Abstract Publication
More than 3,000 abstracts are published in this supplement. Abstracts are arranged by the abstract type**, then by presentation date* for orals, and then by chronological publication number. Abstracts with a “PUB” number will not be presented at the ASN Annual Meeting.

* TH = Thursday, FR = Friday, SA = Saturday
** OR = Oral, PO = Poster, PUB = Publication Only

The presenting author’s name is underlined.

Abstract Author Index
The Author Index lists all abstract authors in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day for orals (TH, FR, or SA), and then the chronological publication number.

Abstract Keyword Index
The Keyword Index lists major keywords from each abstract in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day for orals (TH, FR, or SA), and then the chronological publication number.

Abstract Reference Format
To cite abstracts in this publication, please use the following format: Author Names: Abstract Title [Abstract]. J Am Soc Nephrol 31, 2020: Page(s).

Abstract Disclaimer and Copyright

Background: Roxadustat is an orally administered hypoxia-inducible factor prolyl hydroxylase inhibitor to treat anemia in adult CKD patients (pts). Efficacy and safety of roxadustat versus darbepeoin alfa (DA) were assessed in NDD CKD pts in a randomized, open-label, active-controlled phase 3 study.

Methods: Data from 3 completed randomized Phase 3 studies in NDD-CKD pts were analyzed individually and in the pooled population by iron status. Pts were randomized to roxadustat or placebo for up to 4 years. Baseline (BL) hemoglobin (Hb) and change from BL (CFB) were summarized overall and in pts with iron repletion or iron depletion. Iron repletion was defined as ferritin ≥100 μg/L and transferrin saturation (TSAT) ≥20%; the remainder were defined as iron depleted. Oral iron was allowed on study and IV iron was allowed as rescue.

Results: Across studies, 2391 and 1886 pts with NDD-CKD were treated with roxadustat and placebo, respectively. Mean (SD) BL Hb was 9.10 (0.74) g/dL (roxadustat) and 9.07 (0.73) g/dL (placebo). At BL, 1433 (60%) pts were iron replete for roxadustat and 1127 (60%) pts were iron replete for placebo. Mean CFB in Hb with roxadustat was summarized by study and iron status (Table 1). Hb CFB was similar in iron-replete and iron-depleted patients receiving roxadustat. Roxadustat dose and iron use in subgroups will be explored.

Conclusions: Roxadustat corrected and maintained Hb in patients with NDD-CKD and anemia regardless of iron status at baseline.

Funding: Commercial Support - Fibrogen, Inc.; AstA.Zene Inc; Astellas Pharma Inc.

Change from baseline in Hb overall and by iron status with roxadustat treatment across NDD studies over Weeks 28 to 52 regardless of rescue therapy.

Roxadustat Is Not Associated with an Increased Risk of Neoplasm in Patients with CKD and Anemia
Daniel W. Coyne,1 Steven Fishbane,2 Pablo E. Pergola,3 Robert Leong,4 Ming Zhong,5 Dustin J. Little,3 Kin-Hung P. Yu,6 Washington University in Saint Louis School of Medicine, Saint Louis, MO; 2Northwell Health, Great Neck, NY; 3Renal Associates PA, San Antonio, TX; 4Fibrogen Inc, San Francisco, CA; 5AstraZeneca, Gaithersburg, MD.

Background: Roxadustat is a novel, orally bioavailable, small molecule that reversibly inhibits hypoxia-inducible factor (HIF) prolyl hydroxylase enzymes and activates HIF and transcription of HIF-responsive genes, including for erythropoietin. Preclinical studies of roxadustat in multiple animal species did not demonstrate a carcinogenic signal. We report neoplasm-related adverse events (AEs) and serious adverse events (SAEs) from the roxadustat global phase 3 program.

Methods: Data from six pivotal studies were pooled. 3 compared roxadustat to placebo in patients with non-dialysis-dependent (NDD) CKD, and 3 compared roxadustat to epoetin alfa in patients with dialysis-dependent (DD) CKD. Patients were excluded from the studies if they had a history of malignancy, except for those determined to be cured or in remission for ≥2 years, or for patients receiving chemotherapy for malignant disease.

Results: Of 616 randomized pts (roxadustat, 323; DA, 293), 424 completed 2 years of treatment (roxadustat, 215; DA, 209). Mean BL Hb was 9.55 g/dL in both groups. In the per protocol set, the proportion of pts who achieved BL Hb response during the first 24 weeks was 89.5% (roxadustat; n=256/286) and 78.0% (DA; n=213/273), with a difference of 11.5% (95% CI: 5.6%, 17.3%). Differentially, establishing roxadustat’s noninferiority to DA. Noninferiority of roxadustat to DA was demonstrated for MAP and time to first IV iron use, change in mean arterial pressure (MAP), and occurrence of hypertension. Treatment-emergent adverse events (TEAEs) were assessed.

Results: Of 616 randomized pts (roxadustat, 323; DA, 293), 424 completed 2 years of treatment (roxadustat, 215; DA, 209). Mean BL Hb was 9.55 g/dL in both groups. In the per protocol set, the proportion of pts who achieved BL Hb response during the first 24 weeks was 89.5% (roxadustat; n=256/286) and 78.0% (DA; n=213/273), with a difference of 11.5% (95% CI: 5.6%, 17.3%). Differentially, establishing roxadustat’s noninferiority to DA. Noninferiority of roxadustat to DA was demonstrated for MAP and time to first IV iron use, change in mean arterial pressure (MAP), and occurrence of hypertension. Treatment-emergent adverse events (TEAEs) were assessed.

Results: Of 616 randomized pts (roxadustat, 323; DA, 293), 424 completed 2 years of treatment (roxadustat, 215; DA, 209). Mean BL Hb was 9.55 g/dL in both groups. In the per protocol set, the proportion of pts who achieved BL Hb response during the first 24 weeks was 89.5% (roxadustat; n=256/286) and 78.0% (DA; n=213/273), with a difference of 11.5% (95% CI: 5.6%, 17.3%). Differentially, establishing roxadustat’s noninferiority to DA. Noninferiority of roxadustat to DA was demonstrated for MAP and time to first IV iron use, change in mean arterial pressure (MAP), and occurrence of hypertension. Treatment-emergent adverse events (TEAEs) were assessed.
Results: In the NDD population, 4270 patients were randomized (roxadustat=2386, placebo=1884), corresponding to 3870.7 and 2323.2 patient-exposure years (PEY), respectively. Neopterin-related AE rates were 2.5/100 PEY in both the roxadustat and placebo groups. Neopterin-related SAE rates were 1.1/100 PEY and 1.3/100 PEY in the roxadustat and placebo groups. In the DD population, 3880 patients were randomized (roxadustat=1940, epoetin alfa=1940), corresponding to 3315.3 and 3743.6 PEY respectively. Neopterin-related AE rates were 2.7/100 PEY and 2.3/100 PEY in the roxadustat and epoetin alfa groups. Neopterin-related SAE rates were 1.1/100 PEY and 1.2/100 PEY. In both the NDD- and DD-CKD populations, there were no between-treatment-group differences in neopterin-related AE and SAE rates in the roxadustat phase 3 clinical trials.

Roxadustat Treatment Results in Consistent Improvements in Hemoglobin (Hb) vs. Placebo: An Analysis of Three Multinational Randomized Clinical Trials in Patients with Non-Dialysis-Dependent CKD (NDD-CKD)

Roberto Pegoil-Filho,1,2 Tak Mao D. Chan,1 Elise Hardy,1 Kin-Hung P. Yu,3 Steven Fishbane3, Arbor Research Collaborative for Health, Ann Arbor, MI; 1School of Medicine, Pontifical Catholic University of Paraná, Paraná, Brazil; 2Division of Nephrology, Department of Medicine, Queen Mary Hospital, The University of Hong Kong, Pok Fu Lam, Hong Kong; 3Clinical Research, AstraZeneca, Gaithersburg, MD; 1Fibrogen Inc., San Francisco, CA; 2Department of Medicine, Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY.

Background: Roxadustat is a hypoxia-inducible factor prolyl hydroxylase inhibitor that increases endogenous erythropoietin and enhances iron utilization. To evaluate the consistency of Hb increases across studies and global geographic regions, we analyzed data from three pivotal Phase 3 trials of roxadustat in patients with anemia and NDD-CKD.

Methods: While based on the same trial design, the studies were performed by different investigators and companies in differing global regions. Patients with baseline Hb <10 g/dL and eGFR <60 mL/min/1.73 m² not on dialysis were randomized to roxadustat or placebo (pbo) in the OLYMPUS (North and South America, Asia-Pacific and Europe; N=2781, 1:1 ratio to pbo), ALPS (South America, Europe and South Africa; N=597, 2:1 ratio to pbo), and ANDES (North and South America, Asia-Pacific and Australasia; N=922; 2:1 ratio to pbo) double-blind randomized controlled trials (RCTs). Oral iron was administered unrestricted; intravenous (IV) iron was limited to rescue therapy with roxadustat in those with low iron stores and poor treatment response. The primary endpoint was the mean change in Hb from baseline to the average over Weeks 28–52.

Results: Significant (P<0.001) and consistent improvements in Hb were observed with roxadustat vs pbo across all studies (Figure) and were maintained over time. IV iron rescue therapy use was lower with roxadustat vs pbo (Figure). Overall safety of roxadustat with roxadustat vs pbo across all studies (Figure) and were maintained over time. IV iron rescue therapy use was lower with roxadustat vs pbo (Figure).

Conclusions: Roxadustat consistently improved anemia in patients with NDD-CKD across the global roxadustat clinical program, in studies performed by different investigators and companies and in varying global locations.

Hemoglobin (Hb) Correction with Roxadustat Is Associated with Improved Iron Homeostasis in Patients with Dialysis-Dependent CKD (DD-CKD)

Pablo E. Pergola,¹ Chaim Charytan,² Dustin J. Little,¹ Stefan Tham,³ Lynda Srzcecz,² Steven Fishbane,³ ¹Renal Associates PA, San Antonio, TX; ²New York Hospital Queens, Division of Nephrology, Flushing, NY; ³Clinical Research, AstraZeneca, Gaithersburg, MD; ³Clinical Research, AstraZeneca, Gothenburg, Sweden; ²Fibrogen Inc., San Francisco, CA; ³Department of Medicine, Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY.

Background: Anemia in CKD is multifactorial, with contributions from reduced erythropoietin production and hepcidin-induced functional iron deficiency. Roxadustat, a hypoxia-inducible factor prolyl hydroxylase inhibitor, treats anemia by enhancing erythropoietin synthesis and increasing iron availability via reducing hepcidin and increasing iron transport. We assessed the effect of roxadustat on iron parameters in patients with DD-CKD.

Methods: Patients were randomized to open label roxadustat or epoetin alfa in 3 pivotal DD-CKD trials. Intravenous (IV) iron was administered per usual care with epoetin alfa and was limited to rescue therapy with roxadustat. Mean changes from baseline in Hb, hepcidin, and iron parameters were evaluated. Pooled results are reported.

Results: Overall, 3890 patients were evaluated (roxadustat N=1943; epoetin alfa N=1947; mean baseline Hb 9.7 g/dL for both groups), including 1515 incident dialysis patients and 1355 anemia patients (N=756 epoetin alfa N=799; overall mean baseline Hbvalues ~8.8 g/dL). Mean Hb increased more from baseline averaged over Weeks 28–52 with roxadustat vs epoetin alfa (1.21 vs 0.95 g/dL; P<0.0001). Roxadustat-treated patients used less IV iron, with mean monthly IV iron use over Weeks 28–52 of 80.3 mg for roxadustat and 108.2 mg for epoetin alfa (P<0.0001). Roxadustat reduced hepcidin and increased transferrin and serum iron; transferrin saturation did not change vs epoetin alfa (Figure). Reduction in ferritin occurred predominantly in patients with the highest baseline values when assessed by quartile (>800 μg/L).

Conclusions: Roxadustat facilitated iron transport and utilization by increasing both iron-carrying capacity (transferrin) and serum iron, in contrast to the effects on these parameters seen with epoetin alfa. Overall, these changes contributed to decreased need for IV iron use while achieving greater Hb increase from baseline with roxadustat vs epoetin alfa.

Renoprotective Effects of Ferric Citrate in a Mouse Model of CKD

Mark R. Hanouel,1 Shirley Wong, Kristine Chua, Grace Jung, Bo Qiao, Victoria B. Gabayan, Tommaso Ganz, University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.

Background: Ferric citrate (FC) is an effective phosphate binder and iron replacement product. In the setting of chronic kidney disease (CKD), both decreasing enteral phosphate absorption and improving iron status could lower pathologically elevated FGF23 levels and indirectly improve kidney function. In a murine model of CKD, we assessed how FC (and iron status in general) affects FGF23 levels and kidney function.

Methods: Five-week-old Col4α2 knockout mice were placed on five-week diets containing low iron (4 ppm), standard iron (48 ppm), or standard iron supplemented with FC (48 ppm + 1% FC) (n = 15-20 mice per group). Mice were euthanized at ten weeks of age.

Results: Compared to the standard iron diet group, the mice on low iron diets developed iron deficiency anemia (lower liver iron, lower hemoglobin, lower mean corpuscular volume, and higher red cell distribution width); markedly worsened kidney function (higher serum urea nitrogen, creatinine, and phosphate); and markedly higher FGF23 levels (increased bone and marrow Fgf23 mRNA expression, and approximately ten-fold higher plasma intact FGF23 concentrations) (Figure). Conversely, compared to the standard iron diet group, the mice treated with FC had similar hemoglobin (with increases in liver and serum iron not reaching statistical significance), but decreased serum phosphate; decreased marrow Fgf23 mRNA expression; approximately ten-fold lower plasma intact FGF23 concentrations; decreased systemic inflammation; and markedly improved kidney function (decreased serum urea nitrogen, serum creatinine, urine albumin-to-creatinine ratio, and expression of renal fibrosis markers, along with increased kidney Klotho mRNA expression (Figure).

Conclusions: In the setting of CKD, iron deficiency anemia is associated with markedly increased intact FGF23 levels and worsened kidney function. In this CKD model, compared to either iron-deficient or standard iron conditions, FC decreased serum phosphate, markedly decreased intact FGF23, and dramatically improved kidney function. These data support further human studies of how FC affects CKD progression.

Regional Variation of Erythropoietin-Stimulating Agent Hyporesponsiveness in the Global Dialysate Denusial Study (ASCEND-D)

Ajay K. Singh, Allison Blackorby, Burat Cizman, Alexander R. Cobitz, Sergio A. Godoy, Vivekanand Jha, Kirsten L. Johansen, Gearoid M. McMahon, Amy M. Meadowcroft, Gregory T. Obrador, Muh Geot Wong, Iain C. Macdougall, Brighten and Women’s Hospital, Boston, MA; 3George Institute for Global Health, Sydney, NSW, Australia; 1Hepnevve Healthcare, Minneapolis, MN; 2Universidad Panamericana, Mexico, Mexico; 3Royal North Shore Hospital, St Leonards, NSW, Australia; 4George Clinical, Pilar, Argentina; 5GlaxoSmithKline, Collegeville, PA; 6GlaxoSmithKline, Research Triangle Park, NC; 7King’s College Hospital, London, United Kingdom.

Background: Hyporesponsiveness to erythropoiesis-stimulating agents (ESA) is present in 10%–15% of the prevalent dialysis population. We explored baseline characteristics and predictors of ESA hyporesponsiveness in a global randomized cardiovascular outcomes study comparing an investigational hypoxia-inducible factor prolyl hydroxylase inhibitor (HIF-PHI), denusial, with conventional ESA treatment.

Methods: ASCEND-D (NCT02879305) recruited 2964 prevalent dialysis patients receiving ESA treatment (standardized to weekly intravenous [IV] epoetin) who were iron replete at baseline. Primary ESA hyporesponsiveness definition: ESA Resistance Index (ERI, ESA Units/kg/week/hemoglobin g/L) ≥2 or IV ESA equivalent dose ≥150 Units/kg/week. Predictors of ESA hyporesponsiveness were determined using a multivariable regression model. Alternate hyporesponder definitions were explored.

Results: Using the primary definition, 34% (122 patients) were ESA hyporesponsive. Selected baseline characteristics in the overall population and by ESA responsiveness, along with the results from the multivariable analysis, are shown below. Additional predictors of ESA hyporesponsiveness include a history of heart failure (0.013), dialysis vintage (0.033), smoking status (0.046), aspirin use (0.039), and ACEi/ARB use (0.081).

Conclusions: This is the first global HIF-PHI study to report pre-defined predictors and predictors of ESA hyporesponsiveness. While most of the strong predictors identified in our study have been previously reported, geographic region stands out as an unexpected finding that requires further investigation.

Adverse Event Rates Are Higher Post-Transfusion vs. Overall Follow-up and Independent of Background Anemia Treatment in Patients with CKD

Robert Provenzano, Carol A. Pollock, Roberto Pecotis-Filho, Anjay Rastogi, Rachel Lai, Ming Zhong, Lynda Szczech. Wayne State University, Detroit, MI; The University of Sydney, Sydney, NSW, Australia; Arbor Research Collaborative for Health, Ann Arbor, MI; Pontificia Universidad Catolica do Paraiba Departamento de Medicina, Curitiba, Brazil; University of California Los Angeles, Los Angeles, CA; Fibrogen Inc, San Francisco, CA.

Background: The use of transfusion can treat anemia in the short term but may increase the risk of adverse events. Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitory (HIF-PI) agent that stimulates erythropoiesis and improves iron metabolism. Roxadustat has been shown to decrease the need for transfusions in patients with chronic kidney disease (CKD).

Methods: Data were pooled from three pivotal, phase 3 studies of roxadustat vs. placebo in patients with chronic kidney disease (CKD)-dependent (DD) CKD and three pivotal phase 3 studies of roxadustat vs. epoetin alfa in patients with dialysis-dependent (DD) CKD. We evaluated rates of intravascular volume-related adverse events (AEs; reported from a predefined list [heart failure, pulmonary edema, respiratory failure]) as a direct cause of excess intravascular volume or as a potential symptom) and treatment-emergent adverse events (TEAEs) during the 14-day post-transfusion period and the overall follow-up period (last dose + 28 days) in patients who had a transfusion.

Results: Intravascular volume-related AE and TEAE rates were at least 9-fold higher during the 14-day post-transfusion period vs. the overall follow-up period across all subgroups (Table). Trends in overall TEAE rates were similar across treatment groups.

Conclusions: Intravascular volume-related AEs occurred at higher rates post-transfusion across all populations. The reduction in transfusions for patients taking roxadustat could lower patient risk and healthcare resource use in managing CKD-related anemia.

Funding: Commercial Support - Fibrogen, Inc.; AstZeneca plc; Astellas Pharma Inc.
Results: Deletion of Hif1α delayed progression of CKD, as CDP mice showed reduced bone loss of BUN compared to age-matched Col4a3KO mice (−25%). CDP mice also showed lower FGF23 levels (−80%) vs. Col4a3KO and we obtained similar results in Col4a3KO mice administered with a HIF inhibitor (−80% FGF23, −30% BUN, vs. Ctr-Col4a3KO). CDP mice also improved trabecular and cortical bone parameters (+50% trabecular bone volume, −20% cortical porosity vs. Col4a3KO). Finally, deletion of Hif1α increased alkaline phosphatase (ALP) positive colonies and mineral deposits in Hif1α KO cultures compared to Ctr cells, and led to a 30% reduction in Fg23 expression. In contrast, Hif1α cells showed reduced osteogenic potential, with fewer ALP colonies and mineral deposits, and a blunted Fg23 expression.

Conclusions: Our data suggest that osseous Hif1α stimulates FGF23 production in CKD and is a negative regulator of osteoblast differentiation and function. Thus, inhibition of Hif1α in bone might represent a novel therapeutic strategy to improve bone and mineral outcomes in CKD.

Funding: NIDDK Support

TH-OR13
Deletion of the Sodium/Hydrogen Exchanger Isoform 6 in Mice Is Associated with an Age-Dependent Loss of Bone Volume

Daniela Hanke,1,2 Giuseppe Albano,1,2 Manuel A. Anderegg,1,2 Daniel G. Fuster,1,2 1Department of Nephrology and Hypertension, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland; 2Department for BioMedical Research, University of Bern, Bern, Switzerland.

Background: The sodium/hydrogen exchanger isoform 6 (NHE6) localizes to recycling endosomes, where it mediates endosomal alkalization through K+/H+ exchange. NHE6 function in the endosome is essential for clathrin-mediated endocytosis, resealing recycling and endosomal signaling. Mutations in the SLC9A6 gene encoding the NHE6 isoform cause severe X-linked mental retardation, epilepsy, autism and corticalbasal degeneration in humans. Patients with SLC9A6 mutations exhibit skeletal malformations, and a previous study suggested a role of NHE6 in osteoblast-mediated mineralization. The goal of this study was to explore the role of NHE6 in bone homeostasis.

Methods: NHE6 expression, osteoclast differentiation and cell-mediated resorption were assessed in osteoclast precursor cells isolated from wild-type and NHE6 knockout mice. In a next series of experiments, we used primary osteoblasts, extracted from calcified bone of newborn mice, to study NHE6 expression, proliferation, and cell-mediated mineralization in vitro. To determine the impact of the NHE6 isoforms on structural bone parameters, we performed high-resolution microcomputed tomography (mCT) studies on lumbar vertebral of wild-type and NHE6 knockout mice.

Results: NHE6 expression was observed in both primary osteoblasts and osteoclast precursors. In two studies with osteoclast precursors, derived from NHE6 knock-out mice demonstrated normal osteoclast differentiation and osteoblast proliferation. However, NHE6-deficient osteoblasts exhibited a resorptive deficit, and the mineralization capacity was increased in osteoblasts lacking NHE6. Microcomputed tomography studies revealed a reduced bone volume at a single lumbar vertebral site (L4) but otherwise unaltered structural bone parameters in NHE6 knock-out mice compared to wild-type mice at 3 months of age.

Conclusions: Loss of NHE6 results in an age-dependent loss of bone volume in mice. The results of our in vitro studies argue against a direct bone cell-autonomous cause of the bone phenotype observed in NHE6 knockout mice and suggest extraneous factors as likely mediators.

TH-OR14
Circadian PTH Secretion Is Entrained by Feeding, While the Internal Circadian Parathyroid Clock Is Independent but Affected by CKD

Soren Egestrød,1,2 Anders Nordholm,1,2 Maria L. Mace,2 Mayra Morevati,2 Klaus Olgaard,2 Ewa Lewin,1,2 1Dept. of Nephrology, Herlev Hospital, Copenhagen, Denmark; 2Dept. of Nephrology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark.

Background: We have previously shown that an internal molecular circadian clock operates in the parathyroid gland, regulates its activity and its 24th rhythm of PTH secretion and whether it is impacted by feeding or CKD is unknown.

Methods: Rats were kept in 12h:12h light:dark cycle and fed ad libitum. Blood samples and parathyroid glands were harvested at 4h interval (N=38). Then feeding was restricted to the inactive light phase at ZT2-ZT12 (ZT: zeitgeber time since lights on) for 4 weeks and blood and glands obtained again (N=39). CKD was induced by 5/6 nephrectomy and high phosphate (P) diet for 8 weeks and parathyroid glands were harvested every 4th-hour (N=44). Plasma PTH, P, total calcium, FGF23, and urea were measured. Parathyroid expression of core circadian clock genes was examined by qPCR.

Results: Circadian rhythm was found for PTH (p<0.0002), P (p<0.001), FGF23 (p<0.02), and urea (p<0.0001). Restricted feeding to the habitual inactive period inverted the acrophase timing of PTH (ZT9.6 → ZT23.6), P (ZT8.7 → ZT21), FGF23 (ZT7.4 → ZT22.9) and urea (ZT12.2 → ZT8.4). Restricted feeding did not significantly affect the period, acrophase timing, MESOR or amplitude of circadian clock genes. Bmal1, Per1, Per3, Cry1,2 and Rev-erba. The rhythmicity of parathyroid circadian clock genes was severely deregulated in CKD with significant upregulation of PER1 (p<0.0002), Per2 (p<0.03), and Rev-erba (p<0.004) and downregulation of Npas2 (p<0.05). The
significant rhythmicity of Per1 (p=0.02) was abolished. In CKD the best fitting period of rhythmicity was reduced to 20h as opposed to the normal 24h for Per1, Per2, Per3 and Cry2. Significant shifts in acrophase were found for Npas2, Per3 and Cry1, while amplitude of Rev-erbs increased.

**Conclusions:** Feeding restricted to the inactive period inverted the acrophase of plasma PTH, P and FGF23 and revealed a clear dissociation between the phase of PTH secretion rhythm and the phase of the circadian clock in the parathyroid glands. In CKD the circadian rhythm of core clock genes were significantly interfered, affecting MESOR, phase, period, amplitude as well as rhythmicity.

**TH-OR15**

Shensen Li, Wenwen Li, Qingqing Liu, Haiyan Shen, Bingquan Deng, Changchun Cao. Sir Run Run Hospital, Nanjing Medical University, Nanjing, China.

**Background:** Secondary hyperparathyroidism (SHPT) is one of the common complications in patients with chronic kidney disease. The development of SHPT is accompanied by the change of cell composition, while the exact cell type changes and mechanism are yet to be defined. Therefore, single cell sequencing was conducted to analysis the cell composition of parathyroid gland.

**Methods:** In current study, parathyroids from 3 SHPT patients were digested to obtain single cell suspension. A total of 21519 cells were obtained and the mRNA expression profiles were analyzed by single cell sequencing and bioinformatics. Furthermore, the development separation track of cell subpopulations was constructed by pseudotime analysis (Figure 1A).

**Results:** There may be 21 cell subpopulations in parathyroid, among which 6 subpopulations (clusters 0, 1, 2, 5, 11, 17) are high function subpopulations of parathyroid, which were indicated by high expression of gene (gland cells missing homolog 2), PTH (parathyroid hormone), Cux1/c (calcium sensing receptor) and KL (Klotho) genes (Figure 1B-D). The results of pseudotime analysis in the 6 high function subpopulations show that cluster 0 is at the beginning of the main group separation track, cluster 1, 2, 5 are in the middle, while cluster 11 and 17 are at the end (Figure 1E). Multiple genes may play major role in the differentiation of cluster 0, including tsp1, paxk7, atp6v0b, rpl11, rps8 and etc (Figure 1F).

**Conclusions:** There are 6 subpopulations out of total 21 cell subpopulations of parathyroid cells with higher parathyroid hormone secretion and regulation function in SHPT patients. Among which, cluster 0 may be the initiation differentiation cell of high functional cells, because it may be a subpopulation with high proliferation and differentiation potential.

**Funding:** Government Support - Non-U.S.

**Identification and analysis of subpopulations of uricemic hyperparathyroidism glands.**

Calcium Isotopes: A Novel Biomarker of Bone Mineralization in CKD

Rukshana Li, Wenwen Li, Qingqing Liu, Haiyan Shen, Bingquan Deng, Changchun Cao. Sir Run Run Hospital, Nanjing Medical University, Nanjing, China.

**Background:** Calcium isotopes were measured by plasma-ionization mass-spectrometry in blood, urine, feces and dialysate. The relationship between bone Ca gain and loss was calculated using a compartment model, and expressed as 44/42Ca in 128 children in CKD4-5 and on dialysis (CKD4-5D) and 117 healthy participants (age <30) underwent Ca isotope measurement, bone biomarkers, DXA and tibial peripheral quantitative CT (pQCT), an accurate measure of cortical BMD.

**Results:** In healthy children the 44/42Ca_int and 44/42Ca_pen were higher than in adults (p<0.001), reflecting avid Ca uptake during bone formation. Since urinary Ca excretion is impaired in CKD, 44/42Ca_int was higher and 44/42Ca_pen lower in CKD4-5D compared to controls (p<0.001 for both). In CKD2-5D 44/42Ca_int positively correlated with cholecalciferol (p=0.01) and alfacalcidol (p=0.002) doses, implying increased bone Ca uptake when cholecalciferol is increased. 44/42Ca_pen is positively correlated with biomarkers of bone formation (ALK, p=0.05) and inversely with resorption markers (PTH, p=0.01; TRAP5b, p=0.01 and CTX, p=0.006). 44/42Ca_int is positively correlated with cortical BMD Z-score (p=0.006, R2=0.39), and DXA hip BMD Z-score (p=0.02). Significant and independent predictors of cortical BMD Z-score were 44/42Ca_int (p=0.06, p=0.006) and PTH (p=0.39, p=0.04), together predicting 67% of the variability in BMD.

**Conclusions:** Ca isotope ratios provide a novel, non-invasive method of assessing bone mineralization. Defining an accurate biomarker of BMB forms the basis of future studies investigating Ca dynamics in disease states and the impact of treatments that affect bone homeostasis.

SNF472 Consistently Slows Progression of Coronary Artery Calcification Across Subgroups of Patients on Hemodialysis

Glenn M. Chertow,12 Paolo Raggi,1 Antonio Bellasi,2 David A. Bushinsky,3 Jordi Bover,4 Marianno Rodriguez,5 Markus Ketteler,5 Sneeta Sinha,5 Rekha Garg,5 Claire S. Padgett,6 Joan Perello,7,8,9 Alex Gold,10 Mazankowski Alberta Heart Institute and University of Alberta, Edmonton, AB, Canada; 2Research, Innovation and Brand Reputation Unit, ASST Papa Giovanni XXIII, Bergamo, Italy; 3Department of Medicine, University of Rochester Medical Center, Rochester, NY; 4Department of Nephrology, Fundación Puigvert and Universitat Autònoma, IIB Sant Pau, REDinREN, Barcelona, Spain; 5Nephrology Unit, Hospital Universitario Reina Sofia, IMIBIC, REDinREN, Córdoba, Spain; 6Department of General Internal Medicine and Nephrology, Robert-Bosch-Krankenhaus, Stuttgart, Germany; 7Department of Renal Medicine, Salford Royal NHS Foundation Trust, Salford, United Kingdom; 8Research and Development, Sanifit (now with PharmaDRS Consulting), San Diego, CA; 9Research and Development, Sanifit, San Diego, CA; 10Research and Development, Sanifit, Palma, Spain; 11University of the Balearic Islands, Palma, Spain; 12Department of Medicine, Stanford University, Palo Alto, CA.

Background: In the Cal.JP10 study, SNF472 significantly attenuated progression of coronary artery calcium (CAC) volume score compared with placebo. This pre-specified analysis examined CAC progression in key subgroups.

Methods: Patients were randomized to SNF472 300 mg (n=92), SNF472 600 mg (n=91) or placebo (n=91) infused 3x/week during hemodialysis (HD) for 52 weeks on standard care therapy determined by each investigator. We examined change in log CAC volume score from baseline to week 52 in the combined SNF472 dose groups vs placebo for subgroups of age, sex, diabetes, dialysis vintage, arteriosclerotic cardiovascular disease (ASCVD), use of non-Ca phosphate binders, Ca-based phosphate binders, calcimimetics, activated vitamin D, warfarin, or statins in the modified ITT population (mITT, defined as subjects who received at least one dose of study drug and had an evaluable post-baseline CT scan).

Results: Baseline characteristics were similar across treatment groups: mean age was 64 y, 39% were female; 62% had diabetes, and 41% had prior ASCVD. Median HD vintage was 42 mo; 33% received HD for ≥5 years. Concomitant medications at baseline were: 62% non-Ca phosphate binders, 28% Ca-based phosphate binders, 31% calcimimetics, 51% activated vitamin D, 8% warfarin, and 64% statins. In the overall mITT, CAC volume progression was 11% in the combined SNF472 groups vs 20% in placebo (p<0.016). Treatment differences for CAC volume progression were similar across subgroups (Figure). All interaction p-values were non-significant and comparisons favored SNF472 vs placebo in each subgroup.

Conclusions: SNF472 treatment for 52 weeks attenuated CAC progression compared with placebo in all subgroups.

Pharmacodynamic (PD) Profiling of Reloxaliase in Patients with Severe Hyperoxaluria

Felix Knauf,2,1 Danica Grujie,1 Mira T. Keddis,1 Alicia Weeks,1 Annamaria T. Kausz,1 Allena Pharmaceuticals, Newton, MA; 2University Hospital Charite, Berlin, Germany; 3Mayo Clinic Hospital, Phoenix, AZ.

Background: Hyperoxaluria is a major risk factor for kidney stones and can lead to chronic kidney disease (CKD). With decreasing kidney function, plasma oxalate (POx) rises and oxalate may deposit in the kidneys and other tissues (systemic oxalosis) leading to ESRD. Reloxaliase (REL), a non-absorbed, oxalate specific oral enzyme therapy designed to degrade oxalate along the GI tract, may potentially reduce the systemic and renal oxalate burden in patients with enteric and primary hyperoxaluria (EH and PH). This study tested the PD of REL, and addressed questions regarding potential formate accumulation (by-product of oxalate degradation) and systemic absorption of oxalate decarboxylase (OxDC, the active component of REL).

Methods: This 12-week, open label study enrolled subjects with EH, CKD and hyperoxalemia (UOx ≥40mg/dL, eGFR <45mL/min and POx>5μmol/L, n=10) and PH (UOx ≥40mg/dL, n=5) who received ≥7.500 of REL 5x/day with meals/snacks. Parameters assessed at baseline, and weeks 4, 8 and 12 included POx and UOx (only if eGFR >15mL/min), plasma formic acid (pre- and post-prandial/post-dose; Q’ Solutions) and OxDC (specific ELISA, Absorption Systems).

Results: Reported adverse events (AEs) were mostly GI related; there were no related serious AEs. In EH, both POx and UOx decreased substantially; in PH, UOx did not change, and POx stayed normal at baseline and during treatment (Table). There was no formate accumulation, as all samples were below or within normal range (1-9mg/L). Similarly, there was no detectable absorption of REL, as all samples were below the limit of detection of the assay for OxDC (<0.0001% of the administered dose of 37,500 u/day).

Conclusions: Reloxaliase was well tolerated; the absence of formate accumulation further supports its safety. The lack of REL absorption, in addition to supporting low potential for systemic toxicity, confirms its site of action within the GI tract. This best aligns with the pathophysiology of EH as evidenced by the substantial reduction in both POx and UOx in EH subjects with CKD/ESRD.

Efficacy and Safety of Upacicalcet in Hemodialysis Patients with Secondary Hyperparathyroidism: A Phase 3 Study

Tadao Akizawa,1 Daisuke Honda,2 Masaki Taniguchi,3 Fumihiko Koiwa,4 Showa University School of Medicine, Tokyo, Japan; 5Sanwa Kagaku Kenkyusho Co., Ltd., Nagoya, Japan; 6Sanwa Kagaku Kenkyusho Co., Ltd., Nagoya, Japan; 7Showa University Fujigaoka Hospital, Yokohama, Japan.

Background: Secondary hyperparathyroidism (SHPT) is a major complication of hemodialysis (HD) patients. Calcimimetics suppress the hyperfunction of parathyroid and reduce serum calcium and phosphorus levels, and are currently used for the treatment of SHPT. Upacicalcet (UPA) is a novel intravenous small molecule calcimimetic in late-stage development in Japan to treat SHPT of HD patients. We report the efficacy and safety of UPA in HD patients.

Methods: This study was a phase 3, multicenter, randomized, double-blind, placebo-controlled, parallel-group study. UPA or placebo (PBO) was administered i.v. at the end of HD at an initial dose of 50 mcg or 25 mcg. The doses were subsequently adjusted to maintain serum intact PTH (iPTH) levels between 60-240pg/ml (recommended level of Japanese guideline) every 3 weeks between 25 and 300 mcg during 24 weeks of treatment. The primary endpoint was the percentage of patients who achieved a mean iPTH level of 60–240 pg/ml in weeks 22 to 24. RESULTS: A total of 154 SHPT patients were enrolled, and randomly allocated to UPA group (n=103) or PBO group (n=51). The primary endpoint, percentage of patients achieving the target iPTH range was greater for UPA (67.0%) than for PBO (8.0%) (P<0.001). UPA significantly reduced iPTH and cCa levels compared with PBO (Fig.). Concerning phosphorus, no statistically significant difference between the groups was observed while it tended to decrease in the UPA group. In the safety assessment, treatment emergent adverse events (AE) occurred in 88 patients (85.4%) and 36 patients (72.0%) in the UPA and the PBO groups. The incidences of upper-gastrointestinal-related AE were 20.4% in the UPA and 18.0% in the PBO groups (P=0.8298). As an AE, hypocalcemia did not occur in either group.

Conclusions: This study demonstrates that UPA significantly decreases iPTH without increasing the incidence of upper-gastrointestinal symptoms as compared to PBO. It is suggested that UPA will be a promising calcimimetic agent capable of safe and appropriate management of SHPT.

Primary Cilia and the Glycocalyx Are Flow Sensors for Nitric Oxide Production by Thick Ascending Limbs
Jeffrey L. Garvin, Nancy J. Hong. Case Western Reserve University, Cleveland, OH.

Background: The primary cilium is an organelle found on essentially all epithelial cells. Similarly, the glycocalyx is a matrix-like layer of proteoglycans, glycosaminoglycans (GAGs) and proteins covering the surface of all cells. In vascular endothelial cells, primary cilium and GAGs such as heparan sulfate and chondroitin sulfate mediate responses to the mechanical forces exerted by blood flow. In thick ascending limbs, increases in luminal flow enhance nitric oxide (NO) production, an important regulator of the kidney function including sodium reabsorption; however, the role of primary cilium and the glycocalyx in NO production by thick ascending limbs is unknown. We hypothesized that primary cilium and the glycocalyx act as flow sensors and thus mediate flow-induced NO production by thick ascending limbs.

Methods: We measured flow-induced NO in isolated rat thick ascending limbs using DAF-FM. Intracellular NO was first measured during the control period without and with luminal flow. NO was measured again during the experimental period after treating tubules for 15 min to deciliate cells or to degrade major glycocalyx GAGs. Dibucaine (0.1 mM) was used to remove cilia from cells. Heparinase III (0.2 or 0.4 U/ml) and chondroitinase ABC (0.2 U/ml) were used to degrade heparan sulfate and chondroitin sulfate, respectively.

Results: In untreated control tubules, flow-induced NO did not differ between the two periods, 4.3±1.03 to 4.68±0.84 arbitrary units (AU)/min. Dibucaine decreased flow-induced NO from 4.25±0.62 to 1.19±0.65 AU/min (p = 0.002). Heparinase (0.2 U/ml) attenuated flow-induced NO from 4.02±0.84 to 1.80±0.74 AU/min (p < 0.04); a higher concentration (0.4 U/ml) caused a greater decrease in basal NO from 1.86±0.41 AU/min (p < 0.006). Heat inactivation of heparinase (0.2 U/ml) abolished its effect (3.01±0.34 to 2.83±0.22 AU/min). Chondroitinase (0.2 U/ml) decreased flow-induced NO from 4.17±0.96 to 2.45±0.49 AU/min (p < 0.038).

Conclusions: We conclude that both primary cilium and the glycocalyx act as flow sensors in thick ascending limbs and transduce mechanical stimuli into chemical signals that ultimately result in NO production by this segment.

Cell-Autonomous Expression of Membrane Transport Proteins in Mammalian Distal Nephron

Background: Reabsorption of NaCl in kidney thick ascending limb (TAL) via NKCC2 involves the action of luminal (ROMK) and basolateral (Kir4.1/Kir5.1) multimers) potassium channels, a basolateral calcium sensing receptor (CaSR), and the claudin (Cla) family of proteins. Morphological heterogeneity of TAL cells has been reported, as well as mosaic expression of ROMK and Kir4.1. We hypothesized that this variability between TAL cells extends to other aspects of their function.

Methods: We studied TAL EM morphology, zonal and cell-autonomous heterogeneity of the transport proteins at steady state in mice, rats and humans, and under stimulation by vasopressin (AVP; V2R agonist dDAVP for 72 h) using AVP-deficient Brattleboro rats. NKCC2, phosphorylated (p) NKCC2, ROMK, Kir4.1, CaSR, Clδ-10 and Clδ-16 signals were analyzed by immunofluorescence, in situ hybridization (ISH), EM and Western blot (WB).

Results: Between cortex and medullary kidney zones, TAL morphological cell heterogeneity was observed, but not at a cell-to-cell level within each zone. NKCC2 was continuously expressed in all TAL cells, while pNKCC2 signals were heterogeneous, increasing from inner stripe of outer medulla to cortex and varying between cells of each zone. ROMK and Kir4.1 protein expression showed conspicuous heterogeneity in a mutually exclusive pattern, with stronger pNKCC2 expression in the ROMK-negative, Kir4.1-positive cell type. CaSR and Clδ-16 signals were moderate to absent in ROMK-positive cells, but intensified in ROMK-negative cells, while Clδ-10 was strongly expressed only in ROMK-positive cells. ISH revealed no cell heterogeneity of ROMK mRNA. In Brattleboro rats, 72 h dDAVP increased the number of ROMK- and Kir4.1-positive cells and the overlap of both signals in mTAL, and stimulated NKCC2 phosphorylation. Clδ-10 expression was induced in the outer stripe of outer medulla. Morphological alterations in the TAL included proliferation of microvilli. WB showed 2.2-fold increase of ROMK and 1.3-fold increase of Kir4.1 abundance, but down-regulation of CaSR to 60%.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

Conclusions: These results demonstrate mosaic expression of ROMK, Kir4.1, CaSR, Clδ-10, and Clδ-16 in TAL, which correlate with cell-heterogeneous levels of NKCC2 activation.

Optical Clearing and 3D Imaging Reveal a Sexual Dimorphism in the Structure and Remodeling Response of the Distal Convoluted Tubule
Seyedmohammadreza Tahaei, 1 Richard A. Coleman, 1 Turgay Saritas, 2 David H. Ellison, 3 Paul A. Welling, 4 Johns Hopkins University School of Medicine, Baltimore, MD; 2Oregon Health & Science University Oregon Clinical & Translational Research Institute, Portland, OR; 3University Hospital RWTH, Aachen, Germany.

Background: The abundance of the distal convoluted tubule (DCT) thiazide-sensitive sodium chloride cotransporter (NCC) is greater in females than males. Because structural remodeling of the DCT is dependent on NCC activity, it has been generally assumed that there is a corresponding sexual dimorphism in DCT morphology. Until now, this has never been directly examined. Here, combining new optical clearing techniques with high-resolution histological and ultrastructural analyses, we quantitatively assess DCT morphology in male and female mice and study remodeling response to furosemide.

Methods: Male and Female (3-month-old) were treated with vehicle or Furosemide administered in the food (100 mg/kg per day) for seven days. Total NCC and phospho-active NCC abundance (pNCC) was evaluated by Western Blot in one kidney, the other kidney was perfused and fixed for imaging. Kidneys were cleared using Clear, Unobstructed Brain/Body Imaging Cocktails and Computational Analysis (CUBIC) pipeline, co-stained with antibodies that label the early DCT (DCT1, parvalbumin) and the entire DCT (DCT1 & 2; NCC), imaged using a high-speed spinning disc confocal microscope, and processed with 3D rendering and analysis software (IMARIS).

Results: We confirmed previous studies that females have greater NCC abundance in the basel state. Surprisingly, the length of the DCT was longer in males (~620 μm) than female mice (~360 μm). Furosemide treatment significantly increased the abundance of NCC and pNCC in both sexes equally (~50%) and increased the DCT length and volume. The remodeling response to furosemide was more profound in females (~20% increase in DCT length and 50% in DCT1 volume) than males (~8% and 30%, respectively). The DCT elongation effect of furosemide treatment in females stemmed largely from an increase in DCT1 length. Furosemide expanded the DCT2 significantly in males but not females.

Conclusions: Our study reveals a surprising sexual dimorphism of the DCT. The greater NCC density in a shorter structure may provide a means for females to protect sodium balance under conditions of high sodium delivery, yet have larger reserve and remodeling capacity to adapt to unique physiological stresses.

Positive Allosteric Modulation of the Calcium-Sensing Receptor (CaSR) by Glucose or Fructose Induces Activation of the Sodium-Chloride Cotransporter (NCC)
Jessica P. Bahena-Lopez,1,2 Lorena L. Rojas,1 Silvana Bazua-Valenti,1 Norma H. Vázquez,1 Maria Chavez-Canales,2 María Castañeda-Bueno,1 Magdalena Madero,1 Gerardo Gamba,1,4 Molecular Physiology Unit, INCN/MS and IIB, UNAM, Mexico City, D.F, Mexico; 2Translational Medicine Unit, INICH and IIB, UNAM, Mexico City, D.F, Mexico; 3Instituto Nacional de Cardiologia Ignacio Chavez, Mexico City, D.F, Mexico; 4PPECAM, Facultad de Medicina, UNAM, Mexico City, Mexico.

Background: NCC is activated via the CaSR-WNK4-KSP4-SPAK pathway. Glucose and other sugars act as positive allosteric modulators of the CaSR. This might be relevant in the distal convoluted tubule (DCT), since glucose is reabsorbed proximally and frankovose delivery to the DCT depends largely on dietary intake. Here we studied if positive allosteric modulation of the CaSR by glucose/fructose induces NCC activation via CaSR-WNK4-KSP4.

Methods: We used 1) HEK-293 cells cotransfected with SPAK, WNK4 and/or CaSR and exposed to 0.5 mM extracellular Ca 2+ with 0, 5.5 or 25mM of glucose/fructose. 2) Furosemide administered in the food (100 mg/kg per day) for seven days. Total NCC and pNCC protein abundance was analyzed by Western Blot. 3) Urinary exosomes from male healthy volunteers to assess NCC abundance and activity after exposure to placebo, cinacalcet 30mg at time 0 (n=4) or 5% fructose with +/- calcilytic NPS2143 (30 mg/kg oral gavage). Renal proteins for western blot were extracted 3 h latter. 3) Urinary exosomes from male healthy volunteers to assess NCC activity after exposure to placebo, cinacalcet 30mg at time 0 (n=4) or 5% fructose with water intake (n=3).

Results: Stimulation of HEK293 cells with glucose or fructose increased SPAK phosphorylation, but only if both WNK4 and CaSR were present (p<0.01). In mice, we observed increased pNCC in kidneys, together with increased activation of WNK4-SPAK (p<0.01), after exposure to 20% fructose. Dapagliflozin also induced activation of SPAK and NCC. These effects of fructose and dapagliflozin were abrogated by co-administration of NPS2143 (p<0.01). Preliminary data on human subjects show that when compared to baseline, urinary exosome pNCC/NCC ratio (~1.0), cinacalcet induced a 77% increase in pNCC/NCC ratio (1.77, p=0.018) and fructose induced a near two-fold increase in pNCC/NCC ratio (2.69, p=0.006).

Conclusions: In vitro glucose or fructose increase SPAK phosphorylation in a CaSR-WNK4-dependent manner. In vivo glucose (dapagliflozin) or fructose increases NCC abundance and activity, via increased CaSR and data suggest a calcimimetic-like behavior for glucose or fructose in the DCT. This effect appears to be reproduced in humans and represents the
first evidence of NCC activation via CaSR with cinacalcet in humans. Our results suggest that the presence of glucose or fructose in DCT could increase the activity of NCC via CaSR-WNK-SPAK pathway.

**Cross-Talk Between Epithelial Sodium Channel and Basolateral K_4,1/-K_5,1 Channels in the Cortical Collecting Duct**

Oleg Palygin,1 Elena Isaeva,1 Vladislav Levenchok,1 Jerod S. Denton,3 Alexander Staruschenko.1,2 Medical College of Wisconsin, Milwaukee, WI; 3Clement J. Zablocki VA Medical Center, Milwaukee, WI; 4Vanderbilt University Medical Center; Nashville, TN.

**Background:** The growing body of evidence suggest that inwardly rectifying K⁺ (Kir) channels located on the basolateral membrane of epithelial cells in the distal nephron play a crucial role in K⁺ handling and blood pressure control, making these channels attractive targets for the treatment of hypertension. The purpose of the present study was to determine how the inhibition of basolateral K_4,1 homomeric or K_4,1/K_5,1 heteromeric K⁺ channels affects ENaC-mediated Na⁺ transport in the cortical collecting duct (CCD) principal cells.

**Methods:** Electrophysiological approaches were used to test the effect of fluoxetine, amitriptyline, and recently developed K_4,1 inhibitor, VU0134992, on the activity of K_4,1, K_4,1/K_5,1, and ENaC. Channel activity was recorded in CHO cells transfected with respective channel subunits, cultured polarized epithelial mLCCD cells, and native freshly isolated rat and human CCD tubules. To test the effect of pharmacological K_4,1/ K_5,1 inhibition on electrolyte homeostasis in vivo, Dahl salt-sensitive rats were injected with amitriptyline (15 mg/kg/day).

**Results:** We found that inhibition of K_4,1/K_5,1, but not K_4,1 channel, substantially suppresses both amiloride-sensitive I_sc in mLCCD cells and single-channel ENaC activity in principal cells of rat and human CCD tubules. Furthermore, we demonstrate that the injection of K_4,1/K_5,1 antagonist for three days leads to a significant drop in plasma K⁺ level, triggering sodium excretion, and diuresis.

**Conclusions:** These data uncover a putative mechanism underlying a renal control of blood electrolytes mediated by K_4,1/K_5,1 and introduce a new molecular target for the treatment of salt-sensitive hypertension.

**CIC-K2 Chloride Channel Determines Acid-Base Transport and Chloride Reabsorption in Intercalated Cells of the Collecting Duct**

Na’ulmeh Hassanzadeh Khayvat, Victor N. Tomilin, Oleg L. Zaika, Oleh Pochynuky. University of Texas John P and Katherine G McGovern Medical School, Houston, TX.

**Background:** Intercalated cells (ICs) of the collecting duct (CD) play a critical role in regulation of systemic acid-base homeostasis. In addition, ICs are capable of performing trans-cellular Cl⁻ reabsorption particularly during volume depletion. While the major apical membrane transport systems are well characterized, little is known about mechanisms and contribution of the basolateral membrane in both processes. Kidney Kir5.1 channels in the cortical collecting duct (CCD) are known to play a crucial role in K⁺ handling and blood pressure control, making these channels attractive targets for the treatment of hypertension. The purpose of the present study was to determine how the inhibition of basolateral Kir4.1 homomeric or Kir4.1/K5.1 heteromeric K⁺ channels affects ENaC-mediated Na⁺ transport in the cortical collecting duct (CCD) principal cells.

**Methods:** Cross-talk between epithelial sodium channel and basolateral K_4,1/-K_5,1 channels in the cortical collecting duct was to determine how the inhibition of basolateral K_4,1 homomeric or K_4,1/K_5,1 heteromeric K⁺ channels affects ENaC-mediated Na⁺ transport in the cortical collecting duct (CCD) principal cells.

**Evolutionary Conserved TLDc Domain Defines a New Class of V-ATPase Interacting Proteins**

Amity F. Eaton, Dennis Brown, Maria Merkulova. Program in Membrane Biology Massachusetts General Hospital; Boston, MA.

**Background:** Kidney-specific V-ATPase regulates acid-base homeostasis, and its dysfunction causes distal renal tubular acidosis (dRTA). We recently found that nuclear receptor coactivator 7 (Ncoa7) interacts with kidney V-ATPase, and its deletion in mice resulted in dRTA. Ncoa7 belongs to a group of proteins playing a role in the oxidative stress response, that contain the evolutionarily conserved TLDc domain. We found that another of these proteins, Oxr1, also interacts with the V-ATPase. Here we ask if other proteins from this family, i.e. Tclc1d4, Tclc1d4 and Tclc1d2 interact with V-ATPase in kidney and if their TLDc domains mediate this interaction.

**Methods:** Interaction between endogenous , Tclc1d4, Tclc1d4 and Tclc1d2 and V-ATPase was assessed by co-immunoprecipitation (co-IP) and western blotting of mouse kidney lysates. Interaction with the V-ATPase was also studied by GST pull-downs from kidney lysates using purified GST-tagged wild-type TLDc domains of Ncoa7, Oxr1, Tclc1d4, Tclc1d4, and Tclc1d2, or mutant TLDc domains of Ncoa7 (G802A, G815A, R817A, G845A, G896A, L926A, E938A) followed by western blotting by B1.

**Results:** In Co-IP studies of mouse kidney lysates we found that endogenous Tclc1d4 interacted with the B1 subunit isoform of V-ATPase, but not with the more ubiquitous B2 subunit isoform. However, we did not detect any interaction between V-ATPase and endogenous Tclc1d4 or Tclc1d2 in Co-IPs, possibly due to low sensitivity of the anti-Tlclc1 and anti-Tlclc2 antibodies. Additionally, we found that the purified TLDc domains of Ncoa7, Oxr1 and Tclc1d4, but not Tclc1d4 or Tclc1d2, interacted with V-ATPase in GST pull-downs. Finally, the G815A, G845A and G896A mutants in evolutionarily conserved regions of the Ncoa7 TLDc domain did not interact with V-ATPase, L926A and E938A mutations resulted in a decreased interaction, while S817A or the non-conserved G802A mutation (used as a positive control), did not decrease interaction at all.

**Conclusions:** In the kidney, Tclc1d4 and possibly Tclc1d2, as well as Ncoa7 and Oxr1, interacted with V-ATPase and may play a role in the V-ATPase-dependent regulation of renal acid-base homeostasis. We conclude, that the TLDc motif is a protein-protein interaction domain that defines a new class of V-ATPase interacting regulatory proteins. The evolutionarily conserved amino acids within the TLDc domain of Ncoa7 are critical for its interaction with the V-ATPase.

**Lysine Acetylation of Aquaporin 3 Affects Water Permeability of the Collecting Duct**

Kelly A. Hyndman, Parker R. Davis, Luciano D. Mendoza. The University of Alabama at Birmingham School of Medicine; Birmingham, AL.

**Background:** We recently reported that there are > 400 proteins in the inner medullary collecting duct (IMCD) that are post-translationally lysine acetylated (ac), including the basolateral water channel, aquaporin-3 (AQ3P). The purpose of this study was to determine if lysine acetylated AQ3P (acAQ3P) affects water permeability.

**Methods:** We generated an antibody to detect acAQ3P and found acAQ3P localized to the basolateral membrane of the cortical and outer medullary CD in mice and human kidney biopsies. In mice, following 24 h of water deprivation, acAQ3P was also found in the IMCD. Next, we developed AQ3P K point mutation plasmids; an acetylated mimetic K282Q (AQ3P K282Q), and a deacetylated mimetic K282R (AQ3P K282R). These were stably expressed in vasopressin-responsive mouse cortical CD cells and loaded with a volume sensitive dye. Finally, using CRISPR/CAS we engineered whole body point mutation mice. The AQ3P K282Q, AQ3P K282R and littermate controls AQ3P WT/WT were placed on standard chow and: 1) ad lib water, 2) 5% sucrrose water for hydration, or 3) 24 h water deprivation and urine flow measured.

**Results:** Following osmotic stimulus, we found AQ3P WT/WT cells had the highest water permeability followed by the AQ3P K282Q cells and the AQ3P K282R cells. From our mutant mice, as adults, control and AQ3P WT mice had similar urinary flow on all protocols. However, the AQ3P K282R mice produced double the urine on protocols 1 and 2. Thus, maintenance of deacetylated AQ3P enhances fluid excretion under normal and hydrated conditions. To further determine whether the increased urinary flow was due to impaired water permeability, we immunolocalized AQ3P and AQ3P under ad lib conditions. AQ3P WT/WT mice had enhanced expression of AQ3P in the basolateral membrane, and reduced AQ3P expression in the apical membrane. In contrast, the AQ3P K282R mice had diffuse AQ3P localization in the CD, with no obvious change in AQ2P.

**Conclusions:** Together, these preliminary data suggest that acAQ3P promotes localization to the basolateral membrane of the CD and supports the hypothesis that acAQ3P could serve as an important regulator of CD function in fluid homeostasis.

**Funding:** NIDDK Support
Role of TRPC3 in the Control of Osmosensitivity and Renal Water Handling in the Mouse Collecting Duct

Victor N. Tomlin,1 Mykola Mamenko,2 Nagmeh Hassanazadeh Khayyat,3 Oleg L. Zaika,1 Oleh Pochynyuk,1 University of Texas John P and Katherine G McGovern Medical School, Houston, TX; 2Augusta University Medical College of Georgia, Augusta, GA.

Background: Kidney is central in the control of systemic water balance of the organism. AVP facilitates aquaporin 2 (AQP2) translocation to the apical plasma membrane to augment water permeability of the collecting duct (CD). Inability of CD to respond to AVP signal causes NDI leading to polyuria, dehydration and thirst. Stimulation of CD water reabsorption by AVP can only occur in the presence of positive osmotic difference between the cytosol and luminal fluid. Extracellular hypotonicity increases [Ca2+]i and causes cell swelling due to AQP2-driven water influx. The role of the osmosensitive [Ca2+]i, signaling in renal water transport and urinary concentration remains unknown.

Methods: The employed techniques include simultaneous measurement of [Ca2+]i dynamics with Fura 2 and the rate of cell swelling as a readout of the AQP2-dependent water reabsorption in freshly isolated split-opened CD of wild type and TRPC3−/− mice; immunofluorescent detection of AVP-induced AQP2 trafficking to the apical membrane and metabolic cage balance studies.

Results: TRPC3 is a Ca2+-permeable mechanoo-activated channel abundantly expressed in the CD. We found that TRPC3 deletion or pharmacological inhibition precluded [Ca2+]i elevations induced hypotonicity and severely slowed the rate of cell swelling indicative of diminished water transport in the CD. TRPC3−/− and WT mice had comparable serum and urine osmolality in control conditions, but exhibited a significantly greater bodyweight loss, and urinary volume excretion after 24 h of water deprivation (WD) despite higher AVP levels when compared to WT. Furthermore, osmosensitive [Ca2+]i elevations were greatly increased in CD from WT but not TRPC3−/− animals after 24 h WD. Greatly accelerated rate of cell swelling was observed in WT, while it was only modestly increased in TRPC3−/− mice under the same condition. Using immunofluorescent microscopy, we found that AQP2 translocated to the apical plasma membrane in WT, while maintaining mostly cytosolic localization in TRPC3−/− after 24 h WD. These results show a significant role of TRPC3 in osmosensitivity and regulation of AVP-dependent AQP2 trafficking in the CD. TRPC3 deletion compromises systemic water balance producing an NDI-like phenotype.

Distinct Cellular Osmoregulatory Response in the Skin of Patients with Disturbed Glycosaminoglycan Biosynthesis

Iettta J. Oppedaal,1 Elke Wensing,2 Nienke M. Roije,3 Rik H. Olde Engberink,4 Bert-jan van den born, Jan Aten,5 LiFert Vogt.6 Amsterdam UMC Locatie AMC, Amsterdam, Netherlands.

Background: Several studies have shown that during high Na+ diet (HSD) sodium content of the skin increases. Nuclear factor of activated T cells 5 (NFAT5) is a hypertonicity-driven transcription factor responsive to environmental osmotic changes. Sulfated glycosaminoglycans (GAGs) have been suggested to neutralize Na+-induced hypertonic effects by facilitating a dynamic non-osmotic Na+ storage compartment. Patients with diabetes mellitus type 1 (DM1) and hereditary multiple exostoses (HME) were separated by a 7-to-10-day washout period. After each diet, blood samples and skin biopsies were obtained. With immunohistochemistry, skin NFAT5 expression and GAG sulfation patterns were semi-quantitatively analyzed by researchers blinded for diet status. Disturbances in NFAT5 expression and GAG sulfation patterns were found, indicating a significant role of TRPC3 in osmosensitivity and regulation of AVP-dependent AQP2 trafficking in the CD. TRPC3 deletion compromises systemic water balance producing an NDI-like phenotype.

and LV 1-47 (9.1% vs 4.3%, P=0.636) were high among patients with combined renal and cancer. In this specific compartment of kidney, patients with renal amyloidosis (LV 6-57 was more likely to have G-AL (42.9% vs 26.6%, P=0.399), and LV 1-51 was associated with V-AL (19.2% vs 3.3% vs 0, P=0.019). Patients with LV 2 family had a tendency at increased risk of developing into ESRD compared with other LV families (HR=0.27).

Conclusions: IGVL germline gene usage was associated with organ tropism, renal amyloid deposition patterns and renal survival in Chinese patients with AL amyloidosis. Whereas, the results were preliminary and exploratory, and should be proved in a large cohort of AL amyloidosis patients.

Treatment of AL Amyloidosis with Daratumumab Monotherapy
Rebecca Capogna, Savina Sciortino, Dario Roccatello. Nephrology and Dialysis Unit & CMID (Center of Research of Immunopathology and Rare Diseases), Coordinating Center of the Network for Rare Diseases of Piedmont and Aosta Valley, San Giovanni Bosco Hub Hospital of Turin, and Department of Clinical and Biological Sciences, University of Turin, Turin, Italy, Turin, Italy.

Background: Immunoglobulin light chain amyloidosis (AL) is characterized by poor outcome. Daratumumab (D) is a first in class anti CD38 human antibody (IgG1k) which proved to be effective in combination with bortezomib in MM refractory to conventional bortezomib-based regimens. Its effectiveness and safety in the treatment of AL amyloidosis is under study. This study reports the experience with D monotherapy in a series of severe patients (pts) with AL amyloidosis and multiorgan and biopsy-proven renal involvement.

Methods: Five pts, mean age 64 years were treated with D following antibody testing and extended RBC antigen phenotyping. Treatment protocol was as follows: 16 mg/kg D i.v. administered weekly for 8 weeks, then every 2 weeks (8 doses), and then monthly for 1 year.

Results: In pt #1, in dialysis, who was refractory to conventional therapies D administration resulted in normalization of the FLC ratio with disappearance of serum M-component and Bence-Jones (BJ) proteinuria. In pt #2 who had a relapsing disease, D treatment resulted in a rapid decrease of proteinuria and N-terminal propeptide (NT-pro-BNP) levels with disappearance of serum M-component and BJ proteinuria and normalization of the FLC ratio. Pt #3 was treated front-line. He had an impressive decrease of proteinuria and NT-proBNP levels with normalization of FLC ratio and disappearance of serum M-component. In pt #4, who was intolerant to conventional regimens, D therapy resulted in decrease in proteinuria, disappearance of serum M-component and improvement in the FLC ratio, which were paralleled by a reduction of NT-proBNP levels. Pt #5 had a relapsing disease. D achieved a decrease of proteinuria, a decrease of serum M-component with increase of FLC ratio. This was the only patient who experienced an infusion reaction during the first dose. The 4 pt with still preserved renal function also showed renal response with scr improvement or stabilization and a decrease in proteinuria levels. These data were paralleled by the reduction of NT-proBNP values in the 3 pts with cardiac involvement.

Conclusions: Daratumumab monotherapy resulted in the disappearance of M-proteins in every pt, FLC ratio normalization in 4 out of 5 subjects and impressive decrease of proteinuria and pro-BNP values proving to be an effective therapeutic option for pretreated naïve patients with severe AL with renal involvement.

Immune Checkpoint Inhibitor Use in Kidney Transplant Recipients: A Multicenter Study
Naoko Murakami,1 Leonardo V. Riella,2 Rimda Wanchao,2 Vinay Nair,2 Kenar D. Jhaever.1 Immune Checkpoint Inhibitor in Solid Organ Transplant Consortium ‘Brigham and Women’s Hospital, Boston, MA; 2Northwell Health, Great Neck, NY.

Background: Immune checkpoint inhibitors (ICIs) significantly improved the survival in many cancers, but the data on survival benefit in KTx recipients are lacking. ICIs are reported to be associated with higher acute rejection rate in KTx recipients, but the risk factors of ICI-associated rejection are not fully understood.

Methods: We conducted a multicenter observational study to investigate the clinical characteristics of ICI-associated rejection and the survival outcomes of KTx recipients treated with ICI. 66 KTx patients with a functioning allograft at the time of ICI initiation were collected from 18 institutions. In addition, historical control groups of KTx recipients with advanced stage melanoma (AICC stage III-IV, n=17) and cutaneous squamous cell carcinoma (cSCC; AJCC stage III (unresectable)-IV, n=23), who could be considered as potential ICI candidates, were collected to compare the overall survival (OS).

Results: In ICI cohort, median age was 64, male dominant (83%) and transplant to ICI initiation was median 11 years. cSCC was the most frequent malignancy (n=22), followed by melanoma (n=28) patients (42.4%) experienced rejection, of which 19 (64.2%) lost allograft and returned to dialysis. Median time from ICI initiation to rejection was 26 days. In biopsy-proven rejection (n=13), both mixed acute cell and antibody-mediated rejection (n=7, 53%) and acute cell-mediated rejection (n=6, 47%) were seen. By Chi square test, mTOR inhibitor use (P=0.012) and the use of higher number of immunosuppression drugs (P=0.009) were associated with higher risk of rejection. For both melanoma and cSCC cohort, ICI groups experienced higher rejection rate (57% and 40%, for melanoma and cSCC, respectively), compared to non-ICI control groups (12% and 4.3%), suggesting the higher rejection rate in ICI groups was not solely explained by reduction in immunosuppression. OS didn’t show statistical difference in melanoma cohort (log rank test P=0.22), but OS was significantly longer in cSCC cohort (log rank test P=0.015), when compared ICI vs non-ICI control groups.

Conclusions: Our multi-center study provides a novel data on the survival benefit and the risk factors of rejection in KTx recipients with ICI use compared to non-ICI control groups.

TH-OR35
Daily Caffeine Consumption and Risk of AKI Related to Platinum-Salt Chemotherapy: A Prospective Cohort Study
Aubile Hamroun,1 Decaestecker Antoine,2 David Blum,2 Christelle Cauffiez,2 François Glowacki.1 1Centre Hospitalier Regional Universitaire de Lille, Lille, France; 2Universite de Lille, Lille, France.

Background: Although their efficacy has been well-established in Oncology, the use of platinum salts remains limited due to the occurrence of acute kidney injury (AKI). Caffeine has been suggested as a potential pathophysiological actor of platinum salt-induced AKI, through its hemodynamic effects. This work aims to study the association between caffeine consumption and the risk of platinum salt-induced AKI.

Methods: We conducted a single-center prospective cohort study that has included 108 consecutive thoracic cancer patients receiving a first-line platinum-salt chemotherapy between January 2017 and December 2018. Before the first course of chemotherapy, they were all invited to fill in a previously validated auto-questionnaire, designed for a detailed evaluation of their daily caffeine consumption (mg/day). The association of daily caffeine consumption with the risk of platinum-salt induced AKI was estimated by cause-specific Cox proportional hazard model adjusted for several known confounders (baseline renal function and serum albumin level, nature and dose of platinum-salt, tobacco exposure, and Performans status).

Results: Overall, 34 patients (31.5%) (mean age 61.7 years, 65% men, 80% tobacco users) experienced a platinum salt-induced AKI (67±21) and 47 (43.5±5) died during follow-up (6.2 months [3.4; 8.4]). The group of high-caffeine consumption (a 386mg/day) had a twice higher risk of AKI (HR=2.12 [1.01; 4.45]) in the fully adjusted model. The cumulative incidence of AKI (considering the competing risk of death) was also significantly increased in the high-caffeine consumption group (p=0.03, see figure 1).

Conclusions: In a population of thoracic cancer patients, the group of high-caffeine consumption was exposed to a significantly higher risk of platinum salt-induced AKI.

TH-OR36
Kidney and Cancer Outcomes with Standard vs. Kidney Protective Chemotherapy Regimens for First-Line Treatment of Metastatic Urothelial Carcinoma
Gabrielle Côte,1 Husam A. Alqaisi,1 Srikala S. Sridhar,2 Abhijat Kitchlu.2 1University of Toronto, Toronto, ON, Canada; 2Toronto General Hospital, Toronto, ON, Canada; 1Princess Margaret Hospital Cancer Centre, Toronto, ON, Canada.

Background: Cisplatin-based combination chemotherapy regimen is the optimal initial treatment for metastatic urothelial carcinoma, but kidney function eligibility and nephrotoxicity are treatment-limiting for many patients. For patients unfit to receive cisplatin, other options include alternative administration schedules (e.g. split dose cisplatin), carboplatin-based regimens and non-platinum regimens. The aims of this study were to compare cancer outcomes and incidence of acute kidney injury (AKI) during treatment among 3 regimens of chemotherapy.

Methods: We conducted a single-center retrospective study of patients receiving first-line chemotherapy for metastatic urothelial carcinoma (2005-2019). We compared standard gemcitabine-cisplatin (gem-cis) to: 1) gemcitabine-cisplatin split dose regimen (split) with cisplatin divided over day 1 and 8, and 2) combination of gemcitabine-carboplatin or single-agent gemcitabine (gem-carbo). We used Fine and Gray hazard model. The cumulative incidence of AKI (considering the competing risk of death) was 26 days. In biopsy-proven rejection (n=13), both mixed acute cell and antibody-mediated rejection (n=7, 53%) and acute cell-mediated rejection (n=6, 47%) were seen. By Chi square test, mTOR inhibitor use (P=0.012) and the use of higher number of immunosuppression drugs (P=0.009) were associated with higher risk of rejection. For both melanoma and cSCC cohort, ICI groups experienced higher rejection rate (57% and 40%, for melanoma and cSCC, respectively), compared to non-ICI control groups (12% and 4.3%), suggesting the higher rejection rate in ICI groups was not solely explained...
Results: We identified 183 patients (98 gem-cis, 32 split and 53 gem/gem-carbo). Median age was 67.4 years (range 27-89 yrs). Median number of cycles was 7 (IQR: 5-11). MDRD estimated GFR was 78 mL/min/1.73m² (IQR: 66-91) in gem-cis, 64 (48-77) in split, and 45 (33-57) in gem/gem-carbo. Patients receiving split and gem/gem-carbo were older, had worse performance status, and hypertension was more frequent. Split and gem/gem-carbo regimens were associated with higher mortality and progressive disease relative to gem-cis when adjusted for age, baseline eGFR, ECOG, hypertension and diabetes with hazard ratio (HR) of 1.56 (95%CI: 1.04-2.34; p = 0.03) and 2.02 (95%CI: 1.36-3.01; p = 0.01) respectively. Median time to progressive disease was 242 (IQR: 137-444), 182 (122-279) and 117 (72-207) days in gem-cis, split and gem/gem-carbo groups. There was no significant association between regimen type and AKI with HR of 1.32 (95%CI: 0.62-2.81; p = 0.47) and 0.98 (95%CI:0.46-2.09; p = 0.96) for split and gem/gem-carbo groups versus gem-cis.

Conclusions: Kidney protective chemotherapy regimens were associated with increased disease progression and mortality, without a significant difference in AKI. Alternative kidney protective strategies are needed for patients with CKD and urothelial cancer.

Risk Factors for Nephropathy with High-Dose Methotrexate (HDMTX) in Haematological Malignancies

Background: HDMTX is a key component for treatment of haematological malignancy. Nephrotoxicity remains a significant risk factor for HDMTX and therefore, hypotension, diuretics and urinary alkalisation are employed in its management but despite these measures, nephrotoxicity remains 2-12%. Determination of risk factors is key in order to further stratify and ameliorate the risk of acute kidney injury.

Methods: A retrospective review of the electronic medical record was conducted to identify patients with leukaemia or lymphoma who received HDMTX from 1/1/2002 to 12/31/18. We characterised the incidence of AKI, using the acute kidney injury network criteria, and the time to AKI. We assessed key baseline demographics, underlying malignancy, delivered MTX dose, and previous nephropathy. Significant factors on univariate analysis were further assessed on Multivariate analysis. Analysis was performed on Minitab.

Results: We identified 3091 cycles of HDMTX with lymphoma accounting for 90.7% of cases. The incidence of AKI was 19.1% in the lymphoma cohort and 13.6% in the leukaemia cohort (p = 0.023). The median time to AKI grade shortened with higher severity of AKI (p < 0.001). In those with AKI N3, creatinine increased to this level in a median time of 1 day. All patients requiring dialysis (n=7) developed an AKI at day 1 post HDMTX. Univariate analysis revealed age (p = 0.022), Gender (p < 0.001), higher BSA (p < 0.001), type of malignancy (p = 0.023), nephropathy on previous dose (p = 0.001), cycle number (p < 0.001), GFR by Cockcroft-Gault (p = 0.016) and 48-hour MTX level (p = 0.001). There was no association between AKI and MTX dose (p = 0.225), or GFR by MDRD (p = 0.497). Multivariate analysis revealed increased age (p = 0.001), male Gender (p = 0.001), Lymphoma (p < 0.002), previous AKI (p < 0.001), cycle number (p = 0.032), and 48-hour MTX level (p < 0.001) to be significant risk factors for nephropathy.

Conclusions: Nephrotoxicity remains a significant complication with HDMTX despite current measures. The high AKI occurs early post HDMTX and therefore, risk stratification is vital. Our study identified key risk factors as older, male, AKI on previous dose, diagnosis of lymphoma, elevated 48-hour MTX level and earlier cycle.

Characterizing the Risk of Development of Proteinuria with Bevacizumab Therapy

Thomas L. Guererro Nunez, Abigail B. Shoben, Jason Prosek. The Ohio State University Wexner Medical Center, Columbus, OH.

Background: Bevacizumab is a well-known cause of proteinuria. There are multiple hypotheses regarding mechanism that involve the VEGF receptor, nitric oxide metabolism and increased arteriolar glomerular pressure. The most accepted explanation is that Bevacizumab induces thrombomodulin GPIbαopathy. However, there is no current model or description of potential risk factors to identify at-risk patients who may need close monitoring. The aim of this study was to identify baseline and treatment dependent factors that impact proteinuria development.

Methods: 1224 patients on Bevacizumab were sampled, with 714 having at least one P/Cr value needed for analysis. The time frame in which data was collected was 600 days. Data sampled included, age, baseline P/Cr, status of type 2 diabetes, chronic kidney disease stage 3, hypertension, use of Angiotensin Converting Enzyme inhibition, and sequential P/Cr values. Cox proportional hazard models were used to assess differences in the instantaneous risk of the event by categories, no violations of proportional hazard models were observed. The primary endpoint was defined as a P/Cr of 1.0 g/g, indicative of progression of proteinuria.

Results: A baseline P/Cr above 0.25 (HR 5.83, p = 0.001), Type 2 Diabetes (HR 1.68, p = 0.074), and CKD III (HR 3.25, p = 0.007) were associated with an increased risk of developing proteinuria, while age, hypertension (HR 1.11, p = 0.86), a baseline P/Cr < 0.25 (HR 1.04, CI95%:3,204, p = 0.001) were not. ACE inhibitors had the following association: (Lisinopril; {10 mg, 20 mg, > 20mg}, HR {1.47, 1.76, 1.67}, p = 0.67). Treatment duration was also shown to increase risk of the primary endpoint. The cumulative incidence was 23% after 600 days of treatment.

Conclusions: A presence of a baseline P/Cr greater than 0.25 g/g, type 2 diabetes, and CKD III, all showed a significant increase in risk of progressing to proteinuria of greater than 1.0 g/g. Age and hypertension were not associated with increased risk. Due to lack of randomization and incomplete data, further analysis is needed.

---

TH-OR40

Assessment of Estimated Glomerular Filtration Rate in a Cohort of 1200 Cancer Patients Using Serum Creatinine and Cystatin C

Veronica T. Costa e Silva,1 Luiz A.Gil, Renato A. Caires,1 Elerson Costalonga,1 George B. Coura-Filho,2 Gilberto Castro,1 Lesley A. Inker,2 Paul Mathew,2 Andrew S. Levey,2 Emmanuel A. Burdmann,3 1 São Paulo State Cancer Institute - University of São Paulo School of Medicine, São Paulo, Brazil; 2Tufts Medical Center, Boston, MA; 3University of São Paulo School of Medicine, São Paulo, Brazil.

Background: eGFR using creatinine (eGFRcr) with the CKD-EPI equation is recommended as the first test for GFR evaluation in clinical practice, but CG equation is commonly used for the prescription of chemotherapy, despite increasing evidence of its inaccuracy compared to measured GFR (mGFR). eGFR using cystatin C (eGFRcys)
is less influenced by muscle mass or nutritional status, and eGFR using both markers (eGFRcys) is more accurate than either eGFRcr or eGFRcr-cys, but not widely assessed in cancer patients. Our aim is to compare the performance of eGFR equations (Table) in cancer patients compared to mGFR.

**Methods:** This analysis is a cross-sectional evaluation of a prospective cohort of cancer patients in treatment at the ICESP. mGFR was determined by plasma clearance of 51Cr-EDTA indexed for body surface area. mGFR was the least accurate and was least accurate. eGFRcys underestimated mGFR and eGFRcr-cys had minimal bias and was the most accurate of all equations (Table).

**Conclusions:** All eGFR equations overestimated mGFR in our study. CG was the least accurate and should not be preferred over CKD-EPI. eGFRcr-cys is more accurate and can be used as a confirmatory test.

**TH-OR41**

**Hematopoietic-Specific Melanocortin 1 Receptor Signaling Protects Against Crescentic Glomerulonephritis and Mediates the Beneficial Effect of Melanocortin Therapy**

Xuejing Guan,1,2 Rong Zhou,1 Lance D. Dworkin,1 Rujun Gong,1 Department of Medicine, Division of Nephrology, University of Toledo College of Medicine, Toledo, OH; 2Department of Nephrology, Tanggu Hospital, Tongji University School of Medicine, Shanghai, China.

**Background:** Emerging evidence suggests that melanocortin 1 receptor (MC1R) signaling may contribute to the beneficial action of melanocortins in glomerular diseases. However, whether hematopoietic MC1R signaling is implicated is unknown.

**Methods:** MC1R mutant (e/e) or wild-type (WT) mice were inoculated with rabbit nephrotoxic serum (NTS) and treated with melanocortins, including the Repository Corticotropic Inversion (RCI, Acthar® Gel, Mallinckrodt ARD, LLC), NDP-MSH, and the MC1R selective agonist MS05. Some mice received adoptive transfer of syngeneic bone marrow-derived cells (BMDC) beforehand. Kidney function and injuries were evaluated.

**Results:** Upon NTS injury, e/e mice developed more severe crescentic glomerulonephritis than WT mice, featured by heavier proteinuria, higher serum creatinine levels and exacerbated renal lesions, including crescent formation, renal inflammatory infiltration and fibrosis as well as podocyte damage, marked by loss of expression of podocyte homeostatic markers in glomeruli. Melanocortin therapy substantially improved renal injury in WT mice and this protective effect was blunted in e/e mice. In contrast, adoptive transfer of BMDC derived from WT mice to e/e mice markedly ameliorated NTS nephritis and reinstated the therapeutic efficacy of melanocortins in e/e mice. Mechanistically, the beneficial action of WT BMDC in e/e mice was associated with diminished glomerular deposition of autologous anti-rabbit IgG and reduced fixation of C5b-9 along glomerular capillary loops, entailing a regulatory effect of BMDC-specific MC1R signaling on humoral immune response to NTS antigens. In addition, melanocortin therapy prominently tilted macrophage polarization towards the anti-inflammatory M2 phenotype in NTS-injured kidneys in WT mice. MC1R signaling is likely involved in this modulation of macrophage behavior, because MC1R was evidently expressed in bone marrow-derived macrophage (BMM) prepared from WT mice but absent from e/e BMM. Furthermore, MS05 diminished M1 phenotypes and promoted M2 polarization in M1-primed WT BMM but not e/e BMM, thus denoting a pro-M2 skewing effect of MC1R signaling.

**Conclusions:** Hematopoietic MC1R signaling attenuates NTS nephritis via, at least in part, regulation of humoral immune response and a pro-M2 skewing effect on macrophage polarization.

**Spatial Transcriptomics (ST): Integrating Molecular Profiles with Histomorphology in Kidney Tissue Sections**

Arti M. Raghubar,1 Duy T. Pham,1 Xiao Tan,1 Laura F. Grice,1 Pui Yeng Lam,1 Joanna Crawford,1 Stacey Andersen,1 Sohye Yoon,1 Samuel E. Holland,1 Leo Francis,1 Alexander N. Combes,2 Andrew J. Kassianos,3 Helen G. Healy,1 Quan Nguyen,1 Andrew J. Mallett.1 1The University of Queensland, Saint Lucia, QLD, Australia; 2Monash University Monash Biomedical Discovery Institute, Clayton, VIC, Australia; 3Royal Brisbane and Women's Hospital, Herston, QLD, Australia; 4The University of Queensland Institute for Molecular Bioscience, Saint Lucia, QLD, Australia.

**Background:** Advances in sequencing methods have increased available molecular information on dissociated cells and tissues. Spatially linking this molecular information with histomorphology is needed to understand a complex organ like the kidney, in both health and disease.

**Methods:** Here we used the commercially available 10x Genomics ST platform to investigate the spatially resolved transcriptome expressions in fetal (n=2), adult (n=3) and female (n=3) mouse kidney and a healthy human cortical frozen kidney tissue sections. We utilized Space Ranger (10x Genomics), Scour and stLearn analysis pipelines to explore the spatial transcriptome expression within the kidney tissue sections. Furthermore, we confirmed the robustness of our ST data against matched publicly available mouse and human kidney scRNA-seq data.

**Results:** We identified a unique transcriptome plasticity in fetal and adult mouse kidneys, and healthy human cortical kidney tissue. Further dimensional reduction identified transcriptome clusters which correlated with distinct developing kidney structures in fetal mouse kidney tissue, functional cortical and medulla regions in adult mouse kidney tissue, and scarred and non-scarred regions in human cortical kidney tissue.

**Conclusions:** ST is a non-dissociative sequencing and imaging method which allows molecular profiles to be integrated with histomorphology of frozen kidney tissue sections. This provides a novel opportunity to inform physiological and non-physiological conditions at the cell-cell, nephron and tissue levels.

**Funding:** Government Support - Non-U.S.

**Automated Atubular Glomeruli Detection Using 3D Glomerular Quantification Algorithms**

Haichun Yang,1 Ruining Deng,2 Yuankai Huo,2 Agnes B. Fogo.3 1Vanderbilt University Medical Center, Nashville, TN; 2Vanderbilt University, Nashville, TN.

**Background:** Atubular glomeruli are associated with decreased glomerular filtration rate and kidney disease progression. To identify atubular glomeruli requires serial sectioning with whole slide imaging (WSI). Atubular glomeruli have or does not have connection to the proximal tubule. This process is labor intensive and very time-consuming, limiting its use. We aimed to test feasibility of automatically detecting atubular glomeruli by using Multi-Object Association for Pathology in 3D (Map3D).

**Methods:** The Map3D was created including a glomerular detection algorithm, dual-path multi-object tracking algorithm, and pixel-wise large-scale glomerular association algorithm across routine serial sectioning with whole slide imaging (WSI). Atubular glomeruli counting was done in human mouse kidneys, and 3 mice with diphtheria toxin (DT)-mediated proximal tubule-specific injury in mice with tubular cell expression of the DT receptor, and 4 mice with patchy tubulo-interstitial fibrosis induced by folic acid (FA). Data from this automated approach was compared with standard manual assessment detailed above and correlated with functional and structural parameters.

**Results:** The Map3D substantially reduced the time needed for average atubular glomerular counting per sample (30 min Map3D vs. 30 hours human). Atubular glomerular size were smaller than normal glomeruli. The number of complete (i.e. from pole to pole) glomeruli assessed increased by 25.6% using GQuant-3D (68±8.8 per mouse) vs human counting (72±2.7 per mouse). GQuant-3D recognized 14.3±5.5 atubular glomeruli per mouse sample, slightly less (83%) than the 16.7±4.0 atubular glomeruli per mouse sample.

The Map3D was created including a glomerular detection algorithm, dual-path multi-object tracking algorithm, and pixel-wise large-scale glomerular association algorithm across routine serial sectioning with whole slide imaging (WSI). A Deep-Learning Approach to Kidney Donor Frozen Sections
Richard Davis,1,2 Xiang Li,1 Nao Souma,1 Zehan Wang,1 Yuefei Xu,1 G. Sotolongo,1,2 Jonathan Bell,1 Matthew J. Ellis,1 David N. Howell,1 Xin Li,2 Kyle Li,1 Laura Barisoni,1 Duke University School of Medicine, Durham, NC; 2Duke University Health System, Durham, NC; 3Duke University, Durham, NC; 4Nanjing University Medical School Affiliated Nanjing Drum Tower Hospital, Nanjing, China.

Background: Pre-implant assessment of donor kidney biopsies to determine allograft
viability is often performed by non-renal pathologists, and carries limited accuracy and
reproducibility. The purpose of this work is to develop a deep learning (DL) method for
the classification of relevant histologic primitives from donor biopsies as an aid tool to
pathologist. Non-sclerotic and sclerotic glomeruli were selected to test this approach.

Methods: A total of 268 frozen sections stained with hematoxylin and eosin (H&E) from
cadaveric donor kidney biopsies (128 performed at Duke and 140 at outside
institutions) were scanned into whole slide images (WSI) at 40x (Leica Biosystems
AT). All WSI images were divided into two datasets for training and validation cohorts
(0.8:0.2) and non-Duke WSIs were used as testing dataset. QuPath was employed to
manually annotate non-sclerotic (22767) and sclerotic glomeruli (1366). A 9-layer
convolutional neural network (CNN), based on the common U-NET architecture, was
developed in Python, using randomly selected 256x256 patches from WSI and input
augmentation to boost generalization performance. CNN hyper-parameters were tuned
via cross-validation. The CNN’s performance was quantified based on the Dice Similarity
Coefficient (DSC) between the predicted and ground-truth annotations.

Results: For non-sclerotic glomeruli, the average DSC for train, validation and
testing was 0.93, 0.91, 0.90 respectively. The F1, Recall, and Precision for testing was
0.93, 0.96, 0.90 respectively. For sclerotic glomeruli, the average DSC for train,
validation and testing was 0.89, 0.87, 0.83 respectively. The F1, Recall, and Precision for
testing was 0.87, 0.93, 0.81 respectively. The CNN has higher performance in the regions
of high glomerular density and occasionally, outperformed the pathologists in glomerular
detection. Lower model performance was observed in the presence of image artifacts and
in regions of low glomerular density.

Conclusions: DL applied to image analysis may help standardize and improve
accuracy and reproducibility of quantification of histologic primitives in kidney frozen
sections, enabling the establishment of synergistic machine-human protocols that can
be deployed in clinical practice. The development of DL-segmentation of other relevant
histologic primitives is in process.

Evaluation of a Direct-to-Digital Histology Method for Rapid Evaluation of Kidney Biopsies
Sudhir Perinchery, Randy L. Luciano, Gilbert W. Moeckel, Richard Torres.
Yale University School of Medicine, New Haven, CT.

Background: Digitization of clinical renal biopsy histology is motivated by the
importance of early intervention in acute kidney conditions, assessment by remotely-
based experienced nephropathologists, and application of emerging computerized quantitative
evaluation tools. Despite the interest, image quality and workflow impact are concerns
for digital renal pathology. A newly developed tool for rapid, slide-free microscopic
image preparation called Clearing Histology with MultiPhoton Microscopy (CHiMP) has
demonstrated high efficiency and high quality morphology for diagnostic review in renal
disease in a research environment. We sought to commence clinical validation of CHiMP
for renal biopsy in routine use. We developed an objective scoring system based on
downstream special stains and ability to detect a broad range of clinically relevant pathological lesions in renal biopsies.

Methods: Kidney core biopsies were procured from 50 consented individuals
undergoing renal biopsy for any reason and CHiMP processing was integrated into the
clinical workflow, using previously-described methods. Images were obtained from
entire core biopsies with a prototype fast, high resolution, multiphoton microscope
system (Applivate Technologies, Washington, DC) and visualized with web-
based software. Samples were subsequently processed using standard methods for clinical
interpretation under transmitted-light microscopy, including special stains. A subset of 20
core biopsies underwent detailed morphologic feature detection analysis and quantitative
lesion comparison.

Results: Diagnostic quality remotely-reviewable renal images of 10-16 digital
slices were available within < 3 hours of receipt. H&E detected morphologic findings
were equally detectable in digital images compared to physical, paraffin-embedded
sections including cases showing tubular injury, proliferative glomerulonephritis,
glomerular degeneration disease, and interstitial nephritis. No significant negative effects on
downstream processing were identified.

Conclusions: CHiMP can be used in rapid morphologic evaluation of kidney
biopsies integrated into clinical workflow enabling rapid rendering of preliminary diagnoses
while simultaneously making digital images available for remote expert evaluation and
digital analysis. Continuing validation will test ability to augment detection of rare lesions
and quantitative precision.

Kidney Biopsy Transcript Patterns Offer a Novel Approach to Distinguishing Etiologies of Acute Interstitial Nephritis
Ivy Rosales1, Kristen Tomaszewski2, Ellen Acheampong1, Astrid Weins,1 Ryan Smith2, Meghan E. Siss3, Robert B. Colvin4,1 Massachusetts General Hospital, Boston, MA; 4Brigham and Women’s Hospital, Boston, MA.

Background: One of the challenges in renal pathology is distinguishing causes of acute
interstitial nephritis (AIN). Based on encouraging results from renal allografts, we
sought mRNA transcript profiles of checkpoint inhibitor associated AIN (CPI), drug
induced AIN (Drug), AIN in diabetes (DM), IgG4-related renal disease (IgG4) and T cell
rejection type 1 (TCMR1).

Methods: Three 20 um sections were obtained from 65 FFPE blocks: 9 controls, 46
AIN types (10 CPI, 13 DM, 14 Drug, 9 IgG4) and 10 TCMR1. RNA was extracted and
hybridized with NanoString HOP Panel of 770 probes and analyzed on an nCounter Max
instrument. The gene list is available at nanostring.com. Pathway analysis, differential
expression and cell type scores were analyzed from normalized mRNA counts using
nSolver.

Results: Similarities were found across AIN however each had one or more distinct
patterns of transcripts. CPI AIN was distinguished from the other causes of AIN by higher
IFN-γ signaling pathway scores (Fig 1). CPI AIN had more exhausted CD8 cells (p<0.05)
and NK cells (p<0.001) than drug induced AIN. DM AIN differed from histologically
indistinguishable Drug AIN by several genes (e.g. higher tgfβ2, p=0.007). IgG4 AIN
showed the highest levels of B cell receptor signaling, MAPK and mTOR pathways,
and highest Th17 and Treg differentiation scores. TCMR1 had lower scores for Tgfβ1 and
TNF pathways and lower Treg scores compared with the other causes of AIN. TCMR1
had the most favorable scores for AKI and pathways related to outcome (eGFR later,
GoCAR progression).

Conclusions: Our initial findings suggest that once extended to customized algorithms
and validated, this approach may prove fruitful in distinguishing the underlying diagnosis
and pathogenesis of diverse causes of AIN.
of histopathologic lesions. We tested the associations of each biomarker with clinicopathologic diagnoses, histopathologic lesions, and the risks of kidney disease progression (a 40% decline in estimated glomerular filtration rate (eGFR) or end-stage kidney disease) and death.

**Results:** After multivariable adjustment and correction for multiple testing, 39 proteins were independently associated with clinicopathologic diagnoses and 53 with different histopathologic lesions. Kidney-injury molecule-1 (KIM-1) associated with diabetic nephropathy and glomerular and tubulointerstitial diseases. The top performing markers for acute tubular injury and interstitial fibrosis and tubular atrophy were KIM-1 and tumor necrosis factor receptor superfamily member-9 (TNFRSF-9), respectively. Thirty proteins were significantly associated with kidney disease progression and 35 with death (Figure 1 A, B). The top performing markers for kidney disease progression were placental growth factor (PGF; HR 5.4, 95% CI 3.4 to 8.7) and BMP and Activin Membrane Bound Inhibitor (BAMBI; HR 3.0, 95% CI 2.1 to 4.2); the top performing markers for death were TRAIL-receptor-2 (TRAIL-R2; HR 2.9, 95% CI 2.0 to 4.0) and CUB Domain Containing Protein-1 (CDCP1; HR 2.4, 95% CI 1.8, 3.3). Five proteins were significantly associated with decreased risks of death (Figure 1 B).

**Conclusions:** We identified several biomarkers of kidney disease histology, pathology, and prognosis—many of which have not been reported previously and may represent important avenues for future research.

**Complement Activation Assay in an Ex Vivo Microfluidic Cell-Culture System**

**Martin Reinhardt,** Yulia Kiyan, Hermann G. Haller. *Medizinische Hochschule Hannover Zentrum Innere Medizin, Hannover, Germany.*

**Background:** Discrimination between different diseases in patients suffering from thrombotic microangiopathies is often challenging. Measuring C5b9 deposit on endothelial cells using confocal microscopy have been shown to be convenient in diagnostic and therapy monitoring of Atypical hemolytic uremic syndrome (aHUS) but methods are complex and costly.

**Methods:** We developed a cell-based C5b9-ELISA to measure C5b9-deposits on activated endothelial cells. Patients with suspected aHUS and other thrombotic microangiopathies were identified in early disease stage. Serum was drawn and tested versus healthy controls. After confirmation of the diagnosis aHUS therapy efficiency was monitored using the assay.

**Results:** In patients with the clinical diagnosis of aHUS we were able to show up to six-fold higher C5b9-deposits in contrast to normalized human serum (NHS) (p-value < 0.0001). In comparison to healthy controls, patients suffering from either Shiga-Toxin-HUS or Thrombotic Thrombocytopenic Purpura (TTP) we could demonstrate a two- to three-fold higher deposit (p-value=0.0103 and below). After onset of eculizumab treatment, the amount of C5b9-deposits becomes lower than in healthy controls, proving the efficiency of the therapy. One-Way-ANOVA shows significant differences between aHUS-groups and controls, but not between aHUS patients using Tukeys-multiple comparisons test.

