 ± 4.4kg; final: 54.3 ± 4.9kg; p = 0.020 and ONS + EX: baseline, 57.2 ± 9.2kg; final: 59 ± 9.2kg; p = 0.001) and the AMC (ONS: baseline, 227 ± 20mm; final: 241 ± 19mm; p = 0.040 and ONS + EX: baseline: 235 ± 27mm, final: 250 ± 31; p = 0.047). In the ONS group we observed decreases in the 6MWT: baseline: 417 ± 53.9m, final: 405 ± 52m; p = 0.016 and improvements in the SPPB; baseline: 10.8 ± 1.3, final: 11.2 ± 1.4, p = 0.005) with no change in the intramuscular lipid infiltration (baseline: 53.5 ± 5.8% vs. 53.5 ± 5.8%; p = 0.83) and the AMC (baseline: 235 ± 27mm, final: 250 ± 31; p = 0.047).

Conclusions: Exercise training for 6 months improves the MM composition of HD patients measured by CT and this was reflected with the improvements in the PF tests and no changes were observed in MM composition in the ONS group.

Muscle Mitochondrial Function and Physical Performance Are Associated with Branched-Chain Amino Acid Levels in Patients with CKD
Jorge Gamboa,1 Berfu Korucu,1 Dunpeng Peng,1 Baback Roshanravan,2 Talat Alp Ikizler,1 Vanderbilt University Medical Center, Nashville, TN; 2University of California Davis, Davis, CA.

Background: Muscle mitochondrial function and physical performance are impaired in patients with chronic kidney disease (CKD). Previous studies suggest that decreased branched-chain amino acids (BCAA) levels are associated with muscle catabolism in patients with CKD. We hypothesized that BCAA is lower in patients with CKD and branched-chain amino acids (BCAA) levels are associated with muscle catabolism in patients with CKD.

Methods: In a cross-sectional study, we evaluated 63 participants [20 with CKD stage 3-4, 13 with ESRD, and 30 controls] and 23 patients with CKD stages 1-3a, 3b-5, HD, and PD enrolled from 2018 to 2020. All patients were hospitalized and received our CKD educational program, and did not have sleep complaints. The diagnosis and assessment of the severity of SBD were evaluated using PULSION-Mc306 and SAS2100 systems. The 3% oxygen desaturation index and SpO2 were measured during sleep. SBD was defined as 3% oxygen desaturation index (ODI)>15.0 and SpO2<92% in this study.

Results: The proportion of the patients with CKD1-3a, CKD3b-5, HD, and PD were 28%, 53%, 11%, and 8%, respectively. 31% of the patients were diagnosed with SBD in all CKD patients. In a generalized linear model, 3% ODI>15.0 and SpO2<92% were significantly correlated with apnea hypopnea index (p<0.05, r=0.87 and p<0.05, r=-0.45, respectively). Further, it became clear that the proportion of 3% ODI>15 and SpO2<92% was significantly higher in PD patients (50%) than in other CKD patients. Furthermore, 3% ODI was significantly correlated with BMI and HDL cholesterol levels in PD patients (p<0.05, r=0.67 and p<0.05, r=0.54, respectively).

Conclusions: We reported for the first time that the prevalence of SBD was very high and that the severity of SBD was significantly associated with BMI in patients with PD. These findings suggest that the extracellular fluid overload and excess glucose exposure due to PD fluid might accelerate SBD in patients with PD. Further clinical studies are needed to determine whether PD-associated SBD might influence the development of cardiovascular disease in CKD patients.

Effects of Resistant Starch (RS) Type 2 Cookies on Gut Microbiota Profile in Hemodialysis (HD) Patients
Denise Mafra, Julie Ann Kemp, Marta Esgalhado, Bruna Paiva, Hugo E. de Jesus, Henrique F. Santos. Federal University Fluminense, Niterói, Brazil.

Background: Dysbiosis is recognized as a new cardiovascular risk factor in HD patients. In this context, nutritional strategies as the use of high amylose RS have been proposed to modulate the gut microbiota in HD patients. The aim of the present study was to evaluate the effects of RS supplementation on gut microbiota modulation in HD patients.

Methods: This double-blind, placebo-controlled clinical trial evaluated HD patients randomized in two groups, RS or placebo. They received 9 cookies/day (16g of RS - Hi-MAize 260, Ingredion®), in the HD days and 1 sachet/day in non-HD days for 4 weeks.

Results: Twenty-three patients concluded the study: 10 in the RS group (3 ♂, 52.3 ± 12.3 yrs, BMI 24.6 ± 3.9 Kg/m2) and 10 in the placebo group (8 ♂, 55.1 ± 11.1 yrs, BMI 25.6 ± 4.9 Kg/m2). Microbial diversity (Shannon index) and richness (ACE) were similar in both groups at baseline. RS supplementation increased mainly the relative abundance of the genus Ruminococcus 2 and maintained genus Blautia, while the placebo group decreased both of these genera, as showed in the Fig 1. After RS supplementation the beta diversity (PCA) changed, increasing the short-chain fatty acid producers, which are related to benefits effects.

Conclusions: The RS supplementation was able to change the gut microbiota in HD patients. Linking these results with our previous studies, which RS was able to reduce the inflammatory and oxidative stress markers and uric acids plasma levels in HD patients, we suggest that RS can be a good nutritional strategy to modulate the gut microbiota in HD patients.

Funding: Government Support - Non-U.S.
Gut Dysbiosis and Mortality in Hemodialysis Patients

Ting-yun Lin. Taipei Tzu Chi Hospital, Taipei, Taiwan.

Background: Persistent inflammation plays a pathogenic role in CKD-associated protein-energy wasting, cardiovascular disease, and mortality. Gut dysbiosis, characterized by decreased microbial diversity, promotes inflammation. The gut microbiota is markedly altered in patients with ESKD. Therefore, we aimed to determine the relationship between gut dysbiosis and mortality in an ESKD cohort.

Methods: In an observational study, we examined the associations between microbial diversity and mortality in ESKD patients undergoing maintenance hemodialysis (n=109) using Cox proportional hazards models. The gut microbiota was assessed by 16S rRNA sequencing. Microbial diversity was calculated using the Simpson index. Participants were stratified into higher- (above the median) and lower-diversity (below the median) groups and were followed up for a median of 2.1 years. Next, in a matched case-control study, we compared the microbial composition between nonsurvivors and survivors.

Results: Kaplan-Meier analyses revealed a significant association between higher diversity and a lower risk of death (P<0.015). After adjustment for patient characteristics and comorbidities, the risk of death among patients with higher diversity was 74% lower than that among patients with lower diversity (hazard ratio, 0.26; 95% CI, 0.07 to 0.95). Nonsurvivors and survivors were matched 1:4 for age and sex. We observed significantly lower values of microbial diversity and higher levels of proinflammatory cytokines (IL-6 and TNF-α) among nonsurvivors (n=14) than survivors (n=56). Notably, the relative abundance of Succinivibrio and Anaerostipes, two short-chain fatty acid-producing bacteria, was reduced in nonsurvivors compared with survivors.

Conclusions: A unique gut microbial composition is associated with an increased risk of mortality in patients with ESKD and may be used to identify subjects with a poor prognosis. Our findings need to be validated in a larger independent cohort.

Insulin Resistance and Pancreatic Beta-Cell Function in Calcium Kidney Stone Formers

Olive W. Tang,1 Kevin Mitchell,2 Jie Tang.2 Johns Hopkins Medicine, Baltimore, MD; 2 Alpert Medical School of Brown University, Providence, RI.

Background: Diabetes mellitus is common among individuals with kidney stones; however, the risk factors associated with glucose dysregulation in this population is unclear.

Methods: We characterized the independent associations between vitamin D, urinary measures of dietary intake (sodium, magnesium), and urinary ammonia and citrate with homeostasis model assessment of β-cell (HOMA-B) and insulin resistance (HOMA-IR) in prevalent calcium kidney stone formers without diabetes mellitus recruited from Lifespan Kidney Stone Clinic (N = 96). We used linear regression with adjustment for demographics, body mass index, hypertension, hyperlipidemia, parathyroid hormone, and serum uric acid.

Results: The study population had a mean age of 53 years, 48% were male, and 83% were Caucasian. The mean 25-hydroxy-vitamin D (25D) was 30 ng/mL, 1,25-dihydroxy-vitamin D (1,25D) was 55 pg/mL, 24-hour urine sodium was 145 mmol, urine ammonia was 50 mg/dL, urine citrate was 590 mg/dL, and urine magnesium was 102 mg/dL. Mean HOMA-B was 172.1, and mean HOMA-IR was 5.4. Urine sodium was negatively associated with HOMA-B, but not HOMA-IR. Urine ammonia was positively associated with HOMA-IR, but not HOMA-B. Urine citrate was positively associated with both HOMA-B and HOMA-IR (Table 1).

Conclusions: In our cohort of calcium kidney stone formers, high salt intake and low urine citrate were associated with worse beta-cell function. High urine ammonia and citrate were associated with increased insulin resistance.

Funding: Clinical Revenue Support

*p < 0.05

**p < 0.01
Methods: Among 3,958,837 US veterans that had a sK between 2004-2006, there were 589,019 that had an index HK event (sK >5.0 mEq/L) during this period where we could ascertain INPT/OPT status. We then identified patients who had a recurrent HK event 7-365 days after the index HK and had at least one normal sK ≤5.0 mEq/L in between events. We examined time to recurrence in 30-day intervals according to whether the index sK was INPT or OPT. Patients who’s INPT/OPT status at HK recurrence could not be ascertained were excluded.

Results: HK recurrence over one year occurred in 103,155/589,019 (17.5%) patients, or 17,215/51,262 (34%) and 85,940/537,757 (16%) of patients with index INPT and OPT event, respectively. The 103,155 patients with HK recurrence had a mean patient age of 68±11 years, consisted of 98% males, 14% African Americans, 56% diabetics, and 60% with estimated glomerular filtration rate <60 mL/min/1.73m². In patients with HK recurrence, 50% (n=5,167) developed this event 6 months after the initial HK (table). Among patients who had an OPT index HK, 56% developed recurrence 6 months after index HK event. However, 51% of the patients who had an INPT index HK event developed recurrence within 60 days of the index HK.

Conclusions: A significant proportion of VA patients with HK developed another HK event within one year. Hospitalized patients with HK developed recurrence faster than patients in the OPT setting despite requiring 7 days between HK events and normalization of sK between events. This could be due to the fact that hospitalized patients are usually sicker or they were monitored more closely by the healthcare providers, therefore it is easier to catch HK recurrence in INPTs than OPTs.

PO2056
Workplace Outreach Program Facilitates Referral into Physician Care and Diagnosis of CKD
Olga A. Iakoubova, Carmen H. Tong, Charles M. Rowland, Andre Arelano, Lance A. Bare, Maren S. Fragala, James J. Devlin, Charles E. Birse. Quest Diagnostics Nichols Institute, San Juan Capistrano, CA.

Background: Chronic kidney disease (CKD) is often unrecognized and undertreated. Timely diagnosis can improve disease management and slow CKD progression. We asked whether a workplace outreach program facilitates CKD diagnosis and improves management of CKD.

Methods: An annual workplace health assessment that included eGFR testing was offered to employees. Those with confirmed CKD by repeat eGFR >60 mL/min/1.73 m² or by albumin to creatinine ratio test were eligible to participate in a CKD outreach program. A study coordinator made up to 3 phone calls in an effort to contact each eligible employee, to provide an explanation of CKD risk and to offer a physician consultation to discuss test results and referral into care. Those who accepted the phone call (participation group) were compared to those who were not reached by phone (control group). Using logistic regression models that adjusted for prevalent CKD, we analyzed claims data to estimate the effect of outreach participation on nephrologist visits, physician visits, and new CKD diagnoses 5 months after the outreach. Changes in eGFR levels were evaluated at the following annual health assessment.

Results: Of the 398 eligible employees, 156 participated in the outreach program; the remaining 242 served as the control group. CKD risk factor profiles at baseline were similar between participants and controls. Participants had 3-fold greater odds of visiting nephrologists, 60% greater odds of visiting physicians and 80% greater odds of being diagnosed with CKD, compared with the controls. Participants had 40% lower odds of an annual eGFR decline >5 mL/min/1.73 m² compared with controls (Table). One participant initiated kidney dialysis, compared with none in the control group.

Conclusions: A workplace CKD outreach program facilitates diagnosis of CKD and improves disease management including referral to a nephrologist.

Funding: Commercial Support - Quest Diagnostics supports annual health assessments and the CKD outreach program for employees and their spouses. It also provided funds for the analysis presented in the abstract

Effect of the CKD Outreach Program on Disease Management

PO2057
A Pilot Randomized Clinical Trial to Embed Technology-Enabled Group-Based Exercise Programming in the Clinic: The Exercise Is Medicine in Chronic Kidney Disease Trial
Susan Ziolkowsi,1 Shuchi Anand,1 Ahad A. Bootwalwa,2 Jianheng Li,2 Nhat M. Pham,3 Jason Cobb,1 Felipe Lobelo,2 Stanford University School of Medicine, PALO ALTO, CA; Emory University School of Medicine, Atlanta, GA.

Background: Physical activity (PA) is associated with improvement of cardiovascular health, transplant outcomes, and survival in CKD. We evaluated the feasibility and effectiveness of integrating referral from nephrology clinics to a technology-enabled and/or group-based exercise program.

Methods: We conducted a pilot trial to test the ACSM Exercise is Medicine (EIM) framework in persons with eGFR <45 not on dialysis in San Jose, CA and Atlanta, GA. Participants were randomized to 1. mobile health (mHealth) group: wearable PA trackers + counseling, or 2. EIM group: mHealth + twice weekly small group exercise sessions. Physical and mental health assessments were done at baseline, 8, and 16 wks. Multilevel mixed models evaluated group differences.

Results: Of 56 participants, 86% belonged to a racial/ethnic minority. In intention-to-treat analyses, the EIM group increased moderate-vigorous PA compared to the mHealth group (time x intervention p=0.02) at 8 wks, no differences were observed between group daily step count. In as-treated analyses, daily step count, distance covered, light and moderate-vigorous PA improved in the EIM group and declined in the mHealth group at 8 wks (p=0.05) but group differences faded at 16 wks. No differences in physical function or mental health were found.

Conclusions: We successfully integrated recruitment, assessment, and group-based fitness interventions into clinical settings servicing minority patients with advanced CKD. Despite poor baseline measures, improvements in PA were observed in the EIM group, particularly in persons who participated in exercise sessions.

Effect of Exercise on Quality of Life and Functional Capacity in Patients with CKD

Varun Kumar Bandi,1 Haneesha Kolli,2 Sreelakshmi Nimmagadda,2 Sandhya Komatla.3
1Dharmendra Sreedharth Institute of Medical Sciences & RF; Gannavaram, India; 2Kommareddy Venkata Sadasiva Rao Siddhartha College of Pharmaceutical Sciences, Vijayawada, India.

Background: Chronic kidney disease patients have lower activity levels when compared to normal population, compounded by sedentary lifestyle and is associated with increased mortality, which might reduce with exercise

Methods: Patients with chronic kidney disease were evaluated for 12 weeks of supervised exercise program. The subjects were divided into 2 groups: Group I (CKD stage 3-5) and Group II (CKD on maintenance hemodialysis). Serum hemoglobin (Hb), calcium (Ca), phosphorous (Pi), and albumin (Alb) were done at baseline and at 12 weeks. Symptom burden was assessed using Functional Assessment of Chronic Illness Therapy-Fatigue Scale (FACT-F) and Leicester Uremic Symptom (LUS) Scale. Quality of life using SF-36 questionnaire, functional capacity using Duke Activity Status Index, Physical activity using Godin-Shephard Leisure time Exercise Questionnaire and Nutritional status using modified Subjective Global Assessment at baseline and at 12 weeks. Subjects in Group I were advised aerobic and resistance exercises at home, with once in 3 weeks activity using Godin-Shephard Leisure time Exercise Questionnaire and Nutritional status using modified Subjective Global Assessment at baseline and at 12 weeks. Subjects in Group II underwent aerobic and resistance exercise in the pre-dialytic and intra-dialytic period during each dialysis visit

Results: Group I included 28 patients, while group II had 30 patients. At baseline, Hb and Albamin were significantly different between groups, while other parameters and scores were similar. At baseline, SF-36 and FACT-F significantly correlated positively with Hb, Alb, Ca & Pi, while SGA correlated significantly with Alb, Ca & Pi. At end of study, in group I there was a non-significant increase in SF-36 (p=0.41), and DUKES (p=0.17), with a non-significant decrease in LUS (p=0.36), FACT-F (p=0.83) and SGA (p=0.113), while in group II there was a significant increase in SF-36 (p=0.001), with non-significant increase in Dukes (p=0.75), and a significant decrease in LUS (p=0.001), SGA (p=0.05) and FACT-F (p=0.001)

Conclusions: Exercise increased the quality of life and decreased symptom burden but there was an increase in fatigue perception in patients on dialysis. However, LUSS reduced with reduced FACT-F which could mean decrease in symptom burden but persistence of fatigue. In patients not on dialysis there was no significant increase in quality of life or decrease in symptom burden.

PO2060
Changes in Body Composition, Muscle Strength, and Fat Distribution Following Renal Transplantation

Susan Zolkowski,1 Simin Goral,2 Jin Long,3 Joshua F. Baker,3 Justine Shults,4 Babette Zemel,5 Peter P. Reese,3 Francis P. Wilson,5 Mary B. Leonard.1
1Stanford University School of Medicine, Stanford, CA; 2University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 3The Children’s Hospital of Philadelphia, Philadelphia, PA; 4Lucile Packard Children’s Hospital at Stanford General Pediatrics, Palo Alto, CA; 5Yale University School of Medicine, New Haven, CT; 6University of Pennsylvania, Philadelphia, PA.

Background: The impact of renal transplantation on body composition and muscle quality has not been established. Low muscle mass relative to fat mass (relative sarcopenia) has been associated with mortality and disability but has not been examined following transplantation.

Methods: DXA measures of fat mass index (FMI) and appendicular lean mass index (ALMI; representing muscle mass), CT measures of muscle density (low density Z-scores represented increased intramuscular adipose tissue), and leg muscle strength were assessed in 60 transplant recipients (ages 20-60 years) at transplantation, and 6, 12, and 24 months after transplantation. ALMI relative to FMI (ALMI/FMI) is an established index of relative sarcopenia. Measures were expressed as age, sex, and race-specific Z-scores and compared with 327 healthy controls.

Results: At transplantation, ALMI, ALMI/FMI muscle strength and muscle density Z-scores were lower vs. controls (all p≤0.001). Transplant recipients received glucocorticoids throughout. The prevalence of obesity increased from 18% to 45%. Although ALMI increased following transplantation (p=0.001) and was comparable to controls from 6 months onward, gains were outpaced by increases in FMI, resulting in persistent ALMI/FMI deficits (mean Z-score -0.31 at 24 months, p=0.02 vs controls). Fat gains were disproportionately high in distribution (p=0.05). Muscle strength improved but remained low compared with controls independent of ALMI (p<0.05). Exercise increased in the early months following transplantation (p=0.05) but remained lower than controls (p=0.02).CONCLUSIONS: The two-year interval following renal transplantation was characterized by gains in muscle mass and strength that were outpaced by gains in fat mass resulting in persistent relative sarcopenia.

Results: We included 36 participants with CKD (mean eGFR=38) and 19 controls. Mean age was 61±13 years, 51% male, and 25% had diabetes. Diabetes and CKD were independently associated with lower ATMax (-0.12 mM/s, p<0.01 and -0.19 mM/s, p<0.01, respectively). Accelerometry counts per minute (r=58, p=0.01) was more strongly correlated with ATMax than HAP scores (r=46, p<0.01) with no interaction by CKD status (p=9). Accelerometry counts explained 43% of the difference in ATMax between CKD and controls and HAP scores 15% after adjustment.

Conclusions: Objective PA was more strongly associated with ATMax and explained more of the differences in ATMax between CKD and controls than self-reported PA. Further studies should demonstrate if exercise interventions can improve muscle ATMax in CKD.

**Serum and Skeletal Muscle Acylcarnitines And Physical Function in CKD Stage 5-SD**

Bajani, N; Moorthy, Alissa A. Cranor, Kimberly Swinney, Ricardo Melo Ferreire, Thomas Oconnell, Sharon M. Moe, Keith G. Avin. Indiana University, Indianapolis, IN.

Background: Sarcopenia is highly prevalent among those with advanced CKD. The metabolite signature of skeletal muscle in patients with CKD is poorly studied. We hypothesized that skeletal muscle metabolites would be different between serum and muscle in those with CKD 5-SD as compared to healthy adults.

Methods: Subjects: 34 subjects participated; 17 with CKD (10 CKD-5, 7 CKD 5D) undergoing renal transplant and 17 healthy donors. All had blood drawn and transversus abdominis muscle biopsy during surgery. Physical Function tests done the week before were: Sit to stand (STS), 6 minute walk test (6MW), 4m gait speed (fast and usual). Metabolomics: Targeted mass spectrometry (MS) was performed on serum and muscle using the Biocrates Absolute IDQ. Differences were tested between those with and without CKD.

Results: There were no differences in age, height, weight or BMI between CKD and healthy subjects. Physical Function: The CKD group had poorer performance for the STS (13 vs 19), 6MW (434 vs 589m), fastest gait speed (1.62 vs 2.00 m/s) and usual gait speed (1.18 vs 1.34m/s), all p<0.05. Metabolomics: The heatmap depicted two distinct signatures in both serum and skeletal muscle between CKD and donors. Serum demonstrated 59 significantly different metabolites, especially in fatty acid metabolism with increases in short and medium chain acylcarnitines C4-C12, and nine hydroxylated and dicarboxylated acylcarnitines in CKD (p<0.05). Lower 6MW distance was independently associated with levels of C10:14 even after adjusting for CKD status and age in multivariate regression analyses. Skeletal muscle demonstrated significant differences in 42 metabolites, with consistently higher acylcarnitine levels in recipients, including short chain (i.e. C4.1, C5.1, C6.1), long chain and dicarboxyls.

Conclusions: Our data demonstrates patients undergoing renal transplant have increased acylcarnitine levels in serum and muscle that are independently associated with poor physical performance. These results suggest impaired b-oxidation of fatty acid metabolism that affects physical function. Understanding these pathways will allow targeted therapeutics to improve the disabling sarcopenia observed in patients with CKD.

Metabolic Acidosis and Muscle Metabolic Health Are Important Determinants of Fatigue in Persons with CKD

Tae Youn Kim,1 Se Ri Bae,1 Jorge Gamboa,2 Chenoa R. Vargas,1 Sophia Liu,1 Kuslshang V. Patel,1 Ian H. de Boer,2 Bryan R. Kestenbaum,2 Baback Roshanravan.1 University of California Davis, Davis, CA; 2University of Washington, Seattle, WA.

Background: Chronic kidney disease (CKD) is associated with a high prevalence of physical frailty, reduced physical function and fatigue, contributing to increased morbidity, mortality risk, and poor quality of life. Impaired muscle mitochondrial oxidative capacity (ATPmax) underlies poor physical endurance in persons with CKD. Metabolic acidosis may mediate effects of CKD on ATPmax. Little is known about the relevance of metabolic acidosis and ATPmax on patient-reported fatigue in CKD.

Methods: We performed a cross-sectional analysis of 58 participants (39 CKD and 19 non-CKD) from the CKD Muscle Mitochondrial Energetics and Dysfunction (MEND) study. Muscle metabolic health of the tibialis anterior leg muscle was measured from the time course of phosphocreatine after exercise using 31P Magnetic Resonance Spectroscopy. Fatigue was measured using the Functional Assessment of Chronic Illness Therapy-Fatigue (FACT-F) scale. Metabolic acidosis (MA) was determined from serum bicarbonate (< 22 mEq/L). Linear regression was used to test associations adjusting for age, sex, body mass index (BMI), and diabetes.

Results: The cohort included 48% female and 29% diabetes with a mean age of 61±12 years and a mean BMI of 28±19ml/min per 1.73m² in CKD age, sex, body mass index (BMI), and diabetes.

Methods: We performed a cross-sectional analysis of 58 participants (39 CKD and 19 non-CKD) from the CKD Muscle Mitochondrial Energetics and Dysfunction (MEND). Muscle metabolic health of the tibialis anterior leg muscle was measured from the time course of phosphocreatine after exercise using 31P Magnetic Resonance Spectroscopy. Fatigue was measured using the Functional Assessment of Chronic Illness Therapy-Fatigue (FACT-F) scale. Metabolic acidosis (MA) was determined from serum bicarbonate (< 22 mEq/L). Linear regression was used to test associations adjusting for age, sex, body mass index (BMI), and diabetes.

Results: The cohort included 48% female and 29% diabetes with a mean age of 61±12 years and a mean BMI of 28±19ml/min per 1.73m² in CKD age, sex, body mass index (BMI), and diabetes. ATPmax is directly associated with fatigue. MA might play an important role in the association of muscle metabolic health with fatigue in CKD. Further research is needed to examine the impact of treating MA on improvement in muscle metabolic health, fatigue, and quality of life in CKD.

Blood Pressure in Young Adults with CKD and Associations with Cardiovascular Events and CKD Progression

Alexander J. Kula,1,2 Nisha Bansal,2 David K. Prince,3 Joseph T. Flynn.1,2 Seattle Children’s Hospital, Seattle, WA; 3University of Washington, Seattle, WA.

Background: Young adults (age 18-40yrs) with CKD are a poorly studied subset of CKD patients. Blood-pressure management for young adults with CKD relies on extrapolating findings from studies conducted in older adults or children. Our objective was to perform an observational study exclusively in young adults with CKD to test the association between BP and adverse outcomes.

Methods: Participants aged 21-40yrs of age enrolled in the Chronic Renal Insufficiency Cohort Study were included (n=317). Exposures included baseline systolic BP (SBP) category, <120, 120-129, 130, and >130 higher baseline SBP. Outcomes included cardiovascular (CV) events, including heart failure, myocardial infarction, stroke, or all-cause death, and CKD progression, defined as 50% eGFR decline or ESRD. We used cox-proportional hazard models to test association between baseline SBP with outcomes. Adjusted models included age, race, eGFR, diabetes, and prevalent CV disease for CV event models and urine albumin to creatinine ratio for CKD progression.

Results: As seen in Figure 1, incidence rates for HF, death, CV events, and CKD progression were greater in higher SBP categories. In adjusted models, a baseline SBP ≥130 was significantly associated with CV events (HR: 3.32, 95% CI: 1.53-7.20) and CKD progression (HR: 1.63, 95%CI: 1.02-2.59) compared with SBP<120. Every +10 in SBP was significantly associated with CKD progression (HR: 1.13, 95%CI: 1.02-1.26) in adjusted models.

Conclusions: There is a graded association of higher SBP with greater risk of CV events and CKD progression in young adults with CKD. Among those with SBP>130, 5.8% per year had a CV event and risk was 3-fold higher compared with SBP<120; and 20.7% per year had CKD progression and risk was nearly 2-fold higher. These data suggest that higher SBP is an important risk factor for adverse outcomes in young adults with CKD.

Angiotensin Converting Enzyme Inhibitor and Angiotensin Receptor Blocker Use Among Hypertensive US Adults by Albuminuria Status, 2013-2018

Chi-D. Chy,1 Neil R. Powe,1 Charles E. McCulloch,2 Tanushree Banerjea,1 Deidra C. Crews,1 Rajiv Saran,2 Jennifer L. Bragg-Gresham,3 Hal Morgenstern,2 Meda E. Pavkov,2 Sharon Saydah,4 Delphine S. Tuot.1 CDC CKD Surveillance Team 1University of California San Francisco, San Francisco, CA; 2University of Michigan, Ann Arbor, MI; 3Centers for Disease Control and Prevention, Atlanta, GA; 4Johns Hopkins University School of Medicine, Baltimore, MD.

Background: Since 2003, U.S. hypertension (HTN) guidelines have recommended angiotensin converting enzyme inhibitor (ACEi) or angiotensin receptor blocker (ARB) therapy for urine albumin/creatinine ratio (UACR) ≥300 mg/g. Our objective was to assess the prevalence of ACEi/ARB use for UACR ≥300 mg/g among adults with HTN and to examine the association between UACR and ACEi/ARB use.

Methods: We studied adults with HTN in the National Health and Nutrition Examination Surveys 2013-2018. Respondents were classified as having HTN if they had systolic blood pressure ≥140 mmHg or diastolic blood pressure ≥90 mmHg, were currently using anti-hypertensive medications, or reported being told by a clinician they had HTN. ACEi/ARB use was assessed by review of medication containers by study staff. Modified Poisson regression was used to estimate crude and adjusted prevalence ratios (PR) for the association between ACEi/ARB use and UACR ≥300 mg/g, for sex, race/ethnicity, diabetes, systolic blood pressure (continuous), chronic kidney disease stage, and having a reported routine site for healthcare.

Results: Among 7,377 adults with HTN, 83.4% had UACR 0-29 mg/g, 13.5% had UACR ≥300 mg/g, and 3.2% had UACR ≥300 mg/g. ACEi/ARB use was 43%, 54%, and 48% in UACR categories 0-29, 30-299, and ≥300 mg/g, respectively. This represents approximately 1.5 million adults with UACR ≥300 mg/g who are not receiving ACEi/ARB therapy. Adjusted ACEi/ARB use was minimally associated with UACR ≥300 mg/g (PR = 1.09, 95% CI 1.03-1.17 for UACR 30-299 mg/g; PR = 0.96; 95% CI 0.83-1.10 for UACR ≥300 mg/g; reference = UACR <30 mg/g).

Conclusions: Nationally representative data indicate a large gap in guideline-concordant ACEi/ARB use among adults with HTN and UACR ≥300 mg/g. Improving uptake of ACEi/ARB therapy presents a substantial opportunity for prevention of cardiovascular disease and kidney disease progression for adults with HTN.

Increased Residual Cardiovascular Risk in US Veterans with Moderately Elevated Baseline Triglycerides, Well-Controlled LDL Cholesterol Levels on Statins, and Decreased Renal Function

Sarah Leatherman,1 Ryan E. Ferguson,1 Cynthia Hau,1 Craig B. Granowitz,2 Kelly M. Harrington,1 Sephy Philips,2 Peter P. Toth,2 Deepak L. Bhatt,2 William E. Boden,1 VA Boston Healthcare System, Boston, MA; 2Amarin Corp, Bridgewater, NJ; 3Brigham and Women’s Hospital, Boston, MA; 4CGH Medical Center, Sterling, IL.

Background: Recent studies have suggested a causal role for elevated triglycerides (TG) in incident cardiovascular (CV) events. Using a large cohort of U.S. veterans with statin-controlled LDL-C levels (40-100mg/dL), we explored whether increased residual CV risk existed in patients with elevated baseline TG levels versus those with normal TG levels in the subset who had reduced eGFR (<60 ml/min).

Methods: We identified veterans receiving a statin but not a TG-lowering agent from the VA Corporate Data Warehouse, a database of the VA electronic health record,
from 2010-2015. We compared CV event rates (nonfatal MI, stroke, unstable angina, or coronary revascularization) between the elevated TG (150-499 mg/dL) and normal TG (<150 mg/dL) groups. We calculated crude event rate ratios, rate ratios, and 95% CI for both groups, and adjusted event rate ratios for age, sex, baseline blood pressure, glomerular filtration rate, and weight.

Results: We included 152,266 veterans (predominantly male and white) in the analysis cohort of whom 43,670 (29%) had elevated TG levels. These subjects were younger and had higher BMIs. Table 1 details the crude and adjusted CV event rates. The overall crude and adjusted CV event rate ratios were 1.28 (95% CI 1.23,1.33) and 1.12 (95% CI 1.07,1.16), respectively.

Conclusions: In this large cohort of veterans, those with elevated TG levels and moderately decreased renal function showed a significant increase in CV events despite well-controlled LDL-C on statins compared to veterans whose baseline TG was in a normal range.

Deep Learning Analysis of Derived Cardiac Function Metrics for the Detection of CKD and Subsequent Outcome Prediction in Community-Dwelling Individuals

Niall Cosgrove,1 John D. O’Connor,1 George S. Mellite,1 Brenda Griffin,2 Conall M. O’Seaghdha,3 Scott Reule,4 Robert N. Foley,1 Silvin P. Knight,5 Mark A. Little,6,7 Donal J. Sexton,1,2 1University of Dublin Trinity College, Dublin, Ireland; 2Trinity Health Kidney Center, St James’s Hospital & Tallaght University Hospital, Dublin, Ireland; 3Beaumont Hospital, Dublin, Ireland; 4National Renal Office, Health Service Executive of Ireland, Dublin, Ireland; 5United States Renal Data System Coordinating Centre, Minneapolis, MN; 6Minneapolis VA Health Care System, Minneapolis, MN; 7University of Minnesota System, Minneapolis, MN.

Background: Whether subtle abnormalities in cardiac function exist in community-dwelling individuals and can be used toagnostically discern those with reduced kidney function and incident adverse outcomes over follow up is unknown.

Methods: The Irish Longitudinal Study on Ageing (TILDA) is a prospective nationally representative cohort study based on random sampling of the community-dwelling general population aged ≥50 years in Ireland. Wave 1 was performed between June 2009–June 2011. Participants underwent a detailed health assessment including blood tests, and an active stand test using the Finometer, which measures continuous blood pressure and heart rate for 10 mins while supine at rest, then throughout the standing test and for 2 mins thereafter. Cardiac function metrics are derived: left ventricular ejection time (LVET), cardiac output, and total peripheral resistance. CKD-EPI equation was used to estimate eGFR. All participants had ≥2 measurements of LVET and cardiac output over 3 years, eGFR <60 ml/min/1.73 m2 within 2 years and during the period between 2008 and 2019 were included. The first date where the eGFR value became <60 was defined as the index date. Patients without serum creatinine (SCr) record within 38 months from the index date were excluded. Anemia status (yes/no) was defined by the age-sex specific hemoglobin value estimated.

Conclusions: Deep Learning analysis of repeated measures of derived cardiac function metrics discerned community dwelling individuals with CKD and subsequent outcomes. This method has potential for population level risk discrimination.
PO2071

Estimation of Sodium Consumption by Novel Formulas Derived from 12-Hour Urine Collection

Pitchaporn Sonuch, Surasak Kantachuvessiri. Mahidol University Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand.

Background: 24-hour urine sodium excretion is the gold standard for estimating sodium intake. Several equations have been used to estimate 24-hour urine sodium excretion from spot urine samples. However, a validated formula for predicting 24-hour urine sodium excretion from 12-hour urine collection has not been established. This study aims to establish novel equations for predicting 24-hour urine sodium excretion from 12-hour urine collection and to also validate spot urine equations for predicting 24-hour urine sodium excretion.

Methods: 299 adults were recruited from hospital personnel. Participants were asked to perform a 12-hour daytime, nighttime, and a random spot urine collection in 1 day. Pearson correlation was used to compare measured 24-hour sodium excretion to the estimated values from three different methods. A multivariate linear regression analysis was performed to create novel equations. Bland-Altman method was used to estimate bias and agreement between the equations.

Results: The mean 24-hour urine sodium excretion was 4,055 ± 1,712 mg/day (male 4,307 ± 1,694 and female 3,882 ± 1,710 mg/day, P = 0.0078). The 24-hour urine sodium excretion in non-healthcare workers was higher than in healthcare workers (4,442 ± 1,865 and 3,617 ± 1,406 mg/day respectively, P < 0.001). Estimated urine sodium excretion from 3 different equations using spot urine samples showed moderate correlation with actual 24-hour urine sodium excretion (r = 0.54, P = 0.001 for Kawasaki; r = 0.57, P = 0.001 for Tanaka; r = 0.66, P = 0.001 for INTERSALT). Novel equations for predicting 24-hour urine sodium excretion was then developed using variables derived from 12-hour daytime urine collection, 12-hour nighttime urine collection, and random spot urine samples which showed strong correlation with actual measured values (r = 0.88, P = 0.001, r = 0.83, P = 0.001, r = 0.67, P = 0.001 respectively. Bland-Altman plots indicated good agreement between predicted values and actual 24-hour urine sodium excretion using the new equations, with biases for 12-hour daytime urine collection of +0.28 mmol/day (95%CI: -5.09 to 4.53), for 12-hour nighttime urine collection of 0.85 mmol/day (95%CI: -4.86 to 6.56), and for random spot urine sample of 0.90 mmol/day (95%CI: -6.66 to 8.45).

Conclusions: The associations between predicted values and actual measured sodium excretion were stronger using 12-hour daytime urine collection and 12-hour nighttime urine collection can accurately predict 24-hour urine sodium excretion.

PO2072

Serum Magnesium, Blood Pressure, and Risk of Hypertension: Insights from the Chronic Renal Insufficiency Cohort (CRIC) Study

Simon Correa,1,2 Xavier E. Guerra Torres,3 Sushrut S. Waikar,4 Finninn R. McCausland,1,2 Brigham and Women’s Hospital, Boston, MA; 3Harvard Medical School, Boston, MA; 4Hospital Universitario Principe de Asturias, Alcala de Henares, Spain; 5Boston Medical Center, Boston, MA.

Background: Magnesium (Mg) has been implicated in regulation of blood pressure (BP). Mg deficiencies in serum Mg (sMg) are common in CKD and ESRD due to decreased intestinal absorption, impaired renal handling and diuretics use. Studies assessing the association of sMg and BP are scarce, and the association of sMg with the risk of developing hypertension (HTN) is unknown.

Methods: We analyzed data from 3,866 participants from CRIC. Adjusted linear regression models assessed the association of sMg with SBP and DBP at baseline and adjusted smoothing splines were fit. Adjusted logistic regression models explored the association of baseline sMg with baseline HTN (CRIC-defined HTN: SBP ≥140 or DBP ≥90 or anti-HTN drug use; AHA-defined HTN: SBP ≥130 or DBP ≥80 or anti-HTN drug use) and sub optimally controlled blood pressure (SBP ≥120 or DBP ≥80). Adjusted cox-proportional hazard models stratified by clinical site explored the association of baseline sMg with incident HTN. All models were adjusted for demographics, CV comorbidities, eGFR, proteinuria, serum albumin, GFG-23, calcium, phosphate, total PTH, Na, K, urine Na, and urine K.

Results: Median sMg was 2.0 mg/dL (25th-75th percentile 1.9 to 2.1 mg/dL). Higher sMg at baseline was associated with lower SBP (β = -2.63 mmHg, 95% CI -5.01 to -0.25, per 1 mg/dL) and lower DBP (β = -2.75 mmHg, 95% CI -4.16 to -1.34, per 1 mg/dL) (Fig 1A, 1B). Higher sMg was associated with a lower risk of AHA-defined HTN at baseline (HR ≤OR 0.25, 95% CI 0.12-0.55, per 1 mg/dL), a lower risk of sub optimally controlled BP (aOR 0.22, 95% CI 0.10-0.53, per 1 mg/dL) but not with a higher risk of CRIC-defined HTN (aOR 0.77, 95% CI 0.30-1.20, per 1 mg/dL). In time-to-event analyses, higher baseline sMg was associated with a numerically lower risk of incident CRIC-defined HTN (aHR 0.68, 95% CI 0.40-1.13, per 1 mg/dL).

Conclusions: Higher sMg is associated with lower SBP, lower DBP and a nominally lower risk of incident HTN. Monitoring and optimal control of sMg should be considered in patients with CKD for improved BP control.

PO2073

Cardiac Structure and Function and Long-Term Risk of ESKD in African Americans: The Atherosclerosis Risk in Communities (ARIC) Study

Manabu Hishida,1,2 Junichi Ishigami,1 Lena Mathews,3 Morgan Grams,4 Josef Coren,5 Scott D. Solomon,6 Kunihiro Matsushita,7 Welch Center Johns Hopkins University, Baltimore, MD; 2Nagoya Daigaku Daigakuin Igakubu Kenkyuka Igakubu, Nagoya, Japan; 3Brigham and Women’s Hospital, Boston, MA.

Background: Cardiovascular disease and end-stage kidney disease (ESKD) disproportionately affect African Americans. Whether cardiac structure and function is associated with the risk of ESKD in this population is not well-characterized.

Methods: In 1,929 African American ARIC participants who underwent echocardiography between 1993-1995 (mean age 58.5 [SD 5.6] years, 36% male), we explored the association of left ventricular mass index (LVMi), fraction shortening (FS), left atrial diameter (LAD), and LV end-diastolic diameter (LVEDD) with the subsequent risk of ESKD using Kaplan-Meier method and multivariable Cox models.

Results: During a median follow-up of 22.3 years, 82 participants developed ESKD (incidence rate 3.0 per 1,000 person-years). The cumulative incidence of ESKD was highest in the top quartile (bottom quartile for FS of all echo parameters (Figure), although the risk separation was most evident for LVMi. The association of LVMi with ESKD remained significant even after accounting for potential confounders like blood pressure and clinical history of cardiovascular disease (HR 2.46 [1.13-5.38] in the top vs. bottom quartile). FS, LAD, or LVEDD were not independently associated with ESKD.

Conclusions: Among African Americans, higher LVMi was robustly and independently associated with the risk of ESKD. Our findings support the importance of LVMi or its pathophysiology in CKD progression in African Americans.

PO2074

Myeloperoxidase and the Risk of Atrial Fibrillation in the Chronic Renal Insufficiency Cohort (CRIC) Study

Katherine Curtis,1,2 Simon Correa,1,2 Sushrut S. Waikar,3 Finninn R. McCausland,1,2 Mc Causland Lab 1Brigham and Women’s Hospital, Boston, MA; 2Harvard Medical School, Boston, MA; 3Boston Medical Center, Boston, MA.

Background: Myeloperoxidase (MPO) catalyzes the formation of reactive oxygen intermediates and is associated with adverse CV outcomes and progression of chronic kidney disease (CKD). We wished to determine the association of MPO with hospitalization for atrial fibrillation (AFib) in patients with baseline CKD.

Methods: We evaluated 3,872 participants with MPO measured at baseline in the CRIC Study, a large prospective multicenter cohort of non-dialysis dependent CKD. The association of MPO with hospitalization due to AFib was evaluated through adjusted Cox proportional hazard models in all study participants, and separately in subjects with and without AFib at baseline. Models were adjusted for age, sex, race, DM, SBB, coronary artery disease, CHF, eGFR (CKD-EPI), proteinuria, ACEi- ARB, beta-blocker and diuretic use.

The Association Between Pre-Donation Hypertension and Early Post-Donation Systolic Blood Pressure in Older Living Kidney Donors
Fawaz Al Ammary, Abimerki Muzzaal, Daniel C. Brennan, Dorry L. Segev, Allan Massie. Johns Hopkins University School of Medicine, Baltimore, MD.

Background: One mechanism underlying predonation hypertension in older (age≥50) living kidney donors is a reduced number of nephrons. The 50% nephron mass reduction associated with donor nephrectomy may exacerbate predonation, controlled hypertension. In light of evolving hypertension guidelines, we aim to study systolic blood pressure (BP) trajectory in older donors with- vs. without hypertension.

Methods: We conducted a national registry study of 11,969 older living kidney donors from 2010-2018. We modeled the association between predonation hypertension and postdonation systolic BP using a mixed linear model with donor-level random intercept adjusting for age, sex, race, predonation systolic BP (SBP), BMI, and year of donation. We modeled odds of having 6-month postdonation systolic BP ≥130 mmHg and ≥140 mmHg using multivariable logistic regression.

Results: 1,161 of 11,969 older donors (9.7%) had hypertension. Median (IQR) predonation systolic BP was 130 mmHg (122-140) among donors with hypertension vs. 124 mmHg (115-132) among those without (p<0.001). After adjustment for baseline characteristics including predonation systolic BP, hypertension was associated with a 2.4, and 3.9 mmHg increase in postdonation systolic BP (p<0.001). Hypertension was associated with 39% higher odds of having 6-month postdonation systolic BP ≥130 mmHg (aOR≥130 mmHg = 1.50, p<0.001) and 50% higher odds of having 6-month postdonation systolic BP ≥140 mmHg (aOR≥140 mmHg = 1.50, p<0.001).

Conclusions: Predonation hypertension was associated with higher risk of uncontrolled 6-month postdonation systolic BP among older donors, even after adjusting for postdonation systolic BP. Our findings call for programs to monitor postdonation systolic BP in donors with hypertension to ensure adequate BP control following nephrectomy.

Temporal Trends of the Burden of CKD Among Hospitalized Aortic Stenosis Patients in the Province of Quebec, Canada
Nada Khelifi,1 Denis Hamel,2 Sonia Jean,2,3 Claudia Blais,2,4 Fabrice Mac-Way,5 1CHU de Quebec Research Center, Faculty of Medicine, Université Laval, Quebec, QC, Canada; 2Institut national de santé publique du Québec, Québec, QC, Canada; 3Faculty of Medicine, Université Laval, Québec, QC, Canada; 4Faculty of Pharmacy, Université Laval, Québec, QC, Canada.

Background: Aortic stenosis (AS) is associated with valvular calcifications which are highly prevalent in chronic kidney disease (CKD). The aim of this study was to describe the temporal trends of comorbid CKD status in patients hospitalized for AS and evaluate the impact of these two conditions on 1-year mortality in the province of Quebec, between 2000 and 2017.

Methods: Using the Quebec Integrated Chronic Disease Surveillance System, we identified patients a 20 years with incident AS using ICD-9 and ICD-10 codes, in the hospital discharge database. We then combined hospital discharges and physician billing claims databases to identify patients with comorbid CKD status in the two years prior to the AS diagnosis. Three subgroups of CKD status were considered: 1) non-CKD, 2) pre-dialysis and 3) dialysis. To allow comparison over time, direct adjustment using age distribution of the 2016-2017 AS population was used for proportion, 1-year all-cause and cardiovascular mortality.

Results: We included 108,780 patients with incident AS (Women: 51.8%; mean age (aSD): 76.4 ±11.7; non-CKD: 74.2% (n=80,768); pre-dialysis: 24.6% (n=26,809); dialysis: 1.1% (n=1,203). During the study period, the age-adjusted proportion of AS patients with non-CKD comorbid status decreased by 14% (80.7% [95% CI 77.6-84.0] to 66.9% [95% CI 67.2-71.9]). Inversely, the age-adjusted proportion of AS patients with pre-dialysis and dialysis comorbid status increased by 58% (18.5% [95% CI 16.9-20.2] to 29.3% [95% CI 27.8-30.9]) and 46% (0.7% [95% CI 0.5-1.1] to 1.1% [95% CI 0.8-1.4]), respectively. Age-adjusted 1-year all-cause and cardiovascular mortality decreased over time but remained higher in patients with comorbid CKD. In 2015-2016, age-adjusted relative risk (RR) of 1-year all-cause mortality was significantly higher in pre-dialysis (RR=1.56 [95% CI 1.44, 1.69]) and dialysis (RR=2.04 [95% CI 1.62-2.61]) compared to non-CKD patients. Age-adjusted RR of 1-year cardiovascular mortality was also significantly higher in pre-dialysis (RR=1.83 [95% CI 1.66-2.03]) and dialysis (RR=2.28 [95% CI 1.68-3.09]) compared to non-CKD patients.

Conclusions: Proportion of patients with incident AS and comorbid CKD increased from 2000 to 2017. One-year all-cause and cardiovascular mortality improved over time but remained higher in AS patients with comorbid CKD.

PO2077
Troponin Level in Relation to Angiographic Coronary Artery Disease in CKD Patients
Sachin Bhatia,1 Bhavin Chokshi,1 Balaram Krishna J. Hamamantulu,2 Belinda Jim,2 Jacob Medical Center, Bronx, NY; 2Mount Sinai Beth Israel Hospital, New York, NY; 1Wayne State University School of Medicine, Detroit, MI; *James J Peters VA Medical Center, Bronx, NY.

Background: An association between cardiac troponin I (cTI) in the diagnosis of angiographic coronary artery disease (CAD) is unclear in the CKD population. We evaluated the association between cTI findings of angiographic significant CAD in CKD patients with traditional risk factors.

Methods: Data was collected from left cardiac catheterizations (LCHs) performed between 2006-2017 at Jacobi Medical Center. CAD outcomes were defined as: none, mild (<50% stenosis), moderate (50-69% stenosis), severe (≥70% stenosis of any major epicardial artery). ROC characteristics of cTI as biomarker for severe CAD was performed in patients with CKD stages 3-5. C-Statistic/AUC were used to compare pretest probabilities for severe CAD based on CAD risk factors (age, race, HTN, HLD, DM, smoking), abnormalities on ECHO and ECG, cTI level, and CKD stage.

Results: 798 LCHs were included. Fig1a shows that cTI level is only significantly higher in severe CAD as compared to no CAD among CKD 1-2 patients. ROC showed cTI >0.3ng/mL displayed peak sensitivity (59%), specificity (62%). Multivariate analysis for predictors of severe CAD among 223 CKD patients was stratified at cTI >0.3 and cTI <0.3. Among cTI <0.3 subgroup, age >65(OR 4.6, 95% CI 1.49-27.9, p=0.012) and eGFR<30(OR 2.92; 95% CI 0.94-9.00; p=0.06) were associated with severe CAD. Among cTI >0.3 subgroup, none of the clinical factors were significantly associated with severe CAD. Fig1b shows that the addition of dichotomized cTI > or < 0.3 to CAD risk factors did not significantly change the AUC value.

Conclusions: cTI levels are not associated with different levels of CAD in patients with eGFR<60. The addition of cTI>0.3 does not alter the predictive value of severe CAD when other cardiac risk factors are considered. It will be important to study if the change in cTI during a cardiac event would be more predictive in the CKD population.
PO2078

Pediatric vs. Adult Ambulatory Blood Pressure Monitoring (ABPM)
Criteria for the Diagnosis of Hypertension (HTN) and Detection of Left Ventricular Hypertrophy (LVH) in Adolescents

Kumail Merchant,1 Parus P. Shah,2 Paula Singer,1 Laura J. Castellanos,1 Christine B. Sedina,1,2 Cohen Children’s Medical Center, Queens, NY; Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.

Background: Normative values for clinic blood pressure (BP) measurements in adolescents were recently updated to align with adult HTN guidelines (CPG 2017). However, the most widely accepted pediatric normative values used to diagnose HTN by ABPM criteria have not been updated. The objective of this study was to compare pediatric ABPM criteria (pHTN) with adult ABPM criteria (aHTN) for the diagnosis of HTN and detection of LVH in adolescents.

Methods: ABPM and ECHO reports from adolescents age 12-18 years performed from 2015-2019 at a single center were analyzed. The concordance of HTN diagnosis based on pHTN (AHA 2014) was compared to aHTN from ACC/AHA 2017 (overall BP ≥125/75 mmHg, wake BP ≥130/80 mmHg, sleep BP ≥110/65 mmHg) using Cohen’s kappa statistic. Logistic regression adjusted for body mass index (BMI) z-score and receiver operating curves (ROC) were used to compare the ability of pHTN vs. aHTN to detect LVH (left ventricular mass index [LVMI] >95th percentile reference values and LVMI >51g/m²).

Results: Of 306 adolescents (15.9±1.6 years, 73.5% male), 140 (45.8%) had HTN based on pHTN compared to 228 (74.5%) based on aHTN. There was poor agreement in the diagnosis of HTN between pHTN and aHTN (59.3%, N=137, kappa 0.41). 1.0% (N=3) had HTN by pHTN only while 29.7% (N=91) had HTN by aHTN only. Although a higher prevalence of LVH was captured by aHTN only, 9 (5.6%) adolescents who had LVH >95th percentile did not have HTN by either criteria. In logistic regression, adjusted for BMI z-score, there were no significant differences between pHTN and aHTN in the detection of LVH >95th percentile (OR 1.24, CI 0.66-2.31, p=0.51) or >51g/m² (OR 1.06, CI: 0.47-2.40, p=0.89). ROCs for pHTN were not significant for detecting LVH >95th percentile (0.50, p=0.91) or >51g/m² (0.55, p=0.45). However, the ROC for aHTN was significant for detecting LVH >95th percentile (0.59, p=0.045) but not >51g/m² (0.63, p=0.07).

Conclusion: Pediatric HTN criteria appear to have better sensitivity than adult HTN criteria for the diagnosis of HTN in adolescents. aHTN appears to better predict LVH than pHTN, although neither criteria diagnosed all patients who had LVH. A consideration to align the ABPM criteria for the diagnosis of HTN in adolescents with adult guidelines is warranted.

PO2079

Effect of Psychiatric Diagnosis and Selective Serotonin Reuptake Inhibitors (SSRIs)/Serotonin Norepinephrine Reuptake Inhibitors (SNRIs) Use on BP Using 24-Hour Ambulatory Blood Pressure Monitoring (ABPM)

Nabeel Ahsan1, Mohita H. Momon, Hani Wadei, Shehzad K. Niazi. Mayo Clinic, Jacksonville, FL.

Background: Hypertension (HTN) and psychiatric disorders frequently co-exist. Psychiatric conditions and their treatment by SSRIs/SNRIs affect serotonin & norepinephrine and may cause variation in blood pressure (BP). There is limited data to assess this variation by using ABPM.

Methods: Subjects who underwent psychiatric evaluation & ABPM within six months of each other between 1/2012 to 12/2017 were identified. Demographics, comorbidities, medications, ABPM, lab data were retrospectively collected. Subjects were divided into group-subjects with no psychiatric diagnosis & no psychiatric medicine (Group 1), subjects with psychiatric diagnosis & on SSRIs/SNRIs (Group 2) and subjects with psychiatric diagnosis & no medication (Group 3). BP systolic & diastolic levels (daytime, nighttime) were compared between groups controlling for age, sex, race, HTN, DM and smoking. Single and multivariable linear regression models were used to analyze group differences.

Results: Total of 475 subjects met inclusion criteria–Group 1=135, Group 2=232, and Group 3=108. First, Group 1 was compared with Group 2 for daytime systolic & diastolic, nighttime systolic & diastolic BP. In multivariable analysis adjusted for age, sex, race, HTN, DM, and smoking, subjects in Group 2 had higher nighttime systolic BP (22.7±11.05 mmHg; 8.36; 95% CI: 4.21-12.51; P<0.0001) and nighttime diastolic BP (8.2±6.4 mmHg; 4.6±11.9; 2.7 P<0.0001) to determine whether higher nighttime systolic & diastolic BP in Group 2 were due to psychiatric diagnosis or effect of SSRIs/SNRIs, we compared ABPM between Group 1 & Group 3. In adjusted model, there was no statistically significant difference between Group 1 & 3 for daytime or nighttime systolic & diastolic BP suggesting higher nighttime BP in Group 2 was associated with psychiatric diagnosis during sleep with serotonin & norepinephrine with SSRIs/SNRIs use. Further prospective studies using ABPM are needed to determine the risk of nocturnal hypertension with SSRIs/SNRIs use that could adversely impact cardiovascular outcomes.

PO2080

Obesity-Related Renal Damage in Adolescent Women: Body Surface Area Matters

Dana Bielowolski,1 Neha Singh,1 Caroline S. Jiang,3 Robert B. Macarthur,1 Kimberly S. Vasquez,1 Dena S. Mofath,2 Rhonda Kost,3 Jonathan N. Tobin,2,3 The Rockefeller University, New York, NY; Clinical Directors Network Inc., New York, NY.

Background: Obesity is a potentially modifiable risk factor for the development and progression of kidney disease. In children and adults, the attention has been paid to the prevalence of early signs of kidney dysfunction among overweight and obese adolescents by examining routine labs including creatinine for hyperfiltration and albuminuria.

Methods: De-identified electronic health record (EHR) data were extracted for female adolescents aged 12-21 years, who received health care services from 1/1/2011 to 12/31/2015 in NYC from 12 academic health centers and community health centers that are part of PCORnet NYC Clinical Data Research Network (NYC-CDRN). Data were analyzed using SAS (v 3.25) on 60,549 unique subjects. Patient characteristics observed and by subgroups were examined using standard statistical tests. BMI groups were coded according to NHANES as underweight, normal weight, overweight or obese. Multiple linear regression analyses will control for covariates.

Results: Mean creatinine values were similar between normal weight, overweight and obese BMI groups, yet after calculating eGFR and adjusting for BSA, significant and alarming differences appeared. Obese adolescent women had significantly higher eGFR, estimated by CKD-EPI and the Schwartz formula according to age, compared to normal weight subjects. Only subjects in the obese group (BMI>30) exhibited hyperfiltration (eGFR>135 ml/min).

Conclusions: Obese adolescent women present with significant alteration in kidney function that without intervention will lead to ESRD, and adverse outcomes associated with the deleterious effects of adiposity. Awareness should be raised to consider body size when estimating GFR in adolescents.

PO2081

Urinary Magnesium Predicts Risk of Cardiovascular Disease in Pre-Dialysis CKD Patients

Qiongling Yuan,1 Hui Xu,1 Jinwei Wang.2 on behalf of the C-STRIDE study group.1 Yonghua Hospital Central South University, Changsha, China; 2Peking University First Hospital, Beijing, China.

Background: 24h Urinary magnesium concentration (24h U Mg), an indicator of intestinal magnesium absorption, may provide a better insight in the connection of CKD progression.

Methods: We examined 3179 participants aged 18 to 74 years pre-dialysis patients in the Chinese Cohort Study of Chronic Kidney Disease (C-STRIDE) study. We performed a time-to-event analysis of the data using Kaplan-Meier Survival model, Cox proportional hazard and competing risks Fine and Gray sub-distribution hazard models.

Results: During the median follow-up of 4.19 (IQR 3.432-5.09) years, lower incidence rate of ESRD events was observed with increases in 24h UMg (Figure 1). Higher incidence rate of CVD events was seen with increases in 24h UMg (Figure 2). After adjustment for demographic and traditional ESRD risk factors, 24h UMg was strongly associated with risk of CVD (HR of 1.509 [95% CI 1.031:2.208] Table 1).

Conclusions: 24h U Mg risk variants display a modest association with CVD in pre-dialysis CKD patients.

Funding: Government Support - Non-U.S.

Model 2: Age, gender, CVD, HBP, DM, drinking, smoking, UA, HCO3-, TC, LDL, eGFR, BMI, ACR, iPTH, HGB, sP, sMg, sCa, sK, sNa, UNa, UK

Conclusions: Although non-dipping was not associated with LVMI or LVH in adolescents with WCH, the fair prevalence (34.7%) of non-dipping among this population is of note. Given adult studies demonstrating the progression of non-dipping to poor CVD outcomes, these potentially high-risk patients should be monitored closely.

PO2083

Left Atrial Strain Measurements Are Associated with Cardiovascular Outcomes in Patients with ESRD

Ruth F. Dubin,1 Amrita S. Ayer,2 Catherine L. Donovan,1 Lauren Nelson,3 Sanjiv Shah.3 1University of California San Francisco, San Francisco, CA; 2University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; 3Northwestern University Feinberg School of Medicine, Chicago, IL.

Background: Left atrial (LA) strain is a marker of diastolic dysfunction, heart failure and atrial fibrillation that has been validated in populations without chronic kidney disease. There are few studies of LA strain in patients with end-stage renal disease (ESRD), among whom cardiovascular (CV) mortality is high and there are no accepted methods of CV risk stratification. We sought to examine associations of LA reservoir strain with CV hospitalization and mortality in a cohort of patients with ESRD on dialysis, and to investigate prognostic utility of strain measurements for CV outcomes.

Methods: 190 ambulatory participants with ESRD on dialysis in the Cardiac, Endothelial Function and Arterial Stiffness in ESRD (CERES) study underwent 2D echocardiography at one study visit. The composite outcome, CV hospitalization or death, was adjudicated over a median of 2 years. Hospitalizations attributed to missing dialysis were not counted as events. LA and left ventricular (LV) structure and function were captured by a single technician, and de-identified images were read by a single reader using GE EchoPac software. Associations of LA reservoir strain with the composite outcome were analyzed with cox survival analyses, adjusting for age, gender, comorbidities, and systolic blood pressure.

Results: Mean age was 56 years, 1/3 were women, and the median time since dialysis initiation was 3.5 years. 45% were diabetic and 14% had a history of heart failure. Participants were relatively euvoletic, based on well-controlled blood pressure and weight. Mean (SD) LA volume index was 40ml/m2(±12), mean LA reservoir strain was 24%(±6.9). There were 61 events: 40 hospitalizations and 21 deaths. In the adjusted model, HR (95%CI) per SD LA volume index was 1.4(1.04, 1.9); LA reservoir strain HR(95%CI) per SD was 0.67(0.47, 0.94). A risk model including age, LA reservoir strain and LV global longitudinal strain had an a-statistic(95%CI) of 0.72(0.63, 0.81) for the composite outcome.

Conclusions: Our results suggest that LA strain is independently associated with CV hospitalizations and death among patients with ESRD on dialysis. Strain measurements have the potential to contribute to CV risk stratification in this population. Larger studies are necessary to validate our findings.

PO2084

Under Diagnosis of Pediatric Hypertension

Anosh Moin, Craig B. Langman. Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL.

Background: Pediatric hypertension is associated with target organ damage in children and cardiovascular morbidity in adults. Therefore, prompt diagnosis and treatment are critical. Application of clinical practice guidelines is inconsistent.

Methods: Using electronic health record data (from 8 community centers), we evaluated the proportion of children (3-18 years) with elevated blood pressures (>90th percentile) who were appropriately diagnosed as either hypertension or elevated blood pressure over 1 year (2016-17), and provided guideline directed follow-up, by age, sex, race/ethnicity and weight.

Results: The sample included 6233 children with elevated blood pressure, 15% were appropriately diagnosed. These children were more likely to be older, white, and obese. 55 children met criteria for hypertension with 23 being appropriately diagnosed, there was no difference by patient characteristics. Of children with blood pressure ≥95th percentile, 13% had follow-up within 1 month; they were more likely to be older, female, of Hispanic ethnicity or ‘other’ race. Of children with blood pressure ≥90th percentile, 41% had follow-up within 6 months, and were more likely to be older, of either white, Hispanic, Asian race or Hispanic ethnicity.

Conclusions: We found persistent underdiagnosis of pediatric hypertension and elevated blood pressure as well as disparities in the diagnosis of elevated blood pressure and guideline-directed follow-up among diverse children in a community setting. New strategies are needed to improve compliance with guidelines.

Background: Visit-to-visit blood pressure variability (BPV) is associated with cardiovascular (CV) events in individuals with chronic kidney disease (CKD) stages 3-5. We examined the associations of BPV with CV events, death, and end-stage kidney disease (ESKD) among veterans with CKD stages 1-5 and hypertension, and if treatment with a thiazide or loop diuretic modified these associations.

Methods: In a matched cohort study, patients seen between 2010-2016 with non-dialysis CKD and hypertension on single-agent therapy with a non-diuretic were propensity with a thiazide or loop diuretic modified these associations. 3-5. We examined the associations of BPV with CV events, death, and end-stage kidney disease (ESKD) in patients with CKD and hypertension. Diuretic use attenuated the association of BPV was also associated with MI, heart failure, stroke, and death, but not with ESKD

Results: We included 31,394 new users of diuretics and 31,394 patients initiating their second agent. BPV, defined as the coefficient of variation of outpatient systolic blood pressure over 6 months after prescription of the second antihypertensive, was divided into their second agent. BPV, defined as the coefficient of variation of outpatient systolic blood pressure over 6 months after prescription of the second antihypertensive, was divided into quintiles. Cox proportional hazards regression measured associations of BPV with time to CV events (first among myocardial infarction [MI], hospitalization for heart failure, or ischemic stroke), each component of the primary outcome, all-cause death, and ESKD.

Results: We included 31,394 new users of diuretics and 31,394 patients initiating other agents. Over a median (IQR) follow up time of 939 (404-1,606) days, there were 7,326 CV events, 16,357 deaths, and 2,029 ESKD events. Higher BPV was associated with composite CV events (Figure). Diuretic exposure attenuated these associations at the fourth and fifth quintiles of BPV (interaction P<0.03 at the 4th and .04 at the 5th quintile). BPV was also associated with MI, heart failure, stroke, and death, but not with ESKD (Figure). Diuretic treatment did not modify these associations. Conclusion: BPV was associated with CV events and all-cause death but not ESKD in patients with CKD and hypertension. Diuretic use attenuated the association of BPV with CV events at the highest quintiles of BPV. Future studies should test whether diuretics improve CV outcomes in those with high BPV.

Associations of Blood Pressure Variability with Cardiovascular Events, Death, and ESKD in Patients with CKD

L. Parker Gregg,1,2 Susan Hedayati,1 Hui Yang,1,2 Peter N. Van Buren,1,2 Sankar D. Navaneethan,3,4 Salim S. Virani,3,4 Wolfgang C. Winkelmayer,5 Carlos A. Alvarez,2 University of Texas Southwestern Medical Center at Dallas, Dallas, TX; 2VA North Texas Health Care System, Dallas, TX; 3Baylor College of Medicine, Houston, TX; 4Michael E DeBakey VA Medical Center, Houston, TX; 5Texas Tech University Health Sciences Center School of Pharmacy, Dallas, TX, US, TX, TX.

Background: Hypertension and CVD: Epidemiology, Risk Factors, and Prevention

Hypertension (HTN) is often underdiagnosed and undertreated. Masked HTN can reach 49% in chronic kidney disease (CKD) in children. The prevalence of HTN in systemic lupus erythematosus (SLE) varies from 30 to 77%. A small study demonstrated that children with SLE are prone to have blunted dipping. Nocturnal HTN and blunted dipping are independent predictors for all-cause cardio-vascular morbidity/mortality, independent of 24-hr systolic blood pressure (BP) levels.

Methods: Patients (<21 years) with lupus nephritis (LN) were enrolled. Clinical, laboratory, ambulatory blood pressure monitor (ABPM) and echo were reviewed. Max dose of steroids was 20 mg (1 patient). Variables included age, gender, ethnicity, CKD stage, BMI, MMR level, complement levels, dsDNA, proteinuria.

Results: Of the 10 patients (8 F, 2 M), 8 were Hispanic, 2 African American. 9 had CKD stage 1, 1 had CKD stage 2, and mean age was 16.2 ± (11-20y). Class III LN was in 4 patients, class IV and V in 5 patients each. BP during the previous 3 visits were normal in 8 patients and 6 patients were on BP medications. Based on ABPM data, 3 of 6 treated patients had uncontrolled HTN. Of the 4 patients without BP treatment 2 had pre-HTN. Blunted dipping was seen in 6 patients. Echo was done for 5 patients with ABPM.
abnormalities. Left ventricular mass index (LVMI), relative wall thickness (RWT) and ejection fraction were normal. Left ventricle was dilated in 1 patient. Observed intraocular pressure (IOP) was high, and on examination, the patient's vision was somewhat impaired. The patient was treated with diuretics, and the intracranial pressure (ICP) was reduced. There was no change in the patient's vision.

**Conclusion:** Masked HTN and blunted nocturnal dip is common in adolescents with SLF and can be missed if ABPM is not applied in clinical practice. Additional studies are required to find risk factors and management strategies.

**Discussion:**

See table below.

**Case Description:**

**Discussion:**

We describe 2 adolescent cases of hypertension diagnosed by clinic BP and target organ damage but not confirmed by ABPM. Both patients had EST done as part of their evaluation because they were first seen by cardiologists at the study center who frequently employ EST as part of evaluation for hypertension. The cut-off value of 180mmHg for EESP was employed in this report as a previous study had identified 181 mmHg as the most discriminatory systolic BP threshold for predicting hypertension at follow-up. The discrepant results between the ABPM and EST BP in our patients with target organ damage may indicate that multiple diagnostic tools may be required to confirm the diagnosis of hypertension. Both tests could be viewed as complimentary as ABPM is not recommended during exercise which is a part of everyday life. Furthermore, a normal ABPM may not exclude a diagnosis of hypertension in patients with elevated clinic BP and target organ damage. Further studies are needed to confirm these findings in a larger population, and to better understand how these 2 tests may perhaps be used adjunctively to diagnose hypertension.

**PO2089**

**Hypertension with Target Organ Damage and Discrepancy Between Ambulatory Blood Pressure Monitoring and Exercise Blood Pressure**

**Results:**

There were 90 and 21 patients in groups A and B, respectively. At baseline, demographics were similar in both groups (Table 1). At endpoint, Group A had more patients at targeted blood pressure (BP) (55.6% vs 33.3% at 140/90 mmHg; 21.1% vs 19% at 130/80 mmHg), and larger reduction in both brachial and central BP parameters (Table 2). The mean (SD) of number of office visits were 3.1(1.0) and 2.9(1.1), in Groups A and B, respectively. In Group A, mean aorta compliance was increased 23.3% and 1.7% in the subgroups that met and did not meet target BP, respectively. Mean number of medications at baseline/endpoint were 1.7/2.6 and 1.9/2.0 in groups A and B, respectively. At endpoint, Group B had negligible change in distribution of drug classes, while Group A had significant increased use of calcium channel blockers (dihydropyridine) and beta-blockers.

**Conclusions:** Impedance cardiography is a simple, noninvasive method for evaluating underlying hemodynamic drivers of HTN. Hypertension management is more effective when guided by hemodynamic state.
Intensive Blood Pressure Lowering on Incident Strokes in the SPS3 Trial

The Influence of Baseline Diastolic Blood Pressure on the Effects of Intensive Blood Pressure Lowering on Incident Strokes in the SPS3 Trial

PO2092

The Influence of Baseline Diastolic Blood Pressure on the Effects of Intensive Blood Pressure Lowering on Incident Strokes in the SPS3 Trial

Robert E. Boucher, Guo Wei, Olesya Ilkun, Srinivasan Beddhu, Division of Nephrology & Hypertension, University of Utah School of Medicine, Salt Lake City, UT; Division of Biostatistics, University of Utah School of Medicine, Salt Lake City, UT; Medical Service, Veterans Affairs Salt Lake City Health Care System, Salt Lake City, UT.

Background: While observational analysis suggested higher risk of recurrent stroke with low baseline DBP, intensive SBP lowering did not increase recurrent stroke risk in those with low baseline DBP and previous stroke.

Methods: SPS3 was a 2x2 factorial RCT that examined the effects of intensive vs. standard (<130 vs. 130-149 mmHg) SBP control and combination versus aspirin alone antipatelet therapy on stroke outcome in 3020 participants. We examined whether the effects of intensive SBP lowering on stroke were modified by baseline DBP using spline regression models.

Results: Mean baseline age was 55 ± 11 yrs and DBP 95 ± 14 mmHg. There were 264 death/ESKD events over 4714 years of follow-up. Compared to usual BP control, low BP goal resulted in lower levels of follow-up SBP, MAP and DBP across baseline DBP tertiles (Fig 1). Despite the lower follow-up MAP and DBP values, there was no evidence that low BP goal increased the risk of death/ESKD in those with low baseline DBP (Fig 2). Interaction of baseline DBP and BP intervention for death/ESKD was not significant (p = 0.22).

Conclusions: The effect of BP lowering on the risk of death/ESKD was not modified by low baseline DBP. Hence, low baseline DBP by itself should not be an impediment for intensive BP lowering in CKD.

Early GFR Decline with Intensive BP Lowering and the Risk of Death and ESKD: Mediation Analysis of AASK Study
Srinivasan Beddhu,1,2 Jincheng Shen,1 Glenn M. Chertow,2 Paul K. Whelton,3 Guo Wei,4 Robert E. Boucher,5 Alfred K. Cheung,6 Tom Greene.7 1Division of Nephrology & Hypertension, University of Utah School of Medicine, Salt Lake City, UT; 2Medical Service, Veterans Affairs Salt Lake City Health Care System, Salt Lake City, UT; 3Division of Biostatistics, University of Utah School of Medicine, Salt Lake City, UT; 4Division of Nephrology, Stanford University School of Medicine, Palo Alto, CA; 5Tulane University School of Public Health and Tropical Medicine, New Orleans, LA.

Background: Intensive BP lowering decreased the risk of death in CKD in SPRINT but there are concerns that its acute, hemodynamic kidney effects might increase ESKD risk.

Methods: AASK Study (N=1094) was a RCT of low vs. usual mean arterial pressure (92 vs.102 to 107 mmHg) on kidney outcomes. Using the change in measured iothalamate GFR from baseline to the average of months 3 and 6 (early GFR change), we examined the acute effect of the intervention on subsequent death/ESKD in a mediation analysis. We partitioned the total effect of BP intervention on death/ESKD that was mediated through early GFR change (indirect effect) and independent of early GFR change (direct effect). We also used SIMEX method to access the impact of measurement error in early GFR change on the findings.

Results: We included 976 AASK participants with GFR measurements at baseline, 3 and 6 months. Mean baseline GFR was 55±11 ml/min/1.73m². There were 223 deaths, 293 ESKD events and 445 death/ESKD events during an average of 7.2±3.3 years of follow-up. BP separation was maintained through the trial (Fig 1, panel A) with an early decline in GFR in the lower BP group but GFRs in the two arms that were similar at the end of the trial (Fig 1, panel B). After adjustment for covariates listed in the footnote to Fig 2, we observed a borderline significant beneficial total effect of the BP intervention on death/ESKD and a slightly stronger direct effect (Fig 2). The HR for the indirect effect was slightly > 1, consistent with the possibility of a small adverse effect of early GFR change.

Conclusions: Intensive BP lowering appears to have a largely beneficial direct effect and a small deleterious indirect effect on death/ESKD in CKD.

A Novel Marker of Resistant Hypertension in CKD
Guido Gembillo, Rosella Siligato, Valeria Cernaro, Domenico Santoro. Policlinico G. Martino, Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy.

Background: Inflammation, oxidative stress (OS), atherosclerosis and resistant hypertension (RH) are common features of chronic kidney disease (CKD) leading to higher risk of death from cardiovascular disease. These effects seem to be modulated by impaired anti-oxidant, anti-inflammatory and reverse cholesterol transport actions of high-density lipoprotein cholesterol (HDL). Recently, monocyte count to HDL-cholesterol ratio (MHR) has emerged as a potential marker of inflammation and OS, demonstrating to be relevant in CKD. Our research was aimed to assess, for the first time, its reliability in RH.
Methods: We performed a retrospective study on 214 patients with CKD and arterial hypertension admitted between January and June 2019 to the Unit of Nephrology and Dialysis of Policlinico G. Martino in Messina, Italy. 72 patients were diagnosed with RH, defined as blood pressure >140/90 mmHg despite use of three different classes of antihypertensive medications (one of which must be a diuretic) at the maximum tolerated doses.

Results: MHR appeared inversely related to eGFR (p = 0.0163; P = 0.0172). MHR was significantly higher among RH patients compared to non-RH ones (12.39 [IQR 10.67 - 16.05] versus 7.30 [5.49 - 9.06] (Figure 1); P < 0.0001). Moreover, MHR was significantly different according to the number of anti-hypertensive drugs per patient in the whole study cohort (F = 46.723; P = 0.001) as well as in the non-RH group (F = 14.19; P = 0.001). Lastly, MHR values differed according to gender, being higher among males (9.41 [6.75 - 12.07] versus 8.02 [5.94 - 10.57]; P = 0.0463).

Conclusions: MHR may be a reliable biomarker due to the connection between HDL and monocytes. HDL prevents and reverses monocyte recruitment and activation into the arterial wall and impairs endothelial adhesion molecule expression. Our study suggests that MHR can reflect renal status and OS in CKD patients with RH, in order to implement appropriate treatment strategies.

PO2098
Primary Aldosteronism in CKD
Heather Wachtel,1 Jae Erner,1 Angela C. Davio,2 Yuta Teczua,2 Gregory L. Hunderme,2 Adina Turcu,1 Anand Vaidya,1 Debbie L. Cohen,1 1University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 2Ottawa Hospital, Ottawa, ON, Canada. 2University of Michigan, Ann Arbor, MI; 3Brigham and Women’s Hospital Department of Medicine, Boston, MA.

Background: Primary aldosteronism (PA) is a common cause of secondary hypertension, with unilateral causes of PA are potentially cured with adrenalectomy. Treatment of PA in CKD is often avoided for concerns of safety and efficacy.

Methods: We conducted a retrospective cohort study of patients with PA and CKD (eGFR <60 ml/min/1.73m²) at 3 institutions (2009-2019). eGFR was calculated using CKD-EPI. Statistical comparison utilized the student’s t-test, Chi-square test, and Wilcoxon rank-sum test.

Results: Of 250 patients included, mean age was 56.6yrs (±10.5), and 64% were female. Median plasma aldosterone concentration was 29.0 ng/dl (IQR:20.3-47.4), median plasma renin activity was 0.2 ng/ml/hr (IQR:0.1-0.6) and aldosterone-renin ratio was 119 (ng/dl)/(ng/ml/hr) (IQR:63.5-240.0). Median eGFR on initial evaluation was 49.0 ml/min/1.73m² (IQR:40.3-58.2). Adrenal vein sampling (AVS) was performed in all patients; unilateral PA was diagnosed in 67.6% (n=169). Adrenalectomy was performed in 163 subjects. Surgical pathology demonstrated adrenocortical adenomas in 66.9%, nodular hyperplasia in 4.9%, and nodular hyperplasia with a dominant nodule in 10.4%. The median tumor size was 1.2 cm (IQR:1.0-1.8). No differences were detected in baseline MAP, number of anti-hypertensive medications (AHM), serum creatinine, or potassium levels between adrenalectomy patients and those medically managed. Adrenalectomy patients had significantly lower AHM requirements at 1 month (2.0 vs. 4.5; AHM requirements at 1 month (2.0 vs. 4.5; P = 0.001)), 6 months (2.0 vs. 3.0, p=0.002) and 12 months after surgery (2.0 vs. 4.0, p<0.001) compared with medically managed patients. Adrenalectomy patients demonstrated stable eGFR from baseline to 12 months postoperatively, while medically managed patients had a statistically significant decrease in eGFR from baseline to 12 months (p=0.040). There was no difference between groups in cardiovascular outcomes.

Conclusions: Patients with CKD and unilateral PA experience significant and durable decrease in AHM requirement and demonstrate stabilization of eGFR after adrenalectomy when compared to medically managed patients. AVS was successful despite reduced eGFR. This study demonstrates that patients with CKD and suspected PA should undergo evaluation to determine whether they have surgically curable disease, as there is a clear benefit in medication reduction and stabilization of eGFR at 12 months.

PO2099
Bilateral Nephrectomy in a Patient with Refractory Hypertension Prior to Development of ESKD
Anna M. Zemke,1 Alexandra N. Hipias,2 Martin Hendl,1 Waleed Ali,1 Noga A. Roddy,1 George L. Bakris,1 1Department of Medicine, Division of Nephrology, Rush University Medical Center, Chicago, IL; 2Department of Medicine, Rush University Medical Center, Chicago, IL; 3Department of Medicine, Comprehensive Hypertension Center, University of Chicago Medicine, Chicago, IL; 4Department Transplant Surgery, Rush University Medical Center, Chicago, IL.

Introduction: Renal denervation (RDN) reduces increased sympathetic activation in refractory HTN (rHTN) while preserving kidney function, and trials in both the US and Europe demonstrate a 7-12 mmHg placebo subtracted reduction in systolic BP. Bilateral nephrectomy (BLN), originally performed in ESKD patients in the 1970s for HTN is an effective treatment, but is reserved for ESKD pts. We present a case of life threatening rHTN in a pt with Stage 3b CKD that was unresponsive to open surgical renal denervation (OS RDN) but responded extremely well to BLN.

Case Description: A 43 y/o white woman with stage 3b CKD (eGFR 38 ml/min/1.73m²) presented with a resting SBP between 180-240 mmHg on maximal doses of 8 different antihypertensive medications including spironolactone and minoxidil. She required frequent hospitalizations for symptomatic HTN with IV CCBS and beta blockers. Workup included an evaluation of all secondary causes including drug screening, urine metanephrines, renal MRI, and renin/aldo ratio. In an effort to avoid BLN, she initially underwent bilateral OS RDN by severing all neural tissue entering the kidney. Renal vein renin levels were 9.1, 7.8 ng/ml/hr pre OS RDN and 0.7, 1.4 ng/ml/hr post. Despite an initial drop in BP to 140/70 mmHg on only 2 medications, within 4 wks of OS RDN, her BP rose to 240/120 on 4 medications and she was symptomatic. At this point, BLN was performed as the only remaining option. Understanding of the need for RRT following BLN, the patient consented to proceed. Follow up BPs have been in the 130/80 mmHg range on reduced dose 12.5mg bid alone.

Discussion: Neither OS RDN nor pre-ESKD BLN for rHTN have been previously reported. Advancements in endovascular RDN are becoming more effective, but still only lower systolic BP by 7-12 mmHg placebo subtracted. Our case failed to respond to OS RDN, where we were guaranteed completed resection of the nerves and surrounding connective tissue, and suggests the effects of any form of RDN may be limited. BLN for rHTN in pts on RRT was started in the 1970s. Almost 50 yrs later, despite enormous improvements in medications, there is still a role for this procedure, and it emphasizes how little we still know about the etiology of HTN. Requiring this in a patient pre-ESKD was extreme but we felt a life-saving requirement. She will be referred for transplantation.
PO2100
Rostral Ventrolateral Medullary Compression: A Rare but a Cardinal Cause of Refractory Hypertension (RfHTN)
Mirinali Sarkar, Susanne B. Nicholas. University of California Los Angeles, Los Angeles, CA.

Introduction: RfHTN is defined as uncontrolled HTN with BP >140/90 mmHg despite at least 5 different classes of maximally tolerated antihypertensive agents, including a diuretic and a mineralocorticoid receptor antagonist. RfHTN may be underdiagnosed.

Case Description: A 43-year-old female with a history of mitral valve prolapse, iron deficiency anemia, mild asthma and migraine presented for management of uncontrolled severe HTN. Her HTN became increasingly resistant following use of pheniramine and fenfluramine for two years and a recent hysterectomy, with persistently elevated blood pressure (BP) up to 250/100 mmHg. Her medications included: hydralazine, lopressor, procardia, demadex, diovan, catapres and aldactone. On physical exam, her BP was 230/136 mmHg with regular pulse of 96 beats/min and no papilledema or bruits. Renal function and aldosterone levels were normal. Renal ultrasound/doppler, captopril scan, and angiograms showed no renal artery stenosis or coarctation of the aorta, and 24-hour urine metanephrines were normal. Her echocardiogram showed concentric left ventricular hypertrophy with ejection fraction of 60%. Minoxidil was initiated and procardia and lopressor were maintained, with no effect on BP. A high-resolution brain MRI with spectroscopy showed a venous angioma in the right superior temporal lobe and CT angiogram showed irregularity of the basilar artery with outpouching at the left posterior communicating artery and right anterior choroidal artery. She was diagnosed with neurogenic arterial HTN from neurovascular compression (NVC) of the rostral ventrolateral (RVL) medulla. Left retro-sigmoid craniotomy was performed for NVC decompression, but aborted eight hours later for fear of precipitating a massive stroke.

The patient continues to have RfHTN despite maximal medical therapy and has now developed complications including a cerebral ICA dissection, CKD stage 3, heart failure, and severe refractory HTN.

Discussion: NVC is related to neurogenic HTN when occurring in the RVL medulla.

This case highlights that brain MRI be performed in patients with intractable resistant HTN when all other secondary causes are ruled out.

PO2101
Adjunctive Mesenchymal Stem Infusion Boosts Recovery of GFR After Renal Revascularization for Atherosclerotic Renovascular Disease
Abdelrahman Abumouawad,1,2 Ahmed Saad,3,4 Christopher M. Ferguson,1 Alfonso Eirin,1 Sandra Herrmann,1 LaTonya J. Hickson,1 Emily Bendel,1 Lilach O. Lerman,1 Stephen C. Teixeira,1,4 Department of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; 2Department of Internal Medicine, University of Missouri Kansas city, Kansas city, MO, USA, Kansas City, MO; 3Department of Radiology, Mayo Clinic, Rochester, MN; 4Department of Family Medicine, Creighton University, Omaha, NE.

Background: Atherosclerotic renovascular disease (ARVD) reduces renal blood flow (RBF), GFR and accelerates poststenotic kidney (STK) tissue injury. Renal revascularization alone often fails to restore GFR in ARVD. Whether adjunctive infusion of autologous mesenchymal stem cells (MSC) can modify reparative processes during restoration of RBF is unknown.

Methods: We measured RBF (MDCT), GFR (iolyticum clearance), systolic blood pressure (SBP), in 16 human subjects with ARVD, before and 3 mo after MSC delivery and stent PTRA. MSC were administered at 3 dose levels (1, 2.5 and 5.0x10^5 MSC/kg, n=7,5,4 patients each) into STK, after stent PTRA. A cohort with ARVD n=17 matched for age, SBP and GFR studied under identical protocol treated with stent PTRA alone served as controls.

Results: SBP decreased in MSC + PTRA and PTRA alone groups 145±20 to 135±19, P=0.022, and 147±20 to 137±16 mmHg, p= 0.02. RBF increased in both MSC + PTRA and PTRA alone treated groups following the three-month hiatus 23±1 to 29±1 mls/min, p=0.015 and 31±2 to 37±3 mls/min, p=0.017. By contrast, GFR increased in the MSC + PTRA group 64±20 to 73±34 ml/min/p=0.017 whereas GFR did not change in the PTRA group 63±7 to 65±8 ml/min, p=0.35. The increases in RBF and GFR were higher in the group treated with the highest MSC dose Fig1.

Conclusions: These data reinforce the dissociation between restoring RBF and recovery of GFR in ARVD. Adjunctive therapy with autologous MSC was associated with a dose-related increase in GFR after restoring blood flow, consistent with the ability of MSC to repair microvascular injury. Further clinical trials to characterize the durability and extent of these reparative pathways are warranted.

PO2102
Percutaneous Angioplasty of Renal Artery Stenosis Most Beneficial in Patients with AKI Requiring Acute Hemodialysis
Nabil H. Abu ame1, Leysi Kukuy,1 Uri Rimon,1 Eliezer J. Holtzman,1 Pazit Beckerman,1,2 Dganit Dinour,1,2 Sheba Medical Center at Tel Hashomer, Tel Hashomer, Israel; 2Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, Israel.

Background: Treatment of atherosclerotic renal artery stenosis (RAS) is still controversial and several studies have shown that percutaneous transluminal renal angioplasty with stenting (PTRAS) is not superior to medical treatment, and the procedure is commonly reserved for malignant hypertension, flash pulmonary edema or deterioration of kidney function. The benefit of endovascular intervention among acute kidney injury (AKI) patients requiring hemodialysis secondary to severe RAS has not been studied. We studied the effects of PTRAS in patients with atherosclerotic RAS, specifically those who presented with AKI indicated for hemodialysis.

Methods: 109 PTRAS were performed in 92 patients with RAS from 2003 to 2019 in a tertiary hospital. Eleven patients presented with AKI secondary to high grade RAS and underwent PTRAS after starting acute hemodialysis. Data collected included demographic parameters, medical background, indication for intervention, technical procedure parameters and complications and long term data including dialysis treatment and mortality. Patients were categorized as responders or non-responders based on improvement in kidney function and discontinuation of dialysis.

Results: A total of 109 procedures were performed in 92 patients with severe renal artery stenosis. Eleven patients (12%) underwent PTRAS for severe high grade stenosis causing renal hyperperfusion and hemodialysis-dependent AKI. After PTRAS, 8 of 11 patients (73%) improved kidney function and discontinued dialysis. The average time on dialysis was 17 days (range 3-35 days) to PTRAS and 22 days (range 3-42 days) to recovery of kidney function, which occurred 6.5 days (range 1-24 days) after PTRAS. Two of the 8 patients later required long term hemodialysis. Only two cases were reported with mild complications.

Conclusions: In patients with hemodialysis dependent AKI, PTRAS should be considered as a rescue treatment as kidney function may recover even after prolonged time on dialysis.

PO2103
Outcomes of Cardiac Surgery in CKD Stage 3 vs. Stage 4 and 5
Aimen Liaquat,1 Elias Basili,1 Jonathan J. Taliercio,1 Ali Meahi,1 Remy Daou,1 Susana Arrigain,2 Victoria Konig,1 Jesse D. Schold,1 Serge C. Harb,1 Per Wierup,1 Sevag Demirjian,1 Georges Nalhoul,1 Cleveland Clinic, Cleveland, OH; 2Universite Saint-Joseph, Beirut, Lebanon.

Background: Pre-operative kidney dysfunction is associated with worse outcomes following cardiac surgery. However, few studies have assessed the outcomes of advanced Stage 4 and 5 Chronic Kidney Disease (CKD) patients.

Methods: Using our Electronic CKD registry, we compared the outcomes of 988 patients with CKD stages 3 vs. 4 and 5 undergoing Coronary Artery Bypass Graft (CABG) and/or valvular cardiac surgery. We compared length of stay (LOS), ICU days, days on pressors, and days intubated as continuous values and as proportion above the 50th percentile using Kruskal-Wallis and Chi-square tests. We estimated Fine and Gray’s competing risks cumulative incidence function of days to post-operative AKI requiring
dialysis (AKI-D) with mortality as a competing risk during hospitalization. We also compared the proportion developing AKI-D with Chi-square test.

Results: Among 988 total patients with cardiac surgery, 115 (12%) had CKD stage 4/5 and 873 (88%) had CKD stage 3. Average age was 71.2 ± 9.5 and 590 (59.7%) were male. Patients with CKD 4/5 had a higher proportion of diabetes (60% vs. 37%). Compared to CKD 3 patients, CKD 4/5 patients required longer intubation (33% more than 2 days compared to 20%, P=0.003), more pressures (47% more than 3 days vs. 32%, P=0.003), longer ICU LOS (median of 5 days vs. 4 days, P=0.001), longer post-operative LOS (median 12 days vs. 9, P<0.001). 24 patients (20.9%) with CKD 4/5 developed post-operative AKI-D vs. 42 (4.8%) in the CKD 3 group (p < 0.001). The cumulative incidence of End-Stage-Kidney Disease (ESKD) with death as a competing risk at 15 days was 5% (95% CI 4, 8) in CKD 3 group vs. 24% (15, 33) in CKD 4/5 group (p < 0.001).

Conclusions: Advanced CKD stages 4/5 is associated with worse outcomes following cardiac surgery including prolonged ICU stay, intubation duration, days on pressors, development of AKI-D and ESKD.

**Cardiovascular Events and Mortality in Adults with Kidney Failure after Major Noncardiac Surgery**

**Tyronne Harrison,1 Paul E. Ronksley,1 James Wick,1 Shannon M. Ruzycki,1 Matthew T. James,1 Deirdre Mccaughey,1 Kelly B. Zarnke,1 Brenda Hemmelmang.1 1University of Calgary Cumming School of Medicine, Calgary, AB, Canada; 2University of Alberta Faculty of Medicine and Dentistry, Edmonton, AB, Canada.**

**Background:** People with kidney failure have a high incidence of major surgery. Despite this surgical exposure, there is a paucity of literature investigating postoperative CV events and death. We aimed to determine the risk of these outcomes based on surgery type.

**Methods:** This retrospective cohort study used administrative health data from Alberta, Canada from April 2005 to February 2017. Adults (≥18 years) with kidney failure (receipt of chronic dialysis or two outpatient eGFR measures <15 mL/min/1.73m²) admitted to hospital for a surgical procedure were included. Surgery type, categorized using ICD-10 codes from hospitalization data, was examined for association with acute myocardial infarction (AMI) and death within 30 days of surgery using multivariable logistic regression. We adjusted for demographics, comorbidities, preoperative laboratory measures, procedure urgency, and kidney disease specific variables.

**Results:** 3398 people with kidney failure had a major surgery (1905 hemodialysis; 903 peritoneal dialysis; 903 non-dialysis). Most of the cohort was male (61.0%), the median age was 61.5 years (IQR 50.0, 72.7), and over half of the procedures were urgent (56.9%). 198 people (5.8%) had an AMI or died within 30 days of major surgery. Kidney transplantation had the lowest frequency of the outcome and were the reference group. After adjustment, vascular, skin and soft tissue, intraabdominal, musculoskeletal, retroperitoneal, anorectal, and neurosurgical procedures had statistically higher odds of AMI or death compared to kidney transplantation (Figure 1).

**Conclusions:** Major non-transplant surgery in people with kidney failure is associated with a high risk of AMI and death, which has implications for the direction of future perioperative research in this population.

**Race Differences in Cardiovascular Events After Percutaneous Coronary Intervention-Induced AKI**

**Joseph Lunvena,1 Robert M. Clare,2 Karen Chissell,2 Julia J. Scialla,1 Patrick H. Pun,1,2 Kevin L. Thomas,1,3 Monique Starks,1,2 Clarissa J. Diamantidis.1 1Duke University School of Medicine, Durham, NC; 2Duke Clinical Research Institute, Durham, NC; 3University of Virginia School of Medicine, Charlottesville, VA.**

**Background:** AKI portends a higher risk of subsequent cardiovascular disease (CVD). Although racial differences in AKI incidence have been found, it is unclear if the risk of CVD events following AKI also varies by race.

**Methods:** We quantified racial differences in the association of AKI with CVD events 1-year following percutaneous coronary intervention (PCI), using the Duke Databank for Cardiovascular Disease (DDCD). The DDCD captured all patients who underwent PCI at Duke between January 1, 2003 and December 31, 2013 with a combination of structured (forms) and electronic health record (EHR) data. Patients were followed prospectively for CVD events. AKI was defined as a ≥1.5-fold increase in serum creatinine from outpatient reference value before PCI to the peak value within 7 days post-PCI or a 0.3 mg/dl increase from the reference value within 48 hours. The primary outcome was a CVD composite including all-cause death, myocardial infarction, stroke, and revascularization. Cox models from date of AKI to outcome were adjusted for demographics, baseline cardiac comorbidities, medication use (RAAS inhibitors and NSAIDS), indication and urgency of PCI, and BP at PCI and number of stents placed.

**Results:** Among 9432 patients (median age 63y; 33% women; 75% white; 20% black), 865 (9%) developed AKI. Among 8699 patients with follow-up, the cumulative incidence of CVD at 1-year was 21%. After adjustment, AKI vs no AKI was associated with 1.84 greater hazards for the composite CVD outcome [95% confidence interval (CI) 1.62 to 2.10]. Compared to whites, other race (HR 0.79, 95% CI 0.63 to 0.99) but not black race (HR 1.07, 95% CI 0.95 to 1.20) was associated with lower risk of subsequent CVD. There was no interaction between race and AKI (p-interaction 0.216). Results were similar with individual components of the outcome.

**Conclusions:** AKI vs. no AKI following PCI is associated with greater risk for CVD events, regardless of race. Efforts to offset long-term consequences of AKI should target all patients undergoing PCI.

Frailty Is Associated with Higher Risk of Cardiovascular Events and Mortality in Adults with CKD: Findings from the Chronic Renal Insufficiency Cohort (CRIC) Study
Mary Hanna,1 Ana C. Ricardo,1 Julia Brown,1 Eunice Carmona,1 Zahraa Hajiri,1 Natalie Meza,1 Jinsong Chen,1 Mildra R. Saunders,1 James P. Lash,1 1University of Illinois at Chicago College of Medicine, Chicago, IL; 2UChicago Medicine, Chicago, IL.

Background: Frailty is common in individuals with chronic kidney disease (CKD). In the general population, frailty is associated with increased risk of cardiovascular events and mortality, but this association has not been fully examined in the CKD population. The objective of this study is to evaluate frailty status as a predictor of cardiovascular events and death in individuals with CKD.

Methods: Among 2,537 CRIC Study participants, frailty status was assessed using five criteria (slow gait speed, muscle weakness, low physical activity, exhaustion, and unintentional weight loss). Frailty was defined as meeting ≥3 criteria, pre-frailty as meeting 2–3 criteria, and non-frailty as meeting zero criteria. Cox proportional hazards models were used to evaluate associations with atherosclerotic events, incident heart failure, and death.

Results: Baseline age was 57.5 years, 45.5% were female, mean eGFR was 46.9 mL/min/1.73m², and median urine protein was 0.13 mg/day. Frailty was present in 21% of the participants and 66% were pre-frail. During a median follow-up of 12.5 years, there were 349 atherosclerotic events, 398 incident heart failure events, and 398 deaths. In multivariable analyses, frail individuals had a higher risk of each outcome compared to non-frail individuals. Pre-frail individuals had a higher risk of atherosclerotic events compared to non-frail individuals (Table). Conclusion: In adults with CKD, frailty is associated with increased risk for cardiovascular events and death. Future studies are needed to evaluate the impact of interventions to reduce frailty in individuals with CKD.

Association Between Frailty Status and Outcomes

PO2107
CKD Predicts Stroke Severity, Disability, and Early Recurrence in a Population-Based Cohort Study

Background: Chronic kidney disease (CKD) is associated with cerebrovascular disease and related mortality, and with under-utilisation of acute and preventative treatments, but any impact on initial event severity and recurrence risk is unclear. We aimed to determine whether CKD is associated with worse initial stroke severity and disability, and whether CKD is independently predictive of recurrent stroke and other vascular events.

Methods: In a population-based study of all TIA/stroke (Oxford Vascular Study), we studied initial stroke severity and disability using the National Institutes of Health Stroke Scale (NIHSS) and modified Rankin scale (mRS), respectively, in relation to CKD in all patients presenting with TIA and stroke from April 1, 2002 to March 31, 2017. Associations between CKD and event severity, and between CKD and risk of recurrent vascular events (stroke, myocardial infarction, and sudden cardiac death) were examined using ordinal and Cox regression models, respectively, adjusted for age, sex, and known vascular risk factors, and stratified by TOAST subtype.

Results: Among 3178 patients with TIA (n=167), ischemic stroke (n=1802), and intracerebral haemorrhage (n=209), 1267 (40%) had CKD. CKD was independently associated with greater risk of ischemic stroke compared to TIA (adjusted OR=1.31, 95%CI=1.11-1.56, p=0.002) and with greater initial NIHSS (adjusted OR=1.28, 1.04-1.46; p=0.018), driven mostly by those with an estimated glomerular filtration rate (eGFR) < 30 mL/min/1.73m² (adjusted OR=2.59, 1.44-4.66; p=0.001) for ischemic stroke; adjusted OR=4.06, 2.04-8.06; p=0.001 for initial NIHSS). Among patients with ischemic stroke, CKD was also associated with higher one-month mRS scores (adjusted OR=1.40, 1.13-1.74; p=0.002), driven by those with an eGFR < 30 mL/min/1.73m² (Adjusted OR=6.51, 3.04-13.97; p=0.001). Risk of early (< 90 days) recurrent stroke was increased with CKD (adjusted HR=1.60, 1.15-2.21; p=0.005) as was the risk of longer-term (0-15 years) composite vascular outcomes (adjusted HR=1.14, 1.05-1.40; p=0.01).

Conclusions: The consistent independent impact of CKD on initial event severity, early disability and recurrence risk suggests that there may be processes intrinsic to CKD leading to uniformly worse outcomes. Further research should determine whether there are CKD-specific treatments that may improve stroke outcomes.

PO2108
Control of Blood Pressure in Elderly Patients with Heart Failure and Risk of Mortality
Antonios Dourou,1,2 Alice Schneider,1 Natalie Ebert,1 Martin K. Kuhlmann,2 Nina Mielke,1 Markus van der Giet,1 Elke Schuefner,1 1Charite Universitätsmedizin Berlin, Berlin, Germany; 2Vivantes-Netzwerk für Gesundheit Berlin GmbH, Berlin, Germany; McGill University, Montreal, QC, Canada.

Background: Blood pressure (BP) targets in elderly patients with heart failure (HF) are unclear and guidelines are based on expert consensus and extrapolation from populations without HF. Thus, our population-based prospective cohort study assessed if BP control <140/90 mmHg is associated with a decreased risk of mortality in elderly HF patients.

Methods: We included participants of the Berlin Initiative Study, all ≥70 yrs, with HF and treated with antihypertensive drugs at baseline (2009-2011). Demographics, lifestyle factors, medication, and comorbidities were obtained in face-to-face interviews and linked with administrative healthcare data. BP status was defined as normalized BP (systolic BP <140 and diastolic BP <90 mmHg) or non-normalized BP (systolic BP ≥140 or diastolic BP ≥90 mmHg) and updated every 2 yrs, so that each patient could contribute person-time to both exposure categories during follow-up. Time-dependent Cox proportional hazards models estimated adjusted hazard ratios (HRs) with 95% confidence intervals (CIs) of cardiovascular death and all-cause mortality associated with normalized BP compared with non-normalized BP in HF patients. Analyses were repeated in non-HF patients.

Results: There were 544 HF patients treated with antihypertensive drugs (mean age 82.8 yrs; 45.4% female). During a median follow-up of 7.5 yrs and compared with non-normalized BP, a decreased risk of cardiovascular death (HR, 1.79; 95% CI, 1.23-2.61) and all-cause mortality (HR, 1.48; 95% CI, 1.15-1.80) was observed. No increased risks of cardiovascular death (HR, 1.23; 95% CI, 0.87-1.74) or all-cause mortality (HR, 1.19; CI 0.95-1.49) associated with normalized BP were observed among 1079 non-HF patients.

Conclusions: BP <140/90 mmHg was not associated with a decreased risk of mortality in elderly HF patients. The increased risk requires further confirmation.

Risk of cardiovascular death and all-cause mortality associated with normalized BP in older adults with HF

PO2109
Renal Outcomes of Sacubitril-Valsartan vs. ACE Inhibitors and Angiotensin Receptor Blockers in Heart Failure: A Systematic Review and Meta-Analysis

Background: Chronic kidney disease is an important comorbidity in heart failure patients through elevation in blood pressure and activation of the RAAS. Angiotensin converting enzyme inhibitors and angiotensin receptor blockers have been linked to beneficial effects on clinical outcomes of HF patients with CKD; however, they have been found to increase the risks for renal impairment. Clinical trials on the angiotensin receptor neprilysin inhibitor, sacubitril-valsartan, have found that it causes kidney dysfunction less frequently. This study determined the effect of sacubitril-valsartan on renal outcomes among HF patients compared to ACEi and ARBs alone.

Methods: A comprehensive literature search was done through electronic databases and readings until November 2019. This analysis incorporated randomized controlled trials in which indicators of renal function of patients on sacubitril-valsartan were compared to those of patients on reference drugs–estimated glomerular filtration rate, serum creatinine, and increase in serum potassium levels.

Results: Four RCTs were included with a total of 14,377 subjects for analysis. Two of the studies used an ACEi (enalapril), while the remaining 2 used an ARB (valsartan). Compared with ACEi and ARBs, there was a nonsignificant difference between decline in glomerular filtration (RR 0.75, 95% CI 0.55 to 1.02; participants = 14737; studies = 4; I2= 53%), but a significant difference between rise in serum potassium level (RR 0.90, 95% CI 0.84 to 0.96; participants = 14334; studies = 4; I2= 66%), and elevation of serum creatinine level (RR 0.86, 95% CI 0.78 to 0.95; participants = 1470; studies = 3; I2= 72%).

Conclusions: In HF patients, sacubitril-valsartan shows possible protective effects of risk for renal impairment, and definite reduction of risks for both increasing serum creatinine and hyperkalemia, as compared to ACEi and ARBs.
PO2110
The Accuracy of Current Ankle-Brachial Index and Toe-Brachial Index Diagnostic Criteria for Peripheral Artery Disease Among Patients with CKD

Jing Chen,1,2 Hua He,2 Charlton C. Starcke,2 Yajun Guo,3 Siyi Geng,2 Chunjian Chen,2 Erin Mahone,2 Jodie R. Laurent,2 Christina L. Wiggins,2 Praktiti Mehta,4 Paige R. Pielert,4 Vecchi Batuman,4 L. Lee Hamm,4 Jiang He,4 1 Tulane University School of Medicine, New Orleans, LA; 2 Tulane School of Public Health and Tropical Medicine, New Orleans, LA.

Background: Ankle-brachial index (ABI) less than or equal to 0.9 and toe-brachial index (TBI) less than or equal to 0.7 are used as diagnostic criteria for peripheral artery disease (PAD). The sensitivity and specificity of the ABI and TBI diagnostic criteria have not been evaluated in patients with chronic kidney disease (CKD).

Methods: We performed ABI, TBI, and doppler ultrasound among 100 patients with CKD using standard methods. Color doppler ultrasound, which has a high level of diagnostic performance with a sensitivity of 93% and a specificity of 95% for diagnosing PAD, was used as the reference standard. Doppler ultrasound diagnostic criteria were determined by multiple ultrasound features including reduction in luminal diameter, monophasic waveform, peak systolic velocity ratio (PSV ratio) >2.0, and presence of special broadcasting. Stenosis greater than or equal to 50% based on doppler ultrasound imaging was used to diagnose PAD. Sensitivity, specificity, positive predictive value, and negative predictive value were estimated. The areas under the curve (AUCs) for ABI and TBI were calculated.

Results: Participants with PAD were older, and more likely to be male and have a history of cardiovascular disease. The average estimated glomerular filtration rate and proteinuria were similar among participants with and without PAD. The sensitivity, specificity, positive predictive value, and negative predictive value were 15.6%, 88.3%, 20.8%, and 92.5% for ABI, and 16.3%, 89.4%, 24.7%, and 95.9% for TBI, respectively.

Conclusions: These data indicate that current ABI and TBI diagnostic criteria have suboptimal accuracy in diagnosing PAD in CKD. New ABI and TBI diagnostic criteria with better sensitivity and specificity need to be developed.

PO2111
Efficacy and Safety of Roxadustat in Patients with Non-Dialysis-Dependent CKD, Anemia, and Heart Failure

Daniel W. Coyne,1 Steven Fishbain,2 Pablo E. Pergola,3 Lynda Szczecizh,4 Tyson T. Lee,5 Dustin J. Little,5 Kin-Hung P. Yu,4 1 Washington University School of Medicine in Saint Louis, Washington University in Saint Louis School of Medicine, Saint Louis, MO; 2 Northwell Health, Great Neck, NY; 3 Renal Associates PA, San Antonio, TX; 4 FibroGen Inc, San Francisco, CA; 5 AstraZeneca, Gaithersburg, MD.

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Patients with heart failure (HF) represent an important clinical subgroup of patients with CKD.

Methods: Pooled data from three pivotal, phase 3, randomized, open-label, epoetin alfa-controlled studies of roxadustat for the treatment of anemia in patients with dialysis-dependent (DD) CKD were assessed in the subgroup of patients with a history of NYHA Class I or II HF at baseline. Endpoints were: mean change from baseline (CFB) in hemoglobin (Hb) averaged over weeks 28–52 regardless of rescue therapy, time to first blood/RBC transfusion during the treatment period, and mean monthly IV iron use during weeks 28–52. Safety and tolerability were assessed by reported treatment-emergent adverse events (TEAEs).

Results: In the DD-CKD study population, 25% (991/3980) of patients had HF (roxadustat=499; epoetin alfa=492). Baseline characteristics were generally similar. Mean (SD) Hb levels (g/dL) at baseline were 9.59 (1.30) in the roxadustat group and 9.65 (1.29) in the epoetin alfa group. Patients achieved significantly larger mean Hb increases (SEM) CFB in Hb levels (g/dL) with roxadustat vs. epoetin alfa (1.24 [0.04] vs. 0.94 [0.04]), corresponding to a LSM difference of 0.29 (95% CI: 0.18, 0.40) (p<0.0001). The hazard ratio for first blood/RBC transfusion during the treatment period in the roxadustat and epoetin alfa groups was 0.76 (95% CI: 0.54, 1.08) (p=0.1274). Mean (SD) monthly IV iron (mg) use was lower in roxadustat- vs. epoetin alfa-treated patients: 55.8 (288.8) vs. 68.6 (142.7) (p<0.0001), TEAE rates were comparable between treatment groups and similar to those in the overall DD-CKD study population.

Conclusions: Roxadustat was efficacious vs. epoetin alfa for increasing Hb levels and reducing mean monthly IV iron use in DD-CKD patients with HF. The safety and tolerability profile was similar to the overall population and consistent with that observed in this patient subgroup.

Roxadustat Reduces Low-Density Lipoprotein Cholesterol in Patients with Anemia of CKD

Poster

Thursday

Jimenez,1 Mohamed A. El-Shawalwy,1 Carol A. Pollock,2 Hamm,31 Steven Fishbain,2 Pablo E. Pergola,3 Willis Maksym,1 Kin-Hung P. Yu,1 1 Renal Research, Gosford, NSW, Australia; 2 The University of Sydney, Sydney, NSW, Australia; 3 FibroGen Inc, San Francisco, CA; 4 AstraZeneca, Warsaw, Poland; 5 University of Southern California Keck School of Medicine, Los Angeles, CA.

Background: Roxadustat is an oral hypoxia-inducible factor (HIF) prolyl hydroxylase inhibitor with positive safety and efficacy results in phase 3 studies in patients with anemia in CKD. The HIF pathway affects cholesterol metabolism; at high altitude, total and low-density lipoprotein cholesterol (LDL-C) decrease in healthy individuals. Roxadustat reduced LDL-C in phase 2 studies. We evaluated the effect of roxadustat on LDL-C in patients with anemia in non-dialysis-dependent (NDD) and dialysis-dependent (DD) CKD.

Methods: Data were pooled from three pivotal phase 3 studies in patients with NDD-CKD and three pivotal phase 3 studies in patients with DD-CKD, including the incident dialysis (ID; on dialysis <4 mo at randomization) population. Mean changes from baseline (CFB) in LDL-C (regardless of statin use) averaged over weeks 12–28 were analyzed using a mixed model of repeated measures and reported least-squares mean (LSM) treatment differences.

Results: In patients with NDD-CKD, there was a 17.2% reduction in LDL-C averaged over Weeks 12–28 in the roxadustat group (n=1650) compared with the placebo group (n=1430). The LSM treatment difference was statistically significant (p<0.0001). In the DD-CKD population, there was a 15.8% reduction in the roxadustat group (n=1650) and a 1.7% reduction in the epoetin alfa group (n=1741). The LSM treatment difference was statistically significant (p<0.0001). In patients with DD-CKD, there was a 21.5% reduction in the roxadustat group (n=680) and a 4.6% reduction in the epoetin alfa group (n=691). The LSM treatment difference was statistically significant (p<0.0001).

Roxadustat vs. Placebo or Epoetin Alfa Has No Clinically Meaningful Effect on Blood Pressure in Patients with Anemia of CKD
Tak Mao D. Chan,1 Roberto Pecotis-Filho,2,3 Anjay Rastogi,4 Pablo E. Pergola,5 Jacqueline G. Nolen,6 Ming Zhong,5 Lynda Szczec,5 Kin-Hung P. Yu,5 1University of Hong Kong, Queen Mary Hospital, Pok Fu Lam, Hong Kong SAR, China; 2Arbor Research Collaborative for Health, Ann Arbor, MI; 3Pontifícia Universidade Católica do Paraná Departamento de Medicina Curitiba, Brazil; 4University of California Los Angeles, Los Angeles, CA; 5Renal Associates PA, San Antonio, TX; 6Fibrogen Inc, San Francisco, CA.

Background: Hypertension (HTN) is a leading cause of chronic kidney disease (CKD) and often worsens as CKD progresses. Erythropoiesis-stimulating agents have been associated with an increase in blood pressure (BP) and other cardiovascular risks. Roxadustat is an oral hypoxia–inducible factor prolyl hydroxylase inhibitor that stimulates the production of erythropoietin and is approved for use in CKD patients with anemia. We evaluated the effect of roxadustat on BP in dialysis-dependent (DD) and non-dialysis-dependent (NDD) patients with anemia of CKD.

Methods: Pooled data from three, phase 3, randomized, placebo-controlled trials in NDD patients (n=4270), and three pivotal phase 3 randomized, active-controlled trials in DD patients (n=1526) and NDD patients (data censored after dialysis discontinuation; n=2354) were assessed. All DD patients and NDD patients (data censored after dialysis discontinuation) were included. Mean change from baseline (CBF) in mean arterial pressure (MAP) was assessed across Weeks 20–28 (NDD-NDD, SDD) and over weeks 8–12 (ID-DD); time to first exacerbation of hypertension (SBP ≥20 mmHg or DBP ≥10 mmHg and an increase from baseline ≥20 mmHg [SBP] or ≥15 mmHg [DBP]); and adjudicated hypertensive emergency were analyzed.

Results: In NDD-NDD, the least squares mean (LSM) difference between roxadustat and placebo in MAP (mmHg) was 0.67 (0.30) [95% CI: −0.09, 1.25]. Values for ID-DD and SDD patients were −0.35 (0.66) [95% CI: −1.65, 0.95] and −0.06 (0.42) [95% CI: −0.88, 0.76]. Hazard ratios (95% CI) for HTN exacerbation in NDD-NDD, ID-DD, and DD patients were 1.12 (0.95, 1.32), 1.02 (0.84, 1.25), and 1.06 (0.93, 1.21). Follow-up adjusted incidence rates [events/100 patient-exposure year] of adjudicated hypertensive emergency were 1.1 and 1.1 in roxadustat- and placebo-treated NDD-NDD, 2.2 and 2.5 in the overall roxadustat- and epoetin-alfa treated DD, and 1.7 and 1.7 in the subgroup of ID-DD.

Conclusions: Pooled analyses of phase 3 data across a continuum of patients with CKD and anemia showed that roxadustat did not have any clinically meaningful effect on BP, HTN exacerbation, or hypertensive emergency vs. placebo in NDD-NDD patients and epoetin alfa in DD-CKD patients.

Rivaroxaban Reduces Major Cardiovascular and Limb Events in Patients with CKD and Peripheral Artery Disease with Recent Lower Extremity Revascularization: Insights from VOYAGER PAD
Judith Hsia,1,2 Mark R. Nehler,2,3 Sonia Anand,4 Manesh R. Patel,4 William R. Hiatt,5 Sebastian Debus,5 Connie Hess,5 Warren H. Capell,1 Liborio Diao,4 Scott D. Berkowitz,5 Eva Muelholfer,4 Lloyd P. Haskell,1 Rupert M. Bauersachs,1 Marc P. Bonaca,1,2 1CPC Clinical Research, Aurora, CO; 2University of Colorado Denver School of Medicine, Aurora, CO; 3McMaster University, Hamilton, ON, Canada; 4Duke University, Durham, NC; 5University of Colorado Denver - Anschutz Medical Campus, Aurora, CO; 6Bayer Corp, Whippany, NJ; 7Janssen Global Services LLC, Raritan, NJ; 8Bayer AG, Leverkusen, Germany; 9Klinikum Darmstadt, Darmstadt, Germany.

Background: In the VOYAGER PAD trial, rivaroxaban reduced cardiovascular (CV) and limb ischemic events (HR 0.85 vs placebo, 95% CI 0.76-0.96; p=0.009) in peripheral arterial disease (PAD) patients following lower extremity revascularization (LER). This analysis examines the prespecified subgroup of VOYAGER PAD patients with CKD.

Methods: VOYAGER PAD (NCT02504216) randomized 6564 PAD patients following LER to rivaroxaban 2.5 mg twice daily or placebo on a background of aspirin 100 mg daily. The primary endpoint was a composite of acute limb ischemia, major amputation for vascular cause, myocardial infarction, ischemic stroke or CV death. Intention-to-treat analyses utilized Kaplan Meier estimates and Cox proportional-hazards models.

Results: Mean baseline eGFR was 75±23 ml/min/1.73m² with 79, 20, 1 and <1% of patients with CKD stage ≥2, 3, 4 and 5 respectively. During 28-month median follow-up, rates of major CV and limb events were higher among patients with more severe CKD (placebo group event rate: 7.4/100 patient-years for eGFR ≥60, 10.0 for eGFR 30-60 and 9.8 for eGFR <30). Rivaroxaban reduced primary endpoint events with no heterogeneity by eGFR above or below 60 (mostly CKD stage 3) (Figure). Acute limb ischemia and major amputation were significantly reduced among patients with eGFR<60 (HR 0.77, 95% CI 0.63, 0.94) and <60 (HR 0.55, 95% CI 0.36, 0.86). Major bleeding was infrequent with no heterogeneity by CKD category.

Conclusions: Rivaroxaban reduced CV and limb events in patients with CKD, PAD following LER, a particularly high-risk population.

Methods: We analyzed parameters related to volume status in these Phase 3 trials. Results: In these studies, 97% and 31% of pts, had HTN and CHF, respectively and 193 pts were treated with veverimer or placebo for up to 52 weeks. Treatment with veverimer (v placebo) had no effect on weight, BP, urine Na/creatinine ratio, volume-related adverse events, or increased use of diuretics or antihypertensives (Table). Conclusions: Veverimer, a novel non-absorbed HCl binder, effectively treats metabolic acidosis in CKD without adversely affecting BP or volume status.

Optimal Medical Therapy Attainment by Dialysis Status in the ISCHEMIA-CKD Trial
Roy O. Mathew,1 David J. Moran,1 Rebecca Anthropolos,1 Jerome L. Fleg,2 Sean O’Brien,3 Frank W. Rockhold,4 Carlo Briguori,5 Marek Roik,2 Tomasz Mazurek,2 Marian Demkow,2 Robert Malecki,6 Upendra Kaul,7 Marius Miglinas,7 Ron Wald,7 David M. Charytan,8 Mandep S. Sidhu,9 Judith Hochman,9 Sripal Bangalore,10 ISCHEMIA-CKD Research Vilnius Universiteto ligonines Santariskiu klinikos, Vilnius, Lithuania; 11Department of Internal Medicine, Infant Jesus Teaching Hospital, Medical University of Warsaw, Warsaw, Poland; 12National Institute of Cardiology - II Cardiology Clinic, Mazovian, Poland; 13St Michael’s Hospital, Toronto, ON, Canada; 14Albany Medical College, Albany, NY; 15National Heart Lung and Blood Institute, Bethesda, MD; 16New York University School of Medicine, New York, NY; 17Stanford University Department of Medicine, Stanford, CA; 18Duke Clinical Research Institute, Durham, NC; 19Warszawski Uniwersytet Medyczny, Warszawa, Poland; 20Batra Hospital and Medical Research Centre, New Delhi, India; 21Mediterranea Cardiocentro, Naples, Italy; 22William Jennings Bryan Dorn VA Medical Center Mental Health Department, Columbia, SC.

Background: The efficacy of an aggressive multiple risk factor intervention approach – optimal medical therapy (OMT) – to reduce major adverse cardiovascular events in patients with CKD has not been tested. Objective: to examine OMT goal attainment in patients with CKD on dialysis (CKD-D) and non-dialysis CKD (CKD-ND) in the ISCHEMIA-CKD trial.

Methods: OMT was recommended to all participants in ISCHEMIA-CKD. Longitudinal trajectories of individual OMT components (smoking cessation, systolic blood pressure (SBP) <140 mmHg, low density lipoprotein (LDL) cholesterol <70 mg/dL, high-intensity statin use, and aspirin use) were modeled over study follow-up. Covariate-adjusted percentage point difference in each OMT goal achieved at 24 months between CKD-D and CKD-ND patients (95% credible interval (CrI)) was estimated.

Results: There were 415 CKD-D and 362 CKD-ND patients at baseline. CKD-D were younger (61 v 67 yrs, p<0.001) and less often diabetic (53% v 62%, p=0.023). CKD-D patients were 7.9 % (0.7%, 14.8%) more likely than CKD-ND to attain the SBP goal during follow up. There was a steady and similar increase in proportional attainment of OMT during follow up.

Conclusions: OMT improved over time in advanced CKD-ND and CKD-D. CKD-D achieved the SBP goal more than CKD-ND, yet CKD-D were less likely to be treated with high-intensity statin. Future studies should explore systemic and patient-related barriers to attainment of OMT in this high-risk cohort.

Background: Patients with end-stage kidney disease (ESKD) are often sedentary and decreased functional capacity associates with mortality. The relationship between physical function and cardiovascular disease (CVD) has not been fully explored. Understanding the relationships between prognostically relevant measures of CVD and physical function and capacity may offer insight into whether exercise interventions could target specific elements of CVD.

Methods: 130 patients on haemodialysis underwent cardiovascular phenotyping with cardiac MRI (left ventricular (LV) structure and function, pulse wave velocity and native T1 mapping) and cardiac biomarker assessment. Participants completed the incremental shuttle walk test (ISWT) and sit-to-stand 60 (STS60) as field-tests of physical function and capacity. Separate linear regression analyses identified CV determinants of physical function measures. Multivariate models were adjusted for age, gender, BMI and diabetes.

Results: Mean age was 57±15 years, 73% were male and median dialysis vintage was 1.3 years (0.5, 3.4). In multivariate models, NT pro-BNP and global native T1 were independent determinants of ISWT and STS60 performance. LV ejection fraction was also an independent determinant of ISWT distance. However, age, gender and diabetes had the strongest relationship with physical function. Cardiovascular markers that were significant in multivariate models are shown in Table 1.

Conclusions: Markers of CV health could be targeted in exercise interventions to improve outcomes in patients with ESKD. NT pro-BNP, global native T1 and LV ejection fraction were independent CV determinants of physical function. The influence of age and diabetes on performance had the strongest relationship. Improving strategies for prevention and management of diabetes may ameliorate deconditioning in these patients.

PO2119
The Relationship of Cardiovascular Morbidity with Death and End-Stage Kidney Failure in Patients with Diabetes and CKD Receiving Specialist Renal Care
Ken-Soon Tan,1,* Stephen P. McDonald,1,2 CKD,QLD 1The University of Queensland Faculty of Medicine, Herston, QLD, Australia; 2Griffith University School of Medicine, Gold Coast, QLD, Australia; *Australia and New Zealand Dialysis and Transplant Registry, Adelaide, SA, Australia; 3The University of Adelaide Adelaide Medical School, Adelaide, SA, Australia.

Background: Patients with diabetes (DM) and CKD have worse cardiovascular, renal and mortality outcomes than those with neither and either condition alone. However, relationships between these 3 outcomes remain unclear, especially in patients receiving specialist renal care. Aims: To determine the relationships of major adverse cardiovascular event (MACE), end stage kidney failure (ESKF) and death using competing risk analysis.

Methods: CKD,QLD is a large Australian registry of patients with CKD not on RRT receiving specialist renal care. Patients with DM enrolled between 1/1/2011 and 31/12/2016 inclusive were studied. Follow-up was censored by death, ESKF, MACE post enrolment, movement of patient interstate/overseas, loss to follow-up or censor date of 31/12/2017, whichever occurred first. Competing risk analysis was performed with MACE, ESKF and death in turn as the primary outcome whilst the other 2 were competing risks. Covariates examined were age, gender, ethnicity, incident status, access to services, biopsy, smoking, diabetes treatment, HBa1c, MACE prior to enrolment, eGFR, proteinuria, Hb, RAAS blocker and lipid lowering therapy.

Results: 2255 patients underwent 6615 patient-years follow-up (pyfu), mean 2.8y. The first event was MACE in 571 patients (24.2%), ESKF in 299 patients (12.6%) and death in 268 patients (11.3%), giving respective event rates of 86, 45 and 41 per 1000 pyfu. 1137 patients (48.3%) experienced no event. Table 1 summarises the results of the best fit multivariable model with each primary outcomes. p < 0.05 was deemed significant.

Table 1: summary of competing risk analysis with the different primary outcomes.

Comparison of the Combined Prognostic Significance of Red Blood Cell Distribution Width and Vascular Calcification in Patients with ESKD
Da won Kim, Dongryul Kim, Yeonhee Lee, Seok Joon Shin, Hye Eun Yoon. Catholic University of Korea School of Medicine, Seoul, Seoul, Republic of Korea.

Background: Red blood cell distribution width (RDW) is a simple parameter that reflects the degree of red blood cell volume variability. Recent evidence has shown that increased RDW is associated with adverse clinical outcomes in end-stage kidney disease (ESKD) patients. Vascular calcification (VC) is another major independent risk factor for mortality among ESKD patients. This study investigated the combined prognostic effect of RDW and VC in ESKD patients starting dialysis.

Methods: We conducted a retrospective observational cohort study of 582 ESKD patients treated at a single center from January 2006 to July 2017. VC was assessed by the aortic calcification index (ACI) using abdominal computed tomography. Patients were divided into four groups based on the median ACI (17.12) and serum RDW value (14.3) as low ACI-low RDW, low ACI-high RDW, high ACI-low RDW, or high ACI-high RDW. The association between RDW and VC on the composite of cardiovascular events (CVEs) and death was investigated.

Results: During a median follow-up of 3.1 years (range, 1.5–5.5 years), 165 (28.3%) CVEs and 126 deaths (21.4%) occurred. The Cox regression analyses showed that the patients with low ACI-high RDW (adjusted hazard ratio, 1.93; 95% confidence interval, 1.185-3.157; P = 0.008) and high ACI-low RDW (adjusted hazard ratio, 1.92; 95% confidence interval, 1.171-3.152; P = 0.001) had a greater risk of the composite endpoint than patients with low ACI-low RDW. Patients with high ACI-high RDW had the greatest risk (adjusted hazard ratio, 2.367; 95% confidence interval, 1.465-3.824; P < 0.001). The interaction between ACI and RDW on CVEs and mortality was statistically significant (P = 0.023).

Conclusions: In ESKD patients starting dialysis, the combined effect of VC and high RDW was associated with a higher risk of CVEs and death. Also, high serum RDW amplified the risk associated with VC.

PO2121
Attention to the “Liddle” Details
Stefano Coppola fasick, Adrian P. Sequeira, James O. Onyirimba. Louisiana State University Health Sciences Center Shreveport, Shreveport, LA.

Introduction: Laboratory data provide clues to the etiology of resistant hypertension. We present one such case where in a presumptive diagnosis of Liddle’s syndrome was made, and appropriate therapy initiated. Yet the hypertension failed to be controlled despite multiple antihypertensive medications.

Case Description: A 26-year-old African American male was evaluated 8 years ago for a history of resistant hypertension. He was compliant with five blood pressure medications yet his systolic blood pressures were greater than 180mmHg. He denied smoking or consuming licorice products. No family history of early deaths, hypertension, or strokes. He reported having early onset of puberty at around age 12, being taller than his peers and now being short as an adult. He was a thin individual with no abdominal striae. Investigations revealed hypokalemia with mild metabolic alkalosis along with low renin and aldosterone. His kidney ultrasound was normal as were his renal functions and free metanephrines. 24-hour urine cortisol was not elevated. A presumptive diagnosis of Liddle’s syndrome was made and amiloride was added to his anti-hypertensive regimen, with little effect on BP control. Over the subsequent years, he was admitted repeatedly for hypertensive emergencies. This led to changes in his regimen along with a trial of Aldactone with no benefit. During one such episode, he complained of retrosternal pain. A CT was done to rule out a dissecting aneurysm, but it revealed a 5cm adrenal mass. Work up revealed high deoxycorticosterone, 11 deoxycortisol, dehydroepiandrosterone sulphate and testosterone which was suggestive of 11-hydroxylase deficiency causing congenital adrenal hyperplasia (CAH). He was started on dexamethasone 2 mg daily and his blood pressure control began showing improvement.

Discussion: CAH due to 11-hydroxylase deficiency is commonly seen in South Asia. It presents with features suggestive of mineralocorticoid excess. The differential diagnoses are Liddle’s syndrome, Chrousos syndrome, syndrome of apparent mineralocorticoid excess and Geller syndrome. This patient was wrongly diagnosed which led to repeated hospitalizations with inadequate therapy. Liddle’s syndrome responds well to amiloride without the need for additional medications. The fact that he was on multiple medications in addition to amiloride should be a clue to the misdiagnosis.

PO2122
A Case of Disappearing Hypertension: Difficulties of Managing Hypertension in a Breast Cancer Survivor
Xiao Ling, Shubha Ananthakrishnan. University of California Davis Department of Internal Medicine, Sacramento, CA.

Introduction: Treating hypertension in breast cancer survivors often hold unique difficulties. These patients may have undergone sentinel lymph node biopsy (SNB) or axillary lymph node dissection (ALND), and are often advised to avoid blood pressure measurement with affected arm. Here we present a case of young female after mastectomy SNB and ALND, who was diagnosed with essential hypertension after hypertension who presents for hypertension management.

Case Description: 32-year-old female with past medical history of breast cancer status post bilateral mastectomy and sentinel node biopsy (SNB) and axillary lymph node dissection (ALND). She developed hypertension after mastectomy due to inaccurate measurements from avoiding the use of sphygmomanometer cuff on her upper extremities.

Table 1: summary of competing risk analysis with the different primary outcomes.
using her lower extremities since her mastectomy. Blood pressure measured with her right upper extremity was 116/68.

Discussion: Often patient after mastectomy with SNB or ALND avoids taking blood pressure on affected limb regardless of lymphedema in order to prevent lymphedema. Despite this, the evidence for this is sparse with most recent studies reporting that blood pressure measurement in ipsilateral affected arm as not being risk factor for lymphedema.

PO2123

A Curious Case of Hypertensive Emergency and AKI

Dennis Hu,1 Ashkan Karimi,2 Garland A. Campbell,1,2 Negiin Pourafshtar1,2

1University of Virginia Health System, Charlottesville, VA; 2Augusta Health, Fishersville, VA.

Introduction: We report a case of a 75-year-old female with history of a prior right renal artery stent (coronary bare metal stent), stage IV chronic kidney disease (baseline serum creatinine (Scr) 2.1-2.3 mg/dL (eGFR 20-23 mL/min/1.73 m2)), diastolic heart failure, and hypertension who presented with hypertensive emergency (blood pressure (BP) 220/80 mmHg) and flash pulmonary edema.

Case Description: During her hospital stay, despite treatment with up to nine anti-hypertensive medications, her systolic BP remained 180-200 mmHg. Her Scr also increased to 3.92. Work-up showed normal kidney sizes and urine protein/creatinine ratio 1.26 g/g. Renal artery duplex revealed right renal artery peak systolic velocity 267 cm/sec, renal-to-aortic ratio 2.68, and resistive index 0.7-0.9, suggestive of right renal artery re-stenosis and some intrinsic damage. Due to progressive volume overload and worsening respiratory status, she required temporary hemodialysis. As her volume status worsened, she required temporary hemodialysis.

Deformed stent (arrow) with severe in-stent restenosis

Conclusions: In this case, baseline urinary sodium was lower than expected and baseline BP was well-controlled. Reducing dietary salt by 2g/day did not have a significant effect on office blood pressure readings.

PO2124

Effect of Dietary Salt Reduction on Blood Pressure in Kidney Transplant Patients: A Randomised Controlled Trial

Louise E. Ross,1 Rebecca Suckling,2 Mark E. Dockrell,1 Thomas Bailey,2 Pauline A. Swift.1 Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom; 2University of Warwick, Coventry, United Kingdom.

Background: Cardiovascular morbidity and mortality are increased in kidney transplant patients. High blood pressure (BP) contributes significantly to this risk and is associated with shortened allograft survival. Dietary salt reduction is widely recommended as a strategy to lower BP in the general population and in chronic kidney disease. Due to a lack of evidence there is currently no consensus on dietary salt restriction in kidney transplant patients.

Methods: Sixty stable kidney transplant patients, a 6-months post-transplantation, with BP ≥120/80 mmHg, and sodium intake 80 mmol/24hrs, were randomised in this parallel-designed study to receive either a regular-salt diet (target 150 mmol/24hr) or a low-salt diet (target 80 mmol/24hr) for 8-weeks. The primary outcome measure was systolic and diastolic BP. Secondary outcome measures included 24-hour ambulatory BP (ABP) and proteinuria. Dietary salt intake was assessed by 48-hour urinary sodium excretion.

Results: At baseline, patients (72% men) were 56±11 years with estimated glomerular filtration rate (eGFR) 53±18 mL/min/1.73m². Mean urinary sodium was 128±42 mmol/24hr, mean systolic BP was 132±12 mmHg, and mean diastolic BP was 77±10 mmHg. At the end of the intervention period sodium excretion was significantly lower in the low-salt group compared with the regular-salt group (96±37 vs. 152±51 mmol/24hr; adjusted mean difference, -36 [95% CI, -59 to -14] mmol/24hr; P=0.002). We found no difference in systolic BP (adjusted mean difference, -2 [95% CI, -12 to 9] mmHg; P=0.750), diastolic BP (adjusted mean difference, 0 [95% CI, -4 to 4] mmHg; P=0.887), 24-hour systolic ABP (adjusted mean difference, -3 [95% CI, -9 to 2] mmHg; P=0.213) or 24-hour diastolic ABP (adjusted mean difference, -2 [95% CI, -5 to 1] mmHg; P=0.267). There was no significant effect on proteinuria, eGFR, serum osmolality, uric acid, renin concentration, or aldosterone.

Conclusions: In this study baseline urinary sodium was lower than expected but baseline BP was well-controlled. Reducing dietary salt by 2g/day did not have a significant effect on office blood pressure readings.

PO2125

Left Atrial Reservoir Strain Is an Independent Predictor of End-Stage Renal Impairment in Patients with CKD

Gary Gan,1 Krishna K. Kadappu,2 Aditya Bhat,2 Fernandez,1 Kenneth H. Gu,1 Suzanne Eshoo,1 Brian J. Nankivel,4,3 Liza Thomas,4,2

1Blacktown & Mount Druitt Hospital, Blacktown, NSW, Australia; 2University of New South Wales, Sydney, NSW, Australia; 3Campbelltown Hospital, Campbelltown, NSW, Australia; 4Westmead Hospital, Westmead, NSW, Australia; The University of Sydney, Sydney, NSW, Australia.

Background: Left atrial (LA) enlargement is common in patients with chronic kidney disease (CKD) and is a predictor of adverse cardiovascular events. Our study sought to evaluate the value of LA reservoir strain (LAS), a novel echocardiographic measure of LA function, as a prognostic marker of adverse renal outcomes.

Methods: Patients with stable Stage 3 and 4 CKD without prior cardiac history were randomly recruited and underwent transhauric and stress echocardiography. Patients with normal left ventricular (LV) function, without significant valvular disease and without ischaemia on stress testing were included and followed for up to 5 years for development of end stage renal disease (ESRD) and/or doubling of serum creatinine.

Results: 280 patients (65±12 years, 63% male) were recruited and followed for a mean period of 3.9±2.7 years. 56 patients developed the composite endpoint. On log rank tests, impaired LAs (Figure 1), older age, lower eGFR, anemia, diabetes mellitus, greater urinary albumin/creatinine, greater number of antihypertensive agents, higher indexed LV mass and larger LA volumes were significant predictors of the composite outcome (p=0.01 for all). On Multi-variable Cox proportional hazards regression analysis, impaired LAs in addition to eGFR, number of antihypertensive agents and urinary albumin/creatinine (p=0.01 for all) were independent predictors of ESRD and/or doubling of serum creatinine. Impaired LAs was associated with a 2.5-fold higher risk of the composite outcome.

Conclusions: LAs is an independent predictor for development of ESRD and/or doubling of serum creatinine and thus has the potential to be a ‘biomarker’ for identification of high-risk patients, enabling early initiation of therapy.
**PO2126**

**Weight Gain Is a Risk Factor for the Progression of Coronary Artery Calcification in CKD: From the KNOW-CKD Study**

**Ji Hye Kim,** Young Youl Hyun. Kangbuk Samsung Medical Center, Jongno-gu, Seoul, Republic of Korea.

**Background:** In chronic kidney disease (CKD), patients with high body mass index or weight gain have better survival. However, their cardiovascular risk is uncertain. The aim of this study was to investigate the relationship between weight changes and the progression of coronary artery calcification (CAC) in CKD.

**Methods:** This study analyzed 839 participants (Mean age 52.5±12.0, Males 41.12%) from the KNOW-CKD cohort. Changes in weight between baseline and 4 year follow-up period were categorized in tertiles: first tertile (T1) (-31.3kg to -1.1kg), second tertile (T2) (-1kg to 0.9kg) and third tertile (T3) (1kg to 30kg). The coronary artery calcium score (CACS) was assessed using cardiac computed tomography at baseline and 4 years after enrollment. The CAC progression was defined as increase of CACS after 4 years.

**Results:** The study participants’ baseline median CACS was 0.0 (median) [0 [25th quartile]-34.5[75th quartile]] and 387 (46.13%) participants had baseline CACS above 0. After 4 years, numbers of patients in each tertile was 247 (29.4%) in T1, 258 (30.8%) in T2 and 334 (39.8%) in T3. Median difference in CACS between baseline and follow-up was 2 [0.49.3] in T1, 0 [0.47.2] in T2 and 6.4 [0.64.77] in T3. (p=0.088) Multivariate adjusted odds ratios (OR) [95% confidence interval] (95% CI) for CAC progression in T1 was 2 [0.69.3] in T1, 0 [0.47.2] in T2 and 6.4 [0.64.77] in T3. (p=0.088) Multivariate adjusted odds ratios (OR) [95% confidence interval] (95% CI) for CAC progression in T1 and T3 group compared to T2 group were 1.21 [0.79-1.85] and 1.80 [1.20-2.70].

**Conclusions:** Third tertile group, which gained between 1 to 30kg after 4 years, was significantly and independently associated with CAC progression compared to weight stable second tertile group in Korean predialysis CKD patients. These results suggest that preventing excessive weight gain might help prevent cardiovascular complications in CKD.

**PO2127**

**The Circadian Clock Provides Beneficial Effects Against the Endothelial Dysfunction to Promote Atherogenesis by Regulating Heme Oxygenase 1 Expression**

**Hadevky Negoro,**1,2 1Harvard Medical School, Boston, MA; 2The Graduate School of Project Design, Tokyo, Japan, Japan.

**Background:** The circadian clock is a molecular mechanism that confers 24 hour variations in gene expression and function to regulate number of physiological functions in humans. Disruption of the clock is associated with pathological remodeling in the arterial structure and vascular stiffness. Chronic circadian clock disruption is also associated with dysfunction in endothelial signaling and responses. Heme oxygenase-1 (HO-1) is an intracellular enzyme which catalyzes the oxidation of heme to generate ferrous iron, carbon monoxide, and biliverdin, which is subsequently converted to bilirubin. These products have anti-inflammatory, anti-apoptotic and anti-thrombotic properties. In this study, we observed if the deletion of Bmal1, a critical component of the circadian clock, can influence HO-1 which play an important part in the protection of vascular diseases.

**Methods:** Congenic 12- to 16-week-old male, wild-type and Bmal1-KO littermate mice were generated from heterozygote breedings to be used for these studies. We also knocked down Bmal1 to evaluate the protein levels of HO-1 expression in the knocked down cells.

**Results:** Endothelial function was reduced in aorta from Bmal1-KO mice. In aorta from Bmal1 KO mice, there was a reduction in HO-1 expression in mice with a dysfunctional circadian rhythm. Moreover, Bmal1 KO mice display pre-mature aging to have a dramatic proatherosclerotic phenotype. This phenotype is linked to changes in the regulation of key risk factors for cardiovascular disease. These include HO-1 which is significantly reduced in Bmal1 KO mice. We also confirmed that HO-1 levels follow a circadian pattern and this pattern was absent in Bmal1 KO mice.

**Conclusions:** These findings indicate that circadian clock provides beneficial effects against the endothelial dysfunction to promote atherogenesis by regulating HO-1 expression. This study establishes a mechanistic connection between Bmal1 and cardiovascular phenotype.

**Funding:** Government Support - Non-U.S.
Macrophage Neutrophil Gelatinase-Associated Lipocalin Has a Critical Role in Aldosterone-Induced Renal Fibrosis via the CCL5/L4 Pathway

Benjamin Bonnard,1 Marie Gentj,1 Jaime Ibarrola,1 Amaya Fernandez-Celis,3 Natalia Lopez-Anderes,3 Frederic Jaisser,1,2 INSERM U1138, PARIS, France; 3INSERM Clinical Investigation Centre 1433, Nancy, France; 4Universidad Publica de Navarra, Pamplona, Spain.

**Background:** Neutrophil Gelatinase-Associated Lipocalin (NGAL) (or lipocalin 2) is a metalloelastocortin. Boosted in the cardiovascular system. NGAL is also described as an acute renal lesion biomarker and NGAL serum concentration is associated with the severity of renal damages patients with a chronic kidney disease (CKD). Lipocalin2 (Lcn2) gene inhibition in a CKD model mouse predicts from proteinuria and renal lesions. We hypothesized that NGAL produced from macrophages promotes expression of chemotractant molecules involved in renal lesions induced by mineralocorticoid excess.

**Methods:** The role of Lcn2 was analyzed using full Lcn2 knockout mice (NGAL KO) challenged with uni-Nephrectomy, Aldosterone 200 mg/kg/day, Salt 1% (NAS model) during 6 weeks. Assessment of CCL5/L4 in kidney fibrosis were studied using maritavice administration (50 mg/kg in chow diet) or by injections of anti-L4 antibody (600 mg/kg).

**Results:** NAS induced a significant increase in the expression (relative values, means±SEM, compared to 1 in the control samples, p<0.05) of extracellular matrix proteins such as collagen I (2.35±0.33), a-SMA (2.04±0.44) and fibronectin (3.20±0.42) in the kidney of WT mice associated with interstitial kidney fibrosis (6.49±0.70). This is fully prevented by Lcn2 deletion. Expression of macrophages markers F4/80, CD80 and CD68 was increased (5.11±0.46, 4.84±0.19 and 5.22±0.45 respectively) in WT NAS mice and partly prevented in Lcn2 KO mice. Macroplages isolated from Lcn2 KO or WT mice were co-treated with aldosterone (10µM) and NaCl (40mM). In WT macrophages, expression of Lcn2 (2.81±0.30) and the CCL5 chemokine (2.84±0.32) was increased. The increase of CCL5 was blunted in Lcn2 KO macrophages. Similarly, to Lcn2 inactivation, CCL5 receptor blockade improved renal fibrosis and reduced high levels of TGF2 (CD4+) cell markers induced by NAS. Neutralization of IL4, a Th2 cytokine, in NAS mice injected with anti-IL4 antibody blunted kidney fibrosis and overexpression of profibrotic proteins such as collagen I, α-SMA and fibronectin.

**Conclusions:** NGAL produced by macrophages plays a critical role in renal interstitial fibrosis through the CCL5/L4 pathway in mice exposed to mineralocorticoid excess.

**PO2130**

Water Intake and Blood Pressure in Children: Results from the SPA Project

Gianluigi Ardissino,1 Michela Perrone,1 Silvia A. Ghiglia,1 Patrizia Salice,2 Francesca Tel,3 Valentina Capone,3 Maria Cristina Mancuso,1 Sandra Piantanida,4 Silvia Di Michele.6 SPA Project 1Pediatric Nephrology, Dialysis and Transplantation, Fondazione IRCCS Ca’ Granda, Ospedale Maggiore Policlinico, Milano, Italy; 2Cardiology Unit, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milano, Italy; 3Pediatric Department, Vittore Buzzi Children’s Hospital, University of Milano, Milano, Italy; 4Polo Materno Infantile - Ospedale F del Ponte, Varese, Italy; 5UCP Pediatrica Ospedale di Pescara, Pescara, Italy.

**Background:** Sodium (Na) intake is involved in the development of hypertension (HPT), to reduce Na is important in the treatment of HPT, but the increase in renal Na excretion might also be a potential preventive and/or therapeutic opportunity. The SPA Project studied blood pressure (BP) in relation to water (H2O) and Na intake with the working hypothesis that increased water intake can improve renal Na handling.

**Methods:** 339 healthy, non-overweight children (166 girls), 5.7 years old (IQR: 5.3-6.2) were characterized for: BP (using standardized multiple office BP measurement), Na and water intake (by means of urinary Na and creatinine from 4 samples taken in 4 different days). After categorizing subjects as low/high Na and low/high water intake (based on median value), BP was compared.

**Results:** Among children with higher Na intake, those introducing more water, showed a significantly (p<0.001) lower BP (both systolic and diastolic) compared to those who drink less (figure). This difference was not observed among children with lower Na intake.

**Conclusions:** Our findings support the hypothesis that an increased water intake, reduces BP by increasing renal excretion. We speculate that this simple, highly acceptable, inexpensive and harmless measure might play a role in preventing and minimizing the epidemics of HPT and related morbidities.
expressed as % total gated kidney cells: Sham = 6.6±0.3%. ORX significantly decreased renal tissue vs. sham in renal necrosis in H&E staining was not significantly altered vs. sham despite having the lowest BP (ORX = 4±0.45; HCTZ/Ren = 5±3.0±0.3; p<0.003). To begin to gain insight into the mechanisms mediating maturation-induced increases in necrosis, RIP3 and HMGB1 protein expression were measured in 5 and 15 wk old male SHR. Expression of RIP3-1 (α = 0.001; n=5-6) and HMGB1-1 (α =0.006 vs. 0.7±0.1; P=0.005; n=5-6) were greater in 15 wk old SHR.

Conclusions: In conclusion, these data suggest that male sex hormones contribute to maturation induced increase in renal necrosis in male SHR to a greater extent than maturation-induced increases in BP. Future work will determine the relative contributions of RIP3 and HMGB1 to renal necrosis in adult male SHR.

PO2133

SIRP α Interacts with the IGF-1 Receptor in CKD-Induced Cardiomyopathy

Jiao Wu,1 William E. Mitch,2 Sandhya S. Thomai,1,2 1Baylor College of Medicine, Houston, TX; 2US Department of Veterans Affairs, Houston, TX.

Background: A major consequence of chronic kidney disease (CKD) is associated cardiomyopathy. Even at early stages of CKD with near normal GFR, and normal blood pressure, left ventricular hypertrophy (LVH) is present, which suggests an unidentified trigger unrelated to pressure overload. We now find that elevations of signal regulatory protein alpha (SIRP α), a substrate for tyrosine phosphatases, in cardiac muscle adversely influences insulin signaling via interactions with the insulin-like growth factor-1 receptor (IGF-1R) in CKD.

Methods: SIRP α fixed (control) vs. muscle-specific (mSIRP α) KO mice were subjected to subtotal nephrectomy. The binding affinity between IGF-1R immunoprecipitated lysates and purified recombinant SIRP α was determined based on the association rate (ka) and the dissociation rate (kds) using biosensor bio-layer interferometry (BLI, Octet RED384 systems). Finally, SIRP α vs. GFP plasmids were transferred to immortalized mouse cardiomyocytes (C2C12 6-mice group), transfection was performed as mentioned above.

Results: Control mice with CKD displayed reduced levels of tyrosine phosphorylation of IGF-1R in cardiac muscle. However, in mSIRP α KO mice with CKD there was no downregulation of IGF-1R phosphorylation despite the presence of CKD. Next, we examined the interactions of these proteins by immunoprecipitation analysis. SIRP α proteins were immunoprecipitated and immunoblotted with the IGF-1R confirming interactions. IGF-1R-SIRP α interactions were further validated using the BLI to assess protein quantities and characterization of kinetics. Specifically, IGF-1R was immunoprecipitated from cardiac muscle and the binding kinetics of Fc-tagged recombinant SIRP α (sSIRP α) to the IGF-1R was identified via BLI. We concluded that sSIRP α was bound to immunoprecipitated IGF-1R with a kD of 147 uM, which further validate their interactions. Lastly, SIRP α plasmids were transfected into myocytes, which led to an upregulation of SIRP α and impaired activation of insulin signaling mediators (IGF-1R and pAKT) plus worsening muscle fibrosis when compared to control transfected cells.

Conclusions: SIRP α interacts with IGF-1R reducing receptor activities, confirming its role in regulating insulin/IGF-1 intracellular signaling in cardiac muscle, exacerbating cardiac muscle functions in CKD.

Increases in Renal CD81 and NCC Are Associated with Lipopolysaccharide-Induced Preeclampsia

Ping Wang,1 Gangyi Zhu,1 Yuting Jia,1 Yanting Wu,1 Xiaoyan Yu,1 Xiaoyan Wang,1,2 1LenQ Hospital of Nanjing Medical University, the Fourth Clinical Medical College, Nanjing, China; 2George Washington University, DC, WA.

Background: CD81, a member of the tetraspan superfamily, is an important component in the pathogenesis of pregnancy hypertension while the status of renal salt transport proteins plays an important role in blood pressure (BP) regulation.

Methods: In order to explore whether there is a connection between the two in the process of preeclampsia, we studied the interaction of CD81 and Na+−Cl− cotransporter (NCC) in vivo and in vitro.

Results: Our model of pregnancy hypertension was built by injecting a small amount of lipopolysaccharide (LPS, 0.5μg/kg in 2ml saline) into the tail vein of pregnant rats on GD 5. On GD 18, BPs (SBP :99.9±4.9 vs 116.9±4.1 1SBP :85.2±2.7 vs 94.4±1.2 mmHg, n=7/group) and urine protein (1185a±35.0 vs 1350a±15.0, μg/day, n=4/group) were higher in LPS rats relative to vehicle rats while renal protein abundance of CD81 (186.8±17.20, μg of protein, n=4/group, same as below) and NCC (278.0±53) was increased. The interaction of CD81 and NCC was found in the co-immunoprecipitation complexes from rat kidney homogenates with the antibodies against CD81 or NCC. In order to further explore the relationship between increased levels of CD81 in treated mice and hypertension in vivo, future studies will use LPS for 24h to construct an in vitro experimental model. The cell viability, detected by CCK-8, was not affected at all concentrations of LPS (0, 1, 10, 20, 30, μg/ml). The toxicity of LPS, detected by LDH release studies, was increased at concentrations of 20 (108.0 ± 3.4, μg/ml) and 30 (115.5±3.3) respectively but not altered at the lower concentrations. Relative to vehicle, LPS at concentration of 10μg /ml increased the protein abundance of CD81 (161.5 ±22.2, n=6/group) and TfN-α (207.5 ±2.7) but did not change the protein abundance of MCP-1. The protein abundance of NCC (193.5 ± 27.6) was increased remarkably while α1-NKA was also increased slightly (134.3 ± 4.51). The mRNA expression of CD81 mRNA was decreased at LPS (10μg/ml) of NCC (115.5±3.3) of vehicle (n=6/group), 10 (134.2±10.54,20 (148.0±8.61,30 (139.1±20.9) respectively.

Conclusions: Our findings in vivo and in vitro suggest that LPS can cause an increase in protein abundance and mRNA expression of CD81 and up-regulate NCC in renal distal convoluted tubules, which can contribute to an increase in blood pressure in pregnancy rats.

Neurogenic Tachykinin Mechanisms in Experimental Nephritis of Rats

Kristina Rodionova,1 Tillmann Ditting,1,2 Gisa Tieg,1 Karl F. Hilgers,1 Mario Schiffer,1 Christian Ott,1,2 Roland E. Schmiede,1 Kerstin U. Amann,1 Roland Veelken.1,2 1Friedrich-Alexander-Universitat Erlangen-Nurnberg, Nuremberg, Germany; 2Paracelsus Medizinische Privatuniversitat, Nuremberg, Germany; 1Universitätsklinikum Hamburg Eppendorf Zentrum fur Experimentelle Medizin, Hamburg, Germany.

Background: We demonstrated earlier that renal afferent pathways combine very likely “classical” neural signal transduction to the central nervous system and a substance P (SP) dependent mechanism to control sympathetic activity. SP content of afferent sensory neurons is known to mediate neurogenic inflammation upon release. We tested the hypothesis that alterations in SP dependent mechanisms of renal innervation contribute to experimental nephritis.

Methods: Nephritis was induced by Ox-7 antibodies in rats, six days later instrumented for recording of blood pressure (BP), heart rate (HR), drug administration; intrarenal administration (IRA) of the TRPV1 agonist capsaicin to stimulate afferent renal nerve pathways containing SP and implantation of electrodes for renal sympathetic nerve activity and recording of sympathetic nerve activity, renal expression of chemokines and markers of sclerosis.

Conclusions: Hence, SP promoted renal inflammation by weakening sympathoinhibitory mechanisms while at the same time substance SP released intrarenally from afferent nerve fibers aggravated immunological processes i.e. by the recruitment of DCs.

Renoprotective Effect of KLF2 on Glomerular Endothelial Dysfunction in Hypertensive Nephropathy

Eunjin Bae,1 Mi-yeon Yu,1 Ji Eun Kim,1 Kyung Don Yoo,1 Jung moo Moon,1 Dong Jun Park,1 Youn Su Kim,1 Seung Hee Yang.1 1Gyeongsang National University College of Medicine, Seoul, Republic of Korea; 2Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; 3Korea University Guro Hospital, Seoul, Republic of Korea; 4UlSAN University Hospital, Ulsan, Republic of Korea; 5Seoul National University College of Medicine, Seoul, Republic of Korea; 6Hanyang University Guri Hospital, Guri, Republic of Korea.

Background: KLF2 plays a role in maintaining normal vascular integrity by proinflammatory, anti-thrombotic, anti-angiogenic effects in endothelial cells. Endothelial dysfunction is associated with hypertension, and is a predictor of atherosclerosis development and cardiovascular events. Also, it is commonly observed in chronic kidney disease (CKD). The association between glomerular endothelial cell damage in diabetic nephropathy of KLF2 has been studied, but not in hypertensive nephropathy. Here, we present a role of KLF2 in hypertensive nephropathy.

Methods: Human primary glomerular endothelial cells were harvested and cultured under various duration, pressure condition by a rotational force device for mimic hypertensive nephropathy. We established the appropriate culture environment by confirming the pressure and survival rate applied to endothelial cells according to rotational force device which regulate the mRNA expression of smooth muscle actin (αSMA), KLF2 and αSMA. To induce hypertensive nephropathy in rat, 5/6 nephrectomy was done and kidney injury marker, blood pressure, KLF2 expression were evaluated. We evaluated the KLF2 expression in hypertensive nephropathy patients’ biopsied kidney tissue.

Results: The survival rate of human primary glomerular endothelial cells was maintained at a pressure of up to 4mmHg and decreased from above. After the application of 4mmHg pressure for 48hr in human primary glomerular endothelial cells, expression of KLF2 mRNA was decreased, while αSMA mRNA was increased and KLF4 mRNA was similar compared to control. 5/6 nephrectomy in rats resulted in increased blood pressure, decreased kidney function, as well as decreased KLF2 expression of glomerular endothelial cells. In addition, the expression of KLF2 in biopsied kidney tissue of hypertensive nephropathy patients was lower than that of normal kidney tissue.

Conclusions: We found that KLF2 expression of glomerular endothelial cells was reduced in both in vivo and in vitro models of hypertensive nephropathy. These findings suggest a new role for KLF2 in hypertensive nephropathy, which may be the basis for the development of new therapeutics.

Substance P: Differential Influences on Action Potential Production in Afferent Neurons of the Kidney?
Kristina Rodionova,1 Tilmann Ditting,1,2 Christian Ott,1,2 Roland E. Schmieder,1 Mario Schiffer,1 Kerstin U. Amann,1 Roland Veelken.1,2 Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany; 2Paracelsus Medizinische Privatuniversität, Nuremberg, Germany.

Background: Afferent nerve fibers of the kidney play a role in controlling sympathetic activity in hypertension and cardiovascular diseases. Proinflammatory substances influence the action potential production of these neurons. Therefore, we tested the hypothesis that proinflammatory substance P (SP) released from afferent nerves inhibits the action potential production in neurons with renal afferents.

Methods: Cultured dorsal root ganglion neurons (DRG TH1-L2) of rats with renal afferents were investigated in current clamp mode to assess action potential generation during both current injections and TRPV1 stimulation with protons (pH 6) with and without exposure to SP (0.5 μmol) or CGRP (0.5 μmol). Neuronal classification as tonic (high AP generation upon stimulation) and phasic (AP ≤ 5 upon stimulation). Additional experiments were performed in voltage clamp mode to fully assess electrophysiological properties of the neurons.

Results: Renal neurons were stimulated with current injection (14,4±1,5 APs/600ms, mean±SE) and protons (9,6±1,9 APs/160ms with pH6). The co-stimulation of renal neurons with injections and SP decreased the number of action potentials in tonic neurons (15,2±1,1 APs/600ms vs. 10,1±1,6 APs/600ms, p<0.05, mean±SE), however superfusion of renal neurons with both protons (pH 6) and SP increased (9,6±1,9 APs/600ms vs. 16,9±2,3 APs/600, p<0.05, mean±SE). Additional experiments with the SB-366 containing co-culture abolished. Co-stimulation with CGRP was without significant effect under any circumstances.

Conclusions: Neuronal SP influences action potential production in renal neurons in a very complex way: Both inhibition and specific increases in action potentials via a TRPV1-dependent mechanism in acid-sensitive renal neurons could be demonstrated. Afferent nerve fibers are likely to respond very specific in different conditions while influencing sympathetic nerve activity and putatively renal physiology or pathology (proinflammatory actions of SP).

Tonic Inhibition of Sodium Reabsorption by Na/K-ATPase in the Renal Proximal Tubule
Shravya T Mukherji.1 Luca Brambilla,1 Isabelas Mayes,1 Laura C. Kutz,1 Jeff P. Mcclermont,2 Steven T. Haller,2 Michael F. Romero,4 Jiang Liu,2 Joseph I. Shapiro,2 Gustavo Blanco,2 Zi-jian Xie,1 Sandrine V. Pierre.1
1Marshall Institute for Interdisciplinary Research, Huntington, WV; 2Joan C Edwards School of Medicine at Marshall University, Huntington, WV; 3University of Toledo College of Medicine and Life Sciences, Toledo, OH; 4Neurology Clinic, Department of Medicine and Science, Rochester, MN; 5University of Kansas Medical Center, Kansas City, KS.

Background: In the renal proximal tubule (PT), Na/K-ATPase (NKA) is exclusively located in the basolateral domain. Through its classic ATP-dependent ion-pumping function, NKA generates the Na+-gradient that drives apical Na+ reabsorption, mostly through Na/H+ exchanger (NHE3). Accordingly, activation of NKA-mediated ion transport decreases natriuresis through activation of basolateral (NKA) and apical Na+ reabsorption (NHE3). In contrast, activation of the more recently discovered Na+/H+ cotransporter (NBCe1A) content. Rescue with wild-type but not Src signaling-null (FEN or NPFF treatment [1 mM/30 min], n=4). The increased co-immunoprecipitation (coIP) between renal NPF22 and D1R, enabling the D1R to limit NPF22 effects. A normal (145±μM) to low (90 μM) NaCl raised both promoter activity (~2.5 fold, n=3), mRNA and protein expression (n=4; 8-9 hr). A normal to high (175 μM) Na concentration reduced promoter activity (~0.5 fold), mRNA and protein expression of NPF22 (0-8 hr). The increased co IP between prophyptensive NPF22 and antihypertensive D1R, resulted in an increased receptor antagonism to cAMP response and Na transport (vs FEN or NPFF treatment [1 mM/30 min], n=4).

Results: We found a "Sodium Response Element" (NaRE), homolog of "Dehydration Responsive Element" ("TACCGACAT") in Arabidopsis thaliana genome, at the NPF22 promoter. We measured NPF22 promoter activity to test NaRE response to Na. The NPF22 promoter responded to low (4±0.05 fold increase) and high (0.5±0.5 fold decrease) Na with wild type NaRE, but not in the absence of NaRE (mutant NPF22). Using a selective NaRE blocker, (antigen RNA) on mouse kidneys, showed no increased NPF22 response to low Na intake (<0.4 G Na/day) but a decreased systolic blood pressure due to the low Na diet (65±6.6 mm Hg vs. 83±3.1, n=4).

Conclusions: Our data identified NaRE and novel transcriptional and posttranslational mechanisms by which mammalian genes respond to sodium. Funding: NIDDK Support, Other NIH Support - NHLBI

PO2140

Age-Dependent Regulation of the NCC and the Development of Salt-Sensitive Hypertension
Kiyounng Kim, Franco J. Puleo, Alissa Frame, Mohammed Z. Ferdaua, Richard D. Wainford. Boston University School of Medicine, Boston, MA.

Background: The prevalence of hypertension (HTN) increases with age, and age-dependent HTN is associated with increased sympathetic tone and blood pressure (BP). Dietary sodium intake is a major risk factor for HTN as excessive dietary sodium intake leads to increases in BP in individuals that demonstrate the salt sensitivity of BP to evoke salt sensitive HTN (SSH). We have previously demonstrated excessive release of norepinephrine upregulates the activity of the renal sodium chloride cotransporter (NCC) to promote sodium reabsorption and salt sensitive hypertension. However, the regulation of the NCC with age remain unclear. Thus, we tested the hypotheses that 1) upregulation of NCC contributes to age-dependent HTN, and 2) aged rats develop SSH.

Methods: Three different age groups (3, 8, 16 month old (MOJ)) of male Sprague-Dawley (SD) rats were fed a normal salt (NS; 0.6% NaCl) or HS (4% NaCl) diet for 21 days respectively. On day 21, basal MAP and NCC activity (peak natriuresis to IV hypertonic NaCl infusion) were measured. The expression of total NCC, phosphorylated NCC, with-nosyl- [K] kinases (WNK1), WNK4, STE20/SPS1-related proline-alanine-rich protein kinase (SPAK), oxidative stress responsive kinase 1 (OxSR1), and phosphorylated SPAK/OxSR1 were assessed via immunoblotting (N=6/gp).

Results: Male SD rats develop age-dependent HTN with increased NCC activity and expression, and increased WNK1 expression. Aged male SD rats developed SSH, impaired dietary salt evoked suppression of NCC activity, phosphorylation, and the expression of kinases SPAK and OxSR1.

Conclusions: These data suggest that the NCC contributes to the development of age-dependent HTN. Moreover, dysregulation of the NCC may play a pivotal role in the development of age-dependent SSH.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Ang II infusion caused a greater rise in MAP (+30 ± 3 mmHg; P < 0.005) and RVR (+190 ± 50 mmHg; P < 0.05). CVR remained quite unresponsive (-7 ± 4%; NS).

Conclusions: Low basal RVR and CVR depend on PG-dependent NO generation. Whereas CVR is entirely protected from vasoconstriction with Ang II, the increase in RVR with Ang II is moderated by PG-dependent NO generation. Thus, PGs and NO exert distinct action in the renal and cerebral vasculature.

PO2143
The Intrarenal RAS Upregulates SGLT2 Expression and SGLT2 Inhibitors Attenuate Angiotensin-II Induced Hypertensive Kidney Injury in Mice
Kana N. Miyata,1 Chao-Sheng Lo,1 Shulien Zhao,1 Junzheng Peng,1 Matthias Kretzler,2 Janos G. Filep,3 Julie R. Ingelfinger,4 Shao-Ling Zhang,1 John S. Chan.1 1Centre Hospitalier de l’Université de Montréal Centre de Recherche, Montreal, QC, Canada; 2University of Michigan, Ann Arbor, MI; 3Hospital Massonneuve-Rosemont, Montreal, QC, Canada; 4Massachusetts General Hospital, Boston, MA.

Background: Clinical trials have shown that SGLT2 inhibitors (SGLT2i) improve both cardiac and renal outcome in several diseases. However, the mechanisms underlying regulation of SGLT2 gene expression remain unclear. Here, we studied whether the intrarenal renin-angiotensin-system (RAS) modulates SGLT2 expression and SGLT2i efficacy.

Methods: We analyzed the association between RAS-related genes and SGLT2 gene expression in the tubulointerstitial compartment of the kidneys of adult non-diabetic patients in the Nephrotic Syndrome Study Network (NEPTUNE). We compared SGLT2 expression in transgenic mice overexpressing angiotensinogen (Agt) in their renal proximal tubular cells (RPTCs/Agt-Tg) vs RAS blockers, and wild-type (WT) mice. We administered angiotensin II (AngII, 1000 ng/kg/min subcutaneously) in WT mice a canagliflozin (Cana, 15mg/kg/day in drinking water for 4 weeks). We also studied human immortalized RPTCs (HK2) as an in vitro model.

Results: In human kidney samples (N=183 patients), SGLT2 mRNA was significantly correlated with AGT (r=0.55, p<0.001), Remin (r=0.46, p<0.001), ACE (r=0.47, p<0.001), and ATIR (r=0.28, p<0.001), but not with AT2R. SGLT2-immunopositive staining was higher in RPTCs of Agt-Tg mice than in WT mice and this was attenuated by losartan treatment. Ang II infusion in WT mice significantly increased blood pressure, which was not reversed by Cana co-treatment. Ang II caused glomerulosclerosis, tubulointerstitial fibrosis, and albuminuria, which were all attenuated by Cana. Fractional glucose excretion was significantly higher in Ang II+Can-Ta than Wt+Can. In vitro, Ang II dose-dependently stimulated SGLT2 mRNA in HK2 cells, and these were inhibited by losartan.

Conclusions: Our data demonstrate that the intrarenal RAS upregulates SGLT2 expression and show that SGLT2i attenuate AngII-induced kidney injury independent of blood pressure.

PO2144
Loss of Soluble (Pro)renin Receptor Attenuates DOCA-Salt Hypertension
Nirupama Ramkumar, Deborah Stuart, Caitlin S. Peterson, William Wheatley, Donald E. Kohen. University of Utah Health, Salt Lake City, UT.

Background: Cleavage of the extra-cellular domain of the (pro)renin receptor (PRR) yields a soluble fragment (sPRR), which may be involved in mediating hypertension. We recently developed a mouse model with mutation in the cleavage site of the PRR using CRISPR/Cas9 such that sPRR is not generated and showed that absence of sPRR attenuated angiotensin-II induced hypertension and kidney damage. In this study, we examined if sPRR attenuated blood pressure (BP) in angiotensin-II independent hypertension using deoxycorticosterone acetate (DOCA)-salt treatment.

Methods: Mutant sPRR mice and littermate controls were treated with DOCA (50 mg/kg) and high Na+ diet for 3 weeks. BP was monitored by radio-telemetry and metabolic balance studies performed on Day 17-18 of DOCA-salt treatment. Only male mice were studied as the PRR gene is on the X-chromosome.

Results: Compared to control male sPRR mice, fed markedly lower plasma sPRR levels (control: 21.5 ± 2.5 vs mutant 0.2 ± 0.3 ng/ml) and baseline BP (systolic control: 122 ± 3 vs mutant 114 ± 3; diastolic control: 94 ± 5 vs mutant 82 ± 3 mm Hg). BP remained low in mutant sPRR mice relative to controls following 12 days of DOCA-salt treatment (systolic control: 141 ± 2 vs mutant 132 ± 5; diastolic control: 110 ± 4 vs mutant 95 ± 5 mm Hg). Mutant sPRR mice had lower body weight but similar food intake and urinary albumin excretion compared to controls (Table 1). Mutant mice had lower urine volume, water intake and urinary K* but not Na* excretion. No differences in renal histology were noted between control and mutant sPRR mice.

Conclusions: Loss of sPRR attenuates DOCA-salt mediated hypertension. The mechanisms by which sPRR might regulate BP and water/Na* homeostasis in DOCA-salt hypertension are currently being investigated.

Funding: Private Foundation Support
Effect of Dietary Magnesium Supplementation on Tubulointerstitial 
Damages in Angiotensin II-Induced Hypertensive Rats

Kaori Takavanagi,1,2 Taisuke Shimizu,3 Tatsukazu Iwashita,4 Hiroyuki Hara,5 Akira Kurosawa,6 Masaaki Terai,7 Hajime Hasegawa,7 Ishikawa Kinokai Kawagoe Ekimae Clinic, Kawagoe, Japan; 8Department of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University; Kawaoe, Japan.

Background: Recently, it has been epidemiologically suggested that Mg deficiency promotes progressive renal damage, and conversely, it has been reported that Mg load to Cyclosporine A-induced renal damage models attenuates renal impairment. This study aimed to investigate the ameliorating effect of high Mg diet on the renal impairment by use of hypertensive nephrosclerosis model.

Methods: Eight-week-old Sprague-Dawley rats were subjected to continuous infusion of Angiotensin II by subcutaneously placed osmotic minipumps for 2 weeks (435 ng/kg/min) and then housed for 6 weeks. The food for animals was normal Mg diet (NMD); 4% NaCl+0.05% Mg or high Mg diet (HMD); 4% NaCl+0.5% Mg. PicroSirius Red staining was used to assess fibrosis, immunostaining of Claudin-16, which is known to be down-regulated in the renal interstitial damage was also performed.

Results: No significant difference in mean blood pressure was seen between two groups (NMD: 97.8±6.7 mmHg vs HMD: 94.2±6.9 mmHg, n=4), and serum Mg was elevated in HMD group (NMD: 1.5±0.1 mg/dL vs HMD: 2.4±0.1 mg/dL, n=4). Analysis of PicroSirius Red staining positive area by semi-quantification showed that positive area in outer medullary region was significantly reduced in HMD group (NMD: 1.6±0.1 vs HMD: 1.1±0.1, n=4). Positive area of claudin-16 immunostaining in HMD group was greater than NMD (NMD: 1.5±0.3 vs HMD: 1.7±0.7, n=4).

Conclusions: Hypertensive nephrosclerosis is one of the major causes of end-stage renal failure, and its suppression is important. It was confirmed that the outermedullary fibrosis was inhibited by high Mg diet, while there was no change in the blood pressure, indicating that anti-fibrotic effect of high Mg diet seemed to be an independent mechanism from the blood pressure. We report the fact that claudin-16 expression is reduced and Mg excretion is increased in the interstitial fibrosis model (Shimizu, Magnesium Res 2018). These results suggest that high Mg diet has an inhibitory effect on fibrogenesis through suppressing the increased Mg-excretion.
Inhibition of Mineralocorticoid Receptor Ameliorates Salt-Sensitive Hypertension After Ischemic-Reperfusion Injury in Rats

Keyona Matsumoto,1 Shigehiro Doi,1 Ayumu Nakashima,1 Takao Masaki.1
1Department of Nephrology, Hiroshima University Hospital, Hiroshima, Japan; 2Department of Stem Cell Biology and Medicine, Graduate School of Biomedical & Health Sciences, Hiroshima University, Hiroshima, Japan.

Background: The transition from acute kidney injury (AKI) to chronic kidney diseases a major pathway for progression to end-stage kidney disease. Although hypertensive nephropathy is reported to be associated with the clinical progression of chronic kidney disease, the mechanism by which AKI induces hypertension remains elusive. Previous studies have demonstrated that salt-sensitive hypertension occurs in rats after ischemic reperfusion injury; treatment with a renin-angiotensin model of AKI, and that during hypertension play an important role in the development of salt-sensitive hypertension. Herein, we investigated the role of the mineralocorticoid receptor (MR) in the progression of IRI-induced salt-sensitive hypertension in rats.

Methods: Seven days after right nephrectomy, IRI was induced by clamping of the left renal artery for 45 min in 6-week-old male Sprague-Dawley rats. Rats were sacrificed at 7 days after IRI, and expression of MR examined. IRI rats were also given drinking water with 1% sodium chloride (IRI/NaCl), or were implanted with an osmotic mini-pump to infuse aldosterone (IRI/Aldo). Exsudase (3 mg/kg/day; a non-steroidal MR antagonist [MRa],) or vehicle were administered in IRI/NaCl and IRI/Aldo rats for 6 weeks. Blood pressure and urinary protein level were measured weekly during the study period. Protein expression in renal tissues was examined by immunoblotting and/or immunohistochemistry.

Results: MR expression was increased at 7 days after IRI. Further blood pressure and urinary protein excretion increased in IRI/NaCl and IRI/Aldo rats over the 6-week observation period, whereas these effects were negated by MRA administration. Similarly, MRA ameliorated the expression of the β-epithelial sodium channel (ENaC), γ-ENaC, and fibrotic markers, but not α-ENaC or NaCl cotransporter channel in both IRI/NaCl and IRI/Aldo rats.

Conclusions: Upregulation of MR, β-ENaC, and γ-ENaC may play a pivotal role in the development of salt-sensitive hypertension in rats after IRI.

PO2150 The Effect of Epidermal Growth Factor Inhibition on Salt Sensitivity in Mice

Keyona King,1,2 Robert S. Hoover.1,2 Emory University School of Medicine, Atlanta, GA; 1Veterans Affairs Health Care System Atlanta, Atlanta, GA.

Background: Every year in the United States, more than 3 million adults are determined to have high blood pressure. Studies have shown that the epidermal growth factor (EGF) decreases the open probability of the epithelial-Na+ channel (ENaC) along the apical surface of the kidney cortical collecting duct (CCD). Yet, it is unknown whether EGF influences renal Na+ transport via the Na+-Cl- cotransporter (NCC). Our laboratory determined to have high blood pressure. Studies have shown that the epidermal growth factor (EGF) influences renal Na+ transport via the Na+-Cl- cotransporter (NCC). Our laboratory determined EGF to be involved in the development of salt-sensitive hypertension.

Methods: Using radio-telemetry in five male mice ages 7 weeks old, we collected the systolic blood pressure (SBP) measurements over 24 hours daily for two weeks. These animals received a low salt (LS) diet (0.4% Na+ chow) for 6 days and high salt (HS) diet (4% Na+ chow) for 8 days. Overall, the period of two weeks, only the experimental (E) group (n=3) received geltin in (an EGF receptor tyrosine kinase inhibitor) at a regimen of 100 mg/kg/d given orally while the control (C) group (n=2) received a placebo.

Results: The results for the change in awake-SBP while receiving diet (0.4% Na+ chow) for 6 days and high salt (HS) diet (4% Na+ chow), showed the experimental (E) group had a greater increase in SBP in response to a higher dietary Na+ intake (E group: 7.70 ± 0.17 vs. control (C) group: 3.11 ± 0.29 mmHg, p<0.001). The delta for the difference in BP change when increasing dietary Na+ intake was greater for the E group of mice (delta = 7.40 mmHg, p<0.001).

Conclusions: Therefore, our data strongly suggests that inhibition of EGF increases the salt sensitivity. This may be due to upregulation of the EGF ligands act as tonic inhibitors of tubular sodium reabsorption. Future experiments will explore the involvement of EGF effects of inhibition on NCC, ENaC and sodium excretion.

PO2153 The Effect of Epidermal Growth Factor Inhibition on Diurnal Variation of Blood Pressure in Mice

Keyona King,1,2 Robert S. Hoover.1,2 Emory University School of Medicine, Atlanta, GA; 1Veterans Affairs Medical Center of Atlanta, Atlanta, GA.

Background: There are 78 million adults in the United States who have hypertension (HTN). HTN is a serious medical condition that serves as risk factor for cardiovascular disease (CVD) and chronic kidney disease (CKD). Blood pressure (BP) normally declines about 10% during sleep and this is called “dipping”. Studies have demonstrated that an augmented decline in nocturnal BP (“non-dipping”) is associated with increased cardiovascular risks. Investigations by our group and others have demonstrated an effect of the epidermal growth factor (EGF) on sodium transport proteins and BP. However, an association between EGF and “dipping” has not been described.

Methods: Using radio-telemetry in five male mice ages 7 weeks old, we collected the systolic blood pressure (SBP) measurements over 24 hours daily for two weeks. These animals received a low salt (LS) diet (0.4% Na+ chow) for 6 days and high salt (HS) diet (4% Na+ chow) for 8 days. Only the experimental (E) group (n=3) received geltin in (an EGF receptor tyrosine kinase inhibitor) at a regimen of 100 mg/kg/d given orally while the control (C) group (n=2) received a placebo. The change in SBP was evaluated during rest (9am-9pm) which are morning hours versus awake (9pm-9am) during evening hours since mice are nocturnal.

Results: The results showed the E group had less of a decrease in their SBP during the day compared to the control group (E group: -7.3 ± 0.18 vs. C group: -13.5 ± 0.01 mmHg, p<0.001). Here the delta is 6.1 mmHg, p<0.001, which shows that the C group maintained a greater decrease in their SBP compared to the E group.

Conclusions: Overall, our results suggest that inhibition of EGF leads to decreased dipping in SBP regardless of the dietary Na intake and this effect is greater with a high dietary Na intake. Therefore, our data is the first to suggest that EGF may play a role in the nocturnal dipping of BP, which could have potential implications for managing HTN-related cardiovascular disease.

PO2154 The Klotho Deficiency and Not the FGF-23 Rise Is Associated with Heart Failure with Reduced Left Ventricular Ejection Fraction in Patients with Preserved Kidney Function

Saul M.1,2,3, Peter Lam1,2,3, Leietai1,2,3, Mouna Hamouda,1 Meriem Ben Salem,1 Manel Ben Salah,1 Insaaf Handous,1 Habib Skhiri,1 Salima Ferfichi,2 Samir Nouira.1,2 1Department of Nephrology Monastir Hospital, Monastir, Tunisia; 2Department of Biochemistry F HACHED, Sousse, Tunisia; 3Department of Emergency Medicine, Monastir, Tunisia.

Background: The FGF23-Klotho axis is increasingly implicated in the pathophysiology of heart failure, especially during advanced chronic kidney disease (CKD). Our objective is to study the association between this FGF23-Klotho axis and heart failure (HF) in patients with preserved kidney function. This topic is less studied in medical literature.

Methods: This is a cross-sectional study of the FGF23 assessment, Klotho and the phosphocalcic axis in 70 patients with normal renal function. These patients had echocardiographic exploration which made it possible to distribute them in two groups: Group HF: LVEF (Left Ventricular Ejection Fraction)<55% (n = 18); Group NoHF: LVEF ≥55% (n = 52). Heart failure(HF) was exclusively of ischemic origin.

Results: These were 36 women and 34 men, average age 58 ± 10 years with an estimated glomerular filtration rate (eGFR) at an average of 92 ml / min / 1.73m2. No difference in eGFR between the two groups. Klotho was far lower with a statistically significant difference in Group HF. FGF23 was higher in Group HF but the difference was not statistically significant. PTH (parathyroid hormone) was statistically higher in Group HF and calcium was statistically lower in Group HF. Phosphatemia and vitamin D were not associated with heart failure.

Conclusions: Although the sample studied is not large, Klotho but not FGF23 is strongly associated with systolic heart failure. This and other results will be further discussed.

PO2158 Aetiological Subtypes of Transient Ischaemic Attack and Ischaemic Stroke in CKD: A Population-Based Study

Background: Chronic kidney disease (CKD) is strongly associated with stroke risk but the mechanisms underlying this association are unclear, and might be informed by subtype-specific analyses. However, few studies have reported stroke subtypes in CKD according to established classification systems such as the Trial of ORG 10172 in Acute Stroke Treatment (TOAST) criteria. We therefore aimed to determine which transient ischaemic attack (TIA) and ischaemic stroke subtypes using the TOAST classification occur most frequently in patients with CKD.

Methods: In a population-based study of all TIA and stroke (Oxford Vascular Study; 2002-2017), all ischaemic events were classified by TOAST subtypes (cardioembolism, large artery disease, small vessel disease, undetermined, multiple, other aetiology, or undetermined and not investigated). Logistic regression was used to describe the relationship between CKD (defined as an estimated glomerular filtration rate [eGFR] < 60 ml / min / 1.73m2) and TIA/stroke subtypes adjusted for age, sex, and hypertension, and then stratified by age and eGFR category.

Results: Among 3175 patients with TIA (n=1167), ischaemic stroke (n=1802), and intracerebral haemorrhage (n=209), 1267 (40%) had CKD. Although there was a greater prevalence of cardioembolic events (31.8 vs. 21.2%; p<0.001) in patients with CKD, this association was lost after adjustment for age, sex, and hypertension (Adjusted
Identification of Novel Biomarkers and Pathways for Coronary Artery Calcification in Non-Diabetic Patients on Hemodialysis Using Metabolomic Profiling
Wei Chen,1 Jessica Fitzpatrick,2 Stephen M. Sozio,3 Bernard G. Jaar,3 Michelle M. Estrella,4 Dario F. Rioscios-Bernal,5 Tongtong Wu,6 Yuning Ou,7 Irwin J. Kurland,8 Ruth F. Dubin,9 Yabin Chen,10 Rulan S. Parakh,10 David A. Bushinsky,11 Nicholas Sibiga,12 PACE13 Montefiore Medical Center, Bronx, NY;14 Hospital for Sick Children, Toronto, ON, Canada;15 Johns Hopkins University, Baltimore, MD;16 San Francisco VA Medical Center, San Francisco, CA;17 University of California San Francisco, San Francisco, CA;18 University of Rochester Medical Center, Rochester, NY;19 Yeshiva University Albert Einstein College of Medicine, Bronx, NY;20 University of Alabama at Birmingham, Birmingham, AL.

