**Background:** Acute kidney injury (AKI), with or without proteinuria, has been described in patients with Coronavirus disease 2019 (COVID-19). Kidney involvement in COVID-19 has been reported to be of greater severity in African Americans (AA). Here, we report genetic, histopathological and molecular findings in 6 AA patients with COVID-19 presenting with AKI and de novo nephrotic-range proteinuria.

**Methods:** Percutaneous kidney biopsies were performed in 6 patients with COVID-19 with respiratory manifestations and proteinuric AKI. Peripheral blood was obtained for apolipoprotein L1 (APOL1) risk allele assessment. Kidney tissue was also examined by situ hybridization (ISH) for viral detection and by NanoString for COVID-19 associated genes and genes related to tubular injury.

**Results:** Six AA patients with COVID-19 (4 men, 2 women), mean age 55 years (37-65) were included in the series. At biopsy day, the mean serum creatinine was 6.5 mg/dL (2.9 – 11.4) and the mean urine protein-to-creatinine ratio was 11.5 g (3.6 – 25.0). Five patients were African American, three patients were Hispanic, and two were Caucasian. Nine patients had varying degree of proteinuria. Eight patients had severe COVID-19: Clinical and Basic Science Characteristics

**PO0838**

Purva D. Sharma, Hitesh H. Shah, Kenar D. Jhaveri, Vanesa Bijol. On behalf of the Northwell Renal COVID 19 Consortium Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY.

**Background:** Acute kidney injury (AKI) has been recognized as a common complication of severe COVID-19 in hospitalized patients. Proteinuria and microscopic hematuria have also been observed. While a recent autopsy series of patients who died with severe COVID-19 in China found acute tubular necrosis (ATN) in the kidney, few case reports of collapsing glomerulopathy in COVID-19 have also been reported.

**Methods:** To better understand the clinical and histopathologic findings, we looked at 10 kidney biopsy cases in patients with COVID-19 along with clinical features of AKI with or without proteinuria or hematuria in our institution. We described their clinical features, pathologic findings and outcomes.

**Results:** The mean age of the patients who underwent kidney biopsy was 65 years. Four patients were African American, three patients were Hispanic, and two were Caucasian. Nine patients had varying degree of proteinuria. Eight patients had severe...
AKI necessitating renal replacement therapy. On kidney biopsy, all patients had varying degrees of ATN, with one patient having associated widespread myoglobin casts. In addition, two patients had findings of thrombotic microangiopathy (TMA), one patient had pauci-immune crescentic glomerulonephritis and another patient had global as well as segmental glomerulosclerosis with features of healed collapsing glomerulopathy. Interestingly, all patients had negative immunohistochemistry staining for SARS-CoV-2 on their kidney biopsy material.

Conclusions: This biopsy series reveals ATN as the most common kidney biopsy finding with AKI in COVID-19 infection with no evidence of significant viral presence in the kidney tissue.

PO0839
Kidney Pathology Findings in Patients Dying with COVID-19
Meghan E. Kagy, Jose E. Najul, Michael H. Hines, Brian P. Strollo, Jonathan L. Babin, Pasiat Paueksakon, Mark Lucso, Agnes B. Fogo, Juan Carlos Q. Velez, Vanderbilt University Medical Center, Nashville, TN; 2Ochsner Health System, New Orleans, LA.

Background: The global pandemic caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) leading to coronavirus disease 2019 (COVID-19) has predominantly resulted in a profound hypoxic respiratory disease with a significant subset of patients demonstrating abnormalities in renal function. Acute kidney injury (AKI) in these patients is an independent risk factor for mortality; however, the mechanism for injury is unknown and our understanding of the pathologic findings is limited.

Methods: Kidney tissue from nine patients who died with COVID-19 was obtained at autopsy and evaluated by light, immunofluorescence, and electron microscopy. RNAscope technology was used to perform RNA in situ hybridization (RNA ISH) with probes to the SARS-CoV-2 virus (sense) and for human gene ACE2.

Results: The cohort was comprised of 6 men and 3 women, 78% black, median age of 65 years (37 – 78) and median body mass index 29 (26 – 48) kg/m², of which 6 (67%) had hypertension and 4 (44%) had diabetes. AKI was present in 7 of 9 (78%), 4 (44%) had diabetes and 59% had hypertension. Of the 17 patients, clinical evidence of AKI was present in 12 (71%) patients; 4/12 (33%) had Stage 1 AKI, 6/12 (50%) had Stage 2 AKI, and 2/12 (17%) had stage 3 AKI. Median peak creatinine was 0.96 mg/dL IQR 0.92-1.23 in those without AKI and 2.98 mg/dL IQR 2.11 – 5.99 in those with AKI. 3 patients had urine studies performed, only one of them had AKI and had hematuria, proteinuria, and leukocyturia. On histopathology, 9/17 (53%) had acute tubular injury (ATI) only (Fig 1A & B) and 1/17 (5%) had TMA and ATI (Fig 1C). ATI was present in 4 out of 5 (80%) of patients without AKI. There was no TMA found in patients without AKI. Glomerular pathology included nodular sclerosis in diabetic nephropathy (Fig 1D) and glomerulosclerosis secondary to ischemic hypertension. Virus was found in 4 samples (Fig 1E & F).

Conclusions: There is direct involvement of kidney by SARS-CoV-2 supported by identification of viral particles by TEM, and by ISH RNAscope. The most common histopathologic finding in patients that died with COVID-19 was ATI, which was also present in patients who did not have AKI by serum creatinine criteria.

PO0840
Renal Histopathological Post-Mortem Findings of 17 Patients with COVID-19 in New York City
Nitzy N. Munoz Casablanca, Mohamed Rizwan Haroon Al Rasheed, Judy Hindi, Lili Chan, Steven G. Coca, Fadi Salem, John C. He. Icahn School of Medicine at Mount Sinai, New York, NY.

Background: While acute kidney injury (AKI) is a common and serious complication of patients with COVID-19, the mechanisms are unclear. Histopathological reports of kidney tissue in COVID-19 are limited.

Methods: This was a retrospective case series of autopsy cases with confirmed SARS-CoV-2 infection performed at the Mount Sinai Hospital in patients who died between 3/21/2020 to 4/23/2020. Patients who had a kidney transplant, were on dialysis, or with severe autolysis were present, or had no clinical data were excluded. To identify SARS-CoV-2, sections were examined by Transmission Electron Microscopy (TEM) and stained by In Situ Hybridization (RNAscope) in kidney sections.

Results: 32 patients had autopsies done, of which 17 patients fulfilled our inclusion criteria. The median age was 64 (interquartile range (IQR) 50, 79), 70% were male, 18% were black, 42% had diabetes and 59% had hypertension. Of the 17 patients, clinical evidence of AKI was present in 12 (71%) patients; 4/12 (33%) had Stage 1 AKI, 6/12 (50%) had Stage 2 AKI, and 2/12 (17%) had stage 3 AKI. Median peak creatinine was 0.86 mg/dL IQR 0.92-1.23 in those without AKI and 2.98 mg/dL IQR 2.11 – 5.99 in those with AKI. 3 patients had urine studies performed, only one of them had AKI and had hematuria, proteinuria, and leukocyturia. On histopathology, 9/17 (53%) had acute tubular injury (ATI) only (Fig 1A & B) and 1/17 (5%) had TMA and ATI (Fig 1C). ATI was present in 4 out of 5 (80%) of patients without AKI. There was no TMA found in patients without AKI. Glomerular pathology included nodular sclerosis in diabetic nephropathy (Fig 1D) and glomerulosclerosis secondary to ischemic hypertension. Virus was found in 4 samples (Fig 1E & F).

Conclusions: There is direct involvement of kidney by SARS-CoV-2 supported by identification of viral particles by TEM, and by ISH RNAscope. The most common histopathologic finding in patients that died with COVID-19 was ATI, which was also present in patients who did not have AKI by serum creatinine criteria.

PO0841
COVID-19-Associated Nephropathy (COVAN): An Emerging Entity of Severe Viral Podoocyte Injury and Collapsing Glomerulopathy in Kidney Biopsies
Surva V. Seshan, Steven Salvatore, Billie S. Fye-Kirschner, Ronald Miick, Aqeel A. Siddiqui, Mohamed Kahila, Ramya Ramakrishnan, Richard E. Freundlich, Anthony D. Nicastri, Weill Cornell Medicine, New York, NY; Rutgers The State University of New Jersey New Brunswick, NJ; Albert Einstein Healthcare Network, Philadelphia, PA; SUNY Downstate Health Sciences University, Brooklyn, NY; NewYork-Presbyterian Brooklyn Methodist Hospital, Brooklyn, NY; Newark Beth Israel Medical Center, Newark, NJ; Lankenau Medical Center, Wynnewood, PA.

Background: COVID19 caused by novel Coronavirus SARS-CoV-2 initially presenting primarily as a respiratory illness, is now known to affect several organ systems as part of multiorgan failure including acute kidney injury (AKI), some cases also manifesting nephritic range proteinuria or syndrome.

Methods: 10 renal biopsies from 6 institutions (1 transplant) performed in April-May 2020 were processed for light microscopy, immunostaining (IS) and electron microscopy (EM) for clinco-pathologic analysis.

Results: The 10 patients ranged from 25-73 years (Mean 43), male:female 5:5. 8 African American, 1 Hispanic, 1 Asian Indian, having pre-existing co-morbidities of hypertension (7), Diabetes mellitus (5), obesity (9), presenting with AKI (10), nephrotic syndrome (9), proteinuria ranging from 1.5-25g/24hrs, lung symptoms or pneumonia (7), fever (5). SARS-COV-2 RT-PCR positive (7), IgG antibody positive (2), both negative (1). All kidney biopsies showed widespread acute tubular injury with focal necrosis, 9 with typical features of segmental/global collapsing glomerulopathy in 10-53% of glomeruli, global glomerulosclerosis (0-35%), focal tubular microcystic changes (8), patchy (3) or diffuse (2) active tubulointerstitial inflammation around arterioles (10-40%), diffuse interstitial inflammatory infiltrate, moderate ascites (4).
diabetic kidney disease in 2. No immune deposits were localized by IS. By EM, variated glomerular capillary loop and collapse with segmental or global loss of capillary basement membrane (7), total foot process effacement (7), with hyperplastic and vacuolated epithelial cells having protein droplets are noted. The endothelial cells are variably swollen, with tubulo-interstitial inclusions in 2. Viral particles are identified within cells of glomeruli and tubulo-interstitial area, scattered or in clusters in the cytoplasm and endoplasmic reticulum vesicles, confirmed by IS.

Conclusions: The constellation of typical glomerular collapsing features with tubulointerstitial findings and localization of virus by EM, suggests a distinct viral associated nephropathy, reminiscent of HS associated nephropathy. A role for viral cytopathic effect, cytokines and antibody mediated APLD gene variants could be considered.

PO0842
COVID-19 Renal Pathology Protocols and Pathology Practice in Latin America: Analysis from GlomCon Latin America Working Group (LGlomCon)
Blanca Martinez-Chaquilla,1 Denise Arellano-Mendez,2 Diana Aguirre,4 Desiree Garcia Anto6, Julio A. Gutierrez-Prieto,6 Sonia Rodriguez Ramirez,6 Javri Soto-Vargas,4 Franco H. Cabeza Rivera,5 Carmen Avila-Casado.1 GlomCon Latin America Working Group 1Pathology Department, University Health Network, Toronto, ON, Canada; 2Hospital General de Morelia Miguel Morelia, Mexico; 3Unidad Medica de Atencion Ambulatoria 254, IMSS, Morelia, Mexico; 4Hospital General de Mexico, Mexico City; 5Hospital General de Chihuahua, Chihuahua, Mexico; 6Multi-Organ Transplant Program, University Health Network, Toronto, ON, Canada; 7Hospital General Regional 46 IMSS, Guadalajara, Mexico; 8University of Mississippi Medical Center, Jackson, MS.

Background: A significant fraction of patients with COVID-19 display renal involvement (60%); however, the histological findings and pathology practice in Latin America (LA) have not been reported. The aim is to know how COVID-19 pandemic has affected the protocols for renal pathology and the main pathology findings in the kidney.

Methods: An online survey with 75 questions in 6 sections, directed to pathologists, nephrologists and other specialists from 16 Spanish speaking LA countries treating COVID-19 patients with kidney involvement. We are analyzing the impact of COVID-19 in renal pathology and pathology practice in LA.

Results: From 430 responses, 360 (84%) were considered for analysis. Only 13 participants from 16 countries were renal pathologists but the rest of responders also corresponded to pathologists that respond renal biopsies derived from COVID-19 patients. Acute kidney injury (AKI) (85%) was the most frequent indication for RBx, hematuria-proteinuria (42%), nephrotic syndrome (28%) and subnephrotic proteinuria (21%). Combination of AKI and other syndrome was seen. Handling fresh tissue for immunohistochemistry (IF) is a regular practice in the centers that perform IF (66%). No ultrastructural examination in 90% due to the lack of EM equipment. Postmortem studies only in 3% of the cases. Autopsy and biopsies showed thrombotic microangiopathy (TMA), with acute tubular injury (ATI). Pathology redeployment to clinical areas, ICU and inpatient care is seen in 12%. Only 70% of those received guidance or updating clinical courses.

Conclusions: The survey has highlighted the deep shortage of renal pathologists and the lack of equipment (EM) compromising the best practice of renal pathology in LA. Practical changes for tissue handling for COVID have not been established in any center, adding a burden to the practice. Most frequent indication for renal biopsy is AKI while the presence of TMA and ATI is found in autopsy and renal samples. Collapsing glomerulopathy (CG) has a high prevalence in hispanics and has been described in COVID patients, however CG has not been seen. Outbreaks had forced pathology redeployment to clinical care without proper preparation.

PO0843
Oxidative Stress, the Final Common Pathway in Lung-Kidney Pathophysiologic Cross-Talk in an Experimental Model of COVID-19: Clinical Implications
Firoozeh Farahmand,1 Saint Louis University, Saint Louis, MO.

Background: AKI occurs frequently in patients with COVID-19 disease early in the course, in temporal association with respiratory failure and is associated with a poor prognosis. AKI is primarily seen in Covid-19 patients with respiratory failure, with 90% of patients on mechanical ventilation developing AKI compared to 22% of non-ventilated patients. To develop experimental models investigating pathophysiologic mechanisms of Lung- kidney interactions is an essential part of understanding the mechanisms of organs cross talk, i.e. the complex biological communication and feedback between distant organs mediated via cellular and molecular pathways.

Methods: In a novel experimental model similar to human COVID-19, ARDS followed by AKI developed by single injection of a Toxicoid (TOX). Two days post injection lungs and kidney were analyzed for antioxidant enzyme activities including superoxide dismutase, glutathione peroxidase, catalase and oxidative stress. Lungs wet/ dry weight ratios were measured to evaluate edema. After sacrificing the animals, kidney and the lung were removed for histology.

Results: At 2 days post-TOX injection there was acute lung injury with cytotoxic influx, lung edema, neutrophil infiltration, hypoxemia and pulmonary artery thrombosis. In the kidney there was acute tubular necrosis with inflammatory infiltration. Oxidative stress was increased in the lung and the kidney. Antioxidant enzymes activities of SOD and catalase were decreased in the kidney.

Conclusions: In this experimental model mimicking COVID-19 organ failure, AKI and ARDS in rats correlates with a decrease in antioxidant and increase in oxidative stress in the lung & the kidney. This suggest the role of antioxidant as the potential adjunct therapeutic agents in COVID-19 related organ failure.

PO0844
Renal Pathology of 34 Consecutive COVID-19 Autopsies: A Single-Institution Experience
Steven Salvator, Alain C. Borczuk, Surya V. Seshan. Weill Cornell Medicine, New York, NY.

Background: Patients infected with the novel coronavirus 2019 (COVID19) have a wide spectrum of symptoms ranging from asymptomatic carriers to multisystem organ failure and death. While 20-40% of critically ill patients develop acute kidney injury (AKI) during the course of the disease, only few are biopsied. The most severely affected patients, frequently with multiple co-morbidities, provide insight into renal disease at autopsy.

Methods: 30 of 34 autopsies performed on COVID patients had kidneys available for routine evaluation. Clinicopathologic features are presented.

Results: The 34 patients range in age from 30-100 years (mean 68.5), 24 males and 10 females, 13 Caucasian, 10 Hispanic, 5 African American, 3 Indian, 3 Asian. All cases were positive by RT PCR nasal swab for SARS-CoV-2 except 3 (presumed false negative). All had on average 3.4 comorbidities (range: 0-7; hypertension (HTN), diabetes (DM), obesity, COPD, asthma, stroke, dementia, cancer), frequently HTN (29) and DM (25). 31 required intubation and 18 patients had AKI (53%), 2 previously ESRD, and 5 required renal replacement therapy. Presenting Cr ranged from 0.7-9.6 mg/dl (mean 1.7). Renal pathology included diabetic nephropathy (14, 47%), with tubulointerstitial scarring ranging from ~25% (60%), 25-50% (23%), to >50% (17%), and moderate (40%) or severe (40%) chronic vascular scarring. Other findings: obesity related renal disease (2), atherosclerosis (2), arteriovenous malformations (1), and thrombotic microangiopathy (2). No collapsing glomerulopathy was seen. Tubular autolysis prevents complete assessment of ATN. Platelet thrombi were seen by CD61 staining in 43% of cases to involve 20% of glomeruli and tubulointerstitial capillaries. C6b-9 staining was positive in 2strong, 2-3+ arteriolar in 67% and glomeruli in 20%, suggesting localized complement activation. By electron microscopy, viral particles were identified within cells of glomeruli and tubulo-interstitium.

Conclusions: Pathology in autopsies kidney from 30 patients with COVID display glomerular disease with co-morbidities present that are related to AKI with AKI or ESRD (59%). Despite varied tissue autolysis and the absence of significant proteinuria, the majority of AKI is presumed to be acute tubular injury due to ischemia and other causes. The viral particles in the renal glomerular and tubular cells may play a role in renal cytopathic injury.

PO0845
RAAS Inhibition, Mortality, and Severity in COVID-19 Patients: A Systematic Review and Meta-Analysis
Mahmoud M. Shaker1,2, Ahmed Daoud,3 Tibor Fulop,4 Maria Aurora C. Posadas,4 Michael Casey,1 Vinaya Rao,4 Karim M. Soliman.4,3 The University of Tennessee Health Science Center, Memphis, TN; 2University Hospitals of Birmingham, Birmingham, UK, Birmingham, United Kingdom; 3Cairo University Kasr Alainy Faculty of Medicine, Cairo, Egypt; 4Medical University of South Carolina, Charleston, SC; 5Ralph H. Johnson VA Medical Center, Charleston, SC, USA, Charleston, SC.

Background: The effect of angiotensin-receptor blockers (ARBs) and angiotensin-converting enzyme inhibitors (ACEIs) on outcome and severity in COVID-19 patients has been postulated.

Methods: We performed a systematic review in different databases to identify studies and research work that assessed the association of ACEi/ARBs on the severity of illness and mortality in COVID-19 subjects. Inclusion criteria for our meta-analysis were all studies that included human subjects with COVID-19 infection, reported mortality and research work that assessed the association of ACEi/ARBs on the severity of illness.

Results: Out of 4,702 records reviewed in different databases, 11 papers were included in our meta-analysis. Altogether, 8,643 patients were included in the final analysis. Random-effects model (REM) for (1), bilateral-infection (1) ACE/ARB analysis (2), and thrombotic microangiopathy (2). No collapsing glomerulopathy was seen. Tubular autolysis prevents complete assessment of ATN. Platelet thrombi were seen by CD61 staining in 43% of cases to involve 20% of glomeruli and tubulointerstitial capillaries. C6b-9 staining was positive in 2strong, 2-3+ arteriolar in 67% and glomeruli in 20%, suggesting localized complement activation. By electron microscopy, viral particles were identified within cells of glomeruli and tubulo-interstitium.

Conclusions: Based on the results of this meta-analysis, ACEi/ARB are not associated with increased mortality or severity in COVID-19 subjects.
PO0846

The Use of ACE Inhibitors and ARBs in Patients Admitted for COVID-19

Background: Angiotensin converting enzyme (ACE) 2 receptor has been implicated as an entry point for severe acute respiratory syndrome coronavirus 2 (SARS-COV-2) causing pandemic coronavirus disease 2019 (COVID-19). Experts have postulated the potential benefits of using ACE/ARB to reduce the severity of acute lung injury and as the treatment of hypertension in COVID-19. However, there is limited data in showing the renal outcomes after the use of angiotensin converting enzyme inhibitors (ACEIs) and angiotensin II receptor blockers (ARBs) in COVID-19 patients.

Methods: This is a retrospective, single center study of 300 patients diagnosed with COVID-19 confirmed by real-time reverse transcription polymerase chain reaction. Four groups were divided based on ACE/ARB exposure. Group 1 (n=51 patients; 17%) were initiated on ACEI/ARBs during hospitalization, group 2 (n=58 patients; 19%) were on ACEIs/ARBs at home and discontinued, group 3 (n=76 patients; 25%) were on ACEIs/ARBs at home and continued during hospitalization and group 4 (n=116 patients; 38%) were never treated with ACEIs/ARBs. The primary end points including the incidence of AKI using KDIGO definition, hyperkalemia, the necessity of dialysis and the secondary end points being the length of total hospital stays, the recovery rate, mortality rate were compared between group 1,2,3 with 4 using adjusted odd ratios (ORs).

Results: In group 1, the use of ACEI/ARB has 4 times higher risk of developing AKI than the control group (P= 0.001, 95% CI of 1.78-9.59) and is 4.6 times for stage 2 or above AKI (P= 0.001, 95% CI of 1.8-11.5) or for hyperkalemia is 5.7 (P= 0.001, 95% CI of 2.09-15.5) and for hemodialysis is 3.7 (P= 0.002, 95% CI of 1.2-11.2). Their mortality rate is increased 2.9 times (P=0.026, 95% CI of 1.23-7.44). In group 2, the incidence of AKI is 7.5 times higher (P< 0.001, 95% CI of 3.3-17) and 3.5 times (P=0.001, 95% CI of 1.6-7.7) for stage 2 above AKI. OR for the initiation of hemodialysis and the mortality rate are not statistically significant after adjusted with variables. In group 3, no statistically significant data were found.

Conclusions: Our findings suggest that the initiation of ACEI/ARB in COVID 19 patients have increased risk of AKI, hyperkalemia, necessity of dialysis and mortality rate.

PO0847

Prospective Feasibility Study with the Use of Losartan in COVID-19

Jeanwoo Yoo, Olena Bolotova, Imran Chaudhri, Nisha Nataraj, Hasena Sahib, Farrukh M. Koraishy, Sahar Ahmad, Michelle E. Bloom, Sandeep K. Millipattu. Stony Brook University Hospital, Stony Brook, NY

Background: The risks of administering Angiotensin II Receptor Blockers for hypertension in hospitalized patients infected with SARS-CoV-2 remains debated. To date, there are no prospective studies evaluating outcomes with the use of ARBs in patients with hypertension and COVID 19.

Methods: We conducted a single-center prospective feasibility study to ascertain the safety and efficacy of losartan in patients with COVID-19 and HTN. Inclusion criteria are patients with age ≥ 18yr, PCR confirmed SARS-CoV-2, BP>130/80, and required FIO2 ≥ 0.25 to maintain SpO2 > 92%. These patients were started and titrated on losartan 25mg daily to reach BP goal of <130/80. The vital signs, FIO2 requirements, LFTs, inflammatory markers, serum creatinine and K+ were monitored until discharge, with weekly evaluation of symptoms post-discharge.

Results: 250 patients were screened from April 22 to May 18, 2020, and 16 patients enrolled. Average time to enrollment was 5.5 days, with varying degrees of acuity. 6 patients were removed from the study (see Table 1). Eight patients completed the minimum 7 days of losartan while in the hospital 6/8 patients demonstrated no deterioration of SaO2/FiO2 ratio, SaO2/FiO2 compared on day 1 (201.1 ± 108.1) and day 7 (252.3 ± 148.4), and 2/8 patients improved to room air on day 7. Among all patients, inflammatory markers were not significantly changed from admission to peak values (Table 1).

Conclusions: This study has demonstrated that patients admitted with COVID 19 and hypertension who completed 7 days of Losartan showed no significant deterioration in oxygenation/worsening of inflammatory markers, thereby providing the rationale for a RCT with the use of losartan versus nonRAAS blockade in COVID-19.

Renin-Angiotensin-Aldosterone System Blocking Drugs in Patients with SARS-CoV-2: Systematic Review and Meta-Analysis

Chang Chu,1,2 Shufei Zeng,1,3 Ahmed A. Hasan,2,3 Carl-Friedrich Hocher,1 Bernhard K. Krämer,1 Berthold Hocher,1 Charité – Universitätsmedizin Berlin, Berlin, Germany; 2Department of Nutritional Toxicology, Institute of Nutritional Science, University of Potsdam, Potsdam, Germany; 3Fifth Department of Medicine (Nephrology/Endocrinology/Rheumatology), University Medical Centre Mannheim, University of Heidelberg, Mannheim, Germany.

Background: COVID-19 patients requiring treatment with blockers of the renin-angiotensin-aldosterone system (RAAS) are at highest risk of developing pneumonia and dying. ACE2 is the functional receptor for SARS-CoV-2. Animal studies suggest that RAAS blockers might increase the expression of ACE2 and hence potentially increase the risk of SARS-CoV-2 infection.

Methods: We conducted a systematic review and meta-analysis of published studies on the association of RAAS blocking agents with lung disease related outcomes.

Results: The effect of ACE inhibitor treatment on the incidence of pneumonia in non-COVID-19 patients was analyzed in 25 studies (330,780 patients). ACE inhibitor use was associated with a 27% reduction of pneumonia risk (OR: 0.73, p<0.001). Pooled result from 13 studies (27,704 COVID-19 patients) showed that COVID-19 related severe adverse clinical outcomes were not different between patients who did or did not use RAAS blocking agents (OR: 0.87, p=0.28).

Conclusions: Given the weak evidence coming from animal studies and the clear beneficial data of ACE inhibition in non-COVID-19 patients and the limited but promising data in COVID-19 patients, the use of RAAS blocking agents in patients with SARS-CoV-2 infection is justified. Further clinical studies analysing ARBs and ACE inhibitors separately in COVID-19 patients are needed.

PO0849

Association of Prehospital RAAS Inhibitor Use with AKI and Death in a Cohort of Hospitalized COVID-19-Infected Patients
Ryan Mocerino, Emad Alahiri, Matthew K. Abramowitz, Ladan Golostaneh. Montefiore Medical Center, Bronx, NY.

Background: The relationship of RAAS inhibitors (RAASi) and their purported role in increasing COVID-19 viral attachment and worse outcomes is controversial. In this study we examined the association of RAASi use with Acute Kidney Injury (AKI) and in-hospital death.

Methods: We assembled a cohort of all patients admitted to the 3 main Montefiore hospitals and diagnosed with COVID-19. RAASi use was defined by a prescription within 365 days prior to hospitalization. The association of RAASi use with COVID associated AKI incidence and mortality was evaluated using logistic regression models. Propensity score matching was then used to derive the odds ratio (OR) of AKI and death in those using RAASi compared with controls.

Results: Of 3345 hospitalized patients, 9.3% were prescribed a RAASi prior to hospitalization. The described RAASi use were older (71.9 vs 63.6 years, p<0.001), more commonly Black or Hispanic (RAASi users 41.3% Black and 41.0% Hispanic vs non-RAASi 35.4% Black and 36.9% Hispanic) and had higher Charlson co-morbidity scores (median 4 (IQR 3-7) for RAASi users vs 2(1-3) for non-RAASi users). In unadjusted analysis, RAASi use was associated with a higher OR for AKI (OR 1.3299% CI 1.04-1.68)) and a higher OR for death (OR 1.53 (95% CI 1.18-1.98). Multivariable adjustment for age, demographics, and clinical comorbidity attenuated associations of AKI and death towards the null (AKI: OR 1.00 (95% CI 0.76-1.31); Death: OR 0.92 (95% CI 0.68-1.24)). Similarly, in propensity score analysis there was no association between RAASi use and either AKI (OR 0.96 (95% CI 0.88-1.04)) or death (OR: 0.96 (95% CI 0.89-1.05).

Conclusions: RAASi use prior to hospitalization was not associated with AKI or in-hospital mortality in a cohort of patients hospitalized with COVID-19.

PO0850

Outcomes Associated with the Use of Angiotensin-Converting Enzyme Inhibitors and Angiotensin II Receptor Blockers in Hospitalized Patients with SARS-CoV-2 Infection
Imran Chaudhry,1 Farrukh M. Koraishy,1 Olena Bolotova,2 Jeanwoo Yoo,1 Sandeep K. Mallipattu,1 Stony Brook University Hospital, Stony Brook, NY; 2Northport VA Medical Center, Northport, NY.

Background: SARS-CoV-2 uses the angiotensin converting enzyme (ACE) receptor for cell entry leading to COVID-19. The use of ACE Inhibitors (ACEIs) and Angiotensin II Receptor Blockers (ARBs) in hypertensive COVID-19 patients remains unclear. Since hypertension is a major comorbidity in COVID19, evaluating the efficacy versus adverse outcomes with the use of ACEI or ARB in patients with COVID-19 is essential.

Methods: In this retrospective single-center study, we analyzed electronic medical record data on 300 patients admitted with COVID-19 disease. Data collection included comorbidities, medications, vital signs, and laboratory values (on admission and during hospitalization). Outcomes included inflammatory burden (calculated using composite scores for multiple markers of inflammation), AKI, admission to the intensive care unit (ICU), need for mechanical ventilation, and mortality. For multivariate analyses, generalized linear model (continuous outcomes) and logistic regression (dichotomous outcomes) were used.

Results: Of the 300 patients, 80 patients (26.7%) had history of ACEI or ARB use prior to admission, with 61.3% (48/80) of these patients continuing the medications during hospitalization. Outpatient users of ACEI or ARB had a higher burden of comorbid disease and increased rates of admission and in-hospital AKI in the descriptive analysis, but not on multivariable analysis (after adjusting for multiple covariates). Continuation of ACEI or ARB in an inpatient was associated with lower peak C-reactive protein (CRP) levels, peak inflammation score, ICU admission and mortality in the univariate analysis. On multivariable analysis, continuation of these agents during hospitalization predicted lower ICU admissions (OR=0.25, 0.08-0.81, p=0.02), peak CRP (-6.9 ± 3.1 mg/dl, p=0.03) and peak inflammatory score (-2.3 ± 1.1, p=0.001) as compared to their discontinuation.

Conclusions: In hospitalized patients with COVID-19, the use of ACEI or ARBs as an outpatient was not associated with adverse outcomes despite greater comorbid illness in users. The continued use of these medications during hospitalization was also not associated with adverse events, rather it predicted fewer ICU admissions and decreased inflammatory burden.

Glomerular Diseases and Immunosuppression Practices in Latin America During the COVID-19 Pandemic: Analysis from GlomCon Latin America Working Group (LGlomCon)
Julio A. Gutierrez-Prieto,1 Franco H. Cabeza Rivera,2 Sonia Rodriguez Ramirez,2 Javier Soto-Vargas,2 Denise Arielano-Mendez,2 Desiree Garcia Antunes,3 Diana Aguirre,2 Blanca Martinez-Chagolla, Carmen Avila-Casado,8 GlomCon Latin America Working Group 1Hospital Central del Estado de Chihuahua, Chihuahua, Mexico; 2Hospital General Regional 46, IMSS, Guadalajara, Mexico; 3Unidad Medica de Atencion Ambulatoria 254, IMSS, Morelia, Mexico; 4Hospital General de Morelia “Dr. Miguel Silva”, Morelia, Mexico; 5Hospital General de Mexicali, Mexicali, Mexico; 6University of Missouri, Missouri Medical Center, Jackson, MS; 7Med-Organ Transplant Program, University Health Network, Toronto, ON, Canada; 8Pathology Department, University Health Network, Toronto, ON, Canada.

Background: As COVID-19 spreads across the world, nephrologists are facing difficult decisions regarding the management of active glomerular diseases (GD). We aimed to report how COVID-19 pandemic may have changed the use of immunotherapies among nephrologists In Latin America (LA) for the treatment of glomerulopathies.

Methods: Descriptive analysis extracted from an online survey carried out among nephrologists, renal pathologists and other health workers treating kidney diseases between May 20-27, 2020 from sixteen Spanish speaking LA countries divided into 6 categories. We present the results for the GD and immunosuppression category.

Results: 430 responses were obtained of which 360 (84%) were considered for analysis. The participants were mainly nephrologists 276 (66%), renal pathologists 43 (4%) and physicians in training 11 (3%). 213 (59%) of the respondents treat patients with GD. For patients at risk but without COVID-19 infection, the induction immunosuppression for GD treatment was not changed by 54.1% of the respondents while 24% gave only a fraction of it and 21.7% deferred the induction treatment. For maintenance immunosuppression, the same regimen was maintained by 74.2% of the respondents. 24.3% decreased it and 1.5% suspended it completely. In case of relapse or flare, 53.6% used standard increase of immunosuppression, 39.7% increased it but at lower levels than usual and 6.7% continued the maintenance regimen. For patients already on immunosuppression diagnosed with COVID-19 infection, 42% would decrease immunosuppressive regimens for mild disease, 62.3% in case of moderate disease and 70.8% would consider completely discontinuing immunosuppression in case of severe disease.

Conclusions: Over 40% of the respondents in LA are already prescribing lower than recommended doses of immunosuppression for induction, relapses or flares as a preventive strategy in the context of COVID-19 pandemic. How this change in practice would affect the renal outcomes remains to be seen. The experiences in the treatment of GD in patients with concurrent COVID-19 infection remains limited.
PO0852
Ramipril Decreases Lung and Kidney Angiotensin Converting Enzyme 2 (ACE2) in Diabetic Mice: Lessons for COVID-19 Infection
Ander Vergara,1,2 Conxita Jacobs Cachà,1 Pamela Domínguez Baez,2 Mireia Molina Van den Bosch,2 Anna Giralt-López,2 Clara García-Carro,1,2 Daniel Serrón,1,2 María Jose Soler,1,2 Nephrology Research Group 'Vall d’Hebron Institut de Recerca, Barcelona, Spain; 1Vall d’Hebron, Barcelona, Spain.

Background: ACE2 is a component of the renin-angiotensin system (RAS) that mainly degrades angiotensin II to angiotensin(1-7). It is expressed in renal tubular cells. Lung type 2 alveolar cells also express ACE2 where it acts as a receptor for SARS-CoV-2, which is responsible for the current coronavirus disease 2019 (COVID-19) pandemic. A controversy raised regarding the use of RAS blockers in COVID-19 patients despite its demonstrated efficacy in cardiovascular diseases. We studied the effect of ramipril on ACE2 expression in experimental diabetes.

Methods: 12 weeks old diabetic db/db mice were given ramipril (8 mg/Kg/day) or vehicle during 8 weeks. db/m mice were used as controls. ACE2 expression and enzymatic activity were studied in kidney, heart and lung.

Results: In non-treated db/db, ACE2 mRNA expression was increased in kidney (p=0.0001) and ramipril treatment reversed this effect. In heart, ACE2 expression decreased in db/db compared to db/m (p=0.028) and ramipril had no effect. We found no differences in lung. ACE2 enzymatic activity was increased 23% in kidney and 22% in lung of db/db mice compared to db/m. Ramipril treatment decreased ACE2 activity 25% in the lung and 13% in the kidney when compared to untreated db/db. In the heart, ACE2 activity tended to decrease in db/db mice compared to db/m and increased with ramipril, but did not exceed the cardiac ACE2 activity of the db/m.

Conclusions: ACE2 is increased in the kidney and in the lung, and decreased in the heart of diabetic mice. Ramipril treatment restores ACE2. Our results suggest that diabetes and hypertension may per se be risk factors for COVID-19 and not the treatment with ACE inhibitors, which may exert a protective effect on COVID-19 infection.

PO0853
Caring for Patients with Kidney Disease in the COVID-19 Era: The Kaiser Permanente Northern California Experience
Siite Zheng,1,2 Ali Poyan-Mehr,1 Leonid Pravoverov,1 Sharina Belani,1 The Permanente Medical Groups, Oakland, CA; 2Kaiser Permanente, Oakland, CA.

Background: The COVID-19 pandemic has presented health care system in the United States with unprecedented challenges. Kaiser Permanente Northern California is an integrated health care system with 4.5 million members, who are cared for by The Permanente Medical Group (TPMG), a multiple specialty medical group of 10,000 physicians. Utilizing coordinated care, sophisticated Electric Medical Record system, KPNC Nephrology service line has developed several strategies to mitigate the effect of COVID-19, including rapidly increased video visit appointments for members with CKD.

Methods: After the “Shelter in place” order in March 2020, KP nephrologists started weekly virtual townhall meetings to coordinate care among 85 nephrologists in 19 hospitals covering patients with chronic kidney disease, receiving dialysis, and post kidney transplant. TPMG nephrologists have developed guidelines on: 1. Test for COVID-19 testing for Person Under Investigation (PUI) members; 2. Management of patients with Glomerulonephritis; 3. Post-kidney transplant care; 4. Expand advance care planning; 5. Converting direct patient visits to video visits; 6. Coordinating care with contracted dialysis providers for members on outpatient dialysis.

Results: The video visits have increased 780% from March to April and 1968% from March to May of 2020 (Figure). The top three diagnosis for video visits were: CKD, CKD4, and post kidney transplant. Since April 8, 2020, average 0.038% of dialysis patients were tested positive for COVID-19 and average 0.015% were diagnosed with COVID-19.

Conclusions: As an integrated health care system, KPNC has developed a systematic, collaborative and rapid crisis management of patients with CKD in COVID era. Further studies are needed to evaluate the long-term outcomes of these approaches.

PO0854
Benefits of Telephonic Case Management: Increased Home Dialysis and Decreased Hospitalizations
Rahul Dhawan, Wade M. Bannister, Cindy Gong, Jiang Tao, Kevin Plosser. KRS Team Optum Inc, Eden Prairie, MN.

Background: Home dialysis has been noted to improve quality of life in patients receiving dialysis. Patients at risk for COVID-19 include those on dialysis. The pandemic has resulted in additional focus on social distancing and home dialysis offers this distinct advantage compared to in-center hemodialysis. The ASN also similarly has supported advancing education around home dialysis, and COVID is being noted as a true catalyst to home dialysis care. Our study on a commercial population analyzed cost of care with regards to home versus in-center dialysis.

Methods: The KRS Case Management program identified and educated commerical patients with this case management benefit regarding the options for home versus in center hemodialysis. Patients were enrolled in the program and educated on the benefits of home dialysis, the benefits of permanent access, and the benefits of transplantation. Cost of care analysis was conducted using claims paid until February 2020, and variables studied included in-patient cost, skilled nursing facility cost, professional cost for dialysis service, facility cost for dialysis service, non dialysis outpatient cost and professional cost for physician visits. Patients were educated telephonically of the benefits of home dialysis and permanent access placement, and demographics including age and gender were also calculated.

Results: A total of 6692 members were analyzed. Of these patients 1793 members were attributed to home based dialysis. It is noted that when adjusting for per diseased member per month, there was a 62% decrease in cost of care for in-patient hospitalizations in the home dialysis group. In addition, there was a striking reduction of 247% in skilled nursing facility costs for the home dialysis group as well. After adjusting for all variables, there was a 5% cost savings in the home dialysis group as compared to in-center.

Conclusions: There are cost of care benefits to home dialysis. Further studies are needed to help identify barriers to home dialysis, and given the advent of COVID-19, it is important to consider home dialysis for all patients more now than ever before.

PO0855
Bridging Office-Based Care with the Virtual Practice Care Model: Evolving Care for CKD Patients in the COVID-19 Pandemic—and Beyond
Bingbin Zhao,1 Lei Zhang,1 Peili Ji,1 Jianfeng Lin,2 Jianfang Han,3 Jiaying Li,4 Zijuang Zhou,1 Haiyun Wang,2 Xia Hong,2 Winfred W. Williams,3 Limeng Chen,2 1Department of Nephrology, Olympia Pracical People’s Hospital, Xining, China; 2Department of Nephrology, Massachusetts General Hospital, Boston, MA; 3Department of Nephrology, Peking Union Medical College Hospital, Peking Union Medical College, Chinese Academy of Medical Sciences, Beijing, China; 4Department of Psychological Medicine, Peking Union Medical College Hospital, Peking Union Medical College, Chinese Academy of Medical Sciences, Beijing, China.

Background: Since the outbreak of the coronavirus epidemic, the “virtual” telemedicine has become a critical substitute for patient-provider interactions. However, virtual encounters often face challenges in care for high-risk patients such as chronic kidney disease (CKD) patients. In this study, we explore the patient’s satisfaction and practical effects of a newly established telemedicine program in CKD patients’ care during the pandemic.

Methods: We established an online CKD patient care program, including triage strategy, medical care delivery, and psychological support, based on a smartphone application. A total of 278 CKD patients were invited, at least 3 months before the pandemic or during the pandemic. A pilot survey interrogating medical and psychological Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
conditions was conducted. The feedback to the program and the psychological assessment repeated after one month.

Results: Totally, 181 patients showed active responses to the program, with 289 people-time medical consultations occurred during the study. The virtual care program provided a rapid triage, with 17% patients provided a timely referral to in-patient medical care. The median time from request to response was 75 minutes (IQR 30-120). The program was helpful for 180 patients (94%). One patient (0.5%) believed the program was helpful. The outcome of symptoms (OR 1.309, 95%CI 1.113-1.541; P=0.001) and being enrolled during pandemic (OR 3.939, 95% CI 1.174-13.221; P=0.026) were associated with high stress. After the follow-up, the high-stress CKD group at baseline showed a significant decrease in average CKD stage (9±1.4 vs. 8±1.9, P=0.015).

Conclusions: The delivery of patient care, which has remained largely unchanged for decades and relied primarily upon direct, in-person care, has had to evolve to meet the demands of a world in pandemic. As a result, significant changes have occurred with staffing structure and variations in the way they interact with the pharmaceutical industry.

PO0856

Background: The COVID-19 pandemic and resulting social distancing and stay-at-home orders significantly impacted physician practices across the board. The objective of this study was to evaluate the COVID-19 impacts and responses across different specialties as they unfolded and to understand how the model of patient care delivery will change moving forward.

Methods: Survey data was collected weekly or bi-weekly between March 20th and May 19th. Participants were asked questions about their telemedicine program. Approximately 50 nephrologists participated in each wave, along with 200 neurologists, dermatologists, rheumatologists and gastroenterologists.

Results: The impact of the COVID-19 outbreak on physician practices was swift and monumental. As of early April office visits were down more than 70% across specialties. As noted by May, nephrologists remained one of the hardest hit groups and continued to report 85% fewer patients compared to a typical, pre-COVID week. Nephrology was somewhat buffered from overall declines due to their dialysis patient responsibilities. Not only did these significant drops in patient office visits impact patient access to medical care, patient financial practices also suffered drastic financial impacts. More than half of the specialists reported a “substantial” impact on the financial health of their practice by early May. Practices responded swiftly with telemedicine adoption, and by early April more than 90% of most specialties had adopted some telemedicine capabilities. By the final wave, 78% reported that the COVID-19 experience will have a lasting impact on how their practice operates from the way physicians interact and see patients to long-term staffing structure and variations in the way they interact with the pharmaceutical industry.

Conclusions: The delivery of patient care, which has remained largely unchanged for decades and relied primarily upon direct, in-person care, has had to evolve to meet the demands of a world in pandemic. As a result, significant changes have occurred with the adoption of telemedicine, and given physicians and patients a new way to interact. Additionally, as practices try to rebuild from significant lost revenues, staffing structures and typical in-office activities, such as meeting with pharmaceutical representatives, along with conference attendance, will likely never return to their pre-pandemic levels. a guide to optimize preparedness in the event of facing a “second wave” of COVID-19 in the near future. Delay in implementation has to be accounted for during strategic planning.

PO0858
Telemedicine for Nephrology Outpatient Care in a Large Integrated Health System During the COVID-19 Pandemic
Waled Zafar, Prince Mohan, Evan Norfolk, Jamie A. Green, Alex R. Chang, Geisinger Health, Danville, PA.

Background: The COVID-19 pandemic has necessitated increased use of telemedicine for outpatient care. Accessing a large group of patients impacted access to telemedicine is important to optimize care delivery during the pandemic.

Methods: We examined trends in telemedicine use during the COVID-19 pandemic using data from Geisinger, a large, integrated, predominantly rural health system in central and northeast Pennsylvania. We also examined the association between patient characteristics (age, sex, patient portal status, Charlson Comorbidity Index [CCI]) and use of telemedicine visits.

Results: From 3/15/20-5/29/20, nephrology was the top adult specialty using telemedicine at Geisinger in terms of proportion of office visits using telemedicine (televideo or telephone) with 1911 (94% of all outpatient visits). The proportion of nephrology visits using telemedicine increased rapidly from <1% pre-COVID-19 crisis to 21% (week of 3/15/20) to consistently a95% each week from (3/22/20-5/29/20). Visit completion rate during this time was 84% with 8% same-day cancellations and 8% no-shows/late prior to being seen. The majority of nephrology clinic patients were 65 years old (63%), had severe CCI score 5+ (70%), and had active patient portal status (65%). The proportion of nephrology visits using telemedicine used televideo was 42% overall with large differences by CCI score, and patient portal status (Figure). For example, the proportion of telemedicine visits using televideo was as low as 10% (65+ year old patients, CCI 5+, non-user of patient portal) and as high as 86% (~50 year old patients, CCI score 0-4, active patient portal users).

Conclusions: Telemedicine may serve an important role in providing nephrology care to older patients and many comorbidities who are particularly susceptible to ill effects from COVID-19. Patient portal users were much more likely to use televideo for telemedicine visits. Further investigation into the digital divide (e.g. broadband internet access) is needed to optimize care delivery during the COVID-19 crisis.
Use of Tablo Hemodialysis Systems to Extend Dialytic Capabilities for the COVID-19-Associated Surge of AKI

David S. Goldfarb,1 Jessica M. Yan,2 Matthew A. Gross,3 Clay A. Block,2
1NYU Langone Health, New York, NY; 2Dartmouth College Geisel School of Medicine, Hanover, NH; 3VA New York Harbor Healthcare System, New York, NY, NY.

Background: The COVID-19 pandemic was associated with a greater incidence of AKI than expected. At the NY Harbor VA we faced an overwhelming number of AKI patients who were critically ill with multi-organ failure. We needed to invoke new mechanisms of providing kidney replacement therapy (KRT).

Methods: We obtained 3 Tablo systems in late March, 2019. The machines have self-contained reverse osmosis capabilities and do not require other equipment to operate. They can take dialysate from concentrate and tap water and so do not require special plumbing adaptation. Their self-contained step-by-step procedures are relatively simple to follow and allow rapid training of previously unskilled personnel. Tablo generates 300 ml dialysate per minute, and blood flow was increased up to 400 ml/min as tolerated.

Results: Training was completed by 2 nephrologists and 2 RNs without previous dialysis experience. We used the Tablo Hemodialysis System to provide KRT to critically ill patients. In the first week we demonstrated that water cultures and endotoxin testing were negative, and that AAMI water tests were acceptable. We used the machines to provide KRT for ICU patients with double-lumen dialysis catheters. In addition we used the machines on hospital wards where KRT had not been provided before because of a lack of the plumbing needs of conventional HD machines. We provided multiple treatments 3-6 times per week for 15 AKI patients, mean age 65 years. The mean of the best area reduction ratio achieved in the first 1-4 treatments, if available, was 41% (often limited by hypotension and fulfillment of ultrafiltration, UF, needs). Most treatments were successful and were slowed for hypotension or tachycardia. Some were aborted because of water pressure alarms if sediment filters needed replacement, or lines clotted due to hypercoagulability associated with COVID-19. Personnel availability dictated that most treatments were 3-4 hours (up to 8h), and generally achieved UF goals. Later HD nurses cunnulated arteriovenous fistulas in ESKD patients and left treatment to non-HD nurses to complete.

Conclusions: By incorporating a user-friendly platform and an accelerated training program including nephrologists and RNs without previous dialysis experience, we were able to nearly double our capacity to deliver KRT during the surge.

Funding: Veterans Affairs Support

The Introduction of Quanta SC+ to Critical Care for Haemodialysis During the COVID-19 Pandemic

Jan Rechner1, Ria D. McMullen1, Angela M. Clarke2, Bernice G. Boore7, Emma C. Vaux3, 1Royal Berkshire NHS Foundation Trust, Reading, United Kingdom; 2Berkshire Kidney Unit, Royal Berkshire NHS Foundation Trust, Reading, United Kingdom.

Background: Of 800 patients treated annually in 19 ICU beds (catchment 500,000) 120 require renal replacement therapy (RRT) delivered by Baxter Prismaflex® (continuous veno-veno haemodialfiltration (CVVHDF)). With the onset of the COVID-19 pandemic significant increased incidence of acute kidney injury (AKI) requiring RRT & existing intermittent haemodialysis (IHD) patients contracting COVID19 requiring ICU support raised concerns regarding RRT ICU capacity. Additionally a worrying national shortage of CVVHF/HDF consumables & new machines to deliver this requirement; all critical drivers to seek local solutions for RRT provision beyond usual capacity

Methods: A kidney unit neighbour described their successful experience trialing SC+ in COVID19 patients. Translation of SC+ from home use to safe HD treatment in ICU was quickly apparent alongside ease of supporting technical infrastructure set up & minimal training requirements. Immediate availability & fiscal acceptability of purchasing 4 Quanta SC+ & 2 supporting RO machines were critical determinants in making a realistic & sustainable solution to desperate RRT shortages. Provision of expert technical support and clinical nurse specialist facilitation expedited training of ICU workforce & enabled swift implementation

Results: 27 ICU nurses were trained in 3 weeks (23 in 14 days). Between 22/4/20 & 17/5/20 8 patients (range 37-63 yrs, median 35.5, 7/8 known IHD, 1/8 AKI, 7/8 COVID19 positive) received 20 treatments (1-5/patient) using SC+ in ICU. An agreed ICU IHD protocol was co-designed gaining consensus in an unfamiliar territory of provision of IHD in ICU & differing clinical perspectives in IHD prescription in a critical care setting

Conclusions: At a time of unprecedented national shortage of dialysis machines & increased RRT need associated with COVID19, Quanta provided an effective solution for safe provision of IHD in ICU. Ease of use with training delivered in <6 hours enabled ICU nurses to effectively treat patients independent of dialysis nurses allowing continuity of the chronic HD programme. Learnings identified the importance of training, enabling rapid growth of a critical mass of expertise & confidence. Critical elements included mastering unfamiliar technique, establishing infrastructure, procurement & team communication enabled by online & face-to-face troubleshooting support

COVID-19: Clinical and Basic Science Characteristics
P00863
Design of PREVENT: A Phase 2 Study of the Effect of RBT-9 on Progression of COVID-19 Infection in High-Risk Individuals, Including Those with Advanced CKD
Stacey Ruiz,1 Philip T. Lavin,2 Donald J. Keyser,1 Alvaro F. Guillen,7 Richard A. Zager,2,8 Bhupinder Singh,2 Fred Hutchinson Cancer Research Center, Seattle, WA; 2University of Washington Department of Medicine, Seattle, WA; 3University of California Irvine, Irvine, CA, US, Department of Medicine, Irvine, CA; 4Boston Biostatistics Research Foundation, Framingham, MA.

Background: Coronavirus 2019 (COVID-19) has infected millions of people worldwide, with the US reporting the most deaths. Many individuals are at high risk of disease progression, which may result in multi-organ failure and death. Risk factors include advanced age, cardiovascular disease (CVD), and chronic kidney disease (CKD).

In addition, more than 40% of hospitalized patients develop acute kidney injury (AKI), with 20% of those requiring dialysis. Several therapeutic agents are in development, but patients with advanced CKD or those requiring immunosuppressive therapy are frequently excluded from participation in clinical trials. RBT-9, a proprietary formulation of stannous protoporphyrin, has organ protective effects, as demonstrated in animal models of kidney, liver, and lung injury. RBT-9 also has anti-viral effects, as demonstrated in several enveloped viruses, including influenza, HCV, dengue, and yellow fever. A Phase 2, randomized, placebo-controlled study was designed to evaluate the effect of RBT-9 on progression of COVID-19 infection in high-risk individuals.

Methods: This study will enroll up to 252 subjects with documented SARS-CoV-2 infection who are at risk of progression based on age (≥70 years) or comorbidities, including CKD (all stages, not on dialysis), CVD, chronic lung disease, diabetes mellitus, obesity, and mild hypoxemia. Subjects will be randomized 2:1 to receive a single dose of RBT-9 or placebo and will be followed for 56 days.

Results: Study Objectives The primary objective is to evaluate the effect of RBT-9 versus placebo on clinical status measured using the 8-point World Health Organization (WHO) Ordinal Clinical Scale at Day 28. Secondary objectives include time to first occurrence of death from any cause or new/worsened organ dysfunction, survival, AKI incidence, new or worsening heart failure, hospitalization status and duration, ICU status, days on ventilator, vasopressor utilization or ventricular arrhythmias.

Conclusions: The organ protective and antiviral effects of RBT-9 warrant conduct of this clinical study, which is aimed at preventing progression to severe COVID-19 and organ failure. The first patient is expected to be enrolled in June 2020.

P00864
The COVID-19 Infodemic
Tejas Desai,1 Arvind Conjevaram.1 NOD Analytics, Harrisburg, NC, ‘The Banglore Hospital, Banglore, India.

Background: In Situation Report #13 by the World Health Organization and 39 days before declaring COVID-19 a pandemic, the WHO declared a “COVID-19 infodemic” as “the volume of coronavirus related tweets was far too great for one to find accurate or reliable information. Healthcare workers were flooded with “noise” which drowned the “signal” of valuable COVID-19 information. To combat the infodemic, physicians created healthcare-specific micro-communities to share scientific information with other providers.

Methods: We analyzed the content of six physician-created communities and categorized each message in one of five domains (Symptoms, Diagnostics, Therapeutics, Prevention, Pathophysiology). We programmed 1) an application programming interface to download tweets and their metadata in JavaScript Object Notation beginning 11 March and 2) a reading algorithm using visual basic application in Excel to categorize the content. We superimposed the publication date of each tweet into a timeline of pandemia events. Finally, TD created a free repository of the dataset in the #NephTwitter Archives (https://bit.ly/2M6HJIG) to help healthcare workers find quality information when treating patients.

Results: From 11 March to 27 April, 45% of the 19270 tweets in the dataset were categorized (signal). Tweets about Therapeutics spiked six times; the first coming 4 days after the WHO declared COVID-19 a pandemic. The largest spike came on day 8: 5 days after the US President suggested hydroxychloroquine as a potential treatment. Tweets about antimalarial therapy comprised 15% of tweets in this category. Tweets about Prevention spiked five times; the largest coming 21 days after the pandemic declaration by the WHO. 1 million global cases were reported. Protective equipment comprised 13% of tweets in this category. There were 2210 searches performed of the signal tweets in the #NephTwitter category. Tweets about Therapeutics spiked six times; the first coming 4 days after the WHO declared COVID-19 a pandemic. The largest spike came on day 8: 5 days after the US President suggested hydroxychloroquine as a potential treatment. Tweets about antimalarial therapy comprised 15% of tweets in this category. Tweets about Prevention spiked five times; the largest coming 21 days after the pandemic declaration by the WHO. 1 million global cases were reported. Protective equipment comprised 13% of tweets in this category. There were 2210 searches performed of the signal tweets in the #NephTwitter category.

Conclusions: Algorithmic coding can 1) mitigate the COVID-19 infodemic and 2) identify & elevate illuminating evidence-based tweets. Both outcomes help healthcare workers find higher-quality information to combat the pandemic.

P00865
The Impact of the COVID-19 Pandemic on the Mental Health of Health Workers Treating Patients with Kidney Diseases in Latin America (LA):
Sonia Rodriguez Ramirez,1 Franco H. Cabeza Rivern,2 Julio A. Gutierrez-Prieto,1 Javier Soto-Vargas,1 Blanca Martinez-Chagollena,1 Denisse Arellano-Morales,1 Carmen Garcia-Aguirre,1 Denisse Franco-Avila-Casado,1 GlomCon Latin America Working Group (LGomCon)
Poster

Background: The spread of the COVID-19 pandemic into LA countries where health systems were already facing major limitations might further challenge their physician’s emotional and mental wellbeing. We aimed to describe the perception of health workers managing kidney diseases in the context of the COVID-19 pandemic.

Methods: Descriptive analysis extracted from an online survey carried out among nephrologists, renal pathologists, and other health workers treating kidney diseases between May 20-27, 2020 from sixteen Spanish speaking Latin American countries divided into 6 categories. We present the results for the mental health category.

Results: 430 responses were obtained of which 360 (84%) were considered for analysis and 340 were complete. Participants were mainly nephrologists (276 (86%), renal pathologists 13 (4%), and physicians in training 11 (3%). Ages ranged between 30-49 years old in 271 (75%), mostly working on tertiary centers 258 (71%). 329 (90%) participated in inpatient care. 277 (86%) considered that the COVID-19 pandemic has impacted their mental health. Preventing symptoms were anxiety, insomnia, and depression, with 75.2%, 42.5%, and 18.2%, respectively. Physical or verbal violence from the community was reported by 18% (5%) of the participants because they were seen as a source of viral transmission. 179 (55%) considered personal protective equipment (PPE) was sufficiently provided and 212 (62%) had to invest up to 20% of their income to obtain PPE. In addition, 144 (44%) of the respondents reported a shortage of COVID-19 tests and only 99 (30%) felt their hospital was well equipped to care for COVID-19 patients. 126 (39%) of the health workers responded that they received adequate training, while 105 (32%) endorsed they did not prepare in the management of patients with COVID-19.

Conclusions: This survey reveals the considerable impact that the COVID-19 pandemic is generating among physicians treating patients with kidney diseases in LA. Possible aggravating factors also found in our survey included lack of testing, PPE availability, and overall hospital preparedness.

P00866
Developing a COVID-19 Screening Program for an Emergency-Only Dialysis Cohort Within a Large Public Safety-Net Hospital
Ravi D. Bhattacharya,1,2 Lauren Kasper,1,2 Sarah A. Johnson,1,2 Emory University School of Medicine, Atlanta, GA; 3Grady Health System, Atlanta, GA.

Background: As the prevalence of coronavirus disease 2019 (COVID-19) worsens, one patient population that warrants further inquiry are those receiving emergency-only hemodialysis (EoHD). This cohort specifically at Grady Health System (GHS) in Atlanta, consisting largely of undocumented immigrants, receives 1-3 times weekly hemodialysis (HD) via emergency departments due to legislative restrictions on Medicaid funding. GHS has one of the largest populations of EoHD patients in the nation. The cohort of 91 patients is 89% Hispanic with a mean age of 51. The majority of patients, 69%, reside in Fulton or DeKalb counties, the intended service region for GHS. The remaining patients reside in more distant counties, potentially increasing risk of transmission to a larger area. Prior to our screening program, 6 patients in the cohort had positive diagnostic tests and 4 of these patients required hospitalization (67%). Notably, 3 out of those 4 patients were admitted due to hypertensive emergency with pulmonary edema, so symptomatic COVID disease is debatable. Due to the frequency of hospital visits and requirement of hospital stay, there is a high vulnerability of these patients to COVID-19.

Methods: Over 5 days, we conducted 84 COVID PCR screening tests via nasopharyngeal swab. One patient was excluded due to missed sessions. Patients were asked about symptoms prior to swabs. Swabs were obtained by a single operator in a consistent fashion. Data was collected and stratified by patient demographics.

Results: A total of 84 patients were screened for COVID. Notably, 3 asymptomatic patients had positive results, a rate of 3.6%, and 6 patients had positive diagnostic tests prior to screening, resulting in a rate of 9.9% positive COVID tests. 6 patients were DeKalb/Fulton residents (67%).

Conclusions: The risk of COVID-19 in EoHD patients is an issue that will require a concerted effort to prevent the spread of disease. A collaboration between nephrology and infectious diseases has led to the implementation of a bimonthly screening program. Future directions include antibody screens and contact-tracing to understand more fully the spread of disease as well as elucidating the asymptomatic positive rate vs. actual disease prevalence.

SARS CoV-2 Continuous Quality Improvement Program: Initiation of a Standardized Protocol for AKI Prevention
Adam Dossaji, Asad H. Khan, Spencer Hodgings, Daniel L. Landry, Daniel Engelman, Jonathan Slater, Bill Mcgee, Michael J. Germain. Baystate Medical Center, Springfield, MA.

Background: During the initial phase of the SARS CoV-2 pandemic our institution had high rates of acute kidney injury (AKI) requiring renal replacement therapy (RRT). Nephrocheck (NC), a renal biomarker, indicating renal stress was the basis of a continuous quality improvement (CQI) program to identify patients at risk for AKI & RRT.

Methods: Patients admitted from 4/15-5/15/2020 were all tested for SARS CoV-2. All positive patients ≥ 18 years old & with a creatinine ≥2.0 mg were tested with NC. Values ≥ 0.7 led to nephrology consults & utilization of a renal-protective strategy including monitoring volume status, scrutinizing nephrotoxic medications & urine studies. A “Plan-Do-Study-Act” approach was used to increase utilization of NC and the resulting protocol for positive results. Intervention was biphasic with a follow up maintenance phase, each lasting 10 days. Phase 1 was adding NC to the SARS CoV2 admission order set & Phase 2 was educating hospitalist providers about using and interpreting NC to increase appropriate nephrology consults. Education was reinforced with protocol cards & reminders via encrypted text services. Additionally, intervention team members reviewed charts daily & reminded providers in real time.

Results: In Phase 1, 58% of the SARS CoV-2 positive patients had a NC but only 48% of NC positive patients had a renal consult. In Phase 2, 79% of SARS CoV-2 positive patients had a NC with 80% of positive patients getting a renal consult. In the maintenance phase, 67% of SARS CoV-2 positive patients had NC with 59% of NC positive patients getting a renal consult.

Conclusions: During our CQI project, efforts to mitigate severe AKI by using a biomarker-based alert for nephrology consultation saw the number of SARS CoV2 positive patients screened with NC & the number of positive NC patients seen by nephrologists rise significantly. Barriers to implementation included the weekly turn-over of house staff & a reliable alert system to ensure adequate screening. The multidisciplinary team reviewing charts and reminding hospitalists of the protocol also helped significantly but was difficult to sustain.

PO0868
Renal Critical Care Project Management of COVID-19 Pandemic Surge
Richard L. Barnett, Steven Fishbane, Mark A. Finger. Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.

Background: The COVID-19 surge for the NY area severely stretched hospital resources as critical care areas expanded 2-3 fold. In addition to well chronicled ventilator management of respiratory failure, 37% sustained some degree of AKI with many resources as critical care areas expanded 2-3 fold. In addition to well chronicled ventilator management resources over multiple hospital sites planning which required close integration of physician, nursing, pharmacy and materials management resources over multiple hospital sites.

Methods: The Renal Critical Care Project Management Team (T) initially met on 3/11 and identified likely shortfalls in the quantity of Baxter Prisma machines for Long Island Jewish and NorthShore University Hospital. Of 4579 patients, 51.8% were male. Median age was 65 years, IQR (52-76). 3313 (72.3%) were positive for the COVID-19. Hypernatremia, hyponatremia, hyperkalemia, hyperglycemia, hypocalcemia, and hypoalbuminemia were significantly more common in hospitalized patients with COVID-19 (p<0.0001).

Conclusions: Dysnatremias, hyperkalemia, and hyperglycemia were more common in patients with COVID-19. Hypocalcemia was more common in patients with COVID-19 but this may be due to a higher prevalence of hypocalcemia. Further studies are needed to adjusted models to describe the association between electrolyte abnormalities and clinical outcomes.

PO0869
Electrolyte Abnormalities in Hospitalized Patients with COVID-19
Diane Liu,1 Molly Fisher,2 Abby M. Basalely,1 Neelja D. Kumar,2 Jyotsana Thakkar,2 Ladan Golestaneh,3 Kimberly J. Reidy,1 Wei Chen.2 1Children’s Hospital at Montefiore, Bronx, NY; 2Montefiore Medical Center, Bronx, NY.

Background: Electrolyte abnormalities have been observed in hospitalized patients with COVID-19. Whether the prevalence of electrolyte disturbances differ between hospitalized patients with and without COVID-19 is unknown.

Methods: We performed a retrospective observational study of adult patients hospitalized in a large tertiary healthcare system in the Bronx between March 11-April 26, 2020. We compared the prevalence of the disturbances in sodium, potassium, calcium and magnesium between patients with and without COVID-19 using Chi-square. Electrolyte disturbances were defined as the following: hypernatremia (>145 mEq/L), hyponatremia (<135 mEq/L), hyperkalemia (>5.5 mEq/L), hyperglycemia (<3.5 mEq/L), hypermagnesemia (>2.5 mEq/L), hypomagnesemia (<1.5 mEq/L), hypocalcemia (<8.5 mg/dL) and hypoalbuminemia (<3.5 g/dL).

Results: Of 4579 patients, 51.8% were male. Median age was 65 years, IQR (52-76). 3313 (72.3%) were positive for the COVID-19. Hypernatremia, hyponatremia, hyperkalemia, hyperglycemia, hypocalcemia, and hypoalbuminemia were significantly more common in hospitalized patients with COVID-19.

Conclusions: Dysnatremias, hyperkalemia, and hyperglycemia were more common in patients with COVID-19. Hypocalcemia was more common in patients with COVID-19 but this may be due to a higher prevalence of hypocalcemia. Further studies are needed to adjusted models to describe the association between electrolyte abnormalities and clinical outcomes.

PO0870
Quality Improvement Project: Examining Urine Sediment and Microscopic Findings in COVID-19 AKI Patients
Abdulhadi T. Gelagain, Ajai S. Rajabalan, Janice P. Lea, Jose E. Navarrete, Jason Cobb. Emory University School of Medicine, Atlanta, GA.

Background: The examination of the urine microscopy manually is common in the work-up of AKI. SARS-CoV-2 has been detected in urine samples of infected patients. There have been safety concerns about the handling of urine samples in patient under investigation and COVID-19 confirmed cases. Limitations in personal protective equipment have provided challenges. There have been limited reports of urine microscopic findings during the COVID-19 pandemic. We developed a QI project examining the urine sediment of COVID-19 AKI patients from digital pictures provided by the IRIS IQ200 Microscopy System.

Methods: This QI project took place at Emory University Hospital Midtown. We retrospectively evaluated baseline characteristics, labs, and urine volume. The urinalysis and urine sediment were evaluated for each patient by digital images produced by the IRIS IQ200 Microscopy System.

Results: A total of 17 African American patients with a mean age of 71±12.5 years (range, 35 to 98); 64.7 % were female. Comorbidities included hypertension (94.1%), diabetes (58.8%), CAD (11.9%) and CKD (52.9%). Average serum creatinine was 3.1 mg/dL. 8 patients (47%) were oliguric; 4 patients had FE Na < 1%. 8 patients (47%) had 2+ proteinuria. 9 patients (52.9%) had a positive leukocyte esterase and all were nitrate negative. 8 patients (47%) had ATN with visible muddy brown casts; 6 patients (35%) had a 5 wbc/hpf and 11 patients (65%) had a 5 rbc/hpf. 8 patients (47%) had shock requiring vasopressor support; 8 patients (47%) required dialysis and 13 patients (76.5%) required mechanical ventilation.

Conclusions: Urinalysis and urine microscopy are important in evaluation of AKI, and there is a paucity of data about findings in COVID-19 AKI patients. Without conclusive evidence of the infective potential of urine samples, it is much needed value of this time to device a safe alternative to manual urine microscopic examination. Almost half of our patients had ATN and we were able to arrive at the diagnosis using digital images from this automated urine microscopy system. Use of such technology will help nephrologists safely examine urine sediments and minimize exposure to COVID-19.

PO0871 Clinical Relevance of AKI Trial Data for Severe COVID-19 Patients
Rita N. Barcis, Brian O’Rourke, Sunny H. Nguyen, Arno W. Tilles, Payal Garg, Christopher V. Gemmini, Brian Miller. Sentien Biotechnologies Sentien Biotechnologies, Lexington, MA.

Background: Coronavirus disease 19 (COVID-19), caused by SARS-CoV-2 was declared a pandemic in March 2020 and remains without any approved treatments. After entering the cells, the virus begins to replicate and viral antigen is presented to antigen presenting cells (APCs), the cells that stimulate the body’s normal anti-viral immune response. In severe cases however, this immune reaction becomes dysregulated as evidence by high levels of certain cytokines and chemokines in the blood, a reaction known as cytokine storm. This results in a systemic uncontrollable inflammatory state that triggers a violent attack by the immune system to the body, causes acute respiratory distress syndrome (ARDS) and multiple organ failure, leading to death.

Methods: Mesenchymal stromal cells (MSCs) are a unique source of secreted factors that modulate an inflammatory response and enhance the repair of injured tissue. MSCs have been extensively studied in ARDS and other acute organ injuries. Sentien has created a novel delivery approach to enable sustained exposure to MSCs and their secreted factors, overcoming limits of cell transplantation/infusion while preserving their broad acting and dynamically responsive properties. Our lead product, SBI-101 contains allogeneic human MSCs inoculated into a hollow-fiber hemofilter, which enables communication with patient blood via the semi-permeable membrane, while maintaining MSC viability. Through this interplay, SBI-101 aims to restore balance to the immune system by reprogramming the molecular and cellular components of blood in patients with severe inflammation and organ injury.

Results: Sentien’s Phase I/I clinical study of SBI-101 in critically ill patients with Dialysis-Requires Acute Kidney Injury (AKI-D) has produced data to support the therapeutic hypothesis of SBI-101. Consistent with MSC biology, inflammatory markers, such TNFa and IFNg, were shown to be modulated, suggestive of a shift from a pro- to an anti-inflammatory state in treated patients.

Conclusions: Data obtained in our AKI-D trial showed modulation of many biological molecules and immune populations that may be correlated with severe COVID-19 immunopathology. Here we make the case, using our existing AKI-D trial data, that SBI-101 may be of therapeutic benefit to severe cases of COVID-19.

PO0873 Constitutive Activation of Hedgehog Signaling Disrupts Nephrionic and Stromal Differentiation
Robert D’Cruz,1,2 Yun-Kyo Kim,1,2 Jaap Mulder,1 Norman D. Rosenblum,1,2 1Hospital for Sick Children, Toronto, ON, Canada; 2University of Toronto, Toronto, ON, Canada.

Background: Nephron progenitors (NPs) and stromal cells differentiate from a common Osr1+ progenitor. While maldevelopment of nephronic and stromal tissue is caused by a deficiency of renal dysplasia signaling mechanisms regulating the genesis of stroma relative to NPs are largely undefined. We have shown that increased Hedgehog (Hh) signaling in murine Osr1+ cells in vivo causes urinary tract obstruction through abnormal stromal cell localization (Sheybani-Deloui et al., 2018). Here, we investigated mechanisms that function downstream of Hh to control NP and stromal cell differentiation using human induced pluripotent stem cell (hiPSC) kidney organoids and genetic mouse models.

Methods: Agonists of the Hh receptor, SMO, were added to hiPSCs differentiated into kidney organoids at the stage of cell aggregation. Mature organoids were analyzed by histology, light sheet fluorescence microscopy, and RNA microarray. Processes downstream of Hh signaling were investigated in mouse kidneys with deficiency of Ptc1 specific to FOXD1+ stromal cells (FoxD1Cre;Ptc1-/-) as well as using histology, RNAseq, and scRNAseq.

Results: Stimulation of Hh activity in kidney organoids with SAG (120 nM) or Purmorphamine (10 μM) resulted in a 26% increase in surface area compared to controls. Volumetric analysis using light sheet fluorescent imaging of WT1+ nephronic structures and CDH1+ tubular structures in SAG-treated organoids demonstrated an 88% (n=3; p<0.01) and 67% (n=3; p=0.05) reduction, respectively. In contrast, the mass of non-epithelial cells was increased by 79% (n=2; p=0.05). RNA microarray analysis of SAG-treated organoids (n=5) revealed elevated expression of mediatory stromal markers Tgfα (2.60 fold-change [FC], p=0.01) and Pdgfrβ (1.60 FC, p=0.01), and decreased expression of nephron markers Nephl (0.23 FC, p<0.01), Slc3a1 (0.32 FC, p<0.01), and Slc2a1 (0.08 FC, p=0.01). Mice with constitutive Hh activity in FOXD1+ stromal cells showed a 41% reduction in nephrons at E18.5 (n=4, p=0.05) and a 19.5% decrease in nephron intermediate structures at E15.5 (n=4, p=0.01). In contrast, RNAseq of E13.5 mutant kidney tissue demonstrated increased expression of mediatory stroma genes Trc and Pdgfrb.

Conclusions: Increased Hh signaling in human and mouse increases differentiation of stroma compared to NPs, providing new insights into mechanisms that may underlie nephroblastoma.

PO0874 Caspase Inhibition in a Mouse Model of Prenatal Ureteropelvic Obstruction Rescues Normal Ureteral Development
Ross Villiger, Malia H. Harrison-Chau, Michael Ortega, Ben Fogelgren. University of Hawaii at Manoa, Honolulu, HI.

Background: The most common cause of congenital obstructive nephropathy is ureteropelvic junction obstruction (UPJO). We previously described a unique mouse model of in utero UPJOs through urethral knockdown of Exoc5, a central subunit of the exocyst trafficking complex. In this neonatal-lethal model, UPJO formation is preceded by urethral cell death in the ureter between E16.5 and E17.5. Here, we investigated if normal ureteral development could be restored in this mouse model by blocking cell death pathways, and conversely, if we could induce UPJOs by simply activating urethral cell death during ureter development.

Methods: We utilized the Cre-lox system to achieve either targeted gene knockout or activation during mouse embryonic development. For inhibition of cell death pathways in Exoc5lox/lox-Ksp-Cre ureters, we performed IP injections of caspase inhibitors into pregnant mice at gestational day 16.5. Also, diaphragma toxin (A TA) mice crossed with KspCre-lox/lox mice were used to investigate the effect of inducing urethral cell death with tamoxifen administration at E16.5.

Results: Morphologically, dying Exoc5-KO urethral cells appeared more necrotic than apoptotic, and they were negative for cleaved PARP and active caspase-3. However, a single injection of pan-caspase inhibitor z-VAD-FMK at E16.5 rescued ureteral development in all Exoc5lox/lox-Ksp-Cre mice analyzed. At E18.5, all z-VAD-FMK treated embryos displayed patent ureters with no hydrourephrosis (n=9 from multiple litters). If followed past birth, z-VAD-FMK treated Exoc5lox/lox-Ksp-Cre mice survived to adulthood. Interestingly, caspase-1 inhibitor Ac-YVAD-cmk did induce UPJO at an earlier stage of ureter development when injected at E16.5, supporting the hypothesis that a non-apoptotic pathway is responsible for urethral cell death in this mouse model. Conversely, DTA-induced urethral cell death in E16.5 ureters showed evidence of UPJO formation by E18.5.

Conclusions: Based on these findings, we have shown that urethral cell death is a critical event leading to UPJO pathogenesis and lethality in our mouse model. The data suggest inflammation-associated caspase-1 may play a role in activating cell death in urethral cells with disrupted exocyst trafficking.

Exocyt Inactivation in Urothelial Cells Disrupts Autophagy and Upregulates the Fibroblast Growth Factor-Inducible 14 (Fn14) Receptor

Michael Ortega, Ross Villiger, Malia H. Harrison-Chau, Suzanna K. Lieu, Kadee-Kalia Tamashiro, Amanda J. Lee, Geetika Y. Patwardhan, Ben Fogelgren. University of Hawai’i at Manoa John A Burns School of Medicine, Honolulu, HI.

Background: Despite their prevalence, the etiology of congenital ureter obstructions in infants is poorly understood, with little evidence identifying genetic or environmental causes. We previously reported a unique mouse model of in vitro ureteropelvic junction obstruction (UPJO) in which ureteral urothelial cells with deleted Exoc5 gene failed to differentiate into a striated epithelium and underwent cell death. This resulted in bilateral UPJO, hydroureter, and neonatal lethality. Here, we investigated the urothelial cells prior to cell death to identify the disrupted cell processes necessary for urothelial differentiation and ureter development.

Methods: Gene expression profiling was performed on E16.5 ureters of Exoc5fl/fl; Ksp-Cre mice and control littermates, with validation using real time qPCR and immunohistochemistry. Follow up investigations utilized an evivo ureter explant organ culture model, where mouse embryonic ureters were isolated at E15.5 and maintained in culture for 72 hours. Additionally, we used primary human urothelial cells (pHUCs) and immortalized SV-HU/C1 cells for advanced studies on exocytosis regulation of autophagy, which was measured through immunoblotting and immunostaining of pel, LC3II/III, and autophagy-related genes (ATGs).

Results: Analysis of gene profiling data from E16.5 Exoc5fl/fl;Ksp-Cre ureters revealed that metabolic pathways were significantly downregulated and NF-κB signaling was significantly upregulated, indicating cell stress. The highest upregulated gene was Fn14 (30-fold), a member of the TNF receptor subfamily that binds the ligand TWEAK. Fn14 is upregulated in damaged tissues and can activate non-canonical NF-κB signaling and cell death via multiple pathways. Using ureter explants and cell line models, we found exocytosis is critical for autophagosome, when disrupted, to lead to a high Fn14 increase and cell death.

Conclusions: From our data, we propose that autophagy is necessary for urothelial differentiation during ureter development, and irregular autophagy may trigger urothelial cell death through Fn14 signaling. This disruption of autophagy during a critical stage in ureter development may contribute to UPJOs in humans.

PO0876

Transcription Factor 21 Regulates Nephrin Progenitor Cells Self- Renewal/Induction and Podocyte Development

Gal Fening,1 Tomoko Hayashida,1 Tomokazu Souma,1 Xiaoming Zhao,1 Xiaoyan Liang,1 Tuncer Onay,1 Yoshio Maezawa,2 Susan E. Quigg,2 Northwestern University Feinberg School of Medicine, Chicago, IL; 1Duke University, Durham, NC; 2Chiba-ken, Chiba, Japan.

Background: Most forms of CAFUT arise from mutations in genes of kidney development. We previously showed that Transcription Factor 21 (Tcf21) regulates branching morphogenesis by downregulating GDNF. We now aim to study Tcf21 in nephrin progenitor cells (NPC). During nephrogenesis, WNT9b signals to NPC through the canonical Wnt/β-catenin pathway, which promotes both self-renewal at a state of low β-catenin level, and induce NPC differentiating at state of high β-catenin. Following induction, NPC can either promote cell death for MET to progress. Additional, optimal intensity of β-catenin is essential for NPC differentiation to podocytes. Hence, discrete levels of β-catenin promote disparate cell fates. It remains unclear however what drives this change and direct NPC to exit self-maintenance/survival.

Methods: Kidney organoids were generated from human embryonic stem cells (hESC). Transplantation of Six2CreTcf21fl/fl mice were used for qPCR and immunohistochemistry. MK3 cells were used to study Tcf21 signaling. Recombinant Tcf21 was used for over-expression.

Results: Six2CreTcf21fl/fl kidneys show marked decrease in Cited1 expression from E12.5 through P0 compared to control, while still expressing normal levels of Six2, indicating decreased self-renewing NPC population. Six2CreTcf21fl/fl kidneys also demonstrated low Lef1 expression suggesting decreased NPC epithelization. However, Wnt4, a marker of the prethuber aggregate, was persistently elevated in the developing nephrons of Six2CreTcf21fl/fl. This state of Cited1Wnt4Lef1 is in the mutants suggests arrested MET and persistently elevated β-catenin levels in the differentiating progenitors. In uninduced mesenchymal cell culture (MK3), over-expression of wild-type Tcf21 led to enhancement of genes that mark renewing NPC. Cited1, Talaf, and Plac2β, while over-expression of mutated-Tcf21 abrogated that enhancement, again supporting Tcf21 involvement in NPC dynamics. As to podocyte differentiation, lineage tracing of Tcf21Cre showed its expression in a subset of NPC in the cap-mesenchyme and then in developing and mature podocytes. At P0, Six2CreTcf21fl/fl kidneys showed very low podocyte expression. This suggests that Tcf21 is required for NPC differentiation to podocytes.

Conclusions: Together, these data suggest that Tcf21 modulates Wnt/β-catenin signal intensity spatially and temporally to direct NPC toward self-renewal or differentiation.

A Novel ADPKD Model Using Kidney Organoids Derived from Disease-Specific Human Induced Pluripotent Stem Cells

Yoshihiro Tatsuya Shimizu,1 Shin-ichi Mae,1 Toshikazu Araoka,1 Kunihiro Yamagata,2 Kenji Osafune.1 Center for iPSC Cell Research and Application (CIRA), Kyoto University, Kyoto, Japan; 2Department of Nephrology, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is one of the most prevalent hereditary diseases, accounting for up to 10% of end-stage kidney disease worldwide. Although many disease models have been proposed for ADPKD, the pre-symptomatic pathology of the human disease remains unknown and no definitive therapies are currently available. To elucidate the mechanisms of early cystogenesis, robust and genetically relevant human models are needed.

Methods: Using a stepwise differentiation protocol that we have recently reported (Tsujimoto H. et al., 2020), we generated kidney organoids from two kinds of disease-specific human induced pluripotent stem cells (hiPSCs), PKD1 gene-edited hiPSCs and ADPKD patient-derived hiPSCs. We applied chemical treatment to reproduce cystic phenotypes within kidney organoids, quantitatively analyzed macroscopic cystic lesions, and performed immunofluorescence analyses. ADPKD patient-derived kidney organoids were further utilized to examine the effects of known inhibitors of cystogenesis.

Results: Although wild-type organoids developed cystic lesions under forskolin, PKD1-mutant organoids exhibited significantly larger cystic areas depending on the PKD1 genotype. Importantly, ADPKD patient-derived kidney organoids as well as gene-edited heterozygous PKD1-mutant ones also recapitulated cystogenesis in vitro. Immunofluorescence analyses confirmed that the cyst epithelia predominantly originate from LT1-pattering cells. Furthermore, inhibitor experiments suggested the predictive validity of patient-derived kidney organoids as a disease model.

Conclusions: We established a novel model for ADPKD using kidney organoids differentiated from gene-edited PKD1-mutant and ADPKD patient-derived hiPSCs. Further, we demonstrated the possibility of ADPKD kidney organoids serving as drug-screening platforms. This newly developed model will contribute to identifying novel therapeutic targets, extending the field of ADPKD research.

Kidney Organoids Derived from a Pediatric Patient with Type 1 Diabetes and Steroid-Dependent Nephrotic Syndrome Shows Losses of Podocyte Podocalyxin and Increased Proximal Tubule Injury

Nathan Lee,1 Kyung Iwa Choi,2,3 Shun-Yang Cheng,1,2 Leonard V. Rietta,1 Joseph V. Bonventre,1 Brigham and Women’s Hospital, Boston, MA; 2CHA Bundang Medical Center, Seongnam, Gyeonggi-do, Republic of Korea; 3University of Southern California, Los Angeles, CA.

Background: Whole exome sequencing of a pediatric patient, who at age 3 developed Type 1 diabetes mellitus and steroid-dependent nephrotic syndrome, revealed a de novo heterozygous mutation of the GREM1 gene. Gremlin is a BMP antagonist crucial for kidney development and also implicated later in life in diabetic kidney disease. Specifically, gremlin has been associated with kidney inflammation, Notch activation and fibrosis, and proposed to be a mediator of diabetic nephropathy and other progressive kidney diseases. 3D kidney organoids differentiated from induced pluripotent stem cells (iPSCs) provide a platform technology to explore the effects of genetic changes on pathobiology of human tissue.

Methods: An induced pluripotent stem cell (iPSC) line was created from the patient. Organoids were generated from iPSCs by modifications of our laboratory’s prior published techniques without use of undefined matrices. Structures of kidney organoids were imaged by immunostaining for LTL, CDH1, GATA3, PODXL, NPHS1, NPHS2, and CD31. Organoids were also stained for gremlin, SGLT2, and KIM-1 to investigate the phenotypes.

Results: A de novo heterozygous mutation of the GREM1 gene was identified. The GREM1 mutation specifically eliminates one of the three known GREM1 splicing isoforms while leaving the other two intact. When compared to organoids generated from embryonic stem cells or BJFF iPSCs the patient-derived organoids had several kidney disease phenotypes including decreased expression of podocalyxin, aberrant expression of SGLT2, and pronounced expression of KIM-1, an indicator of proximal tubule injury. The phenotypes could be rescued by treatment of the kidney organoids with recombinant GREM1 protein, altering the balance of long and short forms of gremlin.

Conclusions: Organoids derived from a patient with a GREM1 heterozygous mutation demonstrated decreased podocalyxin, aberrant SGLT2 staining, and increased proximal tubule injury. Better understanding of the relative roles for GREM1 isoforms could lead to better understanding of diabetic progressive kidney disease and organoids can be used to find potential therapies.

PO0883
Successful Introduction of Renovascular Units into the Mammalian Kidney
Oren Plenciczka,1,2 Yehudit Gnatke,1 Barak Rosenzweig,2 Alon Eisner,3 Zohar A. Dotan,2 Leon G. Fine,2 Shoshana Greenberger,1 Benjamin Dekel.1,2
1Pediatric Stem Cell Research Institute, Sheba Medical Center, Tel Hashomer, Ramat Gan, Israel; 2Tel Aviv University-Sackler Faculty of Medicine, Tel Aviv, Israel; 3Cedars-Sinai Medical Center, Los Angeles, CA; 4Sheba Medical Center at Tel Hashomer, Tel Hashomer, Israel; 5Assuta Ashdod Hospital, Ashdod, Israel.

Background: Various cell-based therapies, aimed at replenishing renal parenchyma, have been proposed as means to treat chronic kidney disease (CKD). However, a key limitation to the applicability of these strategies is the failure of in vivo administered cell types to develop donor-derived vessels, resulting in poor graft survival. Similarly, such strategies do not address renal hypoxia, a key factor in CKD progression. We hypothesized that administering self-organizing human renal tubule-forming cells (RTFCs) derived from adult and fetal kidneys, previously shown to exert a functional effect in CKD mice, alongside mesenchymal stromal cells (MSCs) and endothelial colony-forming cells (ECFCs), would result in generation of both vessels and tubules with potential interaction.

Methods: NOD-SCID mice were injected with either RTFCs or a mix of RTFCs, MSCs and ECFCs in Matrigel into the sub-cutis (SC), under the renal capsule or into the renal parenchyma. The resulting grafts were analyzed after 2 weeks.

Results: While RTFC-derived grafts harbored few host-derived vessels, injection of MSC, ECFCs and RTFCs into the SC, sub-renal capsular space, or renal parenchyma, resulted in robust formation of donor-derived renovascular units. These consisted of both well-developed renal tubules, epithelial tube of different neuron segments, and human vascular networks, which connect to host vasculature. The latter demonstrated the presence of both CD31+ endothelium and oSMA+ pericytes, originating from administered ECFCs and MSCs, respectively. Notably, MSC/ECFC-derived vessels augmented in vivo tubulogenesis by RTFCs while in vitro co-culture experiments showed MSC/ECFCs to induce self-renewal and mesenchymal-epithelial transition-associated genes in RTFCs, disclosing paracrine effects.

Conclusions: Combined cell therapy of vessel-forming cells and RTFCs aimed at enhancing tubulogenesis and potentially alleviating renal hypoxia may serve as the basis for new renal regenerative therapies.

PO0884
Elastin-Microfibril Axis Proteins Form Transient 3D Structures During Kidney Development
Sarah N. Lingo,1,2 Andrew L. Schwander,2 David S. Hains,2 Sarah Calve.3,1
1Purdue University System, West Lafayette, IN; 2Indiana University School of Medicine, Indianapolis, IN; 3University of Colorado at Boulder, University of Colorado Boulder, Boulder, CO.

Background: Dynamic changes in the composition and structure of the extracellular matrix (ECM) are understood but critical during renal development. Our recent proteomic study indicated proteins in the elastin-microfibril axis were upregulated with development; however, structural changes during maturation are unclear.

Methods: Mice were decellularized, stained for elastin-microfibril axis protein (EMILIN1), FREM2, and proteoglycans (WGA), imaged using confocal microscopy, and rendered in 3D using Fiji. For comparison, E18.5 cryosections were stained for additional axis proteins were organized in the interstitium surrounding developing tubular and glomerular elements, including vertical fibers connecting to the capsule and medullary ray sheath fibers. Patterning was lost in the adult (Fig. 1). Different elastin-microfibril axis proteins displayed similar staining patterns perinatally (Fig. 2).

Conclusions: The 3D corticomedullary junction structures for elastin-microfibril axis proteins at the perinatal timepoint were consistent with the proteomic trends. We hypothesize the structures are important for nephrogenesis through mechanical support and growth factor modulation.

Funding: Other NIH Support - National Institutes of Health [DP2 AT009833 to S.C.]

Figure 1 (top): 3D visualization of EMILIN1 showed medullary ray sheath fibers transiently formed at E18.5. EMILIN1 was localized to the corticomedullary junction (green, white arrow) fibers surrounding tubules at E14.5 that grouped into medullary ray sheath fibers (*) at E18.5 but regressed in the adult murine kidney. Insets are visualization of the EMILIN1 channel. scale bar=500 μmFigure 2 (bottom): Elastin-microfibril axis proteins displayed similar staining patterns at E18.5. PO0885
Development of Noninvasive Clinically Applicable In Vivo Tracking of Extracellular Vesicles Using Magnetic Resonance Imaging (MRI)
Sargis Sedrakyan,1 Johnny C. Akers,2 Paola Aguiari,1 Hasnial Soloyan,1 Seda Mkhitarian,2 Geyorg Karapetyan,1 Roger E. De Filippo,1 Mya S. Thu,2 Laura Perin,1 Children's Hospital of Los Angeles, Los Angeles, CA; 2VisiCell Medical Inc, San Diego, CA.

Background: Extracellular vesicles (EVs) derived from amniotic fluid stem cells (AFSC) hold great potential for the treatment of chronic kidney diseases (CKD). We have already shown that AFSC-EVs are renoprotective in a mouse model of CKD, Alport syndrome. However, there is an important unmet need for real-time in vivo monitoring of these therapeutic EVs after they are injected into a subject to understand their safety, targeting, and effectiveness. While current optical imaging solutions like bioluminescence and fluorescence are useful for EV tracking studies in animal models, there is limited utility in clinical applications. Here we present a novel in vivo tracking solution for our therapeutic EVs in Alport mice, utilizing clinically applicable MRI technology.

Methods: To generate trackable EVs, AFSC were labeled with a novel magnetic agent (VSCM). EVs secreted by the labeled AFSC were isolated using ultracentrifugation. The viability and morphology of labeled-cells were evaluated, and the in vitro MR properties of EVs were analyzed by magnetometer. Purity, potency and identity of labeled EVs was compared to non-labeled EVs. In vivo biodistribution of labeled EVs was evaluated in WT and Alport mice by MRI at 10 min and 3 hr post injection, and retro-orbital and intra-cardiac routes of delivery were compared.

Results: The magnetic label did not affect the physiological characteristics of the cells and did not change identity, purity and potency (therapeutic effect in vivo) of EVs. MRI phantom studies confirmed the in vitro reality detectability of labeled-EVs. Importantly, as expected MRI studies showed that EV homing to the kidney injected intracardiacally into Alport mice was more efficient vs the retro-orbital route, and Prussian blue staining of sections confirmed EV homing to the kidney.

Conclusions: We have developed a clinically applicable novel magnetic nanoparticle agent that can be used to label and track the biodistribution of EVs in the kidney and other organs using non-invasive, safe, and effective MRI technology that’s widely available. This technology is highly adaptable and can be deployed in both preclinical and clinical settings.

Obesity Blunts the Reparative Function of Human Adipose Tissue-Derived Mesenchymal Stem Cells in Ischemic Murine Kidneys

Nattawat Klomjit,1 James Krier,1 Sabena Conley,1 Xiang yang Zhu,1 Christopher M. Ferguson,1 Kyra L. Jordan,1 Hui Tang,1 Amir Lerman,2 Lilach O. Lerman,3 Division of Nephrology and Hypertension, Department of Medicine, Mayo Clinic, Rochester, MN;2 Department of Cardiovascular Medicine, Mayo Clinic, Rochester, MN.

Background: Obesity is a health burden that can affect cellular processes. Mesenchymal stromal/stem cells (MSC) ameliorate renal injury in several diseases. Obesity impairs MSC function in vitro, but its effect on in vivo reparative function of human MSC remains unknown.

Methods: MSC were harvested from non-obese (‘lean’) (body mass index [BMI] <30 kg/m²) and obese (BMI≥30) human subjects during kidney donation or bariatric surgery, respectively. To test their function in vivo, MSC (5x10⁶-200 μL) or vehicle were injected into 129S1 mice 2 weeks after renal artery stenosis (RAS) or sham surgery (n=6-8/group). Two weeks later, mice underwent magnetic resonance imaging to assess renal perfusion and oxygenation, and kidneys then harvested.

Results: A similar number of lean and obese human MSC engrafted in stenotic mouse kidneys. Vehicle-treated RAS mice had reduced cortical and medullary perfusion. Lean (but not obese) MSC normalized cortical perfusion (p=0.2 vs sham+vehicle) (Figure A&B), whereas both effectively mitigated renal hypoxia. Serum creatinine and blood pressure were elevated in all RAS mice, and lowered only by lean MSC (p=0.4 vs sham+vehicle). Both alleviated renal fibrosis in RAS, but lean more effectively than obese MSC (p=0.02). Tubular and glomerular injury was improved similarly by both.

Conclusions: Lean MSC are superior to obese MSC in repairing ischemic kidney injury and blood pressure in murine RAS, implying dysfunction of the endogenous MSC repair system in obese patients. This should also be considered during autologous cell-based approaches.

Generation of Branching Ureteric Bud Organoids from Human Pluripotent Stem Cells

Kyle McCracken,1,2 Min Shi,2 Wei Tao Zhang,2 Lioba Ester,2 Joseph V. Bonventre.3
1Boston Children’s Hospital, Division of Nephrology, Boston, MA; 2Brigham and Women’s Hospital Department of Renal Medicine, Boston, MA.

Background: Directed differentiation of human pluripotent stem cells (hPSCs) to kidney organoids has been well established; however, the generation of hPSC-derived ureteric bud (UB) which undergoes branching morphogenesis to generate collecting duct (CD) epithelia, has remained a significant challenge. Here we describe a highly efficient method for deriving UB/CD organoids from hPSCs, which form unprecedented branching structures. This method provides a new platform for studying human CD development, physiology, and disease modeling. Moreover, this will provide the opportunity to markedly enhance existing kidney organoids by providing a collecting system and importantly, introducing an iterative branching component that is essential to driving metanephric kidney development.

Methods: First, we modified existing methods to efficiently direct hPSCs into anterior intermediate mesoderm cells in monolayer format. From that point, we optimized a process of 3-D development that included forced aggregation followed by spontaneous budding and then branching of the UB epithelia.

Results: We generated GATA3/PAX2 AIM with >80% efficiency within 5 days of induction, which was then aggregated into 3-D spheres. Over the subsequent days, the cells underwent a spontaneous process of organization and maturation that parallels normal development of the embryonic nephric duct (ND). Nearly synchronously, each aggregate developed a detectable epithelial outgrowth that expressed markers of UB markers PAX2, GATA3, RET, SOX9 and CALB1. Next, we embedded the UB-like buds into a hydrogel matrix, and they underwent a complex branching morphogenetic program driven by growth factor signals. At later stages, we identified culture conditions to stimulate differentiation of the ureteric epithelia into CD principal cells, identified by expression of AQP2 and SCN1A/B. Additionally, GATA3+ UB progenitor cells were maintained and expanded over several passages in our 3-D culture system.

Conclusions: We have developed a novel strategy to generate branching UB tissues from hPSCs, which are also competent to differentiate into CD epithelia. Efforts are ongoing to investigate the functional and physiologic properties of these tissues, as well as to model genetic diseases that impact morphologic development of the collecting system.

Modeling Damage-Associated Molecular Pattern Injury and Fibrosis Using Human Kidney Organoids

Aneta J. Przepiorksi, Eugenel B. Espiritu,1 Alan J. Davidson,2 Neil A. Huknede.3 University of Pittsburgh School of Medicine, Pittsburgh, PA; 2The University of Auckland Faculty of Medical and Health Sciences, Auckland, New Zealand.

Background: Recent developments in generating human kidney organoids in vitro, have provided an invaluable tool to study human renal diseases, injury, and screening new therapeutics. In order to study acute kidney injury (AKI) we have developed a human kidney organoid model of injury with the damage associated molecular pattern molecule (DAMP), hemin, which is released during hemolysis, often occurring after ischemia/ reperfusion and rhabdomyolysis. To spatially and temporally characterize tubule injury in the hemin AKI model, we generated transgenic iPSC lines that carry an early apoptosis biosensor, CytochromeC-GFP. Healthy cells within organoids will localize CytochromeC to the mitochondria but, upon injury, will diffuse into the cytoplasm before activating the apoptotic pathway. This approach provides a real-time readout of injury progression in the kidney organoids.

Methods: Kidney organoids at day 14 of culture were treated for 48 hours with varying concentrations of hemin to determine the optimal dose for measurable injury at day 26. CytochromeC-GFP iPSC lines were generated using AAVS1 Safe Harbor targeting approach. CytochromeC-GFP response in the organoid was validated using menadione (mitochondrial toxin) and tested with hemin to determine the extent of injury. To test efficacy of new therapeutic compounds, hemin injured organoids were treated with varying concentrations of 4-phenylbutanoyl acid (PTBA) analogs for 10 days and analyzed to determine changes in fibrotic, and oxidative stress markers.

Results: We show injury in the organoids with optimal hemin dose leading to a reproducible increase in fibrotic, and oxidative stress response. CytochromeC-GFP biosensor iPSC lines allowed us to monitor organoids under hemin insult. Organoids treated with nephrotoxin or hemin exhibit cytoplasmic GFP signal in the injured cells and morphological changes of the mitochondria. Hemin injured organoids treated with PTBA analogs showed a reduction in fibrotic markers at day 26 suggesting a reduction in fibrotic morphological changes of the mitochondria. Hemin injured organoids treated with nephrotoxin or hemin exhibit cytoplasmic GFP signal in the injured cells and reproducible increase in fibrotic, and oxidative stress response. CytochromeC-GFP iPSC lines were generated using AA VS1 Safe Harbor targeting approach. CytochromeC-GFP response in the organoid was validated using menadione (mitochondrial toxin) and tested with hemin to determine the extent of injury. To test efficacy of new therapeutic compounds, hemin injured organoids were treated with varying concentrations of 4-phenylbutanoyl acid (PTBA) analogs for 10 days and analyzed to determine changes in fibrotic, and oxidative stress markers.

Conclusions: We have developed a reliable injury model using hemin, and together with CytochromeC-GFP as a biosensor, these tools can be exploited to test nephrotoxicity, study acute kidney injury, and new therapeutic compounds in a human based in vitro model.

Delaying Nephrogenesis In Vitro Results in Enhanced Proximal Tubule Alignment and Maturity in Kidney Organoids

Jessica M. Vanslambrouck,1 Ker sin Tan,1 Sean Wilson,1 Sara E. Howden,12 Kyan T. Lawlor,1 Michelle Scurt;1 Melissa H. Little.1,12 Kidney Development, Disease and Regeneration Murdoch Children’s Research Institute, Parkville, VIC, Australia; 2The University of Melbourne, Department of Paediatrics, Parkville, VIC, Australia.

Background: Stem cell-derived organoids represent a promising model for complex organs such as the kidney, with studies of disease, physiology and drug interactions relying mostly on simplistic cell cultures or animals that do not completely recapitulate the complex human environment. However, kidney organoids are still less mature than the in vivo organ, a limitation arguably most apparent in the proximal tubule (PT) compartment. The critical role of the PT in performing the bulk of solute reabsorption makes it a key requirement for drug screening and bioengineering. By inhibiting promiscuous epithelialisation, we report the development of PT-enhanced kidney organoids with improved PT alignment, maturity, functionality and suitability for therapeutic applications.

Methods: Standard and fluorescent reporter iPSC lines were subjected to prolonged monolayer differentiations, with 4 - 5 day initial CHIR exposure durations (modified from: Howden et al, EMBO Rep, 2019; Vanslambrouck et al. JASN, 2019) and precisely-timed modifications to signalling pathways such as canonical WNT, BMP and NOTCH. Organoids were generated as previously published (Takasato et al, Nat Protoc, 2016) and analysed using confocal immunofluorescence, live imaging of fluorescent reporters, transcriptional profiling (single cell RNAseq) and functional transport assays.

Results: PT-enriched organoids could be generated in a highly reproducible manner from multiple cell lines. Proximal tubules showed mature protein and gene expression, as well as transport capacity in multiple assays. Nephron spatial arrangement/directionality, as well as shifts in proximo-distal nephron patterning, were influenced by these modified conditions.

Conclusions: Here, we describe PT-enhanced kidney organoids with improved PT maturity and functionality, with this approach providing a more stringent control over the spatial arrangement of nephrons. Such findings have significant implications for downstream applications including drug screening, toxicity assays and bioengineering of functional replacement cells or tissues.

Glomerular Endothelial Glycocalyx Damage Occurs in Human Diabetic Nephropathy and Could Be Prevented by Early Mineralocorticoid Receptor Inhibition

Michael Crompton, Matthew J. Butler, Karen L. Onions, Anna S. Ogier, Gavin I. Welsh, Rebecca R. Foster, Simon C. Satchell, Bristol Renal University of Bristol, Bristol, United Kingdom.

Background: The glomerular endothelial glycocalyx (GEnGlx) forms the first part of the filtration barrier. In rodent models, damage to the GEnGlx occurs early in the development of diabetic nephropathy (DN). Until now no techniques have been available to quantify GEnGlx damage in human disease. Mineralocorticoid receptor (MR) antagonists slow disease progression, but side effects limit their clinical use. We aimed to develop a method to study GEnGlx changes in human disease and investigate whether MR inhibition could preserve the GEnGlx in a rat DN model.

Methods: Human renal biopsies from patients with DN and thin basement membrane disease (TBMD) were analysed using our novel peak-to-peak confocal imaging method (UEA-1 lectin) to assess GEnGlx depth. Male Wistar rats injected with streptozotocin (50mg/kg IP) were used to study if spironolactone (50mg/kg daily S.C.), an MR inhibitor, could preserve the GEnGlx and limit the development of DN. Our glomerular permeability assay was used to directly measure the albumin permeability (Ps’alb), in isolation from haemodynamic changes. Peak-to-peak (WGA lectin) was validated against electron microscopy GEnGlx depth measurements. MMP2 activity was quantified using a specific activity assay and ELISAs were used to measure urine albumin levels.

Results: In human DN, GEnGlx depth was reduced compared to patients with TBMD (p=0.013). Diabetic rats developed albuminuria and the Ps’alb increased 1.6-fold (p=0.001). Again, GEnGlx depth was reduced in DN compared to controls (p<0.001). Plasma and urinary active MMP2 were increased (p=0.017 and p<0.001). MR blockade preserved the GEnGlx, restored Ps’alb to control values and prevented albuminuria progression. Reduced urinary active MMP2 (p=0.012) were seen following MR blockade in DN. GEnGlx enzymatic degradation, with hyaluronidase, reversed the effect of MR blockade in DN confirming the importance of GEnGlx preservation in this model.

Conclusions: MR blockade in DN preserves the GEnGlx, reduces Ps’alb and retards the development of albuminuria. Alternate approaches to block MR and preserve GEnGlx damage represent a novel potential therapeutic strategy, to reproduce the benefit of MR antagonists without adverse side effects.

Background: TGFβ signaling plays a central role in the development and progression of renal interstitial fibrosis in chronic kidney disease (CKD), which predicts time to dialysis. Systemic blockade of TGFβ has shown serious adverse effects (progression of premalignant lesions) and limited efficacy at doses that were safe for patients, highlighting the need for a targeted inhibition of TGFβ in the kidney. αvβ3 integrins have a unique ability to sequester latent TGFβ through the binding of latency-associated peptide (LAP) to release active TGFβ and therefore can modulate fibrotic processes. Consequently, they have emerged as promising therapeutic targets.

Methods: We generated MED8367, an antibody that specifically binds human integrin αvβ3 and works allosterically reducing its affinity for the LAP domain, thereby preventing [β3-mediated TGFβ] activation but not its cell adhesion function. We confirmed its neutralising activity using a reporter cell in vitro assay that detects TGFβ bioactivity.

Results: To assess its therapeutic effect ITGB8 humanized mice were subjected to unilateral ureteral obstruction to induce fibrosis. Obstructed kidneys showed strong up-regulation of integrin β3 in the tubular compartment and MED8367 significantly improved fibrosis without affecting integrin β3 expression. This was accompanied by inhibition of TGFβ activation, which mimicked the effect of a pan-TGFβ neutralizing antibody. Intraperitoneal injection of MED8367 reduces renal fibrosis by blocking local TGFβ activation. We next tested the effect of targeting integrin β3 in a mouse model of diabetic nephropathy, the db/db-uninephrectomy model. Mice underwent uni-nephrectomy at 8 weeks of age and were randomized to receive either an anti integrin β3/β8 or an anti integrin β6 antibody at 12 weeks of age for 3 weeks. Blocking integrin β3 did not affect albuminuria in these mice while blocking integrins β3/β8 stopped the progression of albuminuria in all the mice tested (n=9). These data suggest that it is the blockade of integrin β3 that has a beneficial effect on albuminuria.

Conclusions: We conclude that targeting integrin β3 in CKD ameliorates kidney dysfunction and reduces fibrosis, an effect that is mediated by inhibition of local TGFβ activation.

Integrated Single Nucleus RNA and ATAC-Seq Implicate Cis-Regulatory Chromatin Interactions That Promote Gluconeogenesis in the Human Diabetic Proximal Tubule
Parker C. Wilson,1 Yoshiharu Muto,2 Sushrut S. Waikar,3 Benjamin D. Humphreys.1,2 Division of Anatomical and Molecular Pathology, Department of Pathology and Immunology, Washington University in Saint Louis School of Medicine, Saint Louis, MO, USA, Saint Louis, MO, 1Division of Nephrology, Department of Medicine, Washington University in Saint Louis School of Medicine, Saint Louis, MO, USA, Saint Louis, MO; 2Division of Genetics, Washington University in Saint Louis, Saint Louis, MO, USA, Saint Louis, MO; 3Division of Nephrology, Department of Medicine, Boston University School of Medicine, Boston, MA, USA, Boston, MA.

Background: Type 2 diabetes is characterized by impaired glucose metabolism, but relatively little is known about cell-specific changes in the kidney. We hypothesized that single cell multi-omic analysis of ATAC-Seq and RNA (snRNA) sequencing of kidney tissue from patients with early diabetes would reveal cis-regulatory chromatin interactions that promote expression of genes that lead to glucose intolerance.

Methods: We analyzed five kidney samples from patients with early diabetes and five healthy controls. Diabetic patients had elevated A1c and two of five had proteinuria. Serum creatinine (mean = 1.01 mg/dl) was not different between groups. Nuclear preparations were processed with 10x Genomics 5’ v2 or Single Cell ATAC kits, sequenced and counted with Cell Ranger. Analysis was performed with Seurat. snATAC peaks were called with MACS2 using SnapATAC. Chromatin interactions were predicted with Bir-CHiP.

Results: A total of 80,576 nuclei were analyzed by snATAC (n=46,564) or snRNA (n=34,012) sequencing and included all cell types. In the diabetic proximal tubule, we observed increased expression of gluconeogenic genes PCK1, ALDOB, FBP1, and G6PC and the sodium bicarbonate exchanger, SLC44A1 (Figure 1; green=upregulated, red-downregulated). Increased expression of G6S and GLUD1 implied glutamine as a gluconeogenic substrate. Transcriptional changes were accompanied by cell-specific differential chromatin accessibility in regulatory regions that were linked to their respective promoters via predicted chromatin interactions. Differentially accessible regions in the proximal tubule were enriched for NFκB binding motifs, suggesting it may regulate chromatin accessibility in diabetes.

Conclusions: This is the first single cell multi-omic analysis of early human diabetic kidney injury. Our analysis reveals that early diabetes induces changes in chromatin accessibility that promote gluconeogenesis and ammogenesis in the proximal tubule, and suggests utility for single cell multi-omic analyses.

Mapping the Response of Murine Diabetic Nephropathy to Therapy at Single-Cell Resolution
Haojia Wu,1 Romer A. Gonzalez-Villalobos,2 Xiang Yao,3 Dermott F. Reilly,1 Matthew M. Rankin,1 Maria chiara Magnone,4 Eugene Myskijn,3 Matthew D. Breyer,1 Benjamin D. Humphreys.1 1CVM Janssen Research & Development, LLC, Boston, MA; 2Division of Nephrology, Washington University in Saint Louis, St. Louis, MO; 3Fox LJ Janssen Research & Development, LLC, La Jolla, CA.

Background: Diabetic Kidney Disease (DKD) is the major cause of kidney failure in the USA. Angiotensin blockers (ACEi/ARBs) and SGLT2 inhibitors (Canagliflozin) are only approved therapies demonstrated to slow the progression of DKD.

Methods: We treated 40 diabetic db/db hypertensive (reninAAV) mice either with ACE inhibitor (lisinopril), an SGLT2 inhibitor (JNJ-3993673), a PPARγ agonist (Rosiglitazone), or vehicle control (n=10/group). Each group received either 2 days or 2 weeks of treatment. We measured BP, glucose and UACR and collected kidneys for snRNA-seq.

Results: Drug treatment at 2d and 2ks significantly reduced BP (lisinopril), glucose (Rosi and JNJ3673), and Uacr (lisinopril, Rosi and JNJ3673) from baseline demonstrating that either BP or glucose control independently impact Uacr in this model. We generated 1,324,051 single nucleus transcriptions, detecting 2,028 unique genes/ cell on average. Unbiased clustering identified 19 cell clusters representing all major cell types, including rare ones such as the JGA (3,614 cells), podocytes (8,851 cells) and macula densa (MD, 4,239 cells), and revealed new insights: DMP4, a fibrotic marker in MD, was strongly expressed in podocytes. Integrative analysis of cell type enrichment and differentially expressed genes across all clusters. These expression changes included JGA renin expression which was strongly downregulated by exogenous renin in ReninAAV db/db mice compared to WT. SGLT2 expression was restricted to the S1 segment of the PT, and SGLT2 inhibition acutely downregulated S1 glucose transporter Slc5a2 (Glut5) probably reflecting compensation. Sglt1 expression was strongly downregulated in db/db reninAAV MD, and Sglt2 inhibition partially restored this expression. MD Sglt1 has been shown to act as a glucose sensor and, inhibit tubuloglomerular feedback, so increased expression would increase GFR.

Conclusions: This is the first comprehensive single cell transcriptional atlas of the effects of diabetic nephropathy therapies in a mouse model. Drug specific and overlapping gene expression patterns were identified and should help elucidate cell-specific mechanisms of therapeutic benefit.

The β3-Adrenergic Receptor Agonist Formoterol Restores Mitochondrial Dynamics and Energy Production in the Diabetic Renal Proximal Tubule
Kristan H. Cleveland, Frank C. Brosius, Rick G. Schnellmann. University of Arizona, Tucson, AZ.

Background: While diabetic kidney disease (DKD) is the leading cause of end stage renal disease, the early pathophysiology of this disease remains poorly understood. In type 2 diabetes mitochondrial dysfunction and changes in energy metabolism occurs in proximal tubules. We examined the effects of formoterol, a β3-adrenergic receptor (AR) agonist previously demonstrated to induce mitochondrial biogenesis and promote recovery from acute kidney injury, on renal mitochondrial homeostasis and energy production in diabetic db/db mice and in renal proximal tubule cells (RPTC) treated with high glucose.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: RTCPT from rabbits were isolated using the iron oxide perfusion method and cultured for 14 days in a 90% glucose or 17 mM mannitol as an osmotic control for 96 hr. ATP, uncoupled oxygen consumption rate (OCR) and mitochondrial dynamics and energetics proteins were measured. D/h dB and non diabetic/dB/m control mice were treated with either vehicle or formoterol (1mg/kg, i.p.) daily for three weeks beginning at 10 weeks of age. At 12 weeks, kidneys were harvested and changes in mitochondrial proteins were measured.

Results: RTCPT treated with glucose for 96 hr exhibited a decrease in ATP, uncoupled OCR and the mitochondrial fusion protein Mfn1. In contrast, the fusion protein Pdpl and ETC complexes I-V increased. Treatment with formoterol (30mM) restored ATP, Mfn1, Pdpl and ETC complex proteins to control levels. Similarly, vehicle treated dB/db mice exhibited increases in ETC proteins complexes I, II, III and V, and Pdpl in renal cortex. Diabetic mice showed a decrease in Mfn1 in renal cortex. Loss of Mfn1 and complexes I, II, III and V, Pdpl and Mfn1 to control levels in dB/db mice. ATP was decreased in dB/db mice and was restored to control levels with formoterol treatment.

Conclusions: Together, these in vivo and in vitro results suggest that increased glucose alters mitochondria dynamics (increase fusion/descrease fusion) and decreases ATP in spite of increased ETC proteins. Formoterol reverses these glucose-induced effects and may be used as a potential therapy to prevent early disease progression of DKD.

PO0988
UCP2 Activates Autophagy to Protect Against Albuminuria and Podocyte Injury in Diabetest Qianqian Gao, Xiaobo Li, Junwei Buadi. Second Affiliate Hospital of Nanjing Medical University, Nanjing, China.

Background: Podocyte injury and albuminuria are leading features of glomerular damage in diabetic kidney disease. Autophagy plays an important role in maintaining podocyte homeostasis. However, the underlying mechanism remains unknown. In this study, we generated a novel model of podocyte injury and autophagy in podocytes by using Cre-LoxP recombination system. Second, autophagosome was detected by transmission electron microscopy. Dual-fluorescence lentiviral mRFP-GFP-LC3 was transfected into podocyte to detect the autophagic flux. Autophagy marker, LC3, p62 and Beclin1, were tested by quantitative real-time PCR and western blot. At last, AMPK activator and mTORC1 inhibitor were used to identify the signaling pathway. UCP2-mediated to regulate autophagy.

Results: UCP2 was upregulated synchronously with autophagy marker during glomerular development. Loss of UCP2 in podocytes led to a decrease of autophagic activity and an increase of podocyte injury. Podocyte-specific knockout of UCP2 aggravated age-related proteinuria and increased podocyte susceptibility to hyperglycemia in streptozotocin (STZ) -induced DKD mice. UCP2 promotes podocyte autophagy through activation of AMPK/mTOR signaling pathway.

Conclusions: Our findings demonstrates a critical protective role of UCP2 in podocyte survival via maintaining autophagic activity through AMPK/mTOR signaling pathway.

PO0899
Darunavir Protects Mice with Type 1 Diabetes Against Kidney Injury Xiao Bao, Guandi K. Tandoh, Heidi Karttunen, Michael J. Ross. Albert Einstein College of Medicine, Bronx, NY.

Background: Despite the success of antiretroviral therapy (ART) in improving the prognosis of HIV-positive patients, the disease still has increased risk of death and kidney disease, and diabetes mellitus are important contributors to this excess mortality. Data from our laboratory demonstrate that the HIV protease inhibitor darunavir (DRV) prevents kidney disease in HIV-transgenic mice via mechanisms independent of HIV protease. Since diabetic kidney disease (DKD) is the most common cause of chronic kidney disease (CKD), and specific individual risk factors, particularly obesity predispose diabetic patients to more rapid progression of CKD, we studied the efficacy of DRV in a non-HIV animal model of DKD.

Methods: eNOS−/−9 week-old C57BL/6 mice underwent induction of diabetes by administration of 5 daily 50mg/kg doses of streptozotocin (STZ) injection. Blood glucose was measured before and after DRV treatment. 14 weeks after STZ induction, mice were treated with either DRV (100mg/kg) or control by daily oral gavage for 4 weeks. Albumin-to-creatinine ratio (ACR) assay, immunocytochemical, western blotting and real-time PCR were performed with routine protocols. Mouse blood pressure (BP) was measured before and after DRV treatment. 14 weeks after STZ induction, mice were treated with DRV or control. We found DRV and formoterol treatment decreased renal injury and prevented loss of synaptopodin expression in podocytes. Since the renin-angiotensin system (RAS) is an important contributor to DKD pathogenesis, we studied whether DRV affects expression of RAS components. Unexpectedly, DRV decreased renin expression and may be used as a potential therapy to prevent early disease progression of DKD.

Conclusions: These data demonstrate that DRV protects mice against type I diabetic renal injury. Further studies are needed to determine whether changes to renal gene expression are due to direct effects of DRV or secondary to reduced renal injury, resulting in normalization of gene expression suppression and BP.

Prostate Mediated NF-E2 Degradation Occurs Upstream of JNK Activation-Mediated CTGF Expression in Renal Tubules and Diabetic Kidneys Madhavi J. Ranc, Ji Li, Shunying Jin, Michelle T. Barati. University of Louisville, Louisville, KY.

Background: TGF-β is a critical mediator of diabetes-induced renal fibrosis. We recently demonstrated that TGF-β and diabetes (Type 1 and type 2) decrease NF-E2 expression and promoted pro-fibrotic signaling in renal cells and kidneys. P38 MAPK and ERK MAPK pathways contributed to proteasome activation and NF-E2 degradation. As JNK pathway is known to induce CTGF expression, current studies examined the contribution of JNK pathway in mediating NF-E2 degradation in TGF-β treated renal tubule cells.

Methods: HK-11 cells were pre-treated with/without JNK inhibitor SP600125, p38 inhibitor SB203580, or p38 and MEK/ERK inhibitor PD98059, or proteasome inhibitor MG132, for an hour prior to treatment with TGF-β for 24 h. Cell lysates were immunoblotted with appropriate antibodies. Kidney homogenates from FVB and OVE26 diabetic mice treated with 10 µg/Kg MG132 daily for 3 mo starting at 3 mo of age vs OVE26 mice already displayed significant albuminuria were immunoblotted with appropriate antibodies. MG132 were injected intraperitoneally at a dose of 10 µg/kg daily for 3 mo starting at 3 mo of age when OVE26 mice already displayed significant albuminuria.

Results: Inhibition of p38 MAPK partially preserved NF-E2 expression but induced CTGF expression, as p38 blockade induced ERK phosphorylation. Blockade of both p38/ERK, prevented NF-E2 degradation and inhibited CTGF expression. Blockade of JNK pathway, inhibited CTGF expression without preserving NF-E2 expression. Interestingly, proteasome inhibition in renal cells and OVE26 mice preserved NF-E2 expression and inhibited JNK activation and CTGF expression suggesting JNK activation occurs downstream of proteasome activation.

Conclusions: Our studies have demonstrated that p38 and ERK MAPK pathways promote proteasome activation and NF-E2 degradation while proteasome activation promotes JNK activation and CTGF expression in renal cells and diabetic kidneys. We have recently demonstrated that NF-E2 over-expression inhibited CTGF expression however, future studies will examine effects of NF-E2 over-expression on TGF-β induced and diabetes-induced JNK activation in renal cells.

Rab27b Repression by Foxo1 Leads to Decreased Exosome Production in Diabetic Kidney Disease

Mengru Zeng,1,2 Jin Wen,1,3 Zheng Dong,3 Department of Nephrology, The Second Xiangya Hospital, Central South University, Changsha, China; 1Department of Cellular Biology and Anatomy, Medical College of Georgia at Augusta University, Augusta, Georgia, USA; 2Yongchuan Hospital of Chongqing Medical University, Chongqing, China; 3West China Hospital of Sichuan University, Chengdu, China.

Background: Diabetic kidney disease (DKD) is associated with changes in exosomes. However, it is unclear whether the production or secretion of exosomes is affected in DKD. This study aims to investigate whether and how the secretion of exosomes is affected in DKD using in vivo and in vitro diabetic models.

Methods: In vivo, exosomes were isolated from kidney cortical tissues of Akita mice and streptozotocin-induced diabetic mice for analysis. In vitro, mouse proximal tubular BUMPT cells were incubated with high glucose (30mM, HG) or mannitol (control) for 8 days to collect exosomes in culture medium. Exosomes were examined by electron microscopy, western blotting, nanoliter tracking assays (NTA), and flow cytometry. Knockdown and overexpression were used to study the roles of Rab27b and Foxo1 on exosome secretion.

Results: In vivo, diabetic mice had a reduced number of exosomes in renal cortical tissues compared with non-diabetic mice. In vitro, HG treatment led to a significant decrease in exosome secretion in BUMPT cells, which was associated with the specific downregulation of Rab27b, a key GTPase for exosome secretion. Overexpression of Rab27b restored exosome secretion in HG-treated cells, suggesting Rab27b functions in decreased exosome secretion in DKD. For the mechanism of Rab27b downregulation, bioinformatic analysis predicted Foxo1-binding sites at Rab27b gene promoter. We demonstrated the phosphorylation of Foxo1 in HG-treated cells, accompanied by less Foxo1 accumulation in the nucleus. Overexpression of Foxo1 increased Rab27b expression, whereas Knockdown of Foxo1 had opposite effects. Moreover, expression of non-phosphorylatable (constitutively active) Foxo1 led to the upregulation of Rab27b and increases in exosome secretion in HG-treated cells.

Conclusions: In diabetic kidney cells and tissues, Foxo1 is phosphorylated and inactivated, leading to decreases in Rab27b expression and consequent secretion of exosomes.

The Decrease in Renal Cystathionine β-Synthase/Hydrogen Sulfide Was Involved in the Pathogenesis of Diabetic Nephropathy

Yanting Yu,1 Zhiyun Ren,2 Gangyi Zhu,2 Weiwang Wang,1 Yutao Jia,1 Xiaoyan Wang,2 The Affiliated BenQ hospital of Nanjing Medical University, Department of Nephrology, BenQ Medical Center; The Affiliated BenQ hospital of Nanjing Medical University, Nanjing, China; 1The Core Laboratory for Clinical Research, BenQ Medical Center, The Affiliated BenQ hospital of Nanjing Medical University, Nanjing, China; 2Department of Medicine, The George Washington University, Washington DC, WA.

Background: Hydrogen sulfide (H2S) and its producing enzymes are associated with human diseases including coronary heart disease, Alzheimer’s disease, diabetic retinopathy and obstructive kidney disease, etc.

Methods: In order to determine their roles in pathogenesis of diabetic nephropathy, we examined plasma H2S levels in diabetic nephropathy patients and mice, renal H2S production & H2S producing enzymes in the mouse model, and the effects of glucose on H2S producing enzymes, mainly Cystathionine β-synthase(CBS), in cultured mouse proximal convoluted tubule cells (mPTC).

Results: Plasma H2S levels were decreased in patients (17.8±0.5 vs 24.8±0.8 umol/l, p<0.05, n=18/group) and mice (18.7±1.6 vs 40.7±1.8 umol/l, p<0.05, n=6/group).

The renal H2S production in mice was decreased (vs 52.1±2.9 vs 81.5±5.8 umol/l, p<0.01) along with the reduction of renal protein expression of CBS (52.1±13.4% of control). A similar protein decrease of CBS/52.5±12.2, p<0.01) was found in cultured mPTC stimulating by high glucose (25mmol/l-D-glucose), but not CSE or MCT. CBS protein expression was correlated negatively with glucose concentration (0.5,10,15,20,25,mM) (p<0.01). The significant decrease of CBS by glucose occurred at 1, 2, 24 and 48 hrs. Uptake/secretion of CBS was increased remarkably (588.7±140, p<0.01) within 5 hr before high glucose stimulation. CBS immunostaining became less strong with high glucose at the time points of 1hr & 2hr while the co-staining of CBS and LAMP2, a lysosome marker, reached the maximum at 30 min. The decrease of CBS mRNA expression was also found at post-Glucose (12hr High glucose treatment).The decrease of CBS mRNA expression was also found at post-Glucose (12hr High glucose treatment). The expression of CBS and NT was increased by inhibition of CBS protein with its siRNA but was reversed by GYY4137, a slow-releasing H2S donor. The expression of NT was not increased by inhibition of CBS protein with its siRNA but was reversed by GYY4137 in normal glucose medium. Furthermore, in diabetic nephropathy mice, the unaltered L66a.6±6.6 vs 117.e6.6 ug/dl, p<0.01) mesangial matrix proliferation and glomerular basement membrane thickening were ameliorated by exogenous supplementation GYY4137 at 20ng/kg for 8 weeks.

Conclusions: These findings suggest that high glucose may decrease renal CBS protein by increasing its ubiquitination / degradation and inhibiting its mRNA, eventually induce proximal tubular cell injury due to loss of protective mechanism of H2S.

Lysosphospholipids Predict Fast Decliners with Diabetic Kidney Disease Kentoaro Yoshikai,1,2 Yusuke Hirakawa,1 Kensuke Kojima,1 Masaomi Nangaku,1 Reiko Inagi,3,4 Kyowa Kirabushiki Kaisha Kenkyu Kairitsu, Chiyoda-ku, Japan; 1University of Tokyo School of Medicine, Bunkyo-ku, Japan; 1University of Tokyo Graduate School of Medicine School of Medicine, Bunkyo-ku, Japan.

Background: In type 2 diabetes, lipid metabolism disorder is frequently complicated due to insufficient insulin secretion and cytoplasms by visceral fat and regarded as one of the most important risk factors for renal dysfunction. However, specific lipid metabolites that have critical effects on renal dysfunction are not fully understood.

Methods: We performed the metabolomic analysis for patients with diabetic kidney disease (DKD) to identify novel metabolites related to renal prognosis. Plasma and urine biosamples in stage G3 DKD patients (n=135) were collected, and the whole metabolites of them were quantified by capillary electrophoresis mass spectrometry (CE-MS). Significantly fluctuating metabolites in patients with rapidly impaired renal function within 5 years (called “fast decliners”; about 10% in total) were statistically extracted. We also validated the metabolomic candidates with animal DKD model of SDT-fat rats, or in vitro study using renal proximal tubular cells (HK-2).

Results: In the clinical metabolomic analysis of the biosamples, over 250 metabolites, including lipids, glycates, and amino acids were identified by CE-MS. Among them, specific urinary lysosphospholipids (named as LPLsX) in the fast decliners of DKD were significantly increased. The LPLsX were moderately correlated with eGFR decline after 3 years (r=0.42, p<0.01). In animal experiments, the level of LPLsX was also increased in both the urine and the kidney in the subnephrectomized SDT-fat rats, while we did not see those damages in normal SDT rats. In vitro experiments: the exposure of LPLsX to HK-2 cells showed a significant downregulation of NT gene expression within 24 h and upregulated pro-apoptotic gene expression. More physiological changes were investigated in reference to transcriptomic analysis, and we could find that LPLsX also damaged the lipid metabolism, estimated by intracellular lipid droplet accumulation, and increased the level of mitochondrial reactive oxygen species. Conclusions: LPLsX predict “fast decliners” in DKD patients or DKD rats and may have crucial roles in renal tubular damage and dyslipidemia. Our findings provide new insights into the pathophysiological understanding of the relationship between lipid metabolism disorder and DKD progression.

Podocyte-Specific Induction of KLF6 Attenuates Diabetic Kidney Disease in Mice

Bismark Owusu Frimpong, Nehaben A. Gujarati, Sandeep K. Mallipattu.
Division of Nephrology, Department of Medicine, Stony Brook University, Stony Brook, NY.

Background: Krippe-Like Factor 6 (KLF6), a zinc finger transcription factor, is a key regulator of cytochrome c oxidase assembly in the podocytes. Podocyte-specific Klf6 knockout increases the susceptibility to streptozotocin (STZ)-induced diabetic kidney disease (DKD). However, salutary effects of podocyte-specific KLF6 induction in DKD remain to be explored.

Methods: Podocyte-specific inducible human KLF6 (hKLF6) was generated in mice using the "Tet-on" system, by breeding NPHS2-rtTA mice with newly generated TRE-KLF6 to generate Klf6flox/flox mice. TRE-KLF6 transgene were generated using the (TetO7/CMV) regulatory element driving the full-length human KLF6 coding sequence (UCDS 7600.1). Transgene was purified from plasmid vector sequences and microinjected into the pronucleus of FVB/N single-celled embryos. Founder mice were selected based on the level of KLF6 induction after doxycycline (DOX) treatment. STZ - Unilateral nephrectomy (STZ-UNX) was utilized to induce DKD in mice. First, DOX diet was administered at 8 weeks of age in all mice. UNX or Sham was performed at 10 weeks of age followed by low-dose STZ or vehicle (VEH) treatment respectively, at 12 weeks for 5 consecutive days. DOX-STZ-UNX treated NPHS2-rtTA, DOX-VEH-Sham treated NPHS2-rtTA and KLF6flox/flox mice served as controls. All mice were euthanized at 20 weeks of age and assessed for functional and histological changes in the kidney.

Results: DOX-STZ-UNX treated KLF6flox/flox mice exhibited significantly lower albuminuria, focal and global glomerulosclerosis, mesangial expansion, and improved mice survival as compared to age and gender-matched DOX-STZ-UNX untreated NPHS2-rtTA mice. DOX-STZ-UNX treated KLF6flox/flox mice also exhibited less tubulointerstitial fibrosis and inflammation (pathology scoring) as compared to age- and gender-matched DOX-STZ-UNX treated NPHS2-rtTA mice.

Conclusions: These data suggest that podocyte-specific induction of human KLF6 attenuates podocyte injury and DKD, and improves overall survival in mice.

nPOD-Kidney, a New Tool for Investigating Diabetic Kidney Disease

Florence Aquastill, Vivek Das, Heather H. Ward, Charles E. Alpers, Xu Zeng, Johnna D. Wesley, Anil K. Karihaloo, "Noyo Nordisk Research Center, Inc., WA, 1University of Washington School of Medicine, Seattle, WA, 2University of Florida Health Pathology Laboratories, University of Florida Health, Gainesville, FL.

Background: Diabetic kidney disease (DKD) is a common complication of diabetes, yet it remains poorly understood. The network for Pancreatic Organ donors with Diabetes - Kidney (nPOD-K) project was initiated to assess the feasibility of evaluating human kidneys from organ donors with long-standing diabetes (>8 years), with the long-term goal of improving our understanding of DKD pathogenesis.

Methods: Formalin-fixed paraffin-embedded sections from nPOD-K were stained for specific renal cell and disease markers by multiplex immunofluorescence, followed by periodic acid-Schiff (PAS) staining. Whole sections were imaged using an Axioscan Z1 scanner (20X objective) and quantitative image analyses were performed using Visiopharm software.

Results: Tissue integrity and histological stage were independently assessed by two renal pathologists. The majority of cases presented a moderate or severe diagnosis, and 20% of the cohort displayed no overt sign of kidney disease despite long-standing diabetes. Algorithms for automatic segmentation of kidney compartments (e.g. glomeruli, tubules) in the PAS layer were then developed using deep convolution neural network DeepLabV3+. We achieved a DICE coefficient of 0.95 for glomeruli and 0.89 for tubules. Quantification of renal markers was performed using machine learning classification methods. In accordance with published studies, our quantitation demonstrated loss of podocyte marker WT1, endothelial marker CD31, and tubular marker Lotus tetragonolobus lectin correlating with the progression of DKD, concomitantly with increased tubular atrophy and expression of fibrotic markers.

Conclusions: In conclusion, kidneys obtained from organ donors are viable and display all expected features of human DKD at the level of light microscopy. This cohort provides a unique opportunity to better understand DKD pathophysiology through analysis of large, CKD stage-specific regions. Similar to the results from the rPOD pancreas cohort, all histological stages of disease can be detected in affected kidneys, providing a pseudo-time-line of the evolution of DKD and supporting the potential to identify novel therapeutic targets.

PO0908
Nerve Growth Factor Protects Podocyte Apoptosis by Regulating Sirt1 Expression

Jing E. Yali Zheng. Ningxia People’s Hospital Ningxia People’s Hospital, Tinchuan, China.

Background: Podocyte injury contributes to the progression of diabetic kidney disease (DKD). In the previous studies, we demonstrate that expression of Cdk5/p35 play an important role in the diabetic kidney and associated with the progression of DKD in human. As know, podocyte can secret NGF and Sirt1 is one substrate of CDK5, so the objective of this article is to investigate the mechanism of NGF protecting podocyte apoptosis by regulating Sirt1 expression and to provide a new biological target for clinical treatment.

Methods: The immortalized mouse podocyte was cultured in vitro, then were transfected with control siRNA or siNGF vector to detect protein level of Sirt1 and apoptosis associated protein Cleaved caspase3 through western blot. In addition, podocytes were also given different concentration of NGF to detect the expression of Sirt1 and Cleaved caspase 3 in order to find the relationship of NGF and Sirt1, and the role of NGF on podocytes.

Results: To understand the role of NGF on podocyte, we stimulated immortalized mouse podocytes with NGF in different concentration, the protein level of Sirt1 was positive associated with NGF expression. 2. Podocytes were transfected with control siRNA or siNGF vector by using ViaFect™ Kit, the effect of siNGF was verified by western blot. knockdown of NGF decreased the expression of Sirt1 and Cleaved caspase 3. 3. When gave NGF stimulation, the protein level of Cleaved caspase3 was decreased.

Conclusions: NGF plays a key role in protection podocyte by regulating the expression of Sirt1, NGF/SIRT1 axis may be a new biological target for preventing podocyte injury.

Integrin αvβ8/TGF-β Activation in Kidney Is Associated with Renal Function Deterioration and Can Be Monitored in Urine

Xiaoqian Wang, James Conway, Kristina Kovacina, Stephanie C. Heasman, Elena Liarte Marin, Sonja Hess, Chelsea Boo, Denis Feliers, David J. Baker, Marvin V. Sinsakul, Iain MacPhee, Viknesh Selvarajah, Sven M. Moosmang, Judith Hsia, Judith Hartleib-Geschwindner.

Funding: AstraZeneca, Gaithersburg, MD; 1University of Colorado, Aurora, CO; 2Astrazeneca, South San Francisco, CA; 3AstraZeneca UK Ltd, Cambridge, United Kingdom; 4AstraZeneca, Gothenburg, Sweden.

Background: Integrin αvβ8/TGF-β activation plays a central role in fibrosis. The specificity of TGFβ activation is regulated by the expression of integrin isoforms in tissues. We set out to study molecular signatures associated with various aetiologies in CKD, the specific integrins that modulate TGFβ activation and fibrotic initiation in the kidney and the potential for non-invasive monitoring of renal TGFβ activation.

Methods: Kidney biopsies were obtained from CKD cohorts of diverse aetiologies and living donor (LD) controls. Gene profiling data (Microarray) were obtained from glomeruli and tubulointerstitial. Renal fibrosis was evaluated and the correlation with TGFβ activation as well as cGFR was assessed.

Results: In the Gene Set Variation analysis (GSVA), fibrosis signatures including collagen signature increased with CKD severity compared to LD. This was more prominent in diabetic nephropathy (DN) in both glomeruli (N=12, p<1.094e-04) and tubulointerstitium (N=17, 2.31e-04). Further analysis showed that renal integrin b8 (ITGB8) was enriched and elevated at CKD stage 2, maintained at the similar level at
stage 3 and 4, ITGB8 was higher in tubular tissues in kidney biopsies from DN patients and co-localized with areas of fibrosis. Moreover, TGFβ activation signature of 30 genes was significantly correlated with ITGB8 expression (R=0.58, p=2.39e-16, N=169) and inversely correlated with sGFR (p<0.02). Active TGFβ was detectable in urine by a Simon immunosassay. The active TGFβ/creatinine ratio was increased by 4.4 fold (p=0.0003) in CKD subjects (median: 7.5 ug/g, N=20) compared to non-CKD controls (1.4 ug/g, N=20). The level of active TGFβ in urine can potentially identify patients at risk for fibrosis and progression of DKD.

Conclusions: In conclusion, fibrosis is associated with CKD severity, most prominent in DN. Integrin b8 is enriched in DN and correlates with TGFβ activation. The fibrosis status may be monitored via measuring active TGFβ in urine.

Funding: Commercial Support - AstraZeneca

PO0910 Omentin 1 and Histone H1 Variants as Remote Candidate Prognostic Biomarkers of CKD Among People with Type 1 Diabetes Mellitus (T1DM)

Michael Merchant,1 Jian Cai,1 Adam E. Gaweda,1 Michelle T. Barati,1 Michael E. Brier,1 Ming Li,1 Minhiao Ye,1 Jaye W. Voss,1 Brad H. Rovin,3 Mark E. Motlich,4 Daniel Ballte,4 Jon B. Klein,1,2 University of Louisville Health Sciences Center, Louisville, KY; 3Robley Rex VA Medical Center, Louisville, KY; 4The Ohio State University Wexner Medical Center, Columbus, OH; Northwestern University Feinberg School of Medicine, Chicago, IL.

Background: It has been difficult to identify biomarkers that antedate the development of CKD. In a previous study we identified omentin-1 and histone H1 (HISTH1) variants as candidate surrogate prognostic biomarkers associated with future CKD development in T1DM Diabetes Control and Complications Trial (DCCT) study participants. We present here the results of this follow-up study from the Epidemiology of Diabetes Interventions and Complications (EDIC) study.

Methods: Pair-designed serum samples from 23 controls (defined as participants with stable renal function) and 23 cases (defined as participants who went on to develop CKD stage 3 (GFR<60ml/min/1.73m2) were examined prior to and following the development of CKD. HISTH1 variant proteins were quantified using a parallel reaction monitoring (PRM) LCM method to quantitively HISTH1 variant specific peptides unique to H1.1, H1.2, H1.3, and H1.4. Omentin-1 was quantified using a commercial ELISA kit for omentin-1 (BioVendor; Asheville, NC). Protein abundance data were analyzed using Kruskal-Wallis rank sum tests with an unadjusted p-value 0.05 considered significant.

Results: HISTH1 peptide levels did not differentiate (p > 0.05) DCCT cases and controls. Omentin-1 levels were significantly increased in EDIC cases over controls. A multivariate logistic regression analysis of histone peptide quantified omentin-1 as the best classifier to differentiate controls from EDIC cases. Omentin-1 quantification confirmed discovery findings (DCC control < case, fold-change 1.2, p <0.05). Additionally, in cases, omentin-1 increased significantly (p = 0.0001) from the DCCT to the EDIC (1.4) whereas it did not (p = 0.06) in controls (fold-change 1.1).

Conclusions: Plasma HISTH1 variants levels did not predict future CKD3 status but did predict DCCT versus EDIC cohorts. Increased plasma omentin-1 levels in EDIC compared to DCC controls were associated with advanced CKD stage 3. These data suggest a role for omentin-1 or pathways regulating omentin-1 expression are associated with progression of kidney function loss in T1DM.

PO0911 Investigations on Urinary Exosomal miRNA Biomarkers That Reflect Pathologic Features of Patients with Diabetic Kidney Diseases

Seo Jung-Woo,2 Yu Ho Lee,2 Miji Kim,2 Yang yun Kim,2 Sangho Jeong,2 Ji Young Lee,2 Hyun Seok Hwang,2 Kyung hwan Jeong,3 Hye yun Jeong,3 So-young Lee,3 Dong Ho Yang,3 Ju young Moon,3 Division of Nephrology, Department of Internal Medicine, Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea; 1Department of Core Research Laboratory, Medical Science Institute, Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea; 2Department of Nephrology, Department of Internal Medicine, CHA Bundang Medical Center, CHA University, Seongnam, Republic of Korea; 3Department of Nephrology, Department of Internal Medicine, Kyung Hee University Medical Center, Seoul, Republic of Korea.

Background: Diabetic kidney disease (DKD) is a leading cause of end-stage renal disease worldwide. Although histological severity of DKD is a well-established predictor of adverse renal outcomes, investigations on the identification of non-invasive biomarkers that can reflect intrarenal status are scarce. The aim of this study was to discover urinary exosomal miRNA biomarkers of DKD and to examine their associations with the degree of advanced pathologic injuries.

Methods: We collected and analyzed urinary samples obtained from 95 patients with biopsy-proven DKD and 32 healthy controls. The candidate microRNAs of DKD were selected based on the analysis of GEO dataset (GPL22895 and GPL24120) and public microRNA databases (miRBase, TargetScan, microRNA). Urinary exosomes were extracted by column-based isolation kit, and the levels of selected candidate microRNAs were measured by quantitative real-time polymerase chain reaction.

Results: Mean estimated glomerular filtration rate and urinary protein-to-creatinine ratio were not significantly different between patients with DKD compared to controls. Plasma creatinine (median 0.9 mg/dl, range 0.5-1.7 mg/dl) and 6.8 g/kg creatinine, respectively. Upon the analysis of public dataset, we identified 9 candidate microRNAs for DKD, whose expression in urinary exosomes were all significantly higher in patients with DKD compared to controls. In particular, urinary exosomal miR-30a-5p and miR-335-5p levels showed positive correlation with the degree of interstitial inflammation and arterial hyalization, respectively. There was no significant association between the remaining microRNAs and the degree of glomerular injury, tubulointerstitial fibrosis, or arteriosclerosis. Finally, we found significant correlation between urinary protein-to-creatinine ratio and the levels of urinary exosomal miR-98-5p.

Conclusions: Urinary exosomal microRNAs could reflect the degree of interrenal pathologic status in patients with diabetic kidney disease.

PO0913 Renoprotective Effect of a GLP-1 Receptor Agonist, Liraglutide, in an Early Phase of Diabetic Kidney Disease in Spontaneously Diabetic Tori Fatty Rats

Shohei Yamada,1 Jun Tanabe,1 Takeshi Sugaya,1 Daisuke Ichikawa,1 Kenjiro Kimura,2 Yugo Shibagaki,1 Atsuko Ikemori,3 Division of Nephrology and Hypertension, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan; 1JCHO Tokyo Takawana Hospital, Shintomicho, Japan; 3Department of Anatomy, St. Marianna University School of Medicine, Kawasaki, Japan.

Background: Early intervention is extremely needed for preventing the progression of diabetic kidney disease (DKD) to end-stage renal disease. The aim of this study is to investigate the renoprotective effect of GLP-1 receptor agonist, liraglutide, in early phase of DKD and to determine the mechanisms underlying its effects using an animal model of type 2 diabetes with various metabolic disorders.

Methods: Male spontaneously diabetic torii (SDT) fatty rats (n = 30) at 8 weeks of age were randomly assigned to three groups; the liraglutide group (n = 11) was subcutaneously injected liraglutide. Another treatment group (n = 6) was subcutaneously administered insulin against hyperglycemia and was given hydralazine against hypertension for 12 weeks. The control group (n = 13) was injected only a vehicle. Urinary tubular marker, L-type fatty acid-binding protein (L-FABP), was measured to evaluate the effect of liraglutide against tubulointerstitial damage.

Results: Control group of SDT fatty rats exhibited hyperglycemia, obesity, hypertension, glomerular sclerosis and tubulointerstitial injury with high levels of urinary albumin and L-FABP, whereas treatment with liraglutide reduced body weight, food intake, both blood glucose and blood pressure levels, as well as, amelioration of renal pathologic findings with lower levels of both urinary albumin and L-FABP. Liraglutide increased in expressions of both phosphorylated (p)-ENO1 and p-AMPK in glomeruli. It also down-regulated renal expression of p-ITOR, and up-regulated renal expressions of LC-3 II, suggesting activation of autophagy. However, these effects were not brought
by the treatments of both insulin and hyaluronic, despite comparable levels of both hypoglycemia and hypotension. These findings imply that the effects of insulin on the glomerular endothelial dysfunction and cellular loss differ from those of hyaluronic.

Conclusions: Lispro may exert a renoprotective effect via prevention of glomerular endothelial dysfunction and cellular loss in the early phase of DKD, independently of both blood glucose and blood pressure levels. Furthermore, urinary 1-FABP may be a useful marker reflecting the therapeutic efficacy of lispro.

PO0914
PLVAP as a Novel Marker for Endothelial Injury in Diabetic Nephropathy
Elena E. Wolf,1 Anne Steglich,1 Friederike Kessel,1 Florian Gembardt,1 Jan J. Wehrend,1 Simon Reicheck-Wurm,1 Kathrin Eidenschink,1 Miriam C. Banas,1 Christian Hugh1, Vladimir T. Todoro1,1 Division of Nephrology, Department of Internal Medicine III, University Hospital Carl Gustav Carus, TU Dresden, Dresden, Germany; 2Department of Nephrology, University Hospital Regensburg, Regensburg, Germany.

Background: Diabetic nephropathy (DN) is associated with endothelial cell dysfunction and progressive loss of kidney function. The plasma membrane vesicle associated protein (PLVAP) has been found to be necessary for the formation of endothelial diaphragms in fenestrates. Previous studies reported glomerular expression of PLVAP in transplant glomerulopathy, in mesangio proliferative glomerulonephritis model and in mice developing renal thrombocytopenia microangiopathy as a consequence of defective GpIa/AMP signaling in renal cells. Therefore, we investigated whether PLVAP expression in glomerular capillaries is induced in different models of DN.

Methods: To induce a model of type I diabetes, one dose of streptozotocin (STZ, 180 mg/kg) was administered by intraperitoneal injection in 6-8 weeks old mice. 16-week-old black and tan brachyuric (BTBR) ob/ob mice, with spontaneous mutation in the leptin gene were used as a model of type 2 diabetes. Immunohistochemical staining and analysis was performed to examine the expression of PLVAP. We co-stained the Intercellular Adhesion Molecule 2 (ICAM2) as a marker for endothelial cells.

Results: Glomerular hypertrophy was found in STZ mice and BTBR ob/ob mice, with spontaneous mutation in the leptin gene were used as a model of type 2 diabetes. Immunohistochemical staining and analysis was performed to examine the expression of PLVAP. We co-stained the Intercellular Adhesion Molecule 2 (ICAM2) as a marker for endothelial cells.

Conclusions: PLVAP expression in glomerular capillaries is induced in different models of DN.

MTORC1/STAT1 Signaling Stimulates CFB Expression and Alternative Complement Pathway Activation to Induce Podocyte Dysfunction and Diabetic Kidney Disease
Qingmiao Lu, Chunsunb Nanjing Medical University, Nanjing, China.

Background: Alternative complement pathway activation has been reported in diabetic kidney disease (DKD). However, the role and mechanisms for regulating alternative complement pathway activation in podocyte dysfunction and DKD are not understood.

Methods: STZ-induced DKD mice, db/db mice, Podocyte-specific TSC1 deletion mice were used.

Results: The analysis of GSE39528 data and the immunohistochemical staining results showed that mTORC1 signaling, STAT1, complement factor B (CFB) and complement alternative pathway were activated in podocytes from patients and animal models with DKD. Knocking down CFB remarkably alleviated podocyte loss, glomerular basement membrane thickening, mesangial expansion, and proteinuria in DKD mice. In addition, ablation of Tsc1 in podocytes led to mTORC1 and STAT1 signaling activation, CFB induction, and alternative complement pathway activation in the glomeruli. In cultured podocytes, high glucose culture could activate mTORC1 signaling, stimulate STAT1 phosphorylation and upregulate CFB expression. Blockade of mTORC1 or STAT1 signaling could significantly reduce proteinuria, thereby downregulated CFB expression in podocytes.

Conclusions: This study uncovers that mTORC1/STAT1 activation in podocytes may promote DKD progression through activating complement alternative pathway.

PO0916
Loss of Nr2 Exacerbates Diabetic Kidney Disease in Akita Mice
Yexin Liu,1 Akira Urano,1,3 Masayuki Yamamoto,1,3 1Department of Medical Biochemistry, Tohoku University Graduate School of Medicine, Sendai, Japan; 2Department of Nephrology, The Second Xiangya Hospital, Central South University, Changsha, China; 3Department of Integrative Genomics, Tohoku Medical Megabank Organization, Tohoku University, Sendai, Japan.

Background: Diabetic kidney disease (DKD) is a devastating microvascular complication with considerable mortality in patients with diabetes mellitus. Excessive reactive oxygen species and inflammation have been identified as major components in the progression of this microvascular complication. Transcription factor Nr2 (NF-E2-related factor) plays essential role in protection against oxidative/taxotoxic stresses, is known to alleviate inflammation and oxidative tissue damage. We hypothesized that keeping Nr2 activated is beneficial for the treatment of DKD.

Methods: To clarify roles Nr2 plays in the pathogenesis of DKD, we generated Nr2 knockout mice and Akita mice (Nr2f2) by crossing Tspo2/2 (Akita) mice (C57BL/6J) with Nr2f2 knockout (Nr2f2/2) mice (C57BL/6J). Phenotypic parameters of male mice were measured, and samples were harvested from the mice at 4 months.

Results: We found that Akita:Nr2f2 mice displayed more pronounced hyperglycemia and hyperlipidemia than Akita mice did. While expression of Nr2-targeted genes Nqo1 and Hmox1 was induced in Akita mouse kidneys; the expression was significantly reduced in kidneys of Akita:Nr2f2 mice. Histologically, Akita mice showed modest mesangial expansion, but Akita:Nr2f2 mouse glomeruli showed marked distended glomerular basement membranes, with significant expansion of the mesangial matrix. ICAM2 was significantly decreased compared to control mice (p<0.05). Expression of CFB and IL-17 and claudin-1, which are targets of TTP and HuR, as evidenced by RNA

Conclusions: These results demonstrate that Nr2 deficiency exacerbated inflammatory response, oxidative stress and interstitial fibrosis in the Akita mouse kidneys, indicating that Nr2 plays important roles in the protection of DKD kidneys.

The Novel Soluble Guanylyl Cyclase (sGC) Activator Runcaciguat Improves Cardiorenal Morbidity in a Diabetic Rat Model of CKD
Antoine Derkinderen,1 John D. Mathar,1,3 Ilka Eidenschink,2 Thomas Todorov,1 Anne Hahn,1 Peter Sandner,1 Bayer AG, Leverkusen, Germany.

Background: Patients with chronic kidney disease (CKD) and Type-2 Diabetes (T2D) have a high risk of kidney failure and cardiovascular events. CKD and T2D are associated with oxidative stress impairing NO/sGC signaling thus driving CKD progression. Runcaciguat is a novel potent and selective, sGC activator able to restore sGC signaling by activating the oxidized and heme-free sGC. Here we investigated the therapeutic potential of Runcaciguat in a rat model of T2D associated CKD.

Methods: Cardiorenal morbidity was studied in diabetic and proteinuric rats. Rats (ZDF/Chr-Lebr-fa/af, 22 weeks old male, n=20 group) were treated orally for up to 42 weeks with Runcaciguat (3 mg/kg) or placebo. Key outcome parameters included mortality, blood pressure, proteinuria, kidney histology, biomarkers of kidney and heart damages, and gene expression.

Results: Proteinuria steadily increased over time in the placebo arm (μgCR/g (mmol) 0.9±0.1 @ baseline, 1.8±0.1 @12 wk, 5.9±0.7 @42 wk) and was significantly reduced in the Runcaciguat arm (0.8±0.1 @ 12 wk, 3.0±0.5 @ 42 wk). Improved proteinuria was paralleled by significantly improved glomerular filtration rates @ 42 wk (55±5 μl/min vs. 36±9 in the placebo arm). Histological examination of kidney revealed that Runcaciguat significantly reduced tubular dilatation, glomerulopathy and accumulation of protein cylinders. Runcaciguat significantly improved left ventricular heart weight as well as several kidney and heart injury markers in urine and in plasma.

Conclusions: The novel sGC activator Runcaciguat improved kidney and heart function in diabetic and diabetic and hypertensive rat model and may become an effective treatment option for diabetic and chronic kidney disease patients.

RNA-Binding Proteins Tristetraprolin and Human Antigen R Are Novel Modulators of Podocyte Injury in Diabetic Kidney Disease
Jia Guo,1 Rujian Gong,2 Zhangsuo Liu,1 Zhengzhou University First Affiliated Hospital, Zhengzhou, China; 2The University of Toledo, Toledo, OH, USA.

Background: Diabetic kidney disease (DKD) is one of the most common complications of diabetes and the most common cause of end-stage renal disease, with no definitive therapy yet available to halt its progression. As key RNA-binding proteins (RBPs) that play pivotal roles in the diabetic and hypertensive rat model and may become an effective treatment option for diabetic and chronic kidney disease patients.

immunoprecipitation. In cultured podocytes, exposure to high ambient glucose amplified HIF-1α expression. Increased HIF-1α expression was associated with diabetic microvascular complications. Other probes expressed gene upregulated IL-17 and class 1-m, and promoted podocyte injury. Thus, TTP hypoxic- and HIF hyperactivity is sufficient and essential to diabetic podopathy. Moreover, in silico analysis revealed that several kinases govern phosphorylation and activation of TTP and HIF, and glycogen synthase kinase (GSK)-3β activated both TTP and HIF, which harbor putative GSK-3β consensus phosphorylation motifs.

**Conclusions:** TTP and HIF are dysregulated in DKD via a GSK3β-mediated mechanism and play crucial roles in podocyte injury via posttranscriptional regulation of diverse molecules implicated in inflammation and podopathy. Our findings provide novel insights into the mechanism of and identify therapeutic targets for diabetic kidney disease.

**Nogo-B and Soluble Nogo-B Modulate VEGFA/VEGFR2 Signalling in Glomerular Endothelial Cells**

Carlo Alberto Ricciardi,1 Ivan Hernandez,2 David A. Long,2 Luigi Grundi,3
1King’s College London Faculty of Life Sciences and Medicine, London, United Kingdom; 2University College London, London, United Kingdom.

**Background:** Nogo-B is an endoplasmic reticulum protein present either as a full-length or circulating soluble isoform (sNogo-B) corresponding to the first ~200aa of the N-terminus. Nogo-B is expressed in the vascular and in glomerular endothelial cells (GECs) and downregulated in diabetic glomeruli. Overexpression of Nogo-B ameliorates diabetic glomerulosclerosis, but the biological mechanisms are unknown. We hypothesise that, in GECs, Nogo-B and/or sNogo-B modulate VEGFA/VEGFR2 signalling and vascular remodelling.

**Methods:** Nogo-B deficient human GECs were generated with CRISPR/CAS9 technology. VEGFA signalling was studied in differentiated, serum starved (5 h, FBS 2%) GECs exposed to VEGFA (50 ng/ml) for 5, 10 and 15 min. VEGFR2 phosphorylation (Tyrosine 1175) was assessed in western immunoblots. Proliferation experiments were conducted in GECs transfected with adenoviral vector expressing sNogo-B or control vector. To investigate the role of Nogo-B on GEC survival, Caspase-3/7 activity was utilised as marker of apoptosis in WT and Nogo-B deficient GECs after 5 h incubation in 2% FBS. In vivo Matrigel-angiogenesis assay in wild-type (WT) and Nogo-B/A deficient mice were conducted in parallel.

**Results:** When compared to WT GECs, Nogo-B deficient cells appeared more elongated with a peripheral distribution of F-actin but maintained expression of endothelial markers (E-selectin, CD31). Phosphorylated VEGFR2 total VEGF:ratio was similar in baseline condition in WT and Nogo-B deficient GECs. VEGFA-mediated VEGFR2 phosphorylation (15 min) was observed in WT GECs but not in Nogo-B deficient GECs (p<0.01). In the presence of sNogo-B, there was significant reduction in VEGFA-mediated VEGFR2 phosphorylation in WT GECs (p<0.05). There was no significant effect of sNogo-B on VEGFR2 phosphorylation in Nogo-B deficient GECs. Apoptosis was higher in Nogo-B deficient GECs when compared to WT ones (p=0.04). Preliminary work in in vivo Matrigel angiogenesis showed that Nogo-B deficient ECs were unable to form vascular structure when compared to wild-type cells (p<0.05). Presence of sNogo-B blunted the angiogenesis in WT mice.

**Conclusions:** Nogo-B is required for VEGFA-mediated VEGFR2 phosphorylation and for vascular remodelling (angiogenesis). Overexpression of Nogo-B blunts VEGFA-mediated VEGFR2 phosphorylation. sNogo-B could represent a tool to modulate VEGFA signalling in diseases.

**Cytosine Methylation Changes in Early Diabetic Kidney Disease (DKD) in a Pima Indian Cohort**

Katie Sullivan,1 Chengxiang Qiu,2 Hongbo Liu,1 Robert G. Nelson,1 Robert L. Hanson,1 Katalin Susztak,1 1University of Pennsylvania, Philadelphia, PA; 2University of Washington, Seattle, WA; 3National Institutes of Health, Bethesda, MD.

**Background:** Pima Indians of Arizona have an extremely high prevalence of type 2 diabetes and DKD. Genetically related Pima Indians living in Mexico, whose lifestyle remains traditional, have a much lower prevalence of these morbidities. In Pima Indians, the role of environmental factors play an important role in disease origins and suggest involvement of epigenetic programming. We analysed cytosine methylation (5mC) changes in Pima Indians from Arizona.

**Methods:** 327 Pima Indians (205 women, 122 men) were selected from a longitudinal cohort, all had an eGFR greater than 60ml/min and ACR <3000mg/g at baseline. DNA methylation from peripheral blood leukocytes was analyzed on an Illumina Infinium HumanMethylation 450 Beadchip. Preprocessing and Quality Control were performed using Minfi Package, normalization was performed using BMIQ. Methylation changes were assessed in biological replicates (N=4), in case of age, sex, duration of diabetes, mean blood pressure, HA1c, genotype, batch, cell count and correction efficiency. P-values were corrected for multiple comparisons.

**Results:** Mean age was 42.4±11.9 years, diabetes duration 7.8±7.5 years, HA1c 8.8±2.4%, GFR 107±16 ml/min and median albuminuria was 20.2±48.2mg/g. Subjects were followed for a median of 10 years (range 3-17 years) and had a mean GFR decline of 2.0±2.8 ml/min/year. Ranked regression, adjusted for key variables, identified 20 probes that passed the corrected significance threshold for kidney function decline. Most significantly enriched on genomic regions associated with metabolism and enhancers. The top identified probe was cg05171186 around the Maternally expressed gene 3 (MEG3)on chromosome 14, (p=2.66E-10). MEG3 is a non-coding gene that is specifically deleted in Wilms tumor and linked to susceptibility to sporadic renal cell cancer. Another probe identified was cg13366628 (p=1.02E-5) in Platelet Derived Growth Factor Alpha (PDGFA) on chromosome 7, a known type 2 diabetes risk gene, as well as cg06392169 (p=3.1E-5) in Interferon Related Factor 4 (IRF4) on chromosome 6 and cg12577105 (p=4.1E-5) in Craniofacial Releasing Hormone Receptor 1 (CRHR1) on chromosome 17 involved in the HPA axis.

**Conclusions:** We identified cytosine methylation changes that correlated with early kidney function decline in Pima Indians with type 2 diabetes.
TSPAN-9 correlated with extent of interstitial fibrosis, proteinuria and serum creatinine. It was significantly upregulated by mannitol and high glucose in vitro, TSPAN9 in HMC. This study aimed to identify compounds that reduce LD accumulation and mitochondrial function by regulating mitochondrial dynamics by targeting OPA1. Overexpression of Loxl4 prevents high glucose-induced decrease of oxygen consumption rate.

Results: Using high-resolution mass spectrometry, we identified 152 hyperacetylated and 19 hypoacetylated proteins in the mitochondria from kidney tubule of diabetic mice compared with control mice. OPA1, a mitochondrial fusion protein was hyperacetylated at lysine 792 and 847 residues under high glucose-induced pathological stress and this posttranslational modification increased mitochondrial fragmentation. Overexpression of a deacetylation-mimetic version of OPA1 recovered the mitochondrial functions of OPA1-null cells, thus demonstrating the functional significance of K228/792/847 acetylation in regulating OPA1 activity. The newly discovered deacetylation hystox oxidase like 4 (Loxl4) interacts with OPA1 in mitochondria. Overexpression of Loxl4 prevents high glucose-induced acetylation, preserved mitochondrial network and protected the high glucose-induced decrease of oxygen consumption rate.

Conclusions: In summary, these data indicated that hyperacetylation of OPA1 regulates mitochondrial fusion and fission under diabetes conditions. Loxl4 promotes mitochondrial function by regulating mitochondrial dynamics by targeting OPA1.

Discovery of a Small-Molecule Drug for Treating Diabetic Kidney Disease
Hassan Al-Ali, Javier T. Varona Santos, Alexis J. Sloan, Sandra M. Merscher, Alessia Fornoni. University of Miami School of Medicine, Miami, FL.

Background: Diabetic kidney disease (DKD) is the leading cause of chronic kidney disease and one of the fastest growing epidemics worldwide. Podocyte injury is a hallmark of DKD. As such, preventing podocyte injury is necessary for effectively treating DKD. Our prior studies demonstrated that the accumulation of lipid droplets (LDs) in podocytes is associated with increased susceptibility to apoptosis in the context of DKD. Conversely, reducing LD accumulation in podocytes prevented renal disease in a mouse model of DKD (BTBR db/db). Thus, compounds that reduce LD accumulation may protect podocytes from injury and prevent the progression of DKD. The goal of this study is to identify compounds that reduce LD accumulation in vivo and lead to the identification of therapeutic candidates for DKD.

Methods: Advances in high throughput synthetic chemistry have enabled the design of combinatorial libraries for efficient screening and identification of novel bioactive compounds. The approach is particularly powerful when combined with a phenotypic screening assay that recapitulates disease biology. We have developed a high content screening assay to quantify LD accumulation in human podocytes in response to stress stimuli. The assay is highly suitable for screening with a Z factor consistently > 0.5.

Results: We performed a pilot screen using 100 compound mixtures, each containing thousands of compounds, obtained from the Torrey Pines Institute for Molecular Studies (TPIMS). We identified one compound mixture (2275) that consistently reduces LD accumulation in a dose-dependent manner. 2275 significantly reduces LD accumulation induced by TNF, a pro-inflammatory cytokine associated with DKD, and induced by sera from patients with DKD. The TPIMS hit deconvolution method will be used to identify the active compound(s) within the 2275 mixture.

Conclusions: We identified compounds that significantly reduce LD accumulation in cultured human podocytes in response to stress stimuli, including sera from DKD patients. Further studies to deconvolve and validate those compounds, and test them in an animal model of DKD, are underway.

safety and efficacy of the ASK1 inhibitor Selonsertib (SEL), higher serum sTNFR1 levels associated with progression to End Stage Renal Disease (ESRD). In vitro, mono-culture studies have demonstrated that ASK1 signaling is required for TNFα induced apoptosis in kidney and other organ systems. Current studies with a microfluidic organ-on-a-chip system to investigate the effects of TNFα in a kidney co-culture system and determine effects of SEL on kidney proximal tubular injury.

**Methods:** After populating cells in a co-culture, microfluidic device (Emulate Bio) containing either Lonza RPTEC (top channel) or kidney microvascular endothelial cells (bottom channel), TNFα (2ng/ml) was added at Day 0 along with SEL (10μM) to allow flow of each channel. After 7 days, RNA was isolated from each channel and gene expression analyzed by qPCR. Outlet supernatant from each channel was analyzed for kidney injury and inflammation markers on Mesoscope Discovery device (MSDA). Data shown as fold-of-change or mean ± standard error of the mean (s.e.m.)

**Results:** TNFα significantly increased expression of both TNFRSF1A and1B in the RPTEC channel (1.4 and 2.6-fold, respectively vs. control), and SEL decreased TNFRSF1A expression by 108% (p=0.0058) and lowered TNFRSF1B expression by 64% (p=0.1549). SEL decreased TNFα-induced expression of IP-10 (6.4 vs. 37.3-fold, p=0.0083) and IL-18 expression (0.67-fold vs 1.6-fold, p<0.0001) in proximal tubules. Osteoactivin and Clusterin, biomarkers used to assess proximal tubule injury were significantly increased in RPTEC supernatant following TNFα stimulation treatment (2.1 and 3.7-fold, respectively, p<0.0001 for each). SEL significantly reduced levels of osteoactivin by 33.7 and 33.7% ± 7.82 ± 0.44 pg/ml (p<0.0001) and clusterin (28.9 ± 44.24 pg/ml, p<0.0001) but downregulated by Empa (0.3-fold and 0.2-fold, p<0.0001 each) as early as 1h and at least for 24h after ligand stimulation in HK-2 and RPTEC cells, respectively. Coadministration of Empa and SEL significantly reduced TNFRSF1A mRNA expression by 1.7-fold (p<0.001) and sTNFR1 protein expression.

**Conclusions:** By demonstrating an inhibitory effect of Empa on basal and IL-1β-mediated CCL2 and endothelin1 expression in two independent HPTCs, we present novel evidence for early non-hemodynamic, nephrro-protective effects of SGLT2.

**Comparison of the Effect of Calorie-Matched High Saturated Fat and High Unsaturated Fat Diets on Lysosomal Renal Injury in Non-Obese, Strepト佐チン-Injected CD-1 Mice**

Tamio Yamaguchi,1 Ayah Yoshimura,2 Masanori Kugita,3 Kanako Kumamoto,4 Kazuya Shigoma,5 Kyongtae T. Bae,6 Shizuko Nagao.2 Department of Clinical Nutrition, Faculty of Health and Medical Science, Chiba University, Chiba, Japan; 3Division of Nutritional Science, Toohoku University, Sendai, Japan; 4Division of Medical Genetics, National Cardiovascular Center Research Institute, Suita, Japan; 5Division of Pharmacology and Cell Function, Faculty of Medical Technology, Tottori University, Tottori, Japan; 6Division of Morphology and Cell Function, Faculty of Medical Technology, Fujita Health University, Toyoake, Japan; 7Department of Radiology, University of Pittsburgh, Pittsburgh, Pittsburgh, PA.

**Background:** Type 2 diabetes mellitus often causes renal injury characterized by autophagic vacuoles. Although many studies with comparisons of high fat versus a normal balanced diet have been reported in diabetic models, there are few studies that equalized calorie intake and body weight. We reported that a high-fat diet induced renal injury with impaired lysosome-mediated autophagic degradation in streptozotocin (STZ) injected mice (AS Nen Kidney Week 2019). However, the effect of fat type, saturated- or unsaturated-fat, was not determined. In the current study, an AIN93DM diet (CONT group) was compared to energy-matched lard derived high saturated fat (LARD group) and soybean oil derived high unsaturated fat (Soy OIL group) diets to compare their effects on biochemical markers and renal morphology with lysosome-associated membrane protein 1 (LAMP1) expression.

**Methods:** Male C57Bl/6J mice were randomly divided into three pair-fed groups with 380 kilocalorie/100g energy from 7 to 20 weeks of age. CONT group: AIN93DM diet with 62% (w/w) cornstarch, 10% sucrose, 4% soybean oil and 5% cellulose; LARD group: Diet with 31% cornstarch, no sucrose, 22% lard oil and 28% cellulose; SOY OIL group: Diet identical to the LARD diet except that soybean oil replaced lard oil. At 17 and 18 weeks of age, STZ (100mg/kg body wt) was injected. At 20 weeks of age, blood was taken for measurements of insulin, triglyceride, total cholesterol, ALT, AST, creatinine and SUN. Kidneys were prepared for H&E staining and immunohistochemical staining to detect LAMP1.

**Results:** Final body weight, total intake of water, food and energy were not different between all groups. No statistical differences in all blood biochemical markers were detected as well. In kidneys, the number of LAMP1-positive renal tubular lipid vacuoles was higher in LARD compared with SOY OIL and CONT groups, whereas no difference was shown between SOY OIL and CONT groups.

**Conclusions:** The results suggest that high intake of saturated-fat may aggravate lysosomal renal injury in a non-obese, streptozotocin-induced diabetes mellitus model.

**Funding:** Government Support - Non-U.S.

**Overexpression of ACE in Macrophages Accelerates Diabetic Kidney Disease**

Keijo Tomita1, Masahito Eriuchi,2 Kumiko Torii,3 Jorge F. Gianì,4 Katsuhiko Kato,2 Kentaro Kato,2 Noritoshi Kato,2 Toshiki Imai,1 Yukiko Kishimoto,2 Tomohito Doke,3 Noritoshi Kato,1 Yukiko Kishimoto,2 Hiroyuki Asanuma,1 Shiochi Maruyama.2 Nagoya University Graduate School of Medicine, Faculty of Medicine, Nagoya, Japan; 2Nagoya Daigaku, Nagoya, Japan; 3University of Pennsylvania Department of Medicine, Philadelphia, PA.

**Background:** SGLT2 inhibitors (SGLT2i) slow the progression of type II diabetic kidney disease (DKD). Although ACE in macrophages has been shown to be important in controlling inflammation, the expression and function of ACE in macrophages in DKD are still unknown.

**Methods:** Diabetes was induced by five consecutive daily intraperitoneal injections of streptozotocin (55 mg/kg) using C57Bl/6J male mice. Primary peritoneal macrophages

**Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only**
were harvested after intraperitoneal injection with 2 mL of 4% thio-glucose solution into mice. Mouse ACE overexpressing plasmid was electroporated into Raw 264.7 to evaluate cytokine release and migration ability. ACE 10/10 mice was deficient of ACE in the whole body but overexpressed only in monocytes/macrophages. We induced diabetes in ACE 10/10 and wild-type mice and analyzed albuminuria or pathological changes of kidney after six months of diabetes.

**Results:** ACE mRNA was increased in peripheral blood monocytes and peritoneal macrophages from diabetic mice. LPS-induced release of IL-6 and nitric oxide was increased in macrophages overexpressing ACE. The migration ability of macrophages overexpressing ACE was higher than that of control vector-expressing cells. In diabetic ACE 10/10 mice, glomerular hyperglycemia and glomerular hyperfiltration were not evident as in diabetic wild-type mice. Although ACE 10/10 mice lacks ACE in vascular endothelial cells and tubular cells, mesangial expansion and interstitial fibrosis in the kidney, and albuminuria from diabetic ACE 10/10 mice were similar to those from diabetic wild-type mice.

**Conclusions:** In diabetes, the expression of ACE in macrophage is enhanced. As a result, dysregulation of macrophage function occurred, and it may be involved in the development of diabetic kidney disease.

**PO0932**

**Transgenic Mechano-Growth Factor Overexpression in Mice Induces Glomerular PKCα and Type I Collagen with Glomerulosclerosis**

Yongxin Gao,1 Fritza Hasan,1 Zaitaya A. Rivera,1 Hongwei Li,2 Charles W. Heilig,1 University of Florida College of Medicine - Jacksonville, Jacksonville, FL; Southern Medical University, Guangzhou, China.

**Background:** Mechano-Growth Factor (MGF), a normally expressed component of several positive feedback loops in the renal glomerular mesangial cells (MC), was implicated by us in the control of glomerulosclerosis. Transgenic mice overexpressing MGF (LK4400-mMGF) were produced to determine the role of MGF in glomerulosclerosis (GS).

**Methods:** Our previous studies demonstrated that MGF was induced in the glomeruli of diabetic mice with subsequent induction of several factors responsible for diabetic GS. In the current study, immunohistochemistry using specific antibodies was performed to compare the expression of glomerular proteins involved in GS, in MGF-overexpressing transgenic mice (MGF Tg) vs. non-transgenic control mice (NT). DAB staining with 0.4° scoring in glomeruli was performed, and p < 0.05 between groups was considered significant. PAS staining was performed to assess development of overall GS. The effects of transgenic MGF overexpression on mouse body weights and kidney weights was also assessed.

**Results:** A 2.5-fold higher expression of MGF was found in glomeruli of MGF Tg as compared to NT mice. This result was in 2.1-fold increased expression of active PKCα, a potential mediator of the 2.2-fold increased GLUT1 expression observed. These changes appeared to drive the 2.2-fold increased Collagen Type 1 (Col-I) in glomeruli. All these prosclerotic factors likely contributed to the resultant GS, evidenced by 2.2-fold increased PAS positive material in MGF Tg glomeruli. All the above results were found to be significant with a P value <0.0001. Adult body weight in MGF Tg tended to be 8% higher in both males and females (NS). Mean kidney weights were 14% larger in MGF Tg vs same gender NT mice (NS).

**Conclusions:** MGF Tg displayed increased glomerular PKCα activation, Col-I protein, and PAS-positive extracellular matrix similar to diabetic GS with increased MGF. Further studies of glomerular MGF inhibition in diabetic mice may help define the potential value of this maneuver in blocking GS.

**Funding:** Private Foundation Support

**PO0933**

**Severe Diabetic Glomerulosclerosis as Chronic Hypoxic Housing of db/db Mice: The Role of Mesangiolysis and Podocyte Injury**

Naoki Takahashi,¹ Haruyoshi Yoshida,² Hideki Kimura,¹ Kazuko Kamiyama,¹ Seiji Yokoi,¹ Kenji Kasuno,¹ Hiroyuki Kurosawa,¹ Yoshiaki Hirayama,¹ Masanori Hara,¹ Masayuki Iwano,² Fuku Daigaku Igarakubo, Shizuoka, Japan; ¹Sugita Genpaku Kinen Koritsu Ohama Byoin, Ohama, Japan; Denka Sekken Kabushiki Kaisha Niigata Kyo, Gosen, Japan; Iwamura Health Promotion Center, Niigata, Japan.

**Background:** Chronic hypoxia may play a pivotal role in the development of diabetic nephropathy (DN). However, the precise mechanisms underlying progressive hypoxia-induced glomerular injury remain unclear.

**Methods:** We housed db/db mice in a hypoxia chamber (12% O2) for up to 16 weeks beginning at 8 weeks of age. Various urine, serum and kidney abnormalities and glomerular mRNA expression were compared with those in age-matched db/db mice housed under normoxia.

**Results:** Levels of urinary albumin and podocalyxin (PCX) were significantly higher in hypoxic mice early during hypoxia. Ultra centrifugation of urine samples revealed that podocytes in the hypoxic mice shed PCX-positive microparticles into the urine. After 16 weeks of hypoxia, the mice also had higher hematuria with lower serum glucose and various degrees of mesangioytic glomerulosclerosis with microaneurysms and the infrequent occurrence of nodular lesions. Immunohistologically, hypoxic mice showed significantly decreased podocyte densities early during hypoxia and decreased podocyte densities later. In both hypoxic and normoxic mice, glomerular macrophage and transforming growth factor-β1 (TGF-β1) staining significantly increased with aging, without changes in vascular endothelial growth factor or endothelial nitric oxide synthase (eNOS). Glomerular mRNA expression of monocyte chemottractant protein-1, eNOS, and TGF-β1 was significantly enhanced in the hypoxic mice.

**Conclusions:** These results indicate that chronic hypoxia induces advanced glomerulosclerosis with accelerated albuminuria triggered by mesangiolysis and podocyte injury in a murine model of DN.

**Funding:** Commercial Support - Daiwa Securities Health Foundation, Government Support - Non-U.S.

Summary of the glomerular changes in db/db mice exposed to chronic hypoxia.

**PO0934**

**Overexpression of Nrf2 Increases Sglt2 Gene Expression and Exacerbates Dysglycemia and Nephropathy Progression in Diabetic Transgenic Mice**

Shuling Zhao,¹ Kana N. Miyata,¹ Chao-Sheng Lo,¹ Anindya Ghosh,¹ Isabelle Chenuer,¹ Janos G. Filep,² Julie R. Ingelfinger,¹ Shao-Ling Zhang,¹ John S. Chan,¹ 1Centre Hospitalier de l’Université de Montreal Centre de Recherche, Montreal, QC, Canada; 2Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; 3Massachusetts General Hospital, Boston, MA.

**Background:** Nuclear factor erythroid-2 related factor 2 (Nrf2), a transcription factor abundantly expressed in renal proximal tubule cells (RPTCs), possesses cytoprotective effects. However, clinical trial with Nrf2 activator (bardoxolone methyl) in T2D patients increased mortality, heart failure rates, heightened hypertension and albuminuria without favorable effect on end-stage kidney disease (ESKD), though the underlying mechanisms remain unknown. We reported previously that Nrf2 deficiency ameliorates hyperglycemia and kidney injury in diabetic Akita (T1D) mice, and we identified putative Nrf2-binding sites in the promoter of SGLT2. We here hypothesized that overexpression of Nrf2 may upregulate Sglt2 expression and contribute to nephropathy progression in diabetes.

**Methods:** We generated Akita Nrf2+/−/Nrf2290°C-Tg mice by cross-breeding Akita Nrf2 knockout mice (Akita Nrf2−/−) with Nrf2 transgenic mice (Nrf2290°C-Tg) overexpressing Nrf2 in RPTCs, studying them until age 20 weeks. Immortalized human RPTC (H2K) stably transfected with plasmid containing SGLT2 gene promoter were also used.

**Results:** Akita Nrf2+/−/Nrf2290°C-Tg mice had increased blood glucose, glomerular filtration rate, urinary albumin-to-creatinine ratio, tubulointerstitial fibrosis and Sglt2 expression as compared to their Akita Nrf2−/− littermates. In vitro, addition of oligotraz (a Nrf2 activator) or transfection of Nrf2 cDNA increased SGLT2 mRNA expression and promoter activity in H2K. These effects were blocked by small interference (si) RNA of NFR2. Deletion of NFR2-responsive elements (NFR2-REs) in the SGLT2 promoter abolished the stimulatory effect of oligotraz on SGLT2 promoter activity. NFR2 bound to NFR2-REs of SGLT2 promoter was seen on gel mobility shift and chromatin immunoprecipitation assays.

**Conclusions:** Our results identify a novel mechanism by which NFR2 mediates hyperglycemia (oxidative stress)-stimulation of SGLT2 expression and exacerbates dysglycemia and kidney injury in diabetes.

Durable Euglycemia by Intraperitoneal Administration of Allogeneic Neo-Istots, 3D Organoids of Pancreatic Islet and Mesenchymal Stem Cells, Effectively Reduces Diabetic Nephropathy in Immune-Component Non-Obese Diabetic Mice

Chi Hong, Korea

Background: We demonstrated that the i.p. administration of allogeneic “Neo-Istots” (NIs), 3D organoids of culture expanded Pancreatic Islet (PI) and Mesenchymal Stem Cells (MSC), induces permanent euglycemia without the need for anti-rejection drugs in NOD mice with auto-immune Type I Diabetes mellitus (T1DM). The NIs engraft in the omentum and physiologically deliver insulin and other islet hormones into the hepatic portal system, while providing auto- and allo-immune isolation, up regulate Th5, stimulate angiogenesis, prevent apoptosis and inflammation. As a significant percentage of patients with T1DM develop diabetic nephropathy (DNP) and other end organ damage, we tested whether the induction of stable euglycemia in NOD mice would prevent or ameliorate DNP.

Methods: Three Groups of adult mice (n=7 each; ~25 g b.wt.; age 12 weeks) were examined: (1) Non-diabetic, age and sex matched C57BL6 mice; (2) Vehicle treated NOD mice with fully developed auto-immune T1DM; (3) NI treated NOD mice with normal blood glucose levels. Animals were followed for 21 weeks post treatment (blood glucose levels, body weights, blood pressures, proteinuria, renal function).

Results: At the termination of the study, kidneys from all groups were examined for glomerulosclerosis and interstitial fibrosis (Tirchome staining). The vehicle treated NOD mice (Group 2) had higher levels of proteinuria, albuminuria and creatinine, lost weight, had systolic hypertension and showed extensive interstitial fibrosis, glomerulosclerosis, proteinuria, hypertension and elevated SCr and BUN levels, while NI treated, euglycemic NOD mice (Group 3) showed significantly lower degrees of glomerulosclerosis, interstitial fibrosis, proteinuria, hypertension and better preserved renal function. All tested variables remained normal in non-diabetic Group 1 control mice.

Conclusions: The presented data demonstrate that NI therapy-induced normalization of glycemia significantly improves the manifestations of DNP without fully correcting them when compared to non-diabetic controls. Modifications in NI treatment protocols are expected to further improve the development of DNP, which, if successful, would further strengthen the translational relevance of this novel therapy. IL-17A Deficiency Attenuates Autophagosome Formation in Streptozoto- cin-Induced Rat Diabetic Nephropathy
Geum-Lan Hong, Kyung-hyun Kim, Ja young Jung, Department of Veterinary Medicine & Institute of Veterinary Science, Chungnam National University, Daejeon, Republic of Korea.

Background: Diabetic nephropathy (DN) is one of the most important medical complications in diabetes mellitus. Autophagy is an important mediator of pathological responses and plays critical roles in inflammation during the progression of diabetic nephropathy. The Th-17 effector cytokine interleukin (IL)-17A can favorably modulate inflammatory responses during DN. In this study, we examined whether IL-17A deficiency affects the autophagy process in streptozotocin (STZ)-induced DN in kidney.

Methods: The autophagic response for IL-17A in the nephrotoxicity of STZ administration induced phenotypes of hyperglycemia and diabetic renal fibrosis. Futhermore, NQO1 deficiency reduced the autophagy down-regulating hVps34 and ATG4L of PI3-complex and increased pro-fibrotic genes including TGF-β1, Snail3, and MMP9, in vitro and in vivo. The fluorescence intensity of both hVps34 and ATG4L was reduced in NQO1 KO mice. However, NQO1 deficiency aggravated the expression of hVps34 and ATG4L but, reduced the expression of TGF-β1, Snail3, and MMP9.

Conclusions: NQO1 deficiency aggravated renal fibrosis mediating autophagy induction and phagophore formation. This results suggested that NQO1 may have a potential role for DN amelioration.

Cell Sex and Sex Hormones Modulate Glucose and Glutamine Kidney Metabolism: Implication for Diabetic Kidney Disease
Sergi Cloet Freixas,1 Julie Anh Dung Van,1,2 Caitriona M. McEvoy,3 Sofia Farkona,4 Aman Mehrotra,5 Adam J. Gehring,6 Minna Woo,6 Ana Konvalinka,1,3 Institute of Medical Science, University of Toronto, Toronto, ON, Canada; 1Department of Immunology, University of Toronto, Toronto, ON, Canada; 2Department of Medicine, Division of Nephrology, University Health Network, Toronto, ON, Canada; 3Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada.

Background: Male sex predisposes to diabetic kidney disease (DKD). We uncovered androgen-induced perturbations in kidney metabolic proteins that may drive faster DKD progression in men. Our goal is to characterize cell sex- and hormone-specific alterations in the kidney cell metabolism.

Methods: Human primary proximal tubule epithelial cells (PTEC) from 3 male and 3 female donors were stimulated with control, dihydrotestosterone (DHT), or estradiol (EST). We assessed glycolysis (extracellular acidification rate, ECAR) and oxygen consumption rate (OCR) in a Seahorse analyzer. We also studied sex differences in 16-week-old diabetic Akita mice.

Results: Male PTEC showed significantly higher ECAR, OCR, oxygen levels, and urinary output was monitored over the course of treatment.

Conclusions: Male PTEC showed significantly higher ECAR, OCR, oxygen levels, and urinary output was monitored over the course of treatment.

Effects of Dagadiluzin-Induced Glucosuria on Urinary Tract Infection Susceptibility
Kristin Bender, Laura Schwartz, John D. Spencer. Nationwide Children's Hospital, Columbus, OH.

Background: Individuals with diabetes mellitus (DM) have a higher risk for urinary tract infection (UTI). The infection is more likely to cause acute kidney injury leading to an increased risk for chronic and end stage kidney disease. Dagadiluzin is one of the proposed mechanisms by which people with DM have increased UTI risk, but this association is understudied and uncertain. In order to study the relationship between glucosuria and UTI susceptibility in vivo, mice were treated with an SGLT-2 inhibitor Dagadiluzin (Dapa) and subjected to experimental UTI.

Methods: Non-diabetic C57BL6/6 female mice were treated via oral gavage with vehicle or Dapa at 0.1, 1, or 10 mg/kg/dose. One group received a 2-dose regimen: 6 hours before and 3 hours post infection. Another group was treated daily for 7 days. Mice were challenged with Escherichia coli (E.coli) UTI 24 hours post infection (hpi). Bacterial burden was enumerated in the urine and bladder. Serum glucose, urine glucose, and urinary output was monitored over the course of treatment.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

323
Results: Compared to controls, Dopa-treated mice developed glucosuria while maintaining normoglycemia and comparable weights. After UTI with the 2-dose regimen, control and Dopa-treated mice had comparable bladder and urine UPEC titers. Mice treated over a longer time course had no significant differences in CFUs in the bladder and urine at 24 hpi – suggesting that glucosuria may not be a primary UTI risk factor. Urea nitrogen was increased in mice treated with Dopa which could impact infection susceptibility.

Conclusions: These data suggest that there is no direct relationship between glucosuria, SGLT2 inhibitors, and UTI susceptibility. Also, glucosuria alone doesn’t explain the increase in ICU-associated UTI risk. More studies are needed to understand the mechanisms that increase UTI susceptibility in individuals with DM.

Systemic Therapies Targeted to Ischemia in a Model of Diabetic AKI

Jeffrey Cleland,1 Rishi Sharma,1 Santiago Appiani La Rosa,1 Jinglei Zhang,2 Audrey Q. Chang,2 Sujatha Kannan,1 Kannan Rangaranamujan.1 Ashvathaa Therapeutics, Inc, Redwood City, CA; 2Creative Biolabs, Shirley, NY; 3Johns Hopkins Medicine, Baltimore, MD.

Background: In acute kidney injury (AKI) and chronic kidney disease (CKD), ischemia in the kidney results in inflammation and tissue damage. The initial response to injury is the infiltration of reactive macrophages into the kidney with subsequent pro-inflammatory cytokine expression. Upon systemic administration, hydroxyl dendrimers selectively target reactive macrophages in the ischemic kidney with renal clearance maximizing kidney exposure.

Methods: Diabetes was induced in Wistar rats by administration of streptozotocin (70 mg/kg) as a single intraperitoneal (IP) injection. Rats with a blood glucose of ≥167 mM were allocated to 4 groups (G1-4; n=3/group). After 6 weeks, ischemia-reperfusion injury (IRI) was conducted with 60 min ischemia (H) 60 min reperfusion (R) (G2), or 45 min I/24 h R (G3 & G4). A sham surgery was performed as a control (G1). Hydroxyl dendrimers labeled with Cy5 (D-Cy5) were administered IP 1 hr after IRI in G1, G2 and G3 and 12 hr after IRI in G4. Renal function was assessed by clinical chemistry, glomerular filtration rate (GFR), and kidney injury biomarkers. Rats were euthanized (G2 or G4) 24 h post surgery. Kidneys were evaluated for tubular damage and tubular epithelial necrosis and stained by DAPI and anti-CD68 antibody (macrophage).

Results: Glucose levels increased to ~330 mM prior to IRI. GFR was significantly reduced from 1.8 mL/min (sham) to 0.8 mL/min in IRI rats. Serum creatinine and blood urea nitrogen were significantly elevated in IRI groups (G4>G3>G2). The degree of kidney injury was not significantly different when the longer reperfusion period was prior to sacrifice (P<0.05; G1, G2 and G3 > G2). In all IRI groups, renal tubular necrosis was moderate to severe and proximal tubule damage was severe. Maximal uptake of the D-Cy5 was observed in renal tubules in reactive macrophages in G2.

Conclusions: A diabetic model of AKI was successfully established to evaluate targeting of hydroxyl dendrimers to reactive macrophages. Prolonged ischemia followed by rapid reperfusion increased reactive macrophages and subsequent uptake of hydroxyl dendrimers. Given the high incidence of diabetic nephropathy and higher risk for AKI in these patients, these results provide a model and treatment strategy to evaluate targeted therapies with hydroxyl dendrimer drug conjugates to treat AKI and CKD.

Novel Analysis Approach for Intravital Single Nephron GFR Measurement in Mice

Hannah Kroeger,1 Friederike Kessel,1 Jan Sradnick,1 Michael Gerlach,2 Vladimir T. Todorov,1 Christian Hugo.1 University Hospital Dresden Center of Internal Medicine - Nephrology, Universitätsklinikum Carl Gustav Carus, Dresden, Dresden, Germany; 2University Hospital Dresden, Core Facility Cellular Imaging, Universitätsklinikum Carl Gustav Carus, Dresden, Dresden, Germany.

Background: Intravital microscopy in animals is an emerging technique with advanced applications in kidney research. Particularly, the measurement of single nephron (SN) GFR in mice comprises a method to assess a key parameter of kidney disease. Filtration in single glomeruli is measured by two-photon microscopy in a time series after intravenous injection of a freely filtered fluorescent dye. From the intraglomerular capillaries to the connected proximal tubules (PT) the glomerular filtration is observed and the intratubular dye intensity shift is measured. However, existing methods for the analysis of the image data in rats (Kang et al. 2006) had limited robustness in mice, due to smaller size, higher tubular curvature and therefore smaller acquisition distances.

Methods: By continuous, rather than punctual measurement of signal intensity across the PT over time against the exact tubular volume, the filtered volume per second is calculated by linear regression.

Results: With the method published by Kang the results were highly variable in our hands. After repeated analysis of image material (10 glomeruli in 5 animals, analyzed 5 times each), the GFR varied by a mean relative SD of 41%. By reducing overall user interaction with our method, this SD could be decreased to 14%. When applying the analysis to image data acquired in healthy and diabetic C57BL/6j mice, we detected a 4-fold increase in SN GFR in diabetic mice. Administration of the ACE inhibitor enalapril for three days ameliorated this effect in diabetic mice by 50%.

Conclusions: To increase the reliability of SN GFR measurements by intravital microscopy in mice, we extended an existing workflow by continuous measurement, 3D-modelling and sophisticated data analysis while reducing manual interaction. User interaction with microscopy data acquired in diabetic and healthy mice prove the general applicability and high reliability of this novel analysis approach. The clinical relevance is apparent in the context of monitoring disease progression as well as effects of medical intervention.

A Hyaluronan Synthesis Inhibitor Delays the Progression of Diabetic Kidney Disease in a Mouse Experimental Model

Loay H. Salman,1 Guillermo Selman,1 Andrea R. Lightle,1 Alejandro E. Aguilar,1,2 Daniel R. Woltmann,1 Laisel Martinez,1 Roberto I. Vazquez-Padron.2 Albany Medical College, Albany, NY; 2University of Miami School of Medicine, Miami, FL; 3Massachusetts Institute of Technology, Cambridge, MA.

Background: There is a paucity of options to treat Diabetic Kidney Disease (DKD) in the clinical practice. Hyaluronan is an important morphological feature of DKD. However, the role of hyaluronan (HA) in the development and progression of DKD as well as the precise mechanisms and consequences of HA involvement in this pathology are still to be clarified.

Aim: In this study, we assessed the effects of hyaluronan synthesis inhibitor 4-Methylumbelliferyl-4-MU (MU) on the development of DKD. As a model, we used the diabetic and moderately hypertensive endothelial nitric oxide synthase/leptin receptor deficient (eNOS C57BL/6J×C57BL/6J) double mutant mice.

Methods: In the diabetic model mice were separated into two similar groups regarding sex, body weight, non-fasting plasma glucose concentrations, and consanguinity; then, experimental animals were fed ad libitum identical artificial diets formulated by Enviro-Teklad, containing or not 5% of 4-MU sodium salt for 9 weeks. Our measures of daily food consumption show that treated animals had a dose of 270±50mg per day of 4-MU (about 6.2g/kg body weight/day). At the end of the experimental period, we found that 4-MU-treated diabetic animals: 1) kept their average GFR, while a significant reduction of GFR was observed in diabetic controls (P<0.042; n=9/8 per group) compared to the average urine ACR and plasma cytokine-c values significantly lower than controls (P=0.049 (n=12 per group) and P=0.043 (n=11/10 per group) respectively); 3) had lower average kidney weight (P=0.041, n=6), and 36% less hyaluronans in kidneys (P=0.095; Effect size=1.32, n=5); and 4) MU-treated animals kept their body weight/stature/maximum weight relationship (P<0.001) (n=5/4) better than diabetic controls (P=0.002, n=16/15 per group) as well as their median survival was 6.4 weeks longer (P=0.048, n=6/5 per group). Moreover, after the treatment, an independent histopathology study showed a significant lower glomerular injury score in kidneys of 4-MU-fed animals (P=0.039, n=5/7 per group).

Conclusions: These results showed that the hyaluronan synthesis inhibitor 4-MU effectively slowed the progression of DKD. 4-MU provides a potential new therapeutic approach to treat DKD.

Therapeutic Benefit of CCR2 Antagonism in a Model of Diabetic Nephropathy Suggests a Mechanism of Action Distinct from Nrf2 Activation

Background: Diabetic nephropathy (DN) affects nearly half of the patients with type 2 diabetes and is characterized by albuminuria and/or a relentless decline in renal function that may lead to ESRD. We have recently shown that a CCR2 antagonist improved renal structure and reduced proteinuria in the db/db murine model of DN, as well as in the Adiraycin and 5/6 nephrectomy models of CKD. To understand the mechanism we compared CXX872, a small molecule antagonist of CCR2, with Bardoxolone methyl, an investigational drug targeting Nrf2 pathway in the db/db murine model of DN.

Methods: The [K51] CCR2 specific inhibitor CXX872 and Nrf2 activator Bardoxolone methyl were formulated in 1% HPMC and dosed for 2 weeks. Proteinuria (urinary albumin excretion rate- UAER) and glomerular filtration rate (GFR) were assessed by measuring urinary albumin ELISA and FITC-insulin, respectively. The kidneys were disrupted non-enzymatically, and preparations enriched in glomerular cells were obtained by filtration. Activated parietal epithelial cells (PECs) were analyzed in these preparations by flow cytometry.

Results: UAER was rapidly and significantly reduced after treatment with CXX872: 59% (p=0.004) and 76% (p<0.0001), versus vehicle by week 1 and 2 respectively. In contrast, Bardoxolone did not improve UAER. The db/db mice had kidney hyperfiltration, which measured 943±36 μl/min at 8 weeks. Bardoxolone reduced hyperfiltration in db/ db mice by 36% versus vehicle at week 2, while CXX872 had no effect on GFR. UAER in CXX872 significantly reduced the number of CD44 positive activated PECs in the glomerular cell preparations(=0.04), while Bardoxolone had no effect on the number of these cells.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only; Underline represents presenting author.
Can Nrf2 Inducers Cause Renal Proximal Tubule Epithelial Cell De-Differentiation?

Jessica Eskridge, Susan M. Isaacs, Madhavi J. Rane, Michelle T. Barati.
University of Louisville, Louisville, KY.

Background: Nrf2 is a transcription factor serving as a master regulator of cytoprotective responses. Nrf2 and its inducers have been shown to mitigate renal injury in animal models of kidney disease. However, use of these agents in the clinical setting is limited and defining/comparing mechanisms of action of different agents remains to be defined. Previous lab studies showed two Nrf2 inducers (Protandim [nutritional supplement] and DMF [Dimethyl fumarate]) caused differing effects on renal protection by different mechanisms in the db/db model of DN.

Methods: Human proximal tubule cells (HK-11 cells) were cultured in high glucose (HG; 25mM) or normal glucose concentrations (NG; 5mM) for 24h, followed by additional treatment with 1 or 10μM DMF for another 24h. To test markers of EMT and cytoskeleton, cells were immuno-stained for vimentin and fibronectin, and actin filaments stained with FITC-phalloidin. Cell extracts were immunoblotted for E-cadherin and vimentin.

Results: Protandim and DMF increased vimentin filament expression by image analysis of immunoblotted cells, and HG+DMF conditions led to a further increase. Treatment with Protandim following culture in both HG and NG caused collapse of actin filaments (as previously observed) and vimentin encasulated and co-localized with the collapsed actin. The cell-cell junction protein E-cadherin was downregulated by DMF and culture in HG prior to DMF was not additive to this effect. Protandim did not alter E-Cadherin expression. Extracellularly deposited fibronectin increased with HG and this effect was augmented by additional treatment with DMF.

Conclusions: Protandim and DMF distinctively regulate the cell cytoskeleton. Increased vimentin filament formation with Protandim may be a compensatory mechanism due to collapse of actin filaments. DMF decreases E-Cadherin and increases vimentin and ECM deposition, suggestive of tubule cell de-differentiation. The disparate effects of these two Nrf2 inducers may lead to varying outcomes if used for treatment of diabetic or other types of kidney disease.

Beneficial Effect of Chloroquine and Amodiaquine on Diabetic Tubulopathy by Attenuating Mitochondrial Nox4 and Endoplasmic Reticulum Stress

So-young Lee,1 Dong Ho Yang,1 Hye yun Jeong,1 Yu ho Lee,1 Hyecheon Lee,1 Taeyoung Yang,1 Sangho Lee,2 1Department of Internal Medicine, CHA Bundang Medical Center; 2CHA University, Seongnam, Republic of Korea.

Background: Oxidative stress induced by chronic hyperglycemia is recognized as a significant mechanistic contributor to the development of diabetic kidney disease (DKD). Nonphagocytic nicotinamide adenine dinucleotide phosphate oxide 4 (Nox4) is a major source of reactive oxygen species (ROS) in many cell types and in the kidney tissue of diabetic animals. We designed this study to explore the therapeautic potential of chloroquine and amodiaquine for inhibiting mitochondrial Nox4 and diabetic tubular injury.

Methods: Human renal proximal tubular epithelial cells (hRPTCs) were cultured in high-glucose media (30 mM D-glucose), and diabetes was induced with streptozotocin (STZ, 50 mg/kg i.p. for 5 days) in male C57BL/6J mice. Chloroquine and amodiaquine were administered to the mice via intraperitoneal injection for 14 weeks.

Results: Chloroquine and amodiaquine inhibited mitochondrial Nox4 and increased mitochondrial mass in hRPTCs under high-glucose conditions. Reduced mitochondrial ROS production after treatment with the drugs resulted in decreased endoplasmic reticulum (ER) stress, suppressed inflammatory protein expression and reduced cell apoptosis in hRPTCs under high-glucose conditions. Notably, chloroquine and amodiaquine treatment diminished Nox4 activation and ER stress in the kidneys of STZ-induced diabetic mice.

In vitro, we observed attenuated inflammatory and albuminuria in STZ-induced diabetic mice after chloroquine and amodiaquine treatment.

Conclusions: We substantiated the protective actions of chloroquine and amodiaquine in diabetic tubulopathy associated with reduced mitochondrial Nox4 activation and ER stress alleviation. Further studies exploring the roles of mitochondrial Nox4 in the pathogenesis of DKD are required for new therapeutic targets for patients with DKD.

In Vivo Evaluation of [18F]Canagliflozin, a Potential PET Tracer for Imaging Tissue Distribution of the SGLT2 Inhibitor Canagliflozin in Type 2 Diabetics Patients In Vivo

Sioukie van der Hoek, Inès F. Antunes, Harry Van goor, Hiddo J. I. Heerspink, Philip Elsinga, Jasper Stevens. University Medical Center Groningen, Groningen, Netherlands.

Background: Sodium-glucose cotransporter 2 (SGLT2) inhibitors are guideline recommended for prevention of kidney and cardiovascular outcomes in patients with diabetic kidney disease. But not all patients benefit from these agents, possibly due to differences in SGLT2 inhibitor tissue distribution. Imaging studies can assist to quantify in vivo tissue drug distribution and SGLT2 density in patients in order to unravel the underlying determinants of this response variability. The objective of this study was firstly to synthesize [18F]Canagliflozin ([18F]CANA) for human use, and secondly, to confirm its affinity for SGLT2.

Methods: [18F]CANA was synthesized by GMP compliant automated substitution of a boronic ester precursor with [18F]fluoride. Its in vitro binding with SGLT2 was tested by incubating human kidney slices with [18F]CANA alone or together with canagliflozin or glucose and analyzing them with autoradiography. [18F]CANA binding sites were compared with SGLT2 distribution using immunohistochemistry on consecutive slices.

Results: [18F]CANA radiochemical yield was 2.6% ± 1.9% within 80 min, molar activity 5.20 GBq/μmol and radiochemical purity ≥99%. Autoradiography shows [18F]CANA binding in kidney slices with a significant reduction in binding in presence of canagliflozin and a clear trend in reduced binding in presence of glucose (Fig 1A and B). The pattern of [18F]CANA binding on autoradiography corresponds with the distribution of SGLT2 in the apical membrane of proximal tubules as shown with immunohistochemistry (Fig 1C).

Conclusions: We showed the successful automated synthesis of the SGLT2 inhibitor [18F]CANA and its specificity to the SGLT2. Given its unchanged structure compared to the marketed compound, canagliflozin tissue distribution and SGLT2 density can now be studied in vivo in human as determinants of between-patient response variability.

Exploring New Targets of Diabetic Nephropathy by Bioinformatics Analysis

Shumo Yu, Xiangcheng Xiao. Xiangya Hospital Central South University, Changsha, China.

Background: The pathogenesis of diabetic nephropathy has not been fully understood and the public platform contains mass data for bioinformatics analysis. Methods: Difference analysis and weighted gene coexpression network analysis were carried out on GSE30529 to obtain target genes and perform functional enrichment analysis. Non-coding RNA analysis was studied to understand the potential mechanism of biological expression of target genes. Using STRING database to build protein-protein interaction network. Enpreseq v5 database can access gene expression characteristics and clinical characteristics.

Results: From the GSE30529, 345 genes were identified through bioinformatics analysis. GO annotations of them included neutrophil activation, regulation of immune effector process and positive regulation of cytokine production. KEGG pathways included phagosome, complement and coagulation cascades and cell adhesion molecules. From mRNA profile, Mir-1237-3p-SH2B3, Mir-1238-5p-ZNF652 and Mir-766-3p-TGFB1I axis may be involved in diabetic nephropathy. C3 is located at the center of PPI network. Correlation analysis with GFR showed STX, CXCL1, LYN, VWF, ANXA1, C3, HLA-E, RHOA, SERPING1, EGF and KNG1 may be related to diabetic nephropathy.

Conclusions: C3 may serve as a therapeutic target for diabetic nephropathy.
PO0948
Apolipoprotein C3 Inhibition Reduces Diabetic Kidney Disease and Atherosclerosis in a Mouse Model
Cheng-Chieh Hsu,1 Farah Kramer,1 Charles E. Alpers,1 Rosanne M. Crooke,2 Jenny E. Kanter,1 1University of Washington School of Medicine, Seattle, WA; 2Ionis Pharmaceuticals Inc, Carlsbad, CA.

Background: Diabetes increases the risk of cardiovascular disease and kidney disease. Importantly, the majority of the excess cardiovascular risk in people with diabetes is observed in those who also have kidney disease. Apolipoprotein C3 (APOC3) is a small lipoprotein that is elevated in insulin-insufficiency and regulates plasma triglyceride levels.

Methods: To test if APOC3, and the dyslipidemia it represents, play a role in diabetic kidney disease (DKD) we treated BTBR wildtype (WT) and leptin-deficient (OB, diabetic) mice with an antisense oligonucleotide (ASO) to APOC3 or a control ASO (cASO), all in the setting of human-like dyslipidemia (accomplished by administration of an LDLR ASO).

Results: APOC3 ASO treatment reduced triglycerides, triglyceride-rich lipoproteins, and prevented diabetes-associated atherosclerosis in the brachiocephalic artery and the aorta (aortic lesion was 9.3 ± 1.5 mm² lesion in cASO-treated OB mice compared to 4.7 ± 0.93 mm² in APOC3 ASO-treated OB mice, p<0.001, n=7-10). Intriguingly, APOC3 ASO treatment reduced diabetes-associated urinary albumin excretion but had no effect on non-diabetic mice (WT mice: 108 ± 24.0 mg urinary albumin/day, OB cASO mice: 1076 ± 219 mg/day and OB mice with APOC3 ASO: 435 ± 63 mg/day, p<0.001, n=7-14). Diabetes resulted in a dramatic increase in glomerular neutral lipid and APOC3-accumulation, which was attenuated by APOC3 ASO-treatment. Diabetes led to a doubling of glomerular volume (45126 ± 1908 μm³/gglomerular volume in OB mice vs. 21775 ± 1041 μm³ in WT mice, p<0.001, n=7-14), increased glomerular PAS-staining indicative of mesangial expansion (2494 ± 332 μm² PAS-positive matrix in OB mice and 822 ± 40 μm² in WT mice, p<0.001), or from 21% in WT to 28% in diabetes, p<0.01, and a significant loss of podocytes (80 ± 2240 μm² glomerular volume in OB mice and 230 podocytes/106 μm² glomerular volume in WT mice, p<0.001), all of which were in part reversed by APOC3 inhibition (glomerular volume in OB mice treated with APOC3 ASO 36331 ± 2240 μm², p<0.05; PAS area 1761 ± 131 μm², p<0.01; and podocyte density 114 ± 9 podocytes/106 μm² glomerular volume, p<0.07, all compared to OB mice treated with cASO).

Conclusions: Together, this suggests that targeting APOC3 and diabetic dyslipidemia might be beneficial for both diabetes-associated atherosclerosis and DKD.

PO0949
Shen-Qi-Yan-Shen Formula Attenuates Diabetic Renal Lipid Deposition by Down-Regulating Proteoglycan Expression
Yinx Li, Wei Jian Xiong. Chongqing Traditional Chinese Medicine Hospital, Chongqing, China.

Background: Renal lipid deposition is a crucial factor in the pathophysiology of diabetic nephropathy (DN). Proteoglycan (PG) is an important component of the extracellular matrix. Shen-Qi-Yan-Shen Formula (SQYSF) is a clinical empirical formula in treating DN. In this study, db/db mice are used to explore the potential mechanism of SQYSF by down-regulating PG expression.

Methods: We divide the mice into db/db normal control group, db/db model group, SQYSF treated group, captopril treated group, and SQYSF + captopril treated group. The groups of mice are given continuous administration of saline, SQYSF, captopril or SQYSF + captopril for 12 weeks, respectively.

Results: We have revealed that treating db/db mice with SQYSF protects them against renal injury. Our finding is supported by lower blood urea nitrogen and serum creatinine and less urinary albumin in the treated mice compared with the saline-treated db/db controls. Mice treated with SQYSF have significantly reduced protein levels of fasting blood glucose (FBG), HbA1c, TG, LDL-c and HDL-c. SQYSF markedly down-regulates protein expression of proteoglycan (PG), apoB and LDL-R receptor in the db/db mice. In addition, captopril exhibits a partial inhibitory effect on PG and other proteins, which can be enhanced by SQYSF.

Conclusions: SQYSF may protect db/db mice by relieving lipid deposition through the down-regulation of PG. These encouraging results corroborate SQYSF’s potential of becoming a novel therapeutic strategy for diabetic nephropathy.

Circulating MicroRNAs Associated with Hyperglycemia and Their Effects on Renal Function Decline in Type 2 Diabetes: Global miRNome Analysis

Background: It has been reported that microRNAs (miRNAs) play an important role in the pathogenesis of diabetic complications. We aimed to search for circulating miRNAs that were associated with hyperglycemia in type 2 diabetes (T2D) and examine their effects on renal function decline.

Methods: Using the next-generation sequencing-based HTG EdgeSeq miRNA platform, a total of 2,083 miRNAs were measured in baseline plasma specimens obtained from 73 subjects with T2D and normal renal function (discovery panel), and 136 subjects with T2D and impaired renal function (replication panel). Subjects in both panels were followed for 6-12 years to determine eGFR decline.

Results: We identified 11 candidate miRNAs that were strongly associated with elevated levels of glycated hemoglobin (HbA1c) in both screening and replication panels. Using bioinformatics analyses, we found that the candidate miRNAs targeted proteins of 6 pathways (the Ras signaling pathway, Signaling pathways regulating pluripotency and the AMPK signaling pathway). Importantly, 4 of these 11 miRNAs were significantly associated with risk of renal function decline.

Conclusions: There were few previous reports about the association between circulating miRNAs, hyperglycemia, and diabetic kidney disease in T2D. The present study comprehensively examined and identified hyperglycemia-regulated miRNAs in human samples. Our findings are novel in that circulating miRNAs regulated by hyperglycemia are associated with risk of eGFR decline.

Longitudinal Changes in Plasma Biomarkers and Diabetic Kidney Disease Progression in VA NEPHRON-D

Teresa K. Chen, 1 Heather Thiessen Philbrook, 1 Wassim Obeid, 1 Linda F. Fried, 1 Hiddo J. L. Heerspink, 1 Chiirag R. Parikh, 1 Steven G. Coca. 2 CKD BioCon 1 Johns Hopkins University, Baltimore, MD; 2 Mount Sinai, New York, NY; 3 VA Pittsburgh Healthcare System, Pittsburgh, PA; 4 UMCG, Groningen, Netherlands.

Background: Pathways of inflammation are central to the pathogenesis of diabetic kidney disease (DKD). We previously reported in VA NEPHRON-D that higher baseline levels of soluble tumor necrosis factor receptors 1 and 2 (sTNFR1, sTNFR2) and kidney injury molecule-1 (KIM-1) were associated with DKD progression. Whether longitudinal changes in these and other promising biomarkers are also associated with subsequent kidney function decline is unclear.

Methods: We measured 6 plasma biomarkers (sTNFR1, sTNFR2, KIM-1, interleukin-18 [IL-18], monocyte chemoattractant protein-1 [MCP-1], chitinase-3-like protein-1 [YKL-40]) at baseline and 12 mths. Using Cox models, we studied associations of each biomarker (at baseline, at 12 mths, and relative change from baseline to 12 mths) with kidney function decline (first occurrence of eGFR decrease ≥30 ml/min/1.73 m² or >50% if randomization eGFR ≥60 and <80, respectively, or ESRD), adjusting for biomarker, sex, race, treatment arm, BMI, HgbA1c, eGFR, UACR at baseline and age, systolic BP, eGFR, UACR at 12 mths. We excluded events before 12 mths (n=5).

Results: Of 754 VA NEPHRON-D participants with baseline and 12-mth plasma samples, mean eGFR=57 ml/min/1.73 m² and median UACR=0.8 g/g. Over a median follow-up of 2.5 yrs, 118 (16%) had kidney function decline. Compared to quartiles 2&3, the highest quartile of delta sTNFR1, sTNFR2, KIM-1, and YKL-40 had 1.7 to 2.0-fold greater risks and the lowest quartile of delta MCP-1 had 52% lower risk of kidney function decline. Higher baseline and 12-mth biomarker levels were also associated with DKD progression [Figure].

Conclusions: Repeated measures of several plasma biomarkers in patients with DKD provided additional prognostic information even after adjusting for baseline biomarker levels, clinical variables, and time-updated eGFR and UACR.

A Polysubiquitinated Form of PTEN Predicts Declining Kidney Function and ESKD in Type 2 Diabetes

Helen C. Looker, 1 Chunru Lin, 1 Viji Nair, 1 Matthias Kretzler, 1 Michael Maurer, 1 Behzad Najafian, 2 Robert G. Nelson. 1 National Institute of Diabetes and Digestive and Kidney Diseases, Phoenix, AZ; 2 University of Texas MD Anderson Cancer Center, Houston, TX; 3 University of Michigan, Ann Arbor, MI; 4 University of Minnesota, Minneapolis, MN; 5 University of Washington, Seattle, WA.

Background: Fibrosis is a major driver of chronic kidney disease and epithelial-mesenchymal transformation (EMT) may contribute to its development. A polysubiquitinated form of phosphatase and tensin homolog (PTEN K27polyUb) promotes EMT in vitro and may be a useful biomarker of progressive kidney fibrosis.

Methods: PTEN K27polyUb was measured in 234 serum samples from American Indians (80 men, 154 women) with early diabetic kidney disease (DKD). Quartiles of serum PTEN K27polyUb were assessed as risk factors for DKD progression (≥40% loss of GFR) or onset of end-stage kidney disease (ESKD) using Cox proportional hazards models adjusted for age, sex, diabetes duration, HbA1c, blood pressure, measured GFR and albuminuria.

Results: Baseline, mean age was 42.8 years (SD 10.5), diabetes duration 11.5 years (7.1), mean arterial pressure 90.5 mmHg (9.5), HbA1c 9.3% (2.4), GFR 151 ml/min (45) and median albumin:creatinine ratio 38 mg/g (interquartile range 14-217). 168 subjects had a ≥40% loss of GFR and 74 (64 with prior ≥40% GFR loss) developed ESKD during median follow-up of 6.3 and 15.8 years, respectively. In univariate analysis, serum PTEN K27polyUb was associated with risk of ≥40% GFR decline and of ESKD (Figure). After adjustment for clinical covariates higher PTEN K27polyUb was associated with greater risk of ≥40% GFR decline [Hazard ratio (HR) for the 4th vs. 1st quartile = 3.67, 95% CI 1.98-6.78, p<0.001] and with ESKD [HR quartile 4 vs. 1 = 5.00, 95% CI 1.77-14.11, p<0.002]. Adding serum PTEN K27polyUb increased the model c-statistics from 0.696 to 0.725 for DKD progression and from 0.738 to 0.766 for ESKD.

Conclusions: Higher serum PTEN K27polyUb is associated with increased risk for GFR decline and ESKD in type 2 diabetes and improves prediction over standard clinical measures.

Background: Albuminuria is a risk factor for kidney disease progression and CV disease. We examined the relative and absolute effects of CANA by baseline albuminuria among CREDENCE participants.

Methods: CREDENCE was a double-blind, randomized study of 4401 participants with eGFR 30-<90mL/min/1.73m2 and uACR >300-5000mg/g who demonstrated that CANA significantly reduced renal and CV outcomes, including the primary composite of end-stage kidney disease, doubling serum creatinine, or renal or CV death. We analyzed the effect of CANA on renal, CV, and safety outcomes by baseline uACR.

Results: At baseline, 2348 (53.4%), 1547 (35.2%), and 506 (11.5%) participants had uACR ≤1000, >1000-<3000, ≥3000mg/g. Higher uACR was associated with higher event rates (Figure). CANA reduced renal and CV endpoints, with no statistical variation by uACR (all p heterogeneity >0.17). CANA led to a greater absolute reduction in renal events in those with higher uACR (number needed to treat to prevent 1 episode of the primary composite: 22 and 8 for uACR >1000-<3000 and ≥3000mg/g). Rates of renal-related adverse events were lower with CANA, and the relative reduction was greater with higher uACR (p heterogeneity =0.003). CANA had no significant effect on acute kidney injury, volume depletion, hyperkalemia, urinary tract infections or hypoglycemia, with no differences by uACR (all p heterogeneity >0.12).

Conclusions: CANA safely reduces renal and CV events in people with type 2 diabetes and substantial albuminuria, with the greatest absolute renal benefit in those with uACR of 3000-5000mg/g.

Lower Cardiorenal Risk with SGLT2 Inhibitor vs. DPP4i Inhibitor in Type 2 Diabetes Patients Without Established Cardiovascular and Renal Diseases

Käre J. Birkeland,1 Johan Bodegard,2 Amitava Banerjee,3 Dae Jung Kim,4 Jan W. Eriksson,1 Marcus Thresson,5 Suguru Okami,5 Kyoung Hwa Ha,6 Nile Kösko,7 Bueneng Cheng,8 Ruiqi Zhang,9 Yoshitaka Toshitake,10 Issel Komuro,10 Takashi Kadokawa.2 1Oslo Universityetstitutshetshu, Oslo, Norway; 2AstraZeneca PLC, Luton, United Kingdom; 3Uppsala Universitet, Uppsala, Sweden; 4Toranomon Byoin, Minato-ku, Japan; 5AstraZeneca PLC, Luton, United Kingdom; 6Jou University School of Medicine and Graduate School of Medicine, Suvon, Gyeonggi-do, Republic of Korea; 7Statisciton, Uppsala, Sweden; 8University College London, London, United Kingdom; 9The University of Tokyo Graduate School of Medicine Faculty of Medicine, Tokyo, Japan; 10Wissenschaftliches Institut fur Gesundheitssystembeike und Gesundheitssyssytemforschung, Berlin, Germany.

Background: Cardiorenal disease, defined by chronic kidney disease (CKD) or heart failure (HF), is a frequent disease manifestation associated with serious risks in T2D patients. We compared new use of sodium-glucose cotransporter-2 inhibitor (SGLT2i) vs. dipeptidyl peptidase 4 inhibitor (DPP4i) and the risk of cardiorenal disease in T2D patients without history of established cardiovascular and renal disease, defined as CVD-free.

Methods: In this observational cohort study, patients were identified in health care databases in England, Germany, Japan, Norway, Sweden, and South Korea between the years 2012 and 2018. New users of SGLT2i were propensity score matched 1:1 with users of DPP4i. Unadjusted Cox regressions were used to estimate hazard ratios (HRs) for outcomes; cardiorenal disease, HF, CKD, stroke, myocardial infarction (MI) cardiovascular (CV) and all-cause death (ACD).

Results: Baseline characteristics were well balanced between the treatment groups (age: 60.5±13.0 in each group) with mean follow up of 1.5 years and 315,015 patient-years. The distribution of follow-up time for SGLT2i and DPP4i types was, dominated by dapagliflozin (91.7%) and sitagliptin/linagliptin (55.0%). SGLT2i was associated with lower risk of cardiorenal disease, HF, CKD, CV- and all-cause death, HR (95% CI) 0.56 (0.42-0.74), 0.71 (0.59-0.86), 0.44 (0.28-0.69), 0.67 (0.59-0.77) and 0.61 (0.44-0.85) respectively. No differences for stroke (0.87 [0.69-1.09]) and MI (0.94 [0.80-1.11]).

Conclusions: In this large multinational observational study of CVD-free T2D patients, the unique preventive effects of SGLT2is on cardiorenal disease reported from clinical trials are confirmed in a real-world setting.

In Patients with Biopsy-Proven Diabetic Nephropathy, 38% Have a Second Significant Diagnosis

Patrick D. Walker,1 Vivek Charu,2 Dao-Fu Dai.4 Arkana Laboratories, Little Rock, AR; 3Stanford University School of Medicine, Stanford, CA; 1The University of Iowa Roy J and Lucille A Carver College of Medicine, Iowa City, IA.

Background: AIM: determine the renal biopsy (Bx) incidence of a second kidney disease (2^nd DX) in patients (Ps) with diabetic nephropathy (DN) Bx ed for various clinical indications. Methods: Of 45,422 non-transplant cases received from 2001-2014 (2222 nephrologists, 39 states), 7,746 Pts with DN were found. 1,749 cases were excluded for insufficient data, 1,398 cases were excluded for lack of renal bx. 4,205 Pts were analyzed (age range: 8 - >89 years; males 53.5%). Bx indication: acute kidney injury (AKI), acute nephritic syndrome (ANS), rapidly progressive renal failure (RPFR), hematuria (Heme), suspect a non-DN renal disease (Non-DN), sudden increase in
proteinuria (Prot) or chronic kidney disease (CKD). We recorded a specific rule out (r/o) diagnosis if one was given. BX DN Grade: 1 EM changes; II Mesangial increase; III Nodular sclerosis; IV > 50% Global sclerosis.

Results: A 2nd DX was found in 1750 (38%) cases. Overall, there were 40 2nd DXs: AT 41%, acute interstitial nephritis 14%, infection-related glomerulopathy (GN) 7%, etc. There were multiple unexpected 2nd DXs: fibrillary GN, amyloid, dense deposit disease among others. The highest odds ratio (OR) of a 2nd DX was in Ps with AKI at 3.25 whereas CKD had an OR of 0.03 (Table). Age correlated with a 2nd DX (p < 0.001) with the Bx incidence ranging from 29% in Pts < 30 to 56% for those ≥ 80. In 1,589 cases, a specific DX was to be ruled out. A 2nd DX was found in 48% of Bx’s with a r/o DX versus 33% when no r/o DX was given (OR=1.83, CI (1.62, 2.08), p < 0.001). Lesser grades of DN significantly correlated with a 2nd DX; I - 75%, II - 64%, III - 38%, IV - 20% (p < 0.001).

Conclusions: In Bx proven DN, a significant 2nd DX was found in 38%, with AKI and ANS most likely to yield a 2nd DX. Age and a r/o DX can further differentiate patient groups most likely to have a 2nd DX. Given the worldwide toll of diabetes, the finding of a potentially treatable 2nd DX in diabetics already at high-risk of end stage kidney disease should provide significant savings in morbidity, mortality and health care expense.

PO0957
Association of Renal Pathological Lesions and Renal Prognosis in Patients with Diabetic Nephropathy and Effect Modification by Proteinuria
Fumihiro Fukata,1 Masahiro Erguchi,1 Hikari Tasaki,2 Riri Furuyama,1 Masatoshi Nishimoto,1 Takaaki Kosugi,1 Kaori Tanabe,1 Katsukiho Morimoto,2 Masaru Misuya,1 Kenichi Samejima,1 Kazuhiko Tatsumi,1 Nara Prefecture Medical University, Kashihara, Japan; 2Nara Prefecture Seiwa Medical Center, Ikoma-gun, Japan.

Background: There are few detailed studies on renal pathological findings in diabetic nephropathy (DN) with low urinary protein (UP). We examined whether the association of renal histology with renal prognosis was modified by UP levels in DN diagnosed by renal biopsy.

Methods: The total of 396 participants diagnosed with DN by renal biopsy were divided into 2 groups by the level of UP; ≥ 0.5 g/day (high-UP group, n = 197) or < 0.5 g/day (low-UP group, n = 199). The association of glomerular lesion (GL) and interstitial and tubular lesion (IFTA) with incidence of end-stage kidney disease (ESKD) was examined using a proportional hazard model with the adjustment for confounding factors in each proteinuria group.

Results: Compared to high-UP group, low-UP group had a higher eGFR (median interquartile range (IQR): 66 [48, 89] mL/min/1.73m2 vs 49 [31, 70], p < 0.001), lower systolic blood pressure (128 [112, 140] mmHg vs 140 [126, 154], p < 0.001), lower prevalence of severe GL (6.1% vs 56.8%, p < 0.001) and IFTA (12.2% vs 61.3%, p < 0.001). During a median [IQR] observation period of 8.3 [3.9, 17.6] years, 14 and 78 patients reached ESKD in low-UP and high-UP groups, respectively. Cox hazard model adjusted for confounding factors showed that both GL and IFTA were significantly associated with renal prognosis in the high-UP group, whereas only IFTA showed significant association in the low-UP group. The association of IFTA with renal prognosis was consistent (p for interaction = 0.45), but that of GL was significantly different between the two groups (p for interaction < 0.01).

Conclusions: IFTA is consistently associated with renal prognosis regardless of UP levels, but GL is associated with renal prognosis only in patients with overt UP.