**Conclusions:** We described a novel, fast and reproducible ELISA to identify aHUS-patients by measuring C5b9-deposits and monitor disease activity. This can give a rise to diagnostic speed and therapy decisions. Further investigation and validation are needed to show interactions with other complement diseases like systemic lupus erythematosus.

**Barriers and Opportunities to Improve Variability in CKD Laboratory Methodology and Reporting: Results from the College of American Pathologists (CAP) 2019 Survey**

**Joseph A. Vassalotti,1,2 Greg Miller,** 1Icahn School of Medicine at Mount Sinai, New York, NY; 2National Kidney Foundation, New York, NY; 3Virginia Commonwealth University, Richmond, VA.

**Background:** Variability in laboratory practices for estimated GFR (eGFR) and urine albumin-creatinine ratio (uACR) is a barrier to optimal CKD testing and interpretation by clinicians. The CAP serial surveys assess CKD laboratory methodology and reporting.

**Methods:** The CAP 2019 General Chemistry Survey conducted in December, included 9 questions regarding CKD tests.

**Results:** Respondents included 7,105 laboratories (83.8% U.S. and 16.2% international) with a response rate of 87.5%. Laboratory reporting of eGFR based on serum creatinine has increased overall from 3% to 92% in CAP surveys between 2003 and 2019. The Figure shows 76% of laboratories were using an isotope dilution mass spectrometry (IDMS) traceable version of the MDRD 4-variable equation (45%) or the CKD-EPI equation (31%), but an incorrect equation was used for IDMS creatinine by 23% of the respondents, resulting in systematic over estimation of kidney function. Barriers for the pediatric population less than 18 years include only 10% of laboratories report the correct bedside Schwartz equation and 20% of laboratories applied an incorrect adult eGFR equation for children. The microalbumin term that KDIGO and KDOQI recommend be included 9 questions regarding CKD tests.

**Conclusions:** Laboratory variability is a call to action for nephrologists to collaborate with clinical laboratories to improve appropriate CKD testing.
Polyclonal Variants Immunotactoid Glomerulopathy: A Rare Entity with Monoclonal and Pathology of Kidney Diseases: Novel Mechanisms and Clinical Correlations

monoclonal ITG and polyclonal ITG. Prognosis is good if the underlying hematologic patients who received kidney transplants.

As compared to polyclonal ITG, monoclonal ITG had a higher incidence of lymphoma composition. This finding was used to distinguish monoclonal ITG from polyclonal ITG.

Immunofluorescence revealed IgG-dominant staining which was light chain restricted and microtubular deposits with diameter of 14-60 nm, hollow cores, frequent parallel staining for DNAJB9 was negative on all cases tested. Electron microscopy showed membranoproliferative (29%) and membranous (29%) patterns. Immunohistochemical had hypocomplementemia. Light microscopy revealed endocapillary proliferative (35%), in 26% (most commonly MGRS). 14% had underlying autoimmune disease and 33%

proteinuria (median 6.6 g/day, 58% with full nephrotic syndrome), hematuria (86%), and renal dysfunction, and 24% progressed to ESRD. The median survival (not reaching (53% vs. 11%), multiple myeloma (8% vs. 0), and MGRS (22% vs. 0). On follow up 0.03, 1.47 [1.04, 2.07].

Background: Hepatorenal syndrome type 1 (HRS-1) is an ominous form of acute kidney injury in patients with cirrhosis. Recently, the results of the randomized placebo (PBO)-controlled trial (RCT) CONFIRM demonstrated that terlipressin (TERLI) is effective in reversing HRS-1 and in reducing the cumulative need for renal replacement therapy (RRT). However, whether TERLI reduces the need for RRT among survivors has not been determined.

Methods: CONFIRM (NCT02770716) was a North American RCT (n=300) that compared HRS-1 reversal rates between patients treated with albumin plus TERLI (n=199) or albumin plus PBO (n=101) (2:1). We conducted a post hoc intention-to-treat analysis to assess the incidence of RRT among CONFIRM survivors. We also conducted a pooled analysis of the 3 TERLI RCTs in HRS-1 (OT-0401 [NCT00089570], REVERSE [NCT01143246], and CONFIRM) to examine 90-day RRT-free survival rates.

Results: In CONFIRM, the cumulative incidences of need for RRT for TERLI at day 14, 30, and 90 were 23%, 26%, and 29% compared with 35%, 36%, and 39% for patients assigned to PBO (P=0.03, 0.07, and 0.1, respectively). Among survivors, significantly fewer TERLI-treated patients remained dependent on RRT at day 14, 30, and 90 (22%, 26%, 30%, respectively) compared with PBO (39%, 43%, and 46%; P=0.01, P=0.03, and P=0.05, respectively). The 90-day RRT-free survival rate was 35% in the TERLI group vs 30% in the PBO group (P=0.08, with a numerically longer median number of days in the TERLI group (20 vs 11). Pooled analysis of the 3 RCTs revealed a greater 90-day RRT-free survival rate for TERLI-treated (n=352) compared with PBO-treated (n=256) patients (37% vs 29%, P=0.03; OR [95% CI], 1.47 [1.04, 2.07]).

Conclusions: Treatment with TERLI added to albumin decreased the rate of RRT and improved RRT-free survival in patients with HRS-1. This is the first pharmacological intervention proven to reduce the need for RRT in patients with HRS-1. Because of the significant impact of RRT on quality of life, this observation expands the clinical benefit of TERLI and enhances the reported efficacy of TERLI in inducing HRS-1 reversal.

A Parsimonious Model for Diagnosis of Biopsy-Proven Acute Interstitial Nephritis Using Electronic Health Record Data

Dennis G. Molendina,1,2 Yu Yamamoto,1 Chirag R. Parikh,1 Francis P. Wilson,1,2 Tulane University School of Medicine, New Haven, CT; 2Clinical and Translational Research Accelerator, New Haven, CT; 3Johns Hopkins Medicine, Baltimore, MD.

Background: Due to its atypical clinical features and difficulty in establishing diagnosis without a biopsy, acute interstitial nephritis (AIN) diagnosis is delayed or missed. We developed a predictive model for AIN using clinical data from all patients who underwent a kidney biopsy available through the electronic health record.

Methods: We obtained data on all patients who underwent a native kidney biopsy at two centers between 2013-18 and obtained corresponding information of demographics, comorbidities, and all laboratory tests collected up to one year before biopsy. We used least absolute shrinkage and selection operator (LASSO) method to select features associated with AIN and performed area under received operating characteristics curve (AUC) analysis in temporally-split training (70%) and test (30%) sets. We also applied this model to a separate cohort of kidney biopsies with AIN diagnosis adjudicated by 3 pathologists and compared it to the clinician’s prebiopsy impression of AIN obtained through chart review.

Results: Among 551 patients who underwent native kidney biopsies, 60 (11%) had AIN on clinical pathology diagnosis. We evaluated 163 potential features for their association with AIN. The five features with the highest AUC were last creatinine at the time of biopsy (AUC, 0.73), serum bicarbonate (0.70), albumin protein (0.62) and urine protein (0.62). The top 4 variables picked using LASSO had an AUC of 0.76 in the test set (table). Applying this model to a separate cohort of participants with adjudicated AIN, we noted an AUC of 0.80 (0.73, 0.87), which was higher than the clinician’s pre biopsy impression of AIN (0.61 (0.52, 0.70), P=0.001).

Conclusions: We noted four variables associated with AIN and the model containing these showed a modest AUC but was an improvement on clinician’s pre-biopsy impression of AIN.

Development and Validation of a Convolutional Neural Network Model for Intensive Care Unit AKI Prediction
Jacob Calvert,1 Angier O. Allen,1 Sidney H. Le,1 Paul M. Palevsky,2 Gregory L. Braden,1 Sharad Patel,1 Emily Pellegrini,1 Abigail Green-Saxena,1 Jana Hoffman,1 Ritankar Das,1 'Dascena, Oakland, CA; 2VA Pittsburgh Healthcare System, Pittsburgh, PA; 3Baystate Medical Center, Springfield, MA; 4Cooper University Health Care, Camden, NJ.

Background: Acute kidney injury (AKI) is common among hospitalized patients and has a significant impact on morbidity and mortality. While early prediction of AKI has the potential to reduce adverse patient outcomes, it remains a difficult condition to predict and diagnose. The purpose of this study was to evaluate the ability of a machine learning algorithm to predict for AKI KDIGO Stage 2 or 3 up to 72 hours in advance of onset using convolutional recurrent neural nets (CNN) and patient Electronic Health Record (EHR) data.

Methods: A CNN prediction system was developed to continuously and automatically monitor for incipient AKI. 7122 patient encounters were retrospectively analyzed from the Medical Information Mart for Intensive Care III (MIMIC-III) database. The CNN machine learning-based AKI prediction model was compared to an established XGBoost AKI prediction model and the Sequential Organ Failure Assessment (SOFA) scoring system. AKI onset was used for the outcome. The model was trained on routinely-collected patient EHR data.

Results: On a hold-out test set, the algorithm attained an Area Under the Receiver Operating Characteristic (AUROC) of 0.85 and PPV of 0.25, relative to a cohort AKI prevalence of 5.21%, for long-horizon AKI prediction at a 72-hour window prior to onset. The ROC curve comparison of 72-hour prediction on the 10% hold-out test set is shown in Figure 1. The CNN model, which was provided text data through Doc2Vec input, outperformed the XGBoost model and the SOFA score.

Outcomes from the Use of the Selective Cytopheretic Device (SCD) in Critically Ill Children Receiving CRRT: A Report of the Multicenter Pediatric SCD (pSCD) Study
Stuart Goldstein,1 Kelli A. Kralman,1 Cassie L. Kirby,1 David J. Askenazi,2 Rajit K. Basu,1 David T. Selewski,1 H. David Humes,1 'Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 2The University of Alabama at Birmingham, Birmingham, AL; 3Children’s Healthcare of Atlanta Inc, Atlanta, GA; 4Medical University of South Carolina, Charleston, SC; 5University of Michigan, Ann Arbor, MI.

Background: Critically ill children who develop acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT) are at increased risk of death. The SCD promotes an immunomodulatory effect in a hypocalcemic environment (ionized Ca (ionCa) < 0.4 mmol/L) in animal models of inflammation. In a randomized trial, adult ICU patients on CRRT treated with the SCD, who maintained CRRT ionCa < 0.4 mmol/L, had improved survival/dialysis independence. We conducted an FDA grant sponsored safety evaluation (adverse and serious adverse events) of the SCD in 16 critically ill children.

Methods: 4 center US study of the SCD in children (<15 kg, ≥22 years) with AKI and multigener failure receiving CRRT. The SCD was integrated post CRRT membrane, changed daily, and circuit ionCa maintained <0.4 mmol/L. Pts received CRRT treatment for up to 7 days or CRRT discontinuation.

Results: 16 pts (8F/8M) completed the study from 12/2016 thru 2/2020. Mean pt age was 12 yr (range 4-21 yr), weight was 53 kg (range 19-111 kg) and PRISM 2 score was 7 (range 2-19). Two pts received ECMO. The most common ICU diagnosis was shock. Circuit ionCa were maintained at <0.4 mmol/L for 90.2% of assessments. Median SCD duration was 6 days (range 1 to 7); 15/16 pts survived CRRT therapy, 12/16 patients survived to ICU discharge. All 12 ICU survivors were dialysis independent at 60 days. No SCD related adverse events were noted.

Conclusions: Our data suggest the SCD is safe in critically ill children who require CRRT. While we cannot make efficacy claims, the 75% survival rate and 100% renal recovery rate in surviving children suggest a favorable benefit to risk ratio.

FR-OR05

Nicotinamide Riboside with Pterostilbene Increases NAD+ in Patients with AKI: A Randomized, Double-Blind, Placebo-Controlled, Stepwise Safety Study of NRPT in Patients with AKI
Petrina Simic,1 Xavier F. Parada,1 Samir M. Parikh,2 Ryan Delling,3 Leonard P. Guarente,4,5 Eugene P. Rhee.6 1Massachusetts General Hospital, Boston, MA; 2Beth Israel Deaconess Medical Center, Boston, MA; 3Elysium Inc, New York, NY; 4Massachusetts Institute of Technology, Cambridge, MA.

Background: Preclinical studies have identified both NAD+ and sirtuin augmentation as potential strategies for the prevention and treatment of AKI. Nicotinamide riboside (NR) is a NAD+ precursor vitamin and pterostilbene (PT) is potent sirtuin activator found in blueberries. Here, we tested the effect of combined NR and PT (NRPT) on whole blood NAD+ levels and safety parameters in patients with AKI.

Methods: We conducted a randomized, double-blind, placebo-controlled study of escalating doses of NRPT in 24 hospitalized patients with AKI. The study comprised of four Steps during which NRPT (5 subjects) or placebo (1 subject) was given twice a day for two days. NRPT dosing was increased in each Step: Step 1 250/50mg, Step 2 500/100mg, Step 3 750/150mg and Step 4 1000/200mg. Blood NAD+ levels were measured by liquid chromatography-mass spectrometry and safety was assessed by history, physical exam, and clinical laboratory testing.

Results: AKI resulted in a 50% reduction in whole blood NAD+ levels at 48 hr compared to 0 hr in patients receiving placebo (p=0.05). There was a trend for increase in NAD+ in all NRPT Steps individually at 48 hr compared to 0 hr, but only the change in Step 2 reached statistical significance (47%; p=0.04), and there was considerable interindividual variability in the NAD+ response to treatment. Considering all Steps together, NRPT treatment increased NAD+ levels by 37% at 48hr compared to 0hr (p=0.002). All safety laboratory tests were unchanged by NRPT treatment, including creatinine, estimated glomerular filtration rate (eGFR), electrolytes, liver function tests, and blood counts. Three of 20 patients receiving NRPT reported minor gastrointestinal side effects.

Conclusions: NRPT increases whole blood NAD+ levels in hospitalized patients with AKI. In addition, NRPT up to a dose of 1000mg/200mg twice a day for two days is safe and well tolerated in these patients. Further studies to assess the potential therapeutic benefit of NRPT in AKI are warranted.

Role of Angiopoietins in CKD Progression After Hospitalization
Sherry Mansour,1 Steven G. Coca,2 Yaqi Jia,1 Vernon M. Chinchilli,4 Wassim Obied,4 Francis P. Wilson,1 Samir M. Parikh,1 Edward D. Siew,1 Talat Alp Ikizler,1 Jonathan Himmelfarb,1 Paul L. Kimmel,1 Chirag R. Parikh,3 ASSESS-AKI Consortium 1 Yale University School of Medicine, New Haven, CT; 2Johns Hopkins University, Baltimore, MD; 3Pennsylvania State University, University Park, PA; 4Beth Israel Deaconess Medical Center, Boston, MA; 5University of Washington, Seattle, WA; 6National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; 7Vanderbilt University Medical Center, Nashville, TN.

Background: The factors determining chronic kidney disease (CKD) progression after an episode of acute kidney injury (AKI) are poorly understood. Angiopoietins play a role in vessel remodeling after AKI, where Angiopoietin-1 (Angpt-1) maintains vessel stability and Angiopoietin-2 (Angpt-2) destabilizes quiescent vessels. We investigated whether the balance of Angpt-1 and -2 was prognostic of CKD and mortality after hospitalization in patients with and without AKI.

Methods: Using plasma samples from ASSESS-AKI, we measured Angiopoietins 3 months after hospitalization. We assessed the ratio of Angpt-1/Angpt-2 with CKD progression (composite of incident and progression of CKD, and end stage kidney disease), and all-cause mortality.

Results: Angiopoietins were measured in 1503 hospitalized patients, among whom 746 (49.6%) had AKI. Median (IQR) age was 65.8 (56.6, 71.9) years, 555 (37%) were female, and 196 (13%) were black. Median times to CKD progression, and all-cause mortality were 4.4 (2.5, 5.7), and 4.9 (3.6, 6.0) years, respectively. CKD progression developed in 293 (19%) and mortality in 314 (21%) participants. The highest quartile of Angpt-1/Angpt-2 ratio was independently associated with 50% reduced risk of CKD progression and 77% reduced risk of mortality as compared to the lowest quartile. Stratified analyses by AKI status revealed stronger associations between Angpt-1/Angpt-2 ratio and both outcomes in the AKI group (Figure).

Conclusions: A higher Angpt-1/Angpt-2 ratio was strongly associated with lower risk of CKD progression and mortality after hospitalization, particularly in patients with AKI. Angiopoietins may help risk stratify patients with AKI after discharge for those in need of close follow-up and CKD management.

FR-OR07
Determinants of Major Adverse Kidney Events (MAKE) in Extra Corporeal Membrane Oxygenation (ECMO) Survivors
Aniesh Bobba,1 Christy Costanian,2 Sola A. Bahous,2 Fadi Tohme.1,2 Washington University in Saint Louis School of Medicine, Saint Louis, MO; 3Lebanese American University School of Medicine, Byblos, Lebanon.

Background: The majority of ECMO patients develop acute kidney injury (AKI) and 40-60% require renal replacement therapy (RRT). Little is known about the effects of AKI on long-term renal outcomes after ECMO. The aim of this study was to examine the determinants of MAKE in ECMO survivors.

Methods: Patients who were admitted to a single-center between 2008 and 2017, were on ECMO for more than 24 hours & survived to hospital discharge were included. MAKE was defined as either doubling of serum creatinine (Scr), incident ESRD or death. USRDS and NDI databases were used to obtain information about ESRD and death. AKI was defined as KDIGO stages 2-3. Complete AKI recovery was defined as a return to 50% of baseline Scr and partial recovery as an improvement in the AKI stage without a return to 50% of baseline Scr. Survival analysis plots & Cox regression models were fitted to examine the associations of AKI status, AKI recovery and other factors with MAKE.

Results: Among 188 ECMO patients who survived until hospital discharge, 63% had AKI, and 41% required RRT. The mean follow-up time was 3.4 years. Patients with AKI were more likely to be on ECMO for a cardiac rather than respiratory indication and had a longer length of stay compared to patients with no AKI. Kaplan-Meier survival curves showed that patients with no/partial recovery from AKI had a higher rate of MAKE compared to those with no AKI (Figure 1). Results of the unadjusted analysis showed that ECMO type and timing of initiation of RRT were associated with MAKE. Multivariate analysis showed that AKI [aHR=1.79 (95%CI=1.00-3.21)], no/partial recovery from AKI [aHR=2.94 (95%CI=1.46-5.92)] and initiation of RRT after ECMO [aHR 5.4 (95%CI=1.14-25.6)] were significant determinants of MAKE after adjustment for potential confounders.

Conclusions: AKI, AKI recovery status, and timing of initiation of RRT are determinants of major adverse kidney events in patients who received ECMO.

FR-OR08
AKI Among African Americans with Sickle Cell Trait and Disease
Kabir O. Olaniran,1,2 Andrew S. Allegretti,1 Sophia Zhao,1 Sagar U. Nigwekar,1 Sahir Kalim.1 Massachusetts General Hospital, Boston, MA; 2University of Texas Southwestern Medical Center at Dallas, Dallas, TX.

Background: Sickle cell trait (SCT) and disease (SCD) are independent risk factors for estimated glomerular filtration rate (eGFR) decline among African Americans (AA). However, our understanding of the risk for acute kidney injury (AKI) and the role of AKI in eGFR decline in patients with SCT/SCD remains limited. We aimed to describe the relative risk for AKI in SCT/SCD and the effect of AKI on eGFR decline in AA.

Methods: We performed a multi-center observational study of adult AA patients with a baseline eGFR ≥15 ml/min, and ≥1 year follow-up between 2005-2018. The presence of SCT/SCD (exposure) and normal hemoglobin phenotype (reference) was determined by hemoglobin electrophoresis. Outcomes of interest (incident All AKI [Kidney Disease: Improving Global Outcomes criteria], incident Severe AKI [doubling of baseline creatinine] and incident Sustained AKI [AKI persisting for ≥72 hours]) were adjudicated by chart review and evaluated by Cox regression. Only first AKI events were used. The effect of All AKI on eGFR decline (mixed linear models) was also investigated. Models were adjusted for predictors of AKI.

Results: We identified 8868 reference, 1279 SCT, and 254 SCD patients with a median follow-up of 7.6 years and mean serum creatinine of 0.8 mg/dl. SCT was associated with Sustained AKI (adjusted hazard ratio [aHR] 1.42; 95% CI, 1.08-1.88) compared to the reference. SCD was associated with All AKI (aHR 3.13; 95% CI, 2.33-4.21), Severe AKI (aHR 3.04; 95% CI, 1.90-4.87) and Sustained AKI (aHR 2.10; 95% CI, 1.24-3.53) compared to the reference. Effect of AKI on eGFR is shown in Figure 1.

Underline represents presenting author.
Conclusions: The risk for AKI is increased in both SCT (Sustained) and SCD (all forms) and may contribute to faster eGFR decline in SCT/D. Further studies are needed to understand the mechanisms of AKI in SCT/D. Such studies will inform best practices that will help attenuate the burden of kidney disease in SCT/D.

Assessment of Kidney Proximal Tubular Secretion in Critical Illness
Pavan K. Bhattraj,1 Edward D. Siew,2 Jonathan Himmelfarb,1 Andrew N. Hooffagle,1 Mark M. Wurfel,1 Bryan R. Kestenbaum.1 University of Washington, Seattle, WA. Division of Nephrology and Hypertension, Vanderbilt University, Nashville, TN.

Background: Serum creatinine concentrations (SCr) are used to determine the presence and severity of acute kidney injury. SCr is primarily eliminated by glomerular filtration; however, most mechanisms of kidney injury in critical illness involve kidney proximal tubules, where tubular secretion occurs. Proximal tubular secretory clearance is not currently measured in the ICU. To estimate the kidney clearance of secretory solutes in critically ill adults.

Methods: We collected matched blood and spot urine samples from 170 ICU patients and from a comparison group of 70 adults with normal kidney function. We measured seven endogenously produced secretory solutes using liquid chromatography-tandem mass spectrometry. We computed a composite secretion score incorporating all seven solutes, and evaluated its associations with 28-day major adverse kidney events (MAKE28), defined as doubling of SCr, dialysis dependence, or death.

Results: The urine/plasma ratio of six of seven secretory solutes were lower in critically ill patients compared with normal individuals after adjustment for SCr. The urine/plasma ratio of six of seven secretory solutes was associated with a 52% lower risk of MAKE28 and did not die in the non-AKI group (m: 9.97 vs 9.21 ng/mL, P = 0.0001). By year 3, a total of 70 patients died; 43 in the AKI group and 27 in the control group. In the AKI group, patients who died had significantly higher PRO-C6 levels than the patients who did not die (m: 12.66 vs 10.68 ng/mL, P = 0.004), whereas there was no difference between patients who died and did not die in the non-AKI group (m: 9.97 vs 9.21 ng/mL, P = 0.23). In a multivariate Cox regression analysis with backwards elimination including age, gender, baseline CKD and diabetes status, albuminuria, serum creatinine, eGFR and PRO-C6, only age (P = 0.04) and albuminuria (P = 0.007) remained in the final model for the non-AKI group. In the AKI group, PRO-C6 had a stronger association with mortality than eGFR, as only age (P = 0.005), albuminuria (P = 0.04) and PRO-C6 (P = 0.004) remained in the final model. When stratified into tertiles, patients with higher levels of PRO-C6 at year 1 were significantly more likely to die (P = 0.0089).

Conclusions: In this study, we compared levels of PRO-C6 in patients with and without AKI, and show that PRO-C6 levels measured in plasma can predict mortality in patients with AKI. Our findings may indicate that PRO-C6 identifies patients with active fibrogenesis after AKI, suggesting that long-term renal injury after AKI is important for patient outcome.

Endotrophin, Released During Collagen Type VI Formation, Predicts Long-Term Mortality After AKI
Nadja Sparling,1,2 Daniel Guldager Kring Rasmussen,1 Federica Genovese,1 Morten A. Karsdal,1 Rebecca A. Packington,2 Nicholas M. Selby,1 Fibrosis, Renal and Cardiovascular Research Nordic Bioscience, Herlev, Denmark; 2Faculty of Health and Medical Science, University of Copenhagen, Copenhagen, Denmark; 1Centre for Kidney Research and Innovation, University of Nottingham, Nottingham, United Kingdom.

Background: Acute kidney injury (AKI) is defined as a rapid decrease in kidney function which may be associated to structural damage. Early markers predicting AKI are emerging, but tools to monitor patients subsequent to AKI are still lacking. The novel biomarker PRO-C6 reflects formation of collagen type VI (COL6) and levels of endotrophin, a bioactive molecule derived from COL6. Here we evaluated the potential of PRO-C6 as a biomarker of mortality in AKI patients.

Methods: We measured PRO-C6 in plasma samples collected 1 year after the episode of AKI, using a novel ELISA in 801 patients from the AKI Risk in Derby (ARD) study, who were then followed prospectively until year three. 393 of the patients had been hospitalized for an episode of AKI, and 408 patients who did not sustain AKI were included as controls (non-AKI). The groups were matched for age, baseline renal function and diabetes.

Results: PRO-C6 levels were significantly higher in the AKI compared to the non-AKI group (median (m): 10.85 vs 9.23 ng/mL, P < 0.0001). By year 3, a total of 70 patients died; 43 in the AKI group and 27 in the control group. In the AKI group, patients who died had significantly higher PRO-C6 levels than the patients who did not die (m: 12.66 vs 10.68 ng/mL, P = 0.004), whereas there was no difference between patients who died and did not die in the non-AKI group (m: 9.97 vs 9.21 ng/mL, P = 0.23). In a multivariate Cox regression analysis with backwards elimination including age, gender, baseline CKD and diabetes status, albuminuria, serum creatinine, eGFR and PRO-C6, only age (P = 0.04) and albuminuria (P = 0.007) remained in the final model for the non-AKI group. In the AKI group, PRO-C6 had a stronger association with mortality than eGFR, as only age (P = 0.005), albuminuria (P = 0.04) and PRO-C6 (P = 0.004) remained in the final model. When stratified into tertiles, patients with higher levels of PRO-C6 at year 1 were significantly more likely to die (P = 0.0089).

Conclusions: In this study, we compared levels of PRO-C6 in patients with and without AKI, and show that PRO-C6 levels measured in plasma can predict mortality in patients with AKI. Our findings may indicate that PRO-C6 identifies patients with active fibrogenesis after AKI, suggesting that long-term renal injury after AKI is important for patient outcome.

Association of Use of Kidney Disease Education Benefit with ESKD-Related Outcomes
Kirsten E. Johansen, James B. Wetmore, David T. Gilbertson, Eric D. Weinhandl, Jianong Liu. Chronic Disease Research Group, Minneapolis, MN.

Background: ESKD onset in the US is marked by poor outcomes, including little use of home dialysis, widespread catheter dependence among patients on hemodialysis, and high mortality. Consequently, in 2010, the Centers for Medicare and Medicaid Services (CMS) initiated a new kidney disease education (KDE) benefit to ensure that beneficiaries with stage 4 CKD are informed about the effects and treatment of kidney disease, diet and nutrition, transplantation, dialysis modalities, and vascular access. Following the US president’s Executive Order on Advancing American Kidney Health in 2019, CMS plans to expand KDE. However, the current use and efficacy of KDE have not been examined.

Methods: We used USRDS data to identify eligible patients and to ascertain KDE receipt of KDE and ESKD outcomes in this matched cohort using logistic regression. We examined patient characteristics associated with receipt of KDE. We matched each KDE recipient with 4 controls using propensity scores and estimated the association between receipt of KDE and ESKD outcomes in this matched cohort using logistic regression.

Results: 3171 patients (3%) received KDE, 56% of whom received a single session. 49.5% of KDE sessions were delivered by nephrologists and 42% by physician extenders. We examined patient characteristics associated with receipt of KDE. We matched each KDE recipient with 4 controls using propensity scores and estimated the association between receipt of KDE and ESKD outcomes in this matched cohort using logistic regression.

Conclusions: A very small percentage of eligible patients reaching dialysis receive Medicare-reimbursed KDE within the previous 2 years. KDE was associated with favorable outcomes, at least among those who advanced to ESKD.

Oral Abstract/Friday
Conclusions: Make future studies more feasible. Prevent relapse. Treatment of AKI is important. AKI is associated with a 52% lower risk of MAKE28 and did not die in the non-AKI group (m: 9.97 vs 9.21 ng/mL, P = 0.0001). By year 3, a total of 70 patients died; 43 in the AKI group and 27 in the control group. In the AKI group, patients who died had significantly higher PRO-C6 levels than the patients who did not die (m: 12.66 vs 10.68 ng/mL, P = 0.004), whereas there was no difference between patients who died and did not die in the non-AKI group (m: 9.97 vs 9.21 ng/mL, P = 0.23). In a multivariate Cox regression analysis with backwards elimination including age, gender, baseline CKD and diabetes status, albuminuria, serum creatinine, eGFR and PRO-C6, only age (P = 0.04) and albuminuria (P = 0.007) remained in the final model for the non-AKI group. In the AKI group, PRO-C6 had a stronger association with mortality than eGFR, as only age (P = 0.005), albuminuria (P = 0.04) and PRO-C6 (P = 0.004) remained in the final model. When stratified into tertiles, patients with higher levels of PRO-C6 at year 1 were significantly more likely to die (P = 0.0089).

Conclusions: In this study, we compared levels of PRO-C6 in patients with and without AKI, and show that PRO-C6 levels measured in plasma can predict mortality in patients with AKI. Our findings may indicate that PRO-C6 identifies patients with active fibrogenesis after AKI, suggesting that long-term renal injury after AKI is important for patient outcome.

Correlation Between Patient Activation and Quality of Life Among Patients with CKD
Mujahed M. Dauleh, Aria Ghaemrahmani, Ali M. Zebi, Nasrollah Ghaemrahmani
Penn State College of Medicine, Hershey, PA.

Background: Quality of Life (QOL) is an important outcome in patients with chronic kidney disease (CKD). We have previously demonstrated that online peer mentoring (PM) improves patient activation and QOL. In this study, we evaluate the correlation between patient activation and QOL among patients with CKD who received online PM.

Methods: We randomized 155 patients with stage 4 or stage 5 CKD to one of 3 groups: online PM, face-to-face (FTF) PM, or usual care. Participants in all 3 groups received a book that contained detailed information about kidney disease. Participants assigned to intervention groups received 6 months of PM, either FTF or through a secure online platform. At baseline and at 18 months, the participants completed the Patient Activation Measure® (PAM) and the Kidney Disease QOL-36 (KDQOL-36) instrument. We used linear mixed effect models to estimate the slope of change of PAM and subsets of KDQOL over time. Then we calculated the correlation between PAM and individual subscales of KDQOL by Pearson’s Correlation Coefficient. We used SAS, version 9.4 (SAS Institute Inc., Cary, NC) for data analysis.

Results: Baseline KDQOL-36 and PAM scores, as well as demographic characteristics were similar among the 3 groups. Among the online PM group, there was a statistically significant improvement in: 1. The mean PAM score between baseline and 18 months (Slope estimate [SE]: 5.65; 95% confidence interval [CI]: 2.75; 8.52; P< 0.0001). 2. The following components of the KDQOL-36 score: Effects of Kidney Disease (EKD) (SE: 4.13; CI: 6.87; 7.4; P= 0.01); Burden of Kidney Disease (BKD) (SE: 5.44; CI: 1.24; 9.64; P= 0.01); Symptoms and Problems of Kidney Disease (SPKD) (SE: 6.00; CI: 3.09; 8.91; P= 0.006); SF-12 Physical Composite Score (PCS) (SE: 2.50; CI: 0.95; 4.06; P= 0.002); SF-12 Mental Composite Score (MCS) (SE: 3.46; CI: 1.78; 5.13; P< 0.0001). Among the online PM group, the improvement in PAM was correlated with improvements in 4 components of the KDQOL-36: EKD (Pearson Coefficient [PC]: 0.36; P= 0.04); BKD (PC: 0.44; p= 0.001); SPKD (PC: 0.47; p= 0.005); PCS (PC: 0.35; p= 0.04). There was no correlation between PAM and MCS.

Conclusions: Among CKD patients who receive online PM, there is a correlation between the improvements in PAM and KDQOL, suggesting that improved QOL may be a result of improved activation. Funding: PCORI

Estimated Glomerular Filtration Rate Equations: Do We Need to Use the Ethnicity Correction Factor in People of African Ancestry Outside of the United States?
Rouvick Gama,1 Amanda Cleyer,2 Kieran R. Palmer,1 Henry A. Kibble,1 Hugh Cairns,1 Claire C. Sharpes,2 Adrien M. Peters,1 Neil Heraghthy,1 Kate Bramham,1,2 Kings College Hospital, London, United Kingdom; 1Kings College London, London, United Kingdom.

Background: Recent African studies suggest ethnicity factors in estimated glomerular filtration rate (eGFR) equations is not required.

Methods: To assess accuracy of eGFR equations, with and without ethnicity factors compared with gold standard 1Cr-ethylendiaminetetraacetic acid (1Cr-EDTA) clearance assays. Patients with albumin <30g/dl, ethnicity referrals, <18 years old, non-white or black, mixed ethnicities were excluded. Accuracy of CKD-EPI and MDRD eGFR equations compared to 1Cr-EDTA GFR were assessed with and without correction factor.

Results: 2,776 1Cr-EDTA studies were identified (Mean age: 54yrs; 43% female; 12% Black ethnicity). In Black patients, CKD-EPI and MDRD eGFR equations significantly overestimated GFR compared to White (p<0.001) but without ethnicity correction factor estimates were considerably improved (p=0.001) (Table 1). Accuracy was superior for GFR>60ml/min/1.73m2 compared to ~60ml/min/1.73m2 using CKD-EPI equation for both White and Black patients (p<0.001).

Conclusions: Overestimation of measured GFR with eGFR equations using ethnicity correction factors identified in this study may lead to reduced rates of CKD diagnosis and under-recognition of CKD severity in people of Black ethnicity in the UK. These findings require prospective validation in other countries.

Table 1: Estimated Glomerular Filtration equations bias, precision and accuracy compared with 1Cr-EDTA clearance for people of Black and White ethnicities according to 1Cr-EDTA GFR categories

Breath Ammonia Is a Useful Biomarker Predicting Kidney Function in CKD Patients
Ya-chung Tian, Linkou Chang Gung Kidney Research Center and Department of Nephrology, Gueishan, Taoyuan, TW, Taoyuan, Taiwan.

Background: Chronic kidney disease (CKD) is a public health problem and its prevalence has increased worldwide; patients are commonly unaware of the condition. Early identification and immediate intervention are crucial to delay CKD progression. Finding a tool to predict kidney function without visiting hospitals is an attractive method for CKD monitoring in COVID-19 pandemic. The present study aimed to investigate whether exhaled breath ammonia measurement could be used for rapid CKD screening.

Methods: CKD patients (n=121), including CKD stage 1-5 patients, were enrolled and breath ammonia was detected. Correlation between breath ammonia and blood urea nitrogen (BUN) levels, serum creatinine levels, estimated glomerular filtration rate (eGFR) were determined. The predictive value of breath ammonia for the presence of CKD was assessed.

Results: Correlation analysis demonstrated a good correlation between breath ammonia and blood urea nitrogen levels (R=0.756, P<0.0001), serum creatinine levels (R=0.735, p<0.0001), eGFR (R=0.535, p<0.0001) and inversed eGFR (R=0.685, p<0.0001). Breath ammonia concentration was significantly elevated with increased CKD stage compared with the previous stage (CKD stage 1/2/3/4/5: 636 ± 98; 1020 ± 120; 1943 ± 326; 4421 ± 1042; 12781 ± 1807 ppb, p<0.05). The receiver operating characteristic curve analysis showed an area under curve (AUC) of 0.835 (p=0.0001) for distinguishing CKD stage 1 from other CKD stages at 974 ppb (sensitivity, 69%; specificity, 95%; positive predictive value [PPV] 0.89; negative predictive value [NPV] 0.36). The AUC was 0.831 (p=0.0001) for distinguishing between patients with/without eGFR ≥60 mL/min/1.73 m2 (cut-off 1187 ppb: sensitivity, 71%; specificity, 87%; PPV, 98%; NPV, 61%). At 886 ppb, the sensitivity increased to 80% but the specificity decreased to 69%. For a non-liveness or non-serious CKD, breath ammonia at a cut-off concentration of 886 ppb is a good screening tool for detection of patients with potential CKD and suitable for kidney function monitoring.

Conclusions: Because CKD is non-life threatening and breath ammonia detection was conducted in real time, inexpensive, easy to administer, and had an acceptable diagnostic accuracy, breath ammonia can be used as a good surrogate for kidney function and a reliable tool for CKD screening.

Mechanism of Higher Incidence of ESKD Among Blacks and Hispanics vs. Whites in the United States
Guofen Yan,1 Keith C. Norris,2 Robert Nee,3 Julia J. Scialla,1 Wei Yu,1 Tom Greene,4 Alfred K. Cheung,5,6 1University of Virginia, Charlottesville, VA; 2University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; 3 Walter Reed National Military Medical Center, Bethesda, MD; 4University of Utah, Salt Lake City, UT; 5VA Salt Lake City Health Care System, Salt Lake City, UT.

Background: In the U.S., Blacks and Hispanics have higher incidence of ESKD than Whites. Whether this is driven by lower mortality prior to ESKD or inherently faster progression to ESKD has not been clearly determined because most studies used prevalent cohorts that created survival bias. We examined this issue using a newly constructed national cohort of patients with new-onset CKD.

Methods: We identified 834,270 individuals with new-onset CKD in the US Veterans Health Administration (VHA) between 2002 and 2015, followed through 2016. CKD onset was defined as the first occurrence when there were two eGFR values (CKD-EPI equation) >60 mL/min/1.73 m2 that were >90 days apart, not in ESKD. We excluded patients in VHA for <2 years at eGFR assessment. The time of study entry should be close to the CKD onset for each individual. We examined jointly the cause-specific (CS) hazards ratios for two competing events, occurrence of ESKD and pre-ESKD death.
**Results:** Upon study entry, 704,557 Whites, 98,082 Blacks, and 31,631 Hispanics had similar mean eGFRs (49.50 mL/min/1.73m²). Ten years after CKD onset, fractions of patients entering ESKD were 1.3-2.5 times greater for Blacks and Hispanics vs. Whites across six age groups (Table). CS hazards for ESKD was 2.1-2.9 times greater for Blacks and 1.2-2.7 times greater for Hispanics vs. Whites. CS hazards for pre-ESKD death were similar for Blacks and only modestly lower for Hispanics vs. Whites across ages.

**Conclusions:** More Blacks and Hispanics to ESKD were driven by their greater hazards for ESKD due to more rapid decline in kidney function, not through lower mortality prior to ESKD. Delineation and elimination of the causes of faster kidney function declines are therefore the appropriate strategies to improve clinical outcomes in Blacks and Hispanics with CKD, instead of attributing the higher incidence to pre-ESKD survival bias.

**Funding:** NIDDK Support

**Incidence of CKD and Environmental Inequities: An Integration of Ecological and Spatial Approaches in US Veterans**

Yun Han,1 Jennifer L. Bragg-Gresham,1 Diane Steffick,1 Xiaosong Zhang,1 April Wyncott,1 Tiffany C. Veint,2 V. G. Vinod Vydyanath,2 Brenda W. Gillespie,3 William Weitzel,4 Karandeep Singh,5 Susan T. Crowley,6 Rajiv Saran,1 University of Michigan Medical School, Ann Arbor, MI; 2University of Michigan, Ann Arbor, MI; 3Veterans Health Administration, Ann Arbor, MI; 4Veterans Health Administration, West Haven, CT.

**Background:** Disparities in chronic kidney disease (CKD) can be linked to social and environmental determinants of health, which vary geographically across the US. We assessed geographic variation and the impact of environmental factors on incident CKD in US veterans.

**Methods:** We used a linked dataset from Veterans Health Administration (2014-18), the American Community Survey 2018; National Environmental Public Health Tracking Network (2018); EPA 2019 and Reference USA 2017. Incident cases of CKD were identified for individuals with eGFR < 60 mL/min/1.73m² and without prior indication of CKD for at least 3 years. The county-level incidence rate of CKD was number of cases/1000 person-years during 2016-18. County-level environmental factors included Townsend deprivation index; neighborhood indices; number of recreational facilities and fast-food restaurants. A geographically-weighted regression model (GWR) was applied to investigate the relationship between environmental factors and incidence rate of CKD.

**Results:** Average of incident rate of CKD was 34.8/1000 person-years (SD=12.3, n=2,718). Incident rate was higher in the rust-belt area and Appalachian region (Fig 1.c). Townsend deprivation index associated with higher incident rate in the Midwest, Northern California and Texas (Fig 1.a). PM2.5 was associated with higher incident rate in the East North Central and East West Central regions (Fig 1.c). Townsend deprivation index associated with higher incident rate in the Midwest, Northern California and Texas (Fig 1.b). PM2.5 was associated with higher incident rate in the East North Central and East West Central regions (Fig 1.c).

**Conclusions:** Different environmental factors were associated with incident CKD in US counties. This highlights the potential importance of allocating resources for varied approaches to preventing and slowing the progression of CKD based on residence.

**Chlorthalidone and Bumetanide in Advanced CKD: HEBE Trial**

Fabio Solis-Jimenez, L. M. Perez-Navarro, Rafael Valdez-Ortiz. Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.

**Background:** Current treatment for hypertension and volume overload in chronic kidney disease consists of loop diuretics, nevertheless, chronic use leads to adaptive changes at the distal nephron, which in turn decreases their efficacy. The use of thiazide diuretics could be another treatment option in these patients, notwithstanding there’s not enough evidence to justify their use in this population.

**Methods:** To evaluate the efficacy and safety of treatment with bumetanide plus chlorthalidone in patients with advanced chronic kidney disease a double-blind randomized controlled trial was conducted.

**Results:** Thirty-two patients with hypertension, chronic kidney disease stage IV/V, and chronic loop diuretic use where divided in two groups. The dual treatment group received bumetanide (2 mg BID) plus chlorthalidone (50 mg BID), while the control group was given bumetanide (2 mg BID) plus placebo, both for twenty-eight days. There was a decrease of systemic blood pressure in the dual treatment group when compared with the control group; systolic blood pressure -26.1±15.3 vs. -10.2±23.3 mmHg (p=0.028), diastolic blood pressure -13.5±10.7 vs. -3.4±11.9 mmHg (p=0.018), and mean arterial pressure -18.1±8.7 vs. -5.4±14.3 mmHg (p=0.006). There was also a decrease of volume overload in the dual treatment group when compared to the control group; total body water -4.3±3.29 vs. -0.75±1.78 liters (p=0.001), extracellular water -2.5±1.1 vs. -0.15±1.2 liters (p=0.001), and extracellular water to total body water ratio -2.9±4.76 vs. -0.24±1.42 (p=0.039).

**Conclusions:** In advanced chronic kidney disease plus hypertension patients whose treatment with loop diuretics is insufficient, combined use of bumetanide plus chlorthalidone can be useful for systemic blood pressure and volume overload control.

Benefits of Icosepat Ethyl Across a Range of Baseline Renal Function in Patients with Established Cardiovascular Disease or Diabetes: Results of REDUCE-IT RENAL

Arjun Maithia,1 Deepak L. Bhatt,1 Allon N. Friedman,2 Michael Miller,3 Philippe Gabriel Sieg,1 Eliot A. Brinton,4 Terry A. Jacobson,1 Steven B. Ketchup,3 Rebecca A. Kettula,5 Lixia Jiao,6 Ralph T. Doyle,3 Craig B. Granowitz,7 Matthew J. Badoff,9 Preston Mason,1 Jean-Claude Tardif,10 William E. Boden,4 Christie Ballantyne.6 REDUCE-IT Investigators 1Brigham and Women’s Hospital, Boston, MA; 2Indiana University School of Medicine, Indianapolis, IN; 3University of Maryland School of Medicine, Baltimore, MD; 4Hospital Bichat - Claude-Bernard, Paris, France; 5University of California Los Angeles, Los Angeles, CA; 6Baylor College of Medicine, Houston, TX; 7Thal lipid Center, Salt Lake City, UT; 8VA Boston Healthcare System, West Roxbury, MA; 9Amarin Pharma Inc, Bridgewater, NJ; 10Institut De Cardiologie de Montreal, Montreal, QC, Canada; 11Emory University School of Medicine, Atlanta, GA.

Background: Chronic kidney disease is associated with adverse outcomes among patients with established cardiovascular disease (CVD) or diabetes. Medications for treatment of CVD among patients with low estimated glomerular filtration rate (eGFR) may be ineffective. 

Methods: The Reduction of Cardiovascular Events with Icosepat Ethyl-Intervention Trial (REDUCE-IT) randomized patients with CVD or diabetes and one additional risk factor to treatment with icosepat ethyl or placebo. Patients from REDUCE-IT were categorized by prespecified eGFR categories for analysis of the effect of icosepat ethyl (IPE) on the primary endpoint (composite of cardiovascular (CV) death, nonfatal myocardial infarction (MI), nonfatal stroke, coronary revascularization, or unstable angina) and key secondary endpoint (a composite of CV death, nonfatal MI, or nonfatal stroke). In post hoc analysis, patients were categorized by additional eGFR cutoffs consistent with current medical guidelines.

Results: Among the 8179 REDUCE-IT patients, median baseline eGFR was 75 mL/min/1.73m² (range: 17 to 123 mL/min/1.73m²). There were no meaningful changes in median eGFR for IPE versus placebo across study visits. IPE benefit was consistent across baseline eGFR for the primary (Figure) and key secondary endpoints. The numerical reduction in CV death was greatest in the eGFR <60 mL/min/1.73m² group (IPE: 7.6%; placebo: 10.6%; HR 0.70, 95%CI 0.51, 0.95, p=0.02). The rate of microalbuminuria in adverse event reporting was lower among IPE-treated patients (0.1% versus 0.3%, p=0.01).

Conclusions: In REDUCE-IT, icosepat ethyl reduced fatal and nonfatal ischemic events across the broad range of baseline eGFR categories.

Dapagliflozin Reduces the Risk of Hyperkalaemia in Patients with Heart Failure and Reduced Ejection Fraction: A Secondary Analysis from DAPA-HF

Soren L. Kristensen,1 Kieran F. Docherty,1 Pardeep Hundi,2 Olfert Bengtsson,2 Silvio E. Inzucchi,3 Mikhail Kosiborod,4 Anna Maria Langkilde,5 Felipe Martinez,5 Piotr Pionkowski,5 Marc S. Sabatine,5 Mikaela Sjostrand,2 Scott D. Solomon,3 John McMurray,1 1BHF Cardiovascular Research Centre, University of Glasgow, Glasgow, United Kingdom; 2AstraZeneca, Gothenburg, Sweden; 3Wroclaw Medical University, Wroclaw, Poland; 4Yale University, New Haven, CT; 5St Luke’s Mid America Heart Institute, Kansas City, KS; 6National University of Cordoba, Cordoba, Argentina; 7Brigham and Women’s Hospital, Boston, MA; 8Rigshospitalet - Copenhagen University Hospital, Copenhagen, Denmark.

Background: Hyperkalaemia often limits the use of mineralocorticoid receptor antagonists (MRAs) in patients with heart failure and reduced ejection fraction (HFHFrE), denying these patients a life-saving therapy.

Methods: The risk of developing mild hyperkalaemia (potassium ≥5.5 mmol/L) and moderate/severe hyperkalaemia (>6.0 mmol/L) was examined in the Dapagliflozin And Prevention of Adverse-outcomes in Heart Failure trial (DAPA-HF) according to background MRA use, and randomized treatment assignment, by use of Cox regression analyses.

Results: Overall, 3370 (70.1%) patients in DAPA-HF were treated with an MRA. Mild hyperkalaemia occurred in 182 (11.1%) and 213 (14.1%) patients treated with dapagliflozin as compared to 204 (12.6%) and 40 (2.4%) of patients given placebo (Table and Figure). This yielded a hazard ratio (HR) of 0.86 (0.70-1.05) for mild hyperkalaemia and 0.50 (0.29, 0.85) for moderate/severe hyperkalaemia, compared to placebo.

Conclusions: Patients with HFHFrE and taking an MRA who were randomized to dapagliflozin had half the incidence of moderate/severe hyperkalaemia, compared to those randomized to placebo.

Funding: Commercial Support - AstraZeneca

Cumulative incidence of hyperkalaemia in patients taking MRA at baseline

Metformin Improves Vascular Function in CKD Patients with Metabolic Syndrome

Everly Ramos,1 Melis Sahinnoz,2 Carlos O. Pena,3 Elvis A. Akwo,1 Christinae Ronnie,1 Zhihong Yu,1 Edward D. Siew,1 Talat Alp Ikizler,2 Adrian Hung,1,3 Vanderbilt University Medical Center, Nashville, TN; 2Tennesse Valley Healthcare System, Nashville, TN; 3Universidad Central de Venezuela, Caracas, Venezuela, Bolivarian Republic of.

Background: Cardiovascular (CV) risk is increased in CKD. Insulin resistance (IR), highly prevalent in CKD patients, contributes to endothelial dysfunction and arterial stiffness, leading to poor CV outcomes. It remains unknown if insulin sensitization with metformin improves CV risk, in patients with CKD Stage 3-4 and metabolic syndrome (MS).

Methods: In a double-blinded randomized trial (NCT02252081), 50 patients with CKD Stage 3, and MS and/or pre-diabetes, received either metformin or placebo for 16 weeks. Dosing was initiated at 500 mg and up-titrated over 7-14 days based on GI tolerance up to 1500 mg/day in CKD3a and 1000 mg/day in CKD 3b. Co-therapies for optimal CV risk reduction were continued. The co-primary outcomes included change in noninvasive carotid intima-media thickness (CIMT) in common (CCA) and internal (ICA) carotid arteries at 16 weeks. Last-observed value was obtained throughout the study for safety.

Results: Participants were 65 ± 10 years old and 80% were men. Mean [SD]: BMI 31.4 ± 5.1 kg/m²; SBP 130.5 ± 16 mmHg; DBP 74 ± 9 mmHg; HLD 46.4 ± 15 mg/dl; fasting glucose (FG) 92.3 ± 10.3 mg/dl; HbA1C 5.7 ± 0.24%; HOHA-IR 2.4±1.5, and eGFR was 50 ± 7 ml/min/1.73 m². There were 18 patients (16%) in CKD Stage 3b, 3 in the metformin and 5 in the placebo group. Compared with placebo, metformin improved FMDmax (baseline: 6.24% ± 4.5% [mean±SD], 16 weeks: 12.06% ± 8.4% [mean±SD] with metformin and baseline: 6.12% ± 3.34% [mean±SD], 16 weeks: 7.6% ± 4.6% [mean±SD] with placebo, P=0.03 [Fig 1], without changing aPWV (P=0.84) or CIMT. F CAA (P=0.10) L CCA (P=0.96) R ICA (P=0.74) L ICA(P=0.44).

Conclusions: Treatment with metformin improved FMDmax, but not aPWV or CIMT in patients with CKD and IR. Studies of larger sample size and longer duration are required to further evaluate the effects on cardiovascular outcomes.

Associations Between Enrollment in ESCR Special Needs Plans and Outcomes
Bryan N. Becker,1 Jiacong Luo,2 Kathryn S. Gray,3 Carey Colson,2 Dena E. Cohen,2 Stephen D. McMurry,1 Bryan W. Gregory,1 Nathan Lohmeyer,1 Steven M. Brunelli,1 DaVita Integrated Kidney Care, Denver, CO;1 DaVita Clinical Research, Minneapolis, MN;1 DaVita Inc., Denver, CO.

Background: Chronic condition special needs plans (C-SPNs) are Medicare Advantage plans that offer care coordination and specialized services for patients with conditions such as end-stage renal disease (ESRD) via specific benefits packages and provider networks. Although ESRD C-SPNs have been offered for over 10 years, an understanding of their impact on patient outcomes is lacking.

Methods: This observational study considered dialysis patients receiving care at a large dialysis organization who enrolled in a C-SPN from January 2013 to September 2017; study data were derived from deidentified medical records. As of C-SPN enrollment date (or matched date for controls), enrollees and controls were matched on the basis of index month, sex, race, etiology, and dialysis modality, as well as a propensity score. Eligible controls were patients who (separately) 1) dialedyzed in the same facility as the C-SPN patient but had not enrolled in the C-SPN, 2) dialedyzed in counties with no C-SPN but that were otherwise socio-demographically similar to C-SPN counties. Outcomes were evaluated from enrollment date through the first of study end (31 Dec 2018) or censoring for death, insurance change, or loss to follow-up. Within each matched cohort, outcomes were compared using generalized linear or Fine and Gray subdistribution hazard models.

Results: Hospitalization rates were 10% to 24% lower among C-SPN enrollees compared to controls, with an incidence rate ratio of 0.90 (95% confidence interval [CI] 0.84, 0.97) for patients in the same facility and 0.76 (95% CI 0.70, 0.83) for patients in similar counties. The mortality rate for C-SPN enrollees was approximately 23% lower than that of controls, with a hazard ratio of 0.77 (0.68, 0.88) for patients in the same facility and 0.77 (0.68, 0.88) for patients in similar counties. No meaningful differences were observed between groups with respect to serum calcium, phosphate, potassium, parathyroid hormone levels, or Kidney Disease Quality of Life scores.

Conclusions: C-SPN enrollment is associated with markedly lower rates of hospitalization and mortality, compared to non-enrollment.

FR-OR22

Organizational Characteristics Associated with High Performance in Medicare’s ESCR Seamless Care Organizations
Kelsey M. Dreyer,1 Amal Trivedi,1 Adam S. Wilk.3 Emory University, Atlanta, GA;3 Brown University, Providence, RI.

Background: In 2016, the 1% of beneficiaries with end-stage renal disease (ESRD) constituted >7% of Medicare spending ($35 billion). To improve the value of care for the ESRD population, CMS implemented an alternative payment model (APM) for ESRD care, the ESRD Seamless Care Organization (ESCO), which shares savings with provider groups that reduce spending for ESRD patients below a defined benchmark. This study evaluated the relationship between key organizational, provider, community characteristics, and ESCO performance.

Methods: We constructed a novel ESCO-level dataset capturing key information for Wave 2 (2017) ESCOs using data from CMS reports, the National Provider Identification registry, and the Area Health Resource File. After describing all 37 ESCOs, we performed bivariate comparisons of high- and low-performing (above vs below median) ESCOs based on gross savings/losses, composite quality score, and standardized mortality ratio (SMR). We then estimated generalized logistic regression models of ESCO performance as a function of organizational, provider, and community characteristics.

Results: ESCO composition and performance were highly varied (ranges: savings/losses -3.9 to 10.2%; quality 76.4-100%; SMR 0.75-1.14). Bivariate analysis showed that ESCOs with above (vs below) median savings had more aligned physicians (58 vs 29, p=0.06), fewer dialysis facilities (8.7 vs 17, p=0.07), a smaller non-Hispanic Black population (14% vs 22%, p=0.06), and higher median household income ($59k vs $49k, p=0.01). Facilities reporting a quality score of 100% (vs <100%) had fewer practices (22 vs 43, p=0.05) and smaller non-Hispanic Black (16% vs 21%, p=0.06) and Medicaid eligible (6.5% vs 8.9%, p=0.14) populations. Low (vs above-median) SMR was associated with higher median household income ($58k vs $48k, p<0.01). Regression model results were consistent with these findings, though small sample size prevented statistically significant estimates.

Conclusions: Our findings offer the first evidence of the impact of organizational composition and social disparities on ESCO performance. We show that the disparity in ESCO composition and savings partially explained the high variation in performance. This study provides crucial evidence that will inform the design and implementation of APMs in nephrology and the decisions of providers considering participation.

FR-OR23

Progress in Preventing Bloodstream Infections in Hemodialysis: Data from the National Healthcare Safety Network, 2014-2018
Shannon Novosad, Lucy V. Fike, Minn Soe, Shunte Moon, Preeti Ravindhran, Erikka J. Woolfolk, Lauren Moccia, Due B. Nguyen, Priti R. Patel. Centers for Disease Control and Prevention, Atlanta, GA.

Background: Patients on hemodialysis are at high risk of bloodstream infections (BSIs) and associated morbidity and mortality. National prevention efforts have resulted in widespread practice changes, including central venous catheter (CVC) care. We analyzed Dialysis Event surveillance data submitted to the National Healthcare Safety Network (NHSN) to describe BSI rates among hemodialysis outpatients from 2014 to 2018.

Methods: Outpatient hemodialysis facilities report BSIs (positive blood cultures collected in the outpatient setting or within 1 day after hospital admission) and the number of hemodialysis patients treated during the first 2 working days of each month to NHSN. For each BSI, the suspected source and vascular access type [e.g., CVC, arteriovenous fistula (AVF) or arteriovenous graft (AVG)] are indicated. Pooled mean rates (per 100 patient-months) were calculated. Annual BSI rate trends were evaluated using a negative binomial regression model including access type, year, and an access-year interaction variable.

Results: More than 6,000 outpatient hemodialysis hemodialysis facilities reported 134,961 BSIs from 2014 to 2018. Of these BSIs, 102,505 (76%) were categorized as access-related. Pooled mean BSI rates decreased 27% from 0.64 to 0.47 per 100 patient-months. Significant decreases in rates occurred across vascular access strata (Table); the reduction was most pronounced among patients with CVCs. BSI rates in patients with CVCs decreased 32% from 2.16 per 100 patient-months to 1.46 (annual average decrease 9.5%).

Conclusions: Substantial reductions in BSI rates among hemodialysis patients occurred during this 5-year period. Improvements in infection prevention practices, including CVC care, have likely contributed. Efforts to increase uptake of known prevention practices and implement new strategies for prevention might contribute to continued decreases in infections.

Funding: Other U.S. Government Support

BSI rates per 100 patient-months and annual trends, by access type, NHSN 2014-2018

Efficacy and Safety of Difelikefalin for Moderate-to-Severe CKD-Associated Pruritus: A Global Phase 3 Study in Hemodialysis Patients (KALM-2)
Thomas D. Wooldridge,1 Kieran Mccafferty,2 Michael Schoemig,3 Botond Szaboles Csky,2 Rafal Zwiech,1 Warren Wen,2 Catherine Munera,1 Frederique Menezghi,3 Nephrology and Hypertension Associates, Ltd., Tupelo, MS;3 The Royal London Hospital - Barts Health NHS Trust, London, United Kingdom;1 Dialysezentrum Heilbronn, Heilbronn, Germany;3 Norbert Barlitzki Memorial Teaching Hospital No. 1 of the Medical University of Lodz, Lodz, Poland;3 Cara Therapeutics, Stamford, CT;3 FMC Satellitza Dialysis Center Pecs, Pecs, Hungary.

Background: Chronic kidney disease (CKD)-associated pruritus (CKD-aP) is a common and distressing condition in CKD patients (pts) and has a serious negative impact on quality of life (QoL). Difelikefalin (DFFK), a novel, peripherally restricted and selective kappa opioid receptor agonist, demonstrated efficacy in a US phase 3 study (KALM-1) in hemodialysis (HD) pts with CKD-aP. Here we report primary results from the global phase 3 study of DFFK in HD pts with CKD-aP (KALM-2).2 NCT03636269.

Methods: HD pts with CKD-aP were randomized to receive intravenous DFFK 0.5 mg/kg (N=237) or placebo (PBO; N=236) after dialysis sessions. The primary endpoint was the proportion of pts who achieved a ≥3-point improvement from baseline (BL) in the weekly mean of the daily Worst Itching Numerical Rating Scale (WI-NRS) score at wk 12. Secondary endpoints were the proportion of pts who achieved a≥4-point improvement in WI-NRS score and mean change in itch-related QoL scores (5-10 itch and SkinEx10) from BL to wk 12.

Results: BL mean weekly WI-NRS scores were 7.3 and 7.1 in the DFF and PBO groups. The primary endpoint was met, with 54% of pts who received DFF achieving Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
a 3-point improvement in WI-NRS score vs 42% in the PBO group (P=0.020). The proportion of pts who achieved a 4-point improvement in WI-NRS score was also significantly greater with DFK vs PBO (41% vs 28%, P=0.010). ICH reduction was evident at wk 1 and was sustained through wk 12. Improvement in itch-related QoL assessed by 5-D Itch and Skindex-10 was observed. Treatment-emergent AEs ≥5% with DFK vs PBO were: diarrhea (8.1% vs 5.5%), fall (6.8% vs 5.1%), dizziness (5.5% vs 5.1%), vomiting (6.4% vs 5.9%), and nausea (6.4% vs 4.2%). The incidence of serious AEs was similar across the groups.

Conclusions: In this second phase 3 study, IV DFK demonstrated rapid and sustained itch reduction in HD pts with CKD-aP in multiple regions of the world. DFK was generally well tolerated; safety was consistent with findings in prior studies. With no approved therapies for CKD-aP in the US or Europe, DFK is a potential therapeutic that may address this unmet need.

FR-OR25
Efficacy and Safety of Roxadustat in Patients with Dialysis-Dependent CKD and Anemia on Hemodialysis
Robert Provenzano,1 Jayant Kumar,2 Pablo E. Pergola,3 Bui Pham van,4 Gregory Snow,5 Clinton A. Streja,6 Hong-Ping P. Yu.7 Henry Ford Hospital, Detroit, MI; 2Renal Medicine Associates, Albuquerque, NM; 3Renal Associates PA, San Antonio, TX; 4Truong Dai hoc Y khoa Pham Ngoc Thach, Ho Chi Minh, Viet Nam; 5Fibrogen Inc, San Francisco, CA; 6AstraZeneca, Gaithersburg, MD

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Dialysis modality in patients with ESRD may impact clinical outcomes and survival. Thus, evaluation of safety and efficacy of roxadustat in patients on hemodialysis (HD) is of clinical importance.

Methods: Pooled data from three pivotal, phase 3, randomized, open-label, epoetin alfa-controlled studies of roxadustat for the treatment of anemia in patients with dialysis-dependent CKD were assessed in the subgroup of patients on HD. Endpoints evaluated were: mean change from baseline (CFB) in hemoglobin (Hb) averaged over Weeks 28-52 regardless of rescue therapy and Hb CFB averaged over Weeks 28-36 censored for rescue therapy. Safety and tolerability were assessed by reported treatment-emergent adverse events (TEAEs).

Results: In the DD-CKD study population, 90% (515/587) of patients were on HD (roxadustat=1761, epoetin alfa=1754). Baseline characteristics were generally similar between treatment groups. Mean (SD) Hb levels (mg/dL) at baseline were 9.64 (1.31) in the roxadustat (RD) CKD group and 9.61 (1.31) in the epoetin alfa (EA) group. Patients achieved a larger mean (SD) CFB to Weeks 28–52 in Hb with roxadustat vs. epoetin alfa (1.49 [0.98] vs. 0.89 [1.51]), corresponding to a least-squares mean (LSM) difference of 0.25 (95% CI: 0.19, 0.31) (p=0.0001). Patients achieved a larger mean (SD) CFB to Weeks 28-36 in Hb with roxadustat vs. epoetin alfa (1.27 [1.63] vs. 1.02 [1.60]), corresponding to a LSM difference of 0.25 (95% CI: 0.16, 0.33) (p=0.0001). TEAE rates were comparable between treatment groups.

Conclusions: Roxadustat was efficacious vs. epoetin alfa for increasing and maintaining Hb levels in patients with DD-CKD on HD. The safety and tolerability profiles were similar to the overall population and consistent with that observed in this patient subgroup.

FR-OR26
Stroke and Bleeding Risk Among US Veterans with Preexisting Atrial Fibrillation Transitioning to ESRD
Cachet Wenzinger,1 John Sy,1 Maria V. Marroquin,2 Kamary Kalantar-Zadeh,3 Csaba P. Kovousy,4 Elleni Straja.1 1Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; 2The University of Tennessee Health Science Center, Memphis, TN; 3VA Long Beach Healthcare System, Long Beach, CA; 4Memphis VA Medical Center, Memphis, TN

Background: Anticoagulation has been the mainstay of stroke prevention in patients with atrial fibrillation (AF). However, end stage renal disease (ESRD) patients on hemodialysis are at higher risk of bleeding and stroke outcomes, even without anticoagulation. It is unclear if patients should be continued on anticoagulation at the time of transition to ESRD.

Methods: We retrospectively examined a cohort consisting of 29,054 pre-dialysis patients with atrial fibrillation (AF) who then initiated dialysis. Patients were subject to the same transition parameters. We assessed how changing transition parameters affects projected dialytic modality distributions.

Results: By prevailing conditions, the simulation projects home dialysis will comprise 12% of the dialysis population in 2025. Increasing home hemodialysis (HD) and peritoneal dialysis (PD) utilization among incident ESRD patients from rates of 0.3% to 7.5% and from 11.5% to 37.5%, respectively, by 2025 will improve home dialysis utilization of 25% in 2025 and 29% in 2030. Concurrently increasing the rate of conversion from in-center HD to home dialysis from 3.0 to 15.0 events per 100 patient-years by 2025 results in home dialysis utilization of 37% in 2025 and 44% in 2030, as displayed. Decreasing home dialysis attrition rates has a smaller effect on home dialysis utilization.

Conclusions: Substantial growth of home dialysis utilization in the next decade will require a two-pronged approach to inflow: higher utilization of home dialysis in incident patients, emphasizing PD, and increased conversion of patients from in-center HD to home dialysis.

Forecasting the Distribution of Dialytic Modalities in the Era of Advancing American Kidney Health
Kristine Kubisbak,1 Eric D. Weinhandl,1,2 Lorien S. Dalrymple,1 Michael A. Kraus,1 Dinesh K. Chatoth,1 Robert J. Kossmann,1 Franklin W. Maddux,5 1Fresenius Medical Care, Waltham, MA; 2Chronic Disease Research Group, Minneapolis, MN

Background: The Executive Order on Advancing American Kidney Health aims to increase home dialysis utilization in patients with end stage kidney disease (ESKD).

Methods: We constructed a simulation projecting dialytic modality distributions between 2019 and 2030 as a function of changing modality transition rates.

Results: We specified the US ESKD population in Dec. 2018 and used Markov chain Monte Carlo methods to randomly assign patients to a dialytic modality, transplant, or death each month until Dec. 2030, according to parameters that regulate the inflow and outflow of each state. Incident ESKD patients entered the cohort each month and were subject to the same transition parameters. We assessed how changing transition parameters affects projected dialytic modality distributions.

Conclusions: By prevailing conditions, the simulation projects home dialysis will comprise 12% of the dialysis population in 2025. Increasing home hemodialysis (HD) and peritoneal dialysis (PD) utilization among incident ESKD patients from rates of 0.3% to 7.5% and from 11.5% to 37.5%, respectively, by 2025 will improve home dialysis utilization of 25% in 2025 and 29% in 2030. Concurrently increasing the rate of conversion from in-center HD to home dialysis from 3.0 to 15.0 events per 100 patient-years by 2025 results in home dialysis utilization of 37% in 2025 and 44% in 2030, as displayed. Decreasing home dialysis attrition rates has a smaller effect on home dialysis utilization.

Hospitalization and Day of the Week: Comparing Peritoneal Dialysis, Home Hemodialysis, and In-Center Hemodialysis
Karthik K. Temmunkote,1 Amicie-Claire Nadeau-Fredette,1 Kara Matheson,4 Christopher T. Chan, Emilie Trinh,1 Jeffrey Perl,1 Dalhousie University, Halifax, NS, Canada; 2Toronto General Hospital, Toronto, ON, Canada; 3Hospital Maisonneuve-Rosemont, Montreal, QC, Canada; 4St. Michael’s Hospital, Toronto, ON, Canada; 5McGill University, Montreal, QC, Canada; 6Nova Scotia Health Authority, Halifax, NS, Canada

Background: Studies have shown that there are daily variations in mortality for patients receiving in-center hemodialysis (HD) but not home HD, peritoneal dialysis or more frequent in-center HD. Less is known about daily variations in hospitalization according to dialysis modality.

Methods: We analyzed all chronic dialysis patients in Canada (excluding Manitoba and Quebec) from 1 Jan 2005 to 31 Dec 2014 using the Canadian Organ Replacement Register (CORR). Dialysis modalities were defined (using CORR) as peritoneal dialysis, conventional HD or frequent HD (nightly or short daily) and HD modalities were further categorized as home versus in-center. All switches between modalities after dialysis initiation were included provided the duration of the switch was >30 days.

Key: TH - Thursday: FR - Friday: SA - Saturday: SU - Sunday: OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
The absolute number of hospitalizations for each day of the week was reported for each treatment type and differences in the distribution of hospitalizations were compared using the Chi-square test.

**Results:** The cohort consisted of 36,334 individuals. Median age was 67 and 61% were of male sex. A total of 81% of patients were receiving hemodialysis at dialysis initiation and the cause of end-stage kidney disease was secondary to diabetes in 37%. Overall, there were 119,466 hospitalizations over the observation period. The cumulative number of hospitalizations was highest for conventional in-center HD (92,707) and lowest for conventional home HD (701). Day of the week admissions for each treatment type are noted in Table 1 (P<0.001). Hospitalizations were least frequent on Saturday and Sunday for all groups. The proportion of admissions was highest on Monday or Tuesday for conventional HD (regardless of location) and frequent in-center HD. In contrast, frequent home HD had a higher proportion of admissions on Wednesday.

**Conclusions:** There are daily variations in hospitalization comparing dialysis modalities. Future planned analyses will evaluate whether there are adjusted differences in day of the week hospitalization across modalities accounting for differences in patient characteristics.

**Improving Supportive Care of Seriously Ill Dialysis Patients with Goals-of-Care Conversations**

*Alvin H. Moss,1 Annette Aldous,2 Glenda Harbert,1 Amanda C. Nicklas,3 Louis Diamond,3 Nancy Armistead,3 Dale Lupu,1 2West Virginia University Health Sciences Center, Morgantown, WV; 2George Washington University School of Public Health and Health Services, The George Washington University Milken Institute of Public Health, Washington, DC; 3The George Washington University School of Nursing, Ashburn, VA.*

**Background:** Dialysis patients are frequently known to receive unwanted high intensity end-of-life care. Families rate the quality of this care lower than families of patients with other chronic diseases. The purpose of this study was to test the feasibility of a supportive care intervention—the Pathways Project, an evidence-based change package of best practices—to identify seriously ill patients (SI), engage them in goals of care discussions, and track outcomes for patient goal concordance.

**Methods:** Pathways researchers recruited 10 dialysis centers with 1,546 patients. Dialysis staff screened patients with the surprise question (SQ)—"Would I be surprised if this patient died in the next 6-12 months?"—to identify those who were SI and recorded patient outcomes including the number screened, SI, goals of care conversations, hospitalizations, referred to hospice, death, and place of death. An odds ratio was calculated for the odds of SI dying versus those who were not SI, and one-sided Cochran-Armitage trend tests were used to assess for increasing goals of care conversations and deaths at home. The study was interrupted at 9 months due to COVID-19.

**Results:** On average, 98.8% of patients were screened monthly, and 18.4% were identified as SI. Of 114 patients who died, the SI constituted 66% of deaths though only 18.4% of patients. The mortality for the SI was 27% versus 3% for those who were not, and the odds ratio for SI dying was 11.22 (95% CI 7.42 to 16.98, P < .0001). Dialysis interdisciplinary teams implemented site-specific approaches to adding goals of care conversations into usual workflow; the number conducting conversations with SI within 30 days of hospital discharge increased from 30% to 80% (P < .02). The proportion of the patients who died at home in the last 2 months was higher than baseline (32.6% vs 18.8%), but a trend was not yet evident (P = .12).

**Conclusions:** The Pathways intervention is feasible to implement supportive care best practices into existing workflow of dialysis centers. It takes time for teams to get comfortable with new processes and communication approaches; after 9 months more centers were conducting goals of care conversations and more patients were dying at home. Future research is needed to determine if the Pathways intervention results in outcomes more aligned with patient preferences.

FR-OR31

**Implementation of a Decision Aid for Recognition and Correction of Volume Alterations (Recova®) in Hemodialysis**

*Jenny Stenberg,1 Magnus Lindberg,2 Hans Furuland,3 1Uppsala University Department of Medical Sciences, Uppsala universitet Institutionen for medicinska vetenskap, Uppsala, Sweden; 2Uppsala University Department of Public Health and Caring Sciences, Uppsala universitet Institutionen för folkhals- och vardvetenskap, Uppsala, Sweden; 3Hogskolan i Gävle, Gävle, Sweden.*

**Background:** Chronic fluid overload is an independent predictor of mortality in hemodialysis. Clinical assessment of fluid status is subjective and unprecise, and 30% of the patients remain fluid overloaded at dry weight. This study evaluates the effects of implementing a recently developed decision aid, Recova®, which combines a systematized fluid status procedure with bioimpedance spectroscopy, for individualized dry weight determination in hemodialysis.

**Methods:** The study was a prospective implementation intervention carried out at two hemodialysis units. The impact of the intervention was measured as the proportion of participants at an adequate dry weight at the end of the study, assessed as change in symptoms, hydration status, and N-terminal pro-brain natriuretic peptide (NT-proBNP). Hemodialysis nurses were instructed to use Recova® every two weeks, assessing the study participants’ fluid status and adjusting their dry weights as appropriate. The process of the intervention was measured as frequencies of fluid status assessments, bioimpedance measurements, and dry weight adjustments.

**Results:** Forty-nine patients were enrolled. In participants with fluid overload (n = 10), both bioimpedance-measured overhydration and fluid overload symptom score decreased. In fluid-depleted participants (n = 20), dry weight adjustment frequency and dry weight increased. The post-dialytic negative overhydration was reduced, but NT-proBNP increased. In the remaining 19 participants, with low volume status scores, no significant changes were observed.

**Conclusions:** Recova® defines how and when dry weight should be evaluated in hemodialysis patients. Its purpose is to provide the multidisciplinary team with a common language, and thereby facilitate early recognition and appropriate response to fluid alterations. Implementation of Recova® in hemodialysis care increased the monthly frequencies of bioimpedance measurements and dry weight adjustments, and contributed to symptom reduction.

**Funding:** Clinical Revenue Support, Government Support - Non-U.S.
present impaired permeability to albumin, due to a dysfunctional assembly of the GBM, typically localized to the GBM and binds to COL4A3/laminin to inhibit podocyte adhesion. Mice lacking ROBO2/SLIT2 signaling negatively regulates nephrin-induced actin polymerization and destabilizes podocyte focal adhesions and attachment to the glomerular basement membrane (GBM) by inhibiting non-muscle myosin II A. Lack of ROBO2 in podocytes are protected from podocyte injury. Based on these findings we hypothesized that blocking this pathway might have therapeutic potential in podocyte injuries. Here we provide evidence to support the hypothesis from a case with a genetic defect in ROBO2 and a rodent model of podocyte injury.

**Methods:** We investigated a patient with a chromosomal translocation that disrupted the ROBO2 gene, produced transcripts encoding dominant negative proteins, and caused high-grade vesicoureteral reflux (VUR). We designed a novel therapeutic ROBO2 fusion protein (ROBO2-Fc, PF-06730512) that inhibits the ROBO2/SLIT2 pathway. In vivo efficacy of ROBO2-Fc was tested in the rat Passive Heymann Nephritis (PHN) model. We also studied the molecular and cellular functions of SLIT2 in kidney glomeruli. Results: In contrast to most adults with long-standing VUR that develop focal and segmental glomerulosclerosis (FSGS) and proteinuria, the patient with a disrupted ROBO2 gene had stable renal function without proteinuria. In vitro, ROBO2-Fc bound to SLIT ligands with high affinity and dose-dependently inhibited SLIT binding to cell surface ROBO2, and it inhibited ROBO2-dependent cell migration ex vivo. ROBO2-Fc has a terminal half-life of about 6 hours in rat and 8 days in monkey. Treatment with ROBO2-Fc reduced proteinuria, shortened podocyte foot process width, and increased slit-diameter density in the rat PHN model. Mechanistically, we found that SLIT2 is localized to the GBM and binds to COL4A3/laminin to inhibit podocyte adhesion.

**Conclusions:** We have generated a novel therapeutic ROBO2 fusion protein that functionally inhibits SLIT ligand-podocyte injury pathway in clinical demand. Inhibiting the ROBO2/SLIT2 pathway therapeutically reduces proteinuria and improves podocyte ultrastructure. A phase 2 clinical trial to evaluate the safety and efficacy of ROBO2-Fc (PF-06730512) in patients with FSGS is currently ongoing (NCT03448692).

### FR-OR34

**Semaphorin 3B-Associated Membranous Nephropathy**

**Sanjeev Sethi,**1 Hanna Debiec,2 Benjamin J. Madden,1 Marina Vivarelli,2 Cristine Charlesworth,1 Ashiwayra Ravindran,1 Louann Gross,2 David Buob,2 Cheryl L. Tran,1 Francesco Emma,4 Francesca Diomed-Camassaci,4 Fernando C. Fervenza,1 Pierre M. Ronco,2,21 Mayo Clinic, Rochester, MN; 2Sorbonne Universite, Paris, France; 3Tenon Hospital, Paris, France; 4Ospedale Pediatrico Bambino Gesu, Roma, Italy.

**Background:** Membranous nephropathy (MN) results from subepithelial antigen-antibody complex deposition along the glomerular basement membrane (GBM). Although PLA2R, THSD7A, and NELL1 account for a majority (approximately 80%) of the target antigens, the target antigen in the remaining MN is not known.

**Methods:** We performed laser microdissection and mass spectrometry (MS) of glomeruli in kidney biopsies of 70 cases of PLA2R-negative MN. We detected high spectral counts of a unique protein Semaphorin 3B (Sema3B) in 3 cases. Immunohistochemistry (IHC) for Sema3B was then performed to confirm MS results. Next, we analyzed 3 validation cohorts (2 French and 1 Italian) of 118 PLA2R-negative MN cases by immunofluorescence microscopy (IF). Confocal microscopy studies were done to confirm colocalization of IgG and Sema3B along the GBM. Next, serum antibodies were detected by Western blotting (WB).

**Results:** MS identified a unique protein, Sema3B in 3 cases of PLA2R-negative MN. MS failed to detect Sema3B in the remaining 67 PLA2R-negative MN, in 23 PLA2R-associated MN, and 88 controls that included IgA nephropathy, diabetes, FSGS and hereditary forms of MN. Sema3B was expressed in tubular basement membrane (TBM) IgG deposits, the TBM deposits were negative for Sema3B. WB analysis in 5 available sera showed reactivity to reduced Sema3B in 4 of 4 patients with active disease and no reactivity in 1 patient in clinical remission; there was also no reactivity in control sera. Eight (73%) of the 11 cases of Sema3B-associated MN were pediatric cases. In 5 of the 8 children, the disease started below the age of 2 years.

**Conclusions:** Semaphorin 3B-associated MN is a distinct type of MN, and is predominantly present in pediatric patients.

---

**Figure 1** shows bright granular capillary wall staining for Sema3B in 3 cases of Sema3B-associated MN.

### FR-OR35

**High Temperature Recombinant Protein A1 (HTRA1): A Novel Antigen in Membranous Nephropathy**

**Laith Al-Rabadi,**1 Tiffany Caza,2 Claire Avillard,3 Aylin R. Rodan,4 B. Williams,1 Josephine Abraham,1 Monica P. Revelo Penafiel,1 Nicole K. Andeen,1 I. Kawai,1 Frederic Clayton,1 Timothy Cummins,1 Michael Merchant,2 Jon B. Klein,1 Christopher P. Larsen,3 Laurence H. Beck.2 (HTRA) for Sema3B-associated MN was performed to confirm MS results. Next, we analyzed 3 validation cohorts (2 French and 1 Italian) of 118 PLA2R-negative MN cases by immunofluorescence microscopy (IF). Confocal microscopy studies were done to confirm colocalization of IgG and Sema3B along the GBM. Next, serum antibodies were detected by Western blotting (WB).

**Conclusions:** Semaphorin 3B-associated MN is a distinct type of MN, and is predominantly present in pediatric patients.

---

**Figure 1** shows bright granular capillary wall staining for Sema3B in 3 cases of Sema3B-associated MN.
Results: Using these combined approaches, we identified HTRA1 as a novel antigen in a subset of patients with primary MN. Serum from these patients reacted with WB with a 51 kDa protein in non-reduced HGE as well as hHTRA1, which correlated with clinical disease activity (Fig A and B). Consistent with PLA2R and THSD7A, anti-HTRA1 antibodies were predominantly IgG4. HTRA1 specifically was detected in a capillary loop fine granular pattern (Fig C) and colocalized with IgG4. Whole-proteome peptide microarrays detected significantly higher titer (6.9 SD) of anti-HTRA1 antibody in the active stage as opposed to the remission stage which was informative of its candidacy as a podocyte targeted protein. We have 3 confirmed cases of HTRA1-associated MN and are currently screening several large biopsy cohorts of MN that are negative for PLA2R, THSD7A, and NELL-1 to better assess the prevalence of this novel form of MN.

Conclusions: This report demonstrates the convergence of conventional with more modern techniques to identify HTRA1 as a target podocyte antigen in MN.

Protocadherin 7-Associated Membranous Nephropathy
Sanjeev FR-OR36
Charlesworth,1 Hanna Madden,1 Charles Debiec,2
1Mayo Clinic, Rochester, MN; 2Sorbonne Universite, Paris, France, Tenon Hospital, Paris, France.

Background: Membranous nephropathy (MN) results from subepithelial antigen--antibody complex deposition along the glomerular basement membrane (GBM). Although PLA2R, THSD7A, and NELL-1 account for a majority (approximately 80%) of the target antigens, the target antigen in the remaining MN is not known.

Methods: We performed laser microdissection and mass spectrometry (MS) of glomeruli in kidney biopsies of 85 cases of PLA2R-negative MN. We detected high spectral counts of a unique protein Protocadherin 7 (PCDH7) in 8 cases. Immunohistochemistry (IHC) for PCDH7 was then performed to confirm MS results.

Results: MS identified a unique protein, PCDH7 in 8 cases (9.4%) of PLA2R-negative MN. MS failed to detect PCDH7 in remaining 77 PLA2R-negative MN, 23 PLA2R-positive MN, and 88 controls that included IgA nephropathy, diabetes, FSGS and minimal change disease. Among the 77 PLA2R-negative MN, MS detected NELL1 (14 cases), EXT1/EXT2 (6 cases), PLA2R (4 cases labeled PLA2R-negative on IF), Sema3B (3 cases), THSD7A (2 cases), and DNAJB9 (4 cases of fibillary GN, misdiagnosed as MN as EM was not done). PCDH7 localized as granular deposits along the GBM by IHC (Figure 1). Kidney biopsy showed a grade II MN in 6 cases, grade I in 1 and grade III in 1 case. Immunofluorescence microscopy showed GBM staining for IgG and C3 in all cases. IgG subclassing done in 2 cases showed IgG4 in both. The mean age was 64 years (+/- 11) and 7 of the 8 patients were males. The average serum creatinine and proteinuria was 1.28 mg/dL (+/- 0.3) and 4.9 g/mL (+/- 3.0), respectively. Interestingly, 3 of 8 cases had associated malignancies. Further studies including evaluation for circulating antibodies are ongoing.

Conclusions: Protocadherin 7-associated MN may represent distinct type of MN.

Nefcon® (Budesonide) Selectively Reduces Circulating Levels of BAFF (BLYS) and Soluble BCMA and TACI in IgA Nephropathy
Karen Molyneux, Jonathan Barratt, David H. Wimbury. Mayer IgA Nephropathy Laboratory, University of Leicester, UK, Leicester, United Kingdom.

Background: Evidence supports a pivotal role for gut-associated lymphoid tissue (GALT) as a major source of poorly O-galactosylated immunoglobulin A (IgA) 1 in patients with IgA nephropathy (IgAN). IgA synthesis in gut memory B cells is regulated by B-cell activating factor (BAFF) [B-lymphocyte stimulator (BLYS)] and APRIL, a proliferation-inducing ligand (APRIL). BAFF and APRIL bind to specific cell-surface receptors: transmembrane activator and calcium modulator and cyclophilin ligand interactor (TACI), B-cell maturation antigen (BCMA), and the BAFF receptor. Elevated levels of BAFF and APRIL have been linked to worse clinical outcomes in IgAN. The therapeutic potential of targeting GALT was demonstrated in the NEFIGAN trial (NCT01738035), which assessed the efficacy of a novel targeted-release formulation of budesonide (Nefcon®), designed to deliver budesonide to the GALT-rich distal ileum in patients with IgAN. The trial comprised 6-month run-in, 9-month treatment, and 3-month follow-up phases: 48 patients received Nefcon® 16 mg/day, 51 patients received Nefcon® 8 mg/day, and 50 patients received placebo. As a result, Nefcon® 16 mg/day, added to optimised renin--angiotensin system blockade, reduced proteinuria and stabilized estimated glomerular filtration rate in patients with IgAN. This study investigated whether Nefcon® treatment altered serum levels of BAFF and APRIL and their receptors.

Methods: Serum levels of BAFF, APRIL, BCMA, and TACI were measured using Luminex technology. Changes in the levels of BAFF and APRIL were compared using a one-way analysis of variance. Significance was set at p<0.05.

Results: A significant, dose-dependent reduction in serum BAFF levels was seen with Nefcon®, which reversed on cessation of Nefcon®. There were similar significant reductions in the levels of soluble BCMA and TACI with treatment, but no effect was seen on circulating levels of APRIL. These changes were mirrored by parallel changes in soluble CD27 levels and were consistent with our previous reports on dose-dependent reductions in circulating IgA-IgG immune complexes, secretory IgA, and galactose-deficient IgA levels with Nefcon®.

Conclusions: Delivering budesonide to the GALT-rich distal ileum modulates key regulators of GALT B-cell maturation and IgA class switch recombination in patients with IgAN.

Tony Muchamuel, Rong A. Fan, Janet L. Anderl, Henry Johnson, Dustin L. Memmin, Brian Tuch, Christopher Kirk. Kezar Life Sciences Inc, South San Francisco, CA.

Background: Selective inhibition of the immunoproteasome blocks progression of nephritis in a mouse model of systemic lupus erythematosus (SLE). Here we describe the effects of KZR-616 in this model and in patients from MISSION (KZR-616-002; NCT03393013), an open-label study of KZR-616 in patients with SLE with and without nephritis.

Methods: 24-week old NZB/W mice were treated weekly with subcutaneous administration of 5 mg/kg KZR-616 for 11 weeks. SLE patients with active disease and stable background medication (N=34) were dosed subcutaneously with KZR-616 at all dose levels and reductions in disease activity parameters were noted. KZR-616 treatment was associated with a reduction in class-switched memory B cells and PC in peripheral blood. Decreased expression of gene modules for PC, T-cell activation, inflammation, neutrophil, and type I IFN responses were seen in response to treatment.

Conclusions: KZR-616 resolves nephritis in a mouse model of SLE/LN by regulating immune effector cell gene expression and glomerular injury. In SLE patients, KZR-616 demonstrated broad anti-inflammatory activity across T, B, and innate immune effector cells. These results support further clinical evaluation of KZR-616 in patients with LN.

NCAM1 Is an Autoantigen in Membranous Lupus Nephritis
Tiffany Cazaa,1 Samar Hassen,1 Michael B. Kuperman,1 Ricky Edmondson,2 Christian Herzen,2 Aaron J. Storey,2 John M. Arthur,2 Željko Dvornjak,1 Shree G. Sharma,1 Daniel J. Kenan,2 Laith Al-Rabadi,2 Christopher P. Larsen.1
1Arkana Laboratories, Little Rock, AR; 2University of Arkansas for Medical Sciences, Little Rock, AR; 3University of Utah Health Hospitals and Clinics, Salt Lake City, UT.
Background: Membranous lupus nephritis is a frequent cause of proteinuria in patients with systemic lupus erythematosus. In patients with membranous lupus nephritis, the target autoantigens are largely unknown. Determination of a target autoantigen can have diagnostic significance, inform prognosis, and enable non-invasive monitoring of disease activity. We utilized mass spectrometry to identify target autoantigens in membranous lupus nephritis and report cell neural adhesion molecule-1 (NCAM1) as a novel target podocyte antigen.
Methods: We utilized mass spectrometry for antigen discovery of laser capture microdissected (LCMD) glomeruli and protein G immunoprecipitation studies to interrogate immune complexes. Confocal microscopy was used to examine co-localization with IgG within glomerular immune deposits. Case series of biopsies from PLAR2-negative membranous nephropathy patients (n=101) and patients with membranous lupus nephritis (n=212) were used to determine the overall frequency of these antigens. Western blotting reacting patient sera against recombinant NCAM1 protein was used to detect circulating anti-NCAM1 antibodies.
Results: NCAM1 was uniquely identified in a subset of patients with membranous lupus nephritis in LCMD glomeruli and protein G immunoprecipitations by mass spectrometry. NCAM1 was localized with IgG within glomerular immune deposits. The prevalence of NCAM1 positivity by immunofluorescence was 6.1% of cases of membranous lupus nephritis and 2.0% of idiopathic membranous nephropathy cases. Additionally, serum from NCAM1 patients showed reactivity to NCAM1 recombinant protein, demonstrating the presence of circulating antibodies.
Conclusions: We propose that NCAM1, a cytoskeleton-linked transmembrane protein, is a target autoantigen in a subset of patients with membranous lupus nephritis and within rare cases of idiopathic membranous nephropathy. The presence of anti-NCAM1 antibodies in vivo could allow for non-invasive monitoring.

Alpha-1-Antitrypsin Diminishes Neutrophil Activation by PR3-ANCA and Endothelial Injury by Neutrophil Serine Proteases
Ralph Kettritz,1,2 Uwe Jerke,1 Claudia Eulenberg-Gustavus,1 Dieter E. Jenne.3
1Experimental and Clinical Research Center, Charité, Max Delbrück Center for Molecular Medicine in the Helmholtz Association, Berlin, Germany; 2Charité Universitätsmedizin Berlin, Berlin, Germany; 3German Center for Lung Research, Helmholtz Zentrum München, Munich, Germany.
Background: Neutrophil serine proteases (NSPs) contribute to ANCA-associated vasculitis (AAV). PR3 is a unique NSP family member because it is both a proteolytic enzyme and an ANCA antigen. Alpha-1-antitrypsin (AAT) is the major natural NSP inhibitor. We hypothesized that AAT protects from ANCA-induced neutrophil activation and neutrophil-mediated glomerular endothelial cell injury.
Methods: We produced recombinant wild-type (wt) AAT and a mutant (mu) form that does not inhibit proteolytic NSP activity. We used flow cytometry to study membrane PR3 (mPR3) and MPO (mMPO), ferricytochrome C assay for superoxide release, FRET assays for proteolytic NSP activity, human neutrophils and glomerular microvascular endothelial cells (gMVEC) for confocal and electron microscopy, and assessed ECs by phalloidin staining and gene expression.
Results: Wt-AAT reduced mPR3 on TNF-primed neutrophils dose-dependently from 0.1 to 10 μM (n=5). Five μM wt-AAT, but not mu-AAT, reduced neutrophil mMPO in suspension, on fibronectin, and on an EC monolayer to approximately 25% (n=3). Parallel comparisons in neutrophil-EC co-cultures using antibodies to different PR3 epitopes showed that 5 μM AAT reduced mPR3 but not mMPO. Importantly, reduced mPR3 by wt-AAT, but not mu-AAT, reduced neutrophil mPR3 in TNF-primed neutrophils dose-dependently.
Conclusions: AAT has protective effects by reducing neutrophil activation in response to PR3-ANCA, and NSP-mediated glomerular microvascular endothelial cell injury. Disturbances of the AAT-NSP balance possibly contribute to neutrophil-mediated vascular injury in AAV, particularly, but not exclusively, in patients with PR3-ANCA.

Harnessing Expressed Single-Nucleotide Variation and Single-Cell RNA Sequencing to Define Immune Cell Chimerism in the Rejecting Kidney Transplant
Andrew F. Malone, Haoja Wu, Joseph Gauth, Benjamin D. Humphreys. Washington University in Saint Louis, Saint Louis, MO.
Background: In solid organ transplantation, donor derived immune cells are assumed to decline with time after surgery. Whether donor leukocytes persist within kidney transplants or play any role in rejection is unknown, however, in part because of limited techniques for distinguishing recipient and donor cells.
Methods: We performed paired whole exome sequencing of donor and recipient DNA and single cell RNA sequencing (scRNA-seq) of 5 human kidney transplant biopsy cores. Exome sequences were used to define single nucleotide variants (SNV) across all samples.
Results: By analyzing expressed SNVs in the scRNA-seq dataset we could define recipient vs. donor cell origin for all 81,139 cells. The leukocyte donor to recipient ratio varied with rejection status for macrophages and with time post-transplant for lymphocytes. Recipient macrophages were characterized by inflammatory activation and donor macrophages by antigen presentation and complement signaling. Recipient origin T cells expressed cytotoxic and pro-inflammatory genes consistent with an effector cell phenotype whereas donor origin T cells are likely quiescent expressing oxidative phosphorylation genes relative to recipient T cells. Finally, both donor and recipient T cell clones were present within the rejecting kidney, suggesting lymphoid aggregation. Our results indicate that donor origin macrophages and T cells have distinct transcriptional profiles compared to their recipient counterparts and donor macrophages can persist for years post transplantation.
Conclusions: This study demonstrates the power of this approach to accurately define leukocyte chimerism in a complex tissue such as the kidney transplant coupled with the ability to examine transcriptional profiles at single cell resolution.