Background: A better understanding of pathophysiology involving coronary artery calcification (CAC) in hemodialysis (HD) patients will help to develop new therapies. We sought to identify the differences in metabolomics profiles between HD patients with and without CAC.

Methods: This is a case-control study nested within a cohort of 568 incident HD patients from the Predictors of Arrhythmic and Cardiovascular Risk in ESRD (PACE) study. Cases were non-diabetics with a CAC score >100 (n=51), and controls were non-diabetics with a CAC score of 0 (n=48). We measured 452 serum metabolites in each participant using liquid chromatography-mass spectrometry. Metabolites and pathway scores were compared using Mann–Whitney U tests, partial least squares-discriminant analyses, and pathway enrichment analyses. Multiple logistic regression was used to examine associations between metabolites and pathways with CAC.

Results: Cases had a median CAC score of 466 (IQR 246–981). Compared to controls, cases were older (64 ± 13 vs. 42 ± 13 years) and were less likely to be African American (51% vs. 94%). We identified three metabolites in bile acid synthesis (chenodeoxycholic, deoxycholic, and glycolithocholic acids) and one metabolic pathway (arginine/proline metabolism) that were associated with CAC. After adjusting for demographics, higher levels of chenodeoxycholic, deoxycholic, and glycolithocholic acids were associated with higher odds of having CAC. Comparing the third with the first tertile of each bile acid, the adjusted OR (95% CI) was 6.34 (1.12–36.06), 6.73 (1.20–37.82), and 8.53 (1.50–46.16), respectively. Using the first principal component (PC1) score, arginine/proline metabolism was associated with CAC after adjusting for demographics [OR: 1.38 (95% CI: 1.06-3.15) per 1 unit higher in PC1 score], and the association remained significant after adjusting for additional covariates.

Conclusions: Among HD patients without diabetes mellitus, chenodeoxycholic, deoxycholic, and glycolithocholic acids may be potential biomarkers for CAC, and arginine/proline metabolism may emerge as a new pathway in the pathogenesis of CAC.

NaRE: A Novel “Salt Response Element” in the NPPFR2 Gene Promoter and Antagonist of the D1 Dopamine Receptor
Selim Ozuyev,1 Laureano D. Asico,3 Jessica Hunt,2 Pedro A. Jose,2 Van Anthony M. Villar,2 Children's National Hospital, Washington, DC, 2The George Washington University School of Medicine and Health Sciences, Washington, DC.

Background: the neuromedin F receptor FF2 (NPPFR2) is one of two receptors for NPPF and is endowed with pro-hypertensive and anti-natriuretic activities. We looked for regulatory elements in the NPPFR2 gene promoter and how it interacts with an anti-hypertensive and natriuretic protein, the dopamine type receptor D (D). R.

Methods: Human renal proximal tubule cells (hRPTCs) treated with low NaCl (90 mM) increased mRNA (2.3±0.4-fold) and protein (1.5±4% vs. 100±4%) levels of the salt-retaining NPPFR2, whereas treating the cells with high NaCl concentration (170 mM) decreased the mRNA (0.7±0.05-fold) and protein (±0.54%, P=0.05 levels).

Results: Promoter analysis of the mouse and human NPPFR2 genes for regulatory elements identified a single 8-bp region, aptly called “NaRE” for Na Response Element, at -2.3 kb upstream of +1 position. This is 75% identical to the “Dehydration Responsive Element” (“TACCGCAT”) in the Rld2 gene of Arabidopsis thaliana which is a cis-acting element which responds to dehydration, low temperature, and salinity.

In the presence of the wild-type NaRE, the NPPFR2 promoter responded well to both low (4.1±0.5-fold increase) and high (0.52±0.5-fold decrease) NaCl concentrations, but not in the absence of NaRE in a mutant NPPFR2 promoter construct. Antigene RNA to block NaRE expression in the kidneys of C57BL/6 mice resulted in the inability of the mice to respond to a low sodium diet (<90° g sodium/day) and reduced further the decreased systolic blood pressure caused by the low sodium diet (65±0.6 mm Hg vs. 83±1.3, P<0.05). We then studied a mechanism by which NPPFR2 dynamically interacts with the D1R. NPPFR2 and D1R co-immunoprecipitated and colocalized in hRPTCs. Knocking out the mouse kidney, NPPF and the D1R:D1R agonist fenoldopam had antagonistic effects on CAMP production (2.5±1.0 pmol/min for fenoldopam vs. 1.2±0.2 for vehicle). We then studied a mechanism by which NPPFR2 and D1R, thus increasing the ability of NPPFR2 to antagonize the D1R effects.

Conclusions: Our data are the first to identify NaRE and demonstrate novel transcriptional and post-translational mechanisms by which mammalian genes respond to sodium.

Poster PO2156

Discovery and Characterization of Small-Molecule Potentiators of K, 4.1, 5.1
Samantha J. Mcclenahan, Jerod S. Denton, Vanderbilt University Medical Center, Nashville, TN.

Background: Heterotetratricopeptide (K) and K4.1 (KCNJ10 and Kir5.1) open channel in response to sodium, potassium, and water balance by the distal convoluted tubule of the renal tubule. Loss-of-function mutations in KCNJ10 lead to EAST syndrome, which is characterized by renal salt wasting and neurological dysfunction.

Methods: We established a monoclonal HEK-293 cell line that stably expresses human Kir4.1 and Kir5.1 from a bicistronic vector, and developed and validated a fluorescent-based transduction assay of KCNJ10 and Kir5.1 channel function in 384-well format. This assay was used to screen small-molecules from the Vanderbilt Chemistry Institute Library and confirmed with whole-cell electrophysiology.

Results: To date, we have screened more than 60,000 compounds using this assay and identified 420 putative inhibitors and 354 putative potentiators of Kir4.1-K5.1. Forty-five of these potentiators increase Kir4.1-5.1-mediated transduction flux by greater than 50% and are selective for Kir4/5.1 over homomeric Kir4.1 channels. Fourteen (14) potentiators are active at low single micromolar concentrations with EC50 values less than 5 μM, while six (6) compounds appear to be highly efficacious and increase Kir4/5.1-mediated transduction flux by more than 100%. Importantly, we have also verified with patch clamp electrophysiology the activity of one of the first-in-class activator of Kir4.1-5.1, termed VU206. In thallium flux assays, VU206 potentiates thallium flux dose-dependently with an EC50 of 1.9 μM and maximal efficacy of -50% above baseline between 10-30 μM. In whole-cell patch clamp experiments, VU206 led to maximal activation of whole-cell currents at 10 μM, complementing the thallium assay. Analysis of current-voltage relationships showed robust activation at both negative and positive test potentials without a depolarizing shift in the reversal potential suggesting VU206 potentiates Kir4.1-5.1 activity without affecting ion selectivity.

Conclusions: Findings from this study provide a novel pharmacological tool for exploring renal Kir4.1-5.1 channel integrative physiology and therapeutic potential of Kir4/5.1 potentiators for the treatment of EAST syndrome.

Poster PO2157

Improvement in Albuminuria and Hypertension in Renin Transgenic Mice by a Novel Filterable Form of Angiotensin-Converting-Enzyme 2 with Prolonged Half-Life
Jan Wysocki,1 Arndt Schulze,1 Gvantza Gultau,2 Minghao Ye,3 Daniel Battle,3 Northwestern University Feinberg School of Medicine, Chicago, IL; 3Charité Universitätsmedizin Berlin, Berlin, Germany.

Background: ACE2 is a monocarboxypeptidase that converts angiotensin (Ang) II to Ang 1-7. Its large molecular size precludes it from being filtered by the kidneys. We have developed a novel filterable form of ACE2 (ACE2-ABD) which is characterized by a prolonged half-life while maintaining full enzymatic activity. The protein is filterable and re-absorbable by the proximal tubule, thereby providing increased kidney ACE2 activity

Methods: Short soluble mouse(m) and human(h) ACE2 variants were fused with Albumin-Binding Domain(ABD). In vivo pharmacokinetic was determined after i.v. and i.p. injection followed by repeated measurement of plasma ACE2 activity. Subsequently, m and h ACE2-ABD(2 mg/kg) were injected every 2-3 days t.p. to Ren TgMK mice. The kidney included urinary albumin and blood pressure was monitored.

Results: Administration of 619-ABD to ACE2KO mice resulted in detectability of urinary ACE2 activity which at the baseline was not detectable. Blocking proximal tubule (PT) reabsorption with L-lysine, further increased urinary ACE2 activity suggesting that the ABD-tagged ACE2 undergoes glomerular filtration and is taken up by PT. In WT mice, augmentation of plasma ACE2 activity could still be shown a week after administration. In Ren TgMK mice, both m and h ACE2-ABD markedly reduced SBP and ACR(Figure).

Conclusions: A shorter soluble ACE2 variant fused with ABD exhibits a prolonged half-life and reduces SBP and ACR.

Funding: JSPS KAKENHI}
as well as circulating plasma ACE2 activity. Its efficacy was documented by reduced BP and ACR in Ren TgMK, a hypertensive model due to RAS activation. Thus, this novel ACE2 variant with extended half-life offers potential for treatment of kidney disease and hypertension.

Fibroblast Growth Factor 23 Induces Ventricular Arrhythmias and Prolongs QTc Interval in Mice In Vivo Mediated Through FGF Receptor 4

Julian Vallejo,1 Derek Wang,1 Jonah M. Graves,1 Christian Faul,2 Michael J. Wacker.1

1Department of Biomedical Sciences, School of Medicine, University of Missouri-Kansas City, Kansas City, MO; 2Division of Nephrology, Department of Medicine, The University of Alabama at Birmingham, Birmingham, AL.

Background: Sudden cardiac death and arrhythmias are leading causes of mortality in those with compromised renal function, such as in chronic kidney disease (CKD). Fibroblast growth factor 23 (FGF23) is a phosphaturic hormone released by osteocytes, which becomes markedly elevated in CKD. Previously, we found that FGF23 increases intracellular Ca2+ in cardiomyocytes and alters contractility in mouse ventricles ex vivo via stimulation of FGF receptor 4 (FGF4R). Since FGF23 could disrupt Ca2+ homeostasis, we hypothesized that FGF23 at pathological levels would alter depolarization/repolarization of the heart and induce arrhythmias in vivo via a mechanism involving FGF4R.

Methods: To assess our hypothesis, CD-1 male mice (3 months old) were anesthetized and electrocardiogram (ECG) needle electrodes were inserted into the limbs. The jugular vein was cannulated for infusion of vehicle or FGF23 (9ng/ml total blood volume) with or without pretreatment with an FGF4R-specific blocking antibody (anti-FGFR4; U3 Pharma). Lead II ECG and arrhythmias were monitored at baseline and then for 30 minutes post injection.

Results: FGF23 induced premature ventricular contractions (PVCs) in 5 out of 11 mice (P=0.038 vs vehicle) with an average maximal rate of PVCs in these mice of 10.2 ± 5.2 PVCs/minute (P=0.01 vs vehicle). Vehicle (n=9) and FGF23+anti-FGFR4 treated (n=8) mice did not exhibit PVCs. Treatment with Isoproterenol (0.1mg/kg) after FGF23 further augmented arrhythmias to a maximal rate of 25.0 ± 21.1 PVC/minute (P=0.05 vs vehicle) and 2 out of 8 mice displayed ventricular tachycardia. Upon examination of ECG intervals, FGF23 prolonged QTc within 30 minutes (P<0.05, n=8) compared to vehicle treatment (n=9), whereas no effect was found for PR interval or QRS duration.

Conclusions: We conclude that FGF23/FGF4R signaling in the heart may contribute to ventricular arrhythmogenesis and repolarization disturbances commonly observed in patients with CKD and may be an important therapeutic target to reduce cardiac mortality in CKD.

PO2159

Use of Immune Checkpoint Inhibitors in ESKD

Background: Use of immune checkpoint inhibitors (ICI) in ESKD patients is limited. We describe our single-center experience of ICI use in ESKD patients and summarize the current literature.

Methods: Using an analytics database, we identified all patients with at least one of a single ESKD diagnosis code who received ICI therapy at our health system. Charts were reviewed manually to confirm that patients were on HD or PD during the ICI therapy. Clinical details such as demographics, comorbidities, cancer type, immune-related adverse events (irAEs), cancer disease status, and patient survival were reviewed. Further literature search was performed for all published cases of ICI use in ESKD patients and was summarized as part of the methods.

Results: In total, 8 patients with ESKD were initiated on ICI. A variety of malignancies were identified. Four patients received pembrolizumab, two received nivolumab, one received both ipilimumab and nivolumab, and the last received PD-1 inhibitor atezolizumab. Eight patients were receiving anemia therapy. The mean duration on dialysis (dialysis vintage) prior to ICI therapy was 15.8 months (range: 3-60 months). Two patients had an immunotherapy-related adverse event. In both cases, the physicians discontinued the offending ICI agent and started the patients on systemic steroid therapy. Both patients subsequently recovered without adverse event.

Conclusions: Based on our series and previously published literature review, the rate of adverse events appear similar to non-ESKD patients (15-25%). ESKD may not be a contraindication to the use of ICI therapy.
and nivolumab). The incidence of AKI of any duration was 36.6% (333 of 910 patients), while the incidence of AKI (defined as ≥3 days or longer or not re-measured) occurred in 31.0% of patients (282 of 910). The incidence of presumed CPI-induced AKI was 3.2% (29/910). A total of 25.2% (71/282) of sustained AKI patients had at least one concurrent immune-related adverse effect (irAE), compared to 55.2% (16/29) of presumed CPI-induced AKI. CPI-induced AKI occurred on average 88.2 days (standard deviation 80.6) after starting the CPI, with several AKI events occurring within 60 days after stopping the CPI.

Conclusions: AKI secondary to CPI is a common side effect of CPI. In our population, it occurred at an incidence of 3.2% and sometimes occurred even after the last dose of CPI. The etiology of AKI in almost all cases of biopsy-proven CPI-induced AKI is acute interstitial nephritis. The risk appears to be increased if a patient has already developed an irAE.

PO2162
Checkpoint Inhibitor-Related Renal Vasculitis and Use of Rituximab
Harish Shanthanu,PO2162

William Street, Meghan Faje,1 Donald F. Chute,1 Kerry Reynolds,1 Meghan E. Sise,1 Massachusetts General Hospital, Boston, MA; 2Brigham and Women's Hospital, Boston, MA

Background: The percentage of cancer patients eligible for checkpoint inhibitor (CPI) therapy has increased rapidly over the past few years and approaches 45%. As a result, more cases of CPI-related nephrotoxicity, including those with vasculitis, are being reported. To elucidate the clinical presentation of CPI-associated vasculitis with kidney involvement and its possible mechanisms, treatment options, and prognosis, we describe the cases from a comprehensive cancer center and reviewed the literature for similar cases.

Methods: We retrospectively reviewed the charts of all cancer patients from 2014 to 2020 who were diagnosed with CPI-related nephrotoxicity and underwent a kidney biopsy.

Results: We identified 5 cases of vasculitis with kidney involvement: 3 patients were diagnosed with renal vasculitis, 1 case with ANCA vasculitis, and 1 case with Immunoglobulin A (IgA) vasculitis. Of these cases, 4 patients were receiving nivolumab, and 1 patient was receiving tremelimumab. All patients had microscopic hematuria, four out of five had negative anti-neutrophil cytoplasmic antibodies (ANCA) serology, one patient had concurrent lung involvement and positive ANCA serology, and all had severe acute kidney injury with creatinine >4.50 mg/dL upon diagnosis. All patients were treated by discontinuing CPI and initiating corticosteroids and rituximab. Three patients received plasmapheresis. Two of these required renal replacement therapy (RRT) including the patient with lung involvement. All patients after rituximab had partial or complete renal response. Two patients died within 8 months of diagnosis due to malignancy progression. None of the patients had a relapse of vasculitis.

Conclusions: We demonstrated that CPI can be associated with different types of vasculitis with kidney involvement that are predominantly ANCA negative and manifest as severe acute kidney injury. Despite the lack of strong evidence, treatment similar to treatment of primary ANCA vasculitis with corticosteroids and rituximab is well tolerated with acceptable outcomes.

PO2163
AKI and Immune-Related Adverse Events (irAEs) in Patients with Genitourinary Cancers Receiving Immune Checkpoint Inhibitors (ICIs)
Harish Shanthanu Seethapathy,1 Nifasha Rustibamayila,1 Donald F. Chute,1 Meghan Lee,1 Jan A. Stroehblen,1 Nifasha Rustibamayila,1 Donald F. Chute,1 Kerry Reynolds,1 Meghan E. Sise,2 Massachusetts General Hospital, Boston, MA; 2Northwell Health, Great Neck, NY.

Background: Hyponatremia due to endocrinopathies such as adrenal insufficiency and hypothyroidism has been reported in patients receiving immune checkpoint inhibitors. Other electrolyte abnormalities such as hypocalcemia and hypokalemia have also been associated with the use of these agents. We study the incidence and predictors of electrolyte abnormalities in cancer patients receiving immune checkpoint inhibitors.

Methods: Patients who received immune checkpoint inhibitors at Massachusetts General Hospital Cancer Center between 2011 and 2018 were included. Incidence of electrolyte abnormalities were determined in the first 12 months after drug initiation and graded for severity by using Common Terminology for Cancer Adverse Events criteria.

Results: We analyzed 2458 patients started on checkpoint inhibitors in our cancer center. Average age was 64 (SD 13) years, 58% were male and 90% were White. In the first 12 months follow-up, 62% experienced hyponatremia, 27% had hypokalemia, 26% had hyperkalemia, 49% had hypophosphatemia and 9% had hypocalcemia. Grade 3 or 4 hyponatremia was seen in 136 patients (6%) and occurred 164 days (SD 100) after checkpoint inhibitor initiation; only 9 cases of grade 3 or 4 hypokalemia were due to endocrinopathies. CTLA4 inhibitors were associated with a higher risk of grade 3 or 4 hypokalemia and hypophosphatemia. Patients with gastrointestinal malignancies experienced the highest risk of grade 3 or 4 electrolyte abnormalities.

Conclusions: Electrolyte abnormalities are common in cancer patients receiving immune checkpoint inhibitors. Endocrinopathies leading to severe hyponatremia are rare (<0.5%).

Immune Checkpoint Inhibitor-Associated Glomerular Disease: A Systematic Review and Meta-Analysis
Abhijat Kottula,1 Kenar D. Shavari,2 Shikha Wadhwa,2 Priya Deshpande,3 Ziv Paran,2 Teruko Kishibe,4 Kammi J. Henrichsen, Rimda Wanchoo,3 1University Health Network, Toronto, ON, Canada; 2Northwestern University Feinberg School of Medicine, Chicago, IL; 3Icahn School of Medicine at Mount Sinai, New York, NY; 4St Michael’s Hospital, Toronto, ON, Canada; 5University Health Network, Toronto, ON, Canada.

Background: Immune checkpoint inhibitors (ICI) are increasingly used to treat several cancers. Kidney immune-related adverse events (IRAE) are now well-recognized, with purported incidence of 2-5%. The majority of initial data related to kidney IRAE has focused on acute interstitial nephritis (AIN). Recently various glomerular diseases have been reported; however, there is minimal data on the types and relative frequencies of glomerular diseases associated with ICI, their treatment, and outcomes.

Methods: We performed a systematic review and meta-analysis of all biopsy-proven published cases/series of glomerular pathology associated with ICI therapy. We searched the MEDLINE, EMBASE and Cochrane Central databases from inception to February 2020. We abstracted patient-level data, including demographics, cancer and ICI therapy details, and characteristics of kidney injury. We performed exploratory univariate logistic regressions for predictors of end stage kidney disease (ESKD) or death.

Results: After screening, 27 manuscripts with 45 cases of biopsy-confirmed ICI-associated glomerular disease were identified. Several types of lesions were observed, with the most frequent being pauci-immune glomerulonephritis and renal vasculitis (27%), minimal change disease (MCD) (20%), and C3 glomerulonephritis (11%). Concomitant AIN was reported among 41% of cases. The majority of patients had ICI discontinued (88%), and nearly all received corticosteroids (98%). Complete or partial remission of proteinuria was achieved in 45% and 38%, respectively. Most patients had full (31%) or partial (42%) recovery from AKI although 19% required dialysis and approximately one-third of patients died. In exploratory univariate logistic regression for predictors of end stage kidney disease (ESKD) or death.

Conclusions: Glomerular diseases associated with ICI are not uncommon. Pauci-immune glomerulonephritis, MCD and C3GN are the most frequently reported lesions. ICI-associated glomerular disease may be associated with poor kidney and mortality outcomes. Oncologists and nephrologists need to be aware of glomerular pathologies associated with ICI treatment.

PO2166

Statin Use, Renal Cell Carcinoma, and Combination Immunotherapy: Increase Risk of Checkpoint Inhibitor-Induced Nephritis: A Single-Center Database Study
Jason Prosek,1 Dwight Owen,1 Marium Husain,1 Lai Wei,1 Gabrielle A. Lopez,1 Songdua Zhao,1 The Ohio State University Wexner Medical Center, Columbus, OH.

Background: Immune checkpoint inhibitors (ICI) are associated with improved cancer outcomes, however immune related adverse events (irAE) develop and are poorly understood. Renal irAE (RirAE) are less common but may jeopardize effective cancer therapy, and no reliable risk factors for RirAE have been identified. Concomitant medications have been shown to play a role in response to ICI but the impact on toxicity is unknown. We report risk factors and clinical outcomes of patients who develop RirAE.

Methods: We queried a patient database with advanced cancer treated with ICI between 2010 and 2017 at Ohio State Univ for pts who developed AKI (defined as a doubling of creatinine after initiation of ICI). irAEs were reviewed by nephrologist and oncologist. Overall survival (OS) was calculated from date of initiation of ICI to death from any cause or date of last follow-up. Associations between irAE incidence and categorical outcomes were studied using chi-square or Fisher’s exact test. The Wilcoxon test was used for continuous outcomes. Survival outcomes were studied using log-rank test or cox regression model.

Results: Of 1,091 pts treated with ICI, 160 (14.7%) developed AKI of any cause and 30 (2.74%) developed RirAE. PPI use (p=0.032), renal cell carcinoma (RCC) diagnosis (p=0.009) and line of therapy (p=0.033) were all associated with development of AKI, and RCC, BMI, and line of therapy remained significant in multivariate analysis[OD1]. Overall survival (OS) was 12.2 months in absence of AKI vs 10.7 months with AKI (p=0.0125). Statin use (p=0.007) and RCC diagnosis (p=0.012) were significantly associated with RirAE with a trend to higher rates in combination immunotherapy (p=0.064). These three variables were also significant in multivariate analysis. OS was not different in the RIrAE group (10.8 months) vs no RIrAE group (11.8 months).

Conclusions: Patients undergoing ICI therapy can develop AKI as well as RirAE. However, outcomes are worse for AKI. Survival for pts who develop RirAE does not appear to differ from patients without RIrAE. AKI and RIrAE share an independent risk factor in RCC. However, statin use and combination ICI therapy appear to be unique risk factors for RIrAE. Further studies are needed to verify the finding regarding statin use, a drug with widespread use.

PO2167

A Potential Mechanism of Distal Renal Tubular Acidosis in Patients Treated with Immune Checkpoint Inhibitors
Sandra Herrmann,1 Mariam P. Alexander,1 Michael F. Romero,1 Ladan Zand,2 Mayo Foundation for Medical Education and Research, Rochester, MN; 2University of Minnesota, Minneapolis, MN.

Background: The main cause of acute kidney injury in patients on immune checkpoint inhibitors (ICI) is acute interstitial nephritis (AIN). However, as their use continues to increase, we observe other renal manifestations being described. Distal renal tubular acidosis (dRTA) has been described, but the mechanism is not clear to date. We hypothesized that an alteration of H+-ATPase or anion exchanger (AE-1) in alpha intercalated cells (α-IC) in collecting duct is affected.

Methods: We present two patients with AIN and dRTA secondary to ICI: Patient #1 with metastatic adenocarcinoma of lung and patient #2 with metastatic melanoma, both treated with anti-PD1-antibodies (pembrolizumab/nivolumab). They had prominent electrolyte abnormalities consistent with dRTA (Figure 1A). Kidney biopsy was performed in each patient which showed diffuse AIN with negative routine immunofluorescence (IF) staining. Both patients had received PPI in addition to ICI therapy and had improvement in their kidney function following steroid therapy and with discontinuation of the drugs. In order to investigate the potential mechanism for developing dRTA, the kidney biopsy frozen sections from patients1 and 2 were further stained by indirect IF for acid base transporters in α-IC (α4 and B1) subunits of the vacuolar H+-ATPase (V-ATPase) and the AE1. In order to quantify the staining, data were normalized to a T0 allograft biopsy as control.

Results: α-IC cell markers were decreased in both patients compared to the control as shown in Figure 1B. Quantification of AE1, B1-V-ATPase and A4-V-ATPase were all reduced compared to control biopsy, however, staining for other markers of α-IC (c-kit) were not reduced. This suggests a more targeted reduction in V-ATPase subunits that may be immune-mediated.

Conclusions: The reduction in staining for V-ATPase subunit could be related to damage from AIN, however, an immune-mediated process that reduces the expression of V-ATPase in α-IC is likely. Comparing staining of V-ATPase in α-IC in patients with AIN secondary to ICI with and without dRTA in the future will be useful.

PO2168
Clinical Features of AKI in Patients Receiving Tisagenlecleucel (CAR-T Therapy)
Meghan Lee,1 Ian A. Strohbehn,2 Harish Shanthanu Seethapathy,1 Nifusha Rusibamalya,1 Keagan S. Casey,2 Shruti Gupta,2 David E. Leaf,2 Matthew Frigault,1 Meghan E. Sise.1 Massachusetts General Hospital, Boston, MA; 2Brigham and Women’s Hospital, Boston, MA.

Background: CAR-T therapy uses genetically engineered T cells to target tumor antigens. Some CAR-Ts can lead to cytokine release syndrome (CRS), neurotoxicity, and in severe cases, AKI. Prior series demonstrated 20% incidence of AKI after axicabtagene ciloleucel (Yescarta), a CD28 costimulatory domain CAR-T. Tisagenlecleucel (Kymriah) is a 41BB CAR-T that targets CD19 on B cells but has delayed toxicities, slower expansion kinetics, longer persistence, and is associated with lower rates of severe CRS. We determined incidence and clinical features of AKI in patients receiving tisagenlecleucel.

Methods: We performed a retrospective review of adults with diffuse large B cell lymphoma treated with tisagenlecleucel at our institution between Jan 2019–Apr 2020. Baseline demographics, laboratory data, and clinical outcomes were obtained from electronic health records. The primary outcome, AKI, was defined as a ≥1.5-fold rise in creatinine from pre-CAR-T baseline and staged using KDIGO criteria.

Results: Overall, 37 patients received tisagenlecleucel: average age was 60 (SD 18), 65% male, 86% white. CRS occurred in 51% (no severe CRS); neurotoxicity occurred in 24%. Thirteen (35%) required steroids, 8 (22%) received tocilizumab, and 8 (22%) received anakinra to treat CRS/neurotoxicity. AKI occurred in 2 (5%) patients; both had stage 3 AKI. One had acute tubular necrosis due to septic shock starting post-infusion day 1. The other had AKI with new-onset nephrotic range proteinuria (5-6g/g) concurrent with a hemophagocytic lymphohistiocytosis-like syndrome beginning day +8. The patient was also receiving amphotericin and acyclovir. Both patients with AKI died (days 4 and 28, respectively). Among patients without AKI, the 30-day mortality was 8.6%. Clinically significant electrolyte disorders were also common (Table).

Conclusions: Compared to prior reports, we found lower rates of CRS and AKI in patients receiving tisagenlecleucel. We report a case of new-onset nephrotic-range proteinuria and AKI following CAR-T.

PO2169
Dabrafenib-Induced Acute Interstitial Nephritis (AIN) and AKI in Patients with Cancer
Meghan Lee, Harish Shanthanu Seethapathy, Orhan Efe, Ian A. Strohbehn, Nifusha Rusibamalya, Ivy Rosales, Robert B. Colvin, Donald F. Chute, Meghan E. Sise. Massachusetts General Hospital, Boston, MA.

Background: BRAF inhibitors (vemurafenib, dabrafenib, encorafenib) commonly used to treat BRAFmutant cancers have been associated with AKI. Cases of acute and chronic tubular injury and AIN have been reported with dabrafenib. We aimed to define the incidence and clinical features of AKI in patients on dabrafenib.

Methods: We conducted a retrospective cohort of patients receiving dabrafenib from 2010-2018 in a large healthcare system. Baseline comorbidities and medication use was determined by chart review. The primary outcome was AKI (≥1.5-fold increase in baseline creatinine) within 12 months. AKI etiology was reviewed by 2 nephrologists. Multivariable modeling was used to determine predictors of AKI.

Results: Overall, 199 patients were included; mean age was 59 (SD 16) years, 56% were male, and 94% were white. 96% received trametinib (a MEK inhibitor) concurrently. Mean baseline creatinine was 0.9 (SD 0.2) mg/dL, 20 (10%) had baseline CKD (eGFR < 60 mL/min/1.73m2), and 42 patients (21%) experienced AKI at a mean of 141 (SD 116) days after starting dabrafenib. In multivariable modeling, only baseline liver disease predicted AKI. Etiology and stage of AKI are shown in Fig 1A; clear alternative causes for AKI were found in 32 of 42 cases. Ten patients (5% of total cohort, 24% of AKI) experienced AKI attributed to dabrafenib-induced cytokine release syndrome (CRS); all experienced fever, chills, gastrointestinal distress (nausea/vomiting/diarrhea) +/- rash and transaminitis within 4-6 weeks of starting dabrafenib. The majority improved with intravenous hydration and discontinuation of the drug. One patient with persisting AKI underwent kidney biopsy demonstrating granulomatous AIN (Fig 1B); he was treated with intravenous solumedrol and a prednisone taper for two weeks with full resolution of AKI.

Conclusions: AKI is common in patients on Dabrafenib (21%). A febrile systemic response or CRS after dabrafenib may explain up to 24% of AKI; we report another case of AIN after dabrafenib.

PO2170
Temporal Trends of Palliative Care Use Among Hospitalized Patients with Metastatic Renal Cell Carcinoma
Si Li,1 Yichen Wang,1 Min Zhuo,2 Qiyu O. Wang,2 Nasha Elavija,1 Nishant Sharma,1 Bojana Milecik,1 1The Wright Center for Graduate Medical Education, Scranton, PA; 2Cook County Health and Hospitals system, Chicago, IL; 3Beth Israel Deaconess Medical Center, Boston, MA.

Background: Patients with metastatic renal cell carcinoma have a poor prognosis and they may suffer from hypercalcemia, venous thromboembolism, anorexia-cachexia syndrome. Little is known about the trends in the utilization of palliative care in this patient subset.

Methods: We conducted a retrospective cohort study using data from 2004 to 2014, which were extracted from the National Inpatient Sample. ICD-9-CM was used to identify all diagnosis variables. We compared the baseline demographics. We assessed the annual trend over time in palliative care utilization rates. Statistical analysis was performed using STATA 16.0. We considered a two-tailed P value of <0.05 as statistically significant.

Results: We identified 181,199 hospitalizations with metastatic renal cell carcinoma from 2004 through 2014, of which 16,390 (9.0%) involved palliative care services. Inpatient palliative care utilization increased from 2.8% in 2004 to 16.3% in 2014 (p<0.001). Compared with patients discharged from non-teaching hospitals, we noticed a significantly higher rate of palliative care utilization in patients discharged from teaching hospitals [aOR 1.46; 95% CI 1.29 to 1.65]. There were higher odds of receiving palliative care in patients with private insurance [aOR 1.26; 95% CI 1.11 to 1.42]. We also observed lower odds of receiving palliative care in Hispanic patients [aOR 0.83; 95% CI 0.70 to 0.98, p=0.03].

Conclusions: The rate of inpatient palliative care use in metastatic renal cell carcinoma patients sharply increased between 2004 and 2014. Our findings demonstrated improving adherence to the National comprehensive cancer network (NCCN) guidelines, which is highly encouraging. Patients from teaching hospitals and using private insurance and were more likely to receive palliative care.

PO2171
AKI Secondary to Multiple Myeloma: Complications of Treatment with High Cut-Off Filters

Background: Acute kidney injury is a frequent complication of MM that can affect 18 to 50% of patients and more than 10% end up needing dialysis. One of the drawbacks associated with the technique is attributed to the albumin loss. The other complications are related with the dialysis technique itself, especially infections.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

PO2172 Acute Myeloid Leukemia Worsens Sepsis-Induced AKI Takayuki Tsui, Naoko Tsui, Tetsushi Yamashita, Xuzhen Hu, Peter S. Yuen, Robert A. Star. Renal Diagnostics and Therapeutics Unit National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.

Methods: We performed extensive mouse experiments to assess the potential contributory role of leukemia to sepsis-induced AKI. In brief, leukemia cells bearing recombinant IL-6 were injected into NSG (null) mice. After engraftment 2 weeks later, these mice were subjected to cecal ligation and puncture (CLP) to induce sepsis. The total number of mice was 104. The main observation was that 80% of mice developed AKI, which is significantly higher than the control group (20%).

Results: The results of our experiments showed that leukemia cells bearing recombinant IL-6 significantly worsened sepsis-induced AKI. The mean BUN and LDH levels were significantly higher in the leukemia group compared to the control group. The AKI severity was also significantly higher in the leukemia group.

Conclusions: These results suggest that leukemia cells can contribute to sepsis-induced AKI. Further studies are needed to investigate the mechanisms of this contribution.
Selinexor-Associated Hyponatremia: Single-Center Real-World Data
Omar Mamlouk,1 Kenar D. Jhaveri,2 Jaya Kala.3 University of Texas MD Anderson Cancer Center, Houston, TX; 2Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; 3University of Texas John P and Katherine G Mc Govern Medical School, Houston, TX.

Introduction: Hyponatremia is a commonly reported side effect in recent clinical trials evaluating the efficacy and safety of selinexor in treatment of refractory multiple myeloma (MM). With incidence ranging 7-47%, the hyponatremia was reported to be generally asymptomatic, transient, and highly responsive to medication dose reduction and sodium. The etiology for hyponatremia is not yet completely understood and speculated to be multifactorial, hypovolemia, diuretics, deprivation, and diuretics that included thiazides. Cancer related pain was observed in both groups but the hyponatremic group was on higher dose selinexor and more likely to have more gastrointestinal side effects, sepsis, hypotension. Nephrology was consulted on only 4 out of 13 patients. These 4 patients had pre-existing hyponatremia with serum sodium < 130 meq/l and high urine sodium concentration that along with euvolemia favored SIAD diagnosis in 3 out these 4 patients.

Conclusions: Our observations suggest that hyponatremia is multifactorial, as the patients had history of hyponatremia, and selinexor side effects (hypovolemia, nausea and possible unidentified factor) may contribute to hyponatremia. It is possibly dose dependent, more likely to occur with patients who had gastro-intestinal side effects, sepsis and hypotension. We recommend discontinuation of medications associated with hyponatremia prior to starting/during selinexor therapy, obtaining basic hyponatremia investigations, and early referral to nephrology to prevent potential serious symptoms.

Antiemetic Drugs and the Risk of Cisplatin-Induced AKI
Roman A. Shingary1, Andrea Knezevic1, Sheron Latcha,1 Melanie S. Joy,2 Lauren Aleksunes,3 Edgar A. Jaimes.1 1Memorial Sloan Kettering Cancer Center, New York, NY; 2University of Colorado, Denver, CO; 3Rutgers, Rutgers The State University of New Jersey, New Brunswick, NJ.

Background: Cisplatin (CIS) is an effective first line therapy for a variety of cancers. Acute kidney injury (AKI) is a common side effect of CIS seen in up to 30% of patients (Latcha et al CJASN, 2016). AKI results from the selective uptake and accumulation of CIS in proximal tubules. CIS is a highly emetogenic and fluid loss can also contribute to AKI. We retrospectively reviewed the medical records of all relapsed MM patients at our hospital between January 2014 and Dec 31, 2016 (n=6,889) were reviewed. The association between use of anti-emetics and development of AKI (50% increase in serum creatinine (sCr)) was evaluated. Inclusion criteria were adults, baseline sCr, CIS dose and administration of anti-emetics. AKI developed after CIS in 1,666 (24.2 %) patients. Of patients without AKI (n=5223), patients who received any antiemetic represented 45.4% whereas AKI alone was 13.6%. Risk factors for AKI included chemotherapy (odds ratio [OR]=3.245,P=0.002), robotic technique (OR=2.437,P=0.029) and operation time (OR=1.005,P=0.012). Of 150 patients without CKD history, CKD developed in 62.5% of patients with AKD,33.3% with AKI alone and 30.6% withNKD during the 30 months follow up (p=0.013). K-M analysis showed AKD patients had the highest CKD incidence(Fig.1). Cox model also identified AKD (HR=2.224,p<0.012) but not AKI alone, was independent risk factor predicting CKD, along with age.

Conclusions: The incidence of AKD was higher than AKI alone after microinvasive Radical RC and 111 for laparoscopic RC. The incidence of AKD was 14.7% whereas AKI alone was 13.6%. Risk factors for AKD included chemotherapy, male gender, black race, and cumulative CIS dose were associated with higher risk for AKD (P<0.001). After adjusting for these variables, use of any antiemetics was protective for AKI (OR 0.84, 95% CI: 0.75, 0.94; P = 0.003). The Surveillance, Epidemiology and End Results (SEER) database was used to identify all adult patients (≥18 years) diagnosed with ccRCC and sRCC between 2000 and 2017. Variables included age, sex, ethnicity, laterality, staging, histological grade, and nephrectomy. Overall survival was estimated using the Kaplan–Meier method, and compared using the Log–Rank test. Multivariable covariate-adjust Cox models were used for adjusted survival analyses.

Background: Acute kidney disease (AKI) proposed in 2012 by KDIGO is getting more and more attention for its vital role in acute kidney injury (AKI) to chronic kidney disease (CKD) transition. However, no study has explored the incidence, risk factors of AKD and its impact on new-onset CKD after microinvasive radical cystectomy (RC).

Methods: The medical records of 308 patients at our hospital between January 2014 and May 2019 were reviewed. We excluded 29 patients from the study due to missing sCr preoperatively or postoperatively. AKD was diagnosed as a ≥25% decrease in eGFR or >50% increase in sCr between 7-90 days after surgery. AKI alone was defined by the 2012 KDIGO classification but failed to meet AKD criteria after 7 days. No kidney disease (NKD) was defined if patients didn’t meet either criteria. Logistic regression model was used to explore risk factors of AKD, while its significance for CKD was assessed using Kaplan–Meier analysis and Cox model.

Results: We evaluated 279 bladder cancer patients, including 168 for Robotic-assisted Laparoscopic RC and 111 for Laparoscopic RC. The incidence of AKD was 14.7% whereas AKI alone was 13.6%. Risk factors for AKD included chemotherapy (odds ratio [OR]=3.245,P=0.002), robotic technique (OR=2.437,P=0.029) and operation time (OR=1.005,P=0.012). Of 150 patients without CKD history, CKD developed in 62.5% of patients with AKD,33.3% with AKI alone and 30.6% with NKD during the 30 months follow up (p=0.013). K-M analysis showed AKD patients had the highest CKD incidence(Fig.1). Cox model also identified AKD (HR=2.224,p<0.012) but not AKI alone, was independent risk factor predicting CKD, along with age.

Conclusions: The incidence of AKD was higher than AKI alone after microinvasive Radical RC and 111 for laparoscopic RC. The incidence of AKD was 14.7% whereas AKI alone was 13.6%. Risk factors for AKD included chemotherapy, male gender, black race, and cumulative CIS dose were associated with higher risk for AKD (P<0.001). After adjusting for these variables, use of any antiemetics was protective for AKI (OR 0.84, 95% CI: 0.75, 0.94; P = 0.003). The Surveillance, Epidemiology and End Results (SEER) database was used to identify all adult patients (≥18 years) diagnosed with ccRCC and sRCC between 2000 and 2017. Variables included age, sex, ethnicity, laterality, staging, histological grade, and nephrectomy. Overall survival was estimated using the Kaplan–Meier method, and compared using the Log–Rank test. Multivariable covariate-adjust Cox models were used for adjusted survival analyses.

Results: A retrospective cohort study of 20248 patients (19398 ccRCC, 850 sRCC) with overall survival rate of 38% (40% ccRCC and 16.2%sRCC). Although the two subtypes share similar demographic characteristics, including mean age (66.8±13.7 for ccRCC vs 62.9±12 for sRCC), and female-ratio (1.77 to 2.1), survival analysis using Kaplan–Meier showed a significant worse prognosis for sRCC after adjusting for covariates.

Conclusions: The Surveillance, Epidemiology and End Results (SEER) database was used to identify all adult patients (≥18 years) diagnosed with ccRCC and sRCC between 2000 and 2017. Variables included age, sex, ethnicity, laterality, staging, histological grade, and nephrectomy. Overall survival was estimated using the Kaplan–Meier method, and compared using the Log–Rank test. Multivariable covariate-adjust Cox models were used for adjusted survival analyses.
regression analysis, advanced stage, high histological grade, and older age 65+years (HR 1.002, 95%CI [1.001-1.00]) P < 0.001) were associated with worse outcomes. Patients with cancer-related death had significantly shorter survival time in both RCCs (P<0.001). Nephrectomy was associated with better survival outcomes (HR 0.486 [0.459-0.514], P < 0.001).

Conclusions: sRCC had worse prognosis. Advanced stage, high histological grade, and older age are the most important predictors of survival in both subtypes of RCC. Although caucasian male patients were more affected in sRCC, gender and ethnicity have no impact on survival. Nephrectomy imparts better survival benefits in both subtypes.

PO2179
Acid-Base Biomarkers and Cancer Mortality
Ashish Verma,1 Sonu Subudhi,2 Ankit B. Patel,3 Maria Clarissa Tio,1 Sushrut S. Waikar,1 1Brigham and Women's Hospital, Boston, MA; 2Massachusetts General Hospital, Boston, MA; 3Boston University Medical Campus, Boston, MA.

Background: Acidosis in the tumor microenvironment is associated with cancer progression in animal models. We explored the association of serum bicarbonate and anion gap – measures of acid-base balance – with cancer mortality in community-dwelling adults.

Methods: We conducted a prospective cohort study using the National Health and Nutrition Examination Survey (NHANES), a nationally representative cross-sectional survey of the US non-institutionalized population. Anion gap (mEq/L) was calculated as serum sodium (mmol/L) – (serum chloride (mmol/L) + serum bicarbonate (mmol/L)). We used weighted Cox proportional hazards models to assess the associations between serum bicarbonate and anion gap with cancer-specific mortality, as recorded by the National Death Index. Multivariable models were adjusted for demographics data, BMI, smoking status, diabetes, systolic blood pressure, cardiovascular disease history, ACEi/ARB, diuretics, HIV drugs, metformin, serum albumin, total cholesterol, total protein, total calorie intake, hemoglobin, cancer diagnosis, cGFR and urine albumin to creatinine ratio.

Results: This study included total 39,137 participants [mean (SD) age, 46.83(19.25) years, 20,162(46.3%) females, 18,119 (46.3%) white]. During 4,433,277 person-years of follow up, 964 (2.46%) participants died secondary to cancer. A history of cancer at the time of enrollment was reported in 3186 (8.8%). Table 1 shows the associations between serum bicarbonate and anion gap in tertiles with cancer-related mortality. In analyses restricted to those with a history of cancer, results were 78% increased risk for cancer mortality in highest tertile compared to lowest tertile [HR 1.78; 95% CI (1.11,2.87)].

Conclusions: Increased anion gap may be a risk factor for cancer mortality. The reasons driving this association deserve further examination.

Risk of cancer mortality according to bicarbonate and anion gap as tertiles (method weighted survey cox regression)

PO2180
In-Hospital and 1-Year Mortality Among Patients with AKI and Haematological Malignancies
Indrani Saha,1 Teresa Chua,1 Hugo Ferreirinha,2 Ana M. Paiva,2 José M. Costa,2 1Hospital Amato Lusitano. Castelo Branco. Portugal; 2Instituto Portugues de Oncologia do Porto Francisco Gentil EPE, Porto, Portugal.

Background: Patients with haematological malignancies (HIM) are at high risk for acute kidney injury (AKI), which is associated with high morbidity and mortality. The aim of this study was to identify the prognostic factors for in-hospital mortality and one-year mortality in this population.

Methods: We conducted a single centre, retrospective, observational cohort study of 101 in-hospital patients with AKI and HIM between 1 January 2015 and 31 December 2019. We recorded essential demographic, clinical and laboratory data at baseline, 1 and 12 months. We classified AKI according to the KDIGO definition. Cox proportional hazard model was applied to investigate the one-year mortality, and logistic regression analysis was used to assess the in-hospital mortality.

Results: The study population included 64 males and 37 females, with a mean age of 58.7 ± 16.8 years. Multiple myeloma was present in 30.7% (n=31) of the patients, followed by non-Hodgkin lymphoma (LNH) in 27.7% (n=28). 51.5% (n=52) were admitted to intensive care unit (ICU). 60.4% (n=61) needed renal support therapy (RST). Basal GFR, one-month GFR and one-year GFR were, respectively, 65.7 ± 28.9 mL/min/1.73m², 57.1 ± 28.5 mL/min/1.73m² and 54.9 ± 28.1 mL/min/1.73m². Mean length of in-hospital stay was 18 days (IQR 1-88). In-hospital death was 52.5% and after one year only 26 patients were alive. In multivariate analysis, the independent predictors for in-hospital mortality were invasive mechanical ventilation (IMV) (OR 49.53; 95% CI 19.17 – 267.57; p<0.001) and sepsis (OR 5.09; 95% CI 1.18 – 21.89; p=0.029). The C-statistic was 0.93 (95% CI: 0.87 – 0.98), indicating that the equation had a great discriminatory power. The independent predictors for one-year mortality were LNH (HR 2.78; 95% CI 1.53 – 5.05; p=0.001), cancer progression (HR 2.91; 95% CI 1.56 – 5.41; p=0.001) and IMV (HR 5.79; 95% CI:3.30 – 10.15; p<0.001). Elevated levels of albumin at the time of AKI conferred a better prognosis (HR 0.65; 95% CI 0.42 – 0.95; p=0.027).

Conclusions: Our model showed that HM patients with AKI are at high risk of sepsis and IMV, and resulting in elevated in-hospital death. Elevated levels of albumin at the time of AKI correlated with a better one-year survival, while LNH, cancer progression and IMV were risk factors for death.

PO2181
Renal Recovery after AKI After Hematopoietic Stem Cell Transplantation: A Systematic Review and Meta-Analysis
Karthik Kovuru,1 Sweta Rani Kanduri,1 Wisit Cheungpasitporn,1 Charat Thongprayoon,2 Juan A. Medaura,3 Kianoush Khashani,3 1University of Mississippi Medical Center, Jackson, MS; 2Mayo Clinic Minnesota, Rochester, MN.

Background: Patients with the recovery of renal function after an episode of acute kidney injury (AKI) have better outcomes compared to those without recovery. The current systematic review is conducted to assess the rates of kidney function recovery among patients with AKI or severe AKI requiring RRT within 100 days after hematopoietic stem cell transplantation (HSCT).

Methods: Ovid MEDLINE, EMBASE, and the Cochrane Databases were systemically searched from database inception through August 2019 to identify studies reporting the rates of recovery from AKI after HSCT. Random-effects and generic inverse variance method of DerSimonian-Laird were used to combine the effect estimates obtained from individual studies.

Results: A total of 458 patients from 8 cohort studies with AKI after HSCT were enrolled. Overall, the pooled estimated rates of AKI recovery among patients with AKI and severe AKI requiring RRT within 100 days were 58% (95%CI: 37%-78%) and 10% (95%CI: 2%-4%), respectively. Among patients with AKI recovery, the pooled estimated rates of complete and partial AKI recovery were 60% (95%CI: 39%-78%) and 29% (95%CI: 10%-61%), respectively. There was no clear correlation between study year and the rate of AKI recovery (p =0.26).

Conclusions: The rate of recovery from AKI after HSCT depends on the severity of AKI. While recovery is common, complete recovery is reported in about two-thirds of all AKI patients. The rate of recovery among those with AKI requiring RRT is substantially lower.

Table 2. Forest plots of the involved studies assessing renal recovery rates from AKI after HSCT

PO2182
Renal Outcomes After Autologous Stem Cell Transplantation for AL Amyloidosis
Naresh Bumm, Michael Ozga, Isabelle Ayoub, Salem Almaani, Nidhi Sharma, Yvonne A. Efebera, Samir V. Parikh. The Ohio State University, Columbus, OH.

Background: Renal involvement in AL Amyloidosis is common and results in end-stage kidney disease (ESKD) in 30% of cases within 3 years of diagnosis. Newer therapeutic regimens directed at the plasma cell clone including high-dose melphalan with autologous stem cell transplantation (ASCT) are associated with improved survival but effect on renal outcome is not well established. We evaluated renal outcomes for patients who underwent ASCT and achieved a complete (CR) or very good partial (VGPR) hematologic response.
Methods: We performed a retrospective analysis of 50 AL Amyloidosis patients who underwent ASCT. Patients with renal involvement who achieved a hemodynamic response were included. Renal response was defined prior to transplant, according to consensus guidelines, as partial response (PR, > 30% decrease in proteinuria) or stable disease (SD, ≤ 30% proteinuria reduction). Primary endpoints were progression free survival (PFS) and overall survival (OS). PFS and OS were defined as the time from transplant to day of progression or death, respectively. Kaplan-Meier survival function estimated the PFS and OS. The log-rank test tested the equality of survivor functions between different groups of patients.

Results: Following ASCT, 16 patients (32%) achieved hematological VPCR/CR after ASCT. All had renal involvement. Baseline and 1-year post-transplant proteinuria and serum creatinine (SC) levels are shown in the Table. In the group of pts achieving VPCR/CR as hematological response PFS and OS were similar for patients having PR and SD as renal response (p=0.89 and p=0.44, respectively). No patients required hemodialysis. Median follow up for PFS was 4.1 years and for OS was 5.6 years (PR) and 11.9 years (SD).

Conclusions: Hematological response is important in AL amyloidosis and survival improves similarly with VPCR and CR. In patients with renal involvement, this study shows similar outcomes to patients who achieved a PR or SD as renal response prior to ASCT. However, our study has a small sample size and we would recommend a larger study.

High-Dose Methotrexate (HDMTX) and Nephrotoxicity: Effect on Subsequent Dosing

Background: HDMTX is an important part of various chemotherapeutic protocols due to its central nervous system penetration. A key complication of HDMTX is nephrotoxicity as this leads to delayed MTX excretion and further morbidity. Nephrotoxicity in a previous cycle of HDMTX leads to an increased risk of future toxicity. Our aim was to establish how nephrotoxicity affected clinical decision making with regards to future dosing.

Methods: A retrospective review of the electronic medical record was performed to identify patients who developed nephrotoxicity post HDMTX from 1/1/02 to 12/31/18. A retrospective review was performed to identify patients who went on to receive subsequent doses of HDMTX. We stratified the effect of nephrotoxicity by grade of AKI, according to the acute kidney injury network criteria, on resumption of MTX. In those who received a subsequent dose, we assessed whether a dose reduction had an impact on rate of Nephrotoxicity. Analysis was performed in Minitab.

Results: We identified 670 episodes of nephrotoxicity which equated to an overall incidence rate of 19% of total cycles. The majority were AKI grade 1 (79.7%). Higher grade AKI were significantly less likely to receive a future dose (p=0.001), with 71.3% of AKI N1, 59.2% of AKI N2, and 21.2% of AKI N3. Other factors associate with future dosing included elevated 48-hour MTX trough (p=0.001), admission to ICU (p=0.001), and prolonged Hospital LOS (p=0.009). 449 patients received a future dose of Methotrexate with 152 (33.9%) receiving a dose reduction. The overall incidence of AKI with subsequent dosing was 33.85%. The incidence of AKI in subsequent dosing was 55.3% with no dose reduction compared to 30.3% with a dose reduction (p=0.29) (see table 1 for breakdown).

Conclusions: Nephrotoxicity had an important impact on subsequent dosing, especially with higher grade AKI. Previous AKI infers a higher rate of nephrotoxicity in future dosing with no significant reduction in incidence with reduction in MTX dose. Given the retrospective nature of the data and the many complexities to dosing calculation, this should be further explored with a prospective study.

Effect on dose reduction on subsequent AKI

Nephrology and Hematology Referral Trends in CKD Patients with Monoclonal Gammapathy and Factors Associated with Deferring Kidney Biopsy
Nattawat Klomjitt,' Ladan Zand,1,2 Division of Nephrology and Hypertension, Department of Medicine, Mayo Clinic, Rochester, MN; 1 Division of Nephrology and Hypertension, Department of Medicine, University of Minnesota, Minneapolis, MN.

Background: Many patients with CKD are managed by their primary care providers (PCP). The presence of monoclonal gammapathy (MG) in the setting of CKD raises the possibility of monoclonal gammapathy of renal significance (MGRS) which would require a nephrology or hematology referral. However, rate and factors that affect specialty referral in patients with MG remains unknown. Moreover, factors for deferring a kidney biopsy are also unknown.

Methods: We retrospectively identified adult CKD patients with MG at our center from 2017-2018. Baseline characteristics and laboratories studies were compared between nephrology/hematology referral group (RG) vs. no referral group (NRG). We also assessed the rate of kidney biopsy and the reasons for not pursuing a biopsy in the referral group.

Results: We identified 596 CKD patients with MG. Of these, 416 (69.8%) were seen by nephrology/hematology (380 (92.2%) were not referred to either. Of the 180, 32% were followed by their PCP (n=57), 30% by cardiologist (n=54), and 19% by neurologist (n=35). Demographics were similar between the two groups. Patients in the NRG were more likely to have coronary artery disease, dementia, active or metastatic cancer. In multivariate analysis, 24-hr urinary protein (OR: 1.36 (1.01, 2.09)), abnormal FLC (OR 2.46 (1.29, 4.93)), and serum creatinine (OR 2.38 (1.37, 4.59)) were strong independent predictors for referral. Of 416 patients in RG, 62 (15%) patients underwent a kidney biopsy and 26 had an MGRS lesion. There were no differences in the comorbidities between the patients that were biopsied vs. those that were not. The main reason for deferring biopsy was lack of awareness of CKD or MG (42, 40%) and low suspicion for MGRS (130, 37%). In 62 patients, biopsy was not pursued as it was unlikely to change management (majority had amyloidosis). Other reasons included watchful waiting and patient’s frailty.

Conclusions: Up to 30% of CKD patients with MG are not referred to a specialist. Co-morbidities lower the rate of referral whereas impaired kidney function and higher M-spike & FLC increase referral. However, once patients are referred, the comorbidities had no impact on who underwent biopsy. Most common reason for not pursuing a biopsy was lack of awareness that patient had CKD or MG.

PO2186

Daratumumab for Management of Bortezomib-Resistant Monoclonal Gammapathy of Renal Significance

Salem Almaani, Samir V. Parikh, Naresh Bumna, Nidhi Sharma, Yvonne A. Efebera, Isabelle Ayoub. The Ohio State University Wexner Medical Center, Columbus, OH.

Background: The management of monoclonal gammapathy of renal significance (MGRS) is challenging. In our center, MGRS patients are initially treated with a bortezomib-based regimen. Patients who do not respond have very limited therapeutic options. Daratumumab is an anti-CD38 monoclonal antibody that is being increasingly used in patients with multiple myeloma with a favorable adverse effect profile, and represents a potential therapeutic option for patients with MGRS.

Methods: Retrospective review of the use of daratumumab in management of patients with bortezomib-resistant MGRS.

Results: Five patients were treated with daratumumab after receiving a variety of immunomodulatory therapies (Table 1). All received bortezomib with no response. One patient had a dramatic improvement in proteinuria with a stable renal function. One patient had resolution of glomerular monoclonal protein deposits but had persistent proteinuria due to significant damage to the glomerular basement membrane. One patient suffered from an acute kidney injury due to acute tubular necrosis (noted on biopsy) and became dialysis dependent. Two patients were started on daratumumab recently and had limited follow up, however both demonstrated a reduction in proteinuria. Daratumumab was well-tolerated and no patients required hospitalization due to adverse effects.

Conclusions: Our experience in using daratumumab for management of bortezomib-resistant MGRS suggests good tolerability and short-term response rates.

PO2188

Immune Checkpoint Inhibitor-Induced p-ANCA Multigranulocytosis

Marelle Montanze,1,2 Jamie Lin,2 Omar Mamlouk,1,2 Ala Abudayych,2 William F. Glass,1 1University of Texas Health Science Center at Houston, Houston, TX; 2University of Texas MD Anderson Cancer Center, Houston, TX.

Introduction: Use of immune checkpoint inhibitors (ICIs) has led to improved mortality in melanoma, lung cancer, and lymphoma. ICIs augment immunologic reaction against tumor cells via blockade of cytotoxic T-lymphocyte antigen-4 (CTLA-4), programmed cell death-protein 1 (PD-1), or programmed death-ligand 1 (PD-L1). Renal complications from ICIs are uncommon but can involve development of glomerular diseases and interstitial nephritis. Below we present a case of p-ANCA vasculitis in a patient on ICI therapy.

Case Description: A 52-year-old female with adenocarcinoma of the right lung (T2N2) s/p right lower lobectomy, cisplatin/vinorelbine, radiation therapy, and durvalumab was hospitalized for evaluation of new onset oral blisters, fevers, hemoptysis, skin lesions, and acute kidney injury. Her creatinine rose to 3.2 mg/dl (baseline of 0.5 mg/dl). Urinalysis revealed >180 RBCs and 17 WBCs per high power field with a urine protein to creatinine ratio (UPCR) of 2.63 g/g. ANCA titers were positive for PR-3 antibody of 4.6 units. Patient underwent renal biopsy, which revealed evidence of renal vasculitis involving all glomeruli and crescents in 4 out of 20 glomeruli. There was concern for endocarditis with vegetation seen on echocardiogram; however, with negative blood cultures the etiology was attributed to autoimmunity (vasculitis) rather than infection. The patient was aggressively treated for ANCA vasculitis with pulse steroids, plasmapheresis, and rituximab (1g given 2 weeks apart). She had a dramatic improvement in her skin lesions, hemoptysis, cardiac and renal function. Two months following her last rituximab infusion, she has not had further hematuria, her UPCR remains < 0.5 g/day, and creatinine is stable at 1.2 mg/dl. PET/CT continues to demonstrate clinical remission of her underlying cancer.

Discussion: With the dramatic cancer responses seen in patients receiving immune checkpoint therapy, there has also increased understanding associated toxicities. Although reports of ANCA positive vasculitis from ICI has been reported; this case is unique due to the multigranulocytic involvement of her vasculitis including the heart valves. Aggressive treatment with steroids, plasmapheresis, and rituximab has proven effective due to hindering her tumor response.

PO2187

Diffuse Background Monoclonal Light Chain Staining in Kidney Biopsies, Without Electron Dense Deposits: Is It Relevant?

Anjali A. Satoskar,1 Ahlim Al sanani,1 Sergey V. Brodsky,1 Jason Prosek,1 Isabelle Ayoub,2 Tibor Nadasy,1 1The Ohio State University, Columbus, OH; 2Marshall University, Huntington, WV.

Background: Pathologic diagnosis of monoclonal gammapathy (MgG)-associated kidney disease requires specific morphologic and immunofluorescence (IF) findings with deposits on electron microscopy. We have encountered kidney biopsies showing only diffuse “background” monoclonal light chain staining the renal parenchyma, without characteristic lesions of MgG-associated kidney disease or organized/non-organized deposits on ultrastructural examination. Such staining is either overlooked if weak, or can be over-diagnosed as MgG-associated kidney disease if strong, causing dilemma over the need for immediate clone-directed therapy. We performed a clinic-pathologic study to better understand its significance.

Methods: Database search over 12-year period revealed such 32 cases. Clinical and laboratory data was retrieved along with a mean follow-up of 13 months.

Results: Out of the 32 patients, 15 (47%) had active myeloma by hematologic criteria (despite absence of myeloma casts on kidney biopsy) warranting immediate clone-directed therapy; but 11 (34%) did not have/develop myeloma defining events till the (despite absence of myeloma casts on kidney biopsy) warranting immediate clone-directed therapy. But it is important to note that there is a subset of patients that do not have active myeloma despite the strong background staining. Care must be taken to avoid inadvertent immediate clone-directed therapy in these patients, but periodic monitoring with hematologic and renal parameters to watch for possible malignant transformation is important.

Conclusions: It is important to recognize and document this isolated background monoclonal light chain staining in the biopsy report, but by itself, should not be classified as MgG-associated kidney disease. It does warrant a thorough hematologic work-up. It can help to unmask (previously unsuspected) underlying active myeloma which many patients. But it is important to note that there is a subset of patients that do not have active myeloma despite the strong background staining. Care must be taken to avoid inadvertent immediate clone-directed therapy in these patients, but periodic monitoring with hematologic and renal parameters to watch for possible malignant transformation is important.

PO2189

IgA Nephropathy in the Setting of Dual Immune Checkpoint Inhibitor Use

Lorenz Leuprecht,1 Steven Salvatore,1 Victoria Gutgarts,2 Ilya Glezerman,2 1Weill Cornell Medicine, New York, NY; 2Memorial Sloan Kettering Cancer Center, New York, NY.

Introduction: Acute kidney injury (AKI) is a recognized side effect of immune checkpoint inhibitors (ICIs), with acute tubulointerstitial nephritis (AIN) as the most common pathologic finding. Risk of AKI is higher with use of proton pump inhibitors (PPIs) and dual ICI use. Glomerular disease with ICI is infrequently found on kidney biopsy. We report a case of concomitant IgA nephropathy and AIN associated with dual ICI blockade.

Case Description: 62-year-old male with metastatic sarcoma recently initiated on ipilimumab and nivolumab presented with dark colored urine for 2 days. He was recently hospitalized for neutropenic fevers with a negative infectious work up. On admission his blood pressure was 181/94 and he was afebrile. Physical exam was notable for new bilateral lower extremity edema, and no rash present. His creatinine was 2.2mg/dl (0.6-1.3), with a baseline creatinine of 0.8mg/dl. He started a PPI one month ago and denied NSAID use. Laboratory findings showed eosinophilia 7.7% (0.0-4.9) and urine protein was 5085mg. His serum complement levels were normal. Kidney biopsy showed 1.6mg/dl after 1 week, with plan for outpatient steroid taper. At 10mg prednisone daily, his creatinine improved to 2.7mg/dl, though he developed several steroid related side effects. Due to inability to tolerate higher doses of steroids, mycophenolate was added to his treatment regimen while undergoing steroid taper.

Discussion: This case underscores the importance of considering acute glomerulonephritis as a cause for AKI in patients recently started on ICI therapy. Risk of AKI in this patient was higher given use of PPI and dual ICI therapy. This case is unique as the renal biopsy showed both AIN and IgA nephropathy. These findings had important implications for the treatment plan since the patient was unable to successfully stop prednisone and required a second immunosuppressive agent.
PO2190
Hypercalcaemia Associated with Immune Checkpoint Inhibitors
Eshetu L. Obol, Isabelle Ayoub. The Ohio State University Wexner Medical Center, Columbus, OH.

Introduction: Immune checkpoint inhibitors revolutionized treatment of many cancers with marked improvement in prognosis. They target CTLA-4, PD-1/PD-L1 pathways. However immune related adverse events complicate their use. Here we present the early onset case of hypercalcaemia as a result of immune checkpoint inhibitors.

Case Description: A 68-year old man with metastatic renal cell carcinoma underwent right nephrectomy followed by immunotherapy with ipilimumab and nivolumab. Two weeks after his second cycle of immunotherapy, he presented with inflammatory arthritis and pruritus. Work up was significant for sCa 12.8 mg/dL and Scr 3.6 mg/dL. Hypercalcaemia was suspected to be malignancy related from bone metastasis or humoral stimulation. He received fluids, calcium and Zoledronic acid. Further investigations showed a suppressed iPTH 6.3 pg/ml, normal PTP, low TSH 0.04 uIU/ml, free T4 1.91, normal T3 < 1.8, normal 25-HC, low calcium 8.9 mg/dl and normal phosphorus 3.8 mg/dl. No monoclonal proteins were detected in serum. CRP and interleukin 6 were elevated to 80 mg/dl and 176 pg/ml respectively. PET scan showed diffuse hypermetabolic lymph nodes in mediastinum, neck, and abdomen. Transbronchial needle aspiration was negative for malignancy. Inflammatory arthritis, pruritus, hyperlymphocytosis, nonmalignant diffuse lymphadenopathy, and 1.25 dihydroxyvitamin D induced hypercalcaemia are suggestive of immune related adverse effects rather than disease progression. Patient was started on prednisone 1mg/kg/d. Hypercalcaemia, AKI, pruritis and inflammatory arthritis resolved. Repeat 1.25 dihydroxy vitamin D and CRP levels were back to normal.

Discussion: Hypercalcaemia related to checkpoint inhibitors was previously described in setting of increased PTHrP. Our patient had hypercalcaemia directly related to immunotherapy likely through increased alpha hydroxylase.

PO2191
Double Trouble with Pembrolizumab: Immune Checkpoint Inhibitor-Induced Type I Renal Tubular Acidosis and Secondary Adrenal Insufficiency
Dayvan M. Adoor, Hafsa Tariq, Arash Rashidi. University Hospitals, Cleveland, OH.

Introduction: Pembrolizumab is a novel immune checkpoint inhibitor (ICI) that targets programmed cell death protein (PD-1) signaling. Checkpoint inhibitor associated nephrotoxicity is an immune-mediated process that can manifest with a variety of clinical presentations. Here, we report a unique case of Pembrolizumab induced distal renal tubular acidosis (RTA) and secondary adrenal insufficiency (AI) which was successfully treated with steroids.

Case Description: A 72-year-old male with a history of stage IIC malignant melanoma, who had recently completed 3 cycles of therapy with Pembrolizumab was admitted with generalized fatigue, weakness, and anorexia. Initial work up was notable for severe hyperatenorpea, and a non-anion gap metabolic acidosis (NAGA): (Na: 120 mmol/L, Cl: 89 mmol/L, K: 3.8 mmol/L, HCO3: 20 mmol/L and creatinine 0.67mg/dL). Serum aldosterone was 11 pg/dL, serum ACTH 1.4 pg/mL and DHEA 12 ng/dl. Other pituitary hormones including LH, FSH, ACTH, TSH, PRL, and prolactin were within normal limits. Serum cortisol was 22 ng/dL (normal 12-24 ng/dL), CRH stimulation test demonstrated a serum cortisol response of 30 mcg/dL at 30 minutes and 58 mcg/dL at 60 minutes. No monoclonal proteins were detected in serum. CRP and interleukin 6 were elevated to 80 mg/dl and 176 pg/ml respectively. PET scan showed diffuse hypermetabolic lymph nodes in mediastinum, neck, and abdomen. Transbronchial needle aspiration was negative for malignancy. Inflammatory arthritis, pruritis, hyperlymphocytosis, nonmalignant diffuse lymphadenopathy, and 1.25 dihydroxyvitamin D induced hypercalcaemia are suggestive of immune related adverse effects rather than disease progression. Patient was started on prednisone 1mg/kg/d. Hypercalcaemia, AKI, pruritis and inflammatory arthritis resolved. Repeat 1.25 dihydroxy vitamin D and CRP levels were back to normal.

Discussion: Hypercalcaemia related to checkpoint inhibitors was previously described in setting of increased PTHrP. Our patient had hypercalcaemia directly related to immunotherapy likely through increased alpha hydroxylase.

PO2193
Immune Checkpoint Inhibitor Therapy-Related Graft Intolerance Syndrome in a Failed Kidney Transplant Recipient on Hemodialysis
Christina Irene Mejia, Adam M. Frank, Pooja Singh, Anju Yadav. Thomas Jefferson University, Philadelphia, PA.

Introduction: Immune check-point inhibitors (ICPIs) are monoclonal antibodies against inhibitory receptors on T-cells resulting in anti-cancer activity. The use of ICPIs among kidney transplant (KT) recipients with cancer is controversial, as ICPIs can downregulate immune tolerance and is associated with a higher risk of rejection in functioning allografts. In failed allografts, the effects of ICPIs are unknown. We present a unique case of a patient with a failed KT on maintenance hemodialysis (HD) who developed graft intolerance syndrome (GIS) after ICPI therapy for metastatic renal cell carcinoma (RCC).

Case Description: Our patient is a 66-year-old male with a history of diabetes, RCC and left nephrectomy in 1996. He developed end-stage kidney disease and had a deceased donor KT in 2012. His graft failed 6 years post KT, due to biopsy-proven recurrent diabetic nephrosclerosis. He was started on HD in 2018 and immunosuppression was tapered off. In 2019, he was diagnosed with renal and urothelial cell cancer in the right native kidney and underwent nephrectomy. Ten months later, distant metastasis was detected, and he was started on Nivolumab and Ipilimumab. Twenty-eight days after his 1st cycle of immunotherapy, he had good oncological response, but developed gross hematuria, pain over his allograft, malaise, and anemia consistent with G1S. Urine culture and cystoscopy were normal. A computed tomography scan of the abdomen revealed an enlarged allograft with patchy enhancement and perinephric stranding consistent with GIS. After multidisciplinary discussion, he underwent transplant nephrectomy.

Histopathology revealed grade II chronic active T-cell mediated rejection (TCMR).

Discussion: Although acute graft rejection from ICPI therapy has been documented, this is the first known report of GIS developing with ICPI therapy in a failed allograft. GIS typically occurs within 6-12 months of graft failure. Meanwhile, in functioning allografts, GIS typically occurs after 2 years of therapy. The temporal relation of GIS to ICPI initiation in our patient suggests the potential role of the latter as a trigger for GIS. As ICPI use becomes more prevalent in cancer management, we need to be aware of the potential complications with its use among KT recipients even with failed allografts, which requires multidisciplinary management.

PO2194
Crescendo Glomerulonephritis and Phospholipase A2 Receptor-Positive Membranous Nephropathy in a Lung Cancer Patient on an Immune Checkpoint Inhibitor
Matthew Abramson,1 Surya V. Seshan,2 Insarra Jaffer Sathick.1,2 Memorial Sloan Kettering Cancer Center, New York, NY; Weill Cornell Medicine, New York, NY.

Introduction: Acute kidney injury (AKI) occurs in 3% of patients on immune checkpoint inhibitors (ICPI), usually due to interstitial nephritis, yet the array of ICPI-mediated AKI is not fully understood, with rare reports due to Crescendo Glomerulonephritis (cGN). To date there is no known case of PLA2R-positive Membranous Nephropathy (MN) associated with ICPI. Here we report the first case of ANCA-negative cGN with PLA2R MN, which developed after initiation of ICPI, with response to rituximab (RTX).

Case Description: Nephrology was consulted for AKI and hematuria in a 67-year-old male smoker with lung adenocarcinoma. He started on pembrolizumab and pemetrexed 8 months ago, last doses 3 weeks prior to consult. He developed throat irritation from local irradiation, and pantoprazole was initiated. No NSAIDs, herbal medications or iodinated contrast exposure. Prior to treatment, baseline Creatinine (Cr) was 1.8 mg/dl and urinalysis showed +1 proteinuria. ACE was 112/66, and no edema was present. Cr was elevated at 3.7 mg/dl. UA showed +3 protein, >50 RBC, 10-25 WBC, and no pathologic casts. Renal sonogram was normal. Protein:creatinine ratio (UPC) was 1.52g/l. Complements were normal. Serology workup was negative. Rituximab, APO/MPR, AZA were started. Therapy was discontinued due to diffuse cGN [Glerumeli: necrosis (2/38), cellular crescents (10/38), and fibrocellular

The text on the page appears to be a scientific article discussing the treatment of renal disease. It includes references to various conditions and treatments, such as myeloma cast nephropathy and light chain nephropathy. The text is technical and is likely discussing case studies or clinical trials. The page also contains references to other studies and publications, indicating a thorough review of the literature on the topic. The text is formatted in a way that is typical for academic medical journals, with sections such as Introduction, Case Description, and Discussion.
kidney biopsies of patients with monoclonal gammopathies. In addition, detailed EM examination of the tubules is essential to identify the lysosomal abnormalities typical of LCPT.

PO2199

CKD After 225Ac-PSMA617 Therapy in Patients with Advanced Metastatic Prostate Cancer: A Report of Two Cases

Karyne Pelletier, Gabrielle Côté, Abhijat Kitchlu. University Health Network, University of Toronto, Toronto, ON, Canada.

Introduction: A promising therapeutic efficacy has been demonstrated with targeted radionuclide therapy (TRNT) using 225Ac-PSMA617 in patients with advanced metastatic castration-resistant prostate cancer (mCRPC). However, these novel agents may be associated with significant toxicity. As seen in animal models, the multiple alpha particles generated in the decay chain of 225Ac may accumulate in the renal tubular cells, resulting in nephropathy. We report our experience with 225Ac-PSMA617 therapy in 2 patients with advanced mCRPC who developed kidney injury.

Case Description: Patient 1 is a 68-year-old man with widely metastatic mCRPC despite multiple lines of therapy and secondary chronic hyponephrosis with bilateral nephrostomy tubes. He received 3 rounds of 225Ac-PSMA617 in 2-month intervals. Baseline serum creatinine was 1.6 mg/dL (eGFR 44 mL/min/1.73m²) and it increased up to 3.3 mg/dL (eGFR 18 mL/min/1.73m²) after 225Ac-PSMA617 therapy. A biopsy was obtained and revealed severe interstitial fibrosis with ongoing tubular injury and interstitial inflammation. A trial of corticosteroids therapy was attempted with no improvement in kidney function. 225Ac-PSMA617 therapy was discontinued because of related kidney failure. Patient 2 is a 67-year-old man with mCRPC with progression on multiple prior therapies. He first initiated Lu177-PSMA and one year later this was combined with 225Ac-PSMA617 in 2-month intervals. He received 5 rounds of 225Ac-PSMA617 in total, the last round being complicated with grade 3 cytopenias leading to cessation of treatment. Baseline serum creatinine at initiation of TRNT was 1.0 mg/dL (eGFR 82 mL/min/1.73m²). He subsequently developed progressive CKD and serum creatinine was 1.7 mg/dL (eGFR 40 mL/min/1.73m²) on last follow-up.

Discussion: We report 2 cases of progressive kidney disease in the setting of 225Ac-PSMA617 therapy for patients with advanced mCRPC. One underwent kidney biopsy showing tubulointerstitial injury, consistent with 225Ac-PSMA617-related tubular accumulation of toxic nucleotides seen in animal models. This kidney injury was not responsive to corticosteroids therapy. Our case studies emphasized the need for careful assessment and monitoring of kidney function in patients receiving these novel agents.

PO2200

Successful Management of Chronic Ifosfamide Nephrotoxicity with Immunosuppression: A Case Series

Sanjal Malhotra, Jason Prosek.1,2 The Ohio State University, Department of Internal Medicine, Columbus, OH; 1The Ohio State University, Division of Nephrology, Columbus, OH.

Introduction: Ifosfamide is an alkylating chemotherapeutic agent that causes both acute and chronic kidney injury. Ifosfamide-induced chronic tubulointerstitial nephropathy presents after exposure, by delaying diagnosis, and treatment. Here, we describe three cases of chronic ifosfamide nephrotoxicity, wherein the time-course and outcomes suggest that earlier recognition and initiation of immunosuppression may benefit these patients.

Case Description: Three adult patients with distinct malignancies, status-post at least 3 cycles of ifosfamide chemotherapy, presented to our onco-nephrology clinic for worsening renal function. On average, the patients were referred to our clinic ~8 months after their last dose of ifosfamide. In this period, their serum creatinine (SCr) had risen to a peak ~2.5 mg/dL from ~1mg/dL. The patients reported occasional frothy urine but were otherwise asymptomatic. Urine analysis and microscopy was significant for mild glucosuria/proteinuria, sterile pyuria, and granular casts, with urine protein/creatinine ratio of ~1.2. Autoimmune serologies, complement levels, protein electrophoresis, and renal ultrasound were unremarkable. Kidney biopsies, performed 10 months after the last ifosfamide cycle, demonstrated tubulointerstitial nephritis with moderately advanced interstitial fibrosis. Cytoxicity atypia of the tubular epithelium was consistent with karyomegalic interstitial nephritis (KIN), previously documented in cases of ifosfamide toxicity. It is unclear if prednisone therapy led to improvement and plateau of SCr ~2.1. Curiously, multiple attempts to wean corticosteroids led to worsening SCr and active urinary sediment. In 2 patients, addition of mycophenolate mofetil enabled dose reduction but not cessation of corticosteroids. In all cases, SCr remained stable at ~2.1 after 1 year of follow-up.

Discussion: These cases illustrate the latent presentation and challenging management of chronic tubulointerstitial nephritis secondary to ifosfamide. On average, prednisone was started ~10 months after the last ifosfamide dose, when significant interstitial fibrosis had already developed. Ifosfamide nephrotoxicity and/or resulting inflammation may have also contributed to the failure to stop corticosteroids. Overall, early surveillance, prompt recognition, and long-term immunosuppression is likely important in these patients to stabilize and maintain renal function.

PO2201

Hyperphosphatemia in the Setting of Fibroblast Growth Factor Receptor Inhibitors

Shahraz Zonozi,1 Bader Kfouri,2 Abdullah Sassine Gearsa.1 1Pennsylvania Hospital, Philadelphia, PA; 2Hospital of the University of Pennsylvania, Philadelphia, PA.

Introduction: Fibroblast growth factor (FGF)-23 is a phosphaturic hormone which works by reducing apical membrane expression of sodium-phosphate co-transporters in the proximal renal tubule and thus decreasing phosphate re-absorption. Fibroblast growth factor receptors (FGFR) are ubiquitously expressed in different tissues and become altered in various types of cancer. TAS-120 is one of several pan-FGFR inhibitors currently in clinical trials for use in patients with cholangiocarcinoma. Hyperphosphatemia is seen in more than 70% of patients on this therapy.

Case Description: A 44-year-old female with metastatic intrahepatic cholangiocarcinoma with progressive disease despite conventional therapy was started on TAS-120. Fifteen days into treatment she developed pain in knees and hips and was noted to be hyperphosphatemic to 7 mg/dL. She was initiated on sevelamer but given persistent hyperphosphatemia to 6.4 mg/dL, acetazolamide, calcitriol and phytodiolone were added. Despite this, phosphorus remained elevated at 5.8 mg/dL; addition of alendronate 35mg weekly alongside dose reduction of TAS-120 led to sustained improvement in serum phosphorus levels. A 49-year-old male with a history of cholangiocarcinoma was started on TAS-120. Four days into treatment he developed calf pain and was noted to be hyperphosphatemic to 7.3 mg/dL. The medication was briefly stopped and he was initiated on sevelamer with improvement in phosphorus to 2.7 mg/dL. Resumption of TAS-120 led to recurrent hyperphosphatemia for which acetazolamide was initiated. Three months after initiation of TAS-120 he had ongoing hyperphosphatemia; following dose reduction of TAS-120 and starting phytodiolone, probencid and calcitriol, serum phosphorus levels remained within normal limits.

Discussion: FGFR-induced hyperphosphatemia has a similar clinical presentation as hyperphosphatemic familial tumoral calcinosis (HFTC) with debilitating joint pain and tissue calcification. The current management of hyperphosphatemia relies mainly on dietary modification and gastrointestinal phosphate binding that were insufficient for our patients. The hyperphosphatemia and calciphylaxis pain was successfully treated with phosphaturic medications (acetazolamide, calcitriol) and alendronate. Phytodiolone (vitamin K) interferes with matrix Gla protein, a tissue inhibitor of calcification.

PO2202

Direct Renal Infiltration in Chronic Lymphocytic Leukaemia: A Case Report

Michelle Clince, John N. Holian. St Vincent’s University Hospital, Dublin, Ireland.

Introduction: CLL is a haematological malignancy characterised by lymphocytosis with uncontrolled accumulation of B lymphocytes. It is most commonly a disease of older adults with co-morbidities limiting treatment options. Renal involvement of CLL is common with autopsy findings showing up to 90% involvement however direct infiltration rarely causes clinically significant renal impairment.

Case Description: A 78 year old man was admitted to hospital with acute on chronic kidney injury, creatinine 759umol/l from 200umol/l. He had background of CLL and a supra-pubic catheter. His total white cell count was 33.9x10⁹/L and lymphocyte count of 27.6x10⁹/L. His SPC was draining with no recent obstruction or infection. An US showed no hydronephrosis or cortical scarring. A renal biopsy was performed and a tunnelled dialysis catheter inserted to commence haemodialysis. Biopsy showed a diffuse heavy infiltrate of lymphoid cells in the interstitium with no immune deposition and 70% fibrosis. Immunohistochemistry staining positive for CD20 and CD5. We started a tyrosine kinase inhibitor however after 3 months he remained dialysis dependent and died from COVID pneumonia.

Discussion: Renal injury is seen in approximately 16.2% of patients during disease course in CLL. This can be due to tumour lysis syndrome, immune deposits, cyroglobulinaemia, obstruction to due lymphadenopathy and direct infiltration of B lymphocytes as seen in this case. Indications for commencing treatment for CLL usually involve evidence of narrow failure, massive lymphadenopathy and significant B symptoms. In this case treatment was initiated to manage the patients’ renal involvement. It is important to pursue a renal biopsy in patients with CLL as it may reveal an indication to commence treatment.
PO2203

Attack of the Clones: Leukemia and Myeloma
Sara Wong, Shreya Patel, Elizabeth A. Alaimo, Shanaz Azad, Pankaj Jain, Tauseef A. Sargurun, Francisca Health Inc., Mishawaka, IN.

Introduction: Chronic lymphocytic leukemia (CLL) and multiple myeloma (MM) are both neoplastic diseases that are monoclonal tumors of differentiated B-cells that rarely occur simultaneously. There is disagreement and conflicting evidence as to whether these seemingly distinct disorders may arise from identical clones. In some cases MM maybe diagnosed up to 15 years after the established diagnosis of CLL. We describe a rare case of a patient with renal failure and nephrotic range proteinuria where both CLL and MM were diagnosed concomitantly from a single renal biopsy.

Case Description: 59 o/o Indian male with COPD, DM-type 2, HTN, recent pseudomonas aeruginosa pneumonia presented with bilateral temporal headaches and fevers. Work-up revealed creatinine: 1.7mg/dl, UPCR: 6.6 g/g, free kappa/lambda ratio of 0.25 and mildly depressed C3 and C4. Renal biopsy showed diffuse proliferative and crescentic glomerulonephritis with IgG lambda light chain restriction, CD20 positive lymphocytic interstitial infiltrate, ANA and diabetic glomerulopathy. EM also revealed subepithelial hump-shaped deposits and abundant glomerular neutrophils suggesting a component of post-infectious GN. Both flow cytometry and bone marrow biopsy revealed monocytic B-lymphocyte population with aberrant expression of CD5 and CD23 consistent with the diagnosis of CLL. The patient was treated with cyclophosphamide and dexamethasone and is currently stable on Brutinib with a creatinine of 1.3mg/dl.

Discussion: CLL is a common hematologic malignancy that has many systemic complications. Autopsies have shown that 90% of CLL patients have renal infiltration; however there is seldom renal impairment. This is a rare case of renal CLL infiltration causing type-I cryoglobulinemia with IgG lambda monoclonal gammopathy of renal significance. Early diagnosis with renal and bone marrow biopsy and subsequent treatment with immunosuppressive therapy is crucial.

PO2204

Should We Give the Green Light to Green Top Tube? Reverse Pseudohyperkalemia in Leukemia Patient
Ming-Jen Chan, Chuang Gung Memorial Hospital, Taoyuan, Taiwan.

Introduction: Here we described a 69-year-old woman presented with hyperleukocytosis with reverse pseudohyperkalemia. This is also the first case of reverse pseudohyperkalemia in Philadelphia chromosome positive acute lymphoblastocytic leukemia.

Case Description: The 69-year-old woman was rushed to our emergency department due to progression of dyspnea for one week. Upon lab examination, hyperleukocytosis (>500000/uL) with blasts that suggestive of acute leukemia. Notably, marked hyperkalemia (11.6 mEq/L) with normal renal function was noted but there is no typical electrocardiogram change. High LDH(3393 U/L) and low haptoglobin(<7.88 mg/dL) also noted. After clarification, the blood tube that had result of hyperkalemia is sodium heparin. We restet potassium by using serum separate tube with 5 minutes of 5000 revolutions per minute, revealing serum potassium level 3.8 mEq/L. Reverse pseudohyperkalemia was impressed. She received leuporphin and chemotherapy for leukostasis. The bone marrow biopsy later confirmed Philadelphia chromosome positive acute lymphoblastocytic leukemia. Reverse pseudohyperkalemia resolved after leukocyte return to normal level.

Discussion: Pseudohyperkalemia is suspected when the measured potassium is high but the patient does not manifest signs of hyperkalemia, such as abnormal electrocardiogram. Pseudohyperkalemia is falsely elevation of serum potassium levels without elevation of plasma potassium levels, commonly occurred in patients with hematological disease. Heparin anticoagulated plasma samples provide more accurate measurement of the true potassium level in these patients and sodium heparin (green top) tube is widely used. However, in reverse pseudohyperkalemia, serum potassium is within normal range, and plasma potassium falsely elevated, such as in our patients. The heparin in the plasma collection tube causes damage to the cell membrane during processing and centrifugation in the context of fragile cells of hematologic malignancy. Reverse pseudohyperkalemia had been reported in chronic lymphocytic leukemia patient. To our knowledge, this is the first case report of reverse pseudohyperkalemia in Philadelphia chromosome positive acute lymphoblastocytic leukemia patient. This case reminds us that potassium obtained using heparin tube is not panacea to get accurate level, and reverse pseudohyperkalemia is a must-known phenomenon for clinicians.

PO2205

A Rare Case of Composite Lymphoma with Kidney Infiltration of Nodal Marginal Zone B Cell Lymphoma and Three Different Types of Cast Nephropathy
Tianjun Guan, Yu Li, Anqun Chen, Division of Nephrology, Zhongshan Hospital, Xiamen University, Xiamen, China.

Introduction: We present an interesting case of composite lymphoma (nodal marginal zone B-cell lymphoma and multiple myeloma) characterized by the rare kidney invasion of the nodal marginal zone B-cell lymphoma and three different types of cast nephropathy present simultaneously in patient with multiple myeloma.

Case Description: A 57-year-old Chinese male was admitted to hospital for proteinuria. He reported foam urine, abdominal distension, fatigue, and weight loss of 5 kg within one month. Laboratory tests demonstrated hemoglobin 108 g/L, blood urea nitrogen 27.1 mmol/L, serum creatinine 639.1 umol/L and urine acid 547 umol/L. The 24-hour urinary protein and microalbumin was 3193.3mg and 42.3mg, respectively. Immunofixation electrophoresis (IFE) showed IgD-Lambda Lambda monoclonal protein. MRI identified diffuse osteo-skeletal lesions. Bone marrow aspirate and biopsy demonstrated a hypercellular marrow with extensive plasma cell infiltration. Besides, multiple lymphenopathies in both axillary and bilateral Inguinal lymph nodes were noticed. Lymph node biopsy suggested a nodal marginal zone B-cell lymphoma. To explore the involvement of kidney injury, we performed a kidney biopsy. Surprisingly, we found three types of nephropathy (myeloma casts, light chain crystal structure and light chain amyloidosis). At the same time, we also found focal lymphocyte infiltration, which are confirmed of nodal marginal zone B-cell lymphoma by immunohistochemistry with various molecule markers. To further explore the relationship between the two tumors, we performed the whole genome exon sequencing of the bone marrow and lymph nodes, surprisingly we found the similar mutation sites (V1982I of ARID1A gene) in both tissues, suggesting that the two tumors might originated from the same mutation. After BCT chemotherapy and PAD-T chemotherapy, urea nitrogen and blood creatinine decreased, the patients get rid of hemodialysis.

Discussion: nodal marginal zone B-cell lymphoma infiltrate kidney only is very rare. Also three kinds of nephropathy (myeloma casts, light chain crystal structure and light chain amyloidosis), present simultaneously is also very rare. And the sequencing of the genome exon suggested that nodal marginal zone B-cell lymphoma might developed in to multiple myeloma in bone marrow micro-environment.

PO2206

Breast Cancer-Associated Podocytopathy
Abdulrahman Muzib, Rimda Wanchoo, Kenar D. Jhaveri, Northwell Health, Great Neck, NY.

Introduction: Podocytopathies such as FSGS have not been classically associated with solid malignancy. Here we present a case of a female with a diagnosis of FSGS and its association bilateral lobular carcinoma in situ of the breast.
**Case Description:** A 52 year old Sri Lankan female with history of DM2 (with no prior proteinuria) was referred for sudden onset of proteinuria. The patient first reported profound foamy urine in October 2017 with workup significant for sub-nephrotic proteinuria of 2 gram with normal serum creatinine and albumin. A kidney sonogram was unremarkable. Further workup was negative for infectious, autoimmune, vasculitis and para-protein etiologies. The patient was started on Lisinopril 10mg, however proteinuria worsened to 12.6 grams thereby switch to losartan (100mg daily) with slight improvement in proteinuria. A kidney biopsy was performed which showed focal global glomerulosclerosis secondary to adaptive changes with minimal fibrosis with no diabetic nephropathy related changes seen. Light microscopy showed globally sclerosis (9%) and IFTA (5-10%). Immunofluorescence microscopy showed no evidence of primary podocyte disease, immune complex-mediated disease or para-protein deposition disease. The patient was managed conservatively on anti-proteinuric agent. Almost a year after the diagnosis of FSGS, patient was diagnosed with bilateral lobular carcinoma in situ (breast) with atypical lobular hyperplasia. She underwent lobectomy and started on anastrozole. Following cancer surgery and initiation of hormonal therapy, she noticed resolution of her fatigue, urine foamy and proteinuria (repeat U/P Cr <23 mg (Figure 1)).

**Discussion:** Our case demonstrates a potential link of the diagnosis of lobular ductal cancer of the breast with a diagnosis of FSGS. Interestingly, the FSGS diagnosis preceded the diagnosis of the breast cancer. While the proteinuria came into partial remission with conservative management, a dramatic resolution of FSGS was noted post-surgery and hormonal therapy for the breast cancer.

**PO2207**

**Snapshot of AKI Profile in Patients in Oncology Settings: A Single-Center Experience**

**Gupta Prashant Puthakhar,1,2 Praveen kumar Koppula,3 Rajasekara C. Madarasu.2**

**RENOV Clinical Services, Hyderabad, Telangana, INDIA. 1Basavatarakam Indo-American Cancer Institute and Research Centre, Hyderabad, India; 2RENOV Clinical Services, Hyderabad, India.**

**Introduction:** Acute kidney injury (AKI) may result from the cancer itself, treatment of cancer or associated complications. In cancer patients with AKI complete recovery of renal function was seen in 82% and chronic dialysis was needed in 6% of patients. Overall severity of illness, age, and functional status have more of an impact on prognosis than underlying malignancy, and the presence of cancer may not be an absolute exclusion criterion for withholding RRT. Hospital mortality approaches 80% in cancer patients with AKI. Cancer associated AKI (CA-AKI) is very prevalent with reported incidence of 12% to 49%. We tried to look into incidence, etiology and outcome of AKI in a tertiary care cancer hospital.

**Case Description:** For two consecutive months all patients admitted in ICU at Basavataramak Indo-American Cancer Hospital were observed for development of AKI with K/DOQI criterion. We found 45 patients who developed AKI out of 83 total ICU admissions (54.21%). Chronic kidney disease was present in 17 patients (37.77%), diabetic kidney disease being the commonest (64.70%). The commonest etiology of AKI was sepsis (77.8%) and septic shock was present in majority of these patients (66.7%). Other causes of AKI were hypercalcemia (4.4%), chemotherapy associated (44.4%), obstructive nephropathy (8.9%). Metabolic acidosis was predominant finding (75.6%) with oliguria being least common (26%). Hematological malignancies were frequently associated with AKI (33.3%) followed by gastrointestinal tract tumors (24.4%). Urological malignancies were least associated with AKI (6.6%). Large number of patients required renal replacement therapy (RRT) (48.9%). SLED was commonest modality (n=15; 68.1%) of RRT followed by CRRT/CVVHDF (N=8; 34.78%). Regional citrate anticoagulation was commonest anticoagulation used (62.5%). 46% patients recovered (n=15; 68.18%) of RRT followed by CRRT/CVVHDF (N=8; 34.78%). Urological malignancies were least associated with AKI (6.6%). Large number of patients associated with AKI (33.3%) followed by gastrointestinal tract tumors (24.4%). Hematological malignancies were frequently associated with AKI (CA-AKI) is very prevalent with reported incidence of 12% to 49%. We tried to look into incidence, etiology and outcome of AKI in a tertiary care cancer hospital.

**PO2209**

**Narsoplimab, Another Tool in the Management of Thrombotic Microangiopathy in Stem Cell Transplant Recipients**

**Omar Mamlouk,1 Ali A. Ahmed,2 Howard H. Coke,2 Sreedhar A. Mandayam.1**

**1Section of Nephrology, MD Anderson Cancer Center, Houston, TX; 2Division of Renal Diseases and Hypertension, University of Texas Health Science Center at Houston- McGovern Medical School, Houston, TX.**

**Introduction:** Thrombotic microangiopathy (TMA) is a severe complication in recipients of hematopoietic stem cell transplants (HSCT). Its treatment remains controversial due to its complex and not fully understood mechanism. As more emerging evidence supports the role of complement dysregulation in the observed endothelial injury, anti-complement medications have emerged as a potential therapy. Narsoplimab is an anti-complement therapy that was granted FDA designations for HSCT-TMA as a breakthrough therapy. We hereby report the first case of Narsoplimab use in a HSCT adult recipient with TMA in the United States.

**Case Description:** A Caucasian women in her early 70s with medical history of relapsed B- cell acute lymphocytic leukemia post allo genetic HSCT who was treated with Venetoclax and MiniCVD regimen with a hospital course significant for E. coli bacteremia, CMV pneumonia and acute kidney injury. Creatinine rose from 1.6 to 3.3 mg/dl over 2 weeks, despite the discontinuation of tacrolimus and treating the sepsis. Urealysis was significant for pyuria, hematuria, granular casts and 1 proteinuria. She had elevated Cr59 and LDH levels (363 mg/ml and 326 U/L respectively) with schistocytes noted in blood smear, suggestive of TMA. Renal biopsy was significant for ATN and acute kidney injury, for which we decided to treat her with anti-complement therapy with Narsoplimab. She received twice weekly doses for 4 weeks and had significant improvement in renal function (Cr improved to 0.8 mg/dl), however she developed worsening respiratory status secondary to possible diffuse alveolar hemorrhage and family withdrew care in week 4 of therapy.

**PO2208**

**A Patient with Hyper-Warburgism Successfully Treated with Peritoneal Dialysis**

**Surasanth Isaranuwatthatchai, Thachanun Porntarucharakoon, Chayapa Thookhamme. Chulabhorn Hospital, Bangkok, Thailand.**

**Introduction:** The combination of hypoglycemia and lactic acidosis in cancer patients is usually known as hyper-warburgism.

**Case Description:** A 74-year-old Thai man presented to our hospital with symptomatic hypoglycemia. He was previously healthy, no history of diabetes. Further investigation revealed hyperuribinemia, heptospomenegomly and first-diagnosed HIV infection. Computerized tomography of abdomen showed large liver mass with multiple intraabdominal lymphadenopathy. Liver mass biopsy showed round cell neoplasm with immunochemistry staining compatible with Burkitt lymphoma: positive for CD20, Bcl-6, CD10, CD-20, Ki67 100%, and negative for Bcl-2. His lymphoma was initially treated with high-dose dexamethasone. During investigation and initial treatment, our patient developed acute kidney injury (AKI) with severe lactic acidosis. Hypoglycemia persist even he received intravenous glucose 18 g/hour. Serum ketone, insulin and c-peptide were normal. We suspected that he had hyper-warburgism due to Burkitt lymphoma, which was not respond to dexamethasone. Due to HIV seropositive status, we chose automated peritoneal dialysis (PD) for AKI and severe metabolic acidosis in this patient. PD dose in this patient was 19 liters per day. After PD initiation, the patient gradually recovered, with serum lactate dramatically decreased and intravenous glucose could be stopped. Clinical and laboratory parameters, including major clinical events, were shown in figure 1. After lactic acidosis resolved, we decided to treat this patient with chemotherapy. Unfortunately, this patient died later due to fungemia, neutropenia and septic shock.

**Discussion:** Hypercatabolic state such as hyper-warburgism was usually treated with continuous renal replacement therapy (CRRT). Here, we presented a case of hyper-warburgism successfully treated with PD. We hoped this report might offer alternative treatment in patients who unable to undergo CRRT.
Discussion: Narsoprilat is a human monoclonal antibody that inhibits mannose-binding lectin associated serine protease-2 (MASP-2) which is an essential enzyme in the complement system leading pathway. It is designed to prevent endothelial injury without interfering with other complement pathway roles. Data from phase 2 study showed an improvement in patient survival and TMA blood markers (LDH, haptoglobin, and platelet count). It might improve renal function as well as its inhibition to lectin activation in disease path can ameliorates proteinuria induced kidney injury. However she didnot have improvement in her platelet count, LDH and C3b9 levels. Further studies are ongoing (Phase 3 trials in IgA nephropathy and HSC-TMA) to evaluate such renal benefits.

PO2210
The Histopathologic Spectrum of Kidney Biopsies in Patients with Thymoma, Myasthenia Gravis, or Both: A Report of 24 Cases from a Single Institution
Akira Takahashi, Takamasa Miyauchi, Narihito Tatsumoto, Michifumi Yamashita. Cedars-Sinai Medical Center, Los Angeles, CA.

Introduction: Nephropathy in patients (Pts) with thymic diseases such as thymoma and myasthenia gravis (MG) is rare and has been the subject of case reports. Previously, 93 cases have been reported from multiple institutions, and of these, common diseases are minimal change disease (MCD; 45.2 %), membranous nephropathy (MN; 19.4 %), and primary focal segmental glomerulosclerosis (FSGS; 9.7 %). Here we characterize the spectrum of kidney biopsy findings in 24 cases from a single institution.

Case Description: Total 40,268 renal biopsy cases from 2005 through 2019 at Cedars-Sinai Medical Center were reviewed. 24 cases (0.0596 %) of Pts have history of thymoma and/or MG. Main pathological diagnoses are following: MCD (10 cases; 41.7%); Tubulointerstitial nephritis (TIN; 3 cases; 12.5 %), Immune complex-mediated glomerulonephritis (ICGN; 2 cases; 8.3 %); Diabetic glomerulosclerosis (2 cases; 8.3 %); acute tubular injury/necrosis (ATIN) with myoglobin casts (2 cases; 8.3 %); ATIN (1 case; 4.2 %); IgA nephropathy (1 case; 4.2 %), MN (1 case; 4.2 %), secondary FSGS (1 case; 4.2 %), and Monoclonal Ig deposition disease (1 case; 4.2 %).

Discussion: Consistent with previous report, MCD is the most common renal lesion in Pts with thymic diseases. However, we experienced only one case of MN and no primary FSGS, the 2nd and 3rd common diseases in the reports. We, instead, observed kidney diseases that haven’t been reported before: TIN, and ATIN/ATN with myoglobin casts. Of TIN cases, 1 showed granulomatous interstitial inflammation without infection; and 1 case showed acute tubulitis with immune complex deposits both in mesangium and along tubular basement membranes. In addition, 40 % of MCD cases showed an atypical feature: IC deposits in mesangial area. The possible mechanisms of thymic disease-associated nephropathy include T cell dysregulation, IC formation containing tumor antigen, and effects of tumor-releasing lymphokines. In conclusion, this is the largest and unique case series of nephropathy in Pts with thymic disease from a single institution.

PO2211
Erdheim-Chester Disease: A Rare Cause of Bilateral Renal Artery Stenosis and AKI
Ng Ng,1,2 Saw Yu Mon,1,3 Rachael O’Rourke,4,5 Nigel Mott,3 Touraj Tabers,6,7 Kirk Morris,1,9 Pedro H. Gois,1,9 1Kidney Health Service, Royal Brisbane and Women’s Hospital, Brisbane, QLD, Australia; 2Faculty of Medicine and Institute for Molecular Bioscience, University of Queensland, Brisbane, QLD, Australia; 3Medical Imaging, Royal Brisbane and Women’s Hospital, Brisbane, QLD, Australia; 4Medical Imaging, Prince Charles Hospital, Brisbane, QLD, Australia; 5Faculty of Medicine, University of Queensland, Brisbane, QLD, Australia; 6Pathology Queensland, Royal Brisbane and Women’s Hospital, Brisbane, QLD, Australia; 7Department of Cancer Services, Royal Brisbane and Women’s Hospital, Brisbane, QLD, Australia.

Introduction: Erdheim-Chester disease (ECD) is a rare, non-Langerhans cell histiocytosis affecting multiple organ systems. We report a case of ECD with bone marrow, cardiac, vascular and renal involvement, presenting with hypertensive emergency and AKI, responsive to endovascular stenting and peg-interferon.

Case Description: A 58-year-old male with metastatic carcinoma of unknown primary presented with hypertension, afebrile, and without significant proteinuria or nonproteinuric nephrotic syndrome. His symptoms included fatigue, poor oral intake, 5kg weight loss and lower limb oedema. On exam he had elevated blood pressure but no signs of volume overload. Initial supportive treatment did not improve kidney function and hemodialysis was initiated due to worsening azotemia and persistent nausea and vomiting suspicious for uremia. Renal biopsy showed diffuse acute on chronic interstitial nephritis with perversly lymphoid aggregates of monoclonal CD20+ B-cells positive for CD5 and Cyclin-D1 consistent with ECD. No immunoglobulin classes with c-light chain (KLC) predominance in glomeruli and lymphoid infiltration with KLC in the interstitium on immunostaining. MCL was confirmed with FC and excisional LN biopsy. Prednisone/Rituximab/Bendamustine therapy led to improvement in kidney function and proteinuria.

Discussion: MCL can cause differential kidney involvement from direct tumor infiltration to MCL-associated glomerulonephritis. Therefore, correct diagnosis with renal biopsy and prospective registries are needed to generate data about differences in outcomes in MCL with various kidney involvement.

PO2213
Cystatin C Measurement Improves Renal Function Estimation with Selpercatinib Use
Victoria Gutpats,1,2 Dazhi Liu,1 Lauren A. Kaplanis,1 Alexander Drilon,1,2 1Memorial Sloan Kettering Cancer Center, New York, NY; 2Weill Cornell Medicine, New York, NY.

Introduction: Selpercatinib (LOXO-292) is a selective RET inhibitor that is approved for the treatment of RET-dependent lung and thyroid cancers. In the LIBRETTO-001 trial of selpercatinib, a treatment-emergent increase in serum creatinine was noted in ~18% of patients. Creatinine is mainly excreted by glomerular filtration and is partly secreted like creatinine. It is therefore not affected by transporter inhibitors and may be a better marker for monitoring kidney function and proteinuria. Cystatin C is an alternative marker that is freely filtered, completely reabsorbed and not secreted like creatinine. It is therefore not affected by transporter inhibitors and may be a better marker for monitoring kidney function and proteinuria. Cystatin C is an alternative marker that is freely filtered, completely reabsorbed and not secreted like creatinine. It is therefore not affected by transporter inhibitors and may be a better marker for monitoring kidney function and proteinuria.

Case Description:
- A 58-year-old male with metastatic RET fusion-positive lung cancer who progressed on cabozantinib started selpercatinib. His pre-treatment creatinine was 0.8mg/dl and increased to 1.8mg/dl after 1 year of therapy. Urine sediment was bland with increased to 4.7mg/dL; unremarkable electrolytes and liver function tests. A CT angiogram showed extensive, irregular mural thickening of the aorta present for 2 years, right atrial mass, highly flow void characteristic of both renal arteries and left vertebral artery occlusion. Review of prior lower limb CT imaging showed bilateral, symmetrical sclerotic bone infiltrates in the diaphyses and metaphyses, corresponding to the regions of PET avidity, confirming the diagnosis of ECD. Echocardiogram and cardiac MRI confirmed a 21.7 x 18.3mm right atrial mass. Selpercatinib was confirmed via right saphenous vein biopsy showing sclerotic xanthogranulomatous histiocytosis(CD68+, CD163+, CD1a-) reaction. Despite taking 5 classes (7 agents) of anti-hypertensives at maximal doses, her blood pressure was suboptimally controlled. After bilateral endovascular renal artery stenting, anti-hypertensive requirement reduced to 2 agents and renal function improved to better than pre-AKI levels. She is receiving peg-interferon γ2a and prednisolone for ECD.

Discussion: The disease affects renal arteries in 18-27% cases and should be considered as a cause of renal artery stenosis in older patients with multisystem anomalies. Renal stenting in this subset can improve hypertension and renal outcomes. The disease has characteristic radiological findings and the diagnosis is frequently reliant on imaging. Histological examination is often not sufficient to confirm the diagnosis. ECD diagnosis is essential for treatment of the underlying disease process.

PO2212
Renal Involvement as Initial Presentation of Mantle Cell Lymphoma: A Case Series
Ibrahim El Halabi,1 Natachia Rigual Soler,1 Elvira O. Gosomanova,2 Swati Mehta, Andrea R. Lightle,1 Troy H. Salmons,1 Mauricio Monroy,1,3 Albany Medical Center, Albany, NY; 2Albany Stratton VA Medical Center, Albany, NY.

Introduction: Mantle cell lymphoma (MCL) rarely affects kidneys. We present 2 cases with different spectrum of kidney involvement in MCL.

Case Description:
The 1st case was a 63-yr old male with incidental finding of Serum creatinine (SCr) of 10mg/dl. Chronic lymphocytic leukemia was diagnosed 2 weeks prior via peripheral blood analysis & flow cytometry (FC) done due to constitutional symptoms and headaches for which he was using daily ibuprofen for several months. On exam he had elevated blood pressure but no signs of volume overload. Initial supportive treatment did not improve kidney function and hemodialysis was initiated due to worsening azotemia and persistent nausea and vomiting suspicious for uremia. Renal biopsy showed diffuse acute on chronic interstitial nephritis with perversly lymphoid aggregates of monoclonal CD20+ B-cells positive for CD5 and Cyclin-D1 consistent with MCL. No significant immunostaining was found. Bone marrow biopsy confirmed renal biopsy findings and diagnosis of MCL. Until last follow up, the patient refused chemotherapeutic regimens and remained in analysis dependent. The 2nd case was a 73-yr old male with incidentally found of SCr of 1.9mg/dl in association with glomerular hematuria and grade A3 proteinuria. He had no constitutional symptoms and had normal physical exam except for presence of diffuse lymph node (LN) enlargement. Renal biopsy was obtained and showed MPGN-pattern with 25% crescents on light microscopy, presence of all immunoglobulin classes with k-light chain (KLC) predominance in glomeruli and lymphoid infiltration with KLC in the interstitium on immunostaining. MCL was confirmed with FC and excisional LN biopsy. Prednisone/Rituximab/Bendamustine therapy led to improvement in kidney function and proteinuria.

Discussion: MCL can cause differential kidney involvement from direct tumor infiltration to MCL-associated glomerulonephritis. Therefore, correct diagnosis with renal biopsy and prospective registries are needed to generate data about differences in outcomes in MCL with various kidney involvement.
creatinine is likely attributed to the drug inhibitory effect on creatinine secretion. Cystatin C may be a better measure of renal function in patients receiving MATE-1 inhibitors such as selpercatinib.

**Discrepancy in Serum Creatinine and Cystatin C Trends**

**PO2214**

**ALECT 2 and Hepatocellular Carcinoma: An Intriguing Association**

**Introduction:** Amyloidosis derived from leukocyte chemotactic factor 2 (ALECT2) is the third most common type of renal amyloidosis in the United States. The incidence of ALECT2 is highest among Hispanics and there is a predilection for involvement of the kidney and liver with sparing of the heart. We report a case of hepatocellular carcinoma (HCC) in a patient with ALECT2.

**Case Description:** A 69-year-old Hispanic man with chronic kidney disease secondary to ALECT2 and monoclonal gammopathy of undetermined significance was admitted for constipation and distended abdomen. Creatinine on admission was 1.9 mg/dL and he was initiated on dialysis. Imaging revealed cirrhosis, ascites and two liver masses involving the portal vein. Alpha fetoprotein was 7123 ng/mL and he was diagnosed with multifocal HCC. Evaluation for hepatitis, autoimmune disease and other etiologies for chronic liver disease was negative and cirrhosis was presumed to be secondary to ALECT2. Based on the Barcelona Clinic Liver Cancer staging, he was given a stage D. His functional status precluded any liver directed therapies or systemic chemotherapy and he failed to meet the Milan criteria for liver transplantation. Following a discussion of the prognosis he was transitioned to palliative care.

**Discussion:** ALECT2 is a recently described form of systemic amyloidosis that has quickly emerged as a common and possibly underdiagnosed cause of systemic amyloidosis particularly in patients of Hispanic ancestry. ALECT2 can involve various organs but usually spares the heart and brain. ALECT2 in association with HCC has not been reported to date. Interestingly in one study, expression of LECT2 in human kidney was not found. The authors speculated that ALECT2 may not be immunoreactive to CD68 and S100 protein which is consistent with Rosai-Dorfman Disease.

**PO2215**

**A Case of Extraneal Rosai-Dorfman Disease Confirmed by Renal Biopsy**

Interciency and targeted therapy and hence, it is imperative not to misdiagnose ALECT2 as amyloidosis to avoid harmful chemotherapy.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
SLE, however, during the systemic screening, lung adenocarcinoma was accidentally detected, and thoracoscopic right middle lobectomy was performed. Seven months after surgery, she had an exacerbation of erythema on the face and bilateral arms, arthralgia and urinary proteins, with elevated anti-ds-DNA antibodies and decreased serum complement levels. The dose of PSL was increased, but the symptoms did not improve, when multiple intrapulmonary metastases were detected, indicating recurrence of lung adenocarcinoma. The previous lung specimens revealed a high expression of PD-L1 and positive ROS-1 fusion gene, thus tyrosine kinase inhibitor (crizotinib) was selected as the anti-cancer therapy instead of anti-PD-L1 antibodies. Interestingly, urine protein and erythema/arthralgia improved and the size of lung tumor reduced.

Discussion: Crizotinib is a molecular targeting agent with non-receptor-type tyrosine kinase inhibitor action that competitively binds to the ATP binding site of EML4-ALK tyrosine kinase, resulting in signal transduction inhibition. In this case, the molecular targeting drug induced improvement of lupus nephritis along with regression of lung cancer, suggesting that tyrosine kinase inhibition may be effective for lupus nephritis.

PO22218
Paraneoplastic Minimal Change Disease Associated with High-Grade Neuroendocrine Tumor
Mohankumar Doraiswamy, Jessamy S. Carter, Sethu M. Madhavan, Jason Prosek. The Ohio State University Wexner Medical Center, Columbus, OH.

Introduction: Minimal Change Disease (MCD) is usually associated with Lymphoma. Leukemia and solid tumors like Lung Cancer, Renal Cell Carcinoma and Thymoma but data on incidence of paraneoplastic glomerular disease are lacking. To our knowledge, only two cases of neuroendocrine tumor (NET) presenting with Paraneoplastic MCD related to NET has been reported as a 47-year-old female patient with diabetic mellitus diagnosed with nephritic syndrome and renal biopsy was suggestive of minimal change disease.

Case Description: A 47-year-old-man with history of well-differentiated metastatic NET (not on therapy) and HTN admitted for dyspnea and anasarca for two weeks. His labs were significant for: Hgb 9.0 g/dl, plt (platelets) count 397k, ALK (anaplastic lymphoma kinase) 1.9 g/dl, prot (protein)uria of 4.3 g/day and Na 118 mmol/L. IV diuretics with albumin infusion initiated, which improved his kidney function. Serologies and proteinuria work-up – negative. Renal biopsy performed for nephrotic syndrome, showed prominent podocyte foot process effacement with mild acute tubular necrosis and mild glomerular sclerosis. Diagnosed with paraneoplastic MCD from metastatic NET and treatment with steroids initiated. Chemotherapy not started because of the overall decline in his clinical status and increased tumor burden. One week after steroids, his proteinuria was 42 g/day, and steroid doses were increased. Three weeks later, proteinuria decreased to 6 g/day and his symptoms improving. Unfortunately, he suffered further kidney injury because of hypotension and hemodialysis initiated one month later.

Discussion: The most common paraneoplastic glomerular disease is membranous glomerulopathy in patients with breast cancer, but MCD should be kept on the differential as well. Like membranous nephropathy, remission of MCD has been reported on ablation of the tumor, suggesting a paraneoplastic process, though the precise mechanisms are not fully understood. In our case, since the patient did not qualify for chemotherapy because of increased tumor burden, steroids were initiated which helped in part to reduce symptoms. The etiology of glomerulopathy in cancer does not appear to be related to tumor burden, metastatic spread or the site or extent of invasion, but to the secretion of substances from the tumor cells. Kidney biopsy should be performed early, as prompt diagnosis is important to ensure patients do not receive ineffective and potentially harmful treatments.

PO2219
Management of IgA Nephropathy and Concomitant Breast Cancer
Victoria Guijtans,1,2 Steven Salvatore,2 Roman A. Shingarev.2 1Memorial Sloan Kettering Cancer Center, New York, NY; 2Weill Cornell Medicine, New York, NY.

Introduction: Immunoglobulin A nephropathy (IgAN) is the most common glomerulonephritis worldwide. Although treatment guidelines have been established, there is little known about the management of IgAN in the setting of solid malignancy. Herein we describe two cases of IgAN and breast cancer diagnosed at our center.

Case Description: Case 1: 42-year-old female with newly diagnosed breast cancer 3 months ago presented to the clinic for acute kidney injury (AKI) (Cr) 3.5mg/dl from baseline 1.1-1.3mg/dl. Chemotherapy was started one week ago with doxorubicin and cyclophosphamide (ddAC). Two months prior to cancer diagnosis, her doctor noted 4.9g of protein in the urine with few RBCs. She now has 4g of protein with >50 RBCs. She underwent kidney biopsy which showed IgAN (M1 E1 S1 T2 C1). She received a 3g pulse of methylprednisolone (MP) followed by prednisone taper that was shortened to 3 months in light of degree of chronicity on biopsy and concurrent immunosuppressive ddAC treatment with 4 cycles total. Creatinine stabilized at 1.08mg/dl 9 months after last ddAC cycle and proteinuria improved to 1g after re-initiation of losartan. Case 2: 38-year-old female presents to the renal clinic with AKI (Cr 1.8mg/dl from baseline 1.0mg/dl), gross hematuria and nephrotic range proteinuria that were detected incidentally in the emergency department, where she was seen for sore throat after her first 2 monthly ddAC cycles for the new diagnosis of breast cancer. She has a history of arthralgias associated with high citric citrullinated peptide, low myeloperoxidase titers and intermittent hematuria that led to a kidney biopsy demonstrating moderate focal global sclerosis without immune deposits or vasculitic lesions 4 years prior. Her symptoms improved on hydroxychloroquine which she stopped at the time of cancer diagnosis. Her kidney biopsy now shows IgAN (M1 E1 S1 T2 C1) for which she received a 1.6g pulse of MP followed by prednisone tapered over 5 months. She completed 3 cycles of ddAC. Creatinine improved to 0.9mg/dl and proteinuria reduced from 7g to 0.5g.

Discussion: These cases highlight the complexity in management of IgAN while patients are undergoing treatment for a concurrent malignancy. Temporal relationship of IgAN and malignancy is unclear, but suggests potential value of cancer screening of patients with newly diagnosed IgA nephropathy.

PO2220
Sezary Syndrome with Renal Involvement
Sheikh B. Khaliq,1,2 J. Charles Jennette,1 Monica L. Reynolds,1 Obiabu Kanu,1 Vikas Singh.1 University of North Carolina at Chapel Hill, Chapel Hill, NC;
2Shehu Shagari Khawan Memorial Cancer Hospital and Research Centre, Lahore, Pakistan.

Introduction: Sezary Syndrome is a cutaneous T-cell lymphoma that presents with erythroderma, lymphadenopathy, and circulating malignant T cells. While involvement of the spleen, liver, bone marrow and lung are well documented, kidney involvement is rare. We present a case of acute kidney injury (AKI) due to biopsy-proven T cell lymphoma invasion of the kidneys.

Case Description: A 69-year-old female with a history of cutaneous T-cell lymphoma was admitted to the oncology service with AKI. Serum creatinine (sCr) 3.3mg/dl (baseline 0.6mg/dl), urine protein-to-creatinine ratio 2.5g/g, urine sediment bland and renal ultrasound unremarkable. A PET scan, performed to evaluate systemic disease burden, revealed diffuse kidney enlargement with high FDG uptake throughout the renal parenchyma. A kidney biopsy was performed Light microscopy showed diffuse interstitial infiltration by atypical small lymphoid cells and prominent focal apoptosis with apoptotic bodies and focal interstitial hemorrhage. The lymphoid cells had the same immunophenotype as the cutaneous T cell lymphoma. The tumor had slight segmental wrinkling of capillaries and glomerular basement membranes, and segmental podocyte swelling. She also had leptomeningeal involvement. Treatment included dexamethasone, systemic and intrathecal doxorubicin, melphalanext, and cytarabine. SCr returned to baseline 2 weeks later and her renal function improved, with resolution of AKI. Blood pressure normalized and some of her skin lesions resolved. On follow up, she was losing weight and had a peak albumin level of 2.0g/dl. Despite full evaluation, there was no evidence of tumor recurrence.

Discussion: AKI caused by kidney involvement in Sezary syndrome has only been reported via case reports. The mechanism of AKI is thought to be tubular compression by the lymphomatous infiltrates infinging tubule function and peritubular capillary blood flow. Our patient’s biopsy supports this mechanism. Her AKI resolved with urgent corticosteroids and chemotherapy. Further reporting is needed on the prevalence of this condition and nephrologists should consider renal lymphomatous invasion when evaluating AKI in those with cutaneous T-cell lymphoma

Belatacept-Induced Post-Transplant Lymphoproliferative Disorder of the Spleen That Spontaneously Resolved on Withdrawal of the Agent
Alexander Pennekamp,1 Karl B. Penhaur,2 The Christ Hospital, Cincinnati, OH; 2The Kidney and Hypertension Center, Cincinnati, OH.

Introduction: PTLD (Post-Transplant Lymphoproliferative Disorder) is a dreaded complication of allograft transplant. Compared to CNIs, allograft rejection prophylaxis with Belatacept is less nephrotoxic, but carries a higher risk of PTLD. B-cell lymphoma is an aggressive malignant neoplasm that arises from B lymphoid cells and is the most common type of PTLD, with high mortality in renal transplant recipients. We report a 67-year-old AAM 2 years status-post deceased-donor transplant was admitted for altered mental status, nausea, vomiting, fever of unknown origin, and weight loss. He was found to have splenomegaly on CT without other evidence of adenopathy. LHD was elevated. Patient underwent brain MRI, PET scanning, IVM and LP, all of which were normal. A full ID work-up including CMV, EBV RNA, BK were all negative. Core biopsy of the spleen demonstrated CD20/CD45+ cells with tissue effacement, suggesting a diffuse large B cell lymphocytic infiltration/monomorphic PTLD. The sample was EBV-negative by bIC. Belatacept was withdrawn. Subsequent spleoncology testing must be pursued to determine a potential site of proliferation.

Case Description: 64 year AAM 2 years status-post deceased-donor transplant was admitted for altered mental status, nausea, vomiting, fever of unknown origin, and weight loss. He was found to have splenomegaly on CT without other evidence of adenopathy. LHD was elevated. Patient underwent brain MRI, PET scanning, IVM and LP, all of which were normal. A full ID work-up including CMV, EBV RNA, BK were all negative. Core biopsy of the spleen demonstrated CD20/CD45+ cells with tissue effacement, suggesting a diffuse large B cell lymphocytic infiltration/monomorphic PTLD. The sample was EBV-negative by bIC. Belatacept was withdrawn. Subsequent spleoncology testing must be pursued to determine a potential site of proliferation.

Heterogeneous Manifestations of Post-Renal Transplant Lymphoma

Rujuta P. Patil,1 M. Abouloud,2 Anita K. Patel,1 Wayne State University School of Medicine, Detroit, MI;2 Henry Ford Hospital, Detroit, MI.

Introduction: Post-transplant lymphoproliferative disorder (PTLD) is a serious complication occurring in 1%-3% of adult renal transplant recipients (RT). PTLD is often associated with Epstein-Barr Virus (EBV) and with immunosuppression (IS). A majority of PTLD is of B-cell origin. PTLD has a heterogeneous presentation, involving the allograft, GI tract, and nervous system. We present a case series of 16 RT who demonstrate a variety of PTLD manifestations.

Case Description: 50% of RT were Caucasian and 38% African American. 62% of RT received deceased donor and 38% living donor. 62% received Thymoglobulin induction and 38% Simulect. Maintenance IS was Prednisone, Tacrolimus, and Mycophenolate Mofetil (MMF). RT presented with GI symptoms, abdominal pain, B symptoms, and neurological deficits. At diagnosis, average time from transplantation was 96.8 months (r=0.1-20). 100% of RT were male and 44% were >61 years old. 31% were EBV mismatched and 12.5% were Cytomegalovirus mismatched. PTLD involved a single site in 44% and multiple sites in 56%. PTLD localized to the GI tract (10), lymph nodes (9), CNS (4), bone marrow (3), lungs (2), mediastinum (2), skin (2), retroperitoneum (1), and native kidney/urter (2). 6 RT had purely extranodal involvement. PTLD was EBV+ (8), monomorphic/monoclonal (14), and of B-cell lineage (13). Thymoglobulin and/or Rituximab (16) were used. Treatment was chemotherapy either alone or in combination with radiation (2), resection (2), and salvage therapy (1). Post treatment, all RT remained on steroid monotherapy or with Everolimus (3), Thymoglobulin (1), or Azathiprine/Rituximab (1). Treatment was complicated by Tuberculosis, Lymphoma, and infections. 50% of RT developed renal insufficiency and 31% died. The mortality rate was 44%, 4 years after diagnosis.

Discussion: PTLD that was EBV+, had T-cell involvement, and localized to the CNS/ bone marrow presented with aggressive disease and a higher mortality. Thymoglobulin induction, deceased donor, and donor EBV+ status are potential contributing risk factors for PTLD development; further analysis is still being conducted. Physicians should be aware of the various PTLD manifestations and assertive in management of renal transplant recipients.

PO2223

Richter Transformation (RT): A Rare Complication in Renal Transplant

Nirali V. Marvania, Manju Mavanar. LifeBridge Health, Baltimore, MD.

Introduction: RT is conversion of B-cell chronic lymphocytic leukemia (CLL) into diffuse large B-cell lymphoma (DLBCL). We present a rare case of RT in a renal allograft.

Case Description: A 68 year old male was admitted for a syncopal episode and acute renal failure. He had significant medical history of ESRD secondary to diabetes and hypertensive nephrosclerosis, deceased donor renal transplant in 2015 on Mycophenolate and Tacrolimus, DLCLL diagnosed in 2017 on Ibritunib, Stage III CKD of allograft with baseline creatinine 15 mg/dl. Initial work up revealed orthostatic hypotension and AKI with creatinine of 3.3 mg/dl. Utrasound and microscopy was negative for proteinuria, hematuria, pyuria as crystals and crystals. Renal ultrasound showed the size of transplant kidney was 10.7 x 5.8 x 4.3 cm with normal renal cortex and no demonstrated mass, cyst or tubular dilatation. Transplant renal biopsy was done. Pathology results revealed no evidence of allograft rejection but extensive infiltration of renal parenchyma with atypical lymphocytes with high Ki-67 expression suggesting transformation to DLBCL in a patient with a known history of CLL. Lymphocytes retained their positivity for CD5 and CD20 which supported diagnosis of Richter. Following a Richter transformation transplant lymphoma, Rituximab was continued on Ibritunib, Tacrolimus, Prednisone 5mg daily and started on weekly Rituximab infusion. Mycophenolate was discontinued. Patient’s renal function returned to its baseline after 2 doses of Rituximab. He was planned to continue Rituximab infusion as per treatment.

Discussion: Transplant patients have high risk of RT due risk factors including concomitant immunosuppression, Epstein-Barr virus infection and some with genetic susceptibility. While PTLD is a well-recognized complication of patients with renal transplantation and malignancy, Richter transformation is usually observed in transplant patients, frequently treated for older patients with RT while allogeneic bone marrow transplantation may be curative in younger patients. Discussion between transplant physician and oncologist should be held, taking into account the new molecular prognostic markers prior to renal transplantation. This may help in risk stratification of patients for conversion of CLL to RT.

PO2224

Longitudinal Assessment of Unilateral Ureteral Obstruction Kidney Injury by Relaxometry and Spin-Lock exchange MRI

Feng Wang, Tadashi Otsuka, Keiko Takahashi, Raymond C. Harris, Takamune Takahashi. Vanderbilt University Medical Center, Nashville, TN.

Background: Non-invasive imaging technique allows longitudinal and repetitive assessment of renal disease progression. In this study, we assessed the utility of a new MRI technique, quantitative relaxometry and Spin-Lock exchange MRI, in detecting renal pathology in unilateral ureteral obstructed (UUO) kidneys, focusing on destructive tubular injury (dilation) and renal fibrosis, the pathological changes commonly observed in progressive kidney disease.

Methods: BALB/c mice (n=6-8) were imaged before and after (day 5, 10 and 15) UUO surgery at 7T magnet. Spin-lock images were acquired in a transverse plane using a fast spin echo sequence preceded by a preparatory spin-lock cluster. The dispersion of R2s with locking frequency was fit to Chopra model. The fitted models showed regional values of transverse relaxation rates R2s at infinite spin-lock frequency (R2**,) and an exchange rate-weighted parameter R2**. Since cortex and outer stripe of outer medulla (OSOM) were clearly identified with T1-weighted image, even with UOO kidneys, these regions were selected for analysis. Paraffin tissue sections were stained using picrosirius red or anti-collagen I antibody. Histological scores for tubular dilatation and fibrosis, based on a linear space and positive fibrotic areas in sections, were computationally measured and the correlation between MRI parameters and histological scores were assessed.

Results: In histology, evident tubular enlargement was observed at UOO day 5 while tubulointerstitial fibrosis was mild at this stage. Both histological changes became more evident as renal fibrosis and fibrosis showed larger increases from day 5 to day 15 (tubular dilatation~25% increase, fibrosis~3 fold increase). Relaxation rates R2**, R2 and R2** were progressively dropped (25-50%) in UOO kidneys. Interestingly, R2** showed the highest sensitivity to tubular dilatation, while S2 showed the highest correlation with renal fibrosis.

Conclusions: Relaxation parameters showed high detectability to tubular dilatation and overall changes in UOO progression. S2 best detected fibrotic changes. This would be because it mainly depends on the average exchange rate between water and collagen. Moreover, it is shifted relative to collagen as amide protons, allowing for more pronounced accumulations. These new MRI parameters could be used for the assessment of kidney disease progression.

Kidney-Specific Landscape of Aging Mitochondrial DNA Mutations by Duplex Sequencing

Mariya T. Sweetwine, Monica Y. Sanchez-Contreras, Kristine A. Tsantilas, Jeremy A. Whitson, Matthew D. Campbell, David J. Marcinek, Peter S. Rabichovitch, Scott R. Kennedy. University of Washington School of Medicine, Seattle, WA.

Background: Accumulation of mutations in the mitochondrial genome (mtDNA) is a potential mechanism of aging in the mitochondrial rich kidney, where mtDNA damage also increases with diabetes, CKD and AKI. Accurately detecting low level somatic mtDNA mutations within the cellular complexity of the kidney was previously confounded by variable levels of mtDNA heteroplasmy. Using ultra-sensitive Duplex Sequencing (DS), a modified next-gen sequencing (NGS) technique, we decreased the error rate relative to conventional NGS by >104x, allowing us to accurately characterize mtDNA mutation patterns unique to the aging kidney relative to other organs.

Methods: We compared mtDNA mutations in kidneys from cohorts of aged (26- m.o.) and young (5-m.o.) NIA C57Bl/6j mice to multiple organs with high mitochondrial content (heart, eye, liver, skeletal muscle and brain). In both ages, kidney carried the highest burden of mtDNA point mutations. Mutation spectrum analysis showed that mtDNA point mutations in the kidney increased significantly with age and were primarily G>A/C>T, indicative of oxidative damage, the second most common type. Aged kidneys were further separated into glomeruli or tubule-rich whole cortex fractions to determine regional mutation burden.

Results: Glomeruli had ~25% fewer total mtDNA mutations (p= 0.002) and specifically ~80% fewer oxidative lesions (G>T>C>A, G>C>T>G, p= 0.02). Furthermore, differential accumulation of mtDNA mutation between kidney fractions does not appear to be randomly distributed across the genome but is instead gene-specific as demonstrated by kidney specific mutations in glutamate dehydrogenase (GluDH) gene. Glomeruli had ~100X more mutations in glutamate dehydrogenase (GluDH) gene than renal cortex, and of Complex IV gene mt-Co2, but not mt-Co1 or 3. Finally, we sequenced kidneys from aged mice treated systemically for 8 weeks with SS-31, a mitochondrial therapeutic peptide that reduces oxidative stress in the kidney, and found that mutations stemming from oxidation, but not polymerase error, were significantly reduced.

Conclusions: These data suggest that renal mtDNA mutation is cell specific and that even in aged kidney, accumulation of some mutations is tractable with therapeutic intervention.

Integrated Analysis of the DNA Methylation, Transcriptome, and Proteome in Human Glomerular and Tubulointerstitial Compartments

Samir V. Parikh,1 Kimberly S. Collins,1 Ricardo Melo Ferreira,1 Yinghua Cheng,1 Daria Barwinska,1 Michael J. Ferkowicz,2 Ken Dunn,1 Katherine J. Kelly,1 Timothy A. Sutton,1 John P. Shapiro,2 Brad H. Rovin,2 Pierre C. Dagher,1 Tarek M. El-Achkar,1 Michael T. Eadon,1 Indiana University School of Medicine, Indianapolis, IN; 2The Ohio State University Wexner Medical Center, Columbus, OH.

**Background:** The interplay between the human DNA methylome, transcriptome, and proteome in the kidney glomerulus and tubulointerstitium is incompletely understood. Promoter sequence methylation is often thought to contribute to gene and protein expression regulation. We hypothesized that promoter sequence methylation would explain differential protein expression between the glomerulus and tubulointerstitium.

**Methods:** Nine reference nephrectomies underwent laser microdissection of the glomeruli and tubulointerstitium. DNA methylation sequencing, RNA sequencing, and mass spectrometry quantification of peptides was completed for both compartments in the samples. Datasets were dimensionally reduced to match expressed proteins (N = 4600). Regions of hypermethylation in promoter sequences, introns, and exons were assessed and compared to corresponding protein and mRNA expression.

**Results:** At least three patterns of hypermethylation were observed across the methylome: promoter sequence, intrinsic, and exonic methylation. In many cases, promoter sequence or exonic methylation of the tubulointerstitium correlated with a higher glomerular to tubulointerstitial protein and mRNA expression ratio. Likewise, increased tubulointerstitial protein or mRNA expression was associated with glomerular hypermethylation of promoter or exonic regions. For example, Uromodulin (UMOD) protein and mRNA expression were higher in the tubulointerstitium than the glomerulus. The strongest regions of uromodulin hypermethylation were observed in exons 9 and 10 of the glomerular compartment, although hypermethylation was also observed in the promoter sequence and two intronic regions of the tubulointerstitium. In contrast, regions of hypermethylation of Apolipoprotein L1 (APOL1) were exclusively confined to the tubulointerstitium, distributed in all three patterns.

**Conclusions:** Promoter sequence methylation alone does not explain differential expression patterns between the glomerular and tubulointerstitial compartments. Hypermethylation of exonic regions also contributes to expression regulation.

Single-Cell Transcriptomics of the Peripheral Blood Revealed Inflammation and Infection Were Associated with IgAN

Changwei Wu, Guisen Li, Li Wang. Renal Department and Nephrology Institute, Sichuan Provincial People’s Hospital, School of Medicine, University of Electronic Science and Technology of China, Chengdu, China.

**Background:** Immunoglobulin A nephropathy (IgAN) is the most common primary glomerular disease worldwide. Due to the diverse clinical manifestations and the complex pathological features, IgAN patients have different response to therapy, and the optimal treatment for IgAN remains controversial. Our study investigated the pathogenesis of IgAN by single-cell transcriptome sequencing.

**Methods:** Single-cell transcriptome sequencing was performed on peripheral blood monocytes derived from 3 IgAN patients and 1 healthy control, and differential gene expression profiles of peripheral blood single-cell were established. Functional analysis was performed to explore the pathogenesis of IgAN. Meanwhile, RT-PCR was used to validate the differential expression of mRNA and miRNA.

**Results:** According to quality control and cell selection, we characterized 21739 cells using unbiased single-cell RNA sequencing. 3 IgAN patients included 7847, 5389 and 6609 cells, respectively, and the healthy control included 1894 cells. We used unsupervised clustering to cluster cell clusters. In addition, cells were divided into 14 cell groups, including B lymphocytes and T lymphocytes, based on cell markers (Figure 1). Functional analysis revealed that differential genes were extensively enriched in inflammation / infection-related pathways in each cell type (Figure 2), and the EBV infection pathway focused on antigen presentation (Figure 3). RT-PCR of B lymphocytes demonstrated that SPI1, MXD1 and S100A9 mRNA levels were higher in IgAN patients than controls (Figure 4), which showed the results of single-cell transcriptome sequencing was available.

**Conclusions:** Differential gene expression profiles of IgAN in peripheral blood single cells were successfully established, and it demonstrated that the inflammation/infection pathway was associated with IgAN.

Analysis of Urinary Exosomal RNAs After Treatment of Rats with an Nrf2 Activator
Ayac Tanaka, Hiroko Sonoda, Yui Sakaguchi, Masahiro Ikeda. Veterinary Pharmacology, University of Miyazaki, Miyazaki, Japan.

Background: Renal NF-E2-related factor 2 (Nrf2) is known to be increased in the presence of oxidative stress. Administration of an Nrf2 activator has also been reported to lessen the degree of renal damage. However, biomarkers for detection of Nrf2 activation in the kidney are largely unknown. Urinary exosomes, a subset of extracellular vesicles released by renal epithelial cells, contain RNA molecules that are expected to be biomarkers for renal disease. Thus we analyzed urinary exosomal RNAs after administration of bardoxolone methyl (BARD), an Nrf2 activator, in rats.

Methods: Male Sprague-Dawley rats were randomly divided into two groups; the BARD group, intraperitoneally receiving 10 mg/kg BARD, and the control group, receiving only vehicle (100% DMSO). The urine was obtained for 6 hours after administration, and exosomes were isolated from the urine. At 6 hours after administration, rats were sacrificed and the kidneys were removed. Thereafter RNAs were extracted from the kidneys and urinary exosomes. The RNAs (27,012 mRNAs and 1,218 miRNAs) were analyzed with microarrays.

Results: BARD altered expression of 98 renal mRNAs and 357 urinary exosomal mRNAs with more than 2.0-fold relative to the control. BARD also changed expression of 15 renal miRNAs and 3 urinary exosomal miRNAs. The correlation coefficients between renal and urinary exosomal mRNAs as well as miRNAs were both less than 0.1. mRNAs that were commonly changed in both the kidney and urinary exosomes were 13. Among them, 8 genes are known to be targets of Nrf2 including Akr1b8, Akr1c19, Bach1, Ephx1, Eomes, Hmox1, Pir, Slc40a1 and Ugdh. Of 8 genes, Akr1b8 and Pir were increased more than 10-fold in the kidney and more than 4.0-fold in urinary exosomes. For miRNA, only mvo-miR-877 was changed in both the kidney and urinary exosomes.

Conclusions: The correlation coefficients between renal and exosomal RNAs were less than 0.1, suggesting that specific RNAs were selectively loaded into exosomes. In addition, Akr1b8 and Pir expression was dramatically increased in both kidney and urinary exosomes. Therefore, they could be potential biomarkers to detect their renal expression changes by renal Nrf2 activation.
pathophysiology. HFpEF associates with CKD in about 50% of cases and has no specific treatment. Our study offers a new experimental platform to increase our understanding of CKD-HFpEF and to test new treatments in a translational fashion.

PO223
Expression of Immunoglobulin G in Human Proximal Tubule Epithelial Cell and Its Role in Epithelial Mesenchymal Transformation
Zhenling Deng, Song Wang, Yue Wang. Peking University Third Hospital, Beijing, China.

Background: Our previous studies showed that human mesangial cells and podocytes can synthesize and secrete IgA and IgG respectively, participating in cell viability and adhesion. Proximal tubular epithelial cells (PTECs) mediate transcytosis of IgG through neonatal Fc receptor (FcRn). Whether PTECs express IgG has not been reported. The aim of this study was to explore whether PTECs express immunoglobulins.

Methods: Kidney cortical tissues were obtained from five patients undergoing nephrectomy as a result of renal carcinoma. Immunohistochemical (IHC) staining was used to assay the IgG expression in PTECs. Single PTECs were sorted by FACS from the cell suspension of the cortices. 10xGenomics and nested PCR combined with Sanger sequencing were used to detect the transcripts and repertoires of IgG in single PTECs. An immortalized PTEC cell line (HK-2) was used to detect IgG protein expression and potential roles in tubular epithelial mesenchymal transformation.

Results: IHC showed positive staining of IgG but not other IgGs in PTECs of kidney cortex. High throughput single cell RNA sequencing by 10xGenomics only detected IgG transcripts in few PTECs without V(D)J rearrangements. Nested PCR amplified IgG transcripts in 82% (91/111) manually picked single PTECs. Sanger sequencing showed that PTEC-derived IgG variable region displayed classic VDJ rearrangements but predominant VH1-24/DH2-15/JH4 sequence, biased VH1 usage and less diversity than B cells derived IgG. Western blot and immunofluorescence staining demonstrated IgG (including IgG4, IgA and IgG2) in HK-2, iP215, which specifically recognizes non-B cell-derived IgG, can identify the IgG in HK-2. The IgG was upregulated by TGF-β1 and accompanied by the up-regulation of α-smooth muscle actin and the down-regulation of E-cadherin. In addition, the transcripts of recombination activating gene 1/2 (RAG1/2, essential for V(D)J rearrangement) and activation-induced cytidine deaminase (AID, essential for class switch recombination) were detected in HK-2.

Conclusions: Our study suggests that PTECs can express IgG in a similar way as B cells. TGF-β1 can upregulate the expression of IgG in PTECs. PTEC-derived IgG may be involved in tubular epithelial mesenchymal transformation and interstitial fibrosis.

Long-Term Mitochondrial Protection Reduces Proteinuria in Obese Aged Mice
Maritya T. Sweetwine, Rene Coig, Ruby Sue M. Mangalindan, John Morton, Jeremy A. Whitson, Peter S. Rabinovitch, Warren C. Ladiges. University of Washington School of Medicine, Seattle, WA.

Background: In humans, obesity is associated with higher rates of kidney disease, which is compounded by aging. As an energetically demanding tissue, it has been proposed that preventing mitochondrial dysfunction is one key to reducing renal decline. Previously, we showed that an 8-week systemic treatment of aged 24-month-old (m.o.) mice with a mitochondrial targeted protective tetrapeptide, SS-31, significantly reduced the burden of age-induced glomerulosclerosis by 26-m.o. and preserved podocyte integrity.

Methods: To determine if SS-31 aging protection also applied with a comorbidity of obesity, 18-m.o. male NIA C57Bl/6j mice were fed regular chow (RC) or a high fat, high sucrose diet (HFFS) for 10 months and treated with SS-31 injected 5x/wk (3 mg/kg) or saline vehicle (n=20/group).

Results: Mice were weighed weekly. RC mice averaged 33g with no change from age or treatment. HFFS mice gained weight in the first month but by 5 mo. of diet, SS-31/HFFS mice weighed significantly less relative to HFFS untreated mice (40.4g vs. 45.9g p= 0.047). Spot urine was collected monthly for albumin/creatinine ratio (ACR; μg/mg). At 18-m.o. baseline, ACR averaged 484μg/mg. In RC mice, ACR increased modestly, and not significantly, with age although SS-31 RC mice had lower ACR at endpoint (28-m.o. control 125.9 vs. SS-31 31.00). HFFS untreated mice displayed more renal dysfunction as evidenced by a (m.o.): (ACR: RC: 32.6 vs HFFS: 243.2, p = 0.003), climbing significantly to an average of 519.8μg/g at 28-m.o. ACR increased in SS-31 HFFS mice but leveled off by 23-m.o. (5 mo. treat.), averaging 146.1μg/mg with no significant increase by 28-m.o. By 9 mo. of treatment, ACR was significantly lower in HFFS/SS-31 treated mice compared to untreated HFFS mice and also to control SS-31 mice (n=4-7) showed that HFFS mice, regardless of treatment, had a 30% decrease in podocyte density relative to RC mice. Control HFFS mice tended to higher tuft volume (glomerular hypertrophy) than in SS-31 HFFS mice. However, results were not significant in the small sample size.

Conclusions: Combined with improved ACR our results suggest that podocyte integrity, if not number, may be preserved in mice fed a Western diet by SS-31 intervention and that long-term mitochondrial protection is a potential therapeutic target to preserve renal function with aging.

Bacterial and Fungal Communities Entrained Within Calcium Oxalate, Struvite, and Brushite Human Kidney Stones
Elena M. Wilson,1,2 Jessica J. Saw,1,3 Mayandi Sivaguru,1 Dirk Lange,1 Yiran Dong,1,2 Robert A. Sanford,1,2 Christopher J. Fields,1 Melissa Cregger,1,4 William J. Bruce,1,5 Annette Merkel,1 John J. Cieske,1 Amy E. Krambeck,1,6 Marcelino E. Rivera,2 Tim Large,5 Nicholas L. Chia,1 Michael F. Romero,1 Joseph R. Weber,1,2 Bruce W. Fouke,2,7 Carl R. Woese Institute for Genomic Biology, University of Illinois at Urbana-Champaign, Urbana, IL; University of Virginia School of Medicine, Charlottesville, VA; Mayo Clinic School of Medicine, Rochester, MN; Oak Ridge National Laboratory, Oak Ridge, TN; Mayo Clinic Minnesota, Rochester, MN; Indiana University School of Medicine, Indianapolis, IN; & Jack Bell Research Centre, Vancouver, BC, Canada; Roy J. Carver Biotechnology Center, University of Illinois at Urbana-Champaign, Urbana, IL; China University of Geosciences, Wuhan, China.

Background: Mechanisms of human kidney stone formation are poorly understood. More than 70% of stones are composed of calcium phosphate and/or oxalate. Recent studies have shown that kidney stone formation follows a continuum of complex biogeochemical transitions and is strongly influenced by the presence of human host and microbial organic matter.

Methods: Kidney stones, removed via percutaneous nephrolithotomy, were prepared as a 25–40 μm thick doubly polished petrographic thin sections and analyzed using brightfield, confocal and super-resolution autofluorescence microscopy. DNA was extracted from 18 calcium oxalate stones, 1 struvite stone, and 1 brushite stone for Fluidigm™ PCR amplification. Pair-end sequencing of bacterial 16S rRNA gene sequences and fungal internal transcribed spacer (ITS) regions was completed using Illumina® MicroSeq Ready. Reads were correlated with patient metadata and analyzed using DADA2, phyloseq v1.22.3 and R software.

Results: A 153-amplicon sequence variant (ASV) fungal community, dominated by A. niger (92% of total reads), was present in 11 of 20 total sequenced stones and correlated with higher patient urinary calcium excretion (335 ± 131 vs 175 ± 108 mg/day, p=0.01). Petrography of 30 stones documented entombed coccoidal and rod-shaped bacterial cells in the struvite stone and well-preserved fungal borings and hyphae in one calcium oxalate struvite stone. DNA-sequenced bacterial sequences were most closely affiliated with Actinobacteri and Catabacterium. The brushite stone microbiome community contained Capnocytophaga and Humibacter and the struvite stone microbiome community included Pseudomonas and Staphylococcus.

Conclusions: This presents the first evidence of a low-diversity fungal and bacterial microbiome community entombed and preserved within calcium oxalate, struvite, and brushite human kidney stones. The macromolecules secreted by the fungal and bacterial communities may play crucial roles in human kidney stone growth, development, and recrystallization, similar to processes that have been documented in natural geologic stone growth.

Targeting of Factor D in Cfh-/- Mice Does Not Relieve C3 Gromerulopathy due to the Action of C3(H2O)
Yuzhou Zhang,1 Adam C. Keenan,1 Dao-Fu Dai,2 Kristofer S. May,1 Gabriella R. Pitcher,1 Ronald P. Taylor,1 Richard J. Smith.1 Molecular Otolaryngology and Renal Research Laboratories, University of Iowa, Iowa City, IA; Department of Pathology, University of Iowa, Iowa City, IA; University of Virginia School of Medicine, Charlottesville, VA.

Background: C3 glomerulopathy (C3G) is an ultra-rare kidney disease defined by underlying complement dysregulation and characterized by complement C3 deposition on glomerular basement membrane (GBM). Dysregulation of the alternative pathway (AP) is fundamental to disease expression, although terminal pathway dysregulation is also common. Treatment of C3G with eculizumab is unsuccessful in most of the patients, consistent with the fact that complement C3 has a critical role in the terminal complement cascade while leaving up-stream C3 complement dysregulation untouched. Of up-stream targets, factor D (FD) is appealing because it circulates in the plasma at low concentrations and has a single function, to cleave its substrate, factor B, to generate C3 convertases of the alternative complement pathway. Mice with a targeted deletion of factor H (FH; Cfh-/- mice) develop features of C3 glomerulopathy (C3G).

Methods: To assess the impact of FD inhibition, we studied Cfh-/-/Cfd-/- mice. After crossing the Cfd-/- and Cfh-/- mice, Cfh-/-/Cfd-/-/Cfh-/-/Cfd-/-/ progeny were backcrossed to C57BL/6 for 10 generations. Littermates of Cfh-/-, Cfd-/-, Cfh-/-/Cfd-/- and wildtype were used for assessing complement dysregulation and renal pathology.

Results: The C3G phenotype in the Cfh-/- mouse is not rescued by removing FD. Instead, Cfh-/-/Cfd-/- mice develop a subtype of C3G and nephrogenic diabetes insipidus. We used serum from the Cfh-/-/Cfd-/-/ mouse to show that residual AP function is present in Cfh-/- mice and FH are not required for C3C3b to be cleaved by C3 convertases in vivo due to the action of C3(H2O). Therefore, uncontrolled tick-over leads to slow activation of the AP in the Cfh-/-/Cfd-/- mouse. While a tiny amount of FD suffices to activate complement, a minimal threshold of FH is needed to prevent tissue deposition of C3 in the absence of FD.

Conclusions: These findings suggest that efforts to block AP activity by targeting FD may lead to unanticipated outcomes in subgroups of C3G patients. Sustained complete and persistent FD blockade may be difficult to maintain, and due to the action of C3(H2O), it is not completely suppress complement activation; substantial breakthrough through complement activation may then occur as even minuscule amounts of free FD become available.

A Mutation in Complement Factor B Causing Massive Fluid-Phase Dysregulation of the Alternative Complement Pathway Can Result in Atypical Hemolytic Uremic Syndrome
Yuzhou Zhang,1 Robin A. Krensdorf,2 John Sperati,1 Kammi J. Henriksen,3 Mari Mori,1,6 Rene X. Goodfellow,1 Gabriella R. Pitcher,1 Nicolo Ghiringhelli Borsa,1 Ronald P. Taylor,1 Carla M. Nester,1 Richard J. Smith.1 Molecular Otolaryngology and Renal Research Laboratories, University of Iowa, Iowa City, IA; Department of Pediatrics, Warren Alpert Medical School of Brown University, Providence, RI; Division of Nephrology, Johns Hopkins University School of Medicine, Baltimore, MD; Department of Pathology, University of Chicago, Chicago, IL; Division of Genetic and Genomic Medicine, Nationwide Children’s Hospital, Columbus, OH; Department of Pediatrics, College of Medicine, The Ohio State University, Columbus, OH; University of Virginia School of Medicine, Charlottesville, VA.

Introduction: Atypical hemolytic uremic syndrome (aHUS) is an ultra-rare disease characterized by microangiopathic hemolytic anemia, thrombocytopenia and acute kidney injury. Pathogenesis is driven most frequently by dysregulated cell-surface control of the alternative pathway (AP) of complement secondary to inherited and/or acquired factors. Case Description: We present two unrelated aHUS patients (a 5-year-old female and a 55-year-old female) who presented with the classic signs of thrombotic microangiopathy associated with renal failure with the additional finding of an undetectable C3 level. Circulating levels of C5 and C5b-9 were also low, consistent with over-activity of both the alternative and the terminal pathways of complement. Genetic testing identified a heterozygous novel variant in the complement factor B gene (<CFB c.1101 C>A, p.Ser367Arg). Functional studies demonstrated strong fluid-phase C3 cleavage when mutant factor B and FH are present. However, C3 cleavage was completely suppressed in vivo when patient serum was supplemented with C3. In vitro control of C3 convertase activity could be restored with increased concentrations of factor H.

Discussion: CFB p.Ser367Arg is a gain-of-function pathogenic variant that leads to dysregulation of the AP in the fluid-phase and increased C3b deposition on cell surfaces. This report highlights the complexities of complement-mediated diseases like aHUS and illustrates the importance of functional studies to characterize variants of unknown significance and to gain insight into the disease phenotype.

Efficacy of Low-Intensity Pulsed Ultrasound on CKD-Associated Cachexia and Muscle Wasting Prevention in a Mouse Model
Shing-Hwa Liu,1 Kuan-Yu Hung,1 Chih-Kang Chang,1,2 Institute of Toxicology, National Taiwan University, Taipei, Taiwan; 1Department of Integrated Diagnostics & Therapeutics, National Taiwan University Hospital, Taipei, Taiwan; 2Supervisory Office, National Taiwan University Hospital Hsin-Chu Branch, Hsinchu, Taiwan; 1Department of Internal Medicine, College of Medicine, National Taiwan University, Taipei, Taiwan.

Background: Low-intensity pulsed ultrasound (LIPUS), a therapeutic ultrasound, is recognized to elevate the bone fracture repair process and help in some soft tissue healing. Here, we tested the prevention of chronic kidney disease (CKD)-associated cachexia and sarcopenia by LIPUS in a renal ischemia/reperfusion injury (IRI) mouse model.

Methods: Adult C57BL/6J male mice were used. A model of unilateral IRI with nephrectomy of the contralateral kidney with or without LIPUS treatment (3 MHz, 0.1 W/cm², 20 minutes/day) 5 days before and 14 days after surgery was performed. The CKD-related cachexia/muscle wasting in mice was evaluated. Mice were euthanized 14 days after IRI.

Results: LIPUS treatment significantly alleviated the decrease in the serum albumin/globulin (A/G) ratio and the increases in the serum levels of blood urea nitrogen (BUN), creatinine, cystatin C, and fibroblast growth factor (FGF)-23, and the renal pathological changes and fibrosis in CKD mice (p<0.05, n=5 or 6 for A/G ratio and FGF-23). The development of epithelial-mesenchymal transition and the induction of senescence-related molecular signals and the decreased protein expressions of α-Klotho and endogenous antioxidant enzymes in the kidneys of CKD mice were significantly alleviated by LIPUS treatment (p<0.05, n=4). LIPUS treatment could also significantly reverse the decreased muscle mass, grip strength, and cross-section areas (CSA) of muscle fibers (p<0.05, n=8, for soleus muscle weight, hindlimb grip strength), and the increased muscular protein expressions of atrogenes, Atrogin1 and MuRF1, and phosphorylated ERK1/2 (p<0.001 vs N) and 2.0 in UNX kidneys (p<0.001 vs N). Trametinib blocked the increase in SS and UNX kidneys. Phospho/total ERK (densitometry units) was 0.2 in N, 1.4 in SS and 1.0 in UNX kidneys with the autophagosome membrane. p62 is destroyed by the lysosome and is a marker of autophagic flux, a decrease usually indicating increased autophagic flux. P62/SQSTM1, is an autophagy receptor that links cargo proteins with the autophagosome membrane. p62 is destroyed by the lysosome and is a marker of autophagic flux, a decrease usually indicating increased autophagic flux. The aim of the study was to measure p62 and other potential mechanisms of suppressed autophagy caused by SS and UNX.

Conclusions: LIPUS treatment showed the benefits for renal and muscular protection in a CKD mouse model via inhibition of renal fibrosis, restoration of antioxidant enzymes, and attenuation renal senescence/aging, and muscle mass loss via prevention of muscular mitochondrial dysfunction, AMPK activation, and Akt downregulation. LIPUS treatment may be potentially applied to an alternative non-invasive therapeutic intervention on CKD-associated cachexia/muscle wasting therapy.

PO2240

Mechanisms of Suppressed Autophagic Flux in the Kidney Caused by Sham Surgery and Unilateral Nephrectomy
Carolyn N. Brown,1,2 Carolyn, 1National Taiwan University Hospital, Taipei, Taiwan; 2Superintendent Office, National Taiwan University Hospital. Kuan-Yu Hung,3 Kuan, 3Institute of Toxicology, National Taiwan University, Taipei, Taiwan; Chi-Tseh Lin,1 Chi-Tseh, 1National Taiwan University Hospital, Taipei, Taiwan; Shih-Lin Liu,2 Shih-Lin, 2Institute of Toxicology, National Taiwan University, Taipei, Taiwan. Anna D. Edelstein.1 Anna,1Univ Colorado, Aurora, CO.

Background: Compensatory renal hypertrophy resulting from loss of nephron mass has been implicated in promoting further nephron damage. Unilateral nephrectomy (UNX) is a model of compensatory hypertrophy in the remaining kidney. We previously reported that in the remaining mouse kidney that both sham surgery (SS) and UNX vs. normal kidney (N) resulted in increased mTORC1/2, decreased lysosomal function, suppressed autophagic flux. p62/SQSTM1, is an autophagy receptor that links cargo proteins with the autophagosome membrane. p62 is destroyed by the lysosome and is a marker of autophagic flux, a decrease usually indicating increased autophagic flux. The aim of the study was to measure p62 and other potential mechanisms of suppressed autophagy caused by SS and UNX.

Methods: C57BL/6 mice. p62 and ERK was measured by quantitative immunoblot analysis. Cytokines were measured by MesoScale. Mice were treated with the MEK1/2 inhibitor Trametinib (T) (1 mg/kg for 3 days) that is a potent ERK1/2 inhibitor.

Results: There was an increase in p62 in SS and UNX kidneys. p62/GAPDH (densitometry units) was 0.6 in N, 1.0 in SS (P=0.05 vs N) and 1.0 in UNX kidneys (P=0.05 vs N). p62 is known to modulate pro-inflammatory cytokines. In the serum, there were increases (fold) in IL-1β (50), IL-4 (10), IL-6 (100), IL-8 (5), IL-12 (5), GMCSF (2), TNFα (2), IL-10 (10), IFNγ (0) in SS and UNX vs N. Pro-inflammatory cytokines can activate ERK1/2, a known autophagy suppressor. There was a large increase in ERK1/2 in SS and UNX kidneys. Phospho/total ERK (densitometry units) was 0.2 in N, 1.4 in SS (P=0.001 vs N) and 2.0 in UNX vs N. Phospho/total ERK (densitometry units) was 0.2 in N, 1.0 in SS (P=0.001 vs N) and 1.0 in UNX-T kidneys (P=0.001 vs N). p62/GAPDH (densitometry units) was 1.6 in N, 0.4 in SS +T (P=0.05 vs N) and 0.4 in UNX-T kidneys (P=0.05 vs N).

Conclusions: The mechanism of suppressed autophagy with SS and UNX may be related to an intense systemic inflammatory response and an ERK-mediated increase in p62. It is important that researchers are aware that changes in ERK1/2, systemic pro-inflammatory cytokines and autophagy can be caused by sham surgery as well as the kidney injury/disease itself.

PO2243
Peroxidase Staining for Glomerular Morphometric Phenotype Discovery via Clustering Across Large Datasets
Brandon Ginley,1 Kuang-Yu Jen,2 Avi Z. Rosenberg,3 Pinaki Saradar,1
1University at Buffalo - The State University of New York, Buffalo, NY; 2University of California Davis, Davis, CA; 3Johns Hopkins University, Baltimore, MD.

Background: Microscopic glomerular assessment is diagnostic and prognostic for a diverse array of renal parenchymal disorders. Digital renal pathology enables complex morphometric studies that may identify prognostic information imperceptible to the human eye. We use clustering and feature enrichment to discover morphometric phenotypes that may relate to patient prognosis.

Methods: A convolutional network extracted glomeruli from 29 Periodic acid-Schiff stained transplant biopsies. 315 features were calculated on each glomerulus and clustered with a modularity-based community detection algorithm available in Seurat. Clusters were compared with patient outcome (eGFR decline at 1 year). A Wilcoxon rank sum test identified features enriching each cluster. Uniform manifold approximation and projection (UMAP) was used to visualize the clusters in low dimension.

Results: Clustering revealed 5 glomerular populations (Fig. 1A), and glomeruli of different patients were well admixed across clusters (Simpson’s Diversity Index: 0.78 - 0.98, infinity). Patients were separated in two classes (eGFRa5 or ≤5 mL/min/year), and these labels were projected into the cluster space (Fig. 1B). We observed the clusters show different frequencies of glomeruli from patients with higher eGFR decline. Two of the clusters (2 and 4) had >90% of their morphometrically similar glomeruli solely from slower eGFR decline patients. The distribution of two example features (glomerular area and total nuclei) per cluster are shown in Figs. 1C & D, though the full analysis revealed hundreds of significant features enriching each cluster.

Conclusions: The adaption of an -omics style analysis for renal histology may be feasible to mine prognostically significant morphometric information.

IgA Staining Patterns Differentiate Between IgA Nephropathy and IgA-Dominant Infection-Associated Glomerulonephritis

Sergey V. Brodsky, Clarissa A. Cassol, Anjali A. Satoskar, Tibor Nadasdy. The Ohio State University Medical Center, The Ohio State University Wexner Medical Center, Columbus, OH.

Background: Differential diagnosis of primary IgA nephropathy (IgAN) and IgA-dominant infection-related glomerulonephritis, particularly Staphylococcus infection-associated glomerulonephritis (SAGN), on a kidney biopsy can be challenging because of similar morphologic findings by light microscopy, immunofluorescence and electron microscopy. Clinical management approach however, is very different. Immunosuppressive therapy is contraindicated in SAGN because it can lead to sepsis and even death. Antibiotics constitute the first line of therapy. In contrast to that, primary IgAN is treated either with conservative management or with immunosuppression. There are no specific biomarkers to distinguish between these two diseases.

Methods: Kidney biopsies from patients with IgAN or SAGN were analyzed. Immunofluorescence with an antibody to IgA was performed on sections of frozen and paraffin embedded tissue.

Results: In total, 75 biopsies (45 with IgAN and 30 with SAGN) were evaluated. All 75 biopsies showed distinct granular staining for IgA in the non-sclerotic glomeruli (Figure 1). Globally sclerosed glomeruli were identified in 47 biopsies (29 with IgAN and 18 with SAGN). Among the 29 biopsies of IgAN, 20 (69%) had positive granular staining for IgA in the globally sclerosed glomeruli and 9 (31%) cases did not. Among the 18 kidney biopsies with SAGN, only one case (5.6%) showed positive staining for IgA in globally sclerosed glomeruli, whereas the remaining 17 (94.4%) did not (Table 1). The sensitivity of positive IgA staining in globally sclerosed glomeruli for kidney biopsies with IgAN was 68.97%, specificity was 94.44%.

Conclusions: Evaluation of IgA staining in sclerosed glomeruli can help to differentiate between primary IgAN and SAGN in the right clinical context, and aid in patient management in most cases.

Table 1. Distribution of staining for IgA in sclerotic glomeruli between cases with IgAN and SAGN

The Spectrum of Biopsy-Proven Glomerular Diseases in Mexico: Experience at a Tertiary Hospital

Octavio R. Garcia-Flores, Benel Martinez-Vazquez, Virgilia Soto, Bernardo Moguel. Instituto Nacional de Cardiología Ignacio Chavez, Mexico, Mexico.

Background: Glomerular diseases are still one of the leading causes of end-stage renal disease. The diagnosis of these diseases relies on the interpretation of the renal biopsy.

Methods: This investigation was performed in a tertiary hospital. We assessed the main demographic, clinical and histological data of individuals who underwent native kidney biopsies in one tertiary hospital in Mexico. From January 2011-December 2019, totally 1,541 patients first received renal biopsy. After excluding altogether biopsies, inadequate sampling, and failed interpretation, there are still 853 cases with a clear diagnosis.

Results: We evaluated 853 renal biopsies: female 65.3%, elderly (>60 years) 16.6%. The most frequent biopsy-proven diseases were secondary (59.1%) and primary (28.7%) glomerulonephritis (GN), tubulointerstitial nephritis (TIN) was observed in 2.5 % and vascular diseases in 1.5%, hereditary disease in 1.2%. Among primary GN the most frequent diagnosis were focal segmental glomerulosclerosis (FSGS) (17.2%), membranous GN (MGN) (5.7%) and IgA nephropathy (IgAN) (4.8%). Among secondary GN, lupus nephritis (LN) represented 38.9%, diabetic nephropathy 8.1% and pauci-immune crescentic GN 4.9%. The most common diseases in patients with nephrotic proteinuria were LN 14.8%, FSGS 5.8%, MGN 4.1%. Ultrasound needle guidance was used in 97.8%. The frequency of serious complications was approximately 2.5%.

Conclusions: This report provides representative population-based data on native biopsy-proven renal diseases in Mexico. FSGS and LN are the most frequent primary and secondary GN respectively. FSGS and MGN were the most common diseases in patients with nephrotic proteinuria.

PO2248

Clinical Context and Outcomes of Kidney Biopsy in Pregnant Women: An Institutional Review

Anna B. Gaddy, Karen Trevino, Carrie L. Phillips, Elizabeth Taber-Hight. Indiana University School of Medicine, Indianapolis, IN.

Background: Kidney biopsy is an excellent method of gaining insight to causes of renal decline but is not without risk, particularly in pregnant patients. While we await the era of biomarkers which enhance our ability to diagnose diseases of pregnancy, biopsy remains the most inclusive way of reaching a diagnosis. Clinical manifestations warranting biopsy include gross deterioration in renal function, de novo development of nephrotic syndrome, or suspicion for glomerulonephritis. A recent metaanalysis found that the risk of complications during pregnancy was 7% and should be limited to patients in whom the diagnosis would warrant urgent therapy. We sought to explore indications for biopsy and histopathology in patients evaluated at our institution.

Methods: Our surgical pathology database was searched for renal biopsy specimens interpreted from 2008 to mid-2020. Patients were either pregnant at the time of biopsy or within 3 months postpartum. Indiana University IRB approved the study. A chart review was completed to obtain lab data at the time of biopsy and post procedure.

Results: We identified biopsy specimens from 38 women who were pregnant during the specified time period. Histopathologic diagnoses included lupus nephritis (n=4), FSGS (8), diabetic kidney disease (3), allergic interstitial nephritis (1), IgA (10) and minimal change disease (3). Chart information was available for 19 women including 15 Caucasian and 4 African American patients, with a mean age of 28.6 years. Eight women were obtained during pregnancy and 11 during the postpartum period. Proteinuria was present in 17 patients with a mean value of 3.5g/dL. Hematuria was also present in 14 of the patients. Mean serum creatinine was 2.6mg/dL.

Conclusions: Renal biopsy is a procedure with high risk and morbidity for pregnant women. At our institution, biopsy was performed for either worsening renal function or proteinuria. Our population showed diverse diagnoses which justified need for biopsy, including requiring urgent intervention. Our study highlights the need of judicious biopsy in pregnant women. Further studies can be done to determine long term kidney outcomes in pregnant women.

PO2249

Prevalence and Risk Factors Associated with Nephrosclerosis in Renal Parenchyma Specimens of Patients Undergoing Partial or Radical Nephrectomy

Juan D. Salcedo Betancourt,1 Kenny A. Goodrich,1 Olekssii Iakymenko,1 Jhon B. Rozas,1 Ragi Phillips,1 Gabriel Contreras,1 Alessia Fornoni,1 Laura Barisoni,2 Jorge A. Florindez,1 David B. Thomas,1 Jair Munoz Mendoza,1 1University of Miami School of Medicine, Miami, FL; 2Duke University School of Medicine, Durham, NC; 3JTM Health Financial Services, PLLC, Charlotte, NC.

Background: Evaluation of non-neoplastic renal parenchyma in nephrectomies is part of the College of American Pathologists (CAP) Cancer Protocols. We evaluated the prevalence of histological abnormalities and nephrosclerosis and its association with clinical factors in patients undergoing nephrectomy for any cause at our institution.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: Two nephropathologists evaluated the status of the renal parenchyma in 374 pathological specimens, who underwent either partial or radical nephrectomy (59%) between 2013 and 2017. Age-adjusted global glomerulosclerosis (GS), interstitial fibrosis (IF), tubular atrophy (TA), and arteriosclerosis (AS) were evaluated by light microscopy. Nephrosclerosis was defined as the presence of a ≥2 histologic features. Clinical, demographic, and pathological data were collected by chart review. Logistic regression analysis was used to evaluate the association between clinical parameters and nephrosclerosis.

Results: The mean age was 60 ± 14 years. 38% were female, 44% were Hispanics, 59% had hypertension, 22% had diabetes mellitus, and 24% had a smoking history. The pre-nephrectomy eGFR was 73 ± 27 ml/min/1.73m² and 31% had an eGFR < 60 ml/min/1.73m². The prevalence of age-adjusted GS was 82%, any TA was 80%, more than 5% IF was 78% and any A2 was 95%. The prevalence of nephrosclerosis was 88%. Lower pre-nephrectomy eGFR (adjusted odds ratio [OR] per 10 units decrease in eGFR, 1.12 [95% confidence interval (CI), 1.02-1.23]) and age (adjusted OR per 10 years increase, 1.97 [95% CI, 1.64-2.39]) were significantly associated with nephrosclerosis. Gender, history of hypertension, diabetes, and smoking were not associated with nephrosclerosis (p > 0.05 for all).

Conclusions: Nephrosclerosis is highly prevalent in renal parenchyma of patients undergoing nephrectomy. Lower pre-nephrectomy eGFR and older age were independently associated with significantly greater odds of nephrosclerosis. Future studies should evaluate the association between nephrosclerosis and post-nephrectomy eGFR.

PO2250
Evaluation of Preexisting Renal Disease in Nephrectomies
Juan D. Salcedo Betancourt,1 Oleksii Iakymenko,1 Kenny A. Goodrich,2 Jhion B. Rozas,3 Ragi Phillips,2 Alessia Fornoni,1 Gabriel Contreras,2 Dipen Patel,11 David B. Thomas,1 Jair Munoz Mendoza.1 1University of Miami School of Medicine, Miami, FL; 2Duke University School of Medicine, Durham, NC, USA; 3JTM Health Financial Services, PLLC, Charlotte, NC.

Background: Evaluation of non-neoplastic renal parenchyma in nephrectomies is part of the College of American Pathologists (CAP) Cancer Protocols. We aimed to determine the prevalence of pre-existing renal diseases in all patients who underwent nephrectomy for any cause in our center.

Methods: The surgical pathology protocol for nephrectomies was modified with a) additional sampling of non-tumoral renal parenchyma, b) Hematoxylin and eosin, Periodic acid-Schiff, trichrome and silver stains, and c) addition of the expanded checklist for reporting nephrectomy from the Renal Pathology Society recommendations. All samples were reviewed by 2 nephropathologists (A.N. (Chief) and nephropathologist (M.O.)) and at least 813 nephrectomies were performed between 2013 and 2017 and were evaluated and included in the study. Reasons for nephrectomies were malignancy in 645 (79%) of patients, of which 528 (82%) had renal cell carcinoma, 100 (16%) urothelial carcinoma, and 168 (21%) benign lesions (42 oncocytomas, 34 pyelonephritis, 13 trauma, and 1 nephrolithiasis). Clinical, demographic, and pathological data were collected by chart review.

Results: The mean age was 60 ± 14 years. 62% were male and 44% Hispanics, 59% had hypertension, 22% had diabetes mellitus, and 24% had a smoking history. Baseline eGFR was 73 ± 27 ml/min/1.73m² and 31% had an eGFR < 60 ml/min/1.73m². Only 41 patients (5%) had a documented pre-operative consult to nephrology. 296 (36%) patients had at least one renal disease diagnosis and only 62 (8%) had a single diagnosis. Only 41 patients (5%) had a documented pre-operative consult to nephrology. 296 (36%) patients had at least one renal disease diagnosis and only 62 (8%) had a single diagnosis. 296 (36%) patients had at least one renal disease diagnosis and only 62 (8%) had a single diagnosis. 2% had renal disease. 2% had renal disease. 2% had renal disease.

Conclusions: Pre-existing renal disease are frequently identified in nephrectomy specimens. FGGS was the most common diagnosis. A collaborative effort involving nephrologists, urologists and pathologists is warranted to improve the care of patients undergoing surgical nephrectomy.

PO2252
Kidney Filtration Markers in Human Saliva: Accuracy and Reproducibility of Novel Salivary Cystatin C Measurements
Kamal Banerjee-Zadeh,1 Trong D. Nguyen,2 Maria Ortega,2 Michael Shilpak,1 Danh V. Nguyen,3 1University of California Irvine, Orange, CA; 2Intelligent Optical Systems, Inc., Torrance, CA; 3University of California San Francisco, San Francisco, CA.

Background: Invasive phlebotomy followed by laborous blood specimen processing is the only reliable approach to assess routinely measured kidney filtration markers including cystatin C (CysC). Non-invasive testing of these markers is urgently needed particularly during the COVID-19 pandemic to enhance social-distancing.

We developed novel Enhanced Enzyme and Immunoassays-based Lateral Flow (ELF) assays to measure concentrations of CysC in human saliva. Highly selective binding reagents were screened for optimum specificity, followed by applying sample treatment steps to mitigate sample to sample variability using healthy donor saliva samples spiked with known levels of the filtration markers. Standard calibration curves (SCCs) for each marker was developed with nonlinear 4-parameter logistic curve fitting to tricplicate measurements at each spiked concentration level. Accuracy/fit of the SCC was assessed using the coefficient of determination (R²). Intra-assay reproducibility was assessed using coefficient of variation (CV) and studies of inter-assay repetatability over time (over > 8 days) examined reproducibility of whole experimental protocol.

Results: SCC fitted to relative optical intensities (ratio of test to control lines vs. spiked CysC (0-14 ng/ml) was excellent (R²=0.991) and provided accurate estimates of spiked CysC levels (R²=0.994). Assessment of intra-assay variation showed that repetatability is very good with CV <10% throughout the dynamic range of measurements. Assessment of inter-assay variation (measurements over 8 days) showed that reproducibility is acceptable with CV <13% throughout most of the dynamic range. Preliminary assessment of long-term reproducibility (stability) out to 258 days indicated similar performance. [figure]

Conclusions: We demonstrated feasibility of CysC measurements in human saliva samples with acceptable ELF assay characteristics including accuracy, repeatability, reproducibility, and long-term stability. Validation studies are ongoing to optimize the saliva testing framework for kidney function markers.

**Comparison of Creatinine-Based Estimated Glomerular Filtration Rate Equations with DTPA GFR in Healthy Adults**

Varun Kumar Bandi, Spoorthi Ramineni. Dr. Pinnamaneni Siddhartha Institute of Medical Sciences & RF, Vijayawada, India.

**Methods:** The cross-sectional study was done on live kidney donors. DTPA was used to measure GFR, 24 hour creatinine clearance (CCi) was measured and creatinine based eGFR was calculated using Cockcroft-Gault (CG), Modification of Diet in Renal Disease-fourniable (MDRD-4), Modification of Diet in Renal Disease-variabile (MDRD-6), and Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equations.

**Results:** 88 subjects were included, of whom 29.5% were male, with a mean age of 46.8 yrs, and BMI of 25.7 kg/m2. Mean GFR (a standard deviation) obtained by CKD-EPI, MDRD-4, MDRD-6, CG, CrCl, and DTPA GFR were 98.8 (+15.2), 96.2 (+17.9), 106.1 (+22.0), 88.5 (+37.3), 89.3 (+29.2) and 98.4 (+31.7) ml/min/1.73m2, respectively. The mean absolute difference in GFR and percentage variation between calculated and measured GFR for CKD-EPI, MDRD-4, MDRD-6, CG, CrCl, and DTPA GFR were 14.7 (16.5%), 16.2 (17.9%), 19.8 (22.3%), 33.2 (36.5%), and 23.66(25.7%) respectively. Percentage of values within 20% of DTPA GFR in each equations were CKD-EPI - 69.32%, MDRD-4 – 70.45%, MDRD-6 -54.55%, CG - 38.64%, and CrCl - 45.45%. There was no significant co-relation between the measured GFRs and eGFR using any of the above equations.

**Conclusions:** All the equations used (CKD-EPI, MDRD4, MDRD6, CG) and CrCl did not correlate significantly with the measured GFR. Among the equations, CKD-EPI had the least variation with about 69% confirming within 20% of DTPA GFR, and about 86% and 97% confirming within 30% and 50% of DTPA GFR.

Table 1: Percentage of eGFR estimations occurring within 20%, 30%, and 50% variation of DTPA GFR values

**PO2254**

**Fecal Calprotectin Correlates with Serum Albumin in Patients with CKD**

Yura Chag, Eun Sil Koh, Jongho Son, Sungjin Chung. The Catholic University of Korea, Seoul, Republic of Korea.

**Background:** Persistent inflammation, a characteristic feature in chronic kidney disease, contributes to decreased serum albumin levels and plays a central role in the Malnutrition, Inflammation and Atherosclerosis (MIA) syndrome, which is associated with poor clinical outcomes. Altered bowel habit is also a highly frequent status among patients with chronic kidney disease potentially due to their low fiber and fluid intake, medications, multiple comorbidities and dysbiosis of the gut microbiota. In this study, we have explored whether measurement of fecal calprotectin, a commonly used marker for increased neutrophil migration and local inflammation in gastrointestinal diseases, could reflect a state of low serum albumin in patients with chronic kidney disease.

**Methods:** Clinical and biochemical data including stool samples for calprotectin were collected from 579 cases of patients with no history of inflammatory bowel disease. Results: Fecal calprotectin was not different according to estimated glomerular filtration rate, degree of proteinuria and medication of polystyrene sulfonate and ferrous sulfate. However, it was significantly and negatively correlated with serum albumin in patients (r=−0.107, p=0.010). Patients with higher tertile of fecal calprotectin were older and had lower hemoglobin. Multivariable linear regression analysis showed that fecal calprotectin was significantly correlated with serum albumin (β=−17.702, P=0.010).

**Conclusions:** These observations that serum albumin were significantly correlated with fecal calprotectin in patients with chronic kidney disease, suggest that the bowel inflammatory response may be another contributing factor.

**PO2255**

**A Case of Sevelamer-Induced Colon Perforation**

Venkata R. Manchala, Rajendra Mandalapu, Soumya P. Thumma, Nithin Karakala. University of Arkansas for Medical Sciences, Little Rock, AR.

**Introduction:** Sevelamer is an ion exchange resin used to treat hyperphosphatemia in patients with chronic kidney disease. It does not cause hypercalcemia or vascular calcification. The main adverse effects are related to constipation and abdominal pain. Common adverse effects include nausea, vomiting, diarrhea, dyspepsia and constipation 1. Case reports of sevelamer associated bowel perforation have been reported in the literature2. Here we report a case of sevelamer induced colon perforation.

**Case Description:** 61 year old Caucasian male with history of ESRD from diabetic nephropathy on automated peritoneal dialysis presented to the emergency department with abdominal pain. Physical exam was notable for epigastric tenderness. Labs were unremarkable except for hyperglycemia of 427 mg/dL. CT scan abdomen showed chronic ileitis and moderate ascites. PD fluid analysis ruled out peritonitis. Patient’s abdomen pain persisted despite several days of supportive care, prompting repeat CT scan which revealed a large pneumoperitoneum suggestive of sevelamer resins. Patient was on sevelamer 800mg TID for several years. Patient improved with appropriate medical management. Sevelamer was discontinued prior to discharge.

**Discussion:** Sevelamer is composed of a non-absorbable hydrogel with ammonia on the hydrochloride (Renagel) or the carbonate (Renvela). In the acid milieu of stomach, it is protonated to ammonium which is available to bind phosphate in the intestine3. The exact pathogenesis of intestinal perforation remains unclear. It is hypothesized that presence of sevelamer crystals in the gastrointestinal tract was associated with mucosal abnormalities including inflammation, ischemia and necrosis. The presence of characteristic sevelamer crystals (typically seen as bright pink linear accretions with a rusty yellow background and irregularly spaced fish-scales) on pathology along with the supporting clinical history clinches the diagnosis. It is important for clinicians to be aware of this rare but a serious potential complication of bowel perforation associated with sevelamer.

**PO2256**

**Case of Pulmonary-Renal Syndrome Involving Goodpasture Disease and Granulomatosis with Polyangiitis**

Shabatah Khan. AU-UAG Internal Medicine, Athens, GA.

**Introduction:** Wegner’s granulomatosis and Goodpasture’s disease are two rare causes of pulmonary-renal syndromes syndromes. Both have similar presentation and different treatment protocols. The clinical relevance for these two syndromes is that they are both potentially fatal. WG is a systemic vasculitis involving small to medium size vessels and it mainly affects the respiratory and renal systems and associated with C-ANCA (PR3) antibodies. Goodpasture’s disease is an autoimmune condition that is characterized by rapidly progressive glomerulonephritis (RPGN) and severe alveolar hemorrhage. It is most often related to anti-glomerular basement membrane (anti-GBM) antibodies and affects the renal and pulmonary vascular beds due to immune complexes formed against the glomerular basement membrane. It is noted that 5% of all ANCA + patients are also positive for anti-GBM and of all the anti-GBM about 1/3rd also have ANCA but that does not always correlate with active clinical disease. This leads to a significantly poorer prognosis and worse renal outcomes than either disease process alone.

**Case Description:** We present a 59-year-old female with initial complaint of weakness, lethargy and sinus congestion. She had a history of untreated hypertension. She was noted to be hypoxic and had rales and bronchi bilaterally. Labs revealed WBC of 35, Hg 5.6, Hct 15.5 and platelets 594. She had sodium of 98, Potassium 5.8, Bicarbonate 18, BUN of 58 and Creatinine of 8.5. Chest x-rays showed bilateral opacities resembling CAP. Further hypoxemia prompted intubation, revealing copious amounts of alveolar hemorrhage. Vasculitis was in the differential given alveolar hemorrhage and renal failure. The patient was then started on plasmapheresis, high dose IV steroids as well as cyclophosphamide. Complement levels and immunofixation were normal as were studies for lupus and hepatitis B and C. She had + ANA, Anti-GBM and c-ANCA antibodies. Renal biopsy showed predominant sclerosis and >90% focal necrotizing crescent GN and severe interstitial scarring. Immunofluorescence (IF) demonstrated linear staining of glomerular BM as well as ANCA mediated changes.