PO0958
Comprehensive Ultrastructural Analysis Strongly Predicts Kidney Function Decline in the Multicenter TRIDENT Cohort
Matthew Palmer,1 Amin Abedini,1 Casey Jackson,1 Shira Blady,1 Shatkaseekh Chatterjee,1 Katie Sullivan,1 Raymond R. Townsend,1 Amy K. Motti,2 Salem Alamanzi,3 Anand Srivastava,4 Rupali S. Avasare,5 Michael J. Ross,2 Jens Brodbeck,5 Katalin Susztak,1 University of Pennsylvania, Philadelphia, PA; 2University of North Carolina at Chapel Hill, Chapel Hill, NC; 3Albert Einstein College of Medicine/ Montefiore Medical Center; Bronx, NY; 4Northwestern University Feinberg School of Medicine, Chicago, IL; 5The Ohio State University Wexner Medical Center, Columbus, OH; 6Oregon Health & Science University, Portland, OR; 7Inflammation & Respiratory Therapeutics, Gilead Sciences Inc., Foster City, CA.

Background: While diabetic kidney disease (DKD) is responsible for more than half of all chronic and end stage kidney disease (ESKD), the association of light (LM) and electron microscopical (EM) structural changes with clinical parameters and prognosis in late stage DKD is not completely determined.

Methods: TRIDENT (Transformative Research in Diabetic Nephropathy) is a multi-center observational cohort aimed to identify changes associated with kidney function decline in an unbiased manner. Sixty-two patients diagnosed with biopsy-confirmed DKD were enrolled. Digital scans of biopsy slides and EM were scored for twelve LM and eight EM parameters. Demographic and clinical features of the patients were recorded at enrollment and patients were followed-up every six months.

Results: The median estimated glomerular filtration rate (eGFR) was 28.91 (20.87 mL/min/1.73m2) and the urine protein to creatinine ratio (UPCR) at enrollment was 1.64 (7.25) mg/mg. During a mean follow-up time of 10.6 months, the median change in eGFR was -25.8% and median fold change in UPCR was 1.29 (2.15) and 17 patients progressed to ESKD. Multiple linear regression analysis revealed that interstitial fibrosis independently associated with eGFR at enrollment. Glomerular lesions including global glomerulosclerosis and mesangiolysis were associated with eGFR decline. Foot process effacement significantly associated with UPCR at enrollment and mesangial hyalinosis predicted UPCR fold change. Unbiased clustering analysis identified three disease subgroups to which cluster 2 (N=11) showed more pronounced damage by LM and EM parameters and had the fastest eGFR decline, while cluster 1 (N=25) had the slowest eGFR decline and the least severe structural lesions. Cox regression analysis showed that the subjects in cluster 2 had the highest risk to reach ESKD (HR=14.8, 95%CI: 1.76-123.73, p < 0.01).

Conclusions: This study confirms association of structural and clinical parameters even in late stage DKD. Furthermore, it highlights specific ultrastructural features that can strongly predict kidney function decline.
PO0959

The Association Between Kidney Biopsy Findings in Diabetic Patients and Renal Replacement Therapy Initiation

Enzo C. Vasquez Jiménez,1 Ana Lucía L. Diez de Sollano Basilia,1 Ivan A. Osuna Padilla,1 Virgilia Soto,2 Magdalena Madero,3 Instituto Nacional de Cardiología Ignacio Chávez, Mexico, Mexico; Instituto Nacional de Enfermedades Respiratorias, Mexico, Mexico.

Background: Diabetic Kidney Disease (DKD) is the leading cause of Chronic Kidney Disease (CKD) worldwide. Nevertheless, about a third of type 2 diabetic patients with kidney involvement have Non-Diabetic Kidney Disease (N DKD). The distinction between DKD and N DKD can only be done accurately with kidney biopsy. There is lack of evidence in regards to the association between N DKD and CKD progression. The objective of this study was to evaluate the association of DKD, N DKD or both with Renal Replacement Therapy (RRT) initiation.

Methods: This is a retrospective study of patients with T2DM who underwent a kidney biopsy between 2006 and 2019 at the Department of Nephrology at the National Institute of Cardiology in Mexico City. The included patients were followed for five years or until start of RRT. According to presence of diabetic nephropathy and non-diabetic glomerular disease, three groups were identified: group 1: patients with DKD, group 2: patients with N DKD and group 3: patients with combined DKD and N DKD.

Results: A total of 141 DM patients were included, the mean age was age 52.4 ± 12.2 years and 48.2%. The main indication for kidney biopsy was nephrotic proteinuria in 46 patients (32.6%), rapidly impaired kidney function in 23 patients (16.3%), nephrotic syndrome in 24 patients (17%) and suspicion of other glomerulopathies in 4 patients (2.8%). Based on kidney biopsy findings, 53 (39.1%) had DKD, 13 (9.2%) had N DKD and 75 (53.5%) had both DKD and N DKD. One hundred and forty (74.5%) achieved RRT in the follow-up, 36 in DKD group, 10 in the N DKD group and 58 in the group with both DKD and N DKD. Patients with highest degree of fibrosis (grade 2 and 3 vs 1) (n = 93) had a higher risk of starting RRT (RR 9.53, CI 95% 1.77- 51.3, p=0.009). Kidney survival was poorer in the DKD and N DKD group (p = 0.002) (Figure 1).

Conclusions: Kidney biopsies is this population could be of use in order to risk stratify this population. Subjects with the combination of DKD and N DKD have the worst renal prognosis.

PO0960

The Aging Kidney: Renal Parenchymal Volumes from MRI, a Comparison Between Type 2 Diabetes and Non-Type 2 Diabetes in 37,450 UK Biobank Participants

Lars Johansson,1 Taro Langner,1 Paul Hockings,1 Lisa Jarl,1 Lukas Maldonis,1 Tove Fall,2 Håkan Ahlström,3,4 Joel Kullberg,3,4 Antaros Medical, Malmö, Sweden; Uppsala universitetet Institutionen for medicinsk biokemi och mikrobiologi, Uppsala, Sweden; Uppsala University, Department of Surgical Sciences, Radiology, Uppsala, Sweden.

Background: It is well known that Type 2 Diabetes (T2D) early on is associated with increased kidney volumes but also can cause Diabetic Nephropathy. UK Biobank (UKB) is a large-scale cross-sectional study aiming to examine 100,000 subjects aged 44 to 82 years using Magnetic Resonance Imaging (MRI). Resulting images allow measurements of Kidney Parenchyma Volume (KPV). The purpose of this study was therefore to quantify KPV and investigate the association with age in T2D and non-T2D subjects.

Methods: An automated deep learning-based method for direct KPV segmentations and measurements was developed and validated and applied to UKB MRI in 37,450 subjects. KPV was analyzed as a function of diagnosed T2D (defined as diagnosis of diabetes after 40 yo), sex and age. Furthermore, correction for lean tissue volumes assessed by MRI was performed in all subjects.

Results: KPVs from 37,450 subjects (47.6% males) as a function of T2D, sex and age are shown in Fig1. In non-T2D a steady decline in KPV is seen in both males and females. KPV is significantly larger in T2D subjects (1126 males, 530 females), over 50 years of age as compared to non-T2D. This is followed by a faster KPV decline in T2D compared to non-T2D subjects. Adjusting for lean tissue volumes from MRI did not change the difference in decline rates between T2D and non-T2D subjects.

Conclusions: T2D subjects have a larger KPV than non-T2D in middle aged subjects but show a faster KPV decline, independent of lean tissue volume differences. The faster decline in T2D can potentially be explained by increased hyperfiltration and oxidative stress in T2D.

Assessment of Histopathological Prognosticators in Diabetic Nephropathy: Single-Center Experience

Ahmad M. Khalaf,1 Awas Nauman,2 Mohamad M. Alkadi,1 Adel A. Abdelaziz,1 Ahmed F. Handi,1 Muhammad Asim,1 Omar Fituri,1 Hassan A. Al-Malki,1 Mohammed Akhtara,1 Essa Abuhelaiqa.2 Hamad Medical Corporation, Doha, Qatar.

Background: Diabetic nephropathy (DN) is the leading cause of end stage kidney disease worldwide. Identification of clinical, laboratory and histopathological predictors of kidney failure in DN may improve outcomes.

Methods: We identified 45 kidney biopsies between 2017 to 2018 that were diagnosed with DN. Clinical, laboratory and histopathological variables were analyzed to prognosticate 1-year kidney failure.

Results: Sixteen of 45 patients with DN had kidney failure within 12 months of kidney biopsy while 29 patients did not. All patients who developed kidney failure had diabetic retinopathy as shown in table 1. Laboratory findings such a serum creatinine (597μmol/L vs. 205μmol/L, P<0.0001) and presence of hematuria (88% vs. 45%, P<0.01) prognosticated kidney outcome, while neither proteinuria or Hemoglobin A1C did. IFTA score (2.4 vs. 1.8, P=0.02) and global glomerular sclerosis (52% vs. 32%, P=0.002) were the only histological findings that prognosticate kidney failure. Patients who have a second kidney diagnosis in addition to DN such as IgA, FSGS and MN had favorable outcomes compared to DN and AIN or DN only [figure 1].

Conclusions: We identified serum creatinine, hematuria, IFTA and glomerular sclerosis as prognosticators of kidney failure at 1-year following DN diagnosis. Identification of patients at risk of kidney failure help individualize therapy and hence improve kidney outcomes.
PO0962
Phosphorylated Akt (pAkt) and Myostatin: The Yin and Yang of the Control of Muscle Protein Metabolism in Patients with Diabetic Kidney Disease

Daniela Picciotto,1 Samantha Milanesi,1 Michela Saio,1 Giuliano Brunori,2 Chiara Venturini,2 Giacomo Garibotto,1 Daniela Verzola.1 1Department of Internal Medicine, Nephrology Division, Policlinico San Martino, Genova, Italy; 2Ospedale Santa Chiara, Trento, Italy.

Background: Muscle wasting is common in patients with diabetic kidney disease (DKD). Both uremia and diabetes cause inflammation and insulin resistance in skeletal muscle, thus promoting wasting. However, the muscle response in DKD is not known yet. Our aim was to evaluate the intracellular signals controlling protein synthesis and degradation in muscle of patients with DKD. We studied intracellular pAkt (a downward effector of the insulin signal), myostatin (MSTN), p38MAPK, MURF and Atrogin in skeletal muscle of patients with diabetic CKD (DKCKD) (n=17, age 69 years±7, eGFR 9±3 ml/min/1.73m²) as compared to non diabetic CKD (NDCKD) (n=32, age 67 years±11, eGFR 7.5±2 ml/min/1.73m²) and controls (C) (n=24, age 67 years±11, eGFR 77±13 ml/min/1.73m²).

Methods: Rectus abdominis muscle biopsies were obtained during the insertion of peritoneal dialysis catheters and during elective surgery for abdominal wall hernias (C). Protein expression (pAkt, MSTN, p38MAPK) was evaluated by immunohistochemistry and western blot, mRNA expression (MSTN, Murf, Atrogin) by q-PCR.

Results: The expression of pAkt was significantly more downregulated in DKD as compared to NDCKD and C (P<0.05). MSTN expression was significantly lower in C as compared to DKCKD and NDCKD (P<0.05). MSTN mRNA was similarly upregulated in DKDCKD and in NDCKD with respectively a 21- and a 18- fold increase compared to controls. Atrogin and MURF mRNA were both upregulated in DKD and in NDCKD; in DKDCKD MURf mRNA presented a 18- and atrogin mRNA a 16- fold increase compared to controls while in NDCKD we found respectively a 12- and a 9- fold increase.

Conclusions: With respect to non DKD, intracellular insulin signaling is particularly blunted in muscle of patients with DKD, while myostatin is similarly overexpressed. In diabetes, the abnormal pAkt levels in conjuction with myostatin overexpression are likely to orchestrate the wasting syndrome.

PO0963
Incident CKD in Diabetes, Hypertension, and Prediabetes

Cami R. Jones,1 Kenn B. Daratha,1 Susanne B. Nicholas,2 Radica Z. Alickic,1 Obiduguw Duru,2 Keith C. Norris,3 Nilka Rios Burrows,4 Katherine R. Tuttle,4 Media E. Pavkov.1 1Division of Medicine, Providence Health and Services, WA; 2Spokane, WA; 3University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; 4Centers for Disease Control and Prevention, Atlanta, GA.

Background: Hypertension (HTN), diabetes mellitus (DM), and prediabetes (PDM) are major risk factors for chronic kidney disease (CKD), yet community-level longitudinal studies of CKD incidence are lacking. The study aim was to determine CKD incidence rates in these at-risk groups by practice- and guideline-based definitions.

Methods: The Center for Kidney Disease Research, Education, and Hope (CURE-CKD) registry is curated from electronic health records with clinical and administrative data from two large non-profit healthcare systems. CKD incidence (95% CI) in adults was calculated over 4, two-year time periods during 2010-2017 adjusted for age, sex, and race/ethnicity. CKD was identified by 2 definitions: 1. Practice-based, CURE-CKD: At least 2 laboratory measures for CKD ≥90 days apart (estimated glomerular filtration rate - eGFR <60 ml/min/1.73m², urine albumin/creatinine ratio - UACR ≥30 mg/g, or urine protein/creatinine ratio - UPCR ≥30 mg/g) or CKD administrative code. 2. Guideline-based, Kidney Disease Improving Global Outcomes (KDIGO): At least 2 eGFRs <60 ml/min/1.73m² or 2 UACRs/UPCRs ≥30 mg/g≥50 mg/g ≥90 days apart.

Results: Overall adjusted CKD incidence rates declined over 2010-2017 by both definitions with lower rates by KDIGO (Table). By CURE-CKD, CKD incidence increased in the HTN group.

Conclusions: The practice-based CURE-CKD definition produced higher estimates of CKD incidence than the stricter guideline-based KDIGO definition. CKD incidence declined in all groups, except for HTN by the CURE-CKD definition, and was highest in patients with DM/HTN. Targeting these at-risk conditions for control may mitigate new onset CKD in these groups.

New Diagnostic Model for the Differentiation of Diabetic Nephropathy from Non-Diabetic Nephropathy in Chinese Patients

Xiaomin Liu,1 Weiguang Zhang, Zheyi Dong, Qian Wang, Yizhi Chen, Yong Wang, Liangmei Chen, Guangyan Cai, Xiangmei Chen. Department of Nephrology Chinese PLA General Hospital, Chinese PLA Institute of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases, Beijing, Beijing, China.

Background: The differential diagnostic criteria of non-diabetic nephropathy (NDRD) and diabetic nephropathy (DN) usually depend on the 2007 KDOQI guideline, which is not accurate enough. Renal pathological biopsy is the gold standard for diagnosis, which is an invasive method and may cause several complications. This study aimed to construct a new noninvasive evaluation method for the differentiation of DN and NDRD.

Methods: We retrospectively screened 1030 patients (January 2005-March 2017). Variables were ranked in terms of importance, and random forest (RF) and support vector machine (SVM) were then used to construct the models. The final model was validated using an external group (338 patients, April 2017-April 2019), and compared with previous models.

Results: A total of 929 patients were assigned for model development. Ten variables were selected for the model development. The area under the receiver operating characteristic curve (AUCROC) for the RF and SVM methods were 0.953 and 0.947. A total of 329 patients were analyzed for external validation. The AUCROC for the external validation of the RF and SVM method were 0.920 and 0.911.

Conclusions: We successfully constructed predictive model for DN and NDRD by machine learning methods, which were better than traditional ways.

Funding: Government Support - Non-U.S.

Performance for SVM and other models in external validation

AUCROC, area under the ROC curve; NPV, negative predictive value; PPV, positive predictive value; SVM, support vector machine; RF, random forest

A Simulation Model for CKD Progression Among Patients with Type 2 Diabetes in the United States
Wen Ye,1 Shihchen Kuo,1 Ryan Farej,1 Rakesh Singh,1 Xueimei Ding,2 Nathaniel Putnam,2 Sheldon Kong,1 Jay Elliott,1 Jason Lott,1 William H. Herman,1 Bayer U.S. LLC, Whippany, NJ; 2Department of Biostatistics, University of Michigan, Ann Arbor, MI; 3Department of Internal Medicine, University of Michigan, Ann Arbor, MI.

Background: Patients with type 2 diabetes (T2D) and chronic kidney disease (CKD) are at a higher risk of end-stage renal disease (ESRD), cardiovascular diseases and mortality. Modeling CKD progression in patients with T2D can help guide disease management for reducing clinical and economic burdens of CKD.

Methods: We developed a discrete-state and discrete-time microsimulation model for predicting changes of underlying risk factors over time and the progression of kidney disease, coronary heart disease, and cerebrovascular disease among patients with T2D and CKD. Transition probabilities were modeled as patient-level characteristics and risk factors, current disease state, and treatment status, with model parameters derived from individual-level data and summary data in published literature. Changes in risk factors for ESRD (urine albumin to creatinine ratio [UACR], estimated glomerular filtration rate [eGFR]), and risk equations for ESRD, myocardial infarction (MI), congestive heart failure (CHF), stroke, and death without ESRD were developed using longitudinal data of a T2D subpopulation in the Chronic Renal Insufficiency Cohort (CRIC). This model underwent calibration and validation against the CRIC patients with T2D and CKD over a 7-year follow-up period.

Results: At baseline, 1,441 CRIC participants with T2D and CKD (mean age: 61.6 years) were available for the model development and validation. Concordance between observed and predicted outcomes for the five risk equations ranged from 0.71 to 0.90. The simulated event rates of ESRD, CHF, MI, and stroke using estimated changes in key risk factors, and the related 95% confidence intervals covered the observed event rates in CRIC.

Conclusion: Our model provided reliable estimates of disease progression among T2D patients with CKD. The modeling disease progression in this population will allow assessment of the impact of early detection and interventions, which may alter the economic and quality of life burden of CKD.

Joint Model of eGFR Slope: Data from LEADER in Patients with Type 2 Diabetes and High Risk of Cardiovascular Events
Johannes F. Mann,1,2 Heidrun Bosch-Traber,3 Soren Rasmussen,3 Benjamin Wolthers,2 Hiddo J. L. Heerspink,4,5 KIH Centre, Munich, Germany; 2Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Germany; 3Novo Nordisk A/S, Sorborg, Denmark; 4University of Groningen, University Medical Center Groningen, Groningen, Netherlands; 5The George Institute for Global Health, University of New South Wales Sydney, Sydney, NSW, Australia.

Background: The LEADER cardiovascular (CV) outcome trial (NCT0179048) suggested that liraglutide provides renal benefits vs placebo in patients with type 2 diabetes and high CV risk. Aiming to improve the modeling of eGFR slope (surrogate marker of renal outcomes), this post hoc analysis compared a joint model with the usual random slope model.

Methods: Two models were applied: 1) random slope model for eGFR using an effect modifier for treatment (liraglutide vs placebo) in change from baseline; 2) joint model using two processes (the same random slope model and a hazard model for time to a composite endpoint [all-cause death or ESRD]). These processes were correlated using a hazard model for time to a composite endpoint (all-cause death or ESRD). The processes were correlated using a hazard model for time to a composite endpoint (all-cause death or ESRD). This model undertook calibration and validation against the CRIC patients with T2D and CKD over a 7-year follow-up period.

Conclusion: The model provided reliable estimates of disease progression among T2D patients with CKD. Modeling disease progression in this population will allow assessment of the impact of early detection and interventions, which may alter the economic and quality of life burden of CKD.

PO0966

Large Database Longitudinal Assessment of Electrolyte Abnormalities in Diabetic Patients Receiving SGLT2 Inhibitors
Harish Shanbhag Seethapathy, Sophia Zhao, Andrew S. Allegretti, Sahir Kalim, Sagar U. Nigwekar. Massachusetts General Hospital, Boston, MA.

Background: In diabetic patients, the osmotic diuresis and natriuresis induced by sodium glucose co-transporter 2 (SGLT2) inhibitors produces changes in the serum level of electrolytes such as potassium, magnesium and calcium. Incidence of electrolyte abnormalities induced by these agents in a ‘real-world’ setting has not been studied.

Methods: We included all patients with diabetes who were prescribed canagliflozin, empagliflozin or dapagliflozin at our healthcare system between 2012-2019. Demographics, baseline medication use, comorbidities, and laboratory values were obtained by querying a centralized research repository. Serum electrolyte levels at SGLT2 inhibitor initiation were compared to electrolyte levels in the 6 months after initiation and the most extreme post-baseline levels were used to determine incidence of electrolyte abnormalities.

Results: In total, 1630 patients were included. Average age was 61 (SD 11) years, 63% identified as male, 71% as white. Hypertension was present in 85%, congestive heart failure in 20%; 18% had an estimated glomerular filtration rate (eGFR) <60 mL/min/m^2 and 12% had uncontrolled diabetes (A1C>10%). ACE inhibitor/ARB use was present in 80% and 5% of patients (n=81) had elevated potassium (>5mEq/L) at baseline. In the first 6 months after drug initiation in patients without elevated potassium at baseline (n=1549), 12% experienced new hyperkalemia (>5 mEq/L) with 4% of patients experiencing a potassium level >5.5 mEq/L. Potassium >6 mEq/L was seen in 1%. Ten percent of patients with eGFR60 mL/min/m^2 experienced hyperkalemia when compared to 21% of patients with eGFR<60 mL/min/m^2 (p=0.01). Hyponatremia (<135 mEq/L) was seen in 12% of patients, with values <130 mEq/L seen in 2%. Hypomagnesemia (<1.5 mg/dL) was present in 3% and hypocalcemia (albumin-corrected calcium<7 mg/dL) was seen in 0.1%.

Conclusion: Patients with eGFR60 mL/min/m^2 are particularly at high risk of developing hyperkalemia post-SGLT2 initiation. Effective monitoring and treatment strategies are needed to mitigate risks associated with hyperkalemia.

Hyperkalaemia Risk and Mortality in Patients with Diabetes
Philip McEwan,1 Michael A. Hurst,1 Louise Hoskin,1 Eskinder Tafesse,2 Karolina Badora,2 Daniel Sugrue,1 Glen James,1 1Health Economics and Outcomes Research Ltd, Cardiff, United Kingdom; 2Global Health Economics, Astrezeneca, Gaithersburg, MD; 3Global Medical Affairs, AstraZeneca, Cambridge, United Kingdom.

Background: Diabetes mellitus (DM) is associated with micro- and macrovascular complications, including chronic kidney disease (CKD) and cardiovascular events. Renin-angiotensin-aldosterone system inhibitors (RAASIs) are recommended for the management of these conditions; however, their usage may increase the risk of hyperkalaemia (HK), a potentially fatal electrolyte imbalance.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: Patients with type 1 or 2 DM aged ≥18 years were identified from linked primary and secondary care data from the UK Clinical Practice Research Datalink and Hospital Episode Statistics, respectively. DM and relevant complications/comorbidities (CKD; history of major adverse cardiovascular events [MACE] comprising arrhythmia, heart failure, myocardial infarction and stroke) were identified through READ codes recorded before the index date (2008–June 2018) or the five-year look-back period (2003–2007). Index date was the latter of 1st January 2008 or initial DM diagnosis. Event rates (adjusted for age and sex) of HK (serum potassium [SK] ≥5.0 mmol/L; ≥5.5 and ≥6.0 mmol/L were also explored) and all-cause mortality (ACM) were estimated over the follow-up period (from diagnosis of DM to the first of: death, loss to follow-up, end of study). Accumulation of complications/comorbidities over time resulted in re-classification.

Results: 288,871 DM patients were included with a mean follow-up of 5.87 years (standard deviation [SD] 3.23 years). Available follow-up (1,000 patient-years [PYs]) was 1,038 for DM + CKD + MACE and 89 for DM + CKD + MACE. ACM incidence increased in line with increasing comorbidity burden, to 146.73 per 1,000 PYs in the DM + CKD + MACE cohort. At the SK threshold of ≥5.0 mmol/L, the incidence of HK was highest in patients with CKD (797.27/635.26 per 1,000 PYs with/without MACE, respectively) and lower in patients without CKD (384.13/246.83 per 1,000 PYs with/without MACE, respectively). The same between-cohort pattern was observed at thresholds of ≥5.5 and ≥6.0 mmol/L. CKD and/or MACE was associated with higher levels of RAAS prescription (61.91% vs 74.86%–76.28%).

Conclusions: DM patients with CKD and/or MACE are at increased risk of HK and ACM. Routine monitoring of SK and prompt management of HK episodes could improve clinical outcomes in DM patients, particularly those with CKD and/or a history of MACE.

PO0971
Advanced CKD Augments the Risk of Hypoglycemia with Insulin Use
Daulton Grube1, Guo Wei,2 Robert E. Boucher,3 Srinivasan Beddhu,2 1University of Washington School of Medicine, Seattle, WA; 2The University of Utah School of Medicine, Salt Lake City, UT

Background: Both insulin use and CKD are known risk factors for hyperglycemia in type 2 diabetes (T2D) but it is unclear whether advanced CKD augments the risk of hypoglycemia with insulin use.

Methods: We analyzed a national veteran cohort (N = 944,891) with T2D defined by ICD-9 codes and outpatient serum creat measurements from 1/2008 to 12/2010. Index date was defined as the date of first outpatient serum creat measurement. Duration of T2D was calculated by the first occurrence of ICD-9 codes for T2D, Hba1C > 6.5% or use of anti-diabetic med from 10/1999 to the index date. Baseline comorbidities were similarly defined by ICD-9 codes. Insulin use at index date was determined by prescription data. Hypoglycemic episodes requiring medical attention were defined by ICD-9 codes and outpatient serum creat measurements from 1/2008 to 12/2010. A propensity score matched cohort was generated using propensity scores of baseline variables including demographics, duration of T2D, Hba1C, retinopathy, BMI, other anti-diabetic med and comorbidities was used to develop propensity scores of baseline insulin use (22% were on insulin at baseline). A propensity score matched cohort (N = 324,064) was used to relate baseline insulin use and CKD stages with subsequent hypoglycemic episodes in Cox regression models.

Results: Baseline mean age was 65.1±11 yrs, 19% black and mean cGFR 71±24. There were 16,648 of hypoglycemic episodes over 1,529, 224 years of follow up. There was a gradual increase in incidence rate of hypoglycemic events by CKD stages and insulin use (Fig). In a Cox regression model adjusted for propensity scores as well as above covariates, compared to cGFR ≥90 with no insulin use (Fig), the risk of serious hypoglycemic episodes was highest in the stage 4 CKD group on insulin (HR 4.79, 95% CI 4.31 to 5.32). Interaction p = 0.018 for insulin use and CKD stages for the risk of hypoglycemia.

Conclusions: Advanced CKD augments the risk of hypoglycemia with insulin use. Whether novel anti-diabetic agents are safer than insulin for the risk of hypoglycemia in advanced CKD needs to be studied.

PO0972
The Effect of Microalbuminuria on Long-Term Outcomes in Elderly Patients with Diabetes
Subin Hwang1, Kyungho Lee,2 Do Hee Kim,1 Hye Ryoun Jang,2 Woosong Hah,3 Yoon-Goo Kim,2 Dae joong Kim,1 Jung eun Lee.1 1Inje University Seoul Paik Hospital, Jung-gu, Seoul, Republic of Korea; 2Samsung Medical Center, Gangnam-gu, Seoul, Republic of Korea

Background: In current aging society, the number of elderly diabetes is rapidly growing worldwide. Despite strong evidence on the prognostic power of microalbuminuria in patients with diabetes, it remains uncertain that moderately increased urinary albumin excretion can identify elderly diabetes at high risk of ESRD (end stage renal disease) or mortality. This longitudinal study evaluated incidence of ESRD and mortality according to albuminuria amounts focusing on elderly diabetes.

Results: 1Bland-Altman analysis results demonstrated that consistency of eGFR-Cys2 equation and Ruijin with sGFR were better than other equation, but all the equation were above the limite professional point. The slopes of EPI-Cys2 equation were closer to the identical line. (2)Bias of EPI-Cys2 equation was smaller than other equations. EPI-Cys2 equation underestimated actual GFR and other equations overestimated GFR. 30% and 6% accuracy rate of Ruijin equation and EPI-Cys2 equation were higher than other equations. (3)As to diagnosis CKD in DM patients, EPI-Cys2 equation was more sensitive and accurate, and the cut-point of EPI-Cys2 equation and Ruijin equation was closer to 60ml/min.

Conclusions: All six equations show bias in estimating actual GFR. Compared with the equations induced by plasma creatine, EPI-Cys2 equation was more accurate and efficient, and followed by Ruijin equation. All equations should be amended when applying to Chinese DM patients.

PO0969
Cumulative Average and Variability of Blood Glucose, Blood Pressure, and Lipids Are Associated with Incidence of Albuminuria, but Not Reduced Kidney Function, Among Patients with Type 2 Diabetes
Jingjian Wang,1 Luxia Zhang,1 Ming Hui Zhao,2 1Peking University First Hospital, Beijing, China; 2National Institute of Health Data Science at Peking University, Beijing, China; 3Peking-Tsinghua Center for Life Sciences, Beijing, China

Background: We evaluated the effect of cumulative average and variability of fasting blood glucose, blood pressure and lipids on the incidence of albuminuria and reduced estimated glomerular filtration rate (eGFR) among a population with diabetes.

Methods: The study was based on the Kailuan cohort in Tangshan of China. The study baseline was the 2014-2015 circle of health examination. Totally, 1569 patients with type 2 diabetes identified in the 2008-2009 circle, with participation of at least 3 circles of health examination (3-5 times) between 2008 and 2015, and with negative finding in dipstick test and a normal cGFR at baseline were included. The occurrence of albuminuria (urine albumin to creatinine ratio ≥30mg/g) and eGFR<60ml/min/1.73m2 (with an absolute decline of ≥10%) was ascertained during 2016-2017. cGFR was determined with the CKD- EPI creatinine equation in the 2014-2015 circle and corresponding cystatin-C equation in the 2016-2017 circle. Cumulative average and intravariandial standard deviation (SD) of fasting blood glucose (FBG), systolic blood pressure (SBP), triglycerides and low-density lipoprotein cholesterol (LDL-C) were calculated. Multivariable logistic regression was used to estimate the association of the average and SD values of each variable with the events.

Results: The mean age of the population was 61.8±8.6 years, with a male dominance (77.6%). In the 2016-2017 circle, there were 499 events of albuminuria and 184 of reduced estimated GFR. Both average and SD of SBP were associated with both albuminuria amounts focusing on elderly diabetes.
Methods: We retrospectively identified 3,065 elderly (aged ≥65 years) diabetes. The primary outcomes were incidence of ESRD (considering competing risk with death) and all-cause death. The association between albuminuria (normoalbuminuria, urine albumin to creatinine ratio [uACR] <30 mg/g, microalbuminuria, uACR 30-300 mg/g, and macroalbuminuria, uACR >300 mg/g) and outcomes focusing on elderly (≥65 years) and very elderly (≥75 years) with diabetes were evaluated.

Results: The age was 71.1 (5.0) years and the duration of diabetes was 13.4 (8.7) years. Median follow-up duration was 89 (19.6) months. Overall, microalbuminuria and macroalbuminuria were observed in 25.5% and 9.4% of subjects, respectively. For normoalbuminuria, microalbuminuria, and macroalbuminuria, probability of ESRD and cumulative all-cause death at 8 years was 1.0%, 6.3%, and 29.7% (P<.0001), and 13.1%, 27.4%, and 31.7% (P<.0001), respectively. Using proportional-hazards regression models, albuminuria amounts were independently associated with increased risk of ESRD (fully adjusted hazard ratios [HR] including kidney function: 3.92 [95% CI, 1.29-6.70] for microalbuminuria, 11.16 [6.47-19.24] for macroalbuminuria). The HR of all-cause death were 1.46 (1.21-1.76) for microalbuminuria and 1.42 (1.08-1.86) for macroalbuminuria. The associations between albuminuria amounts and the risk of ESRD and all-cause death were consistent in very elderly (≥75 years).

Conclusions: We demonstrated that microalbuminuria is a risk factor of incident ESRD and death even in elderly diabetes, as well as in very elderly. Further studies are needed to determine whether albuminuria can be a therapeutic target in this population.

Risk of Cardiovascular Disease, CKD, and Cardiovascular Mortality
According to 2017 ACC/AHA Blood Pressure Categories in Diabetes
Miryung Kim, Jun Young Lee, Jae Won Yang, Seung-Ok Choi, Jae seok Kim, Minseob Eom, Hanwul Shin. Yonsei University Wonju College of Medicine, Wonju, Republic of Korea.

Background: The association between blood pressure (BP) and cardiovascular disease (CVD) and chronic kidney disease (CKD) in diabetes patients remains unclear.

Methods: By using an analysis based on the National Health Insurance Database of Korea, 8, 922, 940 persons were screened between 2009 to 2014. We determined the disease (CVD) and chronic kidney disease (CKD) in diabetes patients remains unclear. For normoalbuminuria, microalbuminuria, and macroalbuminuria, probability of ESRD and cumulative all-cause death at 8 years was 1.0%, 6.3%, and 29.7% (P<.0001), and 13.1%, 27.4%, and 31.7% (P<.0001), respectively. Using proportional-hazards regression models, albuminuria amounts were independently associated with increased risk of ESRD (fully adjusted hazard ratios [HR] including kidney function: 3.92 [95% CI, 1.29-6.70] for microalbuminuria, 11.16 [6.47-19.24] for macroalbuminuria). The HR of all-cause death were 1.46 (1.21-1.76) for microalbuminuria and 1.42 (1.08-1.86) for macroalbuminuria. The associations between albuminuria amounts and the risk of ESRD and all-cause death were consistent in very elderly (≥75 years).

Conclusions: We demonstrated that microalbuminuria is a risk factor of incident ESRD and death even in elderly diabetes, as well as in very elderly. Further studies are needed to determine whether albuminuria can be a therapeutic target in this population.

PO0973

Cardiovascular Disease and Medication Use by CKD Risk Groups in People with Type 2 Diabetes: A Post Hoc Analysis from CAPTURE
Giuseppeina Russo,1 Abdullah Aigualuwe,2 Fahri Bayram,3 Patrione Darmon,4 Timothy Davis,5 Kirsten T. Eriksen,5 Tuan-Pei Hong,5 Margit S. Kaltoff,6 Csaba Lengyel,8 Jose Luis Arenas Leon,6 Ofri Mosenzon,10 Nicolai Rhee,11 Shinichiro Shirabe,12 Katerina Urbancova,13 Sergio Vencio,14 Guillermo Diezzeide,15 University Hospital, Messina, Messina, Italy;1 King Saud University, King Saud University Medical City, Riyadh, Saudi Arabia; 1Erzyes University, Kayseri, Turkey;1 Hôpital de la Conception, Marseille, France; University of Western Australia, Fremantle Hospital, Fremantle, WA, Australia;1 Novo Nordisk A/S, Søborg, Denmark;1 Peking University Third Hospital, Beijing, China;1 University of Szeged, Szeged, Hungary;1 Centro de Atención e Investigación Cardiovascular del Potosí, San Luis Potosí, Mexico;1 Hadassah Medical Center, Diabetes Unit, Hebrew University, Jerusalem, Israel;1 Novo Nordisk Healthcare AG, Zurich, Switzerland;2 H.E. C Science Clinic, Yokohama, Japan, Diabetesologica Interni Ambulato, Ostrava, Czechia;1 Instituto de Ciencias Farmaceuticas, Aparecida de Goiania, Brazil;1 Centro de Atención Integral en Diabetes, Buenos Aires, Argentina.

Background: The CAPTURE study estimated the contemporary (2019) prevalence of cardiovascular disease (CVD) in people with type 2 diabetes across 13 countries. This post hoc analysis describes the occurrence of CVD and medication use by chronic kidney disease (CKD) risk groups.

Methods: CAPTURE was a multinational, cross-sectional, non-interventional study conducted between December 2018 and September 2019. Data on CVD diagnoses, estimated glomerular filtration rate (eGFR), urine albumin level and glucose-lowering agents (GLA)/CVD medication use was collected during routine visits. Participants were categorized by CKD risk by eGFR and urine albumin thresholds according to the KDIGO classification.

Results: Of 9823 participants, 7923 (81%) had eGFR data, 6482 (66%) had urine albumin creatinine ratio (UACR) data, and 5829 (59%) had both measures available. The distribution by eGFR (<60, 60-89, 30-399, ≥300 mg/dl) was 35%, 44%, 18% and 3%, respectively, and by UACR (<30, 30-399, >300 mg/dl) 67%, 25% and 8%, respectively. By KDIGO risk group (low, moderate, high, very high), CVD prevalence was 29%, 44%, 53% and 59%, respectively. Use of GLA decreased with increasing CKD except for insulin which increased. Use of renin angiotensin aldosterone system inhibitors was 49-72% across risk groups (Table).

Conclusions: This post hoc CAPTURE analysis demonstrated a positive association between CVD prevalence and CKD risk. CVD medications with proven CVD benefits, including GLA, were underused.

PO0975
Cardiovascular Autonomic Dysfunction Is Associated with Decline in Kidney Function in Type 2 Diabetes and Healthy Controls
Jens christian Laursen,1,3 Ida Rasmussen,1 Emilie Hein Zobel,1 Christian S. Hansen,1 Marie Frimodt-Moller,2 Bernt Johan Von Scholten,2 Tine Hansen,1 Peter Rossing,1,3 Steno Diabetes Center Copenhagen, Gentofte, Denmark; 2Novo Nordisk AS, Bagsvaerd, Denmark; 3Kobenhavns Universitet, Kobenhavn, Denmark.

Background: Cardiovascular autonomic dysfunction is a prevalent and severe complication in type 2 diabetes. We assessed the impact of cardiac autonomic dysfunction on change in kidney function and albuminuria in a cohort of persons with type 2 diabetes and healthy controls.

Methods: In 2013 we recruited 60 persons with type 2 diabetes and 30 controls. Estimated glomerular filtration rate (eGFR) and urinary albumin excretion rate (UAER) were measured at baseline and follow up. Cardiovascular reflex tests were performed, and continuous parameters of cardiovascular autonomic function was assessed from heart rate variability in a 5-minute resting ECG.

Results: For the follow up, 32 persons with type 2 diabetes and 21 controls were willing to participate and included in the analyses. Median [IQR] follow-up time was 6.2 [6.0 to 6.3] years. At baseline, mean ± SD age was 60 ± 10 years, median kidney function was 12 [5 to 21] years and mean HbA1c in the type 2 diabetes group was 54 ± 11 mmol/mol. At baseline, mean eGFR was similar between groups (type 2 diabetes: 79 ± 21 ml/min/1.73m² and controls: 86 ± 12 ml/min/1.73m²; p=0.183) and median UAER was higher (p=0.001) in the type 2 diabetes group (33.5 [6.5 to 107.5] mg/24-h) than controls (5.5 [5.0 to 6.5] mg/24-h). During follow up, eGFR decreased in both groups of type 2 diabetes: -1.0 [95%CI: -1.4 to -0.5] ml/min/1.73m²/year (p=0.001) and controls: -0.95 [95%CI: -1.4 to -0.5] ml/min/1.73m²/year (p=0.001) and the change was similar between groups (p=0.179). Albuminuria did not change. After adjustment for age, sex, smoking, HbA1c, body mass index, heart rate, 24-hour systolic blood pressure, plasma cholesterol, baseline UAER and baseline eGFR, a lower response in heart rate variability during Valsalva (p=0.016) and a lower SDNN (p=0.029) were significantly associated with a steeper yearly decline in eGFR. Cardiovascular autonomic function was not associated with change in albuminuria.

Conclusions: Cardiovascular autonomic dysfunction assessed by heart rate variability was associated with steeper decline in kidney function during 6 years of follow up. Cardiovascular autonomic dysfunction may be a predictor of higher risk of decline in eGFR. Whether there is a causal link remains to be established.

PO0976
Changes in Cardiac Microvascular Function in Persons with Type 2 Diabetes in Relation to Kidney Function
Ida Rasmussen,1 Philip Hasbak,2 Bernt Johan Von Scholten,1 Jens christian Laursen,1 Emilie Hein Zobel,1 Lene Holmvang,2 Rasmus S. Ripa,2 Peter Rossing,1 Andreas Kjaer,2 Tine Hansen,1 Steno Diabetes Center Copenhagen, Gentofte, Denmark; Rigshospitalet, Kobenhavn, Denmark.

Background: The myocardial flow reserve (MFR) reflects the function of both large epicardial arteries and the microcirculation. Coronary artery calcium score (CACS) is a measure of coronary atherosclerosis. Cardiac ⁸²Rb PET/CT provides a measurement of both MFR and CACS. Knowledge on changes in MFR and CACS over time and the impact of kidney function on these changes is lacking.

Methods: In 2013 we recruited 60 persons with type 2 diabetes (T2D) and 30 non-diabetic controls (C); all free of overt cardiovascular disease. All underwent a cardiac ⁸²Rb PET/CT scan. In 2019, survivors (n=82) were invited for a repeated cardiac ⁸²Rb PET/CT scan after a similar protocol. 29 with T2D and 19 C participated.

Results: Median [interquartile range] duration between visits was 6.2 [6.0–6.3] years. The Table summarizes kidney function, MFR and CACS at the 2 visits. MFR was lower in persons with T2D compared to C but was similar between both groups (p=0.62) and did not differ between visits within the groups (C:p=0.51, T2D:p=0.001). CACS was higher in persons with T2D compared to C at both visits. CACS increased between visits within both groups (C:p=0.015, T2D:p<0.001), and the change was higher in T2D (p=0.002). In the total cohort, lower eGFR at baseline was associated with higher decline in MFR (p=0.027), but not after adjustment (p=0.70). Increase in CACS was higher in men (p=0.03), but not after adjustment (p=0.07). Changes in MFR and CACS were not associated with other risk factors at baseline.

Conclusions: MFR was lower in T2D compared to C but did not change significantly in either of the groups when evaluated over 6 years. Kidney function had no independent impact on changes in MFR or CACS.
The Predictive Value of Diabetic Retinopathy on Subsequently Diabetic Nephropathy in Patients with Type 2 Diabetes: A Systematic Review and Meta-Analysis of Prospective Studies

Tianjun Guan, Yu Li, Anqun Chen. Division of Nephrology, Zhongshan Hospital, Xiamen University, Xiamen, China.

Background: Studies have already demonstrated diabetic retinopathy (DR) was associated with an increased risk of diabetic nephropathy (DN) in patients with type 2 diabetes (T2D), whereas the predictive value of DR on subsequent DN for T2D were not illustrated. Therefore, we conducted a meta-analysis of prospective cohort studies to assess the predictive value DR on further DN risk in patients with T2D.

Methods: The PubMed, Embase, and the Cochrane library were systematically searched for eligible prospective cohort studies through March 2020. The predictive value of DR were assessed using sensitivity, specificity, positive and negative likelihood ratio (PLR and NLR), diagnostic odds ratio (DOR), and area under the receiver operating characteristic curve (AUC).

Results: Ten prospective cohort studies recruited a total of 635 patients with T2D were selected for this study. After pooling all studies, we noted the pooled sensitivity, and specificity of DR for predicted DN were 0.64 (95%CI: 0.54-0.73), and 0.77 (95%CI: 0.60-0.88), respectively. The pooled PLR and NLR of DR for predicted DN were 2.72 (95%CI: 1.42-5.19), and 0.47 (95%CI: 0.33-0.67), respectively. The summary DOR for the relationship between DR and subsequent DN for T2D patients was 5.53 (95%CI: 2.00-15.30), and the AUC of DR for predicted DN was 0.73 (95%CI: 0.69-0.77). The predictive value of DR for subsequent DN could affect by mean age, percentage male, and study quality.

Conclusions: This study found significant associations between DR and subsequent DN risk for patients with T2D, while the predictive value of DR was mild. Further prospective study should be assessed for the predictive value of DR on other conditions in T2D patients with specific characteristics.

Association Between the Urinary Proteome and Diabetic Retinopathy in the DIRECT-Protect 1 and 2 Trials

Viktor Rotbaum Curovic, 1 Pedro Magalhães, 2 Tine Hansen, 1 Harald Mischak, 2 Peter Rossing, 3 1Steno Diabetes Center Copenhagen, Gentofte, Denmark; 2Mosaiques Diagnostics, Hannover, Germany; 3Københavns Universitet, Copenhagen, Denmark.

Background: Diabetic retinopathy (DR) is a complication of paramount importance in type 1 and type 2 diabetes. Given the association of DR and diabetic kidney disease (DKD), we investigated the association between the urinary proteome and the presence of DR in patients with type 1 and type 2 diabetes, and the identified peptide fragments were not conclusively associated to development of diabetic retinopathy.

Methods: Baseline proteomic analysis was performed in both the DIRECT-Protect 1 and 2 studies in a random selection of 800 and 821 subjects respectively. The DIRECT-Protect studies were designed to assess the effect of candesartan in relation to development of DR endpoints. DIRECT-Protect 1 was considered the discovery cohort and DIRECT-Protect 2 the validation cohort. Endpoints were defined as a two-step (RET2) or three-step (RET3) change in DR score according to the Early Treatment Diabetic Retinopathy Study (ETDRS) protocol. Urinary peptide levels were correlated to baseline DR score in the discovery cohort. Thereafter, identified peptide fragments were investigated for association to baseline DR score in the validation cohort and for development of endpoints in both cohorts, adjusted for sex, age, diabetes duration, smoking, total cholesterol, HbA1c, systolic blood pressure, urinary albumin excretion rate, serum creatinine, and randomization group at baseline.

Results: Follow-up ranged from 4.0-4.7 years. Eleven out of 427 peptide fragments were inversely associated to baseline DR in the discovery cohort after adjustment. In multivariate Cox regression analyses lower alpha-1 type I collagen (COL1A1) (seq. ApGΔD–), GKN2C, and LGD1– was significantly (p<0.05) associated to the development of RET2 and lower COL1A1 (seq. LGD2–) and COL1A1 (seq. EDGΔK–) to RET3. However, when attempting to validate these results, only a KER12 fragment was inversely associated to baseline DR in the validation cohort, as well as to development of RET3. Furthermore, lower levels of one COL1A1 fragment (seq. AFGΔS–) was associated to development of RET2 in the validation cohort.

Conclusions: Several urinary peptide fragments were associated to the presence and worsening of DR in type 1 diabetes. However, this could not be validated in type 2 diabetes, and the identified peptide fragments were not conclusively associated to deterioration of DR across both cohorts.
Background: Diabetes (DM) is the leading cause of end-stage renal disease worldwide. Microalbuminuria (MA) is considered a gold standard to diagnose diabetic nephropathy (DN), however its detection of early kidney damage is questionable. Therefore, there is an emergent need for novel biomarkers to capture early molecular alterations preceding MA. Cubilin is a 460 kd size protein lacking a transmembrane domain and is coexpressed with megalin facilitating albumin endocytosis in proximal tubule epithelial cells. We hypothesize that cubilin trafficking is compromised and is amenable to urinary shedding in DM. We propose that urinary cubilin shedding predicts DN.

Methods: This study assessed urinary IL-8, cubulin, monocyte chemotactic factor [MCP-1], NGAL, and VDBG levels did not significantly differ across the groups.

Conclusions: We demonstrated that urinary cubilin shedding is a reliable biomarker for predicting progressive DN in T1D preceding microalbuminuria. Although not statistically significant, IL-8 levels were elevated in patients with significant proteinuria and decline in GFR. The role of urinary cubilin shedding as a biomarker for the diagnosis and treatment of diabetic nephropathy at an early stage should be examined in a larger patient population.

**PO0984**

The Importance of Addressing Multiple Risk Markers in Type 2 Diabetes: Results from the LEADER Trial

Emilie Hein Zobel,1 Tine Hansen,1 Frederik Persson,1 Soren Rasmussen,2 Bernt Johan Von Scholten,1,2 Benjamin Wolthers,3 Peter Rossing,1,2,3 Steno Diabetes Center Copenhagen, Gentofte, Denmark; 2Novo Nordisk A/S, Søborg, Denmark; 3Københavns Universitet, København, Denmark

Background: The benefit of multifactorial intervention in type 2 diabetes (T2D) was demonstrated in the small Steno-2 study in microalbuminuric T2D. Larger studies in more diverse cohorts are limited. We investigated the importance of multiple risk-marker change for micro- and macrovascular outcomes in the LEADER trial.

Methods: LEADER (N=9340, ClinicalTrials.gov number NCT01179048) randomized patients with T2D to lixisenatide or placebo (S11) in addition to standard of care. We categorized patients according to number of risk markers with a clinically relevant change at year 1 of treatment and investigated subsequent risk of an expanded cardiovascular outcome (MACE-6) or nephropathy. We defined clinically relevant change in MACE-6 as: body weight loss ≥5%, HbA1c reduction ≥1%, systolic blood pressure reduction ≥5 mmHg, LDL reduction ≥0.5 mmol/L, eGFR reduction ≥0.1 ml/min/1.73m² and urinary albumin-to-creatinine ratio reduction ≥30% of baseline value. Numbers of risk markers with change were classified as: none (group G0), 1 (G1), 2 (G2), 3 (G3) and 4 (G4). Cox regression analysis risk of the outcomes adjusted for continuous baseline levels of the risk markers.

Results: Compared to patients with no risk-marker change, risk of cardiovascular disease was lowest for patients with 2 (HR [95% CI] 0.81 [0.66–0.98]) or 3 (0.80 [0.65–0.92]) risk-marker changes, and risk of nephropathy was lower for those with 3 (0.50 [0.35–0.72]) or ≥4 (0.45 [0.31–0.73]) risk-marker changes (Table). Test for trend of number of improved risk markers as a continuous variable: p=0.004 and p<0.001, respectively.

Conclusions: Improvement in multiple risk markers within 1 year translates into reduced risk of micro- and macrovascular outcomes in T2D, underscoring the benefit of pleiotropic antidiabetic treatments.
Microscopic Hematuria Is a Risk Factor for ESKD in Patients with Biopsy-Proven Diabetic Nephropathy

Riri Katsuhito, Masashi Eriguchi, Hikari Tasaki, Fumihiro Fukuta, Masatoshi Nishimoto, Takaki Kosugi, Kaori Tanabe, Katsujiro Morimoto, Sadamichi Okamura, Masaru Matsui, Ken-ichi Saimotani, Kazuhiko Tsutuya, Nara Medical University, Kasihara, Japan; Nara Prefectural Western Medical Center, Ikoma, Japan; Nara Prefecture General Medical Center, Nara, Japan.

Background: Microscopic hematuria is rarely observed in patients with diabetic nephropathy (DN). Some studies have reported that hematuria is a risk factor for end-stage kidney disease (ESKD) in glomerulonephritis, but association of hematuria with renal prognosis in DN is unknown.

Methods: The present study is a retrospective cohort study of patients with DN confirmed by renal biopsy between June 1981 and December 2014. The participants were followed until October 2018 or death. Exposure of interest is the presence of hematuria (U-RBC >5) and main outcome was the occurrence of ESKD. The association of hematuria with ESKD was evaluated using Cox hazard model with adjustment for clinically relevant factors [age, sex, eGFR, proteinuria, body mass index, systolic blood pressure (SBP) and pathological evaluations].

Results: Patients who had microscopic hematuria at the time of renal biopsy were defined as a hematuria group (N = 189), and the remainder as the non-hematuria group (N = 306). Hematuria group had more proportion of male, higher SBP, more proteinuria, and lower eGFR compared with non-hematuria group. Pathological findings revealed that glomerular, tubulointerstitial, and vascular lesions in the hematuria group were significantly more severe than those in the non-hematuria group. During a median follow-up period of 80 months, 44 and 52 patients developed ESKD in the hematuria group and non-hematuria group, respectively. Survival analyses showed that incidence of ESKD was significantly higher in the hematuria group (P <0.0001). The significance remained robust even after adjustment for and founding factors (adjusted HR 1.64, 95% CI 1.03-2.60). In the subgroup analyses, the associations of hematuria with ESKD among male and overt proteinuria (≥0.5 g/day) were stronger than those among female and micro proteinuria (<0.5 g/day), respectively (P values for interaction <0.1 and <0.03, respectively).

Conclusions: The presence of microscopic hematuria is an independent risk factor for ESKD in diabetic nephropathy.
PO0990
Virtual Patient Simulation in Diabetic Kidney Disease: Successful Strategy for Improving Recognition and Management
Amy Larkin, Medscape LLC, New York, NY.

Background: We sought to determine if virtual patient simulation (VPS)-based continuing medical education (CME) intervention could improve performance of nephrologists related to recognition and management of diabetes kidney disease (DKD).

Methods: The intervention comprised a patient presenting at two different time points in a VPS platform that allows learners to order lab tests, make diagnoses, and prescribe treatments in a manner matching the scope and depth of actual practice. Tailored clinical guidance (CG), based on current evidence and expert recommendation, was provided following each decision, followed by the opportunity for the learner to modify to their decisions. Decisions were collected post-CG and compared with each user’s baseline (pre-CG) decisions using a McNemar’s test to determine P values. The activity posted August 30, 2019; initial data was collected through November 7, 2019.

Results: 139 nephrologists completed the activity (all decisions within at least 1 case) and were included. Significant improvements were observed after CG: 1) Patient: Diagnosis DKD stage 3b: 28% absolute improvement (19% pre-CG vs 47% post-CG; P<.01) Diagnosis T2D: 33% absolute improvement (5% pre-CG vs 38% post-CG; P<.01) Initiate SGLT2 inhibitor: 53% improvement (17% pre-CG vs 70% post-CG; P<.01) Oral patient education: 15% improvement (52% pre-CG vs 67% post-CG; P<.01) 2) Patient: Diagnosis DKD stage 3a: 33% absolute improvement (24% pre-CG vs 57% post-CG; P<.01) Diagnosis T2D: 41% absolute improvement (10% pre-CG vs 51% post-CG; P<.01) Initiate SGLT2 inhibitor: 36% improvement (48% pre-CG vs 84% post-CG; P<.01) Initiate ACE inhibitor: 18% improvement (82% pre-CG vs 100% post-CG; P<.01) Oral patient education: 14% improvement (59% pre-CG vs 73% post-CG; P<.01)

Conclusions: VPS that immerses and engages specialists in an authentic and practical learning experience can improve evidence-based clinical decisions related to patient identification and management of hyperkalemia.

Effect of Multidisciplinary Care Models on Glomerular Filtration Rate for Patients with Diabetic Kidney Disease: Systematic Review and Meta-Analysis
Andrea Dib, Andric C. Perez-Ortiz, Daniela Conterras Estrada, Laura Cantillo, Lorea Anasagasti, Bani Antonio Aguirre, Diego S. Gutiérrez, Gregorio T. Obrador, Universidad Panamericana, Ciudad de Mexico, Mexico.

Background: Since 2015, the Kidney Disease Improving Global Outcomes guidelines advocate for comprehensive conservative care for diabetic nephropathy (DN) patients. Multidisciplinary care (MCD) models are such strategies that offer integrated care to delay renal disease progression, reduce micro- and macrovascular complications of diabetes, increase the quality of life, and reduce associated costs. Prior reviews have assessed the effect of MCDs in all-cause mortality, hospitalization rate, and need for temporal or permanent renal replacement therapy. However, to date, there are no reviews on their impact on glomerular filtration rate (GFR).

Methods: We conducted a systematic search of observational and randomized trials on DN GFR assessments. We searched Ovid and PubMed databases. Following the STROBE and CONSORT recommendations, we assessed the quality of evidence and any selection/information bias from our resulted pool of evidence. Our primary outcome was GFR quantifications between MCD vs. non-MCD DN treated patients. We performed a meta-analysis of these measurements using random and fixed effects models and examined inter-study heterogeneity with meta-regression models.

Results: There were 93 records from our systematic search. We screened titles and abstracts and retrieved eight records (9,892 participants) for qualitative and quantitative abstracts and retrieved eight records (9,892 participants) for qualitative and quantitative assessments. By subgroup analyses, MCD had a statistically significant effect on GFR among younger patients (<65 years, x±3-fold increase in GFR vs. non-MCD) with long-term follow-up (>2 years, x±57-fold increase in GFR vs. non-MCD) (Table).

Conclusions: Based on eight records with significant sample size, MCDs might have a positive effect on GFR if implemented earlier (preferably before age 65). However, this benefit might not be seen immediately, rather in the long-term. We suggest implementing these approaches as standard of care for DN.

Outcomes of Diabetic vs. Non-Diabetic Patients in the GCC Dialysis Outcomes and Practice Patterns Study
Brian Bieber,1 Saeed Al-Ghamdi,2 Mona Al Rukhaimi,3 Ali AlSahow,4 Issa AlSalmi,5 Fadwa M. Al-Ali,6 Ali Alaradi,7 Bruce M. Robinson,8 Ronald L. Pisoni,9 On behalf of the GCC-DOPPS Study Group 1Arbor Research Collaborative for Health, Ann Arbor, MI; 2King Abdulaziz University, Jeddah, Saudi Arabia; 3Dubai Medical College, Dubai, United Arab Emirates; 4Jahra Hospital, Jahra, Kuwait; 5The Royal Hospital, Ministry of Health, Mascat, Oman; 6Hamad General Hospital, Doha, Qatar; 7Salmaniya Medical Complex, Manama, Bahrain.

Background: Diabetes is a common comorbidity among hemodialysis (HD) patients in the Gulf Cooperation Council (GCC) countries, higher than any other region participating in the Dialysis Outcomes and Practice Patterns Study (DOPPS). Objectives of this analysis were to describe the prevalence of glycated-hemoglobin (HbA1c) measurement, distribution of HbA1c and association of HbA1c with mortality among participants in the GCC DOPPS.

Methods: 2,274 HD patients were analyzed from 6 GCC (Bahrain, Kuwait, Oman, Qatar, Saudi Arabia, United Arab Emirates) participating in DOPPS phase 5 (2012-2015) and 6 (2015-2018). Diabetic status was based on cause of ESKD or medical chart diagnosis. Cox regression was used to assess the associations of diabetes (among all GCC patients) and baseline HbA1c (among diabetic patients) with mortality adjusted for demographics, comorbidities, creatinine, and Kt/V.

Results: Overall 60% of GCC DOPPS participants were diabetic (country prevalence ranged from 45% in Saudi Arabia to 74% in Kuwait). Compared to non-diabetic patients, patients with diabetes were older (60 vs. 47) on dialysis fewer years (1.5 vs. 3.0), and had higher BMI (27.6 vs. 24.9). Diabetes was associated with elevated mortality; adjusted HR(95% CI)=1.69 (1.21-2.34). Measurement of HbA1c within the four months prior to enrollment was variable – ranging from 0% in Bahrain and 33% in Saudi Arabia to 60-78% in other GCC countries. Among diabetic patients with HbA1c measured, median [IQR] HbA1c was 6.8 [5.8-7.1]. A moderate U-shaped relationship with HbA1c and mortality was observed after adjustment.

Conclusions: Although diabetes is highly prevalent in the GCC HD population, measurement of HbA1c remains variable among this population. The relationship of HbA1c with mortality appears similar to that in other DOPPS regions. Further investigation related to frequency of measurement and control of HbA1c via treatment is warranted.

PO0993
Self-Management and Progression of Patients with Diabetic Kidney Disease (DKD): A Retrospective Cohort Study
Yifan Wu1, Ping Wang,2 Li Luo,3 Min Zhang,4 Bingqing Xia,5 Lizhe Fu,6 Fang Tang,7 Xinlong Zhang,8 Xusheng Liu,9 Fuhua Lu,1 Renal Division, 1The Second Affiliated Hospital of Guangzhou University of Chinese Medicine (Guangdong Provincial Hospital of Chinese Medicine), Guangzhou, China; 2Department of Internal Medicine, Yufa Hospital with elevated mortality, adjusted HR(95% CI)=1.69 (1.21-2.34). Measurement of HbA1c within the four months prior to enrollment was variable – ranging from 0% in Bahrain and 33% in Saudi Arabia to 60-78% in other GCC countries. Among diabetic patients with HbA1c measured, median [IQR] HbA1c was 6.8 [5.8-7.1]. A moderate U-shaped relationship with HbA1c and mortality was observed after adjustment.

Conclusions: Although diabetes is highly prevalent in the GCC HD population, measurement of HbA1c remains variable among this population. The relationship of HbA1c with mortality appears similar to that in other DOPPS regions. Further investigation related to frequency of measurement and control of HbA1c via treatment is warranted.

Funding: Commercial Support - This abstract was sponsored specifically by Amgen Middle East FZ LLC. Global support for the ongoing DOPPS Programs is provided without restriction on publications by a variety of funders. For details see https://www.dopps.org/AboutUs/Support.aspx.

Background: Few specifics were proved effective to delay DKD progression while accumulating evidence supported potential merits of self-management on it. This study aimed to evaluate the association between self-management and progression of non-diabetic CKD3-5 DKD patients.

Methods: Data including demographics, procedure notes, laboratory findings, and medication of the included cohort were analyzed. The cohort was divided into self-management group and control group based on previous self-management exposure. The between-group comparison of renal function at 2 years and survival analysis were conducted.

Results: Total 92 patients were included(47 in self-management group and 45 in control group). Declined serum creatinine level and preserved eGFR were detected in self-management group after 2 years both with no significant difference(ΔeGFR=-0.69, P=0.56), while significantly higher serum creatinine level(ΔP=0.01) and decreased eGFR with no evident significance(ΔeGFR=-0.059) after 2 years were found in control group. We defined eGFR<50ml/1.73 m2, initiation of renal replacement therapy and death as composite endpoints, and calculated time-to-event point in self-management group(mean survival time 221.3±12.97 weeks) and 17 in control group(mean survival time 168.3±15.03 weeks) were recorded, with significant difference between group(p=0.012). Further Cox proportional hazards regression with three adjustment models showed that self-management engagement was an independent factor associated with reduced risk of incident endpoints.

Conclusions: The findings documented predisposing preserved renal function of patients with self-management at 2 years and self-management engagement as an independent factor for decreased risk of endpoints, indicating its potential benefits on delaying DKD progression.
PO0994

Attitude Toward Care and Dietary Patterns Differ in CKD and Transplant Patients with and Without Diabetes

Iqra Nadeem, Takisha Morancy, Ahmad Saleh, Kingsley Cruickshank, Maritza Markell. SUNY Downstate Health Sciences University, Brooklyn, NY.

Background: Diabetes mellitus requires dietary changes and increased interaction with the healthcare team over that required by kidney disease alone. We compared dietary adherence and attitudes in pts with kidney disease with and without diabetes in inner-city Brooklyn.

Methods: A face-to-face survey was conducted in a random convenience sample of pts from CKD (23) and transplant (33) clinics. Diet was studied by 24-hour recall using ASA24 software. Healthy Eating Index was calculated using the HEI-15 score. The Beliefs in Medicine Questionnaire (BMQ) was used to elicit attitudes toward the healthcare environment. Comparisons were by t-test.

Results: 15 (45%) transplant (TXP) and 13 (57%) CKD pts had diabetes (DIAB). DIAB were older than pts without diabetes (NODIAB) (62.1±1.98 vs 50.4±2.4 yrs, p<0.0001) but age did not correlate with any finding. Mean creat was 1.8±1.5 mg/dl and did not differ between CKD and TXP, or DIAB and NODIAB. Mean HbA1c was 8.0±0.28, time with diabetes was 97.7±20.3 months and did not differ between clinics. DIAB were more likely to agree that their health depends on medications in the future (1.36±0.12 vs 2.00±0.26, p=0.024), less likely to believe that doctors had more time, they would prescribe fewer medications (3.61±0.25 vs 2.79±0.28, p=0.034) and less likely to believe that medicines are poisons (4.5±0.14 vs 3.93±0.23, p=0.039). DIAB pts ate fewer carbohydrates (137.4±11.6 vs 211.8±13.4, p<0.0001), less sugar (44.7±5.6 vs 89.4±9.5, p<0.0001), less fiber (10.9±1.1 vs 16.1±1.4, p=0.005), less vitamin C (54.2±9.9 vs 110.2±23.3, p=0.031), less fruit (0.3±0.1 vs 1.96±0.6, p=0.015) and less refined grains (3.01±0.43 vs 4.61±0.59, p=0.035). There was no difference for HEI score, total caloric or protein intake.

Conclusions: In our population: 1. Approximately 50% of our pts had diabetes. 2. Pts with diabetes had a more positive opinion of the healthcare environment and ate fewer carbohydrates, sugars and refined grains but less fresh fruit, fiber and vitamin C. 3. Education of our pts with kidney disease and diabetes should reinforce their attitudes towards the healthcare environment while encouraging an eating plan that includes fruits and vegetables, as pts appear to be focusing on restricting sugar and carbohydrates and towards the healthcare environment while encouraging an eating plan that includes fruits and vegetables. 4. The test for glycated hemoglobin, HbA1C, is the basic blood test used for diabetes control measures. This finding was particularly true of White pts to White providers and with Black pts to Black providers.

PO0995

Racial and Ethnic Similarities of Adherence to Diabetic Hemoglobin A1c Testing and Control Measures Between Providers and Patients in Federally Qualified Health Centers in Eastern North Carolina

Aparesh Balla, Rebecca Wurtz,1 Rural Health Group Inc, Roanoke Rapids, NC; 2University of Minnesota Twin Cities, University of Minnesota, Minneapolis, MN.

Background: Type 2 Diabetes is a chronic metabolic disorder that occurs when there is a dysregulation of insulin production and cellular insulin response, leading to hyperglycemia. The test for glycated hemoglobin, HbA1C, is the basic blood test used for diabetes. There is limited exploration of the relationship between adherence to HbA1c testing, diabetes control, and congruent provider/patient race and ethnicity. This study examines the correlations among HbA1c testing, provider race/ethnicity, and patient race/ethnicity.

Methods: Twelve consecutive monthly diabetes reports and dashboards compiled by the Rural Health Group, starting on October 1, 2018, were retrieved and analyzed in the investigation of the racial and ethnic similarities of HbA1c adherence to diabetic testing and control measures between providers and patients in the Federal Qualified Health Center in eastern North Carolina. Comparative statistical analyses permitted the juxtaposition of the comparison groups of patients and providers: White, Black, Hispanic, or other.

Results: As per adherence with the order of testing, there were no statistically significant differences found for White, Black, or Hispanic patients when they were seen by different providers. However, as per adherence to diabetes control measures, Black patients seen by Black providers were more likely to have an HbA1c < 7% (52%) when seen by a Black provider vs. only 45% when seen by a White provider, p-value = 0.0001, 95% confidence interval). Similarly, White patients had an HbA1c < 7% 50% of the time when seen by White providers, but only 43% of the time when seen by Black providers (p-value < 0.05). Therefore, patients who are the same race as their providers are statistically more likely to have an HbA1c, which reflects adherence to diabetes control measures.

Conclusions: Patients who are the same race/ethnicity as their providers did not play a significant role on HbA1c testing than patients who are the same race/ethnicity as their provider. However, patients who are the same race/ethnicity as their provider were more likely to have an HbA1c < 7%, which was statistically significant and reflected adherence to diabetes control measures. This finding was particularly true of White patients to White providers and with Black patients to Black providers.

PO0996

Low Serum Transferrin Saturation Is Associated with Incident Diabetes in Veterans with CKD

Monique E. Cho,1,2 Jared Hansen,1,2 Alfred K. Cheung,1,2 Tom Greene.2

1George E. Wahlen Department of Veterans Affairs Medical Center, Salt Lake City, UT; 2University of Utah Health, Salt Lake City, UT.

Background: Chronic kidney disease (CKD) is associated with increased risk for new-onset diabetes. Decreased circulating iron, as expressed by low transferrin saturation (Tsat), is associated with diabetes in the general population, but it has not been investigated if Tsat or ferritin is independently associated with incident diabetes in CKD.

Methods: We developed a historical cohort using the Veterans Affairs Informatics and Computing Infrastructure. We identified non-diabetic Veterans with CKD (MDRD eGFR <60 mL/min/1.73m2) with at least one set of iron indices between 2006-2015. Veterans with diabetes, end-stage renal disease, genetic or chronic disorders affecting iron metabolism, or those who received intravenous iron or erythropoietin stimulating agents within 3 months of the iron indices were excluded. A generalized additive Cox model was applied to the cohort to explore the joint dose-response relationship of the hazard for incident diabetes following the iron assay. A contour surface plot relating the covariate-adjusted hazard for incident diabetes to both Tsat and ferritin was developed using cubic regression splines.

Results: Of the 1,159,371 Veterans with CKD, 54,990 met the inclusion criteria. The means ± SD for age and eGFR were 73.8 ± 11.8 years and 43.8 ± 10.4 mL/min/1.73 m2, respectively. The median (IQR) Tsat and ferritin values were 23.0 (16.9, 29.7)% and 112.1 (50.6, 210.0) ng/mL. Over the mean follow-up period of 4 years, the risk of diabetes was inversely associated with Tsat, while it was positively correlated with serum ferritin. The surface contour map suggests that lower Tsat range (<20%) has a stronger relationship with incident diabetes than other.

Conclusions: In Veterans with pre-dialysis CKD, decreased Tsat is closely associated with incident diabetes risk, while increased ferritin exacerbates the risk.

Association of Glomerular Hyperfiltration with Glycemic Control and Serum Uric Acid Among NHANES Participants with Diagnosed Diabetes Mellitus
Mitra Mosseselmi,1 Elani Streja,1 Ekamol Tantisattamoo,1 Connie Rhee,1 Keith C. Norris,1 Csaba P. Kovesdy,1 Kamary Kalantar-Zadeh,1 Harold Simonowicz Center for Kidney Disease Research and Epidemiology, Orange, CA; The University of Tennessee Health Science Center, Memphis, TN; 1University of California Los Angeles, Los Angeles, CA.

Background: Glomerular Hyperfiltration (GH) is the earliest sign of diabetic kidney disease (DKD) even prior to the development of albuminuria. Some studies have reported that improvement in glyemic control reduces GH. Since elevated serum uric acid (SA) level may herald worse diabetes outcomes including a higher likelihood of DKD, we sought to examine the association of GH status with glycemic control and SA among diabetics.

Methods: We examined the National Health and Nutrition Examination Survey (NHANES) data from 1999 through 2016, comprising adults (age ≥20 years, n = 47,133, projected to N ~214.9 million US population). We defined diagnosed diabetes cases as those who reported being diagnosed by a doctor or using glycose-lowering medications (n= 5,783, N=19.3M) and defined GH as eGFR ≥120 ml/min/1.73m² (CKD-EPI) vs. normal-filtration as 60 ≤ eGFR <120 (GH: n=110, non-GH: n=3115). Cases with eGFR<60 were excluded (n=2,558). We assessed the association of GH with average glycemic control (HbA1c) and SA levels adjusted for demographic characteristics, diabetes duration, and diabetes treatment, using univariable and multivariable regression models.

Results: The prevalence of GH in persons under 10 years of diabetes was 2.7% but significantly less after 10 years (1.1%, p<0.003). GH was more likely in younger age, female sex, Hispanic ethnicity, higher A1c, higher SA, and those with no diabetes treatment. In the multivariable model, female sex was the strongest predictor followed by Hispanic ethnicity, higher SA, and younger age (Table).

Conclusions: GH is more common in the first 10 years of diabetes and associated with higher SA. It is more common among females, Hispanic race, and younger diabetes patients. Further studies should examine the potential role of sex, ethnicity, age, and SA in the mechanism of GH among persons with diabetes.

Regression model for variables associated with Glomerular Hyperfiltration (GH) among patients with diagnosed diabetes

Continuous Glucose Monitoring in a Diabetic Hemodialysis Patient
Elisa Park,1 Kamary Kalantar-Zadeh,1 Amy S. You,1 David A. Price,2 Connie Rhee,1 1University of California Irvine, Irvine, CA; 2DexCom Inc, San Diego, CA.

Introduction: Diabetes is the leading cause of end stage renal disease (ESRD) in the US. Patients with diabetic kidney disease (DKD) are susceptible to hypo- and hyperglycemia via multiple pathways. Continuous glucose monitoring (CGM) provides automated, less invasive glucose measurements (updated every 5 minutes) and more comprehensive glucose data vs. conventional self-monitored blood glucose (SMBG), and glycemic benefits for CGM use have been established. However, CGM use has been limited in diabetic hemodialysis (HD) patients as devices are not currently approved for use in this population.

Case Description: We describe a 48-year old male with ESRD due to DKD receiving HD. At the age of 26, the patient was diagnosed with diabetes after presenting with recurrent skin infections and unexplained weight loss. He was initially treated with glubride which was changed to metformin, and was later transitioned to an insulin pump. Over time he developed DKD which progressed to ESRD by the time he was 41 years old. His diabetes was also complicated by neuropathy and retinopathy with right eye blindness. For two decades, the patient utilized SMBG with capillary fingerstick measurements to monitor his glycemic status. During this time he had wide fluctuations in his glucose levels with asymptomatic hypo- and hyperglycemia, and his HbA1c levels were typically 10-12%. Due to poor glucose control, his endocrinologist advised him to use CGM (Dexcom G5, later transitioned to Dexcom G6, San Diego, CA). Since transitioning to CGM, the patient reports 1) greater adherence to glycemic monitoring, 2) improved hypoglycemia detection, 3) minimal lifestyle interruption, and 4) improved quality of life. In addition, he has less glycemic variability, increased time-in-target glucose range, and improved HbA1c levels to 6.8%.

Discussion: This case demonstrates CGM is a practical method for glucose assessment with the potential to improve glycemic control in diabetic ESRD patients. Further studies are needed to determine the comparative effectiveness of CGM vs. SMBG in diabetic HD patients.

Pollock,18 1Division of Nephrology, University of British Columbia, Vancouver, BC, Canada; 2The George Institute for Global Health, Sydney, NSW, Australia; 3Stanford Center for Clinical Research, Department of Medicine, Stanford University School of Medicine, Stanford, CA; 4Cardiovascular Division, Brigham Women’s Hospital and Dana-Farber Institute for Clinical Research, Boston, MA; 5Department of Clinical Pharmacy and Pharmacology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; 6The Charles Perkins Centre, University of Sydney and Imperial College London, London, United Kingdom; 7Department of Radiology, Ren JI Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China; 8Nephrology Division, NYU School of Medicine and NYU Langone Medical Center, New York, NY; 9Baim Institute for Clinical Research, Boston, MA; 10Indiana University School of Medicine and VA Medical Center, Indianapolis, IN; 11Division of Medicine, University of Chicago Medicine, Chicago, IL; 12Division of Biostatistics, Department of Population Health Sciences, University of Utah, Salt Lake City, UT; 13Department of Renal Medicine, UCL Medical School, London, United Kingdom; 14Janssen Research & Development, LLC, Raritan, NJ; 15Renal Division of Peking University First Hospital, Beijing, China; 16Lunenfeld-Tanenbaum Research Institute, Mt Sinai Hospital, University of Toronto, Toronto, ON, Canada; 17The Royal North Shore Hospital, Sydney, NSW, Australia; 18Kolling Institute of Medical Research, Sydney Medical School, University of Sydney, Royal North Shore Hospital, St Leonards, NSW, Australia.

Background: Canagliflozin (CANA) reduces the risk of cardiovascular (CV) events and kidney failure in people with type 2 diabetes mellitus (T2DM) and chronic kidney disease (CKD). Inherent in its mechanism of action is enhanced urinary and osmotic diuresis. It is unclear if the efficacy or safety of CANA is modified by concomitant diuretic use.

Methods: CREDENCE randomized participants with T2DM and CKD to CANA or matching placebo. The primary outcome was a composite of end-stage kidney disease, doubling of serum creatinine, CV or renal death. We estimated effects on key efficacy and safety outcomes by baseline use of loop diuretics.

Results: Of 4401 CREDENCE participants, 955 (21.7%) received loop diuretics at baseline. These participants were older (mean age 63.5 vs 62.7 y; P=0.01), with a longer diabetes duration (17.0 vs 15.5 y), lower eGFR (49.7 vs 58.0 mL/min/1.73m2), and were more likely to have a history of heart failure (27.6 vs 11.3%; all P<0.0001). Unadjusted event rates were higher in those using loop diuretics (Figure). Effects of CANA on the primary outcome and other CV and renal outcomes were consistent irrespective of loop diuretic use. The risk of renal-related adverse events, acute kidney injury, and volume depletion was not elevated by loop diuretic use (data not shown; all 95% CI 0.85–1.05).

Conclusions: CANA reduces the risk of CV and renal outcomes in people with T2DM and CKD irrespective of baseline use of loop diuretics, without additional adverse effects.

Acute Declines in eGFR During Treatment with Canagliflozin (CANA) and Its Implications for Clinical Practice: Insights from CREDENCE

Hiddo J. L. Heerspink,12 Megumi Oshina,13 Meg J. Jardine,14 Rajiv Agarwal,6 George L. Bakris,6 Christopher P. Cannon,5 David M. Charytan,5 Dick de Zeeuw,2 Robert Edwards,10 Tom Greene,11 Adeera Levin,12 Kenneth W. Mahaffey,3 Bruce Neal,1 Carol A. Pollock,14 Norm Rosenthal,10 David C. Wheeler,13 Hong Zhang,15 Bernard Zinman,16 Vladko Perkovic,1 The George Institute for Global Health, Sydney, NSW, Australia; 2Division of Nephrology and Laboratory Medicine, Kanazawa University, Kanazawa, Japan; 3Concord Repatriation General Hospital, Sydney, NSW, Australia; 4Indiana University School of Medicine and Veterans Affairs Medical Center, Indianapolis, IN; 5Department of Medicine, University of Chicago Medicine, Chicago, IL; 6Cardiovascular Division, Baim Institute for Clinical Research, Boston, MA; 7Nephrology Division, NYU School of Medicine and NYU Langone Medical Center, New York, NY; 8Baim Institute for Clinical Research, Boston, MA; 9Janssen Research & Development, LLC, Raritan, NJ; 10Division of Biostatistics, Department of Population Health Sciences, University of Utah, Salt Lake City, UT; 11Division of Nephrology, University of British Columbia, Vancouver, BC, Canada; 12Stanford Center for Clinical Research, Stanford University School of Medicine, Stanford, CA; 13Relling Institute of Medical Research, Sydney Medical School, University of Sydney, Royal North Shore Hospital, St Leonards, NSW, Australia; 14Department of Renal Medicine, UCL Medical School, London, United Kingdom; 15Renal Division of Peking University First Hospital, Beijing, China; 16Lunenfeld-Tanenbaum Research Institute, Mt Sinai Hospital, University of Toronto, Toronto, ON, Canada.

Background: CANA slows progression of chronic kidney disease (CKD) in people with type 2 diabetes. CANA also induces a reversible acute decline in estimated glomerular filtration rate (eGFR), which is believed to be a hemodynamic effect. Predictors of the initial decline and its association with long-term eGFR trajectories and safety outcomes are unknown.

Methods: This post hoc study of CREDENCE included 4289 patients with type 2 diabetes and CKD who had eGFR measured at both baseline and week 3. Participants were categorized by percentage decline in eGFR at week 3: greater than 10% decline; between 0 and 10% decline; and no decline. Baseline characteristics associated with acute eGFR drop >10% were evaluated using logistic regression. Long-term eGFR decline and safety outcomes were estimated in each eGFR decline category by linear mixed effects models and Cox regression with adjustment for laboratory measures and medication use.

Results: More participants in the CANA (956 [45%]) versus placebo (PBO) group (450 [21%]) had an acute eGFR decline >10% (p<0.001). A >30% decline occurred infrequently (89 [4%] with CANA and 39 [2%] with PBO; p<0.001). In the CANA but not in the PBO group, older age (OR CANA 1.17, 95% CI 1.05–1.31; per 10 years) and
The SGLT2 Inhibitor Canagliflozin Reduces the Plasma Markers TNFR-1, TNFR-2, and KIM-1 in the CANVAS Trial

Taha S.,1 Jingwei Li,2 Brendon L. Neuen,3 Bruce Neal,4 Chirag R. Parikh,4 Steven G. Coca,3 Vladko Perkovic,5 Dick de Zeeuw,2 Kenneth W. Mahaffey,6 Michael K. Hansen,4 Hidde J. L. HeerINK,7 1Department of Clinical Pharmacy and Pharmacology, University of Groningen, Groningen, Netherlands; 2The George Institute for Global Health, UNSW Sydney, Sydney, NSW, Australia; 3Stanford Center for Clinical Research, Department of Medicine, Stanford University School of Medicine, Stanford, CA; 4Janssen Research & Development, LLC, Spring House, PA; 5Johns Hopkins School of Medicine, Baltimore, MD; 6Division of Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Tumor Necrosis Factor Receptor (TNFR)-1, TNFR-2 and Kidney Injury Molecule 1 (KIM-1) are biomarkers known to predict kidney outcomes in patients with type 2 diabetes (T2D). We assessed the effect of the SGLT2 inhibitor canagliflozin (CANA) on TNFR-1, TNFR-2 and KIM-1 in CANVAS study participants to determine whether changes were consistent with subsequent kidney outcomes.

Methods: The CANVAS trial randomized participants with T2D at high cardiovascular risk to CANA or placebo (PBO). TNFR-1, TNFR-2 and KIM-1 were measured with immunoassays (proprietary multiplex assay performed by RenalytixAI, NY, USA) at baseline and years 1 and 3, and were reported as unadjusted levels.

Results: Among 3827/4330 (67%) CANVAS participants with available plasma samples at baseline and follow-up, median baseline TNFR-1, TNFR-2 and KIM-1 were 25.59, 96.12, and 108 pg/mL. Difference between CANA and PBO in TNFR-1, TNFR-2, and KIM-1 during follow-up were 2.8% (95%CI −3.5, −0.2; P = 0.028) and −26.7% (−30.7, −22.7; P < 0.001). Increases in TNFR-1 and TNFR-2, but not KIM-1, at year 1 were independently associated with a higher risk of the kidney outcome (Table).

Conclusions: CANA reduces TNFR-1, TNFR-2 and KIM-1 in patients with T2D at high cardiovascular risk. Early increases in TNFR-1 and TNFR-2 were independently associated with higher risk of kidney disease progression and have the potential to be pharmacodynamic markers of non-response to CANA.

Canagliflozin and Risk of Skin and Soft Tissue Infections in People with Diabetes Mellitus and Kidney Disease in the CREDENCE Trial
Amy Kang,1 Brenda Smyth,1 Brenda L. Neuen,1 Hiddo J. L. Heerspink,1,2 Gian Luca Di Tanna,1 Bruce Neal,1 Hong Zhang,1 Carmina Hockham,2 Rajiv Agarwal,3 George L. Bakris,4 David M. Charytan,5 Dick de Zeeuw,6 Tom Greene,7 Adeera Levin,1 Carol A. Pollock,5 David C. Wheeler,2 Bernard Zimman,11 Kenneth W. Mahaffey,10 Vladko Perkovic,1 Meg J. Jardine.1
1The George Institute for Global Health, UNSW Sydney, Newtown, NSW, Australia; 2Rijksuniversiteit Groningen, Groningen, Netherlands; 3Peking University First Hospital, Beijing, China; 4Indiana University School of Medicine, Indianapolis, IN; 5University of Chicago, Chicago, IL; 6NYU Langone Medical Center, New York, NY; 7University of Utah Health, Salt Lake City, UT; 8The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada; 9University of Sydney - Camperdown and Darlington Campus Burkitt-Ford Library, Sydney, NSW, Australia; 10Stanford University, Stanford, CA; 11Lunenfeld-Tanenbaum Research Institute, Toronto, ON, Canada; 12University College London, London, United Kingdom.

Background: The skin’s hypertonic microenvironment has a protective antimicrobial function that may be disrupted by sodium glucose cotransporter 2 inhibitors (SGLT2i). We aimed to describe skin and soft tissue infections (SSTI) in the CREDENCE trial and determine whether canagliflozin affects the risk of SSTI.

Methods: We performed a post-hoc analysis of the CREDENCE trial that randomised people with type 2 diabetes and albuminuric stage 2 and 3 chronic kidney disease to either canagliflozin 100mg daily or placebo. Adverse events were assessed by two blinded authors following predetermined criteria for SSTI with discrepancies resolved by consensus. We analysed the risks of SSTIs in the on-treatment population as the more conservative approach, with sensitivity analyses conducted in the intention-to-treat population, for serious events only and for participant subgroups. Univariable time-to-first event regression models were assessed.

Results: Overall 373/4397 (8.5%) participants experienced 478 events comprising 252 bacterial skin infections (including 2 episodes of necrotising fasciitis), 94 fungal skin infections, 109 other skin infections and 23 soft tissue infections. Of these, 136/478 (28%) were serious. Canagliflozin did not increase the risk of SSTI (HR 0.85 [95% Confidence Interval (CI) 0.69-1.04] p=0.11), with similar results in the intention-to-treat population (HR 0.88 [95% CI 0.73-1.07] p=0.20), in analyses confined to serious SSTI (HR 0.83 [95% CI 0.58-1.21] p=0.33) and participant subgroups (all p interaction≤0.10). Both cases of necrotising fasciitis were in patients assigned to canagliflozin and the participants recovered after drug was withdrawn.

Conclusions: Canagliflozin did not increase the risk of skin and soft tissue infections overall or in any subgroup, in CREDENCE trial participants with type 2 diabetes mellitus and albuminuric chronic kidney disease.

Funding: Commercial Support - Janssen sponsored the CREDENCE trial but did not sponsor this post-hoc analysis.

Early Change in Albuminuria with Canagliflozin (CANA) Predicts Kidney and Cardiovascular (CV) Outcomes
Megumi Oshima,1,2 Brenda L. Neuen,1 Jingwei Li,1 Vladko Perkovic,1 David M. Charytan,1 Dick de Zeeuw,1 Robert Edwards,1 Tom Greene,2 Adeera Levin,1 Kenneth W. Mahaffey,1 Luca De Nicola,3 Carol A. Pollock,4 Norm Rosenthal,1 David C. Wheeler,5 Meg J. Jardine,2 Hiddo L. Heerspink,1 The George Institute for Global Health, UNSW Sydney, Sydney, NSW, Australia; 2Department of Nephrology and Laboratory Medicine, Kanazawa University, Kanazawa, Japan; 3Nephrology Division, NYU School of Medicine and NYU Langone Medical Center, New York, NY, USA; 4Department of Clinical Pharmacy and Pharmacology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; 5Janssen Research & Development, LLC, Raritan, NJ, USA; 6Division of Biostatistics, Department of Population Health Sciences, University of Utah, Salt Lake City, UT; 7Division of Nephrology, University of British Columbia, Vancouver, BC, Canada; 8Stanford Center for Clinical Research, Department of Medicine, Stanford University School of Medicine, Stanford, CA; 9Department of Advanced Medical and Surgical Sciences, Nephrology and Dialysis Unit, University Vanvici, Naples, Italy; 10Kolling Institute of Medical Research, Sydney Medical School, University of Sydney, Royal North Shore Hospital, St Leonards, NSW, Australia; 11Department of Renal Medicine, UCL Medical School, London, United Kingdom; 12Cordis Repatriation General Hospital, Sydney, NSW, Australia; 13Department of Clinical Pharmacy and Pharmacology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands.

Background: The association between early changes in albuminuria and kidney and CV events is primarily based on trials of renin-angiotensin system blockade. It is unclear whether this association is comparable regardless of diabetes duration, number of therapies or HbA1C at baseline.

Methods: In this post-hoc analysis of the CREDENCE trial in patients with type 2 diabetes and chronic kidney disease, we assessed the effect of CANA versus placebo on albuminuria at week 26, and the association of early changes in urinary albumin/creatinine ratio (UACR) for the first 26 weeks with kidney and CV outcomes using multivariable Cox regression. Kidney and CV outcomes were defined as (1) end-stage kidney disease, doubling of serum creatinine or death due to kidney disease, (2) major adverse cardiovascular events (MACE) and (3) hospitalization for heart failure (HHF) or CV death.

Results: This analysis included 3836 participants (87.2%) with complete data for early changes in UACR. CANA lowered UACR by 31% (95%CI 27-36%) at week 26 and increased the likelihood of achieving a 30% UACR reduction (OR 2.69, 95%CI 2.35-3.07). We observed log-linear associations of early changes in UACR during 26 weeks with kidney and CV outcomes (all p trend <0.001, Table). Each 30% UACR reduction was associated with a lower hazard for clinical outcomes, overall and in each treatment arm (all p <0.001).

Conclusions: In people with type 2 diabetes and CKD, canagliflozin results in early and sustained reductions in albuminuria, which was independently associated with long-term kidney and cardiovascular outcomes.

Funding: Commercial Support - Janssen

Kidney Effects of Empagliflozin in People with Type 1 Diabetes

David Chemey,1 Petter Bjornstad,2 Bruce A. Perkins,3 Dietmar Neubacher,4 Jythis T. George,3 Jan Marquard,5 Nima Soleymanlou.4

1University Health Network, University of Toronto, Toronto, ON, Canada; 2University of Colorado Anschutz Medical Campus, Aurora, CO; 3Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada; 4(Dallas Diabetes Research Center at Medical City, Dallas, TX; 5Boehringer Ingelheim International GmbH, Ingelheim, Germany; 6Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, CT; 7Boehringer Ingelheim Canada Ltd/ Liedt, Burlington, ON, Canada.

Background: Empagliflozin lowers the risk of cardiovascular and kidney events in type 2 diabetes (T2D). In the empagliflozin in type 1 diabetes (T1D) clinical program (EASE), glycemic control, weight and blood pressure improved with empagliflozin as adjunct to insulin treatment, though diabetic ketoacidosis risk was higher with use of the 10 and 25mg doses vs the 2.5mg dose. The kidney effects of empagliflozin in T1D remain incompletely understood.

Methods: Here we report changes in kidney parameters in phase 3 placebo-controlled trials EASE-2 (empagliflozin 10/25mg, 52-week; n=730) and EASE-3 (empagliflozin 2.5/10/25mg, 26-week; n=975).

Results: MeansDSD baseline estimated glomerular filtration rate (eGFR in mL/min/1.73 m2) in EASE-2/EASE-3 was 97.3±18.2 and 98.5±18.2 and median (interquartile range) baseline urinary albumin-to-creatinine ratio (UACR in mg/g of creatinine) was 6.2 (2.7±14.1) in both studies. After 26 weeks of treatment in EASE-3, mean placebo-corrected eGFR changes with empagliflozin 2.5mg (n=230), 10mg (n=228) and 25mg (n=234) were -0.14 (p=0.87), -2.57 (p<0.0001) and -3.56 (p<0.0001), respectively. Mean placebo-corrected eGFR changes with empagliflozin 10mg and 25mg were −2.05 (p=0.02; n=226) and −2.60 (p=0.002; n=228) after 52 weeks in EASE-2, respectively.

Changes in eGFR 3 weeks after end of therapy (FU) returned to above baseline levels. In participants with UACR<300mg/g, no significant changes in urinary albumin-to-creatinine ratio (UACR) were observed. In a pooled analysis (EASE-2 + EASE-3), in participants with baseline UACR ≥30 mg/g, UACR decreased by 16% (p=0.27) and 30% (p=0.02) with empagliflozin 10mg (n=71) and 25mg (n=77) vs placebo (n=65), respectively, at 26 weeks. In EASE-3, in people with baseline UACR ≥30 mg/g, treatment with empagliflozin 2.5mg (n=36) for 26 weeks did not significantly attenuate UACR vs placebo (n=34). Hematocrit and serum albumin increased in EASE-2 and EASE-3 with empagliflozin treatment.

Conclusions: In conclusion, empagliflozin doses >2.5 mg/day as adjunct therapy to insulin in T1D resulted in short-term changes in kidney markers comparable to changes observed with SGLT2 inhibitor use in T2D.

Empagliflozin Is Associated with Increased Plasma Lipid Metabolites in Type 1 Diabetes

Hongyan Liu,1 Leif E. Lovblom,2 Yuliya Lytvyn,3 Hongping Ye,4 Daniel Monfort,4 Daniel Scarr,5 Bruce A. Perkins,3 Kumar Sharma,1 David Chemey,2 University of Toronto, Toronto, ON, Canada; 2Division of Nephrology, Department of Medicine, University Health Network, Toronto, ON, Canada; 3Lunenfeld-Tanenbaum Research Institute, Mount Sinai Hospital, Toronto, ON, Canada; 4Center for Renal Precise Medicine, Division of Nephrology, Department of Medicine, University of Texas Health San Antonio, San Antonio, TX; 5Division of Endocrinology and Metabolism, Department of Medicine, University of Toronto, Toronto, ON, Canada.

Background: Sodium glucose cotransporter-2 (SGLT2) inhibition reduces the risk of cardiovascular complications in people with diabetes, possibly by altering energy substrate pathways. It has been hypothesized that SGLT2 inhibitors improve mitochondrial efficiency and may induce a shift towards increased lipid utilization as an energy substrate. In this exploratory, post-hoc analysis, we investigated the effects of SGLT2 inhibition on plasma lipid and tricarboxylic acid (TCA) cycle metabolites in patients with type 1 diabetes (T1D).

Methods: In the ATIRMA trial (NCT01392560), patients with T1D were assessed under clamped euglycemia and hyperglycemia at baseline and after 5 weeks of empagliflozin treatment. Plasma samples from the ATIRMA trial were analyzed for lipid and TCA cycle metabolites using the ZipChip method.

Results: Of the 15 lipid metabolites, 5 increased during clamped euglycemia in response to empagliflozin (Figure) while 1 increased after treatment during clamped hyperglycemia. Of the 3 TCA cycle metabolites, 2 increased during clamped euglycemia in response to empagliflozin. None of the metabolites decreased significantly after empagliflozin treatment.

Conclusions: In patients with T1D, SGLT2 inhibition increased plasma TCA cycle metabolite levels, suggesting an impact on mitochondrial function. Lipid metabolite levels were also increased after SGLT2 inhibition, suggesting a possible increase in beta oxidation. Further work is needed to determine if these changes contribute to cardiorenal protection with SGLT2 inhibitors.

PO1010

Effect of Dapagliflozin on Risk for Fast Decline in eGFR: Analysis from DECLARE-TIMI 58 Trial

Otfi Mosenzon,1 Stephen Wiviott,2 Hildo J. Heerspink,1 Jamie P. Dwyer,2 Aviit Cahn,3 Erica L. Goodrich,4 Aliza Rozemberg,5 Ilan Yanuv,1 John P. Wilding,1 Lawrence A. Leiter,3 Deepak L. Bhatt,6 Darren K. Meguire,7 Ronald C. Ma,4 Tsvetatina Tankova,3 Martin Fredriksson,4 Ingrid A. Gause-Nilsson,4 Anna Maria Langkilde,4 Marc S. Sabatine,2 Itamar Raz,9 Hadassah Medical Center, Jerusalem, Israel; 1St. Michael’s Hospital and University of Toronto, Toronto, ON, Canada; 2Dept of Medicine and Therapeutics The Chinese University of Hong Kong, Hong Kong, Hong Kong; 3BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; 4Department of Cardiovascular and Metabolic Medicine, University of Liverpool, UK; 5Liverpool, United Kingdom; 6Brigham & Women’s Hospital, Boston, MA; 7University of Texas Southwestern Medical Center, Dallas, TX; 8Vanderbilt University Medical Center, Nashville, TN, USA; 9Department of Endocrinology, Medical University, Sofia, Bulgaria, Sofia, Bulgaria; 10University Medical Center Groningen, Groningen, Netherlands.

Background: SGLT2 inhibitors may lead to short term decrease in eGFR with later stabilization and long-term reduction in risk for end stage kidney disease. Fast decline (FD) in eGFR can be defined as reduction of ≥3 mL/min/1.73m2/year and is associated with poor long-term renal prognosis. In this post hoc analysis we studied the effect of dapagliflozin (dapa) on risk of FD in the DECLARE-TIMI 58 trial.

Methods: In DECLARE-TIMI 58, 17,160 patients with T2D and established or increased risk for CVD, with mean baseline eGFR of 85.2 mL/min/1.73m2, were randomized to dapa vs. placebo and followed for median of 4.2 years. The risk for FD was compared between treatments.

Results: In the time frame of 0.5 years (after stabilization) to 4 years, the proportion of patients with FD was reduced with dapa vs. placebo (26.8% vs. 37.1%, respectively, p<0.0001) and in all subgroups assessed (Figure). The mean (SD) reduction in eGFR per year was 6.3 (3.7) vs. 0.0 (2.5) mL/min/1.73m2/year in FD (N=4,788) vs. non-FD (N=10,224) patients. In patients that had FD, mean (SD) reduction in eGFR was −5.9 (3.2) vs. −6.6 (4.1) mL/min/1.73m2/year in dapa vs. placebo arm, while in patients that did not have fast decline it was 0.2 (2.5) vs. −0.2(2.5) mL/min/1.73m2/year, respectively. The proportion of patients with FD during entire study period (i.e. 0-4 years) was also reduced with dapa vs. placebo (33.6% vs. 37.0%, respectively, p<0.0001).

Conclusions: Dapa reduced the risk for FD in eGFR in a broad population of patients with T2D and relatively preserved renal function, irrespective of patients’ baseline characteristics.

Renal Outcomes and All-Cause Death Associated with SGLT-2 Inhibitor vs. Other Glucose-Lowering Drugs (CVD-REAL 3 Korea)

Eun Sil Koh,1 Kyungdo Han,1 Hyewon Lee,1 You-Seon Nam,1 Eric T. Wittbrodt,4 Peter Fencik,1 Mikhail Kostobrod,1 Hildo J. L. Heerspink,2 Soon-Jib Yoo,2 Hyuk-Sang Kwon.1 The Catholic University of Korea Yonsei Saint Mary's Hospital, Yeongdeungpo-gu, Seoul, Republic of Korea; 2AstraZeneca Korea Co Ltd, Seoul, Republic of Korea; 3Soongsil University Department of Statistics and Actuarial Science, Dongjak-gu, Seoul, Republic of Korea; 4AstraZeneca, Gaithersburg, MD; 5AstraZeneca, Cambridge, United Kingdom; 6Saint Luke's Mid America Heart Institute, Kansas City, MO; 7University Medical Center Groningen, Groningen, Netherlands; 8The Catholic University of Korea Bucheon Saint Mary's Hospital, Bucheon, Gyeonggi-do, Republic of Korea.

Methods: Using data from the Korean National Health Insurance Service database from January 2014 to December 2017, a total of 701,674 patients were identified with Type 2 DM and CKD. We divided these patients into new-users of SGLT-2i and new-users of other glucose-lowering drugs (oGLD). Using propensity scores, patients in the two groups were matched 1:1. We examined for the risk of end-stage renal disease (ESRD) and all-cause death.

Results: There were 45,016 patients in each group, and baseline characteristics were well-balanced between groups: mean age 58.1±10.6 years; mean estimated glomerular filtration rate (eGFR) 89.2±27.4 ml/min/1.73m²; 8% of patients had proteinuria. We identified 167 incident ESRD and 1,070 all-cause deaths during follow-up. Use of SGLT-2i versus oGLD was associated with a lower risk of ESRD (HR: 0.47; 95% confidence interval [CI]: 0.34 to 0.65) and all-cause death (HR: 0.82; 95% CI: 0.73 to 0.93). In a subgroup analysis by eGFR, initiation of SGLT2i vs oGLD was associated with lower risk of progression to ESRD among patients with eGFR 60-90 and <60 ml/min/1.73m² and lower risk of all-cause death associated with SGLT-2i versus oGLD was observed across the entire range of renal function.

Conclusions: In this large nationwide study of Korean patients with T2D, initiation of SGLT-2i vs oGLD was associated with lower risk of ESRD and all-cause death.

Cardiovascular Outcomes with SGLT-2 Inhibitors vs. GLP-1 Receptor Agonists in Patients with Type 2 Diabetes and CKD: A Systematic Review and Network Meta-Analysis

Takahiko Yamada,1,2 Abhinav Bhalla,1 Makio Watabayashi,3 Hirokata Miyashita,1 Hiroki Ueyama,1 Tomohiro Fujiyuki,3 Takahisa Mikami,1 Kouichi Tamura.1 1Mount Sinai Beth Israel Hospital, New York, NY; 2Nihon Ika Daizakku Fuzoku Byoin, Bunkyo-ku, Japan; 3Yokohama Shiritusu Daigaku Fuzoku Byoin, Yokohama, Japan.

Background: Type 2 diabetes mellitus (DM) and chronic kidney disease (CKD) increase the risk of cardiovascular disease. Sodium-glucose cotransporter-2 (SGLT-2) inhibitors and glucagon-like peptide-1 receptor agonists (GLP-1 RA) are known to reduce cardiovascular disease. However, no study compared the effect of SGLT-2 inhibitors on cardiovascular diseases with that of GLP-1 RA in CKD patients.

Methods: We performed a systematic literature search up to March 2020. We selected randomized control trials. First, we performed meta-analysis to compare SGLT-2 inhibitors vs placebo and GLP-1 RA vs placebo. Next, we performed a network meta-analysis to compare SGLT-2 inhibitors with GLP-1 RA indirectly. Risk ratios (RRs) with corresponding 95% confidence interval (CI) were synthesized.

Results: Total thirteen studies were selected. SGLT-2 inhibitors led to a risk reduction in MACE (RR [95% CI]; 0.80 [0.72-0.89], p = 0.0001). On the other hand, GLP-1 RA did not show significant difference with high heterogeneity (0.88 [0.74-1.04], p = 0.15, I²=58%) (Figure 1). The network meta-analysis did not show significant difference between SGLT-2 inhibitors and GLP-1 RA (0.90 [0.77-1.08]) (Figure 2).

Conclusions: In patients with type 2 DM and CKD, SGLT-2 inhibitors were associated with decreased risk of MACE, but GLP-1 RA did not. Network meta-analysis did not reveal significant difference between SGLT-2 inhibitors and GLP-1 RA.

Comparative Effectiveness of SGLT2 Inhibitors, GLP1 Receptor Agonists, DPP4 Inhibitors, and Sulfonylureas on Risk of Kidney Outcomes: Emulation of a Target Trial Using Healthcare Databases

Yan Xie,1 Benjamin C. Bowe,3 Andrew K. Gibson,1 Janet B. McGill,1 Yan Yan,1 Geetha S. Maddukuri,1 Ziyad Al-Aly.1 1Clinical Epidemiology Center, VA Saint Louis healthcare system, St. Louis, MO; 2Department of Medicine, Washington University School of Medicine, St. Louis, MO; 3Nephrology Section, Medicine Service, VA Saint Louis Health Care System, St. Louis, MO.

Background: The comparative effectiveness of SGLT2i, GLP1, DPP4, and sulfonylureas on risk of kidney outcomes among people with type 2 diabetes mellitus is not known.

Methods: We built a cohort of 216,558 US Veterans initiated on SGLT2i, GLP1, DPP4, or sulfonylureas and followed them for up to 3 years. The outcome was defined as the risk of the major adverse kidney events (MAKE) of estimated glomerular filtration rate (eGFR) decline ≥50%, end stage kidney disease, or all-cause mortality. Risks were estimated using survival models adjusted for pre-defined covariates as well as covariates identified by a high-dimensional variable selection algorithm through application of generalized propensity scores.

Results: During follow up, there were 14612 (6.75%) MAKEs. Adjusted KM curve did not reveal significant difference between SGLT-2 inhibitors and GLP-1 RA.

In patients with type 2 DM and CKD, SGLT-2 inhibitors were associated with lower risk of all-cause death associated with SGLT-2i vs oGLD was observed across the entire range of renal function.

Conclusions: In this large nationwide study of Korean patients with T2D, initiation of SGLT-2i vs oGLD was associated with lower risk of ESRD and all-cause death.

PO1015
Correlation of Anti-Albuminuric Effect by SGLT2 Inhibitor with Tubulointerstitial Impairment
Saecko Sato, Koari Takayanagi, Taisuke Shimizu, Takatsugu Iwashita, Hiroaki Hara, Tomonori Ogawa, Hajime Hasegawa. Department of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan.

Background: This study aimed to examine the anti-albuminuric effect of SGLT2 inhibitor (SGLT2i) in patients with or without renal dysfunction, and to investigate factors associated with the effect of SGLT2i.

Methods: Patients with diabetic nephropathy were enrolled and received 50 mg of Ipagliflozin. Their blood and urine were sampled at 0 M, 1 M and 12 M. Patients with renal dysfunction (DF; \(eGFR<60\)) and with normo-renal function (NF; \(eGFR\geq60\)) were separately analyzed.

Results: In all patients (n=22), urine albumin-to-Cr ratio (ACR) was reduced at 1M and maintained until 12M (median: 236.2 at 0M, 115.0 mg/gCr at 1M), however, eGFR was not changed. In DF, ACR was also decreased (median: 311.8 at 0M vs 107.0 mg/gCr at 1M, n=10). In NF, ACR was similarly decreased at 1M. Next, the patients in DF and NF were divided by %ACR reduction (high responder: HR, low responder: LR). In NF, only %change of eGFR at 12M was significantly different (-6.5±6.0% in HR vs +5.0±7.6% in LR). In DF, ACR was also decreased (median: -33.0±7.3% in HR vs +45.9±33.1% in LR) and %change of NAG at 12M showed significant difference (-33.6±13.5% in HR vs +6.8±28.3% in LR), however, there was no difference in eGFR. Univariate analysis showed significant correlation between %ACR reduction and %MCP-1 at 1M (R=0.734, p=0.016) and %NAG at 12M (R=0.714, p=0.047) in DF whereas no significant correlation was observed in NF. Multivariate analysis confirmed the results.

Conclusions: In patients with normo-renal function, restoring glomerular hyperfiltration might be important for anti-albuminuric effect of SGLT2i. However, in patients with renal dysfunction, the effect of SGLT2i seemed to be associated with reduced tubulointerstitial damage.

PO1014
Comparative Effectiveness of SGLT2 Inhibitors vs. Other Antihyperglycemics on Risk of Kidney Outcomes: A Cohort Study
Yan Xie,1 Benjamin C. Bowe,2 Andrew K. Gibson,3 Janet B. McGill,2 Yan Yan,1 Geetha S. Maddukuri,1 Ziyad Al-Aly.1 1Clinical Epidemiology Center, VA Saint Louis healthcare system, St. Louis, MO; 2Department of Medicine, Washington University School of Medicine, St. Louis, MO; 3Nephrology Section, Medicine Service, VA Saint Louis Health Care System, St. Louis, MO.

Background: In randomized controlled trials, sodium-glucose co-transporter-2 inhibitor (SGLT2i) reduced the risk of adverse kidney outcomes. We aimed to examine the comparative effectiveness of SGLT2i and other antihyperglycemics on the risk of major adverse kidney events (MAKE) of estimated glomerular filtration rate (eGFR) decline >50%, end-stage kidney disease, or all-cause mortality.

Methods: We built a cohort of 379,191 new users of SGLT2i or other antihyperglycemics. Risk of MAKE during follow up served as the primary outcome. Pre-defined covariates and covariates identified by a high-dimensional variable selection algorithm were used to build a propensity score. Linear mixed models were used to estimate the longitudinal change of eGFR and body mass index (BMI) and survival analyses were used to estimate the risk difference of MAKE.

Results: Compared to other antihyperglycemics, SGLT2i use was associated with 0.98 (0.48, 1.53) ml/min/1.73m² less annual reduction in eGFR, 0.24 (0.17, 0.32) kg/m² less annual reduction in BMI, 0.24 (0.17, 0.32) kg/m² less annual reduction in BMI, and reduced risk of MAKE (HR=0.68 (0.64-0.73)). SGLT2i use was associated with reduced risk of MAKE in eGFR <60 to <45 ml/min/1.73m² and in participants with and without albuminuria. The association was evident in per-protocol analyses which required continuation of the treatment. The association was evident in per-protocol analyses which required continuation of the treatment.

Conclusions: Among people with diabetes mellitus type 2, SGLT2i use was associated with eGFR preservation, greater decline in BMI, and reduced risk of MAKE compared to other antihyperglycemics.

PO1016
SGLT2i Prescribing for Type 2 Diabetes and Comorbid Conditions Among 24 US Healthcare Organizations
Nikita Steppenwolfer,1 Cori Rattelman,1 John W. Kennedy,1 Elizabeth Ciemins,1 John K. Cuddeback,1 Yingying Sang,2,3 Jose Cores,2,3 Morgan Grams,2,3 Jung-Im Shin.2,3 1AMGA (American Medical Group Association), Alexandria, VA; 2Johns Hopkins University, Baltimore, MD; 3Welch Center for Prevention, Epidemiology, & Clinical Research, Baltimore, MD.

Background: Sodium glucose cotransporter-2 inhibitors (SGLT2i) are among several glucose-lowering therapies available. Clinical guidelines for type 2 diabetes recommend use of SGLT2i for people with ASCVD, heart failure (HF), or CKD when eGFR is adequate, to control glycemia, reduce cardiovascular risk, and slow progression of kidney disease.

Methods: Using an EHR-derived dataset from 24 AMGA member health care organizations (HCOs), we identified 248,469 patients with type 2 diabetes aged 18–85 who had an ambulatory encounter with a primary care provider and a prescription for a glucose-lowering medication other than metformin and insulin in the past year (9/2018–8/2019). Patients with end stage kidney disease or hospice care were excluded. We explored the proportion of patients with an SGLT2i prescribed in the past year, and used logistic regression to describe differences by eGFR category, comorbid conditions, and specialist visits, adjusted for all predictor variables, age, sex, race, ethnicity, financial class, and HCO.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Results: Across HCOs, median proportion of patients with an SGLT2i prescribed was 22% (range, 12–39%). Prescribing decreased with eGFR category from G1 to G4 (Figure 1). SGLT2i prescribing was lower for patients with HF and those who saw a nephrologist, marginally higher for patients with ASCVD and those who saw a cardiologist, and substantially higher for patients who saw an endocrinologist.

Conclusions: There was significant variation in SGLT2i prescribing across HCOs. While guidelines emphasize use of SGLT2is among patients with ASCVD, HF, or CKD, our findings suggest these recommendations have not been widely adopted in clinical practice. Endocrinologists may play an important role in prescribing new glucose-lowering medications, while nephrologists may be hesitant to prescribe medications for type 2 diabetes.

PO1017
Dulaglutide and Kidney Function-Related Outcomes in Type 2 Diabetes: Post Hoc Analysis from the REWIND Trial
Jonathan E. Shaw,1 Fady T. Bottros,2 Raleigh Malik,2 Charles M. Atitso,2 Hertzl C. Gerstein,1,3 1Baker Heart and Diabetes Institute, Melbourne, VIC, Australia; 2Eli Lilly and Company, Indianapolis, IN; 3Population Health Research Institute, Hamilton, ON, Canada; 4Hamilton Health Sciences and McMaster University, Hamilton, ON, Canada.

Background: Over the median follow-up of 5.4 years in the REWIND trial, which included participants with type 2 diabetes (T2D) and multiple cardiovascular (CV) risk factors, dulaglutide (DU) use was associated with a reduction in composite renal outcomes, defined as the first occurrence of new macroalbuminuria, sustained decline in estimated glomerular filtration rate (eGFR) of ≥30% (using the modification of diet in renal disease [MDRD] equation), or chronic renal replacement therapy. This posthoc analysis evaluated the potential effects of dulaglutide on renal outcomes using an alternative endpoint definition that is commonly used in renal outcomes studies; defined as the composite endpoint of sustained eGFR decline ≥40% (using the chronic kidney disease-epidemiology collaboration [CKD-EPI] equation), end-stage renal disease (ESRD), or all-cause death.

Methods: REWIND participants were randomized (1:1) to DU 1.5 mg once weekly or placebo. Cox proportional hazards model for time-to-first-event analysis was used to determine the risk of renal outcomes. Subgroup analyses were conducted by baseline eGFR and albuminuria status.

Results: At baseline, treatment groups had similar eGFR values (mean ± SD: DU = 77.6 ± 19.4 mL/min/1.73 m²; placebo = 77.1 ± 19.6 mL/min/1.73 m²). The incidence rate of the composite endpoint was significantly lower for the DU group compared with placebo. This effect was consistent regardless of baseline eGFR or albuminuria status (Table).

Conclusions: Treatment with DU 1.5 mg was associated with a 17% risk reduction in the composite renal outcome, suggesting potential delay in progression of diabetic kidney disease in patients with T2D at CV risk.

PO1018
Efficacy and Safety of Cotadutide, a Dual GLP-1 and Glucagon Receptor Agonist, for Patients with Type 2 Diabetes Mellitus and CKD
Victoria E. Parker,1 Thuong Hoang,1 Heike Schlichthaur,2 Yi-Ting Chang,3 Marcella Petrone,1 Lars Hansen,1 Philip D. Ambery,2 Hiddo J. Heerspink,3 Rory McErmimon,4 Lutz Jermutus,1 AstraZeneca, Cambridge, United Kingdom; 2Study Center, SMO MD GmbH, Magdeburg, Germany; 3AstraZeneca, Gothenburg, Sweden; 4University Medical Center, Groningen, Netherlands; 5School of Medicine, University of Dundee, Ninewells Hospital, Dundee, United Kingdom.

Background: Cotadutide is in development for nonalcoholic steatohepatitis and type 2 diabetes mellitus (T2DM). GLP-1 analogues have been shown to delay the development of macroalbuminuria in patients (pts) with T2DM. The glycemic and renal effects of cotadutide were assessed in a phase 2a, randomized, controlled trial.

Methods: The trial enrolled 41 pts with T2DM (HbA1c: a1g.5–a10.5%) and chronic kidney disease (CKD) stage G3 (estimated glomerular filtration rate [eGFR]: ≥30–60 mL/min/1.73m²), on insulin and/or oral therapy, with a BMI of 25–45 kg/m². Pts were randomized to once-daily subcutaneous cotadutide (n=21), titrated up to 300 μg, or placebo (PBO; n=20) for 32 days. Endpoints included glucose response via mixed meal tolerance test (MMTT), HbA1c, body weight (BW), eGFR, urinary albumin creatinine ratio (UACR), and C-peptide levels. The trial was powered based on a 2-sided alpha of 0.1.

Results: Cotadutide significantly reduced MTMM glucose AUC vs baseline (-26.7%, 90% CI: -34.6 to -18.8%) and vs PBO (35.7%; 90% CI: -8.3 to -11.2%; P<0.001), with a 35.2% reduction in insulin dose (P=0.012). Cotadutide significantly reduced BW (-3.7%) and HbA1c (+0.7%; both P<0.001). After 32 days of cotadutide treatment, no significant changes were observed in eGFR or blood pressure. Fasting C-peptide levels in the cotadutide arm increased significantly vs PBO (Δ: 0.07 μg/L, 90% CI: 0.06 to 0.10, P<0.001). No meaningful changes were observed in BW, eGFR, or UACR. C-peptide levels significantly increased (11 beats per minute; P=0.001) by day 32.

Conclusions: In pts with T2DM and CKD, cotadutide improved overall glycemic control and glaucoma responses to an MTMT with acceptable tolerability. Improvements in albuminuria suggest that cotadutide may be beneficial in this population to slow long-term progression of CKD. Further exploration of this effect is warranted.

Hemoglobin A1c Reduction with the GLP-1 Receptor Agonist Semaglutide Is Independent of Baseline eGFR: Post Hoc Analysis of SUSTAIN and PIONEER Programs

David Cherney,1 Samy Hadjadj,2 Thomas Idorn,3 Ofri Mosenzon,4 Sascha Pilemann-Lyberg,5 Vlad Perkovic,6 Katherine R. Tuttle,6* Soren Rasmussen,7,8 Stephen C. Bain,9 Institute of Translational Health Sciences, University of Washington, Seattle, WA; 6Division of Nephrology, University Health Network, University of Toronto, Toronto, ON, Canada; 3Novo Nordisk A/S, Søborg, Denmark; 4Haddassah Medical Center, Hebrew University of Jerusalem, Jerusalem, Israel; 1The George Institute for Global Health, UNSW Sydney, Sydney, NSW, Australia; 2Provience Medical Research Center, Providence Health Care, Spokane, WA; 9Institute of Translational Health Sciences, University of Washington, Seattle, WA; L’institut du thorax, INSERM CNRS, Univ Nantes, CHU Nantes, Nantes, France; 8Swansea University Medical School, Swansea University, Swansea, United Kingdom; 7Diabetes Research Unit Cyrmu, Swansea University, Swansea, United Kingdom.

Background: Hyperglycemia is an established risk factor for the development and progression of chronic kidney disease. The glucagon-like-peptide-1 receptor agonist semaglutide is approved for the treatment of type 2 diabetes (T2D) across a wide range of estimated glomerular filtration rates (eGFRs). We investigated whether baseline eGFR affected glycated hemoglobin (HbA1c) reduction with semaglutide.

Methods: This post hoc, trial-level analysis considered all SUSTAIN (1–10) and PIONEER (1–10) trials where renal impairment was not an exclusion criterion and where the number of subjects receiving semaglutide with eGFR <60 mL/min/1.73m2 was ≥45. It included data for once-weekly subcutaneous semaglutide (SUSTAIN 4–6, pooled 0.5 and 1.0 mg; SUSTAIN 10, 1.0 mg only) and once-daily oral semaglutide (PIONEER 5 and 6). Within each trial, absolute estimated change in HbA1c from baseline to end of treatment (EOT) was compared between eGFR subgroups using a linear mixed model.

Results: Mean HbA1c at baseline ranged from 7.9% to 8.7% across the subgroups. Semaglutide significantly reduced HbA1c at a comparable magnitude across eGFR subgroups in all trials (mean reduction of 1.0–1.7% from baseline to EOT; p<0.048 for difference between eGFR subgroups within each trial; Figure).

Conclusions: Semaglutide (subcutaneous and oral) is an effective glucose-lowering agent in subjects with T2D, independently of baseline eGFR, including in those with chronic kidney disease.

Funding: Commercial Support - Novo Nordisk

Impacts of Glucagon-Like Peptide 1 Analogues and Sodium Glucose Cotransporter 2 Inhibitor on Type 2 Diabetes Patients with Renal Impairment

Takeyuki Hirama, Konan Kosei Hospital, Konan, Japan.

Background: Diabetes mellitus (DM) is a progressive multifactorial disease associated with cardiovascular complications. To prevent the progression of cardiovascular complications in DM patients, we examined impact on cardiac function between glucagon like peptide-1(GLP-1) analogue and sodium-glucose cotransporter-2 (SGLT-2) inhibitors to treat type 2 diabetes patients with renal impairment.

Methods: A total of 156 type 2 DM patients with renal impairment were recruited for this study. All patients were divided into two groups according to the anti-diabetic agents at baseline : Group G; 0.9mg/day liraglutide, n=72, Group S; n=84; 5mg/day dapagliflozin, n=32. Blood glucose levels, glycosylated hemoglobin, was independently associated with greater UACR reduction (\(\beta\)-7.0\% for this study. All patients were divided into two groups according to the anti-diabetic agents at baseline : Group G; 0.9mg/day liraglutide, n=72, Group S; n=84; 5mg/day dapagliflozin, n=32. Blood glucose levels, glycosylated hemoglobin (HbA1c), serum creatinine, and albuminuria were obtained 12 months before and every 3 months for 36 months. Echocardiography, cardio-ankle vascular index(CAVI) were obtained every 12 months for 36 months.

Results: HbA1c and systolic blood pressure were significantly decreased after ADAs. The eGFRs were gradually decreased in both groups. Albuminuria was decreased significantly after initiation of ADAs. Left ventricular mass index (LVMI) and left atrial volume index (LAVI) were significantly decreased in both groups. Cardiac systolic function indicated by ejection fraction and diastolic function indicated by E/e’or left atrial dimension were remained or improved only in group G. Moreover, arterial stiffness indicated by cardio-ankle vascular index (CAVI) was improved in group G (Table1).

Conclusions: These findings suggest that liraglutide and SGLT-2 inhibitor for type 2 DM patients with renal impairment have similar effects on renal function including eGFR and albuminuria and left ventricular and atrial volume. However, liraglutide could provide more benefit for arterial stiffness than SGLT-2 inhibitors.

AKI Associated with Semaglutide

David J. Leehey,1 Maria M. Pickern,3 Mohamed A. Rahman,2 Loyola University Health System, Maywood, IL; 1Nephrology Associates Northern Illinois, Elk Grove Village, IL

Introduction: Recently there have been post-marketing reports of AKI and worsening CKD in patients taking glucagon-like peptide-1 (GLP-1) receptor agonists. Clinical details of these patients have not been published. Herein we report two patients who suffered rapid worsening of renal function after being prescribed semaglutide (Ozempic).

Case Description: Patient 1. An 83-year-old woman with diabetes, hypertension, and CKD was seen in Apr 2020 for increasing leg edema. In Nov 2019 she had been prescribed weekly semaglutide injections. At that time serum creatinine was 1.59 mg/dL (eGFR 30 mL/min/1.73m2) and serum albumin 3.3 g/dL. Rate of decline of eGFR for the previous 6 years had been 1.5 mL/min/1.73m2/yr. Attempts to increase the dose of semaglutide from 0.25 mg to 0.5 mg resulted in nausea and vomiting the day following the injection, so the drug was stopped at the end of March 2020. She had no intercurrent illnesses, hospitalizations, or change in other medications. Examination revealed BP 162/82 and 3rd peripheral edema. Serum creatinine was 3.50 mg/dL (eGFR 11), serum albumin 2.9 g/dL, and urine protein/creatinine ratio (UPCR) 4.9 g/g. Urinalysis revealed 3+ protein. Renal biopsy showed diffuse and nodular glomerulosclerosis with acute interstitial lymphocytic and eosinophilic infiltration and acute tubular injury. There has been no recovery of renal function in the 2 months since semaglutide was discontinued.

Patient 2. A 65-year-old male with diabetes, hypertension, and CKD was initially seen in 2012 for CKD management. BP was well controlled and eGFR stable in the 30-35 range with UPCR of 800-500 mg/g for the next 7 years. In Nov 2019 he was started on weekly semaglutide 0.25 mg increased after 2 weeks to 0.5 mg, after which eGFR decreased to 22 in Mar 2020 accompanied by an increase in UPCR to 1333. The patient denied GI symptoms but did complain of decreased appetite and fatigue. Semaglutide was stopped with resolution of symptoms. His most recent eGFR is 24.

Discussion: AKI has been observed in both clinical trials with GLP-1 receptor agonists and post-marketing clinical experience. Most of these events have occurred in patients who experience adverse GI symptoms. To our knowledge, Patient 1 is the first reported case with biopsy findings. Patients developing new symptoms after starting semaglutide should have laboratory tests performed and the drug discontinued if there is worsening renal function.

**Effect of Oral Supplementation with Curcumin in Diabetic Subjects with Proteinuric Kidney Disease: A Randomized Controlled Trial**

Ana P. Hernandez-Martinez,1 Yao Cheng,1 Alfonso Giindl-Bracho,2 Alejandro Cabrera-Jara,2 Ana K. Fernandez-Yepes,2 Maria F. Martinez-Hernandez,2 L. Gabriela Sanchez-Lozada,1 Edilia Tapia,1 Francisco Eugenio R. Castellanos,1 Armando Rezquez-Zangreel,1 Magdalena Madero,1 1 Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico; 2 Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Tlalpan, Mexico; 3 Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico.

**Background:** Proteinuria remains one of the most important risk factors associated with kidney disease progression. Curcumin is a powerful antioxidant, and different studies have demonstrated the increased expression of cytoprotective proteins through the Keap1/Nrf pathway. We conducted a randomized controlled trial in proteinuric diabetic patients to assess the effect of curcumin on proteinuria.

**Methods:** The trial was conducted between May, 2016 and September, 2019. We included diabetic patients over 18 years of age, with an estimated GFR by CKD EPI > 15 ml/min/1.73 m2 and proteinuria > 1 gram/g despite optimal dose or contraindication to RAAS blockade. We excluded patients without DM, renal replacement therapy, kidney transplantation, or pregnancy. The study group received 3.22g of curcumin powder equivalent to 1.67g of curcumin, divided into three doses every 8 hours for 24 weeks. Primary outcome was proteinuria at the end of follow up. Secondary outcomes included eGFR and blood pressure control. Our power calculation estimated a total of 100 patients. Results were analyzed on an intention to treat basis.

**Results:** 100 diabetic patients were included. The mean age was 58.1 ± 10.3 years, 67% were female, 98% were hypertensive and 83% had proteinuria > 1 gram/g. After 24 weeks of follow up, no significant differences were observed between groups for proteinuria, eGFR or blood pressure control (Table 1).

**Conclusions:** In this randomized double blinded controlled trial in diabetic subjects with nephrotic range proteinuria and moderate CKD, curcumin administration was not effective in proteinuria reduction or eGFR preservation. ClinicalTrials.gov Identifier: NCT03198488.

**Preexisting CKD Increases Risk of Metformin Monotherapy Failure in US Veterans with Type 2 Diabetes**

Elvira O. Gosmanova,1,2 Darren E. Gemoets,1 Laurence S. Kaminisky,1 Csaba P. Koverydy,1,2 Aidar R. Gosmanov,1,2 Albany Stratton VA Medical Center, Albany, NY; 1 Albany Medical College, Albany, NY; 3 Memphis VA Medical Center, Memphis, TN; 4 The University of Tennessee Health Science Center, Memphis, TN.

**Background:** Metformin (MET) is increasingly used for treatment of type 2 diabetes (T2D) in patients with chronic kidney disease stage 3 (CKD3); however, it is unknown if rates of MET monotherapy failure differs in patients with and without CKD3.

**Methods:** This was a retrospective study including 21,142 US Veterans with T2D and estimated glomerular filtration rate (eGFR) ≥30 ml/min/1.73 m2 who initiated MET monotherapy between 01/2010 and 03/2017. CKD3 was established as eGFR 30-59 ml/min/1.73 m2. MET monotherapy failure defined as the 1st >90 day gap in MET refill (MET discontinuation) or the addition of 2nd hypoglycemic agent (HA) during >3 yr follow up was compared between patients without and with CKD3 using univariate and multivariate Cox regression analyses adjusted for case-mix.

**Results:** The mean ± SD age for the total cohort was 59.4 ± 0.2 yrs, 94.3% were males, 79.9 ± 17.3% were Whites and Blacks, respectively. Preexisting CKD3 was present in 1,363 (6.5%) patients. Baseline patients’ characteristics were similar between two groups except CKD patients were older (68.7 vs. 59.3 yrs in non-CKD) and had lower eGFR (54.1 vs. 87.4 ml/min/1.73 m2 in non-CKD). In Kaplan-Meyer analysis there were no difference in rates of MET discontinuation or addition of 2nd HA in patients without and with CKD3.

**Conclusions:** In newly treated patients with T2D the presence of preexisting CKD stage 3 was associated with increased risk of MET monotherapy failure. MET discontinuation may be expected in CKD patients with the progression of CKD; however, our findings of the increased risk of addition of 2nd HA warrant further studies to understand whether hypoglycemic efficacy of MET monotherapy is reduced in CKD stage 3.

**Effect of Pralirigacut, a Once-Daily, Oral Soluble Guanylate Cyclase Stimulator, on Albuminuria in Patients with Diabetic Kidney Disease: A Randomized, Double-Blind, Phase 2 Trial**

John P. Hamrahan,1 Ian H. de Boer,1 George L. Bakris,2 Phoebe Wilson,1 James D. Wakefield,1 Jelena P. Seferovic,1 Jennifer Chicking,1 Michael Cressman,4 Mark Currie,2 George T. Milne,1 Albert T. Profy,1 Cyclerion Therapeutics, Cambridge, MA; 2The University of Washington, Seattle, WA; 3The University of Chicago Medical Center Comprehensive Hypertension Center, Chicago, IL; 4 Covance Inc, Princeton, NJ.

**Background:** Impaired nitric oxide (NO) signaling has been implicated in the progression of diabetic kidney disease (DKD). Pralirigacut (PRL) is a soluble guanylate cyclase stimulator that amplifies NO signaling in vitro and reduces proteinuria and fasting plasma glucose in the ZSF1 rat model of DKD.

**Methods:** We evaluated the safety and efficacy of PRL in adults (25-75 y) with type 2 diabetes, eGFR 30-75 ml/min/1.73 m2, serum uric acid creatinine ratio (UACR) 200-500 mg/g, hemoglobin Alc (HbAlc) <12%, systolic blood pressure (BP) 110-160 mmHg, on stable glucose-lowering and renin angiotensin system-inhibition therapy. Participants were randomized 1:1:1 to placebo (PBO), PRL 20 mg, or PRL 40 mg daily for 12 weeks. Two first morning void specimens for UACR were collected at baseline and weeks 1, 4, 8, 12. Adverse events, 24 h BP and serum chemistry were also assessed. The primary efficacy endpoint was change from baseline (CBF) in UACR to weeks 8 and 12 analyzed by mixed-Effects repeated measures model to compare pooled PRL vs PBO.

**Results:** A total of 156 participants enrolled and 140 completed treatment. Of the 156, 66% were men, 71% were White, 24% Black, and 54% Latino. Model estimates of mean UACR CBF (90% CI) [intent-to-treat (ITT)] were -28% [-36, -18] for pooled PRL and -15% [-27, 0] for PBO; PBO-adjusted UACR CBF was -15% [-31, 4] (p=0.17). Quality checks identified a site with data inconsistent with that from the overall study population. In a post-hoc sensitivity analysis excluding this site, PBO-adjusted UACR CBF for PRL was -20% [-33,-5], nominal p=0.03. PBO-adjusted CBF for other variables at week 12 (ITT) were: 24 h systolic BP -4.2 mmHg [-7.5, -0.8], 24 h heart rate 3.4 bpm [1.6, 5.2], HbAlc -0.27% [-0.50,-0.03], and cholesterol -10.1 mg/dL [-19.2, -1.0]. Mediation analyses indicated that -75% of the UACR decline was independent of SBP decrease. Both pralirigacut doses were well tolerated.

**Conclusions:** PRL did not significantly reduce UACR in the primary ITT analysis, but favorable trends in UACR, BP, and metabolic variables warrant further clinical study of PRL in DKD.

**Utilization of Glucose-Lowering Medications Among US Medicare Beneficiaries with CKD Between 2007 and 2016**

Julie Zhao,1,2 Eric D. Weinhandl,1,2 Angelene M. Carlson,3 Wendy L. St. Peter,1,2 University of Minnesota, Minneapolis, MN; 3 Chronic Disease Research Group, Hennepin Healthcare Research Institute, Minneapolis, MN.

**Background:** Selecting effective and safe glucose-lowering medications for chronic kidney disease (CKD) patients is challenging. Twelve classes of glucose-lowering medications are on the US market today. Information regarding utilization of glucose-lowering medications in patients with CKD is limited.

**Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only**

Underline represents presenting author.
Methods: We evaluated an adult CKD population from Medicare 5% random sample 2007-2016, provided by the United States Renal Data System. Yearly cohorts of patients with CKD and type 2 diabetes were created. Descriptive statistics were used to report proportions of patients using glucose-lowering renal medications. To test overall trends in glucose-lowering medication classes, linear probability models with adjustment for age, sex, race, income, and low-income status were used.

Results: Use of metformin, newer glucose-lowering medication classes (DPP-4 inhibitors, GLP-1 receptor agonists, and SGLT2 inhibitors), and newer insulin analogs (aspart, lispro, glulisine, detemir, glargine, degludec) showed statistically significant upward trends during the study timeframe. Sitagliptin was the most commonly prescribed DPP-4 inhibitor; use increased from 5.6% in 2007 to 15.0% in 2016. Use of liraglutide (approved in 2011) increased from 0.1% in 2011 to 6.0% in 2016. Compared with other GLP-1 receptor agonists, use of liraglutide (approved in 2010) increased more (0.3% in 2010 to 3.9% in 2016), and use was higher in 2015. Use of SGLT2 inhibitors (canagliflozin, empagliflozin, or dapagliflozin) remained very low but in 2016, use was increasing. Use of newer analog insulin therapy increased, especially insulin detemir (2.4% in 2007 to 11.7% in 2016). Insulin was the most highly used single medication class in 2016. The most highly used dual combination therapies in 2016 were metformin and sulfonylureas, metformin and insulin. Combination therapy was less common as CKD stage increased.

Conclusions: Use of metformin and newer glucose-lowering medication classes is increasing in CKD patients with type 2 diabetes. We anticipate that percentages of CKD patients using these newer agents will increase.

PO1030
Role of Roxadustat in Improving Erythropoiesis-Stimulating Agent (ESA)-Resistant Anemia in Patients on Maintenance Hemodialysis
Satoshi Funakoshi,1 Jyunichi Hashiguchi,1 Kenji Sawase,2 Taku Kawazu,3 Mineki Kitamura,1 Kanako Hayashi,1 Kosei Yamaguchi,1 Tomoya Ninomiya,2 Takashi Harada.1 Nagasaki University Hospital, Nagasaki, Japan; 2Nagasaki University, Kagoshima, Japan.

Background: Roxadustat, an oral hypoxia-inducible factor (HIF) prolyl hydroxylase inhibitor, is shown to stimulate erythropoiesis thus improving iron metabolism. Again, while hyperglycemic states are known to be associated with a decreased tissue hypoxia response, data that show that HIF has not been evaluated for its role in improving anemia in patients with or without diabetes in clinical settings.

Methods: A total of 64 hemodialysis patients being treated with epoetin α (9000 units weekly) participated in the study after giving informed consent. They were switched from intravenous epoetin α to oral roxadustat (100 mg 3 times weekly) therapy and were assessed for the improvement in anemia as well as changes for parameters of iron metabolism and C-reactive protein (CRP).

Results: The study included 39 patients without diabetes (mean age, 71.1 ± 12.1 years; mean diabetes vintage, 7.5 ± 7.4 years; mean GA, 16.2 ± 2.9%) and 27 patients with diabetes (mean age, 70.3 ± 10.3 years; mean diabetes vintage, 5.9 ± 5.5 years; mean GA, 24.9 ± 5.5%). As shown in Table 8, after 8 weeks the Hb concentration was significantly increased from 10.3 ± 0.8 g/dL at baseline to 10.7 ± 1.3 g/dL in patients without diabetes (P = 0.03) but was not increased in patients with diabetes (from 10.4 ± 0.6 at baseline to 10.5 ± 1.1 g/dL). Again, the serum iron, ferritin concentrations and the transferrin saturation ratio were decreased, irrespective of whether or not they had diabetes, with no change shown in serum CRP level.

Conclusions: Switching hemodialysis patients with ESA-resistant anemia from ESA to roxadustat led to improvement in anemia only in those without diabetes, while study results suggested the involvement of mechanisms, other than impaired iron utilization or inflammation, in the impairment of hematopoiesis in those with diabetes.

Effects of Roxadustat on HD Patients without or with Diabetes

PO1031
Efficacy and Safety of Roxadustat in Patients with Dialysis-Dependent CKD, Anemia, and Diabetes Mellitus
Simon D. Roge,1 Carol A. Pollock,2 Mohamed A. El-Shahawy,2 William A. Ghali,1 Khalil G. Saikali,1 Kin-Hung P. Yu.1 1Novel Research, Gosford, NSW, Australia; 2The University of Sydney, Sydney, NSW, Australia; 3Renal Associates PA, San Antonio, TX; 4FibroGen Inc, San Francisco, CA; 5University of Southern California Keck School of Medicine, Los Angeles, CA.

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Diabetes mellitus (DM) is a growing health problem often associated with CKD. In patients with DM, 37-54% of patients on dialysis (Stages 4 and 5 CKD) have DM. Use of newer analog insulin therapy increased, especially insulin detemir (0.3% in 2010 to 3.6% in 2016), and use was higher in 2016. Use of SGLT2 inhibitors (approved in 2011) increased from 0.1% in 2011 to 6.0% in 2016. Compared with other glucose-lowering medication classes, linear probability models with adjustment for age, sex, race, income, and low-income subsidy (LIS) status were used.

Results: Use of metformin, newer glucose-lowering medication classes (DPP-4 inhibitor; use increased from 5.6% in 2007 to 15.0% in 2016. Use of liraglutide (approved in 2011) increased from 0.1% in 2011 to 6.0% in 2016. Compared with other GLP-1 receptor agonists, use of liraglutide (approved in 2010) increased more (0.3% in 2010 to 3.9% in 2016), and use was higher in 2015. Use of SGLT2 inhibitors (canagliflozin, empagliflozin, or dapagliflozin) remained very low but in 2016, use was increasing. Use of newer analog insulin therapy increased, especially insulin detemir (2.4% in 2007 to 11.7% in 2016). Insulin was the most highly used single medication class in 2016. The most highly used dual combination therapies in 2016 were metformin and sulfonylureas, metformin and insulin. Combination therapy was less common as CKD stage increased.

Conclusions: Use of metformin and newer glucose-lowering medication classes is increasing in CKD patients with type 2 diabetes. We anticipate that percentages of CKD patients using these newer agents will increase.

Monocyte-to-Lymphocyte Ratio, an Independent Risk Factor of Survival and Cardiovascular Disease in Hemodialysis Patients: Results from the International MONDO Consortium

Rupert B. Bright, Xiaoling Ye, Kevin Woollard, Charles D. Pusey, Peter Kotanko, Neill D. Duncan, Imperial College Healthcare NHS Trust, London, United Kingdom; Imperial College London, London, United Kingdom; Renal Research Institute, New York, NY.

Background: Patients with ESRD have a high prevalence of chronic inflammation and higher risk of death. Monocytes have a crucial inflammatory role, but there has been limited study to date. We aimed to determine the independent relationship between MLR, all-cause and cardiovascular (CV) mortality in a large and ethnically diverse haemodialysis population.

Methods: Four cohorts were described by phases of haemodialysis exposure. Kaplan-Meier (KM) curves were applied to explore the association between MLR quartiles with all-cause and CV mortality in the 4 cohorts. Cox proportional hazards models with spline terms (adjusted for age, gender, race, smoking status, body mass index, diabetes (DM) and congestive heart failure (CHF)) were applied to explore the association between MLR levels and all-cause mortality in the cohorts.

Results: 21,095 patients were included in acute phase cohort; 19,240 in the early-stable phase cohort, 16,680 in the mid-stable cohort, and 13,839 in the late-stable phase cohort. Notably, patients with higher baseline MLR by quartile tended to be older, male and with a higher percentage of DM and CHF as comorbidities. Lower lymphocyte count and higher neutrophil count, NLR, CRP were associated with higher MLR quartile, consistent with the observed association with other markers of inflammation and malnutrition: lower albumin, phosphate and higher ferritin. Adjusted all-cause and CV mortality was observed to be higher in patients with higher MLR quartile both in the KM and spline analyses (Fig1/2).

Conclusions: There is a positive relationship between higher levels of MLR and adjusted all-cause and CV mortality across all phase cohorts, including long-term follow-up in this large and ethnically diverse haemodialysis population. Higher prevalence of DM and CHF are seen in patients with higher levels of MLR. This work supports findings made previously in more restricted cohorts and warrants further mechanistic investigation.

POI035

Warfarin Increases the Risk of Vascular Calcification in Haemodialysis Patients: A Multicenter Case-Control Study

Rezzan Eren Sadioglu, Evren Ustuner, Ilhan Ergun, T. Eckerz, Gokhan Nergizoglu, Kenan Keven. 

Methods: This was a cross-sectional, observational, multicenter study. Vascular calcification (VC) were assessed using Adragao (AS; pelvis and hands) and Kauppila (KS; lateral lumbar spine) scores in 76 haemodialysis patients from six centers. There were 32 patients (4.5%) being treated with warfarin for at least 1 year out of a total of 711 haemodialysis patients and we included 44 control patients with matching parameters of age, sex and dialysis vintage to the study. Clinical characteristics, comorbid treatments, laboratory results were recorded and possible risk factors related to VC were analyzed.

Results: Of the patients, 47% were females, mean age was 65.8 ± 9 years, 23% were diabetics, their mean dialysis vintage was 68.39 ± 38.5 months and mean Kt/V 1.66 ± 0.27. No significant differences in clinical characteristics and basic laboratory results were found between control and warfarin group. In warfarin group, median Kauppila score was higher than control [11 vs 6.5 (25%-75% percentile, 5 vs 15), P = 0.032] and percentages of KS2 score ≥6 - patients were higher, as well (78.6% vs 50%; P = 0.029). Median Adragao score was not significantly different between two groups [7 vs 6, (25%-75% percentile 6 vs 8), P = 0.177]. Logistic regression analysis revealed that warfarin treatment was independently associated with Kauppila scores of ≥6 (OR 3.28, 95% CI 1.17-9.22, P = 0.024).

Conclusions: The results of this study showed that warfarin is a strong risk factor for vascular calcifications, especially in aorta of haemodialysis patients.

Paradoxical Effect of Aldosterone on Cardiovascular Outcome in Maintenance Hemodialysis Patients

Kyu Sang Yun, Sun Ryoung Choi, Hayne C. Park, Do Hyong Kim, Aijn Cho, Juhee Kim, Jung Woo Noh, Youngki Lee, Hallym University Kangnam Sacred Heart Hospital, Seoul, Republic of Korea; Hallym University Dongtan Sacred Heart Hospital, Gyeonggi, Republic of Korea.

Background: Patients with end-stage kidney disease have an increased risk of cardiovascular (CV) events and left ventricular diastolic dysfunction (LVDD) is known to contribute to high occurrence of CV mortality. Although high serum aldosterone level is involved in the development of CV complications in general population, this association is unclear in patients undergoing hemodialysis (HD). We aimed to determine the impact of serum aldosterone on LVDD and CV mortality among HD patients.

Methods: We performed a prospective cohort study of maintenance HD patients without CV disease. Patients were divided into two groups according to the median level of serum aldosterone. All patients underwent echocardiography to evaluate diastolic dysfunction. Proportions of LVDD and CV mortality were compared between high and low aldosterone groups.

Results: We enrolled a total of 60 adult patients (mean age 57.9±12.1 years, male 30.0%). Low aldosterone group had an increased left ventricular diastolic dimension compared with high aldosterone group (52.2±8.4 vs. 30.3±5.2 mm, p=0.033). The E/e' ratio and the proportion of LVDD were significantly higher in the low aldosterone group than the high aldosterone group. Multivariate logistic regression revealed that low log-aldosterone (odds ratio (OR) 0.403; 95% confidence interval (CI) 0.180-0.862) and large left atrial dimension (OR 1.308; 95% CI 1.144-1.536) were independent risk factors for LVDD. During the mean follow-up period of 5.2 years, the cumulative incidence rates of CV mortality were significantly higher in low aldosterone group (log-rank test, p<0.027). In addition, cox regression analysis demonstrated that low serum aldosterone was an independent predictor of CV mortality in HD patients (hazard ratio 0.505; 95% CI 0.294-0.869, p=0.014).

Conclusions: Low serum aldosterone was not only associated with LVDD but also an independent predictor of CV mortality among HD patients.

PO1037
Variations in the Thrombin Generation Profile and Clotting Factor Levels in the Patients Undergoing Maintenance Hemodialysis
Fakhra Siddiqui, Emily Bontecoe, Debra Hoppensteal, Walter Jeske, Vinod K. Bansal, Jawed Fareed, Loyola University Medical Center, Maywood, IL.

Background: Chronic kidney disease (CKD) patients are at high risk of cardiovascular disorders and thrombosis. CKD-V patients undergoing maintenance hemodialysis exhibit varying degrees of hemostatic dysregulation. Endogenous thrombin potential (ETP) is important to the pathogenesis of vaso-occlusive complications. This study investigated ETP and its relevance to circulating coagulation factor levels in CKD-V patients.

Methods: Citrated blood samples from 95 patients with CKD-V were collected prior to their routine hemodialysis. Normal human plasma (NHP) was used for referencing purposes. Plasma levels of coagulation factor VII, IX, X and XIII were measured by ELISA. ETP was measured using a kinetic fluorogenic method. Such parameters as peak thrombin, lag time (LT) and area under the curve (AUC) were compiled. Correlation analysis between peak thrombin and coagulation factors was carried out by using GraphPad Prism software.

Results: CKD-V patients did not show any significant difference in factor VII levels (110.6 % vs 112.5 %) and factor X (81.5 % vs 88.2 %). Factor IX levels were elevated (126.3 %) in the CKD-V group compared to NHP (100.5 %). Similarly, factor XIII levels were significantly higher in CKD-V (104.8 %) in comparison to NHP (82.3 %). In the ETP studies, CKD-V patients showed a wide variation in ETP parameters. Peak thrombin levels (107.1 nM vs 168.3 nM) and AUC (589.8 nM*min vs 815.7 nM*min) were lower while lag time was higher (2.89 min vs 2.17 min) in the CKD-V group in comparison to NHP. Coagulation factor VII, IX and X correlated with peak thrombin levels (r = 0.3) whereas factor XIII did not show any significant correlation.

Conclusions: These studies demonstrate that CKD-V patients exhibit a decreased generation of endogenous thrombin with simultaneous consumption of coagulation factors suggesting an ongoing activation of coagulation system. Almost 10% of the CKD-V patients exhibited increased levels of peak thrombin values which correlated with relatively higher levels of clotting factors suggesting a decreased activation of ETP. These studies indicated that a majority of CKD-V patients are in a sustained state of ongoing thrombin generation which may contribute to the observed thrombotic complications in these patients.

Physical Activity and Mortality in Adults Undergoing Hemodialysis: A DIET-HD Cohort Study
Amelie Bernier-Jean,1 2 Germaine Wong,1 2 Valeria M. Saglimbene,3 6 Marcella Ruoso,1 Suetonia Palmer,1 6 Patrizia Natale,3 6 Vanessa Garcia-Larsen,3 6 David W. Johnson,1 7 Marcello Tonelli,1 7 Jonathan C. Craig,1 5 Giovanni F. Strippoli,1 3 School of Public Health, Faculty of Medicine and Health Sciences, University of Sydney, Sydney, NSW, Australia; 4Centre for Kidney Research, The Children’s Hospital at Westmead, Westmead, NSW, Australia; 5Diaverum Medical-Scientific Office, Diaverum, Lund, Sweden; 6Department of Medicine, University of Otago, Christchurch, New Zealand; 7Department of Emergency and Organ Transplantation, University of Bari, Bari, Italy; 8Program in Human Nutrition, Department of International Health, The Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; 9Department of Nephrology, Princ. Alexander Hospital, Brisbane, QLD, Australia; 10Australasian Kidney Trials Network, University of Queensland, Brisbane, QLD, Australia; 11University of Calgary, Calgary, AB, Canada; 12College of Medicine and Public Health, Flinders University, Adelaide, SA, Australia.

Background: People receiving maintenance hemodialysis (HD) are at higher risk of cardiovascular disease (CVD) and death. Regular exercise training reduces CVD mortality in people with coronary heart disease, but the potential survival benefits for adults undergoing HD are unknown. We assessed the association between self-reported physical activity (PA) and mortality in a very large cohort of people receiving HD.

Methods: DIET-HD is a prospective, multinational study of adults undergoing HD in Europe and South America. We classified participants as sedentary, exercises up to once a week (‘occasional PA’), or exercises twice a week or more (‘frequent PA’), using a self-reported question. We balanced the baseline characteristics, including socio-demographic factors, comorbidities, blood chemistry and dietary intake, across the PA groups using propensity scores. We conducted weighted Cox proportional hazards models with double robust estimation to assess the association between PA and mortality.

Results: Of the 8043 participants initially included in the DIET-HD study, 6147 (76%) had information on PA. 1226 (20%) exercised frequently, 1981 (32%) occasionally and 2940 (48%) were sedentary. During a median follow-up of 3.82 years (19 677 person-years), 2337 (38%) deaths occurred, of which 1050 (45%) were from CVD causes. After propensity score-weighting and adjustment for potential confounders, PA was associated with a lower risk of all-cause mortality, CVD mortality and non-CVD mortality (Table). We observed a dose-dependent effect of PA for CVD death.

Conclusions: Regular PA is associated with a lower risk of CVD mortality in adults receiving HD. Until randomized control trials assess the effect of PA on mortality in HD, it should be considered as part of the clinical management of HD patients.

Funding: Government Support - Non-U.S.
OL-HDF on survival benefit have failed. To date, the survival rate of OL-HDF has not been investigated in a large number of Koreans.

Methods: Using data from the Korean Society of Nephrology, The total 85,643 patients undergoing hemodialysis between 2014 and 2019 were divided into two groups receiving only conventional HD and only OL-HDF with thrice sessions per week, dialysis vintage ≥18months, and a history of diabetes mellitus. Demographic characteristics, hemodialysis patterns, and overall survival were analyzed between the groups.

Results: The study included 8,955 patients (750 OL-HDF, 8,205 conventional HD) with a median follow-up of 2.58 (interquartile range 0.50–4.66) years. The mean age was younger and more male genders, and the dialysis vintage was slightly longer in patients with OL-HDF group compared with these of conventional HD group. We performed propensity score matching in 1:1 with the covariate of age, gender, cause of ESRD, and dialysis vintage. Compared with conventional HD, OL-HDF was associated with improved all-cause-mortality/hazard ratio 0.659, 95% confidence interval 0.465 to 0.934). In cardiovascular mortality, no statistical difference was observed between the groups.

Conclusions: Our results indicate that OL-HDF was associated with reduced mortality without harmful effects on nutritional status across patient subgroups of age, sex and cause of ESRD, dialysis vintage.

Comparison of cumulative probabilities of survival between HD and HD groups

PO1041

Energy Homeostasis Gene Polymorphisms and Survival of Hemodialysis Patients

Background: Patients who undergo hemodialysis (HD) therapy have an increased risk of death compared to the general population. Single nucleotide variants (SNVs) of energy homeostasis influence the susceptibility to diabetes mellitus (DM), dyslipidemia, and coronary artery disease (CAD). We investigated whether selected SNVs related to energy homeostasis are associated with mortality risk in HD patients.

Methods: The study included 471 HD patients who were tested for 11 SNVs in FOXO3, IGFBP3, Fabp1, PCSK9, ANGPLT6, and ANGPLT8 genes using HRM analysis and TaqMan assays. FOXO3, IGFBP3, L-FABP, PCSK9, ANGPLT6, and ANGPLT8 plasma concentrations were measured by ELISA in 71 HD patients. The Kaplan-Meier method and Cox proportional hazard models were used for survival analyses.

Results: Patients with ANGPLT8 rs737337 CC genotype had over 3-fold increased risk of death compared with the carriers of the major allele (log-rank test p = 0.002; HR 3.4; 95% CI 1.5–7.7; p = 0.003). rs737337 CC genotype was in particular a risk factor for cardiac (2e-4; 5.5–15.1; SE-4) and cardiovascular deaths (0.004; 4; 1.5–10.7; 0.007). The association mentioned above remained significant after adjustment for gender, DM, CAD, age at RRT onset, BMI and CRP (p = 0.03, 0.04 and 0.02 for overall survival, cardiac and cardiovascular deaths, respectively). ANGPLT8 rs737337 was also associated with an increased risk of diabetic nephropathy (OR 1.89; 95% CI 1.1–2.9; p = 0.02). Plasma ANGPLT8 levels were increased in patients diagnosed with CAD (p = 0.028). Carriers of IGFBP3 rs3110697 variant A allele had increased risk of cardiovascular mortality (HR 1.3; 95% CI 1.1–1.6; p = 0.02, adjusted pNS). IGFBP3 rs3110697 positively correlated with the diagnosis of CAD (p = 0.006), myocardial infarct (p = 0.01) and dyslipidemia (p = 0.02) as well as with CRP concentrations (p = 0.005). Carriers of FOXP3 rs4946936 CT genotype had increased risk of cardiac death (HR 1.6; 95% CI 1.1–2.4; p = 0.03, adjusted pNS), whereas FOXO3 rs2802292 TT genotype was associated with decreased risk of vascular mortality (HR 0.4; 95% CI 0.2–0.8; p = 0.005). The association remained significant after adjustment (p = 0.002). The analyzed proteins did not correlate with the survival probability of HD patients.

Conclusions: ANGPLT8 rs737337, IGFBP3 rs3110697, FOXP3 rs2802292, and rs4946936 are prognostic factors of survival among HD patients.

PO1042

Short-Term Association of Pre-Dialysis Calculated Serum Osmolality and Its Per-Quarter Change with Mortality in Maintenance Hemodialysis Patients

Takeshi Miyagi,1 Cachet Wenziger,1 Jui-Ting Hsiung,1 Yoko Narasaki,1 Yoshikazu Miyasato,1 Hiroshi Kimura,1 Kunitoshi Iseki,2 Ekamol Tantisattamo,1 Connie Rhee,1 Elani Streja,1 Kamyar Kalantar-Zadeh,3 ‘Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; 2 Ryukyu Daigaku Igakubu Daigakuin Igaku Kenkyuka, Nakagami-gun, Japan.

Background: Homeostatic regulation of serum osmolality (SOsm) is critical for normal cellular function. Since kidney plays an important role in maintaining homeostasis, patients with kidney dysfunction might be unable to maintain homeostasis. However, it is unknown if SOsm can predict risk of mortality in maintenance hemodialysis (HD) patients.

Methods: We identified 16,402 patients who transitioned to maintenance HD in a large U.S. dialysis organization over 5 years (2007–2011) and had available calculated pre-dialysis SOsm (Sodium and Potassium and Blood urea nitrogen (BUN) and Glucose) at baseline. We used the equation with the best fit between measured and calculated SOsm as follows: 2x([Na, in mmol/L]/[K, in mmol/L]) + [Glucose, in mg/dL]/18 [BUN in mg/dL]/28. We divided the patients into ten groups based on their calculated SOsm (SOsm updated at quarterly intervals as a proxy of short-term exposure): <300, 300–304, 304–307, 307–309, 309–311, 311–313, 313–315, 315–317, 317–321 (reference group) and ≥321 mOsm/Kg, and calculated SOsm’s per quarter change from the date of first dialysis: <8.0, 8.0–<8.6, 8.6–<9.0, 9.0–<9.2, 9.3–<9.5, 9.5–<9.8. We estimated mortality rate was estimated using multivariable Cox models.

Results: The patients were 56% male, 48% non-white, and the mean age was 63 ± 13 (mean ± SD) years. Those with low calculated SOsm tended to be older. In time-varying analysis, the association between all-cause mortality showed that patients with the lowest calculated SOsm had the highest hazard ratio after fully adjusted (Figure A). We observed a U-shaped association between all-cause mortality and per quarter change in calculated SOsm such that SOsm change levels ≥8.0 mOsm/Kg were associated with higher mortality risk (Figure B).

Conclusions: This result suggests that short-term and a wide range of changes in serum osmolality may increase the risk of all-cause mortality in hemodialysis patients.

PO1043

Survival Differences Among ESRD Patients in the Mainland United States, Hawaii, and Pacific Islands

Connie Rhee,1 Amy S. You,1 Keith C. Norris,2 Merle R. Kataoka-Yahiyo,3 James Davis,4 Glen Hayashiida,4 Victoria Page,5 Shu-Feng Cheng,6 Roland C. Ng,7 Linda L. Wong,7 Kamyar Kalantar-Zadeh,3 1 University of California, Irvine, CA; 2 University of California Los Angeles, Los Angeles, CA; 3 University of Hawaii Manoa, Honolulu, HI; 4 John A. Burns School of Medicine, Honolulu, HI; 5 National Kidney Foundation Hawaii, Honolulu, HI.

Background: Asians and Native Hawaiians and other Pacific Islanders (NHOPIs) are collectively the fastest growing racial minorities in the US. While certain Asian subgroups and NHOPIs have a high prevalence of kidney disease risk factors, there are sparse data
examining ESRD outcomes in these populations. As Hawaii is among the states with the highest representation of Asians and NHOPIs, we compared ESRD survival among Asians, NHOPIs, and other racial groups residing in the Mainland US vs. Hawaii and the Pacific Islands.

Methods: Using United States Renal Data System (USRDS) data, we examined the impact of geographic residence in the Mainland US vs. Hawaii and the Pacific Islands on associations of race and mortality among incident ESRD patients who transitioned to dialysis over 2010–16. HRs for all-cause mortality were estimated using Cox models adjusted for sociodemographics, comorbidities, dialysis characteristics, pre-ESRD nephropathy care, laboratory tests, and treatment modality. A 3-months baseline period was defined as months 4 to 6 after hemodialysis initiation, all-cause mortality was noted during follow-up. Only patients who survived baseline were included. Censoring events were renal transplantation, modality change, or death. Patients were divided into 4 quartiles according to percentile rank of their comorbidity index (Group1: low risk, Group 2: moderate, Group 3: high, Group 4: very high) and compared in terms of global and annual mortality rates and survival using Log rank analysis. Results: 3983 patients (2177 males, 55%) were included with a mean age of 52.5±16.8 years. Diabetic and hypertensive nephropathies accounted for 78.1% of all causes of death. Average annual mortality rates and survival using Log rank analysis corresponded to the sum of scores assigned to each factor. Patients were divided into 4 groups according to percentile rank of their comorbidity index (Group1: low risk, Group 2: moderate, Group 3: high, Group 4: very high) and compared in terms of global and annual mortality rates and survival using Log rank analysis.

Results: Compared with White incident ESRD patients residing in the Mainland US, Asians and NHOPIs in the Mainland US had lower mortality risk: HRs (95%CI) were 0.47 (0.46–0.50) for Asians and 0.70 (0.67–0.73) for NHOPIs, respectively. When examining Asians and NHOPIs residing in Hawaii and the Pacific Islands, survival benefit was attenuated in Asians and was diminished to the null in NHOPIs. Further studies are needed to determine the factors contributing to the differential ESRD mortality risk across racial groups residing in the Mainland US vs. Hawaii and the Pacific Islands.

PO1044
Association of All-Cause Mortality with Pre-Hemodialysis Pulse Pressure in Chronic Hemodialysis Patients
Hanniis Zhang,1 Allhaji Cherif,2 Peter Kotanko,1,2 Renal Research Institute, New York, NY; Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Pulse pressure (PP) reports cardiac and vascular conditions, where high PP values are associated with atrial fibrillation, arterial insufficiency, low arterial stiffness, low PP values may be associated with aortic valve stenosis, cardiac insufficiency. However, the association of pre-hemodialysis (pre-HD) PP with mortality among hemodialysis patients is not well understood. In this study, we aim to explore the extent to which PP is associated with mortality.

Methods: We analyzed pre-HD PP (calculated as pre-HD SBP minus pre-HD DBP) between 1/2001 and 12/2012 in hemodialysis patients treated in U.S. Fresenius Medical Care facilities. A 3-months baseline period was defined as months 4 to 6 after hemodialysis initiation, all-cause mortality was noted during follow-up. Only patients who survived baseline were included. Censoring events were renal transplantation, modality change, or study end. We built Cox proportional hazards models with spline terms, allowing us to model nonlinear effects of pre-HD PP as a continuous variable and its relationship with all-cause mortality.

Results: We included 152,625 patients. Mean age was 60.8 years, 59% were white and 56% were male. During a median follow-up of 26.0 months 40.4% patients died. We found that for patients with pre-HD PP between 49.2 mmHg and 74.7 mmHg, were associated with better survival. In contrast, a PP below 49.2 mmHg and above 74.7 mmHg were associated with higher mortality. Similar nonlinear effects are seen in SBP for a given pre-HD PP value (see Fig. 1). Figure 1: Association between pre-HD pulse pressure and all-cause mortality. HRs (solid line) and 95% CIs (dashed lines) of pre-HD pulse pressure. The tick marks on the x-axis represents individual patients.

Conclusions: The association of pre-HD PP with mortality is nonlinear, a better understanding will provide further insights into disentangling the associated mediators affecting its dynamics. Our findings may aid risk stratification.

PO1045
Risk Factors and Mortality in Dialysis Patients with Abdominal Aortic Aneurysm

Background: In the general population, abdominal aortic aneurysm (AAA) is associated with increased mortality. Once diagnosed, AAA can be followed noninvasively or corrected surgically. Vascular disease is common in dialysis patients, but there is limited information on the incidence and outcomes for AAA in this population. To address this question, we queried the United States Renal Data System (USRDS) for risk factors associated with diagnosis of AAA, survival of patients diagnosed with AAA, and overall risk factors for mortality.

Methods: Incident dialysis patients from 2005–2014 from the USRDS were queried. ICD-9 and ICD-10 codes were used to define a diagnosis of AAA and identify clinical co-morbidities. Cox proportional hazards (CPH) modeling was used to determine the adjusted hazard ratio (aHR) and 95% confidence intervals (CI) for death.

Results: From a total cohort of 968,799, we identified 22,121 subjects with a diagnosis of AAA. When compared to patients without the diagnosis, AAA patients were older and had higher percentages of white race, male gender, tobacco use, Charlson comorbidity index (CCI), and hypertension as end stage renal disease (ESRD) etiology, but lower percentages of diabetes as ESRD etiology. A bivariate CPH model of survival showed that AAA patients had significantly increased mortality compared to patients without a AAA diagnosis (HR=1.29, p-value<0.0001). However, in the final CPH model, patients with a AAA diagnosis had a decreased risk of mortality (aHR=0.85, 95% CI 0.844–0.860), after controlling for age, CCI, and other demographic and comorbid variables.

Conclusions: ESRD patients with a diagnosis of AAA are more likely to be older, white, male, smokers with hypertension as the cause of ESRD. Patients with AAA are less likely to have diabetes as an etiology of ESRD. AAA is associated with a decreased risk of death, which suggests that AAA in the ESRD population by itself may not increase mortality, but the comorbid factors that come with it do.

PO1046
Composite Comorbidity Scoring System to Predict Mortality in a Saudi Dialysis Population

Background: Most uremic patients starting hemodialysis (HD) have multiple comorbidities, resulting in a high risk of mortality. Our aim was to establish and evaluate a personal scoring system in which we included associated comorbidities, age and, other HD related factors known to predict mortality.

Methods: All patients referred to DaVita-KSA, from October 2014 to December 2019, to continue hemodialysis therapy, were included in this analysis. Cox proportional hazards model was used to identify factors influencing all-cause mortality. A personal scoring system was established based on the score assigned to each factor, according to its weight as predictor of death, judged on the value of the relative risk generated in the preliminary analysis. An index of co-morbidity was calculated for each patient that corresponded to the sum of scores assigned to each factor. Patients were divided into 4 groups according to percentile rank of their comorbidity index (Group1: low risk, Group 2: moderate, Group 3: high, Group 4: very high) and compared in terms of global and annual mortality rates and survival using Log rank analysis.

Results: 3983 patients (2177 males, 55%) were included with a mean age of 52.5±16.8 years. Diabetic and hypertensive nephropathies accounted for 78.1% of all causes of ESRD. After a cumulative follow-up period of 7635 years, 15.3% of patients were transferred to other facilities, 8.7% were transplanted and 14.5% were deceased.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: This new scoring system appears to be easily established at our clinics and may constitute a good predictor for all-cause mortality in our HD population.

Mortality and Cost Track Yearly Changes in ESRD Quality Incentive Program Performance

Eric W. Young,1,2 Zhochen Ding,1 Alissa Kapke,1 Yan Jin,1 Delia Houseal,3 Jeffrey Pearson,1 Marc Turenne,1 1Arbor Research Collaborative for Health, Ann Arbor, MI; 2University of Michigan, Ann Arbor, MI; 3Centers for Medicare and Medicaid Services, Baltimore, MD.

Background: Patients treated in dialysis facilities that receive payment reductions under the ESRD QIP experience higher mortality and cost (Medicare payments) during the same performance year. We asked whether these outcome measures track with yearly changes in the QIP payment reduction.

Methods: Mortality and cost per patient year were analyzed using claims files for dialysis patients enrolled in the traditional Medicare fee-for-service program for performance years 2010-2016.

Results: The table displays index-year mortality and cost (columns) according to the facility QIP payment reduction (PR) for the prior year (rows) and the direction of the change in QIP PR in the index-year (worse, unchanged, better). In almost all cases, mortality and cost were higher for patients in facilities that did worse in QIP and lower for patients in facilities that did better. For example, patients treated in dialysis facilities that received a 1.5% QIP PR in the prior year experienced 18.7% mortality if the index-year PR was unchanged, 16.9% mortality if the index-year PR was lower (≤1%) and 24.5% mortality if the index-year PR was higher (2%).

Conclusions: Patient mortality and average Medicare payments track with changes in facility QIP PRs. The finding suggests that facility efforts to improve QIP performance may translate into improved mortality and lower costs to Medicare. Moreover, it is unlikely that the observed association between outcome measures and QIP is attributable to unmeasured patient case-mix, which tends to be relatively stable from year to year. The findings suggest that the ESRD QIP captures meaningful aspects of quality and value.

**Funding:** Other U.S. Government Support

**PO1048**

Comparison of ESRD Quality Incentive Program (QIP) Performance and Dialysis Facility Compare (DFC) Star Rating

Alissa Kapke,1 Zhochen Ding,1 Claudia Dahlers,1 J. M. Messana,2 Delia Houseal,3 Jesse Roach,1 Marc Turenne,1 1Arbor Research Collaborative for Health, Ann Arbor, MI; 2Nephrology Division, Michigan Medicine, Ann Arbor, MI; 3Centers for Medicare and Medicaid Services, Baltimore, MD.

Background: The DFC quality of patient care star rating system reached its 5-year mark in 2020 and the ESRD QIP surpassed its 10-year mark. Both programs have undergone considerable changes in a continuing effort to help patients make informed choices. We assessed whether ESRD QIP scores and payment reductions aligned with facilities’ star ratings and with t-tests comparing mean QIP Total Performance Scores (TPS) among adjacent PR and star rating levels.

Methods: Payment year (PY) 2020 QIP scores and payment reductions (PR) and CY 2018 star ratings (1-5 stars) were obtained from DFC public data files. Comparisons between the two programs were assessed with cross-tabulations of PR categories and star ratings and with t-tests comparing mean QIP Total Performance Scores (TPS) among adjacent PR and star rating levels.

Results: Facilities with higher PY 2020 QIP scores tended to receive higher star ratings. Facilities with no PR (N=3,920), 78.4% received 4 or 5-stars and 91.7% of facilities with a 2% PR received 1 or 2-stars. The average facility TPS decreased by approximately 10 points with each decrease in star rating, with significant differences between all categories (Table 1).

Conclusions: The ESRD QIP and the star rating program have distinct goals which have led to differences in their design and methodology, such as the use of the small facility adjuster in the ESRD QIP and non-overlapping measures between the two programs. Nevertheless, there is strong overall correspondence between the two programs in the ratings of facility quality of care. These results are reassuring, in that QIP scores and star ratings are providing a consistent message about dialysis facility quality of care in most cases.

**Funding:** Other U.S. Government Support

Comparison of 5-Year Survival Rate Between Hemodialysis and Peritoneal Dialysis Patients: A Prospective Cohort Study with Propensity Score Matching

Mami Miyazaki,1 Shigehiro Doi,1 Ayumu Nakashima,1 Toshiki Doi,2 Takao Masaki,1 Hiroshi Daigaku Byoin, Hiroshima, Japan; 2Harada Hospital, Hiroshima, Japan.

Background: Chronic Kidney Disease patients who require dialysis have increased worldwide. However, whether hemodialysis (HD) or peritoneal dialysis (PD) independently affects prognosis is still controversial.

Methods: A multicenter prospective observational study was conducted from 1 January 2012 to 31 March 2018. Total of 646 HD patients and 72 PD patients were enrolled from Hiroshima Chronic kidney disease outcomes cohort study (Hi-COCS) in Japan. We excluded patients whose follow-up period was less than 3 months. One to one propensity score matching was performed to compare the survival rates between HD and PD patients and to find the factors that would affect prognosis.

Results: Of 621 HD patients and 71 PD patients, the mean average age was 74.2±12.5, 49.7% patients had DM, and 19.2% patients had CVD. The median follow-up period was 41 months. Total of 130 patients were selected with 1:1 propensity score matching (65 HD patients and 65 PD patients). In the PS matched cohort, there was no difference between the two groups in the 5-year survival rates of the overall events. (HD 71.2% vs PD 71.2%, respectively, P = 0.97) PD group had better survival rate of CVD compared with HD group was significantly different between the two groups (P = 0.043). Multivariate Cox proportional hazard model showed that adjusted hazard ratio (HR) of overall events and CVD events were 1.06 (95% confidence interval (CI); 0.53-2.10, P = 0.96) and 4.90 (95% CI 1.37-15.38, P = 0.041), respectively. Age, non-HDL cholesterol and CRP were associated with prognosis in overall events. Only non-HDL cholesterol was associated with prognosis in CVD events.

Conclusions: In this study, we found out that 5-year survival rate was not significantly different between the HD and PD patients in overall events. However, PD group had better survival rate of CVD events than that of HD patients. It suggests that PD may potentially have treatment advantage for patients who have high risk factors of CVD events.

**PO1050**

Effects of Dialysate Magnesium Concentrations on Mortality: Results from the MONDO Initiative

Ger D. von Gersdorff,1 Katherine G. Rascher,2 Adrian M. Guinsburg,2 Jochen G. Raimann,1 Xiaoling Ye,3 Peter Kotanko,1 1Renal Research Institute, New York, NY; 2Fresenius Medical Care AG and Co KGaA, Buenos Aires, Argentina; 3University Hospital, Cologne, Cologne, Germany.

Background: Dialysate magnesium (Mg) is known to be positively associated with serum Mg levels in hemodialysis (HD) patients (pts). We aimed to study the associations between different Mg levels and mortality in HD pts.

Methods: We conducted a retrospective cohort study to examined the associations of different Mg levels (1.0, 1.5, or 2.0 mEq/L) and all-cause mortality. In-center HD pts treated in KfH and MONDO with constant Mg levels during their first year of observation were studied. The primary outcome variable was a 1-year mortality risk. In a second step, we used 1:1 propensity score matching (based on age, gender, catheter, and vintage) to create 4 matching groups: 1)Mg 1.0 versus 1.5 mEq/L (KfH and MONDO), 2)Mg 1.5 versus 2.0 mEq/L (only KfH), 3)1.0 versus 2.0 mEq/L (only KfH). The associations between different Mg levels and mortality after matching were evaluated with Cox proportional hazards models, Kaplan Meier survival curves, and the Log Rank test, respectively.

Results: We studied 32,117 pts from KfH [69 years, 64% males, 42% diabetics, 48% catheter; Dmg 1.0: 31,460 (98%), Dmg 1.5: 395 (1%) and Dmg 2.0: 262 (1%)]; 15,211 pts from MONDO [57 years, 58% males, 41% diabetics, 24% catheter; Dmg 0.75: 2,481

**Key:** TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
(16%), DMg 1.0: 12,508 (82%) and DMg 1.5: 222 (1%). Propensity score-matching created well-balanced cohorts with DMg of 1.0 v.s. 1.5 (KfH and MONDO), DMg 1.5 v.s. 2.0 and 1.0 v.s. 2.0 (KH), respectively. Survival analysis show that DMg 1.5 is not statistically associated with survival benefits compared to 1.0 in both data sets (Table 1, Figure 1 a, d). In addition, compared to both DMg 1.0 and 1.5, we do not observe a survival benefit of DMg 2.0 in KfH's data (Table 1, Figure 1b, c).

Conclusions: Increased DMg was not associated with a survival benefit in either the KfH or MONDO datasets. One of the limitations is the lack of detailed dialysate information. Further studies directly addressing the association between serum Mg and dialysate prescriptions.

PO1052

Electrolyte Changes in Contemporary Hemodialysis: An Analysis of the Monitoring in Dialysis (MID) Study
Simon Correa,1,2 Katherine M. Scovner,1,2 James A. Tumlin,3 Prabir Roy-Chaudhury,1 Finnian R. McCausland,1,2 David M. Charytan1 Monitoring in Dialysis Study Group1 Brigham and Women’s Hospital, Boston, MA; 2Harvard Medical School, Boston, MA; 3New York University School of Medicine and NYU Langone Medical Center, New York, NY; 4UNC Kidney Center, Chapel Hill, NC and WG (Bill) Hefner VA Medical Center, Salisbury, NC

Background: There is a paucity of data examining electrolyte concentrations during and immediately after hemodialysis (HD) sessions. We describe these changes and provide predictive nomograms based on HD prescriptions and pre-HD electrolytes.

Methods: We leveraged patient (n=66) and HD session-level pre- and post-HD laboratory data (n=1,713) from the Monitoring in Dialysis study and fit mixed effects regression models to analyze differences between pre-, 15-minutes post-, and 30-minutes post-HD levels (compared with immediately post-HD) of electrolytes, blood urea nitrogen, creatinine, and albumin as well as the association of post-HD values with dialysate prescriptions.

Results: Serum bicarbonate, calcium, and albumin increased (mean increase 4.9mEq/L ±0.3, 0.7mEq/L±0.1, and 0.4g/dL±0.03, respectively), and potassium, magnesium, and phosphorus decreased immediately post-HD (mean -1.2mEq/L±0.1, -0.3mEq/L±0.03, and -3.0mg/dL±0.2, respectively). Hypokalemia and hyperphosphatemia were present in 34% and 67% of immediately post-HD samples, respectively. Changes were observed in electrolyte concentrations at 15- and 30-minutes post-HD compared to immediately post-HD (Fig A: observed changes; Fig B: predictive nomograms of post-HD electrolytes).

Conclusions: Contemporary HD results in marked changes in electrolyte concentrations during and after the treatment. We report a high frequency of post-HD hypokalemia and hyperphosphatemia and present predictive nomograms relating post-HD changes to dialysate prescriptions. Whether the abnormalities observed in potassium and phosphorus post-HD predispose to adverse symptoms and arrhythmia is unclear and requires further research.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.

Metabolomic Analysis Fails to Identify Uremic Solutes Associated with Pruritus in Hemodialysis Patients

Christian G. Bolanos,1,2 Nhat M. Pham,1,3 Margaret R. Stedman,1 Timothy W. Meyer,1,2 Tammy L. Sirich,1,2 Stanford University, Stanford, CA; 3VA Palo Alto Health Care System, Palo Alto, CA; 4Santa Clara Valley Medical Center, San Jose, CA.

Background: Uremic pruritus is a debilitating symptom in hemodialysis (HD) patients. That uremic solutes contribute to pruritus is suggested by the improvement after transplantation. We aimed to identify solutes associated with pruritus using metabolomic analysis comparing plasma of HD patients with severe pruritus and mild/no pruritus.

Methods: Plasma and ultrafiltrate (UF) samples from 12 HD patients with severe pruritus (Itch) and 24 HD patients with mild/no pruritus (No Itch) were analyzed. Pruritus was assessed using a 100-mm visual analogue scale with severe defined as >70 mm, and lower serum albumin, body cell mass index (BCMI), lean tissue index, fat tissue index (FTI), femoral neck BMD, and right distal mid-third radius BMD.

Results: Of 593 uremic solutes analyzed using a metabolomics platform (Metabolon Inc.), 5 predominate (sodium, potassium, bicarbonate, calcium, and phosphate). plasma and UF were analyzed using a metabolomics platform (Metabolon Inc.). Solutes were first identified as uremic based on the finding of higher normal levels in all 36 HD patients and 16 controls with normal kidney function. Solutes were deemed uremic if their HD/control ratio was >4 in plasma and/or UF with a false discovery rate of <0.05. Peak areas of each solute in the Itch and No Itch HD patients were then compared to identify uremic solutes associated with pruritus.

Conclusions: Metabolomic analysis did not reveal any uremic solutes associated with pruritus in HD patients. The role of uremic solutes in pruritus remains to be established.

Combined Value of Geriatric Nutritional Risk Index, Body Composition, and Bone Mineral Density for Predicting Mortality of Hemodialysis Patients

Sonoko Mizuii,1 Yoshiko Nishizawa,1 Yoshiki Doi,2,3 Kazuomo Yamashita,1 Kenichiro Shimamoto,1 Shiheigo Doi,1 Takao Masaki,1 Hiroshima University 1Ichiyokai Harada Hospital, Hiroshima, Japan; 2Hiroshima University Hospital, Hiroshima, Japan.

Background: Prognostic utility of the geriatric nutritional risk index (GNRI) and the association between body mass index and bone mineral density (BMD) in hemodialysis (HD) patients are uncertain. We assessed the combined predictive value of GNRI, body composition, and BMD in HD patients.

Methods: Pre-dialysis laboratory data, same-day post-dialysis body composition parameters by the Body Composition Monitor (Fresenius), and radius, lumbar spine, and femoral bone mineral density (BMD) using dual energy X-ray absorptiometry were assessed in HD patients at baseline. The data were compared according to GNRI tertiles (T). Logistic regression analysis was used to assess GNRI T1. Kaplan-Meier survival and Cox proportional hazard analyses were conducted. Comparison of multiple receiver operating characteristic curves was performed to assess whether mortality prediction accuracy improved after adding GNRI, body composition, and BMD to established risk factors.

Results: Among 264 patients (male: 65%, diabetes: 42%), mean age was 65±12 years and the median dialysis vintage was 79 (39–144) months. GNRI T1, T2, T3 were 88 (85–91), 94 (93–95), 98 (97–101), respectively. GNRI T1 patients showed older age, lower male frequency, and lower serum albumin, body cell mass index (BCMI), lean tissue index, fat tissue index (FTI), femoral spine, femoral neck, and right distal mid-third radius BMD, but higher overhydration/extracellular fluid than patients with GNRI T2 or T3 (P<0.05). FTI (OR: 0.88), femoral neck BMD (OR: 0.95), age (OR: 1.03), C-reactive protein (OR: 1.37) and hemoglobin (OR: 0.70) were significant predictors of GNRI T1. Kaplan-Meier survival and Cox proportional hazard analyses were conducted. Comparison of multiple receiver operating characteristic curves was performed to assess whether mortality prediction accuracy improved after adding GNRI, body composition, and BMD to established risk factors.

Conclusions: Associations of GNRI, body composition, and BMD were confirmed in HD patients. Combining GNRI, body composition, and BMD to established risk factors improved mortality prediction in HD patients.

Predicting Intradialytic Hypotension with Continuous Hemodynamic Monitoring Throughout Hemodialysis

David F. Keane,1,2 Jochen G. Raimann,2 Hanjie Zhang,2 Stephan Thijssen,2 Joanna Willetts,2 Peter Kotanko,2,3 Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; 2Renal Research Institute, New York, NY; 3Fresenius Medical Care Global Medical Affairs, Waltham, MA.

Background: Intradialytic hypotension (IDH) remains one of the most common complications associated with hemodialysis (HD). The CritLine Monitor (CLM) measures relative blood volume (RBV) and blood oxygen saturation (O2Sat), but uncertainties remain in application of these parameters for predicting IDH. We looked at differences in CLM parameters based on whether an IDH episode was imminent or not as a function of time into a HD session to investigate whether their prognostic ability is dependent on the time into HD.

Methods: We studied routinely collected data from 17 US dialysis clinics. IDH was defined by systolic blood pressure (SBP) below 90 mmHg. The CLM directly measures RBV and O2Sat, interpreted as arterial O2Sat (SaO2) for those with a fistula or graft and as central venous oxygen saturation (SvO2) for those with a central venous catheter. For sessions with SvO2, we also calculated estimated upper body blood flow (eUBBF).

We extracted each parameter every 30 minutes through each treatment. We compared

The study was supported by Fresenius Medical Care Global Medical Affairs, Waltham, MA.
variables dependent on whether IDH occurred in the subsequent 30 minutes. Separate linear mixed models with session as random effect, with each CLM parameter as the dependent variable, IDH status as a dummy-coded predictor and subject as a random effect to account for repeated measures on individuals.

**Results:** We studied 2,791 patients and 197,526 sessions, 160,094 (81%) with SaO2 and 37,432 (19%) with ScvO2 data. IDH occurred in 13% of sessions. RBV was not different in the first 90 minutes for patients approaching IDH compared to those who were not, but was lower thereafter. Differences between the groups were observed throughout HD for ScvO2 and eUBBF, but not SaO2.

**Conclusions:** The ability for RBV to predict IDH depends on the time of onset. ScvO2 and eUBBF better predict IDH than SaO2, reflecting the dependence of ScvO2 on cardiac output while SaO2 more reflects pulmonary function.

**PO1056**

**Time of Hemodialysis and Risk of Intradialytic Hypotension and Intradialytic Hypertension**

**Murali Alostaz,1,2 Simon Correa,1 Susruth S. Waikat,1 Finnian R. McCausland,1,3 1University of California Los Angeles, Los Angeles, CA; 2Brigham and Women's Hospital, Boston, MA; 3Harvard Medical School, Boston, MA; 4Boston Medical Center, Boston, MA.

**Background:** Blood pressure (BP) fluctuates throughout the day following a circadian pattern. BP control is of utmost importance in patients with ESRD undergoing hemodialysis (HD), and both intradialytic hypotension (IDH) and intradialytic hypertension (HTN) are associated with adverse CV events and death. Whether the risk of IDH and intradialytic HTN varies according to the time of the day of the HD session is unknown.

**Methods:** Random effects logistic regression models examined the association of HD start time (before 9:00 am [timecat1], 9:00 am to 12:00 pm [timecat2], and after 12:00 PM [timecat3]) with IDH and intradialytic HTN among adults undergoing thrice-weekly maintenance HD (N=1,938 patients) and 64,503 sessions from the Hemodialysis [HEMO] Study, and N=3,408 patients/n=33,590 from a contemporary large dialysis organization [LDO]). IDH was defined as nadir intra-HD SBP <90 mmHg if pre-HD SBP <160 mmHg or <100 mmHg if pre-HD SBP ≥160 mmHg, and intradialytic HTN was defined as any increase in post-HD SBP compared to pre-HD SBP. Models were adjusted for demographics, CV comorbidities, HD dose, HD flux, pre-HD BUN, pre-HD SBP, UFR, HD vintage and HD session length.

**Results:** Mean age was 55 years and 56% were female in HEMO; mean age was 63 years and 42% were female in LDO. Compared to timecat1, timecat2 and timecat3 were associated with a 9% (aOR 0.91, 95% CI 0.82-1.01) and a 17% (aOR 0.83, 95% CI 0.75-0.94) lower risk of IDH in HEMO, respectively (Fig 1A). Conversely, compared to timecat1, a monotonic increase in the risk of intradialytic HTN was observed for timecat2 (aOR 1.14, 95% CI 1.05-1.24) and timecat3 (aOR 1.40, 95% CI 1.28-1.53) in HEMO (Fig1B). These findings were consistent in LDO (Fig 1). **Conclusions:** In two diverse and large cohorts of HD, we observed a monotonic decrease in the risk of IDH and a monotonic increase in the risk of intradialytic HTN as HD start time progressed throughout the day. Whether HD treatment allocation to certain times of the day in hypotensive-prone or hypertensive-prone patients improves outcomes deserves further investigation.

**Association Between Pulse Pressure and Extracellular to Intracellular Water Ration in Hemodialysis Patients**

**Robert Ekart,1,2 Gasper Keber,1 Masa Knehl,1 Eva Jakopin,1 Benjamin Dvoršak,1 Radovan Hojs,1,2 1University Medical Center Maribor, Maribor, Slovenia; 2Medical Faculty University of Maribor, Maribor, Slovenia.

**Background:** Optimal fluid management is a challenge in patients with end-stage kidney disease (ESRD) on maintenance hemodialysis (HD). Multifrequency bioimpedance spectroscopy (MBIS) is a non-invasive method to estimate body composition, including estimates of extracellular water (ECW) and intracellular water (ICW) and the ratio between both spaces (ECW/ICW). Pulse pressure is a significant risk factor of cardiovascular disease and death in general and dialysis population. Our study aimed to analyse the correlation between systolic, diastolic and pulse pressure with body composition status in ESRD patients before HD.

**Methods:** We performed a retrospective single-centre cohort study in 93 HD patients. The body composition was measured using the portable whole-body MBIS device, Body Composition Monitor-BCM (8) ( Fresenius Medical Care, Bad Homburg, Germany). Blood pressure was measured with OMRON monitors.

**Results:** The mean age of patients was 64 ± 13 years, mean dialysis vintage 63 (1-352) months, 61% were men, all patients had arteriovenous fistula as vascular access. ScvO2-mean (42%) patients were fluid overload (FO) with > 1.1 L overhydration. Other data are presented in table 1. We found a statistically significant correlation between the pulse pressure and ECW/ICW ratio (r=0.258, P=0.033) in FO patients. In contrast, there was no significant correlation between systolic, diastolic blood pressure and ECW/ICW ratio in non-FO patients.

**Conclusions:** Only pulse pressure and not systolic or diastolic blood pressure values measured before HD are associated with ECW/ICW ratio in FO patients.

**PO1058**

**Plasma Refill Rate: A Potential Hemodynamic Marker of Intradialytic Hypotension During Hemodialysis**

**Hao Wang,1 Dan Ngoeouian,1 Sabrina Rogg,1,4 Hanjie Zhang,2 Jesse Y. Hsu,1 Peter Kotanko,1,2 Jochen G. Raimann,2 Laura M. Dember,1 1University of Pennsylvania, Philadelphia, PA; 2 Renal Research Institute, New York, NY; 3Icahn School of Medicine at Mount Sinai, New York, NY; 4Fresenius Kabi AG, Bad Homburg, Germany.

**Background:** Intradialytic hypotension (IDH) is difficult to predict. Continuous hemocrit monitoring (CHM) measures relative blood volume to provide non-invasive dynamic monitoring during hemodialysis (HD). We used CHM data with time-updated ultrafiltration rate (UFR) to estimate plasma refill rate (PRR), a potential mediator of hemodynamic status, and studied its relationship to IDH.

**Methods:** We used CHM performed at 17 Renal Research Institute HD units from 2017 to 2019 to calculate intradialytic PRR standardized to weight and height. We defined IDH as 1) systolic blood pressure (SBP) <90 mmHg and 2) a drop in SBP ≥20 mmHg or aOR; 95% CI. **Results:** We studied 2,637 patients (61±15 yrs, 57% male, 51% white) with 184,044 total treatments, interdialytic weight gain (IDWG) 2.1±4.6 ml/kg/h. Patients with low initial PRR were more likely than patients with high initial PRR to be IDH-prone by definition 1 (aOR 1.95; 1.01-3.72) and definition 2 (aOR 1.50; 0.87-2.56). Patients with low initial PRR had a 10 mmHg associated with symptoms. IDH-prone was defined as having >20% of treatments with IDH. Uni- and multivariable mixed-effects logistic regression were used to evaluate factors associated with low initial PRR (lower quartile) within the first 10 minutes of HD. Bi- and multinomial logistic regression were used to evaluate the relationship between initial PRR and IDH. Data are presented as means±SD or aOR; 95% CI.

**Background:** Extracellular to Intracellular Water Ration in Hemodialysis Patients

**Results:** We studied 2,637 patients (61±15 yrs, 57% male, 51% white) with 184,044 total treatments, interdialytic weight gain (IDWG) 2.1±4.6 kg, and UFR 9.5±4.6 ml/kg/h. IDH occurred in 13.7% and 15.8% of treatments by definitions 1 and 2, respectively. PRR (ml/kg/h) over all sessions was 5.0±8.8, 8.4±6.0, 7.9±7.2, and 7.4±1.1 ± 10m, 1h, 2h, and 3h, respectively, with substantial variability at both patient and treatment levels. Older age, low BMI, female sex, black race, low albumin, and multinobritdrinity were associated with low initial PRR. Patients with low initial PRR were more likely to be IDH-prone by definition 1 (aOR 1.95; 1.01-3.72) and definition 2 (aOR 1.50; 0.87-2.56). Patients with low initial PRR were more likely than patients with high initial PRR to be IDH-prone by definition 1 (aOR 2.12; 1.50-2.74).

**Conclusions:** The dynamics of PRR vary during an HD session and has promise as a marker of hemodynamic instability. We found that several patient and treatment factors classically associated with IDH were also associated with low initial PRR, independent of

**MBIS= multifrequency bioimpedance spectroscopy; HD=hemodialysis**
**PO1059**

**Hypoadosteronism in Chronic Hemodialysis Patients Causes Intradialytic Hypotension and Is Improved with Fludrocortisone**

Spencer Hodgins,1 Bikash Chapagain,1 Jyovani W. Joubert,2 Brian H. Nathanson,1 Daniel L. Landry,1 Gregory L. Braden,1

1 Baystate Health, Springfield, MA; 2Kidney Care and Transplant Services of New England, Springfield, MA; 3Optistatim LLC, Longmeadow, MA.

**Background:** Intradialytic hypotension (IDH) affects up to 30% of chronic hemodialysis (CHD) pts and hypoadosteronism (HA) is common in these pts. Aldosterone (aldo) exerts potent non-genomic hypertensive effects via its arterial aldo receptor & enhanced sympathetic nervous system activity.

**Methods:** We identified 11 consecutive CHD pts with severe IDH & normal coagulation test results that had HA. Mean PRA was 3.3 +/- 7.7 ng/ml/hr & serum aldo was 2.9 +/- 1.6 ng/dL. All pts had failed low temperature dialysate, UF & Na modeling and maximum doses of midodrine. We studied pre & post HD SBP & DBP, number of episodes of systolic BP <100 & mean UF volume (Kg) for the 13 dialysis treatments pre fludrocortisone (FC), 1 month post FC & 6 months post FC. FC dose was 0.1 mg BID. The mean pt age was 69 +/- 11 years & dialysis duration was 5.1 +/- 2.3 years.

**Results:** The mean +/- SD pre & post HD SBP & DBP & the mean number of hypotensive episodes were significantly improved from 1 & 6 months post-FC (Table 1). No changes occurred in UF volume. 4 pts have remained on FC for 2 years or more without side effects and with sustained good results.

**Conclusions:** Refractory IDH is associated with HA in CHD pts. FC therapy decreases IDH episodes as well as improves pre & post SBP & DBP & can be used safely in CHD pts.

**Table 1. Results for pre & post HD SBP & DBP, Hypotensive episodes & UF volume.**

**Feasibility and Benefits of Hemodialyzer Filtration of Contaminated Water in Poor Rural Communities in Ghana**

Friedrich K. Port,1,4 Jochen G. Raimann,1 Joseph M. Boaheng,1 Philip K. Narh,1 Seth Johnson,1,2 Linda L. Donald,2 Hongbin Zhang,3 Nathan W. Levin,1,3 Easy Water for Everyone, New York, NY; 2 Renal Research Institute, New York, NY; 3 City University of New York, New York, NY; 4 University of Michigan, Ann Arbor, MI; 5 Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** Contaminated water supplies for drinking water is a source of health problems in poor communities. Hemodialyzers with a pore size of 0.003 micrometers have been known to be effective in preventing transfer of bacteria and most viruses. Our NGO, “Easy Water for Everyone,” investigated prospectively the incidence of diarrhea, before and after implementation of water treatment utilizing reused hemodialyzers in poor villages lacking electricity and sanitation in Ghana.

**Methods:** Data were collected monthly regarding the incidence of diarrhea and death in 4 “study” villages that have access to river water. River water was pumped weekly into an elevated holding tank to be drawn by households of 8 villages that have no electricity during February to November 2018. In 3 “control” villages, the polluted water was not treated during the same 10 months. We calculated the monthly rate of diarrhea per village per month. After >11 months of daily filtration in 9 villages (population ~2000) none of the filters had to be replaced, suggesting that daily back-flush management prevented hemodialyzer clogging.

**Results:** [1] Monthly rates of diarrhea in the study villages decreased from 18 to 5 per 1000 person-years from the first to the second 5 months. After >11 months of daily filtration in 9 villages (population ~2000) none of the filters had to be replaced, suggesting that daily back-flush management prevented hemodialyzer clogging.

**Conclusions:** We demonstrated feasibility and success of sustaining a simple and effective simple solution in entire rural villages in the absence of electricity.

The continuous function over >11 months indicates low cost of the device over time. The reduction in diarrhea from before to after initiation of the hemodialyzer filtration device is large. The simplicity of hemodialyzer filtration by gravitational feed, low cost and relative case suggests wider application to other needy villages.

**PO1061**

**Combining a Heparin-Grafted Dialyzer with a Citrate-Enriched Dialysate Offers Acceptable Dialysis Adequacy Avoiding Systemic Anticoagulation: Results of the Randomized Noninferiority Evoct Study**

Karlien Francois,1,2 Dieter De Clerck,1,3 Annelies Tonneller,1,4 Marie-Laure Cambier,1 Wilfried Cools,1 Karl M. Wissing,1,2 Yvije Universiteit Brussel, Brussels, Belgium; 3 Universitair Ziekenhuis Brussels Division of Nephrology and Hypertension, Brussels, Belgium.

**Background:** The combined use of a heparin-grafted membrane with a citrate-enriched dialysate is a hemodialysis (HD) strategy with low circuit clotting rates while avoiding systemic anticoagulation. Its adequacy in comparison to HD using systemic anticoagulation is unknown.

**Methods:** Prevalent HD patients were recruited for a randomized crossover non-inferiority trial powered at >90% to detect a prespecified non-inferiority threshold of 10% spKt/Vurea (NCT03887468). HD using a heparin-grafted dialyzer in combination with a 1.0 mmol/L citrate-enriched dialysate (“evohep”) was compared to HD using a heparin-grafted, systemic unfractonated heparin and bicarbonate-based dialysate (“evoceg”). Each treatment arm lasted 4 weeks: 3x4hours HD/week with fixed blood and dialysate flow rates and midweek biological analyses.

**Results:** 26 patients received 617 HD sessions: 307 evoceg and 310 evohep sessions. Mean spKt/Vurea was 1.46±0.23 for evoceg and 1.50±0.24 for evohep sessions (p=0.06). The mean of the paired difference in spKt/Vurea was 0.04 with a 95%CI of -0.002 to 0.08, the upper bound of the estimate lying within the prespecified non-inferiority threshold (i.e. <0.15). URD reduction rate (RR) was 71.5±5.5% vs 72.1±5.7% and time spent on reperfusion RR 37.4±6.8% vs 37.8±8.8% for evoceg and evohep sessions. Processed blood volume was 75.4±3L vs 75.8±5L and online Kt was 47.3±4L vs 48.3±4L for all evoceg and evohep sessions. Circuit thrombosis leading to premature treatment end occurred in 13/307 (4.2%) of evoceg sessions (n=6), but in none of the evohep sessions (p=0.0002), with a median 36(20-46)min treatment time shortening without impact on effective treatment times overall (236±12 vs 238±4min for evoceg vs retransfusion). Retransfusion failure occurred in 3/307 (0.98%) of evoceg sessions and none of the evohep sessions (p=0.25).

**Conclusions:** HD avoiding systemic anticoagulation using a heparin-grafted dialyzer with a citrate-enriched dialysate offers recommended spKt/Vurea dose and is not inferior to HD using systemic anticoagulation in terms of spKt/Vurea. Circuit clotting complications occurred at low rates during evoceg sessions and did not have clinically significant repercussions on dialysis efficacy.

**Cinacalcet Use and the Risk of Gastrointestinal (GI) Bleeding Among Hemodialysis Subjects with Secondary Hyperparathyroidism (SHPT) in the Dialysis Outcome and Practice Patterns Study (DOPPS)**

**Background:** Cinacalcet is an oral calcimimetic for the treatment of SHPT in US adult hemodialysis (HD) patients. We conducted an observational study to evaluate the potential association between cinacalcet and fatal and non-fatal GI bleeding using data from DOPPS, an observational longitudinal data system of a random sample of patients from dialysis facilities in more than 20 countries.

**Methods:** The eligibility criteria for study cohort inclusion was individuals ≥18 years of age with ESRD receiving in-center hemodialysis at a DOPPS facility for a minimum of four months during calendar years 2009-2015, in the following countries: Australia, New Zealand, Canada, France, Germany, Italy, Spain, Sweden, Japan, the UK, and the US. Nested within the cohort, we conducted a matched case-control study (1:4 matching ratio) to estimate the association between cinacalcet use and GI bleeding events. We used a matched sampling and matching ratio of (1) duration of follow-up (at least 21 months of use in 9 villages.

**Results:**[1] Rates of diarrhea in the study villages decreased from 18 to 5 per 1000 person-years from the first to the second 5 months. After >11 months of daily filtration in 9 villages (population ~2000) none of the filters had to be replaced, suggesting that daily back-flush management prevented hemodialyzer clogging.

**Conclusions:** Cinacalcet use was not associated with an increased risk of GI bleeding among dialysis patients from DOPPS, an observational longitudinal data system of a random sample of patients from dialysis facilities in more than 20 countries.

Medium Cut-Off Dialyzer Improves Erythropoiesis-Stimulating Agent Resistance in a Hepcidin-Independent Manner in Maintenance Hemodialysis Patients
Jeong-Hoon Lim, Yong-Jin Kim, Hye-Yeon Jung, Ji-Young Choi, Sun-Hee Park, Chan-Duck Kim, Yong-Lim Kim, Jang-Hee Cho. Kyungpook National University Hospital, Daegu, Republic of Korea.

Background: The response to erythropoiesis stimulating agents (ESAs) is affected by inflammation linked to middle molecules in hemodialysis (HD) patients. We evaluated the effect of a medium cut-off (MCO) dialyzer on ESA resistance in maintenance HD patients.

Methods: Forty-nine patients who underwent high-flux HD were randomly allocated to the MCO or high-flux group. The primary outcome was the changes of erythropoietin resistance index (ERI; U/kg/wk/g/dL) between baseline and 12 weeks. The biomarkers associated with iron metabolism and inflammation at 12 weeks were compared between groups.

Results: The MCO group showed significant decrease in the ESA dose, weight-adjusted ESA dose, and ERI compared to the high-flux group at 12 weeks (all p < 0.05). In the MCO group, the ESA dose, weight-adjusted ESA dose, and ERI did not change until 8 weeks compared to those at baseline, but decreased significantly at 12 weeks (all p < 0.01). Serum iron and transferrin saturation were higher in the MCO group at 12 weeks (both p < 0.05). The MCO group showed a greater reduction in TNF-α and lower serum TNF-α level at 12 weeks compared to the high-flux group (p = 0.025 and p = 0.027), whereas no differences were found in the reduction ratio of hepcidin and serum levels of erythropoietin, erythropoietin, soluble transferrin receptor and hepcidin between groups.

Conclusions: HD with MCO dialyzer improves ESA resistance compared to high-flux HD in maintenance HD patients. The MCO dialyzer provides superior removal of the inflammatory cytokine such as TNF-α and thus improves iron metabolism in a hepcidin-independent manner.

The iron metabolism regulatory pathway. Blue arrows indicate dominant effects.

PO1064
Recent Trends in Acute Care Admissions Among Medicare Beneficiaries Undergoing Dialysis
Eric D. Weimhandl,1,2 Kristine Kubisak,1 Lorien S. Daltymple,1 Fresenius Medical Care, Waltham, MA; 1Chronic Disease Research Group, Minneapolis, MN.

Background: While the rate of hospital admissions has been a bedrock measure of morbidity among dialysis patients, patients today may receive acute care during a hospital admission, observation status, or an emergency department (ED) visit. There are no public reports summarizing the composite rate of these encounters among dialysis patients. We used claims data to estimate rates of acute care admission in dialysis patients with Medicare fee-for-service coverage, mostly because of increasing incidence of observation status admissions and ED visits.

Methods: We studied 493 stable ESRD patients (median age 55 years, 66% males) comprising non-dialysis patients (n=321), prevalent peritoneal dialysis (n=122) and hemodialysis patients (n=50). Plasma dephosphorylated-uncarboxylated matrix-Gla protein (dp-ucMGP), a circulating marker of vitamin K deficiency, and other relevant clinical and biochemical data were determined at baseline. A cohort of 553 controls (median 51 age years, 45% males) was referred to estimate vitamin K status in healthy subjects. Vascular calcification was estimated with coronary artery calcium (CAC, n=237) and aortic valve calcium (AVC, n=223) among ESRD patients undergoing cardiac computed tomography scan.

Results: Plasma dp-ucMGP (median 1445 pmol/L) levels were substantially elevated in ESRD patients compared to healthy subjects (median 376 pmol/L). During median 42 months’ follow-up, 92 patients died (19%) and 128 patients (26%) underwent renal transplantation. 1 SD increase of dp-ucMGP associated with increased all-cause mortality (1.19 (1.01-1.46)), sub-hazard ratio (95% confidence interval), with adjustment for age, sex, presence of cardiovascular disease, diabetes, body mass index, inflammation, handgrip strength and dialysis. In subgroup analysis further adjusted for presence of CAC or AVC, dp-ucMGP remained as an independent risk factor of mortality (1.27 (1.03-1.56) and 1.36 (1.05-1.66), respectively). In multivariate linear regression model, increased dp-uc-MGP levels were not associated with quantified calcification suggested by CAC (p=0.11, R2=0.30) and AVC (p=0.84, R2=0.12).

Conclusions: Vitamin K deficiency is evident in ESRD and strongly associated with an increased risk of mortality which is not modified by the presence of vascular calcification. Plasma dp-ucMGP was not an independent risk factor of calcification quantified by CAC and AVC.

Poor Vitamin K Status Associates with Worse Clinical Outcome Independent of Coronary Artery Calcium and Aortic Valve Calcium in ESRD
Lu Dai,1 Longkai Li,1,2 Abdul Rashid T. Qureshi,1 Jonaz Ripsved,3,4 Torkel B. Brismar,1,4 Olof Heimburger,1 Peter F. Barany,1 Bengt Lindholm,1 Leon J. Schurgers,1 Peter Stenvinkel.1 1Division of Renal Medicine and Baxter Novum, Department of Clinical Science, Intervention and Technology, Karolinska Institutet, Stockholm, Sweden; 2Department of Nephrology, First Affiliated Hospital of Dalian Medical University, Dalian, China; 3Division of Medical Imaging and Technology, Department of Clinical Science, Intervention and Technology, Karolinska Institutet, Stockholm, Sweden; 4Department of Radiology, Karolinska University Hospital, Huddinge, Stockholm, Sweden; 5Department of Biochemistry, Cardiovascular Research School Maastricht, Maastricht University, Maastricht, Netherlands.

Background: Patients with end-stage renal disease (ESRD) are at high risk of vitamin K deficiency and vascular calcification. The association between vitamin K status and vascular calcification is non-affirmative in clinical observations. We investigated the association of vitamin K status with all-cause mortality in ESRD and the modification effect of vascular calcification in this scenario.

Methods: We studied 493 stable ESRD patients (median age 55 years, 66% males) comprising non-dialysis patients (n=321), prevalent peritoneal dialysis (n=122) and hemodialysis patients (n=50). Plasma dephosphorylated-uncarboxylated matrix-Gla protein (dp-ucMGP), a circulating marker of vitamin K deficiency, and other relevant clinical and biochemical data were determined at baseline. A cohort of 553 controls (median 51 age years, 45% males) was referred to estimate vitamin K status in healthy subjects. Vascular calcification was estimated with coronary artery calcium (CAC, n=237) and aortic valve calcium (AVC, n=223) among ESRD patients undergoing cardiac computed tomography scan.

Results: Plasma dp-ucMGP (median 1445 pmol/L) levels were substantially elevated in ESRD patients compared to healthy subjects (median 376 pmol/L). During median 42 months’ follow-up, 92 patients died (19%) and 128 patients (26%) underwent renal transplantation. 1 SD increase of dp-ucMGP associated with increased all-cause mortality (1.19 (1.01-1.46)), sub-hazard ratio (95% confidence interval), with adjustment for age, sex, presence of cardiovascular disease, diabetes, body mass index, inflammation, handgrip strength and dialysis. In subgroup analysis further adjusted for presence of CAC or AVC, dp-ucMGP remained as an independent risk factor of mortality (1.27 (1.03-1.56) and 1.36 (1.05-1.66), respectively). In multivariate linear regression model, increased dp-uc-MGP levels were not associated with quantified calcification suggested by CAC (p=0.11, R2=0.30) and AVC (p=0.84, R2=0.12).

Conclusions: Vitamin K deficiency is evident in ESRD and strongly associated with an increased risk of mortality which is not modified by the presence of vascular calcification. Plasma dp-ucMGP was not an independent risk factor of calcification quantified by CAC and AVC.

Calcium Carbonate-Pre-Added Cheese to Improve Compliance, Nutrition, and Metabolic Balance of Patients on Renal Replacement Treatment
Gianluigi Ardissino,1 Valentine Capone,1 Elisabetta Margiotta,2 Isabella Cropanese,1 Francesca Raffiotta,2 Giovanni Montini,1 Piergiorgio Messa,1 Pediatric Nephrology, Dialysis and Transplantation, Fondazione IRCCS Ca’ Granda, Ospedale Maggiore Policlinico, Milano, Italy; 2Nephrology, Dialysis and Transplantation, Fondazione IRCCS Ca’ Granda, Ospedale Maggiore Policlinico, Milano, Italy.

Background: Patients with chronic kidney disease have several dietary limitations that make their diet unappealing with detrimental consequences as adherence to prescriptions, malnutrition and overall poor quality of life. Cheese, an important component of the Western diet, has high phosphorus (P) content thus its consumption is generally restricted in patients on renal replacement therapy (RRT).

Methods: A special cheese was prepared by adding a fixed concentration of CaCO3 (5 g/100 g) to cow milk prior to production procedures. The cheese was then provided to a cohort of patients on chronic RRT with the working hypothesis that while eating the modified cheese patients would have benefited from the phosphorus-vacuum-binding effect of CaCO3. After a run-in period of 1 month, all patients were randomly assigned to receive standard cheese (SC) followed by modified cheese (FriP) or the opposite sequence in a double blind and cross-over fashion for 1 month for each product. The increase in inter-dialysis (48 hrs) P (DP) was regularly and repeatedly (n = 5) measured during each of the 2 periods. A washout period of 1 week was introduced between treatment periods.

Results: Twenty-one patients were enrolled and 16 successfully completed the 2 treatment periods. Drop outs were due to transplantation, COVID-19 infection or to documented non-adherence to the protocol. Observed mean (sd) DP were as follows: Run-in: 2.8 (0.7) mg/dL, SC: 2.8 (0.85) mg/dL, FriP 2.4 (0.61) mg/dL with the latter being significantly lower compared with both other periods. Pre-dialysis P was also lower with FriP compared with SC: 5.00 (1.00) vs 4.66 (0.91) (p=0.01) while Pre-dialysis Ca was not different: 9.24 (0.73) vs 9.24 (0.63) with SC and FriP, respectively. All patients appreciated both products equally and the mean amount consumed per week was not different: SC: 307 gr vs FriP: 283 gr (p: 0.56). All patients reported a significant gratification by reintroducing cheese consumption in their diet.

Conclusions: In conclusion, FriP cheese may reduce dietary limitations of patients on RRT mith significant benefits on: malnutrition, adherence to P binders prescription and ultimately to quality of life.

PO1067
Efficacy of Double-Dose Influenza Vaccine with a Booster Compared with Standard Dose in Hemodialysis Patients: Randomized Controlled Trial
Ekapol Riteevaradej,1 Kobborn Boonnak,2 Suree Yoowannakul.1 Blumibol Adulyadej Hospital, Bangkok, Thailand; 2Mahidol University Faculty of Tropical Medicine, Bangkok, Thailand.

Background: Patients on hemodialysis may be at higher risk of illness and death from infection of influenza virus. The efficacy of dose of influenza vaccine across dialysis patients is uncharacterized. We assessed the efficacy of double-dose and booster influenza vaccine versus standard-dose in hemodialysis patients.

Methods: A prospective, open-label, randomized study with 100 hemodialysis patients were enrolled. Double-dose and booster group (n=50) received two doses of IM inactivated seasonal quadrivalent influenza vaccine and one dose at the next 2 weeks while standard-dose group (n=50) received one dose of vaccine. Demographics and co-morbidity were collected at baseline. HAI titers were assessed prior to vaccination and at 14, 28 days post-vaccination.

Results: Hemodialysis patients had age of 61 years approximately and had similar baseline laboratory and co-morbidity. Double-dose with booster group had higher rate of seroprotection (100% vs 86%, p=0.006) and seroconversion (84% vs 60%, p=0.008) measured by using HAI against H3N2 were different significantly. Moreover, Double-dose with booster group had higher rate of sustained antibody level at 4 weeks after first vaccination measured by using HAI against H1N1 (88% vs 52%, p=0.006) and H3N2 (84% vs 72%, p=0.003) were significant differences. However, no differences in HAI against B strains were seen. At 4 weeks after first vaccination, HAI against H1N1, H3N2, B/Colorado and B/Yamagata are similar in both groups.

Conclusions: The double-dose with booster influenza vaccine can provide higher seroprotection and seroconversion rates of HAI against in H3N2 but no different in other strains compared to standard-dose. This study is needed to explore the effect of double-dose with booster vaccine against all causes mortality or influenza related outcomes for adults undergoing hemodialysis compared to the standard-dose.

Temporal Trends in Clinical Phenotype, Bacterial Genotype, and Clinical Outcomes in Hemodialysis-Dependent Patients with Staphylococcus aureus Bacteremia
Matthew R. Sinclair,1,2 Maria Souli,1 Felicia Ruffin,1 Lawrence Park,3 Michael M. Dagher,1 Christina M. Wyatt,2 Vance Fowler,2,3 Duke University Hospital, Durham, NC; 2Duke Clinical Research Institute, Durham, NC; 3Duke Global Health Institute, Durham, NC.

Background: Staphylococcus (S.) aureus bacteremia (SAB) is a common and potentially lethal infection among hemodialysis-dependent (HD) patients. The determinants of clinical outcomes in HD patients with SAB are not completely understood. We evaluated temporal trends in SAB-attributable mortality, metastatic infections, and bacterial genotype in HD patients over a 20-year period.

Methods: Hospitalized, non-neutropenic HD and non-HD adults with monomicrobial SAB were prospectively enrolled from Jan 1, 1995 to Dec 31, 2015. Clinical characteristics, bacterial isolates, and outcome data were collected. Isolates were previously genotyped using spa typing. Differences between HD and non-HD patients were estimated using median/quartiles or counts/percentages with statistical significance evaluated with Mann-Whitney-U or Fisher’s Exact test. Proportions of patients experiencing each outcome were calculated overall and by calendar year. Secular trends in proportions were estimated with linear regression and associations between bacterial genotypes, clinical characteristics, and clinical outcomes were estimated using univariate and multivariate logistic regression.

Results: Among 2,347 unique participants, 495 (21.1%) were HD. Compared to the non-HD patients, HD patients were younger (median 57 years (y) vs 60 y, p=0.002) and more likely to be Black (74.6% vs 26% p<0.001), female (48.1% vs 42.1% p<0.019), and to have diabetes (56.2% vs 33.8% p<0.001). HD patients experienced significant increases in the annual prevalence of age- and diabetes-adjusted SAB-attributable mortality (0.49% per year p<0.05), metastatic infections (0.79% per year p=0.028), and infection with the highly virulent Methicillin resistant strain USA300 (0.97% per year, p=0.001). The increase in USA300 infections did not appear to explain the observed increases in metastatic infections (Odds Ratio [OR] 1.33, Confidence Interval [CI] 0.55-3.21) or SAB-attributable mortality (OR 0.57, CI 0.14-2.32).

Conclusions: Clinical characteristics differed significantly between HD and non-HD patients with SAB. Increases in mortality and metastatic infections over time were not explained by the rise in more virulent strains of S. aureus, but may be partially explained by changes in patients’ characteristics.

PO1069
Hemodialysis-Associated Increased Intraocular Pressure: A Vision-Threatening Complication
Chad Y. Lewis,1 Nikhil Batra,2 Eric A. Steffen,3 Martha L. Gruber,3 Dartmouth College Geisel School of Medicine, Hanover, NH; 2Dartmouth-Hitchcock Medical Center, Lebanon, NH.

Introduction: Elevation of intraocular pressure (IOP) is a potential complication of hemodialysis (HD). When patients with risk factors for angle closure undergo HD, aqueous humor volume may increase, thus elevating IOP.

Case Description: A 71-year-old woman (ESRD secondary to type II diabetes and proliferative diabetic retinopathy) had a history of elevated intraocular pressure in both eyes with normal visual fields. She was referred to our unit for further management. Dioptric examination showed no evidence of glaucoma. A normal IOP was measured in both eyes. The patient had no significant past medical history, and was on regular hemodialysis without any significant medications. She returned for a follow-up visit 2 weeks later, and had an increase in IOP to 27 mmHg in the left eye and 28 mmHg in the right eye. She was further evaluated in the clinic with a normal visual field and no evidence of glaucoma. She was then referred to an ophthalmologist for further evaluation.

Discussion: The patient was seen by an ophthalmologist, who determined that the IOP was normal and there was no evidence of glaucoma. The patient was then referred to a glaucoma specialist for further evaluation.

Discussion: The patient was seen by an ophthalmologist, who determined that the IOP was normal and there was no evidence of glaucoma. The patient was then referred to a glaucoma specialist for further evaluation.
during HD. One proposed mechanism for increased IOP is as plasma urea is reduced, the aqueous humor lags, becoming hypertonic relative to plasma. The choroid may also thicken, obstructing outflow. We increased diuresis sodium and reduced HD time and dialysate flow. Other strategies include infusion mannitol or hyperosmolar glucose, ultrafiltration to increase plasma oncotic pressure, and more frequent or peritoneal dialysis. Nephrologists should have heightened awareness for angle-closure glaucoma and conditions predisposing to obstruction of aqueous outflow, including proliferative diabetic retinopathy. Headache, ocular pain, or visual changes during dialysis warrant urgent ophthalmic evaluation.

**Discussion:** Point of care ultrasound (POCUS) is rapidly evolving as a valuable adjunct to bedside clinical examination in internal medicine and subspecialties. However, there is no single accurate sonographic application to determine fluid volume status. While sonographic assessment of inferior vena cava (IVC) is popular among novice POCUS users, its isolated use to determine and monitor volume status is subject to numerous limitations. Similarly, lung ultrasound gives an idea of left sided filling pressures but does not quantify venous congestion, which can have deleterious consequences in various organ systems including kidney. Novel scoring systems like venous excess ultrasound grading (VExUS) allow objective assessment of volume status using portal hepatic venous Doppler waveforms in addition to IVC measurements. Herein, we demonstrate the natural history of these waveforms in a patient with advanced chronic kidney disease (CKD) during the course of ultrafiltration.

**Case Description:** A 39-year-old man with a history of CKD stage 5 presented with generalized weakness, shortness of breath on exertions, worsening leg edema and weight gain despite being compliant with prescribed diuretic therapy. He was admitted and initiated on hemodialysis for refractory volume overload. POCUS showed mild pericardial and pleural effusion as well as an enlarged IVC of ~3cm with <50% collapse. In addition, Doppler ultrasound showed 100% pulsatility of portal vein (normal <30%) with systolic flow reversal and hepatic vein with S wave reversal and only D wave below the baseline. These findings constitute VExUS grade 3, suggestive of severe congestion. While IVC continued to indicate high right atrial pressures, the Doppler waveforms showed parallel improvement with ultrafiltration reaching VExUS grade 1 (mild congestion) at discharge [Figure]. No episodes of intradialytic hypotension occurred.

**Discussion:** POCUS-derived venous waveforms aid in monitoring the effectiveness of decongestive therapy and guide the amount of ultrafiltration.

**PO1070**

**Point-of-Care Ultrasonography to Assess Venous Congestion and Guide Ultrafiltration: Another String to Our Bow?**

Saquib Mahmud, Abhilash Koratala. Medical College of Wisconsin, Milwaukee, WI

**Introduction:** Point of care ultrasound (POCUS) is rapidly evolving as a valuable adjunct to bedside clinical examination in internal medicine and subspecialties. However, there is no single accurate sonographic application to determine fluid volume status. While sonographic assessment of inferior vena cava (IVC) is popular among novice POCUS users, its isolated use to determine and monitor volume status is subject to numerous limitations. Similarly, lung ultrasound gives an idea of left sided filling pressures but does not quantify venous congestion, which can have deleterious consequences in various organ systems including kidney. Novel scoring systems like venous excess ultrasound grading (VExUS) allow objective assessment of volume status using portal hepatic venous Doppler waveforms in addition to IVC measurements. Herein, we demonstrate the natural history of these waveforms in a patient with advanced chronic kidney disease (CKD) during the course of ultrafiltration.

**Case Description:** A 39-year-old man with a history of CKD stage 5 presented with generalized weakness, shortness of breath on exertions, worsening leg edema and weight gain despite being compliant with prescribed diuretic therapy. He was admitted and initiated on hemodialysis for refractory volume overload. POCUS showed mild pericardial and pleural effusion as well as an enlarged IVC of ~3cm with <50% collapse. In addition, Doppler ultrasound showed 100% pulsatility of portal vein (normal <30%) with systolic flow reversal and hepatic vein with S wave reversal and only D wave below the baseline. These findings constitute VExUS grade 3, suggestive of severe congestion. While IVC continued to indicate high right atrial pressures, the Doppler waveforms showed parallel improvement with ultrafiltration reaching VExUS grade 1 (mild congestion) at discharge [Figure]. No episodes of intradialytic hypotension occurred.

**Discussion:** POCUS-derived venous waveforms aid in monitoring the effectiveness of decongestive therapy and guide the amount of ultrafiltration.

**Can the Assessment of Ultrasound Lung Water in Hemodialysis Patients Be Simplified?**

Claudia Torino,1 Rocco Tripepi,2 Maurizio Postorino,1 Giovanni Tripepi,2 Charalampos Loutradis,3 Pantelis Sarafidis,3 Francesca Mallamaci,1,2 Carmine Zoccali.1 1Nephrology Unit, GOM Reggio Calabria, Reggio Calabria, Italy; 2IFC-CNR, Reggio Calabria, Italy; 3Aristotleio Panepistimio Thessalonikes, Thessaloniki, Greece.

**Background:** Lung ultrasound (US) reliably estimates lung water and it is increasingly applied in clinical practice in dialysis patients. Lung water is measured by applying a semi-quantitative US score summing up the US-B lines detected in 28 lung intercostal spaces (LIS). A simplified assessment restricted to 8 LIS only has been proposed. However, the agreement among the scores has not been studied and their prognostic value has never been compared.

**Methods:** We included in the analysis 303 HD patients in which the pre-dialysis US-BL score was measured at baseline with both the semi-quantitative and the simplified method. The time needed for performing the 28-LIS and the 8-LIS score by six independent assessors with various experience on lung US assessment was accurately measured. Patients were divided into 4 categories, according to pre-established cut-offs specific for the two methods (28-LIS score: <5; 5-15; 16-30; >30 US-BL; 8-LIS score: <10; 10-20; 21-50; >50 US-BL). The prediction power of these scores was assessed by the explained variance ($R^2$).

**Results:** The 28-LIS score and the 8-LIS score were highly inter-related (p=0.03, P<0.001). During a mean follow-up of 3 years, 112 patients died and 129 experienced a CV event. At univariate and multivariate analysis, both scores were associated to the study outcomes. The $R^2$ of the 28-LIS score for death was 4.1% and that for CV events 4.6%. The corresponding $R^2$ of the 8-LIS score were 5.4% (death) and 4.7% (CV events), values close to those of the 28-LIS score. Accordingly, when the two scores were separately added to a clinical model including easily available clinical variables the $R^2$ of the model including the 28-LIS score (death:31.1%; CV events:23.9%) were again very similar to those of the 8-LIS score (30.7% and 23.1%, respectively). The median time needed to perform the examination was 3.05 min (IQR 2.22–5.00 min) for the 28 LIS score and 1.35 min (IQR 1.16–2.00 min) for the 8 LIS score.

**Conclusions:** The simplified 8-LIS score is tightly related to the classical 28 LIS score and the two scores hold an almost identical predictive power. Even though the 28-LIS score demands less than 5 minutes, the 8-LIS score can be done in only about 90 sec. and it is therefore better suited for application in everyday clinical practice in hemodialysis units.

**PO1072**

**Longitudinal Assessment of Random Variability in ICH-CAHPS Scores**

Dena C. Cohen, Steven M. Brunelli, Francesca Tentori. Davita Clinical Research, Minneapolis, MN.

**Background:** The Centers for Medicare & Medicaid Services mandates use of the In-Center Hemodialysis Consumer Assessment of Healthcare Providers and Systems (ICH-CAHPS) survey to assess dialysis patients’ experience of care. Survey responses, collected twice annually and reported at the facility level, are intended to evaluate facility performance over time and to compare across facilities at a given time. In order to be useful for these purposes, the random variability in ICH-CAHPS scores must be relatively low.

**Methods:** ICH-CAHPS scores were analyzed among 2735 facilities managed by a large dialysis organization that had at least one ICH-CAHPS score available between 2014 and 2018. The association between Center Global Rating score (1 of the 6 ICH-CAHPS domains) and survey period was assessed using a mixed model with random slopes and intercepts for each facility. Mean squared residuals were calculated for each facility and categorized on the basis of the number of survey responses received at the facility. Facilities with available scores in all 9 survey periods analyzed (N = 1074) were assigned to quintiles based on their position within the distribution of scores in each survey period, and movement across quintiles was assessed longitudinally.

**Results:** The mean Center Global Rating score in the fall of 2018 was 64.9, with an average increase of 0.2 points per period over the subsequent 8 survey periods. However, random variation in scores was considerable and dependent on the number of survey
responses received. The root mean square error, a measure of random variation, ranged from 0.9 points for facilities with ≥27 responses to 9.2 points for facilities with 11 to 12 responses. Among facilities with survey responses available in all 9 periods, movement between quintiles was frequent, with 39.7% of facilities occupying 4 of the 5 possible quintiles at least once, and 11.5% occupying all 5 quintiles.

**Conclusions:** Within facilities, there is substantial random variation in ICH-CAHPS scores over time. This diminishes the utility of ICH-CAHPS for its intended purposes. Improvements to ICH-CAHPS, or development of alternative measures of patient experience, are needed to enable accurate measurement of facility performance and to inform patient care.

**PO1075 Implication of Trends in Timing of Dialysis Initiation on Population Incidence of ESRD**

Chyi-yuan Hsu,1 Rishi V. Parikh,2 Leonid Pravoverov,2 Sijie Zheng,3 David T. Glidden,1 Thida C. Tan,1 Alan S. Go,1-3 University of California San Francisco, San Francisco, CA;1 Kaiser Permanente, Oakland, CA.

**Background:** In the past two decades, eGFR at start of chronic dialysis worldwide have changed notably. How changes over time in the likelihood of dialysis initiation at any given eGFR level impacts the population burden of ESRD has not been well-defined.

**Methods:** We analyzed data from 2001-2015 in successive 3-year intervals among adult members of a large, integrated health care delivery system in Northern California who had ≥1 outpatient serum creatinine in the prior year. One-year risk of initiating chronic dialysis was delineated stratified by starting eGFR levels per 3-year cohort. To assess multivariable-adjusted temporal trends, we evaluated the significance of a 3-year cohort term in a logistic regression model adjusting for age, gender, race, and diabetes mellitus status. We then estimated a potential reduction in dialysis initiation in 2013-2015 using the relative difference between the standardized 1-year risks (95% CI) in 2001-2003 and 2013-2015.