Proteomics Reveals Extracellular Matrix Injury in the Glomeruli and Tubulointerstitium of Kidney Allografts with Early Antibody-Mediated Rejection
Serhi Clot Freixes,1 Caítrona M. McEvoy,1 Ihor Batruch,2 Chiara Pastrello,3 Max Koltyr,1 Madhurangi Arambawela,1 Julie Anh Dung Van,1 Yun Niu,1 Sofia Farkona,1 Alexander Boshart,1,2 Andrea Bozovic,1 Vathulya Kaliastorn,3 Olusegun Famure,1 Joseph Kim,1 Tereza Martini,1 Stephen C. Juvet,1,3 Andrzej Chrusciński,1,7 Rohan John,1,18 Ana Konvalinka,1,19 1Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada; 2Department of Laboratory Medicine and Pathobiology, University health Network, Toronto, ON, Canada; 3Division of Respirology and Toronto Lung Transplant Program, University Health Network, Toronto, ON, Canada.
Background: As donor leukocytes persist within the allograft and can play any role in rejection as of yet unknown, in part because of limited techniques for distinguishing recipient and donor cells. We studied 30 kidney transplant recipients with early AMR, acute cellular rejection (ACR) or acute tubular necrosis (ATN). We targeted microdissected glomeruli and tubulointerstitium and subjected them to unbiased proteomic analysis.
Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Results: We found 107 glomerular and 122 tubulointerstitial proteins significantly differentially expressed in AMR vs ACR (p<0.05). Similarly, 112 (glomeruli) and 124 (tubulointerstitium) proteins were altered in AMR vs ATN. Basement membrane and extracellular matrix (ECM) proteins were decreased in both compartments in AMR, compared to ACR and ATN. We verified decreased glomerular and tubulointerstitial LAMC1 expression, and decreased glomerular NPHS1 and PTPRO expression in AMR. Cathepsin-V (CTSV) was predicted to cleave ECM-proteins in the AMR glomeruli. We identified galectin-1, an immunomodulatory protein increased in AMR glomeruli and linked to the ECM. An external dataset (GSE36059) also demonstrated increased galectin-1 expression and linked anti-HLA-class-I antibodies induced inflammation and significantly increased CTSV expression, and galectin-1 expression and secretion, in human glomerular endothelial cells. We also studied GSTO1, an ECM-modifying enzyme, increased in the AMR tubulointerstitium. GSTO1 expression was significantly increased in TNFα-treated proximal tubular epithelial cells.

Conclusions: Basement membranes are often remodeled in chronic AMR, and we demonstrated that this remodeling begins early in glomeruli and tubulointerstitium. ECM-remodeling in AMR may represent a new therapeutic target.

FR-OR43
Interim Update of the MDR-101-MLK Phase 3 Trial: MERCURY Study
Dixon Kaufman,1 Mark D. Stegall,2 Ethan P. Marin,3 Ahmed O. Gaber,4 Titte Srinivas,5 Erik Stites,6 Stephan Busque,7 Martin L. Mai,8 Matthew Cooper,9 Suzanne Crowley,1 James B. Piper,10 Asher P. Shah,1 Sanjeev Akkina,1 Kenneth Chavin,4 Mercury Study Group1 University of Wisconsin System, Madison, WI; Mayo Clinic Minnesota, Rochester, MN; Yale University Department of Internal Medicine, New Haven, CT; Houston Methodist, Houston, TX; University of Colorado, Denver, CO; Stanford University School of Medicine, Stanford, CA; Mayo Clinic’s Campus in Florida, Jacksonville, FL; MedStar Georgetown University Hospital, Washington, DC; University Hospitals, Cleveland, OH; Medeor Therapeutic, South San Francisco, CA; Inova Health Systems, Falls Church, VA; Jefferson Health, Wayne, PA; Loyola University Health System, Maywood, IL.

Background: The goals of tolerance in patients with kidney transplants (Ktxp) are to eliminate the lifelong need for immunosuppressive (IS) drugs and to prevent graft loss due to rejection or drug toxicity. MDR-101 is a novel cellular immunotherapy, to produce persistent mixed chimerism without graft versus host disease (GvHD) to allow elimination of all IS therapy without rejection, and, thus, to produce operational tolerance. The randomized study evaluated the need for chronic IS therapy in recipients of HLA-matched living donor (LD) kidney transplants as compared to standard of care (SOC) (NCT03363945).

Methods: Eligible adult pairs (donor/receiver) of a first kidney allograft from an HLA-identical LD were enrolled and randomized 2:1 to either the Investigational Arm (IA; n=20) or Control Arm (CA; n=10). Donors in the IA received G-CSF mobilization for 5 days before undergoing apheresis (1 or 2 cycles). IA recipients receive ATG conditioning, low-dose total lymphoid irradiation (TLI) over 10 days and IS followed by an infusion of MDR-101 on d11. After 180 days of persistent mixed chimerism, IA subjects initiated a 6-month taper of CNIs and could withdraw all IS on D365. CA subjects initiated a 6-month taper of CNIs and could withdraw all IS on D365. CA subjects were treated as institutional SOC.

Results: As of June 1 2020, 26 subject pairs (donor/receiver) have been enrolled, comprising 18 pairs randomized to the IA and 8 pairs randomized to the CA. MDR-101 infusion was completed in 12 subjects in the IA, and 9 subjects in the IA have reached Day 180 with 6 months of positive mixed chimerism. Five subjects have reached D365 and were able to withdraw all IS. Two subjects lost chimerism – 1 at D545 (off IS) and 1 at D245 continue to wear IS. There have been no events of GvHD, biopsy proven acute rejection, dnDSA. There have been no graft losses or deaths in either group.

Conclusions: Administration of MDR-101 in HLA-identical LD Ktxp recipients conditioned with ATG and TLI have produced promising results to date. These results show that MDR-101 induces mixed chimerism without GvHD and permits withdrawal of IS without rejection or dnDSA. Further analysis continues.

Single-Cell Profiling of Peripheral Blood Mononuclear Cell Identifies Immune Populations Associated with High Risk of Early Acute Rejection
Weijia Zhang, Samina S. Farouk, Zeguo Sun, Zhengzi Yi, Jia Fu, Chengguo Wei, Miguel Fribourg, John C. He, Paolo Cravedi, Barbara T. Murphy. Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Our previous transcriptomic analysis of pre-peritransplant peripheral blood of 235 kidney transplant recipients in a multi-center GoCAR cohort revealed a 23-gene set predictive of early acute rejection (EAR) post kidney transplant, but the associated immune profile is unknown.

Methods: We first developed a reliable targeted RNA expression (TREX) sequencing assay based on the EAR prediction gene set and applied the assay to assess the EAR risk of 21 dialysis patients who were recruited at Mount Sinai Hospital. We next performed extensive single-cell immune profiling of PBMCs of these patients using 33 surface markers with CyTOF technology. Lastly, using 10X genomics technology, we performed single cell RNA sequencing (scRNAseq) of the PBMCs to identify immune cell (sub) populations and their transcriptomic signatures from two patients with high and low risk of EAR, respectively.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.

**Modified Immune Cell Infusion in Kidney Transplantation**

Christian Morath, 1 Matthias Schauer, 1 Eman H. Ibrahim, 1 Wei Li, 1 Christian Kleist, 1 Gerhard Opelz, 1 Caner Süssel, 1 Mostafa G. Aly, 1 Claudius Speer, 1 Florian Käßle, 1 Christian Nussbag, 2 Luiza Pego Silva, 3 Claudia Sommerer, 1 Angela Hückelhoven-Krauss, 3 Arianeh Mehrabi, 3 Carsten Mueller-Tidow, 3 Jochen Reiser, 2 Martin G. Zeier, 1 Michael Schmitt, 1 Peter Ternes, 1 Anita Schmitt, 1 Volker Daniel, 1 *Ruprecht Karls Universität Heidelberg, Heidelberg, Germany; 2Rush University Medical Center, Chicago, IL.*

**Background:** We have shown that donor blood cells, modified in *vitro* by an alkylating agent (MIC, modified immune cells), induced specific immunosuppression against the allogeneic donor when administered prior to transplantation. An additional finding was an up to 68-fold increase in the frequency of immunosuppressive CD19+CD24hiCD38hi transitional B lymphocytes compared to transplanted controls without MIC infusions. The question arises whether donor-specific immunosuppression and increased regulatory B lymphocytes (Breg) are permanently detectable in MIC-treated patients.

**Methods:** Four patients from a phase-I trial who had received 1.5x10^9/MIC per kg b.w. on day -7 before living donor kidney transplantation and who were on low immunosuppression were compared to 12 transplanted control patients without MIC infusions.

**Results:** MIC-treated patients showed an excellent clinical course with no donor-specific HLA antibodies or rejection. On day 1080 after transplantation, median serum creatinine was 1.59 mg/dL. Patients had absent *in vitro* lymphocyte reactivity against stimulatory donor blood cells while reactivity against third party cells was preserved as an indication of continued donor-specific unresponsiveness. CD19/CD24/CD38+ and CD19+CD24+CD38+ Breg were with 2.2x and 1.0x, respectively strikingly higher than the 0.0x (P=0.001) and 0.0x (P=0.001) in transplanted controls and in the range of the numbers of healthy individuals (N=34, P=0.73 and P=0.60). In addition, significantly higher Breg numbers were found for CD1d+ (P=0.0071), CD19+CD24+CD38+ (P=0.0077), CD19+CD25+CD73-CD71+ (P=0.013), CD19+CD25+CD73+CD71 (P=0.0011), CD19+CD24+CD27+ memory (P=0.029), and IL10+CD19+CD24+CD27+ memory Breg (P=0.042). No such differences were observed for CD4+CD25+CD73+Fox3+ Treg (P=0.60) or different Treg subsets when comparing the four MIC-treated patients to transplanted controls without MIC infusions.

**Conclusions:** Donor-specific immunosuppression after MIC infusion is long-lasting and is associated with a striking increase in Breg at various stages of B cell development, including memory Breg.

**Background:** Normothermic ex-vivo kidney perfusion (NEVKP) results in significantly improved graft function in porcine auto-transplant models of DCDF injury compared to cold storage (SCS); however, the molecular mechanisms underlying these beneficial effects remain unclear.

**Methods:** We performed an unbiased proteomics analysis of 28 kidney biopsies obtained at 3 timepoints from pig kidneys subjected to 30-minutes of warm ischemia, followed by 8 hours of NEVKP or SCS, and auto-transplantation.

**Results:** Of 6593 proteins quantified, 70 were differentially expressed between NEVKP and SCS groups (2-way ANOVA, q<0.05). Proteins increased in NEVKP mediated key metabolic processes including fatty acid ß-oxidation; the TCA cycle and oxidative phosphorylation. Our findings with external datasets of ischemia-reperfusion, and other models of kidney injury confirmed that 47 of our proteins represent a common signature of kidney injury reversed or attenuated by NEVKP. We validated key metabolic proteins (ETFB, CPT2) by immunoblotting. Integrated transcription factor databases identified PPARG1A, PPARA/G/D and RXRA/B as the upstream regulators of our dataset, and we confirmed our increased expression in NEVKP with RT-PCR.

**Conclusions:** The proteome-level changes observed in NEVKP mediate critical metabolic pathways that may explain improved graft function with NEVKP compared to SCS. These effects may be coordinated by PPAR-family transcription factors, and may represent novel therapeutic targets in ischemia-reperfusion injury.

**Cyclosporine-Induced Endothelial Injury and Complement Activation Is Caused by Impaired Complement Factor H Binding to the Glycopalx**

Chin Wei Teed, 1 Carolina Ortiz, 1 Magdalena Riedl Khursiga, 1 Valentina Bruno, 1 Lisa Robinson, 1 Christoph Licht. 1*The Hospital for Sick Children, Toronto, ON, Canada.*

**Background:** Calcineurin inhibitors are associated with nephrotoxicity, endothelial cell (EC) dysfunction and thrombotic microangiopathy. Evolving evidence suggests a central role for complement dysregulation in the pathogenesis of CNI-induced thrombotic microangiopathy. However, the exact mechanism of calcineurin-inhibited complement-mediated injury remains unknown.

**Methods:** In an in-vitro model utilising Blood Outgrowth EC (BOEC) from healthy donors, we evaluated the effects of cyclosporine (CyaA) on EC injury, complement activation (C3a, C9) and regulation (CD46, CD55 and complement factor H [CFH]) on EC surfaces, and on the EC glycopalx, utilising flow cytometry, Western blot, and immunofluorescence imaging. Functional activity of CFH was assessed via CFH co-factor assay. Co-immunoprecipitation of Angiopoietin-2 (Angpt-2), Angiopoietin-1 (Angpt-1) and Tie2 was assessed by Western blot.

**Results:** CyaA resulted in a dose and time dependent enhancement of EC complement damage. The ELISA for C3a, C9, CD46, CD55 and CD59 and complement factor H [CFH] on EC surfaces, and on the EC glycopalx, utilising flow cytometry, Western blot, and immunofluorescence imaging. Functional activity of CFH was assessed via CFH co-factor assay. Co-immunoprecipitation of Angiopoietin-2 (Angpt-2), Angiopoietin-1 (Angpt-1) and Tie2 was assessed by Western blot.

**Conclusions:** Our findings confirm a role for complement in CyaA-induced EC injury, and suggest Angpt-2 mediated glycopalx abolishment, induced by CyaA, as a mechanism leading to complement alternative pathway dysregulation via decreased CFH surface binding and surface co-factor activity.

**Epigenome-Wide Microarray Analysis of Pre- and Post-Transplant Methylation Profiles in Kidney Transplant Recipients**

Katie Kerr, 1 Laura J. Smyth, 1 Jill Kilner, 1 Alexander P. Maxwell, 1,6 Helen Mcaeney, 1 A.J. Mcknight, 1 *Queen’s University Belfast, Belfast, United Kingdom; 2Belfast City Hospital Nephrology Service, Belfast, United Kingdom.*

**Background:** Kidney transplantation is the optimal treatment for suitable individuals with end-stage kidney disease (ESKD). Serious post-transplant complications include infections, cardiovascular events, malignancy, and new onset of diabetes after transplant (NODAT). Our regional nephrology centre has the highest living donor transplant rate per million population in Europe, and promotes research to improve patient outcomes. We compared pre and post-transplant methylation profiles in samples derived from matched participants.

**Methods:** We performed an unbiased methylation analysis of 28 kidney biopsies obtained at 3 timepoints from pig kidneys subjected to 30-minutes of warm ischemia, followed by 8 hours of NEVKP or SCS, and auto-transplantation.

**Results:** Of 6593 proteins quantified, 70 were differentially expressed between NEVKP and SCS groups (2-way ANOVA, q<0.05). Proteins increased in NEVKP mediated key metabolic processes including fatty acid ß-oxidation; the TCA cycle and oxidative phosphorylation. Our findings with external datasets of ischemia-reperfusion, and other models of kidney injury confirmed that 47 of our proteins represent a common signature of kidney injury reversed or attenuated by NEVKP. We validated key metabolic proteins (ETFB, CPT2) by immunoblotting. Integrated transcription factor databases identified PPARG1A, PPARA/G/D and RXRA/B as the upstream regulators of our dataset, and we confirmed our increased expression in NEVKP with RT-PCR.

**Conclusions:** The proteome-level changes observed in NEVKP mediate critical metabolic pathways that may explain improved graft function with NEVKP compared to SCS. These effects may be coordinated by PPAR-family transcription factors, and may represent novel therapeutic targets in ischemia-reperfusion injury.
Methods: Epigene-wide analysis was conducted using the Illumina Infinium MethylationEPIC array to interrogate 862,987 sites across the genome and identify any differentially methylated regions (DMR) in samples derived from peripheral blood mononuclear cells of age and sex matched pre (n=25) and post (n=25) kidney transplant recipients. DNA was extracted in a uniform manner and stored carefully undergoing minimal freeze thaw cycles. Samples were run on the same instrument and regression calibration was performed in R to estimate leukocyte cell proportions.

Results: Association analysis using Partek® GenomicsSuite® identified 53 DMR (FDR adjusted pval<0.01 x 10^(-6), fold change +/-2). Within the top ranked CpG probes we identified DMR within genes dysregulated in melanoma (e.g. EXOC2, VEPH1), genes encoding extracellular matrix proteins that could influence structural glomerular changes (e.g. SPAN1) and genes with prior chronic kidney disease associations (e.g. FNTA). A DMR was also identified within the long intergenic non-protein coding RNA LINC01344, suggesting a possible regulatory function. Additionally, Partek® Pathway® identified enrichment of DMR in the mitogen-activated protein kinase (MAPK) signalling pathway, primarily implicated in malignancy but also ESKD and cardiovascular disease. Gene ontology analysis identified enrichment of terms associated with localization and binding within cells.

Conclusions: This analysis provides a novel epigenomic perspective on molecular changes caused by kidney transplantation, and highlights markers that may be of relevance to post-transplant complications. We provide evidence supporting further methylation and transcriptomic analyses in larger cohorts to help identify epigenetic risk factors associated with post-transplant complications.

Impact of Caspase-1 Deletion on Apoptosis and AKI in a Murine Transplant Model  
Swati Jain,1 Robert J. Plenter,2 Trevor Nydam,1 Alkesh Jani,1,2 University of Colorado, Denver, CO; 3Rocky Mountain Regional VA Medical Center; Aurora, CO.

Background: Prolonged cold ischemia (CI) is a known risk factor for acute kidney injury (AKI) after kidney transplantation. However, the mechanism by which CI leads to AKI is unknown. Caspase-1 knockout mice (Casp1KO) are protected from AKI after warm ischemia/reperfusion injury. We hypothesized that Casp1KO mice would be protected from AKI following transplantation.

Methods: Renal tubular cells (RTECs) were subjected to cold storage and rewarming (CS/REW). C57Bl/6J wild type or Casp1KO kidneys were subjected to CI for 30 min and then transplanted into wild type recipients (CI+Txp). The recipients underwent bilateral nephrectomy to assess transplant function.

Results: In vitro: We observed significantly increased expression of NLRP1 inflammasome protein and Caspase-1 in cells subjected to CS/REW. Using Imagestream flow cytometry we observed spatial overlap between two different fluorescent labels of Caspase-1 and NLRP1 in RTECs exposed to CS/REW compared to control cells. In vivo studies: Wild-type kidneys subjected to CI+Txp demonstrated significantly increased Caspase-1 and NLRP1 protein expression. Caspase-1 deletion results in significantly decreased RTEC apoptosis in transplanted Casp1KO vs WT kidneys. Renal function, brush border injury, cast formation, tubular simplification were similar in both groups and not significantly different [Table 1].

Conclusions: CS/REW and CI+Txp increase NLRP1 and Caspase-1 expression and co-localization. Deletion of Caspase-1 improves tubular cell apoptosis following CI+Txp. However, Caspase-1 deletion did not prevent AKI and necrosis in kidneys subjected to CI+Txp, suggesting that other triggers of inflammation and programmed necrosis may need to be included in addition to deletion of Caspase-1 to fully prevent AKI after kidney transplantation.

Studying Proteinuria in COVID-19 to Define Markers of Severity and New Treatments  
Yask Gupta, Juntao Ke, Jeremiah Martino, Qingxue Liu, Byun hee Kil, Tze Yin Lim, Gina Ying Jin, Dina Ahram, Nicholas J. Steers, Simone Sanna-Cherchi. Columbia University Irving Medical Center; New York, NY.

Background: The recent SARS-Cov-2 pandemic has led to ~375,000 fatalities worldwide as of June 1st. Nearly, 43% of COVID-19 patients have been reported to have proteinuria, which can result from direct podocyte injury, podocytopathy related to cytokine storm, or both. This association between respiratory viruses, proteinuria, and primary kidney disease has also been observed in the context of respiratory syncytial virus (RSV), where patients can develop nephrotic syndrome. Therefore, studying primary and virus-dependent models of proteinuria and podocyte injury is critical to shed light into COVID-19 pathobiology, severity of disease and potential treatments.

Methods: We accessed transcriptional data (RNA-seq) for lung cell lines (A549) infected with three different viruses and identified differentially expressed genes (DEGs) for SARS-CoV-2, RSV and IAV. In parallel, we also investigated DEGs for FSGS and MCD using LIMMA R package. We investigated the statistical correlation between the log-fold change of DEGs (Nephrotic syndrome and SARS-CO2-2) using R. Pathway analysis was performed using WebGestalt. Possible drugs correcting the skewed gene expression in FSGS and SARS-CO2-2 were identified using the Connectivity map (eMAP).

Results: 120 gene signatures were specific to SARS-CoV-2. By using gene expression data from glomeruli of FSGS/MCD we identified 902 DEGs for FSGS and 5 for MCD. Out of these, 6 were upregulated and upregulated in COVID-19 and FSGS/MCD (B2M, EIF2AK2, IFIT1, IFIT2, TC7M and UBE2L6). Strikingly, IFIT2 has been recently reported as a maker of disease severity in COVID-19. We found significant positive correlation between the log2 fold change of 94 FSGS/MCD genes intersecting with the 120 COVID-19. The results were specific to glomeruli and to high proteinuric diseases, supporting a common cellular response in lung and podocytes. We then searched the eMAP data and identified 59 drugs significantly inversely associated with SARS-CO2-2 and 72 for FSGS. Out of these, 7 drugs were in common, representing novel potential drugs for COVID-19 and podocytopathies.

Conclusion: Overall, our results suggest transcriptional congruency between NS and SARS-CO2-2 which can possibly be used to design novel therapies treat these diseases.

Machine Learning for Prediction of Severe AKI in Hospitalized Patients with COVID-19  
Kunnardeep Chandhary, Lili Chan, Aparna Saha, Kinsuk Chauhan, Akhil Vaid, Barbara T. Murphy, John C. He, Steven G. Coca, Girish N. Nadkarni. Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Preliminary reports indicate that acute kidney injury (AKI) is common in coronavirus disease (COVID-19) patients and is associated with worse outcomes. Identification of patients at high risk for developing severe AKI in hospitalized COVID-19 patients in the United States is not well-described.

Methods: This is a retrospective observational study of patients aged ≥18 years with laboratory confirmed COVID-19 admitted to the Mount Sinai Health System between February 27 and April 15, 2020. We trained and tested a machine learning algorithm, extreme gradient boosting (XGBoost), a boosted decision-tree based machine learning (ML) model, with 5-fold cross validation to predict AKI requiring dialysis. Patients from the Mount Sinai (MSH) were randomly split into a training and validation set for the model. To increase model generalizability and help minimize bias, the model’s performance was assessed on a test set composed entirely of patients from the other hospitals in the Mount Sinai Health System (MSHS). Input features for the model included demographics, laboratory values, and vital signs that occurred in the first 48 hours of admission.

Results: Of 3,235 hospitalized patients with COVID-19, AKI occurred in 1406 (46%) patients and 280 (20%) with AKI required dialysis. In the training set (n=1,317 patients), the classifier achieved good performance with an area under the receiver operating characteristic curve (AUROC) of 0.79 and area under the precision recall curve (AUPRC) of 0.38 for predicting AKI requiring dialysis. Performance was similar in the testing set (n=1,918) with 0.79 AUROC and 0.36 AUPRC. The features that had a larger impact on the model included serum creatinine, age, potassium, and heart rate.

Conclusion: A machine-learned model using admission features had good performance for dialysis prediction and could be used for resource allocation.
SA-OR03
SARS-CoV-2 Detection in Urine Sediment Suggests Infection of Kidneys and Correlates with Risk of AKI and Poor COVID-19 Prognosis
Paulo S. Caceras, Gina Savickas, Junior Udumian, Kusam Umanath, Yuvaraj Sharma, Jerry Yee, Shannon Murray, Sarah Sarkar, Jamie Fitzgerald, Dipak Maskey, Adrian Ormsby, Pablo A. Ortiz. Henry Ford Hospital, Detroit, MI.

Background: Since the emergence of the novel severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), most of the focus has been on the respiratory failure caused by the resulting disease, COVID-19. However, the effects of COVID-19 in the kidney are increasingly recognized. Acute kidney injury (AKI) has been identified with varying prevalence around the world with higher rates (37-46%) reported in the USA. It is debatable whether AKI is an indirect consequence of systemic inflammation or a consequence of viral renal cell infection and tropism. We hypothesized that SARS-CoV-2 directly infects kidney tissue and increases the risk of developing AKI, worsening prognosis of COVID-19 patients.

Methods: We studied 88 COVID-19 patients admitted to the Henry Ford Hospital, Detroit after April 15, 2020. Demographics were: mean age 60, 71% African American, 55% male. We quantified viral copies by RT-PCR (S and N) in urine sediments from 52 PCR-confirmed COVID-19 patients. We performed immunofluorescence for Membrane and Spike viral proteins in two COVID-19 biopsies.

Results: The prevalence of AKI was 72%, with 32% of patients admitted to the ICU. The overall mortality rate was 14%, with no deaths in non-AKI patients. Viral proteins M and S were detected in the glomerulus, parietal cells and tubulitis of COVID-19 patients. In some tubules, positive SARS-CoV-2 overlapped with ACE2, the receptor for viral entry. Virus was detected in 61% of urine sediments, with 6-fold greater viral load in AKI- versus non-AKI patients (copies/ng RNA: AKI, 7432±1338 vs No-AKI: 1523±404; p<0.05, n=52). The highest viral loads were detected three weeks post-AKI at 11,374±2248 copies/ng RNA (p<0.01). Among COVID-19 AKI-patients who died, the urine viral load exceeded 8800 copies/ng RNA. Above this threshold, the mortality rate was 55%.

Conclusions: Our data support that direct viral renal cell infection occurs in COVID-19 AKI patients with urinary viral genome detection. Greater urinary viral loads portend increased mortality. Urinary viral detection can facilitate management and treatment of COVID-19 and serve as an early warning signal. This research should focus on studying whether urine contains infective virus or sheds non-infective genomic fragments.

SARS-CoV-2 Receptor Networks in Diabetic Kidney Disease, BK Virus Nephropathy, and COVID-19 Associated AKI
Rajaseer Monen,1 Edgar A. Otto,1 Rachel S. Sealfon,2 Vijl Nair,2 Aaron Wong,2 Chandra L. Theesfeld,2 Xi Chen,2 Yuan Wang,2 Jennifer A. Schaub,2 Celine C. Berthier,3 Sean Eddy,2 Chrysta C. Lienczewski,2 Brad A. Godfrey,2 Ryan Sohany,2 Helen C. Looker,2 Laura H. Mariani,1 Abhijit S. Naik,1 Robert G. Nelson,1 Olga Troyanskaya,4 Matthias Kretzler,1 University of Michigan, Ann Arbor, MI; 2Flatiron Institute, New York, NY; 1National Institutes of Health, Bethesda, MD; 3Princeton University, Princeton, NJ.

Background: COVID-19 shows increased disease burden in patients with diabetic kidney disease (DKD). SARS-CoV-2 uses angiotensin-converting enzyme 2 (ACE2) for host cell entry, so ACE2 levels may influence SARS-CoV-2 susceptibility. We investigated how pre-existing conditions and drug treatments alter receptor expression for host cell entry, so ACE2 levels may influence SARS-CoV-2 susceptibility. We hypothesized that SARS-CoV-2 uses angiotensin-converting enzyme 2 (ACE2) for host cell entry, so ACE2 levels may influence SARS-CoV-2 susceptibility. We investigated how pre-existing conditions and drug treatments alter receptor expression.

Methods: Single cell RNA profiling of 7 healthy living donor kidneys, 44 DKD, 3 BK virus nephropathy (BKVN) and a urine COVID19 patient with acute kidney injury (COVID-AKI) revealed ACE2 expression primarily in proximal tubular epithelial cells (PTEC).

Results: ACE2 mRNA expression levels were higher in proximal tubule epithelial cells (PTEC) in DKD versus LDL, but unaltered by exposures to renin angiotensin aldosterone system inhibitors. Bayesian integrative analysis of public -omics datasets identified molecular network modules induced in ACE2 positive versus negative PTEC in DKD and BKVN (bb.flatironinstitute.org/covid-kidney), that were linked to viral entry, immune activation, endomembrane reorganization, and RNA processing. Similar programs were seen in COV-AKI ACE2-positive PTEC, and overlapped with programs in SARS-CoV2 infected cells.

Conclusions: A consistent ACE2-coregulated expression program in PTEC may interact with SARS-CoV-2 infection processes. These networks can seed further research into developing therapeutic strategies and assessing risk in patients with COVID-19.

Genomic Datasets from Traditional Murine Models of AKI and AKI-Lung Cross-Talk Reveal Molecular Pathways Relevant to COVID-19 Infection
Dmitry N. Grigorev,1 Hamid Rabb.2 University of Chicago Division of Biological Sciences, Chicago, IL; Johns Hopkins Medicine, Baltimore, MD.

Background: COVID-19 infection leads to ARDS and AKI, and there are established mechanistic links between acute kidney injury (AKI) and lung injury. SARS-CoV-2 uses cell entry angiotensin-converting enzyme 2 (ACE2) and transmembrane protease, serine 2 (TMPRSS2), which are expressed in kidney and lung. Using publicly available genomic datasets of ischemia and sepsis induced AKI in mice, we searched for established and novel molecular players of AKI and AKI-lung cross-talk relevant to COVID-19.

Methods: The microarray datasets GSE6730 (AP17 Renal 2007, JASN 2008) and GSE60088 (Shock 2016) were downloaded from Gene Expression Omnibus (GEO). GSE6730: lungs from mice with moderate and severe ischemic AKI were studied at 6h and 36h. GSE60088: kidneys were studied from mice after 6h of pneumonia+mechanical ventilation (PMV). Isolated RNA was hybridized to MG_430 microarray. To identify differentially expressed genes, GEO-built in GEO2R tool was used.

Results: AKI led to downregulated kidney ACE2 gene at both 6h (fold change (FC)=−2.41) and 36h (FC=−3.23) after severe (60min clamp) but not moderate ischemia (30 min clamp; 6 h: FC=+1.3, 36h: FC=+1.16). In lung from AKI mice, ACE2 was significantly downregulated (FC=−2.89, P=5.56e10). Ischemic AKI and PMV led to a decrease in lung TPRSS2 FC=−1.83, P=1.19e10 and FC=−1.68, P=6.58e10, respectively. The filtering for known genes with P-value<0.01 and FC>4 identified 53 kidney genes upregulated by PMV; and 254 lung genes upregulated by AKI, of which 9 genes were common to both organs. 3 of 9 genes were previously linked to kidney-lung crosstalk: Len2 (FC=+8.6, FC=+6.32), Socs3 (FC=+10.5, FC=+10.4), Inhib (FC=+12.0, FC=+6.17). This finding validates our approach and makes other 6 genes appealing candidates, especially Maff (FC=+7.21, FC=+5.98). This gene participates in the cellular stress response and also binds the oxytocin receptor promoter, which may be involved in gender differences in disease severity.

Conclusions: We identified changes in COVID-19 related genes ACE2 and TPRSS2 in traditional mouse models of AKI and lung cross talk. We also found new candidate genes activated in kidney during pneumonia+mechanical ventilation and in lung during AKI, which warrants further investigation of their involvement in the combined kidney-lung injury during COVID-19.

Funding: NIDDK Support
Results: Of 5,449 patients admitted with Covid-19, AKI developed in 1,993 (36.6%). The peak stages of AKI were stage 1 in 46.5%, stage 2 in 22.4% and stage 3 in 31.1%. Of these, 14.3% required renal replacement therapy (RRT). AKI was primarily seen in Covid-19 patients with respiratory failure, with 89.7% of patients on mechanical ventilation developing AKI compared to 21.7% of non-ventilated patients. 276/285 (96.8%) of patients requiring RRT were on ventilators. Of patients who required ventilation and developed AKI, 52.2% had the onset of AKI within 24 hours of intubation (Figure and Table). Risk factors for AKI included older age, diabetes mellitus, cardiovascular disease, black race, hypertension and need for ventilation and vasopressor medications. Among patients with AKI, 1,136 died (57%), 519 (26%) were discharged and 338 (17%) were still hospitalized.

Conclusions: AKI occurs frequently among patients with Covid-19 disease. It occurs early and in temporal association with respiratory failure and is associated with a poor prognosis.

SA-OR07
A Multicenter Observational Study of Clinical Features and Outcomes of AKI in Critically Ill Patients with COVID-19
Shruti Gupta, David E. Leaf. STOP-COVID Investigators Brigham and Women’s Hospital Department of Medicine, Boston, MA.

Background: Acute kidney injury (AKI) is emerging as an important sequela of COVID-19 infection. Existing data on the incidence and clinical features of AKI in patients with COVID-19 are mainly limited to single-center studies. Given the high incidence of severe AKI among patients with COVID-19 and its strong association with mortality in other settings, we conducted a multicenter nationally representative cohort study to examine the incidence, clinical features, risk factors, and outcomes of AKI in critically ill patients with COVID-19.

Methods: We used data from a multicenter observational study that collected granular, patient-level data from >3,000 critically ill adults with laboratory-confirmed COVID-19 admitted to participating ICUs from 67 centers across the United States. Using multivariable logistic regression, we examined risk factors for the primary composite outcome, AKI requiring renal replacement therapy or death (RRT/death) in the 14 days following ICU admission.

Results: Among 3099 patients, 1205 (38.9%) developed the primary outcome of RRT/death (n=637 required RRT, n=792 died within 14 days, and n=224 both required RRT/death) in 14 days. Independent risk factors for RRT/death included chronic kidney disease (odds ratio [OR], 5.02; 95% CI, 3.55-7.10 for eGFR<30 vs. ≥60; OR 1.90; 95% CI, 1.55-2.33 for eGFR 30-59 vs. ≥60), as well as older age, male sex, higher body mass index, and greater severity of hypoxemia on ICU admission (Figure). Patients admitted to hospitals with higher degrees of strain also had a greater risk of RRT/death (OR 1.49; 95% CI, 1.06-2.06 for highest versus lowest quintile of hospital strain). Patients requiring ventilation and developed AKI, 52.2% had the onset of AKI within 24 hours of intubation (Figure and Table). Risk factors for AKI included older age, diabetes mellitus, cardiovascular disease, black race, hypertension and need for ventilation and vasopressor medications. Among patients with AKI, 1,136 died (57%), 519 (26%) were discharged and 338 (17%) were still hospitalized.

Conclusions: This multicenter study identifies several key insights into the risk factors for RRT/death in critically ill patients with COVID-19.

Screening for SARS-CoV-2 (COVID) Infection in Chronic Dialysis Patients: A Nonprofit Provider’s Experience
Harold J. Manley, Karen M. Majchrzak, Ronald Sanders, Serena Cumber, Gideon N. Aweh, Vladimir Ladik, Carol Stewart, Doug Johnson, Antonia Harford, Eduorro K. Gison, Dialysis Clinic Inc, Nashville, TN; Tufts Medical Center, Boston, MA.

Background: The CDC recommends screening of all patients for COVID exposure history and or signs and symptoms prior to treatment. In order to limit the spread of COVID within our facilities, Dialysis Clinic Inc. screens all patients prior their in-center hemodialysis treatment or peritoneal dialysis visit consistent with recommendations.

Methods: We describe the outpatient screening results of our dialysis patients having a positive screen as patients under investigation (PUI) to activate local protocols for isolation and testing. We determined the frequencies of positive screening parameters and rate of identifying COVID patients.

Results: From 2/17 to 5/20, 2020, facilities screened 15,602 patients over 402,002 in-person visits, identifying 959 PUI’s (6%). Among PUIs, 61 of 351 (17%) COVID+ patients were correctly triaged prior to COVID+ diagnosis. In the subset of 788 PUIs screened prior to 4/11/20 where we were able to catalogue reasons for positive screening, 149 (19%) had exposure only and 639 exhibited symptoms (81%), of which 15 had exposure, 34 resided in group home (GH) and 7 had both exposure and GH residence. It was determined 41 (6.4%) were COVID+. Frequency of symptoms elicited by PUI are shown below.

Conclusions: 959 PUIs were identified and isolated by our screening process, resulting in the successful preemptive triage of 61 COVID+ (6%) patients before testing positive, potentially limiting infection spread in the facility. Cough and fever were the most common reasons for positive screen, and fever was most commonly associated with COVID+ diagnosis. However, the majority (83%) of COVID+ patients were primarily asymptomatic and hence not captured by screening.
SA-OR09
Urgent Peritoneal Dialysis Catheter Placement at a New York City Hospital During the COVID-19 Pandemic

**Background:** During the COVID-19 pandemic, there has been an unparalleled burden on nephrology services to provide kidney replacement therapy to patients admitted to the hospital with COVID-19, who develop severe AKI. Given the unprecedented surge in COVID-19 admissions, ability to provide inpatient hemodialysis and continuous kidney replacement therapy (CKRT) was quickly saturated. We present data from our acute peritoneal dialysis (PD) program that was quickly assembled to provide kidney replacement therapy due to shortage of hemodialysis and CKRT resources.

**Methods:** Patients admitted to an academic NYC hospital during COVID-19 pandemic with AKI requiring kidney replacement therapy were evaluated for candidacy for bedside PD catheter placement via cut-down method with the majority having COVID respiratory failure. A dedicated surgery team was assembled to place PD catheters within 12-24 hours of request by the nephrology team. Catheters were placed in patients with BMI up to 51. Patients requiring proning were not excluded. Exclusion criteria were prior lower abdominal surgery, known varices, or imminent death.

**Results:** Thirty-eight PD catheters were placed during the 4 week time period from April 8 to May 8, 2020. Majority of the catheters were placed bedside in an ICU setting (36/38 - 95%), with 2 being placed laparoscopically in the OR. There were no episodes of peritonitis. Three catheters required revision due to poor flows. Six catheters required floseal for bleeding along the catheter tract, which resolved without additional intervention. There were no major bleeding complications during PD catheter placement despite many patients being on systemic antiocoagulants. Dwell volumes of up to 2.2L did not appear to have negative effects on the ability to ventilate patients. One patient required transition to hemodialysis due to catheter malfunction.

**Conclusions:** Acute peritoneal dialysis successfully allowed kidney replacement therapy for patients with severe AKI during the peak phase of the COVID-19 pandemic at our hospital in NYC. There were no major complications with acute PD catheter placements.

SA-OR10
Recovery from AKI and Acute Respiratory Distress Syndrome (ARDS) with the Use of Low-Dose Steroids During COVID-19 Infection in an African American Population: A Retrospective Analysis
Subodh J. Saggi,1 Sridesh Nath,1 Roshni Calus,1 Seena Chittalae,1 Aaliya Burza,1 Patrick Geraghty,1 Jie Ouyang,2 Angelika C. Gruessner,1 Moro O. Salifu1.1 SUNY Downstate Health Sciences University, Brooklyn, NY; 2Saint Barnabas Hospital, Bronx, NY.

**Background:** Corona Virus Disease-19 (CoVID-19) infection associated with AKI and ARDS results in a mortality of 80%. In AA population COVID-19 presentations and outcomes are worse. NIH and Interim WHO guidelines suggest against steroids use unless in the context of clinical trials. We conducted a retrospective analysis on the impact of 2 different doses of IV steroids in AA adult population.

**Methods:** 75 patients between March 1 and April 30, 2020 were enrolled. Primary outcomes (21-day mortality) and secondary outcomes (improvement in lung function and renal function) were analyzed. Comparisons between the steroid doses (methylprednisolone 1 mg/kg/day or 2 mg/kg/day) and no-steroid groups were performed with the Wilcoxon, Kruskal-Wallis, and Chi-Square tests. Factors affecting the recovery of AKI or ARDS were analyzed. AKI recovery was defined as 50% increase of GFR, and cessation of RRT; lung function recovery was defined as improved oxygenation by P/F ratio > 200 and exudation.

**Results:** 38 out 75 patients received steroids. Survival in the steroids group reached 73% at 21 days compared to 36% in the non-steroids group (p=0.0006). Steroids improved the likelihood of renal function improvement by 300% (p=0.06). Lung function was 73% in the steroids group versus 45% in the other (p<0.0006). Use of anticoagulants (16% vs 51%, p=0.0001) seemed to be interacting with steroids on outcomes. Low dose steroids had the most beneficial impact.

**Conclusions:** In patients with COVID-19 infection and ARDS with AKI, low dose IV methylprednisolone was associated with a significantly lower incidence of mortality and higher likelihood of renal and lung function recovery. Further investigation with a randomized control trial consisting of low dose steroids seems warranted.

Podocyte-Derived Extracellular Vesicles Mediate Renal Proximal Tubule Cell De-differentiation via MicroRNA 221 in Diabetic Nephropathy
Hong Su,1 Jiao Qiao,2 Qun Yu,3 Bing Liu,2 Junhui Zhen,2 Zhimei Lv,1,2 Rong Wang,2 Department of Nephrology, Shandong Provincial Hospital, China; 1Department of Nephrology, Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, China; 3Department of Pathology, School of Medicine, Shandong University, Jinan, China.

Background: Podocyte injury is a key event in the initiation of diabetic nephropathy (DN), and the proximal tubule has been regarded as a target of injury. Evidence suggests that cross-talk between podocytes and tubular epithelium is a key component in the pathogenesis of DN, but the mechanisms are not fully understood.

Methods: The podocytes and proximal tubular epithelial cells (PTECs) were co-cultured in high glucose conditions to detect the intercellular communication. Podocyte-derived extracellular vesicles (EVs) was isolated and identified by specific morphology and surface markers. Immunofluorescence, PCR, western blot, electron microscope, and tranwell were conducted to assess the de-differentiation of PTECs. The expression level of miRNA in EVs was detected and Cy3-labeled mimics was used to demonstrate its direct transfer into target cells. A dual-luciferase reporting system was utilized to confirm the binding of miRNA to its target gene. The roles of miRNA and target gene were assessed using specific miRNA inhibitors, mimics and siRNA. In addition, Streptozotocin-induced diabetic mice and a models were constructed, and miRNA antagonem were used to explore its role in proximal tubule injury.

Results: Podocytes induced de-differentiation of PTECs in high-glucose conditions and induced cell-cell interaction. The podocyte-derived EVs was extracted and identified as exosome, and the EVs treatment induced PTECs injury. miR-221 was remarkably increased in EVs and could be directly transferred into target cells, moreover, this miRNA was shown to play a key role in PTECs de-differentiation. The dual-luciferase reporter assay confirmed that miR-221 target DDK2, and miR-221 positively regulated β-catenin activation. Importantly, inhibition of β-catenin markedly diminished the EVs and miRNA induced PTECs de-differentiation. Furthermore, inhibition of miR-221 in diabetic mice reversed the PTECs injury and relative β-catenin activation.

Conclusions: Podocyte-derived EVs in diabetes acted as key mediators of proximal tubule cell injury and the exosomal-miR-221 mediated the cells damage through Wnt/β-catenin signaling. These findings provide unique insights in the mechanisms of proximal tubule cell injury in diabetic nephropathy, and miR-221 can be used as a new target for the treatment of renal fibrosis in DN.

Whole-Genome Sequencing Identifies a Dominant Negative ADIPOQ Mutation in a Type 2 Diabetic Family Enriched for ESRD
Marcus G. Pezzolesi,1 Christopher A. Simeone,1 Joseph L. Wilkerson,1 Joseph M. Lazaro guevara,1 Edgar J. Hernandez,1 Bushra Gors,1 Scott G. Froodsham,1 Kristina V.O’Neil,1 Scott Summers,1 Andrzej S. Krolewski,2 William L. Holland,1 1University of Utah Health Care, Department of Internal Medicine, Salt Lake City, UT, US; 2Salt Lake City, UT, 1Joslin Diabetes Center; Harvard Medical School, Boston, MA, US; 2Boston, MA.

Background: Diabetic nephropathy (DN) is a complex, heterogeneous complication of diabetes. Despite evidence of its strong genetic predisposition, identification of the genetic determinants that contribute to DN and the risk of end-stage renal disease (ESRD) has been challenging.

Methods: We performed whole genome sequencing (WGS) in a multi-generational family with structural parameters.

Results: Using WGS to evaluate this family, we identified a rare loss-of-function mutation in adiponectin (ADIPOQ) (p.R662C), seen only once among 56,810 Finnish Europeans included in the gnomAD database) observed among 6 ESRD cases in this family. This 10-nucleotide deletion results in a premature termination codon and a complete loss of adiponectin’s globular domain. We found that carriers of this mutation have low circulating adiponectin (15% of normal levels) and dramatically high ceramide levels (double the level of C16 ceramides as compared with ADIPOQ wildtype diabetic patients). In cell culture, we observed that ADIPOQ (p.R662C) is degraded by the proteosome. Likely due to its incorporation to trimeric adiponectin, over-expression of the mutant protein decreases stability of wildtype adiponectin and exerts a dominant-negative effect that results in reduced adiponectin levels.

Conclusions: This is the first human family with a dominant-negative mutation in adiponectin. Importantly, while adiponectin is known to play important roles in insulin sensitivity, it also has a protective role in mitigating renal injury in patients with diabetes. Moreover, adiponectin knockout mice are prone to DN and podocyte apoptosis. Together these data provide evidence supporting the role of adiponectin in kidney disease in patients with diabetes.

SA-OR14
Enhancing Kidney DDAH-1 Expression by Adenovirus Delivery Reduces Asymmetric Dimethylarginine and Ameliorates Diabetic Nephropathy
Michael Wetzel,1 Ting Gao,2 Kristen Stanley,1 Timothy K. Cooper,4 Sidney M. Morris,1 Alia S. Awad,1 1University of Texas Health Science Center at San Antonio Department of Medicine, San Antonio, TX; 2University of Pennsylvania College of Medicine, Philadelphia, PA; 3Department of Nephrology, Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, China; 4Department of Pathology, School of Medicine, Shandong University, Jinan, China.

Background: Endothelial dysfunction, characterized by reduced bioavailability of nitric oxide and increased oxidative stress, is a hallmark characteristic in diabetes and diabetic nephropathy (DN). High levels of asymmetric dimethylarginine (ADMA) are observed in several diseases including DN and are a strong prognostic marker for cardiovascular events in patients with diabetes and end-stage renal disease. ADMA, an endogenous endothelial nitric oxide synthase (NOS3) inhibitor, is selectively metabolized by dimethylarginine dimethylaminohydrolase (DDAH). Low DDAH levels have been associated with cardiac and renal dysfunction, but its effects on DN are unknown. We hypothesized that enhanced renal DDAH-1 expression would improve DN by reducing ADMA and restoring NOS3 levels.

Methods: DBA/2J mice injected with multiple low doses of vehicle or streptozotocin were subsequently injected intrareally with adeno virus expressing DDAH-1 (Ad-h-DDAH-1) or vector control (Ad-green fluorescent protein [GFP]), and mice were followed for 6 wk.

Results: Diabetes was associated with increased kidney ADMA (p<0.05) and reduced kidney DDAH activity (p<0.05) and DDAH-1 expression (p<0.05) compared to normal mice but had no effect on kidney DDAH-2 expression. Ad-GFP-treated diabetic mice showed significant increases in albuminuria (p<0.005), histological changes (p<0.005), glomerular macropage recruitment (p<0.001), inflammatory cytokine (p<0.01) and fibrotic markers (p<0.01), kidney ADMA levels (p<0.05), and urinary thiobarbituric acid reactive substances excretion (p<0.01), along with a significant reduction in kidney DDAH activity (p<0.05) and kidney NOS3 mRNA (p<0.05) compared to normal mice. In contrast, Ad-h-DDAH-1 treatment of diabetic mice reversed these effects.

Conclusions: These data indicate, for the first time, that DDAH-1 mediates renal tissue protection in DN via the ADMA-NOS3-interaction. Enhanced renal DDAH-1 activity could be a novel therapeutic tool for treating patients with diabetes.

Cell Type Specificity of Hypoxia Signaling in Early Diabetic Kidney Disease (DKD)
Jennifer A. Schaub,1 Rajasree Menon,1 Viji Nair,1 Edgar A. Otto,1 Joel M. Weinberg,1 Helen C. Looker,2 Robert G. Nelson,3 Matthias Kretzler,1 1University of Michigan Health System, Ann Arbor, MI; 2National Institutes of Health, Bethesda, MD.

Background: Chronic hypoxia is considered a driver of kidney disease progression. Given the spatial heterogeneity of hypoxia, we evaluated the cell type specificity of Hypoxia Related Genes (HRG) in DKD along the nephron and the association of HRG with structural parameters.

Methods: Cell-specific expression and normalized gene signatures (Z scores) were calculated for 217 HRG in single cell RNA profiles of 44 kidney biopsies from American Indians with Type 2 Diabetes (T2D) and 7 healthy living donor kidneys (LD), and replicated in 49 independent micro-dissected biopsies of T2D with DKD (DN).

Results: Mean measured glomerular filtration rate was 159 ml/min (SD 54) in T2D and 147 ml/min (SD 45) in DN, and mean urine albumin/creatinine ratio was 304 mg/g (SD 1542) for T2D and 35 mg/g (SD 90) for DN. Average HgA1c was 9.2 for T2D and 9.3 for DN. HRG expression showed highly cell-type specific elements in both LD and T2D (Figure 1). HRG signature in stressed proximal epithelial cells (sPEC) unique to T2D, was dominated by apoptosis and glycolysis signals, while endothelial cells (EC) signatures expressed more genes involved in fibrosis in T2D compared to LD. In DN, Z score of the EC signature was associated with increased mesangial volume (R 0.33, p-value 0.02) and Z score of sPEC signature was associated with interstitial fibrosis (R 0.35, p-value 0.02), which are strong predictors of long-term outcomes in this cohort.

Conclusions: HRG expression varies by cell type in LD and DKD, suggesting transcriptional regulation changes of HRG in diabetes and DKD. Association of HRG signatures with morphometrics that are associated with progressive GFR loss implicate chronic hypoxia processes in early DKD.

Funding: NIDDK Support
Conclusions: Loss of SCO2 and mutant SCO2 reduced glomerular endothelial injury, oxidative stress, and early diabetic injury in the kidney with improved mouse survival in a murine model of DKD.

SA-OR17
Reversal of Diabetic Nephropathy After 10 Years of Pancreas Transplantation Occurs Despite Parallel Podocyte Loss
Behzad Najafiyan,1 Michael Mauer,2 Paola Fioretto,3 1University of Washington, Seattle, WA; 2University of Minnesota, Minneapolis, MN; 3University of Padova, Padova, Italy.
Background: Diabetic nephropathy (DN) is associated with podocyte (PC) injury and loss. PC injury is believed to play an important role in DN progression. DN reversal following 10 years (10Y) of euglycemia after pancreas transplantation (PTx) is documented (N Engl J Med 2016;375:69-75). We hypothesized that if PC loss has occurred, DN reversal would be associated with PC regeneration and improvement in PC structure.
Methods: Paired kidney biopsies prior to PTx (BL) and 10Y after PTx were compared for classical DN lesions, PC number and foot process width (FPW) using electron microscopy morphometry in 10 type 1 diabetic (T1D) patients with age 33 (30-54) years [median (range)], diabetes duration 23 (16-33) years and albumin excretion rate (AER) 134 (0-951) μg/min at BL. The results were compared with biopsies from 10 age matched living donor biopsies [controls (C)].

Results: Glomerular basement membrane (GBM) width, fractional volume of mesangium/gluomerulus [Vv(Mes/glom)] and fractional volume of mesangial/glomerulus [Vv(MM/glom)] and FPW were all increased at BL compared to C (data not shown). There were significant reductions in GBM width (30%; p=0.0002), Vv(Mes/glom) (21%; p=0.001), Vv(MM/glom) (30%; p=0.002), and glomerular volume (27%; p=0.02) at 10Y compared to BL. However, while PC number density did not change from BL to 10Y, there was a significant decrease in PC number/glomerulus (31%; p=0.049). FPW in T1D patients at BL (p=0.0008) or 10Y (p=0.002) was greater than C with no significant change found from BL to 10Y. No relationship was found between change in GBM width, Vv(Mes/glom) or Vv(MM/glom) and PC number density, PC number per glomerulus or FPW. Creatinine clearance was reduced by 25% from BL to 5y post PTx in these calcineurin treated patients, and remained stable between 5 and 10Y. AER did not change significantly.

Conclusions: Substantial reversal of GBM and mesangial extracellular matrix (ECM) accumulation in T1D occurs following long term PTx despite decrease in PC number, persistence of foot process widening and no change in PC density. This study does not support PC loss to be an important mediator of mesangial extracellular dynamics in DN in T1D. Moreover, despite long-term nornormoglycemia, PC do not regenerate and PC injury does not regress in T1D patients.

Urinary Proteomics Identifies Proteins Associated with Rapid eGFR Decline in Type 1 Diabetes
Christine P. Limongi,1 Lokki Natarajan,2 Erkka A. Valo,2 Manjula Darshi,3 Viktor Drel,4 Andrew N. Hoofnagle,1 Daniel Montemayor,1 Niina Sandholm,2 Tomas Vaiksnarė,1 Jing Zhang,1 Peter Rossing4 Per-Henrik Groop,4 Janet Snell-Bergeon,4 Trevor J. Orchard,1 Ian H. de Boer,1 Kumar Sharma2,3 1University of Washington, Seattle, WA; 2University of California San Diego, La Jolla, CA; 3Fokhaldsen Research Center, Helsinki, Finland; 4UT Health Science Center San Antonio, San Antonio, TX; 5Steno Diabetes Center Copenhagen, Copenhagen, Denmark; 6University of Colorado Denver Barbara Davis Center for Childhood Diabetes, Denver, CO; 7University of Pittsburgh, Pittsburgh, PA.
Background: Varying rates of eGFR decline have been observed in patients with type 1 diabetes (T1D), the pathophysiologic mechanisms of which remain poorly understood.
Methods: We performed a case-control study nested within four T1D cohorts (EDC, CACTI, STENO, FinnDiane) to identify urinary proteins associated with rapid eGFR loss. Cases and controls were defined by annual eGFR decline ≥3 ml/min/1.73 m2 and <1 ml/min/1.73 m2, respectively. We developed a targeted liquid chromatography-tandem mass spectrometry assay to measure 38 peptides of 20 proteins implicated in diabetic kidney disease (DKD), the mechanism mediating this process remains to be explored.
Results: Out of 38 urine peptides, 2 cathepsin D (CatD) peptides were associated with rapid eGFR loss adjusting for demographic but not clinical variables (1.26, 95% CI 1.22-1.88; 1.41, 95% CI 1.14-1.74). In the validation set, CatD peptides were associated with rapid eGFR loss among those with UACR ≥30 mg/gCr in 36% were included. Over 8 years median follow-up, mean eGFR slope was -5.65 and 0.57 ml/min/1.73 m2 per year for cases and controls, respectively. Out of 38 urine peptides, 2 cathepsin D (CatD) peptides were associated with rapid eGFR loss adjusting for demographic and clinical variables with a false discovery rate of <5% in the discovery set (fully-adjusted OR per SD 1.52, 95% CI 1.22-1.88; 1.41, 95% CI 1.14-1.74). In the validation set, CatD peptides were associated with rapid eGFR decline adjusting for demographic but not clinical variables (1.26, 95% CI 0.99-1.60; 1.15, 95% CI 0.91-1.46). When stratified by baseline urine albumin creatinine ratio (UACR), CatD peptides were associated with rapid eGFR loss among those with UACR ≥30 mg/gCr in both discovery (2.36, 95% CI 1.39-4.03; 2.28, 95% CI 1.32-3.92) and validation (1.93, 95% CI 1.10-3.19; 1.84, 95% CI 1.08-3.13) sets. Across several Nephroseq cohorts, CatD transcription was increased in tubulointerstitial and not glomerular specimens in diabetic kidney disease compared to healthy living donors.

Loss of Functional SCO2 Attenuates Diabetic Kidney Disease in db/db Mice
Nehaben A. Gujrati, Alexandra R. Leonardo, Jessica M. Vasquez, Sandeep K. Mallipatni. Division of Nephrology, Department of Medicine, Stony Brook University, Stony Brook, NY.

Background: Synthesis of Cytochrome C Oxidase 2 (SCO2), a Cu2+ metallochaperone located in the inner mitochondrial membrane, is essential for the assembly of Complex IV (COX IV) of the electron transport chain, maintenance of the proton gradient, and redox signaling. Altered COX activity and reduced mitochondrial function have been reported in diabetic kidney disease (DKD), but the mechanism mediating this process remains to be explored.
Methods: db/db mice were bred with Sco2 mutant mice (E129K, most common human missense mutation in the Cu2+ binding domain) to generate Sco2/SCO2:db/db and Sco2/SCO2:db/db mice. Sco2/SCO2, Sco2/SCO2:db/db, and wildtype mice served as controls. All mice were euthanized at 24 weeks of age and assessed for functional and histological changes in the kidney.
Results: Data mining in Nephroseq showed that SCO2 expression was increased in micro-dissected glomeruli in human DKD kidney biopsies (Ju et al. 2013), which we confirmed by immunostaining in human kidney biopsies with DKD compared to healthy donors. Since SCO2+ mice are embryonally lethal, we ascertained the role of mutant and heterozygous knockout SCO2 in DKD (SCO2+/+, SCO2+/-). As compared to db/db mice, SCO2+/+ and SCO2+/- mice had a significant reduction in albuminuria, serum creatinine, glomerular hypertrophy, glomerular oxidative stress (8-oxoG staining) with an increase in podocyte number (WT vs cells per glomerular cross-sectional area), synaptopodin expression, and overall survival. SCO2+/+ and SCO2+/- mice also exhibited less glomerular endothelial injury with a decrease in glomerular capillary loop dilatation and a trend towards decrease in Vv(Mes/glom) and Vv(Cam1) and an increase in Angpt1, Vegfa, Kdr and Klf2 expression as compared to db/db mice.
Conclusions: Among patients with TID and largely normal kidney function, differences in renal lysosomal function as suggested by increased urine CatD may represent a mechanism of rapid eGFR loss early in the course of TID.

Reduction in the Rate of eGFR Decline with Semaglutide vs. Placebo: A Post Hoc Pooled Analysis of SUSTAIN 6 and PIONEER 6
Katherine R. Tuttell,1 David Cherney,2 Samy Hajdadi,3 Thomas Idorn,4 Ofri Mosenson,5 Vlado Perkovic,6 Soren Rasmussen,7 Benjamin Wolthers,8 Stephen C. Bain,9 Institute of Translational Health Sciences, Kidney Research Institute, and Nephrology Division, University of Washington, Seattle, WA; 4Division of Nephrology, University Health Network, University of Toronto, Toronto, ON, Canada; 5Institut du thorax, INSERM, CNRS, University of Nantes, CHU Nantes, Nantes, France; 6Novo Nordisk A/S, Søborg, Denmark; 7University of Connecticut School of Medicine, Farmington, CT; 8University of New South Wales, Sydney, NSW, Australia; 9Diabetes Unit, Department of Endocrinology and Metabolism, Hadassah Medical Center; Hebrew University of Jerusalem, Jerusalem, Israel; 10University of New South Wales, Sydney, NSW, Australia; 11Diabetes Research Unit, Swansea University Medical School, Swansea, United Kingdom.

Background: The SUSTAIN 6 cardiovascular outcomes trial (CVOT) indicated that once-weekly (OW) subcutaneous (s.c.) semaglutide may have beneficial effects on kidney function in subjects with type 2 diabetes (T2D) at high CV risk. SUSTAIN 6 and the PIONEER 6 CVOT (once-daily [OD] oral semaglutide) had similar designs and populations, and both evaluated the effects of semaglutide vs placebo (PBO) on macro- and microvascular outcomes. This post hoc analysis of pooled data from the two trials evaluated the effects of semaglutide vs PBO on kidney function decline.

Methods: Data for 6,480 subjects with T2D from SUSTAIN 6 (OW s.c. semaglutide 0.5 and 1.0 mg or PBO, N=3,297; median follow-up 2.1 years) and PIONEER 6 (OD oral semaglutide 14 mg or PBO, N=3,183; median follow-up 1.3 years) were pooled into two groups: semaglutide and PBO. Annual change in estimated glomerular filtration rate (eGFR) was compared (semaglutide vs PBO) in the overall population and subgroups by baseline (BL) eGFR (≥60 mL/min/1.73 m² and <60 mL/min/1.73 m²) and by eGFR slope from BL was calculated; an interaction p-value <0.05 indicated difference between slope. The estimated treatment difference (ETD) at 1 year between annual rates of decline in eGFR were analyzed using a linear random regression model with individual intercept and baseline eGFR slope from BL.

Results: In the overall population, the annual rate of eGFR change was 0.60 mL/min/1.73 m² (p<0.0001) lower with semaglutide vs PBO. In the eGFR ≥60 mL/min/1.73 m² subgroups and eGFR slope, the ETDs for semaglutide vs PBO were, respectively, 1.07 and 0.48 mL/min/1.73 m²/year, with a non-significant interaction p-value (Figure).

Conclusions: Semaglutide was associated with a significantly smaller decline in kidney function than PBO in subjects with T2D at high CV risk across tested BL eGFR categories; the data suggest the main benefit might be observed in those with kidney function categories; the data suggest the main benefit might be observed in those with kidney disease.

Patience to Enable Spironolactone in Patients with Resistant Hypertension and CKD (AMBER): Results in the Prespecified Subgroup with Diabetes
Rajiv Agarwal,1 Patrick Rossignol,2 Susan Arthur,3 Ansgar Conrad,4 William B. White,5 Bryan Woodward,6 Indiana University School of Medicine, Indianapolis, IN; 1University of Lorraine and FCRIN INI-CRCT, Nancy, France; 6Relypsia, Inc., a Vifor Pharma Group Company, Redwood City, CA; 2University of Connecticut School of Medicine, Farmington, CT; 3University College London (UCL), London, United Kingdom.

Background: Spironolactone (SPIRO) reduces BP in patients (pts) with resistant hypertension (RHTN); however, its use in pts with advanced chronic kidney disease (CKD) is often limited by hyperkalemia (HK). In AMBER, patience (PAT) enabled more persistent use of SPIRO in pts with RHTN and CKD. As SPIRO is recommended in RHTN and diabetes mellitus (DM) increases HK risk, we report results in prespecified subgroups with Type 1 or 2 DM.

Methods: Randomized, double-blind, placebo (PBO)-controlled trial in adults with RHTN and eGFR 25 to ≤45 mL/min/1.73 m². Pts were assigned (1:1) to PBO or PAT, and SPIRO 25 mg QD, with dose titrations permitted after 1 wk for PAT/PBO and 3 wks for SPIRO. The primary endpoint, between group difference at Wk 12 in % of pts on SPIRO, was assessed prospectively in prespecified DM subgroups.

Results: 295 pts were randomized, 145 (49%) DM+ and 150 (51%) DM-. Baseline mean (SD) serum K⁺ (mEq/L) was 4.76 (0.34) in DM+ and 4.67 (0.39) in DM-. Significantly more pts treated with PAT than with PBO remained on SPIRO at Wk 12 in both subgroups (Figure). LS Mean (SE) cumulative SPIRO dose was higher with PAT than PBO, by 438.7 (177.7) mg in DM+ and 317.8 (175.0) mg in DM-. Adverse events occurred in 61% (PBO) and 60% (PAT) of DM+ pts and in 46% (PBO) and 51% (PAT) of DM– pts. Four pts had serum magnesium (Mg²⁺) <1.4 mg/dL between baseline and Wk 12 (none <1.2 mg/dL), including 3 DM+ (1 PBO, 2 PAT) and 1 DM– (PAT) pt. None of these pts had cardiac arrhythmias temporally associated with low Mg²⁺ levels, neuromuscular abnormalities, or serum K⁺ below the LLN (3.5 mEq/L).

Conclusions: PAT enabled more pts with advanced CKD and RHTN to continue treatment with SPIRO, regardless of DM status.

Single-Cell Transcriptomic Analysis to Define Cellular Heterogeneity in Human ADPKD
Yoshiharu Muto,1 Eryn E. Dixon,3 Chidambaram Ratchachandran,2 Andrew J. King,2 Stephen L. Seliger,1 Owen M. Woodward,3 Paul A. Wells,4 Terry J. Watnick,5 Benjamin D. Humphreys,5 1Washington University School of Medicine, St. Louis, MO; 2Chinook Therapeutics, Inc., Vancouver, BC, Canada; 3University of Maryland School of Medicine, Baltimore, MD; 4Johns Hopkins School of Medicine, Baltimore, MD.

Background: Deciphering the molecular pathogenesis of human autosomal dominant polycystic kidney disease (ADPKD) requires a detailed understanding of the distinct cell types and cell states driving cyst growth. Unlike single cell RNA-seq, single nucleus RNA-seq can be performed on cryopreserved samples, and we hypothesized that it might reveal unique cell states from biobanked human ADPKD samples.

Methods: We performed snRNA-seq on 8 ADPKD kidney samples (4 males and 4 females, mean = 50 +/- 8.5 years old, all had ESRD). Cystic kidneys weighed 1631 +/- 728 g. Nuclear preparations were processed using 10x Genomics Chromium 3’ kit and sequenced by NovaSeq. Reads were counted with CellRanger 3.1.0 and analyzed with Scanpy v1.7.0. Gene expression was validated by fluorescence in situ hybridization (FISH).

Results: Samples were stored at -80°C prior to processing (median, 20 mo; range 7-40 mo). All samples yielded good libraries (Avg. genes/nucleus = 1560 +/- 526). 63,289 nuclei originating from all 8 ADPKD kidneys passed quality control filters. Large clusters of cystic epithelial cells could be distinctly identified as originating from PT, TAL and CD. Compared to non-cystic epithelia, TAL-derived cystic epithelia showed strong induction of ERBB4 and gene ontology terms including fibroblasts/ECM and secretion of TGFβ. CDH6 high cystic epithelia expressed the PT injury markers CDH6 and LRPs2 and cystic epithelia expressed the PT injury markers CDH6 and LRPs2 and cystic epithelia expressed the PT injury markers CDH6 and LRPs2.

Conclusions: To our knowledge this is the first single cell transcriptomic atlas of human ADPKD. We demonstrate the utility of this approach by revealing (1) excellent gene expression from all samples including those stored > 3 yrs, (2) segment specific cystic epithelial expression profiles, (3) activated interstitial fibroblast subsets and (4) pro-inflammatory macrophage cell types and states.

Single-Cell RNA Sequencing Provides Insights into the Mechanism Through Which Adaptive Immune Cells Promote Injury-Induced Cyst Formation

Kurt Zimmerman, Bradley K. Yoder, Michal Mrug, Katharina Hopp, 1,2 The University of Oklahoma Health Sciences Center, Oklahoma City, OK; 1The University of Alabama at Birmingham, Birmingham, AL; 2University of Colorado Denver - Anschutz Medical Campus, Aurora, CO.

Background: Inducible deletion of cilia related genes in adult mice results in slow-progressing cystic disease, which can be greatly accelerated by renal injury. However, cells that promote accelerated cystogenesis following renal injury are poorly understood.

Methods: To identify cells that may be responsible for driving rapid, injury induced cystic disease, we performed single cell RNA sequencing on cells isolated from sham operated mice (n=4) and cilia mutant mice after renal injury, such as cyclosporin A (CsA) or meropenem (a primary cilium inhibitor). We then performed cell-cell interaction analysis using NicheNet.

Results: Single cell RNA sequencing data from sham- and injured-cilia mutant mice indicate that renal injury results in major changes in clusters of tubular epithelia and macrophages with minimal effects on T cells. These data suggest that accelerated cystogenesis in cilia mutant mice requires both injury induced changes in T cells as well as cilia-dependent alterations in the injured epithelium and macrophages. Using NicheNet to identify ligand-receptor-gene regulatory networks, we show that T cells from injured cilia mutant mice produce ligands that cause alterations in the gene expression signature of the cilia mutant epithelium and macrophages suggesting that these cells are master regulators of injury induced cystic disease. In agreement with this hypothesis, our data indicate that loss of adaptive immune cells (including T cells) significantly altered cystic phenotype as assessed by kidney weight/body weight ratio, ANOVA interaction p=0.0017. In vitro binding studies indicated that CUD062 interacts with PKD domains 2-17 and most tightly with domains 15-17 in an SDS stable manner. We further showed that extracellular application of pure CUD062 activated cystin-1 (PC1) current (p<0.05). On a cellular level, the receptor for CUD062 is not known. In vivo, CUD062 was shown to be expressed most prominently in the vasa recta (VR) and the endothelium of large blood vessels but not in kidney tubules.

Conclusions: These data suggest that CUD062 might be a circulating ligand for PC1 and carbonic anhydrase 2 (CAII) and Tsc1 (TSC1/2) KO mice as its genetic deletion leads to a milder phenotype than that observed in Pkd1 homozygous null mice.

Activation of AMP-Activated Protein Kinase In Vivo Leads to a Polycystic Kidney Disease

Laura Wilson, 1,2 David Carling, 1,2 University College London Institute of Child Health, London, United Kingdom; 3MRC London Institute of Medical Sciences, London, United Kingdom.

Background: Polycystic kidney disease (PKD) is a genetic disorder in which numerous fluid-filled cysts form in the kidney. Despite having identified the causative gene responsible for the disease, we are still far from understanding the molecular signalling pathways involved in cystogenesis is limited, hindering PKD drug discovery. In this project, we generated a mouse model of AMP-activated protein kinase (AMPK) activation and investigated the effects on PKD.

Methods: AMPK activation mouse models were generated by expressing the AMPKα1 isoform with a D316A mutation under the control of β-actin (global) and Ksp (kidney-specific) promoters using the Cre-LoxP system. A constitutively active form of AMPK is produced when AMPKα1-D316A is incorporated into the enzyme complex. Renal function was assessed using metabolic cages, serum and urine samples were collected for analysis. Kidneys were collected and snap-frozen for biochemical studies or wax-embedded for histological studies. To identify cells that may be responsible for driving rapid, injury induced cystic disease, we performed single cell RNA sequencing on cells isolated from sham operated mice (n=4) and cilia mutant mice after renal injury, such as cyclosporin A (CsA) or meropenem (a primary cilium inhibitor).

Results: Global activation of AMPKα1 resulted in a striking polycystic kidney phenotype. Tubule dilations were evident from 11 days of age, which progressed to heavily cystic kidneys by 3 weeks of age. Adult mice showed signs of polyuria associated with decreased urine osmolality and polydipsia, kidney damage and compromised renal function. Cysts were observed in the collecting ducts of these mice, consistent with the distal nephron being most heavily affected in PKD. Mechanistically, the cystic kidneys had increased AMPK expression and altered lysosomal protein expression. Kidney-specific activation of AMPKα1 also produced polycystic kidneys in mice, demonstrating that AMPK activation within the kidney was causative.

Conclusions: These results show that activation of AMPK causes polycystic kidneys to form, thus raising the possibility that AMPK activation could be a contributing factor in PKD pathogenesis. Disregulation of the cAMP-ERK pathway in this model suggests a possible mechanism for how AMPK activation could be implicated in renal cystogenesis. Future studies should investigate whether AMPK has a pathogenic role in other PKD models.

Intercellular Transmitted and the Cell Signaling Factor FOXI1 Drive the Kidney Cystogenesis in Tuberous Sclerosis Complex

Sharon H. Barong, 1,2 Kamary A. Zahedi, 1 Marybeth J. Brooks, 1 Fabrizio T. Pers, 1,2 Hans W. Kops, 1,2,3 John W. Scherer, 1,2 June J. Yu, 1,2 Manoocher Soleimani. 1,2 University of New Mexico Health Science Center, Albuquerque, NM; 2Raymond G Murphy Department of Veterans Affairs Medical Center, Albuquerque, NM; 3University of Alabama at Birmingham, Birmingham, AL.

Background: The Tuberous Sclerosis Complex (TSC) is caused by mutations in either the TSC1 or TSC2 gene and affects multiple organs, including the kidney. Patients can present with benign tumors (angiomylipomatomata) and cysts, which can lead to kidney failure. Factors that promote cyst formation and tumor growth in TSC are poorly understood.

Methods: Mice with principal cell specific inactivation of Tsc1 were generated. In addition, mice with double deletion of Foxi1 and Tsc1 (Foxi1/Tsc1 double KO) or carbonic anhydrase 2 (CAII) and Tsc1 (CAII/Tsc1 double KO) were generated based on RNA-seq and expression studies.

Results: Foxi1 KO mice showed numerous kidney cortical cysts, which were overexpressed in A-intercalated (A-IC) cells that express Foxi1. In Foxi1/Tsc1 dKO mice (Kidney MRI in image 1) and caused a profound reduction in V H -ATPase expression in the A-IC cells. Mice with double deletion of Tsc1 and CAII, a regulator of V H -ATPase, showed significant reductions in cyst burden and increased longevity vs. Tsc1 KO mice.

Conclusions: We propose that A-IC cells, V H -ATPase and CAII are critical to cystogenesis and their inhibition may be associated with the significant protection against cyst generation and/or enlargement in TSC. Carbonic anhydrase inhibitors may be viable treatments for the prevention of kidney cyst expansion in TSC. Supplementation of carbonic anhydrase inhibitors with HCO3- (to minimize the untoward side effects of metabolic acidosis) may be the way forward.

Genome-wide Analyses Provide Insights into the Architecture of Kidney Function and CKD in African Americans in the Million Veteran Program (MVP)

Bryce R. Rowan,1,2 Cassianne Robinson-Cohen,1 Elvis A. Akwo,2 Hui-Chang Chen,2 Ran Tao,2 Cecilia P. Chung,2 Csaba P. Kovacsdy,4 Katalin Susztak,1 Christopher J. O’Donnell,3 Edward D. Siew,1,2 Adriana Hung,1,2 Boston VA, Nashville, TN; 3VUMC, Nashville, TN; 4Boston VA, Nashville, MA; 5Memphis VA, Memphis, TN; 6Penna Medicine, Philadelphia, PA.

Background: End-stage kidney disease (ESKD) incidence rates for African Americans are more than 3 times higher than for European-Americans. This disparity has been only partly explained by known determinants of ESKD and the presence of high-risk APOL1 variants. The identification of “second hit” triggers may explain kidney outcomes disparities observed in African Americans.

Methods: We performed a GWAS of eGFR among 84,544 African Americans from the MVP at or closest to enrollment. Exclusion criteria were: dialysis, kidney transplant, and BMI>18. We evaluated the association of common (minor allele frequency >1%) SNPs with linear eGFR (by CKD-EPI equation), adjusted for age, sex, BMI, and the top ten principal components of ancestry. Analyses were performed by strata of diabetes and estimates were aggregated with fixed-effects meta-analysis.

Results: We identified 2,275 SNPs in 22 independent loci associated with eGFR (p<5x10^-8). The SNP with the strongest signals replicated previously detected associations at SPATA8L1/GATM (rs24846722, p = 1.7 x 10^-10). Of these, 19 represented previously reported loci from GWAS of kidney function or CKD. Known CKD genes from case-control studies such as APAOL1 (rs73885319 p=9.09x10-28) were included in the known loci. Three were novel loci for the association with kidney function in African Americans. Of the novel variants, we discovered SNPs in ABCA1 (rs10991574 p = 2.97x10^-10) associated with accelerated atherosclerosis and lipid metabolism through PPAR alpha, PIK3AP1 (rs5647676 p = 3.1 x 10^-10) associated with lescolocyte count and BCL-xL (rs9646829 p=2.49 10^-8) associated with colorectal adenoma. Some of the strongest signals previously reported for kidney phenotypes included: DAB2 (rs2542713 p=1.5 x 10^-8), OCT2 (rs2279463, p=1.98 10^-10), UNCX (rs62435145 p=1.97 10^-10) and PRKAG2 (rs10253736 p=3.0 x 10^-10). 70 SNPs were exonic variants overall. SNPs within UMOD/PDLP3, the top hits for kidney function GWAS and CKD progression among European-Americans, did not reach genome-wide (p=9.19x10^-8) significance.

Conclusions: In this large GWAS of eGFR among African Americans to date, we replicate over 19 previously identified loci, identify 3 novel loci associated with kidney function.

SA-OR27

3D Genome Architecture of Human Renal Cortex and Medulla

Selvaraj Mathusamy, Shreeram Akiles.

University of Washington, Seattle, WA.

Background: Genomic DNA is organized in a non-random manner within the mammalian nucleus. How this three-dimensional genome architecture influences cell-type specific phenotypes is poorly understood. Genome-wide methods such as Hi-C can systematically map out 3D genome architecture. However until now, technical and cost limitations have prevented these powerful approaches from being applied to intact human kidney tissues.

Methods: We performed global genome conformation (Hi-C) analysis on macrodissected human renal cortex and medulla from the same individual. Since existing algorithms to identify intra and inter-chromosomal interactions in Hi-C sequencing data are plagued by low concordance, we developed a novel machine learning algorithm used in the domain of computer vision to identify significant contacts in our Hi-C data.

Results: Each kidney Hi-C sample was deeply sequenced to >400 million mapped reads enabling visualization of topologically associated domains (TADs) and contacts at 10kb resolution. Comparing even these highly similar samples, our novel algorithm identified significantly different genome conformation at multiple intra-chromosomal contacts in renal cortex (n=1789) and medulla (n=1841) (figure). Further validation by DNA-FISH and comparison to orthogonal functional genomic data sets (ATAC-seq, RNA-seq) are ongoing.

Conclusions: These high-resolution chromatin conformation maps of intact human kidney will provide an valuable resource for the study of kidney genome regulation. Our novel loop-calling algorithm enabled identification of fine genome architectural differences between renal cortex and medulla. Our data can also be used to link genetic risk loci to target genes in genome-wide association studies.

Clonal Hematopoiesis of Indeterminate Potential and Somatic Mutation Role in CKD: The First Study

Enrico Cocchi,1,2 Ali G. Gharavi,3 Gharavi lab 1Division of Nephrology and Center for Precision Medicine and Genomics, Department of Medicine, Columbia University, New York, NY; 2Universita degli Studi di Torino, Torino, Italy.

Background: Clonal hematopoiesis of indeterminate potential (CHIP) is an age-related somatic mutagenesis associated with inflammation and increased risk of death due to cardiovascular disease. Chronic kidney disease (CKD) is strongly associated with cardiovascular disease, suggesting shared pathophysiologic mechanisms. Inflammation is a well-established component of CKD but CHIP has never been investigated in CKD.

Methods: We analyzed whole-exome sequencing data to determine CHIP prevalence and variant allele frequency (VAF) in a cohort of 2,187 CKD patients and 1,686 age-matched controls. Somatic variants were called using MuTect2 and filtered using strict standard criteria. The presence of CHIP mutations was evaluated for associations with demographic and clinical variables, including age, sex, CKD etiology, treatment with immunosuppressive therapies, end-stage renal disease (ESRD), and history of renal transplant.

Results: In a multivariate logistic regression model focused on the most frequently mutated CHIP genes (DNMT3A, TET2, ASXL1, JAK2), we observed an age-independent association between CHIP and CKD, where both prevalence (p=0.04, OR: 1.62) and VAF (3.48% vs. 1.89%, p=0.004) were higher in CKD cases than in controls. Among CKD cases, CHIP was independently associated with history of renal transplant >10 years (p=0.01, OR: 5.8) and treatment with immunosuppressive therapies (p<0.01, OR: 2.6).

Conclusions: Our analysis of a large case-control cohort suggests an independent association between CHIP and CKD. This association was most evident in patients with ongoing inflammation due to renal transplantation or immune-mediated conditions. These data will require replication in larger human cohorts and validation in animal models.

Loss of Diacylglycerol Kinase α Causes Thrombotic Microangiopathy by Impairing Endothelial Vascular Endothelial Growth Factor A Signaling

Dingxiao Liu,1,2 Qiong Ding,1 Madison Purvis,1 Biswajit Padhy,3 Chou-Long Huang,1 Massimo Attanasio,1 University of Iowa, Iowa City, IA; 2the Second Xiangya Hospital, Central South University, Changsha, China; 3University of Iowa Carver College of Medicine, Iowa City, IA.

Background: Atypical hemolytic uremic syndrome (aHUS) is a thrombotic microangiopathy (TMA) accompanied by hemolytic anemia, thrombocytopenia, and acute renal failure due to glomerular damage. Mutations in complement genes have been identified in about 50% of aHUS cases. We reported that mutations in the gene DGKK, encoding the lipid kinase diacylglycerol kinase epsilon (DGKK) that is unrelated to the

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
complement system, also cause aHUS. In the glomeruli, DGKE is expressed in endothelial cells and podocytes. The molecular mechanisms by which DGKeB causes TMA are not known. Phosphatidylinositol phosphate [PtdIns(4,5)P_2] levels are reduced in DGKE knockout cells. Since the disruption of vascular endothelial factor A (VEGFA) signaling in humans and mice results in glomerular lesions that resemble those in humans with loss-of-function mutations in DGKE, we hypothesized that loss of DGKE may impair VEGF signaling in endothelial cells due to shortage of PtdIns(4,5)P_2.

**Methods:** To test this hypothesis, we performed in vitro studies on DGKE knockdown human umbilical vein endothelial cells (HUVECs) and generated endothelial-specific Tie2Cre;DGKE conditional knockout mice.

**Results:** We found that signaling downstream of VEGFA receptor 2 (VEGFR2) is compromised in DGKE knockdown HUVECs due to decreased activation of Akt, a phenotype that is rescued by supplementation the culture medium with PtdIns(4,5)P_2. Endothelial-specific Tie2Cre;DGKE conditional knockout mice spontaneously developed thrombocytopenia, schistocytosis, and renal insufficiency, indicating that the endothelium is the cellular compartment responsible of the DGKE disease. Remarkably, these mice also developed albuminuria at later times, indicating that the impairment of the glomerular barrier, which is characteristic of the DGKE disease, is a later and secondary event.

**Conclusions:** Our data indicate that loss of DGKE compromises signaling downstream of VEGFR2 in endothelial cells by decreasing cellular levels of PtdIns(4,5)P_2, inducing aHUS and, secondarily, disruption of the glomerular barrier. These results also implicate that pharmacological manipulation of the VEGFA signaling may be used to modify the clinical course of other forms of aHUS.

**Re-Envisioning the APOL1 Cation Channel Structure**

Rusell P. Thompson, Colles M. Asp-348, Glu-355, Yanny Lee, Nadia Terra, Jayne Raper

**Background:** Apolipoprotein L-I (APOL1) is a channel forming protein that protects humans and other primates from African trypanosome infection. African Americans have inherited common APOL1 variants with increased trypanolytic potential; however, these variants are responsible for an increased risk of kidney disease compared with other variants. Human APOL1 forms non-selective cation channels in a strictly pH dependent manner: channel formation requires acidic pH, whereas channel opening requires pH neutralization. Current APOL1 structural models rely on tenuous comparisons with unrelated channel forming proteins. Here we introduce a new model of APOL1 channel structure and topology based on functional characterization of divergent APOL1 orthologs and interspecies chimeras in a planar lipid bilayer system.

**Methods:** We tested interspecies APOL1 chimeras and point mutations in planar lipid bilayers to identify molecular determinants of pH dependence and ion selectivity. **Results:** Strikingly, we demonstrate that cation conductance depends on the C-terminus domain, rather than the N-terminal region as previously suggested, with both pH gating and selectivity functions largely governed by a single residue - aspartate-348. Dual substitution of Asp-348 and nearby glutamate-355 eliminated pH gating, with tyrosine-351 having a steric influence. Acidic residues within a putative hairpin region (residues 177-228) affected the pH-dependence of channel formation.

**Conclusions:** Based on these data we present a radically updated domain structure of APOL1, including a putative 4-pass transmembrane topology and a pore-lining helix near the C-terminus (see Image abstract). We propose a mechanism of channel gating based on dual proton-sensing residues (Asp-348 and Glu-355) within the pore-lining helix, with Asp-348 also determining selectivity for cations over anions.

**Small Molecule Inhibitor of TMEM16A Chloride Channel Blocks Vascular Smooth Muscle Contraction and Lowers Blood Pressure in Spontaneously Hypertensive Rats**

Omar Clif, Xiaolan Chen, Henry Askew Page, Maria C. Jordan, Pyone Myat Thoke, Samuel N. Baldwin, Marc O. Anderson, Iain A. Greenwood, Kenneth P. Roos, Alan S. Verkman, University of California San Francisco, San Francisco, CA; San Francisco State University, San Francisco, CA; University of California Los Angeles, Los Angeles, CA; St George's University of London, London, United Kingdom.

**Background:** Hypertension is a major cause of cardiovascular morbidity and mortality, despite the availability of antihypertensive drugs with different targets and mechanisms of action. There is an unmet need for antihypertensive drugs with novel mechanisms of action for better BP control. TMEM16A (transmembrane member 16A or anoctamin-1) is a Ca<sup>2+</sup>-activated Cl<sup>-</sup> channel expressed in vascular smooth muscle. TMEM16A activation produces membrane depolarization that results in secondary activation of voltage-dependent ion channels that modulate vasoconstriction. TMEM16A is a potential target for hypertension treatment.

**Methods:** We recently identified by high-throughput screening and subsequent medicinal chemistry, small molecule TMEM16A inhibitor TM<sub>23</sub>-23 that inhibits TMEM16A current fully, with IC<sub>50</sub> = 30 nM. Here we tested TM<sub>23</sub>-23 pharmacokinetics in rodents and its effects on vascular smooth muscle contraction (via wire myograph) and BP in spontaneously hypertensive rats (SHR) and wild type rodents.

**Results:** TM<sub>23</sub>-23 pretreatment blocked maximum in vitro vascular smooth muscle contractions induced by a thromboxane mimetic (U46619) in rat mesenteric arteries by 90%. Intraperitoneal (ip) administration of TM<sub>23</sub>-23 to rodents at 10 mg/kg produced sustained systolic blood pressure (SBP) reductions of ~90 µM for ~4 hours. BP measurements by tail-cuff and telemetry showed a maximum ~45 mmHg reduction in SBP in spontaneously hypertensive rats (SHR) after a single dose TM<sub>23</sub>-23 (10 mg/kg, ip) compared to vehicle administration, with BP gradually returning to baseline values within 6-8 hours after TM<sub>23</sub>-23 pretreatment. Minimal effect on BP (less than 10 mmHg decrease in SBP) was seen in wild-type rats and mice with TM<sub>23</sub>-23 treatment (10 mg/kg, ip). Chronic 5-day treatment of SHR with TM<sub>23</sub>-23 (10 mg/kg, ip, twice daily) caused sustained decreases (~25 mmHg) in daily average SBP, DBP and MAP during the treatment period. TM<sub>23</sub>-23 action was reversible, with BP returning to baseline (~170/115 mmHg) by 3 days after discontinuation of treatment.

**Conclusions:** These studies provide validation for TMEM16A as a target for hypertension therapy, and demonstrate the proof-of-concept for efficacy of TM<sub>23</sub>-23 as an antihypertensive with a novel mechanism of action.

**SA-OR32**

**Intravitreal Imaging of Afferent Arteriole Calcium Dynamics and the Role of Connexin 45**

Anne Riquier-brison, Georgia Gruytmans, Janis Peti-Peterdi. University of Southern California, Los Angeles, CA.

**Background:** The glomerular afferent (AA) and efferent (EA) arterioles are the most critical resistance vessels in the autoregulation of renal blood flow and glomerular filtration rate. Calcium dynamics of vascular smooth muscle cells (VSMC), in part mediated by gap junction communication via connexin 45 (Cx45), are important regulators of AA contractility and myogenic tone. We aimed to study the role of Cx45 in renal hemodynamics in vivo.

**Methods:** Intravitreal imaging with multiphoton microscopy (MPM) of renal functional parameters was performed in mice expressing a genetically encoded calcium indicator (GCaMP3 or GCaMP5) in cells of renal lineage with or without connexin 45 knockout (KO). Suramin treatment was used to test the effects of purinergic receptor blockade.

**Results:** Compared to the uniform upstream AA segment, high baseline and A( Ca<sup>2+</sup>)<sub>max</sub> were observed in a few AA VSMCs at the glomerular entrance, which appeared to function as an afferent cell. The diameter of the AA (9.2±3.7 μm WT, vs. 11.3±3.7 μm KO) and EA (7.18±0.36 μm WT, vs. 8.59±0.30 μm KO) were larger in KO animals, although no difference was found in SBP, snGFR and glomerular diameter. Blood flow in AA was also increased (1.42±0.15 μm/s WT, vs. 2.0±0.12 μm/s KO). AA myogenic tone was visualized 3-4 weeks after unilateral ureteral obstruction (UUO). In WT animals, regular AA contractions were observed uniformly in all AAs with an average frequency of 0.12±0.01 Hz, with large magnitude A( Ca<sup>2+</sup>)<sub>max</sub> in VSMCs during every contraction (A( Ca<sup>2+</sup>)<sub>max</sub> ~ 556±855 AU). In contrast, KO animals showed highly heterogeneous and irregular AA vascular activity. In those AAs that did exhibit some myogenic tone or contractile contractions, a higher frequency was observed (0.28±0.02 Hz), however the magnitude of A( Ca<sup>2+</sup>)<sub>max</sub> in AA VSMCs was much lower than in the WT (A( Ca<sup>2+</sup>)<sub>max</sub> ~ 395±249 AU). In both WT and KO animals, treatment with suramin rapidly blocked AA VSMC calcium increases and the myogenic contractions, and the AA became dilated.

**Conclusions:** AA sphincter cells have robust effects on AA (Ca<sup>2+</sup>)<sub>max</sub> dynamics and contractility in vivo, and Cx45 and purinergic signaling are essential components of AA calcium signaling and vascular contractility. Cx45 and purinergic signaling in the AA regulate the myogenic response and renal blood flow, and may be culprit and potential target in vascular pathologies.

Inorganic Nitrite Supplementation Improves Endothelial Function with Aging: Translational Evidence for Suppression of Mitochondria-Derived Oxidative Stress
Matthew J. Rosman,1 Rachel A. Gioscia-Ryan,1 Jessica R. Santos-Parker,1 Brian P. Ziembka,1 Kara L. Lubieniecki,1 Natalie E. Poliektov,2 Lawrence C. Johnson,1 Erzebet E. Nagy,1 Kayla A. Woodward,1 Amy L. Sindler,1 Michel Choncho,1 Douglas R. Seals,1 University of Colorado Boulder College of Arts and Sciences, Boulder, CO; 2University of Colorado Denver - Anschutz Medical Campus, Aurora, CO.

Background: We previously observed improvements in vascular endothelial function with inorganic nitrite supplementation in old mice, which we translated to older humans in a pilot study of sodium nitrite supplementation.

Methods: Here, we sought to confirm the efficacy of sodium nitrite in humans and determine mechanisms of action using: 1) a randomized, placebo-controlled, parallel-group clinical trial with sodium nitrite (80 mg/day, 12 weeks) in older adults (n=49, 68±1 yr) and 2) reverse translation experiments in young (6 mo) and old (27 mo) male C57BL6 mice.

Results: In humans, sodium nitrite increased plasma nitrite (p<0.05) and was well-tolerated over 12 weeks. Endothelial function (brachial artery flow-mediated dilation) was increased by 28% vs. baseline after nitrite supplementation (p<0.05), but unchanged with placebo. Serum from nitrite-treated subjects reduced whole-cell (CellROX) and was increased by 28% vs. baseline after nitrite supplementation (p<0.05), but unchanged with placebo. Serum from nitrite-treated subjects reduced whole-cell (CellROX) and was increased by 28% vs. baseline after nitrite supplementation (p<0.05), but unchanged with placebo.

Conclusions: Nitrite supplementation improves age-related endothelial dysfunction and is associated with increased NO, reduced mito ROS and improved mitochondrial stress resistance.

SA-OR34
Paracrine FGF-23 Signaling in the Heart Causes Cardiac Hypertrophy
Isaac,1 Beatrice Richter,2 Christopher Yauzluc,3 Brian A. Czyza,4 Kylie Heitman,1 Dominik Kerrupt,3 David G. Westbrook,3 Christian Faul,2 University of the Alabama at Birmingham Department of Medicine, Birmingham, AL.

Background: Elevated serum levels of the phosphaturic hormone, fibroblast growth factor (FGF) 23, contribute to cardiac hypertrophy in chronic kidney disease (CKD). FGF23 directly targets myocardic myocytes via FGF receptor (FGFR) 4 to induce hypertrophic growth and FGFR4 blockade not only protects rodent models of CKD from cardiac hypertrophy but also from fibrosis. Our cell culture studies indicate that cardiac fibroblasts do not directly respond to FGF23. It is known that a miscommunication between cardiac myocytes and fibroblasts contributes to pathologic cardiac remodeling. It is unknown if FGF23 does not affect cardiac fibroblasts by regulating paracrine signal mediators in myocytes.

Methods: We treated cultured cardiac myocytes with FGF23 and determined expression levels of established paracrine signal mediators (IL6, LIF, TGFβ) or with high phosphate and analyzed FGF23 expression, all by qPCR. We isolated cardiac fibroblasts from wildtype mice on a high phosphate diet or control chow (0.7%) for 4 days to titrate P[K] over a narrow range (3.7mM (LK), 4.4mM (MK), and 5.1mM (HK)). Blood pressure was monitored by telemetry at each [K] level in mice consuming control or high salt diet (HNa). At the end of each treatment, the BP response to hydrochlorothiazide (HCTZ) was measured to assess the contribution of [K] to BP.