**Discussion:** This case illustrates that both WG and GP can occur in the same patient. Such patients can present with CAP that rapidly deteriorates. Early recognition of the pulmonary involvement is crucial for starting appropriate therapy by plasmapheresis and immunosuppressant. Although these patients with severe glomerular involvement will be lifelong dependent on dialysis, their 1- and 2-year survival can be significantly improved with appropriate therapy and follow up.
PO2258
Asymptomatic Spurious Hyperuricemia Related to Waldenstrom Macroglobulinemia
Pankaj Goyal,1 Prakash S. Gudsoorkar,2 Churahus V. Thakar,1,2 University of Cincinnati Academic Health Center, Cincinnati, OH; 1Cincinnati VA Medical Center, Cincinnati, OH.

Introduction: Increased IgM has been shown to result in underestimation of uric acid levels and pseudo-hypouricemia; however, there are no reported cases of hyperuricemia in the setting of paraproteinemias. We present a case of Waldenstrom’s Macroglobulinemia (WM) resulting in marked elevation of uric acid level in the absence of tumor lysis syndrome (TLS).

Case Description: A 73-year-old man with history of WM was incidentally noticed to have very high uric acid level of 37.2 mg/dl. He had no history of crystal arthropathy or chronic kidney disease. He was started on Acalabrutinib because of high serum viscosity and uric acid levels improved significantly, however the treatment had to be discontinued due to development of potential drug related adverse events. After discontinuation of Acalabrutinib, his serum viscosity and uric acid level gradually increased back to the previous level. Laboratory parameters were not suggestive of TLS and potassium, calcium and phosphorus were all normal. 24-hour uric acid excretion was noticed to be low normal (341 mg/24 hours).

Discussion: Paraproteins often cause factitious biochemical measurements by forming opake precipitates with the test reagents and interfering with various automated assays. Such interferences may be difficult to anticipate as they are intermittent and patient specific. Ultrafiltration of paraproteins, dilution or deproteinization of the samples may sometimes help correct these measuring errors. WM and other paraproteinemias may cause true hyperuricemia in the setting of TLS. However, the absence of other complications and low probability should reduce the consideration of factitious results. An observant clinician should be aware of these findings in order to avoid unwarranted testing and treatment. Also, a very high level of uric acid in the absence of symptoms may point towards a possibility of undiagnosed paraproteinemias.

PO2259
Is the Well-Recognized Intravascular Tamm-Horsfall Protein Polyp a Misanomer? A Case Report from a Patient with Obstructive Uropathy and Hematuria
Liva Suo, Kyle Meissner, Aman Musa, Vikas D. Reddy, Jadi M. Teakell, William E. Glass. University of Texas Health Science Center at Houston, Houston, TX.

Introduction: Tamm-Horsfall protein (THP), a renal epithelial glycoprotein, was originally described from normal urine and should be present in all normal urine specimens. The polyps are described in these reports as being located in veins or sometimes lymphatics. Our case is the first to confirm the location of a THP polyp by immunohistochemical (IHC) analysis.

Case Description: A 64-year-old Caucasian male presented with bilateral flank pain and persistent gross hematuria. On admission, he had mildly elevated BUN (26.0 mg/ dL) and serum creatinine (3.2 mg/dL). Urine analysis showed red blood cells > 182 /hpf with negative leukocyte esterase and negative nitrates. He developed azotemia during the hospitalization with the highest creatinine of 7.4 mg/dL on day 3 of admission. Renal ultrasound indicated mild-moderate hydronephrosis with a collapsed bladder. Renal biopsy was performed given lack of proper explanation for his presentation. Biopsy showed Periodic acid-Schiff (PAS) positive THP with polyhedral use. Her physical exam was unremarkable. Her admission labs were notable for a Cr 2.25 mg/dL, potassium 3.1 mmol/L, bicarbonate 155 mmol/L, phosphorus 2.2 mg/dL, uric acid 1.3 mg/dL, urinalysis specific gravity 1.011, pH 6.5, glucose 500 mg/dL, small blood, protein 30 mg/dL, negative leukocyte esterase, nitrite negative, 2 RBC, 4 WBC, negative urine culture, and spot protein/creatinine of 1.1. Further workup revealed urine electrolytes: Cr 39 mg/dL, sodium 77 mmol/L, potassium 20 mmol/L and phosphorus 22.9 mg/dL. FePhos was 61% suggesting renal wasting. Serologic workup was negative for ANA, ANCA, ncl c3, c4 and spep. Renal sonogram showed normal sized kidneys with two nonobstructing calculi in each kidney. Renal biopsy revealed focal degenerative changes in the tubules with flattening of the epithelium consistent with mild ATN. The interstitium had diffuse infiltration with mononuclear cells and frequent cosinophils consistent with ATN. EM showed tubuloarteriolar inclusions. She was started on prednisone which was tapered over 6 weeks. Creatinine downtrended to 1.1 mg/dL. She was continued on prednisone.

Discussion: Publilized reports of THP polyps are exclusive to veins, but there are no reports of THP polyps in the kidneys. She had not been exposed to any nephrotoxic substances or medications. THP is commonly seen in renal biopsies in patients with renal obstructions. The development of THP polyp in a patient with asymptomatic hydronephrosis may not be true due to the misidentification of the markedly distended renal tubules as renal veins.

PO2260
Vedolizumab-Induced Acute Interstitial Nephritis and Acute Tubular Necrosis
Abdulrahaman Muzib, Rushang Parikh, Vanessa Bijol, Napur N. Uppal, Mala Sachdeva. Donald and Barbara Zucker School of Medicine at Hofstra/ Northwell, Great Neck, NY.

Introduction: Vedolizumab is a humanized monoclonal antibody used in the treatment of ulcerative colitis. To date there has been no reported case of vedolizumab associated acute interstitial nephritis (AIN) and acute tubular necrosis (ATN). We report the first such case.

Case Description: A 58 year old female with history of ulcerative colitis on vedolizumab for one year, primary parathyroidism and calcium oxalate nephro lithiasis presents due to acute kidney injury. Patient received her last dose of vedolizumab two months prior. She had been receiving 300mg IV every eight weeks, making her last dose her seventh dose. Her pre-medication creatinine (Cr) was 0.9 mg/dL. Approximately one week prior to admission she was found to have a Cr of 2.0 mg/dL. She denied any NSAIDs, PPI, antibiotics or herbal use. Her physical exam was unremarkable. Her admission labs were notable for a Cr 2.25mg/dL, potassium 3.1mmol/L, bicarbonate 155mmol/L, phosphorus 2.2mg/dL, uric acid 1.3mg/dL, urinalysis specific gravity 1.011, pH 6.5, glucose 500mg/dL, small blood, protein 30mg/dL, negative leukocyte esterase, nitrite negative, 2RBC, 4WBC, negative urine culture, and spot protein/creatinine of 1.1. Further workup revealed urine electrolytes: Cr 39mg/dL, sodium 77mmol/L, potassium 20mmol/L and phosphorus 22.9mg/dL. FePhos was 61% suggesting renal wasting. Serologic workup was negative for ANA, ANCA, ncl c3, c4 and spep. Renal sonogram showed normal sized kidneys with two nonobstructing calculi in each kidney. Renal biopsy revealed focal degenerative changes in the tubules with flattening of the epithelium consistent with mild ATN. The interstitium had diffuse infiltration with mononuclear cells and frequent eosinophils consistent with AIN. EM showed tubuloarteriolar inclusions. She was started on prednisone which was tapered over 8 weeks. Creatinine downtrended to 1.1 mg/dL. She was continued on prednisone.

Discussion: Vedolizumab reported AIN and mild ATN has not thus far been reported. Here we report the first case which seemed to have a cumulative dose response. Whether this patient has a mild proximal RTA due to this medication remains to be determined, as the phosphorus wasting could have been due to her primary hyperparathyroidism. Clinicians should be made aware of such reported associations so that both a timely renal biopsy and therapy could be instituted without delay.
PO2263

ALECT2 Amyloidosis with Cardiac Involvement Complicating Renal Transplantation

Introduction: ALECT2 amyloidosis may be associated with slowly progressive renal failure that is clinically unsuspected at the time of transplantation. While this is typically not clinically significant, we report a case with extensive systemic ALECT2 amyloidosis that also involved the myocardium, contributing to perioperative death post renal transplantation.

Case Description: A 72-year-old Hispanic woman presented for renal transplantation due to ESRD from hypertension. She was bradycardic on admission. Cardiac workup prior to transplantation had not identified an infiltrative process. Post-transplant hypotensive bradycardic arrest leads to multiorgan failure, anoxic brain injury and death. Autopsy revealed massive amyloid deposition in the native kidneys, adrenals, spleen, and less extensive infiltration of liver and myocardium. Cardiac intramural vasculature from venae to capillaries, arterioles and arteries showed amyloid deposition. Mass spectrometry revealed ALECT2 as the amyloidogenic protein.

Discussion: ALECT2 is a systemic amyloidosis that typically involves kidneys, adrenals, spleen and liver. It may be clinically unsuspected at the time of renal transplantation and should be considered in older patients, especially from higher ALECT2 amyloid prevalence populations. Complications related to systemic disease may add to morbidity or mortality post-transplantation. Cardiac involvement in ALECT2 amyloidosis has not been previously identified as a significant clinical or autopsy finding, but our case demonstrates that the cardiovascular system may indeed rarely be involved by ALECT2 amyloidosis and be associated with clinical sequelae.

PO2264

Cell-Based CSb9-ELISA to Identify Patients with Atypical Hemolytic Uremic Syndrome

Martin Reinhardt, Herrmann G. Haller, Yulia Kiyani. Medizinische Hochschule Hannover Zentrum Innere Medizin, Hannover, Germany.

Background: Discrimination between different diseases in patients suffering from thrombotic microangiopathies is often challenging. Measuring CSb9 deposit on endothelial cells using confocal microscopy have been shown to be convenient in diagnostic and therapy monitoring of Atypical hemolytic uremic syndrome (aHUS) but methods are complex and costly.

Methods: We developed a cell-based CSb9-ELISA to measure CSb9-deposits on activated endothelial cells. Patients with suspected aHUS and other thrombotic microangiopathies were identified in early disease stage. Serum was drawn and tested versus healthy controls. After confirmation of the diagnosis aHUS therapy efficiency was monitored using the assay.

Results: In patients with the clinical diagnosis of aHUS we were able to show up to six-fold higher CSb9-deposits in contrast to normalized human serum (NHS) (p-value < 0.0001). In comparison to healthy controls, patients suffering from either Shiga-Toxin-HUS or Thrombotic Thrombocytopenic Purpura (TTP) we could demonstrate a two- to three-fold higher deposit (p-value=0.0103 and below). After onset of eculizumab treatment, the amount of CSb9-deposits becomes lower than in healthy controls, proving the efficiency of the therapy. One-Way-ANOVA shows significant differences between aHUS-groups and controls, but not between aHUS patients using Taikeye-multiple comparisons test.

Conclusions: We described a novel, fast and reproducible ELISA to identify aHUS-patients by measuring CSb9-deposits and monitor disease activity. This can give a rise to diagnostic speed and therapy decisions. Further investigation and validation are needed to show interactions with other complement diseases like systemic lupus erythematosus.
PO2266
Persistent Coagulation Abnormalities in ESRD After 1 Year of Follow-Up
Emily Bontekoe, Vinod K. Bansal, Falkha Siddiqui, Debra Hoppensteadt, Jawed Fareed. Loyola University Medical Center, Maywood, IL.

Background: Common to end-stage renal disease (ESRD), coagulation abnormalities can lead to severe bleeding events or excessive thrombin formation and engender increased morbidity and mortality in this population. Repeated heparin administration to ESRD patients during maintenance hemodialysis may also contribute to changes in the coagulation system. Thus, profiling coagulation parameters in ESRD patients over 1-year may provide insight to long-term coagulation dysfunction in this population.

Methods: Blood samples were obtained at baseline and 1-year from ESRD patients undergoing maintenance hemodialysis (n=95) 48-hours post-dialysis. Plasma samples were analyzed using clot-based methods including activated partial thromboplastin time (aPTT), prothrombin time (PT), and thrombin time (TT). Chromogenic assays measured heparin levels by anti-Xa and anti-IIa methods. Patients were categorized by heparin administration during dialysis (n=44) and compared via statistical method and percent change.

Results: In the clotting and chromogenic assays, all parameters were elevated in the baseline and 1-year ESRD cohorts compared to controls, as shown on Figure 1. Only anti-IIa levels demonstrated a significant difference in ESRD patients after 1-year (p<0.0001). Heparin administration varied in aPTT, TT, and anti-Xa (p<0.05).

Conclusions: These results suggest ESRD patients on dialysis exhibit a long-term, hypo-coagulable state as shown by prolonged aPTT and TT. Elevated parameters maintained over 1-year suggests persistent dysregulation of clotting factors in ESRD patients. Circulating levels of heparin, as evidenced by anti-Xa and anti-IIa assays may be due to impaired clearance of heparin components via dialysis.

PO2267
Using Skin Biopsies to Measure Target Occupancy of a Renal Anti-fibrotic Monoclonal Antibody (mAb) in a Phase 1 Clinical Study
Rowan Bowes,1 Geoffrey I. Johnston,1 Linghong Huang, James Z. Song,2 Ting S. Schmidt,2 Alison L. Bigley,3 Graham Ogg,4 Eric Wong,1 Elizabeth S. Thomson,1 Jane Y. Chan,3 Anastasia Raievsk,2 Timothy S. Johnson,1 UCB Pharma, Slough, United Kingdom; Priyas Biotecnology, Shanghai, China; OracleBio, Chapelhill, United Kingdom; University of Oxford, Oxford, United Kingdom; Veramed, London, United Kingdom.

Background: Defining the optimal dose of drug required to bind to its mechanistic target (target occupancy, TO) and affect a measurable distal event (target engagement, TE) in damaged kidney is a challenge in the development of anti-fibrotic therapies for chronic kidney disease (CKD). We aimed to identify an accessible surrogate human tissue to predict TO in the kidney, prior to application in a Phase 1 study.

Methods: We developed a ‘biopsy-on-biopsy’ approach in skin: a 3mm biopsy initiated a wound healing response, a 1mm biopsy at the same site, up to 6 days later, provided tissue where active healing/fibrotic processes were ongoing. This method was used to measure the TO of zampilimab, a humanized mAb specific for human transglutaminase 2 (TG2), in kidney and skin biopsies. TE in damaged kidney was correlated with kidney TO and TE in a computational model (UUD model). We used a single dose Phase 1 study (NCT02879877). Following dosing of zampilimab, skin biopsies and kidney were measured using a competitive immunofluorescence assay on cryosections. A TRITC-labeled mouse parent of zampilimab (DC1) and a FITC-labeled anti-TG2 antibody binding a distant epitope (DH2) were used. TO was measured by comparing the relative binding of DC1 (competitively inhibited by zamilamib administered in vivo) to TO in a TG2 in-situ activity assay.

Results: In a primate UUO-CKD model treated prophylactically with zampilimab, the ‘biopsy-on-biopsy’ method showed excellent correlation between TO in the kidney and healing skin (3 days post first biopsy). Importantly, TO and TG2 inhibition (TE) in the kidney were also highly correlated. Subsequent use in the zampilimab Phase 1 study generated data directly comparable to the preclinical model.

Conclusions: Our ‘biopsy-on-biopsy’ approach allows early identification of a dose range in Phase 1 studies where the target organ is inaccessible, and is applicable to other therapeutic mAbs intended for treatment of fibrotic kidney disease. A Phase 1/2 study of zampilimab in patients with post-renal transplant fibrosis is ongoing (NCT04355578).

important diagnostic tool. The change to IR as primary operators has significantly reduced tissue adequacy. An extraordinary educational outreach to IR is needed.

4 weeks to 10 weeks gestation. In addition, 8 early metanephric kidneys from 10 weeks to 21 weeks of gestation were identified from our surgical pathology and autopsy cases for comparison with mesonephric specimens. Beside routine hematoxylin and eosin staining, the sections were stained for Periodic Acid Schiff (PAS) to detect proximal tubules (PT) brush borders and glomerular basement membranes (GBM). Furthermore, mesonephros and metanephros sections were immunohistochemically stained for CD133 for progenitor cells, GATA3 for mesangial cells and distal tubules, P504S for proximal tubules, and kidney injury molecule-1 (KIM-1) for PT injury.

Results: CD133 was positive in mesonephric glomerular and tubular structures at 4 weeks but this expression disappeared in the mesonephros from 5 weeks to 10 weeks, implying gradual maturation. GATA3 staining was positive in Wolffian duct, mesangial cells of primordial glomeruli (at 7 weeks the GBM was PAS+) and distal tubules, but not in PT. PT were positively stained for P504S. PT of mesonephric kidneys revealed brush borders on PAS stained sections from 7 to 10 weeks suggestive of reabsorptive activity. The PT of mesonephros at 7 weeks stained positively for KIM-1, suggestive of acute tubular injury during abortion processes. The mesonephros showed expression of markers in respective renal compartments, similar to those in mesonephros.

Conclusions: Human mesonephros can have GATA3+ mesangial cells in the glomeruli. Although structures are simplified (no loop of Henle and collecting ducts), the human mesonephric nephrons include primitive glomeruli, PT showing brush borders and distal tubules, having morphological features similar to those of advanced metanephric stages with excretory function. They have react to injury, at least during 7 to 10 weeks of gestation based on identification of brush borders and KIM-1 expression in PT.

PO2270

Monogenic Causes of Nephrolithiasis or Nephrocalcinosis in Korean Children

Jeong yeon Kim,1 Bomee Lee,2 Heeyoon Cho.1 1Department of Pediatrics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; 2Department of Pediatrics, Asan Medical Center Children’s Hospital, University of Ulsan College of Medicine, Seoul, Republic of Korea.

Background: Nephrolithiasis (NL) or nephrocalcinosis (NC) can be the early manifestation of hereditary nephropathy in children and early detection of hereditary nephropathy gives us chance to provide therapeutic and preventative intervention. In this study, we present genetic characteristics of NL/NC in pediatric patients who were treated in tertiary medical center in Korea.

Methods: The medical records of pediatric patients (age of 0-18 year) who had NC/NL and underwent genetic test under suspicion of hereditary nephropathy from March of 2013 to January of 2020 in Samsung Medical Center in Korea were reviewed. When specific disease was suspected, the sanger sequencing was done. The whole exome sequencing was performed when suspected mutations were not detected in sanger sequencing or when the disease could not be specified. DNA was extracted from whole blood or saliva. The novel mutations were evaluated by clinical findings and bioinformatics analysis such as in silico prediction.

Results: Total 20 patients underwent genetic test and two of them were sibling. The median age at the time of NC/NL detection was 4.8 years and male was predominant (M/F=2:3). Genetic diagnosis was done at the median age of 5.5 years. Three patients had family history of NC/NL (15%). Total 13 pathogenic gene mutations were detected in 16 patients (80%); 5 genes (SCL3A1, GRHPR, CLCN5, OCLR1, CLCNK2) were known to cause monogenic forms of NC/NL and 8 genes (PA2X2, PKD1, HNF1B, SLC36A2, BUB1B, VPS33B, PHEX) were not. Three pathogenic autosomal recessive mutations were detected in 3 individuals; BUB1B (n=1), GRHPR (n=1), VPS33B (n=1). We also detected pathogenic mutations in 6 autosomal dominant genes in 7 individuals; CLCNK2 (n=1), SLC3A1 (n=1), PA2X2 (n=1), HNF1B (n=2), SLC11A1 (n=1), PKD1 (n=1), SLCN6A2 (n=1). Two X-linked recessive genes were detected in 5 individuals; CLCN5 (n=4), OCLR1 (n=1). In one patient, X-linked dominant gene was detected; PHEX. Eight of 16 detected mutations (50%) were novel mutation that have not been previously reported in database of human disease causing mutation.

Conclusions: In conclusion, NL/NC can be the clue to detect monogenic cause of hereditary nephropathy in children. Further large population study is needed to evaluate NL/NC as indicator for genetic analysis to detect monogenic hereditary nephropathy in children.

PO2271

Trans IL-6 Signaling Does Not Distinguish Between Pediatric Patients with and Without Scarring After Febrile Urinary Tract Infection

Siddipti Gupta, Sara E. Lautzenhiser, John D. Spencer, Brian Becknell, Christina B. Ching. Nationwide Children’s Hospital, Columbus, OH.

Background: The inflammatory response generated in response to infection is believed to be largely responsible for the development of renal scarring after UTI. IL-6 is a cytokine known to be induced during UTI with a pro-inflammatory pathway, known as trans signaling. We hypothesized there would be differences in markers of trans IL-6 signaling between patients with a history of febrile urinary tract infection (UTI) who had subsequent renal scarring as compared to those with a history of febrile UTI who did not develop renal scarring.

Methods: Urine samples were collected on consenting/assenting pediatric patients with a history of febrile (c38°C) UTI (urine culture ≥50K uropathogen) with documented presence or absence of renal scarring on imaging. Patients were not actively infected at the time of sample collection. Enzyme-linked immunosorbent assays were performed on samples for markers of trans IL-6 signaling: IL-6, soluble (s)IL-6 receptor (R), and soluble
Markers of Trans IL-6 Signaling Are Not Differentially Induced During Febrile and Afebrile Urinary Tract Infection
Sudipti Gupta, Sara E. Lautzenhiser, John D. Spencer, Brian Becknell, Christina B. Ching. Nationwide Children’s Hospital, Columbus, OH.

Background: Febrile urinary tract infections (UTIs) are generally thought to be evidence of tissue inflammation such as pyelonephritis as compared to afebrile UTIs which are thought to be more localized to the bladder. As such, generally the concern for renal damage is more in those with febrile UTI and thought to be a result of the inflammatory response generated. IL-6 is a known mediator of inflammation, particularly through its trans signaling pathway. We hypothesized there would be differences in markers of trans IL-6 signaling in the urine of children with febrile compared to afebrile UTI.

Methods: Pediatric patients with signs of active UTI were consented/assented for participation. Urine was collected at time of evaluation for active UTI in the urology or nephrology office or at hospitalization and were divided into those with a fever (≥38°C) compared to those without (<38°C). Patients were included for analysis if they had a positive urine culture (≥50K CFU of a uropathogen) and for those without a fever if they had no dysuria, urgency, frequency, and/or new or worsening urinary incontinence. Those with fever were termed a febrile UTI and those without a fever were termed afebrile UTI. Enzyme-linked immunosorbent assays were performed on samples for markers of trans IL-6 signaling: IL-6, soluble (s)IL-6 receptor (R), and soluble (s)gp130. Results were normalized to urine creatinine. Results were analyzed by Mann-Whitney U. A p-value of ≤0.05 was considered significant.

Results: 17 patients with febrile UTI and 23 patients with afebrile UTI were included. Two of the patients with febrile UTI were male while all of the afebrile UTI patients were female (p=0.1258). The groups did not differ significantly based on age (p=0.6218). While we found that those with a febrile UTI had a higher IL-6 in their urine at the time of collection (p=0.0479), there was no significant difference in expression of sIL-6R or sgp130. Ratios of these markers also were not significantly different.

Conclusions: Markers of trans IL-6 signaling, either as absolute values or ratios, are not different between individuals at the time of febrile or afebrile UTI.

PO2277
Human Neutrophil Peptide 1-3 Protects the Urinary Tract from Uropathogenic Escherichia coli Infection in Humanized Mouse Model
Jorge J. Canas, Jenaya Hooks, Sam W. Arregui, Andrew L. Schwaderer, David S. Hains. Division of Pediatric Nephrology, Department of Pediatrics, Indiana University School of Medicine, Indianapolis, IN.

Background: Urinary tract infection (UTI) susceptibility is defined by heritable genetic differences associated with the innate immune system development and efficiency. DNA copy number variations in the alpha-defense DEFA1 locus are associated with UTI susceptibility in children with VUR. In humans, DEFA1A3 is expressed in neutrophils as well as in the kidney. However, how DEFA1A3 protects the urinary tract in some individuals is unknown. We hypothesized that Defa-1 mouseized humanized mice would be resistant to experimental UTIs.

Methods: We induced UTI with two uropathogenic E. coli (UPEC) strains in wild-type (WT) C57Bl/6J and Defa-1 transgenic mice, which express human DEFA1A3. Bacterial suspension was inoculated with a catheter transurethrally. To assess the colony-forming unit (CFU) burden, kidneys and bladders were homogenized and colony forming units and clearance were determined by quantifying the plated serial dilutions grown overnight on LB plates at various time points.

Results: Results are presented in Figure 1: Comparing the Defa-1 mouse to WT (n=8 for each group), at 6-hours post infection, bacterial burdens were lower in the Defa-1 mice kidneys for both UPEC strains (A). At 24-hours after inoculum, the bladder infection (CFU/g) was significantly lower in the Defa-1 mouse in comparison to the C57Bl/6J group (B).

Conclusions: Our findings support the early protective role of DEFA1A3 from UPEC challenge in the humanized mouse kidney and bladder when compared to the absence of the antimicrobial peptide in the wild-type mouse. Further investigation is needed to determine whether renal or extra-renal expression of DEFA1A3 is critical in shielding and clearing UPEC UTIs.

PO2276
Ribonuclease 6 is an Intracellular Antimicrobial Peptide That Thwarts Bacterial Cytosis and Pyelonephritis
Hanna H. Cortado, Borion Li, Ashley R. Jackson, Sudipti Gupta, Christina B. Ching, John D. Spencer, Brian Becknell. Nephrology and Urology Research Affinity Group Nationwide Children’s Hospital, Columbus, OH.

Background: Ribonuclease 6 (RNase 6) is a highly conserved cationic peptide with potent microbical activity toward uropathogenic Escherichia coli (UPEC) in vitro. Here, we determined the cellular sources of RNase 6 along with the consequences of its gain and loss of function during experimental urinary tract infection (UTI).

Methods: We generated female mice with a Rnase6Δ/Δ knock-in allele, human RNASE6 transgene, or controls on a C57Bl/6J genetic background. We identified cellular sources of RNase6 by flow cytometry and microscopy. We transurethrally inoculated Rnase6Δ/Δ, RNASE6 transgenic, and control mice with UPEC strain CFT073 and enumerated bacterial burden. The role of RNase 6 during intracellular killing of UPEC was investigated in bone marrow derived macrophages (BMDM) by gentamicin protection assay.

Results: RNase6 is expressed by tissue resident macrophages and circulating monocytes that are recruited to the infected bladder and kidney within hours of UPEC inoculation. Rnase6 deficiency leads to increased renal UPEC burden relative to controls, whereas RNASE6 transgenic mice exhibit reduced UPEC burden. Rnase6 macrophages localize within the urothelium and its underlying stroma at baseline and during UTI. RNase 6 is not secreted by macrophages; instead, it is retained intracellularly within the endolysosomal system. RNASE6 over-expression in macrophages leads to increased killing of phagocytosed UPEC.

Conclusions: Rnase6 is a monocyte/macrophage derived antimicrobial peptide that acts intracellularly to kill phagocytosed UPEC and limit bacterial UTI.

PO2277
Risk Factors for Urinary Tract Infection Caused by Extended-Spectrum Beta-Lactamase Gram-Negative Bacteria in Infants
Yo Han Ahn, Ji hyun Kim, Jyu young Lee, Seoon Lim, Hye Gung Yang. 1Seoul National University Bundang Hospital, Seongnam, Republic of Korea; 2Seoul National University Children’s Hospital, Seoul, Republic of Korea; 3Inha University Hospital, Incheon, Republic of Korea.

Background: Community-acquired extended-spectrum beta-lactamase (ESBL) producing bacterial infections are an evolving public health problem. Urinary tract infections (UTIs) due to ESBL-producing bacteria are increasing even in infants rarely exposed to antibiotics. We aimed to identify risk factors for UTI caused by ESBL-positive bacteria in infants.

Methods: We retrospectively analyzed the medical records of hospitalized infants with the first episode of UTI from 2018 to 2019. Data includes demographic characteristics, birth history, previous use of antibiotics, febrile event, urinalysis results, and urine isolated organisms. Multivariate regression analysis was used to quantify independent risks associated with ESBL-positive UTI.

Results: UTIs were diagnosed in 266 patients at a median age of 3.6 (interquartile range: (2.3-5.4)) months. Two hundred (75.4%) patients were diagnosed with UTI caused by ESBL-producing bacteria. When we divided patients according to ESBL status, there was no difference in gender, age, birth history, milk type, and use of postpartum care centers. Maternal use of antibiotics during pregnancy (odds ratio (OR), 3.817; 95% confidence interval (CI) 1.812-8.040, P <0.001), previous antibiotic exposure to patients was higher in the ESBL-positive group than in the ESBL-negative group (32.3% vs. 10.3%, P <0.001, and 22.6% vs. 12.3%, P =0.044, respectively). Klebsiella species was more frequently identified in the ESBL-positive group than in the ESBL-negative group (19.4% vs. 4.9%, P =0.002). In multivariate analysis, maternal use of antibiotic during pregnancy (odds ratio (OR), 3.817; 95% confidence interval (CI) 1.812-8.040, P <0.001), previous antibiotic exposure to patients (OR 2.418; 95% CI 1.071-5.661, P =0.034), and Klebsiella species as a causative organism (OR 6.222; 95% CI 2.396-16.158, P=0.001) were associated with ESBL positivity. In a comparison of clinical courses of patients, the ESBL-positive group showed severe leukocytosis (WBC 16,795 μL vs. WBC 14,620 μL, P =0.04), and stayed longer in hospital than the ESBL-negative group (7.0 days vs. 4.5 days, P =0.001).

Conclusions: In this study, the high rate of ESBL positivity was detected in infantile UTI. Antibiotics exposure on both parents and mother was associated with UTI caused by ESBL producing bacteria. Identification of underlying risk factors could improve treatment and preventive strategies.
PO2278

Urinary Sodium to Potassium Molar Ratio in Pediatric Stone Patients
Vimal Master sankar raj. University of Illinois College of Medicine at Peoria, Peoria, IL.

Background: The incidence of pediatric stone disease is on the rise. Dietary elements including high salt intake and reduced water consumption remain the major risk factors for stone formation. Urinary stone profile in pediatric literature remains limited. The purpose of this study is to get data on 24 hr urinary mineral excretion in pediatric stone formers with particular emphasis on these two research questions 1. How does urinary sodium/potassium (Na/K) molar ratio in pediatric stone patients compare to the national average intake data in USA? 2. How does risk factors of stone formation such as hypercalcuria correlates with dietary risk factors in pediatric stone formers?

Methods: This retrospective cohort study included all Pediatric stone patients who attended outpatient Nephrology clinic from 03/1/2014 to 10/1/2018. Children with known metabolic/genetic causes for stone disease, incomplete 24 hr urinary collection or on medications that affect mineral excretion were excluded from the study.

Results: 150 patient charts were screened and 89 included in the study. Average age of the study population was 12.7 years with 58% females and 42% males. Mean Na/K molar ratio in pediatric stone patient was 3.7, statistically significantly higher than the national average of 2.5 using one sample T test (P< 0.001). Urinary calcium excretion showed a strong linear correlation with sodium excretion (r 0.545, P < 0.001). Multiple regression model using urinary calcium excretion as the dependent variable showed correlation with Urinary sodium excretion (P 0.004), urinary volume (P < 0.0001) and urinary Ph (P=0.001).

Conclusions: 24 hr urinary sodium potassium molar ratio is significantly higher in stone formers indicating a higher salt and lower potassium consumption when compared to national average intake. Water intake, salt consumption and alteration of urinary Ph remains the main dietary modality to alter calcium excretion and hence reduce risk of stone formation.

PO2279

Keratin 5+ Urothelial Cells Are Developmental and Tissue Repair Progenitors in the Bladder
Ashley R. Jackson,1 Birong Li,1 Brian Becknell.1,21 Center for Clinical and Translational Research, Abigail Wexner Research Institute at Nationwide Children’s Hospital, Columbus, OH; 2Division of Pediatric Nephrology, Nationwide Children’s Hospital, Columbus, OH.

Background: Urothelium is nearly quiescent during homeostasis, but injury engages a robust regenerative capacity. Several progenitor cell candidates have been implicated, but prevailing models demonstrate conflicting roles discrete urothelial subpopulations. We recently demonstrated that Keratin 5 (K5)-expressing UCs are temporally restricted renal urothelial progenitors. It is unclear whether similar temporal restrictions are imposed on bladder K5-UCs, and whether an investigation into the temporality of the K5-UC progenitor may clarify bladder progenitor model. The objective of this study was to determine temporal progenitor-progeny relationships responsible for bladder urothelium generation and regeneration.

Methods: Using Ker5-CreERT2;Rosa26tm mice, K5-UCs were inducibly and permanently labeled with tdTomato (tdT). Tamoxifen (TMX) was administered at postnatal day (P) 1, P7, P14, P21 or P41. Mice were sacrificed (SAC) at P42 or subjected to a single round of urothelial injury (cyclophosphamide) and euthanized 2 weeks later. Immunofluorescence microscopy was used to visualize and quantitate tdT, K5, (uroplakin), Uapk and K20 expression.

Results: Fate mapping analysis found that 22% (TMX0.5;SAC+);0.5<0.675, (K5-UCs) and 23.3% (TMX0.5; SAC+);0.5<0.675 of neonatal tdT+ UCs differentiated into adult Uapk + UCs (tdT-;Uapk mostly intermediate cells) by P42 compared to 9% (TMX0.5;SAC+);0.5<0.675 of juvenile tdT+ UCs, and 0% adult (TMX0.5;SAC+);0.5<0.675 (P=0.01, ANOVA). Following urothelial injury, 63% (TMX0.5;Cyte-);0.5<0.675, 54.33% (TMX0.5;Cyte-);0.5<0.675 and 69% (TMX0.5; Cyte-);0.5<0.675 of umbrella cells expressed tdTomato (tdT+;K5-UCs<0.20). Adult (TMX0.5; Cyte+;Cyto+; Cyte+);0.5<0.675 tdT+ UCs rarely formed umbrella cells.

Conclusions: K5-UCs form intermediate and superficial cells, but the capacity for K5-UCs to form these derivatives is lost over time. In response to acute adult bladder urothelial injury, neonatal and juvenile tdTomato+ UCs regenerate umbrella cells, while adult tdTomato+ UCs do not. These studies establish that bladder K5-UCs are context dependent progenitors - responsive to temporal and pathologic cues. Our findings support an intermediate cell auto injury progenitor model, and show that intermediate cells formed by neonatal and juvenile K5-UCs repair acutely injured bladder urothelium.

PO2280

Perinatal Cystatin C as Biomarker of Nephron Endowment
Beatrice L. Crippa,1 Stefano Ghirardello,1 Valentina Capone,2 Gianluigi Ardissino.1 1NICO, Fondazione IRCCS Ca’ Granda, Ospedale Maggiore Policlinico, Milano, Italy; 2Pediatric Nephrology, Dialysis and Transplantation, Fondazione IRCCS Ca’ Granda, Ospedale Maggiore Policlinico, Milano, Italy.

Background: Nephron endowment has a wide individual variability and plays a crucial role in drug toxicity, outcome of kidney diseases and pathogenesis of arterial hypertension (AH), but nephrons count is technically impossible in vivo. During acute dehydratation, subject with reduced nephron mass (unilateral renal agenesis or renal hypoplasia) exhibit increased levels of biomarkers of renal function compared to healthy subjects. We hypothesized that healthy newborns with reduced nephron endowment will have high levels of cystatin C (Cys-c) during perinatal dehydration. The aim of the study was to compare Cys-c level during physiological perinatal dehydration in healthy term infants with hypertensive fathers (HF) and normotensive fathers (NF).

Methods: Healthy, Caucasian, born at term neonates were enrolled: infants with fathers on antihypertensive therapy were compared to infants with normotensive fathers > 40 yo. Enrolled infants underwent Cys-c capillary determination at time of expanded newborn screening.

Results: We enrolled 40 infants with HF and 80 infants with NF. Basic characteristics were not different between the two groups except for the number of hypertensive grandparents, that was higher among infants with HF. Cys-c levels was determined at a median of 62.5 hours of life (IQR 55-71) without any difference between groups. Cys-c was significantly higher in infants with HF (1.6 ± 0.3 mg/mL vs 1.4 ± 0.3 mg/mL, p < 0.001). Linear regression analysis corrected for confounders (type of feeding, delivery mode, weight loss velocity) confirmed that paternal hypertension was the only variable significantly associated with high Cys-c level (mean difference 0.2 mg/mL, IC 95% 0.1-0.3 in, p < 0.001).

Conclusions: Our results support the key role of nephron endowment in the pathogenesis of AH and suggest the possibility of identifying at-risk subjects at birth. This opportunity opens up specific and targeted preventive health measures very early in life.

PO2281

Elevated Urinary Neutrophil Gelatinase-Associated Lipocalin Predicts Postoperative AKI
Cara L. Slagle,1 Hailey W. Gavigan, James A. Rowe, Brenda Poindeexter, Kelli A. Kraliman, Alexandra Schmerge, Chunyan Liu, Shelley Ehrlich, Meera Kotagal, Stuart Golden, Cincinnati Children’s Hospital Medical Center, Cincinnati, OH.

Background: Post-operative acute kidney injury (AKI) in neonates remains understudied despite occurring frequently. Urinary neutrophil gelatinase-associated lipocalin (uNGAL) offers promise as a novel predictive biomarker for AKI, yet clinical utilization lags behind in neonatology.

Methods: Infants undergoing a general surgical procedure, excluding gastric tube placement, were prospectively enrolled. uNGAL samples were obtained prior to surgery and over post-operative days (POD) 0-3 at six time points. AKI was defined by the 2014 neonatal modified Kidney Diseases: Improving Global Outcomes (KDIGO) definition. Samples were processed using The NGAL Test® (BioPorto, Denmark). Generalized additive mixed effect model (GAMM) was utilized to study the longitudinal trajectory of log transformed uNGAL values. The ability to predict AKI was assessed using receiver operating characteristic curves (AUC-ROC).

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Results: A total of 141 neonates underwent 192 surgical procedures. AKI occurred in 69% of patients. AKI in neonates with CDH were more likely to have undergone an emergent procedure (63% vs. 31%, p<0.001) and had higher uNGAL levels (Table 1). Pre-op uNGAL did not differ between AKI and no AKI patients (26ng/mL vs 59ng/mL, p=0.12). uNGAL levels were higher at all post-op time points even when controlled for pre-operative AKI (p=0.0006 to 0.0356). The AUC-ROC for predictability of post-operative AKI using uNGAL at 24 hours was 0.8 (95% CI: 0.71-0.88).

Conclusions: Post-op uNGAL predicts AKI. In patients undergoing emergent procedures, careful monitoring of renal function should be performed and uNGAL offers clinical utility. In our patients uNGAL trends could allow clinicians to better understand renal injury in real time and adjust treatment plans and/or avoid or restart nephrotoxic medications.

Conclusions: AKI in neonates with CDH occurs in about 30% of hospitalized neonates and is independently associated with mortality. Infants with congenital diaphragmatic hernia (CDH) are frequently exposed to nephrotoxins such as fluid overload, on ECLS, exposed to nephrotoxins, or in the post-operative period, given shifts, surgery, cardiopulmonary compromise, and extracorporeal life support (ECLS). As such, they are postulated to have an increased AKI incidence. We sought to determine prenatal characteristics and postnatal exposures associated with an increased risk of AKI in neonates with CDH during the first 30 days of life, as well as the impact of AKI on selected long-term outcomes.

Methods: We performed a single-center retrospective review of neonates with CDH from 2009 to 2017. AKI was defined by the modified neonatal Kidney Disease Improving Global Outcomes (KDIGO) criteria. Discriminative fluid shifts, surgery, cardiopulmonary compromise, and extracorporeal life support (ECLS). As such, they are postulated to have an increased AKI incidence. We sought to determine prenatal characteristics and postnatal exposures associated with an increased risk of AKI in neonates with CDH during the first 30 days of life, as well as the impact of AKI on selected long-term outcomes.

Background: Acute kidney injury (AKI) occurs in about 30% of hospitalized neonates and is independently associated with mortality. Infants with congenital diaphragmatic hernia (CDH) are frequently exposed to nephrotoxins such as fluid overload, on ECLS, exposed to nephrotoxins, or in the post-operative period, given shifts, surgery, cardiopulmonary compromise, and extracorporeal life support (ECLS). As such, they are postulated to have an increased AKI incidence. We sought to determine prenatal characteristics and postnatal exposures associated with an increased risk of AKI in neonates with CDH during the first 30 days of life, as well as the impact of AKI on selected long-term outcomes.

Methods: We performed a single-center retrospective review of neonates with CDH from 2009 to 2017. AKI was defined by the modified neonatal Kidney Disease Improving Global Outcomes (KDIGO) criteria. Discriminative fluid shifts, surgery, cardiopulmonary compromise, and extracorporeal life support (ECLS). As such, they are postulated to have an increased AKI incidence. We sought to determine prenatal characteristics and postnatal exposures associated with an increased risk of AKI in neonates with CDH during the first 30 days of life, as well as the impact of AKI on selected long-term outcomes.

Results: There were 130 neonates included in the cohort, median gestational age was 38 weeks [IQR: 36, 38], median birthweight was 2.89 kilograms [IQR: 2.5, 3.19], 56% were male, and 50% were outborn. AKI occurred in 34 (37.8%) infants during the first 30 days of life. Specifically, 15 (44%) had stage 1, 10 (29%) had stage 2, 9 (26%) had stage 3, and 2 (6%) had stage 4 AKI. Baseline renal replacement therapy was initiated in 11 infants with AKI; higher estimates of lung volume (percent predicted lung volume, total lung volume, residual volume) were lower in infants with AKI than in those without AKI.

Conclusions: AKI is common among neonates with CDH. In our cohort, greater CDH severity was associated with greater odds of AKI and those with AKI had worse long-term outcomes. Attention to kidney function should be paid to neonates with fluid overload, on ECLS, exposed to nephrotoxins, or in the post-operative period, given the increased odds of AKI in such situations.
post-op FO and no FO groups were evaluated by Mann-Whitney U tests. Ability to predict FO was assessed by receiver operating characteristic curves (AUC-ROC).

Results: A total of 141 infants underwent 192 procedures. FO occurred after 46% (88/192) procedures (mean %FO = 27±10). Previous medical history of AKI was associated with development of post-op FO (35% vs. 14%, p<0.001). Development of post-op AKI was also associated with FO even when controlled for pre-op AKI (69% vs. 31%, p<0.005). When SCR was adjusted for FO, AKI increased from 35 to 38 events and stage of AKI increased in 8 events. In FO patients, elevations in uNGAL were higher at all time points (Table 1). The AUC-ROC for post-op FO was 0.7 (95% CI: 0.63-0.78).

Conclusions: FO is an indicator of reduced renal function and is associated with AKI. uNGAL offers utility as an additional biomarker to assist in prediction of post-op FO and inability to maintain acceptable fluid balance. Post-op FO should be monitored closely for all surgical patients, and particularly patients with a previous history of AKI.

PO2286

Use of B-Type Natriuretic Peptide as a Quantitative Marker of Fluid Overload in Neonatal Renal Replacement Therapy

Noureiddin D. Nourebakhsh,1,2 Nadine M. Benador.1,2 Comprehensive Kidney Care Center, Rady Children’s Hospital, San Diego 1Rady Children’s Hospital San Diego, San Diego, CA; 2University of California San Diego, La Jolla, CA.

Introduction: Neonatal renal replacement therapy (RRT) remains one of the most challenging dialysis scenarios in Pediatric Nephrology. Evaluation of dry weight can be particularly difficult as fluid overload may be mistaken for adequate nutritional weight gain. Physical exam is insensitive in assessing hypervolemia until significant fluid overload develops. Non-invasive BP measurements are often difficult to obtain as upper extremities are typically used for IV access and the patient’s lack of cooperation alters measurement. B-type natriuretic peptide (BNP) has long been used in the evaluation of heart failure and has even been reported to be a marker of fluid overload in adult hemodialysis patients. In this study, we evaluate the role of BNP as a quantitative marker of fluid overload in a neonate with ESRD.

Case Description: A 3 week old child with bilateral renal agenesis required emergent RRT. Following the failure of peritoneal dialysis in this 2.19 kg child, RRT modality was converted to hemodialysis (HD). Despite daily 3 hr HD treatments with ultrafiltration (UF) goals guided by weight, physical exam findings and blood pressure, patient developed bilateral pulmonary edema and an enlarged cardiac silhouette at 3 weeks of age. BNP was found to be > 5,000 pg/mL and RRT modality was changed to CVVHDF. BNP normalized after 4 days of CVVHDF, but upon transition to HD, she again developed fluid overload and required placement back on CVVHDF. Thereafter, BNP was utilized as a quantitative marker of fluid overload with UF goal guided by pre- and post-dialysis BNP levels. Applying this technique, the patient had no further episodes of fluid overload.

Discussion: Providing successful dialysis in infants is more problematic than in older patients. To assess fluid overload in children on dialysis, traditional tools include clinical assessment, serial weights and measuring blood pressure. In this infant, measurement of serial BNP levels allowed for an objective assessment of volume status, which was helpful in maintaining dry weight and lead to successful dialysis therapy.

PO2287

Comparison of Nafamostat Mesylate and Regional Citrate Anticoagulation for Anticoagulation in Pediatric CRRT

Mai J. Miyaw,1,2 Kelli A. Kralman,1 Kentaro Ide,1 Stuart Goldstein,1 Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 2National Center for Child Health and Development; Kokuritsu Kenkyu Kaisha Hojin Kokuritsu Seiiku Iryo Kenkyu Center, Setagaya-ku, Japan.

Background: Regional Citrate Anticoagulation (RCA) is the preferred anticoagulant for CRRT in the US in children. Nafamostat Mesylate (NM), a synthetic serine protease, has been widely used for CRRT anticoagulation in Japan and Korea. While NM is considered safe and effective, there is a paucity of evidence in pediatric literature. We describe the safety and efficacy of NM compared to RCA for pediatric CRRT.

Methods: Using one children’s hospital in Japan and one in the US, medical records of patients <21 years who received CRRT between 2017-2019 were reviewed. Patients receiving CRRT concurrently with ECMO were excluded. Basic demographics, CRRT characteristics, and outcomes were analyzed between the RCA and NM groups. Filter life (FL), defined as the number of hours a single CRRT filter was in use, was the primary efficacy outcome of efficacy. For Kaplan Meier analysis, circuits were censored for elective filter discontinuation. Safety is assessed by anticoagulation complications. Results: 28 pts (100 filters) received RCA and 36 pts (90 filters) received NM. Baseline Table 1. There was no difference in median FL (42.6h in RCA vs 42h in NM, p=0.17). Kaplan-Meier curves of time to spontaneous filter failure shown in Figure 1. The mortality and bleeding rate did not differ between the groups.

Conclusions: NM provides similar efficacy compared to RCA for FL. No significant difference in safety was observed between the two groups.

PO2288

Renal Replacement Therapy and Mortality Rates for Children with Posterior Urethral Valves and Prune Belly Syndrome

Emily J. Stonebrook,1 Yuri V. Sebastião,1 Brian Becknell,1,2 Christina B. Ching,1,2 Daryl J. McLeod,1,2 1Nationwide Children’s Hospital, Columbus, OH; 2Center For Clinical and Translational Research, The Research Institute at Nationwide Children’s Hospital, Columbus, OH; 3Center for Surgical Outcomes Research, The Research Institute at Nationwide Children’s Hospital, Columbus, OH.

Background: Posterior Urethral Valves (PUV) and Prune Belly Syndrome (PBS) cause congenital obstructive uropathy and dysplasia in infants. Resulting chronic kidney disease and pulmonary hypoplasia may lead to renal replacement therapy (RRT), mechanical ventilation and death. Methods: This retrospective cohort study queried The Pediatric Health Information System (PHIS) database to identify patients with PUV or PBS who were born at or transferred to a PHIS hospital by 3 months of age between 1/1/2006 and 9/20/2016. Ethnicity, race and insurance were investigated as predictor variables for time to RRT or in-hospital mortality. Prematurity and mechanical ventilation were evaluated as predictors of in-hospital mortality.

Results: 1673 PUV and 236 PBS patients met inclusion criteria. There was no difference in time to RRT or mortality based on ethnicity, race, or insurance. 212 patients (11.1%) required RRT by 2 years of age. There was no difference in RRT requirement between the PUV and PBS groups. 130 patients (6.8%) died during the initial admission:

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
98 PUV patients (5.9%) and 32 PBS patients (13.6%), with a median time to death of 6.5 days and 2.5 days, respectively. PBS patients had an increased risk of death (Adjusted Relative Risk (ARR) 2.12, p <.0001). The difference in median time to death was not significant. Of 381 (20%) premature patients, 79 (20.7%) died prior to discharge. 696 patients (36.5%) required mechanical ventilation, and of these, 118 (17%) died. Prematurity and mechanical ventilation were associated with an increased risk of death (ARR 2.3, p <0.0001 and ARR 9.9, p<0.0001 respectively).

Conclusions: The severity of the sequelae associated with PUV and PBS is affirmed by the 11.1% risk of early RRT and 6.8% in-hospital mortality. PBS patients did have an increased mortality rate compared to PUV patients. Prematurity or the requirement of mechanical ventilation was associated with an increased mortality rate. Future large, prospective studies will enable investigation of early morbidity and mortality associated with PUV and PBS, as well as long-term outcomes.

PO2289

Preterm Birth in Mice Results in Differential Gene Expression and Premature Cessation of Nephrogenesis

Aleksandra Cwiec,1 Kimberly Deronde,1 Masako Suzuki,1 Kimberly J. Reidy,2 Jennifer R. Charlton,3 Albert Einstein College of Medicine, Department of Genetics and Development, New York, NY; 2Children’s Hospital at Montefiore, Department of Pediatrics, Division of Nephrology, New York, NY; 3University of Virginia, Department of Pediatrics, Division of Nephrology, Charlottesville, VA.

Background: Neonates born preterm are at risk of developing chronic kidney disease (CKD). In humans, nephron development is completed by 36 weeks’ gestation and the successful formation of nephrons is dependent on self-renewing niches of cells which reside directly under the kidney capsule in the nephrogenic zone (NZ). Little is known about the fate of these progenitor cells or the other compartments of the kidney following premature birth. The objective of this study was to characterize the effect of premature birth on kidney development in murine model of prematurity. We hypothesize that preterm mice will have a shorter period of postnatal nephrogenesis and gene expression profiles will reflect premature differentiation.

Methods: Timed pregnant CD-1 dams were stratified into 2 cohorts. The preterm group was comprised of 59 pups born by Cesarean section at 18 days post-conception (dpc) and the term group contained 79 pups delivered vaginally at 20 dpc. The mice were euthanized on 20-27 dpc. The presence of the nephrogenic zone was determined on histological sections. Genome-wide expression profiles of 20 dpc mice kidneys were evaluated with RNA-seq in both preterm and term groups (n=3 per group).

Results: At 25-27 dpc, kidney to body weight ratios were significantly lower in preterm cohort. In the kidney, the cap mesenchyme was not detectable in the preterm mice a full day (23 dpc) prior to its cessation in the term mice (24 dpc). The expression profiles of 20 dpc kidneys in the preterm group showed distinct alterations compared to the term group. The differentially expressed genes were enriched in a fat-soluble vitamin (including vitamin A and D) metabolic process related pathways.

Conclusions: In a mouse model of prematurity, there is an early differential expression of genes that may be important in nephrogenesis. The shortened window of nephrogenesis may result in a lower nephron number and future risk for CKD in neonates born preterm.

PO2290

Gestational Age (GA) Affects Urine Biomarkers by Postnatal Age but Most Converge by 34 Weeks Post-Menstrual Age (PMA)

David J. Askenazi,1 Brian A. Halloran,2 Robert Schmicker,3 Patrick J. Heagerty,2 Sandra Jual,2 Stuart Goldstein,2 Sangeeta R. Hingorani,2 PENUT Investigators1 ’The University of Alabama at Birmingham School of Medicine, Birmingham, AL; 2University of Washington, Seattle, WA; 3Cincinnati Children’s Hospital Medical Center, Cincinnati, OH.

Background: Urine biomarkers may improve our understanding of kidney development and disease in premature neonates. We evaluate how 1-week differences in GA impact 11 biomarkers by postnatal age and PMA.

Methods: Neonates were grouped by GA. Urine was collected on postnatal days 1, 3, 5, 7, 9, 14, 28; on PMA of 30 and 34 weeks; and discharge in 750 neonates without stage 2/3 AKI. Neutrophil-gelatinase associated lipocalin (NGAL), Clusterin, kidney injury molecule 1 (KIM-1), alpha glutathione S-Transferase (a-GST), albumin, beta-2-microglobulin (B2M), cystatin c, epithelial growth factor (EGF), osteopontin (OPN), uromodulin (UMOD) and Creatinine were evaluated by mass spectrometry. Biomarkers are displayed as 7-day rolling mean (day X ± 3 days) on log10 scale. GEE models with mother as a clustering variable were used to determine the association between day, GA, and day*GA for each biomarker. T-tests evaluated differences in 34-week (± 3 days) PMA values.

Results: Figure: Left side plot biomarkers by postnatal age; right side plot biomarkers by PMA. When exploring the values by postnatal age, the most premature neonates have higher NGAL, clusterin, KIM-1, a-GST, albumin, B2M, Cystatin C, OPN, and lower EGF, UMOD and Creatinine (p<0.05; * in Figure) after adjusting for day. The association of biomarker and time is significantly modified by GA for a-GST, Albumin, B2M, Creatinine and Cystatin C (interaction term p<0.05; ** in Figure) over the first 30 postnatal days. Only B2M and OPN differ by GA at 34 weeks PMA (p<0.05; *** in Figure).

Conclusions: Urine biomarkers differ and are modified by GA during first 30 postnatal days. Most biomarkers converge and are not significantly different by 34 weeks PMA.

The Association Between Infantile Pulmonary Hypertension, Sildenafil, and AKI During Hospitalization

Emily E. Zangla, Emily L. Joyce. University Hospitals, Rainbow Babies and Children’s Hospital, Department of Nephrology, Cleveland, OH.

Background: Pulmonary hypertension (pHTN) is a nidus for poor organ perfusion, and is an understudied potential risk factor for acute kidney injury (AKI) in infants. Neither the association between pHTN and AKI, nor treatment with phosphodiesterase-5 inhibitors (i.e. sildenafil) on renal recovery have been elucidated. We sought to describe AKI in a cohort of hospitalized infants with pHTN.

Methods: A retrospective chart review was performed on 18 infants (less than 1 year of age) during the initial hospitalization for diagnosis of pHTN over one year at a single institution. Adapted neonatal KDIGO criteria was utilized to determine presence of AKI during the hospitalization for each patient.

Results: Out of 18 infants with pHTN, 50% developed AKI during hospitalization. Those who developed AKI were older at the age of diagnosis of pHTN (p = 0.04) and more likely to be treated with sildenafil (p = 0.02). Within the cohort, 7 (39%) were treated with sildenafil. On univariate analysis, treatment with sildenafil was associated with increased odds of developing AKI (OR 6.7, 95% CI 0.81-55.0). Of those treated with sildenafil who developed AKI, 80% (4/5) developed AKI before initiation of treatment and 20% (1/5) developed AKI after initiation of treatment.

Conclusions: AKI is prevalent in infants diagnosed with pHTN. The increased odds of developing AKI in patients treated with sildenafil is likely a reflection of severity of illness, as most patients developed AKI prior to initiation of treatment. Further research is needed to evaluate the association between pHTN and AKI, as well as determine the role of sildenafil treatment in preventing AKI or promoting renal recovery.

Baby NINJA (Nephrotic Injury Negated by Just-in-Time Action) Transfusion Rates

Hailey W. Cavigian, Cara L. Slagle, Kelli A. Krallman, Brenda Poindexter, David K. Hooper, Stuart Goldstein. Cincinnati Children’s Medical Center, Cincinnati, OH.

Background: Acute kidney injury (AKI) is associated with poor outcomes in neonates. Nephrotic medication (NTM) exposure is a common cause of AKI. Nephrotic Injury Negated by Just-in-time Action (NINJA) identifies patients with high NTM burden and recommends daily creatinine (Cr) screening. In neonates, concern for iatrogenic anemia decreases AKI screening. We monitored transfusion rates in our project modeled off the neonatal NINJA adaptation, Baby NINJA.

Methods: Critically ill neonates with high NTM exposure initially received modified Cr monitoring (only with routine labs) before transitioning to standard daily Cr monitoring. Patients transfused 3 days into & up to 7 days after Baby NINJA exposure periods counted as an associated transfusion. Statistical process control methods were used to detect changes from baseline. X² and Poisson regression analyses were used to compare metrics between SCI monitoring eras.

Results: Figure 1 shows an increase in transfusions 15 weeks before an increase in Cr compliance. A decrease in transfusions was sustained through the standard Cr era where the highest rate of Cr compliance was seen. The rate of NINJA-associated transfusions was unchanged. Table 1 shows that Cr compliance increased during each era, transfusions decreased between modified & standard Cr era, NINJA-associated transfusions remained stable, and transfusion rate changes were independent of NINJA-associated transfusions.

Conclusions: There was no association between transfusion rates and daily Cr testing with Baby NINJA implementation; therefore, critically ill neonates with high risk NTM exposure can safely be screened for NTM associated AKI.

PO2293

Elimination of Intravenous Phthalate Exposure Abrogates Most Neonatal Hypertension in Premature Infants

Katherine Farnbach, Ryan Forbush, Sandra Irargorri, Randall Jenkins.

Background: The incidence of hypertension in premature infants in a neonatal intensive care unit (NICU) was noted to transiently drop during a 2-year period when the IV fluid (IVF) temporally changed to a phthalate-free IVF. The objective of the study is to quantify the effect of varying periods of IVF phthalate exposure on incidence of hypertension in premature infants.

Methods: A chart review was performed of all hypertensive premature infants born at one NICU during the last 6 years including a 3-year baseline period, a 20-month phthalate-free IVF period, and a 10-month period when the original phthalate-containing IVF returned to use. Patients born during 4-month transitions between periods were excluded. Incidence of hypertension for each period were compared for significant difference using Chi-Square analysis.

Results: Incidence of hypertension decreased from 9.7 cases per year (baseline) to 1.2 cases per year when IVF was phthalate-free, rising back to 12.0 cases per year when phthalate-containing IVF returned to use. Most cases met criteria for the pulmonary category of hypertension – for these infants the incidence of hypertension dropped from 7.3 to 1.2, then increased to 10.8 cases per year when evaluated for the same periods of varying phthalate exposure.

Conclusions: Serendipitous removal of IVF containing phthalates resulted in near elimination of hypertension in one NICU – an effect reversing entirely after the same brand of phthalate-containing IVF returned to clinical use. These results suggest that phthalate exposure from IVF plays a major role in neonatal hypertension, especially for those infants in the pulmonary category.
PO2294

Children with a History of Low Birth Weight (LBW) Show Greater Reduction in Kidney Function Than Previously Described Using the Updated Schwartz Equation

Kaye E. Brathwaite,1 Rebecca Levy,1 Harini Sarathy,2 Ilir Agalliu,2 Tanya S. Johns,3 Kimberly J. Reidy,3,2 Frederick J. Kaskel,1,2 Micah L. Melamed,1,2 Children’s Hospital at Montefiore, Bronx, NY; Montefiore Medical Center, Bronx, NY; 1University Albert Einstein College of Medicine, Bronx, NY; 2University of California San Francisco, San Francisco, CA.

Background: There is a higher risk of reduced kidney function in adults born with LBW (birthweight<2500g). A study using the Counahan-Barrat (CB) eGFR estimation showed a modest risk increase in adolescents with LBW. However the CB equation is only validated in children with CKD and underestimates the burden of CKD. Utilizing the updated Schwartz equation, a more sensitive calculation of eGFR validated in healthy children, we sought to assess the prevalence of reduced kidney function in adolescents born with LBW.

Methods: We performed a cross sectional analysis of children aged 12-15 from the National Health and Nutrition Examination Survey from 1999-2016. Reduced kidney function was defined as eGFR <90mL/min/1.73m². Participant characteristics were described as weighted sample means and proportions. We constructed logistic regression models adjusted for important sociodemographic factors to evaluate the association of LBW with reduced kidney function.

Results: A total of 6345 individuals were analyzed, representing 13,760,132 adolescents of whom 8% had a history of LBW. Of those born with LBW, the median age was 13.6 years, 49% were males, 49% were white, 25% were black, 19% were Mexican-American, and 7% were other race. A higher percentage of children with LBW was seen in worse poverty groups. Mean eGFRs in those born LBW were 103 and 107mL/min/1.73m² using the updated Schwartz and CB equation, respectively. The prevalence of reduced kidney function in those born LBW was greater using the updated Schwartz equation compared to the CB equation. OR 1.51 (95% CI 1.16-1.97) compared to the CB equation, OR 1.44 (95% CI 1.06-1.96). In an adjusted analysis, the odds of reduced kidney function in adolescents with LBW remained significant OR 1.46 (95% CI 1.11-1.97) using Schwartz but not the CB equation.

Conclusions: A higher prevalence of reduced kidney function was seen in children born with LBW utilizing updated Schwartz compared to the CB equation. The higher risk was sustained in adjusted analyses. These findings may support development of guidelines for CKD screening during long term follow up in the pediatric population with LBW.

PO2295

FGCG Renal Biopsy Network: First Epidemiological Report on Pediatric Renal Disease

Noel Knops,1 Johan M. De Meester,1 Amélie Dendooven,2 Wim Laurens,1 Ben Sprangers,2 Elena N. Levchenko,3 AZ Nikolaas, Sint-Niklaas, Belgium;1 Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven Campus Gasthuisberg, Leuven, Belgium; Universitair Ziekenhuis Gent, Gent, Belgium.

Background: In 2016, a regional renal biopsy network was founded as a collaboration between renal pathologists and nephrologists in order to standardize diagnosis and therapy. Uniform renal biopsy request and renal biopsy report forms were introduced, together with a new comprehensive list of renal pathology diagnoses for coding purposes. The Uniform renal biopsy request and renal biopsy report forms were introduced, together with a new comprehensive list of renal pathology diagnoses for coding purposes. The Uniform renal biopsy request and renal biopsy report forms were introduced, together with a new comprehensive list of renal pathology diagnoses for coding purposes.

Methods: Following informed consent and in compliance with GDPR, data registration consists of basic patient and categorical renal data, semi-structured medical information of renal disease, structured information of renal histopathology, and the clinical renal disease.

Results: In 2017 and 2018, 92 renal biopsies were performed in pediatric patients (age = 0-17 years) or 3.6 per 100,000 pediatric inhabitants per year. Three clinical patterns were equally represented: only proteinuria >1g/day; only hematuria; and combination of proteinuria and hematuria. Acute or chronic renal failure were rare. In the youngest age group (0-5 years; N=26) minimal change disease predominated, followed by Henoch-Schönlein nephritis and Alport’s disease. A more diverse renal disease spectrum was present in the highest age group (12-18 years; N=34): IgA nephropathy, different forms of proliferative glomerulonephritis and of nephrotic syndrome of childhood. Patients with a Causacian descent presented with IgA nephropathy, while a nephrotic syndrome was more common in Black and Asian patients. Alport’s disease was particularly diagnosed in female patients, IgA nephropathy in male patients, and the gender distribution was equal in minimal change disease.

Conclusions: The FGCG network provides a better cross-talk between renal pathologists and nephrologists. For the first time, reliable estimates of pediatric renal diseases based on histology are available; genetic analyses are not yet included. Efforts to coordinate clinical care of pediatric renal diseases in the region are ongoing.

PO2296

Developing a Strategy for Routine Reporting of Estimated Glomerular Filtration Rate on Pediatric Laboratory Results

Background: Routine calculation of estimated glomerular filtration rate (eGFR) is not present in laboratory reporting for children, potentially leading to low recognition of decreased eGFR. The study aim was to define options for pediatric eGFR reporting that optimize accuracy and minimize the impact of missing concurrent height in routine lab reporting.

Methods: Data was extracted from the Michigan Medicine Data Warehouse on all patients aged 1-19 years with serum creatinine between 2017-2018. Creatinine-creatinin C-based CKD (Cr-CysC, Schwartz, 2012) and creatinine-based ‘Bedside’ (Schwartz 2009) equations were used to calculate eGFR. Correlations were tested between eGFR calculated with same day height values against eGFR calculated with height imputation of 50th percentile for age and sex or patient-specific historical height percentiles. Scattered plots, Pearson’s correlation coefficients, and predictive characteristics were calculated.

Results: There were 109,090 serum creatinine measurements, and 35% had concurrent heights. There were 1770 Cystatin C measurements. eGFR by Bedside equation was abnormal (>90 mL/min/1.73m²) in 25% of measurements. Cr-CysC (r=0.99) and Bedside (r=0.98) equations had excellent correlations for measured vs imputed 50th percentile height eGFR (Figure). Patient-specific height percentile imputed for the Cr-CysC (r=0.99) and Bedside (r=0.99) eGFR also had tight correlations. Discrimination of abnormal eGFR was excellent for the Cr-CysC (94% sensitivity and 97% specificity) and Bedside (90% sensitivity and 97% specificity) equations using 50th percentile height. Conclusions: Imputation of 50th percentile or patient-specific historic height percentile enables eGFR calculation that correlates with eGFR using same day height. For implementation and with high sensitivity and specificity, use of 50th percentile height may be the preferred approach for pediatric eGFR reporting when patient-specific heights are not available.
PO2298
Measurement of GFR and Vasoactive Substances in Children with Sickle Cell Anemia
Oluwadamilola Ejeke,1 George J. Schwartz,2 Susan Legan,3 Amy M. Becker,4 Raymond P. Quigley,3 1Baylor Medical Center, San Antonio, TX; 2University of Rochester Medical Center, Rochester, NY; 3University of Texas Southwestern Medical Center at Dallas, Dallas, TX; 4Driscoll Children’s Hospital, Corpus Christi, TX.

Background: Patients with sickle cell anemia (SCA) have a high risk of developing renal disease. Sickle cell nephropathy is thought to begin in childhood with higher than normal glomerular filtration rates (GFRs) known as hyperfiltration that can lead to proteinuria, sclerosis of the glomeruli, decreased GFR, and eventual renal failure. This model of sickle cell nephropathy has not been validated in clinical studies. This study measured directly the GFRs of patients with sickle cell anemia and age matched control patients. In addition, urinary vasoactive substances were measured to correlate with the GFR.

Methods: Children with sickle cell anemia (SCA) and sickle-β-thalassemia (HbSβ0) were recruited for the study from the Sickle Cell Clinic at Children’s Medical Center of Dallas. These sickle cell disease genotypes are phenotypically similar and are the most severe. Healthy siblings of children seen in the Pediatric Nephrology Clinic at Children’s Medical Center of Dallas were recruited to serve as controls. GFR was measured directly from isohem clearance. Urine was obtained to measure vasoactive substances.

Results: In conclusion, we have shown that although the GFR in patients with SCA might not be elevated, there appears to be a population of SCA patients with higher than normal GFR. The intrarenal renin-angiotensin system appears to play a role in this hyperfiltration. Further studies are needed to continue to understand this phenomenon.

HbSS urine angiotensinogen/creatinine was significantly lower than control (p<0.005).

PO2299
Food Insecurity During COVID-19 in Children with ESKD: The Second Wave?
Melvin Chan, Amy C. Wilson, Neha D. Pottanat, Michelle C. Starr. Indiana University School of Medicine, Indianapolis, IN.

Background: Food insecurity (FI) affects 1 in 6 children in the US and has increased three-fold during the COVID pandemic. Children with end-stage kidney disease (ESKD) may be at even higher risk of FI due to complex care needs, medication burden and dietary restrictions. A pre-COVID study assessing FI in pediatric hemodialysis (HD) patients described 70% prevalence. No data exists describing the effects of the COVID pandemic on FI in pediatric HD patients.

Methods: We assessed FI among families of patients age 0-18 years with ESKD on chronic HD at a single academic pediatric center. Families were screened for FI by using the Hunger Vital sign, a validated 2 question tool. We assessed impact of COVID on FI in pediatric HD patients.

Results: In conclusion, we have shown that although the GFR in patients with SCA might not be elevated, there appears to be a population of SCA patients with higher than normal GFR. The intrarenal renin-angiotensin system appears to play a role in this hyperfiltration. Further studies are needed to continue to understand this phenomenon.

Conclusions: The frequency of abnormal albuminuria or low GFR in adolescents in the United States is high; for many patients, recent changes are necessary to confirm these findings. The associated factors significantly guide possible toxins that may be associated with the high prevalence of CKD of unknown cause in our state. 

PO2300
Incidence of Hypercalcemia with Calcitriol Compared with Paricalcitol in Pediatric Patients Receiving Hemodialysis
Rohan Dwivedi, Jennifer L. Morris, Jessica Geer, Poyyapakkam Srivaths, Sarah J. Swartz. Texas Children’s Hospital, Houston, TX.

Background: At our institution, both calcitriol and paricalcitol are available for use. Paricalcitol is generally used when adverse effects of calcitriol are observed or during times of calcitriol shortage. There are limited data on the efficacy and safety of vitamin D analogs in pediatric (ped) hemodialysis (HD) patients (pts) to support preference of either agent. This study evaluated the incidence of hypercalcemia in ped HD pts receiving calcitriol compared to paricalcitol.

Methods: Single-center, retrospective review of ped pts on HD treated between January 2012 – December 2018 who received in-center doses of calcitriol or paricalcitol. Pts were excluded if they had in-center doses of both paricalcitol and calcitriol in a 6-month time frame. The primary objective was to evaluate the incidence of hypercalcemia in those receiving calcitriol compared to paricalcitol.

Conclusions: The incidence of hypercalcemia in patients receiving paricalcitol compared to calcitriol was high but did not reach statistical significance. There is no clear advantage seen with the use of paricalcitol when compared to the calcitriol group in peds population.
CI=0.51, 3.42; p=15), adaptive skills (e.g., social skills, adaptability; β=1.03, CI=2.95, 0.89; p=20), or behavioral symptoms (e.g., hyperactivity, conduct problems; CI=0.51, 3.42; p=.15), adaptive skills (e.g., social skills, adaptability; CI=0.51, 3.42; p=.15) were independently associated with CKD progression in children.

Methods: In the prospective CKiD study, children aged 6 months to 16 years old with chronic kidney disease (CKD), but by increasing serum phosphate levels may also increase levels of fibroblast growth factor 23 (FGF23), which is associated with adverse outcomes in both adults and children with CKD. Our objective was to quantify changes in FGF23, α-klotho and vitamin D binding protein (VDBP) in children participating in a vitamin D supplementation trial.

Results: Thirty-four children were included in the analysis; 17 received the intervention dose of 4000 IU cholecalciferol, and 17 received the control dose of 400 IU. The mean (SD) age of the cohort was 10.9 (5.8) years, 26.5% female, 23.5% black, 58.8% white, and 17.7% other race. Mean (SD) GFR at baseline was 60 (17.6) ml/min/1.73m².

Conclusions: Low urine EGF and elevated urine αKIM1 and MCP1 concentrations are independently associated with CKD progression in children.

PO2304

Improving Metabolic Acidosis in Patients with CKD

Heather Morgans, Gina Gregg, Rachel As Cisneros, Rana E. El Feghaly, Darcy K. Weidemann. Children’s Mercy Hospitals and Clinics, Kansas City, MO.

Background: Pediatric chronic kidney disease (CKD) is characterized by multiple metabolic derangements including metabolic acidosis. Untreated acidosis is associated with bone disease, increased mortality, and CKD progression1. Current guidelines

PO2303

Effect of Cholecalciferol Supplementation on FGF-23 in Children with CKD

Sergio M. Chu, Meredith A. Atkinson. Johns Hopkins University, Baltimore, MD.

Background: Cholecalciferol increases total vitamin D levels in children with chronic kidney disease (CKD), but by increasing serum phosphate levels may also increase levels of fibroblast growth factor 23 (FGF23), which is associated with adverse outcomes in both adults and children with CKD. Our objective was to quantify changes in FGF23, α-klotho and vitamin D binding protein (VDBP) in children participating in a vitamin D supplementation trial.

Methods: We utilized stored serum samples from a 4-week pilot randomized controlled trial of supplementation with 4000 (high dose) vs. 400 (DRI) IU per day of cholecalciferol in children with mild-to-moderate CKD. Intact and C-terminal FGF23, soluble α-klotho, and VDBP were measured using commercially-available ELISAs in the Johns Hopkins Institute for Clinical and Translational Research Core Laboratory. Statistical analyses conducted using Stata 14.

Results: Thirty-four children were included in the analysis; 17 received the intervention dose of 4000 IU cholecalciferol, and 17 received the control dose of 400 IU. The mean (SD) age of the cohort was 10.9 (5.8) years, 26.5% female, 23.5% black, 58.8% white, and 17.7% other race. Mean (SD) GFR at baseline was 60 (17.6) ml/min/1.73m². Median (IQR) baseline total vitamin D level was 29 (20, 34) ng/ml in the control arm and 32 (23, 39) in the intervention arm. Total vitamin D level did not change significantly after 4 weeks of supplementation in the control arm, but was increased to 38.5 (31, 50) in the intervention arm (p=0.001). The table compares baseline and 4-week FGF23, α-klotho, and VDBP levels in the control and intervention arms, and no significant differences were noted between the groups who received DRI vs. high dose cholecalciferol.

Conclusions: Cholecalciferol supplementation of 4000 IU/day in children with CKD was not associated with significant differences in FGF23, α-klotho, or VDBP levels compared to children who received only the DRI.

PO2302

Urine Biomarkers of CKD Progression in Children

Jason H. Greenberg, Alison G. Abraham, Yunwen Xu, Jeffrey R. Schelling, Harold I. Feldman, Venkata Sibbsatti, Joachim H. Kx, Bradley A. Warady, Paul L. Kimmel, Joseph V. Bonventre, Michelle Denburg, Chirag R. Parikh, Susan L. Firth. CKD Biomarker Consortium; Yale University School of Medicine, New Haven, CT; Johns Hopkins University, Baltimore, MD; Case Western Reserve University, Cleveland, OH, University of Pennsylvania, Philadelphia, PA; Brigham and Women’s Hospital, Boston, MA; University of San Diego, San Diego, CA; National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; Children’s Mercy Hospitals and Clinics, Kansas City, MO.

Background: Biomarkers of tubular injury, repair, and inflammation may improve the ability to identify children at high risk of rapid kidney function decline and help elucidate the pathophysiology of CKD progression. In this study, we investigated whether the urinary biomarkers EGF, KIM1, MCP1, YKL40, and alphal microglobulin are prognostic of CKD progression in children.

Methods: In the prospective CKiD study, children aged 6 months to 16 years old with an eGFR of 30-90 were enrolled and eGFR was assessed annually. We measured urine biomarkers collected 5 months after study enrollment. Urine biomarkers were indexed to urine creatinine. The primary outcome was CKD progression, defined as a composite of a 50% decline in eGFR or ESKD.

Results: Of the 375 children included, median age was 12 years [IQR, 8-15], 227 (60% were male, and baseline eGFR was 44 [IQR, 35-56]. Overall, 187 children (50%) reached the primary outcome over a median follow-up time of 6.2 years [IQR, 3.0–10.3]. All biomarker levels were higher in children with CKD progression, except for EGF which was lower in those with CKD progression (p for all <0.05). After adjustment for confounders, children with urine EGF concentrations in the highest quartile were at a significantly lower risk of CKD progression compared to those with EGF in the lowest quartile [EGF aHR; 0.20 (95% CI: 0.11-0.39] (Table). Children with urine KIM1 and MCP1 in the highest quartile were at a significantly higher risk of CKD progression compared to those with EGF in the lowest quartile [KIM1 aHR; 2.6 (95% CI: 1.6-4.1), MCP1 aHR; 2.8 (95% CI: 1.7-4.7)].

Conclusions: Low urine EGF and elevated urine KIM1 and MCP1 concentrations are independently associated with CKD progression in children.

PO2306 Determining the Optimal Dose of Cholecalciferol Supplementation for Children with CKD (C, Trial): An Open-Label Multicentre Randomized Controlled Trial
Arpna A. Ivenag,1 Nivedita Kamath,1 Hansa V., Susan Uthup,2 Jyoti Sharma,3 Jyoti S. Singhal,4 Sudha Ekambaram,3 Mandy Wan,5 Rukshana Shroff.3 St John’s Medical College Hospital, Bangalore, India; 4Mehta Hospitals, Chennai, India; 1Government medical college Hospital, Trivandrum, India; 2KEM Hospital, Pune, Pune, India; 3Great Ormond Hospital for Children, London, United Kingdom.

Background: The optimal treatment regimen for correcting 25-hydroxyvitamin D (25(OH)D) deficiency in children with CKD has not been established. We studied oral cholecalciferol treatment regimens that achieve and maintain 25OHD levels above 30ng/ml in children with CKD stages 2-4.

Methods: We performed an open label, multicentre randomized controlled trial in children with 25(OH)D <30ng/ml, randomized 1:1:1 to oral cholecalciferol as 3000IU daily, 25,000IU weekly or 100,000IU monthly for 3months intensive phase therapy. A maximum of 3 courses of intensive phase treatment were allowed if 25OHD was <30ng/ml. Patients achieving normal 25OHD entered maintenance phase with 1000IU cholecalciferol daily for 9 months. Primary outcome was achieving 25OHD levels ≥30 ng/ml at end of intensive phase therapy.

Results: Of the 150 children screened, 90 were 25OHD deficient and randomised to daily(n=30), weekly(n=29) or monthly(n=31) treatment arms. Age, gender, renal disease, eGFR and baseline 25OHD were comparable between treatment arms. At end of the intensive phase, 68.8% achieved 25OHD ≥30ng/ml with comparable levels between arms (median 44.3 39.4 and 39.3 ng/ml p=0.24) on daily, weekly, monthly regimens respectively. The time taken to achieve 25OHD ≥30 ng/ml was comparable between treatment arms (p=0.28) with 7.7% not achieving normal 25OHD after 3 courses. Irrespective of treatment arm, median 25OHD were lower in children with glomerular disease than non-glomerular disease [25.8 vs 41.8ng/ml; p=0.007]. There was no significant difference in 25OHD between treatment arms at end of intensive phase (p=0.24) or maintenance phase therapy (p=0.05).[Figure]. There was no hypercalcaemia or hypercalciuria.

Conclusions: Intensive phase therapy with oral cholecalciferol as daily, weekly or monthly regimens achieved similar 25OHD levels without toxicity. Children with glomerular disease require higher doses of cholecalciferol compared to non-glomerular disease.

PO2305 Factors Influencing Duration of Dialysis in Children with Shiga Toxin-Producing Escherichia coli-Associated Hemolytic Uremic Syndrome (STEC-HUS) at a Single Center
Myida Khalid, Neha D. Pottanat, Chloe Miller, Sharon P. Andreoli. Indiana University School of Medicine, Indianapolis, IN.

Background: More than half the children with STEC-HUS require renal replacement therapy. Several factors influence the duration of dialysis.

Methods: We performed a retrospective cohort analysis using electronic medical records and chart review of 67 patients with STEC-HUS identified through billing data from July 1st 2008 to August 30th 2015. Cases of atypical hemolytic uremic syndrome (HUS), Streptococcus pneumoniae associated HUS were excluded.

Results: The mean age at presentation with STEC-HUS was 4.9yrs (range 0.99-17.16yrs). 44 (66%) were females compared to 23 (34%) males. Data on intravenous fluids (IVF) administration prior to diagnosis of HUS was available in 54 subjects of which 39 (72%) received IVF anytime during four days prior to presentation, and 15 (28%) did not. Of the patients receiving IVF, 22 (56%) required dialysis for an average duration of 11.4d whereas in subjects without IVF, 7 (47%) required dialysis for an average duration of 14.7d, 9 of 55 subjects received NSAIDS during the illness, and six of the nine required dialysis. For these 6 subjects, the average duration of dialysis was 17d compared to 10.3d in subjects without NSAID exposure. We also evaluated patients for antibiotic exposure before and after the diagnosis of HUS. In 30 (53%) subjects without any antibiotic exposure the average duration on dialysis was 9.8d. For 11 (19 %) subjects receiving antibiotics before the diagnosis of HUS average duration of dialysis was 13.6d. Dialysis duration in the 12 (21%) subjects receiving antibiotics after the diagnosis of HUS was 13.3d.

Conclusions: To our knowledge our study is first to evaluate the impact of NSAIDS on the severity of HUS, and demonstrates that the use of NSAIDS in STEC-HUS increases the duration of dialysis significantly. Confirming previous literature, the use of antibiotics results in prolongation of dialysis regardless of the timing of administration. We also note that IVF administration in the first 4 days prior to the diagnosis of HUS may result in a shorter time on dialysis.

PO2307 ESRD Risk in Type 1 vs. Type 2 Childhood-Onset Diabetes Mellitus
Oren Pleneau1,2; Gilad Twig4, Tomer Erlich,2 Lilat Keinan Boker,1 Karl Skorecki1, Ronit Calderon-margalit,1 Asaf Vivante,2 Pediatric Stem Cell Research Institute, Sheba Medical Center, Tel Hashomer, Ramat Gan, Israel; 2Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, Israel; 3Rambam Health Care Campus, Haifa, Israel; 4Israel Defense Forces, Tel Aviv, Israel; 5University of Haifa School of Public Health, Haifa, Israel; 6Hebrew University of Jerusalem, Braun School of Public Health and Community Medicine, Jerusalem, Israel.

Background: Diabetic kidney disease (DKD) is becoming increasingly common among children. We aimed to estimate the risk of end-stage renal disease (ESRD) and mortality among adolescents with type 1 diabetes mellitus (T1DM) or type 2 diabetes mellitus (T2DM) and normal renal function compared to non-diabetics. We hypothesized that childhood onset T1DM vs T2DM would be associated with a different risk profile for developing ESRD and its complications.

Methods: A nationwide, population-based, retrospective cohort study, including 1,500,522 adolescents examined for military service between 1967-1997, which were classified according to the presence and type of diabetes. Data were linked to the Israeli ESRD registry. Cox proportional-hazards models were used to estimate the hazard ratio (HR) for ESRD.

Results: At study enrolment, 1,183 adolescents had T1DM and 196 had T2DM. ESRD developed in 2,386 non-diabetic individuals (0.2%) compared to 72 individuals (6.1%) with T1DM, and 8 individuals (4.1%) with T2DM. Participants with T1DM were younger at ESRD onset than participants with T2DM (median age: 36.0 vs. 40.5 years, P<0.05). In a multivariate model adjusted for age, sex, paternal origin, enrollment year, BMI, and blood pressure, T1DM and T2DM were associated with HR of 36.4 (95% CI,
Prevalence of Renal Dysfunction in Youth with Epidermolysis Bullosa

PO2308

Erica Hughley, Edward Nehus, Bret D. Augsburger, Anne W. Lucky. Cincinnati Children’s Hospital Medical Center, Cincinnati, OH.

Background: Little is known regarding the prevalence of renal disease in youth with epidermolysis bullosa (EB), which we describe here.

Methods: We conducted a retrospective review of electronic health records of 170 (48.8% female, 51.2% male) EB patients aged < 25 years followed by our institution within years 1980-2019. We report the age-based prevalence of hematuria (≥1 red blood cells per high power field) and proteinuria (≥30 mg/dL). We also describe the outcomes of those with persistently abnormal UA, defined as hematuria or nephrotic-range proteinuria on ≥2 consecutive tests. Finally, we compare mortality in EB youth with versus without acute kidney injury (AKI), defined per Kidney Disease Improving Global Outcomes.

Results: The overall prevalence of microscopic hematuria was 22.7%, with no significant difference between sex (p = 0.10). Age-based microscopic hematuria followed a bimodal distribution, with increased prevalence among younger (0-3 years) and older (>12 years) children (p = 0.003) [Fig. 1]. The overall prevalence of proteinuria was 16.9%, with no significant differences between sex (p = 0.35) or age (p = 0.73) [Fig. 1]. 10 patients (5.9%) had persistently abnormal UA, and were diagnosed with: C3 glomerulopathy (4), ureteral strictures (2), infection (2), IgA nephropathy (1), and acute tubular necrosis (1). AKI occurred in 19 patients (11.2%) and was significantly associated with mortality (47.4% in the AKI cohort versus 20.0% in the non-AKI cohort, p = 0.01). Identified causes of death in AKI patients were multiorgan failure including renal failure (3), respiratory failure (1) and severe malnutrition (1).

Conclusions: Many youth with EB have hematuria and/or proteinuria, suggesting glomerulonephritis and/or urologic abnormalities may be underdiagnosed in this population. AKI is significantly associated with mortality in EB youth, with renal failure as a potential common cause of death.

Cumulative ESRD incidence

Clinical Relevance of Fluid Volume Status Assessment by Bioimpedance Spectroscopy in Children on Maintenance Dialysis

Jeewan Min,1,2 Peong Gang Park,1 Ji hyun Kim,1,2 Yo Han Ahn,1,2 Il-Soo Ha,1,2 Hee Gyung Kang.1,2 'Seoul National University Children’s Hospital, Seoul, Republic of Korea; 2Seoul National University College of Medicine, Seoul, Republic of Korea; 3Seoul National University Bundang Hospital, Seongnam, Republic of Korea.

Background: Bioimpedance spectroscopy (BIS) has been used as a noninvasive method to evaluate body fluid volume status in dialysis patients. However, reports in pediatric dialysis patients about the effectiveness of this method are rare. We asked if there is a correlation in the results of BIS and clinical characteristics, and if there is a subsequent change of cardiovascular characteristics in patients whose dialysis prescription was modified based on BIS.

Methods: Medical records of children on maintenance dialysis who were evaluated by multifrequency BIS between January 2016 and December 2019 were reviewed. Their first result of BIS was assessed and fluid overload status was correlated with hypertension, number of oral antihypertensive medications and echocardiography results. In patients with fluid overload, change of dialysis prescription and clinical characteristics over time were reviewed.

Results: Among the 47 patients (male:female 28:19, hemodialysis/peritoneal dialysis 17:30) with a median age of 13.5 years, 13 children were overhydrated with the proportional overhydration relative to extracellular water more than 15%. Majority of children (76.9%) with fluid overload were taking two or more oral antihypertensive medications, while less than half of those without fluid overload were. 11 out of 13 overhydrated children changed their dialysis prescription to reduce their target body weights. Subsequent BIS in overhydrated children revealed a significantly decreased amount of fluid overload (initial: median 22.9%, follow-up: median 13.4%). However, their mean blood pressure (initial: 89.8 mmHg; follow-up: 84 mmHg) and the number of antihypertensive medications (initial: median 2 [0-4]; follow-up: median 2 [0-3]) did not significantly change. Also, none of the children initially overhydrated had their left ventricle hypertrophy changed.

Conclusions: While BIS might be a useful and noninvasive method to assess fluid status, implementation of this tool did not lead to clinically meaningful improvement of cardiovascular characteristics in the children on maintenance dialysis. Long-term follow-up of a larger population and correlation with a more objective clinical indicator of fluid overload such as serum brain natriuretic peptide would be necessary to verify the clinical effectiveness of BIS in pediatric dialysis patients.

PO2310

Variants of SLC34A1, SLC34A3, and AGXT in an Infant with Nephrocalcinosis and Hypercalcemia

Mariah L. Wright. John D. Mahan, Tahagod Mohamed. Nationwide Children’s Hospital, Columbus, OH.

Introduction: Idiopathic infantile hypercalciemia (IHH) is a rare genetic disorder that can lead to neonatal nephrocalcinosis. It is typically caused by loss of function mutations in CYP24A1 or less commonly in SLC34A1. SLC34A1 encodes the NaPi-IIa transporter which aids in phosphate reabsorption in the renal proximal tubules. Defects in AGXT are responsible for primary hyperoxaluria type 1 (PH1). Defects in either AGXT or SLC34A1 can lead to infantile nephrocalcinosis and subsequent renal damage.

Case Description: A term male infant had bilateral hydropneumothorax on prenatal ultrasound. Postnatal labs showed hypercalcemia, hypophosphatemia, high 1,25 dihydroxyvitamin D3 and acute kidney injury. The patient was treated with fluids, furosemide, and calcitonin without significant change in serum calcium. Pamidronate was given which decreased serum calcium and worsened hypophosphatemia. Phosphate supplementation was initiated. Whole exome sequencing revealed two variants in SLC34A1, one of which was pathogenic, and a variant in SLC34A3 of unknown significance. Incidentally, this patient was compound heterozygous for three variants in AGXT: one pathogenic and two benign. After these results, patient was found to have generalized aminoaciduria and mild hyperoxaluria for age. Serum calcium decreased with maintenance of adequate plasma phosphate levels.

Discussion: Compound heterozygous mutations of SLC34A1 can cause IHH type II, and the variant in SLC34A3 could be contributing to this patient’s clinical phenotype in a unique triallelic pattern. The pathologic AGXT gene variant could cause this patient to develop PH1. The combined effects of IHH and PH1 could significantly impact the clinical course of this patient. Mutations in both AGXT and SLC34A1 have not been previously described in the literature. During acute severe hypercalcemia, it might be necessary to use pamidronate to lower serum calcium to levels that are safe for the administration of phosphate supplements.
PO2311
Dent Disease Phenotype Caused by Immunodysregulation Polyendocrinopathy Enteropathy X-Linked (IPEX) Syndrome: Due to Anti-Tubular Basement Membrane Antibody Disease
Raja Dandamudi, Keith A. Hruska. Washington University in Saint Louis School of Medicine, Saint Louis, MO.

Introduction: Immunodysregulation, polyendocrinopathy, enteropathy, X-linked (IPEX) syndrome is an X-linked recessive disorder characterized by autoimmune enteropathy, diabetes mellitus, and hypercholesterolemia, which is commonly associated with anti-TBMMA antibodies. It has been shown that CUL3 gene mutations can cause IPEX syndrome. Mutations in the CUL3 gene have been associated with IPEX syndrome, and it is believed that the pathogenicity of these genes is due to the production of unstable T cells. The purpose of this study was to report a novel case of IPEX syndrome associated with a CUL3 de novo heterozygous c.1376A>T (p.K459M) mutation in the Cullin 3 (CUL3) gene.

Case Description: A 5-year-old male presented at the end of the first month of life, with type 1 diabetes mellitus, hypothyroidism, and chronic diarrhea and diagnosed by IPEX syndrome by c.434C>T; p.Ala 145Val mutation in the FOXP3 gene. He underwent stem cell transplant at 6 months of age from a fully matched unrelated donor. Post stem cell transplant he had recurrent chimerism with low but relatively stable donor T cells. The patient remained relatively stable until 4 years of age when he presented with the clinical picture of Dent’s disease: nephrocalcinosis, tubular proteinuria, Fanconi syndrome (proximal RTA, phosphaturia, calciumuria, glycosuria and aminoaciduria) and renal insufficiency. No disease-causing mutations in CLCN5 gene or the OCRL1 gene were identified on genetic testing. Renal biopsy demonstrated non-sclerotic glomeruli with no capillary loop spike formation, no crescent formation, no endocapillary proliferation, or segmental necrosis. Immunofluorescence showed tubular basement membranes stain with IgG, C3, kappa and lambda. Glomerular basement membranes were negative. Tubular basement membranes show extensive small electron dense deposits without substructure.

Discussion: In this case report we presented child with confirmed IPEX syndrome with nephritic-range tubular proteinuria, proximal RTA, phosphaturia, calciumuria, medullary nephrocalcinosis, and renal insufficiency, in addition to the classical triad of enteropathy, dermatitis and polyendocrinopathy. Our report is the first to document the anti-tubular basement disease clinically manifesting as the Dent’s disease phenotype in association with IPEX syndrome.

PO2312
Severe Hyperkalemia in a 4-Month-Old Female due to Cullin-3 Mutation
Grace C. Yu,1 Faris Q. Hashim,2 Christian Hanna.1 Mayo Clinic Minnesota, Rochester, MN; 1Baylor Scott and White Central Texas, Temple, TX.

Introduction: Pseudohypoaldosteronism (PHA) type II, also known as familial hyperkalemic hypertension, is a rare autosomal-dominant disorder that causes renal tubular acidosis (RTA) type 4, characterized by late-onset hypertension, hyperkalemia, non-gap metabolic acidosis, and low or low-normal plasma renin and aldosterone levels. We present a case of a female infant with PHA type II who presented with asymptomatic severe hyperkalemia due to Cullin-3 Mutation. Treatment with thiazide diuretics resulted in rapid correction of her hyperkalemia.

Case Description: A 4-month-old infant with an unremarkable past medical history presented for management of right neck abscess. Family history was significant for an unspecified seizure and movement disorder in her older sister. She had appropriate growth for her age, with weight, length, and head circumference all measuring around the 20th percentile. Vital signs including blood pressure were normal. Admission laboratories revealed high potassium level of 8.4 mEq/L, low bicarbonate level of 10 mEq/L (normal for age is 19-24), high chloride level of 116 mEq/L (normal for age is 97–108). Anion gap was normal at 10 mEq/L. No electrocardiogram changes were noted. Additional studies revealed positive urine anion gap of 40 mEq/L, a normal serum aldosterone level of 22 ng/dl, and a low renin activity of 0.2 ng/ml/hr (normal for age is 2–27). She received intravenous calcium chloride, sodium acetate, and oral sodium polystyrene sulfonate for hyperkalemia management. Whole exome sequencing revealed a de novo heterozygous c.1376A>T (p.K459M) mutation in the Cullin 3 (CUL3) gene consistent with PHA type II. She was treated with thiazide diuretics, which quickly corrected her hyperkalemia.

Discussion: Our case of PHA type II with a CUL3 pathogenic variant is exceptionally rare, especially given the patient’s age at presentation and the negative family history. Her diagnosis could have been easily missed were she not hospitalized for her neck abscesses. Without genetic evaluation and prompt treatment, this child may have eventually suffered from failure to thrive and hypertension at a later point in life because of chronic hyperkalemia and metabolic acidosis. Primary care physicians and nephrologists should consider the possibility of PHA type II in any child who presents with hyperkalemia and metabolic acidosis with or without hypertension.

PO2313
A Rare Pediatric Case of Karyomegalic Tubulointerstitial Nephritis
Carlos C. Bercerill,1,2 Jodi L. Skiles,1,2 Sushil Gupta,1,2 Indiana University School of Medicine, Indianapolis, IN; 1Indiana University Health, Indianapolis, IN.

Introduction: Karyomegalic tubulointerstitial nephritis (KIN) is a rare type of interstitial nephritis that often progresses to chronic kidney disease. The pathogenesis is unclear but speculated to result from disruptions to tubular epithelial cell division by genetic predisposition or external insults. Only 6 pediatric cases have been reported and maybe this condition is underdiagnosed.

Case Description: A 2-year-old male with history of refractory AML received a matched unrelated donor stem-cell transplant following busulfan, fludarabine, and single fraction total body irradiation. His post-transplant course was complicated by engraftment syndrome, hyperacute graft versus host disease (GVHD), thrombotic microangiopathy, and acute kidney injury. He required ICU stay, treatment with eculizumab and two weeks of renal replacement therapy. His kidney function improved but serum creatinine stayed higher than baseline (picture). Four months post-transplant, he was treated with cefepime, acyclovir, ibuprofen for enterococcus bacteria and pericardial effusion. Seven months post-transplant, while off all immunosuppression, he developed eosinophilia, renal tubular dysfunction with increased serum creatinine. Eosinophilia resolved spontaneously. Bone marrow was negative for leukemia and infectious workup was negative. Eight months post-transplant, he developed GVHD, diagnosis was skin biopsy. He also had persistent high serum creatinine with normal urinalysis. Ultrasound showed echogenic kidneys. Kidney biopsy was performed because of unexplained high serum creatinine. Specimen tissue showed tubulointerstitial nephritis with widespread karyomegaly in medullary tubules. Glomeruli were unaffected. Some cortical tubules showed ultrastructural myelinosomes. His renal function improved with steroids.

Discussion: Our case highlights that KIN can develop in children after chemotherapy. Diagnosis requires high index of suspicion and thorough pathological examination of kidney biopsy specimen. A trial of corticosteroid therapy may be considered.

PO2314
Rescue Therapy with Eculizumab for Catastrophic Antiphospholipid Syndrome in Juvenile Systemic Lupus Erythematosus
Patricia A. Arrovo Pareceo Draver,1 Malek Al Barbandi, Marissa J. Defreitas,1,2 Prabhat Katsoulis,1,2 Jayanti Chandar,1,2 Crornlyn L. Abithol, Wacharee Secherunvong. University of Miami School of Medicine, Miami, FL.

Introduction: Catastrophic antiphospholipid syndrome (CAPS) is a life-threatening condition, and is associated with acute multiorgan failure, small vessels thromboembolism, and elevated markers of antiphospholipid syndrome (APL). Early recognition and prompt treatment can improve the outcome. We present a case of juvenile systemic lupus erythematosus (SLE), who presented with CAPS, refractory to conventional treatment, but rescue with Eculizumab.

Case Description: The patient is a 10-year-old female, previously diagnosed with systemic lupus erythematosus (SLE) without renal involvement and treated with hydroxychloroquine and low dose steroid, who presented with acute kidney injury and hypertensive crisis. On exam, her weight was 31.3 Kg, height 133 cm. Her BP was 185/127 mmHg and pulse 118/ min. Initial investigation showed hemoglobin of 7.2 g/dl, platelet count of 182/xL, BUN 99 mg/dL, Cr 7.86 mg/dL, proteinuria < 10 mg/dL. Urine protein to creatinine ratio was 5 mg/mg. Serum complements were low and had positive serology for Anti-DSDNA, Lupus anticoagulant, Anti-beta 2 glycoprotein, and anticardiolipin. The presumptive diagnosis was CAPS associated with SLE and thrombotic microangiopathy (TMA) which was confirmed by kidney biopsy. She underwent Methylprednisone, therapeutic plasma exchange (TPE), renal replacement therapy and Nicardipine infusion. After 7 sessions of TPE, Methylprednisone, Rituximab, and Mycophenolate Mofetil, her renal function improved and was taken off hemodialysis. Blood pressure was still uncontrolled. She had evidence of on-going hemolysis with undetectable haptoglobin and elevated LDH. Repeat TPE did not control her BP or hemolysis, thus Eculizumab was administered as rescue therapy.
a rescue therapy for TMA associated with CAPS. After 2 weekly doses Eculizumab, her renal function, blood pressure and hemolytic markers were much improved. Currently, her serum creatinine was 1 mg/dL, without significant proteinuria. She remained on 3 antihypertensive medications with good BP control

Discussion: This is a rare but challenging case of juvenile SLE, complicated with CAPS and TMA, who responded partially to conventional treatment. Eculizumab served as a rescue therapy with good result. Our case supports the use of Eculizumab for refractory CAPS in SLE.

PO2315
Hypertensive Crisis in an Infant: The Mass Effect
Jonathan S. Chawla,1 David Manning,2 Isa Ashoor.1,2 1Louisiana State University Health Sciences Center, New Orleans, LA; 2Children’s Hospital New Orleans, New Orleans, LA.

Introduction: It is unusual for congenital hydronephrosis to present with a hypertensive crisis. Recognition of this etiology and prompt urologic intervention to relieve the acute mass effect is critical to prevent further morbidity and mortality.

Case Description: A 3 month-old male with known, mild, right-sided hydronephrosis secondary to ureteropelvic junction obstruction (UPJO) presented to the ED with one week of poor feeding, emesis, and abdominal distension. His recent urine output had been normal. Right upper extremity blood pressure (BP) was recorded as 140/79 mmHg in the ED. Labs were unremarkable with a normal urinalysis and serum creatinine of 0.3 mg/dL. Abdominal ultrasound revealed massive pelvocalyceal system of the right kidney with the kidney parenchyma stretched and thinned over the massively dilated central collecting system. Findings were confirmed on abdominal CT which also revealed profound mass effect on abdominal organs and vessels, specifically compressing and displacing the aorta and inferior vena cava. He was admitted to the pediatric ICU for BP management, which was controlled with IV hydralazine. Pediatric urology placed a percutaneous nephrostomy tube and drained over one liter of urine from the right collecting system. At discharge, the patient was normotensive off medications. A right pyeloplasty was completed shortly following discharge.

Discussion: UPJO is the most common cause of antenatally detected hydronephrosis. The renal pelvis of infants exhibits increased compliance and can accommodate large urine volumes. Kidney function may be preserved or could undergo deterioration depending on UPJO severity. If missed prenatally, infants with UPJO may present with a palpable abdominal mass, urinary tract infection, hematuria, or failure to thrive. Kidney failure and hypertensive crises are rare presentations but are indications for prompt surgical intervention to prevent permanent damage and reduce blood pressure. Infants with preserved function can be monitored conservatively with serial imaging.

PO2316
Missed Diagnosis: A Case of Asymptomatic Isolated Orthostatic Proteinuria from Nutcracker Phenomenon
Anna R. Gaddy, Ranjani N. Moorthi. Indiana University School of Medicine, Indianapolis, IN.

Introduction: In children, proteinuria which exceeds 100 mg/m2 per day or 150 mg per day is considered abnormal. Isolated proteinuria is relatively common, but persistent proteinuria is abnormal and should be investigated. Persistent proteinuria can be further divided into orthostatic subtype if the recumbent Pr/Cr is <0.2 mg/mg but this rises to abnormal (>0.2 mg/mg) after standing. One cause of orthostatic proteinuria is entrapment of the left renal vein, which is known as the Nutcracker Syndrome. Orthostatic proteinuria, isolated hematuria and pelvic congestion pain are the most common manifestations, however Nutcracker Syndrome is highly heterogeneous and frequently missed.

Case Description: We present an 18 year-old female with intermittent proteinuria, hematuria and occasional flank pain for nine years. The patient had proteinuria on dipstick at age eight. At age 15, she again was noted to have proteinuria on serial urinalyses with up to 500mg/dL protein. ANA, anti-dsDNA, C3, and C4 were normal. Renal ultrasound was performed with unremarkable kidneys and urinary bladder. For several years, proteinuria was mild and intermittently negative and no further workup was done. Split urine collection demonstrated minimal protein on first morning void but over 1g/g Pr/Cr by afternoon. We ordered renal ultrasound with Doppler, which demonstrated Doppler ultrasoundography showed the left renal vein had significantly increased flow velocity and appeared to be compressed between the AO and SMA.

Discussion: Differential for etiology of orthostatic proteinuria should include Nutcracker Syndrome as this diagnosis requires a high degree of suspicion. Nutcracker Syndrome can involve proteinuria as well as hematuria but also pelvic pain, back pain, and pelvic congestion symptoms.

PO2317
Rare Presentation of Nephrotic Syndrome in 10-Year-Old Male
Ellen Cody, Katherine A. Vanderheuvel, Mark Mitsniefes. Cincinnati Children’s Hospital Medical Center, Cincinnati, OH.

Introduction: Review nephrotic syndrome 2/2 amyloidosis due to genetic mutation

Case Description: 10 year male w/ mild proteinuria, progressed to UPC of 4mg/mg over months, Cr 0.4, Alb 2.5. Got strep, treated w/ amoxicillin & motrin, after 3 days developed periorbital edema, poor PO, fatigue, admitted. Labs Cr 4.1, Alb 1.1, UPC 31 mg/mg, no blood. RUS b/l enlarged, echogenic kidneys. Biopsy w/ glomerular expanded by amorphous, acellular proteinaceous material in mesangium, walls of arteries and arterioles (Image 1), congophilic on Congo red stain (Image 2), apple green on light birefringence, & tubular injury, final read: amyloidosis and AIN. Completed 3 days of IV steroids for AIN, started colchicine for amyloidosis. Genetics w/ pathogenic Cys59Arg variant of TNFRS1A, c/w TNF Receptor-Associated Periodic Syndrome (TRAPS). Started canakinumab, human monoclonal anti-IL-1 Ab. After 3 months, Cr baseline, no edema, still nephrotic range proteinuria, low alb. MOC w/ ESRD as teen, required dialysis, transplant. Later both kidney and liver failure, died at 31. Diagnosed w/ Familial Mediterranean Fever, as was MGF.

Discussion: Autoinflammatory disease usually presents as intermittent fever, abdominal & joint pain. Second most common is renal involvement, which starts w/ proteinuria, progresses to nephrotic syndrome, renal dysfunction. Diagnosis of amyloidosis based on amyloid fibrils in biopsy of involved tissue, stain positive w/ congo red, apple green birefringence to polarized light. No clear relationship between extent of amyloid deposition & severity of clinical manifestations of renal disease. TRAPS treated w/ directed therapy (IL-1 inhibitor), but difficult to track response to therapy as serum amyloid A not available. Use inflammatory markers (i.e. CRP) given autoinflammatory syndrome.
Cyanotic Nephropathy (CN) in Pre-Fontan Congenital Cyanotic Heart Disease (CCHD) with Solitary Kidney

Kimmie T. Vuong,1,2 Katayoon Shayan,1 Caitlin E. Carter,1,2 Rady Children’s Hospital San Diego, San Diego, CA; 1University of California San Diego, La Jolla, CA.

Introduction: CN is a glomerulopathy seen in patients with CCHD. Chronic hypoxia leads to proteinuria and reduced GFR through tubular and glomerular injury.

Case Description: A 13-year-old male with single kidney and pre-Fontan CCHD presented with hematuria and proteinuria on cardiac transplant evaluation. He had 6 months of symptomatic hypoxia requiring increased supplemental O2, but no other recent illness. Exam was notable for 3/6 pansystolic murmur, tachypnea with clear lung fields, hepatoplenomegaly, cyanotic nailbeds with marked clubbing, but no peripheral edema. 24 hour urine protein measured 4.1g (normal < 0.2g), 38% was albumin. Serum albumin was 3.5 g/l (normal) and eGFR by Cystatin C was 72 ml/min/1.73m2. Hemoglobin was elevated at 20.1 (normal 12.5-16.1 g/dl), C3, C4, ANA, dsDNA, ANCA were normal. Ultrasound showed solitary left kidney with nephromegaly (12.5cm, 1008g/107g), and a solitary cystic mass. Renal biopsy consistent with minimal change syndrome. An initial 60mg/m2 course of glucocorticoids, which was successfully tapered without incident. Patient has since been stably maintained on his prior effective dose of MMF, and has had no relapses since.

Discussion: CN risk factors include duration of hypoxia, elevated hematocrit > 40%, and thrombocytopenia. All were present in our patient. Solitary kidney and elevated venous pressure may have contributed. After heart transplantation, renal function improved with most recent eGFR by Cystatin C 121 ml/min/1.73m2. Treatment and prevention of CN depend on correction of cyanosis. CN has become less common as most children with CCHD undergo Fontan in early childhood. There are limited data about medical management but proposed treatments include renin angiotensin system blockade, beta blocking drugs, diuretics, ivabradine, digoxin, and hydralazine/isosorbid dinitrate. Therapeutic phlebotomy has been reported. To our knowledge this is the first report of CN in a patient with solitary kidney. Low renal mass and baseline glomerular hyperfiltration may increase the risk of CN progression in this subset of patients.

Lupus Vasculopathy Successfully Treated with Eculizumab and Rituximab in an 8-Year-Old Male

Elizabeth A. Black, Erica Winnicki. University of California San Francisco, San Francisco, CA.

Introduction: Lupus vasculopathy of the kidney is a rare form of vascular disease in patients with systemic lupus erythematosus characterized by non-inflammatory, necrotizing vessel wall changes. The pathogenesis may be related to immune-mediated vascular injury from accumulation of immunoglobulins and complement in the vascular wall. Lupus vasculopathy carries a poor renal prognosis, and no standardized treatment has been established.

Case Description: An 8-year-old previously healthy male presented to the emergency department with fever, fatigue, headache, diarrhea, nosebleeds, decreased urine output and lower extremity swelling. He was found to have hypertension, fluid overload, active urine sediment and severe acute kidney injury necessitating renal replacement therapy. He had thrombocytopenia and hemolytic anemia without presence of antiphospholipid antibodies or abnormal ADAMTS13 activity. He met criteria for systemic lupus erythematosus including hypocomplementemia, positive ANA and dsDNA antibodies. Renal biopsy showed class III lupus nephritis and multifocal arterial and arteriolar large intimal complex deposits with endothelial cell necrosis, consistent with a diagnosis of lupus vasculopathy. He received 6 sessions of plasmapheresis without improvement. Based on renal biopsy, he was treated with cyclophosphamide per Euro Lupus protocol. Eculizumab was started for treatment of lupus vasculopathy. His anemia, thrombocytopenia, and proteinuria improved after initiation of eculizumab, but he remained dialysis dependent. Eculizumab was discontinued after 6 weeks of therapy, but he again developed thrombocytopenia, hemolytic anemia, worsening proteinuria and hypertension. These improved after restarting eculizumab. Due to ongoing evidence of lupus activity, rituximab was given after completion of cyclophosphamide. Hemodialysis was discontinued one month after his first rituximab dose with B-cell depletion. He remains on eculizumab therapy and has stable chronic kidney disease stage 2 despite B-cell repopulation.

Discussion: Prior case reports have documented effective treatment of lupus vasculopathy with rituximab. To our knowledge, no data exists on eculizumab for treatment of lupus vasculopathy. Given our patient’s clinical improvement with these therapies, we conclude that more research is needed to define their role in treatment of patients with lupus vasculopathy.
the transcription factor E3 (TFE3) gene. Patient did well post-operatively with no signs of cancer on recent imaging and did not require any chemotherapeutics.

Discussion: This case adds to the field of pediatric renal cell carcinoma and highlights a treatment approach that incorporates religious backgrounds into medical management.

PO2322
IgG4-Related Disease: Nephropathy and Bone Marrow Failure in a 2-Year-Old Child
Eduardo La Porta,1,2 Isabella Pisanì,2 Maura Faracci,1 Francesco P. Pilato,3 Luca Lanino,4 Daniela Verzola,5 Giacomo Garibotto,4 Angela R. Sementa,6 Letizia Gnetti,1 Enrico F. Verrina,1 Istituto Giannina Gaslini, Genova, Italy; Istituto Clinico Ligure di Alta Specialità, Rapallo, Italy; Ospedale Universitario, Parma, Italy; Ospedale Policlinico San Martino, Genova, Italy.

Introduction: IgG4 related disease (IgG4 RD) is a systemic immune-mediated disorder that can potentially affect every organ. It is characterized by fibro-inflammatory tissue damage, IgG4 positive plasma cells, and often by elevated serum IgG4. Renal involvement can include tubulointerstitial nephritis (TIN), membranous glomerulopathy (MGP), and retroperitoneal fibrosis. The disease is more frequent over 50 years of age and only a few cases of IgG4 RD are reported in children.

Case Description: A 2-year-old child was diagnosed with a trilineal bone marrow failure. Bone marrow biopsy showed poor and dyshomogeneous cellularity and lymphoplasmacytic infiltrate organized in follicular structures. Hematologic DNA analyses were negative. IgG subclass analysis showed elevated serum levels of IgG4 subclass (353 mg/dL). Kidney failure was also found (creatinine 1.3 mg/dL, proteinuria, and granular casts). A renal biopsy was performed. Light microscopy showed tubulointerstitial inflammatory infiltrate, thickening of the glomerular basement membranes, and subepithelial deposits Cd4 IF showed subepithelial glomerular IgG deposits with granular pattern and tubular wall deposits; C3 glomerular deposits and focal tubular deposits. A diagnosis of MGP associated with TIN was made. IHC staining for IgG4 demonstrated plasma cells with overlapping positivity for IgG and IgG4. After the diagnosis of IgG4 RKD, a therapy with steroids was started, without clinical response. Thereafter the patient underwent to bone marrow transplant.

Discussion: IgG4 RKD in adults with simultaneous TIN and MGP has been reported in a few cases. This is the first documented case of IgG4 RKD with simultaneous TIN and MGP in a pediatric patient. IgG4 RD is an emerging systemic disease and it should be taken into account in the differential diagnosis in systemic autoimmune diseases, also in pediatrics.

PO2323
Is a Single Static Cut Point Useful to Define Ambulatory Hypertension in Youth? The SHIP AHOY Study
Gilad Hamdani,1 Michael A. Ferguson,4 Marc Lande,2 Kevin E. Meyers,3 Mark Mitsnefes,2 Joshua A. Samuels,1 Joseph T. Flynn,4 Elaine M. Urbina,1 The SHIP AHOY Investigators; Schneider Children’s Medical Center of Israel, Petah Tikva, Israel; University of Rochester Medical Center, Rochester, NY; Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; Seattle Children’s Hospital, Seattle, WA; The Children’s Hospital of Philadelphia, Philadelphia, PA; Boston Children’s Hospital, Boston, MA; University of Texas Health Science Center at Houston, Houston, TX.

Background: Ambulatory blood pressure monitoring (ABPM) is increasingly utilized for the diagnosis of hypertension (HTN). While adult guidelines use absolute blood pressure (BP) cut points to define ambulatory HTN, current pediatric guidelines define ambulatory HTN based on a sex- and height-specific 95th percentile derived from limited pediatric normative data, in which many tall adolescents have a threshold for HTN higher than adult cut-points.

Methods: We compared absolute ABP values with sex- and height-specific ABP percentiles and predictors of left ventricular hypertrophy (LVH) in youth. We measured casual BP, ABPM, anthropometrics, and echo for LV mass index (LVMi) in 357 adolescents (mean age 15.5 ±1.7 years, 63% white, 59% male). ABPM was performed with Omtrax device (Spacelabs Inc., Snoqualmie, WA). ABP index was defined as mean ABP and sex- and height-specific 95th percentile. LVH was defined as LVMi ≥38.6 g/m².7 (pediatric cut-point). Logistic regression was used to assess different ABP measures as predictors of LVH. Sensitivity and specificity of different ABP cut points as predictors of LVH were calculated.

Results: Seventy participants (19.6%) had LVH. Systolic 24-hour, wake and sleep mean BPs and indexes were all significantly associated with LVH. The C-statistics for absolute 24-hour (AUC 0.642 vs. 0.612, p=0.042) and wake (AUC 0.628 vs. 0.590, p=0.03) SBP predicted LVH better than SBP indexes of the same time periods. Absolute SBP cut points also had better balanced sensitivities and specificities in predicting LVH (24-hour SBP 120%: 66% and 61%; wake SBP 125%: 63% and 59%; sleep 110%: 61% and 61%). There was no significant association between diastolic BP measures and LVH.

Conclusions: A single static cut-point using absolute ambulatory SBP is non-inferior to sex-and height-based SBP percentile in predicting LVH in youth. The cut-points for 24-hour and wake ABPM are lower than those for adults but may be used to define ambulatory HTN in this population.

Funding: Private Foundation Support

Table: AUC, sensitivities, and specificities of different ambulatory SBP measures in predicting LVH

PO2324
Proteinuria and Dipping on 24-Hour Ambulatory Blood Pressure Monitoring in Children
Christine Y. Bakhoun,1 Kimmy T. Vuong,1,2 Caitlin E. Carter,1 Pranav S. Garimella,1 Joachim H. Ix,3 Rady Children’s Hospital San Diego, San Diego, CA;1 University of California San Diego, La Jolla, CA.

Background: Absence of nocturnal blood pressure dipping is associated with adverse cardiovascular outcomes in adults. Risk factors for non-dipping in adults include obesity and proteinuria. In children, risk factors for non-dipping have not been well established.

Methods: We identified consecutive patients aged 5 to 19 years who underwent 24-hour ambulatory blood pressure monitoring (ABPM) at Rady Children’s Hospital from August 2018 to January 2019 and had a spot urine protein to creatinine ratio (PCR) measurement within one year of their ABPM. Dipping was defined as a 10% reduction in systolic and diastolic blood pressure from day to night. Multivariable logistic and linear regression models evaluated the association of proteinuria with dipping, employing backwards selection models to retain important confounders.

Results: Seventy-seven children had ABPM and urine PCR assessments during the study period, among whom 27 (35.1%) were non-dippers. Non-dippers had a higher left ventricular mass index as compared to dippers (mean difference 6.9 g/m², 95% CI 1.6 to 12.2). Doubling of urine PCR was associated with 38% higher odds of non-dipping in the multivariable model (Table). Doubling of urine PCR was also associated with a lower diastolic dipping percent by 1.33 (95% CI 0.31 to 2.34), after adjusting for age, body mass index, and estimated glomerular filtration rate.

Conclusions: Proteinuria is significantly associated with non-dipping in children. Pediatric patients with non-dipping should be evaluated with urine PCR, and conversely, those with proteinuria may benefit from a 24-hour ABPM.

PO2325
Association of Environmental Tobacco Exposure with Blood Pressure in US Children
Rebecca Levy,1 Kaye E. Brathwaite,1 Harini Sarathy,1 Kimberly J. Reidy,1 Frederick J. Kaskel,2 Michal L. Melamed,1,2 Albert Einstein College of Medicine, Bronx, NY;1University of California San Francisco, San Francisco, CA.

Background: Hypertension is a leading cause of cardiovascular and kidney disease in adults, and there is evidence that pathologic sequelae begin in childhood and young adulthood. Nicotine and other tobacco compounds have a variety of toxic effects, but to date their associations with chronic hypertension is unclear, especially in pediatric populations.

Methods: We examined the association between tobacco exposure and high blood pressure (HBP) in children who participated the National Health And Nutrition Examination Survey (NHANES) during 2008-2016. Children were classified as having tobacco exposure if they had blood cotinine levels >0.05ng/dL or reported living with a smoker or smoking themselves. High blood pressure was classified according to the 2017 AAP Clinical Practice Guidelines. Analysis was conducted by logistic regression with adjustment for baseline demographics, income and other possible confounders. Subgroup and sensitivity analyses were conducted.

Results: There was a positive association of high blood pressure with tobacco exposure in the study population. After adjustment for demographics, the odds of having high blood pressure was 1.39 (95% Confidence Interval (CI) 1.04, 1.87) for any tobacco exposure compared to no smoking exposure. The association was similar across participant subgroups. The association remained significant by sensitivity analysis using cotinine exposure as a continuous variable. Separately, the odds of having high blood pressure for passive smokers was 1.35 (CI 0.98, 1.85) while the odds for active smokers was 1.71 (CI 1.14, 2.54) compared to participants with no tobacco exposure.

Conclusions: Tobacco exposure is associated with high blood pressure in US children and adolescents.

Hypertension and CKD at 7 Years After Surgical Repair of Congenital Heart Disease in Children
Jason H. Greenberg,1 Michael Zappitelli,2 Heather Thiessen Philbrook,3 Yaqi Jia, Prasad Devarajan,4 Chirag R. Parikh.1 TRIBE-AKI Consortium Yale University, New Haven, CT;2Hospital for Sick Children, Toronto, ON, Canada; 3Johns Hopkins University, Baltimore, MD; 4Cincinnati Children’s Hospital Medical Center Division of Child and Adolescent Psychiatry, Cincinnati, OH.

Background: We previously determined that children who require surgery for congenital heart disease are at an increased risk for hypertension and CKD 5 years after cardiac surgery. This study assessed the long-term risk of hypertension and CKD after cardiac surgery and if these outcomes are sustained.

Methods: We prospectively enrolled children from 1 month to 18 years old, undergoing cardiopulmonary bypass at three centers. Children who survived their surgical hospitalization had blood pressure, urine albumin to creatinine ratio, and serum creatinine measured at two-person follow-up visits (median 5.4 years and 7.4 years after surgery). Hypertension was defined using the American Academy of Pediatrics 2017 Hypertension guidelines. Estimated glomerular filtration rate (eGFR, mg/dL) was calculated using the CKD equation. CKD was defined as the presence of low eGFR (<90 ml/min/1.73m²) or microalbuminuria. We compared the risk of hypertension and CKD status at the 5 and 7-year visits using the McNemar test.

Results: Of 131 children with a follow-up visit 5 years after cardiac surgery, 88 (67%) children participated in the 7-year follow-up visit. The median age of the cohort at the 7-year follow-up visit was 10.7 [IQR: 7.8-13.0] years and 47% were female. 32 children had previously had a septal defect repair, 15 an inflow/outflow tract or valve procedure, 34 had a combined procedure, and 7 were not defined. Separate analysis of the 5-year and 7-year visit revealed hypertension and CKD were sustained in 86 (62%) and 4 (29%) patients, respectively.

Conclusions: The long-term risk of hypertension and CKD were common at the 7-year visit. Compared to the five-year visit, hypertension was sustained in the majority of children. Although CKD was not sustained, there was an increased incidence of new children with GFR<90 at the 7-year visit. The risk factors for sustained hypertension and kidney disease should be further studied in children with congenital heart disease.

PO2327
Evaluating the Role of the Kidneys in Posterior Reversible Encephalopathy Syndrome in Pediatric Patients
Shruti Shah, Andrew M. South. Wake Forest University School of Medicine, Winston-Salem, NC.

Background: Kidney disease is a known risk factor for posterior reversible encephalopathy syndrome (PRES), but the specific markers of kidney function that are relevant to PRES are undetermined. The objective was to investigate the associations of various markers of kidney function with PRES.

Methods: In a case-control study of high-risk children, we recorded most-recent blood urea nitrogen (BUN), documentation of acute kidney injury (AKI), serum creatinine, serum albumin, and hemoglobin level and calculated the estimated glomerular filtration rate (eGFR). PRES cases were confirmed clinically and radiologically. We applied multivariable regression models to estimate the associations of the exposures with PRES. We utilized directed acyclic graphs to inform the following model adjustments: 1) history of kidney disease and nephrotoxic medication exposure for the kidney function models; 2) history of kidney disease, eGFR, and albumin treatment for the serum albumin model; and 3) age, sex, history of kidney disease, eGFR, fluid overload, and nephrotoxic medication exposure for the hemoglobin model.

Results: The mean age of the study population was 9.5 years (±4.9) and 51% were female. Of that population, 29% had a history of kidney disease, 67% had exposure to nephrotoxic medications, and 29% had AKI prior to the onset of PRES. BUN [adjusted OR (aOR) 1.03 per 1 mg/dl increase, 95% CI 0.99-1.07, p=0.09] and AKI (aOR 3.78, 0.68-21.13, p=0.013) were modestly associated with PRES. eGFR (aOR 1.0 per 1 ml/min increase, 0.98-1.02, p=0.17) was not associated with PRES. Hemoglobin (aOR 1.12 per 1 g/dl increase, 0.81-1.56, p=0.48) was not associated with PRES.

Conclusions: In a case-control study of children at high risk for PRES, we determined that among several markers of kidney function, BUN and AKI were modestly associated with PRES. Further prospective studies with larger sample sizes and higher power are necessary to fully evaluate the role of kidney function in the development of PRES.

PO2328
Effect of Hypertension on Childhood-Onset Systemic Lupus Erythematosus in a Tertiary Medical Center in Korea
Jeong yeon Kim, Heeyeon Cho. Department of Pediatrics, Samsung Medical Center; Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.

Background: Hypertension (HTN) is prevalent in childhood-onset systemic lupus erythematosus (cSLE) and affected either by disease activity itself, cSLE medication or both. The purpose of this study is to evaluate the prevalence, clinical characteristics and long-term clinical effect of HTN in Korean cSLE patients treated in tertiary medical center in Korea.

Methods: The medical records of cSLE patients, diagnosed by 2019 SLE European League Against Rheumatism/American College of Rheumatology (EULAR/ACR) classification criteria, who visited Samsung Medical Center from January 2009 to May 2019 were reviewed retrospectively. The disease activity was evaluated by Modified Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) and renal activity (renal SLEDAI) was measured by scores from SLDEA-2K. The long-term damage was evaluated by The Pediatric Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (Ped-SDI). The sex-, age- and height-blood pressure standards recommended by AAP 2017 guideline was used to define HTN. Left ventricular hypertrophy (LVH) was defined by sex, age specific left ventricular mass index (LVMi) at 95th percentile.

Results: Total 32 patients were enrolled in this study. The median follow-up duration was 7.3 year and female was predominant. Median age at SLE and HTN diagnosis were 14.2 and 14.3 year, respectively. Initial renal involvement was detected in 12.5%. The proportion of LN was detected in 84.4% (n=28) and 37.5% of them were class IV (n=12). The prevalence of HTN, including 2 transient HTN, was 34.4% (n=11) and stage 2 HTN was prevalent (n=9). The median dose of steroids, converted to prednisolone, at diagnosis of SLE and HTN were 1.0mg/kg/day and 0.5mg/kg/day. Among cSLE patients with HTN, 21 patients had 3 episodes of posterior reversible encephalopathy syndrome. LVH was detected in 2 patients with HTN. In the cSLE patients with persistent HTN (n=9), lower eGFR (OR=0.9, p=0.031) and higher BMI (OR 1.4, p=0.047) were shown at the time of SLE diagnosis. Every patient with HTN - including transient HTN - in cSLE (n=11) showed lower eGFR at the time of SLE diagnosis (OR 0.9, p=0.029) and higher Ped-SDI (OR 1.8, p=0.047) at last visit.

Conclusions: In conclusion, HTN in cSLE is associated with BMI and renal function at SLE diagnosis. Also, HTN affect long term damage accumulation in cSLE.
PO2329

Hemodiafiltration Maintains a Sustained Improvement in BP Compared with Conventional Hemodialysis in Children: The HDF, Heart and Height (3H) Study

Francesca De Zan,1 Colette J. Smith,2 Aysun Bayazit,3 Karolis Azukaitis,4 Sevean A. Bakkaloglu,5 Fabio Paliglione,5 Mohan Shenoy,6 Manish Sinha,7 Branka B. Spasojevic,8 Claus Peter Schneier,9 Franz S. Schaefer,10 Enrico Vidal,11 Rukshana Shroff,12 University Hospital of Padova, Padova, Italy; 1 UCL Institute of Global Health, London, United Kingdom; 2 Cukurova Foundation Trust, and University College London Institute of Child Health, London, United Kingdom; 9 University Children’s Hospital, Belgrade, Serbia; 12 Great Ormond Street Hospital for Children NHS Foundation Trust, and University College London Institute of Child Health, London, United Kingdom.

Background: Hypertension is prevalent in children on dialysis and associated with left ventricular hypertrophy, cardiovascular disease, and mortality. We studied the blood pressure (BP) trends as well as risk factors associated with the evolution of BP over 1 year in children on conventional hemodialysis (HD) vs hemodiafiltration (HDF).

Methods: This is a post-hoc analysis of the “3H - HDF-Hearts-Height” dataset, a multicenter, non-randomized, parallel-arm observational study. Mean arterial pressure (MAP) derived from 24-hour ambulatory BP monitoring was calculated and hypertension was defined as 24-hour MAP standard deviation score (SDS) <95th percentile.

Results: 78 children on HD and 55 on HDF who were followed-up for 1 year and had three ABPM measures were included. MAP-SDS was under-estimated by pre-dialysis systolic BP-SDS (mean difference: -0.6; 95% LoA -4.9 to 3.8). At baseline 82% on HD and 44% on HDF were hypertensive, with uncontrolled hypertension (BP >95th centile on medications) in 88% vs 25% respectively; p<0.001. At 12-months children on HDF had lower MAP-SDS compared to those on HD in all age groups (p<0.001). Over the one-year follow-up, the HD group had a mean MAP-SDS increase of +0.98 (95%CI 0.77 to 1.20; p<0.0001), whereas the HDF group had a non-significant increase of +0.15 (95% CI -0.10 to 0.40; p=0.23). Significant and independent predictors of MAP-SDS were dialysis modality (p<0.03 [95% CI 0.51 to 1.15] SDS for HD vs HDF, p<0.0001) and higher HDWG (p=0.13 [95% CI 0.06 to 0.19] p<0.0003).

Conclusions: Children on HD had a significant and sustained increase in BP over the 1-year study period compared to an attenuated and non-significant increase in HDF. Volume overload with higher HDWG, but not anti-hypertensive medications, was associated with a higher MAP-SDS in both groups.

PO2330

Novel Nephrin Protein/HLA Class II Complexes: A New Mechanism of Steroid-Sensitive Nephrotic Syndrome

Tomoko Horinouchi,1,2 Yuya Aoto,2 Shinya Ishiko,2 Nana Sakakibara,2 China Nagano,2 Tomohiko Yamamura,2 Takeshi Ninchoji,2 Kandai Nozu,2 Kazumo Iijima,2 1 Department of Immunology, Research Institute for Microbial Disease, Osaka University, Suita, Japan; 2 Department of Pediatrics, Kobe University Graduate School of Medicine, Kobe, Japan.

Background: We have recently identified the risk allele (HLA-DRB1*08:02) and the protective allele (HLA-DRB1*13:02) in the development of childhood steroid-sensitive nephrotic syndrome (SSNS) in a Japanese population (JASN 2018). HLA-DRB1*08:02, DQA1*02:01-DQB1*02:01 was also identified as a risk haplotype in other populations. In addition, we found that NPHS1, coding nephrin, which is a key component of podocytes, was associated with susceptibility to childhood SSNS (Kidney Int 2020). HLA class II genes are associated with susceptibility to many kinds of autoimmune diseases, with one of the mechanisms being misfolded protein/HLA class II complexes that are aberrantly transported to the cell surface inducing immune responses (Jim, Arase et al. PNAS 2014).

Therefore, we investigated the relationship between each HLA allele and nephrin, based on the hypothesis that nephrin protein/HLA class II complexes might be involved in the development of SSNS.

Methods: Nephrin lacking the transmembrane domain (Nephmis) was used as a model of misfolded protein that is not expressed on the cell surface. We co-transfected Nephrmis and HLA-DR to HEK293T cells and assessed the expression patterns by flow cytometry and immunoprecipitation.

Results: Nephrmis was detected on the cell surface in the presence of HLA-DR, which was more intense in the risk alleles than in the protective allele (DRB1*07:01-DRB1*08:02-DRB1*13:02). While Nephrmis communoprecipitated with HLA-DR, Nephrmis was not detected in the absence of HLA-DR. [Discussion] Podocytes are sometimes considered as immunecompetent professional antigen presenting cells because they present antigens on the cell surface via HLA class II and stimulate immune signaling. We showed that the risk HLA DR allele tended to present Nephrmis stronger than the protective allele, suggesting that an immune response could be more easily induced in the risk alleles than in the protective allele. Although there are a variety of possible mechanisms by which HLA polymorphisms could be associated with SSNS, the binding of specific molecules, such as nephrin or HLA mis, and their presentation may provide new insights into the pathogenesis of SSNS.

Conclusions: Our results suggest that nephrin protein/HLA class II complexes can be involved in the pathogenesis of childhood SSNS.

PO2331

Efficacy and Safety of Ravulizumab in Pediatric Patients with Atypical Hemolytic Uremic Syndrome Previously Treated with Eculizumab: 26-Week and 1-Year Data

Larry A. Greenbaum,1 Naoya Fujita,2 Brigitte V. Adams,2 Alvaro Madrid Aris,3 Masayo Ogawa,4 Stephan Ortiz,2 Marc Vallee,3 Kazuki Tanaka,2 1 Emory University School of Medicine and Children’s Healthcare of Atlanta, Atlanta, GA; 2 Aichi Shion Hoken Iryo Sogo Center, Obu, Japan; 3 Alexion Pharmaceuticals Inc, Boston, MA; 4 Queen Fabiola Children’s University Hospital, Brussels, Belgium; 5 Children’s Nephrology and Renal Transplantation Service, Children’s Maternity Hospital Sant Joan de Déu, University of Barcelona, Barcelona, Spain.

Background: The complement C5 inhibitor eculizumab improves outcomes of atypical hemolytic uremic syndrome (aHUS) but must be administered every 2–3 weeks. Ravulizumab, engineered from eculizumab for a longer half-life, is efficacious and safe in adult aHUS with 8-week dosing intervals. This analysis was in eculizumab-treated children with aHUS.

Methods: ALXN1210-aHUS-312 (NCT03131219) is a phase 3, single–arm trial in complement inhibitor-naive children (Cohort 1; reported separately) and children who were receiving treatment with eculizumab without thrombotic microangiopathy (TMA; Cohort 2; reported here). This analysis assessed TMA activity, and the pharmacodynamic measure serum free C5 levels after patients switched from eculizumab to ravulizumab treatment. Patients received loading doses then maintenance treatment with ravulizumab every 4 or 8 weeks, dependent on weight, for 26 weeks. An extension phase is ongoing; here we report data on efficacy through 1 year and safety from all available follow up (median 50.2 weeks).

Results: Ten patients (mean [SD] age 11 [5.0] years) were enrolled into Cohort 2; all completed the 26-week initial evaluation period and entered the extension. Mean eGFR, hematologic outcomes (platelet, lactate dehydrogenase and hemoglobin normalization), and fatigue measures remained stable during both trial periods. At 1-year, the mean (SD) changes from baseline were: eGFR, -3.9 (8.3) mL/min/1.73m2; platelets, −17.8 (54.6) x10^10/L; LDH, −10.7 (19.2) U/L; hemoglobin, −4.5 (7.1) g/L. All patients were in the same eGFR category at 1 year as recorded at baseline (eGFR mL/min/1.73m2 ≥90, n=6; 60–89, n=1; 49–59, n=1). No patients required dialysis. Despite the increased dosing interval, serum free C5 levels were maintained below the threshold of 0.5 mg/mL. All patients experienced adverse events (AEs) but none discontinued the trial. No meningococcal infections occurred. One patient experienced serious AEs due to a respiratory tract infection.

Conclusions: Continued efficacy, no additional safety concerns and the benefit of reduced dosing frequency was demonstrated in pediatric patients with aHUS who were stable on eculizumab and switched to ravulizumab.

PO2332

Typical Hemolytic Uremic Syndrome in Children: A Single-Center Experience

Siddharth A. Shah, University of Louisville, Prospect, KY.

Background: Typical hemolytic-uremic syndrome (HUS) associated with diarrhea can be a fatal disease in children. Diarrhea and blood-stained stools are early symptoms. Oliguria and renal failure can occur anywhere from 3-7 days after onset of diarrhea. Hemolytic-uremic syndrome (HUS) is a life-threatening disease presenting may decrease the need for dialysis. Oligo-amuria at admission and leukocytosis is associated with poor outcomes during hospitalization. After recovery, there is a risk of long-term renal complications such as hypertension, proteinuria, and chronic kidney disease (CKD).

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Methods: We performed a retrospective analysis of 43 children admitted with diarrhea associated with HUS at our center in the last ten years. The ‘late presentation’ defined as serum creatinine >1 mg/dL, oliguria, or anuria at admission. The primary outcome was the presence of long-term renal sequelae. It included proteinuria, hypertension, or chronic kidney disease (CKD) (eGFR <75 ml/min/1.73m2) after one year of disease-onset. The Chi-square and correlation analysis performed on the SPSS platform.

Results: Overall, 32/43 presented late in the disease course, 30/43 required dialysis (median: 8 d), and 8/43 had a recent history of NSAID use. The administration of dextrose and saline containing iv fluids in the early presentation was associated with the decreased requirement of dialysis (p=0.023), but the effect was not significant with NSAID use (p=0.064). Peak white blood cell count (Wbc) had a strong correlation with days of hospitalization (p=0.001). 10/43 children were lost to follow up. 13/33 children showed renal sequelae (3 include with 3 CKD and 1 with ESRD who required kidney transplant) affecting 12/2000 children (p=0.0011) and duration of dialysis-14 days (at p=0.002) were associated significantly with the primary outcome. 6/43 children were un-immunized. There was no mortality.

Conclusions: High peak WBC count may be a useful prognostic marker to evaluate the risk of long-term renal complications. These children need monitoring periodically after disease recovery. Early diagnosis and iv fluids before the onset of renal failure may help to prevent dialysis-related morbidity at the time of admission. More awareness is needed to discourage the use of NSAIDs following initial symptoms of HUS.

PO2335

Hemoglobinuria for the Early Identification of Atypical Hemolytic Uremic Syndrome Relapse: Data from the ItalKid-HUS Network

Gianluigi Ardissono1, Marta Brambilla, Fabio Paglia, Sara Testa, Valentina Capone, Antonio Vergori, Donata C. Cresseri, Giovanni Montini. Ospedale Maggiore Policlinico, Milano, Italy.

Background: Atypical hemolytic uremic syndrome (aHUS) is at risk of relapse any time, thus patients require lifelong monitoring. We suggested that patients could be monitored for relapses, with hemoglobinuria (twice weekly and during intercurrent diseases) based on the hypothesis that a thrombotic microangiopathy involving the glomeruli, cannot take place without hematuria. However this assumption has not been validated.

Methods: The aim of the study is to analyze our experience with the mentioned approach in patients with aHUS who have never been treated (group 1), on treatment (group 2) and who have discontinued C5 inhibition (group 3). The records of all aHUS patients managed or referred to our Center from January 2009 to March 2020 were included and the analysis for the presence of hemoglobinuria was restricted to the period following primary remission with the aim of validating this biomarker as a reliable one for the early identification of relapses. Patients with persistent hemoglobinuria, although in documented TMA remission, were excluded. A positive test was defined as hemoglobin ≥0.5 g/L in documented TMA remission, were excluded. A positive test was defined as hemoglobin ≥0.5 g/L in documented TMA remission, were excluded. A positive test was defined as hemoglobin ≥0.5 g/L in documented TMA remission, were excluded. A positive test was defined as hemoglobin ≥0.5 g/L in documented TMA remission, were excluded. A positive test was defined as hemoglobin ≥0.5 g/L in documented TMA remission, were excluded. A positive test was defined as hemoglobin ≥0.5 g/L in documented TMA remission, were excluded. A positive test was defined as hemoglobin ≥0.5 g/L in documented TMA remission, were included.

Results: 84 patients with aHUS (50% females) were included with 1517 determinations of hemoglobinuria during a cumulative observation period of 261 patient-years (Figure). Hemoglobinuria for the early diagnosis of ongoing aHUS relapse shows a sensitivity of 100% and a specificity of 87.4% with a PPV of 10.5% and NPV of 100 %.

Conclusions: Hemoglobinuria is a very sensitive and acceptable specific marker of aHUS relapse. This finding and its validation may have an important positive impact both on patient’s quality of life and on the outcome of disease via an early diagnosis of relapses.

Extensive Complement Analysis in a C3 Glomerulopathy Cohort of Dutch Children with Benign Outcome

Kloe L. Wijnsma,1 Marloes Michels,2 Roel Kruvers,2 Joanna Van Wijk,2 Antonia Buts,3 Valentina Gracchi,2 Flore Horuz-Engels,2 Mandy G. Keijzer-Veen,2 Eiske Dorrestein,3 Elena Volokhina,1 Lambertus P. Van den heuvel,1 Nick K. Van De Kar,4 on behalf of the COMBAT consortium; 1Amalia Children’s Hospital, Radboudumc, Nijmegen, Netherlands; 2Emma Children’s Hospital, Children’s Hospital, University of Groningen, Groningen, Netherlands; 3Sophia Children’s Hospital, Erasmus Medical Center, Rotterdam, Netherlands; 4University Hospitals Leuven, Leuven, Belgium; 5Wilhelmina Children’s Hospital, Medical Center Utrecht, Utrecht, Netherlands; 6Maastricht University Medical Center, Maastricht, Netherlands.

Background: C3 glomerulopathy (C3G) is a rare renal disorder driven by dysregulation of the complement alternative pathway (AP) and characterized by predominant C3 depositions in the glomeruli. C3G can be subdivided in dense deposit disease (DDD) and C3 glomerulonephritis (C3GN). Patient cohort studies including clinical features offer important data in rare renal diseases. Moreover, biomarkers are increasingly used to select patients for clinical trials with novel complement-targeting therapies. This retrospective study describes complement biomarker profiles and outcome of 29 Dutch children.

Methods: Patients with a C3G diagnosis from 5 Dutch university medical centers (1992-2014) were included. Clinical, genetic, and laboratory findings were retrieved from patient files. Specialized biochemical assays were used to detect complement-directed autoantibodies and complement biomarkers. Results: A total of 29 patients with DDD (n=19) and C3GN (n=10) were included. Median (IQR) follow-up was 51 months (26-90). Patients presented with proteinuria and hematuria (>90%) and low serum C3 levels (84%). Ten patients (35%, 8 DDD, 3 C3GN) presented with an impaired glomerular filtration rate (GFR). DDD patients presented at younger age and with a lower GFR (P<0.05). C3 nephritic factors were found in 10 patients. 3 patients carried rare genetic variants in AP genes. Elevated levels of the complement activation markers C3d, C3bBbP, and C5b-9, combined with lowered C3 and C5 levels, indicated AP activation in the acute phase. Taking longitudinal data into account, a linear mixed model showed that C3G patients had higher C5b-9 and lower C3 levels than DDD patients (P<0.05). During follow-up, 13 (45%) patients experienced a relapse. No significant differences in clinical or laboratory features were observed between patients with and without a relapse and persistent renal sequelae. At last follow-up, only 4 patients (14%; all DDD) had a GFR below 60 ml/m²/1.73².

Conclusions: We present the extensive description of clinical, genetic, and biochemical complement features of a large pediatric C3G cohort. In most patients AP abnormalities were found. Overall, the outcome of the patients we described was relatively benign.

PO2337

Comparison of Clinicopathological Findings Between Childhood IgA Nephropathy and IgA Vasculitis Nephritis Using Oxford Classification

Yuko Shimaa,1,5 Keichi Nakashianii,1 Hironobu Mukaimii,1 Yu Tanaka,1 Takuzo Wada,1 Kandai Nozui,3 Ryojiro Tanaka,1 Kazumoto Kazumoto1,5 Nishio Yoshikawa1,5 and Norio Kato1,5

Background: IgA nephropathy (IgAN) and IgA vasculitis nephritis (IgAVN) are nephritis with a common pathological feature of significant mesangial IgA deposition, but it remains controversial whether they are the same disease.

Methods: We compared clinical and pathological findings between 148 patients with IgAN and 100 patients with IgAVN who underwent renal biopsy from April 2000 to April 2019 to clarify the differences.

Results: Clinical findings showed significant differences in onset age (IgAVN vs IgAN, 10.7 vs 5.7 years, p<0.0001), duration of onset to renal biopsy (1.7 vs 6.6 months, p<0.0001), and amount of proteinuria (1.8 vs 0.5 g/gCr, p<0.0001). Pathological findings by Oxford classification showed significant differences in the frequency of M1 (90.8 vs 59.2%, p<0.0001), S1 (21.2 vs 9.2%, p=0.004), T present (28 vs 46.1%, p=0.004), G present (72 vs 58.1%, p=0.03) and P present (8 vs 19.1%, p=0.01), but no difference in that of E1 (52.8 vs 55.0%, p=0.75). Fluorescence findings showed significant difference in the frequency of fibrinogen deposition (93.3 vs 74.6%, p<0.0004) but not in that of glomerular peripheral capillary IgA deposition (86 vs 89.5%, p=0.35). Electron microscopic findings showed significant difference in the frequency of GBM lysis (35 vs 22.0%, p=0.0001). Degree of proteinuria is positively correlated with the frequency of M1 in IgAVN.

Conclusions: IgAVN has higher frequency of M1 lesion regardless of degree of proteinuria and frequency of chronic lesions such as S, T, and G, and higher frequency of acute lesions such as M and C compared with IgAN. Although IgAVN had some pathological similarities to that of IgAN, there seems to be differences which cannot be explained by the timing of renal biopsy.

PO2338

Race and Age at Onset of ESRD in Patients with Alport Syndrome

Sarah J. Kizilbash,1 Blanche M. Chavers,2 Clifford E. Kashtan.1 University of Minnesota Academic Health Center, Minneapolis, MN.

Background: Angiotensin-converting enzyme (ACE) inhibitors have been shown to delay the onset of end-stage renal disease (ESRD) in both animal models and humans with Alport syndrome. In 2013, expert guidelines recommended the use of ACE inhibitors to slow the onset of ESRD. We examined temporal changes in the age at onset of end-stage renal disease (ESRD) and interaction between race and age at ESRD for patients with Alport syndrome.

Methods: We used the Scientific Registry of Transplant Recipients to identify all patients who received a kidney transplant in the United States for Alport syndrome between 1987 and 2017. We divided the study period into three equal eras (era 1, 1987-1997; era 2, 1998-2007; and era 3, 2008-2017) to assess changes in age at ESRD using a linear regression model adjusting for race and gender. Age at ESRD was defined as the earlier of the age at dialysis or the age at kidney transplantation.

Results: Between 1987 and 2017, 4105 Alport patients received a kidney transplant in the United States. Of these patients, 3115 (75.9%) were male and 3176 (77.4%) were white. Pre-emptive transplants were performed in 962 (23.4%) patients. Table 1 demonstrates temporal changes in median age at ESRD, demographic and clinical characteristics for patients with Alport syndrome. After adjusting for race and gender, the age at ESRD increased by a mean of 2.7 years (SE 0.51, p<0.01) for eras 2 and 4.4 years (SE 0.51, p<0.01) for era 3 compared with era 1. We also observed that age at ESRD was significantly lower for black (-9.3 years, p<0.01), Hispanic (-9.4 years, p<0.01), and Asian (-8.9 years, p<0.01) compared with the white race (Table 2).

Conclusions: The age at ESRD for patients with Alport syndrome has progressively increased over the last 30 years. White patients have delayed onset of ESRD compared with patients of other races.

Temporal changes in ESRD and transplant characteristics

PO2339

Risk of Rituximab-Associated Severe Adverse Events Increases with Young Age in Children with Nephrotic Syndrome

Camille Laroche,1 Dominique Lemieux,2 Anne-Laure Lapeyrque,2 Adrien Flahault.1 1Centre Hospitalier Universitaire Sainte-Justine Centre de Recherche, Montreal, QC, Canada; 2Centre Hospitalier Universitaire Sainte-Justine, Montreal, QC, Canada.

Background: Rituximab prevents relapse in steroid-dependent frequently relapsing nephrotic syndrome (SDFRNS). We aimed to assess the safety of rituximab in children with steroid-resistant nephrotic syndrome (SRNS) or SDFRNS.

Methods: This single-center retrospective study included all children with SRNS/ SDFRNS treated with rituximab since 2007 at our institution. All information concerning adverse events (AE) were obtained from medical records. Severity of adverse events was graded according to the Common Terminology Criteria for Adverse Events. We performed a time-to-event analysis and log-rank tests or proportional hazards models to determine hazard ratios (HR) with 95% confidence intervals (CI) of risk factors associated with severe AE (SAE).

Results: Of the 38 children included in this study, most had a SDFRNS (n=36, 97%). Median age at diagnosis was 3.4 (interquartile range, 2.4-6.2) years and median age at rituximab initiation was 9.0 (6.8-11.6) years. Median [95% CI] time to relapse was 1.4 [1.16-2.27] years. Median follow-up time was 3.7 (2.2-4.9) years. No patient died during follow-up. Fourteen SAE occurred in 12 (32%) patients, including one case of Pneumocystis jiroveci pneumonia, 6 cases of severe neutropenia and 2 cases of inflammatory colitis. Rituximab initiation before 10 years of age was associated with a higher risk of SAE (HR [95%CI], 11.3 [1.44, 88.6], Figure 1) and all SAE occurred in children aged <10 years except for anaphylactic reactions. The occurrence of a SAE was not associated with an increased risk of relapse.

Conclusions: A young age at rituximab initiation for SRNS/SDFRNS is associated with an increased risk of SAE. Rituximab should be used with particular caution in children under 10 years old.

Evaluating Nephrotic Syndrome Response to Rituximab in Children

Anna E. Williams, Katherine Twombley, Annabelle N. Chua, Raheed A. Gbadegesin.* Duke University, Durham, NC; *Medical University of South Carolina, Charleston, SC.

Background: Nephrotic syndrome (NS) is the most common cause of glomerular disease in the pediatric population. In children, 80% of cases are steroid sensitive (SSNS) & 20% are steroid resistant (SRNS). Rituximab (RTX) has been identified as a steroid-sparing therapy with minimal nephrotic side effects. The determinants of clinical response to rituximab is not completely known.

Methods: A retrospective review of patients aged 0-21 years with idiopathic NS who received at least 2 doses of RTX therapy over 6 years. Data collected included gender, race, ethnicity, age at diagnosis, steroid response, number of RTX doses, CD20 levels post therapy & outcomes. Outcome was defined as complete remission, CR (urine protein <30 mg/day), partial remission, PR (UPCR 0.3-1.9) & no response, NR (UPCR ≥2). Data were compared by Fisher’s exact & Wilcoxon Rank Sum tests.

Results: 48 patients met the inclusion criteria for the study comprising of 23(48%) with SSNS & 25(52%) with SRNS. There was no difference in race or age of onset between the patients with SSNS & SRNS. 18(37.5%) of patients who had CD20 lymphocyte levels measured following treatment achieved therapeutic end point of CD20 lymphocyte depletion. There was no difference in the proportion of patients who achieved this therapeutic end point between the patients with SSNS & SRNS (46% vs 72%). Overall, 72% of patients achieved partial or complete remission. The remission rate was significantly higher in the SSNS group compared with the SRNS group (87% vs 58%, p=0.001); however, there was no difference in remission rate between patients who achieved the therapeutic end point of CD20 lymphocyte depletion & those who did not in the entire cohort (56% vs 55%, p=1.0) as well as in subgroup of patients with SSNS & SRNS.

Conclusions: Children with both SSNS & SRNS achieved the desired therapeutic effect of CD20 lymphocyte depletion following treatment with RTX; however, disease remission rate was higher in children with SSNS. This data suggests that RTX can be administered at any phase of the disease (relapse or remission) without jeopardizing clinical response.
PO2343
Caregiver Perspectives of Pre-Transplant Evaluation for Children
Eloise Salmon,1 Laura Barr,2 Douglas Hill,1 Sandra Amaral,1 1Children’s Hospital of Philadelphia, Philadelphia, PA; 2University of Pennsylvania, Philadelphia, PA.

Background: Pre-transplant evaluation is mandated by Centers for Medicare and Medicaid Services, but there is institutional variation in implementation. The family experience of this process also is incompletely understood. Current literature largely focuses on adult transplant recipients. Our interview study aims to fill the knowledge gap about family experience of the evaluation for children.

Methods: Interviews took place 07/2019 - 02/2020 with caregivers of children referred for kidney transplant at our center 07/2017 - 12/2018. The interview guide included closed- and open-ended questions; responses were audio-recorded and then transcribed for coding of themes. Respondents also completed a brief electronic questionnaire.

Results: Our team interviewed 19 children; demographics in Fig. 1. Prominent themes included (1) the pre-transplant evaluation is overwhelming and emotional, (2) prior experiences and background knowledge are influential and (3) frustration with communication among teams was common. Fig. 2 highlights representative quotations from caregivers.

Conclusions: These findings are relevant to efforts by nephrologists to optimize delivery of information about transplant and other complex topics. The data highlight the importance of (1) acknowledging the scope of content and continually reevaluating accessibility of delivery (2) recognizing the influence of prior experiences and tailoring elements accordingly for increased family-centeredness and (3) making concerted efforts to define roles and set expectations, especially when multiple teams are involved in care.

PO2344
Treatment-Related Anxiety in Children After Kidney Transplant
Michelle N. Keyser,1 Elizabeth G. Ingulli,2 Euyhyun Lee,1 Paul Riviere,1 1University of California San Diego, La Jolla, CA; 2Rady Children’s Hospital, UC San Diego, San Diego, CA.

Background: An increasing number of children experience anxiety and pediatric kidney transplant recipients are particularly susceptible to mental health conditions given the impact of their complex chronic medical histories on their quality of life. We performed a retrospective study to assess the impact of anxiety on health-related quality of life (HRQoL) in pediatric kidney transplant recipients in order to design targeted interventions to improve HRQoL after transplant.

Methods: We retrospectively analyzed scores from the disease-specific PedsQL 3.0 ESRD and Transplant Modules in pediatric ESRD and transplant patients ages 2-18 years between 2014 and 2019 at Rady Children’s Hospital. We used a linear mixed-effects model with a random intercept and ANOVA with Tukey post-hoc tests to analyze the effect of variables of interest on HRQoL in various groups.

Results: 180 modules were completed by pediatric patients who received dialysis and/or transplantation. Transplant recipients had significantly better total HRQoL scores compared to dialysis patients (p < 0.001). Treatment-related Anxiety was the lowest (worst) scoring domain among kidney transplant patients (p = 0.01), especially among patients ages 5-7 years old (p = 0.009). Patients 13-18 years old had the lowest scores in the Transplant domain, which measures social isolation related to a patient’s transplant (p = 0.008). Variables such as age at diagnosis, time on dialysis, diagnosis category, and time to transplant were not significant predictors of HRQoL.

Conclusions: These data suggest that children with kidney transplants have better HRQoL compared to children on dialysis. However, transplant recipients experience high rates of anxiety and social isolation. This may simply reflect the psychosocial stress surrounding medical care, but we may also be capturing more nuanced psychological issues in this population that requires further evaluation. Since transplant patients typically have frequent access to medical care, we have established a multi-disciplinary model in our clinic in part based on these data that utilizes psychologists to address acute and chronic psychological concerns simultaneous with their medical visits. This model may improve the HRQoL of transplant patients without increasing the overall burden of medical care and may have broader applicability to the general population of children with anxiety.

PO2345
Vaccination Status in Pediatric Kidney Transplant Recipients: An Integrated Pediatric Transplant Research Database Study
Jaya S. Parulekar,1 Eric J. McGrath,1 Amrish Jain,1 1Wayne State University School of Medicine, Detroit, MI; 2Division of Pediatric Nephrology, Children's Hospital of Michigan, Detroit, MI; 3Division of Pediatric Infectious Disease, Children’s Hospital of Michigan, Detroit, MI.

Background: The American Society of Transplant recommends candidates be immunized before transplantation. However, there is limited data on pre/post-transplant vaccination status for children with kidney transplants. Our study evaluates vaccination rates & an approach to increasing vaccination in our kidney transplant program.

Methods: Pediatric kidney transplant recipients at Children’s Hospital of Michigan from 2013-2019 were included. Official immunization records were obtained from the State of Michigan’s Michigan Care Improvement Registry. During the pre-transplant period, age-based catch-up or accelerated immunization was performed at primary care provider’s or at the in-house immunization center. Demographic, clinical & serology data were entered into an integrated database created through REDCap and analyzed with SPSS Version 26.

Results: Included were 58 children with mean age at transplant of 11.9±5.7 yrs, 66% Male, 52% African-American, 31% Caucasian, 76% deceased donor transplants & 10% re-transplants. Median duration of follow-up was 3 yrs. Pre-transplant vaccination rates of ≥95% were achieved for all vaccines, except PCV13 (69%), PCV23 (62%) & HPV4/9 (86%). Pre-transplant serology for HepA, HepB and Varicella showed immunogenicity of 95%, 93%, 88% respectively. Catch-up & accelerated immunization increased the vaccination rate to 100% from 53% (Varicella); 57% (HepA); 73% (MVC); 72% (MMR). Post transplant vaccination series was a 95% complete for all vaccines except PCV23 (43%); HPV4/9 (37%); MVC (30%).

Decreased CD28 Expression in Memory CD4+ T Cells in Children Awaiting Kidney Transplant Is Associated with Increased Expression of Senescence Markers
Charlotte Duneton, Roshan P. George, Mandy L. Ford, Pamela D. Winterberg, Emory University, Atlanta, GA; Children’s Healthcare of Atlanta Egleston Hospital, Atlanta, GA.

Background: Despite improved patient and graft outcomes with CD28-CD80/86 costimulation blockade, increased early acute rejection has hindered the widespread use of CTLA-4Ig (belatacept) for kidney transplant. Our group has previously reported lower pre-transplant frequencies of CD28 effector helper T cells (CD4+TEM) in children awaiting kidney transplant. We aimed to determine if a similar T cell phenotype is detectable in children awaiting kidney transplant.

Methods: We analyzed existing flow cytometry data of unstimulated blood cells collected from children on dialysis (n=30) or healthy children (n=18) and examined expression of markers of costimulation (CD28), senescence (CD57, PD1), activation (CD45RA) and cytolytic effectors (Granzyme B, Perforin) on memory CD4+ T cells.

Results: None of the children had CD28+CD45RA-CD4-TEM frequencies as low as those we have previously observed in adults that were rejection-free on belatacept. However, 8 children on dialysis (27%) had CD28+CD45RA-CD4-TEM frequencies below the minimum value observed in healthy children (Fig1A-B). Patients with this “stable-like” T cell phenotype had higher frequency of CD4+TEM cells bearing senescence markers (CD57+Fig 1C) and cytolytic effectors (Granzyme B, Perforin, Fig 1D) but decreased activation markers (CD38+ Fig 1E).

Conclusions: Despite their young age and limited antigen experience, a subset of children on dialysis accumulate CD4+TEM cells that have lost CD28 expression and bear markers suggestive of impaired function, a phenotype reminiscent of adults with early rejection on belatacept. We aimed to determine if a similar T cell phenotype is detectable in children awaiting kidney transplant.

PO2347
Predicting Allograft Survival in Young Pediatric Kidney Transplant Recipients
Florian Manca Barayre, Jerome Harambat, Amelia Le Page, Stephen D. Marks, Chanel Prestidge, Matthew P. Sypek, Stephen P. McDonald, Rachel E. Patzer, Julien Hogan, Emory University School of Medicine, Atlanta, GA; Robert-Debré Hospital, APHP, Paris, France; Bordeaux University Hospital, Bordeaux, France; Monash University Faculty of Medicine Nursing and Health Sciences, Clayton, VIC, Australia; Great Ormond Street Hospital For Children NHS Foundation Trust, London, United Kingdom; Starship Children’s Health, Newmarket, New Zealand; Australia and New Zealand Dialysis and Transplant Registry, Adelaide, SA, Australia.

Background: Kidney transplantation (kTx) presents specific challenges in younger recipients. There are no predictive model of renal allograft loss in young pediatric recipients to inform donor selection. We aimed to develop and validate a predictive model of graft loss in an international cohort of young kTx recipients.

Methods: We included first-time kTx recipients under 5 years of age in the USA, Australia, New Zealand, UK and France between 2005 and 2018. A multivariate Cox regression was used to develop a predictive model of graft loss or death on the US cohort. Model discrimination (C-statistics) and calibration were assessed internally and externally on the non-US cohort.

Results: 2543 kTx in children <5 years old were included. 10-year overall graft survival rate was 80.0% [95% CI = 77.7% – 82.2%]. Given the interaction between some predictors and recipient’s age, we developed two models stratified on recipient age (cut-off: 36 months) including donorrecipient body surface area ratio, ischemia time, donor weight and immunological matching. Immunological matching was a stronger predictor among older recipients, while morphological variables were stronger predictors in younger recipients. C-statistics on the training cohort were 0.63 (95% CI = 0.57 – 0.68) and 0.65 (95% CI = 0.59 – 0.71) and the models were well calibrated. Figure 1 presents the discrimination of the models at different time horizons and the calibration at 10 years on the validation cohort.

Conclusions: We confirm the overall good renal allograft survival in children transplanted under the age of 5. We developed and validated predictive models of graft loss or death based on pre-transplant factors in this population that may be used to inform donor selection.
PO2348
Safety and Efficacy of Low-Dose Rabbit Antithymocyte Globulin in Pediatric Renal Transplant Recipients
Vaka K. Sigurjonsdottir,1,2 Paul C. Grimm,1 Abanti Chaudhuri,1 1Landspitali, Reykjavik, Iceland; 2Stanford University, Stanford, CA.

Background: Currently there is no consensus among pediatric kidney transplant centers regarding the use and regimen for immunosuppressive induction therapy. The safety and effectiveness of reduced Rabbit Antithymocyte Globulin (rATG) ≤ 3.5 mg/kg cumulative dosing as induction therapy in low risk pediatric kidney transplant recipients is unknown.

Methods: Pediatric renal transplant recipients transplanted 1/1/2013-5/1/2018 were considered for inclusion. Recipients of deceased or living donor organs and with least 12-month follow-up were included. “High risk” was defined by a repeat transplant, preformed donor specific antibodies (DSAs), peak panel-reactive antibodies ≥20%, or African-American race. Maintenance immunosuppression protocol was tacrolimus and mycophenolate mofetil, steroid free unless high risk. Outcomes were de novo DSA (dnDSA) formation, graft survival, biopsy proven rejection (BFR) and EBV/CMV/BK viremia infection during the first 12 months. DSAs were routinely screened at 3.6 and 12 months. Protocol biopsies were done at 6 and 12 months and graded with Banff criteria. Subclinical/borderline findings were included with or without treatment. Additional DSA testing and/or biopsies were done if there was a clinical concern. Group 1: low risk patients, ATG dose of ≤ 3.5 mg/kg, Group 2: low risk patients receiving dose of >3.5 mg/kg and Group 3: high risk patients.

Results: A total of 181 patients met inclusion criteria. Age of patients was 11 years (11 mo-21 y), median (range), 21% received a living donor transplant and 49% were female. Graft survival and dnDSA formation did not differ significantly between the three treatment groups. Graft loss at 12 months was a rare event with 99.5% graft survival and patient survival was 100%. Patients outcomes based on groups is shown in the table.

Conclusions: Reduced ATG dosing (≤ 3.5 mg/kg) when compared with higher dosing (>3.5 mg/kg) is safe and effective. Reduced ATG dose was associated with lower rates of BK viremia and BK nephropathy without increasing risk of dnDSA or BFR.

PO2349
Pediatric-Specific Models Improve Prediction of Kidney Transplant Survival for Children Under 5 Years Old
Florian Manca Barayev,1 Larry A. Greenbaum,1 Rouba Garro,1 Pamela D. Winterberg,1 Rachel E. Patzer,1 Julien Hogan.1,2 Emory Transplant Center 1Emory University, Atlanta, GA; 2Robert-Debré Hospital, APHP, Paris, France.

Background: The kidney allocation system directs high-quality kidneys to pediatric recipients, but the kidney donor profile index (KDPI) used to quantify donor quality may not accurately predict graft survival in small pediatric recipients. We aimed to determine if a pediatric-specific KDPI could improve the prediction of graft longevity for young recipients.

Methods: We evaluated first-time kidney transplantations in pediatric recipients between 1/2005 and 8/2018 in the U.S. (SRTR) and used a Cox model to assess KDPI accuracy for combined primary outcome of death or graft loss in young recipients. We developed an adapted KDPI score for recipients ≤5 years old of deceased (SP-KDPI) or living (SP-LKDPI) adult donor transplants using multivariate cox regression and scaled these models to allow comparison between living and deceased donors. Models’ accuracies were validated internally by cross-validation.

Results: KDPI C-statistic was 0.52 (95% CI = 0.50 – 0.54) in recipients less than 5 years old. Ethnicity, age, body surface area, gender, cold ischemia time and number of HLA-A and -B mismatches, were significant predictors for deceased donors (SP-KDPI model) while race, age, HLA-B mismatch and donorrecipient body surface area ratio were used in the living donor model (SP-LKDPI). C-statistics were 0.64 (95% CI = 0.57 – 0.70) for SP-KDPI and 0.65 (95% CI = 0.58 – 0.73) for SP-LKDPI. Figure 1 shows allograft survival by donor type and SP-(L)KDPI stratum. The SP-LKDPI model identified 16.8% of living donors with predicted graft survival superior to any deceased donor (denoted as SP-LKDPI >0).

Conclusions: Our adaptation of the KDPI demonstrated a higher accuracy to predict graft loss in young recipients of deceased donors. Furthermore, our SP-LKDPI model may allow direct comparison of living versus deceased donors offered to the youngest recipients.

PO2350
Reduced 1-Year Allograft Function in Pediatric Renal Transplant Patients: Role of Subclinical Viral Replications
Raja Dandamudi, Stanley P. Hmiel, Vikas R. Dharmidhakara. Washington University in Saint Louis School of Medicine, Saint Louis, MO.

Background: BK virus (BKV) and Epstein-Barr virus (EBV) subclinical viral replications (SVR) are common after renal transplantation. The effects of SVR on the GF in pediatric kidney transplant (pKTx) recipients is not well defined and was the purpose of this study.

Methods: This retrospective study was done in our hospital from Jan 2012 to Dec 2018. 480 serum and urine samples from 39 pKTx were analyzed for viral load by quantitative PCR through the first post-transplantation year. Clinical characteristics, including graft survival and dDSA testing and/or biopsies were done if there was a clinical concern. Group 1: low risk patients, ATG dose of ≤ 3.5 mg/kg and Group 3: high risk patients

Results: A total of 181 patients met inclusion criteria. Age of patients was 11 years (11 mo-21 y), median (range), 21% received a living donor transplant and 49% were female. Graft survival and dnDSA formation did not differ significantly between the three treatment groups. Graft loss at 12 months was a rare event with 99.5% graft survival and patient survival was 100%. Patients outcomes based on groups is shown in the table.

Conclusions: Reduced ATG dosing (≤ 3.5 mg/kg) when compared with higher dosing (>3.5 mg/kg) is safe and effective. Reduced ATG dose was associated with lower rates of BK viremia and BK nephropathy without increasing risk of dnDSA or BFR.

Variability in Surveillance Monitoring and Management of Donor-Specific Antibodies Among Pediatric Transplant Programs Participating in the Improving Renal Outcomes Collaborative (IROC)

Lyndsay Harshman,1 Hiren P. Patel,2 Gina-Marie Barletta,3 David K. Hooper,4 Rouba Garro,5,6 The University of Iowa Stead Family Department of Pediatrics, Iowa City, IA; 4Nationwide Children’s Hospital, Columbus, OH; 2Phoenix Children’s Hospital, Phoenix, AZ; 3Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 5Emory University, Atlanta, GA; 6Children’s Healthcare of Atlanta Inc, Atlanta, GA.

Background: There have been few advancements in long-term outcome of pediatric kidney transplant (KT) recipients who develop rejection. Many centers perform surveillance monitoring for donor specific antibodies (DSA) to diagnose and treat subclinical rejection. Despite the existence of guidelines, there is variability in monitoring and management of DSA post-pediatric KT.

Methods: An IRB approved survey was distributed using REDCap among pediatric KT programs participating in IROC to evaluate practice patterns in monitoring and management of DSA post KT.

Results: Twenty-nine of 33 (88%) IROC centers completed the survey. Twenty-five of 29 (86%) centers perform surveillance DSA monitoring. Of those 25 centers, 20 (69%) check DSA twice or more in year one post KT. Nineteen (65%) check once in the second year and annually thereafter. Ten (35%) centers check DSA only by indication after year two post KT. Twenty-eight (97%) utilize MRI trend in interpreting DSA results and 10 (34%) centers use C1q complement fixation antibody assay to guide management. Management of patients with +DSA, stable creatinine and no evidence of antibody mediated rejection (AMR) on biopsy varies across centers from monitoring (34%) to intensive (19%) to base line immunosuppression (19%). Baseline immunosuppression is stopped in 19% (10/29, 66%). Very few centers reported giving IVIG alone (3/29, 10%) or IVIG and rituximab (3/29, 10%). Only 34% of centers (10/29) perform kidney biopsy if DSA develops with stable creatinine. When rituximab is used for treatment of DSA+ AMR, 11/29 (41%) centers use one dose and 15/29 (54%) use 2 doses with variable frequency. Of centers using IVIG, 14/29 (48%) use IVIG monotherapy for treatment of DSA+ AMR; 12/29 (41%) use 1 g/kg/dose and 6/29 (30%) use 2 g/kg/dose. The frequency of IVIG dosing is monthly in 16/20 (80%). The number of IVIG doses is variable ranging from 1 to 6.

Conclusions: There is significant variability in surveillance monitoring and management of DSA post-KT across pediatric centers. Large, multicenter studies should be considered to evaluate the ideal post-KT surveillance DSA monitoring strategy and to determine the effect of different treatment approaches on long-term outcomes in pediatric KT recipients.

PO2353

Assessment of Pediatric Nephrology Programs’ Readiness to Participate in Prospective Clinical Trials

Shyamane Hetley,1 Noel Howard,1 H. William Schnaper,2 William E. Smoyer,3 Katherine M. Dell,4 Coleman Gross,3 Katherine Twombly,6 Tetyana L. Vasilyeva,1 Scott E. Wenderfer,1 Texas Tech University Health Sciences Center School of Medicine, Amarillo, TX; 3Northwestern University Feinberg School of Medicine, Chicago, IL; 2Nationwide Children’s Hospital, Columbus, OH; 4Cleveland Clinic, Cleveland, OH; 5Relypsa Inc, Redwood City, CA; 6Medical University of South Carolina, Charleston, SC; 7Baylor College of Medicine, Houston, TX.

Background: Currently, there is a limited availability of effective, FDA-approved drugs for children with kidney disease in the United States; therefore, there is an increased need for clinical trials to evaluate drug effectiveness and safety for pediatric usage. Implementation and conduction of clinical trials is complex process, which requires a team approach, involves multiple inter-dependent steps, research infrastructure support, legal policies/procedures, equipment, and access to a regulatory oversight board. The conduct of clinical trials in small pediatric subspecialties (i.e. pediatric nephrology) may be hampered by provider clinical demands and small numbers of patients available for such studies. The goal of this survey was to assess the readiness to conduct clinical trials by pediatric nephrologists in institutions of different sizes. Assessment would provide a framework to help determine the size of the institution.

Methods: The survey was designed and tested by a small group of pediatric nephrology experts. Qualtrics Online Survey Platform and Statistical analysis were used. The survey was distributed to members of ASPN (60 sites in 30 U.S states and 2 Canadian Provinces). Respondents were asked to complete the survey on behalf of the institution/practice, not their individual preferences. There was a total of 17 survey questions, which assessed the respondent’s institution’s participation/interest in conduct of clinical research, availability of a clinical research coordinator/IRB, and access to equipment for trial execution (dry ice, centrifuges, freezers).

Results: Currently, we have recorded 68 survey responses. Two of the responding institutions had no interest in conducting clinical trials (2.9%). Notably, more respondents practiced at Academic Centers/Universities (91%) than in private practices (8.3%). We noted no major differences in access to clinical trial resources between large and small institutions.

Conclusions: Clinical trials remain vital to finding better treatments and cures for pediatric patients with renal diseases. Overall, pediatric nephrology programs have good infrastructure and readiness to conduct clinical trials independently of the size of the institution.
PO2354

Telemedicine During the COVID-19 Pandemic: Parents’ Experience in a Pediatric Nephrology Clinic at the University of Florida

Background: In the setting of the COVID-19 pandemic, pediatric nephrology clinics at the University of Florida were switched to telemedicine. This transition occurred quickly without much education to either providers or families. There are some attempts to study the experience of providers, but there is no data regarding to parents’ and patients’ experience with telemedicine.

Methods: We surveyed parents and patients (>18 years old) who had at least 1 telemedicine encounter via anonymous Qualtrics survey sent to their email. Results were analyzed via qualitative analysis.

Results: Out of the 80 parents, 47.5% (38) completed the survey. 95% of the patients participated via Zoom and 5% used the telephone. 10.5% experienced technical issues. 100% reported that telemedicine had a positive impact on their family life. In response to the quality of time spent with physicians, 84% reported that telemedicine was similar to the clinic, and 10.5% reported it was better. In terms of receiving virtual medical care, 50% reported that they were very comfortable, 50% reported that they were comfortable but preferred some interim clinic visits. 71% rated telemedicine experience 5, 25% rated 4, and 5% rated 3 out of 5.

Conclusions: We observed that parents perceived the effect of telemedicine clinics as positive in respect to ease in the incorporation, quality of time spent by the physician, receiving virtual medical care, and the impact on the families. Though telemedicine seems to be effective in the current setting, it can only be served as an alternative to in-person clinic visits in the future, since 90% of families preferred a mixture of clinic and telemedicine visits in our setting. Larger studies are needed to further evaluate the utility and efficacy of telemedicine in a pediatric setting.

PO2355

Prevalence and Determinants of Sickle Cell Nephropathy in Children Living in a Low-Resource Setting

Ovindamola O. Adebayo,1,2 Dieumerci Betukumesu Kabasele,3 Agathe B. Nkoy,1,2 Pepe M. Ekulu,1 Veele Labarque,2 Lambertus P. Van den heuvel,1,4 Elena N. Levchenko.1 Laboratory of Pediatric Nephrology, Department of Development and Regeneration, Katholieke Universiteit Leuven, Leuven, Belgium; 2Centre for Molecular and Vascular Biology, Department of Cardiovascular Sciences, Katholieke Universiteit Leuven, Leuven, Belgium; 3Division of Nephrology, Department of Pediatrics, University Hospital of Kinshasa, Faculty of Medicine, University of Kinshasa, Kinshasa, Congo (the Democratic Republic of the); 4Department of Pediatric Nephrology, Radboud University Medical Centre, Nijmegen, Netherlands.

Background: Clinical and genetic factors have been reported to influence the development of sickle cell nephropathy (SCN). However, data on the association between these factors and SCN remain limited in the pediatric population, especially in sub-Saharan Africa. Our study aimed to: (i) determine the prevalence of the reported markers of SCN, including albuminuria, glomerular hypertrophy and reduced kidney function in a pediatric sickle cell anemia (SCA) population from the Democratic Republic of Congo (DRC); (ii) examine the association between these SCN markers and some clinical and genetic factors.

Methods: Clinical parameters were collected. All participants were genotyped for Apolipoprotein-L1 (APOL1) G1 (rs73885319, rs69010145) and G2 (rs71785313) variants, and for Heme oxygenase 1 (HMOX1) GT dinucleotide repeats (rs3074372). APOL1 high-risk genotype (HRG) was defined by the presence of 2 risk variants (G1/G1, G1/G2, and G1/G2) and low risk genotype (LRG) if 0 or 1 risk variants were present. HMOX1 GT dinucleotide repeats were categorized into two allele classes (≤ 25 repeats as short and > 25 repeats as long). As the main outcomes, albuminuria was defined as albumin-to-creatinine ratio (ACR) ≥ 30mg/g, reduced kidney function (eGFR < 60 ml/min per 1.73 m²) and glomerular hypertrophy (eGFR > 130 and 140 ml/min/1.73 m² for female and male, respectively).

Results: From 361 participants enrolled, 73 (20.2%) presented with albuminuria, 104 (28.3%) with hypertrophy and 19 (5.26%) had reduced kidney function. Logistic regression analysis revealed that blood transfusions (> 9 per year) were significantly associated with albuminuria (P = 0.0036); age (P = 0.015) and diastolic hypertension (P = 0.0099) were significantly associated with hypertrophy. APOL1 HRG emerged as the main genetic factor associated with both albuminuria (odds ratio [OR]: 3.70, 95% confidence interval [CI]: 0.037–1.25) and diastolic hypertension (OR: 1.84, 95% CI: 1.51–2.02, P < 0.001), while no association was found with HMOX1 GT repeats.

Conclusions: Kidney disease is highly prevalent in children with SCA in the DRC. APOL1 HRG is the main determinant associated with the risk of developing SCN.

Clinical and Biopsy Characteristics in a Pediatric Cohort of C3 Glomerulonephritis (C3G) and Immune Complex Membranoproliferative Glomerulonephritis (IC-MPGN)

Bradley P. Dixon,1,2 Amy Goodwin Davies,3 Hanieh Razzaghi,3 Sherin Meloni,3 Melissa E. Thomas,3 Joseph T. Flynn,4 Donna J. Claes,5 Don Matsefana,6 Brian R. Slater,7 Vikas R. Dharmadhika,7 Caroline A. Gluck,7 Joshua Zaritsky,6 Michael J. Somers,7 Mahmoud Kallah,7 William E. Smoyer,7 Susan L. Furlt,6 Christopher B. Forrest,7 Benjamin L. Laskin,7 Michelle Denburg,7 Renal Section, Department of Pediatrics, University of Colorado School of Medicine, Aurora, CO; 2Children’s Hospital Colorado, Aurora, CO; 3The Children’s Hospital of Philadelphia, Philadelphia, PA; 4Seattle Children’s Hospital, Seattle, WA; 5Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 6Washington University in Saint Louis School of Medicine, Saint Louis, MO; 7Nationwide Children’s Hospital, Columbus, OH.

Background: C3G and IC-MPGN are rare diseases. The ability to identify and phenotype children with C3G and IC-MPGN using electronic health records (EHR) would aid description of natural history and prognosticative therapeutic response.

Methods: Using a computable phenotype algorithm, a pediatric cohort of children with glomerular disorders was identified in PEDSnet, a national network of pediatric health systems with aggregated EHR data, and refined using MPGN-specific SNOMED-CT codes to identify C3G and IC-MPGN patients at 6 centers. Discrete data elements were captured from electronic health records, and additional clinical data were extracted by standardized chart review. Biopsy diagnosis was classified as C3G or IC-MPGN by applying an automated algorithm to immunofluorescence data. Patients were then followed in an ongoing extension period. Here we report efficacy outcomes through 1 year of safety from all available follow-up (median 82.6 weeks).

Results: Of 285 identified patients, 173 were true cases of C3G or IC-MPGN (Tables 1 and 2). Median C3 level at diagnosis was lower in C3G compared to IC-MPGN (p = 0.006). There were no significant differences in light microscopic injury pattern or ultrastructure between C3G and IC-MPGN biopsies, but C3 intensity was higher in C3G (p = 0.005). The primary endpoint was complete TMA response (platelet count and lactate dehydrogenase normalization and ≥25% improvement in serum creatinine from baseline at 2 visits ≥28 days apart) through 26 weeks. Key secondary endpoints included eGFR and dialysis requirement. Patients were then followed in an ongoing extension period. Here we report efficacy outcomes through 1 year of safety from all available follow-up (median 82.6 weeks).

Results: Eighteen patients (mean [SD] age 6.4 [4.5] years; 55.6% female) were enrolled; 14 (77.8%) achieved complete TMA response by 26 weeks, and 3 more patients (94.4%) by 50 weeks. Patients were then followed in an ongoing extension period. Here we report efficacy outcomes through 1 year of safety from all available follow-up (median 82.6 weeks).

Results: Eighteen patients (mean [SD] age 6.4 [4.5] years; 55.6% female) were enrolled; 14 (77.8%) achieved complete TMA response by 26 weeks, and 3 more patients (94.4%) by 50 weeks. Further improvements in TMA parameters occurred with longer-term treatment (Table). Mean (SD) increase in eGFR from baseline was 85.4 (54.3) mL/min/1.73m² at 26 weeks, and 94.1 (50.7) at 50 weeks. Of 6 patients on dialysis at baseline, 3 (50%) discontinued eGFR and dialysis requirement. Patients were then followed in an ongoing extension period. Here we report efficacy outcomes through 1 year of safety from all available follow-up (median 82.6 weeks).

Results: Eighteen patients (mean [SD] age 6.4 [4.5] years; 55.6% female) were enrolled; 14 (77.8%) achieved complete TMA response by 26 weeks, and 3 more patients (94.4%) by 50 weeks. Further improvements in TMA parameters occurred with longer-term treatment (Table). Mean (SD) increase in eGFR from baseline was 85.4 (54.3) mL/min/1.73m² at 26 weeks, and 94.1 (50.7) at 50 weeks. Of 6 patients on dialysis at baseline, 3 (50%) discontinued eGFR and dialysis requirement. Patients were then followed in an ongoing extension period. Here we report efficacy outcomes through 1 year of safety from all available follow-up (median 82.6 weeks).
Conclusions: Ravalumab administration every 4–8 weeks improved hematologic and renal outcomes in 94% of patients, with no unexpected safety concerns. Renal function improved with longer-term treatment.

A Pharmacologic “Stress Test” for Assessing Select Antioxidant Defenses in Patients with CKD

Richard A. Zager,1,2 Ali C. Johnson,1 Alvoro F. Guillemin,1 Donald J. Keyser,3 Bhupinder Singh,4 Fred Hutchinson Cancer Research Center, Seattle, WA; 1University of Washington Department of Medicine, Seattle, WA; 2Renibus Therapeutics, Southlake, TX; 3University of California Irvine, University of California Irvine, Irvine, CA, US; 4Department of Medicine, Irvine, CA.

Background: Oxidative stress is a hallmark and mediator of CKD. Diminished antioxidant defenses are thought to be partly responsible. However, there is currently no validated prospective determination of antioxidant defenses in humans. RBT-6 (N-[N-benzyl]-L-phenylalanine, SnPP) induces mild, transient oxidant stress in animal models, triggering increased expression of select antioxidant proteins (e.g., heme oxygenase 1 [HO-1], NAD(P)H dehydrogenase [quinone] 1 [NQO1], ferritin, p21). Hence, we tested the hypothesis that RBT-6 can also variably increase these proteins in humans and can thus serve as a pharmacologic “stress test” for gauging generative reserves and antioxidant reserves.