**Results:** Among those with eGFR 16-17 mL/min/1.73m² (N=2753), 14-15 mL/min/1.73m² (N=2074), and 10-13 mL/min/1.73m² (N=2655), the 1-year risk of initiating dialysis increased for every 3-year period by 11% (adjusted odds ratio [aOR] 1.11 [95% CI 1.163-1.481]), 11% (aOR 1.11 [1.03 to 1.20]) and 7% (aOR 1.07 [1.01 to 1.14]) respectively, adjusting for gender, age, race, and diabetes mellitus (Figure). We estimate that incidence of ESRD could have potentially been 16% (95% CI:13% to 18%) lower if there were no changes in system-level practice patterns or patient-related or other factors from 2001-2003 to 2013-2015.

**Discussion:** Our data suggest that approximately two thirds of the target 25% relative reduction in new ESRD cases by 2030 called for in the White House AAKI initiative could potentially be achieved by changes in the timing of initiation of chronic dialysis.

**PO1076 The Impact of Serum Albumin Levels on Excess Hospital Spending**

Linda Ficociello,1 Melissa M. Rosen,2 Claudy Mullon,1 Robert J. Kossmann,2 Michael S. Anger,1 Fresenius Medical Care Renal Therapies Group, Waltham, MA;1 Fresenius Medical Care North America, Waltham, MA.

**Background:** National Kidney Foundation KDOQI guidelines recommend that hemodialysis patients have a serum albumin (sA) levels greater than or equal to 4 g/dL. Serum albumin lower than 4 g/dL has long been associated with an increased risk of morbidity and mortality in dialysis patients. Compared to both low and high flux dialyzers, a mean albumin loss of 3g per dialysis session has been observed with medium cut-off (MCO) dialyzers (Kim et al., BMC 2020; Kirsch et al. NDT, 2017) which may decrease sA levels and increase the risk of hypoalbuminemia (serum albumin <3.5 g/dL). The aim of this analysis was to estimate the impact of sA levels on hospitalization and associated cost.

**Methods:** Prior research conducted by Rocco et al. (J. Am. Soc. Nephrol., 1996) identified sA level as a risk factor for hospitalization in ESKD patients receiving dialysis and estimated hospital utilization associated with sA levels. Data from this analysis was used to show that relative to patients with sA ≥4 g/dL, on average each year, patients with sA of 3.0-3.4 g/dL, sA of 3.0-3.4 g/dL, and sA ≤3.0 g/dL have 3.98, 7.65, and 7.8 more hospital days, respectively. Using an average cost per hospitalization for a dialysis patient of $15,907.18 and the average length of stay (11.3 days) from USRDS, and data from Rocco et al. (1996), we estimated the additional hospital spending associated with reduced albumin levels.

**Results:** Based on previous research demonstrating an association between sA levels < 4 g/dL and increased risk of hospitalization, we estimated the hospitalization costs...
associated with having reduced serum albumin. Relative to hemodialysis patients with a 4 g/dL, we calculated that having a lower average aS level may result in excess healthcare spending of $5,662 for aS of 3.5-3.99 g/dL, $10,769 for aS of 3.0-3.49, and $10,980 for aS less than or equal to 3.0 g/dL.

Conclusions: Lower serum albumin levels are associated with increased hospital admissions, which is estimated to lead to excess hospital spending on average of $5,602, $10,980 per patient per year. Preventing albumin loss in dialysis patients may help to reduce the risk of hospitalization.

POI077
A Pilot Randomized Control Trial of an Energy Management Program for Adults on Chronic Hemodialysis with Fatigue: The Fatigue-HD Study

Janine F. Farragher,1 Pietro Ravani,1 Braden J. Manns,1 Meghan J. Elliott,1 Chandra M. Thomas,1 Maouissa Donald,1 Brenda Hemmenga.1 University of Calgary Cumming School of Medicine, Calgary, AB, Canada; 2University of Alberta Faculty of Medicine and Dentistry, Edmonton, AB, Canada.

Background: How to reduce fatigue and its impact on life participation is a top-ten unanswered research question among patients treated with chronic hemodialysis. We aimed to determine the feasibility of conducting a randomized controlled trial, to investigate an energy management education program for the chronic hemodialysis population.

Methods: We conducted a parallel-arm, 1:1, blinded pilot RCT at six hemodialysis units in Calgary, Canada. Patients who had moderate or severe fatigue on the Fatigue Severity Scale, and met other study eligibility criteria, were invited to participate. Consenting participants were randomized to general self-management education or the Personal Energy Planning (PEP) program, a tailored 7-9 week energy management program that guides participants in practicing efficient energy expenditure during valued life activities. We assessed study eligibility, recruitment and attrition rates. We then computed standardized intervention effects (Cohen’s D statistic) on self-reported fatigue and life participation measures, compared to control, at immediate post-intervention and 12 weeks post-intervention.

Results: Of 253 people on hemodialysis screened, 153 were eligible to be approached (clinically stable and English-speaking). 42 (26%) were interested and consented to participate, and 30 met all study eligibility criteria were enrolled (mean age 62.4, 60% male). 22 (73%) enrolled participants completed all study procedures. Medium intervention effects were observed compared to control on the global life participation scale, global life participation satisfaction scale, and CPM-Performance Counts, participants were separated into 3 categories: sedentary, fairly active, or active if they walked more than 5,000, 5,000 to 10,000, or >10,000 steps per day respectively.

Results: Fifty-six patients were included in this analysis (54.12% years, 71% male, 66% black, 28.6% had diabetes and 23.2% CHF, dialysis vintage 5.8±5.8 years and body mass index of 28.0±7.0 kg/m²). Participants walked an average of 6,470±4,617 steps per day, median of 5,513 [IQR 3,043-8,268] steps/day. Of the 56 participants, 45% (n=25) were sedentary, 39% (n=22) were fairly active, and 16% (n=9) were active (fig.1).

Conclusions: This pilot project, still ongoing study enrolled HD patients from 4 clinics in NYC beginning in May 2018 and followed them up to 1 year. Patients a18 years, HD a3 months, able to walk, owning a smartphone, mobile tablet or PC were enrolled. They were provided with a wrist-based tracking device (Fitbit® Charge 2). We present baseline characteristics and PA levels of the first 7 days of wear. Based on their average daily step counts, participants were separated into 3 categories:sedentary, fairly active, or active if they walked less than 5,000, 5,000 to 10,000, or >10,000 steps, respectively.

POI078
Coffee and Headache in Hemodialysis Patients: The CoffeeHD Trial

Mabel Aoua,1,2 Najla Hilal,1 Chadia H. Beaini,1 Ghassan Sletlflay,1 Joseph Hajal,1 Celine El boueri,2 Dania Chelala,1 Saint-Joseph University, Beirut, Lebanon; Saint-George Hospital, Ajaltoun, Lebanon; 3Université Saint-Esprit de Kaslik, Jounieh, Lebanon; 4Bellevue Medical Center, Mansourieh, Lebanon.

Background: Headache occurs in 40 to 75% of HD patients. Caffeine circulates unbound in the blood and passes the dialysis membrane. Some suggested that headache can result from caffeine withdrawal. This study aims to compare the incidence of headache and hypotension between patients taking or not coffee during dialysis.

Methods: This is a randomized double-blind multicenter trial. Patients of 3 HD units were included. 156 patients were randomized to two groups, group A was given coffee and group B decaffeinated coffee mid-session for 12 sessions. UF rate was fixed to <13 ml/kg/hr. Primary outcome was incidence of headache and secondary outcome incidence of hypotension. This clinical trial received the approval of the ethics committee and was registered on ClinicalTrials.Gov (NCT04057313).

Results: 139 patients completed the trial (6.4% vs 15.4% of withdrawal in A and B respectively). Baseline characteristics are summarized in Table 1. Incidence of headache was not significantly different between A and B (34% vs 37% respectively, p=0.522), nor the incidence of hypotension (27% vs 26% respectively, p=0.539). In subgroup analysis, headache was lower in A (p=0.06) in two categories of patients: those with higher potassium dialysate (K+) and the non-hypertensive patients.

Conclusions: Headache occurred in 34 to 37% of dialysis sessions. There was no difference in headache or hypotensive episodes between patients in the coffee versus decaffeinated group.
PO1080
Feasibility and Acceptability of Symptom Monitoring with Feedback Trial (SWIFT) for Adults on Hemodialysis: A Pilot ANZDATA Registry-Based Cluster Randomized Trial
Rachel L. Morton,1 Kathryn Dansie,2 Paul N. Bennett,3 Emily Duncanson,2 Andrea R. Vescelius,1 Shilpa Jesudason,1 Karen K. Shah,1 Chris Brown,1 Sueotton Palmer,1 Fergus J. Caskey,1 Stephen P. McDonald,1,2 SWIFT NHMRC Clinical Trials Centre, Camperdown, NSW, Australia; 3 Australia and New Zealand Dialysis and Transplant Registry, Adelaide, SA, Australia; 4 Satellite HealthCare, San Jose, CA; 5 Princess Alexandra Hospital, Woolloongabba, QLD, Australia; 6 Royal Adelaide Hospital, Adelaide, SA, Australia; 7 University of Otago Christchurch, Christchurch, New Zealand; 8 University of Bristol, Bristol, United Kingdom.

Background: We designed a registry-based randomized trial to test whether the collection and feedback of symptoms improves health-related quality of life (HR-QoL). The pilot study’s aim was to determine technical feasibility and patient-clinician acceptability of electronic tablet-based data capture and feedback integrated within the ANZDATA registry.

Methods: Hemodialysis units were cluster randomized to 3-monthly symptom monitoring using the Integrated Palliative Outcome Scale-Renal (IPOS-Renal) with feedback to clinicians plus 6-monthly HR-QoL using EQ-5D-5L questionnaire (intervention group) vs HR-QoL alone (control group). Feasibility and acceptability outcomes included, 1) individualized survey generation using QR codes linked to ANZDATA records; 2) patient completion rate and time; 3) delivery of individualized symptom reports.

Results: Technical feasibility was demonstrated by successful development of a Qualtrics survey platform presented on tablet computers, use of QR reader codes to verify correct patients from ANZDATA, with a link to the relevant survey for the patient’s allocation and study timepoint. 226 patients (intervention =109; control =117), from 4 Australian units with median dialysis vintage of 1.6 years, mean age 62 years, 31% females, completed at least one symptom or HR-QoL measure, (72% of eligible patients, range 44-99%). Mean completion time was 6.5 minutes for IPOS-Renal (66% nurse assisted), 3.5 minutes for EQ-5D-5L. Consolidated symptom feedback reports and evidence-based symptom management guidelines for Nephrologists and dialysis nurses were delivered electronically within 2 weeks of measurement.

Conclusions: Electronic symptom monitoring in adults on hemodialysis with feedback to clinicians is feasible. These data support the commencement of the definitive trial in 3,072 patients.

PO1081
Physiological Pre-Dialytic Changes Could Mediate the Effects of Extreme Heat Events on Hospital Admission Risk in Hemodialysis Patients
Richard V. Remigio1, Rodman E. Turpin1, Jochen G. Raimann2, Peter Kotanko3, Franklin W. Maddux1, Len A. Ussyot4, Xin He1, Amir Sapkota1.1 University of Maryland School of Public Health, College Park, MD; 2 Renal Research Institute, New York, NY; 3 Fresenius Medical Care AG and Co KGaA, Bad Homburg, Germany; 4 Fresenius Medical Care North America, Waltham, MA.

Background: Thermoregulatory response to extreme heat events (EHE) includes reduced blood pressure and perspiration. EHE exposure increases the risk of hospitalizations among hemodialysis (HD) patients, although the underlying mechanism for this relationship is unclear. We employed traditional mediation analysis to decompose the total effect between EHE and hospital admissions using pre-HD systolic blood pressure (SBP) and interdialytic weight gain (IDWG) as mediators.

Methods: We assigned EHE exposure metric – calculated using calendar day and pressure (SBP) and interdialytic weight gain (IDWG) as mediators. The Prepare RCT integrated the Quintet Recruitment Intervention (QRI) – a complex

PO1082
Frequency, Risks, and Outcomes of Sepsis Hospitalizations in the ESKD Population in the United States
Pranjal Basu1,2 Remigio Alba1,3,4,5,6,7,8,9,10,11,12, Shilpa Dansie1,2, Kathleen Harrison,1 Samantha M. Kramer,1 Charuhas V. Thakar,1,2 Division of Nephrology, University of Cincinnati, Cincinnati, OH; 2 Cincinnati VA Medical Center, Cincinnati, OH.

Background: Although a biologically plausible link between End Stage Kidney Disease (ESKD) and sepsis exists, little is known about frequency, risk factors, and outcomes of sepsis-related hospitalizations in ESKD patients.

Methods: Of a retrospective cohort of 1,123,731 incident ESKD patients on dialysis (2005 to 2014) from the United States Renal Data System (USRDS), we studied the 508,372 with linked Medicare claims at initiation of dialysis and complete demographic data. Hospitalization data were obtained from Medicare claims with a sepsis hospitalization being identified by previously validated ICD-9 codes. Using Cox proportional hazard models, we examined the risk factors associated with a sepsis hospitalization and effect of a sepsis hospitalization on mortality.

Results: The study cohort was 55% male, 62% white, and had an average age of 70 years. A sepsis hospitalization occurred in 20.8% of the cohort. The overall rate of sepsis hospitalizations was 15.4 per hundred patient years (PHPY), and the trend increased over time from 13.8 PHPY in 2005 to a peak of 16.7 PHPY in 2011. Factors associated with higher likelihood of a sepsis hospitalization included female sex (Hazard Ratio [HR] 1.05, 95% CI 1.03-1.06), age >80 (vs. age <40; HR 1.30, 95% CI 1.24-1.36), dialysis access via catheter (vs. fistula/graft; HR 1.61, 95% CI 1.58-1.63), congestive heart failure (HR 1.28, 95% CI 1.26-1.30), and diabetes mellitus (HR 1.14, 95% CI 1.12-1.16). Compared to black race, minority races had lower likelihood of developing a sepsis hospitalization (Black HR 0.89, 95% CI 0.87-0.90; Hispanic HR 0.82, 95% CI 0.80-0.84; Asian HR 0.79, 95% CI 0.76-0.82; Native American HR 0.80, 95% CI 0.75-0.86). Compared to no hospitalizations, ESKD patients had a twofold increase in mortality following a first non-sepsis hospitalization (HR 2.14; 95% CI 2.12 to 2.16), increasing to ninefold over baseline following a sepsis hospitalization (HR 9.00; 95% CI 8.87-9.13).

Conclusions: Sepsis hospitalizations are frequent and are associated with significant mortality in ESKD patients in the U.S. Further studies need to focus on modifiable risk factors of sepsis and explore optimal therapies for sepsis in ESKD subjects.

PO1083
Optimising Recruitment in Prepare for Kidney Care: A Clinical Trial Comparing Preparation for Dialysis vs. Responsive Management
Alba X. Realpe,1 Leila Roosheenas,1 Jenny Donovan,1 Emer R. Gates,2 Helen L. Winton,1 Fergus J. Caskey.1,3 On behalf of Prepare for Kidney Care team (University of Bristol Faculty of Health Sciences, Bristol, United Kingdom; North Bristol NHS Trust, Westbury on Trym, United Kingdom.

Background: Randomised Controlled Trials (RCTs) are core to evidence-based practice, but often close prematurely or are not attempted for fear of recruitment issues. Prepare for Kidney Care (‘Prepare’) randomises adults aged 80+ to 65+ with comorbidities to prepare for Renal Dialysis or Responsive Management—a form of conservative care. An RCT of this nature has never been attempted, with concerns about recruitment feasibility. The Prepare RCT integrated the Quintet Recruitment Intervention (QRI) – a complex
PO1084
Time Course of Tissue Sodium Flux in Maintenance Hemodialysis (MHD) Patients
Hsin-Yu Fang,1 Luis M. Perez,2 Ryan J. Larsen,3 Deepa H. Shankar,4 Talat Alp Ikizler,1 Kenneth R. Wiluld.1 University of Illinois at Urbana-Champaign, Urbana, IL; 2Vanderbilt University Medical Center, Nashville, TN.

Background: Recent 2Na-MRI studies report that sodium can accumulate in tissues. MHD patients have higher tissue sodium concentration ([Na+]t) than healthy counterparts, while tissue [Na+]c can be partially reduced during hemodialysis (HD). This study aimed to evaluate the magnitude of tissue [Na+]c removed during HD and the time-course for its recalibration.

Methods: Seven HD patients (57% male; 66±12 yr; BMI: 36±10 kg/m²; spKt/V: 1.4±0.3; dialysate [Na+]: 136±1.0 mEq/l; UFR: 7.2±1.4 mL/hr; thrice-weekly HD) had sequential 2Na-MRI scans (3T system) over 3 consecutive days, including 2 HD days and the non-HD day in between, at 4 time points: pre-first HD (T1), post-first HD (T2), 24 hours post-first HD (T3), and pre-second HD (T4). [Na+]c of the medial (MG) and lateral (LG) gastrocnemius, soleus (Sol), tibialis anterior (TA), and the whole lower leg (WL) were quantified from MRI images. Plasma [Na+]c was also assessed at T1, T2, and T4 by colorimetric enzymatic assays (Piccolo). Repeated measures ANOVA and the Bonferroni correction were used to calculate differences in tissue [Na+]c over time.

Results: Tissue [Na+]c was reduced at the end of HD (T2) compared to baseline (T1) in the WL (P=0.006), MG (P=0.043), LG (P=0.006), Sol (P=0.029), and TA (P=0.006). (Figure 1A-E). For the WL and all 4 examined muscles, tissue [Na+]c at both T3 and T4 did not differ from baseline (all P>0.05), indicating that tissue [Na+]c returned to the baseline within 24 hours after last HD. In contrast, plasma [Na+]c did not change over time (P=0.067; Figure 1F).

Conclusions: We found that tissue [Na+]c was reduced by HD but returned to baseline levels within 24 hours that remained stable until next pre-HD. More studies are needed to determine the mechanisms for these shifts, and whether lifestyle or pharmacological interventions can inhibit tissue [Na+]c accumulation or enhance its removal.

PO1085
Association Between Dialysate Sodium Concentration and Interdialytic Weight Gain in Patients Undergoing Twice Weekly Haemodialysis

Background: Chronic kidney disease is highly prevalent in the world with more than two million people worldwide requiring renal replacement therapy. Interdialytic weight gain is the change in body weight between two sessions of haemodialysis. Higher interdialytic weight gain has been associated with increased mortality and adverse cardiovascular outcomes. It has long been questioned whether using a lower dialysate sodium concentration during dialysis would reduce the interdialytic weight gain and prevent these adverse outcomes.

Methods: This was a single blind cross-over study of adult patients undergoing twice weekly haemodialysis conducted over two six week periods. Patients were divided into two groups – the first underwent dialysis with dialysate sodium concentration of 137mEq/l, the other underwent dialysis with a sodium concentration of 140mEq/l. These groups switched over after a six-week period without a washout period. Interdialytic weight gain, pre and post dialysis blood pressures were measured at each dialysis session.

Results: 41 patients were included in the primary analysis after meeting inclusion criteria. Mean age was 61.37 years, and 73% were males. Mean duration for dialysis was 2.53 years. 13% were anuric, 56% were oliguric, and 31% were non-oliguric. 59% of patients had diabetes mellitus and 80% had hypertension. The interdialytic weight gain was not significantly different among the two groups (2.14 for the low NaD (137mEq/l) group and 2.35 for the high NaD (140mEq/l) group, p = 0.97). Mean blood pressures were as follows. Pre-dialysis: DNAs 137mEq/l: systolic 152±10, diastolic 78±9, DNAs 140mEq/l: systolic 154±10, diastolic 78±9. Post-dialysis: DNAs 137mEq/l: systolic 147±2, diastolic 77±8, DNAs 140mEq/l: systolic 151±3, diastolic 76±6. Conclusions: There was no significant difference in the interdialytic weight gain as well as pre dialysis and post dialysis systolic and diastolic blood pressures between the low dialysate sodium concentration and high dialysate sodium concentration. Therefore using a lower dialysate sodium concentration does not appear useful in altering the interdialytic weight gain although further studies with a larger sample size are warranted.

PO1086
Low Sodium Dialysate for Hemodialysis Is Associated with Lower Blood Pressure and Interdialytic Weight Gain, but Not a Lower Pre-Dialysis Serum Sodium
Huyen Nguyen, Andrew I. Chin. University of California Davis, Sacramento, CA.

Background: The use of high dialysate sodium (NaD) concentrations for hemodialysis (HD) is associated with greater interdialytic fluid gain (IDWG). The association with higher blood pressure has not been found routinely. Conversely, use of a lower NaD may improve on these parameters, but may lead to a lower pre-dialysis serum sodium concentration, which may have adverse consequences in this population. We aimed to examine IDWG, blood pressure, calculated serum osmolality and serum Na in HD patients on a high NaD (145) who transitioned to a low NaD (137-138) in HD patients on a high NaD (145) who transitioned to a low NaD (137-138)

Methods: In this retrospective, single-center study of 3-times weekly HD patients without residual kidney function, we queried long-term HD patients who were prescribed NaD of 145 and were then switched to a NaD of 137 or 138, based on change in sodium concentration during dialysis, which may have adverse consequences in this population. We aimed to examine IDWG, blood pressure, calculated serum osmolality and serum Na in HD patients on a high NaD (145) who transitioned to a low NaD (137-138) in HD patients on a high NaD (145) who transitioned to a low NaD (137-138)

Results: We identified 136 patients who were started on HD with NaD of 145 for at least 1 year, subsequently changed to a NaD of 137-138 for at least 1 additional year. See Figure comparison of parameters.

Conclusions: In patients on 3-times a week HD, long-term use of a high NaD of 145, compared to a low NaD of 137-138, was associated with a higher IDWG, similar to what is found in other studies. A lower NaD was associated with lower pre and post-HD systolic diastolic blood pressures, but we found no difference in pre-HD serum Na or calculated serum osmolality. The degree of drop in blood pressure during HD on the low NaD caused hypotensive events in some patients. There are some clinical parameter benefits to a lower NaD and serum Na does not appear to suffer.

Use of Predictive Analytics to Inform Integrated Care Programs to Reduce Hospitalizations Among Hemodialysis Patients

**Methods:** We reviewed electronic medical records of End-Stage Renal Disease Seamless Care Organization (ESCO) enrolled patients discharged home from acute-care hospitals between Nov 2018-Oct 2019 who returned to participating dialysis units. Patients readmitted ≤3 days, died, or entered hospice ≤30 days were excluded. Time-varying propensity score (from age, dialysis vintage, modality, cause and catheter use, prior hospitalization history, albumin, sex, marital status, and race) matched Cox models were constructed comparing hazard ratios for 30-day readmission between Full- and Partial-MTM exposure groups.

**Results:** MTM was provided in 1,752 discharges (456 Partial-MTM; 1296 Full-MTM). Of those, 455 Full- and 455 Partial-MTM cases were matched 1:1. Full-MTM had 25% lower risk for 30-day readmission even when compared to discharges that received partial-MTM services (HR 0.75; 95% CI 0.58-0.98). Full-MTM process was completed ≤14 days in 81% cases (n=1054). Of those, 444 early Full-MTM were matched to 444 Partial MTM cases and demonstrated a significantly lower risk for 30-day readmissions (HR 0.74, 95% CI 0.57-0.95), primarily driving the overall results.

**Conclusions:** Full MTM process is associated with lower 30-day readmission risk compared to Partial-MTM. The results are primarily driven by MTM process completion ≤14 days of discharge. These findings support that timely physician adjudication of pharmacists’ recommendations and subsequent actions (i.e. medication changes as needed) influence the effectiveness of MTM programs to impact readmission rates.

Healthcare Staff Acceptance of Ultrafiltration Rate Recommendations Made by a Novel Feedback Controller

**Methods:** We conducted a prospective, interventional study in chronic HD patients at 3 Dialysis Clinics in Manhattan. RBV was measured with the CLiC® device. CLiC® and Fresenius 2008FT HD machine data were fed into a research laptop running the UFR Feedback Controller software. UFR recommendations (generated every 10 minutes) were evaluated by dialysis nurses who then either implemented or rejected them as they deemed clinically appropriate.

**Results:** 56 HD treatments from 14 subjects had analyzable data. Out of 1,038 UFR recommendations, 926 (89.2%) were accepted, while 112 (10.8%) were overridden. For 25 HD treatments which had at least one recommendation overridden, we analyzed the direction and magnitude of disagreement between the Controller-suggested UFR and the implemented UFR (Fig. 1). From the overridden controller recommendations, 20 implemented UFRs were greater than the respective Controller-suggested UFRs, another 70 implemented UFRs were less than 100 mL/h lower than the Controller-suggested UFRs. Together, these two categories made up 83% of all “disagreements” between the nurse and the Controller. Of the total of UFR recommendations overrides, 59.6% were due to staff preference in the absence of clinical symptoms.

**Conclusions:** There was a high proportion (~90%) of Controller-UFR recommendations that were accepted by the nurses. Of the few cases where nurses overrode the recommendation, the majority (~40%) were due to “staff preference”, this is likely owed to the fact that the nurses exclusively attended one patient at a time for the entire HD session.

**Funding:** Commercial Support - Fresenius Medical Care North America

**PO1093**

Intradialytic Online Multicomponent Total Removed Solute Monitoring in Spent Dialysate by a Novel Miniaturized Optical Sensor

**Methods:** Ten ESKD patients (6 M, 4 F; 60.2±16.8 y.o.) on chronic HDF were enrolled into the study. For each patient 5 midweek dialysis sessions (240min; HD: N=1, Qb=200mL/min, Qd=300mL/min, 1,5m2 ; HDF: N=4, Qb=500mL/min, Qd=500mL/min, V_dial=1.5L, 1.8m and 2.2m2) were included. Spent dialysate from the drain was monitored on-line by the miniaturized sensor prototype (Optoflux Technologies OÜ, Estonia). For the reference, samples from the spent dialysate drain tube of the HD machine were taken 70, 60, 120, 180 and 240 min after the start of the dialysis session. Concentrations of urea and B2M in the dialysate were determined in the clinical laboratory. Concentrations of IS and UA were measured utilizing the HPLC. TRS values were calculated using the tank weight and the lab or optical tank solute concentrations. t-test was used to determine significant differences between the methods (P<0.05).

**Results:** The laboratory and optical TRS values were 489±112mmol and 512±87mmol for urea (R²=0.91), 423±72mmol and 421±75mmol for UA (R²=0.92), 201±90 and 231±40mg for B2M (R²=0.951), 60±33mmol and 61.6±32mmol for IS (R²=0.951), being not statistically different for any uremic solutes. The reason for higher correlation for UA and IS is direct measurements of UA and IS by the optical sensor whereas urea and B2M are estimated indirectly.

**Background:** Urea is the most commonly exploited marker of dialysis adequacy, but also other uremic retention solutes accumulate in ESKD patients. Commonly, the uremic solutes are divided into three physicochemical types with the representative markers urea, uric acid (UA); indoxyl sulfate (IS); and β-microglobulin (B2M). Instead of total dialysate collection for quantification of the amount of uremic solutes removed during dialysis, an optical on-line monitoring has been proposed. The aim of this study was to evaluate intradialytic on-line multicomponent total removed solute (TRS) monitoring in the spent dialysate by a novel miniaturized optical sensor during hemodialysis (HD) and hemodialfiltration (HDF) with different settings.

**Funding:** Commercial Support - Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; 1cuHN School of Medicine at Mount Sinai, New York, NY.
Conclusions: Novel miniaturized optical sensor successfully carried out intradialytic on-line multicomponent TRS monitoring for the uremic solutes urea, UA, B2M and IS in the spent dialysate.

PO1094
Patient Safety in a Large Multinational Renal Services Provider Network

Background: Patient safety is considered of paramount importance under any qualified provision of care, but results from routine tracking of incidents have scarcely been reported, even when that may negatively impact survival. Objectives To analyze all types of incidents in a multinational renal service provider network during 2019.

Methods: For the last 10 years, our institution has tracked all incidents under a structured process program, as well as, educated our staff in the importance of proactively reporting and analyzing incidents in a quarterly basis at the clinic, by country and globally. Incidents are categorized in 4 different types: A-Patient related, B-Staff and visitors, C-Products and D-Equipment. Different incident codes are assigned to each type (up to 54). Communication to Health Authorities applies in accordance with local country regulations. “Serious incidents” are immediately notified to the Corporate Office and to each Country Medical lead.

Results: A total of 92,923 incidents (2.7 incidents/patient/year) have been reported during 2019 (higher than in 2018: 2.2). This means an increase of 20% in the total number of reported incidents. Total incidents/1000 treatments was 17.2 (12.2 patient-related incidents). Reporting follows a heterogeneous pattern among countries, being lowest in Argentina and highest in the UK. Top 5 reported incidents were as follows: Codes A15 (voluntarily shortened treatment) and A14 (Patient did not show up), both related to patient adherence to treatment, accounted for 36% of total incidents, vascular access (VA) complications (A4) for 10.2%, change of dialyzer and/or blood lines due to clotting (A2) for 8.5% and recurrent minor monitor malfunction (D1) for 7.6% of incidents. Codes related with unexpected death or cardiopulmonary arrest are not present among the total global Top 10 Incidents.

Conclusions: Detailed tracking of incidents and comparison between countries have potential to increase quality of care and patients outcomes. Room for improvement recently made the Corporate Medical Office to launch new strategies on VA management, anticoagulation and patient compliance, among others. This large series may help other institutions to better monitor and standardize patient safety on dialysis.

PO1095
Incidence of Intradialytic Hypotension Throughout a Hemodialysis Session: Does the Time of Onset Matter?
David F. Keane,1,2 Jochen G. Raimann,2 Hanjie Zhang,2 Stephan Thijssen,3 Joanna Willeots,4 Peter Kotanko,4 Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; 2Renal Research Institute, New York, NY; 3 Fresenius Medical Care Global Medical Affairs, United States, MA.

Background: Intradialytic hypotension (IDH) is a common complication of hemodialysis (HD). Probability of IDH would be expected to increase during HD as ultrafiltration (UF) volumes increase. We aimed to describe the incidence of IDH throughout HD and associations of the time of IDH with clinical parameters and with survival.

Methods: We studied routinely collected data from 21 US dialysis clinics. IDH was defined as: 1) systolic blood pressure (SBP) < 90 mmHg; and 2) SBP < 90 mmHg and a reduction in SBP > 30 mmHg. Only the first IDH incident per session was included. Time of IDH was defined in 30-minute intervals. Patients who experienced IDH were classified as early- or late-onset based on whether most sessions with IDH had incidents in the first 2 hours or not. Association of early-onset IDH with clinical parameters and mortality were explored with logistic regression and Cox proportional hazard models.

Results: We studied 4,348 patients and 785,682 sessions. For definitions 1 and 2, IDH occurred in 13% and 7% of treatments with a range of 2.6-3.3 and 0.9-2.7 episodes per 100 session-intervals at risk, respectively. IDH occurred in the first 2 hours in 45% and 33% of IDH sessions, respectively. IDH incidence was not associated with time into HD using definition 1; a positive association was observed using definition 2. Adjusted hazard ratios for death comparing early-onset IDH with late-onset were 1.5 and 1.7 for definitions 1 and 2. Early-onset IDH was associated with female sex, higher age and UF rates and lower BMI and SBP.

Conclusions: Early-onset IDH is not uncommon. More consideration of the nature and time of IDH onset, in the context of how it is defined, could help to minimize IDH.

PO1096
Endothelin 1 and Parameters of Systolic Blood Pressure in Hemodialysis Patients
Anika T. Singh,1,2 Suraj Sarvode mothi,2 Ping Li,1 Sushrut S. Waikar,3 Finnian R. McCausland,2,1 Mc Causland Lab 2Harvard Medical School, Boston, MA; 3Brigham and Women’s Hospital, Boston, MA; 1Boston Medical Center, Boston, MA; 2Chinese PLA General Hospital, Beijing, China; 1Boston University, Boston, MA.

Background: Blood pressure (BP) fluctuates widely during intermittent hemodialysis (HD), with greater variability associated with adverse cardiovascular outcomes. As endothelin-1 (ET-1) is a potent vasoconstrictor, we hypothesized that higher concentrations of ET-1 is associated with higher pre-HD systolic BP (SBP).

Methods: ET-1 concentrations were measured at baseline from the DaVita Biorepository (N=784), a longitudinal prospective cohort study with quarterly collection of clinical data and biospecimens. Unadjusted and adjusted linear mixed effects regression models were fit to determine associations of log-transformed ET-1 with SBP at dialysis (pre-HD, nadir intra-HD, post-HD, drop (pre- minus nadir-HD) and delta (pre- minus post-HD). Multivariable models were adjusted for age, sex, race, access, diabetes, heart failure, cardiovascular disease, peripheral vascular disease and pre-HD SBP.

Results: Mean age was 58 years, 59% were males, 40% black. Mean pre-HD SBP was 152 (± 28) mmHg and mean ET-1 concentration was 2.3 (±1.1) ng/mL. Subjects in higher quartiles of baseline ET-1 tended to be younger, diabetic, have higher SBP and lower serum albumin. In fully adjusted models, each unit increase in SD of log-transformed ET-1 was associated with a 3.0 (95% CI 1.8 to 4.2) mmHg higher pre-HD SBP, 1.2 (95%CI 0.5 to 1.9) mmHg higher nadir-SBP, 1.6 (95% CI 0.6 to 2.5) mmHg higher post-SBP, 1.2 (95%CI 0.2 to 1.5) mmHg lower SBP drop and 1.6 mmHg (95% CI 0.6 to 1.08) lower delta SBP. In categorical analyses a monotonic increase in pre-SBP was noted in higher quartiles of ET-1 (Q4: 7.8 mmHg increase (95% CI 4.5 to 11.2, P=0.001) compared with Q1. Similar patterns were noted for the other variables of interest.

Conclusions: Higher ET-1 is independently associated with higher SBP in maintenance HD patients. These results suggest a role for studying ET-1 antagonism in HD patients with resistant hypertension.
Kidney Transplant Access Among Children and Young Adults on Dialysis in the United States

Yusuke Okuda,1 Ekamol Tantisattano,1 Elani Streja,1 Marciana Laster,2 Connie Rhee,1 Kamyr Kalantar-Zadeh.1 Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA;1 University of California Los Angeles, Los Angeles, CA, CA.

Background: Only 20% of children and young adults with advanced CKD receive preemptive kidney transplant (KT). This study aimed to investigate secular trends in KT access among incident US dialysis patients who were ≥18 years old.

Methods: In a cohort of incident dialysis patients ≥18 years of age who initiated dialysis between 1995-2014 from the USRDS database, we examined secular trends in the likelihood of receiving KT, using a Cox proportional hazards regression.

Results: Among 24,860 patients, the median (IQR) age at dialysis initiation was 17 (11-20) years of age, among whom 56% were <18 years old. A total of 16,912 (68%) patients underwent a KT during a median (IQR) follow-up of 2.0 (0.9-4.3) years (total follow-up: 82,244 patient-years). The 1-, 2-, and 3-year probabilities of receiving a KT were 23%, 43%, and 55%, respectively. The likelihood of receiving KT slightly improved but decreased after 2005 among patients <18 years old; a decreasing trend was remarkable among patients ≥18 years old [Figure A]. While increasing among patients <18 years old, the likelihood of receiving a deceased donor transplant declined among those ≥18 years old. For a living donor transplant, there were decreasing trends in both age groups [Figure B].

Conclusions: While the likelihood of receiving pediatric KT declined over two decades, there was an increase in deceased donor transplantation among those ≥18 years old. Since biological factors determine unmet need for KT in pediatric or young adult populations having short waiting time, an old kidney allocation system (KAS), which achieved the goal by transplanting patients with the longest waiting time, may not improve transplant access and outcomes. A new KAS commenced in December 2014, and living donor transplant may provide different trends or improve pediatric KT access, although further long-term studies are needed.

Figure: Time-to-event outcomes for receiving a kidney transplant among pediatric (<18 years old) and young adults (≥18 years old) between 1995 and 2014.A. Unadjusted and case-mixed adjusted models B: Stratified into living and deceased donor renal transplantations

Nephrologists’ Practices, Perspectives, and Experiences Providing Care and Treatment Education to Patients with Varying Amounts of Pre-ESRD Care: A Mixed-Methods Study

Megan Urbanski,1 Crystal A. Gadgebek,1 Laura A. Siminoff,1 Amy D. Waterman,2 Levent Dumenci,3 Heather M. Gardiner.1 Department of Social and Behavioral Sciences, College of Public Health, Temple University, Philadelphia, PA;2 Transplant Research and Education Center, UCLA, Los Angeles, CA;3 Transplant Research and Education Center, UCLA, Los Angeles, CA;1 Lewis Katz School of Medicine at Temple University, Philadelphia, PA;1 Department of Epidemiology and Biostatistics, College of Public Health, Temple University, Philadelphia, PA.

Background: A third of patients newly diagnosed with end-stage renal disease (ESRD) in the U.S. had minimal or no pre-ESRD nephrology care and “crashed” onto dialysis. Little is known about treating nephrologists’ practices and perspectives on renal replacement therapy (RRT) information delivery and decision-making for this subset of patients at the time of their ESRD diagnosis and RRT initiation.

Methods: A convergent mixed methods study design was used, and semi-structured interviews were conducted with nephrologists in Philadelphia and the surrounding region. Participants were queried on general practices and perspectives on RRT information delivery and decision-making practices for patients with varying amounts of pre-ESRD nephrology care and also queried on their experiences providing care to patients recently diagnosed with ESRD. Applied thematic analysis was used to analyze the qualitative responses and all quantitative data were fully described.

Results: A total of 15 nephrologists participated. Participants had been practicing nephrology for a median of 7 years and a third of participants were trainees at the time of the interview (i.e., nephrology fellows). The qualitative analyses revealed 12 themes, including: patients’ clinical presentation guides RRT initiation, RRT initiation often occurs urgently irrespective of pre-ESRD care, utilize direct communication style during diagnosis, reliance on other providers for patient education, challenges to providing patient education, desire improved access to educational resources, and desire engaging patients in shared decision-making for RRT selection and initiation. Notably, participants identified patient- and institutional-level barriers inhibiting their ability to provide quality care and education to patients presenting with ESRD diagnosis for RRT initiation.

Conclusions: Nephrologists face significant challenges in providing quality care to patients with varying amounts of pre-ESRD nephrology care. Increasing availability of nephrology-trained interdisciplinary staff in outpatient chronic kidney disease clinics and hospital settings to assist providers with the logistics associated with RRT education and initiation has the potential to improve care for patients newly diagnosed with ESRD.

Predictors of Extracorporeal Circuit Clotting in Patients Requiring Continuous Renal Replacement Therapy

William F. Towers,1 Michael J. Samarin,1 Danielle L. Padgett,1 Margaret C. Hastings,2,3 Joanna Q. Hudson,1,3 1Methodist University Hospital, Memphis, TN; 2University of the Tennessee Health Science Center, Memphis, TN.

Background: Extracorporeal circuit (ECC) clotting frequently occurs during continuous renal replacement therapy (CRRT) resulting in treatment interruption, blood loss and increased resource use. The purpose of this study was to evaluate risk factors for ECC clotting in patients receiving CRRT.

Methods: A retrospective chart review was conducted to identify adult patients who received CRRT at Methodist Le Bonheur Healthcare for a minimum of 24 hours during January 2015 to October 2019. The primary outcome was the occurrence of ECC clotting which was defined as documentation of a thrombotic event in the ECC. Demographic and laboratory data, anticoagulant medications, and CRRT parameters were evaluated for a maximum of 7 days to determine potential risk factors for clotting. Multivariable logistic regression was used to identify predictors of clotting.

Results: A total of 200 patients were included: 110 (54%) male; mean age 56±13 years; mean sequential organ failure assessment score 12±4; 52 (26%) with past medical history of liver disease; 143 (72%) with acute kidney injury; mean duration of CRRT 3.6±2.0 days; 97% receiving continuous venovenous hemodialfiltration. Overall, 131 (66%) patients experienced an ECC clot with a mean time to first ECC clot of 1.3±1.3 days. Patients receiving an unfractionated heparin (UFH) infusion (n=25) had a lower probability of an ECC clot occurring compared to those receiving no anticoagulation (n=86) (40% and 70%, respectively, p=0.01) and those receiving prophylactic UFH (n=70) (40% and 64%, respectively; p=0.04). Factors associated with an increased odds of clotting in patients not receiving an anticoagulant were non-African American race (odds ratio (OR) 4.0; 95% confidence interval (CI) 1.1-14.6), lower blood flow rates (OR 1.3; 95% CI 1.0-1.6), internal jugular catheters (OR 3.3; 95% CI 1.0-1.9), and no history of hypertension (OR 4.7; 95% CI 1.4-16).

Conclusions: This study suggests a high rate of ECC clotting, particularly in patients not receiving anticoagulation. Eligible patients on CRRT should receive an UFH infusion in preference to no anticoagulation or prophylactic UFH.

Gram-Negative Bacteraemia in Haemodialysis Patients: Pathogen and Source Identification

Anna Naito, Fatima Malik, Christopher M. Cregg, Lisa Bradwell, David Makanjuola. Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom.

Background: Gram-negative bacteremia (GNB) in haemodialysis (HD) patients is associated with significant morbidity and mortality. Efforts to reduce rates of bacteraemia caused by Methicillin Resistant Staphylococcus Aureus have been hugely successful. Epidemiological studies now show the re-emergence of gram-negative pathogens, particularly Escherichia coli (E. coli) in causing bloodstream infections. We aimed to determine the source and pathogens responsible for GNB in our HD cohort.

Methods: On all confirmed bacteraemia in HD patients between 2007 and 2018 were collected from clinical and electronic records from the hospital’s renal and microbiology databases.

Results: 283 episodes of GNB occurred in 1361 patients over the 12-year period. 58.7% were male. The median age was 71 years (range 26-95). 31.8% had arteriovenous fistulae or grafts, the remainder had dialysis lines, of which 21.2% had dual access. The organisms isolated are shown in table 1. E. coli and Klebsiella Pneumoniae were the dominant pathogens, accounting for 40.6% and 15.9% of bacteraemias isolated respectively. The most common sources of infection were HD access related in 31.4% (n=89), urinary tract 18.4% (n=52), hepato-biliary 7.8% (n=22), chest 7.8% (n=22), gastrointestinal 6.0% (n=17), skin/soft tissue in 4.9% (n=14), other in 4.6% (n=13), no information on 4 patients (1.5%) and unknown source in 50 (17%).

Conclusions: E. coli bacteraemias remain a major cause of GNB in our HD population. Dialysis lines are a significant risk factor for bacteraemia, lending further weight to the importance of establishing early definitive vascular access. Resistance trends of gram-negative organisms are of particular and increasing concern. We have noticed changing sensitivity patterns of isolates and it is not clear whether local empiric antibiotic policy is contributing to selection pressures and antimicrobial resistance.

Table 1: Gram negative isolates from blood cultures

POI102

Five-Year Outcome of a Retrospective Cohort Study of Patients with Two Hemodialysis Sessions per Week

Aurora E. Hernandez, L. M. Perez-Navarro, Gloria G. Garcia Villalobos, Elba O. Medina, Rafael Valdez-Ortiz. Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.

Background: The indication of two hemodialysis (HD) sessions per week is a common strategy in patients with chronic kidney disease without social security. Some studies reveal that the indication of fewer HD sessions per week has been shown to be associated with adequate clinical results. Objective: To describe the clinical and biochemical status of patients in HD program twice a week in the last five years

Methods: Retrospective cohort study of patients with two HD sessions per week. Their clinical, nutritional status was evaluated by vectors of impendaneometry and quality of life KDOQOL-SF 36. The statistical package SPSS V 22.0 was used for data analysis.

Results: Forty-one patients with a mean age of 37.9 ± 12.6 years, 56% women, were analyzed. The mean time with renal replacement therapy was 5.1 years; Average session time was 180 minutes; average ultrafiltration of 2726.8 ± 755.96 ml / session and an average Kt / V single pool of 1.54 ± 0.38. In 59% of patients the cause of CKD was undermined. 46% of the patients had an arteriovenous fistula. Laboratory tests with Urea Pre-dialysis 164.5 ± 38.9 mg / dl; hemoglobin 10.32 ± 1.9 g / dl; albumin 3.99 ± 0.4 g / dl; phosphorus 5.3 mg / dl; calcium 8.05 ± 0.9 mg / dl; parathyroid hormone 886 ± 747 pg / dl. Body composition BMI 23.6 kg / m2; R (Q) 622.3; Xc (Q) 48.4; and phase angle 4.3 °. 44% of the patients had mild malnutrition according to the Score Malnutrition Inflammation classification. The generic dimensions of the KDOQOL-SF 36 revealed scores greater than 60 for CKD symptoms and effects, with an SF-12 Physical Health Composite 83.6 and SF-12 Mental Health Composite 56.3.

Conclusions: The costs of hemodialysis (HD) treatment are usually a huge financial burden for health systems and patients. HD sessions twice a week are common practice in many countries in patients without social security. Our results show that this therapy should not be categorized as a suboptimal therapy but as an option for patients with certain clinical characteristics.

POI103

Feasibility of and Adherence to Using a Wrist-Based Activity Tracker in Hemodialysis Patients

Maggie Han,1 Priscilla Preciado,1 Ohnmar Thwin,1 Xia Tao,1 Mirell Tapia,1 Lemuel Rivera Fuentes,1 Mohamad I. Hakim,1 Amrish U. Patel,1 Nadja Grobe,1 Stephan Thijsse,1 Peter Kotanko.1,2 1Renal Research Institute, New York, NY; 2Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Wearables allow insights into patient’s status outside the clinical setting. We aim to quantify how long patients will use a wearable device before requiring an intervention to improve adherence.

Methods: Hemodialysis (HD) patients were enrolled from 4 clinics in New York City from May 2018 and followed for up to 1 year. Patients ≥18 years, on HD ≥3 months, able to walk, owning a smartphone, mobile tablet or PC were enrolled, provided with a Fitbit Charge 2, and instructed on how to use the device and sync data. If a patient failed to sync data for 7 consecutive days, a SMS or email reminder was sent. Time to first intervention (TFI) was evaluated using Kaplan Meier time-to-event analysis. Predictors of TFI, including gender, age, living situation, and education level, was assessed via univariate Cox Regression. Patients were censored at the end of the observation period.

Results: 125 patients were enrolled into our study and 7 failed screening. At enrollment, patients were 54±12 years old with a dialysis vintage of 5.6±5.8 years; 37% lived alone, 56% were single, 59% unemployed, 64% were African American, and 42% had an education level of some college or higher. 82% of the patients required a text message reminder. Mean and median TFI were 101 days (95% CI 80 to 123) and 50 days (95% CI 35 to 70 days), respectively. The probability of no intervention is shown in Figure 1. None of the a priori defined parameters were significant predictors of TFI.

Conclusions: Majority of patients studied required at least some intervention to maintain the use of a wrist-based wearable device. While most patients require an intervention before 2 months, the patients who maintain use independently after that point are unlikely to require intervention.

Routine Measured Cardiac Troponin I and NT-ProBNP as Predictors of Mortality in Japanese Hemodialysis Patients: The Dialysis Outcomes and Practice Patterns Study

Mashiro Eriguchi, Kazuhiko Tsursuya, Marcelo Lopez, Brian Bieber, Keith Mccullough, Roberto Pecots-Filho, Bruce M. Robinson, Ronald L. Pison, Eiichiro Kanda, Kunitoshi Iseki, Hideki Hirakata. 1Nara Medical University, Kashihara, Japan; 2Arbor Health Care Co, Extendicare Health Services Inc, Milwaukee, WI; 3Kawasaki Medical School, Kurashiki, Japan; 4Nakamura Clinic, Urazoe, Japan; 5Fukuoka renal clinic, Fukuoka, Medical University, Kashihara, Japan

Background: Due to the interplay of chronic kidney disease and the heart, it is common for myocardial damage and strain to be present in hemodialysis (HD) patients. The cardiac troponin I (cTnI) and NT-proBNP are widely used as cardiac biomarkers to evaluate the patients at high risk for cardiac disease. However, as the prevalence of atherosclerosis influencing lipid metabolism and exerting antioxidant and anti-inflammatory activities. Particularly relevant for HD patients is BB dialyzability. In non-dialysis patients, the risk of cardiovascular-cerebrovascular event. Use of high-dose statins has failed to identify hemodialysis patients with high risk of future cardiovascular events in hemodialysis patients. This study aimed to evaluate the potential of lipids to assess risk of future cardiovascular outcomes

Methods: From July 2013 to August 2019, we followed up the dialysis patients in our dialysis center for stroke and myocardial infarction events, and these patients’ plasma and hemocytes were stored at the baseline. Lipidomic analyses were performed on an Exion LC-system coupled with a QTRAP 6500 PLUS system. Principal component analysis and orthogonal project to late structures discriminant analysis, and was used to analyze the differences between patients in with(out)adverse cardiovascular-cerebrovascular outcome groups.

Results: A total of 45 plasma samples and 117 hemocytes samples were collected. 9 plasma samples and 28 hemocytes samples were from patients with cardiovascular-cerebrovascular events. 53% of patients were detected in plasma, 237% of patients were detected in erythrocytes. Compared with the patients without cardiovascular-cerebrovascular events, the patients with events presented higher level of plasma PS 34:2 and TAG 44:1 (16:1), lower level of plasma TAG 52:6 (16:2), TAG 38:9 (22:5), LPS 18:0, and lower level of erythrocytes Cer d1:6/2:0, Cer d1:8/1:8 and Cer d1:8/2:1:0 (Fold change >1.5 or <1/1.5, P value <0.05).

Conclusions: These findings revealed novel plasma and erythrocytes lipid predictors for cardio-cerebrovascular diseases in hemodialysis patients.

PO1107

β-Blocker Dialyzability and Adverse Cardiovascular Outcomes in Hemodialysis Patients: A Meta-Analysis

Abhinav Tella, William V. Yang, Eustacia C. Ikeri, Olivia Taylor, Alicia Zhang, Srihari T. Raju, Arcep Ishani. Minneapolis VA Health Care System, Minneapolis, MN

Background: β-blockers (BB) are one of the most common medications among hemodialysis (HD) patients. There are several BB with different pharmacokinetic properties. Particularly relevant for HD patients is BB dialyzability. In non-dialysis patients, abrupt withdrawal of BB has been associated with adverse cardiovascular events (CVE). HD patients receiving dialyzable BB may also be increased. This systematic review aims to determine in HD patients if highly dialyzable BB (HDBB) (metoprolol, atenolol, and acebutolol) compared to poorly dialyzable BB (PDBB) (carvedilol, labetalol, bisoprolol, and propranolol) alters CVE and mortality.

Methods: We searched MEDLINE from 1990 through February 2020 for studies of all forms. All cause mortality (ACM) and CVE were our primary outcomes. Random effects models were used to calculate pooled risk ratios (RR).

Results: An initial search identified 1,066 articles. Exclusion criteria eliminated articles that did not include HD patients or did not compare at least two BB. Ultimately, three cohort studies comparing HDBB and PDBB were identified. All studies were retrospective cohort studies of large HD datasets of patients in the U.S. and Canada. The combined population size of the analyzed studies was 38,580 patients: 24,596 on HDBB and 13,984 on PDBB. There was significant heterogeneity between studies, with two suggesting harm associated with HDBB and one suggesting a reduction in mortality. The risk ratio derived from pooled data across these studies was 1.03 (95% CL: 0.88-1.22) for ACM and 0.94 (95% CL: 0.80-1.11) for CVE. Significant heterogeneity was seen with F2 values of 86% and 84% for ACM and CVE respectively.
Conclusions: After a comprehensive search, only three cohort studies were identified comparing BB of different dialyzabilities. No randomized control trials were identified. The three cohort studies had varying results with two favoring HDBB and one favoring PDBB. Pooled results suggested a greater incidence of CVE in patients on PDBB compared to those on HDBB, while ACM is lower for PDBB than for HDBB. Given the heterogeneity of results it is unclear what type of BB should be used in HD patients. A randomized controlled trial comparing BB of different dialyzabilities is warranted.

PO1108
Pre-Dialysis Transition Predictors of Vascular Access Type in 73,928 Veterans Who Started Hemodialysis Therapy Between 2007-2015
Jui-Ting Hsiung,1,2 Kamary Kalantar-Zadeh,1, Elani Streja,1,2,1 Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; 2VA Long Beach Healthcare System, Long Beach, CA.

Background: Studies showed dialysis patients with central venous catheter (CVC) had worse outcomes compared to arterio-venous fistula/graft (AVF/AVG) patients. It is hypothesized that a CVC may be a surrogate for sicker patients. From the US Veteran transition of care (TC-CKD) cohort, we sought to characterize factors associated with initiating dialysis with CVC vs. AVF/AVG access type within a year prior to dialysis transition.

Methods: Among US veterans who transitioned to end-stage renal disease (ESRD) from 2007 to 2015, we examined predictors of access type using adjusted logistic regression. An adjusted reverse cox model was used to examine predictors at time of dialysis initiation to identify time to access placement surgery prior to transition.

Results: Logistic regression showed patients with higher Charlson comorbidity index, multiple preexisting comorbidities, and higher hospital and primary care visit before access surgery, had a higher odds of receiving CVC versus AVF or AVG. Among a subset of 28,759 patients, those who were older, female, black, had dementia, and had higher serum phosphorus, white blood cells, and eGFR were more likely to have CVC. Patients who were married, had higher serum albumin, calcium, sodium, hemoglobin, had slower 1 year eGFR decline, and higher nephrology visits, were less likely to have CVC. Fully adjusted reverse cox regression showed patients with higher serum alkaline phosphatase and blood urea nitrogen were more likely to have AVF/AVG placed closer to time of transition. Among 44,558 patients who had at least 1 VA primary care visit in the year prior to dialysis, patients with 2 nephrology visits were more likely to have a AVF/AVG placement surgery in the year prior to transition [figure].

Conclusions: We found that starting dialysis with CVC is a surrogate of adverse outcomes and faster CKD progression, while frequent nephrology visits in a year prior to transition is associated to higher likelihood of AVF/AVG placement.

Figure: Time for dialysis transition back to AVF/AVG placement surgery prior to transition.

PO1109
Effect of Treatment According to Intervention Modality with Central Venous Access Phases
Seon Deok Hwang,1 Joon Ho Song,2 Kippy Kim,3 Woo Yeong Park,2 Seoung woo Lee.1 1Inha University, Incheon, Incheon, Republic of Korea; 2Keimyung University Dongsan Medical Center, Daegu, Republic of Korea.

Background: A general cause of hemodialysis vascular access failure, a primary cause of morbidity patients undergoing hemodialysis, is central venous occlusion or stenosis. There are several interventions to resolve problem; however whether method is best for dialysis patients. The purpose of this study is to compare which method is best choice to hemodialysis patients.

Methods: We searched Outcomes included the rate of primary patency, assisted primary patency, secondary patency, re-intervention subjects, re-intervention rate regarding balloon angioplasty, nondrug metal stent, drug-eluting stent, or drug-eluting stent in PubMed, Embase, CENTRAL, Ovid and other relevant websites. We selected and assessed the trials that met the inclusion criteria and conducted a network meta-analysis using the R software.

Results: A total of eighteen studies were included in the network meta-analysis among treatment of intervention group. Overall, 967 patients were reviewed and analyzed for primary and secondary patency rates at 6, 12 months and 24 months post-treatment. Compared with nondrug metal stent, drug-eluting stent group showed a significantly lower secondary patency rates (odds ratio 0.67 [95% credible interval, 0.46-0.92]) at 12 month. However, primary patency and assisted primary patency rates showed no differences among the intervention during observational period. In rank probability, Percutaneous transluminal angioplasty was second in secondary patency rates. However, there is not statistically significant difference in rankgram.

Conclusions: We anticipate that the data of this study will assist physicians in making informed decisions when selecting intervention, such as drug-eluting stent, as a treatment option for central vein stenosis in hemodialysis patients.

PO1110
Comparison of Mortality Risk Across Deciles of Cystatin C and Creatinine Among US Veterans
Cachet Wenziger,1 Elani Streja,1 John Sz,1 Ekaom Tantisattamo,2 Ranny M. Hanna,1 Michael Shlipak,1 Csaba P. Kovesty,1 Susan T. Crowley,1 Kamary Kalantar-Zadeh,1 Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; 2The University of Tennessee Health Science Center, Memphis, TN; 3University of California San Francisco, San Francisco, CA; 4VA Long Beach Healthcare System, Long Beach, CA; 5Memphis VA Medical Center, Memphis, TN.

Background: While both creatinine and Cystatin C (CysC) are markers of renal function, a low serum creatinine level can be related to less muscle mass and hence associated with worse outcomes. Prior studies among elderly persons found that higher serum CysC and creatinine levels were predictors of mortality. However, this relationship has not been examined in contemporary cohorts of US veterans. We sought to examine the relationship of creatinine and CysC with mortality risk in US veterans.

Methods: We examined a historical cohort consisting of 7,849 Veterans with baseline CysC and creatinine data between 10/01/2004-09/30/2015. Veterans were divided into deciles of serum creatinine and CysC levels separately. We examined the association of deciles with all-cause mortality using Cox proportional hazards regression adjusted for demographics, comorbidities, and other lab variables using decade 5 as the reference.

Results: The mean age in the cohort was 69±12, 4% were female, 77% were white, 15% were African American. The median (IQR [interquartile range]) for CysC was 1.28 (0.99,1.71) mg/L, for creatinine 1.24 (0.92,1.68) mg/dl. There were 1872/7849(24%) deaths during follow-up (follow-up time median(IQR): 794(461,1244) days). Patients with the highest decile of either CysC or creatinine had the highest mortality risk compared to the reference. Conversely, risk of mortality was incrementally lower for each decade below the reference for CysC while lower creatinine deciles were associated with a null to higher risk of death [figure].

Conclusions: Among US veterans, there is a linear relationship between CysC and mortality risk while the relationship between creatinine and mortality risk is U-shaped. These clinical results indicate that CysC may be a better marker of risk for adverse outcomes than creatinine, as previously shown in epidemiological studies.
PO1111 Comparative Mortality of ESKD from Nephrolithiasis or Urolithiasis in the United States
Jingvin Yan, Wolfgang C. Winkelmayer, Jingbo Niu. Baylor College of Medicine Margaret M and Albert B Alkek Department of Medicine, Houston, TX.

Background: Patient with nephro-/uroliathiasis (NL/UL), when compared with patients without kidney stone disease, experience higher rates of adverse health outcomes, including increased mortality, cardiovascular morbidity, and progressive kidney disease. Little is known about the epidemiology and outcomes of patients who reach end-stage kidney disease (ESKD) secondary to NL/UL.

Methods: From the USRDS, we identified all patients with incident ESKD who initiated dialysis, 1995-2016. From the Medical Evidence Report (CMS-2728), we ascertained the kidney disease causing ESKD as reported by the patient’s nephrologist. Categories included: NL/UL; diabetes; hypertension; glucomerulonephritis; polycystic kidney disease (PKD); other urologic; and other/unknown/missing. We also noted patients’ age, sex, race, Hispanic ethnicity, Medicaid coverage. Up to 11 comorbid conditions and health behaviors were also abstracted from form CMS-2728. Patients were followed from first dialysis to all-cause mortality, censoring at kidney transplant and end of database (12/2017). Cox proportional hazards regression models, stratified by year, estimated hazard ratios (HR) and corresponding 95% confidence intervals (CI).

Results: We studied 1,979,430 new ESKD patients, of whom 4190 (0.21%) patients had NL/UL as the reported cause of ESKD. Patients with NL/UL had similar age and sex distributions, but more were White (82% vs 66%) and fewer Black (11 vs 28%) or Hispanic (9 vs 13%) than among other causes of ESKD. All-cause mortality during median follow-up of 2.6 years was 173 per 1000 person-years among NL/UL patients. HR and 95% CIs comparing different causes of ESKD with NL/UL, at varying levels of model adjustment, are shown in Table.

Conclusions: Compared to patients whose ESKD was attributed to NL/UL, mortality was significantly higher among patients with DM, HTN, and other/unknown/missing cause of ESKD, but lower among patients with GN or PKD as cause of ESKD.

PO1112 Sleep Patterns and Mortality Risk in a Prospective Hemodialysis Cohort
Amy S. You,1 Sara S. Kalantar,1 Antoney J. Ferrey,1 Miklos Z. Molnar,2 Ronald A. Fischman,3 Michael A. Fischman,3 Avedik Semerjian,3 Yalitzi Guererro,1 Tracy Nakata,1 Csaba P. Kovessy,7 Danh V. Nguyen,4 Kamyar Kalantar-Zadeh,4 Connie Rhee.1 1University of California Irvine, Irvine, Irvine, CA; 2University of Tennessee Health Science Center, Memphis, TN; 3Southland Renal Associates, Long Beach, CA.

Background: While sleep disorders are common in hemodialysis (HD) patients, the association between sleep patterns and mortality. Patients underwent protocolized self-reported sleep questionnaires over 3/2014-6/2019. We examined associations of baseline sleep patterns with all-cause mortality using Cox regression adjusted for expanded case-mix covariates.

Results: In the overall cohort, the median (IQR) sleep duration was 6.0 (4.5, 8.0) hours on dialysis vs. non-dialysis days, respectively. In analyses examining the association of sleep duration with survival on dialysis days, patients with shorter sleep duration (defined as ≤median) had higher mortality (ref: longer sleep duration >median): adjusted HR (aHR) (95%CI) 1.59 (1.09, 2.31) (Fig 1A). Similar findings were observed for patients with shorter sleep duration (defined as ≤median) on non-dialysis days (ref: longer sleep duration >median): aHR (95%CI) 1.51 (1.04, 2.19). When surveying patients with regards to having difficulty sleeping at night, those who reported a high frequency (often to almost always) had higher death risk (ref: never/rarely to sometimes): aHR (95%CI) 1.74 (1.17, 2.58). Upon surveying patients with respect to use of sleeping pills, those who reported using (sometimes to frequent use) had higher mortality (ref: never/rare use): aHRs 2.07 (1.08, 3.97) and 2.00 (1.22, 3.28), respectively (Fig 1B).

Conclusions: In HD patients, shorter sleep duration, frequent sleeping difficulty, and moderate to frequent use of sleeping pills were associated with higher mortality risk. Future studies are needed to determine if interventions that improve sleep patterns increase survival in this population.

Funding: NIDDK Support

PO1113 Self-Reported Sleep Patterns in a Prospective Hemodialysis Cohort

Background: Growing evidence suggests that altered sleep patterns are prevalent in the general population, and are associated with worse health outcomes (obesity, hypertension, cardiovascular disease). However, there has been sparse examination of habitual sleep patterns in chronic kidney disease (CKD) patients, including those receiving dialysis. We thus examined self-reported sleep patterns in a well-defined prospective hemodialysis (HD) cohort.

Methods: Among 452 HD patients from the prospective Malnutrition, Diet, and Racial Disparities in Kidney Disease cohort recruited across 16 dialysis clinics, we administered protocolized sleep surveys during routine dialysis treatments over 10/2011-3/2015. Using self-reported questionnaires, patients were queried with respect to their habitual sleep patterns, including survey items related to 1) sleep duration, 2) sleep quality and disturbances, and 3) mental/emotional and physical symptoms potentially linked with sleep alterations.

Results: The mean±SD age of the study population was 55±14 years, among whom 54% were male, 28% were Black, 51% were Hispanic, and 55% had diabetes. In the overall cohort, the median (IQR) sleep duration was 6.0 (4.0, 8.0) and 7.0 (5.0, 8.0) hours on dialysis vs. non-dialysis days, respectively. Over two-thirds to three-quarters of the cohort reported sleeping during dialysis (76%), having difficulties sleeping at night (68%), and having insufficient sleep (72%); sleeping pill use was reported in 21% of patients. Half of the cohort reported stress/anxiety during dialysis, and 87% vs. 64% described feeling tired/exhausted on dialysis vs. non-dialysis days, respectively.

Conclusions: Our findings uncovered a high prevalence of altered sleep patterns in a well-defined prospective HD cohort. Further studies are needed to identify the modifiable and non-modifiable determinants of sleep alterations, as well as their downstream sequelae in dialysis patients.

Funding: NIDDK Support

PO1114 Self-Reported Sleep Apnea-Related Symptoms in a Prospective Hemodialysis Cohort

Background: Obstructive sleep apnea (OSA) is the most prevalent sleep-related breathing disorder in the general population. While growing data suggests that OSA is more common in hemodialysis (HD) patients, there remains under-diagnosis of this disorder in end-stage renal disease (ESRD) due to symptom overlap with uremia. We thus sought to examine clinical features associated with OSA in a well-defined prospective cohort of HD patients.

Methods: Among 452 HD patients from the prospective Malnutrition, Diet, and Racial Disparities in Kidney Disease cohort recruited across 16 outpatient dialysis clinics, we administered protocolized questionnaires querying clinical features of OSA over 10/2011-3/2015. Using self-reported surveys, information was collected regarding OSA-related symptoms including presence and frequency of snoring and apneic events.
Results: The mean±SD age of the study population was 55±14 years, among whom 54% were male, 28% were Black, 51% were Hispanic, and 55% had diabetes. In the overall cohort, 68% of patients reported snoring, among whom 62% reported having frequent (i.e., sometimes, frequent, or always) symptoms. Approximately 17% of patients reported apnea symptoms, among whom 24% reported having frequent events. While over two-thirds of the cohort reported an OSA-related symptom (e.g., snoring, apnea), only 18% were diagnosed with a sleep disorder and 3% had received treatment.

Conclusions: Our findings suggest that clinical features of OSA are common in HD patients, although only a fraction are diagnosed with this disorder and/or undergo treatment for symptoms. Further studies are needed to identify effective OSA screening tools specific to the ESRD population, as well as the impact of OSA interventions in this population.

Funding: NIDDK Support

High-Frequency Oscillations of Intradialytic Arterial Oxygen Saturation in Hemodialysis Patients

Xia Tao,1 Ohnnmar Thwin,1 Priscila Preciado,1 Matthew S. Cato,1 Stephan Thijssen,1 Peter Kotanko,1,2 1,2 Renal Research Institute, New York, NY; 1Icahn School of Medicine at Mount Sinai, New York, NY.

Background: High-frequency oscillation of arterial oxygen saturation (SaO2) presenting as repetitive “sawtooth” patterns was observed in sleep apnea patients, but it has never been reported during treatment in hemodialysis (HD) patients. In this study, we explored the prevalence of intradialytic “sawtooth” patterns and their clinical correlates in HD patients.

Methods: We prospectively studied chronic HD patients who didn’t use breathing devices, cardiac pacemaker, nasal oxygen, alpha blockers, short-acting nitrates, or have history of sickle cell anemia and non-sinus cardiac arrhythmia. During two visits per subject, we used the Crit-Line® Monitor to record SaO2 at a frequency of 1 Hz, and video recording to capture periods of wakefulness for the entire treatment. SaO2 data were analyzed for occurrence of “sawtooth” patterns (100% increase in standard deviation lasting ≥10s) and oxygen desaturation episodes (ODE, 3% drop from baseline lasting ≥10s).

Results: 16 subjects studied were 54±11 years old, 63% males, 69% African Americans. SaO2 was 94±2±2.1%. “Sawtooth” patterns covered 19.1% of the recorded treatment time, whereas ODE made up only 0.3%. 9 out of 11 subjects who displayed “sawtooth” patterns, showed them in both visits. “Sawtooth” patterns were more likely to occur during the time when subjects were not awake than during wakefulness (25.3% vs. 17.0% of time in each status). Although ODE were rarely seen, 70% were observed during times when “sawtooth” patterns were also present. Figure 1 shows typical SaO2 vs. time in each status. Although ODE were rarely seen, 70% were observed during times when “sawtooth” patterns were also present.

Conclusions: Sleep-related breathing disorders are both highly prevalent and underdiagnosed in HD patients and may be underlying the high-frequency oscillations of intradialytic arterial SaO2 observed in this study. These observations might be useful in identifying sleep-related respiratory abnormalities in HD patients that may warrant diagnostic workup. Further studies are needed to identify sleep-related SaO2 oscillations and their relationship to clinical outcomes.

CKD and Concomitant Sleep-Disordered Breathing Is Associated with Increased Overall Mortality: A Meta-Analysis

Hansrivijit Kanthaputherng,1 Panupong Hansrivijit,1,2 Nasrollah Ghamrarnan,1,2 Charat Thongprayoon,1 Wist Cheungsapitorn,1,3 Drexel University College of Medicine, Philadelphia, PA; 2UPMC Pinnacle, Harrisburg, PA; 3Penn State College of Medicine, Hershey, PA; 4Mayo Clinic Minnesota, Rochester, MN; 5University of Mississippi Medical Center, Jackson, MS.

Background: Sleep-disordered breathing (SDB) is common in advanced chronic kidney disease (CKD) patients. However, the association between CKD with concomitant SDB and overall mortality remains inconclusive. As it has been established that SDB and CKD individually contribute to overall mortality and that a large proportion of CKD patients have concomitant SDB, there comes a question if their morbid effects are compounded together.

Methods: Ovid MEDLINE, EMBASE, and the Cochrane Library were searched for eligible publications, including non-transplant CKD patients older than 18 years-old with co-existing SDB. CKD is defined in this study by estimated glomerular filtration rate of <60 mL/min/1.73m².

Results: Seven observational studies (n = 186,686) were included in the meta-analyses. 94.2% of patients had end-stage kidney disease (ESKD) requiring hemodialysis (HD), 5.0% had ESKD requiring peritoneal dialysis (PD), and 0.8% had non-dialysis CKD. The mean patient age was 76.8 ± 2.2 years. Most patients were male (53.4%) and caucasian (76.8%). Up to 39.3% of patients had diabetes. The mean body mass index was 28.0 ± 0.6 kg/m². Upon analysis, patients with advanced CKD and SDB demonstrated a pooled estimated odds ratios for overall mortality and cardiovascular events were 2.092 (95% CI, 1.594-2.744) and 1.020 (95% CI, 0.929-1.119), respectively compared to patients with CKD alone. No potential publication bias was detected. There were no significant differences in odds ratios for overall mortality, based on subgroup analyses.

Conclusions: Co-existence between advanced CKD and SDB is associated with significantly increased overall mortality, but not cardiovascular (CV) events when compared with CKD alone. The analysis of CV events requires additional studies to corroborate these findings. Moreover, these results suggest clinical interventions should be aimed to prevent the progression of SDB and CKD to mitigate the mortality associated in patients with both diseases.

A Randomized, Double-Blind, Phase 2a Study to Evaluate the Tolerability, Feasibility, and Efficacy of AKST1210 in Patients on Hemodialysis with ESRD and Cognitive Impairment

Jonas Hannestad, Anthony Kalife, Eva Czirr. Alkabest Inc, San Carlos, CA.

Background: Studies show that elevated levels of beta-2-microglobulin (b2M) negatively impact cognition. In patients on hemodialysis (HD) for end stage renal disease (ESRD), b2M levels are up to 60-fold higher than in those with normal kidney function; these patients also have a higher prevalence of cognitive impairment. AKST1210 is a device that removes b2M from plasma. To test if removal of b2M could improve cognition, we administered pooled human HD plasma with and without b2M to mice. Mice that received HD plasma with b2M showed a reduction in neurogenesis, neuronal activity, and synaptic markers, while few detrimental effects were seen in mice that received AKST1210 treated HD plasma, suggesting b2M removal is beneficial. Based on robust preclinical data, a clinical study was initiated to assess safety, tolerability, and feasibility of using AKST1210 during HD in subjects with ESRD and cognitive impairment (ESRD-CI).

Methods: In this study, subjects 40 years or older with ESRD-CI are randomly assigned to receive AKST1210 or control during HD sessions for 3 months. Approximately 26 subjects will be recruited and undergo a screening visit, run-in period, treatment visits, and end of study visit. Safety and tolerability will be assessed at every visit. Cognitive assessments will be administered periodically and b2M and proteomics samples collected at specific timepoints.

Results: Primary endpoints are the safety and tolerability of using AKST1210 in subjects with ESRD-CI undergoing HD. Safety is measured by the incidence of treatment-emergent adverse events and serious adverse events. Tolerability is measured by subject retention and compliance with visit completion. Secondary endpoints assess the change from baseline in cognitive assessments and the feasibility of conducting expanded
Selection of the Best Equation for Serum Osmolality Calculation in Hemodialysis Patients

Tsuyoshi Miyagi,1 Cachet Wenziger,1 Yoko Narasaki,1 Yoshikazu Miyasato,1 Hiroshi Kimura,1 Kunitoshi Iseki,1 Ekamol Tantisattamo,1 Connie Rhee,1 Elani Streja,1 Kamyar Kalantar-Zadeh,2 Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; 1Ryukyu Daigaku Igakubu Daigakun Igaku Kenkyuka, Naojagumi-gun, Japan.

Background: Although the serum osmolality (SOsm) is determined by circulating solutes including sodium, potassium, glucose and urea, calculated serum osmolality formula without potassium ([2(Na, in mmol/L) + (Glucose, in mg/dL) / 18] + [BUN in mg/dL] / 2.8) is commonly used. Several different equations have been previously described to estimate SOsm. Although in hemodialysis patients it is important to monitor homeostasis by means of estimating SOsm, few studies have examined the accuracy of these equations.

Methods: We identified 20 patients who transitioned to hemodialysis therapy and had repeated SOsm data along with, pre-dialysis sodium, potassium, glucose, and blood urea nitrogen (BUN) on the same day. We compared estimated SOsm by the 13 equations used in the previous literature and measured SOsm.

Results: The patients were 52% male, 33% non-white, and the mean age was 60 ± 17 (mean±SD) years. There were 65 measured SOsm and the mean (±SD) was 310.8 ± 12.0 mOsm/kg. The following provided the best fit between measured and calculated SOsm: 2[Na, in mmol/L] + 8K, in mmol/L] + 8Glucose, in mg/dL] / 18 + [BUN in mg/dL] / 2.8 (mean difference, -0.7 mOsm/Kg; 95% confidence interval, -2.12–0.71; P=0.32).

Conclusions: Our result suggests that the equation for estimating serum osmolality in hemodialysis patients should include serum potassium in addition to other components usually used to estimate serum osmolality in non-hemodialysis patient.

Effect of Dialysate Potassium on Interleukin 6 During Hemodialysis in Patients with ESRD

Monika Aggarwal (Gupta),1 George M. Feldman,1 Naveen Samuel,1 Dipankar Bandyopadhyay2, Reuben P. Retnani,3 Shobha Ghosh,1,2 Hunter Holmes McGuire VA Medical Center, Richmond, VA; 1Virginia Commonwealth University, Richmond, VA.

Background: Chronic inflammation is associated with poor outcomes in end stage renal disease (ESRD). Pro-inflammatory markers including interleukin-6 (IL-6) increase during hemodialysis. Efflux of intracellular potassium in cell cultures result in activation of inflammasome and release of inflammatory markers. We studied the effect of potassium efflux during hemodialysis on serum IL-6.

Methods: 15 patients with ESRD on chronic maintenance hemodialysis at Hunter Holmes McGuire VAMC were enrolled. Each subject participated in both interventions, separated by at least two weeks. Intervention A involved 2.92kcal/L for the 1st hour followed by 4k for the second hour. Intervention B involved 4k for the 1st hour followed by 2k for the second hour. After first two hours, dialysate potassium was switched to the pre-prescribed concentration for the remaining time Blood was drawn at 30, 60, 90, 120, 180, and 240 minutes after start of dialysis. Serum IL-6 was measured using ELSISA. Data were analyzed using Mixed linear model with p<0.05 considered significant.

Results: IL-6 was detectable at baseline and increased during dialysis. However, mean levels of IL-6 were parallel between the 2 interventions (Figure 1), implying no change in the rate of IL-6 production over time between the 2 interventions (Table 1).

Conclusions: IL-6 increases during hemodialysis but rate of increase is not affected by dialysate potassium.

Racial Differences in Physician Trust Among ESRD Patients in Upstate New York

Spencer Dahl, Basil S. Kazi, Fahad Saeed. University of Rochester Medical Center, Rochester, NY.

Background: Black patients have worse health outcomes in comparison to White patients, including 2.8 times higher incidence of End Stage Renal Disease, and a significantly higher age stratified risk of death on dialysis. Historically, low levels of physician trust in the healthcare system have been postulated as one of the mediators of healthcare disparities. Previous literature has suggested that black patients are less likely to trust their physicians, however there is a paucity of such data in the dialysis population.

Methods: We surveyed 223/380 (response rate 58%) of hospitalized patients receiving maintenance dialysis in Upstate New York, including 91 white and 82 black patients. We assessed physician trust using the Primary Care Assessment Survey (PCAS). This scale has been previously validated in adult and older adult populations.

Results: We found no difference in the level of trust between black and white patients (3.01 vs 2.95 respectively), assessed on the PCAS scale.

Conclusions: We found no difference in physician trust between black and white patients in our sample. Addressing healthcare disparities is a priority issue for maintenance dialysis patients. Future research to investigate issues related to access to the health care system, health literacy, and socioeconomic status may shed further light into health disparities.

Mobile Health (mHealth) Readiness Among Dialysis Patients

Nael F. Hussein,1 Paul N. Bennett,1 Sloane Pace,1 Shijie Chen,1 Veronica Legg,1 Sami J. Sun,1 Graham E. Abra,1 Brigitte Schiller,2 Satellite Healthcare, San Jose, CA; 1Stanford University School of Medicine, Palo Alto, CA.

Background: Mobile health (mHealth) is the healthcare use of mobile devices such as mobile phones. mHealth has demonstrated improvement in patient-reported outcome measures, resource efficiencies and cost savings. The aim of this study was to examine the status and correlates of mHealth readiness among individuals on dialysis.

Methods: Cross-sectional 30-item questionnaire, adapted from Bonner’s mHealth instrument guided by Khanum’s mHealth readiness model, was distributed to people on dialysis from 13 in-center hemodialysis (HD) facilities and 14 home dialysis centers. Proficiency was determined by reported use of applications of increasing level of complexity. We used regression analysis to investigate the relationship between demographic and social factors with proficiency.

Results: 949 patients (632 HD and 317 home dialysis) completed the survey (56% response rate), 38% were female. 73% of respondents reported using the internet: 90% of
them requiring no assistance. 81% of respondents owned smartphones or other internet-capable devices. 70% had intermediate or advanced mHealth proficiency. Main reasons for using mHealth were appointments (56%), communication with healthcare personnel (56%), laboratory results (55%) and obtaining kidney care information (50%).

Conclusions: The majority of dialysis patients surveyed were ready to use, and proficient in, mHealth. These results are encouraging for the nephrology community to increase endorsement of mHealth technologies in patient care.

Clinician Perspectives on Access to Kidney Replacement Therapy in Rural Communities
Nicole J. Scholes-Robertson, Talia M. Gutman, Allison Tong. Centre for Kidney Research, The University of Sydney School of Medicine, Sydney, NSW, Australia; Centre for Kidney Research, Westmead, NSW, Australia.

Background: Patients with chronic kidney disease (CKD) requiring kidney replacement therapy in rural communities are at higher risk of mortality compared with patients in urban areas, and encounter many barriers in accessing care. We aimed to describe clinicians’ perspectives of patient access to dialysis and kidney transplantation in rural communities.

Methods: We conducted 28 semi-structured interviews with clinicians (nephrologists, nurses, transplant coordinators and social workers) from Australia. Transcripts were thematically analyzed.

Results: We identified five major themes: the tyranny of distance (overwhelming burden of travel, minimizing relocation distress, scarcity of transportation options, concerns for patient safety), supporting navigation of health systems (reliance on local champions, negotiating variability of literacy, providing flexible pathways, frustrating presence of gatekeepers), disrupted care and lacking services (without continuity of care, scarcity of specialist services, fluctuating capacity for dialysis), pervasive financial burden, and complexity and rigidity of the health system. Increased use of telehealth, increased specialist outreach clinics in rural locations and improving flexibility of pathways were suggested to improve access.

Funding: Government Support - Non-U.S.

Estimation and Prediction of Prevalence of Patients Receiving Dialysis in China Based on Claims Data
Chao Yang, Jinwei Wang, Luxia Zhang, Ming Hui Zhao. China Kidney Disease Network (CK-NET) Work Group. Peking University First Hospital, Beijing, China; National Institute of Health Data Science at Peking University, Beijing, China.

Background: The national prevalence of end-stage kidney disease in China has not been well studied. We aimed to estimate the prevalence of patients receiving dialysis and predict the trend using claims data in order to provide evidence for developing prevention strategies.

Methods: Medical claims data from Jan 1, 2013 to Dec 31, 2017 were extracted from a large claims database, which used a two-stage sampling design to obtain a national sample of insured population. Patients receiving maintenance dialysis, including hemodialysis (HD) and peritoneal dialysis (PD), were identified according to medical billings and ICD-10 codes. The age-adjusted prevalence and number of dialysis patients were calculated stratified by age and gender. The Verhulst model was used to predict the short-term prevalence from 2018 to 2025.

Results: From 2013 to 2017, the age-adjusted prevalence of dialysis patients increased from 252.46 per million population (PMP) to 419.23 PMP. In 2017, the age-adjusted prevalence of HD and PD was 384.32 PMP and 34.91 PMP, respectively, and the total number of dialysis patients in China was estimated to be 581,055. The overall trend in the predicted prevalence of dialysis patients was increasing. The predicted prevalence was 533.61 PMP in 2020 and 623.49 PMP in 2025, and the corresponding number of patients was 743,304 and 865,704, respectively.

Conclusions: We have firstly made an attempt to assess the prevalence of dialysis patients in China and establish a national surveillance system based on claims data. It is urgent to formulate prevention and control strategies to reduce the escalating burden of kidney diseases.

Funding: Government Support - Non-U.S.

Low Socioeconomic Status Increases Risk of Mortality and Hospitalization in Korean Maintenance Hemodialysis Patients
Jung Woo Noh, Hayne C. Park, Young Eun Kwon, Do Hyoung Kim, Aijon Cho, Juhee Kim, Kyu Sang Yoon, Youngki Lee. Hallym University Kangnam Sacred Heart Hospital, Seoul, Republic of Korea; Myongji Hospital, Goyang, Gyeonggi-do, Republic of Korea.

Background: The number of hemodialysis (HD) patients and medical expenses are growing rapidly in Korea owing to aging society and accompanying diseases such as diabetes. Whether low socioeconomic status (SES) affects poorer HD outcome is controversial. Therefore, this study was performed to evaluate the effect of SES upon mortality and hospitalization in Korean maintenance HD patients.

Methods: We used HD quality assessment data from the year of 2013 and 2015 for collecting demographic and clinical data. The mortality data was collected until Dec 2017. We used insurance status as a proxy indicator of SES in which the subjects were classified into low SES (Medical Aid recipients) and high SES (National Health Insurance beneficiary). We analyzed mortality and hospitalization risk based on SES using Cox proportional hazard model.

Results: A total of 21,786 HD patients from 2013 survey and 35,454 HD patients from 2015 survey were included in the analysis. The ratio between high and low SES group was 76.7% versus 23.3%. The low SES group was younger and showed higher proportion of male, and lower proportion of diabetes, hypertension, and cerebrovascular accidents compared to the high SES group. The crude mortality rate was 93,100 person-year in 2013 and 106,100 person-year in 2015. After adjusting for age, gender, comorbidity and laboratory parameters, the low SES group showed significantly higher mortality risk compared to the high SES group (hazard ratio 1.151 [95% confidence interval (CI) 1.082-1.225], P = 0.0001 in 2013 survey and hazard ratio 1.073 [95% CI 1.009-1.14], P = 0.0254 in 2015 survey). The low SES group was also an independent risk factor for hospitalization after adjusting for age, gender, comorbidity and parameters (hazard ratio 1.129 [95% CI 1.09-1.17], P = 0.0001 in 2013 survey and hazard ratio 1.142 [95% CI 1.108-1.178], P < 0.0001 in 2015 survey).

Conclusions: Low SES independently increases risk of patient mortality and hospitalization in Korean maintenance HD patients.

PO1125
Iron Overload in ESRD Treated with Dofexomazine for Chelation
Sylvester Barnes. Loyola University Health System, Maywood, IL; Edward Hines Junior VA Hospital, Hines, IL.

Introduction: The patient is a 23-year-old female with a history of sickle cell disease, uncontrolled hypertension, and ESRD on HD 3x week for the past 4 years, requiring transfusions of blood from hemolysis. Due to the patient’s uncontrolled hypertension epoetin alfa was withheld for a few months. The patient presented to Loyola with severe symptomatic anemia, and concerns for iron overload.
Case Description: The patient presented to the hospital with severe anemia and decreased consciousness. Labs revealed a Hgb of 5.8g/dl, SBP of 177mmHg, and platelets of 40,000/ml. Hematology was consulted for further evaluation of anemia and thrombocytopenia. Her reticulocyte index was calculated at only 0.10, LDH 206, haptoglobin < 15, with peripheral smear showing no schistocytes or sicksles. Iron was 13mcg/dl, transferrin 100, ferritin 4284ng/ml, and iron saturation 98%. Bone marrow biopsy was obtained showing normal cellular marrow for her age and iron laden macrophages. Hgb electrophoresis showed Hgb S 3.3% indicating that most of the patient’s blood was transfused blood volume. Epoetin alfa was restarted and chelation therapy was recommended by hematology for iron overload. The patient was started on deferoxamine 50 mg/kg three times per week following hemodialysis. Most recent labs obtained show a ferritin level decreased to 2378ng/ml after receiving several doses of deferoxamine for over a month.

Discussion: This represents a unique case of iron overload from sickle cell disease along with ESRD leading to transfusion dependence. The treatment of iron overload was from the chelating agent deferoxamine. Initial repeat ferritin levels indicate favorable along with ESRD leading to transfusion dependence. The treatment of iron overload was used to confirm that AG was grafted to the PES successfully. Scanning electron microscopy(SEM) showed that the PES-AG membrane could decrease local thrombus formation SEM micrographs of PES and modified membranes.

PO1126
Role of Hemodialysis in Severe Ethanol Poisoning
Devin Driscoll,1 Griffin Bleecker,2 Alicen W. Zhen,1 Jean M. Francis,1 Aala Jaberi.1 1Boston Medical Center, Boston, MA; 2Boston University Medical Campus, Boston, MA.

Introduction: The treatment for acute ethanol intoxication remains largely supportive. About 1% of patients presenting with ethanol intoxication require the utilization of critical care resources. We present a case of a 19-year-old with altered mental status and a serum ethanol level above assay who required hemodialysis for rapid ethanol elimination and made a full recovery.

Case Description: A 19-year-old male with no past medical history presented with unresponsiveness after a night of heavy ethanol use. His serum ethanol level was above assay at >550mg/dL. Methanol and ethylene glycol levels were undetectable. He had normal kidney and liver blood tests, without metabolic acidosis. His osmolar gap was attributed purely to ethanol. Given a Glasgow Coma Scale of 3, he was intubated for airway protection. He then developed atrioventricular dissociation and required atropine, and hypotension requiring vasopressor support. A repeat serum ethanol level at 9 hours remained above assay at >550mg/dL and he remained unresponsive at 14 hours. Decision was made to initiate patient on hemodialysis. Two hours into his hemodialysis session, he became conscious and was successfully extubated at a serum ethanol level of 260mg/dL. His neurologic status returned to baseline and he was discharged from the hospital within 24 hours.

Discussion: The patient’s ethanol metabolism elimination rate without hemodialysis was calculated to be at 15mg/dL/hour. Using this elimination rate, his initial serum ethanol level was predicted to be about 63mg/dL. Without hemodialysis, it would take roughly 41 hours for complete elimination. While on dialysis, the patient’s rate of elimination increased by a factor of four from 15mg/dL/hr to 60mg/dL/hr. Complications of prolonged intubation include cataract and neurologic toxicity from severe ethanol poisoning in this young patient include life-threatening arrhythmias, and possible permanent neurologic damage which was avoided using hemodialysis to expedite ethanol elimination. This case demonstrates the role and benefit of hemodialysis for a critically ill patient who is experiencing organ toxicity and exposes a need for updated recommendations in this specific set of patients.

PO1127
A Polyethersulfone Membrane with a Direct Thrombin Inhibitor to Decrease Local Thrombus Formation
Shuangshuang Fu, Yunmei Liang. Nephrology Department of Hunan Provincial People’s Hospital (The First-affiliated Hospital of Hunan Normal University), Changsha, China.

Background: Extracorporeal circulation, such as hemodialysis, is required systemic anticoagulation to avoid thrombus formation. However, conventional anticoagulation methods may induce hemorrhage complications, especially those patients who have bleeding diseases. As dialysis patients are the main site of thrombosis. Anticoagulant modification of the dialysis membrane may decrease local clotting of the dialyzer membrane, and doesn’t increase the bleeding risk of dialysis patients.

Methods: We chose argatroban(AG), a direct thrombin inhibitor, to modify a polyethersulfone(PES) membrane. Fourier transform infrared spectroscopy(FTIR) was used to confirm that AG was grafted to the PES successfully. Scanning electron microscopy(SEM) was used to observe the characteristic morphology of the membranes. Activated partial thromboplastin time, prothrombin time, and thrombin time were determined to evaluate the antithrombotic property of the modified membrane.

Results: FTIR indicated that argatroban modified PES membranes(PES-AG) were successfully prepared. Compared with the PES membrane, the clotting time value of the PES-AG membrane was significantly prolonged, and the difference was statistically significant, which initially indicated that the PES-AG membrane had a better antithrombosis effect. SEM showed that the PES-AG membrane could decrease local thrombus formation.

Conclusion: Preparation of the argatroban modified PES membrane is feasible, and the anticoagulant performance is superior to the unmodified PES membrane.

PO1128
Filter Operation Mode Affects the In Vivo Performance of a Synthetic Plasma Fractionation Membrane
Detlef H. Krieter,1 Nicolas L. Kiefert,1 Marieke Rueh,2 Horst-Dieter Lemke,2 Christoph Wanner.1 1University Hospital Würzburg, Div. of Nephrology, Würzburg, Germany; 2ExcorLab GmbH, Obernburg, Germany.

Background: The mode a dialyzer or fractionator is operated may affect the fouling processes of the filter membrane and, hence, may determine its capacity and performance. Purpose of the present study was to assess such effects in vivo. To avoid the often varying treatment conditions in humans, a large animal model was used.

Methods: In a prospective, randomized, controlled, crossover trial, four sheep were subjected to double filtration plasmapheresis with a polyethersulfone plasma fractionation membrane intended for lipid apheresis (FractioPES® 200; 3M, Germany). Five different operation modes were tested in each animal: Low (30 mL/min), medium (36 mL/min) and high (42 mL/min) plasma flow rates as well as high flow rate at increased plasma temperature (38.5 °C; thermofiltration) and reversed plasma filtration flow direction (outside-in). The totally treated plasma volume was 1500 mL. Reduction ratios (RR) and sieving coefficients (Sv) at 300, 600, 900 and 1200 mL of treated plasma were determined for LDL cholesterol (2.500-3.000 kDa), HDL cholesterol (175-360 kDa), fibrinogen (305-385 kDa), immunoglobulin IgG (150 kDa) and albumin (67 kDa).

Results: Compared to the other modes (medium flow rate, 0.05±0.02 to, high flow rate, 0.08±0.01), Sv for LDL were significantly higher (P<0.001) in outside-in at 300 mL (0.21±0.03), Sv for LDL were also significantly higher (P<0.001) in both outside-in (0.19±0.07) and at high flow (0.17±0.02) conditions at 600 mL. For IgG at 900 mL, Sv for fibrinogen determined in outside-in (0.37±0.12) was superior to the low and high plasma flow modes (0.08±0.08 and 0.13±0.01, resp.). Several significant differences in Sv were identified at different plasma volumes within the same operation mode. No significant differences in RR were determined between operation modes.

Conclusions: Compared to the other operation modes, outside-in filtration and, less pronounced, also high plasma flow rates increase the permeability of a synthetic fractionation membrane for larger proteins. The differences in Sv did not translate into different reduction ratios.

Online High-Volume Hemofiltration Reduces Pre-Dialysis Levels of Indoxyl Sulfate Compared with High-Flux Hemodialysis: Results from the HDFit Multicentric Randomized Controlled Trial

Jordan D. de Lima,1 Murilo H. Guedes,2 Silvia D. Rodrigues,1 Ana Clara S. Almeida,2 Ana Beatriz L. Barra,2 Maria Eugenia F. Canziani,1 Americo L. Cuvello neto,3 Carlos E. Poli de Figueiredo,2 Roberto Peccois-Filho,2 Lia S. Nakao.1 1Universidade Federal do Parana, Curitiba, Brazil; 2Pontificia Universidade Catolica do Parana, Curitiba, Brazil; 3Fresenius Medical Care, Rio de Janeiro, Brazil; 4Universidade Federal de Sao Paulo, Universidade Federal de Sao Paulo, Sao Paulo, Brazil; 5Hospital Alemão Oswaldo Cruz, São Paulo, Brazil; 6Pontificia Universidade Catolica do Rio Grande do Sul, Porto Alegre, Brazil.

Background: Although HDF improves the clearance and pre-dialysis concentration of middle size molecules, little is known about its effect on concentration of protein-bound uremic toxins (PBUT) particularly in comparison to HD. Here, we investigated whether HDF impacts pre-dialysis plasma levels of the PBUTs indoxyl sulfate (IXs), p-cresyl sulfate (pCS) and indole-3-acetic acid (IAA) compared to HD.

Methods: This is post-hoc analysis of the multicentric randomized controlled trial studying the impact of HDF versus hf-HD on measured physical activity (HDFitclinicalTrials.gov: NCT02787161), which included clinically stable HD patients with a vintage >3 to <24 months. Total plasma levels of IXs, pCS and IAA were determined by high performance liquid chromatography with fluorescence detection at baseline, 3 and 6 months. Mean difference in pre-dialysis PBUTs between HDF and hf-HD during the 6 months was estimated by linear mixed effect models.

Results: One hundred ninety-three patients (mean age 53 years old, 70% males and 60% white) were analyzed. There were no differences between HD and HDF groups regarding clinical and biochemical characteristics at the baseline. In the HDF group, 99% of patients achieved a convective volume higher than 22 L. The mean differences (95% CI) in concentrations over time for PBUTs among HDF and HD groups are shown in the Figure.

Conclusions: In this post-hoc analysis of the HDFit trial, high-volume HDF consistently reduced pre-dialysis concentration of IXs compared to hf-HD. These results demonstrate the sustained effect of mixed-diffuse convective methods in the removal of PBUTs compared to predominantly diffuse techniques.

Figure - Mean differences between groups in the change from baseline along with 95% confidence intervals (CI). Results shown IXs favored by HDF compared to HD.

Use of Cytokine Adsorbing Membranes in Patients with Acute Renal Failure in Intensive Care Units

Eva Jakopic, Martin Hren, Tina Strupnik Galufl, Masa Knehtl, Tadej Zorman, Nina Vodosek Hojs, Robert EKart, Radovan Hojs, Sebatian Beve. Univerzitetni Klinicien Center Maribor, Maribor, Slovenia.

Background: Use of cytokine adsorbents has been proposed as a novel therapeutic approach in sepsis management. Our aim was to evaluate laboratory markers, clinical parameters and SOFA (Sequential Organ Failure Assessment) score in patients who were treated with cytokine adsorbing membrane (CytoSorb®, CytoSorbents Corp. New Jersey, USA) and compare it to conventional haemodialysis.

Methods: We included adult patients with septic shock and acute renal failure. We retrospectively collected laboratory results (leukocytes, thrombocytes, C-reactive protein, procalcitonin, lactate, urea, creatinine, bilirubin, PaO2/FiO2), clinical parameters (mean arterial pressure (MAP), FiO2, residual diuresis), SOFA score and vasopressor use at the beginning and at the end of the procedure.

Results: We included 69 patients, 51 men, aged 56.6 ± 15 years. 51 patients had 1 procedure, 14 patients had 2 procedures, 3 patients had 3 procedures and 1 patient had 4 procedures. Median time from admission to initiation of procedure was 47 hours, median treatment time was 23.6 hours. We discovered significant improvement in procalcitonin (35.36 ± 37.33 ng/mL vs. 24.25 ± 31.8 ng/mL; p=0.001), creatinine (345.06 ± 174.65 μmol/L vs. 233.11 ± 108.82 μmol/L; p<0.0001), SOFA score (14.20 ± 2.64 vs. 12.69 ± 3.52; p<0.001) and FiO2 (48.17 ± 21.7 % vs. 44.63 ± 21.45 %; p=0.020). Patients with more than 1 procedure showed statistically significant reduction in lactate levels (5.40 ± 4.74 mmol/L vs. 2.46 ± 1.74 mmol/L; p=0.010) and vasopressein dose (1.26 ± 1.1 vs. 0.88 ± 3.2 L/H; p=0.022).

Conclusions: We observed potential beneficial effect of adsorptive membrane use in septic patients. According to our results two or more procedures were associated with improved laboratory markers and lower vasopressor requirement.

PO1132

Clinical Safety of a New Hemodialyzer with the Surface Modifying Molecule Enexos™

Jill M. Meyer,1 Dylan Steer,2 Lisa A. Weber,3 Mayuri Thakuraria,4 Chiang-Hong Ho,5,6 Claus Mullon,7 Robert J. Kossmann,8 9California Institute of Renal Research, Chula Vista, CA; 9California Institute of Renal Research, San Diego, CA; 10Research Management Inc./Kansas Nephropathy Research, Wichita, KS; 11Fresenius Medical Care, North America, Waltham, MA.

Background: The new Optiflux Enexos™ dialyzer (OED) contains a fluorourethane surface modifying macromolecule (Enexos™) blended in the membrane during manufacturing. Performance and safety of the dialyzer were assessed in a multi-center, open-label study (NCT# 03536663). This sub-analysis reports additional safety results for OED.

Methods: Subjects enrolled in the study underwent 12 HD treatments on the Optiflux® F160NR followed by 38 HD treatments (visits 13-50) with the OED. Safety was assessed by evaluating: 1) hematology tests and serum chemistry measured pre and post HD at the first use of OED and then measured pre HD for subsequent visits at approximately 2 weeks intervals; 2) Complement activation and serum albumin measured pre and post HD at the first use of OED; and 3) Adverse events recorded during the study. 1171 subjects were included in the study of which 18 subjects (safety population [SPOP]) had at least one HD treatment with the OED for a total of 664 OED treatments. SPOP median age was 63.5 years, female (77.78%) and white (66.67%). Table 1 reports SPOP (n=18) mean (SD) for chemistry and hematology. An increase in mean serum albumin level from 3.94 to 4.23 g/dL was observed, but no overt complement activation was noticed. Thirty-two AEs (4.8%) and 3 SAEs were reported, none were device related. No deaths or AEs leading to study discontinuation occurred.

Conclusions: The novel Optiflux Enexos™ dialyzer was well tolerated in a clinical study including 664 HD treatments in ESRD patients.

PO1133

Changes in Sensitivity Patterns of Gram-Negative Isolates in Bacteraemic Haemodialysis Patients

Fatima Malik, Anna Nielson, Jonathan W. Hurst, Moira Stanley, David Makamjula. Epsom and Saint Heiler University Hospitals NHS Trust, Carshalton, United Kingdom.

Background: Gram-negative bacteremia (GNBs) in haemodialysis (HD) patients are associated with significant morbidity and mortality. While there is a paucity of data around the quantitative impact of drug resistant organisms, it is clear that they result in increased mortality, longer length of illness and higher costs of delivering appropriate treatment. We aimed to determine the sensitivity patterns of GNBs in our HD center.

Methods: Data were collected from clinical records, electronic records, and the microbiology database of all bacteraemias in HD patients between 2007 and 2018. Results: 283 episodes of GNB occurred in 1361 patients over the 12-year period. Excluding Coli and Klebsiella Pneumonie were the dominant pathogens, accounting for 40.6% and 15.9% of bacteremia isolated respectively. Sensitivity pattern analysis reveals that Meropenem was almost universally effective against gram negative isolates, with little change over the study period. Similarly, Gentamicin had sensitivity rates of >80% each year except 2010 (50%). Co-Amoxiclav had a variable sensitivity profile and with little change over the study period. Similarly, Gentamicin had sensitivity rates of >80% each year except 2010 (50%). Co-Amoxiclav had a variable sensitivity profile and with little change over the study period.

Conclusions: Judicious antimicrobial use is a World Health Organisation objective in the fight against antimicrobial resistance. Our local HD policy includes Vancomycin and Gentamicin as empiric therapy. The emergence of Vancomycin-resistant enterococci and more recently staphylococci will influence our future use of Vancomycin. In our patient group, Gentamicin therapy remains effective. Carbenapen resistant organisms are a global health threat so whilst Meropenem is efficacious, it should be reserved for more severe infections or treatments. Resistance is increasing at a rate far greater than production of novel antimicrobials so antimicrobial stewardship is paramount; particularly in HD populations with high rates of infection, morbidity and antibiotic exposure.
Hemodialysis and Frequent Dialysis - 2

dysfunction to the development of premature biological aging and its related morbidities independent of chronological age. Our findings suggest a potential contribution of Nrf2 to antioxidative responses, declines with age and is implicated in the pathogenesis of biological aging, characterized by disproportionately high morbidity and mortality at a younger age. Nuclear factor erythroid 2-related factor 2 (Nrf2) activity, a master regulator of antioxidative responses, declines with age and is implicated in the pathogenesis of age-related disorders; however, little is known about the association between Nrf2 and premature biological aging in ESRD patients.

Methods: In a cross-sectional pilot cohort of 34 ESRD patients receiving maintenance hemodialysis, we measured the expression of Nrf2 and cyclin-dependent kinase inhibitor 2A (CDKN2A, or p16INK4a, a biomarker of biological aging) genes in whole blood and compared them with chronological age, using Spearman’s rank correlation and multivariable linear regression models with adjustment for chronological age, gender, race, and diabetes status.

Results: The mean (SD) age was 62.6 (9.8) years old; 52.9% of patients were male; 70.6% were African American; and 70.6% were diabetic. There was a significant negative correlation between Nrf2 and CDKN2A expression (rho=-0.51, P=0.002; Figure). While no significant correlation was found between Nrf2 expression and chronological age (rho=-0.02, P=0.91), after multivariable adjustment, Nrf2 expression remained significantly and negatively associated with CDKN2A expression (beta coefficient=-0.0151, P=0.01).

Conclusions: Lower Nrf2 expression levels were significantly and negatively associated with higher CDKN2A expression levels in whole blood of patients with ESRD, independent of chronological age. Our findings suggest a potential contribution of Nrf2 dysfunction to the development of premature biological aging and its related morbidities in ESRD patients.

POII134

Association Between Nrf2 and CDKN2A Expression in Patients with ESRD: A Pilot Study

Keichi Sumida, Zhongji Han, Ankur A. Dashputre, Praveen Kumar Potukuchi, Chi-Yang Chiu, Csaba P. Kovészdy, The University of Tennessee Health Science Center, Memphis, TN.

Background: Patients with ESRD display phenotypic features of premature biological aging, characterized by disproportionately high morbidity and mortality at a younger age. Nuclear factor erythroid 2-related factor 2 (Nrf2) activity, a master regulator of antioxidative responses, declines with age and is implicated in the pathogenesis of age-related disorders; however, little is known about the association between Nrf2 and premature biological aging in ESRD patients.

Methods: In a cross-sectional pilot cohort of 34 ESRD patients receiving maintenance hemodialysis, we measured the expression of Nrf2 and cyclin-dependent kinase inhibitor 2A (CDKN2A, or p16INK4a, a biomarker of biological aging) genes in whole blood and examined the association of Nrf2 with CDKN2A expression and with chronological age, using Spearman’s rank correlation and multivariable linear regression models with adjustment for chronological age, gender, race, and diabetes status.

Results: The mean (SD) age was 62.6 (9.8) years old; 52.9% of patients were male; 70.6% were African American; and 70.6% were diabetic. There was a significant negative correlation between Nrf2 and CDKN2A expression (rho=-0.51, P=0.002; Figure). While no significant correlation was found between Nrf2 expression and chronological age (rho=-0.02, P=0.91), after multivariable adjustment, Nrf2 expression remained significantly and negatively associated with CDKN2A expression (beta coefficient=-0.0151, P=0.01).

Conclusions: Lower Nrf2 expression levels were significantly and negatively associated with higher CDKN2A expression levels in whole blood of patients with ESRD, independent of chronological age. Our findings suggest a potential contribution of Nrf2 dysfunction to the development of premature biological aging and its related morbidities in ESRD patients.

POII135

Do Dialysis Facilities Improve Quality After Receiving a Penalty Under the ESRD Quality Incentive Program

Jeffrey Marr, Andrew Breek, Shannon Griffin, Tracy Yee, Dominick Esposito, Jeffrey Pearson, Delia Houseal, Adebola O. Adeleye, Insight Policy Research Inc, Arlington, VA, "Research Collaborative for Health, Ann Arbor, MI; Centers for Medicare and Medicaid Services, Baltimore, MD.

Background: We examined whether quality measures improve at dialysis facilities penalized under the Centers for Medicare and Medicaid (CMS) End-Stage Renal Disease Quality Incentive Program (ESRD QIP) after receipt of a penalty.

Methods: Using data from CMS public use files from payment years (PY) 2014-2017, Medicare claims, and CROWNWeb, we used a difference-in-differences analysis to compare patient level measures of dialysis quality at facilities that did and did not receive penalties before and after the performance period. We also used a regression discontinuity design to compare patient quality measures two years after the performance period at facilities just above and just below ESRD QIP’s performance score penalty threshold.

Results: Patients at penalized facilities had improved dialysis adequacy after the performance periods associated with PY2014-2017 and improved vascular access after the performance period associated with PY2014, compared to patients at nonpenalized facilities. Changes in vascular access after the PY2015 – PY2017 performance periods were not statistically significant. In the 5 years after the performance period associated with PY2014, the percent of patient-months with a fistula in use and the percent of patient-months meeting adult HD Kt/V standard (HD Kt/V ≥1.2) increased by 2.2 percentage points (95% CI 0.9 to 3.4) and 2.9 percentage points (95% CI 1.4 to 4.4), respectively, while the percent of patient-months with a catheter in use decreased by 2.6 percentage points (95% CI -3.7 to -1.5) at penalized facilities compared to nonpenalized facilities. Compared to those at nonpenalized facilities with relatively similar quality scores, patients at penalized facilities had lower catheter use two years after the PY2014 performance period and higher fistula use two years after the PY2016 performance period. However, these estimates are sensitive to specification changes. Other estimates were not statistically significant.

Conclusions: Receiving an ESRD QIP penalty is associated with subsequent improvements in some measures of dialysis quality, though results differ across payment years and analytic method.

Predicting Dialysis Facilities at Risk of Low ICH-CAHPS Quality of Center Scores

Karen Lofty, Yue Jiao, Stephen Weber, John W. Larkin, Len A. Usyvay, Angela McClure, Jeffrey L. Hymes, Franklin W. Maddux, Fresenius Medical Care, Global Medical Office, Waltham, MA; Fresenius Medical Care North America, Waltham, MA; Fresenius Medical Care AG & Co. KGaA, Global Medical Office, Bad Homburg, Germany.

Background: Medicare administers biannual ICH-CAHPS surveys to capture patients’ perceived experience of outpatient hemodialysis (HD) care. Recent operations efforts at a national dialysis provider aimed to develop prediction models to identify HD facilities at risk of low ICH-CAHPS rating in the subsequent survey period.

Methods: We used retrospective data from HD facilities at a national dialysis provider during 2018-2019. Two models were built to predict HD facilities that continued to have (Model 1) or decreased below (Model 2) a +60% top box ICH-CAHPS rating on the dialysis center staff, care, and operations domain in the spring 2019 survey period. Facility variables in 2018 included were: fall and spring ICH-CAHPS ratings; provider during 2018-2019. Two models were built to predict HD facilities that continued to have (Model 1) or decreased below (Model 2) a +60% top box ICH-CAHPS rating.

Results: We found the highest performance using GLM and GAM methods for both Models (Figure 1). The assessment of performance via the area under curve (AUC) showed use of GLM modeling correctly predicted true/false positives in 73% of facilities. The assessment of performance via the area under curve (AUC) showed use of GLM modeling correctly predicted true/false positives in 73% of facilities. The assessment of performance via the area under curve (AUC) showed use of GLM modeling correctly predicted true/false positives in 73% of facilities.

Conclusions: The developed prediction models may be used as a tool in identifying HD facilities at risk of low patient ICH-CAHPS ratings. Prospective use in quality improvement efforts appears warranted.

Variability and Trends over Time and Across Centers in Hemodialysis Weekly Duration in Australia and New Zealand

Isabelle Ethier,1 Yeoung Jee Cho,2 Christopher E. Davies,4,6 Carmel Hawley,1,2 Scott B. Campbell,1,2 Nicole Isobel,1 Elaine Pascoe,2,7 Kean Polkinghorne,8 Matthew A. Roberts,2,10 Emily J. See,2,5 David Semple,1,11,12 Carolyn L. Van Eps,2 Andrea K. Viecelli,2,3 David W. Johnson,2,3 Centre Hospitalier de L’Universite de Montreal, Montreal, QC, Canada; 2Princess Alexandra Hospital, Woolloongabba, QLD, Australia; 3The University of Queensland, Saint Lucia, QLD, Australia; 4The University of Melbourne Faculty of Medicine Dentistry and Health Sciences, Melbourne, VIC, Australia; 5Austin Health, Heidelberg, VIC, Australia; 6Monash Medical Centre Clayton, Clayton, VIC, Australia; 7Monash University Department of Medicine, Clayton, VIC, Australia; 8Australia and New Zealand Dialysis and Transplant Registry, Adelaide, SA, Australia; 9Adelaide Medical School, The University of Adelaide Medical School Research Institute, Adelaide, SA, Australia; 10Monash University School of Public Health and Preventive Medicine, Melbourne, VIC, Australia; 11Department of Renal Medicine, Auckland District Health Board, Auckland, New Zealand; 12School of Medicine, University of Auckland, Auckland, New Zealand.

Background: Hemodialysis treatment prescription varies widely around the world. This study explored patient- and center-level characteristics associated with weekly haemodialysis durations.

Methods: Australia and New Zealand Dialysis and Transplant (ANZDATA) Registry data was analyzed. Characteristics associated with weekly duration were evaluated using mixed-effects linear regression models with patient- and center-level covariates as fixed effects, and dialysis center and state as random effects using the 2017 prevalent in-centre hemodialysis (ICHD) and home hemodialysis (HHD) cohorts. Evaluation of patterns of weekly duration over time analyzed the 2000 to 2017 incident ICHD and HHD cohorts.

Results: Overall, 12,494 ICHD and 1,493 HHD prevalent patients in 2017 were included. Median weekly treatment duration was 13.5 (interquartile range (IQR) 12-15) hours for ICHD and 16 (IQR 15-20) hours for HHD. Male sex, younger age, higher body mass index, arteriovenous fistula/graft use, Aboriginal and Torres Strait Islander ethnicity and longer dialysis vintage were associated with longer weekly duration for both ICHD and HHD. No center characteristics were associated with weekly duration. Variability in duration across centers was very limited in ICHD compared to HHD, with variation in HHD being associated with state. Duration did not vary significantly over time for ICHD, whereas longer weekly HHD treatments were reported between 2006 and 2012 compared to before and after this period.

Conclusions: This study in the Australian and New Zealand hemodialysis population showed that weekly treatment duration was primarily associated with patient characteristics. No center effect was demonstrated. Practice patterns seemed to differ across states/countries, with more variability in HHD than in ICHD.

PO1138

Clinical Outcomes Among Dual-Eligible Medicare and Medicaid Dialysis Patients in the United States

Robert Neg,1 Jenna M. Norton,1 Christina M. Yuan,1 Lawrence Agodoa,2 Kevin C. Abbott,3 Walter Reed National Military Medical Center, Bethesda, MD; 4National Institutes of Health Office of the Director, Bethesda, MD; 5National Institute of Diabetes and Digestive and Kidney Diseases Division of Kidney Urologic and Hematologic Diseases, Bethesda, MD.

Background: Dual Medicare-Medicaid eligible beneficiaries generally live in poverty and account for approximately 28% of the US end-stage kidney disease (ESKD) population, but their clinical outcomes are largely unknown. We compared individual- and dialysis-facility level clinical quality measures and survival between dual-eligible and Medicare-only incident dialysis patients.

Methods: In this retrospective cohort study using the United States Renal Data System, we identified 52,863 patients who had Medicare as the primary payer, initiated on dialysis from January 1, 2016 through December 31, 2016, and followed until June 1, 2018. We incorporated data from the Consolidated Renal Operations in a Network (CROWNWeb) and the Centers for Medicare & Medicaid Services (CMS) Dialysis Facility Compare files. We excluded those who were <18 years, transplanted or died within 90 days of dialysis initiation. We conducted multivariable Cox regression with death as the outcome, adjusted for demographic and clinical factors.

Results: The Medicare-primary cohort consisted of 19,819 (37.5%) dual eligible and 33,044 (62.5%) Medicare-only beneficiaries, with median follow-up of 1.8 years. Dual eligibles were more likely to be female, Black, Hispanic and younger than their Medicare-only counterparts (59 ± 15 vs. 66 ± 14 years, p<0.001). At 12 months after dialysis initiation, individual-level quality measures such as hemodialysis treatment time, K/TV, hemoglobin, albumin, calcium, and phosphorus were similar between the 2 groups. However, a slightly greater proportion of dual eligibles were dialyzed via catheter at 12 months compared with Medicare-only patients (47.2% vs. 43.0%, p<0.001). At a facility level, mortality rates, hospitalization rates, standardized infection ratios for bloodstream infection, and total performance scores were similar between the 2 groups. Adjusted analyses demonstrated higher risk of death in dual eligibles compared to Medicare-only patients (hazard ratio 1.29 (95% CI 1.23-1.34, p<0.001).

Conclusions: The Medicare-Medicaid dual eligibility status, as an indicator of poverty, was independently associated with higher mortality, despite similar individual- and facility-level performance measures. Further studies to delineate factors associated with death in this large segment of the ESKD population are needed.

PO1139

The Implementation of a Clinical Pharmacist in a Hemodialysis Center

Chantalle Daful,1 Henry Ford Health System, Detroit, MI.

Background: Hemodialysis (HD) patients have complicated disease states placing them at a higher risk for drug related problems (DRPs), medication discrepancies, and non-adherence. The objective of the study is to evaluate the impact of a clinical pharmacist in a HD center by assessing the efficacy of medication reconciliation (MR) in HD patients and evaluating the potential impact on the health system.

Methods: This is a retrospective study conducted in Greenfield Health Systems, a division of Henry Ford Health System that operates 14 dialysis centers throughout southeast Michigan. West Pavilion outpatient dialysis clinic, one of the centers in Detroit, Michigan consisting of an interprofessional team. Patients included in the study had at minimum four visits from the clinical pharmacist or pharmacy interns from August 2017 to October 2018. Study aim was to evaluate the impact of a clinical pharmacist in a HD center by assessing the efficacy of MR in HD patients and evaluating the potential impact on the health system. Descriptive statistics were used to collect DRPs and classified based on the modified Hepler-Strand approach.

Results: A total of 1403 DRPs with an average of 8.94 DRPs per patient were found with an average number of 7 visits per patient. Adherence was the most common DRP (31%). The most common drug class the pharmacist made interventions on was for medications used to treat blood pressure (37%) followed by vitamin D analogs/ calcimimetics (29%). A projected total of $447,355 was saved.
Conclusions: Pharmacist in HD clinics has a positive influence on HD patients through medication management and cost savings.

PO1140
Dietary Potassium Intake and All-Cause Mortality in Adults Undergoing Hemodialysis: The DIET-HD Cohort Study
Amelie Berrier-Jean,1 Germaine Wong,2 Valeria M. Saglimbene,3 Marta Monastero,1 Svetlana Palmar, Vanesa Garcia-Larsen,4 Patrizia Natale,5 David W. Johnson,6 Marcello Tonelli,7 Jorgen H. Hugbjaern,8 Jonathan C. Craig,9 Armando Teixeira-Pinto,10 Giovanni F. Pignoni,11 School of Public Health, Faculty of Medicine and Health, The University of Sydney, Sydney, NSW, Australia; 2Centre for Kidney Research, The Children’s Hospital at Westmead, Westmead, NSW, Australia; 3Diaverum Renal Services Group, Sweden; 4Department of Medicine, University of Otago, Dunedin, New Zealand; 5Program in Human Nutrition, Department of International Health, The Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; 6Department of Emergency and Organ Transplantation, University of Bari, Italy, Bari, Italy; 7Department of Nephrology, Princess Alexandra Hospital, Brisbane, Australia; 8Cantonal Hospital Baselland, Switzerland; 9Department of Medicine, University of Otago, Dunedin, New Zealand; 10Department of Nutrition, University of Bari, Italy; 11College of Medicine and Public Health, Flinders University, Adelaide, Australia.

Background: Dietary modification to reduce the risk of hyperkalemia in people undergoing maintenance hemodialysis is standard practice and is commonly recommended in guidelines despite a lack of evidence. A low potassium diet may impair quality of life and nutritional status. We aimed to assess the association between dietary potassium intake and all-cause mortality and whether hyperkalemia mediates this association.

Methods: 9690 adults undergoing maintenance hemodialysis in Europe and South America were recruited in the DIET-HD study, of which 1647 were excluded for lack of data-linkage identifier or incomplete or implausible dietary assessment. We measured baseline potassium intake from the GALEN food frequency questionnaire and performed time-to-event and mediation analyses.

Results: The median dietary potassium intake at baseline was 3.5 g/day (IQR 2.5 to 5.0). During a median follow-up of 3.97 years (25,890 person-years), we observed 2921 (36%) deaths including 1316 (45%) from cardiovascular causes. After adjusting for baseline characteristics including presence of cardiac disease and food groups, dietary potassium intake was not associated with higher serum potassium (B=0.04 mEq/L 95% CI 0.002 to 0.002 and 1.00, 95% CI 0.999 to 1.002, respectively). Higher potassium intake was not associated with all-cause mortality (hazard ratio [HR] 1.00 95% CI 0.999 to 1.002). The PD-efficacy relationship was better described by a linear model. Conclusions: Higher dietary intake of potassium is not associated with hyperkalemia or death in patients treated with maintenance hemodialysis.

Funding: Government Support - Non-U.S.

CACV: Coronary artery calcification score by volume

PO1142
Pharmacokinetics, Pharmacodynamics (PK-PD), and Exposure-Efficacy Evaluation from CaLIPSO, a Phase 2B Study to Assess the Effect of SNF472 on Progression of Cardiovascular Calcification in Patients on Hemodialysis
Joan Pereló,1 Joan J. Alberti,2 Juan Vicente Torres Martin,3 Maria del mar Perez,4 Miquel D. Ferrer,5 Firas Bassissi,6 Carolina Salcedo.7 Sanifit Therapeutics, Palma, Spain; 2Université de les Illes Balears, Palma, Spain; 3Admetra Consulting, Palma, Spain; 4Syntax for Science SL, Palma, Spain.

Background: Cardiovascular calcification (CVC) is a major contributor to increased morbidity and mortality in end stage kidney disease (ESKD) patients on dialysis. SNF472, a selective calcification inhibitor that interferes with the aggregation and growth of ectopic hydroxyapatite (HAP), has showed a significant reduction in CVC progression in CaLIPSO, a randomized, double-blind, placebo-controlled phase 2b trial. The drug is also currently in Phase 3 trial for the treatment of calciphylaxis. Our aim was to perform PK-PD and exposure-response analyses from the CaLIPSO trial.

Methods: PK and PD were assessed at weeks 1, 10, 22 and 52, following intravenous administration thrice weekly over 52 weeks. Efficacy was assessed as % change in coronary artery calcification score by volume (CACV) over 52 weeks. The relationship between PK (Cmax) and PD (ex-vivo inhibition of HAP crystalization in plasma), PK-efficiency and PD-efficiency was evaluated using linear and Emax models.

Results: The analyses included data from 56 patients. Cmax values and PD responses per group were similar over the 52 weeks of treatment, indicating no accumulation of SNF472. Mean plasma Cmax mean PD effect and % change in CACs over 52 weeks per group are shown in the table. An Emax model described well the relationship between PK-PD (E_{max}=8.8%, E_{50}=75.9%, E_{EC50}=7.5 μM); and PK-efficiency (E_{max}=16.9%, E_{50}=14.5%, E_{EC50}=12.2 μM). The PD-efficacy relationship was better described by a linear model.

Conclusions: SNF472’s PK showed no accumulation and PD remained constant over 52 weeks of treatment. E_{max} models showed a robust relationship between SNF472’s Cmax and both the ex-vivo inhibition of HAP crystalization and clinical efficacy measured by % change in CACV over 52 weeks. Higher SNF472 exposure and inhibition of HAP crystalization correlated with a reduction in CVC progression in ESKD patients on dialysis.

PO1143
Associations of Dialysis Facility Clinical Performance with Patient Outcomes in the Medicare ESRD Quality Incentive Program (QIP)
Yan Jin,1 Dongyu Wang,1 Alissa Kapke,2 Delia Houseal,3 Marc Turetta,4 1Arbor Research Collaborative for Health, Ann Arbor, MI; 2Centers for Medicare and Medicaid Services, Baltimore, MD.

Background: In CY2017, CMS implemented the Meaningful Measures Initiative, which aimed to reduce data reporting burden and costs for health care providers and to focus improvement efforts on the most meaningful outcomes for patients. To assure the ESRD QIP is aligned with this initiative and is achieving CMS goals, we assessed whether facility clinical measure performance is associated with improved patient outcomes.

Methods: Patient outcomes at the facility level were evaluated using the CY17 standardized mortality ratio (SMR) and standardized hospitalization ratio (SHR) from Dialysis Facility Compare, and the ESRD QIP CY17 In-Center Hemodialysis Consumer Assessment of Healthcare Providers and Systems (ICH-CAPHS) scores. Facility-level performance in CY17 on ESRD QIP measures for hypercalcemia, fistula, long-term catheter, comprehensive K/V, NIH strokebloodstream infection (BSI) standardized infection ratio (SIR), and standardized transfusion ratio (STIR) was assessed using tetratic. Associations between facility measure performance and outcomes were tested using Poisson models for SMR and SHR and Analysis of Variance (ANOVA) models for ICH-CAPHS scores.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

384
Results: For all ESRD QIP clinical measures, lower levels of performance were associated with higher relative risks (RR) for SMR and SHR (p<0.05; Table). For all clinical measures except STIR and NHSN BSIR, lower levels of performance were also associated with lower ICH-CAHPS QIP scores (p<0.05; Table).

Conclusions: The observed associations of facility performance on individual ESRD QIP clinical measures with mortality, hospitalization, and patient experience with care indicate that the program is incentivizing improvements in care that are related to important patient outcomes.

Types of Incidents (Patient Safety) Managed at Two Different Medical Levels in a Large Multinational Renal Services Provider Network

Background: Patient safety programs need a well-structured organization to facilitate proactive and fair reporting, prompt evaluation analysis and timely feedback followed by measure implementation and auditing. Objectives To analyze all types of incidents in our network during 2019 by two different levels (Corporate and Country) of medical management alert.

Methods: Our institution has tracked all incidents under a structured process program regarding medications and venous needle dislodgment risk assessment. Despite continuous efforts to get better results, there is room for improvement on better staff compliance with our standard operating procedures especially regarding medications and venous needle dislodgment risk assessment.

Results: 92,923 incidents (2.7 incident/patient/year) were reported during 2019. Total incidents/1000 treatments were 17.2 (12.2 were patients related incidents). Causes for alerts at Corporate level (n=81) were cardiopulmonary resuscitation (26%); unexpected death (19%); nonconversion (9%); wrong medication/dosage (9%); hemolysis (7%); severe hypotension (5%) and different mix codes (25%). Reported incidents at country level (n=831) were more than half ascribed to equipment [water supply, power failure and hypotension (5%); seroconversion (9%); wrong disposable/dialyzer (9%); hemolysis (7%); severe anemia. Primary outcomes will be major cardiovascular events. The current analysis was assessing if Roxadustat improves prognosis in at least 250 dialysis patients with renal anemia.

Conclusions: Tracking of incidents has potential to increase quality of care and patients outcomes. Despite continuous efforts to get better results, there is room for improvement on better staff compliance with our standard operating procedures especially regarding medications and venous needle dislodgment risk assessment.

PO1145

Roxadustat in Treating Anemia in Dialysis Patients (ROAD): Short-Term Impact on Serum Triglyceride

Daqing Hong,1 Hen Xue,2 Yanrong Cai,3 Jingdong He,3 Qiang He,4 Guisen Li.1 1Department of Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People’s Hospital, Chengdu, China; 2Department of Nephrology, Ya’an People’s Hospital, Chengdu, China; 3Department of Nephrology, Gao Xin Boli Hospital, Chengdu, China; 4The Second Affiliated Hospital of Chengdu Medical College, Chengdu, China.

Background: Roxadustat has been shown effective in lowering serum cholesterol in treating patients with anemia due to chronic kidney disease. However, its effect on serum triglyceride (TG), especially in dialysis patients that have high prevalence of hypertriglyceridemia remains unknown. This analysis is to provide clinical data of Roxadustat on iron markers in a real-world prospective observational cohort.

Methods: This is a multicenter, prospective, longitudinal observational cohort study assessing if Roxadustat improves triglyceridemia in at least 250 dialysis patients with renal anemia. Primary outcomes will be major cardiovascular events. The current analysis was done in the enrolled 144 patients to compare the changes of iron markers from baseline to last follow up. The serum ferritin at baseline and at the last follow up was 639.1±530.18 pg/ml and 473.52±520.34 pg/ml respectively (p=0.001). TSAT remained stable from baseline to last follow up (36.8±20.5% vs. 36.7±22.7%, p=0.93). In patients with ferritin greater than 245 pg/ml, changes of ferritin were 245 pg/ml (95%CI: 117.6 to 373.46, p=0.001) and 362 pg/ml (95%CI: 99.34 to 580.30, p=0.008). In patients with low responsiveness to ESA, according to ESA dosage (greater than 300U/Kg/Week), 199.41pg/ml, 95%CI: 37.69 to 361.12, p=0.019 or by investigators’ judgement (143.83pg/ml, 95%CI:55.99 to 231.67 pg/ml, p=0.002), the results were similar and significant. TSAT did not change significantly among the whole cohort and in the subgroup analysis.

Conclusions: Roxadustat could increase hemoglobin in dialysis patients in ROAD cohort. It could decrease serum ferritin in dialysis patients, regardless of the high ferritin or responsiveness of ESA treatment and maintains stable TSAT. These might indicate that Roxadustat partially increase hemoglobin by alter iron status even in patients have low responsiveness to ESA treatment.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Relationship Between Fluid Overload (FO) and Hemoglobin Concentration (Hgb) in Hemodialysis (HD) Patients (Pts)

Lemuel Rivera Fuentes,1 Mohamad I. Hakim,1 Ulrich Moissl,2 Ariella E. Mermelstein,2 Jochen G. Raimann,1 Laura Rosales,1 Dewangi A. Kothari,1 Fansan Zhu,1 Stephan Thijsse,1 Peter Kotanko.1 1Renal Research Institute, New York, NY; 2Fresenius Medical Care AG und Co KGaA, Bad Homburg, Germany.

Background: FO is common in HD pts and the BCM (Fresenius Medical Care, Germany) allows the assessment of fluid volumes and FO. We studied the association between FO and Hgb concentration in a cross-sectional study in four urban US dialysis clinics and tested the effects of inflammation and erythropoiesis-stimulating agents (ESA).

Methods: We conducted BCM measurements in participating HD pts, and obtained Hgb, neutrophil-to-lymphocyte ratio (NLR) and ESA usage from the EMR. The association between FO (stratified into tertiles) and Hgb and NLR, resp., was tested using ANOVA and that between FO and ESA usage using Chi-Square Test. We further employed linear regression, stratified by ESA usage (yes/no), to test associations of FO with Hgb and NLR.

Results: We studied 170 pts (40% female, 52.9% black, 28.2% Hispanic, 61.3±14.4 years, FO 2.2±2.4 L, Hgb 10.9±1.3 g/dL, NLR 3.5±1.9). Greater FO associated with higher NLR (Figure 1a) and lower Hgb (Figure 1b) and also with ESA use (P<0.001). Hgb was inversely correlated with NLR (Beta -0.22, P<0.01), whereas its inverse relationship with NLR remained significant in both subgroups.

Conclusions: FO and inflammation inversely associates to Hgb and deserves consideration in anemia management. BIA can help the clinician assess whether FO may be contributing to low Hgb values. As such, it is a valuable diagnostic tool that should find its way into routine care for US HD pts.

PO1148

Automated Early Detection of Hyponatremia in Hemodialysis Patients Derived from Online Conductivity Measurement

Andreas Maierhofer,1 Joachim Harlos,2 Bernard J. Canaud.1 1Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; 2MVZ Dialysezentrum Schweinfurt, Schweinfurt, Germany.

Background: Hyponatremia in dialysis patients is a strong indicator of poor outcome that requires early detection to facilitate clinical workup and management. However, plasma sodium concentration as determined by lab methods (Na-Lab) is measured at the best monthly in clinical practice. Recently, online monitoring of predialytic plasma Na (pPlNa) as estimated from dialysate conductivity using an electrolyte model has become available at every hemodialysis session, thus providing an unprecedented close and almost continuous monitoring of this crucial indicator. This could be used as diagnostic tool to earlier alert the physician of underlying clinical illnesses.

Methods: In a monocentric retrospective clinical study in 114 patients on maintenance hemodialysis (>90% online postdilution HDF) for whom online pPlNa was available for a period of at least 12 months at least once a week, kinetics of pPlNa were analyzed. For 11 patients with hyponatremic episodes as manifested in pPlNa, the agreement between time course of pPlNa and Na-Lab and the correlation to the manifestation of clinical findings was explored.

Results: Time course of pPlNa and Na-Lab showed very good agreement. In addition, in each case the onset of hyponatremia was linked to a subacute illness development (i.e., sepsis, congestive heart failure, …) underrunpinned by various degrees of fluid overload. Correction of the underlying pathology and fluid overload by dry weight adjustment permitted to improve clinical outcome.

Conclusions: The clinical examples show that due to the good agreement of the time course of pPlNa and Na-Lab, pPlNa can be used as adjuvant diagnostic tool for the early detection of onset and progression of morbid events. This online tool will support physicians in decision making for improving dialysis patient management and likely outcome. Further studies are deserved to confirm the clinical value of this tool.

POI149
Prevalence of Fluid Overload in a US Dialysis Population
Ulrich Moisil,1,2 Lemuel Rivera Fuentes,1 Mohamad I. Hakim,1 Laura Rosales,1 Fansan Zhu,1 Dewangi A. Kothari,1 Jochen G. Raimann,1 Stephan Thijsse,1 Peter Kotanko.1,3 Renal Research Institute, New York, NY; 2Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany.

Background: Hypervolemia remains one of the main reasons for increased cardiovascular (CV) morbidity and mortality in chronic hemodialysis (HD) patients. Quantification of fluid status using bioimpedance spectroscopy (BIS) has become routine in many countries outside the United States (US). Due to previous unavailability of FDA-cleared BIS devices, no cross-sectional appraisal of fluid status in HD patients has yet been done in the US. The aim of this study was to perform the first assessment of fluid status in a US dialysis population using a BIS device.

Methods: Fluid overload (FO) was measured in 170 chronic HD patients from four clinics in New York City using the BCM Body Composition Monitor (Fresenius Medical Care) which provides the amount of excess extracellular water (ECW) in liters. Measurements were performed before dialysis, post-dialysis fluid status was estimated by subtracting the removed fluid from pre-dialysis FO.

Results: Pre- and post-dialysis FO were found to be 2.2L ± 2.4 L and -0.2 ± 2.7 L (mean ± SD), respectively. Before the start of HD, 42.9% of patients were fluid overloaded (criterion: FO/ECW > 15% in males, and >13% in females), 53.5% were normally hydrated, and 3.5% were fluid depleted (FO/ECW <7%).

Conclusions: The prevalence of pre-HD fluid overload was significantly higher in this US population (42.9%) than in a previously published large European cohort (29.6%). This suggests the need for more adequate assessment of fluid status to support the clinicians in identifying and treating fluid overload in HD patients.

POI1150
The Use of Loop Diuretics in Newly Initiated Hemodialysis Patients: The Clinician’s Perspective
Tripta Kaur, Steven G. Coca, Girish N. Nadkarni, Lili Chan. Icahn School of Medicine at Mount Sinai, New York, NY.

Background: ESRD patients newly initiated on HD have varying levels of residual renal function (RRF). The loss of RRF is associated with increased cardiovascular and all-cause mortality and decreased quality of life (QOL). There are no studies reported to date that have explored in detail the physicians’ clinical opinion and approach to the use of diuretics after the initiation of HD.

Methods: A one-time anonymous electronic survey was created to explore the clinicians’ opinion and practice pattern of diuretic use in new-start HD patients. 50 nephrologists associated with the Mount Sinai Health System were included.

Results: 23 (46%) completed the survey and 8 (35%) have practiced nephrology for > 15-years. 16 (70%) assess RRF monthly. The level of urine output per day (UOP/d) considered adequate for diuretic use was 200-250 mL by 7 (30%) and 400-500 mL by 12 (52%). While 20 (87%) and 18 (78%) of the physicians felt that diuretics are effective in HD patients and improve quality of life (QOL), respectively, only 5 (22%) always continue diuretics and 13 (57%) sometimes start diuretics after initiation of HD (Fig 1). Physicians with >15 years in practice were more likely to continue diuretics than physicians with less experience (50% vs. 7%, P=0.03). Volume status (70%) and the ineffectiveness of diuretics (64%) were considered more important factors in the decision to use diuretics. Only 5 (26%) routinely use furosemide > 240 mg/day, but only 10 (43%) were influenced by ototoxicity.

Conclusions: While a majority of physicians believe that diuretics are effective and improve patient QOL, few consistently continued diuretics and only half started diuretics “sometimes”. The factors that were considered more important in decisions to continue or start diuretics were volume status and the opinion that diuretics can be ineffective in HD patients.
PO1152

Novel Ultrafiltration Rate Feedback Controller for Attainment of Relative Blood Volume Targets During Hemodialysis

Lemuel Rivera Fuentes,1 Mirell Tapia,2 Sabrina Rogg,3 Stephan Thijsse,1 Peter Kotanko,1,2 Renal Research Institute, New York, NY; 3Renal Research Institute, New York, NY; 4Pennsylvania Medical Care Deutschland GmbH, Bad Homburg, Germany; 5Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Preciado et al. have identified half-hourly relative blood volume (RBV) targets during a hemodialysis (HD) session that are associated with significantly improved patient survival. Attainment of these RBV targets would require incessant empirical adjustments to the ultrafiltration rate (UFR) by the dialysis nurse. We developed a novel proportional-integral controller that takes RBV data from the commercially available CLiC® device as an input and provides UFR suggestions to guide the RBV curve into the desired targets. The clinician specifies the desired UF goal with the maximum allowed upward/downward deviation from this goal, and the UFR Feedback Controller then optimizes the RBV trajectory within the limits of the prescription. The present study aimed to characterize the behavior of this feedback controller.

Methods: We conducted a single-arm, prospective, intervention pilot study in patients on chronic HD at 3 dialysis centers in NYC. RBV was measured with the CLiC® device. CLiC® and HD machine data were fed into a research laptop running the UFR Feedback Controller software. The UFR recommendations (generated every 10 min) were evaluated by dialysis nurses who then either implemented or disregarded them as they deemed clinically appropriate.

Results: 15 subjects (58.9 ± 15.3 years, 53% black, weight gain 2.6 ± 0.8 L, HD time 22.2 ± 28 min) were studied (63 study visits, 4.2 ± 1.9 visits/subject). Of 300 analyzed RBV target points, 63% had RBVs within the desired target range, 33% of the RBVs were above and 4% were below target. Stratified by timepoint, the on-target percentage increased from 37% at 30 min to 73% at 3 h into HD. The rate of intradialytic morbidity events did not appear to be increased. In subjects with at least 4 complete study visits (N=8), on average 71.8% of subjects were within the desired RBV target range at 3 h into HD.

Conclusions: The UFR Feedback Controller behaved as expected, steering the patients’ RBV curves toward the predefined target ranges while strictly observing the prescribed UF goal. Preciado et al. had reported a third of patients within the favorable RBV target range at 3 h into conventional HD. In contrast, with the use of this novel UFR Feedback Controller, approx. 72% of subjects were within the desired RBV target range at 3 h.

PO1153

A Novel Algorithm to Identify Presumably Fluid Overloaded Hemodialysis Patients

Priscila Preciado,1 Hanjie Zhang,1 Peter Kotanko,1,2 Renal Research Institute, New York, NY; 3Mount Sinai Health System, New York, NY.

Background: Adequate volume control is a major challenge in hemodialysis (HD) patients. Relative blood volume (RBV) monitoring evidence suggests that flat RBV curves are associated with significantly better survival. Our goal was to develop an algorithm that would require a much shorter observation period with clinically meaningful sensitivity and specificity to identify (presumably FO) patients with flat RBV profiles (RBV >92% at 3 hours). We categorized patients as either positive (mean RBV >92% at 3 hours) or negative. We computed sensitivities and specificities relative to the positive and negative cases for 1-15 HD sessions and various rates of treatments with flat RBV curves.

Results: Sensitivities, specificities, and Youden’s indices (=sensitivity + specificity – 1) for 1-15 treatments and across the different rates of positive RBV curves are shown. We found a sensitivity of 92%, specificity of 80%, and Youden’s index of 73% when >50% of 10 preceding treatments were positive.

Conclusions: Our algorithm requires only a small number of RBV readings to identify presumably fluid overloaded patients with a clinically acceptable sensitivity and specificity. It would be of interest to compare the performance of this algorithm with volume status as determined by bioimpedance; however, bioimpedance has not yet been approved for use in HD patients in the U.S.

PO1154

Peak Oxygen Capacity in Patients on Dialysis: The Role of Fluid Overload

Vanessa O. Gomes,1 Marília P. Viana, Lizbeth C. Benavides, Marcelo P. Menezes Filho, Jose Mariano S. Pantoja, Luana R. Soares, Jukelson B. Silva, Valkercyo A. Feitosa, Rosa M. Moyses, Rosilene M. Elias. Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.

Background: Exercise capacity is predictive of cardiovascular disease and mortality in patients with chronic kidney disease on dialysis. Fluid overload, a common feature in these patients, may play a role in this pathophysiology.

Methods: The Duke Activity Status Index (DASI) questionnaire was administered to 27 patients on peritoneal dialysis (PD) and 82 patients on hemodialysis (HD). Results were expressed as peak oxygen uptake (VO2peak, mL/kg/min). Electrical bioimpedance was applied to assess body composition. Fluid overload was assessed as the ratio of extracellular water/total body water (ECW/TBW).

Results: The patients on HD and PD have no difference in age (44 ± 15 vs. 49 ± 18 years, p=0.224) and body mass index (25.0 ± 4.9 vs. 26.3 ± 4.9 kg/m², p=0.245), with similar gender distribution (p=0.870), prevalence of diabetes (p=0.404) and smoking habit (p=0.223). VO2peak was lower among patients on PD than HD (21.4 ± 7.5 vs. 25.3 ± 7.6 ml/kg/min, respectively, p=0.023). VO2peak correlated with ECW/TBW (r=−0.436, p=0.0001) and age (r=−0.483, p=0.001) in both groups and within each group. VO2peak correlated with interdialytic weight gain in patients on HD (r=−0.236, p=0.031).

Conclusions: Patients on dialysis present reduced exercise capacity, which is even more pronounced for patients on PD. Volume overload seems to be involved in this pathophysiology.

PO1155

Simplifying the 28-Zone Lung Ultrasound Protocol

Monodou L. Sankó,1 Ivan Kuznetsov,2 Thomas C. Arnold, Cameron Baston, Nathaniel C. Resinger,2 Penn Medicine, Philadelphia, PA.

Background: Lung ultrasound (LUS) using a 28-zone quantitative B-line score (BLS) is a reliable marker of fluid overload (FO) among patients with end-stage kidney disease (ESKD) on hemodialysis (HD), outperforming physical exam and correlating well with cardiovascular outcomes. A trial comparing BLS-guided dry weight probing to usual care showed improved blood pressure and echocardiographic parameters. However, 28-zone BLS study is criticized as impractical for clinical practice. Using a machine learning algorithm we determined whether accurate assessment of FO can be determined using just 4, 6, and 8 scanning zones.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Methods: We analyzed an existing dataset of 28-zone BLS scores obtained from 106 patients on hemodialysis (HD) who were cared at our center at various times. Using linear correlation and discriminant analysis, we fit models that allowed us to approximate the 28-zone BLS based on 4, 6, or 8 zone protocols. We next applied linear discriminant analysis to study whether we could predict FO severity (low: BLS <15, moderate: BLS 15-20, high: BLS >20) based on FO zone 1-8. Finally, we tested whether we could achieve better diagnostic performance with subsets of scan zones that had not previously been reported. Final outcome measures were reported as correlation coefficients and Cohen’s kappa.

Results: We found that the BLS of the 4, 6, and 8 zone scans correlated strongly and linearly with the BLS of the full 28 zone scan with Pearson correlations of 0.95, 0.92, and 0.92, respectively. In determining FO severity based on the limited scanning zones, the model produced resultant Cohen’s Kappa values of 0.74, 0.76, and 0.71 for the 4, 6, and 8 zone protocols, respectively. We identified an underscore 4-zone scan that gave a slight increase in Kappa of 0.82. We found that equal linear weighting of all zones gave the best accuracy.

Conclusions: We found that 4, 6, and 8 zone BLS scores perform similarly to the 28-zone BLS. We identified a subset of 4 zones that gave better accuracy than existing 4, 6, or 8-zone scans. These findings support that a limited number of scanning zones can be used to reliably determine FO. Further work is needed on a larger dataset to validate these findings and to explore the physiological mechanism to support the novel 4-zone scan.

POI1156
Incidence and Outcomes of Gram-Negative Bacteraemias in Haemodialysis Patients: 12-Year Single-Centre Experience
Fatima Malik, Anna Naito, Lisa Bradwell, Christopher M. Cregg, David Makanjula. Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom.

Background: Patients on haemodialysis (HD) are at increased risk of contracting infections. Gram-negative bacteraemia in HD patients is associated with early mortality. In our HD population, we looked at the incidence and clinical outcomes of gram-negative bacteraemias over 12 years.

Methods: Data were collected from clinical records and the hospital's microbiology database of all confirmed bacteraemias in HD patients between 2007 and 2018.

Results: 283 episodes of gram-negative bacteraemia occurred in 1361 patients over the study period (166 (58.7%) were male. The median age was 71 years (range 26-95). The proportion of gram-negative bacteraemias fell significantly between 2007 and 2010 and has plateaued since then. 90 (31.8%) had arteriovenous fistulae (AVF) or grafts, the remainder had dialysis lines, of which 41 (21.2%) had dual access (AVF or graft + line), with AVF/graft not yet in use. The bacteraemias were deemed to be access related in 89 events (31.4%). Of these, 73 (82.0%) were related to dialysis lines, 16 (18.0%) were related to AVF/graft. 190 (67.1%) were from other sources including urinary tract 18.4% (n=22), hepatobiliary 7.8% (n=22), chest 7.8% (n=22), gastrointestinal 6.0% (n=17) and skin/soft tissue in 4.9% (n=14). There was no information on 4 patients (1.5%). Complications of the bacteraemias included: discitis (6, 2.1%); osteomyelitis (5, 1.8%); endocarditis (2, 0.7%); septic arthritis (2, 0.7%); and death (34, 12.0%).

Conclusions: The incidence of gram-negative bacteraemias in our cohort appears to have plateaued, with bacteraemias originating from other sources such as the urinary tract and intra-abdominal accounting for a greater proportion of gram-negative bacteraemias in our cohort - a trend reflected in other similar observational studies in HD populations. Dialysis lines remain a significant risk factor for bacteraemia, lending further weight to the imperative not just in dialysis centres, but also in the community.

POI1157
New Polymeric Dialysis Membrane with Endexo™ Surface Modifying Macromolecule
Chih-Hu He, Colleen M. Fisher, Claudy Mullon. Fresenius Medical Care North America Ogden, Ogden, UT.

Background: Surface-modifying macromolecules (SMM) may improve the hemocompatibility of hemodialysis membranes. We report center for a total of 2800 scored LUS clips. Using linear correlation and discriminant analysis, we fit models that allowed us to approximate the 28-zone BLS based on 4, 6, or 8 zone protocols. We next applied linear discriminant analysis to study whether we could predict FO severity (low: BLS <15, moderate: BLS 15-20, high: BLS >20) based on FO zone 1-8. Finally, we tested whether we could achieve better diagnostic performance with subsets of scan zones that had not previously been reported. Final outcome measures were reported as correlation coefficients and Cohen’s kappa.

Results: We found that the BLS of the 4, 6, and 8-zone scan correlated strongly and linearly with the BLS of the full 28-zone scan with Pearson correlations of 0.95, 0.92, and 0.92, respectively. In determining FO severity based on the limited scanning zones, the model produced resultant Cohen’s Kappa values of 0.74, 0.76, and 0.71 for the 4, 6, and 8 zone protocols, respectively. We identified an underscore 4-zone scan that gave a slight increase in Kappa of 0.82. We found that equal linear weighting of all zones gave the best accuracy.

Conclusions: We found that 4, 6, and 8 zone BLS scores perform similarly to the 28-zone BLS. We identified a subset of 4 zones that gave better accuracy than existing 4, 6, or 8-zone scans. These findings support that a limited number of scanning zones can be used to reliably determine FO. Further work is needed on a larger dataset to validate these findings and to explore the physiological mechanism to support the novel 4-zone scan.

Procalcitonin Is a Biomarker for Inflammation in Outpatient Hemodialysis Patients
Sanjay P Neupane,1 Alana B. Barofsky,2,3 John R. Lee,4 Jeffrey I. Silberzweig,2,5
1New York Presbyterian, Weill Cornell Medical Center, New York, NY, 2The Rogosin Institute, New York, NY; 3Division of Nephrology and Hypertension, Weill Cornell Medicine, New York, NY; 4Department of Transplantation Medicine, New York Presbyterian/ Weill Cornell Medical Center, New York, NY; 5Hackensack Meridian School of Medicine, Natley, NJ.

Background: Procalcitonin is a widely used test to distinguish bacterial infections from viral infections, but its level is influenced by kidney function. The normal range of procalcitonin levels in end-stage renal disease (ESRD) patients on hemodialysis (HD) is not well established. In this study, we evaluated the relationship between Procalcitonin and inflammatory markers and outcomes in ESRD patients on HD.

Methods: We recruited 71 ESRD outpatients on HD from October 1st 2019 to December 15th 2019 and measured their procalcitonin levels prior to dialysis. We evaluated whether procalcitonin levels were associated with clinical characteristics, laboratory parameters, and future hospitalizations and infections.

Results: In this cohort, the median procalcitonin level was 0.38 ng/mL with an interquartile range of 0.23 ng/mL and 0.54 ng/mL. The distribution of procalcitonin values are found in Fig. 1A. African Americans had a significantly higher procalcitonin level than non-African Americans (P= 0.02, Wilcoxon rank sum test). ESRD outpatients with the hypertension, diabetes mellitus, or HIV did not have significantly higher procalcitonin levels than those who did not (P > 0.05). Procalcitonin levels were positively correlated with CRP (r= 0.57, P =0.001) (Fig. 1B) and negatively correlated with albumin (r= -0.28, P =0.02) (Fig. 1C). Procalcitonin levels were not correlated with Kt/V, white blood cell count, and ferritin levels (P>0.05). ESRD outpatients who developed infections or who were hospitalized did not have significantly higher initial procalcitonin levels than those who did not (P > 0.05).

Conclusions: Procalcitonin levels are correlated with inflammatory markers such as CRP and albumin, suggesting its potential use to identify ESRD on HD at high risk for complications, especially in the era of COVID-19.

Funding: Private Foundation Support
accumulates with loss of renal function and is associated with increased mortality. Initially described as a lactation hormone, today it is known that prolactin (PRL) has several actions, from pro-inflammatory effects to accelerated atherosclerosis. The aim of our study was to correlate serum levels of inflammatory cytokines in hemodialysis (HD) patients with normal and elevated PRL levels. With active viral or bacterial infections, active cancer, inadequate KtV, use of medication or disease known to elevate PRL (hypothyroidism, chronic liver disease, macroadenoma), pregnant women and using immunosuppressants were excluded. Clinical, biochemicals and inflammatory cytokines [interleukin (IL)-2, -4, -6, -10, -17A, TNF-α and gamma interferon] were evaluated and compared between HD patients with elevated and normal PRL levels.

Results: Of the 360 regular HD patients, 249 were excluded: 110 temporary access, 87 active infection (viral or bacterial), 23 on drugs, 12 on immunosuppression, 5 cirrhosis, 4 inadequate KtV, 4 cancer, 3 less than 6 months on HD, 1 macroadenoma. Comparing data between patients with high (median) and normal (50th) PRL, no statistical difference was seen in terms of age, sex, BMI, etiology, time on HD, cholesterol, albumin, calcium, phosphorus, PTH, glycated hemoglobin, IL-2, IL-4, IL-17A, TNF-α, gamma interferon. There was a positive PRL correlation with serum levels of IL-6 (r=0.001, r<0.04); between PRL and IL-10, the correlation was negative and also statistically significant (p=0.046, R=-0.2).

Conclusions: HD patients with elevated PRL have been shown to have higher levels of IL-6 and lower levels of IL-10.

Accumulation in Hemodialysis Patients of Solutes Secreted by the Native Kidneys

Seolhyun Lee,1,2 Christian G. Bolanos,1,2 Robert Maier,1,2 Natalie Plummer,1,2 Timothy W. Meyer,1,2 Tammy L. Sirich,1,2 Stanford Medicine, Stanford, CA; 1US Department of Veterans Affairs, Palo Alto, CA.

Background: The native kidneys rapidly clear numerous solutes by tubular secretion, a function not replicated by hemodialysis (HD). We examined which solutes are cleared by secretion accumulate to high levels in the plasma when kidney function is replaced by HD.

Methods: Metabolomic analysis was performed on plasma ultrafiltrate (UF) and urine from 16 control subjects (NL) and on plasma UF from 36 HD patients using an established platform (Metabolon). The fractional excretion (FE) for each solute was calculated as the urine to UF ratio relative to that of creatinine. The extent of accumulation in HD patients was calculated as the ratio of the average UF peak area for each solute in HD relative to NL subjects (HD/NL). An FE > 2 was considered evidence of secretion and only solutes detected in samples from all 16 NL subjects and 36 HD patients were analyzed.

Results: 26 solutes had FE greater than 2 (mean 4±2.7, range 2.0 to 14.2). HD/NL ratios were significantly higher for solutes with greater FE values as shown in the Figure (p=0.045, p<0.001). HD/NL ratios varied however among individual solutes with similar FE values.

Conclusions: Uremic solutes that are rapidly cleared by the kidneys tend to accumulate to high levels in HD patients. Non-renal clearance and differences in generation rate and distribution volumes may result in variable HD/NL ratios for solutes with similar secretory clearances in the native kidney.

POI1160

Biphasic Dynamics of Inflammatory Biomarkers Following Dialysis Initiation: Results from the MONDO Initiative

Xiaoling Ye,1 Dalia E. Youssi,1 Len A. Usyvat,2 Stefano Stuard,3 Adrian M. Guinsburg,1 Jeroen Kooman,4 Frank van der Sande,5 Peter Kotanko,5 Renal Research Institute, New York, NY; 2Fresenius Medical Care AG und Co KGaA, Waltham, MA; 3Fresenius Medical Care AG und Co KGaA, Bad Homburg, Germany; 4Fresenius SE & Co KGaA, Buenos Aires, Argentina; 5Maastricht University Medical Center, Maastricht, Netherlands.

Background: Inflammation is highly prevalent among patients (pts) with end stage kidney disease and is associated with adverse outcomes. We aimed to investigate in a large diverse international cohort of incident hemodialysis (HD) pts firstly the dynamics of inflammatory indicators, namely white blood cells (WBC), neutrophil-to-lymphocyte ratio (NLR), serum albumin (lab) and C-reactive protein (CRP), following initiation of HD. Secondly their predictive power over all-cause of death.

Methods: We included all incident in-center adult HD pts treated 01/2000 to 12/2012 with ≥1 neutrophils, lymphocytes, WBC, and CRP values within the study periods. Following HD initiation, pts were stratified into 7 subgroups: 6 semi-annual groups according to the dialysis vintage at the time of the pts’ death (0 to 6; 7 to 12; 13 to 18; 19 to 24; 25 to 30; 31 to 36 months) and a survivor group (pts who survived ≥37 months). Cubic smooth spline functions were applied to study the trends of each marker. Receiver Operating Characteristic Curve (ROC) Analyses were performed to evaluate the predictive power of each of the markers with 1st year as the baseline and the following 1 year as the follow-up.

Results: In total, 18,276 incident pts who were treated in 25 countries were included. WBC, NLR (Figure 1), and CRP declined sharply after HD initiation and increased before death, while started & remained low in the survivors. In general, WBC, NLR, and CRP were highest at HD initiation and prior to death in non-survivors. Alb levels increased after HD initiation and remained high in the survivor cohort. In contrast, lab levels dropped significantly before death. Alb (AUC: 0.66), CRP (AUC: 0.64), and NLR (AUC: 0.62) all show stronger predictive power than WBC (AUC: 0.55) (Figure 2).

Conclusions: In non-survivors, NLR, WBC, and CRP showed a similar trend after HD initiation and before death. As CRP is not a routinely used marker in many regions of the world and NLR has near comparable predictive power, this marker could be used as an alternative indicator of inflammation in resource-limited areas.

Disease Course of Hyperkalemia in Patients on Hemodialysis

Bruce S. Spinowitz,1 Steven Fishbane,2 Masafumi Fukagawa,3 Martin L. Ford,4 Nicolas J. Guzman,5 Anjay Rastogi,6
1New York Presbyterian Queens, Queens, NY; 2Zucker School of Medicine at Hofstra/Northwell, Donald and Barbara
Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY; 3Toki University School of Medicine, Isehara, Japan;
4King’s College Hospital Nephritis Trust, London, United Kingdom; 5AstraZeneca BioPharmaceuticals Research and
Development, Gaithersburg, MD; 6David Geffen School of Medicine, Los Angeles, CA.

Background: Hyperkalemia (HK) preceding hemodialysis (HD) is associated with increased risk of mortality and hospitalization. Longitudinal data on serum potassium (sk) in this population is sparse. This post-hoc analysis of data from the placebo (PBO) arm of DIALIZE (NCT00303521) explored the course of HK in HD pts.

Methods: In DIALIZE, 196 pts were randomized 1:1 to PBO (n=99) or sodium zirconium cyclosilicate (SZC) (n=97) 5 g starting dose once daily on non-dialysis days for 8 weeks (8w), comprising a 4-week SZC dose-titration phase (max 15 g) to achieve target pre-dialysis sk: 4.0–5.0 mmol/L and a 4-week stable-dose evaluation phase. All pts received HD TiW and dietary counselling. Post-hoc analysis of PBO pts by baseline (BL) pre-dialysis sk included mean pre- and post-dialysis sk by visit, and proportions of pts who had mean pre-dialysis sk of 4.0–5.0 and 4.0–5.5 mmol/L by visit (including pts receiving rescue therapy).

Results: Mean pre-dialysis sk after the long interdialytic interval was 5.9 mmol/L at BL (Day 1) and 5.7 mmol/L at end of treatment (EOT; Day 57) (Figure). Across all BL pt strata, mean pre-dialysis sk remained 5.0 mmol/L for all study visits (Figure). For pts with BL pre-dialysis sk <5.5, 5.5–6.0, 6.0–6.5, and 6.5–7.0 mmol/L, mean pre-dialysis sk at EOT was 5.4, 5.9, 5.6, and 5.9 mmol/L, respectively (Figure). Over 8w, only 7.0–
23.1% and 31.1–60.6% of PBO pts had a pre-dialysis sk of 4.0–5.0 and 4.0–5.5 mmol/L, respectively, at any study visit. Mean post-dialysis sk was 3.9 mmol/L at BL and at EOT.

Conclusions: In pts receiving PBO and counselling following a HK event, mean sk remains high over 8w. Most pts remain hyperkalemic over this period and are therefore at continued risk of adverse outcomes.

A USRDS Database Study on the Use of Pegloticase in Patients Undergoing Dialysis

Anthony M. Blevier,1 Yi Zhang,2 Onkar S. Khrisigar,3 Brad A. Murder,4 Brian LaMoreaux,3 Wake Forest University School of Medicine, Winston-Salem, NC; 2Medical Technology and Practice Patterns Institute, Bethesda, MD; 3Horizon Therapeutics plc, Lake Forest, IL.

Background: Gout is a common co-morbidity of chronic kidney disease, but prevalence in dialysis patients is not precisely known. Oral urate-lowering therapy use is limited in patients with advanced renal disease, particularly end-stage. Pegloticase (PEGylated uricase) rapidly lowers serum uric acid, but phase 3 trials did not include dialysis patients. However, a phase 1 trial in non-gout patients showed that pegloticase efficacy and pharmacokinetics are not affected by dialysis. Beyond this, pegloticase use in dialysis-dependent patients is not reported in the literature. This United States Renal Data System (USRDS) study sought to better quantify and understand real-world use of pegloticase in patients undergoing dialysis.

Methods: Patients with advanced renal disease, who are dialysis-dependent, or who have undergone renal transplant are in the USRDS. USRDS patients who were administered pegloticase and undergoing dialysis were identified in 2012-2017 Standard Analytical Files. Parameters examined included demographics, comorbidities, dialysis type, number of pegloticase infusions, and time between pegloticase infusions.

Results: 58 dialysis centers reported on 136 patients. Pegloticase was most prescribed by rheumatologists (68%) and internal medicine physicians (7%). The majority of patients were white (61%) and male (73%) and patient age averaged 56.9 ± 16.8 years; all adult age groups were represented (18-44 years: 27%, 45-49 years: 35%, ≥56 years: 39%). Hypertension (74%) and diabetes (46%) were the most reported comorbidities. 9 patients (7%) were donor kidney recipients. More patients were undergoing hemodialysis (108 patients [79%]) than peritoneal dialysis (23 [17%]). Patients received 13.4 ± 19.1

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
pegloticase infusions (median: 7, 46 [34%] patients a12) and median time between doses was 14 days (mean: 21 days). This treatment schedule reflected that of pegloticase labeling (biweekly infusions).

Conclusions: The literature contains few reports of pegloticase use in dialysis patients. Our real-world data suggest that pegloticase is well-tolerated in dialysis patients, as indicated by a median of 7 infusions per patient and the expected treatment schedule. Further research is needed to verify these findings.

PO1167
Feasibility Study of Wrist-Based Wearable Activity Trackers in Hemodialysis Patients

Ohnmar Ohnmar,1 Mango Ho,1 Priscilla Preciado,1 Xia Tao,1 Mirell Tapia,1 Lemuell Rivera Fuentes,1 Mohamad I. Hakim,1 Amrish U. Patel,1 Nadja Grobe,1 Stephan Thijssen,2 Peter Kotanko.1

1Renal Research Institute, New York, NY; 2Department of Internal Medicine, University of Massachusetts Medical School, Worcester, MA.

Background: Wearable activity trackers allow physicians to access patient’s physical activity (PA) outside the dialysis clinic. Hemodialysis (HD) population have an increased cardiovascular mortality and they are less active than their healthy counterparts. We aim to assess the feasibility of use of a wearable trackers in a HD population.

Methods: HD patients from 4 NYC clinics were enrolled in the study starting from June 2018, followed up to 1 year. Patients ≥18 years on maintenance HD, able to walk, owning a smartphone, tablet or PC were included. Each patient received a wrist-based monitoring device (Fitbit Charge 2) to wear for a year. They were trained how to use and sync data. A stepwise intervention was created. After 3 in-person visits are completed, patients were deemed non-adherent and withdrawn. Events such as device failure or broken band were not counted as an in-person visit. We used Kaplan-Meier analysis to study time to withdrawal for non-adherence and predictors of time to withdrawal were assessed by univariate Cox Regression. The end of the observation period was May 8, 2020.

Results: 118 patients were studied. Patients were 54±12 years old with a HD vintage of 5.2±5.1 years, 37% lived alone, 59% unemployed, 57% were African American, and 42% had an education level of some college or higher. Seventeen patients were withdrawn due to non-adherence. Mean and median time to withdrawal were 280 days (95%CI 260-301) and 359 days (95%CI 324-365). The probability of retention is shown in Fig. 1. There was no association found between age, gender, race, living status, and education and time to withdraw due to non-adherence.

Conclusions: Only a small number of patients were withdrawn due to non-adherence, and the average time to withdraw was 9 months. We believe that the use of a wrist-based wearable device for remote patient monitoring, at least up to one year, is feasible in the HD population.

Funding: Private Foundation Support

PO1168
Evaluation of Biomarkers in Chronic Hemodialysis (HD) Patients Dialyzed with Optiflux High-Flux Dialyzers

Meijiao Zhou,1 Linda Picciolo,1 Mark Costanzo,1 Claudi Mullon,1 Robert J. Kossmann,2 Presentis Medical Care Renal Therapies Group, Waltham, MA; 2Presentis Medical Care North America, Waltham, MA.

Background: Optiflux® (OPTI) dialyzers are single-use, high-flux dialyzers available in the following sizes: F160NR (1.5 m²), F180NR (1.7 m²), F200NR (1.9 m²), and F250NR (2.5 m²). They are designed to enhance small and middle molecule clearance without increasing albumin loss. Epidemiologic data has shown low serum albumin (sALB) to be a marker of increased mortality risk in dialysis patients (pts). Thus, loss of albumin should be avoided especially in pts with low sALB. This retrospective study aimed to assess changes in biomarkers in pts dialyzed with Optiflux dialyzers for 6 months, including a subset of pts with low sALB levels at baseline.

Methods: 976 in-center HD pts treated exclusively with Optiflux dialyzers for 6 months without liver disease, cancer, HIV, or history of drug abuse were analyzed in this study. Pre-HD labs at the first month of data collection (M1) and Month 6 (M6) were compared using paired t-test. A sub-analysis of pts with hypoalbuminemia (sALB ≤3.5mg/dL) at M1 was conducted. All analyses were performed separately for each dialyzer. Pts dialyzed with F200NR and F250NR were combined into 1 group.

Results: Mean biomarker levels during M1 and M6 are presented for the dialyzer groups (table). Most notably, significant increases of mean sALB and hemoglobin were observed in all groups. In the sub-analysis of pts with hypoalbuminemia at M1 (n=156), 87% of pts had increases in sALB by M6 (48/59=81.4% in F160NR, 82/92=89.1% in F180NR, and 5/5=100% in F200NR and F250NR) and 53.8% (84/156) achieved sALB >3.5 g/dL at M6. 

Conclusions: During a 6-month follow-up, HD patients dialyzed with Optiflux dialyzers showed increases in serum albumin and hemoglobin while maintaining dialysis adequacy.

PO1169
Postoperative Outcomes After Bariatric Surgery in Chronic Dialysis Patients: A Meta-Analysis and Systematic Review

Dharmenaa Palamuthusingham,1 Carmel Hawley,2 Elaine Pascoe,1 David W. Johnson,1 Magid Fahim,3 Logan Hospital, Loganholme, QLD, Australia; 2Princess Alexandra Hospital, Woolloongabba, QLD, Australia; 3The University of Queensland Faculty of Medicine, Herston, QLD, Australia.

Background: Renal transplantation improves longevity and quality of life for patients on chronic dialysis. However, obesity is a growing surgical contraindication in this group such that bariatric surgery is increasingly being considered as a bridge to transplantation. The risks and benefits of bariatric surgery in the dialysis population have not been synthesized.

Methods: Authors performed a systematic review of observational studies indexed in Embase, MEDLINE and CENTRAL till April 2020 that reported postoperative outcomes in chronic dialysis and non-dialysis patients undergoing bariatric surgery. Summary level data on patient demographics and comorbidity were extracted. The primary outcome was death (30-day or in-hospital mortality), secondary outcomes were myocardial infarction, surgical site infection, pneumonia, unplanned return to theatre, sepsis, and rates of kidney transplantation. Random effects meta-analysis was performed to derive summary risk estimates.

Results: Four cohort studies involving 4,096 chronic dialysis and 732,204 non-dialysis patients undergoing bariatric surgery were included. Sleeve gastrectomy (34%), gastric bypass (24%), and roux-en-Y gastric bypass (24%) were the most common procedures performed followed by gastric band or bilipancreatic diversion. There were increased odds of postoperative mortality (0.4-0.5% vs 0.1%; OR 4.7, 95%CI 2.2-9.9, P<0.001; myocardial infarction 0.5-0.9% vs 0.1%; OR 3.4, 95%CI 2.0-5.8, P<0.001; pneumonia 0.3-0.9% vs 0.2-0.4%; OR 2.3, 95%CI 1.4-5.0; P=0.05) in dialysis patients compared to non-dialysis patients. Patients on dialysis also had increased odds of return to theatre compared to non-dialysis patients (3.2-3.4% vs 1.4-2.0%; OR 2.2, 95%CI 1.7-3.0). There were no differences in the odds of surgical site infections, bleeding, or thromboembolic complications. Rates of renal transplant wait-listing among dialysis patients undergoing bariatric surgery were not reported in any of the studies.

Conclusions: Chronic dialysis patients have substantially increased odds of postoperative mortality and myocardial infarction. However, the absolute rates of complications are low and may not be prohibitive if they facilitate successful renal transplantation. Systematic reporting of both the benefits and risks of bariatric surgery in dialysis patients is needed.

Funding: Private Foundation Support

PO1170
Peridialytic Serum Cytokine Levels and Their Relationship with Postdisalysis Fatigue and Recovery in Patients on Chronic Hemodialysis

Astrid Byrne,2 Enrico Di Stasio,1 Bert Lenart,2 Anna Pieca,1 Riccardo Calvani,1 Federico Montezzori,1 Maurizio Bossola,1 Universita' Cattolica del Sacro Cuore Facolta di Medicina e Chirurgia, Roma, Italy; 2Universita' Maastricht Faculty of Health Medicine and Life Sciences, Maastricht, Netherlands; 3Azienda Ospedaliera Universitaria Integrita Verona Unità Operativa Nefrologia e Dialisi, Verona, Italy.

Background: The etiology of postdisalysis fatigue (PDF), an intermittent but debilitating fatigue occurring in 40-80% of chronic hemodialysis (HD) patients after HD treatment, is still unclear. In other illnesses, such as inflammatory diseases, mounting
evidence points toward the involvement of the immune system in the development of fatigue symptoms. Altered serum levels of inflammatory cytokines have also been shown in chronic HD patients and positive associations between interleukin-6 (IL-6) and fatigue symptoms in general in this patient population have been recently reported. Therefore, we investigated whether fatigue specifically occurring after HD (PDF) or the time needed to recover from HD treatment (TIRD) were related to pre and postdialysis serum levels of pro- and anti-inflammatory cytokines (i.e. IL-1β, IL-6, TNF-α and IL-10) or their intradialytic changes (if any).

Methods: Serum levels of IL-1β, IL-6, TNF-α and IL-10 were measured immediately before and after HD in 45 chronic HD patients using commercially available Kits on an ELLA™ automated immunoassay system. The presence and severity of PDF as well as TIRD duration were assessed by self-report measures.

Results: Thirty-three patients (74%) reported PDF, with a median PDF severity index of 2.30 [IQR: 0.00–4.30] on a scale from 1 to 5. Median TIRD was 120 min [IQR: 60–400]. PDF severity correlated strongly with TIRD, r=0.85, p<0.001. Only predialysis IL-10 serum levels significantly and positively correlated with PDF severity (r=0.43, p=0.003). Postdialysis cytokine levels and their intradialytic changes were not significantly related to PDF.

Conclusions: The present study does not support the hypothesis that the immune system may be involved in the development of PDF or TIRD. The positive, but counterintuitive relation between predialysis anti-inflammatory IL-10 levels and PDF severity warrants further research. However, the present findings do not necessarily undermine the previously found positive relationship between IL-6 levels and chronically fatigue experience in HD patients, as fatigue as response to treatment may have other determinants than a more chronically fatigue.

POI171
Tryptophan Removal in ESRD Patients Treated with High-Flux and Medium Cut-Off Dialyzers During Hemodialysis and Hemofiltration

Gabriela F. Dias,1,2 Nadja Grobe,1 Peiyeng Peng,1 Xiaoling Wang,1 Joshua E. Chao1, Jose S. Lopez Gil1, Armando Armenta Alvarez1, Magdalena Madero,1 Jochen G. Raimann,1,3 Magdalena Madero,1,2 Jochen G. Raimann,1,3 Gabriela F. Dias,1 Peiyeng Peng,1 Xiaoling Wang,1 Joshua E. Chao1, Jose S. Lopez Gil1, Armando Armenta Alvarez1, Magdalena Madero,1,2 Jochen G. Raimann,1,3
1Renal Research Institute, New York, NY; 2Pontificia Universidad Catolica do Parana, Curitiba, Brazil; 3Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico.

Background: Tryptophan (Trp) loss in kidney failure patients is likely to be associated with poor nutritional status and depletion due to dialysis. However, Trp removal with medium cutoff (MCO) membranes has not been investigated. Here, we compared Trp reduction ratios (RR) between an MCO dialyzer and a high-flux polysulfone (HFPS) dialyzer.

Methods: Clinically stable, anuric hemodialysis patients on thrice-weekly HD were enrolled. Over the course of 4 weeks, each subject traversed through the following combinations (with 2 study treatments per week, 4 hours per HD session): post-dilution hemofiltration (HDf) with FX120 (Fresenius Medical Care), HD with FX120, HD with Theranova 400 (Baxter), HD with Theranova 400 (Fig. 1). All subjects exercised using stationary bicycles during HD. Blood samples were collected before dialysis (B0) and at 230 min (B230) upstream of the dialyzer. Trp in plasma was analyzed by liquid chromatography–mass spectrometry. RR was calculated using signal intensities for Trp according to RR=(B0-B230)/B0, with correction for hemoconcentration using hemoglobin levels (Schneditz, ASAIO 2012).

Results: Twelve subjects completed the study (30% female, 43.8±7.7 years old). With B2M RR of 0.29 for MCO, 0.33 for HFPS; surface areas 1.7 m2 for Trp according to RR=(B0-B230)/B0, with correction for hemoconcentration using hemoglobin levels (Schneditz, ASAIO 2012)

Conclusions: Use of an MCO dialyzer may result in similar or greater Trp loss as use of an HFPS dialyzer with a much larger surface area. When considering the use of MCO dialyzers, clinicians should consider the potential impact on removal of salutary substances (incl. protein-bound substances), an area that deserves further research.

Funding: Private Foundation Support

Effect of Hemofiltration with Medium Cut-Off Dialyzer on Uremic Toxins Removal

Jose S. Lopez Gil,1 Armando Armenta Alvarez1, Ivan A. Osuna Padilla,1 Nadja Grobe1, Xia Tao2, Joshua E. Chao1, Jochen G. Raimann,1 Stephan Thijssen,1 Gabriela F. Dias,2 Peiyeng Peng,1 Xiaoling Wang,1 Hector Alejandro P. Garza,1 Peter Kotanko,2 Magdalena Madero,1,3 National Institute of Cardiology, Ignacio Chavez, Mexico, Mexico City, Mexico; 2Renal Research Institute, New York, NY; 3Centro de Investigacion en Enfermedades Infectoas CIENI, Mexico City, Mexico.

Background: To our knowledge no study has ever evaluated the use of middle cut-off membranes (MCO) with online hemofiltration (OL-HDF). This study aims to show if the combination of OL-HDF with MCO can achieve a higher reduction ratio of some uremic toxins in comparison to regular OL-HDF.

Methods: Patients from our hemodialysis unit were treated twice with four different modalities, namely combinations of post-dilutional OL-HDF or hemodialysis (HD) with a high-flux dialyzer (Cordura FX120, area 2.5 m2) or the MCO (Theranova 400; area 1.7 m2), respectively. We analyzed the reduction ratios (RR) of erythropoietin, beta2-microglobulin (B2M), phosphate, and urea.

Results: Twelve anemic patients were studied (6 females; mean age 43.8±15.8 years; HD vintage 35.7±27.9 months). Mean blood flow (Qb) was 367±23 ml/min, dialysate flow (Qd) was 493±57 ml/min, ultrafiltration volume was 2382±568 ml. B2M RR of 0.29 for MCO, 0.33 for HFPS; surface areas 1.7 m2 for Trp according to RR=(B0-B230)/B0, with correction for hemoconcentration using hemoglobin levels (Schneditz, ASAIO 2012)

Conclusions: Adding a medium cut-off (MCO) dialyzer to HDF does not add benefit. The B2M RR with HiFlEx exceeds the one of a MCO dialyzer. HDF provides benefit over HD between the B2M RR regardless of the dialyzer used.

POI173
pH-Dependent Protein Binding Properties of Uremic Toxins In Vitro

Suuguru Yamamoto,1 Kenji Sasahara,2 Mio Domon,3 Keichi Yamaguchi,3 Toru Ito,1 Shin Goto,1 Yuji Goto,1 Ichiei Narita,1 Division of Clinical Nephropathy and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; 2Institute for Protein Research, Osaka University, Osaka, Japan.

Background: Patients with chronic kidney disease undergoing dialysis treatment have worse clinical outcomes. One cause is the interactions between various uremic toxins and organ/tissues. Protein-bound uremic toxins (PBUTs), such as indoxyl sulphate (IS) and p-cresyl sulphate (PCS), are difficult to remove by conventional dialysis treatment owing to their high protein binding property. A possible treatment strategy is to weaken the protein binding of PBUTs. Acidic and alkaline pH change the conformation of proteins, which may be associated with the binding of uremic toxins. We examined the influence of pH on the protein binding properties of PBUTs in vitro.

Methods: Albumin concentration at pH 2 to 13 was analyzed using circular dichroism. Albumin reacted with IS at pH 4 to 11. The protein binding behavior was examined using isothermal titration calorimetry and free IS concentration was measured by mass spectrometry. Bovine serum with IS, PCS, indole acetic acid (IAA), or phenyl sulphate (PhS), as well as serum from hemodialysis patients, were adjusted to a pH of 4 to 11, and the concentration of the free form of PBUTs was measured.

Results: Albumin partially unfolded at pH <4 or >12. Calorimetric analyses revealed weakened interaction between IS and albumin at pH <5 or >10. The concentration of free IS in the presence of albumin was significantly increased at pH 4 (89.49±13.85 μg/dL) and pH 11 (22.45±13.85 μg/dL) compared to pH 7 (17.20±8.75 μg/dL) (both p<0.01). Addition of bovine serum to IS, PCS, IAA, or PhS at the physiological concentration of uremic patients and adjustment of pH from 4 to 11 resulted in increased concentrations of the free form of the solutes at acidic and alkaline pH, compared with the concentrations at neutral pH. Adjustment of serum from 19 hemodialysis patients from pH 4 to 11 resulted in increased concentrations of the free forms of IS, PCS, PhS, and IAA at acidic and alkaline pH. (e.g., IS: pH 4, 152.5±77.6 μg/dL; pH 11, 153.8±135.5 μg/dL vs pH 8, 38.8±3.3 μg/dL; p<0.01, respectively).

Conclusions: Acidic and alkaline pH changed albumin conformation and weakened protein binding property of PBUTs in vitro. The findings could inform strategies to increase the removal of PBUTs with convection/diffusion in hemodialysis treatment.
PO1174
Associations Between Prelude eGFR Category and Trajectories of Uric Acid and eGFR Prior to Dialysis Transition Among US Veterans
Nicholas Cuvelier,1 Cachet Wenziger,2,1 Jui-Ting Hsiung,2,1 Ramy M. Hanna,1 Ekamol Tantisattamo,1 Connie Rhee,1 Csaba P. Kovessy,1 Kamyar Kalantar-Zadeh,1 Elani Streja,1,2 Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; 1VA Long Beach Healthcare System, Long Beach, CA; 1Memphis VA Medical Center, Memphis, TN.

Background: Prior studies have demonstrated that elevated uric acid is associated with declining kidney function. However, how uric acid and estimated glomerular filtration rate (eGFR) levels change with progression towards end stage renal disease have not yet been fully characterized. We sought to examine trajectories of eGFR and uric acid 1 year prior to ESRD transition across strata of eGFR 5 quarters prior to transition.

Methods: From a cohort of US veterans who transitioned to dialysis between 10/2007-03/2015, we identified 15,725 patients with a pre-dialysis eGFR measurement 5 quarters prelude (15 months) before transitioning to ESRD and at least 1 uric acid measurement prior to ESRD. Trajectories were modeled across eGFR strata using mixed effects model with random slope and random intercept.

Results: The mean age of the cohort was 67±11 years old and included 2% females and 35% African American. In addition, the mean prelude quarter 5 uric acid level was 8±2 mg/dL and the median eGFR was 21 ml/min/1.73m2. While the trajectories of uric acid were relatively stable for most strata, eGFR steadily declined across all strata. However, in the final 3 months prior to ESRD transition (PQ2 to PQ1), those in the highest PQ5 eGFR category (≥45 ml/min/1.73m2) showed a sharp decrease in eGFR and corresponding sharp increase in uric acid, while there were notable trends for other strata. [Figure]

Conclusions: Patients with the most rapid renal function decline also had a sharp increase in uric acid 3 months prior to transition to ESRD. The mechanism behind this relationship is currently unknown, and should be investigated in future studies. Future studies should also examine the clinical implications of elevated uric acid in patients transitioning to dialysis earlier due to a rapid renal function decline.

PO1175
Insulin Resistance and Hemodialysis
Varun Kumar Bandi, Spoorthi Ramineni. Dr. Pinnanneni Siddhartha Institute of Medical Sciences & RF, Gannavaram, India.

Background: Insulin resistance is an important risk factor in Chronic Kidney disease (CKD) patients. We analysed insulin resistance indices in hemodialysis (HD).

Methods: Subjects with CKD not on dialysis (CKD), and on HD (HD) were included. Age, gender, Body mass index (BMI), Waist:Hip ratio (WHR) were noted. Fasting blood glucose, fasting insulin (Ins), C-peptide (Cp), bicarbonate (HCO3), Calcium (Ca), phosphorus (P), Vitamin D (Vit D), parathyroid hormone (PTH), Albumin (Alb), Ferritin, C-reactive protein (CRP) were measured. HOME-insulin resistance using Ins (IR-Ins) and Cp (IR-Cp), Insulin sensitivity and Beta cell function using Ins (IS-Ins, BS-Ins) and Cp (IS-Cp, BF-Cp) and C-peptide resistance index (CRI) were calculated.

Results: 20 patients with CKD, 22 on HD were analysed. In HD, IR-Cp had significant positive correlation with eGFR, and CRI with HCO3, Vit D, Ca, PI, IR-Cp and negatively with PTH,CRP,eGFR. In CKD, IR-Cp had significant positive correlation with PTH,eGFR and negatively with HCO3,Ca. CRI had significant positive correlation with HCO3, Vit D, Ca, PI, negatively with PTH, IR-Cp. Between groups, IR-Ins, IR-Cp, IS-Ins, IS-Cp and BF-Ins had significant difference (Table). The trajectories of Uric Acid level prior to dialysis transition are shown.

Conclusions: IR-Ins, BF-Ins, IS-Cp, CRI were higher in HD, while IR-Cp,IS-Ins were higher in CKD. Cp based indices could be better markers of IR.

PO1176
Effect of Citrasate Dialysate on Intact Parathyroid Hormone (iPTH) in Prevalent Hemodialysis (HD) Patients: A Matched Retrospective Cohort Study
Meijiao Zhou,1 Linda Fiocicciolo,2 Claudy Mullon,1 Michael S. Anger,1 Robert J. Kossmann,2 Fresenius Medical Care Renal Therapies Group, Waltham, MA; 2Fresenius Medical Care North America, Waltham, MA.

Background: Citrate-acidified dialysate (CAD) has anti-coagulation properties compared to acetate-acidified dialysate (AAD), due to its binding of calcium. PTH regulates the calcium concentration through its actions on bone and kidney. The objective of this study is to assess any long-term changes in iPTH levels when patients (pts) are switched from AAD to CAD.

Methods: A retrospective cohort study of 3 clinics converting from AAD to CAD during 2009 to 2011 matched to 12 geographically proximate AAD clinics, on the same month as CAD conversion. Clinics were selected before year of 2013, so that the follow-up did not include time when the management of mineral bone disease changed at large dialysis organizations (LDOs). In-center HD pts included in the analysis received HD treatment for at least 6 months before (baseline, BL) and 6 months after (follow up, FU) CAD conversion. BL and 6-month FU average values of clinical measures were compared within and between CAD and AAD clinics. Measures included pre-dialysis iPTH and serum calcium (sCa), prescribed (Rx) dialysate calcium (dCa), Rx calcium-based phosphate binders (Ca-based PB), Cinacalcet and IV Vitamin D (VitD).

Results: Changes in iPTH and sCa were not significantly different from BL to FU between CAD and AAD clinics (Table). Mean iPTH decreased by 17 pg/mL (4.1%, p=0.49) in CAD clinics and increased by 13 pg/mL (3.8%, p=0.13) in AAD clinics. However, Rx dCa increased in CAD clinics, but not in AAD clinics. Increases of Ca-based PB and Cinacalcet prescriptions were greater in AAD clinics. No significant differences were observed in changes of VitD over time between CAD and AAD clinics.

Conclusions: Similar trends in iPTH and sCa were observed in clinics switched from AAD to CAD and geographically-matched clinics with continuous use of AAD.

High-Volume Hemodiafiltration Reduces Pre-Dialysis Beta-2 Microglobulin Concentration Compared with High-Flux Hemodialysis: A Post Hoc Analysis of the HDFit Trial
Murilo H. Guedes,1 John W. Larkin,2 Ana Clara S. Almeida,1 Ana C. Santos,1 Ana Beatriz L. Barra,3 Carlos E. Poi de Figueiredo,4 Maria Eugenia F. Canziani,5 Andrea N. Moreno-Amaral,1 Jochen G. Raimann,3 Peter J. Ketano,3 Bernard J. Canaud,6,7 Roberto Pecoits-Filho,8,9 Pontificia Universidade Catolica do Parana, Curitiba, Brazil;4 Fresenius Medical Care North America, Hemodialysis and Frequent Dialysis - 3, Kansas City, Missouri, USA;3 Renal Research Institute, New York, NY;1 Pontificia Universidade Catolica do Rio Grande do Sul, Porto Alegre, Brazil;5 Fresenius Medical Care AG und Co KGaA, Bad Homburg, Germany;4 Montpellier Universite d’Excellence, Montpellier, France;1 Pontificia Universidade Catolica do Rio Grande do Sul, Porto Alegre, Brazil;4 Arbor Research Collaborative for Health, Ann Arbor, MI;9 Clinica de Diálise Ingá, Rio de Janeiro, Brazil.

Background: High-volume hemodiafiltration (HDF) is a diffusive-convective modality that provides higher clearance of middle-size uremic toxins, such as beta-2 microglobulin (β2M), compared to predominantly diffusive high-flux hemodialysis (HD). Previous studies have shown HDF may reduce circulating pre-dialysis concentrations of β2M compared to low-flux HD. We studied to which extent HDF reduces pre-dialysis β2M concentrations compared to high-flux HD.

Methods: HDFit randomized patients with a permanent vascular access time on HD between 3 and 24 months to either high flux HD or high volume HDF (convective volume (CV) target of 22L/session) treatment. Patients were followed for 6 months. Measurements of circulating pre-dialysis β2M levels were made at baseline, 3 and 6 months during mid-week session. Linear mixed effects models were used to model the mean difference (95% confidence interval (CI)) in β2M levels between HDF and HD.

Results: A total of 195 patients (mean age 53±15 years, albumin 4.0±0.4 g/dL) were randomized (HDF n=97, HD n=98). Patient characteristics were balanced across intervention groups. Median treatment time was 235 min in both groups. Monthly mean CV ranged from 27.1 to 27.5L/treatment; the target CV was achieved in 96 out of 97 patients. Compared to HDF, in the HD arm monthly mean pre-dialysis β2M levels were 1.57 μg/mL (95% CI 0.102 to 3.12) higher. In other words, HDF reduced mean circulating β2M levels over time compared to HD. (Figure).

Conclusions: In this post-hoc analysis of the HDFit trial, we describe for the first time that high-volume HDF substantially reduces pre-dialysis β2M concentration compared to high-flux HD. High convective volume was easily achieved with online HDF. Our findings suggest that HDF can be readily implemented and that this treatment modality yields a sustained higher control of middle-size uremic toxins.

Effect of Intradialytic Exercise on the Removal of Tissue Sodium During Hemodialysis
Hsin-Yu Fang, Luis M. Perez, Ryan J. Larsen, Alexis King, Brett Burrows, Kenneth R. Wilund. University of Illinois at Urbana-Champaign, Urbana, IL.

Background: Emerging evidence using 23Na-MRI shows that sodium can be stored in the skin and muscle. Hemodialysis (HD) patients appear to have higher tissue sodium concentration ([Na⁺]) compared to healthy controls, though tissue [Na⁺] appears to be partially reduced during HD. In this study, we thus aimed to determine whether intradialytic cycling (IDC) potentiates the removal of tissue [Na⁺] during HD.

Methods: Seven HD patients (sex: 57% male; age: 60±12 y; BMI: 36±10 kg/m²; spKt/V: 1.4±0.32; dialysate [Na⁺]: 136±1.90 mEq/L; UFR: 7.7±3.4 mL/kg/hr; thrice-weekly HD) underwent 23Na-MRI scans (3T system) before and after HD, on both a control (CON) and exercise (EX) day. Patients performed 30 minutes of IDC during the first hour of HD on the EX day and received standard care on the CON day. [Na⁺] of the proximal (MG) and lateral (LG) gastrocnemius, soleus (Sol), tibialis anterior (TA), and the whole lower leg (WL) were quantified from MRI images by trend analysis. Plasma [Na⁺] was also assessed by a colorimetric enzymatic assay (Piccolo). Repeated measures ANOVA was used to examine changes in muscle and plasma [Na⁺] between the EX and CON treatments from pre to post HD.

Results: There was a significant treatment by time interaction for [Na⁺] in WL (P=.036) and Sol (P=.016), with the EX treatment attenuating the drop in [Na⁺] during HD compared to the CON condition in both WL and Sol (Figure A-B). [Na⁺] of MG (P=.002), LG (P=.001), TA (P=.001), and plasma (P=.042) were reduced during HD, but these changes did not differ by treatment (treatment x time interaction P = N.S. for all; Figure C-F).

Conclusions: Contrary to our hypothesis, it appears that IDC may attenuate, instead of potentiate, the magnitude of tissue [Na⁺] removed during HD. However, this was not a consistent finding across all muscle beds analyzed. More studies are needed to examine if this result is a manifestation of the timing of MRI, the limited sample size, or other factors.

PO1179

Hand Grip and Leg Muscle Strength in Hemodialysis Patients and Its Determinants

Background: Chronic kidney disease is associated with chronic inflammation and progressive loss of peripheral muscle strength and the ability to exercise, and these changes are more pronounced in patients on hemodialysis (HD). We evaluated the hand grip and leg muscle strength in patients receiving HD and tried to find factors associated with muscle strength.

Methods: We screened hand grip (opposite to fistula side) and leg muscle strength (both sides) at single center (n=112) by using digital hand and leg dynamometer (T.K.K.5401 and 5710e/5715, Takei scientific instruments Co. Ltd., Niigata, Japan).

Results: Mean age was 62.6 years, and 73.2% of patients were men. Diabetes was the cause of kidney failure in 50% of patients and median HD vintage was 34 months. 77.7% of patients answered ‘yes’ to regular home exercise and 33% of patients regularly participated in the hospital based latent-band exercise. Hand grip strength (HGS) and leg muscle strength (LMS) showed good correlation (r = 0.715, p < 0.001). HGS (25.1 ± 18.6 kg, p = 0.01) but LMS did not show statistical significance (29.3 ± 23.6 kg, p = 0.19). Serum albumin and creatinine showed positive correlation with HGS and LMS, and hs-CRP was negatively correlated only with HGS. Multiple linear regression analysis proved male sex, younger age, and any type of exercise were factors associated with better HGS and LMS.

Conclusions: Sex, age, and exercise were the most important determinants of muscle strength in HD patients. We need to encourage patients to do regular home or group exercise and introduce new feasible form of exercise for HD patients.

Exercise Training to Improve Patient-Important Outcomes in Adults Undergoing Maintenance Dialysis: A Systematic Review and Meta-Analysis of Randomised Controlled Trials
Amelie Bernier-Jean,1,5 Nadim A. Berani,1 Nicole P. Bondono,1,5 Gabriele J. Williams,1 Armando Teixeira-Pinto,1,5 Jonathan C. Craig,2 George W. Wong,1 School of Public Health, Faculty of Medicine (herein), The University of Sydney, Sydney, NSW, Australia; 2College of Medicine and Public Health, Flinders University, Adelaide, NSW, Australia; 3Western Sydney Local Health District, Westmead, NSW, Australia; 4School of Biomedical Sciences, The University of Western Australia, Royal Perth Hospital, Perth, WA, Australia; 5School of Medical and Health Sciences, Edith Cowan University, Perth, WA, Australia; 6Centre for Kidney Research, The Children’s Hospital at Westmead, Westmead, NSW, Australia.

Background: Multiple trials have assessed the potential for exercise training to improve outcomes in adults undergoing dialysis. However, uncertainties exist in its relevance and sustainable benefits for patient-important outcomes.

Methods: We conducted a systematic search of the Cochrane Kidney and Transplant Specialised Register for randomised controlled trials of structured exercise programs of eight weeks or more in adults undergoing maintenance dialysis (hemodialysis or peritoneal dialysis) compared to no exercise or sham exercise. Two authors independently assessed the trials for eligibility, extracted the data and assessed the risk of bias. We conducted random-effects meta-analyses.

Results: We identified 93 studies involving 4634 participants and 71 studies involving 3973 participants contributed to the meta-analyses. The interventions lasted from 8 weeks to 2 years and most often took place thrice weekly during hemodialysis treatments. Overall, the quality of the included studies was low. In adults undergoing dialysis compared with no or sham exercise, exercise training may improve fatigue, the physical component of health-related quality of life (HR-QoL)DMX 4.5, CI 2.2 to 6.8 points/100: low certainty evidence), depressive symptoms (SMD 0.73, CI 0.39 to 1.07: moderate certainty evidence), pain (MD 0.8, CI 0.3 to 1.1: low certainty evidence), functional capacity measured in terms of the 6 Minutes-Walk Test (MD 49.9 meters, CI 37.2 to 62.6: moderate certainty evidence) and the Sit-To-Stand test (MD 0.4 cycles, CI 0.1 to 0.7: low certainty evidence). The impact on depression was greatest for those who had maintained exercise beyond 4 months (SMD 1.26, CI 0.72 to 1.80). We could not draw conclusions for all-cause mortality, cardiovascular events, the mental component of HR-QoL, blood pressure and the safety of exercise training for adults undergoing maintenance dialysis due to the very low quality of the evidence.

Conclusions: In adults undergoing maintenance dialysis, exercise training is likely to improve depressive symptoms and functional capacity and may improve fatigue, the physical component of quality of life and pain.

PO1181
Comparative Risk of Fall-Related Fractures Among Hemodialysis Patients Newly Initiating Zolpidem vs. Trazodone Therapy
Magdalene M. Assimon, Jennifer E. Flynn1. University of North Carolina at Chapel Hill, Chapel Hill, NC.

Background: Zolpidem, a non-benzodiazepine hypnotic, and trazodone, a sedating antidepressant, are the most common medications used to treat insomnia in the United States. Both drugs have side effects (e.g. drowsiness, dizziness, cognitive and motor impairment) that increase the risk of falls and resultant fracture events. Despite widespread zolpidem and trazodone use, little is known about the comparative safety of these medications in hemodialysis patients, a vulnerable population with an exceedingly high fracture rate.

Methods: We conducted a retrospective cohort study using an active comparator new-user design to investigate the association between zolpidem vs. trazodone initiation and the 30-day risk of hospitalised fall-related fractures among Medicare-enrolled hemodialysis patients in the United States Renal Data System Registry (2013 – 2016). We used an intention-to-treat analytic approach and propensity score weighted survival models, adjusted for numerous demographic and clinical covariates, to estimate hazard ratios (HRs) and their 95% confidence intervals (CIs). Death was treated as a competing event.

Results: A total of 31,055 hemodialysis patients were included in the study, 18,941 zolpidem initiators (61%) and 12,114 trazodone initiators (39%). Newly initiating zolpidem vs. trazodone therapy was associated with a higher risk of hospitalized fall-related fractures, HR [95% CI] = 1.71 [1.11, 2.63]. The association was more pronounced among individuals prescribed higher zolpidem dosages (1.92 [1.4, 3.2]) and in subgroups with fall-related risk factors, such as older and frailter patients (1.89 [1.14, 3.09] and 2.49 [1.31, 4.73], respectively) and individuals using other medications with central nervous system activity (2.04 [1.14, 3.7]). Sensitivity analyses using longer follow-up durations, evaluating a broader definition of hospitalized fracture, and employing an on-treatment analytic approach yielded similar results (data not shown).

Conclusions: Hemodialysis patients newly initiating zolpidem had a higher risk of hospitalized fall-related fracture compared to patients initiating trazodone, suggesting that trazodone may be a safer pharmacologic treatment option for the management of insomnia in this vulnerable population.

PO1182
Relationship of Peripheral Nerve Function with Mobility in ESKD
Simit Doshi, Alissa A. Cranor, Keith G. Avin, Sharon M. Moe, Ranjani N. Moothi. Indiana University School of Medicine, Indianapolis, IN.

Background: Mobility limitation is widely prevalent in patients undergoing dialysis and is associated with frailty, disability, hospitalizations and mortality. Motor and sensory nerve impairments are reported in ESKD but their relationship with mobility is poorly studied. We tested the hypothesis that objective measures of nerve function in the lower extremity are associated with mobility limitation.

Methods: Twenty-five subjects with ESKD underwent nerve testing after their routine dialysis session. Nerve testing was done using the Natus Viking Quest NSC system and vibration detection threshold (VDT) was measured with a Medoc VSA-3000 analyzer. Predictors were nerve action potentials (amplitude) and nerve conduction velocity (NCV) in motor (peroneal) and sensory (sural) nerves as well as VDT quantitatively measured at the pulp of the big toe. Gait speed (mobility outcome) was measured over 4 meters and the better of 2 attempts used. Leg extensor strength, a covariate was measured by a dynamometer. Patient symptoms were assessed using the Neuropathic Pain Questionnaire.

Results: Subjects were 23-74 y, 14 male, 23 black, 14 diabetic, median dialysis vintage 4.5 yrs. Median gait speed was 0.70 m/s (IQR 0.61-0.86). Neuropathic pain was noted in 47% patients, but did not correlate with objective measures of nerve function or gait speed. Median vibration detection threshold was 51u (IQR 26-104) and showed significant negative correlation with gait speed (p < 0.01). Higher sensory (sural) nerve onset and peak latency and lower sensory conduction velocity were correlated with lower gait speed (all p < 0.01). Higher peroneal motor amplitude was positively correlated with gait speed (p < 0.05). Higher VDT remained significantly associated with gait speed in multivariable regression model adjusted for demographics, diabetes, dialysis vintage and muscle strength (model R2=0.74).

Conclusions: In patients with ESKD, objective measures of nerve function are associated with mobility dysfunction regardless of diabetes, muscle strength and dialysis vintage. In contrast, subjective assessment of neuropathy is not associated with mobility dysfunction. These results demonstrate that the neuropathy of ESKD is a contributing factor to the widespread impairment in mobility observed in patients undergoing dialysis and is a key target for intervention required for diagnosis.

Workforce Capacity for ESKD Care: An Analysis from the Global Kidney Health Atlas Study

Parnian Riaz,1,2,3 Mohamed A. Osman,1,2 Meaghan Lunney,1 Feng Ye,1 Syed Saad,1 Adeera Levin,4 David W. Johnson,2,3 Aminu K. Bello.1 Global Kidney Health Atlas Investigators 1University of Alberta Faculty of Medicine and Dentistry, Edmonton, AB, Canada; 2The University of Queensland Faculty of Medicine, Herston, QLD, Australia; 3University of Calgary Cumming School of Medicine, Calgary, AB, Canada; 4The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada.

Background: Despite the rising burden of chronic kidney disease, recent surveys reveal a gap between nephrologists and other kidney health professionals. The objective of the second iteration of the International Society of Nephrology’s (ISN) Global Kidney Health Atlas was to assess inter- and intra-national variability in the capacity for end-stage kidney disease (ESKD) care.

Methods: Data were collected in two steps: desk research and a cross-sectional survey. Desk research used data from online sources, such as the Central Intelligence Agency World Factbook and the World Health Organization Global Observatory. The survey was administered online to key stakeholders worldwide, and all country-level data were analyzed by ISN region and World Bank income classification.

Results: The results of desk research showed that the general healthcare workforce density varied by income level: high-income countries had more healthcare workers per 10,000 population (30.30 physicians; 79.21 nursing personnel; 7.20 pharmacists; 3.47 surgeons) than low-income countries (0.85 physicians; 5.02 nursing personnel; 0.10 pharmacists; 0.03 surgeons). A total of 182 countries responded to the survey, with 160 (88%) countries responding to questions pertaining to the ESKD workforce. Nephrologists were primarily responsible for providing care to ESKD patients in 92% of countries. Global nephrologist density was 9.95 per million population (pmp) and nephrology trainee density was 1.42 pmp. High-income countries reported the highest densities of nephrologists and nephrology trainees (23.15 pmp and 3.83 pmp, respectively), whereas low-income countries reported the lowest densities (0.24 pmp and 0.11 pmp, respectively). Compared to higher income countries, more low-income countries reported shortages of all types of ESKD healthcare providers, including nephrologists, transplant surgeons, peritoneal and hemodialysis access surgeons, and peritoneal and hemodialysis access interventional radiologists.

Conclusions: In this global survey, a significant trend was demonstrated in workforce capacity and distribution for ESKD care across countries. There was limited capacity in low income compared to high income countries. National and international policies are required to build a workforce that can effectively address the growing burden of ESKD.

PO1185

Patient Activation in Prevalent Hemodialysis Patients in the United States

Wael F. Hussein,1,2 Paul N. Bennett,1,3 Sumi J. Sun,1 Marc Reiterman,1 Emily Watson,1 Ian M. Farwell, DSW,1 Brigitte Schiller.1,2 Satellite Healthcare, San Jose, CA; 1Stanford University School of Medicine, Palo Alto, CA; 2Deakin University Faculty of Health, Burwood, VIC, Australia.

Background: Patient activation (PA) is the product of knowledge, skills and confidence that enable a person to manage their health and care. PA is associated with healthy behaviors, disease management and hospitalization rates. This study aimed to investigate the status and correlates of PA among prevalent HD patients in the US.

Methods: We surveyed patients from 10 HD centers using the Patient Activation Measure (PAM-13), which reports a score out of 100 and is categorized into four levels (higher scores or levels denoting higher activation). We described the distribution of PA status, and investigated associations with demographics, vintage, education level and HD center.

Results: 925 respondents completed the survey out of 1374 patients (response rate 67%). Mean age 62 ± 15 years, 40% female, and median vintage 41 months (IQR 19-77). Mean PAM score was 56 ± 13, and 14%, 50%, 25%, and 10% were in levels 1 to 4 respectively. Mean PAM scores were higher in younger patients (<55yrs: 59 ± 14, ≥55yrs: 55 ± 15). Sex was associated with higher education (College: 60 ± 14, High School: 57 ± 14, <High School: 51 ± 10; p<0.001) and in blacks (58 ± 15) compared to non-blacks (55 ± 13; p=0.008). Mean PAM scores varied significantly across centers ranging between 52 and 61 (p=0.004). In regression analysis, there were lower odds of having high activation (levels 3 or 4 vs levels 1 or 2) in association with age (for every 10 years: aOR 0.79 [95% CI: 0.71 – 0.87]) and male sex (0.72 [0.53 – 0.96]). Compared to having less than high school diploma, high school diploma and college were associated with high activation (2.36 [1.60 – 3.47], and 3.52 [2.25 – 5.54] respectively). HD center differences remained significant after adjustment. However, vintage, race, and ethnicity did not have a significant association with activation in the adjusted model.

Conclusions: Patient activation is low in a high proportion of HD patients. Older age, less education and male gender were associated with lower activation. This study is the first to report activation status among individuals on HD in the US, identifying an opportunity to direct resources to high-risk groups and develop programs to improve activation.

PO1186

Analysis of Psychological Detachment of Primary Caregivers of Maintenance Hemodialysis Patients

Jun Yin,1 Jin-mei Yin,1 2Third Affiliated Hospital of Sun Yat sen University, Guangzhou, China; 3the Fifth Affiliated Hospital of Sun Yat sen University, Zhuhai, China.

Background: Long term care for maintenance hemodialysis patients will bring physical, mental and economic burden to the caregivers. If the caregivers cannot detach during non working hours, it will affect their physical and mental health. The goal was to Analysis the psychological detachment level of primary caregivers of maintenance hemodialysis patients and its influencing factors.

Methods: By convenient sampling method,240 caregivers of maintenance hemodialysis patients in our hospital from June to September 2019 were selected and investigated by using Psychological Detachment Scale, Zarit Burden Inventory Scale, and Warwick-Edinburgh Mental Well-being Scale.

Results: The total score of psychological detachment of caregivers in maintenance hemodialysis patients was 1.52 ± 0.74 which was negatively correlated with the burden of caregivers (P < 0.01), and positively correlated with the total score of Warwick Edinburgh positive mental health(P=0.01) and psychological detachment level was high at 53.2% and low at 46.8%.The main influencing factors of caregiver’s psychological detachment were time of care, type of character, burden of care, positive mental health, duration of dialysis and types of complications(P<0.01).

Conclusions: Medical staff should pay attention to the psychological status of caregivers and take positive measures to improve the level of psychological detachment and promote their physical and mental health.

Factors Contributing to Primary Care Provider (PCP) Use in ESKD Patients After Starting Hemodialysis (HD)

Rafael C. Green,1,2 JiYoon B. Ahn,1 Laura Plantinga,1,3 John Sperati,1 Khaldet Abdell-Kader,1,4 Mara McAdams-DeMarco,1 Kelly H. Beers,1,5 Sandeep S. Soman,1,6 Michael J. Choi,1,7 Bernard G. Jaar,1,2 National Kidney Foundation Education Committee 1National Kidney Foundation, New York, NY; 2Johns Hopkins University, Baltimore, MD; 3Emory University, Atlanta, GA; 4Vanderbilt University Medical Center, Nashville, TN; 5Albany Medical College, Albany, NY; 6Henry Ford Hospital, Detroit, MI; 7MedStar Georgetown University Hospital, Washington, DC.

Background: While the importance of primary care is well-recognized, PCP use among HD patients has not been well-characterized and factors contributing to PCP use are unknown.

Methods: We characterized change in PCP use (a1 PCP visit) 1 year before and 1 year after dialysis start among adults age ≥67 years old with Medicare coverage initiating in-center HD between 2008-2014 (data from the United States Renal Data System). We used multivariable logistic models adjusting for demographics, clinical characteristics, and pre-ESKD nephrology care to identify factors associated with continuity of PCP care (defined as PCP use pre- and post-HD start) and new initiation of PCP care post-HD start.

Results: Among 111,424 older HD patients, 34% did not use PCP care post-HD start. Among patients with PCP use pre-ESKD, 5% did not continue to use PCP care post-HD start. Among patients without PCP use pre-ESKD, 70% did not initiate PCP care post-HD start. Black race, Medicaid insurance, impaired functional status, and residence in less urban or higher poverty neighborhoods were associated with lower odds of continuity of PCP care or initiating PCP care after HD start. (Table)

Conclusions: Among older incident HD patients, continuity of PCP care and initiation of PCP care were lower among patients who were black, of lower socioeconomic status,
from more rural areas, or had functional impairments. Research to understand the barriers to PCP use may inform interventions to improve delivery of primary care for these vulnerable populations.

**Status and Trajectory of Patient Activation Among Incident Dialysis Patients in the United States**

Wael F. Hussein,1,2 Anna R. Carrasco,1 Paul N. Bennett,1,3 Emily Watson,1 Sumi J. Sun,1 Brigitte Schiller,1,2 Satellite Healthcare, San Jose, CA; 3Stanford University School of Medicine, Palo Alto, CA; 4Deakin University Faculty of Health, Burwood, VIC, Australia.

**Background:** Patient activation (PA), a measure of knowledge, skills and confidence in managing one’s health, is associated with healthy behaviors, better disease management and improved health outcomes. We investigated the status and correlates of PA among end-stage kidney disease (ESKD) patients at dialysis initiation, and changes in PA after the first 3 months of dialysis.

**Methods:** Adult ESKD patients commencing dialysis at 25 in-center hemodialysis (ICHD) and 12 home dialysis facilities completed the Patient Activation Measure 13-item instrument (PAM-13) at dialysis initiation (t0) and month 4 (t1). Logistic regression was used to examine factors associated with high PA levels at t0 (PAM levels 3 and 4). Paired t-test was used to examine changes in PAM scores from t0 to t1.

**Results:** 227 patients completed the survey at t0 between Jun-Nov 2019; 166 (73%) on ICHD and 61 (27%) on home dialysis, mean age 60 ± 15 years. At t0, mean PAM scores were 65.1 ± 16.8; and 44% of patients had low activation. Mean PAM scores were 63.7 ± 17.3 and 69.4 ± 14.5 in ICHD and home patients respectively. In the adjusted model, higher education level and longer pre-ESRD nephrology care were associated with high PA at t0, while increased age was associated with lower odds of high activation – Figure 1. There was no significant change in PAM scores among 182 participants who completed the survey at t1 (mean 64.8 ± 17.8, mean change: -0.3 ± 17.3, p = 0.80).

**Conclusions:** Low activation is common among incident dialysis patients and is more common among those on ICHD. Patient activation does not seem to improve over the first 3 months of dialysis with current practice.

**PO1189**

**Fully Immersive Virtual Reality-Based Mindfulness Intervention in Hemodialysis Patients: A Pilot Study Assessing Safety and Utility**

Brett Burrows,1 Matthew H. Browning,2 Killivalavan Solai,1 Drew Fast,1 Natalia O. Litbarg,1 Judith T. Moskowitz,4 Kenneth R. Wilund,1 Rosalba Hernandez.1 1University of Illinois at Urbana-Champaign, Urbana, IL; 2Clemson University, Clemson, SC; 3University of Illinois at Chicago College of Medicine, Chicago, IL; 4Northwestern University Feinberg School of Medicine, Chicago, IL.

**Background:** Virtual reality (VR) is an evolving technology that is becoming a more common treatment for pain management and psychological phobias. While non-immersive VR (i.e., Nintendo Wii) has been used in trials involving hemodialysis (HD) patients, no studies to date have used fully immersive VR as a tool for intervention delivery. Because HD treatment and full immersive VR have similar potential adverse side effects (e.g., fatigue, nausea), the current pilot trial tests the initial safety and utility of fully immersive VR during maintenance HD treatment sessions.

**Methods:** HD patients (n=20) were enrolled in a single-arm pre-post pilot study. Participants were exposed to our fully immersive VR program, Joviality™, which delivered mindfulness training and guided meditation using the Oculus Rift head-mounted display. Participants experienced our 25-minute program on two separate occasions during HD treatment sessions. Participants recorded their level of HD treatment and/or motion-related symptoms prior to VR exposure and then again immediately following each VR exposure using the Simulator Sickness Questionnaire (SSQ). Validated utility measures included participant’s ability to be fully immersed in the virtual environment, interact with virtual objects, and find our VR program user-friendly.

**Results:** Mean age was 55.3 ±13.1 years; 80% male; 60% African American; and mean dialysis vintage was 3.56 (±3.75) years. The SSQ displayed significant decreases in total composite symptom score following VR Exposure 1 (22.6 vs. 11.2; p=0.03). Decreases were evident after Exposure 2, though these were non-significant (11.97 vs. 7.29; p=0.18). Participants reported high levels of spatial presence in the VR world with an average of 5.03/7.0 and a System Usability Scores of 82.8/100.

**Conclusions:** HD patients routinely suffer from fatigue, nausea, and dizziness during HD and we hypothesized that fully immersive VR may exacerbate these symptoms. By contrast, we saw a significant reduction in severity of symptoms on at least one of the two exposure days. Fully immersive VR may be a safe mode of intervention delivery during HD.

**Skin the Fat: PLEX for Hypertriglyceridemia-Induced CRRT Clotting**

Ruth Schulman, Larissa Kruger, Krishna A. Agarwal, Esildia Sula Karreci, Jason A. Freed, Melanie P. Hoenig. Beth Israel Deaconess Medical Center, Boston, MA.

**Introduction:** CRRT filter clotting remains a significant barrier to providing adequate dialysis in critically ill patients. Clotting leads to reduced clearance and volume removal, blood loss in the circuit, and increased nursing workload. Elevated triglycerides have been reported to result in filter clotting. Here, we present a case of CRRT circuit clotting in a patient with familial hypertriglyceridemia-induced pancreatitis.

**Case Description:** A 46-year-old man with obesity, hyperlipidemia, recurrent pancreatitis secondary to hypertriglyceridemia, and DMII presents with 2 days of abdominal pain. CT abdomen showed pancreatitis necrosis and stranding prompting admission for pancreatitis. Hospital course was complicated by hypoxic respiratory failure requiring intubation, shock, and oliguric AKI requiring initiation of CVVHD. Shortly after initiation of CVVHD, the filter and tubing clotted with a milky yellow substance. This recurred after circuit exchange and use of regional anticoagulation with Citrate Dextrose 3%. Triglyceride level returned at 3,668 mg/dL (reference range: <150 mg/dL). Given the severe hypertriglyceridemia and inability to effectively provide RRT, he underwent one session of therapeutic plasma exchange (PLEX) with subsequent fall in triglyceride levels to 433 mg/dL. Further CRRT was then effectively provided with typical filter and circuit life.

**Discussion:** This case highlights the impact of elevated triglyceride levels on CRRT filter life. Prior case reports have described clotting and shortened filter life in the setting of lipid infusion and propofol-induced hypertriglyceridemia despite regional Citrate anticoagulation. Triglyceride levels fell and clotting resolved with cessation of the infusions in both situations. In the setting of a non-iatrogenic etiology of elevated triglycerides, we suggest consideration of anticipatory plasma exchange to avoid CRRT filter clotting and to be able to provide more effective dialysis.

Medical Center, Charlottesville, VA.

Given these medications are renal failure given the drug’s pharmacokinetics. Both acyclovir and valacyclovir are toxicity is more likely to present in patients with acute or chronic keratitis and discharged home.

An additional session of hemodialysis was performed due to persistent altered mentation symptoms resolved. The following morning a repeat acyclovir level was 1.1 mcg/mL. After a four-hour session of hemodialysis her mental status improved, and her movement initiation was elevated at 2.6 mcg/mL (typical therapeutic level 0.14 – 1.2 mcg/mL). performed for presumed acyclovir toxicity. An acyclovir level drawn 2 hours after initiation was elevated at 2.6 mcg/mL (typical therapeutic level 0.14 – 1.2 mcg/mL). After a four-hour session of hemodialysis her mental status improved, and her movement symptoms resolved. The following morning a repeat acyclovir level was 1.1 mcg/mL. An additional session of hemodialysis was performed due to persistent altered mentation with subsequent resolution to baseline. She was transitioned to topical ganciclovir for her keratitis and discharged home.

Discussion: This case describes the rare yet potentially underrecognized syndrome of acyclovir neurotoxicity, manifesting as delirium with prominent auditory hallucinations and myoclonus. Such toxicity is more likely to present in patients with acute or chronic renal failure given the drug’s pharmacokinetics. Both acyclovir and valacyclovir are dialyzable (30-60% drug removal in a four-hour session). Given these medications are often prescribed for treatment of infections caused by herpes viruses. Neurological toxicity consisting of hallucinations, seizures, and coma are rare reported side effects occurring predominantly in renal failure as a result of the renal clearance of the drug.

Case Description: A 71-year-old woman with end stage renal disease from amyloidosis on maintenance hemodialysis presented with recent onset of confusion, slurred speech, weakness, and intractable auditory hallucinations described as “Mariachi music.” She had been recently treated for herpes keratitis four days prior to presentation. On exam she was noted to be inattentive with disorganized thought-processes, diffuse hyporeflexia, generalized myoclonus, and up-beating nystagmus with superior gaze. A medication reconciliation revealed that she had been prescribed valacyclovir at a dose of 1,000 mg three times daily. She had additionally continued previously-prescribed prophylactic acyclovir at a dose of 200 mg twice daily. Urgent hemodialysis was performed for presumed acyclovir toxicity. An acyclovir level drawn 2 hours after initiation was elevated at 2.6 mcg/mL (typical therapeutic level 0.14 – 1.2 mcg/mL). After a four-hour session of hemodialysis the mental status improved, and her movement symptoms resolved. The following morning a repeat acyclovir level was 1.1 mcg/mL. An additional session of hemodialysis was performed due to persistent altered mentation with subsequent resolution to baseline. She was transitioned to topical ganciclovir for her keratitis and discharged home.

Discussion: This case describes the rare yet potentially underrecognized syndrome of acyclovir neurotoxicity, manifesting as delirium with prominent auditory hallucinations and myoclonus. Such toxicity is more likely to present in patients with acute or chronic renal failure given the drug’s pharmacokinetics. Both acyclovir and valacyclovir are dialyzable (30-60% drug removal in a four-hour session). Given these medications are commonly prescribed, as well as the severity of neurotoxicity and the rapid improvement with hemodialysis, it is critical to maintain a high index of suspicion and begin treatment promptly. The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of Army/Navy/Air Force, Department of Defense (DoD), or the U.S. Government.

Introduction: After implementation of standard protocols for new start dialysis, Dialysis Disequilibrium syndrome has become rare. Patients with preexisting neurologic damage, head trauma or stroke are more vulnerable to this complication. We present a case report of a patient who had a “near miss” safety event after starting intermittent hemodialysis in the setting of a traumatic brain injury (TBI). His deterioration on dialysis is not fully explained by the current leading theory on the pathogenesis of this syndrome (theory of “reverse urea effect”) implying that either a multifactorial etiology is implicated or that impaired cerebral autoregulation may play a more significant role than previously believed.

Case Description: A 70 year old male was hospitalized after being involved in a motor vehicle accident. He suffered multiple injuries including cardiac arrest from which he was revived. TBI and acute kidney injury (AKI) requiring initiation of hemodialysis using the new start protocol. Trends of intracranial pressure (ICP), cerebral perfusion pressure (CPP) and heart rate (HR) before, during and after intermittent hemodialysis showed clear worsening of these parameters after beginning dialysis with subsequent improvement after discontinuing dialysis (Figure).

Discussion: This case points toward a change in the pattern of presentation of DDS, requiring new guidelines focusing on dialyzing vulnerable TBI patients. These guidelines include early initiation of dialysis, selection of CVVH as preferred modality given reduced dialysis dependency in AKI patients, adjusting dialysis settings to minimize urea clearance per unit time, utilizing ICP monitoring when available, using hypertonic saline to maintain serum sodium > 155 mmol/L and avoiding central lines on contralateral side to an internal jugular dialysis catheter to preserve cerebral venous return. The establishment of these guidelines may help reduce the risk of poor outcomes in this population.

Rescue Hemodialysis for Paroxysmal Hyperammonemic Encephalopathy Sans Cirrhosis Ativa Chachar, Brian Simba, Waqas Memon, Graham T. Gipson, Niraj R. Kothari. Virginia Commonwealth University, Richmond, VA.

Introduction: Ammonia is a product of protein catabolism that is converted to less toxic urea before excretion by the kidneys in urine. Hyperammonemia can be associated with coma, cerebral edema, and herniation. Ammonia levels do not correlate linearly with encephalopathy, especially in patients with chronic hyperammonemia.

Case Description: A 63-year-old female with a history of Roux-en-Y gastric bypass surgery > 20 years ago and malnutrition presented with three weeks of encephalopathy. Initial workup, including head CT and EEG, was negative. She was noted to have normal liver function and an elevated ammonia level of 110 μmol/L which was not responsive to conventional therapies. Continuous veno-venous hemodialysis (CVVHD) was successfully employed to prevent neurologic catastrophes. After discontinuation of CVVHD, she experienced recurrence of hyperammonemic encephalopathy prompting the use of hemodialysis (HD) intermittently throughout the hospital stay. We believe this patient’s paroxysmal hyperammonemic encephalopathy is a consequence of progressive metabolic disarray following gastric bypass surgery coupled with an exceptionally poor diet.

Discussion: There is historical precedent for extracorporeal blood purification in hyperammonemic states, typically related to pediatric inborn errors of nitrogen metabolism or fulminant liver failure with hyperammonemic encephalopathy. Recurrent hyperammonemic encephalopathy in the absence of liver failure has been described after bariatric surgery. Ammonia, a small, water-soluble molecule without significant protein binding, is cleared well with dialysis. Due to a large volume of distribution, ammonia levels frequently rebound after discontinuation of HD. Intermittent HD allows for the highest rate of reduction of ammonia, though CVVHD may be superior in severe encephalopathy. This patient’s ongoing need for HD, either chronically or episodically during decompensations, remains to be determined.

A Case of Polysulfone Membrane-Induced Thrombocytopenia Ivan L. Claudio-Gonzalez, Sarah Nicholls, James T. Someren, Susan M. Wall. Emory University Emory College of Arts and Sciences, Atlanta, GA.

Introduction: The development of biocompatible hemodialysis membranes has been a major advance in the treatment of renal failure. Newer, synthetic membranes such as polysulfone are considered to be more biocompatible than the older cuprophane or cellulose membranes. However, polysulfone dialyzers can interact with and thereby

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
reduce platelet counts. A few isolated case reports have observed thrombocytopenia in patients after initial dose adjustment. Although etiology remains unclear, there was suspicion for drug-induced liver injury caused by hydralazine and high dose statin. Patient had a planned liver biopsy however he decompensated rapidly, and had a cardiac arrest which led to his demise.

**Life Finds a Way: Two Successful Pregnancies in a Woman Without Kidneys**

Anna K. Curtis, 1 Christian C. Lamb, 2 Sarah Atallah, 1 Amit J. Patel. 1 University of Missouri Kansas City, Kansas City, MO; 2US Army Brooke Army Medical Center Medical Library, Fort Sam Houston, TX, USA.

**Introduction:** Bilateral nephrectomy is a controversial and rarely used approach to control refractory hypertension in patients with anuric end-stage renal disease (ESRD) who require dialysis. This extreme measure results in complete dependence on dialysis to maintain metabolic homeostasis. This procedure has become rare due to advancements in pharmacotherapy.

**Case Description:** The patient is a 31-year-old African American woman with aHUS condition during her first pregnancy and was initiated on biweekly infusions of eculizumab after delivery. Seven months after delivery, she underwent bilateral nephrectomy to control her hypertension. Two years following nephrectomy, she presented to the Emergency Department (ED) with dyspnea. Her urine β-HCG was positive and ultrasonography confirmed an intrauterine pregnancy. Throughout this pregnancy, she required iHD six days weekly. She delivered at 27 weeks gestation and was transferred to the neonatal intensive care unit (NICU) where her baby was discharged home in healthy condition. Two years later, the patient presented to the ED and was again found to be pregnant. She was managed with HD six days weekly. This child was born at 23 weeks gestation and was discharged home after several weeks in the NICU.

**Discussion:** The challenge with this case is the need to distinguish aHUS from hypertension and atypical hemolytic uremic syndrome (aHUS). She was diagnosed with aHUS condition during her first pregnancy and was initiated on biweekly infusions of eculizumab after delivery. Seven months after delivery, she underwent bilateral nephrectomy to control her hypertension. Two years following nephrectomy, she presented to the Emergency Department (ED) with dyspnea. Her urine β-HCG was positive and ultrasonography confirmed an intrauterine pregnancy. Throughout this pregnancy, she required iHD six days weekly. She delivered at 27 weeks gestation and was transferred to the neonatal intensive care unit (NICU) where her baby was discharged home in healthy condition. Two years later, the patient presented to the ED and was again found to be pregnant. She was managed with HD six days weekly. This child was born at 23 weeks gestation and was discharged home after several weeks in the NICU.

**Discussion:** The challenge with this case is the need to distinguish aHUS from hypertension and atypical hemolytic uremic syndrome (aHUS). mutant surface proteins. The detectable HBsAg is thus a mixture of wild type and variants, whereas the detectable anti-HBs are only against wild type viruses. These patients are still in the chronic HBV infection category as they typically do not progress to active disease, however acute infection is possible. Given our patient’s low HBV DNA (< 10,000 IU/ml) and mild transaminitis, she fits the chronic, inactive carrier state. Appropriate infection control precautions for HD were taken as established for chronic HBV infection patients.

Case Description: A 47-year-old male with hypertension presented to the emergency department (ED) with complaints of abdominal pain. Initial laboratory studies were concerning for thrombocytopenia and acute renal failure. The patient was urgently admitted to the Intensive Care Unit (ICU) and hemodialysis was initiated. Approximately 20 minutes into the hemodialysis session, the patient became unresponsive. A right eye gaze deviation and right-sided fasciculations of the upper and lower extremities were observed. Hemodialysis was discontinued and a head CT was obtained. Imaging revealed pontine edema with mass effect and cerebellar tonsillar herniation (Figure 1). Intravenous mannitol was initiated. Within 30 minutes of initiation of the mannitol infusion, the right-sided fasciculations and gaze palsy. The follow-up head magnetic resonance imaging (MRI) showed resolution of the midline shift and tonsillar herniation.

Discussion: Historically, even with swift intervention, cerebral herniation due to DDS carries a grim prognosis. Current guidelines stress the importance of preventative measures and the use of IV mannitol if cerebral herniation is suspected. The case reported herein is the first documented account of reversal of the clinical and imaging findings of tonsillar herniation secondary to DDS using intravenous mannitol.

Discussion: Thrombocytopenia is frequently seen in critically ill patients, and it is often difficult to pinpoint a specific cause. In our case, gross and microscopic evidence of platelet clumping were seen in the CRRT filter coincident with thrombocytopenia, which remitted when off and then recurred when restarted on CRRT. Care teams should examine the dialyzer carefully when there is unexplained thrombocytopenia, as platelet activation and trapping within the circuit may be responsible.