Results: BP decreased by ~10 mmHg when [K] increased from 3.7 to 5.1 mM in control mice, coincident with the inactivation of [K]. When the switch was on (LK and MK groups), HNa significantly elevated BP and had no effect when the switch was inactivated by HCTZ. HCTZ significantly reduced BP in the LK/HNa and MK/HNa groups but had no effect on BP in the HK/HNa group, supporting the hypothesis that low K dietary intake is equally important. A ‘renal K switch’ that turns on the thiazide-sensitive NaCl cotransporter (NCC) in response to low dietary K intake and off in response to high K intake has been implicated. Here we test this idea in genetically engineered mice (CA-SPAK) in which the K switch is ‘locked on.’

Conclusions: Kinase-activating mutations were introduced in SPPAK. Expression of the constitutively active (CA) SPPAK mutant was limited to the early DCT and resulted in NCC hyperactivation. BP responses to small changes in plasma [K] in CA-SPPAK were compared to control mice. Dietary K content was varied over 4 days to titrate [K] over a narrow range (3.7mM (LK), 4.4mM (MK), and 5.1mM (HK)). Blood pressure was monitored by telemetry at each [K] level in mice consuming control or high salt diet (HNa). At the end of each treatment, the BP response to hydrochlorothiazide (HCTZ) was measured to assess the contribution of [K] to BP.

A Renal Potassium-Switch Prioritizes Dietary Potassium Over Sodium, Driving Salt-Sensitive Hypertension
Paul R. Grimm,1 Robert Little,2 Robert A. Fenton,3 Eric J. Delpire,2 Paul A. Welling, 4 Johns Hopkins University School of Medicine, Baltimore, MD; 1Vanderbilt University, Nashville, TN; 2Aarhus University, Aarhus, Denmark.

Background: Reducing dietary salt (NaCl) is well appreciated to lower blood pressure, but a growing body of evidence indicates that increasing dietary potassium (K) intake is equally important. A ‘renal K switch’ that turns on the thiazide-sensitive NaCl cotransporter (NCC) in response to low dietary K intake and off in response to high K intake has been implicated. Here we test this idea in genetically engineered mice (CA-SPAK) in which the K switch is ‘locked on.’

Methods: Kinase-activating mutations were introduced in SPPAK. Expression of the constitutively active (CA) SPPAK mutant was limited to the early DCT and resulted in NCC hyperactivation. BP responses to small changes in plasma [K] in CA-SPPAK were compared to control mice. Dietary K content was varied over 4 days to titrate [K] over a narrow range (3.7mM (LK), 4.4mM (MK), and 5.1mM (HK)). Blood pressure was monitored by telemetry at each [K] level in mice consuming control or high salt diet (HNa). At the end of each treatment, the BP response to hydrochlorothiazide (HCTZ) was measured to assess the contribution of [K] to BP.

Results: BP decreased by ~10 mmHg when [K] increased from 3.7 to 5.1 mM in control mice, coincident with the inactivation of [K]. When the switch was on (LK and MK groups), HNa significantly elevated BP and had no effect when the switch was inactivated by HCTZ. Risk of Cardiovascular Events Is Higher in Patients with Glomerular Disease Compared with the General Population
Heather M. Cunningham,1,2 Mark Canney,1,2 Heather N. Reich,1 Yuyan Zheng,1 Anahat Saha,1,2 Seo Am Huh,4 Arenn S. Jawah,4 Sean Barbour,5,2 Caren L. Rose,1 BC Provincial Renal Agency, Vancouver, BC, Canada; Division of Nephrology, University of British Columbia, Vancouver, BC, Canada; Division of Nephrology, University of Toronto, Toronto, ON, Canada; School of Medicine, University of British Columbia, Canada, Vancouver, BC, Canada; ‘British Columbia Centre for Disease Control, Vancouver, BC, Canada.

Background: Cardiovascular (CV) disease is a recognized cause of morbidity and mortality in chronic kidney disease; however, understanding of CV risk in patients with glomerular disease (GN) is limited. We sought to define CV risk in GN patients and compare incidence rates to the general population.

Methods: A centralized kidney pathology registry (2000-2012) was used to capture all incident cases of focal segmental glomerulosclerosis (FSGS, n=540), IgA nephropathy (IgAN, n=759), membranous nephropathy (MN, n=387), and minimal change disease (MCD, n=226) in British Columbia, Canada. The primary outcome was a composite of major CV events, ascertainment from a hospital discharge registry and evaluated using the Kaplan-Meier method. Hazard ratios (HR, 95% CI) were determined using Cox proportional hazards regression. Event rates were age and sex standardized to the general adult population to generate standardized incidence ratios (SIR, 95% CI).

Results: Over a median follow-up of 6.5years there were 338 CV events, 10-year risk (95% CI) was 16.0% (13.8-18.3) and differed by GN type (Figure): IgAN=7.7% (5.4-10.4), MCD=13.2% (7.6-20.4), MN=19.4% (14.3-25.0), and FSGS=27.0% (21.9-32.4). Compared to IgAN, MN (HR=2.6, 1.7-3.9) and FSGS (HR=3.7, 2.6-5.3) had higher risk, but MCD (HR=1.3, 0.8-2.4) did not. Results were similar when comparing CV events before versus after ESKD. CV risk in GN patients was 2.5-fold higher than the general population (SIR 2.5, 2.1-2.8), and was higher in each GN subtype (IgAN=1.4, 1.0-1.8; MCD=1.8, 1.0-2.8; MN=3.0, 2.2-4.0; FSGS=4.0, 3.2-4.9).

Conclusions: Patients with GN are at high risk of CV disease, both before and after ESKD onset. The CV risk for all GN subtypes was higher than the general population, including MCD and IgAN. This suggests CV preventive strategies should be considered in all patients with GN.

Prediction of Atrial Fibrillation Using Clinical and Cardiac Biomarker Data: The CRIC Study
Leila R. Zelnick,1 Michael Shlipak,2 Elsayed Z. Soliman,3 Amanda H. Anderson,4 Robert Christenson,7 James P. Lash,8 Rajat Deo,6 Panduranga S. Rao,4 Farsad Afshininia,5 Jing Chen,4 Jiang He,4 Stephen L. Seliger,7 Raymond R. Townsend,1 Debbie L. Cohen,6 Alan S. Go,9 Nisha Bansal.1 1University of Washington Department of Medicine, Seattle, WA; 2University of California San Francisco, San Francisco, CA; 3Wake Forest University, Winston-Salem, NC; 4Tulane University, New Orleans, LA; 5University of Maryland School of Medicine, Baltimore, MD; 6University of Illinois at Chicago, Chicago, IL; 7University of Pennsylvania, Philadelphia, PA; 8University of Michigan, Ann Arbor, MI; 9Kaiser Permanente Northern California, Oakland, CA.

Background: Clinically available biomarkers of myocardial injury (high sensitivity troponin T, hsTnT) and hemodynamic stress (N-terminal brain natriuretic peptide, NT-proBNP) are strongly associated with atrial fibrillation (AF) in chronic kidney disease (CKD), and have been included in AF prediction models in community-based populations. We investigated the incremental prognostic value of NT-proBNP and hsTnT for AF prediction compared to standard clinical variables in CKD patients enrolled in the Chronic Renal Insufficiency Cohort (CRIC) using machine learning methods.

Methods: Among 2690 CRIC participants without prior AF with complete cardiac biomarker data, we developed a clinically informed clinical only model (CHARGE-AF) using machine learning methods, as well as a previously validated clinical prediction model (CHARGE-AF, using both original and re-estimated coefficients) to predict incident AF. Discriminatory ability of each model was assessed using 10-fold cross-validation; calibration was evaluated graphically.

Results: Mean (SD) age of participants was 57 (11) years, 55% men, 38% black, and 25% with CKD stage 4-5. The median follow-up (years) was 2.8; 251 incident AF events occurred during 7.3 (SD 2.8) years of follow-up. The AUC of the CHARGE-AF model was 0.75 (0.73, 0.76); the AUC of the clinical only model was 0.69 (0.67, 0.71). The difference was statistically significant (p < 0.002).

Conclusions: Cardiac biomarkers NT-proBNP and hsTnT can improve AF prediction in CKD, particularly when paired with machine learning algorithms.

Pooled Analyses of the Phase 3 Roxadustat Studies: Congestive Heart Failure Hospitalization Rates in Dialysis and Non-Dialysis Patients with Anemia Treated with Roxadustat vs. Comparators
Robert Provenzano,1 Lynda Szeczech,2 Ming Zhong,2 Bryant Lai,2 Robert Leong,2 Dustin J. Little,2 Kin-Hung P. Yu,2 Wayne State University, Detroit, MI; 2FibroGen Inc, San Francisco, CA; 1AstraZeneca, Gaithersburg, MD.

Background: Roxadustat is an orally bioavailable hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Phase 3 roxadustat studies were performed to treat anemia of chronic kidney disease (CKD). Congestive heart failure (CHF), a common comorbidity in CKD, was also analyzed. CHF is associated with a poorer prognosis in CKD patients, with a prevalence that increases with CKD severity; approximately 20% in mild CKD (>65 years) to 40% in patients on dialysis.

Methods: Safety data were pooled from pivotal phase 3 studies comparing roxadustat to placebo in Stage 3-5 non-dialysis-dependent (NDD) CKD patients, and to epoetin alfa in the overall dialysis-dependent (DD) CKD patients, and subgroup of incident-dialysis (ID-DD) patients. Patients with baseline (BL) moderate to severe CHF were not enrolled. CHF hospitalization events were a component of the MAE-plus endpoints that were adjudicated by a blinded independent committee, and analyzed by a Cox proportional hazards regression model; these analyses were not powered for individual endpoint outcomes.

Results: In the pooled NDD studies, 4270 patients were analyzed (2386 roxadustat; 1884 placebo). BL CHF history was comparable between roxadustat (25.7%) and placebo (13.6%) arms. Using ITT long-term follow-up, the HR (95% CI) of hospitalization for CHF among the NDD pooled population was 0.89 (0.72, 1.12) for roxadustat vs placebo.

Effect of Apabetalone on Major Adverse Cardiovascular Events in Patients with CKD, Diabetes, and Recent Acute Coronary Syndrome: Results from the BETonMACE Trial

Kamary Kalantar-Zadeh,1 Gregory G. Schwartz,2 Kevin A. Buhr,3 Henry N. Ginsberg,4 Jan O. Johansson,1 Ewelina Kulikowski,1 Stephen J. Nicholls,3 Peter P. Toth,1 Norman C. Wong,3 Michael Sweeney,3 Kausik K. Ray.5 BETonMACE Investigators 1University of California Irvine, Irvine, CA; 2University of Colorado Denver School of Medicine, Aurora, CO; 3Resverlogix Corp., San Francisco, CA; 4Resverlogix Corp., Calgary, AB, Canada; 5Johns Hopkins University School of Medicine, Baltimore, MD; 6Imperial Centre for Cardiovascular Disease Prevention, Imperial College London, London, United Kingdom; 7Columbia University, New York, NY; 8Statistical Data Analysis Center, University of Wisconsin-Madison, Madison, WI; 9Monash Cardiovascular Research Centre, Monash University, Melbourne, VIC, Australia.

Background: Chronic kidney disease (CKD) in type 2 diabetes mellitus (T2DM) patients is associated with increased cardiovascular disease (CVD) and heart failure risk. We hypothesized that a maladaptive epigenetic response engaging the bromodomain and extraterminal (BET) protein transcription system contributes to excess CVD risk. Hence, the efficacy of BET inhibition (BETi) treatment with apabetalone (APB) was assessed according to presence of CKD in the phase 3 BETonMACE trial.

Methods: BETonMACE compared APB with placebo in 2425 pts with T2DM and recent acute coronary syndrome. The primary outcome was CV death, non-fatal myocardial infarction or stroke (MACE). Hospitalization for congestive heart failure (CHF) was a secondary endpoint. Both outcomes were evaluated according to the presence of CKD (estimated GFR <60 mL/min/1.73 m2 at baseline).

Results: CKD pts were older (71 vs. 61 years), more likely female (42% vs. 23%) or non-white (18% vs. 12%), had longer duration of diabetes (mean 11.3 vs. 8.2 years) and higher serum alkaline phosphatase (91 vs. 81 U/L), and were less likely to receive metformin (69% vs. 84%) or SGLT2 inhibitors (6% vs. 13%) (P=0.05 for all). Under placebo, risk of endpoints was higher in CKD vs. non-CKD pts (MACE: 35/164 (21.3%) vs. 114/1041 (11.0%), HR=2.40, 95% CI [1.66, 3.44]; HCHF: 14/164 (8.5%) vs. 34/1041 (3.3%), HR=3.19, 95% CI [1.66,6.12]; P<0.001 for both). Under APB treatment, pts with CKD had significant reductions in MACE (HR=0.50, 95% CI [0.26, 0.96], P=0.034) and HCHF (HR=0.26, 95% CI [0.07,0.94], P=0.028) vs. placebo, see Kaplan-Meier figures.

Conclusions: CKD is a major risk factor for major adverse cardiovascular events in patients with recent acute coronary syndrome. Hence, the efficacy of BET inhibition (BETi) treatment with apabetalone (APB) was substantially reduced in patients with CKD.

Prevalence of Left Ventricular Hypertrophy in Pediatric Patients on Maintenance Dialysis and After Kidney Transplantation: A NAPRTCS Study

Kyle Merrill,1 Shirley Galbiati,2 Mark Mitsnefes,3,4 on behalf of NAPRTCS Investigators 1Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 2EMMES, Rockville, MD; 3University of Cincinnati, Cincinnati, OH.

Background: Left ventricular hypertrophy (LVH) is recognized as the most common cardiovascular complication in children on maintenance dialysis. There have been small single-center, or cross-sectional multi-center studies but there has been no large multi-center studies looking at prevalence of LVH during long-term maintenance dialysis. Using the NAPRTCS database, we determined the prevalence of LVH at time of initiation of maintenance dialysis and changes during long-term dialysis and post kidney transplantation. We also assessed the risk factors associated with LVH in children initiating maintenance dialysis.

Methods: Echocardiographic data were obtained from the NAPRTCS database which initiated collection of echo data in 2013 with the last data obtained in March 2020. LVH was defined as left ventricular mass index (LVMi, height-indexed)>95th percentile for age and sex. Patients with cardiovascular diagnoses, those younger than 1 year old at the time of echocardiography, LVMi values >200 g/m2, and LVMi values based on outlying heights were excluded from analysis. Multivariable logistic regression to assess risk factors for LVH at baseline (within first 3 months after initiation of dialysis) was performed.

Results: The study cohort included 606 patients between 1 and 18 years of age (median 10y (IQR 3.8-15.1), 53% females, 48% whites, 27% African-American, and 25% others/unknown) who had LVH data during time on dialysis. Of 182 patients who had echocardiography within first 3 months after initiation of dialysis (baseline), 67% had LVH. In logistic regression, hyperension (OR 2.9, 95% CI 1.4-6.3), anemia

Biomarker Panels for Discriminating Risk of CKD Progression in Children

Jason H. Greenberg,1 Yuwen Xu,2 Alison G. Abraham,3 Jeffrey R. Schelling,1 Harold I. Feldman,4 Michael Shlipak,4 Venkata Sabbisetti,2 Bradley A. Warady,2 Steven G. Coca,4 Paul L. Kimmel,4 Joseph V. Bouventre,4 Michelle Denburg,4 Chirag R. Parikh,4 Susan L. Furth,4 CKD Biomarker Consortium1 Yale University, New Haven, CT; 2 Johns Hopkins University, Baltimore, MD; 3 Case Western Reserve University, Cleveland, OH; 4 University of Pennsylvania, Philadelphia, PA; 5 University of California San Francisco, San Francisco, CA; 6 Brigham and Women’s Hospital, Boston, MA; 7 Children’s Mercy Hospitals and Clinics, Kansas City, MO; 8 Mount Sinai Health System, New York, NY; 9 National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.

Background: We used multivariate survival trees to identify plasma and clinical biomarkers to predict CKD progression in children.

Methods: The CKiD study prospectively enrolled children aged 6 months to 16 years old with an eGFR of 30-90 and eGFR was assessed annually. The primary outcome of CKD progression was a composite of 50% decline in eGFR or incident ESKD. We used multivariate survival trees to determine combinations of plasma and clinical predictors and plasma biomarkers as well as identify optimal thresholds for predicting the time to the composite event.

Results: Of the 651 children included, median age was 11 years (IQR 8.8-15), 405(62%) were male, 195(30%) had a glomerular cause of CKD, and baseline eGFR was assessed annually using the bedside and complete CKiD equations. Pubertal onset was defined by three separate definitions: transition to Tanner stage 2, peak growth velocity, and menarche. A mixed effects model with random intercept and random slope was used to compare the slope of eGFR before and after pubertal onset. The model was adjusted for age, race, glomerular diagnosis, baseline proteinuria, and BMI.

Results: 339 girls and 552 boys were included; Median age of pubertal onset for girls was 11.0 years (IQR 9.8, 12.1), 14.1 years (IQR 12.4, 17.0), and 14.4 years (IQR 13.1, 15.7) as defined by Tanner stage 2, peak growth velocity, and menarche, respectively. Annual percent change in eGFR declined faster among girls and boys after pubertal onset when defined by all measures, after adjustment. For example, annual percent decrease in eGFR was seen to increase from 2.6% prior to 9.0% after Tanner stage 2 in boys using the complete CKiD equation (p<0.001).

Conclusions: Estimated GFR declined faster after the onset of puberty among girls and boys with CKD. Clinicians should be aware that puberty may be an important time of kidney function decline among children with CKD.

Puberty Is Associated with Decline in Estimated Glomerular Filtration Rate in Children with CKD

Hannah Kim,1 Derek Ng,2 Matthew Matheson,1 Meredith A. Atkinson,1 Yasmin Akhtar,1 Bradley A. Warady,2 Susan L. Furth,2 Rebecca Ruebner,3 John Hopkins University, Baltimore, MD; 1 Children’s Mercy Hospitals and Clinics, Kansas City, MO; 2 The Children’s Hospital of Philadelphia, Philadelphia, PA.

Background: Puberty is a high-risk period for decline in kidney function among children with CKD. We aimed to describe changes in eGFR before and after pubertal onset using different objective markers of puberty among children with CKD.

Methods: We conducted a prospective cohort study using data from the Chronic Kidney Disease in Children (CKiD) study. Children who had onset of CKD after pubertal onset were excluded. GFR was estimated annually using the bedside and complete CKiD equations. Pubertal onset was defined by three separate definitions: transition to Tanner Stage 2, peak growth velocity, and menarche. A mixed effects model with random intercept and random slope was used to compare the slope of eGFR before and after pubertal onset. The model was adjusted for age, race, glomerular diagnosis, baseline proteinuria, and BMI.

Results: 339 girls and 552 boys were included; Median age of pubertal onset for girls was 11.0 years (IQR 9.8, 12.1), 14.1 years (IQR 12.4, 17.0), and 14.4 years (IQR 13.1, 15.7) as defined by Tanner stage 2, peak growth velocity, and menarche, respectively. Annual percent change in eGFR declined faster among girls and boys after pubertal onset when defined by all measures, after adjustment. For example, annual percent decrease in eGFR was seen to increase from 2.6% prior to 9.0% after Tanner stage 2 in boys using the complete CKiD equation (p<0.001).

Conclusions: Estimated GFR declined faster after the onset of puberty among girls and boys with CKD. Clinicians should be aware that puberty may be an important time of kidney function decline among children with CKD.

CLYS1 H310Y Is a Novel Cause of Familial Childhood Steroid-Sensitive Nephrotic Syndrome

Brandon M. Lang,1,2 Megan Chryst-Stangl,1 Guanghong Wu,1 Mohamed A. Shalaby,3 Sherif M. El desoky,1 Jameela A. Kari,3 Rasheed A. Gbadegesin,1,2 Department of Pediatrics, Duke University School of Medicine, Durham, NC; 3 Duke Molecular Physiology Institute, Durham, NC; 4 King Abdulaziz University Hospital, Jeddah, Saudi Arabia.

Background: Nephrotic syndrome (NS) is the most common glomerular disease seen in children. It is estimated that up to 30% of steroid resistant NS (SRNS) may be due to mutations in one of sixty genes reported in cohort of patients with familial or idiopathic SRNS. However, the genetic causes of the more common steroid sensitive NS (SSNS) and the molecular basis for variability in glucocorticoid response have remained elusive. Our overarching hypothesis is that single gene causes of SSNS can be identified in cohorts of children with SRNS. We then hypothesized that mutations in the NS3 complex may contribute to the variability in glucocorticoid response.

Methods: To identify single gene causes of SSNS in a cohort of patients with familial SSNS and examine the molecular basis of glucocorticoid response, we carried out whole genome sequencing in forty families with hereditary SSNS. After identifying a potential disease-causing variant, we examined the effects of loss of gene function in cultured human podocytes through the creation of lentiviral shRNA knockdown and CRISPR-Cas9 knockout cell lines as well as morpholino-based gene knockdown in zebrafish.
Results: We identified a rare homozygous variant, CLVS1 H310Y, that segregates with disease in a consanguineous family with two affected siblings and a cousin. CLVS1 encodes clavinulin, a component of clathrin mediated endocytosis. This variant was not present in a homozygous state in >200,000 chromosomes and is predicted to be pathogenic by in silico analyses. Morpholino knockdown of the orthologous CLVS1 gene in zebrafish resulted in edema, phenotypes indicative of loss of glomerular filtration barrier (GFB) integrity. This edema phenotype could be rescued with wildtype human CLVS1 mRNA but not the H310Y variant. Knockdown of CLVS1 in cultured human podocytes as well as overexpression of the H310Y variant in HEK 293 cells decreased endocytosis of the fluorescently labeled dextrans and increased susceptibility to apoptosis. The rare variants podocyte phenotypes could be rescued in the presence of glucocorticoid, mimicking the steroid responsive phenotype in patients bearing the CLVS1 H310Y variant.

Conclusions: We identified a mutation in CLVS1 as a new cause of hereditary SSNS. Our data demonstrates the requirement of functional mRNA but not the gene in silico

CLVS1 with disease in a consanguineous family with two affected siblings and a cousin.

Cross-Talk Between Neutrophils and Macrophages Dictates the Outcome of Acute Pyelonephritis
Juan de Dios Ruiz-Rosado, Hanna H. Cortado, John D. Spencer, Brian Becknell, Santiago Partida-Sanchez. Abigail Wexner Research Institute at Nationwide Children’s Hospital, Columbus, OH.

Background: Pediatric urinary tract infections (UTI) account for 1.5 million clinic visits annually in the United States. Uropathogenic Escherichia coli (UPEC) causes over 80% of UTIs. Up to 50% of infants with a UTI develop a kidney infection (acute pyelonephritis, APN). To study cell-type specification of renal epithelial cells, we conducted trajectory analysis and resolved the developmental pseudotime along cell differentiation from nephron progenitors. We show that early differentiation of podocytes from the nephron progenitor pool is associated with sustained Foxl1 expression. Differentiation of renal tubule cells followed a more complex pattern, where Hnf4a expression is associated with a more proximal fate, while Tgfb2 is coupled to the distal tubule differentiation. After cell specification, terminal differentiation was strongly linked to metabolic nuclear receptors such as Estra and Ppara for proximal tubules and Estb and Pparg1a in loop of Henle. We also implemented snATAC-seq data to leverage our understanding of human kidney disease development. By overlapping the chromatin landscape with kidney disease GWAS signals, we inferred key cell types for GWAS loci in the proximity of Shroom3 and Dab2 genes. Interestingly, we observed that some kidney disease-associated loci, such as those in the vicinity of Uncx, are only accessible in the developing kidney cells, indicating a developmental stage regulatory role of genetic variants.

Conclusions: Here we present a comprehensive open chromatin and gene expression landscape for developing mouse kidney and illustrate the use of single-cell multi-omics data to study gene regulatory dynamics and its relationship to complex human disease genetics.

Expansion of Human Induced Pluripotent Stem Cell-Derived Ureteric Bud Organoids with Repeated Branching Potential
Makoto Ryosaka, Shin-ichi Mae, Kenji Osafune. Center for iPSC Cell Research and Application (CIRA), Kyoto University, Kyoto, Japan.

Background: The mammalian adult kidney, metanephros, develops by the reciprocal interaction between two embryonic progenitor tissues, metanephric mesenchyme and ureteric bud (UB). UB has epithelial polarity and tubular lumens, consists of two domains, the tip and trunk, and repeats branching morphogenesis. We implemented in vitro monitoring and expansion methods to study gene regulatory dynamics and its relationship to complex human disease genetics.

Methods: We conducted single-nucleus ATAC sequencing (snATAC-seq) and single cell RNA-sequencing (scRNA-seq) of kidneys from developing and adult mice. After quality control, we obtained 66,254 scRNA-seq and 28,316 snATAC-seq profiles.

Results: Through clustering analysis, we identified all major cell types in the kidney. By integrating snATAC-seq and scRNA-seq data, we revealed cell type- and developmental stage-specific cis-regulatory elements and inferred promoter-enhancer regulatory units. We defined key cell identity TFs and their gene targets through co-expression patterns. Cell-type specification of renal epithelial cells, we conducted trajectory analysis and resolved the developmental pseudotime along cell differentiation from nephron progenitors. We show that early differentiation of podocytes from the nephron progenitor pool is associated with sustained Foxl1 expression. Differentiation of renal tubule cells followed a more complex pattern, where Hnf4a expression is associated with a more proximal fate, while Tgfb2 is coupled to the distal tubule differentiation. After cell specification, terminal differentiation was strongly linked to metabolic nuclear receptors such as Estra and Ppara for proximal tubules and Estb and Pparg1a in loop of Henle. We also implemented in vitro monitoring and expansion methods to leverage our understanding of human kidney disease development. Single-Cell Resolution Regulatory Landscape of the Kidney Highlights Cellular Differentiation Programs and Renal Disease Targets
Zhen Miao, Michael S. Balzer, Ziyuan Ma, Hongbo Liu, Junnan Wu, Katalin Suszta. Susztak Lab University of Pennsylvania, Philadelphia, PA.

Background: The kidney cells undergo complex differentiation during development, among which the nephron progenitors differentiate to more than 10 different epithelial cells. However, the driver pathways, cell type specific transcription factors and regulatory circuits are not fully understood.

Methods: Here we conducted single-nucleus ATAC sequencing (snATAC-seq) and single cell RNA-sequencing (scRNA-seq) of kidneys from developing and adult mice. After quality control, we obtained 66,254 scRNA-seq and 28,316 snATAC-seq profiles.

Results: Through clustering analysis, we identified all major cell types in the kidney. By integrating snATAC-seq and scRNA-seq data, we revealed cell type- and developmental stage-specific cis-regulatory elements and inferred promoter-enhancer regulatory units. Rhesus Macaque Serves as a Model for Human Lateral Branching Nephrogenesis
Meredith P. Schuh, Lyan Alkhudairy, Andrew Potter, Steven Potter, Kashish Chetel, Nathan Salomonis, Raphael Kopan. Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

Background: Premature infants are at risk for chronic kidney disease later in life due to low nephron endowment. Lateral branching nephrogenesis (LBN), not occurring in the mouse, is a poorly understood but critical form of human nephrogenesis. Here, we analyze third trimester LBN in the rhesus macaque at the molecular and morphological level.

Methods: The morphology of third trimester rhesus kidneys was assessed by immunostaining after tissue clearing. 3D renderings were created using Bitplane Imaris. Single-cell RNA sequencing (scRNA-seq) and single-nucleus RNA sequencing (snRNA-seq) were performed on 4 kidneys from 4 rhesus using cold protease digestion and 10xGenomics platform. Unsupervised analyses using ICG2 were used to identify distinct cell populations and GO-Elite was used to compare rhesus with human and mouse datasets.

Results: The gestational period of the rhesus lasts 165 days. We determined that cessation of rhesus nephrogenesis occurs between 136- and 138-days gestational age (GA). LBN was observed along the ureteric stalks at 126-138 days GA. We noted rosette-like patterns of ureteric tips and nephron progenitor cells (NPC) in both rhesus and human third trimester archival samples. scRNA-seq was performed on 4 cortical enriched rhesus samples 129-131 days GA revealing 3 transcriptionally distinct cell clusters. C25 was predicted to contain the naïve NPC and included CITED1, MEOX1, and EYA1. snRNA-seq yielded 5,972 nuclei, corresponding to 29 ICGS2 clusters. We found a single cluster (c26), with a near identical GO-Elite enrichment profile to that of the naïve NPC scRNA-seq cluster (c25). snRNA-seq c26 contained many unique markers not found in the naïve NPC markers, BMPR, BFGF, BMPR1A, BMP7, BMPR2, IGF1, PDGFR, and SMAD5. The late-gestation rhesus NPC markers more closely aligned to late-gestation murine NPCs, whereas the 2nd trimester human NPCs more closely aligned to mid-gestation murine NPCs. Novel surface markers predicted in the rhesus include CACNA1E, KIRREL3, and KIRREL2.

Conclusions: The rhesus is the first animal model to demonstrate LBN, suggesting that LBN is conserved in old world primates. We identified novel genes upregulated during LBN and surface markers that could be used for cell-sorting.

Cyclin G1/CDK5-Mediated Dedifferentiation of Proximal Tubular Cells Drives AKI-to-CKD Transition
Kensei Taguchi, Bertha C. Elias, Craig R. Brooks. Vanderbilt University Medical Center, Nashville, TN.

Background: Acute kidney injury (AKI) is associated with increased morbidity and mortality in hospitalized patients and predisposes patients to chronic kidney disease (CKD). While kidney cells, particularly proximal tubule cells (PTCs), can undergo dedifferentiation, proliferation, and redifferentiation to facilitate kidney repair after injury, maladaptive repair resulting in prolonged dedifferentiation of PTCs drives fibrosis. We have found that cyclin G1 (CG1), an atypical cyclin, not only promotes G2/M cell cycle arrest, but also regulates dedifferentiation of PTCs. The aim of the current study is to determine if CG1 regulates dedifferentiation of PTCs through interaction with kinase CDK5.

Methods: 1) Ablation of experimental AKI was induced by administration of three doses of AA in 8 to 12-week-old male wild-type (WT) and CG1 globally knockout mice (CG1KO). 2) Unilateral ureteral obstruction (UO) was performed and kidneys were harvested on day 9. 3) To determine the interaction of CG1, immunoprecipitation (IP) was performed in CG1-overexpressing LLC-PK1 cells treated with AA. 4) To examine the pathological role of CDK5, LLC-PK1 cells or primary PTCs with or without siRNA or pharmacological inhibitors of CDK5 were treated with AA.

Results: CG1 was rapidly upregulated in PTCs in response to kidney injury and remained high in chronic phase following AAN and UUO. Kidney fibrosis and markers of dedifferentiation, such as SOX9, Vimentin, and Snail, were reduced in CG1KO animals following AAN and UUO injuries, compared to WT. IP demonstrated that CG1 binds to p53, mouse double minute 2 homolog (MDM2), and CDK5. Of these, the interaction of CDK5 with SOX9 was confirmed by the observation that CG1 binds to SOX9 knockout mice (CG1KO). Genetic or pharmacological inhibition of CDK5 preserved E-cadherin in AA-induced cellular injury with reduction of profibrotic markers; however, it provided no additive effect in CG1KO PTCs.

Conclusions: CG1 partnering with CDK5 drives a maladaptive dedifferentiation of PTCs after kidney injury, resulting in increased secretion of profibrotic cytokines and progression of fibrosis. As CG1 is highly expressed in injured PTCs, it represents a potential therapeutic target for prevention of kidney fibrosis.

Incorporation of Urine-Derived Stem Cells into Kidney Organoids Derived from Human Induced Pluripotent Stem Cells
Julie Bejoy, Richard C. Welch, Lauren E. Woodard. Woodard Lab Vanderbilt University Medical Center, Nashville, TN.

Background: Donor-derived somatic cells or stem cells can be differentiated into renal cell types for disease modeling, drug screening, or therapeutic studies. Modeling of kidney diseases with kidney organoids derived from human induced pluripotent stem cells (hiPSCs) has been termed a "kidney in a dish." The recent advances in stem cell-based therapies have shown great promise for the treatment of kidney injuries. To evaluate the therapeutic properties, we studied the incorporation of urine-derived stem cells (USCs) into a kidney organoid model of acute kidney injury. USCs are viable cells from urine which can be expanded in vitro for more than ten passages. There is evidence suggesting that USCs are most likely cultured glomerular parietal epithelial cells.

Methods: For this project, we cultured kidney organoids from fibroblast-derived hiPSCs by the established protocol from Takasato and Little, following optimization. Co-culturing of USCs with a membrane dye and Day 25 kidney organoids revealed that USCs were incorporated into the organoids efficiently within two days of the co-culture. For injury models, we established nephrotoxicity in the proximal tubule by adding the nephrotoxic drug Cisplatin (5 μM) at Day 21 of kidney organoid culture.

Results: The kidney organoids formed iPSCs expressed the kidney cell type markers Ecad (dual tubule), GATA3 (collecting duct), LTL (proximal tubule) and NEPHRIN (Glomeruli) at Day 21. The organoids were then treated with 5 x 10^5 USCs at Day 22 for 48 hours and evaluated for the expression of kidney injury molecule-1 (KIM-1). Immunostaining revealed that KIM-1 expression was significantly reduced in the organoids treated with USCs compared to the organoids without USCs, suggesting a positive therapeutic impact of USCs. We are currently performing RNAseq on three sets of whole kidney organoids (Control, Cisplatin, Cisplatin+USC) to provide detailed interrogation of cellular apoptosis and related signaling pathways in these three different sets of organoids.

Conclusions: The ability of USCs to reduce KIM-1 expression in human kidney organoids suggests that further investigation into the therapeutic potential of USC for treatment of acute kidney injury is warranted.

Supramolecular Nanofibers Containing Arginine-Glycine-Aspartic Acid (RGD) Boost Therapeutic Efficacy of Extracellular Vesicles in Kidney Repair
Chunyu Zhang, Jie Wu, Lingling Wu, Xiangmei Chen, Chinese PLA General Hospital, Beijing, China; Nanjian University, Tianjin, China.

Background: Extracellular vesicles (EVs) derived from mesenchymal stem cells (MSC-EVs) have been recognized as a promising cell-free therapy for acute kidney injury (AKI), which avoids safety concerns associated with direct cell engraftment. However,
low stability and retention of MSC-EVs have limited their therapeutic efficacy. RGD peptide binds strongly to integrins, which have been identified on the surface of MSC-EV membranes, yet RGD has not been applied to EV scaffolds to enhance and prolong bioavailability.

**Methods:** Here, we developed RGD hydrogels, which we hypothesized could augment MSC-EV efficacy against AKI.

**Results:** In vivo tracking of the EVs revealed that RGD hydrogels increased retention and stability of EVs. Upon intrarenal injection, EV-RGD hydrogels provided superior rescuing effects at functional, histopathological and molecular levels. Further analysis revealed that the presence of microRNA let-7a-5p in MSC-EVs served as a novel mechanism contributing to the reduced cell apoptosis and elevated cell autophagy in AKI. This study developed an RGD-scaffold to increase the mechanism contributing to the reduced cell apoptosis and elevated cell autophagy in AKI.

**Conclusions:** RGD hydrogels boosted the therapeutic efficacy of let-7a-5p-containing-EVs in AKI repair. This study developed an RGD-scaffold to increase the EV integrin-mediated loading and in-turn improved therapeutic efficacy, therefore providing a new feasible treatment for potentiated AKI.

**Targeting Angiopoietin-Tie2 Signaling in Kidney Ischemia-Reperfusion Injury**

Yanyang Li,1 Tuncer Onay,1 Pan Liu,1 Michael Ryckzo,2 Mohammed Javed Ansari,1 Jing Jin,1 Susan E. Quaggin,1 1Northwestern University Feinberg School of Medicine, Chicago, IL; 2Mannin Research Inc, Toronto, ON, Canada.

**Background:** The endothelial angiopoietin (ANG)-Tie2 signaling pathway is required for vascular development and homeostasis. Dysregulation of ang-Tie2 pathway has been implicated in diseases including venous malformation, glaucoma, diabetic nephropathy, and septic acute kidney injury (AKI). The endothelial-specific specific phosphatase VE-PTP/PTPRB is a negative regulator of Tie2 phosphorylation. Here we investigate the therapeutic roles of Angiopoietin-Tie2 signaling in kidney ischemia-reperfusion injury (IRI).

**Methods:** A biartigenic doxycycline-inducible system (VeptRNAiR, RosA26RiTAiR, tetO-Cre)1 was used to knockout VE-PTP at postnatal day 0 (VE-PTPKO). Adult male VE-PTPKO and littermate control mice underwent bilateral IRI or sham surgery. Serum creatinine was measured on day 1, day 3 and day 7 after surgery by HPLC method. Data were analyzed using two-way ANOVA. Tissues were harvested on day 7 for histology, immunohistochemistry and RNA/protein analysis. Bulk RNAseq was performed with RNA extracted from whole kidney 5 hours after IRI. Normalization and differential expression were determined using DESeq2. For pharmacological studies, adult male C57BL/6J mice were used. A new soluble ANGPT1 mimetic (C4BP-ANG1) or vehicle were administered by intraperitoneal injection.

**Results:** Western blot analysis showed VE-PTP protein levels were increased in kidneys post-IRI and following hypoxia-inducible factor stabilization. Genetic deletion of VE-PTP rescued declined Tie2 phosphorylation in kidney after IRI. While serum Creatinine was elevated 1 day post-IRI in control mice, this increase was minimal in VE-PTP KO mice (p<0.0055). Global gene expression analysis indicated minimal kidney transcriptome change at base line whereas in the setting of IRI, VEPTP KO mice showed a less activated renal endothelium and downregulation of acute stress response genes signature. A corresponding decrease in pro-fibrotic genes was observed in VE-PTP KO mice on day 7. In the pharmacological study, systemic administration of C4BP-ANG1 activated Tie2 and its downstream AKT/eNOS/NO pathways in mouse kidneys in physiological condition. Ongoing studies are analyzing its protective effect in ischemic AKI.

**Conclusions:** Our data provide evidence for augmenting Tie2 activation-induced vascular protection as a promising therapeutic strategy for renal protection following IR-AKI.

**Pannexin 1 Channel Regulates Mitochondrial Function and Cell Survival During AKI**

Nabin Poudel,1,2 Colleen Schinderle,3 Nataliya Skrypnyk,4 Christopher B. Medina,2 Diane L. Rosin,1 Kodi S. Ravichandran,1 Mark D. Okusa.1 Center for Immunity, Inflammation and Regenerative Medicine (CIIR), University of Virginia 1Division of Nephrology and Center for Immunity, Inflammation, and Regenerative Medicine, University of Virginia, Charlottesville, VA; 2Department of Microbiology, Immunology, and Cancer Biology, University of Virginia, Charlottesville, VA.

**Background:** Pannexin 1 (Pannx1) is a membrane associated non-selective channel that, when activated, serves as a conduit for release of small metabolites that have pro- or anti-inflammatory function. We have previously shown that pharmacological inhibition or genetic deletion of Panx1 in mice prior to injury is protective against renal ischemia-reperfusion injury (IRI). How Panx1 contributes to acute kidney injury (AKI) pathology is unknown. We hypothesized that Panx1 induces cell death by mediating both intracellular and extracellular events.

**Methods:** We subjected a novel human Panx1 overexpressing mouse (hPanx1-Tg) to IRI or cisplatin-mediated AKI and assessed plasma creatinine and renal expression of neutrophil gelatin associated lipocalin (Ngal). For in vitro studies, Panx1 overexpressing TKPTS cells (OX) were challenged with cisplatin. Cell death was assessed by flow cytometry using Annexin-V/7AAD. Mitochondrial function was assessed by measuring oxygen consumption rate, mitochondrial membrane potential and ROS production. mRNA expression was assessed using real-time PCR.

**Results:** hPanx1-Tg mice had significant rise in plasma creatinine and expression of Ngal in the kidneys in both models of AKI compared to their littermate controls. Cisplatin-induced cell death was greater in OX cells compared to control cells. Moreover, cisplatin induced greater death in OX cells than control cells when cultured together. Among genes involved in the cell death pathway, OX cells had reduced expression of Bcl2 and a greater increase in Hif-1 after cisplatin exposure. Assessment of mitochondria showed that OX cells had reduced mitochondrial DNA, Ppargc expression, and mitochondrial respiration at baseline, a greater reduction in mitochondrial function and a higher increase in mitochondrial ROS production after cisplatin exposure compared to controls.

Enhancer and Super-Enhancer Dynamics in Repair After Ischemic AKI
Julia Willmes,1,2,3,4 Michaela Willili,1,4 Hye Kyung Lee,2,4 Hannes Olsson,4 Jakub Jankowski,4,5 Takaharu Ichimura,1,5 Reinhold Erben,4,6 M. Todd Valerius,4,6 Lothar Hennighausen,7,8 Joseph V. Bonventre,7,8,9 Brigham and Women’s Hospital, Boston, MA; 2Laboratory of Genetics and Physiology, National Institute of Diabetes, Digestive and Kidney Diseases, National Institutes of Health, Bethesda, MD; 3Division of Renal Medicine, Department of Clinical Sciences, Intervention and Technology, Stockholm, Sweden; 4University of Veterinary Medicine, Department of Physiology, Pathophysiology and Endocrinology, Vienna, Austria

Background: The endogenous repair process of the mammalian kidney allows rapid recovery after acute kidney injury (AKI) through robust proliferation of tubular epithelial cells. There is currently limited understanding of which transcriptional regulators activate these repair programs. Here we investigate the existence of enhancer and transcription factor dynamics in the regenerating mouse kidney.

Methods: Using RNA-seq and ChIP-seq (H3K2ac, H3K4m3, BRD4, BRD2, BRD3, Pol II, HNF4A, GR, STAT3 and STAT5) were performed on samples from repairing kidney cortex 2 days after ischemia/reperfusion injury (IRI) to identify activated genes, transcription factor binding, enhancer and super-enhancers associated with kidney repair. Further, we investigated the role of enhancers in kidney repair through pharmacological BET inhibition using the small molecule JQ1 in AKI models in vivo.

Results: Response to injury leads to genome-wide alteration in enhancer repertoire in vivo. We identified 16,781 enhancer and 380 super-enhancer sites (H3K2ac and BRD4 positive) with a high density of binding in SHAM and IRI samples; 6,516 enhancer, 164 super-enhancer lost and 9,774 enhancer, 214 super-enhancer gained after IRI. The lost and gained enhancer sites can be annotated to 62% and 63% of down- and up-regulated transcripts after AKI, respectively. ChIP-seq profiles of predicted transcription factor-binding sites show specific binding at corresponding enhancer sites with high dynamic binding of HNF4A, GR and STAT3. HNF4A and GR show a reduced binding at enhancer and super-enhancer sites after injury, whereas STAT3 binding can be observed at injury gained enhancer and super-enhancer sites. BET (BRD4) inhibition before IRI leads to suppression of 40% of injury-induced transcripts associated with cell cycle regulation, genome-wide Pol II pausing and significantly increased mortality after AKI.

Conclusions: This is the first demonstration of enhancer and super-enhancer and transcription factor binding dynamics in the repairing kidney. In addition, our data call attention to potential caveats for use of BET inhibitors that are currently being tested in clinical trials. Understanding of enhancer dynamics after acute kidney injury in vivo has the potential to lead to indentation of new targets for therapeutic intervention.

Developmental Reprogramming of Kidney Resident Macrophages During Human AKI and Its Implications to CKD
Abolfazl Zaraji,1,2 Elias Mrug,1 Kurt Zimmerman,3 Jiandong Chen,4 David K. Crossman,1,2 Frida Rosenblum,5 Philit Ch. Chumley,6 Jaling Zhou,6 Anupam David7,8,9

1Brigham and Women’s Hospital, Boston, MA; 2Laboratory of Genetics and Physiology, National Institute of Diabetes, Digestive and Kidney Diseases, National Institutes of Health, Bethesda, MD; 3Division of Renal Medicine, Department of Clinical Sciences, Intervention and Technology, Stockholm, Sweden; 4University of Veterinary Medicine, Department of Physiology, Pathophysiology and Endocrinology, Vienna, Austria

Background: Kidney tissue-resident macrophages (KRM) promote naturally occurring or AKI-induced cystic renal disease in mice. AKI also reprograms KRM into a disease state that promotes fibrosis. Understanding of enhancer dynamics after kidney injury in vivo has the potential to lead to identification of new targets for therapeutic intervention.

Methods: We performed RNA-seq and ChIP-seq (H3K2ac and H3K4m3) data from the Mouse Cell Atlas. We identified 16,781 enhancer and 380 super-enhancer sites (H3K2ac and BRD4 positive) with a high density of binding in SHAM and IRI samples; 6,516 enhancer, 164 super-enhancer lost and 9,774 enhancer, 214 super-enhancer gained after IRI. The lost and gained enhancer sites can be annotated to 62% and 63% of down- and up-regulated transcripts after AKI, respectively. ChIP-seq profiles of predicted transcription factor-binding sites show specific binding at corresponding enhancer sites with high dynamic binding of HNF4A, GR and STAT3. HNF4A and GR show a reduced binding at enhancer and super-enhancer sites after injury, whereas STAT3 binding can be observed at injury gained enhancer and super-enhancer sites. BET (BRD4) inhibition before IRI leads to suppression of 40% of injury-induced transcripts associated with cell cycle regulation, genome-wide Pol II pausing and significantly increased mortality after AKI.

Conclusions: This is the first demonstration of enhancer and super-enhancer and transcription factor binding dynamics in the repairing kidney. In addition, our data call attention to potential caveats for use of BET inhibitors that are currently being tested in clinical trials. Understanding of enhancer dynamics after acute kidney injury in vivo has the potential to lead to identification of new targets for therapeutic intervention.

Endothelial-Derived mir-17–92 Promotes Angiogenesis to Protect Against Renal Ischemia-Reperfusion Injury
Takuto Chiba, Jacqueline Ho, Suner Simps-Lucas, University of Pittsburgh Medical Center, Pittsburgh, PA

Background: Acute kidney injury (AKI), resulting from renal ischemia reperfusion injury (IRI) among others, is an independent predictor of morbidity and mortality, and is identified in as many as 50% of ICU patients. Damage to the renal microvasculature is a hallmark of renal IRI. mir-17–92 encodes 6 polycystic microRNAs that show potent pro-angiogenic capacity by targeting anti-angiogenic factors. The function of mir-17–92 in renal microvasculature after renal IRI remains unknown.

Methods: Antibodies bound to magnetic beads were utilized to selectively enrich for renal endothelial cells from mice. Endothelial-specific mir-17–92 knockout (mir-17–92deo-/-) mice were generated and a renal IRI model was performed. Mice were monitored for the development of AKI using serum chemistries and tissue analysis, and for renal blood flow using a magnetic resonance imaging (MRI). Mice were treated with mirRNA mimics during renal IRI to test its therapeutic efficacies.

Results: We demonstrate that mir-17–92, -18a, -20a, and -19b are up-regulated in renal endothelial cells after renal IRI in mice. mir-17–92deo-/- exacerbates ischemic AKI in male and female mice. Specifically, mir-17–92deo-/- promotes renal tubular injury, increases renal blood flow, promotes microvascular rarefaction, increases renal oxidative stress and promotes macrophage infiltration to injured kidneys. The potent anti-angiogenic factor, thrombospondin 1 (TSP1), is highly expressed in renal endothelium in mir-17–92deo-/- after renal IRI and is a target of mir-18a and mir-19b. Beyond defining a critical role for mir-17–92 in the angiogenic response after ischemic AKI, we show that co-treatment with a combination of mir-18a and mir-19b mimics is sufficient to mitigate ischemic AKI.

Conclusions: These data suggest that endothelial-derived mir-17–92 stimulates a reparative response in damaged renal vasculature during ischemic AKI by regulating angiogenic pathways.

SU-OR11
Inhibition of Cadherin 11 Improves Outcomes in Murine Models of CKD
Tessa Huffman,1,2 Michael A. Raddatz,3 Leslie S. Gewin,4 W. David Merriman,5
1Vanderbilt University, Nashville, TN; 2Vanderbilt University Medical Center, Nashville, TN

Background: Chronic kidney disease (CKD) represents a massive unmet clinical need, as there are virtually no pharmaceutical options for treatment of renal injury. A recent study identified cadherin-11 (CDH11) as a potential biomarker for CKD, as it is present in various kidney biopsies and in samples of CKD patients and its expression is increased in CKD mouse models. We have investigated the role of CDH11 as both a mediator and therapeutic target of CKD.

Methods: In the current study, we used three mouse models of CKD to evaluate the role of CDH11. The first model, a CKD-like injury induced by uninephrectomy/angiotensin II administration. In each of these models, we inhibited CDH11 genetically using transgenic mice and pharmacologically with the administration of a functional blocking antibody to CDH11.

Results: Although CDH11 has been found on immune cells and fibroblasts in other fibrotic diseases, we found that in the kidney CDH11 is exclusively expressed in injured proximal tubules (PTs). PTs play a significant role in CKD, as they are both a target and mediator of chronic injury. In our models of CKD, we found that both genetic and pharmacologic CDH11 inhibition improves renal function (BUN and ACR), diminishes cytotoxic production (TGF-β and IL-6 expression), and reduces tubular injury (expression of KIM-1 and histological analysis). Using primary PT cells, we found that genetic ablation of CDH11 improves cell survival in vitro. Although the specific signaling pathway by which CDH11 mitigates PT injury is still under investigation, preliminary data shows that inhibition of CDH11 increases Wnt/β-catenin activity in the kidneys of injured mice. Wnt/β-catenin signaling promotes cell survival, which in this context could result in reduced tubular atrophy, cytotoxic production, and fibrosis. Such pro-survival signaling could be driving the reduction in renal injury we see when CDH11 is inhibited, as PT death strongly correlates with outcomes in CKD.

Conclusions: These results clearly identify CDH11 inhibition as a novel means of improving outcomes in murine CKD models. The mechanism by which CDH11 inhibition reduces renal injury is likely through CDH11 interactions with the Wnt/β-catenin signaling pathway to enhance PT survival. These results could prove an important step towards developing new therapeutic strategies for the treatment of CKD.

METTL10: A Kidney Disease Risk Gene by Altering Protein Methylation
Hai Long Hu, Katalin Susztak. Renal Electrolyte and Hypertension Division, Department of Medicine and Genetics, University of Pennsylvania, Philadelphia, PA.

Background: Genome-wide association studies (GWAS) have identified more than 300 loci where genetic variants are associated with kidney function, however, the causal variants, genes, cell types and the disease mechanism remain mostly unknown.

Methods: We have generated expression of quantitative trait (eQTL) data from microdissected human kidney tubules and glomeruli. We used Bayesian colocalization of eQTL and GWAS to identify likely causal genes for kidney function. We used single cell RNA and ATACseq data to identify causal cell types. Finally, we generated mice with genetic deletion to study kidney disease mechanism.

Results: Kidney disease associated genetic variants showed a strong association with METTL10 expression. Methytransferase-like protein 10 (METTL10), is a non-histone lysine methyltransferase. Patients with CKD variants showed lower level of METTL10 in their kidneys. METTL10 was relatively broadly expressed in kidney tubule cell by single cell expression analysis. Its expression was markedly reduced in mice and patients with kidney disease. We found that Mettl10 controls methylation and the activity of the eukaryotic translation elongation factor 1 alpha (eEF1A). eEF1A is the alpha subunit of the eukaryotic elongation complex, controlling RNA translation. Methylation of eEF1A was markedly reduced in mice of Mettl10 KO mice. The reduction in eEF1A activity lead to lower protein translation and tubule cell proliferation. Mettl10 KO mice were more susceptible to kidney disease, it showed higher structural damage and collagen expression in the folic acid induced kidney injury model.

Conclusions: Taken together, GWAS and eQTL studies identified Mettl10 a kidney disease risk gene. METTL10 controls the methylation of eEF1A, downstream RNA translation, cell proliferation altering kidney disease risk, defining a novel mechanism for kidney disease development.

Renal Proximal Tubule Cell Differentiation and Metabolism Are Coupled by Nuclear Receptors
Poonam Dhillon,1 Jhwan Park,1 Carmen Hurtado del Pozo,2 Lingzhi Li,2 Shizheng Li,1 Royesh Shrestha,1 Nuria Montserrat,1 Katalin Susztak,1 Susztak Lab 1University of Pennsylvania, Philadelphia, PA; 2Barcelona Institute of Science and Technology, Barcelona, Spain.

Background: Kidney proximal tubule (PT) cells have high mitochondrial density to perform their highly energizing demand function to secrete and reabsorb metabolites and electrolytes. Chronic kidney disease is characterized by tubule epithelial atrophy and dedifferentiation, resulting in a decline in kidney function. In this study, we aimed to define upstream regulators that control PT differentiation.

Methods: We performed scRNA and snATACseq analysis on kidneys of developing and adult mice, kidney organoids, and kidneys from control and folic acid induced kidney injury model. Bioinformatic methods included dimension reduction, differential expression, cell fraction and cell trajectory analysis. Functional studies included mice and cultured tubule cells with genetic deletion of ESRR.

Results: Single cell metabolomic expression analysis identified PT cells as the key vulnerable cell type in kidney fibrosis. Cell trajectory analysis showed a sequential differentiation path from precursor to differentiated PT cell state in development and in adult, and developing mouse PT cells and organoids. Single cell epigenetics data identified the critical role of nuclear receptors; HNF4A, HNF1B, PPARa, and ESRR driving the PT cell differentiation program. These transcription factors did not only directly control FAO and OXPHOS but also the expression of PT differentiation genes. Genetic and pharmacological deletion of these transcription factors lead to marked changes in differentiation state of cultured PT cells. Analysis of healthy and disease human kidney samples and mice with ESRR deletion showed a defect in FAO, OXPHOS and PT differentiation and was more susceptible for injury, defining a novel role for ESRR in PT cells and CKD.

Conclusions: The coupling of cell state and metabolism is established by nuclear receptors such as PPARa and ESRRa that not only control cellular metabolism but also the expression of PT cell-specific genes in mice and patient samples.

SU-OR14
COX17-Mediated Abnormal Mitochondrial Copper Metabolism Promotes Renal Fibrosis
Saiya Zhu, Chen Yu. Department of Nephrology, Tongji Hospital, Tongji University, Shanghai, China.

Background: Copper is a trace element essential for almost all living organisms. Previously, we found that elevated intracellular copper contributes a unique role to kidney fibrosis. Furthermore, copper ions in cells were mainly accumulated in mitochondria, which damage the structure and function of mitochondria. However, the mechanism of the accumulation of copper in mitochondria and how a disturbed copper balance induces mitochondrial dysfunction remain to be identified. Copper chaperone COX17, a protein required for cytochrome c oxidase (COX) assembly, was previously hypothesized to shuttle copper between the cytosol and mitochondria based on its dual localization. We found that in the fibrosis model COX17 was highly expressed and COX activity decreased. Therefore, we speculated that COX17 might be involved in mitochondrial copper overload and renal fibrosis.

Methods: Expression level and pattern of COX17 were examined in ischemia-reperfusion injury (IRI) AKI and diabetic nephropathy (DN) kidneys. The regulation role of COX17 was investigated in renal tubule epithelium cell line (NRK-52E) and rat fibroblasts(NRK-49F) by treating with copper or copper chelator tetrathiomolybdate (copper-chelating agent). ICP-MS, mitoXO, electron microscopy, realtime-PCR and western blot analysis were applied in the current study.

Results: Firstly, the expressions of COX 17, Col1 in the kidney of IRI group were extremely upregulated compared with the sham group. Unexpected, we found dysfunction of mitochondria in IRI kidneys evidenced by it’s appearing swollen and ruptured. Secondly, stimulated by TGF-β1, COX activity was declined, and mitochondrial dysfunction of mitochondrial species analysis were significantly upregulated. More importantly, mitochondrial copper content and coll, fibronectin expression were reduced and mitochondrial function was improved after transfecting with COX17 shRNA. Meanwhile, treatment with copper chelator tetrathiomolybdate also alleviated renal fibrosis both in vivo and in vitro.

Conclusions: COX17 was significantly increased in renal fibrosis and transported excessive intracellular copper ions into the mitochondria. Copper overload inhibits the activity of COX and impairs mitochondria, subsequently leading to renal fibrosis.

SU-OR15
Protective Effect of Prostacyclin in Renal Fibrosis
Jing Li, Chuan-Ming Hao. Division of Nephrology, Huashan Hospital Fudan University, Shanghai, China.

Background: Inadequate repairing process to injury has been reported to play a critical role in renal fibrosis. Mounting evidence suggests that prostaglandins are important in serving as a “buffer” in response to physiological or pathophysiologic insults to tissues including the kidney. Importantly, under certain conditions such as aging and hypertension, prostacyclin (PGI1), an active production of COX/PGI2, Synthase (PGIS), is reduced. The present study provides data showing that low levels of PGI2 are associated with enhanced renal fibrosis.

Methods: Unilateral ureteral obstruction (UUO) was used as a renal fibrosis model. At days 10 after UUO, the mice were sacrificed. Ischemia-reperfusion (IR) model was induced by clamping the left renal pedicle for 30 minutes on D0. After 4 weeks, the right kidneys were removed. The mice were treated with beraprost sodium (300 μg/kg body weight per day by twice daily gavage) or vehicle from D32 to D55, and were sacrificed on D56.

Results: The PGIS heterozygous (PGIS+/−) mice had normal body weight, blood pressure and blood urea nitrogen (BUN) level. Losing one allele of PGIS significantly attenuated the increase of PGIS expression after UUO and aggravated UUO-induced renal fibrosis. IR model was performed on wild-type mice. Treatment with beraprost sodium (BPS), a analog of PGI2, inhibited the expression of fibronectin, collagen I and α-SMA in the kidney and ameliorated extracellular matrix deposition in the kidney tissue study. Furthermore, the level of phosphorylated FAK substrates in the normal obstructed kidney of deficient mice was significantly reduced, suggesting the role of IP receptor. IP agonist treatment reduced the expression of fibroconnectin, collagen I and α-SMA in rat renal fibroblasts (NRK-49F), which were induced by TGF-β.

Conclusions: PGIS/PGI2 plays an important role in protecting the kidney from fibrosis. Lack of PGI2 enhances renal fibrosis, and supplementation with PGI2, analog ameliorates renal fibrosis. PGIS/PGI2, is a potential target for CKD.

Proteomic Risk Assessment of CKD Progression in the Chronic Renal Insufficiency Cohort
Ruth F. Dubin,1 Rajat Deo,2 Zihe Zheng,2 Haochang Shou,2 Yue Ren,2 Hongzhe Li,3 Mark Segal,1 Harold I. Feldman,2 Peter Ganz,2 1University of California San Francisco, San Francisco, CA; 2University of Pennsylvania, Philadelphia, PA.

Background: Quantification of thousands of plasma proteins simultaneously is now feasible in large cohorts using the SomaScan aptamer assay. In this study, we applied large-scale proteomics to patient sera from the regular kidney disease (CKD) to discover new biomarkers and risk models of CKD progression.

Methods: We measured 4638 unique plasma proteins among 3249 participants in the Chronic Renal Insufficiency Cohort(CRIC), with follow-up to 13 years. Mean age was 59 years, estimated glomerular filtration rate (eGFR) 42 ml/min/1.73m2, and 50% were diabetic. The study outcome was 10-year risk of 50% decline in eGFR, end-stage renal disease or renal transplant (n=1171 events). Associations of individual proteins with the composite outcome were analyzed in Cox survival models adjusted for demographics, comorbidities, eGFR and proteinuria. Protein-only risk models were constructed using elastic net regression and compared to the 4-variable Kidney Failure Risk Eq.
Biomarkers that predict the risk of CKD progression. The proteomic risk model has a c-statistic of 0.860 (95% CI: 0.834, 0.885) in the validation set, indicating a strong predictive value. Additionally, we identified 58 protein biomarkers that are unique to progression of diabetic vs. non-diabetic CKD.

Conclusions: Through large-scale proteomics, we discovered numerous novel biomarkers that predict the risk of CKD progression. The proteomic risk model has excellent discrimination, equal to the refit clinical model. Ongoing analyses of the biological functions of the newly discovered biomarkers may identify new therapeutic targets to slow CKD progression.

Molecular Mechanisms Underlying Sex-Specific Association of Circulating Transforming Growth Factor β1 with the Risk of Accelerated Kidney Function Decline

Jon V. Norvik,1,2 Inger Therese T. Enoksen,2 Christopher L. O’Connor,2 Marit D. Solbu,1 Vivi Nørby,1 Matthias Kretzler,2 Wenjun Ju,1 Bjorn O. Eriksen,1 Marit D. Mølën,1,2,3 Universitetstryketskuelen Nord-Norge, Tromsø, Norway; 2UiT Norges arktiske universitet Det helsevitenskapelige fakultet, Tromsø, Norway; 3Universitetet i Bergen, Bergen, Norway.

Background: Study of sex differences in kidney function decline and risk of chronic kidney disease (CKD) is a stated research goal. We recently found serum transforming growth factor β1 (TGF-β1), a key mediator in kidney fibrosis development, to be associated with risk of accelerated age-related loss of glomerular filtration rate (GFR) in women, but not men, in the general population. We therefore investigated the effect of sex on intrarenal TGF-β1 pathway and structural damage in kidney biopsies from a cohort of patients with early kidney impairment.

Methods: Kidney tissue samples from 22 female and 33 male patients undergoing nephrectomy included in the PRECISE study (age 31 to 83 years) were used for transcriptomic analysis of micro-dissected glomeruli (Affymetrix Human Gene 2.1 ST Array). Interaction of the expression of genes in the TGF-β1 signaling pathway with sex was evaluated between expression level and global glomerulosclerosis (GGS), a structural parameter of kidney disease. Genes exhibiting significant interaction with sex were used to generate a sex-dependent TGF-β1 pathway activity score.

Results: Out of the 136 genes downstream of TGF-β1, expression of 20 genes exhibited significant interaction with sex for GGS. BMP6, ID1, MYC, and TNF were among the genes that showed the most significant interaction. An increased activity score for sex-specific TGF-β1 downstream effectors was associated with higher degree of GGS in women (p < 0.001), but with less GGS in men (p = 0.01, p for interaction sex < 0.001, Figure 1).

Conclusions: Higher levels of the sex-specific TGF-β1 pathway activity was associated with higher GGS in women, but with less GGS in men. These results, along with our findings of an association between higher serum TGF-β1 and accelerated GFR decline in women only, point to a sex-specific TGF-β1 driven mechanism of kidney fibrosis that may shed light on sex differences in age-related GFR loss and CKD.

SU-OR18

Defining the Correlation Between Kidney Function and Histopathological Changes

Ghazal Z. Quinn,1 Amin Abedini,1 Matthew Palmer,1 Andrea Havasi,2 Katalin Susztrak,3 University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 1Boston Medical Center, Boston, MA.

Background: Estimated glomerular filtration rate (eGFR) is an imperfect measure of kidney function and does not correlate well with prognosis. Histopathologic analysis of renal biopsy is considered the gold standard to establish disease etiology and prognosis. Kidney biopsy, however, is rarely performed in patients with diabetes due to its associated risks. Here we examined whether we could predict the degree of histological damage and kidney function decline based on clinical and demographic information.

Methods: Descriptive based histopathological analysis was performed in 759 human kidney tissue samples obtained from unaffected portion of tumor nephrectomies. Samples were limited to healthy, hypertensive and diabetic kidney disease. Changes in the glomeruli, arteriolar intima, and the vasculature were scored in an unbiased manner. Regression analyses were performed to assess the association between histopathology based on eGFR quantiles. Decline in renal function over time (eGFR slope in ml/min/1.73m2 per year) was assessed in subjects with at least 3 months of follow up. Validation analysis was performed on 467 clinically indicated kidney biopsies.

Results: Mean subject age was 61, eGFR was 66 ml/min/1.73m2, 70% had hypertension and 37% had diabetes. The association between eGFR and interstitial fibrosis was relatively weak (r2 = 0.3, p < 0.001). There was no association between fibrosis and GFR greater than 45 ml/min/1.73m2. Samples with eGFR below 45 ml/min/1.73m2 showed a reasonably strong association between eGFR and fibrosis (r2 = 0.51, p < 0.001) indicating a non-linear relationship. Hypertension and black race were independently associated with more severe histopathologic changes (p < 0.05). Similar non-linear trends and significant associations were observed in our validation cohort. There was an association between sex and structural histopathologic findings in kidney biopsies with which did not reach significance in the primary cohort but was significant in the validation cohort.

Conclusions: The eGFR is a poor predictor of fibrosis at values > 45 ml/min/1.73m2 but predicts renal structural changes well at lower eGFR. Hypertension and black race were independently associated with renal fibrosis, which may warrant more aggressive therapy in these cohorts. Predictions of kidney function decline are enhanced when eGFR and histopathology are used in combination.

Low Birth Weight for Gestational Age and Risk of Different Groups of Kidney Disease 50 Years During the First 50 Years of Life

Katarzyna Gierga,1 Rannveig Skuanes,2 Hans-Peter Marti,2 Bjorn Egil Viko,2 Haugensund sjukehus, Haugensund, Norway; 1Universitetet i Bergen, Bergen, Norway.

Background: Previous studies have shown that Low Birth Weight (LBW) is associated with increased risk of end-stage renal disease. Few population based studies have investigated risk of Small for Gestational Age (SGA) on kidney disease. Our study investigates SGA and risk of chronic kidney disease (CKD), other kidney diagnoses as well as different stages of kidney failure.

Methods: The Norwegian Patient Registry (NPR) has registered ICD diagnostic codes for all admissions and outpatient visits to Norwegian hospitals since 2008. The Norwegian Medical Birth Registry (MBR) has registered birth weight, gestational age, and several other data on maternal and offspring health for all birth in Norway since 1967. Data from these registries were linked and risk of CKD and other groups of kidney disease were analyzed with logistic regression statistics. Based on birth weight, gestational age and gender, a z-score of birth weight for gestational age has been calculated. SGA defined as birth weight less than the 10th percentile for gestational age and gender with cut-off -1.30 for male and -1.28 for female. LBW (less than the 10th percentile) and preterm birth were independently associated with renal fibrosis, which may warrant more aggressive therapy in these cohorts. Analyses of kidney function decline are enhanced when eGFR and histopathology are used in combination.

Results: Of the 2,663,100 included subjects, 4495 had been diagnosed with CKD and 12,818 with acute kidney disease, glomerulonephritis, hereditary kidney disease or kidney disease due to kidney or urinary tract malformations. SGA was associated with odds ratio (OR) 1.14 (95% CI 1.03-1.23) for acute kidney disease, 1.18 (1.070-1.30) for glomerulonephritis, 1.31 (1.12-1.52) for hereditary kidney disease and 1.13 (1.03-1.23) for kidney disease due to kidney or urinary tract malformations.

Conclusions: SGA is a strong risk maker for diagnosis of all stages of CKD during the first 50 years. The risks seem to increase also for other groups of kidney disease.

Large-Scale Kidney Volumetry from MRI: Initial Results and Relations to Sex, Age, and Body Size in UK Biobank

Joel Kullberg,1 Taro Langner,1 Salvador Daniel Rivas-Carrillo,2 Iris Friedli,2 Tove Hall,1 Robin Strand,1 Håkan Ahlström,1 Lars Johansson,2 Uppsala University, Department of Medical Biochemistry and Microbiology, Uppsala, Sweden; 1Uppsala University, Department of Medical Sciences, Molecular Epidemiology, Uppsala, Sweden; 2Uppsala University, Department of Information Technology, Uppsala, Sweden.

Background: Kidney volume has been associated with age, kidney function, diabetes, and other cardiovascular risk factors. Body size, body surface area (BSA) and lean body mass are important parameters in UK Biobank (UKB) is a large-scale study aiming to examine 100,000 subjects aged 44 to 82 years using MRI. Resulting images allow measurements of kidney volume. Currently 40,264 scans have been released.
Methods: A deep learning-based method for direct kidney parenchymal volume (KPV) segmentations was developed and validated (Accuracy: Dice 0.956, R²=0.95) and applied to UKB MRI. Absolute and relative change with age and associations to body weight, BSA and fat free mass from biomechanical analysis (BIA-FBM) and lean tissue volume from MRI (MRI-LT) were studied using linear regression. Rate changes were compared between and above group means ages. MRI-LT values (n=8,524) were inferred for 30,308 additional subjects by MRI-based deep learning regression with validated R²=0.96(arXiv:2002.06862).

Results: Resulting KPVs from 37,468 subjects (47.6% males) and age changes are shown in Fig. A and Table I. Correlations between total KPV and BSA and MRI-LT over age are shown in Fig. B. The associated overall correlations were (males / females): Body weight: 0.568/0.460, BSA: 0.574/0.496, BIA-FBM: 0.597/0.536, MRI-LT: 0.636/0.600.

Conclusions: Both sexes show continuous volume decline in the studied age interval. Males show an increasing rate of decline with age. MRI-LT showed strongest correlations to KPV.

Variation in Peritoneal Dialysis-Related Peritonitis Outcomes and Treatment Practices: Results from the Peritoneal Dialysis Outcomes and Practice Patterns Study

Muthuna Al sahlawi,1,2 Keith McCullough,1 Ronald L. Pisoni,3 Douglas S. Fuller,1 Junhui Zhao,1 Neil Boudville,1 Yasushiko Ito,1 Talerngsak Kanjanabuch,4 Sharon Nessim,5 Beth M. Piraino,1 Isaac Teitelbaum,6 David W. Johnson,10,11 Graham Woodrow,2 Jeffrey Perl.1 Division of Nephrology, St. Michael’s Hospital and the Keenan Research Center in the Li Ka Shing Knowledge Institute, St. Michael’s Hospital, University of Toronto, Toronto, Ontario, Canada; 2Department of Internal Medicine, College of Medicine, King Faisal University, Al-Hassa, Saudi Arabia, Al-Hassa, Saudi Arabia; 3Arbor Research Collaborative for Health, Ann Arbor, MI; 4Medical School, University of Western Australia, Perth, Australia, Perth, WA, Australia; 5Aichi Medical University, Nagakute, Japan, Nagakute, Japan; 6Center of Excellence in Kidney Metabolic Disorders and Division of Nephrology, Department of Internal Medicine, Chulalongkorn University, Bangkok, Thailand. Bangkok, Thailand; 7Division of Nephrology, Jewish General Hospital, McGill University, Montreal, Canada; 8University of Pittsburgh, Pittsburgh, PA, United States; 9University of Colorado, Aurora, CO, United States, Aurora, CO; 10Department of Nephrology, Princess Alexandra Hospital, Brisbane, Australia, Brisbane, QLD, Australia; 11Australian Kidney Trials Network, University of Queensland, Brisbane, Australia, Brisbane, QLD, Australia; 12Renal Unit, St James’s University Hospital, Leeds, United Kingdom, Leeds, United Kingdom.

Background: Peritoneal dialysis (PD)-associated peritonitis is a leading cause of technique failure and transition to hemodialysis. In the Optimizing Peritonitis Prevention in The United States (OPPUS) study, we explored the impact of various patient, facility and treatment factors on the likelihood of cure following a peritonitis episode.

Methods: Using Peritoneal Dialysis Outcomes and Practice Patterns Study phase 1 (2014-2017) data from Australia and New Zealand, Canada, Japan, Thailand, the UK, and the US, the cure was defined as the absence of a peritonitis relapse or recurrence, PD catheter removal, transition to hemodialysis or death during the 50 days following a peritonitis episode. Multivariable logistic regression was used to test associations between cure and patient, facility, and treatment characteristics.

Results: We identified 1677 peritonitis episodes in 1190 patients across 126 facilities. Overall, 63% of episodes resulted in a cure. Cure was associated with APD (OR v. CAPD=1.35, 95% CI 1.02–1.80), higher serum albumin (OR=1.04 per 0.1 g/dL, 95% CI=1.01–1.06), facility icodextrin use (OR=1.06 per 10% greater icodextrin use, 95% CI = 1.01–1.12), and aminoglycoside use for Gram-negative peritonitis (OR v. cefazidime=3.10, 95% CI=1.02, 9.36). Prior peritonitis (OR v. no prior peritonitis episodes during follow-up=0.84, 95% CI=0.74, 0.97) and concomitant exit-site infection (OR = 0.42, 95% CI=0.28, 0.63) were associated with lower cure odds. Higher odds of peritonitis relapse were seen among patients with greater residual urine volume (OR= 1.14 per 200 ml, 95% CI=1.07, 1.22).

Conclusions: Different characteristics and management practices can impact the likelihood of cure following a peritonitis episode. Our findings can inform future guidelines in addressing the effect of different modifiable patient, facility, and treatment factors on reducing morbidity associated with PD peritonitis.

SU-OR22

Rate of Decline in Residual Kidney Function Before and After Peritoneal Dialysis Initiation: A Post hoc Analysis of the IDEAL Study

Isabelle Ethier,1,2 Young Jee Cho,1,2 Carmel Hawley,1,2 Elaine Pascoe,3 Andrea K. Vicielli,1,2 Scott B. Campbell,1,2 Carolyn L. Van Eps,1,2 Nicole Isbel,1,2 Bruce A. Cooper,4 David Harris,4,5 Carol A. Pollock,4,6 Muh Geot Wong,6,7 David W. Johnson.1,2 Centre Hospitalier de L’Universite de Montreal, Montreal, QC, Canada; 3Princess Alexandra Hospital, Woolloongabba, QLD, Australia; 4The University of Queensland Faculty of Medicine, Herston, QLD, Australia; 5Westmead Institute for Medical Research, Westmead, NSW, Australia; 6The University of Sydney School of Medicine, Sydney, NSW, Australia; 7Royal North Shore Hospital, St Leonards, NSW, Australia; 8George Institute for Global Health, Camperdown, NSW, Australia.

Background: Residual kidney function (RKF) is associated with improved survival and quality of life in dialysis patients. Previous studies have suggested that commencement of peritoneal dialysis (PD) may slow RKF decline compared to the pre-dialysis period. We sought to evaluate the association between PD initiation and RKF decline in the Initiating Dialysis Early And Late (IDEAL) trial.

Methods: In this post hoc analysis of the IDEAL randomized controlled trial, PD participants were included if results from 24-hour urine collections had been recorded within 30 days of dialysis initiation (-30 to +30 days from start), and at least one value pre- and one value post-dialysis commencement were available. The primary outcome was slope of RKF decline, calculated as mean of urinary creatinine and urea clearances. Secondary outcomes included slope of urine volume decline and time from PD initiation to anuria.

Results: The study included 151 participants (79 early-start group, 72 late-start group). The slope of RKF decline was slower after PD commencement (-2.69±1.8 L/min/1.73m²/yr) compared to before PD commencement (-4.09±0.33 L/min/1.73m²/yr); change in slope = -1.19 L/min/1.73m²/yr, 95% CI 0.48±1.90, p<0.001. In contrast, urine volume decline was faster after PD commencement (-0.74±0.05 L/yr) compared to beforehand (-0.57±0.06 L/yr; change in slope = -0.18 L/yr, 95%CI=-1.34—0.01, p=0.04).

No differences were observed between the early- and late-start groups with respect to RKF decline, urine volume decline or time to anuria.

Conclusions: Commencement of PD was associated with a slower decline of RKF compared to the pre-dialysis period.

Steady Concentration Peritoneal Dialysis Increases Ultrafiltration and Sodium Removal Compared with Continuous Ambulatory Peritoneal Dialysis (CAPD)

Olof Heimburger,1 Giedre Martus,2 Martin E. Wilkie,2 Jorgen B. Hegbrand,3 Ola Carlsson,1 Charlotte De Leon,1 Ann Cathrine Johansson,1 Triomed AB, Lund, Sweden; 3Sheffield Teaching Hospital, NHS Foundation Trust, Sheffield, United Kingdom; 1Department of Nephrology, Skåne University Hospital, Malmö, Sweden; 2Department of Nephrology, Lund University, Lund, Sweden; 3CLINTECH, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden.

Background: Fluid and sodium removal (NaR) may be a challenge during glucose-based PD, leading to increased use of high glucose solutions to maintain sufficient fluid removal. This may lead to increased sodium sieving, resulting in reduced NaR. Carry Life® UF uses steady concentration PD (SCPD), where the intraperitoneal (IP) glucose concentration is maintained by infusion of glucose to provide a continuous ultrafiltration (UF) throughout the dwell. The present study investigated the effect of Carry Life® UF vs. CAPD regarding UF, NaR and glucose absorption.

Methods: Eight stable PD patients were included in the study. Subjects were treated with 5-hour Carry Life® UF treatments using three different glucose solutions (11, 14, 20 g/h). An initial fill with 1.5 l, 1.36% glucose PD solution was used. A small volume of dialysate was drained hourly to avoid overfill. A 4-hour peritoneal equilibration test (PET) (2.01, 2.27% glucose) served as control. Data expressed as mean(SD), statistical analysis using ANOVA.

Results: UF volumes were significantly increased during Carry Life® UF treatments (646±256, 739±312, 863±380 ml for 11, 14, 20 g/h) vs. PET (162±242 ml, p<0.001). NaR increased significantly during Carry Life® UF treatments (86±27, 92±33, 110±37 mmol/dwell for 11, 14, 20 g glucose/h) compared to PET (22±33 mmol/dwell, p<0.001).

Conclusions: SCPD performed with Carry Life® UF maintained a stable IP glucose concentration during the treatment (figure a) which generated significantly higher UF volumes compared to PET. During the Carry Life UF treatments glucose usage was made more efficiently, particularly for the two lowest doses, in comparison to PET (figure b). In summary, SCPD using Carry Life® UF increases the efficiency of PD compared to standard, glucose-based CAPD with respect to UF and NaR.

Efficacy and Safety of Roxadustat in Patients with Dialysis-Dependent CKD and Anemia on Peritoneal Dialysis

Tak Mao D, Chau,1 Lynda Szechez,2 Jayant Kumar,2 Anjay Rastogi,3 Carol A. Pollock,1 Gopal Saha,4 Tyson T. Lee,4 Maksym Pola,3 Kin-Hung P. Yu,5 1University of Hong Kong, Queen Mary Hospital, Hong Kong SAR, China; 2Renal Medicine Associates, Albuquerque, NM; 3University of California Los Angeles, Los Angeles, CA; 4The University of Sydney, Sydney, NSW, Australia; 5Fibrogen Inc, San Francisco, CA; AstraZeneca plc, Astellas Pharma Inc.

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Dialysis modality in patients with ESRD is associated with different incidence rates of anemia and clinical outcomes. Therefore, evaluating the safety and efficacy of roxadustat in patients with dialysis-dependent (DD) CKD on peritoneal dialysis (PD) is of clinical importance.

Methods: Pooled data from three pivotal, phase 3, randomized, open-label, epoetin alfalpha-controlled studies of roxadustat for the treatment of anemia in patients with DD-CKD were assessed in the subgroup of patients on PD. Endpoints evaluated were: mean change from baseline (CFB) in hemoglobin (Hb) averaged over Weeks 28–52 regardless of rescue therapy, Hb CFB averaged over Weeks 28–36 censored for rescue therapy, and risk for blood/RBC transfusion during the treatment period. Safety and tolerability were assessed by reported treatment-emergent adverse events (TEAEs).

Results: In the DD-CKD study population, 10% (372/3887) of patients were on PD (roxadustat 1800, epoetin alfa–122). Baseline characteristics were generally similar between treatment groups. Mean (SD) Hb levels (g/dL) at baseline were 9.5±1.2 (223) in the roxadustat alfa group. Patients achieved a larger mean (SD) CFB to Weeks 28–52 in Hb (g/dL) with roxadustat vs. epoetin alfa (1.41 ± 1.45 vs. 1.08 ± 1.53), corresponding to a least-squares mean (LSM) treatment difference of 0.37 (95% CI: 0.11, 0.63) (p=0.0048). Patients achieved a larger mean (SD) CFB to Weeks 28–52 in Hb (g/dL) with roxadustat vs. epoetin alfa (1.53 ± 1.54 vs. 1.01 ± 1.63), corresponding to a LSM treatment difference of 0.46 (95% CI: 0.17, 0.74) (p=0.0018). Risk for blood/RBC transfusion was significantly reduced with roxadustat vs. epoetin alfa (HR, 0.50 [95% CI: 0.26, 0.98]; p=0.0422). TEAE rates were comparable between treatment groups.

Conclusions: Roxadustat was efficacious vs. epoetin alfa for increasing/maintaining Hb levels and reducing the risk for blood/RBC transfusion in patients with DD-CKD on PD. Safety and tolerability profiles were similar to the overall population and consistent with that observed in this patient subgroup.

Cardiovascular Thromboembolic Outcomes by Dialysis Modality Following Primary Total Knee Arthroplasty
Chavelly Valdes Sanchez,1 Matthew R. Lozier,1 Mauricio Tellez,1 Alexandra M. Sanchez,1 Gabriel A. Valle.2 University of Miami at Holy Cross Hospital, Fort Lauderdale, FL; 1The Kidney and Hypertension Group of South Florida, Fort Lauderdale, FL.

Background: There is a paucity in the literature evaluating the impact of dialysis modalities on cardiovascular thromboembolic outcomes following primary total knee arthroplasty (TKA). Therefore, the purpose of this study was to investigate whether patients treated with hemodialysis (HD) or peritoneal dialysis (PD) have higher rates of: 1) medical complications, 2) readmission, and 3) cost of care.

Methods: Patients undergoing primary TKA while receiving HD served as the study group (n = 82,518) and matched 1:1 to a control group of PD patients (n = 82,518) by distribution, age, sex, and Elixhauser-Comorbidity Index (ECI). Outcomes analyzed included rates of 90-day medical complications, readmission rates, and cost of care. Logistic regression analysis was used to calculate odds-ratios (OR) for medical complications and readmission rates. Welch’s t-test was used to test for significance on cost of care and ECI between cohorts. P-value less than 0.05 was considered statistically significant.

Results: Patients undergoing HD prior to primary TKA were found to have a significantly lower incidence and odds of cerebrovascular accidents (PD vs. HD: OR = 0.13 vs. 0.10%, OR: 1.44, p<0.001), specifically deep vein thromboses (0.13 vs 0.10%; OR: 1.75, p<0.001). HD patients did however incur significantly higher 90-day cost of care ($209,611.67; p<0.001). No statistically significant differences were noted in myocardial infarction, pulmonary embolism, or 90-day readmission rates between the two groups.

Conclusions: While incurring a lower 90-day cost of care, patients treated with PD prior to primary TKA may have a greater odds of developing a cerebrovascular accident or deep vein thrombosis when compared to HD.

Prognostic Roles of Peritoneal Dialysis Effluent Mitochondrial DNA Level
Win H. Than,1,2 Cheuk-Chun Szeto,1,2 Carol & Richard Yu Peritoneal Dialysis Research Centre, Department of Medicine & Therapeutics, Prince of Wales Hospital, Shatin, New Territories, Hong Kong; 1Li Ka Shing Institute of Health Sciences (LiHS), Faculty of Medicine, The Chinese University of Hong Kong, Shatin, New Territories, Hong Kong.

Background: Circulating mitochondrial DNA (mtDNA) level is associated with the systemic inflammatory state and prognosis of peritoneal dialysis (PD) patients. We explore the relation between mtDNA level in PD effluent and peritoneal transport characteristics and outcomes of PD patients.

Methods: We measured PD effluent mtDNA levels by quantitative polymerase chain reaction and the result is expressed as copy per 1000 copies of the housekeeping gene. Both PD effluent sediment and cell-free supernatant mtDNA levels were measured. Peritoneal transport was determined by the peritoneal equilibration test and represented as mass transfer area coefficient (MTAC) of creatinine. All patients were followed for technique and overall survival.

Results: 168 PD patients were followed for 41.3 (IQR: 19.3-52.0) months. Their mean age was 60.4±13.9 years; 99 (58.9%) were men. Median PD effluent (PDE) sediment mtDNA was 255.4 ng/ml (IQR: 157.5-451.3); median PDE sediment mtDNA was 206.16 ng/ml (147.8-267.3). PDE supernatant mtDNA level had a modest but significant correlation with MTAC creatinine (r = -0.364, p<0.001) and the number of previous peritonitis episodes (r = -0.235, p=0.002). After adjusting for age, gender, Charlson’s Comorbidity Score, total weekly Kt/V, and residual renal function, PDE sediment mtDNA was a significant predictor of technique survival (adjusted hazards ratio [AHR] 1.002, 95%CI 1.000-1.003, p=0.001). In contrast, PDE sediment mtDNA level did not correlate with technique or patient survival.

Conclusions: PDE supernatant mtDNA level had a significant correlation with peritoneal transport. PDE sediment mtDNA level was a significant predictor of technique survival for PD patients. The mechanism of the differential implications between PDE sediment and supernatant mtDNA levels deserves further investigations.

SU-OR28
Hemodynamics and Geometry of Rat Arteriovenous Fistulas: Effect of Sildenafil Treatment
Hannah M. Northrup,1 Yan-Ting E. Shiu,1,2 Isabelle D. Falzon,1 Maheshika S. Somaratna,1 Timmy C. Lee.1,2 University of Utah, Salt Lake City, UT; 1& Salt Lake City Health Care System, Salt Lake City, UT; 1University of Alabama at Birmingham, Birmingham, AL; 2Veterans Affairs Medical Center, Birmingham, AL.

Background: Arteriovenous fistula (AVF) maturation is dependent on hemodynamics and remodeling of the vessel wall to increase the AVF flow rate and lumen area for dialysis. Sildenafil is a phosphodiesterase 5 inhibitor that promotes vasodilation and is used clinically to treat erectile dysfunction and pulmonary hypertension. Here we investigate the effect of sildenafil on lumen geometry and hemodynamics in rat AVFs.

Methods: Femoral AVFs were created in 12-16 week-old male Sprague-Dawley rats. Sildenafil was administered at 90 mg/kg in drinking water starting 14 days prior to AVF creation surgery (n=4). 21 days post creation, animals were subject to non-contrast MRI scans, and the MR images were used for reconstruction of the AVF lumen and computational fluid dynamic simulations of the AVF blood flow. Hemodynamic parameters (flow rate, wall shear stress (WSS), vorticity, and oscillatory shear index (OSI)) and geometrical analysis (cross sectional lumen area, anastomosis angle (AA), tortuosity, and nonplanarity angle (NA)) were calculated.

Results: Sildenafil significantly increased the lumen area and flow rate of both the venous and arterial limbs of the AVFs when compared to no-treatment controls (p<0.0001) (Fig. 1). WSS, vorticity and OSI of treated rats were also significantly higher than controls (p<0.0001) (Fig. 1). AA, tortuosity, and NA were not significantly different between the two groups. AA was approximately 40° in both groups.

Conclusions: The AA of our AVF rat model is similar to the AA in human radiopaque AVFs in the literature. Sildenafil leads to significantly higher flow rate and larger lumen in both vein and artery than controls. Vorticity, WSS, and OSI are significantly higher in treated rats compared to control, which may be due to the increased flow rate. Sildenafil may have therapeutic potential to enhance AVF maturation by affecting the hemodynamics.

SU-OR29
Single-Center Real-World Experience with Endovascular Arteriovenous Fistulas
Kareem Genena,1 Harold M. Szerlip,1 Neghane Mawla.2 Baylor University Medical Center at Dallas, Dallas, TX; 1Dallas Nephrology Associates Vascular Center - Plano, Plano, TX.

Background: Endovascular arteriovenous fistulas (EndoAVFs) are created percutaneously via an anastomosis between the radial artery and the perforator vein (Ellipsys), or between the ulnar artery and vein or radial artery and vein (Wavelinq). Flow is directed via the perforator vein to the superficial veins.

Methods: We report partial outcomes for 69 technically successful endoAVF creations for patients on hemodialysis between 5/2019 and 4/2020 using 2 catheter-based devices.

Results: 12/69 endoAVFs failed (17%), all before reaching physiologic usability (ok to use) except for 1 which failed due to failure to cannulate at the dialysis center. The most common reason for failure was thrombosis of the perforator vein. In 49 endoAVFs that reached physiologic usability at time of data review, mean duration from creation to physiologic usability was 92 days and mean number of procedures between endoAVF creation and physiologic usability was 1. At time of data review, 9 endoAVFs were pending physiologic usability. 14/49 (29%) of endoAVFs that reached physiologic usability did so with 0 secondary procedures. Mean postoperative brachial artery flow in this subset was 718 ml/min (range 400-1100 ml/min). Mean flow at 4-6 weeks was 843 ml/min. 35/49 (71%) needed at least 1 procedure. Mean postoperative flow in this subset was 545 ml/min. Mean flow at 4-6 weeks was 721 ml/min. In 44 endoAVFs that had been cannulated at time of data review, mean duration from physiologic usability to cannulation was 9 days. In 33 patients whose dialysis catheters had been removed at time of data review, mean duration from first cannulation to dialysis catheter removal was 57 days.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
**Conclusions:** Successfully created endoAVFs have shorter maturation time than surgical AVFs and require less maturation procedures. Immediate postoperative brachial artery flow is an important predictor of endoAVF behavior/outcome. All endoAVFs that reached physiologic usability with 0 secondary procedures had a postoperative flow above 400 ml/min, and mean postoperative flow was higher than those that needed at least 1 procedure. Experience from first cannulation to dialysis catheter removal represents a pragmatic measure for endoAVFs. Cannulation injuries sometimes obligate a period of endoAVF rest. Removal of the dialysis catheter not only indicates functional usability of the endoAVF but also proficiency of the dialysis units in cannulating them.

**SU-OR30**

**Association Between Antimicrobial Barrier Cap Use and Outcomes Among Hemodialysis Patients Using a Central Venous Catheter**

Scott Sibbel,1 Abigail Hunt,1 David B. Van Wyck,2 Lyssa Jordan,1 Francesca Tentori,1 Allen R. Nissenson,2 Steven M. Brunelli.3 1Davita Clinical Research, Minneapolis, MN; 2DaVita Inc, Denver, CO.

**Background:** Bloodstream infections (BSIs) are a common complication of central venous catheter (CVC) use and contribute to hospitalization, mortality, and high costs of care in patients on hemodialysis (HD). In a prior randomized clinical trial, patients using CVCs with antimicrobial barrier caps (AmBC; ClearGuard® HD, Pursuit Vascular Inc, Maple Grove, MN, USA) had significantly lower catheter-related BSI rates compared to patients using CVCs with the historical standard of care. Based on these findings, AmBCs were introduced in May 2019 as standard of care for CVC patients across a large dialysis organization (LDO). This study assessed changes in clinical outcomes in a real-world HD population following implementation of AmBC use.

**Methods:** Study data were derived from LDO electronic medical records over two 3-month periods: Pre (Jul-Oct 2018) and Post (Jul-Oct 2019) AmBC adoption. Included patients were adults receiving in-center HD treatment 3x/week using a CVC. Crude outcome rates were calculated for individual calendar months and for the pre- and post-periods overall; formal comparisons were made using generalized linear models.

**Results:** A total of 37,642 patients in the pre-period and 40,498 patients in the post-period met eligibility criteria. Overall BSI rate fell from 0.54/100 CVC days in the pre-period to 0.36/100 CVC days after AmBC implementation. Hospitalization rates were lower during the post-period versus the pre-period overall and within each calendar month; the contribution of underlying temporal changes (eg, background year-over-year change) could not be quantified.

**Conclusions:** Adoption of AmBCs for use in HD patients using a CVC for vascular access was associated with an early 34% reduction in infections assessed on the basis of change) could not be quantified.

**SU-OR32**

**Complement C5a Receptor Inhibitor Avacopan Improves Renal Function in ANCA Vasculitis**

David R. Jayne1, Peter A. Merkel2, Huibin Yue3, Catherine L. Kelleher,2 Thomas J. Schall,4 Pirow Bekker.1 1Addenbrooke’s Hospital, Cambridge, United Kingdom; 2ChemoCentryx Inc, Mountain View, CA; 3University of Pennsylvania, Philadelphia, PA.

**Background:** Renal impairment is common in anti-neutrophil cytoplasmic autoantibody-associated vasculitis. The resulting chronic kidney disease and exacerbation of the toxicity risks of high dose or prolonged glucocorticoid use, a mainstay of ANCA treatment, are major consequences. Avacopan was tested for efficacy and effects on renal function compared to standard prednisone therapy in a randomized double-blind Phase 3 trial in ANCA vasculitis.

**Methods:** Subjects randomized 1:1 received either prednisone (60 mg tapered to 0 over 20 weeks) or avacopan (30 mg twice daily for 52 weeks), combined with either cyclophosphamide (CYP) or rituximab (RTX). Primary endpoints: Disease remission at week 26 and sustained remission at week 52. Changes in urinary albumin to creatinine ratio (UACR) and estimated glomerular filtration rate (eGFR) were also assessed.