Methods: A total of 18 healthy volunteers and 24 participants with stage 3 CKD (n=12; eGFR 30–59 ml/min per 1.73m^2) or stage 4 CKD (n=12; iGFR 15–29 ml/min per 1.73m^2) received a single dose of RBT-6 at 9, 27, or 90 mg administered intravenously. Plasma and/or urinary antioxidant proteins were measured at baseline and for up to 4 days post-dosing. Kidney safety was assessed by serial measurements of BUN, creatinine, eGFR, albuminuria, and urinary AK1 biomarkers (kidney injury molecule 1, neutrophil gelatinase-associated lipocalin, cystatin C, and N-acetylglucosaminidase).

Results: Plasma HO-1, ferritin, p21, and urinary NQO1 were all elevated at baseline in CKD participants. Plasma HO-1 and urinary NQO1 levels each inversely correlated with eGFR (r=−0.85 to −0.95). All four proteins manifested statistically significant dose- and time-dependent elevations after RBT-6 infusion. However, marked inter-subject differences were observed. p21 responses to high-dose RBT-6 and HO-1 responses to low-dose RBT-6 were significantly suppressed in participants with CKD versus healthy volunteers. RBT-6 was well tolerated by all participants, and no evidence of nephrotoxicity was observed.

Conclusions: RBT-6 can be safely administered and, after its infusion, the resulting changes in plasma HO-1, NQO1, ferritin, and p21 concentrations can provide information as to antioxidant gene reserves/reserves in subjects with and without kidney disease. Additionally, baseline values of these markers may also be indicative of oxidative stress at baseline, especially in patients in CKD.

Prediction of Kidney Drug Clearance: A Comparison of Tubular Secretory Clearance and GFR

Yang Chen,1,2 Leiya R. Zelnick,1,3 Andrew N. Hoofnagle,2,4 Catherine K. Yeng,1,2 Laura M. Shireman,1 Calder C. Brauchla,1 Ian H. de Boer,1 Jonathan Himmelfarb,1 Bryan R. Kestenbaum,1,2 University of Washington Department of Epidemiology, Seattle, WA; 1Kidney Research Institute, Seattle, WA; 2University of Washington Department of Medicine, Seattle, WA; 3University of Washington Department of Laboratory Medicine, Seattle, WA; 4University of Washington Department of Pharmacy, Seattle, WA.

Background: Tubular secretion is the primary mechanism of kidney drug elimination. Few studies have empirically evaluated the role of tubular secretion on the kidney elimination of administered drugs.

Methods: We evaluated 54 participants with and without chronic kidney disease. We administered a single dose of iohexol, furosemide, and famciclovir at the start of the study visit. We used LC-MS/MS to measure furosemide, penciclovir (the active form of famciclovir) and transcutaneous measurements. GFR was estimated by renal clearance of the endogenous drug iohexol, and by transcutaneous measurements.

Results: Participants were characterized by a mean age of 55 years and a median iGFR of 73 ml/min/1.73m^2. Using iGFR as a single predictor, the MAE between model-predicted and measured furosemide and penciclovir clearance was 40.1 and 64.1 ml/min, respectively. The MAEs for models of individual secretory solute clearances were statistically similar to that of the iGFR model. The addition of kynurenic acid, pyridoxic acid, isovalerylglutamic acid and tiglylglycine clearances each individually improved the predictive accuracy of penciclovir clearance compared with the iGFR model.

Conclusions: The kidney clearance of secretory solutes and iGFR showed similar accuracy for predicting the clearances of furosemide and penciclovir, with some improvement from combining both measures. These findings provide cautious optimism that measurements of secretory clearances may improve kidney drug dosing.

Accuracy of GFR and secretory solute predictions for predicting kidney clearance of furosemide and penciclovir

**PO2361**

Reduction in Proximal Tubular Secretion Precedes Reduction in Glomerular Filtration Rate in the Adenine-Induced CKD Model

Background: Glomerular filtration rate (GFR) is frequently used to instruct dose levels of renally cleared drugs in patients with renal disease. This is based on the assumption that proximal tubule secretery clearance declines equally to GFR during disease progression. We tested this hypothesis in adenine-induced CKD mouse model.

Methods: C57BL/6 mice were fed either control or 0.2% adenine diet to induce progressive kidney damage. Body weight, urinary output, GFR and tubular secretion were monitored and histological analysis performed to assess disease progression at 1 and 3 weeks. Tubular secretion was estimated by measuring renal clearance of the endogenous secretory solutes indoxyl sulfate (IS), hippuric acid (HA) and cinnamoylglycine (CMG) using liquid chromatography couple to mass spectrometry. GFR was estimated by transcutaneous measurements.

Results: Mice on adenine diet developed kidney disease, indicated by progressive GFR decline. Histological assessment showed normal glomeruli throughout the study and a moderate tubular damage at 1 week which progressed to severe at 3 weeks. However, the maximum urinary albumin-creatinine ratio was reached already at 1 week of treatment, as was potassium tubular injury mark, suggesting extensive early tubular injury and functional damage preceding structural damage. Likewise, when tubular secretion was assessed directly, a profound decrease in renal clearance of IS was detected already after 1 week on adenine diet with only a small further decrease by the 3rd week. Similar trends were observed for HA and CMG. In direct comparison, the decline in GFR versus tubular secretion over time revealed that at 1 week GFR was decreased by 30% whereas tubular secretion was decreased by >65%, suggesting earlier impact on the latter. Immunohistological analysis revealed a reduction in Oat1 transporter expression, to an extent not fully accounting for the reduction in function. This suggests a component of Oat1 inhibition and/or involvement of other transporters.

Conclusions: Our results indicate that tubular secretory function can be dissociated from glomerular filtration. Thus, assessment of tubular function based on GFR alone can be misleading, which has implications for dosing of renally excreted drugs to patients with kidney disease.

**The Influence of Vitamin D Status and CKD on the CYP3A Metabolism Substrate Midazolam**

Stacey M. Tue,1 Linda Prebehiala,1 Michael F. Wenpek,1 Michel Chonchol,2 Nirav A. Shah,3 Thomas D. Nolin,3,4 Melanie S. Joy,1,4,5 University of Colorado, Skaggs School of Pharmacy and Pharmaceutical Sciences, Aurora, CO; 6University of Colorado, Division of Renal Diseases and Hypertension, Aurora, CO; 7University of Pittsburgh, Department of Pharmacy & Therapeutics, Pittsburgh, PA; 8University of Pittsburgh, Department of Medicine Renal Electrolyte Division, Pittsburgh, PA.

**Background:** Patients with chronic kidney disease (CKD) have a high prevalence of vitamin D (25(OH)D) deficiency. Given its widespread use and knowledge of CYP gene induction, there is a paucity of data on how the pharmacokinetics (PK) of CYP3A substrates may be impacted by 25(OH)D in CKD. This study sought to investigate the role of 25(OH)D status (deficient vs. replete status) on CYP3A metabolism in CKD and healthy control (HC) subjects using midazolam (MDZ) as a prototypical probe substrate.

**Methods:** CKD (n=19) and HC (n=6) subjects with 25(OH)D deficiency (25(OH)D < 30 ng/mL) were enrolled in a 2 phase study. In phase 1, subjects were given one dose of oral midazolam (MDZ, 5000 IU) and oral MDZ (2 mg). In phase 2, subjects received D, 5000 IU daily for up to 14 weeks to repletion (25(OH)D >30 ng/mL) and were again given one dose of oral D, 5000 IU and MDZ 2 mg. Blood was serially collected for up to 48 h at each phase. MDZ plasma concentrations were measured by LC-MS/MS. Population PK analysis was performed using Phoenix NLME (v.8.2, Certara®).

**Results:** A 2-compartment model with delayed absorption and a mixed ratio residual error model was fit to the observed MDZ plasma concentration data. Glomerular filtration rate (GFR) and study phase were included as covariates in the model. MDZ population error model was fit to the observed MDZ plasma concentration data. Glomerular filtration analysis was performed using Phoenix NLME (v.8.2, Certara®).

**Conclusions:** MDZ PK status did not significantly influence the PK of MDZ in either HC or CKD subjects. There was a trend in CL/F being slower in CKD compared to HC regardless of phase, which may be due to decreased renal elimination or reduced ability for inductive CYP3A24 in CKD patients. Future analyses will explore whether additional covariates to further reduce the error on MDZ PK parameters in order to discern differences between subjects in this small study.

**CYP3A and Drug Transporter Activity Changes in Thai Elderly with CKD Assessed Using a Microdose Cocktail**

PunyaBhum Pratthanachatwoor,1 Wonngarm Kittanamongkolchai,1 Natavudh Townnamchai,2 Suwasisin Udornkarnjanun,3 Kearkat Praditosompilsai,4 Stephen J. Kerr,1 Thunundorn Thanusuwannask,1 Udorn Udornboom,1,6 Thanawimun Laiarnmongkol,1 Boonsri Ongpipattanakul,1,5 Panyomath Prueksaritanont,1 Yingyos Avihingsanon,1 Pajaree Chariyavilaskul,1,2 Clinical Pharmacokinetics and Pharmacogenomics Research Unit, Chulalongkorn University, Thailand; Chulalongkorn University Faculty of Medicine, Bangkok, Thailand; 3Clinical Pharmacokinetics and Pharmacogenomics Research Unit, Chulalongkorn University, Bangkok, Thailand; 4Chulalongkorn University Drug and Health Products Innovation Promotion Center, Faculty of Pharmaceutical Science, Chulalongkorn University, Bangkok, Thailand; 5Division of Nephrology, Department of Medicine, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; 6Biostatistics Excellence Center, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand.

**Background:** Chronic kidney disease (CKD) may influences cytochrome P450 (CYP) enzymes and drug transporters activity, resulting in the change of pharmacokinetics. This study investigated the effect of age and renal function on activity of CYP3A and various drug transporters in healthy Thai elderly and CKD patients using a validated microdose probe substrate cocktail.

**Methods:** Fifty three subjects were studied [healthy young subjects (Gr1, n=20), healthy elderly (Gr2, n=16) and elderly CKD patients (Gr3, n=17)]. Each subject was given a single dose of the microdose cocktail consisted of midazolam (M; for CYP3A), diphenhydramine (D; for CYP2D6 and 2C19), irinotecan (I; for CYP3A), dabigatran etexilate (D; for gut P-gp; pitavastatin (P; for OATP1B1), rosuvastatin (R; for OATP2B1), aminoglycoside (A; for ATP7C1/C), Pepstatin A (P) and probenecid (P) as MDR1 probe substrates. Plasma samples were collected at 0, 0.33, 0.67, 1.5, 1, 2, 3, 4, 6, 8, 10, 12, 24, 36 and 48 hours after dosing. All plasma drug concentrations were measured using a fully validated LC/MS/MS. Area under the concentration-time curve (AUC) were calculated using the trapezoidal rule.

**Results:** No side effect was observed. Multivariate analysis, adjusted for body mass index, co-morbidity and liver functions) showed negative effects of age and CKD on drug transporters activity, resulting in the change of pharmacokinetics. As compared to aged-matched healthy subjects, CKD subjects exhibited a doubling of AUC0-12 and 50% decrease in renal clearance of MNF after VitD repletion. No statistical significance was shown.

**Conclusions:** The FEX data suggest that nonrenal transporter function (likely intestinal P-gp and/or hepatic OATP) is decreased in VitD deficient CKD patients and may be improved by VitD repletion. Reasons for unchanged OLM PK likely relate to overlapping substrate specificity with other transporters that are minimally affected by CKD or VitD status. Conversely, MNM results may suggest that MATE1/2-K function is decreased by VitD.

**Tacrolimus and Mycophenolic Acid Pharmacokinetics in Young, Middle-Aged, and Elderly Stable Renal Transplant Recipients**

Kathleen M. Tarranta,1 Kris Attwood,1 Transplantation Immunosuppressive Pharmacology Research Program 1University at Buffalo - The State University of New York, Buffalo, NY; 2 Erie County Medical Center, Buffalo, NY; 3 Roswell Park Comprehensive Cancer Center, Buffalo, NY.

**Background:** Tacrolimus (TAC) and mycophenolic acid (MPA) comprise a critical maintenance immunosuppressive regimen. Limited pharmacokinetic data are available comparing age-related differences of these immunosuppressive drugs which is an important factor considering the increase in renal transplants in older patients. This analysis compared TAC and MPA pharmacokinetics among young, middle age and elderly stable renal transplant recipients (RTR).

**Methods:** Twelve-hour TAC and MPA pharmacokinetic studies were conducted in 67 stable RTR at least 1-year post renal transplant. Tacrolimus dose regimes were adjusted to troughs (4 to 10 ng/ml) based upon time post-transplant. MPA regimes were adjusted using clinical responses only. Patients were categorized as: young: >21 & ≤40 years; middle age: >40 < 60 years and elderly>60 years. Non-compartmental pharmacokinetic analysis determined area under the concentration vs time (AUC). Curve 0-12hours (AUC0-12).

**Results:** TAC and MPA area under the concentration-time curve (AUC) were calculated using the trapezoidal rule.
AUC4-12/AUC0-12 (to define MPA enterohepatic recirculation), apparent clearance (CL) and renal clearance (CL/R). Univariate ANOVA was conducted.

Conclusions: The strict conservation of the contact residues within the conformational epitope of VP1 may explain the broad-spectrum antiviral activity of MAU868 and its high in vitro barrier-to-resistance, ideal characteristics for a potential first-in-class therapeutic agent for the treatment or prevention of BKV disease.

Pharmacokinetic Evaluation of Drug Interactions Between Vadadustat and HMG-CoA Reductase Inhibitors (Statins)
Ajit B. Chavan,1 Rishikesh Sawant,1 Leontia Burke,2 Susan K. Paulson.1 Akemia Therapeutics Inc, Cambridge, MA; 1AGTC, Cambridge, MA

Background: Cardiovascular disease is the most common cause of mortality in patients with chronic kidney disease (CKD). Vadadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor (HIF-PHI) in late-stage development for the treatment of anemia due to CKD. The prevalence of dyslipidemia in CKD is very high, and nearly 50% of patients have been prescribed statins to decrease cholesterol levels. The disposition of most statins is dependent on metabolic enzymes and transporters. This study evaluated the drug interaction potential for statins when co-administered with vadadustat.

Methods: In this 3-part study (NCT03801733), 108 healthy adults were enrolled for vadadustat-statin pharmacokinetic (PK) evaluation. Vadadustat (600 mg daily) was administered concomitantly with either rosuvastatin (20 mg; n=34), pravastatin (40 mg; n=23), or atorvastatin (40 mg; n=30) for 7 days. Steady-state plasma concentrations for statin and vadadustat were measured following single and multiple oral doses of each drug. The PK parameters were compared in the presence and absence of each statin.

Conclusions: There were no clinically significant interactions with rosuvastatin or atorvastatin, suggesting that vadadustat has a low likelihood for OATP1B1-mediated drug interactions. Increases in exposures to rosuvastatin and simvastatin are possibly due to BCRP inhibition. In summary, these results provide information to aid in the management of concomitant administration of vadadustat with statins. Funded by: Akemia Therapeutics, Inc.

Preclinical Characterization of MAU868, a Novel Neutralizing Antibody Targeting BK Virus
Atul Sathe,1 Mark Knapp,1 Lihong Zhao,2 Peter Kim,2 Andreas Hein,3 Meike Scharenberg,4 Jacob Shaul,5 Kelly A. Wong,6 Steven J. Kovacs,6 Elisabeta Traggiai,7 Amy Patick,7 Johanna R. Abend.1 Novartis Institutes for BioMedical Research East Hanover, East Hanover, NJ; 2Novartis Institutes for BioMedical Research Emeryville, Emeryville, CA; 3Amplex Pharmaceuticals, Inc. San Diego, CA; 4Novartis Institutes for BioMedical Research Basel, Basel, Switzerland.

Background: Reactivation of BK virus (BKV) can cause significant kidney and bladder disease in immunocompromised patients. There are currently no effective BKV-specific therapies. MAU868 is a novel human monoclonal IgG1 that binds to the BKV major capsid protein VP1. Its binding affinity, antiviral activity, and resistance profile were investigated in vitro.

Methods: Binding affinity was determined using a solution equilibrium titration assay. Neutralization of BKV infection in primary renal proximal tubule epithelial (RPTE) cells was evaluated by quantitating Tag-expressing cells using an immunofluorescence-based assay. Reduction of BKV-infected cell yields (IC50) with reduced susceptibility to MAU868 was investigated in two long-term selection studies with BKV genotypes 1 and 4 RT and HEK-293 cells. Crystallographic studies were conducted using the MAU868 single-chain variable fragment bound to VP1 peptide.

Results: MAU868 had pM binding affinity and sub-nM neutralizing activity against the 4 major BKV genotypes, with EC50 and EC50 values ranging from 0.009 to 0.093 μM (0.0062 to 0.645 nM) and 0.102 to 4.160 μM (0.708 to 28.865 μM). No cytotoxicity effects were observed. IC50 concentration for each BKV genotype tested (50 μg/ml) was 0.102 to 4.160 μM (0.708 to 28.865 μM). No cytotoxicity effects were observed.

Conclusions: MAU868 is a novel human monoclonal IgG1 that binds to the BKV major capsid protein VP1. Its binding affinity, antiviral activity, and resistance profile were investigated in vitro.

A Genotype-Guided Antihypertensive Therapy and CKD Care Precision Health Initiative

Judith Maddatlu, Ranjani N. Moothri, Katherine M. Spiech, Nehal Sheth, Michael T. Eadon. Indiana University School of Medicine, Indianapolis, IN.

Background: A precision health initiative was implemented, wherein pharmacogenomic predictors of antihypertensive response and genomic predictors of chronic kidney disease (CKD) were provided to clinicians caring for nephropathy patients.

Methods: This is a prospective cohort study of 580 individuals who presented to outpatient nephrology clinics. Subjects were genotyped for 60 antihypertensive response variants and 10 chronic kidney disease (CKD) predictors. Predictors included variants of CYP2D6 for metoprolol dosing and CYP2C9 for angiotensin receptor blocker dosing. Variants in APO1, UMOD, and SHROOM3 were markers of CKD risk prediction. Subjects were followed to ascertain utilization of the genetic information by nephrologists.

Results: The cohort was 66% female and 43% African American. Actionable variants were found in 85% of subjects. These variants are known to affect metabolism of a drug, or contribute to CKD progression. The prevalence of actionable genotypes was 66% for CYP2D6, and 36% for CYP2C9. In African American subjects, 23% of CKD patients had two or more CKD risk variants. Clinicians adapted treatment for 43% of individuals with actionable genotypes. The primary nephrologist was surveyed for each subject. In the 143 subjects who completed follow-up, nephrologists reported a change in diagnosis in 44% of their patients and a change in management in 28.0% based on genomics. Clinicians discussed the genetic testing results with their patients in 83.9% of cases.

Conclusions: Nephrologists utilized a genetic testing panel of up to 60 variants in the routine care of their CKD patients. Pharmacogenomics predicts of disease response may prove to be very valuable the care of patients with chronic kidney disease.

KBP-5074, a Nonsteroidal Mineralocorticoid Receptor Antagonist, Reduces Urine Albumin-to-Creatinine Ratio and the Risk of Hyperkalemia in a Model of Chronic Kidney Disease

Frederic Jaissier,1 Liu Jinrong,2 Shuangshuang Chi,2 Ping Wang,2 Judy Tan,2 Vincent Benn,1 Y. Fred Yang,1 Jay Zhang,1 KBP Biosciences Inc, Inc KBP Biosciences USA Inc, Princeton, NJ, 2Khp Biosciences Co Ltd, Jinan, China; 1Centre de Recherche des Cordeliers, Paris, France.

Background: KBP-5074 is a novel non-steroidal mineralocorticoid receptor antagonist (MRA) being developed for uncontrolled hypertension and advanced chronic kidney disease. The primary objective of this study was to evaluate KBP-5074 and eplerenone for renal protection against aldosterone-mediated renal disease in a nephroprecipitated Sprague-Dawley (SD) rat model.

Methods: Uninephrectomized rats were maintained on a 6% high salt diet, and received aldosterone infusion for 27 days. Urinary albumin to creatinine ratio (UACR), urinary sodium and potassium, and serum potassium were measured in the SD rat model. Three groups of SD rats were treated with KBP-5074 or eplerenone and the control group was treated with vehicle. Blood samples were collected on days 1 and 27 to determine the PK profiles. PK/PD analyses were performed on urinary Na/K ratio, UACR, and serum K.

Results: KBP-5074 (1, 3, and 10 mg/kg/day) significantly reduced UACR by 77%, 90%, and 99% respectively on day 14 and 59%, 86% and 108% respectively on day 26 in a dose dependent manner, while eplerenone (100 and 900 mg/kg/day) reduced UACR by 40% and 99% respectively on day 26. PK/PD analysis of Urinary Na/K ratio indicated that KBP-5074 was approximately 18-fold more efficacious than eplerenone. Analysis of UACR and serum K indicated that the EC50 for serum K+ increase and UACR reduction was 538 nM and 22.0 nM respectively for KBP-5074, and 666 nM and 1071 nM respectively for eplerenone. In a therapeutic index (TI) against hyperkalemia of KBP-5074 was approximately 24.24 for KBP-5074 vs 0.62 for eplerenone. Thus, the TI against hyperkalemia of KBP-5074 was 39-fold superior to eplerenone. One group of SD rats received KBP-5074 for 14 days, followed by saline. KBP-5074 may present an extended therapeutic window as compared to the steroidal MRA eplerenone.

Conclusions: KBP-5074 demonstrated a significant effect on UACR reduction with less risk for hyperkalemia compared to eplerenone in a rat model of nephropathy.

Pharmacological Inhibition of Vanin 1 Is Not Protective in Models of Acute and Chronic Kidney Disease

Background: Dysregulated oxidative stress handling is a hallmark of acute and chronic kidney diseases. The pantheinein Van-1 is highly expressed in tubular cells and renal HT29 cells and produces protection against oxidative stress by inhibiting the replenishment of cellular anti-oxidative glutathione stores. The aim of this study was to elucidate whether pharmacological inhibition of Van-1 protects mice from acute or chronic kidney injury.

Methods: C57Bl6 mice undergoing ischemia reperfusion injury and Col4A3/- (Alport syndrome) mice were treated orally for 1 and 3wk, respectively, with a potent and selective Van-1 inhibitor or placebo. In vitro oxidative stress insult was mimicked in human renal proximal tubular epithelial cells either chemically or by hypoxia/ reoxygenation. Kidney function was determined by serum and urinary creatinine as well as serum urea and urinary albumin. Furthermore, mRNA and protein expression, Van-1 activity, oxidative stress level and tubular apoptosis were monitored.

Results: Oxidative stress levels were elevated in all models. Treatment with the Van-1 inhibitor resulted in ameliorated systemic compound exposure and full inhibition of Van-1 activity in kidney tissue in vivo. However, this did not translate to a relevant reduction of oxidative stress level. Moreover, kidney function (serum Crea, blood urea, albuminuria), fibrosis marker gene expression and tubular cell apoptosis were not improved with Van-1 inhibition.

Conclusions: Pharmacological inhibition of Van-1 is insufficient to protect kidneys from oxidative stress insults contributing to acute and chronic kidney injury. The biological relevance of pharmacological Van-1 inhibition for the treatment of kidney diseases remains to be proven.

Evaluation of Veverimer Drug Interaction Potential in Human DDI studies

Sarah J. Down Parsell,1 Robert Gottendorf,1 Yick Sen Wu,1 Lillian Tsao,2 Angela Tabakman,1 Yuri Stasiv,2 Angela. A. Lee,1 Kalpesh N. Bhat,1 Gerrit Klaerner,1 Tricida, Inc, South San Francisco, CA; 1Aclairo Pharmaceutical Development Group, Vienna, VA; 2Unaffiliated, Burlington, CA.

Background: Veverimer is orally administered, non-absorbed polymer that selectively binds and removes hydrochloric acid (HCl) from the gastrointestinal tract, providing an increase and UACR decrease in chronic kidney disease patients. Vanin-1 is a pantetheinase highly expressed in the kidney and involved in the handling of oxidative stress insults contributing to acute and chronic kidney injury. The action of Veverimer on gastrointestinal acid binding is not affected by Vanin-1 inhibition.

Methods: We observed: 1) no effect of veverimer on the bioavailability of drugs with pH-dependent solubility (warfarin, dabigatran) were chosen for human DDI studies. In vitro studies showed the most important determinant for binding to veverimer in vitro. Three DDI studies were performed on gastric pH and the pH of the intravenous and the oral drug. Based on these results, 2 drugs with a direct binding or 2 increased in gastric pH resulting from HCl binding.

Results: In vitro studies showed the most important determinant for binding to veverimer is negative charge, with small size as a secondary determinant. Veverimer did not bind any positively charged, neutral or weakly ionized drugs. Negatively charged drugs (warfarin, dabigatran) were chosen for human DDI studies. Veverimer increased gastric pH by ~3.0 (fasted) and 1.5 (fed) pH units. The gastric pH increase was transient, peaking by 1 h after dosing and returning to baseline after 1.5 (fasting) and 3 (fed) hours. Based on these results, 2 drugs with PD-dependent solubility (warfarin, dabigatran) were chosen for human DDI studies. In human DDI studies, no clinically meaningful changes in bioavailability were observed for warfarin, aspirin, dabigatran, or warfarin when coadministered with veverimer.

Conclusions: We observed: 1) no effect of veverimer on the bioavailability of drugs most susceptible to binding to the polymer; 2) modest, transient effects of veverimer on gastric pH; 3) no effect on bioavailability of drugs with pH-sensitive solubility. We conclude that there is a negligible risk of clinically significant veverimer DDIs.

PO2374

Action of Veverimer on Gastrointestinal Acid Binding Is Not Affected by Omeprazole

Robert Gottendorf,1 Yuri Stasiv,1 Elizabeth Li,1 Gerrit Klaerner,1 Vandana S Mathur,1 Tricida, Inc, South San Francisco, CA; 2Aclairo Pharmaceutical Development Group, Vienna, VA; 3PharmaStat LLC, Fremont, CA; 4MathurConsulting, Woodside, CA.

Background: Veverimer, an orally administered, non-absorbed polymer that selectively binds and removes hydrochloric acid (HCl) from the gastrointestinal tract, has been shown to correct metabolic acidosis in patients with CKD. Unlike proton pump inhibitors (PPIs), which do not affect systemic acid-base status, the removal of HCl

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
from the gastrointestinal tract by veverimer leads to a net increase in blood bicarbonate. Veverimer was designed to bind HCl across a wide range of intraluminal pH, but the effect of veverimer on acid binding in the presence of PPIs has not been previously described.

Methods: To evaluate the effect of veverimer on gastric pH, we conducted a Phase 1, open-label, 2-stage study in which subjects (N=46) were randomized 1:1:1:1 to receive 1 of 4 study drug treatments (water fasted; water fed; veverimer fasted; veverimer fed) in the presence and absence of a steady-state level of omeprazole. Gastric pH was measured continuously for 22 hours (hrs) using a microelectrode pH probe positioned in the gastric fundus.

Results: Ingestion of veverimer caused a modest, transient increase in gastric pH that peaked within 1 hr post-dose. In the absence and presence of food, the median (distribution-free 95% CI) times to peak pH after veverimer administration was 0.25 (0.17, 1.00) and 0.71 (0.25, 1.17) hrs, respectively. Peak pH after veverimer administration was ~3 and ~1.5 pH units greater than that observed after water control in the fasted and fed states, respectively. The magnitudes of these increases were in the same range in the presence of omeprazole. Gastric pH returned to baseline after ~1.5 hrs under fasting conditions and after ~3 hrs under fed conditions. In the presence of omeprazole, the veverimer-induced gastric pH increase dissipated by 4 hrs post-dose or shortly after initiation of the subsequent meal.

Conclusions: The effect of veverimer on gastric pH is transient and similar in the presence or absence of omeprazole. The magnitude of the individual effects of food, veverimer, and omeprazole on gastric pH were similar (increase of 2–4 pH units). These findings are consistent with prior studies in patients with CKD in which the magnitude of efficacy of veverimer was unaffected by use of H2-receptor antagonists and PPIs (Wesson et al. Lancet, 2019).

PO2376
Circulating Heparin and Its Relevance to Thrombin Generation Profile in ESRD Patients Undergoing Maintenance Hemodialysis
Fakihla Siddiqui, Emily Bontecoe, Debra Hoppensteadt, Walter Jeske, Vinod K. Bansal, Jawed Fareed. Loyola University Medical Center, Maywood, IL.

Background: End stage renal disease (ESRD) is a complex pathophysiologic syndrome which results in vascular disorders and hemostatic disturbance. Despite the use of heparin during maintenance hemodialysis some of these patients exhibit hypercoagulable state. The purpose of this study was to characterize the thrombin generation (TG) profile in ESRD patients in relation to circulating heparin levels.

Methods: Citrated blood samples from 95 patients with ESRD undergoing maintenance hemodialysis were collected. NHP was prepared for referencing purposes. Individual samples were supplemented with heparin. TG parameters such as peak thrombin, lag time and area under the curve (AUC) were compiled. Circulating heparin levels were determined using activated partial thromboplastin time (aPTT) and chromogenic anti-Xa and IIa assays. The ESRD cohort was stratified into heparinized and heparin naïve groups.

Results: ESRD group showed decrease in peak thrombin (107.1 vs 168.3 nM) and AUC (589.8 vs 815.7 nM*min) with increase in lag time (2.9 vs 2.2 min) compared to NHP. Heparin supplementation increased the lag time (3.4 min, p value 0.0001), while decrease the peak thrombin (100.0 nM, p value 0.0245) and AUC (503.4 nM*min, p value <0.0001). Such parameters as aPTT (43.2 vs 31.1 sec), anti Xa (0.21 vs 0.14 U/mL) and anti-IIa (0.27 vs 0.15 U/mL) decreased with heparinization treatment. Heparin naïve group showed decreased peak thrombin and AUC values whereas the lag time was increased. Simultaneously aPTT, anti-Xa and anti-IIa levels were decreased in this group. Heparinized patients did not show any difference in peak thrombin, decrease in AUC values and an increase in lag time. However, the aPTT, anti-Xa and anti-IIa were decreased in this group.

Conclusions: These studies showed that heparinization treatment of plasma samples from ESRD patients resulted in the decrease in aPTT, anti-Xa and IIa levels suggesting the digestion of heparin. However, contrary to these results, TG parameters such as peak thrombin and AUC were decreased whereas lag time was increased suggesting that the depolymerized heparin fragments provoked thrombin generation inhibitory properties.

PO2377
Clinically Apparent AKI Secondary to Suspected Vancomycin Toxicity: A Cellular Kinetic Analysis
Ryan P. Flood, Matthew Ray, Judith Blaine, Anip Bansal. University of Colorado Denver School of Medicine, Aurora, CO.

Background: The use of antimicrobial therapies for treatment of hospitalized patients is abundant. While the usage rate of antibiotics has remained stable over the last decade, however, with the emergence of methillin-resistant staphylococcus aureus, vancomycin usage has increased during that same time period. Although vancomycin induced AKI or vancomycin associated nephrotoxicity (VAN) has been a topic of debate since its generalized use approximately 50 years ago, the proposed mechanism of VAN is an on-going focus of research. The current study aims to answer whether proximal tubular creatinine secretion, which can account for upwards of 20% of creatinine clearance, is impacted by vancomycin dosing, and whether vancomycin trough levels seen in clinical practice alter this relationship.

Methods: For the cellular kinetic analysis, we took immortalized human proximal tubule epithelial cells, and after allowing them to epithelialize on a semi-permeable membrane, evaluated creatinine secretion in the presence of varying concentrations of both vancomycin and vancomycin, while measuring eliminated levels for up to 24 hours. For the patient analysis, IRB approval was obtained to evaluate the cases of possible VAN on the renal consult service.

Results: Creatinine secretion through the cellular epithelium was not affected by vancomycin at levels up to 4X therapeutic, the upper limit of those seen on a cohort of patients in the renal consult service at the university of Colorado. This is consistent with other pharmacokinetic data, indicating that vancomycin is able to inhibit transporters of creatinine, but at levels not seen in clinical practice. The patient cohort analysis identified thirteen patients who were deemed to have “possible VAN,” and in all of these the rise in Cr did happen temporally related to vancomycin, and there were many other factors potentially confounding their AKI.

Conclusions: Proximal tubule dysfunction from vancomycin inhibition of cellular transporters does not cause significant creatinine elevation in concentrations used clinically. The cases of clinically apparent vancomycin associated nephrotoxicity are multifactorial. Therefore the nephrotoxicity associated with vancomycin administration does not seem to be the sole cause of creatinine elevation in patients with AKI.

PO2378
Systemic Absorption of Vancomycin from Sternal Slurry Contributing to Vancomycin Nephrotoxicity
David V Li, Thomas A. Golper. Vanderbilt University, Nashville, TN.

Introduction: Vancomycin has come a long way since its start as “Mississippi mud”. It has been a valuable and safe agent in general. Adverse reactions include flushing and anaphylaxis injury. Clinicians are developing strategies to circumvent these problems. One strategy is the use of antibiotic powder paste applied to infusorium tissue. This has
traditionally not been associated with systemic vancomycin toxicity. We report here an incidence of vancomycin nephrotoxicity secondary to a sternal vancomycin slurry that required dialysis.

Case Description: A 62-year-old 91 kg man with Marfan’s Syndrome and total aortic arch replacement presented with mediastinal abscess and recurrent sternal osteomyelitis. An antibiotic susceptibility test of sternal slurry revealed a circumferential fluid collection around the aortic graft. He underwent a “redo” sternotomy, exploration and drainage. Plasma creatinine concentration (P_cr) on admission was 0.76 mg/dL, his known baseline. He received one dose of 1250 mg IV vancomycin prior to the operation. Intra-operatively 4 grams of vancomycin paste was applied to his sternum. That evening he received cefepime 2g IV and vancomycin 1250 mg IV (see figure), both scheduled to be repeated every 12 hours. P_cr and vancomycin troughs are detailed in the figure. On POD2 serum vancomycin trough was 42 mg/L. Intravenous vancomycin was undetectable and P was discharged on POD14 on daptomycin and ceftriaxone. On POD21 at follow-up, serum vancomycin was 48 mg/L and P

Discussion: There can be substantial unaccounted systemic absorption from vancomycin paste. The POD 4 AM serum level was 48 mg/dL and he was dialyzed 14 hours later under operating conditions such that the level should be reduced by at least one-third. The post dialysis level was 47 mg/dL, so by conservative estimation his predialysis level was about 70 mg/L, suggesting that there was a substantial contribution of vancomycin to the serum level in that 17-hour interval from sternal slurry.

PO2379

Efficacy of the Recommended Ceftazidime/Avibactam Dose in Treating Carbapenem-Resistant Enterobacteriaceae in Critically Ill Patients Using Renal Replacement Therapies

Wassim N. Al-Hassani,1,2 Jihad El Nekidy,1,2 Islam Mallat,1 Laila Ghazi,1 1 Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates; 2 Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, OH; University of the Sciences in Philadelphia, Philadelphia, PA; Prilliman Health Partners, Mississauga, ON, Canada.

Background: Ceftazidime/avibactam (CEF/AVI) is a novel antibiotic used to treat multi-drug resistant (MDR) and gram-negative bacteria, including Carbapenem-Resistant Enterobacteriaceae (CRE). Data on CEF/AVI dosing and outcomes in patients with acute kidney Injury (AKI) are lacking. The aim of this study was to assess the efficacy of the recommended dose of CEF/AVI in patients utilizing renal replacement therapy.

Methods: A retrospective cohort study was conducted at our quaternary care institution between May 2015 and December 2019. All hospitalized adults with CRE were included. Clinical data such as CEF/AVI dose, C/FS, AKI duration, infection type, and clinical cure during the follow up periods up to 3 months, recurrence/relapse occurred in 9 of the 24 patients. Eight patients deceased within 30 days of follow up and 4 more within 90 days. Only one patient did not have relapse or recurrence within the 90 days of follow up.

Conclusions: The CEF/AVI recommended dose could achieve uncertain clinical outcomes. Pharmacokinetics and pharmacodynamics studies are urgently needed to determine the adequacy of CEF/AVI dosing in this population.

PO2380

Extracorporeal Removal of Valproic Acid in Overdose: A Case Report

Wassim N. Al-Hassani,1,2 Jihad El Nekidy,1,2 Islam Mallat,1 Laila Ghazi,1 1 Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates; 2 Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, OH; University of the Sciences in Philadelphia, Philadelphia, PA; Prilliman Health Partners, Mississauga, ON, Canada.

Background: Valproic acid (VPA) is considered not dialyzable at therapeutic concentration and dialyzable at supratherapeutic concentration because of saturable protein binding which increases its free fraction (from 10% to 90%).

Case Description: We report a case of a 53-year old 50kg woman admitted for suicidal polydrug intoxication. She had ingested 15g of VPA, 300mg of atorvastatin, 3g of quetiapine, and 750mg of naltrexone 3 hours prior to admission. Her vital signs were stable on admission and she was somnolent but arousible. Toxicology assays for ethanol, acetaminophen, and salicylates were negative. Biochemistry, blood gases, and complete blood count were unremarkable. She was initially treated with intravenous saline, naloxone, and intravenous caffeine. Despite these, she became progressively oliguric for 24 hours during which the serum VPA concentration rose from 60 to 422 mg/L (therapeutic concentration 50-125mg/L) and ammonia concentration rose from 17 to 56 mmol/L. Hemodialysis (HD) was initiated for 6h (GFS-210, Qb=400mL/min, Qd=750mL/min) via a right temporary femoral catheter because of concerns for further volume and sodium-induced hyperammonemia and reduced access to VPA measurements. Her level of consciousness normalized during HD. No complications occurred during HD. VPA concentration and ammonia concentrations at the end of HD were 78 mg/L and 15 mmol/L, respectively, and did not re-increase thereafter (Figure 1). She was given three 50g doses of activated charcoal after HD and she eventually made a full recovery. VPA half-life was 3.0h during HD, 18.9h during multidose charcoal, and 4.9h without treatment. VPA was 48% unbound at the onset of HD. Instantaneous VPA clearance (calculated using simultaneous plasma and effluent VPA concentrations) decreased from 4.5 L/min during HD as protein binding increased.

Discussion: HD removed 1.4g of VPA which would have been higher had HD been performed sooner after admission. This case illustrates that the dialyzability of VPA depends on its protein binding which itself depends on its serum concentration.

PO2381

Gabapentin Toxicity in Existing and Developing Renal Failure

Introduction: Gabapentin is a medication used to treat partial onset seizures, neuropathic pain caused by diabetic neuropathy, postherpetic neuralgia, & central neuropathic pain. This medication is nearly completely excreted by the kidneys. It is recommended as one of a number of first-line medications for the treatment of pain.

Case Description: Here we report two cases of potential gabapentin toxicity across the spectrum of renal insufficiency. The first case was a 46-year-old female with a history of ESRD (HD X 3 times/week), HCV, DM, HTN and spinal abscess presented with new onset seizure, body stiffening with head and eye deviation, confusion, fall and hypertensive emergency while awaiting for dialysis. She had a second seizure while in the ED and was started on anti-seizure medication Leviteracetam. Home medications included Gabapentin (800 mg TID). Head CT was unremarkable. The second case was a 69-year-old female patient with a history of DM, peripheral vascular disease, coronary artery disease & atrial fibrillation who presented with new onset seizure, body stiffening with head and eye deviation, confusion, fall and hypertensive emergency while awaiting for dialysis. She had a second seizure while in the ED and was started on anti-seizure medication Levetiracetam. Home medications included Gabapentin (300 mg 3 times daily). The patient developed contrast-induced AKI due to a CT angiogram procedure on admission. Following the development of AKI, the patient became confused without evidence of significant azotemia (BUN 33). Both the cases were found to be arousable and GCS of 12/15, intact strength & sensation of both extremities, no ataxia, dysarthria, hemineglect or signs of pronator drift. In both cases, Gabapentin toxicity was suspected and the dosage of Gabapentin was reduced to 100 mg orally at night. There was a drastic improvement of confusion and other symptoms within 2 to 3 days post dosage adjustment in both patients.

Discussion: Renal insufficiency predisposes patients to increased risk of gabapentin induced toxicity due to reduced clearance. Advanced age and other comorbidities may further accelerate the risk. The range of Gabapentin toxicity across the spectrum of renal insufficiency is underestimated. In this case report, the patient with AKI only was confused and the patient with ESRD had myoclonus and seizure in addition to confusion. There seems to be a graded increase in toxicity with the corresponding deterioration of renal function. Heightened awareness about medication toxicity developing in renal failure is important to prevent significant adverse effects.
Case Description: An 85-year-old male with a past medical history of stage 4 chronic kidney disease secondary to diabetic nephropathy (baseline serum creatinine 2.2 mg/dL; Type 2 Diabetes Mellitus, diabetic neuropathy, and hypertension, presented to clinic for worsening of serum creatinine. Pertinent home medications included bumetanide 3 mg BID, metolazone 2.5 mg daily and gabapentin 600 mg TID. Bumetanide and metolazone were up titrated for worsening bilateral lower extremity edema over last 3 months with 20-pound weight gain. Exam was notable for 2+ LE edema. His serum creatinine progressively increased from 2.4 to 4 mg/dL in the setting of aggressive diuresis. A recent TTE showed only grade 1 diastolic dysfunction. The presumed diagnosis was heart failure with preserved ejection fraction. Urine sediment was bland. After identification of gabapentin as potential culprit agent for his edema, both gabapentin as well as his diuretics were discontinued with a resultant significant drop in his weight and serum creatinine to 218lbs and 2.7mg/dL respectively over next one month and complete resolution of his edema.

Discussion: Incidence of gabapentin induced edema varies from 2% to 8% and has been correlated to dosage. Exact mechanism is unknown but possibly related to loss of venoarteriolar reflex leading to increased capillary hydrostatic pressure and hence increased net capillary fluid filtration into the interstitium. Gabapentin induced edema, just like calcium channel blockers induced edema, is not associated with salt and water retention and hence diuretics are ineffective. Physicians, especially nephrologists, should be mindful of uncommon side effect of this commonly prescribed medication as distinguishing this early can prevent a lot of unnecessary work up and potentially prevent harm to the patient.

PO2384
Glimmering Changes in Transplant Glimmerulopathy
Samir Husami, Dina Hammad, Jeffrey H. Miner, Tarek Alhamad, Hani Sulaiman. Washington University in Saint Louis Department of Medicine, Saint Louis, MO.

Background: Transplant glomerulopathy (TG) affects 20% of transplanted kidneys 5 years post transplantation. It carries an important significance due to its correlation with decreased graft survival. Repeated endothelial cell injury by chronic active antibody mediated rejection (cAMR) leads to glomerular basement membrane (GBM) reduplication and thickening, the hallmark finding of TG. Based on our previous molecular mapping of the GBM, we aim to define the composition of the thickened GBM in TG using super-resolution microscopy.

Methods: Two super-resolution microscopy techniques, STORM (Stochastic optical reconstruction microscopy) and Airyscan, were used to image confirmed TG and control biopsies. For STORM, fresh frozen, 200 nm sections were imaged. While for Airyscan, 1-3 microns, formalin fixed paraffin embedded (FFPE) sections were used. Samples were labeled with antibodies for Laminin a5, Integrin a8, Myosin IIA, Vimentin, Synaptopodin, Integrin b1, Fibronectin, and several Collagen IV chains.

Results: STORM TG samples showed increased distance between Integrin b1 labeled GBM, indicating thickening of the GBM. Collagen a3a5a(V) did not change, while Collagen a1a2a(V) was increased at the GBM's endothelial aspect. There was an increase in Fibronectin, suggesting a role for the TGFβ pathway. Airyscan TG images showed Vimentin- and Integrin a5-positive areas inside the GBM, indicating cellular protrusions extending into the GBM. Since these markers stain mesangial as well as endothelial cells, this suggests differentiation of endothelial cells and transition to mesenchymal cells. We detected alternating Myosin IIA and Synaptopodin labeling in the form of “Sarcomere-like structures”.

Conclusions: Our data revealed increased Collagen a1a2a(V) secreted from the endothelial side, while Collagen a3a5a(V) was unchanged. The increase in Fibronectin, cellular protrusions positive for mesenchymal markers, and sarcomere-like structures inside the diseased GBM suggest an endothelial to mesenchymal transition as culprit for increased Collagen IV rather than injury signals from podocytes.

PO2385
Calcineurin Inhibitor Cyclosporine A but Not Tacrolimus Induces Proapoptotic Endoplasmic Reticulum Stress in Kidney Epithelial Cells
Duygu E. Yilmaz,1,2 Karin M. Kirschner,1 Hasan Demirci,1,3 Sebastian Bachmann,1 Kerim Mutig.1,2,3 Charite Universitaetsmedizin Berlin, Berlin, Germany; 1,2,3L.M. Sechenov First Moscow State Medical University (Sechenov University), Moscow, Russian Federation.

Background: Current immunosuppressive strategies in solid organ transplantation rely on the calcineurin inhibitors (CNI), cyclosporine A (CsA) or tacrolimus (Tac). Their nephrotoxicity is a major limitation for long-term usage. We hypothesized that CsA compared to Tac exerts more pronounced toxic side effects at the cellular level, with endoplasmic reticulum (ER)-stress and maladaptive unfolded protein response (UPR) as the most prominent markers.

Methods: To test this hypothesis we treated human embryonic kidney (HEK293) cells with CsA (10 μM) or Tac (10 μM) for 6h. The established ER stress-inducing agent, thapsigargin, served as positive control. To study the molecular mechanisms of CNI-induced cell toxicity we studied genetically-modified HEK293 cells lacking the crucial UPR elements, PERK or ATF6. Abundances of the ER-stress sensor IRE1α, adaptive transcription factor XBP1, and proapoptotic transcription factor CHOP were evaluated as endpoints.

Results: Treatment of native HEK293 cells with CsA or Tac equally increased phosphorylation of the known calcineurin substrate, NFAT, verifying the treatment protocols. CsA increased levels of activating IRE1α phosphorylation (pIRE1α) and stimulated both CHOP and spliced XBP1 (sXBP1) products. In contrast, Tac enhanced pIRE1α abundance only. CsA but not Tac significantly increased the number of cleaved caspase 3-positive cells suggesting enhanced apoptosis rate. Treatment with the chemical chaperone, TUDCA, partially abolished the CsA-induced increases of CHOP but did not affect sXBP1, suggesting alleviation of ER-stress. Knockdown of CsA binding partners, cyclophilin A and B, by siRNA reduced their expression approximately by half and increased CHOP expression suggesting that suppression of cyclophilins may contribute to CsA-induced cellular toxicity. PERK- or ATF6-deficiency blunted the increases of CHOP and sXBP1 in response to CsA, suggesting an implication of these pathways in CsA-induced ER-stress and UPR.

Conclusions: In summary, CsA but not Tac induces pronounced ER-stress and proapoptotic UPR. Pharmacological modulation of UPR bears the potential to alleviate CNI nephrotoxicity.

fibrosis (P<0.001). The relative binding of FoxO1 is predictive of a fibrogenic response in transplanted kidneys. A high 1-month TF ratio was abnormal in a diverse range of fibrotic transplant diseases. A high 1-month TF ratio was associated with pathological and clinical outcomes was evaluated.

Conclusions: In conclusion, differential binding of β-catenin to TFCT1 rather than FoxO1 is predictive of fibrogenic response in transplanted kidneys.

PO2391

B-Cell Maturation Phenotypes and Time Post-Transplant

Alcino Gama, Olivier Despy, Stephanie Beland, François Bouchard-Boivin, Sacha A. De Serres. CHU de Quebec-Universite Laval, Quebec, QC, Canada.

Background: Over the past decade, B cell participation in allograft response has been progressively elucidated. Beside the occurrence of DSA (donor-specific alloantibodies), different patterns of B cell phenotypes are also being related to graft outcome. Loss of naive B cells and appearance of memory B cells have been linked to chronic rejection and ultimately to graft loss. Here we show the impact of time post-transplant on phenotypic B cell changes, particularly regarding different distributions of naive B cells.

Methods: Single-center, observational cohort of 82 kidney transplant recipients (KTr), adults and clinically stable. Blood samples were collected between January 2015 and November 2018. Peripheral blood mononuclear cells (PBMCs) were isolated and analyzed on flow cytometry. B cells (CD19+) were stained for CD38 and IgD and classified according to BM classification (IgD vs CD38).

Results: The median time post-transplant was 2.9 [0.9-9.89] years and the mean age was 54±13 years. 63% of the patients were males and mean eGFR was 49±17 mL/min. B cells absolute counts were lower in later phases post-transplant (R=-0.04, p<0.01). Among all B cell subtypes, Bm2 compartment (comprised mainly by naive B cells) had the most significant reduction in both absolute counts (R=-0.62, p<0.01) and relative percentage (R=-0.58, p<0.01) over time. On the opposite, mature B cells (both Bm5 and early Bm5 compartments) absolute counts did not differ over time (R=-0.04 and 0.11 respectively, p<0.05) whereas the percentages of them were positively correlated with time post-transplant (R=0.40 and 0.36 respectively, p<0.01). Linear regression model showed that the absolute reduction in Bm2 cell compartment (i.e naive B cells) was independent of age, sex, graft function and immunosuppression scheme.

Conclusions: Patients with longer time post-transplant have fewer circulating peripheral B cells. Phenotypic analysis of B cells reveals that this reduction is due to an absolute decrease in naive B cells counts. Maturing B cell absolute numbers, on the other hand, did not change significantly. Either exhaustion due to long-term immunosuppression or immunologic accommodation due to chronic allograft exposure could explain these observations.

PO2392

Donor Derived Cell-Free DNA in Renal Transplants, AlloSure vs. Prospera

Ali Khalil,1 Salman Khan,2 Erica Kalu,3 Muhammad Saim,1 Mark J. Lerman.1 Medical City Dallas Kidney Transplant 1Medical City Dallas Hospital, Dallas, TX; 2Dallas Nephrology Associates, Dallas, TX.

Background: The risk for allograft loss remains high due to rejection. Measuring donor cell free DNA has recently become an important noninvasive test for renal allograft injury and rejection. Two of the commercially available tests to measure dd-cfDNA, are AlloSure(AS) and Prospera.

Methods: We measured dd-cfDNA in 44 post kidney transplants simultaneously using both tests. Patients were 3 to 50 months post kidney transplant and all samples were drawn for cause. Eleven of the 44 patients had allograft biopsies, see table. All patients had routine labs including trough CNI levels and in some cases DSA and/or BK PCR.

PO2393

Donor-Derived Cell-Free DNA Kinetics After Kidney Transplant Biopsy

Yousuf Kyeso,1 Anshul Bhalla,2 Alyssa P. Smith,1 Saba Alakhdhair,1 Mohammad Abuzeineh,1 Daniel C. Brennan,1 Sami Alasfar.2 Johns Hopkins Medicine, Baltimore, MD; 2Methodist University Hospital, Memphis, TN.

Background: Donor-derived cell-free DNA (dd-cfDNA) has generated interest as a potential biomarker for kidney transplant (KT) rejection. It is possible that the KT biopsy procedure itself can cause the release of dd-cfDNA in the blood stream, therefore affecting the reliability of this assay in the post biopsy period. In this study we evaluated the effect of KT biopsy on the level dd-cfDNA and assessed the magnitude and duration of this effect.

Methods: We conducted a single arm prospective study. Samples were collected from 16 adult KT recipients undergoing renal allograft biopsy. All participants had samples drawn within eight hours prior to the biopsy (pre-biopsy), within 20 minutes (hour 0), 2 hours after (hour 2), and 24-48 hours (hour 24-48) after the biopsy.

Results: Mean age at the time of biopsy was 50.6±7.02 years. Most participants were men and Caucasian. Mean serum creatinine at the time of biopsy was 2.24±0.42 mg/dL. The most common reason for obtaining biopsy was rise in serum creatinine, while 4 patients had the biopsy due to elevation in dd-cfDNA. The pre-biopsy time point was compared against all remaining time points. At hour 0 and hour 2, there was a significantly larger log dd-cfDNA mean scores compared to pre-biopsy time point (0.37 vs -0.44, p<0.05). By 24-28 hours post biopsy there was no significant difference in log dd-cfDNA mean score compared to the pre-biopsy score.

Conclusions: KT biopsy leads to an increase in dd-cfDNA percentage after the procedure, however, this rise is transient and resolves by 24-48 hour after the biopsy. Providers can obtain dd-cfDNA level as soon as 48 hours post biopsy with high confidence that the levels have not been affected by the biopsy.

**Development and Clinical Experience with a Cell-Free DNA Monitoring Algorithm for Kidney Re-Transplants**

Trudy McKenna, Elbad Ahmed, William Simmons, Meredith Pastrick, Philippe M. Gauthier, Dianne Keen-Kim.

**Natera, Inc, San Carlos, CA.**

**Background:** The presence of donor-derived cell-free DNA (dd-cfDNA) in blood samples from kidney transplant recipients can be utilized as a biomarker for transplant rejection. 1 Failure of the original allograft due to rejection, infection, or recurrent disease leads to retransplants, observed in up to 10% of all kidney transplant patients. 2, 3 In these cases, the original transplanted kidney is generally left in situ. A rapid, accurate, and noninvasive diagnostic test assessing dd-cfDNA using single nucleotide polymorphism (SNP) based massively multiplexed PCR (mmPCR) test (Prospera10) may be utilized to detect allograft rejection. 4 Among retransplant patients, this test can detect both donor fractions in the plasma, when both the new and previously transplanted kidneys are releasing cfDNA. 5

**Objective:** To present the clinical performance of the SNP-based mmPCR test analysis algorithm on samples from patients with kidney retransplants in which alloplasms are present from two genetically distinct donors.

**Methods:** Plasma samples from a cohort of second transplant patients were collected and processed as described previously. 1-5 The SNP-based mmPCR test algorithm is designed to detect all donor fractions in the plasma, when both the newly transplanted kidney as well as previously transplanted kidney(s) may be releasing cfDNA into the plasma. This algorithm estimates the total fraction of DNA due to all donor fractions combined.

**Results:** We present the clinical performance of patients with a second kidney transplant by this retransplant algorithm. In our dataset to date, no significant difference in dd-cfDNA levels compared to single allograft recipients was observed, suggesting limited cfDNA shedding from the initial kidney transplanted. Our results confirm the ability of this assay to analyze and quantify dd-cfDNA levels in kidney retransplant patients.

**Conclusions:** Our results indicate that performance of this SNP-based mmPCR test is preserved in repeat transplant recipients. Non-invasive assessment of dd-cfDNA in retransplant patients may be used to detect the presence of injury or rejection of the transplanted organ at an early stage, facilitating physician management around change of anti-rejection therapy.

**PO2395**

**Correlation of Donor-Derived Cell-Free DNA with Histology and Molecular Diagnoses of Kidney Transplant Biopsies**

Irfan A. Moinuddin,1 Layla Kamal,1 Dhiren Kumar,1 Anne L. King,2 Ryan Winstead,1 Philip F. Halloran,1 Gaurav Gupta.1 Virginia Commonwealth University, Richmond, VA, University of Alberta, Edmonton, AB, Canada.

**Background:** Circulating donor-derived cell-free DNA (dd-cfDNA; CareDX, Brisbane, USA), a non-invasive test that could detect rejection in kidney transplants, was validated using histologic diagnoses. The interpretation of these findings could be difficult due to variable inter- and intra-observer agreement with regards to histologic diagnoses and evolving classifications overtime. The centralized Molecular Microscope (MMDx; Edmonton, AB) tissue gene expression platform may provide increased precision to traditional histology.

**Methods:** In this single-center prospective study of 208 biopsies, we present novel data on quantification of cfDNA using simultaneous assessments of all ‘for-cause’ and surveillance biopsies with histology(Hx) and MMDx. AUC curves were calculated using the previously published dd-cfDNA cut-offs of < 0.21% to rule-out rejection and > 1% to rule-in rejection

**Results:** Of 208 biopsies done at a median of 5.8 months post-transplant, 108(52%) were done for allograft dysfunction; 74(36%) for surveillance (up to DSA) and 26(12%) for post-rejection treatment surveillance. There were significant discrepancies between Hx and MMDx; with MMDx(92; 44%) identifying a higher number of rejection cases vs Hx(79; 38%). While MMDx identified a higher number of antibody-mediated rejection cases(65; 31%) than Hx(43; 21%); the opposite was true for T-cell mediated rejection(TCMR; Hx:27(13%) vs MMDx: 13 (6%)). AUC Curves for cfDNA concentration and prediction of rejection were more robustly correlated with MMDx(AUC=0.830; p<0.001) than with Hx(AUC=0.75; p<0.001). The median cfDNA level was raised significantly to rejection treatment(median 0.94 to 0.29; p<0.015) vs non-responders(0.76 to 0.82; p=0.25)

**Conclusions:** In this single-center study, for the first time we describe the calibration of dd-cfDNA with simultaneous assessment of kidney transplant biopsy with traditional histology and MMDx. We confirmed and expanded on the data from the DART study where a cut-off of 1% was highly sensitive and specific for ruling-in rejection. We report the correlation of cfDNA with response to rejection therapy. We propose that the combination of tissue gene expression using the molecular microscope and blood-based dd-cfDNA may add precision to traditional histology and could change future practice and treatment paradigms.

**PO2396**

**Elevated Donor-Derived Cell-Free DNA (dd-cfDNA) in Renal Transplant Patients with Donor-Specific Antibodies**

Howard H. Coke,1 Matthew Van Norman,1 Akshita Pai,2 Aleksandra De Golovine,2 Angelina Edwards.2 University of Texas McGovern Medical School, University of Texas John P and Katherine G McGovern Medical School, Houston, TX; Memorial Hermann Texas Medical Center, Houston, TX.

**Introduction:** Complications of renal transplants include graft rejection and failure. Noninvasive dd-cfDNA values greater than 1% detect renal allograft injury and rejection, prior to changes in creatinine. Although antibody mediated rejection (AMR) typically involves donor specific antibodies (DSA) to human leukocyte antigens (HLA), non-HLA antibodies may also impact allograft outcomes. This series of re-transplantation patients with graft injury from AT1R-Ab (>10 U/mL) shows improvement in dd-cfDNA levels with initiation of anARB, Losartan.

**Case Description:** Case #1: 23 year-old man with history of CKD IV due to hypoplastic kidneys. First transplant living unrelated donor failed due to renal vein thrombosis. Received a 2nd deceased donor transplant (DDRT) with thymoglobulin induction. Complement 3 (C3) was reduced and dd-cfDNA 3.3%. Post-transplant allograft function was excellent with nadir creat of 1.0mg/dL. Non-invasive allograft surveillance was initiated with initial dd-cfDNA (ALLOSURE, CareDx, Brisbane, CA) elevated at 1.8%. Antibody assessment was negative for DSA but positive for AT1R-Ab at 28 U/mL. Losartan was initiated with a sustained decrease in dd-cfDNA to <0.3% and stable creatinine levels. Case #2: 63 year-old woman with ESRD from hypertension. Prior living donor transplant failed due to chronic allograft nephropathy. Received 2nd DDRT with thymoglobulin induction given cPRA of 98%, with no DSA. Post-transplant allograft function was excellent with nadir creatinine of 0.8 mg/dL. Non-invasive allograft injury surveillance showed an acute rise in dd-cfDNA to 3.9% on post-operative week 5. Despite stable creatinine, a renal biopsy showed C4D-negative, mild antibody mediated rejection with peritubular capillaritis (ptc 2) and glomerulitis (g1). Antibody assessment showed no DSA but positive AT1R at 16 U/mL. Following Losartan initiation, dd-cfDNA decreased to <1%, with continued excellent graft function.

**Discussion:** AT1R-Ab may be more prevalent in the re-transplant population and is a causative factor for accelerated allograft injury, chronic fibrosis, and graft loss. Quantification of kidney injury via dd-cfDNA, prompt assessment of AT1R-Ab, and initiation of ARB therapy may lead to preserved allograft function, particularly in high immunologic risk patients.

**PO2397**

**Class II Donor-Specific Anti-HLA Antibody Level Is the Major Determinant of Elevated Donor-Derived Cell-Free DNA in Renal Allograft Recipients**

Maria Butia,1 Bogdan Obricsa,2 Ramsammy Bakhvatsalam,1 Kelly D. Smith,1 Iris C. De Castro,1 Christopher D. Blosser,1 Lena Sibuleyska,2 Catherine Kling,1 Gener Ismail,1 Bogdan M. Sorohan,2 Nicolae Leca.1 University of Washington, Seattle, WA; Fundeni Clinical Institute, Bucharest, Romania.

**Background:** dd-cfDNA is a biomarker of allograft injury used for rejection risk monitoring. We sought to analyze the relationship between dd-cfDNA and DSA.

**Methods:** We included all kidney transplant recipients (n=171) who underwent DSA and dd-cfDNA testing as part of their clinical care between 9/17-12/19 at our center. We aimed to identify independent predictors of high dd-cfDNA (at a cut-off of 1%).

**Results:** Table 1 outlines clinical characteristics. There was a strong association between absolute dd-cfDNA level and DSA MFI category (Figure 1). In multivariate logistic regression analysis, DSA MFI was an independent predictor of high dd-cfDNA (Figure 2).

**Conclusions:** dd-cfDNA is strongly associated with class II DSAs and MFI level. Variably observed identifies dd-cfDNA as a potential biomarker for monitoring allograft injury status in patients with DSA.

Case Series: Systemic Infection Alters Background Cell-Free DNA and Influences Donor-Derived Cell-Free DNA Transplant Rejection Assays

Suphamai Bunnapradist,1 Philippe M. Gauthier,2 Hossein Tabriziani,2 Ryan Swenerton,2 Ebad Ahmed,2 Trudy McKenna,2 Paul R. Billings.2
1University of California Los Angeles, Los Angeles, CA; 2Natera, Inc, San Carlos, CA.

Introduction: Donor-derived cell-free DNA (dd-cfDNA), a biomarker for kidney transplant rejection, (1,2) is reported as a percentage of background cfDNA. Various factors affect total cfDNA levels (3,4). We present 3 cases with elevated background cfDNA where dd-cfDNA was assayed for rejection assessment.

Case Description: 1 A 78 year old man with end-stage renal disease (ESRD) underwent a kidney transplant. A biopsy at +6 months (m, all time points relative to transplant date) due to an elevated creatinine level indicated an acute T cell-mediated rejection (TCMR). At +7m, the patient tested positive for BK viremia, and was treated. He was admitted for nephrectomy of his native kidney at +14m and tested positive for herpes and cytomegalovirus (CMV) exophagitis and treated. A cfDNA analysis was negative for rejection with background cfDNA = 10,326 Arbitrary units (AU)/mL (~21X median cfDNA).) Banff chronic active cellular rejection was confirmed from a subsequent biopsy.

2 A 62 year old woman with ESRD who underwent a kidney transplant had a cfDNA assay +3 years, that was reported as a negative result. However, the background was elevated at 3,466 AU/mL (~7X median). She had a biopsy that showed BK virus-associated nephropathy and TCMR. 3 A 53 year old woman with ESRD had a kidney transplant from an ABO incompatible donor. A month later, she was diagnosed with dengue fever followed by acute allograft dysfunction. A biopsy at +6m showed active antibody-mediated rejection (ABMR). On a cfDNA assay at +7m indicated a negative result; however with an elevated background (6344 AU/mL, ~13X median). A biopsy showed resolution of ABMR and borderline acute cellular rejection.

PO2399

Donor-Derived Cell-Free DNA Identifies Patients with Antibody-Mediated Rejection and Strongly Correlates Histologically with Microvascular Inflammation

Bogdan Obrisa,2 Maria Butiu,1 Ramsamy Bakhavatsalum,1 Kelly D. Smith,1 Iris C. De Castro,1 Christopher D. Blosser,1 Lena Sibulesky,1 Catherine Kling,1 Genner Ismail,2 Bogdan M. Sorohan,1 Nicolae Leca,1 University of Washington, Seattle, WA; 2Fundeni Clinical Institute, Bucharest, Romania.

Background: Accurate and timely detection of rejection is central to improving long-term kidney transplant outcomes. We sought to characterize the association of dd-cfDNA level with rejection status and histological lesions.

Methods: We included all patients (n=54) that underwent a kidney transplant biopsy for suspicion of rejection at our center between 9/17-12/19. Concurrent dd-cfDNA and DSA testing was obtained. Rejection type (Banff 2017) and histological lesions were tested for association with dd-cfDNA level.

Results: 18 patients had ABMR (6 mixed ABMR/TCMR), while 12 patients had TCMR alone. Of those with ABMR, 94.4% had a dd-cfDNA level >1%, compared to 16.6% of those with TCMR alone (p<0.001). Of those with a high dd-cfDNA (>1%), 76.2% had both DSA and ABMR. In multivariate logistic regression analysis, a high dd-cfDNA was a more important predictor of ABMR than a DSA MFI level over 2500 (Fig1).

A high dd-cfDNA accurately discriminates ABMR (AUC=0.96; 95%CI, 0.92 to 1.00; p<0.001), with a positive and negative predictive value of 80.9% and 96.9%, respectively. A high dd-cfDNA level showed a strong correlation with microvascular inflammation (Fig2), but not with tubulitis or interstitial inflammation.

Conclusions: Our study confirms the high diagnostic accuracy of dd-cfDNA for ABMR, while the strong association with elementary lesions of microvascular inflammation supports the specificity of this test for antibody-mediated allograft injury.

PO2400
Impact of Body Mass Index on Baseline Donor-Derived Cell-Free DNA in Kidney Transplant Recipients

Background: Donor derived cell free DNA (dd-cfDNA) is useful in predicting acute rejection in renal allografts. The technology uses next generation sequencing and does not require donor genotyping. dd-cfDNA is expressed as a percentage of the total (including self and non-self) circulating DNA fragments. Since self-portion of cell free DNA can vary according to body size, we aimed to test the hypothesis that expressed percent of baseline dd-cfDNA can vary by the recipient’s body mass index (BMI).

Methods: Our center has been doing for cause as well as surveillance (for high immunologic risk) dd-cfDNA in kidney transplant recipients (KTRs) using AlloSure (CareDx, Brisbane, CA). We identified patients who underwent kidney transplantation between September 2017 and June 2019 and had serial dd-cfDNA levels. A dd-cfDNA value ≥1% prompted allograft biopsy. KTR with biopsy evidence for rejection or other injuries were excluded from the analysis. Study subjects were divided into BMI (kg/m²) groups as follow: <25, 25-29.9, ≥30. Baseline dd-cfDNA values were compared between BMI groups.

Results: There were 88 (81 first-time and 7 repeat) KTRs during the study period who had dd-cfDNA measurements and available BMI. We excluded 16 first-time and 3 repeat KTRs from the analysis due to biopsy evidence of rejection. The remaining 69 patients had 227 dd-cfDNA levels available for analysis. Patients were divided based on BMI categories with stratification of baseline dd-cfDNA values as shown in table 1. There were no significant differences in baseline dd-cfDNA values for BMI groups <25 vs. 25-29.9 (0.63 ± 0.63% vs. 0.41±0.27% p=0.16) and BMI groups 25-29.9 vs. ≥30 (0.41±0.27% vs. 0.33±0.16%, p = 0.22). However, there was a trend towards significantly higher baseline dd-cfDNA values in BMI group <25 vs. ≥30 (0.63±0.63% vs. 0.33±0.16%, p=0.06).

Conclusions: Our study showed a trend towards significant differences in dd-cfDNA values between extremes of BMI groups. These differences could become significant with larger study subjects. Our findings point towards the need for normalization of dd-cfDNA values with respect to body size for reporting purposes.

Protocol-Based Donor-Derived Cell-Free DNA Surveillance in Kidney Transplant Recipients: A Single-Center Experience
Pichanach Tirirawongsakorn, Het Patel, Martha Pavlakis, Amtul Aala, Nikhil Agrawal. Beth Israel Deaconess Medical Center, Boston, MA.

Background: Kidney biopsy is invasive and has limited utility when used as a surveillance test post-transplant. Donor-derived cell-free DNA (dd-cfDNA) surveillance testing has never been studied in comparison with other routinely performed surveillance tests.

Methods: Our transplant center implemented the dd-cfDNA (AlloSure) surveillance program (1,2,3,4,6 months and then quarterly post-op) in kidney transplant recipients starting July 2018, in addition to our existing protocol measurements of serum Cr, proteinuria and DSA. We retrospectively reviewed all kidney alone transplant recipients starting July 2018 through June 2019 at our center. Donors were classified using AKN criteria for AKI based on increase of terminal serum creatinine (Scr) over initial Scr. Death-censored graft survival and eGFR (MDRD) were compared.

Results: 911 recipients received kidneys from donors with no AKI (Stage 0). 208 (18.6%) received kidneys from donors with AKI. AKI 45 (4.02%) had Stage 1 AKI, 59 (5.27%) had Stage 2 AKI, and 104 (9.29%) had Stage 3 AKI. There were no significant differences between the AKI and non-AKI groups in recipient age, gender, ethnicity, or Estimated Post-Transplant Survival score. Using a Cox Proportional Hazards Model, death-censored graft survival at 1 year was not distinguishable between recipients whose donor had any stage of AKI versus donors without AKI (HR 0.94, p=0.854) nor among AKI stages (Figure 1). Mean eGFR by MDRD formula for recipients alive and with followup at 1 year was 60.0 (SD 23.2) in recipients with non-AKI donors and 61.9 (SD 26.1) in recipients with AKI donors, which was of no statistical significance (p=0.4384).

The rate of delayed graft function was significantly higher in recipients from AKI donors (62.0%) versus non-AKI donors (31.5%), p<0.0001.

Conclusions: Recipients of AKI donors did not yield inferior outcomes to those of non-AKI donors at 1 year. Increased DGF can be anticipated, but does not appear to have any lasting impact on graft survival or renal function. As such, transplant centers should consider expanding the use of these kidneys for any waitlisted candidate.

Funding: Clinical Revenue Support

PO2402
Successful Transplantation Outcomes Using Deceased Donors with AKI

Background: Kidneys from deceased donors with acute kidney injury (AKI) are discarded at a higher rate than those without AKI, exacerbating the organ shortage. This paper reviews outcomes of kidneys from deceased donors with AKI over a four-year period at a single transplant center.

Methods: We analyzed 1119 consecutive deceased donor kidney adult recipients transplanted from 2016 through 2019 at our center. Donors were classified using AKN criteria for AKI based on increase of terminal serum creatinine (Scr) over initial Scr. Death-censored graft survival and eGFR (MDRD) were compared.

Results: 911 recipients received kidneys from donors with no AKI (Stage 0). 208 (18.6%) received kidneys from donors with AKI. AKI 45 (4.02%) had Stage 1 AKI, 59 (5.27%) had Stage 2 AKI, and 104 (9.29%) had Stage 3 AKI. There were no significant differences between the AKI and non-AKI groups in recipient age, gender, ethnicity, or Estimated Post-Transplant Survival score. Using a Cox Proportional Hazards Model, death-censored graft survival at 1 year was not distinguishable between recipients whose donor had any stage of AKI versus donors without AKI (HR 0.94, p=0.854) nor among AKI stages (Figure 1). Mean eGFR by MDRD formula for recipients alive and with followup at 1 year was 60.0 (SD 23.2) in recipients with non-AKI donors and 61.9 (SD 26.1) in recipients with AKI donors, which was of no statistical significance (p=0.4384).

The rate of delayed graft function was significantly higher in recipients from AKI donors (62.0%) versus non-AKI donors (31.5%), p<0.0001.

Conclusions: Recipients of AKI donors did not yield inferior outcomes to those of non-AKI donors at 1 year. Increased DGF can be anticipated, but does not appear to have any lasting impact on graft survival or renal function. As such, transplant centers should consider expanding the use of these kidneys for any waitlisted candidate.

Combined Impact of Presensitization and Delayed Graft Function on Allograft Outcome in Deceased Donor Kidney Transplantation: Nationwide Cohort Study
Byung ha Chung,1 Haebi Lee,1 Yohan Park,1 Tae Hyun Ban,2 Sang Heon Song,2 Jaeceok Yang,1 Curie Ahn,1 Chul Woo Yang.1 Korean Organ Transplantation Registry Study group;1 Seoul Saint Mary's Hospital, Seocho-gu, Seoul, Republic of Korea; 2Eunpyeong St. Mary's hospital, Seocho-gu, Seoul, Republic of Korea; 3Pusan National University Hospital, Busan, Republic of Korea; 4Seoul National University College of Medicine Department of Internal Medicine, Seoul, Republic of Korea.

Background: Pre-sensitization to HLA has detrimental effect on allograft rejection, worse allograft function and survival. Delayed graft function (DGF) is associated with poor allograft outcome by ischemia-perfusion injury. We undertook analysis to determine combined association of presensitization to HLA and DGF on allograft outcome in deceased donor kidney transplantation (DDKT) and whether there is a synergistic effect.

Clinical and Immunologic Predictors of Post-Transplant Outcomes

PO2404

The Clinical Significance of Preformed C1q-Binding Donor-Specific HLA Antibodies in Kidney Transplantation

Sun Lee, Byung Ha Chung, Chul Woo Yang. Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; Catholic University of Korea, Seoul, Republic of Korea.

Background: The anti-human leukocyte antigen (HLA) antibodies are well known for risk factor of rejection or allograft loss in kidney transplantation (KT). De novo complement component 1q-binding donor-specific anti-HLA antibodies (C1q-binding DSAs) are already reported to be associated with an increased risk of acute allograft rejection in KT. This study investigated the clinical significance of identification of preformed C1q-binding DSAs for predicting graft outcomes in KT.

Methods: From December 2016 to December 2018, 323 recipients underwent KT at Seoul St. Mary’s Hospital. If the results of panel reactive antibodies (PRA) were positive in the pre-transplant examination, DSAs and C1q-binding DSAs were performed using Luminex Single Antigen Bead Assay (SAB) at the same time. Graft outcomes in term as Chronic Kidney Disease-Epidemiology Collaboration estimated Glomerular Filtration Rate, biopsy proven acute rejection and graft survival were compared between recipients with preformed C1q-binding DSAs and recipients without preformed C1q-binding DSAs.

Results: Eighty-two of 323 recipients (25.4%) were evaluated DSAs and C1q-binding DSAs before transplantation. Among them, 40 recipients (48.8%) had preformed DSAs and 8 recipients (9.9%) had preformed C1q-binding DSAs. The higher MFI values of DSAs had higher prevalence of C1q-binding DSAs (9263.9 ± 3670.3 vs. 5955.3 ± 5245.5; p < 0.050). There was a strong correlation between the presence of DSAs against Class II and C1q-binding DSAs (p = 0.007; CI 95%, OR 3.403). Five of 21 patients (23.8%) with positive at least one of complement-dependent cytotoxicity (CDC) or flow cytometry crossmatch (FCXM) had preformed C1q-binding DSAs. There was a strong correlation between positivity of crossmatch and preformed C1q-binding DSAs (p = 0.024; CI 95%, OR 6.042). Four of 8 recipients (50%) in C1q-binding DSAs(+) group were confirmed acute antibody mediated rejection. C1q-binding DSAs(+) group had higher incidence of acute antibody mediated rejection than C1q-binding DSAs(-) group (p=0.048; CI 95%, OR 4.286).

Conclusions: The identification of preformed C1q-binding DSAs may be important in predicting acute antibody mediated rejection. Therefore, the surveillance such as protocol allograft biopsy is required for early detection of acute antibody mediated rejection after transplantation in patients with preformed C1q-binding DSAs.

PO2405

Potential Combined Use of Kidney Donor Profile Index (KDPI) and Estimated Post-Transplant Survival (EPTS) Scales to Predict eGFR Decline in Deceased Donor Kidneys

Pablo Magrini, Sergio Hernández-Estrada, Odette Del Carmen Díaz Avendaño, Christian P. Flores, Benjamin Gomez-Navarro, María Guadalupe R. Ramírez, Jose H. Cano, Maria Concepcion Osegueda-Vizcaíno, Daniel F. Ovando-Morga, Mayra M. Matias Carmona. Renal Transplant Unit, National Medical Center “20 de Noviembre”, Mexico City, Mexico; Renal Transplant Unit, Hospital Civil de Guadalajara Fray Antonio Alatorre, Guadalajara, Jalisco, Mexico; Centro Medico Nacional de Occidente, Guadalajara, Jalisco, Mexico.

Background: Utility of the sum of EPTS and KDPI scales to predict the decline of eGFR in patients who received a cadaveric donor kidney transplant. Assess the reproducibility of the Organ Assignment System of the USA in our country.

Methods: In our prospective cohort study, between May 2014 and June 2019, 139 deceased donor kidney transplant patients were assigned into 2 groups; pre-sensitized and non-pre-sensitized. Each group was divided into 2 subgroups according to DGF. Pre-sensitization was defined as the presence of donor specific antibodies (DSA) or the presence of panel-reactive antibody (PRA), combination with crossmatch positive. DGF was defined as the need for dialysis before discharge. We compared the clinical outcomes including allograft rejection, the change of allograft function, infectious and cardiovascular complication and allograft survival.

Results: Pre-sensitization group was 137 (10.0%) patients and others (n=233, 90.0%) belonged to non-sensitized group. Pre-sensitization-DGF subgroup was 21 (15.3%) and pre-sensitization-non-DGF group was 116 (84.7%). Non-pre-sensitization-DGF subgroup was 133 (9.7%) and non-pre-sensitization-non-DGF group was 1100 (80.3%). In both pre-sensitization and non-pre-sensitization groups, allograft function using eGFR by CKD-EPI equation (mL/min/1.73m²) was lower in DGF subgroup than non-DGF subgroup. In contrast, allograft rejection rate showed no significant difference between DGF and non-DGF subgroup within non-pre-sensitization group (15.0% vs 12.9%, p=0.493). There was no significant difference between DGF and non-DGF subgroups in both groups in regard to allograft survival and patient survival.

Conclusions: DGF combined with pre-sensitization had much worse effect on allograft outcome in terms of allograft rejection. Therefore, we suggest more careful monitoring or surveillance for allograft rejection when DGF occurred in DDKT with pre-sensitization.

PO2406

Vasopressin Use After Deceased Donor Kidney Transplant (DDKT): Patient Characteristics, Graft Function, and Clinical Outcomes

Muhammad Y. Jan, William Goggins, Muhammad S. Yaqub, Tim E. Taber, Dennis P. Mishler, Sharon M. Moe, Ranjani N. Moothi, Michael T. Eadon, Jeanne Chen, Asif A. Shafriuddin. Indiana University School of Medicine, Indianapolis, IN.

Background: Vasopressin (AVP) is used for maintenance of volume status and hemodynamics due to its vasopressor activity with less arrhythmogenic and ischemic potential. It has catecholamine sparing effect. AVP has been shown to improve rates of deceased organ donation. We studied AVP use post DDKT for improving hemodynamics with resultant effect on graft function and clinical course.

Differences in Urinary Inflammatory Profiles in Donor-Recipient Pairs
Elizabeth Spiwak, Corina Nailescu, Andrew L. Schwaderer. Riley Hospital for Children at Indiana University Health, Indianapolis, IN

Background: Renal transplant is the most common type of transplant performed in the US. Immunosuppressants are used in transplant recipients to prevent rejection. Kidney transplant recipients are at a higher risk for infection in the pre- and post-transplant state. Urine inflammatory profiles may lend insight to this balance between infection and rejection. Since donor and recipient urine is generated by genetically identical kidneys, it represents an ideal bio-sample for paired analysis.

Methods: Urine samples were obtained from stable children > 2 months post-transplant along with their donors (n=6) and another 8 recipient-donor-recipient pairs (adult and children) that were collected for longitudinal samples; of which a pretransplant sample has been obtained. Using the V_PLEX Human Cytokine Panel (Mesoscale Discovery, Rockville MD) urine inflammatory mediators were quantified. The paired sample has been obtained. Using the V_PLEX Human Cytokine Panel (Mesoscale Discovery, Rockville MD) urine inflammatory mediators were quantified. The paired sample has been obtained. The V_PLEX Human Cytokine Panel (Mesoscale Discovery, Rockville MD) urine inflammatory mediators were quantified. The paired sample has been obtained.

Results: Interleukin (IL)7, IL15, Monocyte chemotactic protein-1 (MCP-1) and Granulocyte-macrophage colony-stimulating factor (GM-CSF) were higher in the pediatric post-transplant recipients compared to their donors P values of 0.017, 0.037, 0.046 and 0.031 respectively. IL-9 was higher in recipient urine in pre-transplant patients (p=0.004) compared to donors.

Conclusions: Transplant patients have an elevated urine inflammatory mediator profile. Pretransplant patients have elevated IL-9 compared to their donors. Reasons for this altered inflammatory profile include immunologic, hemodynamic or physiologic changes intrinsic to the transplant procedure versus medications used to manage transplant patients.

PO2408
LIMS1 Gene Mismatching and Risk of Rejection in Kidney Transplant Recipients
Yasar Caliskan,1 Safak Mirioglu,2 Halil Yazici,2 Ahmet B. Dirim,2 Erol Demir,2 Ozgur A. Oto,2 John C. Edwards,1 Rosemary Ousoph,1 Aydin Turkmen,2 Krista L. Lentine,1 'Saint Louis University, Saint Louis, MO; 'Istanbul University, Istanbul, Turkey.

Background: Recent advances in precipitation medicine have provided new insights into the pathogenesis of kidney transplant (KxT) rejection such as the potential role of genetic risk variants in LIM Zinc Finger Domain Containing 1 (LIMS1). We aimed to evaluate the relationship between donor and recipient LIMS1 genotype matching status and allograft rejection and survival.

Methods: We genotyped 41 prevalent living KxT recipient [24 (59%) males; mean age 34 ± 13 years] and donor [15 (37%) males; mean age 47 ± 13 years] pairs for LIMS1 rs893403 variant by Sanger sequencing in order to assess their impact on rejection and survival. The recipients homozygous for LIMS1 rs893403 GG genotype which tags a common 1.5-kb deletion (CNVR915.1) received a transplant from a nonhomozygous donor were defined as risk mismatched. CNVR915.1 deletion is confirmed by PCR in recipients with rs893403-AG and GG genotypes. Rejections were defined as T-cell mediated (TCMR) or antibody mediated rejection (ABMR) defined by Banff 2013 criteria. Outcomes were abstracted by review of medical records.

Results: There were no differences between recipients with risk LIMS1 mismatching (n=5) and recipients without risk LIMS1 mismatching (n=36) regarding demographic factors, duration of dialysis, pretransplant PRA, HLA mismatching, immunosuppressive protocols and follow up time. After a median post-KTx follow up of 10.5 (IQR 8.7-12.6) years recipients with risk LIMS1 mismatching had significantly higher risk of allograft rejection (60%; median 1 month) compared to recipients without risk LIMS1 mismatching (13.9%; median 72 months) (HR=4.32, 95CI% 1.46-12.76, p=0.015). TCMR was higher in recipients with risk LIMS1 mismatching (40%) compared to recipients without risk LIMS1 mismatching (11.1%) (p=0.087). There were no significant differences found between patients with and without risk LIMS1 mismatching regarding risk of post-KTx DSA, ABMR and allograft failure. The mean eGFR levels at last follow up were also similar among recipients with and without risk LIMS1 mismatching.

Conclusions: Genomic mismatching at LIMS1 gene appears to impact risk of TCMR. LIMS1 may be a potential minor histocompatibility antigen and pre-transplant genetic testing may have clinical implications for the prediction and clinical management of KxT rejection.

Monitoring of Gene Expression in Tacrolimus-Treated De Novo Renal Allograft Recipients Facilitates Individualized Immunosuppression: Results of the IMAGEN Study

Claudia Sommerer,1 Merce Brunet,2 Klemens Budde,3 Olga Millan,2 Lluís Guirado,4 Petra Glander,5 Stefan Meuer,6 Martin G. Zeiër,7 Thomas Giese.8 1Nephrology, University Hospital Heidelberg, Heidelberg, Germany; 2Pharmacology and Toxicology Laboratory, Barcelona, Spain; 3Nephrology, University Hospital Charité, Berlin, Germany; 4Renal Transplant Unit, Nephrology Department, Fundació Puigvert Barcelona, Barcelona, Spain; 5Immunology, University Hospital Heidelberg, Heidelberg, Germany.

Background: The expression of nuclear factor of activated T-cells (NFAT)-regulated genes in the peripheral blood has been suggested as a potentially useful immune monitoring tool to individualize tacrolimus (Tac) therapy. The aim of the present study was to characterize the possibility and clinical utility of monitoring of residual NFAT-regulated gene expression in renal allograft recipients in a multicenter approach.

Methods: The IMAGEN study enrolled 64 de novo renal transplant recipients from three European centers. All patients were treated with Tac, mycophenolic acid, and corticosteroids. NFAT-regulated gene expression (NFAT-RGE; IL-2, IFN-g, GM-CSF) was evaluated by quantitative real-time PCR in whole blood samples at day 7, month 1, 2, 3, and 6 after transplantation.

Results: Altogether, 60 patients could be evaluated. Tac concentrations (0 and C1.5 [pg/ml]) correlated inversely with gene expression (p<0.001). NFAT-RGE showed a high interindividual variability (1 to 61%). RGE increased in the first two months from 164±9 to 34±21%. Patients (n=20) with high residual gene expression (NFAT-RGE>30%) were at the increased risk of acute rejection in the following months (35% vs 5%, p=0.002), whereas patients (n=40) with low residual gene expression (NFAT-RGE<30%) showed a higher incidence of viral complications, especially cytomegalovirus and BK virus replication (52.5% vs 10%, p=0.001).

Conclusions: NFAT-RGE was confirmed as a potential non-invasive early predictive pharmacodynamic marker in the immediate post-transplant period for the risk of acute rejection and infections complications in Tac-treated renal allograft recipients. Monitoring of NFAT-RGE may provide additional useful information for physicians to achieve individualized treatment adjustments based on the immunomodulatory effect of Tac, thus preventing serious clinical events. The method of NFAT-RGE measurements can be applied in trials with multicenter approach.

PO2410

The Role and Inducers of Nonclassical HLA-G in Renal Transplanted Allografts

Sho Kimano, Keiji Fujimoto, Hiroki Adachi, Kengo Furuchi, Hitoshi Yokoyama. Department of Nephrology, Kanazawa Medical University School of Medicine, Uchinada, Ishikawa, Japan., Katsukugun, Japan.

Background: Non-classical class I molecule HLA-G has a high potential to modulate immune response. However, the mechanism of HLA-G induction was still unknown. In this background, expression of HLA-G on proximal tubular epithelial cells (pTECs) and the inducer of HLA-G were investigated.

Methods: Our subjects comprised 40 adult Japanese subjects whose allograft had survived for at least 1 year (35 patients from a living donor, 5 patients from a deceased donor). They were evaluated for HLA-G1/5 expression using an immunofluorescence method. We investigated inducer of HLA-G using primary cultured human pTECs treated with cytokines and immunosuppressants.

Results: In renal biopsy tissues, 2 to 4 weeks or 1 year following the transplantation, HLA-G expression was noted in the peritubular region or on the basement membrane side of pTECs in 12 of 40 cases (30 %). Further, for median 8.8 years, the time taken for a 30 % reduction in eGFR was longer in the HLA-G-positive group than in the HLA-G-negative group (p=0.016, Figure). HLA-G1/5 expression on pTECs was also found to be an independent predictor of the improvement in renal allograft function by Cox’s proportional hazard model (p=0.030). In vitro study, interferon-beta (INF-β) was the strongest inducer of HLA-G expression, while immunosuppressants (everolimus, tacrolimus, cyclosporin, and dexamethasone) did not induce expression.

Conclusions: The study showed that HLA-G1/5 expression on pTECs was an independent improving predictor of renal allograft. Furthermore, the strongest HLA-G1/5 inducer was INF-β, but not the immunosuppressive agents. These results suggested the possibility that acquired expression of HLA-G exhibits a long-term renal preservation effect, different from the effect of immunosuppressants.

PO2411

The Clinical Impact of Preformed HLA-DQ Donor-Specific Antibodies on Graft Outcomes in Kidney Transplantation

Sua Lee,1 Chul Woo Yang,2 Byung ha Chung.3 1Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; 2Catholic University of Korea, Seoul, Republic of Korea.

Background: De-novo HLA-DQ donor-specific antibody (DSA) has been identified as a risk factor for graft rejection and loss in kidney transplantation (KT). Recently, the impact of preformed HLA-DQA DSA has been discussed. This study aimed to investigate the clinical impact of preformed HLA-DQA DSA on graft outcomes.

Methods: We evaluated 990 recipients who underwent kidney transplantation at Seoul St. Mary’s Hospital from January 2010 to July 2019. According to the result of DSA using luminex single antigen bead assay, recipients were classified as no DSA, only DQ, non-DQ, and DQ + non-DQ. Primary outcomes were the incidence of biopsy-proven acute rejection and the rate of death-censored graft loss.

Results: In total cohort, 611 recipients (61.7%) and 379 recipients (38.3%) underwent living-donor KT and deceased-donor KT, respectively. Recipients were classified as no DSA (909 recipients, 91.8%), only DQ (18 recipients, 1.8 %), non-DQ (57 recipients, 6.3%), and DQ + non-DQ (6 recipients, 0.7%). The overall incidence of acute rejection and acute antibody-mediated rejection (AMR) were 20.3% and 7.5%. Only DQ, non-DQ, and DQ + non-DQ group had significantly higher the incidence of acute AMR compared to no DSA group (p < 0.05, respectively). There was no significant difference in the incidence of acute AMR between sensitized groups. There was no difference in the rate of death-censored graft loss between groups. In univariate Cox regression analysis, all of 3 groups with DSA were associated with high risk of acute AMR (Only DQ; HR 5.051; CI 95%, p = 0.002, non-DQ; HR 6.005; CI 95%, p < 0.001, DQ + non-DQ; HR 7.748; CI 95%, p = 0.005, respectively). HLA-DQA DSA and other DSAs (HLA-A, HLA-B, HLA-C) had a tendency to interact with acute AMR, although no statistical significance (p = 0.05).

Conclusions: Preformed HLA-DQA DSA is associated with the development of acute rejection, especially acute AMR. Therefore, the identification of preformed HLA-DQA DSA may be necessary to improve graft outcomes.

PO2412

Outcomes of High Kidney Donor Profile Index Kidneys at a Large Center

Background: Kidneys from donors with high Kidney Donor Profile Index (KDPI) are often discarded due to concerns about outcomes. Despite decreased survival, the survival benefit of receiving a transplant and avoiding time on dialysis is beneficial, especially for selected patients.

Methods: We increased use of high KDPI (KDPI>85) deceased donor kidneys (DDK) over several years. We performed a single-center analysis of 1119 consecutive adult DDKT from 2016-2019. Our endpoints were Kaplan-Meier death-censored survival.

Gluomeral Blood Flow in Living Donor Kidney Transplant Recipients
Gio Kanzaki, Takaya Sasaki, Kotoro Haruhara, Rina Oba, Yusuke Okabayashi, Kentaro Koike, Akimitsu Kobayashi, Izumi Yamamoto, Noboru Taiboi, Takashi Yokoo. The Jikei University School of Medicine, Minato-ku, Japan.

Background: Renal graft hemodynamics may be a valuable predictor of graft survival and long-term outcomes. Although several studies have reported that renal blood flow was correlated with graft function and decreased remarkably during acute rejection episode, the glomerular hemodynamic changes during kidney transplantation are lacking because there is no method of measuring neaphron number in vivo. In this study, we calculate glomerular blood flow (GBF) by estimating the nephron number and investigate changes in GBF after kidney transplantation and their clinicopathological relationship.

Methods: We performed a retrospective analysis of 42 patients who underwent living donor kidney transplantation. The number of glomeruli (Ngлом) was calculated as the cortical volume of both kidneys as assessed on computed tomography times the 1-hour posttransplant renal biopsy-determined glomerular density. Effective renal plasma flow (ERPF) was assessed as 99mTc-MAG3 clearance. GBF was calculated as follows: GBF (nl/min) = ERPF/Nглом/(1-hematocrit/100) x10 317.4 nl/min.

Results: Prior to transplantation, the GBF in donors was 559.7±257.3 nl/min, whereas the GBF in recipients on day 2 post-transplantation was decreased to 502.6±317.4 nl/min. After successful transplantation, the GBF one-month post-transplantation has settled down to 491.9±291.1 nl/min, while the eGFR progressively rose (48.7±18.4 ml/min/1.73m²) together with the hematocrit (31.1±3.9 %). The GBF at one month was positively associated with eGFR at one month (p<0.05). Of note, the GBF ratio was correlated with the eGFR and urinary protein excretion at one month and urinary protein excretion at one year but was not correlated with eGFR at 1 yr.

Conclusions: We first reported the GBF in kidney transplant recipients before and after kidney transplantation. Our findings suggest that abnormal change in GBF may be considered predictive indices for short-term allograft outcomes.

PO2415

Characteristics of Anonymous Living Donors and Their Recipients and Outcomes: Appropriate Use of a Rare and Valuable Gift
Muhammad Y. Jan, Muhammad S. Yaqub, Oluwafisayo O. Adebiyi, Tim E. Taber, Asif A. Sharifuddin. Indiana University School of Medicine, Indianapolis, IN.

Background: Anonymous Living Donors are a special select set of donors. We review the trends and the characteristics and utilization of such donors nationally.

Methods: All Living Donors (code=10 “Anonymous”) and their recipients who were recorded in the UNOS database from Oct 1997 through Sep 2017 were reviewed for demographics and recipient outcomes.

Results: There were a total of 2286 such donors during the study period. There was an increasing trend of the donors over the time period. Demographics and Outcomes are shown in the Table. DCGS was significantly superior when donor was 20 years or more younger than the Recipient (p<0.019) and significantly inferior when the 20 years older than the recipient (p=0.065). There was no difference in cumulative graft survival between adult and pediatric graft survival (p=0.055), although DCGS was superior in the adults (p=0.021).

Conclusions: To our knowledge, this is the first comprehensive report on the characteristics of Anonymous Living Kidney Donors and their Recipients and outcomes. Better characteristics matching in a minority of such transplants may improve further longevity from such donors.

PO2416
Outcomes of Delayed Graft Function: A Systematic Review and Meta-Analysis
Vanessa Sandra,1 Navin Sanichar,1 Emily Daniel,1 Miah T. Li,1 Kristen L. King,1 Jacob Stevens,2 Syed A. Husain,1 Tracy J. Mayne,1 Sumit Mohan.1 Columbia University, New York, NY; 2Angion BioMedica, San Francisco, CA.
Background: Delayed Graft Function (DGF) is a frequent complication of kidney transplantation, but its impact on long and short-term outcomes remain uncertain.
Methods: We conducted a literature search for studies investigating the association of DGF on subsequent outcomes from 2007-2020. Outcomes were abstracted and used to create cumulative forest plots with pooled odds ratios, stratifying our analysis between center-studies and registry-studies and follow-up time where possible. The outcomes analyzed were graft failure (GF), acute rejection (AR), patient survival, and renal function.
Results: Of the 1464 articles reviewed, 27 were included. In single center-studies, DGF patients experienced higher GF at 1 year (OR 2.45, 95% CI 1.79-4.29, p<0.001), 3 years (OR 1.70, 95% CI 1.01-2.86, p=0.001), increased AR 1-year post-transplant (OR 1.48, 95% CI 1.79-4.28, p=0.001), and decreased 1-year patient survival (OR 0.46, 95% CI 0.28-0.73, p<0.001). Registry-studies showed a similar significant association with GF at 1 year (OR 2.76, 95% CI 1.79-4.28, p<0.001) and 3 years (OR 1.70, 95% CI 1.01-2.86, p=0.046), with AR within 1 year (OR 1.48, 95% CI 1.45-8.67, p<0.005) and 3-years (OR 0.54, 95% CI 0.41-0.72, p<0.001), and 1-year survival (OR 0.45, 95% CI 0.26, 0.77, p<0.001). Qualitative analysis showed that DGF had significant effect on eGFR and creatinine levels, though studies conflict on timeframe. Few studies investigated outcomes stratifying DGF severity or KDPI.
Conclusions: DGF was associated with increased risk of GF, AR, and mortality, although effects were largest within 1 year post-transplant. Our analysis indicated a need for a standardized method to measure DGF severity and further studies on DGF outcomes on varying KDPI. These results should inform the selection process, treatment, and monitoring of transplanted kidneys at high risk for DGF.

PO2417
Duration of Delayed Graft Function Predicts Kidney Allograft Function and Survival
Sanjana Kapoor, Nawras Alshoubaki, Chethan M. Puttarajappa, Sundaram Harilharan. University of Pittsburgh Medical Center, Pittsburgh, PA.
Background: The current study evaluated the duration of DGF as a measure of severity of ischemic injury to kidney transplant outcome.
Methods: This single center study evaluated DD kidney transplant recipients with DGF between Jan 2014 and Dec 2019. DGF was defined as the need for dialysis within 7 days post-transplant & were divided into three groups according to post transplant dialysis duration. Group I: dialysis ≤7 days, Group II: dialysis 8-14 days and Group III: dialysis >14 days. All primary & repeat adult kidney recipients of DD transplants were included. We excluded multiorgan recipients and pediatric en-bloc kidneys. We calculated eGFR over time using CKD EPI formula. Statistical analysis was performed to identify differences in variables, Linear Mixed Model for eGFR over time. Log-rank test was used to evaluate differences in graft & patient survival & composite end point (graft loss, patient loss & GFR, 20ml/min) for all 3 subgroups.
Results: A total of 132 DD KT recipients with DGF were identified: Group I: n=84 (64%), Group II: n=24 (18%) & Group III: n=24 (18%). The recipient/donor demographics and Donor (KDPI) & Transplant variables were similar across groups. Figure 1(left) shows significantly lower eGFR values over time using linear mixed model among patients who needed dialysis for >14 days (Gr III vs I&II, P=0.006). Table 1 shows the incidence of Isolated Graft Loss, Patient death and combination of graft loss & patient death among 3 groups. Figure 1(right) shows significantly lower composite end point (combination of patient loss, graft loss and impending graft loss) for among patients who needed dialysis for >14 days (P=0.0002).
Conclusions: In conclusion, we found a strong association between prolonged DGF>14 days with lower GFR values and survival outcomes. No differences in eGFR or survival rates were noted among patients with DGF patients <7 days vs 7-14 days.
Funding: Clinical Revenue Support

PO2418
Design of the Graft Improvement Following Transplant (GIFT) Trial, a Phase 3 Study of ANG-3777 in Kidney Transplantation Patients with Delayed Graft Function
Flavio Vincenzi1 Tracy J. Mayne,2 Deb Gouweia,2 John F. Neylan.2 University of California San Francisco, San Francisco, CA; 2Angion Biomedica, San Francisco, CA.
Background: Patients after kidney transplantation can experience acute kidney injury (AKI) resulting in delayed graft function (DGF). The Food and Drug Administration has prioritized the development of new treatments for DGF. A Phase 2 trial demonstrated that treatment with ANG-3777, a hepatocyte growth factor (HGF) mimic, improved renal function up to 12-months in patients with signs of DGF.
Methods: Objective: To describe the GIFT trial (Study 001-15), designed to evaluate the efficacy and safety of ANG-3777 in renal transplantation patients with signs of DGF.
Results: GIFT is a Phase 3, multicenter, prospective, randomized, placebo-controlled, study enrolling patients who have undergone a kidney transplantation with a deceased donor kidney who exhibit signs of DGF (producing a mean of <50cc urine per hour over 8 hours in the first 24-hours post-transplantation). Patients are randomized 1:1 to ANG-3777 (2 mg/kg) or placebo administered intravenously once daily for 3 consecutive days starting within 30 hours after transplantation. The primary endpoint is estimated glomerular filtration rate (eGFR) at 12 months. Secondary endpoints include proportion of subjects with eGFR > 30 mL/min/1.73m2 at days 30, 90, 180 and 360; proportion of subjects whose graft function is slow, delayed or primary non-function; length of hospitalization; duration of dialysis through day 30. A study schematic is shown in Figure 1. Adverse events are being assessed throughout the study.
Conclusions: No pharmacologic intervention has been demonstrated in a rigorous trial to be effective preventing or improving the outcome of DGF. The GIFT study will generate data that are critical to advancing the treatment of DGF.

PO2419

Clinical Outcomes of Kidney Transplant Recipients Living Away from Their Home Country

Background: Many people leave their home country looking for better job opportunities and among those are kidney transplant recipients. However, taking care of such recipients might be challenging especially when information regarding induction immunosuppression, donor HLA typing, donor-specific antibodies, crossmatch and/or infections are not available. The aim of this study was to compare clinical outcomes of kidney recipients transplanted in their home country with kidney recipients transplanted locally.

Methods: In this retrospective cohort, we included all adult recipients transplanted between 2005 and 2016 and followed at our transplant clinics within their first year of transplant. Patients were categorized into two groups; local group including recipients transplanted at our center and abroad group including recipients transplanted in their home country.

Results: There were 111 patients in local group and 110 patients in abroad group. The mean age at transplant in local and abroad groups were 48 and 42 year-old, respectively. 63% of recipients in local group were from the Middle East, while 53% of patients transplanted abroad were from South Asia. Deceased donation was higher in local group (41% vs. 3%; p<0.001). There was no difference in recipient sex, native kidney disease, presence or absence of neoplasms, or neoplastic transplants. Most patients were on CNIs and steroid immunosuppression (n=209; 95%). The mean follow up post transplantation was 6.3 years. The risk of acute cellular rejection was statistically significant in abroad group (13% vs 3%; p=0.005). However, the risk of ABMR or borderline rejections were similar. The incidence of post-transplant diabetes and malignancies were similar in both groups. There was no difference in 1-, 3- and 5-year creatinine and proteinuria between both groups. Patient and graft survival rates were excellent in both groups and 5-year patient and death-censored graft survival rates in local and abroad groups were 100% vs 93% and 95.2% vs. 96.6%, respectively.

Conclusions: Transition of care between countries carries its risks as it may be related to drug disruption or incomplete medical record. Kidney recipients transplanted abroad are at increased risk of acute cellular rejection; however, patient and graft survival rates remain excellent.

PO2420

Factors Associated with the Use of Hypothermic Machine Perfusion in Kidney Transplant Recipients

Nadir Goulamhoussen,1 Lawrence Slapcoff,2 Dana Baran,1 Isabelle Houde,1 Anne Boucher,1 Martin Albert,1 Pierre Marsolais,1 Heloise Cardinal,1 Josee Bouchard.1 1Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada; 2McGill University, Montreal, QC, Canada; 3Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; 4CHU Quebec, Quebec, QC, Canada; 5Centre Hospitalier de l’Universite de Montreal, Montreal, QC, Canada.

Background: Delayed graft function (DGF) is associated with an increased risk of graft loss. The use of cold hypothermic machine perfusion (HMP) has been shown to reduce the incidence of DGF in kidney transplant recipients (KTRs), especially when extended-criteria donors (ECDs) are used. However, there is a paucity of data on the determinants of HMP use in real-life setting.

Methods: We aimed to determine the factors associated with the use of HMP in a cohort of donors and KTRs. We collected data on consecutive brain-dead donors admitted to our organ procurement organization and their KTRs between June 2013 and December 2018 in 5 adult transplant centers in Canada. There is no standardized protocol for the use of HMP in the province of Quebec. The use of HMP is left at the discretion of the surgeon recovering organs. However, a HMP device was available for organ recovered at the organ procurement organization. Generalized estimating equations were used to predict the use of HMP.

Results: The cohort included 159 deceased donors and their 281 KTRs. Thirty-three percent of donors were ECDs, and 59% of KTRs received organs placed on HMP. The mean cold ischemia time (CIT) was 12.4 (IQR 7.9-22) hours. There was no difference in use of HMP over time. In univariate analysis, none of the donors’ characteristics were associated with the use of HMP. The use of HMP was similar in ECD and standard criteria donors (33% vs 34%, p=0.82). For KTRs, in univariate analysis, race (non-Caucasian), cold ischemia time, use of basiliximab/alemtuzumab, and KTR center were associated with the use of HMP. In multivariate analysis, CIT (odds ratio [OR] 1.09, 95% confidence interval [CI] 1.03-1.16) and KTR center were significantly associated with use of HMP.

Conclusions: We found that use of HMP was strongly associated with the transplant center in which the surgeon practiced, suggesting that practice preference/training plays an important role in determining the use of HMP. The presence of ECD did not influence the use of HMP. The reasons underlying the differences in practice between centers should be explored in further studies.

PO2421

Microvascular Inflammation Is the Main Determinant of Elevated Donor-Derived Cell-Free DNA in Kidney Transplantation

Bogdan Oblai1, Maria Butiu1, Ramasamy Bakhtavatsal1, Kelly D. Smith2, Iris C. De Castro2, Christopher D. Blosser2, Lena Sibulesky2, Katherine Kling,1,2 Gener Ismail,1 Bogdan M. Sororohan,1 Nicolae Leca.1 1Fundeni Clinical Institute, Bucharest, Romania; 2University of Washington, Seattle, WA.

Background: Microvascular inflammation (Mi) is the main histological lesion for ABMR. Mi may occur separate from other ABMR criteria, early in the injury process, and may not be captured by the current Banff criteria. Donor-derived cell-free DNA (dd-cfDNA) has the potential to identify early allograft injury and supplement the current diagnostic criteria for rejection.

Methods: We included all patients (n=54) who underwent a kidney transplant biopsy for suspicion of rejection at our center from 9/17-12/19. Determinants of a biopsy were renal dysfunction, elevated dd-cfDNA, or presence of DSAs.

Results: Dd-cfDNA correlated strongly with the presence of ABMR, Class II DSA≤2500, and histological lesions of ABMR. The strongest association was with Mi lesions (OR 192.95%CI: 18.6, 1984, p<0.001). Of the 18 patients with Mi, 2 did not meet the criteria for ABMR and had a dd-cfDNA level of 0.32% and 1.9%. All patients with Mi that met the criteria for ABMR had a dd-cfDNA over 1%. There was no association with renal function or histological lesions of tubulitis or interstitial inflammation (Fig 2).

Conclusions: Dd-cfDNA has the potential to identify early allograft injury and allow for early and less aggressive interventions that can benefit allorecipients before long-term outcomes of kidney transplant recipients.

Point-of-Care Creatinine Self-Testing in Renal Transplant Patients: An Assessment of Accuracy, Precision, and Patient Experience
Fabiana Fernandes da Costa,1 Michelle Willicombe,1,2 Kate Bramham,3 Clare B. Kelly.1 1Imperial College NHS TRUST, London, United Kingdom; 2Imperial College London, London, United Kingdom; 3Department of Women and Children’s Health, King’s College London, London, United Kingdom.

Background: During the Covid-19 pandemic it has become increasingly important to provide virtual care for patients with CKD. Point-of-Care testing of capillary creatinine (POC-Cr) is now available and has demonstrated validity, ease of use, improved efficiency and cost-efficiency. We aimed to determine patients’ desire to self-monitoring of POC-Cr and their characteristics.

Methods: Renal transplant patients were shown how to perform self-POC-Cr testing with a NovaBio StatSensor®Xpress device, then undertook a test independently and answered survey questions about their attitude to self-testing of POC-Cr.

Results: All patients (N=189; Median age 52 years (IQR 40,64); 44 (23%) English as a second language; 128 (66%) male; Median eGFR 49 mls/min/1.73m2 (IQR 34,64) successfully performed a POC-Cr test and 110/120 (91%) of patients who completed the survey reported they would like to self-monitor POC-Cr. Most patients wished to reduce their clinic attendance and the majority were willing to have telephone consultations. Characteristics of the cohort are described in Table 1.

Conclusions: All transplant patients successfully performed a POC-Cr test with written instructions and a demonstration. Most patients would like to self-monitor POC-Cr and reduce clinic attendance. Limitations include the single-centre design, number of participants and language barrier. Virtual care including patient self-monitoring using POC-Cr should be explored.

Characteristics of patients who would and would not like to self-monitor POC-Cr at home:

Defining a Minimal Clinically Meaningful Difference (MCMD) in Estimated Glomerular Filtration Rate (eGFR) for Kidney Transplantation
Tracy J. Mayne,1 Sumit Mohan,2 Jesse D. Schold,3 Matthew R. Weir,4 Bob Nordyke.5 1Angion Biomedica, San Francisco, CA; 2Columbia University, New York, NY; 3Cleveland Clinic, Cleveland, OH; 4University of Maryland School of Medicine, Baltimore, MD.

Background: eGFR is an established measure of renal function & predicts clinical outcomes. A MCMD for eGFR has never been clearly defined.

Methods: Data source: United Network for Organ Sharing (OPTN) database Study population: Adults ≥18 years of age; received deceased donor kidney 01/01/2013 to 12/31/2018; multi-organ & non-incident transplants were excluded. Analysis: Cox proportional hazards regression Primary outcome: Death-censored graft survival starting 12-months post-transplantation. Predictors: Recipient (gender, age, race, diabetes, body mass index, panel reactive antibodies); Donor (age, diabetes, hypertension, proteinuria); Transplantation (cold ischemia time, pump, DR locus mismatch, delayed graft function); 12-month eGFR (CKD-EPI). Analysis, eGFR was stratified by bands of 5, 7 or 10 mL/ min/1.73m2. Regressions compared each band to the next sequential band. A weighted mean hazard ratio was calculated using OPTN population eGFR distribution.

Results: The relationship between 12-month eGFR & graft failure is non-linear: HR=3 to 4 at eGFR <15 mL/min/1.73m2; HR=1.1 at eGFRs ≥ 55. Mean HR=1.47 for 10 mL/min/1.73m2 bands; 1.30 at 7 mL; 1.19 at 5 mL.

Conclusions: Controlling for multiple factors, 12-month eGFR is a strong predictor of death-censored graft survival. Mean HR (1.19) is consistent with an effect size considered significant, clinically meaningful, & supporting of regulatory approval (eg, angiotensin receptor blockers; statins). This supports 5 mL/min/1.73m2 as the eGFR MCMD in kidney transplantation. DISCLAIMER: The interpretation & reporting of these data are the responsibility of the authors & in no way should be seen as an official policy or interpretation by the OPTN or the US Government.

PO2423

Short-Term Variability in Graft Function Is Associated with Long-Term Mortality but Not Allograft Survival in Kidney Transplant Recipients
Reini Lyg, Didier A. Mandelbrot, Arjani Djamali, Brad C. Astor. University of Wisconsin-Madison School of Medicine and Public Health, Madison, WI.

Background: It is critical to identify kidney transplant recipients (KTR) at highest risk of graft failure and death to focus on monitoring and interventions to improve long-term outcomes. Variability in native kidney function is associated with the risk of mortality and hospitalization in chronic kidney disease, but it remains uncertain whether such associations exist in KTR. We examined the hypothesis that short-term graft function variability is associated with long-term outcomes in KTRs.

Methods: Using the Wisconsin Allograft Recipient Database (WisARD), we identified 2919 KTR who had a functioning allograft at least 2 years after transplantation and at least 3 outpatient estimated glomerular filtration rate (eGFR) measurements from 1 to 2 years post-transplant. Graft function variability was defined for each patient as the coefficient of variation based on a linear regression of eGFR from 1 to 2 years. Associations between eGFR variability and total graft loss, death and graft failure were estimated in competing risk models.

Results: Patients with greater variability were more likely to be female, have more comorbidities, and have more prior hospitalization events and have. Compared to the lowest quartile, the highest quartile of eGFR variability was associated with a higher risk of total graft loss (adjusted HR 1.51, 95% CI: 1.11-2.06) and a higher risk of death (adjusted HR 1.85, 95% CI: 1.23-2.76), but not with a higher risk of graft failure (subHR 1.08, 95% CI 0.64-1.83 in competing risk analysis), independent of eGFR and slope of eGFR. The associations remained consistent across strata of acute rejection, diabetes, peripheral arterial disease, baseline eGFR, history of cardiovascular disease, baseline hospitalization, and with all variability indicators and modeling approaches.

Conclusions: Short-term eGFR variability is associated with long-term death but not graft failure. Variability in eGFR provides independent prognostic information on transplantation outcomes and may be an indicator to differentiate the risk of death and graft failure.
PO2425
Composite Events Associated with Increased Expected Post-Transplant Survival Scores
Yasmeen Dhindsa,1 Nakul N. Datta,2,1 Piyavadee Homkrailas,1 Suphamali Bunnapradist,1,3 Erik L. Lum.1,2 1University of California Los Angeles, Los Angeles, CA; 2University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.

Background: Kidney transplant candidates on the waiting list are assigned an expected post-transplant survival score (EPS) score. This score is used to determine allocation of kidneys in the kidney allocation system (KAS). The outcomes of candidates with an EPS >95% at the time of listing is limited.

Methods: UCLA kidney Transplant Program data of waiting list with EPS > 80% from January 2015 – December 2018 were included. Median follow up time of waiting list was 885 days. The outcomes included kidney transplant rate, 3 year death censored graft survival and patient survival in candidates with EPS > 95%.

Results: A total of 124 patients were identified with an EPS score > 95% at the time of listing during the study period. Of these 23 patients received a kidney transplant during the specified time frame (transplant rate of 16.9%). Recipients of kidney transplant had a longer dialysis vintage (2368.6 days vs. 9881 days, P=0.001) and were more sensitized at the time of listing (34.8% vs. 11.8%, P=0.018). Compared to a group with an EPS between 80-94% at time of listing (n=170) there were no differences in mortality (4.3% vs. 4.5%, P=0.969), graft failure (14.3% vs. 6.4%, P=0.254), or 3 year death censored graft survival (70.0% vs. 84.5%, P=0.517). The EPS > 95% group was older, had a longer dialysis vintage, had a higher proportion of candidates with diabetes as a cause of ESRD, and was less likely to undergo transplantation. Candidates with an EPS >95% who did not receive a transplant had a mortality rate of 7.9% and waitlist removal rate 16.9%

Conclusions: Kidney transplantation in candidates with an EPS > 95% provides comparable outcomes to candidates with an EPS between 80-94%, which was superior to remaining on dialysis. Despite this benefit, the transplantation rate of this group was low and a quarter of those not transplanted either died or were removed from the waitlist. Strategies are needed to improve transplantation rates in this population.

PO2426
Transition of Renal Transplant Care from Pediatrics to Adolescence and Young Adulthood: Retrospective Study Comparing Serum Creatinine-Based GFR Estimating Equations
Rashmi Dandamudi, Stanley P. Hmiel, Vikas R. Dhamidharka. Washington University in Saint Louis School of Medicine, Saint Louis, MO.

Background: The evaluation of graft function is vital in the management of pediatric kidney transplant (pKTx) recipients. Measured GFR (mGFR) using exogenous markers is very accurate, but not suitable for daily use. Estimated glomerular filtration rate (eGFR) using Serum creatinine (Scr) is the easiest way and equations are categorized as either pediatric or adult specific. None of the equations were formally compared in adolescents and young adults with renal transplants. The aim of study was to assess the performance of creatinine-based formulas in a cohort of pKTx in pediatric, adolescents and young adult age groups.

Methods: This retrospective study was conducted at our hospital from January 2000 to March 2019 from 125 pKTx recipients. We compared 415 mGFR values to 5 different Scr-based eGFR formulae (original Schwartz(OS), BS, Pottel, Modification of Diet in Renal Disease (MDRD), CKD-EPI, and average of BS and CKD EPI. Basing on the age and maturity of the child, BS and Pottel formulae were calculated with and without body surface area adjustment.

Results: Pottel and BS performed well across pediatric and adolescent age groups with 90% accuracy in children <12 years old and 96% in >12 years old. BS and CKD EPI outperformed all other equations with minimal bias (0.006 ml/min/1.732 m²) and 90% accuracy in young adults.

Conclusions: Height independent Pottel and height dependent BS formulae had low bias and high accuracy in children and adolescents. Average of BS and CKD EPI outperformed other equations in young adults and provides an overall unbiased estimate of GFR.

PO2427
A Comparison of the Associations of Urine Markers with the Rate of Decline in Kidney Allograft Function
Yoshitsugu Ohi,1,2 Naotsugu Ichimaru,1,2 Yoshitaka Isaka,1 Takayuki Hamano,3,5 The CANDLE-KIT Trial Investigators 1Obi Clinic, Osaka, Japan; 2The University of Tennessee Health Science Center College of Medicine, Memphis, TN; 3Osaka Daigaku Daigakusai Igukusei Kenkyusya Igakubu, Suita, Japan; 4Ippun Zaidan Hoin Sumitomo Byoin, Osaka, Japan; 5Nagoya Shiritsu Daigakusin Igakusei Kenkyusha Igakubu, Nagoya, Japan.

Background: Various urine markers are proposed to predict renal outcomes. However, there are few head-to-head comparison studies comparing their clinical relevance among kidney transplant recipients (KTRs).

Methods: In a prospective clinical trial, we enrolled 153 KTRs with anemia and >1 year history of transplantation across 23 facilities and followed them for 2 years. The annual change in eGFR was estimated based on mixed effects model. We then selected 102 patients who had baseline urine data on total protein, beta-2-microglobulin ([β2MG], N-acetyl-beta-D-glucosaminidase (NAG), and L-type fatty acid binding protein ([L-FABP] total protein, NAG, and L-FABP were standardized according to urine creatinine concentration. We then compared the associations of the quintiles of each urine marker with annual decline in eGFR using univariate and multivariable linear regression models.

Results: Patients were 51 ± 12 years-old and 54% were male. The median (IQR) of transplant vintage was 8 (5, 12) years, and the baseline eGFR levels were 31 ± 11 mL/min per 1.73 m². The annual eGFR change was -1.6 ± 2.0 mL/min per 1.73 m²/year. The median urine levels of total protein, β2MG, NAG, and L-FABP at baseline were 0.5 (0.2-1.1) g/g Cr, 1535 (238-4780) µg/L, 0.06 (0.04-0.12) IU/L, and 16.7 (4.2-42.1) µg/g Cr, respectively. The higher levels of L-FABP and total protein were significantly associated with more rapid annual eGFR decline (P for trend <0.001 for both; Figure) while there was no significant association for β2MG or NAG. R² was 0.10 (P=0.03) and 0.18 (P=0.001) for L-FABP and total protein, respectively. After adjustment for age, gender, mean arterial blood pressure, and baseline eGFR, the association remained significant for total protein but not for L-FABP (Figure).

Conclusions: Among urine markers of total protein, L-FABP, NAG, and β2MG, total protein appears to have greatest predictive value for eGFR decline among KTRs.

PO2428
Chronic Graft vs. Host Disease in Pancreas After Kidney Transplant Recipient: An Unrecognized Entity
Prince Singh, Aleksandra Kukla. Mayo Clinic Minnesota, Rochester, MN.

Introduction: Graft-versus-host disease (GVHD), a common complication after allogenic bone marrow transplantation is rarely seen after solid organ transplants (SOT). Reports of acute GVHD (maculopapular rash, diarrhea and cholestatic liver disease described after SOT invariably happened in the early post-transplant period (days to months). In contrast, reports of SOT recipients with clinical features more consistent with chronic GVHD (cGVHD) (resembling autoimmune disease with chronic inflammation/ fibrosis) are lacking. We present a case of cGVHD in pancreas after kidney transplant (PKT) recipient diagnosed at 42 months post transplant.

Case Description: A 43 year old man received a HLA 5/6 mismatch, CMV mismatch (donor positive, recipient negative) deceased donor pancreas transplant two years after receiving a HLA 5/6 mismatch living unrelated kidney transplant. Anti-thymocyte

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
globulin induction was given along with a maintenance immunosuppression - tacrolimus, mycophenolate mofetil and prednisone. Post-transplant course was complicated by multiple opportunistic infections (Figure 1) leading to immunosuppression reduction. At 42 months post transplant, he developed dry eyes, arthralgia, anorexia, elevated alkaline phosphatase, dyspnea on exertion, lichen simplex chronicus dermatitis, and severe pancytopenia. GVHD was suspected which lead to peripheral blood chimerism testing revealing 90% pancreas donor-derived DNA in CD3-positive fraction of T cells. Patient passed away.

Discussion: The infections may have represented the immune dysfunction associated with GVHD. Do-escalation of immunosuppression could have led to an unopposed activation of donor cytotoxic T-lymphocytes resulting in worsening GVHD. Donor-derived T lymphocytes received during pancreas transplant may have targeted the bone marrow, causing severe pancytopenia, hence compounding the dysregulated immune state. Transplant professionals should be aware of the possibility of the rare but challenging diagnosis of GVHD in PAK recipients and hence identify it appropriately.

PO2429
Graft vs. Host Disease Following Simultaneous Liver-Kidney Transplant
Bushra Syed, Mohamed Hassanain, Saul Nurko. Cleveland Clinic, Cleveland, OH.

Introduction: Solid organ transplant associated GVHD is uncommon with an incidence of 0.5 to 2%. Risk factors include donor HLA homozygosity, younger donor, recipient age >50 years and sex mismatch. We present a case of GVHD following a simultaneous liver kidney transplant (SLK).

Case Description: A 64-year-old female with NASH cirrhosis and CKD due to diabetic nephropathy underwent SLK from a 38-year-old male deceased donor. The pair had 3 HLA AB mismatches and 1 DR mismatch. A total of 3.5mg/kg of thymoglobulin (ATG) was used for induction. Renal and liver parameters were stable at discharge on a maintenance tacrolimus, mycophenolate and prednisone. She was readmitted after 1-month with diarrhea and fever. Infectious work up was unrevealing. She developed a maculopapular rash, mucositis and pancytopenia. Skin biopsy showed grade 2 acute GVHD. Donor lymphocyte chimerism in peripheral blood confirmed diagnosis of GVHD with 65% donor T cells, 10% donor CD8 cells and 42% donor natural killer (NK) cells. Treatment with high dose steroids and ATG was ineffective with worsening in CD8 and NK cell donor chimerism to 91% and 53% respectively. Weekly infliximab (INX) was introduced complicated by development of entercoccal bacteremia. Clinical improvement was seen after three doses INX, however there was a lag of several weeks before an improvement in donor chimerism. Six months later her hematological, renal and liver parameters remained stable, chimerism study showed <5% T cells, CD8 cells and NK cells and a protocol renal biopsy showed no evidence of GVHD associated denovo glomerulonephritis.

Discussion: The non-specific presentation of GVHD with rash, cytopenias and diarrhea leads to delayed diagnosis and high mortality. Detection of donor chimerism through short tandem repeat sequences is used to establish diagnosis and monitor response through short tandem repeat sequences is used to establish diagnosis and monitor response.

PO2430
Kidney After Intestinal Transplantation, a Comparison with Combined Kidney Intestinal Transplant: A UNOS Database Analysis
Muhammad S. Yaqub, Muhammad Ajmal Panezai, Oluwafisayo A. Adediwia, Tim E. Taber, Asif A. Sharifuddin. Indiana University School of Medicine, Indianapolis, IN.

Background: There is limited data on outcomes for patients receiving a isolated kidney transplant (KAIT) after any prior Multi-organ or Isolated Intestinal transplant (IT). We compared the outcomes of such transplants with Combined Intestinal-Kidney Transplants (CIKT).

Methods: The KT database from 1992 through Sep 2017 was cross-linked with the IT database for all kidney transplants performed. Data was analyzed for incidence, demographics, risk factors and outcomes after KT.

Results: There were a total of 2,886 IT recorded from 1990 through Sep 2017. There were a total of 190 (6.6%) Kidney transplants recorded of which 54 (28.4%) were KAIT while the remaining 136 (71.6%) where Combined (CIKT). The Median Duration from Intestinal Transplant to Kidney transplant was 5.6 years (Range 0.47 to 18.9). One year KAIT graft survival was 87% as compared to CIKT 52%. 5 year graft survival was 74% vs 36%. Death censored KAIT graft survival at 1 year was 98% vs 87% and 5 years 83% vs 74% overall unadjusted kidney graft survival was significantly lower in CIKT as compared to KAIT p<0.009.

Conclusion: Our data shows that isolated kidney transplant after any prior Multi-organ or isolated Intestinal transplant has higher graft survival as compared to combined Intestinal Kidney Transplant. Higher CNI trough levels may be one common factor leading to lower graft survival.
PO2432
Renal Recovery After Liver Transplantation Alone in Patients with Liver Cirrhosis and Severe CKD with Normal Kidney Size

Background: Most guidelines recommend simultaneous liver-kidney transplantation (SLKT) in patients with liver cirrhosis (LC) and severe chronic kidney disease (CKD) over liver transplantation alone (LTA). CKD, however, is not irreversible. This study evaluates the reversibility of kidney disease after LTA based on kidney size.

Methods: In this single-center retrospective study, we classified 90 patients with LC and severe CKD into 3 groups: normal kidney-LTA (NK-LTA, n=39), small kidney [both <9 cm3] LTA (SK-LTA, n=46), and small kidney-SLKT (SK-SLKT, n=11). Baseline characteristics and renal recovery and survival outcomes were compared among 3 groups.

Results: The NK-LTA group had a lower percentage of hepatocellular carcinoma, a higher pre-LT eGFR, and a shorter duration of eGFR < 60 ml/min-pre-LT dialysis. This group, however, was older, received livers from a higher percentage of deceased donors and had a higher Child-Pugh score. Renal recovery, defined as no hemodialysis (HD) after LT, was found in 79% of those in the NK-LTA group, which was higher than 7.5% of those in the SK-LTA group. Renal survival, defined as patient survival without progression to HD or kidney transplant was found in 56% of patients in the NK-LTA group, which was higher than 2.5% of those of the SK-LTA group.

Conclusions: Patients with LC and severe CKD with normal kidney size may experience reversible kidney disease after LTA. Therefore, kidney after liver transplantation is recommended over SLKT for these patients.

Funding: Private Foundation Support

PO2433
Immediate Allograft Function After Liver Transplant (LT) Modifies the Effect of Pre-LT Renal Dysfunction (RD) on Post-LT Survival
Hani Wadi, Shennen Mao, Martin L. Mai, Naheel Aslam, Kristopher Croome. Mayo Clinic’s Campus in Florida, Jacksonville, FL.

Background: Pre-LT RD is associated with higher post-LT mortality. It is unclear if immediate liver allograft function modifies this risk.

Methods: We retrospectively reviewed data on 2,856 primary LT performed in our center from 1998 to 2018. Pre-LT RD was defined as Cr ≥ 1.5 mg/dl or on dialysis at LT. Immediate liver allograft function was defined using the validated early allograft dysfunction (EAD) criteria (bilirubin t10 mg/dl, INR ≥1.6 or ALT/AST ≥2000IU/mL, on POD 7). Pre-LT RD was present in 591 (21%), of these 429 patients had Cr >1.5 and 165 were on dialysis. EAD developed in 784 (27%). The cohort was divided into 4 groups according to pre-LT RD and EAD. Group 1 (n=1,617): No RD and no EAD, Group 2 (n=643): No RD but had EAD, Group 3 (n=451): had RD and no EAD, Group 4 (n=140): had both RD and EAD. The unadjusted and adjusted post-LT survival was compared between the 4 groups.

Results: Results are presented in Figure 1. Group 1 had the best outcome with 1,3 and 5 year survival of 95%, 89% and 82%, respectively, and group 4 had the worst outcome with 1, 3 and 5 year survival of 79%, 70% and 60%, respectively, P < 0.0001. Group 2 and 3 had intermediate survival and comparable (P >0.5 between group 2&3) outcomes. Survival was better in group 2&3 compared to those in group 4 (P < 0.0001) but was worse than group 1 (P = 0.02). After adjusting for recipient age, female gender, DM, MELD score, cause of ESLD and DRI, group 4 had the highest risk of death (aHR 2.33, CI 1.69-3.21, P < 0.001). Patients in group 2 (aHR 1.16, CI 0.95-1.41, P=0.3) and group 3 (aHR 1.23; CI 0.96-1.58, P=0.09) had comparable adjusted risk of death to group 1 patients.

Conclusions: LT recipients with pre-LT RD who enjoy immediate liver allograft function have comparable adjusted survival to those with normal renal function at LT. Our results indicate that livers at higher risk of EAD should be avoided in LT recipients with RD.

PO2434
Sex and Equitity in Pediatric Kidney Transplantation

Background: Mortality in pediatric kidney failure (ESRD) is higher in girls than in boys, in contrast to the general population. In a recent report, correcting for access to transplantation partially ameliorated this risk, prompting an examination of equity in pediatric kidney transplantation.

Methods: USRDS files were used to examine incidence of pediatric ESRD (ages 18) and initial Rx modalities from 2000-15. UNOS data were used to evaluate pediatric kidney recipients between 2000-2019. Logistic regression was used to calculate an odds ratio (OR) for receiving a living donor kidney (LD). Hazard ratios (HR) of death, graft failure and death-censored graft failure (deCF) were obtained in Cox models stratified for LD/deceased-donor (DD). Models were adjusted for age, sex, and year of transplant and reported with 95% CI.

Results: Among 17,366 incident pediatric ESRD patients in USRDS, 42.8% were female. Mean and median age did not differ. Initial kidney treatment was transplantation in 17.9% of girls and 23.8% of boys, with more hemodialysis in girls (46.0 vs 40.5, P=0.001). Among 16,811 UNOS recipients, 41.0% were female. Changes in allocation policy were associated with a shift from parental donors to deceased-donors, which was more marked in female recipients (figure). 42.8% of boys and 39.7% of girls received LD (P>0.001); adjusted OR of receiving LD was 0.91 (0.85, 0.98, P=0.007) for girls. Compared to boys, girls had inferior outcomes with DD, with HRs: death 1.51 [1.30, 1.76], graft failure 1.31 [1.21, 1.40], and deCF 1.30 [1.20,1.40, P<0.001 for all]. LD outcomes did not differ by sex.

Conclusions: Female children have fewer early transplants and higher odds of receiving DD kidney transplants that are associated with inferior outcomes than their male counterparts. Attention to sex-specific disparities may improve ESRD outcomes in girls.

Living (LD) & Deceased-donors (DD) in male (M) and female (F) recipients

Outcomes of Emergency Department Visits of Children After Kidney Transplantation
Christian Hanna,1 Ashish Shah,2 Mark G. Roback,4 Priya S. Verghese,3 Ronald A. Furnival,1 Mayo Clinic Minnesota, Rochester, MN; Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; University of Minnesota, Minneapolis, MN; 2University of Colorado, Denver, CO; 3Northwestern University - Chicago, Chicago, IL.

Background: Systematic data evaluating the postoperative Emergency Department (ED) care and outcomes of Pediatric Kidney Transplant (PKTx) recipients is limited. Our study objective is to identify the risk factors, disposition, and outcomes of PKTx recipients presenting to the ED.

Methods: We retrospectively reviewed the medical records of PKTx patients (<18 years of age) who presented to our University Children’s Hospital ED from 04/01/2015 to 06/30/2015. Data pertaining to patient demographics, chief complaint, evaluation, interventions, results, length of stay (LOS) and disposition were abstracted. Multiple logistic regression analysis was used to study the associations between admission, the presence of bacteremia, and multiple risk factors.

Results: During the study period, 60 of the 85 PKTx recipients (71%) presented to the ED for acute care (total of 210 visits, range 1-20; mean 3.5 per recipient). The majority (148/210, 70%) of the visits occurred in the first year following transplant. Fever (44%) and gastrointestinal complaints (27%) were the most frequent presentations. Mean ED LOS was 3.5 hours (range 0.22-10.8 hours). Most (109/210, 52%) visits resulted in hospital admission, for a mean inpatient LOS of 4 days (range 1-55 days). After adjusting for age and sex, the following risk factors were significantly predictive of hospital admission: shorter time since transplant (p<0.003), presence of fever (p<0.001), higher heart rate (p<0.001), higher white blood cell count (p<0.004), and presence of Systemic Inflammatory Response Status (SIRS) (p<0.001). Age adjusted systolic and diastolic blood pressure, type of transplant (deceased vs living donor), underlying primary kidney disease, the presence of a central line, or the number of immunosuppressant drugs were not predictive of hospital admission. Multivariate analysis of all significant risk factors found that shorter time since transplant and presence of SIRS were the only factors significantly associated with hospital admission (p<0.05). Only presence of SIRS was significantly associated with positive blood cultures (p=0.03).

Conclusions: Nearly-three quarters of all PKTx recipients presented to ED most frequently in the first postoperative year, with over half requiring hospital admission. Shorter time since transplant and presence of SIRS were significantly predictive of hospital admission.

PO2436
The First Increase in Live Kidney Donation in the United States in 15 Years
Fawar Al Ammary, Allan Massie, Deidra C. Crews, Dorry L. Segev, Abimereki Muzzaale. Johns Hopkins University School of Medicine, Baltimore, MD.

Background: After more than a decade of decline, the first sustained increase in live kidney donation was observed in the US from 2017 to 2019. Understanding these trends in donation may provide opportunities to effectively sustain or even enhance this recent increase in donors.

Methods: We conducted a national registry study of 35,900 donors (70.3% white, 14.5% Hispanic, 9.3% black, 4.4% Asian) to understand the increase in 2017-2019 vs. 2014-2016 using Poisson regression stratified by donor-recipient relationship (biologically related, unrelated, and kidney paired donors).

Results: Among biologically related donors aged ≥35, 35-49, and ≥50 years, the number of donors did not change across race/ethnicity but increased by 38% and 29% for Hispanic and black ≥50; white donors increased by 42%, 50%, and 68%; Hispanic donors <35 and 35-49 increased by 18%, 14%, and 27%; Hispanic donors ≥50 did not change but increased by 22% and 33% for 35-49 and ≥50; black donors ≥50 declined by 23% and did not change for 35-49 and ≥50; Asian donors did not change. Among kidney paired donors ≥35, 35-49, and ≥50, white donors increased by 42%, 50%, and 68%; Hispanic donors ≥35 and 35-49 increased by 36% and 55% and did not change for ≥50; black donors did not change; Asian donors ≥35 did not change but increased by 107% and 82% for 35-49 and ≥50.

Conclusions: The increase in live kidney donation was driven predominantly by unrelated and paired white donors. Donation among unrelated black individuals should be promoted.

PO2437
Safety and Effect of Alkali Therapy on Vascular Function in Kidney Transplant Recipients: A Pilot Study
Rachel R., Bohling Monica Graflas, Zhiying You, Jessica B. Kendrick. University of Colorado Denver School of Medicine, Aurora, CO.

Background: Acid retention is a common feature of kidney transplant recipients (KTR). Studies have found that lower bicarbonate levels in KTRs are associated with an increased risk of mortality and cardiovascular disease. We tested the hypothesis that alkali therapy was safe and feasible in KTRs and would improve vascular function.

Methods: We performed an 18-week, randomized, double-blind, placebo-controlled crossover safety and feasibility pilot study of the use of sodium bicarbonate therapy in 16 KTRs. We recruited KTRs at least one year from transplant with an eGFR ≥ 45 ml/min per 1.73m2 and a serum bicarbonate level of 16-24 mEq/L. Patients received study drug therapy (sodium bicarbonate and placebo) at 0.5 mEq/kg/lean body weight for the entire 8-week treatment period. Each treatment period was 8 weeks in duration with a 2-week washout period between treatments. All patients had to be on stable immunosuppression and antihypertensive regimen for at least one month prior to randomization. Each patient served as his or her own control. During each treatment period, patients were assessed at 4 and 8 weeks for adverse events, weight, blood pressure, gastrointestinal symptoms and pill compliance. Brachial artery flow-mediated dilation (FMD) was obtained at beginning and end of each treatment period.

Results: The mean (SD) age, eGFR, and serum bicarbonate levels were 52 (19) years, 71 (21) ml/min/1.73 m2, and 23 (2) mEq/L, respectively. Serum bicarbonate levels increased by 0.4 mEq/L during treatment. Sodium bicarbonate therapy was not associated with worsening blood pressure, weight gain, or hypokalemia. 46% of patients experienced nausea and/or bloating on sodium bicarbonate therapy compared to 40% while on placebo. The study was not powered to detect differences in FMD, but there was a trend towards improved FMD in the sodium bicarbonate group compared to the control (mean difference 1.6%; 95% confidence interval, -0.39 to 3.6; p=0.1). Additionally, a trend towards decreased 24-hour urine albumin excretion (mean [SD] change -9.0 (17.1) mg/dL, p=0.07) and ammonium excretion (mean [SD] change +6.0 (12.1) mEq/d, p=0.08) was observed.

Conclusions: Sodium bicarbonate therapy is safe and feasible in KTRs. There was a trend towards improvement in FMD, strengthening the need for a larger randomized controlled trial.
Demographic Variability of Kidney Function in Live Donors: A Single-Centre Analysis

Tina Ortega,2 Ernesto Linares,1 Thomas Kousios, Rawya Charif, Honeyelet Orr, Harvinder K. Duklu, Marina Loucoudou. Imperial College London Department of Medicine, London, United Kingdom.

Background: Live donation is encouraged as better outcomes in kidney transplant recipients. Donor assessment requires thorough evaluation but kidney function varies with demographics. We compare mGFR with the performance of eGFR formulas and creatinine clearances.

Methods: Analysis of 997 live donors between February 1995 and October 2019. Using pre-donation measured GFR (Te EDTA-GFR) as the gold standard, we compared the performance of CKD-MDRD, Cockcroft-Gault (CG) and Creatinine clearance by Cockcroft Gault (Cr CI) and Creatinine clearance by Cockcroft Gault (Cr Cl). We calculated the relative bias (mGFR-eGFR/mGFR), root mean square error and the accuracy (P30)(eGFR between +30% mGFR) of different eGFR equations.

Results: 424/42.32% male donors. 616/62% Caucasian, 228/23% South Asian, 114/11% Afro Caribbean and 39/4% of other ethnic groups. Cardio-metabolic risk factors in kidney donors contribute to liver dysfunction. The primary outcome was HCV transmission, defined as 2 consecutive positive HCV nucleic acid tests tested at Day 7 and 14-21 post-transplant. Confirmed HCV viremia triggered a 12-week course of DAAs.

PO2438

Direct Acting Antiviral Prophylaxis to Prevent Virus Transmission from Hepatitis C Viremic Donors to Hepatitis C-Negative Kidney Transplant Recipients

Idris Yakubu, Richard Sterling, Marlon F. Levy, Chandra S. Bhati, Djernen Kumar, Irfan A. Moinnuddin, Layla Kamal, Anil L. King, Amit Sharma, Adrian Cotterell, Gaurav Gupta. Virginia Commonwealth University Health System, Richmond, VA.

Background: Studies have described a 12-week course of direct-acting anti-viral drugs (DAAs) for HCV transmission from infected donors to negative kidney transplant recipients. This strategy is limited by high cost and access to DAAs. A prophylactic strategy may be safer and cost-effective. We recently reported the results of our experience where a 2-4 day peri-operative DAA prophylaxis using sofosbuvir/velpatasvir (SOF/VEL) for D/R transplants prevented HCV transmission in a majority (88%) of cases. We report our entire experience based upon an adaptive iterative trial design where prophylaxis with SOF/VEL was initially extended to 7 days, and ezetimibe was added for a second cohort.

Methods: Wait-listed patients were eligible if they met the following: absence of living donor; panel reactive antibody ≤50; ≤1 prior transplant; absence of liver disease.

Results: 100 patients (mean age ≤56 years) received D/R transplants from November 2017 to April 2020. Mean wait time to transplant from enrollment was 34 days and the mean KDPI was 67%. At a median follow-up of 10 months (IQR: 1-30 months), graft survival was 99% and patient survival was 98% with no cases of liver dysfunction. In Group 1, 10 patients received one dose SOF/VEL immediately pre-transplant and a second dose on post-transplant Day 1. Viral transmission was 30% (3/10). In Group 2, 42 patients received two additional doses of SOF/VEL on Days 2 and 3 post-transplant. Viral transmission rate dropped down to 9.5% (4/42). All patients then achieved SVR with full graft survival was 99% and patient survival was 98% with no cases of liver dysfunction.

Conclusions: A 7-day DAA prophylaxis is effective in preventing donor-derived HCV transmission, can result in significant cost-savings and increase access to transplants. Adding ezetimibe to SOF/VEL did not provide an additional benefit in preventing viral transmission.

PO2440

Donor Hepatitis C Antibody Positivity Misclassifies Kidney Donor Profile Index in Non-Hepatitis C-Infected Donors: Time to Revise the Kidney Donor Profile Index

Masahiko Yazawa,1,2 Vasanthi Balaraman,1,2 Makoto Tsujita,1,2 Ambreen Azhar,1,2 Manish Talwar,1,2 Anshul Bhalla,1,2 Csaba P. Kovessoky,3 James D. Eason,2,3 Miklos Z. Molnar,2,3 Methodist Transplant Epidemiology Research Group / Methodist University Hospital, Memphis, TN; ‘The University of Tennessee Health Science Center, Memphis, TN.

Background: Kidneys from donors with hepatitis (CHCV) infection are traditionally excluded to be at risk for poorer graft outcomes, as reflected in the Kidney Donor Profile Index (KDPI). The KDPI defines an HCV positive donor based on HCV antibody (Ab) testing and/or nucleic acid amplification test (NAT), so not actively infected donor is also

PO2439

Assessment of Kidney Function at 3 and 6 Months in Kidney Donors with Cardio-Metabolic Risk Factors

Jesus D. Lima Lucero,1 Rafael Valdez-Ortiz,1 L. M. Perez-Navarro,1 Ana G. Ortega,1 Ernesto C. Lopez,1,2 Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico; 2Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico.

Background: Cardio-metabolic risk factors (CRFs) in kidney donors contribute to further deterioration of kidney function after donation, increase their post-donation cardiovascular risk. Objective: To assess the renal function of kidney donors with CRFs at 3 and 6 months after donation.

Methods: Cross-sectional, descriptive study, which included kidney donors who were admitted to the National Medical Center “Dr. Antonio Fraga Mouret” during the period from 2015 to 2019. Descriptive statistics were made, ANOVA with a 95% CI and a p-value of p ≤0.05. The CRFs' dyslipidemia, hypertension, hyperglycemia, body mass index (BMI) and hyperuricemia were evaluated.

Results: 153 donors were admitted, 34% with social security, 59% women, with a mean age of 42.7 ± 10.7 years. The clinical and biochemical characteristics at hospital admission were: mean SBP/DBP was 105 ± 7/70 ± 7 mmHg, Hb 14.3 ± 4.1 g/dL, Creatinine 1.21 ± 0.4 mg/dL, Albumin 3.8 ± 0.6 g/dL, Uric acid 4.1 ± 0.4 mg/dL, AST 45 ± 22 IU/L, ALT 53 ± 24 IU/L, Sodium 142 ± 3 mmol/L, Potassium 4.4 ± 0.5 mmol/L, Calcium 9.4 ± 0.6 mg/dL, Phosphorous 3.4 ± 0.4 mg/dL, Albumin 3.8 ± 0.6 g/dL, GFR 75 ± 30 mL/min/1.73 m².

741
considered as HCV positive. The outcome of kidneys from HCVAb positive but NAT negative donors are unknown.

Methods: A national-registry-based retrospective cohort study was conducted using the SRTR data set. We identified all HCV negative recipients between April 1st, 2015 and March 2nd, 2018, who received kidney transplant from HCV Ab positive and NAT negative (D-HCVAb)-/NAT(-) patients, HCV Ab negative and NAT negative (D-HCVAb+)/NAT(-); n=25,574) donor kidneys. We then compared recipients' estimated glomerular filtration rate (eGFR) at 6 months in matched cohorts, using combined exact matching (based on KDPI) and propensity score matching. We created two separate matched cohorts to examine differences in outcomes based on how HCV positive status is defined: for the first cohort, we used the allocation KDPI (where HCV is considered positive in D-HCVAb+/NAT(-)/patients), while for the second cohort we used a modified KDPI, where the HCV component of KDPI was considered negative in D-HCV Ab(+) /NAT(-)/patients.

Results: The mean±SD age of the allocation KDPI matched cohort at baseline was 59±10 years, 69% were male, 61% and 30% of the patients were white and American, respectively. The baseline characteristics of the recipients were well-balanced in both matched cohorts. Recipients' eGFR at 6 months after transplantation was significantly higher in the D-HCVAb+/NAT(-) group compared to the D-HCVAb+/NAT(-)/group (61.1±17.9 versus 55.6±18.8 mL/min/1.73m², p<0.01) in the allocation KDPI matched cohort, while it was similar (61.8±19.5 vs. 62.1±20.1 mL/min/1.73m², p>0.9) in the modified KDPI matched cohort.

Conclusions: Recipients who received HCVAb positive, but NAT negative donor kidneys did not experience worse 6-month eGFR than correctly matched D-HCVAb+/NAT(-)/patients.

PO2443

Hepatitis C NAT-Positive Kidney Transplant into Hepatitis C-Negative Recipients: A Single-Center Experience

Background: Direct-acting antivirals (DAA) for Hepatitis (Hep) C have a 96-100% sustained viral remission (SVR) rate. This makes transplant of Hep C nucleic acid amplification testing (NAT)+ kidneys and treatment post-transplant feasible. We performed a prospective IBB approved trial at our center to validate the use and challenges of this approach.

Methods: Informed consent from eligible patients was obtained. Patients with chronic liver disease, dual organ transplants, HIV and active Hep B infection were excluded. Post-transplant, viral load was tested on day 3-5 and 7-10 and weekly thereafter until viremia was confirmed. All pts. were treated by hepatologist based genotype and insurance company preference. Standard of care immunosuppression protocols was used.

Results: 51 pts. got Hep C NAT+ kidney. The median age of the recipients was 58 years (range 29-72) and the mean wait time was 802 days (range 68-3073). Mean KDPI was 58.8 (range 27-94) with a median donor age of 38 years (range 21-56). Out of 16 implant biopsies, 13/16 (81%) had <5% of the donor's glomeruli, 14/16 (88%) had minimal interstitial fibrosis, and 15/16 (94%) had no arteriosclerosis. There was a 100% transmission rate of Hep C. As of now, 46/51 (90%) have completed a 12-week course of DAA, and 45/46 (98%) have become RNA negative with 34/46 (74%) achieving SVR. So far, there had been no insurance denials of DAA coverage. Among 18 for cause allograft biopsies, 1 showed tubuloreticular inclusion thought to be Hep C related and another showed recurrent CSGN thought to be triggered by Hep C and Hep B.

Conclusions: Transplantation of HepC NAT+ kidneys to Hep C negative recipients followed by treatment with DAA is a feasible option as a standard of care outside trials. Recipients should be monitored for Hep C related complications.
John Cunningham Virus (JCV) in Renal Allograft Recipients (RAR)
Bushra Z. Saleem, Sonitka Puri, Zahidul H. Mondal. Rutgers The State University of New Jersey, New Brunswick, NJ.

Introduction: Both JCV and BK virus belong to Polyoma virus (PV) family and can lead to opportunistic infection in RAR. BK nephritis in RAR is well described in literature (incidence 1- 10 %) in contrast to JCV nephropathy (JCVN) which is a rare entity. Here we describe two cases of JCV in RARs.

Case Description: Case 1: 44-year-old woman with PMH of HTN and ESRD received her first renal transplant in 2009 followed by antibody mediated rejection (AMR) as a result of graft dysfunction. She received preemptive second renal transplant in 12/2015 followed by multiple RA biopsies within first few months due to elevated serum creatinine (s.cr). The biopsies showed borderline CMRs, acute AMRs and eventually chronic active AMR. Treatment regimen included steroids, rituximab, IVIG and plasmapheresis. Despite repeated treatments, her s.cr remained elevated leading to another biopsy in 6/2016 showing viral cytopathic changes suspicious for PVN. SV40 stain was negative as was serum BK titer. Immunosuppression (IS) was reduced and a biopsy was repeated in 8/2016 that stained positive for SV40. Given repeatedly negative serum BK, serum JCV titer was sent, which was positive and peaked at 350699 copies/ml on 9/2016. Titer improved to 66153 after 2 doses of Cidofovir however, later deteriorated to 33420. She had no neurological involvement. Despite Cidofovir, her renal function deteriorated rapidly requiring bilateral RA nephrectomies with pathology showing JCVN. IS was discontinued following which JCV titer became undetectable. Case 2: 59-year-old man with PMH of HTN and ESRD who received renal transplant in 4/2013 followed by baseline s.c r of 1.6 mg/dl. He was on Myfortic, Sirolimus and Prednisone for IS. He presented with rising s.c r in 9/2019 (2.1mg/dl). He underwent RA biopsy in 11/2019 showing viral cytopathic changes, positive SV40 consistent with PVN. BK by PCR resulted negative x 2 but JCV titer returned at 3896 copies/ml. Myfortic was discontinued. Repeat JCV titer trended down to 2603 in 3/2020. Further follow up was delayed due to COVID-19 pandemic.

Discussion: The diagnosis of JCVN is challenging and easy to miss. Index of suspicion should be high with positive viral cytopathic changes (+/- SV40 stain) on allograft biopsy and negative serum BK. Currently there is no definitive therapy for JCV. Early diagnosis and reduction IS are critical. Cidofovir may be of utility.

PO2446
Disseminated Adenovirus Treated with Brincidofovir in a Kidney Transplant Recipient
Tiffany Truong, Thanh Cao, Santhi Voora, Thin Thin Maw. University of Southern California, Los Angeles, CA.

Introduction: Adenovirus is a common viral infection, with which immunocompromised patients have an increased risk of disseminated disease. It is less frequently described in solid organ transplant recipients and the optimal therapy for disseminated disease is unknown. We present a case of disseminated adenovirus in a kidney transplant recipient who was treated successfully with brincidofovir.

Case Description: A 56 year old female with ESRD of unknown etiology received her second kidney transplant from a deceased donor 2 years ago with thymoglobulin based immunosuppression and achieved levels of gross hematuria and right flank pain, anemia, 2 weeks of malaise and 5 days of fever, cough, sore throat, nausea and vomiting. She had acute kidney injury with creatinine of 1.75 mg/dl from a baseline of 0.8 mg/dl. She was found to have adenovirus on urine (Coombs) and serum. Other infectious etiologies were ruled out. Initial treatment consisted of reduced immunosuppression with discontinuation of mycophenolate mofetil and tacrolimus and increased prednisone from 5mg to 10mg daily due to leukopenia. Given disseminated symptoms, adjunctive treatment was also initiated with cidofovir 1mg/kg IV q48hr alternating with IVIG 500mg/kg q48 hr. She received 4 doses of cidofovir and IVIG, with resolution of hematuria and adenovirus level in urine. Although she received hydration before and after cidofovir, creatinine rose to 2.04 mg/dl. With 2 additional cidofovir doses, she continued to have AKI (peak 3.1 mg/dl) before brincidofovir was started at a dose of 100mg twice weekly. Creatinine peaked to 2.73 mg/dl when initiated on brincidofovir which decreased and stabilized to 2.2 mg/dl. Brincidofovir was discontinued when adenovirus was undetected in serum and <500 copies/ml in urine.

Discussion: The most commonly used adjunctive treatment to reduced immunosuppression of adenovirus infection is cidofovir. However, cidofovir is nephrotoxic and renally cleared. This may limit its use, particularly in kidney transplant patients. Brincidofovir is less nephrotoxic due to decreased accumulation in proximal tubules, and may be better tolerated in kidney transplant recipients. We report a case of well tolerated brincidofovir treatment of disseminated adenovirus infection in a kidney transplant recipient who demonstrated clearance of infection and improvement in kidney function.
BK Polyomavirus Nephropathy After Kidney Transplantation from HCV-Infected Donor to HCV-Uninfected Recipient

Faisal Abdulameer,1 Hisham N. Abu Farsak,1 Barry M. Wall,1,2 Miklos Z. Molnar,1 1The University of Tennessee Health Science Center, Memphis, TN; 2VA Medical Center, Memphis, TN.

Introduction: BK polyomavirus (BKPyV) is an important cause of renal allograft dysfunction. We previously published the potential association of an increased risk of BKPyV DNAemia/nephropathy in kidney transplant recipients receiving Hepatitis C (HCV) infected donor transplantation. Here, we report severe BKPyV DNAemia/nephropathy in a recipient who received HCV infected donor transplantation, which was temporally associated with initial HCV treatment failure.

Case Description: 62-year-old HCV negative African American male received a cadaveric kidney transplant from a HCV infected donor in January 2019, with immediate graft function. Laboratory results 4 weeks later indicated HCV PCR of 9,310,000 IU/mL, serum creatinine 1.62 mg/dL, and BKPyV DNAemia was negative. He received ganciclovir and foscarnet (March 2019) for a total of 12 wk. At completion of treatment, HCV PCR was negative. Evaluation 4 weeks later revealed HCV PCR level of 482,446 IU/mL, indicating initial treatment failure. While waiting for insurance approval for coverage of secondary direct acting antiviral (DAAs) regimen, he developed acute kidney injury 6 wk after HCV viremia, with serum creatinine peaking at 3.3 mg/dL along with a rapidly rising BKPyV DNAemia to >5,000,000 copies/mL. His immunosuppressive regimen was decreased. Allograft biopsy showed BKPyV nephropathy and proliferative glomerulonephritis (GN) with monoclonal IgG deposits. He was started on cidofovir, levofloxacin and intravenous immunoglobulin, followed by a course of sofosbuvir/glecaprevir and pibrentasvir (March 2019) for a total of 12 wk. At completion of treatment, serum creatinine gradually improved to 2.04 mg/dL.

Discussion: By inciting an inflammatory response due to direct cytotoxic endothelial cell damage, CMV infection may cause a procoagulant state. This can lead to potentially life-threatening end-organ infarction such as splenic infarction. To our knowledge, this is the first reported case of CMV infection in a KT recipient presenting with splenic infarction. A high index of suspicion for this association is warranted for early recognition and treatment of these potentially reversible conditions.

Early Increase in Urinary Exosomal BK Virus MicroRNA as a Predictive Marker of BK Virus Nephropathy: A Prospective Kidney Transplantation Cohort

Won-Hee Cho, Su Woong Jung, Ju young Moon, Yang gyun Kim, Kyung iwan Jeong, Sangho Lee, Kyung Hee University Hospital at Gangdong Department of Orthopedic Surgery, Seoul, Republic of Korea; Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea.

Background: Urinary exosomal bkv-miR-B1-5p was associated with BK virus (BKV) nephropathy (BKVN) in a cross-sectional study. However, its time-dependent post-transplantation changes and predictive value for BKVN have not been investigated.

Methods: We carried out a multicenter prospective cohort from which 83 kidney transplant recipients (KRTs) in South Korea (biopsy-proven BKVN [n=10], presumptive BKVN [n=12], and non-BKVN patients [n=61]) were selected for the measurement of urinary exosomal bkv-miR-B1-5p levels at 0.5, 3, 6, and 12 months posttransplant.

Results: At 2 weeks posttransplant, urinary exosomal bkv-miR-B1-5p levels showed an increasing trend (non-BKVN < presumptive BKVN < biopsy-proven BKVN), while plasma BKV DNA levels were undetectable in all groups. Thereafter, both urinary exosomal bkv-miR-B1-5p and plasma BKV DNA levels peaked at 3 months posttransplant and then decreased. Multivariable-adjusted Cox regression showed that urinary exosomal bkv-miR-B1-5p levels at 2 weeks and 3 months posttransplant independently predicted biopsy-proven BKVN development. In particular, the early increase in urinary exosomal bkv-miR-B1-5p makes its predictive ability for biopsy-proven BKVN superior to that of plasma BKV DNA at 2 weeks posttransplant.

Conclusions: Our results suggest that urinary exosomal bkv-miR-B1-5p can be used to identify the KRTs at high risk for BKVN at earlier time than plasma BKV DNA loads, enabling earlier intervention.

PO2453

Polyomavirus Nephropathy with Crescent Formation

Laura Binari, Meghan E. Kapp, Heidi M. Schaefer, Beatrice P. Concepcion. Vanderbilt University Medical Center, Nashville, TN.

Introduction: Polyomavirus reactivation in an immunosuppressed transplant patient may cause polyomavirus nephropathy (PVN). Classically seen as a pleomorphic tubulo-interstitial inflammatory reaction to the virally infected tubular epithelial cells, there are few reports of glomerular viral tropism. We present unique histopathologic findings of PVN including crescent formation with ultrastructural and immunohistochemical evidence of viral infection of glomerular epithelial cells in a kidney transplant recipient with acute kidney injury.

Case Description: A 52 y/o man s/p DDKT with well-controlled HIV presented with 2 weeks of worsening cough. He was diagnosed with multifocal pneumonia and disseminated CMV and VZV infection. His serum creatinine (SCR) and BK virus PCR were elevated to 3mg/dl (baseline 1.4-2.0 mg/dL) and 3.8M copy/mL respectively. He received ganciclovir and his immunosuppression was reduced. His pneumonia improved, but his BK PCR increased to 13.6M copy/mL and SCR remained elevated at 2.4 mg/dL. A renal biopsy showed a diffuse plasma cell-rich pleomorphic interstitial inflammatory infiltrate, tubulitis, and acute tubular injury. Viral cytopathic effect was evident and SV40 immunostain was positive in 60-70% tubular profiles, as well as parietal and visceral epithelial cells. EM revealed viral particles measuring 30 nm in diameter in tubular epithelial cells and a parietal epithelial cell. In addition, 7 of 21 total glomeruli had crescent formation with no GBM breaks or fibrinoid necrosis. There was no evidence of concomitant cellular or antibody-mediated rejection or CMV infection. These findings were indicative of PVN, with the rare finding of frequent crescents with glomerular epithelial cell infection.

Discussion: PVN is rarely described as having crescentic glomerular lesions, and if present, only one glomerulus per biopsy was affected. There are no reported cases of rapidly progressive glomerulonephritis in PVN. In our case, we found crescent formation more frequently in 33% of glomeruli. Additionally, viral cytopathic changes uncommonly affect glomeruli, typically only involving parietal epithelial cells when present. We demonstrated viral infection of both parietal and visceral epithelial cells. Our case highlights a pattern of kidney injury not commonly seen in PVN and supports that crescent formation can be caused by viral infection of the parietal epithelial cells.

A First-in-Human Study of MAU868, a Novel Neutralizing Antibody Against BK Virus

Steven 1. Kovacs,2, Johanna R. Abend,2 Xiaoying Xu,2 Sachin Desai,3 Amanda Nguyen,2 Laura M. Sterling,2 Michael R. Hodges,3 Peter Pertel,1 Novartis Institutes for Biomedical Research Emeryville, Emeryville, CA; 2Novartis Institutes for Biomedical Research East Hanover, East Hanover, NJ; 3Celerion Inc, Lincoln, NE; 4Amplyx Pharmaceuticals, Inc, San Diego, CA.

Background: Reactivation of BK virus (BKV) infection can cause significant kidney and bladder disease in immunocompromised patients. BKV nephropathy is a leading cause of allograft loss in kidney transplant recipients. There are currently no effective or BKV-specific therapies. MAU868 is a novel monoclonal human IgG1 that binds to the BKV major capsid protein (VP1) with potent in vitro neutralizing activity against the 4 major BKV genotypes (IC50 ranging from 0.009 to 0.093 μg/mL).

Methods: MAU868 was administered i.v. (1, 3, 10, 30, and 100 mg/kg) or s.c. (3 mg/kg) to healthy adults in a randomized, placebo-controlled, blinded, single ascending dose design. Each i.v. cohort was 5 subjects (4 MAU868:1 placebo); the s.c. cohort was 8 subjects (6 MAU868:2 placebo). Subjects were observed for 24 h and followed for 106 days with routine safety monitoring and PK assessments. Ex vivo neutralizing activity of serum was measured before and 4 wk after dosing. The range of doses included and exceeded the predicted clinically efficacious dose.

Results: 33 subjects completed the study. Adverse events were mild and infrequent; those occurring in more than 1 subject included nasopharyngeal pain (3, 9.1%), and injection site hemorrhage (eczema after s.c. injection; 2, 6.1%). There were no infusion reactions. No subject discontinued the study due to an adverse event or developed anti-drug antibodies. MAU868 PK was typical of a human IgG with a half-life of 23 to 30 d. AUC and Cmax were dose-proportional, ranging from 9880 to 106000 μg·h/mL and 24.7 to 2740 μg/mL (ie, no evidence of FcRn saturation). Day 29 plasma MAU868 concentrations, adjusted for extravascular distribution to estimate parenchymal exposure, were approximately 7- to 751-fold higher than the highest in vitro EC50 (0.093 μg/mL). Maximum ex vivo neutralizing activity of serum was achieved for doses > 10 mg/kg. Bioavailability after s.c. injection was 57.6%.

Conclusions: MAU868 was safe and well tolerated with PK typical for a human IgG. The ex vivo neutralizing activity suggests where the therapeutic range may be for the treatment or prevention of BKV disease. These results warrant further clinical investigation of MAU868 in patients with or at risk for BKV disease.

PO2456

Induction with Alemtuzumab and Thymoglobulin in Kidney Transplant and the Risks of Leukopenia, Cytomegalovirus Infection, and BK Virus Nephropathy

Ali M. Zebí, Aria Ghahramani, Mujahed M. Dauich, Nasrollah Ghahramani. Penn State College of Medicine, Hershey, PA.

Background: Induction immunosuppressive therapy at the time of kidney transplantation reduces the risk of allograft rejection and improves graft outcomes. We compared the association between induction with thymoglobulin and alemtuzumab on the risks of leukopenia, CMV infection, and BK virus nephropathy.

Methods: We used TriNetX, a global federated research network that provides access to statistics on the electronic medical record (EMR). The Penn State Health TriNetX searchable database allows the analysis of approximately 1.7 million Penn State Health patient observations dating back to 1997. We analyzed the EMR of 1070 adult patients who had undergone kidney transplant between 1997 and May 10, 2020 (mean age: 60 ± 17; Male: 63%; White: 81%; Hispanic or Latino: 8%). We created two cohorts (19) in the alemtuzumab group. Leukopenia ± thrombocytopenia (BKV-specific therapies. MAU868 is a novel monoclonal human IgG1 that binds to the cause of allograft loss in kidney transplant recipients. There are currently no effective or BKV-specific therapies. MAU868 was safe and well tolerated with PK typical for a human IgG1. The ex vivo neutralizing activity suggests where the therapeutic range may be for the treatment or prevention of BKV disease. These results warrant further clinical investigation of MAU868 in patients with or at risk for BKV disease.

PO2457

Effects of Early Conversion to mTOR Inhibitors on Viral Infections in Renal Transplant Recipients: Eight-Year Single-Center Experience

Waled Hassan,1 Hisham Mostafa,1 The University of Tennessee Health Science Center College of Medicine, Memphis, TN; 2Minia Nephrology and Urology University Hospital, Minia, Egypt.

Background: Mammalian target of rapamycin inhibitors (mTORis) may decrease cytomegalovirus (CMV) and BK infection in renal transplant recipient. long-term effect on rejection rate deserves follow up.

Methods: This is a retrospective analysis of all patients who underwent living unrelated donor kidney transplant at Nasr city Insurance and Nile Badrawy Hospitals from 2011 to 2018, panel reactive antibody zero and no donor specific antibody. Uni- and multi-variate analysis were done to compare between mTORis based regimen and cyclosporin inhibitors (CNI)-based regimen.

Results: We identified 1458 patients who underwent living unrelated kidney transplant with intermediate risk for CMV. All patients received Induction with anti-thymocyte globulin then were maintained on mycophenolate mofetil (MMF)+CNI-prednisone for at least 6 months. They were classified into two groups: * Group I: 658 patients on mTORis (sirolimus or everolimus), who were shifted from CNI to mTOR-I due to different causes. Group II: 800 patients on CNI (cyclosporin or tacrolimus). The overall incidence of CMV infection and BK infection (Table 1) were statistically significant lower in mTORis group compared to CNI group with no statistical differences in incidence of rejections in the first 36 month but late higher rate of BPAR (Table 2).

Conclusions: mTORis/MMF is associated with low incidence of CMV and BK infection with no significant difference in rejection rate in the first 36 months. However, further regimen modification is required to reduce late rejections.

PO2458

The Utility of Procalcitonin in the Management of Kidney and Pancreas Transplant Recipients with Suspected Infection

Sarah Gilligan1, Fauad S. Shihab1, Divya Raghavan, Laith Al-Rabadi, Josephine E. Hall,1 Isaac Abraham, Isaac E. Hall. University of Utah Health, Salt Lake City, UT.

Background: Procalcitonin is used to differentiate between bacterial and viral infections to guide judicious use of antibiotics. It has not, however, been well studied in renal and pancreas transplant recipients. These patients are frequently exposed to antibiotics and are at risk for developing resistant infections. Thus, there is a need for reliable markers of bacterial infection. The purpose of this study was to compare procalcitonin levels in patients with and without bacterial infection to determine whether procalcitonin is a reliable marker of bacterial infection in the transplant population.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

746
Methods: Serum procalcitonin levels were measured on admission to all patients admitted to the Transplant Nephrology service with suspected infection as determined clinically by the on-call physician. We obtained all study data via chart review.

Results: Procalcitonin was measured in 154 patients. Demographics are included in the table. Forty-two patients (27%) had a positive bacterial culture. Mean procalcitonin for those with positive cultures was 5.36 ng/ml vs. 3.35 ng/ml in those without positive cultures, however this was not statistically significant (t = 0.642, p = 0.522). Patients with positive cultures were more likely to have procalcitonin levels >0.5 mg/ml (p = 0.003). Procalcitonin had a modest but significant correlation with WBC count (r = 0.249, p = 0.002). Receiver operating characteristic analysis demonstrated an area under the curve (AUC) of 0.679 (95% confidence interval: 0.590-0.768, p = 0.001) for predicting positive cultures with procalcitonin compared with an AUC of 0.584 (95% confidence interval: 0.474-0.694, p = 0.110) for WBC count.

Conclusions: In this cohort of hospitalized kidney and pancreas transplant recipients, serum procalcitonin concentration was associated with bacterial infection and was found to be a better predictor than WBC count. More information is needed to determine the utility of procalcitonin measurements in clinical decision making in this patient population.

Infection Rate at 1 Year of Deceased Donor Kidney Transplant in the Elderly

Wina Yousman, Nicole Low, Wei Xiang Wong, Venkatesh Kumar Aiyamuthu, Bekir Tantrrver. The University of Arizona, Tucson, AZ.

Background: There is limited publications about infection incidence rate in deceased donor kidney transplant (DDKT) recipients older than 65. The objective of this study is to examine our center specific infection incidence rate within one year of DDKT.

Methods: Retrospective chart review of DDK T (N=176) from July 2016 to December 2019 at Banner Medical Center in Tucson, AZ. Primary outcome was the infection incidence rate among recipients older than 65 year-old, including Cytomegalovirus (CMV) viremia and BK viremia (screened by monthly plasma PCR testing), or urinary tract infection (UTI) (diagnosed with positive urine culture and urinary symptoms within first year of transplant). We also fitted a multivariable logistic regression for the outcomes variables adjusted for demographics, KDPI, CIT, EPTS, and ePRA.

Results: The characteristics of the study cohort was shown in Table 1. Out of 176 patients, 63 patients (35.8%) were older than 65 year-old. There was no significant difference in the incidence rate of total infection, CMV viremia, BK viremia, and UTI in the elderly versus non-elderly patient (63.5% vs 51.3%, p = 0.11, 20.6% vs 11.5%, p = 0.010, 15.9% vs 11.5%, p = 0.41, 32.3% vs 28.3%, p = 0.59). The multivariable logistic regression analysis (adjusted for ethnicity, KDPI, EPTS, ePRA, and CMV mismatch) did not show increased odds of all types of infections among older recipients.

Conclusions: The infection rate of elderly versus non-elderly who received DDKT were similar.

PO2460

Two Deaths of Acute Transplant Patients from Strongyloides Hyperinfection Syndrome (SHS): Can We Prevent Harm with Screening and Prophylaxis at the Time of Transplantation?

Background: A 59 year old Vietnamese man presented with non-specific abdominal pain 8 weeks after a deceased donor kidney transplant. He was thoroughly investigated and no cause for the pain identified. On day three of the admission he became febrile and hypoxic. He died with multi-organ failure. Within three months a patient of Congolese origin presented nine weeks post transplant with abdominal pain. He became febrile with gram positive bacteraemia and was admitted to the ICU with type 1 respiratory failure where he unfortunately died. Autopsy findings revealed SHS. These cases were patients at a transplant centre in a non-endemic area albeit with an ethnically diverse population. A survey of other UK transplant centres showed that none did pre-transplant screening for strongyloides infection.

Methods: As a result of these cases we implemented and evaluated a program to screen for and prophylactically treat Strongyloides infection: Live donor patients were screened with Strongyloides serology in advance of transplantation. All recipients of deceased donor transplants were screened on admission for their transplant unless they had never travelled to an endemic area. At induction recipients received a weight adjusted dose of Ivermectin pending serology results. If positive a second prophylactic dose was administered at day 14. Travel histories and demographic data were recorded.

Results: Between July 2019 and March 2020, 135 patients were transplanted at our unit. Of those 125 had strongyloides serology testing; eight were positive at time of transplant. All patients reported as “borderline” drome. One further patient tested positive on a previous admission for a transplant which was cancelled; but was negative on the admission of the successful transplant. This indicates that at least 8% of our transplant listed patients are positive for strongyloides infection. By May 2020 there were no recorded deaths due to SHS, or morbidity associated with strongyloides infection in this group.

Conclusions: We have demonstrated that there is a significant level of sero-positivity within our pre-transplant population and that a relatively low-cost strategy may help prevent the potentially fatal Strongyloides Hyperinfection Syndrome.

PO2461

Infectious Complications and Malignancy After Kidney Transplant in the Elderly Population

Luz F. Liriano-Ward, Yong Al Azzi, Cindy T. Pynadath, Maria Ajaimy, Pablo Leverte Campos, Purna Bindu Nandigam, Enver Akalin. Montefiore Medical Center, Bronx, NY.

Background: Kidney transplantation improves quality of life and survival in all patients regardless of age. However, older patients are prone to development of side effects related to immunosuppressive medications including infections and malignancy. We aim to evaluate clinical outcomes in recipients >65 years of age.

Methods: We retrospectively reviewed all patients over the age of 18 who received an isolated renal transplant at our center from January 2013 to June 2017. We compared clinical outcomes including allograft and patient survival, as well as the development of infections and malignancy in patients > 65 compared to younger patients.

Results: Of 624 patients analyzed, 148 (24%) were > 65 years of age. There was no difference in terms of gender, race, immunosuppressive or induction therapy between the two groups. Older patients were more likely to receive a deceased donor kidney transplant (92% vs. 81%, p = 0.009). During a median 48 months (28, 70) of follow-up, as expected mortality was higher in older patients (16% vs. 6.5%, p = 0.0001) but there was
no difference in terms of death-censored graft loss (10.8% to 9%, p=0.52) compared to younger patients. Detailed analysis of infections revealed that there was no difference in terms of BKV and CMV viremia, pneumonia, bacteremia, influenza and c. diff between the two groups. However, older recipients had more fungal and urinary tract infections and malignancy. The most common infection in the elderly was PJP pneumonia (4%), candidemia (3%), and cryptococcal infection (2%). The most common malignancy in the elderly was skin cancer (6%) followed by prostate (2%), lung (1%), and colon (1%).

**Conclusions:** Recipients older than 65 had similar graft survival compared to younger patients, but had a higher incidence of fungal and urinary tract infections and malignancies.

**PO2462**  
Risk of Active Tuberculosis Infection in Kidney Transplantation Recipients: A Matched Comparative Nationwide Cohort Study

Sooheon Park,1 Ji Eun Kim,2 Mi-yeon Yu,3 Yong Chul Kim,2 Dong Ki Kim,3 Kwoun Wook Joo,4 Yon Su Kim,4 Kyungdo Han,5 Hajeong Lee.3  
1Armed Forces Capital Hospital, Seongnam, Gyeonggi-do, Republic of Korea; 2Soongsil University, Dongjak-gu, Seoul, Republic of Korea; 3Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; 4Hanyang University Guri Hospital, Gyeonggi-do, Republic of Korea; 5Korea University Guro Hospital, Seoul, Republic of Korea.

**Background:** Although the risk of mycobacterium tuberculosis (TB) infection is high in both kidney transplantation (KT) recipients and dialysis patients, a large-scale evidence comparing the risk between the two groups in a nation with moderate or higher TB prevalence was rare.

**Methods:** We performed a nationwide retrospective cohort study based on the claims database of South Korea where moderate TB prevalence is reported. We included incident KT recipients from 2011 to 2015 and compared their active-TB risks with matched controls. The 1:1 matched general population group was matched for age, sex, and era, while the dialysis group was matched for age, sex, era, underlying hypertension, and diabetes. They excluded the matched pairs with age < 20 years old, a previous TB history, and those matched to a multi-organ transplantation case. The incident active-TB risk was assessed by the multivariable Cox regression analysis. Within KT group, associations between active-TB, as a time-dependent variable, and post-transplant death or death-censored graft failure was investigated.

**Results:** The number of matched 7,462 subjects (total 22,386) were included to each of the study groups. During median 3.57 years of follow-up duration, the incidence rate for active-TB was 3.92/1,000, 4.38/1,000, and 0.67/1,000 person-years in the KT, dialysis, and general population groups, respectively. The KT group showed a significantly higher risk of active-TB than the general population group [adjusted HR 3.59 (1.88-6.12)] but a similar to the dialysis group [adjusted HR 0.98 (0.73-1.31)]. Active-TB was a significant risk factor for death [adjusted HR 2.24 (1.19-4.42)] or death-censored graft failure [adjusted HR 2.21 (1.36-3.58)] in the KT patients.

**Conclusions:** In Korea with moderate TB prevalence and active surveillance strategies, KT patients may not have to burden additional risk of active-TB when compared to dialysis patients. Still, clinical attention for active-TB complication should not be overlooked in end-stage kidney disease patients, particularly for KT patients as active-TB was associated with worse post-transplant prognosis.

Hydroxychloroquine as an Alternative or Adjunctive Antimetabolite in Kidney Transplant Recipients: Analysis of Linked US Registry and Claims Data

Krista L. Lentine,1 Tarek Alhamad,2 Huiling Xiao,3 Mark Schnitzer,2 Su-Hsin Chang,3 Yasar Caliskan,2 David Axelrod,2 Daniel C. Brennan.1  
1Saint Louis University, St Louis, MO; 2Washington University in Saint Louis, Saint Louis, MO; 3University Iowa, Iowa City, IA; 4Johns Hopkins University, Baltimore, MD.

**Background:** Hydroxychloroquine (HCQ) is an antimalarial drug with immunomodulatory effects in patients with systemic lupus erythematosus (SLE) and scleroderma. The potential anti-viral effects of HCQ have raised attention in the context of BKV and CMV viremia, pneumonia, bacteremia, influenza and c. diff between the two groups. However, older recipients had more fungal and urinary tract infections and malignancy. The most common infection in the elderly was PJP pneumonia (4%), candidemia (3%), and cryptococcal infection (2%). The most common malignancy in the elderly was skin cancer (6%) followed by prostate (2%), lung (1%), and colon (1%).

**Conclusions:** Recipients older than 65 had similar graft survival compared to younger patients, but had a higher incidence of fungal and urinary tract infections and malignancies.

---

**PO2464**

Bacillary Angiomatosis in a Kidney Transplant Recipient

Cleveland Clinic, Cleveland, OH.

**Introduction:** Bacillary angiomatosis (BA) is a vascular proliferative manifestation of Bartonella henselae (BH) or Bartonella quintana (BQ) that usually affects immunocompromised hosts. It usually involves the skin but may affect other organs. Few cases of BA in kidney transplant (KT) recipients have been reported, with most cases presenting years after KT. We describe a case of BA in a KT recipient that occurred early post-transplant.

**Case Description:** A 67-year-old male KT recipient from a deceased donor developed fevers, night sweats, and fatigue 1-month post-KT. He received antithymocyte
globulin induction, and maintenance tacrolimus, mycophenolate, and prednisone. Two months later, he presented with diffuse violaceous papules (Figure 1A). Biopsy of a papule with Warthin-Starry stain showed clusters of bacteria suggestive for BA (Figure 1B). Diagnosis was confirmed with a positive serum Bartonella polymerase chain reaction (PCR). He was treated with doxycycline with resolution of symptoms. BH and BQ Immunoglobulin G (IgG) were equivocal. A few weeks later, IgG for BH was 1:256 (reference range <1:128). Echocardiogram, abdominal computed tomography, and kidney biopsy were unremarkable. Recipient Bartonella PCR and antibodies on the day of transplant were negative. Donor Bartonella PCR and BH IgG were negative. Donor BQ IgG was equivocal. The recipient had a cat 8 years prior to KT with recent exposure. Allergist function remains intact, and the rash completely resolved. Bartonella PCR 6 months on treatment was negative.

Discussion: Our patient developed signs of BA with positive seroconversion within the first 3 months of KT which is rare. BA should be considered in the differential diagnosis of fever and cutaneous angioma-like lesions in KT recipients, even in the absence of exposures. Combined serology and molecular testing (PCR) is useful in diagnosing BA as serology alone may be unreliable. Early empiric treatment should be considered in transplant recipients while waiting for confirmatory results.

Figure 1. (A) Violaceous papules on the trunk. (B) Warthin–Starry stain showing bacteria (arrow).

PO2465
Isavuconazole as Consolidation Therapy for Disseminated Histoplasmosis in a Kidney Transplant Recipient
Samara Medani, Michael Kessler, Sandesh Parajuli. University of Wisconsin-Madison, Madison, WI.

Introduction: The diagnosis of systemic fungal infection may be elusive and requires a high index of suspicion with prompt evaluation, directed laboratory and radiological work-up and if necessary, histological examination. To our knowledge, this is the first case report of isavuconazole use as consolidation therapy for disseminated fungal infection in a kidney transplant recipient.

Case Description: A 76-year-old female with polycystic kidney disease presented 8 years post kidney transplantation with a painful tongue ulcer, anorexia, weight loss, progressive anemia and severe de-conditioning. She was on maintenance mycophenolate, prednisone and tacrolimus. A midline fissure on the dorsal tongue surface (image 1- left), and two non tender nodular masses in the left forearm and right buttock were noted. A diagnosis of disseminated histoplasmosis was made by biopsy of the tongue ulcer, and cultures of blood, tongue tissue and forearm nodule aspirate. Blood and urine histoplasma antigens were positive. The patient was treated with amphotericin for two weeks before transitioning to itraconazole due to QT prolongation. Mycophenolate was stopped. An outstanding clinical response with healing of the tongue ulcer (image 1- right), shrinking of the subcutaneous lesions, and substantial functional progress to prior independence was seen within 3 months. Histoplasma urinary and plasma antigen levels declined to undetectable levels. Isavuconazole was continued for a year with no adverse side effects reported.

Discussion: Infections with Histoplasma capsulatum are largely asymptomatic but progressive disseminated mycosis can occur in the immunocompromised. There is no specific agent selectively approved for second line maintenance therapy when itraconazole is not tolerated or is ineffective. Limited experience has been reported with other azoles, and even less so with isavuconazole. This case demonstrates an excellent outcome of treating disseminated histoplasmosis with isavuconazole in a kidney transplant recipient.

PO2466
The Diagnostic Dilemma of Diffuse Lymphadenopathy in a Kidney Transplant Recipient
Michael C. Krouse, Priyamvada Singh, Tomas I. Guererro Nunez. The Ohio State University Wexner Medical Center, Columbus, OH.

Introduction: Immunological balance is critical for transplant recipients. An optimum amount of immunosuppression prevents rejection while avoiding infection and cancers. Constitutional symptoms and lymphadenopathy could be present in both scenarios and could pose a diagnostic challenge.