Case Description: A 47-year-old male with hypertension presented to the emergency department (ED) with complaints of abdominal pain. Initial laboratory studies were concerning for thrombocytopenia and acute renal failure. The patient was urgently admitted to the Intensive Care Unit (ICU) and hemodialysis was initiated. Approximately 20 minutes into the hemodialysis session, the patient became unresponsive. A right eye gaze deviation and right-sided fasciculations of the upper and lower extremities were observed. Hemodialysis was discontinued and a head CT was obtained. Imaging revealed pontine edema with mass effect and cerebellar tonsillar herniation (Figure 1). Intravenous mannitol was initiated. Within 30 minutes of initiation of the mannitol infusion, the right-sided fasciculations and gaze palsy. The case reported herein is the first documented account of reversal of the clinical and imaging findings of tonsillar herniation secondary to DDS using intravenous mannitol.

Introduction: Dialysis disequilibrium syndrome (DDS) is a complication of hemodialysis. Symptoms can include headaches, seizures, and even death. An extensive literature review yielded thirteen documented reports of patients suffering from cerebral herniation secondary to DDS with poor outcomes.

Case Description: A 47-year-old male with hypertension presented to the emergency department (ED) with complaints of abdominal pain. Initial laboratory studies were concerning for thrombocytopenia and acute renal failure. The patient was urgently admitted to the Intensive Care Unit (ICU) and hemodialysis was initiated. Approximately 20 minutes into the hemodialysis session, the patient became unresponsive. A right eye gaze deviation and right-sided fasciculations of the upper and lower extremities were observed. Hemodialysis was discontinued and a head CT was obtained. Imaging revealed pontine edema with mass effect and cerebellar tonsillar herniation (Figure 1). Intravenous mannitol was initiated. Within 30 minutes of initiation of the mannitol infusion, the right-sided fasciculations and gaze palsy. The follow-up head magnetic resonance imaging (MRI) showed resolution of the midline shift and tonsillar herniation.

Discussion: Historically, even with swift intervention, cerebral herniation due to DDS carries a grim prognosis. Current guidelines stress the importance of preventative measures and the use of IV mannitol if cerebral herniation is suspected. The case reported herein is the first documented account of reversal of the clinical and imaging findings of tonsillar herniation secondary to DDS using intravenous mannitol.
PO1203

Association Between Serum Alkaline Phosphatase Levels and Stroke Risk in Patients Receiving Maintenance Hemodialysis: The Q-Cohort Study

Hiromsa Kitamura,1 Shunsuke Yamada,1 Hiroto Hiyamuta,1 Ryuuke Yotsue,2 Masatomo Taniguchi,1 Masanori Tokumoto,3 Kazuhiko Tsuyama,4 Yoshihiko Kanno,4 Takanari Kitazono,5 Fukuoka, Japan; 6Munakata Medical Association Hospital, Munakata, Japan; 7Fukuoka Renal Clinic, Fukuoka, Japan; 8Fukuoka Shika Daigaku, Fukuoka, Japan; 9Nara Kenritsu Ika Daigaku, Kashihara, Japan.

Background: Elevated serum alkaline phosphatase (ALP) levels have been associated with increased risks of all-cause and cardiovascular mortality in patients receiving hemodialysis (HD). However, little is known about the impacts of serum ALP levels on the occurrence of stroke, including brain hemorrhage and brain infarction. This study aimed to explore the association between serum ALP levels and brain hemorrhage or brain infarction separately in HD patients.

Methods: A total of 3,497 maintenance HD patients registered in the Q-Cohort Study, a multicenter observational cohort study in Japan, were examined. The primary outcomes were the first-ever incidence of either brain hemorrhage or brain infarction during the follow-up period. The covariate of interest was serum ALP levels. Patients were divided into tertiles based on the serum ALP levels at baseline [ALP (U/L): T1, <69.3; T2, 69.3–98.4; T3, >98.4]. The risks for brain hemorrhage or brain infarction were estimated using a Cox proportional hazards model and a Fine-Gray proportional subdistribution hazards model with all-cause death as a competing risk. The restricted cubic spline model was used to plot the multivariable-adjusted association between serum ALP levels and hazard ratios (HRs) and 95% confidence intervals (CIs) for brain hemorrhage or brain infarction.

Results: During the follow-up period of four years, 89 patients developed follow-up brain hemorrhage and 195 patients developed brain infarction. The risk of brain hemorrhage in the highest tertile (T3) was significantly higher than that in the lowest tertile (T1): multivariable-adjusted HR [95% CI], 1.93 [1.15–3.35], subdistribution HR, 1.91 [1.10–3.30]. Furthermore, restricted cubic spline curves showed that higher serum ALP levels were significantly and incrementally associated with an increased risk for brain hemorrhage. In contrast, no significant association was identified between serum ALP levels and the risk of brain infarction.

Conclusions: Higher serum ALP levels were associated with an increased risk of brain hemorrhage in patients receiving maintenance HD. Our results suggest that ALP might play some roles in the pathogenesis of brain hemorrhage in HD patients.

Tailoring the Dialysis Prescription in Patients at Risk for Dialysis Disequilibrium Syndrome

Baylor University Medical Center at Dallas, Dallas, TX.

Introduction: The dialysis disequilibrium syndrome (DDS) is a potentially fatal, preventable syndrome in uremic patients treated with dialysis. Urea kinetics can be used to tailor the dialysis prescription to a goal urea reduction ratio (URR) of less than 40%.

Case Description: A 22-year-old female patient presented to the emergency department with severe renal failure and a failing transplant secondary to noncompliance with medications for 1 year. Serum creatinine was 32 mg/dl, blood urea nitrogen (BUN) 226 mg/dl, potassium 9.2 meq/l and serum total carbon dioxide content 6 meq/l. Intermittent hemodialysis was started using a dialyzer with a mass transfer coefficient (Kt/V) of 0.5. Her weight was 60 kg. After 1.5 hours of dialysis, the patient developed generalized seizures secondary to brain edema. BUN 6 hours after dialysis was 137 mg/dl. She was declared brain dead 4 days later.

Discussion: The dialysis disequilibrium syndrome results from osmotic shifts between the blood and the brain compartments. Rapid changes in BUN are known to contribute, but other osmotic substances may contribute to the development of DDS as well. Patients at risk for DDS include those with very elevated BUN, concomitant hypernatremia, metabolic acidosis, and those with low total body water volumes. There is no absolute cut off value for URR that is guaranteed to prevent DDS. However, a URR of 40-45% over 2 hours and a total decrease in serum osmolality no more than 24 mOsm/kg per 24 hours are recommended. A simplified relation between Ki/V and URR is provided by the equation: ki/V = In (1-URR). A URR of 40% is roughly equivalent to a ki/V of 0.5. Thus, targeting a ki/V of 0.5 is a reasonable goal for the initial treatment. ki can be plotted on the nomogram in figure 1 (used with permission) for a given dialyzer koA and blood flow rate. Using a 400 koA dialyzer at a blood flow rate of 200 ml/min for 120 minutes in a patient with a V of 30 l, the estimated ki/V is 0.45 and the estimated URR is <40%.

When low-efficiency dialyzers are not available, other measures to lower clearance such as reversing dialysis lines or CRRT need to be considered. Sodium modeling and mannitol may also mitigate rapid changes in osmolality.
PO1205
Ultrafiltration Accuracy of the Tablo® Hemodialysis System During 24-Hour Therapy
Michael A. Aragon, Amy Kerdock, Josh Schumacher. Outset Medical, Inc., San Jose, CA.

Background: Ultrafiltration (UF) accuracy is vital to ICU management of patients with kidney failure. Replacement options include intermittent hemodialysis, continuous renal replacement therapy and low efficiency dialysis. Regardless of therapy, clinicians need confidence that the dialysis device chosen will accurately remove volume to achieve the prescribed goal. The Tablo Hemodialysis System is an all-in-one system with on-demand water purification and dialysate production indicated for use in clinic, hospital, and home settings. Prior reports have demonstrated UF accuracy over a wide range of conditions up to 12 hours. The objective was to report on the accuracy of Tablo’s unique flow balancing technology over 24 hours of continuous therapy utilizing HD, UF, isolated ultrafiltration, or a sequential therapy modes.

Methods: Bench testing was conducted to evaluate UF accuracy across clinically relevant parameters during a simulated 24-hour treatment with a single cartridge. Ten distinct treatment conditions were created. Effluent was weighed and compared to the prescribed goal at treatment completion. Treatment conditions included: mode (HD, UF, Only, and Sequential therapy (HD—UF only, UF only)—UF only), blood flow rates (Qb) from 150-400 ml/min, dialysate flow rates (Qd) from 50-300 ml/min, UF goals from 0 to 1.9 l/hr, and low to high venous and arterial pressure.

Results: Thirty simulated treatments were performed. Twenty-four treatments were performed with Qb from 150-250ml/min and 6 were performed with Qb 300 or greater. Twenty-seven treatments had fluid removal goals between 250ml/hr to 2000ml/hr and 3 treatments were performed with a UF goal of 0ml/hr. Ninety-three percent of treatments were within 20ml/hr of accuracy (~ 400ml of total error). Sixty-seven percent of treatments were within 10ml/hr of the prescribed UF goal (~ 240ml of total error). Blood flow and UF rate showed correlation to UF accuracy with minimum error between Qb 200-300ml/min and UF rate between 0-1000ml/hr. There was no impact to UF accuracy from treatment mode or dialysate flow rate.

Conclusions: Tablo’s proprietary flow balancing technology maintains a high level of UF accuracy across a wide range of 24-hour treatment prescriptions. Optimal accuracy was noted at parameters typically prescribed in continuous renal replacement therapy.

PO1206
Unfavorable Vintage: Dialysis-Related Amyloidosis Discovered at Transplant
Shilpi Shah, Angelina Edwards. University of Texas Health Science Center at Houston, Houston, TX.

Introduction: Despite its life-sustaining potential, prolonged dialysis and inadequate clearance of middle molecules can have untoward consequences. Largely underdiagnosed, dialysis-related amyloidosis (DRA) is an effect of prolonged dialysis vintage. We present a case of DRA in a patient with nearly 25 years of dialysis-dependence, diagnosed histologically at time of transplant.

Case Description: A 60-year-old man with hypertension, on dialysis since 1996, presented for renal transplant evaluation. Hematology labs showed normal serum protein electrophoresis but elevated free kappa (κ) to lambda (λ) light chain ratio of 10.9. Bone marrow biopsy was normal but patient was found to have elevated serum β2 microglobulin (β2-m) at 23.6 μg/mL. He was listed and immediately received a deceased donor transplant. Intraoperatively, biopsy of a large iliac lymph node was submitted which showed Congo Red positive staining by light microscopy for amyloid but was negative for serum amyloid A (SAA) and κ light chain and λ light chain (AL). Further testing identified the amyloid protein as κ light chain (κ-chain). Retrospective history revealed he had suffered years of joint pain, especially in his shoulders, and had bilateral carpal tunnel surgery. He was chronically dependent on hydrocodone but since transplant he no longer experienced pain. Nadir serum creatinine was 1.3 mg/dl and repeat β2-m level decreased to 4.1 μg/mL.

Discussion: Present on all cell surfaces, β2-m is freely filtered then reabsorbed and catabolized in proximal tubules. Prolonged reduction in glomerular filtration leads to accumulation and deposition of amyloid fibrils particularly in periarticular structures, leading to debilitating arthritis. Although no precise treatment for DRA exists, transplantation leads to renewed clearance and dramatic improvement in symptoms. This case reiterates the importance of remaining alert for such diseases in patients with prolonged dialysis vintage.

PO1207
Baclofen Pump Causing Electroencephalography Seizures
Niraj K. Yadav, Janame J. Kottekay, Josephine Abraham. University of Utah Health, Salt Lake City, UT.

Introduction: Baclofen is a centrally acting muscle relaxant that inhibits monosynaptic and polysynaptic reflexes at the spinal cord level resulting in relief of muscle spasticity. Baclofen is commonly used orally and intrathecally. We present the case of a patient on intrathecal baclofen through a pump presenting with respiratory failure and seizures.

Case Description: A 59 year old male with Atrial fibrillation, right MCA stroke and resultant left hemiparesis was under treatment with intrathecal baclofen through a pump. He underwent fluoroscopy guided pump refill and was found unresponsive later that night. EMS was called and he was intubated en route to the ED. He was hypotensive with recorded blood pressures 48/26-84/45 mm Hg. He had two seizures in ED and received IV lorazepam. Initial labs showed lactate 11.9 mmol/l, PCO2 30 mm hg, pH 6.9 and creatinine 2.0 mg/dl. Urine was positive for opiates and benzodiazepines. CT head did not show acute changes and was consistent with previously seen right cerebral encephalomalacia. He received intravenous fluids and creatinine improved to 0.9 mg/dl with resolving oliguria. Electroencephalography(EEG) was concerning for status epilepticus and he was transferred to our center for further management. Baclofen level was 0.13 mg/ml. The acute encephalopathy, status epilepticus and respiratory failure were attributed to baclofen toxicity and nephrology was consulted for emergent dialysis. He underwent a 4 hour hemodialysis session using a Nipro 17H filter and maximum blood flow with dialysate flow at 600 ml/min. A post hemodialysis baclofen level was undetectable. Continuous EEG on the day after the hemodialysis session had improved.

Discussion: Role of hemodialysis in life threatening baclofen toxicity in a patient with AKI and improved renal function is not well described. Baclofen is small molecule with a molecular weight of 213g/mol that is primarily excreted unchanged by the kidneys with an apparent volume of distribution of 59 liters and is 30 percent protein bound. A single hemodialysis session may be adequate to clear baclofen in patients without advanced CKD. It is pertinent to recognize baclofen as possible cause of encephalopathy and seizures and consider hemodialysis in severe cases.

PO1208
Hep B or Not Hep B: The Mystery of Hepatitis B Serology in a Dialysis Patient
Wala Abusalah, Heather R. LeKowitiz. Newark Beth Israel Medical Center, Newark, NJ.

Introduction: Dialysis patients are susceptible to viral infections due to impaired cellular immunity. HepB remains a major problem in these patients. Hemodialysis, transfusions, frequent admissions and surgery, all increase risk of infections. While the introduction of vaccines and infection control measures have limited the spread of hepatitis infection within dialysis facilities, outbreaks occur and prevalence remains high. Serology testing is used to screen and identify infected patients. Interpretation of these serologies, as in our case, can be challenging.

Case Description: 83 y/o female with HTN, DM and ESRD on HD. Admitted from a NH with viral prodrome and tested +ve for COVID-19. Nephrology consult was requested for maintenance HD. She had HBsAg assay which came back positive. Full Hep B panel showed HBsAb +ve, HBCAB +ve (IgM), HepB DNA PCR –ve, HBeAg & Ab-ve. Surprisingly, old records showed HBsAg positivity 6 months prior to admission and the rest of the serology was identical to this admission. Within the last 6 months, she have had multiple HBsAg tests that all came back -ve. Up to this point, she wasnt receiving HD in dedicated HepB machines. Decision was to apply segregation and to contact the health department to track down all patients that were dialyzed with the same machines.

Congo Red Staining in Vessel Wall Demonstrates Amyloid Deposition
Discussion: The prevalence of HepB in dialysis patients is 1%. Cirrhosis, which can result from HepB, is associated with a 35% increased mortality in dialysis patients. To prevent transmission, measures include barrier procedures, routine screening, disinfection and vaccination. Failure to use dedicated machines may increase incidence of HepB. Serology can identify infected patients. Screening consists of HBsAg, anti-HBs, and anti-HBc. If HBsAg is positive, further testing is recommended to guide clinicians in such cases. In our patient, we decided to consider her a chronic HepB patient for the purpose of dialysis segregation, however, she does not meet criteria for chronic HepB and will unlikely require treatment.

PO1209
Temporal Change in Formula-Derived Creatinine Index as a Surrogate for Lean Muscle Mass Correlates Well with Change in Post-Hemodialysis Weight but Not with the Volume of Urea Distribution
Xiao Ling, Andrew I. Chin. University of California Davis, Sacramento, CA.

Background: In hemodialysis (HD) patients, creatinine kinetic modeling to derive a Creatinine Index (CI) is a measure of lean muscle mass. Loss of lean muscle mass is associated with poor outcomes. This modeling process is complex and not routinely performed. A simplified formula for CI was developed in a previous study. We sought to determine if temporal change in the calculated CI using the simplified formula correlated with more commonly available data used in routine clinical care of HD patients.

Methods: We retrospectively queried long-term HD patients without residual function who had available serum creatinine, urea kinetic, and clinical care data at least 18 months over a 24 month span. We used the simplified formula previously published for creatinine index: CI (mg/kg/day) = 16.21 + 1.12x [1 if male, 0 if female] – 0.06x age (yrs) – 0.08x spKt/Vurea + 0.009x Creat (pre-dialysis). Regression lines were created for each parameter over the 24 months. Slopes in the change of CI, post-HD wt, urea generation rate (G) and kinetic modeled distribution of urea (V) were compared by paired t-tests.

Results: We included 455 long-term HD patients without residual renal function (we measure this routinely) with at least 18 out of 24 months of complete data. Mean HD vintage was 46 months. We found the slope of CI to be poorly correlated to V or G, but did compare favorably to change over time slopes for V and post-HD weight.

Conclusions: In this retrospective analysis in HD patients, the temporal change of calculated Creatinine Index as an indicator of lean muscle mass compared best with change in post-HD weight. While the volume of urea distribution is related to body composition, the change V over time surprisingly did not mirror that of calculated CI. We also compared the slope of V to that of post-HD weight and found a strong association. The simplified equation for CI, applied to our population in Northern California, may correlate poorly with lean muscle mass.

PO1210
Crit-Line Blood Volume Monitoring in a Community Hemodialysis Unit
Carl E. Dukes, Carl E. Dukes, MD PA, San Antonio, TX.

Background: A quality improvement (QI) project on fluid management using Crit-Line Blood Volume Monitors (CLM) was conducted by a nephrologist in one community hemodialysis unit in Texas. A goal of the QI project was to decrease the blood pressure medication burden to facilitate better ultrafiltration during treatment. This analysis examines the changes in blood pressure (BP) medication (Med) and associated changes in post-dialysis weight and systolic BP.

Methods: Chronic HD patients of the nephrologist leading the QI project, receiving care at a specific Crit-Line Blood Volume monitoring site, were included in this analysis. Time was divided into 1-month Baseline, 3-month training period, and 7-month follow-up period. The physician reviewed each Crit-Line session and directed the staff to challenge the patient’s weight based on a positive refill curve. In order to facilitate further fluid removal, the vasodilating anti-hypertensive medications were discontinued. Thereafter, the other anti-hypertensive medications such as beta-blockers and RAASI agents were reduced or discontinued.

Results: Patients (n=38) were on average 63 years old, with a HD vintage of 5 years and BMI of 27.44 kg/m^2. 58% of patients (n=22) were females. Percentage of patients identified as black/African American and 40% identified as Hispanic/Latino. Most patients (74%) had pre-HD systolic BP at baseline in the hypertensive range. 41 patients had BP Med information. During follow-up, 16.7% of patients discontinued BP med, 28.6% reduced BP med pills/day, 4.8% increased BP med pills/day, and the remaining had unchanged BP med. Changes in post and pre HD systolic BP and post-HD weight are presented in the table.

Conclusions: In a single-center QI project addressing fluid management through relative blood volume monitoring, 46% of patient were able to reduce (28.6%) or discontinue (16.7%) their BP medication. Patients able to discontinue the medications, had the largest decrease in post-HD weight.

Use of Triferic and Outcomes of Hemodialysis-Dependent Patients: Initial Analysis Using 2016-2017 USRDS

Yi Zhang,1 Marc L. Hoffman,2 Ajay Gupta,3 *MTTP, Bethesda, MD; 2Rockwell Medical Inc, Wixom, MI

Background: Use of iron oxide nanoparticles (IONP) to replace iron losses in CKD-HD patients has been associated with increased risk of infections. We have examined patient outcomes with ferric pyrophosphate citrate (FPC; Triferic®), a novel iron compound delivered via the hemodialysate, relative to the general U.S. hemodialysis patient population receiving IONPs in US Renal Data System (USRDS). A single outpatient free-standing hemodialysis center with ~57 adult CKD-HD patients between 2016 and 2017, converted to FPC in January 2017. Unadjusted all-cause and infection related hospitalizations and mortality were examined pre-FPC and post-FPC and compared with the general USRDS data during the same period.

Methods: USRDS methods were utilized for calculation of the crude hospitalization and mortality rates. For each calendar year study, the period at risk begins at the later date of either January 1 or day 91 of ESRD, and censoring occurs at death, or December 31.

Results: Consistent with findings from USRDS, unadjusted all-cause hospital and mortality rates for the general ESRD population in 2016 were 2.12 hospital admissions, 16.0 hospital days, 0.35 infection-related admissions, 3.05 infectious hospitalization days per patient year, and 164 deaths per 1,000 patient years. Notably, patients in 2017 exhibited similar rates compared to 2016. In contrast, patients treated in the facility using Triferic experienced a reduction in both mortality and infection-related hospitalizations. Specifically, mortality rates reduced 58% from 101 per 1,000 patient-years in 2016 to 42 in 2017 and infectious hospital admission reduced 73% from 0.49 admissions per patient-year in 2016 to 0.13 admissions in 2017. Furthermore, infection-related hospital days reduced 82% from 3.86 days per patient-year in 2016 to 0.71 in 2017.

Conclusions: This observational cohort study suggests that use of ferric pyrophosphate citrate as an iron replacement therapy is associated with reduction in all cause and infection-related hospitalizations and mortality. Further analysis is needed to confirm the findings from this initial analysis after controlling a variety of patient case-mix factors and dialysis center characteristics with a larger sample size.

PO1214

Association of Geriatric Nutritional Risk Index with Decline in Residual Kidney Function in Incident Hemodialysis Patients

Hiroshi Kimura,1 Cachet Wenziger,2,3 Jui-Ting Hsiung,1 Connie Rhee,1 Elani Streja,1 Csaba P. Kovovsky,1,2 Kamyar Kalantar-Zadeh,1 Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; 2The University of Tennessee Health Science Center College of Medicine, Memphis, TN; 3Memphis VA Medical Center, Memphis, TN

Background: Malnutrition is highly prevalent and is a significant contributor to adverse outcomes among hemodialysis patients. Residual kidney function (RKF) provides effective and continuous clearance of both small and middle molecules, plays an important role in nutritional status. However, the impact of malnutrition on the decline of RKF has not been well studied. The objective of this study was to investigate the association of baseline Geriatric Nutritional Risk Index (GNIr) with a decline in RKF over 1 year after dialysis initiation among hemodialysis patients.

Methods: We included 6,649 hemodialysis patients who initiated dialysis treatment in a large United States dialysis organization between January 1, 2007, and December 31, 2011. Rapid decline in RKF was defined as the percent change in residual urea creatinine (KRU) greater than 50% per year. The associations of GNIr with decline in RKF were retrospectively examined across three strata of GNIr [low (GNIr <92), middle (GNIr 92-98), high (GNIr >98) GNIr group] using logistic regression models adjusted for clinical characteristics and laboratory values. Then, we used the linear mixed-effects model allowing for a random intercept and slope using unstructured covariance matrices to estimate the magnitude and decline of RKF over 1 year according to the GNIr groups.

Results: The median GNIr and baseline KRU were 107.7 and 3.4 ml/min/1.73m², respectively. Lower GNIr was associated with a smaller proportion of diabetes, lower baseline KRU, BMI, nPCR, and serum albumin. Adjusting for patient’s differences, there was an inverse relationship between lower GNIr and a higher odds of rapid decline in RKF [adjusted odds ratio = 1.97 (1.61-2.41) and 1.48 (1.25-1.76) for low and middle GNIr groups, reference: high GNIr group]. KRU trajectories showed greater KRU decline over time in lower GNIr.

Conclusions: Lower GNIr was associated with a rapid decline in RKF, especially in the first 3 months after transitioning to hemodialysis.

PO1215

Prognostic Nutritional Index and Mortality Among Maintenance Hemodialysis Patients

Yoshikazu Miyasato,1 Cachet Wenziger,1 Jui-Ting Hsiung,1 Elani Streja,1 Connie Rhee,1 Csaba P. Kovovsky,1,2 Kamyar Kalantar-Zadeh,1 Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; 2The University of Tennessee Health Science Center College of Medicine, Memphis, TN; 3Memphis VA Medical Center, Memphis, TN

Background: Malnutrition and inflammation are associated with the mortality of dialysis patients. Prognostic Nutritional Index (PNI), which is composed of serum albumin levels and total lymphocyte count, has been suggested as a simple and useful prognostic marker in postoperative cancer patients. We evaluated the usefulness of PNI for predicting mortality in hemodialysis patients.

Methods: This retrospective cohort study included the patients who started hemodialysis in a large U.S. dialysis organization from 2007 to 2011. We examined the association between the quartiles of PNI and mortality using Cox regression model. Besides, we compared the mortality predictability of PNI and its components (serum albumin levels and total lymphocyte count) using the receiver operating characteristic curve (AUROC), net reclassification improvement (NRI) and integrated discrimination improvement (IDI).

Results: The mean age (and standard deviation) of total 101,616 patients was 63±15 years, and 26,622 died during the median follow-up period of 1.4 years. Higher quartiles of PNI were associated with lower mortality; case-mix adjusted hazard ratios (95%CI) were 0.66 (0.64-0.68), 0.49 (0.48-0.51), 0.35 (0.34-0.37) among patients with PNI 39.5-43.1, 43.1-46.6, and 46.6-< (reference: PNI <39.5). PNI showed higher mortality predictability than serum albumin levels and total lymphocyte count; AUROC (95%CI); 0.74 (0.74-0.750), 0.743 (0.739-0.748), 0.711 (0.706-0.716), NRI (95%CI); 0.436 (0.418-0.454), 0.410 (0.392-0.429), 0.174 (0.156-0.192), IDI (95%CI); 0.034 (0.023-0.045), 0.032 (0.030-0.033), 0.003 (0.003-0.004), respectively. The difference in the AUROC was statistically significant between PNI and its components. In subgroup analysis PNI well predicted mortality in younger than 75 year-old patients.

Conclusions: Higher PNI was associated with lower mortality in hemodialysis patients. Compared with serum albumin levels and total lymphocyte count, PNI seems to be a useful predicting marker of mortality.

Figure: Mortality risk associated with PNI

PO1216

Hemodialysis-Assisted Management of Severe Hypoglycemia

Anirudh R. Gong, Michael J. Ross, Corinne Levitus, Montefiore Medical Center Jack D Weiler Hospital, Bronx, NY

Introduction: Many medications are cleared by hemodialysis (HD)but the effectiveness of clearance depends on drug characteristics including molecular weight, protein binding, volume of distribution and water solubility. The effectiveness of HD in clearing endogenous insulin has not been well studied. We present a case of refractory hypoglycemia in a patient with ESRD, which was likely due to ciprofloxacin (cipro)-induced insulin release that was successfully managed with HD.

Case Description: A 77 year old man with ESRD receiving chronic HD and no previous history of diabetes, was admitted for management after he pulled out his tunneled HD catheter. The patient had HCV-induced cirrhosis and had been receiving outpatient ciprof for spontaneous bacterial peritonitis prophylaxis. Initial electrolytes did not warrant urgent HD so was admitted to medical floor pending new HD catheter placement. During first several days after admission, the patient had persistently low blood glucose (BG) despite not receiving any hypoglycemic medications and receiving continuous infusion of dextrose solution and repeated boluses of 50% dextrose. Prior to receiving HD, serum insulin was elevated at 42 nl/ml and 148 nl/ml despite hypoglycemia and c-peptide was 40mg/ml consistent with excessive endogenous insulin secretion. The patient was suspected to have cipro-induced hyperinsulinaemia. Emergently HD was performed to
increase clearance of ciprofloxacin and insulin. After 1 HD session, insulin level decreased to 14.6 with improved BG levels. The patient was subsequently managed on octreotide with stable BG levels without further IV dextrose administration.

Discussion: Fluoroquinolones have been associated with hypoglycemia in diabetic and non-diabetic persons. Animal studies have suggested fluoroquinolones can block the ATP-sensitive K+ channels in B-cells and increase the insulin secretion. Although our patient had a history of cipro-induced endogenous insulin secretion, it is likely that this reduced insulin in our patient by reducing cipro-induced endogenous insulin secretion and via clearance of insulin.

Methods: Twelve HD patients had 3 low sodium meals/day (Mom Meals, Inc) delivered to their homes for 4 weeks. On average they were on 17 medicines among which NRS-T (mean = 1.2), NRS-X (mean = 2.2; p<0.05) significantly reduced nausea and vomiting scores. Thirst and xerostomia were measured at three time points: baseline (BL), after 4 weeks of low sodium meals (INT), and 4 weeks post-meals (POST[SAA1]).

Results: Patients’ mean thirst during the day, thirst after HD, thirst’s influence on social life, dry mouth feeling, total XI, NRS-T, NRS-X scores were significantly lower between INT compared to BL (MeansSD scores from BL to INT: 3.1±2.1; 3.5±2.2; 1.3±0.9; 2.9±1.9 to 1.5±0.5; 28.5±12 to 19.3±3 on the scale of 1-5; 6.3±2.8 and 5.5±3.1 on the scale of 0-10, respectfully; p<0.05). The score of thirst’s influence on social life and NRS-T were significantly higher in POST compared to INT (MeansSD scores from INT to POST: 1.3±0.9 to 1.7±1; 2.8±2 to 4.5±2; p<0.05). NRS-T is significantly lower in POST compared to BL (MeansSD scores from BL to POST: 6.3±4 to 4.5±2; p<0.05).

Conclusions: Multiple domains of subjective thirst and xerostomia decreased after 4 weeks of home-delivered low sodium meal consumption but generally returned close to baseline 4 weeks after cessation of the meal delivery. The feasibility and efficacy of long-term meal provision for reducing thirst, xerostomia, and chronic volume overload need to be further evaluated in future studies.

POI1221

**Surprise Question: A Mortality Predictor in Hemodialysis Patients?**

**Patrícia Valerio,1,2 Ana Farinha,1,2 Centro Hospitalar de Setubal EPE, Setubal, Portugal; 3Fresenius Medical Care Portugal, Setubal, Portugal.**

**Background:** Surprise question (SQ), used in Palliative Care (PC) and Oncology, has already been tested to assess prognosis in several chronic diseases. In Portugal, as worldwide, an elderly and fragile hemodialysis (HD) population has been emerging. Tools to screen patients who might benefit from end of life care would be useful. The present study aims to test SQ mortality prediction value in a Portuguese cohort of HD patients, answered by nephrologists and nurses. The study ran between November 2018 and November 2019.

**Methods:** We design an observational prospective study. All patients on regular HD for more than 3 months were included. Experienced nephrologists and dialysis nurses, but without PC training, answered SQ at the beginning of the follow-up. We collected demographic, clinical and analytical data. At the end of follow-up, we analyzed evolution during follow-up and survival status.

**Results:** We included 194 patients, median age of 69.9 y-o. Median age-adjusted Charlson Comorbidity Index (aCCI) was 6 (5-8). Table 1. After one year of follow-up 22 (11.3%) patients have died. Nephrologist and nurse SQ were both good predictors for mortality within one year, with an OR 7.44 (IC95% 2.92-20.74) and 8.47 (IC95% 2.47-30.34) respectively (both with a p-value <0.001). Institutionalization, aCCI, albuminemia and hospital admissions during follow-up also seems to be important predictors. Table 2. With multivariate analysis, SQ for nephrologists and nurses are no longer statistically significant: OR 1.25 (IC95% 0.31-5.11) and 3.09 (IC95% 0.81-11.86), respectively.

**Conclusions:** Our results showed that SQ answered by nephrologist and nurse are not good mortality predictors, reflecting this method subjectivity and the lack of PC training. Probably, SQ should be reserved to professionals with PC training, a profound gap in nephrologists training in Portugal.

**POI1222**

**Code Status Variability in a Regional Hemodialysis Program**

**Danielle Moorman, Samuel A. Silver, Hasitha Welihinda, Eduard A. Iliescu. Queen’s University, Kingston, ON, Canada.**

**Background:** Patients with end stage kidney disease (ESKD) treated with hemodialysis (HD) have poor life expectancy and may not benefit from aggressive measures at the end of life. Previous studies suggest variability in Do Not Resuscitate (DNR) orders in patients treated with HD but they are limited by missing code statuses and inability to adjust for demographics. In our regional HD program, with complete code status ascertainment that is updated annually, our objective was to examine DNR variability while accounting for demographic factors.

**Methods:** We conducted a cross-sectional study of DNR prevalence in October 2019 in patients treated with in-centre HD in a regional program, which consists of a main centre and six smaller centres. Patients are transferred to smaller centres based on location. Each centre has an attending nephrologist who reviews code status yearly with every patient. Unadjusted DNR prevalence are compared using the Chi-square test and multiple logistic regression is used to control for covariates (age, sex, race, dialysis vintage, HD unit).

**Results:** We included 374 patients, 193 (52%) from the main centre and 181 (48%) from its satellite units. Mean age of patients is 67.2±14.3 years, 52% male, 87% Caucasian, and dialysis vintage 5.2±5.5 years. Code status was full code in 78% and DNR in 22% with significant variation across sites (range of 9% to 46%, p <0.02) (Figure 1). Variation remained significant (p = 0.03) after controlling for covariates.

**Conclusions:** Variability in code status at different HD centres in our regional program persisted despite accounting for differences in patient age, sex, race, and HD vintage. This finding suggests factors related to the HD centre may affect code status decisions, such as local culture, question phrasing, and views of the treating nephrologist. Future studies are planned to determine if a standardized approach to discussing code status would normalize rates.

**POI1223**

**Polypharmacy and Frailty Among Hemodialysis Patients**

**Hiroshi Kimura, John Sy, Connie Rhee, Elani Stejca, Kamyr Kalantar-Zadeh. Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA.**

**Background:** Most patients undergoing maintenance dialysis have multiple comorbidities, most of which require long term medication management and can inevitably lead to polypharmacy. Frailty is also highly prevalent among dialysis patients and has been associated with poor outcomes. With higher frailty and comorbidity rates among dialysis patients, it remains unclear if polypharmacy is still associated with the incidence of frailty among dialysis patients. The aim of this study was to examine the independent association between polypharmacy and frailty among hemodialysis patients.

**Methods:** We examined 337 patients enrolled in the ACTIVE/ADIPOSE dialysis cohort study. The number of prescribed medications and frailty were assessed at baseline, 12, and 24 months. We used logistic regression with generalized estimating equations to model the association of the number of medications and frailty over time; competing-risks regression to assess incidence of frailty.

**Results:** The mean number of medications was 10 ± 5, and 94 patients (28%) were frail at baseline. Patients taking greater than 11 medications showed higher odds for frailty as compared with patients taking less than 8 medications (OR 1.54, 95% CI 1.05-2.26). During two years of follow-up, 87 patients developed frailty among the non-frail patients at baseline. Compared with patients taking less than 8 medications, the incidence of frailty was approximately 2-fold in those taking greater than 11 medications (sub-distribution hazard ratio [SHR] 2.15, 95% CI 1.32-3.48).

**Conclusions:** Using a higher number of medications was associated with frailty and the incidence of frailty among hemodialysis patients. Minimizing polypharmacy may reduce the incidence and prevalence of frailty among dialysis patients.
**PO1224**

**Optimal Patient Positioning for Chest Compressions in Dialysis Clinics: A Randomized Cross-Over Simulation Study**

Patrick H. Pan, 1,2 Kevin T. McNamara, 1 Duke University School of Medicine, Durham, NC; 1Duke Clinical Research Institute, Durham, NC; 2Durham Veterans Administration Medical Center, Durham, NC.

**Background:** Sudden cardiac arrest is the leading cause of death for hemodialysis patients, and often occurs during treatment in hemodialysis units. Resuscitation guidelines emphasize the need for rapid delivery of effective chest compressions to improve survival. How different methods of patient positioning (in the dialysis chair or on the floor) affects chest compression quality is unknown.

**Methods:** This was a prospective randomized cross-over study to assess the quality of chest compressions performed on a simulation manikin (Laerdal SimMan3G). Dialysis staff were recruited from a single center and asked to perform 2 minutes of compressions on the manikin positioned: 1) on a gurney with a code-cart backpack (baseline); 2) on the floor; 3) in a reclined dialysis chair; and 4) in a reclined dialysis chair with a backpack placed underneath. The sequence of manikin positions was randomized to reduce carryover effects and assessments were conducted a 48 hours apart to reduce participant fatigue. Mean compression depth, %compressions at appropriate depth, %compressions fully released and %compressions at adequate rate were assessed for each position and for each participant. Paired sample T-tests were performed to assess the mean differences in compression measures between positions and baseline.

**Results:** 13 dialysis staff members including 7 RNs, 3 MTSs and 3 providers participated in the study. Compared to baseline, mean compression depth (-6.5 mm) and % compressions fully released (-26%) were significantly worse for compressions performed in the dialysis chair, and quality reductions persisted even when a backboard was utilized in the dialysis chair (see Figure 1). No significant differences in compression quality measures were observed with manikin positioning on the floor compared to baseline.

**Conclusions:** Patient CPR in a reclining dialysis chair results in significant reductions in CPR quality. This should be considered in developing dialysis-specific CPR protocols, and further studies should investigate the relative merits of different patient positioning options for optimal CPR delivery.

**PO1225**

**The Plasma Factor Beta-2 Microglobulin Drives Cognitive Impairment in ESRD**

**Background:** Our goal is to decode changes in the plasma proteome in age and disease to identify novel therapeutic targets. We and others have shown that administration of aged human plasma in young immunodeficient mice results in impaired neurogenesis and cognition. We are now extending these findings to plasma from end-stage renal disease (ESRD) subjects undergoing hemodialysis (HD). The prevalence of chronic kidney disease increases with age, and hemodialysis patients have a high incidence of cognitive impairment. The causes for this cognitive impairment are not fully understood and we hypothesize that plasma proteins, specifically beta-2-microglobulin (b2M) are a detrimental factor in HD patients. The Plasma Factor b2M was administered IP to wild-type (WT; C57BL/6) mice, followed by similar analyses.

**Methods:** B2M was administered IP to wild-type (WT; C57BL/6) mice, followed by behavioral testing, and histological and molecular analyses. B2M was administered IP to wild-type mice (WT; C57BL/6) with median hemodialysis vintage of 2.93 years (IQR: 1.76, 5.63) with median HD vintage of 2.93 years (IQR: 1.76, 5.63) with median HD vintage of 2.93 years (IQR: 1.76, 5.63), with median HD vintage of 2.93 years (IQR: 1.76, 5.63) was 3.19 years (IQR: 1.96, 4.51). The median HD vintage among all subjects was 3.19 years (IQR: 1.96, 4.51). In the subsequent multivariate analysis, including all variables that showed significance in the univariate analysis, excluding Fe, age, and induced calcification were observed. In the univariate logistic regression analysis, CACS ≥ 400 had a significant association with TSAT ≥ 20%. Fe ≥ 80 μg/dL, age, and dialysis vintage (P<0.05). In the univariate logistic regression analysis, CACS ≥ 400 had a significant association with TSAT ≥ 20%. Fe ≥ 80 μg/dL, age, and dialysis vintage (P<0.05).

**Conclusions:** Patient CPR in a reclining dialysis chair results in significant reductions in CPR quality. This should be considered in developing dialysis-specific CPR protocols, and further studies should investigate the relative merits of different patient positioning options for optimal CPR delivery.

**Valvular Heart Disease in Prevalent Haemodialysis Patients**

Mohamed Elewa, 1,2 Anuradha Jayanti, 1 Manchester University NHS Foundation Trust, Manchester, United Kingdom; 2Ain Shams University Hospital, Cairo, Egypt.

**Background:** Valvular heart disease is observed in patients with Chronic Kidney Disease. Recent large studies found a prevalence rate of 14%-16% of valvular heart disease (VHD) in haemodialysis patients (2014 USRDS; Hickson et al., 2016). KDIGO consensus group identified several evidence gaps where research is necessary in order to improve our understanding of diagnosis and management of VHD. The aim of our study is to assess the burden of VHD in a haemodialysis cohort in one center in the UK.

**Methods:** A single-center, retrospective, cross-sectional study of echocardiographic findings in prevalent haemodialysis patients. Patients were considered to have VHD if they had significant aortic or mitral valve disease (AVD, MVD) based on standard echocardiographic criteria. Medical records were reviewed for clinical information.

**Results:** This study included 425 haemodialysis recipients. Mean age was 61 years, (SD: 14.96). The cohort was predominantly male (59.3%). The mean BMI was 27.69 (SD: 5.99). 37.1% had a history of smoking. The median renal replacement therapy vintage was 3.19 years (IQR: 1.96, 4.51). In the multivariate analysis, including all variables that showed significance in the univariate analysis, excluding Fe, age, and dialysis vintage (P<0.05). In the univariate logistic regression analysis, CACS ≥ 400 had a significant association with TSAT ≥ 20%. Fe ≥ 80 μg/dL, age, and dialysis vintage (P<0.05). In the univariate logistic regression analysis, CACS ≥ 400 had a significant association with TSAT ≥ 20%. Fe ≥ 80 μg/dL, age, and dialysis vintage (P<0.05). In the univariate logistic regression analysis, CACS ≥ 400 had a significant association with TSAT ≥ 20%. Fe ≥ 80 μg/dL, age, and dialysis vintage (P<0.05).

**Conclusions:** Patient CPR in a reclining dialysis chair results in significant reductions in CPR quality. This should be considered in developing dialysis-specific CPR protocols, and further studies should investigate the relative merits of different patient positioning options for optimal CPR delivery.

The Effect of Intradialytic Potassium and Magnesium Fluctuations on Cardiovascular Functioning in ESRD Patients Undergoing In-Center Hemodialysis

Andy Chiu,1 Gonzalez Matsumura Umemoto,1 Michael I. Rauchman,2,3
Frank J. O'Brien.1 Washington University in Saint Louis, Saint Louis, MO; 2Saint Louis VA Medical Center John Cochran Division, Saint Louis, MO.

Background: Patients with ESRD receiving in-center hemodialysis (HD) have an age-adjusted rate of mortality 4 times the general population. Increased mortality has been attributed to fatal arrhythmias. Mechanisms and risk factors for this are unknown. It has been postulated that changes in serum levels of Potassium(K)/Magnesium(Mg) with HD contribute to arrhythmia generation. Limited data is available to guide personalization of K prescription of HD to reduce this risk. No data exists describing the serum changes in Mg pre-, intra-, and post-HD. We examine the correlation between electrolyte fluctuations, arrhythmia generation, and heart rate variability (HRV) in ESRD patients undergoing in-center HD.

Methods: Single center, prospective, cross-sectional pilot study. 25 patients enrolled to achieve an 80% power. Demographic data, dialysis vintage, and HD prescription were recorded. Arrhythmia data was collected by placement of Holter monitor prior to 1st weekly HD session and recorded continuously for 5 days ending at completion of 3rd weekly HD session. Serum samples were obtained at time intervals 30, 60, 90, and 120 minutes during 1st weekly HD session for electrolytes. Pre and Post HD serum electrolyte analysis occurred during all 3 treatments. Associations were examined by count regression utilizing Poisson or negative binomial methods.

Results: 25 patients were included in data analysis. Mean age 63 and primarily African American (73%). 73% of individuals were dialyzed utilizing 2mmol/L Ectopy data and serum potassium / magnesium data are summarized in Table 1.

Conclusions: There is a trend towards increased ectopy (particularly on HD day 1) and decreased HRV on HD days. There is a trend towards hyper-K post-HD after HD sessions 2 and 3. Serum Mg levels remained stable pre and post HD throughout all HD sessions. Data derived in this study will be utilized to guide a larger future study with the goal towards personalized HD treatments.

Human Factors Testing of the Quanta SC+ Haemodialysis System: Demonstrating Ease of Use with Minimal Upfront Training in Health Care Practitioners and Patients

Paul Komenda, John Millad, Kathryn Compton. Quanta Dialysis Technologies, Alcester, United Kingdom.

Background: Quanta Dialysis Technologies has developed a compact, powerful personal haemodialysis system intended for home and self-care use designed in collaboration with patients and healthcare practitioners. Human factors testing is necessary to demonstrate ease of use with minimal up-front training.

Methods: In compliance with FDA guidance and EU standards, the user interface of the system was evaluated through human factors testing to assess the safe and effective use of SC+. This included a series of user-based tasks whereby representative users independently setup SC+ into a simulated treatment, managed alarms to resolution and external SC+ cleaning/disinfection. All participants received an introduction to SC+ and completed a competency sign off at the end of training. 15 healthcare professionals (6 renal nurses, 8 dialysis technicians, 1 patient care technician) received up to 4 hours of structured training followed by a 1-day learning decay period. In addition, 10 lay users (8 dialysis patients, 2 caregivers) received between 5.5 and 7.5 hours training followed by a 2-day learning decay period.

Results: Between the two user groups, there were a total of 8,110 opportunities for use errors to occur. Despite minimal training and representative learning decay, only 4 significant use events were observed requiring some user manual enhancements. Other use errors captured were minor or could not be mitigated further due to clinical practices and shared inherent risks across all haemodialysis systems.

Conclusions: The results of the human factors testing demonstrated that healthcare practitioners, patients and caregivers successfully operated SC+ independently with a high level of use safety, despite minimal training and learning decay. The SC+ user interface is optimised for safe and effective use under FDA guidance and EU standards.

PO1230

Inpatient Dialysis Provider Type and Duration of Hospital Admissions of Dialysis Patients

Joshua W. Morrison, Daniel Liu, David L. Mahoney, Jeffrey A. Giulian. DaVita Inc, Denver, CO.

Background: Inpatient dialysis treatments may be performed by hospital staff or by a contracted dialysis provider. In this study, we compared duration of hospitalizations of dialysis patients who were admitted to hospitals performing in-house dialysis to that of patients who were admitted to hospitals contracting with a dialysis provider.

Methods: Data for this analysis were derived from the electronic medical records of a large dialysis organization. We identified patients who were hospitalized between Jan 2017 and Sept 2019. Length of stay was compared for patients who were admitted to hospitals performing dialysis in-house versus patients who were admitted to hospitals that contracted with the dialysis organization.

Results: During the study period, we identified 155,458 hospitalizations among 64,662 patients at 572 hospitals in which dialysis was performed by in-house staff. There were 226,059 hospitalizations among 87,213 patients in which dialysis was performed by the dialysis organization. There were no meaningful differences in patient characteristics or reasons for admission among patients admitted to hospitals performing dialysis in-house compared to those of patients admitted to hospitals contracting with the dialysis organization. The mean length of stay for patients admitted to hospitals providing dialysis in-house was 6.0 days versus 5.7 days for patients admitted to hospitals contracting with the dialysis organization, a difference of 5.0%. We made similar observations for hospitals with ≥400 beds, hospitals that were not affiliated with an academic medical center, and hospitals designated trauma levels II to V. These differences were attenuated at hospitals with <400 beds, academic medical centers, and level I trauma hospitals.

Conclusions: These results suggest that use of a contracted dialysis organization may shorten the length of stay for patients who require dialysis during hospital admissions and this trend was more pronounced in smaller, non-university-affiliated hospitals.
PO1231

The Impact of CRRT Modality on Filter Life

László Magy, Iro Honkanen, Rebecca L. Hegeman, Chou-Long Huang, Prerna Kumar, Swie Zin Mar Winhtutoo, Christie P. Thomas, Melissa L. Swee, Benjamin R. Griffin. University of Iowa, Iowa City; IA.

Background: Increasing CRRT filter lifespan would save money, decrease iatrogenic blood loss, increase the time CRRT is actively running, and waste less nursing time. Filter clotting is a common reason for filter loss that can potentially be reduced. CRRT can be performed using convective clearance as in CVVH or diffusive clearance as in CVVHD. Whether convection or diffusion prolongs filter life over the other is unknown, but there are plausible arguments for both. CVVHD has no significant hemocencentration within the circuit, whereas CVVH is subject to hemocencentration as fluid is removed across the filter. However, pre-filter CVVH results in hemodilution prior to entering the filter that may mitigate the effects of the filter hemocencentration. We hypothesize that filter life is longer in patients treated with CVVH than CVVHD.

Methods: In this unblinded prospective randomized trial, patients are assigned to either pre-filter CVVH or CVVHD. The standard treatment protocol at the University of Iowa is to use citrate anticoagulation with a blood flow rate of 200 mL/min and a dose of 25 mL/kg/hr. Using a power of 0.8 and an alpha of 5%, and historical filter loss attributable to clotting of 60%, a total of 1,010 filters are needed to show a hazard ratio of at least 1.3 for filter loss. The primary outcome is average filter life, and secondary outcomes are mortality, intensive care unit LOS, hospital LOS, and renal recovery.

Results: Beginning March 25, 2020, we have enrolled 30 patients using a total of 90 filters (Table 1). The average filter life in CVVH filters is 36.8 ± 26.8, compared to 37.0 ± 31.9 hours in CVVHD filters (p=NS).

Conclusions: Data from 2 months of a planned 12-month prospective study comparing filter life in CVVH vs CVVHD shows no significant difference in filter life.

Acute Dialysis in a High-Dependency Unit: A New Service with a Long-Term Legacy

Nasreen Samad,1,2 Frazel Anci,1 Nick Lever,2 Ian R. Carrasco Barber.3 Barts Heath NHS Trust, London, United Kingdom; Queens Hospital, London, United Kingdom.

Background: Continuous Renal Replacement Therapy (CRRT) in the intensive care unit (ICU) was restricted to the limit during the COVID-19 pandemic. COVID-19 was combined with acute kidney injury (AKI) and intensive care in patients admitted to ICU, in addition to chronic dialysis patients with COVID-19 requiring ICU admission. During the peak of COVID-19 there was a critical national shortage of consumables and dialysis fluids. In the United Kingdom (UK) required for CRRT in ICU. The ICU Service at Queen’s Hospital, Romford, UK, was without critical nerves to develop a viable urgent alternative treatment. A modified prolonged intermittent haemodialysis treatment 4-8 hours every day in selected patients was set up in the high dependency unit. This method required the installation of additional equipment and staff training.

Methods: During the peak of the COVID-19 pandemic, 5 beds in HDU were created with mobile reverse osmosis (RO) units to provide acute dialysis. Within 10 days of service approval, the dedicated area in HDU was equipped with all necessary plumbing work, machines and consumables. In the interim nursing training was provided by the senior dialysis nurse from the satellite dialysis unit based in the hospital who also supervised all sessions of dialysis 6 days a week. Patients selected were relatively stable with or without the need for assisted ventilation and inotrope requirement with Norepinephrine up to 0.6mcg/kg/min. Dialysis treatment was provided 6 days a week for 4-8 hours per session.

Results: 12 COVID-19 patients received haemodialysis in the newly established HDU dialysis unit between 30th April to 30th May 2020. 5 had AKI associated with COVID-19 and 7 COVID-19 patients were receiving dialysis requiring Acute Kidney Injury (AKI) therapy. 45 sessions were provided (range 1-19 sessions per patient). Of the 12 patients 4 died, of whom 4 with AKI and 2 were on chronic dialysis. Of remaining 8, 5 patients were on chronic haemodialysis while 2 AKI patients continue to require haemodialysis and one became dialysis independent.

Conclusions: Prolonged intermittent renal replacement therapy in HDU was a viable alternative during the COVID-19 pandemic. The process was safe and manageable. The resources acquired during COVID-19 pandemic can be utilised in managing AKI and acutely ill chronic dialysis patients in a hospital where this service was not available before the pandemic.

PO1233

Predictors of 30-Day Hospital Readmission Among Minority ESRD Patients Receiving Maintenance Hemodialysis

Dhakrit “Jesse” Rungkitwanatakul, Chiomena Ohanele, Nikuruka Emenezi, Mary K. Maneno, Monika N. Daftary. Howard University College of Pharmacy, Washington, DC.

Background: End-stage renal disease (ESRD) is one of the most prominent disparities as racial/ethnic minorities are 1.5-4 times more likely than others to develop ESRD. Among ESRD patients receiving haemodialysis, more than 1/3 of hospital discharges are followed by a readmission within 30 days. These subsequent readmissions are associated with increased healthcare costs and poor health outcomes. Therefore, knowing the incidence and risk factors for readmission are crucial steps needed for necessary prevention. This retrospective study aims to identify predictors with hospital readmission and outpatient care that contribute to 30-day hospital readmissions among minority ESRD patients receiving maintenance hemodialysis within an outpatient dialysis center located in the District of Columbia.

Methods: Data from electronic medical records were taken for patients who have had at least one hospital admission between January 1, 2017 and August 31, 2019. Descriptive statistical analysis was conducted for all study variables. Univariate and multivariable logistic regression analyses with 30-day readmission as the dependent outcome were conducted to identify and assess predictors of 30-day readmissions.

Results: A total of 969 patients were included in the study. Among these patients, 49 (51%) had 30-day hospital readmission. Overall, patients were predominantly African American (86.5%), age between the age of 60-69 (29.2%), and with a diagnosis of hypertension (89.6%). A diagnosis of secondary hyperparathyroidism, serum calcium < 8.5mg/dL at time of discharge, and serum PTH < 150pg/mL are significantly associated with higher readmission rates in multivariable analyses (p < 0.05). Gender, race, a weekend discharge, and serum phosphate at time of discharge were not associated with 30-day readmission.

Conclusions: Overall, the study findings provide some insight into risk factors associated with 30-day readmissions in minority patients receiving maintenance hemodialysis. These findings suggest that secondary hyperparathyroidism and chronic kidney disease mineral bone disorder (CKD-MBD) markers predict readmissions. Identifying inpatient and outpatient strategies to mitigate risks and prevent readmissions may improve outcomes among this high-risk ESRD population.

PO1234

Role of Lung Ultrasonography to Predict Intradialytic Hypotension in ICU Patients

Yurii Khumin, Daniel Stalbow, Jamie S. Hirsch, Daniel W. Ross. Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.

Background: Lung ultrasonography has emerged as a valuable tool in the assessment of volume status in hemodialysis (HD) patients. A-line profile noted on lung ultrasonography denotes low wedge pressure while B-line profile is associated with hypervolemia. We hypothesized that patients with A-line profile are more likely to experience intradialytic hypotension (IDH).

Methods: We identified all patients admitted to the Medical ICU at two tertiary care facilities in the Northwell Health system between Jan 1st, 2016 and Sep 23rd, 2019 in whom hemodialysis was performed and a lung ultrasound was documented the same day. We manually reviewed clinician documentation and included patients whose lung ultrasound findings demonstrated A-line profile or B-line profile. Patients with other lung ultrasound findings were excluded. IDH was defined as a decrease in systolic BP by ≥ 20 mmHg with a failure to meet UF goal or increase in pressor requirement during HD or associated symptoms of hypotension. In total 105 dialysis treatments were reviewed, 78 were included for analysis. Northwell IRB exempted the study for full IRB review.

Results: There were 55 treatments with A-line profile and 50 treatments with B-line profile on POCUS. The incidence of IDH in HD treatment with A-line profile and B-line profile was 50.9% and 21.7% respectively. 13 HD treatments with A-line profile and 1 B-line profile had an increase in pressor requirement.

Conclusions: Lung ultrasonography provides a quick and effective means of assessing volume status. Our data suggest that IDH occurs more frequently in patients with A-line profile compared to those with B-line profile. Further research should focus on describing the relationship between lung ultrasound and IDH.

PO1235

Relationship Between Cardiac Output (CO) and Estimated Upper Body Blood Flow (eUBBF) During Hemodialysis (HD)

Jochen G. Raimann,1 Gwendolyyn Derk,2 Maria Fox,2 Elizabeth G. Pozzhikunnel,3 Stephan Thijssen,1 Kenneth R. Wilund,2 Peter Kotanko.1 Renal Research Institute, New York, NY; 2University of Illinois at Urbana Champaign, Champaign, IL; 3Harvard.

Background: Cardiopulmonary monitoring during HD could improve outcomes. Upper body oxygen consumption, arterial and central-venous oxygen saturation and hemoglobin concentration are used to calculate eUBBF (Rosales 2019). We studied the association between eUBBF and CO during HD.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: In patients with central-venous catheter we measured central-venous oxygen saturation and hemoglobin levels during HD using the Crite-Line Monitor (Fresenius Medical Care North America, Waltham, USA). We measured CO using the Task Force Monitor (CNSystems, Graz, Austria). We tested the time series for stationarity using the Dickey-Fuller test, employed differencing to make the time series stationary, analyzed the association between the time series using cross-correlations and Granger Causality test.

Results: We studied 13 patients (59±14 years, 5 (38%) male, 93±22 kg pre-dialysis weight 170±7 cm tall) during 34 hemodialyses. Averaged across all treatments, CO and eUBBF were 4.7±1.0 and 1.3±0.4 L/min, respectively. CO showed a weak downward trend during hemodialysis. Cross-correlations showed no meaningful relationship between CO and eUBBF; Granger causality index was less than 20% in 8 treatments, albeit without clearly discernible patterns.

Conclusions: CO and eUBBF remained considerably stable during HD. Cross-correlations showed no significant relationships and Granger causality test suggests some form of a relationship which requires some further investigation. The clinical usefulness of eUBBF and future investigations will need to take additional parameters and dynamic relationships into account. Figure 1: Dynamic of CO and eUBBF flow during 34 HD; correlation coefficient from cross-correlations and Granger Causality index at a lag of -2 minutes.

POI1236
Point-of-Care Ultrasound Findings Among Dialysis Patients with COVID-19

Background: Dialysis patients are vulnerable in the COVID-19 pandemic due to advanced age, comorbidities, and obligate travel with frequent healthcare contacts. Point-of-care cardiac and lung ultrasound (US) has been used to enhance the physical exam in dialysis patients and is a potent tool for assessment COVID-19, comparing favorably to invasive mechanical ventilation and 56% intensive care unit admission. 23 (68%) had pleural effusions, 8 had pleural effusions (3 bilateral). 17 had an ejection fraction (EF) >55%, 3 had EF 30-55%, 1 had 36% required invasive mechanical ventilation and 56% intensive care unit admission. 23 patients had cardiac US. 17 had an ejection fraction (EF) >55%, 3 had EF 30-55%, 1 had 36% required invasive mechanical ventilation and 56% intensive care unit admission. 23 (60%) were discharged with mean length of stay 10 days.

Conclusions: We showed a high prevalence of thickened pleural lines, subpleural consolidations, and multifocal or confluent B-lines among dialysis patients with COVID-19. Most had a normal or collapsed IVC and intact cardiac function. Pleural and pericardial effusions were uncommon. More study is needed to determine whether US findings can help guide fluid management in dialysis patients.

POI1237
Accelerated Renal Replacement Therapy: Single-Institution Experience in Calculating Delivered Clearance During the COVID-19 Pandemic
Jans J. Cho, Shubha Ahy, Cybele Ghossein. Northwestern University Feinberg School of Medicine, Chicago, IL.

Introduction: Continuous renal replacement therapy (CRRT) is commonly used in the intensive care unit (ICU) setting. A minimum delivered dose 20 ml/kg/hr is associated with improved survival. Previous studies have revealed significant discrepancy between prescribed and delivered CRRT dosing. Before the COVID 19 pandemic, CRRT was the main modality used at our medical center. But to accommodate the increase need for RRT and our limited resources, accelerated renal replacement therapy (ARRT), providing the same total RRT clearance but in half the time, was used. To ensure that the delivered dose was appropriate given the reduction in time, we calculated delivered clearance.

Case Description: ARRT delivered dose was based on patient’s weight and time on therapy to achieve the equivalent 20cc/kg/hr over 24 hours. Delivered clearance (k) was calculated using the following formula K= Qd + Qf x FUN/BUN / weight /24 and calculated using the following formula K= Qd + Qf x FUN/BUN / weight /24. Qd >spent dialysate Qr= replacement fluid rate and Quf = net fluid removal rate. FUN = effluent urea nitrogen BUN= blood urea nitrogen. Hourly flowsheet with total time, Quf, Qd, and Qr were recorded during treatment by bedside nurse and reviewed to calculate the delivered clearance. 8 patients underwent 14 uninterrupted ARRT treatments. Total treatment time ranged from 8-10.5 hours. FUN/BUN ratio ranged from 0.5 to 1.05. The ratio between delivered clearance to prescribed clearance ranged from 0.83-1.08. Only 6 treatments (43%) achieved goal clearance.

Discussion: ARRT delivered clearance was only achieved 43% of time. While ARRT is a feasible modality when resources are limited, close monitoring of achieved clearance is needed to ensure that adequate dialysis is being delivered. Careful patient selection is important as delivered dose may be more difficult to achieve in obese patients. Although ARRT may be a practical alternative, continuous therapy would be ideal in the critical setting.

POI1238
Can COVID-19 Personal Hygiene and Social Distancing Reduce Bacteremia and Peritonitis Rates in Dialysis Patients

Background: During COVID-19 pandemic affecting United Kingdom (UK) from March till May 2020 with social distancing guidelines in place (hand washing 5 times a day, 2 meter separation) and shielding in high risk individuals (including renal replacement therapy patients) and strict personal protective equipment (PPE) use in dialysis units we proposed the hypothesis that it may have positive impact on bacteremia in haemodialysis(HD) and peritonitis in peritoneal dialysis(PD) patients.

Methods: We compared Staphylococcus Aureus (SA) bacteremia in HD patients and PD peritonitis rates over three months March, April and May 2020 and compared the results with similar duration during 2019. We also viewed SA colonization rate in a satellite unit during this period.

Results: Quarterly Staph. Aureus bacteremia results showed yearly rate on 31 May 2019, 31 August 2019, 30 November 2019, 28 February 2020 and 31 May 2020 as 0.014, 0.021, 0.039, 0.038 and 0.024 respectively. However yearly PD peritonitis rates were significantly down from 0.386 to 0.238 from January 2019 to April 2020. MRSA colonization data from one satellite unit showed 2 out of 105 patients colonised in January 2019, of whom one decolonized by April 2020 while 16 patients in the same unit had MSSA colonization in January 2019 which was 15 out of 103 patients in February 2020 suggesting no significant difference in SA colonization rate.

Conclusions: Improvement in peritonitis rates is indicative of personal behavioural change with regards to common sense hygienic principles being very important in PD. However, in HD patients it had no impact on bacteremia at similar time one year ago indicating that possibly colonisation with MSSA/MRSA are important and strategies to decolonisation of HD patients may help reduce episodes of bacteremia. There was some reduction in bacteremia rate from preceding quarter ending February 2020 to quarter ending May 2020 although not to May 2019 level. It will be difficult to say at this stage if this trend will be sustained in coming months.

Effect of Lockdown to Stop Spread of COVID-19 on Physical Activity Levels of Hemodialysis Patients
Maggie Han,1 Priscila Preciado,2 Ohmar Thwin,1 Xia Tao,1 Mirell Tapia,1 Lemuier Rivera Fuentes,1 Anirush U. Patel,1 Mohamad I. Hakim,3 Lelia Tisdale,1 Stephan Thijssen,1 Peter Kotanko,1,2 Renal Research Institute, New York, NY; 1Icahn School of Medicine at Mount Sinai, New York, NY.

Background: On March 20, 2020, to stop the spread of the COVID-19, the New York State Governor issued a strict stay at home order for all tasks that were deemed as “non-essential” starting March 22 at 8PM. We would like to determine what change, if any, in physical activity levels (PAL) took place because of the lockdown order in HD patients.

Methods: HD patients were enrolled from 4 clinics in New York City starting in May 2018 and followed for a period of up to 1 year. Patients ≥18 years, on HD ≥3 months, able to walk, and owning a smartphone were enrolled. PAL was defined by steps taken per day measured by with a wrist-based monitoring device (Fitbit Charge 2). Patients still in the study as of March 22, 2020 were included in the study cohort. Average steps per day was calculated for Jan 1-Feb 13, 2020 and the five weeks prior to and after the lockdown went into place. A linear mixed-effect model was used to estimate the average steps per day and 95% confidence intervals. Socioeconomic parameters such as age, race, employment status, and education level were taken at the beginning of the study.

Results: 42 patients were included in this analysis. At enrollment patients were 55.1±11.6 years old with a diagnosis vintage of 4.5±4.4 years, and a BMI of 28.9±8.6 kg/m². 33% lived alone, 48% were single, 50% unemployed, 69% were African American, and 50% had an education level of some college or higher. Results on average steps per day are presented in Figure 1. Steps per day decreased significantly after the lockdown order with the most significant drop when the COVID-19 pandemic was declared a national emergency

Conclusions: There was a decrease in PAL due to the mandated lockdown. As sedentary behavior is a risk factor for negative outcomes in the HD population, we must implement interventions to promote PAL, such as intradialytic exercise.

PO1240

Affecting Factors on Circuit Lifespan in Continuous Renal Replacement Therapy
Hamwon Shin, Miiryung Kim, Jun Young Lee, Jae Won Yang, Jae seok Kim, Seung-Ok Choi, Minseob Lee, Jun Youngang, Jae seok Kim, Wonju Severance Christian Hospital, Wonju, Gangwon-do, Republic of Korea.

Background: CRRT is a useful dialysis modality in hemodynamically unstable patients. But despite use of anticoagulants, clotting of circuit frequently occurs, which reduces efficiency of dialysis and causes the consumption of RBC, platelets, and coagulation factors. Especially, the more severe patient is, the lower blood flow into circuit could help keep patients at home longer. Understanding the reasons for exit from HHD may lead to strategies to reduce patient loss.

Methods: A retrospective cohort study of adult HD patients who entered training for HHD between January 1 2013 to December 31 2018 in AKC-S, followed until exit study end date. Reasons for technique failure (TF) identified, with KM estimates used to determine technique survival, and Cox proportional hazard model used to determine risk factors for TF.

Results: 147 patients entered the HHD program-48(33%) women; 44(30%) DM, 38(25.9%) CAD, 14(9.5%) CVD, mean age of 54(13) years. 12(8.1%) did not complete training. Overall time in program 28 +/- 20 months, average training time 6.7 +/- 3.3 weeks. Reasons for exit include transplant 24(16%), death 6(4.5%), TF 32(24%). TF reasons include medical 9(39.1%), psychiatric 2(8.7%), social 3(13.0%), safety 4(17.4%). Patient request 4(17.4%), change to PD 1(4.3%). Technique survival at 1, 2, and 5 years 91%, 85%, and 63%. Risk factors for TF include DM 2.36(1.06, 5.28) p= 0.036, CVD 4.34(1.8, 10.5) p=0.001 and a longer training time 1.18(1.07, 1.30) p=0.001.

Conclusions: First circuit clotting was significantly related to serum bicarbonate (r=0.454, p=0.005) and creatinine levels (r=−0.359, p=0.026). Blood pressure, infection, blood flow of circuit showed no relationships with circuit lifespan. The use of heparin and nafamostat increased circuit lifespan compared to non-anticoagulant.

PO1241

Home Hemodialysis Patient Loss: A Quality Improvement Initiative to Review Technique Failure in Alberta Kidney Care - South
Bailey Paterson,1 Victoria Riehl-Tonn,2 Elena Qirjazi,1 Jennifer M. MacRae.1
1University of Calgary Cumming School of Medicine, Calgary, AB, Canada; 2Mount Royal University, Calgary, AB, Canada.

Background: The number of dialysis patients has increased 15% over 5 years in Alberta Kidney Care South (AKC-S) with most patients pursuing in-centre hemodialysis. Although home hemodialysis (HHD) offers advantages of improved quality of life for patients and cost savings for programs it has grown at a slower rate. To increase the number of HHD patients, programs need to promote more patients to start on HHD and reduce the number of patients leaving HHD. Understanding the reasons for exit from HHD may lead to strategies to reduce patient loss.

Methods: A retrospective cohort study of adult patients who entered training for HHD between January 1 2013 to December 31 2018 in AKC-S, followed until exit/ study end date. Reasons for technique failure (TF) identified, with KM estimates used to determine technique survival, and Cox proportional hazard model used to determine risk factors for TF.

Results: 147 patients entered the HHD program-48(33%) women; 44(30%) DM, 38(25.9%) CAD, 14(9.5%) CVD, mean age of 54(13) years. 12(8.1%) did not complete training. Overall time in program 28 +/- 20 months, average training time 6.7 +/- 3.3 weeks. Reasons for exit include transplant 24(16%), death 6(4.5%), TF 32(24%). TF reasons include medical 9(39.1%), psychiatric 2(8.7%), social 3(13.0%), safety 4(17.4%). Patient request 4(17.4%), change to PD 1(4.3%). Technique survival at 1, 2, and 5 years 91%, 85%, and 63%. Risk factors for TF include DM 2.36(1.06, 5.28) p=0.036, CVD 4.34(1.8, 10.5) p=0.001 and a longer training time 1.18(1.07, 1.30) p=0.001.

Conclusions: First circuit clotting was significantly related to serum bicarbonate (r=0.454, p=0.005) and creatinine levels (r=−0.359, p=0.026). Blood pressure, infection, blood flow of circuit showed no relationships with circuit lifespan. The use of heparin and nafamostat increased circuit lifespan compared to non-anticoagulant.

Home Dialysis and Kidney Transplant Assessments in the ESRD Treatment Choices Payment Model

Kristine Kubisiak,1 Eric D. Weinhandl,1,2 Lorien S. Dalrymple,1 Robert J. Kossmann.1 Fresenius Medical Care, Waltham, Bouvet Island; Chronic Disease Research Group, Minneapolis, MN.

Background: The End Stage Renal Disease (ESRD) Treatment Choices (ETC) Model is a proposed mandatory payment model that assigns financial bonuses and penalties to dialysis facilities as a function of home dialysis prevalence and kidney transplant incidence among patients with Medicare fee-for-service coverage. We used claims data to estimate distributions of facility-level home dialysis prevalence and kidney transplant incidence.

Methods: Using Medicare Limited Data Sets, we identified all Part B claims for outpatient dialysis for the treatment of ESRD in 2017. In each dialysis facility with a132 adult patient-months, we estimated the percentage of patient-months with any home dialysis treatment. Using Part A claims in 2017, we also estimated the number of kidney transplants among dialysis patients in the facility.

Results: We identified 6263 dialysis facilities and 3,645,655 dialysis patient-months. Overall home dialysis prevalence was 10.8%. The distribution of facility-level home dialysis prevalence exhibited three features, as displayed: (1) over 54% of facilities with exactly 0% home dialysis prevalence; (2) among facilities with any home dialysis utilization, a unimodal distribution with peak prevalence near 12%; and (3) a small subset of facilities (4%) with home dialysis prevalence >90%. Regarding kidney transplant incidence, over half of facilities had ≤1 transplant. The 75th and 90th percentiles of transplant count were 2 and 4, respectively.

Conclusions: In patients with Medicare fee-for-service coverage, facility-level home dialysis prevalence exhibits a nonnormal distribution, while kidney transplant incidence typically manifests few (or no) events per year. Both patterns will complicate statistical analysis of performance in the ETC model. Alternative methodology should consider assessments in regional clusters of facilities.

PO1243

Identifying Barriers to Implementing an Assisted Home Hemodialysis Program in Canada

Drew Hager,1 April Bertrand,1 Nickie L. Cool,1 Thomas W. Ferguson,1 Claudio Rigatto,2 Navdeep Tangri,2 Clara Bohm,2 Michelle S. DiNella,2 Paul Komenda,1 Winnipeg Regional Health Authority, Winnipeg, MB, Canada; 3University of Manitoba, Winnipeg, MB, Canada; 4Seven Oaks General Hospital, Winnipeg, MB, Canada.

Background: Policy changes such as the Advancing American Kidney Health Initiative and the impact of the COVID-19 pandemic will accelerate the trend for more home dialysis. Expanding the pool of patients eligible for HHD will require health care practitioner assisted models to be developed and deployed. We hypothesize that many barriers to delivering assisted HHD (aHHD) exist and implementation of a successful program would require meaningful input from frontline home dialysis nurses. Our primary objective of this study is to survey these key stakeholders to identify these barriers.

Methods: We conducted a semi-structured focus group of leaders within our large Canadian home dialysis program to anticipate key aspects of implementing aHHD, including gauging local demand, identifying eligible patients, and recognizing essential operational components. From this, we constructed questionnaires for frontline nursing staff within HHD, peritoneal dialysis (PD) and assisted PD (aPD) programs. We performed a qualitative analysis to identify common themes and implementation barriers.

Results: Twenty-six responses from three sites were received. 20/21 PD nurses reported existing aPD programs expanded the eligible pool of PD patients. 5/5 HHD nurses felt an aHHD program would keep more patients on the modality and prevent technique failure. Only 2/5 felt aHHD should be offered as a transition to HHD. While 18/21 PD nurses reported they could easily identify patients for aPD, only 2/5 HHD nurses agreed. Patients with sensory deficits, functional impairments, and limited support networks were felt to benefit most from aHHD. Lack of confidence and phobias were not agreed upon. Behavioral and safety issues, clinical instability, and inability to manage complex medical conditions may be barriers to aHHD. Machine set-up, take-down, and establishing access were thought to be essential services. PD nurses felt clinical assessments should be routine. Few nurses felt complete assistance was necessary.

Conclusions: Our findings suggest there is a strong local demand for aHHD provided there is a clear criterion for enrollment and operational plans are well established. Frontline nurses have identified several important barriers to implementation which we will acknowledge and address when deploying our assisted home program over the upcoming year.

PO1244

Timed Repetitive Controlled Rotations of the CAR-170-C NXSTAGE Chronic Cartridge Hemodialysis Filter: An Original Newfangled Maneuver toEnable Heparin-Free Frequent Daily Home Hemodialysis

Macaulay A. Onuigbo,1 Adam Locke. Larner College of Medicine, University of Vermont, Burlington, VT.

Introduction: Heparin-free hemodialysis is usually obligatory in immediate post-operative states, bleeding diathesis and in critically ill patients. Conventionally, this is achieved through normal saline flushes, and regional citrate anticoagulation.

Case Description: An 87-yr white male with ESRD and atrial fibrillation on Warfarin, on maintenance daily Home Hemodialysis (HHD) with a NxStage machine, developed intra-abdominal abscess and sepsis following an urgent laparoscopic appendectomy. He required emergent pericardiocentesis for cardiogenic shock from hemorrhagic pericardial effusion. Upon discharge, he was to continue heparin-free HHD. Despite the use of increasing volumes of normal saline flushes, his system clotted every day during HHD, therefore compromising his ability to carry out HHD. Our HD Senior Technician, had astutely observed that by a controlled timed manual and repeated and fro rotation of the horizontally aligned CAR-170-C NXSTAGE Chronic cartridge, 60 degrees back and forth clockwise and counterclockwise, along the long axis of the filter, every 15 minutes, the filter stopped clotting. He has since then not needed saline flushes for smooth heparin-free HHD for several months.

Discussion: This is the first such report in the English literature. More studies are justified. We have hypothesized a mechanism and have named this the “Adam Locke Onuigbo Maneuver”. If confirmed by subsequent research, we propose that a miniaturized motor set-up that would be programmed to mimic these timed controlled partial rotations of the horizontally aligned CAR-170-C NXSTAGE Chronic cartridge could translate to a commercial success with major clinical benefits to patients needing heparin-free hemodialysis in all settings.

PO1245

The Use of Etelcalcetide in a Special Cohort of Home Hemodialysis Patients with Severe Secondary Hyperparathyroidism
Ahmed A. Ewaida, Bassam O. Bernich. HHD Home Health Care, Al Ain, United Arab Emirates.

Background: Secondary hyperparathyroidism (SHPT), is a common complication of chronic kidney disease. Its clinical consequences include extraskeletal vascular and valvular calcifications, changes in bone metabolism resulting in renal osteodystrophy, and an increased risk of cardiovascular morbidity and mortality. Etelcalcetide is an intravenous calcimimetic that increases sensitivity of the calcium-sensing receptor to calcium and decreases PTH, so it’s indicated for the treatment of secondary hyperparathyroidism (SHPT) in dialysis patients. In this observational study we are reporting our experience in treating SHPT by Etelcalcetide, in a very special cohort of sick, highly co-morbid, bed, and home bound hemodialysis patients, at home with the assistance of a hemodialysis nurse, we called the program as Nurse Assisted Home Hemodialysis (NAHHD).

Methods: This is a retrospective observational sixth months study. Thirty home HD patients, managed by NAHHD program, were included in this study, average age 59.6±6.8, 66% female. Etiology of ESRD was DM in 63%, 53% of them have hypertension. Vascular access AVF & AVG 60%, CVC 37%. Average comorbidities 9.4 (6-16). Patients were either naïve (30%) or switched from cinacalcet to Etelcalcetide due to non-compliance 5%, PTH resistance 11%, and bad tolerance of Cinacalcet 19%.

Results: The medication was well tolerated, two patients had GI side effects (6.5%), only with high dose of Etelcalcetide. The results of treating secondary hyperparathyroidism by Etelcalcetide in a special cohort of the patients for 6 consecutive months are illustrated in the graph.

Conclusions: This study showed that Etelcalcetide is efficient and well tolerated in this special group of sick, highly comorbid, bed and home bound home hemodialysis patients. The drug was well tolerated with minimal GI side effects.

Funding: Government Support - Non-U.S.

PO1246

Clinical Characteristics, Practice Pattern, and Outcome of Home Hemodialysis in India

Background: Maintenance hemodialysis is growing steadily and is the dominant renal replacement modality and Home HD has been in recent times. But, the profile, treatment characteristics could be different from the western context but it remains unknown.

PO1248

Binding of TonEBP and β-Catenin to the E-Cadherin Promoter Is a Key Process of Hypertonicity-Induced Phenotype Transition of Peritoneal Mesothelial Cells (MCs)

Background: Epithelial-to-mesenchymal transition (EMT) of MCs is considered as an early mechanism of peritoneal fibrosis. Tonicity-responsive enhancer binding protein (TonEBP) is a transcriptional factor that enables cellular adaptation to hypertonic osmotic
stress. Recent data demonstrated the role of TonEBP in EMT of cancer cells, however the exact mechanisms how TonEBP regulated cell phenotype were not known. The aim of this study is to investigate the role of TonEBP in hyperosmolarity-induced EMT of MCs and its mechanism. Methods: The expressions of TonEBP and other osmotic stress-related genes including sodium-myoinositol cotransporter (SMIT), betaine-γ-aminobutyric acid transporter (BGT1) and aldose reductase (AR) were evaluated. EMT was evaluated by morphological changes of MCs and the expressions of E-cadherin and α-smooth muscle actin (α-SMA) after stimulation of high glucose (HG, 30-120 mM) and mannitol (30-120 mM). E-cadherin promoter activity was confirmed by luciferase assay. Binding of TonEBP- or β-catenin to E-cadherin promoter was identified by chromatin immunoprecipitation (ChIP) assay. The interaction between TonEBP and β-catenin was analyzed by immunoprecipitation. Results: Both HG or mannitol enhanced the expression of TonEBP as well as SMIT, BGT1 and AR from the concentration of 30 mM. HG induced EMT of MCs with a decrease in E-cadherin promoter activity, however mannitol did not induce EMT. HG (>30 mM) induced nuclear translocation of TonEBP which was associated with an enhanced binding to β-catenin. Mannitol also promoted nuclear translocation of TonEBP only at the highest concentration we tested (120 mM), however it was not associated with nuclear binding of TonEBP to β-catenin. In addition, mannitol induced a transient increase in nuclear β-catenin only with the highest concentration (120 mM) whereas HG showed a persistent increase in nuclear β-catenin. Conclusions: This study demonstrated the role of TonEBP in peritoneal EMT for the first time. Not the increased expression of TonEBP per se but binding of TonEBP and β-catenin to the E-cadherin promoter is a key mechanism by which TonEBP induced EMT of MCs.

PO1250

Geographic Variation of Home Dialysis Utilization in the United States Eric D. Weinhandl,2,12 David T. Gilbertson,1 James B. Wetmore,3,1 Kirsten L. Johansen,1,3,14 Chronic Disease Research Group, Minneapolis, MN; 2 University of Minnesota, Minneapolis, MN; 3 Hennepin Healthcare, Minneapolis, MN. Background: Increasing home dialysis utilization is an aim of the Advancing American Kidney Health Initiative. We estimated geographic variation in home dialysis utilization in a contemporary population of end stage kidney disease (ESKD) patients. We also assessed the extent to which race and payers—possible systemic barriers to home dialysis—account for this variation.

Methods: Using USRDS Standard Analysis Files, we identified all prevalent ESKD patients on December 31, 2017 and ascertainment the dialysis modality—in-facility hemodialysis, home hemodialysis (HHD), or peritoneal dialysis (PD)—of each patient on that date. We categorized patients into 306 Hospital Referral Regions (HRRs), according to ZIP code of the dialysis facility. We estimated the standardized home dialysis ratio (SHDR) of each HRR, with expected home dialysis utilization as a logistic regression of age, sex, primary cause of ESKD, and ESKD duration. Subsequently, we added race and payer to the regression. Results: The cohort comprised 513,669 patients. Home dialysis utilization was 12.0% (10.0% HHD, 12.2% PD). Among HRRs, 5th and 95th percentiles of observed utilization were 5.3% and 23.2%, respectively, whereas 5th and 95th percentiles of SHDR were 0.43 and 1.82, as displayed. There were 87 HRRs (28%) with SHDR significantly <1.0 (P < 0.05) and 116 (38%) with SHDR significantly >1.0. Of the 10 HRRs with largest percent errors, seven—Los Angeles, Houston, Manhattan, Dallas, East Long Island, Philadelphia, and San Antonio—had SHDR significantly <1.0. The addition of race and payer improved the discrimination of logistic regression, with black race and concurrent Medicaid enrollment as negative predictors of home dialysis utilization. However, the distribution of SHDR did not greatly compress. There were 29 HRRs (9%) with SHDR that were revised from significant to non-significant and 22 (7%) with SHDR that was revised from non-significant to significant.

Conclusions: Large geographic variation in home dialysis utilization exists. Race and payer are associated with utilization, but adjustment for these factors does not alter variation in SHDR.

Funding: NIDDK Support

Standardized Home Dialysis Ratio

In the revised SHDR, expected home dialysis utilization also reflects race and payer.

PO1252

Higher Utilization of Peritoneal Dialysis Following the Executive Order on Advancing American Kidney Health Eric D. Weinhandl,1,2 David T. Gilbertson,1 James B. Wetmore,3 Kirsten L. Johansen,1,3 Chronic Disease Research Group, Minneapolis, MN; 2 University of Minnesota, Minneapolis, MN; 3 Hennepin Healthcare, Minneapolis, MN. Background: On July 10, 2019, the president of the United States issued an Executive order which set the goal for 80% of patients to receive treatment at home or a transplant by 2025. To achieve this goal, providers and payers will not only need to encourage the use of PD but also will need to mitigate PD technique failure (TF). McGill et al. (AJKD, 2019) found that 6 out of 7 patients who start treatment with PD experience TF and will switch to hemodialysis (HD) within five years. Of patients who switch, Jaar et al. (BMJ Nephrology, 2009) found that 20% did so by 6 months. Improving PD treatment time is important for patient quality of life and reducing healthcare costs. The goal of this study was to model Medicare cost savings associated with extending patient time on PD.

Methods: Using USRDS data, we calculated total Medicare spending per patient per day to be $226.71 for PD and $266.26 for HD, respectively. We estimated potential savings if treatment with PD could be extended each month up to 1 year using a base case of an incident ESKD patient who transitions to HD after receiving PD for 6 months. We assumed that during this year patients neither had a transplant nor died and that patients received HD once they stopped PD. Results: Extending PD beyond 6 months for incident patients could result in potential savings to payers. Extending PD by 1 month, 2 months, 3 months, 4 months, 5 months, or 6 months could save $1,203.05, $2,406.10, $3,609.15, $4,812.20, $6,015.25, or $7,218.30, respectively per patient. We found that if a patient could avoid TF, $14,436.59 could be saved annually.

Conclusions: Extending the PD treatment time beyond 6 months has the potential to reduce treatment costs by $1,203.05-$7,218.30 for patients on PD 1 month to 6 months longer, respectively. Annually, avoiding TF could result in savings of $14,436.59. Multiple risk factors are associated with TF. Focusing on identifying and addressing modifiable conditions can help keep more patients dialyzing at home.

Funding: Commercial Support - Fresenius Medical Care North America Renal Therapies Group
We assessed whether the period following the Executive Order was characterized by an increase in peritoneal dialysis (PD) utilization in incident end-stage kidney disease (ESKD) patients undergoing dialysis.

### Methods:
We analyzed submissions of form CMS-2728 (“ESRD Medical Evidence Report”) among patients with dialysis initiation in 2017-2019, according to an April 2020 extract from the Renal Management Information System. For each calendar month in 2017-2019, we estimated the percentage of patients whose primary type of dialysis was PD. We used logistic regression to assess whether PD utilization during each quarter of 2019 exceeded corresponding norms in 2017-2018, with adjustment for age, race, and sex.

### Results:
The cohort comprised 375,815 incident ESKD patients undergoing dialysis. PD utilization increased each year, to an apex of 12.0% in 2019. In September and October 2019, PD utilization exceeded 13.0%, as displayed. Relative to corresponding quarters in 2017-2018, adjusted odds ratios of PD utilization in 2019 were 1.06 (95% confidence interval, 1.02-1.11) during January-March, 1.08 (1.04-1.13) during April-June, 1.16 (1.11-1.21) during July-September, and 1.16 (1.16-1.21) during October-December.

### Conclusions:
The Executive Order on AAKH and the proposed ETC Model together marked the advent of a period of significantly higher PD utilization among incident ESKD patients.

#### Disparities in Home Dialysis and Links to Kidney Transplantation: Inequities Among African American ESRD Patients in Detroit, Michigan

Mareena Logan,1 Alexa Lupi,1 Anurag Dawadi,1 Ana Vazquez,1 Todd Lucas,1 Michigan State University 2Michigan State University, East Lansing, MI; 3Wayne State University School of Medicine, Detroit, MI.

#### Background:
African Americans with ESRD continue to fare worse than their White counterparts for graft and patient survival after kidney transplantation. These disparities may partly reflect differential use of peritoneal dialysis (PD) and hemodialysis (HD) among African Americans who undertake maintenance renal replacement therapy – although PD and preemptive transplants are linked to longer survival and better kidney transplantation outcomes, emerging studies suggest that African Americans less often receive PD than Whites. The current analysis sought to explore whether disparate use of PD would persist in the context of an inner-city hospital that serves a majority African American patient population, within a predominantly African American city.

#### Methods:
We compiled electronic medical record data from 2012-2018 for African American (n = 1078) and White (n = 155) ESRD patients who initiated maintenance dialysis through either HD or PD. We also compiled data on successful kidney transplantation in these patients, as well as sociodemographic and health status data, including BMI, age, PRA peak, race, sex, diabetes, and hypertension.

#### Results:
Fisher’s exact tests showed that African American patients were 2.28 times more likely to receive HD than PD as compared to White patients (p = .004), and that patients receiving PD were 2.09 times more likely to be transplanted (p = .01). Although attenuated, a robust relationship between PD and kidney transplantation persisted in a logistic regression that controlled for sociodemographic and health status variables (OR = 1.60, p = .10).

#### Conclusions:
Disparities in use of PD can be observed even in the context of an inner-city hospital serving a predominantly African American population. Aligned with the Advancing American Kidney Health initiative to achieve 80% home dialysis by 2025, future research must identify and intervene on patient and clinician factors that contribute to lower PD use among African Americans.

Trends in Automated Peritoneal Dialysis (APD) Prescriptions in Adult Chronic Dialysis Patients at a Large Dialysis Organization from 2015 to 2019

Linda Ficociello,1 Vidhya Parameswaran,1 Allison Comerford,1 Claude Mulin,1 Michael S. Anger,1 Robert J. Kossmann,2 Harold E. Giles,1,4 Fresenius Medical Care Renal Therapies Group, Waltham, MA; 2Fresenius Medical Care North America, Waltham, MA; 3Nephrology Associates PC, Birmingham, AL; 4Fresenius Medical Care Birmingham Home Clinic, Birmingham, AL.

Background: Benefits of patients dialyzing at home have been well-reported. Peritoneal dialysis (PD) has grown in recent years and is expected to grow further due to the recent executive order encouraging home dialysis. Trends in APD prescriptions have not been well-described in the literature. This current retrospective analysis aims to describe trends in APD prescriptions from 2015-2019.

Methods: All demographic, lab, and prescription data were retrospectively extracted and de-identified from a LDO’s (Fresenius Kidney Care) electronic data warehouse. Patients included in the analysis were adults with chronic kidney disease on dialysis, incident to APD from Jan 1, 2015 to Dec 31, 2019, completed APD training, had at least one APD treatment recorded, and no data quality issues with their records. Patients were stratified by the year they started PD (2015, 2016, 2017, 2018, 2019) and patients’ first APD prescription information was summarized.

Results: 16,047 patients were eligible for inclusion. The number of APD new patients increased from 2,005 patients in 2015 to 4,751 patients in 2019, as did mean patient age (56.0 years in 2015 to 58.3 years in 2019, p<0.05). Few patients were prescribed daytime exchanges (7.6% in 2015 to 4.8% in 2019, p=0.05) and of those with daytime exchanges, the majority (>93% in all years) had 1 exchange. Table describes other prescription parameters by year.

Conclusions: Comparing 2019 to initial PD prescription patterns, there have been reductions in cycler volume, total number of exchanges, and prescriptions for daytime exchanges, the majority (>93% in all years) had 1 exchange. Table describes other prescription parameters by year.

Development of a Robust Peritoneal Dialysis Program

Gabriel A. Vallez,1,2 Barbara K. Valle1,2,3 Kidney and Hypertension Group of South Florida, Fort Lauderdale, FL; 1VIP Kidney Health, Delray Beach, FL.

Background: Despite ample evidence supporting the superior performance of Peritoneal Dialysis (PD) in a value-based healthcare system, this modality remains conspicuously underutilized in the USA. We implemented a multifaceted strategy to develop a high-performing PD facility in 28 months.

Methods: VIPKHD, a private PD Center, was created through an affiliation with a five-doctor nephrology group in Florida and Medicare Certified 8/2017. Our physicians adopted an “upstream” approach to patient selection by promoting timely access to care for CKD 3b/4/5. KD education was mandatory. Social Media storytelling fostered a vibrant virtual CKD community. Patient vetting incorporated multidisciplinary evaluation of support systems and socio-economic and cultural determinants of health within their specific ecosystem. Expedited referral to an expert surgeon for laparoscopic catheter insertion was crucial. Home training and on-demand home visits were conducted routinely. 24/7 tele-access to clinicians and an open-door policy for non-routine care was instituted. Two satellite locations were available. FTE staff included an Administrator/Population RN, two PDRN, Assistant Administrator and PTE RD and MSW.

Results: From 9/2017 through 12/2019 (28 months), 66 patients were admitted to VIPKHD (Program Vintage 58 PD patient-years). Demographics: female 50%, 64.7 years (25-86), Caucasian 55%, African-american 23%, Hispanic 15%. Comorbidities: DM 47%, CHF 36%, DM/CHF 21%, Morbid Obesity 14%. As of 12/31/2017, 37 patients were on CCPD with good adequacy, 29 discharged. 1 Recovery, 7 Transplant, 3 Relocation, 4 Declined, 1 Hospice, 15 Dropouts (5 peritonitis, 1 tunnel infection, 2 leaks, 1 inadequate dialysis, 3 disability, 1 burnout). Performance rates per 100 ESRD patient years (VIPKHD vs Benchmarks): Peritonitis (10 vs 25), tunnel infection (2 vs 8), admissions (72.6 vs 170), hospitalization days (631 vs 1120), 30 day readmission (16.7% vs 37%), ED/Short-Stay (12.1 vs 350), transplant (12.9 vs 3.5), mortality (6.9 vs 22.5).

Conclusions: Our outcomes reflect the delivery of exceptional PD care. Our pragmatic approach to developing a successful PD program encompasses humble leadership which lays the foundation for building powerful relationships between all stakeholders through effective communication, ceflection and collaboration, promotes shared decision-making and facilitates timely access to integrated, longitudinal, patient-centered care.

Acute Peritoneal Dialysis in Obese Patients During the COVID-19 Pandemic

Leian Joseph,1,2 Fnu Ranjeca,1,2 Nina J. Caplin,1,2 Richard Ameling,1,2 NTU Langone Health, New York, NY; 1Bellevue Hospital Center, New York, NY.

Background: Due to increased risk for infection, fluid leak, metabolic complications and poor uremic solute clearance, concerns have been raised in using peritoneal dialysis in obese patients. However, due to unprecedented need for renal replacement therapy (RRT) in New York City during the COVID-19 pandemic, acute peritoneal dialysis (APD) was initiated in patients regardless of body mass index (BMI).

Methods: 36 patients who received PD between April 8, 2020 and May 8,2020 were categorized into 3 groups based on BMI calculated using admission height and weight. Group 1 with BMI <30, Group 2 with BMI 30-40 and Group 3 with BMI > 40 kg/m². Treatment goals included correction of hyperkalemia, hyperphosphatemia, acid-base abnormalities, reduction in blood urea nitrogen (BUN), creatinine and maintaining euveloria. All patients were initially started on manual exchanges every 1-2 hours (Total volume 12.5L to 24 hours) and eventually most were changed to automated PD (Total volume 18-20L/24 hours). We compared the frequency of treatment-related complications among the groups.

Results: Of the 36 patients, 13 had BMI < 30, 18 patients had BMI 30-40, and 5 had BMI > 40, one of whom had BMI > 50 kg/m². Patients showed improvement in serum creatinine, BUN, phosphorus, potassium, and bicarbonate. All had adequate ultrafiltration and improved volume status after optimization of PD prescription. No differences were observed between groups in achievement of treatment goals. No patients in any group required discontinuation of PD because of treatment-related complications or insufficient dialysis.

Conclusions: Acute PD was successfully performed in obese, and morbidly obese patients during the COVID-19 pandemic. Treatment goals were achieved based on relevant parameters and there were no increases in treatment related complications compared to non-obese patients. Acute PD should not be restricted based on elevated BMI.

Peritoneal Dialysis - 1

Comparing Mortality of Peritoneal and Hemodialysis Patients in an Era of Medicare Reform

Virginia Wang,1,2 Cynthia Coffman,1,2 Linda L. Sanders,2 Abby Hoffmann,1,2 Caroline E. Sloan,1,2 Shou-Yih D. Lee,1,3 Richard A. Hirth,1 Matthew L. Maciejewski,1,2 Durham VAHCS, Durham, NC; 1Duke Univ, Durham, NC; 2Univ Mich, Ann Arbor, MI; 3UNC-Chapel Hill, NC.

Background: Medicare’s 2011 prospective payment system (PPS) encouraged the expansion of peritoneal dialysis (PD), which is preferred by many patients and less costly than in-center hemodialysis (HD). Prior studies have shown PD to be associated with lower or equivalent mortality to HD. Expansion of PD services after the PPS may change
the relative mortality of PD and HD if PD is increasingly used by sicker patients. This study examines the competing risks of mortality between PD and HD modalities in cohorts of patients spanning Medicare PPS.

Methods: From the US Renal Data System, we compared 2-year all-cause mortality in a cohort of incident dialysis patients in 2006-2013. Patients were censored at renal transplantation or the end of the 2-year follow-up. Baseline characteristics of HD and PD patients were assessed via standardized differences and Kaplan-Meier curves. To compare HD and PD 2-year survival, a Cox proportional hazards model was fit using inverse probability of treatment weights (IPTW, generated from patient demographic and clinical characteristics) by incident year, adjusting for patient and dialysis market characteristics.

Results: PD use in the first 90 days increased from 9.5% of incident patients in 2006 to 13.6% in 2013. Crude 2-year mortality was 16.7% for PD and 27.6% for HD. There were no differences in patient characteristics between pre- and post-policy cohorts. In IPTW adjusted survival analysis across all incident years, no differences in 2-year mortality were found for those who attempted PD in the first 90-days of dialysis compared to patients receiving HD (example: HR, 0.93; 95% CI, 0.84 to 1.04 for 900 incident cohort). Mortality differences between PD and HD did not change over time (p=0.23).

Conclusions: Growth in PD initiation over time occurred without changing the patient mix towards sicker patients. After adjusting, we found no evidence of mortality differences between PD and HD before and after payment reform. These findings suggest that Medicare PPS improved the value of dialysis care such that PD service use increased without adversely affecting patient mortality. Still, PD uptake in the US still lags that of many countries. Future policy initiatives may be needed to continue to increase clinically appropriate PD use.

PO1260
Duration of Serum Phosphorus Control Associated with Overall Mortality in Patients Undergoing Peritoneal Dialysis
Jun Ai, Zhwen Xiao. Nanfang Hospital, Southern Medical University, Guangzhou, China.

Background: Serum phosphorus (SP) level was closely associated with overall mortality and cardiovascular events, while the role of SP controlled duration was not fully recognized. Our study is to identify the relationships of SP controlled duration with clinical outcomes in patients undergoing peritoneal dialysis (PD).

Methods: This was a retrospective cohort study, including PD patients with regular follow-up in our center from Jan 1st, 2009 to Jun 30th, 2019. Clinical data were collected at baseline and at 3, 6, 12, 18, 24, 30, 36, 48, 72, 96, and 120 months after dialysis. SP levels, changed degree of SP over baseline, and SP controlled duration were analyzed with overall mortality, PD withdrawal, and combined endpoint. Degree of SP change over baseline (%) = (SP level at following-up point - baseline SP level) / baseline SP level. Duration of SP control (months) = PD vintage when patients reached hyperphosphatemia - PD vintage when patients' SP decreased to less than 1.78 mmol/L after PD.

Results: 530 patients entered the analysis [the mean age was 45.4 ± 1.5 years old, 57.2% were male, the median PD vintage were 32 (15-54) months]. 86.0% patients had lower degree was associated with higher overall mortality [HR, 1.012 (1.004-1.020); p = 0.003]. The longer SP controlled duration, the lower overall mortality. We should controll SP were tightly associated with overall mortality, PD withdrawal and combined endpoint. The longer SP controlled duration, the lower overall mortality. We should controll SP levels as early and as long as possible.

Conclusions: In PD patients, the level of SP and the degree of change after dialysis - PD vintage when patients reached hyperphosphatemia - PD vintage when patients' SP decreased to less than 1.78 mmol/L after PD.

PD vintage when patients' SP decreased to less than 1.78 mmol/L after PD.

PO1261
Urgent-Start Peritoneal Dialysis and Outcomes
Stepl Karpiński,1,2 Scott Siebel,1 Denu E. Colen,1,2 Casey Colson,1,2 David B. Van Wyck,1 Arshia Ghaffari,1 Martin J. Schreiber,1 Francesca Tentori,1,2 Steven M. Brunelli,1,2 Davita Clinical Research, Minneapolis, MN; 2DaVita Patient Safety Organization, Denver, CO; 1University of Southern California, Los Angeles, CA; 3DaVita Inc, Denver, CO.

Background: Many patients start dialysis without adequate pre-dialysis planning, and generally initiate hemodialysis using a central venous catheter (HD-CVC). A minority utilize urgent start peritoneal dialysis (USPD), where a peritoneal dialysis catheter is placed without the usual 2-4 week waiting period. Few analyses have compared outcomes between patients utilizing these two dialysis initiation routes.

Methods: All data for this retrospective study were derived from deidentified electronic health records. Patients who initiated dialysis via HD-CVC during 2018 were matched 1:1 to patients who initiated dialysis using USPD during the same period on the basis of insurance type, etiology of end-stage kidney disease, race, and presence of diabetes. Hospitalization, mortality, and scores on the Kidney Disease Quality of Life (KDQOL) survey were evaluated from dialysis initiation through the first of death.

PO1262
Efficacy of Statin Use in Patients Undergoing Peritoneal Dialysis
Hyung Woo Kim, Geun Woo Ryu, Shinchun Kang, Yooju Nam, Becom Lee, Jeck Seok Kim. Yeouido University College of Medicine, Seoulmaem, Seoul, Republic of Korea.

Background: The efficacy of statin use in patients with PD have not been proven in large studies. Because most of studies included only HD patients or a small number of PD patients, there is lack of evidence whether statin have positive effect on PD patients or not. The aim of this study was to reveal the efficacy of statin uses in PD patients.

Methods: From a total 612 PD patients between 2006 and 2018 in 2018 (example: HR, 0.93; 95% CI, 0.84 to1.04 for 2018 cohort). 331 (53.6%) patients were men. The number of statin uses was 390 (63.5%) and the number of patients who use statin before starting PD was 311 (50.8%). The use of statin (as2 ±2 cDDD) was associated with a lower risk of all-cause mortality (HR, 0.32; 95% CI, 0.20-0.52) after adjustment and this association was also consistent regardless of the use of statin before PD initiation. Adjusted hazard ratios for the all-cause mortality were 0.87 (95% CI, 0.53-1.43), 0.39 (95% CI, 0.20-0.75), 0.41 (95% CI, 0.18-0.81), and 0.13 (95% CI, 0.06-0.26) for the 28-365, 366-730, and 731-1095, respectively, compared with cDDD=28. The risk reduction of statin may be dose dependent.

PO1263
Mortality and Hospitalization in a Large International Peritoneal Dialysis Institution During 2018
Zhiwen Van Wyck,2 Arshia Gha fari, 3 Martin J. Tentori, 1,2 Davita Clinical Research, Minneapolis, MN; 2DaVita Peritoneal Dialysis - 1

Background: With the exception of some national registries, data referred to mortality or hospitalization within a single large international peritoneal dialysis (PD) institution are seldom reported. Objectives: To study all-cause mortality, transplantation rate, hospitalizations and peritonitis rates in our large PD program during 2018.

Methods: Observational, prospective registry in 8 countries. The following variables were tracked: crude mortality rate and causes, hospitalization variables (number of hospitalization days per patient; number of hospitalization episodes per patient; number of days per hospitalization episode; causes of hospitalization), peritonitis rate/episode/ year and risk and patient months at risk to a peritonitis episode) and transplantation rate.

Results: By the end of December 2018, 1207 pt. were treated (11 countries) but only 8 countries submitted data. Evaluated population as “patients treated at risk during the year”: AR (319.5), RO (173.5), DE (137), HU (103), PL (97), UR (69.5), CL (27), KZ (7). Crude mortality rate was 13.1%, same if first 90 days on therapy were excluded. Lowest mortality was seen in HR (9.9%) and highest in DE (19.3%). Causes of death: cardiac 32%, all type infections 22% (Sepsis 78%, PD related 11% as 0.7% of total mortality), pulmonary 3.7%, others 7.4%, vascular 10%, gastrointestinal 3.3%, unknown 10% (cardiac 33% of causes); other unknown 6% per patient-year and 7.6 days of hospitalization per patient-year. N. of days per hospitalization episode was 13.7. Causes of hospitalization: PD related 38%, cardiovascular 17%, non-PD infection sepsis 10.7% (higher in LA, 16.6%), vascular access 2.1%, unknown 4.5%, others 23.3%. Global peritonitis rate was 0.18 episodes/patient-year at risk (1 episode every 66 m). However, large differences were seen among countries. Transplantation rate was 6.5% (much higher in UR). PD was withdrawn in 35% of pt. Country specific data have been evaluated but are not shown here.

Conclusions: The use of a common registry in our institution increases quality and allows homogenous comparisons across countries that if promptly addressed may increase patients’ outcomes. Our series may bring light into the PD community as one of the ever largest tracked in a single institution.
Association Between Peritoneal Dialysis (PD) Patient-Reported Family Member Assistance and Peritoneal Dialysis Morbidity Persistence

Nashville, TN
Samantha T. Washington,1 Rachel B. Fissell,1 Ebene M.UMEKUJEE,Devika Nair,1 Kerri L. Cavanaugh,2 Beth Rust,1 Amanda E. Dunn,1 David G. Schlundt,1
1Vanderbilt University Medical Center, Nashville, TN; 2Vanderbilt University, Nashville, TN.

Background: Increasing the number of dialysis patients who start and maintain home therapy is an urgent national priority. PD patients perform their own dialysis procedures at home. Family members may assist with moving dialysate bags, catheter care, dialysis machine set-up and connections, and medication administration. Understanding and supporting caregivers is an important driver of successful home dialysis, necessary to inform program content and activities. This study describes associations between patient reported family member assistance with healthcare tasks, and morbidity persistence.

Methods: Prospective, single site, cohort study of adults receiving PD for kidney failure. A baseline survey assessing family assistance with healthcare tasks at home was administered during a routine outpatient visit. Longitudinal data were tested using Chi-squared (SPSS) for associations between patient reported family member assistance, and PD morbidity persistence at six months.

Results: This sample of N=100 patients was 57% male, 31% African American, and 4% Hispanic/other. Average age was 56 years. 16 years. Most patients reported a family member provided help at home (65%). Among those reporting family member assistance, 20% reported help administering insulin, 65% reported help with the PD procedure, 54% managed medications, and 59% provided wound care. Also, 16% reported help with one or two tasks, 28% help with three tasks, 25% help with five tasks. Patients who self-identified as Black/Hispanic reported less family member assistance than whites (51% vs 71%, p=0.04). In the 74% of the initial sample who completed 6 month follow-up, for patients reporting any family assistance compared to those reporting none, there was a trend toward higher PD morbidity persistence (86.4% vs. 70.4%, p=0.092).

Conclusions: Optimizing family assistance may be a strategy to promote PD morbidity persistence. More work is needed to better characterize the caregiver role and its impact on health outcomes specific to home dialysis.

Patient Outcomes of a Two-Exchange Assisted Continuous Ambulatory Peritoneal Dialysis (CAPD) Programme for Frail Older Patients

Louise A. Ryan,1 Titus Chelaparuth,1 Richard W. Corbett,1 Edwina A. Brown,1 Imperial College Healthcare NHS Trust, London, United Kingdom; 1Imperial College London, London, United Kingdom.

Background: Recognising the burden that hospital haemodialysis (HD) places on frail people in terms of time away from home, transport and haemodynamic shifts, we developed a 2-exchange assisted CAPD programme to enable frail people to receive a home-based therapy. Eligible patients include frail, mostly elderly patients who are symptomatic from advanced kidney disease and have residual kidney function. The focus of the programme is to optimise patients’ symptoms while avoiding a high treatment burden.

Methods: In this observational study, all 2-exchange aCAPD patients attending for routine review are approached for assessment. Frailty is assessed with the Edmonton Frail Scale (EFS), cognitive function with the Montreal Cognitive Assessment (MOCA), treatment satisfaction (treatment-related Quality of Life Questionnaire (RTSQ)) and symptoms with the Palliative Outcome Scale-Symptom Renal (POS-S Renal). Data was collected via patient interviews and chart review.

Results: Of the 17 patients currently receiving 2-exchange aCAPD, results have been collected from 47% (N=8) to date. Mean age is 82 years (77-90) and 50% are male. Mean number of co-morbidities is 4.4. Mean time on 2-exchange aCAPD was 9 months (0-24). 63% had at least mild frailty with an EFS >8/17 (3-11). 75% had memory impairment with a MOCA <26/30 (8-30). Median number of hospital admissions was 1 (0-13). 38% had travelled outside of the UK (with family support) since commencing aCAPD. 85% reported high satisfaction with treatment with a RTSQ of >55/66 (median 62). Patients reported a low symptom score with a median POS-S Renal of 14.5 (7-27). Pain, lack of energy and poor mobility were the most commonly reported symptoms.

Conclusions: Our results demonstrate a frail, elderly population with multiple co-morbidities. Although our population number is small and they are not matched to the assisted PD and HD populations published in the FEPOD study they do compare favourably in terms of the RTSQ score; median of 60 vs 55 for assisted PD and 60 vs 51 for HD. Our population was compared in 2010 with the POS-S Renal symptom scores of 14.5 vs 14 for assisted PD and 14.5 vs 16 for HD. This indicates that 2-exchange aCAPD could potentially become the dialysis modality of choice for the frail, older person requiring dialysis.

A Snapshot for Peritoneal Dialysis Clinic Visits: Addressing Hospitalization Rates with a Checklist

Samantha M. Saggese, Aditya V. Jain, Michael Bond, Janis Cho, Alexander S. Leidner, Tina S. Samuel, Harini Gurram, Vikram Aggarwal, Northwestern Memorial Hospital, Chicago, IL.

Background: Readmission rates are a component of quality metrics in home dialysis follow-up. Common causes of peritoneal dialysis (PD) related hospitalizations have been elucidated through National Readmission Database review. However, a systematic approach to identify individual risk factors leading to the index hospitalization and targeted interventions are not directly designed into clinic workflow. Often information regarding these specific risk factors are not exacted. We identified a need to standardize practice in our PD clinic by conceiving an action checklist for nephrologists and nurses to minimize index admissions.

Methods: Our quality improvement project sought to identify risk factors by analyzing the cause of admission from our cohort of 103 PD patients over 8 months. We divided reasons for admission into related and unrelated to PD. Based on these categories, we created a list of potential contributory risk-factors for admission. We also surveyed providers to determine key clinical components for a clinic checklist to encourage early recognition of the risk-factors.

Results: Of the 105 individual admission events identified from June 2018 to March 2019, 45% were identified as PD-related. Such admissions included peritonitis (34%), bacterial peritonitis (19%), electrolyte derangement (17%), hypotension (13%), new-onset hypertension (10.6%) and catheter dysfunction (10.6%). 37 admissions (35%) were readmissions in the last 30 days, of which 60% were PD-related. From these results we designed a snapshot of trends of the prior 3 months’ vital signs, electrolytes, weights, PET results, PD adequacy results, urine volume, peritonitis history and current medications for clinicians to review pre-visit.

Conclusions: We are currently implementing this checklist in our monthly PD clinic visits. Though the idea was conceived prior to the pandemic, we have increasingly seen the benefit of a clinical trends snapshot readily available as we transition to Telehealth visits to prevent patients’ exposure to COVID-19. This method assists the clinician in triaging remotely. Ultimately, through utilization of this tool, we hope to unify our practice pattern in the clinic to reduce admission rates by promoting proactive, not reactive, interventions.

Lung Comets and Hydration Status in Peritoneal Dialysis Patients

Robert Ekart,1,2 Lucjan Lucic Srajer,1 Katharina Marko,1 Nina Vedodsek Hojs,1 Sebastian Bevc,1 Radovan Bevc,12 University Medical Center Maribor, Maribor, Slovenia; 1Medical Faculty University of Maribor, Maribor, Slovenia.

Background: Multiple diagnostic options to determine hydration status in peritoneal dialysis (PD) patients are available. Multifrequency bioimpedance spectroscopy (MBHS) is a non-invasive method of estimating body composition, including total body water (TBW), extracellular water (ECW), intracellular water (ICW) and the ratio between both spaces (ECW/ICW). Lung ultrasoundography (LUS) and lung B-lines (lung comets) can be used for the evaluation of extravascular lung water. Ultrasound evaluation of inferior vena cava (UVIC) provides a non-invasive assessment of a patient’s hemodynamic and volume status. N-terminal pro-brain natriuretic peptide (NT-proBNP) is related to fluid status and fluid distribution. The aim of our study was to assess fluid status in PD patients comparing four different methods: MBHS, LUS, UVIC and NT-proBNP.

Methods: We performed a single-centre cohort study in 19 PD patients. The body composition was measured using the portable whole-body MBHS device, BCM® (Fresenius Medical Care, Germany), LUS with portable US device (Vscan, GE Corporate), UVIC index with SonoSite US device. NT-proBNP was measured in a one-step sandwich chemiluminescent immunoassay (Siemens Healthcare Diagnostics, Newark, USA).

Results: The mean age of patients was 54±10 years, mean dialysis vintage 53 (10-194) months were men. Thirteen (68.4%) patients had fluid overload (FO)>1.1 L. Data of patients are presented in table 1. We found a statistically significant correlation between the number of lung comets and ECW/ICW ratio (r=0.496, P=0.031) and NT-proBNP (r=0.759, P<0.001). In contrast, there was no significant correlation between the number of lung comets and UVIC (r=0.221, P=0.364).

Conclusions: According to our results, LUS with lung comets, MBHS with ECW/ICW ratio and NT-proBNP are useful and complementary methods for evaluation of fluid status in PD patients.

Outcomes of Urgent-Start Peritoneal Dialysis in a Retrospective Cohort

Gonzalo Matsumura Umemoto, Frank J. O. Brien. Washington University in Saint Louis, Saint Louis, MO.

Background: Peritoneal dialysis (PD) has shown to have early survival benefit and increased patient satisfaction when compared to in-center hemodialysis. Despite this, 86% of patients with End Stage Renal Disease (ESRD) start hemodialysis, while only 10% of patients start RRT via peritoneal dialysis. The Advancing American Kidney Health Initiative was launched in July 2019, with the goal of having 80% of incident ESRD patients on a home modality or transplant by 2025. In this context, major changes will need to ensue so patients starting RRT can have increased access to home dialysis. Conventional start peritoneal dialysis requires the PD catheter to rest for several weeks.
after insertion prior to use. This limits the use of PD for patients that need to start RRT urgently. An alternative is urgent start where the dialysis can be started as soon as 1 day after catheter insertion. There is growing evidence that urgent start PD is a safe and effective alternative to urgent start hemodialysis.

Methods: A retrospective analysis of patients that underwent urgent start peritoneal dialysis from 2013 to 2019 at the Washington University Home Modalities Dialysis Clinic was conducted. Complications (including catheter leak, catheter malfunction, infections and bleeding episodes), hospital admissions in the first 30 days after catheter placement and time patients remained on PD after urgent start were examined. Reasons for transition from PD to hemodialysis (HD) were obtained. Median time from catheter placement to initiation of dialysis was 5 days. Major complications including peri-catheter leakage occurred in 3 patients (7.5%), catheter malfunction in 7 patients, and hospital admissions within the first 4 weeks occurred in 3 patients (7.5%) and 2 patients (4.8%) developed an exit site infection. There was 1 patient that had a major bleeding event after catheter placement. 11 patients (27%) were admitted to the hospital within the first 30 days after urgent start PD. During the follow-up period, the median time patients were on PD after urgent start was 15.9 months, 16 patients (39.02%) transitioned to HD or RRT.

Conclusions: As has been demonstrated in previous studies urgent start PD remains a viable option for initiation of RRT and ensures increased access to home dialysis.

POI1269
Megaloblastic Anemia in a Patient on Peritoneal Dialysis Returning from Kenya

Marie-Laure Cambier, Tom Robberechts, Simon Planken, Rembert A. Mertens, Veerle Beckers, Karlien Francois. Vrije Universiteit Brussel (VUB), Universitair Ziekenhuis Brussel (UZ Brussels), Division of Nephrology, Brussels, Belgium; Vrije Universiteit Brussel (VUB), Universitaire Ziekenhuis Brussel (UZ Brussels), Division of Internal Medicine, Brussels, Belgium; Vrije Universiteit Brussel (VUB), Universitair Ziekenhuis Brussel (UZ Brussels), Division of Hematology, Brussels, Belgium.

Introduction: We describe a case of atovaquone-proguanil (A-P)-related toxicity in a patient treated with peritoneal dialysis (PD).

Case Description: A 40-year old man treated with PD presented 48 hours after return from Kenya with a diffuse erythematous rash, dysphagia, fever and weight loss. Clinical examination showed a maintained general status, diffuse non-pulpable purpura and tonsillolaryngopharyngitis. Laboratory testing revealed an elevated c-reactive protein and pancytopenia. Malaria prophylaxis (A-P) had been prescribed by his general practitioner on return from Kenya with a diffuse erythematous rash, dysphagia, fever and weight loss. Malaria infection was ruled out through blood smear analysis. Broad spectrum antibiotics were administered for tonsillolaryngopharyngitis. Bone marrow examination showed a megaloblastic anemia. Besides, he developed a diffuse nonscarring hair loss within weeks.

Discussion: DNA synthesis requires the presence of thymidylate, a nucleotide present in cells in rate-limiting amounts. Both folate and vitamin B12 are crucial cofactors in the DNA synthesis pathway.

Conclusions: More cases of A-P related toxicity should be reported on peritoneal dialysis patients.
Conclusions: 24-hour ambulatory pulse pressure is the most significant predictor of peritonitis for clinical outcomes in PD patients, and systolic blood pressure is an independent predictor for cardiovascular outcomes. Meanwhile, it suggests that the associations can be explained by vascular calcification and volume status in PD patients.

Differences in Protein Energy Wasting Indicators by Peritoneal Transport Type: A Cross-Sectional Study with Automated Peritoneal Dialysis Patients
Gabriela Leal,1 Enzo C. Vasquez jiménez,1 Ivan A. Osnua Padilla,2 Bernardo Moguel,1 Karla B. Cano Escobar.1 Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico; 1Instituto Nacional de Enfermedades Respiratorias, Mexico City, Mexico; 1Instituto Nacional de Enfermedades Respiratorias, Mexico City, Mexico.

Background: In chronic kidney disease (CKD) population protein energy wasting syndrome (PEW) is a prevalent problem with a multifactorial etiology (uremia, low energy and protein intake, basal energy expenditure increased, inflammation, metabolic acidosis, nutrient loss during renal replacement therapy (RRT). In peritoneal dialysis, patients with high peritoneal transport tend to have enhanced clearance of small solutes and shows low ultrafiltration capacity and higher inflammatory state, that impacts negatively in nutritional status. We evaluate the differences in nutritional status indicators and the association of high type transporter peritoneal protein energy wasting (PEW) syndrome.

Methods: Cross-sectional study of a cohort of 36 patients with CKD on automated peritoneal dialysis (APD) [18 men, 18 women; age, 35.1 ± 13.3 years; dialysis duration, 7 ± 4.3 years]. Peritoneal transport characteristics were classified after a peritoneal equilibration test (PET). The PET study reasons were: baseline study, low ultrafiltration, underdialysis and after an event of peritonitis. Patients were classified according to peritoneal characteristics as a low transporter (LT) [low/low average] and as high transporter (HT) [high/high average transporters]. Weight and height were measured using standard procedures and body composition was assessed by multifrequency bioelectrical impedance analysis.

Results: HT individuals have lower albumin concentrations than LT (3.3 ± 0.42 vs 3.7 ± 0.39, p=0.026). Higher glucose absorption from dialysis solution (p=0.036) and a trend toward in higher c reactive protein plasma concentrations (p=0.089) was observed in the HT group. Higher prevalence of PEW condition (50 vs 23%) was observed in HT group without statistical significance (p=0.144). Higher malnutrition status using malnutrition inflammation score and PEW criteria was observed in HT-PET, without statistical significance.

Conclusions: HT peritoneal membrane confers a risk for hypoalbuminemia and inflammatory state in CKD patients on automated peritoneal dialysis. HT patients are at an increased risk of PEW. Intervention studies to elucidate the best nutritional approach should be designed to improve nutritional status in this population.

PO1274
Monitoring for Early Signs of Peritonitis in Patients Undergoing Peritoneal Dialysis
Michael A. Fischman,1 Benjamin Briggs,1 Glenn M. Chertow.2 1University of California San Francisco, San Francisco, CA; 2Stanford University, Stanford, CA; 3Southland Renal Medical Group, Long Beach, CA.

Background: In 2019 the U.S. Department of Health and Human Services (HHS) established the “Advancing American Kidney Health” initiative, with a goal of increasing home-based dialysis from 12% to over 50% by 2025. To meet this goal, healthcare providers must address the common complications of peritoneal dialysis (PD) that contribute to modality failure and reluctance to opt for PD when starting dialysis. A sharp increase in PD utilization will require new approaches to reducing peritonitis and contribute to modality failure and reluctance to opt for PD when starting dialysis. A

Patient-Reported Factors and Peritonitis Risk: Results from the Optimizing Prevention of Peritoneal Dialysis-Associated Peritonitis in the US Study (OPPUS)
Keith McCullough,1 Jeffrey Perl,2 Muthana Al sahlawi,3 Neil Boudville,4 Yasuhiko Ito,5 Talergonsak Kanjanabuch,1 Beth M. Piraino,5 Douglas E. Schauble6 Martin J. Schreiber,5 Isaac Teitelbaum,5 Graham Woodward,5 Junhui Zhao,1 Ronald L. Pisoni.1 1Archer Research Collaborative for Health, Ann Arbor, MI; 2St. Michael’s Hospital, Toronto, ON, Canada; 3Chulalongkorn University, Bangkok, Thailand; 4University of Pittsburgh, Pittsburgh, PA; 5University of Colorado, Denver, CO; 6University of Western Australia, Perth, NSW, Australia; 7St. James’s University, Leeds, United Kingdom; 8Aichi Medical University, Nagakute, Japan; 9DaVita Inc, Denver, CO; 10University of Pennsylvania, Philadelphia, PA.

Background: Peritoneal dialysis (PD)-associated peritonitis has been found to be associated with depression in a single center study (Troidle 2003). Using international multicenter PDOPPS data, we investigated the association of peritonitis with reported symptoms of depression via the Center for Epidemiologic Studies Depression Scale (CES-D) and quality of life (QoL) measures.

Methods: We used Peritoneal Dialysis Outcomes and Practice Patterns Study phase 1 (2014-2018) data from Australia and New Zealand (A/NZ), Canada (CA), Japan (JP), Thailand (TH), the UK and US in cause-specific recurring-event survival models on peritonitis outcomes, stratified by previous episodes. Patient QoL was estimated using the SF-12 Physical and Mental Health Composite Scores (PCS, MCS), and CES-D. Analyses were adjusted for age, years on PD, serum albumin level, residual urine, black race, sex, heart disease, diabetes, GI bleed, country, and prior peritonitis events.

Results: Peritonitis risk was associated with higher CES-D scores (p=0.05). Patients who reported CES-D scores ≥ 15 had 27% higher peritonitis risk compared to patients who reported scores < 10. While associations were weaker for MCS (p=0.69) and PCS (p=0.40), scores that indicated the lowest tertile of QoL in these areas were associated with 6-7% higher peritonitis risk than scores in the highest tertile (table).

Conclusions: While the association between poorer QoL and peritonitis risk was weak and non-significant, the association between having greater symptoms of depression (per CES-D) and future peritonitis risk warrants further investigation, as depression may be a modifiable risk factor.

Image-Guided Percutaneous Peritoneal Dialysis Catheters: Greater Than the Sum of Their Parts
Anubha Muneja,1 Shilpa Arora,2 Frank J. O Brien,3 Daniel W. Coyne,1 Daniel Picus.1 1Washington University in Saint Louis, Saint Louis, MO; 2Rush University Medical Center, Chicago, IL.

Background: Peritoneal Dialysis (PD) is a favored treatment modality for patients with end-stage kidney disease. PD catheter Complications on adequate and timely insertion of PD catheter. Most centers rely on laparoscopic insertion of PD catheters for PD initiation. Small studies indicate that image guided percutaneous (IGP) PD catheter insertion by interventional radiology (IR) may be non-inferior to laparoscopic catheters. However, there are limited data to compare IGP PD catheters to those inserted with laparoscopic technique. Hence, there are no definitive evidence based recommendations to support which technique may be superior. We conducted a retrospective analysis to compare complication rates and catheter survival in laparoscopic versus IGP PD catheter insertions.

Methods: Patients who underwent laparoscopic or IGP PD catheter placement from Jan 2014–Aug 2019 were included in the analysis. GP with a PACS and employed

Repeat Peritonitis: A New Reality After Staphylococcus aureus Carriage Surveillance Implementation
Marina Reis, Ana Marta Gomes, Daniela Lopes, Clara Santos, João C. Fernandes. Centro Hospitalar Vila Nova De Gaia/Espinho, Vila Nova de Gaia, Portugal.

Background: Peritonitis is one of the major peritoneal dialysis complications and an important cause of technique failure. Notably, repeat peritonitis (RP) have substantial risk of developing further infection episodes that perpetuate peritoneal membrane damage. As Staphylococcus aureus (SA) is a major causative of RP, strategies such as staphylococcus aureus carriage surveillance (SACS) were implemented to decolonization of carriers in order to decrease SA infections. This study aims to describe repeat peritonitis clinical behavior and SACS influence on repeat peritonitis.

Methods: We developed one center retrospective study from 1998 to 2019 that compared RP episodes with a control group in terms of causative microorganisms, cure rate, catheter removal and permanent and temporary transfer to hemodialysis. We also compared the same data in RP episodes before and after SACS.

Results: Overall, RP were caused by gram positive microorganisms and had a significantly higher cure rate (97.1% versus 67.3%, p<0.001) and lower rate of hospitalization (11.8% versus 30.8%) than control group. After SACS, global peritonitis rate decreased (0.54 versus 0.35 episodes per patient-year), and RP rate increased (37.5% versus 7.4%, p<0.001) as Streptococcus became more frequent (56.7% versus 0.0%, p<0.007) and SA less frequent (3.5% versus 60.0%, p<0.001). Also, RP cure rate increased (100% versus 80.0%, p=0.013) and permanent transfer to hemodialysis decreased (6.7%, versus 40.0%, p=0.03).

Conclusions: RP Group have more favorable results than control group that presented higher gram-negative peritonitis rate. After SACS, Streptococcus became more frequent than SA in repeat group, peritonitis outcomes became more favorable but repeat peritonitis rate increased. We believe that as measures to prevent SA infections are implemented more programs will face this reality.

Repeat Peritonitis Causative Microorganisms

PO1278 Strategies to Prevent Infection-Related Losses in US Peritoneal Dialysis Programs by More Actionable Predictive Data Reporting
Martin J. Schreiber, Michelle Cassin, Bram Van hout, Meredith L. Zywyn, Tanvi Rane. DaVita Inc, Denver, CO.

Background: Peritoneal dialysis (PD)–associated peritonitis (PTN) accounts for a significant percentage of patients who transition to hemodialysis due to infection-related technical failure. Data reporting to individual PD home programs on PTN rates is desired to drive a proactive and permanent approach to prevent technical failure. We considered older age, female sex, obesity, diabetes mellitus, diverticulosis, and constipation to be the most important risk factors for endogenous peritonitis in patients undergoing PD. Therefore, we added these six factors as confounding factors into our multivariate logistic regression model.

Methods: Between 2016 and 2020, a standardized reporting of PD-related PTN was carried out for 1487 affiliated PD programs across the United States (66,687 patients). Currently, PTN is reported on a 3-month rolling average for each program, with the most recent calendar month filled with the most current PTN rate at that event. We queried our EMR after 07/30/2013 to preferentially concentrate the inoculum. We used univariate logistic regression models for the above-mentioned risk factors for endogenous peritonitis (p = 0.0036) in our multivariate logistic regression model.

Conclusions: Because smoking and constipation are significant independent risk factors for endogenous peritonitis in PD patients. The management of constipation and discontinuation of smoking may lower the risk of endogenous peritonitis in PD patients.

Impact of Performing Cultures of Peritoneal Fluid Correctly on the Reduction of False-Positive and False-Negative Culture Rates in Patients on Peritoneal Dialysis (PD) Presenting with Peritonitis
Sunil Shergaw, Jie Ouyang, Angelica C. Grussner, Subodh J. Saggi. SUNY Downstate Health Sciences University, Brooklyn, NY.

Background: Peritonitis is feared complication of PD and reason for loss of peritoneal membrane function. It negatively impacts the Quality metrics of home program performance. Preliminary observations in 2013 showed a high failure rate for treating culture negative peritonitis. Intervention based on our root cause analysis from 07/30/2013 to 12/31/2019 done to address disparities in performing proper culture techniques within hospital systems and outpatient home dialysis ambulatory clinics.

Methods: Prior to 07/30/2013 (5-10 ml) of a cloudy PD fluid was injected into an aerobic and an anaerobic blood culture bottle. After 07/30/2013 we implemented a policy whereby 50 ml of PD effluent was used for centrifugation and the pellet was injected into culture bottles to preferentially concentrate the inoculum. We queried our EMR after 07/30/2013 (5-10 ml) of a cloudy cloudy PD fluid was injected into an aerobic and an anaerobic blood culture bottle.

Conclusions: Total of 41 observations met our inclusion criteria for retrospective analysis. We had 26 observations before and 15 observations after the policy implementation. Mean number of tests ordered after 07/30/2013 declined. Number of false positive tests declined and number of true negative tests and true positive tests increased (p<0.02), indicating increasing specificity and a more targeted antibiotic regimen rescuing peritoneal membrane function early. No direct impact on survival nor any impact on technique failure was observed.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: A gap in proper collection of PF fluid was identified. We educated all residents, renal fellows, nursing staff and microbiology laboratory staff across the entire health care systems, and created an order sets within EMR systems to close this gap ultrasound. Repeat microbiology studies showed fungal elements in the PD fluid, later identified as Penicillium species mold. Patient was not started on Steroids and Tamoxifen due to underlying fungal peritonitis. He was transitioned to hemodialysis and treated with a prolonged course of amphotericin. Subsequent peritoneal studies showed increasing burden of mold despite intraperitoneal drainage. His course was further complicated by recurrent upper GI bleed and inability to tolerate hemodialysis due to hypotension. Patient was eventually transitioned to comfort measures.

Discussion: The pathogenesis of EPS is poorly understood. Some of the risk factors include use of PD for > 5 yrs, high dialysate glucose concentrations, repeated episodes of peritonitis, which can lead to peritonitis leak, solved after transtentorialysis for 2 months. In 2002 she was admitted with complete spontaneous PC expulsion (straight Tenckhoff PC 2 cuffs). She had no signs of ESI and denied using any topical medication. A contralateral PC was inserted with no complications. CASE3: 62 year-old woman with CKD due to anti-glomerular basement membrane disease. She received induction treatment with high-dose steroids and cyclophosphamide. She presented Pseudomonas aeruginosa solved after a course of topical antibiotics as well as external cuff shaving. In 2019 she developed again ESI with Pseudomonas aeroginosa, and despite topic treatment as per antibiotic exit site cultures remained positive. One month later she presented a spontaneous expulsion of the PC. A contralateral PC was placed without further infectious complications. These risk factors should be identified and kept in mind to prevent the catheter extrusion.

PO1284
Polymicrobial Peritoneal Dialysis Peritonitis due to Eggertghella lenta, Parabacteroides Species, and Bacteroides distansion
Supriya Gerardin,1 Vesh Srivatana,1 New York Presbyterian - Weil Cornell, New York, NY; 2Rogers Institute, New York, NY.

Introduction: Peritonitis is a severe and common infectious complication among patients on peritoneal dialysis (PD). Most cases are due to Coagulase negative staphylococcus. Anaerobic bacteria constitute < 0.5% of the peritonitis in PD patients. This is a case of anaerobic polymicrobial PD peritonitis of rare pathogens without a clear identifiable source.

Case Description: 92 year old man with end stage renal disease who had a failed deceased donor renal transplant and was started on peritoneal dialysis 6 months ago was admitted for abdominal pain with cloudy peritoneal fluid for 3 days. Peritoneal fluid had cell count of 22,000 cells/ul. He was treated with intraperitoneal amikacin and cefazidime with improvement in abdominal pain and cell count downtrended to 2700/ ul on Day four he was discharged with continued IP antibiotic administration. He was re-admitted in two days for worsening abdominal pain with a cell count of 14,000/ ul. Patient had been correctly administering IP antibiotics with the assistance from his family members. CT abdomen pelvis with intravenous and oral contrast showed small bowel ileus likely due to the peritonitis. At this time the peritoneal catheter was removed and he was converted to hemodialysis. The peritoneal fluid cultures on Day 7 revealed Eggertghella Lenta and Parabacteroides distansion. After a straight Tenckhoff PC, his initial PD fluid culture prior to transfer from outside hospital was positive for Candida parapsilosis and Bacteroides distansion. Sensitivities were reported for only Eggertghella Lenta and Parabacteroides species and they were both sensitive to metronidazole. Antibiotics were broadened to intravenous vancomycin, cefazidime and metronidazole with clinical improvement in his abdominal pain and ileus. He was discharged with continued IP antibiotic administration.

Discussion: To our knowledge, this is the first case of bacterial peritonitis from Parabacteroides species and Bacteroides Distansion. There is only one case report of Eggertghella Lenta causing PD peritonitis and in this case extracorporeal removal was slow growing and this highlights the potential need for anarobic coverage in PD peritonitis without early pathogen isolation and/or failure of initial empiric treatment.
A Rare Case of Trichoderma-Related Peritonitis in a Patient on Peritoneal Dialysis
Ramya Bachu, Stefan C. Hemmings, Suman Siddamreddy. Baptist Health - UAMS Medical Education Program, North Little Rock, AR.

Introduction: Trichoderma spp are saprophytic fungi commonly found in the soil, decaying wood and humid environments. They are known to cause infections in immunocompromised hosts but rarely in peritoneal dialysis (PD) patients. Cases are infrequently reported in the literature and are associated with high morbidity and mortality.

Case Description: A 65yo white male with DM, HTN, HLD, ESRD on PD, was admitted with worsening abdominal pain for 4 weeks with low grade fever, chills, nausea and vomiting. His vitals were stable. Significant findings were a diffusely tender abdomen with rebound tenderness, rigidity, and guarding. His PD effluent was cloudy. Labs were unremarkable. CT abdomen was negative for acute pathology. He was started on intraperitoneal vancomycin and cefazidime as an outpatient as he had two earlier bacterial peritonitis episodes in the year. However, preliminary cultures from his clinic grew fungal elements. This prompted urgent PD catheter removal and conversion to hemodialysis. The fungus identified was Trichoderma and he was started on IV Anidulafungin. Repeat PD cultures were negative and he was discharged on oral Voriconazole with follow up in ID clinic. Over the course of 2 weeks, he was readmitted twice with worsening abdominal pain. On the third admission, he had exploratory laparoscopy and found to have diffuse, thrush-like plaques all over the peritoneum. IV amphotericin B was added to inpatient antifungal regimen. However, he continued to deteriorate and elected to go home on hospice and passed away soon after.

Discussion: Diagnosis of fungal peritonitis in PD is challenging and oftentimes delayed. Occurrences usually follow treatment of bacterial peritonitis and mimics its clinical features. Most isolates of Trichoderma spp have shown resistance to fluconazole and 5-fluorocytosine but show intermediate susceptibility to Amphotericin B, Itraconazole, Ketocanozole and Miconazole. Therefore, it is important to perform antifungal susceptibility tests and then adjust the final treatment. In conclusion, Physicians who treat patients on PD should be aware of the possibility of this opportunistic infection. Prompt antifungal treatment should be considered in cases of recurring peritonitis in the apparent absence of infection. More research is needed to guide early diagnosis and guide effective treatment of this rare fungal disease with high mortality.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

the identification of novel molecular biomarkers of peritoneal EMT may facilitate the diagnosis and management allowing early initiation of treatment targeting peritoneal fibrosis. Hylaroranon (HA) is a glycosaminoglycan component of the extracellular matrix, produced by three members of HA synthase (HAS1, HAS2 and HAS3). HAS are known to be involved in EMT of cancer cells, however there is no information on the association of HAS expression in peritoneum of ESRD patients.

Methods: Peritoneal MCs isolated from overnight dwells dialysates from 16 PD patients (PD_MC) at 2 [baseline peritoneal equilibration test (PET)] and 6 (follow-up PET) months of the PD initiation. We divided PD patients into two groups based on the alteration of baseline and follow-up PD MC morphology (Group 1: epithelial and Group 2: epithelial-mesenchymal). RNA-seq analysis (Ibogen, Korea) was performed in order to detect baseline molecular markers predicting mesenchymal phenotype in follow-up. Based on RNA-seq analysis, the expressions of HAS isoforms were evaluated and in their isoforms determined from omentum (OM_MC) with an exploration of the role of HAS on TGFβ-induced EMT.

Results: RNA-seq analysis demonstrated the difference of gene expression related to EMT (27.6%), angiogenesis (30.2%), cell migration (27.4%), and extracellular matrix remodeling (26.3%). Among them, HAS2 expression in baseline analysis showed the highest fold difference (28.5-folds) between group 1 and 2. In OM-MC, HAS1, HAS2 and HAS3 were constitutively expressed whereas only HAS1 and HAS2 were upregulated by TGFβ. TGFβ-induced changes in cell morphology and the expression of E-cadherin, α-SMA, and fibronectin were ameliorated by siHAS2, but not by siHAS1. HAS inhibitor induced changes in cell morphology and the expression of E-cadherin, TGFβ1 and α-SMA, and fibronectin were ameliorated by siHAS2, but not by siHAS1. HAS inhibitor (4-methylumbelliflorone; 4-MU) also alleviated TGFβ-induced EMT.

Conclusions: This data suggest HAS2 plays a role in TGFβ-induced EMT of peritoneal mesothelial cells and modulation of HAS2 can protect the peritoneal fibrosis in PD patients. Both HA or HAS2 in peritoneal effluent of baseline PET also can be the markers predicting peritoneal EMT and fibrosis.

PO1290
Am80, a Synthetic Retinoic Acid Receptor α-Specific Agonist, Suppresses Peritoneal Fibrosis via Inhibition of Krüppel-Like Transcription Factor 5 (KLF5) in Mice
Kumiko Muta,1 Yuka Nakazawa,2 Yoko Obata,2 Hiro Inoue,3 Kenta Torigoe,3 Kazuo Yamamoto,1 Tomoya Nishino,1 Nagasaki University Hospital, Nagasaki, Japan; 2Hokuyo Central Hospital, Nagasaki, Japan; 3Nagasaki University School of Medicine, Nagasaki, Japan.

Background: We presented previously that Am80, a synthetic retinoic acid receptor α-specific agonist, inhibited the expression of Krüppel-like transcription factor 5 (KLF5) and reduced peritoneal fibrosis in mice. Now, we examined further detail about the mechanism of Am80 in inhibiting peritoneal fibrosis.

Methods: Peritoneal fibrosis was induced by intraperitoneal injection of chlorhexidine gluconate (CG) into peritoneal cavity of ICR mice. Am80 was administered orally for 4 weeks in mice. The numbers of TGFβ positive cells, a smooth muscle actin (αSMA) or F4/80 positive cells were significantly decreased in Am80 treated group. KLF5 was expressed in αSMA, F4/80 or CD31 positive cells. Western blotting for KLF5 showed the tendency that KLF5 expression was decreased in higher concentration of Am80 in mouse fibroblasts stimulated by TGFβ1-in vitro.

Conclusions: These results indicate the KLF5 might not only associate phenotypical differentiation from fibroblasts to myofibroblasts but also regulate inflammatory responses and angiogenesis. Am80 is a promising fibrosis model. Am80 can suppress peritoneal fibrosis through inhibiting these mechanisms.

PO1291
Peritoneal Protein Clearance and Lean Body Mass Index: Relationship in Peritoneal Dialysis Patients
Roberto C. Marques,1 Ana T. Domingos,1 Eduarda C. Carias,1 Anabela M. Guedes,2,12 Idalécio Bernardo,3 Pedro L. Neves,1,12 1Centro Hospitalar Universitário do Algarve, Faro, Portugal; 2Universidade do Algarve, Faro, Portugal.

Background: An important feature of Peritoneal Dialysis (PD) is peritoneal protein loss (PLL) during dialysis. Peritoneal Protein Clearance (PPC) is considered a better index as it reflects the individual differences of PLL and membrane function of both small and large pores. Higher PPC has been reported to be associated with hypoalbuminemia and malnutrition, with some authors stating higher overall mortality. However, new studies failed to draw similar conclusions, arousing new insights on the peritoneal protein metabolism. Lean body mass index (LBMI) has been used as a useful marker of nutritional status in PD patients. The aim of this study was to evaluate the relationship between PPC and LBMI.

Methods: Prevalent PD patients with peritoneal equilibration test and multi-frequency bioelectrical impedance analysis (BIA) were enrolled in the cross-sectional study from January 2014 to December 2019. PPC was calculated as dividing 24h dialysate protein loss by serum total protein. LBMI was assessed by BIA and LBMI was calculated dividing LBMI by body height square. Spearman correlation test was performed to examine the association between body indexes and PPC. Multiple regression linear model was used for exploring the associated factors of PPC.

Results: We included 67 PD patients (54.1±17.3 years, 59.7% male, 31.3% diabetic). The mean evaluated parameters were: total Kt/V 2.5±0.8, nGFR 6.7±4.1 mL/min/1.73m2 and D/P creatinine ratio 0.63±0.01. The median PPL and PPC were 5.2(3.8-6.7) g/day and 0.5(0.3-0.7) mL/min/1.73m2, respectively. PPC was significantly positively associated with LBMI (r=0.401, P=0.001) and BSA (r=-0.327, P=0.007), but not with BMI (r=-0.109, P=0.381). Compared with conventional body indexes, LBMI had better performance in predicting higher PPC. Multiple linear regression model, when adjusted for gender, nGFR (PD), and diabetes, showed that older age (β=0.288, P=0.018), higher D/P creatinine ratio (β=-0.232, P=0.050) and higher LBMI (β=0.334, P=0.014) were independent predictors of PPC.

Conclusions: Higher LBMI is a marker of better nutritional status, which is associated with better survival in PD patients. In this study, higher LBMI was independently associated with higher PPC, partly by explaining conflicting results on the impact of higher PPC on mortality.

PO1292
Burden of Dialysis, Health-Related Quality of Life, and Employment Comparisons Between Peritoneal Dialysis and In-Center Hemodialysis: Findings from the DOPPS Program
Edwina A. Brown,1 Junhui Zhao,2 Keith McCullough,2 Douglas S. Fuller,2 Ana E. Figuereido,1 Brian Biefer,3 Fredric O. Finkelstein,1 Jenny I. Shen,3 Talensagk Kanjanabuch,2 Hideki Kawashini,4 Ronald L. Pisoni,2 Jeffrey Perl,3 Pieter Van Hoof1
1Plantin, support patient questionnaire, we used logistic regression to analyze binary outcomes employment (full- or part-time versus unemployed), depression (CES-D a10 vs. <10), and functional status (a11 vs. <11), and used linear mixed models to analyze continuous outcomes (PCS, MCS, and burden of kidney disease score). Change of outcomes were described descriptively.

Results: There were 3227 PD and 4544 HD patients at baseline. Burden of kidney disease scores were better for PD compared to HD (overall 9-point adjusted difference, [95%CI: 7.4-11.2]) with a higher proportion of patients on PD in the lowest burden range (10%-37%) compared to 8%-24% on HD, depending on country. PD patients also had better PCS and MCS, though these were less marked (overall adjusted difference of 0.9 [0.2-1.6] for PCS, 1.0 [0.2-1.9] for MCS). HD patients had worse functional status scores (adjusted difference of HD vs. PD 0.6 [0.5, 0.8] for score ≥11), were less likely employed (OR=0.6, 0.5, 0.8); and had worse CES-D scores (OR=0.8, 0.7, 1.0 for CES-D > 10). In Australia/ New Zealand, HD patients had better MCS and CES-D scores and a higher proportion being employed than PD patients. 174 PD patients and 254 HD patients died within one year of baseline patients and 532 (19%) PD and 573 (22%) HD patients were lost to follow-up due to changes over time in the continuous measures were small. Trends in employment, CES-D score, and functional status were small and not statistically significant.

Conclusions: Compared to HD patients, PD patients reported a lower burden of kidney disease score and among survivors, remains stable if either PD or HD on 12 months. This information, when shared with patients choosing a dialysis modality, could result in an increased uptake of PD.

H2S May Inhibit Peritoneal Dialysis-Related Fibrosis Through the Sulfhydrylation Regulation of PSMA7
Xiuqiao Chen, Ying Hu. Department of Nephrology, Second Affiliated hospital of Zhejiang University, Hangzhou, China.

Background: Peritoneal dialysis (PD) is one of the first treatment methods for patients with end-stage renal disease, which has advantages on cardiovascular system protection, low toxin clearance and patients’ life quality improvement. But statistics shows that the 5-year withdrawal rate of PD patients was around 50%, and ultrafiltration failure caused by peritoneal fibrosis is the main reason, and there is no effective clinical prevention and treatment. In our previous study, we found that the flora of PD patients was obviously maladjusted, and the production of H2S in the intestine was significantly reduced. Some evidences showed that H2S may alleviate PD-related fibrosis, suggesting that H2S may affect the fibrosis by regulating the level of sulfhydrylation, but the mechanism is not clear.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: Rat peritoneal mesothelial cells were randomly assigned into different groups: 4.5% peritoneal dialysate group (PD group), PD+H2S supplement GYY4137 group and PD+H2S inhibitor PAG group. The expression of pyroptosis associated proteins, inflammatory factors and fibrosis related pathways in different groups were compared. The changes of protein sulfhydryl sulfhydration level were analyzed by HPLC/MS/MS. The target protein and related pathway protein were up/down regulated by siRNA and the downstream pathways expression were observed by PCR and Western blot.

Results: GYY4137 significantly reduced the expression of pyroptosis proteins (NLRP3, cas-1, gsdmd-n), inflammatory factors (IL-6, IL-8, TNF - α) and fibrosis related proteins (p-smad3). Smad, TGF-β, VEGF) response to high glucose PD fluid. We found that the level of PSAM-7 sulfhydration in the PD group decreased significantly, but in GYY4137 group, the level of PSAM7 sulfhydration increased significantly. The expression of pyroptosis proteins, inflammatory factors and fibrosis related proteins were significantly increased after PSAM7 sulfhydration was interfered by mutant plasmids. The expression level of NLRP3 was up/down regulated by siRNA. The expression of downstream inflammatory factors and fibrosis-related proteins were significantly increased/decreased.

Conclusions: H2S has a protective effect on PD-related fibrosis through the PSAM7 sulfhydration regulation, and further break the pathological changes of “pyroptosis- inflammation-fibrosis” axis and avoid the occurrence of inflammatory cascade reaction.

POI1294
Fatigue Predicts Higher Risk of Mortality in Peritoneal Dialysis Patients: A BRAZPD Analysis
Murilo H. Quevedo,1 Liz R. Wallim,1 Camila R. Guetter,2 John W. Larkin,3 Chance Mysayphon,2 Yue Jiao,2 Len A. Usvyat,2 Peter Kotanko,2 Roberto Pecoits-Filho,2 Thiago P. Moraes,1 Pontifícia Universidade Católica do Paraná, Curitiba, Brazil; 4Renal Research Institute, New York, NY; 5Arbor Research Collaborative for Health, Ann Arbor, MI.

Background: End-stage kidney disease (ESKD) patients are often burdened by fatigue. Fatigue is a core outcome to peritoneal dialysis (PD) patients and providers, but its associations with clinical outcomes are unknown. We analyzed a nationally representative cohort of PD patients to test the hypothesis that higher fatigue independently associates with higher mortality risk.

Methods: We analyzed data from adult patients in BRAZPD, a nationwide Brazilian cohort across 122 PD centers. Patients incident to PD with complete KDQOL-SF survey in the first 90 days of dialysis were included. Fatigue was defined by the vitality subscale of KDQOL-SF. Cox proportional hazard models were fitted to examine the association between fatigue and 12-month mortality.

Results: We included data from 1,388 PD patients (mean age 58.5±15.4 years, 64% had RRF). Proportions of patients with high vitality, moderate vitality, moderate fatigue and high fatigue were 21%, 38%, 15% and 26%, respectively. Hazard-ratios (95%CI) for mortality estimated for the high vitality group (compared to high fatigue) were 0.39 (0.23-0.65), 0.41 (0.24-0.68) and 0.39 (0.22-0.68) for Cox, competitive risk and multilevel models, respectively. Results from the smoothing spline regression are shown in the Figure (B).

Conclusions: Higher fatigue in the initial months of PD was independently associated with 12-month mortality risk. Potential interventions targeting ESKD fatigue in PD patients may not only yield benefits in patient-reported outcomes but possibly also improve survival.

POI1295
Urgent-Start Peritoneal Dialysis: Experience in Mechanically Ventilated Prone Patients
Qandeel H. Soomro,1 Nina J. Caplin.2 NYU Langone Health, New York, NY.

Background: Patients with respiratory failure who require prone positioning are not considered good candidates for PD due to the concerns for increased intra-abdominal pressure, impaired diaphragmatic movement, and leaking of peritoneal fluid. We addressed the COVID-related AKI (CRAKI) surge for renal replacement therapy (RRT) by initiating an acute PD program at Bellevue Hospital including prone patients.

Methods: All patients were in the ICU with COVID related hypoxic respiratory failure and acute kidney injury (AKI). 635 patients who received PD were treated for 16 hours per day in the prone position to improve oxygenation. The mean age was 54.6. The average BMI was 35.5. Patients were on mechanical ventilation 12-33 days. 3/6 patients were on CVVH however, switched to PD due to clotting. Patients were on PD for an average of 9.3 days. All PD catheters were placed at the bedside using an open cut down technique. PD was started the same day using manual exchanges. Dwell volume was gradually increased to 2 L. Exchanges were performed q1h while supine and q2h while prone, a total of 4-6 exchanges/day. The PD team coordinated timing with the prone team and ICU nurses to allow the continuation of the PD treatment. Patients were monitored clinically for abdominal distention and changes in respiratory mechanics.

Results: All 6 patients remained on PD for the duration of the hospitalization. There were no incidences of bowel injury, hemorrhage, exit-site infections, or peritonitis. None of the patients had any catheter malfunction. Leaking was addressed with temporarily reducing the dwell volume. Patients experienced slow draining which was due to kinking of the tubing during prone positioning. All patients were able to continue receiving PD without interruptions. Either no change or improvement in ABG and ventilator settings was noted after prone positioning and PD.

Conclusions: Due to COVID related surge, we saw a significant number of patients in the ICU with severe acute respiratory failure requiring prone positioning who also developed AKI requiring RRT. We were able to successfully provide acute PD in ventilator-dependent prone patients suffering from CRAKI. This required a team effort and some modifications in the conventional PD prescription.

Peritoneal Dialysis (PD) Technique Training: What Features Influence Learning Time?
Haridran Sosa Barrios,1,2 Victor Burguera,1 Cristina Campillo,1 Sofia Ortego,1 Eva Lopez Melero,1 Marta Alvarez nadal,1 Daniel E. Villa,1 Milagros Fernandez-Lucas,1,2 Maite Rivera,1,2 Hospital Universitario Ramon y Cajal, Madrid, Spain; 2Universidad de Alcalá de Henares, Madrid, Spain.

Background: The adequate training of patients started on PD is an essential issue for technique success and basic to avoid and/or reduce complications. However, features affecting training duration have not been sufficiently studied so far. AIM: Identify features influencing PD training duration and their relation to first peritonitis episode timing and permanence on PD.

Methods: We retrospectively analysed all training sessions done with first time PD starters in our Unit (January 2001-December 2018). Demographic data on age, gender, end ESRD cause, Charlson morbidity index (CCI), number of training sessions, type of PD start, employment and education status, derivation and PD technique were recorded.

Results: 188 patients were trained, 72% male. Median age 55.4±15 yr, 25% were diabetic. Mean CCI: 4.9. Our patients required a median of 10 sessions (range 2-28) to gain sufficient skills performing the PD technique and feel confident, with a median of 19 days. Number of training sessions required increased with higher age (p=0.05), higher CCI (p=0.05) and diabetics (p=0.05). Neither gender, cohabitation, type of PD start, education level, derivation type nor employment status were statistically significant factors affecting PD training. Assisted PD patients were older (54 vs 71 yo, p=0.00) and they required a higher number of training sessions (10 vs 15.7 sessions). Patients requiring longer training (>23 days) had more peritonitis episodes (p=0.05), the first peritonitis episode happened sooner (15.7 vs 17.4 months, p<NS) and they remained less time on PD (32.57 vs 27.7 months, p=0.01).

Conclusions: The PD training time needed depends on patient’s age, diabetic status and comorbidities but does not relate to social, educational nor employment status. Patient’s requiring less training sessions have less peritonitis episodes and it happens later, remaining longer on PD technique.

Clinical Outcomes of Infection-Related Hospitalization in Incident Peritoneal Dialysis Patients
Yong Kyun Kim,1 Jin Kim.1 Ajou University School of Medicine and Graduate School of Medicine, Suwon, Gyeonggi-do, Republic of Korea; 2Catholic University of Korea School of Medicine, Seoul, Seoul, Republic of Korea.

Background: Infection is the second leading cause of death in patients undergoing long-term dialysis. Peritoneal dialysis (PD) is associated with an increased risk of infection-related hospitalization (IRH) when compared with hemodialysis. However, the effects of IRH on clinical outcomes in PD patients have not been established. In this study, we investigated the influence of IRH on clinical outcomes in incident PD patients.

Methods: In total, 583 incident PD patients were selected from the Clinical Research Center Registry for End-Stage Renal Disease, a nationwide multicenter prospective observational cohort study in Korea. Incident PD patients who had been hospitalized for infection-related diseases were categorized as the IRH group. The primary outcome was all-cause mortality and the secondary outcome was technical failure. The median follow-up period was 29 months.

Results: Seventy-three PD patients (13%) were categorized as the IRH group. Multivariate logistic regression analysis showed that diabetes mellitus was a significant independent predictor for IRH (odds ratio: 2.43, 95% confidence interval [CI]: 1.12–5.29, p=0.007). The most common causes of IRH were peritonitis (64.9%) and respiratory tract infection (11.9%). Multivariate Cox proportional hazard model analysis showed that IRH was a significant independent risk factor for all-cause mortality (hazard ratio [HR]: 2.51, 95% CI: 1.12–5.62, p=0.026) and for the technical failure of PD (HR: 3.23, 95% CI: 1.90–5.51, p<0.001).

Conclusions: Our data showed that after initiation of PD, IRH was significantly associated with higher risk of all-cause mortality and technical failure. Careful consideration of infection-related disease is needed in incident PD patients.
PO1301
Plasminatic Magnesium as a Marker of Nutrition and Inflammation in Peritoneal Dialysis?

**Background:** There’s an important prevalence of hypomagnesemia (hypoMg) in Peritoneal Dialysis (PD), namely due to magnesium (Mg²⁺) losses in the dialysate. HypoMg has recently been associated with increased mortality in PD, a clearer fact in Hemodialysis. Processes involved seem to include alterations in body composition (BC) and inflammation, known as predictors of mortality in PD, beyond the risks immediately associated with hypoMg such as cardiac arrhythmias. The aim of this study was to evaluate the correlations between plasmatic Mg²⁺ (pMg), BC, inflammation and nutrition in PD.

**Methods:** A prospective study included patients admitted at our Unit between 2010 and 2019, with simultaneous acquisition of bioelectrical impedance analysis (BIA) and pMg levels. Clinical and biochemical data were collected from clinical records. Spearman rank-correlation coefficient was used to report correlations.

**Results:** 54 patients were enrolled (mean age of 54.2±17.6 years, 61% men, 86.3% hypertensive and 33.3% diabetic). Mean pMg was 2.1±0.37 mg/dL and high-sensitivity C-reactive protein (hs-CRP) 10.8±4 mg/L. No correlations were found with other nutrition markers. The obesity paradox is still controversial in PD and some authors defend that an elevated BMI is associated with poorer nutrition, increased fat mass and inflammation. Dietary effects are also well described in relation to obesity in PD. In conclusion, hypoMg appears associated with poorer nutrition, increased fat mass and inflammation. Dietary interventions with Mg²⁺ supplementation could address this problem and should be a target of interventional studies.

**PO1302**
Feasibility of Using Platelet PGDprime® Rapid Assay as a Peritonitis Screen for Peritoneal Dialysis Patients
Lisa A. Shenefeld, Nancy B. Best, Remo P. Vallejo. Verax Biomedical Incorporated, Marlborough, MA.

**Background:** Peritoneal Dialysis (PD) patients carry the risk of bacterial infection via the catheter access site and the exit site. Peritonitis is suspected based on patient symptoms and the visual quality of effluent, but may not be confirmed until a sample of the effluent is tested at a central lab via culture. A result may take several days to generate. The Platelet PGDprime rapid test is a multiplexed immunoassay used to detect Gram-positive (GP) and Gram-negative (GN) bacteria in platelet units prior to transfusion. The utility of this rapid test for detection of bacteria in PD effluent was evaluated.

**Methods:** A sample (600 mL) of PD effluent from an asymptomatic patient was obtained and confirmed to be negative for bacteria by aerobic and anaerobic cell culture. Eight bacteria (5 GN & 3 GP) were grown in RPMI media and individually spiked at initially high levels into aliquots of the PD effluent, then serially diluted with the unspiked effluent in tenfold series. The CFU/mL of each starting spiking stock was quantified by OD at 620 nm. Each dilution was tested with PGDprime to determine the observed lowest detectable level of bacterial contamination by ten-fold dilution.

**Results:** The lowest detectable concentrations of bacteria are summarized in Table 1. The true Limit of Detection (LoD) for each species is between the lowest detectable concentration shown and the next lower logfold dilution level. Total test time was 25-35 minutes.

**Conclusions:** The PGDprime rapid test for bacteria in platelets can detect bacteria in PD effluent and may be useful for early detection of peritonitis in PD patients. Additional optimization to further adapt the test for PD effluent testing is underway.

**Funding:** Commercial Support - Verax Biomedical Incorporated

Omentectomy Reduces the Need for Peritoneal Dialysis Catheter Revision in Children: A Study from the Pediatric Nephrology Research Consortium
Meredith P. Schuh,1 Edward Nehus,2 Abdulla Ehlayel,2 Stephanie L. Clark,2 Aftab S. Chishni,3 Alcina D. Edwards, Richards,2 Stephanie M. Jernigan,2 Margaret Kame1,4 Kera E. Lucke1,5 Bliss Magella,1 Asif Ansari,1 Amy C. Wilson,6 Donna J. Claes.1 Cincinnati Children's Hospital Medical Center, Cincinnati, OH; 2University of Kentucky Medical Center, Lexington, KY; 3University of Michigan, Ann Arbor, MI; 4Emory University, Atlanta, GA; 5Indiana University Health, Indianapolis, IN; 6Augusta University, Augusta, GA; 7The Children's Hospital of Philadelphia, Philadelphia, PA, 8Wake Forest Baptist Health, Winston-Salem, NC; 9Children's Healthcare of Atlanta Inc, Atlanta, GA.

**Background:** There are no recommended guidelines for performing omentectomy at the time of peritoneal dialysis (PD) catheter placement in the pediatric population. There are no multi-center studies investigating omentectomy and PD catheter revision in the pediatric dialysis population.

**Methods:** A multi-center, retrospective study was performed through the Pediatric Nephrology Research Consortium (PNRC). Data review included all incident tunneled PD catheters placed between 1/1/2011 - 12/31/2016 for first-time PD patients (ages 0-20).

The primary outcome was the need for catheter revision and/or replacement following initial placement. Multivariable logistic regression was used to determine the independent association of omentectomy with catheter revision/replacement.

**Results:** Data from 184 patients (62.5 % male; 35.4 % glomerulonephritis) from 8 centers were analyzed. Median age at PD catheter insertion was 7.4 years. Omentectomy was performed in 67 children at the time of catheter placement (36.4%). Revision or replacement was required in 63 children (54.2%); median time to revision/replacement was 38.5 days (IQR 20.5, 109) after catheter insertion. Revision/replacement of the catheter occurred in 23.9% who had an omentectomy, compared to 52.2% without omentectomy (p=0.0005). Compared to younger children, those > 6 years of age at the time of PD catheter placement had decreased risk of catheter revision/replacement (18.2% age > 6 vs 56.5% age ≤ 6, p<0.001).

After adjusting for all clinical and surgical covariates, omentectomy reduced need for revision by almost 70%, and revision was 4x more likely in those ≤ 6 years of age.

**Conclusions:** This multi-center study is the first to show that omentectomy at the time of PD catheter placement in pediatric patients is associated with decreased PD catheter revisions. Omentectomy should be strongly considered at the time of PD catheter placement, especially in children ≤ 6 years of age who are at high risk for PD catheter malfunction.

**PO1304**
Quality Improvement Initiative: Suboptimal Utilization of Loop Diuretics in Peritoneal Dialysis Patients
Zeynala Al hadhrami, Omar M. Ghadieh, Edward A. Biersc, Queen’s University, Kingston, ON, Canada.

**Background:** The prescription of high dose loop diuretics is safe and beneficial for PD patients to increase urine output, control of volume status, and decrease the need for high PD fluid glucose concentrations. The aim of this study is to assess the current state and develop an algorithm for rational diuretic use in PD pts to optimize dose, frequency, and reduce pill count in patients with urine output while reducing diuretics in anuric patients.

**Methods:** This was a prospective cohort QI initiative in prevalent PD pts. The algorithm considered PD fluid glucose > 1.5 % used, the volume status, current and historical urine volume trend, and clinical assessment. The dosing of loop diuretics was increased in pts with residual urine output > 200 mL/24 hrs when increased altrilfiltration was needed, while diuretics were stopped in anuric pts. The outcomes were the proportion of pts on loop diuretic in those with and without urine, the dose (median total daily, mean ± SD, range), and the proportion of pts on diuretics when PD volume status was controlled.

**Results:** Of 428 patients, 213 pts received loop diuretics (50%). The mean total daily dose of loop diuretics was 107.6 ± 102.4 mg/day (range 0 – 1360 mg/day). The proportion of pts on loop diuretics was 59.5% in pts with urine output ≥ 200 mL/day vs 25.9% in pts with urine output < 200 mL/day (p = 0.0001).

**Conclusions:** Loop diuretics are used suboptimally in PD patients. The algorithm developed in this study can guide the rational use of loop diuretics in PD patients.
frequency) and the pill count before and 3 months after the intervention. In the algorithm, Furosemide prescriptions of 40 mg tablets were converted to 500 mg tablets divided as needed where possible.

Results: The study included 91 pts, mean age 63 yrs, 45% female, 75% Caucasian, 64% with DM, median time on PD of 1.58 yrs. Furosemide was the only loop diuretic used. At baseline median total daily dose was 120 mg, BID 27 %, OD 73 %, and median pill count was 3.6 pills/day. The proportions of patients prescribed diuretics among those with and without urine output were 54/84 (63%) and 8/17 (47%) respectively. Three months after the intervention the median total daily dose was 240 mg, BID 53 % and OD 47%, mean pill count was 2.96 pills/day, and the proportions of pts on Furosemide for those with and without urine output improved to 85% and 27% respectively (all changes < p 0.05).

Conclusions: This short-term study suggests that QI intervention using an algorithm aimed at optimizing loop diuretic use in PD patients based on PD fluid glucose concentration used, and urine volume can increase the prevalence of diuretic use, increase the single and total daily dose, improve dosing frequency, and reduce pill burden in patients with urine output while reducing unnecessary use in anuric pts. This study is ongoing to examine outcomes of urine volume, glucose load of PD fluid, and electrolytes with the intervention.

PO1305
Assessing Fluid Status of Peritoneal Dialysis Patients with Assistance of Lung Ultrasound (Fluid-PLUS)
Michael Ayuria,1,2 Wael F. Hussein,1,2 Graham E. Abra,1,2 Vladimir Glinskii,1 Brigitte Schiller,1,2 Stanford University School of Medicine, Stanford, CA; 3Satellite Healthcare, San Jose, CA.

Background: Fluid overload (FO) is common in patients on dialysis, and is associated with increased cardiovascular morbidity and mortality. Clinical examination is limited in detecting FO. Lung ultrasound (US) is a portable and relatively inexpensive objective measure of FO. In this study, we aimed to evaluate the potential utility of lung US for evaluation of FO in patients on peritoneal dialysis (PD) in the ambulatory setting.

Methods: This is a cross-sectional, observational study at 4 home dialysis clinics in Northern California. Adult patients on PD attending routine outpatient visits were asked to participate. Patients on PD for less than 3 months or endorsing new or worsening shortness of breath were excluded. Participants underwent lung US examination. Based on the total number of B-lines, patients were classified as no US-fluid overload (< 16 lines), or US FO (≥ 16 lines). Independently, nurses clinically evaluated patients fluid status and determined if a patient had clinical FO or no clinical FO.

Results: 43 patients underwent full examination. Mean age was 55 ± 15, 28% were female, 15% of patients had diabetes mellitus, and median PD vintage was 19 (IQR 10-37) months. Clinically, 13 (30%) of patients had FO. Lung US identified 15 patients (35%) as having FO. Clinical and US findings were congruent in 35 (81%) patients, but discordant in 8 (19%) of patients. Of the 30 patients without clinical FO, 5 (17%) were identified with US FO. On the other hand, of the 13 patients with clinical FO, 3 (23%) had no US FO. – Figure 1. Agreement between clinical examination and lung US was moderate (kappa 0.58, 95% CI 0.32 to 0.84).

Conclusions: Lung US may identify a subset of patients with FO missed by clinical examination. Further studies are required to evaluate the impact of managing patients according to lung US findings on clinical outcomes.

PO1306
Use of Incremental Peritoneal Dialysis: Impact on Clinical Outcomes and Quality-of-Life Measures
Mihran V. Nalayan,1,2 Francesca Tentori,1,4 Abigail Hunt,1,2 Katherine L. McKeon,1,3 Martin J. Schreiber,1 Steven M. Brunelli,1,4 DaVita Inc; Denver, CO; 1LSU School of Medicine, New Orleans, LA; 2Davita Clinical Research; Minneapolis, MN; 3DaVita Patient Safety Organization, Denver, CO.

Background: Incremental peritoneal dialysis (PD), defined as a PD prescription that is less than the standard, full-dose prescription, has been suggested as a means of preserving residual kidney function and offering better quality of life; however, published evidence is limited.

Methods: We considered adult patients initiating PD between 31 Jul 2015 and 31 May 2019. Patients with body weight <40 kg, limb amputation, or estimated glomerular filtration rate (eGFR) >20 mL/min during first 4 weeks on PD were excluded. Exposure group was ascribed (incremental vs full PD) based on PD prescription during dialysis weeks 5 to 8. Incremental PD was defined by treatment frequency, exchanges/day, and exchange volume (for continuous ambulatory PD [CAPD] patients) or by treatment frequency and presence/absence of last fill (for automated PD [APD] patients). Analyses were performed separately for CAPD and APD patients: for each, incremental PD patients were propensity score matched to eligible full PD patients. Patients were followed for up to 12 months until censoring for loss to follow-up or study end. Outcomes were compared using Poisson models (mortality, hospitalization, PD failure), linear mixed models (eGFR), and paired t-tests (Kidney Disease Quality of Life [KDQOL] domain scores).

Results: Among CAPD patients, compared to those on full PD, incremental PD use was associated with better KDQOL scores on 3 domains: physical composite score (42.5 vs 37.7, p=0.03), burden of kidney disease (60.2 vs 45.6, p=0.003), and effects of kidney disease (79.4 vs 72.3, p=0.05). Hospitalization and mortality rates were numerically lower (0.77 vs 1.12 admits/patient-year, p=0.09 and 5.0 vs 10.2 deaths/100 patient-years, p=0.22), there was no association with residual eGFR or PD failure rate. Use of incremental PD was not differentially associated with any outcome among APD patients.

Conclusions: These results suggest that it may be beneficial to use incremental PD in the context of CAPD, particularly with respect to quality of life. No significant benefits were detected among patients initiating APD. No detrimental effects of using incremental PD were observed for either PD type.

PO1307
Combination of Hypertension and Preexisting Cardiovascular Disease and Mortality in Patients on Continuous Ambulatory Peritoneal Dialysis
Xianfeng Wu, Niansong Wang, Junnan Wu. Affiliated Sixth People’s Hospital, Shanghai Jiao Tong University, Shanghai, China, Shanghai, China.

Background: Little is known about whether combination of hypertension and pre-existing cardiovascular disease (CVD) is more strongly associated with outcomes compared with either comorbidity alone in patients on continuous ambulatory peritoneal dialysis (CAPD).

Methods: We conducted a retrospective study of 3073 incident Chinese patients on CAPD from five dialysis centers between January 1, 2005 and December 31, 2018 in a real-world setting. All patients were divided four groups: group 1 (patients without either hypertension or pre-existing CVD); group 2 (patients with only hypertension); group 3 (patients with only pre-existing CVD); group 4 (patients with both hypertension and pre-existing CVD). The association between interesting comorbidities and mortality was analyzed using Cox regression models.

Results: Over a median of 33.7 months of follow-up, 581 (18.6%) patients died, with 286 (9.3%) CVD mortality. The incidence of all-cause mortality was 32.2, 56.1, 74.4, and 131.0/1000 patient-years, and the incidence of CVD mortality was 15.0, 28.2, 34.7, and 69.6/1000 patient-years in group 1, 2, 3, and 4, respectively. Cumulative survival and CVD mortality-free survival were lowest in those with both hypertension and pre-existing CVD (Figure 1). After adjusting for the demographic characteristics and laboratory parameters, group 4, 3, and 2 had 3.07 (95% CI 2.23 to 4.22), 2.05 (95% CI 1.11 to 3.80), and 1.38 (95% CI 1.08 to 1.77) of hazard ratios for all-cause mortality, and 3.20 (95% CI 2.04 to 5.03), 2.09 (95% CI 0.85 to 5.15), and 1.56 (95% CI 1.09 to 2.23) of hazard ratios for CVD mortality, respectively, compared to the group 1.

Conclusions: Combination of hypertension and pre-existing CVD was more strongly associated with mortality compared to either comorbidity alone in CAPD patients.
Methods: We have reviewed electronic charts of patients on PD in the last 8 years in our hospital. We compared survival, residual diuresis and reasons to discontinue PD in 2 groups: patients with graft failure that returned to PD (PD-Ktx, N=17) and other clinical conditions (PD-other, N=153). Reasons for stopping PD therapy included: dialysis inadequacy, kidney transplant, death, transfer to another center, and peritonitis.

Results: The median follow-up was 36 (17,71) months, which was similar between groups [45(18.96) in PD-Ktx vs 35(12.70) months in PD-other, p=0.403]. Patients from PD-Ktx group were lighter than those from PD-other (57.2 ± 14.7 vs 66.1 ± 16.1kg, p=0.022). Initial and final diuresis volumes were similar among groups (p=0.879 and p=0.698, respectively). Reasons for stopping PD therapy in PD-Ktx and PD-other groups were dialysis inadequacy (17.6% and 20.9%, respectively), kidney transplant (17.6% and 15.7%, death (5.9% and 12.4%), transfer to another center (17.6% and 20.9%), and peritonitis (17.6% and 14.6%). These outcomes were not significantly different between groups (p=0.921). Four out of 17 patients from PD-Ktx maintained immunosuppression and none of those had peritonitis. Kaplan Meier survival comparing PD-Ktx and PD-other showed there is no difference in stopping PD due to peritonitis (log-rank 0.543), which was confirmed in a Cox regression adjusted for weight, diabetes, residual diuresis and age (p=0.493).

Conclusions: Clinicians should leverage the risk of peritonitis versus extend PD technique by preserving residual diuresis in patients with allograft failure returning to PD. We have found similar outcomes in the current study. However, whether withdrawal immunosuppression is needed for these patients requires further investigation.

Belen Marron,1 Suzanne H. Pearce,1 Janusz Ostrowski,2 Dan Munteanu,3 Marietta Torok,1 Jaime Garcia-Marron,2 Carlos Lucas,1 Israel P. Silva,1 Filiz Akdeniz,1 Charlotte Wollheim,1 Fernando Macario,1 1Diaverum Services, Medical Office, Hylle, Malmo, Sweden; 2ESIC, Madrid, Spain; 3Diaverum Services, Bucharest, Romania; 1Diaverum Services, Wloclawek, Poland.

Background: Decision-Making Tools (DMTs) are still not widely used but are considered gold standard to ensure patients are well informed to choose renal replacement therapy (RRT) modality. OBJECTIVE: To analyze the impact of a structured modality information program (via DMTs) on RRT modality choice and start.

Methods: All 2014-2017 predialysis patients (pts) with CKD G4-G5 and those starting unplanned dialysis without a prior information process underwent a DMTs program. The choice of DMTs varied from Dec 31st 2018. DMTs included values evaluation, RRT information with different tools, staff deliberation support and patient modality choice. Results shown as percentage of pts who reached a certain stage over the total number of pts under evaluation.

Results: 2012 pts (mean age 61 y) from 48 clinics (cl) in Poland (PL, 19 cl, 980 pts), Romania (RO, 12 cl, 351 pts), Hungary (HU, 10 cl, 341 pts), Germany (DE, 6 cl, 292 pts) and Argentina (AR, 1 cl, 48 pts) underwent DMTs. Staff considered PD contraindicated in 29% of pts, hence optimal candidates for HD/PD were 1408 pts. (mean age 60%, and 46% prone for a home therapy). Early referral (>12 m. in clinic before DMT started): 51%. Aids used included written information (97% of pts), DVD in 27% and HD/Peritoneal Dialysis - 2

PO1311

Peritoneal Dialysis in the Setting of Acute Brain Injury, an Underappreciated Modality

Elaina Wang,2 Ankur Shah.1 1Brown University Warren Alpert Medical School, Providence, RI; 2Division of Nephrology, Rhode Island Hospital, Providence, RI.

Introduction: Dialysis is complicated in the setting of acute brain injury due to a number of factors including acute shifts of solute, acute acid base shifts, need for anticoagulation, and changes in intracranial pressure. For these reasons, CRRT is the modality of choice when renal replacement therapy is needed. PD is less discussed but shares many of the benefits often attributed to CRRT. We describe a case successfully managed with PD.

Case Description: A 25-year-old male with history of ESRD secondary to FSGS on CCPD for 5 years presented to the hospital with headache and altered mental status. He was in his usual state of health until the day prior to admission. Initial imaging revealed a large intraventricular hemorrhage extending to the 4th ventricle. He underwent an emergent right depressive hemicraniectomy and clot evacuation. Patient was admitted to NCCU. Post-operative imaging revealed worsening cerebral edema, intraventricular hemorrhage, and hydrocephalus. As the patient had a functioning tenkoff catheter, we had to make PD for peritoneal dialysis. We continued peritoneal dialysis, which he tolerated well until the need for a percutaneous gastrostomy tube arose. He was transitioned to hemodialysis transiently but returned to peritoneal dialysis once he was able to tolerate oral food. He has now continued on PD for 1 year.

Discussion: In the dialytic management of patients with acute brain injury, a number of considerations must be undertaken including the avoidance of hypotension to minimize ischaemia reperfusion injury and maintain cerebral perfusion pressure, avoidance of anticoagulants that can precipitate or worsen bleeding, the potential for the precipitation of cerebral edema by rapid solute clearance and osmotic dissipation of therapeutic hypernatremia, and the mitigation of intracellular acidosis from bicarbonate delivery. Peritoneal dialysis is an ideal but underreported modality as evidenced by the case presented.

PO1312

Peritoneal Ultrafiltration Is Associated with Improvement of Functional Class in Patients with Congestive Heart Failure

Gajapathi Raju Chamarthi, Amadeep Singh, Hartini Bejanki, Amir Kazory,1 University of Florida College of Medicine, Gainesville, FL.

Background: Congestion is considered an integral component of heart failure syndrome and is a key driver of adverse outcomes. Peritoneal ultrafiltration (PUF) has emerged as an efficient therapeutic modality for management of fluid overload in patients with congestive heart failure (CHF) without end-stage kidney disease (ESKD). The efficacy of therapies of CHF are conventionally assessed through their effect on New York Heart Association (NYHA) classification. We sought to explore the reported impact of PUF on functional class of these patients.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
Blood Urea Nitrogen/Creatinine Ratio and Mortality in Patients on Peritoneal Dialysis
Xianfeng Wu, Junnan Wu, Niansong Wang. Affiliated Sixth People’s Hospital, Shanghai Jiao Tong University, Shanghai, China.

Background: Little is known about the association between the Nitrogen/Creatinine (BUN/Cr) ratio and mortality in continuous ambulatory peritoneal dialysis (CAPD) patients.

Methods: We conducted a retrospective study of eligible 2837 patients on CAPD from five dialysis centers in Chinese between January 1, 2005 and December 31, 2018. We calculated baseline BUN/Cr ratio, and then estimated the hazard ratio (HR) of mortality and 1.66 (95% confidence interval, 1.15 to 2.40) of HR for CVD mortality, after adjusting for baseline characteristics and laboratory variables. Cubic spline showed there was substantial variation in the reporting of time point for various endpoints. These studies unanimously reported improvement in NYHA functional class, which was close to -1 class for those that assessed the entire study population.

Conclusions: Available data based on contemporary clinical trials suggests that PUF, when used for management of patients with CHF, is associated with improvement of NYHA functional class. This finding is in keeping with our previous report on the salutary impact of PUF on volume status of these patients. Future controlled studies are needed to explore whether these benefits would translate into improved survival.

Abstract Withdrawn

PO1315
Between Gradients and Ratios
Nidrit Bohra, Abigayle Sullivan, Haseeb Chaudhary. Reading Hospital, Reading, PA.

Introduction: Hydrothorax due to peritoneal dialysis is a rare but known outcome from dialysis mainly in continuous ambulatory peritoneal dialysis (CAPD). Around 80% cases are due to a pleuropertitoneal fistula (PPF), an abnormal communication between the pleural and peritoneal space allowing leak of dialysate. A pleural fluid glucose to serum glucose gradient of >50 mg/dl is 100% specific for detecting the leak of glucose rich dialysate via the fistula.

Discussion: Previous reports have concluded that the incidence of pleuroperitoneal fistula is higher in PD patients compared to the general population. The incidence of pleuroperitoneal fistula in patients on CAPD has been reported to range from 0.05% to 1%. The incidence of hydrothorax in PD patients has also been reported to be 0.05-0.12%.

PO1316
Impact of Obesity on Success of Peritoneal Dialysis in ESRD Patients
Irene Nunuk, Frank J. O’Brien. Washington University in Saint Louis, Saint Louis, MO.

Background: Obesity rate is rising in the US and 1 in 4 adults are projected to have severe obesity by 2030. Prevalence of obesity in ESRD patients is also rising. Higher BMI has been shown to be associated with better survival in HD patients. However, data is inconsistent for PD patients. We examine the impact of different BMI classes on PD outcomes.

Methods: This is a single center retrospective cohort study. Inclusion criteria includes patients ≥18 yrs, > 3 month PD vintage and patients who received PD from 2014-2018. Exclusion criteria includes patients with BMI<20, patients with no Kt/V data or missing BMI. SAS statistical software was used for data analysis.

Results: 181 total patients are divided into 4 groups. Baseline characteristics were similar in all groups (fig 1). Outcomes include transition from PD to HD, transplantation rate, mortality rate, number of hospitalizations, PD vintage and catheter related infections. Our data showed that there is no difference in outcomes among different BMI groups (tab1, fig 2).
POI1318

Ochrobactrum Peritonitis in Peritoneal Dialysis: A Rare Case and Literature Review

Edward G. Medeiros,1 Lubin Juarez,2 Susie L. Hu,1 Ankur Shah,1,2 Brown University Warren Alpert Medical School, Providence, RI; 1Providence VA Medical Center, Providence, RI.

Introduction: Ochrobactrum are gram-negative facultatively anaerobic, motile bacilli typically isolated in aqueous environments. Reported infections by this pathogen primarily occur in immunocompromised hosts from environmental exposure, nosocomial contamination of sterile fluids and/or indwelling catheter use. Due to impaired immunity and exposure to exogenous microbes, peritonitis is a common and feared complication of peritoneal dialysis. We present a case of Ochrobactrum Antiropi peritonitis and review the literature on similar cases.

Case Description: A 67-year-old male with history of ESRD secondary to IgA nephropathy on CCPD for 4 years presented to the hospital with fevers, nausea, abdominal pain and generalized weakness. He experienced an episode of acute bacterial peritonitis 1-month prior to this hospitalization secondary to Pseudomonas aeruginosa treated with ciprofloxacin and fluconazole, and he completed the antibiotic course with resolution of effluent culture. He was empirically initiated on intraperitoneal ciprofloxacin and no other previous PD complications. A peritoneal effluent sample showed 347 nucleated white blood cells. He was empirically initiated on intraperitoneal ciprofloxacin and fluconazole, and he completed the antibiotic course with resolution of symptoms and peritoneal leukocytosis.

Discussion: We present the 8th case of Ochrobactrum Anthropsi peritonitis in a peritoneal dialysis patient. Zero of the published cases were associated with bacteremia. Attempted treatments have typically included carbapenems, aminoglycosides, gentamicin, and fluoroquinolones. Three of eight cases required removal of the Tenckhoff catheter. Peritonitis related mortality was zero percent. This case and review of the literature can serve to inform future occurrences.

POI1317

Late Onset of Sweet Hydrothorax: A Rare Complication of Peritoneal Dialysis

Amel L. Taha, Tyler Andrea, Swati Arora, Harry K. Williams, Bhavna Chopra. Allegheny General Hospital, Pittsburgh, PA.

Introduction: Peritoneal dialysis (PD) has a variety of complications, with diaphragmatic leak causing pleural effusions occurring in 1.6% of cases within 30 days of initiation of PD. We present a case of late-onset right sided pleural effusion, 14 months after initiation of PD, due to spontaneous pleuro-peritoneal leak and the course leading to this rare diagnosis.

Case Description: A 34-year-old female with polycystic kidney disease, bilateral native nephrectomies, and failed kidney transplant receiving PD presented with three days of right sided chest tightness and shortness of breath associated with ultrafiltration failure on PD. Chest x-ray on admission showed a large right-sided pleural effusion (Figure 1A). The patient received PD using 2.5% dextrose dialysate. 2 hours after catheter placement was performed with placement of a chest tube. Fluid analysis revealed a transudative effusion, with glucose of 322 mg/dL with corresponding plasma glucose of 147 mg/dL, consistent with dianeal solution in pleural space. Figure 1B demonstrates passage of the radiotracer from the peritoneal cavity (B) to the pleural space (A), suggestive of right-sided pleuro-peritoneal fistula (C). PD was discontinued and the patient was transitioned to hemodialysis (HD).

Discussion: This case demonstrates a rare complication of PD. Hydrothorax can occur due to increased intra-abdominal pressure causing migration of dialysis fluid from the peritoneal cavity into the pleural space by opening of defects in the diaphragm communicating the two cavities; negative intrathoracic pressure and transiently increased hydrostatic pressure of the dialysate may cause dialysate leak. This phenomenon typically occurs more frequently in women with polycystic kidney disease due to reduced abdominal capacity. Increased glucose in pleural fluid, CT peritoneography and NM scintigraphy are methods of confirming diagnosis. Transition to HD with monitoring for spontaneous closure of the pleuro-peritoneal leak is first line conservative treatment. If the leak persists, surgical repair of the diaphragmatic defect is definitive treatment to resume PD.
patients who are asymptomatic i.e. without abdominal pain or cloudy dialysate effluent. We will be able to detect elevation of their effluent dialysate, tailored at the time when their dialysis kinetics are being measured. Two samples will be sent to the laboratory to obtain white blood cell count, and bacterial culture. PeriScreen and Multistix 10 SG reagent strips will then be dipped in the remaining two samples. The results from all four strips are reported as positive or negative, and the results of the reagent strips will be compared to the gold standard of white blood cell count and culture. Specificity will then be calculated.

**Results:** Data from 10 patients has been obtained to-date. The average age of these patients was 61.4 (± 14.7) years, with 50% of them being females, and 50% of them were Caucasians. In these patients, the PeriScreen was found to have specificity of 100% and the Multistix 10 SG was found to have specificity of 100%.

**Conclusions:** Based on preliminary results, both PeriScreen and Multistix 10 SG reagent strips appear to have specificity >95%. Using this data, we aim to create a protocol for patients to use these strips at home to help rule out PD-related peritonitis in a more efficient manner.

PO1320

Acyclovir for Herpes Zoster Encephalitis: Panacea or Problem?

Adil Ghaffar, Laura J. Maursetter, Neetika Garg. University of Wisconsin System, Madison, WI.

**Introduction:** Herpes zoster, which is the reactivation of varicella-zoster virus (VZV), is more common in immunocompromised patients, with a higher incidence of encephalitis. The treatment of choice is intravenous acyclovir, with one of its adverse effects being neurotoxicity. We present a case where the disease effects and the medication side effects were difficult to distinguish.

**Case Description:** A 59-year-old man with ESKD and a history of failed allograft and Dialysis 20 years ago was referred to our clinic to have VZV encephalitis evaluated. Lumbosacral puncture showed no pleocytosis, but protein elevation at 90 mg/dL. EEG showed no epileptiform activity and MRI and MRA brain were normal. Because his symptoms started after the initiation of overdosed valacyclovir, medication toxicity was considered more likely than VZV encephalitis. PD MRA brain were normal. Because his symptoms started after the initiation of overdosed valacyclovir, medication toxicity was considered more likely than VZV encephalitis. PD was continued, but he deteriorated with worsening mental and pulmonary status after admission, requiring intubation. Subsequently, he underwent 3 daily hemodialysis (HD) treatments without improvement. On the 3rd day post-intubation, the CSF VZV PCR returned positive prompting intravenous acyclovir at 5mg/kg/day. Over the next day, he showed marked mental status improvement and got extubated. The serum VZV PCR also resulted positive which was diagnostic of disseminated herpes zoster with encephalitis. After 6 days of intravenous acyclovir therapy, he was discharged on valacyclovir 500mg twice daily to complete 21 days of therapy.

**Discussion:** Herpes zoster encephalitis and valacyclovir neurotoxicity can lead to similar presentations and pose a diagnostic challenge. Due to low volume of distribution and low protein binding, valacyclovir is highly dialyzable. Hemodialysis can be helpful in these patients to use these strips at home to help rule out PD-related peritonitis in a more efficient manner.

**Conclusion:** Our patient’s neurologic symptoms started after an inappropriately high dose of valacyclovir, and low protein binding, valacyclovir is highly dialyzable. Hemodialysis can be helpful in these patients to use these strips at home to help rule out PD-related peritonitis in a more efficient manner.

PO1321

Pittsburgh Sleep Quality Index Score Predicts All-Cause Mortality Independently in Chinese Dialysis Patients

Bo Liu,1 Qianqian Han,1 Sha Fu,1 Peifen Liang,1 Bin Li,1 Qiongqiong Yang.1 1Department of Nephrology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China; 2Clinical Trials Unit, the First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China.

**Background:** Poor sleep quality (SQ) is common in dialysis patients. The Pittsburgh Sleep Quality Index (PSQI) is a standard tool for evaluating SQ with high validity and reliability. The relationship of PSQI score to survival in dialysis patients has not been well studied. Less was reported in China. The aim of this study was to explore the association between PSQI score and all-cause mortality in Chinese dialysis patients.

**Methods:** 15237 pts were eligible for inclusion. The majority (72.7%) of pts had ≥1 PD Rx alterations during a mean follow-up time of 418 days (compared to 201-day follow-up for pts with 0 alterations). Most pts (53%) had dwell volumes adjusted, with 52%, 4%, and 44% having increases, decreases, or both increases and decreases in dwell volume, respectively. The table details pt characteristics associated with all-cause mortality.

**Results:** Compared to pts with no Rx alterations, pts with more Rx alterations were heavier, had higher serum phosphorus, lower PD Kt/V, and lower Kru. The number of alterations along with the timing and direction of these changes need to be further studied to help determine if a pattern of changes is associated with risk of PD technique failure and switch to HD.

PO1322

Mitochondric Acid 5 Alleviates Chlorhexidine Gluconate-Induced Peritoneal Fibrosis in Mice

Hiro Inoue,1 Yoko Obata,1 Takehiro Suzuki,2 Miki Torigoe,1 Kenta Torigoe,1 Kumiko Muta,1 Chitose Suzuki,2 Takaaki Abe,2 Takehiko Koji,2 Toru Muxha,1 1Department of Nephrology, Nippon University Graduate School of Biomedical Sciences, Nagaoka, Japan; 2Division of Nephrology, Endocrinology and Vascular Medicine, Tohoku University Graduate School of Medicine, Sendai, Japan; 3Department of Histology and Cell Biology, Nippon University Graduate School of Biomedical Sciences, Nagaoka, Japan.

**Background:** Peritoneal fibrosis is one of important complications induced by long-term peritoneal dialysis. Mitochondrial dysfunction causes an increase of oxidative stress and depletion of ATP. Thus, it may be associated with fibrosis and other diseases in several organisms, mitochonric acid (MA-5), which is the active form of the plant homoeoindole-3-acetic acid, was synthesized and its therapeutic potential for mitochondrial dysfunction in kidney disease models has been reported. In this study, we investigated the effect of MA-5 for peritoneal fibrosis in mice.

**Methods:** Peritoneal fibrosis was induced by intraperitoneal injection of chlorhexidine gluconate (CG) every other day for 3 weeks in C57BL/6 mice. MA-5 was administrated at 2 mg/kg by gavage every day. Control mice received only a vehicle
Longitudinal Changes in the Use of Peritoneal Dialysis Assistance for Patients Maintained on Peritoneal Dialysis

Jorge I. Fonseca-Correa,1,4 Janine F. Farragher,1 Matthew J. Oliver,1 Ashr Jain,1 Sarbjit V. Jassal,1,4 University of Toronto, Toronto, ON, Canada; 2University of Calgary, Calgary, AB, Canada; 3London Health Sciences Centre, London, ON, Canada; 4University Health Network, Toronto, ON, Canada; 5Sunnybrook Health Sciences Centre, Toronto, ON, Canada.

Background: Home dialysis therapies such as peritoneal dialysis (PD) offer flexibility and improved wellbeing for older individuals. However, a substantial proportion require assistance with personal care and health self-management. The study objective was to assess the nature of, and need for, assistance with PD management tasks changes over time. We hypothesized that patients and families would require less assistance as they become more familiar with PD management.

Methods: Using a multicentred, prospective observational study design, we recruited patients aged ≥50 years initiating PD. Patients underwent formal evaluation at baseline using validated components of a Comprehensive Geriatric Assessment. They then completed a monthly questionnaire for 6 months about their need for assistance with PD management tasks.

Results: 111 patients (age 69 ± 10 years, 68% male, 56% diabetic) were followed for a total of 609 patient-months. Assistance for PD management tasks remained generally stable throughout follow-up, and did not vary according to age, frailty, functional dependence or cognitive impairment. The proportion of patients needing assistance varied widely across the 13 different PD management tasks, but the proportion of patients needing help for each task remained relatively stable across time (Figure 1). Of those who needed assistance, 40% had help from a family member and 33% were helped by nurses. The family/nurse caregiver ratio for the different tasks did not change over time.

Conclusions: Our results suggest that MA-5 alleviates peritoneal fibrosis with the reduction of macrophages infiltration. Thus, MA-5 may have a therapeutic potential in the progression of peritoneal fibrosis as well as kidney disease models.

PO1325

Vascular Access Type and Risk of Mortality and Hospitalization Among Elderly Hemodialysis Patients: A Target Trial Emulation Approach

Beini Lyu, Micah R. Chan, Brad C. Astor. University of Wisconsin-Madison School of Medicine and Public Health, Madison, WI.

Background: Evidence is mixed regarding optimal choices of incident vascular access type for elderly patients on hemodialysis (HD). Prior studies have primarily compared functioning arteriovenous fistula (AVF) to arteriovenous graft (AVG) and been limited to survival outcome. We used a target trial emulation approach and intention to treat (ITT) analyses to compare AVF versus AVG placement among elderly patients on HD.

Methods: Patients eligible for the target trial were those ≥67 years old at HD initiation, with no AVF/AVG placed before HD initiation, referred for AVF/AVG placement, and had AVF/AVG within 1 year after HD initiation. Patients would be randomly assigned to AVF or AVG and be followed right after AVF/AVG placement for 5 years. Outcomes including mortality, all-cause hospitalization, and cause-specific hospitalization (infection, cardiovascular disease (CVD), and vascular access (VA) related) would be related within 6 months, 1 year, 3 years, and 5 years would be assessed.ITT analysis based on patients' first AVF or AVG placed would be applied. We used USRDS data from 2010-2016 to emulate the target trial and propensity score (PS) matching to balance the groups' characteristics.

Results: A total of 37,890 (out of 47,912) patients who had AVF/AVG placed within 1 year after HD initiation were included after PS matching. Among them, 28,847 (76%) had AVF placed and 9,043 (23.9%) had AVG placed. AVF was associated with lower risk of mortality over follow-up. Within 6 months after AVF/AVG placement, incidence of all-cause and VA-related hospitalization was significantly lower in the AVF group than AVG (RR 0.75 (95% CI: 0.71 - 0.80) for all-cause hospitalization; RR 0.68 (0.62-0.74) for VA hospitalization), but not infection- or CVD-related hospitalization. AVF was associated with significantly lower incidence of all-cause and VA-, infection-, and CVD-related hospitalizations in longer follow-up time (RR 0.84 (0.82-0.87) for all-cause hospitalization; RR 0.63 (0.59-0.67) for VA-related hospitalization within 3 years).

Conclusions: Our primary analyses found elderly patients on HD may benefit from getting an AVF compared to an AVG. We will further test whether these results hold true in patients within strata of age group, comorbidities, probabilities of AVF maturation, and life expectancy.

PO1326

Implementing Multidisciplinary Pre-ESRD Program to Improve Vascular Access in New-Start Dialysis Patients

Nabhan K. Jabalia,1 Tammy L. Stirich,2,3 Vy D. Nguyen,1 Nhat M. Pham,1,2 Santa Clara Valley Medical Center, San Jose, CA; 2Stanford University School of Medicine, Stanford, CA; 3US Department of Veterans Affairs, Palo Alto, CA.

Background: Tunneled dialysis catheters (TDC’s) are associated with morbidity and mortality in dialysis patients. In the U.S., more than 80% of patients start dialysis with a TDC and even higher rates for ethnic minorities. As part of the Santa Clara County healthcare system, we care for an underserved population, predominately of ethnic minorities. To reduce our TDC rates, we implemented a Pre-ESRD program that encompasses a multidisciplinary team, EMR tracking, access referral guidelines, and culturally relevant patient education. We assessed whether this program reduced the proportion of patients starting dialysis with a TDC and no other vascular access (TDC-Only).

Methods: We performed a retrospective chart review of new start dialysis patients in 2014 (before program implementation) and in 2017 (after program implementation). Patients must have been seen in renal clinic for at least 3 months before starting dialysis. We compared the proportion of TDC-Only between the two groups using the Chi-Square Test. We also compared the type of vascular access placed between the two groups.

Results: 87 patients started dialysis in 2014 and in 2017. There was no difference in age (58 vs 56 years) or diabetes (61% vs 70%) between the two groups. The two groups consisted mostly of minorities (Hispanic: 52% vs 55%, Asian: 31% vs 26%, Black: 7% vs 3%, and White: 10% vs 14%) and non-English speakers (44% vs 46%). The type of access at dialysis start is summarized in the table. The proportion of TDC-Only reduced by 21% after program implementation but did not reach statistical significance: 62% of patients started with TDC-Only in 2014 compared to 49% in 2017 (p=0.09). In addition, AVF placement more than doubled after program implementation (19% vs 42%, p=0.001).

Conclusions: Implementation of a multidisciplinary Pre-ESRD program reduced the number of TDC-Only and increased the number of AVF’s in new dialysis start patients. Our study is unique due to our patient population of predominantly minorities and non-English speakers.

Conversion to Arteriovenous Fistula but Not Arteriovenous Graft Is Associated with Improved Hemodialysis Efficacy Markers in Children: Pediatric Nephrology Research Consortium Study

Ali Mirza Onder,1 Joseph T. Flynn,2 Md Abu Yusuf Anasri,3 Craig B. Langman,3 Chryso P. Katsoulis,1 Marissa J. Defreitas,1 Ellen G. Wood.1 University of Mississippi Medical Center, Jackson, MS; 2Seattle Children’s Hospital, Seattle, WA; 3SSM Health Cardinal Glennon Children’s Hospital, Saint Louis, MO; 4University of Miami School of Medicine, Miami, FL; 5Northwestern University Feinberg School of Medicine, Chicago, IL.

Background: Arteriovenous fistulae (AVF) and arteriovenous grafts (AVG) are preferred vascular access for chronic hemodialysis (HD) patients. Our objective was to investigate the impact of switching from tunneled cuffed catheters (TCC) to AVF or AVG on HD efficacy markers in pediatric HD patients.

Methods: Retrospective chart reviews were completed on individual patients from 20 pediatric HD centers. All the patients used TCC prior to AVF/AVF and each patient acted as his/her own control. Data on dialysis efficacy markers were collected at creation of AVF/AVG and for two years follow-up, along with patient demographics and clinical information. Statistical methods used included hypothesis testing and statistical modeling after adjusting for relevant demographic variables.

Results: First PV A was created in 98 individual children: 87 (89%) were AVF and 11 (11%) were AVG. The mean TCC vintage prior to AVF/AVG was 10.4±17.3 months. At one-year follow-up, AVF patients improved the Kt/V by 0.23 (p=0.008) and URR by 5.4% (p=0.001). At second year follow-up, both Kt/V and URR remained higher than values at creation (p=0.02, p<0.0001, respectively), being similar to first year’s values (p=0.57, p=0.36, respectively). Furthermore, AVF patients improved serum albumin by 0.33 gram/dl (p=0.001) and serum hematocrit by 2.94% (p<0.0001) at one-year and maintained similar improved values at second year follow-up (p=0.001, p<0.0003, respectively). These observations were further supported by the adjusted models. Children with AVG did not demonstrate any statistically significant change in Kt/V, URR, serum albumin or hematocrit at either one-year or second year follow-ups.

Conclusions: Switching to AVF was associated with improved HD efficacy markers (Kt/V, URR, serum albumin and hematocrit). Surprisingly, conversion to AVG was not associated with a similar positive impact for the above markers.

PO1328

Study of Impact of Preoperative Venogram as an Adjunct to Doppler Imaging in Difficult Vascular Access

Viswanath Moturu, Narayana Medical College and Hospital, Nellore, India.

Background: As the number and complexity of patients on dialysis increases, this presents an increasing challenge for vascular access. Successful renal access surgery requires both careful planning and technical skill. Venography offers direct imaging of both peripheral and central veins in the upper limb.

Methods: Venography was done at our institute prospectively for difficult vascular access cases between Oct 2019 & Mar 2020. All patients who had prior 2 failed AVF surgeries were included in study and were evaluated with physical examination, Doppler imaging and Venography. We prospectively analysed venograms and also compared the outcomes before and after venography based on historic control before venogram with same inclusion criteria. Both groups were compared with respect to vascular access type, patency, complications.

Results: During the study period, venography prior to surgery was performed in 30 patients. Venography of one upper limb (right/left: 6/30) was performed in 6 patients(20%). The remaining 80% patients underwent bilateral venography, resulting in a total of 54 upper limb venograms. 9 patients(30%) were considered unsuitable for native AVF creation based on the venograms. 4 underwent a haemodialysis AV graft (AVG) creation (2 autologous saphenous vein AVG grafts, 1 synthetic graft), two opted for CAPD, remaining 4 surgery was not done.

Conclusions: Venography is a useful imaging modality in preoperative venous mapping prior to difficult vascular access surgery along with preoperative Doppler imaging, resulting in increased patency rates. In our study, preoperative venous imaging in adjunct with color Doppler imaging helped in choice of AVF site planning and avoiding complications and ruling out central venous obstruction and a better patency rates although limited by shorter follow up and small size.

PO1329

Analysis of Vascular Distensibility Measured by Ultrasound Speckle Tracking

William Weitzel,1,2 Nirmala Rajaram,1,2 Lenar T. Yessayan,7 Yihao Zheng,3 Brian Thelen,1,4 Timothy Morgan,1 James Hamilton,1 Miguel A. Funes-Lora,2 Veterans Affairs Ann Arbor Health System, Ann Arbor, MI; 3University of Michigan, Ann Arbor, MI; 4Worcester Polytechnic Institute, Worcester, MA; 5Michigan Technical Research Institute, Ann Arbor, MI.

Background: We have developed a novel open source ultrasound software program that measures vascular strain and distensibility using conventional ultrasound Digital Imaging and Communications in Medicine (DICOM) data for use in the dialysis vascular access setting. In this study, we evaluated the variation in measurement from operator point selection and physiologic beat to beat variation of the arterial wall.

Methods: Ten subjects scheduled for arteriovenous fistula (AVF) creation were enrolled in the study. Ultrasound scanning of the brachial/radial arteries was performed. Ten users were prompted to select two points of interest at the top and bottom of the arterial vessel wall in each of the ten subjects. These points were tracked using the Kanade-Lucas-Tomasi (KLT) tracking algorithm.

Results: Sub-millimeter resolution (less than 100 micron) measurements were obtained. We found variation point selection by the users for the ten cine loops to be up to 120 pixels for the top and up to 140 pixels for the bottom of the vessel wall. The range in measured variation attributable to user point selection was 5.79 to 47.29% and inter-cardiac (physiologic) variation was 6.41 to 17.68%.

Conclusions: Despite the low resolution of conventional DICOM images, we are able to measure sub-millimeter distensibility. In order to better understand the physiologic variation in vascular wall compliance, a formalized approach to point selection is needed. We are evaluating algorithms and statistical ensemble methods for use in studies to predict AVF maturation.

Funding: Veterans Affairs Support
data provides a contact-free method to ascertain \( Q_a \) and to indirectly indicate the degree of stenosis. Further study is needed to standardize the quality of video and streamline the methodology.

POI1330

Relationship of Vascular Access Flow and Stenosis Detected by Frequency Domain Analysis of Videos Taken with a Smartphone

Fansan Zhu, Lin-Chun Wang, Alhajj Cherihi, Vaibhav Maheshwari, Ohnmar Thwin, Lela Tisdale, Xia Tao, Paulo Paneque Galuzio, Norbert Sataninberg, Dean C. Preddie, Peter Kotanko,renal Research Institute, New York, NY; AzuraVascular Care, New York, NY; Icahn School of Medicine at Mount Sinai, New York, NY.

Background: We developed a video image processing (VIP) technique with frequency domain analysis to assess arteriovenous fistula (AVF) blood flow. This study aimed to investigate the relationship of heart rate and access blood flow rate (\( Q_a \)) with magnitude in frequency domain analysis.

Methods: We employed VIP pre- and post-endovascular interventions in 90 hemodialysis patients (age 63.3 ± 14.3, 41 females, weight 78.6 ± 21.5 kg). \( F_{\text{Max}} \) and \( F_{\text{Min}} \) were measured pre- and post-intervention by HVT100 endovascular flowmeter (Transonic Systems Inc., Ithaca, NY, USA). The degree of stenosis (%) was quantitated by angiography. Heart rate (HR, beats/min) was expressed as a frequency (\( F_{\text{HR}} \)).

Results: The differences between \( F_{\text{Max}} \) and \( F_{\text{HR}} \) were 1.14±0.74 Hz and 1.38±1.44 Hz, respectively. \( \Delta F \) was associated with \( Q_a \) pre- (Fig 1(a)) and post-intervention (Fig 1(b)). \( \Delta F \) increased most when \( Q_a \) increased from pre- to post-intervention range of 300 to 600 ml/min to post-intervention 600 to 900 ml/min. Fig 1(c) shows the relationship between % stenosis and the change in \( \Delta F \) between pre- and post-intervention. The difference between \( F_{\text{Max}} \) and \( F_{\text{HR}} \) was associated with % stenosis (Fig 1(d)).

Conclusions: The relationship between \( F_{\text{Max}} \) and \( F_{\text{HR}} \) suggests that the signal of \( F_{\text{Max}} \) represents an important hemodynamic component of \( Q_a \). \( \Delta F \) may be used as an index to predict low levels of stenosis. The use of frequency domain analysis from video image

POI1332

The Effect of Nitrate as a Vasodilator to Vascular Access Patency in Patients Undergoing Hemodialysis

Kyu Sang Yun, Juhee Kim, Hayne C. Park, Aijn Cho, Youngki Lee, Sun Ryoung Choi, Jung-woo Noh, Kangnam Sacred Heart Hospital, Yeongdeungpo-gu, Seoul, Republic of Korea; Chan & Cho’s Medical Clinic & Dialysis Center, Seoul, Republic of Korea; Hallym University Dongtan Sacred Heart Hospital, Hwaseong, Gyeonggi, Republic of Korea.

Background: Maintaining the patency of vascular access (VA) is very important to achieve adequate hemodialysis (HD) dose in HD patients. Failure of vascular access is associated with morbidity and mortality. Thus, maintaining the patency of VA is challenging. In this study, we investigated the effects of nitrate as vasodilator on VA patency in HD patients.

Methods: We investigated study on the Korean insurance claims data of the HD patients between January 2012 and December 2017. All patients divided into nitrate therapy group including only patients who received the drug for 30 days or more. The primary outcome was the primary patency of VA. Effect of nitrate treatment was examined using Kaplan Meier analysis and Cox proportional hazard, after adjusting for covariates.
Results: A total of 7,428 participants were included in this study, and nitrate therapy was noted in 7.7% of total patients. 1,178 patients demonstrated an increase in circulating immune cells. After ANCOVA analysis, nitrate therapy was lower proportion of angioplasty than non-user (log-rank, P<0.001). The risk of angioplasty was low in patients receiving mononitrate and nicorandil (hazard ratio (HR) 0.18, [95% confidence interval 0.07-0.43]; HR 0.15, [0.06-0.41]). But, nitrates and molsidomine were not associated with the risk of angioplasty. Multivariate Cox proportional analysis revealed that nitrate therapy with mononitrate and nicorandil had a decreased risk of angioplasty after adjustment for age, sex, hypertension, and diabetes (HR 0.17, [0.05-0.53]; HR 0.14, [0.04-0.45]).

Conclusions: We conclude that while using Ticagrelor in patients with ESRD on HD is safe, the 3 patients demonstrate a therapeutic superiority in preserving the patency of AVF using this drug compared to placebo. This study is limited by the number of patients and more studies may be warranted in the future.

Over 10 weeks of treatment, there was no significant change in platelet counts between the Ticagrelor and Placebo groups. However, a slight decrease in platelet counts was observed in the Placebo group compared to the Ticagrelor group.

PO1335 The Integrated Program of Needle Dislodgement Bleeding Alarm System Is Associated with a Decreased Incident of Venous Needle Dislodgement or Bleeding

Chi yang Hsin,1 Hsuan Ming Lin,1 Hsiang Wei Hu,1 2 An Nan Hospital, China Medical University, Tainan, Taiwan, Taiwan City, Taiwan; 2 National Cheng Kung University, Tainan City, Taiwan; 1 Acusense Biomedical Corp., Tainan City, Taiwan.

Background: A puncture of vascular access is commonly used in clinical treatment, such as hemodialysis or central venous catheters. There are some devices for detecting the presence of needle dislodgement in the market. Still, there are no large-scale reports for the integrated program for needle training and device implantation. This study aims to conduct a program for an integrated training course and the VND device. We hope to reduce the incidence of needle removal and blood leakage.

Methods: This study was divided into two phases, the control period, and the study period. In the control period, the abnormal events of venous needle dislodgement and blood leakage were recorded in the hemodialysis unit room during the first three months. Before the study period, we introduced an integrated program, including the standard process of fistula puncture, care during hemodialysis, an inspection of the venous puncture site, and an alarm system. In the study period, we also conducted the standard program and collected the data of the events of venous dislodgement or bleeding.

Results: The control period was conducted from July 2019 to September 2019, and the study period was performed in November 2019. A total of 62 patients completed the study. During the control period, there were a total of 2087 dialysis treatments, of which 80 needle dislodgements were recorded in the hemodialysis unit room during the first three months. In the study period, we conducted the integrated program and reduced the incidence of needle removal and blood leakage.

Conclusions: This study introduced venous needle dislodgement or bleeding alarm system and training program in the hemodialysis unit. The incidence of venous needle dislodgement or bleeding was lower after the program. The incidence rate in the moderate and severe groups was also decreased. This program can improve the quality of patient care.

PO1336 Evaluation of Stable Permanent Hemodialysis Access Bleeding Time After Dialysis Needle Removal

Samsbita Yalamanchili,1 Paul J. Der Mesropian,2 Gulvahid Gh. Shaikh,2 Loay H. Salmon,2 Elvira O. Gosmanova,1,2 Albany Stratton VA Medical Center, Albany, NY; 1 Albany Medical College, Albany, NY.

Background: Prolonged bleeding time (BT) after dialysis needle removal may signify permanent hemodialysis access (PHA) dysfunction but “normal” BT is not well defined.

Methods: This was an observational study examining 35 patients receiving chronic hemodialysis with PHA using 15-g needles for ≥3 months. Control patients were randomly selected from the dialysis unit and 1:1 matched for age, sex, and race. The mean age of patients was 73 yrs, 97% were males, 63 and 31% were Whites and Blacks, respectively. The mean (SD) hemoglobin concentration and platelet count were 10.4 (1.0)g/dL and 184 (77)×10^9/L, respectively. Sixty and 74% of patients were on oral antplatelet agents and intradialytic heparin. The mean (SD) BT after arterial and venous needle removal with additional (2-1) minutes increments, if needed. The mean BT for arterial and venous sites were calculated for each patient over 1-month period. Associations between BT and baseline characteristics were evaluated using adjusted regression analysis.

Results: The mean age of patients was 73 yrs, 97% were males, 63 and 31% were Whites and Blacks, respectively. The mean (SD) hemoglobin concentration and platelet count were 10.4 (1.0)g/dL and 184 (77)×10^9/L, respectively. Sixty and 74% of patients were on oral antplatelet agents and intradialytic heparin. The mean (SD) BT after arterial and venous needle removal with additional (2-1) minutes increments, if needed. In the adjusted analyses, there was a strong correlation between arterial and venous BT (r2 = 0.98, p<0.016), however, no correlations were seen between arterial and venous BT and any baseline variables (Tables).

Conclusions: In this study, BT after dialysis needle removal was between 10 and 15 min in patients with stable PHA. Future studies are needed to understand what changes in BT may predict PHA dysfunction.
PO1337

Natural Vascular Scaffolding Therapy for Arteriovenous Fistula Development in Rats

Yan-Ting E. Shiu,1,2 Blake Anderson,1 Yuxia He,1 CS Jason Tev,1 Katalin Kauser,1 University of Utah, Salt Lake City, UT; 2VASCCHS, Salt Lake City, UT.

Background: Arteriovenous fistula (AVF) maturation failure results from insufficient lumen dilation and progressive inward neointimal hyperplasia (NIH). Vascular wall distention is likely affected by the integrity of vascular extracellular matrix (ECM). We hypothesized that preserving ECM integrity at the time of AVF creation surgery could improve AVF maturation. Natural Vascular Scaffolding (NVS) Therapy is known to interlink collagen and elastin, the most abundant vascular ECM components, by covalently linking these proteins via photoactivation. We investigated the effect of NVS treatment on AVF development in a rat model.

Methods: Femoral AVFs were created in young Wistar male rats as an end-to-side anastomosis. Immediately after the blood flow was restored to dilate the femoral vein by arterial pressure, a 10 μl-drop of the NVS compound (2 mg/ml in phosphate buffered saline (PBS)) was placed at the anastomosis peripherally and incubated for 5 minutes to allow full vessel wall penetration, followed with 1-min illumination of the anastomosis area by 450-nm light. The control group received a 10-μl drop of PBS and the same light activation. The skin was closed immediately after light activation. Each group had 10 rats. Rats were euthanized 4 weeks post-AVF creation for histology, morphometry, immunohistochemistry of interleukin-6 (IL-6, an inflammation marker), and second-harmonic-generation evaluation by multiphoton microscopy of collagen fibers.

Results: Rats tolerated the NVS treatment well. The NIH area was similar in both groups. The AVF vein’s open lumen area and % open lumen area in treated rats were significantly larger than in control rats (4.20-fold p=0.014 and 1.98-fold p=0.009, respectively). IL-6 intensity was significantly smaller in the NVS group than the PBS group (p=0.027). Collagen fibers in the NVS-treated AVFs trended towards perpendicular alignment with respect to the lumen circumference, with greater roundness, roughness, and eccentricity than in the PBS-treated AVF vessels.

Conclusions: Our studies showed that the NVS treatment significantly increased the AVF open lumen area, without significantly affecting the NIH area. This suggests that NVS treatment may have therapeutic potential by facilitating lumen expansion while allowing a concomitant outward remodeling of the veins potentially leading to enhanced AVF maturation in patients.

PO1338

Geometry and Interuser Variability of Arteriovenous Fistulas in Mice and Rats

Hannah M. Northrup1, Isabelle D. Falzon,1 Savanna Cahoon,1 Yan-Ting E. Shiu,1 Maheshika S. Somarathna,2 Timmy C. Lee,1,2 1University of Utah, Salt Lake City, UT; 2Veterans Affairs Medical Center, Birmingham, Birmingham, AL.

Background: Arteriovenous fistula (AVF) maturation failure is a significant and unresolved clinical issue. Although rodent models have been used extensively to investigate the pathology and treatment of AVF maturation failure, the literature has largely relied on histology to analyze rodent AVF remodeling. Information regarding three-dimensional (3D) AVF lumen geometry in live animals is lacking. Our group has developed a magnetic resonance imaging (MRI)-based protocol to quantitatively characterize 3D AVF lumen geometry in mouse and rat AVFs. Inter-user variability was also determined.

Methods: Carotid-jugular AVFs were created in C57BL/6 mice (n=21). Femoral AVFs were created in Sprague Dawley rats (n=7). Both had the arterial-side-to-venous-end configuration. Black blood MRIs were taken at 7 or 21 days post-AVF creation. Two users reconstructed the AVF lumens and computed the cross-sectional lumen area, anastomosis angle, nonplanarity angle magnitude, and tortuosity, using a centerline-based approach.

Results: Mice had a greater anastomosis angle (94.29° vs. 38.75°) and tortuosity (0.42 vs. 0.035) than rats (p=0.05). The nonplanarity angle magnitude was similar for mice and rats (~8.5°). Geometries of mouse and rat AVFs from the two users are overlaid in Figure 1. Inter-user variability were predominately small, indicating the reliability and reproducibility of our protocol.

Conclusions: Our work is the first detailed study of luminal changes in rodent AVFs using MRI. The anastomosis angles of mouse and rat AVFs are similar to human brachioccephalic AVFs (~70-90°) and radiocephalic AVFs (~30-60°) in the literature, respectively. These data support the clinical relevance of our rodent AVF models and set the stage for future studies on how these geometrical parameters affect AVF maturation and the mechanisms leading to geometrical changes.

PO1339

Longitudinal Geometry of Pig Arteriovenous Fistulas (AVFs)

Savanna Cahoon,1 Isabelle D. Falzon,1 Yan-Ting E. Shiu,1 Alfred K. Cheung,1,2 University of Utah, Salt Lake City, UT; 2VA Salt Lake City Health Care System, Salt Lake City, UT.

Background: Hemodynamics has been postulated to be an important factor contributing to successful versus failed AVF maturation. Pigs, in general, have hemodynamic features that are similar to those in humans, and thus are an attractive animal model for investigating the mechanisms underlying and the interventions for promoting AVF maturation. A few earlier small clinical studies found associations between AVF geometry and maturation. Since geometry is a critical determinant of hemodynamics, we investigated the geometry of pig AVFs using magnetic resonance imaging (MRI) technology.

Methods: Carotid (side)-jugular (end) AVFs were created in female Yorkshire cross domestic pigs. Non-contrast black-blood MRIs were obtained at 1, 2, and 6-10 weeks (wks) post-AVF creation (n=3 per time point) and used to reconstruct AVF lumen geometries. Lumen area, anastomosis angle, venous tortuosity, and nonplanarity angle magnitudes were quantified.

Results: The non-surgery lumen area of the external jugular vein was ~7 mm². The AVF vein lumen area (mean ± standard deviation) significantly (p=0.0370) increased from 25.3 ± 11.1 mm² in wk 1 to 32.3 ± 4.3 mm² in wk 2, then to 62.7 ± 21.3 mm² in wks 6-10 suggesting that our pig AVF is a model for successful AVF maturation. Importantly, we also observed an increasing trend in the lumen areas from wk 1 to 6 wk. 0.10 of the proximal artery (24.0 ± 17.3 mm² vs. 28.0 ± 5.60 mm²) and the distal artery (24.5 ± 16.1 mm² vs. 34.8 ± 13.9 mm²). The anastomosis angles were similar in wk 1 and 2 (51.6° ± 23.2° vs. 50.2° ± 21.0°) then decreased to 25.8 ± 17.3° in wks 6-10. Venous tortuosity slightly increased from 0.13 ± 0.05 in wk 1 to 0.15 ± 0.06 in wk 2 then to 0.17 ± 0.06 in wks 6-10. Non-planarity angle magnitude was 14.9 ± 8.9° in wk 1 then decreased to 10.7 ± 8.5° in wk 2 then increased to 24.6 ± 9.4° in wks 6-10.

Conclusions: This is the first serial and detailed study of pig AVF geometric parameters. The anastomosis angles of our pig AVFs were in line with human radioccephalic AVFs in the literature (~30-60°). Our study sets the stage for examining the role of geometry in alterations in hemodynamic forces and in AVF maturation processes.

PO1340

To Study Real-World Effectiveness of Paclitaxel Drug-Coated Balloon Angioplasty in Hemodialysis Patients

Background: A large, multicenter randomized study has shown that use of drug coated balloon (DCB) in angioplasty improves vascular access patency trend over control at 9-month during 2-year study period. We have conducted a retrospective study to see if there is a real-world effectiveness of DCB angioplasty in maintaining vascular access patency in hemodialysis patients.

Methods: We retrospectively reviewed 83 drug coated balloon angioplasties performed in our hospital from April 2018 to April 2020 and compared them with a control group of 83 angioplasties done by non-drug coated balloon matched by the date

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
of procedure. Target lesions were categorized as central, peripheral, anastomotic and in-stent for both arteriovenous fistula (AVF) and arteriovenous grafts (AVG). Patient demographics (Age, Sex) and risk factors (Hypertension, Hyperlipidemia, Vascular Disease, Diabetes Mellitus) were also compared. The duration of target lesion patency (in days) before and after the DCB interventions were compared with date matched non-DCB interventions (control group).

Results: There are 83 angioplasties in each group (DCB versus control group). The average duration of target lesion patency (in days) before intervention in DCB and control groups were 152 versus 137 (P-value = 0.57) for AVF and 163.3 versus 191.3 (P-value = 0.70) for AVG respectively. The average duration of target lesion patency (in days) after intervention in DCB group and control group were 114.8 versus 161.7 (P value = 0.03) for AVF and 177.9 versus 221.5 (P value = 0.5) for AVG respectively.

Conclusions: As opposed to the randomized controlled trial, our study shows that the average duration of target lesion patency of AVG after drug coated balloon angioplasty was significantly shorter than non-drug coated balloon. Greater severity of lesions in the DCC group could be the reason for this observation.

Estimated Upper-Body Blood Flow and Central-Venous Oxygen Saturation Before and After Percutaneous Transluminal Angioplasty in Newly Created Vascular Access

Laura Rosales, Hanjie Zhang, Marilou Mateo, Brenda K. Chan, Seth Johnson, Stephan Thijsen, Peter Kotanko. Renal Research Institute, New York, NY.

Background: Arterio-venous fistula (AVF) is the most effective vascular access in hemodialysis (HD) patients and, assessing AVF maturation is critical to initiate its timely use. Previously we have demonstrated that central-venous oxygen saturation (ScvO2) and estimated upper-body blood flow (eUBBF) increase during AVF maturation. We assessed ScvO2 and eUBBF before and after percutaneous transluminal angioplasty (PTA).

Methods: We studied HD patients from an ongoing AVF quality improvement project. ScvO2 and hematocrit were measured with Crit-Line (FMG, Waltham, MA) between minutes 5 and 20 into HD. eUBBF was computed and described previously (Rosales, Blood Purif, 2019). Five out of 19 patients underwent PTA during AVF maturation and subsequent successful cannulation.

Results: Three of five patients (mean age 71±11) were males two were incident patients. Four interventions were due to venous stenosis and one was due to arterial anastomosis stenosis. Two patients underwent PTA 2.2 ± 0.3 weeks after AVF creation and the remaining 3 patients within 11.2 ± 4 weeks. Following PTA ScvO2 increased in all, except in patient #1, eUBBF increased in every patient (Table 1).

Conclusions: Our preliminary results indicate that ScvO2 and eUBBF provide functional information that can be obtained non-invasively. These point-of-care bio-signals reflect hemodynamic cardiovascular adaptation following successful PTA. Future studies are warranted if knowledge of ScvO2 and of eUBBB provide shorter catheter residence time.

Association Between FGF-23 Serum Levels with the Maturation Process of a Native Arteriovenous Fistula in Patients with End-Stage CKD

Juan Reyna-Blanco, L. M. Perez-Navarro, Rafael Valdez-Ortiz. Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.

Background: The process of maturation of an arteriovenous fistula (AVF) is complex and difficult to predict. It is known that high levels of fibroblast growth factor 23 (FGF-23) could be related to endothelial dysfunction, which could also influence the maturation of an AVF. Our goal is to know the association between serum levels of FGF-23 and the maturation of an AVF.

Methods: This is a prospective cohort study with patients who underwent an AVF. The primary outcome was ultrasonic maturation at 6 weeks defined by the Birmingham criteria (diameter >0.4 cm and blood flow more than 500 ml/min).

Results: Forty-nine patients with a mean age of 48 ±14 years were included and 24% were women. The most common cause of CKD was diabetic nephropathy (55%), 25%, 10% and 16% were brachycephalic, brachymedian, brachybasilic and other AVF respectively. Thirty nine percent of AVFs did not mature at 6 weeks. No significant differences were identified when comparing the agreement with maturation or not of the AVF in age, comorbidities, BMI, previous number of hemodialysis catheters, history of thrombosed catheter or catheter infection, hemodialysis vintage, residual diuresis, surgical time, hemoglobin, creatinine and serum calcium or phosphorus. However, the length of the arteriostomy was greater in the fistulas that do not mature with respect to the mature fistulas (7 mm vs. 6 mm p = 0.03). Likewise, the use of loop diuretics was more prevalent in an AVF that did not mature (without maturation: 74% vs. maturation: 43%; p = 0.03). None of the distal radiocephalic AVF reached maturity. There were no association between serum levels of cFGF-23 and maturation of AVF, nor was the correlation between serum levels of cFGF-23 and the diameter or flow of the fistulas at six weeks.

Conclusions: The prevalence of maturation failure in AVFs was 39% according to Birmingham criteria. There is no correlation between serum levels of cFGF-23 and the flow or diameter of the AVF at six weeks. A larger population is required to corroborate these results.

PO1343

Effect of Hemodialysis Vascular Access Type on Serum Interleukin-6 (IL-6) Levels in ESRD

Monika Aggarwal (Gupta), George M. Feldman,1 Naveen Samuel,1 Reuben P. Retnam,2 Dipankar Bandypadhyay,2 Shobha Ghosh,1,2 Hunter Holmes McGuire VA Medical Center, Richmond, VA; 1Virginia Commonwealth University, Richmond, VA.

Background: Chronic inflammation is prevalent and associated with poor outcomes in end stage renal disease(ESRD), and may be related to underlying comorbid conditions like diabetes mellitus. It is unclear if dialysis vascular access type may affect inflammation. We evaluated the effect of hemodialysis vascular access type on serum IL-6 level.