**Results:** 330 subjects were treated: 166 to avacopan and 164 to prednisone treatment arms. Avacopan remission at week 26 was 72.3% vs. 70.1%, for prednisone (P=0.0001 for non-inferiority); avacopan was superior to prednisone for sustained remission (week 52, 57.7%, avacopan vs. 54.9%, prednisone, P=0.0066). 81% percent of subjects had renal disease. UACR decreased more rapidly with avacopan than prednisone: week 4 avacopan was 40% below baseline vs. no change for prednisone (week 4=0.0001). Baseline to week 52 eGFR (mL/min/1.73 m²) improvement: avacopan eGFR +7.3 vs. prednisone +4.1 (P=0.029). In subjects with baseline eGFR <30, mean eGFR improved 67% more with avacopan compared to week 52: avacopan eGFR +13.7 vs. prednisone +8.2 (P=0.01).

**Conclusions:** Treatment with avacopan for ANCA vasculitis compared with standard glucocorticoid therapy (both combined with either CYP or RTX) is as effective for remission induction at 26 weeks, and superior to prednisone for sustained remission after 52 weeks. Avacopan led to faster falls in UACR and greater recovery in eGFR when compared to standard prednisone therapy. These findings have important implications for the long term health of AA V patients through better overall disease control, reduced prednisone exposure and reduced severity of chronic kidney disease.

**Prognostic Value of Persistent Proteinuria and Hematuria After Induction Therapy in ANCA-Associated Vasculitis**

Nicolas Induction Therapy in ANCA Vasculitides

Richard Karras.1,2 Thomas A. Kelleher,2 Pierre A. Merkel.3 1Division of Rheumatology, University of Washington, Seattle, WA; 2Addenbrooke’s Hospital, Cambridge, United Kingdom; 3University of Cambridge, Cambridge, United Kingdom.

**Background:** Persistent proteinuria and hematuria (P&P) can occur in ANCA vasculitis patients treated with induction therapy. The long-term significance of P&P is uncertain.

**Methods:** This multicenter, retrospective observational study included 97 patients with ANCA vasculitis who achieved remission induction at 26 weeks, and were followed up to week 104. Patients were followed if they had proteinuria at week 26 (P+26) or week 52 (P+52). Proteinuria and hematuria were recorded at each follow-up visit.

**Results:** At week 26, 34 patients showed P+26, of whom 15 had P+26 and 19 had P+26 + hematuria. At week 52, 53 patients showed P+52, of whom 21 had P+52 and 32 had P+52 + hematuria. At week 104, 13 patients showed P+104, of whom 6 had P+104 and 7 had P+104 + hematuria.

**Conclusions:** P&P at week 26, 52, and 104 were associated with worse renal outcomes, including doubling of serum creatinine, decrease of eGFR, and death. In addition, patients with P&P at week 26 were less likely to achieve sustained remission.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Methods: This is a post hoc study including participants of 5 European randomized clinical trials: AAV (MAINRITSAN, MAINRITSAN2, RUTUXAS, MYCCY-IMPROVE). We examined the association of PCR (urine protein-creatinine ratio) and hematuria on spot urine samples collected at the end of induction therapy with the occurrence of (i) a combined endpoint of death and/or end stage renal disease (ESRD), and (ii) renal relapse during follow-up.

Results: Among 571 patients (59% men, median age 60 years), 60% had PRR-ANCA, 35% had MPO-ANCA, 77% had renal involvement. After induction therapy, 157/526 (29.8%) had persistent hematuria, 165/481 (34.3%) had PCR ≥ 0.5 g/mmol, 136/444 (30.6%) relapsed, and at median follow-up of 12 months (IQR: 18-42), an adjustment for age, gender, antigenic serotype, initial eGFR, persistent hematuria, a PCR ≥ 0.5 g/mmol after induction was associated with risk of death and/or ESRD (adjusted Hazard Ratio (HR) = 4.08, 95% confidence interval (CI) 1.48-11.25, p = 0.006). Persistent hematuria was associated with risk of renal relapse (adjusted subdistribution HR = 2.18, CI 95% 1.14-4.18, p = 0.019) but not with any relapse (adjusted aHR = 1.10, CI 0.78-1.56, p = 0.59) nor with death and/or ESRD (adjusted HR = 1.88, CI 95% 0.83-4.29, p = 0.132).

Conclusions: In this large cohort of AAV patients, persistent proteinuria after induction therapy was an independent predictor of death and/or ESRD, whereas persistent hematuria after induction therapy was an independent predictor of renal relapse. These parameters must be taken into account to assess long-term renal prognosis of AAV patients.

Belimumab (BEL) Improves Renal Outcomes in Active Lupus Nephritis (LN): A Phase 3 Randomized, Placebo (PBO)-Controlled Trial

Brad H. Rovin,1 Frederic Houssiau,2 Richard Furie,3 Ana Malvar,6 Yoe Kie Onno Teng,7 Chi chiu Mok,9 Gabriel Contreras,4 Xueqing Yu,9 Sebastian Dolff,1 Beulah Ji,3 David A. Roth,3 Christi Kleoudis,10 Susan Makowik,9 Anuradha Madan,6 Jennifer Gilbride,9 Yulia Green,9 Division of Nephrology, The Ohio State University, Columbus, OH, 1Pôle de Pathologies Rhumatismales Inflammatoires et Systémiques, Institut de Recherche Expérimentale et Clinique, Université Catholique de Louvain and Service de Rhumatologie, Cliniques Universitaires Saint-Luc, Brussels, Belgium; 2Division of Nephrology, Northwell Health, Great Neck, NY, 3Organización Medica de Investigacion, Buenos Aires, Argentina; 4Expert Center for Lupus-, Vasculitis- and Complement-mediated Systemic Diseases, Department of Internal Medicine – section Nephrology, Leiden University Medical Center, Leiden, Netherlands; 5Division of Nephrology, Division of Hypertension, Department of Medicine, University of Miami Miller School of Medicine, Miami, FL; 6Department of Nephrology, Guangdong Provincial People’s Hospital, Guangzhou, China; 7GlaxoSmithKline, Uxbridge, United Kingdom; 8GlaxoSmithKline, Collegeville, PA; 9Parexel, Durham, NC; 10GlaxoSmithKline, Stevenage, United Kingdom; 11Tuen Mun Hospital Department of Medicine and Geriatrics, Hong Kong, Hong Kong; 12Department of Infectious Diseases, University Hospital Essen, University of Duisburg-Essen, Essen, Germany.

Background: BEL is approved for patients (pts) with systemic lupus erythematosus (SLE) in Europe and the United States (US) for active LN. However, data on its efficacy in active LN are limited.

Methods: This 104-week trial (GSK Study BEL114054; NCT01639339) randomized adults with active LN (class III, IV, and/or V) 1:1 to monthly BEL 10 mg/kg IV or PBO, plus standard therapy (ST) with high-dose corticosteroids + either cyclophosphamide (CyC) or mycophenolate mofetil (MMF) for induction at the investigator’s discretion. CyC was followed by azathioprine (AZA), and MMF by MMF maintenance. The primary endpoint was Efficacy Renal Response (PERR = urine protein/creatinine ratio ≤0.5; eGFR no more than 10% below pre-flare value ≤0.5 g/mmol/1.73m²; no rescue therapy) at Week 104; time to renal event (end-stage kidney disease, doubling of serum creatinine, increased proteinuria and/or impaired renal function, renal disease-related treatment failure) or death. Endpoints were analyzed during follow-up.

Results: 224 pts were randomized to each arm. At Week 104, there were significantly more PERR and CRR responders on BEL vs PBO: (45.0% vs 32.3%, OR [95% CI] 1.6 [1.1-2.3], p = 0.012; 30.6% vs 19.7%, OR [95% CI] 1.7 [1.1-2.7], p = 0.012), respectively. Risk of renal relapse or renal death was lower in BEL pts relative to PBO (HR [95% CI] 0.5 [0.3, 0.8]; p = 0.01). Week 104 PERR response rates in pts on CyC/AZA were significantly higher (27.1% vs 16.3%, OR [95% CI] 1.9 [1.3-2.9], p = 0.002) than for pts on MMF (16.7% vs 10.5%, OR [95% CI] 1.6 [1.1-2.3], p = 0.003). Significant improvements in renal endpoints were also observed with BEL compared with PBO (eGFR ≥0.05 g/mmol after induction was significantly improved in patients treated with BEL (p < 0.001). These results suggest that BEL may improve renal outcomes in patients with active LN.

Conclusions: BEL significantly improved renal responses with no unexpected safety signals. Funding: Commercial Support - EMD Serono Research & Development Institute, Inc. (a business of Merck KGaA, Darmstadt, Germany), Billerica, MA; 6Center University Medical Center, New York, NY.

24-Week Interim Analysis of a Randomized, Double-Blind, Placebo-Controlled Phase 2 Study of Atacicept in Patients with IgA Nephropathy and Persistent Proteinuria

Jonathan Barratt,1 James A. Tumlin,1 Yusuke Suzuki,2 Amy Kao,3 Aida Aydemir,1 Yulia Zima,3 Gerald B. Appel,3 Emory University School of Medicine, Atlanta, GA; 4Juntendo University, Tokyo, Japan; 5University of Leicester, Leicester; 6United Kingdom; 7EMD Serono Research Institute, Inc. (a business of Merck KGaA, Darmstadt, Germany).

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis and currently has no approved therapy. Its central pathogenic feature is circulating immune complexes of poorly O-galactosylated polymeric IgA1 (Gd-IgA1) that often deposit in the kidneys (causing inflammation and scarring) and trigger formation of IgA/G autoantibodies. Atacicept, a human TACI-Ig fusion protein, inhibits B cell-stimulating factors BLyS and APRIL and is associated with reduced serum IgA/G, mature B cells and plasma cells. This Phase II study (NCT02808429) examines atacicept safety and efficacy in reducing Gd-IgA1 and renal activity in IgAN.

Methods: Patients with active IgAN (eGFR ≥ 30 ml/min/1.73m²) and ≥ 0.75 mg/mg on 24-hr urine protein-creatinine ratio (UPCR) despite maximal standard of care (ACE inhibitor and/ or ARB) were enrolled. Patients were randomized to subcutaneous placebo, atacicept 25mg or 75mg weekly. Primary endpoint: change in proteinuria at Week 48; secondary endpoints: changes in eGFR, serum IgA, IgG, and IgM; and Gd-IgA1.

Results: This interim analysis showed that, at Week 24, IgAN patients (placebo=5; atacicept 25mg=6; 75mg=5) had a consistent, dose-dependent reduction in IgA, IgG and IgM, and in Gd-IgA1 (Fig 1A), and a higher median % reduction from baseline in UPCR (placebo vs with placebo (Fig 1B); eGFR remained stable. TEAEs were reported by 81% of patients (mild/moderate, none severe), with no serious related events, severe hypogammaglobulinemia, or fatal outcomes.

Conclusions: These results provide proof of concept for the potential treatment of patients with IgAN and persistent proteinuria with atacicept. Funding: Commercial Support - GSK.

Grading System Utilizing Total Score of Oxford Classification for Predicting Renal Prognosis in IgA Nephropathy

Yoi Miyabe, Kenichi Akiyama, Kazunori Karasawa, Kosaku Nitta, Takahito Moriyma. Department of Nephrology, Tokyo Women’s Medical University, 8-1 Kawada-Cho, Shinjuku-ku, Tokyo, Japan.

Background: The Oxford classification of IgA nephropathy (IgAN) can evaluate each MEST-C score individually. However, no research has evaluated the prognosis of IgAN patients using the MEST-C score comprehensively. Therefore, we aimed to analyze the usefulness of a new grading system that utilized the total score of each MEST-C score in predicting renal prognosis.

Methods: A total of 871 IgAN patients were classified into three groups using the new grading classification system (O-grade) that utilized the total score of each MEST-C score (O-grade I = 0-1, II = 2-4, and III = 5-7 points) according to the renal survival rate (<10%, 10%-30%, >30%, respectively). The 20-year renal prognosis was analyzed, and the O-grade combined with the Japanese clinical classification (C-grade) was also evaluated.

Results: The clinical findings became significantly severer with increasing O-grades, and the renal survival rate by the Kaplan-Meier method was 78.5%, 74.9%, and 42.2% for O-grades I, II, and III, respectively (P<0.001). The hazard ratios (HRs) for O-grades I, II, and III vs. O-grade I were 1.7 (1.2-2.4) and 2.5 (1.9-3.4), respectively. The 20-year renal prognosis was analyzed, and the O-grade combined with the Japanese clinical classification (C-grade) was also evaluated.

Conclusions: The addition of BEL to commonly used ST for the treatment of LN significantly improved renal responses with no unexpected safety signals. Funding: Commercial Support - GSK.
mean blood pressure and renal function, proteinuria, and O-grade (HR, 1.39; 95% CI, 1.05-1.83) were independent factors predicting the renal prognosis. The O-grade in the nine groups classified by the O-grade combined with the C-grade showed HR of 33.7 (P<0.001) in the severest group with reference to the mildest group.

Conclusions: The O-grade classified by the total score of the Oxford classification was associated with renal CR, and renal prognosis could be accurate in predicting the total activity and chronicity of IgAN and prediction of the renal prognosis of this disease.

SU-OR37
Development of a Deep Learning Model to Predict ESKD in Patients with Immunoglobulin A Nephropathy (IgAN) at Kidney Biopsy Time

Background: Many prediction models to support clinical decision making have been developed for decades but they are based on traditional statistic linear methods. Another approach is the application of artificial intelligence (AI) that is based on machine learning or deep learning algorithms. We developed an artificial neural network (ANN) tool to predict progression in IgAN patients at kidney biopsy time.

Methods: The classifier model to predict ESKD was composed of 4 hidden layers with 100 neurons in each layer. The regression model to predict the time-to-event endpoint consisted of 3 layers containing 125 neurons each.

Results: Our tool, based on these two models, was developed in a cohort of 948 IgAN patients of the VALIGA and Greek cohort. Then, the tool was validated in an independent cohort of 167 IgAN patients from 6 nephrology units. After Cox’s regression analysis 7 variables (age, sex, blood pressure values, serum creatinine, daily proteinuria, MESTC classification for the kidney biopsy and therapy at baseline) were chosen to develop the ANN model. The AUC of the ANN model in the study cohort was 0.80. The performance was 0.82 (precision 0.83, accuracy 0.80) for ESKD prediction at 5 years of follow-up and 0.89 (precision 0.81; accuracy 0.83) for patients with 10 years of follow-up. Stable renal function and ESKD were correctly predicted in 91% of IgAN patients in the test cohort.

Conclusions: (i) Our ANN is a promising alternative to the mathematical models in solving non-linear and multidimensional problems. (ii) We have developed a new clinical decision support system that provides additional information to identify IgAN patients at high risk of ESKD (iii) This tool may stratify patients in the context of a personalized therapy.

Complete Remission of Proteinuria in Patients with Focal Segmental Glomerulosclerosis Treated with Sparsradan, a Dual Endothelin and Angiotensin Receptor Antagonist, in the DUET Trial

Background: In FSGS, partial remission (FSGS partial remission endpoint [FPRE]: 40% reduction of the proteinuria/creatinine ratio at 12w [PC1] <1.5 g/m²) and complete remission (CR) of proteinuria are strong predictors of kidney survival. In the DUET trial, sparsradan (SPAR) resulted in greater reductions in proteinuria and higher rate of FPRE vs irbesartan (IRB) over the 8-week double-blind (DB) period. This antiproteinuric effect of SPAR was sustained during the open-label extension (OLE) period of DUET. Here we analyze patients who achieved CR (UP/C <0.3 g/l) of proteinuria in DUET. Here we analyze patients who achieved CR (UP/C <0.3 g/l) of proteinuria in DUET.

Methods: DUET randomized patients age 8-75 years with biopsy-proven FSGS, UP/C <1 g/l, and eGFR>30 mL/min to SPAR or IRB for 8 weeks, followed by OLE with all patients receiving SPAR; the UP/C and other proteinuria measures were every 12 weeks during OLE. This post-hoc analysis included all patients on SPAR treatment regardless of original randomization.

Results: Median follow-up on SPAR was 42.5 months. Of 108 subjects dosed with SPAR, 86 (79.6%) reached CR and other patients reached partial CR (68% of CR patients). CR was achieved by 28 patients within the 1st year on SPAR (Kaplan-Meier estimate: 29%). A history of, or nephrotic syndrome at baseline, was documented in 8 (18%) of CR patients. Of subjects with CR, 14%, 41%, and 45% were originally assigned to 200, 400, and 800 mg/day of SPAR dose cohorts, respectively. No patient achieved CR while on IRB during the DB period. Compared to the overall DUET population, CR patients had similar age, sex, and baseline eGFR, but lower baseline mean UP/C (1.67 g/l vs 2.65 g/l), and higher proportion of baseline immunosuppression (45% vs 35%), in particular with mycophenolate mofetil (18% vs 12%). AChromatic cohort was associated with better preservation of kidney function compared to not achieving CR. In 6 patients (14%), occurrence of CR followed the initiation of new steroid treatment.

Conclusions: In the DUET trial, a high proportion of patients achieved CR on at least one occasion. These observations support the long-term nephroprotective potential of SPAR.

Differences in Kidney Failure Risk by Race/Ethnicity at the Time of GFR-Based Transplant Eligibility

Chu, D., Neel R. Powe, S., Delphine S. Tuo, S. 1, 2 University of California San Francisco, San Francisco, CA; 3 OptumLabs Visiting Scholar, Cambridge, MA; 4 Zuckerberg San Francisco General Hospital and Trauma Center, San Francisco, CA.

Background: Glomerular filtration rate (GFR) less than 20 ml/min/m² is a criterion for kidney transplant listing, but variation in underlying end-stage kidney disease (ESKD) risk distributions by race/ethnicity has the potential to produce systematic racial disparities due to under recognition of the higher progression risk when a singular eGFR threshold is used as a decision point.

Methods: We compared predicted kidney failure risk by race/ethnicity for patients at the time their eGFR fell below 20 ml/min/m² using the OptumLabs® Data Warehouse (OLDW), a longitudinal, real-world data asset with de-identified administrative claims data. We identified patients 18-70 years old from 1/1/2014-6/30/2019 who had at least one eGFR >20 ml/min/m². We calculated 2-year risk of ESKD for each patient using the 4-variable Kidney Failure Risk Equation and compared the distributions by race/ethnicity.

Results: Of 2926 patients, 2024 were non-Hispanic white (NHW), 649 non-Hispanic black (NHB), and 253 Hispanic. At the time of incident eGFR ≤20 ml/min/m², NHWs were older than NHB or Hispanic patients (mean age 59.2 versus 56.2 or 54.3 years, respectively) and had lower median UACR (0.67 versus 1.36 or 1.72 g/g, respectively). Compared to ESKD risk among NHWs (median predicted risk 38.7%), the risk distribution was skewed toward higher risk for NHB and Hispanic patients, who had median predicted risks of 49.4% and 55.8% respectively (Figure).

Conclusions: At the time of incident eGFR ≤20 ml/min/m², NHB and Hispanic populations had greater risk of ESKD. A racial/ethnic disparity in time from GFR-based transplant eligibility to ESKD may exist even with elimination of disparities in timing of transplant referral and waitlisting. Consideration of kidney failure risk might be given greater attention in access to transplantation.

SU-OR42

Exploration of Racial Disparities in the Kidney Transplant Process Among Dialysis Patients

Steven M. Brunelli, Abigail Hunt, Carey Colson, Francesca Tentori. Davita Clinical Research, Minneapolis, MN.

Background: Kidney transplant is generally considered the best long-term treatment for dialysis patients. Before receiving a transplant, a patient must be referred to a transplant center, undergo extensive clinical evaluation, and then be placed on a wait list. Previous studies have observed that black patients are less likely to receive kidney transplants than white patients. However, it is unclear at which points in the transplant process inequity is imparted. In this analysis, we used a single source of data to compare the entire transplant process among black and white patients at a large dialysis organization.

Methods: Eligible patients were those who, between Jul 2015-Jun 2018, were 18-80 years old; were incident to dialysis and began care at the LDO within 30 days of first ever dialysis; and had not undergone a transplant evaluation or listing prior to dialysis start. Exposure was measured based on race as documented in LDO medical records (black or white). Patients were followed forward in time from study entry until 31 Mar 2019 or censoring or loss to follow-up. Transplant referrals, listings, and receipts were compared across exposure categories using time-to-event models adjusted for demographics, comorbidities, biochemistries, and socioeconomic factors.

Results: We identified 60,229 eligible incident patients (23,499 black; 36,730 white). Compared to whites, black patients were 23% more likely to be referred for transplant (hazard ratio [HR] and 95% confidence interval [CI] = 1.23 [1.20, 1.27]). Among referred patients, black patients were 19% less likely to be placed on a wait list than whites (HR [95% CI] = 0.81 [0.77, 0.86]). Among wait-listed patients, black patients were 52% less likely to receive a transplant than whites (HR [95% CI] = 0.48 [0.41, 0.56]). Overall, black patients were only 46% as likely to receive transplants as white patients (HR [95% CI] = 0.46 [0.39, 0.53]).

Conclusions: These results support prior findings that racial disparities exist within the kidney transplant process and indicate that these disparities occur downstream of the referral.

Deceased Donor Families and Authorization for Research: Differences Among Ethnic Groups

Mariella O. Roggens,1,2 Giselle Guerra,1,2 Miami Transplant Institute,1 University of Miami School of Medicine, Miami, FL; 2Miami Transplant Institute, Miami, FL.

Background: Research in transplantation requires next of kin (NOK) to authorize for participation in research. Aim was to determine the rate of research authorization by the NOK within different ethnic groups: African American (AA), White (W) or Hispanic (H).

Methods: Single center study of all deceased donor kidney transplantations referred to our institution during 3/1/2019-10/31/2019 from multiple organ procurement organizations (OPO) across the United States. We looked at the authorization for donation form in DonorNet. We searched for the NOK research authorization agreement at the time of organ donation. Donors were grouped by self-identified ethnic groups as W, AA or H.

Results: We had a total of 297 donors, yielding 401 kidney offers. 71% were imported from 46 different OPOs and 29% from our local OPO. Mean donor age (±SE) was 45.7±6.9. Donor ethnicity distribution was W 180 (60.6%); AA 66 (22.2%) and H 50 (16.8%). Overall 226 (76.1%) donors’ NOK authorized for research and 71 (23.9%) declined research. Donor age <35yr had a lower rate of authorization 62.9% vs 81.3% and 80.6% for 35-49yr and ≥50yr respectively p=0.006. Table 1 shows ethnic distribution on rate of NOK authorization for research, which was significantly lower in multiethnic and genetically diverse cohorts.

Conclusions: In conclusion, self-reported AA race and a genetically-derived continuous measure of African ancestry predict the risk of allograft rejection and failure in multiethnic and genetically diverse cohorts.

Minimum Diagnostic Criteria for Thrombotic Microangiopathy in Renal Allograft: The Banff TMA Working Group Phase I Results

Marian Afrouzian, Banff TMA Working Group University of Texas Medical Branch at Galveston, Galveston, TX.

Background: Thrombotic Microangiopathy (TMA) TMA is a serious complication of renal transplantation, usually with poor outcome. The Banff TMA Working Group (TMA-WG) was formed to study renal transplant TMA (t-TMA) aiming to: 1- Survey current practices used in the diagnosis of t-TMA; 2- Define minimum diagnostic criteria (MDC); and 3- Develop recommendations for accurate diagnosis integrating morphological, clinical, laboratory and molecular findings, where available. The project started with Phase I (pathology phase) and is continuing in Phase II (Nephrology phase).

Methods: Using the Delphi methodology during phase I, 23 nephrologists who had >3 years of experience with t-TMA were asked to list their MDC for t-TMA in the following categories: 1- Light, 2- immunofluorescence, and 3- electron microscopy, 4- clinical history, 5- laboratory findings, 6- genetic testing and 7- raised differential diagnoses. Nine rounds (R) of surveys were designed. At the end of each R, MDC were narrowed down following Delphi rules. R6 and R7 were designated as the validation Rs in which the narrowed criteria were validated on 37 renal biopsies (25 TMA and 12 non-TMA cases) using Aperio Imagescope and whole slide digital images scanned @ X400. For each biopsy, pertinent pathology/history/laboratory/genetic information were provided. Descriptive statistical analysis was performed using SPSS program.

Results: Starting with 338 criteria in R1 and following analysis of total 82,677 data entries, MDC were narrowed down to 35, by the end of R9. The graph illustrates the evolution of the criteria over 9 R. A complete list of 35 MDC will be presented at the meeting.

Conclusions: Applying the Delphi methodology to a cohort of t-TMA biopsies in Phase I of the project, nephrologists from 4 continents generated histopathologic, clinical and laboratory MDC for renal t-TMA. Phase II (Nephrology consensus) and Phase III (consensus of the consensus groups- Combined Phases I & II) will follow Phase I to generate final MDC for t-TMA.

Does Screening for Coronary Artery Disease Predict Cardiac Outcomes Following Renal Transplantation?

Alisha Nimmo, Dominic M. Taylor, Rommel Ravanat, Southmead Hospital, Bristol, United Kingdom.

Background: Screening for asymptomatic coronary artery disease (CAD) prior to transplantation aims to reduce perioperative cardiac events. There is conflicting evidence as to whether this is achieved.

Methods: Individuals recruited to the Access to Transplant and Transplant Outcome Measures (ATTOM) study in England who received a renal transplant between 2011-2017 were studied. Patient demographics and details of screening investigations from ATTOM were linked to outcome data from the Hospital Episode Statistics dataset. Major Adverse Cardiac Events (MACE) comprised unstable angina, myocardial infarction, coronary bypass graft, coronary angioplasty or cardiac death. The effect of screening on MACE was analysed in propensity score-matched groups, using Cox survival analyses, up to 5 years post-transplant.

Results: 2572 individuals received a renal transplant; 51% underwent CAD screening (Figure 1). Age, ethnicity, ischaemic heart disease and diabetes were independently associated with screening. The incidence of MACE at 90 days, 1 and 5 years was 0.9%, 2.1% and 9.4%. After propensity score matching, 1854 individuals were examined. There was no association between screening and MACE at 90 days (HR 0.68, 95% CI 0.28-1.64), 1 year (HR 1.24, 95% CI 0.60-2.54) or 5 years (HR 1.31, 95% CI 0.95–1.79) (Figure 2).

Conclusions: Screening for CAD did not influence the rate of ischaemic cardiac events up to 5 years post-transplant. Units should review protocols with lengthy cardiac workup processes.

Albuminuria in Kidney Transplantation Patients Predicts Cardiovascular Morbidity After Two Years

Dana Bielopolski,1,2 Ruth Rahaminov,1 Boris Zingerman,1 Avry Chagnac,1 Limor Azulay gitter,1 Benaya Rozen-zvi,1 1The Rockefeller University, New York, NY; 2Rabin Medical Center, Petah Tikva, Israel.

Background: Moderately Increased Albuminuria (MIA) is a well characterized marker of kidney malfunction, both in diabetic and non-diabetic populations, and is used as a prognostic marker for cardiovascular morbidity and mortality. A few studies implied that it has the same value in kidney transplanted patients, but the information relies on spot or dipstick urine protein evaluations, rather than the gold standard of timed urine collection.

Methods: We revisited a cohort of 286 kidney transplanted patients, several years after completing a meticulously timed urine collection and assessed the prevalence of major cardiovascular adverse events (MACE) in relation to albuminuria.

Results: During a median follow up of 8.3 years (IQR 6.4-9.1) 144 outcome events occurred in 101 patients. By Kaplan-Meier analysis MIA was associated with increased rate of CV outcome or death (p=0.03), and this was still significant after stratification according to propensity score quartiles (p=0.048). Time dependent Cox proportional hazard analysis showed independent association between MIA and CV outcomes two years following MIA detection (HR 1.83, 95% CI 1.07-2.96).

Conclusions: Two years after documenting MIA in kidney transplanted patients, their CVD risk was increased, most likely, as a result of endothelial dysfunction. This should prompt the caregiver for strict primary prevention and risk factors modification.

Kaplan-Meier analysis showing rate of CV outcome or death in relation to MIA. X axis shows days since urine collection, Y axis shows cumulative survival. Blue curve – patients without MIA, red curve – patients with MIA.

Renal Graft Outcomes in Simultaneous Kidney-Heart Transplant Recipients: Analysis of the UNOS Database from 1987-2018

Krishna A. Agarwal,1 Het Patel,1 Francesca Cardarelli,1 Nikhil Agrawal. BIDMC Beth Israel Deaconess Medical Center, Boston, MA.

Background: Simultaneous kidney and heart transplants (SKHT) are employed for patients with both end-stage heart failure and severely impaired kidney function. Renal outcomes in such recipients have been described, albeit in single-center cohorts. We analyzed the United Network for Organ Sharing (UNOS) dataset comprising of 1702 simultaneous kidney-heart transplant recipients since 1987.

Methods: This is a retrospective analysis of SKHT recipients in the UNOS dataset who received transplants between October 1987 and December 2018. We compared the incidence and risk factors of renal allograft loss in SKHT recipients versus deceased donor kidney (DDKT) alone recipients. The Student t-test or Kruskal Wallis tests were used to compare continuous variables, and the Chi2 test for categorical variables between groups. Cox regression hazard model was used to study the factors associated with graft failure.

Results: SKHT recipients were mostly white, males, 5-years older than DDKT recipients. The SKHT donors were younger than DDKT donors, predominantly white males who died from a CVA. Five year patient survival was similar in both the groups (80%) but 1-year mortality was 3 times higher in the SKHT group (12.5%) than DDKT (4.6%). Nearly 20% recipients in both groups died with a functioning graft. Renal graft survival in SKHT group was lower in the first year but equalized with DDKT group over 5 years. Cox regression analysis revealed male gender [HR 2.14], pre-emptive renal transplantation [HR 6.57] and HLA mismatch >4 [5.60] as significant risk factors for renal graft failure in SKHT recipients as compared to DDKT recipients at 4 years. Predominant cause of graft failure in SKHT recipients was primary failure (30%) and in DDKT recipients was acute rejection (26%).

Conclusions: This is the largest analysis of the UNOS database till date to describe risk factors associated with renal graft loss in SKHT recipients. We also showed that 38% of grafts that fail in SKHT recipients, failed in the first year following transplant and primary failure was the predominant cause. Our analysis provides much needed data to policy makers for future combined organ allocation policies.

SU-OR50

Recurrence of IgA Nephropathy After Kidney Transplantation: TANGO Multicenter Study

Audrey Uffing,1,2 Paolo Cravedi,1 Leonardo V. Riella,3 TANGO-project 1Brigham and Women’s Hospital, Boston, MA; 2Universitair Medisch Centrum Groningen, Groningen, Netherlands; 3Icahn School of Medicine at Mount Sinai, New York, NY.

Background: In patients who received a kidney transplantation for end-stage renal disease (ESRD) due to IgA nephropathy, IgA deposits can recur in the transplanted kidney. The incidence, impact and predictors of these recurrent deposits is unclear.

Methods: As part of The Post-Transplant Glomerular Disease (TANGO) project, we performed a multicenter, international, retrospective study to determine the incidence, predictors and treatment response of recurrent IgA deposits after kidney transplantation. Patients with biopsy-proven IgA nephropathy, transplanted in the period 2005-2015 were selected in 16 TANGO centers in Europe, United States and Brazil.

Results: In a total of 504 patients, recurrent IgA deposits were identified by kidney biopsy in 82 patients (16%; 95%CI: 13-19), with a medium time to recurrence of 3.4 years (IQR 1.4-5.7 years). Kaplan-Meier analysis showed similar graft survival between patients with and without recurrence in the first years after kidney transplant, though after 8 years, graft failure rates were higher in patients with recurrence (10 year death-censored graft survival 76% and 89%, respectively). Multivariable Cox-regression revealed a higher risk for IgA recurrence.
in patients with a pre-emptive kidney transplant (HR 2.56, 95%CI: 1.59-4.17), patients with DSA at time of transplant (HR 2.74, 95%CI: 1.22-6.14) and patients with shorter time from diagnosis to ESRD (HR 0.84 per month, 95%CI: 0.74-0.96). The presence of systemic autoimmune diseases associated with IgA nephropathy did not affect recurrence rates, nor did early steroid withdrawal. In multivariate analysis of post-transplant complications, de novo DSA was associated with recurrence of IgA deposits (HR 1.91, 95%CI: 1.04-3.51).

Conclusions: In our international cohort, IgA deposits occurred in 16% of patients and was associated with worse graft outcomes after 8 years of transplant compared to patients without recurrence. A pre-emptive transplant, shorter time from native diagnosis to ESRD, DSA at time of transplant and de novo DSA after kidney transplantation were associated with recurrence of IgA deposits.

Methods: Renal ischemic reperfusion injury (IRI) rat model was established and RDN was performed. Animals were randomized to IRI with or without RDN. Tyrosine hydroxylase (TH), renal functions, tubular cell apoptosis and histology staining were examined at 24 hours, and renal fibrosis and capillary vessels were measured at 2 weeks. What is more, the expression of miRNAs in injured kidney was determined by micro-array and the target genes were analyzed. Lastly, human renal biopsy samples with chronic kidney disease were picked for the TH and fibrosis analysis.

Results: TH was eliminated and renal functions were improved in the denervation group at 24 hours. RDN reduce tubular cell apoptosis and mitigate the histological lesion. Meanwhile, the increase of capillary vessel density was determined at 24 hours and 2 weeks, and the miRNA targeted pro-angiogenesis, anti-fibrosis and inflammatory pathways were modulated. Lastly, less fibrosis regions were found in TH high expression regions of human renal biopsy samples.

Conclusions: RDN was a reliable method in alleviating IRI induced acute and chronic kidney injury, and the modulation of miRNA related pro-angiogenesis, anti-fibrosis or inflammatory pathways involved in this process.

PO2616

Obesity Has Opposing Effects on Acute vs. Chronic Kidney Disease
Thomas V. Roussele, James D. Eason, Daniel Maluf, Valeria R. Mas, Amandeep Bajwa. UTHSC, Memphis, TN.

Background: With an accumulation of lipid droplets, mitochondria become incapable of upregulating the glucose-dependent response to ischemia and the cell becomes dependent upon glycolysis to satisfy metabolic need. This dysregulation has contributed to the exacerbation of ischemic injury in various tissues in diet-induced obese (DIO) mice. However, very little is known in how DIO can contribute to ischemic kidney disease. We hypothesized that obesity may dampen the response to acute kidney injury (AKI) and further exacerbate the development of dysfunction in chronic kidney disease. In this study, the increase of capillary vessel density was determined at 24 hours and 2 weeks, and the miRNA targeted pro-angiogenesis, anti-fibrosis and inflammatory pathways were modulated. Lastly, less fibrosis regions were found in TH high expression regions of human renal biopsy samples.

Conclusions: RDN was a reliable method in alleviating IRI induced acute and chronic kidney injury, and the modulation of miRNA related pro-angiogenesis, anti-fibrosis or inflammatory pathways involved in this process.

PO2617

Protective Effects of Apelin on Contrast-Induced Nephropathy
Jae Soo Kim, Myung Kim, Hanwul Shin, Jun Young Lee, Jae Won Yang, Minseob Eom, Seung-Ok Choi. Wonju Severance Christian Hospital, Wonju, Gangwon-do, Republic of Korea.

Background: Contrast induced nephropathy (CIN) has no proven preventive measures yet except for saline administration. Apelin is a endogenous ligand to apelin receptor in body, which has physiologic roles such as increasing cardiac output and peripheral vasodilatation. This study aims to examine the protective effect of apelin on CIN.

Methods: A total of 22 rats were divided into 4 groups: Control, Apelin, Contrast and Apelin+Contrast. In order to effectively induce CIN, 50 mg/kg of gentamycin IV was injected daily to all rats from Day-1 to Day-6. On Day-7, the rats were pre-treated as follows; Control and Contrast groups: Saline SQ, Apelin and Apelin/Contrast groups: apelin (500 ng/kg) IV. Apelin/Contrast groups were associated with no treatment, main treatments were followed; Control and Apelin groups: Saline IV. Contrast and Apelin/Contrast groups: Ioxagol-350 mg id/mL, 1.8 g id/kg IV. We performed serum and 24-hour urine tests on Day-0 and Day-9 which was 48 hours after contrast administration. We collected the kidney with sacrifice on Day-9.

Results: The significant increase in serum creatinine (Cr) in only Contrast group (p=0.039). In Contrast (p=0.015) and Apelin/Contrast (p=0.007) groups, urinary Cr excretion significantly increased indicating renal tubular injury. The immunohistochemistry for caspase-3 indicated that Contrast group had significant increase in number of positive cells compared to Control group at 24 hours. The immunohistochemistry for TH, renal functions, tubular cell apoptosis and histology staining were examined at 24 hours, and renal fibrosis and capillary vessels were measured at 2 weeks. What is more, the expression of miRNAs in injured kidney was determined by micro-array and the target genes were analyzed. Lastly, human renal biopsy samples with chronic kidney disease were picked for the TH and fibrosis analysis.

Conclusions: We could identify the protective effects of apelin against CIN in the study.

Male, but not Female, Spontaneously Hypertensive Rats (SHR) Have Sustained Renal Injury Following a Single Ischemic Insult Progressing to CKD
Riyaz Mohamed, Jennifer C. Sullivan. Augusta University, Augusta, GA.

Background: Renal ischemia-reperfusion (IR) is a major cause of acute kidney injury (AKI), which is an independent risk factor for the development of CKD and all-cause mortality. The goal of the current study was to test the hypothesis that hypertensive males will have greater IR injury than hypertensive females resulting in the development of CKD.

Methods: 13-week old male and female SHR were subjected to sham or 30-minute warm bilateral ischemia followed by reperfusion (n=5-6). Systolic blood pressure (BP) measured weekly by tail-cuff.

Results: Plasma creatinine (Pcr) and urine protein creatinine ratio (UPCR) remained elevated at 1-week post IR in male SHR compared to sham (P<0.005). Per and UPCR returned to baseline in SHR females. Histological examination of SHR kidneys 7 days post-IR showed greater increases in vascular congestion (P=0.002) and tubular damage (P=0.001) in males. However, glomerular filtration rate (GFR) and systolic BP were not altered in both male and female SHR at 1-week post IR. To determine if this was sustained dysfunction or simply delayed recovery, additional 13-week old male and female SHR were subjected to sham or 30-minute warm bilateral ischemia followed by 20 weeks of reperfusion (n=4-5). Male SHR showed progressive increases in UPCR (P=0.005) and systolic BP up to 20 weeks post-IR compared to respective sham (P=0.001). Whereas in female SHR, UPCR remained at baseline up to 16-week post IR compared to respective sham. However, at 20 weeks of post IR, both male and female SHR exhibit an increase in UPCR compared to respective sham control; although the increase in UPCR was greater in males (P=0.01; P<0.05). Male SHR also exhibited greater decreases in glomerular filtration rate (GFR; P=0.025; P=0.12) and increases in systolic BP (P=0.0001; P=0.27) compared to females.

Conclusions: Our data demonstrated that impaired renal recovery following IR in SHR males results in exaggerated progression towards CKD.

CLP serum stimulated superoxide production and release of mtDNA into cultured PCT media both were proportionately inhibited by BAM15 (Fig 2A-C). Released mtDNA correlated with superoxide production. BAM15 recovered mitochondrial biogenesis through activation of PGC1α pathway and, inhibited CLP reduction of mitophagy.

Conclusions: Sepsis increased kidney mROS and released mtDNA from PT cells. BAM15 attenuated generation of mROS and inhibited mtDNA release into urine and also circulating mtDNA even delayed BAM15 treatment. In sepsis AKI, BAM15 changed the trajectory of mitochondrial fate. Our results suggest that BAM15 and mtDNA are mechanistically linked via ROS, and form a drug-companion biomarker pair.

Assessment of a Modified Renal Angina Index for the Prediction of AKI in Hospitalized Adult Patients
Ana A_Mariscal-Campos,1 Rolando Clara-Del-Gnnado,2 Clínica Los Olivos, Cochabamba, Bolivia, Plurinational State of,1 IIRSMED; Universidad Mayor de San Simon Facultad de Medicina, Cochabamba, Bolivia, Plurinational State of.

Background: Risk-stratification tools of incident AKI in hospitalized patients are needed. The renal angina index (RAI) was developed and validated in the pediatric population. The purpose of this study was to evaluate the performance of a modified RAI (mRAI) for the prediction of AKI in hospitalized patients.

Methods: We analyzed data from 55 hospitalized patients admitted to our center. Inclusion criteria consisted of age ≥ 18, hospital stay ≥ 3 days, at least 2 serum creatinine (SCr) measures in the first 2 days of hospital stay and one measure at 3-7 days of stay. Exclusion criteria consisted of ESKD, kidney transplant or baseline eGFR <15. At admission, mRAI was calculated using the following formula:

\[
\text{mRAI} = \frac{1}{X} \times \left[ \frac{1}{X} \times \left( \frac{SCr_1 - SCr_2}{SCr_2 - SCr_3} \right) \right]
\]

where X is the number of days between SCr measurements.

Results: Younger adults (age < 65) were less at risk of AKI as compared to older adults (age ≥ 65). The incidence of AKI at 3-7 days of hospital or ICU stay was 52.7%. Most patients fulfilled the AKI sCr criteria. Our results showed that mRAI had robust predictive capacity to identify hospitalized patients at high risk of developing AKI. Incorporation of AKI biomarkers into the RAI may potentially improve prediction. The preliminary data of our ongoing study warrants future studies to validate these findings.

Grb2 Promotes Cardiorenal Syndrome Type 3: Roles of Cardiomyocyte Contractile Cytoskeleton, Mitochondria Damage, and Inflammation
Jin Wang, Xiangmei Chen. Chinese PLA General Hospital, Beijing, China.

Background: Cardiorenal syndrome type-3 (CRS-3) is a damage to heart following acute kidney injury. Although many experiments have found that inflammation, oxidative stress, and cardiomyocyte death are involved in cardiomyocyte pathophysiological alterations during CRS-3, it lacks a non-bias analysis to figure out the primary mediator of cardiac dysfunction. Herein, the aim of our study is to figure out the primary upstream regulator of these intracellular molecular biological events.

Methods: In this study, proteomic analysis was performed in CRS-3 and growth factor receptor-bound protein 2 (Grb2) was identified as a regulator involving AKI-related myocardial damage.

Results: Increased Grb2 was associated with cardiac diastolic dysfunction, mild cardiomyocyte death and prominent myocardial inflammation; these pathological changes could be reversed through administration of Grb2-blocking peptide after AKI. Molecular investigation illustrated that augmented Grb2 promoted cardiomyocytes contractile cytoskeleton degradation through inhibiting the expression of Myosin. In addition, increased Grb2 triggered mitochondrial fission, inactivated mitochondrial autophagy, induced mitochondrial potential reduction, and triggered caspase-9/3 activation. Pro-inflammatory signaling pathways, including NF-κB, MAPK/ Erk, and MAPK/P38, were activated by Grb2 in cardiomyocytes following AKI.

Conclusions: Our results identify CRS-3 is caused by Grb2 upregulation which contributes to cardiac dysfunction, cardiomyocyte apoptosis and myocardial inflammation. This finding provides a potential target for the clinical treatment of patients with CRS-3.

PO0001
AKI Identification: Use of Electronic AKI Alerts vs. Electronic Health Records in Hospital Episode Statistics
Manuela Savino,1 Anna Casula,1 Esther H. Wong,1 Nitin V. Kolhe,2 James Medical,1,a Dorothea Nitsch,1,a UK Renal Registry, Bristol, United Kingdom; 3Royal Derby Hospital, Derby, United Kingdom; 4London School of Hygiene & Tropical Medicine, London, United Kingdom; 5Leicester General Hospital, Leicester, United Kingdom.

Background: Acute Kidney Injury (AKI) refers to an abrupt decline in the glomerular filtration rate (GFR) potentially associated with significant morbidity and mortality. Since April 2015, an automated real-time electronic (e)-alert system for AKI was introduced and progressively implemented in England, with alert data being sent to the UK Renal Registry (UKRR) for collection into a master patient index (MPI). Herein, we aimed to evaluate the performance of the e-alert system in hospitalised patients. The performance of the e-alert system in hospitalised patients is measured in the Hospital Episode Statistics (HES). This project aims to determine whether episodes of AKI identified in the UKRR MPI correspond to coded diagnoses on the discharge record held in HES.

Methods: The UKRR MPI of all AKI e-alerts (stages 1, 2, and 3) in patients aged ≥ 18 years, between 01/01/2017 and 31/12/2017 were linked to HES data to identify a hospitalised AKI population. Descriptive analyses were conducted to describe the demographics and to investigate whether those with an AKI e-alert also had an International Classification of Diseases (ICD)-10 code for AKI (N17) in HES.

Results: From 01/01/2017 to 31/12/2017, 301,504 hospitalised adults received an AKI e-alert. AKI severity was positively associated with the percentage of AKI alerts coded in HES. There was a significant variation in HES coding between hospitals, most pronounced for AKI stage 1 (mean 48.2% SD 14) versus AKI stage 3 (mean 83.3% SD 7.3) (figures 1). Younger adults with AKI e-alerts were less often coded in HES for all three AKI stages (33% people aged 18-29 years versus 64% people aged ≥ 85 years).

Conclusions: In 2017, earlier stages of AKI e-alerts were poorly coded in HES. There was also high degree of inter-hospital variability, particularly at AKI stage 1, reflecting potentially poor clinical recognition and documentation in medical records and subsequent clinical coding. AKI e-alerts were poorly captured in HES for younger adults in comparison to those of older age. Use of HES to identify cases of AKI is likely to underestimate the incidence of AKI, especially for AKI stage 1, though a high proportion of the most severe cases will be captured.

Early Prediction of Hospital-Acquired AKI from Electronic Health Records Using Machine Learning

Gurmukteshwar Singh,1 Yirui Hu,1 David Riviello,1 Jason Brown,1 Sara Saunders,2 André García-Arce,3 Kevin Ho,1 H. Lester Kirchner.1
1Geisinger Medical Center, Danville, PA; 2Sanofi Genzyme, Cambridge, MA.

Background: Hospital-acquired acute kidney injury (HA-AKI) leads to increased mortality and morbidity. Early prediction of HA-AKI using Electronic Health Records may enable clinicians to modify treatment to minimize risk and AKI severity.

Methods: Inpatient admissions from 7/13/2012 – 7/11/2018 who had creatinine measured were included. Patients with end-stage renal disease, length of stay <48 hours and AKI at admission were excluded. A validated algorithm was used to determine baseline renal function. AKI was defined according to KDIGO guidelines. Machine learning algorithms were implemented to predict development of HA-AKI beyond the initial 24-hours of admission. 50 input variables to machine learning algorithms (random forest, XGBoost, logistic regression) included demographics, initial laboratory values taken within the first 24-hours of admission, active medications at time of admission, and prevalent comorbidities. Multiple imputation by chained equations (MICE) was used for missing variables. Univariate Feature Selection was utilized where variables were ranked based on the balance between model simplicity and performance. Variables included in the algorithm should be monitored in real-time to allow early identification and preventive interventions in patients at risk for HA-AKI.

A Meta-Analysis of Clinical Predictors for Renal Recovery and Mortality in AKI Requiring Continuous Renal Replacement Therapy

Panupong Hansrivijit1, Max Puthepura,1 Nasrollah Ghahramani,2 Charat Thongprayoon,2 Wisit Cheungpasitporn,1,2 UMPC Pinnacle, Harrisburg, PA; 2Mayo Clinic Arizona, Phoenix, AZ.

Background: Acute kidney injury (AKI) is a common complication in critically ill patients and can result in a broad spectrum of severity. It is well-established that severe AKI requiring continuous renal replacement therapy (CRRT) carries a significant risk for increased mortality compared to non-dialysis AKI. However, there are no consensus guidelines describing the discontinuation criteria from CRRT. Thus, we performed this meta-analysis to determine the clinical predictors for CRRT discontinuation and overall mortality in patients with AKI.

Methods: Ovid MEDLINE, EMBASE, and Cochrane Library were searched without language restrictions up to January 2020. Our inclusion criteria included patients ≥ 18 years of age requiring CRRT for AKI. Renal recovery was defined by CRRT discontinuation. Intermittent hemodialysis was excluded. Only articles utilizing multivariate analysis were included. We divided our analyses into two cohorts based on the primary outcomes: renal recovery cohort and overall mortality cohort.

Results: For renal recovery cohort (n = 4,497 from 14 studies), the mean effluent dose of CRRT was 24.93 ± 5.87 ml/kg/h with a median duration of CRRT of 3.75 days (IQR 2.45). Increasing urine output at time of CRRT discontinuation (per 100 ml/day), elevated initial SOFA score (per 1 score) and serum creatinine level at CRRT initiation (per 10 mg/dl) were predictive of renal recovery with odds ratio of 1.021 (95% CI, 1.012-1.031), 0.890 (95% CI, 0.805-0.984) and 0.995 (95% CI, 0.991-0.999), respectively. For overall mortality cohort (n = 16,948 from 11 studies), the mean effluent dose of CRRT was 26.22 ± 4.67 ml/kg/h with a median CRRT duration of 4.5 days (IQR 3.40). Age (per 1 year) and presence of sepsis were significantly associated with overall mortality with odds ratio of 1.023 (95% CI, 1.006-1.040) and 2.031 (95% CI, 1.267-3.257), respectively. All analyses remained significant through sensitivity analyses. No potential publication bias was identified.

Conclusions: Urine output at CRRT discontinuation, initial SOFA score, and serum creatinine level are predictive of renal recovery and successful CRRT discontinuation. Increasing age and the presence of sepsis are independent risk factors for elevated overall mortality.

Regional Variation in Recovery of Kidney Function in Patients Requiring Maintenance Hemodialysis with Acute Tubular Necrosis

Yuetting D. Kwong,1 Kirsten L. Johansen,2 Charles E. McCulloch,1 Kathleen D. Liu,1 Barbara A. Grimes,3 Elaine Ku.1 University of California San Francisco, San Francisco, CA; 2Hennepin Healthcare, Minneapolis, MN.

Background: Geographic variations in the likelihood of recovery of kidney function in ESKD attributed to acute tubular necrosis (ATN) has not been well established.

Methods: Using data from United States Renal Data System, we performed a retrospective cohort study of incident maintenance hemodialysis (HD) patients between 1/1/1996-12/31/2015 with ESKD attributed to ATN followed up to 1 year. Recovery of kidney function was defined as discontinuation of HD for at least 90 days and alive without need for kidney transplantation during this period. We used Fine-Gray models to determine unadjusted and adjusted hazard of recovery while accounting for the competing risk of death.

Results: In 48,771 patients included for analysis, 30% recovered kidney function within 1 year. Most patients received HD within a 10-mile radius of their home. Recovery rates at 1 year were lowest in the northeast and highest in the south; lower in metropolitan compared to micropolitan/rural areas. Recovery of kidney function was less likely to occur with distance between patient and dialysis facilities in adjusted analysis.

Conclusions: Patients living in rural/micropolitan locations and receiving dialysis close to home had higher recovery rates. Studies examining regional differences in practice patterns are warranted.

Adequacy of Kidney Follow-Up Among AKI Survivors After Hospital Discharge

Background: Acute kidney injury (AKI) affects 20% of hospitalized patients and results in long-term adverse outcomes. To limit its complications, post-discharge follow-up is advised. The objective of the study was to evaluate the frequency of appropriate follow-up after discharge among AKI survivors.

Methods: This was a population-based cohort study of adult Olmsted County residents hospitalized at their local hospital (Mayo Clinic in Rochester, MN) with an episode of stage II or III AKI between 2006 and 2014. Those dismissed from the hospital on dialysis or who died within 30 days after discharge were excluded. The cumulative incidence of adequate kidney follow-up defined by a serum creatinine (SCr) level and/or an in-person healthcare visit within 30 days, 90-days, or 1-year after discharge was described.

Results: There were 563 survivors of AKI studied [Stage II: N=360 (64%); Stage III: N=203 (36%)]. The 30-day cumulative incidence of follow-up with SCr was 78% (95% confidence interval (CI): 74%, 81%), by provider visit was 80% (95% CI: 77%, 83%), by both SCr assessment and provider visit was 70% (95% CI: 65%, 73%). Within 90-days and 1-year, the cumulative incidences of both SCr assessment and provider visit rose to 81% and 91%, respectively. Within 30-days after discharge, only 13% (95% CI: 10%, 16%) of these stage II or III AKI survivors saw a nephrologist. The statistically significant predictors of receiving both a SCr assessment and provider visit within 30-days included higher body mass index, worse baseline and discharge kidney function, higher comorbidity burden, greater maximum AKI severity, and longer duration of AKI during the hospitalization. Age, sex, race/ethnicity, education status, and socioeconomic status also predicted kidney follow-up.

Conclusions: These data demonstrated that 30% of patients with moderate to severe AKI received insufficient kidney follow-up in the 30-day post-discharge interval. Medical risk factors rather than social/demographic characteristics were the primary determinants of kidney follow-up.

Funding: Other NIH Support - National Institute of Allergy and Infectious Diseases of the National Institutes of Health under Award Number K23AI43882; National Center for Advancing Translational Sciences Grant Number UL1 TR002377; National Institute on Aging of the National Institutes of Health Award Number R01AG036476.

Risk Factors for Mortality and Hospital Readmission Following AKI

Benjamin R Griffin,1,2 Jason Wachsmuth,1,2,3,4 Eli Perencevich,2,3,4 Heather Reisinger,1,5,6 Mary V. Sarrazin,1,2,3 Diana I. Jalal,1,2,3 ‘Center for Comprehensive Access & Delivery Research & Evaluation (CADRE), Iowa City VA Health Care System, Iowa City; 1,2 ‘The University of Iowa Hospitals and Clinics, Iowa City, IA.

Background: Acute kidney injury (AKI) occurs in over 20% of hospitalized patients and is associated with increased short-term and long-term morbidity and mortality. The purpose of this study is to identify risk factors for readmission for renal cause and mortality following a hospitalization with AKI in US Veterans.

Methods: AKI was defined as a creatinine increase of ≥0.3 mg/dL or at admission or discharge to a VA hospital between 2013 and 2018. The primary outcomes were death and hospital readmission for a renal indication. Proportional hazards frailty model was applied. Variables evaluated included demographics, comorbidities, and laboratory data. The final model was chosen based on clinical relevance and parsimony.

Results: From a cohort of 624,822 Veterans with AKI, 218,839 (35%) met inclusion criteria. Reasons for exclusion were <1 year of prior patient data (35%), missing serum creatinine values (14%), palliative status or metastatic cancer (13%), or death during the hospitalization (4%). AKI was present on admission in 71% of patients and developed after admission in 29%. Overall, 48,202 (22%) died within one year. Between 2013 and 2018, 101,170 (46%) died and 21,116 (9%) experienced a readmission. The patient characteristics associated with increased hazard of death included age (HR=1.53 per 10 years, CI 1.52-1.54, p<0.001), male sex (HR=1.27, CI 1.22-1.32, p<0.001), heart failure (HR=1.55, CI 1.53-1.57, p<0.001), prior myocardial infarction (HR=1.14, CI 1.11-1.17, p<0.001), prior cardiovascular disease (HR=1.15, CI 1.13-1.17, p<0.001), short-term inpatient mortality (HR=1.12, CI 1.30-1.33, p<0.001), chronic kidney disease (HR=1.15, CI 1.13-1.17, p<0.001), creatinine at time of admission (HR=1.012, CI 1.009-1.015, p<0.001) and increase from pre-admission values (HR=1.045, CI 1.041-1.048, p<0.001). The same patient characteristics were significant predictors of readmission for a renal indication. The odds ratios for death and readmission were 0.791-0.854, 0.827 (95% CI 0.795-0.858), respectively. Validating these models using eICU dataset, the AUC of LR, XGBoost, RF and MLP were 0.846 (95% CI:0.828-0.864, 0.858 (95% CI:0.850-0.867), 0.858 (95% CI:0.850-0.866), 0.859 (95% CI:0.840-0.870), 0.864 (95% CI:0.851-0.876) and validated in MIMIC were 0.799 (95% CI:0.710-0.824), 0.809 (95% CI:0.730-0.833), 0.814 (95% CI:0.791-0.837), 0.800 (95% CI:0.776-0.825), respectively. When training the model using MIMIC dataset, the intra-ICU mortality AUC of LR, XGBoost, RF and MLE were 0.818 95% CI: (0.786-0.852), 0.821 (95% CI:0.787-0.856) 0.822 (95% CI:0.791-0.854), 0.827 (95% CI:0.795-0.858), respectively. Validating these models using eICU dataset, the AUC of LR, XGBoost, RF and MLE were 0.864 95% CI:0.828-0.864, 0.847 95% CI:0.829-0.865), 0.853 (95% CI:0.835-0.870), 0.846 (95% CI:0.828-0.865), respectively.

Conclusions: In this study, we designed machine learning models to make intra-ICU mortality prediction for patients who required RRT. Our models correlated better than the usual practice in predicting mortality of patients requiring RRT in ICU. All of the models almost had excellent performance in both databases.

Region-wide Implementation of Best Practice in AKI
Anirudh Rao, Kottatharil A. Abraham. On behalf of the Cheshire & Merseyside Acute Kidney Injury Network (CHAMKIN) Liverpool University Hospitals NHS Foundation Trust, Liverpool, United Kingdom.

**Background:** The Cheshire & Merseyside Acute Kidney Injury Network, United Kingdom, rolled out best practice guidelines of 13 interventions for Acute Kidney Injury (AKI) in October 2014. The aim was to assess the impact of the guidelines.

**Methods:** Setting & Population: Hospitals in Cheshire & Merseyside. Predictor: Time period before & after introduction, allowing six-month bedding in period. Outcome: Percentage AKI: Number of AKI per month, divided by total number of admissions/month expressed as %. Percentage AKI deaths: Number of AKI related deaths per month divided by total deaths/month expressed as %. Data analysis: Descriptive & Piecewise Linear Regression.

**Results:** The region saw a notable increase in the number of admissions/month (31,173 vs 38,443) and AKI episodes (4,871 vs 44,493) in the 8 hospitals in pre and post guideline implementation period. Five hospitals were excluded due to guideline implementation pre-roll out (2), implementation dates not provided (2) & no pre-post guideline implementation period. Five hospitals were excluded due to guideline implementation pre-roll out (2), implementation dates not provided (2) & no pre-post guideline implementation period. Five hospitals were excluded due to guideline implementation pre-roll out (2), implementation dates not provided (2) & no pre-post guideline implementation period. Five hospitals were excluded due to guideline implementation pre-roll out (2), implementation dates not provided (2) & no pre-post guideline implementation period. Five hospitals were excluded due to guideline implementation pre-roll out (2), implementation dates not provided (2) & no pre-post guideline implementation period. Five hospitals were excluded due to guideline implementation pre-roll out (2), implementation dates not provided (2) & no pre-post guideline implementation period. Five hospitals were excluded due to guideline implementation pre-roll out (2), implementation dates not provided (2) & no pre-post guideline implementation period. Five hospitals were excluded due to guideline implementation pre-roll out (2), implementation dates not provided (2) & no pre-post guideline implementation period. Five hospitals were excluded due to guideline implementation pre-roll out (2), implementation dates not provided (2) & no pre-post guideline implementation period. Five hospitals were excluded due to guideline implementation pre-roll out (2), implementation dates not provided (2) & no pre-post guideline implementation period. Five hospitals were excluded due to guideline implementation pre-roll out (2), implementation dates not provided (2) & no pre-post guideline implementation period. Five hospitals were excluded due to guideline implementation pre-roll out (2), implementation dates not provided (2) & no pre-post guideline implementation period.

**Conclusions:** The rollout of interventions caused an increased and sustained recognition of AKI, across the hospitals. The % AKI deaths stayed the same except in hospital A. We theorise that the onsite nephrology team in Hospital A aided implementation of the guidelines and training of wider healthcare staff which made the impact. This study highlights the hurdles faced in implementing AKI improvement strategies across various healthcare settings.

**PO0013**
Incidence and Impact of AKI on Patients with Implantable Left Ventricular Assist Devices: A Meta-Analysis
Charat Thongprayoon,1 Wisit Cheungpasitporn,2 Panupong Hansrevijit,3 Tibor Charat,4 Swetha Rani Kandhar,5 Michael A. Mač,6 Kimoshoo Kasadei,1
1Mayo Clinic Minnesota, Rochester, MN; 2University of Mississippi Medical Center, Jackson, MS; 3UPMC Pinnacle, Harrisburg, PA; 4Medical University of South Carolina, Charleston, SC; 5Mayo Clinic’s Campus in Florida, Jacksonville, FL.

**Background:** This systematic review and meta-analysis was performed to evaluate the acute kidney injury (AKI) incidence and its associated risk of mortality in patients with implantable left ventricular assist devices (LVAD).

**Methods:** A systematic literature search in MEDLINE, EMBASE, and Cochrane Databases was conducted through January 2020 to identify studies that provided data on the AKI incidence, and AKI-associated mortality risk in adult patients with implantable LVADs. Pooled effect estimates were examined using random-effects, generic inverse variance method of DerSimonian-Laird.

**Results:** 56 cohort studies with 63,663 LVAD patients were enrolled in this meta-analysis of AKI incidence. The pooled incidence of reported AKI was 24.9% (95%CI: 20.1%-30.4%), but rose to 36.9% (95%CI: 31.1%-43.1%) when applying the standard definition of AKI per RIFLE, AKIN, and KDIGO criteria. The pooled incidence of severe AKI requiring renal replacement therapy (RRT) was 12.6% (95%CI: 10.5%-15.0%). AKI incidence did not differ significantly between types of LVAD (p = 0.35) or indication for LVAD use (p = 0.62). While meta-regression analysis did not demonstrate a significant association between study year and overall AKI incidence (P=0.53), the study year was negatively correlated with incidence of severe AKI requiring replacement therapy (RRT) (slope = -0.068, p <0.001). The pooled odds ratios (ORs) of mortality at 30 days and 1 year in AKI patients were 3.66 (95% CI, 2.00-6.70) and 2.22 (95% CI, 1.62-3.04), respectively. The pooled ORs of mortality at 30 day and 1 year in severe AKI patients requiring RRT were 7.52 (95% CI, 4.58-12.33) and 5.41 (95% CI, 3.63-8.06), respectively.

**Conclusions:** 37% of LVAD patients developed AKI based on standard definitions and 36% developed severe AKI requiring RRT. There was potential improvement in the incidence of severe AKI requiring RRT for LVAD patients. AKI in LVAD patients was associated with increased 30-day and 1-year mortality.

**PO0014**
AKI in the Emergency Department: A Prospective Case-Control Study
Telma H. Ragnarsson,4,1 Margret Kristjansdottir,1 Gisli Gislason,2 Vicente Sanchez-Brunete,3 Margret O. Tomasstorff,1 Olafur H. Samuelsson,1 Runolfur Palsson,1,2 Olafur S. Indridason,1 Landspitali University Hospital, Reykjavik, Iceland; 2University of Iceland, Faculty of Medicine, Reykjavik, Iceland; 3Primary Health Care of the Capital Area, Reykjavik, Iceland.

**Background:** Acute kidney injury (AKI) is an abrupt decline in kidney function that occurs in hours or days. AKI has been thoroughly studied in the hospital setting, however data on community-acquired AKI are scarce. The aim of this study was to investigate the incidence, causes and prognosis of patients presenting with AKI to the emergency department (ED).

**Methods:** This was a prospective case-control study in which serum creatinine (SCr) measurements of all patients presenting to the ED of Landspitali–The National University Hospital in Reykjavik were examined for the presence of AKI. The study started on January 1, 2020, and we present data until March 3, 2020. All patients who met the criteria for AKI were invited to participate. Randomly selected control cases (1:2) were paired according to age, sex and time of ED admission. Participants signed informed consent and were questioned about their medical history, habits and use of medications, including over-the-counter (OTC) medications and supplements, in the week prior to admission. Medical records were also reviewed with regard to prior diseases and medical prescriptions.
Results: From January 1 to March 3, 124 cases of AKI were identified among patients presenting to the ED, 114 (92%) of whom participated in the study. The mean (SD) age of the 114 AKI cases and the 228 controls was 68.7±15.2 years and 68.8±15.0 years, respectively. 43% of cases and controls were female. AKI cases were significantly more likely than controls to have been taking non-steroidal anti-inflammatory drugs (NSAIDs) (36.0% vs 20.6%, p=0.01) in the week preceding the ED visit. In both cases and controls, the usage of OTC NSAIDs was more common than prescription NSAIDs (72.2% and 66.0%). No significant difference was observed between AKI cases and controls in the use of ACE-inhibitors/angiotensin receptor blockers (45.6% vs 39.9%, p=0.314). The use of proton pump inhibitors was less common among AKI cases than controls (27.2% vs 41.7%, p=0.01) and same was true for statins (22.8% vs 33.3%, p=0.045).

Conclusions: These preliminary results suggest a significant contribution of OTC NSAID use to AKI among patients presenting to the ED. A detailed information on adverse events should be provided when these medications are sold over the counter.

Prehospital Systolic Blood Pressure and Lactate Are Early Predictors of AKI After Trauma: A Prospective Validation Study
Toru Nasu,1 Kentaro Ueda,1 Shuji Kawashima,1 Yuko Okishio,1 Kosei Kunitatsu,1 Yasuhiro Iwasaki,1 Seiya Kato,1 1Wakayama Medical University, Wakayama, Japan; 2Wakayama Rosai Hospital, Wakayama, Japan

Background: We have already reported that prehospital systolic blood pressure and lactate can be predictive factors for acute kidney injury (AKI) after trauma. This study is a prospective validation study to determine whether these risk factors are helpful.

Methods: We evaluated all trauma patients who were admitted from January 2019 to December 2019. Patients who were <16 years of age, patients with burns, and patients with chronic kidney disease were excluded from the present study. AKI was defined according to the risk, injury, failure, loss of the kidney function, and end-stage kidney disease (RIFLE) classification from serum creatinine alone.

Results: Four hundred and three patients were included in the analysis. The prevalence of AKI in the overall population was 14.7% including 11.7% of patients with stage R, 2.0% of patients with stage I and 1.0% with stage F. The incidence of stage I and F AKI in the high-risk group (5 of 38 patients, with the positive predictive value of 13.2%) was significantly higher (P<0.001) than that in the low-risk group (7 of 358 patients, with the negative predictive value of 98.1%).

Conclusions: The prehospital systolic blood pressure and early hospital arterial lactate showed good performance in the early prediction of AKI after trauma. These parameters are associated with the early onset of AKI after trauma and may be an early predictor of the effects of treatment to prevent AKI.

PO0016
Association of Race and Risk of Future Scleroderma Renal Crisis at Systemic Sclerosis Diagnosis
Crystal Forman,1 Stephen W. Olson,1 Sarah M. Gordon,2 James B. Hughes,2 Rodger S. Stitt,2 Wayne Bailey,2 Jess D. Edison,2 Robert Nec,2 1San Antonio Uniformed Services Health Education Consortium, Fort Sam Houston, TX; 2Walter Reed National Military Medical Center, Bethesda, MD

Background: Scleroderma renal crisis (SRC) is a rare and severe manifestation of systemic sclerosis (SSc). Although it is well documented that Blacks with SSc have worse morbidity and mortality than non-Blacks, racial predilection for SRC is underreported.

Methods: We examined the association of race and future development of SRC in an SSc cohort.

Results: From January 1 to March 3, 2013 to December 2018. We classified included patients into pure AKI and ACKD two etiology, and renal recovery of biopsy-proven AKI patients.

Background: We retrospectively analyzed the clinical and pathological data of AKI patients who underwent PCI at Duke University Medical Center, Durham, NC.

Methods: We examined the association of self-reported race – black, white, and other – and baseline eGFR with AKI incidence among patients captured in the Duke Cardiac Database for Cardiovascular Disease (DDCD) who underwent PCI at Duke between January 1, 2003 and December 31, 2013. AKI was defined as a 1.5-fold increase in serum creatinine from outpatient reference value before PCI to the peak value within 7 days post-PCI or a 0.3 mg/dl increase from the reference value within 48 hours. We used logistic regression adjusted for demographics, comorbidities, predisposing medications (NSAIDS, RAAS inhibitors, diuretics), PCI indication (presenting with vs without acute coronary syndrome), peri-procedural prophylaxis with IV fluids and n-acetylcysteine, urgency of PCI and BP at time of PCI.

Results: Of 9422 patients (median age 63.6 years [IQR 54 to 72]); 33% female; 75% white, 22% black, 5% other race), 9% developed AKI: 14% of blacks, 8% of whites, 10% in other race groups. After adjustment, black race was associated with greater likelihood of AKI: odds ratio (OR) 1.80 in black (vs white) patients (95% confidence interval (CI) 1.49 to 2.18. Compared to white, other race was not associated with AKI: OR 1.31, 95% CI 0.91 to 1.87. Low baseline eGFR was associated with graded, higher likelihood of AKI: p for trend <0.001. There was no interaction between race and baseline eGFR.

Conclusions: Black patients had nearly twice the likelihood for AKI following PCI than whites despite adjustment for baseline kidney function, prophylaxis and procedural characteristics. Future investigations should identify other factors that predispose black individuals to disparate AKI risk following PCI.

PO0018
The Spectrum of Biopsy-Proven Kidney Diseases in 2027 Patients with AKI
Zulihumaer Abduwwupuer, Shao-shan Liang, Feng Xu, Dandan Liang, Xue Yang, Ying Zhu, Zhihong Liu, Cai-hong Zeng. National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China

Background: Acute kidney injury (AKI) is a group of highly heterogeneous, complicated clinical syndrome. The kidney biopsy plays an irreplaceable role in the evaluation of patients with unexplained AKI and may offer fresh insights into disease heterogeneity. Hence, in this study we aim to analyze the pathological disease spectrum, etiology, and renal recovery of biopsy-proven AKI patients.

Methods: We retrospectively analyzed the clinical and pathological data of AKI patients who went to a kidney biopsy during the hospitalization at our center from January 2013 to December 2018. We classified included patients into pure AKI and ACKD two groups.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Results: The study included 207 AKI patients who had undertaken renal biopsy, while 553 patients were excluded for the total biopsy cases and 31.7% of the total hospitalized AKI cases during the same period. The majority of AKI patients were male (65.1%), with an average age of 42±16.5 years, pure AKI and ACKD account for 21.6% and 78.4%, respectively. Pure AKI mainly presented as AKI-3 (74.8%), while ACKD mostly presented as AKI-1 (53%). The proportion of patients undergoing renal replacement therapy in pure ACKD group was significantly higher than ACKD group (29.3% vs. 11.9%, P < 0.001). In pure ACKD group, acute interstitial nephritis (AIN) was most common (56.1%), followed by acute tubular necrosis (ATN) (34.6%). The main cause of AIN was due to drugs (84.9%) and infections (14%) and more patients required dialysis. AKI patients had a wide spectrum of pathological diseases, and the prognosis of renal recovery was worse than pure AKI.

PO0019
Higher Ambient Level of Nitrogen Dioxide Is Associated with an Increased Risk of AKI
Xin Xu, Yanqin Li, Licong Su, Fan Fan Hou. Xin Xu Nanfang Hospital, Southern Medical University, Guangzhou, China.

Background: Previous studies have suggested that long-term exposure to air pollution increased the risk of chronic kidney disease and its progression. However, the effect of air pollution on the risk of acute kidney injury (AKI) has not been studied.

Methods: We selected from the Epidemiology of AKI in Chinese Hospitalized patients (EACH2 study) AKI cases of which the onset date could be unambiguously determined. We obtained city-specific daily averages of the ambient level of PM2.5, PM10, CO, NO2, SO2, and O3, from the Ministry of Environmental Protection of China. We used the time-stratified case crossover approach to examine the association between the ambient level of air pollutants and the risk of AKI in the selected cases.

Results: A total of 11,293 AKI cases that met the inclusion and exclusion criteria were selected, of which, 3175 (28.1%) were severe AKI (stage 2 or 3). In univariable analysis, the ambient levels of NO2 and SO2 were significantly associated with the risk of AKI in the group. In the multivariable analysis that incorporated all six pollutants in the same model, NO2 was the sole pollutant whose level remained to be associated with the risk of AKI (p < 0.001). The relationship between level of NO2 and the risk of AKI appeared to be linear, with an estimated odds ratio of 1.072 (95% CI: 1.033, 1.113) for each increment of one standard deviation.

Conclusions: Among biopsy-proven AKI patients, pure AKI was relatively rare while ACKD accounts for the majority. Pure AKI tends to be more severe than ACKD and more patients required dialysis. ACKD patients had a wide spectrum of pathological diseases, and the prognosis of renal recovery was worse than pure AKI.

Funding: Private Foundation Support

PO0020
AKI After Procedures of Orthoptic Liver Transplant: Risk Factors, Renal Outcomes and Survival

Background: The incidence of acute renal injury (AKI) after orthotopic liver transplantation (OLT) ranges between 40 and 70%. The etiology of this syndrome is multifactorial.

Methods: Medical records of patients undergoing OLT in the period from January 2012 to August 2019 were reviewed. A total of 355 patients were included. 171 patients presented AKI. Baseline characteristics, variables during surgery and variables during their stay in intensive were analyzed. Renal outcomes and survival were also analyzed.

Results: In the group without AKI age mean was 45.8 years and 37% were men, in the group with AKI the age mean was 51.2 years and 54% were men (P < 0.001). Mean baseline creatinine was 0.77 vs while 0.88 mg/dl (P < 0.001). Fuorescure prior to transplantation was found; 51.6% vs 71.9%, P < 0.001. A difference was also found between the incidence of AKI in the group that underwent transplants in the 3 months prior to transplantation (50%), the 3–6 months prior to transplantation (43.7% vs. P < 0.001) and (0.21 vs. 0.53) During surgery. Difference was found in maximum lactate, maximum dose of norepinephrine and vasopressin use during surgery: (5.1 vs. 5.8 P < 0.014), (0.59 vs. 0.34 P < 0.001), (36% vs. 51% P < 0.003). Differences were also found in drained anesles and anehepatic period: (1508 vs 973 SD vs 1871 P < 0.021) and (52.9 vs 57.4 P = 0.014). In the stay in the ICU, there was a difference in the income of liquidst first and second 8 hours after transplant (1319 vs 1984 P = 0.001) and (1208 vs 1606 P = 0.009), norepinephrine dose in the first 24 hours (0.14 vs 0.27 P < 0.001), use of vasopressin and strakladalin (27.1% vs 42.1% P = 0.02) and (3.8% vs. 13.9 P = 0.001), transfusion of blodd derivatives 33.1% vs 59% (P < 0.001). There was difference in creatinine and GFR at the end of hospitalization (0.67 vs 0.97 P < 0.001) and (104 vs 82.6 P = 0.001). Survival at 7 days after the transplant 100% vs 96.5% P = 0.01. Survival at 1 year: 99.5% vs 93.6% P = 0.002.

Conclusions: The incidence of AKI in the first 7 days was 48%, which is consistent with that reported in the world literature. The development of AKI seems to be multifactorial influencing baseline characteristics of patients before transplantation and renal function during surgery and intensive care stay. AKI was associated with higher mortality at 7 and 30 days, in addition to lower GFR at patient discharge and higher risk of CKD.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

PO0021
Anemia Following AKI After Non-Carcinoid Surgery and Long-Term Outcomes: The NARA-AKI Cohort Study
Masatoishi Nishimoto,1 Miho Murashima,2 Maiko Kobuk,1 Masaru Matsuri,3 Masahiro Eruguchi,1 Ken-ichi Samejima,1 Yasuhiro Aikai,1 Kazuhiko Tsuruya,1
1 Nara Kenritsu Iku Daigaku, Kashiwara, Japan; 2 Nagoya Shiritu Daigaku Igaku Kenkyukyukai, Nagoya, Japan; 3 Nara-kens Sogo Iryo Center, Nara, Japan.

Background: The aim of this study was to investigate whether acute kidney injury (AKI) is an independent predictor of anemia and whether anemia following AKI is a mediator of mortality after AKI.

Methods: This is a retrospective cohort study. Adults who underwent non-cardiac surgery from 2007 to 2011 were included. Those with obstetric or urological surgery, missing data for analyses, or preoperative dialysis were excluded. Subjects were followed until the end of 2015 or loss to follow-up. The exposure of interest was postoperative AKI defined by KDIGO criteria. The outcome variables were hematocrit values measured at 3, 6, and 12 months postoperatively and mortality. Associations between AKI and hematocrit or association between AKI and mortality were examined by multivariable linear regression or cox regression analyses, respectively. Data were adjusted for potential confounders.

Results: Among 6692 subjects, 445 (6.6%) developed AKI. Among those with postoperative data, AKI was independently associated with lower hematocrit values at 3, 6, and 12 months postoperatively, with coefficients [95% confidence interval] of [−0.79 to −1.47] to [−0.11], n=1750, −1.35 [−2.11 to −0.60], n=1558, and −0.91 [−1.59 to −0.22], n=2463, respectively. Higher stages of AKI and longer duration of AKI were associated with more severe anemia. AKI was associated with higher mortality after 3 months postoperatively with hazard ratio [95% confidence interval] of 1.54 [1.12 to 2.12]. Further adjustment with hematocrit values at 3 months attenuated the association (1.45 [1.05 to 2.00]). Median effect was significant (p=0.02) by mediation analysis.

Conclusions: AKI was an independent predictor of anemia following AKI. This might be due to permanent interval damage and impaired erythropoietin production. Higher mortality associated with AKI was at least partially mediated by anemia following AKI. Whether correction of anemia following AKI improves outcome of AKI requires further research.

PO0023
Decreased Urinary Uromodulin Is Potentially Associated with AKI: A Systemic Review and Meta-Analysis
You Ruilian, Hua Zheng, Limeng Chen. Peking Union Medical College Hospital, Beijing, China.

**Background:** Conventional diagnostic criteria based on the serum creatinine isn’t sensitive enough to detect Acute Kidney Injury (AKI) timely. Urinary uromodulin (uUMOD) is one of the novel biomarkers being studied for the value of predicting AKI. However, currently available publications showed inconsistent outcomes. This meta-analysis aimed to evaluate the potential association between uUMOD and AKI.

**Methods:** We searched research articles in Pubmed-Medline, Web of Science, Cochrane library, Embase, China National Knowledge Infrastructure, and Weipu Databases (up to 2020). Random-effects models were used to estimate the standardised mean difference (SMD) between AKI and Non-AKI. The sensitivity analysis was conducted using the leave-one-out method. Random-effects meta-regression was performed to evaluate the impact of potential confounders on age and surgery.

**Results:** The meta-analysis was comprising 2678 subjects of 8 studies, which showed that the uUMOD in the patients with AKI was significantly lower than the Non-AKI patients (SMD:-0.77, P=0.001, 95% confidence interval -1.07, -0.47). Subgroup analysis indicated a significant difference in different ages and surgery group (Figure1-2). Sensitivity analysis displayed the promising diagnostic values and mechanisms in protecting AKI.

**Conclusions:** The study suggests a potential negative association between uUMOD and AKI. Further studies are needed to investigate the promising diagnostic values and mechanisms in protecting AKI.

PO0024
Independent Predictors of Checkpoint Inhibitor-Associated AKI

**Background:** Checkpoint inhibitors (CPI)-associated acute renal injury (AKI) is an adverse effect of these therapies and its incidence is 13-29%. Clinical characteristics and risk factors of CPI-associated AKI were investigated.

**Methods:** Clinical and demographic data of patients receiving CPI March 2018-May 2019 were evaluated. Patients were divided into two groups depending on the development of AKI.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

PO0025
Relationship of Loop Diuretic with Hospital-Acquired AKI: A Multicenter, Propensity Score-Matching Analysis
Yanqin Li, Licong Su, Xin Xu. Nanfang Hospital of Southern Medical University, Nephrology Guangzhou, China; National Clinical Research Center for Kidney Disease; State Key Laboratory of Organ Failure Research, Guangzhou, China.

**Background:** Loop diuretics have been widely used to prevent and treat acute kidney injury (AKI). However, there is no clear consensus on the role of loop diuretics in AKI.

**Methods:** The Epidemiology of AKI in Chinese Hospitalized patients is a multicenter retrospective cohort included 3,044,024 hospitalized patients from 25 tertiary hospitals across China between 2013-2015. Patient data were obtained from the electronic hospitalization information system. We selected 57589 adult patients who had at least two serum creatinine tests within any 7-day window during their first 30 days of hospitalization and excluded those with end-stage renal disease, community-acquired AKI and without prescription data. AKI was defined using the SCr data by the Kidney Disease Improving Global Outcomes criteria. Exposure to Loop diuretics as any filled prescription within 14 days prior to the detection date of AKI in patients with HA-AKI and within 14 days prior to the last SCr testing date in those without AKI. Propensity scores were calculated using a logistic regression model with age, gender, hospital, division, baseline SCr, SCr testing times, comorbidities, operation procedures, need for intensive care and exposure to other nephrotoxic drugs. Moreover, the inverse probability of the treatment weighting (IPTW) method and standardized mortality ratio weighting method was also used.

**Results:** Of 57589 adult analysed, 20599 (35.8%) used diuretics, 17077 (29.7%) used loop diuretics, and 6277 (10.9%) had HA-AKI events during hospitalization. 8,274 pairs matched after nearest-neighbor matching without replacement and within caliper width (0.2*SD of the logit of PS). By IPTW, use of loop diuretics was associated with a significantly increased risk of HA-AKI compared with non-users (OR, 1.39; 95% CI, 1.28-1.52). The associations were consistent across multiple regression models.

**Conclusions:** Loop diuretics were widely used and associated with an increased risk of HA-AKI in hospitalized adult in China.

AKI and Bleeding Risks Associated with Vitamin K Antagonists and Antiplatelet Agents in Patients with CKD

Soleine M. Laville, Marie Metzger, Agnès Hamroun, Katharine Lambert, Christian Jacquelinet, Maurice Laville, Luc Frimat, Denis Fouque, Christian Combe, Roberto Pecotis-Filho, Benedicte Stengel, Ziad Massy, Souda Lameif, Soumaila Diallo, Nisrine Hassouni, Christian Solene, and Cyril Derumeaux

Background: Anticoagulation in patients with chronic kidney disease (CKD) is challenging because of altered pharmacodynamics/pharmacokinetics. Patients prescribed vitamin K antagonists (VKA) are at high risk of bleeding, and possibly also acute kidney injury (AKI). We assessed bleeding and AKI risks associated with VKA and/or antiplatelet agents (AP) prescription in patients with moderate or advanced CKD.

Methods: We studied a cohort of 30,222 nephrology outpatients with CKD stages 2-5 in 2016 and their prescriptions. Drug prescriptions and their duration were collected prospectively. We used cause-specific Cox proportional hazard models to estimate hazard ratios (HRs) of bleeding (identified through hospitalizations) and AKI (as defined according to KDIGO 2012) associated with VKA only, AP only, or VKA + AP prescriptions treated as a time-dependent variable and adjusted for baseline comorbidities, laboratory data, and medications.

Results: At baseline, 65% of the patients were men, median age was 69 (interquartile range (IQR), 60-76), median eGFR was 32 ml/min/1.73m² (IQR, 23-41), 328 (10%) patients were prescribed VKA only, 1196 (40%) AP only, and 100 (3%) both VKA and AP. Over a median follow-up of 3.0 years (IQR, 2.6-3.1), 71 (2%) patients were newly prescribed VKA and 187 (6%) AP; 152 patients experienced a bleeding event requiring hospital visit/stay (crude incidence rate (IR): 1.1% per-person years (IQR, 6.2-2.2)) and 414 patients had at least one interval between two continuous SCr testing <14 days during the first 30 days of hospitalization and medication data from 6 months before until 30 days after first prescription. The greater nephrotoxicity of ibuprofen use was associated with significantly increased risk of HA-AKI (hazard ratios, HR 2.29; 95% CI, 1.41-3.73) compared to the other two groups (82.8% vs. 60.0% vs. 36.1%, P < 0.001).

Conclusions: This study confirms the high risk of AKI associated with VKA prescription in CKD patients. It also highlights the potential aggravating effect of combining VKA and AP on the risk of bleeding in this population.

Use of Ibuprofen and the Risk of Hospital-Acquired AKI in Children

Lisetang Su, Yanqin Li, Xin Xu, Nanfang Hospital, Southern Medical University, Guangzhou, China.

Background: Ibuprofen is widely used in children worldwide, especially in children with cancer, fever or trauma. However, large and high-quality studies on the association between ibuprofen and acute kidney injury (AKI) in children have been lacking.

Methods: The Epidemiology of AKI in Chinese Hospitalized Patients (EACH2 study) is a multicenter, retrospective study of 3,044,023 patients admitted from 2013 to 2015 at 25 academic medical centers in China. Patient-level data were obtained from the electronic hospitalization information system. We included 50,420 hospitalized children aged between 1 month to 18 years who had at least one SCr test during the first 3 days of hospitalization and at least one interval between two continuous SCr testing <14 days during the first 30 days of hospitalization, excluding those with end-stage renal disease, community-acquired AKI, insufficient SCr testing and without prescription. AKI was defined as an increase of at least 0.3 mg/dL in serum creatinine (SCr) and/or any interval between two continuous SCr testing <14 days during the first 30 days after prescription.

Results: We studied 3896 individuals (mean age 64.5 ± 13.3 years) with incident prescriptions: 138 in the NSAID group and 3738 in the non-NSAID group. 30-day AKI and/or hyperkalemia occurred in 525 individuals (13.5%). After adjusting for age, gender, plasma baseline SCr, eGFR, serum potassium, NSAID, RAAS blocker and diuretic, baseline SCr (adjusted OR 1.41, 95% CI 1.03-1.91, p=0.01), RAAS blocker (adjusted OR 1.42, 95% CI 1.15-1.75, p<0.001), diuretic (adjusted OR 1.91, 95% CI 1.53-2.38, p<0.001) and higher baseline serum potassium (adjusted OR 1.36, 95% CI 1.19-1.57, p<0.001) were independent predictors for the outcome. NSAID prescription for patients with a history of AKI was associated with a higher risk of AKI (adjusted OR 1.62, 95% CI 1.09-2.65, p=0.05). The risk of AKI and/or hyperkalemia was markedly increased if NSAID was prescribed concurrently with RAAS blocker (adjusted OR 4.17, 95% CI 1.74-9.98, p<0.001) or diuretic (adjusted OR 3.31, 95% CI 1.99-10.08, p=0.04).

Conclusions: NSAID prescription in individuals with DM may be associated with AKI and/or hyperkalemia, especially with concurrent RAAS blocker or diuretic.

PO0029

A Retrospective Cohort Study of Chemotherapy-Related AKI

Xin Kang, Li Yang, Renal Division, Peking University First Hospital, Peking University, Beijing, China.

Background: Chemotherapy-related acute kidney injury (CR-AKI) is increasing worldwide. However, there is limited information available about CR-AKI in China.

Methods: This is a multicenter retrospective cohort study of cancer patients with CR-AKI screened from a cohort of hospital-acquired adult AKI patients based on a nationwide AKI survey in China. The enrolled CR-AKI patients were divided into three groups according to peak AKI stages (1 to 3) during hospitalization. The primary outcome was all-cause death in hospital, and the secondary outcome was AKI recovery.

Results: Of 3,468 adult inpatients with hospital-acquired AKI identified basing on the China nationwide AKI survey, 258 patients with CR-AKI were enrolled in our study, of which 20.1% (52/258) were 70 years old. A total of 413 person-time chemotherapeutic agents were related to AKI, of which platinum compounds (24.5%, 101/413) were the most common ones, followed by fluoropyrimidines (13.1%, 54/413), and anthracyclines (9.2%, 38/413).

Conclusions: Of 258 CR-AKI patients, 61 (23.0%) reached AKI stage 3, and 37 (14.3%) received RRT in the hospital mortality. 14.9% (38/258) of the 207 surviving patients with a reliable serum creatinine value at discharge, 48.3% (100/207) failed to renal recovery. AKI stage 3 remained the independent risk factor for in-hospital death (OR 2.930, 95% CI 1.156-7.427) after adjustment for gender, age, comorbidities, and medications. It is surprising to note that, although patients of AKI stage 1 had lower levels of SCr both at peak and at discharge compared to patients of AKI stage 2 or 3, there was a higher proportion of patients of AKI stage 1 not achieving renal function significantly improved at discharge (failure to recover) compared to those of AKI stage 2 or 3 (37.1% vs. 41.4% vs. 36.4%, P = 0.032). More importantly, a lot more AKI episodes were not recognized or diagnosed by physicians in charge in patients of AKI stage 1 compared to the other two groups (82.8% vs. 60.0% vs. 36.1%, P < 0.001).

Conclusions: CR-AKI accounted for a considerable proportion of hospital-acquired AKI. Severe CR-AKI increases in-hospital mortality. Mild CR-AKI that overlooked by physicians sustained kidney injury was common in these patients. Recognizing CR-AKI at an early stage and making personalized treatment should be emphasized when offering chemotherapy to patients.
Characterizing AKI from Vancomycin-Associated Nephrotoxicity in Adult Non-ICU Patients at an Inner City Hospital: Incidence and Predictors

Gerald Fletcher,1,2 Levard G. Roberts,1,2 Sai S. Achi,1 Sheldon Ferguson,1 Maryam M. Handoor,1 Richard S. Shephard,2 Aye M. Aung,1 Sudhanshu Jain,1 Sushma,1 Andraly,1 Harlem Hospital Center, New York, NY; Emory University, Atlanta, GA; The University of Arizona Health Sciences, Tucson, AZ

Background: Vancomycin is a widely used antibiotic in the in-patient setting. Concerns of vancomycin-associated nephrotoxicity (VAN) were raised due to impurities associated with the first released parenteral formulations in the 1950s. Nephrotoxicity is reported to have markedly declined with a wide variability in the incidence. There is a dearth of information on the current incidence of VAN as a cause of acute kidney injury (AKI) in adult non-ICU populations. The purpose of this study was to estimate the incidence of VAN AKI and identify risk factors of VAN for this population.

Methods: A cohort of patients admitted between January 2015 and December 2017 with the diagnosis of AKI and who received at least 3 days of parenteral vancomycin therapy were identified through a retrospective chart review. Exclusions were ESRD or CKD history. Our primary outcome was the occurrence of VAN AKI, defined as an increase in serum creatinine by 0.3 mg/dl or 50% above baseline after vancomycin exposure. The incidence of VAN AKI was determined and we estimated risk factors associated with VAN in a logistic regression model.

Results: 587 adult patients received at least 72 hours of parenteral vancomycin for the treatment of sepsis during the period. Demographics were: male 350 (59.6%), female 237 (40.4%) and mean age of 62.3 years. Distribution by ethnicity: non-Hispanic Blacks 71.2%, Hispanics 12.6%, non-Hispanic white 3.4% and 12.4% were other ethnicities. The incidence of VAN AKI was 15.24%. These patients had a longer hospital stay (26.8 versus 21.3 days for no VAN AKI), higher mean vancomycin trough levels, longer duration of exposure to vancomycin and a higher Charlston Comorbidity Index (3.5 versus 2.6). Independent predictors for VAN were: mean vancomycin trough level, hypertension, COPD, congestive heart failure, liver disease, severe obesity and dementia (all p values <0.05). Previous ICU admission and hypotension status did not predict VAN AKI.

Conclusions: We reported an incidence of VAN AKI of 15.24% in non-ICU adult patients with no history of ESRD or CKD. Risk factors associated with the development of VAN include mean vancomycin trough level, hypertension, congestive heart failure, COPD, liver disease, severe obesity and dementia.

Baseline Urinary Protein Biomarkers as Predictors of eGFR Decline in Cancer Patients Receiving Cisplatin

Melanie S. Joy,1 Blessley George,1 Yichun Hu,2 Susan L. Hogan,2 Xia Wen,3 Lauren Aleksunes.3 1University of Colorado, Skaggs School of Pharmacy, Cancer Center, and Division of Renal Diseases and Hypertension, Denver; CO; 2University of North Carolina, Kidney Center, Chapel Hill, NC; 3Rutgers University, Ernest Mario School of Pharmacy, Piscataway, NJ

Background: Previous data from our group reported significant changes in urinary biomarkers of sub-clinical kidney injury over 10 days after receiving i.v. cisplatin. The current study evaluated the performance of single and a combination of two urinary biomarkers at the time of cisplatin initiation in predicting a reduction in eGFR.

Methods: Patients (n=57) with solid tumors receiving i.v. cisplatin (25 mg/m²) were enrolled in a study to characterize concentrations of 9 urinary proteins (Table). For the outcome of eGFR decline, the eGFR (MDRD equation) after the first dose and one measure at 3-7 days of stay. Exclusion criteria consisted of age ≥ 75 years, baseline eGFR <60 ml/min/1.73m², ESKD, or CKD stage 5. AKI was defined as a change of serum creatinine level ≥ 0.3 mg/dL or ≥ 1.5 times in contrast to normal baseline value within 48 hours. We evaluated if the microscopic examination of the urine sediment (score ≥ 2) could be used as a non-invasive detector of renal damage.

Results: Mean (SD) age was 65.1 (17.2), 38.4% were women and 100% Hispanic. The incidence of AKI at 3-7 days of hospital or ICU stay was 34.9%. From the 30 patients that developed AKI, 20 were on stage 1 (66.6%), 8 were on stage 2 (26.6%) and 2 were stage 3 (6.6%). Performance metrics of the urinary score used are reported in Table. A urinary sediment score ≥ 2 exhibited a fair, but not good, AUC of 0.681 (95% confidence interval [CI]: 0.554–0.808) in ROC analysis.