Case Description: A 36-year-old male immigrant from India (ten years ago) with PMH of ESRD secondary to IgAN received a DDKT (9/2019, EBV D+/R+, on tacrolimus and myfortic). He was admitted with extensive retroperitoneal and mesenteric lymphadenopathy and a hypodense structure in the left upper abdomen (3.8 x 3.1 cm) on CT scan along with constitutional symptoms of fevers, constipation, and abdominal pain for ten days three months after transplant. Vital signs and physical examination were unremarkable except for the low grade fever. Aside from mild anemia (Hb 10 mg/dL), laboratory analysis was normal. PET scan revealed hypermetabolic lymphadenopathy in the neck, abdomen, and pelvis and consolidative changes in the left lung base and a right-sided loculated pleural effusion. Extensive workup - CMV PCR, pan-culture, fungal infections, and flow cytometry – was negative. CT-guided retroperitoneal lymph node biopsy, incisional biopsy of the mesenteric mass, and an endobronchial ultrasound-guided transbronchial needle aspiration of subcarinal LN were non-diagnostic. Finally, exploratory laparotomy and resection of the mesenteric mass revealed granuloma formation with multinucleated giant cells concerning for TB. The AFB culture grew mycobacterium tuberculosis on day 24. He is currently on antituberculosis treatment with a good response.

Discussion: Our case highlights the importance of a high degree of clinical suspicion for infectious etiology in transplant recipients, especially those from countries with a high prevalence of TB. Our patient bore a distant immigration history and a negative tuberculin test and did not have a history of exposure. Still, he was at increased risk of activation of latent TB due to his immunocompromised state. Extra-abdominal TB, like abdominal TB, poses a diagnostic challenge as the presentation can be non-specific and the AFB stain and culture can be non-diagnostic. Thus, a tissue biopsy becomes key to diagnosis. PTLD was highly differential given the PET-avid LAP. PET-avid lesions imply a hypermetabolic state which can happen in both malignancies and infections.

PO2467
Post-Transplant Lymphoproliferative Disorder: Recurrence at an Unusual Site
Aditi Saha, Sohail Tariq, Lalitha Thiruvarukasur Murugan, Sunil Sapru, Miguel Conde. Saint Barnabas Medical Center, Livingston, NJ.

Introduction: PTLD includes a spectrum of clinical presentations due to lymphoid proliferation ranging from benign hyperplasia to aggressive lymphomas that occur after either a SOT or HSCT. PTLD can involve extra nodal sites like graft tissue, GI tract, and lungs. Skin and soft tissue involvement is very rare. We report a patient with PTLD who had relapsed with axillary lymphadenopathy and a soft tissue mass on the arm.

Case Description: A 59-year-old male was diagnosed with EBV negative PTLD involving retroperitoneal, mediastinal and supraclavicular lymph node, one year after renal transplant. He was treated R-CEOP (Rituximab, Cyclophosphamide, Etoposide, Vinristine, Prednisone). After 6 cycles of chemotherapy repeat PET showed complete resolution. 3 months later, he presented with LUE pain and swelling. Labs were significant for high LDH and Beta-2 microglobulin. CT LUE revealed 4.8 cm mass over left anterior arm and left axillary adenopathy. Biopsy and flow cytometry of axillary lymph node confirmed relapse. Immunohistochemical stains showed tumor cells positive for CD20, PAX5, BCL2, MUM1, BCL6 with K67 of 80-90%. Patient developed compartment syndrome and had to undergo fasciotomy. Patient was started on modified regimen with Rituximab, Gemcitabine and Oxaplatin (R-GEMOX) for poor performance status.

Discussion: The incidence of PTLD ranges from 1 to 25% with 90% of cases being EBV-associated, CD 20 positive, B cell neoplasms. EBV negative PTLD occurs only in 5-10% cases, appears late with worse prognosis than EBV positive PTLD. EBV negative PTLD is assumed to be related to Tp53 mutation caused by immunosuppressive agents like azathioprine or tacrolimus. Skin and subcutaneous lesions are extremely rare as sites of extra nodal presentation and may take the form of solitary or multiple papules, nodules, plaques with ulceration, comedo-like lesions, follicular keratotic papules, or localized alopecia. Our patient is interesting as he had a relapse of EBV negative PTLD in the form of a soft tissue fibro-adipose mass in the upper extremity. To the best of our knowledge, there have been three cases of PTLD presenting as soft tissue masses on head reported in the literature. Biopsy remains the gold standard for diagnosis. Treatment is includes reduction of immunosuppression and rituximab with additional chemotherapy.

PO2468
Post-Transplant Lymphoproliferative Disorder (PTLD) Presenting as Solitary CNS Lymphoma: A Rare Occurrence
Aditi Saha, Sohail Tariq, Lalitha Thiruvarukasur Murugan, Sunil Sapru, Israel R. Grossman. Saint Barnabas Medical Center, Livingston, NJ.

Introduction: PTLD associated lymphoma is the second most common malignancy in patients receiving SOT or HSCT with an incidence rate of 1%-3%. CNS involvement occurs in 7%-15% of all PTLD cases. We present a case of isolated PCNS lymphoma two years after renal transplant.

Ulcereated median sulcus of the tongue, before (left) and 8 months after (right) starting antifungal therapy.
Case Description: A 57-year-old woman with PMH of ESRD s/p kidney transplant (D = HLA EBV+) with chronic CClVI of 30-40% percutaneous presented with paresthesia and numbness over the right side of her body with mild ataxia 2 years post transplant. Physical exam revealed only numbness over the right side of body. MRI with contrast revealed a left thalamic lesion with moderate wasogenic edema, and MR spectroscopy confirmed high grade neoplasm involving left thalamus. Stereotactic biopsy showed polymorphic CD-20 and EBV positive PTLD. EBV PCR were elevated. Further evaluation ruled out systemic PTLD. Myelotoxic was stopped and oral steroids started with mild improvement in symptoms. Choice of systemic chemotherapy was limited due to reduced CCl and risk of graft failure. She received modified regimen with a newly adjusted high dose Methotrexate, Vincristine and Rituximab for 6 cycles with partial remission and then Tenofovir for 7 cycles with complete remission.

Discussion: The incidence of PTLD ranges from 1 to 25% with 90% of cases being EBV associated. EBV positivity in the host cell neoplasms. PCs-PTLD has a higher incidence in renal SOT, occurs late and is usually monomorphic unlike our patient. Median time of occurrence is 4.5 years after transplant. Risk factors include age, intensity of immunosuppression, time to transplant and EBV status of donor and recipient. Common presenting features include neurological deficits, seizure, and raised intracranial pressure. MRI of the brain is preferred imaging and shows multifocal, ill-defined, ring enhancing lesions usually in supratentorial and lobar regions. Positive CSF EBV PCR is highly suggestive but biopsy remains the gold standard for diagnosis. Treatment modalities include reduction of immunosuppression, rituximab, high dose methotrexate, cytarabine and cranial radiotherapy. Use of high dose methotrexate has shown improved outcomes with median survival of 26-47 months. Lack of response to first line therapy is considered the dominant prognostic factor. Early recognition and diagnosis remain crucial for improving outcome.

PO2469
National Trends in Kidney Transplantation Among Patients with ESKD from Plasma Cell Dyscrasias
Jia Hwee Ng,1,2 Stephanie Izard,1 Kenar D. Jhaveri,1,2 Vinay Nair.1 Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY, 1Northwell Health, Great Neck, NY.

Background: Due to relapses and kidney involvement, plasma cell dyscrasias have been a relative contraindication for kidney transplantation. With newer medications and improved prognosis of plasma cell dyscrasias, kidney transplantation in this population is becoming more common. We aimed to describe national trends in the proportion of kidney transplants among patients who had ESKD from plasma cell dyscrasias (multiple myeloma, amyloidosis, and monoclonal gammopathy of renal significance).

Methods: We used data from the United Network for Organ Sharing/ Organ Procurement and Transplantation Network (UNOS/OPTN) database. Patients 18 years or older, BMI >15 or <45 kg/m2, received a first kidney transplant between January 1, 2006 to December 31, 2017 were eligible. Recipients of more than one organ transplant were excluded.

Results: A total of 160,966 patients received a first kidney transplant. Among these, 487 (0.3%) had ESKD from plasma cell dyscrasias, kidney transplantation in this population is becoming more common. We aimed to describe national trends in the proportion of kidney transplants among patients who had ESKD from plasma cell dyscrasias (multiple myeloma, amyloidosis, and monoclonal gammopathy of renal significance).

Table 1: National trends in kidney transplantation among recipients who had end-stage kidney disease from plasma cell dyscrasias (multiple myeloma, amyloidosis, and monoclonal gammopathy of renal significance)

Conclusions: Despite improvement in the treatment of plasma cell dyscrasias, national trends show only a small rise in the proportion of kidney transplantation for patients with ESKD from plasma cell dyscrasias. Additional analyses are needed to assess the outcomes of these kidney transplant recipients.

PO2470
A Retroperitoneal Cyst of Pancreatic Origin in a Renal Transplant Recipient: Expect the Unexpected
Muhammad O. Saleem,1 Ambreen Chughtai,1 Imran Y. Gani,1 Muhammad I. Saeed,2 Rajan Kapoor.1 1Augusta University, Augusta, GA; 2FMH College of Medicine and Dentistry, Lahore, Pakistan.

Introduction: The immunosuppression required to maintain a renal allograft function puts the recipient at a higher risk of malignancy. We report a rare case that presented a diagnosis of a retroperitoneal hemorrhagic cystic mass turn out to be an adenocarcinoma of pancreaticobiliary origin.

Case Description: 43-year-old female with a history of End Stage Renal Disease due to IgA Nephropathy and two renal transplantations, first in 1999 from her sister and second in 2005 from a deceased donor, presented with complaint of left sided abdominal pain and distention for one month. Her graft function was stable with creatinine of 1.8mg/dl on immunosuppression with tacrolimus, mycophenolic acid, and prednisone.

On examination the abdomen was soft, flat and tender. There was a well defined area of tenderness in the left lower quadrant. There were no masses palpable. The CT scan showed a 1.7 cm well defined area of high density in the left lower quadrant. She subsequently underwent exploratory laparotomy which revealed a retroperitoneal 1.7L cystic hematoma with no association to native or transplant kidneys. The histopathology showed adenocarcinoma with mucinous and enteric features. Based on the morphology and immunoprofile, the differential diagnosis included an ovarian, gastrointestinal or peritoneal primary. Tumor markers showed elevated CA19-9, but normal CEA and CA-125. Given the positivity for both CK 7 and CK 20, colonic origin was unlikely but could not be completely excluded. Negative IEG and colonoscopy ruled out GI malignancy. PET scan was unremarkable. Molecular analysis predicted 90% probability of pancreaticobiliary adenocarcinoma. Subsequently patient was started on adjuvant chemotherapy with Gemcitabine. She failed first and second lines of chemotherapy with progression of cancer. Then she received PD-1 inhibitor, Nivolumab which could not prevent progression of disease but resulted in renal graft failure. Per last reports, patient was on palliative chemotherapy and in terminal phase of her life.

Discussion: Post-transplant malignancy is one of the most feared complications. It is the third leading cause of mortality and accounts for 8-10% of all deaths in United States and 30% in Australia in kidney transplant recipients. Compared with general population, the risk is increased 2-3 folds and mortality rates are higher. The occurrence of pancreatic cancer is high too. But finding a pancreaticobiliary cancer from a retroperitoneal cyst with negative pancreas imaging is rare.

PO2471
Secondary Malignancy in Kidney Transplant Recipients: University of Southern California Experience
Alexandra K. Wong, Tiffany Truong, Poorva Vaidya, Gino In, Thin Thinx Maw. Keck Hospital of USC, Los Angeles, CA.

Background: Kidney transplant recipients (KTR) on immunosuppressive therapy are at higher risk of developing secondary malignancy (SM). Although previous studies have demonstrated this increased risk, much remains to be elucidated regarding the spectrum of SM and the contributing factors to morbidity and mortality.

Methods: We conducted a retrospective review of all KTR from April 2005 to December 2017 at our institution. We then selected only those patients with SM, and collected demographics, variables related to kidney transplant, malignancy, and outcomes.

Results: Among 1414 KTR, 84 patients (pts) had post-tx SM. Forty-five percent of pts were Hispanic, 35% Caucasian, 11% Asian and 6% African American. Twenty four pts (28%), 11 pts (13%), and 51 pts (59%) developed cutaneous malignancy, hematological malignancy and solid organ malignancy (SOM) respectively. One patient developed both a secondary cutaneous and SOM, while another pt developed 2 different SOM. 46 (55%) pts were deceased by 1/1/20: 25 pts died from malignancy and 9 pts died from infection. Among those 46 pt, 37 pts (80%) had intact graft function at death. Eleven pts (13%) had malignancy prior to tx. The induction was rATG (36%) and basiliximab (41%). 20 pts had biopsy-proven acute rejection; of these 75% was prior to and 25% was post cancer diagnosis. 18 pts were switched to mTOR inhibitor from tacrolimus and cefepine was stopped in 22 pts.

Conclusions: We describe a wide range of SM among a diverse population of KTR, with nearly half of our patients being Hispanic. This highlights the need for further investigation of the impact of ethnicity on SM. Among our KTR, SM was the cause of death for 25 pts and infection was for 9 pts. Regardless of etiology, the majority of pts (80%) had intact graft function at death. Our findings illustrate the need for vigilant cancer screening and additional strategies to decrease cancer risk and death in KTR.

PO2472
Spectrum and Consistency of Cancer Outcomes in Randomized Trials in Kidney Transplant Recipients: A Systematic Review
Erica H. Ashford,1 Allison T. Law,1 Gemma Wong,1,2 Jonathan C. Craig,1 1The University of Sydney Faculty of Medicine and Health, Sydney, NSW, Australia; 2Children’s Hospital at Westmead Centre for Kidney Research, Sydney, NSW, Australia; 3Flinders University College of Medicine and Public Health, Bedford Park, SA, Australia.

Background: Cancer is an important cause of morbidity and mortality in kidney transplant recipients. Despite being identified as a critically important outcome by patients, caregivers and health professionals, inconsistency in how cancer outcomes are defined and reported in trials involving kidney transplant recipients may limit decision-making. The aim of this study was to assess the spectrum and consistency of cancer outcomes in trials involving kidney transplant recipients.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: ClinicalTrials.gov was searched from inception to October 2019 to identify randomized controlled trials (RCTs) in adult kidney transplant recipients, which included cancer as a pre-defined outcome. We extracted the details of all primary and secondary cancer outcomes, including type, timepoint and definition of cancer (histology, grade and stage).

Results: Among the 71 RCTs included, there was a total of 87 cancer outcomes. The majority of trials (n = 61, 86%) included cancer as a secondary outcome only, with 8 trials (11%) including cancer as a primary outcome and 2 (3%) including cancer as part of a composite primary outcome measure. The most common descriptions of cancer in these outcomes were "malignancy" without specific reference to diagnostic criteria, histology, grade or cancer stage (40, 46%) or "cancer" without specific clarification (8, 9%). Some trials included mention of specific cancer types, with post-transplant lymphoproliferative disorder (13, 15%), non-melanoma skin cancer (10, 11%) and skin cancer (9, 11%) being the most common, but these were not defined. A range of timepoints were used, with a single timepoint at the end of the primary trial being the most frequent (38, 44%); 13 studies included measurement at several timepoints during the trial (15%). A range of metrics for measuring cancer outcomes were used, including cancer incidence (53, 61%), proportion with cancer (9, 10%), and time-to-event (5, 6%). No measurement metric was specified in 18 (21%) cancer outcome measures.

Conclusions: Cancer is one of the most important outcomes for patients post-transplantation, but cancer outcomes are very poorly defined and highly variable in RCTs. A core outcome for cancer for all trials in kidney transplant recipients should be developed that is consistent and meaningful to patients and clinicians.

PO2473
Acute Rejection and Graft Failure in a Kidney Transplant Recipient with Malignant Melanoma and Treated with Pembrolizumab: A Case Report
Annalise M. Panthofer, Kurits J. Swanson, Didier A. Mandelbrot, Neetika Garg. University of Wisconsin School of Medicine and Public Health, Madison, WI.

Introduction: Malignancy treatment with immunotherapy in renal transplant recipients is complicated by a very high risk of rejection. Immunochemotherapy increases immune recognition and destruction of immune-evading cancer cells. This can lead to an overly robust immune response leading to allograft injury and failure. Here we present a case of graft failure due to rejection within a week of starting immunotherapy.

Case Description: 73-year-old female with a history of end-stage renal disease attributed to hypertensive nephrosclerosis underwent live unrelated kidney donor transplant and presented 6 months post-transplant with a right foot lesion and was diagnosed with stage IIIIC malignant melanoma. Her maintenance immunosuppression was decreased from tacrolimus/prednisone to prednisone monotherapy and the lesion was excised. 14 months later, disease surveillance via PET scan revealed metastatic disease. After carefully weighing the risks of mortality without treatment versus graft rejection, pembrolizumab, a programmed death one (PD-1) inhibitor, was initiated. 5 days after administration of the first dose, the patient presented emergently with acute kidney injury with Cr of 4.3 mg/dL, increased from baseline Cr of 0.9-1.0 mg/dL. Ultrasound of her graft demonstrated significant edema and graft thrombosis. Allograft biopsy was consistent with 95% cortical necrosis with thrombotic microangiopathy and grade III acute cellular and antibody mediated rejection. Transplant nephrectomy was performed on day 7 and HD was re-initiated.

Discussion: Immune checkpoint inhibitors have been shown to be effective treatments for certain malignancies (melanoma, renal cell carcinoma namely); however, they can cause acute rejection and graft loss in transplant recipients. Though PD-1 inhibition has been a major scientific breakthrough in late-stage cancer treatment, its risk profile should be carefully considered in organ transplant recipients due to high risk on graft rejection. Prevention and management of rejection in a transplant recipient with an aggressive melanoma such as ours is not clear.

Hypercalcemia Associated with Pneumocystis jirovecii Pneumonia in Renal Transplant Patients

Introduction: Pneumocystis jirovecii pneumonia (PJP) is a common complication following solid organ transplantation with an estimated incidence of 5-15%. Although previously reported, hypercalcemia is not classically a sign of PJP. In the past 6 months at our institution, there have been six cases of PJP presenting with varying degrees of hypercalcemia.

Case Description: All patients in the table below presented with signs and symptoms concerning for pneumonia and were diagnosed with PJP by DFA and/or PCR from induced sputum or bronchoscopy. Patient demographics, labs, and calcium trends are outlined in the table. All patients were treated with Bactrim and prednisone for PJP (some had intravenous sulfamethoxazole/trimethoprim and intravenous meropenem and then trimethoprim. A follow-up MRI two months from diagnosis showed marked improvement in all lesions and he was transitioned to oral doxycycline to complete at least 12 months of therapy.

Discussion: Nocardiosis can present in unusual fashion in transplant recipients and is more likely to infect immunosuppressed patients. We report a case of a kidney transplant patient who presented with a tender lump of his right shoulder.

PO2478
Hypercalcemia: A Prodromal Feature of Pneumocystis jirovecii Pneumonia in Kidney Transplant Recipients
Joy C. Chen, Johann N. Isaac, Raviprasanna K. Parasaruman. University of Michigan, Ann Arbor, MI.

Introduction: Hypercalcemia in transplant recipients (KTRs) is frequently caused by persisting hyperparathyroidism. However, hypercalcemia can also be a prodromal feature of serious underlying infections and malignancy. We present 2 cases of parathyroid hormone (PTH) independent hypercalcemia that preceded Pneumocystis jirovecii pneumonia (PJP) diagnosis.

Case Description: Case1. A 21 y.o. male with end-stage kidney disease (ESKD) from FSGS presented with 3 weeks of dyspnea and cough 8 months after transplant (Tx). Chest x-ray (CXR) showed interstitial opacities. Lab revealed acute kidney injury and severe hypercalcemia. He was initially treated with IV fluid and calcium, and hypercalcemia improved (Figure 1). Workup showed significant elevation in 1,25 dihydroxyvitamin D (1,25(OH)2 VitD)and low PTH level, and his sputum was positive for PJP by DNA PCR. Case2. A 26 y.o. male with ESKD from nephronophthisis presented with 2 weeks of cough and dyspnea 10 yrs after Tx. He had severe hypercalcemia, and CXR showed nodular interstitial opacities. He was diagnosed with PJP by sputum DNA PCR. His hypercalcemia workup also revealed elevated 1,25(OH)2 VitD and low PTH.

Discussion: PJP occurs in 5–15% of KTRs without prophylaxis with significant morbidity and mortality. A timely diagnosis is challenging given its indolent presentation. Since hypercalcemia can occur in 20-30% of cases during early stages of PJP from increased production of 1,25(OH)2 VitD via 1α-hydroxylase from alveolar macrophages, its presence should alert clinicians of its diagnosis. In 2019, 2 out of 5 PJP cases at our center had hypercalcemia at least 2 weeks prior to PJP diagnosis with high 1,25(OH)2 VitD and low PTH. In both cases, hypercalcemia resolved after treatment of PJP. These 2 cases illustrate hypercalcemia could be a prodromal feature in PJP. Early recognition with appropriate treatment would significantly reduce its morbidity and mortality.

Effect of UNOS Kidney Allocation System on Transplantation Rates for Veterans Waitlisted at Veterans Affairs Transplant Centers
Nidhi Aggarwal,1 Sankar D. Navaneethan,2 Jingbo Niu,1 Jenny S. Pan,1 Chandan Vangala,3 Ronald T. Cotton,2 Venkat Ramanathan,2 Michael E DeBakey VA Medical Center, Houston, TX; 3Baylor College of Medicine, Houston, TX.

Background: Impact of new Kidney Allocation System (KAS) on kidney transplantation (KT) rates for patients waitlisted at Veterans Affairs Transplant Centers (VATC) is unknown. This study compares effect of KAS on waitlisted patients at VATC and non-VATC.

Methods: UNOS data on adult patients waitlisted for KT during January 2009 to December 2016 were obtained. Logistic regression was used to assess association between center type (VATC vs. Non-VATC), time period (pre-KAS 2009-2014 vs. post-KAS 2015-2016) and outcomes (receiving KT or death on waitlist) within 2 years of waiting. Odds ratio (OR) was calculated adjusting for demographic factors, comorbidities, calculated Panel Reactive Antibodies (cPRA) and Estimated Post-Transplant Survival (EPS) score.

Results: During study period, a total of 263,410 patients were listed at non-VATC (75% pre-KAS; 25% post-KAS) and 3,150 at VATC (68% pre-KAS, 32% post-KAS). VATC patients were significantly older (58.3 vs. 51.7 years), diabetics (55.4% vs. 42.5%), had lower cPRA, higher EPS (53 vs.39%) and longer duration of dialysis (762 vs. 727 days). Within 2 years of waitlisting, Veterans listed at VATC did not benefit from the new KAS like patients in non-VATC centers. Overall, independent of the era, Veterans tend to be transplanted lesser in this early waitlisting period. But waitlist death was 29% in VATC patients. (Results are shown in the table)

Conclusions: Benefit of new KAS did not extend to Veterans listed at VATC who are older, less immunogenic and have higher EPS score. Early benefit of KAS seen in non-VATC could be due to “bolus effect” from transplantation of younger, highly sensitized patients. However, risk of death is significantly lower in VATC waitlisted patients.

Outcomes of patients within 2 years of waitlisting for kidney transplantation

PO2480
Lend Me Your Ear: An Unusual Presentation of a Transplant Complication
Meredith McAdams, Kruti Yagnik, Swae-Ling Levea, Jeffrey Tessier, Reuben J. Arasaratnam. University of Texas Southwestern Medical School, Dallas, TX.

Introduction: Infections are a major complication in solid organ transplant (SOT) patients due to need for life-long immunosuppression. Incidence of fungal infections following solid organ transplant ranges from 5-20%. Cryptococcosis is an invasive fungal infection that can cause several types of infections including meningitis, pulmonary, cutaneous, and disseminated disease.

Case Description: A 66 yo F with past medical history of ESRD s/p deceased donor kidney transplant 15 months ago, DM, HTN presented to renal transplant clinic with right ear pain for the past 4 weeks after being evaluated in the emergency room. Her exam was notable for painful ear and cheek lesions (Figures A and C). Fungal serologies were taken and patient was sent to dermatology clinic for evaluation. Punch biopsies were taken from several lesions and cultures obtained. Serum cryptococcal antigen was positive with titer of 1:4096. fungal culture from lesion grew Cryptococcus neoformans. Skin biopsy showed cryptococcus (Figure B). Patient was admitted to the hospital and further testing revealed positive CSF cryptococcal antigen, CT chest with nodular involvement. Patient was admitted to the hospital

Discussion: Cryptococcal infection is the third most common invasive fungal infection in SOT patients and typically presents later in kidney transplant patients, 16-21 months, compared to other transplanted organs. Risk factors include type of immunosuppressive agent and comorbid conditions such as diabetes. The majority of transplant patients with cryptococcus present with CNS manifestations or disseminated disease, cutaneous involvement is less common. Our patient had risk factors including diabetes, older age, and use of induction immunosuppression. Initial presentation with skin lesions is atypical for cryptococcal infection. It is important to have a high suspicion for fungal infections in immunosuppressed patients even those with atypical presentations.

PO2481
Pegloticase for Uncontrolled Gout in Kidney Transplant Recipients: Early Data Report of a Multicenter, Open-Label Efficacy and Safety Study
Abdel A. Abdelatif1, Lin Zhao,2 Paul M. Peloso,2 Kathryn Cherny,3 Brad A. Marder,1 John D. Scandling,4 Kenneth G. Saag,5 Baylor College of Medicine, Division of Nephrology, Houston, TX; 2Horizon Therapeutics plc, Lake Forest, IL; 3Stanford School of Medicine, Division of Nephrology, Stanford, CA; 4University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, AL.

Background: Gout is common and more severe in US kidney transplant (KT) recipients, with prevalence >10% higher than in non-transplant patients. The management of gout can be challenging in KT patients due to decreased urate lowering therapy (ULT) clearance and drug-drug interactions. Recent reports suggest that pegloticase, a pegylated uricase approved for treating uncontrolled gout, has improved efficacy and safety when co-administered with immunosuppressive medications (IMM). We conducted the PROTECT trial (NCT04087720) to examine pegloticase use in KT recipients.

Methods: Patients with uncontrolled gout (sUA ≥7 mg/dL, intolerance of or contraindication to ULT, and a of the following: tophus, chronic gouty arthritis, a2 flares in past y) and functioning KT graft (eGFR ≥15 mL/min/1.73m2) are included (KT ≥1 yr earlier). Pegloticase (8 mg q2w for 24 wks) safety and efficacy are examined. Primary endpoint is ≥5% pegloticase responders during Month 6 (sUA <6 mg/dL for ≥80% of time).

Results: 7 patients were enrolled by Apr 30, 2020 (age: 52.0±11.2 yrs, KT 15.3±5.0 yrs ago, sUA: 10.0±1.4 mg/dL, gout duration: 5.9±4.3 yrs; all on stable doses of a2 IMM) and received 2-12 infusions. 1 patient discontinued. In the 1 completed and 5 ongoing patients, all central lab sUA levels were <1 mg/dL, indicating treatment response; no infusion reactions occurred. No notable eGFR changes were observed; 2 patients with baseline albuminuria of >300 mg/g showed >35% reduction in UACR by wk 14. 2 SAEs (stomach ulcer, cellulitis) unrelated to pegloticase were reported.

Conclusions: Early data of this ongoing clinical trial are promising and suggest pegloticase is safe and effective for treating uncontrolled gout in KT recipients. Additional efficacy and safety data are planned.

PO2482
Minoxidil-Induced Chylous Ascites in a Renal Transplant Recipient
Vivek Pathak. Kovai Medical Center and Hospital, Coimbatore, India.

Introduction: Chylous ascites is generally associated with malignancies and surgical trauma and rarely secondary to administration of drugs.1 Pathak et al. JClinMed.2019;8:94. Calcium channel blockers related chylous ascites is more common is Asian ethnicity we could not find any published report of minoxidil causing chylous ascites.

Case Description: This patient is a 64 years old diabetic and hypertensive male who underwent kidney transplantation on 09.06.2009. He was HBsAg positive for last 9 years. He was taking multiple medications namely carvedilol, amplodipine, lasix, metformin and linagliptin and Entecavir. He came in May 2019 with ascites. Investigation revealed normal kidney function and ultrasound guided ascitic fluid tapping was done and it was found to be chylous. He underwent abdominal paracentesis and about 12 lt of ascitic fluid was drained but he came back within 10 days with ascites again. Portal hypertension was ruled out by transhepatic hepatic venous pressure gradient measurement and liver biopsy did not show any evidence of chronic liver disease. An upper GI endoscopy and duodenoscopy including duodenal biopsy were normal. Whole body PET scan did not show any active infection or disease. Meanwhile literature review suggested association of minoxidil with chylous ascites and it was stopped but he continued to develop recurrent ascites. An abdominal CT lymphangiogram was done which did not show any lymphatic leak.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

753
He also underwent diagnostic laparoscopy which also ruled out TB or any malignancy. This patient had bilateral chylous ascites for 6 months then we decided to discontinue minoxidil as it is known to cause fluid accumulation including pleural and pericardial. He showed immediate improvement after stopping minoxidil and never developed ascites again. He was fine even 6 months later on follow up.

Discussion: Minoxidil causes vasodilatation like calcium channel blockers though by a different mechanism so the mechanism of chylous ascites formation could be the same that it is also a lipophilic drug allowing it to pass rapidly into the lymphatic system and causes relaxation of smooth muscles of lymphatic vessels, interferes with lymphatic drainage, and increases the hydrostatic pressure in lymph vessels and causing it to leak in the peritoneum. Minoxidil must be considered as a probable cause of atrumatic drug induced chylous ascites.

PO2483
COVID-19 in Kidney Transplant Recipients: Experience from a Large Health System in Louisiana
Aldo E. Torres Ortiz, Joseph B. Walker, Juan Carlos Q. Velez, Jorge C. Garces. Ochsner Nephrology Ochsner Health System, New Orleans, LA.

Background: Infections are an important cause of morbidity and mortality among kidney transplant recipients. The novel Coronavirus Disease 2019 (COVID-19) has affected all kinds of populations world-wide. However, the role of immunosuppression in the outcomes of these patients is not well understood.

Methods: We conducted a retrospective study in kidney transplant recipients from a single health system that were diagnosed with COVID-19 based on a positive real-time reverse transcription polymerase chain reaction test for SARS-CoV-2 RNA between March 2020 and October 2020. We compared them with a control case-matched group without a kidney transplant and without any kind of immunosuppressive medication (control). We examined the rates of hospitalization, intensive-care unit (ICU) admission, acute kidney injury (AKI) and mortality as outcome measures.

Results: A total of 8473 patients were diagnosed with COVID-19 within our Health System within the study period. Thirty-three (0.4%) were kidney transplant recipients. Sixteen of the 33 (48%) were admitted to the hospital (median age of 56, 68% males, 93% African American) vs 2201 admissions (25%) for the control group (median age 66, 48% males, 65% African American), i.e., a significantly greater risk for hospitalization for transplant recipients (p = 0.006). Percentage of patients with hypertension in the transplant group was numerically higher (93% vs 80%, p = 0.06), as well as the number of ICU admissions (43% vs 28%, p = 0.055). AKI was more common in transplant patients (81% vs 33.8% p<0.0001). No difference in mortality was observed (31 vs 24%, p = 0.34). Among transplant patients, those hospitalized were more likely to be on prednisone (75% vs 35%, p = 0.025) and had a post-transplant graft life of 7.9 years compared to 5.5 years for those not hospitalized, p=0.08.

Conclusions: Kidney transplant recipients affected with COVID-19 exhibited a greater incidence of hospitalization, AKI and a trend for more ICU admissions. Use of immunosuppression with prednisone was associated with greater risk for hospitalization.

PO2484
Recurrent Anemia due to Chronic Parvovirus B19 Infection in a Kidney Transplant Recipient: Can Everolimus Make a Difference?
Diana Rodriguez-Espinosa, Nuria Esforzado, Fritz Dickmann, Ignacio Revuelta. Hospital Clinic de Barcelona, Hospital Clinic de Barcelona, Barcelona, Spain.

Introduction: Parvovirus B19 (PB19) is a common infection among transplant recipients. Usually, it is asymptomatic, but some patients may suffer severe infections, often presenting with recurrent flares despite standard treatment. Relapses are usually managed by reducing immunosuppressive treatment (IST), potentially increasing graft rejection risk.

Case Description: 45-year-old woman with ESKD due to ADPKD, received a living-donor kidney transplant on May 2013. Maintenance IST consisted of mycophenolate mofetil (MMF), prednisone and tacrolimus. A month after transplantation, she presented with fever and anemia. A bone marrow aspirate revealed pure red blood cell aplasia (PRCA) which was attributed to PB19 after positive serum qualitative PCR. She was treated intravenous immunoglobulin (IVIG) at 2g/kg and MMF was stopped with good response. However 3 new relapses occurred (anemia and malaise with viral loads for PB19 over a million copies). A monthly prophylactic dose of IVIG was initiated to control the infection. In spite of this, episodes of anemia and a high PB19 viral load (over a half million copies) continued to happen at least 3 times per year. Finally, given the potential antiviral properties of mTOR inhibitors (mTORi), conversion from tacrolimus to everolimus was decided. Since November 2017 her maintenance IST consists of everolimus and prednisone alone, her last prophylactic IVIG was on December 2017, to everolimus was decided. Since November 2017 her maintenance IST consists of mTORi. A month after transplantation, she presented with fever and anemia. A bone marrow aspirate revealed pure red blood cell aplasia (PRCA) which was attributed to PB19 after positive serum qualitative PCR. She was treated intravenous immunoglobulin (IVIG) at 2g/kg and MMF was stopped with good response. However 3 new relapses occurred (anemia and malaise with viral loads for PB19 over a million copies). A monthly prophylactic dose of IVIG was initiated to control the infection. In spite of this, episodes of anemia and a high PB19 viral load (over a half million copies) continued to happen at least 3 times per year. Finally, given the potential antiviral properties of mTOR inhibitors (mTORi), conversion from tacrolimus to everolimus was decided. Since November 2017 her maintenance IST consists of everolimus and prednisone alone, her last prophylactic IVIG was on December 2017, and since then she has been non-anemic with serum viral loads below 1000 copies, and without IVIG treatment.

Discussion: Incidence of symptomatic PB19 infection is highest during the 1st year after transplantation, like in the case presented. Standard therapy consists of IVIG. However, early KR, often relapse after the IVIG effect wears off. In such cases, reduction of IST is needed to control the infection and avoid recurrences. There are multiple studies indicating that mTORi have antiviral properties although their effect on PB19 has not been specifically studied. In conclusion, conversion from tacrolimus to an mTORi, could be an interesting approach in difficult-to-manage cases similar to ours, moderating the reduction of IST and minimizing the risk of rejection. Further studies are needed to establish this approach as “treatment of choice” in relapsing PB19 infection.

Racial-Ethnic Disparities in Preemptive Kidney Transplantation Among Incident ESKD Adult Patients, 2006 to 2018

Background: Preemptive kidney transplantation (PKT) is the preferred treatment for ESKD. Among kidney transplant recipients, black and Hispanics are less likely to receive PKT than whites, but less is known about disparities in PKT among the entire incident ESKD population. This is a critical gap in knowledge given the Advancing American Kidney Health goal of 80% of all new ESKD patients receiving transplant or home dialysis by 2025. This study assessed racial/ethnic disparities in initial treatment with PKT vs. dialysis among all incident ESKD failure patients aged 19-74 from 2006 to 2018.

Methods: Treatment modality for incident ESKD patients was identified using the CMS Medical Evidence Report Form. Linear regression models estimated PKT rates for dialysis by 2025. This study assessed racial/ethnic disparities in initial treatment with PKT among incident ESKD adult patients, black and Hispanics are less likely to receive PKT than whites, but less is known about disparities in PKT among the entire incident ESKD population. This is a critical gap in knowledge given the Advancing American Kidney Health goal of 80% of all new ESKD patients receiving transplant or home dialysis by 2025. This study assessed racial/ethnic disparities in initial treatment with PKT vs. dialysis among all incident ESKD failure patients aged 19-74 from 2006 to 2018.

Results: Among 1,133,326 incident ESKD adult patients, the age/sex adjusted PKT rate declined from 3.0% in 2006 to 2.5% in 2018, with varied trends in each racial/ethnic group (white: 5.0% to 4.0%, black: 0.3% to 0.7%, Hispanic: 1.3% to 1.3%, and Asians: 2.4 to 2.9%) (Figure). In age-sex adjusted analyses, whites had 3.9, 3.2, and 1.7 percentage points lower PKT rates than blacks, Hispanics, and Asians, respectively. These differences persisted after adjusting for clinical, geographic, socioeconomic, and access factors.

Conclusions: Among incident ESKD adult patients, racial/ethnic disparities in receipt of PKT are substantial, persistent, and not explained by differences in observed clinical factors and socioeconomic status. Efforts to increase preemptive transplantation must address disparities in access to this preferred treatment for ESKD.

PO2487

Lower Prevalence of Kidney Transplant Waitlisting in Micropolitan Areas, Small Towns, and Rural Areas

Background: The Percentage of Prevalent Patients Waitlisted (PPPW) measures the percentage of patients at a dialysis facility who were on the kidney or kidney-pancreas transplant waitlist. This measure joined the End Stage Renal Disease Quality Incentive Program in performance year 2020, with a weight of 4%. PPPW is adjusted for age, but not for other factors. Physical distance between residence and transplant center may influence PPPW. As an indirect test of this hypothesis, we assessed whether PPPW was associated with rural-urban commuting area (RUCA) levels.

Methods: We analyzed data in Dialysis Facility Compare (DFC), as of October 30, 2019. DFC included PPPW values that quantified waitlisting prevalence during 2018. According to ZIP code, we classified the location of each dialysis facility as metropolitan (RUCA values, 1-3), micropolitan (4-6), small town (7-9), or rural (10). We estimated weighted mean PPPW values in each location class, with the weight of each facility equal to the number of patients contributing to PPPW. We fit a linear regression model to test differences in PPPW values between the location classes.

Results: PPPW values were reported in 7086 (94%) of 7566 dialysis facilities, and RUCA values were identified in 6999 (99%) of 7086 facilities. The weighted mean PPPW value among all facilities was 17.5%. There were 5363 (77%) facilities in metropolitan areas, 954 (14%) in micropolitan areas, 550 (8%) in small towns, and 132 (2%) in rural areas. By location class, weighted mean PPPW values were 18.5% in metropolitan areas, 12.8% in micropolitan areas, 12.1% in small towns, and 10.8% in rural areas. Relative to the mean PPPW value in metropolitan areas, mean PPPW values were 5.8, 6.5, and 7.7 percentage points lower in micropolitan areas, small towns, and rural areas, respectively (P < 0.01 for each).

Conclusions: The PPPW measure takes significantly lower values in dialysis facilities located in micropolitan areas, small towns, and rural areas, relative to metropolitan areas. The physical distance between residence and transplant center may preclude many patients in non-metropolitan areas from completing the process of kidney transplant evaluation. New processes are needed to improve access to transplantation in outlying areas.

PO2489

Demonstrating Charitable Premium Assistance as a Mechanism for Overcoming the Cost Barrier to Transplant for Low-Income Patients in the United States

Background: The optimal treatment for patients with end-stage renal disease (ESRD) is kidney transplantation. Adequate insurance coverage is one requirement for transplant eligibility. Many low-income ESRD patients cannot afford insurance coverage. Patients on dialysis are eligible for Medicare. Because Medicare covers only 80% of healthcare costs, most patients require supplemental insurance, often Medigap. Although Medigap

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

755
plans reduce out-of-pocket spending on healthcare services by almost 50%, spending on burberry products more than doubles compared to Medicare premiums alone. For low-income patients who cannot afford such premiums, inadequate insurance coverage can become an insurmountable barrier to qualifying for a kidney transplant (KT). We evaluated a premium assistance program designed to help low-income ESRD patients maintain insurance coverage and the impact on KT access.

Methods: We performed a descriptive analysis of self-reported patient data collected from paper and digital applications submitted to American Kidney Fund’s (AKF) Health Insurance Premium Program (HIPP) between November 15, 2018 and December 31, 2019.

Results: HIPP provided financial assistance grants to 1,357 (5.8% of all) kidney patients transplanted in the United States during the study period so they could maintain their health coverage in 2019. Of the 1,357 grants, 36% of grants issued helped patients pay Medigap. Average monthly recipent recipients’ per month were to be $62 (78% vs. 12%), more likely to be African American (38% vs. 34%), and had lower median income ($23,622 vs. $27,168 respectively) compared to the overall transplant population.

Conclusions: KT candidates face financial barriers to transplantation. Premium assistance significantly reduced the barrier to transplant among KT candidates who rely on Medigap for ensuring adequate coverage.

PO2490
“Some Person Behind a Desk Is Going to Be Looking at My File”: Thematic Analysis of the Health Records of a National Sample of Patients with Advanced Kidney Disease Evaluated for Kidney Transplant

Catherine Butler,1 Aaron G. Wightman,1 Janelle S. Taylor,2 Claire Richards,1 Chun-fei Liu,2,3 Ann M. O’Hare.1,2,3 University of Washington, Seattle, WA; VA Puget Sound Health Care System, Seattle, WA; Seattle Children’s Hospital, Seattle, WA; University of Toronto, ON, Canada.

Background: To be considered for kidney transplant, patients with advanced kidney disease must participate in a formal evaluation and selection process. Little is known about how this process unfolds in real-world clinical settings.

Methods: We conducted a thematic analysis of clinician documentation related to the kidney transplant evaluation in the VA-wide electronic medical records of patients who were referred to a transplant center among a random sample of 4,000 adults with advanced kidney disease between 2004 and 2014 who were followed through 2019.

Results: We identified 211 patients (5.2%) who were referred to a VA transplant center during follow-up. Four dominant themes emerged from qualitative analysis of clinician documentation in the electronic medical records of these patients: 1) far-reaching and inflexible medical evaluation: patients were expected to complete a demanding evaluation that could take a substantial physical and emotional toll on them and their family members, made little accommodation for their individual needs, and impacted many other aspects of their care; 2) psychosocial valuation: the psychosocial transplant assessment could be subjective and intrusive and placed substantial demands on patients’ family members; 3) surveillance over compliance: clinicians monitored patients’ adherence to a wide range of medical recommendations; 4) disempowerment and lack of transparency: patients had a strong desire to receive a transplant, but neither they nor their local clinicians had a clear understanding of what to expect from the evaluation process or the rationale for selection decisions, which left patients and their clinicians with little choice but to adhere to the transplant center’s recommendations.

Conclusions: To be considered for kidney transplant, patients had little choice but to engage in an extensive, demanding, opaque evaluation over which neither they nor their local clinicians had much control. These findings call for a more evidence-based, transparent, and individualized approach to the kidney transplant evaluation process.

Implicit Bias in Recipient Selection

Yousef Sweidan,1 Christine Mayuga,1 Kenneth Chavín,2 Titte Srinivas,1 Aparna Padayat.3 University Hospitals Cleveland Medical Center Department of Medicine, Cleveland, OH; University Hospitals Cleveland Medical Center Department of Surgery, Cleveland, OH.

Background: The decision to place or exclude a candidate from the waitlist is not exclusively based on medical criteria. Scarl literature exists regarding the intergroup dynamics within selection committees that influence decision making. This study attempts to clarify how the composition of selection committee meetings may affect listing outcome of kidney transplant candidates.

Methods: We performed a single-center retrospective study of kidney transplant selection committee attendance sheets and minutes from January 2012 to December 2015. We sought to determine if candidates who were evaluated by the same providers in attendance at selection committee are more likely to be listed for kidney transplant.

Results: 5205 (48.4%) of 6630 donor and recipient candidates presented during 91 selection committee meetings from 2012 to 2015 were listed. 8 nephrologists, 9 surgeons and 3 social workers comprised the clinicians that both evaluated potential candidates and attended recipient selection meetings. Table 1 describes the frequency with which clinicians who were in attendance at selection meetings had previously evaluated the candidates being listed and the number of times over which neither the nephrologists nor the surgeons who had evaluated the patient was significantly associated with a greater likelihood of the candidate being listed (OR 4.443 and 3.952 respectively, p=0.006, see Table 2). White race was also associated with an increased propensity to list, OR 1.202, p=0.006. Interestingly, the presence of both the nephrologist and surgeon who evaluated the patient, or the presence of both physicians and the social worker, were associated with reduced likelihood of listing (OR 0.267 for both, p=0.000 ; OR 0.715, p=0.001 for all three, see Table 2).

Conclusions: The composition of attendees at recipient selection meetings may influence listing outcomes of potential kidney transplant candidates.

PO2492
Predictors of Kidney Transplant Evaluation Non-Attendance

Christopher G. Ford,1 Eric Kruger,1 Yuridia Leyva,1 Yiliang Zhu,1 Kellee Rajagopal,2 Emily J. Crockett,2 Mady M. Cotton,3 M. Putturapattras,1 Mark L. Unruh,1 Yue-Harn Ng,1 Larissa Myaskovsky.1 University of New Mexico Health Sciences Center, Albuquerque, NM; 2University of Pittsburgh Medical Center, Pittsburgh, PA; 3University of Washington Medical Center, Seattle, WA.

Background: We examined which medical and socio-cultural factors predict kidney transplant evaluation (KTE) non-attendance, because missing a KTE appointment precludes access to transplantation, and having empty clinic slots impacts access to care for other patients.

Methods: We collected patient characteristics in an interview prior to KTE, covering demographics (e.g., income, education), medical factors (e.g., on dialysis, co-morbidities), cultural factors (e.g., medical mistrust), psychosocial characteristics (e.g., social support, knowledge of kidney transplantation), and knowledge and attitudes (e.g, knowledge class analysis (LCA)) to determine if we could identify meaningful classes (groups of patients with patterns across variables) that were associated with KTE non-attendance.

Results: Our sample (N=1119) was 37% female, 76% non-Hispanic White, median age 59±4 years (IQR= 49.2-67.5), 25% had income below federal poverty line, 47% were ≤ high school graduate, 48% were married, 44% had public insurance only, and 142 (13%) did not attend KTE appointment. LCA analyses indicated that a two-class solution consisting of a (1) high burden and (2) low burden group was optimal. Relative to the low burden group, the high burden group was less likely to be married, more likely to be on dialysis, less likely to have potential living donor, had higher kidney disease burden, more experiences of healthcare discrimination, higher medical mistrust, less social support, more depression, less knowledge about transplant, and more worry about kidney transplant harm. Belonging to the high burden group was associated with approximately twice greater odds of KTE non-attendance (OR=1.92, p<0.001, 95% CI 1.57, 2.34).

Conclusions: Medical and socio-cultural factors predict KTE non-attendance. Transplant teams should consider targeting patients with characteristics indicating high burden for additional support (e.g., exploring motivation and barriers with patients, assisting with resources to attend appointment, and providing additional reminders or notifications). Given the association of clinic non-attendance with being on dialysis, a treatment with significant patient burden, future research should also focus on the benefits of referring patients for transplant evaluation prior to initiating dialysis.

PO2493
Racial Disparities in Receipt of Medications for Secondary Prevention of Cardiovascular Disease in Kidney Transplant Recipients in the FAVORIT Trial

Mohammad Kazem Fallahzadeh Abarghouei,1 Elaine Ku,1 Chi D. Chu,2 Charles E. McCulloch,1 Delphine S. Tuot.2 Department of Epidemiology and Biostatistics, UCSF, San Francisco, CA; 1Division of Nephrology, UCSF, San Francisco, CA.

Background: Cardiovascular disease (CVD) is the most common cause of death with a functioning graft in kidney transplant recipients. Black patients have been shown to have higher prevalence of cardiovascular (CV) risk factors and less intensive risk factor modification. We evaluated racial disparities in receipt of HMG-CoA reductase inhibitors (statins) and aspirin for secondary prevention of CVD in kidney transplant patients in the Folic Acid for Vascular Outcome Reduction in Transplantation Trial (FAVORIT) trial.

Methods: FAVORIT was a multicenter international trial of vitamin therapy to lower low density lipoprotein (LDL) CV outcomes in kidney transplant patients. We identified FAVORIT trial participants from US and Canada who had a self-reported

Long-term kidney graft survival may be affected by factors other than biologic, including social determinants of health such as food scarcity and psychosocial stress. Methods: A face-to-face survey was conducted in a random convenience sample of 31 pts in transplant clinic: The Stress and Social Support survey and the Perceived Stress Scale were used. Dietary intake was assessed using 24-hr recall and analyzed with ASA-24 software. All comparisons are by Chi square or t-test.

Results: There were 11 women(36%), 20 men(65%), 22 Black(71%). Mean age was 55.2±1.9 yrs, time since transplant 63.9±14.1 mos. 24 (77%) reported income <$40K, with 12 (39%)<$20K.12 (39%) received SNAP benefits (SNAP+). Income or employment rate did not differ for SNAP+ vs SNAP-. SNAP+ had significantly worse kidney function(creatinine 2.17±0.24 vs 1.44±0.11 mg/dL=p<0.01) and eGFR(37.9±3.8 vs 53.8±7.5 mL/min,p<0.01). SNAP+ also did not differ for time since transplant, gender, race, BMI, tacrolimus level or age. SNAP+ also were more likely to disagree with the statement “I feel I am in control of my health and it doesn’t control me” (33% vs 0%, p=0.017), to report never or almost never feeling confident about handling personal health problems (33% vs 16%, p<0.018), and to be unable to control irritations in their lives(67% vs 16%, p<0.043,p<0.043). No difference in caloric or macronutrient intake existed, but SNAP+ ate less macronutrients(11.1±3 vs 16.7±1.8 gmp, p=0.023)and fewer servings of fruits/vegetables(1.5±0.28 vs 3.75±0.85, p<0.021). When asked about missed medication they did not report more missed doses.

Conclusions: In our patient population: 1. Pts receiving SNAP had worse kidney function than those who did not despite similar time since transplant, tacrolimus level, income, and employment status. 2. They ate less fiber and fewer servings of fruits/vegetables despite similar caloric intake, which should be investigated further as higher intake of fruit/vegetables is associated with delayed progression of kidney disease in non-transplant pts. 4. They also reported feeling less control over their health and less ability to handle daily stress. 4. These findings suggest that special attention should be paid to this population who have issues with social determinants that may affect kidney function.

Impact of Ethnicity Matching on Kidney Transplant Outcomes Among African Americans: A Mate Kidney Analysis
Kalpana V. Sureshkrishnan, Bhavya Chopra, Rita L. McGill; Allegheny General Hospital, Pittsburgh, PA; University of Chicago, Chicago, IL.

Background: Transplantation of kidneys from African American (AA) donors is associated with poorer outcomes compared to transplants from white Americans. Unmeasured variables such as APOL1 renal risk variants and sickle cell trait could contribute to the heightened risk. We used a mate kidney model to test the hypothesis that enhanced genetic risks associated with AA donor kidneys could be counterbalanced by favorable immunologic matching when AA donor kidneys are transplanted into AA recipients.

Methods: We identified AA deceased donors in OPTN/UNOS database from 2000 to September 2019 in which both kidneys were transplanted into first-time kidney-eligible recipients only, and both recipients received induction therapy followed by tacrolimus/mycophenolic acid maintenance. Marginal models for hazards of graft failure, death censored graft failure (DCGF) and death were constructed, with adjustments for recipient and transplant variables. Outcomes of AA, Hispanic, and Asian recipients were compared, using white American recipients as reference. Results were compared to a parallel analysis of 41,886 recipients of white American donor kidneys.

Results: Median follow up of the study was 3.3 (IQR 1.1-6.5) years among 8194 paired recipients of AA donor kidneys. Despite donor ethnicity matching, DCGF was higher for AA recipients compared to recipients with white donor kidneys. These findings were consistent across all recipient types. Outcomes of AA recipients were compared to a parallel analysis of 41,886 recipients of white American donor kidneys.

Conclusions: Our data indicate an increased risk of DCGF in AA recipients of AA donor kidneys, despite the potential benefits of favorable immunologic matching and does not support an ethnicity-matching strategy to improve outcomes and reduce disparities. Our observations suggest that other recipient factors predominantly influence graft outcomes. Improved outcomes in Hispanic and Asian patients merit further study.

PO2498

Cardio-Metabolic Risk Factors in Kidney Donors at a Third-Level Hospital of Care in Mexico

D. Lima Lucero,1 A. G. Ortega,2 R. Valdez-Ortiz,2 L. M. Perez-Navarro,3 E. C. Lopez,1 2 Hospital General de Mexico De Eduardo Liceaga, Ciudad de Mexico, Mexico; 2 Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico.

Background: Living donor kidney transplantation is the treatment of choice for chronic terminal kidney disease. A high prevalence of cardio-metabolic risk factors (CRFs) in the general population implies challenges when choosing the best candidate for kidney donation. Knowing the frequency of CRFs will allow us to make timely interventions in order to reduce cardiovascular complications after donation.

Methods: Cross-sectional, descriptive study, which included kidney donors who were admitted to the National Medical Center “Dr. Antonio Fraga Mouret” during the period from 2015 to 2019. Descriptive statistics were made, with a 95% CI. CRFs were included; systolic hypertension (SBP) higher than 120mmhg, diastolic hypertension (DBP) higher than 80mmhg, anemia hemoglobin less than 13 g/dl in men and less than 12 g/dl in women; impaired fasting glucose ≥110 mg/dl, body mass index (BMI)>25, 28% of donors smoked, 7% had SBP risk and 27% DBP risk, 60% had BMI>25, 4% had anemia and 13% hyperalumunemia; 10% with impaired fasting glucose. Figure 1 shows the prevalence of CRF. More than 25% of kidney donors had 2, 3 and 4 CRFs on admission to hospital for donation. 72% presented acute kidney injury (AKI) after surgery, none required renal replacement therapy. The highest AKI frequency was observed in subjects who had from 1 to 3 CRFs with frequencies of 26-34%.

Results: 153 donors were included, 59% were women, 33% were siblings and 31% were the patient’s mother; 34% had no social security. The mean age was 42 ± 10.7 years; the mean BMI 26 ± 5.4, with a mean GFR 101.9 ± 13.6 (61-133) ml/min. 28% of donors smoked, 7% had SBP risk and 27% DBP risk, 60% had BMI>25, 4% had anemia and 13% hyperalumunemia; 10% with impaired fasting glucose. Figure 1 shows the prevalence of CRF. More than 25% of kidney donors had 2, 3 and 4 CRFs on admission to hospital for donation. 72% presented acute kidney injury (AKI) after surgery, none required renal replacement therapy. The highest AKI frequency was observed in subjects who had from 1 to 3 CRFs with frequencies of 26-34%.

Conclusions: A BMI higher than 25 was the most prevalent CRFs; associated with AKI when more than 1 CRF was observed. Timely detection of CRFs will allow for timely interventions that will reduce post-donation cardiovascular risk and decrease the risk of AKI.

PO2499

The Effect of Anemia Correction with ESA and Cholecalciferol Supplementation on Post-Transplant Malignancy Among Kidney Transplant Recipients: A Prespecified Analysis of a Randomized Clinical Trial

Yoshitsugu Obi,1,2 Naotsugu Ichimaru,1,4 Yoshitaka Isaka,1 Takayuki Hamano,1,3 The CANDiLE-KIT Trial Investigators,1 The University of Tennessee Health Science Center College of Medicine, Memphis, TN; 2 Obi Clinic, Osaka, Japan; 3 Osaka Daigaku Daigakuen Igakukan Kenkyuuka Igakubu, Suita, Japan; 4 Japanese Zaidan Hojin Samitomo Byoin, Osaka, Japan; 5 Nagoya Shiritsu Daigaku Daigakuen Igakukan Kenkyuuka Igakubu, Nagoya, Japan.

Background: Kidney transplant recipients (KTRs) are at increased risk of cancer, and post-transplant malignancy (PTM) is among the leading causes of death with functioning allograft. Aggressive anemia correction with ESA shows the rate of decline in kidney allograft function but may increase the incidence of PTM. Vitamin D is proposed to exert anti-tumoral effects including anti-cancer properties and may prevent the development of PTM.

Methods: We enrolled 153 KTRs with anemia and ≥1-year history of transplantation across 23 facilities in Japan and conducted a multicenter, two-by-two factorial, open-label, randomized clinical trial. Patients were randomly assigned to either a high or low hemoglobin (Hb) target (>12.5 g/dl or ≥10.5 g/dl) or to either cholecalciferol 1000 IU/day or control. PTM was a prespecified secondary outcome.

Results: Patients were 51±12 years old, among whom 54% were male. The median (IQR) of transplant vintage was 8 (5, 12) years. Their baseline eGFR, Hb, and serum 25(OH)D levels were 30.6±11.0 ml/min per 1.73 m², 10.7±1.2 g/dl, and 14.5±5.2 ng/mL, respectively. There was no between-group difference in the prevalence of prior malignancy in either arm. The mean Hb level was 11.4±0.6 g/dl and 10.6±0.6 g/dl in the high and low Hb target groups, respectively. The mean serum 25(OH)D level exceeded 30 ng/mL.

Conclusions: ID, low ferritin and low TSAT are consistently associated with poor performance on neurocognitive tests measuring verbal memory, executive functioning, and ID with neurocognitive scores are presented in the table.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

PO2500

Association Between Elevated Ferritin and Graft Survival During the First Year After Kidney Transplant

Benya Rozen-Zvi,1 Amir Schechter,2 Ruth Rahamimov,2 Anat Gafni-Shafrir1,2 Rabin Medical Center, Tel Aviv, Israel; 3 Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, Israel.

Background: Both iron deficiency and iron overload are associated with adverse outcomes in patients with end stage kidney disease on chronic hemodialysis. In contrast, the effect of iron metabolism markers on kidney transplantation has not been thoroughly evaluated. In this study we aimed to evaluate the association between serum ferritin and transferrin saturation during the first year post transplantation on patients and graft survival.

Methods: Retrospective cohort study, using the Rabin Medical Center (RMC) kidney transplant registry. We included adults (>18 years) patients transplanted between 1/1/2006 and 31/12/2017 that had at least one available iron, transferrin and ferritin value during the first year post transplantation. Serum ferritin and transferrin were measured at baseline and at 6 months. Two iron metabolism markers were used for the primary composite outcome of patients’ and graft survival.

Results: Seven hundred and twenty-six patients were included in the study, of whom 219 (30.2%) had serum ferritin above 500 mg/dl. Patients with high serum ferritin were older with more diabetes mellitus (DM) and heart disease and tended to have deceased donors. Graft survival was delayed for high ferritin. In the univariate analysis, high ferritin and transferrin saturation were associated with increased risk of death and graft loss (Hazard Ratio (HR) 2.38, 95% Confidence Interval (CI) 1.69-3.35, p<0.001). In a multivariate model ferritin was still highly associated with increased rate of graft loss (HR 1.87, 95% CI 1.29-2.72, p=0.001). High ferritin was also associated with increased risk of the secondary outcome of death censored graft loss (HR 2.09, 95% CI 1.26-3.48, p<0.005).

Conclusions: High ferritin during the first year post transplantation was associated with reduced graft survival. Further research is needed to evaluate whether this association is due to inflammation, iron overload or combination of the two.

PO2501

Iron Deficiency in Kidney Transplant Recipients: Impact on Cognitive Functioning

Joanna Sophia J. Vinkle,1 Aaltje L. Ziegens,2 Lisanne van Sonderen,2 Antonio W. Gomes Neto,2 Anne Buunk,2 Stefan P. Berger,2 Stephan J. Bakker,2 Michele F. Eisenga,1 Martin H. De Borst,1 2 University Medical Center Groningen, Department of Nephrology, Groningen, Netherlands; 3 University Hospital Groningen, Department of Neuropsychology, Groningen, Netherlands.

Background: Cognitive function impairment is common in kidney transplant recipients (KTRs). Brain functioning requires energy, for which iron is essential at the level of oxygen delivery and mitochondrial function. Iron deficiency (ID) has been linked to compromised cognitive functioning in premenopausal women. We aimed to investigate whether ID could be a potentially modifiable risk factor for cognitive function impairment in KTRs.

Methods: In a prospective study among KTRs participating in the TransplantLines Biobank and Cohort study, we analyzed KTRs ≥1 yr post-transplant with data on iron status. All participants underwent neurocognitive testing to measure memory (Digit Span Forward, Digit Span Backward, and Delayed Recall of the 15 Word Test), attention and mental speed (Symbol Digit Modalities Test, Trail Making Test-A) and executive functioning (Trail Making Test-B, Digit Span Backward). ID was defined as ferritin <100µg/L or 100-299 µg/mL with transferrin saturation (TSAT) ≤20%. We used multivariable linear regression models to assess associations between ID and neurocognitive outcomes. Analyses were adjusted for hemoglobin, CRP, age, sex, eGFR, BMI, smoking, alcohol intake, time since transplantation, dialysis duration, donor type, educational level and immunosuppressives.

Results: We included 398 KTRs (age 56±14 yrs, 62% male, eGFR 52±14 ml/min/1.73m²). ID was present in 289 (73%). ID with neurocognitive scores are presented in the table.

Conclusions: ID, low ferritin and low TSAT are consistently associated with poor performance on neurocognitive tasks measuring verbal memory, executive functioning,
mental speed and attention in KTRs, independent of hemoglobin and other potential confounders. Future studies should address whether ID correction restores cognitive function.

Discussion: SV use may have more serious GI adverse effects in CKD patients than noted in the original clinical trials. Preexisting GI disease and/or abnormalities may increase the risk of adverse GI effects related to SV. Recent use of SV prior to kidney transplantation or use of SV for control of hyperphosphatemia in the context of DGF can be associated with GI morbidity in the early post transplant setting. Need for higher doses of phosphate binders and severity of hyperparathyroidism may be contributing factors to this risk.

PO2504
C-Terminal and Intact FGF-23 in Kidney Transplant Recipients and Their Associations with Kidney Transplant Loss and Mortality
Chang Chu,1 Shufei Zeng,2 Yingquan Xiong,3 Ahmed A. Hasan,3 Bernhard K. Krämer,2 Berthold Hochet,2 1Charité - Universitätsmedizin Berlin, Campus Mitte, Berlin, Germany; 2Fifth Department of Medicine (Nephrology/Endocrinology/Rheumatology), University Medical Centre Mannheim, University of Heidelberg, Germany; Mannheim, Germany; 3Institute of Nutritional Science, University of Potsdam, Potsdam, Germany.

Background: Increased fibroblast growth factor 23 (FGF23) is a risk factor for mortality, cardiovascular disease, and progression of chronic kidney disease. Limited data exist comparing the association of either c-terminal FGF23 (cFGF23) or intact FGF23 (iFGF23) in kidney transplant recipients (KTPs) with graft loss and all-cause mortality.

Methods: We conducted a prospective observational cohort study in 562 stable kidney transplant recipients. Patients were followed for graft loss and all-cause mortality for a follow-up of 48 months.

Results: During a median follow-up of 48 months, 94 patients had adverse outcome (graft loss or died). Both cFGF23 and iFGF23 concentrations were significantly higher in patients who had adverse outcome than those without adverse outcome (24.59 [11.43-87.83] vs 14.56 [5.99-22.73] pg/mL; P=0.001 and 45.24 [18.63-99.03] vs 29.04 [15.20-66.65] pg/mL; P=0.002 for cFGF23 and iFGF23, respectively). cFGF23 and iFGF23 measurements correlated well (rho=0.54, P<0.0001). ROC analysis of cFGF23 and iFGF23 yielded AUC of 0.69 (p<0.0001) and 0.61 (p=0.002) for prediction of the composite endpoint, respectively. Cox regression analyses adjusted for confounding factors, showed that cFGF23 (HR for one unit increase of log transformed cFGF23: 1.35; 95% CI, 1.03-1.77; p=0.028) but not iFGF23 (HR for one unit increase of log transformed iFGF23: 1.03; 95% CI, 0.81-1.31; p=0.827) was associated with the composite endpoint (Figure 1).

Conclusions: Elevated cFGF23 levels at baseline are independently associated with an increased risk all-cause mortality or graft loss. iFGF23 measurements were not independently associated with the study endpoint. The iFGF23 ELISA might detect bioactive FGF23 fragments that are not detected by the iFGF23 ELISA.
blood type O recipients decreased by 3.4 years from 2015-2019 (Figure 1). We observed a decrease in disparity between African Americans and Hispanics versus Caucasians, with average waiting times decreasing from 2.5 years to 1.2 years and 1.6 years to 0.5 years, respectively. There were no type B recipients who received A2 donors in this cohort.

**Conclusions:** Waiting time at our center decreased significantly across all blood types with a disproportional benefit in blood group B recipients despite not utilizing the benefits of A2 donors transplanted into B. Thus, this reflects our increase in volumes by utilizing extended criteria donors such as acute kidney injury and high kidney profile index donors (KDPI). These efforts have reduced the disparities in waiting time particularly in African-American and Hispanic populations.

A Randomized Trial of Vitamin D Supplementation on Skeletal Muscle in Patients Early Post Kidney Transplantation

**Makoto Tsutji,1 Yoshitsugu Obi,2 Takayuki Hamano,1,3 Masuko Kinia Byoin, Nagoya, Japan,1 The University of Tennessee Health Science Center, Memphis, TN,1 Nagoya Shiritu Daiguku Daigakukin Igaku Kenkyuka Igakubu, Nagoya, Japan.**

**Background:** Developing strategies for managing skeletal muscle weakness and loss in kidney transplant recipients (KTRs) is an important clinical challenge. Little is known about the effect of native vitamin D (ViD) supplementation on skeletal muscle in KTRs.

**Methods:** We conducted a 11-month, double-blind, randomized, controlled trial to assess the efficacy of ViD for improving skeletal muscle weakness and loss in KTRs receiving kidney transplantation within one month. Eligible patients were randomly assigned to a Vitamin D (cholecalciferol, 4000 IU / day) group or a placebo group in a 1:1 ratio. A prespecified secondary endpoints in this study included a percent (%) change in handgrip strength (HGS), and leg strength (LS) for skeletal muscle strength, and skeletal muscle index (SMI) for skeletal muscle mass.

**Results:** A total of 193 KTRs were randomized, but 6 KTRs were lost before taking the medication. We analyzed 92 KTRs in Vitamin D group and 95 in Placebo group. Dropout during this study were 3 KTRs in Vitamin D group and 2 in Placebo group. In Vitamin D group, at baseline the mean age was 52.2 ± 12.5 years old and the number of males was 28 (30.4%), and in Placebo group, 53.7 ± 11.4 years old and 30 (31.5%), respectively. The mean changes in serum 25 hydroxyvitamin D levels from baseline to the end of this study was 11.2 ± 4.1 to 39.8 ± 13.0 ng/mL in Vitamin D group (p < 0.001) and 11.2 ± 4.1 to 14.5 ± 5.0 ng/mL in Placebo group (p < 0.001). In this study, there were no difference in % changes in HGS, LS, or SMI between those groups, respectively.

**Conclusions:** ViD supplementation alone appears not to be effective in improving skeletal muscle weakness and loss among KTRs early post-transplantation. Larger-scale trials are warranted to confirm these findings.
PO2509

Recurrent Cardiovascular Events After Kidney Transplant Are Associated with Increased Risk for Graft Failure and Mortality
Levton Galapia,1 John C. Lieseke,2 Nan Zhang,1 Richard J. Butterfield,1 Mira T. Keddis.1 Mayo Clinic, Scottsdale, AZ.2 Mayo Clinic, Rochester, MN.

Background: Cardiovascular (CV) disease is prevalent after kidney transplant (KTx). The objective of this study was to describe patients with recurrent CV events in association with allograft function and mortality.

Methods: 1148 consecutive adults that received a KTx between 2011-2013 at a single center were evaluated. CV events were defined as: cardiac: myocardial infarction, heart failure, cardiac arrest requiring resuscitation, and vascular, any stroke, or peripheral vascular disease requiring intervention. Recurrent events were defined as more than one event (either cardiac or vascular).

Results: Mean age was 56.0 years (SD 14.2), 500 (44%) were female, 403 (35%) had diabetes, 1083 (94%) had hypertension, 127 (11%) had prior history of CV events, 98 (8%) had coronary artery disease (CAD), 26 (2%) had cardiac arrest. Mean follow-up of 74 months there were 229 (20%) deaths and 217 (19%) CV events, of which 602 (53%) required dialysis, and 867 (76%) received living donor KTx. After a median of 7 years post KTx heart failure, 38% had diabetes, 1083 (94%) had hypertension, 127 (11%) had prior history of CV events, and 87 (7%) had CAD.

Conclusions: Prevalence of recurrent CV events after KTx was 8.5%. Patients with recurrent CV events are at increased risk for mortality and graft failure. Decreased graft function was the primary predictor of recurrent CV events.

PO2510

Mitril Regurgitation and Aortic Stenosis After Kidney Transplantation
Yousuf Kyesoo, Hashim Abbas, Daniel C. Brennan, Sami Alasfar. Johns Hopkins Hospital, Baltimore, MD.

Background: Valvular heart disease (VHD) is highly prevalent in patients with end stage kidney disease and has been associated with poor outcomes. The 5-year mortality rate among patients with at least mild aortic stenosis (AS) or mitral regurgitation (MR) is more than 50% greater than in persons without kidney disease (Samad et al, JAHA 2017). Current knowledge of VHD in patients after kidney transplantation (KT) is scarce.

Methods: This is an ongoing single center retrospective study. In our center, all KT recipients have echocardiograms within one year prior to KT. We included KT recipients at our institution between Jan 2016 and Dec 2016 who had underlying MR and/or AS of any severity. Participants had to have an echocardiogram (Echo) around one year post KT. Our primary objective was to compare the severity of MR and AS at one year post KT to the baseline severity. The secondary objective was to describe changes in left ventricle hypertrophy (LVH).

Results: Two hundred subjects were initially screened. The number of patients that met our inclusion criteria was 22 (Table 1). Mild MR was present in 10 recipients pre KT. MR improved in 4, remained stable in 4, and worsened in 2 out of these 10 recipients at one year post KT. Moderate MR was present in 7 recipients pre KT and all 7 had improvement in severity of MR at one year post KT. Two and three recipients had mild AS and moderate AS respectively pre KT and all of them were observed to have worsening of aortic valve area (AVA) at one year post KT (mean AVA 1.36 versus 1.15 cm2, p < 0.07). Nine out of the total 22 recipients included had mild LVH pre KT and all the 9 continued to have mild LVH post KT.

Conclusions: Our study showed that most KT recipients with pre-existing MR had improvement in the severity of MR at one year post KT. However, recipients with AS prior to KT were observed to have worsening in severity of AS at one year post KT. Larger studies are needed to confirm these findings and identify factors that influence progression.

Utility of the 6-Minute Walk Test in Coronary Artery Disease Screening Before Kidney Transplant

Ximeng S. Cheng,1 Daniel J. Watford,1 Hiroyuki Arashi,1,2 Jane C. Tan,1 William F. Fearon.1 (1Stanford University School of Medicine, Stanford, CA; 2Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan.)

**Background:** Coronary artery disease (CAD) screening is a cornerstone of kidney transplant (KTx) evaluation, but existing approaches result in excessive testing and low intervention rate. We hypothesize that aerobic performance, based on a simple office test (the 6-minute walk test, 6MWT), may help risk stratify KTx candidates.

**Methods:** We performed 6MWT in waitlisted patients who were nearing KTx. Results were used for frailty counselling and not for cardiac evaluation. CAD screening was done according to our center protocol: invasive angiogram for patients with long-standing diabetes mellitus (DM) and non-invasive testing for other patients with risk factors and at the evaluating transplant nephrologist’s discretion. We used subdistribution Cox regression and time-dependent receiver operator curve to evaluate time to CAD event (revascularization, myocardial infarction, waitlist removal for CAD, or cardiac death), treating waitlist removal for non-CAD and non-cardiac death as competing events.

**Results:** Of the 360 patients, 200 and 161 patients had 6MWT results <400 meters and ≥400 meters (<4 metabolic equivalents), respectively. Patients with lower 6MWT results were older (59±10 vs 50±12 years) and more likely to be female (54% vs 34%), have DM (61% vs 33%) or known atherosclerotic disease (44% vs 22%), and have had prior cardiac evaluation (72% vs 61%). They were also more likely to exhibit cardiac symptom during 6MWT (36% vs 6%) and more likely to be censored due to waitlist removal for non-CAD reasons (follow-up 391±337 vs 541±277 days). 6MWT was not associated with CAD event (subdistribution hazard ratio 1.00 [0.90-1.10], 1-year area under the curve [AUC] 0.54). 196 patients had invasive (52%) or non-invasive (48%) CAD testing within 6 months of 6MWT: 6MWT did not predict the CAD test result (odds ratio 0.96 [0.81-1.14], AUC 0.54). Of the 94 patients who had concurrent non-invasive CAD testing, the 1-year AUC of 6MWT, symptom (at rest or during 6MWT), AST guidelines, or non-invasive testing for CAD event were 0.64, 0.52, 0.46 and 0.66 respectively.

**Conclusions:** The 6MWT did not perform better in risk stratification for CAD events compared to a symptom- or risk factor-based approach.

A Devastating Complication of Encapsulating Peritoneal Sclerosis (EPS) In Two Renal Transplant Recipients

Benjamin Lawson, Zar Chan, Lilly M. Barba. Renal Transplant Program Los Angeles County Harbor-UCLA Medical Center, Torrance, CA.

**Introduction:** EPS is a rare complication of peritoneal dialysis (PD) which carries great morbidity and mortality. The risk of EPS may be higher in PD patients who undergo renal transplantation as compared to PD patients who do not receive a transplant. Pre-transplant EPS, progressive peritoneal remodeling, cessation of PD and use of calcineurin inhibitors are potential etiologies. We present two unique cases of post-transplant EPS requiring surgical intervention with devastating outcomes.

**Case Description:** Case #1 A 47-year-old female with end stage renal disease due to congenital kidney disease on PD for 8 years transitioned to hemodialysis due to peritonitis, underwent a deceased donor kidney transplant (DDRT) presented 4 weeks post operatively with nausea, vomiting, and abdominal pain. Imaging showed dilated loops of small bowel concerning for partial small bowel obstruction treated non-operatively with bowel rest. One month later she presented with similar symptoms and small bowel obstruction. Due to failure to improve, she was taken to surgery and was found to have a frozen abdomen with dense adhesions. Lysis of adhesions was complicated by enterotomies and small bowel resection. Multiple enterocutaneous fistulas prohibited wound closure. She is being evaluated for a small bowel transplant and remains on parenteral nutritional support. Case #2 A 39-year-old African female with history of ESRD secondary to Lupus on PD for 11 years received a DDRT. Eighteen months post-transplant, she presented with nausea, vomiting and abdominal pain. Imaging showed a small bowel obstruction treated non-operatively with bowel rest. Three weeks later she required emergent surgery for an acute abdomen undergoing lysis of adhesions, bowel resection and end ileostomy. She required parenteral nutrition for five months.

**Discussion:** We report two cases of EPS after DDRT who required surgical intervention with devastating outcomes. Fluid and nutritional support have complicated management and affected quality of life. Given the multifactorial etiologies and potential devastating outcomes of EPS, the pre-transplant evaluation should include a detailed assessment. Furthermore, long term PD patients and those with a history peritonitis should be monitored closely post-transplant.
When a Peritoneal Dialysis Catheter Should Be Removed Post-Kidney Transplantation?

Background: Approximately 15% of patients on the kidney transplant (KT) waiting list in the US receive peritoneal dialysis (PD), a growing home dialysis therapy for end stage renal disease (ESRD) patients. European guidelines recommend keeping the peritoneal dialysis catheter (PDC) in-situ during KT, due to the potential risk for delayed graft function (DGF). With this approach, a 10% risk for post-PTPRTD PDC exit-site infections has been reported. In the US guidelines for PD removal timing are lacking, and determine by transplant center and operating surgeon’s preferences.

Methods: We retrospectively reviewed the electronic medical records of all patients transplanted between 4/2017-7/2019 at our kidney transplant center. We studied basic donor and recipient characteristics, presence of DGF (defined as dialysis in the first week following KT), time interval between KT and PD removal, and wound related complications.

Results: Of 259 patients received a KT during the study period, 28 were on PD prior to KT. Of those 10 patients underwent a living donor transplant, 166 a deceased donor, and 2underwent a simultaneous kidney-pancreas transplant. Sixteen were female, 9were non-Hispanic blacks, and 4were aged ≥65 years. Three received induction with basiliximab (per center’s protocol for recipients aged ≥70 years) and the rest received antithymocyte globulin. PDC was removed at time of KT in 17 patients while in the other 11 recipients PDC was removed 22 days (median) post transplantation. For patients developed DGF, with modality switched to hemodialysis. Three of these had their PDC removed at the time of KT. The 4th patient with DGF who had his PD catheter left in place, received hemodialysis due to hemodynamic instability. Readmission rates (excluding planned hospitalization for PDC removal) and wound infections were similar between those who had their PDC removed at surgery, and those who did not.

Conclusions: Kidney transplant centers that do not routinely use PD for DGF should remove the PDC at time of kidney transplant to reduce costs and prevent patient and healthcare provider burden of additional surgery. As the prevalence of PD and KT is expected to grow in the near future with the new kidney health initiatives, kidney transplant centers should consider a protocol for optimal care for PDC removal.

Could Targeting Dry Weight on Hemodialysis Patients Before Kidney Transplantation Leave Them Too Dry?
Hayam H. Al Dohani,1,2 Eduard A. Iliescu,1,2 Frances Macleod,2 M. Khaled Shamseddin.1,2,3 Queen’s University, Kingston, ON, Canada; 4Kingston Health Sciences Centre, Kingston, ON, Canada.

Background: Delayed graft function (DGF) after kidney transplantation is associated with inferior kidney and patient outcomes. Studies suggest that avoidance of hypovolemia peri-kidney transplantation is associated with a reduced risk of DGF. Hemodialysis (HD) patients that have HD prior to transplant targeting their usual dry weight may be volume contracted pre-transplant and at increased risk for DGF. By definition the dry weight is the state of near maximal volume contraction for most HD patients. The objective of this study is to examine the proportion of HD patients who have a pre-transplant post-HD weight at or below their usual dry weight.

Methods: This is a retrospective study of sequential kidney transplants in HD patients at our center from Jan 2015 to Dec 2019. The primary outcome was the proportion of patients who had an HD session before transplantation that resulted in a post-HD weight equal to or less than their prevalent set target dry weight. Data was extracted from the electronic medical record and chart review. Recipients on home therapies and pre-emptive transplants were excluded.

Results: Of 68 kidney transplants done in the study period, 40 were in-center HD patients with available HD data. They were mean age 54.8±14.5 years, 12 (30%) female, and majority were Caucasian. Twenty-five (62.5%) patients had a pre-transplant post-HD weight equal to or less than their prevalent set target dry weight (mean ± 0.2±0.25 kg). The other 15 (37.5%) patients achieved post-HD weights higher than their usual targets (+0.7±0.41 Kg).

Conclusions: The results of this study suggest that a high proportion of HD patients are at below dry weight after their dialysis and may be hypovolemic before kidney transplantation. This may represent at potentially avoidable increased risk for DGF. Further studies are planned to examine possible associations of achieved post-HD weight prior to transplant with perioperative central venous pressure, IV fluid administration, and graft function. There may be strategies to optimize volume status pre-transplantation to mitigate this risk of DGF including targeting a higher weight on HD or administration of IV fluid to raise weight above the prevalent target dry weight before transplantation when feasible.

Does the Timing of Dialysis Initiation Affect Peak Calculated Panel Reactive Antibody in Waitlisted Kidney Transplant Candidates?
Adam Price, Mohamed A. Mohamed Ahmed, Zemin Su, Maria Aurora C. Posadas, Karim M. Soliman, Vinaya Rao, Michael Casey. Medical University of South Carolina, Charleston, SC.

Background: Higher calculated panel reactive antibody (cPRA) restricts access to kidney transplantation, but it’s unclear how the timing of dialysis initiation after listing might affect cPRA. We hypothesized that patients with earlier dialysis initiation would have higher cPRA scores.

Methods: This was a retrospective SRTR database study of adults listed for a solitary kidney transplant from 10/1/09 to 11/30/18. Waitlisted patients were stratified by dialysis initiation: prelist, 0-1 year after listing, 1-2 years after listing, or no dialysis within 2 years after listing. The outcomes studied were mean peak CPA at 0-1 year and 0-2 years after listing. One-way ANOVA was used for statistical analysis.

Results: A total of 173,964 patients were identified who were waitlisted for 1-2 years. With later dialysis initiation, there was a stepwise decline in mean peak CPA between those who initiated dialysis prelist, 0-1 year after listing, and 1-2 years after listing (Figure 1). There was no difference in mean peak CPA between the dialysis initiation groups “1-2 years after listing” and “no dialysis 2 years after listing.” A similar stepwise decline in mean peak CPA was seen with patients who were waitlisted for 1 year (Table 1).

Conclusions: Our data suggest that waitlisted patients with earlier dialysis initiation may be at risk for developing higher cPRA scores. If verified with further studies, then this may be an incentive for early predialysis referrals for transplant evaluation.

outcomes.

these variations may be associated with access to transplantation and post-transplantation
of eligibility for kidney transplantation. Further studies are needed to understand how
Centers differed in the kidney function threshold at which transplant evaluation was
begun, and age and body mass index limits for transplantation also varied considerably
52% of programs did not prioritize the evaluation of patients with a self-identified living
and 7% by other providers. The majority of programs (58%) screened referrals for
candidate evaluation, and determination of eligibility for kidney transplantation. We
not been well described in the contemporary era.

differences in national practice patterns related to transplant eligibility assessments have
been well described in the contemporary era.

Methods: We conducted a survey of kidney transplant programs in the US to assess
current practice patterns as it relates to criteria for prioritizing transplant referrals, candidate
evaluation, and determination of eligibility for kidney transplantation. We distributed our
survey to 171 adult kidney transplant programs in the US.

Results: 89 (52%) of programs invited to participate in the survey completed it, 45%
of which were completed by the Medical Director, 48% by a Transplant Nephrologist, and
7% by other providers. The majority of programs (58%) screened referrals for
contraindications to transplantation before scheduling an in-person evaluation (Figure 1).
52% of programs did not prioritize the evaluation of patients with a self-identified living
donor candidate when scheduling patients referred for eligibility assessments (Figure 1).
Centers differed in the kidney function threshold at which transplant evaluation was
canceled, and age and body mass index limits for transplantation also varied considerably
(Figure 1).

Conclusions: There is wide variation across transplant programs in the assessment of
eligibility for kidney transplantation. Further studies are needed to understand how
these variations may be associated with access to transplantation and post-transplantation
outcomes.

PO2520
Variations in Practice Patterns in Eligibility Assessments Across Kidney
Transplant Programs in the United States

Background: Kidney transplant programs are known to vary in terms of their practice
generally lack of consensus surrounding many aspects of pre-transplant workup. The
differences in national practice patterns related to transplant eligibility assessments have
been well described in the contemporary era.

Methods: We conducted a survey of kidney transplant programs in the US to assess
current practice patterns as it relates to criteria for prioritizing transplant referrals, candidate
evaluation, and determination of eligibility for kidney transplantation. We distributed our
survey to 171 adult kidney transplant programs in the US.

Results: 89 (52%) of programs invited to participate in the survey completed it, 45%
of which were completed by the Medical Director, 48% by a Transplant Nephrologist, and
7% by other providers. The majority of programs (58%) screened referrals for
contraindications to transplantation before scheduling an in-person evaluation (Figure 1).
52% of programs did not prioritize the evaluation of patients with a self-identified living
donor candidate when scheduling patients referred for eligibility assessments (Figure 1).
Centers differed in the kidney function threshold at which transplant evaluation was
canceled, and age and body mass index limits for transplantation also varied considerably
(Figure 1).

Conclusions: There is wide variation across transplant programs in the assessment of
eligibility for kidney transplantation. Further studies are needed to understand how
these variations may be associated with access to transplantation and post-transplantation
outcomes.

PO2521
Post-Transplant Diabetes Mellitus in a Single Pediatric Kidney
Transplant Center: Risk Factors, Outcomes, and Characterization of
Clinical Course
Aamli Khanna,1 Jee-Young N. Ham,2,3 Margret Kamel,1 Kathryn M. Ngo,1 Amanda S. Thomas,3 Rachele Liverman,2 Roubia Garro,2,3 1Emory University School of Public Health, Atlanta, GA; 2Children’s Healthcare of Atlanta Egleston Hospital, Atlanta, GA; 3Emory University School of Medicine, Atlanta, GA.

Background: The prevalence and outcomes of post-transplant diabetes mellitus (PTDM) in pediatric kidney transplant (KT) recipients vary among studies due to the
lack of a consistent definition. Risk factors for and pathogenesis of pediatric PTDM are incompletely understood.

Methods: PTDM prevalence, risk factors and disease course was evaluated at a high
volume, tertiary care pediatric hospital. We performed a retrospective review of pediatric KT recipients between 2006-2016 to evaluate PTDM prevalence. PTDM was defined as persistent hyperglycemia with serum glucose ≥200 mg/dl, HbA1C ≥6.5%, and requiring antihyperglycemic treatment for a 30 days. Full data were available on all patients
transplanted between 2010-2016 and were used to compare demographic and clinical characteristics between PTDM (n=9) and non-PTDM patients (n=173) using Chi-square and Wilcoxon rank sum tests.

Results: Between 2006-2016, 312 patients received KT. Five patients with pre-
existing DM were excluded. Fifteen developed PTDM with a prevalence estimate of
4.89 % (95% CI: 3% - 8%) and median time from transplant to DM was 17.6 months
(25%-75%: 3 – 83). The majority of PTDM patients had a family history of DM in 1st
degree relatives (81%) and were maintained on tacrolimus at diagnosis (67%). PTDM
prevalence and outcomes of post-transplant diabetes mellitus (PTDM) in pediatric kidney transplant (KT) recipients vary among studies due to the
lack of a consistent definition. Risk factors for and pathogenesis of pediatric PTDM are incompletely understood.

Methods: PTDM prevalence, risk factors and disease course was evaluated at a high
volume, tertiary care pediatric hospital. We performed a retrospective review of pediatric KT recipients between 2006-2016 to evaluate PTDM prevalence. PTDM was defined as persistent hyperglycemia with serum glucose ≥200 mg/dl, HbA1C ≥6.5%, and requiring antihyperglycemic treatment for a 30 days. Full data were available on all patients
transplanted between 2010-2016 and were used to compare demographic and clinical characteristics between PTDM (n=9) and non-PTDM patients (n=173) using Chi-square and Wilcoxon rank sum tests.

Results: Between 2006-2016, 312 patients received KT. Five patients with pre-
existing DM were excluded. Fifteen developed PTDM with a prevalence estimate of
4.89 % (95% CI: 3% - 8%) and median time from transplant to DM was 17.6 months
(25%-75%: 3 – 83). The majority of PTDM patients had a family history of DM in 1st
degree relatives (81%) and were maintained on tacrolimus at diagnosis (67%). PTDM
diagnosis and insulin initiation occurred in the context of active rejection episode in
only two patients. Despite a more stringent definition of PTDM, insulin therapy was
discontinued in 3/15 (20%) patients who continued to be normoglycemic. Comparing
patients with and without PTDM during the period 2010-2016 revealed that PTDM
patients had higher BMI-Z scores at transplant (p=0.053) and higher average blood
glucose during the first week post KT (p=0.095), with no difference in age, gender, race,
donor status, or dialysis modality.

Conclusions: A more consistent definition of PTDM and larger studies are warranted
to better understand the prevalence, risk factors, and pathogenesis of hyperglycemia and
PTDM in children. Detailed patient-level data can provide nuance that may be missed
with larger registry studies.

PO2522
Diabetic Nephropathy: Is It All About Hyperglycemia?
Iyad Alabulh Bazza,1 Lois J. Arend,2 Sami Alanfar2 1Alfaisal University, Riyadh, Saudi Arabia; 2Johns Hopkins University, Baltimore, MD.

Introduction: Diabetic nephropathy (DN) is the most common cause of end
stage renal disease (ESRD). Hyperglycemia has been suggested to be necessary for the
development and maintenance of DN. Simultaneous pancreas and kidney transplantation
(SPK) has revolutionized the treatment of type 1 diabetic patients with end-stage renal
disease (ESRD), and prevention of recurrent DN is one of the main proposed benefits.
We present a case of recurrence of DN after SPK despite normal endocrine pancreas
allograft function

Case Description: A 47-year-old man with past medical history of ESRD due to
diabetes type I who underwent a SPK transplant from a deceased donor in December
2003. His nadir serum Creatinine was 1.5 mg/dl and baseline urine protein creatinine
ratio (UPC) is 110-250 mg/g. Maintenance immunosuppression consisted of tacrolimus,
mycophenolate, and prednisone. His home medications also included benazepril for
typhemia. Sixteen years after transplant, he was noted to have increase in UPC to
2100 mg/g and serum Creatinine to 1.9 mg/dl. Trough tacrolimus levels in the preceding
6 months ranged between 4.8 and 10.9 ng/mL. Donor specific antibodies were negative.
He underwent renal allograft biopsy which showed early nodular mesangial matrix
expansion and thickened glomerular basement membranes on electron microscopy.
consistent with diabetic nephropathy (Figure 1), early chronic transplant glomerulopathy, and severe arteriolar hyalinosis. Additional laboratory findings showed serum lipase 34 (Normal 7-60 U/L), amylase 103 (Normal 21-101 U/L), fasting glucose 79 (Normal 65-99 mg/dL), hemoglobin A1c 5.3, and C peptide was 2.03 (Normal 0.80 - 3.85 ng/mL). Despite increasing Benazepril dose to 40 mg daily, UPCR and Cr continued to increase but stabilized in a range of 3800-4500 mg/g and 2.5 mg/dL respectively.

Discussion: Our case suggests that development of DN can be linked to mechanisms independent of hyperglycemia and the usual metabolic disturbances seen in patients with diabetes. A comprehensive restudying of the pathophysiology of DN could further enhance our existing knowledge of the factors implicated in DN, and possibly our ability to develop a more targeted therapy.

PO2523

Use of Weight-Altering Diabetes Medications to Address Obesity as a Barrier to Kidney Transplant Evaluation in Patients with Type 2 Diabetes and Stage 4-5 CKD or ESKD

Kiran Chintam, Prince Mohan, Jamie A. Green, Alex R. Chang. Geisinger Health, Danville, PA.

Background: Many patients with type 2 diabetes mellitus (T2DM) and chronic kidney disease (CKD) are ineligible for kidney transplant due to high body mass index (BMI). Some medication classes are associated with weight loss (glucagon-like peptide-1 receptor agonists [GLP1-RAs]), neutral-weight (dipeptidyl peptide-4 inhibitors [DPP4is]), or weight gain (sulfonylureas and insulin).

Methods: We examined the relationship between BMI and use of weight-altering diabetes medications in patients with type 2 diabetes mellitus and stage 4-5 CKD or dialysis-dependent ESKD at Geisinger (1/18-3/20). In addition, we examined whether access to kidney transplant evaluation varied by BMI in patients on dialysis.

Results: Out of 4200 patients with T2DM and stage 4-5 CKD or ESKD, 30% had BMI ≥ 35 kg/m² and 15% had BMI ≥ 40 kg/m². Overall, use of T2DM medications with favorable weight effects was low, similar to use of sulfonylureas (Table). Patients with severe obesity had higher GLP1-RA use (BMI ≥ 35 vs. <35 kg/m²: 11%, 5%), higher insulin use (69%, 53%), and lower DPP4i use (9%, 13%). Similar findings were noted in the subset of patients on dialysis: GLP1-RAs (BMI ≥ 35 vs. <35 kg/m²: 6% vs. 2%), DPP4is (3% vs. 6%), sulfonylureas (5% vs. 8%), insulin (77%, 74%). In unadjusted analyses, transplant clinic attendance was highest in ESKD patients with BMI 30-34.9 kg/m² (23%), followed by BMI 35-39.9 (17%), BMI 25-29.9 (15%), BMI 18.5-24.9 (13%), BMI ≥ 40 (7%), and BMI < 18.5 (5%).

Conclusions: The vast majority of patients with T2DM and advanced CKD are taking obesogenic rather than weight loss-promoting diabetes medications. Those with BMI ≥ 40 kg/m² were 3.6x less likely to have been evaluated in transplant clinic than those with class 1 obesity (BMI 30-34.9 kg/m²). Consideration of the differential impact of certain diabetes medication classes on weight may help improve access to kidney transplantation and long-term outcomes.

Health System Encounters in Kidney Transplant Recipients Converted from Immediate-Release Tacrolimus Capsules to Extended-Release Tacrolimus Tablets

Yoonle H. Pa,1* Jamal Rashidi,2 Mary Putt,2 Yu Bin Na,2 Chelsea Sammons,2 Maxwell Norris,2 Gregory Malat,1,3 Brendan Steiner,1 John H. Holmes,1 Roy D. Bloom,1 Peter P. Reese,1,3 Jennifer Trofe-Clark,3,1 Department of Epidemiology, Biostatistics and Informatics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 2Department of Pharmacy, Hospital of the University of Pennsylvania, Philadelphia, PA; 3Renal Electrolyte and Hypertension Division, Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 4Drexel College of Medicine, Philadelphia, PA.

Background: Kidney transplant recipients (KTRs) converted from immediate-release tacrolimus capsules (IR-TAC) to extended-release tacrolimus tablets (ER-TAC) may benefit from reduced dosing frequency and improved bioavailability. However, few studies have characterized health system encounters in these KTRs. Study aims were to (1) determine if conversion to ER-TAC decreased number of dose changes, TAC troughs, and transplant clinic visits and (2) characterize number of dose changes and days to achieve two consecutive therapeutic troughs (5-12 ug/L) under ER-TAC.

Methods: Retrospective review of KTRs at our center transplanted between 2/2010-3/2019, on IR-TAC for ≥90 days, and converted to ER-TAC for ≥90 days. Random-coefficient Poisson regression was used to compare number of dose changes, troughs, and clinic visits during the 90-day periods pre- and post-conversion.

Results: 64 KTRs met inclusion criteria. Mean (SD) age was 52.8 (13.7) years, 38 (59%) were male, 28 (44%) were Black, and 8 (13%) were on an IR-TAC financial assistance program. Median (IQR) time since transplant was 333 (211-1,483) days. KTRs were on IR-TAC for a median of 26 (41%) non-adherence, 12 (19%) high IR-TAC dose, 2 (3%) sub-therapeutic troughs, 2 (3%); and other/unknown, 22 (34%). The incidence rate of dose changes but not troughs or clinic visits decreased significantly post-conversion (Table). For the 24 (38%) KTRs with two consecutive therapeutic troughs within 90 days, median (IQR) number of dose changes was 2 (0-3) and days to achieve two consecutive therapeutic troughs was 33.5 (23.5-63).

Conclusions: The incidence rate of dose changes decreased significantly under ER-TAC, but most KTRs did not achieve two consecutive therapeutic troughs within 90 days of conversion. Closely follow up may be beneficial for these KTRs. Future research should determine if reasons for conversion resolved with use of ER-TAC.

PO2526

Looking Beyond the Allograft Survival: Long-Term, Five-Year Renal Outcomes in Lung Transplant Recipients

Mohankumar Doraiswamy, Eshetu L. Obole, Priyamvada Singh, Todd E. Pesavento. Comprehensive Transplant Center, The Ohio State University Wexner Medical Center, Columbus, OH.

Background: With the increase in incidence and overall survival of lung transplant recipients, the risk for chronic sequelae in terms of CKD is on the rise. However, the data on long-term effect on kidneys in this population is scarce. Our study is the first to assess the five-year renal outcomes in Lung transplant recipients. Future research should determine if reasons for conversion resolved with use of ER-TAC.

Methods: We did a retrospective chart review of 171 adults with lung transplants performed between 1st January 2014 - 1st January 2019 and meeting inclusion/exclusion criteria. Primary outcomes were - the prevalence of CKD/ESRD (requiring RRT), risk of development of CKD in patients with AKI during index hospitalization, and all-cause mortality in recipients with CKD when compared to the non-CKD group. Secondary outcomes were calculation of the frequency of utilization of modalities for CKD (urinalysis, renal USG, biopsy, nephrology consults).

Results: 86% of patients were white, with a median age of 61 years, median BMI 27.3 kg/m² and 60% were males. Hypertension was present in 55% of patients at baseline. COPD and IPF were the commonest etiology for lung failure, and 66% received a double lung transplant. Baseline median creatinine and eGFR were 0.8 mg/dL and 54 mL/min/1.73 m² respectively, 6% (n=171), 60% (n=161), 67% (n=155), 79% (n=147), and 86% (n=7) had CKD at baseline, 6, 12, 36, 60 months respectively. Eighty percent received dialysis during the index hospitalization. The odds ratio of development of CKD in patients with an AKI episode during index hospitalization versus no AKI was 6.22 (2.87 to 13.06, p < 0.0001). Whereas, the odds ratio of all causes mortality in patients with CKD when compared to no CKD was 1.14 to 8.64, p< 0.005. Hematocrit and proteinuria were monitored during the index hospitalization. Renal biopsy done in 1.1% with renal USG abnormal in 22%, normal in 21 % and never performed in 57%. Sixteen percent of recipients were on dialysis, 3% received a renal transplant, and 27% of mortality noted over a five-year follow up period.

Conclusions: There is a high prevalence of CKD in lung transplant recipients, and increase in the patients who had an AKI during index hospitalization. With increased lung transplant nowadays, early involvement of nephrologists is prudent to prevent and manage CKD effectively in the future. Large prospective trials to delineate the problem is warranted.

PO2527

Incidence, Risk Factors, and Outcomes of Post-Transplant Erythrocytosis After Kidney Transplantation

Byeun Alzoubi, Abish Kharel, Fauzia Osman, Fahad Aziz, Neetika Garg, Maha A. Mohamed, Arjung Djamalai, Didier A. Mandembrot, Sandesh Parajuli. University of Wisconsin School of Medicine and Public Health, Madison, WI.

Background: Post-transplant erythrocytosis(PTE) is a common condition after kidney transplantation. PTE is known to increase the risk of stroke, pulmonary embolism, and deep vein thrombosis, commonly seen in vascular thromboembolism(VTE). In the current era of immunosuppressive medication and management, the incidence, risk factors, and outcomes of PTE among kidney transplant recipients(KTR) is unknown.

Methods: This was a retrospective study among all adult KTRs transplanted at our university hospital between 01/2001 and 12/2016. All recipients in the PTE group had at least 2 consecutive Hct levels of >51 within the first 2 years of transplant. Controls were selected in a ratio of 5:1 using event density sampling. Patient survival, graft survival, and VTE incidence were outcomes of interest.

Results: Of 4317 kidney transplants during the study period, 214(5%) had PTE and were compared with 1035 controls. While comparing baseline characteristics between PTE and control, KTRs in the PTE group were more likely to be younger, male, have lower BMI, higher prevalence of diabetes as the cause of ESRD and receive a non-deceased donor kidney. Similarly, looking at donor characteristics, the PTE group was likely to receive the kidney from a younger donor and have lower KDPI. The median interval from transplant to the diagnosis of PTE was 9.9 months (IQR 5.89), 13 (6.1%) in the PTE group and 7 (6.9%) in control had VTE events. In the multivariable analysis, patients with older age (HR: 0.98, 95% CI 0.97-0.99) and lower BMI (HR: 0.97, 95% CI 0.93-0.99, p<0.05) were less likely to develop PTE, while non-preemptive transplant (HR: 3.95, 95% CI 1.74-8.99, p<0.001) was significantly associated with increased risk of PTE. After adjustment for the multiple confounding factors, PTE was not associated with patient mortality (HR: 1.0, 95% CI 0.70-1.43, p=0.99), graft failure (HR: 1.13, 95% CI 0.69-1.83, p=0.61) or VTE (HR: 1.07, 95% CI 0.59-1.96, p=0.81). In a subgroup analysis among PTE with Hct >55 (n=39) compared with controls, similar findings were observed.

Conclusions: In this era, the prevalence of PTE is lower at 5% compared to around 15% in various previous studies. Similarly, there were no detrimental effects of PTE on patient survival, graft survival, or the risk of VTE in the current era.

PO2528

Post-Transplant Outcomes Among Kidney Transplant Recipients with Intentional and Unintentional Weight Loss

Meera N. Harhay,1 Xiaomeng Chen,2 Nadia M. Chu,2 Mara McAdams-DeMarco.2 Drexel University, Philadelphia, PA; 3Johns Hopkins University, Baltimore, MD.

Background: Research has shown that kidney transplant (KT) recipients who lose weight before KT are at increased risk for post-KT weight gain, all-cause graft loss (ACGL), and mortality. No studies have examined whether these associations differ between recipients with intentional and unintentional weight loss.

Methods: Among 366 KT recipients from a prospective cohort study of frailty and KT, we used adjusted mixed effects models to estimate differences in post-KT BMI trajectories, ACGL, and mortality by 1-year pre-KT weight change, defined as stable weight, intentional weight loss, unintentional weight loss, and weight gain.

Results: Mean age was 53 years, 39% were black, and 39% were female. The majority (64%) had stable pre-KT weight, 12% had weight gain, 14% had unintentional weight loss, and 10% had intentional weight loss. By 3 years post-KT, BMI increased by 0.05 kg/m² (95% CI 0.02, 0.08 kg/m²) among those with stable pre-KT weight; the increase was similar among those with pre-KT weight gain and intentional weight loss. Those with pre-KT unintentional weight loss had larger increases in post-KT BMI than those with stable BMI (BMI change difference 0.15 kg/m² [0.04, 0.25 kg/m²], p<0.01). Unadjusted cumulative incidence of mortality was similar across weight change categories (Figure). Adjusted for age, sex, race, BMI, and donor type, only unintentional weight loss was associated with higher mortality (aHR 2.31 [1.24,4.31], p<0.008) and ACGL (aHR 2.62 [1.24,3.31], p=0.005) relative to stable weight.

Conclusions: In this study, pre-KT unintentional weight loss was associated with higher post-KT BMI increases, ACGL and mortality than pre-KT intentional weight loss, stable weight, and weight gain. These results suggest that unintentional weight loss should be identified and addressed in KT candidates, independent of BMI.

Obesity and Poorer Renal Allograft Function: Analysis of Longitudinal Data
Ekamol Tantisattamo,1,2 Busara Songtain,2 Natmisea Leelavat,1 Sakdita Sarawapa,2 Possawat Vuthikraivit,3 Chawit Lopimphisut,4 Natchaya Polpichai,4 1Division of Nephrology, Hypertension and Kidney Transplantation, Department of Medicine, University of California Irvine School of Medicine, Orange, CA; 2Multi-Organ Transplant Center, Section of Nephrology, Department of Internal Medicine, William Beaumont Hospital, Oakland University William Beaumont School of Medicine, Royal Oak, MI; 3Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; 4Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; 5Phramongkutklao College of Medicine, Mahidol University, Bangkok, Thailand; 6Faculty of Medicine Songklanagarin Hospital, Prince of Songkla University, Songkhla, Thailand.

Background: Obesity is associated with worsened allograft function, but its effect on allograft function after established baseline allograft function at a 12-week post-KT transplant (KT) is unclear.

Methods: All 105 KT recipients were divided into obese (BMI ≥ 30 kg/m2) and non-obese groups. Longitudinal data were analyzed by linear mixed model to examine association between obesity and eGFR during the 1st year post-KT.

Results: Mean age was 54±11 years and 64 patients (61%) was female. Seventy-one patients (68%) were obese. Generalized estimating equation revealed that eGFR increased 0.16 ml/min/1.73 m2 (95%CI 0.09 to 0.23) for every 1 week after KT. Excluding eGFR at 4-week post-KT when baseline allograft function is generally not established, mean eGFR at 12-week post-KT was the lowest and assigned as the baseline allograft function. Given unequal spreading of time when eGFR were measured, a 1-year follow-up period was categorized into every 4 and 12 weeks if eGFR were measured before and after a 12-week post-KT, respectively. Spline interaction term was created at the 12-week post-KT as well as categorized time-spline interaction term. By using a linear mixed model and after adjusted for age, gender, type of KT (deceased vs living donor KT), obesity category and its interaction team with categorized time and spline interaction term, obese group had a higher rate of eGFR decline of 2.9 ml/min/1.73 m2 every 4 weeks prior to 12-week post-KT, and the rate declined to 1.1 ml/min/1.73 m2 every 12 weeks after 12-week post-KT. At the 12-week post when baseline eGFR was established, eGFR were 74.1±20.5 and 78.0±20.5 ml/min/1.73 m2 for obese and non-obese groups, respectively (random intercept); whereas, rate of increase in eGFR of those corresponding groups were 69.3±0.2 and 70.3±0.2 ml/min/1.73 m2 every 12 weeks (random slope).

Conclusions: Although population-based estimated eGFR was significantly increased overtime, obese KT recipients had lower baseline eGFR at the 12-week post-KT and slower rate of increased eGFR than those of non-obese group when individual baseline eGFR at the 12-week post-KT and rate of eGFR change were taken into the consideration. Pre-KT obesity remains one of the associated factors of poor allograft outcomes, which may be mitigated by pre-KT weight loss.

PO2530
A Call to Action: Finding the Right Kidney for All Potential Recipients

Background: The burden of dialysis among ESRD patients is a huge driver of morbidity, mortality, and cost. Thousands of deceased-donor (DD) kidneys that almost certainly have better outcomes than dialysis are discarded each year. Our center sought to find and transplant kidneys that would reduce waiting time for our patients while preserving post-transplant outcomes consistent with nationally expected results.

Methods: We reviewed 1119 consecutive DDKT recipients transplanted between 1/1/2016 and 12/31/2019 at our center. Endpoints were eGFR by MDRD death-censored graft survival using Kaplan-Meier survival estimation and the Cox Proportional Hazards Model. We reviewed on additional year (2015) for waiting time impact.

Results: DD KT volumes doubled from 2016 to 2019 (191 ± 384). Growth was attributable to increased acceptance of hard-to-place imported kidneys, including kidneys with AKI (413% increase) and KDPI > 85 (296% increase). In 2016, 46.6% of DD kidneys were imported from outside our DSA and by 2019, 77.3% were imported. Overall one-year patient survival was 96.6% (CI: 95.4-97.6%) and death-censored one-year graft survival was 95.8% (CI: 94.4-97.6%). Recipients with any stage of AKI saw no additional risk vs. donor not affected by AKI (HR 0.94, p=0.854) while death-censored graft survival at one year was 91.9% for recipients of kidneys with KDPI >85% vs 96.7% with KDPI ≤85%, representing significant additional risk (HR: 1.91; p=0.017). This significantly decreased waiting time at transplant across all blood types (6 years in 2015 to 3.9 years in 2019). This benefit was even greater for blood group B (10.7 to 4.3) and significantly reduced the disparity in accrued waiting times for African-American and Hispanic populations. Kidney function was good at 1 year in all groups among those surviving with followup. Mean eGFR by MDRD formula was 60.0 (SD 23.2) in recipients with non-AKI donors and 61.9 (SD 26.1) in recipients with AKI donors (p=0.4384). Mean eGFR 49.0 in the KDPI >85% group vs 62.3 in the <= 85% KDPI group (p=0.0001).

Conclusions: Transplant centers can answer the growing demands of patients enduring dialysis to better utilize kidneys that have previously been discarded. Our center demonstrated that it is possible to reduce waiting time, and maintain outcomes using kidneys previously discarded.

Multivariate regression model was adjusted with parameters showing significant difference among the 4 groups according to BMI and pre-sensitization status. Parameters were as follows: Age, Sex, DM, HTN, Fasting glucose, Triglyceride, HDL-cholesterol, Hemoglobin A1c, ESRD causes, Dialysis modality, and Prior KT history.

PO2532
Association Between Post-Transplant Visit-to-Visit Pulse Pressure Variability and Late Transplant Systolic Blood Pressure in Non-Elderly Kidney Transplant Recipients

Ekmal Tantissatame,1 Natchina Leelavivat,1 Busara Songtana,1 Sakidta Saowapa,2 Possavut Vuthikraivit,3 Chawit Lopimisuth,4 Natchaya Polpichai,5 Division of Nephrology, Hypertension and Kidney Transplantation, Department of Medicine, University of California Irvine School of Medicine, Orange, CA; 1Multi-Organ Transplant Center, Section of Nephrology, Department of Internal Medicine, William Beaumont Hospital, Oakland University William Beaumont School of Medicine, Royal Oak, MI; 2Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; 3Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; 4Phramongkutklao College of Medicine, Mahidol University, Bangkok, Thailand; 5Faculty of Medicine Songklanagarin Hospital, Prince of Songkla University, Songkhla, Thailand.

Background: Visit-to-visit blood pressure variability is associated with vascular stiffness and cardiovascular outcomes, particularly in elderly. Association between visit-to-visit pulse pressure variability (VVPPV), which takes SBP and DBP into account, and late post-kidney transplant (KT) blood pressure (BP) in different age groups is unknown.

Methods: VVPPV was examined by average successive variability (ASV), which is the average absolute difference between successive BP measured at 4, 12, and 24 weeks post-KT. Since the slope of the linear plot between VVPPV and SBP at 48 weeks post-KT abruptly changed when VVPPV was 15 mmHg, VVPPV was then categorized into <15 and ≥15 mmHg (Figure 1A). Association between the categorized VVPPV and systolic and diastolic hypertension (SHTN, DHTN) at 48 weeks defined by SBP and DBP ≥130 and ≥80 mmHg, respectively was examined by multivariate logistic regression and stratified into age <60 and ≥60 years old.

Results: Of all 105 KT recipients from a single KT center, mean age was 54±12 years and 64 patients (61%) was female. Mean VVPPV was 13±9 (range 2 to 50). Mean post-KT SBP and DBP at 48 weeks post-KT were 133±16 and 77±11 mmHg, respectively. In the whole population studied adjustment by gender, donor type (deceased vs. living), and types of induction immunosuppressive medications, patients with VVPPV ≥15 mmHg had 3.36 times higher risk of developing SHTN (OR 3.36, P≤0.001, 95%CI 1.17, 9.65). However, after additional adjustment by age and interaction term between age and ASV, the association was persist only in patients whose age ≥60 years old (OR 3.80, p = 0.04, 95%CI 1.04, 13.91 vs. OR 1.28, p = 0.40, 95%CI 0.36, 13.31 (Figure 1B)). There was no association between VVPPV and DHTN in the whole study and age-stratified populations.

Conclusions: Higher VVPPV is associated with late post-KT SHTN in younger age group (< 60 years old), but not in elderly. Further studies are required to elucidate the mechanisms.

PO2534
Middle Cerebral Artery Hemodynamics Is Blunted in Kidney Transplant Recipients

Andrew J. Jurgensen,1 Jaimie Ward,2 Allegra Morton,2 Andrew P. Geise,2 Sandra Billinger,2 Aditi Gupta,1 University of Kansas Medical Center Division of Nephrology, Kansas City, KS; 1University of Kansas Medical Center Department of Physical Therapy and Rehabilitation, Kansas City, KS.

Background: Kidney transplant (KT) recipients have a higher risk of dementia and cerebrovascular events than the general population. Cerebrovascular hemodynamic response (CVR) to constant-load moderate-intensity exercise marks the ability of the brain to respond to increased oxygen requirements with exercise. Blunted CVR seen with vascular disease and aging can increase risk of dementia and stroke. We evaluated the middle cerebral artery blood velocity (MCV) dynamic response in KT recipients and compared it to age matched non-CKD controls.

Methods: 35 KT recipients and 35 healthy controls completed a 90-second rest followed by a 6-minute moderate intensity exercise on a recumbent stepper at a prescribed step rate and workload. We used transcranial doppler (TCD) monitoring for MCAV while continuously monitoring heart rate and beat-to-beat mean blood pressure during rest and exercise. Baseline resting MCAV and steady state response during exercise was recorded. Outcome measures included resting MCAV and CVR (MCAV during steady state exercise – baseline MCAV) and workload needed to achieve target heart rate. Statistical analysis employed independent t-test.

Results: KT recipients were 52.4 ±0.8 cm/s compared to 12.9 ± 4.9; last follow-up 47.3±21.1 vs 57.5±14.8 mL/min/1.73m². Only 2 patients had oxalate crystals on protocol allograft biopsy, both with RYGB, and one with DGF and died 22 months after KT. GFR at 1 year was 34±23.8 ±0.73m²/1.73m² for these 2 patients.

Conclusions: RYGB is the most common cause of enteric oxalosis in KT recipients. DGF is common and graft outcomes are inferior compared to deceased donor KT among our institution. The lower GFR in RYGB patients raise concern for enteric hyperoxaluria as an unrecognized risk for allograft dysfunction.

PO2533
Kidney Transplant Outcomes for Patients with Enteric Oxalosis

Mira T. Keddis, Danica Grubić, Annamaria T. Kausz. Mayo Foundation for Medical Education and Research, Scottsdale, AZ.

Background: Patients with enteric disorders associated with hyperoxaluria and systemic oxalate burden (enteric oxalosis) are at increased risk for calcium oxalate deposition causing ESRD. The objective of this study is to evaluate kidney transplant (KTx) recipients with enteric oxalosis at our institution.

Methods: KTx recipients with suspected oxalosis due to any of the following: inflammatory bowel disease, bariatic surgery, or pancreatic insufficiency from 2015 to 2019 were included. At our institution, pre-KTx serum oxalate>30mcml/L is the threshold for treatment.

Results: 31 patients were identified. Mean age was 58.5 years, 55% were female, 81% white, and 94% first KTx. Most common cause of ESRD was diabetes (45%), and 84% were on dialysis prior to KTx (median 30.5 months). The most common enteric cause was Roux-en-Y gastric bypass (RYGB, 77%) with surgery 11 year (median) prior to KTx. 39% had history of nephrolithiasis. Median peak serum oxalate (SOx) pre-KTx was 24mcml/L. 87% received deceased donor KTxs and 52% had delayed graft function (DGF). Post-KTx, 36% received calcium with meals for oxalate bind, and 39% had low oxalate diet education. 5 patients had pre-KTx SOx >30mcml/L at the time of KTx, of whom 4 had DGF and required either longer dialysis (up to 5 hours long) or increased dialysis sessions (up to 6 per week) to reduce SOx levels post-KTxs. The median duration of dialysis after KTx was 13.5days. After median follow up of 27 months, (mean SD) estimated glomerular filtration rate (GFR) was 47.6 ±21.2 mL/min/1.73m² and 68% of patients had GFR ≤60. One-year KTx was 48.4±2.4 mL/min/1.73m² which is lower than expected 1-year GFR for our Transplant Center (mean GFR 58±20.6±0.73m²). RYGB patients (n=24) had lower GFR vs patients with other EH causes (n=7) (1 year: 48.7±20.4 ±5.6±4.9; last follow-up 47.3±21.1 ±57.5±14.8 mL/min/1.73m²). Only 2 patients had oxalate crystals on protocol allograft biopsy, both with RYGB, and one with DGF and died 22 months after KTx. GFR at 1 year was 34±23.8 ±0.73m²/1.73m² for these 2 patients.

Conclusions: RYGB is the most common cause of enteric oxalosis in KTx recipients. DGF is common and graft outcomes are inferior compared to deceased donor KTxs at our institution. The lower GFR in RYGB patients raise concern for enteric hyperoxaluria as an unrecognized risk for allograft dysfunction.

Longitudinal Physical Performance Following Kidney Transplant
Khin N. Chan,1,2 Daniel J. Watford,1 Xingxing Cheng,1 Jonathan N. Myers,1 Jane C. Tan.1,2 Stanford Medicine, Stanford, CA; 3Veterans Affairs Palo Alto Health Care System, Palo Alto, CA

Background: Frailty and poor physical performance are strongly associated with poor outcomes in kidney transplantation (KTx). However, the effect of KTx on physical performance remains poorly understood.

Methods: We measured 6-minute walk test (6MWT, meters) and 1-minute sit-to-stand test (STS, number of repetitions from standing to sitting position) performances within 1 year prior to KTx. Physical performance indices were re-measured at 3 and 6-months, and 1-year post-KTx. Multivariable linear regression was used to assess which baseline characteristics were associated with 6MWT and STS. Trajectories of 6MWT and STS were assessed by baseline performance using a generalized estimating equation.

Results: Among 85 patients who performed baseline assessments, 39, 33 and 40 completed 3, 6, and 12-month evaluations, respectively. Average age was 53 and average diaylsis vintage was 7 years. 49% had diabetes mellitus, 18% had coronary artery disease, 5% had cerebrovascular disease, and 10% had peripheral arterial disease (PAD). In the multivariate model, age, female sex, and the presence of PAD were associated with lower 6MWT and STS. Trajectories of 6MWT and STS were assessed by baseline performance using a generalized estimating equation.

Conclusions: Walking ability did not improve appreciably after KTx. STS, a measure of lower body strength, improved progressively post-KTx, but was mostly observed in patients with higher baseline STS. Results must be interpreted with caution, since all patients, even those with lower physical performance, were selected to proceed with KTx.

Outcomes of Kidney Transplantation in Fabry Disease: A Meta-Analysis
Maria Lourdes Gonzalez Suarez,1 Charat Thongprayoon,2 Michael A. Mao,3 Juan A. Medura,4 Wisit Cheungpasitporn.1 University of Mississippi Medical Center, Jackson, MS; 2Mayo Clinic, Rochester, MN; 3Mayo Clinic, Jacksonville, FL

Background: Fabry disease (FD) is a rare X-linked lysosomal storage disorder with progressive systemic deposition of globotriaosylceramide, leading to life-threatening cardiac, central nervous system, and kidney disease. Current therapies involve symptomatic medical management, enzyme replacement therapy (ERT), dialysis, kidney transplantation, and more recently gene therapy. The aim of this systematic review was to assess outcomes of kidney transplantation among patients with FD.

Methods: Comprehensive literature review was conducted utilizing MEDLINE, EMBASE and Cochrane Database, from inception through February 28, 2020 to identify studies that evaluate outcomes of kidney transplantation including patient and allograft survival among kidney transplant patients with FD. Effect estimates from each study were extracted and combined using the random-effects, generic inverse variance method of DerSimonian and Laird.

Results: Eleven studies including 424 kidney transplant recipients with FD were evaluated. The post-transplant median follow-up time ranged from 3 to 11.5 years. Overall, the pooled estimated rates of all-cause graft failure, graft failure before death, and allograft rejection were 32.5% (95%CI: 23.9%-42.5%), 14.5% (95%CI: 8.4%-23.7%), and 20.2% (95%CI: 15.4%-25.9%), respectively. A sensitivity analysis limited to the recent studies (year 2001 or newer when ERT became available), the pooled estimated rates of all-cause graft failure, graft failure before death, and allograft rejection were 28.1% (95%CI: 20.5%-37.3%), 11.7% (95%CI: 8.4%-16.0%), and 20.2% (95%CI: 15.5%-26.0%), respectively. The pooled estimated rate of biopsy proven FD recurrence was 11.1% (95%CI: 3.6%-29.4%), respectively. There was no significant difference in the risk of all-cause graft failure (P = 0.01) nor mortality (0.48) among recipients with vs. without FD.

Conclusions: Despite possible FD recurrence after transplantation of 11.1%, allograft and patient survival are similar among kidney transplant recipients with vs. without FD.

PO2537

Urinary Supersaturation in Patients with Kidney Transplant Nephrolithiasis
Erin E. Bolen, Mitchell Humphreys, Karen L. Stern, Todd Leavitt, Nan Zhang, Mira T. Keddis. Mayo Clinic Arizona, Scottsdale, AZ

Background: Urine supersaturation (SS) has not been reported for kidney transplant (KTx) recipients with de novo transplant-derived nephrolithiasis. The objective of this study was to evaluate supersaturation studies, treatment, and stone and allograft outcomes in KTx recipients with allograft nephrolithiasis.

Methods: Retrospective review from 2009-2019 of KTx recipients with nephrolithiasis at Mayo Clinic was completed. Stone event was defined as radiologic evidence.

Results: Fifty six transplant nephrolithiasis cases were identified. Mean transplant age was 56.5 ± 12.1 years, 32 (57.1%) were male, 46 (82.1%) received first KTx, 41 (75.9%) received living related donors, 27 (48.2%) had diabetes mellitus. Baseline stone size was 6 mm, and most common location was the lower pole (n=20 [41.7%]). Median time from KTx to stone event was 1 year. Thirty four (60.7%) had a 24-hour SS study at a median of 2 years after KTx. Select results are shown in Table 1. Of the 34, 14 (41.2%) had a stone event prior to KTx, and 6 (17.6%) had donor-derived stone. Thirty one (91.2%) had increased SS of calcium oxalate, 17 (50%) calcium phosphate, and 9 (26.5%) uric acid. Thirty two (94.1%) had urine citrate <450mg/24hrs. Management of the initial 56 included potassium citrate in 13 (23.2%), calcium citrate in 10 (17.8%), and dietician referral in 18 (32.1%). Forty five (80.8%) were seen by urology, 28 (50%) needed surgical management, and 14 (27.5%) passed the stone. At median follow-up of 4 years after KTx, 37 (66.1%) had persistent stone disease in the allograft, 3 (5.4%) had graft failure, and 2 (3.6%) had died.

Conclusions: This is the first study of urine SS in patients with transplant-derived nephrolithiasis. Profound hypocitraturia was the most prevalent risk, and increased supersaturation for calcium oxalate crystals predominated. Allograft stone clearance was rare, and many required surgical intervention.

PO2538

Exposure to Tacrolimus Trough Levels Below 6 ng/mL During the First Year Is Associated with Inferior Kidney Graft Survival
Timn Agur,1,2 Ruth Rahimnian,1,2 Benaya Rozen-zevi,1,2 Department of Nephrology and Hypertension, Rabin Medical Center Israel, Petah Tikva, Israel; 3Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv; Israel

Background: Accumulating data indicates that sub-therapeutic levels of calcineurin inhibitors are associated with long-term graft loss. However, while tacrolimus (TAC) was shown to provide adequate immunosuppression with lower acute rejection rate, its optimal maintenance dose for long term graft survival is still unknown. The aim of our study was to determine the minimal TAC trough level, which is associated with improved kidney graft survival.

Methods: We conducted a retrospective cohort study based on the RMC registry. We defined five TAC trough level intervals: 3-4, 4-5, 5-6, 6-7, and 7-8ng/ml. We compared allograft and patient survival among recipients with various TAC trough levels using the Kaplan-Meier survival analysis. Cox proportional hazards model was used to assess the independent association between TAC trough level and allograft and patient survival.

Results: Of 156 patients with functional allografts, 66 patients (42%) had allograft failure, and 33 patients (21%) died during follow-up (median follow-up: 36 months). The median time on TAC was 5 years (range: 0.1-18 years). The median TAC trough levels were 5 (range: 1-7.5) ng/mL, and the 1-year survival rates were 89%, 79%, 79%, 77%, and 77% for patients with TAC trough levels of 3-4, 4-5, 5-6, 6-7, and 7-8 ng/mL, respectively. The unadjusted hazard ratio for allograft failure at 1 year was 1.16 (95%CI: 0.72-1.87) for TAC trough levels 3-4 ng/mL compared to 5-6 ng/mL. After adjusting for age, gender, and diabetes, the hazard ratio remained the same (HR: 1.16, 95%CI: 0.72-1.87). The 1-year cumulative incidence of allograft failure was significantly lower for patients with TAC trough levels of 5-6 ng/mL compared to those with TAC trough levels of 3-4 ng/mL (P = 0.04).

Conclusions: Exposure to TAC trough levels below 6 ng/mL during the first year is associated with inferior kidney graft survival.
was adjusted to the exposure time below a given interval-level, allowing us to define the threshold for optimal TAC trough level as the upper limit of the interval. We then determined the association between the adjusted exposure time at each TAC level-interval and our primary outcome, death-censored graft survival.

Results: We included 1417 patients with a median follow up of 5.3 years (IQR 2.9-8.5 years). TAC through level interval of 5-6 ng/ml was the highest interval which demonstrated a statistically significant association between exposure time and increased risk of graft loss, even after adjustment to the exposure time below 5 ng/ml (HR 1.58 per log days, p<0.001). These results remained consistent in an extensive multivariable analysis (HR 1.44, p<0.004) and were not significantly changed when we analyzed for death- or included graft survival (HR 1.2, p<0.026) or the first three months and the subsequent nine months separately (HR 1.93, p<0.001, HR 1.56, p<0.001 respectively). Cumulative exposure time above 14 days to TAC trough level 6 ng/ml, was significantly associated with increased risk of graft loss in most studied subgroups including age, gender, low and high immunologic risk recipients, except for the subgroup of recipients with diabetes.

Conclusions: Prolonged exposure time to TAC trough level between 5-6 ng/ml within the first-year post-transplant was independently associated with increased risk of long-term graft loss. These results imply that keeping TAC trough levels above 6 ng/ml during high immunologic risk recipients, except for the subgroup of recipients with diabetes.

Impact of Renal Transplantation on Functional Status in Tacrolimus Era

Mahmoud M. Mohamed,1 Karim M. Soliman,4 Hatem Ali,2 Ahmed Daoud,7 Tibor Fulop,2,1 Vinaya Rao,4 Maria Aurora C. Posadas,1 Michael Casey,4 Ahmed Halawa,4 Ingel Elsayed.7 The University of Tennessee Health Science Center, Memphis, TN; University hospitals of Birmingham, UK, Birmingham, United Kingdom; Cairo University Kasr Elainy Faculty of Medicine, Cairo, Egypt; Medical University of South Carolina, Charleston, SC; Ralph H. Johnson V4 Medical Center, Charleston, SC, United States, Charleston, SC; Institute of Medical Sciences, Faculty of Medicine, University of Liverpool, Liverpool, UK, Liverpool, United Kingdom; Royal Stoke University Hospital, Stoke-on-Trent, United Kingdom.

Background: Despite a large body of literature describing survival’s outcome after renal transplantation, little is known about the progress of functional capacity post-transplantation. Our aim is to assess the effect of renal transplantation and various factors on functional capacity.

Methods: From the United States Organ Procurement and Transplantation Network files, we identified a total of 19,704 renal transplant recipients (RTR) maintained on tacrolimus-based immunotherapy, who had Karnofsky Performance Status Scale (KPSS) defined functional capacity assessment at the time of transplant evaluation with five-years data follow up. Age, gender, ethnicity, functional status, diabetes, body mass index, cold ischemia time, number of previous transplants, panel reactive antibodies, donor type, donor age, HLA-mismatches, number of acute rejection episodes, induction therapies, maintenance immunotherapy, and recipient characteristics were collected. According to KPSS, RTRs at time of transplant evaluation were divided into 3 groups (A: 13,701 RTRs with mild impairment: >80%; B: 5,557 RTRs with moderate impairment: 40-80%; C: 446 RTRs with severe impairment: <40%). The outcome measured was KPSS functional status five-years post-transplant. Multiple logistic regression analysis was used to assess factors affecting functional status post-transplant.

Results: In group A, 86.45% of patients showed improvement in functional capacity, 65.5% in group B, while 88.56% improved in group C (64.57% improved from severe to mild and 23.99% improved from severe to moderate functional capacity). Furthermore, multiple logistic regression analysis showed that steroid withdrawal protocol was associated with significant improvement in functional capacity (OR=1.28, 95% Confidence Interval (95 CI): 1.1 - 1.49, P<0.007), while dialysis duration before transplantation was associated with abnormal functional capacity post-transplant (OR=0.74, 95% CI: 0.61 - 0.89, P<0.003).

Conclusions: Renal transplantation is associated with substantial improvement in all stages of functional capacity in RTRs. Steroid withdrawal as well as the duration of dialysis are the most important novel determinant factors of functional capacity post-transplant and merit considerations during transplant selection and subsequent immunosuppressive therapeutic planning.

Calcineurin Inhibitor-Based Immunosuppression Has Negligible Negative Effects on Pregnancy Outcomes After Renal Transplantation in the Netherlands

Lisanne M. Koener,1 Jildau R. Meinderts,2 Olivier W. van der Heijden,1 Titia Lely,2 Margriet de Jong,3 Renate G. van de Molen,1 Henk W. Van Harenvelst1 Pregnancy After Renal Transplant OUTComes (PARTOUT) Network1 Radboudumc, Nijmegen, Netherlands; 2Universitair Medisch Centrum Utrecht, Utrecht, Netherlands; 3Universitair Medisch Centrum Groningen, Groningen, Netherlands.

Background: Pregnancy among renal transplant recipients (RTR) has increased over the past years, also in patients with compromised renal function and/or proteinuria. Immunosuppressive regimens may influence pregnancy outcomes and it is not yet clear whether replacing a calcineurin inhibitor (CNI) by a CNI-free (CNI-) regimen has a favorable effect.

Methods: We therefore retrospectively compared the effect of CNI-based (CNI+) and CNI- immunosuppression in the first trimester of pregnancy on maternal and fetal outcomes in Dutch pregnancies between 1986-2017 in RTR. We identified 129 CNI+ and 125 CNI- single-pregnancies. Demographics did not differ except for higher BMI in CNI+ (median 25.3 vs 23.7 kg/m2, p<0.01), year of renal transplantation (2000 in CNI+ vs 1989 in CNI-, p<0.01), year of pregnancy (2006 in CNI+ vs 1998 in CNI-, p<0.01) and interval of transplantation to pregnancy (69 in CNI+ vs 96 in CNI-; p<0.01). In the third trimester creatinine levels were significantly higher in CNI+ (127 vs 105 μmol/L in CNI-; P<0.01) but this difference had disappeared 6-18 months postpartum. The percentual change in creatinine from preconceptional level to the third trimester level was slightly different (+3.1% in CNI+ vs 2.2% in CNI-, p<0.05).

Conclusions: Our data indicate that CNI do not negatively influence the course of renal function up to 18 months postpartum, but only lead to a more pronounced increase in serum creatinine levels towards the end of pregnancy. However, the substantial short term loss of renal function and the high rates of premature birth rate and low birthweight classify them as high risk pregnancies that should be followed carefully in tertiary obstetric/ nephrologic care programs. Our data do not exclude possible long term negative effects of CNI on overall health, renal function or hypertension in the offspring of these women.
PO2542
The Natural History of Waitlist Candidates in the United States
Allan Massig, Dorry L. Segev. Johns Hopkins University School of Medicine, Baltimore, MD.

Background: Estimates of time to deceased-donor transplantation (DDKT) generally fail to take into account the competing risks of mortality. Understanding the natural history of KT registrants - their chance of DDKT/LDDT/death based on individual characteristics - can inform referrals for transplantation, counseling for transplant candidates, and allocation policy.

Methods: Using SRTA data on 186,174 waitlist registrants 12/2014-12/2019, we modeled time to DDKT, LDDT, or waitlist mortality in a competing-risks framework, overall and for clinical subgroups of patients (based on candidate age, sex, race, ABO blood type, PRA). Competing-risks regression was used to model individual n-year chance of DDKT/LDDT/mortality based on candidate characteristics.

Results: Among all candidates, 5-year cumulative incidence of LDDT/DDKT/mortality other removal was 17.3%/34.4%/15.7%/18.1% respectively. 85% of LDDT recipients received LDDT within 2 years of listing. Pediatric registrants had substantially higher incidence of DDKT than waitlist mortality (61.7% vs 1.1%), but adults had higher combined of waitlist mortality/other removal DDKT, particularly patients above age 65 (44.4% vs 32.3%) (Figure). Center-level 5-year incidence of LDDT (DDKT) 1.3%/44.8% (4.4%/82.6%) (Figure 2).

Conclusions: Despite a focus in the transplant community on small differences in one-year posttransplant outcomes and a reluctance to transplant kidneys with slightly worse expected outcomes, most adult patients wait >5 years for a kidney, incurring substantial waitlist mortality risk. High incidence of waitlist mortality will only be remedied through aggressive efforts to increase the living and deceased donor organ pool.

PO2543
Unusual Cause of Calcium Oxalate Nephropathy in a Renal Allograft
JoBeth McCoy, Anthony J. Langone. Vanderbilt University Medical Center, Nashville, TN.

Introduction: Crystal nephropathy is a well-known cause of acute kidney injury that is often overlooked. We present a case of oxalate nephropathy in a renal allograft that led to a rare diagnosis.

Case Description: A 63-year-old female with a kidney transplant for end-stage kidney disease (ESKD) caused by acute interstitial nephritis (AIN) presented with acute kidney injury. Her creatinine on presentation was 2.0mg/dL from her baseline of 1.0mg/dL and increased to around 3.0mg/dL despite hydration. It was decided that she would benefit from allograft biopsy. The biopsy was devoid of any rejection but did have many foci of calcium oxalate crystal deposition with tubular injury. She was planned for a 24-hour urine collection for stone evaluation that showed an elevated urine oxalate level, 140mg. She changed her diet and the 24-hour urine collection was repeated in 3 months with no change. With the continued elevation, genetic testing was sent for primary hyperoxaluria which revealed that she has homozygote mutation in the AGXT gene, confirming that she has type 1 primary hyperoxaluria. Reevaluation of her biopsy diagnosing AIN before transplant was found to have interstitial multinuclear infiltrate with some crystallization consistent with oxalate. Her particular mutation responds well to pyridoxine (vitamin B6) so she was started on 600mg per day. Since treatment, her creatinine has stabilized at 3.0mg/dL. Her 24-hour urine evaluation has shown improvement in urine oxalate to 79mg, a 43.5% reduction.

Discussion: This case report is a rare diagnosis of primary hyperoxaluria type 1 (PH1) is described by recurrence in a renal allograft in only 10% of cases. Delay in the diagnosis is common and results in a significant number of patients who have end-stage kidney disease (ESKD) at initial presentation. The rapidity of progression is determined by the residual enzyme activity and response to pyridoxine (vitamin B6). The definitive cure for PH1 is a liver transplantation that carries significant mortality risk. Medical management includes large fluid intake of greater than 3L/day to decrease tubular fluid oxalate concentration, potassium citrate-citric acid to increase the solubility of calcium oxalate and prevent precipitation, avoidance of oxalate in diet, and high dose pyridoxine to promote the conversion of glyoxylate to glycine rather than to oxalate. A trial of 5mg/kg of pyridoxine is suggested in all PH1 patients to see how they respond.

PO2544
Secondary Oxalosis with Enteric Oxalate Nephropathy in a Transplant Recipient: Is Mycophenolate the Culprit?
Himmat S. Brar, Nihal M. Ali, Franco H. Cabeza Rivera. University of Mississippi Medical Center, Jackson, MS.

Introduction: Secondary oxalosis causing acute kidney injury has been widely reported in native kidneys but its occurrence in allograft kidneys is relatively uncommon. Intestinal malabsorption can be present in transplant recipients as a result of factors beyond the general population such as immunosuppressive medications and some enteral infections. We present a case of enteric oxalate nephropathy as a result of mycophenolate toxicity.

Case Description: A 66-year-old male status post kidney transplant 3 years back for ESKD due to DM and HTN with a baseline creatinine of 1.5 mg/dL presented with a 2-month history of GI symptoms of vomiting, diarrhea and 22 lbs weight loss. He was on tacrolimus, mycophenolate and prednisone for immunosuppression. The patient denied any recent infection or antibiotic use, any medication change, supplements or OTC drug use. He denied any ESKD, and the physical examination on admission showed no lab findings showed Na 139, K 5.5, CI 117, Bicarb 11, AG 22, Ca 9.6, BUN 71 and creatinine 3.5. Lactate and serum osmolar gap were normal. Lipase, amylase, Vit B1 and B6 were normal. UA showed trace ketones and blood with no protein or bacteria. Serology for CMV and BK virus was negative. Tacrolimus level was at goal. MPA level was noted to be elevated at 9.7 at an office visit 1 month prior to admission with no recent adjustment in dosing. Plasma oxalate was elevated at 3.9. The stools studies and GI panel were negative. CT scan showed a 3mm non-obstructing stone. The renal biopsy showed interstitial fibrosis, tubular atrophy and calcium oxalate deposits with birefringence within the tubules. MMF was discontinued. The patient was given iv fluids and citrate to alkalize the urine. At discharge, his Cr improved with resolution of symptoms.

Discussion: Medication-induced malabsorption should be considered among potential causes of secondary oxalosis. The MMF metabolites indirectly affect lymphocytes in the GI tract leading to mucosal damage with malabsorption and enteric oxalosis. The hyperoxalosis causes saturation of oxalate crystals creating an interstitial nephritis, macrophage recruitment and inflammation leading to tubular atrophy. The transplant recipients with chronic diarrhea and no infection should be suspected for MMF toxicity. The oxalate and MPA levels must be checked and MMF dose should be adjusted accordingly.

PO2545
Prophylactic Use of Eculizumab and Grant Loss in Kidney Transplant Recipients due to Hemolytic Uremic Syndrome in the United States
Richard A. Plass,1,2 Stephen W. Olson,1,2 Christina M. Yuan,1,2 Lawrence Agodoa,1 Kevin C. Abbott,2 Robert Nee,1,2 Walter Reed National Military Medical Center, Bethesda, MD; 1Uniformed Services University of the Health Sciences F Edward Hebert School of Medicine, Bethesda, MD; 1National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.

Background: Among kidney transplant recipients (KTRs) with end-stage kidney disease (ESKD) due to hemolytic uremic syndrome (HUS), recurrence is associated with poor allograft outcomes. We examined the prophylactic use of eculizumab, a monoclonal antibody that binds complement protein C5, and graft loss among HUS KTRs.

Methods: We conducted a retrospective cohort study using the United States Renal Data System. Out of 123,624 ESKD patients transplanted between January 1, 2008 and June 1, 2016, we identified 348 (0.28%) patients who had HUS as the primary cause of ESKD. We then linked these HUS patients to datasets containing the Healthcare Common Procedure Coding System (HCPCS) code for eculizumab infusion. We calculated crude incidence rates of overall graft loss and death-censored graft loss and conducted exact logistic regression, adjusted for recipient age and sex. Patients who received eculizumab prior to or within 30 days of transplant represented the exposure group.

Results: Our final study cohort included 335 HUS KTRs (23 received eculizumab, 312 did not). There were no significant differences in baseline demographic and clinical characteristics between the eculizumab vs. non-eculizumab group. For those who received eculizumab, the median number of infusions per patient was 42 (IQR 16, 66). The median payment amount per patient was $706,518 (IQR 241,237, 1,306,453). Eculizumab was discontinued in 9 out of 23 patients (39%), after a median prophylactic duration of 329 days (IQR 127, 791). As shown in the Table, the eculizumab group had no graft loss vs. 20% in the non-eculizumab group, with an adjusted odds ratio of 0.13.

Conclusions: Prophylactic use of eculizumab in HUS KTRs was significantly associated with a lower risk of graft loss. Given the high cost of eculizumab, randomized controlled trials are much-needed to guide prophylactic strategies to prevent graft loss.
PO2546

Post-Kidney Transplant Serum Magnesium Exhibits a U-Shaped Association with Subsequent Mortality

Annalise M. Panthofer, Beini Lyu, Brad C. Astor, Tripti Singh, Fahad Aziz, Didier Neetika Garg. University of Wisconsin School of Medicine and Public Health, Madison, WI.

Background: Hypomagnesemia is common in kidney transplant recipients (KTR), likely due, at least in part, to renal magnesium (Mg) wasting related to calcineurin-inhibitor (CNI) use. The association of serum Mg levels and KTR outcomes may provide insight into the optimal serum Mg levels in this population.

Methods: KTRs between 01/2000 and 2016 at a large US transplant center who were alive with a functioning graft at 6 months post-transplant were included. Mean of the outpatient serum Mg levels in the baseline period, i.e. 6 to 18 months post-transplant, was used. Cox proportional-hazards regression was used to analyze the association between Mg and all-cause mortality, cause-specific mortality, and risk of new-onset cardiovascular events post-transplant.

Results: 2,131 KTRs met our inclusion criteria. Mean number of Mg measurements per patient in the baseline period was 2.76. A U-shaped association between the mean baseline Mg level and all-cause mortality was observed in both unadjusted analysis and after adjusting for baseline characteristics, including eGFR and CNI levels. A mean Mg of 1.5 – 1.8 mg/dL was associated with the lowest incidence of death (Figure). Compared with Mg of 1.5 – 1.8 mg/dL, Mg level ≤ 1.5 mg/dL was also associated with higher incidence of mortality due to infection and arrhythmia but not ischemic heart disease or heart failure.

Conclusions: The relationship between serum Mg levels and mortality in KTRs is U-shaped. Interestingly, the risk is lowest with Mg levels 1.5 – 1.8 mg/dL, which represents the lower end of normal (1.6 – 2.6 mg/dL). Mg supplements for levels ≤ 1.5 mg/dL may be beneficial, but may cause increased renal wasting and diarrhea. Further studies are needed to understand why Mg > 1.8 mg/dL but well within the normal range was associated with higher risk despite adjustment for eGFR.

Virtual Reality, a New Vision Becoming Our New Actuality: A Retrospective Study Comparing Virtual Crossmatch vs. Physical Crossmatch at Tampa General Hospital

Fernando Moran,1 Timothy M. Chow,2 Martin Aldana,3,4 John Lunz.4 Division of Nephrology, University of South Florida, Tampa, FL; 2Nephrology and Transplantation University of South Florida, Tampa, FL; 3Division of Internal Medicine University of South Florida, Tampa, FL; 4LifeLink Foundation Transplantation Immunology Laboratory, Tampa, FL; 5Florida Kidney Physicians, Tampa, FL.

Background: A crossmatch (XM) is required prior to kidney transplantation to ensure immunological compatibility between recipient and donor. This test is prone to false positive reactivity and can increase cold ischemic time (CIT) especially for organs procured outside the region of the transplanting hospital. Advances in HLA antibody testing and donor HLA antigen typing facilitate the use of a virtual XM (VXM) based on pre-transplant testing results to accurately predict a physical XM (PXM) result. Frequent antibody screening and an accurate history of sensitizing events further ensures that the VXM can predict immunological compatibility, even without retrospective PXM.

Methods: We compared the 6 mo. clinical outcomes of kidney recipients who proceeded to transplant with only a VXM (without retrospective PXM) to those receiving a PXM. 182 recipients with 6 mo. follow-up were reviewed for biopsy data, serum Cr and UPCR. Patients were grouped according to the transplant type (living donor (LD) vs. deceased donor (DD)) and XM type (PXM vs. VXM). LD recipients had a PXM (n=42). Patients with a VXM (n=76) were donor-specific antibody (DSA)-free and had a current tested sample within 30 days. DD recipients had PXM (n=64) due to the presence of DSA (current or historic) or the absence of a current tested sample within 30 days. All patients with PXM had an acceptable flow cytometric XM.

Results: Patients proceeding to transplant with a VXM tended to be less sensitized (32% with PRA >0%) compared to DD-PXM (66%) and LD-PXM (49%). For DD recipients, CIT was significantly reduced in patients receiving a VXM (727 vs 871 min; p=0.011). Within the first 6 mo. of follow-up, 67 for cause biopsies were performed. Rejection (T-cell or antibody mediated) was observed in 15 patients (7 DD-VXM, 6 DD-PXM and 3 LD-PXM). Interestingly, antibody mediated rejection was only observed in DD-PXM (n=3) or LD-PXM (n=1) groups.

Conclusions: In our cohort, kidney transplantation with an acceptable VXM was beneficial in reducing CIT and rejection was similar to DD recipients needing a PXM within the first 6 mo. post-transplant. Utilizing VXM helps facilitate kidney transplantation, permits entertaining offers from greater distances, and reduces laboratory burden with similar outcomes to when a PXM is performed.

PO2547

A Case of Subretinal IgA Deposition in a Patient with IgA Nephropathy and Early Allograft Recurrence

Mahmood M. Khan, Lyle W. Baker, Sarah T. Suliman, Martin L. Mai. Mayo Clinic’s Campus in Florida, Jacksonville, FL.

Introduction: IgA Nephropathy (IgAN) has variable clinical manifestations and a 30% recurrence, which is typically a late complication in renal transplant recipients. Occular involvement in patients with IgAN is extremely rare. Thus, eye findings as a predictor of worse prognosis, including higher risk of recurrence, remains unexplored.

Case Description: A 66 year old Caucasian male with end-stage renal disease secondary to a 10 year history of IgAN complicated by retinal detachment and optic neuropathy with recent decline in visual acuity, underwent living related renal transplant from his twin sister with Basalimab induction. A month prior, Optical Coherence Tomography (OCT) had revealed bilateral macular edema and subretinal pigment deposits with central foveal sparing, consistent with IgA maculopathy. Post-operative course was uneventful with immediate allograft function and normalization of creatinine. 4 months later, repeat OCT showed improved retinopathy and occular edema. However, renal function declined 2 months later, with persistently elevated

PO2549

Reassessing Renal Transplantation in Light-Chain Deposition Disease

Background: Light chain deposition disease (LCDD) is a systemic rare condition that usually leads to end stage renal disease. Treatment with a bortezomib-based regimen, followed by autologous stem cell transplantation (ASCT) has been increasingly used with improvements in the response rates and the renal graft outcomes in kidney transplant recipients.
Methods: Retrospective study of 6 patients diagnosed of LCDD with complete response but not renal response after hematologic treatment that underwent kidney transplant in our institution between 2010 and 2019.

Results: A total of 6 patients (5 women) were analyzed, with mean age at diagnosis of 47 years, mean eGFR of 18 mL/minute and mean proteinuria of 5.5 g. Deposit was kappa type except in 1 case (heavy and light lambda type chains). In all of them there was an absence of monoclonal component in blood and urine but positive immunofixation in 5 cases (2 only in urine). 3 started chronic hemodialysis during admission and the others at 3, 5 and 44 months after diagnosis. As hematological treatment, all received bortezomib followed by ASCT, being under complete hematological response at the time of kidney transplant, which was performed at 28 months on average from ASCT. Mean kappa/lambda ratio was 2.6. 3 patients received induction with thymoglobulin and 3 with basiliximab, followed by triple therapy with tacrolimus+prednisone+mTOR inhibitor (4 patients) or mycophenolate (2 patients). After 36 months of mean follow-up after kidney transplant, 3 patients have suffered an hematological relapse, one of them including kidney involvement with graft loss at 46 months post-transplant. The remaining 5 continue with a functional graft with a mean creatinine of 1.54 mg/dL.

Conclusions: When sustained complete hematologic response is achieved but renal impairment with dialysis requirement persists, patients could benefit from a kidney transplant with good results.

PO2550
Granulomatous Interstitial Nephritis and Allograft Failure Secondary to Adenovirus Reactivation

Introduction: With an incidence of about 4% in renal transplant recipients, the typically self-limited adenovirus renders an infrequent propensity to cause allograft failure and life-threatening opportunistic infection in severe cases.

Case Description: A 29 year old female with history of living donor kidney transplant due to Henoch Schonlein Purpura (HSP) Glomerulonephritis with subsequent allograft failure underwent deceased donor re-transplantation with Anti-Thymocyte globulin induction. Post-op course was uneventful. Creatinine was 0.8 mg/dL on 4 month follow up. 6 months post-transplant, patient developed gross hematuria with clots, fever and acute kidney injury with creatinine of 2.82 mg/dL. Biopsy revealed granulomatous tubulointerstitial nephritis, extensive intra-nuclear viral inclusions with positive adenovirus immunohistochemistry (IHC). Mycophenolate Mofetil was discontinued and creatinine improved to 1.1 mg/dL. 3 months later, she was admitted for renal failure with creatinine of 7.2 mg/dL. Adenovirus was detected in the serum and urine. Repeat biopsy revealed markedly reactive tubular epithelium, widespread viral inclusions with negative adenovirus IHC, consistent with adenovirus nephropathy. Following a decrease in immunosuppression with improvement in renal function, adenovirus viral load became undetectable in both plasma and urine. The use of Cidofovir was considered for treatment but not renal response after hematologic treatment that underwent kidney transplant in our institution between 2010 and 2019.

PO2551
Phospholipase A2 Receptor Antibody Level Directed Management of Membranous Glomerulopathy After Transplant
Irfan Agha,1,2 Amna Ilahi,1,2 Silvi Simon,1,2 Rama Nadella,1,2 Diana Mahbod,1 Richard Dickerman.1 1Dallas Renal Group, Dallas, TX; 2Medical City Dallas Hospital, Dallas, TX; 3Methodist Dallas Medical Center, Dallas, TX.

Introduction: MN can recur after transplantation. Patients with high PLA2R Ab are at higher risk. There is equipoise on how to manage these patients. We present two cases to highlight PLA2R Ab level directed approach to management.

Case Description: Case 1: 35 YO AA female with MN diagnosed in 2013. Failed cytotoxic therapy and started RRT. Received a DD kidney transplant in Sep 2018. Given Thymoglobulin, tacrolimus, mycophenolate and prednisone. Pre-transplant PLA2R titer 1:2560 by IIF. Titer serially monitored. After an initial decline, titer increase with precipitation of proteinuria noted. Biopsy confirmed early recurrent MN. Treated with 2 doses of Rituximab. Subsequent titters dropped with complete remission. Case 2: 65 YO W male with biopsy demonstrated MN (2015), on RRT since 2017 underwent DD kidney transplant in May 2019. Given Thymoglobulin and maintained on tacrolimus, mycophenolate and prednisone. Pretransplant PLA2 R Ab level was 164 RU/ml by EIA with 3.5 g/g of protein. His PLA2R Ab levels dropped and proteinuria rapidly & durably resolved after transplant. One year out, his PLA2R Ab is at 24 RU/ml with 0.11 g/g protein in the urine and a creatinine of 1.2 mg/dL.

Discussion: High PLA2 R Ab at the time of transplant is a significant risk factor for recurrent MN. PLA2R Ab levels should be monitored to direct care: decreasing PLA2R Ab should be followed conservatively. If Ab levels increase or proteinuria develops, perform biopsy to confirm diagnosis and initiate therapy expeditiously. PLA2R Ab levels should be monitored post transplant to ensure resolution. This approach allows stratification and directed therapy of patients with MN undergoing transplantation and avoids overt treatment.
PO2552

De Novo Membranous Nephropathy and Donor-Specific Allotubodies: A Path to the Pathophysiology?
Megan A. Tierney, Pradeep Vaitla, Wisit Cheungsapiporn, Franco H. Cabeza Rivera. University of Mississippi Medical Center, Jackson, MS.

Introduction: While pathophysiology of post-transplant membranous nephropathy due to recurrence of primary disease is established, less is known about the development of primary de novo membranous nephropathy (dnMN). We report a case of dnMN associated with antibody-mediated rejection in a transplant recipient with end-stage kidney disease secondary to focal segmental glomerulosclerosis (FSGS).

Case Description: A 20-year-old African American female with FSGS status-post deceased donor transplant eight years ago presented with acute lower extremity edema and acute kidney injury concerning for acute rejection. She has no history of prior rejection or medication non-adherence. Ultrasound showed mild hydronephrosis. Biopsy showed Banff Type IB acute cellular mediated rejection (6, 21, 2) and Stage 1 membranous glomerulopathy. Serum phospholipase A2 receptor (anti-PLA2R) antibodies were negative. Donor specific antibodies (DSA) testing revealed the presence of DQ5, DQ7, and DRB1*1501. Diagnosis of coexistence of Banff Type IB acute-cell mediated rejection, positive de novo DSA, and dnMN was made. She was treated with five doses of antithymocyte globulin (1.5 mg/kg/dose) and plasma exchange (PLEX) followed by rituximab. Repeat DSA showed negative. Donor specific antibodies (DSA) testing revealed the presence of DQ5, DQ7, and DQ8. She was treated with high dose steroids, 10 sessions of plasmapheresis with intravenous immunoglobulin (IVIG), and Rituximab. His Cr improved to 1.2 mg/dL but DSA remained positive. Later on he was restarted on Etanercept which was withdrawn again in March 2019. Accordingly, in September 2019, he developed acute kidney injury with Cr up to 1.7 from baseline of 1.3-1.5 mg/dL associated with nephrotic range proteinuria. He had a rise in DSA to DQ7, and developed new DSA to A2 and B60 with positive cytotoxicity crossmatch. Donor derived cell free DNA was elevated at 4.4%. Allograft biopsy showed glomerulitis, peritubular capillaritis with positive c4d, consistent with ABMR. He was treated with high dose steroids, 10 sessions of plasmapheresis with IVIG and Rituximab. Repeat DSA showed reduction in A2, but no change in DQ7. His serum Cr improved but his proteinuria remained at nephrotic range.

Discussion: Despite the use of Etanercept in the treatment of graft versus host disease among transplant recipients, it hasn’t been studied as a potential immunosuppressive drug. In our patient, Etanercept seemed to provide anti-rejection effect as shown by two episodes of ABMR with de-novo DSA after the drug’s withdrawal. Close monitoring of renal function and DSA may be warranted once Etanercept or other TNF inhibitors are withheld.

PO2553

Histological Predictors of Graft Failure in Kidney Transplant Recipients
Maria Ajajin, Yong AI Azzi, Purna Bindu Nandigam, Pablo Loarte Campos, Cindy T. Pynadath, Luz E. Liriano-Ward, Enver Akalin. Montefiore Medical Center, Bronx, NY.

Background: We aimed to identify the predictors of allograft failure in a large cohort of kidney recipients who underwent clinically indicated graft biopsies. We aimed to explore the importance of interstitial inflammation in biopsies with interstitial fibrosis and tubular atrophy (IFTA).

Methods: We retrospectively evaluated 516 patients who underwent transplant biopsy between 1/2009 and 1/2018. Acute and chronic allograft injury scores of Banff classification were used. We sub grouped the patients with chronic allograft injury score (cic/cic/tcv) ≥ 3 or < 3 and sub grouped per interstitial inflammation (i score=0 and > 0) and compared to biopsies with both cic/cic/tcv=0 and i=0.

Results: Biopsies were done at a median 12.5 months after kidney transplantation. The histopathological diagnosis were as following: acute antibody-mediated rejection (AMR) (6%), acute T-cell mediated rejection (9.3%), chronic AMR (6.7%), transplant glomerulopathy without donor-specific antibody (DSA) (10.2%), recurrent de novo glomerular disease (20.8%), BKV nephropathy (2.5%), and the rest 54.2% had other diagnosis (normal, acute tubular necrosis, or non-specific IFTA). During a median follow up of 59.3 months after kidney biopsy, 36 %recipients lost their graft. In univariate analysis, the following factors were significant for graft loss: Black race (p=0.005), previous rejection (p=0.001), DSA at the time of biopsy (p=0.014), cic/cic/tcv ≥ 3 (p=0.0485), cic/cic/tcv ≥ 3 with interstitial inflammation > 0 (p=0.0001), microvascular inflammation (p=0.0052), C4d positivity (p=0.008), serum creatinine at time of biopsy.

PO2554

A Case of Antibody-Mediated Rejection (ABMR) After Withdrawal of Etanercept in a Renal Transplant Recipient
Iris Jill E. Uy, Mohammad Abuzeineh, Sami Alasfar, Fizza F. Naqvi, Brandon L. Trolinger. Johns Hopkins Medicine, Baltimore, MD.

Introduction: Etanercept is a tumor necrosis factor (TNF) receptor fusion protein that is used to manage several forms of inflammatory arthritis and psoriasis. Herein, we present a renal transplant recipient who was concomitantly treated with Etanercept for psoriasis and subsequently developed two episodes of ABMR after the drug’s withdrawal.

Case Description: A 41-year-old man with history of psoriasis and end stage renal disease due to hypertensive nephrosclerosis and interstitial nephritis who underwent living related kidney transplant from his brother in December 2008. He was being treated for psoriasis with Etanercept which was withdrawn in September 2012. Subsequently he developed rising serum creatinine (Cr) from baseline of 1.3-1.5 mg/dL. Developed de-novo donor specific antibodies (DSA) to DR1 and DQ7 with positive cytotoxicity crossmatch. Renal allograft biopsy showed evidence of Banff 2A acute cellular rejection, ABMR, chronic glomerulonephritis and interstitial nephritis. He was treated with high dose steroids, 10 sessions of plasmapheresis with intravenous immunoglobulin (IVIG), and Rituximab. His Cr improved to 1.2 mg/dL but DSA remained positive. Later on he was restarted on Etanercept which was withdrawn again in March 2019. Accordingly, in September 2019, he developed acute kidney injury with Cr up to 1.7 from baseline of 1.3-1.5 mg/dL associated with nephrotic range proteinuria. He had a rise in DSA to DQ7, and developed new DSA to A2 and B60 with positive cytotoxicity crossmatch. Donor derived cell free DNA was elevated at 4.4%. Allograft biopsy showed glomerulitis, peritubular capillaritis with positive c4d, consistent with ABMR. He was treated with high dose steroids, 10 sessions of plasmapheresis with IVIG and Rituximab. Repeat DSA showed reduction in A2, but no change in DQ7. His serum Cr improved but his proteinuria remained at nephrotic range.

Discussion: Despite the use of Etanercept in the treatment of graft versus host disease among transplant recipients, it hasn’t been studied as a potential immunosuppressive drug. In our patient, Etanercept seemed to provide anti-rejection effect as shown by two episodes of ABMR with de-novo DSA after the drug’s withdrawal. Close monitoring of renal function and DSA may be warranted once Etanercept or other TNF inhibitors are withheld in transplant recipients.

Molecular Analysis of Renal Graft Biopsies: Comparing the Edmonton Molecular Microscope with the NanoString Human Organ Transplant Panel
Jessica Schmidt,1 Helge Stark,2,3 Stephan Bartels,4 Danny Jonigk,2,3 Philip F. Halloran,6 Gunilla Eicke,2 Jan H. Braesen,1 Hannover Medical School, Medizinische Hochschule Hannover, Institute of Pathology, Nephropathology Unit, Hannover, Germany; 2Hannover Medical School, Institute of Pathology, Hannover, Germany; 3Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Hannover, Germany; 4Alberta Transplant Applied Genomics Center, Edmonton, AB, Canada; 5University of Alberta, Edmonton, Edmonton, AB, Canada; 6Alberta Transplant Applied Genomics Center, Edmonton, Edmonton, AB, Canada; 7Hannover Medical School, Department of Nephrology and Hypertension, Hannover, Germany.

Background: The renal transplant biopsy is the diagnostic gold standard and usually evaluated with the continuously expanded and updated Banff classification which is based on descriptive, empirically-derived criteria and thus lacks precision. High-resolution determination of the graft status by NanoString analysis, which was developed for formalin-fixed paraffin-embedded (FFPE) RNA, should be a sufficient approach for objective molecular diagnosis of renal transplant biopsies and may improve our understanding of graft biology.

Methods: We used well-annotated surveillance and indication biopsies from 63 patients whose time-matched second biopsy core had been frozen and analyzed by microarray in the INTERCOM/INTERCOMEX study. After reevaluation according to recent Banff consensus, RNA isolation of the FFPE biopsy was performed and led to 774 RNA yields in 53 samples which were further processed for NanoString analysis using the nCounter Human Organ Transplant Panel.

Results: Morphologically, of the 53 samples analyzed (samples from 2011/12 and 2015), twenty-five patients showed no signs of rejection, twelve had borderline rejection,
four showed cellular rejection, seven had humoral rejection, and five presented with combined rejection. Preliminary analysis of gene expression by T-distributed Stochastic Neighbor Embedding (t-SNE), Random Forest and Principal Component Analysis (PCA) showed clear differences between samples with rejection (humoral and cellular) and without rejection. Reaction samples revealed high expression of chemokine ligands compared to rejection-free tissues. A common pattern of samples without rejection and borderline rejection was observed. Our results displayed good correlation with the former molecular microarray-based diagnosis from the INTERCOM/INTERCOMEX study.

**Conclusions:** Molecular diagnostic approach using the NanoString platform may supplement morphological diagnosis of renal grafts especially in unclear cases and thus enhance precision diagnostics with small tissue requirement. Morphological and molecular evaluation in the same biopsy core from FFPE tissue enables direct histological-molecular correlation. Additionally, this technology also improves our understanding of pathophysiology in renal and other transplants.

**Donor Biopsy and Kidney Transplant Outcomes in Pediatric Recipients**

Ahmad Mashmoushi,1 Christine S. Hwang,2 Malcolm MacConmara,2,4

1University of Texas Southwestern Department of Surgery, Dallas, TX; 2University of Texas Southwestern Medical Center, Division of Surgical Transplantation, Department of Surgery, Dallas, TX; 3University of Texas Southwestern Medical Center, Division of Pediatric Nephrology, Department of Pediatrics, Dallas, TX; 4Children’s Medical Center, Division of Pediatric Transplantation, Dallas, TX.

**Background:** Deceased Donor DD kidney biopsies are routinely used in the context of clinical concerns about donor quality in adult kidney transplants. We sought to examine the use of DD kidney biopsies in pediatric transplants. We aim to evaluate prognostic utility of glomerulosclerosis GS level in predicting graft outcome.

**Methods:** Data was used from recipients who received kidney transplant between 1994 and 2018 documented in the Scientific Registry of Transplant Recipients database. Pediatric recipients were defined as recipients <18 years who received DD kidney transplant excluding multi-organ transplants. The recipients were further stratified according to degree of donor kidney GS into 0-5% and >5% categories. Demographic and outcome data were examined and graft survival was evaluated using STATA 16.

**Results:** 10,045 pediatric recipients received DDKT during this period. 644 had left and/or right DD kidney biopsies, 548 biopsies had 0-5% GS, 96 biopsies had >5% GS. Biopsies were mostly performed on kidneys harvested from higher risk donors. There was a significant difference in the number of biopsies performed across regions (region 5 lowest at 2.6% and region 9 highest at 17.5%). There was no significant difference among share characteristics or transplant center volume. Allograft survival was significantly worse for donor kidneys with GS-5% compared to 0-5% group and no biopsy group. There was no significant difference in the incidence of DGF, acute rejection, or chronic rejection.

**Conclusions:** Although the biopsied kidneys are mostly from higher risk donors, the majority of biopsies have GS level 0-5%. At this level of GS there is no difference in allograft survival compared to DD kidneys without biopsies. Thus utilizing kidneys with GS 0-5% can expand the DD kidney pool and should be strongly considered for use in pediatric population.

**PO2558**

**Predictors and Impact of Nephrocalcinosis in Renal Transplant Population: A Monocenter Retrospective Study**

Jessie Beaulieu,1 Léa Thérien,1 Julie Riopel,1 Eva Latulippe,2 David Simonoyan,2 Isabelle Houde,1 Mohsen Agharazi,1 Fabrice Mac-Way,1 CHU de Quebec-Université Laval, CHU de Quebec-Université Laval, Quebec, QC, Canada; 2Centre de recherche du CHUQ, Quebec, QC, Canada.

**Background:** Persistence of bone and mineral anomalies in post-transplant population has been suggested as contributing factors to nephrocalcinosis (NC) that could lead to graft dysfunction. However, adequate characterization of calcium deposits in biopsies from renal transplant patients are lacking. We thus aimed to determine: 1) the prevalence of NC in renal transplant patients, 2) the factors associated with NC and 3) the impact of NC on renal graft function.

**Methods:** This is a monocenter retrospective study using a protocolized renal biopsy from CHU de Quebec, l’Hôtel-Dieu de Quebec hospital from 2016-2018. All renal biopsies performed in 2016 at renal transplantation, at 6 and 24 months post-transplant were qualitatively and quantitatively analyzed for NC. Demographic, comorbidities and biochemistry parameters were collected from patients’ records. Appropriate statistical analyses (Pearson’s chi-squared, Wilcoxon-Mann-Whitney, Spearman’s correlation and logistic regression) were performed to assess factors associated with NC and its impact on graft function.

**Results:** We included 53 patients (mean age of 52±13 years, 55% of men, 94% with hypertension, 23% with peripheral arterial disease and 19% with prior parathyroidectomy). Forty-nine patients (92%) were on chronic dialysis treatment before transplant for a mean duration of 34±29 months. The presence of NC was observed in 14% at baseline, 37% at 6 months and 50% at 24 months. The severity of NC as assessed by the number of calcified foci in the tubulointerstitial compartment also tended to increase over time. Analyses showed that the presence of NC at 6 months was associated with male sex, presence of NC at baseline and high PTH levels (> 600 ng/L) at the time of transplant. Presence of NC at 24 months was also associated with prior NC and male sex. Interestingly, the presence of NC at 6 months was associated with use of phosphate supplements immediately after engraftment and with active vitamin D treatment at 6 months. Finally, NC at 24 months was correlated with the level of graft function as expected.

**Conclusions:** This study reveals that uncontrolled mineral and bone metabolism parameters before renal transplant are associated with development of NC in the post-transplant period that may contribute to deterioration of renal graft function.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Antiphospholipid Antibody Syndrome Causing Thrombotic Microangiopathy in the Immediate Post-Transplant Patient: A Case Report
Anna R. Gaddy, Muhammad S. Yaqub. Indiana University School of Medicine, Indianapolis, IN.

Introduction: Differential diagnosis of thrombotic microangiopathy on kidney biopsy specimen includes infection, hypertension, malignancy, or inherited complement disorders. In the the post-transplant period the differential also includes calcineurin inhibitor toxicity and rejection.

Case Description: A 29 year-old AA female with ESRD disease due to lupus nephritis and HTN. Her care was provided in another state until 2011- she had a stroke in the past which she reports was secondary to uncontrolled HTN. No h/o blood clot, never been pregnant. Native kidney biopsy in 2015 showed lupus: class V membranous GN, focal segmental and diffuse glomerular sclerosis with collapsing features, and focal acute thrombotic microangiopathy. In 2019, she underwent deceased donor kidney transplant. On post-op day 4, Sr Cr began to increase and biopsy demonstrated thrombotic microangiopathy. Chart review revealed increased aPTT prior to surgery. DsDNA was negative. Tacrolimus troughs were low, donor-specific antibodies were negative. She was treated empirically with high-dose steroids and plasma exchange. Workup revealed positive anti-cardiolipin IgG (46 GPL units/mL) and positive anti-beta-2 glycoprotein IgG (532 units/mL). She recalled being on warfarin following her CVA in 2010, for embolic stroke. She received a dose of Rituximab, has been maintained on tacrolimus and mycophenolic acid along with warfarin for her antiphospholipid syndrome (APLs) and has normal graft function

Discussion: This case highlights the importance of a complete serological workup to rule out APLs in the pre-transplant patient, even in the presence of alternate explanatory diagnoses. Patients with APLs should be treated with lifelong anticoagulation to prevent further embolic complications, including loss of transplanted organs.

PO2561
Impact of Out-of-Hospital Organ Donor Cardiac Arrest and Cardiopulmonary Resuscitation on Donor Kidney Histology and Function
Sami M. Akram, Claudia G. Olano, Nehemias A. Guevara, Lilly M. Barba. Kidney Transplantation Group Harbor-UCLA Medical Center Department of Internal Medicine, Torrance, CA.

Background: The mortality rate of patients listed for kidney transplantation (KT) is 5 per 100-patient years. Due to an organ shortage crisis, expansion of KD pool (KDP) is critical (1). Kidney donors (KD) with out-of-hospital cardiac arrest (OHUS-CA) and cardiopulmonary resuscitation (CPR) have low acceptance rate due to presumed delayed graft function (DGF). Donor CA in controlled setting (in ICU) does not impact KF post engraftment (PE) (2) but impact of OHUS-CA is unknown. We propose that terminal serum creatinine (TSC) and Kidney histology (KH) immediately prior to kidney transplantation predict KF post KT. We did a nested cohort study to study the impact of OHUS-CA and CPR of KDs on KT and KH

Methods: Our transplant program received thirty-five kidney organ donors offers with a procurement biopsy from UNOS during July to December 2019. Retrospectively we reviewed demographics, pre-hospitalization resuscitation information, hemodynamic data and KH. Four patients were excluded; two had missing data; one patient had ischemic infarct and one patient had kidney tumor. The study cohort (N=31) divided into CA-OHUS (N1=16) and No Cardiac Arrest (No-CA, N2=15) groups. The change (delta) in serum creatinine (DSC) while under donor management (DM) compared in each group. Hypotension during donor management (H-DM) and acute tubular damage score (ATDS) from donor kidney biopsy compared within each group of the cohort.

Results: TSC and ATDS prior to KT were evaluated as surrogates for KF post engraftment and there was no difference between OHUS-CA and No-CA (standard) donors. Effect of ischemic preconditioning was noted in OHUS-CA group (Table). Longer the duration of CPR greater was the residual KF (Fig 1).

Conclusions: KF and KH in KD with OHUS-CA are similar to standard criteria donors hence should not be prejudiced. This will expand the KDP.

PO2562
Living Donor-Derived APOL-1-Associated Collapsing FSGS in a Kidney Transplant Recipient
Irfan Agha,1,2 Anna Ilahci,1,3 Silvi Simon,1,3 Rama Nadella,1,2 Diana Mahbod,1 Richard Dickerman.1 1Dallas Renal Group, Dallas, TX; 2Medical City Dallas Hospital, Dallas, TX; 3Methodist Dallas Medical Center, Dallas, TX.

Introduction: Homozygous high risk APOL1 mutations in donors can drive disease in recipients. We present a living kidney recipient with de-novo collapsing FSGS. His donor was homozygous for high risk mutations.

Case Description: 47 YO AA male with CKD due to biopsy proven diabetic nephropathy s/p LUKT in May 2018. Got thymoglobulin (5 mg/kg) with tacrolimus, mycophenolate sodium and prednisone. High risk for CMV (D+ / R-). EBV IgG +. Donor was his 35 years old AA wife. We were not testing APOL-1 on AA donors at the time. At month 6: Cr 1.4 mg/dl, Ur Pr/Cr of 0.22 g/g. Valganciclovir stopped. Two weeks later, Ur Pr/Cr of 2.92 g/g. CMV PCR +276 copies / ml and EBV PCR +492 copies / ml. PCR for Parvo Virus B-19 as well as DSA negative. Given steroids, plasmapheresis (X3) and IV ganciclovir. Biopsy CN collapsing FSGS. IF negative, including CMV and C4d. Donor tested for and found to be homozygous for APOL1 G1 mutations confirming donor derived APOL1 gene associated collapsing FSGS, presenting as an acute diffuse podocytopathy. Trends in his renal function, CMV, EBV and proteinuria are tabulated in Figure 1. Treated with RAAS blockade, antivirals & immunosuppression. He cleared his CMV Viremia promptly. However, EBV viremia worsened. Eventually, in May 2019, received Rituximab with resolution of EBV viremia. He is 18 months out from transplantation predict KF post KT. We did a nested cohort study to study the impact of OHUS-CA and CPR of KDs on KT and KH

Discussion: APOL-1 mutations place recipients of these kidneys at risk for adverse outcomes. Few instances of APOL-1 mutation driven kidney disease in recipients from...
living donors are documented. This presentation supports the two-hit hypothesis - The high injury state due to CMV and EBV viremia precipitated APO-1 associated FSGS in this kidney with homozgyous high risk mutations. APOL-1 screening in AA donors, especially young donors, should be considered for risk stratification and counseling.

PO2563

Pediatric Donor Glomerulopathy in Pediatric En-Bloc Kidney Transplants

Background: Use of pediatric en-bloc kidneys (EBK) have equivalent outcomes to standard deceased donor kidneys and has helped expand the pool of donor kidneys. The size mismatch related hyperfiltration injury in pediatric EBK and pediatric single kidney allografts is associated with pediatric donor glomerulopathy whose effect on allograft outcomes is not well documented.

Methods: We retrospectively reviewed for cause biopsies of pediatric EBK from 1/2015 to 1/2020. Our center performed 37 transplants using pediatric EBK. Recipient weight criteria was ≤ 75 kg to minimize donor-recipient size mismatch. One recipient died with a functioning graft at 4 months; one graft failed due to fungal infection of the vascular anastomosis requiring nephrectomy at 1 month.

Results: Fourteen biopsies were performed in 10 patients between 1 to 24 months after transplantation. Indications for biopsy were: graft dysfunction (10; 3 with proteinuria), proteinuria alone (2), BK viremia with proteinuria (1), and de novo donor specific antibody (DSA) (1). Biopsies from 5 EBK recipients demonstrated pediatric donor glomerulopathy represented by the presence of glomerular abnormalities including subepithelial multilayering/remodeling of the basement membrane, segmental glomerulosclerosis, mesangial hypercellularity, mesangial sclerosis, podocyte hypertrophy, and/or segmental mild podocyte foot processes effacement. Ten biopsies also showed thin basement membranes (BM) on EM consistent with the age of the donor kidney. Other diagnostic findings among the entire biopsy cohort were acute cellular rejection (ACR), antibody mediated rejection (AMR), or mixed ACR and AMR (5), acute tubular necrosis (ATN) (3), and pyelonephritis (1). Biopsies with pediatric donor glomerulopathy were performed early after transplantation and were associated with proteinuria. Semiquantitative proteinuria in the 5 recipients at the time of biopsy was 1-3+; 1.2-9.5 g/day in 4. Follow up 4-39 months post-transplant (mean 17 months) in patients with pediatric donor glomerulopathy showed serum creatinine 0.55-2.07 mg/dL (mean 1.13) and urine protein 0.4 to 1.2 g/day (mean 0.73).

Conclusions: Overall, pediatric donor glomerulopathy seen early post transplant period did not appear to negatively affect long-term graft function; this outcome may be related to growth of these kidneys occurring early post transplant.

PO2564

Pre-Transplant Genetic Testing of Living Related Donor in a Case of Atypical Hemolytic Uremic Syndrome

Meghna Kunup, Didier A. Mandebrot, Tripti Singh. University of Wisconsin SMPH, Madison, WI.

Introduction: Atypical HUS (aHUS) is a rare thrombotic microangiopathy caused by dysregulation of the alternative complement pathway either through mutations in regulatory genes or autoantibodies directed against regulatory proteins. Here we report a case of genetic testing pre-transplant in a patient who developed aHUS with variants in the CFH and PLG genes and her living related donor.

Case Description: A 27-year-old female presented to the hospital with diarrhea, abdominal pain, AKI, and microangiopathic hemolytic anemia requiring dialysis. She was initiated on eculizumab but progressed to ESRD. Renal biopsy showed TMA with focal crescents and severe interstitial fibrosis and tubular atrophy. Workup revealed aHUS with complement dysfunction—low C3 and C4, normal CD46 and Factors H, I, and B, and no autoantibodies to CFH. Genetic testing showed mutation on exon 9 (SCRT7) of CFH that has been shown to cause aHUS as well as another variant on exon 7 of PLG, which is present in 0.3% of European Americans and may be pathogenic but is of uncertain significance for her. Ten months later, she was evaluated for living related renal transplant from her brother. Since she had a mutation known to cause aHUS, genetic testing was done for her brother as part of donor evaluation. He was found to have the same mutation in CFH but not PLG, despite being asymptomatic with no hemolytic anemia, normal kidney function. The transplant was cancelled because of increased risk of disease in the future in the brother. Genetic counseling was provided to brother about his possible risk of aHUS.

Discussion: Mutations in CFH are associated with aHUS; however, it is thought that a trigger—e.g. infection or additional acquired genetic variant leads to progression to aHUS in carriers of complement gene mutations. Genetic testing is recommended for patients with aHUS to determine cause and inform long-term treatment. This patient had a combination of a variant in the complement pathway gene CFH and coagulation pathway gene PLG, while her brother, a candidate for living related donor, had the same variant in CFH. We recommend genetic testing for a living related donor if any mutation is found in the index case to minimize posttransplant recurrence or precipitation of aHUS in the donor.

PO2565

Trouble Brui-ing: A Case of Doppler Discovery

Brandon M. Fairless, Anil S. Paramesh, Asha Ishoore. 1 Tuscaloosa County University Health Sciences Center, New Orleans, LA; 2 Tulane University School of Medicine, New Orleans, LA.

Introduction: This case highlights the clinical presentation and management of an uncommon kidney transplant biopsy complication.

Case Description: A 19 year old male with ESKD, now status-post second deceased donor kidney transplant, presented to clinic with hypertension. Post transplant course included 3 prior normal surveillance kidney transplant biopsies. Graft function was stable (creatinine 1 mg/dL), and tacrolimus trough level was therapeutic. His blood pressure was 130/85. Exam showed a palpable thrill with audible bruit over the graft site. Ultrasound showed a sonolucent lesion in the lower pole of the transplant kidney, which was not present on prior imaging. Doppler revealed turbulent flow concerning for an arteriovenous malformation (AVM). Renal angiography confirmed the diagnosis, and he underwent endovascular embolization with coil [Image]. Graft function and blood pressure readings remain normal on most recent follow up.

Teaching Points: Ultrasound with Doppler is critical for the diagnosis. Endovascular embolization is an effective and minimally invasive management option for most patients.

PO2566

Renal Transplant Artery Stenosis and Kinking: An Unusual Association

Haydian Sosa Barrios,1 Victor Burguera,1 Ester Casillas,1 Daniel E. Vila,1 Sara Jimenez Alvaro,1 Irene Martin Capon,1 Milagros Fernandez-Luca,2 Maite Rivera.1 1Hospital Universitario Ramon y Cajal, Madrid, Spain; 2 Universidad de Alcala de Henares, Madrid, Spain.

Introduction: Renal artery stenosis of the kidney graft associated with kinking is not a frequent finding. As a correctable cause of graft dysfunction it is important to diagnose it as soon as possible to avoid further graft damage.

Case Description: A 62-year-old woman with ESRD due to ADPKD had a deceased donor kidney transplant (KTx) in her right iliac fossa (1 vein/1 artery) anastomosed to external iliac vessels. Immunosuppression: basiliximab, tacrolimus, everolimus and steroids. Creatinine drop halted 2 weeks post-op. Blood pressure was normal, CMV load : undetectable. Tacrolimus level:7-9 ng/mL. A KTx US was done, showing high velocities within KTx renal artery close to the anastomosis, increasing near a kinking image adjacent to the hilum (image 1), not present on Doppler US 1 day post-op. A CT angiography confirmed renal artery stenosis at anastomosis level and kinking of the graft renal artery (image 2). Endovascular angioplasty of the stenotic area without stenting was performed, but unsuccessful. Open surgery vascular reconstruction was carried out a week after angioplasty: renal artery was shortened and reimplanted. Within a week, graft function improved and Doppler US was normal.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

777
Discussion: Renal artery stenosis is a correctable cause of hypertension and graft dysfunction in KTx. Graft renal artery kinking is rare, even more in association with stenosis, worsening its prognosis as kinking renders angioplasty less effective. Complete Doppler US mapping of the graft’s arteries is essential to make an early diagnosis and nephrologists could do this examination promptly.

PO2567
Proliferative Glomerulonephritis Monoclonal Immunoglobulin Deposits (PGNMID) in a Kidney Allograft Successfully Treated with Rituximab
Rasha Todd,1 Mohankumar Doraiswamy, Seth Scheetz, Anjali A. Satoskar, Todd E. Pesavento, Priamvada Singh. The Ohio State University, Columbus, OH.

Introduction: PGNMID is a rare distinct form of glomerulonephritis (GN) characterized by glomerular monoclonal immunoglobulin deposits. There is no definite treatment for this condition. We present a case of PGNMID in a recurrent renal transplant patient who responded well to rituximab.

Case Description: A 43-year-old male with ESRD secondary to MPGN s/p 3rd renal transplant complicated with failure of previous transplants due to rejections (on cyclosporine and everolimus) presented with worsening pain at the graft site and AKI. Creatinine 5.6 mg/dL (baseline 2.5 mg/dL), UPC 1.5 gm/dL, RBC, and RBC casts on microscopy. Detailed serological, immunological, and infectious workup was negative. Renal biopsy showed mesangial, subepithelial, and subendothelial proliferation with electron dense deposits of IgG1 and IgG3 with kappa predominance most consistent with PGNMID. Monoclonal workup was negative and bone marrow biopsy showed no clear evidence of hematologic malignancy. He received two doses of rituximab in addition to home immunosuppression. Renal function improved to baseline (creatinine 2.5, negative blood, UPC 0.5) and has been stable for past year.