Methods: 15 patients with ESRD on chronic maintenance hemodialysis at McGuire Hunter Holmes VAMC were enrolled. Blood samples were drawn at 0, 30, 60, 90, 120, 180, and 240 minutes after starting dialysis. Serum IL-6 was measured using ELISA. Data were analyzed using t-test and is presented as Mean±SD.

Results: 6 patients had catheter (mean age 71.3±3.3 years), and 9 (mean age 64.5±4.4 years) had AV access. All were male. 5 patients in each group were African-American. 2 patients with catheter and 7 patients with AV access had diabetes. IL-6 level was higher at all time points(statistically significant) in patients with catheter compared to patients with AV access (Fig 1. and Table 1.)

Conclusions: ESRD patients with catheters had higher serum IL-6 levels compared to AV access inspite of lower proportion of diabetics. Catheters may contribute to inflammation, which may partly explain worse outcomes seen with catheters.

Assessment of Arteriovenous Fistula Dysfunction with Access Stenosis in Hemodialysis Patients Using Smartphone Videos

Lin-Chun Wang,1 Fansan Zhu,1 Ohnumar Thwin,1 Lela Tisdale,1 Xia Tao,1 Vaibhav Maheshwari,1 Alhaji Cherif,1 Norbert Shtaynberg,2 Dean C. Preddie,2 Stephan Thijssen,1 Peter Kotanko.1,3 Renal Research Institute, New York, NY; 2Azura Vascular Care, New York, NY; 3Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Hemodynamically relevant stenoses in arteriovenous fistulas (AVF) lead to a reduction in access flow rate (Q_a). We hypothesized that these changes in blood flow patterns may be detectable in video recordings done with commercially available smartphones.

Methods: We studied HD patients with AVF dysfunction requiring balloon angioplasty. One-minute video recordings of the skin above the AVF and Q_a measurements were conducted before and after the intervention by an iPhone 6S. Q_a was measured by HVT100 Transonic flowmeter. Degree of stenosis was assessed by angiography. Frame-to-frame pixel changes in video images were amplified; time-domain data were transformed into the frequency-domain signals. Fifty random 10-second segments were sampled per one-minute video, and the frequency with the lowest magnitude (F_min) was determined in each sample (Fig. 1). The average F_min was assessed for its association with the degree of stenosis.

Results: Ninety subjects were studied (63±14 years, HD vintage 4.1±3.5 years). Post-intervention Q_a (1638±714 ml/min; P<0.01, paired t-test) was on average 1.23-fold higher than pre-intervention Q_a (1373±684 ml/min; P<0.01, paired t-test). Subjects were grouped by degree of stenosis, and the number of subjects in each category is shown in Fig. 1B. Higher degrees of stenosis were associated with greater increases in Q_a from before to after the intervention (Fig. 1C). Interestingly, the degree of AVF stenosis was also positively related with the change in F_min from before to after the intervention (Fig. 1D).

Conclusions: Smartphone video recordings of AVF appear to contain frequency-domain information that correlates with hemodynamic changes caused by AVF stenoses. While the F_min metric employed in our analysis is not ideal, these results should encourage the quest for other parameters that exhibit higher correlations with vascular access dysfunction, allowing timely referrals and avoidance of emergency interventions.
Efficacy and Long-Term Patency of Kissing Stent Technique for Endovascular Reconstruction of the Axillary Vein: A Case Report with Long-Term Follow-Up
Sami M. Akram, Khurrum Saleem, Mohamed A. Rahman. Nephrology Associates of Northern Illinois and Indiana, Oak Brook, IL.

Background: Purpose: to report the endovascular reconstruction (EVR) of axillary vein (AXV) with kissing stent technique (KST) following AXV obstruction due to proximal stent migration (PSM) from the cephalic arch (CA). We suggest a strategy to minimize this problem. PSM in venous system is rare but dreadful complication of EVR. Increasing venous sizes towards the heart predisposes to PSM. We report a case of AXV obstruction due to stent migration into subclavian vein (SCV). We describe the successful use of kissing stent technique (KST) to reconstruct the AXV.

Methods: Case report and review of literature.

Results: Case report: MS is an 81-yr-old female with right brachiocephalic arteriovenous fistula (R BCAVF) for chronic hemodialysis. She has recurrent cephalic use of kissing stent technique (KST) to reconstruct the AXV.

Conclusions: KST for EVR of the Axillary vein is technically feasible and has long term efficacy.

Funding: Other U.S. Government Support

Partially migrated stent

Conclusions: KST for EVR of the Axillary vein is technically feasible and has long term efficacy.

Funding: Private Foundation Support

Results: The degree of reporting concordance between CLM and CW was high for fistula use (κ=0.95; p<0.01) and slightly lower for catheter use (κ=0.76; p<0.01). The agreement of all access types increased from 90% in CY12 to 97% in CY18. National trends in vascular access were consistently worse for CW-based measures, although this gap narrowed over time (Figure). PY20 data indicate facilities achieved a lower median SFR (0.8% vs. CLM-based AVF rate) and higher median LTCR by 1.4% (vs. CLM-based LTCR); however, accompanying changes to performance standards (using baseline data) result in simulated ESRD QIP measure scores increasing by approximately 0.5 points.

Conclusions: Vascular access reporting concordance in CLM and CW improved considerably in CY 2018, which corresponds to the first year of use in the ESRD QIP. The CW-based vascular access performance rates were worse than CLM-based rates; these differences are primarily attributed to the poorer performance of non-FFS patients included in the CW-based measures. Whether new vascular access measures have worse performance rates, average ESRD QIP measure scores increase slightly.

Hemodialysis Access Surveillance Evaluation (HASE) Study
Lovy H. Salaman,1 Abid A. Rizvi,2 Gabriel Contreras,2 Christina E. Manning,1 Paul J. Feustel,1 Ivy Machado,3 Patricia L. Briones,1 Aamir Z. Jamal,4 Nicolle Bateman,1 Laisel Martinez,2 Roberto I. Vazquez-Padron,2 Arif Asif,5 1Albany Medical College, Albany, NY; 2University of Miami School of Medicine, Miami, FL; 3University of Miami School of Nursing and Health Studies, Coral Gables, FL; 4California Kidney Specialists, San Dimas, CA; 5Dialysis Clinic Inc, Nashville, TN; 6Jersey Shore University Medical Center, Neptune City, NJ.

Background: Arteriovenous (AV) access thrombosis remains one of the most troubling AV access related complication affecting hemodialysis patients. It necessitates an urgent and occasionally complicated thrombectomy procedure and increases the risk AV access loss. The routine use of AV access surveillance for early detection and management of stenosis to reduce thrombosis remains controversial.

Methods: We conducted a multicenter, prospective, randomized clinical trial comparing standard of care with monthly Ultrasound Dilution Technique (UDT) flow surveillance using a Transonic flow measurement device (Transonic Systems Inc., 34 Dutch Mill Road, Ithaca, NY 14850, USA) to standard of care alone.

Results: We prospectively randomized 436 patients with end stage renal disease (ESRD) on hemodialysis with arteriovenous fistula (AVF) or graft (AVG) using cluster (i.e. dialysis shift) randomization to either standard of care with monthly blood flow surveillance or standard of care alone. There were no statistically significant differences in the baseline demographics and data between the two groups except for ethnicity (p<0.017). Patients were followed on average for 15.2 months. There were significantly less per patient thrombotic events (Poisson rate) in the surveillance group (0.12/patient) as compared to the control group (0.23/patient) (p=0.012). There was no significant difference in total number of procedures between the two groups, irrespective of whether thrombectomy procedures were included or excluded. There was no statistically significant difference between the two groups in the rate of or the time to a first thrombotic event or number of catheters placed due to thrombosis.

Conclusions: The use of monthly AV access surveillance with UDT flow measurement in this multicenter randomized control trial reduced the per patient thrombotic events without significantly increasing the total number of angiographic procedures. Even though there is a trend, surveillance did not reduce the first thrombotic event rate.

Funding: Transonic Systems Inc., 34 Dutch Mill Road, Ithaca, NY 14850, USA

PO1347
Understanding the Transition to Standardized Fistula Rate (SFR) and Long-Term Catheter Rate (LTCR) Measures in the Medicare ESRD Quality Incentive Program (QIP)
Donnyu Wang,1 Alissa Kapke,1 Jeffrey Pearson,2 Adebola O. Adeleye,2 Delia Houselaw,3 Eric W. Young,4 1Arbor Research Collaborative for Health, Ann Arbor; 2Centers for Medicare and Medicaid Services, Baltimore, MD.

Background: In ESRD QIP Payment Year (PY) 2021, vascular access measures change to the SFR and LTCR measures. The changes involve transition of the data source from Medicare claims (CLM) to CROWNWeb (CW), expansion from Medicare fee-for-service (M-FFS) to all ESRD patients, revised numerator criteria (e.g. multiple access types), expanded patient exclusions (e.g. limited life expectancy), and case-mix adjustment for SFR.

Methods: The degree of concordance in reporting vascular access type reported in CLM and CW was assessed and trends in arteriovenous fistula use (AVF) and long-term catheter use (LTC) with the CLM-based and CW-based methods were evaluated from calendar year (CY) 2012-2019. Facilities’ performance rates for the CW-based measures were calculated using PY20 data and compared to their PY20 performance for the CLM-based measures.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Results: We identified 425 individuals on HD. Of these, there were 141 ambulatory TTEs, of which 64 TTEs met all inclusion criteria. RVD is defined as abnormality in any of the following echocardiographic parameters: S’ (< 9.5 cm/sec), TAPSE (<17 mm), Free Wall Right Heart Strain (>-20%), or RV Fractional Area Change (<-35%). Of the 64 TTEs, 19 had one or more parameters indicating RVD. Select findings with bivariate analysis are presented in Table 1. Continuous variables are expressed as means (S.D.) and analyzed by ANOVA. By multivariate logistic regression, diastolic vantage <10 years, history of vascular disease, and absence of AVS were associated with RVD. There was a trend with OSA. Limitations include retrospective analysis, small numbers, and heterogeneity in patients with respect to history of dialysis access type prior to undergoing TTE.

Conclusions: RVD is common finding on TTEs in HD patients, but is under recognized. A larger prospective study is needed to identify factors that are associated with development of RVD that could potentially be modifiable.

PO1350

Catheter Care in a Hemodialysis Unit: “Do It Daily,” a Multimodal Patient Education Approach

Miten Dhruve, Michael Garron Hospital Foundation, Toronto, ON, Canada.

Background: Central venous catheters or CVLs are the leading cause of mortality and morbidity in the dialysis population. The HDU personnel wanted to empower the patients to manage and care for their catheters. We developed a standardized educational framework in collaboration with healthcare professionals and the Patient Experience Panel (PEP). Our ultimate goal was to reduce the rates of catheter infections in our hemodialysis unit by improving patient’s knowledge, confidence, and skills related to catheter self-care. Our immediate goal was to improve patients’ catheter care knowledge and skills and to standardize and optimize nursing skills and knowledge.

Methods: The patients were given a pre-education survey to establish baseline knowledge, attitudes and skill levels. Educational materials were developed based on the patients’ feedback, knowledge and needs, and also on practice guidelines and best practice recommendations from CDC, KDOI, and ORN. Nursing education involved updating nursing policies, and a nursing catheter care certification program. Educational materials included a video, posters, pamphlets and fridge magnets using the catchphrase “Do it Daily”. The acronym “DAILY” represents the following: D for “dressing, soiled wet or damaged”, A for “any rash, itching or broken skin”, I for “infection at catheter site”, L for “length of catheter changed” and Y for “you have redness, pus, fever”. Post education surveys were conducted to assess the patients’ knowledge and skill levels.

Results: Thirty-three patients completed baseline surveys, education programs and post education surveys. No significant difference in proportion of patients answering yes to Knowledge or Skill assessment pre- and post-education survey. Although, there was a trend of patients who had received enough teaching about catheter care knew how to keep catheter clean and dry, recognize complications and not adjust catheter by themselves. Eighty-nine percent of patients found the education/training easy to understand and feasible tool to help patients understand proper care of their dialysis catheters.

Conclusions: Use of Multi-Modal patient education material is an easy to understand and feasible tool to help patients understand proper care of their dialysis catheters.

PO1351

A Retrospective Study of Tunned Dialysis Catheters with Exposed Cuff and Risk of Subsequent Catheter-Related Bloodstream Infection

Zachary J. Bauer, Aecan Hana, Christopher Kassab, Amulya Rajagopal, Lalathaksha Murthy Kumbar. Henry Ford Hospital, Detroit, MI.

Background: Tunneled dialysis catheters (TDC) are prevalent in patients with end stage renal disease (ESRD) on hemodialysis (HD). Exposure of catheter cuff leads to increased risk of infection if exchanged over guidewire. Methods: This single-center retrospective study reviewed TDCEx procedures in patients with ESRD on HD using a TDC for at least 14 days. The primary endpoint was catheter-related bloodstream infections within 30 days or within 90 days of catheter exchange. Infection rate (IR) were reported as total infections per 1000 catheter days. Results: 1030 procedures were reviewed; 537 were included TDCEx for mechanical dysfunction (n=305) and exposed cuff (n=130) were compared to TDC with infection (n=102). Catheters with infection were mainly treated with removal and delayed insertion. IR based on indications were, 0.78 (95% confidence interval [CI], 0.38-1.38) for CR, 0.64 (95% CI, 0.24-1.14) for exposed cuffs, 0.46 (95% CI, 0.25-0.76) for mechanical dysfunction. When comparing all TDCEx due to non-infectious reason to the catheters with infection, no significant difference was found for IR within 30 days (hazard ratio [HR], 0.78; 95% confidence interval [CI], 0.21-2.82; p-value 0.700) or within 90 days (HR, 0.51; 95% CI, 0.24-1.07; P=0.075). Comparing TDCEx due to exposed cuff with TDCEx for a mechanical dysfunction, insignificant difference in IR was noted at 30 days [HR, 1.59; 95% CI, 0.45-5.63; P=0.474] and at 90 days [HR, 1.65; 95% CI, 0.71-3.87; P=0.026]. No significant difference was seen in IR between catheters with infection and TDCEx for exposed cuffs at 30 days [HR, 0.95; 95% CI, 0.21-4.25; P=0.948] or at 90 days (HR, 1.42; 95% CI, 0.53-3.51; P=0.442). Catheters with infection compared to TDCEx for mechanical dysfunction had a significantly increased IR at 90 (HR, 2.36; 95% CI, 1.01-5.37; P=0.042) with no significant difference at 30 days [HR, 1.52; 95% CI, 0.38-6.06; P=0.556].

Conclusions: TDCEx for catheters with exposed cuff do not increase the risk for catheter-related bloodstream infections at 30 or 90 days. Infected catheters continue to have a higher risk for CRBSI at 90 days even with removal and delayed insertion.

PO1352

Meta-Analysis of Antibiotic and Non-Antibiotic Lock Solutions for Prevention of Hemodialysis Catheter-Related Infections

Sohail Abdul Salim,1 Wisit Cheungpasuthiporn,1 Charat Thongprayoon,4 Karim Karimi,1 Fatih,1 Fatih 1Medical Center, Jackson, MS; 2-Cegled Hemodialysis Units, Cegled, Hungary; 3Hatvan Hemodialysis Units, Hatvan, Hungary; 4Mayo Clinic Minnesota, Rochester, MN; 5Medical University of South Carolina, Charleston, SC.

Background: Catheter-related bloodstream infection (CRBSI) associated with hemodialysis catheters are associated with increased mortality and morbidity whilst posing a significant financial burden on health care. The effects of antibiotic and antimicrobial locking solutions in reducing the risk of CRBSI were assessed.

Methods: From inception to April 2020, we looked for relevant clinical controlled trials in the following databases: EBSCO, PubMed, Cochrane CENTRAL, MEDLINE, EMBASE, clinicaltral.gov, Google Scholar and performed a meta-analysis of the identified studies.

Results: 26 studies with 4,967 patients reported on the incidence of catheter-related bacteremia (CRBSI). The overall pooled Risk Ratio (RR) was lower in the intervention group signaling a 70% lower incidence of CRBSI compared with the heparin group (RR=0.30, 95% CI [0.25, 0.36], p=0.0001). Group analysis showed that the administration of antibiotic regimens led to a 72% decrease in the risk of CRBSI episodes (RR=0.28, 95% CI [0.21, 0.37], p<0.0001), whereas non-antibiotic antimicrobial solutions reduced the risk of CRBSI by 68% (RR=0.32, 95% CI [0.25, 0.41], p<0.0001). A test for subgroup differences revealed no significant difference favoring either of the two interventions.

Conclusions: Both antibiotic and antimicrobial solutions are effective in reducing CRBSI.

PO1353

The Catheter Tip Position as the Main Non-Infectious Cause of Catheter Replacement Survival

Joan G. Navarro gallery, Pablo Maggiani, Noe Martinez murillo, Jorge J. Font, Jonathan Chavez, Jose A. Torres, Christian P. Flores. Universidad de Guadalajara, Guadalajara, Mexico.

Background: Identify the risk factors associated with catheter (Cath) replacement (CR). Novel anatomic variables analyzed

Methods: Our objectives: Identify risk factors associated with CR. The Cath were placed guided by ultrasonus (US). We analyze age, gender, height, previous number of blood punctures, jugular vein (JV) collapsibility, lab tests, blood pressure, anatomic position, extrasystoles, # of punctures, Jugular Vein (JV) collapsibility, Cath TUG, TIP and TOP, tunneled or not, Heparin, complications, Skin-JV Distance, Neck circumference, cath insertion to clavicula distance (UCID), JV and Carotid diameter and distance between JV and Carotid.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Multivariable logistic regression model to determine the variables associated with catheter replacement during the 180 days follow-up

PO1354
NitriCap Hemodialysis Catheter Insert to Prevent Catheter-Related Bloodstream Infection

Background: Tunneled dialysis catheters (TDCs) are associated with blood stream infections. We developed a novel nitric oxide (NO) eluting catheter insert and tested its effects in vitro and in sheep for two weeks to assess its bacteriocidal activity.

Methods: Two cm long inserts using S-nitrosoglutathione (GSNO) as the NO donor and various other components were prepared and tested for their real-time NO release. In vitro studies were done to test the insert's bactericidal effects in a real catheter hub antimicrobial model with S. aureus and P. aeruginosa. NO releasing inserts (NitriCap) were compared to a control (without NO releasing). After 72 h of incubation at 24°C, the amount of viable bacteria in the fluid was quantified for each sample. Subsequently, the antimicrobial/anti-biofilm efficacy of NitriCap was tested in a 14-day ovine model with NO releasing inserts (NitriCap) and in sheep for two weeks to assess its bacteriocidal effects.

Results: A total of 39,036 patients were included. Among them, 31,190 (79.9%) had AVF and 7846 (21.1%) had AVG placed. A substantially lower proportion of patients in the AVG group relied on catheter for HD early after VA placement (88.2% vs 91.9% in AVG and AVG, respectively, at 1m after placement; 23.3% vs 64.3% at 3m; 16.4% vs 28.9% at 6m; Fig1). In longer follow-up, proportion of catheter dependency was similar between A VF and A VG, respectively, at 1m after placement; 23.3% vs 64.3% at 3m; 16.4% vs 28.9% at 6m (Fig1). In longer follow-up, proportion of catheter dependency was similar between A VF and A VG, respectively, at 1m after placement; 23.3% vs 64.3% at 3m; 16.4% vs 28.9% at 6m; >3.4 cm CR

Conclusions: AVG is associated with substantially less catheter dependency than AVF in the short-term and only slightly higher catheter dependency at one year and beyond. AVG placement may be beneficial in selected elderly patients to minimize catheter use.

PO1355
Catheter Dependency After Vascular Access Placement Among Elderly Patients on Hemodialysis: An Intention-to-Treat Analysis

Background: Evidence is mixed regarding optimal choices of incident vascular access type for elderly patients on hemodialysis (HD). Arteriovenous fistula (AVF) may be desirable given its better long-term outcomes. However, many elderly patients have a lower probability of AVF maturation and limited life expectancy that may limit the potential long-term benefit of AVF. We aimed to use an intention-to-treat (ITT) analysis to assess catheter dependency after incident AVF/arteriovenous graft (AVG) placement among elderly patients on HD.

Methods: Patients who were 66 years old at HD initiation, with no AVF/AVG placed before HD initiation, and had a first AVF/AVG placed within 1 year after HD initiation between May 2012 and May 2017 in the USRDS were included. Patients were followed from the first AVF/AVG placement using ITT analysis principles. Vascular access in use for HD was assessed using CROWNWeb data. Catheter dependency was defined as using catheter only or using AVF/AVG combined with a catheter for HD.

Results: A total of 39,036 patients were included. Among them, 31,190 (79.9%) had AVF and 7846 (21.1%) had AVG placed. A substantially lower proportion of patients in the AVG group relied on catheter for HD early after VA placement (88.2% vs 91.9% in AVG and AVG, respectively, at 1m after placement; 23.3% vs 64.3% at 3m; 16.4% vs 28.9% at 6m; Fig1). In longer follow-up, proportion of catheter dependency among patients remaining on HD in both groups, with slightly higher proportion in the AVG group observed at 1 year and beyond (14.8% vs 12.3% at 12m; 14.6% vs 9.6% at 24m). Risk of mortality was high in both groups (24.8% in AVG vs 27.8% in AVG by 12m; 42.4% in AVG vs 46.7% in AVG by 24m after VA placement).

Conclusions: AVG is associated with substantially less catheter dependency than AVF in the short-term and only slightly higher catheter dependency at one year and beyond. AVG placement may be beneficial in selected elderly patients to minimize catheter use.
is associated with adverse events such as bloody shunting, internal hemorrhage, and hypotension.

Methods: This is a single-center, retrospective study of patients treated for HD catheter dysfunction. The medical records were reviewed for demographic data, catheter dysfunction symptoms, and outcomes.

Results: A total of 159 HD catheter dysfunction cases were identified. The most frequent symptoms were hematoma (52.8%) and malposition (40.7%). The primary interventions were removal (51.8%) and mobilization (27.8%). The mean catheter dysfunction duration was 14 days. The catheter survival rate was 65.7% after a year.

Discussion: HD catheter dysfunction is a common complication. Early recognition and appropriate management can improve patient outcomes. The choice of intervention should be guided by the severity of the complication and the patient's clinical status.

PO1358

Use of Diphenhydramine as Adjutant to Conscious Sedation in Patients Undergoing Interventional Nephrology Procedures

Background: Benzodiazepines and opioids are commonly used for conscious sedation during interventional nephrology procedures but are associated with adverse events such as bradycardia and respiratory depression. We are proposing to use Diphenhydramine as adjutant medication to decrease the required dose of benzodiazepine and opioid.

Methods: We compared patients who received conscious sedation with IV midazolam and IV fentanyl as per standard practices to patients who received IV diphenhydramine prior to IV midazolam and IV fentanyl. Level of sedation was managed as per guidelines of moderate sedation. Data collected included baseline patient characteristics, dose of midazolam and fentanyl used, duration of the procedure, type of the procedure and incidence of bradycardia and hypoxia during procedure. We also looked at if sedation was administered by physician vs nurse.

Results: Out of total 407 patients included in the study, 225 patient received Diphenhydramine as adjuvant conscious sedation. Demographically the diphenhydramine use significantly reduced midazolam (2.2 mg vs 2.88 mg, p value <0.001) and fentanyl (88.2 mcg vs 102.07 mcg p value 0.005) dose requirements during procedures. It was not associated with increased rates of bradycardia and hypoxia. When comparing who administered sedation, physician administered sedation was associated with lower midazolam (2.18 mg vs 3.37 mg, p value < 0.001) and fentanyl (09.29 mcg vs 105.97 mcg, p value 0.04) dose without any difference in the rate of side effects, as compare to nurse administered sedation.

Conclusions: Our study indicates that the use of IV diphenhydramine is safe and effective as conscious sedation for patient undergoing Interventional Nephrology procedures and associated with reduction in benzodiazepine and opioid dose requirements.
PO1361
Percutaneous Thrombectomy of an Ipsilateral Arteriovenous Dialysis Graft in a Patient with Dextrocardia
Alexander Hlepas, Anna M. Zemke, Monnie Wasse. Interventional Nephrology Rush University Medical Center, Chicago, IL.

Introduction: Dextrocardia with situs solitus (DSS) is a rare condition. In affected patients with end-stage kidney disease (ESKD) the preferred dialysis access type and site are unclear, however anatomical variations may impact feasibility and success of dialysis access related procedures. In the setting of the altered anatomy, drainage of an access to the right atrium takes an altered pathway with differing technical concerns for stent deployment and avoidance of thrombus propagation in a clotted AVG.

Case Description: We report a rare case of covered stent placement during thrombectomy of a clotted ipsilateral right forearm AVG in the setting of DSS in an ESRD female. Given a severe venous anastomotic lesion and severe draining brachial vein stenosis, a covered stent was placed across the length of the stenosis. However, a guidewire could not be passed in the IVC to safeguard against potential stent migration to the heart, given the presence of dextrocardia, and the procedure was associated with a high risk of thrombus migration. An associated DLSVC draining into the CS (Coronary Sinus) was present, thus creating a direct path from the AVG through the central veins and the CS down to the heart. A right brachiocephalic vein was not present, and the right subclavian vein drained directly into the persistent right SVC (right part of duplicated left). After repeating the angiogram, measuring the length and marking it on the imager, a 6.10 cm Viabahn stent graft was passed to the level of the stenosis bridging the lesion with the CS down to the heart. A right brachiocephalic vein was not present, and the right subclavian vein drained directly into the persistent right SVC (right part of duplicated left). After repeating the angiogram, measuring the length and marking it on the imager, a 6.10 cm Viabahn stent graft was passed to the level of the stenosis bridging the lesion with the CS down to the heart. A right brachiocephalic vein was not present, and the right subclavian vein drained directly into the persistent right SVC (right part of duplicated left). After repeating the angiogram, measuring the length and marking it on the imager, a 6.10 cm Viabahn stent graft was passed to the level of the stenosis bridging the lesion with the CS down to the heart. A right brachiocephalic vein was not present, and the right subclavian vein drained directly into the persistent right SVC (right part of duplicated left).

Discussion: DSS is a rare malformation which may impact the preference of dialysis access site and type in ERSD patients. Possible complications due to the altered anatomy need to be further evaluated. Appropriate precautions to prevent thrombus migration from a clotted ipsilateral graft in the setting of dextrocardia need to be further discussed. This case shows the feasibility of stent placement in a clotted AVG despite the inability of placing a guidewire down the IVC due to dextrocardia.

PO1362
Missed Central Venous Stenosis Causing Unilateral Arm Swelling
Sylvester Barons, 1,2 Loyola University Health System, Maywood, IL; 3 Edward Hines Jr VA Hospital, Hines, IL.

Introduction: The patient is a 67YOM with a history of ESRD, right mandible SCC treated with resection, chemotherapy, and radiation with a right sided PowerPort placed for chemo, removed after roughly 1 year. Prior to initiation of dialysis the patient had a right upper extremity brachiocephalic fistula created leading to unilateral right arm swelling shortly afterwards.

Case Description: Fistulogram was performed showing no significant stenosis. Persistent arm swelling continued. CT venogram showed no areas of central stenosis nor any external mass compression (figure 1). Repeat fistulogram showed similar findings; however, pressure wire measurement was obtained showing a gradient of 20 mmHg at the right innominate/SVC junction. Catheter directed injection revealed a near complete stenosis (figure 2). Angioplasty was performed with an 8 mm balloon. Repeat pressure measurements showed a decrease to 10 mmHg with angiogram demonstrating significant improvement in the lesion.

Discussion: Over two weeks he had swelling resolution. This case highlights physical exam findings of central vein stenosis. Despite being absent on multiple imaging modalities persistent physical exam findings necessitated continued evaluation. The validity of pressure wire measurements to help guide further imaging and treatment options is also highlighted.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Discussion: These two cases showed that prolonged dialysis access thrombosis can be complicated with arterial embolic events that require high suspicion and immediate treatment.

POI1364
Associations Between Length of Dialysis Facility Ownership and Vascular Access
David T. Gilbertson,1,2 Yi Peng,1,2 William Eggert,1,2 Mahesh Krishnan,3,4Chronic Disease Research Group, Minneapolis, MN; 2Hennepin Healthcare Research Institute, Minneapolis, MN; 3DaVita HealthCare Partners, Denver, CO.

Background: Length of dialysis facility ownership may be associated with facility performance in achieving guideline-recommended clinical indicators and outcomes measures. Using publicly available dialysis facility-level data, we sought to assess facility performance on 2 clinical indicators prior to and after facilities were acquired by a large dialysis organization (LDO).

Methods: Using data from Dialysis Facility Compare, we compared units that the LDO acquired during 2013 through 2016 to existing units by looking at 3 time frames: change from the year prior to acquisition, the year of acquisition, and the year following acquisition. These were compared to facilities under LDO ownership for at least 3 years and facilities not owned by the LDO. The measures assessed were percentage of patients with a catheter in use for more than 90 days and percentage of patients with an arteriovenous (AV) fistula in use.

Results: Sixty-seven units were acquired by the LDO during 2013 through 2016. Units acquired by the LDO had a higher percentage of patients with catheter use ≥90 days in the year prior to acquisition than units owned by the LDO for at least 3 years and units not owned by the LDO and improved during the year acquired and the year following acquisition (14.1%, 12.8%, 11.4%, respectively). Similar improvements were observed for AV fistula use (see Table).

Conclusions: Prior research has posited both positive and negative effects of acquisition on quality of patient care. The current results do not find negative effects and suggest possible improvements in care over the course of 1 to 2 years following acquisition, which suggests that implementation of LDO patient care protocols in newly acquired facilities may take time to unfold.

Data-Backed Multidisciplinary Care Substantially Improves Renal Replacement Therapy Outcomes
Xiuyan Wang,1 Olle Fielding,1 Jung Hoon Son,1 Edward M. Lee,1 Andrew Bohmar,1 Frank Liu,2 Jeffrey L. Silberzweig,2 The PEAK team 1pulseData, New York, NY; 2The Rogosin Institute, New York, NY.

Background: The Rogosin Institute created the Program for Education in Advanced Kidney Disease (PEAK), a multidisciplinary care team that assists patients in making a smooth transition to renal replacement therapy (RRT) in 2015. In October 2018 the PEAK team transitioned to using a machine learning (ML) algorithm and care platform devised by pulseData to identify their highest risk patients and increase the rate of optimal RRT starts and increase support for patients in choosing a home dialysis modality.

Methods: The ML model continually surveys the Electronic Health Record (EHR) to identify patients at risk of progression to an eGFR <10 or RRT start in the next six months for referral into the PEAK program. The patient review platform presents a longitudinal view of the patient’s data, allows for the documentation of the RRT care plan and is used to review the high risk patients at a weekly care planning session. The care team updates patient progress and the platform highlights patients who have had no recent care actions.

Results: Home dialysis rates increased 50% after the ML/platform deployment (30% vs 20%). Home dialysis rates among graduates of the PEAK program are now 10x the NYC average (27% since January 1, 2019 vs 2.5%). Patients who spend more time in the PEAK program are more likely to receive an optimal dialysis start (as an outpatient and with venous access) (p<0.00002, unequal variances t-test); the mean PEAK duration for an optimal start is 316 days vs. 196 for non-optimal starts. Optimal starts are also associated with a greater number of PEAK appointments, (4.9 appointments vs 3.7; p=0.0004, unequal variances t-test). Further, of patients starting dialysis using a central venous catheter (CVC), PEAK program graduates remove them significantly sooner (mean 88.57 days for non-PEAK vs. 54.71 mean days for PEAK, p=0.02, unequal variances t-test).

Conclusions: The PEAK MDC-pulseData partnership has dramatically improved care coordination resulting in a substantial increase in home dialysis modality and optimal dialysis starts and reduced the amount of time dialysis patients spend using a CVC.

Funding: Commercial Support - pulseData

POI1366
Education and Experience Gained Through Nephrology Business Leadership University (NBLU) Provide Valuable Benefits to Graduating Nephrology Fellows: A Survey-Based Study
Diana Mahbod,1 Manasi Bapat,1 Samir Nangia,1,2 Dallas Renal Group, Dallas, TX; 2Texas Christian University, Fort Worth, TX; 3East Bay Nephrology, Berkeley, CA.

Background: Nephrology fellowship programs provide excellent clinical training but education regarding the economic, business, and leadership aspects of practicing as a nephrologist are lacking. Nephrology Business Leadership University (NBLU) addresses these needs in order to provide graduating fellows with practical tools for navigating their early private practice or academic careers.

Methods: We surveyed attendees of NBLU from each of the four years since the conference was created. An anonymous survey was sent to alumni electronically and focused on how the experiences and knowledge gained at NBLU have impacted their early careers.

Results: Seventy-one percent of fellows who were contacted responded to the survey. Respondents represented all four years of NBLU and all geographic areas of the U.S. All fellows indicated that they would recommend NBLU to other fellows, with 91% indicating that they would highly recommend it. Respondents reported that NBLU increased their knowledge about the nephrology job market, the economics of nephrology practice, and the various ways to engage in leadership opportunities in nephrology, including by using social media platforms for education and networking. Fellows reported enhanced knowledge regarding both private and academic nephrology careers and most established lasting relationships with colleagues from across the country which they intend to maintain throughout their careers.

Conclusions: Nephrology fellowship programs report a significant need for business and leadership education which is currently lacking from fellowship programs. NBLU provides a week-long curriculum which has a lasting positive impact on graduating nephrology fellows. Empowering nephrology trainees on the verge of entering the workforce has the power to strengthen the field as these early career nephrologists inspire other trainees to join this challenging yet fulfilling field.
PO1367

Medicine Residents’ Perception of the Nephrology Specialty

Georges Nakhour,1,2 Ali Mehdi,1,2 Jonathan T. Taliercio,1,2 Patricia F. Kao,3 Grace Mcnutt,1 Jessica Greenfield,1 Abby L. Spencer,1 John F. O’Toole,1,2 Joseph V. Nally,1,2 John R. Sedor,1,2 S. beth Bierer,1 1Cleveland Clinic, Cleveland, OH; 2Case Western Reserve University, Cleveland, OH; 3Washington University in Saint Louis, Saint Louis, MO.

Background: Interest in nephrology as a specialty has been declining among residents. As a result, more than half of the programs remain unfilled. The residents’ perceptions of the nephrology field that might account for this loss of interest are unknown. We aimed to identify factors influencing residents’ views on pursuing a career in nephrology.

Methods: We used the results of our previously published qualitative analysis on residents’ perception of nephrology to inform and design a survey of 60 questions. The survey was delivered using the secure web application “REDCap to 680 residents across eight medicine residency programs in different regions nationally.

Results: 184 residents (27%) responded to the survey. 56% (103) were male, 77% (142) were American graduates and 21% (42) were international graduates. Major positive perceptions of nephrology were: intellectually challenging, positively impacts patients’ lives, opportunity to obtain the job of choice with possibility to practice in an academic setting, and a good work-life balance (Fig. 1A). Those aligned well with the top factors influencing residents’ choice of specialty (Fig. 1B). The major negative perceptions included: inability to perform procedures, financial compensation, and patient population (Fig. 1A). Those aligned poorly with many of the key factors influencing residents’ choice of specialty (Fig. 1B).

Conclusions: Nephrology is well perceived in the top three categories of factors that influence residents’ specialty choices. This suggests that negative factors such as inadequate financial compensation, inability to perform procedures, lack of innovation, and a difficult patient population greatly outweigh the positives. In order to attract more candidates, the nephrology community should highlight the innovations and policy initiatives such as the Kidney Precision Medicine Project, the Kidney Innovation Accelerator, and the Advancing American Kidney Health initiative. Nephrologists should also consider creating/expanding interventional nephrology programs and increasing resident exposure to outpatient nephrology.

Funding: Private Foundation Support.

Clinical Practice Guideline Adoption and Nephrologist Demand

Joseph Launera,1 Kurtis Pivert,1 Stephen M. Sozio,2 (American Society of Nephrology, Washington, DC; Johns Hopkins University, Baltimore, MD; 1Duke University, Durham, NC.

Background: It is unknown how clinical practice guidelines (CPGs) can affect subspecialty consult (and subspecialist) demand. This study sought to quantify how residents’ specialty choices. This suggests that negative factors such as inadequate financial compensation, inability to perform procedures, lack of innovation, and a difficult patient population greatly outweigh the positives. In order to attract more candidates, the nephrology community should highlight the innovations and policy initiatives such as the Kidney Precision Medicine Project, the Kidney Innovation Accelerator, and the Advancing American Kidney Health initiative. Nephrologists should also consider creating/expanding interventional nephrology programs and increasing resident exposure to outpatient nephrology.

Funding: Private Foundation Support.

PO1369

Association Between Different Payment Models, Workload, and Job Satisfaction of Nephrologists in Lebanon and Jordan

Mabel Aoun,1,2 Nour Bretche,1 Kassem M. Kassak,1,2 (Saint Joseph University, Beirut, Lebanon; American University of Beirut, Beirut, Lebanon.

Background: The main challenges that nephrologists are facing worldwide are lower income, dissatisfactory payment models, long work hours and burnout. This study aimed to identify factors associated with nephrologists’ satisfaction in Lebanon and Jordan.

Methods: An online survey was sent to all 250 Lebanese and Jordanian nephrologists, including data on demographics, education, academic activities, job satisfaction, burnout, workload and reimbursement.

Results: A total of 59 nephrologists responded. Mean age was 46.9 ±12.5 years, 39% women. Respondents reported low rates of satisfaction in job opportunities (20%), income (25%) and administrative support (32%). On the other hand, 68% reported that nephrology is stressful. High satisfaction rates were found in relationship with patients (78%) and colleagues (73%). Income was significantly higher among males than females (p < 0.001). Satisfaction towards income was significantly lower in females, mean score difference 0.71 ± 0.30 (95%CI: 0.10,1.32; p=0.024). A greater proportion of male over female practitioners wanted to follow above the 40-dialysis-patient regulation (p=0.001) and preferred pay-for-performance over fee for service. Satisfaction with income and work-life balance was positively correlated with age and young nephrologists had significantly lower satisfaction with job opportunities (11%). Driving over 1 hour daily to work was significantly associated with dissatisfaction in work-life balance (p<0.029), stress and burnout (p=0.016). Using regression analysis, longer delay in payment predicted worse work-life balance among Lebanese nephrologists (p=0.04). Compared to male practitioners, female practitioners spent more time on teaching (p<0.001), and more female had academic rank and publications (p<0.001). Gender discrimination was perceived significantly among women.

Conclusions: Unfair and delayed reimbursement is associated with dissatisfaction among the surveyed nephrologists. Gender differences are very significant with lower income and satisfaction rates among women. Similarly, it seems that the younger generation perceives low job opportunities. Decision makers need to urgently empower women, address payment delays conduct market analysis and accordingly regulate nephrologists’ entry to avoid oversupply or unemployment.

PO1370

Evaluating Nephrology Competency in General Pediatrics

Amrit Kirpalani,1,2 Natasha Jawa,1 Charushree Prasad,1 Adelle R. Atkinson,1 Mark E. Feldman,1 Justin M. Jeffers,1 Damien G. Noone,1 (Hospital for Sick Children, Toronto, ON, Canada; London Health Sciences Centre Children’s Hospital, London, ON, Canada; McMaster University Faculty of Health Sciences, Hamilton, ON, Canada; Johns Hopkins University, Baltimore, MD.

Background: General pediatricians may be the first-line providers to care for children with kidney disease, however studies suggest they find nephrology to be a difficult subject. This study aimed to identify areas of lowest perceived competency and importance within nephrology for general pediatricians.

Methods: A web-based survey was distributed to general pediatricians through the Pediatricians of Ontario network to all Pediatrics Residency Program Directors in Canada and Canadian Pediatric Nephrologists in the Canadian Association of Paediatric Nephrologists. Pediatricians were asked to rate nephrology objectives of training on a 5-point Likert scale for perceived competence and importance. Program Directors and Nephrologists were asked for perceived importance of each objective for general pediatricians. Scores were equally weighted using Student’s t-test and mean scores were calculated. Knowledge Gap scores were calculated as the difference between perceived importance and competence scores.

Results: General Pediatricians, 60/350 (17%) responded to the survey. Domains scoring significantly below the mean in terms of competency (2.9/5) and importance (3.2/5), respectively, were kidney stones (2.5 and 2.6), AKI (2.5 and 2.4), CKD (1.9 and 2.1), Tubular disorders (1.8 and 2.0), and kidney transplant (1.6 and 1.7). Hypertension had the most significant knowledge gap score (0.8/5, 16%, p<0.05). Program Directors.
PO1371
Assessment of Faculty Developed e-Curriculum in Hemodialysis
Namrata Krishnan,1 2 Yale teaching and learning center 1Yale University School of Medicine, New Haven, CT; 2Veterans Affairs Medical Center, West haven, CT

Background: E-learning is gaining popularity in medical education and offers several advantages. We have developed a comprehensive, hands-on online e-curriculum in hemodialysis based on ACGME competency requirements. The curriculum includes two online modules on Hemodialysis kinetics/adequacy; and Hemodialysis access. In this study we assessed the experience among nephrology trainees, of using this e-Curriculum, and assess its effectiveness as a teaching tool.

Methods: This pilot study sample included 11 nephrology fellows (8 from Yale and 3 from other US nephrology programs). Design: A mixed methods approach using a triangulation model. Data collection: A Qualtrics survey was distributed to the participants after curriculum completion. This was followed by a 15 minute zoom interview of each individual participant. This study was approved by our local IRB.

Results: The study sample had an even distribution of participants across all levels of nephrology training, identified as visual learners. Irrespective of the learner type, animated videos were the most desired feature of the E-modules and helped visualization of abstract concepts. Concepts of flux vs. efficiency, convection vs. diffusion, Kt/V, physical examination of an AV fistula, and access recirculation were topics reviewed repetitively. Based on survey data, there was 100 % agreement among the learners that the websites were easy to navigate; the content represented common clinical scenarios and the interactive knowledge testing helped in concept retention and improving student engagement. Statistical analysis (paired t-tests) showed that there was significant improvement in knowledge by the learner in 6 core competencies after module completion (p<0.01). The advantages of an E-curriculum were reported to be simplified visualization of key concepts; excellent clinical application, time flexibility/repetitive review, standardization of content, learner centric approach; and a flipped classroom model. The disadvantages were the lack of community learning and the inability to ask questions immediately.

Conclusions: In conclusion, the hemodialysis E-curriculum was an effective educational platform for nephrology fellows. Although an E-curriculum allows standardized learning with a learner-centric approach, it can cause social isolation and reduced self-motivation. A blended learning approach, combining E-learning and traditional methods may be ideal.

PO1372
Implementation and Assessment of Virtual Standardized Patient Sessions to Teach Communication Skills to Nephrology Fellows During COVID-19
Racquel J. Holmes,1 Jonathan Fischer,1 Jared Lowe,1 Jane O. Schell,2 Samira S. Farouk,2 Matthew A. Sparks,1 Duke Nephrology 1Duke University, Durham, NC; 2University of Pittsburgh Medical Center, Pittsburgh, PA; 1Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Standardized patients (SP) are routinely used in medical education teaching learners how to communicate in traditionally challenging environments like end-of-life discussions or delivery of a difficult diagnosis. Adherence to the need for social distancing during COVID-19 has eliminated in-person SP encounters and necessitated virtual sessions using a video conferencing software. We assessed the impact of virtual, SP-based communication skills workshops on a cohort of nephrology fellows.

Methods: Over two weeks, nephrology fellows were invited to participate in two 90-minute communications workshops with a SP conducted over Zoom. Workshops included a didactic portion and SP interviews simulating difficult conversations. Fellows observed each other and provided feedback during the interviews. A 10-question survey was then distributed to the participants to evaluate the training sessions and compare themselves to analogous in-person communication workshops.

Results: All invited fellows participated in at least one session and completed the survey (100%, 12/12). Five first-year fellows (42%, 5/12), 5 second-year fellows (42%, 5/12), and 2 third-year fellows (17%, 2/12) participated. 67% (8/12) of participants reported that they found the sessions useful. Of the fellows who had attended a prior in person simulation-based workshop (67%, 8/12) with standardized patients, 88% (7/8) rated the virtual session as good as or better than in-person role-playing. 83% (10/12) of participants reported that skills learned during the virtual session would be used in their clinical practice. 83% (10/12) felt observing their co-fellows was useful. Write-in comments indicated a barrier to using virtual role playing was a challenge in recognizing emotion and empathy.

Conclusions: Virtual training sessions with SP actors were rated highly by the fellows and provided an opportunity for them to practice communication skills to incorporate into current practice. The virtual workshops were easily implemented, well-received, and should be considered as an alternative training format, especially when in-person workshops cannot be conducted. Future trainings can incorporate communication challenges that arise during telemedicine video or telephone encounters.

PO1373
Dose Adjustment of Rheumatoid and Allergic Medications in CKD: Awareness and Knowledge Among Internal Medicine House Staff
Jessica M. Loizides,1 2 Joshua Fogel,1 Sofia Rubinstein,1 2 New York Institute of Technology College of Osteopathic Medicine, Old Westbury, NY; 3Nassau University Medical Center, East Meadow, NY; 2Brooklyn College Department of Business Management, Brooklyn, NY.

Background: Patients with chronic kidney disease (CKD) are at increased risk for adverse drug events due to medication dosing errors. We study the awareness and knowledge among Internal Medicine house-staff (IMH) of proper dose adjustment of commonly used rheumatology and allergy/immunology medications for patients with CKD.

Methods: We surveyed 353 IMH to evaluate their awareness of medication dose needs adjustment for patients with CKD and knowledge for medication adjustment by level of glomerular filtration rate for common rheumatology and allergy/immunology medications.

Results: There was lack of awareness and knowledge for both rheumatology and allergy/immunology medications. Not correct awareness and knowledge were: allopurinol (21.2%, 73.4%), colchicine (19.0%, 75.9%), diphenhydramine (34.0%, 34.0%), ketotifen (82.2%, 92.2%), and montelukast (34.0%, 34.0%). Exploratory logistic regression analyses showed PGY1 residents had higher odds for lack of awareness for allopurinol (OR:2.57, 95% CI:4.69, 99.13, p<0.001), colchicine (OR:3.98, 95% CI:1.00, 10.51, p<0.01), diphenhydramine (OR:2.24, 95% CI:1.10, 4.54, p<0.04), and montelukast (OR:2.45, 95% CI:1.20, 5.00, p<0.05) than PGY3 residents. Nephrology rotation in medical school was associated with lower odds for incorrect knowledge for allopurinol (OR:0.46, 95% CI:0.25, 0.87, p<0.05) and montelukast (OR:0.50, 95% CI:0.27, 0.92, p<0.05).

Conclusions: Overall, awareness and knowledge was poor among IMH for dose adjustments of rheumatology and allergy/immunology medications in patients with CKD. Proper education and exposure to nephrology during training may improve quality and safety of care for patients with CKD.

PO1374
Emerging Therapies for Managing Patients with Alport Syndrome: Online Medical Education Improves Knowledge and Confidence of Nephrologists
Amy Larkin,1 Donald Blatherwick,1 George Boutsalis,1 Ellie Kelepouoris,2 1Medscape Education, New York, NY; 2Drexel University College of Medicine, Philadelphia, PA.

Background: As new therapies for Alport syndrome continue to progress through development, nephrologists require increased understanding of these therapies. The objective of this study was to determine if online education for nephrologists could improve clinical knowledge and confidence in managing patients with Alport syndrome with current and emerging treatment strategies.

Methods: The continuing medical education (CME) activity was an online video panel discussion among 3 faculty on current and emerging strategies for the management of Alport syndrome. Multiple-choice knowledge questions and 1 self-reported confidence question were presented both before and immediately after the CME activity. A repeated pairs pre-post-assessment study design was used and a chi-square test (P <0.05 is considered significant) assessed educational effect for each activity. Cramer’s V was used to calculate the effect size (0.06-0.15 is a noticeable effect, 0.16-0.26 considerable, >0.26 considerable). The activity launched online on March 1, 2019, and data were collected through April 3, 2020.

Results: Overall, knowledge and confidence improved among nephrologists (n = 71, V= 0.348, P=0.001) from pre- to post-assessment: 24% demonstrated improved understanding of important factors when prescribing renin-angiotensin-aldosterone system (RAAS) inhibitors in patients with Alport syndrome (V=0.26 (considerable educational impact), P<0.05) 32% demonstrated improved recognition of efficacy data for bardoxolone methyl in Alport syndrome increase in the number of nephrologists (V= 0.297 (extensive educational impact), P=0.001) 63% demonstrated improved identification of adverse effects for emerging treatments for Alport syndrome (V=0.51 (extensive educational impact), P=0.001), 38% reported increased confidence in understanding role that chronic renal inflammation plays in AS Continued educational gaps: 41% failed to recognize impact of bardoxolone methyl on Alport syndrome 20% did not recognize important factors when prescribing RAAS inhibitors in patients with Alport syndrome.

Conclusions: The online video panel discussion CME activity demonstrated success in improving knowledge and confidence of nephrologists related to current and emerging therapies for the management of Alport syndrome. Continued knowledge gaps were identified for future educational targets.

Funding: Commercial Support - Reata
PO1375
Online CME Effectively Improves Nephrologists' Knowledge, Competence, and Confidence Related to Hyperkalemia Management

Methods: The online CME curriculum consisted of 6 activities. Of these, 5 were video-based and used repeated post-assessment questions designed with McNemar’s test ($P < 0.05$ is considered significant) to assess educational effect. The last activity was a medical patient simulation that utilized tailored clinical guidance (CG), based on current evidence and expert recommendation, followed by the opportunity for the learner to modify to their decisions. Decisions were collected post-CG and compared with each user’s baseline (pre-CG) decisions. The activities launched in 2019 and data were collected for up to 12 weeks.

Results: The education reached over 14,000 physicians, including over 3,200 nephrologists. Overall, knowledge improved by 29%, competence by 14% and performance by 150% (all relative improvements, $P<.001$) by nephrologists. Specific improvements: 22% relative increase in knowledge related to rationale for optimizing RAAS inhibitors in patients with chronic hyperkalemia ($P<.001$) 15% relative increase in competence related to effective use of potassium binders ($P<.001$) 441% and 231% relative increases in performance (2 patient simulation cases) related to effective use of pharmacotherapy for hyperkalemia ($P<.001$). Of the nephrologists who were included, 36% reported increased confidence in managing hyperkalemia, with the largest confidence gains being related to effective use of potassium binders.

Conclusions: The current observations demonstrate that by designing knowledge and competence related to hyperkalemia management in a curriculum approach, large improvements in performance can be achieved (over 90% were effectively using pharmacotherapy post-CG). Learners, on average, knew 70% of the information assessed and still require more education to optimizing RAAS inhibitors in patients with chronic hyperkalemia and use of diet to manage hyperkalemia. Among the learners, 36% gained confidence regarding hyperkalemia management in practice, but are still not fully confident. As such, further education is needed in these areas.

Funding: Commercial Support - Relypsa, a Vilor Company

PO1376
Case-Based, Interactive Medical Education Significantly Improves Management of Chronic Hyperkalemia in Complex Patients
Amy Larkin, Donald Blatherwick, George Boutsalis. Medscape LLC, New York, NY.

Background: We sought to determine if interactive, case-based online continuing medical education (CME) for nephrologists could improve clinical knowledge, competence, and performance in the area of chronic hyperkalemia management in complex patients.

Methods: The instructional method consisted of an online, case-based, interactive text activity. Clinicians were presented with 2 patient cases that included multiple-choice questions allowing them to make clinical decisions about treatment. Educational effect was assessed using a 4-question repeated pairs pre-post-assessment and McNemar’s chi-squared test questions allowing them to make clinical decisions about treatment. Educational effect was assessed using a 4-question repeated pairs pre-post-assessment and McNemar’s chi-squared test. P values are shown as a measure of significance; $P$ values $<0.5$ are statistically significant. Cramer’s $V$ determined the effect size ($<0.05$ no effect; $0.06-0.15$ small effect; $0.16-0.30$ medium effect; $>0.30$ large effect).

The activity launched May 15, 2019; data were collected through June 24, 2019.

Results: Significant overall improvements were seen (n = 59; $P=.003$; $V=0.156$) as a result of participation in the CME activity. Specific areas of improvements include: 8% of nephrologists ($P=0.05$; $V=0.179$) improved at using a loop diuretic when a low-potassium result of participation in the CME activity. Specific areas of improvements include: 8% of nephrologists ($P=0.05$; $V=0.179$) improved at using a loop diuretic when a low-potassium levels (N=188; V=191; P <.001) 24% increase in recognition of long-term data for newer potassium binders (N=183; V=193; P <.001) 26% (N=183) had a measurable increase in confidence in using a potassium binder to treat a patient hyperkalemia (N=184) had a measurable increase in confidence in applying team-based strategies to better manage patients with HF who present with hyperkalemia Persistent knowledge/competence gaps remain: 56% of nephrologists (N=183) incorrectly identified incidence of hyperkalemia in patients with heart failure treated with renin-angiotensin-aldosterone system (RAAS) inhibitors 49% of nephrologists (N=183) could not recognize long-term efficacy data for newer potassium binders 74% of nephrologists (N=188) made an incorrect clinical decision in a patient who was euvoletic but had elevated potassium levels.

Conclusions: This study demonstrates the success of an online curriculum with multiple educational components at improving knowledge, competence, and confidence of nephrologists related to hyperkalemia management. Persistent gaps were identified for future educational targets.

Funding: Commercial Support - independent educational grant from AstraZeneca

PO1377
Curriculum-Based Online Education Effectively Improves Nephrologists’ Ability to Manage Hyperkalemia in Practice
Amy Larkin, Donald Blatherwick, George Boutsalis. Medscape LLC, New York, NY.

Background: The goal of continuing medical education (CME) is professional growth and improved patient care. We sought to determine if a series of online continuing medical education (CME) activities could improve the clinical knowledge, competence, and confidence of nephrologists related to hyperkalemia management.

Methods: The online CME curriculum consisted of 6 activities. Of these, 5 were video-based and used repeated post-assessment questions designed with McNemar’s test ($P < 0.05$ is considered significant) to assess educational effect. The last activity was a medical patient simulation that utilized tailored clinical guidance (CG), based on current evidence and expert recommendation, followed by the opportunity for the learner to modify to their decisions. Decisions were collected post-CG and compared with each user’s baseline (pre-CG) decisions. The activities launched in 2019 and data were collected for up to 12 weeks.

Results: The education reached over 14,000 physicians, including over 3,200 nephrologists. Overall, knowledge improved by 29%, competence by 14% and performance by 150% (all relative improvements, $P<.001$) by nephrologists. Specific improvements: 22% relative increase in knowledge related to rationale for optimizing RAAS inhibitors in patients with chronic hyperkalemia ($P<.001$) 15% relative increase in competence related to effective use of potassium binders ($P<.001$) 441% and 231% relative increases in performance (2 patient simulation cases) related to effective use of pharmacotherapy for hyperkalemia ($P<.001$). Of the nephrologists who were included, 36% reported increased confidence in managing hyperkalemia, with the largest confidence gains being related to effective use of potassium binders.

Conclusions: The current observations demonstrate that by designing knowledge and competence related to hyperkalemia management in a curriculum approach, large improvements in performance can be achieved (over 90% were effectively using pharmacotherapy post-CG). Learners, on average, knew 70% of the information assessed and still require more education to optimizing RAAS inhibitors in patients with chronic hyperkalemia and use of diet to manage hyperkalemia. PO1378
An Analysis of Scienteometrics and Social Media in Nephrology
Neha G. Vaghiyani,1 Nishi Shah,2 Natsal Lal,3 Tejas Desai,3 Anna Vinnikova,1 Thyrocare Commonwealth University School of Medicine, Richmond, VA; 3NOD Analytics, Charlotte, NC.

Background: In the past decade, the use of social media to disseminate scientific literature, particularly in the Nephrology community, has exponentially increased to educate, network, mentor. The hallmark of scientometrics has traditionally been based on Journal Impact Factor (JIF), calculated from the citations of each article. It has been previously demonstrated that twitter mentions of published works, correlate with citations, and therefore JIF, in the fields of Urology, Biomedical Science, and Ecology. However, this relationship has yet to be established in the field of Nephrology.

Methods: The top 5 journals in Nephrology, based on impact factor (Kidney International, Nature Reviews Nephrology, AJKD, IASJ and CJASN), published 76 articles in January of 2018 in print. Altmetrics bookmarklet was used to collect twitter demographics on each article (number of tweets, by whom, and number of followers). Citation data was sourced from Web of Science’s InCites Journal Citation Reports.

Results: Articles were categorized as ‘highly cited or tweeted’ when they were ≥ 75th percentile of citations or tweets, and ‘less cited or tweeted’ at ≤ 25th percentile.

PO1379
Qualitative Interview Study on Advanced Care Planning for Patients with Advanced CKD and Their Families: The Impact of the MY WAY Advance Care Planning Intervention
Tinsley Grimes Webster,1 Ellis M. Pearson,2 Natalie C. Ernecoff,1 Jane O. Schell2 (1University of Pittsburgh School of Medicine, Pittsburgh, PA; 2University of Pittsburgh Medical Center, Pittsburgh, PA).

Background: Despite recommendations for shared decision-making approaches to advance care planning (ACP) for people with life-limiting illnesses (e.g., End of Life Care Pathway-CKD), doctor-patient conversations about ACP are infrequent. The MY WAY educational and patient-coaching intervention aims to elicit patient values to increase rates of ACP. This qualitative sub-study sought to: (1) gain understanding of participant responses to MY WAY ACP materials, and (2) learn without patient wishes to kidney care within ACP.

Methods: We conducted semi-structured interviews with participants from the intervention arm of the MY WAY study. Fifteen people with CKD were queried about their experiences of the MY WAY print materials and coaching session. Interviews were recorded, transcribed for simultaneous coding by two researchers. Data were analyzed using thematic analysis.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Results: Fifteen intervention participants ages 59-87 were interviewed (10 women, 5 men). The major themes emerged: participant advice for interventionists; experience with ACP before and after the intervention; participant experience of printed materials; participant response to coaching session; and chronic kidney disease thoughts and communication. Differences between participant experiences of general and CKD-specific ACP emerged, including willingness to discuss care wishes with family members and clinicians.

Conclusions: Participants perceived the coaching session to have high utility in facilitating ACP, but expressed less engagement with CKD-specific care plans. Findings suggest that while the coaching activities of the coaches included problem-solving and prompting change in daily life, participants noted that empathy and problem-solving played a key role in participant comfort with ACP conversations, and that engagement with ACP may not correlate with engagement with CKD-specific care wishes. Notably, even participants who engaged actively with general ACP expressed that kidney-specific care would be better addressed with their nephrologists if or when the need arose. Future studies should further explore the interrelational of general ACP and CKD-specific care planning.

PO1380
Enhancing Patient Care by Partnering with Patients in Kidney Health Research

Background: Canada’s Strategy for Patient-Oriented Research (SPOR) has raised awareness of the need to generate knowledge that is more relevant to patients and to accelerate the translation of evidence into clinical care. Members of the Canadian nephrology community have come together to develop a national patient-oriented research network, Can-SOLVE CKD, that is partnering with patients to close existing gaps in kidney disease knowledge in order to deliver better health outcomes. The Can-SOLVE CKD Network brings together patients and nephrology researchers to transform treatment and care for Canadians living with or at risk for chronic kidney disease.

Methods: The network’s 18 research projects are informed by two national priority-setting exercises conducted with patients, their families and care providers. As the network executes the projects, patients have been integrated into research teams, bringing an enhanced “patient lens” to bear on all aspects of the research life cycle: design, development, data collection, analysis, interpretation, and dissemination. Patients are also at the centre of the network’s governance model, which incorporates a Patient Governance Circle and an Indigenous Peoples’ Engagement and Research Council.

Results: Can-SOLVE CKD researchers have reported the positive impact of partnering with patients. “My research is better” is often cited as an outcome of patient engagement within the network. Patient partner involvement on the network’s Research Operations Committee has enriched the annual review of projects, resulting in valuable, real-world feedback to project teams. Respondents to the network’s patient engagement survey report feeling better informed about and having greater trust in kidney research as a result of their participation.

Conclusions: We have witnessed a shift in the culture of nephrology research in Canada paralleling the broader movement toward patient-oriented research. The traditional role of patients as research subjects has evolved to include patients as valuable and equal members of Can-SOLVE CKD’s research projects.

Funding: Government Support - Non-U.S.

PO1381
Online Patient/Caregiver Education on Hyperkalemia Can Improve Knowledge and Confidence as Well as Prompt Real-Life Changes
Amy Larkin, Donald Blatherwick. Mediscape LLC, New York, NY.

Background: Managing hyperkalemia with a strict diet is limiting and difficult for patients. We sought to measure the impact of online education for patients/caregivers on knowledge confidence as well as prompting change in daily life.

Methods: The caregiver education was designed as 2 online, interactive activities. Both were comprised of text and visual images, the second also included a patient commentary video. Demographic questions were asked prior to starting the education. A knowledge question was asked both before and after the activity to assess learning gains, as well as intent to change and confidence questions at the end. The activity was staged in March and May of 2019, and data was collected through September 2019.

Results: To date, 72,440 learners have participated in the patient/caregiver activity. Activity 1: Do You Have High Potassium? Here are Some Tips for Managing Potassium In Your Diet Participants: 35, 889 Completers of all questions (included in outcomes analysis): 4,305 Demographics: 65% female; 63% white, non-Hispanic; 67% over the age of 54; 45% have hyperkalemia, 42% were interested in learning more about the condition and problem-solving; 79% reported increased confidence talking to their doctor about ways to lower their potassium levels Activity 2: Are Medicines That Lower Potassium Right for You? Participants: 36, 551 Completers of all questions (included in outcomes analysis): 2,987 Demographics: 59% female; 78% white, non-Hispanic; 82% over the age of 54; 58% were interested in learning more about the condition and 29% have this condition Knowledge changes: 23% improvement in recognizing how potassium binders work to treat hyperkalemia (42% pre to 65% post) Intent-to-act: 69% plan to talk to their providers about higher than ideal low-protein diet before the follow-up visit; 73% reported increased confidence talking to their doctor about medicines that can treat hyperkalemia

Conclusions: The metrics and outcomes gathered in this assessment are a strong indication that these patient/caregiver-focused online educational activities improved knowledge and confidence, and prompted intent to act by patients/caregivers related to hyperkalemia.

PO1382
Rethinking Renal Caregiving in Anthropological Terms: An Interdisciplinary Methodological Approach
Insa M. Schmidt. Boston University Medical Center, Boston, MA.

Background: Rethinking caregiving in nephrology through an anthropological lens may bring a new perspective to a holistic understanding of renal care by encouraging health professionals to reflect critically on the complex webs of care, culture, and ethics in which renal medicine is enmeshed.

Methods: This study draws on anthropological methodology and ethnographic research to develop a framework for reconceptualizing renal care. An extensive review of the anthropological literature on renal care is used to illustrate some of the multifaceted challenges of caregiving in nephrology and to develop a framework for use in the clinical encounter to better understand patients’ illness-related beliefs and their relevance for clinical practice.

Results: The key domains in renal care are framed by diverse cultural, societal, and individual beliefs regarding the organ’s function and the causes of kidney disease. Ethnographic data from dialysis and renal transplant patients in the United States, Europe, Mexico, and China show that diverse and controversial disease and treatment beliefs pose a different kind of challenge to the communication between health professionals and their patients. Based on these findings, a framework has been developed that can be integrated in medical education programs and provides a guide for health professionals to think through the complex psychological, ideological, and ethical underpinnings of nephrology’s central therapeutic modalities such as transplantation and dialysis.

Conclusions: Bringing an anthropological sensibility to the clinical care may help to understand the cultural and moral world in which the caregiver-patient relationship needs to be formed. The integration of the medical humanities into the educational programs of renal care providers can be used to develop a better understanding of patients’ diverse disease and treatment beliefs which may ultimately improve the caregiver-patient relationship.

WeChat Platform and Specialty Nursing Outpatient Clinics to Improve the Compliance of a High-Quality Low-Protein Diet in Patients with CKD Stage 3-5
Haixia Xiong, 1 Hui-qun Li, Fangfei Ren, 1 Yin Zhou, 1 Chunlin Hu. 1’the third affiliated hospital of Sun Yat-sen University, Guangzhou, China; 2’THe First Affiliated hospital of sun-yat sen university, Guangzhou, China.

Background: Low protein diet (LPD) has become one of the important means to treat chronic kidney disease (CKD) patients. At present, the low protein diet compliance of CKD patients in China is not ideal, the compliance rate is only 48.3% - 54.5%. The dietary compliance of CKD patients is based on the knowledge of diet, and the survey shows that CKD patients and their families have a low level of knowledge of diet of kidney disease. Therefore, in order to improve the low protein diet compliance of CKD-5 patients and reduce the incidence of malnutrition, we set up a wechat group through the network platform to guide the low protein diet of CKD-5 patients. The nutrition team regularly issues the low protein diet knowledge, and makes an appointment for the follow-up of patients to the specialized nursing clinic every 1-3 months to provide one-to-one guidance services. To explore the effect of continuous care based on We-Chat platform and Specialty Nursing Outpatient Clinics on the compliance of high-quality low-protein diet in patients with Chronic Kidney Disease (CKD) stage 3-5.

Methods: 46 cases of diagnosed CKD 3-5 patients were randomly divided into a control group (22 cases) and an observation group (24 cases). The control group conducted routine nursing and diet to treat hyperkalemia (42% pre to 74% post) Intent-to-act: 69% plan to talk to their providers about higher than ideal low-protein diet before the follow-up visit; 73% reported increased confidence talking to their doctor about ways to lower their potassium levels Activity 2: Are Medicines That Lower Potassium Right for You? Participants: 36, 551 Completers of all questions (included in outcomes analysis): 2,987 Demographics: 59% female; 78% white, non-Hispanic; 82% over the age of 54; 58% were interested in learning more about the condition and 29% have this condition Knowledge changes: 23% improvement in recognizing how potassium binders

Results: To date, 72,440 learners have participated in the patient/caregiver activity. Activity 1: Do You Have High Potassium? PO1384
A Kidney Education Program Integrated into Middle School Science Classes Increases Student Kidney Knowledge, Improves Health Behaviors, and Increases Kidney Health Literacy

Background: Chronic kidney disease (CKD) is a serious and growing public health problem. Literature shows primary disease prevention is successful when incorporated early in life. There are few reports about CKD prevention efforts in youth.

Methods: A 3-lesson kidney program was designed by health and wellness staff, school teachers and researchers, and aligned with U.S. school science standards. It was integrated into two middle school science classes, located in high-risk areas of renal failure. The 3-lesson program covered kidney physiology, epidemiology and environmental and genetic risk factors. Students were tested before and after the kidney program. We used linear regression to examine bivariate and multivariate associations between demographics and test responses comparing pre- and post-tests.

Results: Two-hundred and nine 6th and 7th grade students received the 3-lesson kidney program. One-hundred and eighty (57%) were male, 44 (23%) non-Hispanic Caucasian, 26 (12%) non-Hispanic African American, 26 (12%) other races, and 98 (53%) were Hispanic. Students reported increases in daily activity and reduced consumption of fruit juices. In analyses adjusted for school, race, gender, ethnicity and age, health literacy, kidney general knowledge (2.3 (1.1) to 3.9 (1.6) p<0.01), students also reported increases in daily activity and reduced consumption of fruit juices. In analyses adjusted for school, race, gender, ethnicity and age, health literacy, kidney general knowledge, kidney physiology, kidney importance and behaviors remained significantly improved.

Conclusions: A 3-lesson kidney program seamlessly delivered by teachers during science classes at two middle schools in high-risk areas for renal failure improved student health literacy, knowledge and behaviors. Next steps will be to examine impact in larger cohorts and clinical indices over time.

PO1385
Nephrology Exposure and Quality of Education in Residency and Medical School
Georges Nakhoul,1,2 Ali Mehdi,1,2 Jonathan J. Taliercio,1,2 Patricia F. Kao,3 Grace Menut,1,2 Jessica Greenfield,1,2 Abby L. Spencer,1,2 John F. O’Toole,1,2 Joseph V. Nally,1,2 John R. Sedori,1,2 S. Beth Bierer,1,2 Cleveland Clinic, Cleveland, OH. *Cleveland Clinic Foundation, Cleveland, OH, 1Washington University in Saint Louis, Saint Louis, MO.

Background: Interest in nephrology as a specialty has been declining among residents. Lack of exposure to nephrology has been identified as one of the factors possibly accounting for this loss of interest.

Methods: We used the results of our previously published qualitative analysis on residents’ perception of nephrology to inform and design a survey of 60 questions. The survey was delivered using the secure we application REDCap to 880 residents across eight medicine residency programs in different regions nationally.

Results: 184 residents (27%) responded to the survey. 56% (103) were male and 77% (142) were American graduates. During medical school, 82% of respondents were taught nephrology. Only 6.3% of residents identified a mentor in nephrology. Only 5.8% of residents selected nephrology. Only 6.3% of residents identified a mentor in nephrology as a unique discipline, while 33.5% rotated on a nephrology service. During residency, 75% of respondents rotated in nephrology and the rotation took place during PGY1 for 68% of the respondents. On a scale of 1 (poorest) to 100 (best), the quality of residency, 75% of respondents rotated in nephrology and the rotation took place during PGY1 for 68% of the respondents. Out of 134 residents (73%) who expressed interest in pursuing fellowship training, only 5.8% selected nephrology. Only 6.3% of residents identified a mentor in nephrology vs. 29.7% in general medicine and 26.6% in cardiology (Table 1).

Conclusions: We observed a “dip” in the quantity and quality of nephrology exposure during the clinical years of medical school. More work is needed to characterize the significance of this dip and to understand whether or not this may represent an opportunity to improve the visibility and impact of nephrology on trainees.

PO1386
Internal Medicine Residents’ Perceptions of Nephrology as a Career: A Focus Group Study
Natalie Beck, Seth B. Furgeson, Michel Chonchol, Jessica B. Kendrick. University of Colorado Denver School of Medicine, Aurora, CO.

Background: The interest in nephrology as a career has declined dramatically over the past several years. Only 62% of nephrology fellowship positions are filled for the upcoming 2020 appointment year. The purpose of this study was to identify perceptions, attitudes, motivators and barriers to a career in nephrology among internal medicine residents.

Methods: Focus groups of internal medicine residents (N=25) from the University of Colorado were performed. Questions were aimed at exploring perceptions, attitudes, and barriers to a career in nephrology and ways to increase interest in nephrology. All focus groups were conducted on the University of Colorado Denver Anschutz Medical Campus. Focus groups were recorded and transcribed. Thematic analysis was used to identify key concepts and themes.

Results: Residents’ described many barriers to a career in nephrology including lack of exposure, lack of advances in the field, low monetary compensation, too complex, lack of role models/mentors and low prestige/non-competitive. Most residents had no exposure to outpatient nephrology. Lack of new therapeutics was a significant deterrent to nephrology. Nephrology teaching in medical school was described as not clinically relevant and too complicated. Several residents felt they were not smart enough for nephrology. Only 3 residents had a role model within nephrology. Residents used the word “stigmatized” to describe nephrology and discussed how low prestige decreases their interest in a field. Participants expressed suggestions to increase interest in nephrology through earlier and more outpatient nephrology exposure, enhanced interactions with nephrologists and research and advancements in the field.

Conclusions: Residents’ identified several modifiable barriers to a career in nephrology. Changing how nephrology is taught in medical school, enhancing interactions with nephrologists through increased exposure and highlighting research and advancements in nephrology may change the perception of nephrology and increase the number of residents entering the field.

PO1387
Changes in the Demographics and Research Focus of Renal Physician-Scientists in the United States
Delaney C. Abood, Susan M. Wall. Emory University School of Medicine, Atlanta, GA.

Background: The enormous strides in biomedical research made over the past 50 years are in large part due to the contributions of physician-scientists. However, while the renal physician-scientist workforce has been thought to be falling, these changes have not been quantified. The purpose of this study was to compare changes in the demographics and the research focus of established physician and non-physician principal investigators.
(PIs) with active kidney-focused RO1s in 2005 and in 2020. We also compared changes in the demographics and research focus of more junior physician PIs by examining the K series grants over the same period that have focused on the kidney.

**Methods:** We mined NIH RePORTER for NIDDK-funded, kidney-focused RO1s and K series grants to determine the PI demographics, the terminal degree(s) of the PIs (physician versus non-physician) and to determine the relative number of clinical and basic science proposals. As an age-surrogate, we compared the year at which the respective RO1 PIs received either their M.D. (physicians) or their Ph.D. (non-physicians) degrees. Taking these values, along with published data as to the median age at which students received their M.D. or Ph.D. in the U.S. in both 2005 and 2020, we estimated the ages of the NIDDK RO1-funded physician and non-physician workforce doing kidney research in the U.S.

**Results:** Amongst grants focused on kidney, the apparent median age of non-physician, RO1-funded PIs is approximately 6 years older in now in 2020 than that in 2005. While the number of basic science grants was similar for physician PIs in 2005 and 2020, the number of clinically-focused RO1s increased. The number of NIDDK K series-funded physicians peaked in 2010 and then declined. However, the percent of physician-scientist RO1s held by women has risen from 15% in 2005 to 25% in 2020, while physician-scientist K series awards held by women has risen from 35% to 48% over that time period.

**Conclusions:** The representation of women in the physician-scientist workforce doing kidney research has increased. However, this physician-scientist workforce is older and relatively fewer are engaged in basic science research.

**Funding:** NIDDK Support

**POI388**

“I Hear and I Forget. I See and I Remember. I Do and I Understand.” Incorporating Emergency Room-Based, High-Fidelity Medical Simulation into the Undergraduate Nephrology Course

Ewa Pawlowicz, Michelle Kulesza, Aleksandra Szymanska, Anna Masajtis-Zagajewska, Maria K. Bartczak, Michal P. Nowicki. Medical University of Lodz, Uniwersytet Medyczny w Lodz, Lodz, Poland.

**Background:** Medical simulation develops clinical skills by implementing scenario in a real-life environment, but without exposing patient to any risk. There has been no information on use of high-fidelity simulation in undergraduate nephrology teaching. Scenarios are provided in Fig. 1. Aim of this study was to analyze students’ opinions and reactions to the simulation module in nephrology.

**Methods:** The survey consisting of the Satisfaction with Simulation Experience scale (SSES) and open-ended question concerning the overall impression of classes was conducted among 103 5-year medical students, who took part in the simulation training in nephrology. SSES consisted of three parts (debriefing, reasoning, education). Statements from the open-ended question were interpreted by means of the Atlas.ti software for qualitative data analysis.

**Results:** The overall score for simulation classes was 4.39±0.69 points. Students rated debriefing, reasoning and education at 4.43±0.78, 4.32±0.7 and 4.39±0.73 points, respectively. 87.4% and 84.5% of participants agreed that simulation developed their clinical reasoning and decision-making skills in nephrology, respectively. Thematic analysis revealed that students evaluated the module as ‘interesting’, ‘useful’ and ‘informative’, but they found number of classes significantly insufficient. Students pointed out that due to the small emphasis placed on practical aspects in the existing curriculum e.g. routes of drug administration and conversion of doses, they could not fully benefit from simulation.

**Conclusions:** Medical simulation is a valuable constituent of the nephrology course. Putting greater emphasis on practical aspects from the beginning of training may enable students to benefit more from simulation modules.

**POI390**

The Skeleton Key Group: Teaching Electrolyte Disorders Using Social Media Tools and Spaced Learning

Sayna Norouzi, Joel M. Topf, Amy Yau. 1Icahn School of Medicine at Mount Sinai, New York, NY; 2Oakland University William Beaumont School of Medicine, Rochester, MI; 3Baylor College of Medicine, Houston, TX.

**Background:** Social media is being adopted by healthcare professionals as a platform for education. It’s ability to close geographic gaps and flex to busy schedules is increasing the demand for online educational platforms. The Skeleton Key Group (SKG) is a free open access medical education (FOAMed) platform focusing on electrolyte physiology and management. Group members collaborate to publish a monthly case report with learning objectives on the Renal Fellow Network (RFN) website. Content is supplemented by a visual abstract, tweetorials and follow up quizzes to ensure effective long-term learning and reach multiple learning styles.

**Methods:** An anonymous survey was conducted and disseminated on Twitter to gather information from users to evaluate if SKG teaching methods added to their education. Questions were designed as multiple-choice answers or qualitative responses on a 0-100 scale.

**Results:** There were a total of 130 responses from 32 different countries. The majority were nephrology fellows (33%), followed by internal medicine residents/interns (29%), attending physicians (23%), other specialty trainees (10%) and medical students (5%). On a scale of 1-100 (100 is considered highest quality), the mean score was 91±15.5 for the quality of our case reports. Overall, 95% of surveyors found our educational materials useful with tweetorials ranked highest (Fig 1). As training level progresses, a
larger percentage of readers found the tweetorial more useful compared to the case report. Around 80% confirmed their educational experience was affected during the pandemic, and 90.4% found the SKG an effective educational experience during this time period.

Conclusions: Innovative teaching methods provided by the SKG was found to be beneficial in teaching complicated electrolyte concepts. Our data reinforces the ability of FOAMed to cater to different learning styles and to complement traditional medical education specifically during periods of social distancing such as COVID19 pandemic.

POI1391

Glomerular Disease Education Across Nephrology Fellowship Programs
Savina Norouzi,1 Harish Shanthanu Seethapathy,2 Ali Poyan-Mehr,2 Baylor College of Medicine, Houston, TX; Kaiser Permanente, San Francisco, CA; Massachusetts General Hospital, Boston, MA.

Background: Glomerular disease (GN) education is an important, albeit a challenging component of nephrology fellowship training. We hypothesized that trainee experience varies widely across programs, leading to differences in self-reported competency levels in the diagnosis and managing of GN.

Methods: The Glomerular Disease Study & Trial Consortium (GlomCon) conducted an anonymous online survey to evaluate the educational experience of nephrology trainees. We used multiple-choice questions to obtain data about a) curriculum-based education, b) dedicated specialty clinic, and c) exposure to pathology. We leveraged a visual analogue scale of 1-100 (higher number indicating a higher comfort level) to assess self-reported levels of clinical competency. The survey was disseminated via email, the GlomCon website, and Twitter.

Results: There were 107 responses across all years of fellowship training – first-year (25%), second-year (34%), third-year (22%), and fourth-year (19%). A total of 44% reported no GN clinic at their institutions. The presence of an onsite nephropathologist was reported by 63% of responders and 37% reported no onsite nephropathologist or limited exposure. In a visual analogue, the mean competency for GN diagnosis and treatment were 59±26 and 52±25, respectively. Trainees with no onsite nephropathologist and those with limited exposure scored significantly lower in diagnosing GN as compared to those with an onsite nephropathologist (51±25 vs. 64±26, p<0.05). Trainees with more exposure to GN specialty clinic had a higher comfort level in treating GN (Figs). Figure demonstrates frequency of trainees in each group with a comfort level above the overall median score (51).

Conclusions: Trainees report a wide variation in GN education across fellowship programs. A lack of exposure to onsite nephropathologist and a dedicated GN curriculum were associated with lower scores in self-reported clinical competency in caring for patients with glomerular disease.

POI1392

Frequency and Severity of Moral Distress in Nephrology Fellows: A National Survey
Fahad Saeed,1 Paul Duberstein,3 Ronald M. Epstein,1 Valerie J. Lang,1 Scott E. Liebman,1 University of Rochester Medical Center, Rochester, NY; 2Rutgers School of Public Health, Piscataway, NJ.

Background: Moral distress is a negative affective response to a situation that conflicts with an individual’s values. Health care practitioners who care for chronically ill patients frequently experience moral distress. Little is known about the frequency and severity of moral distress in nephrology fellows.

Methods: We used the modified Moral Distress Scale-Revision to assess the frequency and severity of moral distress in nephrology fellows. Using a 5-point (0-4) scale, fellows rated both the frequency (never to very frequently) and severity (not at all disturbing to very disturbing) of scenarios commonly encountered in training. Responses of a 3 were used to define “frequent” and “moderate-to-severe” moral distress. We identified scenarios most commonly associated with moderate-to-severe moral distress. The survey was sent to 148 program directors with a request to forward to their fellows.

Results: The survey was forwarded by 64 fellowship directors to 386 fellows, 142 of whom (40%) responded. Their mean age was 33 ± 3.6 years; 43% were female; and 55% were international medical graduates. The most common scenarios causing moderate to severe moral distress included: Other providers giving overly optimistic descriptions of the benefits of acute (54% seeing frequently, 64% rating the distress as moderate to severe) or chronic dialysis (43%; 64%), initiating dialysis in patients when they deemed it futile (50%; 77%), continuing dialysis in a hopelessly ill patient (45%; 81%) and carrying a high patient census (43%; 75%). Approximately 27% considered quitting fellowship training during, including, 9% at the time of survey completion.

Conclusions: Moral distress is frequently encountered by nephrology trainees and is often moderate to severe in intensity. To address this issue, organizational changes (e.g., robust workflow, ethics guidelines), curricular changes (emphasizing primary palliative care, communication, and ethical decision-making skills) as well as opportunities for reflection and self-care (e.g., Balint groups, Schwartz rounds) may be helpful.

Funding: NIDDK Support, Private Foundation Support

POI1393

The Sustainable Pediatric Nephrology Workforce Project (SUPER-POWER): A Pilot Study of Burnout and Resilience
Susan S. Halbach,1 Kartik Pillutla,2 Alan Schwartz,2 Patricia Seo-Mayer,2 Darcy K. Weidemann,3 John D. Mahan,2 Seattle Children’s Hospital, Seattle, WA; 2 Nationwide Children’s Hospital, Columbus, OH; 3 Dell Children’s Medical Center of Central Texas, Austin, TX; 4University of Illinois at Chicago, Chicago, IL; 5Nova Fairfax Hospital, Falls Church, VA; 6Children’s Mercy Hospitals and Clinics, Kansas City, MO.

Background: Physician well-being is an important contributor to both job satisfaction and patient outcomes. Rates of burnout among physicians vary by specialty, ranging from 35-70%. Among pediatric residents, longitudinal data demonstrates consistent rates of burnout around 50-60%, although little is known about burnout among pediatric nephrology fellows. The degree of burnout among pediatric nephrology fellows specifically remains unknown. We sought to evaluate prevalence and predictors of burnout among U.S. pediatric nephrology fellows and faculty, and their interactions.

Methods: A multi-center pilot survey of United States pediatric nephrology training programs was conducted from February – April 2020. Burnout was assessed through the Maslach Burnout Inventory and predictors included demographic, job-related and career satisfaction questions. Other validated assessments included: quality of life, perceived stress, resilience and sleep.

Results: A total of 30/34 available fellows and 86/102 faculty from 11 institutions (of 42 programs nationally) completed the survey. The prevalence of burnout was 13% among fellows and 16% among faculty. Demographic (age, gender, year of training, faculty rank, marital status) and program factors (fellowship size, faculty size, current block/rotation, vacation or weekend off timing) were not significantly associated with burnout. Faculty and fellows with burnout reported significantly lower quality of life (5.3 vs 7.9), higher perceived stress (2.4 vs. 1.4) and lower satisfaction with career choice (66% vs. 22%) and work life balance (28% vs. 0%), compared to those without burnout (p<0.05 for all). Other important factors associated with burnout included lower institutional support for wellness programs and lower satisfaction with both colleague and faculty support.

Conclusions: Larger studies are needed to explore if burnout is truly less prevalent among pediatric nephrology fellows and faculty than pediatric residents and graduate physicians. Future studies should explore how to promote well-being through addressing key factors such as overall learning/environment, stress reduction, and building resilience.

POI1394

Protein Kinase A Catalytic-α and Catalytic-β Proteins Have Non-Redundant Functions
Visvanathan Raghuram, Chin-Rang Yang, Euijuang Park, Mark A. Knepper, National Institutes of Health, Bethesda, MD.

Background: Vasopressin regulates osmotic water transport in the renal collecting duct by PKA-mediated control of the water channel aquaporin-2 (AQP2). Collecting duct principal cells express two seemingly redundant PKA catalytic subunits, PKA catalytic α
Single-Cell RNA Sequencing Reveals Transcriptomes of DCT1, DCT2, Macula Densa, and Two Subtypes of Cortical Thick Ascending Limb Cells

Chi, Chen, Chung-Lin Chou, Mark A. Keppner. National Heart Lung and Blood Institute, Bethesda, MD.

Background: Several distinct epithelial cell types have been proposed to form the transition region from the cortical thick ascending limb of Henle (CTAL) to the distal convoluted tube (DCT) to the connecting tube (CNT). However, a complete understanding of the cellular composition and transcriptional profiles of the cells in this region remains lacking.

Methods: We developed a FACS protocol to enrich cells from the mouse CTAL-DCT-CNT region and carried out single-cell RNA-seq analysis (scRNA-seq) of 9099 such cells. We also used small-sample RNA-Seq to determine transcriptomes of microdissected renal tubule segments.

Results: Unbiased clustering and UMAP visualization revealed a single cluster of cells showing Slc12a3 expression without Prlwh, which we identified as DCT2 cells. These cells express ENaC subunits but little or no Hollid12 or Agnp2 mRNA. These DCT2 cells also express Cdh1, Slc1a2, Slc26a1, Ptg1, and Ptg3. In contrast, there were 6 tightly arranged clusters of cells expressing both Slc12a3 and Prlwh, which we identify as DCT1 cells. DCT1 heterogeneity appears to be associated with variable expression of Slc9a1, Cdh1, and Ckb among other mRNAs. An additional cluster (Slc12a3 Prlwh-) showed marked enrichment of cell cycle and cell proliferation associated mRNAs (e.g., Pena, Mki67, Cdki, and Top2a), which fits with the known plasticity of DCT cells. In addition, scRNA-seq identified three distinct CTAL (Slc12a1+) cell subtypes. One of these expressed Nos1, Apet1a, and Papag2, consistent with macula densa cells. The other two CTAL clusters were distinguished by Cldn10 and Pappa2, one and Cldn10 and Palla, in the other. These two CTAL types were also distinguished by alternative expression of Iroquois homeobox transcription factors, with Irx1 and Irx2 in the Cldn10+ CTAL cells and Irx3 in the Cldn10- CTAL cells.

Conclusions: This work identifies unexpected diversity among cell types populating the CTAL and DCT. The new data have allowed the creation of a publicly accessible web resource for the support of future studies.

Dietary Potassium Restriction Induces Nephrogenic Diabetes Insipidus

Lama Al-Qusairi, Paul R. Grimm, Paul A. Welling, Ava Zapf. Johns Hopkins University, Baltimore, MD.

Background: Dietary potassium deficiency is well-recognized to induce diabetes insipidus (DI) but the underlying mechanisms have not been established.

Methods: C57BL6J mice were randomized to control or diets with graded reductions in dietary K+ for 8 days. Kidney function tests were performed in metabolic cages, and tissues were harvested for western blotting and immunocytochemistry at the end of the experiment.

Results: We found that C57BL6J mice rapidly develop DI when potassium is eliminated from the diet, coinciding with the development of hypokalemia. Loss of free-water reabsorption, polyuria and polypdipsia was observed within four days, despite increased plasma copeptin, a vasopressin surrogate. In contrast to control mice, desmopressin treatment failed to increase urine osmolality and urine volume after dehydrating, further indicating diabetes insipidus (DI). Data indicate that dietary potassium restriction induces nephrogenic DI (NDI). Characterization of responses to graded reductions in dietary K+ diet revealed NDI was dependent on the development of hypokalemia. Females were more prone to develop hypokalemia, even in response to maintained potassium levels in dietary potassium and displayed more severe DI than males. Females also exhibited a much greater increase in AQP2 and phosphorylated s26AQP2 in response to dietary potassium deprivation.

Conclusions: These data together indicate i) hypokalemia-induced DI is nephrogenic, ii) a tight relationship links hypokalemia to renal concentrating ability, iii) females are more prone to develop hypokalemia and as a consequence, more prone to NDI.

Funding: NIDDK Support P01397

Tfp2a Integrates Cellular Patterning and Barrier Formation in the Renal Collecting Duct

Janna Leitz,1,2 Christian Hinze,1,2 Kai M. Schmidt-Ott.1,2 Department of Nephrology and Intensive Care, Charite - Universitätsmedizin Berlin, Berlin, Germany; 1Max-Delbrück-Centrum für Molekulare Medizin in der Helmholtz-Gemeinschaft, Buch, Germany.

Background: The renal collecting duct plays important roles in fine-tuning urinary composition, electrolyte and water balance, blood pressure, as well as acid-base regulation. The patterning and molecular signatures of principal cells (PCs) and intercalated cells (ICs) of the collecting duct are tightly controlled by transcriptional processes and determine collecting duct physiological function and related clinical abnormalities. The transcription factor Tfp2a has previously been implicated in epithelial differentiation, in pronephros development in zebrafish, and in human congenital kidney defects. Using an integrated bioinformatics approach, we predicted that Tfp2a may critically control collecting duct functions. We tested our hypothesis using experimental model systems.

Results: We developed an in vitro model of collecting ducts. Additionally, mouse inner medullary collecting duct (IMCD3) cells were engineered to harbor CRISPR-Cas9-induced knockouts (KO) of Tfp2a. Deregulated genes were identified by mRNA sequencing. Patterns of principal and intercalated cells in mouse kidneys were analyzed by digital in situ hybridization. In vivo model was used in metabolic studies to analyze urinary concentration function.

Conclusions: More lacking Tfp2a in the collecting duct were viable and fertile but showed a defect of urinary concentrating ability. mRNA sequencing of Tfp2a-deficient kidneys revealed that Tfp2a and subsequent gene ontology analysis indicated an impact of Tfp2a on molecular processes including Notch signaling, focal adhesion formation and tight junction formation. Further experiments indicated abnormalities of PCs/CIC patterning in Tfp2a-deficient collecting ducts.

Funding: Our data suggest that Tfp2a controls transcriptional processes that integrate patterning and barrier formation in the collecting duct.

The Phosphorylated States of Human Aquaporin 2 Revealed by Liquid Chromatography Coupled to Tandem Mass Spectrometry: Phosphoproteomic Analysis of Urinary Exosomes

Kenichi Ishibashi,1,2 Sei Sasaki,1 Tadashi Yamamoto,1 Keiko Yamamoto,2 Yasuko Tanaka.1 1Meiji Pharmaceutical university, Kiyose, Japan; 2Dept Nephrology, Tokyo Medical and Dental University, Tokyo, Japan; 3Biofluid Biomarker Center, Niigata University, Niigata, Japan.

Background: Aquaporin-2 (AQP2) is a key water channel to enhance water permeability of collecting ducts. Multiple phosphorylation sites at the C-terminal of AQP2 have been identified including S256 (serine at the 256 residue), S261, S264 and S/T269. As AQP2 is abundantly excreted in urine, the in vivo model was used in metabolic studies to analyze urinary concentration ability.

Results: More lacking Tfp2a in the collecting duct were viable and fertile but showed a defect of urinary concentrating ability. mRNA sequencing of Tfp2a-deficient kidneys revealed that Tfp2a and subsequent gene ontology analysis indicated an impact of Tfp2a on molecular processes including Notch signaling, focal adhesion formation and tight junction formation. Further experiments indicated abnormalities of PCs/CIC patterning in Tfp2a-deficient collecting ducts.

Conclusions: Our data suggest that Tfp2a controls transcriptional processes that integrate patterning and barrier formation in the collecting duct.

PO1399
Bayesian Identification of Transcription Factors That Regulate Aqp2 Transcription
Hiroaki Kikuchi,1 Hyun Jun Jung,2 Euijuung Park,1 Lihe Chen,3 Viswanathan Raghuram,2 Mark A. Knepper.1 National Institutes of Health, Bethesda, MD; Johns Hopkins University, Baltimore, MD.

Background: Renal collecting duct and connecting tubule cells selectively express the water channel aquaporin-2 (AQP2) and Aqp2 gene transcription is strongly regulated by vasopressin. However, the transcription factors (TFs) responsible for regulation of expression of AQP2 remain largely unknown. Here, we used Bayesian data integration techniques to identify these TFs.

Methods: The general strategy is to use Bayes’ Rule to integrate several -omic datasets to stratify a curated list of 1344 TFs present in the mouse genome with regard to probability of regulating Aqp2 gene transcription. First, existing proteomic and transcriptomic data were used to select the TFs most strongly expressed in mpkCCD cells. Then, we used our existing ATAC-Seq, histone H3K27-acylation ChIP-Seq, and RNA-polymerase II ChIP-Seq data to identify enhancer regions in the CTCF loop surrounding the Aqp2 gene. The sequences within these enhancers were analyzed to identify recognized TF binding motifs within them; and these motifs were matched to TFs on the Bayesian list to identify the TFs most likely to bind Aqp2 regulatory regions.

Results: The analysis showed that the TFs most likely involved in regulation of AQP2 gene expression are associated with six enhancer regions in the CTCF loop surrounding the Aqp2 gene. Of the six enhancers, of particular interest is a 517 bp region identified 5.0 kb upstream from the Aqp2 transcription start site (TSS) that is predicted to bind Tcf1, Tcf3, and Tcf7 (p-value < 1 × 10^-16). By using a method that predicts function based on positional features, we predicted that the identified 517 bp region might be involved in the regulation of AQP2 expression. Then we asked how protein chaperones like heat shock protein H1 (Hsp1) as well as chaperonin GroEL (Hsp60) found that in addition to Hsp1, there are over 500 osmotically-induced genes that are regulated transcriptionally. The PRO-seq assay was used to identify where within enhancer regions high probability binding sites for TFs specifically identified to regulate Aqp2 gene transcription, viz. Nfia/Ref5/Neat3, Nktx1/Rela, and Grib1. In addition, enhancer regions identified by the ENCODE project, namely Cebpα, Ap-1 (Jun/Fos2), and E2F/E4, as well as sites for several TFs that are so far unannotated for with respect to Aqp2 regulation.

Conclusions: The Bayesian analysis has defined the enhancer regions within the CTCF loop surrounding the Aqp2 gene and identified the TFs most likely to bind to these regions, providing a roadmap for future studies to understand regulation of Aqp2 gene expression.

Kidney Osmoregulation Is Regulated by RNA Polymerase Pausing
Jason A. Watts,1,2 Nimmi Soerianto,3 Joshua T. Burdick,2 Vivian G. Cheung.2,4
1Department of Internal Medicine, University of Michigan, Ann Arbor, MI; 2Howard Hughes Medical Institute, Chevy Chase, MD; 3Life Sciences Institute, University of Michigan, Ann Arbor, MI.

Background: Osmoregulation is a complex but critical component of renal physiology that relies on the regulation of gene expression. While many genes and some transcription factors that are involved in osmoregulation have been identified, the initiating regulatory step that triggers the gene expression response to changes in osmolality remains unknown. To address this knowledge gap, we identified the pausing regions of the AQP2 gene and identified the TFs most likely to bind to these regions, providing a roadmap for future studies to understand regulation of Aqp2 gene expression.

Methods: We used the Precision nuclear Run-on and Sequencing assay to identify locations of nascent RNA bound to actively transcribing RNA polymerases in inner medulla collecting duct cells (IMCD).

Results: We began by studying Akr1b3, the gene that encodes aldose reductase which is the enzyme that reduces glucose to sorbitol and is essential for osmoregulation in the kidney. We exposed IMCD cells to increasing concentrations of sodium chloride and did not alter the VP-induced phosphorylation state of AQP2 at residues serine-256, threonine-254, and threonine-258 but did alter VP-induced phosphorylation at residues serine-238 and serine-240. In plasma membrane preparations of MKD cells subject to low and high FSS, AQP2-LW NK1 abundance was 5.4±0.3 and 10.6±1.7 fold greater, respectively, to that measured in the absence of flow (p<0.001). In static MKD cells, Bkct did not colocalize with L-WNK1 at the apical membrane; however, colocalization of the two proteins was detected in cells subject to low or high FSS.

Conclusions: In conclusion, (i) apical expression of L-WNK1 in ICs in microprepared CCDs is rapidly stimulated by increases in luminal flow rate, and (ii) FSS favors apical colocalization of L-WNK1 with Bkct, responses that may facilitate BK channel-mediated FIKS in the CCD.

STCH Regulates NKCC2 Biogenesis by Both the Endoplasmic Reticulum-Associated Degradation and the Endoplasmic Reticulum-to-Lysosome-Associated Degradation Pathways
Dhal Bakhos Al Donaity,1 Elie Seayaflan,2 Sylvie Demaretz,1,2 Mehdi Hamdani,1,2 Martin Kömhoff,2 Kamel Laghamani,1,2 Team 3 Sorbonne Université, Paris, France; 1Centre de Recherche des Cordeliers, Paris, France; 2Philips Univ Marburgunersity, Marburg, Germany.

Background: Mutations in the apically located Na-K-2Cl co-transporter NKCC2 lead to type I Bartter syndrome, a life-threatening kidney disease. We previously showed that export from the ER constitutes the limiting step in the maturation and cell surface expression of NKCC2. Yet very little is known about the molecular components of NKCC2 ER quality control. Using the yeast two hybrid system and co-immunoprecipitation assays, we identified chaperone stress 70 protein (STCH), as a binding partner of the immature form of NKCC2. STCH is supposed to function as an ER chaperone but the precise molecular role of STCH remains obscure.

Methods: Protein expression was monitored in transiently transfected HEK cells, using immunoblot and confocal imaging. Protein maturation and stability were assessed by Endo-H digestion and cycloheximide chase (CHX) assay.

Results: Co-immunolocalization experiments revealed that NKCC2 interacts with STCH mainly at the ER. However, CHX assay together with Endo-H digestion revealed that STCH is initially synthesized in the ER as a core-glycosylated protein before being gradually converted to a hybrid N-glycosylated form. These data are in an agreement with a previous study showing that STCH contains a mannose-6-phosphorylation site, suggesting therefore that STCH expression is not restricted to the ER. STCH knock-down increased NKCC2 protein abundance in a dose-depend manner, whereas STCH over-expression had the opposite effect. CHX assay showed that in cells over-expressing STCH, NKCC2 stability and maturation are heavily impaired. STCH induced reduction in NKCC2 expression were offset partially by the proteasome inhibitor MG132. Interestingly, leupeptin and chloroquine, two potent inhibitors of the lysosome, mimicked MG132 effect on NKCC2 regulation. Accordingly, the simultaneous presence of proteasome and lysosome inhibitors, completely abolished STCH-induced down-regulation of NKCC2.

Conclusions: Our data demonstrate the presence of an STCH mediated ER quality control of NKCC2 in renal cells. They suggest a model whereby, in addition to the proteasome-dependent ERAD, the ER quality control of NKCC2 mediated by STCH, involves also the ER-to-lysosome-associated degradation pathway, revealing therefore a new regulatory mechanism governing the co-transporter biogenesis.

P2Y, Receptor Directly Mediates Collecting Duct Remodeling Induced by Acid Loading in Mice
Marshall R. Reeder,1,2 Kalani L. Raphael,1,2 Audrey Iruzahara,3 Bellamkonda K. Kishore,1,2 Janos Peti-Peterdi,3 1University of Utah Health, Salt Lake City, UT; 2VA Salt Lake City Health Care System, Salt Lake City, UT; 3University of Southern California, Los Angeles, CA.

Background: Previously we reported that genetic deletion of P2Y2-R suppresses lithium(Li)-induced collecting duct (CD) remodeling. Since genetic depletion of P2Y2-R has a generalized ameliorating effect on Li-induced diabetes insipidus, here we evaluated the direct effect of P2Y2-R in CD remodeling using a model of acid loading.

Methods: Groups of WT or P2Y2-R knockout (KO) mice (B6D2; N = 3 or 4/group) were fed standard rodent chow and given tap water with/without addition of 0.28 M NaHCl for 9 days and humanely euthanized. AQP2 and [H]-ATPase double immunolabeling was used to identify the principal (PC) and intercalated (IC) cells of the medullary CD, respectively.

Results: As reported previously, KO mice developed more severe metabolic acidosis than WT after NH4Cl loading (not shown here). Furthermore, as shown in the pie charts, statistical analysis of the numbers of cells found a marked increase in the number of medullary ICs in NH4Cl-treated vs. untreated control (CT) mice in WT (28 ± 2 vs. 6 ± 1), but only a blunted response in P2Y2 KO mice (10 ± 1 vs. 4 ± 1, P = 0.001 WT vs. KO). These increases in ICs was associated with significant decreases in the proportion of PC cells in NH4Cl-treated vs. untreated CT mice in WT (72 ± 2 vs. 94 ± 1), and again a blunted response in P2Y2 KO mice (90 ± 1 vs. 96 ± 1, P = 0.001 WT vs. KO).

Conclusions: The data clearly show that P2Y2 receptor has a "direct effect" on CD remodeling in the kidney following acid-loading.

Resolving the Kidney’s Reaction to Acute Dehydration on the Single-Cell Level
Christian Hinze,1,2 Felix Boivin,1 Janna Leiz,2,3 Nikos Kariakos,3 Anastasiya Boltengagen,1 Christine Kocks,2 Nikolaus Rajewsky,2 Kai M. Schmidt-Ott.1 Charité-Universitätsmedizin, Berlin, Germany; 2Max Delbrück Center for Molecular Medicine, Berlin, Germany; 3Berlin Institute for Medical Systems Biology MDC, Berlin, Germany.

Background: Dehydration is a common clinical finding and frequent among the elderly or patients with chronic diarrhea. Acute kidney injury frequently develops as a result of a fluid deficit. There is growing evidence that recurrent dehydration can cause chronic kidney disease. The kidney’s response to fluid deprivation is incompletely understood. Having a gene expression atlas of the kidney’s reaction to fluid deprivation at single cell resolution could help to understand biological mechanisms but also to identify biomarkers and therapeutic targets.

Methods: We performed single-cell RNA sequencing of dissociated mouse kidneys after 24 hours of water restriction (n=2) and control kidney (n=2). We assigned cell type information based on known marker genes, and systematically analyzed gene expression differences between baseline and water-restricted animals within different cell types. We furthermore applied a computational approach to spatially sort cells based on gene expression similarities to investigate corticomedullary gene expression profiles.

Results: Our data show cell type-specific differential gene expression in all kidney tubule cells with the most prominent response in collecting duct principal cells (CD-PC). Pathways dysregulated in CD-PC included sodium and water reabsorption, immune system modulation and endoplasmic reticulum (ER) stress. Pathway activation displayed regional cortico-medullary differences.

Conclusions: Fluid deprivation induces regional and cell type-specific responses in kidney cells. Genes and pathways identified by single cell transcriptomics comprise biomarkers and therapeutic targets for dehydration-associated pathologies.

Angiotensin II Receptor Blockade Alleviates Calcineurin Inhibitor Nephrotoxicity by Restoring p38 MAPK/NF-kB/COX-2 Signaling in Kidney Cortex
Junda Hu,1 Yan Xu,1 Sebastian Bachmann,2 Kerim Mutig,1,2 Charité-Universitätsmedizin Berlin, Berlin, Germany; 1Sechenov First Moscow State Medical University, Moscow, Russia, Federation.

Background: Immunosuppression based on calcineurin inhibitors (CNI) such as cyclosporine A (CsA) is the current standard for patients undergoing organ transplantation. Nephrotoxic side effects of CNI include reduction of renal cortical cyclooxygenase 2 (COX-2) expression along with pathophysiological alterations of glomerular filtration rate and sodium balance. The underlying molecular mechanisms are poorly understood. Since CNI stimulate the renin-angiotensin system (RAS), we hypothesized that the suppression of COX-2 is related to enhanced RAS activity.

Methods: To test this hypothesis, short- (3 days) and long-term effects (3 weeks) of CsA(25mg/kg’d), candesartan (5mg/kg’d), celecoxib (50 mg/kg’d) or their combinations

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
were evaluated in Wistar rats to monitor COX-2 and RAS, as well as kidney morphology, with a histopathological examination. Cultured macula densa (MD) cells were treated with Ca2+-<ins>angiotensin II</ins> (Ang II), p38 MAPK inhibitor or NF-kB inhibitor in various combinations to reveal molecular pathways mediating effects of RAS on COX-2.

Results: Inhibition of calcineurin in cultured MD cells using CsA or siRNA increased COX-2 expression and protein expression by 3.8 MAPK and NF-kB. Coconcentrating the action of Ang II abolished these effects suggesting a dominant role for RAS. In rats, 3 days and 3 weeks CsA treatments led to increased renin biosynthesis, decreased cortical COX-2 expression, reduced creatinine clearance, and sodium retention due to activation of mineralocorticoid receptor (MR), NCC2, and NCC. The transcriptional repression of Cldn19 variant B is completely normalized by simultaneous administration of a RAS inhibitor candesartan for 3 days or 3 weeks, respectively. In contrast, administration of a selective COX-2 inhibitor, celecoxib, largely recapitated effects of CsA and significantly reduced the beneficial effects of the renin-angiotensin drug administration. Therefore, COX-2 suppression is a major factor contributing to CNI nephrotoxicity.

Conclusions: In summary, the present study established calcineurin as an endogenous COX-2 inhibitor, acting via suppression of p38 MAPK and NF-kB activity in MD cells. CNI-induced RAS activation critically reduces cortical COX-2 activity, thus overriding local stimulatory effects of calcineurin inhibition. Our data support the use of RAS inhibitors for alleviation of CNI nephrotoxicity.

A Novel Mouse Model for Familial Hyperparathyroidism with Hypercalcuria and Nephrocalcinosis (FHHCN) Bearing the Most Frequent Human CLDN16 Mutation

Caroline Prot-Bertovyre,1 Camille Griveux,1 Lydie Cheval,1 Honoré A. Langlais,1 Gaëlle Bideau,1 Pascal Houillier.1 Centre de Recherche des Cordeliers, INSERM-Université Paris5, Université Paris Diderot, Curie, ERL8228, Paris, France; 2Service de Physiologie, Hôpital Édouard-Hippolyte Georges Pompidou, Assistance Publique-Hôpitaux de Paris, Paris, France.

Background: Mutations of claudin (CLDN) 16 and CLDN19 cause FHHCN, characterized by a urinary loss of calcium (Ca) and magnesium (Mg), hypomagnesemia, nephrocalcinosis, and renal failure. Cldn16 and Cldn 19 are co-expressed at the tight junction (TJ) of the thin ascending limb (TAL) of Henle’s loop and play a key role in paracellular reabsorption of Ca and Mg. Here, 25% of filtered Ca and 70% of filtered Mg are reabsorbed. Cldn16 knock-out mouse failed to faithfully recapitate the human disease, as it was complicated by neither nephrocalcinosis nor renal failure. Cldn 16 knock-down mice have a renal loss of Na and hypercalcemia. We hypothesized that a more frequent CLDN16 mutation (p.L151F) would be helpful to delineate the abnormalities caused by mutated Cltn16.

Methods: Clndn16<sup>L151F/L151F</sup> mice were generated by CRISPR Cas9-based mutagenesis. Cldn16<sup>L151</sup> and Cldn16<sup>L151F/L151F</sup> female mice were housed in metabolic cages at 3 months of age. Daily fluid and water intake, body parameters (Na, Cl, Ca, Mg, Pi, creatinine), were recorded. Blood and urine were collected. Claudin 16 and Cltn19 expression were analyzed by qRT-PCR.

Results: At 3 months weight, food and water intake, blood parameters (Na, Cl, Ca, Mg, Pi, creatinine) did not differ between Cldn16<sup>L151</sup> and Cldn16<sup>L151F/L151F</sup> mice. Cldn16<sup>L151</sup> mice had significantly higher urinary excretions of Ca, Mg and Pi and a lower urinary pH; urine volume, osmolality, Na, K and aldosterone were unaltered. At 6 months calcitriol was significantly increased in Cltn 16<sup>L151F</sup> mice. No nephrocalcinosis was seen at 12 months. Cldn 16 was almost never seen at TJ and Cldn 19 seems to be less expressed on Cldn19 expression.

Conclusions: In summary, the present study established calcineurin as an endogenous COX-2 inhibitor, acting via suppression of p38 MAPK and NF-kB activity in MD cells. CNI-induced RAS activation critically reduces cortical COX-2 activity, thus overriding local stimulatory effects of calcineurin inhibition. Our data support the use of RAS inhibitors for alleviation of CNI nephrotoxicity.

Sex Differences in Expression of Renal Urate Transporters

Victoria J. Halperin Kuhns,1 Owen M. Woodward.1 University of Maryland School of Medicine, Baltimore, MD, MD.

Background: Elevated urate (UA) levels in the serum (hyperuricemia, HUA) contribute to the development of diseases, including kidney stones, chronic kidney disease, cardiovascular disease, metabolic syndrome, and gout. Men are 5x more likely to have HUA than women, yet this risk increases in women 4x after menopause. This suggests premenopausal women are protected against developing HUA, but the mechanisms have yet to be elucidated. These differences are echoed in our HUA mouse model, where injection of orthotopic or pathological UA transplanted into male of the most frequent (p.L151F) would be helpful to delineate the abnormalities caused by mutated Cltn16.

Methods: SiRNA-Seq was performed on male and female wild type (WT) and Q140K mice, followed by Deseq2 analysis to determine differentially expressed genes between both sexes of each genotype.

Results: Targets of interest included 12 transporter and 3 transcription factor (TF) genes associated with serum UA levels in humans in recent genome wide association studies. We found small (0.49–2.1-fold) but statistically significant changes in many of these genes. Specifically, female mice had lower expression of UA transporters SLC22A12, SLC22A14, and ABCA1. These genes have variants that associated with lower UA levels in human populations, consistent with female mice potentially more efficiently excreting surplus UA. Females also had significantly increased urinary excretion of calcitriol and ABCG2 transcripts, consistent with a possible mechanism of differentiation. The Q140K mice Deseq2 analysis reveals 273 alterations in male Q140K kidney gene expression as compared to WT, including 5 potentially compensatory SLC transporters. None of these changes were observed in female mice. These changes are the result of the elevation in SUA and not due to mutant ABCG2 protein.

Conclusions: Female sex may confer protection from developing HUA and related conditions. Further understanding this mechanism should lead to improved understanding of UA homeostasis and new insights into HUA treatment.

SPAK Signaling Stimulates the Activity and Protein Expression of Large Conductance Ca<sup>2</sup> -Activated Potassium (BK) Channels

Ye Bi,1 Chunmei Li,1 Xiaonan H. Wang,1 Eric J. Delpier,1 Robert S. Hoover,2,3,4,5,6,7 Douglas C. Eaton,1 Hui Cai,1,2 Emory University School of Medicine, Atlanta, GA; 3Atlanta VA Medical Center, Decatur, GA; 4Qingdao University Affiliated Hospital, Qingdao, China; 5Vanderbilt University Medical Center, Nashville, TN.

Background: Sex differences in the renal UA handling between the sexes. We hypothesized that these differences in UA excretion may contribute to the development of diseases, including kidney stones, chronic kidney disease, cardiovascular disease, metabolic syndrome, and gout. Men are 5x more likely to have HUA than women, yet this risk increases in women 4x after menopause. This suggests premenopausal women are protected against developing HUA, but the mechanisms have yet to be elucidated. These differences are echoed in our HUA mouse model, where injection of orthotopic or pathological UA transplanted into male of the most frequent (p.L151F) would be helpful to delineate the abnormalities caused by mutated Cltn16.

Methods: Electrophysiology, cell culture, western blot, siRNA knockdown, and protein expression in kidney.

Results: We first determined the effects of SPAK gene deletion using SPAK KO mice on BK channel activity in the isolated, split-opened renal collecting ducts (CD) from WT and SPAK KO mice. We found that there is no BK channel activity in principal cells (PCs) of cortical CD (CCD) in SPAK KO mice, whereas there is BK channel activity in PCs from WT mice. We further investigated the effects of overexpression and siRNA knockdown of SPAK expression on BK in HEK293 cells. Overexpression of SPAK markedly increased BK protein expression with concomitant increase in BK channel activity. Moreover, overexpression of SPAK activated BK channel activity in HEK293 cells. We found that SPAK knockdown decreased BK channel activity and protein expression in the CD165 BK channel and its protein expression via the ERK1/2 signaling pathway. It remains largely unknown whether SPAK kinase directly modulates the BK activity and protein expression in kidney.

High Dietary K+ Attenuates Salt-Nduced NCC and mTORC1 Activity in Dahl Salt-Sensitive Rats

Mohammed Z. Ferdaus, Jesse D. Moreira, Kiyomu Kim, Franco J. Puleo, Richard D. Wainford.1 Pharmacology & Experimental Therapeutics, Boston University School of Medicine, Boston, MA, MA.

Background: Na+ reabsorption by renal Na<sup>-</sup>Ca<sup>2+</sup> cotransporter (NCC) plays a key role in blood pressure (BP) regulation. Dahl Salt-Sensitive (DSS) rats exhibit aberrant NCC activity and salt-sensitive hypertension (HTN) when fed a high-salt diet. The renal medullary target of ramiprilat complex 1 (mTORC1) is also implicated in the pathogenesis of DSS HTN. Studies in normotensive mice suggested an inverse relationship between blood [K+] and NCC activity; however, the effect of dietary K+ on NCC activity in DSS rats is still controversial. Moreover, the impact of dietary K+ on mTORC1 activity is unknown.

Hypothesis: Dietary K+ supplement downregulates salt-induced NCC and mTORC1 activity in DSS rats.

Methods: 3 month old male DSS rats were randomly placed on high salt (4% NaCl, HS) or low salt diet (LS) for 14 days. HS→HS+HK (4% NaCl) diet for 28 days. Another group of DSS rats, maintained on HS diet for 14 days, were placed on HS+HK for another 14 days (HS→HS+HK, n=4). NCC activity was assessed by Hydrochlorothiazide (HCTZ, NCC antagonist) injection (20 mg/kg, intraperitoneal) induced natriuretic response. Protein abundance was determined by western blotting. The ratio of phosphorylated ribosomal protein S6-(Ser240/244) to total S6, was used as mTORC1 activity marker.

Conclusions: In response to HCTZ, urina excretion was trending lower in HS+HK than HS alone, the baseline excretion was unaltered. Total NCC (nCC) and phosphorylated NCC (pNCC) abundance, a surrogate for NCC activity, were significantly lower in HS+HK than HS alone.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underlines represents presenting author.

Poster
were trending lower in HS→HS+HK compared with HS group. Interestingly, mTORC1 activity was significantly reduced in HS→HS-HK.

**Conclusions:** Trending lower response in HS+HK and HS→HS+HK to HCTZ suggests that dietary K+ may counteract and reduce salt-induced NCC activation. Downregulation of mTORC1 reveals that dietary K+ can reverse salt-induced mTORC1 activation. Critical new data suggest that compared with the initial phase, K+ is more effective in reducing salt-induced NCC and mTORC1 activity when added later to the diet, which may attenuate established HTN in DSS rats.

**Four Weeks of Dietary Potassium Restriction Causes Distal Convoluted Tubule Remodeling**

**Xiao-Tong Su,** Turgay Saritas, Chao-Ling Yang, Paul A. Welling, David H. Ellison, Oregon Health & Science University, Portland, OR; University Hospital RWTH Aachen, Aachen, Germany; Johns Hopkins University School of Medicine, Baltimore, MD.

**Background:** Previous studies have described a ‘renal salt switch’ within the distal nephron that turns on the thiazide-sensitive Na–Cl cotransporter (NCC) in the distal convoluted tubule (DCT) in response to low potassium intake and off the response to high potassium intake. Studies using genetically modified mice indicate that decreased NCC activity is associated with decreased DCT length and mass; increased NCC activity is associated with increased, DCT length and mass. The aim of our study was to test whether dietary potassium intake may cause the DCT remodeling physically.

**Methods:** Male C57Bl/6 mice were provided either control potassium diet or low potassium diet for four weeks and blood and kidneys were harvested. To determine the length of the DCT in three dimensions, we used Ethyl-cinnamate-based optical clearing, combined with whole-mount immunolabeling, confocal microscopy and three-dimensional morphometric analysis.

**Results:** Mice on low potassium diet for four weeks were severely hypokalemic (plasma potassium <2 mEq/L) compared with mice on control diet (4.2 mEq/L). Western-blot analysis of the whole kidney identified that total and phosphorylated NCC were higher in mice on low potassium diet, compared to mice on control diet. By immunolabeling with pThr55-NCC antibody, we visualized the DCTs in optically cleared kidney slices. Three-dimensional morphometric analysis suggested that four-weeks of low potassium diet (46 ± 19 mm, n=6) significantly decreased DCT length by 13% compared to NK diet (49 ± 29 mm, n=5).

**Conclusions:** Our results indicate that the DCT remodels physiologically to maintain potassium homeostasis. Additional animals are currently being studied.

### POI1412

**Pendrin Null Mice Develop Hypokalemia During Dietary Na+ Restriction Through an Epithelial Sodium Channel-Dependent Mechanism**

Truyen D. Pham, Jill W. Verlander, Chao Chen, Spencer A. King, Anthony J. Eblengick, Paul A. Welling, Susan M. Wall, Emory University, Atlanta, GA; Johns Hopkins University, Baltimore, MD; University of Florida, Gainesville, FL.

**Background:** Pendrin is an electroneutral Cl/HCO3− exchanger expressed in the apical regions of intercalated cells. It is thought to modulate NaCl absorption, while mitigating urinary K− loss. However, the effect of pendrin gene ablation on K+ homeostasis has not been examined directly. The purpose of this study was to determine if pendrin gene ablation reduces serum K+ concentration, the conditions under which this occurs and the mechanism(s) responsible.

**Methods:** Pendrin null and wild type mice were given a diet deficient in Na+, K− and Cl− or diet supplemented with Na+, K− and/or water. We measured urine and serum electrolytes as well as K− channel and Cl− transporter abundance by immunoblot and immunohistochemistry.

**Results:** Serum K− was −1 mEq lower in pendrin null than in wild type mice after 7 days of the Na−, K−, Cl− deficient diet. This difference was attenuated, but not eliminated, with moderate dietary K− supplementation. Differences were eliminated with either dietary K− supplementation or with ENaC blockade, while differences were enhanced when ENaC was constitutively upregulated. Further studies determined whether the lower serum K− observed in the pendrin null mice occurs from greater urinary K− excretion. Over the first 3 days of the Na−, K−, Cl− deficient diet, pendrin null mice develop a lower serum K− and a higher arterial pH and HCO3− concentration, likely from greater intravascular volume contraction from their enhanced urinary Na+ excretion, although urinary Na− excretion was similar in both groups over this time period. However, starting at day 4 of the diet, the pendrin null mice excrete more K+ than the wild type mice. At day 8 of the ion-deficient diet, pendrin null mice have marked hypokalemia, likely due to both the metabolic alkalosis as well as greater urinary K+ excretion, in part, from inappetance and high Maxi-K+ channel abundance.

**Conclusions:** Pendrin null mice develop marked hypokalemia during dietary Na+ restriction in part due to a contraction alkalosis as well as increased urinary K− excretion that occurs in part from relatively high Maxi K+ channel abundance.

**Architecture of the Distal Neprhon Mineralocorticoid Receptor-Dependent Transcriptome Defined**

Hyun Jun Jang, Xiaoyong Su, Lamia Al-Qassar, David H. Ellison, Johns Hopkins University School of Medicine, Baltimore, MD; Oregon Health and Science University, Portland, OR.

**Background:** The mineralocorticoid receptor (MR, Nrsr2) is responsible for aldosterone-regulation of Na+ and K+ balance and blood pressure. Although a handful of aldosterone/MR-dependent genes have been identified, their regulation cannot fully explain how aldosterone activates electrogenic Na+−K+ exchange in the aldosterone sensitive distal nephron (ASDN). Here, we apply RNA-Seq and bioinformatic approaches in isolated tubule segments of MR KO vs. Control mice to define a more complete inventory of MR-dependent genes.

**Methods:** MRKO/Pax rats vs. control rats, were used as a doxycycline (DOX)-inducible Nr3r2 gene KO model. After DOX treatment, four groups were prepared to distinguish between MR effects on mice on normal K+ diet (CT-NK) or 21 high K+ diet (KO-LK) RNA-seq analysis was carried out in the micro-dissected connecting tubule and cortical collecting duct tube segments (5-6 mice per group and ~10 fresh ASDN tubules per mouse). Differential expression (DE) genes were identified (FDR < 0.05) and used for further bioinformatic analyses.

**Results:** 927 and 2010 DE genes were identified from comparisons of MR-KO NK vs. CT-NK and MR-KO-LK vs. CT-HK, respectively. Diet effects were not detected. Absence of transcripts on the third exon of Nr3r2 gene confirmed complete disruption of Nr3r2 gene in the MR KO. All known aldosterone-response genes, including Spk1, Scnn1a, Nrg2, Per2, Tsc2d3, Zbtb16, Milp and App1al were significantly decreased in MR KO-LK compared to CT-HK. In addition, 5 DE genes (Spk1, Scnn1a, Nrg2, Fxydh and Hmx1) were more highly expressed in the NKO group compared with the control group (458 ± 14 m). Analysis of the whole kidney confirmed that total and phosphorylated NCC were higher in MR KO-LK vs. CT-HK (KO-NK) or 4 low K+ diet (KO-LK). RNA-seq analysis was carried out in the micro-dissected connecting tubule and cortical collecting duct tube segments (5-6 mice per group and ~10 fresh ASDN tubules per mouse). Differential expression (DE) genes were identified (FDR < 0.05) and used for further bioinformatic analyses.

**Conclusions:** The inventory of MR-regulated genes in the ASDN is much larger than previously imagined. In addition to pathways that directly up-regulate epithelial sodium channel (ENaC) and the Na+−K+ ATPase, the data suggest that aldosterone-MR may directly influence metabolism to make energy-consuming transport highly efficient.

**Effect of Patriomer and Sodium Zirconium Cyclosilicate on Blood Pressure in a Rat CKD Model Induced by 5/6th Nephrectomy**

Lingyun Li, Ansgar Conrad, Alain Romero, David A. Bushinsky, Relypsy, Inc., a Vifor Pharma Group Company, Redwood City, CA; University of Rochester School of Medicine, Rochester, NY.

**Background:** Patriomer (PAT) is a sodium-free, non-absorbed polymer drug approved for treatment of hyperkalemia (HK) in adults. In clinical studies of patients with CKD and HK, decreases in BP were observed during PAT treatment. The objective of this study was to evaluate effect of PAT and another K+ binder, sodium zirconium cyclosilicate (SZC), on BP in a CKD rat model.

**Methods:** Sprague Dawley (SD) rats underwent 5/6th nephrectomy (Nx) and each had a telemetry device implanted. Animals were randomized into 3 groups of 12, PAT (4 g/kg), SZC (4 g/kg), or vehicle (6 g/kg), for 24 hrs once weekly for 8 wks. Blood pressure data was collected for 24 hrs once weekly for 8 wks. Blood and urine samples were collected weekly. All values are mean ± SD.

**Results:** Systolic BP from BL to WK 8 increased in vehicle-treated rats (136 ± 4.0 mmHg to 154 ± 4.8 mmHg), PAT-treated rats (132 ± 3.7 mmHg to 140 ± 3.6 mmHg) and SZC-treated rats (135 ± 4.1 mmHg to 158 ± 5.3 mmHg). PAT-treated rats had significantly lower systolic BP at WK 8 compared to rats in vehicle and SZC-treated groups (P < 0.001 (Figure)). Mean BP change from BL in PAT-treated rats (8 ± 3.2 mmHg) was significantly lower vs. vehicle group (16 ± 2.9 mmHg, P = 0.001) and vs. SZC-treated group (24 ± 4.2 mmHg, P = 0.001). While mean BP change from BL in SZC-treated rats was significantly higher vs. vehicle group (P < 0.005). Serum K+ levels were in range of normokalemia (4.0-6.2 mEq/L in normal SD rats) from BL to WK 8 in all groups (5.6 ± 0.26 mEq/L to 5.5 ± 0.22 mEq/L in vehicle-treated rats, 5.6 ± 0.43 mEq/L to 5.3 ± 0.25 mEq/L in PAT-treated rats, and 5.3 ± 0.43 mEq/L to 4.9 ± 0.35 mEq/L in SZC-treated rats). There was no difference in serum creatinine levels among the 3 groups during the study.

**Conclusions:** With 8 wks of PAT treatment, SD rats with 5/6th Nx exhibited significantly lower BP compared to vehicle-treated and SZC-treated rats. Additional analyses are warranted to determine GALNAc 3′-SMT’s effect on BP in this model of CKD.
PF-06869206 Is a Selective Inhibitor of Phosphate Transport: Evidence from In Vitro and In Vivo Studies
Linton Thomas, Jianxiang Xue, Jessica Dominguez Rieg, Timo Rieg. USF Health Morsani College of Medicine, Tampa, FL.

**Background:** The kidneys are key players in maintaining the body's phosphate (P) homeostasis, and patients with chronic kidney disease (CKD) develop hyperphosphatemia. Two renal transporters mediate the majority of P reabsorption, the Na+-phosphate cotransporters Npt2a and Npt2c, with Npt2a accounting for ~80% of P reabsorption. The aim of the current study was to determine the in vitro effects of a Npt2a-I (PF-06869206) in opossum kidney (OK) cells as well as its in vivo effects in Npt2a knockout (Npt2a-/-) mice.

**Methods:** To study the in vitro effects of Npt2a-I (0.1-100 μM/L) on P uptake, 14C phosphate was used as a tracer.

**Results:** In vitro, Npt2a-I dose-response (3-300 μM/L, 1% by oral gavage) effects on urinary P excretion were observed in metabolic cages for 3 hours in wild-type (WT) and Npt2a-/- mice. Effects on Plasma P, were studied before (baseline) and 2 hours after application of Npt2a-I (30 μM/L, 1% by oral gavage).

**Conclusions:** Our studies show that PF-06869206 is a competitive inhibitor of P transport in OK cells and the effect on urinary P excretion can be observed at plasma levels of Npt2a-I. Hexokinase IV is clearly the best kinase to identify if Npt2a is a useful treatment for hyperphosphatemia.

**Critical Role of Threonine Residue in PDZ-1 Binding Motif of Type 2a Sodium-Phosphate Cotransporter (Npt2a)**
Kenneth Gagnon,1 Michelle T. Barati,1 Kathleen Kitterman,1 Adrienne M. Bushau-Sprinkle,1 Barbara Clark,1 Eleanor D. Lederer.2
1University of Louisville Health Sciences Center, Louisville, KY; 2University of Texas Southwestern Department of Internal Medicine, Dallas, TX.

**Background:** Npt2a brush border membrane (BBM) expression is the major determinant of proximal tubule phosphate reabsorption. Binding of the Npt2a carboxy terminus Class I PDZ binding motif (ST-x-x-x-COOH) to NHERF1 (sodium-hydrogen exchange regulatory factor 1), a PDZ protein, is critical for Npt2a BBM expression. We have shown that NHERF1 deficiency results in reduced binding of Npt2a to 14-3-3 epsilon in an IRES-containing bicistronic mammalian expression vector. We transiently transfected these cDNA constructs in NHERF1-deficient opossum kidney cells, assessed membrane expression by confocal microscopy, and Npt2a function by (32P) phosphate uptake.

**Results:** Npt2a (T635), Npt2a (E635), or Npt2a (A635) alone showed dense cytosolic expression and negligible 32P phosphate uptake. Npt2a (T635) with NHERF1 colocalized at the plasma membrane and increased 32P uptake seven-fold. Npt2a (E635) and Npt2a (A635) appeared at the plasma membrane, but neither co-localized with NHERF1 nor showed 32P uptake. Each Npt2a plus 14-3-3 construct DNA construct exhibited apparent membrane localization, but none co-localized with 14-3-3 epsilon or exhibited significant 32P uptake.

**Conclusion:** We concluded that the Thr of the Class I PDZ binding motif of Npt2a is essential for interaction with NHERF1 and functional activity of the cotransporter. 14-3-3 promotes Npt2a membrane localization but not function in NHERF1 deficient states and may not be dependent on the phosphorylation status of the -2 Thr.

**POI1417**

**Metabolic Acidosis Exacerbates Pyelonephritis in Mice Prone to Vesicoureteral Reflux**
Jeffrey M. Parkinson, Janine L. Corley, George J. Schwartz. University of Rochester Medical Center, Rochester, NY.

**Background:** Acute pyelonephritis is a serious bacterial infection in children. The prevalence of acute pyelonephritis is due at least in part to gicusgericetal gulos (VUR). Although an association between pyelonephritis and abnormalities in acid-base balance is common in young children, the impact of metabolic acidosis (MA) on progression of acute pyelonephritis is not fully understood. In the current study the effect of metabolic acidosis on pyelonephritis was studied in C3H mouse strains prone to VUR.

**Methods:** MA was induced in female C3H mice via NH4Cl (2%/w/w) supplementation of food. Acid-base state was assessed by blood gas analysis using an iSTAT G3+ and urine pH with U-TEST. Urinary Tract Infection of mice (6-8 wks) with Uropathogenic E. Coli (UPEC strain CFT073) 0.5 X 10^11 cfu/50 μl was performed via the transurethral injection of bacterial blander and kidney was determined by culture of tissue homogenates. Collecting duct (CD) fragments and neutrophils were enriched from collagenase-digested kidney by magnetic-sorting utilizing DBA-lectin and monoclonal antibodLtLy6G (1A8). Cytokine (IL-1β, TNFα, IL-6) and chemokine (CXCL1, CXCL2, CXCL5) RNA in CD cells was quantitated by qRT-PCR. Ly6G-cells were enumerated by imaging utilizing a Cellometer K2 Image Cytometer. Statistics: T-test or two-tailed Mann-Whitney U-Test p<0.05 or P≥0.02 for Bonferroni correction.

**Results:** NH4Cl fed mice were acidic (HCO3-): 17±0.6*, Ur pH: 5.8±0.02* compared to normal (HCO3-): 22±0.01, Ur pH: 6±0.05. MA concurrent with UPEC-UTI markedly increased kidney UPEC burden in innate immune competent HeN mice (HeN = 4E5 versus MA HeN= 1E6±1E6; p<0.02 MW-U-TEST), but not Th1-deficient HeF mice (HeF = 2E6±1E6 versus MA HeF = 5E5±1E5). MA markedly increased CD inflamed neutrophil infiltrates (HeN = 6E5; p<0.02 MW-U-TEST), but not Th1- or Th2-deficient HeF mice (HeF = 2E5±1E5; p≥0.02 for Bonferroni correction).

**Conclusions:** Concurrent metabolic acidosis exacerbates pyelonephritis in innate immune competent mice that is characterized by an elevated cytokine and chemokine expression and kidney neutrophil infiltrates.

**POI1418**

**Oxidized Alkyl Phospholipids Stimulate Proximal Tubule Sodium Transport via PPARγ/ERK Pathway**
Tomohito Mizuno,1 Motonobu Nakamura,1 Nobuhiko Satoh,1 Hiroyuki Tsukada,1 Yusuke Sato,2 Shoko Horita,1 Haruki Kume,2 Masashi Suzuki,3 Masaomi Nangaku,4 1Division of Nephrology and Endocrinology, The University of Tokyo, Tokyo, Japan; 2Department of Urology, The University of Tokyo, Tokyo, Japan; 3Tokyo Tamei Medical Center, Tokyo, Japan.

**Background:** We previously reported thiazolinediones stimulated proximal tubule (PT) sodium transport via non-genomic PPARγ/ERK pathway. However, the contribution of endogenous PPARγ ligands to PT transport has been unknown. In this study, we investigated effects of 1-O-hexadecyl-2-azelaoyl-sn-glycero-3-phosphocholine (azPC), an endogenous lipid oxidation product (LOP) acting as a potent PPARγ agonist, on PT sodium transport.

**Methods:** We measured basolateral Na/HCO3- cotransporter 1 (NBCe1) activity in lumen-collapsed PTs and luminal Na/H+ exchanger (NHE) activity in freshly-isolated rat and human PTs obtained during surgery for renal cell carcinoma by using a pH-sensitive dye BCECF. NBCe1 activity in lumen-collapsed PTs was measured by the rate of pH decrease in response to HCO3- reduction. Luminal NHE activity in lumen-opened PTs was measured by the rate of pH decrease caused by Na+ removal in the presence of VAPase inhibitor, Belafoncim A. To examine the signaling pathway of azPC, we used a PPARγ antagonist (GW9662) and a MEK inhibitor (PD98059) and siRNA against PPARγ. The expression of PPARγ mRNA was determined by quantitative PCR. ERK phosphorylation was analyzed by western blotting.

**Results:** In freshly-isolated human and rat PTs, 0.3 μM azPC stimulated NBCe1 activity and NHE activity. The stimulatory effects were completely suppressed by GW9662 or PD98059 without affecting the basal activities. siRNA against PPARγ completely suppressed the stimulation of both NBCe1 and NHE activities by azPC in rat PTs. We
found that azPC enhanced ERK phosphorylation in human and rat renal cortex tissue. This phosphorylation was also completely suppressed by GW9662 or PD98059.

**Conclusions:** These results indicated azPC stimulated both NBCe1 and NHE activities through PPARγ/ERK pathway in PTs. The stimulatory effect of azPC, one of the LOPs on PT sodium reabsorption, could be a novel mechanism of volume expansion and hypertension induced by atherosclerosis.

**POI1419**

**A Novel Distal Convoluted Tubule-Specific Tamoxifen-Inducible Cre-Recombinase Driven by the NaCl Cotransporter Gene**

**Ryan J. Cornelius,** Avika Sharma, Xiao-Tong Su, David H. Ellison, Andrew P. McMahon, James A. McCormick, Oregon Health & Science University, Portland, OR; 2VA Portland Health Care System, Portland, OR; 3Keck School of Medicine of the University of Southern California, Los Angeles, CA.

**Background:** The use of knockout and transgenic mouse models coupled with Cre-lox technologies has revolutionized research in kidney transport physiology by allowing site-specific genetic recombination in individual nephron segments. Although several groups have tried to generate a distal convoluted tubule (DCT)-specific mouse, Cre-recombinase driven by the thiazide-sensitive NaCl cotransporter (NCC) promoter, this goal has remained elusive. The only previously recognized mouse model available, allowing targeted gene modification in the DCT is the DCT-specific mouse with Cre-recombinase under control of the Pshgl gene encoding parvalbumin. The model, however, has limitations including activity in neurons that prevent comprehensive characterization of transport pathways in the DCT.

**Methods:** CRISPR/Cas9 was used to introduce Cre-ERT2 into the 3′ UTR near the stop codon of the Slc12a3 gene encoding NCC (Slc12a3-Cre-ERT2 mice). Here, we crossed Slc12a3-Cre-ERT2 mice with VFP floxed mice to test whether the Cre expression would mimic that of NCC, and to determine whether the construct is ‘leaky’.

**Results:** Without tamoxifen, approximately 6% of NCC positive cells expressed YFP, indicating minimal leakiness. After five days of tamoxifen injection, mice showed YFP expression in almost all NCC positive cells and there was complete overlap of YFP expression in NCC positive cells. Crossing to TdTomato mice revealed higher leakiness (64.5%), suggesting differential sensitivity of the floxed site. Western blotting revealed no differences in abundances of total or the active-phosphorylated form of NCC in Slc12a3-Cre-ERT2 mice of either sex compared to controls. Furthermore, functional analysis of NCC showed no effects on NCC activity in Slc12a3-Cre-ERT2 mice. Plasma K+ and Mg2+ concentrations, and thiazide-sensitive Na+ and K+ excretion did not differ in Slc12a3-Cre-ERT2 mice compared to controls.

**Conclusions:** Thus, the Slc12a3-Cre-ERT2 mice have high recombination efficiency and complete fidelity in cell-specificity. Our data show that Cre expression is entirely localized to the DCT and the genetic modification has no effect on NCC expression and renal function. The Slc12a3-Cre-ERT2 mice are the first mice generated with Cre recombinase activity along the entire DCT, and will be a powerful tool to study DCT function.

**A Case of Central Diabetes Insipidus due to Pituitary Adenoma Complicated by Amphotericin-Induced Nephrogenic Diabetes Insipidus**

Meenakshi Sambharia, Lama A. Nouredin. University of Iowa, Iowa City, IA.

**Introduction:** Amphotericin B (Amph B) is an anti-fungal agent that exhibits its action by binding to ergosterol, the main component of the fungal cell wall and shares a similar structure to the human cell membrane. Its main site of action is the principal cell where it causes an increase in membrane permeability by insertion of pores into the membrane, causing leakage of potassium into tubular lumen leading to hypokalemia. It also causes nephrogenic diabetes insipidus (NDI) by preventing insertion of vasopressin-induced aquaporin 2 (AQP-2). Reports in the literature have suggested that liposomal Amphotericin B also causes nephrogenic diabetes insipidus (NDI) by preventing insertion of vasopressin-a similar structure to the human cell membrane. Its main site of action is the principal cell where it causes an increase in membrane permeability by insertion of pores into the membrane, causing leakage of potassium into tubular lumen leading to hypokalemia.

**Case Description:** A 37-year-old male with history of pituitary adenoma s/p trans-sphenoidal resection of pituitary tumor with subsequent central diabetes insipidus (CDI) on maintenance desmopressin DDAVP 1mcg Bid presented to hospital for suspected meningitis. He was started on liposomal Amph B Smg/kg (550mg) for empiric fungal coverage. Lumbar drain cultures returned positive for Candida albicans on Hospital Day (HD) 1 and Amph B was continued. Renal was consulted for evaluation of worsening polyuria. Increased dose of DDAVP was recommended. He continued to be polyuric despite dose adjustment. Amph B induced NDI was suspected secondary to refractory polyuria and hypokalemia. Amph B was discontinued on HD 7, after which his polyuria improved gradually. He was switched to furocarnozole to complete the remainder of the treatment duration.

**Discussion:** Our patient with h/o CDI developed worsening polyuria on Amph B treatment, unresponsive to escalating DDAVP. Improvement with cessation of Amph B supports causality of concurrent drug-induced NDI. Amph B renal toxicity frequently presents with AKI with potassium wasting. NDI induced by Amph B is rare. A high index of suspicion is required for diagnosis of NDI occurring on top of CDI. Early discontinuation of Amph B usually leads to resolution of symptoms.

**POI1449**

**Water Load Test in the Diagnosis of Syndrome of Inappropriate Antidiuresis (SIAD): Results from the Waterline Study**

Raphael R. Cohen, Elise Bouderlique, Côme Bureau, Riyad N. Seerwai, Anne Blanchard, Pascal Houllié, Laurence Vrigneaud, Jean-philippe Bertoccio. 1 Waterline study investigators Hospital européen Georges-pompidou pole cardio-vasculaire renel metabole, Paris, France; 2 university of texas MD Anderson Cancer Center, Houston, TX; 1 hoptel priv le louviere, lille, france; 3 U1155 Inserm, Tumen Hospital, Paris, France; 4 center for precision environmental Health, Baylor college of Medicine, Houston, TX.

**Background:** SIAD is caused by an inadequate kidney reabsorption of water, mainly under the action of antidiuretic hormone. The latest international recommendations stated the diagnosis of SIAD relies on hypotonic hyponatremia with inadequate urine osmolality. Blood volume has to be normal, with adrenal, thyroid, and renal insufficiency excluded. These guidelines ruled out the usefulness of abnormal response to water load test (WLT) due to the lack of published evidence.

**Methods:** In the Waterline study (NCT04256499), we retrospectively analyzed data from patients who underwent a WLT (oral administration of 20 mL/kg of water) in our department.

**Results:** From 02/2001 to 10/2019, 173 adults were included. Out of them, 80(46%) had a SIAD and 21(12%) were considered ‘normal’, 72(42%) had hyponatremia of other origin. Among the SIAD patients, 33(41%) had a fasting plasma sodium (PNa) ≥135mM (‘nephrogenic SIAD’), 47(59%) had ‘hyponatremic SIAD’. We found no differences in demographic data or medical history between these two groups. During WLT, ‘nephrogenic SIAD’ patients behaved specifically by exerting hyponatremia (while normal individuals did not), resembling ‘hyponatremic SIAD’ patients (Figure 1). While their fasting urine osmolality (U-Osm) was initially higher, ‘nephrogenic SIAD’ and ‘hyponatremic SIAD’ patients reached the same minimum U-Osm (389±257 vs. 350±203mOsm/kgH,O, p=0.76). Additionally, they reached a higher minimum value of PNa than ‘hyponatremic SIAD’ patients (132±2 vs. 127±3mM, p<0.0001). These results were confirmed in an independent cohort of 38 WLT where 24(63%) were ‘nephrogenic SIAD’.

**Conclusions:** We conclude that, without WLT, a diagnosis of SIAD could be missed in 40 to 65% of SIAD patients.

**POI1430**

**Reconsidering the Edelman Equation: Impact of Individual Total Body Cation Content and Body Weight**

**Background:** Treatment of hypo- and hyponatremia is guided by formulas that are a highly heterogeneous population. However, the Edelman equation does not account for the recently uncovered body compartment where Na+ can be temporarily stored and released without affecting TBW.

**Discussion:** Our patient with h/o CDI developed worsening polyuria on Amph B treatment, unresponsive to escalating DDAVP. Improvement with cessation of Amph B supports causality of concurrent drug-induced NDI. Amph B renal toxicity frequently presents with AKI with potassium wasting. NDI induced by Amph B is rare. A high index of suspicion is required for diagnosis of NDI occurring on top of CDI. Early discontinuation of Amph B usually leads to resolution of symptoms.
Methods: We performed a post-hoc analysis of original data from the Edelman study. In a linear regression model, the effects of important clinical characteristics on the relation between (Na\(^+/\))\(\times\)TBW and serum [Na\(^-\)] were examined: sex, body weight and presence of edema. Using piecewise regression, we analyzed differences in slope and \(y\)-intercept for increasing values of (Na\(^+/\))\(\times\)TBW. Serum [Na\(^-\)] was calculated by multiplying serum water [Na\(^+\)] by 0.93.

Results: Data was available for 85 measurements in 82 patients; 57 males, 25 females, with a mean age of 57±15 years. Serum [Na\(^-\)] ranged from 103 to 150 mmol/L. The association between serum [Na\(^-\)] and (Na\(^+/\))\(\times\)TBW was different for high and low weight categories (table). Sex or presence of edema did not alter the association. In piecewise regression, a significant change in slope was found in 149 mmol/L (Na\(^+/\))\(\times\)TBW (figure; 1.12 vs 0.56, \(p<0.01\)).

Conclusions: The coefficients of the Edelman equation are significantly affected by weight and body cation content. The less steep slope for the higher (Na\(^+/\))\(\times\)TBW and high weight groups may reflect an increase in osmotically inactive Na\(^+\) storage. This may explain the inaccuracy of Edelman based formulas in daily clinical practice.

PO1431

Hypotenatremia: It’s in the Eye of the Beholder
Muhammad Y. Jan, Richard N. Hellman. Indiana University School of Medicine, Division of Nephrology and Hypertension, Indianapolis, IN

Introduction: An 85 year old American female presented with 2 days history of worsening right eye pain, headache, scalp tenderness, and hypertensive urgency. Medical history was notable for keratoconjunctivitis sicca, osteoarthritis, and central retinal occlusion of the left eye. Initial labs showed erythrocyte sedimentation rate of 75 mm/hr and C reactive protein of 3 mg/dL. A presumptive diagnosis of Giant Cell Arteritis (GCA) was made. She was started on high dose oral prednisone. Hypertension was treated with labetalol, amlodipine, and pain with opioids. Over the course of the next 24 hours she began to have somnolence. Initial sodium (Na) on admission was 131 mmol/L, with prior normotremia. She was given a normal saline bolus followed by infusion due to concern for encephalopathy and reduced oral intake. This resulted in a consistent drop in her serum sodium acutely to 116 mmol/L and a nephrology consultation was sought.

Case Description: Our evaluation showed euvolemia with confusion and obtundation. Labs showed serum osmolality of 252 mosm/kg, urine osmolality of 626 mosm/kg and Urine Na consistently around 90-129 mEq/L. A diagnosis of SIADH with desalination was made. She was treated with free water restriction, 3% saline, salt tablets, and furosemide. Na improved to 120 mmol/L however it dropped again next day to 117mmol/L requiring repeated doses of 3% Saline. Daily urine osmolality continued to decrease to 500s mosm/kg and later to 360 mosm/kg as did urinary sodium 48 hours after these interventions. Peri-ocular swelling and a herpes zoster rash appeared on her eye 48 hours later. PCR for herpes was positive.

Discussion: Acyclovir was started and corticosteroids stopped. Over 8 days the hypotenatremia resolved with Herpes Zoster Ophthalmicus (HZO) treatment. HZO is a rare cause of SIADH thought to be due to dysregulation of stimulating signals from nucleus hypothalami.

PO1432

Acute Hemodialysis Prescription in Severe Hypotenatremia Patient
Yasmine Wardowo,1,2 Donnie L. Gaol,1,3 Parlingdungan Siregar.1 1Rumah Sakit Dr Cipto Mangunkusumo, Central Jakarta, Indonesia; 2Rumah Sakit Umum Pusat Fatmawati, Jakarta, Indonesia; 3Fakultas Kedokteran Universitas Kristen Indonesia, Jakarta, Indonesia.

Introduction: Severe hypotenatremia in end-stage renal disease with fluid overload give rise to clinical dilemma. Dialysis and ultrafiltration are needed to reduce uric acid and fluid overload, yet there is a danger of osmotic demyelination syndrome if blood sodium level rapidly increase above the permissible range.

Case Description: A 60 years old male patient was admitted with acute pulmonary oedema due to chronic kidney disease. He came with uremia 140 mg/dL, creatinin 20.3 mg/dl and had severe hypotenatremia 94 mEq/L. He underwent hemodialysis with low blood flow rate (50 ml/min) and low dialysate sodium (130 mEq/L). Second hemodialysis was done with blood flow rate 100 ml/min and dialysate sodium 130 mEq/L. With this approach, we succeeded in increasing sodium gradually, not exceeding the limit of 10 mEq/day.

Discussion: In order to avoid rapid increment of serum sodium level, the sodium in dialysate can be set as low as possible to 130 mEq/L. We aim to limit the increment of serum Na to 10 mEq/day. Since the patient’s total body water is approximately 36 L, an increase of 3 mEq/L/hour during 3-hour dialysis session would require a transfer of 108 mEq of Na per hour or total 324 mEq. We set a very slow blood flow rate, set dialysate rate to 800 ml/min and we assume that there is a 100% equilibration of Na between the patient’s blood and the dialysate, resulting in net transfer of 36 mEq Na (Na\(\text{dialysate} \cdot \text{Na}_\text{dialysate} \cdot \text{Na}_\text{serum}) / \text{total blood flow rate} \cdot \text{dialysate sodium} 130 mEq/L. Second hemodialysis was done with blood flow rate 100 ml/min and dialysate sodium 130 mEq/L. With this approach, we succeeded in increasing sodium gradually, not exceeding the limit of 10 mEq/day.

Should Sodium Monitoring Be Included in Routine Prenatal Care?
Talar Kharadjan, Mitra Jamshidian, Cynthia Miracle. University of California San Diego, La Jolla, CA.

Introduction: The American College of Obstetricians and Gynecologists does not recommend serum chemistries as part of routine prenatal care. Our case demonstrates the clinical utility in diagnosing hyponatremia prior to symptom development in mother or newborn.

Case Description: A 39-year-old pregnant female with no known prenatal issues underwent a spontaneous vaginal delivery; the infant was initially apneic and had a witnessed seizure. His initial serum sodium was 120 mEq/L, and he was treated with phenobarbital and hypertonic saline. Serum sodium corrected by 4 mEq/L during the first 7 hours, and increased from 120 to 133 mEq/L over the first 24 hours. Brain MRI performed on day 4 demonstrated no abnormal findings. The mother’s baseline sodium level was unavailable. She received 1L of D5LR and 1L of LR during labor. She had urinary retention following delivery and a Foley catheter immediately drained 2L of urine. Her initial postpartum sodium level was 123 mEq/L without associated symptoms. Urine osmolality was 64 mOsm/kg on admission. History revealed typical daily fluid consumption of 6L. Two days prior to admission, she abruptly increased fluid intake to 13L per day in response to contractions. Twelve hours into admission, serum sodium corrected from 123 to 134 mEq/L in the setting of a relative reduction in fluid intake to 5L. Due to concern for a chronic component of hyponatremia, free water and DDAVP were given to slow the rate of correction. With the effect of DDAVP, urine concentrated to 695 mOsm/kg, illustrating the regeneration of an osmotic gradient within 30 hours.

Discussion: Primary polydipsia served as the leading driver of acute hyponatremia in this mother and infant, appropriately associated with ADH suppression. Although well-known drivers of increased ADH secretion were present, such as urinary retention and labor pain, their effects were less significant, as evidenced by very dilute urine on presentation. She was not exposed to the antidiuretic effects of oxytocin, which is an additional consideration in the peripartum period. Higher plasma volume during pregnancy and chronic polydipsia increased the mother’s propensity to develop clinically significant hyponatremia in this case. This may have been detected earlier had serum sodium testing been included in routine prenatal care.

Hyponatremia: A Real Headache
Jordan R. Evans,1,2 Matthew Rodrigues,1 David N. Dado.1 US Army Brooke Army Medical Center, Fort Sam Houston, TX; 1University of Texas Health Science Center at San Antonio, San Antonio, TX.

Introduction: Pituitary apoplexy is a condition characterized by pituitary gland injury via either infarction or hemorrhage. This can result in endocrinologic dyscrasias. We describe a case of SIADH secondary to pituitary apoplexy.

Case Description: A 70 year old female with a past medical history of atrial fibrillation on rivaroxaban presented to the hospital with nausea, vomiting, and new onset headache for 1 week. She received 1L of saline in the emergency room and her nausea resolved. Basic chemistry was significant for a serum sodium of 124 mEq/L. A physical exam including neurological assessment was unremarkable as was a CT scan of the head. The patient was admitted and placed on a 1.5 L fluid restriction. By the next morning, she had a serum sodium of 112 mEq/L, serum osmolality of 238 mOsm/kg, urine osmolality at 434 mOsm/kg, urine sodium at 143 mmol/L, and urine potassium at 45 mmol/L. The patient was immediately transferred to the ICU and nephropathy was consulted for severe hyponatremia due to SIADH. Given the acute drop from 124 mEq/L to 112 mEq/L over a 24 hour period, the patient was aggressively treated with hypertonic saline boluses as well as continuous infusion. Fluid restriction was tightened to 500 ml daily. SIADH was initially thought to be due to hypovolemia and vomiting, however, the differential was revisited when the severe hyponatremia persisted despite resolution of her nausea and hypovolemia. Given the new onset headache in an older adult, a MRI of the brain was obtained which revealed a convexity in the sella that was identified as a 1 cm pituitary hemorrhage. Rivaroxaban was discontinued. Further evaluation of pituitary hormones were all within normal limits. The hyponatremia corrected over 3 days and the patient was discharged home with a sodium of 132 mEq/L.

Discussion: SIADH is a rare finding in pituitary apoplexy that can be seen transiently 3-11 days after a pituitary surgery or injury. The mechanism is not known but is suspected to be due to the release of intracellular ADH stores from injured posterior pituitary cells. Pituitary apoplexy should be considered in the differential diagnoses for SIADH in the setting of recent brain surgery or new red flag neurological symptoms.

Dysnatremias and Mortality in CKD: Analysis of the Chronic Renal Insufficiency Cohort (CRIC) Study
Mohamed Hassanein, Susana Arrighian, Jesse D. Schold, Georges Nakhoul, Jonathan J. Taliercio. Cleveland Clinic, Cleveland, OH.

Background: Dysnatremias have been associated with increased mortality in patients with chronic kidney disease (CKD). We studied the association of dysnatremias with mortality and end-stage kidney disease (ESKD) in patients with CKD.

Methods: We included 5,444 patients from the Chronic Renal Insufficiency Cohort (CRIC) for a median follow-up of 8.8 years. We analyzed baseline and time-dependent hyponatremia (<136 mmol/L) and hypernatremia (>145 mmol/L) with all-cause mortality and risk of ESKD using Cox proportional hazard models and competing risks models.

Peripheral Administration of 3% Sodium Chloride Is Not Associated with Local Infusion Reactions
Michael L. Moritz,1,2 Juan Carlos Ayus,1,2b Joel B. Nelson,1,2 1University of Pittsburgh Medical Center, Pittsburgh, PA; 2University of Pittsburgh School of Medicine, Pittsburgh, PA; 2Renal Consultants of Houston, Houston, TX; 3University of California Irvine, Irvine, CA.

Background: Three-percent sodium chloride (3% NaCl) is a hyperosmolar agent indicated for the treatment of hyponatremic ephelathapathy or to raise the serum osmolality in other cases of increased intracranial pressure. A barrier to the use of 3% NaCl is the perceived risk of a local infusion reactions when administered through a peripheral vein (Front Med. 2019 Mar 15;6:47), even though it has not been reported in large case series of 3% NaCl (AJKD. 2015 Mar;65(3):435-42). We sought to evaluate reports of local infusion reactions associated with 3% NaCl over a 10-year period throughout a large healthcare system.

Methods: A query was conducted through Risk Master database to determine if there were any local infusion reactions associated with peripheral 3% NaCl administration throughout the entire UPMC health system over a 10-year time period from May 14, 2010 to May 14, 2020. Search terms included infiltrations, extravasations, phlebitis, IV site issues and IV solutions.

Results: In over 1.1 million events (figure), there were 23,714 intravenous events which were non-chemotherapeutic or non-contrast of which 14,648 (19.7%) were in children. 617 (2.59%) of these events were deemed serious by a patient safety officer. There were no reported local infusion reactions with 3% NaCl.

Conclusions: There were no reported local infusion reactions associated with 3% NaCl in a large healthcare system despite widespread use of 3% NaCl and numerous intravenous events reported. This suggests that 3% NaCl can be safely administered through a peripheral IV.

POI1439
Hyponatremia: Mind the (Osmolar) Gap
Joy Ayyoub, Shahzard Zonoozi, Pooneh Alborzi. Penn Medicine, Philadelphia, PA.

Introduction: Hyponatremia, one of the most commonly encountered electrolyte abnormalities, is associated with considerable mortality and morbidity. It is important to rule out pseudohyponatremia by determining serum toxicity.

Case Description: 65-year-old female with history of hypertension presented with worsening painless jaundice. Initial investigation was notable for an obstructive liver injury; total bilirubin of 28.4 mg/dL (direct 19.5 mg/dL and indirect 8.9 mg/dL), ALP 1225 U/L, AST 237 U/L, ALT 384 U/L and GGT 2274 U/L. She was also found to have a sodium of 126 mmol/L and potassium of 2.5 mmol/L. With fluids and potassium repletion, her sodium plateaued at 131 mmol/L. Further investigation revealed a measured serum osmolality of 301 mOsm/kg with an osmolar gap of 33 mOsm/kg, and a urine osmolality of 589 mOsm/kg. Sodium analysis using ion-selective electrode (ISE) showed a correction in the sodium from 131 mmol/L to 139 mmol/L on the same specimen, confirming the diagnosis of pseudohyponatremia. Lipid panel showed severe hypercholesterolemia (total cholesterol 1016 mg/dL, LDL 868 mg/dL, HDL 31 mg/dL and triglycerides at 604 mg/dL). Patient underwent endoscopic retrograde cholangiopancreatography and biliary sphincterotomy with biopsy consistent with adenocarcinoma of the pancreas. Following sphincterotomy, lipid panel and serum sodium normalized without further intervention.

Discussion: Serum cholesterol is elevated in cholestasis because its metabolic degradation and excretion are impaired. Much of the cholesterol is in the form of lipoprotein-X, an abnormal lipoprotein observed only in patients with cholestasis. Standard methods of sodium analysis, indirect ISE, calculates electrolyte concentration on the assumption that the non-aqueous portion of serum, predominantly proteins and lipids, comprises approximately 7% of a patient’s plasma volume. In our patient with significant hyperlipidemia, this led to falsely low indirect ISE values. Direct potentiometric measurements use undiluted samples and are not subject to this artifact, a method also used in blood gas analysis. This case demonstrates a rare presentation of pseudohyponatremia and highlights the importance of its consideration in cases where the serum osmolality is normal or when an osmolar gap is present suggesting reduced plasma water content or the presence of ineffective osmoles.

Development of Hyponatremia and Overcorrection in a Patient with COVID-19 and Vasopressin Exposure
Meghana Eswarappa, Nirali Patel, Samira S. Farouk. Icahn School of Medicine at Mount Sinai, New York, NY.

Introduction: Hyponatremia in the setting of elevated antidiuretic hormone (ADH) is a common phenomenon. However, exogenous ADH from vasopressin administration for hemodynamic support does not cause clinically relevant hyponatremia, despite its widespread use. Further, discontinuing vasopressin may lead to rapid rises in sodium that may be missed. Here, we present a case of a critically ill patient who developed hyponatremia in the setting of vasopressin use, with subsequent rapid overcorrection that required re-lowering of serum sodium after discontinuing vasopressin.

Case Description: A 40-year-old male with no known history was admitted to the ICU for respiratory failure due to COVID-19 pneumonia. Initial labs showed normal renal function and electrolytes. He received azithromycin, hydroxychloroquine, and lipoprotein-X, an abnormal lipoprotein observed only in patients with cholestasis.

Case Description: A 40-year-old male with no known history was admitted to the ICU for respiratory failure due to COVID-19 pneumonia. Initial labs showed normal renal function and electrolytes. He received azithromycin, hydroxychloroquine, and lipoprotein-X, an abnormal lipoprotein observed only in patients with cholestasis.

Case Description: A 40-year-old male with no known history was admitted to the ICU for respiratory failure due to COVID-19 pneumonia. Initial labs showed normal renal function and electrolytes. POI1441
Continuous Renal Replacement Therapy (CRRT) for Overcorrection of Hyponatremia After Left Ventricular Assistance Device (LVAD) Placement
Abdulhadi T. Gelalidin, Pooja D. Amaraparkar, Jonathan J. Suarez. Emory University School of Medicine, Atlanta, GA.

Introduction: Rapid correction of severe hyponatremia can result in osmotic demyelination syndrome, central pontine myelolysis and locked-in syndrome. Rapid correction is defined as an increase in serum sodium (Na) by 10-12 mEq/L in the first 24 hours and 18 mEq/L in the first 48 hours. Rapid lowering serum Na in a short period after rapid correction of hyponatremia could prevent these complications. Conventional strategies use hypertonic intravenous fluids and desmopressin to lower overcorrected hyponatremia. However, CRRT can correct serum sodium in a very predictable and controlled manner.

Case Description: A 35-years old woman with a history of non-ischemic cardiomyopathy with an ejection fraction of 5-10% was admitted with an acute CHF exacerbation. Her hospitalization was complicated by AKI and hyponatremia. She underwent LVAD placement and her sodium increased from 111 to 137 mEq/L within 18 hours of surgery. She was started on CRRT using continuous venovenous hemodiafiltration (CVVHDF) with post-filter 5% dextrose in water to lower her sodium level to close to 120 meq/L. The patient tolerated the treatment very well with no immediate central nervous system complications or even delayed neurological complications at the two month follow up.

Discussion: To our knowledge, this is the first case report describing the use of CRRT for overcorrection of hyponatremia after LVAD placement. The overcorrection of hyponatremia after LVAD placement was likely due to the kidney’s restored ability to excrete diluted urine from improved renal perfusion. Given the total fluid volume of hypertonic intravenous fluids and unpredictability of desmopressin we recommend considering early initiation of CRRT to treat overcorrection of hyponatremia after LVAD placement. Another consideration should be made for Initiation of CRRT prior to LVAD placement in patients with severe hyponatremia to prevent the rapid correction from occurring in the intraoperative setting.

POI1442
Neuroprotective Hyponatremia in Acute Liver Failure Using CRRT: A Challenging Scenario
Jean Maxime Cote.1 1Centre Hospitalier de l’Universite de Montreal, Montreal, QC, Canada; 2University College Dublin, Dublin, Ireland.

Introduction: Acute liver failure is associated with severe complications, including encephalopathy. Cerebral edema may occur, leading to increased intracranial pressure. Urgent medical management sometimes includes neuroprotective hyperosmolality and ammonia control using convective techniques. We describe a patient where high-volume CVVHDF was used to increase ammonia clearance while maintaining therapeutic hyponatremia.

Case Description: A 64-year-old female with severe bipolar disorder presented into the ED ~24hours after voluntary ingestion of ~150 tablets (75g) of acetaminophen. She was initially confused with normal blood pressure. Laboratory work showed severe metabolic acidosis with the following values: lactate 9.1 mmol/L, pH 6.99, ammonia 409 mmol/L, ALT 6398 U/L, creatinine 44 mg/dL. NAc and IV bicarbonate were quickly initiated, and a short plasmapheresis treatment was started 12hours later, inducing moderate hypercalcaemia, hyponatremia (153 mmol/L) and normalising INR temporarily. Encephalopathy, oliguria and hemodynamic instability progressed. High-volume CVVHDF (90 mL/kg/h) was started at day 3 to optimise ammonia clearance and electrolytes. Hyperonc NaCl 23.4% (50 mmol) was added to a low-chloride IV fluid in 5 mL dialysate production (PrismaCalc2) to obtain Na of 150 mmol/L. Over the next 3 days, additional hypertonic NaCl was required (until 80 mmol) (dialysate Na 155 mmol/L) to reach the ~150 mmol/L serum sodium targeted. However, after numerous medical complications, the patient was electively inelible to liver transplantation and palliative care was initiated. She died 3 weeks after initial admission.

Discussion: Usage of high-volume CRRT in severe hepatic encephalopathy increases despite the paucity of evidence. Commercial standard solutions of dialysate used for CRRT usually have fixed sodium concentration (140 mmol/L). Adding sterile hypertonic NaCl into the dialysate bag allows us to modify its tonicity to obtain neuroprotective hyponatremia. However, as shown in our case, complete sodium equilibration between dialysate and patient, even when using high-volume CVVHDF, is unlikely because of residual kidney function and concomitant hypo- and isotonic IV medications. To obtain and maintain therapeutic hyponatremia in these conditions, the CRRT dialysate tonicity should be slightly higher than the targeted serum sodium.

POI1443
Unraveling the Role of Serum Chloride Level as a Strong Predictor of Outcomes in Patients with Heart Failure: A Systematic Review and Meta-Analysis
Ankur Jain,1 Shriharsha Kallahlali Jayarami,1 Abhilash Koratala,2 Amir Kazory.1 University of Florida, Gainesville, FL; 2Medical College of Wisconsin, Milwaukee, WI.

Background: The field of heart failure (HF) is conventionally sodium-centric. Low serum sodium concentration has long been recognized as an established marker of adverse outcomes and is commonly included in HF risk prediction models. Not only could the mechanisms leading to hyponatremia result in concurrent hypochloremia, but chloride also has distinct biological roles (e.g., modulating renin secretion) that are relevant in HF. We sought to explore the impact of hypochloremia on the outcomes of patients with a HF.

Methods: This is a PRISMA-guided systematic literature review and meta-analysis (registered in PROSPERO). We searched PubMed, Cochrane, and Embase databases from March 2010 to March 2020 for clinical trials exploring relationship between serum chloride and the outcomes of HF patients. A cumulative analysis of Hazard Ratios (HR) with 95% confidence intervals (CIs) was done using comprehensive meta-analysis software.

Results: A total of 9 studies with 15,979 patients were eligible for analysis; 5 had patients with systolic HF, 3 with both systolic and diastolic HF, and 1 with diastolic HF only. These studies reported HR for risk of mortality with change in serum chloride levels stratified by unit, standard deviation, or predefined groups, and adjusted for serum sodium and a variety of potential confounders. On cumulative analysis we found that serum chloride levels are inversely associated with risk of long-term mortality HR 0.92 (95% CI 0.77 - 0.96; p<0.01).

Conclusions: Based on the data from currently available studies, we identified low serum chloride level as a strong independent predictor of mortality in various phenotypes of HF. While it remains to be elucidated whether it represents a marker of disease severity or reflects an actual pathogenetic mechanism, our results suggest that inclusion of serum chloride in HF risk models is likely to improve their predictive value.
PO1445
Post-Discharge Outcomes Among Hyperkalemic Patients Treated with and Without Sodium Polystyrene Sulfonate in the Inpatient Setting
Jill Davis,1 Rubeen K. Israni,1 Erin Cook,2 Fan Mu,2 Keith Betts,2 Deborah A. Anzalone,3 Emma Billmeyer,2 Esteban J. Lemus Wirtz,2 Let Yin,2 Harold M. Szerlip,2 Gabriel I. Uwafio,3 Vivian A. Fonseca.3 AstraZeneca, Wilmington, DE; 2Bayou Interim Medical Center, Dallas, TX; 3Ochsner Medical Center, New Orleans, LA; 4Tulane University Medical Center; Tulane University School of Medicine, New Orleans, LA.

Background: Sodium polystyrene sulfonate (SPS) is a common treatment option for hyperkalemia (HK) in the inpatient (IP) setting. However, the post-discharge outcomes of patients with HK treated with and without SPS in the IP setting are not well characterized.

Methods: Adult patients with a 1 IP stay with HK (≥3 potassium [K] lab >5.0 mEq/L) were identified using electronic medical record data from the Research Action for Health Network (2012-2018). Patients treated with SPS during the IP stay were matched 1:1 to patients not treated with SPS on discharge status (dead/alive) and HK severity (most severe K lab during IP stay). Patient characteristics, K levels, HK treatments, length of stay (LOS), and deaths during IP stay were described. All-cause and HK-related IP readmission, and HK recurrence (in any setting) within 30, 60 and 90 days post-discharge were described and compared using conditional logistic regressions.

Results: A total of 4,847 SPS users were matched to non-SPS users (23.2% K=5.0-5.5, 36.8% K=5.6-6.0, 40.4% ≥6.0 mEq/L). During the stay, the 11.7% of patients died in both cohorts. Mean age was 65.7 and 62.1 years for the SPS and non-SPS users. SPS users had a higher burden of comorbidities than non-SPS users, including CKD (79.1% vs 57.2%) and heart failure (49.8% vs 37.7%; both p<0.001). The average LOS was similar for SPS and non-SPS users (9.0 v 9.1 days) and most patients had their last K level normalized (≥5.0 mEq/L) during the stay (83.0% vs 86.2%; p<0.001). Use of temporizing agents was common for SPS and non-SPS users (58.2% vs 43.5%; p<0.001); however, very few SPS users received SPS at discharge (0.4%). The 30-day all-cause and HK-related IP readmission rates were 27.0% and 13.6% for SPS users and 19.3% and 5.4% for non-SPS users, respectively. HK recurred within 30 days in 23.0% of SPS users and 7.1% of non-SPS users. The differences remained after adjusting for baseline and IP stay characteristics (odds ratio [95% CI]: all-cause readmission=1.4 [1.2, 1.6]; HK readmission=2.4 [2.0, 2.9]; HK recurrence=3.1 [2.7, 3.6]). The adjusted results were similar for 60 and 90 days post-discharge.

Conclusions: Despite treatment with SPS in the IP setting there was a high burden of readmission and HK recurrence among patients with HK.

PO1446
Serum Potassium Levels at Hospital Discharge and 1-Year Mortality Among Hospitalized Patients
Michael A. Maq,1 Charat Thongprayoon,2 Wisit Cheungsapitorn,2 Sorlko Thirunavukkarasu,2 Api Chewcharat,2 Stephen B. Ericsson,1 Mayo Clinic’s Campus in Florida, Jacksonville, FL; 3Mayo Clinic Minnesota, Rochester, MN.

Background: The aim was to assess the relationship between discharge serum potassium levels and one-year mortality in hospitalized patients.

Methods: All adult hospital survivors between years 2011 and 2013 at a tertiary referral hospital who had available admission and discharge serum potassium levels were enrolled. End-stage kidney disease patients were excluded. Discharge potassium was defined as the last potassium measured within 48 hours prior to hospital discharge and categorized into ≤2.9, 3.0-3.4, 3.5-3.9, 4.0-4.4, 4.5-4.9, 5.0-5.4 and ≥5.5 mEq/L. Cox proportional hazard analysis was performed to assess the independent association between discharge potassium and one-year mortality after hospital discharge, using discharge potassium as the reference group.

Results: Of 57,874 eligible patients, with a mean discharge serum potassium of 4.1±0.4 mEq/L, the estimated one-year mortality rate after discharge was 13.2%. A U-shaped association was observed between discharge potassium and one-year mortality, with nadir mortality in the discharge potassium of 4.0-4.4 mEq/L. After adjustment for clinical characteristics, including admission potassium, both discharge potassium of ≤3.9 mEq/L and ≥4.5 mEq/L were significantly associated with increased one-year mortality, compared with the discharge potassium of 4.0-4.4 mEq/L. Stratified analysis based on admission serum potassium showed similar results except that there was no increased risk of one-year mortality if discharge potassium group was ≥3.9 mEq/L in patients with an admission potassium of ≥3.0 mEq/L.

PO1447
Mitragyna speciosa (Kratom)-Induced Hyperkalaemia
Aldo E. Torres Ortiz, Muhammad Alqudsi. Ochsner Nephrology Ochsner Health System, New Orleans, LA.

Introduction: Kratom is a non-controlled herbal supplement that has been used for its opioid-like effects. Case reports of different organ toxicities from Kratom have been reported in the literature. However, little is known regarding its effects on potassium (K+) homeostasis. We present here the first case-report of kratom-induced hyperkalaemia.

Case Description: A 61 yo male with a history of degenerative disc disease and hyperlipidemia, referred to nephrology clinic for unexplained hyperkalaemia for the past 2 months. He was asymptomatic. His only home medication was rosuvastatin. Serum K+ was elevated in four different occasions with 5.5 mmol/L being the highest (non-hemolyzed samples). He denied NSAID or antibiotic use, smoking, alcohol intake, illicit drug abuse, sickness, or high (K+) diet intake. No family history of renal diseases. Physical exam was unremarkable with a blood pressure of 140/90 mm Hg without orthostatic changes. Serum creatinine (Cr) was 0.8 mg/dL, eGFR=60 mL/min, plasma aldosterone was 3.6 ng/dL, rennin activity was 0.88, urine (K+) was 14 mmol/L and urine Cr was 16 mg/dL, (K+) fractional excretion was 15%, sodium of 141 mmol/L, CO2 33 mmol/L and the rest of the electrolytes were normal. TSH, CPK, AM cortisol, and WBC were within normal limits and he had no hematuria or proteinuria. Kidney ultrasound was normal. Upon re-interrogation, patient admitted taking daily Kratom for recreational purposes for the past 4 months as herbal supplement. A repeat blood chemistry 4 weeks after patient confirmed abstinence from Kratom, revealed normalization of (K+) down to 4.6 mmol/L.

Discussion: Mitragyna speciosa (Kratom) is a herbal supplement with potential abuse due to its opioid-like properties. Our patient had hyperkalaemia unexplained by low renal clearance, adrenal insufficiency, medication use, or other etiologies. A study in cultured heart cells revealed a blocking effect of the cardiac (K+) inward rectifier channels (Kir 2.1) by Mitragynine causing prolonged QT interval arrhythmia. Kir family does exist along the nephron with little known about Kir 2.1, or other Kir channels is yet to be further studied. This case-report serves to highlight the importance of the identification of lesser-known supplements with potential abuse that can cause life-threatening side-effects.

PO1448
The Relationship Between Comorbidities and Hyperkalaemia in Patients with CKD
Eskinder Tafesse,2 Glen James,1 Daniel Sugrue,1 Michael A. Hurst,1 Louise Hoskin,1 Karolina Badora,1 Philip McEwan.1 Health Economics and Outcomes Research Ltd, Cardiff, United Kingdom; 2Global Health Economics, AstraZeneca, Gaithersburg, MD; 3Global Medical Affairs, AstraZeneca, Cambridge, United Kingdom.

Background: Hyperkalaemia (HK) is common in patients with chronic kidney disease (CKD) due to the role the kidneys play in maintaining normal potassium (K+) homeostasis. The presence of comorbidities in patients with CKD may further increase HK risk. Therefore, this study explored the incidence of HK in CKD patients with different comorbidities.

Methods: A retrospective cohort study was conducted using primary and secondary care data from the UK Clinical Practice Research Datalink and linked Hospital Episode Statistics, respectively. Eligible patients had non-dialysis dependent CKD, with or without resistant hypertension (RHTN), heart failure (HF) or diabetes (type 1 or type 2) recorded between January 2003 – June 2018. Patients were grouped according to CKD severity (stage 3a, 3b, 4 and 5) and follow-up time was partitioned based on their current exposure status. The incidence rates of HK per 1,000 patient-years were assessed for each group and the data was further categorised according to HK-defining potassium K+ thresholds: ≥5.0, ≥5.5 and ≥6.0 mmol/L.

The Kaplan-Meier plot of one-year mortality based on discharge serum potassium levels

Poster
Results: In total, 229,350 patients with CKD stage 3+ contributed to follow-up, including 514, 250, 114 and 39 thousand patient years in the CKD only, RHTN, diabetics and HF cohorts, respectively. Declining renal function was consistently associated with increasing incidence of HK at all K- thresholds. Additionally, within the same CKD stage, comorbidities were also consistently associated with an increase in HK incidence. Patients in the diabetes cohort were consistently at the greatest risk of HK, with a significant ($\alpha = 0.05$) increase in risk of HK (defined at ≥5.0 mmol/L) compared with other comorbidity groups. Conversely, patients without any comorbidities were at the lowest risk of HK, regardless of CKD stage and HK threshold.

Conclusions: In patients with CKD, comorbidities – specifically HF, diabetes, and RHTN – increase the risk of HK. This risk increases as renal function declines. As such, CKD patients, particularly those with comorbidities, may benefit from additional monitoring for HK.

Hyperkalaemia Secondary to Carabapenem Use
Sabine Karam. Saint George Hospital University Medical Center, Beirut, Lebanon.

Introduction: Hyperkalaemia can be a life-threatening complication and can often occur in the hospital setting as the result of the use of certain medications. In particular, hyperkalaemia has already been described as a rare complication of etephane use.

Case Description: A 24-year-old gentleman with no past medical or surgical history presented with a known history of renal disease with end-stage renal disease on chronic haemodialysis. He underwent a CT scan that showed a perforated appendix with small abscesses. Upon admission, his creatinine level was 1.26 mg/dL and his potassium level was 4.24 mg/dL. He was initiated on intravenous fluids and etephane 1g IV once daily. His renal function improved and his creatinine level decreased to 0.83 mg/dL however he developed hyperkalaemia with a potassium level that peaked at 5.9 mg/dL. He was switched to meropenem, however the hyperkalaemia persisted and resolved only when he was switched to ciprofloxacin.

Discussion: Carabapenem use is associated with severe hyperkalaemia and this complication seems to stem from a class-effect rather than the effect of a specific drug.

Relationships Between CKD Duration, Serum Potassium Level, and Adverse Outcomes
Eskinder Tafesse,1 Glen James,1 Michael A. Hurst,1 Louise Hoskin,1 Karolina Badora,1 Daniel Sugrue,1 Philip McEwan.1 Health Economics and Outcomes Research Ltd, Cardiff, United Kingdom; 2Global Health Economics, AstraZeneca, Gutthursburg, MD; 3Global Medical Affairs, AstraZeneca, Cambridge, United Kingdom.

Background: Patients with chronic kidney disease (CKD) are at increased risk of hyperkalaemia as the kidneys are important in maintaining potassium homeostasis. This study examined the relationships between CKD duration, serum potassium level (K-) and rates of adverse clinical outcomes.

Methods: This retrospective cohort study used linked primary and secondary care data from that UK Clinical Practice Research Datalink (CPRD) GOLD and Hospital Episode Statistics (HES), respectively. Eligible patients were aged ≥18 years with new or existing CKD stage 3+ (READ code or estimated glomerular filtration rate (eGFR) ≤60 mL/min/1.73m² without prior dialysis) between January 2008 and June 2018, or during lookback (2003 to 2007). Index date was 01 January 2008 (prevalent cases) or CKD diagnosis date (incident cases); whichever occurred later. Adverse outcomes were all-cause mortality (ACM) and major adverse cardiovascular events (MACE), a composite of arrhythmia, heart failure, myocardial infarction, and stroke. Crude incidence rates of ACM and MACE were estimated over follow-up from index date to event or end of follow-up (earliest of death, loss to follow-up or study end) based on 1,000 patient years. Published risk equations for ACM and MACE were refitted with adapted coefficient values to include CKD duration (≥5 and >5 years). Reference category for incidence rate values was K- level 4.5 to <5.0 mmol/L.

Results: Among 297,702 CKD patients, 58.6% were female and mean age was 74.7 years (standard deviation, SD 11.3) at index, with mean follow up of 5.6 years (SD 3.20). Mean eGFR at index was 49.7 mL/min/1.73m² (SD 11.6). Crude rates of ACM and MACE in patients with CKD duration ≥5 years were 60.8 and 1,000 patients year (95% confidence interval (CI) 60.3-61.3) and 102.6 (95% CI 102.0-103.3). Rates in patients with CKD duration >5 years were 76.3 (95% CI 75.4-77.2) and 127.4 (95% CI 126.2-128.5), respectively. Irrespective of duration of CKD, K- ≥4.5 or ≥5.0 mmol/L were associated with increased rate of MACE/ACM in comparison with 4.5 to <5.0 mmol/L.

Conclusions: CKD patients with K- outside the normal range are at increased risk of ACM and MACE of CKD duration. Improved management of K- may reduce adverse clinical outcomes in these patients.

Can Potassium Be a Predictor of Cardiovascular Mortality?
Catarina Mateus,1 Carolina Ormonde,2 Catarina Brizid0,1 Ana Rita M. Martins,1 Patricia Q. Branco.1 1Centro Hospitalar Lisboa Ocidental - Hospital de Santa Cruz; Lisboa, Portugal; 2Hospital do Divino Espirito Santo de Ponta Delgada EPE; Ponta Delgada, Portugal.

Background: Epidemiologic data demonstrates association between hyperkalaemia and mortality. Patients with ST-segment elevation myocardial infarction (STEMI) often have comorbidities that are associated with hyperkalaemia, such as Chronic Kidney Disease (CKD) and Diabetes Mellitus (DM). The aim of our study was to analyse hyperkalaemia as a prognostic factor in patients with STEMI.

Methods: Retrospective single-center analysis of all patients admitted for STEMI and undergoing primary percutaneous coronary intervention in a two-year period (January 2009 to December 2010). Demographic aspects, comorbidities, potassium level at admission and outcomes were evaluated. Hyperkalaemia was defined as potassium level superior to 5 mmol/L.

Results: Overall, 276 patients were included (mean age 62 ± 14 years, 75% males), 55% had hypertension, 20% diabetes mellitus and 14% previous myocardial infarction. Only 14% were pretreated with renin-angiotensin-aldosterone system inhibitors (RAASI). The median potassium at admission was 4 mmol/L (IQR 3.7 - 4.4 mmol/L), and the median creatinine level at admission was 0.88 mg/dL (IQR 0.74 - 1.1 mg/dL). 5-year all-cause mortality was 23%. Univariable analysis revealed that age (p < 0.001), previous myocardial infarction (p 0.038) and hyperkalaemia at admission (p 0.039) were associated with 5-year all-cause mortality. After adjustment for therapy with RAASIs, higher potassium level at admission was associated with 5-year all-cause mortality (adjusted HR 1.55, 95%CI 1.01-2.38; p 0.045).

Conclusions: In our study, potassium at admission was a predictor of 5-year all-cause mortality. Potassium measurement is an easy tool to help in risk stratification in this population. Further studies are needed to access if pharmacological control of potassium levels will change prognosis.

Machine Learning Models for Risk Prediction of Adverse Events in Hyperkalemic Patients

Fitchiro Kanda,1 Shun Kohsaka,2 Suguru Okami,3 Masafumi Okada,4 Xiaojun Ma,5 Toshitaka Yajima,1 Kazuaki Medical School, Kurashiki, Japan; 2Keio University, Tokyo, Japan; 3AstraZeneca K.K., Osaka, Japan; 4IQVIA Solution K.K., Tokyo, Japan.

Background: Hyperkalemia is a common electrolyte abnormality in heart failure (HF) and chronic kidney disease (CKD) patients. Although increased risks of adverse events in hyperkalemic patients have been well reported, there is limited information on causality of adverse events. Considering multifactorial conditions of hyperkalemic patients, we aimed to develop predictive models using novel machine learning algorithms.

Methods: We utilized a Japanese hospital claims registry, Medical Data Vision. We extracted hyperkalemic patients with either CKD and/or HF aged ≥18 years, defined as patients with ≥2 serum potassium values ≥5.1 mmol/L, from April 2008 to September 2018. Extracted dataset was split into 80:20 for training and validation. The risk of adverse clinical events including all-cause death, hospitalization for cardiac events, hospitalization for HF, and renal replacement therapy (RRT) introduction over 3 years after hyperkalemic episodes was modeled using gradient boosted tree (XG), neural network (NN), and logistic regression (LR) based on 81 clinical variables collected in 12 months before hyperkalemic episodes.

Results: Of 74,974 hyperkalemic patients, 8,480 patients were included. Mean age was 75.6 years and 53.7% were male. The ROC curve and calibration analyses showed excellent performance for death (AUC=0.841 [XG], 0.815 [NN], 0.838 [LR]), hospitalization for cardiac events (AUC=0.782 [XG], 0.718 [NN], 0.743 [LR]), HF (AUC=0.775 [XG], 0.850 [NN], 0.855 [LR]), and RRT (AUC=0.958 [XG], 0.917 [NN], 0.946 [LR]) (Table). Clinical variables with high importance were identified (Figure).

Conclusions: The machine learning model successfully identified high-risk hyperkalemic patients for adverse events. Despite the need for model validation, these results support the use of predictive models to select high-risk-hyperkalemic patients.

Extracellular Volume and Plasma Potassium Determine Urinary Prostaglandin E2 Excretion in Kidney Disease

Frank Geerts,1 Bovse,2 Martin Gritter,1 Erik J. van Bommel,3 Catherine A. Cuevas,1 Daniel H. van Raalte,1 Robert A. Fenton,2 Ewout J. Hoorn,1 Erasmus MC, Rotterdam, Netherlands; 2Aarhus University, Aarhus, Denmark; 3Amsterdam Universitair Medische Centra, Amsterdam, Netherlands.

Background: Prostaglandin E2 (PGE2) is the most abundantly produced prostaglandin in the kidney where it plays a key role in renin secretion and electrolyte handling. It is unknown whether urinary PGE2 excretion is a reflection of these functions in patients with kidney disease. Here, our aims were to (1) analyze the changes in urinary PGE2 excretion during interventions modulating extracellular volume (ECV) or electrolyte homeostasis and (2) identify the determinants of urinary PGE2 excretion.

Methods: Urinary PGE2 and PGE2 metabolite (PGEM) excretions were measured in 72 patients with kidney disease. Here, our aims were to (1) analyze the changes in urinary PGE2 excretion during interventions modulating extracellular volume (ECV) or electrolyte homeostasis and (2) identify the determinants of urinary PGE2 excretion.

Results: A low Na+ diet, amiloride/hydrochlorothiazide, and dapagliflozin reduced ECV and increased plasma renin. Amiloride/hydrochlorothiazide and dapagliflozin increased total urinary PGE2 excretion by 5.3% (95% CI 1.9-8.7%) and 5.8% (95% CI 0.9-10.8%), respectively, while a low Na+ diet increased PEGM excretion by 5.9% (95% CI 1.2-10.6%). Potassium supplementation had no effect on ECV, plasma renin, or urinary PGE2 excretion. The linear regression model of total urinary PGE2 excretion was associated with plasma renin (β ± 0.3, 95% CI 0.2-0.4), urinary Na+ excretion (β ± 0.003, 95% CI 0.0007-0.006), and plasma potassium (β ± 0.7, 95% CI 0.3-1.0).

Patient and Clinician Preferences for Hyperkalemia Treatment: A Qualitative Study

Rubeen K. Israfi,1 Anne B. Brooks,2 Tommi Tervonen,3 Joanna C. Huang,1 Harold M. Seerlip,4 AstraZeneca, Wilmington, DE; 2Evidera, London, United Kingdom; 3University Medical Center Groningen, Groningen, Netherlands; 4Baylor University Medical Center, Dallas, TX.

Background: Treatment options for chronic hyperkalemia include the potassium binders Kayexalate®, Veltassa®, and since 2018, Lokelma®. In a qualitative research study, we explored which treatment characteristics are important to patients with hyperkalemia and treating clinicians.

Methods: Adult patients in the US who had received treatment for chronic hyperkalemia in the past 12 months and US clinicians who had treated ≥10 patients with chronic hyperkalemia with potassium binders in the last 3 months participated in focus group discussions consisting of concept elicitation and a ranking exercise, guided by a semi-structured discussion guide, with potential attributes identified through review of product labels.

Results: Twenty-five patients (52.4 ± 14.8 years; 56% male; 32% on diastolic; 20% kidney transplant recipients) and eight clinicians (n=4 nephrologists, n=2 cardiologists, n=2 endocrinologists) participated. For patients, the most commonly reported medication side effect was diarrhea (64%), followed by abdominal pain and cramping (56%), nausea and/or vomiting, bloating/flatulence, and cramping in hands and legs (all 36%). The most disliked treatment characteristic was the medication’s taste/texture; 58% of patients ranked it among the five most important treatment characteristics. Among most patients reported gastrointestinal-related side effects, 54% did not rank diarrhea and 46% did not rank abdominal cramping in the top three characteristics. For clinicians, the most commonly encountered medication side effect was diarrhea (50%), followed by abdominal cramping (25%) and constipation (25%), and the most commonly considered treatment characteristic when prescribing a binder was taste/texture (50%), followed by time before/after taking medications (38%), time to onset (38%) and adherence (38%). Sustained efficacy followed by time to onset were ranked by 88% of clinicians as the two most important characteristics. Medication preparation, medication storage, and consumption were ranked low by both patients and clinicians.

Conclusions: Different potassium binder characteristics are most important to patients (taste/texture and abdominal cramping) and clinicians (sustained efficacy and time to onset). Clinicians showed that they take preference into consideration when prescribing a potassium binder.

Patient Palatability and Preference Study of Three Potassium Binders in Patients with CKD and Hyperkalemia: Rationale and Design of the APPETIZE Study

Glen James,1 Henning Sondergaard,2 Carol P. Moreno Quinn,3 Katarina Hedman,1 Niklas Karlsson,4 Jonatan Hedberg,1 Eric T. Wittbrodt,5 Ian Sabir,1 Eskinder Tafesse,1 Jennifer Kim,1 Robin L. Allgren,1 Harold M. Seerlip,4 AstraZeneca, PLC, Cambridge, United Kingdom; 2Danish Kidney Association, Copenhagen, Denmark; 3AstraZeneca, Gothenburg, Sweden; 4AstraZeneca, Gaithersburg, MD; 5University College London, London, United Kingdom; 6AstraZeneca, Taipei, Taiwan, “AstraZeneca, Gainesville, FL.

Background: Patients with CKD are at risk of hyperkalemia (HK) which has been associated with a higher risk of cardiovascular events and mortality. Recently approved K+ binders provide new treatment options to fulfill the unmet need for HK treatment beyond traditional K+ binders, which are poorly tolerated by patients and are associated with GI side effects.

Methods: APPETIZE is a cross-sectional, randomised cross-over study with the aim to evaluate the palatability of and patient preference for 3 currently available K+ binders: Sodium Polystyrene Sulphonate (SPS) or Calcium Polysulphonate (SPS), Sodium Zirconium Cyclosilicate (Lokelma®) and Calcium Patiromer Sorbitex (Veltassa®). A single (patient) blind side-by-side, sip and spit taste-test approach will be utilised where patients will be presented with a single full, per label dose of each product to replicate the real-world patient experience. Patient ratings, assessed on a 0-10 scale and emotional response using the AdSAM tool®, will be evaluated (Appeal, Engagement and Empowerment) will be used to assess patient centric attributes: taste (primary outcome), texture, smell, mouthfeel and likelihood of adherence (secondary outcomes) of each product. Preferential ranking will be performed after all 3 products have been tested. Sixty CKD patients (both dialysis and non-dialysis) with HK per country (480 overall) from US, Canada, Spain, Italy, Germany, France, Sweden and Norway will be included, with equal proportions of patients ever-treated and never-treated with K+ binders.

Funding: Appropriate Support - AstraZeneca
Results: APPETIZE will describe, compare and rank palatability and preference of 3 currently available K+ binders by country. Initial results are anticipated towards end of 2020.

Conclusions: Utilizing innovative methodology, APPETIZE will generate evidence intended for patients and physicians (including nephrologists and cardiologists) regarding patient palatability, patient preference and predicted likelihood of adherence for currently available K+ binders.

PO1457
Fixing the Kidneys to Fix the Heart: BRASH Syndrome, a Case Report

Introduction: BRASH (bradycardia, renal failure, AV-nodal blockade, shock, and hyperkalemia) is a multi-system syndrome. Immediate potassium removal is necessary and will result in normalization of cardiac arrhythmia.

Case Description: A 69 y/o male presented with generalized weakness, oliguria for 2 weeks and subsequence anuric. Lab was significant for hyperkalemia (6.2). EKG showed sinus bradycardia (HR 30), but without pathognomonic features of hyperkalemia. (Fig 1) Medical history significant for nephrectomy from an MVA injury, and IgA nephropathy s/p right renal transplant, hepatitis C, diabetes on insulin, and heart failure on Carvedilol 25mg BID. The patient was admitted to ICU and treated with calcium gluconate and insulin. Cardiology team was consulted for temporary pacers with eventual pacemaker insertion planned. However, upon discussion with the nephrology team, suspicion of BRASH syndrome was raised. Urgent CRRT was started. Rapid correction of potassium resulted in normalization of heart rate immediately. The patient received CRRT for 24 hours, and discharged on scheduled hemodialysis.

Discussion: BRASH syndrome is an uncommon presentation of a vicious cycle in the setting of hyperkalemia from acute kidney leading to the accumulation of AV node blockade medications. This synergizes bradycardia and hypoperfusion. Hypoperfusion, in turn, worsens renal failure leading to a cycle that continues until the patient deteriorates into lethargy, shock, and potentially death. Nowadays, despite commonplace to see patients with chronic kidney injury and cardiac diseases requiring AV nodal blocking medication, BRASH is still an underrecognized syndrome with only a handful of reported cases. Mild hyperkalemia without EKG changes make this diagnosis difficult, as such it is vital to recognize this syndrome from a multi-organ perspective - treatment with immediate correction of potassium via CRRT or hemodialysis can result in resolution without unnecessary transvenous pacing or pacemaker insertion.

PO1458
Laxative Use and Plasma Potassium Trajectory in Patients with Advanced CKD Transitioning to Dialysis
Keiichi Sumida,1 Ankur A. Dashputre,1 Praveen Kumar Potukuchi,1 Fridjof Thomas,1 Yoshitsugu Obi,2 Miklos Z. Molnar,1 Elan Streja,1 Kamyar Kalantar-Zadeh,3 Csaba P. Kovesdy,1,1 1The University of Tennessee Health Science Center, Memphis, TN; 2University of California Irvine, Irvine, CA.

Background: Intestinal potassium excretion is increased in patients with advanced CKD. This compensatory mechanism may be enhanced by laxative use; however, little is known about the association of laxative use with longitudinal potassium (K+) balance in advanced CKD.

Methods: In 34,697 US veterans who transitioned to ESRD from 2007-2015 and with ≥2 K+ measurements during the last 1-year period before ESRD transition, we examined the association of time-varying laxative use with change in K+ (slope) over the 1-year pre-ESRD period, using multivariable linear mixed-effects models. The difference in K+ slope by laxative use status was tested by the interaction of laxative use with time for K+ slope in the mixed-effects models.

Results: Overall, the mean age was 68 years; 98% were male; 32% were African American; and 76% were diabetic. In the crude model, there was a significant difference in K+ slope between laxative use and non-use, with declining K+ slope observed only for laxative use (median, -0.010 vs. 0.008 mEq/L/year, P=0.02; Table). Although the magnitude of K+ slopes was clinically negligible, the between-group difference remained significant even after multivariable adjustment, with laxative use being associated with decline in K+ (median, -0.013 vs. 0.003 mEq/L/year, P=0.02; Table).

Conclusions: Laxative use was modestly and independently associated with decline in K+ over the last 1-year pre-ESRD period, suggesting enhanced intestinal potassium excretion by laxatives. Further studies are warranted to test whether active interventions with laxatives can improve potassium management in advanced CKD beyond their traditional indication.

PO1459
Effect of Lactated Ringer Solution Use on Serum Potassium in Advanced Kidney Disease
Arun Rajasekaran, Naveen K. Bade, Abolfazl Zarjou. UAB, The University of Alabama at Birmingham, Birmingham, AL.

Background: Lactated Ringer’s (LR) solution is a balanced crystalloid containing 4 mEq/L of potassium (K). Its use is restricted in hyperkalemia and in those with advanced kidney disease given potential concerns of exacerbating hyperkalemia. We assessed the effect of LR on serum K levels in patients with advanced kidney disease [defined by estimated glomerular filtration rate (eGFR) of < 30 ml/min/1.73m2 - including patients with acute kidney injury (AKI)], chronic kidney disease (CKD), and end-stage kidney disease (ESKD) either on dialysis or post renal transplantation] admitted at the University of Alabama at Birmingham Hospital between 9/1/2017 to 9/1/2018 who received LR for resuscitation and its effect on serum K levels. We stratified patients based on renal function; accounted for concomitant medication use and frequently potentiate hyperkalemia, use of K supplements, blood transfusions immediately prior to LR use, presence of sepsis, and administration of tube feeds.

Results: Average age of patients was 59 years. 19 patients had AKI, 60 patients had AKD on CKD, 20 patients had known CKD, and 61 had ESKD (including 11 who had renal transplantation). Average LR use was 1.9L per patient. Hyperkalemia [defined by serum K ≥ 5.2 mEq/L] was seen in 27 patient encounters (14.1% of the study population). However, 16 of these patients had average K of 5.8 mEq/L prior to LR use. 11 among them were managed with medications alone and 4 patients needed dialysis. Average and highest K levels among all patients within 24-hour post LR use were 4.2 mEq/L and 4.4 mEq/L respectively. 131 patient encounters had sepsis. There was 1 death attributable to hyperkalemia.

Conclusions: 27 out of 191 patient encounters (14.1%) with advanced kidney disease without hyperkalemia were within 24 hours post LR use. Our study demonstrates that LR use is not independently associated with hyperkalemia in advanced kidney disease, a population subset who frequently cannot renally excrete K adequately. Further large scale clinical studies are warranted to confirm our findings.

PO1460
Association Between Dyskalemias and Short-Term Hospital/Emergency Department Visits in Patients with Advanced CKD Transitioning to Dialysis
Ankur A. Dashputre,1 Keiichi Sumida,1 Justin Ghatwood,1 Fridjof Thomas,1 Oguz Akbilgic,2 Praveen Kumar Potukuchi,1 Yoshitsugu Obi,1 Miklos Z. Molnar,1 Elan Streja,1 Kamyar Kalantar-Zadeh,3 Csaba P. Kovesdy,1,4 1The University of Tennessee Health Science Center, Memphis, TN; 2University of California Irvine, Irvine, CA; 3Merck & Co, Inc, Rahway, NJ; 4University of Alabama at Birmingham, Birmingham, AL.

Background: Patients with advanced CKD may experience immediate hospital/ emergency department (ED) visit due to dyskalemia-associated adverse events (e.g. arrhythmias). The association of dyskalemia within 24 hours post-LR administration, and 16 had known hyperkalemia prior to LR use. Our study demonstrates that LR use is not independently associated with hyperkalemia in advanced kidney disease, a population subset who frequently cannot renally excrete K adequately. Further large scale clinical studies are warranted to confirm our findings.

Methods: From among 102,477 US Veterans transitioning to dialysis between 2007-2015, we identified 21,150 patients with pre-dialysis eGFR <30 ml/min/1.73m2 and a concurrent plasma potassium (K) measurement. We examined the association of hypokalemia [K <3.5], hyperkalemia [K ≥5.5] and normokalemia [3.5-5.5, reference] with hospital/ED visits within 2 days of plasma K measurement using logistic regressions adjusted for sociodemographics, smoking status, comorbidities, BMI, healthcare encounters, SBP, medications and eGFR.

Results: The mean age of the cohort was 67.3 years; 98% were male; 32% were African American. The mean eGFR and K were 22.3 ml/min/1.73m2 and 4.6 mEq/L, respectively, and 7% and 3.5% of patients were hyper- and hypokalemic, respectively.

Funding: NIDDK Support

Changes in plasma potassium concentration associated with time-varying laxative use status during the last 1-year pre-ESRD period (n=34,697)

Funding: NIDDK Support

Changes in plasma potassium concentration associated with time-varying laxative use status during the last 1-year pre-ESRD period (n=34,697)
Three % of patients experienced a hospital/ED visit. Both hyper- and hypokalemia were significantly associated with higher risk of a hospital/ED visit in the crude (ORs [95% CIs] 2.73 [2.22-3.37] and 2.28 [1.68-3.09], respectively) and multivariable-adjusted models (2.47 [1.98-3.09] and 1.88 [1.37-2.58], respectively) (Figure).

Conclusions: Hyper- and hypokalemia are associated with higher short-term risk of hospital/ED visits in patients with advanced CKD. Preventing dyskalemias may help in reducing the incidence of short-term hospital/ED visit.

Funding: NIDDK Support

Association between dyskalemias and short-term hospital/emergency department visits in patients with advanced CKD

PO1461
Characteristics of CKD Patients with Hyperkalemia: A Report from the DISCOVER CKD Retrospective Cohort
Glenn James,1 Juan J. Carrero,2 Supriya R. Kumar,3 Steven Fishbane,4 Carol P. Moreno Quinn,1 Eric T. Wittbrodt,1 Eiichiro Kanda,5 Katarinia Hedman,5 Naoki Kashihara,5 Mikhail Kosiborod,6 Lam S. Carolyn,1,14 Carol A. Pollock,4 Peter Stenvinkel,5 David C. Wheeler,6 Roberto Pecorino-Filho,11,12 AstraZeneca UK Ltd, Cambridge, United Kingdom; Karolinska Institutet, Stockholm, Sweden; AstraZeneca, Gaithersburg, MD; Northwell, Manhasset, NY; Kawasaki Medical School, Kurashiki, Japan; AstraZeneca, Gothenburg, Sweden; Saint Luke’s Mid America Heart Institute, Kansas City, MO; University of Sydney, Sydney, NSW, Australia; Karolinska Universitetssjukhuset, Stockholm, Sweden; University College London, London, United Kingdom; Pontificia Universidad Catolica do Parana, Curitiba, Brazil; Arbor Research Collaborative for Health, Ann Arbor, MI; National Heart Centre Singapore, Singapore, Singapore; Duke-NUS Medical School, Singapore, Singapore.

Background: Hyperkalemia (HK), defined as serum potassium (sK+) >5.0 mmol/L, is a potentially fatal condition most often observed in patients with chronic kidney disease (CKD), heart failure (HF) or diabetes and exacerbated by medications that inhibit the renin-angiotensin aldosterone system (RAAS). This real-world study describes characteristics of patients with HK in a large observational international study of CKD patients.

Methods: The DISCOVER CKD retrospective cohort was extracted using the US TrifectaX hospital-EMR and Japan Medical Data Vision (IMDV) databases. The study included patients aged ≥18 years (>20 IMDV) with a diagnostic CKD code (stage 3A to Stage 5 including renal replacement therapy [RRT]) or 2 estimated glomerular filtration rate (eGFR) measures <75 mL/min/1.73m2 at least 90 days apart between January 2008 and March 2020. The index date was last sK+ measurement ≥5.0 mmol/L. Descriptive analyses were used.

Results: Preliminarily, 16436 CKD patients with HK (43% female, mean±SD age 72.2±13.7 years) were identified. Common comorbidities included HF, hypertension and type 2 diabetes, which increased in prevalence with increasing HK severity. Table 1. Mean eGFR was 43.3±24 mL/min/1.73m2 and mean sK+ was 5.4±0.5 mmol/L. HK severity, RAAS and diuretic use increased as mean eGFR decreased.

Conclusions: HK was more common in patients with significant comorbidities where RAAS inhibitors have evidence-based indications. Future analyses will determine whether HK limits appropriate management of these comorbidities.

PO1462
Ambulatory Treatments for RAAS Inhibitor-Related Hyperkalemia and the 1-Year Risk of Recurrence
Gregory L. Hundemer,1 Navdeep Tangri,2 Silvia J. Leon mantilla,2 Marish M. Sood.3 1Ottawa Hospital, Ottawa, Ottawa, ON, Canada; 2University of Manitoba, Winnipeg, MB, Canada.

Background: Hyperkalemia commonly occurs with RAAS inhibitor (RAASI) use. The effectiveness of common outpatient interventions in preventing recurrent hyperkalemia has never been directly compared.

Methods: Population-based, retrospective cohort study of Ontario (Canada) residents ≥66 years old on RAASI therapy with ≥1 outpatient hyperkalemia (≥5.3 mmol/L) measurements between 2007-16. RAASI included ACE inhibitors, ARBs, MR antagonists, and ENaC inhibitors. Patients were included if they had one of the following interventions performed within 30 days of the hyperkalemia measurement: a) RAASI discontinuation, b) RAASI dose decrease, c) new K+ wasting diuretic prescription, d) K+ wasting diuretic dose increase, or e) sodium polystyrene sulfonate [SPS] prescription. The primary outcome was recurrence of hyperkalemia within 1 year. Secondary outcomes included major adverse cardiovascular events (MACE) and all-cause mortality within 1 year. Multivariable Fine and Gray sub-distribution models accounting for the competing risk of death were used for recurrent hyperkalemia and MACE outcomes. Multivariable Cox proportional hazards models were used for the all-cause mortality outcome.

Results: A total of 21,723 patients were included: RAASI discontinuation (N=13,539), RAASI decrease (N=5,075), new diuretic (N=1,010), diuretic increase (N=1,245), and SPS prescription (N=154) interventions. RAASI discontinuation was associated with a lower risk for recurrent hyperkalemia and MACE over 1 year compared with other common hyperkalemia interventions (see Figure). However, there was no clear difference in 1-year all-cause mortality among these interventions.

Conclusions: RAASI discontinuation is associated with a lower 1-year risk for recurrent hyperkalemia and MACE compared with other common ambulatory interventions for hyperkalemia.
Case Description: A 63-year-old female with a history of diabetes mellitus, warm antibody autoimmune hemolytic anemia was admitted to the hospital with hypotension and hyperglycemia diagnosed on outpatient labs. Her hospital course was complicated with fevers, severe lactic acidosis, worsening thrombocytopenia and anemia. Infectious and rheumatologic workup was negative. Presumed diagnosis of secondary HLH was made with elevated serum ferritin (100,000 ng/ml), elevated triglyceride levels (346 mg/dl), low fibrinogen levels (70 mg/dl), fevers, bicytopenia and elevated soluble IL-2 receptor levels (34177 units/ml). She was treated with etoposide and dexamethasone for secondary HLH. Nephrology was consulted for hyperkalemia, metabolic acidosis and secondary HLH. Despite medical management with intravenous bicarbonate, the hyperkalemia persisted so RRT was initiated. Her potassium levels did not improve despite her serum pH increasing to 7.33. Serum lactate remained persistently elevated to 21 mmol/L. Neither high dialysate flow rates (DFR) up to 7.5 liters per hour with a 2 meq/ dl potassium bath nor hemodialysis which followed, using a zero potassium dialysate bath, lowered the potassium level. The patient continued to have a wide complex QRS interval on her ECG and episodes of ventricular tachycardia and zero potassium dialysate bath, lowered the potassium level. The patient continued to have excessive cytokine overproduction. Often, CRRT with higher DFR than recommended has been used in the past to achieve solute clearance. Our case was unique as the patient suffered from a cardiac arrest when her potassium was 6.9 meq/dl. Suspected malignancy was made with elevated serum ferritin (100,000 ng/ml), elevated triglyceride levels (346 mg/dl), low fibrinogen levels (70 mg/dl), fevers, bicytopenia and elevated soluble IL-2 receptor levels (34177 units/ml). The associations of laxative use with dyskalemias remained statistically significant even after multivariable adjustment (adjusted ORs [95% CI] for hypo- and hyperkalemia, 1.08 [1.02-1.13] and 0.79 [0.76-0.83], respectively; Table). The associations of laxative use with dyskalemias were independent of other confounders; the associations of laxative use with dyskalemias remained statistically significant even after multivariable adjustment (adjusted ORs [95% CI] for hypo- and hyperkalemia, 1.08 [1.02-1.13] and 0.79 [0.76-0.83], respectively; Table).

Results: The mean (SD) age of the cohort was 68 (11) years; 98% were male; 32% were African American; and 76% were diabetic. In the crude model, laxative use (vs. non-use) was significantly associated with higher risk of hyperkalaemia (OR [95% CI], 1.19 [1.13-1.25]) and lower risk of hyperkalaemia (0.74 [0.71-0.78]) (Table). The associations of laxative use with dyskalemias remained statistically significant even after multivariable adjustment (adjusted ORs [95% CI] for hypo- and hyperkalaemia, 1.08 [1.02-1.13] and 0.79 [0.76-0.83], respectively; Table).

Conclusions: Laxative use was independently associated with higher and lower risk of hypo- and hyperkalaemia, respectively, during the last 1-year pre-ESRD period. Our findings suggest the potential role of constipation in potassium disarray and the need for careful consideration for the risk-benefit profiles of laxatives in potassium management in advanced CKD.

Funding: NIDDK Support

Adjusted odds ratios (95% CI) for dyskalaemia associated with time-varying laxative use (vs. non-use) during the last 1-year pre-ESRD period (n=34,697)

1Model was adjusted for demographics, smoking status, BMI, comorbidities, length of hospital stay, in-hospital AKI, number of outpatient medical visits, and time-varying medication use and eGFR

Laxative Use and Incidence of Dyskalemia in Patients with Advanced CKD Transitioning to Dialysis

Keiichi Sumida,1 Ankur A. Dashputre,1 Praveen Kumar Potukuchi,1 Fridtjof Thomas,1,2 Yoshitsugu Obi,1 Miklos Z. Molnar,1 Elani Streja,2 Kamyar Kalantar-Zadeh,3 Csaba P. Kovessy,1 The University of Tennessee Health Science Center, Memphis, TN;2University of California Irvine, Irvine, CA.

Background: Intestinal potassium excretion is increased in patients with advanced CKD. This compensatory mechanism may be enhanced by laxative use; however, little is known about the association of laxative use with dyskalemias in advanced CKD.

Methods: In 34,697 US veterans who transitioned to ESRD from 2007-2015 and with ≥2 plasma potassium (K+) measurements during the last 1-year period before ESRD transition, we examined the association of time-varying laxative use with incidence of dyskalemia over the 1-year pre-ESRD period, using generalized estimating equations with adjustment for potential confounders. K+ levels were categorized as <3.5, 3.5-<5.5 (reference), and >5.5 meq/L at each K+ measurement and treated as a repeated measure.

Results: The mean (SD) age of the cohort was 68 (11) years; 98% were male; 32% were African American; and 76% were diabetic. In the crude model, laxative use (vs. non-use) was significantly associated with higher risk of hyperkalaemia (OR [95% CI], 1.19 [1.13-1.25]) and lower risk of hyperkalaemia (0.74 [0.71-0.78]) (Table). The associations of laxative use with dyskalemias remained statistically significant even after multivariable adjustment (adjusted ORs [95% CI] for hypo- and hyperkalaemia, 1.08 [1.02-1.13] and 0.79 [0.76-0.83], respectively; Table).

Conclusions: Laxative use was independently associated with higher and lower risk of hypo- and hyperkalaemia, respectively, during the last 1-year pre-ESRD period. Our findings suggest the potential role of constipation in potassium disarray and the need for careful consideration for the risk-benefit profiles of laxatives in potassium management in advanced CKD.

Acquired Bartter-Like Syndrome: An Unusual Presentation of Disseminated Tuberculosis

Isabelle Dominique V. Tomacruz, Anthony Russell Villanueva. Philippine General Hospital, Manila, Philippines.

Introduction: Acquired Bartter-like syndrome is a rare renal tubular disorder described to occur in granulomatous disorders such as sarcoidosis, but, its propensity to occur in tuberculosis (TB) is less known.

Case Description: We report the case of a 33-year-old Filipino woman with a 2-week history of lower extremity weakness. She had normal blood pressure and mild weakness on manual muscle testing. Abdominal examination revealed an incidental left lower quadrant mass. Workup revealed hypokalaemia with urinary potassium wasting, hypercalciuria, hyponogonadism, hypochloremia, and metabolic alkalosis, all consistent with Bartter-like syndrome. Abdominal CT scan findings were suggestive of disseminated TB. Ultrasound guided aspiration of the psoas abscess and pigtail insertion were done. Abscess aerobic, anaerobic, and fungal cultures did not isolate any organisms. Histopathology did not reveal any malignant cells. Detection of acid fast bacilli by Zielh-Neelsen stain and culture confirmed the diagnosis. The patient was started on anti-TB therapy and was maintained on spironolactone, potassium and magnesium supplementation upon discharge. On follow up, electrolyte abnormalities resolved after four months of anti-TB therapy.

Discussion: TB may be a rare acquired cause of Bartter-like syndrome. Management involves treatment of the underlying cause, spironolactone and electrolyte supplementation.
POI1466
Curious Case of Bartter Syndrome-Like Phenotype Unmasked by Diuretics
Prathima Gopinath, Krishna S. Ravipati, Pramodh Chanumolu, Siddhartha Kattamanchi. Marshfield Clinic Health System, Marshfield, WI.

Introduction: SLC12A1 mutations have been associated with Bartter syndrome type 1. Here we present a case of severe hypokalemia with diuretics which when investigated led to discovery of a novel SLC12A1 mutation which might have predisposed the patient to Bartter syndrome like phenotype.

Case Description: 68 y/o f with no history of hypokalemia developed heart failure with preserved ejection fraction and was started on low dose loope diuretics which was gradually increased to1-1.5 mg daily Bumetanide. She developed severe hypokalemia with diuretics which worsened with increasing diuretic doses, needing enormous amounts of potassium supplements. She continued to have persistent hypokalemia (serum potassium 3.0-3.5 mmol/L) with significant urinary potassium excretion despite being on 260 mEq of oral potassium supplement/day, which improved mildly with addition of Amiloride. She also was hypotensive and was alkalotic secondary to diuresis. Given the significant kaliuresis leading to severe hypokalemia which was out of proportion to the dose of diuretics we did Genetic testing for presence of Bartter’s mutation. Genetic testing revealed a novel heterozygous variant mutation in SLC12A1 gene. It showed 1972 C>T transition in exon 16 of SLC12A1 gene. This change converts a codon for leucine (CTT) to a codon for phenylalanine (TTT).

Discussion: Bartter syndrome (BS) type 1 is an autosomal recessive disorder caused by loss of function mutations. Mutations in SLC12A1 gene leading to dysfunction of NKCC2 co-transporter is one of the known mutations associated with Bartter’s syndrome. Bartter syndrome type 2 involves mutations in the ATP2B1 gene leading to loss of function mutations. Mutations in SLC12A1 gene leading to dysfunction of the NKCC2 co-transporter is one of the known mutations associated with Bartter’s syndrome. Our patient is unique as she has a novel heterozygous variant mutation in SLC12A1 gene and this mutation has not been reported to be associated with bartter syndrome. We believe this mutation might cause mild bartter phenotype. Our patient probably has a mild subclinical Bartter like phenotype secondary to heterozygous variant of the mutation and developed severe hypokalemia when exposed to loop diuretics. Pursuing genetic testing for appropriately severe hypokalemia needing exorbitant amount of potassium supplementation in a patient due to loop diuretic is a worthy consideration. Further research into this variant is needed to confirm it’s pathogenicity.

POI1467
A Case of the Cons: How Contraception Confused Congenital Adrenal Hyperplasia for Conn

Introduction: Drospirenone is a synthetic progestin oral contraception (OCP) with anti-androgen and anti-mineralocorticoid properties. We present a case of hypokalemic alkalosis and hypertension masked by drospirenone use.

Case Description: A 21-year old female with presumed polycystic ovarian syndrome (PCOS) was referred for hematuria, facial rash, and positive ANA concerning for lupus nephritis. Her only medication was drospirenone-ethinyl estradial for oligomenorrhea, acne and hirsutism. Blood pressure (BP) was 98/67mmhg and heart rate 88 bpm with orthostasis. She had male pattern hair loss and dense comedones on cheeks. Labs were significant for normal renal function, 2+ hematuria with ischemic RBCCs, negative BHCG and ANA titer 1:64. Glomerulonephritis and rhabdomyolysis work-ups were negative. Hematuria was attributed to breakthrough uterine bleeding. Gynecology held her OCP to allow for withdrawal bleeding. At 6-week follow-up, she reported muscle cramps and increased facial hair. BP was 176/98 mmhg. Hypertension was confirmed with ambulatory BP monitoring. Labs were significant for potassium 2.8 meq/L, bicarbonate 37 meq/L, urine sodium 14 meq/L, potassium 54 meq/L, chloride 38 meq/L. Mineralocorticoid excess due to primary hyperaldosteronism (Conn’s syndrome) was suspected but plasma renin activity was <1 and aldosterone was <1. Syndrome of apparent mineralocorticoid excess was considered but the presence of hirsutism prompted investigation of congenital adrenal hyperplasia (CAH). Work-up found elevated levels of ACTH (146 pg/ml), DHEA-S (694 mcg/dl), 11-deoxycortisone (452 ng/dl), and testosterone (92 ng/dl), but normal 17-OH progesterone, LH and FSH. Ultrasound showed bilateral adrenal enlargement, normal right and left ovaries with two dominant follicles. She declined genetic testing for 11-beta hydroxylase deficiency (11BHD). Clinical and lab findings were consistent with non-classical CAH due to 11BHD. She started hydrocortisone with suppression of ACTH, decrease in 11-deoxycortisone, and normalization of BP and electrolyte abnormalities.

Discussion: 11BHD is rare form of CAH, which can be confused with PCOS and other syndromes of mineralocorticoid excess. In this case, drospirenone use controlled symptoms but potentially delayed diagnosis of 11BHD. Clinical trials should assess drospirenone in treatment of endocrinopathies.
An Interesting Case of Hypokalemia

Adil Ghaffar, Tripti Singh. University of Wisconsin System, Madison, WI.

Introduction: Hypokalemia (serum potassium <3.5 mEq/L) is one of the most common abnormalities encountered in nephrology practice. With careful history and laboratory investigations, the cause can usually be found.

Case Description: A 68-year-old caucasian male with Hypertension was referred to the endocrinology department with a diagnosis of hypokalemia. Medica- tions included KCL 360 mEq/day, amlodipine, carvedilol, doxazosin, hydrozalcine, and losinopril. Labs showed hypokalemia (2.4 mmol/L) and metabolic alkalosis (HCO3 31 mmol/L). Urinary potassium losses were raised catecholamines. Adrenal hormone workup detected raised cortisol levels and ACTH levels. Renal potassium wasting was found.

Discussion: In the distal nephron, cortisol is inactivated to cortisone by 11-beta-dehydroxysteroid dehydrogenase 2 (11βHSD2). Hypercortisolism causes relative deficiency of 11βHSD2 due to enzyme saturation. Cortisone then stimulates non-selective MC receptor. Systematic workup led to diagnosis of ACTH-secreting pheochromocytoma. After resection of ectopic ACT source, patient became normokalemic and was discharged with steroid replacement.

Thyrotoxic Periodic Paralysis: A Stunning Diagnosis
Piotr Starakiewicz, Syed A. Husain. Columbia University Irving Medical Center, New York, NY.

Introduction: Thyrotoxic periodic paralysis (TPP), acute hypokalemia and proximal muscle weakness in the setting of thyrotoxicosis, is primarily seen in Asian men with undiagnosed hyperthyroidism in the 2nd-4th decade, often with family history of paralysis and thyroid disease. We describe a case of a young male presenting with acute TPP.

Case Description: A 28-year-old white male with no medical history presented with acute onset diffuse weakness with inability to get out of bed, preceded the night prior by leg stiffness. He exercised 2 days prior. He reported marijuana use and a balanced diet. He denied recent travel, medication or supplements. His father had Hashimoto’s thyroiditis. Exam showed tachycardia (106 bpm) and hypertension (132/74 mmHg), and EKG revealed sinus tachycardia with QTc 629. Labs showed: K+ 1.7 mEq/L, HCO3- 25mmol/L, Cr 0.7 mg/dL, TSH <0.01, fT4 >6ng/dL, and T3 320ng/dL. Fractional excretion of K+ was 3.2%. He was treated with 120mEq KCl with repeat K+ of 5.6 mEq/L in 4 hours and symptom resolution. Elevated TSH receptor, anti-thyroglobulin, and thyroid stimulating antibodies with a homogenous radioactive iodine uptake scan [Fig 1] confirmed Grave’s disease. He was started on metoprolol and methimazole and discharged home without further episodes.

Discussion: TPP results from acute intracellular K+ shift due to Na/K-ATPase activation in myocytes from a hyperadrenergic state (increased number and sensitivity of β-receptors) and thyroid hormone stimulation. Muscle hyperpolarization and loss of excitability required for contraction results. Body K+ stores remain unchanged. Episodes are associated with high insulin or epinephrine states (e.g. mornings, exercise, high-carbohydrate meal). Paralysis, lasting minutes to days, is ascending, symmetrical, and proximal, chiefly affecting legs (bulbar or respiratory involvement is rare). Usually painless, it can be preceded by muscle aches or cramps. Sinus tachycardia is common and life-threatening arrhythmias can occur. Labs demonstrate normal acid-base status and low urinary K. CPK can be elevated. Low TSH, elevated free T4 and T3 confirm the diagnosis. Treatment involves cautious K replacement (due to risk of rebound hyperkalemia), non-selective β-blockers, and therapy for hyperthyroid state.
CYP24A1-Hypercalcemia in Pregnancy

Sana J. Shaikh,1,2 Anitha Vijayan.1 1Washington University in Saint Louis, Saint Louis, MO; 2Barnes-Jewish Hospital, Saint Louis, MO.

Introduction: Hypercalcemia due to primary hyperparathyroidism and malignancy is common. However, rare genetic mutations in VitD metabolism (CYP24A1 & SLC34A1) are often culprits.

Case Description: 33-year-old woman with chronic hypercalcemia, nephrocalcinosis, CKD 3, HTN was admitted at 34-weeks of gestation for symptomatic hypercalcemia (13.2 mg/dL). Labs showed ↓PTH (9 pg/mL), ↓25-VitD (35 ng/mL) & ↑↑1,25-VitD (65 pg/mL). Defect in VitD pathway was suspected. 25-VitD:24,25-VitD ratio returned (13.2 mg/dL). Labs showed ↓PTH (9 pg/mL), ↓/↔25-VitD (35 ng/mL) & ↑↑1,25-VitD & 25-VitD. 25-VitD:24,25-VitD > 80 warrants genetic analysis. Azoles inhibit 1-hydroxylase & urinary calcium, ↓PTH,

Discussion: CYP24A1 gene encodes 24-hydroxylase which inactivates 25-VitD and 1,25-VitD to 24,25-VitD and 1,24,25-Vit D. Biochemical profile includes ↑ serum & urinary calcium, ↓PTH, ↓25-VitD:24,25-VitD ratio & ↑ 1,25-VitD & 25-VitD. 25-VitD:24,25-VitD > 80 warrants genetic analysis. Azoles inhibit 1-hydroxylase and ↓1,25-VitD, and can be utilized. Steroids ↓1,25-VitD production by activated macrophages, inhibit intestinal calcium absorption and induce CYP24A1, but this cohort is often resistant. Pregnancy upregulates 1-hydroxylase, rendering patients with CYP24A1 mutations sensitive to hypercalcemia. Antepartum therapy options are limited. To limit adverse impact on maternal and fetal health, delivery may be required.

Maternal hypercalcemia with CYP24A1 mutations

POI473
A Case of Medication-Induced Hypercalcemia: But It Is Not What You Think
Harsha Aramada, Ashish Sharma, Khaled Nashar. Allegheny General Hospital - Western Pennsylvania Hospital Medical Education Consortium, Pittsburgh, PA.

Introduction: Hypercalcemia is a life-threatening complication of CKD. Patients with diabetes mellitus, congestive heart failure, and those receiving renin angiotensin aldosterone inhibitors are at particularly high risk of developing hypercalcemia. We present a case of hypercalcemia, possibly related to patiromer.

Case Description: A 71-year-old man with past medical history of hypertension, right nephrectomy for renal cell cancer and chronic kidney disease stage G1bIV A3. Serum Cr levels range was 3.5-3.9 mg/dL. Patient was placed on losartan 100 mg to slow the progression of his CKD, and as result he developed mild to moderate hypercalcemia (5.6-2.0 ng/dL). His hypercalcemia persisted despite dietary modification. Patiromer was begun at a dose of 8.4 g/day. Dose was uptitrated to 25.2 g/day to maintain potassium levels < 5.5 mEq/dL. A few months later he developed mild hypercalcemia with serum calcium levels ranging between 10.4-11.5 mg/dL. The patient was not receiving any oral calcium or vitamin D supplements. His work up included 25 hydroxy Vit D and 1-25 dihydroxy vitamin D levels which were normal at 28 mg/mL and 40 pg/mL respectively. Magnesium levels were normal 1.8-2.0 mg/dL. His PTH level was suppressed for his level of kidney function at 13pg/mL. TSH level was normal at 4 mIU/L. PTH-rp was 13 (normal: 14-27). Urine and serum protein electrophoresis did not reveal paraproteinemias. Given the absence of a clear explanation for his non-PTH mediated hypercalcemia, we present a case of hypercalcemia, possibly related to patiromer.

Discussion: Patiromer is a cation exchange resin approved by the FDA in 2015 for the treatment of hypercalcemia. It binds to potassium in exchange for calcium predominantly in distal colon, facilitating increased fecal potassium excretion. Clinical trials that led to the approval of patiromer did not find any increase in serum calcium levels. However, hypomagnesemia was noted. This prompted the recommendation for the need to monitor magnesium levels while receiving the drug. There are only two other reports in the literature of hypercalcemia attributed to patiromer. Our findings call for further investigation and the need for monitoring serum calcium following the initiation of this treatment.