Conclusions: Cellular casts and granular casts are occasionally observed in hospitalized adult patients with risk factors for AKI. The urinary sediment score proposed by Perazella et al. could be a potentially useful marker for early documentation of hospital-acquired AKI.

Funding: Private Foundation Support

Table: Performance of the urinary sediment score for the prediction of AKI in hospitalized patients
Methods: 107 patients (23-77 years, 53 females) when they were first prescribed RASb for primary hypertension (PHT) (n=25), diabetic nephropathy (DN) (n=12), PHT+DN (n=8), congestive heart failure (n=26) and proteinuric nephropathies (n=36). Changes in serum creatinine (Scr), mean sUA levels and systolic (SBP) and diastolic (DBP) blood pressures (mmHg) were obtained from records before and 3, 1±0.2 months after RASb.

Results: Baseline eGFR (ml/min/1.73m²) was 43.6±2.81 and 64.4±8.89 in male and female patients, respectively. 55% male and 51% female patients increased Scr with RASb but only 8 male and 2 female patients increased baseline Scr more than 0.3mg/dl. RASb reduced significantly SBP (pre130±7.167 vs. post124.1±5.71, p=0.004) but not DBP. Reduction in eGFR was found in 87% of the patients in whom SBP was reduced by RASb. Reduction of SBP was unrelated to the increase in Scr. sUA (mg/dl) was 6.9±0.1 (males) and 6.1±0.2 (females) (p=0.09). In female there was no relation between UA levels and change in Scr. In male there was a direct relationship between changes in Scr (Scr/pre-Scr/Post) and the mean serum UA levels (sr=0.36, p=0.008) that was unrelated to SBP changes. Relationship was stronger in male patients with sUA ≥7.0 (f<0.051).

Conclusions: Since 14% of the male patients treated with RASb increased Scr more than 0.3 mg/dl and deterioration of kidney function was directly related to sUA levels, the potential benefit of reducing sUA in male patients treated with RASb should be investigated further.

PO0036 Seizure-Induced Hyperuricemia and Associated Urate Nephropathy: A Prospective Cohort Study

Jean Maxime Coté,1,2 Guillaume Bolle.1 Centre Hospitalier de l’Université de Montréal, Montréal, QC, Canada; 2University College Dublin, Dublin, Ireland.

Background: Urate nephropathy is an uncommon cause of acute kidney injury (AKI). Although most factors are associated with tumor lysis syndrome and rhabdomyolysis, occurrence following severe seizure has also been described. There are effective ways to prevent and treaturate-associated AKI, when adequately identified. However, uric acid measurement following convulsion episodes is rarely performed and therefore, the incidence of hyperuricemia in this context is unknown. Our objective was to quantify these metabolic disturbances following severe generalised tonic-clonic seizures (GTCS).

Methods: We prospectively recruited patients admitted in our hospital for severe GTCS (≥5 min or a series of seizures with an incomplete return to baseline) and described the kinetics of serum uric acid, creatinine, creatine kinase and lactate during a 72h follow-up. The creatine-urate ratio was used to monitor urate tubular toxicity.

Results: From August 2018 to September 2019, 13 patients with a median GTCS duration of 5.0 minutes (IQR 2.0-12.5) were included. The median serum uric acid was initially 346.0 µmol/L (IQR 155.0-377.5) and decreased to 178.0 µmol/L (IQR 140.0-297.5), while serum creatine passed from 73.0 µmol/L (IQR 151.0-80.0) to 57.0 µmol/L (IQR 44.0-70.0) over follow-up (Figure). AKI occurred in 4 patients (KDIGO Stage A1).

Conclusions: Serum uric acid levels increase acutely following a severe GTCS than return to baseline within 3 days. During that period, there is an increased risk of AKI that might be associated with urate nephropathy. To quickly identify and manage patients at risk of acute hyperuricemia, related complications, measurement of uric acid following a GTCS might be beneficial.

PO0035 Relationship Between Serum Uric Acid Levels and Reduction in Kidney Function Associated With Blockade of the Renin-Angiotensin System

Marcos G. Nava,1 Maria Guadalupe C. Núñez,1 Pedro Gudiño Bravo,1 Alfredo Fonseca Chávez,2 Bernardo Rodríguez-Iturbe,1,2 Magdalena Madero,1 1Instituto Nacional de Cardiología Ignacio Chávez, Nephrology Department, Mexico, Mexico; 2Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubiran, Departamento de Nefrología y Metabolismo Mineral, Tlalpan, Mexico.

Background: Renin-angiotensin system blockade (RASb) induced by treatment with angiotensin type 2 receptor antagonists and angiotensin converting enzyme inhibitors is frequently associated with a reduction in glomerular filtration rate (GFR). Experimental hyperuricemia is associated with dysregulation of renal hemodynamics and reduced GFR. We studied if serum uric acid (sUA) levels are related to the depression of renal function associated to RASb.
Late Presentations of Secondary Oxalate Nephropathy
Muna Hale, Pranay Kathuria. The University of Oklahoma - Tulsa, Tulsa, OK.

Introduction: Secondary Oxalate nephropathy is an important differential diagnosis for acute kidney injury (AKI) in chronic malabsorptive disease. Mean presentation is typically within 1-2 years. The following three cases are example of late, abrupt presentations of secondary oxalate nephropathy.

Case Description: Our first case includes a 69-year-old female, with gastric bypass surgery 14 years prior, who presented to emergency room (ER) with AKI. Six months prior her creatinine (Cr) was 1.6 mg/dL, but abruptly increased to 5.99 mg/dL. Serologic work up was negative. Renal biopsy was obtained that revealed deposition of oxalate crystals within renal tubules (Figure 1). Our second case showed a 59-year-old male with history of recurrent pancreatitis due to bulimia that presented to the ER for nausea and vomiting. In the ER, patient had a serum Cr of 5.79 mg/dL. Two months prior, Cr was 1.1 mg/dL. Renal biopsy showed widespread oxalate crystals in the interstitium. The last case was a 48-year-old male with chronic pancreatitis who presented with AKI with suspect acute tubular necrosis. He had been diagnosed with chronic pancreatitis for at least 6 years with Cr 0.9 mg/dL. Patient’s Cr remained at 4.00 mg/dL one month later. Renal biopsy revealed interstitial fibrosis and calcium oxalate crystals.

Discussion: Secondary oxalate nephropathy is a side effect of malabsorptive gastrointestinal (GI) disorders. According to prior case series, the mean presentation of oxalate nephropathy is 1-2 years. These cases illustrate that secondary oxalate nephropathy can present at a later course with rapid onset. Patients also likely progress to ESRD after diagnosis. A systemic review of 108 cases, with 13 months follow up, showed 55% of patients required hemodialysis. Currently, there is no treatment and lifestyle changes include a low fat, oxalate diet. Secondary oxalate nephropathy should be considered in the differential of all patients with malabsorptive states presenting with AKI.

Presentation and Outcome of Oxalate Nephropathy Without Known Genetic or Gastrointestinal Cause
Erin E. Bolen,1 Mina Abdelmalek,1 John C. Lieske,2 Mira T. Keddis.1 1Mayo Clinic Arizona, Scottsdale, AZ; 2Mayo Clinic Minnesota, Rochester, MN.

Background: Oxalate nephropathy (ON) is a frequent and often unexpected finding on kidney biopsy. This study aimed to characterize causes and outcomes in biopsy-proven ON not due to known enteric cause or primary hyperoxaluria (PH) in a multisite health system.

Methods: Cases were identified based upon diagnosis of ON on kidney biopsy between 2009 to 2020 without known enteric or primary cause.

Results: Thirty-four cases were identified with a median follow-up of 11.9 months. None had known fat malabsorption. Genetic testing for PH was negative in 11, and there was no clinical suspicion of PH in the rest. Likely causes of ON included documented high dietary oxalate (7, 21%), oral and/or IV vitamin C supplementation (7, 21%), ethylene glycol (3, 9%), and orlistat (1, 3%). No cause could be identified in 16 (47%). Table 1 shows variables across three etiologies: unknown cause, diet-related, and vitamin C. All cases except one had diffuse intratubular calcium oxalate deposition on biopsy. End stage kidney disease (ESKD) was present in 53%. AKI stage III at biopsy was predictive of ESKD at last follow-up (p=0.05). Treatments included low oxalate diet (29, 85%), calcium supplementation (18, 53%), pyridoxine (12, 35%), and prednisone taper (12, 35%). Diet-related ON appeared to have lower rates of AKI stage III at diagnosis (5, 67%), ESKD (3, 43%), and mortality (2, 29%) compared to vitamin C-related ON and ON of unknown etiology.

Conclusions: This is the largest study of ON not due to PH or enteric cause. The most common causes were high-oxalate diet and high-dose vitamin C. In 47% of cases no cause was identified. ESKD was common, and AKI severity at presentation predicted ESKD at last follow up. Cases attributed strictly to dietary excess may have better short and long term outcomes.

Funding: Clinical Revenue Support
Incidence of AKI After IV Vitamin C Treatment for Septic Shock: A Cohort Analysis of Real-World Application

Thomas R. McCune,1,3 Jaingtao Luo,1,2 Brynn E. Sheehan,1,2 Stephen T. Petri,1 Muhammad K. Sherehi,1 Sunita Dodani,1,2 1Eastern Virginia Medical School, Norfolk, VA; 2EVSMS-Sentara Healthcare Analytics and Delivery Science Institute (HADS), Norfolk, VA; 3Neurology Associates of Tidewater, Norfolk, VA.

Background: Septic shock patients exhibit a high prevalence of vitamin C deficiency, and intravenous vitamin C (IVC) may provide a survival advantage. Preliminary findings from early studies were promising, however, recent studies fail to show a benefit of vitamin C on mortality. Case reports observed that IVC may be related to acute kidney injury (AKI) through oxalate-nephropathy. While IVC in sepsis merits further research, clinicians at one institution began the use of IVC as additional treatment for septic shock.

Methods: This study is a retrospective analysis of real-world evidence to evaluate the effects of IVC on AKI in patients with septic shock.

Results: A total of 22980 patient visits were evaluated. Of the 2067 patients who were admitted through the ED with a discharge diagnosis of septic shock, 433 (20.9%) received one dose of IV-C 1500mg and were categorized as the IVC+ group; 1634 (79.1%) did not receive IVC. A chi-square analysis can be seen in Table 1.

Conclusions: This retrospective study EMR observed that IV-C in the treatment of septic shock is associated with an increase in the incidence of AKI.

Funding: Clinical Revenue Support

Table 1. Chi-square Analysis Examining the Relationship between IVC and the Development of AKI among Inpatients with Septic Shock.

Note: A logistic regression revealed that the odds of AKI were 2.57 times higher for IVC patients compared to non-IVC patients (95% CI 2.053, 3.23).
PO0043
Zolpidem Mega Dose Resulting in Hemodialysis

Introduction: Depression and hyperventilation syndromes are factors that may be overlooked when prescribing Zolpidem. Although hypnotics are not directly associated with rhabdomyolysis, they can lead to severe intoxication and prolonged immobilization. This can lead to compartment/ crush syndromes and depressed respiratory drive and may cause seizures. As consequence of the above renal failure ensued and hemodialysis was required.

Case Description: This portrays a 36-year-old law student who tried to end his life with the ingestion of 90 Zolpidem pills. As consequence of his metabolic derangement he had seizures, rhabdomyolysis and renal failure that required hemodialysis. Due to prompt intervention, hemodynamic stability and full recovery were achieved.

Discussion: The ingestion of 90 Zolpidem pills is a dangerous scenario. In our case, within 4 days of ingestion, the patient presented with myalgias, rhabdomyolysis, acute kidney injury, metabolic acidosis, and respiratory failure. The patient was admitted to the ICU with a Glasgow Coma Scale of 3 and underwent 18 days of renal replacement therapy (RRT) with CVVH initially and then iHD.

PO0044
Severe Exertional Rhabdomyolysis with AKI Associated with Sickle Cell Trait
Zi R. Zhang, Edward Qian, Roger A. Roddy. Rush University Medical Center, Chicago, IL.

Introduction: Exertional rhabdomyolysis (ER) is a pathological breakdown of muscle cells which can result in acute kidney injury (AKI) from multiple mechanisms including tubular toxicity from hemoglobin, pigment, cast formation, and volume depletion. ER has a host of etiologies including drugs, infections, infections, electrolyte abnormalities, trauma, venom, and metabolic disorders. Sickle Cell Trait (SCT), a generally asymptomatic condition, has been rarely associated with ER. We present a case of severe ER with AKI in a previously healthy patient who was determined to have SCT as the only risk factor.

Case Description: A 39 y/o previously healthy black police recruit on no medications presented with myalgias and dyspnea following a routine training regimen. He was found to have diffuse tenderness and weakness of arms and legs. Initial labs showed serum creatinine (sCr) 2.0 mg/dL, Na 148 mmol/L, CO2 <5 mmol/L, Creatine Kinase (CK) 1,516 U/L. A peripheral blood smear showed few sickle cells. His urine was dark tea-colored and on urinalysis had large blood and minimal RBCs. Illicit drug panel, autoimmune studies, myophosphorylase deficiency, and myostatin panel including anti-SSA, anti-PM/Scl, and anti-U1RNP were normal or negative. A hemoglobin electrophoresis demonstrated 35% Hgb S and 62% Hgb A consistent with SCT. He was oliguric and was started on renal replacement therapy (RRT) with CVVH initially and then iHD. His CK and sCr peaked at 565,000 U/L and 13.9 mg/dL respectively (figure 1). He required 18 days of RRT. His sCr after discharge improved to 1.4 mg/dL.

Discussion: SCT is normally a relatively benign condition as there is enough normal Hgb to prevent significant sickling. However, increased O2 demand with exertion may promote clinically significant sickling and lead to vaso-occlusion and hypoxic muscle injury. ER in SCT is rare and unpredictable and therefore specific recommendations for re-introduction of exercise are not available. However, guidelines for Exercise Collapse Associated with Sickle Cell Trait (ECAST) can be used to guide long term patient management.

**PO0046**

**Postrenal AKI due to a Rarely Seen Neoplastic Phenomenon in an Adolescent**

Ana J. Prashad cortes,1 Rasheda Amin,3 Carly R. Varela.1 1Inova, Falls Church, VA; 2Pediatric Specialists of Virginia, Fairfax, VA

**Introduction:** AKI is an important cause of morbidity & mortality in adult and pediatric patients. Based on a lit review by Cleto-Yamane, et al., the pediatric incidence & mortality of AKI in the USA in 2013 was 0.39% and 15.3%, respectively. In general, a patient’s presentation may provide clues to the etiology of AKI (i.e. prerenal, intrarenal and postrenal). AKI due to postrenal/obstructive causes is less common in children as compared to adults and is usually associated with congenital abnormalities e.g. posterior urethral valves, or acquired due to stones or tumors. We report the case of a 14 yo previously healthy female with a unique clinical presentation due to lower urinary tract obstruction secondary to a tumor.

**Case Description:** The patient presented with 3 weeks of back pain, R leg swelling, headaches, urinary frequency, n/v and hematuria. In the ED, her BUN and creatinine were 107 mg/dL and 21.1 mg/dL, respectively. A RUS showed enlarged non-echogenic kidneys with mild bilateral hydronephrosis & a heterogeneous pelvic mass. Further labs revealed anemia, low PT, normal complement levels, ASO & ANA titers. A LE Doppler study was negative for venous thrombosis. A non-contrast MRI revealed a pelvic mass & possible obstruction secondary to a tumor.

**Rasburicase was given & CRRT was initiated. She received emergent chemotherapy with Cyclophosphamide, doxorubicin & vincristine. Bilateral percutaneous nephrostomy tubes were placed with improvement in UOP & renal function allowing CRRT to be stopped.**

**Discussion:** Our patient’s clinical presentation was atypical in that her initial US findings of mild hydronephrosis were not consistent with the severity of her renal injury. Her AKI was likely a combination of obstructive uropathy from the large pelvic tumor compressing her lower urinary tract & uric acid nephropathy. Decompression of the urinary system, management of hyperuricemia & initiation of tumor directed chemotherapy resulted in marked improvement of kidney function. Our case highlights the importance of considering an obstructive etiology in older children presenting with AKI.

**PO0047**

**Profiling AKI Trajectories: Early Results from the Million AKI Project**

Benjamin C. Bowe.1,2 Yan Xie,3,4 Andrew K. Gibson,1 Miao Cai,1,2 Hong Xian,2 Geetha S. Maddukuri,1 Ziyad Al-Aly.1 1VA St. Louis Health Care System, St. Louis, MO; 2Saint Louis University, Saint Louis, MO.

**Background:** Clinical guidelines for risk stratification of acute kidney injury (AKI) patients are based on peak increases in serum creatinine (SC). These definitions do not consider other characteristics of change in SC that may provide information on risk of adverse outcomes. Identification of patient groups that display distinct patterns in trajectory of SC and outcome profiles may lead to more nuanced risk-based definitions of AKI.

**Methods:** Data from the United States Veterans Health Administration were obtained. A latent class growth model identified patient groups based on similar patterns of trajectory in serum creatinine during a hospitalization with an AKI. Regression models obtained. A latent class growth model identified patient groups based on similar patterns of AKI.

**Results:** We constructed a cohort of 480,575 veterans with an AKI during an inpatient stay (a subset of the Million AKI Project cohort). Of these, 343,471 (71.5%), 63,665 (13.3%), and 73,439 (15.3%) met KDIGO AKI stages 1, 2, and 3 criteria. 9.4% died during their hospitalization. We identified 9 latent trajectories summarized by 4 phenotypes: a mild increase in SC from low baseline (66%), and varying degrees of increase in SC with no (9%), moderate (17%), and near-full recovery (8%). Higher systolic blood pressure (OR=1.02; 95% CI=1.01-1.02 per 1 mmHg), sepsis (2.24; 2.10-2.39), non-use of ACE/ARB (1.54;1.47-1.61), diuretic use (1.16; 1.12-1.20), albuminuria (1.36; 1.31-1.41), and prior history of AKI (1.27; 1.22-1.32) were associated with trajectories with larger increases in SC, while major surgeries (2.48; 2.37-2.60) were associated with trajectories that recovered. Compared to the mild increase group, those with partial or no recovery had a higher odd of in-hospital mortality (1.64; 1.57-1.71) that increased in magnitude with higher baseline SC and a greater increase in SC (2.73; 2.66-2.80). Groups that experienced near-full recovery showed no evidence of a difference in mortality profile (0.97; 0.90-1.05) despite differences in other aspects of the trajectory.

**Conclusions:** Leveraging the depth and breadth of a high-quality longitudinal electronic health record system, we characterized nearly half a million cases of AKI; our results suggest that profiling of AKI trajectories informs risk stratification and may guide deployment of post AKI care.

**Trends in Nephrology Follow-Up After an Episode of AKI in US Veterans**

Ryann Sohaney,1 Houssam Mhanna,1 Maggie Yin,1 Diane Steffick,1 Vahakn Shahinian,1 Nilka Rios Burrows,2 Meda E. Pavkov,3 Raymond K. Hsu,3 Neil R. Poe,4,5 Kara Zivin,6,7 Rajiv Saran,3 Michael Heung.1 1University of Michigan Division of Nephrology, Ann Arbor, MI; 2Centers for Disease Control and Prevention, Atlanta, GA; 3University of California San Francisco, San Francisco, CA; 4Zuckerberg San Francisco General Hospital and Trauma Center, San Francisco, CA; 5University of Michigan, Ann Arbor, MI; 6US Department of Veterans Affairs, Ann Arbor, MI.

**Background:** KDIGO guidelines recommend evaluating patients following AKI for new onset or worsening CKD. Yet, historically nephrologist referral post-AKI has been low. We sought to determine recent trends in outpatient nephrologist follow-up after a hospitalization with AKI.

**Methods:** We assembled a national cohort of US veterans surviving 30-days post hospitalization with KDIGO creatinine-defined AKI from 2008 to 2017, excluding those with ESRD or kidney transplant, those requiring dialysis within 30 days of hospital discharge, or discharged to hospice. The primary outcome was the proportion of AKI survivors completing an outpatient visit with a nephrologist within 6 months of their AKI hospitalization. To assess trends, we assessed the association of year (as a continuous variable) with follow-up in a Cox proportional hazards model adjusting for age, race, sex, AKI stage, hypertension, diabetes, CKD, Charlson Comorbidity Index, ICU utilization, acute myocardial infarction, acute heart failure, and hospital admitting service.

**Results:** Of the 480,200 survivors of AKI, 12.2% had a visit with a nephrologist within 6 months. The proportion of patients with nephrology follow-up ranged from 10.0% in stage 1 AKI to 43.8% in patients with AKI requiring inpatient dialysis. The proportion of patients receiving post-AKI care increased across the study period, from 11.8% in 2008 to 15.4% in 2017 (figure). Upon adjusting for demographics, comorbid conditions, and hospitalization characteristics, year remained a significant predictor of increasing nephrology follow-up after AKI (per year HR 1.024, 95% CI 1.021-1.027, p<0.01).

**Conclusions:** From 2008 to 2017, there was a modest increase in post-AKI follow-up that persisted after accounting for changing demographic, comorbid conditions and hospitalization characteristics. However, most patients with severe AKI did not have an outpatient visit with a nephrologist at 6 months, highlighting opportunities to improve processes of post-AKI care.

Elevated Serum Tenasin C Predicts All-Cause Mortality in Critically Ill Patients with Multiple Organ Dysfunction
Qionghong Xie, Xu Yunyu, Chuan-Ming Hao. Huashan Hospital Fudan University, Shanghai, China.

Background: Tenasin-C (TNC) is a matricellular protein that is rarely expressed in most of adult tissues, but re-induced following injury. This study aimed to evaluate serum TNC in predicting all-cause mortality in critical ill patients with multiple organ dysfunction.

Methods: Adult critical ill patients who met the criteria of at least two organs dysfunction and acute organ injury with an increase of SOFA ≥ 2 points within 7 days were prospectively enrolled in one derivation cohort (Medical ward) and one external validation cohort (Emergency ward). Serum TNC was measured within the first 24 hours after enrollment and the association between serum TNC and 28-day all-cause mortality was analyzed.

Results: A total of 113 patients with median age 56 (38, 66) years and male of 65.2% in derivation cohort, and 120 patients with median (quartile) age of 64 (53, 73) and male of 67% in validation cohort were enrolled. Serum TNC was 210.2 (96.8, 469.6) ng/ml in derivation cohort and 229.4 (141.6, 472.5) ng/ml in validation cohort, both significantly higher than that in healthy controls (median 80.9 ng/ml, n=46, p<0.01 for both). The TNC levels were associated with the critical illness scores such as SOFA, APACHE II and SPAS II, as well as 28-day death probability (p<0.01 for all). Compared to the patients with TNC<300ng/ml, patients with TNC≥300ng/ml had a remarkably higher 28-day mortality (38.6% vs. 14.1%, p=0.003 in derivation cohort; 57.8% vs. 13.8%, p=0.001 in validation cohort). Serum TNC was independently associated with the mortality after adjustment for age, gender and SOFA in both cohorts. The areas under the Receiver Operating Curve of TNC for 28-day mortality was 0.797 in derivation cohort and 0.803 in validation cohort, not inferior to SOFA (0.844 and 0.808), APACHE II (0.86 and 0.762) and SPAS II (0.872 and 0.779).

Conclusions: Serum TNC was significantly increased in critical ill patients with multiple organ dysfunction and was positively associated with the severity of illness and all-cause mortality. It was a useful prognostic tool for predicting all-cause mortality in critical ill patients.
PO0053
Urinary Waxy Casts Are Associated with Persistence of AKI Requiring Dialysis
Maria Soledad Rivera,1 Vinip Varghese,2 Akanksh Ramanand,1 Ali Al Alawan,2 Juan Carlos Q. Vélez,1,2 Ochsner Nephrology, Ochsner Clinical School- University of Queensland, New Orleans, LA; 2Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA.

Background: Waxy casts (WxCs) can be identified during microscopic examination of the urinary sediment (MicrExUrSeD) and they have been classically linked to chronic kidney disease (CKD). We previously showed that WxCs predict severity of acute kidney injury (AKI). Thus, we hypothesized that WxCs may inform about duration and persistence of AKI and AKI requiring renal replacement therapy (AKI-RRT).

Method: We conducted a prospective observational study in patients seen in inpatient nephrology consultation with AKI stage 2 (AKIN) over the 2.5 years. On the day of consult, MicrExUrSeD was performed to determine the percentage of low power fields with WxCs. The outcome measures were persistence of need for RRT at the time of hospital discharge (AKI-RRT-Persist) and sCr increase in serum creatinine (sCr) from baseline at the time of hospital discharge (AKI-Persist).

Results: Urine specimens from 286 patients [median age 60 (20 – 88), 37% women] were assessed. The etiology of AKI de novo 67% AKI, 7% on CKD 33% was ischemic ATI (47%), toxic ATI (9%), ischemic/toxic ATI (11%) or other (33%). WxCs were found in 85 patients (30%), 61 (72%) of which had de novo AKI. Median sCr for those with WxCs was 3.5 (0.9 – 22.0) mg/dL and 3.1 (0.9 – 12.5) mg/dL for those without WxCs (p=0.12). AKI-RRT at any point during the course of AKI was seen in 45% (38/85) of those with WxCs compared to 32% (54/201) of those without WxCs (p=0.043). There was a greater risk for AKI-RRT Persist for those with WxCs [15.3% vs 7.5%, odds ratio (OR): 2.2, CI 1.1 – 4.9, p=0.046]. Presence and abundance of WxCs were also associated with a greater risk for Persist AKI [62% (94/152), 75% (45/60), 81% (29/36) and 93% (13/14), for those with no WxC, any WxC, >10% WxCs and >50% WxCs, respectively; chi-square for trend, p=0.014].

Conclusions: In patients with AKI, the presence and abundance of WxCs are associated with a greater risk for persistent need for RRT and persistent increase in sCr at the time of hospital discharge. These findings suggest that WxCs inform about the severity of AKI and the timeline of significant AKI recovery.

PO0054
Retrospective Analysis of the Efficiency of Caplacizumab in the Treatment of Acquired Thrombotic Thrombocytopenic Purpura: Results from the REACT-2020 Study Group
Lucas Kuehne,1 Jessica K. Kauflé,1 Jan Menne,2 Paul T. Brinkketter,2 Linus A. Volker,1 REACT-2020 study group 1University of Wuppertal Hospital, Wuppertal, Germany; 2Hannover Medical School, Medizinische Hochschule Hannover, Hannover, Germany.

Background: Acquired thrombotic thrombocytopenic purpura (aTTP) is a rare but life-threatening disorder, caused by the formation of inhibitory and occasionally non-inhibitory autoantibodies against ADAMTS13. Despite plasma exchange and immunosuppression, long-term mortality and morbidity associated with acute episodes remain high. Here, caplacizumab – a nanobody approved in Germany in 2018 – has recently expanded the therapeutic options.

Methods: Retrospective analysis of the use of caplacizumab in more than 60 patients with acute aTTP immediately. ADAMTS13 activity measurements are central for a rapid screening of timing and adjunct treatment modalities. Based on this real-world experience and in a sustained reduction of the vWF activity.

Results: 76 patients (30%), 61 (72%) of which had de novo AKI. Median sCr for those with WxCs was 3.5 (0.9 – 22.0) mg/dL and 3.1 (0.9 – 12.5) mg/dL for those without WxCs (p=0.12). AKI-RRT at any point during the course of AKI was seen in 45% (38/85) of those with WxCs compared to 32% (54/201) of those without WxCs (p=0.043). There was a greater risk for AKI-RRT Persist for those with WxCs [15.3% vs 7.5%, odds ratio (OR): 2.2, CI 1.1 – 4.9, p=0.046]. Presence and abundance of WxCs were also associated with a greater risk for AKI-Persist [62% (94/152), 75% (45/60), 81% (29/36) and 93% (13/14), for those with no WxC, any WxC, >10% WxCs and >50% WxCs, respectively; chi-square for trend, p=0.014].

Conclusions: In patients with AKI, the presence and abundance of WxCs are associated with a greater risk for persistent need for RRT and persistent increase in sCr at the time of hospital discharge. These findings suggest that WxCs inform about the severity of AKI and the timeline of significant AKI recovery.

Survey of US Critical Care Practitioners on Perspectives Toward Net Ultrafiltration Prescription and Practice
Huwen Chen,1,2 Raghavan Murugan.2 1University of Pittsburgh Medical Center; Pittsburgh, PA; 2University of Pittsburgh, Pittsburgh, PA.

Background: Previous studies suggest international practice variation in net ultrafiltration (UFnet) among critical ill patients with acute kidney injury treated with kidney replacement therapy. We examined U.S. critical care practitioner attitudes toward UFnet prescription and practice.

Methods: Secondary analysis of a multinational, cross-sectional, internet-assisted, open survey administered to intensivists, nephrologists, advanced practice providers, ICU and dialysis nurses in the U.S.

Results: Of 1,569 international survey respondents, 465 (29.6%) practitioners were from the U.S. Practitioners were mostly nurses and nurse practitioners (58%) and intensivists (38.2%). Median duration of practice was 8.7 (IQR, 4.2-19.4) years and 63.4% practiced in a university- based hospital. Practitioners reported using continuous kidney replacement therapy (CKRT) in 20% (IQR 12-34%) of their patients with medians UFnet rate of 51 mL/h (IQR 25-100 mL/h) for hemodynamically unstable and a maximal rate of 285 mL/h (IQR 200 – 341 mL/h) for hemodynamically stable patients. 58.3% (range 28.7%-79.2%) of practitioners assessed net fluid balance hourly. Hemodynamic instability was reported in 25% (IQR, 10-100%) of the patients, and practitioners decreased the rate of fluid removal (71.2%); started or increased dose of a vasopressor (56.8%); completely stopped fluid removal (44.5%); and administered a fluid bolus (28.7%). Most clinicians (79.8%) reported patient intolerance as a major barrier. Other barriers include frequent interruptions (50.1%), under prescription (17.3%), inability to achieve the target (17.3%), high mortality (13.8%) and availability of resources (13.1%).

Conclusions: This study provides new knowledge on UFnet in practices in the U.S. We also identified barriers and specific targets for quality improvement initiatives. Our data reflect the need for evidence-based practice guidelines for UFnet.

PO0057
A Pilot Trial to Evaluate the Clinical Usefulness of Contrast-Enhanced Ultrasound in Predicting Renal Outcomes in Patients with AKI
Suveon Hong,1 Da won Kim,2 Dongryul Kim,2 Seok Joon Shin,2 Hye Eun Yoon.1 1Uijeongbu St. Mary’s Hospital, Uijeongbu, Republic of Korea; 2Incheon St. Mary’s Hospital, Incheon, Republic of Korea.

Background: Contrast-enhanced ultrasound (CEUS) enables the assessment of real-time renal microcirculation. This study investigated CEUS-driven parameters as hemodynamic predictors for renal outcomes in patients with acute kidney injury (AKI).

Methods: Forty-eight patients who were diagnosed with AKI were prospectively enrolled and underwent CEUS at the occurrence of AKI. Parameters measured were the wash-in slope (WIS), time to peak intensity (PI), area under the time–intensity curve (AUC), mean transit time (MTT), time for full width at half maximum, and rise time (RT). The predictive performance of the CEUS-driven parameters for Kidney Disease Improving Global Outcomes (KDIGO) AKI stage, initiation of renal replacement therapy (RTK), AKI recovery, and chronic kidney disease (CKD) progression was then assessed.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
assessed. Receiver operating characteristic (ROC) analysis was performed to evaluate the diagnostic performance of CEUS.

**Results:**
- **Cortical RT (Odds ratio [OR] = 1.21) predicted the KDIGO stage 3 AKI.**
- **Cortical TMT (OR = 1.07) and RT (OR = 1.20) predicted the initiation of RRT.**
- **Cortical WS (OR = 76.23) and medullary PI (OR = 1.25) predicted AKI recovery.**
- Medullary PI (OR = 0.97) and AUC (OR = 1.00) predicted CKD progression. The areas under the ROC curves showed reasonable performance for predicting the initiation of RRT and AKI recovery. The sensitivity and specificity of the quantitative CEUS parameters were 60–83% and 62–77%, respectively, with an area under the curve of 0.69–0.75.

**Conclusions:** CEUS may be a supplemental tool in diagnosing the severity of AKI and predicting renal prognosis in patients with AKI.

**Funding:** Government Support - Non-U.S.

**PO0058**

**A Clinical Score to Predict Recovery in ESKD due to AKI**

**Silvi Shah, Anthony C. Leonard, Kathleen Harrison, Karthikayan Meganathan, Annette Christianson, Samantha M. Kramer, Charusha V. Thakar, University of Cincinnati, Cincinnati, OH; Cincinnati VA Medical Center, Cincinnati, OH.**

**Background:** Acute kidney injury (AKI) is a major contributor to end-stage kidney disease (ESKD). About one-third of patients with ESKD due to AKI recover kidney function. However, there is lack of clinical models to predict kidney recovery in ESKD due to AKI.

**Methods:** Using data from the United States Renal Data System (2005-2014), we developed a clinical score to predict kidney recovery by 90-day post-dialysis initiation in patients with ESKD due to AKI (N=22,922). We used multivariable logistic regressions to model the effects of patient demographics, comorbidities, and laboratory measures on kidney recovery. The resulting logistic parameter estimates were transformed into integer point totals by doubling and rounding the estimates. The predictive accuracy of the score models was compared to the underlying logistic models by comparing areas under the receiver operating characteristic curves (AUROC) and internal validation was performed.

**Results:** In ESKD due to AKI, kidney recovery within 90-days occurred in 24% of patients. Median recovery time for patients who recovered was 2 months; 72% recovered within 90-days. In the logistic models of recovery at 90-days, older age, lower body mass index, hemoglobin < 12 g/dl, Black and Native American race, Hispanic ethnicity, congestive heart failure, amputation, poor functional status, and pre-dialysis nephropathy care were associated with a lower likelihood of recovery. Eight patient characteristics were included in the final clinical score: age, body mass index, race, congestive heart failure, amputation, functional status, and prior nephropathy care. Recovery scores ranged from zero to 11, with corresponding recovery rates ranging from 6% to 86%. Three risk categories (score range of 0-5, 6-7, and 8-11) exhibited 90-day recovery rates of 11%, 23%, and 45%. The internal validation assessment showed no overfitting of the models. The AUROC of the score was 0.70, similar to the original AUROC of 0.71.

**Conclusions:** A simple clinical score derived from information available at incident dialysis can accurately predict kidney recovery at 90 days in ESKD due to AKI. This predictive tool can be utilized by dialysis providers and policymakers to individualize care, and to improve the quality and processes of care.

**AKI in Hospitalized Patients with Influenza Is Associated with Worse Outcomes: A Study of National Inpatient Sample from 2012 to 2014 in the United States**

**Nasha Elavag, Si Li, Ibithola Yusuf, Bojana Milekic. The Wright Center for Graduate Medical Education, Scranton, PA.**

**Background:** Influenza causes significant morbidity and mortality every year. Physiologically, kidneys receive only 25% of the cardiac output in an average weight adult and therefore often develop acute kidney injury (AKI). Our study determines outcomes of AKI in adults hospitalized with influenza between 2012 and 2014 in the US.

**Methods:** We analyzed adult patients with a principal diagnosis of influenza from the 2012 to 2014 National Inpatient Sample. ICD-9-CM was used to identify the diagnosis variables. Patients were divided into two cohorts; with and without AKI. Patient characteristics between both groups were compared. Chi-squared analysis for categorical variables and multivariate regression analysis was done using STATA 16.0 to determine the relationship of outcomes. P <0.05 was used as the level of statistical significance.

**Results:** 120,730 hospitalizations with influenza were sampled. 16,270 (13.5%) of these had AKI (image 1). After adjusting for potential confounders, patients with AKI had higher odds of mortality (adjusted odds ratio (aOR): 3.83; 95% confidence interval (CI) 3.00-4.89, p<0.001), developing severe sepsis (aOR 8.65; 95% CI 6.46-11.57), septic shock (aOR 9.53; 95% CI 6.42-14.16), rhodanomylsis (aOR 3.03; 95% CI 2.39-3.84), requiring intubation (aOR 5.57; 95% CI 4.61-7.64, p<0.001), a longer length of stay (1.8 days; 95% CI 1.52-2.08, p<0.001) and higher costs ($508.44; 95% CI $398.88-$6190.1, p<0.001).

**Conclusions:** Influenza complicated with AKI in hospitalized patients is associated with a worse outcome in terms of morbidity and mortality along with increased healthcare costs and a longer length of stay.

**Impact of Chloride-Rich Crystalloids on Sepsis-Associated Communi-
yty-Acquired AKI Recovery in Critically Ill Patients**

**Shahzad Tehrani, Khaled Shawa, Erin F. Barreto, Casey M. Clements, Kianoush Kashani. Department of Medicine, Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; Department of Pharmacy, Robert D. and Patricia E. Kern Center for the Science of Health Care Delivery, Mayo Clinic, Rochester, MN; Department of Emergency Medicine, Mayo Clinic, Rochester, MN; Department of Medicine, Division of Pulmonary and Critical Care Medicine, Mayo Clinic, Rochester, MN.**

**Background:** The use of chloride-rich crystalloids for resuscitation is associated with developing acute kidney injury (AKI). We aimed to explore the impact of resuscitation with chloride-rich crystalloids compared to balanced crystalloids on the recovery of kidney function in patients presenting with established sepsis-associated community-acquired AKI (SACA-AKI).

**Methods:** This was a single-center, historical cohort study of patients admitted to the intensive care unit (ICU) who presented to the emergency department (ED) with SACA-AKI at Mayo Clinic, Rochester, MN, from January 2011 to April 2018. We divided the cohort into two groups based on the primary type of crystalloids received in the ED and the first 48-hours of ICU. The first group received primarily normal saline with <20% balanced solutions, and the second group received at least ≥20% balanced crystalloids during the initial volume resuscitation.

**Results:** We included 736 patients who were resuscitated with crystalloids after SACA-AKI diagnosis (mean age 64±16, n = 463 (63%) males). There were 286 (39%) patients in the second group, found to have higher positive fluid balance during the first 48-hours of admission compared to the first group [median 5.7 [IQR: 3.8; 8] vs. 3.8 [IQR: 2.1; 6.1], P <0.001]. By multivariable logistic regression, the patients in the second group had a higher rate of kidney function recovery after adjustments for known recovery risk factors (OR 1.4; 95% CI 1.04-2, P = 0.027).

**Conclusions:** The use of balanced crystalloids during the initial resuscitation is associated with higher odds of kidney function recovery in patients with SACA-AKI.

**The Effect of Care Bundles for AKI: A Systematic Review and Meta-
Analysis**

**Yixin Chen, Fangfang Zhou, Qun Luo. HwaMet Hospital, University of Chinese Academy of Sciences, Ningbo, China.**

**Background:** Acute kidney injury (AKI) is common and associated with increased morbidity and mortality. Implementation of a set of evidence-based AKI care bundles may have some benefits to patient outcomes by reducing variable standards of care. We aimed to systematically review the literature to quantify the effect of AKI care bundles on patient outcomes.

**Methods:** We searched Pubmed (Medline), EMBASE and Cochrane databases for studies that compare the effect of AKI care bundles with usual standard care in patients with or at risk of AKI from database inception to December 31, 2019. The quality of included studies was assessed using the Newcastle-Ottawa Scale. Heterogeneity was
assessed using Cochrane Q test and I² test statistics. Data were analyzed by RevMan 5.3 and Comprehensive meta-analysis (CMA 3.0). The primary outcome was in-hospital or longest follow-up mortality. Secondary outcomes included AKI incidence and AKI severity.

Results: A total of 11 studies (23,491 patients) were included in the meta-analysis. The implementation of AKI care bundles significantly reduced mortality in all patients (odds ratio, 0.87; 95% CI, 0.79–0.94; P = 0.001; I² = 0%; Fig 1). In patients at high risk for AKI (identified by novel biomarker, risk prediction score or electronic alert), care bundles significantly reduced AKI incidence (odds ratio, 0.62; 95% CI, 0.44–0.86; P = 0.005; I² = 20%; Fig 2) and rates of AKI severity (odds ratio, 0.52; 95% CI, 0.35–0.76; P = 0.001; I² = 41%; Fig 3). In addition, there was no evidence of publication bias among the included studies.

Conclusions: The introduction of AKI care bundles can effectively improve outcome in patients with or at risk of AKI, especially when combined with novel biomarker, risk prediction score or electronic alert to manage AKI at early stage. However, the evidence so far is limited and not strong enough to make definite conclusions.

PO0062

Block Randomized Implementation of a Decision-Making Algorithm for Renal Replacement Therapy Initiation in AKI Compared with Standard Care on AKI-Related Outcomes

Yvelynne P. Kelly,1 Salman Ahmed,1 David E. Leaf,1 Ernest I. Mandel,1 Emily S. Robinson,1 Gearoid M. McMahon,1 Peter G. Czarnecki,1 David M. Charytan,1 Sushrut S. Waikar,2 Mallika L. Mendoza,1 Brigham and Women’s Hospital, Boston, MA; 1Boston Medical Center, Boston, MA

Background: Acute kidney injury (AKI) requiring renal replacement therapy (RRT) is associated with high mortality and utilization. Clinical decision-making related to AKI-RRT initiation in the intensive care setting is not standardized.

Methods: We conducted a 12 month single center block randomized controlled trial in the intensive care units (ICUs) of a large academic tertiary medical center; alternating use of an AKI Standardized Clinical Assessment and Management Plan (SCAMP), a decision-making algorithm to guide front-line clinicians, with use of a “sham” control form in 4-6 week randomization blocks. The SCAMP provided recommendations about optimal indications for initiating RRT on the basis of various clinical parameters, whereas the sham control form did not provide any recommendations for management of AKI-RRT.

Results: 122 patients were managed with AKI-SCAMP while 102 patients were managed using the sham control form. There was no significant difference in the primary outcome of odds of inpatient, 30-day or 60-day mortality associated with use of the AKI-SCAMP. With respect to secondary outcomes, use of the AKI-SCAMP resulted in a 3.6 and 4.6 week randomization blocks. The SCAMP provided recommendations to guide front-line clinicians, with use of a “sham” control form in 4-6 week randomization blocks. The SCAMP provided recommendations about optimal indications for initiating RRT on the basis of various clinical parameters, whereas the sham control form did not provide any recommendations for management of AKI-RRT.

Results: 122 patients were managed with AKI-SCAMP while 102 patients were managed using the sham control form. There was no significant difference in the primary outcome of odds of inpatient, 30-day or 60-day mortality associated with use of the AKI-SCAMP. With respect to secondary outcomes, use of the AKI-SCAMP resulted in a 3.6 and 4.6 week randomization blocks. Renin Levels Are Higher in Patients with AKI and Associate with Mortality and Major Adverse Kidney Events
Víctor M. Ortiz-Soriano,1 Fabiola Gianella,2 Alexander H. Flannery,1 Xiulong Li,3 Chirag R. Parikh,4 Sherry Mansour,5 Orson W. Moe,6 Stuart Goldstein,7 Javier A. Neyra,5 University of Kentucky, Lexington, KY; University of Texas Southwestern Medical School, Dallas, TX; Yale University School of Medicine, New Haven, CT; Johns Hopkins University, Baltimore, MD; Cincinnati Children’s Hospital Medical Center, Cincinnati, OH.

Background: Renin is a marker of tissue perfusion and may be useful in predicting mortality in critically ill patients. Renin might also reflect structural kidney damage in heterogeneous AKI settings. We examine if renin levels are different in patients with vs. without AKI and if renin levels associate with adverse outcomes in critically ill patients.

Methods: Multicenter observational study utilizing blood samples of critically ill patients (KLAKI) and patients undergoing cardiac surgery (TRIBE-AKI). Renin was measured by ELISA in serum from 296 critically ill patients at 24-48 h of AKI diagnosis (KDIGO ≥2) or ICU admission (controls), and peroperatively in plasma from 105 patients undergoing cardiac surgery (35 with AKI [≥0.3 mg/dL increase or ≥50% increase in serum creatinine from baseline preoperative level to postoperative level] and 70 controls without AKI). The association of renin levels with hospital mortality and major adverse kidney events at hospital discharge (MAKE: composite of death, need of renal replacement therapy or inability to recover more than 75% of baseline eGFR) was evaluated in the critically ill group.

Results: Renin levels were higher in critically ill patients with AKI vs. ICU controls without AKI (median [IQR], 67.9 [21.7-343.7] vs 22.2 [6.4-73.0] pg/mL, p < 0.001). Similarly, patients undergoing cardiac surgery who developed postoperative AKI had pre and postoperative renin levels differentially higher than those without AKI, sustained increase in renin and OR: 3.44, 95%CI: 1.08-11.02 when the highest tertile was compared vs. no AKI, p = 0.003). In adjusted models, higher renin levels independently associated with increased risk of hospital mortality (OR: 1.27, 95%CI 1.02-1.58 for every 1-unit increase in renin and OR: 3.44, 95%CI: 1.08-11.02 when the highest tertile was compared to the lowest tertile). Further, every 1-unit increase in renin increased the risk of MAKE by 16% (95%CI: 1.33%-33%).

Conclusions: Renin levels are differentially higher in patients with heterogeneous AKI when compared to controls without AKI. Renin levels associate with hospital mortality and MAKE in critically ill patients and therefore its utility in risk-stratification should be further explored in this vulnerable population.

PO0065

Angiotensin 1-7 as a Novel Biomarker of AKI in Pediatric Kidney Transplant Recipients
Lauren Ehrhardt-Humbert, Ashton Chen, Andrew M. South. Wake Forest University School of Medicine, Winston-Salem, NC.

Background: While graft survival rates of pediatric kidney transplant recipients have improved dramatically, acute kidney injury (AKI) accounts for up to 21% of graft failure in pediatric patients and prompt diagnosis of AKI is difficult. AKI activates the renin-angiotensin system (RAS), leading to increased angiotensin (Ang) II-induced inflammation and fibrosis. The ACE2/Ang-(1-7) pathway mitigates these effects but may be downregulated in AKI. The objective was to investigate Ang II and Ang-(1-7) as biomarkers to predict AKI in pediatric kidney transplant recipients. We hypothesized that changes in Ang II and Ang-(1-7) over time would predict biopsy-proven AKI in the first 6 months post-transplant.

Methods: This was a prospective cohort study of children recruited from a kidney transplant evaluation clinic. Blood and urine were collected pre-transplant and post-transplant at several time points. Ang II and Ang-(1-7) were measured with radioimmunoassays. Participants underwent cause or surveillance biopsies and histologic findings were recorded. We applied directed acyclic graph-informed Cox proportional hazards regression analysis with robust standard errors adjusted for age to estimate the association of time-varying Ang II and Ang-(1-7) with AKI.

Results: Of the 27 participants, mean age was 11.7 ± 6.1 years, 63% were male, and 44% were Caucasian. The most common cause of kidney failure was congenital anomalies of the kidney and urinary tract (30%) and 74% received a deceased-donor transplant. Ten patients (37%) had AKI, most commonly due to tacrolimus toxicity (19%). In the urine, a 1-unit increase per day in Ang II (HR 0.97, 95% CI 0.93-1.0), Ang-(1-7) (0.99, 0.98-0.999), and Ang II/Ang-(1-7) (0.56, 0.28-1.11) over time predicted AKI, while blood levels did not.

Conclusions: Among pediatric kidney transplant recipients, changes in urinary Ang II and Ang-(1-7) over time predict biopsy-proven AKI in the first 6 months post-transplant. Conversely, our findings suggest that for every 1-unit per day decrease in urine Ang-(1-7)[AMSM]1, AKI risk increases by 16% (95% CI 1-33%). Our findings support the notion that both pathways of the renin-angiotensin system are involved in transplant AKI. Larger studies are needed to confirm the utility of measuring Ang II and Ang-(1-7) as biomarkers to detect transplant AKI and inform its pathophysiology.

PO0066

Biomarker and Safety Results from a Phase 1b Study of RBT-9 in Healthy Volunteers and Subjects with CKD Stage 3/4
Richard A. Zager,1 Bhupinder Singh,2 Alvaro F. Guillem,3 Stuart Goldstein,4 Fred Hutchinson Cancer Research Center, Seattle, WA; 2University of Washington Department of Medicine, Seattle, WA; 3Renibus Therapeutics, Southlake, TX; 4University of California Irvine, Irvine, CA; 5Cincinnati Children’s Hospital Medical Center, Cincinnati, OH.

Background: Acute kidney injury (AKI) remains a major unmet medical need without any FDA approved preventive or therapeutic options. Safe administration of pharmacologic agents that can prevent AKI in the hospital setting have great potential given the high rate of AKI-related morbidity and mortality. Organ preconditioning to elicit a state of induced cytoreistance prior to insult, such as cardiac surgery, is a mechanism by which the drug RBT-1 has been shown to be protective in various animal models of AKI including glycercol-induced rhabdomyolysis, maleate-induced hypoxic/ischemic renal injury, and ischemia reperfusion injury. RBT-1 is composed of proprietary formulations of stannous protoporphyrin (RBT-9) and iron sucrose (RBT-3). We conducted three phase 1 clinical trials to study the effect of RBT-1, RBT-3, and RBT-9 on biomarkers of cytoprotection observed in experimental animals and on clinical safety. Herein, we report results from the Phase 1b study of RBT-9 in both healthy volunteers and subjects with CKD Stage 3/4.

Methods: Forty-two subjects were enrolled and received a single dose of RBT-9 at 9 mg (N=6), 27 mg (N=18), and 90 mg (N=18). None of the subjects in the 9 mg group had CKD; 12 subjects (67%) in each of the 27 and 90 mg groups had CKD. Mean age was 59.5 years.

Results: RBT-9 dose-dependently induced cytoprotective biomarker responses (heme oxygenase-1 [HO-1], ferritin, NADPH dehydrogenase [quinone 1] [NQO1], and interleukin-10 [IL-10]) in both healthy volunteers and CKD subjects. Treatment-emergent adverse events (TEAEs) were reported in 20 subjects (47%), the majority of which were photo sensitivity events and largely confined to the 90 mg treatment group. TEAEs were generally mild in severity. Only 3 TEAEs were moderate; no TEAEs were severe. No serious adverse events were reported. All TEAEs resolved during follow-up. There was no evidence of renal injury, as assessed by albuminuria and various biomarkers of renal tubular injury (KIM-1, NGAL, cystatin C, NAG).

Conclusions: We conclude that RBT-9 was safe and well tolerated in healthy volunteers and subjects with CKD. Adverse events were generally mild and related to photosensitivity reactions. Dose-dependent cytoprotective protein responses were observed that have previously corresponded with AKI protection in experimental animals.

PO0067

Analysis of AKI in Patients with Systemic Lupus Erythematosus
Si Li, Yichen Wang, Nascha Elavia, Bojana Milekic. The Wight Center for Graduate Medical Education, Scranton, PA.

Background: Renal involvement is commonly seen in systemic lupus erythematosus (SLE). The goal of our study is to analyze the impact and burden of acute kidney injury (AKI) on patients with SLE.

Methods: We analyzed the Healthcare Cost and Utilization Project Nationwide Inpatient Sample from the years 2012 to 2014. We included patients aged 18 years or older with either a primary or secondary diagnosis of SLE. Descriptive analyses were performed with a focus on patient characteristics and comorbidities. We used weighted multivariable survey regression methods to assess outcomes. Statistical analysis was performed using STATA 16.0. We considered a P value of <0.05 as statistically significant.

Results: We identified a total of 101,615 hospitalizations with SLE, of which 9,475 (9.3%) had AKI. Patients with a diagnosis of AKI were younger (mean age 39.3 vs. 45.4), more likely to be male (16.3% vs. 8.9%), black (45.6% vs. 33.3%), discharged from a teaching institution (72.2% vs. 65.4%). Patients with AKI had a higher prevalence of chronic kidney disease (53.2% vs. 10.1%), hypertension (74.5% vs. 47.5%). After adjustment with the patient and hospital level of confounder, the presence of AKI was independently associated with increased overall in-hospital mortality in patients with SLE (adjusted odds ratio [aOR] 12.1, 95% confidence interval [CI] 6.5-22.4, p < 0.001). Length of stay (LOS) was 5.0 days longer (95% CI 4.5-5.6, p < 0.001) in patients with AKI, and total hospital costs were $12485.6 more than in patients without AKI (95% CI 10655.1-14315.2, p < 0.001).

Conclusions: Patients with AKI were more likely to die in the hospital, had a longer length of stay, higher inpatient care costs. Thus, the presence of AKI poses a significant burden on patients with SLE. Close monitoring and early treatment are warranted in this population.

PO0068
AKI After Lung Transplantation: A Retrospective Analysis from a Single Transplantation Center
Johanna Wik,1,2 Sven-Erik Ricksten,1,2 Göran Dellgren,3 Per Ederoth,4 Edgars Grins,4 Lukas Lannemyr,1,2 Department of Anesthesia and Intensive Care, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; 2Department of Cardiothoracic Anesthesia and Intensive Care, Sahlgrenska University Hospital, Gothenburg, Sweden; 3Cardiothoracic Surgery, Sahlgrenska University Hospital, Gothenburg, Sweden; 4Department of Thoracic Anesthesia and Intensive Care, Skåne University Hospital, Lund, Sweden.

Background: Acute kidney injury (AKI) is a common and serious complication after lung transplantation (Ltx). No data from the Swedish Ltx program have been published, and thus we performed a retrospective analysis of AKI after Ltx at our unit.

Methods: After ethical board approval, all patients ≥18 years who underwent Ltx in Gothenburg, Sweden, between 2012-2016 were assessed. Exclusion criteria were: death within 48 hours, multiple organ transplantsations or pre-operative dialysis. AKI was defined according to the KDIGO creatinine criteria and the AKI group was compared to the patients without AKI using Mann-Whitney U-tests or Chi²-tests as appropriate. A multivariate logistic regression model for pre- and intraoperative predictors of AKI was built.

Results: In total, 211 patients were transplanted 2012–2016, and 197 patients were analyzed. Of these, 37% developed AKI within 1 week after Ltx (grade 1; 58%, grade 2; 12%, grade 3; 29%). AKI was associated with increased mortality at 30 days (5.5% vs. 0.8%, p=0.044) and at 1 year (26.0% vs. 8.9%, p<0.001). In the regression model, higher body mass index, diabetes mellitus, measured GFR < 60 ml/min, tricuspid regurgitation and the use of extra-coraporeal circulation during Ltx were independent predictors of postoperative AKI (p<0.001).

Conclusions: AKI affected more than 1/3 of the patients after Ltx, and was associated with increased time on mechanical ventilation, longer stay in the intensive care unit and increased mortality. The multivariate regression model had a modest predictive value, with increased time on mechanical ventilation, longer stay in the intensive care unit and thus we performed a retrospective analysis of AKI after Ltx at our unit.

AKI was associated with increased mortality at 30 days (5.5% vs. 3.5%, p<0.001). Receiver operating characteristic curves (ROC) for the diagnosis of AKI on day 1 and day 7 were drawn, the area under the curve (AUC) of urine cyst-C on day1 and day7 was 0.922 vs. 0.849, the sensitivity was 0.900 on day (when set the critical value for AKI as 25.19ng/ml), and the sensitivity on day 7 was 1(When the critical value was set 23.16ng/ml), and the specificity of urine cyst-C on day 1 vs. day7 was 0.795 and 0.737 separately. The area under the curve (AUC) of uNGAL for AKI diagnosis was 0.860(day1) and 0.867(day7).

When the critical value for AKI diagnosis was 100.12 g/L, the sensitivity for uNGAL was 1, and the specificity was 0.695. The positive value for uNGAL on day1 and day7 were 96% and 100% separately.

Conclusions: NGAL and cyst-C in urine can be used as biological indicators for the diagnosis of AKI in premature infants.

PO0070
AKI in Sickle Cell Disease
Si Li, Nasha Elavia, Yichen Wang, Bojana Milekic. The Wright Center for Graduate Medical Education, Scranton, PA.

Background: Sickle cell disease may cause acute injury to the kidney, especially during sickle cell crisis. Which mainly related to underlying stress-induced renal vasculopathy and alterations in glomerular hemodynamics. There is a paucity of national-level evidence showing the effect of acute kidney injury (AKI) on patients hospitalized with sickle cell disease. We aim to quantify the relationship between AKI and mortality and resource utilization in patients with sickle cell disease.

Methods: We analyzed adult patients admitted from 2012 to 2014 with a primary or secondary diagnosis of sickle cell disease using the Nationwide Inpatient Sample (NIS). The NIS is the largest publicly available inpatient database in the United States (U.S.). It contains data from approximately 8 million hospital stays each year, representing a 20% stratified sample of all U.S. non-federal hospitals, and is sponsored by the Agency for Healthcare Research and Quality and the Healthcare Cost and Utilization Project (HCUP). The International Classification of Diseases, Ninth Revision, Clinical Modification Coding System (ICD-9-CM) was used to identify comorbidities. Survey multivariate regression analysis was performed using STATA 16.0.

Results: We included 240,550 admissions with sickle cell disease, majority of them were black patients (93%). 10,825 (4.5%) of sickle cell disease patients had AKI. Patients with AKI were older (mean age 41.3±12.5 vs. 31.1±10.4, p<0.001), more likely to be male (53.1% vs. 44.4%, p<0.001). Sickle cell disease patients had higher prevalence of hypertension (49.9% vs. 16.8%, p<0.001), coronary artery disease (6.3% vs. 2.1%, p<0.001), congestive heart failure (22.5% vs. 4.4%, p<0.001), diabetes mellitus (9.8% vs. 3.5%, p<0.001). After adjusting for patient and hospital-level confounders, patients with AKI had higher odds of mortality (adjusted odds ratio [aOR] 11.3, 95% confidence interval 7.94–18.34, p<0.001), a longer length of stay (2.6 days, 95% CI: 2.21–2.93 days, p<0.001), higher costs ($6707.2; 95% CI: $5812.6–$7598.3, p<0.001).

Conclusions: The demographic characteristics were significantly different between patients with or without AKI. Sickle cell nephropathy imposes a burden on both individual and health care systems. Randomized controlled trials are needed to investigate the role of vaso-occlusive events on AKI development.

Plasma Metabolites Do Not Change Significantly After 48 Hours in Patients on CRRT

Benjamin R. Griffin,1 Matthew Ray,2 Kristy Roloff,1 John T. Brinton,2 Javier A. Neyra,2 J Pedro Teixeira,4 Kirby Mayer,1 Katja M. Gist,2 Muhammad Afzab,2 Diana I. Jalal,3 Julie Haines,2 Sarah Faubel,2* University of Iowa, Iowa City, IA; 2University of Colorado, Denver, CO; 3University of Kentucky, Lexington, KY; 4University of New Mexico, Albuquerque, NM;
5Iowa City VA Medical Center, Iowa City, IA; 6VA Eastern Colorado Health Care System, Aurora, CO.

Background: Continuous renal replacement therapy (CRRT) is used in critically ill patients with hemodynamic instability. One of the primary aims of CRRT is to remove solutes that accumulate due to impaired kidney function. Surprisingly, few studies have assessed plasma solute levels during CRRT, and the duration of CRRT necessary to achieve adequate solute removal is unknown.

Methods: To assess the effect of CRRT on plasma solutes, metabolites were determined via untargeted ultra-high pressure liquid chromatography coupled to mass spectrometry (UHPLC-MS) in 13 critically ill patients requiring CRRT. Metabolites were assessed on plasma collected prior to CRRT initiation, and on plasma and effluent collected on days 1, 2, and 3 thereafter.

Results: A total of 101 annotated metabolites were evaluated. Plasma levels of 22 metabolites (21.8%) were significantly reduced by Day 1 of CRRT, and included creatinine, phosphate, lactate, and the amino acids alanine, proline, and cysteine. Only 2 metabolites (2.0%) were significantly reduced between Day 1 and Day 2, and none were reduced between Day 2 and Day 3. Figure 1 demonstrates that marginal changes in solute levels decrease as CRRT progresses. All metabolites were detected in the effluent, and the sieving coefficients for metabolites that were reduced versus not reduced after CRRT were not statistically different.

Conclusions: No further reduction in plasma metabolites occurred after 48 hours of CRRT. Since the median CRRT treatment time is 4-7 days nationwide, with some patients treated substantially longer, these data bring into question the utility of prolonged, uninterrupted CRRT therapy, and have major potential implications for the duration of CRRT in the ICU population.

Bicarbonate May Not Be the Best Treatment for Rhabdomyolysis: A Retrospective Cohort Study

Hye Won Kim,1 Yunseo Lee,2 Sejoong Kim,1 Seoul National University Bundang Hospital, Seongnam, Republic of Korea; 2Seoul National University College of Medicine, Seoul, Republic of Korea.

Background: It is controversial whether the use of bicarbonate solution, which has been traditionally attempted to treat rhabdomyolysis, has the beneficial effect of reducing acute kidney injury (AKI) and mortality, compared with the use of non-bicarbonate solution. The purpose of this study is to analyze whether bicarbonate therapy versus non-bicarbonate therapy may be effective in preventing AKI and death in patients with rhabdomyolysis.

Methods: We collected 4077 hospitalized patients with creatinine kinase (CK) > 1000 U/L and divided them into 2 groups: patients who received fluid with bicarbonate and who received fluid without bicarbonate. Patients were subgrouped into low (<2ml/kg/hr), middle (2-4ml/kg/hr) and high (>4 ml/kg/hr) amounts of fluid to receive in first 72 hours of admission. Cox regression analysis models were used to identify risks for dialysis and mortality. Safety profiles were assessed by volume overload and electrolyte imbalances.

Results: In a total of patients with a mean age of 57.9 years (male 66.7%), bicarbonate-containing solution was used in 61.1% of the participants. The proportion of the subjects were 34.6%, 36.5%, and 28.9% for the low, middle, and high fluid group, respectively. The bicarbonate group showed higher incidence rate of AKI (OR 4.5), higher 1-year mortality (OR 3.1) and longer hospital stay (26.6 ± 54.4 vs. 22.0 ± 22.7 days) than the non-bicarbonate group. Patients given high amount of fluid therapy showed higher incidence rate of AKI (OR 3.1), higher rate of dialysis dependency (OR 2.7) and higher 1-year mortality (OR 1.4), compared with low fluid group, regardless of the use of bicarbonate. The use of bicarbonate (adjusted HR [aHR] 1.55), volume overload (aHR 1.28) were associated with higher mortality while the use of furosemide (aHR 0.8) showed the preventive effect. Baseline CK or peak CK were not related to the risk of dialysis or death. Volume overload was significantly higher in the bicarbonate group compared with the non-bicarbonate group.

Conclusions: We showed bicarbonate therapy or high-volume fluid management in patients with rhabdomyolysis were not beneficial in preventing AKI and death, compared with the non-bicarbonate therapy or low-volume fluid management. It suggests that limited use of bicarbonate and adjustment of fluid volume may improve the short-term and long-term outcome of rhabdomyolysis.

Funding: Government Support - Non-U.S.
(10% Ca gluconate at fixed rate 5 ml/hour) was needed in 10/41 treatments, with rapid normalization of serum Ca++. No new cardiac arrhythmia episode or hemorrhagic events were observed.

Conclusions: Our preliminary data suggests that a simplified RCA protocol for SLED using a conventional dialysis machine is easy and safe, also ensuring a good match between prescribed and actual dialysis dose administered.

PO0075

Prediction of AKI in Inpatient General Medical Ward Units

Cassandra Chiao, Rachel Urban, Fauzia Osman, Tripti Singh. University of Wisconsin System, Madison, WI.

Background: Acute kidney injury (AKI) is common in hospitalized patients (A). A few scoring systems have been proposed to predict the risk of developing AKI in certain populations, such as cardiac catheterization patients (B, C, D, E, F). However, there is no scoring system for predicting AKI in patients on the general medical wards. Our aim is to predict the development of AKI in acute general medical patients.

Methods: Retrospective single center study of all adult patient admitted to a tertiary care university hospital between July 2016-July 2018. AKI was defined by the KDIGO definition of AKI and all stages of AKI were included. We used chi-squared tests, ANOVA, and Kruskal Wallis to determine statistically significant factors. We calculated odds of AKI using logistic regression models. All analyses were conducted using STATA SE 15.

Results: A total of 10,981 were included in the study, 1573 (14.3%) with AKI and 9408 (85.7%) without AKI. Baseline demographics were significantly different between the two groups including age, race, length of hospital stay (>0.001). In the univariate analysis, history of cancer and diabetes, proteinuria, admission BUN, hemoglobin (HGB), and hypotension during admission were predictive of AKI. After adjustment for significant univariate factors, age (OR 0.97 [0.96-0.99], P<0.001), admission BUN (OR 1.02 [1.01-1.04], P<0.001), and HGB (OR 0.79 [0.73-0.85], P<0.001) were significant in the multivariate analysis (Table 1).

Conclusions: We found that the age, admission BUN, and HGB were predictive of AKI in inpatient general medical units. These criteria can be used in acute general medicine patients to create a scoring system to determine the likelihood of developing AKI and therefore prevent AKI and its downstream complications in these patients.

PO0076

Is Procalcitonin a Reliable Marker of Bacterial Infection in Patients with AKI?

Mariam Charkviani, Sumit Sohal, Natia Murvelashvili, Maria Yanez Bello, Daniela Trelles, Alisha Sharma. Amita Saint Francis Hospital, Evanston, IL.

Background: Procalcitonin (PCT) is a biomarker that helps to distinguish bacterial infections from other causes of infection or inflammation and can be used as a helpful adjunct to clinical judgment for resolving diagnostic uncertainty. Limited data is available about the diagnostic value of PCT in patients with acute kidney injury (AKI). We aimed to assess the diagnostic usefulness of serum PCT level as a marker of bacterial infection in patients with AKI and assess the correlation of serum creatinine clearance to serum PCT level.

Methods: This retrospective case-control observational study involved patients admitted to the hospital during the study period and had PCT checked. Patients were categorized into proven, possible, and no bacterial infection groups. We compared PCT level in AKI group with proven bacterial infection vs no bacterial infection and PCT level during proven and no bacterial infection groups with AKI vs non-AKI. Patients with end-stage kidney disease and other causes of elevated PCT (pancreatitis, cancer, sepsis) were excluded.

Results: 379 patients were analyzed, 24 patients were excluded from the study. 66 patients classified into the AKI group and 226 into the non-AKI group. 107 patients were in a proven bacterial infection group and 98 Patients in no bacterial infection group. The mean value of PCT was significantly higher with confirmed bacterial infection compared to no bacterial infection in all patients despite their renal function (4.9±8.75 vs 1.66±4.88, p=0.001). PCT level was higher in the AKI group than in the non-AKI group (10.99±12.24 vs 2.39±2.93, p<0.001) in patients with a proven bacterial infection. Patients with no infection had much higher PCT level in the AKI group as compared to the non-AKI group (5.76±14.67 vs 0.7±1.39, p=0.003). PCT level was also significantly higher during confirmed bacterial infection vs no bacterial infection in patients with AKI (9.2±11.05 vs 0.7±2.17, p=0.04). There was a weak positive correlation between creatinine clearance and PCT level (correlation coefficient -0.125, p=0.15).

Conclusions: Higher cutoff level of PCT is needed in patients with AKI to use it as a marker of infection. The specificity of PCT may decrease in patients in AKI if current reference cutoff values are used to guide clinical decisions.

PO0077

Predicting Outcomes After AKI: Are You Better Than a Machine?

Tanima Arora, Aditya Biswas, Yu Yamamoto, Michael Simonov, Melissa Martin, Francis P. Wilson. Clinical and Translational Research Accelerator, Yale School of Medicine, New Haven, CT.

Background: While multiple studies have used statistical models to predict outcomes after AKI, no studies have compared these models to physician intuition at the time of AKI consult. We studied the accuracy of physicians in predicting outcomes after AKI and compared it to the strength of predictive statistical models.

Methods: Our pilot study focuses on the prediction of 3 outcomes after AKI: Recovery, progression to dialysis and mortality. Postgraduate years 4 and 5 level Nephrology providers were asked, at the time of initial renal consult, to forecast outcomes at 3 timepoints: 24hr, 48hr and 7 days. We compared physician prognosis to a gradient boosted trees model trained using retrospective EHR data. Our primary measure of performance was area under the receiver operating characteristic curve (AUROC) at each time point.

Results: Data was captured from 56 patients with stage 2 AKI. Nephrology providers (n=7) were good at predicting dialysis at all three timepoints and death at 48 hours and 7 days. In contrast, their ability to predict recovery of AKI was relatively poor. The statistical model performed significantly better at predicting death at all timepoints, however was poorer at predicting dialysis (Figure 1.0).

Conclusions: Both physician clinical acumen and our statistical model showed good performance in predicting need for dialysis and death after AKI, however performed poorly when predicting recovery. This highlights the need to conduct further in-depth research into this area and implement strategies to enhance prediction of recovery after AKI.

PO0078

Short-Term Prognosis of Patients with Cardiorenal Syndrome Type 1-Induced AKI Requiring Continuous Renal Replacement Therapy

Yusuke Watanabe, Kei Sugiyama, Daichi Fukaya, Hiroaki Amano, Tsutomu Inoue, Hirokazu Okada. Saitama Medical University, Iruma-gun, Japan.

Background: Cardio-renal syndrome (CRS) type 1 is a condition wherein an acute heart failure (AHF) leads to the development of acute kidney injury (AKI). Continuous renal replacement therapy (CRRT) is used to remove excess solutes and fluids in CRS type 1 patients who have diuretic resistance. However, little is known about the outcomes of CRS type 1 patients who undergo CRRT.

Methods: We reviewed the clinical data of 74 consecutive CRS type 1 patients treated with CRRT from 2012 to 2015. Patients who underwent cardiovascular surgery and those who had chronic kidney disease stage 5 prior to admission were excluded. The primary outcome examined was in-hospital mortality.

Results: The mean age of patients was 70.6±13.6 years old. The causes of AHF were ischemic heart disease (54.1%), valvular disease (13.5%), and other diseases. At the time of the CRRT initiation, the mean serum creatinine was 2.8±1.0 mg/dL. The in-hospital mortality rate was 77.0%. Compared with non-survivors, the survivors had fewer number of previous hospitalizations for heart failure (50.9% vs. 23.5%, p=0.046), higher systolic blood pressure (97.7±22.2 mmHg vs. 112.3±21.1 mmHg, p=0.02), better ejection fraction (31.4±17.9% vs. 42.0±15.7%, p<0.03), smaller inferior vena cava (IVC) diameter (18.0±5.8 mm vs. 14.8±4.4 mm, p=0.04), lesser respiratory variations in the IVC diameter (59.6% vs. 13.3%, p=0.002), lesser vasopressor requirement (96.5% vs. 31.9%, p=0.001), and lesser respirator support (36.1% vs. 23.5%, p=0.02) at CRRT initiation. The survivors required a shorter CRRT duration over the non-survivors (6.1±6.9 days vs. 11.7±12.4 days, p=0.03). Through the multiple logistic regression analysis, certain factors were associated with a poor short-term prognosis. These factors were history of previous hospitalizations for heart failure, vasopressor requirement upon start of CRRT, and the need for respirator support at CRRT initiation.

Conclusions: In our single-center experience, the use of CRRT for treating AKI caused by CRS type 1 was associated with a high in-hospital mortality rate. Patients with a history of previous hospitalization for heart failure, those who required vasopressors, and patients needing respirator support at CRRT initiation had an especially poorer prognosis.
Roux-en-Y Gastric Bypass Is the Most Common Current Cause of Biopsy-Proven Oxalate Nephropathy

Swetha Reddy,1 John C. Lieske,2 Mira T. Keddis.1 1Mayo Clinic Arizona, Scottsdale, AZ; 2Mayo Clinic Minnesota, Rochester, MN.

Background: The objective of this study was to analyze patient characteristics and outcomes of biopsy-proven oxalate nephropathy likely due to an enteric cause at a single large tertiary health system.

Methods: Cases of oxalate nephropathy were identified based on documented kidney biopsy findings between 2009-2019 in patients with an associated enteric process likely to cause fat malabsorption.

Results: A total of 30 cases were identified (mean age of 65.2 ± 8.56 years; 18(60.0%) female) with a median follow-up of 5 months; Risk factors included hypertension in 21(70%), diabetes in 14 (46.7%), chronic kidney disease (CKD) stage 3A or greater in 16(53.3%) and prior kidney stones in 6(20%). The most common enteric causes were Roux en Y gastric bypass (RYGB) in 17(56.7%), pancreatic insufficiency in 6(20%), inflammatory bowel disease in 4(13.3%), and recurrent C. difficile infection in 3(10%). At the time of diagnosis, acute kidney injury (AKI) stage II and stage III were present in 9 (30%) and 15 (50%) respectively, while 11(36.7%) required dialysis. Urinalysis revealed proteinuria in 16(55.2%), oxalate crystals in 10(33.3%), and hematuria in 9(30%). Median plasma oxalate at the time of biopsy was 18.3 [reference <2.0] μmol/L in 26 patients and median 24 hour urine oxalate excretion was 53 [reference [7.9-40.5]] mg/24 hrs in 17 patients. RYGB patients had a higher plasma oxalate compared to patients with other enteric causes (median 24.6 vs 16.5 μmol/L, p=0.03). Renal biopsy and clinical outcomes are shown in table 1. Patients with acute tubular injury had greater number of tubules with calcium oxalate crystals by biopsy (median 19 vs 4), as did patients with CKD5 at last follow-up (20 vs 6). Features at the time of biopsy predictive of CKD5 at follow-up included AKI severity (p=0.002), dialysis at diagnosis (p=0.0008), and the presence of moderate to severe tubulointerstitial atrophy (p=0.001).

Conclusions: In this series RYGB was the most common enteric cause of biopsy-proven oxalate nephropathy. Severity of AKI at presentation and degree of tubulointerstitial fibrosis were both associated with worse renal outcome. The amount of renal crystal deposits at diagnosis associated with the short and long term renal injury.

Renal Histology (A) & Outcome (B)

Impact of AKI on In-Hospital Outcomes in Chinese Patients with Community-Acquired Pneumonia

Dawei Chen, Xin Wan. Nanjing First Hospital, Nanjing, China.

Background: Acute kidney injury (AKI) is common in community acquired pneumonia (CAP). However, the impact of AKI on in-hospital outcomes of patients with CAP in the population of Chinese remains largely unknown.

Methods: Multiple Cox regression models were employed to identify the association between AKI and in-hospital mortality and 30-day mortality.

Results: A total of 4213 patients were included, and 950 (22.5%) patients were AKI. The independent risk factors for AKI were age, male, hypertension, cardiac dysfunction, diabetes, chronic kidney disease, acute respiratory failure, diuretic, vasoactive drugs, and CURB-65. After multivariable Cox regression, independent risk factors of in-hospital mortality and 30-day mortality were similar: AKI, ACEI/ARB, hypertension, CURB-65, acute respiratory failure, and using vasoactive drugs. Patients developed AKI in the population of Chinese remains largely unknown.

Conclusions: The addition of IV contrast was not associated with an increased risk of Contrast-induced nephropathy (CIN) has been described as a significant cause of acute kidney injury (AKI). Although the nephrotoxic potential of vancomycin has widely been published, the contributory effect of these two agents towards AKI has not been fully elucidated. We sought to better define this interaction.

Methods: The primary objective of this retrospective cohort study was to compare the incidence of AKI among adult patients receiving vancomycin (VAN) and vancomycin plus IV contrast (VC) within 96 hours of administration. Secondary outcomes included time to AKI development, hospital length of stay (LOS), and 30-day, all-cause mortality. A logistic regression was performed to identify potential risk factors for AKI among vancomycin-treated patients.

Results: A total of 114 patients receiving 4 consecutive days of vancomycin were included, 50 receiving VAN and 64 receiving VC. An additional 50 patients who received IV contrast alone were independently assessed for CIN, of which only 3 (6%) developed AKI. In the unadjusted analysis, no statistically significant difference in the rate of AKI (10% vs 20.3%; p=0.13), days until AKI (6 days vs 5 days; p=0.37), highest vancomycin trough (16.7 vs 17.8; p=0.62), and hospital LOS (7.5 days vs 8 days; p=0.62) were found between VAN and VC patients. The addition of IV contrast to vancomycin was not an independent risk factor for AKI after adjusting for relevant confounders (aOR 1.65; 95% CI, 0.48-5.65; p=0.42).

Conclusions: The incidence of CIN was not associated with an increased risk of AKI in vancomycin-treated patients. The incidence of CIN was rare.
PO0082
Mortality Prediction of Serum Neutrophil Gelatinase-Associated Lipocalin in Patients Requiring Continuous Renal Replacement Therapy Byung ha Chung,1 Yohan Park,1 Hyung Duk Kim,1 Eun jeong Ko,1 Tae Hyun Ban,2 Cheol Whee Park,1 Chul Woo Yang.1 Seoul Saint Mary’s Hospital, Seoo-co-gu, Seoul, Republic of Korea; 2Eunpyeong Saint Mary’s Hospital, Eunpyeong-gu, Seoul, Republic of Korea.

Background: We investigated whether serum neutrophil gelatinase-associated lipocalin (NGAL) can predict mortality in patients with acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT).

Methods: This study enrolled 169 patients who underwent serum NGAL testing at CRRT initiation from June 2017 to January 2019. The predictive power of serum NGAL level for 28-day mortality was compared to the Acute Physiology and Chronic Health Evaluation-II (APACHE-II) score and Sequential Organ Failure Assessment (SOFA) score via area under the receiver operating characteristic curve (AuROC) value.

Results: There were 55 survivors and 114 non-survivors at 28 days post-CRRT initiation. Median serum NGAL level was significantly higher in the non-survivor group than in the survivor group (743.0 vs. 504.0 ng/mL, P=0.003). The AuROC value of serum NGAL level was 0.640, which was lower than APACHE-II score and SOFA score values (0.767 and 0.715, respectively). However, in the low APACHE-II score group (<27.5), AuROC value of serum NGAL was significantly increased (0.698), and it was an independent risk factor for 28-day mortality (hazard ratio 2.405, 95% confidence interval 1.296-4.783, P=0.012).

Conclusions: In patients with AKI requiring CRRT, serum NGAL levels may be useful for predicting short-term mortality in those with low APACHE-II scores.

Funding: Government Support - Non-U.S.

Figure 1. Predictive value for 28-day mortality of serum NGAL level, APACHE-II score, and SOFA score in low APACHE-II score group

PO0084
Prevalence, Length of Stay, and Hospitalization of AKI in Patients with and Without Sjogren Syndrome Mohamedanwar M. Ghandour, Yahya M. Osman Malik. Wayne State University School of Medicine, Detroit, MI.

Background: Acute Kidney Injury (AKI) has emerged as a significant cause of morbidity and mortality in patients with autoimmune diseases. However, this has not been examined in patients with Sjogren’s syndrome (SJS). To achieve this, we examined the prevalence, mortality, outcomes, Length of Stay (LOS), and hospital charges in patients with AKI with SJS compared to patients without SJS from a National Inpatient Sample database in the period 2010-2013.

Methods: Data retrieved from the National Inpatient Sample (NIS) for adult patients admitted with a principal diagnosis of acute kidney injury between 2010 and 2013, using the respective ICD-9 codes. The study population divided into two groups, with and without Sjogren’s disease. Multivariate and linear regression analysis conducted to adjust for covariates.

Results: The study population represented 97,055 weighted patient discharges with acute kidney injury. Analysis revealed acute kidney injury patients with Sjogren’s compared to patients without Sjogren’s had statistically significant lower hyperkalemia rates (adjusted Odds ratio (OR)0.65, CI 0.46 to 0.92; p =0.017). There was no statistically significant difference in mortality, length of stay, hospital charges, and other outcomes. Moreover, The charges of hospitalization and length of stay were found to be statistically insignificant by the adjusted linear regression model. In addition, nearly three quarters of patients had Medicare, followed by privately insured patients with the least number being on Medicaid. More than half of the population have received their treatment in a tertiary center hospital. Charlson’s index reported more than two-thirds of study subjects to have two or more co-morbidities.

Conclusions: At present, our study is unique as it has examined the prevalence, mortality, and outcomes of Sjogren’s in patients with acute kidney injury. Patients with Sjogren’s has significantly lower hyperkalemia during the hospitalization. Further research is needed to identify the underlying protective mechanisms associated with Sjogren’s that resulted in lower hyperkalemia.

PO0085
Clinical Characteristics and In-Hospital Outcomes for 1519 Consecutive Patients with AKI Christina J. Montogomerie,1 Jonas Spaak,1 Marie Evans,2 Stefan H. Jacobson.1 1Karolinska Institutet, Danderyd University Hospital, Department of Clinical Sciences, Division of Nephrology, Stockholm, Sweden; 2Karolinska University Hospital Huddinge Department of Renal Medicine, Stockholm, Sweden.

Background: Acute kidney injury (AKI) occurs in about 15% of hospitalized patients. Patients who recover from AKI have a higher long-term risk of end-stage kidney disease and death. The aim of this large single center study was to report differences in laboring optimal treatment strategies and optimal findings for patients outcomes in relation to cause of AKI in consecutive patients in a nephrology department.

PO0087
One-Year AKI Stage 3 Outcome in Elderly Patients at a Secondary Care Hospital in the United Kingdom
Jeetendra R. Rathod, Matthew James, Syed A. Shaqfat, Jonathan Kwan. Darent Valley Hospital, Dartford, United Kingdom.

Background: Elderly patients are prone to Acute Kidney Injury (AKI) 3 due to multiple co-morbidities and frailty. The short term and long term outcome and mortality in this group of patients is unclear.

Methods: We prospectively collected data on patients aged over 70 years with AKI 3 from the daily e-alert sent by the hospital biochemistry lab. 117 patients attended or admitted to secondary care hospital in West Kent, UK over 6.5 months between 13 December 2018 and 26 May 2019 were analysed and followed up for next 12 months. AKI 3 was defined as per KDIGO Criteria. Data was collected for age, co-morbidities, serum creatinine at admission, peak, discharge and 12 months, cause of AKI 3 and mortality. Exclusion criteria: AKI stage 1, stage 2 and patients on regular dialysis.

Results: 57% patients had community acquired and 43% developed AKI 3 while as in-patient. The mean age was 80.1 ± 6.2 years with co-morbidities of Chronic Kidney Disease (>3) 64.7%, Cardiovascular disease (CVD) 50%, Diabetes Mellitus 42.2% and Malignancy 8.7%. The stable baseline, peak and discharge s. creatinine (mean ± std dev) were 127.7 ± 85.6, 420.9 ± 227.4 and 184.5 ± 184.5 μmol/L respectively. 59.5% patients were reviewed by nephrologists and 20.7% were transferred under renal care. 30.4% had oliguria at presentation. The reasons for AKI 3 were classified as pre-renal (59.48%), urina ry obstruction (11.2%) and renal that included sepsis (13.79%), cardio-renal syndrome (3.45%), drug induced nephrotoxicity (2.6%), other inclusion ATN (9.70%). Renal function recovery was complete in 44.8%, Partial in 22.4% whereas 32.8% did not have any recover. 6 (1.7%) patients needed acute haemodialysis, of these 2 died and 4 (66.6%) were discharged off dialysis and were alive at 12 months. 47.4% patients were alive at discharge with s.creatinine of 173.2 ± 143.2 μmol/L while only 32% of the overall patients were alive at 12 months with s.creatinine (eGFR) (mean ± std dev) 161.8 ± 127.4L (48 ± 28 ml/min) with mean follow up of 331 ± 112 days. All patients that did not recover from AKI died.

Conclusions: We conclude that short and long term outcome in patients with AKI 3 aged more than 70 years has high mortality at discharge (52%) and 12 months (68%). AKI 3 is common in patients with co-morbidities of CKD, CVD and Diabetes mellitus. Outcome of acute haemodialysis is effective in select group of patients.

PO0088
Urine Analysis and Urine Electrolytes Among Patients with COVID-19
Infection and AKI

Background: Determining intravascular volume status for patients who have COVID-19 infection and AKI is critical for guiding decisions about fluid management and treating AKI. In this study, we present data on urinalysis and urine electrolytes among patients with COVID-19 infection who developed AKI at our hospital.

Methods: This is a convenience sample of patients with COVID-19 who were diagnosed with AKI at our center in Spring of 2020 and had a urinalysis performed within 48 hours of diagnosis of AKI. When applicable we used Mann-Whitney test to compare groups.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Recovery of Renal Function Among Left Ventricular Assist Device Patients with Severe AKI Requiring Renal Replacement Therapy: A Meta-Analysis
Sweetha Rani Kanduri, Wisit Cheunprasitporn, Karthik Kovvuru, Pradeep Vaithal, Charat Thongprayoon, Kianoush Kashani, University of Mississippi Medical Center, Jackson, MS; Mayo Clinic Rochester, Rochester, MN.

Background: Acute kidney injury (AKI) is a common and severe complication after left ventricular assist device (LVAD) implantation with an incidence of 37%; 13% of which requiring renal replacement therapy (RRT). Severe AKI requiring RRT in LVAD patients is associated with high short-term and long-term mortality, compared with those without RRT. While recovery of renal function is associated with better outcomes, the rates of recovery of renal function among LVAD patients with severe AKI requiring RRT are unclear.

Methods: Ovid MEDLINE, EMBASE, and the Cochrane Databases were systematically searched from database inceptions through January 2020 to identify studies evaluating the rates of recovery from severe AKI requiring RRT after LVAD placement, which is defined by regained kidney function resulting in the discontinuation of RRT. Random-effects and generic inverse variance method of DerSimonian-Laird were used to combine the effect estimates obtained from individual studies.

Results: A total of 268 patients from 14 cohort studies with severe AKI requiring RRT after LVAD were enrolled. Follow-up time ranges from hospital discharge up to 12 months. 78.5% of renal recovery occurred at the time of hospital discharge or within 30 days. Majority (85%) of patients used continuous-flow LVAD. Overall, the pooled estimated rates of AKI recovery among patients with severe AKI requiring RRT was 50.5% (95%CI: 34.0%-67.0%), respectively. While the data on pulsatile-flow LVAD were limited, subgroup analysis of continuous-flow LVAD demonstrated the pooled estimated rates of AKI recovery among patients with severe AKI requiring RRT of 52.1% (95%CI: 36.8%-67.0%). Meta-regression analysis did not demonstrate a significant association between study year and AKI recovery rate (p = 0.08). There was no publication bias as assessed by the funnel plot and Egger’s regression asymmetry test in all analyses.

Conclusions: Recovery of renal function after RRT after LVAD can be expected in 50-55% of patients, although these estimates vary by LVAD type. Further studies are needed to understand the predictors of recovery after LVAD and its impact on patient survival.

PO0090
Early Nephrologist Interventions to Avoid Kidney Replacement Therapy in AKI
Christian P. Flores, Pablo Maggiani, Jonathan Chavez, Jorge J. Font, Joana G. Navarro gallardo, Noe Martinez murillo, Jose A. Torres, Juan Gómez Fregoso, Hospital Civil de Guadalajara Unidad Hospitalaria Fray Antonio Alcalde, Guadalajara, Mexico; Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico.

Background: It is well known that early nephrologist involvement in patients with AKI improve outcomes. Determine which intervention has a greater impact on avoiding the need for RRT will be an important advance.

Methods: Our objective was to Identify which nephrologist intervention decrease the need of RRT. We analyze age, gender, comorbid conditions, cause of AKI, pharmacology therapy, cause of RRT, early interventions: fluid, antibiotic and nutritional adjustment, nephrotoxic withdrawal and removal of hyperchloremic solutions and death. Kaplan Meier survival analysis. Multivariable logistic regression model was performed. P < 0.05 which is significant.

Results: From 2017 to 2020 288 patients with AKI where analyzed prospectively with a 10 days follow-up, 45 (15%) patients die, overall survival of 84.4% (IC 95% 0.80 – 0.88) (Figure 1). Only fluid adjustment decreases the risk of KRT (OR 0.74, 95% CI 0.68-0.81, p < 0.001) while having AKI KDIGO 3 increases the risk (OR 1.12, 95% CI 1.05-1.20, p = 0.001) being fluid overload the main cause of KRT (IC 95% 0.76, 95% CI 0.65-0.89, p < 0.001). (Table 1)

Conclusions: In AKI, fluid adjustment was the most important nephrologist intervention to avoid KRT.
Usefulness of the Neutrophil-to-Lymphocyte and Platelet-to-Lymphocyte Ratios in Community-Acquired AKI

Jose M. Pena Porta, Almudena Castellano, Ana Coscojuela Otto, Jose F. Gasco, Alejandro Tomás, Pablo J. Inigo Gil, Rafael Alvarez Ipe. Nephrology Service, Hospital Clinico Universitario Lozano Blesa, Zaragoza, Spain.

Background: The neutrophil-to-lymphocyte (NLR) and platelet-to-lymphocyte (PLR) ratios have been identified as markers of inflammation and endothelial dysfunction. To date, its usefulness as prognostic markers in community-acquired acute kidney injury (CA-AKI) has not been evaluated.

Methods: We established a cohort of patients with CA-AKI admitted to our Nephrology service from January 2010 to February 2015. NLR and PLR ratios were obtained with the first analysis performed.

Results: We studied 308 patients with CA-AKI, 58% were men, mean age 73.22. Etiology of CA-AKI: prenephritic 69.5%, renal 23.1%, obstructive 7.5%. AKI KDIGO stages: I, 14.6%; II, 11%; III 74.4%. CKD was detected in 68.8% of cases required hemodialysis and 12.5% died. Mean NLR was 9.14 ± 8.47. Mean PLR was 236.99 ± 228.41. NLR according to etiology was: prenephritic 8.55±6; renal 9.37±9.8; obstructive 13.99±14.82 (significant differences between obstructive and prenephritic). PLR according to etiology: prenephritic 228.31±216.34; renal 236.15±233.77; obstructive 320.37±304.89 (non-significant differences). Within the group prenephritic, 79 cases were complicated by acute tubular necrosis (ATN). These cases presented a higher NLR (10.7±8.47, p=0.026). There were no significant differences between the PLR of both groups. The NLR showed a significant correlation with the peak creatinine (r=0.186; p=0.001) and the baseline (r=-0.237; p<0.001). The PLR also showed the same correlations (r=0.134, p=0.018 and r=0.165, p=0.07). The NLR, but not the PLR, was associated with the length of hospital stay (multiple linear regression analysis). Through a multivariate binary logistic regression analysis, the variables that were independently associated with mortality during admission were the利亚lo individual severity index and the NLR (OR 1.060; IC 95% 1.014−1.108). The best cut-off point of the NLR to predict mortality was 6.68 (AUC 0.584; sensitivity 0.60; specificity 0.58; Youden index 0.178).

Conclusions: In our CA-AKI patients cohort, the NLR was associated with the morbidity and the mortality. More studies are needed to confirm this finding, but the easiness of obtaining it and its economic cost make it cost-effective, giving the NLR a leading role in assessing the risk of CA-AKI.

Clinical Characteristics and Histologic Descriptions of Acute Tubular Injury: A Systematic Review

Yunpeng Wen,1 Chen Yang,2 Steven Menz,1 Avi Z. Rosenberg,1 Chirag R. Parikh,1 Johns Hopkins Medicine, Baltimore, MD; 2Memorial Sloan Kettering Cancer Center, New York, NY.

Background: The term acute tubular injury (ATI) represents histopathologic renal tubular injury and often manifests clinically as acute kidney injury (AKI). Studies systematically summarizing the clinical presentation and histologic changes in human ATI are limited.

Methods: We comprehensively searched human studies of ATI from 1936 to July 2019. We extracted study characteristics, clinical characteristics and histologic descriptions of ATI by bright field, immunofluorescence or electron microscopy (EM) and by immunohistochemistry. We also compared histology of tubular cell injury as a function of tissue procurement timing and etiologies.

Results: We included 292 studies comprising of 1987 patients. The majority of studies (76%) were single center case reports. The mean age of patients included was 47 years old. 39.3% of patients had hypertension and 24.9% of them had diabetes mellitus. Baseline, peak and latest creatinine were 1.29 mg/dL, 7.04 mg/dL and 1.86 mg/dL respectively. 48.9% of studies were native kidney biopsy cases, of which 86.7% were obtained with the first analysis performed.

Conclusions: Tubular injury manifests with diverse histological changes. Efforts to establish protocols to harmonize biopsy practices, handle kidney biopsy and report results across clinical practice are needed to improve our understanding of this complex disease.

AKI and CKD Distribution in the Novel Clinical Phenotypes for Sepsis

Luca Molinari,1 Gaspar Del Rio-Pertuz,1 Sadudee Peecarrorontara,1,4 Hernando Gomez Daniels,1,2 John A. Kellum,1,3 Center for Critical Care Nephrology, Department of Critical Care Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA; 4Department of Translational Medicine, Università degli Studi del Piemonte Orientale, Novara, Italy; 1Clinical Research Investigation and Systems Modeling in Acute illness (CRISMA) Center, Department of Critical Care Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA; 2Excellence Center for Critical Care Nephrology, Division of Nephrology, and Department of Laboratory Medicine, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand.