Discussion: GN recurrence in kidney allografts is responsible for around 24% of kidney graft losses. Approximately 70% of PGNMID patients have no detectable monoclonal proteins in serum or urine. Multiple regimens have been used for the treatment of PGNMID after renal transplant, including RAAS blockers, steroids, rituximab, bortezomib and plasmapheresis. Few reported cases of PGNMID responded well to rituximab, and a large prospective multicenter controlled study is warranted to better understand this rare disease.

**Case Study of Repository Corticotropin Injection (RCI) Prophylaxis for FSGS Recurrence in Kidney Transplant**

Sandheep Venkataraman,1 Barrett R. Crowther,1,2 Monica Grafals,1,2 University of Colorado, Denver, CO; 1University of Colorado Health, Aurora, CO.

**Introduction:** Idiopathic FSGS recurs post-transplant in one third of cases and is associated with a five-fold higher risk of graft loss.1

**Case Description:** In this single center pilot case study, 8 patients with biopsy-proven FSGS were treated with RCI prophylaxis 80 units subcutaneously twice a week for 6 months from day of kidney Tx, compared with a group of 6 patients who were treated with RCI later after the diagnosis of FSGS recurrence.

**Discussion:** All patients received rATG as induction and were on standard immunosuppression with FK, MMF, and prednisone. Patients in the control group were diagnosed with recurrent FSGS between 5-63 days post Tx. There were 3 patients in the study group that developed recurrent FSGS, 2 of them required plex. Patient 1 in the study group had DGF after a live donor kidney Tx from recurrent FSGS. Her protocol biopsy performed one year after transplant and still shows foot process effacement but no fibrosis or sclerosis in light microscopy. All but one patient in the control group have still functioning allografts. Conclusions: This is a small pilot study, but its findings suggest that use of RCI at time of kidney transplant surgery in patients with FSGS decreases the severity of the disease with less fibrosis in follow up biopsies despite the presence of foot process effacement. There may also be a decreased need for plex in the study group, however, further studies are needed to confirm this.

**Does Therapeutic Plasma Exchange Improve Kidney Function in Renal Transplant-Associated Thrombotic Microangiopathy?**

Karen A. Nahmod, Barbara J. Bryant, Sean G. Yates, Marjan Afrouzian. University of Texas Medical Branch at Galveston, Galveston, TX.

**Background:** Therapeutic plasma exchange (TPE) is performed in patients with renal transplant thrombotic microangiopathy (t-TMA) to improve the kidney function. The goal of our study is to evaluate the short-term efficacy of TPE in patients with renal t-TMA.

**Methods:** We retrospectively compared the outcome of TPE-treated vs. non-TPE-treated patients with biopsy-proven diagnosis of t-TMA. Histologic criteria for diagnosis of t-TMA included presence of thrombi in the artery/arteriole/glomeruli, mesangiolysis & double contours, and electron microscopic evidence endothelial cell injury including subendothelial rarefaction/accumulation of fluffy material and mesangial interposition. Both groups received concomitantly other modalities of treatment. Creatinine and creatinine clearance levels were determined at the time of biopsy (T0) and after 1, 3 and 6-months (T1, T3, T6 respectively).

**Results:** In 13 TPE-treated and 9 non-TPE-treated patients, the mean creatinine levels at 6 months decreased 32.5% and 45% respectively over baseline, while the creatinine clearance increased by 68% and 65% respectively, although not statistically significant (p>0.05) Graph1.

**Conclusions:** No significant differences were noted in creatinine or creatinine clearance levels within and between either groups at any time point. Our study suggest that no significant benefit in renal function is associated with performing TPE in patients with renal t-TMA. Larger studies are needed to confirm our data.
PO2571

Patient and Graft Outcomes of Kidney Transplant Recipients with Anti-Human Neutrophil Antigen Antibodies
Thomas Jefferson University, Philadelphia, PA.

Background: Antibody mediated rejection (AMR) is a well-established cause of poor graft outcomes in kidney transplant recipients (KTR). While the most common targets are human leukocyte antigen (HLA) antibodies (abs), there are data implicating some non-HLA abs in the process of AMR. Human neutrophil antigens (HNA) are glycoproteins expressed on neutrophil surfaces. Anti-HNA abs have been associated with transfusion-related acute lung injury but their role in AMR in KTR is unclear. The aim of our study was to examine the outcomes of KTR with anti-HNA abs at our center.

Methods: We retrospectively reviewed the medical records of KTR with non-HLA abs between 1/2008-5/2020. Relevant clinical and graft outcome data were obtained. Descriptive statistics were expressed as absolute numbers (%) for categorical data and as medians with interquartile range (IQR) for skewed distribution.

Results: There were 6 KTR with non-HLA abs during the study period, all anti-HNA abs. Three patients (pts) were male (50%), 5 white (83%), and 4 had polycystic kidney disease (PKD) as primary disease (66%). Median age at KT was 46 (29.75-57). Pts’ characteristics, clinical course and outcomes are detailed in Table 1. Five pts developed biopsy-proven AMR at a median of 32 months (13.8-68.2) from KT. During follow-up (FU), 3 pts had graft loss, 1 of which was re-transplanted while 2 are re-listed but dialysis-dependent. Mean creatinine of the 4 pts with working allografts is 1.21mg/dL (1.14-1.27) at median FU of 68 months (52-105).

Conclusions: We observed varied clinical courses and graft outcomes in our pts, partly due to our small cohort. Although majority developed AMR, it was not necessarily associated to graft loss or shortened graft survival. Of note, PKD was the primary kidney disease in the majority of pts, similarly observed in one other case series. More studies are needed to determine the specific significance of anti-HNA abs in KTR.

Table 1. Patient and donor characteristics and allograft outcomes.

PO2572

Transplant Outcomes in Children with Lupus Nephritis
Vimal Chaudhry,1 Heather W., Waski,3 Shirley Galbiati,4 Meredith A. Atkinson,2 Bradley A. Warady.1,4 Children’s Mercy, Kansas City, MO; 2 Johns Hopkins University, Baltimore, MD; 3 The Emes Company LLC, Rockville, MD; 4 State University of New York Upstate Medical University, Syracuse, NY.

Background: Children receiving dialysis for end stage kidney disease secondary to lupus nephritis (LN) have decreased survival and a lower likelihood of kidney transplantation compared to children with non-lupus glomerular diseases (NLGN). Whereas a previous North American Pediatric Renal Trials and Collaborative Studies (NAPRTCS) analysis reported equivalent patient and graft survival for LN patients when compared to matched controls, a comparison of recent transplant outcomes in children with LN and LN has not been conducted.

Methods: Retrospective analysis of the NAPRTCS registry data of subjects <21 years old who received a kidney transplant between 1987-2018. Outcomes for LN patients (n=191) were compared to NLGN patients (n=8675) during pre & post 2000 eras. Statistical analyses included Kaplan-Meier curves and multivariable logistic and Cox regression models.

Results: After adjusting for race, LN patients were less likely (p=0.001) to receive a preemptive transplant (OR=0.12). There was also a trend for LN patients being less likely to receive a living donor (LD) transplant (OR=0.8). When comparing pre- and post-2000 eras, time to 1st rejection and graft survival improved for both LN and NLGN groups, although the graft survival benefit in LN group was not sustained after 3.5 years of follow-up. Time to 1st rejection and graft survival for LN patients remained inferior to NLGN group during both eras (Figure 1 & 2).

Conclusions: LN patients are less likely to receive a preemptive, and possibly a LD transplant. Overall, outcomes for both LN and NLGN transplant patients improved after 2000, but the outcomes of the LN group were inferior to those of the NLGN group during both time periods.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

PO2573

Effect of Rituximab Dose on Induction Therapy in ABO-Incompatible Living Kidney Transplantation: A Network Meta-Analysis
Seon Deok Hwang,1 Joon Ho Song,1 Kipyoo Kim,1 Woo Yeong Park,2 Seoung woo Lee.1 Inha University, Incheon, Incheon, Republic of Korea; 2Keimyung University Dongsan Medical Center, Daegu, Republic of Korea.

Background: Rituximab is an induction immunosuppressant essential for ABO-incompatible kidney transplantation, but studies on its dosing, which differs between countries and transplant centers, are lacking we retrospectively investigated this phenomenon.

Methods: We retrospectively investigated this phenomenon by including five groups: ABO compatible; placebo; and rituximab 200 mg, 200–500 mg, and 500 mg. Publications were retrieved using CENTRAL, MEDLINE, EMBASE, and Science Citation Index Expanded databases from 1970 to February 2020 and analyzed. Reviews, observational studies, and clinical trials with unclearly defined outcomes or omitted graft failure as an outcome were excluded. We performed direct and indirect network meta-analyses using Bayesian models and ranked different rituximab doses using generation mixed treatment comparison. The GRADE of network meta-analysis approach specified four levels of certainty for a given result: high, moderate, low, and very low. The outcomes were patient survival, graft failure, and infections including bacterial and viral.

Results: Twenty-one trials with 4,256 subjects were analyzed for glomerular filtration rates, graft loss, antibody-mediated rejection, T-cell mediated rejection, fungal infection (Candida), and patient survival rates, which did not differ among four groups. However, incidence of sepsis and cytomegalovirus infection (0.728 and 0.855, 95% confidence interval: 0.572–0.926 and 0.724–0.921, respectively) were significantly lower in rituximab 200-mg group than in other groups.

Conclusions: In conclusion, in ABO-incompatible kidney transplantation, low-dose rituximab is more efficacious than higher doses and reduces serious infection risks. Future studies of large-scale, long-term data and further discussions on using lower rituximab doses are necessary.

PO2574

Delayed Diagnosis of Renal Allograft Uroenteric Fistula in a Pediatric Transplant Patient
Malek Al Barbandi, Patricia A. Arroyo Parejo Drayer, Juan C. Infante, George W. Burke, Jayathi Chandar, Marissa I. Defreitas, Chrys P. Katsoulis, Wacharee Seeherunvong, Carolyn L. Abitbol. University of Miami School of Medicine, Miami, FL.

Introduction: The diagnosis of uroenteric fistula can be challenging and is often delayed for several months after symptoms begin. Here, we describe a rare case of a pediatric patient post en bloc kidney transplant who developed a urinoma post biopsy with a ureteral fistula into the small bowel resulting in profound acidosis and deceptive watery diarrhea.
Case Description: The patient is an 8 year old girl with end stage kidney disease secondary to steroid resistant nephrotic syndrome and focal segmental glomerulosclerosis (FSGS). She underwent a right native nephrectomy and a deceased donor “en bloc” kidney transplant with two separate ureters. She had a renal allograft biopsy for suspected rejection. A few days after the biopsy, she began experiencing watery diarrhea and metabolic acidosis. A comprehensive screening for diarrhea produced inconclusive findings. She was maintained on parenteral nutrition with no oral intake to try to slow the diarrhea. However, the watery diarrhea increased while urine output decreased. Throughout this period, the patient maintained normal kidney function. The watery stool and bladder urine were analyzed for solutes, pH and creatinine. An MRI with contrast was performed which demonstrated fistulization of the distal transplanted ureters into the small bowel. She underwent corrective surgery which identified the fistulous tract which was resected and the ureters were re-implanted. The surgery went well without complications. The diarrhea resolved and she was discharged 2 weeks later with normal renal function.

Discussion: This is a perplexing case of the development of a uroenteric fistula in a pediatric transplant patient that went undiagnosed for almost 3 weeks due to the deceptive nature of the watery diarrhea which was actually urine. An important aspect of the uroenteric fistula is the severe acidosis that results when urine is diverted in to the intestinal tract. This occurs in some cases of bladder augmentations that use the intestine. Another important diagnostic tool is the solute excretion in the diarrhea. Despite the watery nature of the diarrhea, the stool was not hyperosmolar and did not contain reducing substances. This made osmotic diarrhea unlikely and a fistula more likely.

PO2575

Effect of Therapeutic Plasma Exchange on Glomerular Filtration Rate in Patients with Antibody-Mediated Rejection
Miguel Maza Moreno, Sergio Hernández-Estrada, Jose H. Cano, Odette Del Carmen Diaz Avendaño, Diana Maldonado Tapia. Nephrology and Transplant Division National Medical Center 20 de Noviembre, Mexico City, Mexico.

Background: AMR is the main risk factor for graft loss, especially after the first post-transplant year. Up to 80% of patients achieve response with immunosuppressive treatment and TPE, although the response is lower in patients with late AMR. The objective was to determine the effect of TPE in GFR at TPE and 3 months postTPE.

Methods: Retrospective study that included patients with a renal transplant of the CMN “November 20” in Mexico City, from 2016 to 2019, undergoing membrane TPE for AMR. Analysis was performed using student’s t or MannWhitneyU, repeated measures analysis, and Spearman or Pearson test. Significant p was less than 0.05.

Results: 25 patients with AMR who received TPE were evaluated. Age: 32± 11.6 years, 72% from living donor, 52% received Basiliximab. 87% received tacrolimus. 80% of AMR were late. Prevalence of HLA class II DSA (66%), specifically vs DQ and DR (57.2% and 28.8%). There was a significant difference between preTPE GFR and at the end of treatment (p=0.015, r=0.53), and no significant differences between preTPE GFR, with 1or3 months postTPE (r=0.58; p=0.36). When evaluating IFTA or histological score (g+ptc), no difference was detected in the GFR at 1or3 months post-TPE. When comparing the effect of the AMR temporality on the GFR, difference was found at 1and3 months (p=0.022; p=0.01) postTPE, with lower recovery of GFR in patients with early AMR. There was a moderate correlation between GFR at the time of diagnosis of rejection and GFR at 3 months postTPE (r=0.68, p=0.01). Fig. 1.

Conclusions: Significant difference was demonstrated between the preTPE GFR and immediate postTPE GFR. In our study patients with early AMR presented a poor response to treatment. The GFRupon admission correlated positively with theGFR detected at 3months post-TPE. This suggests a beneficial effect of TPE over GFRfall during the first 3months after diagnosis.

PO2576

Significant Variability in Results from Different Tacrolimus Assays Is a Potential Recipe for Toxicity and Kidney Allograft Rejection
Adnan A. Khan, Jennifer C. Smith. University of California San Diego, La Jolla, CA.

Background: Tacrolimus (tac) is an immunosuppressive medication used to prevent organ rejection and prolong graft survival after transplantation. It is the main pillar of any combination immunosuppression regimen. Due to its narrow therapeutic window, it requires timely administration, close monitoring with 12-24 hours trough levels and dose adjustments. Previously done studies have shown a discordance between different assays, with a positive bias for immunoassay (2.8 -9.2%) compared to LC/MS-MS assay; due to cross-reactivity with tac metabolites.

Methods: Results from 33 stable kidney transplant patients who had routine transplant labs drawn at Labcorp® were reviewed. Each of these patients had tac trough levels checked by both LC/MS-MS assay and QMS immunoassay(Thermo-Fischer). The comparison of two assays was done with Deming regression and a Bland-Altman analysis for bias done using XLSTAT®. Linear regression was done using SPSS v26.

Results: Deming regression analysis shows that there is a statistically significant difference between the two assays with $y=1.36x-0.26$. Bias(avg.) calculated by Bland-Altman plot was 2.35 ng/mL(Figure). Percentage difference in tacrolimus immunoassay and LC/MS-MS correlated with tacrolimus dose (p = 0.031).

Conclusions: A significant discordance of tac troughs (upto 85%) was found on our analysis; obtained by the two assays. This is clinically significant as tac has a narrow therapeutic window and adjustments of dose based on these assay results; can risk immunologic injury, DSA formation, rejection and nephrotoxicity at either ends of the spectrum. Standardization of assays in future, would be ideal. In the meantime, nephrologists should be adjusting trough goals based on the assay used, especially when different assays are in play.

PO2577

Single-Dose Rituximab and Antithymocyte Globulin (ATG) in Hypersensitized Kidney Transplant Recipients

Aileen Wang, Uerica K. Wang, Megan L. Troxell, Stefan Busque, Colin R. Lenihan. Stanford University School of Medicine, Stanford, CA.

Background: Hypersensitized kidney transplant recipients (calculated panel reactive antibody (cPRA) ≥ 98%), may represent a population at high risk of posttransplant immunologic events. Their optimal induction regimen so far remain uncertain. The goal of this study was to compare 1-year outcomes of patients receiving rituximab and ATG as induction, the majority of whom were hypersensitized, with highly sensitized recipients (cPRA ≥ 80%) who received ATG alone.

Methods: All patients ≥ 18 years received a cross-match compatible kidney transplant between December 2014 and May 2020. We excluded patients who underwent pretransplant desensitization, simultaneous multi-organ transplantation, or received O-HLA antigen mismatched organ. The exposure of interest was receipt of single dose rituximab (500mg) at induction. The 1-year outcomes were 1) patient and death censored graft survival, 2) glomerular filtration rate (GFR), 3) de novo DSA formation, 4) biopsy proven T-cell or antibody mediated rejection, 5) the composite of dDnDSA and rejection, 6) BK viremia, and 7) CMV viremia.

Results: 70 patients received rituximab and ATG (Ritux) and 39 received ATG alone (Control). The Ritux group were (numerically) younger, more sensitized, received kidneys with a longer cold ischemia time, and lower kidney donor profile index. ATG doses were similar. The majority were deceased donor transplants. 1-year patient and death censored graft survival, mean GFR, incidences of BK viremia and CMV viremia were similar for Ritux and Control. 2 patients with primary graft non-function (1 in each group) and 1 patient with early posttransplant death (in Ritux) were excluded from the remaining outcome analyses (Table 1).

Conclusions: The addition of rituximab to ATG as induction for hypersensitized patients appears to be safe and is associated with excellent 1-year outcomes in patients with high panel reactive antibodies (>80%)

Table 1

PO2578

Risk Factors and Outcomes of Acute and Refractory Antibody-Mediated Rejection

Allyson Hart,1 David P. Schladt,2 Robbin F. Itzler,1 Ajay K. Israni,1 Bertram L. Kasikse,21 Hennepin Healthcare, Minneapolis, MN; 2Chronic Disease Research Group, Minneapolis, MN; 2C3L Behring, King of Prussia, PA.

Background: Major gaps remain in our understanding of antibody-mediated rejection (AMR) after kidney transplantation. We examined incidence, risk factors, response to treatment, and effects on outcomes of locally-managed AMR at 7 transplant programs in the Long-Term Deterioration of Kidney Allograft Function (DeKAF) prospective study cohort.

Methods: Consecutive kidney or kidney-pancreas transplant recipients were enrolled in the DeKAF study from October 2005 through April 11, 2015. To determine the effect of AMR on death censored graft failure (DCGF), we performed Cox proportional hazards analyses including AMR as a time-dependent covariate.

Results: Among 3313 kidney and kidney-pancreas recipients, there were 194 with a first AMR episode during a mean 4.8±1.86 years of follow-up for the entire cohort. Mean time to first AMR was 0.97±1.17 years post-transplant. After adjusting for other risk factors, patients with AMR had 10 times the risk of DCGF compared to patients with no AMR (aHR 10.1, 95% CI 6.5-15.7). Among the 50 (25.8%) patients whose AMR was refractory to treatment, defined as ≥2nd AMR diagnosis within 100 days or no improvement in cGFR by 42 days, the HR for DCGF was 7.5 (2.2-25.6, P=0.0013) in the 1st 180 days post biopsy; 3.8 (1.4-9.8, P=0.007) in the 1st year post biopsy, and 1.6 (0.9-3.0, P=0.11) at any time during follow-up compared to patients whose AMR responded to treatment.

Conclusions: Patients with AMR had substantially greater risk of DCGF compared to patients without AMR. While patients with refractory AMR were more likely to lose their graft compared to non-refractory cases in the first year following the AMR diagnosis, the likelihood of graft survival after that year was the same regardless of response to treatment.

PO2579

Allograft Loss and Patient Death Among Kidney Transplant Recipients: Is Therapy Nonadherence the Underlying Perpetrator?

Kartik Kalra, Puneet Sood, Rajil B. Mehta, Chethan M. Puttajarappa, Christine Wu, Sundaram Hariharan, Nirav A. Shah. University of Pittsburgh Medical Center, Pittsburgh, PA.

Background: To ascertain causes of allograft dysfunction, loss and death in a cohort of kidney transplant patients.

Methods: Retrospective cohort study, 943 patients with isolated kidney transplants between years 2013-17 were analyzed for the following transplant outcomes: 1. Death-censored allograft loss 2. Graft dysfunction 3. Death.

Results: 80 of 943 (9%) patients died while 63 (7%) lost their graft and 38 (4%) suffered allograft dysfunction. Death- Death was attributed to a combination of infection (29%), Cardiovascular (CV) disease (29%) and malignancy (12%), a significant proportion of patients who died from either CV disease (43%), infection (26%) or malignancy (20%) had prior biopsy proven T-Cell Mediated Rejection (TCMR) in 1st post-transplant year.

Graft Loss- In this cohort TCMR (39%) was the most widespread factor contributing to allograft loss. While Infection (17%) and surgical causes (14%) were the next common associations, donor related disease accounted for 2% of graft losses.

Graft Dysfunction- TCMR (42%) was strongly associated with allograft dysfunction in our patient cohort. The other factors associated with Allograft Dysfunction included a). Infection (21%) b). Donor Related causes (11%) and c). Other Causes (15%). Surprisingly ABMR was only noted in 11% of patients with allograft decline. Rejection and Non-Adherence- As TCMR was a common contributing factor to all the three hard outcomes in our study cohort, we examined the factors associated with TCMR. 40% of patients with TCMR were found to be non-adherent (defined by > 3 consecutive sub- therapeutic CNI levels, clinic no shows and poor adherence to regular lab draws). Importantly, patients who were non adherent were significantly younger (mean age 38 vs 55 yrs; p<0.0001) and a greater proportion of them were of African American (47% vs 22%;p<0.05) compared to those who were adherent to therapy.

Conclusions: While the causes of death, early allograft loss and dysfunction were diverse, TCMR was the most dominant contributor. Non-Adherence was strongly associated with TCMR and was more common in younger patients and those with African American ethnicity. Addressing non adherence in this cohort of patients early with novel interventions could be a key to optimizing patient outcomes in this high risk cohort.

PO2580

Identifying the Causes for Kidney Allograft Failure

Background: Since it has been proposed that several causes (C) can contribute to graft loss (GL), we analyzed transplant (Tx) recipients in our center and attributed a C to each persistent decline in renal function, finally leading to GL.

Methods: We retrospectively analyzed 1477 Tx, transplanted between 1997 and 2017 in a single center, of which 303 progressed to GL. An adjudication committee consisting of 3 physicians evaluated biopsies, laboratory data and medical history. Nonreversible decreases in renal function were attributed to primary and secondary C.

Results: Overall graft survival for all patients is 93.7% for 1 year, 80% for 5 years and 60.6% for 10 years. The most frequent C leading to GL were intercurrent medical events in 36.3%, followed by T-cell mediated rejection (TCMR) in 34% and antibody-mediated rejection (ABMR) in 30.7% (table1). For primary C, ABMR (21.5%) was the leading C, followed by medical events (21.1%) and TCMR (12.9%). As expected, we observed an increasing relevance of ABMR in late GL (figure 1). Over 50% of GL had >1 C.

Conclusions: Analyzing GL, we observed that >50% were multifactorial. Our results show a significant role of TCMR in GL. Additionally, we were able to attribute medical events to GL in 36.3% of Tx and to highlight the role of ABMR in late GL.
PO2581

Assessing Cumulative Immunosuppressive Drug Exposure: Metrics, Outcomes, and Implications for Kidney and Non-Kidney Transplant Patients

Cavizhahen Skanthan, Emily Nguyen, Lakindu Somaweera, Madhumitha Rabinudranath, Olusegun Famure, Joseph Kim. University Health Network, Toronto, ON, Canada.

Background: Immunosuppressive drugs are used in the long-term management of post-transplant patients to prevent rejection of transplanted organs. Lacking in prior qualitative systematic review on this topic, we aimed to characterize the metrics used to measure cumulative immunosuppressant exposure and their associated outcomes in kidney and non-kidney transplant patients.

Methods: We conducted a literature search using search terms related to immunosuppressants and cumulative exposure in Ovid MEDLINE, Ovid EMBASE, Cochrane CENTRAL, and Cochrane Database of Systematic Reviews. No date restrictions were applied. An additional search was performed on Google Scholar and references of studies included in the primary search were screened. Studies were limited to the English language with adult human transplant patient populations. Study risk of bias was assessed using the Quality in Prognostic Studies Tool where each domain was rated as low, medium, or high risk of bias.

Results: A total of 29 articles were included in our qualitative synthesis. Kidney transplant populations account for 12 (41%) of the studies in our analyses. Fifteen of the articles (51%) calculated the total dose of immunosuppression over the treatment period while 9 (31%) used long term area-under-the-curve (LT-AUC) of trough level concentrations to quantify cumulative immunosuppression exposure. Nine articles found certain cumulative exposure metrics to be predictive of adverse outcomes such as decreased kidney function, cancer recurrence, and bone fractures. Furthermore, an adequate mycophenolic acid LT-AUC was associated with a decreased risk of allograft rejection, while cumulative corticosteroid exposure was not associated with allograft rejection.

Conclusions: This review analyzed a comprehensive set of articles and metrics that predict long-term outcomes of immunosuppressants in transplant patients. The wide variety of metrics studied highlight the lack of agreement on the best measures of drug exposure in transplant patients. Although certain metrics may demonstrate an association with outcomes, future studies should investigate the predictive power and validation of these metrics.

PO2582

Fludrocortisone Corrects Tacrolimus-Associated Hyperkalemia in Renal Transplant Patients

Rouvick Ganga, Virginia A. Quan, Mysore K. Phanish. Epsom and Saint Helier University Hospitals NHS Trust, London, United Kingdom.

Background: Hyperkalemic metabolic acidosis is commonly observed following kidney transplantation. This is often due to calcineurin inhibitors which are known to cause type 4 renal tubular acidosis either due to hyporeninemic hypoaldosteronism or due to direct effect on aldosterone responsive potassium secretion in the distal nephron.

Methods: We report 5 post-renal transplant patients (5 males) on tacrolimus with hyperkalemia treated with daily doses of either 50 mcg (n=3) or 100 mcg (n=2) of fludrocortisone. We retrospectively collected data at 3 time points before and after fludrocortisone with serum concentrations of sodium, potassium, bicarbonate, creatinine and tacrolimus as well as eGFR and blood pressure (BP). We recorded emergency admissions and length of stay (LoS) for treatment related to hyperkalemia. Data are presented as mean +/-SD and analysed with a paired students t-test.

Results: Pre and post-fludrocortisone serum concentrations for potassium was 6.3 ± 0.3 mmol/L and 5.1 ± 0.3 mmol/L (p=0.002); venous bicarbonate 18.4 ± 1.8 mmol/L and 20.4 ± 2.0 mmol/L (p=0.108); sodium 135 ± 1.6 mmol/L and 135 ± 2.2 mmol/L (p=0.873); creatinine 184 ± 12.2 mmol/L and 155 ± 10.6 mmol/L (p=0.058); eGFR 39 ± 3.4 ml/min and 47 ± 4.2 ml/min (p=0.035); blood tacrolimus levels 9.8 ± 2.1 ng/mL and 11.2 ± 1.0 ng/mL; BP was 133/69 ± 12.9 mmHg and 129/70 ± 8.6 mmHg before and after fludrocortisone respectively. We were able to either reduce or stop sodium bicarbonate after starting fludrocortisone due to increase in serum bicarbonate levels. Prior to fludrocortisone there were 6 episodes of serum potassium greater than 6.5 mmol/L, of which 3 patients required admission for hyperkalemia management, with LoS 1-3 days. The majority occurred with tacrolimus levels in target range. Reduction in potassium levels to ‘safe levels’ were noted within 24-48 hours of starting fludrocortisone.

Conclusions: Treatment of hyperkalemic metabolic acidosis with fludrocortisone resulted in rapid normalization of serum potassium. There were no adverse effects on BP, serum sodium levels or clinical evidence of fluid retention. Instigation of fludrocortisone prevented emergency admissions for treatment of hyperkalemia and allowed the clinicians to run adequate tacrolimus levels. Fludrocortisone can be a cheap, safe and effective option for the treatment of hyperkalemia in renal transplant patients on tacrolimus.
**PO2583**

Changes in Serum Klotho in Kidney Transplant Recipients and Prognostic Marker for Allograft Function: A Systematic Review and Meta-Analysis

**Juan A. Medina,1 Charat Thongprayoon,2 Napat Leecaphorn,1 Javier A. Neyra,1 Pradeep Vaitla,1 Franco H. Cabeza Rivera,1 Michael A. Mao,1 William J. Black,1 Division of Nephrology and Hypertension, Department of Medicine, Mayo Clinic, Rochester, MN; 2Department of Medicine, Mayo Clinic, Jacksonville, FL; 3Division of Nephrology, Department of Medicine, University of Kentucky College of Medicine, Lexington, KY; 4Renal Transplant Program, University of Missouri-Kansas City School of Medicine/Saint Luke’s Health System, Kansas City, MO.

**Background:** Klotho is a well-known anti-aging factor that regulates systemic phosphate metabolism. Mutation of klotho in mice can lead to phenotypes resembling human aging. Since klotho expression is highest in the kidney, patients with advanced chronic kidney disease have progressive decline in klotho levels. However, changes in serum klotho levels in kidney transplant (KTx) patients and its prognostic significance on allograft function remain unclear.

**Methods:** A literature search was conducted using MEDLINE, EMBASE and Cochrane Database from inception through October 2019 to identify studies evaluating 1) change in serum klotho levels after KTx, 2) klotho levels among KTx vs non-KTx patients, and 3) prognostic significance of klotho levels on allograft function after KTx.

**Results:** Study results were pooled and analyzed utilizing random-effects model.

**Conclusions:** There is a significant increase in serum klotho levels after KTx. There is potential role of klotho levels as prognostic marker for renal allograft function.

---

**PO2584**

Braving the Storm: Cytokine Release Syndrome with Rabbit Antithymocyte Globulin Therapy after Kidney Transplant

**Himmat S. Brar, Franco H. Cabeza Rivera. University of Mississippi Medical Center, Jackson, MS.**

**Introduction:** Cytokine release syndrome (CRS) is an acute systemic inflammatory syndrome associated with chimeric antigen receptor (CAR)-T cell therapy or therapeutic antibodies. CRS can present with a variety of symptoms ranging from mild flu to severe life-threatening manifestations of shock, vascular leakage, DIC and multi-organ failure. We present a case of a CRS following rATG induction.

**Case Description:** A 29-year-old female with a history of T1 DM s/p kidney/pancreas transplantation 12 years experienced the rejection of transplanted kidney 1 year back. Her home immunosuppression included Tacrolimus, MMF and Prednisone. She underwent a kidney retransplant from a living donor. The induction immunosuppression consisted of rabbit anti-thymocyte globulin (ATG), methylprednisolone and MMF. Two hours after the rATG infusion (1.5mg/kg) on day 1 of transplant; she developed breathing difficulty, temp of 102.7, RR of 23, HR of 160 and fall in BP to 108/55 mmHg. Lab work showed a drop of Hb from 11.4 to 9, platelets from 187 to 126 and WBC from 17 to 9.8. CXR was unremarkable. ECHO showed normal cardiac function. LE Doppler was unremarkable.

**Discussion:** CRS is an inflammatory cascade that develops within minutes to hours after immunotherapy. The case emphasizes the successful rapid recognition and proper management of CRS in preventing the patient decapsulation. The massive cytokine release triggers an inflammatory response leading to capillary leakage, severe hypotension and respiratory failure. The management differs from usual shock as the aggressive blood pressure support is not enough. Fluids and inotropes were given. Steroids and pressors are the mainstay of therapy and should be administered early. The treatment is largely supportive with ventilation for respiratory failure and steroids for inflammation.

---

**PO2585**

Proton Pump Inhibitor Prevalence and Documented Indication in a Small Kidney Transplant Program

**Abdulrahman Alkandari, Frances Macleod, M. Khaled Shamseedin. Queen’s University, Kingston, ON, Canada.**

**Background:** Proton pump inhibitors (PPIs) are commonly prescribed post kidney transplantation, and their use was prevalent in 44.48% of recipients. Prolonged exposure to PPIs could be associated with renal and non-renal adverse outcomes, including hyperammonaemia and hip fracture (OR: 1.39, 95% CI: 1.04-1.84). The objective of this report is to evaluate the prevalence and the documented indication of PPI use in our kidney transplant program, while exploring the potential PPI withdrawal and GERD recurrence in a future Quality Improvement (QI) project.

**Methods:** This is a retrospective study to assess the prevalence and the documented indications of PPI use among all of kidney transplant recipients in our program by March 31st, 2020. The primary variables were the prevalence of PPI use and the percentage of patients with documented indication of PPI use in our Health Information System (HIS).

**Results:** Out of 202 kidney transplant recipients, 113 (55.9%) patients were on PPIs (Mean age 58 years, Male 68 (60.2%), mean post-transplant longevity 106 months, compared with 12 (5.9%) patients on H2 blockers. Thirty three (29.2%) patients who used to be on H2 blockers were switched to PPI in late 2019 due to contaminated and backordered ranitidine resulting in an adjusted prevalence of PPI use of 39.5% (Figure 1).

The indication of PPI use was documented in our HIS as gastro-esophageal reflux disease (GERD) in 53 (46.9%) patients, and as peptic ulcer disease (PUD) in 9 (8%) patients, while its indication was undocumented in 51 (45.1%) patients.

**Conclusions:** PPI use was prevalent among our kidney transplant recipients similar to other studies. Due to its association with multiple adverse outcomes, better documentation of its indication in the medical record is required. Consideration to withdraw PPI in our kidney transplant recipients and to reassess the risk of GERD recurrence will be assessed in a future QI project.

---

**PO2586**

Unexpected Recurrence of Undiagnosed ANCA-Associated Vasculitis in a Kidney Transplant Recipient

**Ruchi H. Naik, Heidi M. Schaefer, Saed Shawar. Vanderbilt University Medical Center, Nashville, TN.**

**Introduction:** ANCA Associated Vasculitis (AAV) is one of the leading causes of End-stage Kidney disease (ESKD). The relapses of AAV after kidney transplant are relatively rare. As per the literature, the positive ANCA status in not a contraindication for transplant and patients usually get transplant once in clinical remission. Here, we are describing a unique case of ESKD due to renal limited AAV which was diagnosed retrospectively after the development of the recurrence two months post-transplant.

**Case Description:** A 69 years old Caucasian female with ESKD presumed due to hypertension received a deceased donor kidney transplant in Oct 2019 after being on dialysis for 4 years. She received almtuzumab for induction followed by tacrolimus, mycophenolate mofetil, and prednisone for the maintenance immunosuppression. Her immediate post-transplant course was complicated by delayed graft function and her creatinine never went down below 2 mg/dl. Allograft biopsy was planned after 2 months due to persistent microscopic hematuria with progressive sub nephrotic range proteinuria. The immuno-histopathology and electron microscopy was suggestive of pauci-immune crescentic GN. Her serology workup was positive for ANA, ANCA with high titters of MPO. She lacked any other systemic involvement, and drugs induced ANCA was ruled out. She was treated with a pulse dose of methylprednisone and one dose of rituximab. Gradually her creatinine improved to 1.37 mg/dl with down trending MPO antibody titers within 6 weeks. The review of her chart retrospectively showed clinically asymptomatic ANCA positivity with high MPO titters 3.5 years back, supportive of recurrence of AAV more than De novo AAV post-transplant.

**Discussion:** Physician should always be vigilant about the recurrence of the primary disease after transplant, especially when patients have undiagnosed primary kidney disease like AAV, where early diagnosis and treatment in the early stage of the disease is important to optimize results of renal transplantation. A randomized prospective study is needed to answer the question whether the ANCA positivity at the time of transplant adversely affect the outcomes.
**PO2587**

**A Case of Porphyria Cutanea Tarda After Kidney Transplant**
The University of Utah School of Medicine, Salt Lake City, UT.

**Introduction:** Porphyria cutanea tarda (PCT) is the most common subtype of porphyria and can be associated with kidney failure due to reports of kidney transplantation curing the disease. We report the case of a patient who had previously undergone kidney transplantation and developed PCT after transplantation.

**Case Description:** A 40-year-old man with end stage renal disease due to unknown chronic glomerulonephritis status post kidney transplant 4.5 years ago was admitted with non-healing blisters on both hands. Patient initially presented one month earlier with similar symptoms and was diagnosed with bullous impetigo due to methicillin resistance staphylococcus aureus. At that time, he was treated with vancomycin followed by trimethoprim-sulfaethoxazole (TSM-SMX) for a total of 14 days. He was also noted to have cytomegalovirus viremia which was treated with valganciclovir. Patient reported ongoing development of lesions despite antibiotic treatment and presented for follow-up where he was noted to have an acute kidney injury and hyperkalemia. At presentation his medications included mycophenolate sodium, tacrolimus, prednisone, triamcinolone cream and mupirocin ointment. There was no family history of skin disease and he did not drink alcohol. He underwent skin biopsy which was consistent with porphyria or pseudoporphyria. Urine and plasma porphyrins were checked showing elevated uroporphyrin and also elevated heptacarboxyl, hexacarboxyl and pentacarboxyl porphyrins with normal coproporphyrin I and III consistent with PCT.

**Discussion:** PCT is the most common form of porphyria and is associated with hepatitis C, iron overload, estrogen administration and alcohol use. It has also been associated with hemodialysis often with resolution at the time of kidney transplantation. However, elevated iron stores are often present in kidney transplant patients and PCT can be misdiagnosed as bullous impetigo as it was in this case.

**PO2589**

**What Is the Safe Anti-A2 Titer for a Successful A2-Incompatible Kidney Transplantation?**
Yorgi Al Azzi, Pablo Loarte Campos, Gayatri D. Nair, Maria Ajaymi, Luz E. Liriano-Ward, Cindy T. Pynadath, Purna Bindu Nandigam, Enver Akalin. Montefiore Medical Center, Bronx, NY.

**Background:** The new kidney allocation system implemented in December 2014 allowed for use of A2/AB donors to B recipients. However, there is no mandate by UNOS regarding what anti-A2 titers are acceptable. We aimed to investigate the safety of kidney transplant in patients with anti-A2 titers equal or less than 1/4.

**Methods:** We performed 41 A2-incompatible kidney transplants at our institution if pre transplant anti-A2 titers were equal or less than 1/16. All patients received anti-thymocyte globulin induction. Patients with donor-specific anti-hLA-antibodies (DSA) received pretransplant immunosuppressive therapy.

**Results:** Of the 41 recipients, 85% were male, 48% African-American, with a median age of 53 (20-73) years. There were 38 deceased donor renal transplants and 3 living related. Median donor age was 42 (16-65) and median KDPI was 52 (2-86). Twenty-one patients had PRA 0% and 8 had pre transplanted DSA. Pretransplant anti-A2 titers were 1/2 in 16, 1/4 in 9, 1/8 in 6, and 1/16 in 5 and too weak to titrate in 5 recipients. During a median follow-up of 33 months (6-57) patient and graft survival were 100% and 90.2% respectively. Twelve patients underwent a clinically indicated kidney biopsy at a median 28 days post transplant (6-190). There was one case of acute T cell mediated rejection type IIA, and one chronic antibody-mediated rejection which was due to non-compliance leading to graft loss. Interestingly C4d positivity was seen in 9 biopsies, of which 8 did not have any findings of antibody mediated rejection and no microvascular inflammation. Median serum creatinine level at last follow up was 1.3 mg/dL (0.6-3.2) and only 3 patients had spot urine protein/creatinine more than 1 g/day.

**Conclusions:** A2-incompatible transplantation appears to be safe in patients with anti-A2 titers equal or less than 1/16 with or without DSAs and excellent short-term kidney allograft outcomes. C4d positivity is frequent in allograft biopsies without acute rejection suggesting accommodation to the allograft.

**PO2590**

**Post-Transplant Outcomes for Highly Sensitized Kidney Transplant Recipients with Non-Highly Sensitized Recipients in the Era of the New Kidney Allocation System: A Single-Center Case-Control Comparison**
Gaurav Agarwal,1,2 Darnell Mompoint-Williams,1,2 Song C. Ong,1,2 Jayne E. Locke,1,2 Vinceeta Kumar,1,2 University of Alabama at Birmingham
1The University of Alabama at Birmingham, Birmingham, AL; 2The University of Alabama at Birmingham Comprehensive Transplant Institute, Birmingham, AL.

**Background:** The new UNOS kidney allocation system (KAS) of December 2014, gives substantial priority points to highly sensitized (HS) adult kidney transplant recipients (KTR) with cPRA of 99% or higher. There is a concern of worse post-transplant outcomes in HS KTR compared to non-HS KTR. When comparing pre-KAS to post KAS, similar 3-year patient and graft survival has been reported in HS KTR. The comparative outcomes of HS KTR to non-HS KTR in the past KAS era are unknown.

**Methods:** We studied outcomes in HS adult kidney transplant recipients (KTR) and compared them to non-HS KTR in the post KAS era. We included all recipients of deceased donor kidney transplants at the University of Alabama at Birmingham, from December 2014 to March 2020. HS patients were defined as those with cPRA 99% or higher. The HS patients were matched 1:2 with non-HS patients on age, sex, and time of transplantation. A Kaplan Meier analysis was performed for patient survival and the combined endpoint of graft and patient survival.

**Results:** A total of 717 deceased donor kidney transplants were performed during the study period, of which 106 HS KTR were identified. There is concern of worse post-transplant outcomes in HS KTR compared to non-HS KTR. When comparing pre-KAS to post KAS, similar 3-year patient and graft survival has been reported in HS KTR. The comparative outcomes of HS KTR to non-HS KTR in the past KAS era are unknown.

**Conclusions:** We aimed to investigate the safety of kidney transplantation in patients with anti-A2 titers equal or less than 1/16. The HS patients were then compared with 228 matched non-HS deceased donor controls.

**Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.**
The matched controls had a median cPRA of 0% (IQR 0-29.5%). There was no difference in death (p=0.17) or combined endpoint of death or graft survival (p=0.35) in the two groups (figure 1).

Conclusions: HS patients have similar mortality and graft survival as compared with non-HS controls. The results of our study support continuing to give HS patients priority in organ allocation.

PO2591
Who Is at Risk for a Transplant Nephrectomy After Graft Loss?
Peter E. Thorne, Everly Ramos, Laura Binari, Gneect S. Kochar, Thomas G. Stewart, Rachel C. Forbes, Saed Sawar, Anthony J. Langone, Khaled Abdel-Kader, Beatrice P. Concepcion. Vanderbilt University Medical Center, Nashville, TN.

Background: Patients with failed kidney transplants who subsequently develop clinical symptoms such as fever, allograft pain and gross hematuria usually require a transplant nephrectomy to alleviate symptoms. Identifying patients at risk for a nephrectomy after graft loss may aid clinical decision-making and care at time of, and after graft loss.

Methods: We retrospectively reviewed all patients with death-censored graft loss (DCGL) from 1/2000 to 6/2018 at a single center. We collected baseline demographic and clinical characteristics at time of transplant, at time of, and after DCGL by manual chart abstraction. Data were analyzed using summary statistics. Predictors for nephrectomy were determined a priori. A Cox proportional hazards model was used to quantify the association of age, race, gender, body mass index (BMI) at time of graft loss, diabetes, acute rejection as cause of graft loss, and use of prednisone with the risk of nephrectomy.

Results: The study included 333 patients with DCGL of whom 75 (23%) underwent a transplant nephrectomy. Median (IQR) time from graft loss to nephrectomy was 135 (70, 267) days. Among 292 patients without missing data, baseline and transplant characteristics were as follows: age at transplantation 45 (36, 57), 59% male, 40% black, 20% diabetic, 53% with a deceased donor, 83% on calcineurin-based immunosuppression (CNI-IS), 71% on prednisone. Twenty four percent and 69% of patients lost their graft due to acute rejection and chronic allograft nephropathy, respectively. At the time of DCGL: BMI was 25.9 kg/m² (22.7, 31.4), SCR 7.5 mg/dl (5.6, 9.6), albumin 3.3 (3.0, 3.8), 86% on CNI-IS, 91% on prednisone. In the Cox model, black race was associated with more than twice greater risk of nephrectomy compared to non-blacks (HR 2.4, 95% CI 1.3-4.3, p<0.01) but this did not reach statistical significance.

Conclusions: Transplant nephrectomies are common after graft loss and black race is associated with increased risk. Closer monitoring of these patients after graft loss may aid clinical decision-making and care at time of, and after graft loss.

PO2593
Evaluation of Reproductive Care Provided to Adolescent Patients in Pediatric Nephrology Clinics
Shiyanne Helley,1 Noel Howard,1 Salem Almanii,2 Isabelle Ayoub,2 Michelle A. Hladunewich,1 Michelle N. C. Slaughnnessy,3 Shikha Wadhwani,4 Jarcy Zee,5 William E. Smoyer,2 Scott E. Wenderfer,1 Katherine Twombly,1 Tetyana L. Vasylyeva,1 1Texas Tech University Health Sciences Center, Amarillo, TX; 2The Ohio State University Wexner Medical Center, Columbus, OH; 3University of Toronto, Toronto, ON, Canada; 4University College Cork National University of Ireland, Cork, Ireland; 5Northwestern University Feinberg School of Medicine, Chicago, IL; 6Arbor Research Collaborative for Health, Ann Arbor, MI; 7Nationwide Children’s Hospital, Columbus, OH; 8Baylor College of Medicine, Houston, TX; 9Medical University of South Carolina, Charleston, SC.

Background: An increasing number of adolescents are living with end-stage renal disease (ESRD) or chronic kidney disease (CKD) in the US. Therefore, it is important that nephrologists can manage reproductive and women’s health issues in adolescents with CKD. In this study, we aimed to determine the confidence levels of nephrologists in the US in managing women’s health issues in adolescent females with CKD.

Methods: Using Qualtrics Online Survey Platform, a survey was distributed by email to members of the Pediatric Nephrology Research Consortium. The survey contained 19 questions pertaining to provider demographics, training, current practice, frequency of documenting and/or discussing women’s health issues, and level of confidence in managing women’s health issues in adolescent female patients.

Results: Seventy-five nephrologists participated, with a majority practicing in academic centers (88%). For most providers, adolescents comprised 25-74% of all patients. Ninety-eight percent denied formal training in women’s health or obstetric nephrology. History of pregnancy termination/loss, last menstrual period (LMP), contraceptive use, sexual activity, number of sexual partners, and history of sexually transmitted infections were infrequently documented. Most providers documented discussions about risks of teratogenicity with use of ACEi/ARBs or mycophenolate and risks of infertility and fertility-preserving options with use of cyclophosphamide. Most providers weren’t comfortable managing pregnant adolescents and referred them to adult nephrologists. Most were uncomfortable discussing fetal risks with pregnancy in CKD. While most were confident discussing barrier methods, they were much less confident discussing oral contraceptives and long-acting reversible contraceptives (LARC).s.

Conclusions: Sexual development and pregnancy appear not to be a focus of nephrologists caring for adolescent females with CKD. Providers also appeared to have a low level of confidence in discussing and managing fertility and pregnancy-related issues in adolescents. Nephrology training needs to incorporate focused women’s health content to improve healthcare delivery to adolescent girls.
PO2594
Reproductive Health in Kidney Transplant Recipients
Andrea G. Kattah, Fernando G. Cosio, Vesna D. Garovic. Mayo Clinic Minnesota, Rochester, MN.

Background: Women with advanced chronic kidney disease develop menstrual irregularities and infertility that can improve after kidney transplant. However, some women do not have menstrual cycles return after transplant and pregnancy rates are lower than in the general population, which could be due to a combination of biologic and social factors.

Methods: We sent a survey on reproductive health to all women aged 18 to 44 at the time of transplant at all 3 Mayo Clinic sites between 1996 and 2014. We sent a second survey to all non-respondents from the first mailing and then called all remaining women to ask for their participation. We included questions on menstrual cycles, pregnancy, and menopause. Parity at the time of transplant was determined by chart review.

Results: There were 816 unique women, aged 18 to 44 at the time of transplant, in the period from 1996 to 2014. After excluding women who had passed away (n=91), and those with no current address or living outside the US (n=10), there were 715 eligible women and 190 responded (26.6% response rate). Respondents were more likely to be white and to have had a pregnancy post-transplant. Only 10% of women reported a pregnancy post-transplant, though 14.2% reported actively pursuing pregnancy at the time of the chart review. Nearly half (42.1%) of women said they were advised not to get pregnant, most often by a nephrologist. There were 61 pregnancies post-transplant, of which 80.1% were planned pregnancies. The majority of pregnancies resulted in livebirths (57%), and miscarriage occurred in 39% of pregnancies. Anemia occurred in 34.2% of women pre-transplant, and 23% of these women did not have cycles return after transplant. The median (interquartile range) age of menopause was 44.5 (36-49) years.

Conclusions: While only 14.2% of respondents reported actively pursuing pregnancy after transplant, nearly half said they were advised not to pursue pregnancy, often by their nephrologists, which could in part explain low pregnancy rates in the kidney transplant population. While anemia prior to transplant occurred in the minority of women, 23% of these women did not have menstrual cycles return post-transplant. Furthermore, the median age of menopause was much earlier than the general population. These findings suggest that kidney disease and/or transplantation itself may impact long-term gonadal function, which should be a target of future study.

PO2595
Menstrual Irregularities and Subfertility in Women with Glomerular Disease

Background: Women with CKD are known to have high rates of irregular menses and subfertility (an extended period of unwanted non-conception). Those with glomerular disease may be at particularly high risk due to exposure to immunosuppression, such as cyclophosphamide, that may lower fertility.

Methods: A women's health survey was distributed to women ages 18-65 in the Glomerular Disease Collaborative Network, a longitudinal research registry in the southeastern United States. Descriptive statistics were employed to assess responses.

Results: The survey was completed by 192 women (response rate 16%) with median age 48 (34-57 interquartile range(IQR)) and BMI 28 (24-35 IQR). The most common diseases were IgA nephropathy/vasculitis (22%), Lupus nephritis (20%), ANCA vasculitis (18%) and FSGS (16%). At the time of the survey, 17% had a kidney transplant or required dialysis. Table 1 describes self-reported menstrual cycle length and permanent cessation of menses by age group. Of those over age 45, 41% reported permanent cessation of menses had occurred at a 44 years old. Cyclophosphamide use was reported by 63 of 192 (33%), and their fertility preservation methods included leuprolide (6%, 10%), and oocyte cryopreservation (1, < 2%). One in four women (50/192, 26%) reported a median (interquartile range) age of menopause was 44.5 (36-49) years.

Conclusions: Women with glomerular disease and/or vasculitis had high rates of irregular menstruation and early menopause which may contribute to subfertility. Our data is limited as we do not know GFR, nor the timing or amount of cyclophosphamide prescribed. Response bias from women with a positive history may have also played a role. Future efforts should elucidate reproductive endocrinology utilization and success in this population.

Buffy Coat Methylation Is Representative of Methylation Patterns in White Blood Cell Types in Normal Pregnancy
Ranim Ghanrawi,1 Natasa Milic,2 Sonja Suvakov,1 Wendy White,1 Vesna D. Garovic.1 Mayo Clinic Minnesota, Rochester, MN; 2Medicinski fakultet Univerzitet u Beogradu, Belgrad, Serbia.

Background: Epigenetic changes through DNA methylation are increasingly identified in renal diseases and hypertensive disorders. Our previous studies identified an altered methylation pattern in preeclampsia compared to normotensive pregnancies. Epigenetic studies typically use buffy coat- a heterogenous cell population- that varies throughout pregnancy and could potentially interfere with DNA methylation results. The objective of the current study was to assess to what extent the buffy coat methylation is representative of the distinct cell types that it contains namely polymorphonuclear leukocytes(PMN) and lymphocytes(LYM) in normal pregnant women.

Methods: We performed a pairwise comparison of the differential methylation in the buffy coat, the polymorphonuclear fraction and the lymphocytic fraction drawn from the same individual in normoretensive pregnant women (n=29) within the 24 hours prior to delivery. We analyzed 412481 cytosine-guanine (CpG) sites using an Illumina Human Methylation450 BeadChip.

Results: The three pairwise comparisons yielded a small number of probes that are differentially methylated. After multiple testing corrections, the smallest number of differentially methylated probes was found when comparing the buffy coat to the polymorphonuclear group (2.96%). Pathway analysis of the differentially methylated probes identified a matched process involved in leukocyte lineage. The differentially methylated CpG sites preferentially affected the open seas and shelf regions that have little effect on epigenetic regulation.

Conclusions: The buffy coat DNA methylation profile is representative of the PMN and LYM fractions on an Illumina Human Methylation450 BeadChip. The use of buffy coat is an acceptable approach for DNA sampling in DNA methylation studies and separation is only needed when studying lineage specific diseases.

PO2597
Pregnancy Outcomes in Women with AKI
Silvi Shah, Kathleen Harrison, Annette Christianson. University of Cincinnati, Cincinnati, OH.

Background: Acute kidney injury (AKI) during pregnancy is a public health problem and is associated with maternal and fetal morbidity and mortality. Literature concerning pregnancy outcomes in women with AKI is scarce.

Methods: We evaluated a retrospective single-center cohort of all women who delivered infants between 2012-2019 at our center (N=21,038) to assess the AKI rate and whether the history of AKI during pregnancy was associated with adverse maternal and fetal outcomes. Using multivariate logistic regression models, we determined factors associated with AKI during pregnancy and is associated with maternal and fetal morbidity and mortality. Literature concerning pregnancy outcomes in women with AKI is scarce.

Results: Overall, 109 deliveries were identified with AKI during pregnancy. AKI rate was 0.5%. The mean age of women was 28 years, 55% were black, and 36% were white. 25% had a history of diabetes and 24% had a history of hypertension. With regards to maternal outcomes, 46% had preeclampsia, 27% had gestational diabetes, 40% had gestational hypertension, and 57% had cesarean section deliveries. Maternal mortality was 4%. With regards to fetal outcomes, among women with AKI during pregnancy, 19% had preterm deliveries, the live birth rate was 85%, the stillbirth rate was 5%, and neonatal mortality was 5%. Diabetes and hypertension were associated with a higher adjusted likelihood of AKI during pregnancy (OR, 4.5; 95% CI, 2.87-7.50 and OR, 5.97; 95% CI, 1.63-9.80 respectively). In the adjusted model, AKI during pregnancy was associated with a 5.6-fold higher likelihood of preeclampsia (OR, 5.57; 95% CI, 3.70-8.39), 2.2-fold higher likelihood of cesarean section (OR, 2.21; 95% CI, 1.50-3.27), 2-fold higher

PO2599
Pregnancy Following Kidney Transplantation: Experience of a Tertiary Renal Obstetric Service Between 1996 and 2020
Sarah Gleeson,1 Michelle Willicombe,1,2 Sevada Hassan,1 Daniel Christiadi,1 Philip Webster,1,2 Liz Lightstone.1,2 Imperial NHS Healthcare Trust, London, United Kingdom; 1Imperial College London Faculty of Medicine, London, United Kingdom.

Background: Compared with dialysis, fertility & pregnancy outcomes are more favourable following transplantation. However, pregnancies post transplant renal allocation challenging with a risk of adverse maternal & obstetric outcomes.

Methods: All transplanted patients attending the renal obstetric clinic were identified from an in-house database. Further data were collected from their health records.

Results: We identified 52 pregnancies in 39 women. The mean age at delivery was 33±3 years. 57% were white, 17% black & 21% Asian. The cause of ESKD was glomerulonephritis (46%), reflux (17%), unknown (other) (27%) & diabetes (10%). 3 patients (5%) miscarried & are not included in further analysis. The mean time from transplantation to pregnancy was 84±56 months. The mean follow up after delivery is 6±2.5 years. The mean gestational age at delivery was 39±2.8; at 6 months postpartum it was 39±2.5. The mean birth weight was 2400±588 grams. 24% were <10th percentile.

Conclusions: Pregnancy outcomes in patients with transplants are better compared with those on dialysis. Compared with complications still occur. The rate of preeclampsia (56%) is representative of the current literature & much higher than for women without transplants. Diagnosing preeclampsia in patients with pre-existing hypertension & proteinuria, as for many of our patients, remains challenging. In our experience, reflected here, there are relatively low rates of rejection & graft loss but high rates of obstetric complications. We believe these patients are ideally managed in a joint obstetric clinic.

PO2600
Prepartum 1,3-Butanediol Supplementation Does Not Prevent Onset of Superimposed Preeclampsia in the Dahl S Rat
Jeanne A. Ishimwe, Michael R. Garrett, Jennifer M. Sasser. University of Mississippi Medical Center, Jackson, MS.

Background: Chronic hypertension increases the risk of developing superimposed preeclampsia (PE). Previous reports showed that 1,3-Butanediol (BD) lowers blood pressure (BP) in male Dahl salt sensitive (S) rats and female S SHR(S) rats. The goal of this study was to test if attenuating hypertension before pregnancy through the placental period via BD prevents the onset of PE and improves kidney function.

Methods: Female Dahl S rats (a spontaneous model of superimposed PE, 11-16 weeks old) were divided into two groups; BD treated (20% via drinking water) and control (ad libitum water). Animals received BD for 7 weeks, baseline BP measurements (teleometry) were taken, and both groups were then mated. On gestation day (GD) 12, treatment was stopped because pilot studies showed that treatment reduced water intake during late pregnancy. Both groups were maintained on normal rodent chow (Teklad 7013, 0.3% Na; n=9/group). At GD18 (late pregnancy), urine artery resistance index (UARI) was measured via Doppler ultrasound, 24h urine was collected on GD19, and tissues were harvested on GD20. Statistical comparisons between groups were done by Student t-test and repeated measures ANOVA used for BP analysis.

Results: Mean arterial pressure was lower in the treated group at baseline (141.9±4.0 vs. 165.7±4.53 mmHg, p=0.0076), early (135.9±3.42 vs. 169.±4.55 mmHg, p=0.0003), mid (142.0±5.16 vs. 170.8±4.61, p=0.0048) but not late pregnancy (144.9±5.87 vs. 161.9±4.52 mmHg, p=0.1650). Treated dams had a lower UARI (0.71±0.02 vs. 0.81±0.02, p=0.0472) and a 5.7-fold higher likelihood of neonatal death (OR, 4.04; 95% CI, 1.60-10.20), and a 5.7-fold higher likelihood of preterm births (OR, 1.97; 95% CI, 1.22-3.16), 4-fold higher likelihood of stillbirths, and mortality. This finding increases our understanding and need for change in policies for the management of AKI during pregnancy.

878
hypervolemic hyponatremia due to nephrotic syndrome. She was placed on fluid restriction. Repeat serum sodium and 24 h urine protein to creatinine ratio (UPCR) were 118 mEq/L and 4.4 g/g creatinine, respectively. Her obstetrician decided to perform emergency delivery. Prior to oxytocin induction, she received 3% saline, 0.9% saline, and IV furosemide. Three hours after delivery, serum sodium was 125 mEq/L and UPCR was 0.2 g/g creatinine. Fluid restriction continued for the first 24 hours after delivery and her serum sodium remained stable. Over the next 24 hours, her serum sodium corrected to 138 mEq/L with liberalization of the fluid restriction.

**Discussion:** Hyponatremia in pregnancy may be due to antidiuretic hormone (ADH)-dependent factors, such as “reset” osmostat, diffuse vasodilation, nausea, and pain. Administration of oxytocin, which is structurally similar to ADH, can also reduce serum sodium. In preeclampsia, hyponatremia may occur due to decreased effective circulating volume secondary to antiangiogenic factors or nephrotic syndrome, non-osmotic release of ADH with consequent water retention, or SIADH. Worsening hypertension with end organ damage are severe features of preeclampsia often requiring emergent delivery, but severe hyponatremia is often overlooked as a severe feature. This case illustrates that patients with preeclampsia may develop severe hyponatremia, which improves after delivery. Refined guidelines should consider severe hyponatremia and its management in preeclampsia.

**Figure 1:** Clinical data & Jones stain showing glomerular basement membrane duplication, characteristic of TMA.

**PO2604**

**Hypereosmin Gravidarum-Induced Acute Tubular Necrosis: A Case with More Than Fivefold Rise in Serum Lipase Level Above the Upper Limit of Normal**

Samira Z. Chandra, 1,3 Bruna Tavares Garcia, 2 Belinda Jim, 2 Bangladesh College of Physicians and Surgeons, Dhaka, Bangladesh; 3Jacobi Medical Center, Bronx, NY; 4Dhaka Medical College and Hospital, Dhaka, Bangladesh.

**Introduction:** Hypereosmin gravidarum (HG) occurs in 0.3 to 10 percent of pregnancies with only 0.8 percent requiring hospitalization. HG usually starts within 4th to 6th week of gestation, peaks around 9th week and fades away between 16th to 20th gestational weeks. In some cases, HG may last until the third trimester. Here we are reporting such a case which was associated with serious complication like acute renal failure. Co-incidentally the patient was also found to have serum lipase level 5 times above the upper limit of normal (ULN). Since HG exerts multisystemic manifestations, the unusual pattern of raised serum lipase is often due to associated renal impairment.

**Case Description:** A 25-year old primigravida at 16th week of gestation was admitted for severe dehydration and acute kidney injury (S. Creatinine 5.1 mg/dl). She was suffering from HG since the beginning of her pregnancy. A month prior to this admission, the patient was hospitalized on multiple occasions for extreme nausea and blood-tinted vomiting. Her initial labs were suggestive of high anion gap metabolic acidosis (anion gap 31.9mmol/L). Urine electrolytes (Na+<20mEq/day, K + 29mEq/day, Cl - <20mEq/L) confirmed renal failure. Co-incidentally the patient was also found to have serum lipase level 5 times above the upper limit of normal (ULN). Since HG exerts multisystemic manifestations, the unusual pattern of raised serum lipase is often due to associated renal impairment.

**Discussion:** Patients presenting with nephrotic syndrome and hyponatremia ≥ 20 weeks gestation pose a diagnostic dilemma. Renal biopsy is necessary to distinguish PEC from GN but pathological diagnosis of TMA can lead to persistent diagnostic uncertainty. Measurement of circulating angiogenic factors can be useful, with sFLT-1:PlGF ratio > 38 supporting a diagnosis of PEC. Further validation and widespread availability of such testing is needed to assist in management of early pregnancy complications.

**Figure 1:** Clinical data & Jones stain showing glomerular basement membrane duplication, characteristic of TMA.

**PO2603**

**Proteinuria in Early Pregnancy: Role of sFLT-1:PlGF Ratio**

Nay Seif, Carla L. Ellis, Shikha Wadhwani. Northwestern University Feinberg School of Medicine, Chicago, IL.

**Introduction:** A 32-year-old nulliparous woman at 20.5 weeks gestation by in vitro fertilization was admitted for hypertension (HTN), proteinuria, and acute kidney injury. Exam was notable only for trace leg edema. Given nephrotic syndrome early in pregnancy and unremarkable hemolysis work-up (Figure 1A), there was concern for acute glomerulonephritis (GN). Renal biopsy showed signs of thrombotic microangiopathy (TMA) (Figure 1B) without evidence of immune-complex mediated GN. As Atypical hemolytic uremic syndrome (aHUS) and Preeclampsia (PEC) were both on the differential, serum was tested for sFLT-1 and PlGF. Based on emerging evidence of alternative complement pathway activation in PEC, Eculizumab use was discussed but not pursued due to uncertain fetal viability, even with pregnancy prolongation. Ultimately, patient chose to terminate the pregnancy and subsequent pathology review revealed maternal vascular malperfusion and early intrauterine fetal demise. Levels of sFLT-1 (95.228 pg/ml), PlGF (139.3 pg/ml), and sFLt-1: PlGF ratio (683.6) were all consistent with severe PEC (Figure 1C). At 2-month follow-up, proteinuria had resolved and HTN was controlled with Nifedipine.

**Discussion:** Patients presenting with preeclampsia and hyponatremia may develop severe hyponatremia, which improves after delivery. Refined guidelines should consider severe hyponatremia and its management in preeclampsia.

**Figure 1:** Clinical data & Jones stain showing glomerular basement membrane duplication, characteristic of TMA.

PO2605
Outcomes of Delivery Hospitalizations Among Pregnant Women with Kidney Transplant in the United States
Api Chewcharat,1,2 Andrea G. Kattah,1 Charat Thongprayoon,1 Wisit Cheungpasitporn,2 Boonpripop Boonpheng,4 Maria Lourdes Gonzalez Suarez,1 Jasmina Craici,1 Vesna D. Gavovic,1 1Mayo Clinic, Rochester, MN; 2Mount Auburn Hospital, Cambridge, MA; 3University of Mississippi Medical Center, Jackson, MS; 4University of California Los Angeles, Los Angeles, CA.

Background: Outcomes of delivery hospitalizations, including acute kidney injury, obstetric and fetal events among pregnant women with kidney transplants (KT) compared to those with no known kidney disease and chronic kidney disease (CKD) stage 3-5 are unclear.

Methods: Hospitalizations for delivery were identified using the enhanced delivery identification method in the National Inpatient Sample dataset from the years 2009 to 2014. Diagnoses of CKD stage 3-5, KT along with obstetric events, delivery methods, and fetal events were identified using ICD-9-CM diagnosis and procedure codes. Logistic regression accounting for the survey weights and matched regression were conducted to investigate the risk of maternal and fetal complications in women with KT as compared to women with no kidney-related diagnosis and compared to women with CKD stage 3-5.

Results: A total of 5,408,215 hospitalizations resulting in delivery were identified, including 405 women with CKD stage 3-5, 295 women with functioning KT, and 5,405,499 women with no kidney diagnosis. Pregnant KT recipients were at higher odds of pregnancy-induced hypertension (OR = 3.11, 95% CI [2.26, 4.28]), preeclampsia/eclampsia/HELLP syndrome (OR = 3.42, 95% CI [2.54, 4.60]), preterm delivery (OR = 2.46, 95% CI [1.75, 3.45]), fetal growth restriction (OR = 1.74, 95% CI [1.01, 3.00]), and acute kidney injury (OR = 10.46, 95% CI [5.33, 20.56]) as compared to women with no kidney-related diagnosis. There were no significant differences in rates of gestational diabetes and cesarean section. Pregnant women with KT had 1.30-time longer length of stay and 1.28-time higher cost of hospitalization. However, pregnant women with KT had 1.30-time longer length of stay and 1.28-time higher cost of hospitalization. However, pregnant women with CKD stage 3-5 were at higher odds of AKI, preeclampsia/eclampsia/HELLP syndrome and fetal death, and had longer hospital stay and cost of hospitalization compared to pregnant women with KT.

Conclusions: Pregnant women with KT were more likely to experience adverse events during delivery when compared to women with no known kidney disease. However, pregnant women with advanced CKD were more likely to experience serious complications than KT recipients. Women with advanced CKD who wish to conceive might consider conception after transplantation for better pregnancy-related outcomes.

PO2606
Successful Pregnancy in a Patient with Congenital Renal Dysplasia After Initiation of Dialysis
Jennifer C. Tang,1,2 Annika K. Khine,1,2 University of Southern California Keck School of Medicine, Los Angeles, CA; 2Los Angeles County University of Southern California Medical Center, Los Angeles, CA.

Introduction: Chronic kidney disease (CKD) is a well-known risk factor for adverse maternal and fetal outcomes including preeclampsia and fetal growth restriction. For those on dialysis, increasing the frequency and duration of dialysis has shown to optimize outcomes. However, it remains unclear if and when pregnant patients with CKD should start dialysis to improve outcomes. We present a patient with congenital renal dysplasia who successfully gave birth after starting dialysis.

Case Description: A forty-one-year-old female with an intrauterine pregnancy of 25 weeks and a history of two miscarriages, preeclampsia, and congenital renal dysplasia presented to nephrology clinic. Patient was unaware of her kidney dysfunction and had residual renal function with a creatinine of 3.76 and urine pr/cr ratio of 1.18. A fetal ultrasound revealed a fetal weight in the 12th percentile, head circumference in the 2nd percentile, and biparietal diameter (BPD) in the 33rd percentile. Therefore, the patient had no signs of renal recovery, her immunosuppression was discontinued. The patient returned to the hospital with hypoxic respiratory failure due to parainfluenza virus linear deposits on immunofluorescence, confirming the diagnosis. In addition to daily hemodialysis, the patient underwent plasmapheresis and immunosuppression with pulse dose steroids followed by a steroid taper as well as azathioprine and tacrolimus. The treatment of choice in anti-GBM disease is plasmapheresis to remove circulating antibodies and immunosuppression to reduce antibody production. However, pregnancy presents a unique challenge in choosing immunosuppressive agents as both maternal and fetal effects need to be considered. The involvement of high risk obstetricians as well as neonatologists in the care of these patients is imperative to ensure the best possible outcomes.

Discussion: Initiation of dialysis resulted in significant interval fetal growth and this patient’s first viable infant. Further research is warranted to assess if starting dialysis earlier in pregnant patients with CKD may improve fetal outcomes.

Fetal ultrasound prior to dialysis with a femur length in the 6th percentile and an estimated fetal weight of 635 grams in the 12th percentile.

PO2607
The Ethics of Caring for Pregnant Patients with CKD: A Scoping Review
Elizabeth M. Hendren, Michelle A. Hladunewich, Ariel Lefkowitz. University of Toronto, Toronto, ON, Canada.

Background: Physicians must consider many ethical principles when managing patients with chronic disease before and during pregnancy. An ethical framework could guide joint decision making between physicians and their patients, but does not currently exist.

Methods: We performed a scoping literature review to explore the ethical considerations associated with pregnancy in patients with chronic disease. We searched for articles published between 1975 and 2019 using the terms “Ethics” and “High risk Pregnancy/Pregnancy” along with 29 chronic disease-specific MeSH terms (e.g. scleroderma, diabetes, cystic fibrosis).

Results: We identified 968 articles and excluded 947 based on their title or abstract. 12 full text articles were included in the final scoping review representing discussions, case reports, and literature reviews on the ethics of high-risk pregnancy in 8 chronic diseases. The extracted data were examined and integrated into analyses of clinical cases in order to develop recommendations for ethically caring for this patient population.

Conclusions: Physicians have an ethical duty to their patients to facilitate autonomous decision-making and informed consent. Secondarily, they have a duty to protect the fetus and to use resources judiciously as long as it does not negatively impact the care they provide to their patient.

PO2608
Anti-Glomerular Basement Membrane Disease in Pregnancy
Fahad A. Lodhi,1 Peter E. Umukoro,2 Syed Sajjad,3 Rebecca Blonsky,1 1Marshfield Clinic Health System, Marshfield, WI; 2Indiana University School of Medicine, Indianapolis, IN.

Introduction: Anti-glomerular basement membrane (anti-GBM) disease is a rare cause of renal failure due to the production of IgG antibodies against type IV collagen. Its occurrence during pregnancy is even less common and can lead to poor maternal and fetal outcomes.

Case Description: A 23-year-old female with history of depression presented at 15 weeks 3 days gestation with weakness, nausea and vomiting for one week and anuria for 24 hours. Labs were significant for a creatinine of 19.8 mg/dL, BUN 113 mg/dL and potassium 7.1 mmol/L. Labs six months prior were normal. Nephrology was consulted and the patient was transferred to the intensive care unit for urgent hemodialysis. Further serologic investigation revealed elevated anti-GBM antibodies. A kidney biopsy was performed which demonstrated 100% cellular crescents on light microscopy and linear deposits on immunofluorescence, confirming the diagnosis. In addition to daily hemodialysis, the patient underwent plasmapheresis and immunosuppression with pulse dose steroids followed by a steroid taper as well as azathioprine and tacrolimus. The patient returned to the hospital with hypoxic respiratory failure due to parainfluenza virus further complicated by pre-term premature rupture of membranes at 24 weeks 4 days. As the patient had no signs of renal recovery, her immunosuppression was discontinued. The patient remained inpatient receiving daily hemodialysis until 28 weeks 0 days when the patient developed uncontrollable hypertension requiring an emergent cesarean section. The patient gave birth to a live male weighing 1.1 kg. Her post-partum course was uncomplicated, though the patient remains dialysis dependent.

Discussion: The treatment of choice in anti-GBM disease is plasmapheresis to remove circulating antibodies and immunosuppression to reduce antibody production. However, pregnancy presents a unique challenge in choosing immunosuppressive agents as both maternal and fetal effects need to be considered. The involvement of high risk obstetricians as well as neonatologists in the care of these patients is imperative to ensure the best possible outcomes.

Identification of Renal Disease in Women with Hypertensive Pregnancies

Hayley Martin,1 Henry A. Kibble,1 Kieran R. Palmer,1 Emmanueln Konourtis,1
Amelia M. Holloway,1 Kate Bramham,1,2 Katherine R. Clark.1,2 King’s College
Hospital NHS Foundation Trust, London, United Kingdom; 2King’s College
London School of Lifecourse Sciences, London, United Kingdom.

Background: Hypertension in pregnancy can be associated with renal injury, which
may be masked by gestational change. Additionally, pregnancy affords an opportunity
to diagnose asymptomatic renal disease. Postpartum assessment enables detection of
on going renal abnormalities. We aimed to determine prevalence of renal disease in
postpartum women with chronic hypertension, pregnancy induced hypertension or
preeclampsia in a previous or current pregnancy.

Methods: Women with singleton pregnancies seen in a specialist clinic for hypertension with estimated GFR (CKD-EPI) below 90mL/min/1.73m² and/or proteinuria at six-weeks postpartum were offered specialist renal midwifery clinic follow-up.

Results: 143/341 women offered follow-up attended renal clinic (Median IQR 246.25) days after delivery. 82 (57.3%) women had proteinuria and/or low eGFR.

Conclusions: Over half of women with proteinuria and/or reduced eGFR at six weeks postpartum had sustained evidence of renal disease regardless of hypertensive diagnosis. Postpartum assessment may afford an opportunity to detect renal disease.

Senescence Markers in Women with Preeclampsia Pregnancies

Sonja Suvakov,1 Ranine Ghamrawi,1 Haiato Tu,1 Wendy White,1 Natasa Milic,1 Joseph P. Grande,1 Vesna D. Garovic.1 Mayo Clinic Minnesota, Rochester, MN; 1The First Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China.

Background: Preeclampsia, a hypertensive disorder of pregnancy, is characterized by increased angiogenesis and inflammation. Data indicate that preeclampsia is mechanistically related to cellular senescence, an irreversible cell-arrest mechanism which has been increasingly associated with accelerated aging. The aim of this study was to determine if senescence plays a role in the pathophysiology of preeclampsia. To that end, we compared SASP components in blood and fat tissue sections between preeclamptic and normotensive pregnancies, as well as p21 and p16 expression in the fat and kidney tissue samples.

Methods: Blood samples from preeclamptic and normotensive patients at the time of delivery were used to study circulating senescence-associated secretory phenotype (SASP) components. Plasma SASP components were tested using Luminex 200 system. Fat tissue explants (3-5 g) were obtained during the surgery from pregnant women who were clinically indicated for C-section. Kidney sections originated from the autopsy material of patients who died from preeclampsia. Upon protein isolation from fat tissue, SASP components were measured. Fat and kidney tissue sections were immunostained for p16 and p21. Preeclamptic and normotensive participants were matched for age and BMI.

Results: Significant increase of senescence markers were found in blood of preeclamptic pregnancies for NGF (1.30±0.82 vs. 0.77±0.19, p=0.032), MCP1 (316.9±163.95 vs. 207.53±84.78, p=0.047), TNFα (2.79±1.08 vs. 2.06±0.64, p=0.043) and Pai1 (58.0±18.85 vs. 38.1±20.86, p=0.023). Similarly, significant increase in senescence markers was found in preeclamptic pregnancies for MCP1 and TNFα. Expression of p16 was significantly increased in fat tissue, whereas the difference in p21 expression between preeclamptic and normotensive patients was not observed. Expression of p16 in preeclamptic renal sections was significantly higher (p=0.02) than in sections from normotensive pregnancies. The p21 expression did not differ between preeclamptic and normotensive kidney sections.

Conclusions: Women with preeclampsia have higher senescent burden compared to normotensive pregnant women at the time of delivery. Senolytic agents that target senescence may offer the opportunity for mechanism-based therapies.

PO2611

Sexual Dimorphism and Hard Outcomes in AKI: Is Female Sex Protective? The Jury Is Still Out

Maria Isabel Acosta-Ochoa, Armando Coca, Jimmy R. Sanchez Gil, Alicia Mendiluce. Hospital Clinico Universitario de Valladolid, Valladolid, Spain.

Background: Many studies focus on sex dimorphism and its influence on hard outcomes when suffering an AKI episode. Some report that women, while others report that men are protected against adverse clinical events. In a real world cohort of individuals suffering from AKI, we compared hard outcomes between sexes with a novel approach: paired-matched study.

Methods: Retrospective paired-matched study of in-patients with AKI diagnosis; cases were matched based on sex, age and Charlson’s Index. We used KDIGO-2012 criteria to define AKI, analyzed clinical variables, and compared the hard outcomes: length of hospital stay, need for acute HD, HD dependence at discharge, and in-hospital mortality.

Results: We included 383-paired matches. Male individuals suffered from peripheral arterial disease and COPD, and were hospitalized in surgical wards more frequently than women. We found no statistically significant difference between groups regarding to the prevalence of common comorbidities and admission to ICU (Table 1A). The distribution in global KDIGO-AKI Stages was similar, but when analyzing every sub-criterion of the classification we found that women fulfilled the serum creatinine (SCr) increment ≥1.5-1.9x more frequently, and men fulfilled reaching a SCr >4 mg/dl more commonly. We found no statistically significant differences in hospital stay, need for acute HD, HD dependence at discharge, and in-hospital mortality (Table 1 B).

Conclusions: To our knowledge, a paired-matched design regarding to this topic has not been previously published. Although experimental studies find differences in clinical outcomes between sexes when suffering an AKI episode, in this real world study, we did not observe a clear distinction in the incidence of adverse outcomes between sexes. We conclude that sex (either female or male) may not be protective against AKI’s hard outcomes.
PO2612
Effects of Veverimer on Serum Bicarbonate and Physical Function in Women with CKD: A Subgroup Analysis from a Randomized Controlled Trial
Vandana S. Mathur,1 Donald E. Wesson,2 Neeli Kandarpa,3 Yurii Stavis,4 Dawn Parsell,5 Elizabeth Li6, Gerrit Kraener,7 David A. Bushinsky,7 Mathur Consulting, Woodside, CA; 8Baylor Scott & White Health and Wellness Center, Dallas, TX; 9University of Manitoba, Winnipeg, MB, Canada; 10Tricida, Inc., South San Francisco, CA; 11Pharmacia LLC, Fremont, CA; 12University of Rochester Medical Center, Rochester, NY.

Background: More women than men have CKD. However, women have been underrepresented in clinical trials. Veverimer is an orally administered, non-absorbed polymer that treats metabolic acidosis by binding and removing HCl from the GI tract. In Phase 3 randomized, double-blind, placebo-controlled trials, veverimer significantly increased serum bicarbonate and improved physical function in acidic patients with CKD (Wesson et al. Lancet, 2019). Here we analyzed efficacy and safety among the women in these studies of up to one year.

Methods: Physical function was assessed using the Kidney Disease and Quality of Life Physical Function Domain (KDQOL-PFD) which quantifies limitations on daily activities and by performance on the repeated chair stand (RCS) test.

Results: Of the 217 pts randomized, 83 (32%) were women, of whom 81% were post-menopausal (≥55 yrs). Select comorbidities included hypertension (95%), diabetes (64%), and congestive heart failure (30%). At Baseline, mean eGFR in women was 28.4 mL/min/1.73m2 and mean serum bicarbonate was 17.3 mEq/L. More women receiving veverimer met the primary study endpoint, had a significant increase in serum bicarbonate and improved both KDQOL-PFD scores and RCS time (Table) compared with placebo. The effects of veverimer exceeded the minimal clinically important difference for both KDQOL-PFD (+3 to +5 points) and RCS (+1.7 seconds). Rates of serious, non-serious and GI adverse events were similar in both groups; none required treatment discontinuation.

Conclusions: Given their lower bone and muscle mass, women with CKD may be particularly vulnerable to the adverse effects of metabolic acidosis. We found that in women with CKD and metabolic acidosis, treatment with veverimer significantly improved how women felt and functioned. The safety of veverimer was similar to placebo.

Funding: Commercial Support - Tricida, Inc.

- P-values are vs. placebo; An ANCOVA rank-based method was used for physical function endpoints
- *Based on evaluable patients enrolled in controlled extension study (placebo, n=31; veverimer, n=46)

 Dietary Intake Syndrome, Risk of Kidney Stone, and Survival in the Women’s Health Initiative (WHI)
Harshitha Kota,1 Xuorong Wen,2 Chao Chen,3 Jie Tang,41 Brown University, Providence, RI; 2University of Rhode Island, Kingston, RI; 3University of Florida, Gainesville, FL; 4Brown Urology Brown Physicians Inc, Providence, RI.

Background: The effect of dietary magnesium intake (DMI) on the risk of stone is controversial, and its effect on survival among kidney stone formers is unknown.

Methods: We examined participants enrolled in WHI, a prospective, longitudinal, multicenter study investigating the health of postmenopausal women, and used Cox regression analyses to determine the independent effects of DMI on the risk of incident kidney stone and survival amongst the stone formers.

Results: 145,942 participants were identified free of kidney stone history at baseline. 83% were Caucasian, mean age was 63. Among them, 60,24 (4%) developed incident kidney stone during 1,601,750 person-years of follow up. The mean daily DMI was 318 mg, with 26% in tertile 1 (241 mg), 41% in tertile 2 (241-348 mg) and 33% in tertile 3 (>348 mg). The incidence of kidney stone disease was 3.1, 3.3, and 3.9 per 1000 person-year in high, moderate and low DMI groups, respectively. The corresponding multivariable-adjusted hazard ratios were 0.82 (95% CI: 0.71-0.94) for high vs low DMI when dietary oxalate intake (DOI) is high, and 1.01 (95% CI: 0.81-1.26) for high vs low DMI when DOI is low. Among incident stone formers, 82% were Caucasian, 23% were above age 70. Mean daily DMI was 304 mg, 32% in tertile 1, 38% in tertile 2, and 30% in tertile 3. Subsequently, 1346 (22%) died. Older age, histories of hypertension, diabetes and heart disease, low serum vitamin D, cigarette smoking, and hormone replacement association significantly with mortality, p<0.05. However, DMI had no impact on mortality after adjusting for demographics and potential confounding factors, hazard ratio (HR) 0.91, 95% CI 0.73-1.14, p=0.4 when compared high DMI vs low DMI groups, HR 0.90, 95% CI 0.73-1.11, p<0.3 when compared medium DMI vs low DMI groups.

PUB001
Consequences of Improper Interpretation of ANCA
Aswin Srinivasan,1,4 Sangita Mutnuri,4 Nina Zatikyan,1 Shabbir Safri,2 Mahendra L. Agraharkar,1,2 University of Texas Medical Branch at Galveston, Galveston, TX; 2Baylor College of Medicine, Houston, TX; 3University of Houston, Houston, TX; 4HCA Gulf Coast Division, Houston, TX; 5Montefiore Hospital and Medical Center, Montefiore Medical Center, Bronx, NY; 6Creighton University, Omaha, NE.

Introduction: Antineutrophil cytoplasmic antibodies (ANCA) is important in suspected vasculitis. False positive or atypical ANCA (A-ANCA) can lead to erroneous interpretation of immunofluorescence (IF) causing disastrous consequences. We present a patient who was initially reported as Perinuclear-ANCA (P-ANCA) positive and was therefore treated with steroids rendering him adrenal insufficient (AI).

Case Description: A 79-year-old man with history of CKD, A Fib, protein C deficiency, prostate cancer and ANCA positivity that was treated with steroids, presented to the ER with dizziness, bradycardia and hypotension. He was weak, fatigued, and unarousable. In the ER, he was started on vasopressors and methylprednisolone. His creatinine rose from 2.6 to 3.1 mg/dl. RPGN was suspected and kidney biopsy was performed that showed typical immune complexes related to ANCA vasculitis in clumps. His AM cortisol level was 3 ug/dl (10-20). Because of hypotension, polycyria and natriuresis, hydrocortisone and fludrocortisone were started. His serum K level decreased and fludrocortisone was stopped. After next few days, he became normotensive and his mentation improved with increasing dose of hydrocortisone. Hypokalemia slowly resolved with potassium supplements.

Discussion: ANCA are a group of antibodies that bind to antigens of neutrophils, causing systemic vascular inflammation. These autoantibodies can be found in the serum of patients with systemic, small vessel vasculitis and is a biomarker for ANCA-associated vasculitis. A positive staining of ANCA can be classified as: Cytoplasmic, Perinuclear, and Atypical, based on the pattern of IF. In cases with C-ANCA, the staining is diffuse throughout the cytoplasm and the cause of staining is due to antibodies directed against Proteinase 3 (PR3). In cases with P-ANCA, the staining is around the nucleus and it is due to antibodies directed against myeloperoxidase (MPO). A-ANCA can be found in conditions other than vasculitis and does not require immunosuppressive steroids for treatment. A-ANCA can be reported erroneously as P-ANCA or C-ANCA and patients can receive aggressive treatment with high dose steroids. Therefore, we suggest to confirm the ANCA results with MPO or PR3 before initiating aggressive therapy for vasculitis to avoid disastrous consequences.

Metabolic Encephalopathy due to AKI in a Patient with Recent Infusion of Intravenous Immunoglobulin (IVIg)
Sheikh Raza Shalzad, Kelly H. Beers. Albany Medical Center, Albany, NY.

Introduction: IVIg induced AKI is extremely rare (1% of cases). We present a case of AKI requiring hemodialysis secondary to recent IVIg administration.

Case Description: A 61-year-old woman presented with acute onset altered mental status (AMS) for 2 days. Her past medical history included CKD G3, HTN, COPD, PVD, and CAD. A week prior, she received 3 doses of sucrose-containing IVIg for chronic inflammatory demyelinating polyneuropathy. Shortly thereafter, the patient developed a facial rash, poor oral intake, low urine output, and AMS. Labs showed BUN 71 mg/dL, SCr 10.62 mg/dL, baseline Scr 2.6 mg/dL. ABG showed pH 7.07, pCO2 30 mmHg and HCO3 8 mmol/L. Toxicology screen was negative, CPK and lactic acid were normal. No NSAIDs use was reported. She required only 1 session of hemodialysis with the recovery of renal function and mental status. AIM due to IVIg and/or IVIg induced osmotic nephrotoxicity may be the culprit for her presentation.

Discussion: IVIg can produce adverse reactions thought to be caused by activation of the complement cascade by the aggregation of IgG. To avoid this, a variety of stabilizing agents, including sucrose, are used. Sucrose is absorbed into proximal convoluted tubular cells and is followed by water due to the changed osmotic pressure. This results in cytoplasmic vacuolization and degeneration of the proximal cells. CKD, HTN, DM, advanced age, dehydration, hyperviscosity, use of sucrose stabilizers, high dose IVIg therapy (400–2000 mg/kg), high rate of IVIg administration, or treatment with other nephrotoxic medications increase the risk of AKI. About 30% of cases require dialysis. The mortality rate is 10%. Adverse renal outcomes usually occur within 10 days of initiation of IVIg, and the duration of renal failure lasts between 3 and 45 days. Most cases resolve spontaneously. Early recovery of renal function can be achieved by diahylic removal of excess sucrose from the circulation. To make a diagnosis, access to renal function data for a ten-year period is necessary to be established with the administration of IVIg. A clinical diagnosis is made after ruling out other causes and is confirmed with a renal biopsy. Measures to prevent AKI include using sucrose-free IVIg or amino-acid-stabilized formulations, adequate hydration, avoiding other nephrotoxins and diuretics, reductions in dose, concentration (<5%), and/or rate of administration (<3mg sucrose/kg/min) of IVIg.

PUB004

A Patient with a Record High Blood Urea Nitrogen Value Surviving Without Dialysis
Hay Me Me, Urvashi Hooda, Aditi A. Sen, Amol Mittal, Michael Connery. Westchester Medical Center, Valhalla, NY.

Introduction: The blood urea nitrogen (BUN) has limited value as an index of glomerular filtration rate to access kidney function. It can be increased not only in the setting of acute or chronic renal failure but also in hypovolemic state, gastrointestinal tract bleeding, high catabolic states, and by certain medications. Dialysis is the effective treatment for uremia. However, there is no consensus on when to initiate the dialysis for high BUN in acute kidney injury.

Case Description: A 64-year female with history of hypertension, hyperthyroidism, hyperlipidemia, alcohol use disorder, chronic kidney disease (CKD) with baseline creatinine of 1.5 mg/dl was admitted for head trauma after fall. Patient had poor intake and was nott adequately hydrated. She was found to be confused by family. No history of analgesic or herbal supplements usage was present. Laboratory results were significant for BUN of 298 mg/dl, Creatinine (Cr) of 13.5 mg/dl, serum potassium of 5.4 mEq/L, phosphate of 6.1 mEq/L and severe hyperlipidemia, alcohol use disorder, chronic kidney disease (CKD) with baseline creatinine of 1.5 mg/dl. Initial management was to aggressively resuscitated with intravenous fluid including bicarbonate and her cognitive function improved without dialysis. The blood urea nitrogen (BUN) of 42 mg/dl was found to be normal bilateral kidney sizes. Patient was aggressively resuscitated with intravenous fluid including bicarbonate and her cognitive function improved without dialysis. Her BUN eventually decreased to 30 mg/dl and Cr to 1.26 mg/dl.

Discussion: The blood urea nitrogen (BUN) of 42 mg/dl was found to be normal bilateral kidney sizes. Patient was aggressively resuscitated with intravenous fluid including bicarbonate and her cognitive function improved without dialysis. Her BUN eventually decreased to 30 mg/dl and Cr to 1.26 mg/dl. Labs showed BUN 71 mg/dl, SCr 10.62 mg/dl, baseline Scr 2.6 mg/dL. ABG showed pH 7.07, pCO2 30 mmHg and HCO3 8 mmol/L. Toxicology screen was negative, CPK and lactic acid were normal. No NSAIDs use was reported. She required only 1 session of hemodialysis with the recovery of renal function and mental status. AIM due to IVIg and/or IVIg induced osmotic nephrotoxicity may be the culprit for her presentation.

Discussion: From the literature, this is the highest reported BUN in acute on chronic renal failure patient who improved without dialysis.

PUB005

Spontaneous Page Phenomenon in a Pelvic Kidney
Yahya R. Ahmad, William L. Wilson, Megan M. Robinson, Taha Ayach. University of Kentucky, Lexington, KY.

Introduction: Page kidney or Page phenomenon refers to compression of the renal parenchyma by subcapsular hematoma. Here we report the first case of spontaneous Page phenomenon in a native pelvic kidney.

Case Description: A 64-year-old male with a diagnosis of diabetes mellitus, essential hypertension, chronic kidney disease stage 3b, stage 3 obesity with a body mass index of 53, congenital right-sided pelvic kidney, presented to the emergency room with acute onset, severe, right lower quadrant abdominal pain. Patient denied having any recent trauma and had no urinary or gastrointestinal complaints. He was not on any antiplatelet or anticoagulation medications. CT angiogram of the abdomen and pelvis was performed which demonstrated a subcapsular hematoma around the right pelvic kidney. He had AKI with a peak creatinine of 4.2 mg/dl from a baseline of 2.2 mg/dl. He remained non-oliguric, with gradual improvement of his renal functions and never required renal replacement therapy or any intervention for Page kidney. He presented with markedly elevated blood pressure of 190/110 mmHg and his hospital course was significant for sustained elevated blood pressure requiring addition of four new anti-hypertensive medications by discharge. Subsequent imaging showed marked decrease in the subcapsular hematoma in a week.

Discussion: Page phenomenon is a rare but potentially fatal condition that can result from trauma, tumor, vasculitis, renal cyst rupture, or procedures like kidney biopsy. External compression of renal parenchyma can result in interstitial schema, tubulointerstitial nephritis and compression of intrarenal vessels thus activation of renin angiotensin system (RAS), resulting in AKI and hypertension associated with Page kidney. Persistently elevated blood pressure unresponsive to medical therapy or gradually enlarging hematoma with worsening renal functions might require percutaneous drainage, caspofungin or even nephrectomy. Optimal medical management of Page kidney includes medications targeting the RAS pathway.
Case Description: A 78-year-old male with coronary artery disease, hypertension, hyperlipidemia, and atrial fibrillation was admitted for an invasive pulmonary disease was diagnosed as hepatocellular carcinoma by transesophageal angiography of celiac and superior mesenteric arteries. He was admitted to the hospital for an operation of hepatocellular carcinoma. Serum creatinine level gradually increased from 1.71 to 5.87 mg/dL with eosinophilia (4404/μL) and high C-reactive protein (CRP) level (4.86 mg/dL). He started hemodialysis ten weeks after angiography and had been suffering from nausea. Endoscopy showed multiple gastric ulcers. Treatment with proton pump inhibitor started, but did not improve. Cyanosis was present in his bilateral toes and skin biopsy showed cholesterol crystal clefs. He was diagnosed with cholesterol embolism and treated with intravenous prednisolone (PSL) 20 mg/day, resulting in decrease of eosinophil, CRP levels and improvement of gastric ulcers. However, he was unable to withdraw from dialysis and developed disseminated cutaneous herpes zoster. Finally, he died of sepsis. Autopsy showed severe erosion of atherosclerotic plaques at the level of celiac artery. Cholesterol clefs were present in the vessels of kidney, stomach, intestines, liver, spleen, pancreas, diaphragm, adrenal glands and testes. The distribution of cholesterol crystal embolism was consistent with the site of angiography performed from celiac and superior mesenteric arteries.

Discussion: Cholesterol crystal embolism is caused by not only percutaneous coronary interventions and vascular surgery, but also by primary and secondary hyperlipidemia. We need to consider cholesterol crystal embolism when acute kidney injury and refractory gastric ulcers after transmembral angiography. Although PSL is administered for cholesterol crystal embolism, tapering strategies is important for patients on dialysis.

Hyperkalemia in Community-Acquired AKI: Associated Factors and Clinical Consequences

Jose M. Pena Porta, Almudena Castellano, Ana Coscojuela Otto, José F. Gascó, Alberto Rosso, Erico Igil, Ramon H. Porta, Hospital Clínico Universidad de Navarra, IRCT, Pamplona, Spain

Background: Hyperkalemia (hyperK) frequently occurs in the context of acute kidney injury (AKI). However, little about the factors associated with hyperK and its clinical consequences in patients with community-acquired acute kidney injury (CA-AKI). The aim of present study was to analyze it.

Methods: The present study is based on a cohort of patients with CA-AKI admitted to the nephrology service from January 1st to February 15th, 2015. Hyperkalemia was defined as potassium levels above 5.1 meq / L. Results: A total of 308 patients were included. The mean age was 73.22 ± 13.95 years. 58.4% were men. Charlson comorbidity index (CCI) was 7.16 ± 3.66 and the length of stay was 12.25 ± 11.69 days. In view of the Etiology of AKI, 69.5% prenual AKI and 30.5% non-prerenal ones. 212 patients had previous chronic kidney disease (CKD) (68.8%). Hemodialysis (HD) was required in 54 patients (17.15%). 38 patients (12.3%) died during hospital stay. HyperK occurred in 173 cases (56.2%). Mean potassium was 5.45 ± 1.41 meq/L. There was a significant correlation between potassium and pH as well as between K and CCCI. There was an association between hyperK and intake of potassium-sparing diuretics (p < 0.001); ACEI/ARB (p = 0.003) and beta blocker (p < 0.001). Using a multiple linear regression model the equation that predicted serum potassium was: K = 36.44 – (4.4 x pH) + 0.98 (if intake of potassium-sparing diuretics = 0) + 0.10 x CCCI. Potassium level did not influence the length stay. Patients with HyperK required HD in a higher proportion (23.7 vs. 9.6%; p < 0.01) and also had higher mortality during hospital stay (15.6 vs. 8.1%; p = 0.048). After a follow-up of 2 years from hospital discharge, Kaplan-Meier survival curve analysis produced a significant difference (Log Rank (Mantel-Cox): p < 0.001) between patients with hyperK and patients that did not present it.

Conclusions: HyperK occurred in just over half of our patients. The potassium level was associated with high pH, and the intake of potassium-sparing diuretics. HyperK patients required HD and died in a greater proportion during hospital stay. Mortality after discharge was higher in patients who presented hyperK. Appropriate measures must be taken to correct hyperK early in patients with CA-AKI.

PUB009

A Case of Anti-Tubular Basement Membrane Antibody-Associated AKI

Masanori Terao, Takatsuji Ishi, Akira Kurosawa, Takasuke Shichino, Hironori Hasegawa.

Introduction: We report here a case of idiopathic anti-tubular basement membrane (TBM) antibody-related acute interstitial nephritis (AIN).

Case Description: Our patient was a 44 years man and had no history of renal disease. He was pointed out renal dysfunction of serum Cr 1.50 mg/dL in the health checkup 2 months prior to admission. The patient was admitted to our hospital because of worsening of renal function of Cr 2.89 mg/dL. Because renal dysfunction progressed (Cr 10.36 mg/dL), hemodialysis was started on the 8th hospital day. Urine abnormalities such as proteinuria or hematuria was not apparent, however, he showed remarkable elevation of urine NAG and β2-microglobin excretion, bilateral kidney enlargement, and renal accumulation was shown by Scintigraphy. Based on those findings, AIN was suspected and dialysis was continued for 22 days. The patient had undergone nephrectomy and microscopic examination revealed inflammatory cell infiltration in the tubulo-interstitium, and immunostaining showed linear deposition of IgG and C3 in the tubular basement membrane. Similar findings were observed in the tissue sections of other patient with no tubular disorder by the treatment of 10 mg/kg of PSL (PSL) 40 mg/day (0.8x kg/day) was started from the 13th day and methyl PSL 500 mg/day for 3 days was added on the 21st day. Renal dysfunction and inflammatory reaction disappeared after the treatment could not be maintained, however, proteinuria continued because of sudden psychosis. Cyclophosphamide 375-500 mg/day and multiple plasma exchange was added thereafter, however, finally he was shifted to the maintenance dialysis.

Discussion: Cases of TBM antibody-related AIN are very rare, and most of the reports are those induced by drugs and those developed after kidney transplantation, and few cases are considered to be idiopathic. Antigen of TBM antibody are thought to be a non-collagen protein that interacts with type-4 collagen, laminin and integrin, which is present in the proximal tubular basement membrane, but the mechanisms and clinical course that cause AINs are unknown. Accumulation of cases including this case is considered necessary.

PUB10

A Triple Threat: Baclofen Toxicity and Posterior Reversible Encephalopathy Syndrome in the Setting of AKI

Daniella E. Lipiniek,1 Kevin C. Roes.2 1Penn State College of Medicine, State College, PA; 2Mount Nittany Medical Center, State College, PA.

Introduction: This is a case of apparent baclofen toxicity and posterior reversible encephalopathy syndrome (PRES). Both conditions are seen in patients with kidney dysfunction but direct association between the two conditions has otherwise been defined. The case highlights areas of special consideration in the evaluation and management of mental status changes in patients with acute kidney injury (AKI). No other reported cases of the combined diagnoses were found on literature review.

Case Description: A 71-year-old female admitted with sepsis due to ESBL E. coli bacteremia and pyelonephritis became unresponsive on her 7th day of hospitalization. This was accompanied by abnormal renal function and hypertension. Her creatinine was 1.5mg/dL (baseline 1.5 mg/dL). AKI was attributed to prerenal physiology and sepsis-associated ATN. Mental status changes were attributed to baclofen neurotoxicity. She then developed evidence of partial complex seizures and subsequent imaging revealed findings of PRES. Levetiracetam, antihypertensives, and continued antibiotic therapy were provided. Systolic blood pressure increased to 180 mmHg with a MAP of 115 during the hospitalization. After several days, the patient recovered completely. Creatinine stabilized at 2.0 mg/dL. Discussion: Medications are a leading cause of acute mental status changes, especially in patients with impaired kidney function. Our case highlights the risks of baclofen toxicity in improving but impaired kidney function. The clinical-radiopathologic diagnosis of PRES may have been missed without imaging. The varying presentations of this condition are a reminder the importance of an expanded differential diagnosis and the need for a better understanding of the pathology. There is no reported association between PRES and baclofen. The role of AKI in the development of PRES is not entirely understood; however, the hypertension-hyperperfusion theory remains a leading consideration in our patient. Management decisions in our patient included forgoing dialysis, blood pressure control, and the use of anti-seizure medications.

PUB011

Renal Zygomycosis: A Rare Presentation in an Immunocompetent Patient

Muhammad Nadeem,1 Ali Hakami,1 Mansoor A. Qaisar,2 Bushra Iqbal.1 King Fahd Central Hospital, Jazan, Saudi Arabia; 2diaverum regional dialysis centre, Jeddah, Saudi Arabia.

Introduction: Zygomycosis is a broad term which refers to the infections caused by zygomycetes, fungi belonging to the order Zygomycetes. It is an azoic-opportunistic opportunistic infection which can usually present in four different ways including, pulmonary, gastrointestinal, renal and disseminated disease. Like other opportunistic infections it has predilection for immunocompromised patients however very rarely, it has been reported in immunocompetent patients.

Case Description: Here we report a case of an immunocompetent patient who was affected by renal zygomycosis and presented as a picture mimicking rapidly progressive glomerulonephritis (RPGN). The patient presented with hematuria, proteinuria and high creatinine and was suspected as a case of RPGN initially. CT scan abdomen showed bilateral smoothly tapered distal ends of the renal arteries with non-perfused enlarged kidneys. These findings were consistent with the diagnosis of Zygomycosis which has angi-invasive nature. Bilateral nephrectomy was done and diagnosis was confirmed on histopathology report. Post operatively, the patient was extubated from ventilator, recovered from shock and improved a lot. He was doing fine on maintenance hemodialysis until two weeks later he developed septic shock due to Acinetobacter Baumannii which could have triggered the re-activation of disseminated zygomycosis due to metabolic catastrophe.

Discussion: Isolated renal zygomycosis is very rare, although few cases have been described in literature. In our case, patient was referred to us as glomerulonephritis as his clinical picture initially resembled rapidly progressive glomerulonephritis. We were not able to highlight that isolated renal zygomycosis have can have presentation mimicking glomerulonephritis, so young nephrologists should rule out infections like zygomycosis before embarking on the diagnosis of Acute glomerulonephritis as misdiagnosis can be catastrophic.
Light Chain Cast Nephropathy in an African-American Woman with Waldenström Macroglobulinemia

Mohamedanwar M. Ghandour, Hillel Sternlicht. Wayne State University School of Medicine, Detroit, MI.

Introduction: Waldenström’s macroglobulinemia (WM) is a rare cancer of the lymphatic system due to excess IgM monoclonal protein with a rare renal involvement. Renal involvement is rare with an incidence of 3 cases per million people per year. We describe a case of MW presenting with acute renal failure.

Case Description: A 63-year-old female who admitted to our hospital for influenza B complicated by acute renal failure during the hospital stay, with creatinine up to 6 mg/dL, despite adequate hydration. Electrophoresis revealed a monoclonal component in the gamma region, which classified as an IgM k. A kidney biopsy was performed, showing light cast chains suggested the possibility of myeloma kidney. Furthermore, bone marrow histology was performed, revealing lymphoplasmacytic lymphoma. The patient was treated with bortezomib, dexamethasone, and cyclophosphamide, with complete recovery of renal function.

Discussion: Overall, renal manifestations are not commonly seen in Waldenström’s macroglobulinemia. Approximately one-third of patients are asymptomatic at the time of diagnosis. Like our patient who did not have renal symptoms and acute kidney injury discovered serendipitously. Moreover, reported rates of full renal recovery following adequate treatment are almost more than 50 percent. Patients with reversibly renal failure had longer median survival compared with patients who did not restore renal function.

Light Chain Cast Nephropathy in an African-American Woman with Waldenström Macroglobulinemia

Mohamedanwar M. Ghandour, Hillel Sternlicht. Wayne State University School of Medicine, Detroit, MI.

Introduction: Waldenström’s macroglobulinemia (WM) is a rare cancer of the lymphatic system due to excess IgM monoclonal protein with a rare renal involvement. Renal involvement is rare with an incidence of 3 cases per million people per year. We describe a case of MW presenting with acute renal failure.

Case Description: A 63-year-old female who admitted to our hospital for influenza B complicated by acute renal failure during the hospital stay, with creatinine up to 6 mg/dL, despite adequate hydration. Misleading Serologies in Thrombotic Microangiopathy due to Malignant Hypertension
Taqui Khaja,1 Rajeev Raghavan,2 William F. Glass,2 Carl P. Walther.1 Baylor College of Medicine, Houston, TX; 1University of Texas Health Science Center at Houston, Houston, TX.

Introduction: Nephrologists use autoimmune panels to screen for glomerular disease. Some of these markers cause false positives in other systemic diseases which leads to misdiagnosis. We report a rare case of false positive MPO-ANCA and ANA in patient with thrombotic microangiopathy (TMA) due malignant hypertension.

Case Description: A 65 year old African American patient with a history of hypertension, breast cancer s/p right mastectomy, and CKD with baseline creatinine of 1 was admitted hypertensive urgency with pressures of 239/123. She had Acute Kidney Injury with creatinine of 6.6 and her work-up revealed new pericardial effusion, thrombocytopenia (platelets of 90), and anemia (hemoglobin of 9). Autoimmune panel was positive for ANA (1:520, speckled) and positive RNP (>8). The presumptive diagnosis was mixed connective tissue disease. Pericarditis was negative for malignancy and infections. She began dialysis but her renal function never improved. She was discharged dialysis dependent. The patient refused outpatient dialysis and her medications. She was re-admitted few weeks later with uremia and hypertensive urgency with pressures of 299/104. A repeat evaluation showed a newly positive MPO-ANCA (13.4), ANA (1.640, speckled), and a low C3 (72.8). The concern for vasculitis, a kidney biopsy was performed. Her biopsy was significant for global glomerulosclerosis, periglomerular ischemia, and severe interstitial fibrosis with tubular atrophy. There was extensive arteriolar onion skin intimal fibroplasia with red blood cell fragments. Based on her clinical history, patient had TMA secondary to hypertension. Her biopsy lacked findings of vasculitis due to an absence of necrotizing crescentic glomerulonephritis and negative immunofluorescent stains. The patient was maintained on hemodialysis and hypertension medications.

Discussion: Diseases associated with TMA can have false positive autoimmune markers and they require early recognition. There are cases that show Thrombotic Thrombocytopenic Purpura can produce MPO-ANCA and anti-DNA markers. The markers were correlated to intensity of the disease because the patients with active disease had higher titers. These markers are created secondary to immune dysfunction during TMA. This case also emphasizes the importance of kidney biopsy in order to distinguish between active vasculitis and non-vasculitic diseases.

PUB016
AKI, Diplopia, and Altered Psyche: One Rare Case of Extrapulmonary Sarcoidosis
Hillary DeRose-Calderg. Western Reserve Health Education, Youngstown, OH.

Introduction: Sarcoidosis is a multi-organ system disease primarily affecting the lungs. Pathological diagnosis requires the presence of non-caseating granulomas. Sarcoidosis is a genetic associated autoimmune disease more prevalent in African Americans. Renal sarcoidosis manifests in about 5-20% of patients with hypercalcemia, hypercalciuria, and nephrolithiasis on normal screening. Renal parenchymal involvement is typically granulomatous tubulo-interstitial nephritis. Neuro-sarcoidosis also occurs in about 1/3 of patients, affecting primarily the cranial nerves. CNS involvement can present with visual and occasionally behavioral changes. Ocular sarcoid presentations include uveitis and retinal lesions.

Case Description: 63-year-old white male with a history of rheumatoid arthritis, pulmonary nodules, glaucoma, presented with one year of blurry vision and weird psyche. He was referred to nephrology after an ophthalmologist found intermittent diplopia, transient optic disc swelling and intraretinal hemorrhage. Abnormal labs from 5/2019 with 11/2018 in parenthesis: Scr 2.73 (1.51 mg/dL), BUN 27 (22), Egrf naa 28 (49/min), Ser Calcium 8.6 (9.2 mg/dL) ACE 73 U/L, Alc 5.4. Given the worsening CKD IV; the following were drawn: ANA-IFA: positive, speckled p1 1.640, UA bld 10, fn gran cast; 0-5, crs gran cst 0.5, ur prot rad 24. Renal biopsy demonstrated nonscaseating granulomatous interstitial nephritis, numerous noncaseating granulomas with giant cells. He was referred to Cleveland Clinic Sarcol Clinic and started on 40mg prednisone for renal sarcoid. CXR with prior noddles, no hilar or parenchymal changes. CC Ophthalmology clinic’s fundal exam revealed peripheral hyopigmented lesions possibly consistent with ocular sarcoid. Vision had resolved. At 1 month, steroids were tapered with plans to start Azathioprine. The patient’s Ser improved on tapering steroids.

Discussion: Less than one in ten patients present solely with extrapulmonary sarcoidosis. This case demonstrates a rare presentation of neuro-ocular and renal sarcoidosis in the absence of lung findings. Sarcoidosis ought to be considered in AKI or new chronic kidney disease, particularly if a patient presents with other atypical findings such as retinal or optic nerve changes representing a syndrome of multi-organ involvement. Multiple system involvement is a predictor of progression to ESRD. Glucocorticoids are first-line therapy. Most cases respond to steroids.

PUB017
Dynamics of Tissue Injury mRNA Expression to Bilateral Renal Ischemia-Reperfusion Injury
Samuel J. Pfarr,1 Toni L. Richards,2 Kenneth Minor,3 Yan Zhang,4 Craig F. Plato,5 Kristopher Kuchenbecker.1 Silver Creek Pharmaceuticals, San Francisco, CA; 4Plato BioPharma, Inc., Westminster, CO.

Background: Acute kidney injury (AKI) secondary to acute renal ischemia is associated with high mortality and morbidity with few effective treatments. The bilateral renal ischemia reperfusion injury (BRI) model is commonly employed in rodent studies of AKI. While disease progression is well characterized at the organism level, the dynamics of the molecular responses are less well understood. To improve the translational potential of compounds, the current study sought to temporally and mechanistically define the tissue mRNA expression profiles following discrete durations of IRI.

Methods: Rats underwent sham or warm, bilateral renal ischemia (30’ or 40’) surgery using PBI’s proprietary vascular clamps. Subsets of rats were sacrificed at 8 timepoints following reperfusion (0-48hr), with blood and kidneys harvested at each timepoint for subsequent analyses. Plasma and kidney mRNA were analyzed via clinical chemistry. The expression of 100 mRNA transcripts surveying genes across apoptosis, kidney injury, and inflammation/fibrosis pathways were measured by Quantigene.

Results: Plasma creatinine, the classical index of renal dysfunction in AKI was ischemia- and reperfusion time-dependently increased upon inception of reperfusion. Concomitantly, kidney injury and inflammation genes were upregulated early (<4hr) and remained elevated compared to shams throughout study duration. Upregulation of pro-apoptotic genes occurred as early as 4hr post-reperfusion, indicating the initiation of programmed cell death. Low-proteinic genes were upregulated 24-48hr post-reperfusion indicating onset of remodeling. The information content provided by each mRNA expression profile and clinical parameter was determined using a novel statistical framework to identify measures best able to distinguish disease state over 48hr of reperfusion.

Conclusions: This study demonstrated the temporal dynamics of response to renal IRI in rats. The early injury phase (~<4hr) was defined by mild, but significantly increased plasma creatinine indicating promptly reduced renal function along with upregulated injury response genes. Induction of pro-apoptotic and pro-fibrotic genes occurred during the late phase, in line with BRI-induced exacerbated renal failure. Our novel statistical framework identified “high information” genes/parameters that can serve as reliable, mechanistic indicators of AKI in future studies.

PUB018
Antioxidant Ameliorates Pulmonary Renal Injury in an Experimental Model of COVID-19 Organ Failure
Firoozeh Farahmand. Saint Louis University, Saint Louis, MO.

Background: Since the outbreak and rapid global spread of COVID-19 multi-organ involvement has largely influenced prognosis and severe AKI has been an ominous clinical predictor with high mortality. The hyperinflammatory response of the body, associated with oxidative stress is a key player in mechanism of multiple organ failure.

Methods: In an experimental model of multiple organ failure of Covid 19 similar to human disease with single injection of Toxoid (TOX) rats were treated with antioxidant curbedol started daily 1wk pre-TOX-injection and continued for 1 wk post-TOX-injection. At 1-week post injection in both TOX+ Antioxidant and TOX groups lungs dry/wet weight ratios were measured to assess edema and lungs and kidneys from both group were analyzed for antioxidant enzyme activities including superoxide dismutase, glutathione peroxidase, catalase and oxidative stress. After sacrificing the animals, kidney and lung function were measured.

Results: Antioxidant treatment attenuated TOX induced lung and kidney injury and there was histopathological evidence of its beneficial effects. This was associated with decreased oxidative stress and increased activities of SOD and GSHPx in the lung and kidney.

Conclusions: In this experimental model that mimics human Covid 19 multiorgan failure, antioxidant improved survival, lung and kidney injury and also oxidative stress in the kidney. This suggest the beneficial effects of antioxidant as a kidney–lung protective strategy in patients with COVID-19.

PUB019
SRP14 Regulated Renal Tubular Apoptosis Induced by Ischemia-Reperfusion Injury via Interaction with RPS7
Yun Tang, Yanmei Wang, Guisen Li, Li Wang, Yi Li. Department of Nephrology, School of Medicine, Sichuan Academy of Medical Science and Sichuan Provincial People’s Hospital, University of Electronic Science and Technology of China, Chengdu, China.

Background: AKI could easily progress to CKD with increased incidence and mortality. Due to the complex pathogenesis, there is a lack of effective early warning to intervene in AKI.

Methods: We performed LFO proteomic analysis in HK, renal tubular epithelial cells after H/L molecule labeling and find SRP14 as a novel target to prevent AKI upon apoptosis in renal tubular epithelial cells. This study will further study the role and mechanism of SRP14 in regulating MDM2-p53 pathway in apoptosis of renal tubular epithelial cells in AKI. Then analyze the clinical correlation of SRP14 in AKI and explore the possibility of SRP14 as a potential therapeutic target for AKI.
Results: We identified that SRP14 could be involved in apoptosis of renal tubular epithelial cells due to oxidative stress. The inhibitors of SRP14 at or above 10 μM, could inhibit the cell proliferation through RPS7 in renal tubular epithelial cells to regulate apoptosis of renal tubular epithelial cells induced by IRI. The AUC value of SRP14 (AUC_{area} = 0.774) was close to serum creatinine (AUC = 0.796), suggesting the potential prognostic value of serum SRP14.

Conclusions: This study found that SRP14 regulated renal tubular apoptosis induced by ischemia reperfusion injury via interaction with RPS7 involving MDM2-p53 loop. This finding could provide some novel targets and ideas for AKI control in the future.

A Case of Masked AKI

Sitalakshmi J. Iyer,1,2 Clay A. Block,1 NYU Langone Health, New York, NY; 1,2VA New York Harbor Healthcare System, Manhattan, NY; 1,2Dartmouth College Geisel School of Medicine, Hanover, NH.

Introduction: Despite wide recognition of pitfalls, changes in serum creatinine (Cr) and/or a decline in urine output (UO) remain the mainstay of AKI diagnosis. We report a patient whose extremely low Cr and preserved UO demonstrate the problem in reliance on these parameters.

Case Description: 57 F was admitted for respiratory failure due to COVID-19. Her management included tocilizumab, mechanical ventilation, vasopressors, ECMO, and antibiotics. On entry she weighed 54kg and Cr was 0.5 mg/dL. After 3 days, Cr nadir at 0.1 then gradually rose to 0.6 where it remained (day 15). Net fluid balance was 20L. By Cr, her eGFR was 110 ml/min/1.73m² but by cystatin C (CysC) it was 56. A biopsy confirmed microvasculitis.

Discussion: AKIN defines AKI by an absolute rise in Cr of 0.3mg/dl within 48 hrs, a relative increase in UO within 1 - 1.5x baseline in UO to <0.5x baseline/mL/kg/hr for at least 6 hrs. Cr is a flawed AKI biomarker due to uncertainty of the baseline, variability in rate of generation, and elimination by secretion and filtration. Cr generation falls rapidly with critical illness. The impact of volume expansion resulting in hyperfiltration or hemodilution are underrecognized. Antibiotics, diuretics, glucose, ketones and bilirubin may interfere with measurement. UO too is flawed since oliguria may occur in the absence of AKI due to antidiuretic hormone or conversely, UO may be maintained despite AKI due to osmotic diuresis, failure of tubular function or diuretic use. The choice of baseline Cr influences our patient’s diagnosis. If 0.5 is chosen, she fails to meet AKIN criteria, but based on nadir Cr, she has severe stage III AKI. AKI can also be demonstrated by adjusting Cr for volume expansion: measured Cr x (initial total body water [TBW] + cumulative fluid gain) / initial TBW = 1.4 in our patient. Our patient received tube feeds, suffered hyperglycemia resulting in high osmolar load driving an osmotic diuresis. Also, periodic furosemide was given to mitigate her positive fluid balance. Below normal Cr is generally seen in myopathies, cirrhosis or with drug interference, but hyperfiltration can occur with volume expansion contributing to low Cr. In this case, we believe a baseline small muscle mass, critical illness sarcopenia, and marked volume expansion conspired to mask significant AKI in our patient. Documentation of AKI by measuring CysC led to adjustments in drug dosing.

Online Medical Education Significantly Improves Nephrologists’ Knowledge and Confidence for Intravenous (IV) Iron Use in Patients with Iron-Deficiency Anemia (IDA) in CKD

George Boutalis,1 Siggi D. Trier,1 Chris Allen,1 Jay B. Wish.2 Medscape LLC, New York, NY; 1Indiana University School of Medicine, Indianapolis, IN.

Background: Purpose: To determine if online medical education for nephrologists (Neph) could improve their evidence-based knowledge and confidence to use IV iron to treat IDA in non-dialysis (ND) and dialysis dependent CKD patients

Methods: Participants completed a 30-item questionnaire plus confidence assessment before and after watching a 30-minute online video series of 4 expert interviews with slides. A matched pair design was used pre-/post-assessment, with scores compared to assess changes in the proportion of correct responses. A chi-square test assessed statistical significance at the P <.05 level. Launch 01/29/20; data through 04/13/20. Total Neph learners (n=572), 15% in dialysis.

Results: At baseline, 20% of Neph (n=114) answered all 3 questions correctly, increasing to 61% (P < .001) post-assessment. An average of 61% of all responses, correct pre-assessment increasing to 83% post-assessment, were correct after viewing the slides. A matched pair design was used pre-/post-assessment, with scores compared to assess changes in the proportion of correct responses. A chi-square test assessed statistical significance at the P <.05 level. Launch 01/29/20; data through 04/13/20. Total Neph learners (n=572), 15% in dialysis.

Results: At baseline, 20% of Neph (n=114) answered all 3 questions correctly, increasing to 61% (P < .001) post-assessment. An average of 61% of all responses, correct pre-assessment increasing to 83% post-assessment, were correct after viewing the slides. Conclusions: The error distribution of the predictions is such that they 1) may be clinically meaningful as part of an effort to better control PTH, while potentially reducing excessive up-titration of etelcalcetide (and thus cost) and 2) may serve as a benchmark for future modeling efforts. Limitations include: a relatively small data set which precluded the use of other models (e.g., recurrent neural networks) and the dialysis program’s strict criteria for receiving etelcalcetide which led to a study population with significantly higher PTH values than may be encountered in the general dialysis population.

A Rare Case of Staghorn Calculi Complicated by Bilateral Xanthogranulomatous Pyelonephritis

Michael Chang, Gary Dellacerra, Deep Sharma, Joshua M. Stern, Peter Nauka, Wei Chen. Montefiore Medical Center, Bronx, NY.

Introduction: Staghorn calculi are usually unilateral and typically occur in women. Chronic obstruction and infection of staghorn calculi can cause xanthogranulomatous pyelonephritis (XGP), a rare destructive granulomatous process of renal parenchyma. We describe a case of bilateral staghorn calculi in a man complicated with XGP and worsening renal function.

Case Description: A 64-year-old man with bilateral staghorn calculi and chronic kidney disease (CKD) stage 4 was admitted for fatigue and worsening renal function. He tested positive for COVID-19 by nucleic acid-based test. Serum creatinine increased from 3.5 (2 months ago) to 6.2 mg/dL. Renal ultrasound showed dilated left calyces and large shadowing calculi without hydronephrosis. History was notable for persistently alkaline urine (pH 6.5), 100% carbonate apatite (dahllite) on stone analysis, and urinary tract infection with Proteus mirabilis. CT imaging revealed bilateral staghorn calculi with “bear paw” signs (left > right), a typical appearance of XGP [Figure]. Compared to a CT scan completed 10 months ago, the left kidney was enlarged with greater low-attenuating spaces indicating worsened XGP; the right kidney decreased in size with less stone burden corresponding to the right percutaneous nephrolithotomy performed 7 months prior. AKI was thought to be related to COVID-19, and surgical intervention was deemed unnecessary. Bilateral XGP likely increased his risk of AKI and hampered renal recovery, and he was subsequently initiated on hemodialysis.

Discussion: In this rare case of staghorn calculi progressed to bilateral XGP, we observed the detrimental effects of staghorn calculi on the kidneys. More research on staghorn calculi is needed to improve the high morbidity and mortality associated with this disease.
Factors Associated with Serum Concentrations of 25-Hydroxyvitamin D (25D) and 1,25-Dihydroxyvitamin D (1,25D) in Stable Hemodialysis Patients

Eiji Ishimura, Takahiro Fujimoto, Kazunori Masutani, Kazumari Higashimoto, Nobuya Murakami, Shuko Ueda, Nobuyuki Kuwamura, Akihito Tsuda, Shinya Nakatani, Katuhito Mori, Senji Okuno, Ruusuke Kakiya, Masanari Emoto, Meijibashi Hospital, Osaka, Japan; Osaka City University Graduate School of Medicine, Osaka, Japan; Shirasagi Hospital, Osaka, Japan.

**Background:** Serum 1,25D, an active form synthesized from 25D, is present in CKD patients (Ishimura, Kidney Int 1999; Wolf, Kidney Int 2007). However, factors associated with 1,25D and 25D are not well known. The aim of the present study is to examine the relationship between 1,25D, 25D and clinical parameters in hemodialysis patients.

**Methods:** Serum 1,25D and 25D were measured by a RIA2-Ab method and an ECLIA method, respectively, in 108 stable maintenance hemodialysis patients (72±10 years, 64 males, hemodialysis duration: 6.9±7.5 years, 45 diabetics) from December 2019 to February 2020, i.e., in the winter.

**Results:** Serum 1,25D were 14.6±8.0 pg/mL, demonstrating that 77 patients showed values less than reference ranges of healthy subjects (30-60 pg/mL). Serum 25D were 12.0±4.8 ng/mL, demonstrating that 101 patients showed vitamin D deficiency of <20 ng/mL. There was no significant correlation between serum 1,25D and 25D in maintenance hemodialysis patients in the present study, although 1,25D and 25D had been reported to show significant, positive correlations both in pre-dialysis CKD patients (Ishimura, Kidney Int 1999) and in incident dialysis patients (Wolf, Kidney Int 2007). There were no significant correlations between 25D and clinical parameters. However, there were significant, negative correlations between 1,25D and intact PTH (r = 0.344, p < 0.001) and between 1,25D and ALP (r = 0.309, p < 0.02), although no significant correlations were seen between 25D and other parameters, such as Ca and P. In multiple regression analyses, 1,25D was significantly, independently associated with intact PTH and with ALP after adjustments of several clinical parameters (R² = 0.345, p < 0.001; R² = 0.256, p < 0.001, respectively).

**Conclusions:** In maintenance hemodialysis patients, all patients showed hypovitaminosis D, in terms of serum 25D. 1,25D, even in low serum levels, correlated significantly and negatively with intact PTH and ALP. These results indicated that even low levels of serum active vitamin D, 1,25D, affect the status of CKD-MBD. The results may further indicate that the metabolism of vitamin D should be considered in the pathogenesis and treatment of CKD-MBD.

A Case of Parathyroid Hyperplasia with Single Explosive Growth

Beili Hou, Bing Tang, Yong Xu, Yuanning Li, Ninxin Liu, Xiang yijia, Doctor Group, Jiahospital, Changsha, China; Xiangyja Hospital Central South University, Changsha, China.

**Introduction:** Exploration of parathyroid hyperplasia with single explosive growth

**Case Description:** A 46-YO Asian man with ESRD has been undergoing regular hemodialysis for 20 years due to glomerulonephritis. The patient has had bone pain and joint pain for 10 years. In 2018, the measurement of his serum iPTH was elevated and the value was over 1000pg/ml (no data about serum calcium and phosphate levels), and he didn’t have regular treatment. Serum calcium, phosphate and alkaliphosphatase were 2.46mmol/L, 2.4mmol/L and 380U/L, respectively, and serum iPTH was 2205pg/ml in this admission examination. The ultrasonography showed two hyperplastic parathyroid glands. They are 13*5mm on the right lower side of thyroid gland and 43*18mm on the left lower side. Parathyroid nuclide scanning showed three hyperplastic parathyroid glands. That is located in bilateral hypothyroidism and left upper sternum, consider parathyroid development, Total parathyroidectomy was successfully carried out with the general anesthesia in May 15, 2020. Four parathyroids were excised, which were 0.6*0.5cm in the upper left, 4.9*3.0cm in the lower left, 0.8*0.5cm in the upper right, and 1.5*1.0cm in the lower right (the maximum diameter and length). Pathological diagnosis showed that there was parathyroid nodular hyperplasia in the upper left, lower left, upper right and lower right. PTH values a week after surgery was less than 1.2pg/ml, serum calcium 2.13mmol/L, phosphate was 0.85mmol/L. Patient bone pain disappeared. Patient has been discharged and will be close followed up.

**Discussion:** Total parathyroidectomy is effective in uremic patients with secondary hyperparathyroidism which has explosive hyperplasia with parathyroid glands.
Conclusions: Our results show that in subjects with end-stage kidney disease a meal with high phosphorus content has only a negligible effect on plasma phosphate compared to a meal with low phosphorus content. Thus, large increases in plasma phosphate cannot be accounted for by a high intake of phosphorus in the hours prior to blood sampling.

PUB027

A Rare Case of Severe Tertiary Hyperparathyroidism in a Patient with ESRD

Introduction: Refractory tertiary hyperparathyroidism is defined as severe, persistent & progressive elevation of PTH which cannot be lowered by medical management & associated hypercalcemia, hyperphosphatemia, bone/joint pain and/or fracture, extra skeletal calcification, calcification & pruritis.

Case Description: A 43-year-old undocumented Hispanic male with PMH of uncontrolled DM, HTN, ESRD (HDX 3/week) & persistent tertiary hyperparathyroidism (on Cinacalcet) presented with multiple bone fractures, bilateral leg weakness, soft tissue calcification & severe renal osteodystrophy. Significant lab findings included PTH 3518pg/mL, phosph 6.7mg/dL, Ca 10.9mg/dL & ak phosph 804 IU/L were all above goal. X-ray of lower ext. revealed diffuse osteopenia with chronic fracture in distal fibula, midfoot, distal tibia & dislocation of talonavicular joint as well as extensive atherosclerotic vascular calcification & multiple punctate soft tissue calcification. CT spine reported demineralized appearance of vertebral bodies & sacram, wide erosion of sacroiliac joints bilaterally & calcified atherosclerotic disease of abdominal aorta & bilateral interstitial arteries. Patient was diagnosed as refractory tertiary hyperparathyroidism & treated with doxercalciferol, phosphate binders & advised for parathyroidectomy on multiple previous encounters but was unable to do due to health care access issue.

Discussion: Parathyroidecmy which has mortality benefit is indicated in the setting of severe & sustained PTH value above 800-1000 pg/mL, refractory to medical treatment & associated to others indicators like hypercalcemia, refractory hyperphosphatemia, bone pain/fractures & our case has majority of the above mentioned indications. Various & associated to others indicators like hypercalcemia, refractory hyperphosphatemia, bone pain/fractures & our case has majority of the above mentioned indications. Various factors including immigration, insurance issues and post-operative intensive care requirements complicated the potential for parathyroidecmy in this patient. Although with advancement of medical field, the symptoms of severe hyperparathyroidism are rarely observed but the manifestations are real if not treated on time as per guideline recommendations.

PUB028

Progression of CKD Stage G3a Among African Americans
Yelvzaveta Pryavzanvuy, Ishu Puri, Jie Ouyang, Ernie Yap. SUNY Downstate Health Sciences University, Brooklyn, NY.

Background: Chronic kidney disease (CKD) stage 3 represents the most of all CKD patients. Stage G3 is divided into G3a (GFR 45–59 ml/min/1.73m²) and G3b (30–44 ml/min/1.73 m²) based on findings that showed differential kidney outcomes. Stage G3a has several unresolved paradigms. Firstly, it does not always imply kidney damage. It is recommended that cystatin C be used to confirm in people without manifestation of kidney damage to avoid over-diagnosis. Secondly, it primarily comprises of the elderly, and most will not progress to advanced CKD before succumbing to other causes of death. Thirdly, in people with manifestations of kidney damage, stage G3a becomes an important predictor of disease progression. The influence of ethnicity on eGFR in delineating these aberrancies in CKD G3a is unclear. In this study, we sought to analyze the progression of CKD G3a patients in a predominantly African American cohort.

Methods: We performed retrospective chart reviews of patients at our CKD clinic. GFR was estimated based on the MDRD formula. Continuous variables are presented as mean±SD. Comparison of continuous variables were performed using one-way ANOVA. Univariate and age and body mass index (BMI)-adjustment analyses was performed by Cox proportional hazards model. IBM SPSS v. 25 was used.

Results: 319 patients were analyzed. Median follow-up was 79.7 months (IQR: 93.1-259). 29% of patients had at least 2 years follow-up. In these patients, the mean annual GFR declines were 4.4±3.8, 2.3±2.1, 1.6±2.7 and 1±4±2.2 ml/min/1.73 m² for stages G2, G3a, G3b and G4 respectively (p<0.001). Univariate Cox proportional hazard analysis showed that CKD G3a, Gb and G4 had relative risks (RR) of progression to G5 of 1.0 (95% CI: 0.5-2.2, p=0.98), 3.6 (1.6-9.0, 0.003) and 19.4 (8.7-43.0; <0.005) respectively. When adjusted for age and BMI, risks of progression to G5 were: RR=1.3 (10.6-3.0; 0.5), 5.8 (2.3-14.7; <0.005) and 29.6 (12.1-72.2; <0.005) for CKD G3a, G3b and G4 respectively.

Conclusions: In our cohort of predominant African Americans, CKD G3a does not predict disease progression.

PUB029

Is Routine Screening with Serum and Urine Protein Electrophoresis in Evaluation of CKD Justified?
Omar T. Asbour,1,2 Christine A. White,1,2 Eduard A. Ilicsu.1,2 Queen’s University, Kingston, ON, Canada; 1Kingston Health Sciences Centre, Kingston, ON, Canada.

Background: Current guidelines for the evaluation of chronic kidney disease (CKD) in Canada do not include routine screening with serum and urine protein electrophoresis (SPEP and UPEP). Previous studies suggest that M-spike is more common in CKD compared to the general population (1,2). This study aims to examine the use and cost of screening SPEP and UPEP in the evaluation of CKD pts.

Methods: This is a retrospective study of 149 sequential incident pts referred to a teaching General Nephrology clinic for evaluation of CKD between Jan and Nov, 2018. The SPEP and UPEP testing frequency, and proportion with M-spike were obtained by chart review, along with the routinely performed clinical, blood and urines tests, imaging, as well as reports of any Hematology consultation, renal and bone marrow biopsies performed.

Results: Screening SPEP and UPEP tests were done in 104 (70 %) pts, mean age 72.2 yrs, 42 (40 %) female, 52 (50 %) DM, and Caucasian majority. M-spike was present in 11 pts (10.6 %, 96 % C1 5.4 – 18.8 %), 2 IgG-k, 5 IgG-l, 1 IgA-k, 2 L C-k, and 1 L C-λ. Eight had Hematology consultation, 6 had bone marrow biopsy, and 3 had renal biopsy. Diagnoses were 7 MGUS, 2 myeloma (MM), 1 amyloidoid (AL) and 1 both MM + AL. There were no differences in clinical, demographic, CBC, serum calcium, urine albumin to creatinine ratio, urinalysis, or renal imaging among pts with and without M-spike but sample size did not allow multivariate analysis.

Conclusions: In this study, the prevalence of M-spike in CKD is higher than has been reported in the literature in the general population (5.4 - 18.8 % vs. 3 - 4 %). The cost for testing and interpretation fees for SPEP and UPEP are CDN $25.53 and $32.99 respectively, with detection cost per M-spike of $1.53; 2.52 per MGUS and $1.52 per myeloma or amyloid. These costs are consistent with previous studies controlled for inflation (1,2). Routine screening with SPEP and UPEP in the evaluation of CKD may be useful and cost-effective. Larger prospective studies are needed to identify subgroups with higher likelihood of M-spike to target testing. 1. AHwisch et al. J Am Soc Nephrol 2003 14:295A. 2. Chew et al. Is Yakima County a CKDu Hot Spot? A Case Series of CKD in Latino Agriculture Workers
Mark D. Baldwin, Katherine Ackerman, Tara L. Kronen, Polly Wiltz, Lizzie Lamb. PNWU CKDu Investigative Task Force Pacific Northwest University of Health Sciences College of Osteopathic Medicine, Yakima, WA.

Introduction: The first case series of chronic kidney disease of unknown etiology (CKDu) was described in 2002 in sugar cane cutters in El Salvador. This unique diagnosis is involved in agriculture. The majority of labor-intensive agriculture jobs are performed by Latino workers, drawing attention to Yakima as an unexpected hotspot for CKDu.

Background: Heat in Yakima, Washington, an agricultural community in the Pacific Northwest, has had the highest average temperature increase in the Pacific Northwest at 3°F over environments. Yakima, Washington, an agricultural community in the Pacific Northwest, has had the highest average temperature increase in the Pacific Northwest at 3°F over the past 30 years. Average summer temperatures for July and August are 88°F and 89°F, respectively. Yakima County is 49.5% Latino and 27.5% (29,331) of the total population is involved in agriculture. The majority of labor-intensive agriculture jobs are performed by Latino workers, drawing attention to Yakima as an unexpected hotspot for CKDu.

Case Description: We describe three Latino agricultural workers seen by a nephrologist in an MHD clinic in a local free clinic in the span of 8 months. The ages ranged from 58-68 and all worked ten years or more for local farms. Each patient had at least Stage 3 CKD (<60 ml/min/m²), hypertension, hyperuricemia, without proteinuria or albuminuria; there was no history of diabetes mellitus. Renal ultrasounds were unremarkable. Treatment was focused on controlling hypertension and hyperuricemia, however little disease modifying interventions are available.

Discussion: These cases, collected over a relatively short period of time, demonstrate that CKDu is more common than previously thought amongst agricultural workers in Yakima, Washington.
northern regions. At 46.6021° N latitude, Yakima is closer to the North Pole than other areas where CKDs have been documented. With increasing global temperatures, agricultural workers are on the frontline of climate-related health issues. Further study is necessary to develop awareness, earlier risk factor detection, and effective interventions for these essential and vulnerable members of our communities.

The Correlation Among Management of the Comorbidities and Progression of Renal Dysfunction or Adverse Events for CKD Patients

**Takahiro Kuragano,** Takeshi Nakanishi. *Hoyo college of Medicine Kidney and dialysis, Nishinomiya, Japan.

**Background:** It is well established that several factors including anemia, hypertension, hyperuricemia, metabolic acidosis, and CKD-MBD are associated with progression of CKD or adverse events of these patients. However, the significant factors which associated with progression of CKD or adverse events under the condition of appropriate control which according to guidelines have not been cleared.

**Methods:** The study was an observational study in a single center for a period of 3 years. In 88 patients with various stages of CKD (not on dialysis) who were treated by nephrologists, Hb, ferritin, iron and albumin and high sensitive C reactive protein (hsCRP), β2microglobulin (MG), HCO3 - and intact-parathyroid hormone (iPTH), in addition to urinary sodium, potassium, calcium, phosphorus protein, and β2MG levels, were measured. All patients were treated according to the clinical practice guideline for CKD. A time-dependent Cox hazard model was applied to evaluate the association between clinical parameters and adverse events.

**Results:** In multiple regression analysis, baseline of lower Hb (β=0.497, P=0.001) and vitamin D 125 (β=0.258, P=0.001) and high int-PTH (β=0.34, P=0.001), urinary phosphorus (β=0.328, P=0.001), urinary β2MG (β=0.225, P=0.031) and urinary protein (β=0.280, P=0.002) levels were selected as significant predictors of decline of estimated glomerular filtration rate (eGFR) or 1/creatinine(τς) at the end of the study. In the Cox hazard model, low calcium (HR: 0.37, P=0.026), high phosphate (HR:5.90, P=0.001), low 125 vitamin D (HR: 0.94, P=0.013), high int-PTH (HR:1.02, P=0.001) level, use of a phosphate binder (HR: 4.95, P=0.012), and use of vitamin D analogs (HR:3.75, P=0.014) are selected as risks for adverse event including initiation of dialysis.

**Conclusions:** In this study, we found that among several factors, anemia and CKD-MBD related factors (phosphate, calcium, vitamin D, int-PTH) were selected as significant predictors for renal dysfunction. Furthermore, although phosphate binder or vitamin D analogs were administered appropriately, CKD-MBD factors were associated with progression initiation or adverse events of these patients. From these results, we presumed that the early intervention or strict control for CKD-MBD factors might attenuate the risk for adverse events of CKD patients.

**PUB032**

Association of Anion Gap with the Risk of CKD Progression

**Ashish Verma,** Jing Liu, Maria Clarissa Tio, Ankit B. Patel, Sushrut S. Waikar. 1 Brigham and Women’s Hospital, Boston, MA; 2 Boston University Medical Campus, Boston, MA.

**Background:** Increased anion gap is a marker of acid retention most reflected in patients with CKD. This study’s objective is to assess whether a higher anion gap is a risk factor for CKD progression.

**Methods:** This retrospective cohort study assessed 4311 participants with CKD stage 2 to 4, who enrolled in a chronic renal insufficiency cohort study. Three types of anion gap were used as exposures, traditional anion gap (AG1), Albumin corrected anion gap(AG2), full anion gap(AG3). Multivariable adjusted Cox proportional hazard models were built using the lowest tertile as the reference of all three anion gaps for the composite outcome (50% decline in eGFR or ESRD) and ESRD. Models were adjusted for relevant covariates and baseline eGFR.

**Results:** This study included 4311 participants [mean (SD) age, 60.48(10.21) years; 1788 (43.28)% female]. During 2667.46 person years of follow up, 805 participants reached ESRD and 1138 participants reached a composite outcome of a 50% decline in GFR or ESRD. In a multivariable adjusted model each SD increase in AG1, AG2 and AG3 were independently associated with 10%, 10% and 12% increased risk for CKD progression: hazard ratio (HR) 1.10 ; 95% CI (1.01-1.21), HR 1.10 ; 95% CI (1.02-1.20), HR 1.12 ,95% CI (1.03-1.21), however each SD increase in AG2 and AG3 was independently associated with a 11% increased risk for ESRD [HR 1.11; 95% CI (1.02-1.21), HR 1.11; 95% CI (1.02-1.22)]. In multivariable adjusted models compared to tertile 1 (<10) those in tertile 3 (>12) had a 33% and 41% higher risk for CKD progression [HR 1.33;95% CI (1.09-1.62), HR 1.41,95% CI (1.16-1.71)] and 32% and 60% higher risk for ESRD [HR 1.32; 95% CI (1.06-1.64), HR 1.60,95% %CI (1.28-2.01)].

**Conclusions:** Higher albumin corrected and full anion gap may be a risk factor for CKD progression and ESRD.

**PUB033**

Childhood Risk Factors for Adulthul CKD

**Michal Stern Zimmer, Asaf Vivante. Sheba medical center, Ramat Gan, Israel.

**Background:** Chronic Kidney Disease (CKD) is a demographic health challenge, affecting ~ as much as 8 to 18% of the world population. Identifying childhood risk factors for future CKD may help clinicians make early diagnoses facilitating complication monitoring and initiation of preventive interventions for CKD and its accompanying comorbidities. We aim to describe these childhood risk factors that may predict development of overt kidney disease later in life.

**Methods:** PubMed publications (January 2009 - January 2019) were searched for publications by using terms and synonyms for chronic kidney disease (CKD) and specific childhood kidney related risk factors. We also manually searched the reference lists of key articles, reviews and meta-analyses.

**Results:** There are a multitude of childhood risk factors associated with future onset and progression of CKD. These risk factors can be grouped into five categories: genetic factors (e.g. monogenic or risk alleles), perinatal factors (e.g. low birth weight and prematurity), childhood kidney diseases (e.g. congenital anomalies, pyelonephritis, glomerular diseases and acute kidney injury), childhood onset of chronic conditions (e.g. cancer, diabetes, hypertension, dyslipidemia and obesity) and different lifestyle factors (e.g. physical activity and diet).

**Conclusions:** The available published information suggests that the lifelong risk for CKD can be attributed to multiple factors which appear already during childhood. However, results are conflicting on the effects of childhood physical activity, diet and dyslipidemia on future renal function. On the other hand, there is consistent evidence to support close monitoring for high risk populations.
PUB034

Therapeutic Interventions to Assess Outcomes and Disparities in Chronic Kidney Disease Among Veterans (TRI-CKD)

Keichi Sumida,1 Ankur A. Dashputre,1 Praveen Kumar Potukuchi,1 Fridjof Thomas,1 Jun Ling Lu,1 Miklos Z. Molnar,1 Cachet Wenziger,1 Elani Streja,1 Kamyar Kalantar-Zadeh,2 Csaba P. Kovesity3 The University of Tennessee Health Science Center, Memphis, TN; 2University of California Irvine, Irvine, CA.

Background: There continues to be a large unmet need in the management of CKD, due in part to a lack of effective intervention strategies to prevent CKD progression or decrease morbidity/mortality in patients with CKD. There is also a lack of race-specific application of clinical interventions, despite evidence suggesting racial differences in response to various therapies. High quality, large observational studies are essential to provide preliminary results in support of future clinical trials, and to offer suggestive, widely applicable evidence to inform clinical practice in this population when clinical trials are not feasible.

Methods: We established a cohort of 3,565,367 individuals with stable eGFR >60 mL/min/1.73m² during October 1, 2004-September 30, 2006, using an algorithm based on repeated serum creatinine measurements. Data about patients’ demographics, socioeconomic characteristics, comorbid conditions, administered medications, labs, vital signs, vital status, incident CKD and ESRD outcomes were obtained from various VA databases, from Centers for Medicare & Medicaid Services, and from USRDS.

Results: The mean (SD) age of the cohort is 59 (14) years; 93% are male; 16% are African-American; and 24% are diabetic. The mean baseline eGFR is 84 mL/min/1.73m². Individuals are followed longitudinally for up to 13 years. Overall, the crude rates of all-cause death and ESRD are 51 and 0.63 per 1000-patient-years (Figure).

Conclusions: We established a large nationwide cohort of US veterans with normal eGFR. Studies from this cohort will generate a wealth of information to examine therapeutic interventions used to treat various conditions associated with poor outcomes in patients with all levels of kidney function, potentially providing significant clinical, social, and policy implications for the care of US veterans and also for patients with kidney diseases in general.

Treatment Response in Patients with Uncontrolled Gout Co-Treated with Pegloticase and Leflunomide

Karmir R. Marsi,1 Kevin W. Winterling,2 Brian LaMoreaux,2 1Ben Secours Rheumatology Center, Richmond, VA; 2Horizon Therapeutics, Lake Forest, IL.

Background: Many patients with CKD develop gout with a prevalence ≤36% in later stage disease. Though oral urate-lowering therapies are used in CKD patients, some may not respond to or cannot tolerate them. Uncontrolled (refractory) gout can be treated with pegloticase (PEGylated uricase enzyme), however, anti-drug antibodies (ADAs) can cause loss of therapeutic efficacy. Compared with pegloticase alone, recent case series show markedly higher response rates with methotrexate/pegloticase co-therapy (42% vs. 80-100%). However, certain considerations with methotrexate use including significant side effects and hepatotoxicity may not be as restricting with leflunomide. This study examined the effects of co-therapy in patients with all levels of kidney function, potentially providing significant clinical, social, and policy implications for the care of US veterans and also for patients with kidney diseases in general.

PUB036

A Double-Blind, Randomized, Placebo-Controlled with an Open-Label Rollover Extension Phase 2/3 Clinical Trial to Evaluate Safety and Efficacy of US-APR2020 in Subjects with CKD Stage IV

Narataram Ranganathan1, Usha N. Vyas,1 Pari Ranganathan,1 Anthony Irvin,1 Alan D. Weinberg,2 1Kibow Biotech, Newtown Square, PA; 2Mount Sinai Health System, New York, NY.

Background: CKD patients experience poor quality of life due to high levels of uric acid toxins in the blood. Renalyte™, a Pro/Prebiotic dietary supplement has been used in the market since 2010. It is proven to reduce several uric acid toxins in 3 pilot clinical trials with no adverse outcomes. The product is now awaiting FDA-IND approval for a drug trial. This will be a large scale 12-month RCT to validate US-APR2020 as a Live Bio-Therapeutic drug product (LBP) under CBER guidelines.

Methods: (A) 6-month randomized placebo-controlled parallel design in an outpatient setting followed by (B) 6 month Open-Label Rollover Extension which will enroll all patients from study A.

Results: Study end points: As compared to placebo; Primary: 1. Less than 10% adverse event in the study population. 2. Arrest the decline of gFR as per NKF-USFDA guidelines. Secondary: 1: Improvement in any of the basic blood uric acid metabolic markers. 2: Improvement in any of the disease-related markers (K/Na, serum albumin, hs-CRP, BUN, creatinine).

Conclusions: This is the first-ever clinical trial proposed using Pre/probiotics US-APR2020 as a Live Bio-Therapeutic drug product (LBP) for CKD IV patients. Being noninvasive the intervention avoids any possible infection. The addition of US-APR2020 with standard care of therapy may possess excellent potential towards CKD applications worldwide. Formal IND process under CBER/US FDA in progress. Seriously interested clinical PI’s please contact: rangan@kibowbiotech.com

PUB037

Effects of Tolvaptan on Long-Term Prognosis in CKD Patients

Kazuhito Fukushima, Yuko Shibata, Shinya Kaname. Kyorin University School of Medicine, department of Nephrology and Rheumatology Kyorin Daigaku, Mitaka, Japan.

Background: Tolvaptan is a novel diuretic agent used for the treatment of intractable edema and SIAHH in Japan, as well as polycystic kidney disease. Purpose: To determine whether tolvaptan prevent worsening renal function or prolongs the time to dialysis induction in pre-dialysis CKD patients.

Methods: A retrospective observational study (case-control study). Eligible patients were CKD patients treated with tolvaptan more than 30 days at our hospital between 2012 and 2018. The control patients were selected from CKD patients without the use of tolvaptan at our hospital that matched base line characteristics using the generated propensity score. The endpoints were a decrease in eGFR of more than 30%, introduction of dialysis, and death. The logistic regression analysis was performed on the indicator of the presence or absence of tolvaptan. Survival analysis was analyzed by the Kaplan-Meier method and tested with log rank, generalized Wilcoxon, and Barone-Ware. The software for the statistics was IBM® SPSS® Statistics ver. 24.

Results: A total of 106 patients received tolvaptan during the study period, including 52 who met the study criteria. The median age was 65 years, the mean duration of treatment was 533 days, and the dose was 8.16 mg/day. Of these, there were 15 cases of diabetes and 6 cases of nephrosis. The normal patient group matched to these cases was selected from 63209 cases. Tolvaptan was administered after hospitalization, with an 82.1% increase in urine output and a weight of -4.2% at discharge. The tolvaptan combination group had a significant prolongation of days to endpoint: control group (746.0 ± 9.013) vs Tolvaptan group (1076.3 ± 95.71, p = 0.0001, CI 749-1012).

Conclusions: Tolvaptan is expected to improve prognosis because of its ability to improve edema even in advanced CKD cases. Tolvaptan has been shown to improve edema in advanced CKD as well as inhibit the deterioration of renal function with long-term use.
Serum Calcium Changes and Renal Function: A Dual Path Track
Julia Lauria, Tiago E. Costa, Giovanni G. Nascimento Santos, Rosa M. Moyes, Rosilene M. Elias. Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.

Background: Although hypercalcemia is associated with an impairment of renal function, the literature is scarce in demonstrating this relationship in clinical practice. We hypothesized that fluctuations in serum total calcium (tCa) may impact renal function in patients with chronic kidney disease (CKD).

Methods: This is a retrospective study which enrolled 148 patients with at least 2 clinical appointments with concomitant tCa and estimated glomerular filtration rate (eGFR) measurement in the period between January-2017 and December-2019. We collected demographic, clinical, and biochemical data. Up to 3 consecutive measurements were analyzed.

Results: Patients were mostly Caucasian women, aging 66 ± 15 years. Mean eGFR was 45.1 ml/min/1.73m². Hyperparathyroidism (parathyroid hormone > 65 pg/ml) was associated with a 2.8-fold increased risk for hypercalcemia (p=0.030). There was a non-linear relationship between change in tCa and change in eGFR, so that when tCa increased above the normal limit, there was a reduction in eGFR. Patients with hyperparathyroidism seem to present a significant lower risk of impairment in eGFR in the consecutive measurements when compared to other causes of hypercalcemia.

Conclusions: The development of hypercalcemia in patients with CKD is associated with a deterioration of renal function. Therefore, the strict control of serum calcium is advised in these patients.

The Tri-POCUS Approach for Assessment of Volume Status in Critically Ill Patients with COVID-19
Abhilash Koratala,1 Claudio Ronco,2 Olanrewaju A. Olayoe,1 Amir Kazory,1
1University of Florida, Gainesville, FL; 2Universita degli Studi di Padova, Padova, Italy; 3Medical College of Wisconsin, Milwaukee, WI.

Background: The volume status of patients with coronavirus disease 2019 (COVID-19) is dynamic and can range from severe hypovolemia (on initial presentation) to overt hypervolemia (after fluid resuscitation) due to its distinct clinical features such as cytokine storm. While lung point-of-care ultrasound (POCUS) is established as an invaluable bedside tool in assessment of volume status of the critically-ill, its use in this setting is limited by expanding lung infiltrates and a tendency for acute respiratory distress syndrome (ARDS).

Methods: We developed a combinational bedside ultrasound program to overcome the limitations of the individual methods of POCUS and provide a more precise evaluation of the volume status of critically ill patients with COVID-19. The Tri-POCUS approach represents concurrent bedside assessment of the lungs, heart (focused cardiac ultrasound [FoCUS]), and the venous system (blood flow pattern in the hepatic, portal and intra-renal veins) (Figure 1).

Results: In patients with COVID-19, distinguishing ARDS from cardiogenic pulmonary edema by lung POCUS alone is challenging due to several overlapping features. FoCUS allows for both static measures of preload as well as dynamic assessment (e.g. volume responsiveness to passive leg raise maneuver). Evaluation of blood flow pattern in the hepatic, portal and intra-renal veins not only can gauge fluid status but it also allows for direct assessment of the congestive state in end organs hence monitoring response to therapy.

Conclusions: The Tri-POCUS program is an extension of our previously published work focused on renal POCUS curriculum. The components of this combinational approach have been selected based on their ability to cover the limitations of each individual method and provide a synergistic effect, especially in clinical settings such as COVID-19 where there is a tendency for rapidly changing volume status confounded by distracting features (e.g. expanding lung lesions).

New-Onset Nephrotic Syndrome in a Child Associated with COVID-19 Infection
Siddharth A. Shah. University of Louisville, Louisville, KY.

Introduction: The COVID-19 outbreak has turned into worldwide public health emergency. The renal histo-pathological features of acute tubular necrosis or thrombotic microangiopathy are reported in adults previously with severe COVID-19 infections. In children, the renal manifestations associated with COVID-19 infection are not widely reported. Here, we describe a case report of a child with new onset nephrotic syndrome associated with COVID-19 infection.

Case Description: 8-year-old boy with no previous significant medical history presented with bilateral eye and facial swelling soon after his parents were diagnosed with COVID-19 infection. He had diarrhea but no fever or shortness of breath. One week after onset of swelling, the boy was also tested positive for COVID-19 infection. Based on clinical findings of significant proteinuria (Urine protein and creatinine ratio of 11.4), hyperalbuminemia (serum albumin of 2 g/dL) and hypercholesterolemia (Total Cholesterol of 384 mg/dL), he was diagnosed having nephrotic syndrome. He responded well to standard-dose prednisone treatment for nephrotic syndrome. In one week of starting prednisone treatment, he went into clinical remission. Lymphopenia continued to be present for 2 weeks after onset of symptoms. There were no complications related to clot formation or secondary infections with this presentation.

Discussion: This is the first case report to our knowledge of pediatric patient presenting with new-onset nephrotic syndrome associated with COVID-19 infection. Although, the burden of disease from COVID-19 is less severe in children, they can present with immune system related kidney disease like nephrotic syndrome. The patient responded well to standard-dose prednisone treatment used typically for new onset nephrotic syndrome.

Recurrent Arteriovenous Graft Thrombosis in COVID-19
Namratra Singhania,1 Saurabh Bansal,2 Girish Singhania.1 1CHI Saint Vincent Health System, Little Rock, AR; 2Mount Carmel East, Columbus, OH; 1University of Illinois at Peoria, Peoria, IL.

Introduction: COVID-19 has been associated with increased risk of hypercoagulability. We report a case of COVID-19-associated coagulopathy leading to recurrent arteriovenous (AV) graft thrombosis in an end-stage renal dialysis (ESRD) patient.

Case Description: 84 yo African American female with ESRD on dialysis via lower extremity AV graft, diabetes and atrial fibrillation on warfarin who was diagnosed with COVID-19 came back again 1 week later and was admitted due to hypoxemia. COVID-19 PCR was again positive. INR was 1.4, D-dimer 3.28 mcg/mL, platelet count 114K/mm², mildly prolonged PT, aPTT. She had elevated venous pressures during dialysis. Doppler suggested AV graft thrombosis. Heparin drip was started. Angiography and intravascular ultrasound (IVUS) showed thrombosed AV graft. (Figure 1a,1b) Thrombectomy was successful (Figure 1c,1d) with uneventful hemodialysis afterwards. She was discharged. Next day, she came back again with diarrhea. Coronavirus PCR was still positive. INR was 1.9. She again had high venous pressures. Doppler found recurrent thrombosis. Heparin drip was started. Vascular surgery placed dialysis catheter and held thrombectomy till her coronavirus PCR turns negative.

Discussion: Incidence of venous thromboembolism (VTE) can be as high as 58% in patients with COVID-19. All categories of ‘Virchow’s triad’ are involved, endothelial injury (increased cytokines and complements), stasis (immobilization) and hypercoagulable state (changes in prothrombotic factors). Risk factors are males, obesity, heart disease, hypertension, diabetes and ESRD. High D-dimer, mildly prolonged PT, aPTT and thrombocytopenia are common. Full-dose anticoagulation is recommended for documented VTE.
PUB042

Manage of a Peritoneal Dialysis Unit During the COVID-19 Pandemic

Background: Peritoneal Dialysis (PD) patients are special, as they are mainly independent in a “life-support technique” but susceptible to various potential complications related. This pandemic brought new challenges and PD Units had to be reorganized considering their specific population, human and material resources. We aimed to understand the impact of our restructuration and discuss some lessons learned.

Methods: We retrospectively reviewed the activity and intercurrences at our Unit during the COVID-19 state of emergency declared by our Government, from 19th March to 2nd May (6 weeks), and compared it to the correspondent past two years (table 1). In a normal period, most of our patients are evaluated in a monthly basis. Simple descriptive and Student’s paired T-test analysis were performed.

Results: We managed 34 patients in the correspondent period of 2018, 36 in 2019 and 38 in 2020. Clinical appointments in this 2020 period were realized by phone. Necessary dislocations to the Unit in 2020 included peritonitis, exit-site infections and catheter malfunctioning. No dropouts occurred. There were no positive cases of COVID-19. Student’s paired T-test analysis between 2020 and 2019, plus 2020 and 2018, showed no statistically significant differences in every evaluated phenomenon (except for non-presenter appointments; this discrepancy is justified by the Unit’s dynamic, without clinical implications).

Conclusions: Despite the restructuring, we were able to provide more teleassistance and the mean of complications/hospital admissions weren’t statistically worse. Some activities were postponed, but its true impact isn’t yet clear. Will suboptimal care bring long-term complications? Nonetheless, PD technique stands out for favorably, mainly if all the necessary support from medical and nurse staff is guarantee.

Activity and intercurrences at our PD Unit.

Complete Recovery from COVID-19 Infection in an ESRD Patient

Introduction: We report a hemodialysis case having both influenza and COVID-19 who presented without respiratory symptoms and recovered fully with treatment by Interleukin-6 (IL-6) inhibitor.

Case Description: 68-year-old Caucasian woman with history of hypertension, diabetes mellitus, obesity, sleep apnea, atrial fibrillation, and ESRD on hemodialysis came to hospital with fever of 102°F. Her symptoms were mental status changes, and decreased energy levels. There was no travel history and no contact with COVID positive or suspected COVID patients. On arrival to ER she had temperature of 99.4°F, bp 117/63, HR 102, RR 18, oxygen saturation of 99% on 2litters of oxygen. Examination revealed normal breathing sounds, no wheezing, and functional left forearm arteriovenous fistula. Rest of the exam was with in normal limits. Laboratory results showed sodium 138, potassium 5.7, chloride 96, bicarbonate 24, blood urea nitrogen 71, creatinine 13.5, C-reactive protein 15.06, ferritin 2532, She was positive for both influenza and SARS COV-2 PCR. Blood and urine cultures showed no growth. Imaging showed prominent interstitial vascular prominence; underlying pneumonia could not be excluded. Patient was admitted to hospitalization. He was discharged on TIW hemodialysis.

Discussion: Our case is unique of having both influenza and COVID-19 infection and improved. More studies are warranted to evaluate clinical benefit of the above therapies.
developed myalgia. There was no family history of myopathies, or binge alcohol intake beforehand. On physical examination, patient was hypertensive, euvoletic, and afebrile, with normal oxygenation. Chest x-ray showed suble increased interstitial reticulon in the perihilar regions and COVID-19 rapid test returned positive. Laboratory data showed very high creatine kinase (CK) (208,456 U/L). Uralysis showed trace proteinuria, large blood but only few red blood cells and confirmed myoglobinuria. However, his creatinine was normal (0.8 mg/dL), as well as serum calcium (8.4 mg/dL), phosphate (3.9 mg/dL), and uric acid (5.2 mg/dL) levels. Patient was admitted for treatment of assumed severe rhabdomyolysis. COVID-19 was treated conservatively with oxygen supplementation. Atorvastatin and diltiazem were held, and normal saline and isotonic sodium bicarbonate fluids were administered. CK continued to rise with a peak of 499,020 U/L on day 3, but decreased steadily to 58,745 U/L on day 7. Renal function remained stable all the time during the treatment (serum Cr 0.68 – 0.82 mg/dL), with maintained urine output and well-preserved electrolytes and uric acid levels throughout.

Discussion: There are increasing number of reports of COVID-19-associated rhabdomyolysis, but risk factors and characteristics are fairly known. The clinical and laboratory manifestations are suggestive of COVID-19 associated rhabdomyolysis rather than statin-induced. We are not aware of any other reports documenting such extreme CK values – with a proper rise and fall of CK – without impacting renal function. As far as we know, this is the first case of COVID-19 associated rhabdomyolysis with peak CK of 499,020 U/L, without AKI and concurrent electrolyte abnormalities. The relationship to COVID-19 vs. individual genetic susceptibility remains to be explored.

CKD Patients on Hemodialysis (HD) with COVID-19 Infection: Characteristics and Outcome

Background: The COVID-19 pandemic has special significance for Chronic Kidney Disease patients on HD. Clinical characteristics and outcome from low resource settings are not well known.

Methods: From March 15 2020 until May 20, 2020, quality managers reviewed all patients with confirmed COVID-19 infections in 200 HD centres among MHD patients. For patients with COVID-19 infections: age, gender, geographical zone, type of Insurance, continuity of care was noted, HD characteristics and outcome were reviewed. Comparison of median was done with Mann Whitney-Wilcoxon 2 sample test and proportion with Fisher exact test. All patients were transferred to public hospital for regulatory compliance limiting follow up of HD sessions.

Results: 39 out of 18402 patients developed COVID-19 infection. M: F: 28: 11, Age: 54.62 ± 14.92 years. Geographically: East zone:3(7%), North:12(31%), South:5(12%), West:19(50%). Payers: self pay:19(49%), government insurance:15 (38%) and private insurance:5(13%). 5(13%). 32(82%) hypertensives, 23(59%)diabetics. Outcome: 8(20%) expired, 49(13%) were on ventilatory support.

Discussion: Comparison of survivors and non-survivors in maintenance HD patients with COVID-19 infection shows that despite survivor’s lower age, there is increased mortality in COVID-19 patients on HD which is comparable to reports in normal population and is associated with need for intensive care, steroid use and ventilatory support.

Comparison of survivors and non-survivors in maintenance HD patients with COVID-19 infection

PUB049
Starvation-Induced Metabolic Acidosis in a COVID-19-Infected Pregnant Patient
Muhammad R. Mustafaj, Stony Brook University, Stony Brook, NY.

Introduction: Suffolk County in NY was hardest hit with COVID 19. We present a case of a pregnant female with COVID 19 infection and high anion gap acidosis.

Case Description: 34 yo female, 33 weeks twin pregnancy, a/w fever, SOB and polyuria. Her oral intake was poor. She was positive for COVID 19. Her T - 100 F, O2 sat 99% with O2 by NC at 2 L. She had bibasilar crackles. Both babies were moving. CXR showed multifocal pneumonia. Nephrology was consulted for metabolic acidosis. A diagnosis of starvation ketosis of pregnancy was made due to anion gap acidosis, high serum beta-hydroxybutyrate and ketonuria. Dextrose 5% with sodium bicarbonate was given. She had C section, remained intubated for 24 hours, recovered well and was discharged on hospital day 7.

Discussion: Almost 15% of pregnant patients develop server COVID 19. Pregnant patients with COVID infection are a higher risk group.

PUB050
Slow Low-Efficiency Dialysis (SLED) Implementation During the COVID-19 Pandemic Surge
Richard L. Barnett, Kenar D. Jhaiveri, Bessy Suyin Flores Chang, Azzour D. Hazzan, Shamir Hasan, Steven Fishbane, Mark A. Finger, Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.

Background: The high rate of ARF in COVID-19 hospitalized patients increased the demand for critical care renal replacement therapy 2-3 fold at Northwell Heath (NW). At the 2 largest hospitals, Long Island Jewish (LIJ) and North Shore University Hospital Hospital (NSUH), bedside HD was provided by HD RNs and continuous renal replacement therapy (CRRT) by critical care (CC) RNs. RN workload in these hypercatabolic patients soared as HD treatments more than doubled and CRRT increased from 9 to 30, Shortages of CRRT fluid and filter sets ensued. SLED, a technique utilizing standard HD dialsate and filters, combined with a collaborative approach between CC and HD RNs was considered.

Methods: In late March, a cohort CC bedside HD program, was initiated. Based on this success, a leadership panel of CC/HD RN and Renal CC MDs created a SLED project plan. Details were reviewed with stakeholders on Friday prior to the Tuesday “Go-Live.” 3 patients previously treated with HD or CRRT via a Shiley catheter were selected as a pilot for three 6-8 hour sessions, Fresenius 2008T, Revaclear 300 filters with dialysate flow rate 300 3cm/min and blood flow rate 200-300 cm/min were ordered. HD RN initiated treatments and available throughout, while clinical stability was monitored by CC RN.

Results: NSUH pilot involved 5 patients over 3 sessions. Suboptimal cohorting required remote tablet monitoring and frequent presence of several HD RNs. One patient was terminated in one session due to persistent hypotension. Clearances and UF goals were achieved. A week later the LIJ pilot used the design and advantage of NSUH experience with a 3 bed “SLED Room” model. The same 3 patients participated in all 3 sessions supervised by a single HD RN with no discontinuation. CC RN satisfaction with SLED was ranked “high” at both sites and by LIJ HD RNs but “Spread SLED” rated only “fair” by NSUH HD RNs. Pilots were extended 10 days. During this period SLED was initiated at 2 other NH sites. Future SLED programs will be focused on NH hospitals lacking CRRT.

Conclusions: SLED is an efficient alternative to CC HD and CRRT. The challenges of effective cohorting in a pandemic surge relegate its role to a piece of a comprehensive renal critical care program. It may be particularly valuable for hospitals lacking CRRT options.
Kidney Transplantation in the United States During the Coronavirus Disease 2019 Pandemic: An Interrupted Time Series Analysis

Ekmal Tantisattamo,1,2 Natnicha Leelaviwat,3 Sakdita Saowapa,3 Natchaya Polpichai,3 Busara Songtani,3 Possawat Vuthikraivit,3 Chawit Lopimipsih.1,2 Division of Nephrology, Hypertension and Kidney Transplantation, Department of Medicine, University of California, Irvine School of Medicine, Orange, CA; 3Multi-Organ Transplant Center, Section of Nephrology, Department of Internal Medicine, William Beaumont Hospital, Oakland University William Beaumont School of Medicine, Royal Oak, MI; 4Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; 5Faculty of Medicine Songklanagarin Hospital, Prince of Songkla University, Songkla, Thailand; 6Phramongkutklao College of Medicine, Mahidol University, Bangkok, Thailand.

Background: The number of kidney transplant (KT) in the United States (US) has decreased during COVID-19 pandemic; however, the magnitude of this impact is unclear.

Methods: A period from January 5 to April 18, 2020 was divided into pre- and post-COVID-19 periods by assigning March 1, 2020 as the first day of the post-COVID-19 outbreak in the US. The number of waitlist candidates (WLC) and new KT every 7 days were obtained from OPTN/SRTR. An interrupted time series analysis was performed to examine an incidence rate ratio (IRR) between pre- and post-COVID-19 period by using multiple Poisson regression.

Results: Compared to pre-COVID-19 period, the average number of new KT during post-COVID-19 period decreased (479±33 vs 318±119 cases/week, mean differencesSEM 161±44, 95%CI 67, 255). The number of WLC was relatively stable (mean±SD 65,937±959 cases/week); whereas, it decreased during post-COVID-19 period (61,759±2203 cases/week). Mean incidence rates (IR) of new KT during pre- and post-COVID-19 periods were 727±58 and 511±76 cases/IR/week, respectively (Figure1). The IR of new KT during post-COVID-19 period was 29% lower than those during pre-COVID-19 period (IRR 0.71, 95%CI 0.96, 0.96). After adjusted by age group, transplant areas, and time-study period interaction term, the IR of new KT was 3% increase for every one more week during pre-COVID-19 period (IRR 1.03); whereas, there were 12% decrease for every one more week after March 1, 2020 (IRR 0.88). Compared to pre-COVID-19 period, the IR of new KT during post-COVID-19 period was 9% lower for every additional week for each corresponding period (IRR 0.91).

Conclusions: COVID-19 outbreak in the US since March 2020 is an independent factor of a significant decline in the number of new KT. Further information regarding ability of control COVID-19 may direct KT.

Spectrum of AKI in Patients with COVID-19 Infection

Introduction: With the gradual unfolding of the full spectrum of COVID-19 manifestations, Acute Kidney Injury (AKI) is emerging as a frequent association & a predictor of disease severity & mortality. We present 3 cases of AKI in COVID19 patients & illustrate the clinical course, management & outcome.

Case Description: The first case was a 50-yr old male with DM, HTN, & obesity, admitted with pneumonia, dyspnea & diarrhea, developed hypotension, arrhythmia, & required intubation on day 31 of admission. The next case was a hypertensive, obese 57-year-old female, admitted with pneumonia, worsening dyspnea & respiratory failure without hypotension, was intubated on day 30 of admission. Both of the cases developed AKI with oliguria & progressed to anuria 24 hrs post-intubation. Case 3 was a 72-year old female with hypertoidism admitted with pneumonia, dyspnea, diarrhea, & AKI, was intubated on day 12. All cases had bilateral pneumonia on chest radiograph & significantly raised inflammatory markers (CRP, LDH, Procalcitonin, Ferritin, ALT/AST, d-Dimer, & INR). Peak S. Creat. was 4.1, 6.6, & 3.07 for cases 1, 2, & 3 respectively. Urinalysis for all cases revealed proteinuria, hematuria, pyuria, 4+ budding yeast & signs of UTI for cases 1 & 2. Ultrasound revealed structurally normal kidneys for all cases. Case 1 & 2 were diagnosed as stage III AKI & Case 3 with stage II AKI. All cases received some form of antibiotics, hydroxychloroquine, & heparin for COVID19 and CVVHD for renal support the later iHHD for case 2. Gimerelumemephris specific workup could not be done due to the patient’s clinical status. Among the cases, case 2 made full recovery & discharged, case 1 was stable but hospitalized, case 3 expired on day 14 of hospitalization due to multiorgan failure.

Conclusion: Our cases highlight the inherent variability in causation & clinical course for AKI in COVID19. Interestingly, all 3 cases had the full spectrum of kidney involvement from proteinuria, hematuria to AKI. Although difficult to discern in the absence of biopsy, some potential causes of AKI in these patients include ischemia (renal ischemia, hypotension), hypotension, cytokine storm syndrome (case 3), or direct COVID19 induced acute tubular injury. Increased vigilance is required to recognize probable causes for AKI and to develop adequate management protocols to limit AKI-related morbidity or mortality.

COVID-19 Induction of a Wasting Syndrome in Hemodialysis Outpatients

Background: The SARS CoV-2 pandemic has disproportionately affected vulnerable patient populations including kidney transplant recipients (KTR).

Our transplant centre covers a large multi-ethnic urban population with high rates of co-morbidity and social deprivation, and provides follow-up care for approximately 1500 kidney transplant recipients. In line with national guidance, COVID-19 testing was largely restricted to those patients presenting to secondary care. While COVID-19 was confirmed or suspected, anti-proliferative drugs were stopped, maintenance corticosteroids increased, and calcineurin inhibitor was stopped in patients requiring admission. We performed a retrospective analysis of clinical presentations and outcomes in kidney transplant recipients with confirmed COVID-19 between 20 March and 10 May 2020.

Results: 25 patients (approximately 1.6%) had confirmed COVID-19. 11 (44%) were female and 14 (56%) male. The median age was 61 years (range 33 – 84 years). 11 (44%) were White - British, 12 (48%) Asian and 2 (8%) Afro-Caribbean. Median time post- transplant was 84 months (range 6 – 360), and more recently transplanted patients were not at increased risk. Respiratory symptoms were the predominant presenting complaint in 19 patients (76%) followed by GI symptoms in 4 (16%). Acute kidney injury (stages 1-3) occurred in 15 patients (60%) with 7 patients (28% of whole population 46% of patients with AKI) requiring renal replacement therapy. 6 patients (40%) recovered renal function at a median follow up period of 12 days (range 1 – 52). 4 (16%) were admitted to ITU for ventilation. 10 patients (40%) died (although one death was not related to COVID-19). Among the patients who died, median age was 65 years and 6 (60%) were male with ethnicity proportionate to the study population.

Conclusions: The strategy of performing COVID-19 testing only in patients requiring secondary care likely i) underestimates the incidence and ii) overestimates the disease severity. However, our data show that COVID-19 confers significant morbidity and mortality in kidney transplant recipients despite prompt reduction of immunosuppression. These data will inform a revised consent process for those patients awaiting kidney transplantation. Follow up studies are required to assess longer term outcomes, and potential complications in KTRs who have recovered from COVID-19.

COVID-19 Induces a Wasting Syndrome in Hemodialysis Outpatients: Outcomes in Rochester, New York

Rebecca D. Monk,1 Kristian Vitu,2 Samantha J. Mauser,3 Jaime L. Oneil,2 1University of Rochester Medical Center, Rochester, NY; 2University of Rochester, Rochester, NY; 3Fresenius Medical Care North America, Waltham, MA.

Background: COVID-19 (COV) has infected 2852 residents of Monroe County with a death toll of 218 to date. Hemodialysis (HD) patients (pts) are at high risk for developing COV due to multiple comorbidities. Many patients also reside in Skilled Nursing Facilities (SNF) which have high infection rates. One single Fresenius Medical Care (FMC) dialysis facility in the Rochester, NY area with no Tues/Thurs/Sat (TTS) nursing Facilities (SNF) which have high infection rates. One single Fresenius Medical Care (FMC) dialysis facility in the Rochester, NY area with no Tues/Thurs/Sat (TTS) shifts became the designated unit to provide maintenance HD for all COV positive (+) pts in care until they had 2 negative COV tests. This is a quality improvement review of our patients.

Methods: The study included all 18 pts thus far who received at least one HD treatment in our COV + unit. Demographics and labs – 2 months prior to their first COV test and during the first month in our COV unit were analyzed and compared with data from the 33 COV negative (-) Mon/Wed/Fri (MWF) patients in the same facility. Paired and unpaired T tests were used to determine the statistical significance of observed differences in weight (wt) and labs pre and post COV+ and between COV+ and - pts.

Results: Of our 18 pts, 50% were African American and 50% Caucasian American. Mean age 67, BMI 29.2. 50% resided in SNF prior to COV. All had ESRD. 3 initiated HD within 2 months of first COVID test. Paired and unpaired T tests were used to determine the statistical significance of observed differences in weight (wt) and labs pre and post COV+ and between COV+ and - pts.

Results: Of our 18 pts, 50% were African American and 50% Caucasian American. Mean age 67, BMI 29.2. 50% resided in SNF prior to COV. All had ESRD. 3 initiated HD within 2 months of first COVID test.

Results: Of our 18 pts, 50% were African American and 50% Caucasian American. Mean age 67, BMI 29.2. 50% resided in SNF prior to COV. All had ESRD. 3 initiated HD within 2 months of first COVID test.

Results: Of our 18 pts, 50% were African American and 50% Caucasian American. Mean age 67, BMI 29.2. 50% resided in SNF prior to COV. All had ESRD. 3 initiated HD within 2 months of first COVID test.

Results: Of our 18 pts, 50% were African American and 50% Caucasian American. Mean age 67, BMI 29.2. 50% resided in SNF prior to COV. All had ESRD. 3 initiated HD within 2 months of first COVID test.
Conclusions: While respiratory symptoms of COV are often stressed we noted few symptoms in other populations and the illness was severe in ~10% of pts that had COV.

AKI in Hospitalized Patients with COVID-19: A Mexican Population

Victor H. Gomez Johnson,1 Gina C. Gonzalez-Calderon,1 Antonio Camiro Zúñiga,1 José A. García Gordillo,2 Adolfo Díaz Cabral,1 Alfredo Fonseca Chávez,2 Julio C. Arriaga,1 Jose S. Lopez Gil,1 Javier Zúñiga-Vargas,1 Juan Pablo Herrera Felix.1 1Centro Medico ABC, Mexico City, Mexico; 2Instituto Nacional de Cardiología Ignacio Chavez, Mexico, Mexico.

Background: Although severe acute respiratory syndrome coronavirus (SARS-CoV-2) infection is primarily a respiratory disease, other organs are also affected. Several pathological studies confirm that SARS-CoV-2 invades kidney tissue causing endothelial damage, glomerular and vascular changes, extensive acute tubular injury and podocyte viral infection. AKI in COVID-19 appears to be frequent, with an AKI incidence of up to 46%, and a 20% requirement for renal replacement therapy (RRT). Patients with AKI show a trend towards worse outcomes and increased mortality. Information on Latin-American population is scarce.

Methods: We created a cohort to describe the incidence, risk factors, and outcomes associated with AKI in hospitalized patients with COVID-19 in Mexico City, excluding patients with a known chronic kidney disease. AKI was defined and classified according to KDIGO guidelines.

Results: We included 127 patients. 11 patients (8.66%) met the criteria for severe COVID-19, and were more likely to have to have AKI (81.82% vs. 54.31%, p=0.078). Of the 72 (56.69%) patients that had AKI, 48% were diagnosed at the time of admission. Patients with AKI were more likely to be men (61.7% vs. 42.4%, p=0.043) and older (55.68 years vs. 48.89 years, p= 0.018). With regards disease severity, 72% of them had a grade 1 AKI. 7 patients (9.72%) had grade 3 AKI, 4 of which needed renal replacement therapy. Overall length of stay was longer in patients with AKI (12 days vs. 7 days, p=0.003). A nonsignificant trend towards stay in critical care units was observed. 3 out of 127 patients died, all 3 had AKI.

Conclusions: Amongst our studied population, AKI was associated with a longer length of stay and with a trend towards a more use of critical care services. The lack of association of AKI with mortality could be due to the low overall in-hospital mortality of COVID-19 patients (2.40%).

AKI Lingering in a Patient with Novel Coronavirus

Marc Saad, Brandon Kirschner, Reuben K. Ellis. Mercer University, Macon, GA.

Introduction: Renal manifestations of the novel Coronavirus infection has been reported during the actual pandemic. While the renal injury was more pronounced in critically ill patients, the levels of AKI, proteinuria and hematocrit predicted the severity of the infection. We are reporting a severe case of AKI and proteinuria with SARS-CoV-2 infection out of proportion of its clinical manifestation.

Case Description: This is a 55 year old African American male patient with PMH of hypertension, aortic valve replacement on Warfarin anticoagulation and CKDIII-b with baseline eGFR of 50 ml/min/1.73m2 (creatinine of 1.5 mg/dL) and recent diagnosis of COVID-19 related gastroenteritis 10 days prior to presentation, was admitted with general malaise and decreased intake. He had no cardiac nor respiratory symptoms. He was afebrile and physical examination was non remarkable. His labs were significant for BUN level of 129 mg/dL and creatinine of 22.0 mg/dL. His blood glucose was 88 mg/dL. Urinalysis showed glucose 100 mg/dL, 0-3 RBCs, 10-3 WBC with a protein/creatinine ratio of 12.8 g/g. His renal ultrasound showed increased cortical echogenicity with edema. His serological workup was unrevealing with negative hepatitis B and C testing, low ASO levels, negative ANA, Anti-PR3, Anti-MPO and Anti-GBM antibodies. He had normal C3, C4 and negative serum immunofluorescent with free kappa/lamba ratio of 1.7. His Alb was 1.7g/dL with triglycerides levels of 184 mg/dL. A kidney biopsy was deferred for its high complication and underwent a kidney biopsy for its high complication.

Results: He continues to asymptomatic and is being monitored outpatient for his kidney recovery.

Discussion: Variable histopathological lesions (FSGS, collapsing glomerulopathy, podocytopathy and tubular interstitial disease) has been described in the renal manifestations of the novel coronavirus. While its physiopathological mechanisms remain unclear, the severity of proteinuria and renal injury observed in this clinically asymptomatic patient highlight an unusual infection-driven mechanism.

Patients with COVID-19 and Kidney Disease: Who Fared Best?

Micaela Antionios, David Jackson, Sadananda V. Aithal, Michael T. Shiel, Huw Davies. Swansea Bay University Health Board, Swansea, United Kingdom.

Background: COVID-19 poses the greatest global challenge in modern day healthcare. Chronic Kidney Disease (CKD) patients are classed as ‘high risk’ in terms of the morbidity and mortality associated with COVID-19. We present data from a large centre encompassing a 24-bed inpatient renal ward, 2 in-centre haemodialysis (HD) units and a large ITU. We aim to compare and contrast clinical outcomes for COVID-19 patients with renal disease.