POI474
An Unusual Source of Hypercalcemia
JoBeth McCoy. Vanderbilt University Medical Center, Nashville, TN.

Introduction: Hypercalcemia is a common electrolyte abnormality seen in daily practice. This case describes elevated serum calcium from a common cause, but an unexpected source.

Case Description: A 62-year-old female presented with complaints of fatigue, weight loss, and weakness. She was found to have a calcium level of 14 mg/dL, acute kidney injury with a creatinine of 2.9 mg/dL from a baseline of 1.6 mg/dL, and severe weight loss of 60lbs in the past 6 months. She had been evaluated for malignancy with no concerning findings. Initial workup included: parathyroid hormone (PTH) 8pg/mL, 25, vitamin D 22ng/mL, and creatinine phosphokinase 75u/L. There was concern for occult malignancy so further workup included a serum and urine protein electrophoresis that was negative, parathyroid hormone-related protein (PTHrp), 1,25 dihydroxy vitamin D, and Histoplasma antigen. She had a full-body computed tomography (CT) scan without contrast to look for occult malignancy which was negative for any granulomas, masses, adenopathy, or bony lesions. 1,25 vitamin D was elevated at 238 pg/mL. PTHrp was...
PO1475
Amiloride Effects on Urine Calcium in the Setting of Urolithiasis
Kian Ahmadied,1 Jonathan Moore,1 Maya Patel,1 Mira T. Keddis,1 Karen L. Stern.1 1Mayo Clinic Arizona, Scottsdale, AZ; 2The University of Arizona College of Medicine Phoenix, Phoenix, AZ.

Background: Medical management of urolithiasis often targets the biochemical properties of urine to prevent further development of stone burden. Thiazide diuretics are commonly used for recurrent stone formation in patients with hypercalciuria. However, data related to the use of potassium-sparing diuretic amiloride is relatively scarce and the aim of this study is to investigate amiloride’s effects on urinary calcium and other properties of urine in prevention of urolithiasis.

Methods: All nephrolithiasis patients who were prescribed amiloride for treatment of hypercalciuria between the years 2011 and 2019 at a single tertiary care center were retrospectively reviewed. Patients met criteria if they had a pre and post treatment 24 hour urine collections. Pre and post urinary calcium levels were compared. Other comparative measures include levels of other stone risk factors measured on urine collections, stone events on treatment and adverse reaction to medication.

Results: A total of 15 patients were started on amiloride. Of those, 15 patients tolerated the medication and completed follow-up urine testing. Amiloride was given due to intolerance of thiazide (11, 73%), persistent hypercalciuria on thiazide (3, 20%), or as combination with thiazide (1, 7%). Maximum treatment dose ranged from 2.5 mg daily to 5 mg BID. Mean duration on treatment was 57.2 months (SD 32.5;9-96). Three (20%) patients stopped due to delayed intolerance and 2 (13%) due to elevated urinary calcium. In the overall cohort, there was no significant difference in urine parameters (Table 1) including urinary calcium (286.3 mg/day pre vs 310.0 mg/day post, p=0.552). Daily urine calcium ranged from 11 mg to 165 mg. Three (20%) patients had a 24 hour urine collection with values greater than 12 mg and were started on thiazide. Amiloride was given to one patient due to intolerance of thiazide, one patient due to persistent hypercalciuria on thiazide, and one due to progression of stone disease.

Conclusions: In patients that have failed thiazides for treatment of hypercalciuria, switching to or adding amiloride did not result in lower urinary calcium levels.

PO1476
Hospital-Acquired Phosphate Derangements and Associated In-Hospital Mortality
Michael A. Mao,1 Charat Thongprayoon,2 Wisit Cheungpasitporn,3 Api Chewcharat,2 Kianoush Kashani.3 1Mayo Clinic's Campus in Florida, Jacksonville, FL; 2Mayo Clinic Minnesota, Rochester, MN; 3University of Mississippi Medical Center, Jackson, MS.

Background: We aimed to report the incidence of hospital-acquired hypophosphatemia and hyperphosphatemia along with their associated in-hospital mortality.

Methods: We included 15,869 adult patients hospitalized at a tertiary medical referral center from January 2009 to December 2013 that had normal serum phosphate levels at admission and at least two serum phosphate measurements during their hospitalization. The normal range of serum phosphate was defined as 2.5-4.2 mg/dL. In-hospital serum phosphate levels were categorized based on the occurrence of hospital-acquired hypophosphatemia and hyperphosphatemia. We defined hypophosphatemia as phosphate level <0.5 mg/dL and hyperphosphatemia as phosphate level >4.2 mg/dL.

Results: Fifty-four percent of patients developed new serum phosphate derangements during their hospitalization. The incidence of hospital-acquired hypophosphatemia and hyperphosphatemia was 11% and 1%, respectively. Hyperphosphatemia was associated with odds of 1.56 and 2.60 for in-hospital mortality, respectively (P-value<0.001 for both). Compared with patients with persistently normal in-hospital phosphate levels, patients with hospital-acquired hypophosphatemia only (OR 1.64), hospital-acquired hyperphosphatemia only (OR 2.74), and both hospital-acquired hypophosphatemia and hyperphosphatemia (i.e., phosphate fluctuations; OR 4.00) were significantly associated with increased in-hospital mortality (all p-value<0.001).

Discussion: Hospital-acquired serum phosphate derangements affect approximately half of hospitalized patients and are associated with increased in-hospital mortality rate.
Discussion: Hypermagnesemia is a rare event and occurs in the context of high dose Mg infusion (ie. eclampsia treatment) or Mg ingestion in acute or chronic kidney disease. Mg acts as a calcium channel blocker, causing hypotension, bradycardia, muscle paralysis, somnolence, hypocalcemia, respiratory failure, and eventually cardiac arrest. The severity of manifestations is concentration dependent. Management includes IV fluids (if the patient is making urine). Hemodialysis is often required for those with severe AKI or ESRD. This case illustrates the challenges of care coordination and duplicate medication prescribing among multiple physicians/ practices. OIC was preventable with a bowel regimen. She received 3 different NSAIDs while on AKI. Magnesium citrate was rapidly absorbed systemically in the context of ileus and Mg toxicity developed in the setting of low GFR. Nephrology consultation was delayed, resulting in prolonged severe hypotension, late hemodialysis initiation and ultimately death. These complications were entirely avoidable with a more thoughtful approach to medication prescribing.

Introduction: Magnesium is a relatively safe over-the-counter cathartic and antacid, but may have dangerous side effects. Hypermagnesemia can be precipitated by renal insufficiency, active gastrointestinal illness, or excessive intake of magnesium. Symptoms, which include neuromuscular and cardiovascular effects, can start when levels exceed 4.8mg/dL.

Case Description: A 60-year-old female with a medical history of bipolar affective disorder, seizures, migraines, type 2 diabetes, and past subarachnoid hemorrhage presented with slurred speech and weakness leading to a fall. She complained of chronic constipation and had taken an unknown amount of milk of magnesia with her docusate. Neurologic exam revealed slowed speech and symmetric muscle weakness. Labs revealed sodium 128 mmol/L, creatinine 1.03 (baseline 0.5) mg/dL, magnesium 10.0mg/dL, calcium 8.0mg/dL, and phosphate 6.5mg/dL. After imaging ruled out any intracranial pathology, the patient was diagnosed with hypermagnesemia, then started on IV fluids and loop diuretics. Her electrolytes and kidney function continued to correct with hydration, diuretic therapy, and stopping all magnesium-containing medications. It was discovered that she had ingested 52 grams of magnesium by drinking two 26oz bottles. Her weakness improved throughout the second day and returned to full muscle strength by the third. She was discharged with a magnesium level of 2.3mg/dL.

Conclusion: This case demonstrates the importance of physician awareness regarding the effects of hypermagnesemia. Although hypermagnesemia is multiple symptoms, “few clinicians associate these symptoms with high levels of serum magnesium, due to an overall unfamiliarity with this condition.” An article reported that more than 86% of patients with hypermagnesemia are clinically unrecognized, and in most hospitals, the treatment is based on the physician’s judgement. Treatment consists of magnesium removal (IV fluids, loop diuretics, or dialysis), stopping magnesium use, and gastrointestinal decontamination. Calcium can also be used as an antagonist by competitively inhibiting magnesium. Prompt recognition is necessary because when magnesium levels are greater than 7.2mg/dL, patients can develop hemodynamic changes (bradycardia, hypotension) and once levels exceed 12mg/dL, symptoms could become fatal (respiratory failure, heart block, cardiac arrest, and flaccid quadriplegia).

PO1480 Clinicopathological Characteristics and Long-Term Prognosis of Monoclonal Immunoglobulin Light Chain-Associated Fanconi Syndrome Jiaying Li, Xiaoxiao Shi, Peng Xia, Limeng Chen. Peking Union Medical College Hospital, Dongcheng-qu, China.

Background: Monoclonal immunoglobulin light chain associated Fanconi syndrome (LC-FS) is a rare disease which involved the proximal tubules. As most of the cases came from western countries, we aimed to analyze the clinicopathological characteristics of Asian LC-FS and its long-term prognosis.

Methods: From January 1998 to February 2019, 26 patients who were diagnosed with both FS and monoclonal gammopathy in Peking Union Medical College Hospital were included in this study. Clinicopathological data was retrospectively reviewed.

Results: At diagnosis, the mean age of the 26 Asian LC-FS patients was 54.7±26.4) ml/min/1.73m2, with 33% were notable for edema at the most recent visit. Indeed, overall the rate of edema increases as renal function declines. More recently, metabolic acidosis has been identified as a key risk factor for the progression of CKD in addition to being linked to increased risk of renal osteodystrophy and muscle wasting. Presently, there are no FDA indicated therapies for the treatment of chronic metabolic acidosis, though sodium bicarbonate is commonly used to try to maintain serum bicarbonate levels in the normal range (22 – 29Eq/L). We sought to understand how prevalent metabolic acidosis is in a real world setting.

Methods: Patient level data was collected online via a HIPAA-compliant form in November 2019 as part of an independent chart audit. A total of 1,008 patient records were submitted by 201 nephrologists. Records were selected based on the most recently seen non-dialysis patients in the outpatient setting with an eGFR<60mL/min/1.73m2.

Conclusions: Metformin is a first line medicine in the treatment of diabetes mellitus, but it rarely cause lactic acidosis, usually in patients with acute or chronic kidney disease stage III onwards. We report a case of lactic acidosis associated with severe lactic acidosis in a patient with diabetes on metformin and show that the ophthalmologic symptoms may not be a direct result of the severe lactic acidemia.

Case Description: A 77 year old female with CKD stage III and type 2 diabetes on metformin twice daily developed confusion, hypoglycemia and sudden visual loss. Over the prior 3 days, she had nausea, vomiting and diarrhea as well as a reduced urine output. On admission to the hospital, her vitals were stable. She had no other focal neurologic deficits. Her creatinine was 4.4 mg/dl (with a baseline of 1.4), potassium 5.9 mmol/L, bicarbonate 3.3 mmol/L and blood lactate 23.8 mmol/L. Her arterial blood pH was 6.7. She underwent emergent hemodialysis and mid-way through her 4 hour session, she had complete resolution of her visual loss. By the end of her dialysis, her bicarbonate rose to 18. Ultimately, in a few months, she recovered her renal function back to a serum creatinine of 1.8–1.9, a little higher than her baseline.

Discussion: Some publications suggest vision loss (due to effect on retinal horizontal cell function) and optic nerve ischemia are associated with metformin induced lactic acidosis (MALA) at pH <7.09. It improves after correction of acidosis. But, in our case, the vision improved even before the acidemia corrected. We suggest that, since acute reversible blindness has been described with MALA, but not in patients with hypotension- or sepsis-induced lactic acidosis, this neurologic symptom may be a direct result of abnormal retinal horizontal cell function induced by metformin at a low pH, or the metabolic effects of metformin, rather than due to the acidemia alone. Hemodialysis helps correct electrolyte abnormalities and lactic acidosis. Also, metformin has a large volume of distribution. Its removal by dialysis is uncertain. But there are some case reports suggesting its clearance by HD. Further studies are thus warranted.

Metabolic Acidosis Is a Predictive Factor for All-Cause Mortality in Patients with CKD

Navdeep Tangri,1 Nancy L. Reaven,2 Susan E. Funk,2 Vandana S. Mathur,3
1University of Miami, Winnipeg, MB, Canada; 2Strategic Health Resources, La Canada, CA; 3Mathur Consulting, Woodside, CA.

Background: The consequences of metabolic acidosis are wide-ranging, consistent with the fact that many critical cell functions require physiologic pH (Salameh AI, Am J Physiol Regul Integr Comp Physiol 2014). The extent to which metabolic acidosis contributes to mortality in patients with chronic kidney disease (CKD) is unknown.

Methods: Optum® de-identified Electronic Health Records dataset 2007 to 2017 was queried to identify patients with non-dialysis CKD Stages 3-5 with available metabolic acidosis laboratory values. The study population included patients ≥ 21 years of age with ≥ 2 abnormal metabolic acidosis values measured at ≥ 24 hours apart. The primary outcome assessed was all-cause mortality. Secondary outcomes included all-cause readmissions within 1 year. The analysis was adjusted for age, sex, race, pre-existing comorbidities, and baseline eGFR and ACR.

Results: 51,558 patients qualified for analysis; 17,350 with metabolic acidosis, 34,208 with normal serum bicarbonate at baseline. Unadjusted rates of mortality within 2 years were higher among patients with metabolic acidosis vs. normal serum bicarbonate (30.9% vs. 10.2%, respectively, P < 0.0001) and within all CKD stages (P < 0.001). Each 1 mEq/L lower serum bicarbonate value was independently associated with a 15% higher risk of all-cause mortality, OR: 0.853, 95% CI: 0.846-0.861. These findings were consistent in subgroup and sensitivity analyses.

Conclusions: The presence of metabolic acidosis was associated with a high 2-year risk of all-cause death in patients with CKD. This finding was independent of age, sex, race, pre-existing comorbidities, and baseline eGFR and ACR.

PO1485

Lactate Gap as Initial Indicator for Ethylene Glycol Toxicity

Varun Madireddy, Mark A. Finger. Zucker School of Medicine at Hofstra/ Northwell, Great Neck, NY, Hempstead, NY.

Introduction: Ethylene glycol poisoning is a medical emergency which on initial presentation can be missed if the clinician does not have a high index of suspicion. Treatment of ethylene glycol toxicity is time dependent in preventing morbidity and mortality, thus early recognition and intervention is of critical value. In this case report we aim to focus on the lactate gap as the first indicator of ingestion.

Case Description: 50-year-old female was brought in by EMS after being found unresponsive and covered in vomitus. Vital signs were stable. The patient was thought to have had a severe causing the lactic acidosis and was post ictal. Labs are shown below. Ethylene glycol toxicity was made the presumptive diagnosis. The patient was transferred to the medical ICU and given a loading dose of fomepizole while hemodialysis was being arranged. The patient then had one session of hemodialysis in the medical ICU and repeat blood gas is displayed below.

Discussion: The diagnosis of ethylene glycol poisoning remains challenging due to non-specific signs and symptoms on presentation. Presentation and lab values may differ depending on the time and amount since ingestion. Access to real-time ethylene glycol concentration is uncommon in many health facilities, so the diagnosis relies upon a high index of suspicion. Laboratory studies, specifically the “lactate gap”, can be used in aiding the diagnosis. The “lactate gap” is a lab artefact due to a chemical cross reaction. Most POC whole blood analyzers use the enzyme lactate oxidase which cross reacts with the breakdown products of ethylene glycol, specifically glycolate. The lab instrument cannot differentiate between lactate and glycolate because of their structural similarity. Laboratory serum analyzers which are used for routine venous blood samples have less cross-reactivity and thus show a minimal elevation of lactate in comparison. In addition to securing the diagnosis, the lactate gap can be used to monitor clearance of the glycolic metabolites.

Anion Gap (AG) and Negative Osmotic Gap (OG) due to Remdesivir's (R) Exciipient

Sameer Alaqssamii,2 Octavio Chavez,1 Claude Bassili,1 Pranal Jain,3 Jacques A. Durr.1 USF Health Nephrology and Hypertension ’USF Health Morsani College of Medicine, Tampa, FL; 2Jazan University Faculty of Medicine, Jazan, Saudi Arabia; 3Florida Kidney Physicians, Tampa, FL.

Introduction: The FDA authorized R for COVID-19. Excess Na sulfobutyl ether (SBE) substituted β-cyclodextrin (CD) solubilizes R (PMID: 32376442). Minute accumulation of SBECD can cause an AG as its substitution in R contributes to mortality in patients with chronic kidney disease (CKD) is unknown. The extent to which metabolic acidosis contributes to mortality in patients with chronic kidney disease (CKD) is unknown.

Methods: Optum® de-identified Electronic Health Records dataset 2007 to 2017 was queried to identify patients with non-dialysis CKD Stages 3-5 with available metabolic acidosis laboratory values. The study population included patients ≥ 21 years of age with ≥ 2 abnormal metabolic acidosis values measured at ≥ 24 hours apart. The primary outcome assessed was all-cause mortality. Secondary outcomes included all-cause readmissions within 1 year. The analysis was adjusted for age, sex, race, pre-existing comorbidities, and baseline eGFR and ACR.

Results: 51,558 patients qualified for analysis; 17,350 with metabolic acidosis, 34,208 with normal serum bicarbonate at baseline. Unadjusted rates of mortality within 2 years were higher among patients with metabolic acidosis vs. normal serum bicarbonate (30.9% vs. 10.2%, respectively, P < 0.0001) and within all CKD stages (P < 0.001). Each 1 mEq/L lower serum bicarbonate value was independently associated with a 15% higher risk of all-cause mortality, OR: 0.853, 95% CI: 0.846-0.861. These findings were consistent in subgroup and sensitivity analyses.

Conclusions: The presence of metabolic acidosis was associated with a high 2-year risk of all-cause death in patients with CKD. This finding was independent of age, sex, race, pre-existing comorbidities, and baseline eGFR and ACR.

Anion Gap and Cardiovascular Mortality
Ashish Verma,1 Sonu Subudhi,2 Ankit B. Patel,1 Maria Clarissa Tio,1 Sushrut S. Waikar,1 1Brigham and Women’s Hospital, Boston, MA; 2Massachusetts General Hospital, Boston, MA; 3Boston University Medical Campus, Boston, MA.

Background: Anion gap has been shown to be independently associated with hypertension, but the association of anion gap and cardiovascular mortality has been unexplored.

Methods: We conducted a prospective cohort study using the National Health and Nutrition Examination Survey (NHANES), a nationally representative cross-sectional survey of the US non-institutionalized population. Anion gap (mEq/L) was calculated as serum sodium (mmol/L) - (serum chloride (mmol/L) + serum bicarbonate (mmol/L)). We used weighted Cox proportional hazards models to assess the associations between anion gap with cardiovascular specific mortality, as recorded by the National Death Index. Multivariable models were adjusted for demographics data, BMI, smoking status, diabetes, systolic blood pressure, cardiovascular disease history, ACEi/ARB, diuretics, serum albumin, total cholesterol, total protein, total calorie intake, hemoglobin, cancer diagnosis, eGFR and urine albumin and creatinine ratio.

Results: This study was performed on 39,189 participants (mean [SD] age, 46.86 [19.25] years; 20,194 (51.5%) female). During 875 (4436210 weighted) person-years of follow-up, 936 participants (3169889 weighted participants) died of cardiovascular disease. A history of cardiovascular disease at the time of enrollment was reported in 3875 (9.8%). Figure 1 shows the associations between anion gap in tertiles with cardiovascular related mortality. In analyses restricted to those with a history of cardiovascular disease the results were 116% increased risk for cardiovascular mortality [HR 2.16; 95% CI (1.37,3.4)].

Conclusions: Higher anion gap may be a risk factor for cardiovascular-related mortality in adults.

Figure 1. Risk of cardiovascular mortality according to anion gap as tertiles (method = weighted survey cox regression)

POI1488
Profound Lactic Acidosis due to Dextrose Infusion and the Role of Thiamine
Kristen B. Lile, Sarah Faubel. University of Colorado, Denver, CO.

Introduction: Severe metabolic acidosis due to dextrose infusion is a rare but life-threatening complication for which treatment options are poorly described. Normally dextrose is metabolized to pyruvate during glycolysis. Pyruvate is converted to acetyl-CoA via pyruvate dehydrogenase (PDH); this requires abundant oxygen. Thiamine is an essential cofactor for PDH. During anaerobic conditions pyruvate is converted to lactate during a process known as anaerobic glycolysis, producing a type A lactate. Pyruvate may also be converted to lactate when oxygen levels are normal via aerobic glycolysis. Aerobic glycolysis produces type B lactate and occurs due to a number of conditions, including thiamine deficiency.

Case Description: A 54-year-old woman with malignant insulinoma was admitted for severe hypoglycemia. The patient was given continuous 20% dextrose infusion; she developed severe lactic acidosis on day seven. Serum bicarbonate was undetectable on blood gas at the time of renal consult; serum lactate was >20. The patient was decompensated due to the acidosis, became obtunded, was intubated, and was placed on continuous renal replacement therapy (CRRT). The acidosis failed to improve for 36 hours. Thiamine therapy was begun in an attempt to restore function of the PDH complex and restart the metabolism of pyruvate through the citric acid cycle, limiting further type B lactate production. Within hours, lactate levels fell with parallel rise in serum pH. The patient was extubated, alert, and taken off CRRT within 24 hours of beginning thiamine therapy.

Discussion: This patient developed a profound metabolic acidosis secondary to type B lactic acidosis via accelerated glycolysis from dextrose infusion. This case highlights the intricate regulation of dextrose metabolism as well as thiamine as a vital therapy in type B lactic acidosis. Thiamine therapy was key, presumably reinitiating aerobic respiration through the PDH complex and ultimately leading to cessation of lactate production. Given the critical role of thiamine in this case, it is plausible that thiamine could be crucial for other cases of metabolic acidosis, particularly those secondary to type B lactic acidosis.

POI1489
Persistent Lactic Acidosis due to Thiamine Deficiency
Mita Zahra E. Co,1 Zhwei Zhang,2 Loma Linda University Medical Center, Loma Linda, CA; 1VA Loma Linda Healthcare System, Loma Linda, CA.

Introduction: Lactic acidosis is one of the most common causes of metabolic acidosis in hospitalized patients. Clinically it is usually associated with obviously impaired tissue oxygenation, but also occurs in situations where systemic impairment in oxygenation does not exist or is not readily apparent. Here we present a case of persistent lactic acidosis found to be due to thiamine deficiency and resolved rapidly after thiamine supplementation.

Case Description: A 38-year-old woman presented with 4-day history of abdominal pain, vomiting, diarrhea, and not able to eat. She has a history of alcoholism in remission, vitamin B12 deficiency, FTSD and bipolar disorder. Her medications included ciprofloxacin, delirium tremens, lithium, trazodone, and risperidone. Vital signs were normal except for mild sinus tachycardia, and the rest of her examination was unremarkable.

Laboratory results indicated normal CBC, glucose, BUN, Cr, LFT, and urine analysis. Serum Na, K, Mg, Ca, and PO4 were all low. Serum ethanol and salicylate were not detected, and urine drug screen was negative. Serum HCO3 was low at 14 mmol/L with anion gap of 26. Serum ketone was negative, but serum lactic acid was severely elevated at 9 mmol/L. ABG was consistent with compensated metabolic acidosis. Cardiac echo and other imaging studies did not reveal significant abnormalities. The patient received intravenous fluid replacement and supplementation for various electrolyte abnormalities.

While her symptoms of gastroenteritis had improved, the serum lactic acid continued to remain high (7-9s). Since most of the apparent causes of lactic acidosis were excluded in this patient, thiamine deficiency was suspected and thiamine level was confirmed to be low at 59 nmol/L (normal 78-185). Supplementation was initiated with rapid normalization of lactic acidosis.

Discussion: Thiamine is essential for normal aerobic metabolism, and its deficiency may lead to accumulation of pyruvate and conversion to lactic acid. Because thiamine is water soluble, its stores are limited. Thiamine deficiency can occur readily if intake is suboptimal in people who have risk factors, such as long-term heavy alcohol ingestion in this patient. Teaching points Thiamine deficiency is a potential cause of lactic acidosis that is reversible with supplementation. A high index of suspicion is necessary for diagnosis in patients with risk factors but no other apparent cause of lactic acidosis.

POI1490
Methanol Intoxication Secondary to Adulterated Cane Alcohol “El Chorrillo”

Introduction: Methanol intoxication is a rare and lethal form of poisoning that may cause severe anion gap and osmolar metabolic acidosis (MA), visual disturbances, neurological dysfunction and death. We present a group of seven unrelated cases with methanol intoxication from cities in southern Mexico of a total of 106 intoxicated patients and 43 deaths reported.

Case Description: Upon arrival to Hospital Civil of Guadalajara a group of seven patients presented with severe MA, high anion and osmolar gap, neurologic and visual deterioration, respiratory failure requiring mechanical ventilation and hemodynamically unstable requiring vasopressor. Intake of methanol was accidental, since a batch of adulterated alcoholic bottles was identified and distributed by “El Chorrillo” store. Methanol concentrations is not available in our hospital. CT Scan revealed hemorrhage in basal ganglia and white matter involvement in all of them. Fomepizole is not available in Mexico so an ethanol infusion with vodka was started. All patients initiated hemodialysis (HD) as soon as possible and all underwent at least two sessions. Acid base balance was restored but five (71%) of the seven patients died. The remaining two patients persist in critical conditions requiring mechanical ventilation, no neurologic response and vasopressor dependent.

Discussion: This case series illustrates the poor clinical outcomes suffered by patients with methanol poisoning and the limitations of our public health system. Unfortunately the time lapse upon arrival was prolonged and organ damage irreversible leading to mortality in the majority of the cases.

Starvation Ketoacidosis in a Patient with Muscular Dystrophy
Khaled Srour, Bilal Shahzad Azam Khan, James E. Novak. Henry Ford Hospital, Detroit, MI.

Introduction: Patients with muscular dystrophy have low muscle mass; thus, they have lower glycogen stores and are more prone to develop ketoacidosis with minimal stress or decreased oral intake. Here we present a rare presentation of ketoacidosis in a patient with muscular dystrophy with concurrent ketoacidosis and hyperchloremic metabolic acidosis who was treated successfully with lactated Ringer’s (LR) and dextrose (D5W).

Case Description: A 48 year old woman with a history of muscular dystrophy and chronic, ventilator dependent respiratory failure was referred to our hospital for evaluation of granulation tissue in her trachea. Body mass index was 18 kg/m². Laboratory data on admission were significant for sodium of 132 meq /L, potassium of 4.5 meq /L chloride 114 mEq/L, bicarbonate 12 mEq/L, creatinine < 0.1 mg/dL, and pH 7.23 (venous blood gas) consistent with non anion gap metabolic acidosis. The following day, laboratory data showed sodium 137 mEq/L, chloride 113 mEq/L, bicarbonate 8 mEq/L, and pH 7.29. The calculated anion gap was 16 mEq/L with albumin 4.2 g/ dL. The urine anion gap was 30 mmol/L. Serum β-hydroxybutyrate (BHB) was elevated at 6.6 mmol/L. Because of muscular dystrophy with decreased oral intake, the patient’s anion gap metabolic acidosis was attributed to starvation ketoacidosis. The non anion gap metabolic acidosis was attributed to renal tubular acidosis. LR and D5W solutions were administered to treat non anion gap and anion gap metabolic acidosis (starvation ketoacidosis), respectively. After 1-2 days, BHB decreased and electrolytes normalized.

Discussion: Few cases have been reported regarding ketoacidosis in patients with muscular dystrophy, and all of these were treated with dextrose and 0.9% saline. In our case, we used LR and D5W due to concurrent non anion gap and anion gap metabolic acidosis, as 0.9% saline administration was projected to worsen the hyperchloremic acidosis. Anion gap metabolic acidosis in patients with muscular dystrophy and without diabetes should raise suspicion for starvation ketoacidosis requiring D5W. LR should be substituted for 0.9% saline in patients with concurrent hyperchloremic acidosis.

PO1492

Metabolic Acidosis Associated with Linezolid Toxicity
Carmen E. Cervantes,1 Steven Menez,2 Jose M. Monroy-Trujillo,1 Mohamed A. Hanouneh.1,2 1Johns Hopkins University School of Medicine, Baltimore, MD; 2Nephrology Center of Maryland, Baltimore, MD.

Introduction: Linezolid is an oxazolidinone antibiotic that inhibits bacterial protein synthesis. It can impair mitochondrial ribosomal function leading to severe lactic acidosis, liver toxicity and myelosuppression.

Case Description: A 65-year-old Caucasian woman with PMH of compensated NASH cirrhosis, osteoarthritis diagnosed 4 weeks prior to presentation and now on linezolid, was admitted with abdominal pain. Her vital signs and cardiopulmonary exam were unremarkable. Her abdomen was distended with mild epigastric tenderness. Figure 1 outlines the initial laboratories. Urinalysis was benign and blood cultures were negative. CT abdomen revealed moderate ascites. The anion gap metabolic acidosis (AGMA) were likely explained by Linezolid toxicity. The respiratory alkalosis is related to liver cirrhosis which is associated with increased level of progesterone leading to hyperventilation. Linezolid was stopped and repeat laboratories at 72 hours demonstrated normalization of bicarbonate and lactate values.

Discussion: Our patient has a primary AGMA (Corrected AG = 31) with mild respiratory alkalosis (calculated PaCO2 by Winter’s formula = 23). She had an osmolar gap of 5 (The calculated osmolality = 282 mOsm/kg). The AGMA is likely secondary to lactic acidosis (figure 2). The patient does not have signs of hypovolemia. Ethylene glycol (EG) can lead to a false elevation in L-lactate. However, the normal OG makes EG and methanol toxicity less likely. Normal beta hydroxybutyrate level excludes ketoacidosis. Major risk factors for linezolid toxicity include prolonged exposure, administration of relatively higher doses, and baseline chronic liver or kidney disease. Lactic acidosis often resolves rapidly following discontinuation of Linezolid.

The Real Life of Oral Alkalization by Urologists and Nephrologists on Extracellular Volume: The AlcalUN Study

Jean-philippe Bertocchio,1,2 Julie Moriniere beaume,2 Lucille Figuieres,2 Michael Bobot,2,3 Olivier Aubert,2 Louis De laforcade,2 Hanza Ayari,2 Thibault Dolly-Hitz,2 Victor Guetin,2 Antoine Braconnier,2 Leonard Goldberg,1,4 Salvatore Citarda,2 Guillaume Seret,2,5 Lisa Beliard,2 Raphael R. Cohen,2 Yusu Luque,2,5 Riyad N. Serevai,2 Camille Overs,1,12 AlcalUN study investigators 1University of Texas MD Anderson Cancer Center, Houston, TX; 2Club des Jeunes Néphrologues, Paris, France; 3Association Varoise pour l’Organisation de la Dialyse a Domicile, Toulon, France; 4Centre de Recherche en Transplantation et Immunologie, Nantes, France; 5Paris Centre de Recherche Cardiovasculaire, Paris, France; 6Centre Hospitalier et Universitaire de Bourgoin-Jallieu, Bourgoin-Jallieu, France; 7Hospital European Georges Pompidou, Paris, France; 8AUB Santé. Saint-Malo, France, Saint-Malo, France; 9AURA Paris Plaisance, Paris, France; 10University Hospital of Rennes, Rennes, France, Rennes, France; 11Hospital Universitaire Pitie Salpetriere, Paris, France; 12Tenon University Hospital, Paris, France, France; 13Association des Urologues en Formation, Paris, France; 14University hospital of Grenoble, Grenoble, France; 15University hospital of Reims, Reims, France; 16ECHO Santé, Pôle Santé Sud, Le Mans, France; 17CALYDIAL, Irigny, France; 18Center for Precision Environmental Health, Baylor College of Medicine, Houston, TX; 19Hopital de la Conception Centre de nephrologie et de transplantation renale, Marseille, France.

Background: Oral alkalization with sodium bicarbonate (NaHCO₃) or citrate is prescribed to treat conditions ranging from metabolic acids to nephrolithiasis. While most nephrologists/urologists use these treatments regularly, extracellular volume (ECV) increase is a main feared adverse event for NaHCO₃ use. To date, no clinical trial has specifically addressed this in clinical routine.

Methods: AlcalUN (NCT03035812) is a multi-center, prospective, open-label study aiming to assess the impact of a chronic oral alkalization on ECV. Patients receiving oral alkalization without NaHCO₃ (citrate) comprised the control group. Increased ECV (primary outcome) was assessed based on body weight (BW), blood pressure (BP), and edema at first follow-up visit.

Results: From 02/2017 to 02/2020, 156 patients were enrolled (129 received NaHCO₃, 27 citrate). Out of them, 127 (80%) participants had at least one follow-up visit. Normalizing for demographics, patients in the NaHCO₃ group had higher incidence of chronic kidney disease (68 vs. 30%, p=0.002) and hypertension (75 vs. 35%, p=0.001), while patients in the No-NaHCO₃ group (citrate) had more nephrolithiasis (95 vs. 28%, p=0.001). At baseline, BW, BP, and presence of edema were similar in both groups. After a median of 90 days of treatment, 91 (72%) patients reached the primary outcome, with similar distribution in both groups (71 vs. 75%, p=0.79). We found similar results after post-hoc propensity score matching.

Conclusions: Chronic oral alkalization with NaHCO₃ does not increase ECV more than citrate, even though it is used in higher-risk population. These results confirm secondary outcomes from other trials, potentially highlighting the role of chloride load instead of sodium load.

Effect of Sodium Bicarbonate on Kidney Injury: A Secondary Analysis of the BASE Pilot Trial

Kalani L. Raphael,1 Brett Larive,2 Tamara Isakova,3 Joachim H. Ix,4 Michael S. Dominec R. Raj,4 Susan R. Mendel1,7 Linda F. Fried,3 Cynthia A. Kendrick,2 Jennifer J. Gassman,2 Donald E. Wesson,9 Alfred K. Cheung,1 CKD Pilot Studies Consortium 1University of Utah Health, Salt Lake City, UT; 2Cleveland Clinic, Cleveland, OH; 3Northwestern University Feinberg School of Medicine, Chicago, IL; 4University of California San Diego, La Jolla, CA; 5Duke University School of Medicine, Durham, NC; 6George Washington University Medical Faculty Associates, Washington, DC; 7National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; 8University of Pittsburgh Medical Center, Pittsburgh, PA; 9Baylor Scott and White Health, Dallas, TX.

Background: NaHCO₃ is used to treat metabolic acidosis in CKD. In the Bicarbonate Administration to Stabilize eGFR (BASE) Pilot trial, a dose-dependent increase in albuminuria was observed with NaHCO₃ over 28 weeks, suggesting that NaHCO₃ may promote kidney injury. We investigated the effect of NaHCO₃ on kidney tubule injury markers (KIM-1 and NGAL) in BASE participants.

Methods: Urinary KIM-1 and NGAL were measured in 176 BASE participants at baseline, week 12, and week 28. Change in urinary KIM-1/Cr and NGAL/Cr was compared within and between the three treatment groups (Placebo, n=49; Lower-Dose [0.5 mmol/kg/d] NaHCO₃, n=48; and Higher-Dose [0.8 mmol/kg/d] NaHCO₃, n=79) using linear mixed models.

Results: Mean±SD baseline values were: age 67±12 years, systolic BP 126±13 mm Hg, eGFR 35±40 ml/min/1.73 m², serum tCO₂ 24±2 mmol/L. Median (IQR) urinary values at baseline were: KIM-1/Cr 185 (24, 767) mg/g Cr, NGAL/Cr 0.43 (0.36, 1.26) ng/mg, and NGAL/Cr 14.3 (6.44, 34.0) mg/kg. At week 12, urinary KIM-1/Cr levels were not different from baseline in any group. However, at week 28, KIM-1/Cr levels were significantly lower in all three groups. NGAL/Cr was significantly higher in the Higher-Dose NaHCO₃ group at week 12; however, there were no other significant within group differences at week 12 or 28. In the between group comparisons, there were no significant differences in KIM-1/Cr (p=0.16) or NGAL/Cr (p=0.07) at either week 12 or 28.

Conclusions: Among BASE Pilot Trial participants, NaHCO₃ had no significant effect on urinary KIM-1/Cr or NGAL/Cr levels over 28 weeks.

PO1497
A Case of Extreme Alkalosis: A Perfect Combination of Perpetuators
Patricia Valério,1 Hugo Ferreira,2 Teresa Chauva,3 Ana M. Paiva,2 Inês Neves,2 Filomena Faria,2 José M. Costa,2 Centro Hospitalar de Setúbal EPE, Setúbal, Portugal;1 Instituto Portugueses de Oncologia do Porto Francisco Gentil EPE, Porto, Portugal.

Introduction: Metabolic alkalosis results from retention of alkali excess. Normally, a physiological response leads to hyperventilation with a secondary increase of PaCO2. The most common cause is H+ loss, through kidney or gastrointestinal tract, usually with concurrent loss of Cl− and K+.

Case Description: 70 y/o caucasian man was admitted for a scheduled surgery due to a stage II urothelial carcinoma. The immediate postoperative period occurred without complications. The patient presented with abdominal distention and gastric stasis. He remained fasting, with gastric tube draining freely. Surgical team performed an exploratory laparotomy with correction of a small bowel internal hernia. In the postoperative period Nephrology collaboration was requested due to acute kidney injury (AKI), with a creatinine (Cr) of 3.39 mg/dL (baseline 1.5 mg/dL) and urea 89.5 mg/dL. On examination the patient was prostrate, severely dehydrated and bradycnepic, with oxygen supply FiO2 28%. He maintained gastric passive drainage for 5 days, around 3 to 3.5 L/day. Blood work showed Cr 4.15 mg/dL, urea 103.9 mg/dL, hyponatremia 147 mEq/L, hypochloremia 78 mEq/L, hypokalemia 3.2 mEq/L, uric acid 16.8 mg/dL, albumin 3.2 g/dL and a total corrected calcium 9.5 mg/dL. Urinalysis revealed a pH of 9.0 and arterial blood gas analysis presented severe metabolic alkalosis (pH 7.63, PaO2 90 mm Hg, PaCO2 99 mm Hg, bicarbonate 104.1 mmol/L), low ionized calcium 0.86 mmol/L and lactate 1.9 mm/dL. The patient was immediately admitted in ICU, starting aggressive IV hydration with NaCl 0.9%, IV potassium supplementation and parenteral nutrition.

Discussion: This is an extreme case of metabolic alkalosis where a myriad of contributors gathered in a perfect storm to achieve a bicarbonate concentration above 100 mmol/L, thought to be incompatible with life and, to our knowledge, never reported in the literature. However, the pH value was maintained in life-compatible values by an extreme respiratory compensation which may have saved the patient before treatment initiation. An approach correcting the cause and, at the same time, the perpetuators are the key factors to successfully treat a metabolic alkalosis. Due to severe AKI and alkalosis, and with low bicarbonate dialysis may be indicated.
POI499
Renal Negative Pressure Treatment as a Novel Therapy for Cardiorenal Syndrome
Jennifer L. Asher, Christopher D. Maulion, Olyvia Gleason, Grace Meegan, Juan B. Ivey-Miranda, James H. Fleming, Veena Rao, Jeffrey M. Testani. Yale University School of Medicine, New Haven, CT.

Background: Decongestion is the primary therapeutic objective in acute decompensated heart failure (ADHF). However, congestion itself can worsen renal function and limit diuresis. Renal pelvis negative pressure treatment (rNPT) should reduce tubular pressure, allowing improved kidney function and diuresis. We hypothesized that rNPT would improve diuresis, natriuresis & renal function in a congestion predominated heart failure (HF) model.

Methods: Ten ~80 kg pigs underwent thoracotomy with implantation of a pericardial, Swan Ganz, & bilateral ureteral JuxtaFlow™ catheters. High dose furosemide (400mg bolus, then 80mg/hr) was administered since HF clinical use of rNPT will be in conjunction with loop diuretics. Each animal served as its own control with randomization of L vs. R bolus, then 80mg/hr) was administered since HF clinical use of rNPT will be in conjunction with loop diuretics. Each animal served as its own control with randomization of L vs. R

Results: Prior to HF induction, rNPT increased urine output (UOP) & creatinine clearance (CrCl) compared to the control kidney during furosemide diuresis (p<0.001 for all, Figure). HF induction achieved the target hemodynamic profile with stable cardiac output & elevated filling pressures (Figure). UOP, sodium excretion, & CrCl decreased during HF (p<0.001 for all, Figure), but were higher consistently in rNPT kidney vs. control (p=0.05 for all, Figure). UOP (p=0.38) was the same in rNPT during HF as control prior to HF (Figure).

Conclusions: rNPT increased UO and CrCl, with & without HF. Notably, rNPT rescued the congested cardio-renal phenotype with equivalent diuresis & natriuresis during HF with rNPT compared to the non-HF period without rNPT.

Accurate Estimation of Individual Sodium Intake with Repeated Spot Urine Sampling
Bigin N. Ginos,1 Liffert Vogt,1 Petra Frings-Meuthen,1 Martina D. Heer,2 Rik H. Olde Engberink.1 1Amsterdam University Medical Centres, location Academic Medical Centre, University of Amsterdam, Amsterdam, Netherlands; 2Institute of Nutritional and Food Sciences, University of Bonn, Bonn, Germany; 3German Aerospace Center (DLR), Institute of Aerospace Medicine, Cologne, Germany.

Background: In clinical practice, individual sodium (Na+) intake is estimated by measuring Na+ excretion in one 24-h urine collection (UC), whereas long-term Na+ balance studies indicate that 7 consecutive 24-h UCs may be needed. To reduce the burden of 24-h UF, single spot urine based alternatives have been suggested, but this approach has been shown to be very inaccurate. Whether the use of repeated spot UCs is an appropriate alternative for (multiple) 24-h UCs to estimate Na+ intake is unknown.

Methods: We performed a post-hoc analysis of a metabolic ward study in 8 healthy male adults who consumed a 7-d diet with a fixed amount of 200 mmol/d Na+. Urine was collected in 4 daily intervals (7-13h, 13-19h, 19-23h and 23-7h). After reaching steady state, we estimated Na+ intake by single and repeated 24-h UCs and repeated spot UCs, using the Kawasaki formula with measured 24-h urine creatinine excretion.

Results: After day 5, mean 24-h Na+ excretion matched intake, indicating that steady state was achieved (Fig 1A). Mean absolute differences (Δ) between measured Na+ intake and 3-d spot UC estimates were 18.8 (SD 14.6), 32.3 (SD 18.7), 74.6 (SD 30.0) and 28.2 (SD 19.8) mmol for interval 7-13h, 13-19h, 19-23h and 23-7h, respectively (Fig 1B). With the exception of samples collected between 19-23h, Na+ intake estimates by 3-d spot UCs did not significantly differ from Na+ intake estimates by single (Δ 29.8 mmol; SD 23.9) and three 24-h UCs (Δ 22.9 mmol; SD 11.4).

Conclusions: Bias in Na+ intake estimation did not significantly differ between repeated spot UCs and single and repeated 24-h UCs. Adequately powered studies need to confirm whether repeated spot UCs are an accurate and low burden alternative to 24-h UCs.

Funding: Private Foundation Support

Figure 1. (A) Mean 24-h Na+ excretion during 7-d diet. (B) Comparison of the performance of three consecutive spot UCs (blue), single 24-h UC (green) and three consecutive 24-h UCs (red) for estimating Na+ intake (200 mmol/d). Absolute differences between estimated and measured Na+ intake. Data are mean and SD.

Utility of Doppler Ultrasound-Derived Hepatic and Portal Venous Waveforms in the Management of Heart Failure Exacerbation
Shashank S. Singh,1 Mir tariqi Ali,1 Abhilash Korattala,2 1The University of Texas Health Science Center at San Antonio, San Antonio, TX; 2Medical College of Wisconsin, Milwaukee, WI.

Introduction: Careful evaluation of the fluid volume status and systemic hemodynamics is of paramount importance in patients with heart failure. With growing interest in point of care ultrasonography, non-invasive parameters such as hepatic and portal vein waveforms are assuming importance as markers of systemic venous congestion.

Case Description: 43 year old male was admitted for right lower extremity necrotizing fasciitis requiring below the knee amputation. Postoperatively, he subsequently developed volume overload with pulmonary edema and acute renal injury. Given the patient's sensitive hemodynamic state, volume depletion was driven by doppler ultrasound, specifically portal vein and hepatic vein doppler. After a few days of therapy, the patient had improvement of his renal function, leading to a cessation of dialysis and return of renal function to near baseline.

Discussion: In patients with acute decompensated heart failure, residual clinical congestion at hospital discharge is associated with worse outcomes. A standard assessment of congestion is the measurement of right atrial pressure (RAP) and pulmonary capillary wedge pressures using pulmonary artery catheterization, though its invasive nature precludes routine use. Estimating baseline RAP using inferior vena cava (IVC) ultrasound is now common, though it is not without numerous pitfalls limiting its utility. For example, IVC changes in size in the IVC depend on variations in intrathoracic pressure and lung compliance. Using portal and hepatic vein waveforms can add another piece of information for volume assessment. As shown in our images, the changes initially seen on doppler with hypervolemia can direct management for diuresis/volume removal. These changes seen on doppler waveform aids in management for decongestive therapy.
Patients with CKD Closely with Hypertension and Target Organ Damage in Chinese

Abnormal Circadian Rhythm of Urinary Sodium Excretion Correlates

Results: A total of 1,099 Chinese CKD patients were recruited, 308 patients were excluded, and 791 patients were final enrolled in this study. Among them, 291 patients were normotensive and 500 were hypertensive CKD patients. A 1:1 propensity score matching (PSM) analysis was performed with age and estimated glomerular filtration rate (eGFR) matched between 190 normotensive and hypertensive patients. In the full cohort and PSM cohort, multivariate regression analysis showed that the night/day urinary sodium excretion ratio was an independent risk factor for clinical hypertension, whereas 24 h urinary sodium excretion, diurnal and nocturnal urinary sodium excretion were not. When the night/day urinary sodium excretion ratios were further divided into tertiles (tertile 1 < 0.47, tertile 2, 0.47-0.84 and tertile 3 ≥ 0.84), multivariate analysis showed that tertile 3 was independently associated with hypertension in the full and PSM cohorts. In addition, tertile 3 was also independently associated with eGFR ≤ 60 mL/min/1.73 m² and left ventricular hypertrophy.

Conclusions: These data suggested that an abnormal circadian rhythm of urinary sodium excretion was independently associated with hypertension and target-organ damage. Individualized salt intake and therapeutic strategies should be used to normalize the natriuretic dipping profile in CKD patients.

Mirabilite External Application for the Treatment of Nephrotic Edema: A Randomized Controlled Study

Background: Lower limb edema is the main symptom of nephrotic syndrome (NS). In addition to well established treatment for edema, external mirabilite application (EMA) around swollen areas could potentially benefit patients with NS. Mirabilite is hydrous sodium sulfate mineral that quickly turns into thenardite which is known for its ability to highly absorb water.

Methods: A randomized, single-blinded study included 52 patients with NS who were randomly assigned to the experimental group (EMA-diuretic therapy, n=26) and the control group (diuretic therapy, n=26). The study was approved by IRB of the 1st Affiliated Hospital of Guangzhou University of Chinese Medicine. Mirabilite treatment was applied via special cloth bag placed around swollen area on legs, 6 hours per day for 10 days. The primary outcome was the change in leg circumference (LC) and biochemical characteristics of patients. The secondary outcome included body weight and urine output.

Results: Patients from experimental group had significant decrease in LC compared to controls (P=0.002), yet small changes in urine volume output (P=0.436). However, significant correlation of LC with weight gain of mirabilite was observed (r=−0.586, P=0.002). Concentration of electrolytes did not change significantly in the groups. Similar effect was observed regarding liver function markers. However, albumin concentration increased significantly in both experimental and control group. After EMA-diuretic treatment patients had significantly lower body weight (P=0.000). Moreover, weight loss was significantly positively correlated with decrease in LC (r=−0.612, P=0.000).

Conclusions: This study suggests that MEA is effective in relieving the symptoms of lower extremity edema in NS patients, but it does not help much in the state of water and sodium storage.

PO1502

Multiple Spot Urine Sampling Is More Precise and Accurate Than 24-Hour Urine Collection for Estimating Urinary Sodium Excretion

Background: The estimate of sodium excretion (NaE) is important for the management of hypertension, but 24 hours urine collection (24-hrs-UC), the current standard of care, can be inaccurate, unpractical and poorly representative of the usual Na intake. Multiple spot urine sampling is not affected by any of these errors, so we hypothesized that it can be equally or more precise than 24-hrs-UC for estimating NaE.

Methods: 4/subject 24-hrs-UC and the related 439 urine samples (1/voiding), were analyzed for uNa and uCr. uNaE (in mEq/Kg/day) was derived from the means of uNa/uCrR derived from 2, 3 and 4 random samples from different days for both precision and accuracy using the mean of all the 24-hrs-UC as individual "gold standard". Precision in estimating the gold standard of the 2 methods was measured by comparing the respective coefficient of variations (CV). Accuracy was measured by comparing the P30 and P20 of the 2 methods after transforming uNa/uCrR into uNaE in (mEq/kg/day) by means of the equations (one for children and one for adults) derived from the study data set.

Results: CV of 24-hrs-UCs was 25.7% and that of uNa-to-uCrR as derived from the mean of 2, 3 and 4 samples were respectively 37.1, 28.2 and 22.5%. The CVs were significantly higher in children. Accuracy: P30 and P20 of the 24-hrs-UC were 62.5% and 78.7%, respectively. The corresponding figures obtained from all the 20,258 possible means of 4 samples randomly taken from different days were 73.1% and 94.2%. The internal validation performed by the same subjects 1 year after and the external validation in 8 subjects confirmed the superiority of multiple spot urine sampling.

Conclusions: In real life, with various sources of error systematically affecting 24-hrs-UCs, uNa-to-uCrR will have an even higher precision and accuracy and should be preferred for estimating uNaE.

Abnormal Circadian Rhythm of Urinary Sodium Excretion Correlates Closely with Hypertension and Target Organ Damage in Chinese Patients with CKD

Patients with CKD

Background: Whether the abnormal circadian rhythm of urinary sodium excretion is associated with hypertension in chronic kidney disease (CKD) is poorly understood. In this study, we assessed the relationship between the circadian rhythm of urinary sodium excretion and hypertension.

Methods: Urinary samples were collected during both the day (07:00 to 22:00) and night (22:00 to 07:00) to estimate night/day urinary sodium excretion ratios. Blood pressure (BP) and clinical data were also measured.
Reappraisal of Urinary Sodium Excretion as a Predictor of Clinical Outcomes in Heart Failure
Harini Bejanki,1 Eddy J. De Jesus,2 Vijay Damarin,3 Amir Kazory,2 Decatur Memorial Hospital, Decatur, IL; 1University of Florida, Gainesville, FL.

Background: Congestion is established as the driver of adverse outcomes in heart failure (HF). Since removal of excess fluid and sodium is often the primary therapeutic objective in this setting, accurate monitoring of the progress of diuretic therapy is of critical importance. While weight change and fluid balance have conventionally been used for this purpose, inconsistent collection, inherent delay in data availability, and lack of distinction between water and sodium balance are among their limitations. We sought to explore the contemporary data on the use of urinary sodium (UNa) as a predictor of outcomes in these patients.

Methods: Articles cited in the PubMed database using keywords “heart failure” and “urine sodium” were searched. Available data from clinical trials published between June 2015 and May 2020 were included. The studies were selected if they prognosticated outcomes in the HF population through use of UNa. Pertinent data on clinical and laboratory parameters (e.g. dose and timing of diuretic therapy, eGFR, serum sodium, and UNa) were extracted and reviewed.

Results: A total of 14 studies with 2,350 participants were included, of which 11 were prospective. The study populations consisted of 12 acute HF cohorts, 1 chronic, and 1 with both. The mean age was 67 years (64% men) with an ejection fraction of 35% and an eGFR of 50 ml/min. Most studies (12 out of 14) used UNa concentration, 2 used fractional excretion and clearance of sodium. Surprisingly, while there was substantial variation across studies in the timing of the applied metric, those exploring clinical endpoints unanimously reported a correlation between low UNa excretion and various adverse outcomes (e.g. worsening renal function, HF readmission, and mortality).

Conclusions: Over the past few years, UNa has been the focus of much investigation as a tool for monitoring of therapy and prognostication in patients with HF. The findings of our study are two folds: 1) Regardless of the applied metric and its timing, contemporary data supports the use of UNa as a potent predictor of clinical outcomes in HF that lacks the limitations of conventional methods. 2) There is no consensus on the optimal cut off and time point for measurement of UNa in this setting. In order for UNa to be applied widely as a consistent and reliable tool, this knowledge gap needs to be addressed in future studies.

Defective NAD+ Homeostasis in ADPKD and the Effects of PC1CTT on Redox Modulation and Disease Progression
Laura Onuchic,1 Valeria Padovano,2 Nikolay P. Gresko,3 Giorgia Schena,1 Vanathy Rajendran,1 Michael J. Caplan.1 1Yale University School of Medicine, New Haven, CT; 2Broad Institute, Cambridge, MA.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is caused by mutations in the genes encoding polycystin-1 or 2 (PC1 or PC2). Defective metabolism is a hallmark of ADPKD. The C-terminal cleavage product of PC1 (PC1CTT) can translocate to mitochondria and its expression in Pkd1 KO cells may rescue defective mitochondrial phenotypes. Altered oxidoreductase activity is detected in an ADPKD model. Here we assess the degree of redox imbalance between NAD/NADH in mitochondrial phenotypes. Altered oxidoreductase activity is detected in an ADPKD model. Moreover, we use an in vitro model to express variations of PC1CTT that localize to different subcellular compartments and reveal an association between PC1CTT localization and Redox modulation. Finally, we show that expression of a PC1CTT variant with predominant nuclear as opposed to mitochondrial localization exacerbates the cystic phenotype in a Pkd1 KO mouse model.

Methods: We quantified the ratio between NAD+ and NADH in lysates from Pkd1+/- and Pkd1-/- mouse renal epithelial cells. We also assessed the NAD/NADH ratio in kidney lysates from ADPKD mouse models and WT controls. We generated 3 variations of PC1CTT with either an N-terminal HA-tag (2HA-PC1CTT), a C-terminal HA-tag (PC1CTT-HA) or no additional tag, and applied the assay to lysates from HEK cells transfected with these constructs. Finally, we expressed 2HA-PC1CTT in a Pkd1 KO mouse model and observed phenotypic differences.

Results: The NAD/NADH ratio was 80% higher in Pkd1+/- cells in comparison to Pkd1-/- cells. Kidney lysates from WT mice had double the NAD/NADH ratio compared to that observed in cystic and pre-cystic animals. Transfection of HEK cells with the PC1CTT constructs revealed distinct patterns: 2HA-PC1CTT localized to nuclei, PC1CTT-HA localized to mitochondria and PC1CTT was found in both. PC1CTT and PC1CTT-HA expressing HEK cells exhibited 40% and 60% higher NAD/NADH ratios than those measured in 2HA-PC1CTT-expressing cells. ADPKD mice expressing 2HA-PC1CTT exhibited a 3-fold increase in kidney-weight/body-weight in comparison to control ADPKD mice.

Conclusions: ADPKD is characterized by defective NAD+ homeostasis. Mitochondrial localization of PC1CTT can potentially rescue this redox imbalance, while nuclear localization of PC1CTT appears to aggravate this imbalance and exacerbate the cystic phenotype in animal models.

Cardiac Dysfunction in Pkd1-Deficient Mice Is Associated with Metabolic Rewiring
Andressa G. Amural,1 Camille C. Silva,1 Kinulpe H. Sampaio,1 Amaro N. Duarte-Neto,1 Antonio C. Bloise,1 Laura Cassina,2 Alessandra Boletta,2 Adriano B. Chaves-Filho,2 Marcos Y. Yoshinaga,2 Sayuri Miyamoto,2 Silvana A. Bordin,3 Alicia J. Kowalowski,1 Luiz F. Onuchic.1 1Universidade de Sao Paulo, Sao Paulo, Brazil, 2IRCCS Casa Sollievo Sinfonie, San Raffaele, Milan, Italy; 3Universidade Federal dos Vales do Jequitinhonha e Mucuri, Diamantina, Brazil.

Background: Myocardial abnormalities are associated with significant clinical burden in ADPKD but the underlying pathogenesis is still largely unclear.

Methods: We investigated the metabolic basis of the ADPKD-associated cardiac phenotype using a mouse hologemous for a Pkd1 hypomorphic allele that prevents PCD cleavage (Vv) with early cardiac dysfunction.

(10% K Bicarbonate/Citrate) dramatically accelerated cystogenesis despite augmented renal TRPV4 expression. TRPV4 activity (estimated as a GSK1016790A-dependent rise in [Ca^{2+}] in freshly isolated cyst monolayers from Pck453 rat kidneys) was approximately 2 fold larger in cyst cells from high K+ diet-treated compared to control. Basal [Ca^{2+}] and flow-induced [Ca^{2+}] levels were also higher on this condition. In contrast, TRPV4 activity was 2 fold larger in cysts on high K+ high alka diet.

**Conclusions:** We show a positive correlation between TRPV4 functional status and the time course of ARPKD progression in PCK 453 rats. Chronic alcali load renders TRPV4 to an inactive state, which contributes to exacerbated cystogenesis in Pck453 rats. Studies of TRPV4 of TRPV4+/- vs TRPV4-/- with high K+ high alka diet will be instrumental to attenuate the rate of PKD progression in clinical.

**Somatic Tubular Epithelial Cell Model of Type II Polycystic Kidney Disease Reveals Phenotypes of Altered Ciliary Length and Polycystin-1 Intracellular Complexes in Drosophila**

**Anklin Roy,1,2 Courtney E. Vishy,1 Louisa Helm,1,2 Ivan G. Gomez,1,2 Jonathan Harrison,1,2 Bethamy S. Freedman,1,2 University of Washington, Seattle, WA, 1,2Kidney Research Institute, Seattle, WA.**

**Background:** Autosomal dominant polycystic kidney disease (PKD) is a life-threatening inherited disease that affects around 12 million people worldwide, commonly due to loss-of-function mutations in PKD1 or (type II) PKD2, encoding polycystin-1 (PC1) and polycystin-2 (PC2), respectively. These form a receptor-channel complex in the primary ciliary whose molecular function remain uncertain, making it difficult to develop targeted therapeutic. Mice that lacks one of these proteins can exhibit PKD phenotypes, but are slow and complex, posing challenges for mechanistic analysis.

**Methods:** To establish a somatic cell model of PKD, we generated five clones of porcine proximal tubule cell line (LLCPK1) completely lacking PC2 using the CRISPR-Cas9 system, alongside five isogenic control lines. Mutations were verified for each allele by TOPO cloning and clones were derived from a single subclone to minimize heterogeneity. Cystic index was 21.0 ± 0.1% for the Pkd1 RC/RC kidneys, respectively. Pkd1 RC/RC mice also had elevated renal fibrosis and BUN levels at 9 months, consistent with a decline in renal function.

**Conclusions:** This study demonstrates that heterozygous loss of Pkd2 accelerated the onset of cystogenesis in Pkd1 RC/RC mice, supporting the hypothesis that PC-1 and PC-2 function in a common pathway and that lowering the expression of the polycystins is sufficient to initiate cystogenesis. We think that the increased progression of cystic disease in Pkd1 RC/RC, Pkd2 mice makes it a promising model for evaluating therapeutic interventions.

**FPC, TFAP2B, and MCM3 Function in a Species-Specific Regulome That Modulates Myc/MYC Expression: Implications for ARPKD**

**Naoe Harafuji,1 Chaozhao Yang,1 Maryanne Odinkakuchukwu,1 Maqing Wu,1 Ljubica Caldovic,2 Lisa M. Guay-Woodford1 1Center for Translational Research, Children's National Medical Center, Washington, DC, 2Center for Genetic Medicine Research, Children's National Medical Center, Washington, DC.**

**Background:** Mutations in PKHD1 cause human ARPKD (MIM 263200), but mouse Pkd1 mutants have limited or no renal cystic disease. We previously showed that MYC is elevated in mice with human ARPKD kidneys but not in mouse Pkd1 mutant mice, and that mouse FPC-C-terminal domain (FPC-CTD) activates MYC (ASN 2018). Trudel (2019) has reported that Myc is a central driver in Pkd1-induced pathogenesis. Relevant to the current study, mice express three TFAP2B isoforms while humans express only one, VTAP2B. Here, we describe a species-specific regulatory framework (regulome) in which FPC-CTD, TFAP2B, and MCM3 regulate Myc/MYC expression in renal collecting duct (CD) cells.

**Methods:** Human and mouse CD cells line, Myc-tagged TFAP2B, Tpap2b, and Tpap2b Cry2-ha tagged human and mouse FPC-CTD constructs, and Cyp1, Pkd1 and MHC-PMY promoter constructs were used to perform dual luciferase and co-IP assays.

**Results:** In mouse cells, TFAP2B & 2 positively regulated expression of Pkd1 and Cyp while Myc was positively regulated by TFAP2B but negatively regulated by TFAP2B. In Pkd2 mice, TFAP2B negative regulation of Myc was epistatic over FPC-CTD activation. MCM3, previously identified as a FPC-CTD binding partner, positively regulated Myc promoter activity. Human MYC was activated by FPC-CTD and negatively regulated by TFAP2B.

**Conclusions:** We show that in both mouse and human, FPC-CTD and TFAP2B regulate Myc/MYC expression. Notably, mouse TFAP2B isoforms differentially regulate Myc expression, while humans lack a MYC activating isoform. Based on our data, we propose a model in which a regulome that includes FPC-CTD, TFAP2B, and MCM3 modulates Myc/MYC expression in CD cells in a species-specific fashion. Species-specific renal phenotypes could be attributable to differences in constituent proteins, isoform diversity, and epistatic interactions within the proposed regulome. We speculate that this model may explain the differential effects of PKHD1/Pkd1 deficiency on renal cystogenesis and provide initial clues for putative renoprotective mechanisms in Pkd1 mutant mice.

**Characterization of Porcine Models of Autosomal Recessive Polycystic Kidney Disease**

**Jessica M. Smith,1 Alexander W. Coutts,2 Barbara R. Tischida,2 Harrison H. Wells,1 Daniel F. Carlson,2 Peter C. Harris,1 1Mayo Clinic Minnesota, Rochester, MN; 2Recombinetics, St Paul, MN.**

**Background:** Autosomal recessive polycystic kidney disease (ARPKD), a relatively common form of mainly infantile PKD, is caused by biallelic mutations to PKHD1. The missense change, p.T36M, is the most common pathogenic allele (~15% of the total) and associated with severe disease. Mouse and rat models do not display the classical ARPKD presentation of early onset, enlarged, echogenic kidneys. Therefore, to better understand the pathomechanism, we developed and characterized porcine ARPKD models. The pig has a similar anatomy (multi-papillary structure) and physiology to humans, and thus it makes an ideal model system to study disease progression and test treatment options in this disorder.

**Methods:** Using the CRISPR/Cas9 methods and homology directed repair (HDR), we genetically engineered pigs with the p.T36M or null PKHD1 alleles. The following genotypes were breed (WT, T36M/T36M, T36M/KO, KO/KO) and characterized longitudinally to 5-months old (where possible) using MRI and a blood chemistry panel, and analyzed histologically.

**Results:** Two KO/KO pigs were sacrificed at one and two days of age with a phenotype of greatly enlarged cystic kidneys with severe functional loss as well as fibrotic, cystic livers, matching classical human ARPKD. Four T36M/KO pigs were imaged monthly to five months but they only developed a few kidney cysts that did not grow significantly during follow up, and without a decline in function. Similar analysis of two T36M/T36M pigs revealed only occasional kidney cysts.

**Conclusions:** Through gene editing, an authentic porcine model of early onset ARPKD kidney and liver disease was developed that will be valuable for understanding the pathomechanism of neonatal ARPKD. MRI and biochemical assays enabled detailed

**Cystin Deficiency in Cystic Kidney Disease**

**Prashant Kumar,** 1 Fahad Al-Zadjali, 1 Ying Yao, 1 John J. Bissler, 1,2 The University of Tennessee Health Science Center College of Medicine, Memphis, TN; St. Jude Children’s Research Hospital, Memphis, TN.

**Background:** The severity of tuberous sclerosis complex (TSC) manifestations seem to be different depending which TSC locus is affected. This is a puzzling finding, given that the gene product of both loci heterodimerize to regulate mTORC1 activity, so loss of either one releases the repression and results in constitutive mTORC1 activation.

**Methods:** To begin to understand possible mechanisms for this difference, we have used mouse inner medullary collecting duct (mIMCD) cells with either the Tsc1 or the Tsc2 gene disrupted by a CRISPR/CAS9 strategy. We have previously characterized the Tsc2 mutant cell line derived EVs, and present here intriguing differences between the extracellular vesicles (EVs) derived from cells with mutant Tsc1 or Tsc2 genes.

**Results:** To characterize the EVs, we used tunable resistive pulse sensing, dynamic light scattering, transition electron microscopy and immunoblot analysis.

**Conclusions:** The size of the EVs, we used tunable resistive pulse sensing and dynamic light scattering. The parental cell line had an average size of 123.5 ± 5.7 nm and mutant Tsc1-derived EVs had an average size 131.5 ± 8.3 nm. The surface charge for the two cell lines were -16.3 ± 2.1 mV and -19.8 ± 2.7 mV respectively. The isolated nanosized vesicle had excellent purity as assayed using transmission electron microscopy.

Both cell lines had a heterogeneous population of EVs based on size, and more than 90% of the EVs were larger than 500 nm. Quantitative PCR analysis showed the downregulation of miR-212a-3p and miR-99a-5p in EVs derived from Tsc1 which are sought to contribute the more TS severity as compared to TSC1. In addition, miR-212-3p/mTORC1 and miR-99a-5p/mTORC1 axis are could be a novel therapeutic and biomarker strategy for TSC disease.

**Tsc2 Mutation Induces Renal Tubular Cell Nonautonomous Disease**

**John J. Bissler,** 1,2 Prashant Kumar, 1 Ying Yao, 1 Fahad Al-Zadjali, 1 The University of Tennessee Health Science Center, Memphis, TN; St. Jude Children’s Research Hospital, Memphis, TN.

**Background:** Tuberous sclerosis complex is associated with both renal tumors and cysts in most affected patients. The renal cystic disease is poorly understood and has no approved treatment. Using a new principal cell-targeted murine model of the Tsc2 gene deletion, we found that the renal cystic epithelium was mostly composed of type 1 renal proximal tubular epithelial cells.

**Methods:** We used lineage tracing experiments to understand the tubular cell fate, and dynamic light scattering, tunable resistive pulse sensing, transition electron microscopy and western blot analysis to characterize the extracellular vesicles. We used microarray analysis to characterize the expression of the extracellular vesicles on target tubule cells.

**Results:** Using lineage tracing experiments, we find that while principal cells are involved and undergo clonal expansion, they contribute a surprisingly small number of cells to the cyst. We identify that cystic kidneys contain more interstitial extracellular vesicles than noncystic kidneys, excrete fewer extracellular vesicles in the urine, and contain fewer extracellular vesicles in the cyst fluid. We demonstrate that the loss of the Tsc2 gene in the cells producing the extracellular vesicles greatly changes the effect of extracellular vesicles on renal tubular epithelium, such that they develop increased secretory and proliferative pathway activity. mTORC1 activity is not the only controller of extracellular vesicles production, but mTORC1 inhibition does reduce the extracellular vesicle production and greatly changes the effect of extracellular vesicles from treated cells. This may be, at least in part, why mTORC1 inhibitors have a beneficial effect in patients.

**Conclusions:** Taken together, these results contribute to the mechanistic understanding of how genetically intact cells contribute to the disease phenotype.

**Funding:** Other U.S. Government Support

Whole-Exome Sequencing in 97 Families with Renal Ciliopathies Reveals a Causative Mutation in a Known Kidney Disease Gene in 62% and Identifies Potential Novel Causative Genes

Konstantin Deutsch,1 Verena Klambt,1 Thomas M. Klitzler,2 Tilman Jobst-Schwann,1 Shirlee Shih,1 Shrikanth M. Mane,2 Friedhelm Hildebrandt.1 Boston Children’s Hospital, Department of Medicine, Boston, MA; 4 Yale University School of Medicine, New Haven, CT.

Background: Nephronophthisis-related ciliopathies (NPHP-RC) represent the most frequent genetic cause of end-stage renal disease in the first three decades of life. Affected children present with increased echogenicity and/or cysts on renal ultrasound. As mutations in 96 recessive genes have been identified as disease-causing (Kidney Int 95:914, 2019), whole exome sequencing (WES) represents the best approach for the identification of the causative mutation (Nephrol Dial Transplant 31:1802, 2016). In a previous study of consanguineous or familial cases of NPHP, we identified causative mutations in 63% of all patients (Kidney Int 89:468, 2016) by WES.

Methods: To reveal the percentage of causative mutations in NPHP-RC and to identify potential novel disease genes, we evaluated WES data from 97 families with childhood-onset NPHP-RC for causative mutations in 178 monogenic chronic kidney disease genes. Clinical inclusion criteria were increased renal echogenicity or identification of ≥2 renal cysts on renal ultrasound.

Results: In 60 out of 97 families (62%), we identified a mutation in a known monogenic kidney disease gene as causative for the phenotype. Out of these, 47 families harboured mutations in one of the known ciliopathy genes. 13 families were diagnosed for a disease that phenocopies NPHP-RC. Amongst these, CAKUT represented the most frequent phenocopy disease (7/13 families), followed by Alport syndrome, metabolic diseases and nephrocalcinosis (2/13 families each). In 10 families, in which a mutation in known disease genes was excluded, we identified a biallelic mutation in a potential novel causative gene candidate.

Conclusions: By whole exome sequencing we identified a disease-causing mutation in 62% of families with a diagnosis of NPHP based on renal ultrasound and identified 10 potential novel causative gene candidates.

Using Whole-Exome Sequencing to Identify PKD1 and PKD2 in 50,000 UK Biobank Participants

Krittaya Sukcharoen,1 Coralie Bingham,1 Daniel P. Gale,2 Michael Weedon,2 Richard A. Oram.1 Royal Devon and Exeter NHS Foundation Trust, Exeter; United Kingdom; 2University College London, London, United Kingdom; 3University of Exeter, Exeter, United Kingdom.

Background: Studies have demonstrated that genetic testing using whole-exome sequencing (WES) detects undiagnosed monogenic kidney disease in up to 2% patients with predefined clinical phenotypes and/or strong family histories of kidney disease. We aimed to take advantage of newly available datasets with WES and medical information on 50,000 people from UK Biobank (UKBB) to identify PKD1 and PKD2 variants in a sample not selected for kidney disease, to compare their phenotypic features to people with ICD 10 codes for PKD in UKBB.

Methods: We analysed data from the subset of 50,000 individuals from UK Biobank (n=500,000) who have had WES data released. We looked for mutations in PKD1 and PKD2. Our primary analysis involved looking for a subset of mutations, protein-truncating variants, that had a very high likelihood of being disease-causing. We performed standard quality control which included visual inspection and assessing individual mutation on genome databases.

Results: We found 53 protein truncating variants (44 in PKD1 and 9 in PKD2). The average age for those with mutations was 57, the same as the UKBB population. We excluded 33 variants on the basis that they were either very common in Gnomad therefore unlikely to be pathogenic or did not pass visual inspection on IGV plot. This left 20 likely pathogenic mutations (13 PKD1 and 7 PKD2). An ICD 10 code for PKD on hospital records was found in 8 of those with mutations. The 8 individuals with mutations and a PKD ICD 10 code had a more severe phenotype; 7/8 (88%) were hypertensive compared with 6/12 (50%) in those with mutations but without a PKD ICD10 code. Their renal function was worse (63% vs 15% had Cr≥175 μmol/l, p=0.01) and 1 individual received a renal transplant.

Conclusions: We were able to find disease causing mutations in PKD1 and PKD2 and link this to phenotype in UKBB. People with protein truncating mutations and hospital codes for PKD had independent evidence of kidney disease however those without an ICD 10 code of PKD could either have milder undiagnosed PKD, or non-pathogenic mutations. The genetic complexity of PKD1 and 2, and the difficulty of ascertainment mutations with exome sequencing means that further work needs to be done to see if prevalence of PKD, and in particular undiagnosed mutations, could be assessed using WES from the complete UKBB dataset when available.
PO1525
PKD1 Compared with PKD2 Genotype and Cardiac Hospitalizations in the HALT-PKD Studies
Cortney Steele,1 Zhijing You,1 Berenice Y. Gitomer,1 Godela M. Brossman,1 Peter C. Harris,1 Vicente E. Torres,1 Kaleb Abee,1 Theodore I. Steinman,4 Alan S. Yu,1 Ronald D. Perrone,2 William E. Braun,1 Arlene B. Chapman,† Michel Cholunchl,3,1 Kristin L. Nowak,1 University of Colorado Denver - Anschutz Medical Campus, Aurora, CO; 2Mayo Clinic Minnesota, Rochester, MN; 3University of Pittsburgh Medical Center, Pittsburgh, PA; 4Beth Israel Deaconess Medical Center, Boston, MA; 5University of Kansas Medical Center, Kansas City, KS; 6Tufts Medical Center, Boston, MA; 7Cleveland Clinic, Cleveland, OH; 8University of Chicago Pritzker School of Medicine, Chicago, IL.

Background: Polycystin 1 and 2 are expressed in vascular endothelial and vascular smooth muscle cells. While the hallmark of autosomal dominant polycystic kidney disease (ADPKD) is the development and continued growth of multiple renal cysts that ultimately result in loss of kidney function, cardiovascular complications are the leading cause of death. Although hypertension occurs earlier and more frequently in PKD1 vs. PKD2, both genotypes seem to confer equal risk of developing intracranial aneurysms. It is currently unknown if PKD1 vs. PKD2 confers a different risk of cardiovascular events.

Methods: 864 individuals with ADPKD who participated in the 5-yr HALT-PKD study A or B and had genotype data with either a PKD1 or PKD2 mutation were included in this analysis. Since the number of cardiac events in the HALT-PKD studies was limited, we determined the association of genotype with the adverse cardiac event with the highest frequency (cardiac hospitalization; defined according to the Common Terminology Criteria for Adverse Events v.4.0 of the National Cancer Institute and adjudicated by an endpoints committee). The association of genotype with cardiac hospitalization was determined using logistic regression.

Results: Among the 864 included participants, individuals with the PKD1 genotype (84%) were slightly younger (42 yrs; range 20-95) vs. PKD2 (16%) (47 yrs; range 20-95 yrs, p=0.0001) and had a slightly lower blood pressure, body mass index, and baseline estimated glomerular filtration rate (eGFR; 70.2±16.2 vs. 75.4±16.2 ml/min/1.73 m², p=0.01). Cardiac hospitalization (n=43) was more common in individuals with a PKD2 genotype (9.2%) compared to a PKD1 genotype (4.1%; p=0.01). After adjustment for age, sex, race, and study randomization, PKD2 was associated with an increased odds of cardiac hospitalization (OR; 2.14, 95% CI: 1.04-4.41 vs. PKD1). This association was slightly attenuated after further adjustment for cardiac history, systolic blood pressure, body mass index, and baseline estimated glomerular filtration rate (OR; 2.12, CI: 0.99-4.52).

Conclusions: In early- and late-stage participants in the HALT-PKD studies, PKD2 genotype was independently associated with increased odds of cardiac hospitalization. Funding: NIDDK Support

PO1526
A Novel Case of Turner Syndrome and Autosomal Dominant Polycystic Kidney
Rachel Styer,† Faris Q. Hashim,2 Departments of Pediatrics, Texas A&M Health Science Center, Baylor Scott & White McLane Children Medical Center, Temple, TX; 2Division of Pediatric Nephrology, Texas A&M Health Science Center, Baylor Scott & White McLane Children Medical Center; Temple, TX.

Introduction: Turner Syndrome (TS) is a sex chromosome disorder resulting from the complete or partial loss of one of the X chromosomes. Short stature is common in TS and is commonly treated with growth hormone (GH). Autosomal dominant polycystic kidney disease (ADPKD) is a multisystem disorder that has bilateral renal cysts and is an important cause of end stage renal disease (ESRD).

Case Description: A 5-1/2 yr old girl with TS with 45 X, treated with GH since the age 2 yr with good clinical response. She presented to nephrology clinic for evaluation of bilateral, large kidneys for age (RK 10.0 cm, LK 9.7 cm) per recent renal ultrasound (US). No hypertension was found on her exam. Family History was negative for polycystic kidney disease (PKD), hypertension, renal disease, hemodialysis, renal transplant or intracranial aneurysms. On follow up US 1 year later, a few bilateral cysts measuring < 1 cm and persistent renal enlargement was noted. Due to concerning findings of progressive renal cysts with further growth of the kidneys potentially secondary to GH treatment, her GH treatment was stopped. After 6 months off GH therapy, renal enlargement was uncontrolled with enlargement of her cysts. Patient got genetic studies for PKD and was found to be heterozygous for pathogenic variant in the PKD1 gene consistent with the diagnosis of ADPKD. Parents both tested negative for PKD1 mutation suggestive of de novo mutation.

Discussion: Patients with TS often have short stature requiring GH treatment in order to achieve normal adult height. TS has multi-organ system manifestations including an increased risk for renal anomalies like simple renal cyst, horseshoe, duplicated, or absent kidney. This case highlights the potential increased risk for patients with TS who are on GH therapy and develop kidney disease. To the best of our knowledge, the association of TS and ADPKD has not been described yet. The current clinical practice guidelines state that patients with known TS should receive a renal US at time of diagnosis with no further follow up renal imaging has been recommended at this time. Given the potential role of GH in cyst proliferation and frequency of GH therapy in this patient population, we recommend reevaluation of current renal screening guidelines for patient with TS. Early diagnosis and treatment could potentially reduce morbidity associated with renal disease and growth hormone deficits.

PO1527
CYP24A1 Mutations Are Associated with Renal Cystic Disease

Background: Loss-of-function mutations in the CYP24A1 gene cause a rare hereditary disease leading to reduced 24-hydroxylase enzyme activity, characterized by increased serum 1,25-dihydroxyvitamin D, levels, hypercalcemia, hypercalciuria, nephrocalcinosis, and/or nephrolithiasis. Renal cysts in CYP24A1 mutations were first reported in a single case study from our institution. However, to date a possible association between CYP24A1 mutations and renal cysts has not been examined.

Methods: Retrospective review of all patients with confirmed CYP24A1 mutations and complete renal imaging studies at a tertiary academic center between 2010 and 2020. Cyst location, number, and diameter were measured by contrast-enhanced computed tomography (CT), non-contrast CT, ultrasound or magnetic resonance imaging.

Results: Among the 13 patients with CYP24A1 mutation, 46% were male and 38% children. The mean age at diagnosis was 24.7 ± 18.8 years (range I-60). Medullary and/or corticomedullary junctional renal cysts were present in all 13 cases (5 with unilateral and 8 with bilateral cysts). The mean age at imaging with first detected cyst was 31.1 ± 20.5 years (range 3-61). The median number of cysts per patient was 3 (IQR 1-5). The mean size of the smallest and largest cyst were 3.6 ± 2.2 mm (range 2-8) and 11.9 ± 6.9 mm (range 2-30) respectively. All 13 had normal age-adjusted renal size and none had a family history of polycystic kidney disease. The number of cysts (a 5 mm in size) in 63% of adult patients was above the 97.5th percentile of an age- and sex-matched control population (Figure 1).

Conclusions: This study suggests an association between CYP24A1 mutations and cystic kidney disease. Further studies are needed to evaluate the role of CYP24A1 and vitamin D metabolism in renal cyst formation, and whether cysts enhance CKD risk in patients with CYP24A1 deficiency, or modify nephrocalcinosis/urinary stone risk.
more dense collagen, and collagen hybridizing peptide labeling showed more denatured collagen in pkd2 zebrafish kidney. Preliminary data from Pkd10.3−/− mice show similar patterns of collagen density and denaturation.

**Conclusions:** To our knowledge, this is the first report of any phenotype in pkd2 zebrafish (adult or embryo). The presence of a dominant phenotype and a collagen defect suggests conservation of disease etiology. A collagen defect in the absence of cysts indicates independence of collagen changes from cyst formation, suggesting collagen changes may be a primary defect in PKD pathophysiology.

**Funding:** NIDDK Support

Increased collagen density in kidney of pkd2 mutant zebrafish visualized by staining with picrosirius red and imaging using polarized light (left) quantified using image thresholding in ImageJ (right). Pixels are binned by color indicating density as shown.

**Cystic Kidney Disease in Patients with Thin Basement Membrane Disease (TBMD)**

**Janina Paula F.C. Prince, M. Singh, S. Nasr, T. Chebib.**

**Background:** TBMD is a benign glomerular disease typically manifesting as microscopic hematuria with/without minimal proteinuria and with preserved kidney function. A few reports described the finding of kidney cysts in TBMD patients, but this association remains uncertain.

**Methods:** A retrospective study of patients seen at a tertiary academic center (2009-2019) and had a kidney biopsy with reported diffuse glomerular basement (GBM) thinning was done. The diagnosis of TBMD was confirmed by a careful review of the biopsy findings, including EM images. Patients with clinical and/or pathologic features of Alport disease or with unavailable abdominal imaging were excluded. Cyst number and size were recorded on the first available imaging.

**Results:** Among 49 TBMD patients, 29 (59%) had kidney cysts (cystic), and 20 and 19.6 (± 24) mm respectively. The number of cysts (≥ 5 mm) in 34% of cystic patients (cystic) and 20% and 19.6 (± 24) mm respectively. The number of cysts (≥ 5 mm) in 34% of cystic patients vs. 39 yrs). Hematuria was the major indication for biopsy. Hematuria and dysmorphic RBCs were found in 72% and 41% of cystic patients respectively vs. 80% and 10% in noncystic patients. Cystic patients had lower mean eGFR at time of biopsy (69 vs. 93 mL/ min/1.73 m2), higher mean 24-h proteinuria (968 vs. 172 mg/d), and comparable mean serum creatinine (1.1 vs 1.7 mg/dL) at the end of follow-up, and MCD was the only risk factor for the progression of CKD (p < 0.00). Patients with MCD had higher Scr (2.1 vs 1.1 mg/dL, p = 0.004) and lower eGFR (41.7 vs 77.2 mL/min/1.73m2, p = 0.00) at the end of follow-up, and MCD was the only risk factor for the progression of CKD (p = 0.004). Patients with MCD had higher Scr (2.1 vs 1.1 mg/dL, p = 0.004) and lower eGFR (41.7 vs 77.2 mL/min/1.73m2, p = 0.00) at the end of follow-up, and MCD was the only risk factor for the progression of CKD (p = 0.004). Patients with MCD had higher Scr (2.1 vs 1.1 mg/dL, p = 0.004) and lower eGFR (41.7 vs 77.2 mL/min/1.73m2, p = 0.00) at the end of follow-up, and MCD was the only risk factor for the progression of CKD (p = 0.004). Patients with MCD had higher Scr (2.1 vs 1.1 mg/dL, p = 0.004) and lower eGFR (41.7 vs 77.2 mL/min/1.73m2, p = 0.00) at the end of follow-up, and MCD was the only risk factor for the progression of CKD (p = 0.004). Patients with MCD had higher Scr (2.1 vs 1.1 mg/dL, p = 0.004) and lower eGFR (41.7 vs 77.2 mL/min/1.73m2, p = 0.00) at the end of follow-up, and MCD was the only risk factor for the progression of CKD (p = 0.004). Patients with MCD had higher Scr (2.1 vs 1.1 mg/dL, p = 0.004) and lower eGFR (41.7 vs 77.2 mL/min/1.73m2, p = 0.00) at the end of follow-up, and MCD was the only risk factor for the progression of CKD (p = 0.004). Patients with MCD had higher Scr (2.1 vs 1.1 mg/dL, p = 0.004) and lower eGFR (41.7 vs 77.2 mL/min/1.73m2, p = 0.00) at the end of follow-up, and MCD was the only risk factor for the progression of CKD (p = 0.004). Patients with MCD had higher Scr (2.1 vs 1.1 mg/dL, p = 0.004) and lower eGFR (41.7 vs 77.2 mL/min/1.73m2, p = 0.00) at the end of follow-up, and MCD was the only risk factor for the progression of CKD (p = 0.004). Patients with MCD had higher Scr (2.1 vs 1.1 mg/dL, p = 0.004) and lower eGFR (41.7 vs 77.2 mL/min/1.73m2, p = 0.00) at the end of follow-up, and MCD was the only risk factor for the progression of CKD (p = 0.004). Patients with MCD had higher Scr (2.1 vs 1.1 mg/dL, p = 0.004) and lower eGFR (41.7 vs 77.2 mL/min/1.73m2, p = 0.00) at the end of follow-up, and MCD was the only risk factor for the progression of CKD (p = 0.004).

**Conclusions:** MCD is frequently observed in TBMD patients and is a risk factor for the progression of CKD.

PO1532
Identifying and Assessing the Phenotypic Features of HNF1B Deletions and Duplications in UK Biobank
Kittiya Sukcharoen,1 Coralie Bingham,1 Michael Weedon,2 Richard A. Oram.2
1University of Exeter; Royal Devon and Exeter NHS Foundation Trust, Exeter, United Kingdom; 2University of Exeter Medical School, Exeter, United Kingdom.

Background: Heterozygous mutations of hepatocyte nuclear factor 1β (HNF1B) are the most common known monogenic cause of developmental kidney disease. Renal cysts are the most frequently detected feature. Other features include early-onset diabetes and abnormal liver function. It is thought that duplications of HNF1B do not result in strong phenotypic features. The true pathogenicity and penetrance of many rare putative disease-causing copy number variants (CNVs) is uncertain and may be over-estimated by clinical ascertainment. We aimed to assess the pathogenicity and penetrance of HNF1B deletions and duplications in UK Biobank (UKBB) and to describe any associated phenotype.

Methods: We used data from 388,714 UKBB participants to assess CNVs of HNF1B in a population-based setting using SNP chip intensity data. We tested the association of these CNVs with diabetes and other clinically-relevant traits. We assessed the UKBB phenotype and biomarker information and correlated these with the deletions and duplications.

Results: We identified 11 individuals with large deletions relating to HNF1B and 106 with duplications. There were no significant difference in the average ages of deletion (53), duplication (56) and UKBB population (57). Of the 11, 3 were reported to have glomerular disease, 1 had haematuria, 1 had a renal transplant, and 6 had diabetes (55% vs. 5% amongst the rest of the UKBB, P=2×10^-6). The penetrance of diabetes was 30% and average eGFR was 71 (45% with eGFR<60) compared to 91 (40%) in UKBB population. Their liver function is comparatively different. Gamma GT 110 v 37.4 (32%), polyuria (30%), renal pain (25%), blood creatinine increase (23%) and nocturia (22%); the rates were similar between the 2 subgroups. One incidence of hepatic enzyme increase with one of hemodialysis and one death (unrelated to TOL) was only observed in Subgroup 2.

Conclusions: HNF1B deletions and duplications can be detected in a large unselected dataset. Deletions are more pathogenic than duplications. However, HNF1B duplications do not have an effect in phenotype, which has not been previously described. The frequency of both HNF1B deletions and duplications may be higher than previously estimated.

PO1533
Late-Onset Hepatocyte Nuclear Factor 1β-Associated Kidney Disease
Emad Alahri, Molly Fisher. Montefiore Medical Center, Bronx, NY.

Introduction: Hepatocyte Nuclear Factor 1β (HNF1β) is an important transcription factor for kidney development. HNF1β mutations are rare, associated with multisystemic disease and heterogeneous kidney involvement. HNF1β-associated kidney disease may not manifest until adulthood. We present a case of an older female with chronic kidney disease and heterogeneous kidney involvement. HNF1β-deleted kidney cysts due to a heterozygous deletion in the HNF1β gene.

Case Description: 66 y/o Puerto Rican female with a history of recurrent urinary tract infections, pre-diabetes, hypertension, arthritis, congenital absence of left ovary and baseline SCr 0.9 mg/dL was referred for evaluation of bilateral kidney cysts and chronic hypogammaglobulinemia. Review of magnetic resonance imaging and ultrasound going back to 2003 showed normal sized kidneys and presence of more than 4 cysts in each kidney, some of which were mildly complex. No extrarenal cysts were noted and she denied family history of kidney cysts. Chronic symptomatic hypogammaglobulinemia was present since at least 2015 with serum magnesium ranging from 1.1-1.6 mg/dL, resulting in emergency room visits and hospitalizations. Fractional excretion of magnesium was 29%, consistent with renal magnesium wasting. Serum potassium and bicarbonate were normal. Intact parathyroid hormone ranged from 83-112 pg/mL, but serum calcium, phosphorus, 25 dihydroxyvitamin D were normal. Urinalysis was bland. She was sent for genetic testing and underwent whole exome sequencing. Results demonstrated a heterozygous deletion in the HNF1β gene consistent with HNF1β nephropathy. She was started on amiloride and slow release magnesium supplementation with near normalization of her serum magnesium.

Discussion: HNF1β-associated kidney disease is a challenging diagnosis given extreme variability in phenotypes. De novo mutations occur in up to half of patients leading to diagnosis later in life. Our patient’s constellation of medical problems including glucose intolerance, mild hyperparathyroidism, hypogammaglobulinemia, unilateral ovary agenesis and genitourinary (GU) tract abnormalities are all features of HNF1β-associated kidney disease. This diagnosis should not be overlooked in patients with GU abnormalities, electrolytes disturbances and/or signs of tubulointerstitial kidney disease. Additionally, these patients should be monitored for progressive kidney disease and undergoing periodic screening for renal cell carcinoma.

PO1534
A Post Hoc Analysis of Tolvaptan (TOL) Efficacy and Safety in Slowing Rate of Renal Function Decline in Subjects with Very Late-Stage Autosomal Dominant Polycystic Kidney Disease (ADPKD)
Vicente E. Torres,1 Ron T. Gansevoort,2 Arlene B. Chapman,2 Ronald D. Perrone,2 John Ouyang,3 Jennifer Lee,1 Hina Japes,1 Tao Wang,2 Mayo Clinic Minnesota, Rochester, MN; 3Bijlkhuis University Groningen, Groningen, Netherlands; 4University of Chicago, Chicago, IL; 5Tufts Medical Center, Boston, MA; 6Osuka Pharmaceutical Development and Commercialization Inc, Rockville, MD.

Background: ADPKD is a progressive disease that causes end-stage renal disease in ~50% of the affected individuals by age 60. TOL, a selective vasopressin V2-receptor antagonist, has been shown to slow the progression of renal function decline in ADPKD subjects with an eGFR of 25 mL/min/1.73m2 or higher. The efficacy and safety of TOL in subjects with lower eGFR remain understudied. This post-hoc analysis evaluated the efficacy and safety of TOL in subjects with stage 4 CKD (eGFR of <30 mL/min/1.73m2).

Methods: This is a retrospective analysis of a subgroup of ADPKD subjects who enrolled in the TOL open-label extension (OLE) trial (NCT02251275). Included subjects had a baseline eGFR of <30 mL/min/1.73m2, received ≥1 TOL dose, and were randomized to the placebo group in the REPRISE trial (NCT02160145). Two subgroups of subjects were analyzed, one with baseline eGFR of 25-30 (Subgroup 1) and one <25 (Subgroup 2). The variables evaluated included demographics, adverse event (AE) profile, and intra-subject comparison of change in annualized eGFR decline during the OLE trial to that during placebo use in the REPRISE trial. Annualized eGFR change slopes in the treatment period were calculated using eGFR values between Month 1 and 12 visits to compensate for the acute hemodynamic effect of tolvaptan. Comparison was made by linear mixed model.

Results: Of 1,803 subjects enrolled, 159 (8.8%; 76 in Subgroup 1 and 83 in Subgroup 2) met the selection criteria. Annualized eGFR change slopes for all subjects (n=148) were -5.28 in the REPRISE trial and -3.16 in the OLE trial with a treatment effect of 2.11 (95% CI: -0.05, 4.26, p=0.066). The treatment effects were 1.99 and 2.17 for Subgroups 1 and 2, respectively (p=0.0001 for both subgroups). The 5 most common AEs were thirst (32%), polyuria (30%), renal pain (25%), blood creatinine increase (23%) and nocturia (22%); the rates were similar between the 2 subgroups. One incidence of hepatic enzyme increase, one of hemodialysis and one death (unrelated to TOL) was only observed in Subgroup 2.

Conclusions: This post-hoc analysis demonstrated that TOL significantly decreases the rate of eGFR decline in ADPKD subjects with stage 4 CKD, including those with an eGFR of <25 mL/min/1.73m2.
PO1536

Impact of Long-Term Tolvaptan Treatment for Autosomal Dominant Polycystic Kidney Disease: A Single-Centre Retrospective Japanese Cohort Study

Junya Yamamoto, Saori Nishio, Daigo Nakazawa, Tatsuya Atsumi. Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Japan.

Background: Several clinical trials have revealed the efficacy of the tolvaptan for autosomal dominant polycystic kidney disease (ADPKD) in various years. Our objective is to verify the impact of tolvaptan in our Japanese ADPKD cohort.

Methods: We retrospectively investigated the efficacy of tolvaptan for ADPKD patients who initiated tolvaptan from June 2014 to March 2020 in Hokkaido University Hospital. Patients treated with tolvaptan for more than 1 year were included for analyses. Patients never treated by tolvaptan were set as control. Patients in CKD stage 5 or 3D at baseline or post-kidney transplantation were excluded from analyses. Patients stratified by Mayo classification (Class 1A-1E). Analyses included the comparison of the annual changes of eGFR at eGFR (mL/min/1.73m²/year) and total kidney volume (ATKV (>2cm³/year)) between pre and post-treatment, and AeGFR or ATKV between tolvaptan-treated and control.

Results: 109 tolvaptan-treated and 139 control patients were included. 24 patients in each group were excluded. About 40% of tolvaptan-treated patients belonged to advanced CKD stage (CKD5-3B). Duration of treatment was 3.3±1.3 years. eGFR of tolvaptan group were lower and hATKV of tolvaptan group were higher compared to those of control group at baseline (eGFR: 53.7±22.8 vs 65.7±30.0, p=0.06. hATKV: 1198±157 vs 829±799.5 mL/min, p<0.0001). There was no significant difference in AeGFR between treatment (53.9±2.86 vs 53.8±2.86) or control group (53.8±2.86 vs 53.8±2.86). However, in tolvaptan group AeGFR improved compared to pre-treatment (-2.95±2.86 vs -4.33±5.72, p=0.027) and this improvement lasted at least for 36 months in 50 patients. ATKV of tolvaptan group was lower than that of control (21.99±30.3 vs 30.43±6.05 vs 5.10±4.06±1.6, p<0.01) and this trend was also found in Mayo class 1B-1D. ATKV also decreased compared to pre-treatment (2.19±0.33 vs 4.06 vs 4.67±0.57-6.76, p<0.01).

Conclusions: Tolvaptan dramatically reduced ATKV, while there was no beneficial effect for AeGFR compared to control. However tolvaaptan improved AeGFR compared to that of pre-treatment. The discrepancy between our results and previous reports might arise from the fact that our cohort mainly comprised advanced CKD stage patients or limited sample size. Further long-term observation is required to validate the effect of tolvaptan.

PO1537

Canadian Real-World Assessment of Tolvaptan in ADPKD: C-MAJOR Study and Safety Monitoring and Distribution Program

Philip McFarlane,1 Patrick S. Parfrey,2 Daniel G. Bicht,3 Luc Bergeron,1 Annick Laporte,1 1Otaka Canada Pharmaceutical Inc, Montreal, QC, Canada; 2St Michael’s Hospital, Toronto, ON, Canada; 3Memorial University of Newfoundland, St. John’s, NL, Canada; 4Univeisite de Montreal, Montreal, QC, Canada.

Background: Tolvaptan is the only approved treatment in Canada for slowing renal function decline and kidney enlargement in ADPKD patients. As per Health Canada Mitigation Strategy (REMS), which is a mandatory program for patients prescribed tolvaptan, tolvaptan treatment pattern analysis and to report on treatment persistence and liver transaminases elevation rate through the HSMDP.

Methods: Descriptive analyses were conducted on the following baseline measures: demographics, hereditary kidney disease. Tolvaptan (Jynarque®), the first and only approved treatment in the US, has been shown to slow kidney function decline in clinical trials. An understanding of characteristics of the real-world patients initiating treatment with tolvaptan in the US is needed.

Results: An observational, retrospective analysis assessing baseline measures was conducted among patients with ADPKD who had initiated treatment with tolvaptan from 14 May 2018 through 9 January 2020 in the US. Data were obtained by linking the Symphony Health Integrated Dataverse (IDV), a nationally representative billing database, with Specialty Pharmacy (SP) data from the tolvaptan Risk Evaluation and Mitigation Strategy (REMS), which is a mandatory program for patients prescribed tolvaptan to treat ADPKD. The study index date was the date of first shipment of tolvaptan. Descriptive analyses were conducted on the following baseline measures: demographics, hereditary kidney disease, and disease characteristics. All measures were identified within the 6-month period prior to the index date in the Symphony Health IDV.

Conclusion: This is the first real-world study to describe characteristics of ADPKD patients initiating treatment with tolvaptan in the US.

PO1538

Early Findings of Patients with Autosomal Dominant Polycystic Kidney Disease Initiating Tolvaptan in the United States: A Claims-Based Analysis

Irene Cosmatos,1 Sunning Tao,1 Gretchen S. Dieck,1 Michele L. Julian,1 Timothy Wilt,2 Kristin Pareja,2 Mylene Sanon.3 United BioSource LLC, Blue Bell, PA; 2Otsuka Pharmaceutical Development and Commercialization Inc, Princeton, NJ.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common hereditary kidney disease. Tolvaptan (Jynarque®), the first and only approved treatment for ADPKD in the United States (US), has been shown to slow kidney function decline in clinical trials. An understanding of characteristics of the real-world patients initiating treatment with tolvaptan in the US is needed.

Methods: An observational analysis assessing baseline measures was conducted among patients with ADPKD who had initiated treatment with tolvaptan from 14 May 2018 through 9 January 2020 in the US. Data were obtained by linking the Symphony Health Integrated Dataverse (IDV), a nationally representative billing database, with Specialty Pharmacy (SP) data from the tolvaptan Risk Evaluation and Mitigation Strategy (REMS), which is a mandatory program for patients prescribed tolvaptan to treat ADPKD. The study index date was the date of first shipment of tolvaptan. Descriptive analyses were conducted on the following baseline measures: demographics, hereditary kidney disease, and disease characteristics. All measures were identified within the 6-month period prior to the index date in the Symphony Health IDV.

Results: Analysis was conducted for 4,355 patients. The mean age at tolvaptan initiation was 48.8 years (Standard Deviation: 12.3), with 51.7% (n=2,251) female. Hypertension was the most commonly observed comorbidity (n=3,520, 80.8%), followed by diabetes (n=273, 6.3%). The distribution of CKD stage, available for 1,566 (36.0%) participants, was: 6.2% (n=97) in CKD Stage I, 13.4% (n=210) in CKD Stage II, 55.2% (n=864) in CKD Stage III, 22.9% (n=359) in CKD Stage IV, and 2.3% (n=36) in CKD stage V.

Conclusions: This is one of the first real-world studies to describe characteristics of ADPKD patients initiating treatment with tolvaptan in the US. Stage III was the most commonly reported CKD stage among patients with a known CKD stage during their baseline period. Additional analyses evaluating the real-life impact of tolvaptan on clinical outcomes, healthcare utilization, and quality of life are needed.

Early-World Descriptive Findings on Tolvaptan-Treated Patients with Autosomal Dominant Polycystic Kidney Disease in the United States Mylene Sanon,2 Sunning Tao,1 Irene Cosmatos,1 Gretchen S. Dieck,1 Michele L. Julian,1 Timothy Wilt,2 Kristin Pareja,2 Alvin Estilo,2 Carol I. Matthews.1 United BioSource LLC, Blue Bell, PA; 2Otsuka Pharmaceutical Development and Commercialization Inc, Princeton, NJ.

Background: Tolvaptan is the first and only treatment for autosomal dominant polycystic kidney disease (ADPKD) approved in the United States (US). The Food and Drug Administration (FDA) required a Risk Evaluation and Mitigation Strategy (REMS) to mitigate the risk of liver injury, which is the most severe adverse event potentially associated with tolvaptan. The aim of this interim analysis is to describe baseline characteristics of patients at initiation of tolvaptan through the C-MAJOR study and to report on treatment persistence and liver transaminases elevation rate through the HSMDP.

Methods: A retrospective analysis of patients with ADPKD enrolled in C-MAJOR was conducted. All patients treated with tolvaptan for more than 1 year were included for analyses. Patients who initiated tolvaptan from June 2014 to March 2020 in Hokkaido University Hospital. Patients never treated by tolvaptan were set as control. Patients in CKD stage 5 or 3D at baseline or post-kidney transplantation were excluded from analyses. Patients stratified by Mayo classification (Class 1A-1E). Analyses included the comparison of the annual changes of eGFR at eGFR (mL/min/1.73m²/year) and total kidney volume (ATKV (>2cm³/year)) between pre and post-treatment, and AeGFR or ATKV between tolvaptan-treated and control.

Results: A total of 5,366 patients who initiated tolvaptan in the REMS comprised the study population. Mean age at tolvaptan initiation was 46.8 years (standard deviation [SD]: 11.6); 2,751 (51.3%) were female. Of the patients with a known race (n=2,705, 50.4%), the majority were white (n=2,153, 79.6%). Of those with known ethnicity (n=2,190, 94.0%), 759 (35.1%) were non-Hispanic or non-Latino. Overall, 2,366 (44.1%) tolvaptan initiators had at least 1 year of follow-up after the index date and were included in the treatment pattern analysis. The most frequent dose of tolvaptan was 45/15 milligrams daily (47.5%). The mean MPR was 0.74 (SD: 0.32); mean persistence was 325.9 days (SD: 173.2).

Conclusions: This is the first descriptive demographic report of real-world ADPKD patients in the US initiating tolvaptan. Based on the data currently available, most patients were between 35-55 years, equally male or female, and were non-Hispanic or non-Latino which is consistent with the patient population included in the treatment pattern analysis remained on tolvaptan close to 1 year.

**Benefit of Tolvaptan on Time to ESRD for Patients with Rapidly Progressing Autosomal Dominant Polycystic Kidney Disease (ADPKD): A Disease Progression Model**

Gregory Mader,1 Molly F. Purser,1 Deirdre M. Mladsi,1 Myrlene Sanon,2 Dorothee Oberdian,1 Terry J. Watinick,1 Stephen L. Seliger,1 RTI Health Solutions Research Triangle Park, Research Triangle Park, NC;2 Otsuka America Pharmaceutical Inc, Rockville, MD;3 University of Maryland School of Medicine, Baltimore, MD.

**Background:** The efficacy and safety of tolvaptan in adults with ADPKD was initially established in a 3-year phase 3 clinical trial (TEMPO 3:4; NCT00428948). Tolvaptan was approved in the United States in 2018 for patients with ADPKD at high risk of progression. A published ADPKD progression model predicted longer-term outcomes including eGFR decline and time to ESRD. The model incorporated an equation used to predict eGFR based on Mayo subclasses 1C, 1D, and 1E as indicators of rapid progression. To estimate treatment benefit, long-term outcomes were modeled for patients treated with and without tolvaptan based on the TEMPO 3:4 cohort.

**Methods:** In the base case, the annual absolute reduction in eGFR decline for tolvaptan versus placebo of 1.2 ml/min/1.73m2 was applied to the predicted rates of eGFR decline in the absence of treatment. Additionally, in a sensitivity analysis based on a post-hoc analysis of TEMPO 3:4, the effect on eGFR decline by subclass 1C, 1D, and 1E was applied. CKD progression and time to ESRD were estimated for both cohorts.

**Results:** The predicted time to ESRD was longer for all patients in CKD stages 1-3 treated with tolvaptan, with greater estimated absolute benefit when treatment was initiated for patients in early CKD stages (Image).

**Conclusions:** The model estimates that patients treated with tolvaptan versus no treatment spend more time in earlier CKD stages and later onset of ESRD. Results were consistent across CKD stages and Mayo subclasses. Findings highlight the potential long-term value of early intervention with tolvaptan in patients at risk of rapid ADPKD progression.

**PO1542**

**Urinary Lithogenic Risk Profile in ADPKD Patients Treated with Tolvaptan**

Matteo Baraschi,1 Nassar Dhayat,2 Pietro Manuel Fuster.3

**Background:** Nephrolithiasis is a common health problem in autosomal dominant polycystic kidney disease (ADPKD) and significantly contributes to patient morbidity. Recently, Tolvaptan has been introduced for the treatment of ADPKD, but if it is associated with alterations of the urinary lithogenic risk profile remains unknown.

**Methods:** We conducted an analysis of participants enrolled in the Bern ADPKD registry, a prospective observational cohort study. 24 hour urine analyses were performed at baseline and then at yearly follow-ups. Relative supersaturation ratios for calcium oxalate, brushite and uric acid were calculated with the program EQUIL2. Unadjusted and multivariable mixed-effects linear regression models, adjusted for age, sex, body mass index, the urinary glomerular filtration rate, net acid excretion and height-adjusted total kidney volume were used to assess the association of Tolvaptan with urinary parameters relevant for kidney stone formation. Maximum individual follow-up time was 3 years, median follow-up time 1.9 years and cumulative follow-up time was 169 years.

**Results:** 125 participants (38 with and 87 without Tolvaptan treatment) were included in the analysis. In multivariable analysis, Tolvaptan treatment was associated (adjusted estimate of the difference Tolvaptan vs. no Tolvaptan = 95 CI) with lower urine relative supersaturation ratios for calcium oxalate (-0.56; -0.82 to -0.3, p < 0.001), brushite (-0.33; -0.54 to -0.11, p = 0.004) and uric acid (-0.02; -0.38 to 0.37, p < 0.001) and with increased urine citrate in mmol/mmol creatinine per day (0.25; 0.050-0.46, p = 0.02) and calcium in mmol/mmol creatinine per day (0.31; 0.090-0.53, p = 0.006) excretion. In addition, Tolvaptan treatment was associated with decreased net acid excretion in meq/mmol creatinine per day (-0.54; -0.90 to -0.17, p = 0.004) and increased net gastrointestinal alkaline absorption in meq/mmol creatinine per day (0.57, 0.26-0.88; p < 0.001).

**Conclusions:** Tolvaptan treatment is associated with a significantly improved urinary lithogenic risk profile in ADPKD patients.

**The Effect of Trichlormethiazide in Patients with Autosomal Dominant Polycystic Kidney Disease Using Tolvaptan: A Randomized Cross-Over Controlled Trial**

Kiyotaka Uchiyama,1 Yoshitaka Ishihashi,2 1Keio University School of Medicine, Shinjuku-ku, Japan; 2Japanese Red Cross Medical Center, Shibuya-ku, Japan.

**Background:** The vasopressin V2 receptor antagonist tolvaptan has been shown to slow the progression of autosomal dominant polycystic kidney disease (ADPKD). However, some patients discontinue tolvaptan due to severe adverse aquaretic events. This open-label, randomized, controlled, counterbalanced, crossover trial investigated the effects of trichlormethiazide, a thiazide diuretic, on reducing urinary volume and improving ADPKD tolerability in patients with ADPKD on high-dose tolvaptan, based on the effects of thiazides in patients with nephrogenic diabetes insipidus.

**Methods:** A total of 10 patients with ADPKD on high-dose tolvaptan (median age, 49 years; 4 males) received antihypertensive therapy with or without trichlormethiazide in random order for 12 weeks. The starting doses for trichlormethiazide were 2 and 4 mg in patients with estimated glomerular filtration rates of ≥30 and <30 mL/min/1.73 m2, respectively. Target blood pressure range was 110/70–130/80 during the study period. Primary outcomes were 24-hour urine volume and urine osmolality. Secondary outcomes were health-related quality of life (HRQOL) assessed by the Kidney Disease Quality of Life-Short Form questionnaire, rate of decline in renal function, serum/urinary electrolytes, serum/urinary biomarkers associated with chronic kidney disease and ADPKD progression, and office blood pressure.

**Results:** The urine volume was significantly reduced (3324 ± 614 vs. 4169 ± 729 mL; p < 0.001) along with an increase in urine osmolality (179.0 ± 26.6 vs. 139.1 ± 39.6 mosm; p = 0.001) in patients on antihypertensive therapy with trichlormethiazide. Moreover, trichlormethiazide improved several HRQOL subscales including effects of kidney disease, sleep, emotional role functioning, social functioning, and role/social component summary. There were no significant differences in the slope of estimated glomerular filtration rate assessed by creatinine and cystatin C or serum/urinary biomarkers between the patients on antihypertensive therapy with and without trichlormethiazide. Office blood pressure was not significantly different between the treatment groups.

**Conclusions:** In patients with ADPKD treated with high-dose tolvaptan, trichlormethiazide may improve tolvaptan tolerability and HRQOL by reducing urinary volume without affecting ADPKD-related parameters.

**Global Real-World Evidence of Tolvaptan in Patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD)**

Brett A. Maisie,1 Jennifer A. Colby,1 Kristin Pareja,1 Annick Laplante,2 Xinyu Wang,3 Linda McCormick,1 Ali Noirabakh,2 Tao Wang,4 Myrline Sanon,4 Xcenda LLC, Palm Harbor, FL;3 Otsuka Canada Pharmaceutical Inc, Saint Laurent, QC, Canada;2 Otsuka Pharmaceutical Europe Ltd, Wesham, United Kingdom;4 Otsuka Pharmaceuticals Development & Commercialization, Princeton, NJ.

**Background:** ADPKD is a rare, hereditary, systemic kidney disease characterized by progressive renal damage. Patients frequently develop end stage kidney disease, requiring dialysis or transplantation. Treatment options are limited, and research in ADPKD is ongoing to improve outcomes. The vasopressin V2 receptor antagonist tolvaptan has been shown to slow ADPKD progression, and office blood pressure. The urine volume was significantly reduced (3324 ± 614 vs. 4169 ± 729 mL; p < 0.001) along with an increase in urine osmolality (179.0 ± 26.6 vs. 139.1 ± 39.6 mosm; p = 0.001) in patients on antihypertensive therapy with trichlormethiazide. Moreover, trichlormethiazide improved several HRQOL subscales including effects of kidney disease, sleep, emotional role functioning, social functioning, and role/social component summary. There were no significant differences in the slope of estimated glomerular filtration rate assessed by creatinine and cystatin C or serum/urinary biomarkers between the patients on antihypertensive therapy with and without trichlormethiazide. Office blood pressure was not significantly different between the treatment groups.

**Conclusions:** In patients with ADPKD treated with high-dose tolvaptan, trichlormethiazide may improve tolvaptan tolerability and HRQOL by reducing urinary volume without affecting ADPKD-related parameters.
PO1544

Predictors for Suppressing Polycystic Liver Progression of ADPKD by Tolvaptan
Hiroki Mizuno, Yoshifumi Ubara, Junichi Hoshino. Toranomon Byoin, Minato-ku, Japan.

Background: Polycystic liver disease (PLD) is one of the fatal complications of ADPKD, which leads to abdominal compression, cyst infection, and liver failure. Although PLD progresses after reaching ESKD, few drugs can effectively inhibit its growth. Tolvaptan (TVP), V2 receptor antagonist, has been known to suppress the growing rate of polycystic kidney disease, but the effect on PLD has not been studied yet. In order to evaluate the tolvaptan's effect on PLD, an observational cohort study was conducted.

Methods: ADPKD patients with PLD taking tolvaptan were enrolled in this study. Total liver volume (TLV) was measured by CT and calculated by automated calculated application, WINCENT®. Annual change of TLV (ΔTLV) was defined by the approximate slope estimated from more than two points. If the patients had some interventions including cyst drainage, surgical fenestration, and transcatheter trans-arterial embolization, the observational period was excluded for one year after such interventions. We compared ΔTLVs before and after TVP initiation, and defined “responder” as patients whose post-ΔTLV were smaller than pre-ΔTLV. Factors associated with “responder” were analyzed by the logistic regression model, adjusting sex, age, BMI, blood pressure, height-adjusted total kidney volume(hTKV) and ATLV before taking TVP(preATLV), by using R version 3.4.3.

Results: 85 patients were eligible to this study. Median observational periods were 1.9 years in pre-prescription period and 2.8 years in post-prescription period respectively. Median age was 55 years old and 31 cases were female. Median hTLV and hHTKV before taking TVP was 1747[557-7432] (ml/m) and 909[226-4152] (ml/m), respectively. The reduction of ΔTLV were observed in 46 cases, who were significantly older, had higher preTLV and had higher rate of taking ursodeoxycholic acid. Logistic regression analysis showed older age (OR 2.60[1.36-5.72],p<0.01) and higher preTLV (OR 1.25[1.12-1.46], p<0.01) were the predictors of the reduction of ΔTLV.

Conclusions: In this study, more than half of ADPKD patients experienced reduction of ΔTLV after taking TVP. Our study suggests that elder age and higher pre-ΔTLV would predict the reduction of the progression of PLD after TVP use, though it was reported younger female tend to have larger PLD.

PO1545

Use of Lixivaptan in a Patient with Autosomal Dominant Polycystic Kidney Disease (ADPKD) Who Previously Experienced Liver Toxicity with Tolvaptan
Neil H. Shusterman1, Lorenzo Pellegrini2, Elaine R. Richardson3, Marie C. Hogan4. 1Pulendia Biosciences, Horsham, PA; 2Mayo Clinic Minnesota, Rochester, MN.

Introduction: Blockade of the vasopressin V2 receptor has beneficial effects on the renal manifestations of ADPKD, the most prevalent inherited renal cystic disease in humans. Tolvaptan, a vasopressin V2 receptor antagonist, is the only approved pharmacologic therapy for the treatment of ADPKD patients; however, it is associated with potentially serious idiosyncratic liver toxicity. Lixivaptan is a novel, potent antagonist of the V2 receptor in Phase 3 development for the treatment of ADPKD. Evidence from non-clinical and in silico studies predicts that lixivaptan will have a safer liver toxicity profile in patients with ADPKD. Here we provide the first clinical evidence of lixivaptan’s superior liver safety compared to tolvaptan.

Case Description: A female patient with ADPKD presented with severe bilateral, intractable flank and abdominal pain. The patient had been treated with tolvaptan previously in an attempt to improve her pain; however, tolvaptan therapy had to be permanently discontinued after the patient developed clinically-meaningful alanine aminotransferase (ALT) elevations on each of three sequential attempts to treat her. The patient was screened and enrolled in an open-label study of lixivaptan under a US IND expanded-access protocol (PA-103). After treatment with therapeutic doses of lixivaptan for 12 months, there have been no elevations of ALT or other liver chemistry tests. Improved pain control has allowed resumption of more normal daily activities and the cessation of use of opioid pain medications. Pharmacodynamic effects including tests. Improved pain control has allowed resumption of more normal daily activities and

PO1546

Generation of Collecting Duct Kidney Organoids from Human Induced Pluripotent Stem Cell

Background: Polycystic kidney disease (PKD) is one of the most common human genetic disorders without effective therapy. During its progression, fluid-filled cysts develop from normal collecting duct (CD) tubules causing end-stage renal failure. The lack of disease-relevant in vitro models of PKD has hampered early drug discovery and needs more efficient and robust tools.

Methods: Here we modified a previously published protocol [1] and established a high-throughput and highly efficient method for the generation of CD kidney organoids from human induced pluripotent stem cells (hiPSC). We employed a dynamic modulation of cell signaling pathways in combination with 3D extracellular matrix support to induce CXCR4+/c-kit+/ureteric bud (UB) cell progenitors and further UB branching. The UB gives rise to renal collecting ducts and the lower urinary tract. We observed the development of UB-like cytorarchitecture including, bifurcated ureteric tip expressing specific markers (RET, WNT9B, HOXB7). Using single-cell RNA sequencing (scRNAseq) we identified two major cell populations in differentiated CD organoids – collecting duct cells and stromal cells. CD cells express typical markers of UB trunk (CK19), the ureteric epithelium (CDH1, CK8), as well as mature markers (AOP2, CALB1, MUC1) including principal (AOP3) and intercalated cells (AQP5). Moreover, we identified cilia formation on the inner surface of the luminal cavity of CD tubules forming a urinary tract model. We have shown that collecting duct cells can differentiate into kidney organoids from pluripotent stem cells. Cell Stem Cell; 21: 730-746

Fluidic Model of ARPKD Using Vascularized Kidney Organoids Identifies HIF-1 as a Potential Therapeutic Target
Ken Hiratsuka,1,2 Tomoya Miyoshi,1 Katharina T. Kroll,1 Navin R. Gupta,1 M. Todd Valerius,1,2 Takuya Matsumoto,1,2 Jennifer A. Lewis,1,3 Ryju Morizane,1,3 1Massachusetts General Hospital/Harvard Medical School, Boston, MA; 2Wyss Institute/Harvard University, Boston, MA; 3Harvard Stem Cell Institute, Boston, MA; 4Brigham and Women’s Hospital/Harvard Medical School, Boston, MA.

Background: We have recently reported a method to generate vascularized kidney organoids from fluidic chips. Vascularized kidney organoids derived from PKHD1-/- mutants demonstrated clinically relevant phenotypes that recapitulate cystogenesis in distal nephrons unlike static models with forskolin which induces cysts in proximal tubules. Here, we utilized this new PKD model to elucidate pathomechanisms and identify potential therapeutic targets for ARPKD patients.

Methods: PKHD1-/-hiPSCs were generated by CRISPR/Cas9 genome editing and differentiated into kidney organoids by following our reported protocol. Cystogenesis was stimulated by either fluidic flow on fluidic chips or forskolin in static culture. Cystic phenotypic change quantification was performed by immunostaining. Gene expression was evaluated by 3D-gene microarray, and signal pathways were assessed by Metacore. Based on signal pathway results, candidate compounds were tested, and phenotypic improvement was evaluated by measuring tubular/cyst diameters using whole-mount immunostaining.

Results: Fluidic flow altered 407 signal pathways in PKHD1-/- organoids when compared to PKD1+/+/- organoids while 63 pathways were changed by forskolin in conventional static culture. In those pathways, 32 were involved in both flow- and forskolin-induced signal changes. In the common 32 pathways, HIF-1 pathway was top ranked with lowest p value of 3.71x10^-15, suggested as a potential pathomechanism of ARPKD. To validate the result, we treated vascularized kidney organoids with HIF-1 inhibitor from day 16, the earliest stage of nephron differentiation. The distal nephron diameter was increased from 36.2 ± 7.7 μm (n=96) to 54.8 ± 21.8 μm (n=59) by fluidic flow (p=8.65x10^-21), which mimics normal kidney development. Using pharmacological approaches, we were able to induce cysts formation in response to forskolin and choler toxin treatment, thus, simulating the abnormal CD response to excess cAMP in PKD or normal rodent embryonic kidneys [2].

The Effect of Trehalose on Autophagy-Related Proteins and Cyst Growth in a Hypomorphic Pkd1 Mouse Model of Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Daniel Atwood, Deepak Pokhrel, Carolyn N. Brown, Katharina Hopp, Charles L. Edelstein. Univ Colorado, Aurora, CO.

Background: There is growing attention on understanding the role of impaired autophagy in ADPKD. Trehalose (TRE) is a natural sugar that is used as a food additive. TRE increases protein stability, aggregate clearance and autophagy in neurodegenerative diseases. TRE treatment in wild type (WT) mice resulted in increased expression in the kidney of Atg12-5 complex and Rab9a (Table), autophagy-related proteins that play a role in the formation of autophagosomes. Thus, the aim of the study was to determine the effect of TRE on cyst growth and autophagy-related proteins, in the Pkd1<sup>+/−</sup> (RC) mouse model.

Methods: Autophagy proteins determined by immunoblot analysis. Male RC mice were treated with TRE from 50-120 days of age.

Results: In RC kidneys, expression of the Atg12-5 complex was inhibited by TRE resulting in increased free Atg12. TRE was unable to rescue the deficiency of the Atg12-5 complex. Rab9a was decreased in RC and unaffected by TRE. The TRE-induced increase in p62, a marker of autophagic cargo, that was seen in WT was blocked in RC kidneys. In RC kidneys, there were decreases in autophagy-related proteins (Atg12-5 complex, Atg5, Atg16l1), decreased Rab9a and increased mTORC1 (p56, p-mTOR) proteins. 2 kidney/body weight ratio (2K/BW), cyst index/count, BUN were not different in TRE vs. Veh treated RC kidneys.

Conclusions: The autophagy phenotype in RC kidneys was characterized by decreases in essential autophagy related proteins. TRE increased Atg12-5 complex, Rab9a and p62 in WT kidneys, but was unable to rescue the deficiency in autophagy proteins or suppress mTORC1 in RC kidneys and did not protect against cyst growth.

Suppressed Autophagic Flux in the Heart in a Hypomorphic Pkd1 Mouse Model of ADPKD

Daniel Atwood, Carolyn N. Brown, Katharina Hopp, Charles L. Edelstein. Univ Colorado, Aurora, CO.

Background: Heart disease is largely unexplored in mouse models of ADPKD. The aim of the study was to determine mTOR signaling and autophagy in the heart in Pkd1<sup>+/−</sup> (RC) mice.

Methods: Proteins were determined by immunoblot analysis. Male RC mice were treated with autophagy inducers 2-deoxyglucose (2-DG) or Tat-Beclin1 peptide (Tat).

Results: There was increased heart weight/body weight ratio (HW/BW) in 180 d old RC mice. In 70 day old RC hearts, there was no increase in mTOR but a large increase in p-AMPK, an autophagy inducer. In 150 day old RC hearts, there was an increase in p-S6, p-Akt, p-Beclin, an autophagy regulator and activating molecule in Beclin-1-regulated autophagy (AMBR1A). There was suppressed autophagic flux (lack of an increase in LC3-II, a marker of autophagosomes, with the lysosomal inhibitor bafilomycin-Baf), in 70 and 150 d old RC hearts compared to an increase in wild type (WT) hearts. In 120 d old RC hearts there was no increase in proliferation (PCNA) or apoptosis (TUNEL). Both 2-DG and Tat treatment increased heart weight and had no effect on kidney weight.

Conclusions: There was a large increase in p-AMPK and suppressed autophagy in RC hearts. Unexpectedly, autophagy inducers increased heart weight.

PO1550

Ferroptosis Promotes Cyst Growth in Autosomal Dominant Polycystic Kidney Disease

Xiaoxin Zhang, Hao Ding, Xiaoyan Li, Peter C. Harris, Xiaogang Li. Mayo Clinic, Rochester, MN.

Background: Ferroptosis is a newly discovered form of non-apoptotic cell death which is dependent on accumulation of lipid reactive oxygen species (ROS). Recent studies have shown that ferroptosis is involved in the pathophysiological processes of many diseases, such as cancer. However, the roles of ferroptosis in ADPKD remain unknown.

Methods: To evaluate whether ferroptosis occurs in ADPKD, we detected the levels of ROS with C11-BODIPY and 4-HNE staining, and the expression of glutathione peroxidase 4 (GPX4), a key protein in the ferroptotic pathway, by western blot and qRT-PCR in cystic cells and kidneys. To understand the role of ferroptosis in ADPKD, we treated Pkd1<sup>−/−</sup> mice with erastin, a ferroptosis inducer, and Ferrostatin-1, a ferroptosis inhibitor.

Results: We found that the levels of free radical-induced oxidation and 4-HNE, a bioproduct of lipid peroxidation, were increased in Pkd1<sup>−/−</sup> renal epithelial cells and tissues as examined by C11-BODIPY and 4HNE staining. Erastin treatment resulted in smaller-than-normal mitochondria with increased density, a morphological feature of ferroptotic cells, in Pkd1<sup>−/−</sup> renal epithelial cells under electronic microscopy. We further found that treatment with erastin promotes cyst growth as seen by increased cystic index, kidney weight (KW)/body weight (BW) ratios, blood urea nitrogen (BUN) levels, cyst lining epithelial cell proliferation, and lipid peroxidation in Pkd1<sup>−/−</sup> mice (all p<0.01).

PO1551

Cux1 Regulates Cilia Length in Polycystic Kidney Disease

Greg Vandenberghe,1 Zhi Nee Wee,2 Conner L. Holthaus. 1Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI; 2Kalamazoo College, Kalamazoo, MI.

Background: Renal cyst development in ADPKD results from mutations in the PKD1 or PKD2 genes, which encode the proteins polycystin1 (PC1) and polycystin2 (PC2). PC1 and PC2 proteins are localized to primary cilia where they are proposed to form a receptor channel complex that detects flow transmitting a calcium-mediated signal. Primary cilia are critical to the pathogenesis of ADPKD, which is one of the many ciliopathies that exhibit renal cystic disease. Cux1, a murine homolog of the Drosophila gene Cat, is a cell cycle dependent transcriptional repressor that regulates the cyclin kinase inhibitor p27. Cux1 is highly and ectopically expressed in mice carrying a collecting duct (CD) specific mutation of Pkd1 (Pkd1 knockout) and in human ADPKD cells. Mice carrying mutations in both Cux1 and Pkd1 have reduced cystic disease and an increased life span. A role for Cux1 in regulating genes involved in cilia assembly and function has recently been identified in the Galapagos cormorant, however the role of Cux1 in cilia in the mammalian kidney is not known.

Methods: To begin to determine whether Cux1 regulates ciliogenesis we evaluated cilia morphology and the expression of the ciliary protein, ODF1 (oral-facial-digital-1),
PO1552
Low-Dose Repeated Cisplatin-Induced Renal Injury Promotes Cyst Formation in Both Ciliostatic and PC2 Mutant Mouse Models
Zhane Li, Courtney J. Haycraft, E.J. Aloria, Bradley K. Yoder. The University of Alabama at Birmingham, Birmingham, AL.

Background: Multiple renal cystic diseases, including PKD, are caused by dysfunction of the primary cilia on the tubule epithelium. Links between cilia dysfunction, cyst formation, and renal injuries have been reported. In animal models, injury (e.g. ischemia reperfusion) exacerbated the rate of cyst formation. Cisplatin is an antitumor drug used widely in treatment of varieties of malignancies that displays severe nephrotoxicity side effects. Here we evaluate whether a second form of renal injury induced by a low dose of Cisplatin also leads to mal-repair of the kidney and to increased cyst formation in mouse models with cilia function perturbation.

Methods: To test the effects of cisplatin-induced renal injury on cyst formation, we utilized a low-dose repeated cisplatin treatment of C57Bl6J (BW; IP once a week for 4 weeks) on adult-induced conditional Ihh88 and PC2 mutant mice. We preformed IF staining for the injury marker kim1 and flow cytometry analysis of immune cells from WT and cilia dysfunctional kidneys 3 days after 2° cisplatin treatment to evaluate renal injury. Cyst index was analyzed at 5 weeks in PC2 mutant and at 9 weeks in Ihh88 mutant after the final dose.

Results: Low-dose repeated cisplatin treatment resulted in increased kim1 expression, mainly in the cortex, compared to vehicle treatment group in both Ihh88 mutant and PC2 mutant mice as compared to control. Analysis of flow cytometry data showed that there was minimal immune cell accumulation, including macrophages, NK, B or T cells, at 3 days after 2° cisplatin injection, similar to that in controls. Additional time points are currently being evaluated. While we did not observe major changes in immune cell response at the earlier time point prior to cyst formation, in both PC2 and Ihh88 mutants there was a marked increase in cyst severity, accompanied with massive immune cell accumulation compared to vehicle treated mutants at 5 and 9 weeks after the final cisplatin injection, respectively.

Conclusions: These data indicate cilia function is important in regulating repair processes following injury, defects in which contribute to more aggressive rates of cystogenesis. Additionally, it suggests multiple forms of injury induce cyst formation and that the cisplatin protocol could be used as an alternative approach to IRI to accelerate cyst formation in PKD animal models.

Primary Cilia Defects Reflect Specific Bone Cell Activity in Human ADPKD Osteoblast Cells
Renata C. Pereira,1 Berenice Y. Gitomer,2 Peter C. Harris,3 Isidro B. Salusky,1 Lauren V. Albrecht,1 1University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; 2University of Colorado Denver School of Medicine, Aurora, CO; 3Mayo Clinic Minnesota, Rochester, MN.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is predominately caused by mutations in primary cilia genes polycystic kidney disease PKD1 and PKD2. Recent studies show that ADPKD is associated with abnormal bone health with increased bone formation and low bone serum alkaline phosphatase, even when kidney function is preserved. Knowledge of the regulatory links between ADPKD, cilia, and human bone health is lacking.

Methods: We assessed primary cilia in cultured pre-osteoblasts derived from ADPKD patients with PKD1 or PKD2 mutations, relative to healthy controls and non-ADPKD chronic kidney disease (CKD) patients. Cilia were quantified by immunofluorescence staining of pericentrin and acetylated-tubulin. Cilia responsiveness was examined following treatment with lithium chloride (LiCl), an activator of the canonical Wnt signaling pathway. Additionally, circulating bone ALP levels were decreased in ADPKD osteoblasts, which is consistent with the lowered circulating bone ALP levels.

Results: Compared to healthy control cells, ADPKD osteoblasts displayed longer cilia at baseline and were significantly more responsive to elongation with LiCl. In contrast, non-ADPKD CKD osteoblasts had shorter cilia and lacked LiCl responsiveness. Despite similar histological features and adynamic bone characteristics, ADPKD osteoblasts mineralized faster than osteoblasts from non-ADPKD CKD. The ALP activity levels were decreased in ADPKD osteoblast cells, which is consistent with the lowered circulating bone ALP levels.

Conclusions: Together, these data support a model whereby altered cilia responsiveness in ADPKD osteoblasts is linked to bone cell activity and mineralization defects that are distinct from adynamic bone of non-ADPKD CKD patients.

Characterization of the Nuclear Factor Erythroid 2-Related Factor 2 (Nrf2) Response in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Jared J. Lutsig, Yahya Alswaf, Peter C. Harris, Vicente E. Torres, Maria V. Izazabal. Mayo Foundation for Medical Education and Research, Rochester, MN.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by progressive development and enlargement of bilateral renal cysts. Abnormal epithelial cell proliferation, along with the inability to maintain planar cell polarity, underlies cyst formation and enlargement. Therefore, processes that stimulate renal cell proliferation will have the potential to generate the cystic phenotype. Interestingly, an increased nuclear factor erythroid 2-related factor 2 (Nrf2) response has been shown to direct cancer cells into an anabolic mode that favors cellular proliferation, and has been associated with renal cyst formation in experimental and human fumarate hydratase deficiency. However, the Nrf2 response has not been described in ADPKD. We hypothesized that early ADPKD presents with an elevation in the Nrf2 response that favors cellular proliferation and contributes to cystogenesis.

Methods: We sought to longitudinally characterize the Nrf2 response and association with cystogenesis and fibrosis in a slow progressing mouse model of ADPKD (Pkd1RC/RC) and its wildtype controls (n=6 males, 6 females per group). Urine and plasma samples were collected at 30, 60, 120, and 180 days for chemistry and metabolic profiles, and cystic index (CI), and total kidney volume (TKV) were determined from abdominal MRI. Nrf2 levels and related response enzymes, as well as cell proliferation and fibrosis were analyzed using western-blot, immunofluorescence, and assay kits.

Results: At 30 days, Pkd1RC/RC mice presented increased CI and TKV/BW. However, serum creatinine and fibrotic markers were not different compared to controls. Pkd1RC/RC mice exhibited elevated Nrf2 expression and immunoreactivity early on that declined as ADPKD progressed from 30 to 180 days and correlated directly with cell proliferation (R²=0.693, p<0.05) and inversely with fibrotic markers (R²=0.672, p<0.05).

Conclusions: Our study shows longitudinal changes in the Nrf2 response in Pkd1RC/RC mice that are associated with cystogenesis early on and renal fibrosis at later stages of the disease. These findings have significant implications for the treatment of human ADPKD, and suggest that Nrf2 modulators might represent an advantageous intervention for the disease.

Dietary Protein Load Increases Kidney Macrophage and Accelerates Polycystic Kidney Disease

Jifeng Huang, Jung-Shan Hsu, Takamitsu Saigusa. Department of Medicine, Division of Nephrology, University of Alabama at Birmingham, Birmingham, AL.

Background: The disease severity for autosomal dominant polycystic kidney disease (PKD) is highly variable even among families with the same gene mutation, suggesting factors other than genetics may affect cystogenesis. One factor that accelerates cyst growth in PKD mouse is compensatory renal hypertrophy triggered by unilateral nephrectomy or a high protein diet. We recently reported that unilateral nephrectomy increases kidney macropages, cytokines and accelerates cystogenesis in Pkd1-knockout mice. We hypothesized that Pkd1-knockout mice fed a high protein diet, similarly increases kidney macrophages and accelerates cyst growth.

Methods: We used adult tamoxifen inducible Pkd1fl/+ mice with or without CAGG-cre. After cre induction, mice were fed either a high protein (HP: 60%), a normal protein (NP: 18%) or a low protein (LP: 6%) diet for a total of 1 or 6 weeks. Some mice fed a HP diet were treated with liposomal clodronate (to deplete macrophage) or phosphate buffer saline (intraoperatively twice a week) for a total of 6 weeks. Mice were euthanized at the end of the experiment for kidney histology, measurements of cytokine and macropages by ICS.

Results: Pkd1-knockout mice fed a HP diet for 6 weeks resulted in increased number of kidney resident macrophage (CD11b+, F4/80+) and infiltrating macrophages (CD11b+, F4/80+). Mice fed a HP diet had increased kidney pro-inflammatory cytokines, chemokines and severe kidney cysts growth compared to NP or LP diet fed mice. Early after dietary protein modification (1 week), Pkd1-knockout mice fed a HP diet had larger kidneys, higher cystic index and kidney mTOR level compared to LP diet fed Pkd1-knockout mice but there were no differences in the number of macrophages, chemokine and cytokine levels in the kidney. HP diet fed Pkd1-knockout mice treated with liposomal clodronate, resulted in decreased number of macrophages, cytokine and fewer cysts compared to PBS treated Pkd1-knockout mice.

Conclusions: Dietary protein load increases kidney macrophages, inflammatory cytokines and chemokines production and accelerates cyst growth in adult Pkd1-knockout mice. HP diet stimulates kidney cyst expansion prior to the recruitment of macrophages early on, but subsequent macrophage depletion therapy slowed the acceleration of cyst growth.

Probenecid Inhibits Cyst Development in Pkd1<sup>RC/RC</sup> Mice

Sergey N. Arkhipov, Regina F. Sutulova, Tania Ilatovskaya, Tengis S. Pavlov, 1University of South Carolina, Charleston, SC.

Background: ADPKD cysts contain high levels of ATP that contribute to cyst enlargement. Among other effects, ATP excess leads to a reduced reabsorption in cyst-lining epithelium and cyst fluid accumulation. We demonstrated that Probenecid, a known inhibitor of the sodium-1 transport, slows cystogenesis in Pkd1<sup>RC/RC</sup> mouse kidneys. We now report the effect of Probenecid in the mouse model of Pkd1<sup>RC/RC</sup> mice.

Methods: Probenecid, a hypomorphic model of Pkd1<sup>RC/RC</sup>, aged with osmotic minipumps were implanted to deliver Probenecid for 42 days. After treatment, 30 cm<sup>3</sup>/min/100g at 12 months age. 42 days long Probenecid treatment of Probenecid on Na<sup>+</sup> reabsorption was tested on mpkCCD cells seeded onto permeable chamber. ATP excess leads to a reduced reabsorption in cyst-lining epithelium and cyst fluid accumulation. We demonstrated that Probenecid, a known inhibitor of the sodium-1 transport, slows cystogenesis in Pkd1<sup>RC/RC</sup> mouse kidneys. We now report the effect of Probenecid in the mouse model of Pkd1<sup>RC/RC</sup> mice.

Results: After treatment, 10 months old mice were subjected to glomerular filtration rate (GFR) measurements and kidneys were collected for histomorphological studies. Effect of Probenecid on GFR showed that GFR was reduced significantly as compared to control, 0.94±0.08 ml/min/100g at 12 months age. Probenecid treatment of Probenecid on Na<sup>+</sup> reabsorption was tested on mpkCCD cells seeded onto permeable chamber supports with open-circuit current measurements.

Conclusions: Probenecid inhibits cyst development in Pkd1<sup>RC/RC</sup> mice and supports with open-circuit current measurements. Probenecid demonstrates therapeutic potential against ADPKD cyst progression in a Pkd1<sup>RC/RC</sup> mouse model by reducing cyst size, renal hypertrophy and supporting GFR and reabsorption from the cyst space. Pharmacological Inhibition of β-Catenin-Activated Transcription Slows Cystogenesis in a Postnatal Mouse Model of ADPKD

Valerie A. Schuchert,1,2 Yoon Joon Jung,2 Jordan A. Kreidberg,1,2 Boston Children's Hospital, Department of Urology, Boston, MA; 2Harvard Medical School, Boston, MA.

Background: The Wnt signaling pathway has an important role in nephron development and elevated expression of β-catenin, a master regulator of the Wnt signaling pathway, has been shown to correlate with cystogenesis in autosomal dominant polycystic kidney disease (ADPKD). Here we provide evidence that pharmacological inhibition of β-catenin-mediated suppression of cystogenesis is achievable in vivo and in vitro through the use of a novel β-catenin inhibitor.

Methods: To understand the pathological contribution of Wnt signaling to ADPKD, we measured expression of Wnt genes and β-catenin in vivo using a postnatal murine model of ADPKD. We also tested the effect of a selective β-catenin-CBP inhibitor on cyst formation.

Results: We observed both increased expression of Wnt 7a and higher levels of β-catenin in cystic kidneys of CAGG-CreER<sup>+</sup>/Pkd1<sup>fl/fl</sup> mice. In addition, fibronectin, a known transcriptional target of β-catenin was significantly overexpressed in murine kidney culture derived from human ADPKD kidneys. JCK cells exhibited decreased mitochondrial number, defective mitochondrial morphology and function, and increased expression of CAMP and cyst dynamics as compared to normal kidney. We measured expression of Wnt genes and β-catenin in vivo using a postnatal murine model of ADPKD. We also tested the effect of a selective β-catenin-CBP inhibitor on cyst formation.

Conclusions: Small-molecule activators of β-catenin in postnatal murine kidneys inhibit cystogenesis. We tested CAGG-CreER<sup>+</sup>/Pkd1<sup>fl/fl</sup> mice with a small molecule, ICQ-001, that blocks the interaction of β-catenin with CBP. We detected significant reduced cyst formation as measured by reduced kidney/body weight ratio (0.047±0.004 vs 0.022±0.001) and the cyst area per kidney area (37.8±3.1 vs 13.7±3.1) and also observed a significant reduction in fibronectin after ICQ-001 treatment. Interestingly, cysts that may have formed prior to the start of the treatment remained large suggesting that ICQ-001 may primarily act on inhibiting cyst initiation, rather than inhibiting the enlargement of pre-existing cysts. Importantly, ICQ-001 treatment did not affect the growth of the mice.

Glucosylceramide Synthase Inhibition Preserves Mitochondrial Function and Reduces Reactive Oxygen Damage in the Jck Mouse Model of Poly cystic Kidney Disease

Tyler Picariello, Kelly A. Rogers, Laurie A. Smith, Christina M. Bracken, Nikolay O. Bukanov, Oxana Beskrovnya, Thomas A. Natoli. Rare and Neurological Disease Research, Framingham, MA.

Background: Glucosylceramide synthase inhibitor (GCSi) treatment blocks disease progression in PKD mouse models. Defective mitochondrial morphology and function are observed in kidneys of ADPKD patient and murine models. We assessed the impact of GCSi treatment on mitochondrial function in the jck mouse model of PKD and jck derived kidney epithelial cells.

Methods: Twenty-six-day-old WT or jck mice were treated with vehicle or 60 mg/kg GCSi (Genes671611) in food for 38 days prior to tissue harvest. mRNA expression was measured using RT-PCR. protein levels were measured by western blot. Mitochondrial DNA content was measured using real-time PCR. Oxidized DNA was detected using anti-8OHdG antibodies. Oxidized proteins were measured using the Oxylight system (Millipore).

Results: Reductions in electron transport chain and mitochondrial membrane potentials as well as mitochondrial DNA were observed in control jck mouse tissues, jck cell lines, and ADPKD patient samples. GCSi treatment inhibited disease progression in jck mice, reducing oxidative stress and correcting mitochondrial dysfunction. Reductions in mitochondrial dysfunction in Jck mice following GCSi treatment correlates with preserved mitochondrial function.

Oral Delivery of Nanoparticles for Renal Disease

Jonathan Wang, Kenneth R. Hallows, Eun ji Chung. University of Southern California, Los Angeles, CA.

Background: Nanomaterials are promising for drug delivery, but few have been successful for oral delivery, the optimal route for chronic diseases like polycystic kidney disease (PKD). Drug candidates that slow cyst growth require high dosages leading to side effects like hepatotoxicity. To limit this, we previously developed kidney targeting micelles (KM) and found they accumulated in the kidneys. To augment this system for oral delivery, herein, we load KM and metformin (met), a diabetes drug with PKD promise, into chitosan nanocapsules (CS-NC) to overcome the barriers of the gastrointestinal (GI) tract. We hypothesize that CS-NC will deliver met via the GI tract and show efficacy in PKD mice models. Furthermore, we characterize KM loaded into CS-NC to serve as a platform for future oral delivery of targeted therapeutics.

Methods: CS-NC were synthesized via ionic gelation. To confirm KM loading into CS-NC, dynamic light scattering (DLS) was performed for the following: KM loaded into CS-NC, CS-NC, mixed with CS-NC, CS-NC, or KM. To assess the oral delivery performance, we orally gavaged 300 mg/kg met loaded in CS-NC or free met to Pkd1<sup>fl/fl</sup>, Pkd1<sup>fl/fl</sup>Rc/Rc mice. On P22, kidneys were excised to assess kidney morphology.

Results: We observed increased expression of Wnt 7a and higher levels of β-catenin in cystic kidneys of CAGG-CreER<sup>+</sup>/Pkd1<sup>fl/fl</sup> mice. In addition, fibronectin, a known transcriptional target of β-catenin was significantly overexpressed in murine kidney culture derived from human ADPKD kidneys. JCK cells exhibited decreased mitochondrial number, defective mitochondrial morphology, and increased expression of CAMP and cyst dynamics as compared to normal kidney. We measured expression of Wnt genes and β-catenin in vivo using a postnatal murine model of ADPKD. We also tested the effect of a selective β-catenin-CBP inhibitor on cyst formation.

Conclusions: Mitochondrial dysfunction and increased oxidative stress were observed in jck mouse tissues, jck cell lines, and ADPKD patient samples. GCSi treatment inhibited disease progression in jck mice, reducing oxidative stress and correcting mitochondrial dysfunction. Reductions in mitochondrial dysfunction in Jck mice following GCSi treatment correlates with preserved mitochondrial function.

Long-Term Effect of Novel Morphometric 3D Capsule Device to Constrain Growth in Polycystic Kidney: Comparison Between Wild-Type, Cy/+ , and PCK Rat Models

Kyomae T. Bae,1 Aya Yoshimura,2 Kanako Kumamoto,2 Masanori Kugita,2 Tamio Yamaguchi,1 Shigey Horig,4 Junu Bae,2 Shizuko Nagao,2 1University of Pittsburgh, Department of Radiology, Pittsburgh, PA; 2Fujita Health University, Education and Research Center of Animal Models for Human Diseases, Toyoake, Japan; 3Suzuka University of Medical Science Faculty of Health Science, Department of Clinical Nutrition, Suzuka, Japan; 4Junto Dental University Faculty of Medicine, Department of Urology, Tokyo, Japan; 5Ohio State University College of Medicine, Columbus, OH.

Background: As a potential therapeutic method to halt the progression of polycystic kidney disease, we developed and implanted a computed tomography (CT) image-derived morphometric 3D capsule device to cease a kidney. In this study, the long-term effect of the capsule device on size, function, and histology of polycystic kidneys were assessed using wild-type, Cy/+ and PCK rat models.

Methods: Kidney capsule devices were designed from CT images of rats and surgically implanted on left kidneys, while sham operations performed as controls, in wild-type (n=2), Cy/+ (n=2) and PCK (n=3) rats. After operation, rats were followed to grow. Monthly CT scans were performed and used to measure kidney volume. At the final follow-up, rats were sacrificed and kidney weight, serum BUN and creatinine (Cre) were measured. Histological analyses including cystic area measurement and immunohistochemistry were performed.

Results: In wild-type rats, kidney weights in sham and encapsulated (Enc) rats were similar (Right [R]: 2.2g, Left [L]: 2.1g sham vs. 2.3g, L 2.2g Enc). In Cy/+ rats survived over 6 months, kidney weights, BUN, and Cre were all lower in Enc rats than those in sham rats (Weight: R 4.7g, L 4.6g sham vs. 3.6g, L 2.9g Enc (Figure); BUN mg/dL: 113.8 sham vs. 44.9 Enc; Cre mg/dL: 2.06 sham vs. 0.71 Enc). In PCK rats survived over 3 months, kidney weights, BUN, and Cre were all lower in Enc rats than those in sham rats (Weight: R 5.6g, L 6.0g sham vs. R 4.5g, L 3.8g Enc; BUN: 30.6 sham vs. 22.9 Enc; Cre: 0.43 sham vs. 0.36 Enc). Encapsulated kidneys of polycystic rats showed smaller histologic cystic area with reduced cell proliferation and macrophages than unencapsulated kidneys.

Conclusions: Both Cy/+ and PCK rats in long-term follow-ups showed considerable reductions in size of the kidneys that were encapsulated with morphometric 3D capsule devices as well as reduction in BUN and creatinine, demonstrating proof of concept toward a novel potential therapeutic avenue for halting progression of polycystic kidney disease.

Quantifying Murine Total Kidney Volume with Robotic 3D Ultrasound

Tomasz J. Czernuszewicz,1,2 Nathan Beaumont,1 Heather L. Holmes,2 Juan D. Rojas,2 Ryan Gesser,1 Paul Dayton,1 Timothy L. Kline,1 Michael F. Romero,1 1SonoVol, Inc., Durham, NC; 2Mayo Clinic Minnesota, Rochester, MN; 3University of North Carolina at Chapel Hill, Chapel Hill, NC.

Background: Polycystic kidney disease (PKD) is a genetic disorder characterized by renal cyst formation and kidney enlargement. Noninvasive staging of PKD can be accomplished by measuring total kidney volume (TKV). While TKV has been readily implemented in the clinic, its adoption in preclinical research with small animals has lagged. In this study, a new high-throughput imaging device, based on robotic ultrasound (US), was evaluated as a complementary approach for measuring TKV in murine models and validated against in vivo and ex vivo gold standards (MRI and Vernier calipers).

Methods: Two cohorts of mice were evaluated in a cross-sectional study. Cohort 1 included a range of mature Pkd1 mice (N = 14 kidneys) that were imaged in 3D with both US and MRI. Cohort 2 included healthy mice (N = 16 kidneys) spanning both sexes and two ages (4k16 wks). Mice from Cohort 2 were imaged with 3D US in vivo, euthanized, and TKV measured ex vivo with Vernier calipers (length/width). Agreement was assessed with correlation and Bland-Altman (BA) analysis. US images were segmented by 4 independent readers and inter-reader reliability was assessed via intra-class correlation coefficient (ICC).

Results: US-TKV correlated strongly with both MRI and caliper measurements (r² = 0.97 and 0.93, respectively). Against MRI, BA-analysis demonstrated no significant bias and a limit of agreement (LOA) of 70 mm³ between the techniques. Against calipers, a small but statistically significant overestimation was detected of kidney length/width by in vivo US imaging (0.87 mm). Inter-reader agreement for TKV was strong with an ICC of 0.93 (95%CI: 0.83–0.97).

Conclusions: These results show that robotic 3D US, performed by a novice operator, can produce rapid, accurate, and consistent in vivo measurements of TKV in murine models. Future studies will include larger cohort sizes and additional models of kidney disease (e.g. fibrosis) making this approach ideal for therapeutic screening.

Rapid, Quantitative Measures of ARPKD Kidney Disease with Novel Magnetic Resonance Fingerprinting

Christina J. Macaskill,1 Dan Ma,2 Yong Chen,2 Chris Flask,2 Katherine M. Dell,1,2 1Case Western Reserve University, Cleveland, OH; 2Cleveland Clinic Children’s Hospital, Cleveland, OH.

Background: Autosomal recessive polycystic kidney disease (ARPKD) is a rare but potentially lethal genetic disorder characterized by diffuse collecting tubule microcysts. There are currently no disease-specific treatments, although several therapies have shown promise in ARPKD animal models. Clinical trials for ARPKD patients have not been possible due to the lack of sensitive measures of ARPKD kidney disease progression. We previously identified renal T1 and T2 relaxation as potential imaging biomarkers of ARPKD. The goal of this study was to evaluate a novel, rapid magnetic resonance imaging (MRI) technique, magnetic resonance fingerprinting (MRF), in kidneys of healthy volunteers and pediatric ARPKD patients.

Methods: MRF is a quantitative MRI technique that simultaneously generates maps of multiple MRI parameters (e.g., T1, T2), while also showing resistance to motion artifact, allowing for more rapid and comprehensive assessment of tissue composition and pathology. We developed a kidney MRF acquisition protocol to generate T1 and T2 maps in a single breath-hold (~15 seconds/slice). This MRF method was first validated in vitro using standardized T1 and T2 maps, which were then obtained from 10 healthy volunteers and 3 ARPKD patients.

Results: MRF-based T1 and T2 maps demonstrated good agreement with reference values in standardized phantoms. MRF experiments in healthy volunteers further showed repeatable assessments of the renal cortex (T1: 1318±91 ms; T2: 71±6 ms) and medulla (T1: 1529±63 ms; T2: 73±5 ms), consistent with literature values. Repeated kidney MRF scans for 3 ARPKD patients (age 7-13 yrs, estimated glomerular filtration rates 52-97 ml/min/1.73m²) on 2 successive days demonstrated good reproducibility (< 3% differences for T1 and T2). Significant differences were seen between the volunteer and ARPKD patient populations for both mean kidney T1 (p<0.007) and T2 (p<0.04).

Conclusions: This novel kidney MRF acquisition protocol provides fast, accurate, and repeatable kidney T1 and T2 maps in pediatric ARPKD patients. The short acquisition times, coupled with resistance to motion artifact, suggest that MRF could allow rapid, quantifiable imaging assessments of ARPKD kidney disease even in younger children, which could be used to identify high risk patients and/or assess therapeutic efficacy in clinical trials.

Human Factors Impact on the Development of Software as a Medical Device (SaMD): A Case Study Using the System Usability Scale (SUS)

Mosaddeq Hossain,1 Mary Dixon,1 Annie Lutz,1 Jeff Horvath,1 Innovenn, Inc., Madison, WI; 2Otsuka Pharmaceutical Development and Commercialization, Inc., Princeton, NJ; 3Balanced Experience, LLC, Madison, WI

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is an inherited, progressive, cystic kidney disease and is the fourth leading cause of end-stage renal disease (ESRD). Total kidney volume (TKV) is the most relevant imaging biomarker for tracking and predicting the natural course of ADPKD. Accurate prognostic tools may help predict outcomes and optimize clinical management to slow the loss of renal function. The ADPKD Progression Management (APM) System is a web-based, clinical-decision support software that offers a consistent method for estimating TKV and renal function. The ADPKD Progression Management (APM) System is a web-based, clinical-decision support software that offers a consistent method for estimating TKV and renal function. Accurate prognostic tools may help predict outcomes and optimize clinical management to slow the loss of renal function.

Methods: The SUS was used in 4 human factors studies of the APM System. Participants included nephrologists and radiologists who completed test cases using mock data. Participants had no prior experience with the software and received no training on the system. Participants entered clinical information, utilized the automated image measurement to calculate TKV, and generated the automated statistical calculation of predicted growth of TKV, a marker of disease progression. Participants then completed a SUS questionnaire. In a global SUS score was calculated, a total of 79 participants contributed to the global SUS scores: 37 nephrologists, 28 radiologists and 14 nephrologist/radiologist support staff.

Results: APM System received the following SUS scores in studies one through four: 72, 78, 80, and 80. The SUS score increased an 8 point from the first study to the fourth study. 4 New functions (e.g. Consultation workflow) introduced.

Conclusions: The SUS results demonstrate the impact of iterative improvements in the design and usability of the APM System. The SUS global scores provide evidence that the perceived usability is above average and comparable to the average SUS score for the top 10 apps across iPhone, Android and tablets.

PO1568

Correlation of Baseline Urinary Metabolic Biomarkers with ADPKD Severity in the TAME-PKD Study

Cystic Kidney Diseases: Emerging Concepts, Biomarkers, and Clinical Trials

Poster

Thursday, June 2019, 62 patients who met the conditions of no tolvaptan use, GFR ≥ 60.1 ml/min/L, the median TKV was 1137 mL, and the median urine NAG index (NAG-to-Cr ratio) was 4.64 U/mg Cr. In the reduced renal function group (30aCrGFR < 60 mL/min, n=32), we observed a correlation between NAG index and RKVP in single-regression analyses (R² = 0.330, p < 0.003), but not with eGFR. This is also crucial in considering indication of tolvaptan. However, the evaluation of RKVP requires multiple imaging studies, and problems with costs and complexities. Considering that ADPKD is a disorder primarily affecting tubulo-interstitium, we aimed to examine the clinical potential of urine NAG to evaluate RKVP by retrospective observation.

Methods: Among ADPKD patients treated in our hospital between January 2010 and June 2019, patients who met the conditions of no tolvaptan use, GFR<60, duration of treatment in our hospital≥1 year, and multiple TKV measurement by CT scanning were included in the analysis.

Results: The mean age was 46.3 years, 62.9% men, the mean baseline eGFR was 68.47 mL/min/1.73m², the median TKV was 1137 mL, and the median urine NAG index (NAG-to-Cr ratio) was 4.64 U/mg Cr. In the reduced renal function group (30aCrGFR < 60 mL/min, n=32), we observed a correlation between NAG index and RKVP in single-regression analyses (R² = 0.330, p < 0.003), but not with eGFR, TKV. However, there was no significant correlation between all parameter and RKVP, including NAG index, in the normal renal function group (eGFR≥60 mL/min, n=30). Multiple regression analysis showed that NAG index was a predictor of RKVP in the reduced renal function group (p = 0.005). Based on the approximate equation in the single-regression analyses and multiple regression analyses, the predict RKVP by NAG index (U/mg Cr) and eGFR<60 mL/min, n=32, using the estimated equations will be shown.

Conclusions: To varying degrees, proteinuria, lactate, PKM2 and PDK1 urinary concentrations correlated with RKVP at baseline in the TAME-PKD study population, consistent with the idea that upregulated glycolytic flux is a feature of ADPKD severity. Future analysis will reveal how treatment with metformin may affect both disease progression and the various urinary metabolic biomarkers in patients throughout the study.

Urine NAG Is an Effective Clinical Parameter to Presume Disease Activity of Autosomal Dominant Polycystic Kidney Disease

Poster

Thursday, June 2019

Background: Patients with ADPKD are mixed with those who progress to ESRD and those who maintain stable, and should be assessed separately from disease activity shown in rate of kidney volume progression (RKVP), disease progression shown in total kidney volume (TKV), and also renal function shown in eGFR. This is also crucial in considering indication of tolvaptan. However, the evaluation of RKVP requires multiple imaging studies, and problems with costs and complexities. Considering that ADPKD is a disorder primarily affecting tubulo-interstitium, we aimed to examine the clinical potential of urine NAG to evaluate RKVP by retrospective observation.

Methods: Among ADPKD patients treated in our hospital between January 2010 and June 2019, patients who met the conditions of no tolvaptan use, GFR≥60, duration of treatment in our hospital≥1 year, and multiple TKV measurement by CT scanning were included in the analysis.

Results: The mean age was 46.3 years, 62.9% men, the mean baseline eGFR was 68.47 mL/min/1.73m², the median TKV was 1137 mL, and the median urine NAG index (NAG-to-Cr ratio) was 4.64 U/mg Cr. In the reduced renal function group (30aCrGFR < 60 mL/min, n=32), we observed a correlation between NAG index and RKVP in single-regression analyses (R² = 0.330, p < 0.003), but not with eGFR, TKV. However, there was no significant correlation between all parameter and RKVP, including NAG index, in the normal renal function group (eGFR≥60 mL/min, n=30). Multiple regression analysis showed that NAG index was a predictor of RKVP in the reduced renal function group (p = 0.005). Based on the approximate equation in the single-regression analyses and multiple regression analyses, the predict RKVP by NAG index (U/mg Cr) and eGFR<60 mL/min, n=32, using the estimated equations will be shown.

Conclusions: To varying degrees, proteinuria, lactate, PKM2 and PDK1 urinary concentrations correlated with RKVP at baseline in the TAME-PKD study population, consistent with the idea that upregulated glycolytic flux is a feature of ADPKD severity. Future analysis will reveal how treatment with metformin may affect both disease progression and the various urinary metabolic biomarkers in patients throughout the study.

Funding: Other U.S. Government Support
Conclusions: In ADPKD patients with renal dysfunction (CKD stages3), it was confirmed that NAG index may be useful as a predictor of the disease activity associated with RKVP and, if it is 6.0 U/mgG or greater, may be presumed to be associated with higher disease activity.

PO1570

Overweight and Obesity Are Predictors of Pain in the HALT-PKD Studies

Wei Wang,1 Zhiying You,1 Berenice Y. Gitomer,1 Godela M. Brosnahan,1 Peter C. Harris,2 Dana Miskulin,3 Vicente E. Torres,2 Kaleab Abebe,4 Theodore I. Steinman,5 Alan S. Yu,4 Ronald D. Perrone,4 William E. Braun,5 Arlene B. Chapman,1 Michel Choncho,1 Kristen L. Nowak,5 HALT-PKD Study Group,1 University of Colorado Anschutz Medical Campus, Aurora, CO; Mayo Clinic Minnesota, Rochester, MN; Tufts Medical Center, Boston, MA; University of Pittsburgh Medical Center, Pittsburgh, PA; Beth Israel Deaconess Medical Center, Boston, MA; University of Kansas Medical Center, Kansas City, KS; Cleveland Clinic, Cleveland, OH; University of Chicago Medicine, Chicago, IL.

Background: Pain is a frequent complication of autosomal dominant polycystic kidney disease (ADPKD) and includes back and abdominal pain. Level of pain was previously found to be unrelated to kidney size in participants in the 5-yr HALT-PKD studies. We hypothesized that overweight and obesity would be independently associated with greater self-reported back, abdominal, and radicular pain at baseline and that weight loss would be associated with reduced pain over the follow-up period.

Methods: In 376 individuals with ADPKD who participated in the 5-yr HALT-PKD study A or B were included in a cross-sectional analysis. The association of baseline BMI with pain was evaluated using multivariable ordinal logistic regression (likert-scale responses). In a longitudinal analysis, the association of annual change in BMI as a time-vertexing predictor with annual change in pain was evaluated using a generalized estimating equation analysis.

Results: Participants were 43±10 years old and baseline estimated glomerular filtration rate (eGFR) was 71±26 ml/min/1.73m². Back, abdominal, and radicular pain were reported more frequently in individuals with overweight/obesity (p<0.05). After adjustment for demographics, exercise, pain medications, eGFR, and mutation class, overweight/obesity was associated with increased odds of greater back pain and radicular pain, but not abdominal pain. Associations remained similar after further adjustment for baseline height-adjusted kidney and liver volume (Study A only; n=436); back pain: overweight OR: 1.28 [1.07, 1.55]; radicular pain: overweight: 2.28 [1.13, 4.60], obese OR: 2.68 [1.25, 5.76]. Longitudinally (n=823), overweight: 1.66 [1.02, 2.68], obese OR: 1.77 [1.03, 3.03]; radicular pain: overweight ± 2/yr, p= 0.04) and a faster median rate of eGFR decline (-2.2 vs -2.0 ml/min/1.73m²). Back, abdominal, and radicular pain were reported more frequently in individuals with overweight/obesity (p<0.05).

Conclusions: The mean volume growth rate of the liver cyst was 6 times greater than that of the liver. Similar to the kidney imaging classification, the severity of polycystic liver may be categorized on the basis of patient’s age and liver cyst volume. Thus, the purpose of the study is to evaluate and classify polycystic liver progression in patients with ADPKD based on participant’s age, sex, height-adjusted liver cystic volume (htLCV) and height-adjusted liver volume (htLV) measurements.

Methods: We used longitudinal MRI data (CRISP and HALT studies) from 695 patients with ADPKD over a maximum follow-up of 14.23 years were evaluated to measure LCV and LV. Among them, 258 patients with LCV > 50ml and at least 2 time-points were included in the analysis. Linear mixed models on log-transformed htLCV and htLV were fitted as a function of participant’s age and study class as well as a random intercept and slope. The slope coefficient was used to approximate the mean annual rate of change (MAROC) for each outcome. Using the age of 15 years as the hypothetical initial age for LCV=0, differential growth trajectories were plotted to categorize the participants according to their LCV growth rate and age.

Results: Overall, the MAROC was 10.8% for htLCV and 1.8% for htLV (P<0.0001). 232 participants had net-increases (last measurement > first) on htLCV, while 26 participants had net-decreases (or values remained the same) on htLCV. For the net-increase group, MAROC was 12.7% for htLCV and 2.2% for htLV (P=0.0001). For the net-decrease group, MAROC was 7.3% for htLCV (P=0.0168) and -2.1% for htLV (P=0.1116). According to the annual growth rate, 5 classes (A <5%, B 5-<10%, C 10-<15%, D 15-<20%, E ≥20%) were defined. The numbers for female and male participants in each class were fitted (BMI: A: 317; B:48.15; C: 49.51; D: 127.16; E: 9.5).

Conclusions: The mean volume growth rate of the liver cyst was 6 times greater than that of the liver. Similar to the kidney imaging classification, the severity of polycystic liver may be categorized on the basis of patient’s age and liver cyst volume. PO1573
Baseline Characteristics and Associations with Renal Function in a Greek Cohort of Polycystic Kidney Disease

George I. Tsirpanlis,1 Myro Kostopoulou,2 Michaela Louka,2 Konstantina Kanellopoulou,1 Vasiliki Gkika,2 Stavros Fokas,1 Anastasia Karolina Koutsogianii,1 Konstantinos Lympereopoulos,1 Magnetic Resonance Department, General Hospital of Athens “G. Gennimatus”, Athens, Greece; 2Nephrology Department of General Hospital of Athens “G. Gennimatus”, Athens, Greece.

Background: Recent advances in the treatment of Autosomal Dominant Polycystic Kidney Disease (ADPKD) highlight the interplay between the clinical and the laboratory profile of the disease. This study aims to present the baseline characteristics of patients followed in a large ADPKD cohort from a single center in Greece, and explore possible associations between demographic, clinical and laboratory parameters.

Methods: Patients followed in a specialized outpatient PKD clinic from December 2018 up to December 2019 were recruited in this study. At enrollment, demographics, medical and family history and laboratory data were recorded using a standardized form. Estimated glomerular filtration rate (e-GFR) was calculated and Magnetic Resonance Imaging for total kidney volume (TKV) measurement was performed.

Results: One-hundred three females and 83 males with a mean age of 41.4 ± 13 years (18.8 % < 30 years) were enrolled. Overall, 60.8% of them were classified as Chronic Kidney Disease (CKD) stage 1 and 2. The ADPKD was diagnosed at a mean age of 26.5 ±12.5 years. Thirty four percent out of 186 patients were diagnosed before the age of 20 and 9% of them before the age of 10. A positive family history was present in 89% of patients. In this subgroup, the median age of the affected parent that reached end stage renal disease was 55 (range 28-87) years. Hypertension was diagnosed in 89% at a mean age of 37.2 ± 10.5 years. Hepatic cysts were present in 70.3% of patients, urinary tract infections, nephrolithiasis, macroscopic hematuria and pain in 44.3%, 42.5%, 24.8% and 54.4% respectively. A history of intracranial bleeding in family was present in 21.5%. In multivariable analysis, lower e-GFR was associated with younger age at the time of PKD diagnosis (p < 0.002), younger age at hypertension diagnosis (p < 0.08) and greater values of TKV (p < 0.001), height adjusted TKV (p < 0.001) and Body Mass Index (BMI) (p = 0.02).

Conclusions: The patients with ADPKD were diagnosed at a young age and hypertension developed early on the course of the disease. Both these factors together with ht-TKV were independently associated with low eGFR.

PO1574
Identification of Factors Associated with Progression, Prognosis, and TOlvaptan Indication in Polycystic Kidney Disease Patients

George I. Tsirpanlis,1 Myro Kostopoulou,1 Michaela Louka,1 Stavros Fokas,1 Eirini Tigka,2 Angelos Drakopoulos,1 Vasiliki Gkika,2 Niki Markou,1 Konstantina Kanellopoulou,1 Michail Tsagatakis.1
1Department of Nephrology, General Hospital of Athens “G. Gennimatus”, Athens, Greece; 2Geniki Apikonistiki, Medical Imaging, Athens, Greece.

Background: The identification of risk factors for the progression of Autosomal Dominant Polycystic Kidney Disease (ADPKD) is an emerging field. The present study explores the associations between epidemiological, clinical and imaging data in a large cohort of ADPKD patients.

Methods: All patients included in the study had a Magnetic Resonance Imaging (MRI) for measurement of Total Kidney Volume (TKV). For all patients, the Mayo Clinic Imaging Consensus (MCIC) score of early stage ADPKD patients is limited to End Stage Renal Disease (ESRD) were calculated. Patients eligible for tolvaptan treatment (MCIC 1C,1D,1E, age <55 years old and estimated-GFR (e-GFR) ≥25ml/min/1.73m2) were identified. Individual medical history, clinical and laboratory data were examined for associations with renal and imaging parameters using linear regression models.

Results: 158 patients in total were included. Based on measurements of height-adjusted TKV (ht-TKV) and age, 5% of the patients were classified as 1A, 20% as 1B, 34% as 1C, 25% as 1D and 16% as 1E, MCIC. In multivariable analysis, patients' age (p<0.01), male sex (p=0.001), parent's age at time of ESRD (p=0.001) and proteinuria (p=0.04) were associated with ht-TKV. Parent's age at ESRD differed significantly between the MCICs of the offspring (means(SD)), 70.83 (12.90) in 1A, 63.79 (11.39) in 1B, 57.32 (10.42) in 1C, 51.42 (19.81) in 1D and 47.94 (5.73) years old in 1E (p<0.001). Similarly, there were differences in the presence and age of hypertension onset (p=0.004 and p=0.003, respectively). In 104 patients eligible for tolvaptan treatment, age at ESRD diagnosis, age at hypertension onset and parent's age reaching at ESRD were all significantly lower (p<0.001 for all) when compared to non-eligible patients. Finally, factors associated with the prediction score of ESRD (e-GFR 10ml/min) were hypertension, uric acid and the age at ESRD of the affected parent (p<0.001, 0.02, 0.01, respectively).

Conclusions: The age at which an affected parent had reached ESRD, heritability estimator, was significantly associated with a worst phenotype, prognosis and tolvaptan indication. Early diagnosis of the disease, hypertension and its early onset, proteinuria and male sex are also possible risk factors for the progression of ADPKD.

PO1575
Design, Development, and Characteristics of a National Patient Registry in ADPKD

Elise Hoover,1 David Baron,1 Beverly A. Benson,1 Berenice Y. Gitomer,4 Klee R. Kleber,4 Amy Manelli,1 Michail Drug,5 MEY坪,2 Chris Rusconi,4 Stephen L. Seliger,6 Ronald D. Perrone,7 Terry J. Watnick.8 1PKD Foundation, Bethesda, MD; 2University of Maryland Baltimore, Baltimore, MD; 3Tufts Medical Center, Boston, MA; 4University of Colorado Denver - Anschutz Medical Campus, Aurora, CO; 5University of California San Francisco, San Francisco, CA; 6The University of Alabama at Birmingham, Birmingham, AL.

Background: Most patients with autosomal dominant polycystic kidney disease (ADPKD) do not participate in clinical research. To empower ADPKD patients in the US to participate in research and to encourage the development of optimal prognostic and treatment strategies, the PKD Foundation designed a national ADPKD Registry of patient-reported data.

Methods: The ADPKD Registry is hosted on a secure, online platform (IQVIA, oc-meridian.com/pkdcure). Participants are registered and consented through the online system and asked to complete a series of modules quarterly. The PKD Questionnaire asks about diagnosis, latest kidney function lab values, current symptoms, and comorbidities. Participants are also asked about family history, diet and lifestyle, and quality of life.

Results: The ADPKD Registry was launched on September 4, 2019. As of May 2020, 1023 ADPKD patients across the US have registered and completed the Core Questionnaire. Participants have a median age of 52 years, and 72% are female, 4% Caucasian, 4% self-identifying as Hispanic/Latino and 2.4% as African American. 76% have not reached end stage renal disease, 4% are treated with dialysis, and 21% received a renal transplant. A family history of the disease was reported in 79% of participants, 2% reported a genetic test for PKD, and 89% reported having cysts observed by imaging. At the time of entering the registry, 78% reported having hypertension and 62% had liver cysts (although only 28% reported a diagnosis of polycystic liver disease (PLD)).

Conclusions: The ADPKD Registry is a longitudinal research tool intended to capture high-quality patient-reported data with respect to ADPKD and is designed to impact research in multiple ways. All participants have consented to be contacted about future clinical trials for which they will likely qualify and a process has been established to enable researchers to submit content for new outcome modules. Thus far modules addressing extra renal complications such as PLD and vascular aneurysms have been developed. In addition, the variety of disease stages reported by participants will allow for a range of research questions related to the clinical management of ADPKD from early stage disease through dialysis outcomes and post-transplant complications.

First in Canada: A Comprehensive Autosomal Dominant Polycystic Kidney Disease (ADPKD) Patient Registry in British Columbia (BC)

Sharon Gradin,1 Janet L. Williams,1 Adeera Levin,1 Ognjenka Durdjevic,1 Sanford Kong,2 Karin Jackson,3 Micheli U. Bevilacqua.2,1 1The University of British Columbia, Vancouver, BC, Canada; 2BC Provincial Renal Agency, Vancouver, BC, Canada.

Background: Early identification, assessment of renal progression and implementation of appropriate treatments are key components of modern ADPKD care. Existing BC Renal programs focus on patients in later disease stages when they access chronic kidney disease clinics, renal replacement modalities, or renal formulary drugs, but data are sparse of those reported data with respect to ADPKD and is designed to impact research in multiple ways. All participants have consented to be contacted about future clinical trials for which they will likely qualify and a process has been established to enable researchers to submit content for new outcome modules. Thus far modules addressing extra renal complications such as PLD and vascular aneurysms have been developed. In addition, the variety of disease stages reported by participants will allow for a range of research questions related to the clinical management of ADPKD from early stage disease through dialysis outcomes and post-transplant complications.

Funding: Private Foundation Support

Conclusions: Through creation of a comprehensive ADPKD registry, greater numbers of ADPKD patients have been identified in BC, particularly patients earlier in their disease course. The registry will continue to build on this with next steps including greater engagement of nephrologists’ office to support the new workflow of identifying and registering patients.

Results: With the ADPKD registry, the number of ADPKD patients registered in PROMIS has increased from 545 to 1065 between January 2015 to January 2020. The increase in patient registration has been most prominent in early stage patients not on dialysis or transplant (increased from 237 to 703). In those not on dialysis or transplant increase in patients registered was most pronounced in those at earlier CKD stages; from 2015 to 2020, in those with eGFR 15-59ml/min, registration increased from 27 to 34 patients per year. After 2015, with eGFR 15-30ml/min registration increased from 43 to 117, with eGFR 45 to 60ml/min registration increased from 19 to 109, and in those with eGFR >60ml/min, registration increased from 32 to 237 patients.

Conclusions: Through creation of a comprehensive ADPKD registry, greater numbers of ADPKD patients have been identified in BC, particularly patients earlier in their disease course. The registry will continue to build on this with next steps including enhancements to clinical data, patterns of treatment use, quality metrics for care delivery, and clinical outcomes.

Funding: Commercial Support - Creation of the registry was assisted via an unrestricted grant from Otsuka Canada Pharmaceuticals Inc.

STAGED-PKD: An Enriched, Seamless, Two-Stage Study for Venglustat Safety and Impact on TKV Growth and eGFR Slope in ADPKD

Ronald D. Perrone,1 Ali Hariri,2 Pascal Minini,3 Curie Ahn,4 Arlene B. Chapman,5 Shigeo Horie,2 Bertrand Knebelmann,6 Michal Mrug,2 Albert C. Ong,2 York P. Pei,7 Vicente E. Torres,8 Vijay Modur,9 Ron T. Gansevoort;10 Division of Nephrology, Tufts Medical Center, Tufts University School of Medicine, Boston, MA; 1Sanofi Genzyme, Cambridge, MA; 2Sanofi, Chilly Mazarin, France; 3Department of Internal Medicine, Seoul National University, Seoul, Seoul, Republic of Korea; 4Department of Medicine, University of Chicago, Chicago, IL; 5Department of Urology, Juntendo University Graduate School of Medicine, Tokyo, Japan; 6Université Paris-Descartes, Faculté de Médecine, AP-HP, Service de Néphrologie, Hôpital Necker-Enfants Malades, Paris, France; 7Department of Medicine, University of Alabama at Birmingham, Birmingham, AL; 8Department of Infection Immunity & Cardiovascular Disease, University of Sheffield, Sheffield, United Kingdom; 9Division of Nephrology, University of Toronto, Toronto, ON, Canada; 10Mayo Translational Polycystic Kidney Disease Center, Mayo Clinic, Rochester, MN; 11Department of Nephrology, University Medical Center Groningen, Groningen, Netherlands.

Background: Autosomal dominant polycystic kidney disease (ADPKD) occurs due to cyst formation and growth, resulting in increased total kidney volume (TKV) preceding kidney function decline by decades. The natural history of ADPKD complicates testing of new therapies. Venglustat, a glucosylceramide synthase inhibitor, inhibits cyst growth and reduces kidney failure in PKD mouse models. STAGED-PKD determines venglustat safety and efficacy and was designed using enrichment for progression to ESRD and extensive modeling from prior ADPKD trials.

Methods: STAGED-PKD is a two-stage (Phase 2/3), international, double-blind, randomized controlled trial in adults with ADPKD with increased TKV (Mayo Imaging Classification IIC–IIE) and eGFR 45–90 mL/min/1.73 m2. Target enrollment in Stages 1 and 2 is 240 and 320 patients, respectively. Stage 1 randomizes patients 1:1:1 to venglustat dose 1, dose 2 or placebo. Stage 2 randomizes patients 1:1 to placebo or venglustat preferred dose based on Stage 1 safety data. Primary endpoints are TKV growth rate over 18 months in Stage 1 and eGFR[CKD-EPI] slope over 24 months in Stages 1 and 2 (n=560).

Results: Baseline characteristics for Stage 1 are shown (Table; n=225). Mean patient age is 42.7 years; mean eGFR[CKD-EPI] is 65.5 mL/min/1.73 m2. Overall, 55.1%, 30.7% and 14.2% are of Mayo Imaging Class 1C, 1D and 1E, respectively.

Conclusions: STAGED-PKD enables optimal dose selection and evaluation of venglustat safety and impact on TKV growth and eGFR slope in ADPKD. Stage 1 TKV assessment via a nested approach allows early efficacy evaluation, increasing trial design efficiency.

Funding: Commercial Support - Sanofi Genzyme

PO1578

STAGED-PKD: Patient Enrichment and Model-driven Efficient ADPKD Trial Design

Ronald D. Perrone,1 Ali Hariri,2 Pascal Minini,3 Arlene B. Chapman,4 Shigeo Horie,2 Bertrand Knebelmann,6 Michal Mrug,2 Albert C. Ong,2 York P. Pei,7 Vicente E. Torres,8 Vijay Modur,9 Ron T. Gansevoort;10 Division of Nephrology, Tufts Medical Center, Tufts University School of Medicine, Boston, MA; 1Sanofi Genzyme, Cambridge, MA; 2Sanofi, Chilly Mazarin, France; 3Department of Medicine, University of Chicago, Chicago, IL; 4Department of Urology, Juntendo University Graduate School of Medicine, Tokyo, Japan; 5Université Paris-Descartes, Faculté de Médecine, AP-HP, Service de Néphrologie, Hôpital Necker-Enfants Malades, Paris, France; 6Department of Medicine, University of Alabama at Birmingham, Birmingham, AL; 7Department of Infection Immunity & Cardiovascular Disease, University of Sheffield, Sheffield, United Kingdom; 8Division of Nephrology, University of Toronto, Toronto, ON, Canada; 9Mayo Translational Polycystic Kidney Disease Center, Mayo Clinic, Rochester, MN; 10Department of Nephrology, University Medical Center Groningen, Groningen, Netherlands.

Background: Total kidney volume (TKV) and eGFR slope are key endpoints in autosomal dominant polycystic kidney disease (ADPKD) trials, indicative of cyst growth and kidney function decline. To date, unequivocal demonstration of drug effect on these endpoints required two trials. STAGED-PKD assesses the effect of glucosylceramide synthase inhibition with venglustat on both endpoints in one efficient, short-duration trial.

Methods: Retrospective analysis of TKV and eGFR slope data from CRISP (3-yr) and HALT-A combined identified rapidly progressing patients for enrichment. A statistical relationship between TKV growth vs eGFR slope was derived by modeling. Meta-analysis was conducted of randomized clinical trials assessing treatment impact on both TKV and eGFR. These analyses enabled study powering for both endpoints. Comparison of design efficiency was performed vs prior trials.

Results: Retrospective analysis of CRISP and HALT-A confirmed a significant correlation between TKV growth and eGFR slope (correlation 0.346, p<0.0001; Figure). Different statistical approaches showed that in rapidly progressing ADPKD patients, 50% reduction in TKV growth and 30% reduction in eGFR slope is associated with a ~30% reduction in eGFR slope. Thus, STAGED-PKD is powered to detect 50% reduction in TKV growth and 30% reduction in eGFR slope. STAGED-PKD is highly efficient vs HALT-A and -B, TEMPO 3:4, and REPRISE.

Conclusions: Modeling allowed the design and powering of a two-stage study to assess venglustat impact on TKV growth and eGFR slope. STAGED-PKD improves efficiency via modeling and patient enrichment to reduce patient number and trial duration.

Funding: Commercial Support - Sanofi Genzyme

PO1579

Biological Efficacy and Safety of Niacinamide in Patients with Autosomal Dominant Polycystic Kidney Disease

Mireille El Ters,1 Xia Zhou,2 Rebecca J. Lepping,2 Pengcheng Lu,2 Jonathan D. Mahnken,3 William M. Brooks,3 Franz Winklhofer,3 Xiaogang Lu,2 Alan S. Yu,1 Mayo Foundation for Medical Education and Research, Rochester, MN; 2University of Kansas Medical Center, Kansas City, KS.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by progressive cyst enlargement, leading to kidney failure. Sirtuin-1 is upregulated in ADPKD and accelerates disease progression by deacetylating p53. Niacinamide is a dietary supplement that inhibits sirtuins at high doses.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Methods: We conducted an open-label, single arm intervention trial (Study 1, N=10), and a randomized, double blinded, placebo-controlled trial (Study 2, N=36) to assess the biological activity and safety of niacinamide. Patients with ADPKD were given 30 mg/ kg oral niacinamide or placebo, for 12 months. Primary endpoint was ratio of acetylated p53 to total p53 protein in peripheral blood mononuclear cells. Secondary outcomes were changes in height-adjusted total kidney volume (ht-TKV) and overall pain and quality of life scores. Other biomarkers of efficacy included serum creatinine, CRP, urine protein/creatinine and urine MCP1/creatinine ratios.

Results: There were no statistically significant differences in the baseline characteristics between placebo and treatment arms. There was no significant effect of niacinamide on acetylated/p53 ratio in either study. In study 1, the ratio was higher at 1 month (p = 0.003) but not at 6 and 12 months and no difference was noted between placebo and niacinamide arms in study 2 (p=0.51). There was no difference in the change of ht-TKV from baseline to 12 months between niacinamide and placebo. Ht-TKV increased slightly from 1049 to 1082 ml/m^2 (p=0.71) with small eGFR decline from 83.6 to 81 ml/min/1.73 m^2 (p=0.084) in niacinamide treated patients (combined study 1+2). Furthermore, there was no statistical difference in urine MCP1/creatinine, urine protein/creatinine and quality of life scores over time. Niacinamide was generally well-tolerated. Most common adverse effects were nausea, diarrhea, gastroesophageal reflux (combined GI symptoms:70% in study 1,78% in study 2 niacinamide treatment arm and 58% placebo), headache and exacerbation of acneiform rash with no difference in their incidence between niacinamide and placebo.

Conclusions: Niacinamide is safe and well-tolerated in ADPKD patients. However, we were unable to detect a sustained inhibition of sunitinib activity over 12 months of treatment, and there was no signal to suggest a beneficial effect on any efficacy measure.

Curcumin Therapy to Treat Vascular Dysfunction in Children and Young Adults with Autosomal Dominant Polycystic Kidney Disease (ADPKD): Design and Baseline Characteristics of Participants
Heather Farmer-Bailey,1 Melissa A. Cagnapprornchai,2 Zhiling You,1 Diana George,3 Wei Wang,1 Anna Jovanovich,1,3 Danielle Soranno,1 Benny L. Nowak,1 University of Colorado Denver - Anschutz Medical Campus, Aurora, CO; 2Rocky Mountain Pediatric Kidney Center, Rocky Mountain Hospital for Children at Presbyterian St. Luke’s Medical Center, Denver, CO; 3Rocky Mountain Regional V4 Medical Center, Aurora, CO; 4Children’s Hospital Colorado, Aurora, CO.

Background: Complications of ADPKD begin in childhood. While the hallmark of the disease is the development and continued growth of multiple renal cysts that ultimately result in loss of kidney function, cardiovascular complications are the leading cause of death. Vascular dysfunction (endothelial dysfunction and large elastic artery stiffness) is evident from a very young age and appears to involve increased oxidative stress and inflammation. Treatment options to prevent cardiovascular disease in adults with ADPKD are limited; thus, childhood may represent a key therapeutic window.

Methods: Curcumin is a safe, naturally occurring polyphenol found in the Indian spice turmeric, with a unique ability to activate transcription of key antioxidants, suppress inflammation, and reduce proliferation. We are conducting an ongoing randomized, double-blinded clinical trial to assess the effect of curcumin therapy (25 mg/kg/d) on vascular function (brachial artery flow-mediated dilation [FMD]), and aortic pulse-wave velocity [aPWV]; co-primary outcomes) and kidney growth (change in height-adjusted total kidney volume [ht-TKV]) in children/young adults 6–25 yrs with ADPKD.

Results: The study is fully enrolled. Of the 68 screened participants, all 68 were randomized to receive either the curcumin or placebo. Participants ranged in age from 6-25 yrs, n=25 (37%) were children <18 yrs, and mean±S.D.estimated glomerular filtration rate was 117±16 ml/min/1.73 m^2. FMD_d was 9.3±0.5%, aPWV was 516±107 cm/sec, and median (IQR) ht-TKV was 333 (234, 475) ml/min. In the sub-group of young adults who received a supraphysiologic infusion of ascorbic acid to inhibit vascular oxidative stress (n=24), FMD_d improved vs. isovolumetric saline (13.6±5.2% vs. 11.3±4.3%), indicating baseline vascular oxidative stress. Greater baseline aPWV was independently associated with larger baseline ht-TKV.

Conclusions: The trial will be completed in December of 2020. This study has the potential to establish a novel, safe, and facile therapy for the treatment of arterial dysfunction, and possibly renal cystic disease, in an understudied population of children and young adults with ADPKD.

Funding: NIDDK Support, Other NIH Support - National Center for Advancing Translational Sciences, Commercial Support - Verdeur Sciences (provided curcumin and placebo), Private Foundation Support

PO1581
End-of-Study Results from ACQUIRE: A Study Measuring Quality of Life, Treatment Preference, and Treatment Satisfaction of Autosomal Dominant Polycystic Kidney Disease Patients in Europe
Dominique Joly,1 Helen Doll,2 Anne De Jong-Laird,2 Madhusudan Kabra,2 Nephrology Department, Necker Hospital, Paris, France; ‘Clinical Outcomes Solutions Ltd, Folkestone, United Kingdom; ’Otsuka Pharmaceutical Europe Ltd, Wexham, United Kingdom.

Background: Little is known about health-related quality of life (HRQoL) and patient (pt) reported outcome (PRO) measures in early autosomal dominant polycystic kidney disease (ADPKD), and longitudinal studies are lacking.

Methods: ACQUIRE (NCT02848521) was a prospective, non-interventional, real-world observational study in pts with early and rapidly progressing ADPKD (chronic kidney disease [CKD] stages 1–3) across 7 European countries. The primary objective was to measure changes in Physical Health Composite Scale (PCS) scores of the 12-item Short Form Health Survey (SF-12) over 18 months. Other objectives included changes in SF-12 Mental Health Composite Scale (MCS) scores, ADPKD-specific PROs including the ADPKD-Impact Scale (IS), -Urinary Impact Scale (UIS) and -Pain & Discomfort Scale (PDS), and treatment satisfaction questionnaire (TSQM-9).

Results: Patient demographics were previously reported. Overall 305/403 (75.7%) were included in the PRO analysis set. Changes from baseline in SF-12 (PCS and MCS), ADPKD-IS (Physical and Emotional domains) and TSQM-9 (Global Satisfaction) through Month 18 are presented in Figure 1. CKD-1 pts and pts not receiving tolvaptan reported the lowest treatment satisfaction. No consistent changes were observed for ADPKD-IS and ADPKD-PDS (not shown).

Conclusions: Over an 18-month timeframe, pts reported reduced scores in the PCS component of SF-12, deterioration in the physical components of ADPKD-IS and reduced treatment satisfaction. These data suggest that continued disease progression negatively impacts the HRQoL of pts with early stages of ADPKD and implies there may be current unmet treatment needs in this pt population.

Figure 1. Change from Baseline in PROs

Funding: Commercial Support - Otsuka Pharmaceutical Europe Ltd.
Methods: ESRD patients treated with dialysis or transplant with at least one ADPKD diagnosis code and a reported ESRD service date from January 1, 2014, to December 31, 2016, in the US Renal Data System (USRDS) were included. Mortality rates were estimated overall, by sex, by race, and by age group (with a patient’s follow-up potentially spanning two age groups). Both unadjusted mortality and adjusted mortality by 2016 US population age distributions for 65 years and older were estimated.

Results: Of 3,208,884 ESRD patients in the USRDS database, 76,428 patients (2.4%) had ADPKD and of those, 14,756 were aged 65 years and older in the study period. Among elderly ADPKD patients, mean age was 70.8 years and overall mortality was 99.8 per 1,000 patient-years (129.6 age-adjusted).

Conclusions: These findings fill an important gap in the literature on ADPKD mortality in the US.

Risk of Severe Herpes Zoster Infection in Patients with Polycystic Kidney Disease: A Nationwide Cohort Study with Propensity Score-Matching Analysis

Tung-Min Yu. Taichung Veterans General Hospital, Taichung, Taiwan.

Background: Polycystic kidney disease (PKD) should be considered as a systemic disorder rather than only a kidney disease. Significantly lower lymphocyte cell counts, including B and T lymphocyte decrease, is noted in patients with PKD. This lymphopenia poses a risk of viral infection. Data to elucidate the herpes virus infection risk in patients with PKD are lacking; therefore, we conducted a national-wide population-based cohort study to investigate the herpes virus risk in PKD patients.

Methods: Patients who were hospitalized at least once with a diagnosis of autosomal dominant PKD were defined as PKD patients; patients without any diagnosis of PKD during the study period were grouped into the non-PKD cohort. The index date was set as the date when the patients were newly diagnosed with PKD. All study patients were followed up until the occurrence of herpes zoster infection, herpes simplex infection, death, withdrawal from the National Health Insurance Research Database for other reasons, or until December 31, 2013.

Results: We included 4358 PKD patients and 4358 non-PKD patients. The incidence rates of the risk of developing herpes zoster and herpes simplex were estimated using multivariate stratified analyses. PKD patients had an overall 2.43-fold risk of herpetic infection (aHR = 2.43, 95% CI 1.47–4.04) and 2.36-fold risk of herpes zoster (aHR = 2.36, 95% CI 1.34–4.13) in subgroup analyses compared with the non-PKD cohort. PKD patients without any comorbidities had a significantly higher risk of herpes zoster or herpes simplex (aHR = 3.38, 95% CI 1.51–7.56).

Conclusions: This is the first study to reveal the severe risk of herpes zoster infection in patients with PKD. High index suspicion of severe herpes zoster infection should be maintained in clinical professionals. Whether patients with PKD should be prophylactically universally with anti-varicella-zoster virus vaccine needs to be investigated in the future.

PO1584

The Use of a Visual Four-Score Scale Improves the Yield of [18F-FDG PET-CT Imaging in the Diagnosis of Cyst Infection in Patients with Autosomal Dominant Polycystic Kidney Disease

Background: [18F]FDG PET-CT proved useful in the diagnosis of renal and hepatic cyst infection (CyI) in patients with autosomal dominant polycystic kidney disease (ADPKD). However, the definition of CyI by [18F]FDG by uptake in case of CyI based on a visual 4-point scale.

Methods: All ADPKD patients who were hospitalized between January 2007 and March 2019 for suspected CyI and who underwent an [18F]FDG PET/CT scan were retrospectively identified. CyI was defined based on 5 concomitant criteria: (i) fever ≥38°C; (ii) abdominal pain; (iii) peak plasma C-reactive protein level ≥70 mg/L; (iv) no other cause of inflammation; and (v) favorable outcomes after antibiotics for ≥21 days.

First, all [18F]FDG PET/CT images were qualitatively interpreted by 2 blinded board-certified nuclear medicine physicians in nuclear medicine. CyI was diagnosed in case of (i) homogeneous or (ii) heterogeneous [18F]FDG accumulation in cyst wall, or (iii) diffuse [18F]FDG accumulation within the cyst. Next, the uptake of [18F]FDG of the suspected CyI was scored in comparison to blood pool and liver activities. An accumulation of [18F]FDG around the cyst equivalent or inferior to the blood pool was scored as 1. If it was superior to the blood pool but inferior or equal to the hepatic [18F]FDG background, it was scored as 2. If it was slightly superior to the liver, it was scored as 3. If it was largely superior to the hepatic [18F]FDG activity, it was scored as 4.

Results: A total of sixty [18F]FDG PET/CT scans with a mean age of 50.7 ± 18.0 years of patients with ADPKD were performed for suspected CyI in 38 ADPKD patients: 29 episodes met the gold-standard criteria for CyI. The visual assessment of PET/CT images reached a sensitivity of 73.1% and a specificity of 70.6%. The pattern of [18F]FDG accumulation around or within the suspected cyst was not discriminant. By contrast, the 4-point scale improved the diagnostic yield (specificity of 85.3%) with a diagnostic threshold of [18F]FDG uptake ≥3, i.e. higher than the hepatic background.

Conclusions: [18F]FDG PET-CT imaging helps in the diagnosis of CyI in ADPKD patients, and the use of a 4-point scoring of [18F]FDG uptake improves its yield, with positive and negative predictive values of 78.3% and 78.4% respectively.

PO1585

Liver Cyst Infection After Hepatic Transcatheter Arterial Embolization in Patients with Autosomal Dominant Polycystic Kidney Disease

Yasuhito Oda, Dai sushi Ikuma, Hiroki Mizuno, Akinari Sekine, Masayuki Yamanouchi, Tatsuya Suwabe, Junichi Hoshino, Yoshifumi Ubara. Toranomon Hospital Kaj igaya, Kawasaki, Japan.

Background: Hepatic transcatheter arterial embolization (TAE) is a non-surgical treatment to reduce the volume of enlarged liver in patients with autosomal dominant polycystic kidney disease (ADPKD). The incidence of liver cyst infection after hepatic TAE is not known.

Methods: Patients with ADPKD who underwent hepatic TAE between January 2014 and July 2019 in Toranomon Hospital Kajigaya to reduce the volume of enlarged liver were retrospectively analyzed for their history of liver cyst infection before and after hepatic TAE.

Results: 107 patients were included in the study. The mean ± standard deviation (SD) of age and height-adjusted total liver volume was 53.9 ± 9.6 years and 5.048 ± 2.124 mL, respectively. 26 patients (24%) were men, and 36 patients (34%) were on renal replacement therapy. Seven patients (7%) had a history of liver cyst infection before hepatic TAE. During the follow-up period, 16 patients (15%) experienced 20 liver cyst infections in total after hepatic TAE, and only one of them had a history of liver cyst infection before hepatic TAE. The mean ± SD of the follow-up period was 714 ± 601 days, while median [interquartile range] was 467 [225–1,078] days. 10 out of 16 patients were on renal replacement therapy, which were all hemodialysis. Four out of 20 liver cyst infections occurred within three months of hepatic TAE. The incidence rate of liver cyst infection after hepatic TAE was 96 cases per 1,000 person-years.

Conclusions: This is the first report on the incidence of liver cyst infection after hepatic TAE. Although comparison with a control group without hepatic TAE is necessary to evaluate the risk of liver cyst infection caused by hepatic TAE, setting a control group with a similar background is difficult and remains a research question.

PO1586

3D Facial Gestalt Analysis of Individuals with Mutated PKD1 and PKD2 Genes in Polycystic Kidney Disease: Results of a Czech Pilot Study

Michaela Zelinova,1,2 Veronika Moslerova,1,2 Martin Schwarz,1,2 Marek Turnovec,1,2 Dana Thomasova,1,2 University Hospital Motol, Prague, Czechia; 2Univerzita Karlova, Praha, Czechia.

Background: Pathogenic variants in PKD1 and PKD2 genes cause autosomal dominant polycystic kidney disease (ADPKD) that can also manifest in the liver, pancreas or cardiovascular system. Nonetheless, association of ADPKD with 3D facial gestalt has not been studied so far. Here we present our first results of 3D facial morphology in a Czech ADPKD patients.

Methods: Thirty ADPKD cases were enrolled and analyzed by the 3DMD Face System. Morphometric analyses were performed using the Morphoex3s software by comparing cases versus age and sex matched controls. Results: We observed that 3D facial gestalt in ADPKD patients differs from controls. ADPKD patients have more prominent nasal region, most significantly in the area of the tip of the nose. In addition, there is retraction of the eyebrows area, midface-zygomatic prominence and retraction of the lateral buccal region. Most of the ADPKD cases have thin upper lip (red part of lip) in opposition to a prominent lower lip.

Conclusions: The preliminary results of this pilot study suggest that there could be a distinct 3D facial gestalt in ADPKD. ADPKD is an ideal candidate for “phenotype-driven variant prioritization”, where molecular genetic analysis could be linked to 3D morphometry. In ADPKD families, where molecular genetics failed to identify a causative variant, 3D morphometry could be used as a predictive marker of the risk of disease in non-affected parents. Supported by Charles University Grant Agency, project number 44120.

Increased Phosphorylation of ACTN4 Leads to Podocyte Dysfunction and Focal Segmental Glomerulosclerosis Mimicking Disease-Causing Mutations
Di Feng,1,2 Mukesh Kumar,1 Jan Muntel,1 Susan B. Gurley,1 Gabriel Birnac,1 Isaac E. Stillman,1 Lai Ding,1 Minxian Wang,1 Saima Ahmed,2 Johannes S. Schlondorff,1 Seth L. Alper,1,3 Thomas Ferrante,1 Susan Marquez,1 Carlos E. Ng,1,4 Richard Novak,1 Donald E. Ingber,1,5 Hanno Steen,1 Martin R. Pollak,1,6,7 Beth Israel Deaconess Medical Center, and Harvard Medical School, Boston, MA; 1Wiss Institute for Biologically Inspired Engineering at Harvard University, Boston, MA; 2Biognosys AG, Schlieren, Switzerland; 3Oregon Health & Science University, Portland, OR; 4Broad Institute of Harvard and MIT, Boston, MA; 5Brigham and Women’s Hospital, Boston, MA; 6Boston Children’s Hospital, Boston, MA.

Background: Genetic mutations in ACTN4 have been linked to focal segmental glomerulosclerosis (FSGS) in humans through cytoskeletal disruption and impairment in podocyte response to mechanical stress. ACTN4 is phosphorylated at S159 in podocytes, but the effect of this post-translational modification on podocyte and kidney function is not known.

Methods: We used phosphomimetic ACTN4 to investigate the effects of this phosphorylation in vitro and in vivo. The effect of phosphorylation on the interaction between ACTN4 and F-actin was assessed through F-actin bundling assays, and the effect on F-actin alignment was assessed by immunofluorescence staining and quantified using autocorrelation analysis. Microfluidic organ-on-a-chip technology was used to measure the rate of podocyte detachment when simultaneously exposed to fluid flow and cyclic strain. A phosphomimetic mouse model was generated, subjected to subtotal nephrectomy, (to simulate glomerular hyperfiltration), and assessed for renal injury. Targeted mass spectrometry was used to determine whether injurious stimuli to podocytes increased ACTN4 phosphorylation.

Results: Compared to wild type (WT) ACTN4, phosphomimetic ACTN4 led to increased F-actin bundling activity and higher spatial correlation of F-actin alignment in podocytes. When subjected to mechanical stress in organ-on-a-chip culture devices, phosphomimetic podocytes demonstrated nearly a 3-fold higher rate of detachment (28/154 podocytes, 18.2%) in comparison with WT (12/170 podocytes, 7.1%, p<0.05). Phosphomimetic Actn4 mice developed proteinuria and glomerulosclerosis after subtotal nephrectomy. Finally, phosphorylation of ACTN4 at S159 in podocytes was stimulated by high extracellular glucose and TGF-b.

Conclusions: Increased phosphorylation of ACTN4 at S159 leads to biochemical, cellular, and renal pathology that is similar to pathology resulting from human disease-causing mutations in ACTN4. Stimulation of this phosphorylation by glucose and TGF-B suggests potential mechanisms of ACTN4-mediated kidney disease that extend beyond its original genetic etiology.

PO1588
Toward a Molecular Mechanism for Low-Molecular-Weight Proteinuria in Dent Disease
Katherine E. Shipman, Kimberly R. Long, Youssef Rbaibi, Catherine J. Baty, Ora A. Weiss. University of Pittsburgh School of Medicine, Pittsburgh, PA.

Background: Dent disease is a progressive X-linked disorder caused by loss of function of the CI/FH exchanger CLC-5. Early symptoms include low molecular weight (LMW) proteinuria resulting from inefficient recovery of filtered proteins by megalin and cubilin receptors in the proximal tubule (PT). Knockout of Clc-5 in mice recapitulates the LMW proteinuria observed in human disease and decreases protein (but not mRNA) levels of megalin and cubulin. How loss of Clc-5 leads to reduced receptor expression remains unknown. Previous gene expression studies in Clc5 KO mice suggest there are alterations in cholesterol and lipid metabolism. Elevated cholesterol levels have been demonstrated to alter the organization of the endothelial pathway and impair receptor recycling in cultured cells. We hypothesize that altered cholesterol metabolism impairs megalin traffic through the recycling pathway and promotes its degradation.

Methods: We used siRNA knockdown (KD) and CRISPR/Cas9 knockout (KO) and rescue approaches in an opossum kidney (OK) cell culture model that recapitulates morphologic and functional features of the PT in vivo to study the role of Clc-5 in the endothelial pathway. Additionally, we assessed PT function, megalin/cubilin expression, and protein distribution in cultured CRISPR/Cas9-generated Clc-5 KO cells.

Results: KD or KO of Clc-5 resulted in significantly decreased endothelial uptake of fluorescently labeled albumin that was fully rescued by heterologous expression of wild-type human CLC-5. Additionally, the half-life of megalin was reduced in Clc-5-depleted cells. We confirmed LMW proteinuria in the KO mouse. Heterozygous females also have reduced PT uptake and megalin expression. We observed an accumulation and a redistribution of cholesterol in PTs of heterozygous mice and in Clc-5 KO cells.

Conclusions: Our new cellular models for Dent disease should enable us to identify the molecular mechanism that results in reduced megalin/cubulin expression and determine whether altered cholesterol metabolism contributes to the LMW proteinuria observed in Dent disease.

Super-Resolution Imaging of the Filtration Barrier Suggests a Role for Podocin R229Q in Genetic Predisposition to Glomerular Disease
Linus Butt,1 David Unnersjö-Jess,1 Martin Höhne,1 Robert Hahnfeld,1 Dervla Reilly,1 Markus M. Rinschen,3 Ingo Plagmann,1 Paul T. Brinkkoeetter,1 Hjalmir Brismar,1 Hans Blom,1 Bernhard Schermer,1,3 Thomas Benzing,1,4 Department II of Internal Medicine and Center for Molecular Medicine Cologne, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany; 2Center for Mass Spectrometry and Metabolomics, The Scripps Research Institute, La Jolla, CA; 3Royal Institute of Technology, Stockholm, Sweden; 4CECAD, University of Medicine and University Hospital Cologne, Cologne, Germany.

Background: Breakdown of the three-layered glomerular filtration barrier is a leading cause of end-stage kidney disease. Whereas extensive research led to a growing understanding of hereditary glomerular diseases in children, most adult patients lack a genetic diagnosis. p.R229Q is a common missense variant in NPHS2, the gene encoding podocin, and it is associated with albuminuria in the general population. However, epidemiologic studies suggest that p.R229Q is only disease-causing in trans-association to additional genetic alterations.

Methods: We assessed the predisposition of p.R229Q to glomerular disease by introducing the equivalent point mutation in mice using CRISPR/Cas9-mediated gene editing. By applying super-resolution STED microscopy and functional measurements, we characterized the phenotype of Podc229Q mice. Additionally, we evaluated the podocin229Q protein stability in human cultured podocytes.

Results: Although Podc229Q mice do not develop overt glomerular disease, super-resolution microscopy and morphometric analyses revealed ultrastructural alterations that have recently been linked to disease predisposition. Ultrastructural alterations were even more prominent in homozygous Podc229Q mice eventually resulting in microalbuminuria in aged mice. Consistent with a recently published study, the slit diaphragm length correlated significantly with levels of albuminuria. Podocin229Q protein levels were decreased in Podc229Q mice as compared to WT. However, cultured podocytes expressing the variant. Mechanistically, increased proetional degradation resulted in a decreased protein stability of podocin229Q in human cultured podocytes.

Conclusions: Collectively, our data suggest that podocin R231Q may contribute to genetic predisposition in adult patients.

PO1590
Reduced Glomerular and Neprhin Injury due to Albumin Knockout in the Heavily Nephrotic, Polymerization-Defective GBM Laminin B2-Del44 Mutant Mice
Steven J. Funk, Jeffrey H. Miner. Washington University Department of Medicine, Division of Nephrology, Saint Louis, MO.

Background: Increased proteinuria is associated with adverse outcomes in chronic renal disease. Much evidence indicates that increased albumin filtration through the glomerular filtration barrier exacerbates nephron injury, but in vivo evidence is conflicting. Although it was previously shown that Nagase anabuminic rats exhibit little or no increase in renal injury following multiple insults, Alport mice lacking albumin were previously shown to have surgically increased lifespan with delayed injury to glomeruli and nephrin epithelium.

Methods: We mated CRISPR-mediated, albumin-knockout mice with laminin B2-Del44 mice, which exhibit heavy albuminuria, but delayed foot process effacement and fibrosis. Mice were monitored until their natural deaths or euthanized at 9, 10, or 12 months for analyses. Plasma was analyzed for BUN. Glomeruli were analyzed by electron microscopy to determine foot process effacement. Nephren projection was analyzed by immunofluorescent microscopy to determine status of injury markers.

Results: Alport mice express a significant increase in albumin-Del44 double mutant mice exhibited a significantly increased proteinuria as well as increased glomerular injury, which is suggestive of glomerular injury.

Conclusions: Collectively, our data suggest that podocin R231Q may contribute to genetic predisposition in adult patients.
was decreased at younger ages. Neophren tubule epithelium exhibited reduced KIM-1 expression at early ages, indicating delayed injury. 

**Conclusions:** Similar to Alport mice, the absence of albumin in Lamb2-Del44 mice resulted in increased lifespan with delayed renal injury. These data support a significant role of albumin in nephron injury in murine models of nephrotic syndrome.

**Klotho Improves Renal Function in Autosomal Dominant Tubulointerstitial Kidney Disease (ADTKD-UMOD)**

**Jing T. Zhang,1 Mingzhu Nie,1 Iyotshna Gattineni,1 Elisabeth Kemter,2 Thomas Froehlich,2 Matthias T. Wolf,1 University of Texas Southwestern Medical Center at Dallas, Dallas, TX; 3Ludwig-Maximilians-Universitat Munich, Munich, Germany.**

**Background:** Heterozygous Uromodulin (UMOD) mutations cause ADTKD but no therapies are available. We tested if Klotho improves renal function in a murine model for ADTKD-UMOD.

**Methods:** To generate a stronger phenotype we crossed homozygous mutant UmodC93F/C93F mice with Klotho-overexpressing (TgKl) mice. We studied wild-type (WT), TgKL, UmodC93F/C93F and TgKl/UmodC93F/C93F mice at 6 and 13 months. For quantitative proteome analysis (LC-MS/MS) we harvested kidneys at 3 months.

**Results:** 1. Compared to UmodC93F/C93F mice, TgKL/UmodC93F/C93F animals had significantly lower serum BUN, creatinine, cystatin C (see Figure 1), PTH, FGF23 values, significantly lower serum potassium level was (2.68±0.13mmol/L, serum magnesium level was (0.58±0.13mmol/L, ninty-four patients(88.68%) had hypernagnesemia, seventy-nine patients(81.44%,79/97) had hypercalciuria. Eighty-three different mutations in SLC12A3 were identified within these 106 GS patients, including 32 novel mutations and 4 recurrent ones,5 large genomic rearrangements. Recurrent mutations were p.T660M (22.86%),c.965-1_976delGCGGA CATTGTTGmACCCAAAATT(T6.19%),p.D486N(i.76%), p.I535K(r.76%). Triple mutations was identified in 8 patients, compound heterozygous mutations were identified in 70 patients, homoyzgous mutations were identified in 18 patients, whereas 10 patients had only one heterozygous mutation. The 5 large genomic rearrangements were exon deletion, including E7,E8 deletion, E8,E23 deletion, E20-E24 deletion, E8 deletion,E4-E6 deletion. The sensitivity of genetic testing was sequencing was 90.57%.

**Conclusions:** We identified 83 mutations related to GS, containing 32 novel variants and 4 high frequency ones, 5 large genomic rearrangements. TES combined with MLPA significantly increased the sensitivity of genetic sequencing and facilitate more accurate diagnosis of GS.

**Funding:** Government Support - Non-U.S.

**POI592**

**Spectrum of Mutations in 106 Chinese Patients with Gitelman Syndrome**

**Lijun Mou, Xujiao Chen, Ying Hu. Nephrology Department. Zhejiang University School of Medicine, Zhejiang University School of Medicine, Hangzhou, China.**

**Background:** Gitelman’s syndrome (GS) is an rare, autosomal recessively inherited salt-losing tubulopathy(SLT) characterized by hypokalemic metabolic alkalosis. GS is caused by the mutations in SLC12A3 gene encoding for the thiazide-sensitive NaCl cotransporters (NCC). However, the sensitivity of genetic sequencing was low. No large genomic rearrangements in Chinese patients with GS was previously identified.

**Methods:** Targeted gene sequencing (TES) by next generation sequencing associated with SLS was performed for patients suspected of GS. Then, a search for large genomic rearrangements by ligation-dependent probe amplification(MLPA) assay was performed in patients with heterozygous for point mutations and patients with homoyzgous mutations without consanguinity history.

**Results:** Fifty-nine patients(56.67%) were female, the age was (34.87±15.36) years, serum potassium was (2.68±0.13)mmol/L, serum magnesium level was (0.58±0.13)mmol/L, ninty-four patients(88.68%) had hypernagnesemia, seventy-nine patients(81.44%,79/97) had hypercalciuria. Eighty-three different mutations in SLC12A3 were identified within these 106 GS patients, including 32 novel mutations and 4 recurrent ones,5 large genomic rearrangements. Recurrent mutations were p.T660M (22.86%),c.965-1_976delGCGGA CATTGTTGmACCCAAAATT(T6.19%),p.D486N(i.76%), p.I535K(r.76%). Triple mutations was identified in 8 patients, compound heterozygous mutations were identified in 70 patients, homoyzgous mutations were identified in 18 patients, whereas 10 patients had only one heterozygous mutation. The 5 large genomic rearrangements were exon deletion, including E7,E8 deletion, E8,E23 deletion, E20-E24 deletion, E8 deletion,E4-E6 deletion. The sensitivity of genetic testing was sequencing was 90.57%.

**Conclusions:** We identified 83 mutations related to GS, containing 32 novel variants and 4 high frequency ones, 5 large genomic rearrangements. TES combined with MLPA significantly increased the sensitivity of genetic sequencing and facilitate more accurate diagnosis of GS.

**Glucosylceramide Synthase Inhibition with Venglustat in Classic Fabry Disease Patients Leads to Progressive Reduction of Endothelial Cell Globotriaosylceramide Inclusion Volume**

**Behzad Najafian,1 William Wilcox,2 Robert Hopkin,3 Elena Lukina,4 Patrick B. Deegan,1 Charlotte Sensinger,1 Eric Hailman,1 Vijay Modur,1 Michael Maurer.1 Department of Pathology, University of Washington, Seattle, WA; 2Emory University School of Medicine, Atlanta, GA; 3Division of Human Genetics, Cincinnati Children’s Hospital Medical Center, University of Cincinnati College Medicine, Cincinnati, OH; 4National Research Center for Hematology, Moscow, Russian Federation; 5Lysosomal Disorders Unit, Addenbrooke’s Hospital, Cambridge, United Kingdom; 6Sanofi Genzyme, Cambridge, MA; 7Departments of Pediatrics and Medicine, University of Minnesota, Minneapolis, MN.**

**Background:** Fabry disease (FD) is a rare disorder caused by mutations in the gene for the lysosomal enzyme alpha-galactosidase A (αGal-A). Progressive accumulation of globotriaosylceramide (GL-3) in vascular endothelial and other cell types leads over decades to renal, cardiovascular, and other severe clinical manifestations. In a phase 2 study, glucosylceramide synthase inhibition with venglustat led to reduction in microscopic (LM) scores of lysosomal GL-3 inclusions in skin capillary endothelial cells (EC) after 3 years, although not after 6 months. We applied quantitative unbiased stereological methods to better characterize the effect of venglustat on skin EC GL-3 inclusions.

**Methods:** Skin biopsies were obtained from classic male Fabry disease patients (N = 11) at baseline and during daily treatment with venglustat (NCT0228460, NCT02489344). Images from at least 50 randomly selected superficial skin capillaries per biopsy were obtained using transmission electron microscopy (EM) at 7,500 X magnification. The fraction of the volume(Vv) of EC cytoplasm occupied by GL-3 inclusions (Vv[EC/Endo]) was estimated using point counting by a masked reader. Two-sided paired t tests were used to evaluate changes from baseline to post-treatment values at each time point.

**Schematic diagram of mutations in 106 ChineseGS patients**
Results: Venglustat therapy led to a significant reduction from baseline in Vv(Inc/Endo) of 0.62 (21.1%; p<0.001) after 6 months and 0.19 (38.7%; p<0.001) after 2 years of treatment.

Conclusions: Treatment with venglustat led to reduction in skin capillary GL-3 inclusion fractional volume which was detectable after 6 months using precise quantitative 1H NMR methods, but not by LM scoring. This was followed by further reduction over the next 2 1/2 years. We posit that, in the absence of β-glucuronidase activity, inhibition of GL-3 production with venglustat allowed other enzymatic or non-enzymatic mechanisms to progressively reduce EC lysosomal GL-3 content. Long-term venglustat therapy may therefore prevent or reverse progressive tissue injury in Fabry disease.

Atypical Histological Abnormalities in Patients with Nephronophthisis Diagnosed with NPHP1 Deletion

Maiko Akiyama,1 Hiroshi Suzuki,2 Arisa Ikeda,3 Masako Iwashaki,4 Daisuke Honda,5 Hisatsugu Sakakibara,1 Shigeki Tomita,1 Hisaki Rimoo,6 Yusuke Suzuki,7 Juntendo University Urayasu Hospital, Urayasu, Japan; 2Juntendo University Faculty of Medicine, Tokyo, Japan.

Introduction: Nephronophthisis (NPHP) is a chronic tubular interstitial disorder that exhibits autosomal recessive genetic forms, causing progressive renal failure in children. It is rare to show urinary abnormalities, edema and hypertension in patients with NPHP. Thus, it is often detected only when the renal failure becomes advanced. NPHP is divided into three types leading to the age of end-stage renal failure, i.e., infant type (around five years old), juvenile type (around 13-14 years old), and adolescent type (around 19 years old). In present study, we report a case of NPHP diagnosed at twenty-six years old who was detected renal dysfunction by annual medical check-up.

Case Description: A 26-year-old woman has not been recognized any growth disorder, and has never been pointed out any urinary abnormality in a school checkup. She was detected renal dysfunction (ser C2-2.3mg/dL) by annual medical check-up at 26 years old. Urine test indicated low specific gravity urine, but not proteinuria and microscopic hematuria. However, urinary β2-MG was high (0.055g/L), and renal biopsy was performed for definitive diagnosis. Histological findings showed no significant findings in glomeruli. However, moderate fibrosis was observed in the interstitial area, and moderate atrophy was observed in the tubules. There was no significant finding in the immunofluorescence analysis, and no electron dense deposits was detected by electron microscopy. Although cyst-like expansion of the tubules was not clear, tubular atrophy was dominantly found in the distal tubules by CK7 staining. Then, we performed genetic analysis of NPHP1 gene, and found complete deficiency of NPHP1 gene, leading to definitive diagnosis of juvenile NPHP.

Discussion: NPHP is often progress to ESRD at an average age of 13-14 years old. Thus, it is exceedingly rare to find NPHP in adult. Although present case did not show the typical histological abnormalities, such as cyst-like expansion of the tubular lesion, we could diagnose by genetic analysis of NPHP1 gene. In patients with renal failure caused by NPHP, interstitial disease is dominantly in distal tubule, it is necessary to discriminate NPHP even in the adult case.

PO1597

Biobank of Urinary Cells and Human Kidney Organoids Reveals Nephropathic Cystinosis Phenotypes and Gene Therapy Strategy

Louis Helms,1 Ivan G. Gomez,1 Dries David,2 Nelly M. Cruz,1 Elena N. Levchenko,2 Rik Gijsbers,1 Benjamin S. Freedman.3 University of Washington, Seattle, WA; 3Katholieke Universiteit Leuven Groep Biomedische Wetenschappen, Leuven, Belgium.

Background: Cystinosis is a rare disorder caused by mutations in CTNS encoding a cystine transporter, leading to renal Fanconi syndrome and kidney failure. Cysteamine treatment slows the disease, but does not prevent these outcomes and animal models fail to exhibit Fanconi syndrome. Stem cell models of kidney organoids exhibit structure with segmental, nephron-like segments, providing an in vitro platform to study nephropathic cystinosis. As a monogenic disorder, gene therapy is an attractive therapeutic approach which can be optimized in kidney organoids. However, cystinosis patients are rare, and iPS cells representing this population are needed.

Methods: Cells from the urine of 16 patients with cystinosis and control subjects were reprogrammed into iPS cells via Sendai virus. CRISPR gene editing was applied to non-cystinotic iPS cells generating 8 CTNS’lines with isogenic controls. Patient-derived and CRISPR-derived CTNS mutant and control iPS cell cohorts were differentiated into kidney organoids and propagated in suspension culture to assess cystinotic phenotype. Organoids were transduced at different stages of differentiation with lenti and aden-associated viruses with fluorescent reporters to assess efficacy of gene transfer.

Results: Patient-derived and CRISPR-derived stem cells exhibited >100 fold increased intracellular cystine content and vacuole-like structures, compared to controls. Both patient and CRISPR iPSCs differentiated into kidney organoids with proximal and distal tubules and podocyte segments. However, cystinotic organoids developed lobular cyst-like structures in suspension culture, while control organoids developed cystinotic organoids with cyst-like structures in suspension culture, while control organoids developed cystinotic organoids with cyst-like structures in suspension culture, while control organoids developed cystinotic organoids. Cysteamine treatment lentiviral delivery and AAV transduction successfully entered kidney organoid structures and co-localized with nephron markers when transduced at early stage of differentiation.

Conclusions: We have established a biobank of urinary and iPS cells representing over 20 cystinotic phenotypes, with phenotypes in both patient- and CRISPR-derived CTNS mutant lines that show improvement with cysteamine. Viral transduction of kidney organoids can be timed to produce high levels of entry. This biobank provides a comprehensive resource for patient-specific development of more efficacious therapeutics for cystinopathic nephropathy, including gene therapy.

The Role of Claudin Variants in the Formation of Kidney Stones

Yu-Chia Hsiao,1 Jasmine El andaloussi,4 Susan Andonian,1 Bertrand J. Jean-Claude,1 Aimee K. Ryan,1 Indra R. Gupta,1 McGill University Faculty of Medicine, Montreal, QC, Canada; 2Research institute of McGill university, Montreal, QC, Canada.

Background: Genetic risk factors contribute to the formation of calcium-based kidney stones. The majority of calcium is reabsorbed via paracellular transport through tight junctions along the human nephron epithelium where Claudins proteins are expressed. Claudins determine the selectivity and permeability of different nephron segments. Studies have shown that CLDN gene sequence variants are associated with kidney stones. I hypothesize that sequence variants in Claudin genes that regulate paracellular renal transport of calcium will be associated with the formation of kidney stones.

Methods: Patient DNA was analyzed by Fluidigm Next Generation Sequencing and Sanger sequencing by standard methods. Rare variants (MAF<1%) were compared to the gnomAD database. In silico prediction software was used to predict the impact of the amino acid change. Human claudin variants were generated by site-directed mutagenesis and cloned into a mammalian expression vector, pEGFP. Immunofluorescence was performed on HEK293 cells that were transiently transfected with both variant and WT sequences.

Results: Ninety adult patients (45 females, 45 males) with recurrent calcium-based kidney stones were recruited from one urologist’s kidney stone clinic. Seventy-two percent (n=59/50) of the patients self-defined as Canadian-European. Sixty-two percent (56/90) of the patients presented with the first kidney stone less than 40 years of age. Four novel heterozygous missense variants were identified in the following: CLDN11 S157F, CLDN16K292E, CLDN17 A94V, and CLDN19 H122D. Nine rare variants include CLDN4 A91T, CLDN9 A113T, CLDN10 4555, CLDN20 M209V, CLDN23 A90T, and CLDN24 V97L. CLDN4 A82T, CLDN8 A94V, CLDN11 S157F, and CLDN17 A94V are predicted to be deleterious. HEK293 cells were transiently transfected with CLDN4 A82T and the mutant protein was unable to localize to the tight junction, unlike the WT CLDN4 protein which did co-localize with ZO-1 by immunofluorescence. Other CLDN variants are under evaluation.

Conclusions: The role of Claudin variants in the formation of kidney stones needs further investigation. Claudins determine the selectivity and permeability of different nephron segments. Claudin variants may contribute to the formation of kidney stones if they alter the paracellular renal transport of calcium.

Elucidation of Molecular Pathogenesis of Lowe Syndrome and Dent Disease Type 2

Nana Sakakibara,1 Kandai Nozu, Shinya Ishikho, Yuya Aoto, China Nagano, Tomoko Horinouchi, Tomohiko Yamamura, Takeshi Ninohji, Kazumoto Iijima. Department of Pediatrics, Kobe University Graduate School of Medicine, Kobe, Japan.

Background: Lowe syndrome and Dent disease-2(Dent-2) are two X-linked kidney diseases caused by OCRL gene anomalies. However, the severity of these diseases are quite different. Genetic studies have shown that patients with truncating mutation in exon 1-7 of OCRL gene were diagnosed with Dent-2, and those with truncating mutations in exon 8-24 were diagnosed with Lowe syndrome. OCRL protein encodes a 5-phosphatase that acts on phosphatidylinositol 4,5-bisphosphate (PI(4,5)P2) and is related to cellular functions by regulating intracellular calcium. The molecular mechanism by which deficiencies in OCRL gene anomalies lead to the disease phenotype by the gene product has not been clarified until now, but it is suspected that an isoform consisting of exon 8-24 exists and it works partially as a 5-phosphatase. However, isoform has not been identified yet.

Methods: We extracted mRNA from cultured urine derived cells of healthy controls and Dent-2 patient with truncating mutation in Exon5 of OCRL gene and then examined 5’-end of mRNA of these cells by using rapid amplification of cDNA ends (5' RACE) method. We also prepared three types of OCRL protein expression vector: wild type model, Dent-2 model harboring truncating mutation in exon 4 and 7, and Lowe syndrome model harboring truncating mutation in exon 16 and exon 22. These vectors were transfected into Hela cells and analyzed the protein expression and 5-phosphatase activity.

Results: As a result of 5’ RACE, the 5’ end starting from Exon 6 was detected in both cells of healthy control and Dent-2 patient. In fluorescent immunostaining of transfected Hela cells, strong protein expression was observed in the wild type model, relatively weak expression was observed in Dent-2 models and no expression was observed in Lowe syndrome models. Western blot analysis detected two bands of 105kDa and 90kDa in the wild type model, single band of 80kDa in Dent-2 models, and no bands in Lowe syndrome models. 5-phosphatase activity of Dent-2 models was 59-85% of that of wild type model, whereas that of Lowe syndrome less than 2% of that of wild type model.

Conclusions: An isoform OCRL protein with 5-phosphatase activity is synthesized by alternative transcription of OCRL gene. This isoform contributes to the mild clinical phenotype in Dent-2.

Clinical and Genetic Features of Autosomal Dominant Alport Syndrome
Monica Furlano,1,2 Victor Martinz Jimenez,2 Marc Pybus,1 Andrea Domingo Gallego,1,2 Nadia Ayasreh,1,2 Silvia Benito Garcia,1 Rosa Arlandis Gallego,1 Elisabet Ars,1 Roser Torra,1,2 Fundacio Puigvert, Barcelona, Spain; 1Universitat Autonoma de Barcelona, Barcelona, Spain; 2Hospital Clinico Universitario Virgen de la Arrixaca, El Palmar, Spain; 3Hospital General de Castellon, Castellon de la Plana, Spain.