Background: Sepsis is the most common cause of Acute Kidney Injury (AKI) in critically ill patients. Four clinical phenotypes (alpha, beta, gamma, delta) of sepsis have been recently described. Our objective was to investigate which of these sepsis phenotypes were associated with severe AKI, chronic kidney disease (CKD), AKI with CKD, and acute kidney disease (AKD).

Methods: We examined the 4 phenotypes using patient data from a previously published multicenter sepsis trial. After excluding patients with end-stage kidney disease and missing data, we analyzed 1243 patients with septic shock. We described the prevalence of severe AKI within the first 24 hours defined as KDIGO stage 2 or 3 or stage 1 with [TIMP-2]/[IGF-BP7] at 6 hours >2.0. AKD was defined for patients with severe AKI as the presence of any AKI on day 7 or, if death occurred before 7 days, death without AKI recovery. The Chi-square test was used to compare distributions between groups, if p<0.05 then a pairwise comparison between groups was made using the Chi-square test adjusted with Bonferroni correction.

Results: We found a total of 633 patients with severe AKI (53.6%) within 24h. The rate of severe AKI at 24h was different across phenotypes being highest in the delta and beta phenotypes (80.8% and 73.6% respectively), and lowest in the alpha phenotype (31.0%, overall p<0.0001). The delta was most common in the beta phenotype (52.8%, overall p<0.0001) while in the others was lower (31.4% in alpha, 28.6% in gamma, and 35.0% in delta). The highest prevalence of AKI with CKD was again in the beta phenotype (52.8%), compared to alpha (25.0%), gamma (26.6%), or delta (34.8%, p<0.0001). AKD occurred more often in the delta (57.4%) and beta (50.0%) phenotypes compared to alpha (32.7%) and gamma (40.1%, p=0.0002).

Conclusions: Severe AKI was significantly more common among patients with beta and delta phenotypes. However, the beta phenotype had a higher level of underlying CKD that predisposed to new AKI. Alpha and gamma phenotypes not only had lower rates of AKDI but these cases were less likely to progress to AKD.

Funding: NIDDK Support, Other NIH Support - The data of the abstract refer to: ProCESS trial (NCT00510835) funded by NIH/National Institute of General Medical Sciences grand R01GM076595, ProGReSS-AKI study funded by NIH/National Institute of Diabetes and Digestive and Kidney Diseases grant R01DK085961, SENECA project funded by NIH grants R35GM119519, R34GM102696, R01GM101197, GM107231, R01LM12095, K08GM117310-01A1, and GM61992.
Day 1 biomarkers of GS-CSF, IL1, IL6, IL8, TNF-alpha, IL10, TNFR1, TNFR2, MIF, IGF 1, and IGF 2 were not statistically different between the two subgroups. However, patients in the Low HU subgroup had higher IL8, TNFR1, TNFR2, and DRS levels at day 8.

Conclusions: Using a person-centered analytic technique (i.e., LCA), we found two subgroups of patients with distinct health utility profiles with 90-day survival following acute kidney injury. Demographic, clinical, and biomarker characteristics associated with each subgroup may be used to identify patients at high risk of poor HRQOL.

PO0097

Safety and Efficacy of a New Simplified Regional Citrate Anticoagulation Protocol for Continuous Venovenous Hemodiﬁlration and Sustained Low-Efﬁciency Dialysis Focused on Acid-Base Balance Optimization and Prevention of Kidney Replacement Therapy-Induced Hypophosphatemia

Enrico Fiaccadori,1, Giovanni Maria Rossi,1,2, Valentina Pirotta,1,2, Santo Morabito,1,2, Enrico Fiaccadori,1, Nephrology Unit, Parma University Hospital, Parma, Italy
1UO Nefrologia, Azienda Ospedaliera-Universitaria Parma, Parma, Italy; 2Umberto I Policlinico di Roma, Roma, Italy.

Background: Regional citrate anticoagulation (RCA) is the first-line anticoagulation strategy for Kidney Replacement Therapy (KRT) in Acute Kidney Injury (AKI). Hypophosphatemia is a common electrolyte disorder in the ICU, especially in course of prolonged and highly efﬁcient KRT. This pilot study is aimed at evaluating a simplified RCA protocol for Continuous Venovenous Hemodiﬁlration (CVVHDF) and Sustained Low Efﬁciency Dialysis (SLED), based on the combination of a low-concentration citrate solution with a phosphate-containing solution.

Methods: KRT was performed in ICU patients with AKI by the Prismax system (Baxter) and polyacrylonitrile AN69 filters (ST 150, 1.5 m2, Baxter), combining a 18 mmol/l pre-dilution trisodium citrate solution (Registoc 180, Baxter) with a phosphate-containing solution used as both dialysate and post-dilution replacement (TRALI 0, HPO 45, 1, Mg2+ 0.75, HCO3 - 22 mmol/l, Biphosphyl, Baxter). Calcium chloride (CaCl 10%) was infused in a central venous line to maintain the systemic Ca2+ within a normal range. In each patient three consecutive daily 8-h SLED sessions or 72-h CVVHDF were evaluated. Phosphorus (P) losses were replaced, when needed, with sodium glycophosphate pentahydrate (Glycophos® 20 mmol/20 ml, Fresenius Kabi Norge AS, Halden, Norway).

Results: 20 patients with AKI on SLED and 10 on CVVHDF were studied (mean APACHE II score 23.8). No premature interruptions for irreversible filter clotting occurred. Minimum dialyzed dosage was delivered in 95% of cases. No statistically signiﬁcant differences were observed between systemic ACT measured at KRT start and at different times during KRT. No major hemorrhagic events nor clinically relevant episodes of hypo- or hypercalcemia were observed. Acid-base status and serum phosphorus levels were effectively maintained.

Conclusions: Our simpliﬁed RCA protocol is safe and efficacious both for SLED and CVVHDF, allowing to optimize acid-base balance and to preventing KRT-related hypophosphatemia.

PO0098

Relationship Between the Presence of Infectious Disease and Clinical Outcomes of Patients with Cardiorenal Syndrome Type 1

Jonathan Chavez,1,2 Guillermo Garcia-García,1,2 Jorge I. Michel González,1,2 Hospital Civil de Guadalajara Unidad Hospitalaria Fray Antonio Alcalde, Guadalajara, Mexico; 1Universidad de Guadalajara, Centro Universitario de Ciencias de la Salud, CUCS, Guadalajara, Mexico.

Background: Cardiorenal Syndrome type 1 (CRS-1) can be triggered by an infection. The pathophysiological basis is vascular congestion, which is why it has been treated with different strategies of diuretics, but in the presence of infection, the inflammatory, neurohumoral and hemodynamic effects can compromise the efficacy of the diuretic therapy and potentially worsen clinical evolution. Here we compare the clinical evolution during hospitalization of CRS-1 patients with and without infection.

Methods: This is a retrospective cohort study conducted in the Hospital Civil de Guadalajara “Fray Antonio Alcalde”, from January 2015 to September 2018. Conducted in CRS-1 patients, we showed the clinical evolution and diuretic strategies analyzed accounting for the presence or absence of infection.

Results: We identified 63 patients classified as having CRS-1, 28 (44.4%) were classified as having an infectious disease. The mean age was 62 years (±14.6) and 58 (±12.4) in the group with infection and no infection, respectively. There were no statistically signiﬁcant differences between the clinical outcomes of both groups. The median length of hospital stay was 8 days in the group with infection and 7 days in the group without infection (p=0.065). Three patients (10.7%) of the group with infection received renal replacement therapy and 1 patient (2.9%) in the group without infection (p=0.015). In the group with infection 31% of patients died (71%), whereas in the uninfected group there were no deaths (p=0.194). SCR values tend to diminish in a similar manner in both groups. We found that all patients received furosemide at least during the first five days of hospitalization and the strategy of the diuretic chosen was similar between groups. No statistical differences were observed in the clinical evolution of patients with CRS-1 is similar in the presence or absence of infection. We anticipate that this study may be a reason to expand knowledge in patients with CRS-1 and the presence of infection.
Design of START: A Phase 2 Study Evaluating the Safety and Efficacy of RBT-1 on Preconditioning Response Biomarkers in Subjects Undergoing Cardiac Surgery

Bluipinder Singh,1,2 Philip T. Lavin,1 Andreas Orfanos,3 Stacey Ruiz,2 Donald J. Keyser,2 Alvaro F. Guillen,2 Richard A. Zager,6,3 Navdeep Tangri,6 Jean-Claude Tardif,2 1University of California Irvine, University of California Irvine, Irvine, CA, US, Department of Medicine, Irvine, CA; 2Renibus Therapeutics, Southlake, TX; 3Montreal Health Innovations Coordinating Center, Montreal, QC, Canada; 4Fred Hutchinson Cancer Research Center, Seattle, WA; 5University of Washington Department of Medicine, Seattle, WA; 6University of Manitoba, University of Manitoba, Winnipeg, MB, CA, Winnipeg, MB, Canada; 7Institut De Cardiologie de Montreal, Montreal, QC, Canada; 8Boston Biostatistics Research Foundation, Framingham, MA.

Background: Cardiac surgery is associated with an increased risk of acute kidney injury (AKI). RBT-1 induces non-ischemic tissue preconditioning that has shown organ protective effects in several animal models of AKI. Markers of cytoprotection observed with RBT-1 treatment in animals were also found to be upregulated in a Phase 1 study of RBT-1 in healthy volunteers and subjects with Stages 3 and 4 chronic kidney disease (CKD). Based on these data, we have designed a Phase 2, placebo-controlled, double-blind, randomized, multicenter study that will assess the effect of RBT-1 on preconditioning response biomarkers in subjects scheduled to undergo cardiac surgery.

Methods: Study Design: This study will enroll 126 subjects scheduled to undergo coronary artery bypass graft (CABG) and/or cardiac valve surgery. Eligible subjects will be randomized to receive a single dose of RBT-1 or placebo via intravenous infusion between 24 and 48 hours prior to scheduled cardiac surgery. Subjects will be followed through Day 90.

Inclusion/Exclusion Criteria: Subjects eligible for enrollment include adults who are scheduled to undergo non-emergent, on-pump coronary artery and/or cardiac valve surgery. Major exclusion criteria include CKD with eGFR ≤ 20 ml/min/1.73m2 or need for dialysis.

Results: Objectives: The primary objective of this study is to evaluate the efficacy of RBT-1 on preconditioning response biomarkers from baseline through Day 3 post-cardiac surgery. Based on preclinical data, plasma heme oxygenase-1 (HO-1), ferritin, and interleukin-10 (IL-10) have been identified as the relevant biomarkers for this study. Secondary objectives include change in tubular injury biomarkers and incidence of AKI.

Conclusions: The multinational START study will assess the cytoprotective preconditioning response to RBT-1 in subjects undergoing cardiac surgery.

Use of Azathioprine in Treating Severe Corticosteroid-Resistant Acute Interstitial Nephritis
Sanam K. Lodhi,1 Sravan Jasti,1 Hareem Ghazanfar,1 1Carle Foundation, Urbana, IL; 2King Edward Medical University, Lahore, Pakistan.

Introduction: Acute interstitial nephritis (AIN) is a pattern of renal injury characterized by inflammatory infiltrate in renal interstitium leading to decline in renal function. It is commonly caused by drugs such as penicillin, diuretics and proton pump inhibitors. Other causes include autoimmune diseases or systemic infections. Treatment involves removing the offending agent and steroids in severe cases. We describe a case of drug induced severe AIN refractory to steroids that is treated with azathioprine, an immunosuppressant drug that inhibits purine synthesis.

Case Description: A 20 year old Caucasian female with past medical history of gastroesophageal reflux disease (GERD) presented to the emergency with severe nausea, vomiting and oliguria. She had been taking omeprazole for 2 weeks prior to presentation. Initial labs indicated eosinophilia, raised creatinine levels of 3.5 mg/dl and Blood Urea Nitrogen of 27 mg/dl. Renal biopsy was done which showed severe acute interstitial nephritis with raised eosinophils. The diagnosis of Acute Kidney Injury secondary to drug induced AIN was made and patient was given pulse dose steroids for 3 days. She was discharged on 60 mg of prednisolone daily. A month later, the patient’s creatinine improved to 1.75 from a peak of 6.27 mg/dl. The steroid dose was tapered to 40 mg. However, the creatinine raised to 2.7 mg/dl again due to which prednisolone dose was

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Discussion: In past, azathioprine has shown promise in treatment of lupus nephritis and IgA nephropathy. To our knowledge, this is the first reported case of successful treatment of steroid resistant severe drug induced AIN with azathioprine. As it has lesser side effects and better compliance than steroids, it is suggested that azathioprine may be considered in future as an adjuvant or alternative first line of treatment for AIN. Larger, randomized clinical trials need to be conducted in order to establish optimal dosing and long term effectiveness of azathioprine in treating AIN.

PO0103
The Successful Treatment of Bile Cast Nephropathy with Plasma Exchange
Sweeth Reddy, Theresa Kinard, Margaret Ryan, Leslie F. Thomas. Mayo Clinic Arizona, Scottsdale, AZ.

Introduction: Bile cast nephropathy is a condition of renal dysfunction in the setting of hyperbilirubinemia. There are very few cases of this condition reported in literature, and there is a lack of established treatment guidelines. We report the successful management of Bile Cast Nephropathy with bile cast nephropathy using therapeutic plasma exchange (TPE).

Case Description: CASE 1: A 59 year old man with stage 3 colon carcinoma on Cepectabine developed chemotherapy-induced liver toxicity resulting in severe cholestasis and biopsy-proven bile cast nephropathy. He underwent TPE. CASE 2: A 69 year old man with colon cancer post remote ileocolic anastomosis and lower extremity edema was admitted with pruritus and acute kidney injury (AKI). CT abdomen without contrast showed a 6 cm liver mass with bile duct dilatation, a biopsy proven metastasis from his previous colon cancer. A kidney biopsy confirmed bile cast nephropathy. The patient was started on hemodialysis (HD), and a biliary stent was placed. He was treated with TPE. He opted for hospice due to cancer CASE 3: A 38 year old man was admitted with severe acute alcoholic hepatitis and AKI. A kidney biopsy confirmed bile cast nephropathy. He underwent TPE and a total of four sessions of HD. The clinical course in our patients with biopsy proven bile cast nephropathy prior to and after TPE therapy is noted in Table 1.

Discussion: In 1970, TPE was introduced as a treatment modality for chronic liver disease. 1-2 plasma volume exchange was performed with each procedure with a combination of plasma and 5% albumin. A good response to TPE in decreased total bilirubin level and improvement in renal function was noted. There were no serious adverse events, and all procedures were tolerated well by the patients. Medical management of bile cast nephropathy such as steroids and cholestyramine have shown limited or no benefit. Renal replacement therapy has also been shown to be of limited benefit and should be mainly instituted for the treatment of AKI. In bile cast nephropathy, TPE may help in the clearance of bile acid crystals and reduction of proinflammatory molecules which contribute to acute liver and kidney injury. In this small case series, institution of TPE appeared to improve the clinical course of patients with bile cast nephropathy.

PO0104
An Unusual Case of IgA Nephropathy Associated with Parvovirus B19
Lalith S. Lakhanli, Hashim Abbas, Mohamed G. Atta. Johns Hopkins University, Baltimore, MD.

Introduction: Parvovirus is known to cause upper respiratory infections in children and the immunosuppressed. It’s association with kidney disease has been sporadically reported in literature, mostly causing hepatitis like glomerulonephritis with endocapillary proliferation. We describe a unique case of IgA Nephropathy (IgAN) in an African American patient associated with Parvovirus B19.

Case Description: A 23 year old African American female with a history of Hemoglobinopathies was diagnosed with a 6 cm liver mass with bile duct dilatation, a biopsy proven metastasis from his previous colon cancer. A kidney biopsy confirmed bile cast nephropathy. The patient was started on hemodialysis (HD), and a biliary stent was placed. He was treated with TPE. He opted for hospice due to cancer CASE 3: A 38 year old man was admitted with severe acute alcoholic hepatitis and AKI. A kidney biopsy confirmed bile cast nephropathy. He underwent TPE and a total of four sessions of HD. The clinical course in our patients with biopsy proven bile cast nephropathy prior to and after TPE therapy is noted in Table 1.

Discussion: In 1970, TPE was introduced as a treatment modality for chronic liver disease. 1-2 plasma volume exchange was performed with each procedure with a combination of plasma and 5% albumin. A good response to TPE in decreased total bilirubin level and improvement in renal function was noted. There were no serious adverse events, and all procedures were tolerated well by the patients. Medical management of bile cast nephropathy such as steroids and cholestyramine have shown limited or no benefit. Renal replacement therapy has also been shown to be of limited benefit and should be mainly instituted for the treatment of AKI. In bile cast nephropathy, TPE may help in the clearance of bile acid crystals and reduction of proinflammatory molecules which contribute to acute liver and kidney injury. In this small case series, institution of TPE appeared to improve the clinical course of patients with bile cast nephropathy.
Renal Artery Thrombosis in a Patient Homozygous for Plasminogen Activator Inhibitor-1 4G Allele

American College of Physicians, Philadelphia, PA.

Introduction: Renal artery thrombosis is a serious, uncommon, and often undiagnosed condition. Physicians need to consider this diagnosis in unexplained flank pain, especially in the presence of risk factors. Plasminogen activator inhibitor-1 (PAI-1) is the major inhibitor of tissue-type plasminogen activator. Fibrinolysis is impaired due to increased plasma PAI-1 levels which play an important role in the pathogenesis of thrombotic disorders. Homozygous for the 4G allele had increased plasma PAI-1 concentrations.

Case Description: A 53 years old male with hypertension, presented to the emergency room complaining of abdominal pain and pink urine for 3 days. His BP was 186/120 mmHg and pulse 100/min. Physical exam was consistent with right flank tenderness. Urinalysis showed high gravity, high amount of protein, glucose and blood. Creatinine was 1.6 and the baseline was unknown. CTA showed right renal artery occlusion. The patient was transferred to ICU and started on levodipine and heparin drip. Arteriogram and directed thrombolysis were performed. Despite these interventions, his creatinine trend peaked at 2.85, whereas hemoglobin started dropping substantially. High rate IV fluids, a workup for malignancy, and hypercoagulable were started with subsequent stent placement for reperfusion. After 3 days of directed thrombolysis, he was transferred to wards. Urine output decreased and a Foley catheter was placed. The patient’s medical condition improved. He was discharged and advised to follow up as an outpatient.

Discussion: Studies have proven the link between PAI-1 4G and thrombotic events, however, most of the evidence shows a link between PAI-1 4G and venous thrombosis. In this patient, the fact of him being homozygous for PAI-1 4G allele led to arterial thrombosis. Therefore, it might be prudent to include a PAI-1 workup in prothrombotic settings. In renal artery thrombosis, a cause must be established. Although there are other common causes of arterial thrombosis, PAI-1 4G should be considered as a potential cause in patients with few or no risk factors. This case report glimpses the relationship between an uncommon genetic mutation and a rare diagnosis.

Ganja Kidney: Acute Tubular Injury Associated with Synthetic Marijuana, A Rising Incidence

Ivette Cardenas Espritu,1,2 Fernando Lopez Osma,1,3 Don H. Espritu.1,3 1Northern Florida Kidney Care by NPS, Gainesville, FL; 2North Florida Regional Medical Center, Gainesville, FL; 3Universidad del Sagrado Corazon, San Juan, Puerto Rico; 4Hospital Provincial Universitario Camilo Cienfuegos, Sancti Spiritus, Cuba.

Introduction: Synthetic cannabinoids (SC), “Ganja”, have been used as recreational drugs producing a increasing popularity among young adults but have significant toxicity. We present a case of acute kidney failure in a relatively healthy young male individual after using marijuana pills.

Case Description: 31-year-old Hispanic male with no known past medical history presented to the emergency room with nausea and vomiting for 2 days. He stated that he has recently started taking “Ganja” pills to help with relaxation after losing work due to the Covid-19 pandemic. Vital signs were within normal limits and physical findings were unremarkable. Laboratory data were significant for serum creatinine of 10.14 mg/dl, blood urea nitrogen of 91 mg/dl, estimated glomerular filtration rate of 8 mL/min, and serum potassium of 7 meq/l. Urine toxicology was positive for cannabinoids. Complements and serologies were all negative. Renal ultrasound was unremarkable. A renal biopsy showed acute tubular injury with tubular dilatation, cytoplasmic simplification and vacuolization. Interstitial hemorrhosis was identified but later discontinued after renal recovery. On discharge, serum creatinine was 1.2 mg/dl.

Discussion: Cannabinoids are found in natural marijuana and contain many active compounds, but delta-9 tetrahydrocannabinol (THC) and cannabidiol (CBD) are of most interest. THC is the primary ingredient in marijuana that makes people “high”. Synthetic cannabinoids are analogs of natural occurring cannabinoids that are chemically synthesized. This synthetic compound is added to the natural marijuana or other herbs to appear as a natural product. The clinical effects can be like natural marijuana which include tachycardia, conjunctival injection, slurred speech, and increase appetite due to the partial or full agonistic effect at the cannabinoid receptors. Compared to cannabis, synthetic cannabinoids have a greater risk for serious neuropsychiatric toxicity and severe acute kidney injury. We need more clinical research to identify the specific nephrotic agents.
PO0110
The Emerging Role of Bedside Doppler Ultrasound for Precise Assessment of Venous Congestion in Cardiorenal Syndrome
Abhilash Koralata,1 Saqib Mahmud,1 Olanrewaju A. Olayo,2 Amir Kazory.2
1Medical College of Wisconsin, Milwaukee, WI; 2University of Florida, Gainesville, FL.

Introduction: Congestion is an integral component of cardiorenal syndrome and the primary reason for hospitalization in patients with heart failure (HF). Making it a key target in the management of these patients. Routinely used parameters to monitor response to decongestive therapy such as physical examination, B-type natriuretic peptide, changes in weight and net fluid balance, even inferior vena cava ultrasound (IVC US) are all error prone. Doppler ultrasonography (DUS) of the portal, hepatic and when possible, intrarenal veins is an attractive alternative that can be used at bedside to accurately assess the degree of congestion and guide management strategies.

Case Description: A 55-year-old man with a history of HF with reduced ejection fraction of ~25%, hypertension and chronic kidney disease stage 3 presented with acute kidney injury of uncertain etiology. Serum creatinine (Scr) was 3.5 mg/dl for a baseline of 1.6 mg/dl. He had no symptoms except for his usual dyspnea on exertion. Physical examination was significant for crackles at lung bases and mild pitting pedal edema. Bedside US revealed increased extravascular lung water and a dilated but collapsible IVC. DUS revealed stigmata of severe congestion with a pulsatile portal vein and systolic flow reversal, and a hepatic vein with only diastolic (D) component below the baseline. Therefore, the diagnosis of congestive renal failure due to acute cardiorenal syndrome was made and high dose intravenous diuretics were initiated. The follow up DUS on days 3 and 5 showed remarkable improvement (reversal of waveforms to normal pattern) indicating progressive decongestion [Figure]. His diuretic therapy was titrated based on these findings and Scr improved to 2 mg/dl at discharge.

Discussion: Bedside DUS assessment of hepatic and portal veins aids in management of patients with HF by non-invasively monitoring the efficacy of decongestive therapy, and serves as a valuable adjunct to conventional clinical evaluation.

PO0112
Hypothyroidism-Induced AKI: A Case Series
Soomathi Ramnieni, Varun kumar Bandi. Dr. Pinnamaneni Siddhartha Institute of Medical Sciences & RF, Gannavaram, India.

Introduction: Thyroid hormones affect the development and various functions of the kidney. Such effects are partly mediated by direct renal action and partly by cardiovascular and systemic effects.

Case Description: We present a series of 3 patients who presented with unexplained acute kidney injury (AKI). All patients were male, and one was hypertensive on amlopidine. Investigations showed blood urea levels ranging from 20 to 88 mg/dl, serum creatinine between 1.3 to 3.65 mg/dl with estimated glomerular filtration rate (eGFR) of 17.88 to 63.18 ml/min/1.73m2. Urine routine and ultrasound abdomen did not reveal any abnormalities. The patients had features suggestive of hypothyroidism and thyroid evaluation was done. Thyroid stimulating hormone (TSH) was elevated in all patients and T3 and T4 were decreased. The TSH levels ranged between 88.4 to 100 mIU/L. Creatine phosphokinase (CPK) level was modestly elevated in only one case, with absent urine myoglobin in all cases. A possibility of hypothyroidism induced AKI was considered and renal biopsy was deferred. After starting levothyroxine, complete renal recovery was seen in 2 patients and partial recovery in one within 8 weeks (Table 1).

Discussion: AKI has been reported in patients with severe hypothyroidism, and most cases were suspected to be due to rhabdomyolysis and had rapid normalization. Few cases of slower and incomplete recovery have been noted in cases with prolonged periods of severe hypothyroidism. In our series, normal urinalysis, absence of myoglobin, and normal or modest elevation of CPK makes rhabdomyolysis unlikely. The AKI could be due to hypothyroidism induced changes in renal hemodynamics. Our study relies on eGFR for renal function, and extent to which this reflects true changes in GFR is unclear. Hypothyroidism is a reversible cause of AKI and should be evaluated in cases with unexplained AKI. These patients can attain normal renal function with prompt initiation of levothyroxine therapy.

PO0111
Furosemide: An Unusual Cause of Acute Interstitial Nephritis Requiring Hemodialysis: First Case Report
Hassan Alhalaibi. Dallas Nephrology Associates, Irving, TX.

Introduction: Furosemide, a loop diuretic, is widely used for volume control and is a known cause of acute interstitial nephritis. However, AIN due to furosemide is not typically associated with abrupt and severe acute kidney injury (AKI). Here we report a patient who developed severe AKI requiring hemodialysis shortly after receiving furosemide.

Case Description: A 65 year old male with a history of hypertension was started on oral furosemide 20 mg daily for edema in his legs. One week later he presented to the emergency room complaining of oliguria and worsening edema. Laboratory findings were significant for a serum creatinine of 37.8 mg/dl and potassium 7.8 mmol/L. Patient required emergent hemodialysis for volume control, clearance and hyperkalemia, and continued to require HD every other day. Serologic work-up included a normal C3, C4, ANA, ANCA, anti-GBM, and SPEP/UPEP. Urinalysis showed small blood, no protein, 12-15 RBC’s, 10 WBC’s. Renal ultrasound was normal. A kidney biopsy was performed which demonstrated interstitial edema with patchy inflammatory cell infiltrates with eosinophils. The tubules were dilated and showed significant degenerative changes in tubular epithelial cells. The patient was started on treatment for acute interstitial nephritis with oral prednisone 60 mg daily with a subsequent slow taper. Kidneys did not recover and he was placed on hemodialysis three times a week with close monitoring of kidney functions.

Discussion: Furosemide, a loop diuretic, is widely used for volume control. To our knowledge, this is the first report of AIN associated with loop diuretics that resulted in severe and requiring hemodialysis. Unfortunately, our patient did not respond to high dose steroids and he continued to require hemodialysis three times a week. Our report highlights the importance of close monitoring of any potential toxicities that may be associated with such medications.
Introduction: Renal cortical necrosis (RCN) is a rare cause of acute kidney injury (AKI) accounting for 1-2% of cases. It is most often associated with obstetric emergencies in developing countries. The most common non-obstetric etiology is hemolytic uremic syndrome, but it has also been described in renal allograft rejection, sepsis, and in rare cases pancreatitis where ten cases have been reported. We describe a case of severe renal cortical necrosis in a previously healthy young man with acute pancreatitis.

Case Description: A 29-year-old man with no significant medical history presented with severe epigastric pain and anuria for three days. He was diagnosed with alcohol-induced pancreatitis with a lipase level of 35,534U/L and AKI with a creatinine of 5.8mg/dL (baseline 1.2mg/dL). The anuria did not improve with fluid resuscitation, the AKI progressed and he was initiated on hemodialysis. Evaluation of AKI with hepatitis B and C serologies, HIV, complement levels and ANA was unremarkable. Kidney ultrasound showed increased echogenicity without hydronephrosis. An abdominal CT scan with IV contrast done for worsening fever and leukocytosis showed diffuse areas of non-enhancement involving bilateral renal cortices consistent with acute renal cortical necrosis. To note, throughout his presentation and admission, the patient was not hypotensive. He remained dialysis dependent for three months with oliguria that eventually improved and dialysis was discontinued with a stable eGFR of 20ml/min/1.73m². He has remained off dialysis for the past five months and is undergoing transplant evaluation.

Discussion: RCN is thought to be an irreversible cause of AKI secondary to decreased perfusion, vasospasm and endothelial injury resulting in ischemia. It is frequently associated with hypotension but in our case the patient was normotensive. The mechanism leading to RCN associated with pancreatitis remains poorly understood. Acute pancreatitis, on the other hand, has been associated with other vasoocclusive ischemic complications (e.g. Purtscher’s retinopathy). RCN is a devastating complication that often leads to dialysis dependence. Despite our patient showing signs of recovery, his prognosis remains poor. Further study is needed to understand its pathophysiology and potentially mitigate its consequences.

DRESS Syndrome and Acute Interstitial Nephritis Relapse: A Case for Caution

Introduction: The syndrome of drug reaction with eosinophilia and systemic symptoms (DRESS) is a rare but potentially life-threatening drug-induced type IV hypersensitivity reaction that usually occurs 2-6 weeks after drug initiation. Typical findings include skin eruption, fever, hematologic abnormalities, and visceral organ involvement. Prolonged corticosteroid treatment is often required as relapse after initial improvement is not uncommon.

Case Description: A 62-year-old woman with a history significant for right total hip arthroplasty complicated by a prosthetic joint infection requiring hardware exploitation and antibiotic spacer placement initially presented to the ED with fever, rash, and pruritus. She was treated with cefepime and vancomycin for probable intra-operative bacterial cultures. Urinalysis showed pyuria (51-100/hpf) and eosinophils (1-5%). Skin biopsy showed a drug reaction. She was diagnosed with DRESS syndrome and acute interstitial nephritis (AIN) secondary to the antibiotics, which were then changed to aztreonam and daptomycin. She was treated with systemic and topical steroids and was discharged on daptomycin. She was started on a higher dose of oral prednisone (80 mg daily) and had clinical improvement. She was then discharged with plan to taper by 10 mg every 2 weeks over 4 months.

She was seen again the ED 5 days after discharge with fever and worsening rash and pruritus. Physical examination was notable for mild facial swelling and scattered pink macules coalescing into patches on both upper and lower extremities and on the groin. Laboratory studies revealed leukocytosis with peripheral eosinophilia [7.35x10^9/L] (on discharge: 0.87), elevated serum creatinine of 4.8 mg/dL, and elevated LFTs, ESR, and CRP. She was diagnosed with DRESS syndrome and AIN relapse secondary to rapid steroid taper. She was discharged on a higher dose of oral prednisone (80 mg daily) and had clinical improvement. She was seen again the ED 5 days after discharge with fever and worsening rash and pruritus.

Discussion: Long-term supra-physiologic doses of steroids are necessary to treat DRESS syndrome even after patients appear to have improved. Relapses do occur and frequently follow treatment discontinuation or rapid steroid taper, leading to increased morbidity and mortality. In such cases, a more prolonged steroid treatment is needed, which can cause well-known adverse events and complications. Close monitoring is thus required.

Rivaroxaban-Induced Anticoagulant-Related Nephropathy

Introduction: Anticoagulant-related nephropathy (ARN) is a rare and newly recognized cause of acute renal failure (ARF). A lack of serologic studies and hesitancy to perform high risk biopsies due to concerns for thrombosis or hemorrhage, make ARN a challenging diagnosis. The pathophysiology is believed to be from diffuse glomerular hemorrhage which manifests as numerous RBC casts. These RBC casts obstruct and damage tubular epithelial cells resulting in renal failure. We will examine a case of ARN.

Case Description: An 83-year-old Caucasian female presented with complaints of lower extremity weakness and was found to have ARF on laboratory investigation (Cr 5.18mg/dL from 1.1mg/dL one month prior). The patient was recently started on rivaroxaban for 5 days. Preliminary results showed IgA nephropathy with oxford classification score 5.18mg/dL from 1.1mg/dL one month prior). The patient was recently started on rivaroxaban for 5 days. Preliminary results showed IgA nephropathy with oxford classification score 5. Prolonged corticosteroid treatment is often required as relapse after initial improvement is not uncommon.

Discussion: The use of novel oral anticoagulants (NOAC), has become prevalent in the medical community as a treatment strategy for various diseases. While previous cases have been mostly described in patients on warfarin, this case illustrates the importance of recognizing the new phenomenon of ARN as a risk factor for patients on NOACs. Due to limited data and no prospective studies, expert opinion has recommended switching one oral anticoagulant to another or reducing the dose of the offending agent. Further research is needed to understand this disease process to help design prevention and treatment strategies.

Gross Hematuria, Intense Interstitial Hemorrhages, Red Blood Cell Casts: An Atypical Triad of Amoxicillin-Clavulanate-Induced Acute Tubulointerstitial Nephritis
Ramzi A. Rahman, Farooq Ahmad, Mohammed Akhtar, Muhammad Asim. Hamad Medical Corporation, Doha, Qatar.

Introduction: Drug induced tubulointerstitial nephritis (TIN) usually presents with acute kidney injury, pyuria, white cell casts and micro-hematuria. We report this case to highlight a unique pattern of presentation.

Case Description: A 33-years-old man presented with gross hematuria and acute kidney injury three weeks after a throat infection treated with Amoxicillin-Clavulanate. He denied any previous episodes of hematuria, family history of renal disease or use of any other medication. Physical examination was normal other than mild cervical and axillary lymphadenopathy. Laboratory tests revealed serum Creatinine of 5.3mg/dL, hematuria, sterility pyuria and minimal proteinuria. Immunoregulation screen and renal ultrasound were normal. Peripheral blood smear demonstrated eosinophilia and 7% blast cells. Flow cytometry and bone marrow studies confirmed Acute T-cell Lymphoblastic Leukemia. Kidney biopsy showed acute interstitial nephritis but normal glomeruli. The most striking features were multifocal intense interstitial hemorrhages, abundant red blood cells casts (RBC) in several tubules and RBC casts in some. Direct immunofluorescence, SV40 staining and immunohistochemical studies for leukemia infiltration were negative. Treatment with systemic steroids was initiated. Serum creatinine started to decrease within 3 days. Steroids were continued as a part of induction chemotherapy instituted subsequently for leukemia. Renal function normalized and hematuria subsided within 2 months.

Discussion: Drug induced TIN can present with atypical features masquerading as glomerulonephritis, vasculitis or infectious interstitial nephritis. It is plausible that severe infection led to a major decrease in circulating interstitial vascular walls resulting in interstitial hemorrhages that extended into the tubules through ruptured basement membrane producing gross hematuria and RBC casts.
PO0123

IgG4-Related Disease with Renal Involvement in a Patient with HIV Infection
Karen Flores, Samir V. Parikh, Ganesh B. Shidham. The Ohio State University, Columbus, OH.

Introduction: Immunoglobulin G4-related disease (IgG4-RD) is a fibroinflammatory disease that can affect multiple organs. It is characterized by lymphadenopathy and diffuse enlargement of one or multiple organs. Pathologic features include tissue infiltration by IgG4-positive plasma cells, storiform fibrosis, and increased tissue eosinophils. Tubulointerstitial nephritis is the most common renal manifestation. We describe a case of IgG4-RD in a patient with co-existing HIV infection.

Case Description: A 60-year-old male with CKD 3, hypertension, hepatitis B, and HIV was hospitalized due to malaise and acute kidney injury with serum creatinine of 4.2 mg/dL and 1.5 g/dL proteinuria. HIV was controlled with undetectable viral load on treatment. Infectious work up was negative. CT scan showed diffuse retroperitoneal lymphadenopathy. PET scan showed diffuse lymphoproliferative disease and increased uptake in lymph nodes of the neck, axilla, and anterior and posterior mediastinum. Right inguinal lymph node biopsy showed dense interfollicular T-cell infiltrate and dense polytypic plasmacytic infiltrate with a kappa/lambda ratio of 3:1 by IGH. TCR gene rearrangement and IGH studies were negative for a monoclonal population. Testing for HIV and HBV was negative. SPEP showed a small Bence-Jones clone (0.3 g/dL). UPEP showed a small amount of lambda free light chains. Bone marrow biopsy showed no evidence of T cell lymphoma but revealed hypolamellar marrow. Total IgG (5048 mg/dL) and IgG (572 mg/dL) were elevated and both C3 and C4 were low. Kidney biopsy revealed dense interstitial infiltration of plasma cells strongly positive for IgG (>50/hpf) and no electron dense deposits. The patient was diagnosed with IgG4-RD with renal involvement. He was treated with high dose prednisone and mycophenolate mofetil. Renal function improved from 4.6 mg/dL to a 1.9mg/dL after 3 months of IgG4 levels improved 70mg/dL and C3/C4 normalized suggesting disease control had been achieved.

Discussion: We describe a case of IgG4-RD with renal involvement in a patient with HIV infection. There are only a few reports in the literature. Differential diagnosis of kidney disease during HIV infection is broad. IgG4-RD is a severe systemic disorder that can be mistaken for infection or malignancy. IgG4-RD should be considered in the differential for acute kidney injury in the setting of HIV.

PO0124

Renal Replacement Therapy in Pheochromocytoma
Jennifer Griffliths, Hay Me Mc, Aromma Kapoor. Westchester Medical Center, Valhalla, NY.

Introduction: Pheochromocytoma is a rare tumor derived from chromaffin cells of the sympathetic nervous system. The triad of headache, palpitations and diaphoresis is often present, but catecholamine excess can present in various contexts. Tumors secreting epinephrine can present with episodic hypotension; rapid cycling fluctuations of hypotension and hypertension also occur. Most acute kidney injury (AKI) in the setting of pheochromocytoma crisis is due to ischemic acute tubular necrosis (ATN). For cases requiring renal replacement therapy, there are no studies supporting one form over another. We describe a patient with Pheochromocytoma who developed AKI requiring renal replacement therapy (RRT).

Case Description: 29 year old woman with history of migraines presented to outside hospital with headache and chest pain, and found to be in hypertensive emergency with mild elevation of troponins. Patient was transferred to our hospital for evaluation of possible myocardial infarction. Cardiac catheterization showed clear coronaries. Patient became hypotensive during the procedure and Intra-Aortic Balloon Pump was placed. Imaging showed high density mass in the left adrenal gland. Patient was started on Phenoxybenzamine. Biochemical tests confirmed Pheochromocytoma. Labs showed creatinine of 5.38. Patient became amric and RRT was initiated with intermittent hemodialysis (iHD). Due to the acute dialysis need, high dose hydroxyurea and mycophenolate mofetil had good pressure fluctuations and became hypotensive with decreased responsiveness. Imaging was negative for acute bleed but concerning for cerebral edema. RRT was switched to continuous renal replacement therapy (CRRT) which was better tolerated.

Discussion: Our patient experienced an acute hypertensive crisis followed by cardiovascular collapse likely precipitated by intravenous glucocorticoids given for presumed myocarditis. Glucocorticoids increase catecholamines; the excess causes cardio toxicity which in turn leads to ischemic ATN. Patient was able to tolerate iHD however, as the Phenoxybenzamine was up titrated, the fluctuations included hypertensive episodes and was worsened on dialysis. Given the unpredictable fluctuations in blood pressure and the possibility of associated hypertensive encephalopathy and/or...
cerebral edema in the setting of Pneumocystis jirovecii, it may be prudent to choose CRRT when RRT is warranted, though there are no guidelines regarding which modality is superior in these patients.

PO0125
Blast from the Past: A Rare Case of AKI from Sulfadiazine-Induced Nephrolithiasis

Introduction: Sulfadiazine has been used for the treatment of neurotropic ophthalmia in patients with HIV infection. Nephrotoxicity is a known complication of high-dose sulfadiazine therapy. However, this complication is rarely seen in HIV patients due to improved antiretroviral therapy. We present a rare case of sulfadiazine-induced nephrolithiasis in a patient with AIDS.

Case Description: A 57-year-old female with DM and HTN was hospitalized for worsening mental status and CT scan finding of frontal lobe mass. During hospital stay, pt. also found to have HIV infection and a very low CD4 count. Antiretroviral therapy and high dose intravenous sulfadiazine 1,500 mg every 6 hours was initiated for presumed neurotropic ophthalmia. On admission, serum creatinine (Scr) was 0.68. Seventeen days after initiation of sulfadiazine therapy, Scr increased to 2.42. Urinalysis revealed microscopic hematuria. Kidney sonogram showed left hydronephrosis and echogenic foci in both kidneys concerning for kidney stones. Sulfadiazine was discontinued and patient was started on sodium bicarbonate infusion to alkalize her urine but Scr remained to worsen, peaking at 4.73 within few days. Serial kidney sonograms revealed alternating fullness of the collecting systems of both kidneys. Urology team was consulted and patient underwent cystoscopy with bilateral ureteral stent placement. Scr subsequently returned to normal limits within one week of ureteral stent placement.

Discussion: Our patient developed severe but reversible post-obstructive AKI secondary to high-dose sulfadiazine-induced nephrolithiasis. In the modern era of antiretroviral therapy, sulfadiazine-induced nephrotoxicity is a very rare occurrence in clinical practice. Hence, clinicians and nephrology care providers should be aware of this rare cause of AKI in patients with HIV infection.

PO0126
Rhabdomyolysis as Initial Presentation of COVID-19
Hugo Andrade paz, Mala Sachdeva, Nupur N. Uppal. Northwell Health, Great Neck, NY.

Introduction: Rhabdomyolysis has infectious etiology including Mycoplasma pneumonia infection, Legionella, and Influenza. To date, there has been one case report from Wuhan China of a patient who developed rhabdomyolysis from COVID-19 during their hospitalization. We report a case where acute kidney injury and rhabdomyolysis was the initial presentation.

Case Description: A 57 year old African American male with history of HTN for more than 10 years, presented with complaints of decreased urine output for 3 days associated with dark urine that progressed to anuria, fever for 11 days, decreased appetite and oral intake and generalized muscle weakness. Labs on admission were notable for acute kidney injury (creatinine 1.77mg/dL) which progressively increased to a peak creatinine of 11.10mg/dL within 72 hours, and other electrolyte abnormalities including mild hyperkalemia and acidosis. His CPK was 92,000U/L. Admission and COVID-19 PCR was positive. Other labs included: peak AST 1692 U/L and ALT 291U/L, ferritin 1436 ng/ml, 4.86fmg/dL, D-Dimer 2330 2Dd, urinalysis specific gravity 1.030 with large blood, 10RBCs, 20WBCs, urine spot protein/creatinine 2.1 and random urine sodium 65. Serologic workup was negative for glomerular etiology. He was presumed to have acute kidney injury due to rhabdomyolysis. He was treated initially for admission for anuria and worsening of renal function. He was maintained on hemodialysis with minimal ultrafiltration three times a week, intravenous fluid resuscitation along with intermittent doses of bumex. He received total of five hemodialysis treatments until he became pre-oliguric and started showing signs of recovery. He was taken off dialysis approximately three weeks after his initial presentation. His creatinine decreased and is 1.4 mg/dL one month after being taken off of hemodialysis.

Discussion: COVID-19 has its usual presentation of fevers, shortness of breath, dry cough and myalgias. This case highlights the importance that rhabdomyolysis can be one of the presenting features of COVID-19. Chances CPK levels should be an included part of not only acute kidney injury workup in the COVID-19 patient but also for any COVID-19 newly diagnosed case as this diagnosis requires prompt and specific treatment.

PO0127
Lymphomatous Infiltration of the Kidney: A Sonographic Diagnosis
Bhavna Bhasin, Abhishek Koratala. Medical College of Wisconsin, Milwaukee, WI.

Introduction: The purpose of this case study is to illustrate the sonographic findings seen in kidney infiltration by lymphoma.

Case Description: A 56-year-old man with a history of hypertension, diabetes mellitus type 2 and follicular lymphoma with transformation to diffuse large B-cell lymphoma presented with worsening fatigue, headache and diplopia. MRI of the brain demonstrated central nervous system involvement by the lymphoma. He was also found to have worsening renal function with a serum creatinine of 4.5 mg/dL (baseline: 1.6-2 mg/dL). A renal sonogram (RUS) was performed, which demonstrated bilateral enlarged kidneys (~15 cm each) with irregular outlines and multiple parenchymal hypoechogenic to heterogeneous lesions. No internal vascularity was noted on color Doppler. These findings are consistent with lymphomatous infiltration of the kidneys, confirmed later by PET (positron emission tomography) scan [Figure]. The renal function continued to worsen despite supportive care, and he required initiation of hemodialysis. Acute kidney injury was initially attributed to poor oral intake and mild hypercalcemia, but lymphomatous infiltration likely contributed to his renal impairment as well. Renal biopsy was not undertaken due to progression of the lymphoma and limited life expectancy.

Discussion: Kidney is the most common extra-reticular site of leukemic and lymphomatous infiltration, and tumor-cell infiltrates in the kidney are seen in up to 30% of patients with lymphoma. Rarely, renal involvement may be the first manifestation of the lymphoma. The kidneys may appear normal on RUS because of the small size of the nodular infiltrates or with the typical findings described above. Unilateral and perirenal infiltration with lymphoma has also been described. Hydronephrosis may be noted on RUS if there is compression of the renal hilum or ureters by the lymphomatous tissue. Nephrologists performing point of care ultrasonography should be aware of these findings. These patients will require a prompt referral to the Hematology & Oncology team when renal ultrasonography leads to a new diagnosis of lymphoma.

PO0128
Minimal Change Nephrotic Syndrome Superimposed on Anti-Glomerular Basement Membrane Antibody Glomerulonephritis: A Case Report
Yuko Shibata, Kazuhiro Fukuoka, Shinya Kaname. Kyorin university school of medicine Kyorin Daigaku, Mitaka, Japan.

Introduction: Background: The renal prognosis of anti-GBM glomerulonephritis (anti-GBM GN) is extremely poor as renal dysfunction often progresses acutely before the initiation of treatment. It is also known that once the disease activities are controlled by aggressive treatment, its recurrence is rare. Here we experienced a case of anti-GBM GN that improved from severe renal dysfunction but later relapsed. A possible cause was thought to be a rare complication of minimal change nephrotic syndrome (MCNS).

Case Description: A 50-year-old man was admitted to our hospital because of general malaise, fever, oliguria and renal dysfunction. The patient’s laboratory data showed serum creatinine as high as 6.6 mg/dl and severe inflammation (C-reactive protein 20.6mg/dL). Anti-glomerular basement membrane antibody (anti-GBM Ab) was detected in his serum, leading to a diagnosis of anti-GBM GN. Treatment was initiated with high-dose glucocorticoid (GC) and plasma exchange therapy (PE), and the patient’s renal function and oliguria improved rapidly and he was discharged 40 days after admission. Renal biopsy findings showed cellular crescents associated with linear IgG depositions along the glomerular tufts compatible with anti-GBM GN, but only about one-third of the glomeruli was involved, suggesting that it still remained an early stage of the disease. However, two months after discharge, he had a relapse and was readmitted due to severe proteinuria associated with positive anti-GBM Ab. On the second admission, he was treated with high-dose GC and PE combined by intravenous cyclophosphamide, and completed remission was achieved a few weeks later. Electron microscopy of the biopsy that returned later showed significant foot process effacement on podocytes in the apparently normal glomeruli without electron dense deposits.

Discussion: Considering clinical course and renal pathology findings, it is suggested that the present case was a rare complication of an early stage of anti-GBM GN and MCNS. Although the cause of concurrent development of anti-GBM GN and MCNS associated with anti-GBM antibody titers is unclear, it might have been precipitated by influenza infection or some unknown factor.

PO0129
Thrombotic Microangiopathy with Acute Interstitial Nephritis

Introduction: Thrombotic Microangiopathy (TMA) and Acute Interstitial Nephritis (AIN) are well recognized entities that individually cause significant morbidity and mortality. The relationships with several medications have been described, but the two conditions coexisting are rare.

Case Description: 28-year-old man with no significant past medical history presented with bilateral lower extremity edema, excoriations, discharge, and weakness for one week. He initially presented to an outpatient clinic and was discharged on trimethoprim-sulfamethoxazole (TMP/SMX). His symptoms progressed leading to admission. Physical examination revealed generalized edema and decreased bilateral lower extremity pulses. The patient was started on hemodialysis and his renal function improved and he was discharged from dialysis. However, he was rehospitalized two weeks later due to return of bilateral lower extremity edema. Additional symptoms included one week of general malaise, persistent cough, and left lower quadrant pain. The patient was found to have worsening renal function with a serum creatinine of 4.5 mg/dL (baseline: 1.6-2 mg/dL). A renal sonogram (RUS) was performed which demonstrated bilateral enlarged kidneys (~14.5 cm each) with irregular outlines and multiple parenchymal hypoechogenic to heterogeneous lesions. No internal vascularity was noted on color Doppler. These findings are consistent with lymphomatous infiltration of the kidneys, confirmed later by PET (positron emission tomography) scan [Figure]. The renal function continued to worsen despite supportive care, and he required initiation of hemodialysis. Acute kidney injury was initially attributed to poor oral intake and mild hypercalcemia, but lymphomatous infiltration likely contributed to his renal impairment as well. Renal biopsy was not undertaken due to progression of the lymphoma and limited life expectancy.

Discussion: Kidney is the most common extra-reticular site of leukemic and lymphomatous infiltration, and tumor-cell infiltrates in the kidney are seen in up to 30% of patients with lymphoma. Rarely, renal involvement may be the first manifestation of the lymphoma. The kidneys may appear normal on RUS because of the small size of the nodular infiltrates or with the typical findings described above. Unilateral and perirenal infiltration with lymphoma has also been described. Hydronephrosis may be noted on RUS if there is compression of the renal hilum or ureters by the lymphomatous tissue. Nephrologists performing point of care ultrasonography should be aware of these findings. These patients will require a prompt referral to the Hematology & Oncology team when renal ultrasonography leads to a new diagnosis of lymphoma.
examination revealed an obese man with bilateral lower extremity edema, eczematous rash, and mottled discoloration on both feet. Initial laboratory results were significant for a creatinine of 5.2 mg/dL and oliguria. Urinalysis revealed proteinuria, hematuria, and pyuria. He then developed thrombocytopenia and anemia. Haptoglobin and lactate dehydrogenase were elevated, and schistocytes were identified on peripheral smear consistent with microangiopathic hemolytic anemia. He also had eosinophilia. Work-up for autoimmune infectious, and connective tissue diseases was ordered and results were unrevealing. ADAMTS13 activity was decreased at 42%. The patient started hemodialysis and a kidney biopsy was performed with findings of acute tubular necrosis, thrombotic microangiopathy, and acute interstitial nephritis. TMP/SMX was discontinued and he was started on steroids. His renal function improved, and he was discharged home without need for further dialysis.

**Discussion:** Thrombocytopenia is characterized by endothelial damage causing microangiopathic hemolytic anemia, thrombocytopenia, and end-organ damage. TMA can be attributed to genetic or acquired autoimmunity, or may emerge secondary to medical diseases. AIN is a common cause of kidney injury and is associated with multiple drugs. This case demonstrates the unique coexistence of TMA and AIN in a patient receiving TMP/SMX, which has been related to decreased creatinine clearance, bone marrow suppression, hyperkalemia, and hypersensitivity reactions. This case supports the cessation of the offending drug and the use of steroid treatment as an option for TMA and AIN.

In conclusion, TMA and AIN may occur simultaneously as an adverse drug reaction.

**PO0130**

**Rhabdomyolysis in SARS-CoV-2 Infection**

Zhubiz Solhjou,2 Ignacio A. Portales Castillo,2 Bassem Mikhail,2 Nicholas Chedid,1 Ebrahim Barkoudah,1 Alice M. Sheridan.2 Brigham and Women’s Hospital, Department of Medicine, Boston, MA; 2Brigham and Women’s Hospital, Renal Division, Boston, MA.

**Introduction:** Acute kidney injury (AKI) is a common complication of SARS-CoV-2 infection. Multiple mechanisms have been proposed including acute tubular necrosis (ATN) due to shock, cytokine release syndrome, hypoxia or vascular injury and thrombosis. Despite the viral injury to tubular epithelial cells and podocytes, rhabdomyolysis has also been described. Rhabdomyolysis has been reported in infection with SARS-CoV-2, Respiratory Syncytial Virus and Influenza A. Although mild CK elevation was reported in cohorts of patients with COVID-19 and there is a single case report of late onset rhabdomyolysis, overt rhabdomyolysis in SARS-CoV-2 infection has not been described. To our knowledge this is the first patient with presented with signs and symptoms of severe rhabdomyolysis and AKI that was likely secondary to SARS-CoV-2 infection.

**Case Description:** A 51 year-old male with hypertension and diabetes, presented with 4 days of diffuse myalgia and mild dry cough with shortness of breath. He denied trauma, new medications, changes in diet, strenuous exercise or illicit drug use. Physical exam notable for fever and mild tachypnea, but no hypoxia. Lungs were clear and all muscle groups were soft and non-tender. Pneumocystis carinii pneumonia was by positive for SARS-CoV-2. Serum creatinine was 2.4 mg/dL (baseline 1.3 mg/dL). Urinalysis showed 3+ blood, 2+ protein and 1+ RBC by high power field. Initial serum creatinine kinase was 340,000 U/L and peaked at 464,000 U/L on day 4. Serum and urine myoglobin levels were elevated at 15,175 mg/L and >5000 mcg/L respectively on day 5. He received isotonic intravascular (IV) fluids but developed oliguria on day 2, requiring diuresis to maintain urine output. BUN and creatinine increased to 130 and 19 mg/dL respectively by day 8 and hemodialysis was initiated. Renal clearance and urine output then slowly improved, and dialysis was discontinued by day 15.

**Discussion:** Myalgia and fatigue are common symptoms of COVID-19 infection. In addition, dictship hematuria is reported in up to 10% of patients. Thus diagnosis of rhabdomyolysis and myoglobinuria requires a high index of suspicion. Early consideration and timely diagnosis of rhabdomyolysis and the treatment of myoglobinuria with intravenous fluids is especially important to prevent ATN. However, administration of IV fluids may be challenging in COVID-19 patients at risk of hypoxia and acute respiratory distress syndrome.
fear and eosinophilia, and is usually a diagnosis of exclusion. On renal biopsy (Bx), DI-AIN usually presents with interstitial inflammation rich with eosinophils and plasma cells and, in rare occasions, with neutrophils. Here, we report a Zosyn induce neutrophil-rich AIN case.

**Case Description:** A 40-year-old female with medical history breast cancer came with fever, pain and induration over her left breast. On admission she got Zosyn for suspected breast abscess. Next day, AKI noted, creatinine (Cr) increased from 0.6 to 3.3mg/dL. She remained hemodynamically stable. Laboratory showed no anemia, leukocytosis or peripheral eosinophilia. BUN/Cr of 38/4.7. Urinalysis negative for protein, blood, crystals, casts, white blood cells, red blood cells, nitrites, uric acid, and chloride <20mmol/L, positive urine eosinophils. Negative autoimmune and hepatitis B/C work up. Blood and urine cultures were negative. Renal bladder ultrasound (US) showed normal kidney size with no sign of infection. Breast US findings were concerning for neoplasm. Zosyn was held and prednisone (1mg/kg) was given for suspicious of DI-AIN. Renal Bx was done showing interstitial inflammation rich with neutrophils and neutrophilic cast without glomerular injury. Immunofluorescence with negative IgG, IgA, IgM, C3, C1q, fibrinogen, albumin, kappa and lambda light chains. Electron microscopy was unremarkable. Cr at 3rd day peaked at 4.7mg/dL, then trended down. Upon discharge BUN/Cr of 2.36. One week after at renal clinic visit her kidney function came back to her baseline. We continued steroids for 3 weeks due to suspicion of AIN as repeated renal imaging and urine culture remained negative.

**Discussion:** This is a rare case where Zosyn was promptly stopped and prednisone was initiated early in the course of AIN despite neutrophil infiltration on renal Bx. DI-AIN can present with predominant neutrophilic infiltration; however, this makes the diagnosis more challenging. High suspicion, prompt antibiotic discontinuation and early initiation of steroid can prevent further kidney injury or potential chronic kidney disease.

**PO0134**

A Case of BK Polyomavirus-Associated Nephropathy of Native Kidneys in a 19-Year-Old Woman with a History of Orthotopic Cardiac Allotransplantation

**Introduction:** BK polyoma virus associated nephropathy (BKPvAN) is common among kidney transplant recipients. Approximately one to ten percent of kidney transplant recipients will develop BKPvAN. BKPvAN can lead to failure of the transplanted kidney allograft.

**Case Description:** A 20-year-old woman who had orthotopic cardiac allotransplantation in November of 2016 presented to the hospital in January of 2020 with upper respiratory tract infection like symptoms. Her baseline serum creatinine was 1.4 mg/dL three months prior to presentation. Her maintenance immunosuppression included tacrolimus and sirolimus. On admission her serum creatinine was 4.4 mg/dL.

**Discussion:** BK polyoma virus associated nephropathy of native kidneys is relatively rare. Upon our research we have only found a few case reports.
Urinary abnormalities in 20 patients with EVALI

Kidney Biomarkers and Major Adverse Kidney Events in Critically Ill Patients

Alexander H. Flannery,1 Victor M. Ortiz-Soriano,2 Fabiola Gianella,2 Victor E. Prado,3 Robert D. Toto,1 Orson W. Moe,1 Javier A. Neyra,2 University of Kentucky College of Pharmacy, Lexington, KY; 1University of Kentucky College of Medicine, Lexington, KY; 2University of Texas Southwestern Medical Center at Dallas, Dallas, TX.

Background: Several biomarkers of acute kidney injury (AKI) have been examined for their ability to predict AKI earlier than serum creatinine. Few studies have focused on using kidney biomarkers to better predict major adverse kidney events (MAKE), an increasingly used composite outcome in critical care nephrology research.

Methods: Single-center prospective collecting blood and urine samples from critically ill patients with AKI KDIGO stage 2 or above, and matched controls from a single, tertiary care intensive care unit. Samples were collected at 24-48 hours after AKI diagnosis (cases) or ICU admission (controls), 5-7 days later, and 4-6 weeks following discharge for AKI patients. The primary outcome of interest was MAKE at hospital discharge.

Results: Serum/urinary neutrophil gelatinase-associated lipocalin, serum/urinary cystatin C, and urinary kidney injury molecule-1 early in the AKI or ICU course were all significantly higher in patients with MAKE compared to those not experiencing MAKE. Serum cystatin C, and to a lesser extent serum NGAL, significantly improved upon a clinical prediction model of MAKE as assessed by the area under the receiver operating characteristic curve. Patients without MAKE experienced a greater decline in serum NGAL from initial measurement to second measurement than those patients experiencing MAKE.

Conclusions: Early values of kidney biomarkers in critically ill patients are associated with MAKE. This relationship appears to be greatest with serum NGAL and cystatin C, which display additive utility to a clinical prediction model. Trending serum NGAL may also have utility in predicting MAKE.

Urine Biomarkers and Risk of Long-Term Kidney Outcomes After Cardiac Surgery: the TRIBE-AKI Study

Steven Menez,1 Dennis G. Moledina,2 Amit X. Garg,3,4 Heather Thiesen Philippbrook,5 Eric McArthur,5 Yaqi Jia,3 Wassim Obeid,1 Sherry Mansour,2 Michael Shlipak,2 Steven G. Coca,2 Chirag R. Parikh,1 TRIBE-AKI Consortium 1Johns Hopkins University School of Medicine, Baltimore, MD; 2Yale University School of Medicine, New Haven, CT; 3Western University Schulich School of Medicine and Dentistry, London, ON, Canada; 4Institute for Clinical Evaluative Sciences, Toronto, ON, Canada; 5University of California San Francisco, San Francisco, CA; 6King School of Medicine at Mount Sinai, New York, NY.

Background: The urine biomarkers epidermal growth factor (EGF) and monocyte chemoattractant protein-1 (MCP-1) show promise as biomarkers of chronic kidney disease (CKD) progression in settings such as diabetes mellitus, but their role in the transition from AKI to CKD remains unclear. EGF is produced specifically by renal tubular epithelium of the thick ascending limb and MCP-1 is extensively studied as a marker of kidney inflammation. We evaluated the associations of urine EGF and MCP-1 with CKD incidence or progression after cardiac surgery.

Methods: In this sub-study of the prospective TRIBE-AKI cohort, we evaluated 865 adult patients who underwent cardiac surgery from 2007–2010 at two sites in Canada and the US. We tested the association of first post-operative urine EGF and MCP-1, and the ratio EGF/MCP-1, with the composite outcome of CKD incidence or progression. We assessed for interaction by peri-operative AKI status.

Results: Over a median (IQR) follow-up of 5.8 (4.2-7.1) years, 266 (30.8%) patients developed the composite outcome at an event rate (95% CI) of 55.4 (49.2-62.5) per 1,000 person-years. Elevated levels of first post-operative urinary EGF and MCP-1 were each independently associated with the composite outcome, in opposing directions (Table 1), and the ratio (EGF/MCP-1) was strongly associated with decreased risk of CKD incidence or progression in both continuous and categorical analysis (aHR 0.50 [0.33-0.74] for T3 compared to T1). There was no interaction by AKI status.

Conclusions: Urine EGF and MCP-1 may be useful for risk prediction of future CKD outcomes after peri-operative injury in cardiac surgery.

PO0140

Higher Plasma KIM-1 Is Associated with Increased Mortality and Decreased Renal Recovery in Patients with AKI Requiring Renal Replacement Therapy

Yvelyne P. Kelly,1 Finnian R. McCausland,2 Mallika L. Mendu,1 Venkata S. Sibbesse,1 David E. Leaf,1 Sushrut S. Waiwa.3 Brigham and Women’s Hospital, Boston, MA; 2Boston Medical Center, Boston, MA.

Background: Plasma kidney injury molecule-1 (KIM-1), a protein synthesized by renal proximal tubular cells, increases during periods of ischemia and thereby acts as a sensitive marker for AKI severity. We hypothesized that higher plasma KIM-1 levels assessed prior to commencing renal replacement therapy (RRT) would associate with higher mortality and RRT dependence in critically ill patients with severe AKI.

Methods: We measured plasma KIM-1 levels in 806 Day 0 samples from participants in Acute renal failure Trial Network (ATN) trial, a randomized controlled trial of intensive versus less-intensive RRT. For our primary analysis we used a logistic regression model to assess the risk of 28-day mortality and an inverse probability weighted logistic regression model to assess the odds of 28-day renal recovery, per doubling in log-transformed Day 0 KIM-1. Both models were adjusted for components of the ATN trial mortality risk score (age, chronic hypoxemia, CVS disease, malignancy, immunosuppressive therapy, ischemic AKI, post open surgery and vital signs at RRT initiation).

Results: Higher levels of plasma KIM-1 were associated with an increased risk of death within 28 days (adjusted odds ratio 1.15; 95% CI 1.03-1.29; p = 0.02) per doubling in log-transformed plasma KIM-1. Higher levels of Day 0 plasma KIM-1 were also associated with an increased risk of persistent RRT dependence at 28 days (adjusted odds ratio 0.76; 95% CI 0.66-0.87; p < 0.0001) per doubling in log-transformed plasma KIM-1.

Conclusions: Higher plasma KIM-1 levels measured prior to initiation of RRT are independently associated with higher 28-day mortality and lower probability of 28-day renal recovery in critically ill patients with severe AKI.

Estimated vs. Measured Glomerular Filtration Rate in Acute Decompensated Heart Failure
Jutta S. Swojusky,1 Enkhuvshin Tuvshinbat,1 Fabian Knebel,2 Niklas P. Nerger,2 Caroline Lemke,1 Daniel Meier,3 Edis Gasanin,4 Veselin Mitrovic,5 Kai-Uwe Eckardt1, Bruce A. Moltoris,6 Kai M. Schmidt-Ott1.1 Charité Universitätsmedizin Berlin, Department of Nephrology and Medical Intensive Care, Berlin, Germany; 2Charité Universitätsmedizin Berlin, Department of Cardiology and Angiology, Campus Mitte, Berlin, Germany; 3FAST Biomedical, Indianapolis, IN; 4Kerckhoff-Klinik Department of Cardiology, Bad Nauheim, Germany; 5Indiana University School of Medicine, Indianapolis, IN.

Background: Kidney function is closely monitored in patients with acute decompensated heart failure (ADHF). Recent studies indicate that rise in endogenous filtration markers (serum creatinine (Scr) or cystatin c (Cys)), is neither associated with tubular injury nor with adverse outcomes when accompanied by efficient diuresis. The imperfections of Scr or Cys to estimate GFR in non-steady state could contribute to misinformation of kidney function in ADHF. In this study we measured GFR (mGFR) in patients treated for ADHF and correlated them with estimated GFR dynamics.

Methods: In a prospective cohort study in 50 hospitalized subjects treated for ADHF, mGFR was measured using a two-component intravenous visible fluorescent injectate (VFI) at two timepoints 48h apart. Serum concentrations of a high molecular weight dextran component of VFI were measured 15 and 60 min after injection to quantify plasma volume (PV) using indicator-dilution principle. Concentrations of a low molecular weight component of VFI were measured to determine mGFR based on PV-normalized plasma pharmacokinetics. Pearson’s r, Bland-Altman plots, precision, accuracy and bias were calculated for 4 established equations (CKD EPI Scr, CKD EPI Cys, CKD EPI Cr, sMDRD) and kinetic GFR (kGFR, Chen et al., JASN 2013). 38 subjects had complete serial mGFR data.

Results: GFR calculated by any estimating equation correlated significantly with measured GFR (CKD EPI Scr, r=0.81; CKD EPI Cys, r=0.81; CKD EPI Cr, r=0.84; sMDRD, r=0.81; kGFR, r=0.81, p=0.0001). CKD EPI Cr had the best overall performance with an accuracy (P30) of 75%. However, changes in mGFR during 48h of ADHF treatment were not adequately reflected in corresponding changes of eGFR. KIDGO Scr-based AKI criteria frequently failed to detect relevant decreases of mGFR (Sensitivity 55%).

Conclusions: In patients hospitalized for ADHF undergoing decongestion, GFR estimates based on Scr and CC display substantial deficits in estimating GFR. In particular, changes of Scr- and CC-based GFR displayed a remarkable disconnect from mGFR dynamics. KIDGO Scr criteria displayed a poor sensitivity in detecting relevant decreases of mGFR, indicating a need for improved diagnostic approaches to identify true worsening renal function in ADHF.

PO0142

Multiple Beneficial Effects of Renal Exosomes on Ischemic Injury
Katherine J. Kelly,1,2 Jesus H. Dominguez,1 1Indiana University School of Medicine, Indianapolis, IN; 2Richard L Roudebush VA Medical Center, Indianapolis, IN.

Background: Ischemic injury to the kidney and other organs is deadly and expensive. We have demonstrated the effectiveness of adult cell-based therapies in multiple models of renal failure. Given the large benefits of relatively few cells, we hypothesized that exosomes from transplanted cells were the therapeutic effector. We and others have shown beneficial exosomes in renal injury models. To define the mechanisms of benefit from renal exosomes, the effects of exosomes from platelets and dermal epithelia were compared to those of renal exosomes.

Methods: The hypothesis that renal exosomes improve multiple pathways of injury postischemia and contain anti-oxidant and anti-inflammatory cargo was tested in a renal ischemia model. Exosomes from post-ischemic kidneys, platelets or skin were isolated by serial centrifugation. Renal function was estimated from serum creatinine. Oxidative stress and inflammation were assessed by immunostaining for 4-hydroxynoneal and neutrophils, respectively. Anti-inflammatory cytokine levels were measured by enzyme-linked immunosassay.

Results: We found significant improvements in renal function (figure) and structure with renal exosomes, given 24 hours postischemia, when renal failure was present. Exosomes from skin epithelia or platelets were not effective. Renal, but not skin or platelet, exosomes decreased evidence of oxidative stress in post-ischemic kidneys by 67%, with preservation of catalase and superoxide dismutase. Significantly less renal neutrophil infiltration was found in the renal exosome group as compared to postischemia groups that received vehicle or skin or platelet exosomes. Anti-inflammatory IL-10 levels were significantly higher in post-ischemic kidneys in the renal exosome group.

Conclusions: Exosomes derived from kidney cells effect multiple pathways of injury to improve postischemic kidney function.

Although Human Mesenchymal Stem Cells Effectively Treat AKI in Rats, They Elicit an Immune Response, Abolishing Their Subsequent Protective Activity
Anna Gooch,1 Ping Zhang,1 Zhuma Hu,1 Christof Westenfelder,1,2 SymbioCellTech, LLC, Salt Lake City, UT; 1University of Utah, Salt Lake City, UT.

Background: Preclinical and clinical studies have shown reprotective effects of allogeneic Mesenchymal Stem Cell Therapy (MSC) in preventing AKI, obtained without eliciting an antibody response, confirming MSCs’ immune privileged/immune-modulating properties. Many groups have attempted to enhance MSCs’ potency by introducing beneficial genes via xenogeneic expression vectors. Whether such alterations conserve MSCs’ immune privileged characteristics is unknown. We here tested whether (1) the expression of human antigens by MSCs from Fischer344 (F344) rats transgenic for human Alkaline Phosphatase (hPAP) in human MSCs (hMSC) or human Adipose-derived Stem Cells (hASC) alters the cells’ reprotective function in female F344 rats with IRI-induced AKI; (2) whether the administration of these cells elicits an antibody response; (3) whether such a response affects the re-protective efficacy of the cells in subsequent treatments.

Methods: RBC AKI (42 min. bilateral pedicle clamp) was induced (n=6/group). Post reflow, groups were infused with the suprarenal aorta (s.a.) with hPAP+MSC, hASCs or hMSC, 0.5-2x10^6 cells), or vehicle. Ten days post-AKI, serum samples were obtained and analyzed by FACS to assess for antigenic responses (IgG antibodies to (1) MSC-specific genes, or (2) hPAP. Two more groups of F344 rats (n=6 each) were inoculated i.p. with hASC (5x10^5). Immune response to hASCs was assessed 14 days post inoculation, and RBC AKI was induced as above, followed upon reflow by an identical s.a. infusion of hASCs or vehicle.
Results: Versus controls, all 3 cell types significantly protected renal function and hastened AKI recovery (p<0.05). Autologous marrow or allogeneic exosomes elicited a significant IgG antibody response (57-99%) against the infused cell type. Rats inoculated i.p. with hASCs and confirmed to have positive immunity to hASCs were no longer renoprotected by hASCs when treated with them for IRI AKI.

Conclusions: While xenogeneic use of MSCs/ASCs is renoprotective, the demonstrated induction of an immune response makes such applications unsafe/ineffective in pre-clinical studies. Caution is advised in interpreting results of studies using cell lines containing xenogeneic expression vectors for genes meant to enhance MSCs' clinical efficacy. (Not U of Utah work)

Point-of-Care Prevention and Treatment of AKI with Adipose-Derived Stem Cells: Efficacy and Cost Advance over Culture-Expanded Bone Marrow-Derived Mesenchymal Stem Cells

Anna Gooch,1 Ping Zhang,1 Zhuma Hu,1 Christoph Westenfelder.1,2 SymbioCellTech, LLC, Salt Lake City, UT; University of Utah, Salt Lake City, UT.

Background: Our pre-clinical studies (AJP 2005) and a Phase I Clinical Trial (Nat Rev Neph 2010) show that administration of bone marrow-derived, culture expanded, allogeneic Marrow Stromal Cells (MSC) is effective in the prevention and hastened recovery from experimental AKI, and safe and renoprotective in on-pump cardiac surgery patients at high risk for post-op AKI. Significantly, MSC treated unlike historical control on-pump cardiac surgery patients did not develop Chronic Kidney Disease (CKD) long term (>7 years). Expansion and banking of MSCs is expensive and time consuming. To address these limitations, we compared treatment with syngeneic, culture-expanded MSCs or vehicle to treatment with either syngeneic, minimally manipulated, Adipose Derived Stem Cells (ASCs) or autologous Stromal Vascular Fraction (SVF) immediately isolated from fat, containing ASCs, endothelial precursor and other cells) for efficacy in preventing AKI. ASCs share therapeutically critical activities with MSCs and are harvested in sufficiently high numbers/gm fat to present an alternative to culture-expanded MSCs.

Methods: ASCs and SVFs were isolated by minimal processing from abdominal fat harvested from male Fisher344 (F344) rats. IRI AKI was induced (bilateral renal pedicle clamping x 40 min) in 5 groups of male F344 rats (~200 g wt.; n=7 each). Upon reflow, groups were infused (suprarenal aorta) with either (1) 1x10^6 ASCs, (2) 1x10^6 autologous SVF cells, (3) 1x10^6 syngeneic, cultured MSCs, (4) and (5) vehicle in animals with or without fat harvest.

Results: Outcome were compared to those of sham treated animals (n=7). Renal failure assessed by serum Cr (SCr) in ASC or SVF treated animals was significantly better protected, and recovery more rapidly achieved compared to vehicle and MSC treated rats.

Conclusions: Our data suggest therefore that autologous ASCs and the SVF, obtained by minimal manipulation from a patient’s liposaprate, have the potential to treat that same patient with an efficient, inexpensive and safe point-of-care protocol to prevent or treat AKI and prevent subsequent progression to CKD. Administration of Exosomes from Mesenchymal Stem Cells Provides Effective Survival Benefits and Functional Rescue from Severe, Progressive Ischemia-Reperfusion Injury-Induced AKI in Rats

Anna Gooch,1 Mikhail Skliar,2 Ping Zhang,1 Zhuma Hu,1 Christoph Westenfelder.1,2 SymbioCellTech, LLC, Salt Lake City, UT; University of Utah, Salt Lake City, UT.

Background: While administration of Mesenchymal Stem Cells (MSCs) has been demonstrated clinically to prevent Acute Kidney Injury (AKI) such as that caused by cardiac bypass surgery, administration 48 hrs post insult was found to be ineffective or potentially damaging, likely because the introduction of large cells (~50μm) into the compromised microvasculature may impair renal function. MSCs' reperfusion is mediated by their paracrine release of anti-inflammatory and trophic cytokines and their exosomes. Exosomes signal, post uptake by target cells, through the lateral transfer of mRNAs, miRNAs, DNA, proteins, and lipids. Since MSC-derived exosomes can prevent AKI we tested whether their small size and ability to move through the compromised renal microvasculature might allow them to provide effective rescue therapy for late stage AKI.

Methods: Exosomes from Sprague Dawley (SD) rat MSCs were isolated post 24 hr culture, purified using the ExoQuick-TC kit, and characterized for size (nanosight), protein and gene expression of relevant markers. I/R AKI (52 min bilateral renal pedicle clamp) was induced in female SD rats. If the SCr value on Day 2 was greater than that on Day 1, demonstrating progressive AKI, then rats were administered via left carotid artery either 1 ml of Vehicle (PBS; n=8), Exosomes (200μg protein equivalent; ~4x10e10 exosomes; n=6), or MSCs (2x10e6; n=6) on Day 3.

Results: 1x10e6 MSCs secrete ~ 4.9x10e10 exosomes and other microvesicles (mode 1.36; median 0.87 x10e10) and they express CD44 and CD29, and carry mRNAs of renoprotective genes expressed in MSCs. While both MSC and exosome administration improved survival over PBS, renal function only showed significant and sustained improvement in exosome-treated rats.

Conclusions: MSC-derived exosome therapy days 3 post progressive AKI, when renal blood flow is significantly impaired and when most clinical AKI is diagnosed, is superior to MSC therapy, likely due to their ability to deliver their renoprotective cargo into the compromised renal microcirculation. These data have, we posit, significant translational promise for the development of an effective rescue therapy for advanced AKI. (No University of Utah resources were used for this work.)

Microparticles Released in Response to AKI May Influence Glucose and Salt Metabolism

Begoña Campos,1 Kathleen Harrison,1 Samantha M. Kramer,1 Bassam G. Abu Jawdeh,1 Charalambos V. Thakar.1,2 University of Cincinnati College of Medicine, Cincinnati, OH; Cincinnati VA Medical Center, Cincinnati, OH.

Background: Renal epithelial injury due to ischemia or toxic/inflammatory insults is the primary cause of acute kidney injury (AKI). Due to their high metabolic activity renal tubular epithelial cells (RPTEC) are especially vulnerable to damage leading to a clinical syndrome of disruption in salt, water and glucose homeostasis. We have previously shown that microparticles (MP) derived from renal epithelial cells are released in the setting of kidney injury and can be detected in vitro as well as in human plasma, and can carry the biological activity.

Methods: In this study, we evaluated the release of MP carrying SGLT2, and SL12123 (NCC) in response to kidney injury. Immortalized RPTEC lines were treated with Oxidative stress (H2O2) or inflammatory stress (TNFα) agents by the validated methodology to study in vitro models of AKI. Human samples were derived from a prospectively collected repository (31 cases of AKI in critically ill patients compared to 22 living kidney donor healthy controls). Samples were prepared to measure MP (standard methods), and flow cytometric analysis was evaluated using antibodies against SGLT2, and SL12123 (NCC). FlowJo software was used for analysis. Mann-Whitney test was used for comparisons.

Results: RPTEC models of injury (H2O2) resulted in a significant increase in the release of MP positive for SGLT2 MP 5.49 X 10^10/ml vs 0.41 X 10^10/ml for control cells (p=0.05) and NCC (SL12123) 4.2 x 10^6 vs 0.63 X 10^6 for control cells (p=0.05). Similar changes were observed when cells were treated with TNFα (p=0.05) for SGLT2 and NCC. We also confirmed the presence of MP containing SGLT2 and NCC in AKI (104.60 X10^10/ml and 1.77 X 10^10/ml, respectively). However, when compared to controls, the difference was statistically similar.

Conclusions: This is one of the first reports to confirm that key transporters from renal epithelium can be released and detected as MP in both in vitro and clinical settings of AKI. These findings may provide novel insights into the mechanisms of glucose, salt and water dysregulation during kidney injury and repair.

PO0147

Sex as a Biological Variable in Cardiac Outcomes after AKI in Mice

Danielle Soriano,1 Lara A. Kirkbride-Romeo, Chris Altmann, Peter B. Baker, Sarah Faubel. University of Colorado, Denver, CO.

Background: Acute kidney injury (AKI) is common in patients, and predisposes patients to cardiovascular disease. Estrogen is known to protect against ischemic AKI, however it is unknown whether it also protects against the cardiac sequelae of AKI. We report a 1 year study evaluating the cardiac and metabolic effects of bilateral renal ischemia-reperfusion injury in male and female C57BL/6 mice.

Methods: Males received 25 minutes of ischemia, while females received 34 minutes. Serial glomerular filtration rate (GFR), echocardiograms and blood pressure assessments were performed with sacrifice at 1 year. Plasma and cardiac metabolites were measured. Mead's resource calculation was utilized to calculate sample size of n = 5-11. Comparison between two groups was performed using unpaired t tests assuming Gaussian distribution with Welch's correction, P < 0.05 for statistical significance.

Results: Serial measurements of GFR showed that the AKI model was matched with Welch's correction, P < 0.05 for statistical significance.

Conclusions: This is the first study to show chronic diastolic dysfunction after AKI and variations in cardiorenal outcomes with regards to sex. Diminished cardiac ATP is a potential cause of cardiac dysfunction.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
Results: We report that all 3 variants had altered cell surface KIM-1 expression compared to wild-type. Importantly, the phagocytes phenotype of apoptosis was significantly reduced in HEK-293 cells expressing each of the KIM-1 variants compared to those expressing wild-type KIM-1, indicating that mutations in these coding regions contribute to a functional impairment of KIM-1 activity.

Conclusions: This is the first study suggesting that human polymorphic variants in HAVCR1 may have consequences on the functional role of the KIM-1 protein in the kidney. This work strengthens the plausibility of a biological role for KIM-1 during AKI.

Sympathetic Signaling in Macrophages Mitigates Systemic Inflammatory Response and Renal Ischemia-Reperfusion Injury

Sho Hasegawa,1 Tsuyoshi Inoue,2 Masaoi Nangaku,1 Reiko Inagi.1  'The University of Tokyo, Tokyo, Japan; 2Nagasaki University, Nagasaki, Japan.

Background: The sympathetic nervous system is known to control immune cell dynamics. However, the detailed role of sympathetic signaling in inflammatory diseases is still unclear. Here, we focused on sympathetic signaling in macrophages and aimed to determine whether its activation attenuates lipopolysaccharide (LPS)-induced sepsis and renal ischemia/reperfusion injury (rIRI).

Methods: In vivo Three types of macrophages (RAW 264.7 cells [murine macrophage cell line], murine peritoneal cells, and differentiated U937 cells [human monocyte cell line]) were used to determine the effects of sympathetic signaling, especially β, adrenergic receptor (ADRB2) signaling, on LPS-induced proinflammatory cytokine (TNF-α) production. In vivo: We examined the effects of salbutamol (β2-selective agonist) on LPS-induced sepsis and rIRI models. Macrophage-specific ADRB2 conditional knockout (ADRB2 cKO) mice were used to elucidate the contribution of ADRB2 signaling in macrophages.

Results: In vivo Norepinephrine, a main sympathetic neurotransmitter, reduced LPS-induced TNF-α production in the three types of macrophages. This anti-inflammatory effect was also induced by salbutamol and reversed by butoxamine (β, selective antagonist) in a dose-dependent manner, indicating the importance of ADRB2 in this process. Furthermore, T-cell immunoglobulin and mucin-3 (TIM-3) expression was upregulated in macrophages by ADRB2 signaling and partially mediated the anti-inflammatory phenotype. In vitro: Salbutamol administration immediately before LPS treatment significantly reduced plasma TNF-α levels in mice, which was mitigated in macrophage-specific ADRB2 cKO mice. Salbutamol administration 24 h before rIRI also attenuated acute kidney injury, which was relieved in macrophage-specific ADRB2 cKO mice. The protection against rIRI was abolished in the mice in which splenectomy was performed 10 days before salbutamol administration, which suggests the contribution of splenic macrophages to the protective effects. In fact, adoptive transfer of salbutamol-treated splenic macrophages conferred protection to the recipient mice subjected to rIRI.

Conclusions: Sympathetic signaling via ADRB2 in macrophages attenuates systemic inflammatory response and rIRI. Phenotypic alterations in splenic macrophages might play critical roles in the protection against rIRI.

Glomerular Filtration Fails to Increase During Pregnancy After Cardiac ATP whereas Females did not.

AKI Mechanisms - 1

Gillis, Michael1, Brands, Jennifer C.1, Sullivan, Augusto1, Augusta, G.A.

Background: Renal demands are increased during normal pregnancy due to the large increase in plasma volume and cardiac output, with a corresponding increase glomerular filtration rate and decreased blood pressure (BP). Recent studies in our laboratory have reported that pregnancy after recovery from ischemia reperfusion (IR) injury results in poor maternal and fetal outcomes, including decreased fetal weight, increased fetal demise, and mild uremia in the dams. In the current study, we hypothesized that glomerular filtration failure to increase during pregnancy in these dams after recovery from IR.

Methods: Female Sprague Dawley rats (10 weeks of age, n=3) were implanted with telemeters into the femoral artery for continuous BP measurements. Following 10 days of recovery, rats were randomized to receive either 45 minutes of warm, bilateral renal ischemia or sham surgery. Rats were then given 1 month to recover. Full recovery from IR was confirmed by return of plasma creatinine and urine protein excretion to baseline prior to mating. Vaginal smears were performed daily once mating began, to identify gestational day 1. Glomerular filtration rate was calculated using creatinine clearance (using 24 hour urine collection from gestational days 19-20 and plasma creatinine on gestational day 20).

Results: BP decreased to a similar extent (7±1.2mmHg in control vs 8±1.2mmHg in IR dams) by gestational day 20, however the decrease in BP was delayed in the IR dams, resulting in an overall higher pressure load as determined by area under the curve analysis (2080±33 vs 2184±16, p<0.05, t-test). Glomerular filtration rate was significantly higher in control vs 1.2mmHg in IR dams (3.1±0.7ml/min vs 1.6±0.1ml/min, p<0.05).

Conclusions: These data suggest that after recovery from IR, the kidneys are unable to appropriately increase glomerular filtration rate during pregnancy. Ongoing studies in the laboratory are focused on alterations in plasma volume expansion during pregnancy after IR. We propose that plasma volume expansion, characteristic of normal pregnancy, is essential to maintain renal perfusion and prevent fetal growth.

Polymorphisms in HAVCR1 Alter KIM-1-Mediated Phagocytosis

Ji Yun Lee,1 Brady Shrum,1 Lakshman Gillis,1,2 Western University

Background: Renal ischemia reperfusion injury (IRI), necrotic cells, and apoptotic tubular epithelial cells (TECs) undergoing secondary necrosis, release their immunogenic contents into the extracellular milieu, exacerbating inflammation. Kidney Injury Molecule-1 (KIM-1) is a cell-surface glycoprotein upregulated on TECs during acute kidney injury (AKI). We previously uncovered that KIM-1 protects against renal IRI by enabling TECs to bind and engulf dying neighbouring cells, limiting inflammation and tissue damage. The gene encoding KIM-1 (HAVCR1) and tissue damage. The gene encoding KIM-1 hypothesized that the relevance of human KIM-1 polymorphisms in renal IRI has not been studied. We assessed the in vitro activity of HAVCR1 in immortalized cell lines and tissue samples. HAVCR1 expression in immortalized renal cell lines was significantly reduced in HEK-293 cells expressing each of the KIM-1 variants compared to those expressing wild-type KIM-1, indicating that mutations in these coding regions contribute to a functional impairment of KIM-1 activity.

Methods: Using site-directed mutagenesis, we generated constructs for 3 high-frequency HAVCR1 coding variants in addition to an expression plasmid encoding wild-type KIM-1 (pcDNA3-KIM-1). We then expressed the pcDNA3 vector, or HAVCR1 variants in HEK-293 cells using stable transfection.

Conclusions: While serum creatinine and GFR were significantly reduced in HEK-293 cells expressing each of the KIM-1 variants compared to those expressing wild-type KIM-1, indicating that mutations in these coding regions contribute to a functional impairment of KIM-1 activity.

Myeloid Lactate Dehydrogenase A (LDHA) Regulates Macrophage Polarization and Promotes Fibrosis in AKI

Gunars Osts,1 Amie Traylor,1 Hannah Eckentrode,1 Laurence M. Black,1 Steven L. Cochran,1 Anupam Agarwal.1 University of Alabama at Birmingham, Birmingham, AL.

Background: Renal ischemia/reperfusion injury (IRI), a major cause of AKI, is characterized by an initial decrease in blood flow, followed by its subsequent reperfusion injury. IRI facilitates infiltration of proinflammatory macrophages as well as proliferation of intrarenal resident macrophages that, upon activation, undergo glycolytic switch, and can further exacerbate injury by inducing excessive inflammation. LDHA, a key enzyme involved in the glycolytic switch, catalyzes the conversion of pyruvate to lactate, regenerating NAD+ from NADH. Here we investigate the role of LDHA in myeloid cells and its effect on AKI.

Methods: To test the hypothesis that myeloid LDHA expression regulates macrophage polarization, BALB/c mice were perfused with radiolabeled [3H]LDHA-labeled macrophages (BDMD) from wild-type and LysM-Cre LDHA knockout (LDHA KO) mice grown in M-CSF for 7 days and then polarized with IFN-γ for 24 h. To test the effect of myeloid deletion on AKI, in vivo studies were performed using wild-type and LDHA KO mice using a bilateral IR model. In vivo LDHA KO mice had a significant decrease in essential glycolytic switch machinery in addition to the decrease in the efficiency of oxidative phosphorylation. As a result, LDHA deficient BDMD showed a diminished proinflammatory and fibrotic profile ensuing lesser renal fibrosis despite similar functional injury in both genotypes. These results suggest that LDHA is a potential target to manipulate immunometabolism in the pathogenesis of AKI.

**PD-1 Regulates Metabolic Fitness of Tregs in Protection from Kidney Ischemia-Reperfusion Injury**

Murat Dogan, Rajkumar Venkatadri, Vikram Sabapathy, Sandhya Xavier, Didier Portilla, Rahul Sharma. University of Virginia, Charlottesville, VA, USA

**Background:** Regulatory T cells (Tregs) protect the kidney in models of ischemia reperfusion injury (IRI). Previous studies suggested programmed cell death protein 1 (PD-1) expression by Tregs is required for their protective function in AKI. However downstream mechanisms of PD-1 signaling in Tregs in AKI is not clear. We aimed to investigate the role of PD-1 in Tregs with respect to mitochondrial function in AKI.

**Methods:** We induced AKI in male C57Bl/6 mice with 26 min bilateral renal IRI. CD4+CD25+ Tregs were isolated from PD-1+/+ and PD-1−/− Foxp3-GFP mice and then injected (100,000 cells/200ul) via tail vein into recipient mice 24h prior to ischemia reperfusion surgery. Kidney function was determined by measuring creatinine and tissue KIM-1 and NGAL mRNA expression levels. Histological damage was assessed by light microscopic analysis of H&E stained kidney sections. In different sets of experiments to understand the metabolic fitness of Tregs, we treated isolated T-cells from PD-1+/+ and PD-1−/− mice and incubated them overnight with anti-CD3-Ab to mimic antigenic stimulation or with IL-2, which is critical for Treg survival and function. Mitochondrial membrane potential of Tregs was measured with TMRE to monitor the mitochondrial fitness. FACs-sorted Tregs from PD-1+/+ and PD-1−/− mice were also analyzed for the expression of genes involved in mitochondrial dynamics and biogenesis.

**Results:** In the mouse kidney IRI, PD-1+/− Tregs offered no protection from AKI. Compared with PD-1−/−, PD-1+ Tregs had reduced mitochondrial mass and mitochondrial membrane potential. In FACs-sorted Tregs, expression of markers of mitochondrial function, antioxidant pathways as well as those for mitochondrial dynamics were remarkably attenuated in the Tregs from PD-1−/− mice as compared to PD-1+/+ mice.

**Conclusions:** Ability of Tregs to protect kidney from IRI-induced AKI is dependent on PD-1 expression by Tregs. Mitotracker green and TMRE experiments suggest that in the absence of PD-1, Tregs have reduced mitochondrial number and/or function. Tregs require mitochondrial fitness for their development and optimal function. Additionally, these genes may regulate cytoskeleton rearrangement and microtubule movement related to cell motility, granule release and cell division.

**ST2/IL33 Signaling Axis in Tregs Critical for Restoring Kidney Tissues Homeostasis on Injury**

Vikram Sabapathy,1 Nardos T. Cheru,2 Airi Price,1 Rajkumar Venkatadri,3 Murat Dogan,3 Saleh Mohammad,3 Brian K. Stevens,3 Rahul Sharma.3 1University of Virginia School of Medicine, Charlottesville, VA, USA; 2National Institutes of Health, Bethesda, MD.

**Background:** Renal diseases are a major cause of morbidity and mortality worldwide. Thus, leading to a great financial burden on health care systems. Inflammation elicited by a variety of cytokines and chemokines is a major player in the initiation and progression of the disease. Interleukin 33 (IL-33) acts as an ‘alarm’ that regulates the immune response during injury. IL-33 acts in an autocrine/paracrine manner through membrane receptor (ST2) aka IL33R or IL-1 receptor-like 1 (IL1RL1), triggering an innate and adaptive immune response. There is no evidence determining the importance of the ST2/IL33 axis in Tregs during kidney injury. In this study, we attempt to delineate the role of the ST2/IL33 pathway in Tregs cells using murine renal injury models and kidney organoids.

**Methods:** Murine ischemia-reperfusion injury (IRI) model was used to investigate the importance of cell-specific ST2/IL33 signaling using IL1RL1+/+ and Foxp3-cre mice to delete ST2 expression in Tregs. RNA sequencing analysis, flow cytometry, histology, immunohistochemistry, quantitative gene expression, and biochemical analysis were applied to dissect the role of ST2/IL33 signaling. Kidney organoid based 3D cell culture platform was used to setup co-culture experiments with ST2+/− and ST2+/+ Tregs for invitro evaluation.

**Results:** The RNA sequencing analysis of ST2-High Tregs indicated higher expression of regenerative factors such as angiopoietin (AREG) and Growth/differentiation factor 15 (GDF15). The in vitro renal injury experimental data indicated that elimination of ST2/IL33 axis was critical in exacerbation of renal injury leading to worsening of renal function as determined by plasma creatinine, blood urea nitrogen, kidney injury markers (Kim) and NGal) and fibrosis markers (Coll1α, Col3α1, SMA, and vimentin). Co-culture of kidney organoids with ST2+/+ expressing Tregs protected organoids from cellular apoptosis under invitro ischemia-reoxygenation conditions compared to ST2−/− Tregs.

**Conclusions:** Impairment of ST2/IL33 signaling in Tregs leads to worsening of renal function following ischemic injury. This indicating that activation of ST2/IL33 signaling in Tregs is critical in the regulation of inflammation, apoptosis, and repair in renal tissue during inflammation and injury.