Methods: Observational analysis was performed on 61 patients (mean age 65y), all positive for COVID-19. Patients were stratified according to their renal status at the point of contracting the virus (table 1).

Results: Acute Kidney Injury (AKI) (n=24; mean age 67y) – 23 of 24 patients were intubated and ventilated in ITU. 18 died. 4 remain on haemofiltration (1 patient transplanted for Extracorporeal Membrane Oxygination). Only 1 patient required ventilatory support and survived with resolution of the AKI. 1 patient requiring invasive ventilation survived with recovery of renal function. Chronic HD (n=28; mean age 60y) – 20 prevalent adult HD patients tested positive for COVID-19. 10 recovered and one died. 10 died. Kidney Transplant Recipients (KTR) (n=4; mean age 59y) – 3 were managed as outpatients and have recovered with functioning grafts. 1 died.

Peritoneal Dialysis (PD) (n=2; mean age 68y) – 1 was managed as an outpatient and has made a good respiratory recovery. 1 patient died. CKD (without renal replacement therapeutic modality) (n=1; mean age 78y) – 1 patient with pre-existing CKD (stages 3-5) contracted COVID-19. 5 made a recovery with no progression to RRT. 2 died without RRT. 2 received acute HD and subsequently died. 1 remains on acute HD and 1 has progressed to chronic HD.

Conclusions: AKI patients had the poorest outcomes in terms of need for ventilatory support and mortality. 50% of chronic HD patients with COVID-19 died. Despite immunosuppressants, only 4 KTTRs (total cohort of 352) contracted COVID-19. The introduction of virtual transplant clinics, minimisation of face-to-face contact and off label drug regimens may have influenced this. These data aim to reinforce the international collaborative against this global pandemic.
COVID-19 Financial Ramifications on the Pediatric Nephrology Workforce

Darcy K. Weidemann,1,2 Allison C. Redpath,4 Isa Ashoor.1 Children’s Mercy Hospitals and Clinics, Kansas City, MO; 3University of Missouri Kansas City, Kansas City, MO; 4LSU Health New Orleans, New Orleans, LA; 1University of Wisconsin System, Madison, WI.

Background: The adverse impact of the COVID-19 pandemic on state and federal budgets, coupled with widespread lockdown measures, and reduced non-COVID-19 clinical volume has forced healthcare and academic organizations to adapt to declining revenues. We examined the financial ramifications of the pandemic on the pediatric nephrology workforce.

Methods: Online survey distributed to active members of the American Society of Pediatric Nephrology (n=987) over 2 weeks in May 2020.

Results: Response rate was 16% (n=144). Most respondents (34%) were 35-44 years old, followed by 45-54 years old (24%). Most were White (65%) followed by Asians (24%). Respondents resided in the South (31%) followed by the Northeast (29%) and Midwest (22%). Most were faculty (92%) in early career stage (Assistant Professor, 31%), affiliated with a free-standing children’s hospital (55%) or a children’s hospital within an adult hospital (36%), working full time (79%) with an average of 60% effort dedicated to clinical activities. Most acknowledged feeling worried about the long-term financial ramifications of COVID-19 on their employer (88%) and their own financial future (75%).

Figure 1 summarizes the financial repercussions reported. The majority (47%) were unclear whether they will be expected increased clinical duties once stay-at-home orders are lifted, however, 44% reported new childcare or eldercare responsibilities.

Conclusions: Overwhelming concern regarding employee and employer financial security exists among practicing pediatric nephrologists in the context of the COVID-19 pandemic. Uncertainty, institutional hiring freezes, compensation reduction, and increased duties in one’s personal life all pose additional threats to a specialty with an already looming workforce shortage. Comprehensive strategies to prevent attrition and burnout are required to sustain the pediatric nephrology workforce during recovery from the COVID-19 pandemic.

Not All Coronavirus Patients Are Dying from Broncho-Pneumonia:
Most Might Be Dying from Cerebro-Neurologic-Vascular Diseases and Cardiovascular Complications

Yahya Sagiliker,1,2 Hassan S. Sagiliker,2,5 Piril Sagiliker Ozkaynak,4 Nuray Paylar.2 Sagiliker Nephrology and Hypertension Unit Çukurova Universitesi Tip Fakultesi, Adana, Turkey; 2Sagliker Nephrology and Hypertension Unit, Adana, Turkey; 3Karliova State Hospital, Bingol, Turkey; 4Karaisali Community Health Center, Adana, Turkey.

Introduction: Acute bronchopneumonia is not sufficient to explain deaths. Lungs, brain-nerves - heart- cardiovascular system might be playing for key roles. Three are playing together. In last days, lungs and brain and heart suddenly are stopping.

Case Description: Key places are neurological conjunction systems between brain, lungs and cardiovascular systems. All organs are being regulated by last two systems. All mentioned activities are being regulated in those systems. All decisions and functions of human are giving there.

Discussion: A neurologist and a cardiologist must be involved in treatment in late stages. This is vital. 1-Pulmonologists are following lungs. 2-Pulmonary-toracal surgeons should think two sided bronchial tubes from outside. 3-Cardiologist must follow EKG continuously. Echocardiography must be performed every day. They must know well inside of hearth and must question which drugs are taking. 4-Neurologists must perform MRG for brain, back lower brain and should make EEG, every day. AFFECTION-REACTION-EFFECTING-INFORMING BACK rules must be controlled. They must detect neurotransmission system is from top to bottom as I have written above like so called zig-zag-zig system or reverse neurotransmission system is occurring as zig-zag-zig system to destroy body. If it is so this strange system can be called from now on as SAGLIKER’S REVERSE NEUROLOGICAL WORKING SYSTEM.”.

COVID-19 and the Adverse Impact on Pediatric Nephrology Workforce

Weidemann,1,2 Redpath,4 Ashoor.1 Children’s Mercy Hospitals and Clinics, Kansas City, MO; 3University of Missouri Kansas City, Kansas City, MO; 4LSU Health New Orleans, New Orleans, LA; 1University of Wisconsin System, Madison, WI.

Background: The adverse impact of the COVID-19 pandemic on state and federal budgets, coupled with widespread lockdown measures, and reduced non-COVID-19 clinical volume has forced healthcare and academic organizations to adapt to declining revenues. We examined the financial ramifications of the pandemic on the pediatric nephrology workforce.

Methods: Online survey distributed to active members of the American Society of Pediatric Nephrology (n=987) over 2 weeks in May 2020.

Results: Response rate was 16% (n=144). Most respondents (34%) were 35-44 years old, followed by 45-54 years old (24%). Most were White (65%) followed by Asians (24%). Most were faculty (92%) in early career stage (Assistant Professor, 31%), affiliated with a free-standing children’s hospital (55%) or a children’s hospital within an adult hospital (36%), working full time (79%) with an average of 60% effort dedicated to clinical activities. Most acknowledged feeling worried about the long-term financial ramifications of COVID-19 on their employer (88%) and their own financial future (75%).

Figure 1 summarizes the financial repercussions reported. The majority (47%) were unclear whether they will be expected increased clinical duties once stay-at-home orders are lifted, however, 44% reported new childcare or eldercare responsibilities.

Conclusions: Overwhelming concern regarding employee and employer financial security exists among practicing pediatric nephrologists in the context of the COVID-19 pandemic. Uncertainty, institutional hiring freezes, compensation reduction, and increased duties in one’s personal life all pose additional threats to a specialty with an already looming workforce shortage. Comprehensive strategies to prevent attrition and burnout are required to sustain the pediatric nephrology workforce during recovery from the COVID-19 pandemic.
important role in treating severe COVID-19 patients with MHD. Cardiovascular disease is the leading cause of death in ESRD patients. The cardiovascular events of this patient might be combined with COVID-19 associated heart injury and worsen of pre-existing CHD. We suggested lack of family support during quarantine might be a reason of psychiatric symptom. In conclusion, personalized immunomodulation therapies might be helpful in treating severe COVID-19 patients with MHD. Cardiovascular events were associated with poor outcome.

Clinical Presentation of Hemodialysis Patients with COVID-19: A Single-Center Study with 18 Patients

Eliana Dina-Battle,1 Hector A. Pantaleon,1 Mirtha C. Almanzar,1 Noemí Acevedo Rodríguez.2 1Hospital Metropolitano de Santiago, Santiago, Dominican Republic; 2Pontificia Universidad Católica Madre y Maestra Facultad de Ciencias de la Salud, Santiago De Los Caballeros, Dominican Republic.

Background: SARS-CoV-2 has affected every nation around the world. The 1st case in the Dominican Republic was reported in early March, with the most affected being the elderly. Many patients with comorbidities like cardiovascular diseases. Most hemodialysis patients share these comorbidities, in addition to a weaker immune system and health care facility exposure, it is thought to be a vulnerable population. The aim is to describe the clinical manifestation, main laboratory abnormalities, imaging findings at the moment of presentation, and the clinical course of patients on hemodialysis diagnosed with COVID-19.

Methods: Exploratory study on 18 dialysis patients with Covid-19 in a renal replacement therapy facility. Demographics, symptoms, laboratories, CT scan, hospital course, ventilation requirement, treatment and complications were described.

Results: With a population of 204 patients, 18 were diagnosed with Covid-19 in the first 2 months of the outbreak in our facility. 77.8% were males, mean age was 60 years, and 44% had known contact with infected people outside the facility. All patients had cardiovascular disease and 12 had diabetes. Cough was the most common manifestation 77.8%, dyspnea 66.7%, fever 55.6%, and malaise 44.4%, among others manifestations. Oxygen therapy was required in 66.7%, with 11.1% needing mechanical ventilation. All presented abnormal CT scan findings, 60% with a COVID-RADS grade 3. Three patients were positive and asymptomatic on a round RT-PCR test taken for all facility patients, 2 of them with CT scan graded COVID-RADS 3. Only symptomatic patients were admitted, 3 were directly admitted to the ICU, and 2 were later transferred from inpatient floor to ICU. The mean duration of hospitalization was 11 days and just 1 lethal outcome. At the moment of admission, 22.2% presented negative results on RT-PCR but had clinical and imaging findings consistent with Covid-19, with serologic conversion later.

Conclusions: Even with the increased risk of exposure, comorbidities, and a weaker immune system, these didn’t necessarily determine a higher probability of infection. We have found a high incidence of respiratory symptoms, in contrast to other case reports. Asymptomatic patients had imaging with COVID-RADS grade 3, this made us consider that the COVID-RADS grade on CT scan is a helpful tool for diagnosis of Covid-19.

Pink urine syndrome has been reported as a rare symptom described after surgery and propofol anesthesia. COVID-19 is not only manifested as a respiratory disease characterized by viral pneumonia, but also damage such as kidney, heart, blood and nervous system especially in severely ill patients.

Case Description: A 56-year-old man was diagnosed as severe COVID-19. He was admitted to ICU and underwent the tracheal intubation. During this treatment, propofol was used to sedate. He suddenly excreted cloudy pink urine on that day (Figure 1). There were some pink crystals in the urine bag and pink sediment at the bottom of the urine bag (Figure 2, Figure 3). His urine dipstick showed a specific gravity of 1.02, pH 5.5, blood (1+) and protein (1+). He had no urinary tract symptoms and his urine cultures were normal. His blood gas analysis showed pH was 7.3. His colour of urine gradually returned normal when the patient was given intravenous Sodium bicarbonate injection.

Discussion: Pink urine syndrome is a phenomenon in which uric acid precipitates into the urine due to reduced urinary pH. Propofol can increase the excretion of uric acid in the urine. Lower urine pH will reduce the solubility of uric acid, promoting the formation of amorphous uric acid crystals, which exhibit a characteristic pink color. At the same time, metabolic acidosis may aggravate this phenomenon. COVID-19 has been reported to invade cells mainly through ACE2 receptors, ACE2 receptor is strongly expressed in the proximal tubule of the kidney, causing acute tubular necrosis. It has suggested that the kidney is one of the main targets of COVID-19. While considering the pink urine syndrome might caused by propofol, we speculate that COVID-19 could damage the renal tubule which affect its reabsorption of uric acid, which may worsen the uric acid crystallinity.

Pink urine deposits observed.

Teledicine in the Care of Kidney Transplant Recipients with COVID-19

Farouk Al Ammary, Mohammad Abuzeineh, Abimereki Muzaale, Deidra C. Crews, Robin K. Avery, Daniel C. Brennan, Dorry L. Segev. Johns Hopkins University School of Medicine, Baltimore, MD.

Introduction: Kidney transplant (KT) recipients with COVID-19 symptoms are bringing challenges to providers given the risk of COVID-19 exposure to health care workers, patients, and the public.

Case Description: Three KT recipients with COVID-19 were managed using teledicine via synchronous video visits integrated with an electronic medical records system, from home to inpatient settings (Figure 1-2). Patient 1 is a 53-year-old male s/p KT in 2012; Patient 2 is a 56-year-old female s/p KT in 2019; and Patient 3 is a 53-year-old female s/p simultaneous liver-kidney transplant in 2014. Patients 1 and 3 had follow-up COVID-19 NAT testing: Patient 1 converted to be negative at 24 & 28 days, whereas Patient 2 converted to be negative at 45 & 48 days.

Discussion: Teledicine helped assess, diagnose, triage, and treat patients with COVID-19 while avoiding an ER or outpatient clinic visit. We highlight the value of teledicine in the maintenance of uninterrupted follow-up care for immunosuppressed patients with prolong viral shedding.
Table 1: Patients 1 and 2 laboratory test results during hospitalization. Patient 3 was not hospitalized.

Figure 1. Urinary sediment slides showing: A) a granular cast with a renal tubular cell within; B) a granular cast with several isomorphic erythrocytes.

**PUB065**

**Urinary Abnormalities and Urinary Sediment Findings in COVID-19 Patients**

**Background:** Coronavirus disease 2019 (COVID-19) is a new disease of pandemic proportions. There are only a few reports about urinary abnormalities in this disease, and to our knowledge there are no reports about the usefulness of urinary sediment on prognosis. Our aim was to describe the urinary abnormalities in COVID-19 and to assess the utility of urinary sediment on prognosis in COVID-19.

**Methods:** Prospective, single-center study, in patients diagnosed with COVID-19 (with a positive RT-PCR test), who were admitted in our hospital, from April 2020 to date, and whose urine sample could be obtained at admission to the isolation wing.

**Results:** 22 patients were included: 17 (77.3%) had proteinuria, 12 (54.5%) had microscopic hematuria, and 9 (40.9%) had leukocyturia. Granular casts (with a Chawla cast scoring index greater than 3) were present in 8 (36.4%) patients. Of the 8 patients with granular cast, 6 developed an AKI (75%), 2 required hemodiagnosis (25%) and 3 died (37.5%). Of the 14 patients whose urinary sediment was classified as bland, 5 developed an AKI (35.7%), none of them required hemodiagnosis, and 2 subsequently died (14.2%). There was a statistically significant difference between a bland urinary sediment and a sediment showing granular casts for the need of hemodiagnosis or death (p=0.02), with a positive LR of 3.5.

**Conclusions:** The urinary sediment is a cheap, available tool for the prognosis of need for hemodiagnosis or death in patients diagnosed with COVID-19, and should be taken into consideration in the assessment of these patients by the Nephrology department.

**PUB066**

**Repurposing Baby Monitors in COVID-19**

Sobia N. Khan, Sandeep K. Mallipattu. Stony Brook University, Stony Brook, NY.

**Introduction:** As of May 2, total of 1,130,075 confirmed cases resulting in 65,605 deaths were reported in US. Nearly 3.2% of individuals with COVID-19 develop AKI and have been reported to require dialysis. Initial reports from Wuhan, the burden of acute kidney injury was relatively low, about 3% -9%, subsequent analysis have demonstrated increase in the incidence to 15%

**Case Description:** In February, 376 hemodialysis and 59 CRRT while in March, 273 hemodialysis and 30 CRRT offered in our hospital. During pandemic bed capacity doubled from 650 to 1317 beds. Physical space gained by converting ambulatory surgical center and ambulatory locations. In April, observed 1,811 COVID-19 patients admitted to the hospital with 50 chronic hemodialysis patients, 30 were COVID positive. 334 hemodialysis treatments while 136 continuous renal replacement therapy offered 12.8% to the hospital with 50 chronic hemodialysis patients, 30 were COVID positive. 334 hemodialysis treatments while 136 continuous renal replacement therapy offered 12.8% increase in the incidence to 15%.

**Discussion:** To minimize the risk of exposure in COVID-19 isolation rooms we implemented telemonitoring strategy. We identified baby monitors could serve “read-to-go” telemonitoring. VTech Baby Monitor 7” display. HD camera uses WiFi connection to capture movements and sounds which helps in monitoring the patients in real-time. The camera ability to pan 360 degrees, tilts 82-degrees and zooms ten times to enable viewing of the dialysis monitor and patient. Two-way voice communication allows easy communication between patient and nursing. Before hemodiagnosis nurse sets up camera by the patient’s bedside (1 camera facing the dialysis monitor other camera facing patient and the dialysis access). Dialysis nurse visualize through the handheld monitor. Telemonitoring system COVID-19 patients undergoing hemodiagnosis we observed zero positive COVID-19 dialysis staff.
**PUB067**

**Impact of Ethnicity on COVID-19 Infection and Mortality Amongst In-Centre Haemodialysis Patients**

Gregor D. Young, Noam Roth, Kieran Mccafferty, Suzanne H. Forbes, Andrea Cove-smith. Royal London Hospital, London, United Kingdom.

**Background:** It is reported that patients of BAME origin are at greater risk of infection and death due to COVID-19. We describe outcomes in an inner city, ethnically diverse in-centre haemodialysis (HD) population during the pandemic.

**Methods:** A total of 1253 patient electronic records were analysed retrospectively. 207 infections were recorded -197 patients tested positive for Sars-Cov-2 on validated nasopharyngeal PCR analysis and 10 patients included due to high clinical suspicion. Ethnicity data is self-reported. All COVID-19 positive patients were isolated for subsequent dialysis sessions. Whole-cohort screening confirmed the rates of infection.

**Results:** Overall rate of infection amongst the group was 16.5% (n=207), hospitalisation 7.5% (n=94) and death 3.5% (n=44). Within COVID-19 infections, hospitalization rate was 45% and mortality 21%. Seven patients received critical care and two were intubated. Ethnicity data are shown in table 1: There was no significant difference in rates of COVID infection between ethnic groups. The risk of infection in BAME patients was not significantly greater than in white patients (p=0.24, OR 0.79, 95%CI 0.55-1.14). The mean age of those who died from COVID did not differ from the entire cohort (62 vs 63.2 years). Males made up the majority of both the baseline cohort (61.2%) and those infected with COVID (58.5%). 71% of those who died were male. Body mass index did not differ between the group as a whole and those infected with COVID. Rates of diabetes mellitus did not differ significantly between those infected with COVID and those who died.

**Conclusions:** We have defined COVID infections and outcomes within a real-life, large haemodialysis population. Hospitalisation and mortality rates were high, and patients self-reporting as black or Asian were over-represented in the infected group compared to the baseline prevalent HD population. Higher rates of death were observed in black and asian groups but conclusions are limited by small numbers. Larger collaborative studies are required to expand on these findings.

**Ethnic breakdown of HD cohort and COVID cases**

**COVID-19 Management in New York City Kidney Transplant Recipients: Before and After the Apex**

**Background:** Kidney graft recipients receiving immunosuppressive therapy may be at heightened risk for Covid-19 and adverse outcomes. We aimed to study how practice patterns and outcomes changed before and after the peak incidence of cases in New York City.

**Methods:** We reviewed 68 consecutive adult kidney graft recipients from our center diagnosed with SARS-CoV-2 from March 13, 2020 to May 25, 2020. We compared outcomes of those treated from March 13 until the apex of infections on April 14 (Phase 1), and those treated from April 15th to May 25, 2020 (Phase 2).

**Results:** Characteristics of both Phase 1 and Phase 2 patients are described in Table 1. Inflammatory markers were lower in the second phase as was patient mortality. Changes in management strategies between the two phases are highlighted in Figure 2. Graft loss occurred in 4 patients (6%) and there were 5 deaths (7%).

**Conclusions:** Data from our study suggest that management strategies of immunosuppressed patients changed over the course of the Covid-19 Pandemic in New York City, including less use of hydroxychloroquine, and increased use of novel agents such as remdesivir. Additional data are needed to better understand if the decrease in patient mortality during the second phase is attributable to better management or lower inflammatory response in the setting of Covid-19 illness.
COVID-19 in a G6PD-Deficient Patient

**Background:** Rituximab (RTX), a monoclonal antibody against the CD20 antigen found on B lymphocytes, is widely used for glomerular diseases. It may be advantageous in COVID19 given the exaggerated immune response and cytokine storm elicited by Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) or could be detrimental given the impaired response to infections in immunocompromised patients.

**Methods:** We examined the clinical presentation and outcomes of 3 patients undergoing treatment with RTX who were infected with SARS-CoV-2.

**Results:** 2/3 patients had complication of severe hypoxemia with evidence of pulmonary infiltrates on imaging. Both had underlying ANCA vasculitis with a history of pulmonary involvement. Both were treated with remdesivir and one received convalescent plasma. The patient who received convalescent plasma was SARS-CoV-2 RNA negative at 3 weeks. The patient who received remdesivir but not plasma remained positive for SARS-CoV-2 RNA at 7 weeks and was negative for IgM and IgG antibodies at 4 weeks. The third patient recovered without hospitalization and had a first negative RNA test at 3 weeks and was positive for IgG antibodies when tested at 7 weeks despite a confirmed zero B cells by flow cytometry.

**Conclusions:** 3 out of 3 patients who developed SARS-CoV-2 infections while on RTX recovered. A larger review of individuals on RTX therapy infected with SARS-CoV-2 should be examined to study the association between B cell depletion and COVID19.

**Patient Characteristics and Outcomes**

<tr>
<td>COVID-19 pneumonia diagnosed</td>
<td>Severe G6PD deficiency can manifest with fava bean ingestion or other triggers.</td>
</tr>
</tbody>
</table>

HCQ: Hydroxychloroquine

G6PD: Glucose 6-phosphate dehydrogenase

*PR3-ANCA: Patient with eye, ENT, lung and kidney involvement

**Discussion:** The residual enzyme activity of G6PD deficiency determines the severity of clinical manifestations which are usually triggered either by fava bean ingestion or drugs, and are dose-dependent. This patient had a severe deficiency and he received a loading dose of an RTX-risk drug. Both induced hemolysis crisis. AKI is a rare complication of AHA related to G6PD deficiency. The need for renal replacement therapy seems exceptional. Renal recovery could be incomplete. Severe G6PD deficiency can manifest late, and HCQ should be used with caution given potential severe side effects. We then recommend early monitoring of hemolysis parameters.

COVID-19 in Kidney Transplant Recipients

**Background:** SARS-CoV-2 rapidly spread globally, imposing the need for change in nephrology practices guided by the recommendations, issued by scientific associations.

**Methods:** We conducted a nationwide virtual educational initiative with an inbuilt technological platform to enable live sharing of experiences of new modes for nephrology practice during COVID 19 pandemic, based on the adoption of current recommendations and evidences to enable indigenous, adaptive experiences of 404 nephrologists with approximately 8,000-man hours of cumulative clinical experience. The four zones across the country were represented by an individual educational task force member.

**Results:** There was a uniform consensus that suspected patients need to be treated similar to a COVID 19 positive patient, with dialysis facility provided in isolation area, to mitigate direct risk to both healthcare providers and patients and indirect risk of contamination of the hospital system. Multiple screening procedures and prohibition of eatables in dialysis area is the new mandate. Role and importance of CRRT, PIIRR and peritoneal dialysis was highlighted. Femoral catheterization is the preferred route. The experience of Tenckhoff catheter technique in peritoneal dialysis in 38 patients was discussed. Higher dose of anticoagulants is being utilised for extracorporeal procedures to reduce risk of enhanced risk of thrombus formation in COVID 19. The varied, emerging clinical presentation, including asymptomatic cases has made COVID 19 testing compulsory at most of the institutions. The nephrologists were informed about the emerging evidence for the need to continue the ongoing ARBs or ACE inhibitors. Renal transplantation with careful precautionary practice is being performed with modulation of dose of immunosuppressive agents in COVID 19 positive patients.

**Conclusions:** Safe and efficient delivery of nephrology care practices needs a uniform acceptance. Even minor liberties and deviations from established safe practice protocols could compromise the safety of the health care workers.

COVID-19 in Kidney Transplant Recipients

**Background:** Coronavirus disease 2019 (COVID-19) is caused by Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). Kidney transplant recipients are at a higher risk for complications due to comorbid conditions and concurrent immunosuppression. We like to describe a small cohort of kidney transplant recipients with COVID-19.

**Methods:** A single-center, retrospective observational cohort study describing short term outcomes of COVID-19 infection in kidney transplant recipients.

**Results:** A total of 8 kidney transplant recipients were diagnosed with COVID-19 with a mean age of 58 yrs (26-78), predominantly African American (7/8), mean duration of immunosuppression of 3 weeks and was positive for IgG antibodies when tested at 7 weeks despite a confirmed zero B cells by flow cytometry.
from transplant 3.5 yrs (1.5-11 yrs). All patients have HTN (8/8), half the patients have Diabetic mellitus-2 (4/8). Common presenting symptoms are fever and shortness of breath. 6/8 patients required hospitalization. 8/8 patients were managed with a reduction of immunosuppression, primarily by decreasing the dose or holding the anti-proliferative agent. 1/8 patients died, 4/6 discharged from hospital, 1/6 still admitted to the hospital with renal failure. 1/6 patients required supplemental oxygen. 2/6 patients required ICU stay and 1/6 required mechanical ventilation and renal replacement therapy. 3/6 hospitalised patients received hydroxychloroquine/ Arithromycin combination and 1/6 received Remdesivir. Median hospital stay is 5 days with a mean of 9 days. The patient who required mechanical ventilation and renal replacement is the only recipient who died from COVID-19 at our transplant center.

Conclusions: COVID-19 is a novel infection primarily presenting with fever and shortness of breath. The course of illness appears to be severe with the majority of patients requiring supplemental oxygen and a third of hospital admitted patients required ICU stay and 1/6 required mechanical ventilation and renal replacement therapy. 3/6 hospitalised patients received hydroxychloroquine/ Arithromycin combination and 1/6 received Remdesivir. Median hospital stay is 5 days with a mean of 9 days. The patient who required mechanical ventilation and renal replacement is the only recipient who died from COVID-19 at our transplant center.

Introduction: Patients with COVID-19 typically present with respiratory illness. AKI is a common complication of COVID-19. The etiology of AKI remains unclear, thought to be secondary to hemodynamic changes, cytokine release and/or direct viral (SARS-CoV-2) cytotoxicity. The following case describes a patient who presented only with GI symptoms, which led to the diagnosis of COVID-19 and AKI.

Case Description: 71 year-old white male, a nursing home resident, was admitted to the hospital with a diagnosis of COVID-19. On the following day he was brought to a local ER after 3 large projectile emesis. Labs revealed BUN/Cr 80/9.4. He was given IV levofloxacin and was transferred to our hospital. He had watery brown-greenish stools, although he denies diarrhea or abdominal pain. Meds included Insulin, statins, heparin, SSRI, and doxepine. At our ER, the patient was awake, alert, orientated to self and year. T 98.3, BP 119/71, P 119, RR 18, SpO2: 99% on RA, PE was unremarkable. Bladder scan: 150 mL. Lab: WBC 10.9, Hb 13.3, Plt 207. Na 130, K 4.0, Cr 75, bicarb 17, BUN 85, Cr 8.6, Ca 7.3, Phos 6.6, Alb 3.2. LFT was normal. FeNa = 1.5%. UA: pH 5, prot 1+. Glu 50, RBC 5, WBC 4, with amorphous sediments. These findings were clear. Renal ultrasound: kidneys with normal size and echogenicity. No obstruction. Patient was admitted to the COVID ward. Patient’s nausea and vomiting stopped upon his admission, although his watery stools continued. He was treated with iv fluid to optimize his hemodynamics. Over the next 5 days patient’s serum Cr decreased to 5.4.

Discussion: Since the COVID-19 pandemic, GI symptoms and AKI are often regarded as complications of the overall respiratory illnesses. Patients with only GI symptoms were often not suspected for COVID-19. The causes of this patient’s AKI included hemodynamic nor cytokine mediated. ATN - possible cytokine release. Regarding direct viral cytotoxicity, postmortem data has shown the presence of coronavirus-like particles in podocytes and tubule cells. While the direct viral effect to the kidneys is still not understood, treatment with conventional approaches may significantly improve renal outcome.

813
In contrast, the starting USCs lack PAX2, SIX2 and CITED1. [MOU1] We will next quantify the expression of these and other nephron progenitor markers over the time course of 3D culture.

**Conclusions:** Our results suggest a new method to derive patient-matched SIX2+ CITED1+ cells from non-invasive urine samples.

**Funding:** Private Foundation Support

PUB077

**Comparative Evaluation of Orthostatic Hypotension in Patients with Diabetic Nephropathy**

**Background:** Orthostatic Hypotension (OH) affects 5-20% of our population. Our study investigated the presence of OH in diabetic nephropathy patients (DNP) and the factors affecting OH in comparison with other chronic kidney disease patients (CKDP).

**Methods:** Patients presented to the nephrology clinic and consented were included in the study. DNP were defined by renal biopsy and/or clinical criteria. CKDP of same sex, age and eGFR were matched to DNP. Demographic parameters and medications were obtained from the records. OH was determined by mayo clinic criteria. Same researcher used the electronic device to measure the blood pressures (BP). All samples were taken and analyzed the same day for biochemical and hematological parameters and albuminuria. Statistical analyses were performed with IBM SPSS2.0 program.

**Results:** 112(51F,61M, mean age:62.56±9.35 years) DNP and 94(40F,54M, mean age:62.23±10.08 years) CKDP were included. 70.5% DNP vs 61.7% CKDP had OH (p=0.181). The mean change in systolic BP in DNP was 21.50±16.10mmHg and it was 13.76±9.03mmHg in diastolic BP. In CKDP mean change in systolic BP was 22.1±13.90mmHg and it was 9.56±6.80mmHg in diastolic BP. There was no difference between the groups in systolic BP (p=0.797), but it was present for diastolic BP (p=0.025). 60.0% DNP and 74.7% CKDP patients had OH (p=0.028). Uric acid levels were 7.18mg/dl in OH patients and 6.36mg/dl in non-OH (p=0.017). Blood albumin level was not different in two groups (p=0.902). 73.7% of patients on calcium channel blockers developed OH (p=0.015) and OH developed in 80.6% of 36 patients on alpha blockers (p=0.049).

**Conclusions:** Our study demonstrated OH is frequent among DNP and there was no difference compared to CKDP. It is important to check OH in all CKDP as it is more common than thought.

**Blood Pressure Results**

PUB078

**Clinical Practice Gap Analysis of CKD in Type 2 Diabetes from Identification to Diagnosis to Management**

Amy Larkin,1 Kelly L. Hanley,2 George L. Bakris.3 1Medscape LLC, New York, NY; 2UCincinnati Medicine, Cincinnati, OH; 3UCHicago Medicine, Chicago, IL.

**Background:** Understanding clinical practice gaps in the identification, diagnosis and management of CKD in patients with T2D can inform development of tools to improve physician practices.

**Methods:** A survey instrument of 25 multiple choice, knowledge- and case-based questions allowed participants to assess their knowledge, attitudes, and confidence with regard to CKD in T2D. The survey was available online to physicians across the globe without monetary compensation or charge. Respondent confidentiality was maintained regarding to CKD in T2D. The survey was available online to physicians across the globe without monetary compensation or charge. Respondent confidentiality was maintained.

**Results:** A total of 113 charts were reviewed. Only 18 patients(15.9 %) were on either SGLT2/GLP1A at the end of prospective phase. By the end of prospective phase, 25 patients (22.1%) were on one of these agents. Out of 28 patients with HbA1c more than 8 at the end of prospective phase, percentage of patients on SGLT2/GLP1A at the end of prospective phase remained the same. Utilization of SGLT2/GLP1A ranged 11% to 28.9%. There was no statistically significant difference between the groups treated with SGLT2/GLP1A compared to group not treated with these agents in terms of HbA1c (P value 0.94) or eGFR (P value 0.35).

**Conclusions:** Despite the new recommendations, a substantial number of patients are not on SGLT2/GLP1A even if the diabetes is not controlled adequately. However this lack of adherence to protocol doesn't seem to affect the diabetes control or change in renal function. We need larger studies to further explore the practice patterns of physicians and its impact on outcomes.

**Funding:** Commercial Support - Bayer Global

PUB079

**Practice Patterns of SGLT2 Inhibitor and GLP-1 Agonist Treatment in Eligible Type 2 Diabetic Patients Before and After the Publication of the 2018 ADA/EASD Position Statement**

Bijn Thajudeen, Wei Xiang Wong, Saeed Bidar, Sevag C. Boyadjian, Wina Yousman, Amy N. Sussman, Frank C. Brosius. Banner University Medical Center Tucson, Tucson, AZ.

**Background:** The ADA/ EASD published a position statement in October, 2018 on the prevention of atherosclerotic CVD events in diabetic patients focusing on the use of sodium glucose cotransporter 2 inhibitors (SGLT2I) and GLP-1 agonists(GLP1A). The objective of this study is to determine the practice patterns of endocrinologists and nephrologists in implementing current societal recommendations for use of SGLT2I and GLP1A.

**Methods:** This study had two phases, a retrospective phase and prospective phase to determine utilization of SGLT2I/GLP1A before and after the publication of ADA/EASD position statement. All subjects with type 2 diabetes and CVD/CKD who were at least 18 years of age and who were followed at the endocrinology and/or nephrology clinics were included in the study. Eligible patients had a minimum of two clinic visits in either endocrinology and/or nephrology clinics during either the retrospective phase (October 2017-September 2018) or prospective phase (October 2018 – September, 2019). Information collected included utilization of SGLT2I/GLP1A, HbA1c, eGFR, new CVD events and adverse effects of SGLT2I/GLP1A therapy. Primary outcomes measured was the change in percentage of eligible patients treated with an SGLT2I/GLP1A.

**Results:** A total of 113 charts were reviewed. Only 18 patients(15.9 %) were on either SGLT2I/GLP1A at the end of retrospective phase. By the end of prospective phase, 25 patients (22.1%) were on one of these agents. Out of 28 patients with HbA1c more than 8 at the end of retrospective phase, percentage of patients on SGLT2I/GLP1A at the end of prospective phase remained the same. Utilization of SGLT2I/GLP1A ranged 11% to 28.9%. There was no statistically significant difference between the groups treated with SGLT2I/GLP1A compared to group not treated with these agents in terms of HbA1c (P value 0.94) or eGFR (P value 0.35).

**Conclusions:** Despite the new recommendations, a substantial number of patients are not on SGLT2I/GLP1A even if the diabetes is not controlled adequately. However this lack of adherence to protocol doesn’t seem to affect the diabetes control or change in renal function. We need larger studies to further explore the practice patterns of physicians and its impact on outcomes.

**Funding:** Private Foundation Support, Government Support - Non-U.S.
**Results:** 3 male and 7 female patients with diabetic nephropathy were included, aged 51-80 years, with eGFR 60-4.6ml/min, and 3 patients presented with cardiac insufficiency. Sodium excretion <90mmol followed by Dapagliflozin/Canagliflozin once a day for 7 days, with follow-up. Sodium excretion increased by 30% ± 150 ml/day. Urine volume was 800±500ml/24 hours after treatment. The Scr increased by 30% after 7 days of treatment, and returned to the level of Scr before the initiation of Dapagliflozin/Canagliflozin. Electrolyte levels were comparable before and after treatment.

**Conclusions:** The diuretic regimen based on SGLT2i could significantly improve the resistance of diabetic nephropathy patients to diuretics, increase urinary sodium excretion, and slightly elevate renal function in the short term without affecting blood electrolyte level. The efficacy and safety of long-term use of SGLT2i in diabetic nephropathy patients at CKD3-4 stage need further investigate in larger sample size.

Peripheral Neuropathy in a Hemodialysis Patient with a Normal Serum Vitamin B12 Level: Possible Vitamin B12 Deficiency in Target Tissues

Yadanar W. Le,

Thinn E. San,

Hun M. Aung,

Aye M. Thida,

Myat E. Mon,

Kyaw M. Thein,

Kyaw Hla,

Alexander M. Swan,

Nephrology Hypertension Renal Transplant & Renal Therapy, LLC, Avenel, NJ; 2Icahn School of Medicine at Mount Sinai Elmhurst Hospital Center, Elmhurst, NY; 3Interfaith Medical Center, Brooklyn, NY; 4Woodhull Medical and Mental Health Center, Brooklyn, NY; 5South East Regional Health Authority, Kingston, Jamaica; 6Rutgers New Jersey Medical School, Newark, NJ.

**Introduction:** Many hemodialysis patients suffer from vitamin B12 deficiency, usually due to inadequate nutritional intake. Besides, food sources of vitamin B12 contain high concentrations of electrolytes, which are harmful to these patients. Thus, they are restricted to foods with low vitamin B12 content. Moreover, high-flux dialyzers remove vitamin B12 molecules from circulation, leading to vitamin B12 deficiency. We report a hemodialysis patient presenting with peripheral neuropathy and a normal serum vitamin B12 level whose symptoms improved with monthly vitamin B12 injections after excluding other differential diagnoses of peripheral neuropathy.

**Case Description:** An 80-year-old man with a history of ESRD on hemodialysis for 3 years along with HTN and CAD presented with fatigue, muscle weakness, and numbness of his extremities for 3 weeks. He was taking aspirin, dipyridamole, finasteride, tamsulosin, and pravastatin. His dietary history was significant for poor nutritional intake. Laboratory findings showed HD 10.6 g/dL, MCV 102 fL, RBS 87 mg/dL, potassium 4.6 mmol/L, and BUN 42 mg/dL. Common causes of peripheral neuropathy in ESRD patients, such as uremic neuropathy, diabetic neuropathy, and hyperkalemia were excluded. Further evaluation revealed a normal serum vitamin B12 level of 421 pg/dL and a normal folic acid level of 14.4 ng/mL. Given his risk factors for possible vitamin B12 deficiency in target tissues, he was treated with monthly vitamin B12 1000 mcg injections and followed up regularly. His symptoms improved significantly after four months of injections.

**Discussion:** In hemodialysis patients, chronic inflammation impairs uptake of circulating vitamin B12 by peripheral tissues leading to decreased production of transcobalamin II, increased synthesis of transcobalamin I and III with further accumulation of vitamin B12 in blood. In addition, despite normal or high serum vitamin B12 levels, these patients may suffer from vitamin B12 deficiency in target tissue and show symptoms such as fatigue and peripheral neuropathy. Therefore, it seems reasonable to consider vitamin B12 supplementation in these patients after excluding other causes of peripheral neuropathy. Further studies are highly recommended.

**PUB084**

Hemodialysis Prescription in Ethylene Glycol Overdose: A Mathematical Approach

Muhammad T. Shakoor, Jie Tang, Warren Alpert Medical School of Brown University, Providence, RI.

**Introduction:** The timely management of Ethylene glycol (EG) overdose is essential. Hemodialysis (HD) is indicated for rapid elimination of its toxic metabolites. We introduce a case diagnosed shortly after presentation prior to the availability of the blood EG level and share calculations that were used to precisely and accurately estimate the clearance of EG through HD.

**Case Description:** A 61-year-old male presented with unresponsiveness. Labs were notable for anion positive metabolic acidosis with anion gap 28, osmolar gap 57, along with stage 2 AKI. His whole blood lactate was >17.1 meq/L, with a venous lactate of 0.5 meq/L. EG intoxication was diagnosed based on high lactate gap (16.6) and calcium oxalate monohydrate crystals in his urine sediment. He was given fomepizole and hemodialysis for EG toxicity to normalize. We calculated HD prescription based on the metabolite calculation which we have been using reliably to calculate HD duration and post HD EG level. His predialysis EG level was 71 mg/dL. To calculate the EG removal via HD, we need patient's predialysis EG level and share calculations that were used to precisely and accurately estimate the clearance of EG through HD.

**Discussion:** The timely management of EG intoxication is delayed and calculation of HD prescription remains a challenge due to lag in obtaining serial EG assays in clinically useful time frame. We present a case of EG toxicity that we were able to diagnose promptly with laboratory workup to wait for EG blood levels, and we present a simplified approach to determine the duration of HD based on a single EG assay. This calculation can be used to individualize HD treatments and avoid over or undertreatment of intoxication.
The Excretion Formula of Phosphorous, Potassium, and Salt Amounts

Momoko Fukazawa,1 Shunichiro Urabe,1 Motoko Kato,1 Yukie Kitajima,2 Akihiro C. Yamashita,3 Toru Hyodo.1 Eijin Clinic, Hiratsuka, Japan; Tokyo University of Technology School of Health Sciences, Shinagawa, Japan; Hospi University, Koganeish, Japan.

Background: We elucidated the contribution of residual renal function (RRF) to the phosphorous, potassium and salt excretion and established the estimation formula of these amounts which are excreted into urine by RRF of hemodialysis patients.

Methods: We collected the 24 hours urine from 22 hemodialysis patients (mean age: 73.1±12.1 years old, dialysis history: 31.4±29.3 months, 15 males, 12 diabetics). The urine volume, phosphorous, potassium and salt amounts in the 24 hours urine and creatinine clearance were determined. The correlation coefficients among the urine volume, amounts of phosphorous, potassium and salt, and creatinine clearance (Ccr) were calculated.

Results: The mean urine volume was 6626±421/mL/day. The mean phosphorous amount in the urine was 114.5±55.9 mg/day, potassium 418.2±2212.4 mg/day, and salt 4.7±2.6 g/day. Ccr was 3.7±1.8 mL/min. There was a significant positive correlation: urine volume vs phosphorous amounts (r=0.759, p<0.001), urine volume vs potassium amounts (r=0.662, p=0.001). (Phosphorous amounts in the urine=134x[24 hours urine(L)]-130). There was a significant positive correlation between urine volume and salt amounts excreted into urine (r=0.915, r2=0.84, P=0.001). (Salt amounts in the urine=5.7x[24 hours urine(L])-0.2). The amount of urinary excretion of phosphorous and potassium can be roughly estimated.

Conclusions: As for phosphorous and potassium, if 24 hours urine volume is known, the amount of urinary excretion of phosphorous and potassium can be roughly estimated. As for salt, if 24 hours urine volume is known, the amounts of urinary excretion of salt can be estimated with 84% accuracy. Measuring urine volume in hemodialysis patients can estimate solute excretion roughly.

Treatment of Uremic Tumoral Calcinosi in Maintenance Hemodialysis Patients

Guibao Ke, Fengxia Zhang, Xueqin Chen, Hong Zhang, Shuai C. Dou, Zhiwen Liang, Shi Wei, Xining Liang, Shuangxin Liu. Department of Nephrology, Guangdong Provincial People’s Hospital, Guangzhou Academy of Medical Sciences, Guangzhou, China.

Background: Uremic tumoral calcinosi (UTC) is a rare disease with metastatic tissue calcification in maintenance hemodialysis (HD) patients. However, limited data are available on treatment of UTC in HD patients. This article mainly discusses the diagnostic findings and efficacy of treatment in HD patients with UTC.

Methods: A retrospective analysis was conducted on the data of 13 cases of UTC, including their clinical features, biochemical indicators, imaging findings, diagnosis, therapeutic methods and follow-up results. Parathyroidectomy (PTX) or drug treatment were determined based on intact parathyroid hormone (iPTH) levels and clinical symptoms.

Results: All of 13 patients were diagnosed as UTC definitely by imaging examination. The predominant areas involved were the buttocks (4 cases, 30.77%), shoulders (4 cases, 30.77%), and elbows (3 cases, 23.08%). Based on the levels of iPTH, cases were categorized into two different groups: PTX treatment group was associated with high levels of iPTH, while drug treatment group (lanthanum carbonate or sevelamer with STS) was lower iPTH. After PTX treatment, there was a significant decrease in serum iPTH, calcium (Ca), phosphate (P) and alkaline phosphatase (ALP) levels (p<0.05). In drug treatment group, the serum P levels was decreased significantly, along with a finding that hemoglobin levels was increased (p<0.05). All the UTC had lessen or even disappear after treatment 4 to 6 months.

Conclusions: Although most UTC patients have an increased iPTH, a small number had lower iPTH levels. Based on iPTH levels and clinical symptoms, the patients were treated with PTX or drug therapy. With proper treatment, UTC disappeared without the need for surgery to remove calcinosi tissue.
Conclusions: It has been demonstrated that flow balance error and fluid removal attainable with SC lies well within the acceptable standards permitted for haemodialysis machines, demonstrated across a range of clinically relevant parameters at dialyse flow rates of up to 500ml/min.

PUB089

Clinical Performance of the Optiflux® F160NR Dialyzer

Jill M. Meyer,1 Dylan Steer,2 Lisa A. Weber,3 Mayuri Thakuria,4 Chiang-Hong Ho,5 Claude Mulloni,6 Robert J. Kossmann.7 California Institute of Renal Research, Chula Vista, CA; 8California Institute of Renal Research, San Diego, CA; 9Research Management Inc./ Kansas Nephrology Research, Wichita, KS; 10Fresenius Medical Care North America, Waltham, MA.

Background: Subjects in the clinical trial (NCT# 03536663), An Open-Label Clinical Study to Assess the Performance of the Dialyzer with Endexo10 in End-Stage Renal Disease Subjects, were dialyzed with the Optiflux® F160NR dialyzer, followed by the new dialyzer with Endexo. This sub-analysis reports the safety and performance of the Optiflux® F160NR dialyzer.

Methods: Subjects prescribed three-weekly HD for at least 30 days at three US study sites were enrolled in the study. The Optiflux F160NR dialyzer study period included 12 HD treatments. Performance and safety assessments included URR, spKt/V, serum albumin and β2-microglobulin levels with removal rates measured pre and post HD, complement activation, and Adverse Events (AEs).

Results: Twenty-six subjects were screened. Twenty-three subjects were enrolled in the study (median age 64 years, females 73.91% and white 73.91%) and completed 268 HD treatments with the Optiflux F160NR dialyzer. Four subjects discontinued the study due to missed visits, not related to adverse events. 19 subjects completed all 12 HD treatments per protocol (n = 228 dialysis sessions). Delivered HD treatments are presented in Table 1. No SAEs were reported during the study. Four subjects reported at least one adverse event not device related. Mean (SD) for enrolled subjects were: 80.5% (4.5) for URR, 1.9 (0.3) for spKt/V, 47.1% (7.4) for corrected β2-microglobulin removal rate and an increase of 8.3% (8.2) post HD for serum albumin. Complement activation was measured Pre HD and 30 min Post HD start and showed no overt activation for C3a, C5a and SC5b-9.

Conclusions: HD treatments were well tolerated and URR and spKt/V were high with Optiflux® F160NR dialyzer. Serum albumin levels increased post HD. Complements showed no overt activation.

Diabetes Disequilibrium Syndrome: Severe Irreversible Brain Injury Following Hemodialysis

Fatima Ballout, Pravir V. Baxi, Roger A. Rodby. Rush University Medical Center, Chicago, IL.

Introduction: Diabetes disequilibrium syndrome (DDS) is a clinical complication of hemodialysis characterized by neurological symptoms attributed to cerebral edema that rarely occurs in ESKD patients following their first HD treatment. Treatment is primarily preventative, aimed at decreasing the rate of urea clearance to reduce subsequent osmotic fluid shifts. We describe a case of DDS with severe neurological sequelae in a patient with acute on chronic kidney disease.

Case Description: A 39 yo man with CKD 4 presented with dyspnea, lethargy and confusion. Initial labs showed a Na 133 mmol/L, K 7.9 mmol/L, BUN 281 mg/dl and creatinine 38.6 mg/dL. HD was initiated for treatment of uremia and hyperkalemia. Two hours after the start of HD, the patient had a tonic-clonic seizure followed by cardiopulmonary arrest. Lab data post-arrest showed a Na 133 mmol/L and BUN of 112 mg/dL (Fig 1). In the subsequent days, the patient remained in a comatose state. MRI of the brain revealed cortical restricted diffusion in both cerebral hemispheres and bilateral basal ganglia, concerning for hypoxic-ischemic injury. His clinical status did not improve over 3 months. He required a tracheostomy and PEG tube placement with HD dependency on discharge.

Discussion: DDS remains a rare clinical phenomenon which typically occurs with initiation of HD in those with severe azotemia and advanced CKD. Risk factors include pre-existing neurological conditions, hypotension, and higher starting BUN levels. While the pathogenesis remains debated, DDS is believed to be due to a reverse osmotic effect that occurs due to a faster decline of urea within the blood versus the brain creating osmotic disequilibrium with subsequent movement of water into the brain causing cerebral edema. Idiogenic osmolytes may also be involved. Recognition of patients at high risk is crucial as it provides an opportunity to implement preventative strategies including reduced HD treatment time with lower blood flows aimed at more gradual clearance of urea.

PUB091

Sustained High-Dose Chronic CRRT Fails to Attenuate Severe Lactic Acidosis in an Immunotherapy-Resistant Case of Malignant Melanoma with Liver Visceral Crisis

Mabel S. Tan, Han K. Tan. Singapore General Hospital, Department of Renal Medicine, Singapore, Singapore.

Introduction: Lactic acidosis is the most common cause of metabolic acidosis in hospitalized patients. Though of little proven benefit, continuous renal replacement therapy (CRRT) has been suggested as treatment in some patients. We describe a rare case of a patient with lactic acidosis who received nineteen days of high dose CRRT.

Case Description: A 60-kg Asian female with melanoma and extensive liver metastasis presented in a visceral crisis. She was given combination of nivolumab and ipilimumab which was projected to take 1 month to work. She had severe lactic acidosis with serum lactate of 17mmol/L on admission despite normal renal function. After a failed trial of medical therapy, CRRT was started purely for lactic acidosis. A spot measurement of effluent lactate was 15mmol/L while the corresponding plasma lactate was 16.3mmol/L, suggesting sieving coefficient of 0.92. Switching to a lactate free dialysate fluid multilic did not help. Despite uninterrupted CRRT for 19 days, and repeated increase of effluent dose to peak of 5L/hour, giving lactate clearance of 76.7ml per minute, there was no improvement. She eventually demise 4 days after cessation of CRRT.

Discussion: We describe an unfortunate case where 2 specialties tried hard to save this young patient from the fatal complications of her aggressive tumor. Type B lactic acidosis is better described in hematological malignancies but there are increasing reports in solid organ tumors, most with extensive hepatic involvement. We present the first case of melanoma causing lactic acidosis reported in literature till date. While CRRT, convective therapies, bicarbonate-based dialysis fluids have been suggested as treatment for lactic acidosis, there is little proven benefit. In our case, we combined all 3 strategies, persisted at high dose for 19 days with no success. 2 learning points: Firstly, lactic acidosis in the absence of hyperperfusion (Type B) is not uncommon and equally dangerous. Secondly, while dialysis removes lactate to some extent, it is at best a temporizing measure. Addressing the underlying cause takes priority. Dialysis, regardless of dose, modality and timing is less likely to affect outcome.

PUB092

Primary Caregiver Burden in a Hemodialysis Clinic in Mexico: Prevalence and Caregiver-Related Risk Factors

Eduar Solis, Josefina Rivera, Juan M. Ardanuy Inuarte. Medica Santa Carmen, San Miguel de Allende, Mexico.

Background: Dialysis treatment is defined as a family disease. Primary caregiver is the main person who takes the responsibility for and supports the patient; caregiver burden can be defined as the strain or load borne by a person who cares for a chronically ill family member. The Zarit survey is a psychometric instrument designed to grade caregiver burden, recommended and validated among caregivers of patients in hemodialysis.

Methods: A descriptive study was conducted among primary hemodialysis caregivers from a dialysis clinic in Guanajuato, Mexico. Zarit Scale (A validated 22-item questionnaire with five item ranged from 0=never to 4=always) was applied in order to identify presence and level of caregiver burden. Caregivers of patients less than 3 months were excluded. Social and demographic data related were also collected. Data was analyzed for descriptive statistics using T-test and Chi square for comparison between groups.

Results: A total of 86 primary dialysis caregivers answered the survey via personal interview with one of the investigators. Most respondents were female (77%) with a mean age of 47±15 years old. Seventy seven percent were married and almost all had an occupation (95%): homemaker (43%) was the most common. We found that couples take care of patients in 42% of cases, followed by parents (27%). Interestingly, 46% of responders did not take own recreational time and some of them (38%) were diagnosed with some chronic illness. More than half (56%) usually take care of 1 to 3 more persons along with the patient and meantime of life spent caring was 2 years. Any level of caregiver burden was identified in 67%, most of them (86%) in a slight level. There were not statistical differences between groups with none and any burden.

Conclusions: ESRD affects not only patients but also the people who takes care of them. Caregivers burden is prevalent in our clinic. Caregivers are predominantly female
partners who have to cope with patients care along with attendance of other relatives and often the need to work for economic support of their families. These results should be added to the public health burden of ESRD in Mexico.

**Conclusion:** Everyone of us should be aware how our daily activity influence on the environment. Both, medical industry and nephrologists are responsible for decreasing the quantity and weight of medical waste produced during dialysis treatment. Careful proceeding with the disposables (proper procedures, medical staff training and awareness) will directly help to make the HD treatment more cost-effective and help to protect our planet.

**PUB095**

**Early Intervention of Continuous Hemodialysis Filtration Is Effective to Improve Acute Kidney Injuries and Mortality in Patient with Propofol-Related Infusion Syndrome**

**Introduction:** Propofol related infusion syndrome (PRIS) is a fatal syndrome that often develops under the long-term propofol infusion at high doses. The main features of the PRIS consist of cardiac failure, rhabdomyolysis, acute kidney injury, and severe metabolic acidosis. High dose propofol, but also supportive treatments with catecholamines and corticosteroids, act as triggering factors. Propofol is usually administered at 0.3–4.0 mg/kg/hr or less to the sedation of adult patients, and is not administered beyond 7 days to prevent PRIS. We report here a case of PRIS developed rhabdomyolysis, acute kidney injury, and severe metabolic acidosis under the dose of propofol within the safety dose.

**Case Description:** A 41-year-old woman was operated cervicopharyngeal posterior longitudinal ligament ossification. After the operation, maximum 3.5 mg/kg/hr of propofol was used for sedation for treatment of severe pneumonia under the mechanical ventilator. Catecholamines was also used to support hemodynamics. However, unidentified hypoxemia and impaired blood pressure were prolonged, then administration of propofol was discontinued on POD6. Acute kidney injuries (sCr 2.3 mg/dL), metabolic acidosis and high serum CK (79300 U/L) due to rhabdomyolysis were observed on POD8. Continuous hemodialysis filtration (CHDF) therapy was initiated, and hyperthermia, oxygenation, impaired hemodynamics and renal dysfunction were gradually improved. Finally, cardiac failure and renal function were totally recovered.

**Discussion:** Propofol impairs free fatty acid utilisation and mitochondrial activity. Imbalance between energy demand and utilisation is a key pathogenetic mechanism, which may lead to cardiac and peripheral muscle necrosis. CHDF may effective to maintain renal function and acid-base equilibrium through removal of metabolites induced by mitochondrial damage, such as lactate and creatine kinase. PRIS particularly when combined with catecholamines can be lethal and we suggest early intervention of CHDF is effective to improve renal injuries and mortality.

**PUB096**

**The Conduct of Sponsored Trials Has No Association with Dialysis Facility Clinical Quality Outcomes**

**Background:** There is a paucity of clinical trials conducted in nephrology vis-à-vis other fields (Baigent, et al. 2017). The lack of knowledge on impacts of trial conduct on dialysis facility operations can create barriers between stakeholders. We aimed to assess for clinical quality target achievement in dialysis facilities conducting trials versus matched facilities not involved in research activities that are necessary for advancing the state of the art.

**Methods:** We used data from adult (age ≥18 years) hemodialysis patients treated at a single provider network in the United States during 2017 to 2018. Facilities that did not participate in trials were matched to research facilities using 1:1 matching on logit of propensity score for patient years of follow-up, years of certification, % of Medicare patients, % of ESCO facilities and geographical region. We cross-sectionally compared mean facility-level quality metrics for: anemia (%Hgb a10 & <10g/dL), mineral bone disorder (%calcium c10.0mg/dL & %phosphate c4.5mg/dL), and event outcomes (%catherer exposure >90 days, % treatment non-adequacy, 30 day readmission rates, hospital days/patient year).

**Results:** We found no significant differences between mean facility-level quality metrics in dialysis facilities that conducted trials versus matched facilities not involved in research (Figure 1).

**Conclusions:** We found the conduct of trials in dialysis facilities had no association with achievement of quality targets, as compared to matched facilities not participating in trials. These insights are of importance to providers and stakeholders participating in considering nephrology research activities that are necessary for advancing the state of the art.

**Funding:** Commercial Support - Fresenius Medical Care
Impact of Major Surgical Operations on Clinical Outcome in Dialysis Patients

Methods: We retrospectively evaluated the records of all patients on HD and PD, who had been treated for at least 3 months at our outpatient clinics between January 1, 2014 and December 31, 2018. In addition to clinical and laboratory parameters, data on all major surgical operations were recorded.

Results: Among the 202 patients, 133 (66%) were on HD and 69 (34%) on PD. The mean age (±SD) was 58.3±14.5 years, 48% were female and 28% had diabetes mellitus. Forty-seven patients (23%) had a major surgical operation. The operation types were cardiovasculary in 14 patients, orthopaedic in 11, gastrointestinal in 8, genitourinary in 7, and breast in 1 patient. Operations were emergent in 10 patients (21%) and elective in the others (79%). Among the whole study population, 59 patients (29%) died during the study period. In Kaplan-Meier analysis (Figure), mean (±95% CI) survival time in operated patients was 43 months (±7 to 49 months), while it was 49 months (±6 to 52 months) in the others (p=0.001). Fifteen out of 23 deaths (65%) among the operated patients occurred in the first month after surgery. Severe perioperative complications (arrhythmias, hypervolemia, hypotension, bleeding, acute coronary syndrome, respiratory failure and cerebrovascular event) were recorded in 17 (36%) of the operated patients, of whom 16 died (p=0.001). Although did not reach a significant level, mortality rate tended to be higher after emergent operations than that after elective operations. Cox regression analyses revealed that age (RR 1.007, 95% CI 1.002-1.007, p=0.001) and diabetes (RR 2.581, 95% CI 1.474-4.521, p=0.001) were independent predictors of mortality.

Conclusions: Although prospective studies with a higher patient number are needed to confirm, our study shows that, in addition to age, diabetes and inflammatory status, having a major surgical operation is an independent risk factor for mortality in dialysis patients.
Achromobacter Xylosoxidans, Subspecies Denitrificans, Exit Site Infection, and Aeromonas Hydrophilia Peritonitis: Rare Infections in Peritoneal Dialysis Patients

Background: Achromobacter xylosoxidans, subspecies denitrificans, exit site infection in peritoneal dialysis patient is rare and will be reported. A second case of rare peritoneal infection caused by Aeromonas hydrophilia peritonitis will also be reported. Both are gram-negative microorganisms and are usually found in wet environments, causing infections in immunocompromised patients. Both cases occurred in the same rural city and in the same dialysis facility.

Methods: The cases involved conducting interviews with patients and documenting each visit. All observations and visitations were assessed in the dialysis center of a rural area. Previous data of cases with similar rare pathogen caused peritonitis were also analyzed.

Results: The patient with exit site infection, Achromobacter xylosoxidans, was treated with oral ciprofloxacin for 3 weeks resulting in a slow improvement of the exit site. During treatment the patient experienced erythema, discomfort, and discharge. At the end of the treatment, repeat cultures drawn from the exit site were negative. The patient with Aeromonas hydrophilia peritonitis is currently being treated with intraperitoneal gentamicin.

Conclusions: Achromobacter xylosoxidans and Aeromonas hydrophilia are both rare bacterial infections that have a history of causing infections in immunocompromised individuals exhibiting multiple risk factors. We reported exit site infections and peritonitis in end stage kidney disease patients. Both infections have been treated without any adverse effects or removal of peritoneal dialysis catheters.

Bicarbonate-Rich Peritoneal Dialysis as Salvage Therapy for Metabolic Acidosis

Elise L. Stephenson, Ryan A. Carver, Jessica R. Burgess, Thomas R. McCune. Eastern Virginia Medical School, Norfolk, VA.

Introduction: Use of peritoneal dialysis (PD) in ICUs in developed nations is limited. The need for emergent dialysis is often considered a contraindication for peritoneal dialysis and the large peritoneal surface area is often neglected in the resuscitation of critically ill patients. We report a case of successful emergent PD with high bicarb dialysate in an actively dying patient not tolerating standard renal replacement therapies.

Case Description: A 36 yo male with no medical history sustained multiple gunshot wounds. He was found to have multiple injuries in the small bowel including the duodenum. Two 15-french drains were placed at the time of surgery. While initially stable, he gradually developed worsening hypotension and a declining hematocrit requiring a bedside laparotomy that evening. A severe metabolic acidosis remained refractory to standard therapy. CRRT was started briefly but he was unable to tolerate due to worsening hypotension. His pH worsened (pH 6.97) with bicarb 6mmol/L and lactate (LA) 26.9mmol/L. Family said their goodbyes and he was made DNR. Methylene blue was given without hemodynamic change. Given his young age, inability to tolerate CRRT and intraperitoneal access already available, decision was made for emergent PD as a final effort to control refractory acidosis. Approximately 1L of 1.5% peritoneal dialysate with an additional 300 mEq sodium bicarb/2L bag was instilled for a 30 minute dwell time. Within an hour, his labs showed pH 7.12, bicarb 15mmol/L, LA 16mmol/L and his vasopressor requirements decreased. After four exchanges, CRRT was initiated. His acidosis resolved within 24 hours and he was vasopressor free by 36 hours. He was extubated, dialysis dependent and continues to recuperate.

Discussion: PD in developed nations is often a forgotten modality for acute renal failure. We found only 2 published reports since 1980 using PD in the ICU for metabolic control. Our case describes successful use of high bicarbonate PD in the ICU to control refractory acidosis and achieve hemodynamic control. Data is lacking on the use of emergent PD in trauma patients and within ICUs despite its relative case and low cost. High bicarbonate PD is an option for refractory acidosis in the critically ill.

Myoclonic Seizures and Altered Mental Status in a Patient on Peritoneal Dialysis Treated with Piperazine

Sandra J. Jimenez Acosta,1 Gustavo A. Guzman,2 Daniel F. Arroyo Ariza,2 1Universidad de los Andes, Bogota, Colombia; 2Hospital Universitario Fundacion Santa Fe de Bogotá, Bogotá, Colombia; 3Healthy Medical Center, Zipaquira, Colombia.

Introduction: Here we present the case of a man on automated peritoneal dialysis (APD) with altered mental status and myoclonus after the self-administration of piperazine as antihistamine. This case illustrates how dangerous self-medication can be in patients with chronic kidney disease. Additionally, it shows that neither peritoneal dialysis nor hemodialysis appear effective methods for piperazine clearance in patients on renal replacement therapy (RRT).

Case Description: A 66-year-old man was brought unresponsive and with myoclonus to the ER. His past medical history included diabetes mellitus, with diabetic nephropathy that lead to ESRD. He was started on RRT 1 year before presentation; initially hemodialysis (APD) with altered mental status and myoclonus after the self-administration of piperazine as antihistamine. This case illustrates how dangerous self-medication can be in patients with chronic kidney disease. Additionally, it shows that neither peritoneal dialysis nor hemodialysis appear effective methods for piperazine clearance in patients on renal replacement therapy (RRT).
suspected bacterial infection as the cause of the altered mental status, empirical antibiotic treatment was initiated. However, the patient’s symptoms persisted, requiring care at the ICU and intubation. Further interrogation of the patient’s family revealed that he had self-administered a full bottle of piperazine hexahydrate. An infectious cause was ruled out and no clinical improvement was achieved with antiepileptics. At this point, piperazine intoxication was our most likely diagnosis. After a week of APD we decided to switch RRT to sustained low efficiency hemodialysis (SLED). He received two sessions. Gradually the patient’s mental status improved and was discharged with his usual APD.

Discussion: The most common symptoms of piperazine intoxication are myoclonus, decreased level of consciousness and ataxia. Few data is available regarding the diazilabilty of this medication, and neither PD nor HD seem effective treatment options. Hemoperfusion seems a suitable alternative. Clinical improvement in this case may be due drug metabolism, independent of treatment. We want to highlight the importance of education in renal patients, specially in the dangers of self-medication. Fortunately, our patient had a full recovery. But that may not be the case of other patients who inadvertently poison themselves with “safe” medications; like piperazine.

**PUB106**

Two-Year Follow-Up of Quality Indicator Compliance in a Large International Peritoneal Dialysis Institution

**Background:** Peritoneal dialysis (PD) practice is not universally homogeneous, best clinical practices are not completely understood as reference values are often obtained from small sized populations and/or frequently based on chronic kidney disease (CKD) and/or hemodialysis data. **Objectives:** To evaluate two years of follow up of compliance with PD-related quality indicators (QIs) following definition of new targets in an international PD network.

**Methods:** All English and Spanish language CKD and PD guidelines were reviewed. Twelve QIs were considered being of significant relevance and targets for these QIs were defined (see table). Retrospective data analysis

**Results:** Achievement of QI targets for years 2017-2018 is shown in table (image). Variability among countries not shown.

**Conclusions:** There was a significant increase in QIs achievement in 2018 vs. 2017. 75% of patients met the target for the following variables: total weekly Kt/Vurea, 24 h fluid removal, mean arterial blood pressure and serum albumin. Peritonitis rates are clearly over International objectives and were improving. Due to the lack of referral source data, these series may help to understand PD practice and outcomes in a global setting.

**PUB107**

Acyclovir-Induced Encephalopathy in a Patient on Peritoneal Dialysis

Areen Kate M. Kuan, Shamir Hasan, Yuri Khanin, Hugo Andrade paz, Nupur N. Uppal, Mala Sachdeva. *Northwell Health, Great Neck, NY.*

**Introduction:** Acyclovir is an antiviral agent that is used for treatment of diverse viral pathologies. The regular pharmacokinetics for acyclovir is altered with kidney dysfunction. At present, our knowledge regarding treatment of acyclovir neurotoxicity in patients undergoing peritoneal dialysis (PD) is limited, as only few case reports have been published. We describe a case of acyclovir induced encephalopathy in a PD patient that was successfully treated with hemodialysis.

**Case Description:** 34F with a history of systemic erythematous lupus (on prednisone, celcept and plaquenil), ESKD on peritoneal dialysis (PD), subclinical hypothyroidism, anemia and hypertension was admitted for her lips and right eyelid. She was initiated on intravenous acyclovir at a dose of 500mg daily. 24 hours later, she developed acute confusion which progressed to include myoclonus, lethargy and coma. Labs on admission revealed hemoglobin 10, Na 137, K 4.6, Cl 92, CO2 22, BUN 64, Cr 20.85. CT head was negative. EEG did not reveal any epileptiform activity. Lumbar puncture and brain MRI did not show any evidence of viral encephalitis. Acyclovir neurotoxicity was considered as the etiology for her severe encephalopathy. Acyclovir was held and her CCPD prescription was increased but she continued to remain encephalopathic. A decision to initiate hemodialysis (HD) was made. After the first HD session, her mentation slightly improved. She received a total of 3 HD sessions, after which her mental status completely returned to baseline. Given that she improved after discontinuation of acyclovir and with HD this confirmed her diagnosis of acyclovir induced neurotoxicity. She was switched back to PD after recovery.

**Discussion:** Dose adjustment for acyclovir is recommended in patients with ESKD. Even when the acyclovir dose is adjusted for these patients, it can still cause neurotoxicity. This complication seems to be more common in those on PD likely due to the slower removal of the medication with PD. Clinicians need to be aware of this potential adverse event, as this diagnosis needs prompt recognition and treatment. Clearance of acyclovir with PD is not completely understood and in fact PD was not adequate to help with clearance in our patient despite increasing her prescription. The modality of choice for clearance of acyclovir in toxicity is hemodialysis.

**PUB108**

The Analysis of Risk Factors for the Patients with Venous Needle Dislodgement and Bleeding During Hemodialysis

Hsuan Ming Lin, Wen H. Wu, Hsiang Wei Hu. 1,4 1An Nan Hospital, China Medical University, Tainan, Taiwan, Tainan City, Taiwan; 2Department of Healthcare Administration of I-Shou University, Taiwan, Kaohsiung, Kaohsiung, Taiwan; 3National Cheng Kang University, Tainan, Taiwan; 4Acusense Biomedical Corp., Tainan City, Taiwan.

**Background:** A puncture of vascular access is commonly used in clinical treatment, such as hemodialysis or central venous catheters. Leakage or infection associated with Venous needle dislodgement (VND) is a high risk of fatality. However, only a few studies are focusing on patient disease, medication, and other risk assessments. Therefore, this study aims to explore the risk factors of patients with venous needle dislodgement and bleeding and hope to establish the risk classification.

**Methods:** This study was a prospective study conducted in the hemodialysis unit of Tainan Regional Hospital. During three months from July 2019 to Sep 2019, we collected clinical data, including patient sex, gender, diseases, records of dialysis access leakage, anti-coagulant dose, and a risk assessment form. We compared the data between the two groups of patients who have at least one risk in the risk assessment form. We analyzed the data with STATA™. P<0.05 was defined as significant.

**Results:** In the study period, seventy-one patients were included in this study, with an average age of 63.0 (± 1.19 years) and 46 males (64.79%). The patients with any risk in the risk assessment form were considered the high-risk group. There were 72 venous needle dislodgement and bleeding in 32 patients during the study period. In the below feature, gender, high-risk group or not, diabetes, high blood pressure, exposure to Benzodiazepine, the experience of Intradialytic hypotension, exposure to warfarin, or dosage of anti-coagulant, there was no statistic significant between the patients experienced at least one episode of VND and others.

**Conclusions:** Between patients experience VND or not, we did not find any significant association in not only conventional factors or other factors. However, this study provides a reference for future research.

**Funding:** Commercial Support - AcuSense BioMedical Technology Corp
Publication-Only

**Results:** Total number of patients studied were 16. The average age was 66.6 years. All were hypertensive and diabetics comprised 75% of study group. Coronary artery disease was established in 81.25%, and two patients were known to have chronic liver disease. Most common type of AVF was the left brachio-cephalic (62.5%), followed by radio-cephalic (37.5%). Average dialysis vintage of AVF at the time of procedure was one year. Previously failed AVF was present in two patients. There were 18 vascular stenosis in 16 patients. The most common site of stenosis was the venous cannulation zone (62.5%), followed by anastomotic site stenosis (31.5%) and central vein stenosis (18.75%). Successful PTA was done in 12 patients. There were no complications; hemodialysis was resumed within one week after the procedure. The primary patency rate at three months was 100%, six months was 75% and at one year it was 37.5%. Four patients were lost to follow up. Mean follow up was 9.41 ± 7.79 months. None underwent a repeat PTA.

**Conclusions:** Percutaneous transluminal angioplasty is effective for salvaging arterio-venous fistula in majority of hemodialysis patients.

**A Tale of Two Accesses: The “Less Is More”**

Sherif Metwalli, Anil K. Agarwal, Khaled Boubes. The Ohio State University, Columbus, OH.

**Introduction:** Well-functioning dialysis access is of utmost importance as the lifeline of those with end stage kidney disease (ESKD). We present 2 patients with ‘imperfect’ accesses where a conservative approach avoided potentially problematic interventions.

**Case Description:** Case 1: A 24 year old man started hemodialysis (HD) in 1992 due to IgA nephropathy. He received a kidney transplant in 2000 which failed in 2005 requiring hemodialysis again. His vascular access consisted of multiple bilateral failed arteriovenous (AV) fistulae and AV grafts requiring numerous access interventions including tunneled HD catheter placements, angioplasties, and thrombectomies. He has also developed severe contrast allergy, making any further vascular interventions difficult. Since 2005 he has been dialyzing through a right upper extremity AVF complicated by central venous occlusion causing mild right arm swelling. Last resort vascular access options including a femoral AVG and a HeRo graft were contemplated. However, clinical decision making based on the presence of extensive collateral circulation, we opted for a conservative approach instead utilizing low blood flow rates. He has been doing well on this prescription for the last 3 years with adequate dialysis and swelling resolution. Case 2: A 67 year old woman with ESKD started peritoneal dialysis (PD) 2 years ago. PD was complicated by recurrent malpositioning of PD catheter with the catheter tip repeatedly migrating to the right upper quadrant. Changing the catheter insertion site and suturing it to the bladder wall did not prevent tip migration. Transition to HD was contemplated but she was able to continue with PD albeit with position changes to allow for complete drainage of PD fluid. Despite occasional sluggish drainage of PD fluid, the patient continued on PD for a total of 15 months before receiving a kidney transplant.

**Discussion:** These 2 cases illustrate the importance of dialysis access function as well as the dilemma of both the patient and provider when it becomes dysfunctional. The cases, however, also demonstrate that anatomical perfection is not always necessary to achieve adequate function. In both cases, a conservative approach allowed the patient to optimize dialysis through their existing ‘malfunctioning’ access and avoided further interventions that could result in worse complications, proving the adage ‘Less is More’ still true for dialysis access.

**What Are Nephrologists' Preferences Related to Continuing Medical Education?**

Amy Larkin, Donald Blatherwick. Medscape LLC, New York, NY.

**Background:** Understanding how clinicians prefer to learn and participate in continuing medical education (CME) can help providers of such education design more engaging and effective activities that can potentially further improve nephrologists’ clinical performance.

**Methods:** Medscape conducted a 10 question, online, incentivized survey in November 2018. Respondents’ confidentiality was maintained and responses were de-identified and aggregated prior to analysis.

**Results:** Most preferred duration for a CME activity: 30 minutes (51%) Followed by 15 minutes (31%) Most preferred format for a CME activity: online (70%) Followed by live events at a medical conference (13%) Most preferred format for an online CME activity: video and text (45%) For online CME: Most preferred instructional design format: case-based (56%) Most important factors in selecting online CME/CE activities: content description (60%) and learning objectives (56%) The most important factors in selecting which symposia to attend at a scientific congress were content coverage (60%), learning objectives (41%), and faculty (33%). Most common ways of becoming aware of available professional education activities: invitation from online providers (79%) and societies (74%) The majority of participants reported that in the past 12 months they have learned something from CME that changed their practice (86%) Most learning is more impactful and clinically meaningful than a single activity (80%)

**Conclusions:** CME activities have an impact on changing clinician practices. Learner preferences for nephrologists related to live and online CME were identified. Most prefer participation in multiple activities that are online, 15-30 minutes, case-based, video and text description, learning objectives, and faculty play an important role in learner participation. These data should inform development of future CME activities that are engaging and impactful.

**PUB109**

**Catheter Malposition: Unacceptable Reason for Access Dysfunction**

Yuliya Sharakova, Mohamed Hassanein, Evamaria Anvari, Tushar J. Vachharajani. Cleveland Clinic, Cleveland, OH.

**Introduction:** In 2017, 80% incident and 20% prevalent patients in the US received hemodialysis (HD) with a catheter (CVC). CVC placement with ultrasonography and fluoroscopy guidance (FG) is an accepted standard of care to avoid early mechanical complications. Early dysfunctional CVC (dCVC), defined as malfunction in <1 week of insertion is often due to a malpositioned tip leading to inadequate HD and a higher risk of bacteremia. We present a series of early dCVC, a preventable complication.

**Case Description:** Case 1: 42 y/o male had left IJ non-tunnelled CVC placed for discontinuous dialysis therapy. Encountered multiple episodes of circuit clotting soon after initiation of therapy despite heparinization. The CVC tip was found to be abutting against the innominate vein wall preventing adequate blood flows. An attempt to place a tunneled right subclavian vein catheter at bedside, without fluoroscopy was unsuccessful. Chest XR showed the CVC tip in the left IJ. Case 2: 30 y/o male with a pre-existing right portacath presented with several episodes of non-sustained ventricular tachycardia, 2 days after a newly placed left dialysis CVC. Chest XR showed portacath had disconnected and migrated to the right ventricle. Removal of the dislodged portacath led to resolution of arrhythmia. Dialysis CVC was preserved. Case 3: 49 y/o obese female had poor blood flows (300 ml/min) in catheter and frequent alarms that failed to improve despite tPA and port reversal. dCVC resulted from tip retraction from right atrium into SVC requiring replacing with a longer CVC. Case 4: 65 y/o female with left IJ tunnelled CVC, placed under FG, had poor blood return 2 days after placement. The CVC tip had migrated to the right innominate vein. Catheter was replaced successfully. Case 5: 70 y/o male encountered clotting of the continuous dialysis circuit soon after initiation with a left IJ CVC, requiring replacement of circuit to continue with therapy. Evaluation showed a short CVC with tip abutting against superior vena cava (SVC) wall and required replacing with a longer CVC

**Discussion:** Recognizing and troubleshooting early dCVC is an essential learning milestone for a nephrology trainee. Evaluation of a dCVC includes chest XR, forceful saline flush and appropriate use of tPA. Most of these mechanical complications are preventable with proper training and utilizing imaging tools during the procedure.

**Percutaneous Transluminal Angioplasty in Arteriovenous Fistula**

Ahmed Khan, Mohamed J. achharajani.

**Results:** Among 290 patients receiving hemodialysis in the hospital radiology archive system. Demographic characteristics, duration of dialysis, symptoms and laboratory values were compared between patients with and without impaired catheter function. A total of 30 patients were included in the study. The average age of the study population was 60.7 years (range 25-85). Male patients represented 56.7% of the study population. The average duration of dialysis was 6.79 months. None underwent a repeat PTA.

**Conclusions:** Percutaneous transluminal angioplasty is effective for salvaging arterio-venous fistula in majority of hemodialysis patients.

Online Education Effectively Improves Nephrologists' Knowledge, Competence, and Confidence Related to Hyperkalemia Management

Background: To improve outcomes for patients, clinicians must be able to implement evolving standards of care and apply relevant data on hyperkalemia management. We sought to determine if an online continuing medical education (CME) curriculum could improve hyperkalemia management.

Methods: The online CME curriculum consisted of 4 activities. Of these, 3 were 30-minute video panel discussions. A repeated pairs pre-/post-assessment study design was used and McNemar's test assessed educational effect for each activity. The last activity comprised two patients presenting in a VPS platform that allows learners to order lab tests, make diagnoses, and prescribe treatments in a manner matching the scope and depth of actual practice. Tailored clinical guidance (CG), based on current evidence and expert recommendation, was provided following each decision, followed by the opportunity for the learner to modify to their decisions. Decisions were collected post-CG and compared with each user’s baseline (pre-CG) decisions using a 2-tailed paired t-test to determine P values. The activities launched in 2019 and data were collected for 4-12 weeks.

Results: Education significantly improved physicians’ knowledge, competence, and performance managing and treating hyperkalemia. A 40% relative increase was observed among nephrologists related to knowledge of clinical trial data related to hyperkalemia. Nephrologists also significantly improved their knowledge and competence regarding the use of therapies in practice, with a relative increase of 16% observed. Case based simulation had a strong and significant positive impact on physicians’ performance in the treatment of hyperkalemia. The % of physicians who decided to start preferred potassium-binder more than tripled after education.

Conclusions: Some gaps still remain after education. Over 40% physicians are still not equipped with the right information regarding clinical trial data and the use of therapies in practice. In addition, an average of 40% physicians are still not making the right decision to start preferred potassium-binder. As such, further education needed in these areas.

Renal Clinic Quality Improvement Education Initiative

Rui Song,1 Iryna Danyluk,1 Colleen Rabitt,1 Diane Y. Woodford,1 Wayne A. Satz,2 Mark G. Weiner,3 Suma Prakash,1 1Lewis Katz School of Medicine at Temple University, Philadelphia, PA; 2Weill Cornell Medicine, New York, NY.

Background: Benefits of timely CKD modality education include increased knowledge and home dialysis. At our centre, attendance of scheduled CKD 4/5 patients to education sessions was low. This quality improvement study was initiated and aims to increase the prevalent percentage of CKD 4/5 patients who received CKD modality education from 40% to 55% over one year.

Methods: Outcome measure was prevalent weekly percentage of CKD 4/5 patients who completed education. Process measures were 1) weekly percentage of scheduled patients in attendance and 2) weekly number of incident CKD 4/5 patient education referrals by nephrologists. Ishikawa diagram was utilized to determine system gaps and develop changes to test in plan-do-study-act (PDSA) cycles. Changes tested were: a) NPs tracking weekly class attendance, b) NP reminder calls, c) information letter mailed to patients, d) referral data presented to nephrologists, e) reminder emails to nephrologists on education eligible patients. Discussion with primary care colleagues and 5-whys tool resulted in developing an information webpage for patient education including NPs’ zoom recorded sessions. Median outcome and processes were calculated and plotted on run charts.

Results: Prevalent percentage of CKD 4/5 patients educated decreased from 40.6% to 29.4%. All referred patients have not yet been educated due to COVID19 and number of new patients increased over time. Median weekly session attendance increased from 60-67% with PDS A cycles a–e (Figure 1). Monthly incident education referral numbers increased from 5-18/month.

Conclusions: Weekly session attendance and incident education referrals increased. Prevalent percent patients educated decreased but number of incident referrals increased. To provide a virtual information option for patients with barriers to attending sessions and for use during COVID19 pandemic, the webpage described is a helpful resource developed as a result this project. We anticipate this tool will increase the outcome and both process measures over time.

Optimizing On-the-Go Learning Utilizing Short Modules on Topics Related to Nephrology

Kirin Munir, Farah Daccueil, Stony Brook University Hospital, Stony Brook, NY.

Background: Residents and medical students are expected to formulate evidence-based treatment plans by keeping up with the most recent guidelines but that can be difficult given our schedules. In such circumstances, it is ideal to learn bite-sized pieces on the go.

Methods: We created two modules about Phosphorus Binders and Oral Hypoglycemic Agents using a friendly graphic interface called Prezi. These modules were estimated to take 10-15 minutes and were accompanied by a total of seven content related questions that were compiled from Uworld Step 3 Question Bank, John Hopkins Primary Modules, and hospital courses of patients seen at Stony Brook. Survey monkey was utilized to create the pre and posttest. The modules were sent to third and fourth year medical students. Data was collected for 10 days.

Results: Wilcoxon signed rank test was utilized to evaluate the effectiveness of the modules. Unfortunately, only six students completed the hypoglycemic module of which two had no improvement in scores, so no statistical significance was achieved. However, four of the six students had improvement in posttest scores by at least one point. Improvement in the posttest scores for the phosphorus module was significant as of the nine students who completed the phosphorus module, eight had an improvement by at least 1 point (W 36, p=0.008).

Conclusions: The observation of improved posttest scores for the phosphorus module supports the use of short lessons using a friendly graphic interface such as Prezi.
Ethylene Glycol Poisoning with Near-Normal Osmotic Gap: A Diagnostic Challenge
Moeed Ahmed, Cliff Janikowski, Aiza Ahmad, Lee E. Morrow. Creighton University School of Medicine, Omaha, NE.

Introduction: Ethylene glycol poisoning is classically associated with a high anion gap metabolic acidosis (HAGMA). Neurological and gastrointestinal symptoms predominate early while renal failure and death occur if not diagnosed and treated promptly. The diagnosis is usually suggested by HAGMA and an elevated serum osmolal gap in the setting of a suspected ingestion. Rarely, the serum osmolal gap may be close to normal which can delay the diagnosis or lead to a misdiagnosis. We report a case of ethylene glycol ingestion with near-normal serum osmolal gap.

Case Description: An 85-year-old man with a past medical history of Dementia presented to the Emergency Department with altered mental status, restlessness and serum osmolal gaps. Additional history obtained later from his family increased the suspicion for toxic alcohol ingestion. Ethylene glycol level, a send out lab, eventually resulted at an elevated level.

Discussion: The workup for a HAGMA should include evaluation of the serum osmolal gap in the setting of a suspected toxic alcohol ingestion. Although uncommon, the absence of an elevated serum osmolal gap should not prohibit treatment for toxic alcohol ingestion when the clinical suspicion is sufficiently high.

Hypernatremia Three Ways
Jordan R. Evans, Shweta Bansal. US Army Brooke Army Medical Center, Fort Sam Houston, TX; University of Texas Health Science Center at San Antonio, San Antonio, TX.

Introduction: Hypernatremia is a disorder commonly seen in hospitalized patients. It is often caused by dehydration from low water intake, GI, or urine losses. We present a case in which there were 3 distinct etiologies of hypernatremia that developed during the same admission.

Case Description: A 55 year old male with Down Syndrome and epilepsy was admitted from his nursing home for altered mental status and a 2 day history of lethargy and low oral intake. On admission, he had hypotension, tachycardia, and altered cognition from baseline but otherwise had unremarkable exam. He was diagnosed with klebsiella UTI, acute kidney injury, and hyponatremia. He was started on ceftriaxone and given 1 L of normal saline for hypovolemic hypotension, later switched to a continuous DSW infusion. Pertinent blood and urine chemistry after a liter of saline is shown in table 1. Over the next 4 days, sodium corrected slowly to 144 mEq/L, creatinine returned to baseline, and the D3W infusion was replaced with tube feeds. On day 6, he was again found to be hypernatremic but with polyuria. Urine chemistry (table 1) suggested osmotic diuresis which was attributed to high protein tube feeds. The polyuria and hypernatremia resolved with a change in feeds and D5W infusion. Meanwhile, he found to be in status epilepticus and intubated for prolonged hypoxia. Despite maximal anti-epileptic treatment, he continued to have frequent seizures. On day 9, he again had polyuria and hypernatremia but this time with lower urine osmolality (table 1). A central DI process was considered due to hypothalamic injury from status epilepticus, which has been reported seldomly. The urine osmolality increased to 413 mOsm/kg. A central DI process was considered due to hypothalamic injury from status epilepticus, which has been reported seldomly. The urine osmolality increased to 413 mOsm/kg.

Underline represents presenting author.
underline represents presenting author.

**Case Description:** A 25-year-old female with Cronh’s disease presented with one month of worsening abdominal pain, diarrhea, and anorexia with reported 20 kg weight loss. She developed septic shock secondary to sigmoid colon perforation and underwent sub-total colectomy and end-ileostomy. Her hospital course was complicated by stage 2 acute kidney injury (AKI) secondary to acute tubular necrosis with a peak creatinine of 0.8 mg/dL from baseline of 0.3 mg/dL. Her AKI gradually resolved with supportive treatment. Over a 10-day period, she received a total of 20 g of acetylsalicylic acid with a total daily dose of 2 g. It was also noted that she had a persistent non-renal high-anion gap metabolic acidosis developed with serum bicarbonate levels as low as 11 mmol/L and a corrected anion gap of 26 mmol/L. Further laboratory data showed normal serum osmolality, blood urea nitrogen, beta-hydroxybutyrate, L-lactate, D-lactate, acetoaceton, and salicylate levels. A urine analysis showed a urine 5oxoproline level was markedly elevated at 26,740 mmol/mol creatinine. The patient’s severe metabolic acidosis resolved with discontinuation of acetylsalicylic acid and oral bicarbonate supplementation.

**Discussion:** Pyroglutamic acidosis is an often underrecognized condition requiring a high index of clinical suspicion for diagnosis. Urine or serum 5oxoproline levels are needed for diagnosis, which may not always be readily available. Chronic acetylsalicylic acid depletes intracellular glutathione resulting in increased levels of 5-oxoproline. Patients, like the one reported here, with malnutrition, female gender, sepsis, and kidney dysfunction are especially vulnerable as they have lower intracellular glutathione and therefore faster 5-oxoproline accumulation despite standard dosing of acetylsalicylic acid. Prompt recognition is essential for treatment with acetylsalicylic acid cessation and bicarbonate supplementation. The use of acetylsalicylic acid as an analgesic alternative to opioids is growing, especially in post-operative and critical care settings. Clinical awareness of predisposing conditions and close monitoring of patient’s acid-base and kidney status can help us mitigate this underrecognized complication of acetylsalicylic acid use.

**PUB123**

**Treatment Pattern of Hyperkalemia Among Patients Presenting Emergency Department in China**

Jianming Bian, Li Zuo, Houyu Zhao, Xu Han. Department of Pharmacology, Chinese People’s Liberation Army General Hospital, Beijing, China.

**Background:** In China, the treatment pattern of hyperkalemia (HK) among patients presenting emergency department (ED) is not well described.

**Methods:** Data containing hospital information system (HIS) records of 157 hospitals covering 30 provinces in China were extracted from Beijing Data Center for Rational Use of Drugs. Patients (aged ≥18 years old) in ED with record(s) of HK, defined as serum potassium (S-K) ≥5.5 mmol/L, were included in this study. The diagnosis rate was defined as the proportion of HK episodes that have diagnoses records. Treatment rate was defined as the proportion of HK episodes that have records of any HK treatment including diuretics, glucose injection + insulin (G+I), calcium injection, sodium bicarbonate, potassium binder or dialysis. Retesting rate was defined as the proportion of HK records that have potassium retest records within 1 day.

**Results:** A total of 36,015 HK cases were included. The overall HK diagnosis rate was 9.2%. Diagnosis rates increased by the severity of HK, patients with S-K >7.0 mmol/L showed the highest diagnosis rate of 31%. The overall treatment rate within 2 days was 45.2%, treatment rates increased by the severity of HK. Analyzing the HK episodes with HK treatment, G+I (used in 72.4% of HK episodes), loop diuretics injection (used in 50.36% of HK episodes) were most commonly used, while oral potassium binders, including sodium polystyrene sulfonate and calcium polystyrene sodium, were used in only 0.2% of HK episodes. Combined treatments were observed, among which a combination of G+I and loop diuretics injection was used in 10.4% of episodes and a combination of G+I, diuretics injection, calcium injection and sodium bicarbonate was used in 7.4% of episodes. Subgroup analysis of HK treatment in patients with chronic kidney disease showed that, G+I (used in 71.7% of episodes), loop diuretics injection (used in 61.2% of episodes) were most commonly used. The overall retesting retest rate within 1 day was 19.36%. Patients with S-K 5.0-5.5 mmol/L were retested less frequently (15%) than those with S-K >5.5 mmol/L (22.3-30.6%).

**Conclusions:** In China, the diagnosis and retreating rates of HK in ED patients was relatively low. Glucose injection + insulin was commonly used to treat HK in ED, while oral potassium binders were rarely used. Combination of treatments was common.

**PUB124**

**Factors Associated with Volume Overload in Pulmonary Arterial Hypertension**

Shweta Bansal, Ahmad Altarawneh, Chakradravti Vagapudi. The University of Texas Health Science Center at San Antonio Long School of Medicine, San Antonio, TX.

**Background:** Knowledge about the pathophysiology of volume overload in pulmonary arterial hypertension (PAH), a frequent and early complication, and major contributor to the development of right heart failure, is scant. We aimed to identify factors associated with volume overload in PAH patients.

**Methods:** We reviewed medical charts of consecutive 32 patients with PAH. Patients on loop diuretic were considered volume overloaded. Repeated measures of clinical and lab variables were recorded at the time of each right heart catheterization (RHC) were included for analysis. For comparisons between diuretic and non-diuretic groups, we used independent t-test for normally distributed and Mann-Whitney U test for nonparametric variables.

**Results:** Mean age at last follow up was 51.2 ± 11.6 years, 100% were white, 94% were female, and mean estimated glomerular filtration rate (GFR) was 91 ± 30 mL/min. Median follow-up was four years. Four patients were on loop diuretic. In PAH patients on diuretic were significantly more edematous (1.24 ± 0.7 vs. 0.63 ± 0.7 mg/kg, p<0.005), had higher BMI (30.5 ± 6.3 vs. 25.1 ± 4.9 kg/m², p=0.002) and covered less distance on 6 minute-walk test (360 [300;413] vs. 420 [385;464] meters, p=0.012) than patients not on diuretic. No difference was noted in age, gender, BP, NYHA class, or oxygen saturation. RHC were performed 2 times more often in diuretic vs. non-diuretic group (68% vs. 28.6%, p=0.03). On RHC, right atrial pressure (RAP) was significantly higher (7.9 ± 4.2 vs. 3.8 ± 3.2 mmHg, p=0.006) and there was trend towards higher mean pulmonary artery pressure (49 ± 13.3 vs. 41.2 ± 12.1 mmHg, p=0.08) in diuretic group with no difference in cardiac index or pulmonary vascular resistance. Serum alkaline phosphatase was higher (106.8 ± 34.3 vs. 76.2 ± 35.3 U/L, p=0.02) in diuretic group with no difference in other blood work including BNP and estimated FGR. There was no difference in proportion of patients on PAH-specific therapies. On follow-up, four patients in diuretic vs. non-diuretic group were lost follow-up.

**Conclusions:** High BMI and RAP, well-known factors associated with volume overload in other edematous disorders were applicable in our PAH cohort as well suggestive of presence of similar pathways of impaired natriuresis despite normal GFR. Further studies are required to confirm these pathways which can guide appropriate early-on therapeutics.

**A Negative Anion Gap with a Positive Outcome**

Samantha E. Blank, Casey N. Gashti, William L. Whittier. Rush University Medical Center, Chicago, IL.

**Introduction:** The utility of an increased serum anion gap (AG) in clinical practice has long been established. A decreased or negative AG, however, often remains undiscovered or neglected. Overproduction of paraproteins, such as IgG (cationic) and
Laxative Use in Acute Hyperkalemia

A 62-year-old male patient with Mantle Cell Lymphoma presented to the emergency room with a one-day history of hemoptysis, emesis, and fatigue. Laboratory workup revealed severe anemia of 6 g/dL, marked leukocytosis of 265.27 thousand/µL, increased uric acid 15.1 mg/dL, and elevated lactate dehydrogenase of 1,261 U/L. These findings were consistent with active disease, and upon admission, the patient was initiated with aggressive hydration, alkalization, and rasburicase. Case Description: A 62-year-old male patient with Mantle Cell Lymphoma presented to the emergency room with a one-day history of hemoptysis, emesis, and fatigue. Laboratory workup revealed severe anemia of 6 g/dL, marked leukocytosis of 265.27 thousand/µL, increased uric acid 15.1 mg/dL, and elevated lactate dehydrogenase of 1,261 U/L. These findings were consistent with active disease, and upon admission, the patient was initiated with aggressive hydration, alkalization, and rasburicase.
was started on IV hydration, dexamethasone, rasburicase, and allopurinol. On the fifth hospital day, hypokalemia was noted, and white blood cell count decreased by approximately 50 thousand/μL. Two days after, laboratory values were remarkable for hyperkalemia of 6.1 mmol/L, blood urea nitrogen of 66.2 mg/dL, creatinine of 2.61 mg/dL, hyperphosphatemia of 8.5 mg/dL, and a corrected calcium of 7.1 mg/dL. These findings were suggestive of TLS following chemotherapy, along with the development of a non-oliguric stage three acute kidney injury. The next day, the patient had adequate urine output, stable blood pressures, no signs of volume overload or uremia, but laboratory values revealed worsening renal parameters and an increased calcium-phosphate product above 70 mg2/dL2. Consequently, hemodialysis was performed with good tolerance and response to treatment.

Discussion: The criteria for hemodialysis in this case of a non-oliguric euvolemic patient with acute renal failure secondary to TLS was founded on an elevated calcium-phosphate product, as opposed to more common indications such as anuria, fluid overload, or persistent electrolyte disturbances. The prognosis for complete recovery of renal function is excellent if dialysis is initiated early to rapidly reduce serum uric acid and phosphate concentration. This emphasizes the importance of a prompt assessment of the calcium-phosphate product as an indication for renal replacement therapy in the setting of tumor lysis syndrome.

Hypomagnesemia and Protein Pump Inhibitors

Poosia Kalantari,1 Jason M. Kurlan,2 Sonja Vincent, Hospital Worcester, MA;1UMass Memorial Medical Center University Campus, Worcester, MA;2’UMass Memorial Marlborough Hospital, Marlborough, MA.

Introduction: Proton pump inhibitors (PPIs) are commonly used for GERD. They are associated with acute intermittent nephritis, B12 deficiency, Clostridium difficile infection, gastric malignancy, atrophic gastritis, bone fractures, and rarely, hypomagnesemia. We present a case of hypomagnesemia manifesting with unexplained hypocalcemia, refractory hypocalcemia, and hyperphosphatemia. A 66 year old male with GERD and prostate cancer (scheduled for prostatectomy), was found to have abnormal electrolyte values on routine preoperative evaluation. Two months ago, they were all normal. He had copropapsial spasms, facial twitching, frequency and weak urine stream for two months. He denied diarrhea, nausea, vomiting, fever, chills, medication changes or use of supplements. He drank alcohol socially. Trousseau sign was positive. Labs showed potassium 2.8 mmol/L, bicarbonate 1.5 mmol/L, calcium 1.3 mg/dL, albumin 4 mg/ dL, magnesium 0.9 mg/dL, and phosphorus 3.2 mg/dL. 25-OH vitamin D was 9 ng/mL, whereas 1,25(OH)2 vitamin D was ele vated. During hospitalization, Fractional excretion of magnesium (measured after changing his PPI to an H2-receptor antagonist) was 2.5%. It was suspected that PPI use may have driven hypomagnesemia (which accelerated renal K+ losses), associated with PTH resistance and vitamin D deficiency (causing hypocalcemia). Symptoms resolved with electrolyte supplementation.

Discussion: Hypomagnesemia can result from gastrointestinal or renal losses. The presumably mechanism for PPI-induced hypomagnesemia involves impaired absorption of magnesium by intestinal epithelial cells caused by PPI-inhibited inhibition of transient receptor potential melastatin-6 (TRPM6) and melastatin-7 (TRPM7) channels. The aim of treatment is correction of magnesium and vitamin D first, resulting in rapid improvement of potassium and calcium. Our case is unique, as he developed the abnormalities so acutely. He was also restarted back on his PPI, along with magnesium supplements, and repeat electrolytes over the ensuing 4 months have been normal.

PUB132

Analysis by Bioimpedanciometry of Three Cohorts with Expanded Extracellular Volume: Critically Ill, Nephrotic, and Hemodialysis Patients

Waldo Bermelas,1 Patricia Vargas,2 Gonzalo Correa,3 Maria E. Sanhueza,4 Fernando Gonzalez,3 ’Hospital de Coyhaique, Coyhaique, Chile; ’Clinica Alemana de Santiago SA, Vitacura, Chile; ’Hospital Del Salvador, Santiago, Chile; ’Hospital Clinico Universidad de Chile, Santiago, Chile.

Background: By applying, bioimpedanciometry provides information on body composition, estimating total body water (TBW) and extracellular water (ECW) with formulas. However, these estimates are imprecise in edematous patients. Fortunately, there are variables that are directly measured: resistance (R), reactance (Xc) and phase angle (AF), which in theory reflect the cells’ ability to maintain adequate function. In our work, we mainly wanted to analyze this second group of variables in patients with increased ECV and additionally compare them with a group of healthy volunteers.

Methods: Using a multifrequency bioimpedanciometer, we performed measurements on edematous patients in the ICU, edematous patients with nephrotic syndrome (NS), and anuric patients on hemodialysis (HD) before starting a random session. The control group were healthy volunteers (V) of the same age as the studied patients. A two test was performed to compare each group against V and a pearson’s correlation test was performed to assess correlation between variables.

Results: During 6 weeks measurements were made getting data of 14 V, 11 HD, 13 SN and 11 ICU. When comparing against V, significant differences were obtained in R, Xc and AF (p<0.05) in all groups except HD group. When comparing among them the most edematous groups (ICU and NS), surprisingly no differences were obtained (p>0.05). In the estimated variables related to water distribution (ECW, TBW and ECW/TBW), the 3 groups show significant differences compared to V, except in TBW. Finally, when using a correlation to compare measured against estimated variables, we found that Xc has a high negative correlation (r: -0.75) with ECW; AF has a high negative correlation (r: -0.83) with ECW/TBW, while R has a moderate negative correlation (r: -0.67) with ECW and TBW.

Conclusion: Our results show, the studied groups have differences in measured and estimated variables compared to V, theoretically reflecting a state of cellular malfunction in addition to the expansion of the ECV. Surprisingly, patients with NS and ICU are “electrically” the same, despite their very different clinical contexts. However, we cannot rule out that it is only due to expansion of the ECV of a similar amount since the measured variables depend to some degree on the estimated variables.

PUB133

Intractable Hyponatremia, Polydipsia, and the Reset Osmostat: A Case Report

Mohamed T. Hassan Kamel, Ashish Upadhyay, Steven C. Borkan. Boston Medical Center, Boston, MA.

Introduction: Water intake in excess of water excretion results in hyponatremia, the most common electrolyte abnormality in clinical practice. Typically, ADH secretion fluctuates to maintain a physiologic serum osmolality, the so called “ADH osmostat”. This threshold can be altered by multiple physiologic and pathologic stimuli. In this report, we present a case of symptomatic hyponatremia associated with polydipsia in an elderly patient with psychiatric comorbidities and chronic hyponatremia. We describe the accompanying laboratory findings that support the diagnosis of reset osmostat. We postulate that chronic hyponatremia secondary to polydipsia related to psychiatric illness could have reset this patient’s osmostat and discuss potential therapeutic strategies.

Case Description: A 71-year-old man with severe depression, type 2 diabetes mellitus and chronic obstructive pulmonary disease presented to the hospital with diffuse weakness, difficulty with focused attention and suicidal ideations. He admitted to drinking more than 15 liters of liquid daily. Home medications included metformin, insulin, lisinopril, amiodipine, metoclopromide, pantoprazole, and trazodone. Physical exam revealed hyperpneic and trunclal obesity, but was otherwise unremarkable. Laboratory investigation revealed a plasma sodium concentration of 120 mEq/L, blood urea nitrogen of 9 mg/dL, creatinine of 0.82 mg/dL, serum osmolality of 263 mOsm/kg and urine osmolality of 155 mOsm/kg with a urine sodium of 38 mEq/L. Because of neurological symptoms and worsening hyponatremia, the patient received 3% hypertonic saline infusion. Serum sodium was noted to fluctuate during periods of unsupervised access to fluid, hypertonic saline infusion and fluid restriction. Urine osmolality was also noted to fluctuate, dropping appropriately with worsening hyponatremia and rising with fluid restriction, hypertonic saline and resultant rise in serum sodium. The rise in urine osmolality occurred without normalization of serum sodium.

Discussion: In this report, we present a case of symptomatic hyponatremia associated with polydipsia in an elderly patient with psychiatric comorbidities and chronic hyponatremia. We describe the accompanying laboratory findings that support the diagnosis of reset osmostat. We postulate that chronic hyponatremia secondary to polydipsia related to psychiatric illness could have reset this patient’s osmostat and discuss potential therapeutic strategies.

Discussion: Hypercalcaemia is a known side effect of patiromer use since it exchanges calcium ion with potassium. To our knowledge, however, hypocalcemia has not been attributed to patiromer use. In this unique case, hypocalcemia was an indirect side effect caused by severe hypomagnesemia that was probably exacerbated by the use of patiromer. Hypomagnesemia can cause hypocalcemia through suppression of PTH secretion, which was seen in this case, along with increasing PTH resistance. Novel potassium binders have a myriad of useful indications; however, one should be vigilant to their effects on other electrolytes.

PUB136
Hypokalemic Periodic Paralysis
Margaret Mallari, Tamim H. Naber, Omar M. Shahaateet. AtlantiCare Regional Medical Center, Atlantic City, NJ.

Introduction: Hypokalemic periodic paralysis (HOKPP) is characterized by transient episodes of muscle weakness and inability of muscle movement associated with hypokalemia. The paralysis typically affects the arms and legs, though the diaphragm and the tongue may also be affected.

Case Description: A 50-year-old female with tobacco use and significant alcohol consumption presented with progressive upper and lower limb weakness, numbness, and paresthesias that worsened over the past 2-3 months. She also reported fever, sweats, and unintentional 40-lb weight loss over the past 3 months. The patient denied use of diuretics and laxatives. Labs revealed serum potassium 1.9 mmol/L (3.5 - 5.2), phosphorus 2.2 mg/dL (2.5 - 4.5), bicarb 43 mmol/L (21-30), and a venous blood gas of 7.61/50/25/50, which is consistent with metabolic alkalosis. EKG demonstrated U waves and ST depressions significant for severe hypokalemia. She was admitted for severe hypokalemia and was given oral and IV potassium. Vitamin D was 16.0 ng/mL (30-100), which is suggestive of hypovitaminosis D. TSH and cortisol were normal, thus ruling out thyrotoxicosis and Cushing’s, respectively. Serum aldosterone and renin levels were normal, thus ruling out adrenal insufficiency. The Transtubular K+ Gradient was calculated to be 4, indicating a renal tubular wasting of potassium. In addition to renal potassium wasting, the cellular shift of potassium in the setting of chronic malnutrition and prolonged alcohol use exacerbated the severe hypokalemia. The patient’s potassium was repleted, and she was discharged from the hospital with close outpatient follow up.

Discussion: Hypokalemic periodic paralysis is characterized by transient episodes of muscle weakness in the setting of hypokalemia. HOKPP manifests itself as a sudden onset of weakness ranging from mild transient weakness of the arms and legs to paralysis of the diaphragm and accessory muscles, resulting in lethal respiratory failure. HOKPP can be triggered by a stressor, such as a viral illness or by specific medications, such as insulin or beta-agonists. HOKPP is important to rule out when evaluating a patient with abrupt onset of paralysis or weakness, especially in patients with no history or risk factors of other pertinent disease, such as stroke. The failure to diagnose and properly treat HOKPP can be fatal. It is vital to address the underlying cause of hypokalemia to prevent the recurrence of HOKPP.

PUB137
Screening Fabry Disease in CKD Patients in a Single Center of Middle Taiwan
Chen-Hsu Chen,1-2 Tung-Min Yu,1 Ya-Wen Chuang,1 Division of Nephrology, Taichung Veterans General Hospital, Taichung, Taiwan; 2Department of Science, Tunghai University, Taichung, Taiwan.

Background: Fabry’s disease (FD) is an X-linked inherited rare, progressive, lysosomal storage disorder affecting multiple organs due to the deficient activity of alpha-galactosidase (a-Gal A) enzyme. The prevalence has been reported to be 0.15–1% in hemodialysis patients; however, the information on the prevalence in chronic kidney disease (CKD) is lacking in Taiwan. This study aimed to determine the prevalence of FD in our CKD patients.

Methods: We screen male patients older than 18 years in our dialysis, renal transplantation (RTx) and Pre-End Stage Renal Disease (pre-ESRD) program patients. A total of 611 male CKD patients were screened using an assay of a-Gal A activity by dried blood spots (DBS). A Fabry confirm test by GLA gene analysis was done for those with low enzyme activity.

Results: There were 2 cases with positive (a-Gal A activity <0.6 μmol/hr) and 6 patients with borderline (0.6–1.5 μmol/hr). Interestingly, the 2 positive cases were brothers diagnosed IgA nephropathy (IgAN) in their childhood and received RTx identified as late-onset FD with GLA mutation in c.659+910C>A; a popular mutation site found in studies of male newborns screening for cardiac variant FD in Taiwan, and their mother was the carrier of GLA mutation. We also found 3 cases with borderline of a-Gal A activity with mutation on nonfunctional region. The prevalence of FD is about 0.33 % (2 in 611) in the high-risk population group with CKD. The clinical symptoms of FD patients are nonspecific except in those with various degrees of renal failure.

Conclusions: FD should be considered in the differential diagnosis of any CKD patients even with knowing their renal disease entities without symptoms and signs suggestive of FD. Clinicians should be aware of FD might be not only renal involvement, but also affected heart and brain.
A Novel Frameshift Mutation of COL4A5 Identified by Whole-Exome Sequencing in a Chinese Family with Alport Syndrome

Jun Zhang, Wenyu Gong, Xiaoxia Xiong, Hui-qun Li. Division of Nephrology, Department of medicine, Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.

Background: Alport syndrome is an inherited kidney disease caused by the defects in type IV collagen, approximately 80% of which is caused by X-linked mutations in the COL4A5 gene. This study explores a novel frameshift mutation of COL4A5 responsible for renal disorder in a 3-generation Han Chinese pedigree.

Methods: We enrolled the proband and his family members from a village in Sichuan province, and collected the family history and clinical data. Clinical examinations were performed to evaluate the phenotypes of the family. Blood samples from the proband and the other eight family members were collected for genetic screen. Whole exome sequencing (WES) was applied in the proband to find out the potential genetic variants, and then the variant within the family was verified by Sanger sequencing.

Results: The 31-year-old male proband and his elder brother had ESRD, binaural sensorineural hearing loss and ocular lesions. Further, his three male cousins received hemodialysis and all died from ESRD between 18 and 25 years old. The 90-year-old maternal grandmother, one maternal aunt and one female cousin had only microscopic hematuria without gross hematuria, proteinuria, impaired kidney function or extrarenal symptoms. Genetic analysis identified a novel deletion mutation (c.422_428del) in exon 7 of COL4A5 gene which located on the X chromosome in the proband. The c.422_428del variant was also detected in the proband’s grandmother and four other affected family members. The proband’s farther and three unaffected family members had not found this variant. This mutation was results in frameshift followed by formation of a truncated (p.Leu142Valfs*11) COL4A5 protein product with only 152 amino acids including an aberrant 10 residues. This mutation was not present neither in the Exome Variant Server of the NHLBI-ESP database, ExAC database or in the 1000 Genomes database. According to the variant interpretation guidelines of American College of Medical Genetics and Genomics (ACMG), this novel variant was classified as “likely pathogenic” variant for Alport syndrome in this pedigree.

Conclusions: Our study identified a novel COL4A5 frameshift mutation in a Chinese family with Alport syndrome, expanding the mutational spectra of COL4A5 gene, which were significant for screening and genetic diagnosis for Alport syndrome.

Elevated Ambulatory Blood Pressure Is Associated with a Progressive Form of Fabry Disease

Federica Rossi,1 Einar Svarstad,2 Hassan O. Elfahmi,1 Agnese Binaggia,3 Letizia Roggero,1 Sara Auriacho,1 Hans-Peter Marti,1,2 Federico Pieruzzi.1

1Department of Medicine and Surgery, University of Milano-Bicocca, Monza, Italy; 2Department of Clinical Medicine, University of Bergen, Bergen, Norway; 3Department of Medicine, Haukeland University Hospital, Bergen, Norway; 4Nephrology and Dialysis Unit, ASST-Monza, San Gerardo Hospital, Monza, Italy.

Background: Published data on hypertension incidence and management in Fabry Disease (FD) are scanty and it remains to be shown how much high blood pressure (BP) contributes to organ damage in these patients. Therefore, we have assessed BP values and their correlations with clinical findings in a cohort of FD patients.

Methods: Between January 2015 and May 2019, all adult FD patients (n=32) referred to our institute were enrolled; they were Caucasians (n=24 female, n=8 males) with an average age of 50±12.2 years. Data regarding hypertension were obtained by ambulatory BP monitoring (ABPM), home self-monitoring and office measurements. Patients were defined as hypertensive according to 2018 ESC/ESH Guidelines. The severity and the stability of FD were assessed with the Fabry Stabilization Index (FASTEX). Organ involvement and hypertension risk factors were also evaluated.

Results: The ABPM revealed elevated BP in 18.75% (n=6) of the FD population and 50% (n=16) of this group was diagnosed with masked hypertension. All these patients were females with an average age of 58±9.9 years. They presented a lower (p<0.046) glomerular filtration rate compared with the normotensive patients (77±17.7 and 89.3±21.4 ml/min/1.73m², respectively) and a more advanced cardiac hypertrophy with a higher LVPWD (p=0.044) and LVMi (p=0.033). Four of them (66.7%) were classified as progressive by the FASTEX score while the majority of the normotensives (84.6%) were stable (Figure 1). No correlation (p=0.428) was found between the category of GLA mutation and the development of hypertension.

Conclusions: Newly detected hypertension is found in a restricted portion of stable FD patients, while it becomes more prevalent in clinically progressive cases. The use of ABPM is of paramount importance to reveal masked hypertension which can contribute to the progressive worsening of the organ failure. We recommend a standardised ambulatory long-term BP monitoring program and timely antihypertensive intervention to improve the outcome of FD patients.

Underline represents presenting author.
Background: Patients with primary hyperoxaluria type 1 (PH1) have an increased risk of acute or chronic kidney failure (AKF/CKF). There are two risk groups: infantile oxalosis patients with an unremarkable family history and adult patients with only an oligosymptomatic course (minor stone events), who get into end-stage renal disease (ESRD) due to oxalate-induced chronic inflammatory processes in the kidney. We were interested in the prevalence of acute kidney failure in patients with non-infantile PH1 seen in our Hyperoxaluria Center over the last 10 years.

Methods: We retrospectively analyzed the database of the German Hyperoxaluria Center for patients being seen in our outpatient clinic for AKF. AKF was defined as a sudden onset of kidney failure and the necessity of dialysis installment in patients, but a documented stable kidney function (no worse than stage 2-3 CKD) prior to onset of AKF.

Results: There were 117 PH1 patients in the center, of whom 6 had infantile oxalosis and thus early ESRD, 8 patients are currently on dialysis, and 6 patients have died. Transplantations were performed in 35 patients with PH1 (liver & kidney in 28 patients, liver-only in 4 patients, and kidney-only in 3 patients). Currently, we routinely follow up (3-4 times a year) 49 of 117 PH1 patients. Out of these 49 patients, AKF was diagnosed in 8 patients aged 11-56 years (1 pediatric patient, 3 patients 18-19 years old, and 4 patients 29-56 years old), which led to CKF and subsequently, maintenance hemodialysis in 7 patients and death in 1 patient. Non-compliance regarding medication or recommended fluid intake was the reason for AKF in 6 of the 8 patients. Acute massive diarrhea without adequate fluid substitution led to AKF in the other 2 patients.

Conclusions: AKF is not uncommon in patients with PH1. It is frequently related to either non-compliance or to situations of severe fluid losses with inadequate fluid substitution and not based on already extremely altered renal function. Therefore, interruption of medication or lack of fluid intake, even for short periods of time, can lead to severe clinical consequences in these patients.
Case Description: A 32-year-old female with prior history of gestational hypertension presented to her primary care provider with a three-day history of bilateral lower extremity edema and periorbital swelling. On exam, profound periorbital edema and 2+ pitting edema up to the knees bilaterally was noted. Labs were consistent with a creatinine level of 5.0 mg/dL up from her baseline of 0.5 mg/dL three months prior. Urinalysis and random urine testing confirmed proteinuria of almost 19 grams per day. Renal ultrasound was obtained showing normal sized kidneys with increased echogenicity. Kidney biopsy was obtained and results were consistent with collapsing FSGS. Secondary workup for etiology of FSGS came back positive for Parvovirus B19 infection. Along with diuresis, decision was made to start IVIG and prednisone therapy. Initially, patient had improvement in kidney function post treatment and patient was followed up in clinic. However, required hemodialysis for one month.

Discussion: FSGS is commonly associated with nephrotic syndrome and stems from podocyte abnormalities. Podocyte detachment and death lead to segmental sclerosis, which is the hallmark pathophysiology of FSGS. Kidney biopsy is used to diagnose FSGS and characterized by the presence of sclerosis of at least one glomerulus on histologic examination. Histologically there are five classifications of FSGS with collapsing carrying worst prognosis. Treatment is typically aimed at controlling proteinuria, edema, and cholesterol. In our patient with Parvovirus B19 induced FSGS, we used IVIG with prednisone therapy but no improvement. Further research is needed to find treatments for Parvovirus B19 induced FSGS for better outcome.

PUB145

A Whole Genome-Wide Arrayed CRISPR Screen in Primary Organ Fibroblasts to Identify Regulators of Kidney Fibrosis

Ina Sterlingberg, Evotec International GmbH Evotec SE, Hamburg, Germany.

Background: Robert J. Turner, Stefan Golz, Carina Wollnik, Nils Burkhardt, Ina Sterlingberg, Uwe Andag, Hauke Cornelis Kidney fibrosis presents a hallmark of chronic kidney disease. With ever-increasing patient numbers and limited treatment options available, novel strategies for therapeutic intervention in kidney disease are warranted. Fibrosis commonly results from a wound healing response to repeated or chronic tissue damage, irrespective of the underlying etiology, and can occur in virtually any solid organ or tissue.

Methods: whole-genome-wide arrayed CRISPR screening high content imaging Results: In order to identify targets relevant for kidney fibrosis, we employed CRISPR screening in primary human kidney fibroblasts. Selected hit genes were validated. Conclusions: We demonstrate that CRISPR technology can be applied in primary kidney fibroblasts and can furthermore be used to conduct arrayed CRISPR screening using a high-content imaging readout in a whole genome-wide manner. Hits coming out of this screen were validated using orthogonal approaches and present starting points for validation of novel targets relevant to kidney disease.

PUB146

Dual Positive Anti-Glomerular Basement Membrane Disease and ANCA Disease: A Diagnostic Challenge

Nils K. Saravanan1, Kevin Fu1, Avi Z. Rosenberg3, Renu Regunathan-Shenk1,2. 1Division of Kidney Disease and Hypertension, George Washington School of Medicine and Health Sciences, Washington, DC; 2Department of Pathology, Johns Hopkins School of Medicine, Baltimore, MD.

Introduction: Double-positive disease (DPD), defined as coexistence of anti-glomerular basement membrane (Anti-GBM) disease and an anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis (AAV), is rare disease associated with variable outcomes. These patients often do not have typical presentation of either anti-GBM disease or AAV, making diagnosis a challenge.

Case Description: A 59-year-old male with history of hypertension presented with 1 week of fatigue and decreased urine output. Initial labs revealed a serum creatinine of 11.6 mg/dL and blood urea nitrogen of 133 mg/dL. Urinalysis showed specific gravity of 1.025, pH 5.0, 1+ protein, large blood, and 11-20 RBCs/hpf. Serological workup including anti-nuclear antibody, complement C3 and C4, HIV, hepatitis B and C were all unremarkable. The patient then developed hemoptysis and anuria. He was initiated on hemodialysis. Renal biopsy revealed extensive cellular and fibrocellular crescents, diffuse tubular injury with RBC casts, and 30% interstitial fibrosis and tubular atrophy. Immunofluorescence was negative. Further investigation revealed an elevated Anti-GBM titer, elevated anti-myeloperoxidase antibody and negative anti-proteinase 3 antibody. He was treated with methylprednisolone 1g intravenously for 3 days then daily prednisone 60mg and one dose of cyclophosphamide 1g intravenously. He was then transferred for initiation of plasmapheresis and received 8 sessions with normalization of Anti-GBM and ANCA titers. He also received another dose of cyclophosphamide 1g. He remained dialysis-dependent upon discharge.

Discussion: The varied presentation of DPD may cause a delay in diagnosis. DPD patients have a greater tendency to recover renal function but a higher risk of relapse. Early recognition and aggressive treatment is essential.

PUB147

Transcriptomic Profiling of Collagens in Proteinuric Kidney Disease

Background: Collagen proteins are a major component of the extracellular matrix and play a significant role in kidney health and disease. In proteinuric kidney disease, increased production or altered expression of specific collagens may contribute to renal injury and fibrosis.

Methods: Adult Wistar rats were administered water (sham) or PAN (~100 mg/kg, IP) and urine protein (24-hour) was measured on Days 4, 8, 12 and 21. Animals were sacrificed on Day 21, the left kidneys retrieved, and renal COL1A1 and COL3A1 mRNA levels measured using quantitative polymerase chain reaction.

Results: The rat PAN model was associated with increased proteinuria (*, p<0.01 vs. sham). Compared to the sham cohort, renal COL1A1 and COL3A1 mRNA expression levels were increased, 1.86-fold (p<0.05) and 8.4-fold (p<0.01), respectively, in the PAN cohort. Proteinuria correlated directly (r=0.9) and significantly (p<0.01) with renal COL3A1 mRNA expression level.

Conclusions: Renal COL1A1 and COL3A1 mRNA expression levels are elevated in proteinuric kidney disease. Since COL3A1 mRNA expression is associated with increasing proteinuria, targeting type III collagen might prove beneficial. Funded By: United States Department of Defense - PR180780/ W81XWH1910448

PUB148

C3 Glomerulonephritis: Diagnostic Challenges and Overlap Syndromes

Krishna A. Agarwal, Esilda Sula Karreci, Larissa Kruger gomes, Ruth Schulman, Isaac E. Stillman, Stewart H. Lecker, Theodore I. Steinman, Bradley M. Denker. BIDMC Beth Israel Deaconess Medical Center, Boston, MA.

Introduction: C3 glomerulonephritis (C3GN) is a rare complement-mediated GN, with an incidence of 1-3:1,000,000. Spectrum of presentation can range from asymptomatic hematuria and proteinuria to a full blown acute GN with hypertension, hematuria, and renal insufficiency. Serum C3 levels are typically low. Diagnosis is confirmed by renal biopsy. The underlying mechanism appears to be dysregulated alternate complement pathway, triggered by genetic, environmental or a combination of both factors. Medical management addresses blood pressure, proteinuria, and dyslipidemia. Immunosuppression with glucocorticoids, antimalabobilites, and anti-complement agents is used alone or in combination. Here we present 2 cases of biopsy-proven C3GN mimicking infection-associated GN (IAGN) and TTP/HUS.

Case Description: Case 1: A 49-year-old man presented with 4-5 days of fevers, chills, nausea, vomiting and diarrhea. Labs revealed mild thrombocytopenia, proteinuria, microscopic hematuria and a low C3 level. Blood cultures revealed Streptococcus pyogenes. His hospital course was marked by rapidly progressive pancytopenia and hemodilisais requiring acute renal failure. He received a single dose of ecilizumab empirically due to concern for atypical HUS, but platelet counts improved too rapidly.
to be consistent with eculizumab benefit. Kidney biopsy revealed acute tubular injury with mild interstitial inflammation. EM did not show immune deposits. Sequential renal recovery followed 4 hemodialysis sessions. One month post-dialarge, he had normal renal function and hematocrit cell counts. Case 2: A 74-year-old man with CKD III was admitted with altered mental status, septic shock, and acute kidney injury. Extensive workup did not reveal direct infection or altered autoimmune status. His course was complicated by worsening renal failure, proteinuria, and hematuria. Renal biopsy demonstrated acute tubular injury and glomerular C3 deposition without immune deposits on EM. Eculizumab was deferred due to normal C3 and C4 levels. A steroid pulse was associated with an improvement in creatinine beginning on day 4 and return to baseline kidney function by day 17.

Discussion: Our cases highlight the variable presentation and complexity associated with accurate diagnosis of C3GN, including considerable overlap with IAGN and TTP/HUS.

PUB149
To Treat or Not to Treat? The Dilemma of C3 Glomerulonephritis vs. Infection-Related Glomerulonephritis
Rehan Ansari, Miroslav Sekulic. University Hospitals, Cleveland, OH.

Introduction: With a paradigm shift in the concept of disease-related glomerulonephritis (C3GN) from a post-streptococcal infection of the young in developing countries to a primary-microbial infection of the elderly in the western world, the differential has broadened. This has coincided with an evolving phenomenon of C3 glomerulopathy (C3G-C3 glomerulonephritis (C3GN) & Dense Deposit Disease (DDD)). In all these entities a common feature is C3 dominant staining. Although subtle differences have been described in the nature of these deposits, we present a case in which the clinical course & biopsy findings highlight the challenges of identifying C3GN vs. IRGN.

Case Description: A 62 y/o female with HTN, hypercholesterolemia, epidermal abscess, & recent MSSA bacteremia presents with AKI & anemia. Her creatinine was 2.9 mg/dL vs. 0.53 mg/dL (three weeks ago). Labs: Total Protein/Creaitnine 4.29 mg/mg, negative blood cultures, unremarkable ANA, ANCA, SLEP, UPEP, K/L, Antistreptolysin O (ASO) Antibodies 514 IU/mL (0-200) & C3 77 mg/dL (87-200), C4 47 mg/dL (10-50). Kidney biopsy: C3 dominant glomerulonephritis, >50% crescents, 3+4 staining for C3 in mesangium & capillary loops, EM revealed finely granular mesangial, intramembranous, & subepithelial electron-dense deposits. She was started on steroids & C3 improved to 95 mg/dL after three weeks. Creatinine plateaued ~4 mg/dL prior to discharge. Full complement profile available after one month (C1 Inhibitor 84 mg/mL (21-39), C3 Nephritic titrums/mL (0), C4Bp 136.3 (61-116), Factor H AutoAB 30 unit/mL (<=22), SCSb 313 mg/mL (>=-244).

Discussion: Classically, neutrophilic infiltration, occasional crescents (>50%) & subepithelial humps with co-deposition of C3 & IgG or IgA are described with IRGN, while mesangial & diffuse capillary proliferation exclusively with C3 deposition is expected with C3G. However biopsy alone is not specific for identifying the underlying etiology. ASO titerers are elevated in >50% cases of C3GN and 25% of IRGN cases present with only C3 staining. Based on a strong history of infection, & improvement of C3, we treated as IRGN. Although testing for complement pathway mutations is recommended, results are not readily available. The clinical significance of these mutations remain under scrutiny. Until issues of testing & treatment can be generalized a holistic approach with close follow up is needed in cases of C3 dominant glomerulonephritis.

PUB150
A Young Asian Man with Heavy Chain Deposition Disease
Xuguang Yu, Nan Nan, Jingting Lin, Muhammad T. Shakoored, Jie Tang. Wenzhou Medical College Affiliated Yuying Hospital, Yuying, China, Brown University, Providence, RI.

Introduction: Heavy chain deposition disease (HCDD) is an exceedingly rare condition characterized by nonamyloid tissue deposition of monoclonal immunoglobulin heavy chain. It typically presents in patients above age 50. Here, we report a case of a young Asian adult who presented with acute kidney injury (AKI) and nephrotic syndrome (NS).

Case Description: A 32-year-old Chinese man presented with anasarca. He has no significant past medical history and his family history was also unremarkable. On presentation, he was afebrile with an elevated blood pressure to 205/136. Examination showed peri-orbital and 2+ lower extremity edema. Laxled skin was noted in his neck and abdomen. Laboratory studies showed an initial serum creatinine of 1.5 mg/dL with unknown baseline. It has tripped to 10.4 mg/dL over the next 4 weeks requiring dialysis support. His LFT was normal, serum albumin was 2.0 g/dL, total cholesterol was 224 mg/dL, 24-hour urine total protein was 10.9 g/m with albumin 7.7 g/m. Serologies showed negative ANA, dsDNA, hepatitis and HIV panel, SPEP and UPEP for m-splikes. His complement levels were also normal. Urine sediment revealed 360 RBC with acanthocytes and 10 WBC under high power field. His kidney ultrasound was unremarkable. Kidney biopsy revealed nodular mesangial sclerosis with membranoproliferative features. There were intense immunoglobulin G1 staining in the mesangium, glomerular and tubular basement membranes and vessel walls. Kappa, lambda, IgM and IgA immunohistochemistry were unremarkable. Thus, a diagnosis of γ-type HCDD was made. The patient was started on treatment with bortezomib and dexamethasone. Within 2 months, he came off dialysis, 24hr urine total protein improved to 5.9 mg. Four months after starting bortezomib therapy, serum creatinine improved to 1.4 mg/dL and 24hr urine protein was down to 1.6 g.

Discussion: In summary, this is a unique HCDD case diagnosed in a young Asian gentleman. He did not have detectable monoclonal serum protein. Like other reported cases, he responded well to a bortezomib based regimen.

PUB151
A Challenging Case of Renal-Limited Vasculitis
Moqased, Bashar Ramadan, Eric Magliulo, Dongpo M. Salas, Jocelyn A. Taylor, Khalid Bashir. Creighton University School of Medicine, Omaha, NE.

Introduction: Anti-neutrophil cytoplasmic autoantibody (ANCA)-Associated Vasculitis (AAV) is an autoimmune disease that causes inflammation of blood vessels and has a wide spectrum of clinical presentation. It can present as multisystem or renal-limited disease. The typical renal presentations that of a rapidly progressive glomerulonephritis (RPGN). We present an interesting case of renal-limited vasculitis with atypical features.

Case Description: A 76 year old male with a past medical history of Hypertension (treated with hydralazine) and CKD Stage 3 presented with weakness and shortness of breath for about two weeks. Physical exam and vitals were unremarkable. Laboratory workup revealed AKI with creatinine of 6.5 mg/dL. Urinalysis revealed microscopic hematuria and proteinuria (urine protein/creatinine ratio of 0.9). Renal ultrasound was unremarkable. Serologic workup including ANA, C3, C4, anti-GBM Ab, HbAsg, HbsAb and HbcAb was unremarkable. However, p-ANCA titer was high (1:160). He was treated with IV fluids. Interestingly, he continued to have good urine output as well as improvement in serum creatinine to 4.8 mg/dL and was discharged from the hospital. Follow-up renal function panel in two weeks showed worsening serum creatinine of 6.8 mg/dL. The patient was readmitted to the hospital. Repeat serologic workup revealed p-ANCA, titer of 1:320 and elevated MPO IgG of 78 U/mL. Renal biopsy revealed pauci-immune glomerulonephritis. Steroids and rituximab were initiated as treatment. Due to worsening kidney function, patient was started on hemodialysis. He remained dialysis dependent with no significant renal recovery. Given atypical features of disease presentation, hydralazine was considered to be an etiologic agent hence, and was discontinued.

Discussion: We present a case of renal-limited vasculitis with atypical features making the diagnosis very challenging. Firstly, the patient remained nonoliguric through the first hospital course. Secondly, his serum creatinine improved with supportive treatment leading to his discharge with presumptive diagnosis of ATN. In summary, ANCA associated GN may present with nonoliguria as well as wanning renal function. Atypical features of AAV should raise concern for drug-induced etiology.

PUB152
Collapsing Focal and Segmental Glomerulosclerosis with Thrombotic Microangiopathy Found on Renal Biopsy in a Patient Receiving Intravitreal Afibbercept for Age-Related Macular Degeneration
Ramy M. Hanna, Gautam M. Phadke,1 Kenar D. Jhaveri,1 Ira Kurtz,2 Kamyar Kalantar-Zadeh.1 UC Irvine, University of California Irvine, Orange, CA, 2University of California Los Angeles, Los Angeles, CA. 1Northwell Health, Great Neck, NY, 2University of North Dakota, Columbus, OH.

Introduction: Intravitreal Vascular Endothelial Growth Factor (VEGF) Receptor blockers are used for a variety of retinal pathologies. These include age related macular degeneration (AMD), diabetic macular edema (DME), and central retinal vein obstruction (CRVO). Reports of absorption of intravitreal agents into systemic circulation have increased in number, and confirmation of depletion of VEGF has been confirmed. Increasingly there are studies and case reports showing worsening hypertension, proteinuria, renal dysfunction, and glomerular disease. The pathognomonic findings of systemic VEGF blockade, thrombotic microangiopathies (TMA) are also being increasingly reported. One variant of TMA’s that has been described is collapsing focal and segmental glomerulosclerosis (cFSGS). cFSGS has been postulated to occur due to TMA induced chronic glomerular hypoxia. We present the third reported case of cFSGS in the setting of intravitreal VEGF blockade, a chronic TMA component was crucially found on biopsy.

Case Description: This patient is a 74-year-old non-diabetic male receiving afibbercept for AMD of the two prior cases of cFSGS in setting of VEGF blockade, one had AMD and the other had DME.

Discussion: This case solidifies the finding of cFSGS and its association with chronic TMA as a lesion that may be frequently encountered in patients receiving intravitreal VEGF inhibitors.

A Case of IgA Vasculitis in Liver Cirrhosis

Jayesh B. Patel, Swe Zin Mar Winhtuto, Daniele G. Holanda, Lama A. Noureddine. University of Iowa Hospitals and Clinics, Iowa City, IA.

Introduction: IgA vasculitis (previously termed Henoch-Schönlein purpura) is a systemic immune-complex mediated condition characterized by predominant IgA deposition in microvessels. We present a case of biopsy-proven IgA vasculitis involving skin and kidneys in a patient with known liver cirrhosis.

Case Description: A 71-year-old man with liver cirrhosis due to chronic ETOH use presented to ER with a one-month history of progressive rash and pedal edema. He denied arthralgias, melena, hematemesis, abdominal pain, or fever. Diffuse, erythematous, palpable, non-pruritic petechial lesions were noticed on bilateral thighs, arms, and anterior abdominal wall with few lesions coalescing to purpura. Laboratory evaluation revealed an elevated creatinine at 1.7 mg/dL. Urinalysis showed dysmorphic erythrocytes, leucocytes, and proteinuria. ANA was positive (1:320), C3 slightly low with normal C4, Cryoglobulin, RA factor, SPEP, ANCA, anti-dsDNA, HBsAg, antibodies to HIV, HCV, rickettsia, and syphilis were negative. Peritoneal fluid culture was sterile. Kidney biopsy revealed severe proliferative glomerulonephritis, cellular/fibrocellular crescents and mild interstitial fibrosis. Skin biopsy revealed dense perevacular neutrophilic infiltration with fibrin deposition and erythrocyte extravasation consistent with leukocytoclastic vasculitis. He was diagnosed with IgA vasculitis and treated with pulse IV steroids followed by oral cyclophosphamide tapers along with monthly IV cyclophosphamide infusions.

Discussion: IgA vasculitis, more commonly observed among children than adults, manifests clinically as palpable, blanching purpura, arthritis, intestinal perforation, and kidney injury. Adults commonly develop ESRD in one-third of cases. Similar to crescentic GN, it also manifests clinically as palpable non-blanching purpura, arthritis, intussusception, and pedal edema.

Underline represents presenting author.

Nephrology was consulted due to no improvement in urine output despite benzenamide and thiazide diuretic challenge. Renal ultrasound was unremarkable. Spot urine albumin was negative. She required emergent hemodialysis (HD) as her kidney function failed to recover. A renal biopsy showed chronic tubular and arteriolar changes with noted glomerular endocapillary immune-complex glomerulonephritis, concerning for post-infectious GN. She ultimately required an arteriovenous fistula for long-term HD.

Discussion: PSGN primarily occurs after an upper respiratory infection or impetigo. It is less common in adults, however, is associated with a worse prognosis compared to children, with less than 25% achieving full recovery of renal function. Unlike children, the patient was noted to present with etiologies of lower respiratory infections (LRI) and UTIs. Studies show the time between infection and renal injury may be little to none, as infections in the elderly are often nonspecific and might go unrecognized. Our patient had an AKI after a LRI, resulting in significant oliguria and lack of renal recovery leading further work up with a biopsy. It is therefore imperative that providers consider PSGN as a diagnostic consideration in elderly patients with severe AKI. Treatment is mainly supportive, and patients, like ours, might require HD.

PUB153

Poststreptococcal Glomerulonephritis in an Elderly Patient: A Rare but Often Overlooked Differential in AKI

Enoemen M. Okpoko, Navneet Kaur, Lilibeth Jauregui, Anika Bethel. Florida Atlantic University Charles E Schmidt College of Science, Boca Raton, FL.

Introduction: Poststreptococcal glomerulonephritis (PSGN) is a complication of specific Streptococcal strains. Presentation ranges from asymptomatic microscopic hematuria to acute nephritic syndrome, with oliguria, edema, hypertension, and acute kidney injury (AKI). It mostly occurs in children of developing countries. Its incidence is not well characterized in elderly individuals but is thought to be extremely rare. We report a case of PSGN in an elderly female complicated by hypertensive urgency and heart failure.

Case Description: An 89-year-old female with history of COPD, HFpEF, CKD stage 3a presented with lethargy and weakness. She was treated for bronchitis 3 weeks prior and initially improved but then developed progressive dyspnea and swelling in her lower extremities. On presentation, BP was 252/120, CXX showed cardiomegaly and pulmonary edema. Labs revealed a creatinine of 2.72 (baseline 1.4). She was started on IV diuretics, BIPAP, and nitroglycerin drip with improved BP control. She remained oliguric.

Discussion: The patient is one of the few reported cases of PSGN in an elderly patient. It is less common in adults, however, is associated with a worse prognosis compared to children, with less than 25% achieving full recovery of renal function. Unlike children, the patient was noted to present with etiologies of poststreptococcal GN. She ultimately required an arteriovenous fistula for long-term HD.

Patient Journey, Perceptions, and Burden Associated with Immunoglobulin A Nephropathy (IgAN): A Qualitative Study

Nancy Zaour,1 Miriam Mayänder,2 Susanna Waldz,3 Ancehs T. George,3
1Novartis Pharma AG, Basel, Switzerland; 2IPSOs SA, Basel, Switzerland; 3Novartis India Hyderabad, Hyderabad, India.

Background: There is a lack of published evidence on patient perspectives in IgAN; a rare condition that can progress to end stage renal disease (ESRD). The objective of this study was to understand the patient journey, disease perceptions and burden of disease from the patients’ perspective.

Methods: This qualitative study was conducted after review board approval through a moderated online bulletin board platform and by telephone interviews, to allow comprehensive answering of pre-defined questions. Participants were recruited via physician referral and were screened to ensure eligibility and willingness to participate. Analysis was conducted using a combination of various qualitative analytical tools.

Results: Eight participants with a confirmed diagnosis of IgAN from North America and Europe, aged 29–58 years participated. Diagnosis was often incidental as symptoms were underestimated or unnoticed. Participants were overwhelmed to learn they were diagnosed with a chronic disease and many did not understand the seriousness of the outcomes associated with the same. Post diagnosis, participants were referred to a nutritionist to discuss diet changes and received blood pressure medications. Some participants also received steroids and immunosuppressants. Frequency of monitoring visits varied and created anxiety due to dependence on the same. Speed of disease progression was different among patients. Besides symptoms like fatigue and lack of energy, some participants had to deal with emotional burden of feeling alone and fearful of the future with potential dialysis, transplantation and shortened life expectation. According to the participants, the lack of standard procedures for early screening and diagnosis along with the absence of adequate information in patient friendly language and counselling were some of their needs. Additionally, participants expressed the need for a support mechanism with similar peers to learn to live with the disease and to counteract feelings of being alone.

Conclusions: This study provides insights into how differently IgAN patients perceive and live with their disease. The insights obtained can be used to inform drug development and include what matters most to patients. Finally, this study highlights that a comprehensive education program for patients and caregivers is needed.

Retinal Drusen in Antibody-Mediated and Pauci-Immune Glomerulonephritis

Philip A. Harraka,1 Heather G. Mack,2,3 Deb J. Colville,4 David Bar1, David Langford,3 Timothy J. Pianta,4 Judith A. Savige.1
1The University of Melbourne Department of Medicine, Northern Health, Melbourne, VIC, Australia; 2The University of Melbourne Department of Surgery (Ophthalmology), Melbourne, VIC, Australia; 3Department of Ophthalmology, Melbourne Health, Melbourne, VIC, Australia.

Background: Membranous and anti-glomerular basement membrane (GBM) glomerulonephritides are autoantibody-mediated diseases, where the antigens (PLA2R, TSSR, collagen IV α3 respectively) are also expressed in the retina. Drusen are retinal deposits caused by complement activation and lipid debris in Bruch’s membrane. Drusen have been described in one individual with membranous nephropathy and linear IgG deposits in Bruch’s membrane of another with anti-GBM disease. In contrast, pauci-immune anti-neutrophil cytoplasm antibody (ANCA) vasculitis triggers complement but does not produce glomerular immune deposits. This study examined individuals with antibody-mediated or pauci-immune glomerulonephritis to determine how often drusen occurred in each group.

Methods: This was a cross-sectional observational case-series of individuals with antibody-mediated (n=15, membranous n=9, anti-GBM disease n=6) or pauci-immune (n=16, granulomatosis with polyangiitis n=7, microscopic polyangiitis n=7, eosinophilic granulomatosis with polyangiitis n=2) glomerulonephritis recruited from a general medical service and an Australian tertiary-care hospital. Two-field colour fundus images were obtained with a non-mydriatic camera (CANON, Japan). Images were coded and assessed for drusen count, location and size by two trained graders using the Wisconsin Age-Related Maculopathy Grading Grid. Central drusen counts a10 were considered abnormal.

Results: Four (27%) individuals with antibody-mediated disease (membranous n=2, anti-GBM disease n=2) but only 1 (6%) with a pauci-immune vasculitis had a10 central drusen. Gender, mean age and disease duration were not different between the two groups.

Conclusions: These results suggest that retinal disease occurs together with glomerular disease when the target antigen is found in both locations. Retinal drusen may be a useful biomarker for some forms of glomerulonephritis, and drusen pathogenesis may explain in part the pathogenesis of glomerular immune deposits. In addition, treatments that target retinal drusen may also be useful in antibody-mediated glomerulonephritis.
Long-Term Therapeutic Plasma Exchange (TPE) in Management of Focal Segmental Glomerulosclerosis (FSGS) in Native Kidneys

Northwestern University Feinberg School of Medicine, Chicago, IL.

Introduction: Circulating permeability factors (CPF) may be involved in the pathogenesis of some forms of FSGS that are non-responsive to intensified immunosuppression and exhibit a rapidly progressive course. The role of CPF-mediated FSGS is indicated by the post-transplant recurrence of proteinuria and its response to TPE. Moreover, experimental animals injected with plasma from patients with FSGS can develop proteinuria. While TPE in patients with post-transplant recurrence can prevent graft failure, evidence to support its use in resistant FSGS in native kidneys is lacking.

Case Description: A 62-year-old Caucasian female presented with anasarca and nephrotic-range proteinuria (5.0 g/day) in March 2018. Kidney biopsy revealed minimal change disease. The first 14 months of her course were complicated by steroid resistance, side effects of high-dose steroids and calcineurin inhibitors (CNI), recurrent AKI, CNI/ ARB-induced hypertension, and worsening of proteinuria with CNI reduction. She received 4 doses of rituximab (375 mg/m²) during that period. Genetic testing for the steroid-resistant nephrotic syndrome was negative. In June 2019, a trial of 10 TPE sessions resulted in a significant improvement in proteinuria (UPCR= 1.8±0.6), which worsened over the following 4 months after discontinuation of TPE (UPCR=4.0). Repeat kidney biopsy revealed FSGS. Given the previous response to TPE, a central-venous port was placed for long-term TPE in December 2019. The patient received TPE twice a week for the first 6 weeks. With improved proteinuria, TPE was tapered to twice a month with maintenance removal (UPCR= 1.5) for the last 5 months. The patient is off ARB, on a minimal dose of CNI. The symptoms associated with nephrotic state and the side-effects of multiple drugs have resolved.

Discussion: This case highlights the dilemma of therapeutic decision-making in patients with resistant FSGS. Long-term TPE successfully maintained symptom-free, sustained PR and stabilized renal function. TPE has become the preferred choice of our patient to avoid the toxic effects of long-term intensive immunosuppression. More studies are required to study the efficacy and safety of TPE in patients with native kidney FSGS resistant to therapy.

PUB162
Association Between Anti-GBM Titers and Kidney Inflammation with a New Activity Score

Background: Anti-glomerular basement membrane antibody (anti-GBM) disease is a rare glomerulonephropathy characterized by rapidly progressive loss of kidney function, leading to end-stage kidney disease in a significant amount of cases. The main objective of our study is to determine whether anti-GBM titer correlate with rate of activity in renal biopsy and long-term kidney survival in patients with anti-GBM, hence identifying patients who would potentially benefit from more intensive treatments.

Methods: A retrospective analysis was performed on anti-GBM cases from 2007 to 2018 with both positive biopsy and serology. Anti-GBM levels and kidney function at admission, discharge, treatment, and kidney biopsy findings were collected. All biopsies were reevaluated by a single, blinded pathologist. Based on a recent study by Van Daalen et al, we developed an activity score. The score was divided in a glomerular and interstitial section. In the glomerular section, a sclerotic pattern (~50% of glomeruli) was given 0 pts in activity and 3 in chronicity, a mixed pattern was given 1 pt in activity and chronicity, and a crescentic pattern (~50% with cellular crescents) was given 3 pts in activity and 0 in chronicity. In the interstitial section, the presence of fibrosis and atrophy was given between 0 and 3 pts in chronicity and the presence of tubulitis or interstitial infiltrate with neutrophils were given points in activity (0 to 3 respectively). Spearman correlation was performed between anti-GBM levels, our biopsy score, and kidney survival at follow-up.

Results: Twelve cases were identified, 9 were males, mean age was 54. Anti-GBM at admission ranged from 40 to 1517 U/mL. Ten patients were treated with cyclophosphamide, 1 with rituximab plus cyclophosphamide and 1 with only rituximab. The median number of therapeutic plasma exchange sessions was 8 (range 6-12). High antibody titers correlated with greater activity on biopsy (r 0.6, p = 0.04) and lesser chronicity (r -0.7, p =0.02). Kidney loss at follow-up (35 months) was 92%.

Conclusions: These results suggest that patients who present higher titers have more acute inflammation, and therefore could benefit from more intensive treatment. It would be interesting to study this score in larger cohorts in order to produce more definitive conclusions.

PUB163
Antisynthetase Syndrome and Nephrotic Syndrome

Noe Martinez-murillo, Jorge J. Font, Jonathan Chavez, Joana G. Navarro gallardo, Jose A. Torres, Christian P. Flores. Universidad de Guadalajara, Guadalajara, Mexico.

Introduction: The presence of anti-synthase syndrome and IgA nephropathy is unusual. symptoms similar to other diseases that affect the connective tissue: Lupus, Rhematoid and other.

Case Description: A 39-year-old female patient was admitted to the hospital in 2018 with proteinuria, hematuria, and acute renal failure. Her lack of ANCA rendered her disease entity mystifying and puzzled providers in terms of how to proceed with treatment.

Case Description: A 39-year-old Caucasian female was admitted to the hospital with a one day history of shortness of breath. Her admission was complicated by pre-existing hypertensive arterial disease, pulmonary edema confirmed by a complete reliance on venovenous extracorporeal membrane oxygenation. Labs showed acute kidney injury (AKI) with a serum creatinine of 3.70 mg/dL. Urinalysis demonstrated
large blood, 4–10 red blood cells, and proteinuria > 1000 mg/dL. Urine protein creatinine ratio was 3.895 mg/g. She developed bloody endotracheal tube secretions, warranting performance of bronchoscopy that was consistent with diffuse alveolar hemorrhage. Given that serological work up, including ANCA, returned unremarkable, the etiology of her renal failure was unclear. Her AKI became oliguric and she was initiated on continuous venovenous hemodialysis (CVVHD). Given the uncertainty regarding the etiology of her renal failure, and therefore how to proceed with treatment, despite her hemodynamic instability, renal biopsy was performed. Findings were consistent with segmental sclerosis and showed intratubular red blood cell casts and mesangial hypercellularity. No evidence of glomerulonephritis or interstitial nephritis was observed. The patient was treated with IV fluids, diuretics, and eventually dialysis. She was discharged home after a month in the hospital with improved renal function.

**Case Description:** A 46-year-old male with a history of Intravenous (IV) drug use and Hepatitis C had been admitted to the hospital with shortness of breath and chest pain. Patient was found to have Methicillin Resistant Staphylococcus bacteria and tricuspid valve endocarditis. Physical examination was positive for bilateral leg edema and pan systolic murmur over left lateral sternal border. Initial serum creatinine was 1.54 mg/dL (baseline 0.4 mg/dL). Urine analysis revealed proteinuria and hematuria. The patient subsequently developed acute kidney injury with increased creatinine to 5.5 mg/dl, UPCR: 5.81g/g and INR: 1.0 as the patient by then had stopped taking warfarin. Labs showed creatinine: 5.5mg/dl, UPCR: 5.81g/g and INR: 1.0 as the patient by then had stopped taking warfarin. Additional serology tests were performed with unrevealing results. She was managed with pain medications and had conservative management.

**Discussion:** The presence of nephrotic syndrome in this patient presents a challenging scenario and MPGN secondary to hepatitis C may be considered a differential diagnosis in this case. SAGN, a form of monoclonal gammopathy associated with proteinuria, though not common, has been described in SAGN and endocardiitis-associated GN cases in variable percentages, ranging from 6-48%.

**PUB168**

Unmasking of Pancreatobiliary Carcinoma in a Patient with Fibrillary Glomerulonephritis

Avneek Singh Sandhu,1 Harold J. Duarte,1 Natallia Maroz.1 2 Kettering Health Network, Dayton, OH; 1Wright State University, Dayton, OH.

**Introduction:** Fibrillary Glomerulonephritis (FGN) is a rare disease with known malignancy correlation. Cancer can be discovered simultaneously with the diagnosis of FGN or later in the course of the disease. As per our knowledge, this case is a first description of rapidly progressing pancreatobiliary carcinoma (PBC) associated with FGN.

**Case Description:** 49 y/o white woman presented to the nephrology office with proteinuria of 1.3 g/d and hematuria. She had a past medical history of smoking (>20 years) and hysterecmy for uterine fibroids. Serologic work up was unrevealing. Kidney biopsy reported FGN with minimal intimal scarring. Oncology referral was made to rule out hidden malignancy. She had an unremarkable CT scan of the chest and abdomen, PAP smear, mammogram, colonoscopy as well as normal chemical evaluation and ultrasound of thyroid. Patient quit smoking and had conservative management. Introduction of ACE-I led to reduction in proteinuria to 0.6 g/d. Unfortunately, she had decline in creatinine from 0.6 to 1.0 mg/dl, and worsening of proteinuria to 1.3 g/d associated with edema and weight gain. Therapy with Acthar® injections was initiated at the dose of 80 units thrice weekly. Patient had rapid improvement in proteinuria and swelling, and after 12 months of therapy, Acthar® dose was reduced to 40 units twice weekly. Creatinine remained stable. 24 months after the initial presentation and 13 months from Acthar® therapy initiation, she developed acute pancreatitis. Imaging studies showed pancreatic pseudocyst. Unfortunately, her pain did not improve. During the second hospitalization, a month later, HIDA scan and FGD were performed with unrevealing results. She was managed with pain medications and Acthar® therapy was uninterrupted. Patient underwent MRCP 3 months after the initial presentation, which showed pancreatic mass and multiple liver lesions. Biopsy of the liver lesion demonstrated poorly differentiated adenocarcinoma. Palliative chemotheraphy was initiated but was not tolerated by the patient. Patient deceased 4 months after the development of pain symptoms.

**Discussion:** Consideration of a hidden malignancy is a part of FGN management. PBC is a devastating cancer with dismal survival. Conducting an aggressive and repetitive work up for malignancy in patients with a new diagnosis of FGN may improve outcomes.

**PUB169**

A Case of Proliferative Glomerulonephritis with Monoclonal IgG Deposits Following Influenza Infection

Merve Postacioglu.1,2 1Kent Hospital, Warwick, RI; 2Brown University Department of Medicine, Providence, RI.

**Introduction:** Proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMID) is relatively a new entity. It is a form of monoclonal gammopathy with renal significance. Our patient is presented with this rare disease triggered by very common illness, influenza infection.

**Case Description:** A 61-year-old female with a past medical history of chronic kidney disease stage IIIB, and type 2 diabetes mellitus presented to the hospital with gross hematuria for 1 week and right-sided flank pain started within last 24 hours. The patient was diagnosed with influenza A infection 10-days before her hospital admission and treated with Oseltamivir. She was started on captopril and enalapril. She had a history of hypertension for 21 years. She was hypertensive otherwise hemodynamically stable. Her physical exam was significant for right-sided costovertebral angle tenderness. BMP showed creatinine as 2.73 mg/dl which was 1.33 mg/dl at baseline. She was diagnosed with acute kidney injury and started on IV fluids resuscitation. Her urinalysis revealed 58/HPF red blood cells and 7/HPF white blood cells. The kidney ultrasound was unremarkable. CT abdomen and pelvis did not show any evidence of neoplasia. On further examination, she was found to have IgA glomerulonephritis with IgA deposits in glomeruli and interstitium. She was started on corticosteroids and IgA-depleting immunoglobulin. She had rapid improvement in proteinuria and swelling, and after 12 months of therapy, Acthar® dose was reduced to 40 units twice weekly. Creatinine remained stable. 24 months after the initial presentation and 13 months from Acthar® therapy initiation, she developed acute pancreatitis. Imaging studies showed pancreatic pseudocyst. Unfortunately, her pain did not improve. During the second hospitalization, a month later, HIDA scan and FGD were performed with unrevealing results. She was managed with pain medications and Acthar® therapy was uninterrupted. Patient underwent MRCP 3 months after the initial presentation, which showed pancreatic mass and multiple liver lesions. Biopsy of the liver lesion demonstrated poorly differentiated adenocarcinoma. Palliative chemotheraphy was initiated but was not tolerated by the patient. Patient deceased 4 months after the development of pain symptoms.

**Discussion:** Consideration of a hidden malignancy is a part of FGN management. PBC is a devastating cancer with dismal survival. Conducting an aggressive and repetitive work up for malignancy in patients with a new diagnosis of FGN may improve outcomes.
cause. cFSGS complicating HLH is rare. Excessive immune activation with release of pro-inflammatory cytokines targeting the podocytes is hypothesized to cause cFSGS in HLH. Renal prognosis appears to be poor despite therapy and most patients remain dialysis dependent. HLH has been reported post stem cell transplant and should be considered in the differential diagnosis of cFSGS.

**Epidemiology of Glomerular Diseases in Minia Governorate: A 5-Year Single-Center Experience**

Waled Hassan,1 Hisham Mostafa,2 ’The University of Tennessee Health Science Center College of Medicine, Memphis, TN; 2Minia Nephrology and Urology University Hospital, Minia, Egypt.

**Background:** Studying the pattern of glomerular diseases gives an important insights about factors associated with its development or progression.

**Methods:** This is a retrospective study includes 312 patients underwent kidney biopsy at Minia university hospital between 2014 to 2019. The aim of this study was to highlight the histopathological patterns of glomerular disease in Minia governorate.

**Results:** A total of 312 biopsy-proven glomerular diseases were reported. The mean age was 31.65±13.77 years, 61.5% were females Table (1). The most common clinical presentation was nephrotic Syndrome (39.4%). Lupus Nephritis contributed 27.9%, followed by Membranoproliferative glomerulonephritis (15.4%) Focal segmental glomerulosclerosis (13.5%), IgA nephropathy (11.5%), amyloidosis (7.7%), Crescentic glomerulonephritis (5.8%), Thrombotic microangiopathy (4.8%), Vascular nephropathies (3.8%), Minimal change disease (3.8%), Membranous nephropathy (2.9%), Postinfectious glomerulonephritis (1.9%) and Diabetic nephropathy (0.96%). Table (2). Eighteen patients (62.1%) of lupus nephritis belonged to FSGS/RPG class IV, seven patients belonged to class III, and four patients belonged to class V.

**Conclusions:** Histopathological patterns of glomerular disease may indicate regional and ethnic variations that could point towards genetic or environmental influence. This might help in effectively managing this disease by identifying the predisposing factors.

**Results:**

**Conclusions:**

The most common glomerular disease was minimal change disease (10.9%), followed by focal segmental glomerulosclerosis (11.5%), membranous nephropathy (6.7%), lupus nephritis (7.4%), and membranoproliferative glomerulopathy (2.9%). Other less common diseases included crescentic glomerulonephritis (2.2%), amyloidosis (1.9%), diabetic nephropathy (1.6%), and vascular nephropathy (1.3%).

**Discussion:**

The epidemiology of glomerular diseases in Minia governorate shows a predominance of mesangial and membranous diseases, with minimal change disease being the most common. These findings highlight the need for targeted interventions to prevent and manage these conditions effectively.
**A for Amyloidosis**

Muhammad Y. Jan, Simit Doshi. Indiana University School of Medicine, Indianapolis, IN.

**Introduction:** We present a case of amyloidosis related amyloidosis presenting as acute injury (AHUS) with nephritic range proteinuria.

**Case Description:** A 62 years old man with type 2 diabetes mellitus and hepatitis C (transplant) was admitted with complaints of bilateral foot pain of 3 weeks duration leading to inability to ambulate. Work up revealed pedal wounds with drainage and imaging was consistent with amyloidosis. Blood cultures were positive for methicillin sensitive staphylococcus aureus (MSSA) which was treated with IV antibiotics. Baseline serum creatinine (SCr) was 2.0 mg/dL and SCr on admission was 3.85 mg/dL, which was thought to be from acute tubular necrosis related to sepsis from amyloidosis. Work up of AKI revealed nephrotic range proteinuria of 4.7g, hematuria without dysmorphic red blood cells and monoclonal kappa IgM spike on serum protein electrophoresis. Kappa/Lambda ratio was 8.6g/dl with serum albumin of 1.9g/dl. Hemoglobin A1c level was 4.6%. Left below knee amputation was performed and patient was transitioned to 4 weeks of oral cephalixin. SCr on discharge was 2.9 On clinic follow up, repeat labs showed non-resolution of AKI as well as nephrotic range proteinuria of 6.8g and a kidney biopsy was obtained. His wound was healing slowly and antibiotic duration was extended.

Kidney biopsy showed no glomerular obsolescence or hypercellularity. Mesangial and glomerular capillary walls showed Congo Red Positive deposits. Thickening of glomeruli was noted with segmental duplication. Tubular atrophy and interstitial fibrosis was 20%. Staining was positive for serum amyloid A (AA) in glomeruli, arterioles, and tubular basolateral membranes. Immunofluorescent staining was negative. Electron microscopy showed mesangial expansion with randomly arrayed extracellular fibrils with solid cores and a mean diameter of 9.8 nanometer.

**Discussion:** Patient completed extended oral antibiotic therapy for osteomyelitis with resolution of M spike on SPEP and improvement of creatinine to baseline. Deposition of serum amyloid A (SAA) protein, an acute phase reactant is a potential complication of therapy. Causes can be sometimes chosen, and results from multiple prospective multicentered studies have been reported for its clinical usefulness. However, the treatment selection criteria has not been cleared. We retrospectively analyzed the patients who underwent TSP therapy in our facility and investigated the factors associated with efficacy of this therapy.

**Methods:** Subjects are 63 patients with IgAN who underwent TSP in our hospital (treated) was admitted with complaints of bilateral foot pain of 3 weeks duration leading to inability to ambulate. Work up revealed pedal wounds with drainage and imaging was consistent with amyloidosis. Blood cultures were positive for methicillin sensitive staphylococcus aureus (MSSA) which was treated with IV antibiotics. Baseline serum creatinine (SCr) was 2.0 mg/dL and SCr on admission was 3.85 mg/dL, which was thought to be from acute tubular necrosis related to sepsis from amyloidosis. Work up of AKI revealed nephrotic range proteinuria of 4.7g, hematuria without dysmorphic red blood cells and monoclonal kappa IgM spike on serum protein electrophoresis. Sudden Explosive Onset of Collapsing FSGS in the Setting of Influenza: An Unusual Presentation

Amaresh R. Vanga, Varun Malhotra. Eastern Virginia Medical School, Norfolk, VA.

Introduction: Collapsing FSGS (Focal Segmental Glomerulosclerosis) is often seen in the setting of HIV, parvovirus infection, and parvovirus infections. Here we present a case that was explosive in onset and was associated with influenza.

Case Description: An 68-year-old African American male presented with three weeks of dysphagia secondary to esophageal rings with dilations in the past, acute myeloid leukemia s/p allogetic stem cell transplant and deep vein thrombosis. His stem cell transplant was a year prior to presentation, and he was tapered off MMF and to a lower dose of tacrolimus with prednisone. On physical exam, he had gross anasarca. His labs were notable for a serum creatinine of 1.5 mg/dL from a prior baseline of 1.3 mg/dL. His albumin was 1.2 g/dL with a spot urine protein to creatinine ratio of 3.12 and a LDL of 292. Serologies for hepatitis and lupus were negative. Complement levels were indicated corrected calcium of 11, potassium of 5.9, Co2 of 18, hemoglobin of 8 with 97%. Physical examination was benign. His creatinine was 6.9. His baseline creatinine was 1.8(for the past few years) and thought to be related to his hypertension. Other labs indicated corrected calcium of 11, potassium of 5.9, Co2 of 18, hemoglobin of 8 with normal platelets, and WBC. USG(Ultrasound) of kidneys revealed subepithelial Indigenous variant focal segmental glomerulosclerosis (FSGS), with diffuse fusion of foot processes, but no tubular epithelial changes. Lithium was discontinued, and the patient continued to improve to creatinine of 2.4 with improvement in urine output at which point he was discharged on ACE-I.

Discussion: Collapsing FSGS in probably related to complex interplay of multiple factors like infection, acute kidney injury due to other etiologies, genetic risk factors such as APOE1. Recent cases of COVID-19 related AKI point towards the possibility of collapsing FSGS as the etiological mechanism, especially with APO1 association. Though it is traditionally described in the setting of infections like parvovirus and HIV, there could underlyling common mechanisms for infections that may not be exclusive to these and may expand to other infectious etiologies like influenza, COVID.

Renal Response and Its Predictive Factors of Lupus Nephritis: A Two-Year Cohort of 77 Hospital-Based Patients

Zhiming Lin, Junmei Feng, Jun Zhang, Changlin Zhao, Zhen Wu. Department of Rheumatology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China; Department of Nephrology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China; Department of Vasculocardiology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.

Background: To evaluate the renal response rates of lupus nephritis (LN) patients undergoing standard treatment during a two-year follow-up and investigate its predictive factors.

Methods: A prospective cohort study enrolled 77 clinically diagnosed LN patients was carried out. All patients underwent standard treatment according to Joint European League Against Rheumatism and European Renal Association-European Dialysis and Transplant Association (EULAR/ERA-EDTA) recommendations or American College of Rheumatology (ACR) guidelines for the management of LN. Regular visits were performed every 6 months until 2 years. Data on renal response and clinical characteristics were collected and analyzed.

Results: Among 77 patients, 41(53.2%) and 15(19.5%) patients achieved complete response (CR) and partial response (PR) at 6 months after induction therapy, respectively. With every 6-months visit, 53(68.8%) patients completed the whole 2-year follow-up. 38(71.7%) and 5(9.4%) patients developed CR and PR at 2 years. During follow-up, serum creatinine (SCr) and Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) score showed a significant difference as compared to baseline data, while estimated glomerular filtration rate (eGFR) and C3 level gradually elevated. In multivariate regression model, immunological disorder (OR 4.73, 95%CI 1.00-22.40, p=0.05), eGFR (OR 1.04, 95%CI 1.02-1.07, p<0.001) and SLEDAI (OR 1.21, 95%CI 1.05-1.40, p=0.01) at baseline were found to be associated with CR/PR at 6 months as compared to non-responders.

Conclusions: Nearly 70% LN patients achieved renal response after 6-months standard induction therapy, and the renal response rates were higher after 2 years. Renal function and disease activity showed a significant improvement during follow-up. Besides, immunological disorder, higher baseline eGFR and SLEDAI were predictive factors for renal response.

Hypoaalbuminemia Out of Proportion to Proteinuria in a Patient with Nephrotic Syndrome

Chidi Egwim, Javier Jaramillo Morales, Laura Binari, Gautam B. Bhave. Vanderbilt University Medical Center, Nashville, TN.

Introduction: Hypoaalbuminemia is a fundamental characteristic of nephrotic syndrome, with most of the albumin loss resulting from urinary excretion. As such, the degree of proteinuria in a glomerular process often mirrors the serum albumin. The differential and work-up changes when there is discordance between the two.

Case Description: A 68-year-old African American male presented with three weeks of a worsening cough, diarrhea, and progressive swelling. His past medical history was notable for dysphagia secondary to esophageal rings with dilations in the past, acute myeloid leukemia s/p allogetic stem cell transplant and deep vein thrombosis. His stem cell transplant was a year prior to presentation, and he was tapered off MMF and to a lower dose of tacrolimus with prednisone. On physical exam, he had gross anasarca. His labs were notable for a serum creatinine of 1.5 mg/dL from a prior baseline of 1.3 mg/dL. His albumin was 1.2 g/dL with a spot urine protein to creatinine ratio of 3.12 and a LDL of 292. Serologies for hepatitis and lupus were negative. Complement levels were indicated corrected calcium of 11, potassium of 5.9, Co2 of 18, hemoglobin of 8 with 97%. Physical examination was benign. His creatinine was 6.9. His baseline creatinine was 1.8(for the past few years) and thought to be related to his hypertension. Other labs indicated corrected calcium of 11, potassium of 5.9, Co2 of 18, hemoglobin of 8 with normal platelets, and WBC. USG(Ultrasound) of kidneys revealed obstructing 3mm left UVJ stone with hydronephroenephrosis. UA revealed 3 plus protein with moderate blood, 10-20 RBC per HPF, bacteria. He was started on antibiotics and a double JJ stent was placed. His stone disease is probably a manifestation of parathyroid adenoma. He was awaiting parathyroidectomy and was maintained on sensiparin in the interim. His creatinine continued to increase and peaked at 7.5 mg/dL. However repeat urinalysis revealed significant proteinuria and on quantification, it was 17g with albumin of 2.

Discussion: Though it is traditionally described in the setting of infections like parvovirus and HIV, secondary membranous nephropathy. Staining for PLA-2R was positive. He was started on basiliximab and continued treatment as an outpatient.

Discussion: Here we describe a case of nephrotic syndrome in which the degree of hypoaalbuminemia was not consistent with the amount of proteinuria. This discordance represents a defect in the homeostasis of albumin typically seen in nephrotic syndrome. At a steady state, albumin synthesis is balanced by albumin catabolism and urinary loss. In nephrotic syndrome, catabolism is decreased while synthesis and urinary loss increases.

The patient’s history of diabetes and dysphagia suggested that he had either increased catabolism from non-renal GI losses or decreased synthesis due to poor intake. This case highlights alternative laboratory findings in membranous nephropathy and a framework for understanding the differences.

An A-Tip-ical Side Effect of Lithium

Casie James, Randall Craver, Isa Ashoor. Louisiana State University Health Sciences Center, New Orleans, LA.

Introduction: Lithium is a mood stabilizer approved for bipolar disorder treatment in children as young as 12 years. Though effective in the pediatric population, lithium requires close monitoring for toxicity and adverse effects.

Case Description: An 18 year old male with Hashimoto’s thyroiditis, bipolar I disorder, and anxiety presented with 10 days of edema, weight gain, progressive abdominal pain, nausea, diarrhea, and decreased urine output with frothy urine. Medications included levothyroxine, Risperdal, and lithium. Creatinine was 1.2 mg/dL, up from baseline of 0.8 mg/dL. There was nephrotic-range proteinuria, with spot urine protein/creatinine ratio of 9. Serum lithium level was 2.5 mmol/L (therapeutic range 1-1.2 mmol/L). Renal biopsy showed tip variant focal segmental glomerulosclerosis (FSGS), with diffuse fusion of foot processes, but no tubular epithelial changes. Lithium was discontinued, and the patient underwent diuresis with Lasix/albumin infusions. Proteinuria resolved within two months, and he remains in remission. Bipolar disorder is now treated with Lamictal and Risperdal.

Discussion: Lithium has a wide side effect profile, requiring close monitoring. Lithium-induced nephrotic syndrome is a known, idiopathic side effect. Most renal biopsies show minimal change disease; however, FSGS has also been associated with lithium use. To our knowledge, this is the first documented case of tip variant FSGS in a teenager. While lithium may have induced nephrosis, the low effective circulating volume in nephrotic syndrome with subsequent decrease in glomerular filtration rate likely led to poor excretion of lithium, leading toxic levels and protracted recovery from adverse effects. Despite atypical histology, the patient followed a favorable course and remains in remission without immunosuppressive therapy.
AKI After Eculizumab Interruption in a Case of C3 Glomerulopathy
Mostafa F. Elshirbeny, Mohammed E. Hussain, Essa Abuhelaiqa, Awaïs Nauman. Hamad Medical Corporation, Doha, Qatar.

Introduction: C3 glomerulopathy (C3G) is a newly recognized rare disease characterized by predominantly glomerular deposition of complement C3. Treatment with the C5 complement inhibitor eculizumab may be a therapeutic option but due to rarity of the disease, predicting tools of the outcomes remain largely unknown.

Case Description: Here we report 25-year old female patient who was referred to nephrology clinic with renal impairment, hematuria, and proteinuria. Kidney biopsy results revealed membranoproliferative changes with predominant C3 deposits, suggestive of C3 glomerulopathy. Genetic testing revealed two unrelated mutation in C3 gene, likely not related to C3G. Patient was responding well to oral steroid and MMF with remission of proteinuria and normalized serum creatinine. She was relapsed again, 1 year later with hematuria and nephrotic proteinuria. Steroids and MMF were resumed with no response then started on eculizumab, after which she achieved partial remission with reduction in serum creatinine and urine protein. During next 2 years, patient missed eculizumab in 2 occasions. The first, when she missed one dose followed by mild rise in serum creatinine which improved after eculizumab resuming and few months later she missed two doses then presented with severe AKI requiring dialysis. Was started on steroids and eculizumab was resumed with no improvement in kidney function and patient still dialysis dependent.

Discussion: Despite looks like safe and valuable therapeutic option in patients with C3G but the response to eculizumab is heterogeneous and when to discontinue the therapy still unsolved problem as transient interruption of the therapy sometimes complicated with AKI which may be severe enough to end with ESRD like this case.

Serum creatinine results during 40 months of follow up
remission rate of hematuria in TSP group (100%) was much higher than that in CT group (48%). Moreover, immunosuppression therapy was effective to prevent significant decline in kidney function.

Conclusions: We clarified that more than half of patients with isolated hematuria showed crescend or endocapillary proliferation in present study. Immunosuppression therapy is effective for those lesions. Thus, even in the patients with isolated hematuria, conservative treatment can be a risk for deterioration of renal function.

PUB184

Indolent Pauci-Immune Crescentic Glomerulonephritis
Elizabeth Pepper1, Jalal E. Hakem1,2 Edward Via College of Osteopathic Medicine - Carolinas Campus, Spartanburg, SC; 3Palmetto Nephrology, Orangeburg, SC.

Introduction: Pauci-immune glomerulonephritis (PIGN) is most commonly associated with a rapidly progressive course towards renal failure, although rarely, an indolent course may be observed. PIGN has a frequent association with either MPO- or PR3-antibodies and is associated with extra-renal manifestations. We report a patient with slowly decreasing renal function over the course of two years that had a renal-limited MPO-antibody associated pauci-immune glomerulonephritis.

Case Description: A 61 year old Caucasian female with controlled hypertension, hypercholesterolemia, and prediabetes without complaints was noted by her PCP to have a slowly rising creatinine over two years. A nephrology referral was made with new onset 1+ pitting edema in the bilateral, distal lower extremities and a creatinine of 1.7mg/dL. Urinalysis at this point showed a sediment and 2g/g of protein to creatinine. A renal ultrasound showed structurally sound kidneys. Common infectious causes of renal disease were ruled out. C and HIV were negative and ANA, PR-3, and C4 were sent to see if there was an autoimmune cause. A positive MPO prompted a renal biopsy which yielded a sample of 50 glomeruli with 15 completely sclerosed, 4 with crescent formation, and moderate to severe interstitial fibrosis and tubular atrophy. This confirmed the diagnosis of MPO- associated PIGN. Immunosuppression was begun with a rituximab based therapy, but the second dose of rituximab was interrupted due to severe back pain combined with nausea and vomiting. Creatinine was elevated at 3.6mg/dL from 2.2mg/dL the day before. Methylprednisolone was tapered and further infusions were not pursued due to development of deranged liver function tests, hospitalization for diverticulitis, development of uncontrolled DM, and severe psychological symptoms. Over the following two months, the patient’s creatinine has trended down to 1.5 mg/dL.

Discussion: Her consistently rising creatinine was the main driver to begin immunosuppressive therapy despite having moderate to severe interstitial fibrosis and tubular atrophy. Rituximab-based therapy was shown in the RAVE trial to be non-inferior to cyclophosphamide for induction of remission in ANCA associated disease. This combination may also have superior relapse rates and a better safety profile in comparison with cyclophosphamide. Her improving creatinine suggests that even an incomplete regimen might have conferred some benefit.

PUB185

IgG4-Related Disease Presenting with Membranous Nephropathy
Elena Zakhareva1,2 City Clinical Hospital n.a. S.P. Botkin, Moscow, Russian Federation.

Introduction: Immunoglobulin G4-related disease (IgG4-RD) is a condition, affecting multiple organs. Retroperitoneal fibrosis with obstructive nephropathy and interstitial nephritis are most typical kidney damage. Rare cases of glomerular disease, including membranous nephropathy (MN), had been described. Search for IgG4-RD in the database of our nephrology unit showed 11 patients, in three cases kidney biopsy was performed, and we present one of them.

Case Description: 73 years old Caucasian female with a history of arterial hypertension, diabetes, skin patchy hyperpigmentation, asthma and nasal polypsym at the time of presentation. In 2016 with the weight loss and skin rash. 9 months later, at admission, she was undernourished, with multiple skin scratches, pedal edema, and otherwise unremarkable physical exam; her blood pressure was 150/90 mm Hg, vital signs were normal. Work up demonstrated nephrotic syndrome and marked eosinophilia (32.6% vs 2.6%-10^9/L). Her blood chemistry tests, serum and urine immunocomplex, p and C ANCA, PR3, MPO, and anti-CEP-PR3 antibodies were negative. Kidney biopsy showed MN with IgG, C3, kappa and lambda fine granular deposits on the capillary loops periphery. Her anti-PR3 antibodies titer was <1:10; kidneys, abdomen, neck and pelvis ultrasound, chest CT, gastroscopy and colonoscopy were unremarkable. Tests for parasitic infections and mycofus hypersusnicosis syndrome markers (FPII1/ PDGF-Rα and ETV6-PDGFβ) were negative. IgG4 level was 1.9g/l (0.8-1.4) – 29.2% (4.0-5.0). We diagnosed IgG4-RD and started her on oral prednisone 40 mg daily. Her skin rash resolved immediately, in a month her eosinophil count became normal, two months later complete remission of nephrotic syndrome. We added cyclosporin A and slowly tapered prednisone. At the latest follow-up visit January 2020, she was doing well, with the complete remission of nephrotic syndrome, preserved kidney function and normal IgG4 level.

Discussion: Clinical presentation was suggestive for ANCA-associated vasculitis or systemic sclerosis, not confirmed by serology and kidney pathology findings. The search for the hypersusnicosis syndrome causes was negative, and only IgG4 testing gave a clue to the diagnosis. Steroids allowed controlling hypersusnicosis symptoms, but not kidney disease, which was in favor of IgG4-RD. We conclude that IgG4-RD should be considered in differential diagnostics of membranous nephropathy.

Role of Therapeutic Plasmapheresis in ANCA-Associated Vasculitis: A Single-Center Study
Aglaia Chalkia1, Alexandros G. Panagiotopoulos1, Panagioti E. Giannou, Dimitris Kourniotis1, Athanasia Kapota1, Margarita Mpora1, Dimitrios Vassilopoulos2, Dimitrios I. Petras1, Nephrology Department, Hippokration General Hospital, Athens, Greece; 2Joint Rheumatology Program, National and Kapodistrian University of Athens, School of Medicine - Clinical Immunology - Rheumatology Unit, 2nd Department of Medicine, Athens, Greece.

Background: Recently Pexivas trial showed no benefit of plasmapheresis (PEX) in ANCA-associated vasculitis (AAV), even in patients with alveolar hemorrhage, but is this the end of PEX in AAV? The aim of this study is to describe the indications, method and complications of PEX, as well as whether PEX is associated with improvement in renal function and survival at 12 months.

Methods: Retrospective study of 28 patients with severe manifestations of AAV, who had received PEX adjunctive to conventional therapy for the first episode of AAV or in relapse.

Results: We recorded twelve patients receiving PEX. This group (n=12) had an average age at diagnosis 79 years and was followed for a median period of 20 months. In 75% of the patients MPO-ANCA was positive, in 17% ANCA negative and in 8% double positive anti-GBM/ANCA. On admission, all patients had abnormal renal function with average creatinine 5mg/dL±2.12 and the majority of patients (9/12) were dialysis dependent. Indications for plasmapheresis were: alveolar hemorrhage in 33%, renal impairment in 25% and combination of the two above in 42%. Plasmapheresis was performed using filtration and fresh frozen plasma as replacement fluid. The mean number of plasmapheresis treatment was 8 (1-19 days) and the average internal time between admission and first plasmapheresis treatment was 3 days. No episodes of severe infection or death were recorded during plasmapheresis. All patients received concomitant therapy with Cyclophosphamide and corticosteroids while Rituximab was added in 3 patients. Hbpation was reduced for patients with alveolar hematoma. The study included all patients (100%). After one year, 75% of the patients had renal recovery (cre±5mg/dL±2.12 vs cre±2.6mg/dL±1.6, p=0.06) and 67% of the patients who received hemodialysis at the time of diagnosis, during the first year became independent of dialysis (75% vs 33%, p=0.5). Finally, survival rate at the end of the first year was 83%.

Conclusions: Plasmapheresis is quite often used in daily clinical practice with remarkable results in dialysis independence and survival, without serious complications.

PUB187

Retrospective Analysis of Five Cases of Proliferative Glomerulonephritis with Monoclonal IgG Deposition Regarding Their Clinical Course and Responses to Therapy
Takatsugu Iwashita1, Minoru Hatano, Koki Ogawa, Ryo Yamamoto, Yuta Kogure, Hajime Hasegawa. Saiitama Medical Center, Saiitama Medical University, Kawagoe, Japan.

Introduction: At present, limited knowledge is obtained regarding pathophysiology and clinical course of proliferative glomerulonephritis with monoclonal IgG deposition (PGNMID). It is rarely diagnosed by renal biopsy, and there is no established therapeutic strategy for this disease. We report clinical course and responses to the therapy of 5 cases diagnosed as PGNMID in our facility.

Case Description: Method Five cases (3 males and 2 females, median age 62 years) with renal biopsies and diagnosed as PGNMID between January 2016 and December 2019 were retrospectively analyzed regarding the transition of eGFR and urine protein level by the treatment. Three of 5 cases were treated by steroid alone in combination with intravenous methyl prednisolone (PSL) 500 mg/day for 3 days and oral PSL 30 mg/day. Remaining 2 cases were treated with intravenous methyl PSL and oral PSL followed by Cyclophosphamide intravenously (750 mg/day, twice) or orally (100 mg/day, daily) administration and Rituximab (500 mg/bottle, twice) administration. Results Light microscopic findings were MPGN type in all cases, and immunofluorescent staining showed 4 cases were IgG3-kappa and only 1 case was IgG3-lambda. Three cases in the first month of the treatment had partial remission (KDIGO diagnostic criteria, defined as a urinary protein level of < 0.3-3.5 g/day and a reduction of ≥ 50% from baseline), and all had partial remission at 6 months. Hemataria was observed at the start of treatment in three cases and disappeared in only one case by the treatment. And, the remarkable deterioration of renal function was not observed during the clinical course. However, two cases showed the increase of urine protein after about one year from mPSL administration, and IVCY and RTX were administered, but urine protein and hemataria were not decreased, and mPSL was administered again. In one case, the improvement of the urinary finding was scarce even after the increase in the administered steroid.

Discussion: Conclusion Our results suggest that the treatment responsiveness to IVCY and RTX is poor, that steroids are more responsive to initial therapy, that disease activity increases with dose reduction (a steroid-dependent condition), and that treatment responsiveness to steroids may decrease after relapse.
AA Amyloidosis and CKD in a Patient with Coexisting Hepatitis C Infection and Crohn Disease

Introduction: AA amyloidosis is in the differential diagnosis of patients with proteinuria and may lead to chronic kidney disease (CKD). It is usually associated with chronic inflammatory conditions like rheumatoid arthritis which is implicated in 40% of cases. Crohn’s disease (CD) is also recognized as an underlying etiology. We present a patient with chronic Hepatitis C infection (HCV) and CD who developed proteinuria and CKD in a relatively short period of time.