Background: Alport Syndrome is the second most frequent genetic kidney disease, accounting for around 2% of patients with end-stage kidney disease. It is caused by pathogenic variants in COL4A3, COL4A4 and COL4A5 genes. The aim of this study was to evaluate the clinical and genetic spectrum of patients with autosomal dominant Alport syndrome.

Methods: Retrospective cohort study of 82 families (252 patients) with autosomal dominant Alport Syndrome. Clinical, genetic, laboratory and pathological data were collected. Renal survival, estimated glomerular filtration rate (eGFR) decline, genotype-phenotype correlation and extrarenal features were analyzed.

Results: A pathogenic DNA variant in COL4A5 was identified in 106 patients (34 families) while 134 harbored a pathogenic variant in COL4A4 (44 families). Complex digenic inheritance was observed in 12 patients without clear genotype-phenotype correlation. Overall median renal survival was 67 years (95% CI, 58-75), without significant differences related to gender, causative gene or type of variant (p = 0.85 and p = 0.28 and p = 0.81 respectively). Microhematuria was the most common renal manifestation (93%) while extrarenal features were rare. The results of kidney biopsies ranged from normal to focal segmental glomerulosclerosis. Hypertension was common and the age at its diagnosis correlated with age at end-stage kidney disease (p = 0.01). The slope of eGFR decline was -1.66 mL/min/1.73m² per year (-1.9 to -1.42) for the overall group, with no significant differences between COL4A4 and COL4A5 genes (P=0.60).

Conclusions: This study shows that autosomal dominant Alport Syndrome patients present a wide spectrum of symptoms ranging from asymptomatic to end-stage kidney disease, regardless of the affected gene or type of variant. This broad phenotype contributes to underdiagnosis in clinical practice and makes autosomal dominant Alport Syndrome diagnosis very challenging.

PO1599
Beneficial Effect of Oxalobacter formigenes Treatment on Nephrocalcinosis in a Rat Model of Primary Hyperoxaluria
Anja Verhulst,1 Bastian Delmelm,1 Elisabeth Lindnelt,2 Maria E. Akerman,2 Patrick C. D’Hasee.1,1 Universiteit Antwerpen, Antwerpen, Belgium; 2Oxthera, Oxthera, Stockholm, Sweden.

Background: Hyperoxaluria leads to urinary calcium-oxalate supersaturation and crystal retention in renal tissue (nephrocalcinosis). In case of primary hyperoxaluria (PH), increased hepatic oxalate production because of a rare genetic defect often leads to severe nephrocalcinosis and early ESRD. Secondary hyperoxaluria is generally less severe, however more common and often related to intestinal oxalate hyperabsorption. Current therapy is often unsatisfactory. Oral administration of Oxalobacter formigenes (OxF), an oxalate-degrading bacteria, is thought to reduce intestinal oxalate absorption and to derive oxalate from systemic sources by inducing enteric oxalate secretion. Here, the ability of OxF treatment to prevent or reduce PH induced nephrocalcinosis, by using an ethylene glycol (EG) rat model to mimic increased hepatic oxalate production, was investigated.

Methods: Eighteen rats were administered EG (0.75% in drinking water) for 6 weeks, of which 9 were treated by oral gavage with OxF and 9 received vehicle. Five control rats did not receive EG/OxF. Plasma and urinary oxalate levels, calcium-oxalate crystalluria, urinary volume, fluid intake, and serum creatinine were monitored during the study period. At sacrifice, nephrocalcinosis was quantified.

Results: Vehicle treated EG animals showed clear hyperoxaluria, hypercalciuria, calcium-oxalate crystalluria and nephrocalcinosis. In OxF treated EG animals the plasma oxalate levels were lower compared to vehicle-treated ones (significant at week 4: 47.6±20.9 vs 88±8.9 µM). Nephrocalcinosis was completely absent in the EG/OxF group. Urinary output of oxalate (crystals) was similar in OxF and vehicle treated EG animals which indicates that, taking into account the absence of crystals in renal tissue of OxF treated EG animals, the amount of oxalate offered to the kidney for excretion was higher in the EG/vehicle group. EG administration significantly increased urinary volume, renal mass and fluid intake, most probably due to osmotic diuresis and partially reversed by OxF. Serum creatinine levels of EG animals (both vehicle/OxF) stayed at baseline levels throughout the study.

Conclusions: This study shows a beneficial effect of OxF treatment on the development of PH-induced hyperoxaluria, hypercalciuria, and nephrocalcinosis, pointing to OxF treated enteric oxalate elimination.

The Knockdown of RPL36A Downregulates GLA Expression Associated with Fabry Disease In Vitro Model
Mohammed A. Al-Obaide, Texas Tech University Health Sciences Center, School of Medicine, Amarillo, TX.

Background: Mutations in the galactosidase alpha (GLA) locus can cause Fabry disease. The GLA locus is mapped in the reverse strand of the RPL36A-HNRNPH2 readthrough locus. The study aimed to show the influence of the siRNA downregulation of the RPL36A expression (the first gene in the RPL36A-HNRNPH2 locus) on the GLA expression.

Methods: The siRNA method was used to downregulate the expression of RPL36A in HEK293 cells. The expression of the two genes RPL36A and GLA in vitro was analyzed by RT qPCR. The protein products of the two genes were analyzed by ELISA and Western blot.

Results: The RT qPCR results of the RPL36A knockdown by siRNA showed a significant decrease not only for RPL36A expression but also for GLA expression (p=0.05) compared with the results of the untreated HEK293 cells. ELISA and Western blot assays showed a decrease in the GLA protein following knockdown of the RPL36A gene, but the two assays did not show a decrease in the expression for RPL36A protein. Alignment analysis by EMBOSIS Matcher showed RPL36A protein amino acid sequence (Length: 106; Mass (Da): 12,441) is 99.1% like RPL36A protein amino acid sequence (Length: 106; Mass (Da): 12,469). Intriguingly, the sequence of mRNA transcripts of both genes showed an 85.3% similarity. The designed siRNA was specific to RPL36A transcript NM_021029.6 and not to RPL36A transcript NM_001001.5, which may explain the RT qPCR results.

Conclusions: The data provided evidence that malfunction in the expression of the RPL36A locus located at the start of the RPL36A-HNRNPH2 readthrough locus can cause an error in the expression of GLA. These findings revealed the importance of the RPL36A-HNRNPH2 readthrough region in Fabry disease. The work was supported by Sanofi-Genzyme Project GZ-2017-11708.

Focal Segmental Glomerulosclerosis with Glomerular Basement Membrane Abnormalities Caused by Compound Heterozygous Myosin 1E Gene Mutations
Claudia Aiello, Dhriti P. Chen, J. Charles Jennette, Keisha L. Gibson, University of North Carolina at Chapel Hill, Chapel Hill, NC.

Introduction: Nephrotic syndrome due to focal segmental glomerulosclerosis (FSGS) in children is often associated with genetic mutations in podocyte structural proteins. This clinical case report highlights a pediatric patient with nephrotic syndrome and FSGS found to have two genetic mutations in myosin 1E gene (MYO1E) encoding the motor domain of the protein. While both of these mutations have previously been identified as variants of unknown significance individually, we report a case of compound heterozygous mutations resulting in FSGS.

Case Description: An 11-year old white male presented with proteinuria and hematuria. Family history of kidney disease included a paternal cousin with hematuria that spontaneously resolved. The patient had no history of recurrent urinary tract infections, kidney stones or excessive NSAID usage. Kidney biopsy revealed FSGS with basket-weaving, splitting and segmental thickening of glomerular basement membranes (GBM) on electron microscopy. Genetic testing was negative for Alport mutations but identified two variants in MYO1E gene (Table). Parental testing revealed each had one variant inherited by the patient, resulting in compound heterozygous mutation in the patient.

Discussion: Both missense mutations in this patient encode the motor domain of myosin 1E protein (residue 19-692), essential for podocyte motility and structural integrity. Hereditary mutations at other locations encoding the motor domain of MYO1E have been described and associated with FSGS. Functional studies showed that MYO1E motor domain variants led to protein mis-localization and disruption to the podocyte structural integrity (Mele et al. NEJM, 2011). MYO1E depletion in mice causes GBM abnormalities similar to lesions in this patient (Chase et al. Am J Physiol Renal Physiol, 2012). While each individual mutation inherited by the patient is not known to be pathogenic, we hypothesize that the combination of non-conservative mutations in the patient resulted in abnormal myosin-1E protein function that caused GBM abnormalities and FSGS.

Genetic diagnostic testing results for proband and parents
PO1602
Metabolic State Modeling of Kidney Single Nuclei Data Reveals Cell-Specific Signatures at Baseline and in Disease
Frienc-Heidi Sahlom,1,2 Anna Greka,1,2 Harvard Medical School, Boston, MA; 1Broad Institute, Cambridge, MA.

Background: The kidney is a metabolically active and cellularly diverse organ. Perturbations in metabolic pathways, such as lipid metabolism, is a well-established sequelae of chronic kidney diseases, such as diabetic nephropathy. Single cell RNA sequencing has allowed for an unprecedented understanding of the kidney’s transcriptionic complexity. However, until now, understanding the diverse metabolic states of the kidney has been limited to either expression analysis of single metabolic enzymes or bulk metabolomics experiments. Given the highly interconnected nature of metabolic networks and the kidney’s cellular complexity, integrating a systems-level understanding of metabolic perturbations with single cell sequencing has the potential to reveal previously unappreciated metabolic cell states and disease perturbations.

Methods: We have applied the newly developed Flux Balance Analysis (FBA) algorithm, for single cell sequencing data, (Compass: doi: 10.1101/2020.12.23.912717), to a dataset of 36,560 single nucleus transcriptomes from mouse kidney comprised of three healthy mice and three mice with CoQ-deficiency proteinic kidney disease.

Results: First, Compass correctly predicted well-established cell-specific kidney transport processes. Next, when comparing proximal tubule cell clusters, corresponding to S1, S2 and S3 segments, the S3 segment was found to have both high activity of branched chain amino acid (BCAA) metabolism and high activity of fatty acid oxidation (FAO). This previously unknown link between BCAAs and FAO in the kidney is of particular cellular metabolic interest, as the most highly downregulated. Downstream of metabolic disease. Finally, when comparing transcriptomes between disease and healthy mice, podocyte-specific changes in FAO and steroid metabolism were observed which correlated with podocyte cytoskeletal regulation, a hallmark of podocyte injury.

Conclusions: Overall, the combination of an enhanced resolution of single nucleus transcriptomics with a systems-level analysis of metabolic networks in the kidney, has revealed cell-specific metabolic states at baseline and in disease. Future application of this analysis to human data will provide important validation for the generalizability of these findings and further understanding of metabolic perturbations in human disease.

Metabolic Dysfunction of Glomerular Endothelial Cells in Alport Syndrome
Hasnik Soloyan,1 Matthew E. Thornton,2 Valentina Villani,1 Patrick Khatchadourian,1 Paolo Cravedi,1 Andrea Angeletti,1,2 Brendan Grubbs,2 Roger E. De Filippo,1,2 Laura Perin,1,2 Sargis Sedrakyan,1,2 Children’s Hospital of Los Angeles, Los Angeles, CA; 1University of Southern California, Los Angeles, CA; 1Mount Sinai Health System, New York, NY; 1Orsola University, Bologna, Italy.

Background: Glomerular endothelial dysfunction plays a key role in the development of chronic kidney disease (CKD), but its impact on Alport syndrome (AS), characterized by mutations in the genes COL4A3, COL4A4, and COL4A5 is unknown. We have previously shown that glomerular endothelial cells (GEC) are damaged in AS mice, manifested by enlarged fenestrations and alteration of the glyocalyx in the early stage of disease. In the present study we report the early transcriptional changes in AS GEC as an indication of endothelial dysfunction and contributing factors for CKD progression.

Methods: We generated endothelial aTomato reporter AS mice and isolated GEC at 4 month of age by FACS. We studied aEd specificity in GEC by flow cytometry, WB, and by monophon and confocal microscopy, and their transcriptome by RNA-seq analysis. Transcriptomes were compared to WT-GEC. The combination of single nucleus transcriptomics with a systems-level analysis of metabolic networks in the kidney, has revealed cell-specific metabolic states at baseline and in disease. Future application of this analysis to human data will provide important validation for the generalizability of these findings and further understanding of metabolic perturbations in human disease.

PO1604
NPHS1 Variants Can Cause Persistent Asymptomatic Proteinuria: Genetic and Clinical Characteristics of Patients with NPHS1 Variants in Japan
Tomohiko Yamamura,1 Tomoko Horinouchi,1 Shinya Ishikto,1 Yuya Aoto,1 Nan Sakakibara,1 China Nagano,1 Takeshi Ninchiyo,1 Yuko Shima,1 Koichi Nakashima,1 Kandai Nozu,1 Kazumoto Iijima,1 1Department of Pediatrics, Kobe University Graduate School of Medicine, Kobe, Japan; 2Department of Pediatrics, Wakeyama Medical University, Wakayama, Japan; 3Department of Child Health and Welfare (Pediatrics), Graduate School of Medicine, University of the Ryukyus, Nishihara, Japan.

Background: NPHS1 gene, which encodes nephrin, is known as a causative gene of congenital nephrotic syndrome (CNS). In addition, recently, it had been recognized that NPHS1 variants present with childhood steroid resistant nephrotic syndrome (SRNS) or focal segmental glomerular sclerosis (FSGS). However, it is not well known that this gene variants account for more milder phenotypes such as asymptomatic proteinuria.

Methods: 347 unrelated patients with CNS, infantile nephrotic syndrome, FSGS and asymptomatic proteinuria were screened for podocyte related genes including NPHS1 by using targeted exome sequencing. A retrospective review of clinical information was conducted for the cases with pathogenic variants in NPHS1.

Results: We identified 15 NPHS1 autosomal recessive pathogenic variants in 15 cases including 2 siblings. Regarding clinical manifestation, 6 cases showed CNS, 5 cases showed SRNS and 4 cases showed only asymptomatic mild to moderate proteinuria. The median age developing proteinuria in cases with CNS and SRNS and asymptomatic proteinuria was 6 years old. Pathological evaluation for 12 cases revealed that 11 cases showed minor glomerular abnormality and 1 case showed findings resemble membranous nephropathy. Genetic analysis revealed the variants c.2464G>C p.(V822M) and c.2515del were variably hotspot in the Japanese population and all 6 cases having V822M showed milder phenotypes such as SRNS (n=2) or asymptomatic proteinuria (n=4) and no one showed CNS.

Conclusions: In this study, NPHS1 variants were detected not only in cases with CNS and SRNS, but also in cases with asymptomatic proteinuria. Shono et al. have previously reported that V822M was a causative variant in cases with familial nephrotic syndrome who showed complete remission and functional analysis revealed that this variant leads to milder phenotype through mechanisms of (1) mild reduction of cell surface expression, (2)motion and trafficking restriction on surface and (3)interfering with assembly of microdomain on surface (Hum Mol Genet. 2009). Our study confirmed this variant leads to very mild phenotypes of SRNS or even the asymptomatic proteinuria and broadened the understanding of clinical manifestations of cases with NPHS1 variants.

PO1605
Ckd. Qld fabry Epidemiology (aQuickE) Study: Fabry Disease Prevalence Amongst Patients with CKD
Andrew J. Mallett,1 Phoebe J. Kearney,1 Andrew Cameron (Salisbury),1 Helen G. Healy,1 Charles P. Dunro,1 Mark A. Thomas,1 Vincent W. Lee,2 Maria Fuller,3 Wendy E. Hoy,1 1aQuickE Study Team 1Royal Brisbane and Women’s Hospital, Herston, QLD, Australia; 2The University of Queensland Faculty of Medicine, Herston, QLD, Australia; 3Royal Perth Hospital, Perth, WA, Australia; 1Westmead Hospital, Westmead, NSW, Australia; 2Genetics and Molecular Pathology Laboratory, SA Pathology, Adelaide, SA, Australia.

Background: Fabry disease (FD) is a rare, genetic disorder resulting in absence or deficiency of alpha-galactosidase A (α-Gal A), leading to accumulation of glycosphingolipids (GBLs) and GBL-related proteinuria. Fabry disease severity varies due to renal, cardiac and cerebrovascular manifestations. General population prevalence is ~0.0025%. Dialysis population prevalence is estimated at 0.12-0.36%. Little is known about the prevalence of FD amongst wider chronic kidney disease (CKD) populations. To this end, we report the prevalence of FD amongst those with CKD.

Methods: A prospective cross-sectional study of FD prevalence amongst CKD patients in public Queensland nephrology services was undertaken across 7 sites Oct 2018-Aug 2019. Patients with all stages of CKD including Stage 5D/5T were eligible to participate, irrespective of prior CKD aetiology or diagnosis. 3,000 CKD patients were screened using dried blood spot (DBS) testing. Repeat DBS and/or Lyso-GB3 testing was recommended for patients with positive DBS screening. All biochemical and genetic testing was undertaken in an accredited genetic laboratory.

Results: 6 unrelated cases (0.20%) of FD were identified. 3 were patients with a previously identified diagnosis of FD (100% sensitivity). 3 were patients with a new diagnosis of FD as a result of study participation. Of these 6 identified cases, 5 were male and 1 was female. The mean age at diagnosis was 48 years (range 18-72) and 0.3% of all male and 0.08% of all female participants respectively. All newly diagnosed cases were male with two being CKD Stage 5T, and one being CKD Stage 5D. One case was in a participant who identified as Indigenous, the first known case in this population. In total, an additional 28 at-risk family members were identified who may benefit from family screening. No readily identifiable pattern of symptoms was identified.

Conclusions: Our results support the potential feasibility and utility of a cascade testing strategy primarily using DBS, as a primary screening method for FD in adult populations. Further, our results confirm that a significant proportion of prevalent cases of FD amongst those with CKD remains undiagnosed.

Systems Analyses of Renal Fabry Transcriptome and Response to Enzyme Replacement Therapy (ERT) Identifies a Cross-Validated and Druggable ERT-Resistant Module
Oystein Eikeren,1,2 Nicolas Delaleu,1,4 Philipp Strauss,1 Miroslav Sekulic,3 Camilla Tendel,1 Sabine Leb,3 Einar Svarstad,2 Rannveig Skrunes,2 Albina Nowak,3 Elena-Emamuela Rusu,3 Tarig A. Osman,1 Hans-Peter Marti,1 Renal Research Group Bergen,1 University of Bergen, Bergen, Norway; 2Haukeland University Hospital, Bergen, Norway; 2SyCBioMed, Contra, Switzerland; 3Oncology Institute of Southern Switzerland, Bellinzona, Switzerland; 3UH Cleveland Medical Center, Cleveland, OH; 4University Hospital of Zurich, Zurich, Switzerland; 5Fondent Clinical Institute, Bucharest, Romania; 6Carol Davila University of Medicine and Pharmacy, Bucharest, Romania.

Background: Fabry nephropathy (FN) is caused by mutations in the α-galactosidase A gene and can be managed with ERT. Via understanding the molecular basis of FN and long-term ERT impact, we aim at a framework for selection of biomarkers/targets.

Methods: Obtained from normal controls and two independent FN-cohorts, mRNA-isolates from archival kidney biopsies (n=41) taken prior and up to 10 years of ERT were subjected to RNAseq and partly IHC. Combining pathway-centered analyses with network-science allowed computation of transcriptional landscapes from glomeruli, proximal/distal tubuli & arteries and integration with existing proteome and drug-target data.

Results: Despite inter-cohort heterogeneity, FN seemed well controlled, esp. via early introduced ERT. Pathways consistently altered in both FN-cohorts pre-ERT vs. controls were limited to glomeruli and arteries and commonly pertained to same biological themes. While glomerular keratinization-related processes were ERT sensitive, a majority of alterations, such as transporter activity and responses to stimuli, remained disregulated or remerged despite ERT. Inferring an ERT-resistant genetic module on this basis identified targets suitable for drug repurposing (Figure 1).

Conclusions: Transcriptional landscapes of kidney compartments reflected differences in FN-cohorts. ERT can revert FN molecular state to closely match controls. We identified and cross-validated ERT-resistant modules, when leveraged with external data, allowed estimating their suitability as biomarkers and targets for adjunct treatment.

Circular RNA-Based Biomarker Profile of Patients with Fabry Disease
Albina Nowak1, George Haddad,4 Andreas D. Kistler,3 Steller Nlanu khodo,4 Rudolf P. Wuthrich,3 Johan M. Lorenzen,3 Malte Kölling,2 University Hospital Zurich - Department of Endocrinology, Zurich, Switzerland; 2University Hospital Zurich - Department of Nephrology, Zurich, Switzerland; 3Cantonal Hospital Frauenfeld - Department of Medicine, Frauenfeld, Switzerland; 4University of Zurich - Institute of Physiology, Zurich, Switzerland.

Background: Fabry disease is a rare X-linked lysosomal storage disease, caused by mutations in the α-galactosidase A gene. Deficient activity of α-galactosidase A leads to glycolipid accumulation in multiple organs. Circular RNAs represent strong regulators of gene expression. Their circular structure ensures high stability in blood. We hypothesized, that blood-based circular RNA profiles improve phenotypic assignment and therapeutic monitoring of Fabry Disease.

Methods: A genome-wide circular RNA expression analysis was performed in blood of 58 genetically diagnosed patients with Fabry Disease and 14 age- and sex matched healthy controls. Most highly increased circular RNAs were validated by quantitative real-time PCR. A disease control cohort of 109 patients with acute kidney injury was included. Linear regression analyses were performed for validated circular RNAs and clinical patient characteristics.

Results: A distinct circular RNA transcriptome signature identified patients with Fabry Disease. Circular RNAs hsa_circ_0006853, hsa_circ_0083766 and hsa_circ_002397 distinguished patients with Fabry Disease from healthy controls and patients with acute kidney injury. Furthermore, a female-specific circular RNA expression pattern. Circular RNA level were significantly related to galactosidase α gene mutations, early symptoms, phenotypes, disease severities, specific therapies and long-term complications of Fabry Disease.

Conclusions: The discovery of circular RNA-based and Fabry Disease specific biomarker may advance future diagnosis and therapeutic monitoring to diminish long-term complications of Fabry Disease.

PO1608
Outcome of Primary Hyperoxaluria Type 3: Clinics, Diagnostics, and Follow-Up
Cristina Martin Higuera,1 Sander F. Garrels,2 Bodo B. Beck,3 Marcin Zaniw,4 Pzenyslaw Sikora,5 Bernd Hoppe,6 Dept. Ciencias Médicas Básicas, Fac. Medicina, Universidad de la Laguna, Tenerife, Spain; 2Amsterdam Medical Center, Amsterdam, Netherlands; 3Institute of Human Genetics, University Hospital Cologne, Cologne, Germany; 4University of Zielona Gora, Zielona Gora, Poland; 5Department of Pediatric Nephrology, Medical University of Lublin, Lublin, Poland; 6German Hyperoxaluria Center, Bonn, Germany.

Background: Primary hyperoxaluria type 3 (PH3) is said to be the most benign form of PH and the risk of chronic kidney disease (CKD) and even end stage renal disease (ESRD) is reported to be low. We collected clinical, diagnostic and follow up data from our PH3 patients to evaluate the true disease characteristics.

Methods: We retrospectively screened the Oxalate Registry for data of PH3 patients known to the German Hyperoxaluria Center and analyzed them for clinical and laboratory parameters.

Results: From the 90 PH3 patients enrolled in the OxalateRegistry, 45 had all laboratory analysis done at the Hyperoxaluria Center (3-45 years of age, 43 males). Genetically confirmed diagnosis revealed 21 different biallelic mutations in HOGA1. The main symptom was recurrent urolithiasis, most prominently found in the first 3 years of life (>25% of patients). Nephrocalcinosis was seen in 7 patients. Mean follow up for all patients was 7.76 (0.25-34) years, median age at first symptom was 0.06 (0.17-10) and median age at diagnosis (based on genetics) was 4.57 (0.25-16.86) years. Not all patients experienced clinical remission: 3/6 patients > 20 years of age have ongoing kidney stone development. A high amount of stone removal procedures during the first years of life, but also later in life was observed. Urinary oxalate (Uox) excretion was significantly and continuously elevated over time. There was no significant difference in Uox between PH1 (1.37 mmol/1.73m2/24h), PH2 (1.40 mmol/1.73m2/24h) and PH3 (1.13 mmol/1.73m2/24h) with the exception of a lower Uox in PH1 patients sensitive to B6 medication (0.84 mmol/1.73m2/24h) vs. PH3 patients (p=0.05). A decline in kidney function was seen in 3 patients with a significant change in eGFR over a period of 15 years (134 to 68.1 ml/min/1.73m2), which we would relate several lithotripsy procedures (n=16), but also ongoing hyperoxaluria.

Conclusions: Our analysis from a subgroup of European PH3 patients provides additional information on clinical outcome. PH3 patients seem to have the highest kidney stone burden during the first years of life, but they do not stop producing stones. Some PH3 patients progress to CKD and lose kidney function over time. Uox is comparable to non B6 responsive PH1 and also to PH2 patients.

PO1609
Patient Journey in Alport Syndrome
Mariah Loshire,1 Dhivat Joshi,2 Rebecca Gould,3 Emily Wu,4 Daniel Day,5 Ali Harrir,6 Sanofi Genzyme, Cambridge, MA; 1Fulcrum Research Group, Walhamp, MA.

Background: Patients with Alport Syndrome(AS) experience difficulties in diagnosis. Misdiagnosis remains frequent even after detailed clinical and pathological assessment. Qualitative interviews were conducted with patients diagnosed with AS and caregivers, to better understand the patient experience.

Methods: Thirty-nine Interviews (16 male and 23 females <18 years) from the United States, United Kingdom, France, Japan, and Germany were conducted with patients and caregivers. Respondents were recruited by each country's Alport advocacy groups. Responses were summarized and presented quantitatively and qualitatively.

Results: Thirty-nine participants (20 patients, 4 caregivers, 15 respondents being patients themselves and caregivers) completed the interview; and shared their experience as patients or that of the patients they care for (interviews reflect 32 firsthand patient experiences, and 7 patient experiences from caregivers; mean age=34). Thirty-four patients experienced their first symptoms as children (mean=9 years). Seventy-nine percent experienced hematuria before diagnosis. Despite early signs, diagnosis was delayed.
Males recorded hearing loss more than females (2/3 vs. 1/3 respectively) and at earlier ages (median age of males in 20-30s consulted a nephrologist earlier than females (median age: 12 vs. 28) and were diagnosed ~15 years earlier than females (median age=16, female=31). The median delay in diagnosis from first symptom onset was 15 years (males=11, females=26). Two-thirds of patients were diagnosed with genetic testing (n=143, 70%), with subsequent genetic testing performed by a panel of genes (16 genetic, 16 biopsies, 9 others). Patients on delayed diagnosis sometimes receive inconclusive or no biopsy results. Based on current standard of care, dialysis or transplant is seen as inevitable future outcome. The same population included patients with undiagnosed (n=5) eligible participants perceived transplant as an improvement of renal symptoms compared to dialysis.

Conclusions: Diagnosis can take years. Initial symptoms such as hematuria alone would not raise the suspicion for AS. Delays in diagnosis have significant psychosocial impact on patients and caregivers. While dialysis and transplant are considered inevitable future outcomes, transplant is seen as inevitable future outcome. The same population included patients with dialysis (n=7) and transplant (n=5) experience. Participants perceived transplant as an improvement of renal symptoms compared to dialysis.

Multidisciplinary Renal Genetics Clinics: Family Perspectives and Preferences

Fiona J. Wilkins,1,2 Catherine Quinnlan,1 Andrew J. Mullett,1 Zornitza Stark,1,2 1Victoriaean Clinical Genetics Services Ltd, Parkville, VIC, Australia; 2Murdoch Childrens Research Institute, Parkville, VIC, Australia; 1The Royal Children’s Hospital Melbourne, Parkville, VIC, Australia; 2Royal Brisbane and Women’s Hospital, Herston, QLD, Australia.

Background: Multidisciplinary genetics clinics (MGCs) comprising nephrologists, clinical geneticists, and genetic counsellors operate in 15 public hospitals across Australia with the goal of providing family-centred care and definitive molecular diagnoses to patients. However, little is known about family perspectives of multidisciplinary clinics or of undergoing genomic testing in this context.

Methods: Patients having genomic testing were surveyed following initial MGC attendance and after results disclosure. We explored patient experiences of the clinic, perceived impact of the disease on the family and reproductive planning, understanding of the test, and hopes and expectations relating to testing. Surveys included the Decision Readiness and Genetic Counselling Outcomes scales.

Results: Of 221 respondents to the baseline survey (RR=72%), most preferred the multidisciplinary clinic model to seeing specialists in separate clinics (n=145, 70%). A better understanding of the condition and implications for relatives were most commonly ranked as the most important as the two most important reasons for patients. Patients gave an average of 144.3% for having further information about the disease. Respondents agreed they received enough information during pre-test counselling (n=180, 92%) and had the opportunity to ask questions (n=181, 94%). The majority of respondents understood that the test analyses many genes (n=115, 59%), causative variant(s) may not be identified (n=143, 73%), and results may be of uncertain significance (n=142, 73%). Despite this, 44% of respondents thought the test was likely / highly likely to identify the cause of the condition (n=85).

Conclusions: Understanding patient and family experiences and opinions, and the short- and long-term impacts on families will guide the design and delivery of MGCs and associated genomic testing programs. A full author list is available online at www.kidgen.org.au.

PO1611

Autosomal Recessive Renal Tubular Dysgenesis Caused by a Founder Mutation of Angiotensinogen (AGT)

Min-hua Tseeng,1 Shih-Hua P. Lin,1,2 Chang Gung Memorial Hospital, Taoyuan, Taiwan; 3-Tri-Service General Hospital, Taipei, Taiwan.

Background: Autosomal recessive renal tubular dysgenesis (ARRTD) caused by inactivation mutations in AGT, REN, ACE, and AGTR is a very rare but fatal disorder with incomplete knowledge about pathogenesis and a lack of therapeutic options.

Methods: We report six Taiwanese with ARRTD from six unrelated families diagnosed by renal histology. Clinical features, prevalence of carrier heterozygosity, and potential rescue therapy were examined.

Results: All patients exhibited antenatal oligohydramnios, postnatal anuria, pulmonary hypoplasia, and profound hypotension refractory to interventions. AGT (Angiotensinogen) protein levels were diminished in the liver along with reduced serum AGT, angiotensin I (Ang I) and II (Ang II) levels. Neonatal demise occurred in all but one. All carried the same homozygous E3, E4 del:287bp deletion/9bp insertion in AGT. The allelic frequency of this heterozygous AGT mutation was approximately 1.2% (6/500), suggesting that ARRTD may not be exceedingly rare in Taiwan. This mutation results in skipping of exons encoding the serpin domain of AGT, which is important for renin interaction and the generation of truncated protein (1-295 amino acids). In silico modeling revealed a diminished interaction between mutant AGT and renin, and proximity ligation assay demonstrated a significant decrease in the amount of this truncated protein.

Conclusions: This AGT mutation leads to the diminished interaction with renin and decreased Ang I and II generation. Hydrocortisone may potentially rescue the cases of ARRTD caused by this truncated AGT.

PO1612

KIDNEYCODE: A Genetic Testing Program for Patients with CKD

Prasad Devarajan,1 Gerald B. Appel,1 Geoffrey A. Block,1 Kenneth V. Lieberman,1 Stephen McCalley,1 Jim McKay,1 Colin J. Meyer,1 Bradley A. Warady,1 Alex R. Chang,1 Kristina A. Robinson,1 1Cincinnati Children's Hospital Medical Center, Cincinnati, OH; 2Columbia University Irving Medical Center, New York, NY; 3US Renal Care Inc., Plano, TX; 4University of Missouri Kansas City, Kansas City, MO; 5Hackensack University Medical Center, Hackensack, NJ; 6Reata Pharmaceuticals Inc, Irving, TX; 7Kidney Health Research Institute, Geisinger Medical Center, Danville, PA; 8Invitae Corporation, San Francisco, CA.

Background: The International Society of Nephrology recommends the adoption of genetic testing with a goal of providing precision medicine based on individual risk. A recent whole-exome sequencing study showed that genetic inheritance may be responsible for up to 10% of CKD diagnoses. We designed a gene panel to prospectively provide genetic testing in a subset of patients with CKD.

Methods: Reata Pharmaceuticals is partnering with Invitae on KIDNEYCODE, a US program that provides no-charge genetic testing using next generation sequencing (NGS) to enable diagnosis of a subset of rare monogenic causes of CKD: Alport syndrome (AS), autosomal dominant polycystic kidney disease (ADPKD) due to PKD2 variants, focal segmental glomerulosclerosis (FGS), and autosomal recessive PKD due to PKHD1 variants. Invitae's renal disease panel includes 17 genes (ACTN4, ANLN, CD2AP, COLA43, COLA44, COLA45, CRB2, JNF1A, IN2, LMX1B, MYO1E, NPHS1, NPHS2, NX2, PKD2, PKHD1, and TRPC6). Patients at risk for hereditary CKD (eGFR < 90 mL/min/1.73m2 plus hematuria or a family history of CKD) or known or suspected AS or FSGS are eligible. Family members of those with known or suspected AS or FSGS are also eligible.

Results: Of 455 test results, a genetic variant was reported in 278 patients. Of those, 206 patients had 219 variants in COLA43, 4, or 5 genes [112 Pathogenic/ Likely Pathogenic (P/LP), 107 Variants of Uncertain Significance (VUS)], 87 patients had 95 variants (32 associated with Fabry disease has become more important with the introduction of novel therapy (migalastat, which may not be compatible with numerous pathogenic mutations). The sensitivity of this genetic screen for the diagnosis of Fabry disease has become more important with the introduction of novel therapy (migalastat, which may not be compatible with numerous pathogenic mutations). The sensitivity of this genetic screen for the diagnosis of Fabry disease has become more important with the introduction of novel therapy (migalastat, which may not be compatible with numerous pathogenic mutations). The sensitivity of this genetic screen for the diagnosis of Fabry disease has become more important with the introduction of novel therapy (migalastat, which may not be compatible with numerous pathogenic mutations). The sensitivity of this genetic screen for the diagnosis of Fabry disease has become more important with the introduction of novel therapy (migalastat, which may not be compatible with numerous pathogenic mutations). The sensitivity of this genetic screen for the diagnosis of Fabry disease has become more important with the introduction of novel therapy (migalastat, which may not be compatible with numerous pathogenic mutations).

Conclusions: Initial results with the KIDNEYCODE panel demonstrate the utility of NGS. Combining genetic testing with clinical presentation and medical history can improve the accuracy of diagnosis of hereditary CKD.

PO1613

Very Rare Mutation Identified in Female Patient with Multisystemic Fabry Disease in the United States

Sam Kant,1 Steven Menez,1 Mohammad A. Hanouneh,1 Mohamed G. Atta,2 Johns Hopkins University School of Medicine, Baltimore, MD.

Introduction: Fabry disease is an X-linked lysosomal storage disorder characterized primarily by kidney, cardiac and central nervous system dysfunction. Over a 1000 mutations have been identified to be associated with disease. We describe a patient with biopsy confirmed Fabry disease identified to have very rare mutation not listed in genetic databases.

Case Description: A 48 year old female with past medical history of chronic kidney disease G4A3 (previously biopsy proven Fabry disease), dilated cardiomyopathy, atrial fibrillation, previously treated breast cancer, was referred to our clinic by a nephrology group given progressive worsening of kidney function and consideration for migalastat. Patient was diagnosed with Fabry disease at the age of 32 (normal renal function at the time), and subsequently received agalsidase beta for a period of 3 years thereafter. However, therapy was ceased due to insurance issues. In the interim, patient has progressive decline in renal function (creatinine 2.5 mg/dL on referral), worsening proteinuria, along with development of dilated cardiomyopathy and neurology. We proceeded with genetic testing to identify mutation of galactosidase A (GLA gene) and kidney biopsy (image 1). Genetic testing revealed a novel mutation variant c.328G>C (p.Gly274Arg) deemed to be heterogeneous and of unknown significance by the laboratory. Kidney biopsy revealed classic finding of glomerular inclusions (podocyte and mesangium) with diffuse renal parenchymal scarring. Patient was eventually prescribed agalsidase beta, given non amenability to migalastat.

Discussion: This case highlights identification of a very rare mutation of the GLA gene that appears to have late onset manifestations. Pursuing genetic testing in patients with Fabry disease has become more important with the introduction of novel therapy migalastat, which may not be compatible with numerous pathogenic mutations.
PO1614

A Unique Case of COL4A3/4 and ACTN4 Mutations Combined

Estibaliz L. Perez Leal,2 Joshua T. Kuehne,3 Pablo E. Pergola,1 1Renal Associates PA, San Antonio, TX; 2Universidad Autonoma de Guadalajara, San Antonio, TX, 3University of the Incarnate Word School of Osteopathic Medicine, San Antonio, TX.

Introduction: Alport syndrome is due to mutations of the COL4A gene. Males with COL4A mutations present with proteinuria and CKD, hearing impairment and anterior lenticonus. Disease in women ranges from mild hematuria and proteinuria to a syndrome similar to that of X-linked males. Patients in families with mutations of the Alpha-actinin-4 gene (ACTN4; autosomal dominant inheritance) present histologically and clinically with focal segmental glomerulosclerosis. We present the first ever-reported case of a patient with both COLA4 and ACTN4 mutations.

Case Description: Family pedigree is shown in the figure. Subject II: 1 is a female with Alport’s syndrome diagnosed by kidney biopsy, CKD3 (in her 50’s) had genetic testing showing a COLA4 mutation. Her husband (II:2, in his 50’s), had ESRD presumed to be secondary to diabetes (DKD). Given concerns for possible disease in their 2 sons, genetic testing was performed. The oldest son (III:1; in his 30’s) showed the same COLA4A3 mutation as II:1 but an additional ACTN4 mutation. He has microalbuminuria (90mg/g) and GFR >90 ml/min. The younger son (III:2; in his 20’s) showed the ACTN4 mutation but no COLA4 mutation (clinical tests are pending). Given the ACTN4 mutations in the sons, subject II: 2 was tested, showing an ACTN4 mutation (suggesting DKD was not the single etiology of his ESRD). Family history showed both paternal grandparents had ESRD, unknown etiology for I:4 (died in her 50’s) and presumed to be due to DKD for I:3 (died in his 80’s).

Discussion: ACTN4 and COLA4 mutations have not been reported in a single patient before. The identification of 2 mutations known to be associated with CKD will allow for early intervention with management of comorbid conditions like hypertension, obesity and diabetes and use of RAAS inhibitors. Distinct disease patterns may emerge associated with specific genetic abnormalities allowing a more personalized treatment. Genetic testing should be considered for all patients presenting with proteinuria as findings may dictate changes in management.

PO1615

Kidney Tubuloids Model Cystinosis and Allow Drug Screening

Fiodor Yousef Yengej,1,2 Amer A. Jamalpoor,3 Maarten B. Rookmaker,1 Carola Ammerlaan,1,2 Esther A. Zaal,1 Celia Berkers,1,4 Rosalinde Masereeuw,1 Manoe J. Janssen,1 Hans Clevers,1 Marianne C. Verhaar.1

1Department of Nephrology and Hypertension, University Medical Center Utrecht, Utrecht, Netherlands; 2Hubrecht Institute – Royal Netherlands Academy of Arts and Sciences and University Medical Center Utrecht, Utrecht, Netherlands; 3Division of Pharmacology, Utrecht Institute for Pharmaceutical Sciences, Utrecht University, Utrecht, Netherlands; 4Division of Cell Biology, Metabolism and Cancer, Department of Biomolecular Health Sciences, Faculty of Veterinary Medicine, Utrecht University, Utrecht, Netherlands.

Background: Cystinosis causes progressive damage to the kidney and other organs. In cystinosis, a CTNS mutation causes lysosomal cystine accumulation and other metabolic abnormalities including alpha-ketoglutarate (aKG) accumulation in patient cells and serum. Excess KG associates with aggravated apoptosis, abnormal autophagy and proximal tubule dysfunction, suggesting a key role in cystinosis pathology (Jamalpoor et al. BioRXiv: 2020). Current treatment with cysteamine reduces cystine and delays, but does not stop, progression of renal insufficiency nor restores tubular dysfunction. Therefore, new therapies are needed. Here, we use patient kidney tubuloids to model cystinosis and to test the efficacy of a novel drug combination.

Methods: Tubuloids were grown from primary renal cells from the urine of two cystinosis patients and compared with two healthy controls. Tubuloid origin and composition were assessed by qPCR and stainings. The effect of cysteamine and/ or bicalutamide treatment was studied by a large-scale metabolic screen using LC-MS. Potential toxicity of bicalutamide was tested by measuring ATP levels as proxy for tubuloid viability at increasing doses.

Results: Urine-derived tubuloids consisted of kidneys cells (PA8*pd63) and not urothelium (PA8*pd63). Tubuloids contained proximal tubule, loop of Henle, distal tubule and collecting duct epithelium. Patient tubuloids showed hallmark cystine accumulation (1.25 ± 0.12 vs. 0.16 ± 0.01 mmol/mg protein in controls, p<0.05). Although cysteamine normalized cystine levels, it failed to restore aKG accumulation. The novel combination of cysteamine with bicalutamide more potently lowered cystine and reduced aKG in tubuloids (aKG peak area reduction of 16-28% with bicalutamide and 21-37% with the combination, both p<0.05). Finally, the used bicalutamide dose did not compromise the viability of cystinotic tubuloids.

Conclusions: Tubuloids model cystinosis in vitro and allow personalized drug screening. Moreover, tubuloids show that the combination of cysteamine and bicalutamide is more effective in normalizing the metabolic abnormalities in cystinosis than cysteamine alone.

PO1616

Case Report: Familial FSGS Associated with a Novel Variant of WT1

Alexandra Stewart, John S. Thurlow. Walter Reed National Military Medical Center, Bethesda, MD.

Introduction: The underlying causes of Familial FSGS are currently being elucidated by exome sequencing. WT1 has been reported in association with Frasier Syndrome, Denys-Drash syndrome and isolated nephrotic syndrome. WT1 variants have emerged as a common cause of autosomal dominant FSGS.

Case Description: We report a case of a 22 year old male who presented at age 17 with nephrotic range proteinuria progressing to ESRD over 4.5 years. His renal biopsy at that time revealed FSGS and exome sequencing (Next Generation Sequencing) demonstrated a WT1 variant of uncertain significance. Family history was significant for the following: mother with microalbuminuria (229mg/24hr on spot protein) and hypertension (onset 2 years prior to proteinuria); paternal uncle with congenital unilateral renal agenesis and later End Stage Kidney Disease requiring transplant at age 29 years; and maternal grandfather who died in his 60s on dialysis for unknown reasons. Genetic analysis in the patient and mother revealed the same heterozygous variant in WT1 (c.1078G>T; p.Gly360Cys).

Discussion: WT1-related renal disease is associated with autosomal dominant inheritance. We strongly suspect the WT1 variant described was pathogenic, as evidenced by a family history of both FSGS and genitourinary tract malformations. We review the association of WT1 with nephropathy and postulate a potential interaction with XY karyotype, similar to other WT-1 associated disease. Disclosure: The views expressed are those of the authors and do not reflect the Department of Army or U.S. Government.
PO1617
Positive Identification of Genetic Causes of FSGS Increases with Proper Patient Selection
Jing Miao,1,2 Ladan Zand,1 Filippo Vairo,1 Marie C. Hogan,3 Stephen B. Erickson,3 Carri Prochnow,4 Mireille El Ters,5 Andrew J. Bentall,5 Aleksandra Kukla,6 Eddie L. Greene,1 Loren P. Herrera Hernandez,1 Sanjeev Sethi,1 Fernando C. Fervenza,1 Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN; 2Department of Clinical Genomics and Center for Individualized Medicine, Mayo Clinic, Rochester, MN; 3Department of Internal Medicine, Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; 4Center for Individualized Medicine, Mayo Clinic, Rochester, MN.

Background: FSGS is a histological lesion with diverse pathogenesis, commonly divided into primary, secondary (maladaptive, virus or drugs), and genetic forms. Differentiation of these forms is challenging but important for management and prognosis. We aimed to identify clinicopathologic factors that could be predictive of finding a genetic diagnosis in individuals with unknown forms of FSGS.

Methods: Cohort study included 51 FSGS patients with either a secondary “form” of FSGS without an identifiable cause or with presumed “primary” FSGS who failed to respond to immunosuppressive therapy (IS). Seven patients with primary FSGS in remission following IS served as negative control. Patients were classified as having pathogenic/likely pathogenic variants (Group 1a), relevant variants of uncertain significance (reducing VUS; Group 1b), and no relevant variants (Group 2). Clinicopathologic characteristics are presented in Table 1.

Results: A pathogenic/likely pathogenic genetic variant or relevant VUS was found in 41.2% (n=21/51) and in 11.8% (n=6/51) of the patients, respectively. 55.6% were in CGA (INF2/NPHS2/TRPC6/NPHS1), and 11.1% in other genes (DLC1/SMARCAL1/UMOD). Family history of kidney disease was present in 75% (n=15/20) of the patients in Group 1a, 16.7% (n=1/6) in Group 1b, and 20.8% (n=5/24) in Group 2 and 0% (n=0/7) in the negative control. There was a negative correlation between proteinuria and the probability of finding a genetic variant. Severe foot process effacement on EM and nephotic syndrome were significantly more common in the negative control group compared to Group 1a.

Conclusions: Over 50% of adult patients with FSGS who could not be categorized into primary or known secondary forms were found to have a genetic diagnosis. Positive family history and absence of nephrotic syndrome increased the likelihood of identifying a pathogenic/likely pathogenic variant. Genetic testing is therefore highly recommended in such population.

PO1618
A Rare Case of Nephrotic Syndrome Associated with Dent Disease

Introduction: Dent’s disease is a rare X-linked condition caused by a mutation in the CLCN5 or OCLR gene, which impair the megalin-cubulin receptor-mediated endocytosis in kidney’s proximal tubules. Thus, it may manifest as nephrotic-range proteinuria, hypoalbuminemia and edema formation are the key features of nephrotic syndrome (NS) and is often associated with progressive tubulointerstitial kidney disease. The presence of renal calcifications and no proliferation of mesangial cells. Electron microscopy showed renal medulla with calcium deposition in the renal medulla. Our case supports and reinforces the possibility of a single organ-limited mitochondrial disease develop CKD. Importantly, examples of mitochondrially inherited tubulointerstitial kidney disease in subjects with no other systemic organ involvement have been recently reported, suggesting the possibility of a single-organ mitochondrial disease.

Case Description: A 12-year-old boy presented with short stature, low body weight, increased serum creatinine (1.9 mg/dL) and increased blood urea nitrogen (30 mg/dL). Blood analysis showed anemia, vitamin D deficiency, hyperparathyroidism and negative antinuclear antibodies (ANA) and antineutrophil cytoplasmic antibodies (ANCA). Urine analysis showed small kidneys (< 5th percentile). A kidney biopsy showed mild, non-specific chronic tubulointerstitial nephropathy on light microscopy. Immunofluorescence was negative. Electron microscopy showed markedly enlarged and dysmorphic mitochondria. Given this striking histopathologic finding, genetic testing was performed. Next generation sequencing of mitochondrial DNA from the tissue biopsy showed the presence of a homoplasmic single, missense mutation in position 616 (m.616T>C) of the mitochondrially encoded transfer RNA phenylalanine (tRNAphe) gene. Analysis of blood derived mtDNA from mother and maternal uncle, who were on dialysis since their 30s, confirmed the same homoplasmic mitochondrial mutation, supporting our hypothesis. The renal biopsy findings, genetic findings, and pattern of inheritance were strongly suggestive of a diagnosis of mitochondrially inherited tubulointerstitial kidney disease. Importantly, no additional symptomatic organ involvement was present in these subjects.

Discussion: Our case supports and reinforces the possibility of a single organ-limited mitochondrial disease, regardless of the systemic mitochondrial DNA mutation status, potentially radically changing management and prognosis of these patients. Careful analysis of mitochondria by electron microscopy should be performed in patients with tubulointerstitial nephropathy and family history of kidney failure.
PO1620
Discovery of CHK-336: A First-in-Class, Liver-Targeted, Small Molecule Inhibitor of Lactate Dehydrogenase for the Treatment of Primary Hyperoxaluria
Jennifer H. Cox,1 Marc-Olivier Boily,1 Alex Caron,1 Amandine Chesfon,1 Oliver Chong,1 Jim Ding,1 Valerie Damiaus,1 Samuel Mcintosh,1 Robert Gomez,1 James Guthrie,1 Ross P. Holmes,1 Andrew J. King,1 John Knight,1 Jeff Lester,1 W. T. Lowther,1 Renata Oballia,1 Michael D. Percival,1 Tao Sheng,1 Jayakumar Surendradoss,1 Joyce Wu,1 David A. Powell.1 Chinox Therapeutics Inc., Vancouver, BC, Canada; 2University of Alberta at Birmingham, Birmingham, AL; 3Wake Forest University, Winston-Salem, NC.

Background: Primary hyperoxalurias (PH) 1-3 are autosomal recessive disorders involving excess hepatic oxalate production resulting in frequent kidney stones, progressive CKD and ESRD. Few therapeutic options currently exist for these patients. Lactate dehydrogenase (LDH) catalyzes the final and only committed step in hepatic oxalate synthesis and represents a potential therapeutic target for all forms of PH. Herein we describe the profile of a potent and selective LDH inhibitor.

Methods: CHK-336 was evaluated in LDH activity assays and in an AGXT knockout mouse model. Additional characterization of drug properties was performed.

Results: CHK-336 demonstrates potent and selective inhibition of LDH in enzyme assays (IC50 = 0.4 nM) and hepatocyte assays (IC50 = 80-142 nM). To minimize the potential for extra-hepatic LDH inhibition, a liver-targeted tissue distribution profile was engineered into the molecule. CHK-336 demonstrates exceptional liver-targeting across species mediated by OATP-uptake into hepatocytes and tight binding to LDH resulting in a long liver half-life that supports once-daily oral dosing. In a PH1 mouse model, CHK-336 produced significant and dose-dependent reductions in urinary oxalate to levels observed in wild-type mice. Wide safety margins were established in rodent toxicity studies to support continued development of CHK-336.

Conclusions: By potently blocking LDH, the terminal step in hepatic oxalate synthesis, along with engineering of liver-targeted tissue distribution, CHK-336 is a promising oral small molecule development candidate with the potential to treat patients with hyperoxaluria.

PO1621
Disease Manifestations, Treatment, and Healthcare Resource Use (HRU) in Primary Hyperoxaluria Type 1 (PH1): An International Online Chart Review Study
Xingolane Wang,1 David S. Danese,1 Thomas A. Brown,1 Jessica Baldwin,1 Gautham Sajeev,1 Erin Cook,1 Yao Wang,1 Chunyi Xu,1 Hongbo Yang,1 Michael L. Morrill,1 Aylima Pharmaceuticals Inc, Cambridge, MA; 2Analysis Group Inc, Los Angeles, CA; 3University of Pittsburgh Medical Center, Pittsburgh, PA; 4Cleveland Clinic Department of Nephrology and Hypertension, Cleveland, OH.

Background: Few multinational studies have examined the clinical burden of PH1.

This online retrospective chart review evaluated disease manifestations, treatments, and HRU in a large international sample of PH1 patients.

Methods: Nephrologists in the US, Canada, UK, France, Germany, and Italy provided data from PH1 patients in their care via an online platform. Eligible patients had PH1 confirmed by genetic testing or liver biopsy and ≥2 office visits from 2016-2019. Data on disease manifestations, treatment and HRU were collected.

Results: Overall, 86 patients (56% from North America; 63% female) from 41 unique providers were analyzed. Mean age at diagnosis was 21.2±11.6 yrs, with a mean of 6.7±9 yrs to diagnosis from first symptoms. Mean age at index (first office visit in past 3 yrs) was 25.3 yrs; 71% had stage ≥3 CKD at index (median eGFR: 44mL/min/1.73m²). Mean follow-up was 1.6±1 yrs. The most common PH1 manifestations during follow-up were uro-/nephrolithiasis (57.1%) and urinary tract infection (UTI; 56.0%). Additionally, 29.8% of patients had ≥1 acute renal decline episode, of which 53% resulted in lasting renal function loss. In total, 11.6% of patients had ESKD at or before index, and 8.1% developed ESKD post-index; 2.3% had ESKD with timing not noted. Dialysis and transplant (liver and/or kidney) at any time were reported in 22.2% and 10.3% of patients, respectively. In terms of HRU during follow-up an acute stone removal procedure (lithotripsy: 38%; ureteroscopy: 28%; percutaneous nephrolithotomy: 9%). Hospitalization and ER visits were required by 85.9% and 84.6% of patients, respectively, where data was reported (n=73).

Conclusions: There is significant delay between PH1 presentation and diagnosis. Patients with PH1 suffer progressive renal function decline, with many progressing to ESKD. During follow-up, almost all patients required ER visits and hospitalization, and most had stone episodes and UTIs and required stone removal procedures. These findings highlight our current and future patients’ experience of acute events that contribute to ongoing morbidity, HRU and impaired quality of life, underscoring the need for early intervention with effective PH1 treatment.

Recurrent SLC12A3 Mutations in Taiwanese Families with Gitelman Syndrome: A Rapid Detection for the Higher Prevalence
Shih-Hua P. Lin,1 Sung-Sen Yang,1 Chih-Chien Sung,2 Min-hua Tseng,2 1Division of Nephrology, Tri-Service General Hospital, Taipei, Taiwan; 2Division of Pediatrics, Taoyang, Taiwan.

Background: Recurrent mutations in SLC12A3 gene responsible for autosomal recessive Gitelman syndrome (GS) are reported to be common with uncertain prevalence. Recurrent detection of the recurrent hotspots may help early diagnosis of GS but remain challenging. We aim to investigate the prevalence of recurrent SLC12A3 mutations in a large Taiwan cohort of GS families and develop a simple, novel, and rapid method to detect recurrent SLC12A3 hotspots.

Methods: One hundred and thirty independent families with genetically-confirmed GS referred from different regions of Taiwan were consecutively enrolled to define recurrent SLC12A3 hotspots and determine their prevalence. Using Taqman MGB probe-based real time primer chain reaction (RT-PCR), hotspots-based mutation detection plate was designed and optimized to recognize all hotspots. We validated this mutation detection plate and also tested the feasibility in 12 newly-diagnosed GS patients.

Results: A total of 57 mutations in SLC12A3 gene were identified from our cohort and 22 different mutations including two deep intronic mutations were found in at least two unrelated family families, comprising 87.5% of all allelic mutations including biallelic triple mutations. These 22 hotspots-based detection plate was fully validated with excellent sensitivity and specificity in GS patients carrying biallelic SLC12A3 mutations and healthy subjects. In the clinical validation, recurrent mutations were recognized in 87.5% of all mutations of 12 newly-diagnosed GS patients within 4 hours and all confirmed by direct sequencing.

Conclusions: Recurrent SLC12A3 mutations are very common in Taiwanese GS patients. This novel hotspots-based detection plate may be time, cost, and labor saving to rapidly identify the recurrent hotspots and provide an early molecular diagnosis of GS in patients with chronic hypokalemia.

AVR-RD-01, an Investigational Lentiviral Gene Therapy for Fabry Disease, Reduces Gb3 Substrate in Endothelial Cells of Renal Peritubular Capillaries
Mark A. Thomas,1 Mirjam Trame,1 Chris Mason,1 Birgitte Volck,2 1Royal Perth Hospital, Perth, WA, Australia; 2AVROBIO, Cambridge, MA.

Background: Lysosomal disorders are attractive candidates for ex vivo gene therapy based on the potential to transform a patient’s own cells into a drug product to deliver sustained functional protein/enzyme after a single treatment. Fabry disease (FD) is caused by mutations in the GLA gene that result in functional deficiency of the lysosomal enzyme, alpha-galactosidase A (AGA), which leads to pathological accumulation of substrates and metabolites, including globotriaosylceramide (Gb3) and globotriaosylsphingosine (lysogb3-Gb3). Significant morbidity and early mortality result from damage to kidneys, heart, and brain. Herein we report: AVR-RD-01 is an investigational ex vivo gene therapy that involves transplantation of autologous stem cells genetically modified with a lentiviral vector which inserts into the human genome a complementary deoxyribonucleic acid (cDNA) sequence that encodes for functional human AGA.

Methods: In a Phase 1 trial of AVR-RD-01, 5 patients, previously on enzyme replacement therapy (ERT), after gene therapy demonstrated increases in plasma and leukocyte AGA activity and decreases in substrate (Gb3) and metabolite (lysogb3-Gb3) in plasma, now sustained up to 32 months. A Phase 2 clinical trial in 8-12 treatment-naive males (16-50 years) with classic FD investigates the safety, tolerability, and efficacy of AVR-RD-01, including its effect on substrate accumulation in the kidney after 48 weeks. Kidney biopsy results for the first patient in the Phase 2 clinical trial demonstrated reduction in renal peritubular capillary (PTC) Gb3 inclusions, quantitatively assessed by the BLISS methodology. At 24 weeks, Gb3 inclusions were reduced from an average of 3.55 to 0.47 per PTC corresponding to an 87% reduction versus baseline (BL). Leukocyte and plasma Gb3 activity increased, associated with declines in plasma and urine Gb3 and lysogb3-Gb3, including an 87% reduction in plasma lysogb3-Gb3 at 48 weeks versus BL. Adverse events were as expected with the particular conditioning regimen and subsequent gene therapy.

Underline represents presenting author.
Results: As of May 2020, 16 participants were enrolled (13 PH1, 3 PH2) in this study. Total exposure (based on 15 participants) to monthly dosing of nedosiran has exceeded 3 years based on the cumulative duration of patient participation in the trial. Seven participants have had exposure to at least 3 monthly doses of nedosiran. Treatment-emergent adverse events (AEs) were observed in 11 participants. Seven participants experienced 33 AEs considered related to study drug: administration of drug, blood chemistry findings (6), pain (2), dysuria (1), nasal congestion (1), edema (1), and erectile dysfunction (1). Three AEs were uncoded at this time. None of the participants experienced injection-site reactions (defined as occurring 4 hr or more after injection). All drug-related AEs were mild. There were no drug-related serious AEs. Six out of the 7 participants who have had exposure to at least 3 monthly doses of nedosiran showed normalization or near-normalization of urinary oxalate excretion (defined as ≤ 0.46 mmol/24 hr/1.73 m² and ≤ 0.46-0.60 mmol/24 hr/1.73 m², respectively) on at least 2 visits at the specified dose.

Conclusions: Nedosiran has shown an acceptable safety profile in the interim analysis. This and the sustained reduction of urinary oxalate excretion are encouraging signs of potential long-term safety and clinical benefit of a multidose regimen of nedosiran.

A Case of De Novo X-Linked Alport Syndrome Treated by Kidney Transplantation from the Patient’s Healthy Mother
Atsuya Hane,1 Mika Fujimoto,2 Ryosuke Saike,2 Keiko Oda,1 Yosuke Hirabayashi,3 Ayumi Haruki,4 Tomohiro Murata,1 Kan Katayama,1 Mie Daigaku Daigakusen Igakukan Kenkyukai Igaku Tsu, Japan.

Introduction: X-linked Alport syndrome is a hereditary nephritis that leads to end-stage kidney failure by 40 years of age in most affected males. Although kidney transplantation is well tolerated in X-linked Alport syndrome, donors should be carefully selected since the proband’s mother is usually the gene carrier.

Case Description: The patient was a 38-year-old man. Microhematuria had been present since during his early childhood and had been diagnosed with Alport syndrome based on the results of a kidney biopsy at 5 years of age. He developed bilateral sensory deafness at 20 years of age and started hemodialysis due to end-stage kidney failure at 28 years of age. Although an X-linked mode of inheritance was suspected, none of the patient’s relatives, including his mother, had kidney disease. Since his mother had no renal urinalysis results, living kidney transplantation from his mother was performed when he was 34 years of age. A genetic diagnosis at a later date revealed a splicing variant at c.3107-2A>G in COL4A5 of the patient. However, there was no apparent genetic mutation in COL4A5 of his mother, indicating that the patient had a de novo mutation.

The kidney function of both the patient and his mother was stable at 4 years after transplantation.

Discussion: For transplantation in cases of hereditary nephritis, it is preferable to avoid transplantation from an affected individual or the gene carrier. The kidney prognosis of female X-linked gene carriers is reported to be worse than expected. Although there was no genetic mutation in the donor in the present family case, if an X-linked form is suspected, a genetic diagnosis of the donor candidate should be performed before kidney transplantation is considered.

Clinical and Economic Impact of Primary Hyperoxaluria: A Retrospective Claims Analysis
Bernard Hoppe,1 Abigail Silber,2 Gavyn Miyasato,3 Tom Koenig,2 Jeffrey L. Sklar,4 Craig B. Langman,5 Trinity Life Sciences, Waltham, MA; 2Dicerna Pharmaceuticals Inc, Cambridge, MA; 3Ann and Robert H Lurie Children’s Hospital of Chicago, Chicago, IL.

Background: Primary hyperoxaluria (PH; types 1, 2, and 3) are rare genetic disorders resulting in the overproduction of oxalate in the liver and that manifest in renal complications. This study sought to quantify the healthcare resource utilization (HCRU), costs, and clinical characteristics of PH patients.

Methods: This retrospective study analyzed claims data from IQVIA PharMetrics® Plus (1/2014-12/2019). PH cohort inclusion was an ICD-10 code for PH (E72.53) and any evidence of secondary hyperoxaluria (SH). A random sample of patients without PH or SH served as a control cohort (non-PH). Clinical outcomes, including kidney transplantation, were compared between the cohorts for a 12-month period. The Charlson Comorbidity Index (CCI) was used to characterize comorbidities.

Results: The annualized median and mean costs per patient for the PH cohort (n=525; median $1,079; mean $5,041) were significantly higher (p<0.001) than the non-PH cohort (n=2,579,352; median $1,079; mean $5,041). Costs were significantly higher for PH patients across age groups (table 1) and care settings, including inpatient/outpatient settings (p<0.001). The majority of PH patient cost (62%) was associated with outpatient visits. The PH cohort saw significantly higher use of specialists compared to non-PH patients (p<0.001), including nephrologists (19% vs 1%) and urologists (66% vs 3%). Over one year, 80% of the PH cohort had at least one kidney stone. The CCI scores for the PH and non-PH cohorts were 0.79 and 0.22, respectively.

Conclusions: The median cost for the PH cohort was 10 times higher than the non-PH cohort over all age groups annually, and the PH cohort showed substantially greater HCRU compared to the non-PH cohort. Additional research is required to better understand these costs in an effort to enable more efficient healthcare utilization and improve care delivery to these at-risk patients.

Identification of Genetic Drivers of Age-Related Renal Histopathology
Susan M. Sheehan, Ron Korstanje. The Jackson Laboratory, Bar Harbor, ME.

Background: Studies to understand age-related changes in the human kidney have been performed by measuring kidney function and damage markers in the urine. These studies have provided valuable information, including clear genetic components underlying kidney disease. However, due to the highly invasive nature of kidney biopsies, it is not possible to identify early causal changes in humans by histological analyses that are hypothesized to precede changes in function and renal damage. However, mouse models provide access to kidneys at specific time points enabling us to conduct histological analyses across lifespan. We established the Aged Mouse Kidney Resource, which consists of kidneys from 600 genetically diverse mice (males and females) at three ages (6, 12, and 18 months). Scanned PAS slides for all mice are publicly available at korstanjelab.jax.org, as well as gene expression, protein expression, and DNA methylation data for a subset of kidneys.

Methods: Renal histology has been mostly a qualitative or semi-quantitative discipline. We leveraged new approaches in image analysis and machine learning to develop a high-throughput pipeline that uses machine learning on scanned slides, which allows us to automatically segment glomeruli and quantitatively measure matrix expansion (MMX) in a high-throughput fashion.

Results: Applying our pipeline on the 12-month kidneys from our Resource shows an estimated heritability (h²) of 0.76 for MME and genetic analysis identifies three significant loci with $\Delta w\tilde{al}a13$ and $C\tilde{E}2$ as strong candidate genes for two of these loci. On the other hand, we find that the heritability drops to 0.61 and no significant loci were found in the 18-month old kidneys. We hypothesize that this is caused by the increasing effect of environmental variation with age and death before 18 months of age.

Conclusions: Our results demonstrate the importance of genetic factors contributing to histological phenotypes and the power of combining pathomics and genetics to identify genes involved in age-related histological changes.

Epigenome-wide Association Study of Kidney Function
Nora Franceschini,1 Charles E. Breeze,2 Josef Mychaleckyj.2 COGENT-KIDNEY Consortium, University of North Carolina System, Chapel Hill, NC, 2University of Virginia, Charlottesville, VA 3UCL Cancer Institute, University College London, London, United Kingdom.

Background: DNA methylation regulates gene regulation and may influence estimated glomerular filtration rate (eGFR).

Methods: The study included over 13,000 participants from multi-ethnic studies for discovery and replication. We tested the associations between whole blood DNA methylation and eGFR using normalized beta values from Illumina 450K or EPIC arrays. Analyses were performed in study- and race-stratified samples using linear mixed models for discovery and replication. We tested the associations between whole blood DNA methylation and eGFR using normalized beta values from Illumina 450K or EPIC arrays. Analyses were performed in study- and race-stratified samples using linear mixed models for discovery and replication.

Results: The study identified 93 DMPs genome-wide significantly associated with eGFR, of which 35 replicated in independent samples. We also replicated 6 previously published DMPs including the ZNF20-ZNF780 locus. Identified DMPs showed significant overlap enrichment with DNAs 1 hypersensitive sites in kidney tissue, sites associated with the expression of genes in cis, and transcription factor motifs, in addition to pathways associated with kidney development. Among main findings, we identified a DMP at the KANK1 gene, which has been previously associated with podocyte dysfunction and nephrotic syndrome.

Conclusions: We identified DMPs associated with eGFR and uncovered associations with genomic regions related to regulatory function in kidney tissue. These findings shed light on epigenetic mechanisms associated with kidney function, bridging the gap between eGFR-associated DNA methylation and tissue-specific chromatin context.

Generation of Monogenic Candidate Genes Diseases of the Kidney
Ana C. Onuchic-Whitford,1,2 Verena Klambt,3 Youqing Mao,1 Ronen Schneider,1 Florian Buerger,1 Hanan E. Shamseldin,1 Konstantin Deutsch,1 Thomas M. Kitzler,1 Makiko Nakayama,1 Amar J. Majmundar,1 Nina Mann,1 Heidi L. Round,1,6 Shirikant M. Mane,3 Fozwiz S. Alkuraya,1,3 Shirleel Shriv,3 Friedhelm Hildebrandt,1 1Boston Children’s Hospital, Boston, MA; 2Brigham and Women’s Hospital, Boston, MA; 3King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia; 4Broad Institute, Cambridge, MA; 5Massachusetts General Hospital, Boston, MA; 6Yale University School of Medicine, New Haven, CT; 7Alfaisal University College of Medicine, Riyadh, Saudi Arabia.

Background: Steroid-resistant nephrotic syndrome (SRNS) is a frequent cause of chronic kidney disease in childhood. The finding of ~60 single-gene causes of SRNS, mainly through whole-exome sequencing (WES), has contributed to the understanding of its disease mechanisms. Whereas in ~12-30% of cases with onset <25yo, a monogenic cause is detected, most cases remain molecularly unsorted. This indicates that additional monogenic causes of SRNS may exist.

Methods: We generated 3 independent lists of candidate genes: 1) 63 published monogenic mouse models of nephrotic syndrome (NS) or proteinuria, obtained from stringent review of published databases and literature; 2) 64 genes, whose podocyte expression is regulated by WT1 (Leefevre Kidney Int 88:321, 2015); and 3) a discovery set of 120 candidate genes that we generated by WES analysis of 1,382 NS families over 12 years. We first validated candidate lists 1) and 2) for overlap with known human SRNS genes. We then overlapped candidate lists 1) (mouse genes) and 2) (WT1-regulated genes) with our 120 WES-derived candidate genes (3), in order to identify potential novel genes that may cause monogenic NS.

Results: Twelve of the 63 NS mouse models (1) and 5 of the 64 WT1-regulated genes (2) overlapped with the control set of 63 known human SRNS genes, indicating relevance of the 2 candidate gene lists. When we evaluated for overlap with our 120 WES-derived candidate genes, 6 overlapped with 36 mouse candidate lists (1), 7-4 with the WT1-regulated candidate list (2). Of note, 3 genes (STNPO, SEMA3G, ITGB8) were shared by all 3 lists. We found a homogenous STNPO mutation (c.2540C>T, p.P847L) in a 4yo patient with NS. We show that loss-of-function of STNPO decreases CDC42 activity and reduces podocyte migration rate, both required by overexpression of wild type cDNA, but not by cDNA representing the patient mutation.

Conclusions: By overlapping 2 candidate gene sets with a set of 120 genes resulting from WES analysis in 1,382 NS families with NS, we identified STNPO as a potential novel monogenic cause of NS.

An International Cohort Study of Mutations in REN Causing Autosomal Dominant Tubulointerstitial Kidney Disease
Anthony J. Bleyer,1,2 Martina Zivna,1 Kendrah O. Kidd,1 Gregory Papageorgiou,1,2 Luca Rampoldi,3 Myassa Abdelwahed,4 Matthew R. Sinclair,5 Howard Trachtmann,6 Tal H. Kopel,7 Marisa Santostefano,8 Claudia Izzo,9 Agnieszka Laszkiewicz,10 Anna Jakubowska,11 Mohamad Zaidan,11 Katerina Hodanova,11 Bertrand Knebelmann,12 Federico Bocci,13,14 Waechter,14,15,16 H. Edward Huber,17,18 Alkuraya,8,7,19 Shril,17 Miriam S. Alberti,20 1University of Washington, Seattle, WA; 2UCLA School of Medicine, Los Angeles, CA; 3University Karlova 1 lekarska fakulta, Praha, Czechia; 4IRCCS Ospedale San Raffaele, Milano, Italy; 5Université de Montreal Faculté de Medecine, Montreal, QC, Canada; 6Université de Sfax, Sfax, Tunisia; 7NYU School of Medicine, New York, NY, USA; 8Lausanne Medical University Department and Clinic of Paediatric Nephrology, Switzerland; 9Medical University of Warsaw, Warsaw, Poland; 10Laboratory of Molecular and Cellular Immunology, Hirszenfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Wroclaw, Poland; 11Necker Hospital, APHP, Université de Paris, Paris, France.

Background: There have been few clinical reports of Autosomal Dominant Tubulointerstitial Kidney Disease due to REN Mutations (ADTKD-REN), limiting clinical characterization.

Methods: We formed an international collaboration that identified and characterized 111 individuals from 30 families with heterozygous REN mutations.

Results: Sixty-nine (62%) individuals had a REN mutation in the signal peptide region (signal group), 27 (24%) in the prosegment (prosegment group), and 15 (14%) in the mature renin peptide (mature group). Laboratory investigations revealed that REN signal peptide mutations prevent protein degradation and translocation of prorenin to the endoplasmic reticulum (ER), prosegment mutations led to abnormal deposition of renin and prorenin in the ER Golgi intermediate compartment (ERGIC), and mutations in mature renin led to deposition of prorenin and renin in the ER. Signal and prosegment patients were more severely affected, often presenting at <10 years (see Table 1) with anemia, hyperkalemia, and acute and chronic kidney disease. While eGFR was approximately 50 ml/min in children <10 years, eGFR remained stable until age 20, with mean age of end-stage kidney disease (ESKD) >50 in this cohort. The mean hemoglobin level in children was not by cDNA representing the patient mutation.

Conclusions: By overlapping 2 candidate gene sets with a set of 120 genes resulting from WES analysis in 1,382 NS families with NS, we identified STNPO as a potential novel monogenic cause of NS.

Funding: NIDDK Support
bicarbonate values increased in 9 patients taking fludrocortisone (4.7±0.55 mEq/L vs. 4.3±0.65 mEq/L, p<0.05) and 3.5 mEq/L vs. 25±9.23 mEq/L, p=0.003). Patients with mutations in mature renin presented with 20g with gut and chronic kidney disease.

**Conclusions:** There are 3 subtypes of heterozygous REN mutations that are pathophysiologically and clinically distinct.

Whole-Exome Sequencing Reveals a Monogenic Cause of Disease in 23.1% of 276 Families with Steroid-Resistant Nephrotic Syndrome
Ronen Schneider,1 Ana C. Onuchic-Whitford,1 Konstantin Deutsch,1 Abdul A. Halawi,1 Youyao Mao,2 Florian Burger,1 Verena Klambt,1 Amar J. Majmundar,1 Thomas M. Kitzler,1 Shrikant M. Mane,1 Shiree Shril,1 Frömhelm Hildebrandt,1 1Boston Children’s Hospital, Boston, MA; 2Brigham and Women’s Hospital, Boston, MA; 3Yale University School of Medicine, New Haven, CT.

Background: Steroid-resistant nephrotic syndrome (SRNS) overwhelmingly progresses to end-stage renal disease. To date, more than 59 monogenic genes have been identified to cause SRNS. We previously detected causative mutations in 25% using whole exome sequencing (Warpekoj CASSN 13.5:2018) and in 29.5% of patients with SRNS using targeted panel sequencing (Sadowski JASN 26:1279, 2015). However, whole exome sequencing (WES) has become more accessible, with the advantage of detecting not only known monogenic causes of SRNS, but also novel candidate NS-causing genes.

Methods: We employed whole exome sequencing (WES) to detect monogenic causes of SRNS in a large international cohort of 276 families with nephrotic syndrome (NS).

Results: Samples were recruited from April, 1998 to December, 2018 (21 years). WES was performed at the Yale Center of Mendelian Genomics. First, we examined the WES data for mutations in 59 genes known to cause SRNS. In 64/276 families (23.1%), we identified mutations in 22 of the known genes. There were also 7 genes that were identified as phenoalleles of SRNS, e.g. CO4LA3. In 42 families (15.2%), we have identified mutations in a potential novel candidate gene for SRNS. We found a 39.5% solve rate in consanguineous individuals and 10.8% solve rate in non-consanguineous individuals, recapitulating similar solve fractions to what has been previously published (Sadowski 2015; Warpekoj 2017).

Conclusions: This study confirms that in ~23% of families in our cohort, NS is due to monogenic causes. WES is a viable way to diagnose the underlying cause of NS in children and young adults, and to suggest novel monogenic candidate genes of NS.

Recovery from Dialysis in Responsive Primary Hyperoxaluria Type 1
Elizabeth C. Lorenz, John C. Lieske, Barbara M. Seide, Julie B. Olson, Ramila A. Mehta, Dawn S. Milliner. Mayo Clinic Minnesota, Rochester, MN.

Introduction: PH1 is a genetic disorder characterized by hepatic overproduction of oxalate and eventual end-stage kidney disease (ESKD). The only established treatment to reduce hepatic oxalate production is the use of pharmacologic doses of pyridoxine in responsive patients including those with G170R mutations, though emerging therapies to block specific hepatic enzymes are under clinical trial and appear promising. However, whether reducing oxalate production can result in recovery of kidney in a subset of patients with advanced chronic kidney disease (CKD) is unknown. Here we report a series of three G170R homozygous patients with ESKD who experienced recovery of kidney function that allowed dialysis discontinuation following treatment with pyridoxine.

Case Description: Data from the Rare Kidney Stone Consortium PH Registry was reviewed. Among the 41 G170R homozygous patients, 23 progressed to ESKD, including those who are the subject of this report. Median age at initiation or resumption of pyridoxine treatment following ESKD among these three patients was 37 years (range 20-53), POx was 8.8 mg/kg/d (range 6.8-14.0 mg/kg/d). Median duration of dialysis prior to renal recovery was 10 months (5-19). Plasma oxalate (POx) improved after recovery of renal function even while still on dialysis. At a median of 3 months (range 2-46) following discontinuation of dialysis, estimated glomerular filtration rate was 34 ml/min/1.73 m^2 (range 23-52), POC was 8.8 mmol/L (4.6-11.3), and U/Ox was 0.93 mmol/24 hours (0.47-1.03). Kidney function was maintained during a median of 3.2 yrs (range 1.3-3.8) of follow-up.

Discussion: Our findings challenge the conventional wisdom that ESKD in PH1 is always irreversible. Rather, in selected PH1 cases advanced CKD could potentially be reversed if hepatic oxalate production is reduced promptly after dialysis initiation. Thus new or emerging treatments may prevent the need for kidney transplantation in a subset of PH1 patients, even after ESKD ensues.

Baseline characteristics of G170R homozygous PH1 patients who recovered renal function after treatment with pyridoxine

The Distribution of APOL1 Risk Variants and Their Association with CKD in Rural East Africa: The SEARCH–CKD Study
Anthony N. Muiru,1 Assurah W. Elly,1 Jane Kabami,2 Mucunguzi Atukunda,3 Wendy Chan,1 Jennifer Puck,4 Edwin Charlebois,1 Diane Havlir,1 Moses Kannya,2 Michelle M. Estrella,1 Chi-yuan Hu,5 University of California San Francisco, San Francisco, CA; 2Kenya Medical Research Institute, Nairobi, Kenya; 3Infectious Diseases Research Collaboration, Kampala, Uganda.

Background: APOL1 protein level (APOL1) high-risk genotypes (G1/G1, G1/G2 or G2/G2) are well-known CKD risk factors that arose in sub-Saharan Africa. The G1 and G2 allele frequencies may be as high as 45% and 24%, respectively in some West African countries, but few studies have examined the association of high-risk genotypes and CKD in Eastern Africa.

Methods: We conducted a study of CKD prevalence among a population-based sample of 3,686 participants (PMCT055898) nested within an HIV trial in rural Uganda and Kenya. We collected dried blood spots (DBS) on filter cards for subsequent genetic studies. After DNA extraction, we genotyped APOL1 risk variants and used multivariable logistic regression models to assess the association of APOL1 high-risk genotypes with prevalent CKD defined as a serum creatinine-based eGFR <60 mL/min/1.73 m^2 or proteinuria (urine dipstick ≥1+).

Results: We successfully obtained DBS from 90% of all individuals approached for the study. We have extracted DNA and genotyped 492 (~10%) samples (convenient selection). Un-weighted CKD prevalence among these individuals was 7.7% (95% CI: 5.2-11.2%). The overall allele frequencies for APOL1 G1 and G2 variants were 6.1% and 5.8%, respectively and varied by region (Figure 1). Only 2.2% of individuals had APOL1 high-risk genotypes. The adjusted odd ratio for association of APOL1 high-risk genotypes with CKD was 1.5 (95% CI 0.15-15) in this limited sample.

Conclusions: Our study is one of the largest studies to define the prevalence of APOL1 risk variant frequencies and evaluate the association of APOL1 high risk genotype with CKD in rural East Africa. Our preliminary results show a relatively low prevalence of APOL1 risk variants—supporting the distinctive west-east Africa cline in APOL1 distribution previously reported. Further genotyping will permit more precise estimation of the association of APOL1 and CKD.

Funding: NIDDK Support.

APOL1 risk variant frequencies by study region

APOL1 Cytotoxicity Is Variant and Dose Dependent
Oreneta A. Oluabi,1 Somenath Datu,2 Jayadevan G.2,3 Savannah Moore,2 R. J. M. Pettipher1,2,3,4,1 Nathan Zahler,1 Martin R. Pollak,2 1Duke University, Durham, NC; 2Beth Israel Deaconess Medical Center, Boston, MA; 3Harvard Medical School, Boston, MA; 4Duke University School of Medicine, Durham, NC; 5Massachusetts General Hospital, Boston, MA; 6Icahn Inc, Durham, NC.

Background: Two coding renal risk variants (RRVs) of APOL1 gene (G1 and G2), are associated with large increases in chronic kidney disease (CKD) rates among populations of recent African descent, but the underlying molecular mechanisms are unknown. In vitro mammalian cell cultures models are widely used to study cytotoxicity of RRVs, but results have been contradictory. It remains unclear whether cytotoxicity is RRVs-dependent or driven solely by variant-independent overexpression. It is also unknown whether the reference APOL1 allele, G0 could prevent cytotoxicity of RRVs.

Methods: We generated tetracycline-inducible APOL1 expression in HEK293 cells and examined the effects of increased expression of APOL1 (G0,G1,G2,60G0,G0G1,G1G0 or G0G2) on known cytotoxicity phenotypes including reduced cell viability, increased cell swelling, cellular potassium loss, aberrant protein phosphorylation, and dysregulated energy metabolism. Furthermore, whole genome transcriptome analysis was performed to discover deregulated canonical pathways.

Results: At moderate expression, RRVs but not G0 caused cytotoxicity. RRVs-induced cytotoxicity is dose-dependent and is not reduced by co-expression of G0. RRVs also have dominant effects on canonical pathways relevant for cellular stress response.

Conclusions: In HEK293 cells, RRVs have dominant gain-of-toxic function that worsens with increasing expression. These observations suggest that high steady state levels of RRVs may underlie cellular injury in APOL1 nephropathy, and that interventions that reduce RRVs expression in kidney compartments may be effective for mitigating APOL1 nephropathy.

Funding: Other NIH Support - Common Fund (NIH Director’s New Innovator Award), Private Foundation Support.
was found to have MH. The results suggested that both the transplant candidate and her daughter presented with a genetic diagnosis consistent with Alport type nephropathy.

Discussion: Pathogenic or likely pathogenic variants in COL4A3 and COL4A4 cause FSGS and AR and AD Alport syndrome. Up to 50% of causal variants are a substitution of glycine in the Gly-X-Y repeat sequence disrupting the triple helical structure of the collagen molecule causing abnormalities in the GBM. The presence of these variants may also manifest with thin basement membrane disease. In this transplant candidate with IgAN and GBM abnormalities, the relative contribution of the COL4A3 variant to her CKD cannot be ascertained. Consequently, the daughter’s long-term renal outcome cannot be predicted. The co-existence of both IgAN and Alport syndrome is rarely described in the literature and the importance of the consideration of genetic renal disease is emphasized here in the context of living donor safety.

PO1642
Discovery of Genetic Modifiers in Thin Basement Membrane Nephropathy (TBMN) Using Pedigree-Based Whole-Exome Sequencing

Background: TBMN is caused by heterozygosity in COL4A3 or COL4A4, and is the carrier state of autosomal recessive Alport syndrome (ARAS). TBMN is less severe than ARAS, but its phenotype can range from asymptomatic microscopic hematuria and/or low-grade proteinuria, focal segmental glomerulosclerosis, to end-stage renal disease (13-25% in patients >60 years). The cause of phenotypic heterogeneity in TBMN is unknown. Previously, we found an autosomal dominant pattern of transmission of isolated microscopic hematuria and low-grade proteinuria in two large pedigrees in Utah with ARAS, which led us to hypothesize that genetic modifers may affect the severity of TBMN.

Methods: Based on pedigree analysis, 64 participants from two large families with characterized COL4A3 mutation were recruited for WES. In order to identify candidate disease-modifying genes, we performed VAAST (p=9.4E-04), a probabilistic algorithm for disease gene prioritization that uses pedigree information to perform linkage analysis. Candidate modifying genes were analyzed using Phevor, an algorithm that performs re prioritization based on information about phenotype, gene function, and disease.

Results: We found 17 candidate modifier genes that co-segregated with hematuria, proteinuria and renal dysfunction (Figure). Of note, GRIP1 co-segregated with the Alport allele, hematuria, proteinuria, renal dysfunction (P=9.4E-04), and had a high biologic correlation score (Phevor score=4.1).

Conclusions: GRIP1 is involved in cell adhesion to extracellular matrix proteins, crucial for kidney morphogenesis, and compound heterozygosity in GRIP1 causes renal agenesis and Fraser syndrome. Whole-exome sequencing in large pedigrees reveal 17 candidate disease-modifying genes in TBMN. Validation studies will be needed to ascertain their role in TBMN.
Results: In 30 of 211 (14%) families, we detected mutations in one of the 44 genes for isolated CANKT or in one of the 179 syndromic CANKT genes. In particular syndrome cases, reverse phenotyping was helpful to increase certainty of the deletoriusness of a genetic variant. In the remainder, we performed a targeted analysis for novel candidate genes. In 40 families of this subset, we identified likely deleterious mutations in 36 genes not previously reported to cause CANKT.

Conclusions: In a large, international cohort we detected causative mutations in 14% of families with a diagnosis of CANKT. We show that when combined with homozygosity mapping and segregation analysis, WES is useful in identifying potential candidate genes in consanguineous families or families with multiple affected.

PO1644
Extremely Rare Variants in Four Complement Genes Contribute to Genetic Susceptibility to Atypical Hemolytic and Uremic Syndrome

Background: The study of complement genetics has dramatically changed the landscape of atypical hemolytic uremic syndrome (aHUS) and has paved the way for highly tailored therapy. However, the assessment of the contribution of each identified variant to aHUS pathogenesis still remains a challenge. In this study we aimed to analyze the enrichment of rare variants in 6 aHUS-associated genes, including C3, CFH, CFI, CD46/MCP, CFB and THBD, in comparison with a reference population.

Methods: We analyzed the distribution of rare variants in 433 adult patients with a diagnosis of aHUS without co-existing condition of systemic lupus erythematosus (SLE) as a control group and 1440 European individuals from the 1000 Genomes project (N=503), focusing on the 6 genes of interest. We analyzed the enrichment of genetic variants in the aHUS cohort compared to the reference population.

Results: A total of 168 variants in complement complex genes, with a minor allele frequency (MAF) <1%, involved 247 alleles, were identified in 224 patients (51.7%). 115 of the identified variants were not reported in the population database gnomAD, including 75 variants detected in CFI gene (65%). Variants with a MAF of <0.01% in the C3 and MCP genes and variants with a MAF <0.1% in the CFH and CFI genes were enriched in the aHUS population as compared to controls. In contrast, rare variants in CFB and THBD genes were not significantly enriched in the aHUS population. We identified 18 variants overrepresented in patients, including the CFCHFHR1 hybrid genes. Among those variants, we observed functional deficiency in the encoded protein in the C3 variant p.Lys155Gln associated with risk of advanced age-related macular degeneration was not significantly increased in the aHUS population. Finally, multiple rare variants in a single individual were more frequently present in aHUS patients compared to controls.

Conclusions: We showed the enrichment of extremely rare variants limited to CFI, CFI, CD46/MCP and C3 genes. The study confirms that a variant with a MAF <0.01% should not be considered at risk for developing aHUS. Our study indicates that targeting these variants resulting with functional deficiency in the encoded protein the C3 variant p.Lys155Gln associated with risk of advanced age-related macular degeneration was not significantly increased in the aHUS population. Finally, multiple rare variants in a single individual were more frequently present in aHUS patients compared to controls.

PO1645
Whole-Exome Sequencing Identifies Likely Causative Variants in Four Candidate Genes in 16 Families With Spina Bifida

Background: Spina bifida (SB) is the most common central nervous system malformation compatible with life and the second leading cause of birth defects. The following lines of evidence support the hypothesis that SB may be caused by multiple monogenic genes: i) congenital nature, ii) familial occurrence, and iii) existence of monozygotic twins. However, only few monogenic genes have been described so far. The majority of the candidate genes from these models has been studied in human SB.

Methods: We evaluated the literature and generated a list of 95 candidate genes from four categories: i) known genes from human (isolated SB), ii) 11 genes from human syndromic SB, iii) 35 genes considered risk factors for human SB, and iv) 42 genes from mouse models. We evaluated whole exome sequencing (WES) data obtained from 16 individuals with SB who were enrolled at Boston Children’s Hospital from 06/2019 to 11/2019.

Results: In 4 of 16 families (25%), we identified 4 likely deleterious heterozygous (het) mutations in each one potential SB candidate gene. All variants are very rare with a frequency of less than 0.01% in a control database of 125,000 healthy control individuals (gnomAD). Specifically, in family B4110 with myelomeningocele, we identified a C6LS1 (p.Glu652Gly) variant. In family B4113 with myelomeningocele, we identified a single nucleotide variant in the GTF2H11 gene (p.Lys155Gln) associated with risk of advanced age-related macular degeneration was not significantly increased in the aHUS population.

Conclusions: We identified two novel APOL1-gene interactions, highlighting that secondary genes may modify the effect of APOL1 on kidney function, which may uncover underlying biological mechanisms and be useful for prevention.

PO1647
Results from the Ongoing Phase 2 Open-Label Extension Study of Lumasiran, an Investigational RNAi Therapeutic, in Patients with Primary Hyperoxaluria Type 1 (PH1)

Background: PH1 is a rare genetic disorder characterized by hepatic overproduction of oxalate, leading to recurrent kidney stones, nephrocalcinosis, progressive renal failure, and multiorgan damage from systemic oxalosis. There are no approved pharmacologic therapies for PH1. Lumasiran is a subcutaneously-administered investigational RNAi therapeutic that decreases hepatic oxalate production by targeting glycolate oxidase. We designed this phase 2 open-label extension (OLE) study to explore long-term safety and efficacy following the completion of the phase 2a, 12-month, open-label (OL) study (NCT03127663).

Methods: Phase 2 OLE includes patients with PH1, ages 6 years old, urinary oxalate (UOX) <0.7mmol/1.73m2/day, and eGFR >45mL/min/1.73m2 who completed the Phase 2a study. Patients received lumasiran 1mg/kg monthly, 3mg/kg monthly or 3mg/kg quarterly, and all transitioned to 3mg/kg quarterly. Endpoints include safety and efficacy assessments.

Results: This trial enrolled all 20 patients from the Phase 1/2 study. At baseline of the parent study, patients had a mean age 14.9 years (range: 6-43), mean baseline UOX of 0.7mmol/1.73m2/day, and eGFR >45mL/min/1.73m2 who completed the Phase 2a study. Patients received lumasiran 1mg/kg monthly, 3mg/kg monthly or 3mg/kg quarterly, and all transitioned to 3mg/kg quarterly. Endpoints include safety and efficacy assessments.

Conclusions: Through whole exome sequencing, we detected likely deleterious mutations in 5 affected individuals with a diagnosis of SB. We show that composing a list of 95 candidate genes based on established mouse models and genes known to be related to SB in human facilitates the detection of monogenic causes for SB. We are expanding this study to a larger cohort.

PO1641
APOL1 by Second-Generation Interaction on eGFR Among African Americans Without Diabetes: The Million Veteran Program

Background: Two high-risk variants in the Apolipoprotein L1 (APOL1) gene are associated with eGFR and a substantial increase in risk of end-stage renal disease (ESRD) among African Americans without diabetes. Not all individuals with high-risk variants develop kidney disease, suggesting that unidentified genetic factors may modify the effects of APOL1.

Methods: We tested interactions between the APOL1 haplotype and single nucleotide polymorphisms (SNPs) from 22 independent loci associated with eGFR among 55,004 African Americans without diabetes in the Million Veteran Program. We used linear regression to investigate multiplicative APOL1*SNP interactions on eGFR at enrollment, adjusting for age, sex, body mass index and the first 5 principal components of ancestry, with Bonferroni-correction for multiple testing (alpha=0.05/22=0.002).

Results: We detected significant interactions between APOL1 high-risk variants and SNPs at two loci (GATM/SPATA5L1 rs662024678, p-interaction = 0.0012) and UBE2Q2 (rs74024050, p-interaction = 0.0014) (Table). SPATA5L1 is a protein-coding gene with elevated expression in the kidney and previous associations with familial juvenile hyperuricemic nephropathy. UBE2Q2 is also a protein-coding gene with gene expression in the distal kidney tubule of a murine model.

Conclusions: Our results identify two novel APOL1-gene interactions, highlighting that secondary genes may modify the effect of APOL1 on kidney function, which may uncover underlying biological mechanisms and be useful for prevention.

Funding: NIDDK Support, Veterans Affairs Support
2.24 mmol/1.73m²/day (range: 0.94, 5.18). As of January 2020, patients were dosed in OLE for a median of 15 months (range: 11–22). Adverse events were reported in 19/20 (95%) patients; all were mild or moderate and the majority were assessed as unrelated to study drug. There were no discontinuations or drug-related serious adverse events. The median reduction in 24h UOx relative to Phase 1/2 baseline was 74.5% (N=17) and 17/18 patients achieved normal or near normal levels of UOx. Plasma oxalate levels also decreased (mean max reduction 55.2%, N=19). Plasma and urinary glycolate increased and later stabilized, consistent with the effect of lumasiran on glycolate oxidase.

Conclusions: Lumasiran had an acceptable safety profile. Continued therapy with lumasiran maintained reduction of UOx to levels near or below the upper limit of normal, consistent with the Phase 1/2 study. These data further enable ongoing Phase 3 studies to evaluate lumasiran in patients with PH1 of all ages and at all stages of renal impairment.

Genome-wide Association Study of Lupus Nephritis in Chinese Han Population

Kangkang Song,1 Xiaodong Zheng,2 Xiaomin Liu,1 Xuejun Zhang,1,2 Xiangmei Chen.1 Department of Nephrology, the First Medical Centre, Chinese PLA General Hospital, Beijing, the PLA, Chinese PLA Institute of Nephrology, State Key Laboratory of Kidney Disease, National Clinical Research Center for Kidney Diseases, Beijing Key Laboratory of Kidney Diseases, Beijing, China; 1Institute of Dermatology and Department of Dermatology at No.1 Hospital, Anhui Medical University, Hefei, China; 1Institute of Dermatology and Department of Dermatology, Huashan Hospital, Fudan University, Shanghai, China.

Background: Lupus nephritis (LN) is one of the most common and serious complications of systemic lupus erythematosus (SLE). The genetic factors play a vital role in the pathogenesis of LN. The purpose of this study was to screen for susceptible variants of LN in Chinese Han populations in whole genome.

Methods: A genome-wide association study (GWAS) was performed in 592 LN patients and 453 SLE patients without LN, Fifty-six single nucleotide polymorphisms (SNPs) in 34 loci were selected for replication in independent cohort of 188 LN and 171 SLE without LN patients. Besides, gene-based analysis of selected loci was performed in the enlarged population (2336 LN and 2466 SLE without LN patients) based on exome Asian array data.

Results: We identified 9 SNPs suggesting a correlation with LN (P<10^-4). The most significant SNP was rs12606116 (18p11.32) with P=6.75x10^-10. The rest SNPs were rs11826924 (11p15.2, INSC), rs10151371 and rs17124022 (14q31.3, GPR65), rs14055744 (5q31.1, CD274), rs203339 and rs433091 (12q24.23, CIT), rs7157731 (14q32.2, WDR25), rs2372192 (3p14.1, MAGI1). Gene-based analysis results showed 11 suggestive SNPs in 11 loci (P<0.05): GPR139 (16p12.3, TH), TH (11p15.5), SEMA6D (15q21.1), EPHA5 (4q34.1, CD274), rs203339 and rs433091 (12q24.23, CIT), rs7157731 (14q32.2, WDR25), rs2372192 (3p14.1, MAGI1). Gene-based analysis results showed 11 suggestive SNPs in 11 loci (P<0.05): GPR139 (16p12.3, TH), TH (11p15.5), SEMA6D (15q21.1), EPHA5 (4q34.1, CD274), rs203339 and rs433091 (12q24.23, CIT), rs7157731 (14q32.2, WDR25), rs2372192 (3p14.1, MAGI1).

Conclusions: Association Analysis of LN was performed in Chinese Han SLE patients for the first time. Multiple susceptible genes were identified and moderately associated with LN which may advance our understanding of the genetic basis of LN.

Genotyping of Renal Transplant Patients

Susan L. Murray,1 Katherine A. Benson,1 Claire Kennedy,1 Sarah Cormican,2 Kendrah O. Kidd,1 Anthony J. Bleyer,1 Mark A. Little,1 Gianpietro Cavalleri,1 Peter J. Conlon,3 Royal College of Surgeons in Ireland, Dublin, Ireland; 2University of Dublin Trinity College, Dublin, Ireland; 1Beaumont Hospital, Dublin, Ireland, 4Wake Forest University, Winston-Salem, NC.

Background: There is an increasing recognition that though individual inherited kidney diseases are rare, when considered as a single cohort inherited forms of kidney disease may account for up to 10% of CKD. This can have implications for potential living kidney donors who are often related to the recipient and at higher lifetime risk of kidney failure. We sequenced patients undergoing renal transplantation to assess what proportion of kidney failure was caused by monogenic kidney disease.

Methods: We identified adult patients undergoing living or deceased renal transplantation. We excluded those with psoriatic arthritis, systemic lupus erythematosus, drug-induced causes and those with renovascular kidney disease over the age of 50. Patients underwent targeted next generation sequencing using a custom panel of 127 genes known to cause renal disease. All suspected disease-causing variants were classified by American College of Medical Genetics guidelines and discussed by a multidisciplinary team (KB1).

Results: We sequenced 99 patients who presented for renal transplantation. We were able to detect an ACMG-classified pathogenic/likely pathogenic variant in 27 (26%) patients. The most common disease-causing variant identified was in PKD1, which was identified in 14 patients (14%), accounting for 52% of all individuals with a disease-causing gene identified. Four others (16%) had pathogenic variants in COL4A4 or COL4A5 genes. No other disease-causing variant was present in more than one individual.

Conclusions: It is possible to identify monogenic causes of kidney disease in a carefully selected population with ESRD, and this may be useful in stratifying risk in potential living renal donors.
PO1651
21%-51% of a Single-Center, 15-Year Cohort of All Patients with ESKD
Prior to the Age of 50 Have Monogenic Kidney Disease
Rozemarijn Zoek,1 Richard H. van Jaarsveld,1 Tri Q. Nguyen,2 Edith Peters,1
Martin Efferink2, Robert F. Ernst,2 Maarten B. Rookmaaker,3 Marc Lilien,4
Eric Spiersing,5 Roel Goldschmeding,5 Nine V. Knoers,5 Bert Van der zwaag,5
Arjan D. Van Zuilien,5 Albertien M. van Eerde.1 Nephrologists @ UMCU
1Department of Genetics, UMC Utrecht, Utrecht, Netherlands; 2Department of
Pathology, UMC Utrecht, Utrecht, Netherlands; 3Department of Nephrology,
UMC Utrecht, Utrecht, Netherlands; 4Pediatric Nephrology, Wilhelmina's
Children Hospital, UMC Utrecht, Utrecht, Netherlands; 5Department of
Genetics, UMC Groningen, Groningen, Netherlands; 6Department of
Immunology, UMC Utrecht, Utrecht, Netherlands.

Background: Often only CKD patients with high likelihood of genetic disease are
offered genetic testing. Early genetic testing could obviate the need for kidney biopsies,
allowing for adequate prognostication and treatment. To test the viability of a ‘genes
first’ approach for CKD, we performed genetic testing in a group of renal transplant
recipients <50 years, irrespective of cause of transplant.

Methods: From a cohort of 273 transplant patients, we selected 110 that were in
care at the UMC Utrecht, had DNA available and were without clear-cut non-genetic
disease. Forty patients had been diagnosed with a genetic disease prior to enrollment,
and 70 patients were performed a whole exome sequencing based 379 gene panel analysis.

Results: Genetic analysis yielded a diagnosis in 51%. Exonatoplated to the 273 patients,
who did not all fit the inclusion criteria, the diagnostic yield was still 21%. Retrospectively,
43% of biopsied patients the kidney biopsy would not have had added diagnostic
value if genetic testing had been performed as a first tier diagnostic.

Conclusions: The burden of monogenic disease in transplant patients with ES KD of
ages up to 50 varied from 51%. Early genetic testing can provide a non-invasive
diagnostic, impacting prognostication and treatment and obviating the need for
an invasive biopsy. We conclude that in patients who one expects to develop ES KD prior
to the age of 50, genetic testing should be considered as first mode of diagnostics.

PO1652
Genome-Wide Analyses Provide Insights into the Genetic Architecture of Kidney Function and CKD Among Hispanics in the Million Veteran Program
Elvis A Akwo,1,2 Cassianne Robinson-Cohen,1,2 Bryce Rowan,1,2 Edward D. Siew,2,3 Tan Tao,2,4 Christopher J. O'Donnell,2,4 Adriana Hung,2,5
1Nashville VAMC, Nashville, TN; 2VUMC, Nashville, TN; 3VA Boston Health Care System Jamaica Plain Campus, Boston, MA; 4B Brigham and Women’s Hospital Department of Medicine, Boston, MA.

Background: Hispanics (HAs) have a higher risk of progressing to end-stage renal disease (ESRD) than non-Hispanic American Europeans. Genetic variants influencing kidney function have been identified through genome-wide association studies (GWAS) of CKD and ESRD, as well as estimated glomerular filtration rate (eGFR), however, small sample sizes have stalled discovery in the Hispanic population.

Methods: We performed a GWAS of eGFR in 32,821 Hispanics from the Million Veteran Program (MVP); eGFR was estimated using the CKD EPI equation with IDMS calibrated creatinine. Patients on dialysis, transplant recipients, or with BMI >18 kg/m² were excluded. eGFR was regressed on to common genetic variants (minor allele frequency > 1%) imputed to the 1000 Genomes reference panel adjusted for age, sex, BMI, and the top ten principal components. Analyses were performed by strata of diabetes, estimates from which were aggregated with fixed-effects meta-analysis.

Results: A total of 397 SNPs representing 8 loci exceeded genome-wide significance. The most significant association was at a previously known locus, SPATA5/GATM on chromosome 15 (p-value = 3.78E-12). Two novel loci were detected. One in SLC30A4 (rs2653718 p-value = 4.51x10⁻⁸) a protein-coding gene for zinc transmembrane transporter, and one on LINC00972 (rs12889732 p-value = 2.68x10⁻⁸). Other previously reported signals in the European American population for kidney phenotypes were also found with genome-wide significance: UMOD/PDILT (rs7114135 p-value = 1.13x10⁻⁸), PRKAG2 (rs10224210 p-value = 1.99x10⁻⁸), UORC3 (rs720359 p-value = 2.22x10⁻⁸), SLC2A4 (rs318236 p-value = 1.29x10⁻⁸) and ALMS1 (rs1271588 p-value = 4.14x10⁻⁸). Several additional important CKD loci were associated with kidney function at p-values below the genome-wide threshold including: APOL1 (rs5092573 p-value = 2.98x10⁻⁸), TPRKB (rs33805651 p-value = 5.49x10⁻⁸), SHROOM3 (rs50259470 p-value = 3.63x10⁻⁸). Five of the variants that reached genome-wide significance were in non-coding variants.

Conclusions: Our study results emphasize the transethnic nature of genetic variation contributing to kidney function. Overall, this is the largest GWAS of eGFR in Hispanics to date, which replicates previously identified loci in tranethnic analysis and detects two novel loci in Hispanic populations.

PO1653
Assessing Alport Syndrome and Thin Basement Membrane Nephropathy (TBMN) by Optical Coherence Tomography (OCT)
Laith Al-Rabadi, Lydia Sauer, Alex Vitale, Edwin Lin, Ragheed Aldailumia, Alun Thomas, Paul Bernstein, Martin C. Gregory. University of Utah Health, Salt Lake City, UT.

Background: Using OCT to identify temporal macular thinning has diagnostic importance in patients with X-linked Alport syndrome (XLAS) but little prior research has been done to evaluate temporal macular thinning in COL4A3 and COL4A4 compound heterozygotes (ARAS) and simple heterozygotes. (TBMN) Individuals with heterozygous COL4A3 or COL4A4 mutations usually have TBMN, which is considered the carrier state of autosomal recessive Alport syndrome (ARAS). The aim of this study is to assess ophthalmologic findings in simple and compound heterozygotes and to compare them to normal control and XLAS.

Methods: Genotyping was done to detect COL4A3 and COL4A4 mutations and to classify family members as ARAS, TBMN or normal. Temporal thinning index (TTI) was calculated from OCT measurements of the more severely affected eye by comparing the ratio of the retinal thickness of the temporal (T) to the nasal (N) subfields with a published normative database. (Figure, y axis) Student’s T-test and ANOVA were used to identify binary and multiple groups differences. In addition, multivariate linear regression was performed controlling for age, gender and interaction terms between different variables.

Results: We report results from 12 normal controls, 16 COL4A3 or COL4A4 simple heterozygotes, 7 compound heterozygotes and 18 hemizygous males with XLAS. Mean TTI was 5.75, 7.4, 9.45 and 9.37 in these four groups, respectively. TTI in each group (simple heterozygotes, compound heterozygous, and XLAS) was significantly greater than normal controls (P < 0.01). TTI was not significantly different between simple and compound COL4A3 heterozygotes (P = 0.13). Age, gender, and GFR were not associated with significant differences in the regression analysis.

Conclusions: This is the largest study that systematically assessed ophthalmologic findings in XLAS, ARAS and TBMN. OCT may guide our evaluation of family members who are potential donors.

LAMA5 Gene Mutations in Japanese Cases with Infantile Nephrotic Syndrome
China Nagano, Kandai Nozu, Shinya Ishiko, Yuya Aoto, Nana Sakakibara, Tomoko Horinouchi, Tomohiko Yamamura, Takeshi Ninchihi, Katsuto Iijima. Kobe University Graduate School of Medicine, Kobe, Japan.

Background: Steroid resistant nephrotic syndrome (SRNS) have high risks to progress to end stage renal disease. Mutations in genes encoding podocyte-associated proteins have been implicated in about 30% of SRNS cases in children. Recently, LAMA5 gene variants were detected in two families. The patient 1 and 2 were siblings. They presented with proteinuria at 6 months old. She was subsequently found to have compound heterozygous mutation for LAMA5 gene (c.9232C>G, p.Arg3078Ter), and the other was splice site mutation (c.1282+1G>A). The patient 3 presented with proteinuria at 6 months old. She had congenital cataract and hypoplastic kidney. Her renal pathology showed remarkable irregular form of glomerular basement membrane. She was subsequently found to have compound heterozygous mutation for LAMA5 gene: (c.302G>T, p.Arg101Ter).(ELOF270Fe), c.1282+1G>C. We performed immunohistochemistry analysis of laminin e5 and her renal pathology showed completely negative staining pattern.

Variation in Phenotype in Utah Families with Autosomal Recesssive Alport Syndrome
Laith Al-Rabadi, Edwin Lin, Lydia Sauer, Alex Vitale, Paul Bernstein, Martin C. Gregory. University of Utah Health, Salt Lake City, UT.

Background: Individuals with heterozygous COL4A3 or COL4A4 mutations usually have thin basement membrane nephropathy (TBMN), which is often considered the carrier state of autosomal recessive Alport syndrome (ARAS). Patients with ARAS usually progress to end-stage renal disease (ESRD) by the fourth decade of life. While ocular abnormalities, hearing loss and renal impairment are classically absent with TBMN, a subset of patients develop focal segmental glomerulosclerosis (FSGS) and 13-25% of patients progress to ESRD. It is unclear why some individuals with heterozygous COL4A3 mutations follow a milder course with isolated microscopic hematuria or low-grade proteinuria while others with the same mutations develop progressive renal dysfunction. It is also unclear why some family members show hematuria while others with the same mutation do not.

Methods: This study was designed to address these clinical questions using unbiased Whole Exome Sequencing (WES) in a population of patients harboring a limited number of pathogenic heterozygous COL4A3 mutations. Our work has focused on detailed examinations of patients carrying the same mutation to assess carefully the inter and intrafamilial variability and assess the impact of mutation on pathology.

Results: Two Utah families (figure) with a unique combination of two pathogenic mutations were identified. These pathogenic mutations have been reported before. However, the compound heterozygous status in each family is unique and has not been reported before. The probands are compound heterozygotes sharing one mutation (c.2083G>A, p.Gly695Arg) but differ in the second mutation (c.4981C>G, p.Arg1661Cys and c.4471T>C, p.Leu1474Pro).

Conclusions: This study expanded the phenotypic spectrum of COL4A3 mutation carriers. Our findings showed the significant overlap between phenotypes induced by COL4A3 variants and the considerable intra and inter-familial variability and renal disease progression in patients with COL4A3 mutations.

PO1656
Whole-Exome Sequencing as a Predictive Tool for Severe CAKUT Phenotypes
J Brandon Erken, Kenneth Kaufman. Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

Background: Congenital Anomalies of the Kidney and Urinary Tract (CAKUT) affect about 1% of births, with about 20% secondary to genetic causes. The Cincinnati Fetal Center is one of the few centers worldwide offering fetal interventions including amnioinfusion and for infants with oligo/anhydramnios. As these infants are phenotypically severe, we predict they will be genetically enriched. We hypothesized that identification of rare homozygous variants in infants with CAKUT will aid in determination of clinical course and improve parental counseling.

Methods: We collected blood from infants whose mothers underwent fetal interventions for oligo/anhydramnios for the purpose of Whole Exome Sequencing as well as blood samples from parents for this purpose.

Results: We completed variant calling for 2 singleton and 1 maternal sample. Both patients’ mothers underwent multiple amnioinfusions, and the patients required initiation of RRT within week 1 of life. In both patients, we identified a nonsynonymous SNV of HSPG2 on chromosome 1. HSPG2 encodes for perlecan, which has a role in renal embryogenesis, specifically the maturation of the epithelial and mesenchymal tissues of the kidney. We identified a rare heterozygous variant found in 0.28% of the population in 1 patient. In the other patient, we identified 2 variants, which form a state of compound heterozygosity. We found a rare heterozygous nonsynonymous SNV mutation in T-box transcription factor-18 (TBX18) in 1 sample. TBX18 is imperative for the development of ureteric mesenchyme and is expressed in the renal capsule and glomerular mesangial cells. This patient had bilateral VUR and dysplastic kidneys. The other patient had a rare heterozygous nonsynonymous SNV in the transcriptional repressor GLI3 which is implicated in renal morphogenesis. Variants in GLI3 have been described in renal dysplasia and aplasia. This patient was born with bilateral multicystic dysplastic kidneys.

Conclusions: In our pilot data of WES of 2 singletons and 1 maternal sample, we revealed rare heterozygote genes, HSPG2, TBX18, and GLI3, all of which are necessary for renal and urinary tract development, specifically glomerular and ureteric development and transcriptional regulation. In a small cohort, we demonstrate that WES of a severely affected population provides insight into the molecular mechanisms underlying CAKUT, which can aid in prognosis and parental counseling in the future.

PO1657
Perspective Clinical Utility and Barriers to Genetic Testing in the Adult CKD Population: A Survey of General Nephrologists
Trudy McKanna, Philippe M. Gauthier, Christine Seto, Christie Chong, Monica L. Johnson. Natera, Inc, San Carlos, CA.

Background: Genetic testing for chronic kidney disease (CKD) can lead to personalized medicine, family planning opportunities, and living kidney donor screening. Comprehensive genetic testing in CKD patients with a suspected genetic cause or predisposition is important for accurate diagnosis. However, the uptake of genetic testing among nephrologists is still low despite the increasing prevalence of genetic testing and advances in genetic counselors. Genetic testing in clinical practice to elicit feedback on the use of genetic testing in clinical nephrology care. The questions focused on perceived utility and potential barriers to ordering genetic testing.

Methods: An online, multiple choice survey was sent to 400 general nephrologists in clinical practice to elicit feedback on the use of genetic testing in clinical nephrology care. The questions focused on perceived utility and potential barriers to ordering genetic testing.

Results: Early findings suggest that while clinical utility is acknowledged in many situations, there are opportunities to provide physician education regarding test results and insurance coverage that may increase test adoption. The perceived lack of genetic counseling resources and ethical concerns may inhibit the ordering of genetic testing in patients with CKD. We will present results from the complete dataset of responses to this survey of practicing general nephrologists and provide insights into their concerns about ordering genetic testing.

Is There a Contribution of Genes Involved in Hereditary Nephropathies to AKI?
Sol M. Carriazo, Maria Dolores Sanchez-Nino, Laura J. Castañeda Infante, Alberto Ortiz. Hospital Universitario Fundacion Jimenez Diaz, Madrid, Spain; Universidad Autonoma de Madrid, Madrid, Spain.

Background: The diagnosis of hereditary kidney disease has been improving with the use of novel diagnostic tools in the last decades. More than 600 genes have been detected using techniques such as whole exome sequencing. However, it is not clear if those genes causing hereditary nephropathies have any independent contribution in the pathogenesis of acquired nephropathies.

Methods: We analyzed the kidney transcriptomic after 24 hours of acute kidney injury (AKI) induced by folic acid in a murine model. In this database we evaluated if 625 genes described as responsible for hereditary nephropathies have any independent contribution in the pathogenesis of acquired nephropathies.

Results: Among 23051 genes, 7443 (29.7%) were found to have a significant modification in their expression in AKI (p<0.05). When analyzing 625 responsible for hereditary nephropathies, we identified 615 in our dataset. 260 (41.6%) of these genes were differentially expressed in our model. An association between 241 of those 260 differentially expressed genes and glomerular filtration rate in human nephropathies was identified. The most enriched GO process were “complement activation”, “protein association receptosome”, “activation of immune response” and “RNA processing”. 7 of the 241 mentioned genes, showed changes greater than twofold. On the other hand, 18 of the 241 showed more than a half-fold change. We have validated the expression of 2 of the genes in acute kidney injury (SCLC3A3, FN1), which supports the relevance of the transcriptomic results.

Conclusions: Several genes responsible for familiar nephropathies are differentially expressed in acquired nephropathies, suggesting that they could play a role in its

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
pathogenesis, through complement activation, protein activation of immune response and the regulation of the RNA processing. The identification of those genes showing a more significant change will allow us to select biomarkers for further studies and new possible therapeutic targets in kidney damage.

**Features of Hereditary Nephropathy with COQ8B Mutation**

Jiwon M. Lee,1,2 Chungnam National University, Daejeon, Daejeon, Republic of Korea; 1Chungnam National University Hospital, Daejeon, Daejeon, Republic of Korea.

**Background:** Mutations in the genes related to biosynthesis of Coenzyme Q (COQ8B, ubiquinone) cause primary COQ8B deficiency resulting in various clinical phenotypes. COQ8B (also known as ADCK4) has been first reported in association with nephropathy in 2013, and previously a Korean cohort has reported six patients, notably accompanied by medullary nephrocalcinosis in all the six cases. Because these patients can benefit from COQ8B replacement, early differential diagnosis is essential. This study systematically reviewed clinical features and genotypes of patients with COQ8B-associated nephropathy.

**Methods:** Electronic databases were searched using related terms (till March 30, 2020). A report adhered to the Preferred Reporting Items for Systematic Reviews and Meta-analyses guidelines.

**Results:** From 126 articles searched, there were 11 eligible studies with 49 patients with COQ8B-associated nephropathy. Of them, 26 patients were Caucasian and 21 were Asian (the rest had no data regarding ethnicity). Female to male ratio was 2:1. Median age at diagnosis was 14.6 years. Proteinuria was reported in 100% of the patients with median serum albumin level of 3.7 g/dL and creatinine level of 1.45 mg/dL. Twenty two patients (45%) had chronic kidney disease and twelve patients had end-stage renal disease (25%). Transplantation was performed in 6 cases out of which 5 had no recurrence. Of 33 patients available for pathology reports, most (32/33, 97%) patients showed histology compatible with focal segmental glomerulosclerosis (FSGS) and seven (14%) patients had abnormal mitochondrial aggregation in the podocyte cytoplasm visualized by electron microscopy. Severe proteinuria was present in medullary nephrocalcinosis in all 7 patients, notably all Koreans. Outcomes related to COQ8B replacement was reported in 14 cases and half of them reported partial or complete remission. Effect of calciumin inhibitors were reported in 7 cases which showed partial remission in 4 cases. Two patients had COQ8B-associated FSGS is a rare, hereditary nephropathy which can greatly benefit from early diagnosis and COQ8B supplementation. Ablent mitochondrial accumulation in the cytoplasm of the podocytes and increased medullary edechergency may add to diagnostic suspicion. So far, all patients with COQ8B mutation reported in South Korea had medullary nephrocalcinosis.

**PO1660**

**CKD in Patients with Primary Hyperoxaluria Type 3: A Meta-Analysis from Literature**

Cristina Martin Higuera,1 Kelly Barrios,2 Bernd Hoppe,1,2 Depart. Ciencias Medicas Basicas, Fac. Medicina, Universidad de la Laguna, Tenerife, Spain; 2Dicerna Pharmaceuticals, Inc., Lexington, MA; 3German Hyperoxaluria Center, Bonn, Germany.

**Background:** Primary hyperoxaluria type 3 (PH3) is considered the most benign phenotype of all forms of primary hyperoxaluria. Being it typical that patients with PH type 1 and 2 develop chronic kidney disease (CKD) or end-stage renal disease (ESRD), it appears to be more or less uncommon that patients with PH3 are on risk of CKD and even do not develop ESRD. We now aimed to determine the number of PH3 patients reported to have any kind of CKD.

**Methods:** We performed a literature meta-analysis, searching in PubMed and Embase with the following keywords: primary hyperoxaluria, PH, primary hyperoxaluria type 3, PH3 or PH3.

**Results:** We found 151 patients in 18 relevant papers published between 2010-2019. Age of diagnosis/disease onset ranged from 1 month to 48 years of age. Most of the patients suffered recurrent urolithiasis, most often during the first years of life, but recurrent kidney stone episodes were also found later in life. The most common mutations found were the c.700+5G>T splice site mutation (37%) and the p.E315del mutation (22%). In 77 patients any information was provided with regard to renal function, in 22 of those kidney function was said to be normal, but no eGFR or CKD stage was mentioned. In 25 patients kidney function was found to be normal based on eGFR levels. CKD stage 1 was reported in 21 patients, CKD stage 2 in 5 patients, CKD 3- in 2 patients and 1 patient each had CKD stage 4 or ESRD, respectively. In 10 patients, follow-up measures were available, as their data were included in two papers (5 years apart from each other). Here, in 1 patient eGFR significantly declined from 34 to 68 ml/min/1.73 m², while 2 patients remained in CKD 1 and in 5 kidney function remained normal over time. In 1 patient kidney function ameliorated under standard treatment of care from CKD 1 to normal.

**Conclusions:** There is a massive bias in the data published, as data on kidney function is mostly not completely reported. Kidney function was normal only in 22 of the 54 patients (41%) with complete information. CKD 2 or worse was observed in 16.7% of PH3 patients, and even one patient with ESRD was described. Also, one PH3 patient had died at age 4 months because of respiratory failure and not because of PH. Thus, as long-term follow-up data is still missing, we nevertheless suspect PH3 not being as benign as currently being reported.

**Segmental Expression of Nephrin in the Slit Diaphragm of a Patient with a Nonsense Mutation in NPHS1**

David Unnerjö-Jess,1,2 Linus Butt,1,2 Lina Hieronymi,1,2 Martin Hohne,1,2 Hans Blom,3 Peter Hoyer,1 Bernhard Schermer,1,2 Thomas Benzing,1,2 1Department II of Internal Medicine and Center for Molecular Medicine Cologne (CMMC), University of Cologne, Cologne, Germany; 2Colege Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases (CECAD), University of Cologne, Cologne, Germany; 3Pediatric Nephrology, Pediatrics II, University of Duisburg-Essen, Cologne, Germany; 4Science for life Laboratory, Dept. of Applied Physics, Royal Institute of Technology, Solna, Sweden.

**Background:** Nephrotic syndrome due to nonsense mutations in the NPHS1 gene typically presents with a severe congenital proteinuria. However, patients harboring nonsense mutations close to the carboxyl terminus of the NPHS1 encoded nephrin protein can present with a milder phenotype. In this study, we use high-resolution microscopy to investigate the expression pattern of nephrin p.1160X in a patient with such a mutation.

**Methods:** We used confocal and stimulated emission depletion (STED) microscopy to visualize the distribution of nephrin p.1160X at the glomerular filtration barrier and to study the correlation between nephrin expression and foot process morphology.

**Results:** Confocal microscopy revealed a highly heterogeneous expression pattern of nephrin p.1160X. While most glomerular capillaries showed absence of nephrin, there were sharply defined patches with almost normal levels (see figure). To clarify whether this unexpected pattern was due to sporadic re-expression of a wild-type nephrin, we used antibodies raised against the carboxyl terminus of nephrin which is lacking in the mutant protein. These data confirmed expression of nephrin p.1160X. Moreover, qPCR and cell culture experiments indicated normal levels of nephrin mRNA, but a decreased stability of p.1160X nephrin which could partly be rescued by inhibition of proteasomes.

**Conclusions:** We here show, that mutations in NPHS1 may result in heterogeneous expression patterns of the truncated protein. We also found a directly observable link between insertion of nephrin in the slit diaphragm and normal foot process morphology. Taken together, these data suggest potential therapeutic interventions targeting proteasomal degradation of nephrin as a novel treatment strategy in selected patients with congenital nephrotic syndrome.

**A Delayed Diagnosis of Gordon Syndrome: Better Late Than Never!**

Megnukshi Sambharia, Christie P. Thomas, L sama A. Nousreddie. University of Iowa, Iowa City, IA.

**Introduction:** Gordon syndrome, also known as Pseudohypoaldosteronism Type II (PHA-II) or Familial Hyperkalemic Hypertension (FHH), is a rare Mendelian syndrome causing hypertension(HTN), hyperkalemia and non-anion gap metabolic acidosis. Genes responsible are the with-no-lysine kinase 1 and 4 (WNK1/WNK4), kelch-like 3 (KLHL3) and culin 3 (CUL3). WNK1/WNK4 are expressed in the DCT, collecting tubule and collecting duct. WNK4 reduces cell surface expression of the thiazide sensitive Na-Ci co-transporter (NCC) and the potassium channel, ROMK. WNK1 prevents WK4 from interacting with NCC. KLHL3 and CUL3 are part of a ubiquitin ligase complex that targets WNK4 for degradation. While FHH from WNK1, WNK4 and CUL3 have an autosomal dominant (AD) mode of inheritance, disease from KLHL3 can be autosomal recessive (AR) or AD. AR disease presents at an earlier age with severe hypertension and hyperkalemia.

**Case Description:** A 56-year-old Caucasian male with history of recurrent atrial fibrillation with multiple cardioversions was referred to renal clinic for evaluation of chronic hyperkalemia. Upon presentation, he had been on furosemide 40mg and sodium polystyrene sulfonate (SLS) 30mg daily for the last 6 years for K+ values as high as 7 mEq/L.

Burden of Alport Syndrome in the United States: A Retrospective Study

**Background:** To understand patient characteristics, treatment patterns and natural history of patients diagnosed with Alport syndrome (AS) in the US.

**Methods:** The study was a retrospective, observational cohort study of electronic health records (EHRs) in the Optum Humedica database. Patients were identified from January 1, 2000 to March 31, 2018, with at least 1 year of activity prior to the AS diagnosis. All patients had 12 months of activity prior to the AS diagnosis.

**Results:** A total of 628 patients met the AS criteria; 624 were matched with 2,496 non-AS controls. Median age was 38 years (47.6% were 40 years or older) and 43% were female. All patients had 12 months of activity prior to the AS diagnosis.

**Conclusions:** Alport syndrome has a significant unmet medical need due to the burden of kidney disease and short time to onset ESRD.

A Case with Somatic and Germline Mosaicism in COL4A5 Detected by Multiplex Ligation-Dependent Probe Amplification in X-Linked Alport Syndrome

**Introduction:** X-linked Alport syndrome (XLAS) is a progressive hereditary kidney disease caused by mutations in COL4A5 gene encoding the type IV collagen α5 chain. To date, 11 cases with somatic mosaicism in COL4A5 have been reported; however, all of them involved single-nucleotide variations (SNVs). Copy number variations (CNVs) in COL4A5 have also been reported, and pathogenic CNVs are relatively rare. Here, we report a female XLAS patient with somatic mosaicism identified by CNVs in COL4A5.

**Case Description:** The case was a 35-year-old female, the mother of the proband, whose only clinical symptom was hematuria. The proband was the son of this patient. His hematuria was detected at 3 months of age, and gross hematuria was occasionally exhibited. At the age of 2, proteinuria was detected, and then kidney biopsy was performed. The pathological findings showed diffuse thin basement membrane and partial basket-weave capillaries. His hematuria was detected at 3 months of age, and gross hematuria was occasionally exhibited. His hematuria at the age of 2, proteinuria was first detected by MLPA. This information was important for the genetic counseling of the patient.

**Discussion:** Previous XLAS cases with somatic mosaicism in COL4A5 had SNVs, and these changes could be detected by sequencing analysis. In contrast, our case had somatic mosaicism of CNVs in COL4A5. CNVs in COL4A5 are relatively rare (5%) and are rarely diagnosed with XLAS with somatic mosaicism.

**Results:** We have identified 23 mutations, 13 being novel and 10 previously reported. We are presenting genotype-phenotype correlation for Croatian patients with X-linked AS. Next generation sequencing for COL4A3, COL4A4 and COL4A5 was performed as part of the nationwide project “Genotype-phenotype correlation in Alport syndrome and thin basement membrane nephropathy (TBMN)”. We were 24 male and 26 female patients from 36 unrelated families. Probands were selected based on the kidney biopsy findings.

**Results:** We have identified 23 mutations, 13 being novel and 10 previously reported. In two patients additional COL4A4 mutations were found. Male patients, median age 27 years, presented with hematuria (95%), proteinuria (91%), sensorineural hearing loss (27%) and ocular changes (4.5%). Most patients (62%) had normal, 17% mildly and 21% moderately reduced kidney function. No one had severe renal insufficiency or ESRD. Kidney biopsy was performed in 18 male patients and AS was the most common diagnosis (67%) followed by TBMN with FSGS (17%) and isolated TBMN (11%). In one patient (5%) the diagnosis was inconclusive for AS or TBMN. Female patients, median age 16 years, presented with hematuria (89%) and proteinuria (19%). There were no ocular abnormalities and the hearing loss was present in 5% of patients. Most females (73%) had normal kidney function while 8% had mild, 12% moderate, 3.5% severe reduction of renal function and 3.5% had ESRD. The kidney biopsy was performed in 14 female patients. The most common diagnosis was AS (65%) followed by isolated TBMN (21%) and TBMN with FSGS (7%). Only 1 specimen (7%) was signed out as inconclusive for AS or TBMN.

Clinomics Implementation in the Mayo Clinic Nephrology Practice

Table 1: Results of Genetic Analysis by Disease Group

POI667

CD11b Activation Suppresses Pro-Inflammatory suPAR in Myeloid Cells and Reduces Lupus Nephritis in Mice

Background: Lupus nephritis (LN) is a debilitating glomerular disease and a comorbidity of systemic lupus erythematosus (SLE). CD11b, the alpha-chain of integrin CD11b/CD18, plays a critical role in cell signaling. Several mutations in the gene ITGAM, encoding CD11b, are associated with SLE and LN, these mutations are reported to reduce integrin function. suPAR is produced by myeloid cells upon pro-inflammatory stimulation. suPAR is downstream of CD11b activation and is a circulating risk factor for glomerular diseases. suPAR is downstream of CD11b activation and is a circulating risk factor for glomerular diseases. suPAR is produced by myeloid cells upon pro-inflammatory

Results: In silico predictions, disease database classifications and functional characterization were performed.

Discussion: In silico predictions and functional characterization classified all 9 definitely pathogenic COLA43/A4/AS variants in the FSGS cohort correctly. In silico predictions classified the majority (93-97%) of definitely pathogenic COLA43/A4/AS variants in ClinVAR, ARUP, and LOVD. However, a significant proportion of benign variants were predicted as pathogenic. Thirty-five percent of COLA43/A4/AS missense variants obtained from gnomAD were also predicted deleterious. In silico predictions tended to overestimate the effects of COLA4 variants of uncertain significance (VUS) when compared to functional characterization.

POI668

Drug-Induced Thrombotic Microangiopathy as a “Second-Hit” Phenomenon

Introduction: Thrombotic Microangiopathy (TMA) syndrome is a diverse group of inherited or acquired diseases characterized by microvascular thrombosis and endothelial damage. TMA includes diseases such as thrombotic thrombocytopenic purpura, strokes due to medullary uremic syndrome (HUS), and complement mediated HUS. Environmental triggers are proposed as a second hit precipitating the disease process in some cases of typical HUS. We hereby present a case of drug induced TMA in a patient with an underlying pathogenic mutation for aHUS.

Case Description: 41-year-old male with presented to an outside hospital with AKI requiring dialysis and uncontrollable hypertension. He had a positive urine toxicology admittance to marijuana, amphetamines (crystal meth), and heroin use. Labs revealed severe anemia and thrombocytopenia. C3 and C4 were reduced and low in some cases of atypical HUS. The patient was treated with apheresis and dialysis dependent on discharge. Unfortunately, he was then lost to follow up.

Discussion: Thrombotic Microangiopathy (TMA) syndrome is a diverse group of inherited or acquired diseases characterized by microvascular thrombosis and endothelial damage. TMA includes diseases such as thrombotic thrombocytopenic purpura, strokes due to medullary uremic syndrome (HUS), and complement mediated HUS. Environmental triggers are proposed as a second hit precipitating the disease process in some cases of typical HUS. We hereby present a case of drug induced TMA in a patient with an underlying pathogenic mutation for aHUS.

In Silico Prediction Performance for Type IV Collagen Variants

Cole Shulman,1 Emerald Liang,1 Misato Kamura,1 Khalil Udwan,2 Tony Yao,2 Daniel C. Catran,3 Heather N. Reich,4 Michelle A. Hladunewich,6 York P. Pei,6 Judith A. Savige,5 Andrew Paterson,1 Mary Ann Suico,5 Hirofumi Kai,5 Mourita Baru,5 Kumanoto Daigaku, Kumanoto, Japan; Sunnybrook Health Sciences Centre, Toronto, ON, Canada; Toronto General Hospital, Toronto, ON, Canada; Hospital for Sick Children, Toronto, ON, Canada; The University of Melbourne, Melbourne, VIC, Australia.

Background: Advances in genomics technology and knowledge has led to increased sequencing for diagnosis, including in kidney disease. However, sequencing can reveal rare missense variants for which the relationship to disease is unclear. To address this need, in silico programs have been developed to assign variant categorization. Recently, pathogenic variants in COLA43/A4/AS have been reported to account for a significant proportion of chronic kidney disease. Here we evaluate the performance of in silico programs for type IV collagen variants.

Methods: Rare COLA43/A4/AS missense variants were identified in an FSGS cohort, unscreened controls (gnomAD) and disease databases (ClinVAR, ARUP, LOVD). Comparisons between in silico predictions, disease database classifications and functional characterization were performed.

Results: In silico predictions and functional characterization classified all 9 definitely pathogenic COLA43/A4/AS variants in the FSGS cohort correctly. In silico predictions classified the majority (93-97%) of definitely pathogenic COLA43/A4/AS variants in ClinVAR, ARUP, and LOVD. However, a significant proportion of benign variants were predicted as pathogenic. Thirty-five percent of COLA43/A4/AS missense variants obtained from gnomAD were also predicted deleterious. In silico predictions tended to overestimate the effects of COLA4a variants of uncertain significance (VUS) when compared to functional characterization.
Conclusions: Our results demonstrate that in silico programs are sensitive but not specific, leading to many putative or uncertain variants. Limitations of our computational work include overestimation of in silico program sensitivity given that they have likely been used in the categorization of variants labelled as pathogenic in disease databases; and the lack of clinical data to correlate rare variants in gnomAD controls.

Goldstein,1 Simone Sanna-Cherchi,1 Sanna Cherchi Lab 3 Columbia University Irving Medical Center, New York, NY; 2Divisione di Nefrologia, Ospedale di Montichiari, Brescia, Italy; 3Department of Pediatrics, University Hospital of Split, Split, Croatia; 4Department of Pediatric Nephrology, Dialysis and Transplantation, University Hospital Center Zagreb, Zagreb, Croatia; 5Department of Medicine, University of Bari Aldo Moro, Bari, Italy; 6Saint Louis University Medical School, Saint Louis, MO; 7Division of Nephrology, Nephropathy, Dialysis, and Transplantation, University of California, Los Angeles, CA; 8Division of Nephropathy, Department of Medical Sciences, University of Milan, Milan, Italy; 9Department of Internal Medicine and Nephrology, University of Parma, Parma, Italy; 10Department of Nephrology, Dialysis and Transplantation, University of Genoa, Genoa, Italy; 11Nephrology and Dialysis, Belcolle Hospital, Viterbo, Italy; 12Pediatric Nephrology, University of California Los Angeles, Los Angeles, CA; 13Renal Unit, Department of Medicine, University Hospital of Verona, Verona, Italy; 14Clinical and Experimental Medicine Dept, University Hospital of Parma, Parma, Italy.

Background: Idiopathic nephrotic syndrome (NS) is a major cause of renal failure. NS and its complications, including venous thrombosis, hypercholesterolemia and cancer display strong genetic predisposition. We hypothesize that the utility of exome sequencing (ES) will optimize precision medicine for clinical management of NS and its factors.

Methods: ES was performed in 2007 NS patients with variable onset age and steroid responsiveness. ACMG guidelines for clinical variant interpretation were used to classify monogenic causes and risk predisposition for a) NS in curated gene lists (glomerulopathies, N=127; expanded nephropathies, N=679); b) Incidental variants in 59 ACMG actionable-genes; c) Genetic risk for NS complications (Coagulation, N=100; lipid metabolism/cardiovascular risk, N=35); d) Germline cancer predisposition (N=77).

Results: We identified a monogenic cause for NS in 13% of cases, with COL4A3 (2.2%), COL4A5 (1.8%) and WT1 (1.3%) representing the lead causes. Monogenic causes were enriched in FSGS and steroid resistant nephrotic syndrome cases. Analysis of the expanded nephropathy gene panel revealed an additional diagnostic rate of ~1%, representing coincidental diagnoses or phenocopies.

Conclusions: Our results reveal the importance of ES in the diagnosis of NS and its complications, with implications in risk stratification and clinical management. We showed that one every 4 cases carried a genetic variant that has potential to help clinicians optimize precision medicine approaches at the single-patient level. Our results enable designing cost-effective panels to maximize yield in routine clinical practice.

PO1671

Additional Mutations in NRIP1 in Families with Congenital Anomalies of the Kidneys and Urinary Tract (CAKUT)

Bixia Zheng,1 Sophia Schneider, Konstantin Deutsch, Chunyan Wang, Steve Seltzma, Makiko Nakayama, Chen-Han W. Wu, Shirlee Shril, Friedhelm Hildebrandt.1 Boston Children’s Hospital, Boston, MA.

Background: Congenital anomalies of the kidneys and urinary tract (CAKUT) are the most common cause of chronic kidney disease in the first three decades of life. In a previous study, we identified a dominant mutation in nuclear receptor interacting protein 1 (NRIP1) as causing urinary tract malformations via dysregulation of retinoic acid signaling (JASN 28:2364, 2017), which remains the only family with NRIP1 mutation reported so far.

Methods: To identify additional families with NRIP1 mutations, we performed whole exome sequencing (WES) in 232 families with CAKUT. We also screened for mutations in NRIP1 in a cohort of 59 affected individuals with small kidneys and a suspected diagnosis of nephropensorphysis (NPHP).

Results: By WES analyses, we discovered three heterozygous mutations (one frameshift and two missense) in three unrelated CAKUT families. In particular, individual B3864 with bilateral hydrourereteronephrosis and right grade 5 vesicoureteral reflux (VUR) carried a heterozygous frameshift variant (c.2028_2031del; p.Asn676fs*27). Individual A3460 with left renal agenesis harbored a heterozygous missense variant (c.970C>T; p.His324Ty). In individual A782 with right renal agenesis, we identified a heterozygous missense variant (c.1343G>A; p.Arg448Gln). Family B3977 with an NPHP diagnosis, showing bilaterally increased echogenicity and corticomedullary cysts, carried a heterozygous missense variant (c.2252T>G; p.Leu751Arg). The four variants occurred 2, 0, 2, and 17 times, respectively as heterozygous in the gnomAD database of 125,000 healthy control individuals. All affected individuals exhibited an isolated CAKUT phenotype.

Conclusions: This study confirms that germline mutations in the transcription co-factor NRIP1 gene are a novel genetic cause of human autosomal dominant CAKUT and strengthens the association between retinoic acid and renal malformations.

PO1672

Recessive Mutations in SEMA3G as a Potential Novel Cause of Nephrotic Syndrome

Florian Buergel1, Verena Klambt,1 Ana C. Onuchic-Whitford,12 Ronen Schneider,1 Konstantin Deutsch,1 Amar M. Jamundar,1 Shirlee Shril,1 Friedhelm Hildebrandt,3 Boston Children’s Hospital, Boston, MA; 4Brigham and Women’s Hospital, Boston, MA.

Background: Steroid resistant nephrotic syndrome (SRNS) is the second leading cause of chronic kidney disease in the first three decades of life. The identification of monogenic causes of SRNS has revealed ~60 single-gene etiologies. While in 12-30% of patients with SRNS a causative mutation may be detected, many remain without a molecular diagnosis (Sadowski JASN 26:1279, 2015). These genes are predominantly expressed in glomerular podocytes and the encoded proteins merge onto molecular complexes and pathways that are essential to podocyte development or homeostasis.

Methods: To identify novel monogenic causes of NS, we performed whole exome sequencing (WES) in an international cohort of 1,382 NS patients.

Results: We identified homozygous mutations in SEMA3G in 3 unrelated children with nephrotic syndrome, 1 nonsense mutation (c.1079C>T; p.Arg360*), 1 essential splice site mutation (c.460-2A>G, predicted to lead to skipping of exon 5 and thus causing a frame-shift and truncation of the protein) and 1 missense mutation (c.2225G>A, p.Arg742Gln). SEMA3G is a secreted protein that has been implicated in cell migration and axon guidance, and shown to protect podocytes from inflammatory kidney disease in a mouse model (Ishibashi Sci Rep 6:25955, 2016). We evaluated publicly available kidney single-cell RNA sequencing datasets and found SEMA3G to be predominantly expressed in podocytes (Karaiskos JASN 29:2060, 2018). We then performed co-immunofluorescence staining in adult rat kidney sections for SemA3g and established markers of podocytes (neprhin), endothelial cells (CD31), and mesangial cells (oSMa). The SemA3g signal was strongest in podocyte foot processes as indicated by partial overlap with nephrin but lack of overlap with CD31, or oSMa signal.

Conclusions: We, here, identified recessive mutations in SEMA3G as a potential novel cause of nephrotic syndrome in children.

Gaslini, Genoa, Italy, Genoa, Italy.

Background: Several focal segmental glomerulosclerosis (FSGS) genes have been discovered through family studies. Rare-variant case-control studies, however, have been largely underpowered and/or restricted to a single ancestry.

Methods: We performed exome sequencing of 1,998 cases with FSGS and compared them to 18,835 controls. Using gene-based collapsing, we looked for genes with an excess of rare qualifying variants (QVs) in cases or controls. Standard collapsing was complicated by the diverse ancestry of our cases that not only included African, Asian, and Hispanic samples, but also Caucasian subpopulations not well represented in public databases or our controls. Therefore, we extended our collapsing workflow by a clustering step based on principal components reflecting ancestry. We performed coverage harmonization and frequency filtering within the clusters to capture population-specific differences. We used the Cochran-Mantel-Haenszel test to test for an association between disease status and QV status while controlling for cluster membership.

Results: Collapsing analyses were conducted on all cases together and on pediatric, adult, African, Asian, and steroid-sensitive subgroups. We detected a significant enrichment of QVs in known FSGS genes WT1, INF2, and NPHS2; additional signals in other FSGS genes (e.g. PAX2, COL4A3, COL4A5, CD2AP); and two novel ones that did not reach study-wide significance due to the limited sample size and phenotype heterogeneity. In several models and subgroups, the majority of the top 10 genes was formed by known FSGS genes, confirming the robustness of our novel approach.

Conclusions: We show that our new collapsing approach decreases inflation when samples with different ancestries are analyzed together, while preserving the underlying disease signals. We are currently more than doubling our case cohort, which should increase the power to detect significant signals in known FSGS genes, clarify the suggestive signal in two new genes, and allow well-powered sub-phenotype analyses.

Alpha Lipoic Acid Supplementation Prevents the Age-Related Decrease in Nuclear Reduced Glutathione Levels in Kidneys from Old Female Lewis Rats

Mariania J. Zamiausk-Tucker, Bingwei Ye. Ball State University, Muncie, IN.

Background: The purpose of the present study was to investigate whether supplementation with alpha lipoic acid reverses the decrease in nuclear reduced glutathione (GSH) levels in kidneys from old rats. GSH is the major antioxidant inside cells, and a decrease in GSH levels is associated with increased oxidative damage caused by free radicals.

Methods: There were three groups of female Lewis rats used in the study. The Young Control rats (n=4) were 3 months of age, the Old Control rats (n=4) were 22 months of age, and the Old Experimental rats (n=4) were 22 months of age. Only the Old Experimental rats received alpha lipoic acid (100 mg/Kg body wt) by i.p. injection for one week. The kidneys were harvested from anesthetized rats, and the cortex and medulla were separated and homogenized. The nuclear fractions were isolated using differential centrifugation. The GSH levels were measured with a spectrophotometric assay. Comparisons between groups were done using ANOVA followed by the Fisher’s LSD post hoc test. All data are shown as X ± SEM. Statistical significance was determined at p ≤ 0.05.

Results: Supplementation with alpha lipoic acid reversed the age-related decrease in nuclear GSH levels in the kidney cortex and medulla from old rats. The GSH levels were not different from the levels observed in young rats.

Conclusions: The findings suggest that dietary supplementation is beneficial to cell nuclei in rat kidney by preventing the decrease in GSH levels observed with age.

PO1674

eNOS/NO Signaling Attenuates Progression of Age-Related Kidney Diseases via Suppression of Inflammammasome

Background: Ageing affects the function of the immune system and leads to immunosenescence, which is characterized by defective immune responses and increased systemic inflammation (also termed inflamaging). Inflamaging is maladaptive and results from multiple mechanisms, including aberrant inflammasome activation. The ASC is an essential component of inflammasome. Endothelial dysfunction is also a common pathophysiology of aging-related organ damage. Nitric oxide (NO) produced by endothelial nitric oxide synthase (eNOS) is an important mediator in the maintenance of vascular homeostasis. We’ve reported that the eNOS-NO pathway attenuates the progression of kidney injury via suppression of inflammasomes. However, the relationship between the eNOS-NO pathway and inflamaging in the kidney remains unclear. To determine if the eNOS-NO pathway attenuates kidney damage via the regulation of inflammasome in ageing kidney, we used eNOS-deficient mice (eNOSKO) and eNOS-ASC double-knockout mice (eNOS-ASC-DKO).

Methods: Wild-type mice (WT) and eNOSKO were used to determine the role of the eNOS-NO pathway in ageing kidneys. WT and eNOSKO were sacrificed at 18 months of age to harvest kidney tissue. The localization of inflammasome activation in the kidney was evaluated with immunohistochemical analyses. To determine the role of inflammasomes in ageing kidneys, we generated eNOS-ASC-DKO. The mRNA expression of inflammasome components were determined in isolated glomeruli.

Results: The glomerular injury was more exacerbated in eNOSKO-18M than in WT-18M. In the immunohistochemical, the expression of ASC coexisted with the macrophages detected by F4/80 staining in eNOSKO-18M. These data suggested that the inflammasome activation was located in the macrophages. In the isolated glomeruli, mRNA of inflammasome components were higher in eNOSKO-18M than in WT-18M. The glomerular damage were ameliorated in eNOS-ASC-DKO-18M compared to eNOSKO-18M. In summary, in eNOSKO, inflammasomes were activated in macrophages, and interstitial fibrosis was exacerbated. However, in eNOS-ASC-DKO-18M mice, the tubulointerstitial damage was attenuated.

Conclusions: Endothelial NOS/NO signaling ameliorates kidney damage in the aging process via the modulation of inflamaging associated with inflammasome-activation.
SIRT3 Confers Protection and Mediates Sex Differences in Aging-Related Kidney Injury
Huiyun Shen,1 Michael Holliday,1,2 Qingtian Li,1 Li Tan,1,3 David Sheikh-Hamad,1,2 Jenny S. Pan,1,2 Baylor College of Medicine Department of Medicine - Nephrology; Houston, TX; 1Michael E. DeBakey VA Medical Center; Renal Section, Houston, TX; 2West China Hospital, Chengdu, China.

Background: Fibrosis and mitochondrial dysfunction are hallmarks of most progressive kidney diseases. Studies suggest women have slower progression of CKD and lower ESKD incidence before menopause vs. men. SIRT3, a major mitochondrial acetyltransferase, is critical in maintaining mitochondrial homeostasis and anti-inflammatory defense. We observe higher kidney mitochondrial SIRT3 (mSIRT3) in females vs. males. mSIRT3 declines with age but sex differences persist. We hypothesize that SIRT3 protects from and mediates sex differences in aging-related kidney injury and fibrosis.

Methods: Male and female WT, SIRT3 transgenic (Tg), inducible kidney tubule-specific SIRT3 knockout (KO) or global SIRT3 KO mice were aged under physiologic conditions. Kidney fibrosis was detected by trichrome staining and expression of fibrosis markers (α-SMA; fibronectin). 6-month (mo) old male or female WT mice were treated with S.C. implantation of a 200 mg, 21-day-release testosterone pellet for 3 wks.

Results: In male mice, we observed that lower kidney mSIRT3 expression vs. age-matched females is associated with higher baseline ROS generation, and development of tubular cytoplasmic vacuoles by 6-mo and fibrosis by 14-mo. Aging-related changes are attenuated in SIRT3 Tg males. Conversely, 6-mo iKO male mice display higher ROS, tubular injury and fibrosis vs. age-matched control males. In contrast to male mice, WT females display minimal tubular vacuolization or fibrosis at 14-mo. SIRT3 knockout aggravates tubular injury and fibrosis in aged 14-mo iKO females; outcomes similar to WT males. Furthermore, young (2-3 mo) male and female global SIRT3 KO mice display baseline kidney injury characterized by: increased urinary albumin excretion, ROS and tubular injury vs. WT. Mechanistic studies show that testosterone (T) administration to WT males increased serum T ~4-fold, decreased kidney mSIRT3, and caused kidney injury (decreased CrCl and increased tubular vacuolization). T increased kidney mSIRT3 and caused no measurable kidney injury in WT females, possibly due to an associated increase in serum estradiol.

Conclusions: 1) SIRT3 is critical for kidney tubular epithelial cell survival under physiologic conditions, and inhibits development of tubular injury and fibrosis in aged kidneys; 2) sex-dependent differences in kidney SIRT3 expression may mediate sexual dimorphism in CKD outcomes.

Efficient Follow-Up and Its Effects on Questionnaire Responses in the EQUAL Study in the United Kingdom
Emer R. Gates,1 Barnaby D. Hole,1,2 Samantha J. Hayward,1,2 Fergus J. Caskey,1,2 EQUAL Investigators ’North Bristol NHS Trust, Westbury on Trym, United Kingdom; ’University of Bristol, Bristol, United Kingdom.

Background: Minimising patient contact is more important amidst the COVID-19 pandemic; yet altering follow-up data collection methods may introduce unintentional bias. We describe our findings from the European Quality (EQUAL) study in which UK patients switched from ‘traditional’ clinic follow-up (TFU) to ‘efficient’ postal follow-up (EFU).

Methods: EQUAL is a prospective study on treatment in people aged ≥65 with advanced chronic kidney disease (eGFR <20/mL/min). UK patients were recruited to EQUAL from 2013-2017. During TFU, patients were invited to complete a questionnaire (SF-36, Dialysis Symptom Index and Renal Treatment Satisfaction Questionnaire) at research clinics every 3-6 months. In 2018, all alive patients were invited to switch to EFU, which used an abbreviated questionnaire administered centrally by post. Questionnaire response and error rates for six-monthly TFU and the first EFU are presented for UK patients who consented to EFU.

Results: In total, 506 UK patients were recruited. In 2018, 236 of these patients were alive and almost half (n=111) consented to the change in follow-up. Of those consenting to EFU, response rates fell from 88.2% (98/111) to 59.0% (65/110) for patients who completed 1.5 years of TFU. Of those who were recruited earlier and had completed 3.5 years of TFU, response rates fell again to 20% (3/15). The response rate for the first EFU questionnaire was 59.6% (59/99) of those alive. Errors almost trebled throughout TFU, before falling to baseline at the first EFU.

Conclusions: In this prospective study of older people with advanced CKD, response rates fell and error rates rose during TFU. On introducing a shorter postal questionnaire, response and error rates improved to levels resembling early TFU. This suggests that even in older people with advanced CKD, returning questionnaires by post is acceptable and may provide more complete data than costly TFU. This is acutely relevant in this period of limited contact in the COVID-19 pandemic.
CKD in the Very Elderly: When Is It Only Aging?

Background: Chronic kidney disease (CKD) diagnosis is increasingly common in the elderly and is associated with increased morbidity and mortality. As life expectancy increases, so does the prevalence of risk factors for CKD such as hypertension and diabetes. On the other hand, it is known that over 40 years, glomerular filtration rates decrease progressively, in a process called renal senescence. This study aims to identify risk factors for progressive CKD versus renal senescence in patients over 80 years.

Methods: We developed a single center retrospective study with 101 patients over 80 years of age. eGFR was calculated by a nephrologist with CKD (estimated glomerular filtration rate (GFR) = 60 mL/min/1.73 m²) diagnosed for at least for 5 years. Progressive disease was defined as GFR decline greater than 5 mL/min/1.73 m²/year and in about 66% GFR decline rate was less than 5 mL/min/1.73m²/year.

Results: Of 101 patients, 55.4% (n = 56) were male. Thirty eight percent presented CKD complications, 37.6% had anemia and 18.7% needed hypothyroid-stimulating agents. No patient was under phosphate binders and 4% needed vitamin D analogues. About 20.9% presented metabolic acidosis requiring supplementation. In the progressive CKD group, there was a higher prevalence of obesity (OR 4.1, p = 0.04) and metabolic acidosis (OR 6.1, p = 0.01). Nephrologist follow-up time was also statistically different (13.1 ± 9.6 years versus 8.4 ± 6.6 years) in the progressive CKD group.

Conclusions: In over 80 years, average rate of progression of CKD was 2.0 mL/min/1.73 m²/year, which, associated with the reduced life expectancy of patients in this age group, allows us to state that the vast majority will not reach CKD stage 5.

Using the Difference in Estimated Glomerular Filtration Rate by Cystatin C vs. by Serum Creatinine (eGFRdiff) to Assess Muscle Mass and Frailty in Older Adults
O. Alison Potok,1 Joachim H. Is,1 Michael Shlipak,2* Nisha Bansal,3 Ronit Katz,4 Stephen B. Kritchevsky,1 Dena E. Ritkin,1,4 University of California San Diego, La Jolla, CA; 2University of Washington, Seattle, WA; 3Wake Forest University School of Medicine, Winston-Salem, NC; 4San Francisco VA Medical Center, San Francisco, CA; 5University of California San Francisco, San Francisco, CA; 6VA San Diego Healthcare System, San Diego, CA.

Background: Preliminary work has shown that the difference in estimated glomerular filtration rate by cystatin C vs by creatinine (eGFRdiff) is associated with frailty and mortality. As creatinine is influenced by muscle mass, more so than creatinine, we aim to determine whether muscle mass explains the relationship between eGFRdiff and frailty.

Methods: In the Health Aging Body Composition study, 2980 (97% of HABC) had baseline GFR calculated using CKD-EPI equations (cystatin-based [eGFR Cys] and creatinine-based [eGFR Cr], respectively), and eGFRdiff was defined as eGFR Cys - eGFR Cr. Total thigh muscle area was evaluated on computed tomography. Frailty was scored on a continuous scale based [eGFR Cys] and creatinine-based [eGFR Cr].

Results: Mean age was 74 (± 7) years, eGFR Cys was 72 (± 15) mL/min/1.73 m². Compared to participants with minimal difference in eGFR (within 10 mL/min/1.73 m²), those in the positive eGFRdiff group (≥ 10 mL/min/1.73 m²) were less likely to have fallen in the past year (19% vs. 21%), had stronger grip strength (31 vs. 30 kg) and walked faster (1.22 vs. 1.17 m/s). Higher eGFRdiff was significantly associated with larger thigh muscle area. In cross-sectional analyses, each 1 SD increment in eGFRdiff was associated with 30% lower odds of frailty.

Conclusions: Preliminary work has shown that the difference in estimated glomerular filtration rate by cystatin C vs by creatinine (eGFRdiff) is associated with frailty and mortality. As creatinine is influenced by muscle mass, more so than creatinine, we aim to determine whether muscle mass explains the relationship between eGFRdiff and frailty.

The Difference in eGFR by Cystatin C vs. Creatinine Is Strongly Associated with Mortality Independent of Measured GFR
O. Alison Potok, Dena E. Ritkin, Joachim H. Is, Michael Shlipak, Alice Schneider, Nina Mielke, Elke Schaeffner, Natalie Ebert.1 University of California San Diego, La Jolla, CA; 2San Francisco VA Medical Center, San Francisco, CA; 3Charité Universitätsmedizin Berlin, Berlin, Germany; 4VA San Diego Healthcare System, San Diego, CA; 5University of California San Francisco, San Francisco, CA.

Background: In preliminary work, we have shown that the difference in glomerular filtration rate (eGFR) estimated by cystatin C [eGFR Cys] and creatinine [eGFR Cr], was associated with risk of frailty, hospitalization, cardiovascular events and mortality. Prior studies lacked directly measured GFR so it remained uncertain if associations were influenced by kidney function.

Methods: 567 participants of the Berlin Initiative Study (BIS) had baseline GFR measured by ioehoxel clearance (mGFR), as well as serum creatinine and cystatin C levels. eGFR Cys and eGFR Cr were calculated using CKD-EPI equations, and eGFRdiff was defined as eGFR Cys - eGFR Cr. Mortality was recorded during up to 8 years follow-up. The association between eGFRdiff and mortality was assessed using Cox regression.

Results: Average (SD) age was 79 (± 6) years, eGFR Cys 63 (± 21), and eGFR Cr 69 (± 17) for an eGFRdiff of -6 (± 12) mL/min/1.73m². Compared to participants with minimal differences in eGFR, those with a substantially positive difference eGFRdiff (a10 mL/min/1.73 m²) were younger (76 vs. 78 years), less diabetic (17% vs. 24%) and fewer took antihypertensives (59% vs. 76%). Those with a substantially negative eGFRdiff (< -10 mL/min/1.73 m²) were at much higher death risk which was minimally increased with or without adjustment for measured GFR, age, sex, and urine albumin/creatinine ratio (Table).

Conclusions: In BIS, an eGFR Cys estimate that was substantially less than an eGFR Cr estimate was associated with significantly higher risk of death. This association remained after adjusting for mGFR. Important clinical information beyond kidney function is embedded in eGFRdiff.

Funding: Private Foundation Support

Table. Association of eGFRdiff with Mortality in Older Adults in the Berlin Initiative Study

Outcomes of Haemodialysis in Incident Elderly Haemodialysis Patients: Single-Centre Experience
Rouskas Gama, Jocelyn Heins, David Makanjuola, Subash Somalanga. St Helier Hospital, Carshalton, United Kingdom.

Background: In the UK, elderly patients represent the most rapidly expanding group of the dialysis population. However, there remains little evidence to suggest improved quality of life or increased life expectancy, particularly in those over 80 years old.

Methods: We retrospectively reviewed patients who were initiated on haemodialysis (HD) between January and October 2019 in a tertiary renal centre in the United Kingdom. Data were collected using an electronic database. Baseline characteristics, 3 and 12-month mortality were recorded. Data were presented as counts with percentages and mean ± SD.

Results: There were 263 patients initiated on HD, of which 120 (45.6%) were over 70 years, 67 were aged 70-79 years (group A) and 53 were aged 80-90 years (group B). Mean age was 78.1 ± 5.3 years and 74% were of white ethnicity. Baseline characteristics are summarized in table 1. Sixty patients remained on HD, 14 recovered, 6 moved to other modalities and 40 died. The 90-day mortality was 21% (18% in group A, 25% in group B); 6-month mortality was 35% (35% in group A and 44% in group B); 1-year mortality was 35% in group A and 35% in group B. In those established on HD (>90 days), 1-year mortality was 12% (17% in group A, 4% in group B).

Conclusions: We report a high 1-year mortality of 35% in the elderly population. However, the majority occurred during the 1st 90 days. For those established on HD, mortality is 12%; this is substantially lower than the UK renal registry data for over 75s which was 23% in 2017. Mortality was comparable between age groups, although we were limited by small sample size. A key question is whether there is a difference in quality of life and life expectancy in this cohort.
Baseline characteristics and mortality in elderly incident haemodialysis patients.

POI1684
Cost Effectiveness Study of Hyperkalemia Management
Nihar Desai,1 Christopher G. Rowan,2 Paula J. Alvarez,3 Jeanene Fogli,3 Steven G. Coca,4 *Yale University, Center for Outcomes Research and Evaluation, New Haven, CT; 3COHRDATA, Santa Monica, CA; 4Relypsy, Inc., a Vifor Pharma Group Company, Redwood City, CA; 5Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** Patiromer (PAT) is a sodium-free, non-absorbed potassium (K⁺) binder approved for the treatment of hyperkalemia (HK). There is limited real-world evidence on the cost implications associated with PAT treatment of HK. The objective of this study was to assess the cost-effectiveness of treating HK with PAT vs. no K⁺ binder in a Medicare Advantage population.

**Methods:** This retrospective, matched cohort study was conducted using the de-identified Optum Clinformatics® Data Mart Database from 1/1/16–12/31/18. Two HK cohorts were identified: PAT exposed and unexposed (NoPAT). Patient inclusion criteria included pre-index serum K⁺ ≥5.0 mEq/L and HK diagnosis (ICD-10 code) and ≥6 months insurance enrollment post-index. Propensity score matching and censored exact matching with baseline variables were used to identify the complete set of matching unexposed and exposed HK episodes. Follow-up began on index date and ended at the first censoring event (insurance disenrollment, death, 12/31/18, sodium polystyrene sulfonate or sodium zirconium cyclosilicate initiation, PAT discontinuation [exposed only], PAT initiation [unexposed only]). Cost outcomes were measured over 6 months post-index: total, inpatient, emergency department (ED), outpatient services and outpatient pharmacy (mean US$ [CI 95%]).

**Results:** The study population was 2004 patients (1002 matched pairs). Overall, mean age was 74 years and 60% were male. Patients had a mean of 5 comorbidities. Comorbidities included: DM (73%), CHF (35%), and ESRD (10%). At 6 months post-index, 300 (150 matched pairs) PAT and NoPAT patients remained uncensored. Total PAT mean cost difference (avings) of $7220 ($2211, $9584) was observed at 6 months post-index (P<0.01). This cost difference included a pharmacy increase of $3904 ($964, $2224) and a decrease in medical costs, specifically, inpatient $4718 ($2222, $7215), outpatient $4781 ($2274, $7288), and ED $815 ($488, $1142).

**Conclusions:** At 6 months post-index, PAT cohort observed a 27% reduction in cost compared with the unexposed cohort for HK management. Further study is warranted to replicate these findings in a large cohort.

POI1685
Effects of Veverimer on Serum Bicarbonate and Physical Function in Elderly Patients with Metabolic Acidosis in CKD
Donald E. Wesson,1 Vandana S. Mathur,2 Navdeep Tangri,3 Yuri Stativ,4 Dawn Parsell,5 Elizabeth Li6, Gerrit Klarenbergh7, David A. Bushinsky,8 *Baylov Scott & White Health and Wellness Center, Dallas, TX; 2MathurConsulting, Woodside, CA; 3University of Manitoba, Winnipeg, MB, Canada; 4Tricida, Inc., South San Francisco, CA; 5PharmaStat LLC, Fremont, CA; 6University of Rochester Medical Center, Rochester, NY.

**Background:** Use of NaHCO₃ to treat acidotic pts with CKD increases daily Na load, which may be particularly detrimental to elderly pts who may have hypertension and congestive heart failure. Veverimer is a non-absorbed polymer that treats metabolic acidosis (MA) by binding and removing HCl from the GI tract. It is not an exchange resin and does not introduce unwanted cations such as Na or K. In Phase 3 randomized, blinded, placebo-controlled trials, veverimer significantly increased serum bicarbonate and improved patient-reported objective measures of physical function in pts with MA in CKD (Wesson et al. Lancet, 2019). Here we report data from pts aged ≥65 yrs from these studies.

**Methods:** Patients were treated for up to 1 yr with veverimer or placebo with frequent determinations of blood bicarbonate. Physical function was assessed at Baseline and Weeks 12, 40, and 52 using the KDQOL-PF which quantitates limitations on daily activities and by performance on the repeated chair stand (RCS) test.

**Results:** Of the 217 pts randomized, 113 (52%) were ≥65 yrs (mean 72 yrs). Select comorbidities included HTN (98%), diabetes (67%), and CHF (40%). At Baseline, the mean eGFR was 30.7 ml/min/1.73m² and the mean serum bicarbonate was 17.2 mEq/L. In this elderly cohort, more pts receiving veverimer met the primary study endpoint, had a significant increase in serum bicarbonate, and improved both KDQOL-PF scores and RCS time (Table 1) compared with placebo. These effects of veverimer exceeded the minimal clinically important difference for both the KDQOL-PF (+3 to +5 points) and RCS (-1.7 seconds). Safety was similar in both treatment groups.

**Conclusions:** In older adults with CKD, treatment with veverimer significantly increased serum bicarbonate levels and improved how pts felt and functioned. The safety of veverimer was not different from placebo.

POI1686
Design of a Consensus-Based Geriatric Assessment Tailored for Older Patients Approaching ESKD
Carlin G. Voorhees,1 Noeleen C. Berkhout-Byrne,1 Adry Dienenbroek,2 Casper F. VanJessen,3 Wilma A.W. Jager,1 Simon Mooijart,1 Marjolijn Van Buren,1 on behalf of principal investigators of the POLDER study 1Leids Universitair Medisch Centrum, Leiden, Netherlands; 2Universitair Medisch Centrum Groningen, Groningen, Netherlands; 3Sint Antoniesziekenhuis, Nieuwegem, Netherlands.

**Background:** Routine geriatric evaluation in older patients approaching end stage kidney disease (ESKD), benefits disclosure of highly prevalent unidentified functional and cognitive impairments. Although recommended in guidelines, a suitable standardized geriatric test set is lacking. We aim to propose a consensus-based test set for geriatric assessment useful in both routine care and research in older (≥65 year) patients approaching ESKD.

**Methods:** A multidisciplinary expert panel of physicians, nurses and supportive disciplines with clinical and/or scientific experience in geriatric nephrology was assembled. Preconditions and selection-criteria for the selection of potential measures resulted from general geriatric principles, critical appraisal of literature, inventory of conventional instruments, and focus group meetings with patients, caregivers and health professionals. Older patients (aged ≥65 years) approaching end-stage kidney disease (eGFR < 20 ml/min/1.73M²) were selected as the target population. An expert panel meeting and subsequent round of comments by email led to agreement on the best suitable test set.

**Results:** The final consensus set contains instruments in functional, cognitive, psychologic, and somatic domains, and patient preferences, nutritional status and fall risk. The set comprises a patient questionnaire (six instruments) and a professional-administered test set (including ten instruments). Estimated time for administration in practice was 20 and 40 minutes respectively.

**Conclusions:** We propose a consensus-based nephrology-tailored geriatric assessment, to benefit clinical care for older (pre-)ESKD patients and enhance research comparability. Future research should investigate effectiveness, feasibility of implementation, patient satisfaction and the value for treatment decision making and outcome improvement.

**Funding:** Private Foundation Support

POI1687
Correlation Between Patient-Reported Physical Limitation and Objective Physical Performance on the Repeated Chair Stand Test Among Patients with Non-Dialysis Dependent CKD and Metabolic Acidosis
Vandana S. Mathur,1 Michael Walker,2 Gerrit Klarenbergh,1 MathurConsulting, Woodside, CA; 2Walker Biosciences, Carlsbad, CA; 3Tricida, Inc., South San Francisco, CA.

**Background:** CKD accelerates the loss of physical function, in part due to the development of sarcopenia caused by metabolic acidosis (MA). Decline in the ability to rise from a seated position is consequential as it can lead to loss of independence. However, physical performance is not routinely measured in CKD clinical practice.

**Methods:** We evaluated the correlation between patient-reported limitation on daily activities on the Kidney Disease and Quality of Life Physical Function Domain (KDQOL-PF, a 10-item survey in which possible responses are “not limited at all”, “limited a little”, and “limited a lot”) and the standardized 5-times repeat chair stand time (RCS) using data from a 1 year randomized trial of pts (N = 196) with MA in CKD (Wesson et al. The Lancet, 2019). These measures showed an ability to detect change - pts in the veverimer group improved significantly on both.

**Results:** There was a significant, direct correlation between improvement (i.e., higher score) over 1 yr on the KDQOL-PF total score and improvement on the RCS (i.e., faster time), (Pearson’s product-moment correlation, 0.33, P < 0.001). Additionally, 5 of the 10 individual KDQOL-PF activity limitations correlated significantly with RCS time: “lifting or carrying groceries”; “bending, kneeling, or stooping”; “walking one block”; “walking several blocks”, and “bathing or dressing yourself” (P-value < 0.05 for

Mobility in Older Hemodialysis Patients: A Mixed Methods Study

Christine Liu,1,2 Janet J. Scov,3 Kristen A. Wright,3 Dayeon Lee,3 Jennifer Moye,1,4 Jonathan Bean,1,3 Daniel E. Weiner,1 1Boston University, Boston, MA; 2Tufts University, Medford, MA; 3VA Boston Health Care System Boston Vet Center, Boston, MA; 4Harvard University, Cambridge, MA; 5Mount Sinai Health System, New York, NY.

Background: Mobility, or the ability to move reliably and safely, impacts quality of life and predicts future disability and mortality. This is especially relevant for older adults, who comprise a large part of the hemodialysis (HD) population. For older hemodialysis patients, factors that limit mobility and which specific components of mobility are involved are not well-defined. Using a mixed methods approach, we investigated these factors and components in older HD patients.

Methods: Eligibility criteria were age ≥60 years and receipt of maintenance HD. Participants had a single survivor interview assessment that occurred in their home when feasible. We administered the Short Physical Performance Battery (SPPB) to assess balance, walking speed, and lower leg strength (range 0-12 for full SPPB, range 0-4 for individual domains). We conducted semi-structured key informant interviews, using an interview guide based on the literature. Interview transcripts were descriptive coded and major themes were extracted using both deductive and inductive approaches.

Results: A total of 31 persons enrolled, with an mean age of 72.5±8.1(S.D.) years and mean vintage of 4.6±3.5 years; 42% were female and 68% African-American. Mean overall SPPB was 4.4±3.2 points; mean scores for balance, walking and lower leg strength were 2.3±1.1, 1.8±1, and 1.3±0.7 points, respectively. Mean gait speed was 0.46±0.22 meters/second. Coding inter-rater reliability > 0.8. Three major themes emerged: 1) losses in balance and walking are the most debilitating, 2) fluctuations in mobility are frequent, and 3) post-HD procedure fatigue and the presence of amputations limit mobility (Table). Based on the literature. Interview transcripts were descriptive coded and major themes were extracted using both deductive and inductive approaches.

Funding: Other NIH Support - K23AG057813, Government Support - Non-U.S.

Key themes regarding mobility in older hemodialysis patients

<table>
<thead>
<tr>
<th>Theme</th>
<th>Quote</th>
</tr>
</thead>
<tbody>
<tr>
<td>Symptomatology mobility (i.e. forearm balance and walking)</td>
<td>&quot;Oh, give me more balance or my book will fall every time I take a walk.&quot; (female, age 70)</td>
</tr>
<tr>
<td>Frequent changes in mobility</td>
<td>&quot;I get off the machine, cross the room to the car. ‘Cause I have my good legs and my bad legs they both do it...&quot; (male, age 65)</td>
</tr>
</tbody>
</table>

Conclusions: In a diverse sample of older HD patients, mobility is significantly limited with multiple domains affected. Patients identified balance and walking as the most problematic, and cope with frequent changes in mobility. Future studies should focus on improving balance and walking, and include strategies to mitigate fluctuations in mobility.

Rehabilitation in CKD

Clemens Grupp,1,2 Thomas Tuemena,3,1 Jens Troegner,1 Walter Swoboda,1 Karl-Guentner Gassmann,1 1Academic Teaching Hospital Bamberg, Bamberg, Germany; 2Georg-August University, Department of Nephrology and Rheumatology, Goettingen, Germany; 3GIB-DAT Head Office, Nuernberg, Germany; 4Academic Teaching Hospital St. Marien, Amberg, Germany; 5Waldkrankenhaus St. Marion, Erlangen, Germany.

Background: Older patients with impaired renal function (renal patients: RP) often show the criteria of a geriatric patient with increasing stages of CKD. Geriatric phenomena such as frailty are considered a predictor of poor outcomes particularly during acute illness in these patients. These consequences can be alleviated in patients without renal insufficiency (HP) by rehabilitative measures both in acute geriatrics units (AG) and in inpatient rehabilitation facilities (RG). So far it is largely unknown whether RP benefit from this type of rehabilitation to the same extent as HP. We have now examined this question by evaluating a large geriatric database.

Methods: The Geriatrics in Bavaria-Database (GiB-DAT) was established with the support of the Ministry of Health as a quality assurance project. It comprises the vast majority of anonymized records of cases treated in Bavarian AG and RG. In this study all data records for the years 2012-2019 from AG and RG were evaluated. The following parameters were examined: At admission: age, gender, cognition (Minimal Status Examination: MMSE), emotion (Geriatric Depression Scale: GDS), degree of care (DC); at discharge: number of diagnoses and medication; at admission and discharge: self-help ability (Barthel Score: BS), mobility (Timed Up and Go Test: TUG) and place of residence.

Results: Both in AG and RG, HP (AG/ RG n=11653/248831) and RP (AG/ RG n=27294/8984) did not relevantly differ in age, gender, MMSE, GDS and DC. The number of diagnoses (AG: 10.7 vs. 9.3; RG 10.3 vs. 8.3) and drugs (AG 10.1 vs. 9.3; RG 9.9 vs. 9.0) was slightly higher in RP compared to HP. No major differences between RP and HP were observed at the beginning of the rehabilitation in BS, TUG and place of residence. In RP/HP, BS improved during rehabilitation by 11.4/14.4 (AG) and +21.1/21.9 (RG) points and the number of patients "able to walk" in the TUG by +22.1/20.6% (AG) and +14.3/14.5% (RG) respectively. Living could be maintained in 66.0/68.9% (AG) and 81.6/81.5% (RG). Subgroup analysis of CKD-severity showed no relevant difference for any of the examined parameters both in AG and RG.

Conclusions: RP benefit to a similar extent as HP from rehabilitative measures both in AG and RG with respect to improvement of self-help ability, mobility as well as the preservation of private residence. This was observed regardless of the stage of renal insufficiency.

Predictors of Functional Status Change in Patients with CKD Between Two Hip Fracture Events: A 6-Year Prospective Study

Henry Wu,1,2 Rene Van Mierlo,1,2 Ajay P. Dhaguyige,1,2 Sandip Mitra,1,2 Andrew C. Nixon,1,2 Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom; 3The University of Manchester, Manchester, United Kingdom; 4Manchester University NHS Foundation Trust, Manchester, United Kingdom.

Background: Patients with chronic kidney disease (CKD) are susceptible to recurrent hip fractures (Hip#). Functional status decline after Hip# is transient, exacerbated by frailty, sarcopenia and co-morbidities. We studied the prognostic value of clinical and laboratory parameters for functional status change in CKD after recurrent Hip#.

Methods: Patients with CKD G3b-5 admitted with 2 separate Hip# events between June 2013 and Dec 2019 in a North West UK tertiary care hospital were included. Difference in Karnovsky Performance Status (KPS) Scale between 1st and 2nd Hip# admission determined functional status change. KPS is a linear scale between 0 (dead) and 100 (normally active). Parameters assessed included Clinical Frailty Scale (CFS), Hopkins Frailty Score (HFS), CKD Fl-LAB, Smerbo Score, Charlson’s Co-morbidity Index, Nottingham Hip Fracture Score, ASA Score and Abbreviated Mental Test Score. Differences in each parameter score between 1st and 2nd Hip# admission were recorded.

ROC curve analyses was performed to assess discriminative ability among individual scoring tools.

Results: 37 patients met inclusion criteria (F:M 1.8:1; mean age 84.5±10.2 yrs). 10 were receiving long-term dialysis, whilst non-dialysis CKD patients had a mean eGFR 33±15 mL/min/1.73m2. Mean age difference between Hip# is 1.4 yrs (p=0.032). Mean KPS difference between Hip# is 10.6 (p=0.028). AUC values from ROC analyses are shown in Table 1.

Conclusions: There was a significant decline in functional status between Hip#. Frailty assessment tools (CFS, HFS and CKD Fl-LAB) had the best predictive performance for functional status change. Frailty measures may be utilized as risk prediction tools of functional status change from first Hip# admission. Further Research is needed to evaluate whether Hip# interventions that aim to maintain functional status and reduce subsequent fracture risk.

Which Parameters Best Predict Mortality After Hip Fracture for Patients with CKD? Insights from a 6-Year Prospective Analysis

Henry Wu,1,2 Rene Van Mierlo,1,2 Ajay P. Dhaguyige,1,2 Sandip Mitra,1,2 Andrew C. Nixon,1,2 Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom; 3The University of Manchester, Manchester, United Kingdom; 4Manchester University NHS Foundation Trust, Manchester, United Kingdom.

Background: Hip fracture is more prevalent in patients with CKD and has associated worse clinical outcomes than those without CKD. Uncertainties remain on which clinical and laboratory parameters best predict mortality outcomes following hip fracture for patients with CKD.

Methods: Patients with CKD G3b-5 admitted to a tertiary hospital in North West UK with hip fracture between June 2013 and Dec 2019 were included. Mortality outcomes...
Methods: We performed a systematic literature search up to April 2020. We selected randomized control trials (RCTs) and cohort studies which compared the risk of falls in the intensive BP control group with that in the less intensive control group the elderly. Risk ratios (RRs) with corresponding 95% confidence interval (CI) were synthesized.

Results: Five studies (three RCTs and two cohort studies) were included, with 11,245 patients. The characteristics were shown in Table. Intensive BP control was associated with significantly increased risk of falls, but the results showed high heterogeneity. (RR [95% CI]: 1.10 [0.87-1.39], I2= 73%)

Conclusions: In older patients, intensive BP control was not associated with an increase in rate of falls, but with high heterogeneity. The proportion of frail patients might be a source of heterogeneity. Further studies that stratify patients with risk of frail are needed.

Tailoring the Beers Criteria for Mortality Risk Stratification Among Older Adults Initiating Hemodialysis

Rasheedah K. Hall,1 Abinereki Muzala,1 Dorry L. Segey,2 Mara McAdams-DeMarco,1 Durham VA Medical Center, Durham, NC; 2Duke University School of Medicine, Durham, NC; 3Johns Hopkins University, Baltimore, MD.

Background: American Geriatrics Society’s Beers Criteria lists potentially inappropriate medications (PIMs) that carry more risk of harm than benefit in older adults, but PIM risks may differ in kidney failure. To tailor the Beers Criteria, we developed a novel mortality risk score for older patients initiating hemodialysis.

Methods: We assembled a USRDS cohort of 39,098 adult aged ≥65 initiating hemodialysis (2013-2014) and enrolled in Medicare Part D by 90 days post-initiation. We used Part D claims to quantitatively assess prescription drug use (Beers Criteria). In a training cohort (60% sample), we identified which of 38 PIM classes was associated with mortality using Cox modeling; censoring for loss of Medicare coverage, mortality change, or 9/1/2015. Models were adjusted for demographics, initiation year, comorbidities, drug dependence, smoking status, inability to ambulate, and institutionalization. PIM classes that were associated with mortality were summed to create a PIM count risk score. We used Cox models to estimate the association of PIM count risk score (time-varying) with mortality in training and validation cohorts.

Results: The training cohort (n=23,521) had mean age 75 years, 43% women, 21% black, and 75% (n=17,706) had ≥2 PIM fills/month. We identified 15 PIMs (HR ≥1) to include in the risk score (Figure). Patients with ≥2 fills/month (vs. no fills) were more likely institutionalized (13.8% vs. 10.1%), non-ambulatory (20.8% vs. 17.2%), and have cardiovascular disease (62.4% vs. 50.7%). Compared to those with no fills, there was increased mortality risk among those with 1 fill (ahR=1.32;1.25-1.39) and ≥2 fills (ahR=1.66;1.56-1.75).

Conclusions: We identified 15 of 38 PIM classes associated with mortality to yield a novel PIM count risk score. This score facilitates tailoring the Beers Criteria to promote age-appropriate prescribing in older adults initiating hemodialysis.

Symptoms and Suffering at the End of Life in ICU Patients Receiving Dialysis

Sarah Ramer, Martin Viola, Holly G. Prigerson. Weill Cornell Medicine, New York, NY.

Background: Patients with end-stage kidney disease (ESKD) on dialysis suffer from a significant burden of physical symptoms. Little is known, however, about the symptoms that intensive care unit (ICU) patients receiving dialysis experience at the end of life.

Methods: This is a cohort study conducted at NewYork-Presbyterian/Weill Cornell Medical Center and Brigham and Women’s Hospital from September 2015 to March 2017. Nurses who cared for deceased ICU patients were interviewed within 3 weeks of the deaths about patients’ physical and psychological symptoms in their last week of life. On a 1-10 scale, nurses rated 16 different symptoms on how much they contributed to a patient’s suffering and rated the patient’s overall suffering in the last week of life. Study staff abstracted demographic and clinical data from patient charts.

Results: One-hundred nurses completed interviews on 200 deceased patients, 67 of whom underwent dialysis in the last week of life (for ESKD or acute kidney injury). Mean dialysis patient age was 63 years; 39% were female; 52% were non-white; 12% were Hispanic. The nurses rated patients who underwent dialysis in the last week of life as having significantly more suffering from painful, broken skin than non-dialysis patients (mean 4.6 ± 3.5 vs. 10, P=0.045) but significantly less suffering from hunger (mean 2.4 ± 3.6 of 10, P=0.012) or thirst (mean 3.2 ± 4.8 of 10, P=0.005). There was a trend towards more suffering from swelling in the dialysis patients (mean 6.2 ± 5.3 of 10, P=0.083). No unadjusted linear regression model revealed that receipt of dialysis in the last week of life was significantly associated with perceived overall suffering (β=1.35, P=0.006); however, after adjustment for painful, broken skin (β=0.19, P=0.04) and swelling (β=0.20, P=0.007) in the model, the relationship between dialysis and overall suffering was attenuated (β=0.84, P=0.074).

Conclusions: Nurses rated ICU patients who received dialysis in the last week of life as suffering from more painful, broken skin but less hunger or thirst than non-dialysis patients. The relationship between dialysis and perceived overall suffering was attenuated by painful, broken skin and swelling, suggesting that attention to these problems might reduce suffering at the end of life in ICU dialysis patients.

PO1697

Want to Reduce Regret with Dialysis Initiation? Implement Shared Decision-Making

Fahad Saeed, Basil S. Kazi, Nicole L. Mayo, Spencer Dahl. University of Rochester Medical Center, Rochester, NY.

Background: The American Society of Nephrology’s “Choosing Wisely Campaign” recommends that nephrologists should not initiate chronic dialysis without implementing a shared decision-making (SDM) process. The current literature lacks details on the relationship of SDM with outcomes such as quality of life and decisional regret.

Methods: We surveyed 223/380 (response rate 59%) hospitalized patients receiving maintenance dialysis in the Upstate, NY, and asked them about their experience with dialysis decision-making using the SDM-9 Questionnaire. Quality of life and decisional regret were assessed by KDQOL-36 and Decisional Regret Scale, respectively. Candidate predictors in the final linear regression model included age, sex, time on dialysis, race, marital status, income level, education level, quality of life, fear of death, and decisional regret.

Results: Nearly 41% of patients were <65 years old, 47% were women, and 41% were White. The mean scores for SDM were 25.9 ± 12.2. In the bivariate analyses, patients who were married or in a relationship had greater mean SDM scores (p=0.01) than those who were single. Patients with higher scores on SDM had less anxiety over death and less decisional regret (R2 = 0.17 and 0.29, respectively). The candidate predictors in the final model together explained 21.4% of the variance in SDM (p = 0.02). SDM decreased for every 0.15 unit increase in decisional regret score (C1: -0.25, -0.07) when controlling for all other predictors in the model.

Conclusions: We found that patients with higher scores on the SDM-9 Questionnaire had less decisional regret regarding their decision to initiate dialysis. Future interventions to improve SDM in clinical settings are a top research priority.

PO1698

Attitudes Towards Physician-Assisted Death in Patients Receiving Maintenance Dialysis

Fahad Saeed, Basil S. Kazi, Nicole L. Mayo. University of Rochester Medical Center, Rochester, NY; University of Rochester, Rochester, NY.

Background: During recent years, the debate about the legalization of physician-assisted death (PAD) has intensified at both public and policy levels. Surveys and polls on this issue have included seriously ill patients such as those with cancer; however, voices of patients receiving maintenance dialysis are not represented in the current literature.

Methods: We surveyed 223/380 (response rate 59%) hospitalized patients receiving chronic dialysis in Upstate, NY. We asked patients about their views on PAD using the following two questions: (1) Which of the following best describes your views about whether a physician should ever be allowed to take the final action in response to a patient’s request for assisted death? (2) In case you had a great degree of pain and suffering and if physician-assisted death was legally available, do you think you might request it for yourself? Response options for the first and second questions included: (a) support/yes (b) oppose/no (c) uncertain. Candidate predictors in the final logistic regression model included age, time on dialysis, race, marital status, income level, education level, spirituality, social support, symptom burden, sense of burdensomeness, fear of death, and fear of the dying process.

Results: Nearly 41% of patients were <65 years old, 47% were women, and 41% were White. Fifty-five percent supported PAD, 22% expressed uncertainty, and 22% available: 37% said yes, 44% no, and 17% chose the unsure option. In the bivariate analyses, those who supported PAD had lower mean spirituality, higher anxiety about the dying process, and had spent more time on dialysis compared to those who opposed or were uncertain (p=0.05) about it. In the final model, none of the candidate predictors were significant for support or opposition/uncertainty about PAD.

Conclusions: More than half of hospitalized dialysis patients supported PAD, while fewer would actually use this option in case of pain and suffering. In the absence of the legalization of PAD in the NY state, the promotion of palliative care and hospice services and high-quality end-of-life care for dialysis patients are high priority policy issues.

PO1699 Perspectives on Conservative Management of Advanced Kidney Disease: A Qualitative Study of US Patients and Family Members

Susan P. Wong,1,2 Taryn Oestreicher,1,3 George G. Gaye,1,3 Ann M. O’Hare,1,2 J. Randall Curtis,1,4 1University of Washington, Seattle, WA; 2VA Puget Sound Health Care System, Seattle, WA; 3Cambia Palliative Care Center of Excellence, Seattle, WA.

Background: Growing recognition of the limits of maintenance dialysis for some groups of patients has led to the emergence of conservative care models for advanced kidney disease in several countries outside the US. There is strong interest in replicating similar models in the US, however little is known about how these models are perceived by US patients and family members.

Methods: We conducted a qualitative study using cognitive interviews with 14 patients aged ≥75 years with advanced kidney disease and 6 of their family members about their perception of conservative care approaches in other countries as described in available patient decision aids on treatment of advanced kidney disease. We performed an inductive thematic analysis of interviews to identify themes reflecting participants’ understanding and receptivity to conservative care.

Results: Subjects were mostly white (n=15) and had at least some college education (n=16). 4 prominent themes emerged from analysis of interviews: 1) Core elements of conservative care: aspects of conservative care that were appealing to participants included a whole-person, multidisciplinary approach to care that focused on symptom management, maintaining current lifestyle and managing health setbacks; 2) Importance of how conservative care is framed: participants were more receptive to conservative care when this was framed as an active rather than passive treatment approach and when uncertainty in disease prognosis; 3) An explicit approach to shared decision-making: participants believed decisions about conservative care or dialysis address considerations about risk and benefits of treatment options, family and clinician perspectives and personal goals, values and preferences; and, 4) Relationship between conservative care and dialysis: although conservative care models outside the US are generally intended to serve as an alternative to dialysis, participants’ comments implied that they did not view conservative care and dialysis as mutually exclusive.

Conclusions: Although participants in this study found many aspects of conservative care models developed in other countries to be appealing, models will likely require adaptation to meet the needs and preferences of US patients and their families.

PO1700 Feasibility and Acceptability of Telepalliative Care in Rural Dialysis Units

Katharine L. Cheung,1 Manjula Kurella Tamura,2 Michael A. Lamantia,1 Terry Rabionowiz,2 Renee Stapleton,1 Bob Gramling.1 1University of Vermont College of Medicine, Burlington, VT; 2Stanford University School of Medicine, Stanford, CA.

Background: Limited access to palliative care is a key barrier to its integration in routine dialysis care. We evaluated the feasibility and acceptability of telepalliative care while patients received dialysis in rural units.

Methods: The target population included any patients with end-stage kidney disease receiving dialysis. Palliative care physicians and APPs conducted consultations as per their usual practice and a large wall mounted screen with centrally positioned camera was used to view an iPad attached to a IV pole positioned next to the dialysis chair. Patients were provided the option of having family present, receiving the consult on dialysis or off dialysis in a private room. Feasibility was measured by 1-month completion rate. Acceptability was measured using an adapted telemedicine questionnaire.

Results: We recruited 40 patients to undergo a telepalliative care consultation while receiving dialysis. Four specialty palliative care clinicians (3 physicians and 1 nurse practitioner) conducted the visits. The recruitment rate was 35% (40/113), scheduling rate was 97.5% (39/40) and completion rate was 85% (33/39). Thirty-six patient participants (15 women, 21 men) completed the baseline survey. One patient requested family to be present during the conversation. No patients requested to have the conversation off dialysis in a private room. Audiovisual aspects of the conversation were rated highly. More than 3/4 reported the visit being at least as good as an in-person visit and 40% felt the televisit was better. Patients felt the appointment was relevant to them, but they were less certain that they learned new things about their condition, and they were mixed about whether the appointment changed the way they think about dialysis.

Conclusions: Telepalliative care is acceptable to patients receiving dialysis and is a feasible approach to integrating palliative care in rural dialysis units.

PO1701 Abstract Withdrawn

PO1702 Modestly Low eGFR Is Not Associated with Cognitive Decline in the Elderly

Linda McEvoy Cheung,1 Taryn Oestreicher,2 Ann M. O’Hare,2 J. Randall Curtis,1,4 1University of Washington, Seattle, WA; 2VA Puget Sound Health Care System, Seattle, WA; 3Cambia Palliative Care Center of Excellence, Seattle, WA.

Background: Kidney disease is associated with cognitive impairment. Whether mild to moderate CKD is associated with cognitive decline in older adults is not clear. We evaluated changes in cognition in relation to baseline eGFR in the elderly Alzheimer’s Disease Neuroimaging Initiative (ADNI) participants.

Methods: ADNI is an NIH funded, multicenter study, which includes participants with normal and impaired cognition who were administered a comprehensive battery of neuropsychological tests every six months. We related the CKD-epi eGFR with previously validated composite scores for memory (ADNI-Mem) and executive function (ADNI-EF) in multivariable linear regression analysis.

Results: 1127 participants with a mean age of 73.8±7 years, 57% men, 97% Caucasian, and mean follow up for 6±2.6 years were included. Mean baseline eGFR was 76.4±19 ml/min/1.73 m². ADNI-Mem and ADNI-EF scores declined across all eGFR categories (figure). Older age and lower education were associated with declines in both ADNI-Mem and ADNI-EF scores. Baseline eGFR was not associated with declines in either ADNI-Mem or ADNI-EF scores (table).

Conclusions: There is no association between baseline eGFR and cognitive decline in elderly persons with mild-moderate impairment in kidney function.

Funding: Other NIH Support - K23-AI055666

DNA Double-Strand Breaks of Human Glomerular Endothelial Cell-Induced Collagen Type IV Excretion and Nodular Lesions in Various Kidney Diseases

Ai Fujii,1 Yumi Sunatani,2 Kengo Furuchi,1 Keiji Fujimoto,1 Hiroki Adachi,1 Kuniyoshi Iwabuchi,1 Hitoshi Yokoyama,1 Kanazawa Medical University School of Medicine, Department of Nephrology, Kanazawa, Japan; 2Kanazawa Medical University School of Medicine, Department of Biochemistry, Kahokugan, Japan.

Background: Collagen deposition is the common histologic end-point of progressive chronic kidney diseases (CKDs). We focused on collagen type VI (COL6) which is known as components of nodular lesions. This study was performed to test the hypothesis that glomerular endothelial cells with DNA double-strand breaks (DSBs) induce the accumulation of COL6 in various kidney disease and evaluated the mechanism of COL6 accumulation after DSBs.

Methods: We examined various kidney diseases (n=180) in which DSBS and glomerular fibrosis were detected by phospho-histone H2AX (γ-H2AX) expression and COL6 accumulation. In vitro study, we investigated the relationship between DSBS and COL6 excretion and the intracellular signal pathways in human glomerular endothelial cells (HRGECs) using mitomycin C (MMC)-induced DNA damage, and other two agents; Neocarzinostatin (NCS) and camptothecin (CPT). We examined the effect of DSBS on response signal pathways, i.e. ATM, ATR and DNA-PK using their specific kinase inhibitors (KU55933, VE-821, N7441).

Results: COL6 and γ-H2AX were detected in glomeruli in which the γ-H2AX-positive area was identified as the independent factor for the % COL6-positive area (β: 0.553, t = 2.642, p = 0.009). Furthermore, COL6 was a component of the nodular lesions found in various kidney diseases. In vitro study of MMC-induced DNA damage, COL6 excretion detected by the decrease of COL6 positive cells was suppressed in the ATR-inhibited group (p <0.01 for 2 h, p <0.001 for 24 h). Moreover, CPT treated cells induced the COL6 excretion as well as MMC treated cells (p <0.001 for MMC, p =0.002 for CPT).

Conclusions: This study showed that DNA damage-sensing kinase of ATR was activated in response to DSBS and induced COL6 secretion of human glomerular endothelial cells. Furthermore, DNA damage may induce the nodular glomerulosclerosis in various kidney diseases.

PO1709
Protection of the Remnant Rat Glomeruli from Mechanical Stress Through Structural Adaptation and Pharmacological Intervention After 5/6-Nephrectomy: A Modeling Study
Owen Richfield,1 Ricardo Cortez,2 L. Gabriel Navar,3 Tulane University Biinnovation PhD Program, New Orleans, LA; Tulane University Department of Mathematics, New Orleans, LA; Tulane University Department of Physiology, New Orleans, LA.

Background: 5/6-nephrectomy leads to increased blood flow and pressure in the remaining glomeruli, ultimately resulting in scarring. It is hypothesized that these hemodynamic alterations increase mechanical stresses, including shear stress on the glomerular endothelial cells and circumferential hoop stress on podocytes, however these mechanical stresses have not been rigorously quantified. In renalopd conditions glomerular capillary diameters increase, and it is unclear how these structural adaptations affect the mechanical stress magnitudes.

Methods: A mathematical microvascular hemodynamic model was developed to simulate blood flow and plasma filtration on each capillary segment of an anatomically-accurate rat glomerular capillary network. Model parameters were adjusted to match glomerular hemodynamic data for control and 5/6-nephrectomized conditions with and without the presence of the ACE inhibitor, enalapril (Meyer TW et al. Kidney Int. 1987;31(3):752-759). Glomerular capillary diameters were increased according to experimental imaging data (Ferrell, Nicholas, et al. J Am Soc Nephrol 31: 2020) to simulate glomerular structural adaptations post-5/6-nephrectomy.

Results: Post-5/6-nephrectomy, glomerular capillary structural adaptations reduced mean network shear stress from 156.5 to 92.8 dynes/cm². Without structural adaptations enalapril reduced mean shear stress to 136.1 dynes/cm². The increase in glomerular capillary diameter reduced shear stress while the increased diameters combined with glomerular hypertension increased mean hoop stress from 90.9 to 104.3 kPa. The combination of enalapril and structural adaptations resulted in a mean network shear stress of 81.1 dynes/cm² and hoop stress of 69.7 kPa.

Conclusions: Our results indicate that glomerular structural adaptations protect the glomerular endothelial cells from increased levels of shear stress, thus preserving kidney function. However, these structural adaptations in turn lead to increased hoop stresses. The combination of enalapril with structural adaptations reduces mechanical stress, providing protection and maintaining function for longer periods.

Major Vault Protein Contributes to Increased Interstitial Fibrosis in a Murine Model of CKD
Cheuk Yin Wong, Susan Yung, Caleb C. Chan, Tak Mao D. Chan. The University of Hong Kong, Hong Kong, Hong Kong.

Background: Chronic kidney disease (CKD) is a global health issue characterized by interstitial fibrosis and tubular atrophy, and progressive CKD results in kidney failure. There is currently no effective intervention for interstitial fibrosis. We previously showed that major vault protein (MVP), a key component of the vault complex, contributed to increased matrix protein deposition in murine unilateral ureteral obstruction (UUO) animal model. We extended our investigations to a murine model of CKD.

Methods: CKD was induced in MVP wild-type (WT) and knockout (KO) mice by feeding standard chow containing 0.2% adenine for 8 weeks, after which time mice were sacrificed and kidneys were harvested and examined. Spot urine albumin-to-creatinine ratio was also measured. Mice were fed with standard chow served as controls.

Results: MVP WT mice with CKD showed increased MVP expression, predominantly in proximal tubular epithelial cells, compared to MVP WT control mice, and this was accompanied by development of proteinuria, tubularatrophy, tubulo-interstitial macrophage infiltration, and increased interstitial e-smooth muscle actin, fibronectin and collagen. III expression. MVP KO mice with CKD showed less proteinuria (P<0.05) and less severe kidney histopathological features with reduced immune cell infiltration, and also reduced expression of fibrosis mediators compared to WT CKD mice. Exogenous TGF-α, IL-6, or MCP-1 increased MVP expression in cultured renal proximal tubular epithelial cells.

Conclusions: The data suggest that progressive CKD in this murine model is accompanied by increased renal tubular epithelial MVP expression, and MVP may contribute to the pathogenesis of tubulo-interstitial injury and damage.

Signaling at the Mesangial Cell (MC) Membrane in Light Chain Deposition Disease (LCDD) and AL-Amyloidosis (AL-Am) Involves Sorbin-Related Receptor (SORL1), Caveolins, and C-Fos

Jiunn Teng,1 Chun Zeng,1 Elba A. Turbat-Herrera,1 Takahito Moriyama,2 Luis Del Pozo-Yauney,2 Bing Liu,2 Xinggui Shen,1 Guillermo A. Herrera. Department of Pathology, 1University of South Alabama, Mobile, AL; 2Tokyo Joshi Ika Daigaku Fuzoku Kogenbyo Ryumachi Tensu Center, Shinjuku-k, Japan; 3Louisiana State University Health Sciences Center Shreveport, Shreveport, LA.

Background: AL-Am and LCDD are two diametrically opposed glomerulopathies in terms of mesangial alterations produced by glomerulopathetic light chains (GLCs). Their pathogenesis involves surface MC interactions resulting in cytoskeletal changes, c-fos translocation, phenotypic transformations, lysosomal activation (AL-Am), rough endoplasmic reticulum expansion (LCDD), and ultimately, mesangial matrix alterations.

The present study addressed signaling pathways involved. Methods: Human (H) MCs (both caveolin-1 wild type / knock-out) were incubated with monoclonal LCs purified from the urine of renal biopsy-proven AL-Am, LCDD, myeloma cast nephropathy (MCN) patients or albumin for up to 96 hours at different time frames. The samples were analyzed using light, immunofluorescence and electron microscopy, including immunolabeling for c-fos, kapa / lambda light LCs, caveolin-1 and SORL1.

Results: Co-localizations in cup-shaped MC membrane indentations (caveolae) of GLCs with caveolin-1, and SORL1 were documented using double immunofluorescence and immunogold labeling ultrastructural techniques. Upon interactions with GLC (but not MCNLCs or albumin) caveoleae on the surface of MCs increased dramatically, SORL1 was activated and c-fos translocated from cytoplasm to nucleus.

Conclusions: SORL1 is a key component of GLCs signal transduction in MCs. Co-localization supported the notion that Interactions of GLCs with MCs occurred in caveolae activating SORL1. Caveolin-1 knock out HMCs abolished c-fos translocation from cytoplasm to nucleus and the downstream mesangial alterations (i.e. mesangial expansion / increased protein production) in LCDD group. In ALLC group, c-fos translocation and amyloid production were decreased but not totally abolished, suggesting that other mechanism may be involved in amyloidogenesis. C-fos plays a crucial role following SORL1 activation to promote mesangial cell phenotypic transformation essential for amyloidogenesis and extracellular matrix over production, in AL-amyloidosis and LCDD, respectively.

Compartmental Differences Within the COL3A1 Network in Proteinuric Kidney Disease: Informing Drug Activity Using the Jaccard-Tanimoto Index

Background: In proteinuric kidney disease, type III collagen (COL III) participates in mesangial expansion, capillary transformation, and glomerulosclerosis. Matrix deposition within the tubulointerstitium is associated with worse prognosis. A semi-quantitative analysis was conducted to understand compartmental differences within the COL3A1 transcriptomic network, and to inform therapeutic potential of drugs that mitigate COL III deposition.

Methods: Proteinuria and renal COL3A1 day mRNA were measured in adult male Wistar rats administered PAN (~100 mg/kg, intraperitoneal). HumanBase was used to build glomerular (G) and tubular (T) COL3A1 transcriptomic networks. Network analysis was restricted to 51 elements each, inclusive of COL3A1, with a minimum interaction confidence of 0.01. The Jaccard-Tanimoto similarity index was used to calculate common elements within the two compartments.

Results: The rat PAN model was associated with increased proteinuria (*, p<0.01 vs. sham) which correlated directly and significantly with renal COL3A1 mRNA expression level. Network analysis revealed a strong relative glomerular COL3A1 interactome with an average strength of 0.84±0.08 and a relatively weaker tubular COL3A1 interactome with an average strength of 0.56±0.01. The Jaccard-Tanimoto similarity index between the glomerular and tubular COL3A1 signaling elements was 5.1%.

Conclusions: Glomerulosclerosis in proteinuric kidney disease may result from a relatively strong COL3A1 transcriptomic network within that compartment. Tubulointerstitial matrix deposition is rare in proteinuric kidney disease, possibly due to a weaker COL3A1 transcriptomic network in that compartment. Drugs designed to specifically mitigate COL III deposition might be most effective against glomerulosclerosis.

The Correlation Between Urinary MicroRNA-21 and Renal Parameters in Patients with IgA Nephropathy

Akira Aramai, Tsukasa Osaki, Kazunobu Ichikawa, Masafumi Watanabe, Tsuneo Konta. Yamagata University Faculty of Medicine, Yamagata, Japan.

Background: The expression of microRNA-21 (miR-21) in renal tissue is reported to be related to tubulointerstitial fibrosis and renal outcome in IgA nephropathy. In this study, we examined whether the urinary concentration of miR-21 is related to clinicopathological parameters and short-term changes in renal function in patients with IgA nephropathy.

Methods: Urinary microRNAs and proteins were extracted and quantified in morning spot urine in 88 patients with IgA nephropathy at biopsy and five control subjects, and examined the relationship between clinical and histological parameters, one-year changes in eGFR and urinary miR-21. The concentrations of microRNAs and proteins were corrected to the concentration of urinary creatinine and were log-transformed for simple correlation analysis.

Results: The urinary excretion of miR-21 was detected in all subjects, and the urinary concentration of miR-21 in patients with IgA nephropathy was significantly higher than those in controls. Among 88 patients with IgA nephropathy, urinary miR-21 levels showed a significantly positive correlation with the urinary concentration of total microRNA (r=0.65), total protein (r=0.40), beta2-microglobulin (r=0.62), and N-acetyl-beta-D-glucosaminidase (NAG) (r=0.37), but not with baseline GFR, and urinary red blood cells. In contrast, the urinary miR-21 levels did not show a significant correlation with histological changes, including glomerular proliferation/sclerosis and tubulointerstitial fibrosis. The one-year changes in eGFR after biopsy showed a significant inverse correlation with the urinary concentration of miR-21 (r=-0.31) and total protein (r=-0.37), but not total microRNA, beta2-microglobulin, and NAG. The correlation between urinary miR-21 and one-year eGFR change was similar in the subjects with and without steroid treatment.

Conclusions: In this study, the urinary excretion of miR-21 was associated with clinical parameters and one-year changes in renal function in patients with IgA nephropathy, suggesting that urinary miR-21 might be used as a biomarker of IgA nephropathy.

Diagnostic Delay and the Clinical Prognosis in US Adults with Systemic Light Chain (AL) Amyloidosis with Renal Involvement

Laura Hester,1 Dina Gifkins,1 Kevin Bellew,2 Jessica Vermeulen,3 Jordan Schecter,2 Victor Dishy,1 Brendan Weiss,2 Janssen Research & Development LLC, Titusville, NJ; 3Janssen Research & Development LLC, Spring House, PA; 4Janssen Research & Development LLC, Leiden, Netherlands; 5Janssen Research & Development LLC, Rarity, NJ.

Background: Early therapy for AL can reverse renal impairment, but AL diagnosis (dx) is often delayed. We report the first population-level study of the diagnostic delay and associated adverse outcomes in systemic AL patients (pts) with prior signs/symptoms (S/Sx) of renal impairment.

Methods: Pts with renal S/Sx at AL dx were identified in the US Optum Clininformatics® claims data since June 2001. AL was defined as ≥1 inpatient or ≥2 outpatient AL codes, followed by ≥2 anti-plasma cell therapy in 2 yrs. Renal S/Sx were defined as ≥1 prior dx code for stage 1-3 chronic kidney disease (CKD), renal failure/ESRD, nephrotic syndrome, acute kidney injury, or proteinuria. We described prevalence and overlap of S/Sx and time from first S/Sx to AL dx in renal AL pts. Kaplan-Meier estimates and log-rank tests compared time to AL diagnosis by prior monocular gammopathy (MG).

Results: Of 870 renal AL pts (67% of AL pts), 70% had CKD, 46% had renal failure, 58% had acute renal failure, 29% had nephrotic syndrome, and 61% had proteinuria by AL dx. Median time since first renal S/Sx and AL dx was 196 days, with a median of 205 days since CKD dx and 23 days from first nephrotic syndrome dx (Figure). Among renal AL pts, 89% had cardiac S/Sx, 67% had neurologic S/Sx, and 57% had ≥3 systems involved.

**Case of Leukocyte Cell-Derived Chemotaxin 2-Associated Renal Amyloidosis**

Anita Kamarzarian, Masoud Mahmood, Golriz Jafari. Olive View Medical Center, Sylmar, CA.

**Introduction:** Amyloidosis is a disorder characterized by the abnormal deposition of insoluble protein fibrils in tissues. The most recently described form of amyloidosis is derived from leukocyte cell-derived chemotaxin 2 (LECT2).

**Case Description:** 60 yo with history of HTN and COPD referred for evaluation of proteinuria. Laboratory tests showed microalbuminuria and negative ANA and dsDNA. She had been treated and is being followed for diabetics. She presented with new onset proteinuria and edema. 

**Discussion:** ALECT2 protein is a multifunctional factor involved in chemotaxis, inflammation, immunomodulation, and the damage/repair process. Most patients with ALECT2 present with minimal proteinuria, bland urine sediment and impaired renal function, and the diagnosis of ALECT2 is usually incidental following biopsies for unrelated conditions or uncertain diagnoses. ALECT2 is a slowly progressive disease likely due to the selective involvement of the interstitium. A full nephrotic syndrome is uncommon in renal ALECT2. Neither the renal function nor the proteinuria correlates with the amyloid load in the renal biopsy. There is no specific therapy for ALECT2. Transplantation remains the only effective treatment. But there is a high risk of recurrence in view of ongoing synthesis of the abnormal protein by the liver. In addition to the renal biopsy findings, confirmation of ALECT2 diagnosis requires immunohistochemistry of chemical analysis by tandem mass spectrometry.

**PO1716**

**Idiopathic Fibrillary Glomerulonephritis: A Report of Two Cases**

Garri Sharma Priyamvada,1 Anvesh S. Kallapur,2 Josue A. Lozano,3 Pankaj Jawa,4 Koyal Jain,1 1University of North Carolina at Chapel Hill, Chapel Hill, NC; 2Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India; 3Department of Pathology and Laboratory Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC.

**Introduction:** Fibrillary glomerulonephritis(FGN) is a rare glomerular disease characterized by the presence of fibrillar deposits in glomeruli and is associated with poor prognosis, often leading to end stage renal disease(ESRD). Previously considered to be idiopathic, new data suggests there is a secondary association in 30-50% of cases with underlying hepatitis C infection, malignancy, dysproteinemia and autoimmune disease. Immunohistochemical staining for DNA-J heat shock protein B9(DNAJB9) is emerging as a marker for rapid diagnosis of FGN.

**Case Description:** We report two patients with FGN who initially presented with monoclonal gammopathy(MG), but varied clinical courses. First patient, 60 year-old female presented with MGIgG4 subclass, acanthocyturia and nephrotic syndrome. Renal biopsy showed PAS positive deposits in capillary loops and mesangium; Immunofluorescence microscopy showed IgG, C3, κ and λ light chains. Electron microscopy showed 20nm non-branching randomly arranged fibrils. Five years later, she is still in remission after treatment with bortezomib, cyclophosphamide and dexamethasone. Another 63 years old female presented with renal failure, positive pANCA and MG. Biopsy showed DNAJB9-positive sclerosing and proliferative FGN with 10% cellular crescents and severe interstitial fibrosis and tubular atrophy. She was treated with corticosteroids and rituximab for idiopathic FGN mimicking type III RPGN. However, she became dialysis dependent.

**Discussion:** FGN has broad presentation and course despite aggressive therapy. A study determined the strongest predictor of outcome to be initial serum creatinine. Other predictors were age, degree of glomerulosclerosis and proteinuria. Knowledge on pathogenesis along with renal pathology can help differentiate this from other fibril deposition diseases like amyloidosis and immunotactoid glomerulopathy. It is imperative to promptly identify FGN as it often progresses to ESRD and has limited data on optimal therapy.

**A Case of Secondary Focal Segmental Glomerulosclerosis and Thrombotic Microangiopathy in a Heart Transplant Patient**

Neha Deval, Hay Me Me, Jennifer Griffiths, Aromma Kapoor, Savneck S. Chugh. Westchester Medical Center, Valhalla, NY.

**Introduction:** A few case reports have shown that focal segmental glomerulosclerosis (FSGS) can lead to thrombotic microangiopathy (TMA) in chronic kidney disease patients with severe hypertension. One case report presented the development of FSGS and TMA in liver transplant patient on Tyrosine kinase inhibitor. We present a case of FSGS without vascular injury despite clinically diagnosed TMA in heart transplant patient.

**Case Description:** A 42-year old female with history of postpartum cardiomyopathy with implantable cardioverter defibrillator since 2005 was admitted for heart transplant evaluation. Patient developed rapid progressive worsening of renal failure requiring hemodialysis after the heart transplant. Urinalysis showed proteinuria, hematuria; blood work showed hemolytic anemia, thrombocytopenia and schistocytes. TMA was diagnosed and eculizumab was started while continuing with hemodialysis. Heart biopsy showed no rejection, but kidney biopsy revealed the pathological diagnosis of secondary FSGS of not otherwise specified type without vasculitis under both light and electron microscopy. No significant glomerular staining seen on immunofluorescence microscopy as well. Patient was maintained on immunosuppressive regime with mycophenolate, tacrolimus and prednisone, receiving eculizumab weekly for 3 months, and subsequently recovered from hemodialysis.

**Discussion:** It is very rare to have FSGS without microangiopathy in hematologically confirmed TMA. Calcineurin induced inhibitors (CIN) are known to cause various forms of acute kidney injury including FSGS. In our case, presumed calcineurin induced nephrotoxicity presented as secondary FSGS without angiopathy. This case reflects the unpredictability of the etiology of kidney disease based solely on clinical features and blood tests. No improvement in kidney function necessitated the renal biopsy. It also raises the challenging points in treatment regime in transplant patient populations.

**PO1718**

**D-Penicillamine-Induced ANA(+)ANCA(+) Crescentic Glomerulonephritis in Wilson Disease**

Shinichiro Kojo. Section for Nephrology and Hypertension, Department of Medicine, Tokyo Metropolitan Police Hospital, Tokyo 166541, Japan.

**Introduction:** Wilson’s disease is an inherited autosomal recessive disorder caused by loss of function of a copper exchange adenosinetriphosphate encoded by ATP7B, which results in impaired biliary copper excretion and accumulation of copper in plasma and tissues. In the kidney, copper accumulation may affect tubular cells, but was never associated with glomerular lesions. Some patients have been reported as crescentic glomerulonephritis with Wilson’s disease treated with D-penicillamine.

**Case Description:** A 45 years old female was consulted to adult nephrology clinic on worsening chronic kidney disease. She had prescribed 800mg metalcaptase for 3 months for Wilson disease. She was consulted to our nephrology clinic with declining renal function. She initially presented with almost 50% fall in creatinine. She was started on regular dialysis and is still in remission after treatment with bortezomib, cyclophosphamide and dexamethasone.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
years on compound heterogenous Wilson’s disease diagnosed by liver biopsy, Western blotting and gene sequence on ATP7B. Serum creatinine(Cr) was around 4.5 mg/dl, antimalperoxidase(MPO)-ANCA 350 U/ml, antinuclear factors titer 1/640. Both anti-proteinase(PR3) antibody and anti-glomelular basement membrane(GBM) antibody were negative. Renal biopsy specimen show pauci-immune crescentic glomerulonephritis with 7/9 fibrous or fibrocellular crescents, and 2/9 global collateral sclerosis. Also, mild diffuse interstitial fibrosis was found with lymphoid and other chronic inflammatory cells. No pathological finding was detected on vasculitis. Diagnosed as ANCA-associated glomerulonephritis, methyl-prednisolone(PSL) pulse therapy was given and preceded with 7/9 fibrous or fibrocellular crescents, and 2/9 global collateral sclerosis. Also, mild proteinase(PR3) antibody and anti-glomelular basement membrane(GBM) antibody were detected. Antimyeloperoxidase(MPO)-ANCA 350 U/ml, antinuclear factors titer 1/640. Both anti-MPO-ANCA<3.5 U/ml.Cr was improved to 1.5mg/dl in spite of presence of mild diffuse interstitial fibrosis. Hereafter 15 years, no medication except metilacaptase was given, but regrettably Cr has been deteriorated to 4.5mg/dl,MO-ANCA–15–25 U/ml. Other paraproteinemia or malignant diseases including multiple myeloma was excluded. Taken together for these 25 years, D-penicillamine-associated interstitial nephritis\cite{40} has suspected. Oral zine acetate was once truncated due to gastroenterological side effect, then planned to change to trientine.

**Discussion:** The pathogenesis of drug-induced ANCA-associated vasculitis has not been proven. There is a hypothesis that MPO binds to drug metabolites and alters the MPO antigenic property\cite{41}. Treatment of AAV is usually with mPSL pulse, cyclophosphamide, and/or rituximab. **In Silico Prediction of Potential New Biomarkers of IgA Nephropathy**

Fenge Zha$^{1}$, Guangyan Cai,$^{2}$ Yujing Ke,$^{2}$ Xiangmei Chen.$^{1}$ *Department of Nephrology, Chinese PLA General Hospital, Chinese PLA Institute of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases, Beijing, China; $^{2}$Guangdong Pharmaceutical University, Guangzhou, China.*

**Background:** IgA nephropathy remains one of the major causes of end stage renal diseases globally. Interstitial lesion in IgA nephropathy is correlated with unfavorable prognosis. This study aims to find new potential biomarkers in IgA nephropathy patients with interstitial lesion based on an in silico method.

**Methods:** Proteomics matrix data from IgA nephropathy patients are obtained from a local renal biopsy patient cohort. Discovery is determined using the Two-stage linear step-up procedure of Benjamini, Krieger and Yekutieli, with Q = 1%. Transcriptomic data from peripheral mononuclear blood cell of IgA nephropathy patients are obtained from GEO (GSE73953). Detection of transcriptomic difference genes are made with limma method in GEO2R.

**Results:** Multiple t test indicates 887 differentially expressed genes between IgA nephropathy interstitial lesion (T1 or T2) and control renal tissues. KEGG pathway annotation reveals that cytochrome c450 related drug metabolism pathway and oxidative phosphorylation pathway are significantly clustered in IgA nephropathy patients with interstitial lesion. No herbal medicine or drug use (apart from ACEI or ARB) were recorded. Differential gene analysis reveals a total of 250 genes with positive discoveries in peripheral mononuclear blood cell of IgA nephropathy patients are obtained from GEO (GSE73953). Further screening of overlapping genes demonstrates that ABCD3, CLPTM1, FM04, RAR52, SFXN2 are the most significantly enriched proteins in IgA patients with interstitial lesion.

**Conclusions:** Preliminary results from this in silico study of proteomics and transcriptomics data in IgA nephropathy patients using a T score specific and overlapping screening approach provide a new possibility of noninvasive detection of interstitial lesion in IgA nephropathy patients.
upregulate signaling specifically in MD cells. MD gene profiling validated by data from Human Protein Atlas was used to confirm expression of various pathways and regulators of protein synthesis and vesicular exocytosis.

**Results:** OPP experiments in mMDβ- cells in vitro showed that low salt (5.9 ± 1.15) and lithium (5.67 ± 0.24) treated cells had significantly higher protein synthetic activity as compared to control (3.13 ± 0.15). Similarly, MD cells in vivo in wildtype mice on a low salt (2.59 ± 0.26) or lithium diet (2.00 ± 0.26) had significantly higher OPP fluorescence as compared to control diet (1.16 ± 0.18). Upregulation of MD-Wnt signaling in MD-Wntα- mice (1.36 ± 0.04) also resulted in a significant increase in MD protein synthesis as compared to control (0.67 ± 0.06). The expression of MD-specific detected proteins (Ccn1, Pappa2, Nov, Cxcl14) was enhanced in activated MD cells. Finally, results from MD gene profile analysis with HPA validation showed high and MD-specific expression of several pathways involved in mRNA translation (p=0.056, eIF3C, eEF2), chaperones (HSP70) along with markers of protein synthesis and vesicular exocytosis.

**Conclusions:** In summary, the unique MD microanatomy and cell-specific protein synthetic machinery support the robust synthesis and secretion of a diverse array of tissue remodeling and angiogenic proteins which are regulated by mTOR and Wnt signaling in these cells. The regulatory pathways MD protein synthesis and secretion may be targeted to enhance endogenous glomerular and vascular tissue remodeling and repair.

**Kidney Transcription-Wide Association Study Analysis Identifies Dach1 as a Kidney Disease Risk Gene**

Tomohito Doki,1 Shizheng Huang,1 Chengxiang Qiu,1 Xin Sheng,1 Hongbo Liu,1 Jianfu Zhou,2 Aili Cao,2 Jianhua Li,2 Lewis Kaufman,2 Richard G. Pestell,2 Katalin Susztak,1 University of Pennsylvania, Philadelphia, PA; 1Icahn School of Medicine at Mount Sinai, New York, NY; 2Shanghai University of Traditional Chinese Medicine, Shanghai, China; 3Pennsylvania Cancer and Regenerative Medicine Research Center, Philadelphia, PA.

**Background:** Genome-wide association studies (GWAS) has identified more than 300 loci where genetic variants are associated with kidney function, however, the causal variants, genes, cell types and the disease mechanism remain mostly unknown. Transcription-wide association studies (TWAS) is a method to prioritize GWAS-identified variants by linking gene expression data to phenotypic and genetic variation.

**Methods:** We obtained genotype and gene expression data for 121 microdissected human kidney tubule and glomerular samples. We applied a variety of TWAS models, such as Mendelian Randomization, TWAS Fusion, Metaxcan. Bulk kidney epigenome mapping and single cell ATAC-seq data were used for fine-mapping. We generated tubule specific DACH1 knock-out (Kapre-Dach1i-fox) and transgenic (Pax8-TRE-Dach1) mice to define the functional role of Dach1 in kidney disease development. Murine cultured tubule cells and single cell RNA sequencing were used for functional studies.

**Results:** Integration of the 3 TWAS methods with CKD GWAS datasets highlighted only 5 genes those levels were consistently influenced by the GWAS variants and expression of DACH1; a transcription factor, was lower in tubules of patients with CKD risk variant. Immunofluorescence analysis indicated that DACH1 was mainly expressed in podocytes and in distal convoluted tubule (DCT) in the kidney. Bulk and single cell ATAC showed that DACH1 risk variants knock-out DACH1 regulatory region in the DCT. Mice with tubule specific Dach1 deletion developed more severe renal fibrosis when challenged with folic acid (FA) compared to controls. Mice with tubule specific Dach1 overexpression were protected from FA-induced kidney fibrosis. Single cell RNA sequencing and cultured primary tubule cell cultures showed that Dach1 plays role in controlling cell proliferation and inflammatory gene expression contributing to fibrosis development.

**Conclusions:** Integration of GWAS, TWAS, single cell, epigenome analysis, mouse models and cultured cell systems identified Dach1 as a causal gene for CKD.

**PO1723**

**Role of Plin5 Deficiency in Podocyte Lipotoxicity and the Progression of Alport Syndrome**

Jin Ju Kim,1 Sydney S. Wilson,1 Judith T. Molina David,1 Sandra M. Merscher,1 Flavia Fontanesi,2 Jeffrey H. Miner,1 Alessia Fornoni,1 University of Miami School of Medicine, Miami, FL; 1Washington University in Saint Louis School of Medicine, Saint Louis, MO.

**Background:** Alport Syndrome (AS) is a hereditary disease caused by mutations in collagen type IV. We and others have demonstrated pathogenic renal lipid accumulation in experimental AS (Col4a3Ko mice). Excess lipids stored in lipid droplets (LD) as cholesterol ester and triglyceride (TG) are known to cause lipotoxicity. Excessive FFA catalysis resulting from excessive lipolysis of TG is a major contributor to cell injury in obesity and diabetes. Perilipin 5 (PLIN5) is a LD-related protein that mediates FFA catabolism resulting from excessive lipolysis of TG. PLIN5 deficiency in podocytes and tubule cells may uncouple the mitochondria, leading to mitochondrial dysfunction and apoptosis. Moreover, exosomes, which in vivo improved kidney function was found in in vitro restorePLIN5 expression in a dose-dependent manner.

**Conclusions:** Our study suggests that podocyte PLIN5 deficiency may cause podocyte injury in AS through excessive TG lipolysis and mitochondrial dysfunction.

**Funding:** Private Foundation Support

**PO1724**

**The Mesenchymal Stem Cell Marker Meflin Defines a Novel Subset of Renal Fibroblasts and Counteracts the Action of TGF-β**

Shun Minatoguchi, Shoji Saito, Shiochi Maruyama. Nagoya university graduate school of Medicine, Department of Nephrology, Nagoya, Japan.

**Background:** Fibroblasts proliferation is the hallmark of renal fibrosis and is important for the progression of CKD. Recently developed single-cell sequencing technology has revealed the substantial heterogeneity of cells that constitute the kidney in health and disease. The heterogeneity of renal fibroblasts, however, has not been completely understood. We recently reported that a fibroblast subset marked by Meflin, a marker of undifferentiated mesenchymal stem cells, has a role to suppress fibrosis in cardiac disease conditions and pancreatic cancer. In the present study, we examined the role of Meflin and the distribution of Meflin-positive fibroblasts in kidney by using cultured fibroblasts and mouse models.

**Methods:** We evaluated the expression of Meflin in normal and fibrotic kidney by in situ hybridization (ISH). To assess the expression of Meflin at a cellular level, we used the rat renal fibroblast cell line NRK49f.

**Results:** ISH revealed that Meflin was expressed by some rare stromal cells found in the interstitial and peri-glomerular areas in the normal kidney. Meflin-positive cells were detected in the wall of middle-sized vessels in the medulla of the kidney. Induction of renal fibrosis by obstructive nephropathy(UUO model) led to a significant proliferation of Meflin-positive cells, which seemed to be distinct from eSMA positive myofibroblasts. Consistent with this, the analysis of single-cell transcriptomic databases showed Meflin and eSMA are expressed in distinct subsets of fibroblasts in the kidney. The expression pattern of Meflin was also confirmed by lineage tracing assay. In the UUO model, some of Meflin-lineage cells were positive for eSMA, suggesting that they give rise to myofibroblasts in the progression of fibrosis. Finally, we assessed the function of Meflin using NK49f. Meflin expression was significantly downregulated by TGF-β1 stimulation, and exogenous Meflin overexpression led to the suppression of TGF-β1 induced eSMA expression and vimentin expression.

**Conclusions:** Our present study identified a new subset of renal fibroblasts, which is positive for Meflin but negative or weakly positive for eSMA. Consistent with our previous studies, Meflin has a role to counteract the action of TGF-β, implying that Meflin-positive fibroblasts have a role to suppress or alleviate renal fibrosis.

**CD14 Contributes to Increased Inflammation and Fibrogenesis in Lupus Nephritis**

Jing Yu, Chi pang Tai, Susan Yung, Tak Mao D. Chan. University of Hong Kong, Hong Kong, Hong Kong.

**Background:** CD14 is a GPl-anchored membrane protein that serves as a pattern recognition receptor in the clinical setting of sepsis. CD14 transfers lipopolysaccharide (LPS) to LPS receptors in the cell membrane to initiate signal transduction and cytokines release. Serum CD14 level is increased in SLE patients, but little is known about its clinical significance or pathogenic role in lupus nephritis (LN).

**Methods:** Serum LPS and CD14 levels were determined in LN patients and healthy subjects using commercially available assays. CD4 level is increased in SLE patients, but little is known about its clinical significance or pathogenic role in lupus nephritis (LN).

**Results:** Serum LPS and CD14 levels were determined in LN patients and healthy subjects using commercially available assays. CD4 level is increased in SLE patients, but little is known about its clinical significance or pathogenic role in lupus nephritis (LN).

**Conclusions:** Serum LPS and CD14 levels were determined in LN patients and healthy subjects using commercially available assays. CD4 level is increased in SLE patients, but little is known about its clinical significance or pathogenic role in lupus nephritis (LN).

CircZNF609 Participates in the Pathogenesis of Focal Segmental Glomerulosclerosis by Sponging miR-615-5p
Junjun Luan, Hua Zhou. Department of Nephrology, Shengjing Hospital of China Medical University, Shenyang, China.

Background: Focal segmental glomerulosclerosis (FGS) is the most common cause of adult nephrotic syndrome, but its mechanism remains unclear. We recently identified and validated that circZNF609 increased in renal biopsies of lupus nephritis patients. We aim to verify whether circZNF609 participates in the pathogenesis of FGS and the underlying mechanisms.

Methods: FGS was induced by Adriamycin (ADR) injection to mice. Proteinuria and serum albumin were examined six weeks after ADR administration. Glomerulosclerosis and tubulointerstitial fibrosis were verified on PAS and Masson staining. Podocyte injury indicated with Wilms tumor 1 (WT1) and Podocin, pro-fibrotic proteins including collagen 1 (COL1) and transforming growth factor-beta1 (TGF-β1) were analyzed by western blotting. Further, renal circZNF609 and miR-615 were measured by qPCR and fluorescence in situ hybridization (FISH). The correlation between renal circZNF609 and above indices were analyzed. In vitro study, circZNF609 in bovine serum albumin (BSA) stimulated HK2 cells for 24 h, which mimics the toxicity of proteinuria from FGS to tubules. CircZNF609, miR-615, COL1 and TGF-β1 were analyzed by qPCR. Lastly, The renal localization of circZNF609 in FGS patients was stained by FISH.

Results: In vivo study, proteinuria and hypoalbuminemia were six weeks after FGS onset by ADR injection. Glomerulosclerosis and tubulointerstitial fibrosis showed on PAS and Masson staining. CircZNF609 was upregulated while miR-615-5p was downregulated in FGS mice analyzed by qPCR and FISH. Podocyte proteins WT1 and Podocin were decreased; pro-fibrotic proteins COL1 and TGF-β1 were increased on western blotting. Renal circZNF609 positively correlated and miR-615-5p negatively correlated with podocyte injury and renal fibrosis. Importantly, circZNF609 and miR-615-5p co-localized on glomeruli and tubules on FISH. Perfect match seeds were found between circZNF609 and miR-615-5p and COL-1. In vitro study, circZNF609 increased and miR-615-5p decreased after BSA stimulation and negatively correlated between each other. COL-1 and TGF-β1 were upregulated and negatively correlated with miR-615-5p. Lastly, circZNF609 was confirmed to increase in glomeruli and tubules in renal biopsies from FGS patients.

Conclusions: We conclude that circZNF609 may play an important role in FGS by sponging miR-615-5p and may be a novel therapeutic target.

Methods: All patients in the MAINTANCAVAS trial were included. Patients were enrolled after a 2 years of continuous B cell depletion. B cells were measured at 3-month intervals with a 2 week window. Days to B cell return were calculated as the time from the last rituximab dose (1000 mg) to date of first detectable CD20 B cells by flow cytometry. Kaplan Meier curves were produced for each round of B cell depletion.

Results: We analyzed data from 109 patients. Median (IQR) duration of B cell depletion was 280.0 (272.0 – 363.0) days until first episode of recovery (Table 1). >80% of subjects had B cell return by 1 year and <10% had B cell return prior to 6 months (Figure 1). Median (IQR) duration of B cell depletion was 265.0 (247.0 – 354.5) days for patients who received a second round of rituximab (Table 1).

Conclusions: This data suggests that after 2 years, maintenance RTX dosing can be extended beyond 6 months for many patients. Further analysis is needed to determine optimal dosing based on B cell return vs ANCA titer and the associated adverse event profiles and RTX utilization.

Predictive Significance of Urinary CD11b and CD163 for the Renal Outcomes in ANCA-Associated Glomerulonephritis
Naotake Tsujii,1 Yuki Yokoyama,2 Takahiro Inaizumi,2 Akimitsu Kitagawa,1 Shoichi Maruyama,1,2 Department of Nephrology, Fujita Health University Graduate School of Medicine, Toyoake, Japan; 3Department of Nephrology, Internal Medicine, Nagoya University Graduate School of Medicine, Nagoya, Japan.

Background: We hypothesized that the detection of leukocyte-derived CD11b (a subunit of integrin Mac-1) and CD163 (scavenger receptor) in urine may reflect renal inflammation and predict the renal outcomes in anti-neutrophil cytoplasmic antibody-associated glomerulonephritis (ANCA-GN). The aim of this study was to evaluate the clinical significance of urinary CD11b (U-CD11b) and CD163 (U-CD163) as alternative noninvasive tests for ANCA-GN.

Methods: U-CD11b and U-CD163 levels were measured using ELISA in ANCA-GN urine samples from institutional cohort (n = 88) and a nationwide cohort (n = 138), and their association with renal histology were analyzed. Logistic regression analyses were performed on a nationwide ANCA cohort to determine the associations of the two urinary molecules with renal remission failure at 6 months or with yearly eGFR slope over a 24-month observation period.

Results: The significant elevations of U-CD11b and U-CD163 were observed in ANCA-GN patients histologically classified to the crescentic category. Histological analyses focusing on the distributions of CD11b+ or CD163+ leukocyte subsets in diseased glomeruli demonstrated dominant distribution of CD11b+ cells in undisrupted area than in glomerular crescent as contrasted with global distribution of CD163+ cells in diseased glomerulus. In addition, levels of U-CD11b and U-CD163 significantly correlated with crescent formation rate, respectively with CD11b+ cell and CD163+ cell number in glomerular crescents. Association analyses of both urinary molecules with post-treatment renal outcomes at 6 months after the treatment demonstrated that U-CD163 levels were significantly reduced and those at the time of diagnosis were already increased in patients who failed to remission or progressed renal insufficiency. Although these associations were not found in U-CD11b, analyses to determine the associations of the two urinary molecules and other clinical parameters with yearly impairment of renal function over a 24-month observation period demonstrated U-CD11b, but not U-CD163, at diagnosis as an independent factor predicting renal recovery.

Conclusions: Although both U-CD11b and U-CD163 reflect renal leukocyte accumulation, U-CD11b at diagnosis predicts the recovery rate after the treatment of ANCA-GN.

Urinary Biomarkers as a Tool for Monitoring Remissions and Predicting Relapses in Autoimmune Glomerulonephritis
Suzanne Dominique Genevet,1,2 Myriam Khalili,2,1 Jean-Philippe Rioux,2,1 Jérémy Quadry,1,2 Arnaud Bonnefoy,1,2 Stephan Troyanov,1,3 Université de Montréal, Montreal, QC, Canada; 2Hôpital du Sacré-Coeur de Montreal, Montreal, QC, Canada; 3Centre Hospitalier Universitaire Sainte-Justine, Montreal, QC, Canada.

Background: Complement-mediated injury, inflammation and fibrosis play central roles in the pathogenesis of autoimmune glomerulonephritis. The use of urinary biomarkers as a surrogate of these pathways of injury could assist clinicians during the clinical follow-up. We investigated the value of urinary biomarkers of complement activation, inflammation and fibrosis during periods of sustained remission among patients with autoimmune glomerulonephritis.

Methods: We prospectively examined 100 patients with ANCA-associated vasculitis, focal segmental glomerulosclerosis, IgA nephropathy, lupus nephritis, membranoproliferative glomerulonephritis and membranous nephropathy. Proteinuria, urinary sC5b-9, monocyte chemoattractant protein-1 (MCP-1) and transforming growth factor-β (TGF-β), expressed as creatinine ratios, were measured at presentation and during follow-up visits. We used standard definitions of remission and relapse for each type of glomerulonephritis. Wilcoxon signed-rank test was used to compare changes in urinary biomarkers during remissions and relapses.

Results: We identified 95 periods of active disease and 82 episodes of sustained remission. Inactive periods lasted a median of 22 (11-32) months. Eighty percent (n=66) of these were not followed by a relapse. During these episodes of remission, urinary biomarkers continued to steadily decrease, achieving a reduction of 40% for proteinuria, 38% for urinary sC5b-9, 38% for MCP-1 and 40% for TGF-β (all p < 0.05). Twenty percent (n=16) of inactive periods reflected relapses with subsequent relapses. Biomarker levels during the inactive period preceding relapses did not significantly change for proteinuria (+9%), urinary sC5b-9 (+15%) and MCP-1 (+21%) while they decreased for TGF-β (-30%, p<0.02). During relapses, we observed a 3.2-fold (1.98-8.3) increase in proteinuria and a significantly greater 8.5-fold (4.2-56.9) increase in urinary sC5b-9 (p<0.001). By contrast, urinary MCP-1 and TGF-β decreased significantly less than proteinuria.

Conclusions: Failure to achieve a sustained reduction in urinary biomarkers during remission was associated with a subsequent risk of relapse of autoimmune glomerulonephritis. Urinary sC5b-9 appears to be a more discerning marker of immunological relapse.

POI1733
Clinical Impact of PRTN3 Polymorphism in Antineutrophil Cytoplasmic Antibody (ANCA) and Similar Vasculitides

Background: Genetic variants associated with ANCA vasculitis include a single-nucleotide polymorphism (SNP) at the proteinase 3 (PRTN3) locus, however the impact of this risk variant on demographics and disease characteristics has not been fully described.

Methods: 401 patients with ANCA and similar vasculitides from the Glomerular Disease Collaborative Network were genotyped for the PRTN3 SNP (rs62132293): myeloperoxidase (MPO) (n = 197), proteinase 3 (PR3) (n = 170), dual positive (n=9), and seronegative (n=25). SNP homzygous (“GG”) were compared to heterozygotes (“CG”) and homzygous (“CC”). PRTN3 expression was measured by quantitative polymerase
chain reaction amplification of cDNA from patient peripheral blood polymorphonuclear leukocytes during active disease. Comparisons were done using Fisher exact and Wilcoxon tests or ANOVA. Bonferroni correction and Tukey test used for multiple comparisons Cox regression was used for multivariable time to relapse and end stage kidney disease (ESKD), with hazards ratios (HR), 95% confidence intervals (CI) reported.

Results: 179 CC, 181 CG and 41 GG patients with median follow-up of 4.8 years were studied. GG patients were significantly younger at disease-onset than others (FIGURE, A). There were no statistical differences in race/sex categories, ANCA seropositivity, organ involvement, or estimated glomerular filtration rate between groups. In a subset of the cohort (n=298) GG had significantly higher peak expression of PRTN3 (FIGURE, B). In the entire group, renal disease was predominant (CC 78%, CG 83%, GG 76%, p = 0.34) and the majority of the treated patients reached remission (91% CC, 88% CG and 90% GG, p=0.79). Upon remission there was no difference in time to first relapse in GG vs. others (HR 1.02, CI 0.62,1.68, p=0.94) and time to ESKD (HR 0.62, CI 0.15, 2.67, p=0.52) adjusted for age and seropositivity.

Conclusions: Disease starts at an earlier age among GG patients, with no clear impact on outcomes. Higher PRTN3 expression may explain earlier disease onset.

The Compositional and Functional Changes of Gut Microbiota in Crescentic Glomerulonephritis

Huanhuang Yin, Xiaoxiao Shi, Peng Xia, Limeng Chen. Department of Nephrology, Chinese Academy of Medical Sciences & Peking Union Medical College Hospital, Beijing, China Peking Union Medical College Hospital, Beijing, China.

Background: Crescent glomerulonephritis (CreGN) is the most dangerous glomerulonephritis, but the specific mechanism remains unclear. Recent evidences suggested that gut microbiota was associated with kidney injury. This study aimed to observe the role of gut microbiota in CreGN.

Methods: A comparative analysis of the gut microbiota was performed in 10 CreGN patients and 10 matched healthy controls by 16S rDNA amplicon sequencing, and half of each group were also analyzed by metagenomics for further function analysis.

Results: The mean age of the 10 CreGN patients was 54.8 ± 17.1 years, with 70.0% were female. The median eGFR was 5.4 (interquartile range: 3.6-9.5) ml/min/1.73m². Compared to controls, CreGN patients showed a significant lower richness (683.2 ± 133.4 vs. 800.1 ± 73.5, p = 0.015) despite a similar level of Shannon index(diversity) 5.4 ± 0.6 vs. 5.6 ± 0.5, p =0.579). PCoA showed a different pattern of clustering in CreGN (p = 0.036, Fig. 1a). There were 66 differentially enriched bacteria genera, with a significant (q<0.05) lower relative abundance of Agathobacter, Prevotellaceae, Faecalibacterium, Dialister, Megamonas, and Alloprevotella genera, and a higher relative abundance of Faecalitalea, Anaerostipes, Paraprevotella, and Streptococcus genera(top 10) in CreGN. All the genera above showed significant correlations with renal injury indicators. For example, Agathobacter was significantly correlated with creatinine (r=-0.77, 24h urine protein(r= -0.86), and eGFR(r=0.73)(Fig. 1b). Besides, Agathobacter, Prevotellaceae, Faecalibacterium, and Dialister were also confirmed as significant biomarkers by LEfSe(Fig. 1c). Metagenomics showed 21 significant differentially enriched functional genera, with a decreased proportion of genes involved in digestive system (q<0.02) and an increased risk of infectious diseases: bacterial (q<0.01) in CreGN.

Conclusions: Gut microbiota in CreGN differed at compositional and functional levels compared with healthy controls, and correlated well with renal injuries.

POI1735

Role of Repeated Renal Biopsy in ANCA Vasculitis

Background: Pauci-immune necrotizing crescentic glomerulonephritis is a severe renal complication of AAV. Despite immunosuppressive therapy, relapses are frequent during the course of the disease. Kidney biopsy is routinely used to diagnose AAV at initial presentation. Although the activity of renal AAV is not easily evaluated by plasma or urine biomarkers, kidney biopsy is rarely performed when relapse is suspected. We herein analyze the clinical, laboratory and renal pathology data from patients who underwent repeated kidney biopsies during the course of AAV.

Methods: We retrospectively reviewed data from 37 patients who underwent at least 2 kidney biopsies in our centre, between 2002 and 2018. The first renal biopsy (B1) was constantly performed at diagnosis. A follow-up biopsy (B2) was performed for purpose, either for suspicion of refractory disease or confirmation of renal relapse. Modifications of renal pathology between B1 and B2 were studied, by comparing presence of active and chronic lesions.

Results: The median delay between B1 and B2 was 3.3 ± [0.9-5.8] years. B2 was done for suspicion of refractory disease (n=8) or of renal relapse (n=29). Causes of B2 were: persistence or reappearance of haematuria in 78% of cases, increase of creatinine in 43%, increase of ANCA titer in 67%. Systemic AAV activity was more important at B1 vs B2 (median BVAS 18 vs 9), as well as renal dysfunction (median sCr 200 vs 156 μmol/l). Active glomerulonephritis was constantly found at B1 but was present in only 35% of B2. Presence of cellular crescents decreased from 71.4 to 29.7% (p = 0.002), whereas fibrinoid necrosis decreased from 80.6 to 35.1% (p = 0.0003). Five factors were significantly associated with the presence of active lesions: presence of at least one extra-renal AAV manifestation (p = 0.0006), increase of ANCA titer (p = 0.0022), CRP>30mg/l (p = 0.001), absence of IF/TA (p=0.02) and high percentage of normal glomeruli (p=0.014) at B1. Interestingly, level of proteinuria and persistence of haematuria were not associated with histological activity at B2 (p = 0.64 and 0.22 respectively). In contrast, chronic lesions were more severe at B2 compared to B1 (p < 0.0001 and 0.014 respectively).

Conclusions: Despite several clinical and laboratory signs suggesting active renal AAV, B2 revealed no relapse in 2/3 of cases, allowing avoidance of a new immunosuppressive induction treatment.

POI1736

Single-Center Experience of Antineutrophil Cytoplasmic Autoantibody-Associated Vasculitis in a Region of Central Appalachia

Muhammad M. Aljuhani, Devan Makati, Abigail Hoff, Vishy Chaudhary, Bethany S. Pellegrino, Rebecca J. Schmidt, Dinesh Kannabhiran. West Virginia University Health Sciences Center, Morgantown, WV.

Background: Antineutrophil cytoplasmic autoantibody-associated vasculitis (AAV) is a rare disease with significant morbidity and mortality. Suspicions that our caseload of AAV might exceed the estimated 3 in 100,000 incidence estimates prompted us to investigate the characteristics of our patients with AAV.

Methods: A retrospective study of all patients diagnosed with AAV at our center prior to December 31, 2019 was performed. Patients were identified based on ICD10 (349),
ICD 9 (1846) codes or diagnosis of a positive ANCA lab test (589). Charts were reviewed for demographic and clinical information. Incidence was estimated for the 10-year period being January 1, 2009 using population estimate.

**Results:** A total of 225 patients had a confirmed diagnosis of AAV of whom 114 were males (50.6%) and 111 females (49.4%). 94.7% were Caucasian, 2.2% African American and 2.2% Hispanics, reflective of our population. Most were older (50.2% ≥60 years). The kidneys (67.6%), lungs (42.7%) and ENT organs (30.2%) were most commonly involved. The predominant ANCA subtype was p-ANCA (52.3%), followed by c-ANCA (43%) and ANCA-negative (4.7%). p-ANCA was most common in patients with renal involvement (58.8%) and c-ANCA was most common in patients with ENT involvement (60%); p <0.01. Of those with renal involvement, 51 needed dialysis (33.6%), 47 of whom became dialysis-dependent (30.9%). Mortality was high in patients with kidney (32.2%) and lung involvement (30.2%) compared to those with ENT involvement (16.2%); p=0.04. Preliminary estimates suggest a regional incidence that may exceed that of other states.

**Conclusions:** In our population, p-ANCA was the predominant subtype and incidence estimates did not mirror those of other areas. These findings suggest that AAV may differ in subtype predominance and incidence by geographic setting.

**Exploring the Role of Type I Interferons in ANCA-Associated Vasculitis**

*Isabella Batten,*1 Mark W. Robinson,*1 Arthur White,*2 Barbara Fazekas,*3 Cathal D. Walsh,*4 Jason Wysc,*5 Suzanne D'Arcy,*6 Antonia Baetnen,*7 Mark A. Little,*8 Nollaig M. Bourke,*9 Trinity Health Kidney Centre, Trinity Translational Medicine Institute, Trinity College Dublin, Ireland, Dublin, Ireland; *School of Computer Science and Statistics, Trinity College Dublin, Dublin, Ireland, Dublin, Ireland; *Department of Biology, Human Health Institute, Maynooth University, Kildare, Ireland, Maynooth, Ireland; *Department of Mathematics and Statistics, University of Limerick, Limerick, Ireland; *Centre for Medical Gerontology, School of Medicine, Trinity Translational Medicine Institute, Trinity College Dublin, Dublin, Ireland, Dublin, Ireland; *Regenerative Medicine Institute, School of Medicine, National University of Ireland Galway, Galway, Ireland, Galway, Ireland.

**Background:** ANCA-associated vasculitis (AAV) is a group of autoimmune diseases characterised by inflammation of small blood vessels. Type I interferons (IFNs) are cytokine mediators of the innate immune response, most known for their anti-viral properties. Dysregulation of type I IFNs is a major factor in the development of several autoimmune diseases, now termed type I interferonopathies, and thought to be the pathogenic link with chronic inflammation in these conditions. Despite evidence of type I IFNs driving autoimmunity, they have not been comprehensively studied in AAV. We hypothesised that type I IFN responses are systemically dysregulated in AAV, indicative of a type I interferonopathy.

**Methods:** Matched whole blood and serum samples collected from healthy individuals (n=67), disease control patients (n=32) and AAV patients (n=71) were obtained from the Rare Kidney Disease Biobank of Ireland. qPCR was used to measure gene expression of type I IFN- and ISG regulated genes (ISGs) characterising type I interferonopathies: IFI27, IFI44L, IFIT1, ISG15, RASD2, SIGLEC1 and STAT1. Serum type I IFN regulated proteins (CXCL10, MCP-1 and CCL19) were assessed by ELISA.

**Results:** No significant difference in ISG gene expression was observed between control samples and AAV patients for any ISG analysed, irrespective of treatment received, age or sex. No significant differences in MCP-1, CCL19 and CXCL10 expression were observed between each cohort. CXCL10 levels were significantly lower in AAV patients than controls. No significant differences in CXCL10 expression were observed. 

**Conclusions:** Systemic type I IFN responses are not dysregulated in AAV and are unlikely to contribute towards AAV pathogenesis; therefore AAV should not be considered as a type I interferonopathy.

**PO1738**

**Angiostensin Converting Enzyme-Overexpressing Neutrophils Suppress Glomerular Injury in Crescentic Glomerulonephritis**

*Narihito Tatsutomo,*1 Suguru Saito,*1 Hiroshi Nishi,*1 Kenneth E. Bernstein,*2 Michihiro Yamashita,*1 Division of Nephrology and Endocrinology, The University of Tokyo Graduate School of Medicine, Tokyo, Japan; *Department of Pathology and Laboratory Medicine, Cedars-Sinai Medical Center, Los Angeles, CA; *Department of Biomedical Sciences, Cedars-Sinai Medical Center, Los Angeles, CA.

**Background:** Angiostensin Converting Enzyme (ACE) is well known as the responsible enzyme to regulate blood pressure by producing angiotensin II in renin-angiotensin system, yet recent studies have revealed that ACE has a novel function in immune cells. We previously found that ACE overexpressed myeloid lineage cells promoted an inflammatory response resulting in increasing resistance to bacterial infection and tumor growth. These results prompt us to investigate the effect of overexpressed ACE in myeloid lineage cells on immune complex (IC)-mediated crescentic glomerulonephritis (GN).

**Methods:** We induced the nephrotoxic serum nephritis (NTN) in C57Bl6/J WT, and NeuACE mice that overexpressing ACE in neutrophils. In addition, IC uptake and IC-mediated responses were investigated in both WT and NeuACE neutrophils by ex vivo experiments.

**Results:** Seven days after induction of NTN, NeuACE mice showed less severe proteinuria, histological glomerular injury, and less number of macrophages infiltration into the glomeruli than those in WT mice. While production and serum level of autologous antibody titer were comparable, IC deposits in glomeruli were reduced in NeuACE mice compared to WT mice. In ex vivo experiments, IC uptake was significantly promoted in NeuACE neutrophils as compared to WT cells. As an underlying mechanism of the promoted IC uptake in neutrophils, we found that serum level of complement C3b and expression of complement receptor CR1/2 on neutrophils were significantly elevated in NeuACE mice. Furthermore, we confirmed that anti-CR1/2 blocking antibody and anti-ACE blocking antibody abolished the IC uptake in both normal and ACE overexpressing neutrophils. These results suggest that ACE in neutrophils directly or indirectly pre-activate C3, and that both the elevated CR1/2 expression and the increased serum C3b play the pivotal role in IC uptake by neutrophils. Despite the increase in IC uptake, neutrophils from NeuACE mice showed better cell survival after IC stimulation compared to those from WT mice.

**Conclusions:** Overexpressed ACE in neutrophils contributes to the effective elimination and suppression of IC deposits in glomeruli via C3b-CR1/2 axis, ameliorating glomerular injury in crescentic GN. These results indicate a novel immunological aspect of ACE in GN.

**PO1739**

**Recurrent of Anti-GBM Disease: An Epiphrenomenon?**

*Sri Vihavari Guntupalli,*1 Robert Mark Black. Saint Vincent Hospital, Worcester, MA.

**Introduction:** The simultaneous presentation of anti-GBM antibodies with ANCA-associated glomerulonephritis occurs in about 40% of individuals with anti-GBM disease. However, recurrence of anti-GBM disease is rare. We report a case of relapsing disease where the recurrent anti-GBM may have been caused by the ANCA-induced glomerular injury.

**Case Description:** A 62-year-old woman presented with generalized weakness and arthralgia. Creatinine was elevated to 1.7 mg/dL from 0.8 mg/dL, urinalysis showed 3+ blood and 1+ protein with dysmorphic RBCs. Her serologies showed an elevated anti-MPO and a moderately high anti-GBM titre. Her renal biopsy revealed crescentic glomerulonephritis with segmental linear IgG staining of the glomerular basement membrane on immunofluorescence. In 2015, at the time of her presentation, she was treated with plasmapheresis, cyclophosphamide and maintained on tapering doses of azathioprine and prednisone. In 2017, as her immunosuppression was tapered, her PCR rose, her urine showed RBCs and her anti-GBM titer, which had been undetectable each month, again became positive. She was retreated with a similar regimen. In 2019, she had another relapse with a higher ANCA titer, a mild rise in creatinine and hematuria. Her anti-GBM, by comparison, remained negative. She repeat renal biopsy was consistent with anti-MPO positivity. A re-review of her initial biopsy showed that there was linear staining, but it was discontinuous and segmental.

**Discussion:** On initial presentation, this patient appeared to have anti-GBM disease with concomitant ANCA positivity, a not uncommon combination. Both titers rose with each relapse. However, during her second recurrence she was noted to have an elevated anti-MPO with necrotizing vasculitis and was promptly treated. At that time, her anti-GBM remained negative. We suggest that this patient has an ANCA-positive vasculitis and that the anti-GBM may have been a secondary or epiphrenomenon due to release of GBM antigens as a result of glomerular damage by anti-MPO antibodies [1]. We believe that this might explain the unusual recurrence of anti-GBM serology in this patient.

Activation of the cGAS-STING Signaling Pathway Is Associated with Glomerular Diseases

Antonio M. Fontanella, Shamroop Kumar Mallala, Judith T. Molina David, Jin Ju Kim, George W. Burke, Sandra M. Merscher, Alessia Fornoni, Alla Mitrofanova. Katz Family Division of Nephrology and Hypertension University of Miami School of Medicine, Miami, FL.

Background: Podocytes express elements of the innate immune system which may play a role in the local immune response and contribute to chronic inflammation and glomerular damage. The cGAS-STING pathway is activated as part of the innate immune response to pathogens or host cytosolic DNA and has been shown to regulate inflammation and energy homeostasis under obesity conditions, kidney fibrosis and acute kidney injury. Whether cGAS-STING pathway contributes to development and progression of glomerular diseases remains largely unknown. This study aimed at filling this gap.

Methods: Immunohyalized human podocytes were cultured in RPMI medium and differentiated for 14 days. c-diAMP treatment (10 μM) was performed for 24h. Real-time PCR and Western blot analysis were used to evaluate mRNA and protein expression. Male and female, 8-week-old C57BL/6J mice were randomly divided into two groups: control (n=7) and I.P. injected with a single dose of c-diAMP, 25 mg/kg (n=9). The animals were sacrificed 72 h after injection, blood and kidneys were harvested and processed for in-depth phenotypical analysis, including urinary albumin-to-creatinine ratio, histological analysis, transmission electron microscopy analysis (foot process effacement quantification), immunohistochemistry, glomerulot isolation and serum analysis.

Results: In vitro, podocytes showed expression all of the cGAS-STING components at the mRNA and protein level under physiological conditions and treatment with c-diAMP, an antagonist of STING, lead to activation of the cGAS-STING pathway. In vivo, treatment of mice with c-diAMP resulted in an increased expression of all components along the cGAS-STING pathway at both the mRNA and protein levels. Histology data show that c-diAMP-treated mice have a lower number of podocytes per glomerulus and a lower podocyte density, showing an increase in foot process effacement. This is further confirmed by increase in blood urine nitrogen and serum creatinine levels and in the urine albumin-to-creatinine ratio.

Conclusions: Genes of the cGAS-STING pathway are expressed in human podocytes and the pathway can be activated both in vitro and in vivo. Activation of the cGAS-STING pathway in mouse models is associated with increased podocyte injury and contributes to the glomerular diseases.

C5a Enhanced the Recruitment of CD16+ Monocytes by CX3CL1-CX3CR1 Axis in ANCA-Associated Vasculitis

JiLe Tang, Zhonghua Liao, Xiao Zhao Li. Xiangya Hospital Central South University, Changsha, China.

Background: Monocytes play a major role in ANCA-associated glomerulonephritis. The mechanism is not well understood. Additionally, it is a consensus that C5a participates ANCA-associated vasculitis (AVV) pathogenesis. The relevance of C5a in terms of monocytes recruitment, as well as the nature and function of monocytes has not been well studied in AVV.

Methods: Monocytes in blood was counted and its phenotypic characteristics were analyzed by Flow cytometry. C5a and monocyte - related cytokines and chemokines was detected in AAV. The phenotype of monocytes in Kidney tissues from MPO-AV patients were studied by immunohistochemistry and immunofluorescence. The chemotractant activity of chemokines produced by human renal glomerular endothelial cells (HRGEC) for monocytes was observed.

Results: Monocytes were higher in activated MPO-AAV patients. The proportion of CD16+ monocytes in the peripheral blood of the patients was significantly reduced and CX3CR1 was highly expressed in CD16+ monocytes. C5a, IL-6, TNF-α, and chemokine CX3CL1 were significantly increased in serum of activated MPO-AVV patients. CD16+ monocytes were clearly seen in the glomeruli of MPO- AVV patients. Chemokine CX3CL1 was expressed in glomerular endothelial cells. Consistently, we demonstrated CX3CL1 expression of CD16+ monocyte via CX3CL1 produced by TNF-α- induced HRGEC in vitro.

Conclusions: We report an altered distribution of monocyte subsets in MPO-AVV patients; CD16+ monocytes may be recruited to kidney through CX3CL1-CX3CR1 axis to aggravate ANCA-associated GN.

Melanocortin 5 Receptor (MC5R) Deficiency Aggravates Glomerular Injury and Proteinuria in the Autologous Phase of Nephrotic Syndrome (NTS) Nephritis

Bohan Chen, Lance D. Dwoorkin, Rujun Gong. University of Toledo Medical Center, Toledo, OH.

Background: The successful use of corticosteroid in steroid-resistant nephrotic glomerulopathies suggests a unique proteinuria-reducing activity of adrenocorticotrophic hormone that is steroidogenic-independent and may be attributable to its melanocortinergic activity. It remains uncertain which melanocortin receptor conveys this beneficial effect. Emerging evidence implicates MC3R signaling in the regulation of immune response. However, the role of MC5R in glomerular disease is unknown.

Methods: NTS nephritis was induced in MC5R knockout (MC5R−/−) and wild-type (WT) mice. Kidney function, proteinuria and renal pathology were evaluated in the autologous phase.

Results: On 14 days after NTS injection in the autologous phase, MC5R−/− as compared with WT mice exhibited an exacerbated kidney dysfunction and injury, as evidenced by higher serum creatinine levels, heavier proteinuria and aggravated renal pathology, featured by crescent formation, glomerular hypercellularity, mesangial expansion, protein casts in renal tubules, inflammatory infiltration in both glomeruli and tubulointerstitial and renal fibrosis. Consistent with the worsened proteinuria, MC5R−/− mice displayed more severe podocyte injury and loss, as evidenced by diminished WT-1 staining and loss of homeostatic podocyte markers, like synaptopodin and podocin, as determined by immunohistochemistry staining and immunoblot analysis of isolated glomeruli. Mechanistically, although glomerular basement membrane-reactive rabbit IgG was found to deposit in glomeruli in both MC5R−/− and WT mice to a comparable magnitude, MC5R−/− mice demonstrated much more glomerular deposition of autologous anti-rabbit IgG together with enhanced fixation of the terminal complement complements C3b-9 along glomerular capillary loops in the autologous phase, suggesting that a potentiated humoral immune response to NTS antigen resulting from MC5R deficiency may contribute to the aggravated NTS nephritis.

Conclusions: MC5R signaling is essential for protection against glomerular injury and proteinuria in murine NTS nephritis via, at least in part, a regulatory effect on humoral immune response.

Glomerular Complement Proteins in Thrombotic Microangiopathy

Lilian M. Palma,1 Meera Sridharan,2 Kenneth L. Johnson,3 Benjamin J. Madden,2 Cristina Charlesworth,2 Sanjeev Sethi.1 Universidade Estadual de Campinas, Campinas, Brazil; 2Mayo Clinic, Rochester, MN.

Background: Thrombotic Microangiopathy (TMA) is a clinicopathological entity resulting from complement abnormalities (atypical hemolytic uremic syndrome, aHUS) and a number of secondary causes including malignant hypertension, autoimmune diseases and drugs. Distinguishing aHUS from secondary TMA is a challenge. A comprehensive evaluation of complement burden in TMA has not been done.

Methods: Glomeruli were laser microdissected and mass spectrometry (MS) was performed. The glomerular complement protein profile was analyzed in aHUS (n=12) and secondary TMA (n=12). The spectral counts obtained from MS are semiquantitative with regards to abundance of the protein.

Results: C3 was the most abundant complement protein in all cases (Figure). The remaining complement proteins were grouped into classical (C1/C4A/C4B), terminal pathway (C5/6/7/8A/9), and complement regulatory proteins (C1r/C1s, C4BP, C3B, Factor H). Among the secondary TMA, drug-induced TMA showed the highest accumulation of complement proteins compared to autoimmune and hypertension-induced TMA (306.9 vs. 217 vs. 219.9, respectively). Finally, CRP were present in all TMA, of which CFH was the most abundant protein.

Conclusions: Complement proteins of all pathways were identified in TMA. C3 followed by C4A/C4B and C9 were most abundant proteins. Higher counts of C3 in aHUS versus higher counts of C4A/C4B in secondary TMA, suggests a greater role of alternative pathway in aHUS and a greater role of classical pathway in secondary TMA.

PO1744

Complement 3 Glomerulonephritis in a Patient with Microscopic Polyangiitis

Hamad Siddiqui, Ayesha Ahmed, Bushra Z. Saleem. Robert Wood Johnson University Hospital, New Brunswick, NJ.

Introduction: C3GN is a rare disorder of excessive alternative complement pathway activation, with renal biopsy characteristic of C3 deposits. We present a unique case, where patient has H/O MPA, admitted for AKI and hematuria, found to have C3GN on renal biopsy.

Case Description: 69 yo M with H/O CKD stage 4 due to microscopic polyangiitis (baseline Cr 2.6 - 2.9), spinal stenosis, HTN and BPH, presenting with complain of painless hematuria, decrease UOP and weight gain x 4 days. He was diagnosed with MPA in 2005 after a renal biopsy, received treatment with steroids, Cyclophosphamide for 18 months, switched to MMF for 2 years and then to Azathioprine which was discontinued after discontinuation.

Renal biopsy showed active crescents with strong C3 global glomerular staining in the mesangium and the capillary wall and trace to no staining of IgG, IgA, IgM, C1q, kappa, lambda. S. EM showed mesangial and sub endothelial deposit suggestive of active crescentic C3 GN.

Discussion: C3 GN is rare in clinical practice. Incidence is estimated to be 2-3 cases per 1,000,000 in the United States. MPA, like other ANCA-associated vasculitides, is typically associated with a pauci-immune GN. We presented a case with signs, symptoms, and clinical features of systemic sclerosis sine scleroderma. Patient was commenced on hypertension and severe accelerated acute kidney injury (AKI) with rapidly declining GFR. TMA was attributed to immunotherapy and atypical HUS genetic testing panel returned negative. Pt was admitted with preliminary diagnosis of AKI on CKD 2/2 MPA flare and C4 normal. AH50 was low (36.1%). Hepatitis panel, C-ANCA, PR-3 and anti-GBM were negative.

Patient was admitted for hypertension urgency and acute kidney injury following 2 cycles of Bintrafusp-alpha therapy targeting TGF-beta and PD-L1.

Case Description: A 41 year old man with metastatic cholangiocarcinoma was admitted for hypertension urgency and acute kidney injury following 2 cycles of Bintrafusp-alpha therapy targeting TGF-beta and PD-L1. Exam was remarkable for BP 180/100 mmHg, pulse 62/min, muscle wasting and anasarca. His labs revealed hemoglobin 8.9 g/dL, platelets 109 x 10^9/L, occasional schistocytes, lactate dehydrogenase 626 U/L (112-222 U/L), undetectable haptoglobin, serum creatinine 2.8 mg/dL, microscopic hematuria and protein creatinine ratio 2.79g/g. ADAMTS13 activity 72% (undetectable haptoglobin, serum creatinine 2.8 mg/dL, microscopic hematuria and protein creatinine ratio 2.79g/g. ADAMTS13 activity 72% (undetectable haptoglobin, serum creatinine 2.8 mg/dL, microscopic hematuria and protein creatinine ratio 2.79g/g. ADAMTS13 activity 72% (undetectable haptoglobin, serum creatinine 2.8 mg/dL, microscopic hematuria and protein creatinine ratio 2.79g/g. ADAMTS13 activity 72%

Discussion: Here we report a case of newly diagnosed SRC with TMA that clinically responded to TGF-beta blockade and ACEI. Kidney function rapidly improved on treatment from a peak creatinine of 9.5mg/dL to 2.1mg/dL over 4 weeks without requiring dialysis, combining of resolution to all TMA features. Eculizumab was stopped after 3 months, without sign of relapse 2 months after discontinuation.

Conclusion: Eculizumab use in scleroderma renal crisis with thrombotic microangiopathy

Claire Avyllach, Aula Jaberi, Laurence H. Beck, Jean M. Francis. Boston Medical Center, Boston Medical Center, Boston, MA.

Introduction: Scleroderma renal crisis is a life-threatening condition with increased mortality and morbidity leading to end-stage renal disease in about 25% of cases. Here we report a case of newly diagnosed scleroderma renal crisis with thrombotic microangiopathy (TMA) successfully treated with eculizumab.

Case Description: A 44-year-old African American female with no significant past medical history, presented with acute pulmonary edema in the setting of malignant degeneration (AMD) and Diabetic Retinopathy (DR) among other ophthalmologic conditions, albeit at lower doses than those given for systemic indications. Systemic absorption of anti-VEGF agents when given intravitreally has been shown consistently with evidence of significant intravascular VEGF expression. While worsening hypertension has only been seen in some large-scale studies, case reports show worsening proteinuria and diverse glomerular diseases. These include TMA-associated lesions like focal and Segmental Glomerulosclerosis with Collapsing Features (cSGS).

Case Description: In this paper, we report 3 cases of TMA likely associated with use of intravitreal anti VEGF therapy. These patients developed the signature lesion of VEGF blockade in a 6 month – 11 month time frame after starting intravitreal VEGF inhibitors.

Discussion: This literature is reviewed showing similar cases. Intravitreal VEGF blockade may cause these adverse events in a hitherto unidentified subgroup of patients. Further studies are needed to determine the event rate and identify which patients are at increased risk for hypertension, proteinuria worsening, renal injury, and glomerular diseases from intravitreal VEGF blockade.

Eculizumab Use in Scleroderma Renal Crisis with Thrombotic Microangiopathy

PO1746

Thrombotic Microangiopathy and AKI Induced After Intravitreal Injection of Vascular Endothelial Growth Factor Inhibitors

Ramy M. Hanna,1 Sapna S. Patel,1 Nguyen G. Tran,2 Kenar D. Jhaveri,2 Kamyar Kalantar-Zadeh,1,3 Ira Kurta,2 1University of California Irvine, Orange, CA; 2Northwell Health, Great Neck, NY; 3University of California Los Angeles, Los Angeles, CA; 4Long Beach Medical Center, Long Beach, CA.

Introduction: Vascular Endothelial Growth Factor (VEGF) inhibition can cause worsening hypertension, proteinuria, acute and chronic kidney injury, as well as glomerular disease from Thrombotic Microangiopathy (TMA) and other nephrotic disorders when given systemically. These same agents are given intravitreally for age related macular degeneration (AMD) and Diabetic Retinopathy (DR) among other ophthalmologic conditions, albeit at lower doses than those given for systemic indications. Systemic absorption of anti-VEGF agents when given intravitreally has been shown consistently with evidence of significant intravascular VEGF expression. While worsening hypertension has only been seen in some large-scale studies, case reports show worsening proteinuria and diverse glomerular diseases. These include TMA-associated lesions like focal and Segmental Glomerulosclerosis with Collapsing Features (cSGS).

Case Description: In this paper, we report 3 cases of TMA likely associated with use of intravitreal anti VEGF therapy. These patients developed the signature lesion of VEGF blockade in a 6 month – 11 month time frame after starting intravitreal VEGF inhibitors.

Discussion: The literature is reviewed showing similar cases. Intravitreal VEGF blockade may cause these adverse events in a hitherto unidentified subgroup of patients. Further studies are needed to determine the event rate and identify which patients are at increased risk for hypertension, proteinuria worsening, renal injury, and glomerular diseases from intravitreal VEGF blockade.

PO1747

Bintrafusp-alpha-Associated Thrombotic Microangiopathy

Jacob Ninan, Swetha Reddy, Musab S. Hommos. Mayo Clinic, Phoenix, AZ.

Introduction: Immune check point inhibitors (ICPIs) have been reported to cause acute kidney injury. Acute tubulo-interstitial nephritis is the most common finding on renal biopsy. This has resulted in recommendations for forgoing renal biopsy in some patients and therapy with empiric steroids. Here we present a different renal pathology related to use of Bintrafusp-alpha, a novel therapy targeting TGF-beta and PD-L1.

Case Description: A 41 year old man with metastatic cholangiocarcinoma was admitted for hypertension urgency and acute kidney injury following 2 cycles of Bintrafusp-alpha therapy targeting TGF-beta and PD-L1.

Discussion: TMA is characterized by microangiopathic hemolytic anemia and thrombocytopenia. The most studied secondary cause of TMA is drugs. The pathogenesis of drug-mediated TMA is either the generation of an immunologic reaction or its direct dose- and time-dependent toxicity. ICPI monotherapy has a nephrotoxicity incidence of 2.5%. In the largest retrospective study of 1016 patients treated with ICPI therapy, 17% developed AKI, 2% experienced stage 3 AKI and 0.4% required dialysis. TMA was documented in 1 patient receiving Ipilimumab and was HD-dependent. The National Comprehensive Cancer Network guidelines recommend empirically starting AKI in some
patients with steroids. We believe renal biopsy is essential, if safe, to rule out causes of AKI that are not remediable with steroids. Renal biopsy would expand our knowledge on the pathology of AKI post-ICPI treatment. We report the first case of TMA associated with the new bifunctional immunotherapy for solid cancers.

PO1748
Atypical Hemolytic Uremic Syndrome Associated to Complement Dysregulation in Setting of Metastatic Prostate Cancer Patient
Matthew Van Norman,1,2 Omar Mamlouk,1 Biruh Workeneh,2 1University of Texas Health Science Center at Houston, Houston, TX; 2University of Texas MD Anderson Cancer Center, Houston, TX.

Introduction: Thrombotic microangiopathy (TMA) is a collection of syndromes, with the most frequent types encountered being hereditary uremic syndrome (HUS), thrombotic thrombocytopenic purpura (TTP), and atypical HUS. Atypical HUS (aHUS) may be attributed to inherited or acquired complement abnormalities, or secondary causes such as pregnancy, malignancy, transplantation, drugs. Malignancy-associated aHUS is caused by a two-hit event with complement activation playing minor role while in primary aHUS, the primary hit is complement dysregulation. We describe an unusual case of aHUS in a metastatic cancer patient attributed primarily to complement dysregulation.

Case Description: A 64-year old male with history of metastatic prostate adenocarcinoma with spinal involvement presented with a chief complaint of new onset hypertension. He reported dark “coke-colored” urine for one day with intermittent episodes of hematuria. Patient last received chemotherapy with cabazitaxel five months prior. Rest of history and physical exam was unremarkable. Laboratory findings were significant for thrombocytopenia, anemia, and peripheral smear demonstrating schistocytes. Ct peaked at 6.58 mg/dL, ADAMTS13 activity was 100%, and stool PCR was negative for shigella. Complements C3 and C4 were within normal limits. Patient became oliguric with worsening acidosis and was initiated on renal replacement therapy. He underwent a bone marrow biopsy showing no evidence of infiltration of malignancy into the bone marrow. He then had a renal biopsy with pathology showing acute TMA with fibrin thrombi in approximately 50% of the glomeruli. C5b9 levels were elevated. He was initiated on Eculizumab 900mg once weekly and began to show signs of renal recovery. Within two weeks, he was transitioned off renal replacement therapy.

Discussion: Primary aHUS as a result of complement dysregulation can occur in patients with malignancy. This patient had elevated C5b9 complex levels with increased alternative pathway activation. He responded to eculizumab, monoclonal antibody inhibiting activation of C5, with full recovery of his renal function. In cases of aHUS presenting in patients with malignancy, physicians should be aware that aHUS may still occur secondary to the primary hit of complement dysregulation and should consider treating this complement pathway.

PO1749
An Unusual Case of Complement-Mediated Thrombotic Microangiopathy
Sobia N. Khan, Wilfred Lieberthal. Stony Brook University, Stony Brook, NY.

Introduction: Thrombotic microangiopathy is a specific pathologic lesion in which abnormalities in the vessel wall of arterioles and capillaries lead to microvascular thrombosis. Diagnosis is made by tissue biopsy Complement mediated TMA is hereditary deficiency of regulatory proteins that restrict activation of alternative pathway or hereditary abnormality of proteins that accelerate activation of this pathway. Deficiency of complement factor H or C1r can also be acquired.

Case Description: 19-year-old female with ulcerative colitis presented with bloody diarrhea and decreased oral intake for one week. She endorsed not taking mesalamine and use of naproxen daily for two daily weeks. Laboratory data, leukocytosis 22k with 84% neutrophils, 5% bands and schistocytes, hemoglobin 6.1g/dL, thrombocytopenia, BUN 77 mg/dL, creatinine 7.16 mg/dL, Lactate dehydrogenase 1042IU/L and haptoglobin granular, basement membrane, electron dense deposits within glomerular and tubular Basement menbrane. He was initiated on Eculizumab 900mg once weekly and began to show signs of renal recovery. Within two weeks, he was transitioned off renal replacement therapy.

Discussion: Primary aHUS as a result of complement dysregulation can occur in patients with malignancy. This patient had elevated C5b9 complex levels with increased alternative pathway activation. He responded to eculizumab, monoclonal antibody inhibiting activation of C5, with full recovery of his renal function. In cases of aHUS presenting in patients with malignancy, physicians should be aware that aHUS may still occur secondary to the primary hit of complement dysregulation and should consider treating this complement pathway.

PO1750
A Case of “Immunofluorescence-Negative” Lambda Light Chain Deposition Disease
Kunal B. Buech, Satyanarayana R. Vaidya, Sheryl C. Caberto, Alton B. Farris. Emory University, Atlanta, GA.

Introduction: Light chain deposition disease (LCDD) is the most common form of monoclonal immunoglobulin deposition disease (MIDD). Pathologically, monomer LCDD develop nodular expansion of mesangial regions and deposits of monoclonal light chain (LC) positive, electron dense deposits within glomerular and tubular Basement membrane. The majority of monoclonal LC in LCDD are of kappa type. (1,2) We report a case of lambda LCDD with negative immunofluorescence microscopy (IF), but with characteristic granular, basement membrane, electron dense deposits on ultrastructural examination.

Case Description: A 42-year-old Caucasian female with no PMHx, no NSAID, Chinese herbal or PPI use presented with fatigue, malaise and dark urine for 2 weeks. She had a normal BP and no edema. Labs: Scr was 2.4 mg/dL with unknown baseline levels, BUN 26 mg/dL, Hb level 9.0 gm/dL with MCV of 90 fl, with a negative autoimmune panel. Urine microscopy showed 10 RBC/HFP and 24-hour protein excretion was 460 mg. SPEP and immunofixation detected a Lambda LC monoclonal paraprotein. Serum free Lambda LC level was 1044 mg/dL with free kappa/lambda LC levels ratio of 0.03. A kidney biopsy revealed nodular expansion of glomerular mesangial regions, modest arteriectasis of JET, RBCs and red cell casts were present in tubules. Direct IF microscopy with FITC-conj. anti-human IgG, IgM and IgA heavy chains and Kappa/lambda light chains was negative with testing performed in duplicate. Ultrastructural examination revealed powdery, granular electron dense deposits diffusely along tubular and glomerular basement membranes with focal areas of podocyte process effacement. Bone marrow biopsy revealed cell plasma neoplasm.

Discussion: Our patient underwent autologous SCT after pretreatment with Melphalan. Renal function has been stable at stage III CKD. She never developed HTN or significant proteinuria, which usually are some of the presenting features of LCDD. She had lambda LC paraproteinemia, which is a more common feature of heavy chain deposition disease than LCDD. Direct IF microscopy was negative, which could be due to abnormal LCs being truncated in the tissue deposits, and commercially available, FITC-conj. anti-human Abs might not have been able to detect them. (4) This case emphasizes the fact that negative staining by routine direct IF microscopy methods does not exclude the presence of MIDD.
PO1752
A Case of Granulomatosis with Polyangiitis Complicated by Renal Mass-Like Lesion
Daichi Kaiko, Koichi Sato, Hisayuki Ogura, Taro Miyagawa, Tadasu Toyama, Shinji Kitajima, Akinori Harai, Yasunori Iwata, Norihiko Sakai, Miho Shimizu, Takashi Wada. Department of Nephrology and Laboratory Medicine, Kanazawa University, Kanazawa, Japan.

Introduction: Granulomatosis with polyangiitis (GPA) is a multiorgan systemic disease. Some cases of GPA may mimic IgG4-related disease (IgG4-RD) on histologic examination. Here we report a case of GPA complicated by renal mass-like lesion with infiltration of IgG4-positive plasma cells.

Case Description: A 76-year-old woman was diagnosed with otitis media with effusion 6 years before admission, and scleritis 3 years before admission. She developed nasal leaks and nasal bleeding a year before admission, and high fever and general malaise a month before admission. She visited nearby hospital and was detected a mass-like lesion in the right nasal cavity. Contrast-enhanced computed tomography (CT) of the head revealed an enhanced soft-tissue from the right middle meatus to the nasal septum and cervical lymphadenopathy. Serum proteinase 3-antineutrophil cytoplasmic antibody (PR3-ANCA) was positive (271.7 U/mL) with high C-reactive protein (CRP) level (29.7 mg/dL). Urinalysis showed minor proteinuria (0.1 g/gCr), but elevated tubular injury markers such as urinary beta 2-microglobulin. So, she admitted to our department. Contrast-enhanced CT of the abdomen revealed a 47-mm large mass-like lesion in the right kidney, and CT-guided renal biopsy was performed. Cellular to fibro-cellular crescent and fibrinoid necrosis were observed in the glomerulus. In the interstitium, granulomas with multinucleated giant cells and infiltration of IgG4-positive (IgG4+) plasma cells were observed. In addition, cell infiltration into the arteriole wall and the rupture of lamina elastica were observed. From these findings with small vessel vasculitis, we diagnosed her as GPA with infiltration of IgG4+ plasma cells. After two courses of methylprednisolone pulse therapy, we added two courses of cyclophosphamide pulse therapy. With improved symptoms and serum data (PR3-ANCA level reduced from 266.8 to 39.0 U/mL), mass-like lesions in nasal turbinate and right kidney diminished.

Discussion: We experienced a case of GPA complicated by renal mass-like lesion. Renal biopsy revealed a coexistence of microvasculitis and infiltration of IgG4+ plasma cells. Further investigation will be required to clarify the role of IgG4+ cells in the pathogenesis of GPA.

PO1753
Granulomatosis with Polyangiitis and Acute Tubulointerstitial Nephritis in the Absence of Glomerulonephritis
Weiven Guo, Cynthia C. Lim, Jason Choo Chon Jun, Singapore General Hospital, Singapore, Singapore.

Introduction: Isolated TIN in the absence of glomerular involvement is uncommon in ANCA-associated vasculitis (AAV).

Case Description: 77 year old female with normal renal function presented with acute kidney injury (AKI) with peak SCr 482 μmol/L and anti-PR3 was 4.4U/ml. A year later, she presented with PR3-ANCA GPA that presented with isolated glomerular abnormalities and acute TIN with interstitial non-necrotising granuloma and multinucleated giant cells. Ziehl-Neelsen stain was negative. Immunofluorescence, electron microscopy were significant for granular mesangial deposits. The patient was empirically pulsed with intravenous steroids for three days. She was notable for sinus tachycardia and tenderness to palpation over maxillary sinuses. Urinalysis revealed active sediment with dysmorphic red blood cells. Initial workup was significant for serum creatinine of 1.35 mg/dl (baseline of 0.7 mg/dl), positive C-ANCA 1:160, anti-Proteinase-3 antibody 28.4 μmol/L (normal <3) and 24-hour urine protein of 576 mg. Preliminary native kidney biopsy light microscopy showed active and organizing crescentic glomerulonephritis involving 15 of 34 (44%) non-globally sclerotic glomeruli. Immunofluorescence and electron microscopy were significant for granular mesangial staining for IgA and lambda light chain and presence of few mesangial electron-dense deposits. The patient was empirically pulsed with intravenous steroids for three days. She was given one dose of Rituximab with a planned second dose two weeks after discharge.

Discussion: Rapidly progressive ANCA associated crescentic GN along with mesangial staining for IgA and lambda light chain is extremely uncommon with limited literature. By presenting this case, we highlight the significance of a renal biopsy as an essential tool for diagnostic purposes and the need to have a low threshold to biopsy in otherwise clinically straightforward cases given unexpected histologic and immunologic findings that could affect therapy and consequently patient’s morbidity and mortality.

PO1754
Coexisting Proteinase 3 Antineutrophil Cytoplasmic Antibody-Associated Crescentic Glomerulonephritis, Immunoglobulin A Nephropathy, and Lambda Light Chains
Ariun L. Kalaria, Amoghavarsha Puli, Sheldon Bastacky, UPMC, University of Pittsburgh Medical Center, Pittsburgh, PA.

Introduction: Rapidly progressive glomerulonephritis (RPGN) is a clinical syndrome that develops within weeks and is manifested by glomerular disease that is histologically delineated by crescent formation and progressively worsening renal dysfunction. The most common causation of RPGN includes auto-antibody mediated crescent staining (ASCA) vasculitis, immune complex-mediated injury, and anti-glomerular basement membrane disease. We report a case of proteinase-3 (PR-3) ANCA associated crescentic glomerulonephritis with concurrent immunoglobulin A (IgA) nephropathy and lambda light chain. The co-existence of ANCA associated crescentic GN, IgA nephropathy and lambda light chain is rare.

Case Description: A previously healthy 53-year-old Caucasian woman with newly diagnosed Granulomatosis with Polyangiitis (PR-3 ANCA positive) presented with cough, acute renal failure over the past 2 months. Physical examination. Here we report a case of proteinase-3 (PR-3) ANCA associated crescentic glomerulonephritis with concurrent immunoglobulin A (IgA) nephropathy and lambda light chain. The co-existence of ANCA associated crescentic GN, IgA nephropathy and lambda light chain is rare.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
overlapping of the standard regimen is safe and effective in older age group. If the patient remained refractory cases while continuing standard therapy until the 2nd dose of rituximab, with oliguria, low creatinine and anti-GBM antibody levels, negative ANCA, involvement of upper limb occurred on day 75, antibody levels were undetectable and on day 147 she remained dialysis free.

Discussion: It was a novel case of MPA with RPGN accompanied by ITP. It was recently recognized that diversity existed in both pathogenesis and clinical characteristics in patients with both ITP and RPGN. Present case showed the possibility for an association of pathological mediator for both diseases. Although further studies are needed to confirm this idea, present findings provide clues for our understanding of this association for a better management of these diseases.

PO1756
Rituximab Rescue in Anti-GBM Nephritis
Shikha Shahily, Lorin Berman, Sofia Rubinstein. Nassau University Medical Center, East Meadow, NY.

Introduction: Anti-GBM nephritis is a rare, severe autoimmune disease. If left untreated or in patients requiring dialysis at presentation, it has a renal survival of 8% at 1 year. Conventional therapy includes corticosteroids, cyclophosphamide and plasmapheresis. An anti-B-cell agent, rituximab is more recently being used in refractory cases (defined as no response after 4 weeks of standard therapy).

Case Description: 59-year-old female with hypertension presented with 1 month of fever, generalized malaise, and cough following recent travel to Africa. Laboratory evaluation showed serum creatinine 1.3 mg/dl with hematuria and proteinuria (0.6 g/dl). ANA, ANCA, RF, Hepatitis B/C, HIV, RPR, and streptococcal panel were negative. Renal and pulmonary imaging were unremarkable. With creatinine rising rapidly, renal biopsy was performed revealing acute focal segmental necrotizing and crescentic glomerulonephritis involving 50% of glomeruli. Anti-GBM antibody level was 8U. Plasmapheresis daily, cyclophosphamide and steroids were initiated. She remained nonoliguric, but developed edema requiring intermittent diuresis. On day 15, plasmapheresis was reduced to every 48 hours. Anti-GBM antibody failed to decline, therefore the report of rituximab infusion was initiated 3 weeks later. Standard therapy was continued until the second dose of 1gr of rituximab 2 weeks later. Patient was discharged with creatinine stable at 4 mg/dl, anti-GBM antibody level at 1.4U and on prednisone taper. On follow up day 75, antibody levels were undetectable and on day 147 she remained dialysis free.

Discussion: Our patient presented with favorable prognostic markers including nonoliguria, low creatinine and anti-GBM antibody levels, negative ANCA, involvement of 50% of glomeruli, and no dialysis requirement. Despite these factors, she did not respond to standard therapy alone. Our patient was initiated on rituximab earlier than reported in refractory cases while continuing standard therapy until the 2nd dose of rituximab, with a favorable outcome of remaining dialysis free. We suggest early use of rituximab with overlapping of the standard regimen is safe and effective in older age group.

PO1757
Rare Case of Myeloperoxidase-ANCA-Positive Polyarteritis Nodosa
Bhaktidevi Makadia.1 Sandeep K. Mailipattu.1 Monica P. Revelo Penafiel.2 1Stony Brook University Hospital, Stony Brook, NY; 2University of Utah Health, Salt Lake City, UT.

Introduction: Polyarteritis Nodosa (PAN) is systemic necrotizing vasculitis involving medium-size vessels. PAN is typically not associated with positive antineutrophil cytoplasmic antibodies (ANCA) titer. Here, we report a patient who presented with abdominal pain, hypertension, and bloody diarrhea who tested positive for anti-GBM disease. Treatment with Eculizumab was started, but diffuse alveolar hemorrhage (DAH) developed 19 days after admission and thus plasmapheresis and cyclophosphamide were initiated without delay.

Case Description: 75-year-old male with a history of tobacco use was admitted for oliguric acute kidney failure requiring initiation of dialysis. Kidney biopsy showed linear IgG4-related kidney disease (IgG4-RKD). Neurologic involvement is less common and known to manifest as hypophysitis and pachymeningitis. Neurologic involvement is less common and known to manifest as hypophysitis and pachymeningitis.

Discussion: Anti-GBM disease and complement-mediated TMA are both exceedingly rare clinical entities. While hemolysis has been reported in the literature, this is the first report of complement-mediated TMA driving hemolysis in the setting of anti-GBM. Dysregulated activation of the alternative pathway in complement-mediated TMA and literature reports supporting a role for both classical and alternative pathways in anti-GBM disease suggests a possible link between the two diseases and a previously unrecognized role for complement dysregulation in cases of hemolysis observed in the setting of anti-GBM.

PO1758
Complement-Mediated Thrombotic Microangiopathy in a Patient with Anti-GBM Disease: A Case Report
Yuliya Sharakova, Mohamed Hassanaein, Rhayd Matidz, Leal C. Herlitz, John F. O’Toole. Cleveland Clinic, Cleveland, OH.

Introduction: Anti-glomerular basement membrane (anti-GBM) disease is a rapidly progressive glomerulonephritis, caused by pathogenic antibodies directed against the gC1qC epitope of type IV collagen, and accompanied by pulmonary hemorrhage in about 50% of cases. Here we present a case of anti-GBM disease in combination with hemolysis, a rare and poorly understood association.

Case Description: A 22 y/o male with a history of tobacco use was admitted for oliguric acute kidney failure requiring initiation of dialysis. Kidney biopsy showed linear GBM staining for IgG, α, and β, suggesting the diagnosis of anti-GBM nephritis with crescentic involvement of all glomeruli and positive serum anti-GBM antibody. High dose corticosteroids were given but additional immunosuppression was held due to low probability of benefit in the setting of severe renal limited disease. One week after biopsy, the patient developed fever, and his Hb decreased to 6 g/dl due to microangiopathic hemolytic anemia with low haptoglobin, elevated LDH, mild platelet decline, and negative Coombs test. Additional workup was negative for malignancy, coagulopathy, deficiency, malignant hypertension, or infection including shiga-toxin, showed normal ADAMTS13 activity, C3, C4, factor H, I, B, and no CFH autoantibody, but an elevated sc5b9 level demonstrating terminal complement activity. Repeat kidney biopsy revealed an acute thrombotic microangiopathy (TMA) along with previously diagnosed anti-GBM disease. Treatment with Eculizumab was started, but diffuse alveolar hemorrhage (DAH) developed 19 days after admission and thus plasmapheresis and cyclophosphamide were initiated with reduction of anti-GBM titers and hemolysis and resolution of DAH.

Discussion: Anti-GBM disease and complement-mediated TMA are both exceedingly rare clinical entities. While hemolysis has been reported in the literature, this is the first report of complement-mediated TMA driving hemolysis in the setting of anti-GBM. Dysregulated activation of the alternative pathway in complement-mediated TMA and literature reports supporting a role for both classical and alternative pathways in anti-GBM disease suggests a possible link between the two diseases and a previously unrecognized role for complement dysregulation in cases of hemolysis observed in the setting of anti-GBM.

IgG4-Related Kidney Disease Associated with an Unusual Vasculitic Peripheral Neuropathy
Muhammad T. Bang, Anjali A. Satoskar, Benjamin Jiang, Miriam L. Freimer, Isabelle Aqousb. The Ohio State University Wexner Medical Center, Columbus, OH.

Introduction: IgG4-related disease is a systemic autoimmune fibro-inflammatory disorder showing lymphoplasmacytic infiltrates with predominance of IgG4+ plasma cells and variable amounts of storiform fibrosis in the affected tissues. When kidneys are the only organs involved it is called IgG4-related kidney disease (IgG4-RKD). Neurologic involvement is less common and known to manifest as hypophysitis and pachymeningitis.
Peripheral neuropathy is rare. Our case illustrates an unusual presentation of IgG4-RKD with vasculitic neuropathy, which has never been reported before.

Case Description: A 55-year-old Southeast Asian woman with allergic rhinitis presented to her PCP with burning and tingling from the knees down and difficulty with gait for about 6 months. Neurological examination was notable for weakness of ankle dorsiflexion and plantar flexion and loss of pinprick sensation in all toes. This was attributed to iron deficiency anemia and a compressed nerve. However, her symptoms worsened on iron supplements and gabapentin and were accompanied by weight loss. CT scan of abdomen showed heterogeneous masses of the kidneys with few enlarged retroperitoneal lymph nodes. Kidney biopsy was performed and showed storiform fibrosis and plasma cell rich interstitial infiltration (>30 IgG4+ plasma cells/HPF) suggesting IgG4-RKD. Further work up was significant for serum IgE 1309 IU/ml (1.5-165), IgG4 177 mg/dl (2.4-121), ANA >1:1280, positive MPO-ANCA, RF 38 IU/ml (<14), ESR 77 mm/hr. CRP, complement levels and kidney function were normal. Prior to initiating therapy for IgG4-RKD she was referred for sural nerve biopsy for concern of associated vasculitis. Nerve biopsy showed severe myelinated and unmyelinated fiber loss in all fascicles, a recanalized epineural blood vessel, and dense perineural mononuclear cell infiltrates consistent with vasculitic neuropathy. Additionally, immunostaining showed IgG4 plasma cells up to 10 HPF. Her symptoms resolved with steroids, IVIG and rituximab. Serum IgG4 level improved to 26 mg/dl.

Discussion: IgG4-RD can have varied systemic manifestations. Although neurologic disease is less commonly seen in IgG4-RD, we report for the first time an associated vasculitic neuropathy that should be considered and worked up in symptomatic patients.

PO1760
Differential Expression of Interferon-Stimulated Genes in ANCA-Associated Vasculitis
Prasanti Koter, Eoin F. McKinney, Paul A. Lyons, Kenneth G. Smith, Smith Laboratory of University of Cambridge, Cambridge, United Kingdom.

Background: Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is a multi-systemic, necrotising vasculitis, causing severe morbidity and mortality. It is characterised by the presence of auto-reactive antibodies against neutrophil granule components, myeloperoxidase (MPO) and proteinase 3 (PR3). The disease course remains variable, and patients suffer substantial morbidity and mortality. Therapeutic advances are hampered by a lack of understanding of the mechanisms driving both initial disease susceptibility and long-term clinical outcome. To increase our understanding of disease mechanism and to uncover untargeted pathways for treatment, we studied the transcriptomes and serum proteomes of patients with active AAV.

Methods: The transcriptional profiles and protein expression of patients with AAV (31 PR3-ANCA, 15 MPO-ANCA, 1 dual ANCA positivity, 4 ANCA-negative) were studied at the time of diagnosis or during an active flare, whilst on minimal immunosuppression, along with healthy controls. AAV patients were profiled longitudinally at 3 and 12 months. Separated leucocyte transcriptomes were profiled, using Affymetrix HuGene ST1.1 gene expression microarray. Transcriptional profiles were available on peripheral blood mononuclear cells (PBMCs), neutrophils, monocyes and CD4 and CD8 T cells. Protein expression was assessed on the SOMAscan platform. Analytical techniques included differential gene-expression, weighted gene co-expression network, gene set enrichment and multi-omics factor analyses.

Results: Here we identify, a module of interferon stimulated genes (ISG) that distinguishes the serological subtypes of AAV, MPO- and PR3-ANCA. This module of ISG was upregulated in MPO compared with PR3-ANCA during the time of active disease and at 3 months post treatment. The signature was present in the neutrophil, monocyte and PBMC transcriptome but was absent in T cells. Multi-omic factor analysis revealed a parallel upregulation of interferon like proteins in serum, coinciding with the increase in gene expression.

Conclusions: AAV causes severe morbidity and mortality. The differential expression of ISG in MPO compared with PR3-ANAA highlights potential differences in pathogenesis. The presence of an interferon response in MPO-AAV opens new avenues for targeted treatment with agents such as JAK inhibitors and monoclonal anti-IFN-α antibodies.

PO1761
IL-23-Induced Remission from Lupus Gleromerulonephritis Involves Regulation of Mitochondrial Function and Canonical WNT Signaling
Rahul V. Venkatadri, Vikram Sabapathy, Murat Dogan, Saleh Mohammad, Shu man Fu, Rahul Sharma. University of Virginia, Charlottesville, VA

Background: We recently showed the efficacy of a hybrid cytokine IL-23 to protect mice from lupus glomerulonephritis (GN). We have now investigated the status of mitochondrial function, canonical Wnt signaling and metabolic fitness of regulatory T cells (Tregs), risk factors known to be associated with lupus GN to further delineate the mechanisms of protection offered by IL-23.

Methods: We made use of the recombinant hybrid cytokine (IL-23) bearing activities of IL-2 and IL-33 and tested its efficacy to prevent glomerular nephritis in the adenovirus (Ad)IFNa Acelerated lupus GN NZM2258 model. Kidney lysates were screened for transcripts of mitochondrial and Wnt inhibitor genes by real time PCR and Western blotting. (mitochondrial CRP, p53, and p21) and (mitochondrial CRP, p53, and p21). Extracts from IL-23 treated glomerular endothelial cells (MGECS) was investigated by flow cytometry and Seahorse assay. Metabolic fitness of Tregs with and without IL-23 treatments were investigated by Seahorse assay by employing ex vivo and in vivo approaches.

Results: Analysis of transcript levels of mitochondrial function and biogenesis related genes (Pgc1a, Nrf1, Nrf2, Tkctm, Drp1, and Mfn1) confirmed that IL-23 treated kidneys displayed an elevated status. In vitro, changes in Pge1 and its downstream target Nfκb were recapitulated in treated MGECS cells. IL-23 treated Tregs (ex vivo and in vivo) and MGECSs (in vitro) also exhibited better mitochondrial metabolic fitness and displayed elevated levels of basal respiration, maximal respiration and ATP production investigated by the Seahorse assay. Wnt activators LRPE, Dvl3 and Wnt mediators - Axin1, GSK3a and GSK3b were significantly reduced in IL-23 protected kidney. Levels of Axin2 was significantly upregulated with IL-23 treatment indicating activation of a negative feedback loop for Wnt inhibition.

Conclusions: We present in depth mechanistic evidence of the observed remission from lupus GN with IL-23 treatment. IL-23 treated kidneys exhibit better mitochondrial dynamics and function. We show in vitro, in vivo and ex vivo evidence of IL-23 treatment leading to betterment of mitochondrial function and metabolic fitness. Canonical Wnt signaling was attenuated. The data presented confirms the therapeutic efficacy of IL-23 as a promising therapeutic agent for lupus nephritis and kidney injury.

PO1763

A Prospective Randomized Study on Preemptive Immunosuppressive Therapy in Lupus Nephritis Patients with Asymptomatic Serological Reactivation
Desmond Y. Yap, Paul Lee, Irene Yam, Tak Mao D. Chan. University of Hong Kong, Hong Kong, Hong Kong.

Background: The optimal management for asymptomatic serological reactivation (ASR) in lupus nephritis (LN) patients remains undefined. Our previous retrospective study suggested that pre-emptive moderate increase in immunosuppression may prevent subsequent clinical relapses.

Methods: We prospectively randomized LN patients with ASR (defined as ≥2-fold increase of anti-dsDNA to >100 IU/mL, with or without change in complement level, and absence of clinical lupus exacerbation) to receive pre-emptive treatment or unchanged management (‘Control’ group). Pre-emptive treatment included increasing prednisolone to 0.5 mg/kg/D, and the dose of mycophenolate to 1g/D or azathioprine to 75 mg/D, then tapered over 12-16 weeks back to the original dosages.

Results: Eighteen patients pre-emptive group and 17 in control group respectively). Pre-emptive group showed lower anti-dsDNA and higher C3 levels after 12 weeks compared with Controls ($p$<0.001, for both) (Figure 1). Pre-emptive group showed significantly lower incidence rates of all clinical relapses and renal relapse during subsequent 9 months follow-up compared with Controls (11.1% vs 41.2%, $p$<0.02, and 0% vs 17.6%, $p$<0.03, respectively). The pre-emptive group showed lower serum miR-148a compared with baseline value and also the Controls ($p$<0.001, for both). There was no clinically significant adverse event.

Conclusions: Our results suggest that pre-emptive moderate increase of immunosuppressive treatment reduces the risk of disease flare in LN patients with ASR and is well tolerated.

Funding: Government Support - Non-U.S.

Kidney Thrombotic Microangiopathy Associated to Lupus Nephritis Is Mediated by the Activation of the Alternative Complement Pathway
Juan M. Mejia, Ismael A. Gómez Ruiz, Rossa A. Méndez, Cristina Cruz, Luis E. Morales-Buenrostro, Ricardo Correa-Rotter. Department of Nephrology and Mineral Metabolism, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico.

Background: Thrombotic microangiopathy (TMA) in the context of lupus nephritis is a rare disease whose pathogenesis has been linked to complement activation. This study aimed to evaluate complement pathway activation products in plasma and urine from patients with LN associated TMA (LN-TMA) and to compare its levels to patients with active LN (aLN), patients with inactive lupus (iSLE) and kidney donors (KD).

Methods: Plasma and urine samples were obtained from 19 patients with active LN-TMA and 19 patients with biopsy-proven aLN matched by histologic activity index, Patients with iSLE (n=16) and kidney donors (n=10) were included as controls. Complement activation fragments C3a, C4a, C5a, Ba, C5bC9, and factor H were assessed by ELISA. Kidney C4d deposition was detected by immunohistochemistry. After 12 months, complement activation products were re-assessed after treatment.

Results: Both, the acute LN-TMA and aLN patients had increased plasma Ba and C5bC9 along with decreased plasma C3, C4, C4a, and factor H. Urine C5a, Ba, and C5bC9 were higher in patients with active LN-TMA than in aLN. The levels of the urine complement fragment correlated with the degree of interstitial inflammation, interstitial fibrosis, and tubular atrophy in the kidney biopsy. After treatment, the levels of circulating C3, C4, and factor H increased, and the levels of urine C5bC9 decreased. In two patients with repeated LN-TMA episodes, factor H and urine C5a levels decreased, while urine Ba and C5bC9 increased after treatment in each episode. There was no difference in C4d fragment deposition in glomerular capillaries, tubular basement membrane, peritubular capillaries, and arterioles, between patients with aLN and those with acute LN-TMA.

Conclusions: The levels of plasma and urine complement activation products suggest that the pathogenesis of acute LN-TMA is mediated through activation of the complement alternative pathway.

Funding: Government Support - Non-U.S.

Glycol Chitosan-Based Tacrolimus-Loaded Nanomicelle Therapy Ameliorates Lupus Nephritis
Chang Seong Kim, Tae ryom Oh, Hong sang Choi, Eun Hui Bae, Seong Kwon Ma, Soo Wan Kim. Chonnam National University, Gwangju, Jeollanam-do, Republic of Korea.

Background: Hydrophobically modified glycol chitosan (HGC) nanomicelles loaded with tacrolimus (HGC-TAC) enhance the renal delivery of tacrolimus. Here, we determined whether the administration of HGC-TAC nanomicelles decreases kidney injury in a model of lupus nephritis.

Methods: Lupus-prone female MRL/Pr mice were randomly divided into 2 groups and given either intravenous vehicle or HGC-TAC (0.5 mg/kg tacrolimus) weekly for 8 weeks. Age-matched MRL/MPj mice without Fas+R mutation were treated with a vehicle and used as healthy controls.

Results: Weekly treatment with intravenous HGC-TAC remarkably reduced genetically attributable lupus activity, blood urea nitrogen, and proteinuria in lupus nephritis-positive mice. In addition, HGC-TAC treatment mitigated renal dysfunction and histological injury, including glomerular proliferative lesions and tubulointerstitial infiltration. Furthermore, HGC-TAC treatment reduced renal inflammation and inflammatory gene expression, as well as ameliorated the increased glomerular fibrosis. Moreover, the administration of HGC-TAC appeared to regulate renal injury via the TGF-$
\beta$
1/p38MAPK/NF-$\kappa$B signaling pathway.

Conclusions: Our study clearly indicates that weekly treatment with HGC-TAC nanomicelles reduces kidney injury resulting from lupus nephritis by preventing inflammation and fibrosis. This advantage of HGC-TAC nanocarriers may improve drug adherence and treatment efficacy in lupus nephritis patients.

Renal Activity Index for Lupus Nephritis Distinguishes Active Renal Disease Among Lupus Patients

Najla F Aljaberi,1 Arjun Mathur,1 Steffy Jose,2 Theresa Hennard,3 Angela Merritt,1 Qing Ma,1 James Rose,1 Rashmi Sahay,2 Chunyan Liu,3 Hermine Brunner,1 Scott E. Wunderfer,2 1 Baylor College of Medicine, Houston, TX; 2 Texas Children’s Hospital, Houston, TX; 3 Cincinnati Children’s Hospital Medical Center, Cincinnati, OH.

Background: Conventional tools to identify active nephritis in SLE (LN) fail to supersede invasive kidney biopsy. The renal activity index in lupus (RAI) was developed using 6 urinary biomarkers to reflect disease activity (Brunner, et al. 2016). Our objective was to test RAI for identifying active LN in childhood-onset SLE.

Methods: Urine samples obtained from cross-sectional sampling of 2 cSLE cohorts, classified as active LN, inactive LN or non-LN SLE. RAI scores were calculated from ELISA or nephelometry data for six urine markers (NGAL-1, ceruloplasmin, MCP-1, adiponectin, hemepoxin, kidney injury molecule-1). Data collected included ISN/RPS histologic classification and extra-renal component of SLE disease activity index (SLEDAI) score.

Results: Among 117 cSLE patients, 37 had active LN; 30, inactive LN; 50, no-LN. RAI scores of inactive LN and non-LN group largely overlapped, so they were combined (Group 2) and compared to active LN (Group 1, Table). Group 1 had higher RAI score (0.7 vs. -1.1). After adjusting for age and extra-renal SLEDAI score, RAI score odds ratio was 2.16 (95%CI 1.43-3.3, p<0.001) for active LN. A receiver operating curve (ROC) for an adjusted RAI cut-off score of 0.35 produced an AUC=0.9 (sensitivity 86%, specificity 84%) for active LN. Adjustment for urinary protein and creatinine did not influence results.

Conclusions: The RAI score is highly accurate in distinguishing active from inactive LN and non-LN SLE. Scores >0.35 identify cSLE patients who very likely have active LN.

Clinical characteristics and distribution of RAI scores among Group 1 (active LN) and Group 2 (inactive LN + non-LN SLE) patients

A Novel Inflammatory Dendritic Cell in Lupus Nephritis

Latha Priyab Jacket,1 Ana Malvar,2 John P. Shapiro,3 James M. Turman,1 Hennorda, 1 Bruno J. Lococo,1 Sethu M. Madavan,1 Anjali A. Satsoskar,1 Daniel J. Birmingham,1 Wael Jarjour,1 Brad H. Rovin,3 Samir V. Parikh,3 OSU Nephrology,1 The Ohio State University Wexner Medical Center, Columbus, OH, 2Hospital Fernandez, Buenos Aires, Argentina.

Background: Progress in Lupus Nephritis (LN) management has been limited and treatment outcomes remain sub-optimal. Knowledge on intra-renal changes during LN flare and the major immune cells that drive local inflammatory damage will lead to improved outcomes in LN.

Methods: We performed transcriptomic analysis on serial kidney biopsies of proliferative LN (n=58). Glomeruli and Tubulointerstitium (TI) were isolated using LCM, and 580 immune transcripts were analyzed using NanoString human immunology panel. Guided by transcriptomic analysis, multi-color, high-resolution confocal laser capture microdissection, and 580 immune transcripts were analyzed using NanoString human immunology panel. Guided by transcriptomic analysis, multi-color, high-resolution confocal laser capture microdissection (LCM), and 580 immune transcripts were analyzed using NanoString human immunology panel.

Results: Transcriptomic analysis identified Fe receptor gamma chain (FeRγ), to be the most significantly overexpressed glomerular immune transcript (Fold change (FC): 3.5, P<1E-10) and also overexpressed in the TI (FC: 1.7, P<0.001) compared to controls. Confocal IF analysis found FeRγ to be abundantly present in the per-glomerular (PG) region and to a lesser extent in the TI during LN flare. FeRγ was weakly expressed in controls. Further IF analysis identified the phenotype of FeRγ expressing cells to be CD11c+CD-SIGN+SIGN+C4dII-H,CD64+CD14+, CD16+CD206,CD68,CD123,CD11b+. This signature aligns with a dendritic cell (DC) phenotype but distinct from plasmacytoid dendritic cell. It is most commonly associated with an inflammatory dendritic cell (iDC) phenotype. Importantly, confocal IF identified CD3+ T cells present in close proximity to PG and iDC.

Conclusions: In this study, we identified a novel population of iDC not previously described in LN. During LN flare, iDC are present in abundance in the PG region. Their presence next to T cells suggests iDC dictate the nature of the T cell response during LN flare. Targeting iDC or their associated T cell phenotype may attenuate renal inflammation and improve outcomes in LN.

Burden of Illness of Lupus Nephritis in Patients with Systemic Lupus Erythematosus

Christopher F. Bell,1 Benjamin Wu,1 Bin Xie,2 Shirley Huang,1 Benjamin Chaste,2 Berinnie Rubin,1 Joan Von Feldt,3,4 Gary Bryant,3 1GlaxoSmithKline, Research Triangle, NC; 2Opunt, Eden Prairie, MN; 3GlaxoSmithKline, Philadelphia, PA; 4University of Pennsylvania, Philadelphia, PA.

Background: Approximately 35% of adults with systemic lupus erythematosus (SLE) develop lupus nephritis (LN). LN is associated with an increased risk of renal failure, cardiovascular disease, and death. Little is known about healthcare resource utilization (HRU) or costs of care for patients with LN versus those without SLE.

Methods: This retrospective cohort study used Optum Research Database administrative claims data (GSK Study 213062). Patients with LN had ≥2 renal diagnosis codes during 08/01/2017–07/31/2018 and ≥1 patient or ≥2 outpatient SLE diagnosis codes >30 days apart in the 12 months prior to index; index date was the date of first renal diagnosis code. The control cohort had plan members with no diagnosis codes for SLE or LN during 08/01/2016–7/31/2018. Control patients were matched 1:1 to patients with LN based on baseline demographics. Inclusion criteria: ≥18 years of age at index, and continuous medical and pharmacy coverage in the 12 months pre and post index. HRU in the 12 months post index captured health plan– and patient-paid amounts and adjusted using the Consumer Price Index.

Results: Across the LN and control cohorts, 2326 patients met study criteria; 38.5% were 45–64 years of age, 44.1% were ≥65 years of age, 85.6% were female, 58.1% were located in Southern USA states, and 66.3% were covered by Medicare. The LN cohort had a significantly higher mean (standard deviation (SD)) number of ambulatory visits (53.93 [55.54]) than the control cohort [18.27 [21.61]], ED visits (2.87 [7.91] vs 0.66 [2.31]), and hospitalizations 0.86 [1.48] vs 0.12 [0.51]) versus the control cohort, respectively. Mean (SD) total costs were $50,958 ($86,100) for the LN cohort, which were significantly higher than $10,737 ($21,741) in the control cohort. Differences in costs were largely driven by mean (SD) medical expenses for the LN cohort versus the control cohort ($40,648 [$78,134] vs $6,781 [$14,773], respectively). All p-values were <0.001.

Conclusions: All-cause HRU and costs were higher for patients with LN than patients without SLE. This study quantifies the economic burden associated with LN.

Funding: Commercial Support - GSK

A Clínico-Pathological Associations with Serum Thrombomodulin Level in Patients with Lupus Nephritis

Tak Mao Chan,1 Kelvin K. W. Yip, Desmond Y. Yan, Susan Yung. The University of Hong Kong, Hong Kong, Hong Kong.

Background: Conventional serological markers do not always correlate with clinical activity or histopathology in lupus nephritis (LN). There is evidence of endothelial activation and injury in LN pathology. Thrombomodulin (TM), a component of endothelial glycocalyx, is shed into the circulation in endothelial cell injury. We investigated clinicopathological associations of circulating TM level.

Methods: TM level was measured by ELISA in sera collected serially every 3–4 months over ≥2 years (n=482) from 31 patients with biopsy-proven Class III/IV LN. Patients with non-renal SLE or non-LN kidney diseases (CKD) and healthy subjects were included as Controls.

Results: Patients with active LN had the highest serum TM level, compared with LN patients in remission, patients with active non-renal SLE, CKD patients, or healthy subjects (P<0.01, for all). Serum TM level correlated with anti-dsDNA antibody titre, proteinuria, serum creatinine, SLEDAI-2K and renal SLEDAI-2K score; and inversely correlated with eGFR and C3 (r=0.86, for all). Patients with blood samples collected before disease flare, and 6 showed increased TM level (3.6±5.2 vs 16 months before clinical flare). All episodes of LN flare were accompanied by elevated TM level, which decreased after treatment. A temporal relationship was noted between TM level and anti-dsDNA titre and proteinuria (r=0.86, for all). Patients with active severe flare had the highest TM level, compared with patients with mild/moderate flare (r=0.54, for all). In a multivariable model, TM level was significantly associated with eGFR (P<0.01), proteinuria (P<0.01) and anti-dsDNA (P<0.01).

Conclusions: Determination of serum TM level may facilitate early diagnosis of active LN, and may be useful in monitoring the response to treatment.

Enhanced Na-K-ATPase Expression Mediates B-Cell Survival in Lupus Kidneys
Irene Chernova, Joseph Craft. Yale University School of Medicine, New Haven, CT.

Background: Systemic lupus erythematosus (SLE, lupus) is a multi-organ autoimmune disease characterized by antibody deposition in target organs, including the kidney. Kidneys of affected patients are characterized by lymphocytic infiltrates that correlate with tissue damage and disease severity. The kidneys are also characterized by a high salt environment not found elsewhere in the body. Thus, infiltrating lymphocytes are presented with the unique challenge of surviving in a high salinity environment which may define their phenotype and function. We now describe the molecular mechanisms utilized by immune cells when faced with this hypertonic microenvironment.

Methods: We utilized lupus-prone (MRL(lpr)) and wildtype (C57BL/6) mice and renal biopsy samples from lupus nephritis patients for this study. B cells from mice were cultured in vitro standard versus high salt conditions. Kidney immune cell subsets were identified using flow cytometry and immunofluorescence techniques.

Results: B cells from lupus-prone (MRL(lpr)) mice have enhanced survival when exposed in vitro to a high salt environment, compared to cells from control, non-autoimmune mice. The salt transporter Na-K-ATPase, and specifically its gamma subunit Fxyδ2, is upregulated in the kidney and is necessary for kidney epithelial (tubular) cell survival under high salt conditions. We hypothesized that infiltrating lymphocytes also utilize Na-K-ATPase upregulation to survive in the hypertonic environment of the kidney. We found high expression of Na-K-ATPase alpha and gamma subunits on kidney-localized B cells of lupus-prone mice and high gamma subunit expression in B cells from human lupus kidney biopsies. Inhibition of Na-K-ATPase activity with a small molecule inhibitor ouabain led to increased cell death when lupus-prone B cells, but not control B cells, were cultured in high salt conditions, suggesting a role for Na-K-ATPase in the enhanced survival of MRL(lpr) B cells in high salt. In vivo treatment of MRL(lpr) mice with ouabain depleted renal-infiltrating B cells, but not T cells. MRL(lpr) mice lacking the gamma subunit of Na-K-ATPase appear to phenocopy the ouabain-treated mice in preliminary analyses.

Conclusions: These studies identify a novel role for Na-K-ATPase in B cell survival in the hypertonic renal microenvironment and suggest it is a potential therapeutic target in lupus nephritis.

TNIP1/ABIN1 Mutation Contributes to Lupus Nephritis via Chemokine IP-10 Induction
David W. Fowell, Makaya Brady, Michelle T. Barati, Dawn J. Caster. University of Louisville School of Medicine, Louisville, KY.

Background: We previously reported TNIP1 gene variants as risks for lupus nephritis (LN). TNIP1 encodes the protein ABIN1, which is a polyubiquitin binding protein that negatively regulates the prominent immune regulatory transcription factor NF-kB. We reported that transgenic mice with impaired ABIN1 ubiquitin binding function (ABIN1[D485N]) spontaneously develop SLE-associated autoimmunity and LN and that ABIN1 determines the severity of LN via activation of kidney and immune cell inflammation. Interferon gamma-inducible protein -10 (IP-10) is a pro-inflammatory chemokine and NF-kB target that has been implicated in the pathogenesis and as a diagnostic marker of LN. The current project tested a hypothesis that LN development is mediated by induction of IP-10 expression due to loss of cellular ABIN1 activity.

Methods: In order to test our hypothesis, we measured urine and serum IP10 in ABIN1[D485N] mice using ELISA and utilized IHC techniques to measure kidney IP10 expression. Additionally, we used ELISA to measure urinary IP10 levels in human subjects with LN (with and without TNIP1 variant rs4958881) and in healthy controls.

Results: We found that serum, urine, and kidney cell IP-10 expression is enhanced in ABIN1[D485N] mice. We also found that urinary IP-10 levels are higher in LN patients with TNIP1/ABIN1 variant rs4958881 when compared to LN patients without the TNIP1 variant and healthy controls. The rs4958881 variant also correlated with disease severity.

Conclusions: Our findings indicate that TNIP1/ABIN1 mutation contributes to the pathogenesis of LN via kidney and immune cell induction of IP-10 secretion and that serum and urinary IP-10 are promising diagnostic markers for LN especially in patients with TNIP1 variants. Further, successful Phase 2 clinical trials with IP-10 mAb for ulcerative colitis indicate its potential for effective LN treatment.

Comparative Cross-Tissue and Cross-Species Transcriptome Analyses Predict Lupus Nephritis in Human Systemic Lupus Erythematosus and Guide Therapy in a Tissue-Specific Manner
Eleni A. Frangou,1-3 Panayiotis Garantziotis,2 Maria Grigoriou,2 Angelos Banos,2 George Bertisias,2 Anastasia Filia,2 Dimitrios Bounous,1 Genoko Koskomeio Lemosou, Lemosou, Cyprus; 3Iridyma IatratologiKwn Ereunen tes Akademias Athenon, Athens, Greece; 1Ethniko i Kapodistriatko Panepistemio Athenon, Athens, Greece; 2PaneHopistemo Kretes Iatrike Schol, Heraklion, Greece.

Background: Despite advances, morbidity and mortality in systemic lupus erythematosus (SLE) and lupus nephritis (LN) remain increased. Most clinical trials on novel therapeutic interventions targeting pathways enriched within individual tissues.

Methods: We applied RNA-sequencing to spleen, kidneys and brain from NZB/W-F1 lupus-prone mice at three stages: the pre-puberty, pre-autoimmunity and nephritic stage. Differentially expressed genes (DEGs) were analyzed with DESeq and functionally annotated with gProfiler. CheA and Genes2Network were used to infer transcription factors and identify proteins that physically interact with them, respectively. KEA was used to link kinases predicted to regulate DEGs. Implications for human disease were explored in our whole-blood RNA-sequencing dataset of 120 SLE patients [55 LN and 65 non-LN SLE patients and 58 healthy individuals (HI)]. The L1000CD58 engine was used to identify drugs/small molecules predicted to reverse DEGs. Human orthologies of DEGs were compared to human DEGs. Using machine learning, orthologs from the mouse dataset were used to predict LN in the human dataset, which was split in training and validation sets.

Results: We define lupus-susceptibility and lupus-progression signatures that reveal pathways and gene hubs, and a common cross-tissue signature that depicts transcription factors as putative upstream regulators and kinases as potential targets. Tissue-specific signatures uncovers distinct tissue response and repair mechanisms in end-organ injury and distinct targets. 7 small molecules/drugs are predicted to reverse gene signatures in both murine and human SLE.193 orthologs accurately predict LN patients from HI (accuracy=0.86, sensitivity=0.82, specificity=0.91 in the validation set) and 30 orthologs with age and gender best predict LN from non-LN SLE patients (accuracy=0.71, sensitivity=0.73, specificity=0.69 in the validation set).

Conclusions: A murine cross-tissue transcriptome analysis uncovers gene signatures, pathways and tissue-specific targets. The cross-species transcriptome analysis predicts LN in human SLE and guides therapy in a tissue-specific manner.

PO1773
An Inducible Model of Early Lupus Nephritis

Background: Lupus nephritis (LN) is characterised by polyreactive antibodies targeting ‘planted’ glomerular autoantigens. But how these deposits recruit inflammatory mediators and the roles of resident and recruited cells is unclear. Distinguishing damaging pathways from protective tissue responses is a major challenge. With disease progression, non-specific signals of fibrosis become dominant and human tissue comparisons are confounded by genetic and environmental heterogeneity. A way to separate these early and late pathological events is to use mouse models of nephritis. Topical treatment with toll like receptor-7 (TLR7) agonist 4-methylumbelliferyl (MUFQ) for 8 weeks has been shown to induce glomerulonephritis (GN), significant weight loss and mortality. Using detailed renal and immune phenotyping we explored the suitability of this model to study the very early, active stages of LN.

Methods: 6-week female BALB/c mice were treated 3 times weekly for 5 weeks with topical IMQ or Vaseline control (n=6/group). Immune profiling of spleen, bone marrow and mesenteric lymph node was by flow cytometry. Kidneys were fixed and processed for Periodic Acid Schiff, immunofluorescence and TEM. Serum was assayed for creatinine, urea and albumin.

Results: Treated mice had increased numbers of activated splenic CD4 and CD8 T cells (CD40/CD25<sup>+</sup>, P<0.001), Tregs (CD4<sup>+</sup>CD25<sup>+</sup>FOXP3<sup>+</sup>, P<0.001) and activated B cells (B220<sup>+</sup>CD19<sup>+</sup>CD68<sup>+</sup>CD69<sup>+</sup>, P<0.001). IMQ did not result in weight loss, mortality or significant changes in serum creatinine or urinary protein creatinine ratio but kidney histology showed mild mesangial hypercellularity with strong glomerular positivity for IgG, C1q and C3. TEM showed early basement membrane duplication, focal subendothelial and mesangial deposits and mild podocyte effacement.

Conclusions: This study characterises the IMQ model of LN revealing CD4<sup>+</sup> T cell activation and TEM evidence of immune deposits reminiscent of human class II lupus. Treatment for 5 weeks is well tolerated without overt renal failure and creates a model for studying the early pathways involved in immune complex GN and associated therapeutic targets.
PO1774

Efficacy and Safety of Non-Mitogenic Anti-CD3 in the Treatment of Lupus-Prone Mice
Masashi Morita, Masayuki Mizui, Satoshi Masuyama, Yoshitaka Isaka. Osaka University Graduate School of Medicine, Suita, Japan.

Background: Armenian hamster anti-mouse CD3e monoclonal antibody (145-2C11) is known to suppress T cell function in vivo by reducing T-cell receptor (TCR) expression and inducing T cell depletion. However, it also has mitogenic potentials through the functional Fe portion. Although in vivo administration of Fe-depleted 145-2C11 Fab(’)2 was reported to ameliorate lupus in mice, the detailed mechanisms are still unclear. Recently developed Fe-modified 145-2C11 (2C11 silent; 2C11S), which lacks the ability to bind complement or Fe receptors in vivo, is expected to be stable and safe in vivo as compared with native 145-2C11 (2C11N). Whether 2C11S has therapeutic potential in lupus remains to be elucidated.

Methods: Twenty micrograms of Armenian hamster anti-CD3e (hamster 2C11N), mouse anti-CD3e (mouse 2C11N), mouse anti-CD3e Fe-silent (2C11S), or isotype control IgG1 (IC) were injected intraperitoneally to C57BL6 mice. Lymphocyte number, TCR expression and plasma cytokines from peripheral blood were checked in time series. Next, 2C11S, 2C11N, and IC were administered (100 µg / week, 4 times, intraperitoneally) to NZBW/F1 mice at the age of 10 (early phase) and 29 (active phase) weeks, respectively. Renal histology, immune cell infiltration, and gene expression of cytokines/chemokines were examined.

Results: As compared with 2C11N, 2C11S reduced TCR expression on T cells in vivo for longer period (more than 96 hours) without inducing cytokine release. In early phase of lupus, the rate of change in anti-dsDNA IgG titers (day28 / day0) were significantly reduced in 2C11S group (IC: 2.9±2.0, 2C11N: 2.1±3.0, 2C11N; 2.0±1.8, IC vs 2C11S; p<0.03), which was associated with the decreased number of both follicular helper-T cells and germinal center B-cells in spleen. In active phase, glomerular hypercellularity was diminished in 2C11S group (glomerular cell number: IC; 53±18, 2C11S; 44±6.1, 2C11N; 47±6.6, IC vs 2C11S; p<0.03) and lymphocyte infiltration into kidney was significantly reduced in 2C11S group. In addition, reduction of inflammation-related genes such as IFNy and IL-2 in kidney indicated improvement of lupus nephritis by 2C11S.

Conclusions: 2C11S, but not 2C11N, suppressed autoantibody production and ameliorated lupus nephritis, possibly through stable down-regulation of TCR. Targeting CD3 to modulate TCR expression could be a novel therapeutic approach in lupus.

PO1775

Suboptimal Serological and Clinical Remission on Supportive Therapy in Phospholipase A2 Receptor Membranous Nephropathy
Jennifer A. Pham, Juan Carlos Q. Velez. Ochsner Nephrology Ochsner Health System, New Orleans, LA.

Background: A traditional notion is that one third of patients with primary membranous nephropathy (MN) are expected to achieve spontaneous clinical remission without immunosuppressive therapy (IST). Thus, Kidney Disease Improving Global Outcomes (KDIGO) recommends at least 6 months of supportive therapy (SUPPT) without IST in patients with primary MN with low risk for developing end-stage renal disease. Recently, phospholipase A2 receptor (anti-PLA2R) antibody titers have been evaluated across a variety of glomerular diseases in a manner similar to RAAS blockade. Immunologic and metabolic changes that have the potential to be leveraged therapeutically for longer period (more than 96 hours) without inducing cytokine release. In early phase of lupus, the rate of change in anti-dsDNA IgG titers (day28 / day0) were significantly reduced in 2C11S group (IC: 2.9±2.0, 2C11N: 2.1±3.0, 2C11N; 2.0±1.8, IC vs 2C11S; p<0.03), which was associated with the decreased number of both follicular helper-T cells and germinal center B-cells in spleen. In active phase, glomerular hypercellularity was diminished in 2C11S group (glomerular cell number: IC; 53±18, 2C11S; 44±6.1, 2C11N; 47±6.6, IC vs 2C11S; p<0.03) and lymphocyte infiltration into kidney was significantly reduced in 2C11S group. In addition, reduction of inflammation-related genes such as IFNy and IL-2 in kidney indicated improvement of lupus nephritis by 2C11S.

Conclusions: 2C11S, but not 2C11N, suppressed autoantibody production and ameliorated lupus nephritis, possibly through stable down-regulation of TCR. Targeting CD3 to modulate TCR expression could be a novel therapeutic approach in lupus.

Glomerular Proteomics Reveal Shared Pathways Across Several Disease
Salem Almaalou,1 Isabelle Ayoub,1 John P. Shapiro,1 Sethu M. Madhavan,2 Anjali A. Satoskar,1 Michael Merchant,1 Jon B. Klein,1 Brad H. Rovin,1 Sarah V. Parikh.1 The Ohio State University, Columbus, OH; 2University of Louisville, Louisville, KY.

Background: Glomerular diseases are caused by a variety of immunologic and metabolic disturbances. While there is considerable disease heterogeneity, morphologic patterns of injury are limited and clinical phenotypes are similar across diseases. This suggests that mechanisms of inflammation and the glomerular response to injury is similar across disease states. Characterizing these mechanisms may provide insights into the common pathways of glomerular injury and lead to new insights in pathogenesis and treatment. As a first step, we used an agnostic proteomics approach to identify common regulated pathways across a variety of glomerular disorders.

Methods: Kidney biopsies from 36 patients across several glomerular diseases and 21 controls (transplant donor biopsies) were used. Glomeruli were isolated using laser-capture microdissection, processed, and submitted for LC-MS/MS. Peptides were analyzed for spectral count quantitation. Spectral counts of each disease were compared to control samples that were analyzed in the same batch. Only peptides with a spectral count coefficient of variation <25% were included in expression ratio calculations. Disease- to-control expression ratios >2 or <0.5 were used for pathway analysis using Reactome. The top 10 pathways were grouped into domains and are depicted in figure 1.

Results: Pathways involved in complement regulation and activation, fibrin clot formation, and platelet aggregation were downregulated in most disease categories. Assessment of GC toxicity has not been assessed in this cohort. This study looked at the GC toxicity of patients in the year following treatment completion1,2

Conclusions: Proteomic analysis of a heterogenous population of glomerular diseases identified several shared dysregulated pathways that may reflect common final pathways associated with glomerular injury. These pathways reflect important immunologic and metabolic changes that have the potential to be leveraged therapeutically across a variety of glomerular diseases in a manner similar to RAAS blockade.

PO1777

Glucocorticoid Toxicity in the Ponticelli Regimen
Abby J. Huckle, Ajay P. Dhargule. Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom.

Background: Idiopathic membranous nephropathy (IMN) is an immune complex mediated renal disease and the leading cause nephrotic syndrome in non-diabetic adults. Long term relapse data for modern drugs like Calcineurin inhibitors and B-cell therapy are lacking. Modified Ponticelli regimen offers 70% relapse free survival for 10 years however toxicity of cyclophosphamide and glucocorticoids(GC) remains major concern. Assessment of GC toxicity has not been assessed in this cohort. This study looked at the GC toxicity of patients in the year following treatment completion1,2

Methods: The glucocorticoid toxicity index (GTC) was calculated for 15 IMN patients treated with modified Ponticelli regimen at time of treatment completion(0) and then 6 and 12 months post treatment completion, and compared to pre-treatment baseline. The total dose of steroids received during treatment was also calculated.

Results: Mean cumulative prednisolone dose was 11.05g. The results at 0.6 and 12 months post completion of the Ponticelli regimen for individual patients is shown on the report. A completion 12/15 patients demonstrated GC toxicity. 7 at 6 months improving to 6/15 at 12 months. Effect on blood pressure (BP) was the most common indicator of GC toxicity at 12 months: 4/15 patients. 6 patients were in negative points at 12 months, however toxicity of cyclophosphamide and glucocorticoids(GC) remains major concern. Assessment of GC toxicity has not been assessed in this cohort. This study looked at the GC toxicity of patients in the year following treatment completion1,2

Conclusions: Overall apart from BP, only 2/15 patients had evidence of damage due to GC exposure at 12 months in spite of very high cumulative GC doses. This lower level incidence of GC toxicity could be due to less impact on hypoalalbuminemia due to unusual dosing regime of alternating months. Limitations: Relatively small cohort and in 1/8 (12.5%) and 3/8 (37.5%) of patients under SUPPT and in 3/17 (17.6%) and 8/17 (47%) of those under IST (p=0.75 and p=0.86, respectively).

Conclusions: Despite baseline characteristics denoting less aggressive disease, patients with PLA2R-MN under SUPPT therapy did not achieve greater rates of clinical remission and exhibited a lower rate of serological remission. Current algorithms dictating choice of SUPPT as initial treatment in low-risk PLA2R-MN should be revisited.
PO1778

Experimental Membranous Nephropathy in a Novel Transgenic Rat Model of Decay-Accelerating Factor Deficiency Generated by CRISPR-Associated Protein 9 (Cas9) Genome Editing

Maria Detsika,1,2 Harikleia Gakiopoulou,1 Erini Grapsa,2 Elias Lianos,3,4 National and Kapodistrian University of Athens, School of Medicine, 1st Department of Critical Care Medicine and Pulmonary Services, GP Livanos and M Simos Laboratories, Evangelismos Hospital, Athens, Greece; 1National and Kapodistrian University of Athens - Nephrology Clinic, Aretaieio Hospital, Athens, Greece; 2National and Kapodistrian University of Athens, Pathology Department, Athens, Greece; 3Thorax Research Center of Intensive and Emergency Thoracic Medicine, Athens, Greece; 4Salem VA Medical Center and Virginia Tech Carilion School of Medicine, Salem, VA.

Background: Decay accelerating factor (DAF), controls extent of formation of C3 and C5 convertases. Using clustered regularly-interspaced short palindromic repeats, CRISPR/associated protein 9 (Cas9) genome editing a DAF deficient (daf-) rat model was generated. The present study describes the renal and extrarenal phenotype of this model and responses to podocyte injury in experimental membranous nephropathy (MN).

Methods: daf-/- rats were produced by injecting multiple CRISPRs targeting Cd55 exon 2 into Sprague-Dawley rat embryos. A founder harboring a net 4-bp deletion in exon 2 was backcrossed to the parental strain and litters were genotyped. 1 ml of anti-Fx1A serum was injected in daf+/+ and daf-/- rats to induce MN. Control rats received a single dose (1ml) of normal rabbit serum. DAF protein and mRNA levels were determined by western blotting and Real time PCR. Renal function assessment involved measurement of serum urea and creatinine or in urine protein excretion. There was a significant increase in glomerular or tubulointerstitial lesions in daf-/- rats compared to daf+/+ and no change in dog-/- rats. There was no effect on glomerular Crry and CD59 protein expression. There were no changes in serum urea and creatinine levels and urine albumin/creatinine ratio. C3 deposition was confirmed by immunofluorescence (IF) and western blot (WB) analysis.

Results: daf-/- rats were healthy, viable and able to reproduce normally. DAF was completely absent in renal and extrarenal tissues (lung, heart) at protein and mRNA level. There was no effect on glomerular Crry and CD59 protein expression. There were no glomerular or tubulointerstitial lesions in daf-/- rats compared to daf+/+ and no change in serum urea and creatinine or in urine protein excretion. There was a significant increase in proteinuria 14 days following anti-Fx1A injection in daf-/- rats accompanied by increased glomerular C3 deposition.

Conclusions: In experimental MN, DAF attenuates proteinuria. The daf-/- rat model provides a valuable tool to assess role of DAF in regulating complement activation in glomerular diseases, such as MN, which is best characterized in this species.

PO1779

T-Cell Epitopes of M-Type Transmembrane Phospholipase A2 Receptor in Primary Membranous Nephropathy

Xiao-dan Zhang, Cui Zhao. Peking University First Hospital Department of Nephrology, Beijing, China.

Background: PLA2R is the major autoantigen of pMN. There is no information on T cell epitopes. We previously identified the risk HLA molecules DRB1*1501 and DRB1*0301.

Methods: 123 linear peptides, each consisting of 15-22 amino acids and overlapping by 8-12 amino acids, were synthesized across PLA2R. Their binding capacity to DRB1*1501 and DRB1*0301 protein was assayed by flow cytometry. Proliferation of CD4+ T cells from patients with anti-PLA2R positive pMN was analyzed after peptide stimulation using CFSE dilution assay. Cytokines produced by activated PBMC were measured by cytometric beads array.

Results: We found 17 peptides that bound to both DRB1*1501 and DRB1*0301 molecules with high capacity. Among them, 11 peptides induced significant proliferations of CD4+ T cells from patients with anti-PLA2R positive pMN: PLA2R<sub>36-52</sub>(CysR3), PLA2R<sub>60-76</sub>(CysR10), PLA2R<sub>101-117</sub>(CysR12), PLA2R<sub>158-174</sub>(FnII-3), PLA2R<sub>285-301</sub>(CTLD3-9), PLA2R<sub>362-378</sub>(CTLD3-10), PLA2R<sub>413-429</sub>(CTLD3-11), PLA2R<sub>464-480</sub>(CTLD5-2-1), PLA2R<sub>505-521</sub>(CTLD7-1) and PLA2R<sub>556-572</sub>(CTLD7-2).

Conclusions: Thus, we identified 11 potential T-cell epitopes on PLA2R.
PO1780
Investigating the Role of Complement in Membranous Nephropathy Using a Novel Ex Vivo Podocyte Model
Sarah M. Moran,1 Carolina Ortiz,1 Moin Saleem,1 Daniel C. Catran,2 Christoph Lichter,1 The Hospital for Sick Children, Toronto, ON, Canada; 1Toronto General Hospital, Toronto, ON, Canada; 2Bristol Royal Hospital for Children, Bristol, United Kingdom; 1Queen’s University Faculty of Health Sciences, Kingston, ON, Canada.

Background: Membranous nephropathy (MN) is an immune-mediated glomerular disease and is the commonest cause of nephrotic syndrome in adults. Progressive loss of kidney function leading to end-stage kidney disease occurs in up to one third of patients. We aimed to explore the potential functional link between antibody positive primary MN and the innate immune complement system using an ex vivo model of human podocytes.

Methods: Using a human podocyte ex vivo model, we evaluated complement activation via immunofluorescence staining for deposition of C3b and C5b-9, and functional alterations (demonstrated by cytoskeletal rearrangement) via IF staining for ActinGreen. Activation of complement via the classical pathway was used as positive control (incubation of podocytes with anti-C5b5 and 50% NHS for 30 min), whereas NHS-only treated cells were used as negative control. Four patients with biopsy proven primary membranous nephropathy and detailed clinical phenotype were recruited from the Toronto ON Registry. To determine the role of complement in MN pathogenesis, podocytes were incubated with patient serum for 30 min.

Results: 2/4 patients who were nephritic, antibody (aPLA2R or THSD7A) positive with no current immunosuppression demonstrated (1) positive C3b and C5b-9 staining confirming complement activation (Fig. 1A), and (2) reduced actin staining confirming impaired cytoskeletal organization (Fig. 1B). The remaining 2 patients with negative findings were Ab positive and treated with rituximab at the time of sample collection.

Conclusions: We successfully applied a new ex vivo model using podocytes to demonstrate complement activation in non-immunosuppressed MN patients. Further studies are needed to elucidate the detailed structural and functional consequences of complement activation in MN.

PO1781
Red Herrings: Delayed Immune Checkpoint Inhibitor-Associated Interstitial Nephritis with Membranous Glomerulonephritis and Myeloperoxidase-ANCA Antibodies
Orhan Efe,1,2 Ivy Rosales,1 Veronica E. Klepeis,1 Robert B. Colvin,1 Andrew S. Allegretti,1 Massachusetts General Hospital, Boston, MA; 1Brigham and Women’s Hospital, Boston, MA.

Introduction: Immune checkpoint inhibitor (ICI) indications are expanding. The most common renal pathology is interstitial nephritis. Here, we report a late presentation of ICI-induced interstitial nephritis with concurrent membranous glomerulonephritis (MGN) and MPO-ANCA antibodies.

Case Description: A 52-year-old woman with stage IV small cell lung cancer and patient was diagnosed with ICI-associated interstitial nephritis, likely provoked by PPI. She developed secondary adrenal insufficiency, which was considered an immune-related adverse event (irAE) with Nivolumab after the first dose, and oral hydrocortisone was initiated. In March of -1 year, mediastinal and hilar lymphadenopathy and skin pruritus, which were considered to be immune-related adverse events, were observed again, so Nivolumab was once discontinued, but it was resumed in April after improvement of the skin symptoms. However, proteinuria with hypoalbuminemia was appeared in June, Nivolumab was stopped again and the patient was finally consulted to our department in July. His serum albumin was 2.8 g/dL and urine protein was 5.9 g/gCr. Since the right kidney was atrophic, the open kidney biopsy was carried out in September. Light microscopy did not reveal thickening of the basement membrane, spike formation or bubbling appearance, however, immunofluorescence staining showed granular staining of IgG, C3, C1q and all of IgG subclasses although PLA2R staining was negative. Electron microscopy revealed electron-dense deposits under the epithelium, suggesting secondary membranous nephropathy. Though the urine protein tended to decrease after discontinuation of Nivolumab, Prednisolone 40 mg/day was started and resulted in the complete remission in the 19th hospital day.

Discussion: There are several reports of interstitial nephritis by Nivolumab, however, the report of nephritic syndrome is rare. Particularly, no case of membranous nephropathy by Nivolumab has ever been reported and this case is considered to be valuable.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
mycophenolate mofetil, and prednisone as a maintenance immunosuppressive regimen for both recipients. A kidney biopsy was performed two weeks after in recipient A due to delayed graft function. It was compatible with MN with both PLA2R and IgG4 subepithelial deposits. The donor’s kidneys biopsies were reexamined, revealing MN, with high intensity for PLA2R and IgG4 in IHC. Recipient B 3rd-month protocol allograft biopsy revealed histology compatible with MN, without the presence of PLA2R and IgG4 in IHC. At one year follow-up, both recipients maintain graft function and the protocol biopsies showed a negativization of IgG4 but the persistence of PLA2R in IHC, this positivity was attributed to the variability inherent to the technique.

Discussion: Given the reversal of PMN changes in the grafts, it is probably safe to transplant a patient from an asymptomatic donor with PMN as long as he maintains unaltered renal function. Observation of IgG4 immune complexes is more accurate to assess histological remission.

PO1784

Coexistence of Bullous Pemphigoid and Membranous Nephropathy

Brigette Thomas, Dhishna Chaudhary, Anika Bethel, Enoemem M. Okpokpo. Florida Atlantic University Charles E Schmidt College of Medicine, Boca Raton, FL.

Introduction: Bullous pemphigoid (BP) is an autoimmune disease with linear deposition of IgG and C3 in the skin basement membrane. BP is rarely associated with renal abnormalities like membranous glomerulonephropathy (MN). We describe a rare case of MN in a patient with BP.

Case Description: 75-year-old male, intermittently treated with prednisone for upper extremity (UE) skin lesions, presents with bilateral UE pruritic bullae, bilateral lower extremity (LE) and scrotal edema. He was previously treated for LE edema. Renal indices confirmed nephrotic range proteinuria. Kidney biopsy showed subepithelial immune deposits consistent with primary MN (immunostain negative for PLA2R). He was treated with furosemide and lisinopril. Skin biopsies of his bullae were inconclusive. His LE edema and UE bullae progressed due to lack of follow up, leading to this hospitalization. Labs revealed eosinophilia, hypoalbuminemia and nephrotic range proteinuria. HIV, hepatitis panel, ANA, SPEP and UPEP were negative. Malignancy was ruled out. Diagnosis of BP was finally confirmed via positive indirect immunofluorescence and ELISA testing. Treatment was limited to ethacrynic acid since ACEis/ARBs and furosemide are known to induce BP. Initiation of prednisone and rituximab resulted in cessation of new bullae and decrease in proteinuria.

Discussion: Both BP and MN are immune complex diseases involving two different basement membranes, so their occurrence together is not coincidence. Although our patient’s kidney biopsy had negative immunostaining, the electron microscopy identified only subepithelial deposits, characteristic of primary, not secondary MN. This coincides with few cases in literature identifying BP occurring exclusively with primary MN. Our patient developed BP manifestations prior to MN and received intermittent prednisone without formal diagnosis of BP. Perhaps corticosteroids suppressed his MN symptoms leading to delay in diagnosis. Improper treatment of MN with known BP inducing medications led to persistent bullae formation. As the severity of skin lesions decreased, so did the proteinuria, suggesting that progression of bullae may be a sign of worsening MN. This case highlights the importance of thorough history taking, detail review of medications and appropriate patient follow up.

PO1785

Phospholipase A2 Receptor (PLA2R) Positive Membranous Nephropathy (MN) in Celiac Disease

Luba Muaddi, AGH Nephrology Fellowship Allegheny General Hospital - Western Pennsylvania Hospital Medical Education Consortium, Pittsburgh, PA.

Introduction: In a 2011 study, PLA2R antibody (Ab) was detected in lupus MN, HBV MN, and solid tumor associated MN, with IgG4 stained glomeruli. PLA2R+ patients did achieve remission with HBV treatment and tumor resection, suggesting a coincidental occurrence of primary membranous nephropathy (PMN). PLA2R Ab levels in cases of PMN were higher (87.5%) than non-membrane nephropathy (0%) in a 2018 study. PLA2R was positive in 40 cases of secondary membranous nephropathy SMN (25%), including lupus MN, HBV MN, and atypical MN. In 2014, a case of celiac disease (CD) and H. Pylori infection with PLA2R+ MN was reported. Remission was achieved by H Pylori eradication without immunosuppression. In 2002, 2007 and 2009, three cases of renal failure due to MN in CD patients were reported raising the possibility of a link between the two conditions. We report the fourth case on the association of CD and MN to date.

Case Description: 40-year-old male with iron deficiency anemia and small bowel biopsy proven CD presented with pleural effusions, hypoxia, and generalized anasarca. Infections and rheumatologic work up was negative. Lung biopsy showed hemosiderosis reaching diagnosis of Lane-Hamilton Syndrome (LHS) (idiopathic pulmonary hemosiderosis (IPH), CD, chronic anemia). Three years prior, he was diagnosed with PMN by PLA2R+ renal biopsy and had nephrotic range proteinuria >9g. He was treated with losartan and diuretics with improvement in his symptoms and decrease in proteinuria to 6g. Serum creatinine rose from baseline of 1.9 mg/dL. He was then started on high dose prednisone for IPH and cyclosporine for MN with further improvement in proteinuria to 2.6g and creatinine to 1.3 mg/dL. Anti-thrombospondin type I domain-containing 7A Ab was negative against PMN. He had been trying to adhere to gluten free diet but was not consistent.

Discussion: CD is known to cause IPH and chronic anemia. It was hypothesized that chronic gastrointestinal inflammation triggers auto antibody formation against PLA2R1, which is present in duodenal and gastric cells in addition to glomerular cells. This would favor a causal relationship rather than coincidence of two idiopathic processes. Gluten free diet and steroids are the mainstay of therapy for LHS. We hope to prove that adherence to strict gluten free diet in our patient in addition to sustained low dose prednisone would lead to remission of MN without need for cyclosporine.

PO1786

Hydralazine-Induced Membranous Nephropathy

Tudor Gradinaru, Bruce A. Jones, Sandeep S. Soman. Henry Ford Hospital, Detroit, MI.

Introduction: Hydralazine is associated with a variety of rare renal diseases including drug-induced lupus, ANCA vasculitis and membranous nephropathy (MN) with associated crescentic GN. We present a case of a patient with features of hydralazine-induced MN with some FSGS but no features of vasculitis. This would be the first such reported case to the best of our knowledge.

Case Description: This 67-year-old female with a medical history of HTN, DMT2, ant-CrKD stage 3 initially presented to our clinic for evaluation of her renal function. Patient had increasing Cr up to 1.9 mg/dL over the course of 2 years. Her work up demonstrated modest albuminuria with several UACR results between 37.9 and 196.7 mg/g; UA demonstrated unremarkable chemistry and only 2 RBC and 1 WBC /plf. Serology showed positive ANCA 1:640 homogenous; dsDNA resulted negative; anti-histone Ab returned positive at 3.2 units (normal <1) as did her anti-MPO of 85 units (normal <20). Of note, C3 and C4 returned normal. Patient remained asymptomatic but had rapidly worsening Cr rising from 1.9 to 2.69 mg/dL over 1 month, prompting a renal biopsy and stopping hydralazine therapy. The biopsy showed areas of scarring and FSGS on light microscopy and membranous nephropathy on EM but demonstrated none of the classic necrotizing or crescentic lesions associated with drug-induced vasculitis or any of the typical findings of lupus nephritis. Follow-up PLA2R, thrombospondin, and Hep returned negative. Age appropriate cancer screening was negative. Repeat blood work showed Cr returning to prior baseline after 1 month off hydralazine. We decided together with the patient to continue to monitor and forgo more aggressive therapy. Renal function remained baseline for the next 6 months.

Discussion: This case represents an up-to-now unreported case of hydralazine-induced MN without associated vasculitic lesions. Patient fit the classic serological findings for a drug-induced vasculitis and her renal function stabilized upon cessation of exposure to hydralazine, giving us a high suspicion for causality. Given renal decline during work-up, re-exposure was not attempted. This patient never demonstrated any clinical or lab findings of MN disease: no severe proteinuria, no sequalae of nephrotic syndrome, and no associated diseases. Additionally, no lupus-like findings were appreciated on biopsy. We believe we have identified a novel association of hydralazine-induced MN.
An Atypical Presentation of Lupus Nephritis

Gaurry Kiri,
Jairedep U. Hingorani,
USF Health Morsani College of Medicine, Tampa, FL;
Charlotte Nephrology Associates, P.A., Port Charlotte, FL.

Introduction: Lupus nephritis in the absence of ANA and dsDNA, and normal C4 levels is a rare, atypical presentation. To arrive at the diagnosis requires EM examination of renal biopsies and is responsive to immunosuppressive therapy. We present a report of such a case.

Case Description: A 49-year-old female was referred for asymptomatic hematuria and nephrotic-range proteinuria (4.9 g/g) in March 2014. Her creatinine (0.77 mg/dL), C4, ANA, dsDNA, and Rheumatoid factor were normal with low C3. Labs were normal for Hepatitis B, C, HIV, ANCA, RNP, and Sm antibodies. She was started on lisinopril, and initially the proteinuria improved (2.3 g/g) and renal functions were stable. HematURIA was initially suspected to be secondary to MPGN. Renal biopsy immunofluorescence showed IgG, C3, IgM, kappa/lambda, and C1q (in lesser quantity). EM showed deposits in subendothelial, subepithelial and mesangium. She was diagnosed with immune complex glomerulonephritis without evidence of systemic lupus. Over the next 2 years, proteinuria worsened from 1.9 to 5.7 g/g despite increasing lisinopril to maximum dosage (40 mg/day). HematURIA and low C3 levels persisted. In February 2017, creatinine worsened (1.33 mg/dL). Cellcept (1000 mg/day) was started in March; by June, there was no response. Lisinopril was stopped in May due to low BP. A second renal biopsy (November 2017) showed a lupus picture with a full house pattern (3+ IgG, 1+ IgM, 2+ C3, 3+ C1q, 2+ kappa/lambda, IgA+ tubular casts). EM showed subendothelial and scattered subepithelial deposits, and GBM duplication. She was diagnosed as Class IV Lupus Nephritis. She was started on Cytoxan (500 mg q 2 weeks x6 weeks) and prednisone (60 mg/day). She showed improvement and was started on Imuran in May 2018 for maintenance. Her proteinuria (400mg/g) and creatinine (0.93mg/dL) improved, C3 normalized, and hematURIA resolved.

Discussion: Diagnosis of lupus nephritis can be missed on the basis of atypical labs and requires a high degree of suspicion and a biopsy. This case represents such an atypical presentation without systemic lupus. Initially, thought to have C3 nephritis; but later, the diagnosis was confirmed by renal biopsy and electron microscopy. The Full House immunofluorescence pattern seen in this patient is characteristically indicative of lupus nephritis, and she was responsive to immunosuppressive therapy.

Lupus Nephritis Classification Should Consider Lupus Arteritis in the Activity Score

Nora M. Alzahrani,
Ismael K. Almokayed,
Scott D. Cohen,
Renu Regunathan-Shenk,
Sanjeev Sethi.
George Washington University School of Medicine and Health Sciences, Washington, DC; Mayo Clinic Department of Laboratory Medicine and Pathology, Rochester, MN.

Introduction: Lupus nephritis (LN) complicates 20-49% of systemic lupus erythematosus (SLE) patients. Vascular lesions are not considered in the activity index of LN pathology classification. We report a case of LN with severe necrotizing arteritis without proliferative glomerular lesions, prompting a more aggressive intervention.

Case Description: A 36-year-old woman with known SLE with Class II LN, as well as vasculitis, resulting in multiple digital amputations presented with eight days of abdominal pain, vomiting, fever, and tea-colored urine. Labs showed creatinine of 1.4 mg/dL, microscopic hematuria, urine protein/creatinine of 5 g/g, low complements, positive anti-double-stranded DNA of 14, an elevated antinuclear antibody of 1:320, 1.4 mg/dL, microscopic hematuria, urine protein/creatinine of 5 g/g, low complements, positive anti-double-stranded DNA of 14, an elevated antinuclear antibody of 1:320, elevated Myeloperoxidase (MPO)-Antineutrophil Cytoplasmic Antibody (ANCA) of 59. She received induction therapy with intravenous (IV) methylprednisolone 1 g daily x3, followed by prednisone 60 mg daily and mycophenolate mofetil (MMF) 500 mg twice daily. A repeat kidney biopsy was performed, and 12 glomeruli showed only mesangial proliferation. She was classified as International Society of Nephrology and the Renal Pathology Society (ISN/RPS) class IIIA LN based on two arteries revealing severe arteritis with transmural necrosis causing occlusion, inflammation, and rupture of the vessel walls. Consequently, we switched MMF to IV cyclophosphamide 1g/m2 monthly. Creatinine improved to 1 mg/dL on discharge and 0.9 mg/dL two months later.

Discussion: There is limited attention to non-glomerular vascular lesions among patients with LN. Prior case reports show that LN patients with vascular involvement have worse outcomes and may require more aggressive treatment. The vasculitis in this case was attributed to the MPO Antibody. Given the potential prognostic and therapeutic implications of vascular involvement in LN patients, we suggest that lupus arteritis be considered in the LN pathology classification.

Hepatitis B-Associated Lupus-Like Nephritis

Anita Vincent-Johnson, Mohammed Y. Al Mulhim, Helen P. Cathro,
Tushar Chopra, Nequin Pourashfar.
University of Virginia, Charlottesville, VA.

Introduction: The spectrum of renal disease with hepatitis B virus (HBV) is broad including different glomerular lesions related to the presence of viral antigens. HBV-associated lupus-like nephritis (HBLN) is characterized by immune deposits of polyclonal immunoglobulins linked to polytropic complements in glomeruli, structures reminiscent of lupus nephritis (LN). There is a dearth of literature regarding differentiation of HBLN and LN along with differing management and outcomes.

Case Description: We report a 46-year-old male with known HBV infection with 3 weeks of progressive dyspepsia and edema. The serum creatinine (Scr) rose from a baseline of 0.8 mg/dL to 5.2 mg/dL with proteinuria of 1.7 g/g and microscopic hematuria. Serology showed transiently positive ANA, negative anti ds-DNA, and low levels of C3. Hepatitis B e Ag and hepatitis B surface Ag were positive, and the viral load was 2483 IU/mL with normal liver enzymes. A renal biopsy revealed severe diffuse endocapillary hypercellularity, a “full house” immunofluorescent pattern, and numerous subendothelial and mesangial immune deposits ultrastructurally, findings consistent with a diagnosis of HBLN. The patient was started on Entecavir for treatment of hepatitis B. After 2 months of treatment, the Scr improved to 1.97 mg/dL with improvement in initial symptoms.

Discussion: Our case highlights the inherent difficulty in recognition of renal failure secondary to HBLN with associated pathology findings consistent with LN in the presence of hepatitis B infection. Although the full-house immunofluorescent pattern generally implies a diagnosis of LN, renal biopsy findings have to be interpreted in the clinical context. All the findings in renal biopsies of LN can also be seen in HBLN. Renal manifestations in both groups, including proteinuria and Scr, can be similar. Although considerably lower C3 levels in patients with lupus may suggest more widespread extrarenal disease, low C3 levels have also been reported in HBLN. The distinguishing feature between HBLN and LN is the presence of HBsAg and hepatitis B DNA. Our case is an unusual presentation of hepatitis B with renal involvement with effective diagnosis and management. While there is limited data for the treatment of HBLN with most studies excluding patients with an elevated Scr, small studies suggest first-line treatment with antiviral agents to achieve viral clearance.

A Unique Case of Autoimmune-Mediated Cryoglobulinemic Glomerulonephritis

Monika Sadia,
Sumaya Muneer, Amit K. Rajput.
TrinityHealth, Cincinnati, OH.

Introduction: Cryoglobulinemic syndrome is a disease in which immunoglobulin components are deposited within tissues, resulting in various end-organ damage. Subtypes Type II and III contain mixed monoclonal and polyclonal immunoglobulins, thereby referred to as Mixed Cryoglobulin Syndrome (MC). MC is often associated with infections such as hepatitis C; however, it can also be secondary to autoimmune diseases. While the most common associations are with Systemic Lupus Erythematosus and Sjögren’s disease, occasionally, MC can be seen with other rheumatologic conditions. We examine a rare case of Overtiap Syndrome (OS) induced cryoglobulinemic glomerulonephritis (CG).

Case Description: A 44-year-old woman with a history of OS, presented with symptoms of fatigue, generalized edema, weight gain of 20lbs, and found to have an acute kidney injury (AKI). She was admitted to the hospital with a diagnosis of decompensated heart failure. The diagnosis of OS was confirmed with elevated ANA, SSA, RNP antibodies, as well as negative dsDNA and anti-smith antibodies. Previously, she was unsuccessfully treated with methotrexate and hydroxychloroquine. She was on hydroxychloroquine monotherapy at the time of admission. During the investigation for her AKI, she was found to have hematuria and non-nephritic range proteinuria (UCPR 2.65g/dL), raising concerns for glomerulonephritis. Subsequent renal biopsy showed autoimmune-mediated cryoglobulinemic glomerulonephritis. She was treated with a combination of methylprednisolone/prednisone and rituximab, which resulted in normalization of renal function.

Discussion: This case illustrates a patient with a history of OS with biopsy proven autoimmune mediated CG. The patient’s underlying diagnosis of OS is likely the leading risk factor for renal impairment secondary to immunoglobulin deposits. Treatment
is focused on immunosuppression, including steroids, rituximab, or mycophenolate mofetil. Combination therapy with a non-steroid immunosuppressant is preferred over monotherapy with steroids. The patient was treated with steroids and rituximab, with recovery of renal function. Given the varying presentation of CG, physicians should be mindful of keeping a broad differential, particularly in patients with rheumatological history presenting with proteinuria, hematuria, and signs of renal dysfunction.

POI1791
Bartonella Buried in the Aortic Valve

Introduction: Bartonella species are the most common cause of culture-negative endocarditis in the United States. We report a case with culture negative Bartonella endocarditis masquerading as Antineutrophil cytoplasmic antibody (ANCA) associated vasculitis.

Case Description: A 46 year old male presented with leg rash and swelling. Physical exam was notable for diastolic murmur in aortic area and a systolic murmur in the mitral area and non blanching purpura on the lower extremities. Labs showed BUN 39mg/dL, creatinine 1.54 mg/dL. Urinalysis showed non nephrotic range proteinuria and urine microscopy showed dysmorphic hematuria. ANA was 1:160, RF was 541 IU/mL, complement C3 and C4 levels were low and serum cryoglobulin was positive. ANCA titer was elevated with myeloperoxidase ANCA of 38 AU/mL and serine proteinase 3 ANCA of 580 AU/mL. Anti-Smith antibodies were 68AU/mL. Echocardiography showed severe mitral and aortic regurgitation with mitral and aortic vegetations. Ceftriaxone and vancomycin were started after blood cultures were obtained which remained negative. The aortic valve was replaced with mitral and tricuspid valve repair. Bartonella Quintana IgG titer was positive at 1:1024. Valve tissue cultures were negative and tissue PCR was positive for B. Quintana. He was eventually started on gentamycin and oral doxycycline. Ceftriaxone 1 month later was 1.2 mg/dL.

Discussion: Bartonella in the most common cause of culture-negative endocarditis in the United States with a reported association with pauci-immune glomerulonephritis. In our case serological testing and valve PCR were helpful in establishing the diagnosis. In conclusion, SBE induced glomerulonephritis with false positive serology for ANCA in the United States with a reported association with pauci-immune glomerulonephritis. IC-MPGN (immune complex-mediated glomerulonephritis) is a histopathological finding that is associated with infection, immune-complex deposition, monoclonal gammopathies as well as autoimmune disorders such as lupus, Sjögren’s, and rheumatoid arthritis. MPGN traditionally has been classified as I-III depending on the pathology findings. More recently, an alternative classification system based on the pathological process has been developed (immune complex-mediated vs complement-mediated). In cases of IF showing IgG +/- C3, a tentative diagnosis of immune-complex mediated MPGN can be made. MPGN treatment is aimed first at treating the underlying cause. In the case where a cause cannot be found, as in our case of biopsy-proven IC-MPGN with negative serologies, the underlying mechanism is not clear.

Case Description: 71-year-old female with PMHx aortic valve replacement, HTN, CKD-I presented with constitutional symptoms, and AKI on CKD with proteinuria. She was found to have biopsy-proven immune complex mediated MPGN, but the etiology was unclear during negative: ANA, anti-Smith, anti-Ro/SS, anti-La/SSB, Hec B/C, cryoglobulins, CCP, CRP, ESR, K/L. The biopsy pattern was consistent with Lupus Type IV/V, with EM findings showing scattered sub endothelial dense deposits and full house IF staining pattern. CT abdomen/pelvis was negative. Further testing and workup for malignancy were negative. She was started on high-dose steroids for initial treatment of presumptive seronegative lupus nephritis. Serologies were repeated and all were negative. Patient showed improvement with initiation of mycophenolate ± steroids; proteinuria and creatinine improved on follow-up.

Discussion: The optimal initial treatment of idiopathic/seronegative immune complex-mediated MPGN has not been established. In this case, the patient improved with aggressive steroid treatment with a tapering dose after starting mycophenolate. Proteinuria which was initially nephritic at 14 g/g is now near 0.2 g/g.

POI1792
Clinopathological Analysis of Renal Dysfunction due to Idiopathic Multicentric Castleman Disease in Japan
Hiroki Mizuno, Junichi Hoshino, Yoshifumi Ubara. Toranomon Hospital, Minato Ward, Japan.

Background: Renal dysfunction is a fatal complication of idiopathic multicentric Castleman disease. Although AA amyloidosis and glomerular endotheliosis with severe proteinuria were reported due to this disease, human immunodeficiency virus (HIV) were positive in these previously reported cases. On the other hand, HIV-negative cases are common in Japan, and the precise renal involvement of Japanese cases has not been studied yet.

Methods: Case-series was designed for analyzing the clinopathological features of renal dysfunction accompanied with Castleman disease. Inclusion criteria of the object was renal biopsy specimens between 1990 and 2019 and the patients who were diagnosed as Castleman disease. Clinical and pathological data was collected from the electrical medical record.

Results: Eight patients were eligible to the study. Seven out of eight cases were plasma cell type, while anti-HIV antibody test was negative in all cases. Laboratory data at the time of renal biopsy showed; median serum creatinine was 0.75(0.6-5.0) mg/dL, urine protein was 1.28(0.04-8.9) mg/dL. In glomerular lesion, following involvement were found: two cases of AA amyloidosis and membranous nephropathy respectively, while IgA deposition and nephrosclerosis in one case each. Nephrotic range proteinuria was found in two cases of AA amyloidosis as well as one case of membranous nephropathy. Among two cases diagnosed as membranous nephropathy, immunofluorescent analysis about IgG subclass showed that IgG1 was dominant in one case and IgG2 was in the other. IgG4 was negative in both cases. In interstitial lesion, chronic tubulointerstitial nephritis was diagnosed in one case.

Conclusions: Heterogenous glomerular lesions were found in our cohort. Previous cohort study showed that membranous nephropathy was rare, but in this study, two out of eight cases turned out to be membranous nephropathy. In addition, analysis of IgG subclass suggests that either IgG1 or IgG2 was dominant in secondary membranous nephropathy due to Castleman disease and that deposition of immunoglobulin complex could be associated to the onset of proteinuria of Castleman disease.

Role of the IgA Immune Complexes Bound to FcεRI/CD89 in IgA Nephropathy
Xue Zhang, Jing Jin, Jicheng Lv, Manliu Wang, Hong Zhang. Peking University First Hospital, Beijing, China; Northwestern University Feinberg School of Medicine, Chicago, IL.

Background: Studies have demonstrated the pathogenic role of circulating polymers of IgA immune complexes (poly-IgA ICs) in IgA nephropathy (IgAN). In this study we aim to evaluate the role of poly-IgA ICs specifically bound to FcεRI/CD89 in the kidney development of IgAN.

Methods: rCD89 protein was produced from a HEK293 cell expression system. A novel ELISA method that using rCD89 as the ‘capturing’ probe was established for detecting poly-IgA ICs. The plasma levels of poly-IgA ICs were measured in 181 IgAN patients and 35 patients with glomerular diseases of unrelated etiologies. Another 85 age-, gender-, and geographically-matched healthy individuals were enrolled as controls.

Results: rCD89-bound poly-IgA ICs were analyzed by mass spectrometry.

Conclusions: Higher level of rCD89-bound poly-IgA ICs was a potential useful diagnostic biomarker in patients with IgAN which was also associated with the severity of the disease. The findings suggest that the role of CD89 in eliminating IgA ICs and it may be a new approach to improve the clinical progress of patients with IgAN.
Plasma levels of CD89-bound poly-IgA ICs in groups

**Racial Heterogeneity of IgA, Hinge Region O-Glycoforms in Patients with IgA Nephropathy**

Yukako Ohyama,1 Samantha Chiuriia,2 Sharon N. Cox,2 Nikoletta-Maria Kouri,1 Marija J. Stangou,3 Hisateru Yamaguchi,2 Kazuki Nakajima,1 Dairo Inaguma,1 Midori Hasegawa,1 Yukio Yuzawa,1 Naotake Tsobo,1 Aikaterini Papagianni,2 Francesco P. Schena,2 Kazuo Takahashi,1 Fujita Health University, Toyoake, Japan; 2University of Bari and Schena Foundation, Valenzano, Italy, Aristotle University of Thessaloniki, Thessaloniki, Greece.

**Background:** IgA with galactose (Gal)-deficient hinge region (HR) O-glycans (Gd-IgA1) plays a crucial role in the pathogenesis of IgA nephropathy (IgAN). The microRNAs, named let7b and miR-148b, which affect IgA1 HR (Gd-IgA1) plays a crucial role in the pathogenesis of IgA nephropathy (IgAN). The difference in HR O-glycosylation, shown differences in serum levels between Caucasians and Asians, suggesting a racial difference in HR O-glycosylation. To understand race-specific IgA1 HR O-glycoform heterogeneity at the molecular level, we compared Greek and Japanese profiles of IgA1 HR O-glycoforms in patients with IgAN.

**Methods:** IgA1 from sera of 10 Japanese healthy controls (J-HC), 36 Japanese IgAN patients (J-IgAN), 16 Greek HCs (G-HC), and 23 Greek IgAN patients (G-IgAN) were O-glycoforms in patients with IgAN.

**Results:** Twelve variants of the IgA1 HR O-glycopeptide were detected in both HCs and IgAN patients. The disease-specific IgA1 HR O-glycoforms were 3GalNAc2Gal in Japanese (P < 0.001) and 3GalNAc2Gal (P = 0.007) and 5GalNAc2Gal (P = 0.043) in Greek individuals. The amount of GalNAc per HR showed a common tendency to decrease in patients from both racial groups, compared with healthy subjects, and was more prominent in G-IgA1 than in J-IgA1 (P = 0.027). The amount of Gal per HR decreased in the following order: IgA1-G, H-IC, J-IC, and G-IgA1, and was significantly lower in G-IgA1 than in J-IgA1 (P = 0.001).

**Conclusions:** The amount of GalNAc per HR decreased in patients of both races and was prominent in G-IgA1. The difference in GalNAc levels between G-IgAN and J-IgAN showed correspondence with previously reported serum let-7b racial differences, which were associated with the regulation of the initial glycosylation of HR. Further studies regarding upstream factors and changes downstream of GalNAc glycosylation are required to understand the pathogenesis of IgAN.

**Funding:** Government Support - Non-U.S.
Identifying of Proteins Associated with IgA, Containing Circulating Immune Complexes in Patients with IgA Nephropathy
Mary A. Bunten,1 Amanda Holloway,2 Audra A. Hargett,1 Stacy D. Hall,1 Zhi qiang Huang,2 Nicolas Maillard,2 Bruce A. Julian,1 Jan Novak,3 Matthew B. Renfrow,1 University of Alabama at Birmingham, Birmingham, AL; Louis Pasteur University Jean Monnet de Saint-Etienne, Saint-Etienne, France.

Background: IgA1-containing immune complexes (IgA1-ICs), consisting of galactose-deficient IgA1 (Gd-IgA1) bound by IgG specific for Gd-IgA1, are central to the pathogenesis of IgA nephropathy (IgAN). We have shown that IgD-IgA1 alone is not sufficient to induce mesangial-cell proliferation and that additional serum proteins are required for IgA1-ICs to become nephritogenic. To elucidate the composition of IgA1-ICs, we have developed a novel proteomic-bioinformatic workflow to identify proteins in IgA1-ICs in patients with IgAN.

Methods: IgA1-ICs from sera of 20 patients and 20 healthy controls were isolated by lectin affinity chromatography followed by size-exclusion chromatography (SEC). Quality-control tested confirmed that most IgA1-ICs and free IgA1 were captured by affinity chromatography. IgA1-ICs were separated by SEC from monomeric and polymeric IgA1. After IgA-specific protease and LS-MS sequence-grade trypsin digestion, each IgA1-IC sample was analyzed by liquid chromatography coupled on line with mass spectrometry (LC-MS). After standard proteomic database searches, LC-MS results were extensively curated by use of Scaffold perSpectrE to identify proteins enriched in IgA1-ICs of IgAN patients vs. healthy controls. Additional comparisons included polymeric and monomeric IgA1.

Results: Seventy-nine proteins were identified in IgA1-ICs samples from IgAN patients, with a false discovery rate of 1%. After proteomic-bioinformatic curation, we generated a list of 38 proteins with high-confidence identification that were uniquely enriched in the IgA1-ICs from patients with IgAN. Using Principle Component Analysis, we confirmed that protein content differentiated the three molecular forms of IgA1, monomeric, polymeric, and IgA1-IC. Pathway analysis indicated that proteins in IgA1-ICs were part of the complement cascade, with seemingly more enrichment in the regulation of complement, and the plasma lipoprotein pathway.

Conclusions: Our new workflow enabled targeted identification and evaluation of proteins associated with IgA1-ICs in IgAN patients. These proteins represent new targets to be evaluated for their roles in the formation and activity of the nephritogenic IgA1-ICs in IgAN.

Low Serum IgG4: A Remarkable Diagnostic Biomarker for IgA Nephropathy
Xinyu Tian, Song Wang, Zhenling Deng, Yue Wang. Peking University Third Hospital, Beijing, China.

Background: Reports regarding IgG subclasses in IgA nephropathy (IgAN) are scarce. Low serum IgG4 levels in IgAN were noticed in our preliminary experiment. We aim to verify the low IgG4 levels in IgAN and investigate the related immune mechanism.

Methods: Three groups of IgAN patients were enrolled, including the newly diagnosed IgAN-N (n = 58), IgAN-F (n = 28) with a follow-up interval of 19 (± 11) months, and IgAN-10 patients (n = 27) who have been diagnosed over 10 years. Healthy individuals (n = 56) and patients with idiopathic membranous nephropathy (IMN, n = 30) were enrolled as controls. Serum IgG4, IgG, galactose-deficient IgA1 (Gd-IgA1), and urine IgG4 levels were detected by ELISA. The IgG4+B, Th1, and Th2 cells were measured by flow cytometry. Receiver operating characteristic curves and logistic regression analyses were performed to evaluate the diagnostic and predictive abilities of IgG4.

Results: The serum IgG4 levels in IgAN patients with different courses, severity, and outcomes were all significantly lower than those of healthy controls and IMN (all P < 0.001). The total value of IgG4 in differentiating IgAN from healthy individuals and IMN was respectively 0.26mg/ml (sensitivity 98.3%, specificity 82.1%, AUC 0.938), < 0.0001 and 0.24mg/ml (sensitivity 96.6%, specificity 73.3%, AUC 0.869, P = 0.0001). The risk of IgAN in subjects with low IgG4 levels was 28 times higher than that of normal IgG4 (OR 281.11, 95% CI 34.33-2301.97, P = 0.0001), and a negative correlation between serum Gd-IgA1 and IgG4 levels was observed in healthy controls (r = 0.240, P = 0.077) instead of IgAN-N patients (r = 0.066, P = 0.629). Similar results were obtained when IgG4/IgG was analyzed in the same patients and controls. The urine IgG4 levels [µg (mg G)] in IgAN-N (278.16 (398.75, 513.56)) were higher than healthy controls [27.87 (31.51, 208.40), P < 0.001], but were similar to IMN [1153.39 (378.83, 2108.40), P = 0.341]. The IgG4+B cells (0.29 ± 0.17 vs. 0.61 ± 0.56, P = 0.017) and Th1/Th2 (0.54 ± 0.27 vs. 0.87 ± 0.44, P = 0.037) of IgAN were significantly lower than those of healthy controls.

Conclusions: Serum IgG4 levels of IgAN patients are generally low, and the low IgG4 level may be a risk factor for IgAN. Serum IgG4 may be a remarkable diagnostic biomarker for IgAN. Decreased IgG4+B and Th2 cells may contribute to the low IgG4 levels.

PO1800
Comparing the Lectin and Mass Spectrometry-Based Approaches to Quantify Galactose-Deficient IgA, in IgA Nephropathy
Olivier Lardinois,1 Patrick H. Nachman,1 Jason G. Williams,2 Leesa Detertling,2 1University of Minnesota, Division of Renal Diseases and Hypertension, Minneapolis, MN; 2NIEHS, Mass Spectrometry Research and Support Group, Research Triangle Park, NC.

Background: Abnormalities in O-glycosylation of circulating IgA, are implicated in the pathogenesis of IgAN and initially demonstrated as altered binding of lectins with specificity for O-linked glycans and confirmed later by mass spectrometry. Nevertheless, combining and interpreting the results from these two orthogonal techniques is difficult, due to their different levels of complexity. We applied the two approaches to quantify galactose-deficient IgA, (Gd-IgA1) in plasma samples of IgAN patients and matched controls. We aim to identify potential sources of discrepancy between the two analytical methods.

Methods: IgAs were affinity purified from plasma samples from 23 patients with IgAN and 36 controls. We used enzyme-linked lectin assay and the lectin from Vicia villosa (VVL) to measure defective galactosylation of O-linked oligosaccharides. Monomeric (mIgA) and polymeric (pIgA) forms of IgA, were size-separated by gel electrophoresis. IgA-containing bands were in gel digested with trypsin, the released glycopeptides were analyzed by electrospray ionization liquid mass spectrometry.

Results: A significantly larger fraction of IgA, molecules in the circulation of IgAN patients exist as high molecular mass complexes, as compared with the control group (48.8± 42.8%, P= 2.45E-02). The reactivity of VVL lectin with unfractonated IgA1, was higher in the IgAN group compared with healthy controls (10.9± 9.1 A.U., P= 6.0E-02). Both Gd-IgA1 and IgA, binding by VVL lectin was much stronger for pIgA1 than mIgA1. Mass spectrometry showed that the level of Gd was higher in pIgA1 than in mIgA1 (3.66 vs. 3.54 Gal/Heavy Chain, P= 6.3E-05). However, no significant differences in glycan composition was detected between patients and controls. In all the experiments, the interindividual differences in glycan composition were large, which may have obscured the signals from the disease-related galactose-deficient IgA1.

Conclusions: Our results suggest that the apparent increased abundance of Gd-IgA1, in circulation of patients with IgAN, is at least in part, attributable to a greater abundance of polymeric IgA1, compared with controls. However, the glycosylation profile of each form of IgA1, appeared indistinguishable in the IgAN group when compared to the corresponding form in the control group.

Anuprava R. Rajajopan1, Ishwarya Venkatesh, Rabab Aslam, Vinnet Gupta,2,3 Drug Discovery Center, Department of Internal Medicine, Rush University Medical Center, Chicago, IL; 2Division of Hematology, Oncology and Cellular Therapies, Department of Internal Medicine, Rush University Medical Center, Chicago, IL; 2Division of Hematology, Oncology and Cellular Therapies, Department of Internal Medicine, Rush University Medical Center, Chicago, IL

Background: Patients with IgA nephropathy (IgAN) have elevated serum levels of IgA1 with some hinge-region (HR) O-glycan deficient in galactose (Gal; Glc-IgA1). Glc-IgA1 is recognized by IgG autoantibodies, resulting in the formation of pathogenic immune complexes. Our group has established a quantitative ELISA for Glc-IgA1 using Gal-specific lectins (e.g., from Helix pomatia; HPA). This test enabled determinations of genetic basis of IgA1 Gal deficiency and provided a better understanding of IgAN pathogenesis. However, understanding of IgA1 O-glycosylation at a molecular-level is needed.

Methods: We used liquid chromatography with high-resolution mass spectrometry (LC-MS) to analyze and quantify O-glycans of monomeric (m) and polymeric (p) IgA1 in sera of IgAN patients (n=31) and healthy controls (HC; n=10). Total serum IgA1 was isolated from the affinity chromatography and m and p forms were separated by size-exclusion chromatography. Glc-IgA1 was measured by lectin ELISA. HR glycopeptides generated by an IgA-specific protease and trypsin, were analyzed by LC-MS using LTQ Orbitrap Velos MS. LC-MS data were analyzed with the Pinnacle software.

Results: Quantitative LC-MS O-glycosylation profiling of IgA1 HR was performed, and results were calculated as relative abundance of individual glycoforms and as ratios of Gal-containing vs. Gal-deficient glycoforms. Both LC-MS data and lectin ELISA confirmed that pGlcA1 exhibited higher degree of Gal deficiency than mGlcA1. LC-MS data provided additional insight into the molecular basis of the variability of Glc-IgA1 serum levels in IgA nephropathy. For example, IgA1 HR glycoforms GlcGalA1 was more abundant for the pGlcA1 in the patients with high vs. low serum levels of Glc-IgA1 (p<0.005). LC-MS analysis enabled identification and quantification of individual HR glycoforms and defined the Glc-IgA1 glycoforms detected by lectin ELISA.

Conclusion: LC-MS IgA1 glycoforms confirmed pGlcA1 as the main form of IgA1 detected by Glc-IgA1 lectin ELISA. Furthermore, we identified several different Gal-deficient glycoforms in pGlcA1, an observation that enables quantitative molecular-level assessment of Glc-IgA1 glycoform phenotype.

Background: Chronic Kidney Disease (CKD) is an emerging global health challenge, affecting 10-15% of the population. Lack of reliable biomarkers precludes the early diagnosis of CKD. The progression of CKD is known to be dictated by renal tissue inflammation. For example, the case of Diabetic Nephropathy, disease progression is accompanied by considerable changes to the glomeruli including the thickening of the glomerular basement membrane and mesangial expansion, extracellular matrix accumulation, reduced podocyte number, inflammation of the renal tissue, the influx of immune cells which ultimately lead to tissue damage and progression to CKD. Understanding these tissue-centered events on a deeper level is imperative to reduce morbidity associated with CKD and for early diagnosis.

Methods: To aid high-level multiplex staining of these tissues by immunofluorescence, we developed a novel multiplex staining method called SeqStain. The SeqStain multiplex platform uses DNA tagged antibodies and Fab fragments to stain while endomucinases are used to achieve gentle de-staining after each round. We designed a SeqStain multiplex platform with antibodies to probe different histological regions relevant to the kidney. Antibodies or Fab fragments were tagged with DNA oligonucleotide duplex which carries multiple fluorophores. Labeled Fab fragments were pre-complexed with primary antibodies for staining.

Results: SeqStain modified antibodies and Fab fragments efficiently labeled multiple markers in tissue sections. Kidney tissues were stained with the SeqStain reagents and de-stained using endomucinases and provided a simple, gentle, and rapid technique for multiplex imaging of the tissues. The method was implemented using a custom flow chamber and allowed the labeling of tens of antigens on a single tissue section. Image alignment and deconvolution of spatial data on multiple cell types in the tissue.

Conclusions: SeqStain method offers a robust yet gentle multiplex staining method to profile the CKD kidney tissues and comprehend the tissue-centered events that could play a role in the disease progression. Currently, we are profiling the CKD tissues in multiplex staining experiments and comparing it to healthy human kidney tissues to generate the spatial maps.

Background: PDGF is involved in the pathogenesis of IgA nephropathy, namely in the activation of mesangial cells (MC). Our kinomic profiling revealed that receptor tyrosine kinase Axl and non-receptor tyrosine kinase ABL were the top upregulated protein-tyrosine kinases in MC stimulated by PDGF-AB. In this study, we describe crosstalk between Axl and PDGF receptor (PDGFR-β) in human MC stimulated with PDGF-AB.

Methods: Quiescent primary human MC were stimulated with PDGF-AB for 15 min. Cell lysates were analyzed with SDS-PAGE; Western blotting was performed to evaluate PDGFR-β, Axl, and downstream signaling. Immunoprecipitation with antibodies specific for PDGFR-β or Axl was used to assess association of Axl and PDGFR-β. To test the role of Axl in crosstalk with PDGFR-β, the Axl/ABL inhibitor R428 and an Axl-specific siRNA knock-down (k/d) were used. Cellular proliferation was measured by BrdU incorporation – 20 hr after PDGFR-AB stimulation.

Results: PDGF-AB stimulated cellular proliferation of MC. PDGF-AB induced phosphorylation of multiple kinases, including Axl, PDGFR-β, Akt1, and ERK1/2 in MC. Immunoprecipitation experiments revealed association of Axl and PDGFR-β. The Axl/ABL inhibitor R428 inhibited PDGF-AB-induced phosphorylation of Axl, PDGFR-β, Akt1, and ERK1/2, and partially reduced PDGF-AB-induced MC proliferation. siRNA k/d of Axl reduced expression of Axl, but did not prevent PDGF-AB-induced phosphorylation of Akt1, ERK1/2 and PDGFR-β, and did not reduce proliferation of MC.

Conclusions: In summary, PDGF-AB induced multiple signaling events in cultured human MC that included crosstalk between PDGFR-β and Axl. MC cellular signaling induced by PDGF-AB was blocked by the Axl/ABL inhibitor R428 but not by Axl siRNA k/d. These findings suggest a role for the non-receptor tyrosine kinase ABL in a crosstalk between the two receptors. We postulate that the PDGFR-β/Axl/ABL pathway may represent a possible therapeutic target in the treatment of IgA nephropathy.

Galactose-Deficient IgA1-Containing Immune Complexes Deposit with Complementary Activity in Mesangium Through Endothelial Cell Injuries

Yusuke Makita, Hitoshi Suzuki, Daisuke Nakano, Toshiki Kano, Akira Nishiyama, Yusuke Suzuki. 1Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; 2Department of Nephrology, Juntendo University Urayasu Hospital, Chiba, Japan; 3Department of Pharmacology, Kagawa University, Kagawa, Japan.

Background: IgAN is defined by the presence of dominant mesangial IgA1 immune deposits, accompanied by C3 deposits, and deposition of IgA1 includes galactose-deficient IgA1 (Gd-IgA1). However, the pathogenic role of Gd-IgA1-containing IC with regard to mesangial immune deposits is still unclear. The endothelial surface glycocalyx modulates microvascular function. Loss of the glomerular endothelial glycocalyx is involved in albuminuria. In present study, we hypothesized that Gd-IgA1-containing IC deposit in mesangium through glomerular endothelial cell injuries.

Methods: Gd-IgA1 and recombinant anti-glycan IgG were used to form IC (Gd-IgA1-IgG IC) to inject i.v into nude mouse. After various time intervals, mice were sacrificed and kidney was harvested to determine mesangial deposition and kidney injuries. To investigate that Gd-IgA1-IgG IC stimulation increases permeability of glomerular microvascular resulted in renal injuries, the renal microvascular endothelial cells were determined at 8 am and 4 pm at 6, 8, and 12 W. Kidney biopsies were taken at the end of the study at 12 W of age and 30 glomeruli/animal were scored for the percentage of GS. Serum IgA and glycosylation of IgA was measured using ELISAs.

Conclusions: 8 weeks of treatment with SP significantly attenuated increases in albuminuria and GS associated with the development of IgAN in gddY mice. If translated to the clinic, these data support SP as a new approach to the treatment of IgAN.

PO1808
Sparvastran Protects Against Development of Albuminuria and Glomerulosclerosis in the gddY Mouse Model of IgA Nephropathy

Hajime Nagasawa, Hitoshi Suzuki,1,2 Yusuke Fukao,1 Maiko Nakayama,1 Tomoyuki Otsuka,1 Kai Liu,1 Radko Komers,1 Yusuke Suzuki. 1Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; 2Department of Nephrology, Juntendo University Faculty of Medicine, Chiba, Japan; 3Retrophin Inc, San Diego, CA.

Background: gddY mice are an IgA nephropathy (IgAN) model that develops albuminuria by 8 weeks (W) of age with glomerular IgA1, IgG, and C3 deposits and progressive mesangiproliferative glomerulonephritis. A previous study in the ddY mouse model (the predecessor to gddY mice) using the endothelium type A receptor (ET, R) antagonist FR199317 resulted in amelioration of proteinuria and preservation of kidney function. Treatment of ddY mice with the angiotensin II type 1 receptor (AT, R) blocker valsartan resulted in significant protection from glomerulosclerosis (GS) without a significant prevention in proteinuria. We examined the effect of sparvastran (SP), a dual ET, R and AT, R blocker, on development of albuminuria and GS in gddY mice.

Methods: 8 W old gddY mice fed with control (C) chow (n=5) or chow containing 900 ppm (n=10) or 1800 ppm (n=10) SP (180 and 360 mg/kg/day) for 8 W. Albuminuria (U-Alb) was assessed at 4, 6, 8, and 12 W of age and plasma levels of SP were determined at 8 am and 4 pm at 6, 8, and 12 W. Kidney biopsies were taken at the end of the study at 12 W of age and 30 glomeruli/animal were scored for the percentage of GS. Serum IgA and glycosylation of IgA was measured using ELISAs.

Results: gddY mice fed SP for 8 W from 4 W of age demonstrated significantly (P<0.05) decreased U-Alb vs mice fed C diet (Fig 1). Development of GS in SP-fed mice was significantly (P<0.05) attenuated vs C diet (Fig 2). Plasma levels of SP taken at 8 am and 4 pm after 8 W of treatment were (means±SD) 281±107 and 105±62 ng/ml respectively for 900 ppm SP and 774±874 and 304±176 ng/ml respectively for 1800 ppm SP. Weight gain in mice fed SP was not different from mice receiving C diet. There was no difference in serum levels of IgA or aberrantly glycosylated IgA.

Conclusions: 8 weeks of treatment with SP significantly attenuated increases in albuminuria and GS associated with the development of IgAN in gddY mice. If translated to the clinic, these data support SP as a new approach to the treatment of IgAN.

PO1809
Dysregulation of B-Cell Differentiation in IgA Nephropathy Model Mice Yoshihito Nihei, Hitoshi Suzuki, Yusuke Fukao, Maiko Nakayama, Mingfeng Lee, Rina Kato, Toshiki Kano, Yuku Makita, Yusuke Suzuki. 1Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; 2Department of Nephrology, Juntendo University Faculty of Medicine, Chiba, Japan.

Background: Several novel drugs targeting B cells are reported to be effective in the treatment of IgA nephropathy (IgAN). On the other hand, we have reported that the abnormal B cells expressing APRIL (a proliferation-inducing ligand) are present in tonsils of human IgAN. Given these reports, dysregulation of B cells may be involved in the pathogenesis of IgAN. To elucidate the abnormality in B cells of IgAN, we analyzed characteristics of B cells by using IgAN prone mice with (O-ddY) or without (NO-ddY) full onset of this disease. Furthermore, we recently developed a novel culture system mimicking germinal center in mucosa, by which nearly 50 % of B cells undergo class switch (CS) to IgA. Here, we aim to evaluate characteristics of B cells in O-ddY mice using this novel B cell culture system.

Methods: Splenic B cells from O-ddY or NO-ddY mice were stimulated with membrane-bound IgM and CD40 for 48h and then proliferation of B cells was evaluated by Thyminde uptake analysis. To examine CS to IgA, naïve splenic B cells from O-ddY or NO-ddY mice were cultured for seven days under the newly developed culture system. The frequency of IgA CS was evaluated by flow cytometry.

Results: We found that naïve B cells of O-ddY mice proliferated more than those of NO-ddY mice in response to stimuli through CD40 and membrane-bound IgM. There was no significant difference in the frequency of class switch to IgA between splenic B cells from O-ddY mice and those from NO-ddY mice.

Conclusions: These data indicate that B cells in O-ddY mice are hyper-sensitive to stimuli by B cell and T cell help without increasing the IgM to IgA switch (CS) to IgA. Here, we suggest that such dysregulation of B cells may be involved in the pathogenesis of IgAN.

Novel Model for IgA Nephropathy Using Synthetic Polymeric IgA
Xinfang Xie,1,2 Pan Liu,1 Jing Jin.1 1. Division of Nephrology and Hypertension, Northwestern University Feinberg School of Medicine, Chicago, Illinois, USA; and Feinberg Cardiovascular and Renal Research Institute, Northwestern University Feinberg School of Medicine, Chicago, Illinois, USA. 2. Department of Nephrology, The First Affiliated Hospital of Medical College, Xi’an Jiaotong University, Xi’an, China. Division of Nephropathy and Hypertension, Northwestern University Feinberg School of Medicine, Feinberg Cardiovascular and Renal Research Institute, Northwestern University Feinberg School of Medicine, Chicago, IL. 2. Department of Nephrology, The First Affiliated Hospital of Medical College, Xi’an Jiaotong University, Xi’an, China.

Background: IgA nephropathy (IgAN) is characterized by polymeric IgA deposition in the glomerulus. The mechanism for IgA deposition remains elusive. We constructed a reproducible IgA polymerized by streptavidin to model the initiation and development of IgA.

Methods: To model IgA complex, we produced recombinant rat and human IgA CH2-CH3 segments. By fusing them with Avi-tag, adding biotin and tetrameric streptavidin to form 4-8 unit multimers. Both dimeric IgA and polymeric IgA constructs were IV injected in rats. Renal deposition of the IgA was detected by immunofluorescence. Polymer IgA was used to stimulate mesangial cells and IL-6 production was measured by ELISA.

Results: Through BirA enzymatic reaction, single biotin was added to the Avi-Tag at the N-terminus of IgA. The total molecular sizes of IgA with and without streptavidin were measured by size-exclusion chromatograph. As expected, uninduced IgA was a standard dimer of 65 kDa, whereas streptavidin-induced IgA formed multimers of 4-8 units, resembling poly-IgA in IgAN. These dimeric and polymeric IgA at 2 mg/kg. BW were injected in 5 week-old Wistar rats. 1h, 24 and 48 h after injection, the kidney and the liver were harvested for detection of IgA. Exclusive IgA deposition in the glomerulus mesangial areas was found (Figure). In general, the staining intensity gradually diminished over 24 hrs period. However, rats received daily doses of the induced IgA for 2 and 5 days showed enhanced intensity of IgA deposition. In contrast, the dimeric IgA was not detectable in kidney. Furthermore, EM and PAS staining of the renal sections showed mesangial proliferation. Ex vivo stimulation of human mesangial cells also showed increased levels of IL-6 in the medium.

Conclusions: The findings indicate streptavidin-induced poly-IgA causes specific renal mesangial deposition and mesangial cells proliferation, which can be used to study the kinetics of mesangial accumulation and clearance of IgA deposition, as a new model for investigating IgAN pathogenesis.

Nephritic Factor Function Over Time
Christopher Calek,1,2 Monica D. Hall,1,2 Yuzhou Zhang,1,2 Richard J. Smith,1,2 Carla M. Neeter,1,2 1Molecular Otolaryngology and Renal Research Laboratories, Iowa City, IA; 2University of Iowa, Iowa City, IA.

Background: Nephritic factors (Nef) are autoantibodies that stabilize and dysregulate the function of the C3 convertase, the cornerstone of complement amplification. Their association with renal inflammation central to the C3 Glomerulopathies (C3G) is well defined and pathologic renal disease is associated with the dysregulation of the complement pathway, leading to deposition of C3 complement in the glomeruli, with or no immunoglobulin deposits. While it is known that membranoproliferative glomerulopathies carry a risk of recurrence after transplant, no large-scale meta-analysis was done after 2015 to assess the precise recurrence risk and remission duration for C3 glomerulopathies. The goal of this work is to determine if there is currently enough literature specific for C3G to conduct such a metaanalysis.

Methods: Our research protocol was guided by the PRISMA protocol, and the Joanna Briggs Institute Critical Appraisal Tools. A search was conducted in 3 databases using a specific search string, at the conclusion of which, 230 papers were found. The identified papers were subsequently screened by the 2 authors independently using precise inclusion and exclusion criteria. The screening resulted in the final inclusion of 6 papers, on which a qualitative synthesis was performed. The information extracted was organized on the basis of demographics, time of transplantation, disease recurrence, and disease-free period post-transplantation.

Results: Among the 6 papers selected, 2 were case series and 4 were case reports. In total, 25 patients were reported as having a recurrence of C3G. The age of the patients ranged between 7 and 60 years of age. Among the 25 patients, 11 of them were male, while 6 of them were females. The C3G subtype was determined for 25 patients, with 16 were classified as having C3GN and 8 having DDD. The age of transplant was reported for 21 patients, ranging from 13 to 64 years old. The disease-free interval between the kidney transplant and the recurrence of the disease ranged from 14 days to 91 months, with 1 case series paper only reported the median time to recurrence in months (59[27-91] for C3GN patients and 41[0-71] for DDD patients). While C3G, with its multiple subtypes, has been well-defined entities for a decade, our review reveals that little research about the post-transplant evolution and recurrence of these diseases has been done. While extensive research can be found on the recurrence risks of Membranoproliferative Glomerulonephritis, we believe that with the new classification, more data on the new subtypes is necessary to guide the decision-making of clinicians and their patients.

POI1813
C3 Glomerulonephritis: A Rare Complication of Chronic Lymphocytic Leukemia
Khaled Srouj, Jayanth Lakshminanthan, Chandrika Chittruri, Mark D. Faber. Henry Ford Hospital, Detroit, MI.

Introduction: Kidney disease develops in chronic lymphocytic leukemia (CLL) patients via multiple mechanisms including infiltration, obstruction, tumor lysis syndrome, and glomerular disease. We present a rare case of C3 glomerulonephritis (C3GN) associated with pulmonary renal syndrome that we believe was an autoimmune manifestation of CLL.

Case Description: A 76 year old male with a 15 year history of SLL/CLL, DVT, HTN, DM and Stage 3 CKD developed SOB and dry cough. At ED presentation he was in respiratory distress with BIPAP resistant hypoxia requiring intubation. Labs included T7.1 m/dL, K 5.7 mEq/L and uric acid 12.2 mg/dL. CXR showed vascular congestion. Prior to developing anuria urine sediment showed RBC casts. Bronchoscopy DAH, consistent with a pulmonary renal syndrome. Patient was started on plasmapheresis, high dose steroids and CRRT. Autoimmune workup including ANA, anti GBM and ANCA was negative. Kidney biopsy showed diffuse proliferative and sclerotic glomerulonephritis with lymphocytic infiltrates consistent with involvement by patient’s known CD5+, CD23+ B cell lymphoproliferative disorder. If showed diffuse C3 staining. Steroids and
plasmapheresis was continued. Renal function improved and dialysis discontinued, with Cr at last follow up 1.9. Chemotherapy for CLL has been ordered. Lymphocytes were negative for CD3, CD10, Bcl6, and cyclin D1; with a MIB1 nuclear proliferation rate within the lymphoid infiltrates less than 5%.

**Discussion:** We present a case of C3GN and DAH secondary to CLL autoimmune etiology, a rare complication of CLL which usually affects the kidney by infiltration and by toxicity of the CLL treatment. Recent case reports suggest improved outcomes of CLL associated C3GN when CLL is treated.

POI1814

Fibrillary Glomerulonephritis or Complement 3 Glomerulopathy: A Rare Case of Crescentic Glomerulonephritis with C3 Dominant Glomerular Deposition and Positive DNAJB9

Lyle W. Baker,1 Mahnoor M. Khan,1 Cherise M. Cortese,2 Nabeel Aslam,3 Mayo Clinic Florida, Department of Nephrology and Hypertension, Jacksonville, FL; Mayo Clinic Florida, Department of Pathology, Jacksonville, FL.

**Introduction:** Fibrillary glomerulonephritis (FGN) and complement 3 glomerulopathy (C3G) are two rare forms of GN. FGN is diagnosed by electron microscopy (EM) showing randomly oriented fibrils ranging in diameter from 15-25 nm. Immunofluorescence (IF) in FGN typically is IgG-predominant. C3G is diagnosed by isolated C3 (>3+ intensity) or dominant C3 (≥2 orders of intensity from other deposits) on IF. We present a rare case of crescentic GN with dominant C3 glomerular staining–consistent with C3G–but EM findings suggestive of FGN.

**Case Description:** A 57-year-old female with history of HTN, type 2 DM, questionable SLE (not on therapy), presented with gross hematuria & lower extremity edema. BP 113/71, pulse 88. Creatinine 1.82mg/dl (0.75 two months prior). Urinalysis with 132RBC/hpf & 51WBC/hpf. Urine Prot Cr 24. Cultures grew mixed flora in urine & Serratia marcescens in blood, treated with ceftriaxone. Other labs included serum albumin 1.8 g/dl, ANA >12.0, SS-A >8.0, C3 202, C4 57, & HbA1c 7.3%. Anti-dsDNA, & Serratia marcescens in blood, treated with ceftriaxone. Other labs included serum albumin 1.8 g/dl, ANA >12.0, SS-A >8.0, C3 202, C4 57, & HbA1c 7.3%. Anti-dsDNA, & Serratia marcescens in blood, treated with ceftriaxone. Other labs included serum albumin 1.8 g/dl, ANA >12.0, SS-A >8.0, C3 202, C4 57, & HbA1c 7.3%. Anti-dsDNA, & Serratia marcescens in blood, treated with ceftriaxone. Other labs included serum albumin 1.8 g/dl, ANA >12.0, SS-A >8.0, C3 202, C4 57, & HbA1c 7.3%. Anti-dsDNA, & Serratia marcescens in blood, treated with ceftriaxone. Other labs included serum albumin 1.8 g/dl, ANA >12.0, SS-A >8.0, C3 202, C4 57, & HbA1c 7.3%. Anti-dsDNA, & Serratia marcescens in blood, treated with ceftriaxone. Other labs included serum albumin 1.8 g/dl, ANA >12.0, SS-A >8.0, C3 202, C4 57, & HbA1c 7.3%. Anti-dsDNA, & Serratia marcescens in blood, treated with ceftriaxone. Other labs included serum albumin 1.8 g/dl, ANA >12.0, SS-A >8.0, C3 202, C4 57, & HbA1c 7.3%. Anti-dsDNA, & Serratia marcescens in blood, treated with ceftriaxone. Other labs included serum albumin 1.8 g/dl, ANA >12.0, SS-A >8.0, C3 202, C4 57, & HbA1c 7.3%. Anti-dsDNA, & Serratia marcescens in blood, treated with ceftriaxone. Other labs included serum albumin 1.8 g/dl, ANA >12.0, SS-A >8.0, C3 202, C4 57, & HbA1c 7.3%. Anti-dsDNA, & Serratia marcescens in blood, treated with ceftriaxone. Other labs included serum albumin 1.8 g/dl, ANA >12.0, SS-A >8.0, C3 202, C4 57, & HbA1c 7.3%. Anti-dsDNA, & Serratia marcescens in blood, treated with ceftriaxone. Other labs included serum albumin 1.8 g/dl, ANA >12.0, SS-A >8.0, C3 202, C4 57, & HbA1c 7.3%. Anti-dsDNA, & Serratia marcescens in blood, treated with ceftriaxone. Other labs included serum albumin 1.8 g/dl, ANA >12.0, SS-A >8.0, C3 202, C4 57, & HbA1c 7.3%.

**Discussion:** It is important to keep ITG in the differential diagnosis as high-dose steroid or cyclophosphamide might prevent rapid glomerulonephritis progression. Treatment of underlying disease such as light-chain deposition disease might have some benefit on renal disease.

POI1815

A Case with Immunotactoid Glomerulonephritis with Masked Monoclonal Light-Chain Deposition Disease

Merve Postalioglu,1,2 Kent Hospital, Warwick, RI; 3Brown University Department of Medicine, Providence, RI.

**Introduction:** The immunotactoid glomerulonephritis (ITG) is a rare disorder that is characterized by proteinuria, hematuria, hypertension, and kidney failure. Its diagnosis and timely treatment are important in order to decrease morbidity, conserve kidney function, and improve survival.

**Case Description:** An 82-year old man with a past medical history of uncontrolled hypertension and cerebrovascular disease presented with myalgia, profound weakness and persistent vomiting for 9 days. In the emergency department, his vital signs were significant for blood pressure 220/109 mmHg, BNP revealed creatinine as 3.48 mg/dl, which was 0.9 mg/dl at baseline. The patient was diagnosed with hypertensive urgency and acute kidney injury. Urinalysis showed 107/10F red blood cells and protein >500 mg/dl. Spot urine albumin/creatinine ratio was 869.9 mg/g. Serum C3 decreased to 29.5 mg/dl (reference: 88-201) and C4 decreased to 2.5 mg/dl (reference: 16-47). Hepatitis B and C were non-reactive. Kidney biopsy was planned and pulse dose steroid, 500 mg IV daily, was prescribed for 3 days. The patient’s kidney function continued to worsen and he required hemodialysis. His serum free kappa level elevated to 4.54 mg/dl (reference 0.33-1.54), lambda level was normal 2.54 mg/dl (reference 0.57-2.63), free kappa/lambda ratio elevated to 1.80 (normal 0.26-1.65). Serum immunofixation study showed Igk/IgG kappa monoclonal ab without M-peak; urine protein electrophoresis showed elevated protein level with no apparent M-peak. Initially, kidney biopsy suggested proliferative glomerulonephritis with C3 deposits with light-microscopy. However, repeat immunofluorescence was consistent with diffuse proliferative immunotactoid glomerulonephritis with “masked” monoclonal IgG1-kappa deposits. Congo red stain was negative, ruling out amyloidosis. The patient was continued on daily high-dose steroid treatment. He was referred to Hematology/Oncology for bone marrow biopsy for concern of plasma cell neoplasm or lymphoproliferative disorder. Dialysis was discontinued at the time of discharge as patient’s kidney function improved with steroid treatment.

**Discussion:** It is important to keep ITG in the differential diagnosis as high-dose steroid or cyclophosphamide might prevent rapid glomerulonephritis progression. Treatment of underlying disease such as light-chain deposition disease might have some benefit on renal disease.

POI1816

Rare Association of Monoclonal Gammopathy of Renal Significance with Acquired Angiodema

Sasmit Ray,1,2 Subhasish Bose,1,2 Lynchburg General Hospital, Lynchburg, VA; Lynchburg Nephrology Physicians, Lynchburg, VA.

**Introduction:** Acquired angiodema (AA) due to deficiency of C1 esterase inhibitor is also abbreviated as C1NH-AAE. This rare syndrome presents with recurrent angioedema episodes, without urticaria, and sometimes is associated with B-cell lymphoproliferative disorders. Kidney involvement is rare with AA. The monoclonal immunoglobulins are secreted by a nonmalignant B-cell or plasma cell clone, causing renal damage representing a group of disorders called monoclonal gammopathy of renal significance (MGRS). We present a rare association of these two entities.

**Case Description:** 64 year old female patient came to the emergency department with complaints of 2 week duration waxing, waning maculopapular rashes in all extremities, chills, hoarseness of voice and lower extremity swelling. She had no family history of angiodema. Positive examination findings were rashes and bilateral pedal edema. With a normal baseline creatinine, admission serum creatinine was high at 2.4 mg/dl. Positive laboratory findings were very low complements level (C4> C3), low C1q level, high C1 esterase inhibitor level. Other immunological workup including serum, urine immunoelectrophoresis, kappa lambda ratio, serum immunofixation were normal. Kidney biopsy undertaken revealed monoclonal gammopathy–associated diffuse proliferative glomerulopathy. She responded well to steroids only and is in clinical remission with normal renal function.

**Discussion:** Paraproteinemia is characterized by clonal proliferation of B-cells and/or plasma cells resulting in overproduction of monoclonal proteins and can cause significant renal dysfunction. Paraprotein-induced renal disease can occur without malignancy, now termed as monoclonal gammopathy of renal significance. MGRS includes a wide spectrum of disorders like light/heavy chain deposition disease, C3 glomerulopathy, proliferative glomerulonephritis with monoclonal immunoglobulin deposition(PGNMID), and primary amyloidosis. MGRS necessitates strict monitoring,
PO1817
Clinical Biomarker Trend in C3 Glomerulopathy
Monica D. Hall,1,2 Christopher Culek,2 Yuzhou Zhang,2 Richard J. Smith,2 Carla M. Nester2 1Molecular Otolaryngology and Renal Research Laboratories, Iowa City, IA; 2University of Iowa, Iowa City, IA.

Background: There is a paucity of data defining the natural history of the clinical and complement biomarker characteristics of C3 Glomerulopathy (C3G). Patients may have different disease presentations and their disease course is highly variable. Whether these characteristics remain stable over time is unknown. In this study we assessed stability in clinical and complement biomarker characteristics of C3G patients over time.

Methods: All C3G patients seen at our institution were included. Demographics, clinical and laboratory data were collected. The patients were followed for a median of 5 years. For each 1-year span of observation, statistics were calculated describing the change in each parameter. We then correlated these changes with baseline values.

Results: Fifty-four patients were included. The median age of patients was 56 years. Thirty-five percent were male. The median initial and endpoint serum C3 levels were 124 mg/dL and 124 mg/dL respectively. The median serum C3 decreased 16 mg/dL over the course of follow-up. The mean and median change in UPCR/creatinine over a 1-year period was a decrease of 9.2% and 10.9%. The mean and median change in GFR per year was a decrease of 6.7% and 8.3%. When considering baseline GFR, baseline UPCR and baseline C3, patients were categorized into three groups: those who had a C3 within 25 mg/dL of their entry C3, those who had a C3 within 10 mg/dL of their entry C3, and those who had a C3 outside of 25 mg/dL and 10 mg/dL of their entry C3. In only three 1-year spans did a patient start with matched C3, UPCR and GFR data were identified. Mean and median statistics across these groups were calculated. These results suggest that treatment approaches that effect an improvement in C3 may have a beneficial effect on GFR.

Conclusions: These data indicate that C3 levels vary little from baseline over a 1-year period and that loss of GFR correlates with baseline C3. These results suggest that loss of GFR most closely correlated with baseline C3 (Figure, p <0.01).

PO1818
A Case Series of Proliferative Glomerulonephritis with Monoclonal Immune Deposits
Deepa A. Koshit, Ramesh Saxena. The University of Texas Southwestern Medical Center, Dallas, TX.

Introduction: Monoclonal gammopathy of renal significance (MGRS) comprises B-cell and plasma-cell clonal proliferative disorders that do not require treatment for the clonal disease but produce nephrotic monoclonal immunoglobulins (mgd) that elicit a variety of kidney manifestations. One such presentation is proliferative glomerulonephritis associated with monoclonal immune deposits (PGNMID), typically presenting as membranoproliferative glomerulonephritis (MPGN) and non-organized glomerular mgd deposits. We describe 3 unique cases of PGNMID from our institution.

Case Description: Case-1: A 16-year old female presented with abdominal pain, gross hematuria, nephrotic proteinuria, edema and normal renal function. Protein electrophoreses and bone marrow (BM) biopsy were unremarkable. Kidney biopsy showed MPGN with monoclonal IgG3 lambda deposits. She had inadequate response to prednisone and rituximab. Kidney biopsy revealed mesangial hypercellularity and monoclonal IgG3 lambda deposits and met criteria for Western light. She had minimal proteinuria and a partial response to rituximab. She is currently being treated with plasma cell targeted therapy with good response.

Discussion: PGNMID is a subset of MGRS with variable histologic pattern and histological features of immune complex glomerulonephritis; however, the immune deposits are monoclonal and are seldom associated with serum-free light chains. Our patient was younger than those reported in literature and had variable histologic patterns. None had M spike or clonal B or plasma cells. The response to treatment was variable. Two patients showed no response to B-cell depleting therapy. One patient did not respond to plasma-cell directed therapy, but the other did. The third patient is currently receiving B-cell depleting therapy.

Urinary Single-Cell RNA Sequencing in Focal Segmentsal Glomerulosclerosis Reveals Inflammatory Signatures in Immune Cells and Podocytes

Khun Zaw Latt,1 Jurgen Heymann,1 Joseph H. Jesse,1 Avi Z. Rosenberg,2 Sean Eddy,3 Teruhiko Yoshida,1 Yongmei Zhao,4 Vicky Chen,4 George W. Nelson,4 Margaret Cam,4 Parimal Kumar,6 Monika Mehta,4 Michael C. Kelly,7 Matthias Kretzler,7 Cheryl A. Winkler,4 Jeffrey B. Kopp,4 1National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; 2Johns Hopkins Medicine School of Medicine, Johns Hopkins University School of Medicine, Baltimore, MD; 3University of Michigan, Ann Arbor, MI; 4Frederick National Laboratory for Cancer Research, Frederick, MD.

Background: Individuals with focal segmental glomerulosclerosis (FSGS) typically undergo kidney biopsy only once, which limits the ability to characterize cell populations within kidney over time.

Results: Using single cell transcriptomic analysis of 23 urine samples from 12 FSGS subjects, we identified immune cells, predominantly monocytes, and renal epithelial cells, including podocytes. Further analysis revealed two subtypes consistent with M1 monocytes (produce pro-inflammatory cytokines, initiate immune response) and M2 monocytes (participate in tissue repair). Shed podocytes in urine showed high expression of marker genes for epithelial-to-mesenchymal transition (EMT). We selected the 16 most highly expressed genes from urine immune cells and 10 most highly expressed EMT genes from urine podocytes as immune and EMT signatures, respectively. Using transcriptomic data from kidney biopsies from the Nephrotic Syndrome Study Network (NEPTUNE), we found that urine cell immune- and EMT-signature genes were more highly expressed in FSGS biopsies compared to minimal change disease biopsies.

Conclusions: The identification of monocyte subsets and podocyte expression signatures in FSGS subjects’ urine samples suggests that urine cell profiling might serve as a diagnostic and prognostic tool in the context of nephrotic syndrome. Further, this approach may aid in the development of novel biomarkers for FSGS and for identifying personalized therapies targeting particular molecular pathways in immune cells and podocytes.

PO1823
Retinal Drusen and Atrophy in Focal and Segmental Glomerulosclerosis: A Complement-Mediated Disease?

Philip A. Harraka,1 Heather G. Mack,2,3 Deb J. Colville,1 David Barin,1 David Langford,4 Timothy J. Pianta,1 Judith A. Savidge,1 1The University of Melbourne Department of Medicine, Northern Health, Melbourne, VIC, Australia; 2The University of Melbourne Department of Ophthalmology (Ophthalmology), Melbourne, VIC, Australia; 3Department of Ophthalmology, Melbourne Health, Melbourne, VIC, Australia.

Background: Retinal drusen are yellow-white deposits typically found in age-related macular degeneration but also with dense deposit disease, lupus nephritis, IgA disease, and membranous and post-streptococcal glomerulonephritis. Drusen and glomerular immune deposits result from complement activation, are similar in composition and share a subepithelial location. Focal and segmental glomerulosclerosis (FSGS) is a heterogeneous clinical-pathological entity in which immune deposits comprising IgM and C3 may be seen. This study investigated a cohort of individuals with FSGS for retinal drusen.

Methods: This was a cross-sectional observational case-control study of individuals with FSGS recruited from a general renal clinic in an Australian tertiary-care metropolitan hospital. Previous structural renal disease in FSGS was noted. Two-field colour fundus images were assessed by two trained graders for drusen count, location and size using the Wisconsin Age-Related Maculopathy Grading Grid. Central drusen counts ≥10 were considered abnormal. Retinal atrophy and pigmentation were recorded by a retinal expert.

Conclusions: The identification of monocyte subsets and podocyte expression signatures in FSGS subjects’ urine samples suggests that urine cell profiling might serve as a diagnostic and prognostic tool in the context of nephrotic syndrome. Further, this approach may aid in the development of novel biomarkers for FSGS and for identifying personalized therapies targeting particular molecular pathways in immune cells and podocytes.

Funding: Government Support - Non-U.S.
Results: Forty-nine individuals with FSGS were compared with 49 matched controls. Mean age was 55 ± 14 years and 29 (59%) were male. One (2%) with FSGS had co-existent structural renal disease, two (4%) had thin basement membrane nephropathy and three (6%) had syndromic FSGS. Twenty-five (51%) had reached end-stage kidney failure, and 16 (33%) had transplants. Central drusen count was 9 ± 25 in FSGS and 3 ± 8 in controls with normal renal function (p = 0.02). Central drusen counts ≥10 were present in nine patients with FSGS (18%) and four controls (8%) (p = 0.23). Seven of these nine (78%) were younger than 60 years which excluded age-related macular degeneration. Medium-sized drusen (>63 μm) were more common in FSGS (20, 41%) than controls (10, 20%) (p = 0.048). Retinal atrophy was present in 9 with FSGS (18%) and no controls (p = 0.003).

Conclusions: Drusen are more abundant and larger in FSGS than controls. Drusen reflect complement activation and their similarities in composition and subepithelial location with glomerular immune deposits suggests that some of the mechanisms underlying drusen are also relevant to FSGS. Retinal atrophy occurs more often in FSGS and may reflect podocyte loss.

PO1824

Idiopathic Glomerular Endotheliosis
Sheikh B. Khalid, J. Charles Jennette, Vimal K. Derebail. University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC.

Introduction: Glomerular endotheliosis is a form of thrombotic microangiopathy (TMA) seen with preeclampsia, anti-vascular endothelial growth factor (VEGF) therapy for cancer, and some forms of Castleman’s disease. We present a case without these usual conditions.

Case Description: A 31-year-old female with rheumatoid arthritis, ulcerative colitis (UC), and hypothyroidism presented with abdominal pain and emesis. Medications included alendalumab and levothyroxine. Abdominal imaging and upper endoscopy were unremarkable. Serum chemistries were initially normal. Pregnancy testing was negative. Abdominal computed tomography showed mild cecal inflammation. Calciprotection was elected. Oral budesonide was given for suspected UC flare. Symptoms worsened and she was given intravenous methylprednisolone. She developed proteinuria (up to 3.5 g/day) by 24h urine and worsening renal function. Serum complement was only mildly reduced - C3 (72) and C4 (10). C-reactive protein and erythrocyte sedimentation rate were elevated. Autoimmune serologies were unremarkable. Serum creatinine peaked at 5 mg/dl prompting hemodialysis. Kidney biopsy demonstrated severe glomerular endotheliosis but no other features of TMA (Figure). Pulse dose steroids were given and then daily prednisone; she had 2 sessions of plasmapheresis (PLEX). Renal function improved, attributed to steroids; and PLEX was held. At 4 weeks, she had only modest proteinuria (1.4 g/24hr) and improved renal function (serum creatinine 0.9 mg/dl).

Discussion: Glomerular endotheliosis is thought to occur due to VEGF inhibition in podocytes (by VEGF-inhibitors or by soluble fns-like tyrosine kinase in preeclampsia). Patients with endotheliosis of unknown cause have been reported to respond to immunosuppression (steroids, cyclophosphamide). Endotheliosis occurs in Castleman’s disease and may improve with IL-6 inhibitors. The etiology in our patient remains unknown but she has demonstrated improvement with corticosteroids.

PO1825

Minimal Change Disease Relapse Following Administration of an Anti-IgE Monoclonal Antibody, Omalizumab
Cliona Cowhig, Vicki K. Sandsy, Sinead Stoneman, Colm Magee. Beaumont Hospital, Dublin, Ireland.

Introduction: Minimal Change Disease (MCD) is incompletely understood with immune cells, circulating factors, and glomerular basement membrane all considered potential precipitants. We present the first reported case of reactivation of MCD following administration of omalizumab.

Case Description: A 59-year-old lady presented with lower limb oedema two days following a second dose of Omalizumab for treatment of severe eosinophilic asthma. Her background was significant for two previous episodes of biopsy-proven MCD. Exam was sta, a blood pressure of 118/86 mmHg, and proteinuria on urine dipstick. Urine PCR was 473 mg/mmol on presentation with preserved GFR. Treatment for a presumed MCD relapse was commenced with prednisolone and diuresis and omalizumab was discontinued indefinitely. Clinical and biochemical remission was achieved and she was followed at 2-weeks and maintained at 6-month follow-up.

Discussion: Omalizumab is indicated as add-on therapy in patients with severe persistent allergic asthma, the primary mechanism of which is the binding of the active drug to IgE. The clinical effects of omalizumab are not accounted for solely by IgE: antagonism with further immune regulatory effects hypothesised. Notably reduction in IL4, IL13, and IL8 have been described post-treatment. Immune system dysregulation, a hypothesized circulating factor, medications, and atopy are all considered to play a role in development of MCD. Studies have supported an imbalance of T-cell subpopulations and cytokines in MCD. Of note, the IL13 and IL4 and IL-13 can interact directly with the glomerular basement membrane and are acted upon by omalizumab. In particular IL13 has been described as being related to a nephritic syndrome in animal studies, and high levels are seen in paediatric nephrotic syndromes, with IL-13 levels increasing following corticosteroid administration. This is the first reported case of MCD in the context of omalizumab administration. IL13 and IL4 appear key to the hypothesised pathophysiology of MCD and mechanism of action of omalizumab. This case provides an insight into the interactions between MCD, atopy, and biologic medications, presenting MCD as a novel complication of omalizumab.

PO1826

Neurorenal Syndrome: Two Cases of Tip-Variant Focal Segmental Glomerulosclerosis Associated with Guillain-Barré Syndrome
Drew Hagge, James M. Ziegler, Jan W. Collier, Laura Hungwala. University of Manitoba College of Medicine, Winnipeg, MB, Canada.

Introduction: Glomerular disorders have been associated with immune-mediated polyneuropathies in previous case reports. We present two cases of tip-variant focal segmental glomerulosclerosis (FSGS) associated with a variant of Guillain-Barré syndrome (GBS) in Winnipeg, Manitoba.

Case Description: Two previously healthy males aged 62- and 55-years old presented to our hospital with extremity weakness and paresthesias. They each progressed to flaccid paralysis and respiratory failure despite IV immunoglobulin (IVIG) and plasma exchange therapy (PLEX). Initial investigations were consistent with Acute Motor-Sensory Axonal Polyneuropathy (AMSAN), a variant of GBS. Nephrotic syndrome was identified after four months in case one and immediately in case two. Both cases had 20 g/day of proteinuria, preserved renal function, and histologic diagnostic of tip-variant FSGS on renal biopsy. Both cases responded to high-dose corticosteroids initially. Case one relapsed during his taper requiring re-initiation of steroids and addition of mycophenolate mofetil (MMF). He was discharged following thirteen months in hospital with complete remission of proteinuria and ongoing neurologic recovery. Case two achieved complete remission of proteinuria and was discharged after six months with ongoing neurologic recovery.

Discussion: Our cases have similar presentations and responses to therapy suggesting they may share a common circulating autoantibody reacting against shared neural and glomerular podocyte antigens. Circulating autoantibodies including anti-contactin-1 and neurofascin have previously been implicated in chronic inflammatory demyelinating polyneuropathy (CIDP), a chronic variant of GBS. Identifying the culprit immune target in primary FSGS is limited due to the absence of immune complex deposition. The timing of podocytopathy development compared to GBS is highly variable in cases reported throughout the literature. The onset and diagnosis of FSGS in Case 1 was either delayed or unrecognized illustrating the importance of educating clinicians about this neuro-renal syndrome. Although not routinely used in GBS, corticosteroids have led to favorable outcomes in our cases and those reported throughout the literature. Recognition of a co-existing nephritic syndrome with GBS could significantly change management and impact treatment outcomes.

PO1827

Hemophagocytic Lymphohistiocytosis Presenting as Nephrotic Syndrome

Introduction: Minimal change disease (MCD) is a podocytopathy resulting from systemic T cell dysfunction. Although frequently a primary disease, MCD can be secondary to immune dysregulation in malignancy or autoimmune disease. Hemophagocytic
Glomerular Tip Lesion of FSGS

Case Description:
A 55 year old man with a history of HTN, ex-smoker, and bladder cancer in 2014, presented with leg edema and raised creatinine. His bladder cancer was treated with cystoprostatectomy. Chemotherapy included methotrexate, vinblastine, doxorubicin, and cisplatin (2015), pembrolizumab and epacadostat (7/2016-5/2018) and pembrolizumab and atezolizumab (6/2018-12/2018). Pembrolizumab was given again Dec 2018-July 2019. On physical examination he had 3+ edema up to his knees. Labs showed creatinine 1.4 mg/dl (baseline 1.0 mg/dl). Urinalysis showed proteinuria without hematuria. Protein excretion was 19.5 g/day. Kidney biopsy showed 8 out of 24 glomeruli were globally sclerotic. Of the remaining 16 glomeruli, 4 displayed cellular lesions of FSGS and one glomerular tip lesion (GTL). There was GBM duplication and focal endothelial swelling, suggestive of mild endothelial injury (i.e. thrombotic microangiopathy).

Discussion: Glomerular tip lesion (GTL) is a prognostically favorable variant of FSGS with presenting features intermediate between FSGS and MCD. There are reports of MCD with pembrolizumab but no reports of GTL. Given the clinical presentation and similarities between MCD and GTL, it is likely that pembrolizumab contributed to the development of GTL in this case. His FSGS was treated with steroids and pembrolizumab was withheld. His proteinuria started to improve and renal function stabilized.

PO1829
Collapsing Glomerulopathy in Mixed Connective Tissue Disease: Case Report

Mohammad Ata,
Josephine M. Ambrus,
Talal Nakkar,
Mohammad Sharshir,
Osaid Saqqa,
Erik E. Simon.
Tulane University School of Medicine, New Orleans, LA; arkana laboratory, Little Rock, AR.

Introduction: Collapsing glomerulopathy (CG) is a form of podocytopathy with segmental or global wrinkling and collapse of capillary walls and overlying epithelial cell proliferation but may be distinct from other forms of focal and segmental glomerular sclerosis (FSGS). CG may be idiopathic or associated with infections, autoimmune diseases, malignancies, genetic diseases, certain drugs and in post-transplant setting. Although CG has been reported in lupus nephritis, it was rarely reported in the setting of mixed connective tissue disease (MCTD).

Case Description: A 30 y/o African American male with a history of muscle aches, nontraumatic rhabdomyolysis, evanescent skin rashes and weight loss was found to have a creatinine of 5.1 mg/dl (1.4 I year earlier) with urine protein/creatinine ratio (upCR) of 10,136 mg/g. CPK was 1697 U. erythrocytes sedimentation rate > 120, a positive speckled ANA of 1:640, positive anti-SAA 5.9, anti-chromatin >8, anti-sm RNP >8, -anti-RNP >8. Kidney biopsy showed mesangial immune complex deposition, collapsing glomerulopathy and diffuse podocytopathy, immunofluorescence showed global mesangial IgG staining (3+), IgM (1+), C3 (2+), and kappa (2+) and lambda (3+) light chains. Electron microscopy revealed several mesangial electron-dense deposits with mild increase in mesangial matrix and hypercellularity and severe epithelial foot processes effacement without glomerular or tubular basement membrane deposits. Muscle biopsy confirmed the diagnosis of dermatomyositis. The patient was treated with pulse methylprednisolone 1 gm IV for three days followed by prolonged prednisone taper. Later, MMF was started at 500 mg bid, lisinopril 40 mg daily, hydroxychloroquine 200 mg bid and bunetamide 2 mg bid. By 4 months creatinine had stabilized at 2.6 mg/dl, upCR was 1,824 mg/g, and CPK was 55 U.

Discussion: Here we describe a case of collapsing glomerulopathy in the setting of MCTD (SLE and dermatomyositis), with at least partial response to high dose prednisone for 16 weeks, hydroxychloroquine and late initiation of MMF. CG can present in association with autoimmune diseases including but not limited to SLE. This case represents the second such as this case of CG in the setting of MCTD and is notable for its response to immunosuppressive therapy.

PO1830
A Case of AKI with Nephrotic Syndrome After Intraperitoneal Infection With Methicillin-Sensitive Staphylococcus aureus (MSSA)

Issi Okunaga, Shinishi Makino, Masashi AIzawa, Katsuhiko Asanuma. Chiba Daigaku Daigakuin Igaku Kenkyuin Igakubu, Chiba, Japan.

Introduction: Postinfectious glomerulonephritis (PIGN) causes acute nephritic syndrome complicated with uric acid protein and hematuria after infection but rarely leads to nephrotic syndrome. The effectiveness of steroid for PIGN has been reported, but still controversial. We report a case of refractory nephrotic syndrome caused by PIGN treated with steroid.

Case Description: A 78-year-old man presenting with nausea and dizziness was admitted. He had pancreatocystic for intraductal papillary mucinous tumor two months before. He was diagnosed as postoperative pancreatic fistula with intraperitoneal infection caused by MSSA. During treatment for the infection, he presented acute kidney injury with nephrotic range proteinuria and hematuria, and required hemodialysis. Renal biopsy revealed diffuse endocapillary proliferative glomerulonephritis with cellular crescents. He was diagnosed as nephrotic syndrome caused by PIGN after intraperitoneal infection with MSSA. Since renal failure was persistent despite infection resolution, he started steroid treatment, lead to improve kidney injury.

Discussion: Antibacterial treatment is important for treatment of PIGN, but if the improvement is still poor, steroid treatment may be effective.

Mitochondrial Injury May Be a Ubiquitous Finding in the Pathogenesis of Various Glomerulonephritides

Byung chul Yu, Moo Yong Park, Soo Jeong Choi, Jin kuk Kim, Seung D. Hwang, Division of Nephrology, Department of Internal Medicine, Soonchunhyang University Bucheon Hospital, Bucheon, Gyeonggi-do, Republic of Korea.

Background: Previous study showed that mitochondrial injury is associated with IgA nephropathy (IgAN). It is not clear whether mitochondrial injury is a unique finding in IgAN or a ubiquitous finding in various glomerulonephritides (GN). To clarify this, we analyzed urinary mitochondrial DNA (mtDNA) levels and expression of the stimulator of interferon genes (STING) pathway activated by mtDNA leakage in various GN.

Methods: We prospectively enrolled age-sex matched healthy volunteers (HV) and biopsy-proven IgAN patients, minimal change disease (MCD), acute tubulointerstitial nephritis (ATIN), and focal glomerular abnormalities (MGA) (n=30, 8, 10, and 7 each, respectively). Urinary copy number of the mtDNA genes cytochrome-c oxidase-3 (COX3) and nicotinamide adenine dinucleotide dehydrogenase subunit-1 (ND1) were measured by quantitative polymerase chain reaction. We analyzed STING expression in prostatic carcinoma specimen as control and kidney tissues obtained from each GN patients by immunohistochemistry staining.

Results: log_COX3/mtDNA and log_ND1/mtDNA were significantly higher in IgAN (p<0.001, p=0.002), MCD (p<0.001, both), ATIN (p<0.001, both), and MGA (p<0.001, both) compared with HV (Figure 1). Urinary copy number of the mtDNA genes cytochrome-c oxidase-3 (COX3) and nicotinamide adenine dinucleotide dehydrogenase subunit-1 (ND1) were measured by quantitative polymerase chain reaction. We analyzed STING expression in prostatic carcinoma specimen as control and kidney tissues obtained from each GN patients by immunohistochemistry staining.

Conclusions: Elevated urinary mtDNA copy numbers and STING activation were observed in various GN. These results suggest that mitochondrial injury would be a ubiquitous finding in the pathogenesis of various GN.

Single-Cell Transcriptomic Profiling Reveals Aberrant Signaling Responses to Tfh Cytokines in IgA-Secreting Cells from IgA Nephropathy Patients

Colin Reily,1 Shigeki Nakazawa,2 Masakazu Kamata,2 David K. Crossman,1 Dana Rizk,1 Bruce A. Julian,1 Jan Novak. 1University of Alabama at Birmingham, Departments of Medicine, Microbiology and Genetics, Birmingham, AL; 2Osaka University Graduate School of Medicine, Department of Urology, Osaka, Japan.

Background: IgA nephropathy (IgAN), a common primary glomerulonephritis, is characterized by glomerular IgA1 immunodeposition enriched for galactose-deficient IgA1 (Gd-IgA1). These immunodepositions are likely derived from Gd-IgA1-containing immune complexes that are elevated in the circulation of IgAN patients. Gd-IgA1 is produced by IgA1-secreting cells due to abnormal expression of several glycosyltransferases in IgAN. Furthermore, some cytokines can enhance production of Gd-IgA1 by IgA1-secreting cells from IgAN patients but not those from healthy controls. We hypothesize that pro-inflammatory factors, such as those identified by GWAS or produced during episodes of synpharyngitic hematuria in IgAN patients, may further dysregulate IgA1-secreting cells and lead to enhanced Gd-IgA1 production.

Methods: As an experimental model, we used T-follicular helper (Tfh) cell-derived cytokines (IL-4, IL-6, IL-21, CD40L) to stimulate for 30 min immortalized Ig-producing cells derived from peripheral blood of IgAN patients and healthy controls. Then, single-cell transcriptomic analysis was performed. IgA1 splice variants were integrated into the hg38 reference genome to identify IgA1-secreting cells and the data analyzed using Seurat and Altairx workflow. siRNA knock-down (k/d) was used to confirm involvement of candidate regulatory elements in cytokine-mediated overproduction of Gd-IgA1.

Results: Single-cell transcriptomics identified discrete populations of IgA1-secreting cells with differential C1GALT expression after Tfh cytokine stimulation. Furthermore, these subpopulations exhibited reduced expression of cytokine-signaling regulatory elements, SOCS3, SOCS1, PTEN2, and PTEN (p = 0.07, 0.04, 0.02, 0.07), indicating dysregulation of cytokine-signaling JAK/STAT pathways in IgAN-derived cells. Involvement of SOCS3 in Gd-IgA1 production was further supported by the observation that SOCS3 siRNA k/d increased Gd-IgA1 production in healthy-control cells (p = 0.01).

Conclusions: Single-cell transcriptomics with stratification of IgA1-secreting cells based on C1GALT expression and siRNA k/d experiments revealed that aberrant regulation of Tfh cytokine signaling was associated with enhanced Gd-IgA1 production in IgAN.

The NefIgArd trial: The Effect of Nefecon® (Budesonide) in Patients with Primary IgA Nephropathy at Risk of Developing ESRD

Jonathan Barratt,1 Jens Kristensen,2 Andrew M. Stone. 1Mayer IgA Nephropathy Laboratory, University of Leicester, UK, Leicester, United Kingdom; 2Calliditas Therapeutics AB, Stockholm, Sweden.

Background: The gut-associated lymphoid tissue (GALT) has been identified as the potential source of poorly O-galactosylated immunoglobulin A (IgA1) that triggers the formation of nephritogenic immune complexes in IgA nephropathy (IgAN). The NEFIgArd trial (NCT01738035), which assessed the safety and efficacy of a novel targeted-release formulation of budesonide (NEFECON®), highlighted the potential of selectively targeting GALT in patients with IgAN. After 9 months’ treatment, urine protein-creatinine ratio (UPCR) was reduced by 29.3% in the NEFECON® 16 mg/day group vs placebo. Estimated glomerular filtration rate (eGFR) decreased by 4.7 ml/min/1.73 m2 in the placebo group, but with no deterioration seen with NEFECON® 16 mg/day. The incidence of patient-reported adverse events was similar in all groups. Based on these data, the phase 3 NefIgArd study was designed to assess the efficacy and safety of NEFECON® 16 mg/day in patients with IgAN at risk of end-stage renal disease.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

571
Methods: NeffGard is a randomized, double-blind, placebo-controlled trial with two parts, recruiting a total of 360 patients across 150 nephrology clinics in 20 countries. Patients must be aged ≥18 years with biopsy-confirmed primary IgAN, proteinuria >1 g/24 h and eGFR 35–90 mL/min/1.73 m² (CKD-EPI) despite optimized renin–angiotensin system blockade. Part A of the study, comprising the first 200 dosed patients, will form the basis for submission for accelerated/conditional regulatory approval to the FDA and EMA. The primary outcome will assess the effect of NEFFCON® 16 mg/day on UPCR at 9 months vs placebo, consistent with the 2019 Kidney Health Initiative White Paper “Proteinuria Reduction as a Surrogate End Point in Trials of IgA Nephropathy”. Part B is a post-approval confirmatory trial to validate the surrogacy of the Part A UPCR endpoint. For this purpose, and based on the 2018 NKF/FDA/EMA workshop supporting eGFR slope as an endpoint for full approval, the primary outcome will assess the effect of NEFFCON® on a 2-year eGFR-based endpoint vs placebo.

Results: In 2019 the 200 patients needed for Part A were randomized, with top-line data expected in Q4 2020.

Conclusions: Randomization will continue until 360 patients are reached for Part B, which is expected to report in 2022.

PO1834
Effect of Hydroxychloroquine in Patients with IgA Nephropathy with Insufficient Responses to Immunosuppressive Therapy: A Retrospective Case-Control Study
Chen Tang,1 Jicheng Lv,2 Sufang Shi, Yuqiong Chen, Lijun Liu, Hong Zhang. Peking University First Hospital, Beijing, China.

Background: Hydroxychloroquine, a well-known immunomodulator, has recently been used in IgA nephropathy (IgAN) due to its antiproteinuric effects. We aimed to verify the effect of HCQ in patients with IgAN whose proteinuria remained above 1 g/d after conventional immunosuppressive (IS) therapy.

Methods: This was a retrospective case-control study. Twenty-six patients with IgAN who received HCQ and had insufficient responses to IS therapy (corticosteroid (CS) therapy with/without IS agents) were included. 26 matched historical controls who received conventional IS therapy were selected by propensity score matching. The clinical data from 6 months were compared

Results: Proteinuria at baseline was comparable between the “IS therapy plus HCQ” and “conventional IS therapy” groups (2.35 [interquartile range (IQR), 1.47, 2.98] vs. 2.35 [IQR, 1.54, 2.98] g/d, p=0.902). There was a significant reduction in proteinuria in patients with IgAN with HCQ treatment (2.35 [IQR, 1.47, 2.98] vs. 1.10 [IQR, 0.85, 1.61] g/d, p=0.002). The percent reduction in proteinuria in 6 months was similar between the two groups (-39.81% [-66.26, -12.37] vs. -31.99% [-67.08, -9.14], p = 0.968). The cumulative frequency of patients with a 50% reduction in proteinuria during the study was also comparable between the two groups (53.8% vs. 57.7%, p=0.780). No serious adverse events were observed during the study.

Conclusions: HCQ could further reduce proteinuria in patients with IgAN who had insufficient responses to conventional IS therapy

PO1835
IgA Nephropathy Study: A Multicentric Study in Portugal
Sofia Santos,1 Jorge Malheiro,1 Ana Marta Gomes,2 Grupo de Estudo da Nefropatia de IgA e Nefropatia Membranosa em Portugal (ENIGAM), Sociedade Portuguesa de Nefrologia, Portugal ‘Centro Hospitalar Universitario do Porto EPE, Porto, Portugal; 1Centro Hospitalar de Gaia / Espinho, Gaia, Portugal.

Background: In the last decade, an attempt to correlate the histopathological lesions with renal prognosis in IgA Nephropathy (IgAN) was developed in order to identify patients that benefit from IS therapy.

Methods: A multicentric, longitudinal and retrospective (2007-2019) study was developed in Portugal: adult patients with histological diagnosis of IgAN. Biopsy date defined study entrance and data was collected.

Results: 167 patients were analyzed. The coorte was divided in 2, according the use of steroid therapy: 105 in group with no steroids (noCST) and 62 in the group with steroids (wCST). Endocapillary hypercellularity (29% vs 16%, p=0.049) and crescents (34% vs 10%, p=0.001), were significantly more frequent in wCST group. Median time until the beginning of steroids was 55 days (IQR 7-251), and median duration was 195 days (IQR 96-239). Follow up time was 39 months (IQR 15.1-65.8), significantly superior in wCST group (56.5 vs 29.8 months, p=0.004). No difference between groups concerning infections, AKI, CV disease or death. Renal survival at 7 years was 70% in noCST group and 85% at wCST group, p=0.184. Multivariable analysis identified HT (OR 3.81), proteinuria (OR 2.80) and crescents (OR 2.72) as significant factors associated with steroids use. Table 1 defines the independent predictors for ESRD (Cox regression analysis). When we analyze the steroids effect on renal survival, we saw that the average time until renal replacement therapy (RRT) was 47.7 months (IQR 34.6-60.7) in noCST group and 81.6 months (IQR 63.8-99.3) in wCST group. The average treatment effect with steroids was 33.9 months (11.9-55.9, p=0.002), that means that if we treat all, this was the time that we could delay beginning of RRT.

Conclusions: In this group of patients, use of steroids was an independent predictor for delaying CKD progression and the beginning of RRT. HT, degree of proteinuria and crescents presence were significant predictors for its use. In spite of the controversy about the use of steroids therapy in IgAN, this study showed their effectiveness without risk increase.
therapy was reversed by presence of crescent (no crescent: HR 1.75 95% confidence interval [CI] 1.07–2.84, presence of crescent: HR 0.26 95%CI 0.11–0.61), in finding the interaction between corticosteroid therapy and presence of crescent (p<0.001). Tonsillectomy had also a favorable effect on renal survival (HR 0.43 95%CI 0.20–0.91). *Conclusions:* Present findings revealed that corticosteroid therapy improved renal survival in Japanese IgAN patients with crescent and are thus suggestive for the indication of this therapy.

**Vitamin D Deficiency and Outcome of IgA Nephropathy in North Indian Patients**

Naba Farooqui, Soumi Bagchi, Arunkumar Subbiah, Pradeep Chaturvedi, Hem Satl, Dipankar M. Bhowmik, Sanjay K. Agarwal. All India Institute of Medical Sciences, New Delhi, India

**Background:** Vitamin D has been shown to be beneficial in reducing proteinuria in patients with chronic kidney disease (CKD). IgA Nephropathy (IgAN) is one of the leading causes of CKD in India and worldwide. Asians, especially Indians develop more severe IgAN. We conducted this study to evaluate 25-hydroxy vitamin D (25(OH)D) level as a prognostic marker for disease progression and outcomes in a cohort of Indian patients with IgAN.

**Methods:** In this retrospective cohort study, demographic and clinical data of Indian adult patients with biopsy proven IgAN, diagnosed between 2015 and 2019, was obtained. Patients with a minimum follow-up of 6 months were included for analysis. A 25(OH)-vitamin D assay was performed on serum samples collected at the time of kidney biopsy. 25(OH)D levels <10 ng/mL were considered as deficient.

**Results:** Of the 105 patients included in the study, 69.5% were males. The mean age was 34.0+10.6 yrs. The mean baseline creatinine and 24 hr proteinuria was 1.37+0.51mg/dl and 3.12±2.45 g/day, respectively. The mean baseline vitamin D levels were 15.88±11.85 ng/mL. 39% patients were 25(OH)D deficient. The median duration of follow up was 23.5 months (range: 6–56 mon). Eleven patients (10.5%) progressed to end stage renal disease (ESRD) during follow-up. Vitamin D deficiency was not significantly associated with progression to ESRD (p=0.61) or proteinuria remission (0.83). Risk for ESRD was reduced in patients with lower baseline creatinine levels (p=0.00) and patients on ACE inhibitors (p=0.03). Remission of proteinuria was more common in patients with lower baseline protein levels (p=0.006) and normotenstive patients (p=0.03). Baseline creatinine (HR = 14.49; 95% CI, 1.02 – 202.15), 24 hr proteinuria (HR = 0.93; 95% CI, 0.00-0.85) and disease remission (HR = 0.01; 95% CI, 0.00-0.32) were predictors of risk for ESRD.

**Conclusions:** Vitamin D deficiency is common in Indian patients with IgAN. Baseline vitamin D deficiency did not affect outcomes of IgAN.

**Long-term Beneficial Effects of Tonsillectomy on Patients with Immunoglobulin G A Nephropathy**

Takahito Moriyama, Kazunori Karasawa, Yoei Miyabe, Kenichi Akiyama, Norio Hanafusa, Kosaku Nitta. Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan

**Background:** Tonsillectomy may treat immunoglobulin (Ig) A nephropathy (IgAN) by reducing the levels of galactose-deficient IgA1. Hence, we aimed to analyze the long-term effects of tonsillectomy as an initial treatment and a treatment at any time in their lives on patients with IgA Nephropathy (IgAN).

**Methods:** In this retrospective cohort analysis, 1147 patients with IgAN were grouped according to whether or not they had undergone tonsillectomy at any time in their lives (Study 1) or within 1 year after renal biopsy (Study 2). The patients who underwent tonsillectomy (T1) and who did not undergo tonsillectomy (T0) were propensity score grouped according to whether or not they had undergone tonsillectomy at any time in their lives.

**Results:** In both studies, the groups' clinical data, histological data according to Oxford classification, and treatments such as immunosuppressants and inhibitors of renin-angiotensin systems were similar after propensity score matching (Study 1, n=179/each group; Study 2, n=143/each group (T1 vs. T0); median eGFR: 81.0 vs. 81.5 mL/min/1.73m², p=0.48). In Study 1, the renal survival rates at the primary and secondary endpoints were 50% reduction in estimated glomerular filtration rate or ESKD (8.4%) other ethnicity. Complete case analysis was done with 93 patients. The 5-year risk of the primary outcome at 5 years post-biopsy was 15.0%. Oxford T2 histologic score was removed from the full model analysis as the R² for the full models with and without race when applied to our patient dataset over 11 years (Jul 2009 to Oct 2020) using external validation of survival model. The study included 119 patients; mean age of 43.3 (± 16.66) years; 62 (52.1%) were male; 90 (75.6%) Chinese, 12 (10.1%) Malay, 7 (5.9%) Indian and 10 (8.4%) other ethnicity. Complete case analysis was done with 93 patients. The 5-year risk of the primary outcome (50% reduction in estimated glomerular filtration rate or ESKD) was 15.0%. The Oxford T2 histologic score was removed from the full model analysis as the number of observations is low (n=2). The original study reported AIC of 6338 for full model with race, 6379 for full model without race, vs 107.35, and 111.90 respectively in our study. The R² for the full models with and without race when applied to our validation cohort were 39% and 32% respectively, both were similar or better than the R² for the same models applied to the original derivation and validation cohorts (26.3%, 25.3%, and 35.3%, respectively). The C statistics for the full model with race was 0.858 (95% CI, 0.687-1.000), without race was 0.811 (95% CI, 0.399-1.000), comparable to the C statistics from the original derivation and validation analysis. Both full models were well-fitted in our cohort, with high agreement between predicted and observed risk of the primary outcome at 5 years post-biopsy.

**Conclusions:** The 2 full models with or without race were shown to be validated in our multi-ethnic Singapore IgAN cohort for predicting disease progression.

Associations of Genetic Variants Contributing to Gut Microbiota Composition in IgAN

**Jiawei He, Xujie Zhou, Yanna Wang, Lijun Liu, Sufang Shi, Jicheng Lv, Hong Zhang, Peking University First Hospital, Beijing, China.**

**Background:** Gut microbiota is observed to be associated with IgAN, as immune response in the gut is assumed to be one of the triggers of its development. And because the microbial composition is heritable, we hypothesize that genetic variants controlling gut microbiota composition may associate with susceptibility to IgAN or clinical phenotypes.

**Methods:** 175 gut-microbiome-associated genetic variants were retrieved from GWAS Catalog. Genetic associations were examined in 1511 patients with IgAN and 4469 controls. Sub-phenotype associations and microbiome annotations were undertaken for better understanding how genes shaped phenotypes. Likely candidate microbes suggested in genetic associations were validated using 16S rDNA sequencing in 29 patients with IgAN and 20 controls.

**Results:** Nine genetic variants associated with susceptibility to IgAN (P values from 4.1×10⁻² to 1.39×10⁻⁴). The rs1889714-AA/AG risk genotypes associated with higher serum levels of Gd-IgA1 (A). Other significant findings included the associations between rs14830122-CC risk genotype and early age of onset (B), rs6065904-AA/AG risk genotypes and worse kidney function (C), rs9363741-GG/GA risk genotypes and severer hematuria (D). Besides, rs1889714-AA/AG risk genotypes associated with decreased abundance of beneficial Dialister; whereas rs6065904-AA/AG and rs9363741-GG/GA risk genotypes associated with increased abundance of detrimental Erysipelotrichaceae and Lachnospiraceae, respectively. 16S rDNA sequencing data validated the decreased Dialister (E), and a tendency of increased Erysipelotrichaceae and Lachnospiraceae abundance in faeces from IgAN (F/G).

**Conclusions:** Our results provided supporting evidence that gut microbiota in IgAN was affected by host genetics and shed light on candidate bacteria for future pathogenesis studies.

IgA Nephropathy: Quantifying Remission Duration on Clinical Outcome

**Hong Zhihong, Peking University First Hospital, Beijing, China.**

**Background:** Quantitative assessment of remission duration is required for understanding the risk of disease progression in IgAN.

**Methods:** In this retrospective international cohort of adult patients with biopsy-proven IgAN, we defined remission based on: (i) a ≥25% reduction in proteinuria from the peak value after biopsy; (ii) an absolute reduction in proteinuria to <1g/day; (iii) peak proteinuria prior to remission ≥1g/day. The total duration of first remission was treated as a time-varying exposure using longitudinal proteinuria measurements. Time-dependent Cox proportional hazards models were used to quantify the association between duration of remission and the primary outcome (ESKD or 50% reduction in eGFR).

**Results:** Of 1864 patients who entered a first remission, 274 (14.7%) experienced the outcome during median follow-up of 3.9 years. The relationship between duration of proteinuria remission and the primary outcome was non-linear (Figure). Each 3 months in sustained remission up to 51 months was associated with an additional 9% reduction in the risk of disease progression (HR 0.91, 95% CI 0.89-0.93). Each additional 3 months in remission beyond 51 months was associated with a non-significant risk reduction (HR 0.99, 95% CI 0.96-1.03). Results were robust to multivariable adjustment and consistent across subgroups including immunosuppression exposure.

**Conclusions:** We observed a non-linear dose-response relationship between the duration of proteinuria remission and the risk of disease progression in IgAN. When considering proteinuria as a surrogate outcome, our findings illustrate the need to consider the duration of remission in addition to the magnitude of proteinuria reduction when evaluating the anticipated impact on long-term clinical endpoints.

Results of a Phase 1 Trial to Investigate the Safety, Tolerability, Pharmacokinetics, and Pharmacodynamics of BION-1301 in Healthy Volunteers

**Jeanette Lo,1 Sharon Yavrom,1 Jessy Fan,1 Aaron N. Endsley,2 Tamara Schroeder,2 Jonathan Barratt,2 David M. Essuyan.3 Aduro BioTech Inc, Berkeley, CA; 1Certiara LP, Princeton, NJ; 2ONCORD, Inc., Westlake Village, CA; 3University of Leicester, Leicester, United Kingdom.**

**Background:** IgA nephropathy (IgAN) is an autoimmune disease with no approved treatments. Key steps in IgAN pathogenesis are the production of galactose-deficient IgA1 (Gd-IgA1), the generation of anti-Gd-IgA1 autoantibodies and the formation of immune complexes resulting in kidney inflammation and damage. Patients with IgAN have elevated levels of a proliferation-inducing ligand (APRIL) which regulates B cell differentiation and proliferation. In a study of patients with IgAN, those with high plasma APRIL levels had elevated levels of Gd-IgA1 and proteinuria and lower eGFR. BION-1301, a first-in-class humanized anti-APRIL antibody, was well-tolerated with no dose-limiting toxicities in a Phase 1/2 first-in-human study in multiple myeloma. This 3-part Phase 1 trial characterizes the safety, pharmacokinetics (PK), and pharmacodynamics (PD) of BION-1301 in healthy volunteers (HV) and patients with IgAN.

**Methods:** (NCT03945318) Parts 1 and 2 are double-blind, randomized, placebo-controlled single and multiple ascending dose studies, respectively. Part 1 enrolled 36 HV in 5 dose cohorts, randomized in a 3:1 ratio to receive a single dose of BION-1301 or placebo delivered by IV infusion. Part 2 enrolled 27 HV in 3 dose cohorts, randomized in a 2:1 ratio to receive 3 doses of BION-1301 or placebo delivered by IV infusion every two weeks. Part 3 assesses a multiple dose regimen in patients with IgAN and is currently enrolling.

**Results:** BION-1301 was well-tolerated with low incidence of non-neutralizing ADAs in HVs. The PK profile was well behaved with a half-life supporting monthly dosing. Durable target engagement, suppression of IgA and IgM, and to a lesser extent IgG were observed following BION-1301 administration. IgG values remained in normal ranges with no increase of infections post-treatment. Updated data will be presented including B cell immunophenotyping of HVs and results from patients with IgAN, if available.

**Conclusions:** BION-1301, an anti-APRIL antibody, offers a pharmacodynamic window to exploit IgA suppression while tempering impact to IgG. BION-1301 may provide a novel approach to address the pathophysiology of IgAN.

Clinical Significance of Intensity of Galactose-Deficient IgA Deposition in Patients with IgA Nephropathy
Maiko Nakayama,1 Hitoshi Suzuki,2 Yusuke Fukao,1 Mingfeng Lee,1 Toshihiko Kano,1 Yoko Makita,1 Yusuke Suzuki,2 1Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; 2Department of Nephrology, Juntendo University Urayasu Hospital, Chiba, Japan.

Background: Galactose-deficient IgA (Gd-IgA) has a crucial role in the pathogenesis of IgA nephropathy (IgAN). It was reported that Gd-IgA1 specifically deposit on glomeruli of primary IgAN using Gd-IgA1-specific monoclonal antibody (KM55 mAb). However, the association between intensity of Gd-IgA1 deposition and histological severity and clinical parameters are not clear.

Methods: We performed immunostaining with anti-IgA and KM55 mAbs in 74 patients who were diagnosed as IgAN at Juntendo University Hospital. We quantified the intensity of glomerular Gd-IgA1 by Image J software, and analyzed its association with histological findings. We also analyzed the association of intensity of glomerular Gd-IgA1 with serum levels of Gd-IgA1 and creatinine, urinary Gd-IgA1 and proteinuria.

Results: Glomerular Gd-IgA1 was positive in all 74 primary IgAN cases, we divided into high-intensity (n=45) and low-intensity groups (n=29) by Image J software. In the Gd-IgA1 high-intensity group, acute lesions such as cellular crescents are dominant compared with low-intensity group (P<0.01). Moreover, the levels of proteinuria and urinary Gd-IgA1 were significantly high compared with Gd-IgA1 low-intensity group (P<0.05). Next, we analyzed the pathogenic significance of merge ratio of glomerular IgA and Gd-IgA1. Interestingly, levels of proteinuria and urinary Gd-IgA1 were correlated with high merge ratio of glomerular IgA and Gd-IgA1.

Conclusions: Present study suggested that high intensity of glomerular Gd-IgA1 deposition is associated with histological severity, especially acute lesions. Moreover, levels of proteinuria were correlated with high merge ratio of glomerular IgA and Gd-IgA1. Thus, glomerular Gd-IgA1 staining may be considerable index for therapeutic intervention.

Glomerular Galactose-Deficient IgA, Expression Analysis in Pediatric Patients with Glomerular Diseases
Shinya Ishihara,1 Kandai Nozu,1 Rika Fujimaru,1 Yoko Shima,2 Hiroshi Kaito,3 Ryojiro Tanaka,4 Shingo Ishimori,5 Yuya Aoto,1 Nana Sakakibara,1 China Nagano,1 Tomoko Horinouchi,1 Tomohiko Yamamura,1 Takeshi Ninchoji,1 Koichi Nakanishi,3 Norishige Yoshikawa,4 Kazumoto Bijima,5 1Kobe University Graduate School of Medicine, Kobe, Japan; 2Wakayama Medical University, Wakayama, Japan; 3University of Rikkyu, Nishikawara, Japan; 4Takatsuki General Hospital, Takatsuki, Japan; 5Osaka City General Hospital, Osaka, Japan; 1Hyogo Prefectural Kobe Children’s Hospital, Kobe, Japan.

Background: Galactose-deficient IgA (Gd-IgA1) has been identified as a key molecule in the pathogenesis of IgA nephropathy (IgAN). Using a Gd-IgA1-specific monoclonal antibody (KM55), glomerular Gd-IgA1 deposition has been detected in patients with IgAN and IgA vasculitis with nephritis (IgAV-N), but not other glomerular diseases. However, this specificity is controversial and there are currently no studies in pediatric cases.

Methods: We conducted a retrospective, multicenter study to examine double-immunofluorescence staining of IgG and Gd-IgA1 (KM55) in 60 pediatric patients with various glomerular diseases.