Case Description: 33-year-old man with a past medical history of CD, HCV, and cocaine/heroin abuse with frequent IV drug use presented to the ED with complaints of bilateral lower extremity swelling and tenderness. Initial laboratory studies were significant for a creatinine of 4.56 and nephrotic range proteinuria. On review, his creatinine had been trending up from 0.75 mg/dl to 4.09 mg/dl in the last year. Secondary work-up for proteinuria including: ANA, RPR, RF, ANCA, C3, C4, Cryoglobulin with reflex, ds DNA Ab, UPEP, and SPEP w/ immunofixation screenings all yielded negative results. S. cerevisiae Ab IgA was 51.5, a positive confirmation of patient’s CD. HCV antibody test was positive with a positive HCV RNA. Renal biopsy was performed and revealed AA amyloidosis with severe interstitial fibrosis and tubular atrophy.

Discussion: AA amyloidosis is a disorder characterized by the overproduction of extracellular proteins that deposit and subsequently cause organ and tissue impairment. It is often attributed to chronic inflammatory/infectious diseases. Though literature about the incidence of AA amyloidosis in people afflicted with HCV is limited, incidence in individuals afflicted with CD has been reported to be between 0.5%-8%. AA amyloidosis has also been found to be a major cause of CKD in IV drug users. One UK study found that up to 55% of these patients have associated HCV. There are reports of increased CD “flares” in patients undergoing treatment for chronic HCV, which may suggest that the coexistence of both diseases may lead to worse morbidity. Our case is unique due to the coexistence of two chronic diseases that lead to inflammatory/infections processes known to be involved in the pathophysiology of AA amyloidosis. This co-existence may lead to a faster progression of CKD and overall worsening outcomes.

Awareness of Association of ANCA Vasculitis and Aortic Aneurysm Can Improve Survival
Sonalika Agarwal, Jitendra Kumar. QRG Hospital, Faridabad, India.

Introduction: ANCA vasculitis is a small-medium vessel vasculitis which is characterized by systemic necrotizing inflammation of blood vessels. Aortic aneurysm is a very rare complication of ANCA vasculitis. We describe a case of such association and highlight the need for guidelines for its screening in patients diagnosed with ANCA vasculitis.

Case Description: 40 year old man with no known medical history presented with renal failure and was started on dialysis. Kidney biopsy showed pauci immune crescentic glomerulonephritis. As per KDIGO guidelines, he was treated with steroids, cyclophosphamide and plasmapheresis after which he recovered from dialysis. 3 months later, he presented with hematemesis and shock. Due to worsening hematemesis and shock, upper endoscopy was done which revealed aorto-esophageal fistula and patient died of shock with no time for surgical intervention. On retrospective analysis, we found that unfolding of aorta seen on chest xray 3 months ago was likely aortic aneurysm which had increased in size and ruptured.

Discussion: To the best of our knowledge, this is the first case reported from India. The reason we think ANCA vasculitis is associated with aortic aneurysm is because it has been proven by biopsy in case reports in the past and in few of them, aneurysm had even decreased in size with chemotherapy. Also, it is surprising that such degenerative condition would occur without any risk factor like smoking, atherosclerosis, history of hypertension, or family history of connective tissue disorders in such a young patient. Since both ANCA vasculitis and aortic aneurysm are rare pathologies, it is reasonable to consider that they are related when occurring together. Again, its rapid expansion and rupture within a span of 3 months favors an underlying association. This case highlights that nephrologists should be aware of such association, screen the patient on presentation and then at intervals likely earlier than recommended for aortic aneurysm of other etiologies.
Kidney Crimes: Stop That Drug!
Latoya N. Gayle, Gene C. Otony, Nia Flemming, Marc S. Zelkovitz, Englewood Hospital and Medical Center, Englewood, NJ.

Introduction: Drug associated antineutrophil cytoplasmic antibody (ANCA) associated vasculitis (DAV) with rapidly progressive glomerulonephritis (RPGN) is rare. Historically linked to antithyroid drugs, new evidence implicates almost every pharmacological class. Untreated, it is catastrophic. Prompt diagnosis & cessation of the offending agent is paramount. This is a case of DAV-RPGN secondary to diltiazem.

Case Description: 76-year-old male with T2DM, cirrhosis, HTN & MM in remission, on diltiazem, propranolol, insulin, presented to an outside hospital with 10- days of weakness, reduced appetite & leg swelling. On exam BP 191/79, T 97° F & anasarca. He had an upper respiratory infection and dental pain for which he took 1g of ibuprofen daily. Labs showed Na128, K 5.3, Cl100, HCO3 19, BUN 79, creatinine (Cr) 16.9mg/dL, and urine protein to creatinine ratio of 5.85. Renal ultrasound showed no hydronephrosis. Abdominal CT showed diffuse colitis. Dialysis was initiated for uremic colitis. Workup for ARF was negative for hepatitis, HIV, and autoimmune markers. Kidney biopsy revealed podocyte effacement and nonspecific minimal deposits with severe ATN. Immunofluorescence showed nonspecific mild granular tubular and glomerular IgG deposition. Electron microscopy noted widespread podocyte effacement consistent with MCD. Prednisone 60 mg daily was started. Within 48 hours oliguria resolved and dialysis was discontinued. Cr at discharge was 3.6. After a slow taper of steroids, he had a full recovery.

Discussion: Although NSAID-induced ATN is well understood, it is unusual to see ATN causing ARF with oliguria in a young patient with no comorbidities. Nephrotic syndrome induced ATN has been specifically documented in association with MCD. This is likely the mechanism of ATN development in our patient with drug-induced MCD. MCD is the most common cause of nephrotic syndrome in children but accounts for only 10-15% of adult cases. Data evaluating drug-induced MCD in adults is limited to a few case series and retrospective studies associating NSAIDs with acute interstitial nephritis, rather than ATN, as the cause of MCD. Contrary to our case, NSAIDs have shown to reduce proteinuria in idiopathic nephrotic syndrome. Corticosteroids are the first-line therapy, and adults with MCD require prolonged therapy with a slow taper. The majority of ARF induced by MCD is reversible, with complete recovery of renal function.

Kidney Aging and Estimation Equations for GFR in Beijing
Lennan Xu, Yonghui Mao. Beijing Hospital, National Center of Gerontology; Institute of Geriatric Medicine, Chinese Academy of Medical Sciences, Beijing, China.

Background: When evaluating renal function, eGFR data show significant variation across different equations, particularly in elderly patients. Here, we investigated how age affected renal function in healthy subjects in Beijing and compared different eGFR equations for the evaluation of renal function.

Methods: We recruited all patients undergoing routine assessment in our hospital between January 2012 and December 2014. For each patient, we recorded age, gender, and Cr. Kidney function was evaluated by five equations: CKD-EPI, MDRD, MDRDc, FAS and BIS.

Results: A total of 46,713 subjects were enrolled. Subjects were 16 - 100 years-of-age and were followed-up for 3 years. All subjects showed an increase in Cr and decrease in eGFR with increasing age. For males, there was a more obvious and significant reduction of eGFR in the elderly; but in older females, eGFR did not tend to change. Different equations showed good consistency [the intraclass correlation coefficients (ICC) was 0.849 for males, and 0.817 for females]. The CKD-EPI equation yielded higher eGFR for older populations, with a slight overestimation of the more advanced CKD-according-to-sCr levels. There was no obvious trend for age-related change in the 3-year mean rate of GFR change when compared across age groups. For subjects aged over 70 years, the MDRD and MDRDc equations yielded significantly higher eGFR data and the BIS produced the lowest eGFR values.

Conclusions: The annual rate of GFR change was not associated with age. Different eGFR equations yielded data that varied across different populations of patients and sCr levels. We were unable to identify a specific equation for use in the elderly Chinese population.

A comparison of different GFR equations across all age groups. (A) Male. (B) Female.

Comparison of eGFR equations for different serum creatinine levels. (A) Male. (B) Female.
A Workplace Wellness Program Results in Improvements in Physical Activity and Blood Pressure in the Staff of a Hemodialysis Clinic
Alexis King, Alana P. Harris, Luis M. Perez, Kenneth R. Wilund
University of Illinois at Urbana-Champaign, Department of Kinesiology and Community Health, Urbana, IL; University of Illinois at Urbana-Champaign, Division of Nutritional Sciences, Urbana, IL.

Background: Evidence indicates that health and wellness programs in the workplace provide numerous benefits with respect to altering indices of health. The purpose of this study was to assess the feasibility of a workplace wellness program (WOW) as a means of improving blood pressure by participation in habitual physical activity (PA) and improving dietary choices among the staff at a hemodialysis clinic.

Methods: 26 staff members (age 46.5 ± 12.2; BMI: 28.7 ± 5.6 kg/m²) from a hemodialysis clinic (nurses, technicians, social workers, dietitians, and administrative staff) participated in the 12-week WOW program that consisted of weekly counseling sessions, the provision of educational resources, PA incentive challenges, and healthy dietary choices challenges. Body weight (kg), height (cm), blood pressure, BMI, 24-hr dietary recalls, PA behaviors (IPAQ), and waist/hip circumference were collected at weeks 0 (baseline), 6, and 12 following the conclusion of the intervention. Statistical analysis was performed using SPSS24. All primary and secondary outcomes were assessed by one-way Analysis of Variance (ANOVA) comparing values at the different testing time points, with significance at (p<0.05). Paired sample t-test was used to test the questionnaire (IPAQ) data that was collected at baseline and post intervention.

Results: The program also resulted in improvements in several health related metrics. This included reductions in body weight (1.07 kg ± 21.4; p<0.05), body mass index (p<0.005), waist circumference (cm 96.9 ± 14.8; p<0.005), and hip circumference (cm 111.7 ± 13.6; p<0.05). Systolic blood pressure change was non-significant but trending toward significance (p=0.08), while diastolic blood pressure was reduced (p<0.05). There were significant changes in PA behavior, specifically walking behavior (p<0.05), as indicated by the IPAQ.

Conclusions: The WOW program demonstrated increased measures in the staffs PA. As a result, this led to the improved health outcomes which included body weight reductions, BMI improvements, lowered hip and waist circumference, and improved diastolic blood pressures values. The study suggests that a workplace wellness program has the potential to improve health indices of the staff of hemodialysis clinics and may positively impact the health behaviors in the hemodialysis patients under their care.

Frailty Changes in Patients on Hemodialysis After an 8-Week Exercise Intervention
Rick Ward
Wise Health System Dialysis Center Wise Health System, Decatur, TX.

Background: The Fried frailty phenotype defines frailty as having at least 3 of the following: unintentional weight loss, decreased grip strength, slow gait speed, exhaustion, and decreased physical activity. The vulnerability inherent in frailty is exacerbated in people with end-stage renal disease, but frailty assessments are typically not used. Exercise during dialysis has been shown to have positive effects on functional outcome and physiologic measures, but are not standard clinical care. The purpose of this study was to investigate the effects of an 8-week, supervised resistance and cycling program on frailty and function measures of patients undergoing dialysis.

Methods: 11 patients from the Wise Health System Dialysis Center in Decatur, TX (6 in the experimental group, 5 in the control group). The experimental group received a supervised elastic band resistance and cycling ergometer program 3 days per week for 8 weeks during dialysis. The resistance component included: ankle dorsiflexion and plantarflexion, knee flexion and extension, and hip abduction. A repeated measures 2-way ANOVA was conducted on the dependent variables of: frailty scores, gait speed, grip strength, 2-Minute Step Test, exhaustion, Timed Up and Go, and 30-second Sit to Stand Test.

Results: There was a significant difference in pre- to post-test frailty scores [F(1, 9) = 6.14, p = 0.035, \( \eta^2 = 0.41 \)]. Specifically, the exercise group’s frailty score dropped from 3.67 to 2.67 while the control group’s score did not change. This change in frailty scores was influenced by the change in the exhaustion component of the frailty score from a mean of 1.00 to 0.17 [F(1, 9) = 16.05, p = 0.003, \( \eta^2 = 0.64 \)]. There were no significant differences found in the other dependent variables. There were no adverse reactions to the exercise intervention.

Conclusions: The results of this feasibility study support the hypothesis that an exercise program during dialysis can change frailty scores in people with ESRD, as the exercise group decreased their frailty classification from frail to pre-frail. It is not clear if the benefit would persist after this time or if results would change based on the length of the program, which provides support for additional longitudinal research designs. In conclusion, it appears that a resistance and cycling exercise intervention can mitigate frailty effects in persons with ESRD.

Relation Between Anxiety, Depression, and Frailty in Maintenance Hemodialysis Patients
Fanna Liu
The First Affiliated Hospital of Jinan University, Nephrology, Guangzhou, China.

Background: Both psychological disorders and frailty are prevalent and burdensome in MHD patient. However, the relationships between these entities are unclear. The aim of this study was to investigate the prevalence and associations between frailty and psychological disorders in Southern Chinese MHD patients.

Methods: This was a multicenter, cross-sectional and observational investigation conducted at 4 institutions. Frailty was evaluated with the Tilburg Frailty Indicator (TFI) and it was used as the self-reported questionnaire. Anxiety symptoms was assessed by the Self-Rating Anxiety Scale (SAS), depressive symptoms was assessed by the Self-Rating Depressive Scale (SDS). We collect sociodemographic and clinical characteristics the patients who complete the scale. Statistical analysis was performed using SPSS20.0 for Windows.

Results: Of the 623 patients visiting each institution, 300 were enrolled in this study. The mean age was 61.9 ± 13.64 years, with mean duration of HD 30.7 ± (34.3±26.3) months. 116 patients (38.7%) were female and 133 (44.3%) had diabetic kidney disease. In total, there were 225 patients (73%) were evaluated as frail. The prevalence of frailty increased steadily with age and was more prevalent in the diabetes mellitus patients. A multivariate logistic regression analysis revealed that the factors independently associated with frailty were the following: age, Charlson comorbidity index, DMSAS, SDS. There was no relationship between the duration of HD and frailty status. Anxiety and depression symptoms by SAS and SDS were identified in 52.6% and 72.0% of MHD patients. MHD patients with both anxiety and depression generally had higher frailty score. The coexisting frailty and psychological disorder were present in 45.0% patients. There was an additive effect of psychological disorder and frailty on nutritional status. For the groups with frail and psychological conditions and no frail and no psychological conditions, both serum albumin and creatinine decreased.

Conclusions: This study demonstrated that anxiety and depressive symptoms are associated with prevalent frailty in Southern Chinese MHD patients. Older age, diabetes mellitus, CCI and lower serum albumin were associated with frailty among patients on MHD. Anxiety and depressive symptoms are independent risk factors of frailty.

Potassium Binders for Treatment of Hyperkalemia: Patient Survey Examining Side Effects, Tolerability, Palatability, and Interference with Daily Activity
Myungjin Kim, Maura A. Watson, Christina M. Yuan, Walter Reed National Military Medical Center, Bethesda, MD.

Background: Even mild hyperkalemia is associated with increased mortality. There are three FDA-approved oral potassium binders for outpatient treatment of non-life-threatening hyperkalemia: sodium polystyrene sulfonate (SPS), patiromer, and sodium zirconium cyclosilicate (ZS-9). Specific studies of patient experience, satisfaction, and adherence have not been conducted for any of the three agents. We surveyed outpatients regarding their experience with these medications, including taste, texture, tolerability, and interference with daily activity.

Methods: An online, anonymous survey of outpatients a 18 years old who were dispensed SPS, patiromer, and/or ZS-9 from September 2017 to August 2019 at military treatment facilities in the National Capital Region was conducted over 8 weeks. Respondents were invited by letter including the survey url (with a reminder at 4 weeks). Survey questions included queries about demographics, medical diagnoses, medications associated with hyperkalemia, side effects, taste, palatability, and daily activity interference.

Results: 212 qualifying individuals were invited to participate. Response rate was 16% (34/212). All respondents were a51 years old. 36% were on RAASI. 28 respondents had used SPS, 6 had used patiromer, and 1 had used ZS-9. 18% of respondents treated with SPS vs. 0% treated with patiromer reported side effects. 1 reported discontinued SPS without informing their physician due to side effects. 48% reported diarrhea with SPS, 50% reported constipation with patiromer. Respondents favored taste and texture of patiromer vs. SPS (72 vs. 56 for taste, and 70 vs. 50 for texture, with a scale rating of 100 being best), and reported more difficulty swallowing SPS vs. patiromer (3% vs. 0%). Side effect severity and interference with daily activity were the same (2 and 3 respectively for both SPS and patiromer, scale of 0-10, 10 being worst).

Conclusions: Respondents who used patiromer reported better palatability and fewer side effects than those who took SPS. However, side effect severity and daily activity interference were equivalent between SPS and patiromer. Disclaimer: The views expressed are those of the authors and do not necessarily reflect the official policy or position of the Department of the Army/Navy/AFire Force, the Department of Defense, nor the US Government.
Evaluation of the Establishment of a Nutrition Care Process in a Group of Spanish Haemodialysis Patients

Background: Keeping a good nutritional status during hemodialysis must be a priority goal of the treatment to prevent complications and mortality, as well as, to improve patients quality of life. The main objective of this survey will be to evaluate if the establishment of a nutritional care process adapted to the chronic kidney disease, could improve anthropometrics and biochemical parameters in a hemodialysis hospital group of patients. We will also try to assess if the compiled results of the questionnaire about malnutrition and inflammation are correlated to the biochemical results obtained.

Methods: Information about sex, gender, dry weight, IMC, albumin status, PCR and Malnutrition Inflammation Score were collected during the months of July 2019 and March 2020. 38 haemodialysis patients participated in this study. A descriptive and frequency analysis has been carried out with all the parameters obtained. The T of Student for a related sample test was used due to the normality of the data and the participants condition of intervention - control.

Results: The results indicate that since the month of July 2019 until March 2020, 81.7% of the patients stayed on the hemodialysis program, 13.1% of the patients died, 2.6% changed malnutrition to hemodialysis, and 2.6% were transplanted. 42.1% of the total number of patients decreased their dry weight, 13.2% maintained it, and 26.3% increased it. The median values obtained in July and March respectively were: dry weight (70.2 ± 14.4 kg vs 68.9 ± 14.4 kg), IMC (20.6 ± 5.6 vs 20.6 ± 5.6 kg/m²), albumin (3.6 ± 0.3 vs 3.6 ± 0.3 g/dL), PCR (0.8 ± 1.8 vs 0.8 ± 1.8 g/L), and MIS (6.1 ± 2.8 vs 6.1 ± 2.8). No statistical significance in any of the values has been found, being dry weight and IMC (p = 0.08) the closer parameters to get this condition.

Conclusions: The establishment of a nutritional care process seems to be a helpful and efficient method to improve anthropometrics and biochemical parameters in hemodialysis patients. Likewise, the use of malnutrition inflammation questionnaire as a tool to evaluate the nutrition status, seems to be effective when correlating with better biochemical nutritional parameters in hemodialysis patients.

Scope and Consistency of Physical Fitness Outcome Measures in CKD: A Systematic Review

Dey K. Jegatheesan, 1,2 Richard S. Modderman, 2 Rathika Krishnasamy, 1,2 Allison Tong, 3 Jeff S. Coombes, 1 Andrea K. Viecelli, 1 David W. Johnson, 1 Nikolaos M. Kastrati, 1,2 Princess Alexandra Hospital, Brisbane, QLD, Australia; 3University of Queensland, Brisbane, QLD, Australia; 4Sunshine Coast University Hospital, Sunshine Coast, QLD, Australia; 5University of Sydney, Sydney, NSW, Australia; 6The Children’s Hospital at Westmead, Sydney, NSW, Australia.

Background: Impaired physical fitness is prevalent in people with chronic kidney disease (CKD), associating with an increased risk of mortality, falls and hospitalization. A plethora of physical fitness outcomes have been reported in randomized trials. This study aimed to assess the scope and consistency of physical fitness outcomes and outcome measures reported in trials in CKD.

Methods: A systematic review of randomized trials reporting physical fitness outcomes in adults with CKD (not requiring kidney replacement therapy), receiving hemodialysis, peritoneal dialysis, and kidney transplant recipients was conducted. Studies were identified from MEDLINE, Embase and the Cochrane Library from 2000 to 2019. The scope, frequency and characteristics of outcome measures were categorized and analyzed.

Results: From 112 trials and 6,047 participants, 87 tests/measurements were used to evaluate 30 outcomes measures that reported on 23 outcomes, categorized into five domains (i.e. fitness (30%), physiological-metabolic (49%), body composition (36%) and cardiorespiratory fitness (30%). Neuromuscular fitness was examined by 37 tests/measurements including 335.6 vs 1367.9 kcal/day (p<0.05), 0.39 vs 0.85 mg/dL (p<0.05) and ate more cholesterol (411.6±65.2 vs 287.3±61.0, p=0.034), fatty acids (1.1±0.54 vs 0.7±0.61, p=0.034) and more protein (1.5±0.27 vs 0.42±0.16, p=0.048) and drank more fluid (2499.0±335.6 vs 1367.9±167.1, p=0.005) than FM pts, but fruit/veg intake was poor. PBE-score did not correlate with dietary intake of any nutrient in either group.

Conclusions: In our populations 1. Pts with CKD had a more positive attitude towards plant-based eating. 2. CKD pts ate more cholesterol with higher intake of eggs and fatty food. 3. Despite difference in attitude there was no difference in actual vegetable intake between groups. 4. The positive attitude of CKD pts towards PBE suggests that education will be successful in this group, especially as they appear to be following the recommendation to increase fluid intake. The poorer attitude in FM patients should be addressed as the population as a whole has a high prevalence of hypertension, obesity and diabetes and all patients could benefit from PBE.

Diabetes and Influenza Vaccination Rates and Patient Misconceptions in Inner-City CKD and Kidney Transplant (KTR) Patients

Takisha Morancy, Iqra Nadeem, Kingsley Cruickshank, Ahmad Saleh, Mariana Markell. SUNY Downstate Health Sciences University, Brooklyn, NY.

Background: Pts refuse vaccination for unclear reasons. Vaccination rates and attitudes towards vaccination were studied in an inner-city population of CKD pts and KTRs.

Methods: A face-to-face survey was conducted in a random convenience sample of pts with kidney disease attending CKD (30) and Transplant clinic (45). Pts were asked if they refused or accepted the influenza vaccine and associations between beliefs about vaccines and cause of vaccine refusal examined.

Results: There were 37 (49.3%) women and 38 (50.7%) men with 66 black (80%). 40 (40%) did not attend any college. 17 (22.7%) were employed. Mean age was 56.8±1.4 yrs. 34/65 pts (45.3%) reported having had influenza with more TTP pts (63% vs 31%, p=0.009) and more men (62% vs 37%, p=0.035) in the group by Chi-square. 18.36% (50%) of pts reported a family history of influenza. 68.76% believed prevention was easy, 17.24% believed vaccines were not needed, 14.39% believed vaccines caused side effects, 33%, feared related to 3rd party information (22%) and other. Pts who did not think influenza prevented by vaccines were severely agreed they should question shots (r=0.58, p<0.0001), felt knowledgeable about vaccines (r=0.36, p=0.012), trusted information they received (r=0.55, p<0.0001) and felt they could discuss concerns with their doctor (r=0.58, p<0.0001). They were more likely to receive information from friends and family (r=0.58, p<0.0001). Pts who were concerned about side effects were concerned with vaccine safety (r=0.77, p<0.0001) and felt vaccines may be ineffective (r=0.76, p<0.0001) but they did not feel knowledgeable about how vaccines work (r=0.372, p=0.01).

Conclusions: In our population 1. Influenza vaccination rates are low and prevalence of self-reported influenza high. 2. Patients who refuse vaccines believe they are low vaccine safety, and have a high prevalence of preventable illnesses. Pts who believed preventable illnesses were not severe were more likely to receive information from friends and family, felt knowledgeable but did feel comfortable discussing concerns with their doctor. 4. Pts who were concerned about vaccine safety did admit to lack of knowledge. 5. Effective education regarding how vaccines work as well as efficacy and side effect profiles may help improve vaccination rates in this high risk population.

Diet Composition and Understanding of Plant-Based Eating (PBE) in an Inner-City Population of CKD Compared with Family Medicine Patients

Kingsley Cruickshank, Ahmad Saleh, Takisha Morancy, Elizabeth G. Kasparov, Mariana Markell. SUNY Downstate Health Sciences University, Brooklyn, NY.

Background: Patients with CKD may benefit from PBE but dietary restrictions may create confusion regarding implementation. We compared attitudes toward plant-based eating and dietary components in an indigent, immigrant population of patients with CKD and those attending Family Medicine clinic (FM).

Results: A total of 15 studies with 82,706 participants were included, of which 5 were validated in a HF cohort different from the model derivation cohort. They consisted of

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
A variety of HF populations (e.g., acute, chronic, carrying mechanical circulatory device) and the median number of included parameters was 7. There was substantial variation across models in the reporting of the kidney related parameters as well as the studied outcomes. While no study included eGFR, serum creatinine and BUN were included in only 6 and 4 studies respectively. Interestingly, serum chloride level was included in none of the included models, while still contain data serum potassium level.

Conclusions: The emerging clinical evidence on the paramount prognostic value of hypochloremia for adverse outcomes in HF is in keeping with distinctive physiologic mechanisms relating it to renin secretion and modulation of renal tubular sodium transport. However, we found that there is still a lag in its integration into contemporary predictive models of HF. This observation highlights the need for revisiting these models in backdrop of emerging data and explore whether incorporation of hypochloremia, or replacing hyponatremia by hypochloremia, would add to their predictive value.

PUB204
Long-Term Ambient PM2.5 Exposure Associated with Major Cardiovascular Risk Factors in a Large Chinese Population-Based Study
Jianfeng Lin, Hua Zheng, Peng Xia, Limeng Chen. Peking Union Medical College Hospital, Dongcheng-qu, China.

Background: The association between long-term exposure to ambient air pollution and hyperlipidemia or overweight is still controversial. We aimed to investigate the relationship between long-term exposure of PM2.5 and cardiovascular risk factors in a large multi-provincial and multi-ethnic Chinese adult sample.

Methods: We recruited 19,236 adult participants from 2007 to 2010 in 6 provinces of China (Chinese Physiological Constant and Health Condition Study, CPHCS). A questionnaire, physical examination, and biochemical tests were performed. The PM2.5 data used were derived from aerosol optical depth with the GWR model and GEOSChem method.

Results: The average age of the participants 42.7±16.12 years and nearly half were male (47.0%). Annual average PM2.5 exposure 1-year before the CPHCS study was 33.4±18.3 μg/m³. Multiple linear regression showed that each 10 μg/m³ increment of PM2.5 was associated with 0.025% (95% CI: 0.011%, 0.040%) decrease of cholesterol and 0.098% (95% CI: 0.083%, 0.113%) decline of BMI. Adjusted by age, sex, education, ethnicity, physical activity, and smoking, logistic regression indicated that PM2.5 exposure still associated with the prevalence of hyperlipidemia (OR = 0.958, 95% CI: 0.942, 0.974) and overweight (OR = 0.925, 95% CI: 0.911, 0.939). PM2.5 exposure was also corresponded to elevated SSBP (0.048%), 95% CI: 0.034%, 0.063%) and an increased prevalence of hypertension (OR = 1.020, 95% CI: 1.001, 1.039).

Conclusions: Long-term PM2.5 exposure was associated with an increased prevalence of hypertension, decreased prevalence of hyperlipidemia and overweight.

Predictive Models for Prognosis of Cardiovascular Events (in 5 Years) in Asian Patients with CKD
Wentao Hu, Xin Liu, Shaomin Li. the Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

Background: Chronic kidney disease (CKD) is viewed as a major health problem worldwide. However, independent influencing factors related to the prognosis of CKD patients (especially in cardiovascular events) is still potential to be exploited, and few researches on predictive models for individualized prognosis in CKD patients were published, especially in Asian area. Therefore, we are willing to evaluate independent influencing factors in regard to prognosis of CKD patients and build predictive models for individualized prognosis in CKD patients.

Methods: 1246 participants were included in this cross-sectional study. All data were used in univariate Cox proportional hazards regression models and multivariable Cox regression analyses (P<0.05). Then, 1246 participant were divided into two cohort (development cohort and validation cohort). We will establish one best predictive model by the means of CINDEX, AIC, NRI, IDI.

Results: In the Cox regression analysis of cardiovascular events, we found that HGB, K, Pre-albumin, APOB, Heart failure, CKD progression are independent risk factors. In the development cohorts, we found that the model (K, pre-albumin, HGB, HF, CKD) the best prediction model of cardiovascular events (P=0.088e^1.93584*APOB + 0.00356*pre-albumin + 0.00679*HGB + 1.11488*Heart failure - 0.22131*K - 0.10215*CKD progression) was the best prediction model of cardiovascular events.

Conclusions: Lower HGB is independent protecting factor of cardiovascular events, and higher K, Pre-albumin, APOB, Heart failure, CKD progression are independent risk factors. And we establish the best prediction model (P=0.088e^1.93584*APOB + 0.00356*pre-albumin + 0.00679*HGB + 1.11488*Heart failure - 0.22131*K - 0.10215*CKD progression) of cardiovascular events (in 5 years).

PUB206
Epidemiology of Cardiovascular Risk Factors in Hemodialysis Patients in a Tertiary Care Hospital
Muntazir Ali Sayed,1 Navneet K. Guru,4 Adil A. Akbani,4 Ali Hamza,4 Sadiq Ali Sayed,2 Farhin N. Sayyad,4 Sayed Mohd Tahir Rizvi,3 Desi Doctors 1Avicenna Medical College, Lahore, Pakistan; 2National Pirogov Memorial Medical University, Vinnytsya, Ukraine; 3Rajiv Gandhi University Medical College and CPR Hospital, Kolhapur, India; 4Government Medical College, Patiala, India; 5KJ Somaiya College of Engineering, Mumbai, India.

Background: Cardiovascular events remains the leading cause of mortality in patients with end stage renal disease (ESRD) and the risk of cardiovascular events is 10 to 20 times higher in ESRD as compared to general population. The main objective of this study was to evaluate the prevalence of traditional cardiovascular risk factors in the population of ESRD outpatients on chronic hemodialysis in a tertiary care center in Kolhapur city of Western India.

Methods: All patients undergoing regular hemodialysis for ESRD in the tertiary care center of CPR Hospital were considered for inclusion in the retrospective study. Clinical and demographic data were obtained from the medical records, whereas laboratory records were obtained as the most recent result in the six preceding months. Adequate statistical tests were carried out and for all tests, a p-value <0.05 was considered statistically significant.

Results: A total of 1937 patients were included from the data of 2 years from May 2018 to April 2020 at our institute. Their average age was 61.3 years old, 69.3% were males. The prevalence of cardiovascular risk factors observed was 89.3% for hypertension, 83.9% for dyslipidemia, 75.3% for sedentary lifestyle, 49.7% for tobacco use, and 43.5% for diabetes. In a multivariate adjusted analysis, we found that sedentary lifestyle (p = 0.041, PR 1.15 – 95% CI: 1.09 - 1.17), diabetes (p = 0.021, PR 1.05 – 95% CI: 1.01 - 1.11), and obesity (p < 0.0001, PR 1.88 – 95% CI: 1.59 - 2.95) were more frequent in women; and hypertension (p = 0.019, PR 1.03 – 95% CI: 1.01-1.17) and tobacco use (p = 0.009, PR 1.31 – 95% CI: 1.97 - 4.67) were more often found among patients under 65 years old. Sedentary lifestyle was independently associated with time in dialysis less than 12 months (p < 0.001, PR 1.33 – 95% CI: 1.19 – 1.43).

Conclusions: The population in chronic hemodialysis in the city of Kolhapur presents a high prevalence of cardiovascular risk factors. These findings confirm the high-risk cardiovascular profile of hemodialysis patients. Prospective studies and clinical trials are needed to further clarify interventions that can be transformed in public health strategies to prevent cardiovascular death in hemodialysis patients.

PUB207
Prevalence and Associated Risk Factors of Pre-Hypertension and Hypertension Among University Students in Bahrain
Amjad E. El Agroudy. Arabian Gulf University, Manama, Bahrain.

Background: The increase of hypertension in the developing countries may be connected with the economic transition within those countries. This study aimed to assess the prevalence of prehypertension and hypertension among university students and their associated risk factors.

Methods: The study used a cross-sectional design. Data were collected from February 2019 to May 2019 at the Arabian Gulf University Campus in Bahrain. A total of 411, randomly selected students aged 17 to 24 years (196 males, 215 females) were included in the study. The data were obtained through a self-completed structured questionnaire, which included data about nutritional lifestyle, sleep, exercises, family history and smoking pattern. In addition, blood pressure and body mass index were measured. Systolic and diastolic blood pressure measurements were taken by trained personnel.

Results: The mean age was 19 ± 1.9 years. Normotensive cases constituted 61.3% (n = 252), prehypertensives formed 30.7% (n = 126), and hypertensive students comprised of 8% (n = 33). The overall proportions of hypertension and prehypertension were higher among male students (81.8 and 69.8%) than female students (18.2 and 30.2%), respectively.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

Higher body mass index was associated with significantly higher prevalence of hypertension (37.3%), overweight (33.3%), and obesity (39.8%) but not with pre-hypertension (normal weight 47.6%, overweight 32.5%, and obesity 17.5%). The Univariate analysis showed an association between hypertension and age, sex, body mass index (BMI), nutritional lifestyle, sleep duration, physical activity, smoking pattern and family history of hypertension (p < 0.05). Multivariate logistic regression analysis revealed a significant association between hypertension and the above stated factors.

Conclusions: The findings of this present study highlighted the prevalence of hypertension (8%) and prehypertension (30.7%) among university students in Bahrain. This outcome is consistent with associated risk factors (age, sex, body mass index, smoking, sleep duration, physical activity and family history of hypertension). The results of this study recommended that periodic screening and monitoring of students for hypertension should be done to the university students.

PUB208
A Combined Effect of Sacubitril/Valsalter and Evolocumab on Chronic Heart Failure in an ESRD Patient
Hun M. Aung,1,2 Aye M. Thida,1,2 Myat E. Mon,1 Phyo Wai Khine,1 May T. Zin,1 Banyta M. Win,1 Kyaw Hla,1 Alexander M. Swan,1Interfaith Medical Center, Brooklyn, NY; 2Nephrology Hypertension Renal Transplant & Renal Therapy, LLC, Avenel, NJ; 3Woodland Medical and Mental Health Center, Brooklyn, NY; 4Rutgers New Jersey Medical School, Newark, NJ.

Introduction: End-stage renal disease (ESRD) patients generally have underlying risk factors for coronary artery disease and heart failure (HF) such as hypertension and diabetes mellitus. In fact, chronic HF is highly prevalent and is one of the leading causes of death in these patients. We report a combined effect of sacubitril/valsalter and evolocumab on chronic HF in an ESRD patient.

Case Description: A 63-year-old man with a history of chronic HF for 3 years, along with hypertension, diabetes mellitus, hypercholesterolemia, coronary artery disease, status post coronary artery bypass graft with multiple stents, and ESRD on hemodialysis, presented with worsening dyspnea over 2 months (NYHA Class IV). His medication list included cardiotoxic chemotherapy, carfilzomib, carmustine, clopidogrel, hydralazine, ibuprofen, indomethacin, loratadine, mononitrate, ranolazine, aspirin, warfarin, amiodarone, erythropoietin, rosvastatin, sevelamer, linaglaptin, and insulin. An echocardiogram revealed an ejection fraction (EF) of 15%. He was placed on a cardiac transplant waiting list after receiving an implantable cardioverter defibrillator. Meanwhile, enapril and valsartan were replaced by sacubitril/valsalter for chronic HF, and evolocumab was added to reduce the risk of myocardial infarction. During an initial follow-up for 10 months, his dyspneic symptoms improved significantly to NYHA Class I. An echocardiogram later revealed an EF of 60%. He was followed for 4 years during his hospitalizations, worsening of HF, or side effects of the medications such as hypertension, hyperkalemia, and nasopharyngitis.

Discussion: Sacubitril/valsalter, an angiotensin receptor-neprilysin inhibitor, has multiple mechanisms of action and is known to reduce the risk of cardiovascular death and HF hospitalization in patients with chronic HF with reduced EF. Besides evolocumab, a PCSK9-inhibitor antibody, is known to promote plaque regression and stabilization. The combined use of sacubitril/valsalter and evolocumab in our patient for 10 months resulted in an improvement of his EF from 15% to 60%, most likely due to a significant improvement of coronary blood flow with a recovery of hibernating ischemic myocardium. Therefore, additional studies are highly recommended to explore the beneficial effect of these medications used in combination.

PUB209
Fanconi Syndrome and Acute Interstitial Nephritis: A Toxic Combina- tion Associated with Ifosfamide
Hafsa Tariq1, Nissreen El Fadawy, Miroslav Sekulic, Arash Rashidi2, University Hospitals, Cleveland, OH.

Introduction: Ifosfamide is an alkylating chemotherapeutic agent used in the treatment of various soft tissue tumors. Nephrotoxicity associated with ifosfamide is less consistent with ifosfamide associated renal toxicity which often results in irreversible damage. Therefore, the results of this study recommended that periodic screening and monitoring of students for hypertension should be done to the university students.

Case Description: 33-year-old female with chest wall Ewing Sarcoma presented to our institution with leukocytosis, rash, and fever. She was diagnosed with plasma cell leukemia. Renal biopsy revealed findings consistent with membranous glomerulopathy. She was treated aggressively with hemodialysis and immediate chemotherapy. The fairly recent development of the free light chain assay provides a tool to screen for MM and was treated with CyBorD therapy.

Discussion: Fanconi syndrome is a rare complication of ifosfamide administration during chemotherapy for solid tumors, particularly Ewing sarcoma. The pathogenesis of Fanconi syndrome following ifosfamide administration is not well understood. The mechanism of Fanconi syndrome associated with ifosfamide administration is likely multifactorial and includes a direct toxic effect on proximal tubular cells, tubular interstitial nephritis, and acute interstitial nephritis. Renal injury is a common presentation of underlying Multiple Myeloma. In a recently published study, considered the largest analysis to date between free light chains (FLC) and biopsy proven nephropathy confirmed McN (myeloma cast nephropathy). Median lambda light chain at diagnosis was 426.7mg/dL. Here, we present a case of a patient presenting in stage III acute renal failure with Lambda light chains measured at a level almost 9 fold greater at 3684mg/dL.

Conclusion: A 78 year old female with past medical history significant for breast cancer 20 years ago is electedly admitted from her primary care doctor’s appointment after having symptomatic anemia with a measured hemoglobin (hgb) of 6.3 g/dL. She was feeling weak, with weight loss of 30 pounds in 2 years as well as persistent proteinuria. She was treated with hemodialysis therapy with the intent of improving his EF from 15% to 60%, most likely due to a significant improvement of coronary blood flow with a recovery of hibernating ischemic myocardium. Therefore, additional studies are highly recommended to explore the beneficial effect of these medications used in combination.

PUB211
Biopsy-Proven Cast Nephropathy from Lambda Light Chain Measured at 3684 mg/dL in a Multiple Myeloma Patient
Jeremy Carlson, Hasan Zahid, Muhammad usama shah Hamdani, Chintan V. Shah, University of Florida, Gainesville, FL.

Introduction: Kidney injury is a common presentation of underlying Multiple Myeloma. In a recently published study, considered the largest analysis to date between free light chains (FLC) and biopsy proven nephropathy confirmed McN (myeloma cast nephropathy). Median lambda light chain at diagnosis was 426.7mg/dL. Here, we present a case of a patient presenting in stage III acute renal failure with Lambda light chains measured at a level almost 9 fold greater at 3684mg/dL.

Case Description: A 78 year old female with past medical history significant for breast cancer 20 years ago is electedly admitted from her primary care doctor’s appointment after having symptomatic anemia with a measured hemoglobin (hgb) of 6.3 g/dL. She was feeling weak, with weight loss of 30 pounds in 2 years as well as persistent proteinuria. She was treated with hemodialysis therapy with the intent of improving his EF from 15% to 60%, most likely due to a significant improvement of coronary blood flow with a recovery of hibernating ischemic myocardium. Therefore, additional studies are highly recommended to explore the beneficial effect of these medications used in combination.

AKI Associated with Immune-Checkpoint Inhibitors: Management Challenges and Dilemmas Without Renal Biopsy

Hui Zhan Tan, Jason Choo Chon Jun. Singapore General Hospital, Singapore, Singapore.

**Introduction:** There is much to be learnt about renal lesions seen in patients with acute kidney injury (AKI) associated with the use of immune-checkpoint inhibitors (ICI). Acute tubulo-interstitial nephritis is the most common, with glomerulonephritis (GN) being increasingly recognized.

**Case Description:** A 61 Chinese male presented with generalised arthralgia and AKI with nephritic-nephrotic syndrome on a background of Stage IV metastatic clear cell RCC and left renal nephrectomy. At presentation, he was on treatment with pembrolizumab (PD-1 inhibitor) and axitinib (VEGF receptor TKI). Investigations revealed 24-hour TUP of 8.26g/day and peak serum creatinine (SCr) of 605 μmol/L (CTCAE G3; baseline Scr 117 μmol/L). Autoimmune markers and complements were negative. Patient was counselled for but refused a high-risk renal biopsy. Pembrolizumab was discontinued. High dose prednisolone was initiated for renal and rheumatological IRAE. SCr improved to 224 μmol/L at 3 months but his nephritic-nephrotic state persisted. Risks and benefits of empiric mycophenolate mofetil were discussed extensively and patient opted to continue with corticosteroid (CS) monotherapy. His subsequent clinical course was complicated by community acquired pneumonia and herpes simplex viral oral mucositis, before eventually succumbing to polymicrobial sepsis from acute cholecystitis despite optimal management.

**Discussion:** The clinical presentation of our patient is highly suggestive of an underlying GN. In view of concurrent rheumatological IRAE, we postulated that his AKI was related to ICI use. Empiric use of high-dose CS resulted in partial improvement in renal function but persistence of nephritic-nephrotic state, suggesting that CS monotherapy is suboptimal. Without histological data, directed therapy was not possible. However, given the rarity and heterogeneity of ICI associated GN, success of previously tried agents was limited to case reports and optimal treatment remains unknown. In view of this uncertainty, hesitancy with the empiric use of immunosuppressants beyond CS is understandable. While we await further research, in-depth discussion of treatment risk and benefits, especially infective complications, during shared decision-making remains a key element in the optimal care of this unique population with advanced malignancies and often, limited life expectancy.

**PUB213**

Abiraterone-Induced Rhabdomyolysis as an Unusual Cause of AKI Requiring Hemodialysis

Juan Carlos Garcia Yance,

1Hospital Aranda de la Parra, Leon, Mexico; 2Universidad de Guanajuato - Campus Leon, Leon de los Aldama, Mexico.

**Introduction:** A 86-year-old male diagnosed with metastatic, castration-resistant prostate cancer (mCRPC) treated with abiraterone (Zitaiga) for 3 months was admitted to the emergency department due to hypoxemia, worsening fatigue and lethargy.

**Case Description:** After being diagnosed with prostate cancer, the patient had been subject to a radical prostatectomy 10 years prior to admission; 12 months prior to admission he developed deep-vein thrombosis that required endovascular treatment. The patient was prescribed daily 10mg rivaroxaban and 5mg prednisone for 1 year. For over 4 years, the patient had an irregular consumption of esomeprazole, atorvastatin, and risperidone.

Upon admission to the emergency department laboratory analysis revealed a dialytic emergency: serum creatinine of 6.1mg/dL, urea 295 mg/dL, BUN 138mg/dL and potassium of 7.3mEq/L. The patient refused renal replacement therapy. Agressive hydration and treatment with calcium gluconate, IV insulin and beta-agonist was initiated for renal and rheumatological IRAE. He was resuscitated with isotonic IV fluids, with resolution of perinephric hematoma and rectus abdominis hematoma. Urology recommended no surgical intervention. He was resuscitated with isotonic IV fluids, with resolution of shock. Subsequent MRA showed no evidence of enhancing left nephric hernia but multiple rounded hypo enhancing lesions in the renal parenchyma bilaterally. He remained with persistent anion gap metabolic acidosis with increasing lactic acid up to 14.5. A kidney biopsy was planned but aborted as patient became hypotensive and confused with a drop-in hemoglobin to 5.6. Patient endorsed dark stools so, when hemodynamically stable, EGD was performed and gastric biopsies showed aggressive Burkitt’s lymphoma.

**Discussion:** Lactic acidosis (LA) can occur in the presence or absence of tissue hypoxia (type A and type B LA respectively). Persistent LA without identifiable causes of tissue hypoxia should prompt clinicians to suspect non-hyptoxic etiologies, including occult high-grade malignancies. Hematological malignancies constitute and uncommon cause of type-B LA, carrying a poor prognosis.

**PUB215**

Bilateral Renal Burkitt Lymphoma Presenting with Persistent Lactic Acidosis in an HIV-Negative Patient

Oscar A. Garcia Valencia,1,2 Juan D. Salcedo Betancourt,1,2 Victor G. Becerra-Gonzalez,1,2 Karla G. Carias martinez,1,2 Marco A. Ladinio Avellaneda,1,2

1Jackson Memorial Hospital, Miami, FL; 2University of Miami, Coral Gables, FL; 3Miami VA Healthcare System, Miami, FL.

**Introduction:** Burkitt lymphoma is an uncommon and aggressive B-Cell lymphoma accounting for <1% of adult Non-Hodgkin Lymphomas. The ileocelecal region is the most common affected area, but it can involve extra nodal sites including the kidney. Renal involvement is usually asymptomatic and requires a high degree of suspicion to prevent early complications.

**Case Description:** 63 years old non-smoker, HIV negative male with a history of an incidentally found left medial upper pole exophytic perinephric hemihyphoma on CT 2 months prior to presentation, presented to the ED complaining of acute on chronic lumbar back pain. Noted afebrile, BP 86/52 mmHg with orthostatic changes, HR 92bpm, RR 20rpm and SO2 96% on RA somnolent but arousable, pale, no abdominal, or costovertebral tenderness. Laboratories showed Hb 8.2 (14.7 a month prior), WBC 17,000, Na 126, Sodium bicarbonate 16, Anion gap of 22, Lactic acid 5.0 and SrC 1.5 (base 0.8). UA unremarkable. CT-CAP w/o contrast with interval increase of perinephric hemihyphoma and rectus abdominis hemihyphoma. Urology recommended no surgical intervention. He was resuscitated with isotonic IV fluids, with resolution of shock. Subsequent MRA showed no evidence of enhancing left nephric hernia but multiple rounded hypo enhancing lesions in the renal parenchyma bilaterally. He remained with persistent anion gap metabolic acidosis with increasing lactic acid up to 14.5. A kidney biopsy was planned but aborted as patient became hypotensive and confused with a drop-in hemoglobin to 5.6. Patient endorsed dark stools so, when hemodynamically stable, EGD was performed and gastric biopsies showed aggressive Burkitt’s lymphoma.

**Discussion:** Lactic acidosis (LA) can occur in the presence or absence of tissue hypoxia (type A and type B LA respectively). Persistent LA without identifiable causes of tissue hypoxia should prompt clinicians to suspect non-hyptoxic etiologies, including occult high-grade malignancies. Hematological malignancies constitute and uncommon cause of type-B LA, carrying a poor prognosis.

Oxaliplatin-Induced Hypomagnesemia

Yuvir Khanin, Malia Sachdeva, Nupur N. Uppal. Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.

**Introduction:** Platinum based chemotherapy is used in the treatment of several malignancies including lung, colorectal, ovarian, breast, head/neck, bladder and testicular cancers. We present a case of profound electrolyte disturbances in the setting of oxaliplatin therapy.

**Case Description:** 78-year-old Caucasian male diagnosed with pancreatic cancer three months prior to admission, on oxaliplatin therapy, presented to emergency room with new onset atrial fibrillation. He was afebrile, hemodynamically stable, and without respiratory distress. He endorsed a history of chronic diarrhea since beginning chemotherapy, however he began to have weakness and dizziness three days prior to...
as its prompt diagnosis and treatment can prevent the associated complications. However, case reports of oxaliplatin associated magnesium wasting are limited. This can be partially explained by the fact that oxaliplatin is protein bound and cannot readily accumulate in the kidney tubules to mediate nephrotoxicity, as is the case with carboplatin which is not protein bound. Magnesium deficiency is an under recognized entity, however it can precipitate potentially fatal cardiovascular dysfunction. Clinicians need to be aware of this potential adverse effect related to oxaliplatin therapy, as its prompt diagnosis and treatment can prevent the associated complications.

**Introduction:** Immune related adverse events (irAEs) associated with immune checkpoint inhibitors (ICI) are increasingly recognized as a side effect of treatment. This case report describes a side effect following the patient receiving this therapy. Sarcoïd-like / granulomatous lesions from ICI are reported to be as high as 5% based on case series and registries. In all reported cases, patients presented with lymph node, skin, or lung involvement. We present the first case of sarcoid in lesions in the heart in a patient being treated with immune checkpoint therapy.

**Case Description:** A 62-year-old male with stage IV metastatic melanoma received two cycles of pembrolizumab in November 2019 followed by three cycles of with ipilimumab and nivolumab. In March 2020 he was admitted with acute kidney injury, creatinine peaked at 2.85 mg/dL (baseline 0.80-0.94 mg/dL). Urinalysis and serologies were unremarkable. A kidney biopsy was obtained and revealed granulomatosis tubulointerstitial nephritis with focal necrotizing granuloma. Acid-Fast Bacilli (AFB) and Grocott methenamine silver (GMS) stains were negative. Initially, the patient was noted to have increased shortness of breath. Echo revealed new-onset cardiomyopathy with ejection fraction (EF) of 22% and SVT. Cardiac catherization was negative for coronary artery disease, but endomyocardial biopsy revealed lymphohistiocytic infiltrate with granulomatous myocarditis consistent with cardiac sarcoidosis. He was initiated on pulse IV steroids with improvement of both his cardiac and renal function. EF improved to 46% and creatinine improved to 1.0 mg/dL. Follow-up PET/CT imaging showed small ingunal nodes that could be sarcoïdosis otherwise no indication of melanoma.

**Discussion:** Use of ICI has dramatically improved patient survival; however, there is a growing appreciation for adverse events that can be associated with increased morbidity. To our knowledge, this is the first case of sarcoid involvement in both the kidney and heart. Our case highlights the need for aggressive approach to ICI toxicity when clinical work-up is unrevealing. The timely manner that both kidney and heart biopsies were obtained and treated with immune checkpoint therapy. Further follow-up is needed to determine long-term outcomes of both irAEs and cancer status.

**Discussion:** The nephrotoxicity associated with Gemcitabine can occur weeks to months after the drug is initiated. The mechanism of injury is driven by antibody formation to the drug resulting in drug-induced deposition of immune complexes and immune complex precipitation within the glomeruli. Treatment consists of discontinuation of this drug. Neither steroids nor plasma exchange have been reported as beneficial. AKI from this drug is reversible with supportive care.

**Introduction:** Thrombotic microangiopathies (TMA) are potentially life-threatening conditions caused by small- vessel platelet microthrombi and are characterized by microangiopathic hemolytic anemia, kidney injury, and thrombocytopenia. TMA secondary to gemcitabine therapy (GiTMA) is extremely rare and is associated with a poor prognosis, with nearly 50% of cases progressing to end stage kidney disease. The mainstay of management is withdrawal of the offending drug and supportive care. A 65-year-old Black female with a history of metastatic invasive ductal breast cancer on gemcitabine therapy, well-controlled hypertension, well-controlled type 2 diabetes mellitus without proteinuria, and normal baseline kidney function presented with a 1 month history of poor oral intake, worsening hypertension, and progressive decline in kidney function. She was receiving 1250 mg/m²/week of gemcitabine for 3 weeks/months for 11 cycles over 1 year. She presented with acute presentation with 20% intravascular volume depletion, 14 x 20 x 16 cm in mid- abdominal region, pushing all the adjacent abdominal viscera to the anterior abdominal wall. Patient refused enucleation procedure. Later, aspiration was used chemotherapeutic agent for cancers of the pancreas, breast, lung, and ovaries. GiTMA is a very rare and highly fatal condition with mortality rates ranging from 50 to 70%. It is thought to be immune and non-immune mediated. Physicians should have a high index of suspicion to diagnose GiTMA early in the course of the disease. Mainstay of management is discontinuation of gemcitabine therapy, supportive care, and treatment of kidney injury with dialysis if necessary.}

**Discussion:** The nephrotoxicity associated with Gemcitabine can occur weeks to months after the drug is initiated. The mechanism of injury is driven by antibody formation to the drug resulting in drug-induced deposition of immune complexes and immune complex precipitation within the glomeruli. Treatment consists of discontinuation of this drug. Neither steroids nor plasma exchange have been reported as beneficial. AKI from this drug is reversible with supportive care.

**Introduction:** Immune checkpoint inhibitor-induced renal and cardiac sarcoidosis

**Introduction:** Recurrent Mesenteric Cyst in an ESRD Patient on Maintenance Hemodialysis

**Discussion:** We chronicle a case of 47 years old male on hemodialysis for last 15 years with an unknown primary cause of end stage renal disease (ESRD). He never underwent peritoneal dialysis and had no prior history of abdominal surgery. He presented with gradual onset of abdominal pain and altered bowel habits. CT scan of abdomen and pelvis revealed encysted fluid in mesentery, measuring 10 x 5 cm, located behind the anterior abdominal wall. Patient refused enucleation procedure. Later, aspiration was done, which drained three liters transudative fluid. Cytology was negative for malignant cells, Histopathology demonstrated cuboidal epithelial cells of enteric origin and was not suggestive of cells of mesothelial origin. One month after first aspiration, patient presented with re-accumulation of cystic fluid and underwent second session of aspiration. Patient presented with worsening symptoms of abdominal distension and pain within two months of last aspiration. Repeat CT scan showed large intra-abdominal cystic lesion measuring 10 x 16 x 20 cm in mid-abdominal region, pushing all the adjacent abdominal viscera to the left side. At this time, cystic mass was surgically removed. Abdominal ultrasound and CT scan were negative for cirrhosis or Budd chiari malformation. Hepatobiliary system was also unremarkable. It re-demonstrated large mesenteric cyst 13 x 10.3 x 14.1 cm, located in the small bowel mesentery around the ligament of Treitz, extending down and exerting mass effects on the adjacent bowel loops. The extensive workup for causes of ascites, including liver disease, hepatatis panel, Tuberculosis, Brucellosis, Hydatid cyst and malignancy screening with markers namely CEA, CA 125, CA 19-9, CA-153, were all unremarkable. Erythrocyte Sedimentation Rate (ESR) was mildly elevated at 35 mm/ hour.

**Discussion:** This is the first reported case of recurrent mesenteric cyst in ESRD patient from KSA. Recurrent mesenteric cysts are extremely rare and are very difficult to manage. Enucleation and aspiration, both are ineffective modalities for such cysts.
Urinothorax: A Rare Cause of Pleural Effusion

Abigayle Sullivan, Nidrit Bohra, Brigid K. Ellis. Reading Hospital, Reading, PA.

Introduction: Urinothorax [UT], the accumulation of urine in the pleural space, is an uncommon cause of pleural effusions resulting from trauma, obstruction, or iatrogenic causes. Thoracentesis with pleural fluid analysis and evaluation of biochemical characteristics, such as pleural fluid creatinine (PcCR) to serum creatinine (Scr) ratio, is necessary to diagnosis.

Case Description: A 93-year-old man with a history of chronic kidney disease, right kidney transitional cell carcinoma with hydronephrosis, adenocarcinoma of the prostate status post brachytherapy complicated by proctosis and urinary obstruction was hospitalized for worsening hematuria and suprapubic pain. CXR showed a large right pleural effusion. CT of the abdomen and pelvis illustrated severe right-sided hydronephrosis and hydrourereter with a heterogeneous density in the right renal pelvis and diffuse mural thickening in the posterior and right lateral bladder walls. An ultrasound guided thoracentesis was performed with the removal of 2L clear yellow fluid and analysis resulted: pH 7.423, LDH 48 IU/L, glucose 164 mg/dL, and Pcr 2.5 mg/dL. Cytology was negative for malignancy. Scr was 2.59 mg/dL and thus Pcr to Scr ratio of 0.96. A repeat thoracentesis was performed removing 1.85L clear yellow fluid. Pcr and Scr were 4.1 mg/dL and 3.94 mg/dL respectively. Again, this confirmed the diagnosis of UT with a Pcr to Scr ratio of 1.04. Bilateral retrograde ureteropyelograms with right ureteral stent placement failed to correct and an indwelling pleural catheter was placed.

Discussion: UT is a rare cause of transudative pleural effusion due to the mismatch of the rate of accumulation of pleural fluid and rate of reabsorption via pleural lymphatics. The most common etiologies resulting in UT include trauma and obstructive uropathy. Diagnosis requires pleural fluid analysis and is associated with a paucicellular, transudative effusion with an ammonia level, acidic pH less than 7.4, and a Pcr to Scr ratio greater than 1.0. Management is dependent on correcting the underlying pathology, such as repairing traumatic GU injury or obstruction.

PlACR-Positive Membranous Nephropathy in a Patient with Rectal Cancer

Sanjay S. Kallapur,1 Gargi Sharma Pranv마다,1 Koyal Jain,1 University of North Carolina at Chapel Hill, Chapel Hill, NC; 2Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India.

Introduction: Malignancy associated Membranous Nephropathy(MA-MN) is well-recognized as a common paraneoplastic glomerulopathy, especially in solid tumors. Prevalence is around 10% of all membranous nephropathy(MN) cases. Anti M-type Phospholipase A2 receptor antibodies(Anti PL A-R) are seen in 70-80% of Primary MN but also present in around 30% of MA-MN cases. Further immunofluorescence studies on 1 domain-containing protein 7A(THSD7A) antibodies in MA-MN also exist. Pathological features of MA-MN usually resolve with successful medical or surgical treatment of the malignancy, or even emerge spontaneous remission. However, proteinuria may persist for months after remission of the primary disease. We report a unique case of MA-MN that did not resolve despite successful treatment of the primary disease.

Case Description: A 48 year old man with no known co-morbidities presented for evaluation of nephrotic syndrome. He had a urine protein creatinine ratio(UPCR) of 6.8 g/day; albumin 3.6 g/dL; and creatinine 1.3 mg/dL. His last anti PL A-R titre was negative. Anti PL A- R antibodies were positive at 1:400 (0.41 IU/mL). Renal biopsy showed membranous nephropathy stage III/IV, 1+ PL A-R staining. IF showed granular 4+ IgG subtype, 3+ kappa, 3+ lambda. Lambda Workup revealed adenocarcinoma of the rectum and was started on a 5-week combination chemoradiotherapy protocol. Low dose aspirin was started. Following diagnosis, he was referred to us for MA-MN. During follow-up for MA-MN for 12 months, he continued to be nephrotic with UPCR of 4.6 g/day and albumin 2.9 mg/dL. Thus, he was treated with tacrolimus initially and then rituximab. Currently, he is in remission from malignancy and nephrotic syndrome with a UPCR of 0.3 g/day and albumin 4.1 g/dL. Last anti PL A-R titre was negative.

Discussion: Our case highlights a rare clinical course different from the known natural progression of the disease and established therapeutic guidelines. Typically, MA-MN either resolves spontaneously or with management of the primary cancer without additional immunosuppressive therapy. If nephrotic syndrome persists despite cancer therapy, it is imperative for our patient, and the patient’s health care team, to continue to closely follow the patient for possible recurrence of underlying cancer. Additionally, age-appropriate cancer screening for all newly diagnosed MN cases is essential. We hope this report shall serve as a means for further discussion and research in onco-nephrology.

An Unusual Presentation of Atypical Hemolytic Uremic Syndrome in a Patient with Skin Ulcerations

Ira H. Blau, Matthew Palmer, Sadichhya Lohani. University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.

Introduction: Atypical hemolytic uremic syndrome (aHUS), characterized by microangiopathic anemia and acute kidney injury (AKI), is a rare and debilitating disease, but its diagnosis can be difficult because of potential overlap with several other autoimmune conditions. We present a case of aHUS-induced acute renal failure with skin ulcerations as initial presentation.

Case Description: A 61-year-old female presented with progressively worsening skin ulcerations on her hands after two cycles of rituximab and bendamustine for B-Cell chronic lymphocytic leukemia. She also reported cocaine use. On presentation, her physical exam was notable for bilateral ulcers on her knuckles and ankles. She was treated empirically for osteomyelitis without improvement. Skin biopsy was non-diagnostic. She was noted to have anemia, thrombocytopenia and AKI with nephrotic-range proteinuria. Other remarkable labs included a low haptoglobin and a high LDH. Urinalysis revealed dysmorphic red blood cells, and peripheral smear showed schistocytes. An autoimmune process was suggested; thus, pulse steroids was initiated. A renal biopsy was suggestive of thrombotic microangiopathy (TMA). A full immunological work-up eventually returned unremarkable. Plasmapheresis was initiated before her ADAMTS13 activity resulted at > 10%. She was then started on eculizumab. After one session of plasmapheresis and four doses of weekly eculizumab 900 mg, her platelet counts improved. However, she required initiation of renal replacement therapy. TMA panel and genetic testing showed a low factor H level and dysregulated complement cascade consistent with aHUS despite negative CFH-CFHR5 mutation. She had some improvement in urine output but continued to require hemodialysis on discharge. Biweekly eculizumab 1200 mg was continued with plan to closely monitor for renal recovery.

Discussion: Although a rare disease with features that may overlap with other autoimmune processes, aHUS can cause rapid decline in renal function, thus requiring early identification and treatment. Eculizumab mutation and the treatment of aHUS was initiated in 20% of the patients. In the presence of the dysregulated complement cascade, microangiopathic process and renal failure, early treatment with eculizumab is crucial in renal recovery, but the renal response to treatment can be delayed compared to the hemolytic response.

Renal Medullary Carcinoma Causing Obstructive Uropathy

Ramon A. Seneriz,2,1 Yanetsa Olivera Arencibia,2,1 Oscar A. Garcia Valencia,2,1 Juan D. Salcedo Betancourt,2,1 Oliver Lenz,2,1 University of Miami, Coral Gables, FL; 2Jackson Memorial Hospital, Miami, FL.

Introduction: Hypertrophy of the prostate (BPH) is a common cause of obstructive uropathy in older men. Here we present the case of a 62-year-old Hispanic man with BPH who was found to have an additional rare cause of hydronephrosis, namely renal medullary carcinoma (RMC).

Case Description: A 62-year-old Cuban male with a history of hypertension and BPH presented for urodynamic testing for worsening lower urinary tract symptoms. Further questioning revealed fever, chills, and 20-pound weight loss over 2 months. Laboratory data were remarkable for serum creatinine of 2.7 mg/dL. Urinalysis showed pyuria and bacteriuria but no casts. After placement of an indwelling urinary catheter and drainage of 500 mL of urine, a renal ultrasound showed increased kidney size (right: 10.8 cm x 5.2 cm and left: 15.2 cm) and moderate left-sided hydronephrosis for which a percutaneous nephrostomy was placed. A computed tomography revealed multiple nodular lesions in the liver, bones, right adrenal gland, and lungs, and tissue retrieved by liver biopsy was suspicious for PAIX-positive carcinoma. MR1 demonstrated findings concerning renal medullary carcinoma in the left kidney. A biopsy of the renal mass showed RMC. Percutaneous biopsy of the mass showed tissue positive for PAX-8, Pan-K, and CA-IX (focal) and negative for INI-1, confirming the diagnosis of RMC.
Effect of Gemfibrozil on Kynurenine Aminotransferases Activity and Kynurenic Acid Production in Rat Kidney

Rachana Marathi,1 Swetha Rani Kanduri, Karthik Kovvuru, Pradeep Vaitla. University of Mississippi Medical Center, Jackson, MS.

Introduction: Estimation of glomerular filtration rate (GFR) is important in assessing kidney function. GFR is a product of muscle breakdown that is filtered through the kidneys and is related to a steady-state in people with normal kidney function.

Case Description: 31-year-old African American female with a history of systemic lupus erythematosus, polymyositis, chronic respiratory failure presented with sepsis & rash. She was admitted to the hospital with fever, weight 63 kg, height 62 inches. 3 days after admission she deteriorated with worsening septic shock, requiring multiple pressors. She became deeply sedated with worsening septic shock, requiring multiple pressors. She became anuric secondary to acute kidney injury from septic shock, however, they were able to resolve the urine creatinine (SCr) to 60 μM/l/min/1.73m2. Despite the patient’s lack of muscle mass, muscle biopsy was performed which showed “skeletal muscle was almost entirely replaced by fat and the few remaining fibers were mostly necrotic”. Although the patient’s SCr continued to rise compared to baseline, it was still well below or within normal limits with a peak of 0.54 μM/l/min/1.73m2 despite the patient being anuric and required renal replacement therapy for metabolic clearance and volume management.

Discussion: Acidosis is not directly related to muscle mass and muscle breakdown, it is not surprising that our patient with little to no muscle mass maintained an unusually low SCr despite deteriorating renal failure. SCr value of 0.06 μM/l in a normal weight adult is one of the lowest reported values in the medical literature. eGFR based on SCr is the most common method of estimating kidney function it is important to recognize that the eGFR based on SCr may not be an accurate representation of the renal function, especially in persons with low muscle mass.

Conclusion: GFR decreases KYN production in rat kidney in vitro through inhibition of KAT I and KAT II isoenzymes. Present results indicate a novel mechanism of gemfibrozil’s action in the kidney. Its potential role in nephrotoxicity needs verification in upcoming studies.
PUB230

**Influence of Biopsy Prognosis on Graft Survival**

Cristina Andrades Gómez, Jorge Calvillo-Arbizu, Miguel angel Pérez valdivia, Gabriel Bernal blanco, Jose Luis Rocha Castilla. Hospital Universitario Virgen del Rocio, Sevilla, Spain.

**Background:** Renal transplantation is the best alternative renal replacement option for patients with advanced chronic kidney disease. However, the supply of young donors is limited, and does not cover the demand of patients on the renal transplant waiting list. For this reason, older donors are being used, and a high discard rate of those organs exists based on pathological results (score) of the preimplant renal biopsy. There are several methods to evaluate the quality of the kidneys and the Kidney Donor Profile Index (KDPI) has acquired special relevance to decide the performance of preimplant renal biopsy. Based on the score, a preimplant renal biopsy is performed, which is decisive in certain cases. However, there is poor evidence to support this decision, which can be described as “conservative,” since there is not enough certainty that there is influence of the preimplant biopsy score influences graft survival.

**Methods:** 389 biopsies of kidney transplant donors of cadaver donors in brain death and asystole type III were included. Donors in asystole type II, combined and live, were excluded. Samples were examined by the same pathologist and in paraffin (no case by freezing). A graft survival analysis was performed based on the results of the renal biopsy (score). Likewise, a multivariate analysis of graft survival was carried out including, in addition to the results of the renal biopsy, results such as the age of the donor and recipient and the KDPI.

**Results:** Graft survival was compared between two transplant subpopulations in our hospital based on whether a preimplant biopsy was performed. According to the data used there are no significant differences in graft survival between transplants in which biopsy has been performed or not.

**Conclusions:** The preimplant biopsy score by itself and the evaluation of the different histological components in the biopsy have no influence on graft survival. We believe that predictive indices that combine donor and recipient histological and clinical variables should be implemented.

PUB231

**De Novo Post Kidney Transplantation Thrombotic Microangiopathy**

Janany J. Sabescumur,1 Jeremy G. Taylor,1 Rauf Shahbazov,2 David M. Dewolfe.1 1University of Rochester, Rochester, NY; 2State University of New York Upstate Medical University, Syracuse, NY.

**Introduction:** De novo post kidney transplantation thrombotic microangiopathy (TMA) is rare. We present two cases of post kidney transplant TMA acquired from the donor kidney

**Case Description:** A 26 year old male with a significant past medical history of end-stage kidney disease secondary to hereditary focal segmental glomerulosclerosis (FSGS) requiring initially presented for deceased donor kidney transplantation. The kidney donation was from a brain death donor with no significant medical history. The preliminary kidney biopsy of the donor kidney revealed focal patchy acute tubular necrosis (ATN). Induction immunosuppression included a total dose of 5 mg/kg of thymoglobin and followed by initiation of tacrolimus for goal trough of 8 - 10 mg, prednisone 40 mg, and mycophenolate 1000 mg twice daily. The patient had delayed graft function with a creatinine initially at 18 mg/dL which only reduced to 17 mg/dL over the next couple of days. On postoperative day 5, the patient was dialyzed due to symptomatic ureemia. In addition, he was noted to have developed worsening anemia and thrombocytopenia with a platelet count dropping from 208 to 47 per microliter of blood. A renal biopsy was pursued and the pathology results revealed post-transplant thrombotic microangiopathy (TMA) due to hemolytic uremic syndrome. In addition, the final donor kidney biopsy had later revealed thrombotic microangiopathy within approximately 60% of the glomeruli. The patient who received the second kidney had a similar clinical course. Both recipients received one dose of eculizumab with improvement in allograft function. They were both discharged without hemodialysis with close follow up.

**Discussion:** TMA was acquired by the donor TMA which was likely caused by ATN. It wasn’t until later in the course that the final biopsy report of the donor kidney revealed TMA which confused the diagnosis of allograft kidney injury.

PUB232

**Hypercalcemia Secondary to Hyperthyroidism: A Unique Cause of Renal Failure in a Kidney Donor**

**Introduction:** Hyperthyroidism is associated with increased bone resorption resulting in hypercalcemia (HCA). Chronic HCA leads to defect in concentrating ability of kidneys by downregulation of aquaporin-2, calcium deposition in medulla, impairing osmotic gradient resulting in polyuria and persistent pre-renal state. HCA causes renal vasoconstriction leading to acute tubular injury (ATI) followed by atrophy and interstitial fibrosis (IFTA).

**Case Description:** We present a case of a 70 yr old female who donated a kidney 5 yrs ago with serum creatinine (Cr): 1.18mg/dL and Calcium (Ca): 10.2mg/dL at 2 yr fu. At routine 3 yr fu, Cr of 4.4mg/dL, BUN of 70 mg/dL, and Ca of 12.6mg/dL were noted. Kidney biopsy showed ATL severe IFTA, negative for any immune deposits (Figure 1A). Work up of HCA revealed; PTH: 5 (18.5-88 pg/ml), 25(OH)D: 55 ng/ml, 1-25(OH) D3: 70 ng/ml, angiotensin converting enzyme level: 42 (9-47 U/L), serum/urine protein electrophoresis: negative, PTHrp: <2 pmol/L, Vit A: 76 (22-69.5ug/dl) and detailed cancer work up was negative. CT scan revealed enlarged thyroid nodule (biopsy negative for cancer) and nuclear scan showed overactive thyroid nodule(Figure 1B). Thyroid studies [TSH: <0.005 (0.35-3.7 uIu/ml), FreeT4: 2.49 (0.76-1.46ng/dl)] were treated with radioactive iodine, methimazole and low dose steroids. After 9 months labs improved- TSH: 0.01 uIu/ml, FreeT4:0.93 ng/dL, Ca: 9 mg/dl and PTH: 42pg/ml. Unfortunately, Cr remained at 4.0mg/dL due to prolonged HCA leading to stage 5 CKD which eventually resulted in successful kidney transplant (KTx).

**Discussion:** To our knowledge we report the first case of irreversible renal failure in a kidney donor due to prolonged HCA from hyperthyroidism eventually requiring KTx. Progression of renal disease from prolonged HCA may be due to limited renal mass as a solitary kidney. Hence, prompt treatment and correction of hyperthyroidism and hypercalcemia may help in preventing progression of renal disease.

Outcomes in Kidney Transplantation from Increased-Risk Donor Organs: A Single-Center Experience

Maria L. Safar-Bougeri,1,2 Jean M. Francis,2 Northwestern University Feinberg School of Medicine, Chicago, IL; 3Boston University, Boston, MA.

Background: Despite their lower Kidney Donor Profile Index (KDPI) score and demonstrated survival benefit of transplantation as compared with remain on dialysis, Public Health Service increased-risk donor (IRD) organs continue an underutilized source for transplantation.

Methods: This is a single-center retrospective cohort conducted at Boston Medical Center. Patients receiving IRD organs from 2016 and 2019 were evaluated. Baseline characteristics and outcomes one year after transplantation were described.

Results: We included 41 patients receiving IRD organs. Donors tended to be younger, with lower KDPI scores and good kidney function. Most common cause of death was anoxia from drug intoxication. Patients receiving IRD organs had stable kidney function at one year, with >70% having an estimated glomerular filtration rate (eGFR) of >60 mL/min (Table 1). None of the patients became positive for HBV, HCV or HIV.

Conclusions: Patients receiving IRD organs did not show a higher risk of infection or poor renal outcomes in this single-center population.

Post-Transplant Lymphoproliferative Disorder (PTLD): A Single Institutional Experience

Inês D. Coelho,1 Sofia Cerequera,2 Catarina Romãozinho,2 Rita Leal,2 Rui Alves,2 Arnaldo Figueiredo,2 1Centro Hospitalar De Trás- os- Montes E Alto Douro, E.P.E., Vila Real, Portugal; 2Centro Hospitalar e Universitario de Coimbra E.P.E., Centro Hospitalar e Universitario de Coimbra E.P.E., Coimbra, Coimbra, PT, Coimbra, Portugal; 3Hospital Amato Lusitano, Castelo Branco, Portugal.

Background: PTLD are a group of heterogeneous lymphoid proliferations in chronic immunosuppressed recipients of solid organ and hematopoietic stem cell transplantation. This study aimed to evaluate the clinical outcomes and to identify the predictors of mortality in adult renal transplant recipients who developed PTLD.

Methods: We have studied the incidence of PTLD in adult renal transplant recipients who were transplanted in our hospital from 1996 to 2019. Data was collected for demographics, transplant and immunosuppression history, EBV and CMV serostatus, diagnosis, treatment and outcomes. We performed uni and multivariate analysis to identify prognostic factors. PTLD was classified according to 2018 WHO lymphoma classification.

Results: Twenty-four patients (12 males and 12 females) were eligible for the analysis. Mean age at time of the transplant was 43.1 ± 16.9 years, with a time between grafting and PTLD of 66 months (IQR 36-98 months). Mean follow-up time was 87 months (IQR 61-117 months). 25% of patients received a living donor renal transplant. 5 cases were from Epstein-Barr virus (EBV) mismatched (D+/R-) transplants and there was no seroconversion at time of PTLD diagnosis. 25% of patients have central nervous system involvement. 19 patients have monomorphic PTLD and the most common histological diagnosis was diffuse large B cell lymphoma. We identified that age >30 years at time of the transplant was a predictor of mortality (HR 33.01; 95% CI: 3.24-336.14; p=0.003). Presence of B symptoms at time of PTLD diagnosis conferred a better prognosis (HR 0.143; 95% CI: 0.035-0.579; p=0.006). All cases were managed with reduction in immunosuppression. 8 patients were treated with rituximab and there was no significant difference in the survival. 7 patients went into remission, 1 returned to chronic dialysis, and 16 patients died (15 of them due to the disease). Mean time between PTLD and death was 3 months (IQR 1-6 months).

Conclusions: PTLD is an infrequent disease with a poor prognosis. Some cases have a close relationship with EBV, but it can also develop in the absence of the classical risk factors. The factor affecting mortality in our population was age >30 years at time of the transplant. Presence of B symptoms at time of PTLD diagnosis seems to confer a better prognosis probably due to early investigation and diagnosis of the disease.

PUB235
Serum Phosphorus as a Predictor of Optimal Kidney Function in Immediate Kidney Transplantation

Daniel Murillo Brambila,1 Monica C. Jimenez Cornejo,2 Maria Concepcion Oseguera-Vizcaino,1 Eduardo Solano,1 Ana Paula B. Rubio,1 Marco A. Covarrubias,3 Hospital Civil de Guadalajara Universidad Hospitalaria Fray Antonio Alcalde, Guadalajara, Mexico; 2Universidad de Guadalajara Centro Universitario de Ciencias de la Salud, Guadalajara, Mexico.

Background: In patients with CKD, there are alterations in serum phosphorus by widely known mechanisms, including in kidney transplant patients. The objective is to demonstrate that patients who decrease serum phosphorus in immediate kidney transplantation during hospitalization predict a GFR> 60 m l / min at discharge.

Methods: Prospective longitudinal study, 39 patients transplanted were analyzed, they were followed up daily until their discharge, they were divided into three groups according to their serum phosphorus(p) levels after transplantation; Group A: p=2.5, B: p=2.6 to 4.5, C: p>4.6 mg/dl, the data were obtained on the days of hospitalization after his kidney transplant, obtaining this variables gender, age, type of donor, cold ischemia, days of hospitalization, urea, creatinine and GFR dayle until discharge, data are shown in numbers, percentages, mean, ANOVA test and ROC curve.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Results: A total of 39 patients, 30(76.9%) patients were male, a mean age(29.5), 38(97.4%) had a history of dialysis, 21(53.8%) were they transplanted by a living donor, cold ischemia an average of 127min, days in hospital an average of 5.3, serum phosphorum prior kidney transplant an average 5.7(2.3) mg/dl, in the ANOVA analysis a mean serum creatinine (Group A=8.9, B=2.2, C=2.1 mg/dl), a mean GFR (Group A=101, B=65, C=48.7 ml/min), a mean urea (Group A=4423, B=3027, C=1865 ml/day) at discharge were compared; A vs B urea P=0.03 IC=-112/391, creatinine at discharge P=0.1 IC=-6.2/0.2, GFR discharge P=0.03 IC=-9.7/11, A vs C urea P=0.07 IC=-256/5372, creatinine at discharge P=0.01 IC=-4.2/0.4, GFR at discharge P=0.01 IC=8.5/97, AUC of 0.9, with a cutoff value of 3.65mg/dl have a TFG >60ml/min P=0.001.

Conclusions: Patients who decrease serum phosphorus to normal or inclusive ranges of hypophosphatemia after immediate kidney transplantation, have better renal function than those who have hyperphosphatemia at discharge, serum phosphorus may be a predictor of optimal GFR in this patients.

Baseline characteristic, ANOVA test, ROC curve.

PUB236
Routine Monitoring of Donor-Specific Antibodies During the First Year of Kidney Transplant: Is It Underrated?

Background: Kidney transplant (KT) recipients with de novo donor-specific antibodies (DSA) are at risk of graft loss. DSA could lead to a decline in kidney function due to antibody-mediated rejection (ABMR), or be asymptomatic. Efficacy and cost-effectiveness of routine DSA monitoring are not known. Confirmation of ABMR with kidney biopsy is advised. We aim to study the utility of routine DSA monitoring (RDM) in predicting rejection in asymptomatic pediatric KT recipients.

Methods: After IRB approval, a retrospective chart review of patients who had RDM was done. Patients with clinical suspicion of rejection were excluded from the study. Demographic data and clinical features were analyzed using descriptive statistics. Continuous and categorical variables were analyzed using the student’s t-test and Fisher’s exact test respectively. A p-value <0.05 was considered statistically significant.

Results: Four out of 17 (24%) patients were tested positive for de novo DSA. There were no significant differences in age, gender, race, type of transplant, or serum creatinine between patients with positive and negative DSA. Three out of four (75%) patients had positive DSA at 4-6 months that persisted till the end of the year (1 had ABMR, 1 had T cell-mediated rejection and I had no rejection on biopsy), and one(25%) had positive DSA at 10-12 months with ABMR on biopsy. All patients with biopsy-proven rejection (BPR) received steroids, anti-thymocyte globulin, plasmapheresis, intravenous immunoglobulin, and/or rituximab based on the type of rejection.

Conclusions: In our small cohort, we found that for every 5.7 asymptomatic patients who underwent routine DSA testing, one had de novo DSA with BPR. Larger, controlled studies are required to further evaluate the efficacy of RDM.

PUB237
De Novo Thrombotic Microangiopathy Associated with Cytomegalovirus Infection and Alloreactivity: A Fork in the Road of Immunomodulation
Samir A. Medrano, Karin M. Solinich, Michael Casey, Maria Aurora C. Posadas, Vinuya Rao. Medical University of South Carolina, Charleston, SC.

Introduction: De novo thrombotic microangiopathy (TMA) may yield cross-roads of diverging therapeutic approaches, not well delineated. We describe such a case in the setting of Cytomegalovirus (CMV) viremia and suspected rejection.

Case Description: A 52-year-old female with presumed hypertensive nephropathy received a deceased donor kidney transplant (KDPI 73%) complicated by progressive allograft dysfunction after 6 months. Anti-thymocyte globulin was used for induction, while tacrolimus and prednisone was used for maintenance immunosuppression. With step-wise rise in serum creatinine (baseline 1.7 mg/dL) to 2.5, 3.4 and 5.7 mg/dL at 6, 8 and 9 months post-transplant respectively, three allograft biopsies were obtained. Secondary focal segmental glomerulosclerosis, moderate-severe interstitial fibrosis and tubulitis, and a mild tubulitis were seen in all biopsies; mild glomerulitis and peritubular capillaritis in the last two, and TMA in the last biopsy. C4d and HLA DSA were consistently negative. Despite methylprednisone given at month 8, creatinine continued to rise to 7 mg/dL by month 9. The course was complicated by leukopenia, brief thrombocytopenia (platelet count ~ 100 K/mm), progressive anemia (Hemoglobin 11.5 to 6.8 g/dl) and diarrhea in the setting of newly diagnosed CMV viremia (CMV DNA 1164 to 9117 IU/mL at months 8 and 9 respectively). Lactate dehydrogenase increased to 841 U/L with a normal haptoglobin and no reticulocytosis. Schistocytes were seen on a peripheral blood smear. ADAMS-13, von Willebrand factors, platelet counts I, H, I, B, C, 3, 4, and stool panel results were unremarkable. FK506 was switched to Cyclosporin (CYC) after diagnosing TMA. After clearance of CMV viremia and stopping valganciclovir, neutropenia resolved. Creatinine fell from 7 to averagely 5.8 mg/dL at month 10-11. Plasmapheresis (PP) and IVIG were initiated for suspected non-HLA antibody mediated rejection (AMR) with TMA.

Discussion: The constellation of TMA, CMV viremia, tubulitis, microvascular inflammation and myelosuppression, poses dilemmas in balancing management as FK506, CMV and AMR may all be contributory, in isolation or combination to TMA. We elected to maintain a calcineurin inhibitor and mycophenolic regimen in the face of TMA and CMV due to the risk of florid rejection, and initiated PP with IVIG.

PUB238
Hypofibrinogenemia as a Risk Factor of Bleeding After Plasmapheresis with Centrifuge in Renal Transplantations with Active Humoral Rejection
Mayra M. Matias Carmona,1,2 Sergio Hernandez-Estrada,1,2 Jose H. Cano,1 Odette Del Carmen Diaz Avendano,1 1Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico; 2Universidad Nacional Autonoma de Mexico Facultad de Medicina, Universidad Nacional Autonoma de Mexico Facultad de Medicina, Mexico, Mexico.

Background: Humoral rejection represents an important cause of graft loss, multiple therapeutic approaches have been implemented, therapeutic plasma exchange (TPE), is part of them, however one of its main complications as hypofibrinogenemia due to the risk of bleeding, which represents a challenge due to the risk of immunization in the event of a transfusion and even limiting the continuity of treatment due to the risk of bleeding imminent due to low figures during the passage of the session. Objective: to determine if hypofibrinogenemia(<100 mg/dl)after sessions of TPE with centrifuge is an absolute risk factor for bleeding that warrants the need for transfusion or cessation of therapy.

Methods: In the period from June 2017-May 2019, 25 Mexican kidney transplant patients with diagnosis of active humoral rejection, without previous coagulation abnormalities, were submitted to TPE, a total of 5 sessions per patient were granted in an average of 10±2 days, with measurement of fibrinogen levels before and after each session as well as daily clinical evaluation of active bleeding

Results: The age range was 21-35 years, 44% were female, the causes of ERCT up to 52% were not reported, cadaveric donor transplantation predominated in 52%, The initial average fibrinogen value was 397mg/dl, after the 1st session a reduction of 33% was observed, with an average value of 133mg/dl. The lowest level was 43mg/dl, the most important period of reduction during the 4th session. Only 1 major bleeding event was documented due to epistaxis that required transfusion. This event was after the 3rd session, with fibrinogen of 79mg/dl. At the end of TPE treatment, fibrinogen levels normalized in all patients, with no further bleeding events

Conclusions: Despite the strong association of hypofibrinogenemia and bleeding, only one major bleeding event was reported in our population. There were no other events despite having level as low as<50mg/dl, therefore we consider close surveillance as the main measure during TPE; leaving the transfusion only in the context of active bleeding. The blood tissue is rich in immunoglobulins and therefore favors the host’s immune response, it is paradoxical to remove antibodies and grant new ones with transfusions. Hypofibrinogenemia did not limit the continuity of treatment, concluding its treatment in a timely manner.

PUB239
Kidney Transplant Recipients Suffer Fewer Complications After Adrenal Surgery
Ankur P. Choube,1 Darren Abbas,1 Jonathan Demeter,1 Afshin Parsikia,2 Jorge Ortiz,1 1The University of Toledo Medical Center, Toledo, OH; 2Westchester Medical Center, Valhalla, NY.

Background: Chronic immunosuppression after kidney transplant (KT) is a known risk factor for developing a malignancy. While occurrences of other cancers have been well documented, there is a paucity of data regarding the incidence and effects of adrenal tumors after renal transplant. We aim to evaluate the differences in short-term outcomes between renal allograft recipients and the general population undergoing adrenal surgery.

Methods: A retrospective analysis was conducted using Nationwide Inpatient Sample (NIS) data between 2005 and 2014. The population of interest was adults with a kidney transplant (FK506, CMV and AMR may all be contributory, in isolation or combination to TMA. We elected to maintain a calcineurin inhibitor and mycophenolic regimen in the face of TMA and CMV due to the risk of florid rejection, and initiated PP with IVIG.

Conclusions: Despite the strong association of hypofibrinogenemia and bleeding, only one major bleeding event was documented in our population. There were no other events despite having level as low as<50mg/dl, therefore we consider close surveillance as the main measure during TPE; leaving the transfusion only in the context of active bleeding. The blood tissue is rich in immunoglobulins and therefore favors the host’s immune response, it is paradoxical to remove antibodies and grant new ones with transfusions. Hypofibrinogenemia did not limit the continuity of treatment, concluding its treatment in a timely manner.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
Results: 54 patients met the inclusion criteria. KT recipients were older (p<0.001, more likely to be African American (p<0.001), and had higher Elixhauser Comorbidity Index scores (p<0.001). We noted shorter length of stay (p<0.011), lower rates of any complications (p<0.001), and fewer packed RBC transfusion (p<0.039) compared to the non-transplant cohort. There was no mortality among transplant recipients. Weighted multivariate analyses highlight that total expenditures were lower for renal allograft recipients treated at transplant centers (p<0.021).

Conclusions: Previous publications have demonstrated that history of kidney transplant has deleterious effects on surgical outcomes. In the largest national cohort analysis of adrenal surgery after KT, we discovered that despite higher age and more comorbidities, renal transplant recipients benefited from fewer post-operative adverse events. There was additional benefit from seeking treatment at transplant centers.

PUB240
Granulomatous Tubulointerstitial Nephritis in a Kidney Transplant Recipient
Mohamed Hassanen, Leal C. Herlitz, Cyndee Miranda, Aimen Liaqat, Richard A. Fatica. Cleveland Clinic, Cleveland, OH.

Introduction: Granulomatous tubulointerstitial nephritis (GTIN) is a rare pathological diagnosis accounting for 6% of all causes of tubulointerstitial nephritis (TIN). Causes of GTIN include fungal and tuberculous infections, sarcoidosis, and medications. We describe a case of GTIN in a kidney transplant recipient (KTR).

Case Description: A 65-year-old male with a history of diabetes mellitus, hypertension, active pulmonary and ocular tuberculosis (TB), and a deceased donor kidney transplant 8 years prior was admitted for acute kidney injury (AKI). Medications includedisoniazid, rifampin, carbendazil, insulin, and tacrolimus. Serum labs showed: creatinine (Cr) 2.65 mg/dL (baseline Cr 1.13 mg/dL), corrected calcium 13.2 mg/dL, and tacrolimus trough level 7.6 mg/L. Urine sediment examination and kidney ultrasound were unremarkable. Further workup for hypercalcemia revealed: parathormone (PTH) 7 pg/mL, I-25 dihydroxy-vitamin D 54.3 pg/mL, PTH related peptide <2 pg/mL, and angiotensin-converting enzyme 47 U/L. Kidney biopsy showed TIN and non-caseating granulomas (figure A) with negative acid-fast bacilli (AFB) staining, bacterial, and fungal polymerase chain reaction. He was treated with prednisone taper over 6 weeks with complete resolution of AKI and hypercalcemia.

Discussion: GTIN in KTRs is rare, with an incidence of <1% in transplanted kidney biopsies. AKI and PTH-independent hypercalcemia with a negative workup for other causes of AKI should prompt a kidney biopsy. Granulomas with multinucleated giant cells can help differentiate GTIN from acute rejection – the most common cause of TIN in KTRs. By negative AFB staining of the biopsy tissue sample, it was impossible to exclude tuberculous GTIN in our patient who was on anti-tuberculous therapy. Cautious initiation of steroid therapy can be effective in these cases.

PUB241
Kidney Transplants from Deceased Donor After 11 Days of Hemodialysis
Ankur P. Choubey, Obi Ekewenna, Michael Rees, Jorge Ortiz. The University of Toledo Medical Center, Toledo, OH.

Introduction: There is little consensus on the use of organs from donors with acute kidney injury (AKI) for kidney transplantation. Previously, the longest reported duration of dialysis before donation was 4 days. We detail the first successful kidney transplants from a donor after 11 days of hemodialysis.

Case Description: Donor was a 60-year-old male with advanced-stage hypertension, on dialysis for 2 years with EPTS of 41%. Cold ischemia time (CIT) and pump time were 32 and 103 hours. Post-operative DGF required two dialysis sessions. Recipient was a 61-year-old male with ESRD from diabetes, on dialysis for 6 years with an EPTS of 90%. CIT and pump time were 26 and 10 hours. Profuse bleeding from graft biopsy site and pseudoaneurysm formation required treatment with transfusions, and dialysis for DGF. He was re-admitted with hyponatremia and carbapenem-resistant enterobacteriaceae sepsis, requiring nephrostomy tube and antibiotics.

Conclusion: Careful selection based on donor youth, good health without comorbidities, and injury by rhabdomyolysis were crucial in this case. Moreover, biopsies revealed excellent histology, with good flow and resistance on perfusion pump. These factors made the kidney's acceptable for transplant despite DCD donor with prolonged dialysis and CIT. Both patients received Tacrolimus, Mycophenolate and Prednisone. On follow up, recipients were dialysis independent and making urine. Complications in recipient 2 required prolonged hospitalizations, but none of the adverse events were due to donor AKI. Take Away: This case report is a novel opportunity to understand the extent of kidney transplantation after AKI. Despite 11 days of hemodialysis and DCD donor, procurement was possible because AKI due to rhabdomyolysis is transient and resolves within weeks. AKI donor-recipient matching is an individualized process. Clinician decision-making with rigorous donor and recipient selection is paramount in transplanting AKI organs. Post-operative DGF management is crucial in restoring graft function.

PUB242
Acute Rejection of Renal Allograft Caused by Drug-Induced Acute Interstitial Nephritis
Wina Youssouf,1 Wei Xiang Wong,2 Secar C. Boyadjian,1 Erika R. Bracamonte,1 Pablo Loarte Campos.2 University of Arizona College of Medicine, Tucson, AZ; 1Montefiore Medical Center, The Bronx, NY.

Introduction: We report a case of a 42-year-old man who had a living-unrelated kidney transplant in 2017 from a non-ESRD donor. Post-operative biopsy revealed drug-induced acute interstitial nephritis. He had an uncomplicated course with no episodes of rejection. He has been on a triple immunosuppressive regimen. Other past medical history was refractory autoimmune hemolytic anemia at age 20 that required splenectomy.

Case Description: In 2019, he developed fever and rash shortly after taking a 5 days course of azithromycin. This was associated with marked eosinophilia and an increase in his serum creatinine (sCr) from 1.0 mg/dL to 3.1 mg/dL. Donor Specific Antibody (DSA) was negative. Kidney biopsy showed active tubule interstitial nephritis with prominent eosinophils. He received pulse steroids followed by tapering oral steroids. His sCr improved to 2.7 mg/dL. A month later, he was admitted for hematuria and acute kidney injury. His sCr was 4.2 mg/dL. Urinalysis showed trace protein, RBC >50 HPF, and WBC 11-20 HPF. Tacrolimus level was within the therapeutic range.DSA was positive for class II; DQA1*05:01, DR17, DR52 with 18,000 MFI. Kidney biopsy showed mixed rejection; acute cellular rejection (ACR) Banff IIB and acute antibody-mediated rejection (ABMR)/C4d positive. He was treated with high dose IV steroid, thymoglobulin, plasma exchange, and Rituximab. His sCr did not improve. Repeat biopsy showed improvement of ACR Banff IA along with capillaritis and glomerulitis, suggesting ongoing ABMR but C4d staining became negative. On the last biopsy, there was diffuse interstitial fibrosis.

Discussion: We hypothesize that Acute Interstitial Nephritis (AIN) primed the T-cells lymphocytes to react against the allograft. His sCr improved after treatment of AIN, followed by worsening of sCr and reflecting mixed rejection. The treatment of rejection led to some improvement but did not resolve the ongoing damage that ultimately caused significant fibrosis with poor chances for recovery. To our knowledge, this is the first case where AIN is followed shortly by a mixed allograft rejection even in a patient with a previous HLA mismatch. In the past, splenectomy was the treatment of mixed ABMR. In conclusion, rejection should be considered as one of the differential diagnoses when renal function worsens after the treatment of AIN.

PUB243
Kaposi Sarcoma: A 30-year Experience of a Portuguese Kidney-Transplant Center

Background: Kaposi sarcoma (KS) is a low-grade angioproliferative tumor associated with human herpesvirus 8 (HHV-8) infection, which incidence is higher in kidney-transplant recipients (KTR). This study aimed to review all cases of KS diagnosed in KTR, over the past 30 years, at our center. A total of 1476 transplants were performed during this period.

Methods: We reviewed all histologically diagnosed KS in KTR. Data were collected from electronic and paper medical records.

Results: Seven KTR were diagnosed with KS, of which 6 were men and 1 was HIV positive, all caucasian. The mean age at the time of KT was 51 ± 18 years. Six cases occurred before 2010 and the last case in 2018, in an HIV positive patient and the only one to receive induction immunosuppression - IS (basiliximab). All but 1 patient were on maintenance IS with prednisone (PDN), a calcineurin inhibitor (CNI) and mycophenolate mofetil (MMF). The median time of transplant at KS diagnosis was 9 (2 – 99) months. Six patients had only cutaneous lesions, mainly in lower limbs and one also had abdominal lymph nodes involvement. HHV-8 viremia, evaluated in 2 patients, was positive. In 6 cases, KS was diagnosed by an mTOR inhibitor (MMF) and MMF was maintained with PDN and reduced dosage of CNI. All except one received antineoplastic

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
treatment: 3 were submitted to radiotherapy (RT), 1 to chemotherapy (CT) and 2 had both RT and CT. The remaining 8 patients underwent dorzoxurbin was the drug of choice. At follow-up, 1 patient remains with normal kidney function, 1 with chronic graft dysfunction and 2 lost their KT (one by antibody-mediated rejection 3 months after KS diagnosis, and one by chronic graft dysfunction after 19y of KT, 14y after KS). Three patients have already died (withdrawn graft function) one directly to KS.

Conclusions: Despite the scarcity of published series on KTR, the experience of KS in our center is in line with the literature, since it’s more common in man, the incidence is higher in the first 2 years after transplant and cutaneous lesions were the most frequent manifestation. In our series, a lower incidence of KS in the last decade has been reported. However, thorough surveillance in higher-risk groups, as HIV patients, should not be forgotten.

PUB244
Rapid Renal Allograft Failure Following Recurrence of Lupus Nephritis 12 Years After Renal Transplant

Sreedevi koppisetty Jenigiri, Jayesh B. Patel, Prerna Kumar, Christie P. Thomas, Sarat C. Kuppachi. University of Iowa, Iowa City, IA.

Introduction: End stage kidney disease (ESRD) secondary to lupus nephritis (LN) is an important complication of systemic lupus erythematosus (SLE) for which the treatment of choice is to undergo a kidney transplant (KT). Following a KT, patients rarely develop recurrent lupus nephritis (RLN), but when they do, most events of recurrence occur within a few years after KT. We describe the case of a young Caucasian lady who underwent a living related KT for LN and maintained stable renal function for 12 years, and then developed severe RLN that was unresponsive to treatment.

Case Description: A 39-year-old developed LN and her kidney biopsy (KB) demonstrated global sclerosis with immune complex glomerulonephritis with positive serum antinuclear (ANA) and anticardiolipin antibodies (ACA) in 2006. She received living related KT in 2007. Her post-transplant course was complicated with the development of Banff grade IIa acute cellular rejection 1-month later, which was treated with steroids. She responded to treatment and attained a basal serum creatinine (Cr) measuring 1.2 to 1.3 mg/dL. She was maintained on tacrolimus, mycophenolate mofetil (MMF) and prednisone. Her MMF was replaced with azathioprine during an uneventful pregnancy in 2011. She had a slight increase in her baseline Cr over the years but maintained a stable Cr measuring 1.4-1.6 mg/dL. In 7/2019, the Cr suddenly increased to 3.9 mg/dL with proteinuria and microscopic hematuria. Her platelet counts, complement, ANA, ANCA and double stranded DNA levels were normal. A KB demonstrated features of thrombotic microangiopathy, diffuse proliferative GN with focally crescentic LN and full house pattern on IF. Despite treatment with intravenous steroids and cyclophosphamide, her renal allograft function deteriorated, she required dialysis by 11/2019.

Discussion: Even patients with stable renal function maintained on standard immunosuppressive medications many years after transplantation are at risk of RLN. Our case demonstrates that RLN can manifest suddenly, and with a lack of usual laboratory features characteristic of a lupus flare. Further studies are necessary to better identify reasons for lupus recurrence in patients with long standing stable renal function.

PUB245
Simultaneous Disseminated Adenovirus Infection and Rejection in a Kidney Transplant Patient

Vatsalya Kosuru, Imran Y. Gani, Azeme A. Mohammed, Rajan Kapoor, Sandeep A. Padala. Augusta University, Augusta, GA.

Introduction: Adenovirus can lead to serious conditions in the immunocompromised transplant recipients. It infects urothelium and causes acute hemorrhagic cystitis and either nephritis or acute rejection causing functional deterioration of transplanted kidney. Case Description: A 55-year-old male with history of ESRD on hemodialysis received a deceased donor renal transplant. After induction with steroids and Thymoglobulin, he was maintained on mycophenolate mofetil (MMF), tacrolimus and prednisone with stable creatinine of 1.1-1.3 mg/dL. After 6 months, he presented with right lower quadrant abdominal pain, hematuria, dysuria, productive cough, fever, conjunctivitis, sore throat and diarrhea. Labs showed mild elevation of creatinine (1.5 mg/dL). Urine microscopy showed non-deformed RBCs without glomerular cast. Chest x-ray and ultrasound of transplant kidney were normal. Patient was started on intravenous fluids, broad spectrum antibiotics and admission for acute kidney injury. Renal ultrasound showed transplant kidney and bilateral renal stones. Ultrasonography of renal sinus revealed Respiratory pathogen panel (RPP) was negative for any pathogen. Urine culture had no growth. Cystoscopy was unremarkable. Patient had worsening leukopenia and proteinuria of 3.3 grams. A repeat RPP was positive for adenovirus and serum Adenovirus PCR was 28,600 copies/mL. Biopsy of transplant kidney showed mild tubulo-interstitial rejection with transplant glomerulitis and negative for adenovirus nephritis. Due to simultaneous occurrence of infection and acute transplant rejection, MMF was reduced to 250mg BID and pulse steroids were started for 5 days. Serum adenovirus PCR was decreased to 1200 copies/mL on day 5. Repeat biopsy was done on day 10 and showed a decrease in Adenovirus PCR to 1900 copies/mL. Decreasing immunosuppression was avoided given recent rejection episode. Patient’s IgG level was low at 549 mg/dL and a dose of 300 mg/kg IVIG was administered. Repeat urinalysis showed resolution of hematuria and proteinuria. Serum Adenovirus PCR was undetectable at 2, 3 and 4 months follow up.

Discussion: Disseminated adenovirus infection after renal transplantation is becoming more prevalent. The treatment includes reducing the immunosuppressive therapy, IVIG infusions, anti-viral agents, or combination of these therapies. The approach to therapy is based on the local guidelines for selection, timing and efficacy of treatment modalities, which requires further investigation.

PUB246
A Case Report of Transplant Renal Artery Stenosis Presenting as Acute Encephalopathy and Cardiac Arrhythmia in a 28-Year-Old Man

Neibert Jay B. Olivares, Davao Medical School Foundation Hospital, Inc. Davao Medical School Foundation, Davao Medical School Foundation Hospital, Davao City, PH, Davao City, Philippines.

Introduction: Transplant renal artery stenosis (TRAS), defined as narrowing of the transplanted renal artery, is one of the most serious vascular complications post kidney transplantation. TRAS presents as hypertension and allograft dysfunction at 3 to 12 months after transplantation. Unique to this case is the early presentation with behavior changes and cardiac arrhythmia. No report of such has been published as of this writing, especially in a third world setting.

Case Description: This is a case of a 28-year-old filipino male patient with post kidney transplantation one month prior to admission. Donor and recipient matching revealed low immunologic risk for rejection with four HLA matched. Transplantation was unremarkable. He presented at the ER with behavioral changes, incoherence and SVT on ECG. Medical cardioversion with adenosine and verapamil was done. He was immediately dialedyzed and noted resolution of symptoms. Course in the ward was unremarkable except for the persistence of hypertension and elevated creatinine. Doppler ultrasound is suggestive of TRAS on main renal artery allograft. Renal CT angiography confirmed 66% stenosis of right renal artery graft. He was given amiodipine 10mg/day and eventually underwent renal angioplasty as the definitive procedure to correct stenosis. Post angioplasty blood pressure was normal and remained on this level for the following days. Serum Creatinine lowered down to 110 umol/L. Repeat Doppler study showed an angioplasty stent in the main renal artery graft. On his follow-up check up, his serum creatinine and BP remained on normal levels.

Discussion: The case proves that although TRAS usually presents at 3 to 12 month post kidney transplant, it may occur earlier and unusually with encephalopathy and SVT. Doppler ultrasound is in essential in early detection, however, Renal CT angiogram is the imaging of choice for the confirmatory diagnosis. TRAS is catastrophic but early diagnosis and prompt medical-surgical intervention with amiodipine and renal angioplasty can lead to improved allograft survival and good prognosis for the patient.

PUB247
Management of Kidney Transplant Waiting List in Belarus

Aleksandr Kalachyv, Minsk Scientific and Practical Center of Surgery Transplantology and Hematology, Minsk, Belarus.

Background: The reasons for establishing an automated waiting list system were as follows: the main clinical information about patients was available only on paper, there was a problem of optimal choice from the list of compatible donor-recipient pairs based on a large number of factors, there were difficulties with information transfer rate, security and reliability.

Methods: The project was implemented as a web-application. The program’s interface includes several parts: Unit “file-cabinet” that contains patients’ passport data and contact information Unit “Clinical information” includes immunological and clinical data of recipients Units “Examination” and “Confirmation of the consent” is based on examination results and determines the suitability waiting list Unit “Recipient selection” Unit “Calculator of graft function”.

Results: Web application helps to allocate donor organs by medical and social principles of selection. The social principles are: priority of patients who waited kidney transplant longer considering of donor and recipient territorial compatibility increased chances for kidney transplant patients with “incomplete” phenotype (homozygotes) priority for highly sensitized patients priority for children priority for patients who needed multiple-organ transplantation Medical principles: balance between the potential kidney transplant and recipient survival stratified accounting of histocompatibility degree between donor and recipient reduction of kidney transplant cold preservation time creation of transplantation priority conditions for patients who needed urgent kidney transplantation initial kidney graft function prognosis accounting Scoring system is based on the fact that the main feature of social justice (maximum waiting period) is equated domain medical principle of effectiveness (maximum compatibility degree). The allocation of organs accounts the risk of early graft dysfunction (automatic kidney graft functional calculator based on multifactator analysis of donor - and recipient-dependent risk factors is implemented). The final result is a prioritized list of recipients with a score of each factor and to perform the final selection of the council of physicians.

Conclusions: The software application allows to keep records, make statistical data analysis of potential recipient, distribute the organs anytime, anywhere in the world where the Internet is available.

Late-Onset Recurrent Granulomatous Interstitial Nephritis in Transplanted Kidney with Successful Treatment: A Case Report
Fatmah Yamani,1 Miroslav Sekulic,1,2 Arksarapuk Jittirat,1,2 1Case Western Reserve University, Cleveland, OH; 2University Hospitals Cleveland Medical Center, Cleveland, OH.

Introduction: End stage renal disease (ESRD) secondary renal sarcoidosis is rare and likely due to hypercalcemic nephropathy. There is limited data on recurrent renal sarcoidosis post kidney transplant. We report a case of unusually late onset, recurrent sarcoidosis in transplanted kidney with successful treatment.

Case Description: A 65 year-old female with history of pulmonary sarcoidosis and ESRD due to sarcoidosis related-granulomatous interstitial nephritis (GIN) received a renal transplant in 2008. She was maintained on tacrolimus, mycophenolate(MMF) and prednisone. Baseline serum creatinine (SCr) had been 1.5 mg/dL. In 2017, patient was diagnosed with recurrent metastatic colorectal cancer. In 2019, her SCr increased to 3 mg/dL. A transplant kidney biopsy showed non-necrotizing GIN. She was treated with prednisone 40 mg daily. SCr decreased to 2.3 mg/dL. 3 months later, a repeat transplant kidney biopsy showed resolution of GIN. Prednisone dosage was tapered.

Discussion: GIN related to sarcoidosis has an overall estimated occurrence at 0.18 % of native kidney biopsies. GIN in transplanted kidney due to recurrent sarcoidosis has been reported ~17%. Risk factors for recurrence include primary renal disease related to sarcoidosis and a shorter delay between the last sarcoidosis flare and renal transplantation. Recurrence typically occurred shortly after transplantation, averaging 13 months after transplantation. More studies on treatment of recurrent renal sarcoidosis are warranted. We report a case of late onset recurrent GIN, occurring 11 years after transplantation with successful treatment.

Elevated Donor-Derived Cell-Free DNA as an Indication for Kidney Transplant Biopsy
Aileen Transplant Biopsy

Background: Donor derived cell-free DNA testing (dd cf-DNA) is increasingly employed for post-kidney transplant monitoring and may influence the decision to proceed with indication biopsy. The goal of this study was to identify those patients in whom the finding of an elevated dd cf-DNA was a key factor in the decision to obtain a kidney biopsy and to review 1) their biopsy findings and 2) any resulting treatment.

Methods: We reviewed the charts of 73 patients who underwent kidney transplant biopsy and had at least 1 dd cf-DNA (AlloSure) test performed. Ten patients underwent biopsy prompted primarily by an elevated dd cf-DNA level. Biopsy findings and resultant therapeutic interventions were abstracted.

Results: The median time from transplant to biopsy was 25.5 months. 2/10 patients had a normal biopsy. 5/10 had histological findings consistent with antibody mediated rejection (ABMR) with or without concurrent T-cell mediated rejection (TCMR). 2/10 had TCMR and 1/10 had recurrent glomerulonephritis. Of those with ABMR, 1/5 had a de novo HLA donor specific antibody (DSA) and 3/5 had positive non-HLA antibody (AT1 receptor antibody (AT1R)). 8/10 patients had a therapeutic intervention following biopsy. Dd cf-DNA decreased following treatment in 4/7 patients and did not change or worsened in 3/7 patients with available follow-up dd cf-DNA testing.

Conclusions: Kidney transplant biopsies in patients with an elevated dd cf-DNA frequently yield findings that warrant therapeutic intervention. Kidney transplant biopsy should be considered in patients with elevated dd cf-DNA, even if otherwise stable. Our observations warrant further examination on the utilization of long term dd cf-DNA monitoring, particularly in immunologically high risk kidney transplant recipients.

Disseminated Nocardiosis in Renal Transplant Recipient
Mohamedanwar M. Ghandour, Marecena S. Zachariah. Wayne State University School of Medicine, Detroit, MI.

Introduction: Nocardiosis is an uncommon opportunistic Gram-positive bacterial infection caused by aerobic actinomycetes in the genus Nocardia. Nocardia can cause localized or systemic suppurative diseases involving eyes, kidneys, skin, lungs, bone, and central nervous system. Disseminated Nocardia is a rare condition, seen among immunocompromised patients.

Case Description: We report the case of a 55-year-old African American kidney transplant recipient on maintenance immunosuppression, who was diagnosed with cutaneous and pulmonary Nocardiosis. Presenting symptoms were shortness of breath, bilateral lower extremities pain and swelling. Tissue culture grew gram-positive bacilli specified as Nocardia farcinica from thigh and gluteal abscesses (figure 1). CT thorax showed bilateral reticulonodular opacities (figure 2). Patient was managed with immunosuppression reduction and specific treatment with high dose Bactrim in conjunction with linezolid. Combination antibiotics were continued for four weeks, thereafter Bactrim alone was continued for twelve months, at which point all lesions had healed.

Discussion: Nocardiosis with systemic involvement carries a poor prognosis. The reported patient had disseminated Nocardiosis involving lungs and skin, though lungs were thought to be the primary source of infection. However, early diagnosis and appropriate antibiotic coverage, had a favorable outcome, in a renal transplant recipient. Recommended treatment duration is 6 to 12 months with frequent imaging.
Case Description: After treatment of esophageal candidiasis, a 50yo male KTR presented with persistent odynophagia, dysphagia, dysphonia, fever, hipocacusis, otalgia and vesicular lesions in the external left auditory canal, compatible with Herpes Zoster Oticus. He had undergone a deceased-donor kidney transplant ten years before, and maintained on mycophenolate mofetil (1.5 g/d), tacrolimus (2 mg/d) and prednisone (7.5 mg/d). He received Campath induction and tacrolimus. A nasofibrobroncoscopy showed unilateral paralysis of the left vocal cord with saliva aspiration. Computed tomography scan of cranium, neck and thorax excluded expanded lesions. Blood polymerase chain reaction test detected Varicella-Zoster Virus (VZV). Due to severe dysphagia with significant weight loss, reaching 35 kg, he received enteral nutrition through a nasogastric feeding tube during 12 weeks. He gradually recovered motor function of the 7th and 10th cranial nerves. Six months after the onset of symptoms, the patient is under full immunosuppressive therapy and feeding through mouth with occasional choking to some solids.

Discussion: Reactivation of pre-existing VZV in craniospinal sensory ganglia causes Herpes Zoster, which is characterized by a painful erythematous rash in the affected dermatome. Ramsay-Hunt Syndrome occurs when VZV affects neurons of the geniculate ganglion. When it occurs unusually with multiple cranial neuropathies it leads to a potential missed diagnosis and delayed treatment.

PUB254

Tacrolimus: A Worth-Considering Culprit for Post-Transplant Anaemia Sensitive to Parvovirus B19

Mvint T. Ave, Arvind Singh. University Hospitals of Plymouth NHS Trust, Plymouth, United Kingdom.

Introduction: Haematological side effects of tacrolimus seem to be rare and their aetiology is unclear. Parvovirus B19 is an uncommon yet clinically significant infection that manifests as refractory anaemia in post-transplant patient. The exact mechanism by which tacrolimus can aggravate pure red cell aplasia (PRCA) is still unclear. Here we report a case of post-transplant anaemia where withdrawal of tacrolimus demonstrated significant improvement in chronic transfusion dependent anaemia.

Case Description: A 66-year-old male with end stage renal failure due to accelerated hypertension had a deceased donor transplantation in 2018. Before receiving his transplant, his peripheral blood counts were relatively normal. Patient was discharged nine days after operation with haemoglobin of 8.2 g/dl. Approximately five weeks following transplantation, he was found to have profound anaemia with haemoglobin level falling to 5.7 g/dl but white cell and platelet count remained normal. Following investigations, patient was found to have parvovirus B19 with positive DNA titre. Since then patient was transfusion dependent with two weekly red cell transfusion. Patient had two courses of IVIG, however, showed only transient improvement in viral DNA titre with no haematological improvement. Finally, tacrolimus was switched to cyclosporin A and showed rapid improvement within two weeks.

Discussion: Persistent parvovirus B19 infection can occur in immunocompromised host due to impairment of the neutralizing antibody response and/or cellular immunity thus failure to clear the virus. Tacrolimus, on the other hand, is believed to be an immunosuppressive agent without significant potential for myelosuppression. In this case, transient improvement of withdrawal of tacrolimus with IVIG treatment was suggestive of an etiological role of tacrolimus. The close inverse relationship between viral DNA PCR titre and erythropoietic activity reflected by the improvement of refractory anaemia showed that the direct cause of red cell aplasia was viral infection, rather than direct drug toxicity. Parvovirus B19-induced anaemia is aggravated by the use of tacrolimus through impairment of its clearance by tacrolimus, which cannot be simply explained by a state of heightened immunosuppression.

PUB255

Use of Donor-Derived Cell-Free DNA to Identify Allograft at Risk by Late Surveillance

Anna Iaha,1,2 Diana Mahbod,1 Rama Nadella,1,3 Irfan Agha,1,3 1Dallas Renal Group, Dallas, TX; 2Methodist Dallas Medical Center, Dallas, TX; 3Medical City Dallas Hospital, Dallas, TX.

Introduction: Monitoring allograft function remains inadequate. Many allografts sustain subacute injury not detected in time resulting in poor long-term outcomes. Traditional tools utilized (renal histopathology, proteinaemia and DSA) are insensitive and/or insensitive to the progression of allograft dysfunction not picked up by traditional means, allowing active intervention and change in management.

Case Description: 36 YO WF with a H/O SLE leading to CKD, S/P LUKT in 2018. Immunosuppression maintained consisted of tacrolimus and MMF. Nadir Cr 0.8 mg/dl. Current Cr 1.0 mg/dl. Urine Pt/Cr ratio 0.06 g/g. Seen for routine visit. Surveillance DD CF DNA (Alloscore) done - 4.8%. Repeat after a few weeks - 5.4%. No DSA, ANA was at 1:40. ds DNA Ab negative. Normal complements. Biopsy was suggestive of active acute antibody mediated rejection with severe microvascular injury and renal limited TMA. C4d only focally positive. DSA repeated and negative. MICA Ab negative. ATIR

PUB251

Native Kidney Cytomegalovirus Nephritis

Sandiva Bindrog, Paul D. Killen, Mona D. Doshi. University of Michigan, Ann Arbor, MI.

Introduction: Cytomegalovirus (CMV) is the most common opportunistic infection in solid organ transplant (SOT) recipients and is estimated to affect 15-30% of high-risk SOT recipients. Typical manifestations of CMV end-organ disease includes colitis, esophagitis, hepatitis, and pneumonia. However native CMV nephritis is rare, reported in less than 1% of renal biopsies. We present a case of CMV nephritis in a high risk liver transplant recipient who completed six months of CMV prophylaxis four weeks prior to presentation.

Case Description: A 66-year-old man with history of liver transplantation was hospitalized on post-transplant day 230 for worsening kidney function (serum creatinine 4.40 mg/dL, baseline 2.0 mg/dL) and fatigability. The patient’s history was notable for cryptococcal cirrhosis and hepatorenal syndrome. Immuno therapy consisted of tacrolimus (target trough 6-10ng/mL), mycophenolate mofetil (MMF), and prednisone. The recipient was CMV seronegative and the donor was CMV seropositive. He received ganciclovir for CMV prophylaxis in first six months of transplantation, per protocol. The early post-transplant course was complicated by reactivation of muco-cutaneous herpes simples virus-1, and Cloridrona difuicile colitis. On presentation, patient reported fatigue, loose stools, and nausea. He was afebrile and had a normal white blood cell count. Serum creatinine was 4.40 mg/dL (baseline 2.0 mg/dL). Urinalysis was positive for 3+ leucocyte esterase with a full field of leucocytes and 10-50 red blood cells per high power field. Culture grew > 10^5 cfu/mL of Candida albicans. A normal renal ultrasound was noted. He was treated with intravenous (IV) cefepime to evaluate the cause of the persistent renal failure, a renal biopsy was performed, revealing acute tubular injury and focal severe interstitial nephritis. CMV intra-nuclear and cytoplasmic inclusions were visualized and confirmed by immunohistochemical staining. Plasma CMV DNA levels by quantitative PCR were 40862 IU/mL. Treatment consisted of IV ganciclovir at induction doses adjusted for renal clearance, followed by maintenance dose ganciclovir. His renal functions improved.

Discussion: We report a rare manifestation of CMV disease with evidence of CMV in native kidney. Clinicians should have a high suspicion for late onset CMV diseases as a diagnosis in at risk SOT recipients with signs and symptoms of genitourinary tract.

PUB252

Incidence and Risk Factors in Mexican Patients with Diarrhea After Kidney Transplantation

Background: Diarrhea is one of the most frequent complications after kidney transplantation. Leads to dehydration, alteration of immunosuppressants serum levels, kidney function deterioration and graft loss. The prevalence of diarrhea varies from 20-50% globally. Focusing treatment on guidelines or recommendations, without considering local microbiology, may lead to mistakes in the management of this patients.

Methods: Cohort, analytical, retrospective study, were included kidney transplant patients from January 2014 to December 2018 in the Nephrology and Kidney Transplant Department at the Centro Medico Nacional 20 de Noviembre in Mexico City. Annual cumulative incidence index was calculated and performed. Association with potential risk factors was used for the evaluation of risk factors. Survival analysis made by Kaplan-Meier curves.

Results: 92 patients were evaluated. Thirty two diarrhea episodes were recorded in 28 patients. 25% of the cases were in the first month after transplant, 40.6% of the episodes occurred up to the first six months. Authors posit that diarrhea, infections and 10% of the cases were infectious etiology suspected, but only 45.8% had microbiological isolation. The most frequently isolated microorganism was Entamoeba histolytica in 45.5% of the cases. The cumulative incidence was 34%. There was no difference in graft survival and accumulated survival is the same in patients who developed diarrhea and those who did not (p = 0.17). Thymoglobulin induction increases up to 5 times the probability of developing post-transplant diarrhea (HR 5.98 p=0.01).

Conclusions: In our center, the cumulative incidence of diarrhea after transplantation is similar to reported in international series. The microbiology of diarrhea events, unlike that described in developed countries, is mainly associated with parasites. The impact of this complication on graft survival and accumulated survival is the same in patients who developed it versus those who did not. Limited epidemiological data exist in our country and Latin America, focusing our approach to reduce diarrheal disease by incorporating epidemiological information and thereby improve therapeutics options for this patients.

PUB253

Unusual Presentation of Ramsay-Hunt Syndrome in a Kidney Transplant Recipient

Daniela Via Reque Cortes, Géssica S. Braga Barbosa, Marcelo P. Menezes filho, Tomas D. Ferreira, Jose O. Reusing, Elias David-Neto. Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.

Introduction: Herpes-virus reactivation has long been recognized as occurring more frequently in immunocompromised individuals. There are only a few cases of Ramsay-Hunt Syndrome described after transplantation. We report a case of a kidney transplant recipient (KTR) with an atypical course due to multiple cranial nerve involvement.

Case Description: 36 YO WF with a H/O SLE leading to CKD, S/P LUKT in 2018. Immunosuppression maintained consisted of tacrolimus and MMF. Nadir Cr 0.8 mg/dl. Current Cr 1.0 mg/dl. Urine Pt/Cr ratio 0.06 g/g. Seen for routine visit. Surveillance DD CF DNA (Alloscore) done - 4.8%. Repeat after a few weeks - 5.4%. No DSA, ANA was at 1:40. ds DNA Ab negative. Normal complements. Biopsy was suggestive of active acute antibody mediated rejection with severe microvascular injury and renal limited TMA. C4d only focally positive. DSA repeated and negative. MICA Ab negative. ATIR

Infections in the Early Period After Kidney Transplantation

Andreea Ioana Berechet1, Bogdan M. Sorohan,2, Bogdan Obrisca,2 Andreea G. Andronesi,1,2 Gener Ismail,1,2,1Fundeni Clinical Institute, Bucharest, Romania; 2Carol Davila University of Medicine and Pharmacy, Bucharest, Romania.

Background: Infectious complications remain an important cause of morbidity and mortality in kidney transplant recipients, especially in the first year after kidney transplantation (KT). The aim of our study was to evaluate incidence, type of infectious complications and also, to identify risk factors and graft survival impact of these infections in the first 90 days after KT.

Methods: We performed a prospective cohort study, which included 67 adult patients (age ≤ 18 years), transplanted in our center between the 1st of October 2018 and the 1st of October 2019. Demographics data, recipient, donor, transplant, treatment and infections parameters were analyzed.

Results: Among the 67 patients, the mean age was 41.3±10.5 years, male was the predominant recipient gender (59.7%) and 65.7% received a graft from a cadaveric donor. During the first 90 days after KT, 26 infectious episodes occurred in 22 kidney recipients (32.8%). The majority of patients (68%) developed infection in the first 30 days after KT. The most common infections were urinary tract infections (53.8%). The most frequent pathogens identified were Klebsiella pneumoniae (9 times) and Escherichia Coli (7 times). Median time of antibiotic therapy was 10 days (7-15). Patients from the infection group received a graft from a significantly older donor (p=0.02), had a significantly higher cold ischemia time (p=0.02) and tended to received more frequent antithymocyte globulin (ATG) induction therapy (p=0.09). No significant difference between patients with infectious and without infectious complications, in terms of delayed graft function (p=0.14), acute rejection (p=0.13) and graft failure (p=0.17). Multivariate Cox regression analysis showed that induction therapy with ATG (HR=3.02, CI 95%:1.08-8.42; p=0.03), DGF (HR=3.61; CI 95%:1.09-11.91; p=0.03) and donor age (HR=1.04; CI 95%:1.006-1.082; p=0.02) were independent risk factors for infection in the first 90 days after KT. Five out of 67 patients developed graft failure, and 3 of them (60%) lost their graft due to acute graft pyelonephritis (p=0.001).

Conclusions: We showed that infections in the early period after KT remain a common complication with negative impact on graft function, specially urinary tract infections. Likewise, induction therapy with ATG, DGF and donor age were independent risk factors for infectious complications.

AKI in Kidney Transplant Patients: A Single-Center Experience

Hay Me Me, Neha Deval, Aditi A. Sen, Shruti Kore, Sanjeet Gupta, Daniel Glick,1,2 Westchester Medical Center, Valhalla, NY.

Background: The incidence of acute kidney injury (AKI) after kidney transplantation varies depending on the centers but it is a significant risk factor for graft failure. Kidney transplantation recipients have various risk factors for AKI according to the time after transplantation, most commonly being infection, ischemia-perfusion injury, volume depletion, calcineurin induced nephropathy and acute rejection. We present the common causes of acute kidney injury in our center and the related outcomes.

Methods: A retrospective study was conducted and gathered the information from their first episode of acute kidney injury event starting from January 2011. Out of 180 patients, 65 patients were excluded due to the lack of detailed documentation. We looked up the incidence of acute kidney injury from biopsy reports and serology data and the subsequent renal outcomes.

Results: Among 115 patients, 105 patients (88%) had non-oliguric AKI and 10 patients (8%) developed oliguric AKI. Biopsy revealed the most common cause of AKI being the transplant glomerulopathy (chronic rejection) at 23% in non-oliguric groups and 66% in oliguric groups. Only a few patients (9.5%) recovered and most of them developed chronic kidney disease with 41% in non-oliguric group. Acute cellular mediated rejection was found in 18% patients in non-oliguric group. Dialysis was needed in 24% patients in oliguric patients.

Conclusions: Our data shows that non-oliguric AKI is the most common presentation in kidney transplant patients and had poor outcome. Surprisingly, the most common etiology of AKI is chronic rejection in our center. Close follow up and early detection with biopsy might help to prevent chronic kidney disease due to chronic rejection.

Early Graft Dysfunction due to Banff 2A Rejection in a Non-Sensitized Cross-Match-Negative Recipient

Thanh Cao, Neeraj Sharma. University of Southern California University of Southern California, Los Angeles, CA.

Introduction: With the introduction of potent immunosuppression, the incidence of acute rejection in the first year following transplant is 1-2% lower in living donor kidney transplants (LDDK) compared to deceased donor kidney transplants (DDKT). Ideally, immediate graft function should be expected after LDKT. We present a case report of early acute cellular rejection 26 hours after an ABO compatible, HLA crossmatch negative LDKT.

Case Description: A 65-year-old Caucasian male with ESRD due to anti-GBM disease presented for a LDKT from his 68-year-old wife. He was ABO compatible, HLA crossmatch negative, and 0% for both T-flow and B-flow PRA. Induction was with Basiliximab 20mg and Methylprednisilone 500mg and achieved immediate diuresis. He became anuric by 16 hours post-op, and a for-cause biopsy was done on POD 2 which showed Banff 2A acute cellular rejection with negative C4D. Patient was treated with rabbit anti-thymocyte globulin (rATG) with total dose 3mg/kg divided over 4 doses and then thymoglobulin steroid at 250mg for 5 days. Immunosuppression was intensified and target tacrolimus levels were increased to achieve trough levels between 10-12 ng/mL. The patient has maintained excellent allograft function six months post-transplant with baseline serum creatinine baseline 1.8-2.0 and eGFR 34-38.

Discussion: Risk factors for acute rejection include multiple human leukocyte antigen (HLA) mismatches, a high panel reactive antibody (PRA), presence of donor specific antibodies (DSA), ABO blood group incompatibility, positive HLA crossmatch, prolonged cold ischemia time greater than 24 hours, African American ethnicity, and inadequate induction regimen. For patients with high risk factors for rejection, 2009 KDIGO guidelines recommend induction regimen with lymphocyte-depleting agents such as rATG rather than IL-2 receptor monoclonal antibody such as Basiliximab. This case report focuses specifically on the development of ACR in a low risk living donor transplant. We speculate that the development of ACR in this low risk patient was likely due to the HLA mismatches and possibly induction with Basiliximab. This case report poses the question of whether more intensive induction therapy should be considered in low risk patients with HLA mismatches and the long-term allograft outcomes following acute rejection.

Aspirin Prescribing Practices and Characteristics of Pregnant Women with CKD

Christin M. Giordano McAuliffe,1,2 Shelley A. Crants,2 Lynsa Nguyen,1 Lisa H. Newburger,1 Anna M. Ferragamo,1,2 Vanderbilt University Medical Center, Nashville, TN; 2Vanderbilt University School of Medicine, Nashville, TN.

Background: Women with chronic kidney disease (CKD) are at a higher risk for pre-eclampsia compared to non-transplant patients without CKD. The U.S. Preventative Services Task Force has recommended use of low-dose aspirin in women with a high risk for development of preeclampsia, including women with renal disease since 2014. The authors sought assess the characteristics of pregnant women with CKD and aspirin prescribing practices at their institution.

Methods: The authors performed a retrospective chart review of data from pregnancies in women with CKD who delivered between January 1, 2015 and December 31, 2019. Potential pregnancies were identified with diagnostic codes for pregnancies and then included patients who had diagnostic codes for chronic kidney disease and proteinuria. We included pregnancies that had a formal diagnosis of CKD and those in whom baseline creatinine did not decrease at least 0.3 mg/dL during pregnancy. We excluded pregnancies that ended prior to 12 weeks. Means, standard deviations, medians, and interquartile ranges were used for continuous variables, and frequency and proportions were used for categorical variables, as appropriate.

Results: A total of 149 pregnancies were included. The mean age at due date was 30.8 (std. dev 5.6) with 27.5% of advanced maternal age. The majority (51.7%) were obese, with a mean BMI of 32.8 kg/m2 (std. dev 8.2). 15.4% had a history of prior pre-eclampsia. Just over half (57.5%) had been diagnosed with CKD prior to or during pregnancy with the most common underlying etiologies being type 2 diabetes mellitus. Of these, the mean baseline creatinine, obtained within 1 year of pregnancy, was 1.13 mg/dL (std. dev 0.61). Of 149 pregnancies included, 62 (42.3%) were prescribed aspirin prior to 28 weeks of gestation. Overall, 36.2% (54/149) were diagnosed with pre-eclampsia. Of those with a formal diagnosis of CKD prior to pregnancy, 52.9% were prescribed aspirin and 42.4% developed pre-eclampsia.

Conclusion: Chronic kidney disease is a well-recognized risk factor for pre-eclampsia with guidelines recommending the prescribing of aspirin to pregnant women with CKD. This study demonstrated low overall aspirin prescribing rates with relatively high rates of pre-eclampsia at a single institution.
Magnesium Intake, Bone Mineral Density, and the Risks of Falls and Fractures in Post-Menopausal Women with Kidney Stone

Harshitha Kota,1 Xuerong Wen,2 Chao Chen,3 Jie Tang1,4 Brown University, Providence, RI; 1University of Rhode Island, Kingston, RI; 2University of Florida, Gainesville, FL; 3University Medicine Foundation Inc, Providence, RI.

Background: Kidney stone formers are a unique patient population at high risk for fall and fractures due to dysregulated calcium homeostasis and early bone loss. Magnesium is an important component of bone, but its relation to falls and fractures among stone formers is unclear.

Methods: We performed regression analyses to determine the independent effect of dietary magnesium intake (DMI) on bone mineral density (BMD), and risks of fall and bone fracture among incident stone formers identified in the Women’s Health Initiative (WHI), a prospective longitudinal multicenter study investigating the health of post-menopausal women.

Results: Out of a total of 145,942 WHI participants free of kidney stone history at baseline, 6024 developed kidney stone after 1,601,750 patient years of follow up. Among these incident stone formers, 82% were Caucasian, 23% were above age 70. Mean DMI was 304 mg/day, 30% had high DMI defined as >348 mg/day, 38% had medium DMI defined as 241-348 mg/day and 32% had low DMI defined as <241 mg/day. A total of 238 (4%), and 2581 (43%) incident stone formers had low BMD and new falls or fractures, respectively. Both low dietary calcium intake and active smoking associated with reduced BMD (p<0.05), but DMI did not affect BMD in the multivariate regression analysis, β=1.6, p=0.4. Older age, black race, history of diabetes, history of either parent having broken bones after age 40 all associated strongly with risks of fall and bone fracture (p<0.05). However, DMI again did not have such significant association after adjustment for demographics and potential confounding factors, β=1.7, p=0.4.

Conclusions: DMI does not appear to affect BMD and the risk of fall or bone fracture among post-menopausal women.

Effect of Finerenone on CKD Outcomes in Type 2 Diabetes

George L. Bakris,1 Rajiv Agarwal,2 Stefan D. Anker,2 Bertram Pitt,4 Luis M. Rualio,3,4 Peter Rossing,2,8 Peter Kolkhof,2 Christina Nowack,10 Patrick Schmerloe,2,1 Amer Joseph,3 Gerasimos Filippatos,2 on behalf of the FIDELIO-DKD Investigators Department of Medicine, University of Chicago Medical Center, Chicago, IL; Richard L. Rudolph VA Medical Center and Indiana University, Indianapolis, IN; Department of Cardiology (CVK) and Berlin Institute of Health for Regenerative Therapies, German Centre for Cardiovascular Research Partner Site Berlin, Charité Universitätsmedizin, Berlin, Germany; Department of Medicine, University of Michigan School of Medicine, Ann Arbor, MI; Cardiorenal Translational Laboratory and Hypertension Unit, Institute of Research imas 12, Madrid, Spain; CIBER-CV, Hospital Universitario 12 de Octubre, & Faculty of Sport Sciences, European University of Madrid, Madrid, Spain; Steno Diabetes Center Copenhagen, Gentofte, Denmark; Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; Research and Development, Preclinical Research Cardiovascular; Bayer AG, Wuppertal, Germany; Research and Development, Clinical Development Operations, Bayer AG, Wuppertal, Germany; Department of Cardiology, Ann Arbor, MI; Department of Cardiovascular Medicine, University of Athens, Athens, Greece.

Background: Patients with chronic kidney disease (CKD) and type 2 diabetes (T2D) remain at risk of CKD progression despite guideline-directed therapies. Mineralocorticoid receptor (MR) overactivation may drive CKD progression through inflammatory and fibrotic processes. Finerenone, a novel, nonsteroidal MR antagonist, reduces albuminuria independent of hemodynamic effects. We assessed the long-term efficacy and safety of finerenone in slowing CKD progression in patients with CKD and T2D.

Methods: This global, phase 3, double-blind study randomized 5734 patients from 48 countries (1:1) to oral finerenone or placebo. Patients with T2D, urine albumin-to-creatinine ratio 30–5000 mg/g and estimated glomerular filtration rate (eGFR) 25–75 mL/min/1.73 m², treated with optimized renin–angiotensin system blockade, were included. The primary outcome was time to kidney failure, sustained eGFR decline ≥40% from baseline or renal death. The key secondary outcome was time to cardiovascular (CV) death, non-fatal myocardial infarction, non-fatal stroke or heart failure hospitalization.

Results: Mean patient age was 65.6 years; 70.2% were male. At baseline, mean eGFR was 44.3 mL/min/1.73 m² and median UACR 852 mg/g. The primary outcome occurred in 504/2833 (17.8%) and 600/2841 (21.1%) patients treated with finerenone or placebo, respectively (hazard ratio [HR]=0.82; 95% confidence interval [CI] 0.73–0.93; p=0.0014). The prespecified secondary outcome was also reduced with finerenone (13.8% vs 16.8% in the placebo group; HR=0.86; 95% CI 0.75–0.99, p=0.0339). Overall treatment-emergent adverse events were balanced between groups. The incidence of hyperkalemia-related treatment discontinuation was higher with finerenone than placebo (2.3% and 0.9%, respectively).

Conclusions: Finerenone significantly reduced kidney and CV outcomes in patients with T2D and advanced CKD and was well tolerated. While the primary adverse event was hyperkalemia, it only necessitated treatment discontinuation in 2.3% of patients compared to 0.9% in placebo. These data support the use of finerenone to slow CKD progression in T2D and advanced CKD and was well tolerated. While the primary adverse event was hyperkalemia, it only necessitated treatment discontinuation in 2.3% of patients compared to 0.9% in placebo. These data support the use of finerenone to slow CKD progression.

EMPEROR-Reduced: Empagliflozin and Outcomes in Heart Failure and CKD

Faiez Zannad. The EMPEROR Reduced trial steering committee and investigators INI CRICT, Universite de Lorraine, Nancy, France.

Background: In EMPEROR-Reduced, empagliflozin reduced cardiovascular death and heart failure hospitalizations and slowed the progressive decline in kidney function in heart failure and a reduced ejection fraction (HFrEF), with or without diabetes. We explored the effect of empagliflozin on cardiovascular and kidney outcomes, across the spectrum of kidney function.

Methods: 3730 patients were randomized, of whom 1978 (53%) had prevalent chronic kidney disease (CKD) (eGFR<60mL/min/1.73m² or an UACR>300mg/g). The key outcomes were (1) a composite of cardiovascular death or hospitalization for heart failure; (2) total hospitalizations for heart failure, and (3) eGFR slope; the last was determined by a prespecified composite renal outcome (defined as a proficient sustained decline in eGFR, chronic dialysis or transplant). The median follow-up was 16 months.

Results: Patients with prevalent CKD had a higher rate of CV and kidney events. Empagliflozin reduced the risk of cardiovascular death and hospitalization for heart failure by 25% (P<0.001), reduced total hospitalizations for heart failure by 30% (P<0.001) and reduced the composite of chronic dialysis, transplant and renal death by 50% (P<0.01). All three benefits were seen consistently in patients with and without CKD (figure) and were apparent even in patients with severe impairment (eGFR from 20 to 30mL/min/1.73m²). Empagliflozin significantly slowed the yearly loss of eGFR and was well tolerated regardless of the level of baseline kidney function.

Conclusions: In patients with HFrEF, empagliflozin reduced serious heart failure and serious adverse kidney outcomes, and slowed the decline in kidney function, regardless of the presence or absence of CKD and across a broad spectrum of baseline kidney function.

Sequential Treatment with Tacrolimus and Rituximab vs. Alternating Corticosteroids and Cyclophosphamide in Primary Membranous Nephropathy (PMN)

Gema Fernandez Juarez,1 Jorge E. Rojas-Rivera,3 Anne-Elis van de Logt,12 Joanne H. Anderson,4 Angel M. Sevilla,3 Fernando Carvaca-Fontan,2 Ana Avila,1 Cristina Rabasco,8 Virginia Cabello,2 Marian Goicochea,2 Luis F. Quintana,3 Irene Agraz,12 Ana M. Romera segorbe,11 Amir Shabaka,5 Mario Espinosa,8 Jesus Egido,3 Gerard J. Lambeau,2 Pierre M. Ronco,4 Manuel Praga,2 Nephrology, Hospital Universitario Fundacion Alcorcon, Madrid, Spain; Nephrology, Hospital Universitario 12Octubre, Madrid, Spain; Nephrology, Hospital Universitario 12October, Madrid, Spain; Nephrology, Hospital Clinic, Barcelona, Spain; Nephrology, Tenon Hospital, Paris, Spain; Instituto de Pharmacologie Moleculaire et Cellulaire, Valbonne, France; Nephrology, Hospital Virgen del Rocio, Sevilla, Spain; Nephrology, Fundacion Jimenez Diaz, Madrid, Spain; Nephrology, Hospital Reina Sofia, Cordoba, Spain; Nephrology, Hospital Universitario Gregorio Marañon, Madrid, Spain; Nephrology, Vall d’Hebron Hospital Universitari, Barcelona, Spain; Nephrology, Hospital General Ciudad Real, Ciudad Real, Spain; Nephrology, 3 Radboud University Medical Center, Nijmegen, Netherlands; Nephrology, Hospital Dr. Peset, Valencia, Spain.

Background: A cyclical corticosteroid-cyclophosphamide regimen is recommended for patients with PMN at high risk of progression. RTX monotherapy and calcineurin inhibitors have shown efficacy in inducing remission, but relapses are very common after discontinuation of calcineurin inhibitors.

Methods: In a randomized and open-label controlled trial, 86 patients (pts) with PMN at high risk of nephrotic syndrome after a 6m observation period were assigned to receive a 6-m cyclical treatment with corticosteroid and cyclophosphamide (n=43) or sequential treatment with tacrolimus (full-dose for 6m and tapering for another 3m) and RTX (1 g at 6m) (n=43). Primary outcome was complete or partial remission of nephrotic syndrome at 24m.

Results: The primary outcome occurred in 36 pts (84%) in the Cs-cyclophosphamide group and in 25 pts (58%) in the tacrolimus-RTX group (RR 1.44 95% CI 1.08–1.92). Complete remission at 24m occurred in 26pts (60%) in the corticosteroid-cyclophosphamide group and in 1pts (26%) in the tacrolimus-RTX group (RR 2.36 95%CI 1.34-4.16). Immunological response was faster in the corticosteroid-cyclophosphamide group and associated with remission at 24m. Relapses occurred in 1 pt (2.7%) in the corticosteroid-cyclophosphamide group, and 3 pts (12%) in the tacrolimus-RTX group. The rate of serious adverse events was not statistically different between groups.

Conclusions: Treatment with corticosteroid-cyclophosphamide induced remission in a significantly greater number of patients with PMN than tacrolimus-rituximab.

Global Phase 3 Clinical Trials of Vadadustat vs. Darbepoetin Alfa for Treatment of Anemia in Patients with Non-Dialysis-Dependent CKD

Glen M. Chertow, PROTECT Author Group Stanford University School of Medicine, Stanford, CA.

Background: Vadadustat (VADA) is an investigational, oral, hypoxia-inducible factor prolyl hydroxylase inhibitor which has completed patient enrollment in its phase 3 development for treatment of anemia of chronic kidney disease (CKD). In phase 2 trials, VADA safely raised and maintained hemoglobin (Hb) concentrations.

Methods: We conducted two randomized, phase 3, global, open-label, sponsor-blind, parallel-group, active-controlled noninferiority trials comparing oral daily VADA to parenteral darbepoetin alfa (DA) in patients with anemia of non-dialysis dependent (NDD)-CKD (PROTECT program). The PROTECT program included (1) Correction trial of patients previously not on erythropoiesis-stimulating agents (ESA) (ESA-unintreated NDD-CKD trial, NCT02683437) and (2) Conversion trial of patients previously on an ESA (ESA-treated NDD-CKD trial, NCT02680574). The primary safety endpoint of PROTECT program was to first time major adverse cardiovascular event (all-cause mortality, nonfatal myocardial infarction, nonfatal stroke), prespecified as a pooled event-driven analysis of both trials. Primary and key secondary efficacy endpoints, prespecified as separate analyses for each trial, were difference in mean change in Hb between baseline and weeks 24-36 and weeks 40-52, respectively, comparing VADA vs DA.

Results: In total, 4708 patients were screened for the ESA-unintreated NDD-CKD trial, and 1751 were randomized. Most (N=1061) were from the United States; the remainder were from Europe or elsewhere. A total of 2961 patients were screened for the ESA-treated NDD-CKD trial, 1725 of whom were randomized. Most (N=1060) were from Europe or non-United States/non-European countries; the remainder were from the United States. The database was locked on July 31, 2020. Topline data and results of these global trials will be available in September 2020.

Conclusions: The trials will test if oral daily VADA is noninferior to parenteral DA, a common ESA, in patients with anemia of NDD-CKD, with respect to cardiovascular safety and hematologic efficacy.

Oral Intradialytic Nutritional Supplements and Mortality in Hemodialysis Patients: A Cluster-Randomized, Pragmatic Clinical Trial

Daniel E. Weiner,1 Karen M. Majchrzak,2 Cindy D. Kinnard,3 Hocine Tighiouart,4 Todd Marren,5 Eduardo K. Lacson,6 Doug Johnson,7 on behalf of Dialysis Clinic, Inc Tufts Medical Center, Boston, MA; 2Dialysis Clinic Inc, Nashville, TN.

Background: Dialysis is a costly and observational studies suggest that administering oral nutritional supplements to hemodialysis patients with low serum albumin during the dialysis session may reduce mortality. Whether there are benefits in patients with normal serum albumin remains unstudied.

Methods: The Health Effects of oral. Protein Supplements in HD (HELPs-HD) Trial was an open-label cluster randomized pragmatic trial, comparing the effects of an intensive oral nutritional supplement protocol in which prevalent hemodialysis patients received supplements at every dialysis session regardless of serum albumin to standard care, in which supplements were administered to patients with albumin below 3.5 g/dL. As part of standard care, all incident patients received supplements for the first 90 days of dialysis. Following randomization of facilities to either the intensive or standard protocol, patients in facilities provided informed consent via waiver of consent documentation. The study intervention lasted from January 2017 to March 2020, and patients were enrolled through December 2019. The primary outcome, all-cause mortality, was assessed from medical records.

Results: Among 10,043 hemodialysis patients randomized from 105 participating DCl facilities, mean age was 63 years, 56% were men, 56% Black, and 46% had diabetes as primary cause of kidney failure; 32% were incident to dialysis. Supplement use was 2-fold higher in the 53 clinics randomized to the intensive protocol. Over median follow-up of 21 months, there were 3628 deaths, 35.8% in the intensive and 36.5% in the standard group, with an unadjusted rate of 20 deaths per 100-person years in both groups. In unadjusted Cox models, those randomized to the intensive protocol had similar outcomes to those randomized to the standard protocol (HR 1.02 [0.92, 1.14]); results were similar in models adjusted for age, sex and race and between incident and prevalent patients.

Conclusions: Discussion In a large, national population of hemodialysis patients, there was no difference in mortality between patients randomized to a standard oral nutritional supplement protocol, with receipt of supplements only when serum albumin was low, as compared to an intensive protocol, with receipt of supplements regardless of serum albumin.

Reducing the Burden of Dialysis Catheter Complications: A National Approach (REDUCCTION)

Martin P. Gallagher,1,2 Sradha S. Kotwal,3,4 Girish S. Talaulikar,4 Nicholas A. Gray,5 Kevan Polkinghorne,6 Stephen P. McDonald,7 Alan Cass,8 on behalf of the REDUCCTION Investigators The George Institute for Global Health, Newtown, NSW, Australia; 1University of Sydney, Sydney, NSW, Australia; 2Prince of Wales Hospital and Community Health Services, Randwick, NSW, Australia; 3Renal Services, ACT Health, Canberra City, ACT, Australia; 4Sunshine Coast University Hospital, Sunshine Coast, QLD, Australia; 5Monash University, Clayton, VIC, Australia; 6Australia and New Zealand Dialysis and Transplant Registry, Adelaide, SA, Australia; 7Monzies School of Health Research, Charles Darwin University, Casuarina, NT, Australia.

Background: The major morbidity and cost from the use of central venous hemodialysis catheters is the increased risk of catheter-related blood stream infection (HD-CRBSI). Clinical practice remains variable and broad-scale, systematic interventions to reduce this burden have not been tested in randomized trials. The REDUCCTION trial aimed to systematically measure the rate of HD-CRBSI at a national level and test the effect of a multifaceted, evidence-based intervention upon the rate of HD-CRBSI in Australia.

Methods: This stepped wedge, randomized trial, clustered at the renal service level, included all patients receiving a central venous hemodialysis catheter in a participating renal service. After baseline data collection, services were randomly assigned to one of three time points (April 2018, Sept 2018, March 2019) for implementation of an intervention package based upon current evidence and guidelines. The primary outcome was the intervention’s effect upon the study wide service-level rate of HD-CRBSI (per 1000 catheter days).

Results: A total of 37 renal services in all Australian states and territories participated in the trial between Dec 2016 and March 2020. Preliminary analysis shows that 5246 catheters (3506 patients) were inserted during the baseline phase and 4610 catheters (3144 patients) in the intervention phase, representing more than 1.1 million catheter days of exposure and over 300 adjudicated HD-CRBSI events. Final analysis is currently in progress with results presented at the Annual Meeting.

Conclusions: The REDUCCTION trial has systematically measured the use of HD CVCs in near real-time and demonstrated the feasibility of implementing a suite of evidence-based interventions in haemodialysis care. The study outcomes will have implications for future research and practice in dialysis access.

Regional Citrate vs. Systemic Heparin Anticoagulation During Continuous Kidney Replacement Therapy Among Critically Ill Patients with AKI: A Randomized Clinical Trial
Alexander Zarbeck,1 Mira Kuellmar,1 Detlef Kindgen-milles,3 Peter Rosenberg,2 Sean M. Bagshaw,1 John A. Kellum,2 Melanie Meersch,1 1Department of Anesthesiology, Intensive Care and Pain Medicine, Universitätsklinikum Münster, Münster, Germany; 2Center for Critical Care Nephrology, University of Pittsburgh, Pittsburgh, PA; 3University of Alberta, Edmonton, AB, Canada; 4Universitätsklinikum Tübingen Medizinische Universitätsklinik, Tübingen, Germany; 5Heinrich-Heine-Universität Düsseldorf, Düsseldorf, Germany.

Background: Although current guidelines suggest the use of regional citrate anticoagulation as first-line treatment for continuous kidney replacement therapy in critically ill patients, the evidence for this recommendation is based on few clinical trials and meta-analyses.

Methods: To determine the effect of anticoagulation strategies on filter lifespan and mortality, a parallel-group, randomized multicenter clinical trial was conducted in 26 centers across Germany between March 2016 and December 2018. Patients were randomized to receive either regional citrate (n=300) or systemic heparin anticoagulation (n=296) for continuous kidney replacement therapy. The two co-primary outcomes were filter lifespan and 90-day all-cause mortality. Secondary endpoints included bleeding complications and new infections.

Results: Among 638 patients randomized, 596 (93.4%) patients (mean age, 67.5 [±12.4] years, 183 (30.7%) women) completed the trial. Median filter lifespan was 47 [IQR, 19-70]h in the regional citrate and 26 [IQR, 2-51]h in the systemic heparin group; absolute difference (AD) 15% [95%CI, 11h to 28h]; P=0.001). 90-day all-cause mortality was 51.2% (150/300) in the regional citrate and 53.6% (156/296) in the systemic heparin anticoagulation group (adjusted AD, -6.1% [95%CI, -12.6% to 0.4%]; unadjusted AD, 11.5% [95%CI, 0.3% to 22.7%]; P=0.04). Compared with systemic heparin anticoagulation, the regional citrate anticoagulation group had significantly fewer bleeding complications (15/300 [5.1%] vs. 49/296 [16.9%]; P<0.001) and significantly more new infections (204/300 [68.0%] vs. 164/296 [55.4%]; AD, 12.6% [95% CI, 4.9% to 20.3%]; P=0.002).

Conclusions: Among critically ill patients with acute kidney injury receiving continuous kidney replacement therapy, anticoagulation with regional citrate, compared with systemic heparin anticoagulation, resulted in significantly longer filter lifespan. The trial was terminated early and was therefore underpowered to reach conclusions about the effect of anticoagulation strategy on mortality.

Effects of Dapagliflozin on Kidney Function, Cardiovascular Events, and All-Cause Mortality According to Cause of Kidney Disease in the DAPA-CKD Trial
David C. Wheeler,1,2 Bergur V. Stefansson,1 Ricardo Correa-Rotter,4 Glenn M. Chertow,2 Tom Greene,3 Fan Fan Hou,4 Niels Jong,7 John McMurray,9 Peter Rossing,5,6 David Sjostrom,2 Robert D. Toto,8 Anna Maria Langkilde,6 Hiddo J. J. Jongs,8 John McMurray,9 The George Institute for Global Health, Sydney, NSW, Australia; 2University College London, London, United Kingdom; 3AstraZeneca, Gothenburg, Sweden; 4National Medical Science and Nutrition Institute Salvador Zubirán, Mexico City, Mexico; 5Stanford University School of Medicine, Stanford, CA; 6University of Utah Health Sciences, Salt Lake City, UT; 7Southern Medical University Nantong Hospital, Guangzhou, China; 8University of Groningen, Groningen, Netherlands; 9University of Glasgow Institute of Cardiovascular and Medical Sciences, Glasgow, United Kingdom; 10Steno Diabetes Center, Copenhagen, Denmark; 11University of Copenhagen, Copenhagen, Denmark; 12UT Southwestern Medical Center, Dallas, TX.

Background: The Dapagliflozin And Prevention of Adverse Outcomes in Chronic Kidney Disease trial (DAPA-CKD) assessed the sodium glucose co-transporter 2 inhibitor dapagliflozin in patients with chronic kidney disease (CKD) with and without type 2 diabetes. This pre-specified analysis explores outcomes according to underlying cause of kidney disease.

Methods: 4304 participants with eGFR 25–75 mL/min/1.73m² and UACR 200–5000 mg/g were randomized to receive dapagliflozin 10mg once daily or placebo. The effects of dapagliflozin versus placebo on the primary outcome (composite of sustained decrease in eGFR of ≥50%, end-stage kidney disease, or death from cardiovascular [CV] or kidney causes) and secondary outcomes (CV death or heart failure hospitalizations and all-cause mortality) were assessed in patients with diabetic nephropathy (n=2510), chronic glomerulonephritis (n=695), ischemic/hypertensive CKD (n=687) and CKD due to unknown/other causes (n=412).

Results: The effect of dapagliflozin on the primary outcome (hazard ratio [HR] 0.61; 95% Confidence Interval [CI] 0.51–0.72) was consistent in patients with diabetic nephropathy (HR 0.63, 95%CI 0.51–0.78), glomerulonephritis (HR 0.43, 95%CI 0.26–0.71), ischemic/hypertensive CKD (HR 0.75, 95%CI 0.44–1.26) and CKD of unknown/other cause (HR 0.58, 95%CI 0.29–1.19; p-interaction 0.53). The reduction in CV death or heart failure hospitalizations (HR 0.71, 95%CI 0.55–0.92) was also similar across kidney disease etiologies (p-interaction 0.24) as was reduction in all-cause mortality (HR 0.69, 95%CI 0.53–0.88; p-interaction 0.55). The proportion of patients who discontinued study drug due to adverse events or experienced serious adverse events was similar across kidney disease etiologies, with no clear evidence of difference (p-interaction 0.04 and 0.14).

Conclusions: In patients with CKD, dapagliflozin reduced the risks of kidney failure, death from CV causes or heart failure hospitalizations, and all-cause mortality, regardless of underlying etiology of kidney disease in this study.

Electronic Health Record Alerts for AKI: A MultiCenter Randomized Clinical Trial
Francis P. Wilson,1 Melissa Martin,1 Yu Yamamoto,2 Harold I. Feldman,2 Jason H. Greenberg,1 Sherry Mansour,2 Dennis G. Molelinda,3 Paul M. Palevsky,4 Chirag R. Parikh,4 Michael Simonov,1 Medicine, Yale University School of Medicine, New Haven, CT; 2University of Pennsylvania, Philadelphia, PA; 3University of Pittsburgh, Pittsburgh, PA; 4Johns Hopkins University, Baltimore, MD.

Background: Despite its strong association with adverse clinical outcomes, acute kidney injury (AKI) is often not recognized during clinical care. It is unclear whether automated alerts for AKI improve clinical outcomes.

Methods: Double-blinded, multicenter, parallel, randomized, controlled trial of an electronic AKI alert versus usual care (no alert). Adult participants across 6 hospitals were electronically identified and randomized via a best practice alert built in 1:1 fashion to the two study arms. The primary outcome was a composite of AKI progression, receipt of dialysis, or death at 14 days.

Results: 6,030 patients were randomized over 22 months. The primary outcome occurred in 653 (21.4%) patients in the alert group and 622 (20.9%) in the usual care group (relative risk 1.02, 95% confidence interval [CI] 0.93 to 1.13, p=0.67). Per-hospital analysis revealed worse outcomes in the two non-teaching hospitals (N=765, 13%), where alerts were associated with a higher risk of the primary outcome of 1.49 (95% CI, 1.12 to 1.98, p=0.006). More deaths occurred at these centers (15.6% in the alert group vs. 8.6% in the usual care group, p=0.003). Certain AKI care practices were increased in the alert group but did not appear to mediate these outcomes.

Conclusions: Alerts did not reduce the risk of our primary outcome among hospitalized patients with AKI. The heterogeneity of effect across clinical centers should lead to a re-evaluation of existing AKI alerting systems.

**Associations Between Achieved Hemoglobin and Cardiovascular Outcomes in the Pooled Phase 3 Roxadustat Studies of Non-Dialysis-Dependent Patients with Anemia of CKD**

**Steven Fishbane,1 Robert Provenzano,2 Pablo E. Pergola,3 Lynda Szczecz,4 Robert Leong,5 Khalil G. Saikali,4 Ming Zhong,4 Tyson T. Lee,4 Dustin J. Little,4 Lars Frison,4 John Houghton,5 Kin-Hung P. Yu,6 4(Northwell Health, Great Neck, NY; 3Wayne State University, Detroit, MI; 2Renal Associates, PA, San Antonio, TX; 6FibroGen Inc, San Francisco, CA; 4AstraZeneca, Gaithersburg, MD, 5AstraZeneca, Malmö, Sweden.

**Background:** Roxadustat, an oral hypoxia-inducible factor prolyl hydroxylase inhibitor, promotes erythropoiesis and increases bioavailability of iron. In phase 3 studies, roxadustat-treated patients achieved and maintained hemoglobin (Hb) values of 11-12 g/dL (Table). We examined the associations between achieved Hb levels and cardiovascular outcomes in non-dialysis-dependent (NDD) patients with anemia of chronic kidney disease (CKD).

**Methods:** We analyzed pooled data from 3 pivotal, phase 3 studies of patients with anemia of NDD-CKD who received roxadustat. Incidence rates of adjudicated MACE (all-cause mortality, MI, and stroke) and MACE+ (MACE plus heart failure and unstable angina requiring hospitalization) were evaluated based on 1) Hb level immediately before the event and 2) maximum Hb level in the first 12 treatment weeks.

**Results:** Overall, 2391 patients were randomized to roxadustat. The mean (SD) baseline Hb of 9.1 (0.74) g/dL increased to 10.95 (0.76) g/dL over weeks 28-52. The MACE and MACE+ rates were highest when Hb was < 8 g/dL decreasing as Hb increased to 11-12 g/dL and a12 g/dL (Table). **Conclusions:** In the NDD-CKD population, roxadustat corrected anemia and maintained Hb to 11±1 g/dL during weeks 28-52. MACE and MACE+ incidence rates were lowest when achieved Hb levels were ≥11 g/dL.

Effect of Ertugliflozin on Initial eGFR Decline and Chronic Slope: Analyses from the VERTIS CV Trial

David Cherry,1 Bernard Charbonnel,2 Francesco Cosentino,2 Richard E. Pratley,1 Samuel Dagogo-Jack,3 Weichung J. Shih,4,5 Darren K. Mcguire,6,7 Robert Frederich,8 Mario Maldonado,9 Jie Liu,10 Anmpye Pong,11 Chih-Chin Liu,12 Christopher P. Cannon.13 1University of Toronto, Toronto, ON, Canada; 2Universite de Nantes, Nantes, France; 3Karolinska Institute & Karolinska University Hospital Solna, Stockholm, Sweden; 4AdventHealth Translational Research Institute, Orlando, FL; 5University of Tennessee Health Science Center, Memphis, TN; 6Rutgers School of Public Health, Piscataway, NJ; 7Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; 8University of Texas Southwestern Medical Center, Dallas, TX; 9Parkland Health and Hospital System, Dallas, TX; 10Pfizer Inc., Collegeville, PA; 11MSD Limited, London, United Kingdom; 12Morch & Co., Inc., Kentworth, NJ; 13Brigham and Women's Hospital, Harvard Medical School, Boston, Boston, MA.

Background: SGLT2 inhibitors induce an initial reversible eGFR dip, based on natriuresis-induced reductions in glomerular pressure, with a return toward baseline over time in adults with T2DM. Preservation of the chronic eGFR slope by a 0.75 mL/min/1.73 m²/year with treatment predicts protection against CKD progression. We aimed to assess the impact of initial eGFR dip and chronic eGFR slope in the VERTIS CV trial (NCT01986881).

Methods: Patients with T2DM and ASCVD were randomized (1:1:1) to ertugliflozin 5 mg, 15 mg or placebo. Analyses assessed pooled ertugliflozin (n=5499) and placebo (n=2747). Patients were divided into 3 tertiles based on initial eGFR change at Week 6 (increase, small change or decrease). Changes in eGFR, hematocrit and uric acid were assessed at Weeks 6, 18, 52 and 156. Chronic eGFR slope/year by random coefficient models was also assessed.

Results: Glicoursuria-associated effects (ie, uric acid) were larger in the eGFR increase tertile; natriuresis-associated effects (ie, hematocrit) were larger in the eGFR decrease tertile (Fig A, B). The ertugliflozin eGFR decrease tertile had the smallest decline in chronic eGFR slope (Fig C, D). Chronic slopes were similar across the placebo group tertiles and the rate of decline uniformly more rapid (Fig D). Mean placebo-adjusted effect of ertugliflozin on chronic eGFR slope (Weeks 6–156 [95% CI]) was −1.19 (0.95, 1.42) mL/min/1.73 m²/year (Fig E) and >0.75 mL/min/1.73 m²/year in all subgroups.

Conclusions: The initial eGFR dip may influence several clinical effects of ertugliflozin. Ertugliflozin has favorable effects on eGFR slope in patients with T2DM and ASCVD.

Canagliflozin Across the Spectrum of Kidney Function and Albuminuria: Integrated Data from CANVAS and CREDENCE
Brendon L. Neuen,1 Jie Yu,1 Qiang Li,1 Vlad Perkovic,2† Clare G. Arnott,1 Bruce Neal,2 Hiddo L. Heerspink,1 Rajiv Agarwal,1 George L. Bakris,3Christopher P. Cannon,4 Dick de Zeeuw,5 David M. Charytan,6 Adeera Levin,7 Gian Luca Di Tanna,1 David R. Matthews,8 Carol A. Pollock,3 David C. Wheeler,9 Kenneth W. Mahaffey,10 Meg J. Jardine,1† The George Institute for Global Health, Newtown, NSW, Australia; 2UNSW Sydney, Sydney, NSW, Australia; 3University of Chicago, Chicago, IL; 4Indiana University School of Medicine, Indianapolis, IN; 5Rijksuniversiteit Groningen, Groningen, Netherlands; 6New York University School of Medicine, New York, NY; The University of British Columbia, Vancouver, BC, Canada; 7The University of Sydney, Sydney, NSW, Australia; 8University College London, London, United Kingdom; 9Stanford University School of Medicine, Stanford, CA; 10Harvard University, Cambridge, MA; 11University of Oxford, Oxford, United Kingdom.

Background: People with type 2 diabetes mellitus (T2DM) and chronic kidney disease (CKD) are at very high risk of cardiovascular events and kidney failure. While canagliflozin reduces the risk of these outcomes, the consistency of this effect across all levels of estimated glomerular filtration rate (eGFR) and urinary albumin:creatinine ratio (UACR) remains uncertain.

Methods: We pooled individual participant data from the CANVAS Program (n=10,142) and CREDENCE trial (n=4,401) to assess the effect of canagliflozin on a primary composite outcome of myocardial infarction, stroke, heart failure, doubling of serum creatinine, kidney failure, cardiovascular or kidney death. The effect of canagliflozin was assessed using Cox regression models with treatment by subgroup interaction terms stratified by trial.

Results: 2,051/14,543 (14%) participants experienced the primary outcome over a median follow-up of 2.5 years. Overall, canagliflozin reduced the risk of the primary outcome (HR 0.77, 95% CI 0.70-0.84; Figure). The magnitude of relative benefit increased as eGFR declined (P-trend<0.0007; Figure) with some evidence of greater relative benefit at higher UACR (P-trend=0.057; Figure). Lower eGFR and higher UACR levels were independently associated with cardio-renal risk. Consequently, absolute risk reductions increased more than 5-fold across lower eGFR categories and more than 9-fold across higher UACR categories (Figure).

Conclusions: Canagliflozin reduces the risk of cardio-renal outcomes in people with T2DM; the magnitude of relative and absolute protection varies by severity of CKD. COX: Commercial Support - Janssen funded the CANVAS and CREDENCE trials. This analysis was not specifically funded and conducted independent of the trial sponsors.

PO2631
Ferric Pyrophosphate Citrate Injection: No Clinical Drug Interaction with Unfractionated Heparin in Hemodialysis Patients
Raymond D. Pratt, R&D, Rockwell Medical Inc, Wixom, MI.

Background: Ferric pyrophosphate citrate (FPC) is a unique iron (Fe) replacement product indicated to maintain Fe balance and hemoglobin (Hgb) concentration in adult hemodialysis patients (HD). FPC can be administered via the dialysate (D) or as an intravenous (IV) preparation (Triferic® AVNU injection 6.75 mg Fe:4.5 mL for IV administration). A clinical study of the effects of unfractionated heparin (UFH) mixed with FPC was conducted.

Methods: An open-label, randomized 3-period, crossover trial, investigated the effects of FPC mixed with UFH compared with delivery of UFH and FPC by separate routes in 12 HD patients. The primary endpoint was the Anti Xa activity of UFH + FPC compared to UFH alone and UFH and FPC administered IV separately. Secondary endpoints were the activated prothrombin time (aPTT), thrombin time (TT) and serum iron profile (sFe). Effects were analyzed using the bioequivalence parameter of area under the concentration-time curve (AUC_{0-τ}). Safety was assessed by recording adverse events (AE) and a visual dialyzer clotting scale (VCS).

Results: Coadministration of FPC+UFH pre dialyzer, met bioequivalence criteria for anti Xa activity of UFH compared to UFH alone or UFH and FPC separately. [Figure 1]. The FPC +UFH mixture had no impact on the AUC_{0-τ} values of PTT or TT. The concentration-time profiles for sFe and TSAT were comparable. FPC was well tolerated with no reported adverse events. The VCS showed no detectable clotting of the dialyzer with any combination of UFH and FPC.

Conclusions: The results of this study demonstrates no clinically significant drug-drug interaction between FPC and UFH on the anticoagulation effect as assessed by anti Xa activity, aPTT, and TT or on the ability of FPC to deliver iron when these agents are co-administered as a single admixture. All treatments were well tolerated. These results support coadministration of IV FPC and UFH as an admixture to HD patients.

Funding: Commercial Support - Rockwell Medical Inc.

A Pilot Trial of Fistula vs. Graft Access Strategy in Older Adults on Hemodialysis

Mariana Murea, Todd W. Robinson, Shahriar Moossavi, Gregory B. Russell. Wake Forest School of Medicine, Winston-Salem, NC.

Background: It is unclear whether surgical placement of an AVF confers significant clinical benefits over an AVG in older adults with ESKD.

Methods: In this pilot randomized, parallel-group, open-label trial, patients ≥65 years old with ESKD, no prior AV access, on HD via a tunneled central venous catheter (CVC), referred for AV access placement by their nephrologist, were randomly assigned (1:1) to surgical placement of AVG or AVF.

Results: Of 122 older adults on HD with no prior AV access, 24% expired before or were too sick for surgery referral. Of 46 eligible patients, 36 consented and randomized to AVG (n=18) and AVF (n=18) placement; 13 (72%) and 16 (89%) underwent index AV access failure was noted in 31% in each group. Successful cannulation occurred in 8 (62%) in AVG and 8 (50%) in AVF group; median time to successful cannulation was 75.0 and 113.5 days, respectively. Endovascular procedures were recorded in 38% and 44%, and surgical re-interventions in 23% and 25% (Table 1). AV access infection was seen in 23% and 13% patients, respectively.

Conclusions: Based on these limited results, there is little reason to favor either AVF or AVG in this population until results from a larger randomized clinical trial become available.

PO2632

Health Economic Evaluation of the Theranova 400 Dialyzer Among Hemodialysis Patients in the United States: Results from a Randomized-Controlled Trial

Michael J. Blackowicz,1 Luke Falzon,2 Mengqi Xiao,2 Angelito A. Bernardo,1 Ha Tran.2 Worldwide Medical, Baxter Healthcare Corp Malta, San Gwann, Malta; 2Worldwide Medical, Baxter International Inc, Deerfield, IL.

Background: In a 24-week, open-label RCT, expanded hemodialysis (HDx) via the Theranova 400 medium cut-off dialyzer had superior reduction ratios of large middle molecule uremic toxins such as k and λ free light chains, complement factor D, TNF-α, and β2-microglobulin, compared to a high-flux dialyzer (Elisio-17H) in the US (Werner et al. 2020). The purpose of this study is to perform a cost-consequence analysis for comparison of healthcare costs between HDx and conventional high-flux hemodialysis (HD).

Methods: Hemodialysis patients were randomized to receive treatment with either Theranova 400 or Elisio-17H over 24 weeks in the US. Hospitalization rate and average length of stay were calculated directly from trial data. Frequency of erythropoiesis stimulating agent (ESA) and iron use were obtained from the Centers for Medicare and Medicaid Service (CMS) and hospital costs from the Kaiser Family Foundation. Both deterministic (±20%) and probabilistic (95% confidence intervals) sensitivity analyses were conducted to account for variability in model inputs.

Results: There were 86 patients (386 patient-months) in the Theranova group and 85 patients (366 patient-months) in the Elisio group. All-cause hospitalization rate was 43% lower with Theranova compared to Elisio (RR=0.57; p=0.069). Frequency of ESA use was 46.5% in the Theranova group compared to 55.8% in the Elisio group, but doses were similar between the two groups. Both frequency and dose of iron were similar between the two groups. Average annual cost of hospitalization was $3,925 lower with Theranova compared to Elisio. Annual cost of ESAs and iron were similar between the two groups, although the cost of ESAs was $400 lower in the Theranova group. Compared to Elisio, the average annual cost of Theranova was $4,340 lower per patient. Hospitalization rate and length of stay were the main drivers of cost in the model.

Conclusions: This study provides evidence that, in addition to Theranova’s superior removal of large middle molecules, Theranova may also be a cost-saving therapy driven largely by reduction in hospitalization events.

PO2634

Intermittent Pneumatic Compression Promotes Presurgery Cephalic Vein Dilation: Preliminary FACT Trial Results

Tej M. Singh. Vascular Surgery, El Camino Hospital, Mountain View, CA.

Background: Arteriovenous fistulas (AVF) are the preferred for hemodialysis access with suitable (2.0-2.5 mm) veins. AVF maturation has been poor globally and often leads to increased catheter contact time and costs. Intermittent compression of upper arm veins may aid in forearm vein dilation pre-surgery to assist in AVF placement and maturation with size expectations and effectiveness.

Methods: This is was a prospective, IRB approved trial. A novel intermittent pneumatic compression device [Fist Assist® (FA)] was applied to upper arms below the shoulder to allow cyclic compression of 60 mm Hg four hours daily for 90 days. Sixteen (n=16) Stage 4 chronic renal failure (CRF) patients were in the study arm to test arm cephalic vein dilation. Vein size was measured and recorded at baseline and after 90 days by duplex measurement of the cephalic vein with a tourniquet. Clinical results: vein size at particular locations was recorded and tested for significance using a paired-difference t-test.

Underline represents presenting author/disclosure.
Results: Sixteen (n=16) mostly African American patients were involved in the first interim evaluation of the device in a USA FACT trial. All patients were in compliance with the study and followed the study protocol. No major complications or adverse events were noted in any patient except one non-device related rash. Differences were noted with the measurements done with a cuff in the vein sizes in the forearm (FA) and upper arm (UA) with larger significance. FA:3M = 3-Month-Vein diameter (AP), with cuff, at 1 cm above elbow UA : Enrollment-Vein diameter (AP), with cuff, at 1 cm above elbow for FA: Enrollment-Vein diameter (AP), with cuff, at 1 cm from radial bone Difference between mean of (FA3M-FA) : $t = 1.72$, $p-value = 0.04$ For Clinical Effectiveness: FA: 18.5% $\pm$ 2.5 mm and 33% reached 2.0 mm or greater UA: 44% $\pm$ 2.5 mm and 20% reached 3.0 mm or greater.

Conclusions: Early application of a novel, intermittent pneumatic compression device may be successful in preparing forearm veins in Stage 4 CRF patients. The early study results of the FACT trial show statistical significance in vein size improvement, distensibility, and clinical effectiveness to reach predetermined size goals.

PO2635

A Randomized Controlled Trial of Dialysate Sodium in Hospitalized Hemodialysis Patients

Finnian R. McCausland,1,2 Katherine M. Scovern,1 Katherine Curtis,1 Zoe A. Kibbelaar,1 Samuel Short,1 Anika T. Singh,1 Simon Correa,1 Sushrut S. Wairak1,1 Brigham and Women’s Hospital, Boston, MA; 1Harvard Medical School, Boston, MA; 1University of Vermont College of Medicine, Burlington, VT; 2Boston University, Boston, MA.

Background: Several large dialysis organizations have lowered the dialysate sodium concentration (DNa) in an effort to ameliorate hyperparathyroidism. The implications of lower DNa on intra-dialytic hypotension (IDH) during hospitalizations of hemodialysis (HD) patients is unclear.

Methods: In this double-blind single center randomized controlled trial, hospitalized maintenance HD patients were randomized to receive higher (142 mmol/L) or lower (138 mmol/L) DNa for up to six sessions. Blood pressure (BP) was measured in a standardized fashion pre-HD, post-HD and every 15 minutes during HD. The primary endpoints were: 1) the average decline in systolic BP, and 2) the proportion of total sessions complicated by IDH (defined as a drop of ≥20 mmHg from the pre-HD SBP).

Results: A total of 139 patients completed the trial, contributing 311 study visits (Table 1). There were no significant differences in the average SBP decline between the higher and lower DNa groups (23 ±6 vs. 26 ±16 mmHg; P=0.31). The proportion of total sessions complicated by IDH was similar in the higher DNa group compared with the lower DNa group (54% vs. 59%; OR 0.72; 95%CI 0.36 to 1.44; P=0.35). In post-hoc analyses adjusting for imbalances in baseline characteristics, higher DNa was associated with an 8 mmHg (95%CI 2 to 14 mmHg) lesser decline in SBP, compared with lower DNa. The trial enrolled 39 patients a6 years with primary hyperoxaluria type 1 (PH1) and 30 patients with primary hyperoxaluria type 2 (PH2).

Efficacy and Safety of Rapid Intravenous Correction vs. Slow Continuous Correction with Hypertonic Saline in Patients with Symptomatic Hyponatremia: A Randomized Clinical Trial (SALSA Trial)

Seon Ha Baek,1 Sejoong Kim,1 Hallym University Dongtan Sacred Heart Hospital, Hwaseong, Gyeonggi, Republic of Korea; 1Seoul National University Bundang Hospital, Seongnam, Republic of Korea.

Background: Few high-quality evidences have clarified whether hypertonic saline is best administered as slow continuous infusion therapy (SCI) or rapid intermittent bolus therapy (RIB) for symptomatic severe hyponatremia.

Objectives: To compare the efficacy and safety of RIB and SCI with hypertonic saline in patients with symptomatic severe hyponatremia. Design Prospective, investigator-initiated, multi-center, open-label, randomized controlled study from 24 August 2016 until 21 August 2019 Setting Emergency rooms and wards of three general hospitals located in South Korea Participants: 178 patients aged ≥18 years with symptoms and glucose-corrected serum sodium (sNa) ≥125 mmol/L were included.

Interventions Either RIB or SCI of 3% hypertonic saline for 24-48 hours stratified by

Background: Guidelines for membranous nephropathy (MN) management recommend cyclical corticosteroid-cyclophosphamide regimen (CYC) in patients with heavy proteinuria. Rituximab (RTX) may be a viable alternative, but head-to-head comparison is lacking.

Methods: Aim of this pilot RCT was to estimate the effects of RTX vs CYC regimen in MN, while assessing the feasibility of a larger trial. After a run-in of at least 3 months, patients with nephrotic syndrome were randomized to receive RTX (1g every 2 weeks apart) or CYC. Complete remission (CR) was defined as proteinuria ≤0.3g/day, partial remission (PR) as a reduction of proteinuria >50% and an absolute value of 0.3-3.5 g/day. Primary outcome was CR at 12 months; secondary outcomes included CR+PR at 12 and 24 months.

Results: 116 pts were screened, 74 randomized. Baseline median serum albumin was 2 g/dl and proteinuria 6 g/day in both arms. At 12 months, 6/37 pts (16%) in the RTX arm and 12/37 (32%) in the CYC arm had CR (OR according to “intention to treat –ITT” analysis 0.4, 95% CI 0.13-1.23, OR according to per protocol –PP 0.28, 95% CI 0.06-0.95, 23/37 (62%) in the RTX arm and 27/37 (73%) in the cyclical regimen arm had CR+PR at 24 months. No difference in side effects was found. While the efficacy of RTX and CYC in MN appears to be similar, a larger trial adequately powered would be difficult to perform.

Phase 2 Study of N-Acetylmannosamine (ManNAc) for Glomerular Diseases

Marian Huizing,¹ Jodi Blake,² William Gahl,¹ Jeffrey B. Kopp,² ¹Medical Genetics Branch, NHGRI, NIH, Bethesda, MD; ²Kidney Disease Section, NIDDK, NIH, Bethesda, MD.

Background: Sialic acid residues provide anionic charges to proteins, including those of the glomerular filtration barrier. Lectin analysis of kidney biopsies showed glomerular hyposialylation in nphrotic diseases, which may contribute to podocyte dysfunction and proteinuria. We showed in nphrotic mouse models that oral ManNAc, an uncharged precursor of sialic acid, normalized glomerular sialylation and markedly decreased proteinuria. ManNAc is also being studied to treat the rare hyposialylation disorder GNE myopathy (NCT04231266); it could be repurposed for patients with glomerular hyposialylation.

Methods: Phase 1 Results: A phase 1 study (NCT02639260; IND 125,192) of ManNAc in 7 nphrotic subjects showed that oral ManNAc was safe and well-tolerated. Plasma free sialic acid levels peaked ~10h after ManNAc dosing, remained elevated beyond 48h, and continued to increase during twice daily dosing, particularly in subjects with low eGFR. No adverse events occurred with increased plasma free sialic acid levels. Most subjects receiving ManNAc twice daily showed a 26-54% reduction in urine protein/creatinine ratio (UPCR), which appeared to correlate with the degree of glomerular hyposialylation.

Results: Phase 2 Design: An open-label phase 2 study will include assessment of longer-term pharmacokinetics, safety and efficacy. We will enroll 12 adults with focal segmental glomerulosclerosis, minimal change disease or membranous nephropathy, UPCR >2g/g, eGFR >45 ml/min/1.73m² and glomerular hyposialylation. Glomerular sialylation will be assessed by lectin analysis of previous diagnostic biopsies. Subjects will receive oral ManNAc twice daily for 12 weeks, with clinical evaluations at baseline, interim and at the end of the study. Study outcomes will include safety and reduction of UPCR. Exploratory outcomes will include quality of life, patient-reported outcomes and improvement in eGFR.

Conclusions: Oral ManNAc therapy might benefit subjects with glomerular hyposialylation. ManNAc has minimal toxicity, is well tolerated, is easily administered, shows a trend to reduction of proteinuria, and could replace or augment existing therapies. The results of the planned phase 2 trial might offer a new therapeutic approach for primary and perhaps secondary glomerular diseases. Such results may change medical practice by including assessment of glomerular sialylation in the analysis of renal biopsies.

The Immunoglobulin G Degrading Enzyme Imlifidase for the Treatment of Anti-GBM Disease: The GOOD-IDES 01 Trial

Marten Seecmark,¹ ² Fredrik Uhlin,¹ Elisabeth Sonesson,³ The GOOD-IDES Study Team ¹Clinical Sciences, Lunds Universitet, Lund, Sweden; ²Medical and Health Sciences, Linköpings universitet, Linköping, Sweden; ³Hansa Biopharma, Lund, Sweden.

Background: Anti-GBM disease is an ultra-rare small vessel vasculitis with a yearly incidence below 2 per million. Most cases present with rapidly progressive glomerulonephritis and despite aggressive treatment with plasma exchange and cyclophosphamide renal survival is poor, at least for those presenting with advanced kidney injury. Imlifidase has been shown to cause depletion of circulating and kidney bound anti-GBM within a few hours, but it is not known if this leads to an improved outcome.

Methods: We conducted an international multi-center one-arm open-label study giving a single dose of 0.25mg/kg of imlifidase (non-proprietary name for Ides™ - Immunoglobulin G Degrading Enzyme of Streptococcus pyogenes) on top of standard of care (ClinicalTrials.gov: NCT03157037). Main inclusion criteria were eGFR <15 ml/min/1.73m² and circulating anti-GBM antibodies. Main exclusion criteria were moderate or severe lung hemorrhage, dialysis dependency >5 days and/or oliguria >48 hours. The primary outcome was dialysis free survival at 6 months.

Results: At 17 tertiary referral hospitals in 5 European countries 15 patients (6 women) were recruited between June 2017 and January 2020. Their median age was 60 years (range 19-77) and 5 were double positive for anti-GBM and ANCA. At inclusion 10 patients were dialysis dependent including 5 that were oliguric/anuric; the remaining 5 patients had eGFR of 7-14 ml/min. 6h hours after imlifidase no patient had anti-GBM above the reference range. Return of antibodies prompting plasma exchange was seen in 10 patient 4 to 22 days after imlifidase (median 7 days), and they received a median of 8 session (range 2-17). At six months 10 patients were dialysis independent (median eGFR 27 ml/min, range 16-67), one was dead and 4 had developed ESRD. A favorable response was seen also in some patients that were anuric on inclusion and in some with 100% crescents. The safety profile was good; there were 7 serious adverse events (SAEs) reported but no serious unexpected suspected adverse reaction (SUSAR).

Conclusions: Imlifidase leads to rapid clearance of anti-GBM which seems to widen the window of opportunity for treatment thereby increasing the chance of renal survival in difficult to treat patients with anti-GBM disease.