**Toll-Like Receptor 4 Blockade Ameliorates Kidney Ischemia-Reperfusion Injury**

**Background:** Renal ischemia-reperfusion injury (IRI) is a key mechanism in various clinical conditions including sepsis and transplantation, and animal studies have demonstrated that toll-like receptor 4 (TLR4) is a key mediator of IRI. Since few study have tried the pharmacologic inhibition of TLR4 in renal IRI, we investigated the effect of TLR4 blockade on this condition with the goal of persuing better therapeutic options.

**Methods:** We subjected C57BL/6 mice to 25 minutes of renal pedicle clamping followed an intraperitoneal injection of TLR inhibitor peptide (TIP1), a TLR4 inhibitor, or vehicle. Sham mice underwent only a flank incision. Then, the kidneys were harvested after 24 hours of reperfusion for histology, western blot, RT-PCR, and flow cytometry. We also performed primary mouse renal tubular cell culture to assess the effects of TLR4 inhibition on tubular epithelial cells under hypoxia and subsequent reoxygenation.

**Results:** TIP1 pretreatment lowered the magnitude of an increase in serum creatinine levels and attenuated tubular injury. In addition, TIP1 administration decreased mRNA expressions of inflammatory cytokines, and apoptotic cells, and lowered oxidative stress in postischemic kidneys. The kidneys pretreated with TIP1 also showed less infiltration of macrophages and T helper 17 cells. In primary mouse tubular cells subjected to hypoxia and reoxygenation, the addition of TIP1 into culture media ameliorated the magnitude of an increase in mRNA levels of KIM1 and inflammatory cytokines.

**Conclusions:** Our data demonstrated that inhibition of TLR4 with TIP1 reduced tubular injury and an inflammatory and immune response in a mouse model of IRI.

**Funding:** Government Support - Non-U.S.

**Six1 Activation Is Involved in Cell Proliferation and Migration and Anti-Inflammation of Acute Ischemia-Reperfusion Injury in Mice**

Yong Jin,1 Xin Wan,2 Changchun Cao.1 1Department of Nephrology, Sir Run Run Hospital, Nanjing Medical University, Nanjing, China; 2Department of Nephrology, Nanjing First Hospital, Nanjing Medical University, Nanjing, China.

**Background:** Nephrogenic proteins are re-expressed during the regeneration process after ischemia reperfusion (IR) injury, while the role of these proteins in the repair of kidney injury is still unknown. We found that Six1, a developmentally regulated homeoprotein is reactivated in tubular epithelial cells (TECs) after IR injury.

**Methods:** We established Six1 overexpression cell lines to confirm its effect on kidney repair in vitro. Cell proliferation and cell migration was detected by flow cytometry and wound healing assays respectively. In different set of experiment, to detect the anti-inflammation capacity of Six1 overexpressing cells, and chromatin immunoprecipitation (ChIP)-qPCR was used to analyze Six1 protein occupancy of the indicated genes. In vivo,
we injected adeno-associated viral vector serotype 9 (AAV9)-Six1 into uninjured renal pelvis before IR injury, then assessed morphologic and functional parameters and gene expression in IR injury.

Results: We demonstrated that Six1 promoted cell proliferation by upregulating cyclin and glycolytic genes, and that cell migration through increasing the expression of matrix metalloproteinases (MMPs) in the cell model. Notably, the overexpression of Six1 could suppress inflammation through NF-κB-mediated pathway. Six1 target the phenotype of DC. However, the role of IRF8 dependent mechanism during AKI is not well known. Hence, we hypothesized that the dynamically altered expression of IRF8 in DCs could contribute to AKI.

Methods: AKI was induced by transient renal pedicle clamping in C57BL/6J. Knees, lymph nodes and spleens were collected on D1, D3 and D7. MRCs were identified by Flow cytometry. Expression of IRF8 and MHC II were quantified by IHC. Six1 could suppress inflammation through NF-κB-mediated pathway. Six1 target the phenotype of DC. The hematopoietic transcription factor IRF8 mediates the phenotype of DC. However, the role of IRF8 dependent mechanism during AKI is not well known. Hence, we hypothesized that the dynamically altered expression of IRF8 in DCs could contribute to AKI.

Methods: AKI was induced by transient renal pedicle clamping in C57BL/6J. Knees, lymph nodes and spleens were collected on D1, D3 and D7. MRCs were identified by Flow cytometry. Expression of IRF8 and MHC II were quantified by IHC. Six1 could suppress inflammation through NF-κB-mediated pathway. Six1 target the phenotype of DC. Six1 could suppress inflammation through NF-κB-mediated pathway. Six1 target the phenotype of DC. However, the roles of Pax2 in the regeneration of kidney injury is unknown. Here we hypothesized that Pax2 reactivation is involved in the regeneration of injured tubular cells.

Methods: To determine the function of Pax2 reactivation in mouse proximal tubules, we generated kidney proximal tubule-specific Pax2 conditional knockout (KO) mice. The conditional KO mice were established by KAP (kidney androgen regulated protein) Cre mice and Pax2 flox mice. Six to eight-week-old male mice were used for ischemia-reperfusion (IR) injury (left kidney, 60 minutes). The intensity of cell proliferation and fibrosis of injured kidney was evaluated. A Pax2 inhibitor (EG1) was used to evaluate the roles of Pax2 in the hypoxia condition of cultured tubular epithelial cells (0, 5%, 24 hour).

Results: The number of Pax2-positive cells and Pax2 mRNA increased after IR injury. However, the reactivation of Pax2 was significantly suppressed in conditional KO mice (p<0.05). In vitro study revealed that hypoxia condition of cultured tubular epithelial cells (0, 5%, 24 hour).

Results: The number of Pax2-positive cells and Pax2 mRNA increased after IR injury. However, the reactivation of Pax2 was significantly suppressed in conditional KO mice (p<0.05). In vitro study revealed that hypoxia condition of cultured tubular epithelial cells (0, 5%, 24 hour).

The Proximal Tubule Is a Source of de Novo NAD+ Synthesis, the Metabolites of Which Are a Valuable Predictor of AKI

Yujia Wang, Chuan-Ming Hao. Huashan Hospital Fudan University, Shanghai, China.

Background: Reduced NAD+ is reported to increase the susceptibility of AKI. De novo synthesis pathway from tryptophan is an important source of NAD+ in the liver and probably kidney. In the present study, we characterized the expression of the enzymes of de novo NAD+ synthesis pathway in the human kidney. We then examined the association of the urine metabolites in this pathway and AKI development in patients who received high-dose methotrexate (HDMTX) chemotherapy or liver transplantation (LT) and analyzed their predictive value for AKI.

Methods: The expression of the enzymes of de novo NAD+ synthesis pathway was examined by immunohistochemistry. To examine the predictive value of urine tryptophan metabolites in AKI, 71 patients who received a total of 191 HDMTX treatments were prospectively enrolled as a discovery cohort and 49 patients receiving LT were enrolled as a validation cohort. Urine samples were collected within 72 hours before chemotherapy/ surgery. AKI was defined by KDIGO criteria. Urine tryptophan metabolites were measured by LC-MS and adjusted by creatinine. The performance of these metabolites to predict AKI after HDMTX/LT was analyzed.

Results: Enzymes of de novo NAD+ synthesis pathway including KMO, KYNU, HAAO, QPRT, and ACMSD were detected in renal tubules that were positive for LTL, but not labeled by AQP2, NCCT, nor THP, consistent with proximal tubule expression. A total of 191 HDMTX treatments were included in the discovery cohort and AKI developed after 35 HDMTX treatments (18.3%). In those who developed AKI, the urinary level of 3-hydroxyanthranilic acid (3-OH AA) was significantly higher while the level of quinolinic acid (QA) was significantly lower compared with those who did not develop AKI (3-OH AA: 4.42[2.74-9.32] vs 3.57[1.86-5.73], p = 0.023; QA: 13.43[9.69-22.34] vs 20.64[14.80-32.05], p = 0.004). The area under the receiver operating characteristic curve (AUC) of urine 3-OH AA for AKI prediction was 0.748. The discrimination ability of the urine QA/3-OH AA on AKI susceptibility was validated in LT cohort, with the AUC as 0.729.

Conclusions: The proximal tubules are an important source of de novo NAD+ synthesis reduced. Urine QA / 3-OH AA ratio is associated with development of AKI. The present study suggests that urine QA / 3-OH AA ratio is a potential biomarker to predict AKI and NAD+ synthesis pathway is a potential therapeutic target.

Sphingolipid Transporter 2 (Spsn2) Expression, Localization, and Role in AKI

Nataliya Skrypnik,1 Shuaiqun Zheng,1 Sylvia Checova,1 Nabin Poudel,1 Kevin Lynch,1 Mark D. Okusa.1 Division of Nephrology and Center for Immunity, Inflammation, and Regenerative Medicine, University of Virginia, Charlottesville, VA; 2Department of Pharmacology, University of Virginia, Charlottesville, VA.

Background: The sphingosine 1-phosphate (S1P) transporter Spns2 exports S1P and its role in kidney function was evaluated by measurement of plasma creatinine. Spns2 localization and its expression was validated by western blot (WB), quantitative real time PCR and IF.

Methods: We generated clone with the highest expression by the method of limited dilutions in TKPTS; Spns2 expression was assessed by western blot (WB) of membrane-enriched fractions of kidney. Renal activation of S1P receptors can protect kidneys from acute injury, but little is known of the role of Spns2 in kidney. In these studies, we investigated the expression, localization, and role of Spns2 in the kidney after ischemia-reperfusion injury (IRI).

Results: Spns2 is expressed in high abundance in kidney and is localized to the brush border of S1–S3 segment of proximal tubules (PT) and wheat germ agglutinin a marker of parasympathetic ganglionic blocker hexamethonium. Moreover, ablation of the splenic nerve abolished the renal protection elicited by vagal sensory afferent stimulation (afferent VNS). The protective effect of afferent VNS persisted after blocking the rise in corticosterone with mifepristone or after subdiaphragmatic vagotomy, but was abolished by the sympathetic/parasympathetic ganglion blocker hexamethonium. Moreover, ablation of the spleen (predominantly sympathetic nerve) and splenectomy abolished the protective effect of afferent VNS. Finally, adoptive transfer of splenocytes from mice subjected to IRI but not to sham stimulation, protected recipient mice from kidney IRI, suggesting that splenocytes activated through the splenic nerve mediate the kidney protection.

Conclusions: Spns2 is expressed in high abundance in kidney and is localized to the brush border of S1–S2 segments of the PT. Following IRI, PT Spns2 expression is reduced and appears in the urine. Spns2 can serve as a potential target to prevent AKI, however further studies are needed to determine whether the protective effect of Spns2 inhibitor was due to lymphopenia or to a direct effect of Spns2 expressed in PT.

Dietary Omega-3 Fatty Acids After the Lipid Mediator Profile and the Fatty Acid Composition of Membrane Phospholipids but Is Not Enough to Improve Renal Insufficiency

Ryo Shioda,1,2 Airi Jo,1 Yusuke Suzuki,1,3 Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; 2Department of Pharmacology, Juntendo University Graduate School of Medicine, Tokyo, Japan.

Background: The efficacy of omega-3 fatty acids on ischemia-induced AKI has been reported, but the underlying mechanisms remain poorly understood. There have been no reports that demonstrated how dietary omega-3 fatty acids influenced the components of membrane phospholipids in the kidney. In this study, we focused on the effect of dietary omega-3 fatty acids on the membrane phospholipids components in the kidney, and examined the disease course of ischemia-induced AKI in the presence of the lipid mediator alterable by dietary omega-3 fatty acids.

Methods: Male 4-week-old wild-type Sprague-Dawley rats were fed for 2 months on AIN-93M, which contains 4% soy oil, or modified AIN-93M, which contains 4% perilla oil instead of soy oil. AKI was induced by unilateral ischemic reperfusion with right nephrectomy. Left renal ischemia was induced by using non-traumatic vascular clamps for 30 min. At 24 h after reperfusion, left kidneys and serum were collected. The fatty acid composition of membrane phospholipids and lipid mediators were quantified by HPLC-tandem mass spectrometry (HPLC/MS/MS).

Results: In the kidney of omega-3 diet-fed rats, the levels of arachidonic acid-derived proinflammatory lipid mediators, except for 5-HETE, were not reduced compared with omega-6 diet-fed rats. Eicosapentaenoic acid (EPA) and EPA-derived lipid mediators were significantly increased in the kidney of omega-3 diet-fed rats. Furthermore, membrane phospholipids which contained EPA and docosahexaenoic acid (DHA) were significantly increased in the kidney of omega-3 diet-fed rats. However, there was no significant difference in serum creatinine, blood urea nitrogen or histological damage between omega-3 diet-fed rats and omega-6 diet-fed rats.

Conclusions: Dietary omega-3 fatty acids altered the lipid mediator and the fatty acid composition of membrane phospholipids, but was not enough to improve renal insufficiency or histological damage.

A Vago-Sympathetic Reflex Mediates Kidney Protection from Ischemia-Reperfusion Injury

Shinji Tanaka,1 Chikara Abe,1,2 Shujiu Zheng,1 Yusuke Yamaoka,1,3 Jonathan E. Lipsey,1 Nataliya Skrypnik,1 Junlan Yao,2 Tsuyoshi Inoue,3 Daniel S. Stornetta,2 Stephen Abbott,2 Diane L. Rosin,2 Ruth Stornetta,2 Patrice G. Guyenet,1 Mark D. Okusa.1 Division of Nephrology and Center for Immunity, Inflammation, and Regenerative Medicine, University of Virginia, Charlottesville, VA; 2Department of Pharmacology, University of Virginia, Charlottesville, VA; 3Department of Physiology, Gifu University Graduate School of Medicine, Gifu, Japan; 4Division of CKD Pathophysiology, The University of Tokyo Graduate School of Medicine, Tokyo, Japan.

Background: We recently showed that electrical stimulation of the cervical vagus nerve (VNS) protected mouse kidneys from ischemia-reperfusion injury (IRI) by activating the cholinergic anti-inflammatory pathway (PMID: 27088005). Whether the protection is caused by the activation of vagal efferent or afferent fibers needs clarification.

Methods: We generated choline acetyltransferase-channelrhodopsin-2 (Chat-ChR2) mice and vesicular glutamate transporter 2 (Vglut2-ChR2) mice, which express ChR2 in vagal efferent and afferent neurons, respectively. Selective optogenetic stimulation of vagal sensory afferent fibers (Vglut2-ChR2 mice) or efferent fibers (Chat-ChR2 mice) was performed 24 h before bilateral renal IRI, and mice were euthanized 24 h after IRI.

Results: Optogenetic VNS protected kidneys from IRI in both Chat-ChR2 and Vglut2-ChR2 mice as shown by decreased plasma creatinine, reduced renal Kim-1 expression and improved kidney histology. Next, we sought to identify the circuitry responsible for the renal protection elicited by vagal sensory afferent stimulation (afferent VNS). The protective effect of afferent VNS persisted after blocking the rise in corticosterone with mifepristone or after subdiaphragmatic vagotomy, but was abolished by the sympathetic/parasympathetic ganglion blocker hexamethonium. Moreover, ablation of the splenic nerve (predominantly sympathetic nerve) and splenectomy abolished the protective effect of afferent VNS. Finally, adoptive transfer of splenocytes from mice subjected to IRI but not to sham stimulation, protected recipient mice from kidney IRI, suggesting that splenocytes activated through the splenic nerve mediate the kidney protection.

Conclusions: Stimulation of either vagal efferent or afferent neurons protected the kidneys from IRI. The beneficial effect of afferent VNS requires the spleen and is mediated via a vago-sympathetic reflex.

Kidney Functional Improvements by a Novel Potent and Selective Vasopressin V1a Antagonist After Ischemia-Reperfusion Injury (I/RI) in Rats
Karoline Droebner, Hana Cernecka, Chantal Fuerstner, Marie-Pierre L. Collin, Mira Pavkovic, Peter Hein, Frank Eitner, Peter Kolkhof. Bayer AG, Wuppertal, Germany.

Background: Alteration in renal perfusion is a key pathologic mechanism implicated in the development of ischemic acute kidney injury (AKI). We have reported that activation of V1a receptor decreases renal blood flow (RBF) and oxygenation in settings of increased vasopressin (AVP) levels. Here we studied the role of BAY 2327949, a recently identified potent and selective V1a antagonist, in a rat renal I/RI model.

Methods: In a first setting, rats were infused with BAY 2327949 (100 µg/min/kg i.v.) or vehicle and baseline measurements were determined for 20 min. Unilateral ischemia was induced by clamping of left kidneys for 15 min, followed by 20 min of reperfusion. RBF and intrarenal oxygenation (pO2) were continuously measured via Laser Doppler Flowmetry. In a second setting, kidney function parameters 24 h post I/RI as compared to placebo treated rats.

Results: Unilateral clamping resulted in an immediate drop of RBF and pO2 that partially recovered during reperfusion (figure). Treatment with BAY 2327949 significantly ameliorated the severity of ischemic hypoxia and resulted in an improved and almost complete restoration of RBF and pO2 during reperfusion (figure). In the second setting, preventive treatment with BAY 2327949 resulted in dose-dependent, significant improvements of kidney function parameters 24 h post I/RI as compared to placebo treated rats.

Conclusions: BAY 2327949 is a novel potent and selective vasopressin V1a receptor antagonist blocking the detrimental effects of elevated vasopressin levels on renal perfusion and oxygenation. For these reasons, BAY 2327949 could become a viable treatment option in conditions of increased AVP levels, such as AKI and CKD.

Augmenter of Liver Regeneration Protects Kidney from Ischemia-Reperfusion Injury via Regulation of TLR4/MAPKs Signaling Pathway
Ying Li,1,2 Wei Jian Xiong,1,2 The Second Affiliated Hospital, Chongqing Medical University, Chongqing, China; 1Chongqing Traditional Chinese Medicine Hospital, Chongqing, China.

Background: Toll-like receptor 4 (TLR4) expressed within the ischemic kidney is a crucial mediator of innate activation and inflammation. The augmenter of liver regeneration (ALR) is an immunoregulator which is highly expressed in kidney upon induction of renal I/R injury. It has been shown that exogenous ALR can protect kidney against I/R injury. However, whether ALR’s protective effect results from its immune regulatory function has yet to be determined. In this study, we show that treating renal I/R induced-rats with recombinant human ALR (rhALR) protects them from kidney I/R.

Methods: Rats were randomized into 4 groups as follows: sham-operated group; 1/R group; 1/R+rhALR1 group; 1/R+rhALR2 group. TLR4, neutrophils and macrophages were detected by immunochemistry. ERK, JNK, and p38 proteins were tested by WB. mRNA of HMGB-1, Biglycan, HAS1, HAS2 and HAS3 was detected by real-time PCR. The cytokines and chemokines were measured by ELISA.

Results: This result is corroborated by less tubular damage on rhALR treated rats than those on untreated rats. rhALR treated rats have significantly less apoptosis in tubular epithelial cells, less tubulointerstitial fibrosis by neutrophils (24 h) and macrophages (72 h), as well as lower levels of inflammatory cytokines compared to the untreated control rats. Furthermore, rhALR downregulate mRNA expression of endogenous ligands for TLR4 and restrain activation of TLR4 and downstream signaling molecules (ERK, JNK, and p38) on rats with renal I/R injury.

Conclusions: rhALR protects kidney from I/R injury by regulation of TLR4 signaling pathway

PO0166
DPP-4 Inhibitor Attenuated Renal Vasocostriction Following Ischemia-Reperfusion Injury in Cirrhotic Rats
Chiao-Lin Chuang,1,2 Hui-Chun Huang,1,2 Department of Medicine, Taipei Veterans General Hospital, Taipei City, Taiwan; 1Department of Medicine, National Yang-Ming University School of Medicine, Taipei, Taiwan.

Background: Cirrhotic patients may develop esophageal varices to cope with portal hypertension. Variceal bleeding is usually associated with hypotension and ischemia-reperfusion injury (IRI) which may activate endogenous vasoconstrictors, leading to severe renal vasoconstriction and renal failure (so called hepatorenal syndrome). Previous studies reported that dipetidyl peptidase-4 inhibitor (DPP4i) could attenuate the endothelin-1 (ET-1) induced vasoconstriction and increase vasodilation. The aim of this study is to delineate the effect of DPP4i in renal vascular reactivity of cirrhotic rats following IRI.

Methods: Male S-D rats were used for experiments. Biliary cirrhosis was created by common bile duct ligation (CBDL). Control group received sham surgery (SHAM). After surgery, Linagliptin (3 mg/kg/d) or distilled water (DW) was administered for 28 days. On the 29th day, bilateral renal pedicles were clamped with microvascular clamps for 45 minutes in IRI group. The clamps were then removed followed with 60 minutes of reperfusion. Kidneys were perfused in situ via right renal artery for continuous monitoring of renal perfusion pressure.

Results: There was no difference in mean arterial pressure, heart rate, portal pressure, and blood sugar between DW and DPP4i treated rats. IRI enhanced renal vascular response to ET-1 in both SHAM (p=0.027) and CBDL (p=0.025) rats, implying renal vasoconstriction. Compared with corresponding DW-treated rats, DPP4i treatment abrogated renal hyperreactivity following IRI in CBDL rats (p=0.036), but not in SHAM rats (p=0.737).

Conclusions: We concluded that DPP4i may attenuate the development of renal vasoconstriction following IRI in cirrhotic rats. The potentially mechanisms remained to be elucidated.
Mediated Apoptosis
PTEN Protects Against Ischemia Reperfusion-Induced AKI via Concentration-response curves to ET-1 in perfused kidneys of SHAM (A) and BDL (B) rats.

J Am Soc Nephrol 31: 2020

whether PTEN involves in acute kidney injury (AKI) remains unclear. α

induced injury possibly via regulating cytoskeleton and TNF-α biomarker for early prediction and evaluation of AKI. PTEN protected HK-2 from IR-induced injury in IRI-AKI mice, suggesting that PTEN is promising to be a serum marker for evaluating renal injury in IRI-AKI mice. PTEN intervention including knock-down (si-PTEN) and knock-in (lentivirus-PTEN) was performed in HK-2 to reveal the role and mechanism of PTEN in IRI-AKI.

Results: PTEN was significantly reduced in renal tissue and serum in AKI mice at 6-hour post-reperfusion vs. control (p<0.05) relative to control, determined by TUNEL assay. Mitochondrial DNA (mtDNA) content was reduced by 23% in I/R-placebo group (p=0.067) from control, starting by 1-hour post-reperfusion. In contrast, treprostinil preserved mtDNA content to control levels (p<0.001) relative to control, determined by TUNEL assay. Treprostinil also prevented I/R-mediated apoptosis at 24-hour post-reperfusion. Treprostinil was administered subcutaneously via an osmic minipump. Blood and kidney tissue were collected for analysis. Results: Treprostinil significantly reduced peak elevated Scr vs. placebo (0.6 ± 0.05 vs. 2.1 ± 0.2 mg/dl, p<0.001) at 24-hour post-reperfusion. Treprostinil also prevented I/R-mediated apoptosis at 6-hour post-reperfusion vs. placebo (1.0 ± 0.01 vs. 1.4 ± 0.01, p<0.001) relative to control, determined by TUNEL assay. Mitochondrial DNA (mtDNA) copy number was reduced by 23% in I/R-placebo group (p=0.067) from control, starting by 1-hour post-reperfusion. In contrast, treprostinil preserved mtDNA content to control levels (p<0.01). In addition, placebo increased cytotoxicity release into cytotox by 2.4-fold vs. control (p=0.05) at 1-hour post-reperfusion, which treprostinil prevented. Non-targeted semi-quantitative proteomics data using SWATH-MS show decreased renal ATP levels in placebo, which were restored by treprostinil to that of control at 6-hour post-reperfusion (p<0.05).

Conclusions: Our results demonstrate that treprostinil reduces mitochondrial-mediated renal apoptosis, evidenced by reduced cytotoxicity C release, restored mtDNA copy number and ATP protein concentration to that of control kidney levels, thereby accelerating mitochondrial recovery and protecting renal tubules from I/R-induced apoptosis. These results suggest that treprostinil is a viable therapy to reduce renal I/R injury.

DNA Repair Factor KAT5 Acts Against Ischemia-Reperfusion Injury Through Promoted DNA Repair and KCC3-Dependent TGF Regulation in Proximal Tubular Cells

Akihito Hishikawa, Kaori Hayashi, Toshiaki Monkawa, Hiroshi Itoh. Keio University School of Medicine, Tokyo, Japan.

Background: It is known that an episode of ischemia-reperfusion (IR) results in tolerance to subsequent IR, which is so-called “pre-conditioning (PC) effect”. However, the underlying mechanisms of the pre-conditioning effect have not been elucidated. We have recently discovered that DNA double strand break (DSB) DNA repair tolerance factor KAT5 is essential for maintenance of podocyte integrity (Cell Rep. 2019). Here we investigated the role of KAT5 in PC effect.

Methods: Wild-type (WT) mice and proximal tubular epithelial cell (PTEC)-specific KAT5 knockout (KO) mice underwent IR injury by clamping bilateral renal arteries for 30 minutes followed by reperfusion. Ischemic pre-conditioning was performed 1 week prior to IR injury. In vitro studies using cultured human PTECs (HK2 cells) were conducted with ATP depletion by Antimycin A (AMA), an in vitro model of acute tubular cell damage.

Results: Serum UN, Cr, urine NGAL, DNA DSB marker γHAX and KAT5 expression of the PTECs were increased and chloride transporter KCC3 expression was decreased at 24 hours after IR. IR with PC showed an attenuated increase in serum UN, Cr, urine NGAL and DNA DSBs with accelerated KAT5 and KCC3 expression. Mass spectrometry imaging of the kidney cortex following the first IR demonstrated elevated glomerular adenosine, which is used as a marker of accelerated tubule-glomerular feedback (TGF), whereas it was decreased after the second IR with PC in WT mice, suggesting attenuated TGF in the second IR. Therefore, increased chloride uptake through KCC3 was observed in WT mice, suggesting attenuated TGF in the second IR. Therefore, increased chloride uptake through KCC3 in PTECs may contribute to the suppression of TGF, which maintained GFR. In KAT5 KO mice, PC effect was attenuated with increased DNA damage and decreased KCC3 expression. In vitro studies showed elevated KAT5 and KCC3 expression following second treatment with AMA. Chromatin accessibility assay showed promoted chromatin accessibility of the KCC3 promoter region after the second treatment with AMA. ChiP analysis revealed that KAT5-binding KCC3 promoter region was significantly increased after the second injury compared with the first injury, indicating that elevated KCC3 expression was caused by increased binding of KAT5 to the KCC3 promoter region.

Conclusions: PTEC KAT5 may act against IR injury through promoted DNA repair and regulation of TGF via KCC3 expression.
of urine NGAL is from the plasma, our next step was to examine the renal handling of plasma NGAL.

**Methods:** Mice: C57Bl/6. Interventions: bilateral kidney ischemia reperfusion (IR) - 27 minutes; maleic acid (MA) (400mg/kg pH 7.4 in saline, IP); furosemide (4mg, IP); unjured vehicle animals served as a control. Recombinant human (rh) NGAL (5ug, IV) was injected to dissect the fate of circulating NGAL. Measurements: transcutaneous glomerular filtration rate (GFR), rhNGAL and mouse (m) NGAL in the plasma and urine, megalin in the urine. To link proximal tubular (PT) function with plasma and urine NGAL levels, we calculated the fractional excretion of rhNGAL (FE-rhNGAL) = [(urine rhNGAL) / x plasma creatinine])/[(plasma [rhNGAL] x urine creatinine)] x 100.

**Results:** Unjured vehicle: mice had 100% GFR and low levels of plasma and urine (rh)NGAL. IR (ATI model) and MA (PT injury model): 1% and 29% GFR respectively, increased plasma and urine rNGAL in both models. Furosemide (PT injury model): GFR ~ 30%, plasma and urine rhNGAL was slightly elevated, urine rNGAL was similar to control. FE-rhNGAL was less than 1% in normal and PRA mice, and it was greater than 20% in IR and MA treated mice. mNGAL plasma and urine levels, and FE-mNGAL were similar to rhNGAL treated mice. Megalin is expressed on the brush border of proximal tubular cells in the mouse kidney. To link the PT function with plasma and urine NGAL concentrations, we performed microarray analysis of plasma and urine NGAL concentrations in the mouse kidney. Megalin expression was increased in the kidney of mice with high ngAL plasma concentrations.

**Conclusions:** Our data suggest that normal PT function is required for the clearance of plasma NGAL. Consideration of plasma NGAL with FE-NGAL is important to interpret urine NGAL levels and PT function and effectively distinguishes PRA from ATI.

**Funding:** Veterans Affairs Support

---

**Case Description:** A 40-year-old man with hypertension and tobacco use presented with bilateral flank pain and gross hematuria. Urinalysis showed hematuria, pyuria, and proteinuria. He had oliguric acute kidney injury (AKI) with creatinine (Cr) of 3.2 mg/dL. Renal ultrasound showed bilateral hydronephrosis. Renal function deteriorated over 3 days to Cr of 7.4 mg/dL with proteinuria of 10 g/day. Serologic markers revealed mildly elevated PR3-ANCA. Pulse steroid therapy was begun and kidney biopsy was performed. Pathology report described acute tubulointerstitial nephritis with TTH polyps and interstitial non-caseating granulomas. Immunohistochemistry assay showed TTH polyps within markedly dilated renal tubules, consistent with obstructive nephropathy. Nephrology and urology consultation was requested for evaluation of obstruction. Further studies indicated the presence of a factor VIII inhibitor. He improved with transition from steroids to mycophenolate mofetil. A few months later, his renal function returned to normal with a bland urinalysis, proteinuria less than 100mg/d and resolution of hydronephrosis.

**Discussion:** We encountered a rare presentation of acquired hemophilia with macroscopic hematuria and AKI. We suspect that bladder clots and associated intraluminal clots resulted in increased tubular pressures causing obstructive nephropathy and the formation of intratubular TTH polyps. Administration of immunosuppressive therapy has been used to treat TTH polyps, and there is evidence that factor VIII inhibitor production, reinforcing our hypothesis. Anti-factor VIII antibodies are a rare complication of solid tumors and urologic malignancy work-up is ongoing.
Case Description: 39-year-old man with no past medical history referred from another institution with COVID-19 pneumonia, for which he completed 4 days of hydroxychloroquine. On admission, patient was found to have SCr of 2.0 mg/dL, which increased to 10.8 mg/dL during a 3-day period. Urinalysis showed dysmorphic RBCs but no casts. Total albumin/creatinine ratio in urine was 3.2 mg/g and FeNa >1%. Renal ultrasound showed no obstruction or masses. Other laboratory results showed methemoglobinemia (14 mg/dL), acute liver failure, schistocytes in the peripheral smear and a G6PD assay with marked deficiency. Other serologies were negative. Patient reported prior ingestion of 1 gr acetaminophen (APAP) every 4 hrs for several days; treated with 48 hrs of N-acetylcysteine infusion. The AKI was complicated by hyperkalemia, severe anion gap metabolic acidosis and volume overload requiring long term renal replacement therapy after failure of resuscitation with crystalloid, albumin, and vasopressors.

Discussion: Our patient presented with significant abnormalities in multiple organ systems, including AKI. An analysis of comorbid conditions and typical AKI diagnostics allowed an expansive differential diagnosis (fig 1). One remaining interrogate was the role of COVID-19 as a cause of our patient’s AKI. COVID-19 has been associated with acute kidney injury, increased inflammation, and toxicity to multiple organs. In previous reports, patients with severe COVID-19 pneumonia have experienced elevated levels of inflammatory cytokines (i.e., IL-6, IL-10, TNF-α) and increased kidney injury biomarkers (i.e., NGAL, IL-18). The similarity of these findings to our patient’s case is striking. Our case exemplifies the challenging but common scenarios and dilemmas that nephrologists face every day. AKI is a well-described entity, yet its diagnosis is complex and dynamic.

PO0179
Catch 22: The Vicious Cycle of Malignant Hypertension and Worsening Renal Thrombotic Microangiopathy
Sneha Lakshman,1 Larissa Kruger gomes,2 Jeffrey H. William.2 1North Shore Medical Center, Salem, MA; 2Beth Israel Deaconess Medical Center, Boston, MA.

Introduction: Renal Thrombotic microangiopathy (TMA) may arise from multiple distinct etiologies. Malignant hypertension is one of these conditions that can precipitate and worsen renal TMA. The detection of C5b-9 on endothelial cells may help determine the timing and selection of treatment to break the vicious cycle of malignant hypertension and worsening renal TMA.

Case Description: 54-year-old woman with a history of gestational hypertension, presented to the ED with complaints of headache and visual changes. She was found to be in an hypertensive emergency with an SBP in the 200s. She was a non-smoker and did not use drugs or alcohol. She denied having any other symptoms or any recent medication use. Her labs were notable for hemolytic anemia and acute kidney injury with a creatinine of 4.0 mg/dL. A peripheral smear confirmed schistocytes, along with a normal serum ADAMTS 13 activity at 89. Extensive work-up for atypical hemolytic uremic syndrome was negative and complement levels were normal. Renal ultrasound showed diffusely increased renal cortical echogenicity. Renal biopsy confirmed the diagnosis of acute-on-chronic TMA with global granular mesangial and basement membrane staining for IgG, IgA, IgM, C1q, C3, free kappa and lambda light chains of <5 RBC/HPF. Her urine toxicology screen was positive for opiates and cannabinoids. Renal biopsy revealed widespread edema of the interstitium and a mild to focally moderate inflammatory infiltrate involving approximately 80% of the cortical area. Tubular dilation, cytoplasmic vacuolization, and rare mitoses were seen in the tubules. He reported 2 sessions of hemodialysis, but he had a rapid resolution of his kidney failure with steroid initiation. A repeat chest CT showed resolution of bibasilar opacities, although with persistent upper lobe ground glass opacities consistent with smoking and vaping-related injury.

Discussion: Synthetic cannabinoids use should be considered in young healthy patients who present with unexplained AKI, as there are more case reports suggesting its direct nephrotoxicity. The etiology of tubulointerstitial injury from synthetic cannabinoids remains elusive, but a dysregulation of the endocannabinoid system in kidneys via endogenous cannabinoid receptors, CB1 and CB2, may be part of the mechanisms of injury. The cannabinoid receptors are now recognized to play potential roles in diabetic nephropathy and chronic kidney disease progression, and our future research may shed light on their possible role in immune activation.

PO0180
Acute Interstitial Nephritis and Diffuse Pulmonary Infiltrates in Recreational Drug User
Jessica Cruz Whitney,1 Samuel Mon-Wei Yu,2 Pui Susan W. Cheung.1 1Massachusetts General Hospital, Boston, MA; 2Brigham and Women’s Hospital, Boston, MA.

Introduction: Synthetic cannabinoids are designer drugs smoked as an alternative to marijuana with lower cost and greater potency. Here we describe a patient who presented with acute kidney injury and diffuse pulmonary infiltrates with recent inhaled synthetic cannabinoids use.

Case Description: A 26-year-old man with history of alcohol and recreational drug abuse including marijuana, tobacco and vaping, presented with acute kidney injury and diffuse pulmonary infiltrates. He recalled attending a party a week ago where he smoked someone else’s marijuana. On presentation, he was hypertensive to 170/115 mmHg with benign physical examination. Laboratory values were significant for serum creatinine of 17 mg/dL and BUN of 162 mg/dL. Urine sediment showed no cellular casts, but some monomorphologic red blood cells, rare dysmorphic red blood cells and white blood cells. He had a spot protein/creatinine ratio of 230 mg/g. Chest X-ray showed bilateral pulmonary infiltrates. Renal ultrasound showed normal kidneys. Laboratory studies were all negative including CK, ANCA, anti-GBM, ANA, dsDNA, SFP and legionella urinary antigen. His urine toxicology screen was positive for opiates and cannabinoids. Renal biopsy revealed widespread edema of the interstitium and a mild to focally moderate inflammatory infiltrate involving approximately 80% of the cortical area. Tubular dilation, cytoplasmic vacuolization, and rare mitoses were seen in the tubules. He reported 2 sessions of hemodialysis, but he had a rapid resolution of his kidney failure with steroid initiation. A repeat chest CT showed resolution of bibasilar opacities, although with persistent upper lobe ground glass opacities consistent with smoking and vaping-related injury.

Discussion: Synthetic cannabinoids use should be considered in young healthy patients who present with unexplained AKI, as there are more case reports suggesting its direct nephrotoxicity. The etiology of tubulointerstitial injury from synthetic cannabinoids remains elusive, but a dysregulation of the endocannabinoid system in kidneys via endogenous cannabinoid receptors, CB1 and CB2, may be part of the mechanisms of injury. The cannabinoid receptors are now recognized to play potential roles in diabetic nephropathy and chronic kidney disease progression, and our future research may shed light on their possible role in immune activation.
Postpartum Thrombotic Microangiopathy of Unknown Etiology: Is It Too Late to Save the Kidneys?
John K. Guirguis, S. J. Sher, Simit Doshi. Indiana University School of Medicine, Indianapolis, IN.

Introduction: Thrombotic microangiopathy (TMA) is a rare (0.004%) but life threatening complication in pregnancy. Differentials include uncontrolled hypertension, Hemolysis elevated liver enzymes low platelet count (HELLP) syndrome, atypical Hemolytic Uremic Syndrome (HUS), Thrombotic Thrombocytopenic Purpura (TTP) among others. Lack of randomized trials and absence of gold standard laboratory tests can make diagnosis and treatment challenging. We present a patient with post-partum TMA confirmed on renal biopsy with no conclusive etiology identified.

Case Description: A 36 years old African American patient, G7P5 with history of Hypertension (HTN) and preeclampsia was noted to have blood pressure elevated to 180/103 mmHg during an antenatal care visit at 36 weeks of gestation. Serum Creatinine (sCr) was 0.5mg/dl with urine protein/Cr ratio (UPCR) of 0.75 g/g. She had an induced labor with persistent HTN postpartum. She left against medical advice and was readmitted 10 days later with acute kidney injury (AKI) with sCr of 6 mg/dl and UPCR was 4g/g, urinalysis showed positive protein but no RBCs. BP was elevated to 143/97 mmHg. Laboratory data showed AST 33 U/L, ALT 24 U/L, Hb 9.5 g/dL, platelet counts 211 X10^9/L, C3 of 74 mg/dL, C4<2 mg/dL, negative ANA, ADAMTS 13 >94. Cryo results was inconclusive although RF was elevated at 160 IU/mL. Blood smear showed no schistocytes. She was started on pulse steroids for clinical suspicion of eclampsia.

Results: Serum troponin-I was 0.02 ng/mL with negative immune-florescence (IF), minimal interstitial fibrosis/tubular atrophy, no schistocytes. She was started on pulse steroids for clinical suspicion of eclampsia. Result of RF was inconclusive although RF was elevated at 160 IU/mL. Blood smear showed no schistocytes. She was started on pulse steroids for clinical suspicion of eclampsia related TMA. While awaiting biopsy therapeutic plasma exchange (TPE) was initiated, it was stopped after 3 sessions. Kidney biopsy on day 12 of delivery showed TMA, with negative immune-flourescence (IF), minimal interstitial fibrosis/ubular atrophy, focal 2/15 glomerular crescents and minimal arterial intimal thickening. Patient became progressively oliguric, requiring hemodialysis. At the time of writing this report, there has been no recovery at 4 weeks as patient remains oliguric on thrice weekly dialysis.

Discussion: Peri-partum care is crucial in early detection and prompt management of TMA in patients with pre-eclampsia/Eclampsia. Benefit of TPE in post-partum period is not well established. A kidney biopsy was obtained but the diagnosis remained elusive with negative IF in setting of reduced complement levels. Further studies should evaluate treatment strategies in the late-presenting patient to avoid irreversible kidney injury.

Thrombotic Microangiopathy as a Complication of Malignant Hypertension

Hany Eskarous. Easton Hospital, Easton, PA.

Introduction: Thrombotic microangiopathies (TMA) are defined as disorders characterized by the presence of microangiopathic hemolytic anemia (MAHA), thrombocytopenia, and microthrombi. Of all the known causes of TMAs, malignant hypertension is one of the most underreported ones.

Case Description: A 23-year-old African American male patient presented to the emergency department with a 2-week history of nausea, vomiting, diarrhea, and abdominal pain. His past medical history is significant for hypertension treated with lisinopril, but the patient is noncompliant with his medication. He had a blood pressure of 245/176 mmHg. Laboratory tests revealed hemoglobin of 10.7g/dl, platelet count of 88,000/microliter, white blood count of 14,300/microliter, blood urea nitrogen of 29 mg/dl, creatinine of 4.7 mg/dl (unknown prior creatinine levels), lactate dehydrogenase of 900 units/l, low haptoglobin, serum potassium of 2.1mg/dl and normal coagulation profile. With control of blood pressure, the platelet counts improved. ADAMTS13 test and stool Shiga toxin were negative. Peripheral blood smear showed schistocytes. Workup for secondary hypertension were all negative. A diagnostic CT guided left kidney biopsy revealed active and chronic TMA.

Discussion: In our patient presenting with renal TMA and severe hypertension, TTP was thought to be less likely as the patient did not have the classical presentation of fever and neurological symptoms. In addition, thrombocytopenia and LDH levels normalized with aggressive control of blood pressure. Hence, plasma exchange was deferred. Since the patient presented with diarrhea, HUS was high on the differential, but a negative Shiga toxin PCR ruled out the possibility. Renal biopsy revealed acute and chronic TMA in renal blood vessels with focal severe arteriolarocclusion, fibrin, and onion skinning of arteries supporting the diagnosis of malignant nephroclerosis as the cause of TMA.

Drug-Induced Thrombotic Microangiopathy from Trimethoprim-Sulfamethoxazole

Krishna A. Agarwal, Larissa Kruger gomes, Esilda Sula Karreci, Ruth Schulman, Yael K. Heher, Bradley M. Denker. BIDMC Beth Israel Deaconess Medical Center, Boston, MA.

Introduction: Thrombotic microangiopathy (TMA) is a common condition manifesting with microangiopathic hemolytic anemia, thrombocytopenia and end-organ damage including, acute kidney injury. TMA can be associated with many clinical syndromes and is most often due to malignant hypertension, malignancy or complement dysregulation but can also be triggered by medications. Here we describe a rare case of TMA caused by trimethoprim-sulfamethoxazole (TMP-SMX).

Case Description: A 62-year-old man with recent diagnosis of Sweet’s syndrome was started on high dose prednisone and TMP-SMX for prophylaxis. He presented 4 days later with confusion, profuse diarrhea and “brown-colored” urine. He was normotensive on exam, without cardiac murmurs, clear lungs, soft non-tender abdomen and no skin rashes. Initial labs showed microangiopathic hemolytic anemia, thrombocytopenia and acute kidney injury with hyperkalemia. Blood smear showed schistocytes. He received emergent hemodialysis followed by plasma exchange for suspected TTP/HUS. Extensive workup during his hospital admission revealed a normal ADAMTS13 activity, negative blood and urine cultures, negative G157H stool antigen, negative urinary streptococcal antigen, negative autoimmune screen, negative hepatitis and HIV serologies, normal vitamin B12 level, normal bone marrow and pan-imaging without malignancy. A renal biopsy confirmed TMA. He remained anuric and dialysis dependent on discharge.

Discussion: Patients with TMA have symptoms arising from anemia, thrombocytopenia, renal failure, or from underlying diseases like systemic infections, malignancies or drug toxicities. Once TMA is confirmed, elucidating the cause of TMA is important because there are specific treatments available for primary TMA syndromes like TTP and complement-mediated TMA. High suspicion of TTP requires urgent plasma exchange until ADAMTS13 levels return, and if complement-mediated TMA is likely, the terminal-complement inhibitor eculizumab can be used. Drug-induced TMAs require prompt discontinuation of the drug and supportive management. Trimethoprim-sulfamethoxazole is a rare cause of thrombotic microangiopathy, and the exact mechanism is not understood. Our case highlights the importance of considering TMP-SMX as a potential cause in patients presenting with TMA.

Hemoglobin Cast Nephropathy in Rifampin-Induced Hemolytic Anemia

Saqib Mahmud, Carl S. Dernell, Naveel Bal, Abhallir Korata, Alexander J. Gallan, Daniel A. Sturgill. Medical College of Wisconsin, Milwaukee, WI.

Introduction: Hemoglobin released after intravascular hemolysis causes acute kidney injury (AKI) by various mechanisms including hemoglobin cast nephropathy. This can resemble other causes of AKI such as acute tubular necrosis, acute interstitial nephritis (AIN) and thrombotic microangiopathy (TMA). Few studies have demonstrated immunohistochemically-proven hemoglobin casts on kidney biopsy associated with intravascular hemolysis. Below is a case of Rifampin-induced hemolysis associated hemoglobin cast nephropathy.

Case Description: A 64-year-old female with recurrent pulmonary Mycobacterium Avium Complex (MAC) infection treated with Rifampin, Ethambutol and Azithromycin presented with nausea and vomiting two weeks after starting therapy. Physical exam was remarkable for small purpuric lesions on the back. Labs showed a serum creatinine of 6.6 mg/dL, BUN 66 mg/dL, hemoglobin 11.1 g/dL and platelets 9,000/uL. Haptoglobin was normal. LDH was elevated at 507 units/L. A direct antibody test was negative. Urinalysis showed large blood and microscopy showed 2-5 RBCs per hpf and dark granular casts.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Renal ultrasound was unremarkable. Plasma exchange was initiated for possible TMA but discontinued when ADAMTS13 level returned normal. On day four, serum creatinine was 8.1 mg/dL. She received methylprednisolone 120 mg daily for three days due to concern for possible Rifampin induced AIN. A kidney biopsy was planned and hemodialysis was performed to optimize platelet function. Kidney biopsy demonstrated intratubular pigmented casts that were strongly positive for hemoglobin A immunohistochemical stain confirming the diagnosis of hemoglobin cast nephropathy [Figure 1]. She received supportive care with kidney function gradually improving. Creatinine was 2.87 mg/dL on discharge and 1.18 mg/dL four weeks later.

**Discussion:** Hemoglobin cast nephropathy is a rare diagnosis and requires high index of suspicion in patients with hemolysis and AKI. Diagnosis is multifaceted requiring a clinical history, exam, lab workup and most importantly, a kidney biopsy.

**Case Description:** A 39-year-old woman who underwent laparoscopic hysterectomy presented to ED 4 days following surgery with abdominal pain. Her vitals revealed hypotension and tachycardia. Initial laboratory values were as follows: WBCs 18.0x10^9/L, Na 134 mmol/L, K 4.9 mmol/L, Cl 101 mmol/L, HCO3 17 mmol/L, BUN 45 mg/dL, serum Cr 7.4 mg/dL, lactate 2.4 mmol/L. UA was remarkable for hematuria with 25 isomorphic RBCs/HPF. Abdominal US revealed moderate ascites. An indwelling bladder catheter was placed, and she underwent diagnostic paracentesis, with WBC noted at 1288/μl (35% neutrophils) and ascpites-to-serum Cr ratio of 2.14. CT abdomen with IV contrast confirmed a full-thickness tear of the superior wall of the urinary bladder, with the bulk of the indwelling catheter extending beyond the bladder and an associated urinoma surrounding the catheter (Figure 1). She was diagnosed with bladder perforation and underwent open bladder repair emergently. Her serum Cr improved to 0.5 mg/dL in 24 hours.

**Discussion:** Uropertoneum can result in the reabsorption of urine into the systemic circulation, while sodium and chloride ions move in the opposite direction. This results in hyponatremia, metabolic acidosis, azotemia and rise in serum Cr. Uropertoneum should be expected when ascites to serum Cr ratio is >1.0. It is essential to recognize that the rise in serum BUN and Cr is due to pseudo-azotemia from the reabsorption of urine and not from true kidney dysfunction. Bladder injury is diagnosed by CT cystography, which was deferred in our patient giving the clear evidence of bladder injury in the CT abdomen. Complex extraperitoneal and all intraperitoneal bladder injuries require surgical repair.
glomerulosclerosis (FSGS). Anabolic steroids are directly toxic to renal glomeruli. Chronic and interstitial fibrosis, severe interstitial fibrosis, and glomerular sclerosis and focal remodeling of the glomerular basement membranes consistent with arteriolar hyalinosis. The patient was counseled at length about long term renal replacement therapy and the gravity of his diagnosis. He underwent placement of a tunneled dialysis catheter and was discharged with close outpatient follow up.

Anabolic steroids bind to podocyte androgen receptors resulting in the apoptotic destruction of podocytes. The patient’s clinical course highlights the significant risk of renal failure in young athletes using anabolic steroids and high-protein supplements.

Crystal Clear: A Case of Oxalate Nephropathy

Deanna N. Jones, James L. Pickle. Wake Forest University, Winston-Salem, NC.

Introduction: Oxalate nephropathy is an uncommon and potentially devastating cause of acute kidney injury that can lead to end-stage kidney disease. Oxalate nephropathy can be hereditary (as in hereditary hyperoxaluria), related to toxins (such as ethylene glycol), medications, like high-dose vitamin C, or enteric malabsorption (such as gastric bypass surgery or malabsorptive disorders). Oxalate nephropathy occurs when calcium oxalate crystals form and deposit in the renal tubules and interstitium, leading to acute tubular necrosis.

Case Description: A 71 year old female with a medical history of pulmonary adenocarcinoma s/p Whipple procedure seven months earlier and chronic kidney disease stage 3 (baseline creatinine 1.0 mg/dL) presented to the hospital with elevated serum creatinine found incidentally on outpatient labs. Initial evaluation was concerning for volume depletion, as she improved with intravenous fluids. Over the next several months, she had repeated hospital admissions with worsening non-oliguric renal failure that seemed to respond to intravenous fluids in the hospital but worsened at outpatient visits. Urinalysis repeatedly showed no microscopic hematuria and low-level proteinuria, and urine microscopy showed coarse granular casts, consistent with acute tubular necrosis. Kidney biopsy was consistent with acute tubular injury and extensive tubular calcium oxalate deposition concerning for oxalate nephropathy.

Discussion: Oxalate nephropathy is a rare complication of pancreatic surgery and ascorbic acid use. Vitamin C is metabolized to oxalate and then excreted in the urine. In malabsorptive disorders, a higher concentration of fatty acids are present in the gastrointestinal tract, which bind calcium, leaving less to bind oxalate, and thus more oxalate is absorbed. High urinary oxalate can cause crystallization in tubules, leading to acute renal failure. Treatment is supportive, with removal of offending agents, oral calcium supplementation, and adequate oral hydration. Despite this, our patient progressed to end-stage renal disease requiring dialysis.

Triptan-Induced Vascular CKD, the Importance of a Differential Diagnosis

Kevin Mitchell,1,2 Ankur Shah,1,3 Brown University, Providence, RI; Providence Veterans Affairs Hospital, Providence, RI.

Introduction: Triptans are selective (5-HT) receptor agonists resulting in vasoconstriction reversing the vasodilatory mechanisms of migraine headaches. Animal studies have shown 5-HT2 receptors in the renal arteries and intense vasoconstrictive effect of 5-HT on the renal arteries. We describe a case of progressive CKD with biopsy proven vascular injury due to sumatriptan use.

Case Description: A 52-year-old male with history of CKD stage 3, migraine headaches, and hyperlipidemia presented to nephrology clinic for evaluation of CKD. Review of records revealed a rise in sCr from 1.2 to 2.8 mg/dl over the preceeding 4 years. Urinalysis was negative for hematuria, proteinuria, and pyuria. CT revealed symmetric kidneys without dilation. A kidney biopsy was performed and showed patchy cortical atrophy and interstitial fibrosis with moderate vascular sclerosis and focal remodeling of the glomerular basement membranes consistent with prior vascular injury as well as acute tubular injury. A hematologic evaluation did not reveal an etiology and further history revealed use of sumatriptan 8-10 times per month. After discontinuation of sumatriptan the creatinine improved in spite of increased NSAID use. Currently botulinum injections are being used as migraine prophylaxis. This case highlights the importance of a review of all medications and for potential nephrotoxicity.

Roid Renal Failure

Margaret Mallari, Priyesh T. Thakkar. AtlantiCare Regional Medical Center, Atlantic City, NJ.

Introduction: Athletes and bodybuilders often utilize anabolic steroids and high-protein supplements to gain muscle mass, however the use of such performance enhancers comes with a significant risk of renal failure.

Case Description: A 34-year-old male weightlifter presented with worsening exertional dyspnea, hemoptysis, and bilateral leg swelling over 2-3 months. He admitted to weekly testosterone injections, testosterone-increasing supplements, and a high-protein diet for the past 5 years. To address his lower leg swelling, the patient started Exel, an over-the-counter potassium-sparring diuretic, 2 months ago. Labs were significant for bicarb 19 mmol/L (21-30), BUN 166 mg/dL (8-25), Cr 13.4 mg/dL (1.0-1.2), CPK 2630 U/L (26-308). Chest X-ray showed right lower lobe pneumonia. Urinalysis showed proteinuria. Renal ultrasound revealed cortical echogenicity with no dilation. A kidney biopsy was performed to evaluate for CKD.

Discussion: This case highlight the broad differential diagnosis of acute and chronic kidney injury. The biopsy findings of primarily vascular injury were initially felt to be cryptogenic, but further review revealed the etiology to most likely be triptan induced. After discontinuation of sumatriptan the creatinine improved in spite of increased NSAID use. Currently botulinum injections are being used as migraine prophylaxis. This case highlights the importance of a review of all medications and for potential nephrotoxicity.

A Novel Flow Cytometry Approach Identifies Kidney Mononuclear Phagocyte Subsets Involved in Mouse Kidney Injury Models

Background: Mononuclear phagocytes (MNPs) are heterogeneous in phenotype and function, which reflects their double-edged role as drivers of inflammation and repair after kidney injury. Dissection of this complex network of cells into functional subunits has been challenging, and more granular approaches could help to identify relevant subsets in preclinical kidney injury models. Here we used a novel flow cytometric approach to phenotypically and functionally dissect renal MNPs and perform a thorough comparison of MNP dynamics between two different kidney injury models.

Methods: The dynamic regulation of MNP subsets was monitored over 10d in two frequently used murine kidney injury models: ischemia reperfusion injury (IRI) and unilateral ureter obstruction (UUO). Using flow cytometric markers F4/80 and CD11b, kidney MNPs were phenotypically divided into five distinct subsets, which were further subdivided into functional subsets of proinflammatory M1-like (CD16+/MHCII+CD206-), and regulatory M2-like (CD206+). Results: Three of the five renal MNP subsets were heavily contributing to both M1- and M2-like cell pools in both IRI and UUO, highlighting their functional multimodality regarding for example in vitro phagocytosis. The F4/80+ MNP subset contributed most M2-like cells as from day 3 with a comparable MNP profile in both models. However, M1-like cells from two CD11b+ subsets spiked 24h after IRI, while this spike was shifted to day 3 in the UUO model, which had a temporary early influx of M1-like F4/80+ cells after 3h in turn.

Results: Three of the five renal MNP subsets were heavily contributing to both M1- and M2-like cell pools in both IRI and UUO, highlighting their functional multimodality regarding for example in vitro phagocytosis. The F4/80+ MNP subset contributed most M2-like cells as from day 3 with a comparable MNP profile in both models. However, M1-like cells from two CD11b+ subsets spiked 24h after IRI, while this spike was shifted to day 3 in the UUO model, which had a temporary early influx of M1-like F4/80+ cells after 3h in turn. After 10d, total MNP numbers were decreasing in the UUO model, while M2-like F4/80+ cells persisted in IRI kidneys.
Conclusions: Our novel flow cytometric approach unravels functional multimodality among MP subtypes and identifies new therapeutic targets for an earlier M1 response and a more persistent M2 response in IRI compared to UUO. These results might support preclinical model selection and disease understanding in kidney injury. Funding: Commercial Support - Bayer AG

Microparticles Containing M2 Monocyte and Other Inflammatory Markers Are Released in AKI
Begoña Campos,1 Kathleen Harrison,1 Samantha M. Kramer,1 Bassam G. Abu Jawdeh,1,2 Charuhas V. Thakar,1,2 1University of Cincinnati College of Medicine, Cincinnati, OH; 2Cincinnati VA Medical Center, Cincinnati, OH.

Background: Renal epithelial cell injury in AKI and induces a pleiotropic inflammatory cell response. Monocyte phenotypes (M1 = CD14+/CD16−; M2 = CD14+/CD16+) are associated with various acute and chronic renal injury states. While it is known that MP are released in the early phase of AKI, which can influence tissue modelling and repair.

Methods: In this study, we evaluated presence of MP expressing markers of inflammation in AKI (defined by standardized criteria). Human samples were derived from a prospectively collected repository (31 cases of AKI in critically ill patients compared to 22 living kidney donor healthy controls). Samples were prepared to measure MP (standard methods), and flow cytometric analysis was evaluated using antibodies against inflammatory proteins. FlowJo software was used for analysis. Mann-Whitney test was used for comparisons.

Results: The average age was 54 years; mean albumin creatinine was 1.8 mg/dL and the time between admission and sample collection was 3-4 days. MP containing M2 Monocyte markers were significantly higher in AKI patients compared to controls (347.03 vs 27.14 mL/mL, p = 0.02). MP containing M1 markers were similar compared to control (177.85 vs 285.40 mL/mL, p = 0.19). AKI cases also showed significantly higher levels of MP containing other inflammatory markers: leukocytes (CD45, p = 0.015), coxinophilins (CD66b, p = 0.0001), and also in platelets (CD42b, p = 0.05).

Conclusions: MP containing monocyte/macrophages of M2 phenotype are released in the early phase of AKI, which can influence tissue modelling and repair. Moreover, a pattern of MP representing markers of M2 and other inflammatory cells may have prognostic significance to predict the severity of tissue injury or the prospect of recovery.

PO0194
Novel Immune Defense Cells of the Kidney Epithelia
Katherine Xu, Run Banlengchit, Abraham D. Levitman, Tian Shen, Jonathan M. Barasch, Krzysztof Kiryluk, Peter A. Sims. Columbia University Irving Medical Center, New York, NY.

Background: Urinary tract infections (UTIs) are one of the most common bacterial infections worldwide, affecting infant boys, older men, and most prominently, women of all ages. It is predominately caused by uropathogenic E. coli and can lead to urethritis and kidney failure if untreated. We have found a major role for kidney epithelia, specifically the intercalated cells (IC), that are activated in defense against bacteria. Given the heterogeneity of kidney cell types, we hypothesized that there could be other cells that respond to a UTI.

Methods: We performed 10x Genomics single cell RNA-seq (scRNAseq) of whole kidneys from mice with UTI at 12 hrs and from mice without infection. We also performed scRNAseq of IC from lipopolysaccharide (LPS)-induced mice at 0, 8, and 24 hrs using a novel mRNA profiling method, pooled library amplification for transcriptome expression (PLATE)-seq. We used ROSA26-nT-nG mice, known to have immune properties, to dissect the LPS-induced IC. After LPS induction (525 cells) further revealed time-dependent activation of immune responses. We found that these IC/DP cells increased Umod expression in both UTI (1.6 fold change; padj=1E-2) and LPS (1.7 fold change; padj=1E-6) analyses. Umod, known to have immune properties, is commonly expressed in the loops of Henle and distal tubule, but may be a novel bacterial defense role in the IC/DP cells.

Conclusions: We found a novel immune defense role of the double positive collecting duct cells in response to UTI. These transectually active cells induce genes involved in cytokine and innate immunity and can provide new insights into the epithelial defense of the kidney.

Role of Glomerular Filtration Rate (GFR)-Modifying Drugs in Prevention of Anticoagulant-Related Nephropathy (ARN)
Sergey V. Brodsky, Ajay kumar Medipally, Min Xiao, Anjali A. Satoskar, Tibor Nadasy, Lee A. Hebert. The Ohio State University Wexner Medical Center, Columbus, OH.

Background: Acute kidney injury (AKI) with red blood cell (RBC) tubular casts secondary to different anticoagulants has been recognized as ARN. ARN is seen in patients with underlying kidney diseases. 5/6 nephrectomy (5/6NE) animal model reproduces morphologic features of ARN. One of the possible pathogenetic mechanisms of ARN proposed to be increased GFR. Aim of the current study was to investigate the role of GFR-modifying drugs in prevention of ARN.

Methods: 5/6NE rats 3 weeks after the surgery were treated with direct thrombin inhibitor dabigatran (150mg/kg/day) and with GFR-reducing Enalapril (1.5 mg/kg/d) or GFR-increasing Albuterol (4 mg/kg/day) for 7 days. Daily monitoring of serum creatinine (Scr), blood pressure and hematuria was performed. Morphology of the kidney was evaluated at day 7 after animals were euthanized.

Results: Dabigatran resulted in gradual increase in Scr (Fig 1), hematuria, acute tubular necrosis (ATN) and RBC tubular casts in all treatment groups. Neither of GFR-modifying drugs significantly changed there parameters. ATN was 0.75 ± 0.27, 0.67 ± 0.25 and 0.70 ± 0.27 in Dabigatran, Dabigatran + Enalapril and Dabigatran + Albuterol treatment groups, respectively. Systolic blood pressure was reduced with Enalaprilbut did not change significantly with Albuterol. Diastolic blood pressure was not changed significantly with either treatment.

Conclusions: Our data indicate that GFR-modifying drugs do not prevent or aggravate ARN at least secondary to direct thrombin inhibitor.

Tubular β-Catenin Ameliorates AKI by Regulating Apoptosis and Necroptosis
Hongyu Li,1 Joseph C K Leung,1 Loretta Y.Y. Chan,2 Bin Li,3 Wai Han Yiu,1 Kar Neng Lai,1 Sydney C. Tang.1,2 The University of Hong Kong, Hong Kong, China; 1Queen Mary Hospital, Hong Kong, China.

Background: Renal tubular β-catenin signaling plays a protective role in acute kidney injury (AKI) but the underlying mechanisms remain debatable. Apoptosis and necroptosis of tubular cells are responsible for the renal dysfunction in AKI. This study aims to investigate the role of β-catenin activation in tubular cell death upon AKI and its underlying mechanism.

Methods: Transgenic ‘Tubcat’ mice conditionally expressing stabilized β-catenin in renal tubules following tamoxifen administration were used to establish septic LPS (induced) and non-septic (ischemia-reperfusion injury or IRI-induced) AKI models. Tubcat mice and their littermate controls were divided into the LPS and IRI groups. LPS mice received intraperitoneal injection of LPS (20 mg/kg). IRI mice received bilateral ischemia for 28 minutes, followed by 24 hours of reperfusion. All the mice were sacrificed at 24 hours. Apoptosis and necroptosis were evaluated by real-time quantitative PCR, western blot and TUNEL assay. Signaling cascade was examined by western blot.

Results: Compared to the controls, Tubcat mice under septice and non-septic AKI showed significantly delayed renal functional changes (lower serum creatinine levels) and reduction of (i) tubular injury score; (ii) apoptosis (Bax:Bcl2 ratio and number of renal TUNEL-positive apoptotic cells); (iii) necroptosis (expression of RIP1, p-RIP3 and p-MLK1); and (iv) renal expression of phospho-p53. Renal expression of phosphorylated Akt was increased significantly.

Pulsed Ultrasound Improves Dysregulated Oxygen Metabolism and Reduces Tissue Injury in Sepsis-Associated AKI

Background: Sepsis associated-acute kidney injury (SA-AKI) results in part from oxygenation in septic and non-septic AKI. Tubular β-catenin might play a critical role in AKI by regulating cell death via modulating the p53/Akt signaling pathway. Fundings: General Research Fund (HKU 17119818), RGC Collaborative Research Fund (Ref: C7018-16G) and Hong Kong Society of Nephrology Research Grant (2019).

STC1 Prevents Lipopolysaccharide-Induced AKI via TGF-β
Li Tan, Wei Qin, Yi Tang. Sichuan University West China Hospital, Chengdu, China.

Background: Lipopolysaccharide (LPS)-induced epithelial injury plays a critical role in the pathogenesis of acute kidney injury (AKI). Stanniocalcin-1 (STC1), a pleiotropic glycoprotein, has been reported to protect ischemic renal injury by reducing renal oxygen species, modulating inflammatory release, and inhibiting cell apoptosis. However, regulators of STC1 expression as well as its physiologic function in kidneys were unknown. We sought to elucidate the relationship between TGF β and STC1 in LPS-induced kidney injury in vitro and in vivo and to define the functional role of STC1 expression in renal tubular epithelium.

Methods: C57BL/6 J mice, STC1-/- (C57BL/6 J background) mice were randomly divided into blank control group, experimental control group and a mouse model of AKI was established. Primary mouse renal tubular epithelial cells isolated from wide type mice and STC1-/- mice were cultured. We detected changes in serum creatinine (Scr) and blood urea nitrogen (BUN) before and after model establishment, observed and scored renal tubular injury, and measure the expression of signal pathway proteins and downstream inflammatory factors.

Results: LPS caused elevation of Scr, BUN level, morphological injury and tubular apoptosis, enhanced NLRP3 and Col I expression, and increased expression of TGF β and STC1 (p<0.05).

Conclusions: Our study reveals a novel TGF β-STC1 pathway that has homeostatic as well as LPS-induced cytoprotective functions in renal tubular epithelium. STC 1 has protective effects on LPS-induced acute renal tubular injury in mice, possibly by targeting TGF β, enhancing TLR4 expression, regulating the TGF β-STC1 signaling pathway, and inhibiting the expression of downstream inflammatory factors.

Lipopolysaccharide Induces NEAT 1 Expression in AKI via TLR4/NF-κB Signaling
Wai Han Xue,1 Wai Han Yiu,1 Sarah W. Y. Lok,1 Loretta Y. C. Chan,1 Joseph C K Leung,1 Kar Neng Lai,1 Hui Y. Lan,2 Sydney C. Tang,12 University of Hong Kong, Hong Kong, Hong Kong; 1The Chinese University of Hong Kong, Hong Kong, Hong Kong.

Background: Toll-like receptor 4 (TLR4) Nuclear factor kappa-light-chain-enhancer of activated B cells (NF-κB) have been implicated in the pathogenesis of acute kidney injury (AKI). Nuclear Paraspeckle Assembly Transcript 1 (NEAT1) is a long non-coding RNA that plays key roles in a variety of biological processes and is involved in many other diseases. Beyond its fundamental role of maintaining function of the nucleus, NEAT1 is an enhancer of activated B cells (NF-κB) signaling and NEAT1 is implicated in the process of the development of AKI.

Methods: Septic AKI model was established with injection of LPS into mice. Mouse tubular cells were stimulated with LPS for the study of tubular inflammation. The role and upstream regulatory mechanisms of NEAT1 in the inflammatory processes were studied by using signaling inhibitors.

Results: In LPS-induced AKI, NEAT1 expression was upregulated in tubular cells, accompanied by elevated TLR4/NF-κB signaling. In vitro, tubular cells treated with LPS also showed increase in NEAT1, prior to the production of proinflammatory factors.
cytokines including IL-6 and CCL-2, whereas treatment with an inhibitor of TLR4 or NF-κB signaling suppressed LPS-induced NEAT1 expression.

Conclusions: NEAT1 expression was induced in LPS-induced AKI model via TLR4-NF-κB signaling, suggesting its potential role in the inflammatory process. Our findings open the door to exploit NEAT1 expression as a potential novel therapeutic approach for AKI and other inflammation-related renal diseases.

PO0203
Renal Angiotensin (Ang) Receptor Changes Following Cecal Ligation and Puncture (CLP)-Induced AKI

Jake R. Lehman,1,2 Daniel E. Leisman,1 Tiago Fernandes,1 Matthew D. Taylor,1,3 Marianna R. Brewer,1,3 Mabel N. Abraham,1 Clifford S. Deutsman,1,3 Northwell Health Feinstein Institutes for Medical Research, Manhasset, NY; 2Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; 3Cohen Children’s Medical Center, Queens, NY; 4Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Angiotensin-II (Ang2) modulates renal function and thus may contribute to sepsis-induced acute kidney injury (SIAKI). We have shown that CLP reduced renal Ang2 type-1 receptors (AT1R), but effects on non-classical Ang receptors are unknown. We hypothesized that CLP altered renal abundance of Ang2 type-2 receptors (AT2R) and Ang1 (1-7), Mas receptors (Ang1 (1-7)R, Mas8), initiators of signaling axes that oppose AT1R.

Methods: C57BL6 mice were randomized to euthanasia at 6, 24, or 48hrs post-CLP (n=5/group). Unoperated mice (T0) served as controls. Mice were resuscitated (50mL/kg NS SQ) immediately and 24 hrs post-operatively. Prior to sacrifice we removed the kidneys under deep isoflurane anesthesia to minimize tissue ischemia. We obtained blood by cardiac puncture. Kidney Injury Molecule-1 (KIM-1) was measured in whole tissue homogenate (ELISA), AT1R, AT2R, and MasR were measured within specific regions of the kidney using immunofluorescence, (IF). We also used IF to compare kidney sections collected from sepsis patients within an hour of death (n=7) to sections from healthy controls (n=10).

Results: KIM-1 and BUN increased 6th post-CLP. Creatinine increased 48th post-CLP. 33% of mice died by 48hrs, 30% were euthanized before full bleeding. Decreased AT1R in arterioles, macula densa, and glomeruli. However, CLP did not alter MasR abundance in any region (p<0.05). The ratio of total renal MasR to AT1R more than doubled by 6hrs post-CLP (p<0.001 vs. T0). Renal AT2R intensity was increased in renal mesangium by 24h and in glomeruli by 48h (p<0.01 for both). We previously showed decreased AT1R in human sepsis kidney sections. In contrast, human sepsis kidneys did not show any decrease in MasR (p=0.05), again suggesting an increase in the MasR to AT1R ratio.

Conclusions: 1. Data on CLP-induced changes in KIM-1 in tissue and BUN in biomarkers that are these are significant markers of CLP are consistent with a severe AKI from the classical response. 2. CLP and septic AKI may be associated with a shift from classical to non-classical angiotensin signaling in the kidney. Studies of non-classical angiotensin system modulation in septic AKI may enhance understanding of pathobiology and reveal therapeutic targets in septic AKI.

PO0204
The Fibrogenic Response to Renal Injury Is Epigenetically Regulated Through the Activation of Bivalent Genes

Elizabeth D. Nguyen,1,2 Daryl M. Okamura,1,2 Scott R. Houghtaling,2 Seattle Children’s Hospital Department of Pediatric Nephrology, Seattle, WA; 1,2Seattle Children’s Research Institute, Seattle, WA.

Background: Bivalent genes are regions of epigenetically modified nucleosomes that carry both H3K4me3 and H3K27me3 marks and the presence of these two marks has been shown to affect gene regulation and transcription. In vitro models of AKI in HK-2 cells have demonstrated an increase in bivalent genes in AKI conditions.

Methods: Through peak annotation of CUT&RUN results, 1546 bivalently marked genes were identified in the normal kidney. With the onset of UUO, 62% of these bivalent genes were activated bivalent genes are associated with upregulation of genes that drive the response to unilateral ureteric obstruction (UUO) in the mouse.

Conclusions: In conclusion, derepression of CLP-induced AKI and mitochondrial damage. Over-expression of FOXO1 could improve renal function and mitochondrial dysfunction, at least partly via PGC1-α and mitochondrial morphology and structure. Compared with LPS group, HNG reduced the renal expression of IL-1α, IL-6 and HMGB1 and significantly increased the expression of PGC1-α and TFAM in the kidney.

Conclusions: In conclusion, derepression of FOXO1-mediated gene expression following AKI and mitochondrial damage. Over-expression of FOXO1 could improve renal function and mitochondrial dysfunction, at least partly via PGC1-α and mitochondrial morphology and structure. Compared with LPS group, HNG reduced the renal expression of IL-1α, IL-6 and HMGB1 and significantly increased the expression of PGC1-α and TFAM in the kidney.
PO0205
The Effect of Overexpression of Intestinal Alkaline Phosphatase (IAP) on Intestinal Permeability and Renal Failure in Lipopolysaccharide (LPS) Treated IAP Transgenic (IAPtg) Mice
Siddhartha S. Ghosh, Austin J. Mullaly, Shobha Ghosh, Todd W. Gehr. Virginia Commonwealth University, Richmond, VA.

Background: LPS associated sepsis is known to cause intestinal dysfunction in septic AKI. IAP is known to dephosphorylate LPS and render it inactive. We generated IAPtg mice who overexpress human IAP. We hypothesized that if IAPtg mice were subjected to septic AKI their kidney function and intestinal barrier permeability will be better preserved than non-transgenic mice.

Methods: IAPtg mice were developed in C57Bl6 background using human chimeric IAP under the control of villin promoter making them intestine and kidney specific overexpressing IAP. LPS (10 mg/Kg) was given to IAPtg (IAPtg+LPS) and C57Bl6 (C5LPS) to induce septic AKI. The control IAPtg (IAPtg-LPS) and C5Bl6 (C5-LPS) received saline. FITC-Dextran (FD) was gavaged 2 hours before sacrifice to measure intestinal permeability. Blood, intestine (duodenum, jejunum, ileum), and colon were harvested for biochemistry and immunoblot analysis.

Results: Serum urea and creatinine of IAPtg mice were 0.6 mg/dl and 65 mg/dl respectively which were 2 and 1.5 fold lower than C5-LPS mice (p<0.05). Serum FD levels of IAPtg>LPS (1.2± 0.1 ng/ml) were 2.5 fold lower than C5-LPS (p<0.05) suggesting improved intestinal integrity. Expression of tight junction protein (ZO-1), pro-apoptotic proteins (Caspase3, Bax), antiapoptotic protein Bcl2 in the colon, and intestine was measured by immunoblot. ZO-1 expression in the intestine and colon of C5-LPS was significantly higher than IAPtg-LPS (p<0.05). The expression of intestinal and colon caspase 3 in the IAPtg was 4 fold lower than C5-LPS (p<0.01). Intestinal and colon Bax of IAPtg/LPS were lower and Bcl2 higher than C5-LPS (p<0.05). Apoptotic markers of IAPtg+LPS were not significantly different from the control suggesting lower apoptosis in IAPtg. Plasma TNFα and IL-6 levels of IAPtg>LPS were 70±20 and 95±26 pg/ml respectively which were about 1.5 fold lower than C5-LPS (p<0.05) suggesting decreased inflammation in transgenic mice.

Conclusions: Improved ZO-1 expression probably due to reduced apoptosis decreases intestinal permeability in transgenic mice subjected to endotoxic insult. This can prevent leakage of bacterial contents from the gut and result in improved renal function and decreased inflammation, as evidenced by decreased plasma cytokines, in IAPtg group.

Changes in NAD and Lipid Metabolism Drive Acidosis-Induced AKI
Milica Bugarski,1 Susan Ghazi,1 Marcello Polesel,1 Joana R. Martins,2,3 Andrew Hall.1,2,3 Institute of Anatomy, University of Zurich, Zurich, Switzerland, 1Center for Microscopy and Image Analysis, Zurich, Switzerland, 2Dep. of Nephrology, University Hospital Zurich, Zurich, Switzerland.

Background: The kidney has an important role in maintaining normal blood pH. Mitochondria in the proximal tubule (PT) produce ammonia and bicarbonate from glutamate, and during metabolic acidosis (MA) this pathway (ammoniagenesis) is acutely upregulated. MA is frequently associated with acute kidney injury (AKI); however, to what extent the former causes the latter was unclear.

Methods: Multiphoton imaging of mitochondrial function in mouse kidney cortical slices and in vivo; oxygen consumption rate (OCR) in isolated PTs; histological analysis and electron microscopy (EM) in fixed tissue. MA was induced using an established protocol (gavage of 0.8 g/kg NH4Cl).

Results: Acutely lowering extracellular pH to 6.5 decreased mitochondrial NADH fluorescence signal specifically in PTs, without changing total NADH content, baseline OCR or mitochondrial membrane potential. However, maximal OCR was decreased and response to rotenone was exaggerated, suggesting a switch to complex I and increased oxidation of NADH to NAD+, which is required for ammoniagenesis. PTs in acidic animals displayed intense Oil Red O staining and large multi-lamellar bodies (MLBs), consistent with a major decrease in lipid metabolism. Supplementing or reducing NAD (with lactate) and increasing pH back to 7.4 inhibited/reversed the appearance of MLBs, implying that changes in NAD and lipid metabolism are linked. Histological analysis of acidic animals showed thinning of PTs and shedding of debris, indicative of AKI. Intravital imaging revealed that mitochondria remained energized, but endocytosis of fluorescently labeled dextrans was markedly decreased, confirming a severe functional defect in solute transport. Partially reversing MA with intravenous injection of bicarbonate (0.42 g/kg) or supplementing NAD with nicotinamide (0.4 g/kg, prior to MA induction) both substantially improved dextran uptake.

Conclusions: MA induces major changes in PT NAD and lipid metabolism that result in a functional AKI state, which can be reversed or prevented. These findings might also help to explain why MA accelerates decline in function in chronic kidney disease.

PO0207
Loss of HDAC8 Leads to h2AX-Induced Cellular Repair and Decreased Epithelial-Mesenchymal Transition in Renal Tubule Epithelial Cells

Background: Acute kidney injury (AKI) remains a significant worldwide problem. Our previous work has shown that hdac8-lav larval zebrafish model of AKI improved survival and increased repair and proliferation after AKI. However, these mechanisms have not been elucidated. AKI is known to induce double stranded DNA breaks (DSB), activating factors including the phosphorylation of the histone variant h2AX producing γH2AX. Damaged cells undergo a complex multifactorial fate determination leading to either DNA repair and cell survival or apoptosis.

Methods: hdac8(lav/lav) and hdac8(lav/+)+tupant mutant zebrafish were injected with gentamicin to induce AKI. Immunofluorescent microscopy, fluorescently activated cell sorting (FACS) of renal tubule epithelial cells (RTEC) were isolated for RNA-seq. Results were validated by qPCR on RTEC. h2ax−/− mice were used to examine AKI in WT and hdac8−/− zebrafish with and without AKI. There were a greater number γH2AX foci in RTEC of the h2ax−/− larvae with AKI than in either the uninjured h2ax−/− or WT AKI larvae. h2ax−/− mice exhibited less apoptosis compared to WT zebrafish with AKI, and as expected there were undetectable levels of TunNEL positive cells in WT and h2ax−/− uninjured tubules. We observed more Paxa2 positive cells in h2ax−/− larvae with AKI than WT larvae with AKI. Immunohistochemical analysis of Na/K-ATPase, a marker for epithelial polarization, in h2ax−/− zebrafish tubules maintain partial to full polarization during AKI, whereas WT larvae with AKI had complete mis-polarization of RTEC. RNA-Seq data analysis confirmed the epithelial polarization data demonstrating increased expression of mesenchymal genes and decreased epithelial gene expression in WT tubules with AKI compared to h2ax−/− in AKI injured zebrafish.

Conclusions: This study suggests a mechanism of repair and recovery after AKI in h2ax−/− zebrafish is mediated through increased γH2AX at sites of DNA damage. h2ax−/− mutant zebrafish preferentially uses mechanism of DDR for repair and proliferation, as opposed to apoptosis. The absence of apoptosis in h2ax−/− tubules can prevent complete depolarization and maintain membrane and maintain their epithelial gene signature, whereas the WT zebrafish lose their polarization and begin EMT. These data support our hypothesis that the loss of HDAC8 allows cells to repair after injury from AKI.

Protein Phosphatase 2A 2C Regprograms Cellular Energy Metabolism to Promote Tubular Cell Death and Kidney Injury
Mengyu Gu, Chunsun Dai. Nanjing Medical University, Nanjing, China.

Background: Protein phosphatase 2A (PP2A), one of the primary serine-threonine phosphatases in mammalian cells, regulates various biological processes. The role and mechanisms for PP2A in kidney injury remains to be determined.

Methods: Generating the mice with PP2Aца ablation with Cre-Loxp system. Mice were injected with cisplatin to induce AKI. UO was performed on the mice to induce kidney fibrosis.

Results: In this study, we found that the expression of protein phosphatase 2A (Cot) protein in tubular cells was significantly upregulated in both patients and animal models with acute and chronic kidney injury. Ablation of PP2Aца in tubular cells alleviated cisplatin-induced acute kidney injury and unilateral ureteral obstruction-induced kidney fibrosis in mice. In cultured tubular cells, ablation of PP2Aczę promotes oxidative phosphorylation of fatty acids by increasing p-ACC levels and thus protects against cisplatin-induced cell death and TGFβ1-induced fibroblast production.

Conclusions: This study reveals the essential role for PP2Aczę in regulating tubular cell energy metabolism and survival, which may shed light on treating patients with kidney injury.

PO0209
In Vitro Inhibition of Renal OCT2 and MATE1 Secretion by Antiemetic Drugs
George1, Xia Wen,1 Edgar A. Jaimies,2 Melanie S. Joy,3 Lauren Aleksunes.1 Rutgers The State University of New Jersey, Piscataway, NJ; 2Memorial Sloan Kettering Cancer Center, New York, NY; 3University of Colorado Denver - Anschutz Medical Campus, Aurora, CO.

Background: The organic cation transporter 2 (OCT2) and multidrug and toxin extrusion protein 1 (MATE1) regulate the renal secretion of drugs including metformin, cisplatin, and entecavir. Studies suggest that ondansetron, an antiemetic drug and 5-HT 3 receptor antagonist, has unknown effects on OCT2 and MATE1.

Methods: Transport of the fluorescent prototypical cation ASP (25 μM) was assessed in the presence and absence of 5-HT 3 antagonists (0.5-20 nM) using two in vitro models: 1) HEK293 kidney expressing human OCT2 or MATE1 and 2) double-transfected hOCT2-MATE1 MDCK cells. Cimetidine (50 μM) was used as a positive control.

Results: The relative order of potency for inhibition of ASP uptake by OCT2 was palonosetron > ondansetron > tropisetron > granisetron and in MATE1 was ondansetron > palonosetron > tropisetron > granisetron > dolasetron. In hOCT2-MATE1
Inhibition of OCT2-MATE1 Secretion of ASP by Ondansetron in MDCK Cells

PO0210
Klotho Deficiency Intensifies Hypoxia-Induced Expression of INF-α/β Through Upregulation of Rig-I
Asako Urabe,1 Shigehiro Doi,1 Toshiki Doi,1,2 Ayumu Nakashima,1,3 Takao Masaki,1 Department of Nephrology, Hiroshima University Hospital, Hiroshima, Japan; 2Harada Hospital, Hiroshima, Japan; 3Department of Stem Cell Biology and Medicine, Graduate School of Biomedical & Health Sciences, Hiroshima University, Hiroshima, Japan.

Background: Hypoxia is a common pathway to progression of end-stage kidney disease. Although numerous studies have provided evidence that inflammation plays a major role in this process, the mechanism by which hypoxia induces inflammatory responses remains unknown. Retinoic acid-inducible gene-1 (RIG-I) encodes an RNA helicase that recognizes viruses including SARS-CoV2, which is responsible for production of interferon (IFN)-α/β to prevent the spread of a viral infection. Recently, RIG-I activation has been found under hypoxic conditions, and klotho deficiency intensified the activation of RIG-I in mouse brains. However, the roles of these functions in renal inflammation remain elusive.

Methods: In vitro, expression of RIG-I and INF-α/β was examined in normal rat kidney (NRK)-52E cells incubated under hypoxic conditions (1% O₂) for 30, 60, 90, and 120 min. Next, siRNA targeting RIG-I or scramble siRNA was transfected into NK52E cells to examine expression of RIG-I and INF-α/β under hypoxic conditions. In vivo, we induced renal hypoxia by clamping the renal artery for 10 min in wildtype mice (hypoxic WT mice) and Klotho knockout mice (hypoxic KI’ mice). Lastly, we investigated the expression levels of RIG-I and INF-α/β in 33 human kidney biopsy samples diagnosed with IgA nephropathy.

Results: In vitro, the expression levels of RIG-I and INF-α/β were increased significantly under hypoxic conditions. In vivo, we observed increased expression of RIG-I and INF-α/β in Klotho knockout mice compared to wildtype mice under hypoxic conditions. In human kidney biopsy samples, the expression levels of RIG-I and INF-α/β were significantly higher in IgA nephropathy compared to normal kidney tissues.

Conclusions: These findings suggest that hypoxia induces expression of INF-α/β through upregulation of RIG-I, and that klotho deficiency intensifies this hypoxia-induced expression.
Using a Kidney Microphysiological Device

Associated Nephrotoxicity from Polymyxin and Tobramycin Antibiotics

PO0213

and pathologic mitochondrial changes. Transmission electron microscopy, renal proximal

AKI Mechanisms - 2

PO0214

and tobramycin exposure, no genes were differentially regulated compared

to controls. However, the use of these antibiotics is limited due to concerns of acute kidney

PO0215

polymyxin and aminoglycoside antibiotics are ever more important for effective bacterial

injury (AKI). We have employed a kidney microphysiological device system (MPS) with

cultured human primary proximal tubule epithelial cells (PTECs) to identify potential

injury. sFas and KIM-1 concentrations rose the earliest after antibiotic exposure. In

RNAseq analyses, we found that pathways of metallothionein and cholesterol biosynthesis

were dysregulated after colistin exposure. Finally, we found minimal PTEC injury with
tobramycin, suggesting that this antibiotic may be less toxic than previously believed.

Future work seeks to test these candidate biomarkers in human urine samples.

Conclusions: We found that different biomarkers have variable kinetics after PTEC

injury. SAS and KIM-1 concentrations rose the earliest after antibiotic exposure. In

RNAseq analyses, we found that pathways of metallothionein and cholesterol biosynthesis

were dysregulated after colistin exposure. Finally, we found minimal PTEC injury with
tobramycin, suggesting that this antibiotic may be less toxic than previously believed.

Background: Vagus nerve stimulation protects from kidney injury by activating the cholinergic inflammatory pathway (CAP). It is considered that α7 nicotinic acetylcholine receptor (α7nAChR) in splenic macrophages are important for CAP activation. To elucidate the mechanism of receptor signaling, we promoted further experiments using macrophage-specific α7nAChR knockout mice.

Methods: We generated macrophage-specific α7nAChR-deficient mice by crossbreeding LysM-Cre and α7nAChR flox mice. In vivo, GTS-21 (an α7nAChR specific agonist) was intraperitoneally injected to either wild type C57BL/6J mice (WT) or macrophage-specific α7nAChR-deficient mice prior to administration of lipopolysaccharide (LPS). 4 hours after LPS administration, the mice were euthanized and, plasma TNF-α level, plasma creatinine, BUN were evaluated. In vitro, murine macrophage cell line RAW264.7 and primary porcine macrophages from either WT or α7nAChR-deficient mice were used. These cells were stimulated with LPS after nicotine (pan nicotinic acetylcholine receptor agonist) or GTS-21 was administered, then TNF-α level was evaluated 4 hours later.

Results: GTS-21 protected the kidney and suppressed the increase of plasma TNF-α induced by LPS in WT mice. Interestingly GTS-21 decreased plasma TNF-α level induced by LPS in not only WT mice but also macrophage-specific α7nAChR-deficient mice. In vitro experiments, GTS-21 or nicotine treatment suppressed TNF-α induction by LPS in RAW264.7 cells or porcine macrophages from WT mice. Furthermore, nicotine also suppressed the induction of TNF-α by LPS even in peritoneal macrophages from α7nAChR-deficient mice.

Conclusions: These results suggest that nicotine or GTS-21 might suppress the inflammation independent of α7nAChR in macrophages in vivo and in vitro.

Platelets vs. Neutrophils as Therapeutic Targets in Cholesterol Embolism-Related Arterial Occlusion, Kidney Infarction, and AKI

PO0215

Chongyu Shi, Hans J. Anders, Medizinische Klinik und Poliklinik IV, AG Klinische Biochemie, Klinikum der Universität München, München, Germany.

Background: Cholesterol crystal embolism (CCE), a life-threatening complication, is a consequence of the rupture of atherosclerotic plaques in patients with advanced atherosclerosis. CCE: often missed as a cause of AKI. CCE contributes to CCE-related artery occlusion leading to AKI and kidney infarction.

Methods: C57/BL6 mice were injected with various doses of cholesterol crystals (CC) to induce CCE in kidney. Primary endpoint: GFR. Secondary endpoints: infarct size, vascular occlusions. 3D MRI and μCT. In vitro studies CC with neutrophils, platelets, endothelial cells.

Results: At 24h, MRI and μCT showed peripheral edema around ischemic lesion and vascular rarefaction in CCE kidney. CC-induced clots causing a dose-dependent GFR loss and infarct size. Immunostaining revealed crystal clots contained fibrin, platelets, ecDNA, neutrophils. To study the role of platelets in this process, we treated mice with platelet antagonist clopidogrel. At 24h, clopidogrel completely protected mice from intravascular obstructions, GFR loss, and kidney infarction. In contrast, neutrophil depletion significantly decreased kidney infarction but not arterial obstructions or GFR loss. Maybe because mononuclear cells had partially replaced neutrophils within clots and ecDNA was still present. DNase I treatment also significantly reduced the percentage of ecDNA positive clots, occluded arterial, GFR loss, infarct size. In vivo studies show, CC-induced clot formation and enhanced fibrinogen release from platelet granules which promotes fibrin clot formation. DNase I can strongly inhibit ATP secretion, fibrin formation, also normalized collagen-driven platelet aggregation.

Conclusions: In summary, not CC itself but the CC-induced fibrin clots obstructed peripheral arteries causing tissue infarction and organ failure. Platelets and ecDNA are central for crystal clots formation. Hence, crystal clots represent the primary target for therapeutic interventions. Among the possible molecular targets in thrombosis, especially enhancing fibrinolysis or inhibiting platelet purinergic signaling could reduce arterial occlusions, infarction, and organ failure. DNase I could have a synergistic effect on CC-induced clot formation in mice and might be a prophylactic/therapeutic approach in human patients with a risk for procedure-related CC embolism.

Characterizing De Novo Lymphangiogenesis During AKI Using 3D Imaging and Tissue Cytometry
Laurence M. Black,1 Seth Winfree,2 Malgorzata Kamocka,3 Suraj Deepak Khochare,2 Amie Traylor,4 Stephanie Esman,5 Shehnaz Khan,3 Abolzaf Zarejou,1 Anupam Agarwal,6,7 Tarek M. El-Achkar.1 1University of Alabama at Birmingham, Birmingham, AL; 2Birmingham VA Medical Center, Birmingham, AL; 3Indiana University School of Medicine, Indianapolis, IN.

Background: The renal lymphatic system is essential for fluid and electrolyte homeostasis, lipid and cholesterol transport, and immune surveillance with lymphatic vessels (LV) primarily intertwined with the blood vasculature. LV development, or lymphangiogenesis (LA) is regulated by its master transcription factor, prospero-related homeobox-1 (Prox-1), which determines lymphatic cell fate. LA is accentuated during inflammation or injury states such as acute kidney injury (AKI), though mechanisms of LA in AKI remain unclear. Understanding the LA process is essential because it will elucidate potential therapeutic targets in AKI.

Methods: Using 10-week old male Prox1-ttdTomato lymphatic reporter mice (ProxTom), we investigated the effect of AKI on the abundance and distribution of Prox-1+ cells at the mesoscale level using large scale three-dimensional (3D) imaging and tissue cytometry. ProxTom mice and their controls were subjected to ischemia-reperfusion (IR) or no surgery and kidneys were fixed on day 3. Large scale 3D imaging with confocal microscopy was done on 50um thick sections spanning the entire cross section of the kidney, followed by tissue cytometry using the volumetric tissue exploration and analysis (VTEA) software tool.

Results: The average number of cells surveyed per specimen was 347,360 ± 36,647. Using VTEA, a gating strategy was devised to account for autofluorescence in the red channel, which was increased after IR due to cell debris and injury. IR samples displayed a significant increase in Prox-1+ cells compared to baseline controls: 717.2 ± 161.8 vs. 174.4 ± 62.1 Prox-1+ cells/mm², respectively (p<0.05). In baseline controls, Prox-1+ cells were well-organized and predominately localized around large vessels in the hilum. However, after injury, the distribution of Prox-1+ cells shifted to the hilar parenchyma and inner medulla in a consistent pattern. Few cells could also be detected in the outer medulla and cortex.

Conclusions: We demonstrate a scale of analytics that is amenable to characterizing de novo renal LA during AKI, which informs the origin and distribution of renal LVs and the dynamics of LA. Such findings will enhance our understanding of the functional role of LVs during injury and help identify novel therapeutics for intervention in AKI.

PO0217
Peritubular Transcytosis Enables Mesoscale Nanoparticle Treatment of AKI
Ryan Williams,1 Janki Shah,2 Edgar A. Jaines,2 Daniel A. Heller.2 1City College of New York, New York, New York, NY; 2Memorial Sloan Kettering Cancer Center, New York, NY.

Background: In prior studies we demonstrated that mesoscale nanoparticles (MNP) localize to the kidneys up to 26-fold more than to any other organ and that they specifically target the renal tubular epithelium. In this study we investigated the mechanism of MNPs localization to the renal tubules and evaluated this platform’s potential for therapeutic delivery in a model of cisplatin-induced acute kidney injury (AKI).

Methods: We synthesized ~400 nm diameter MNPs from the biocompatible polymers poly(lactic-co-glycolic acid) and polyethylene glycol (PLGA-PEG). MNPs were encapsulated with a fluorescent far-red dye or the reactive oxygen species scavenger edaravone. Male C57BL/6 mice, were sacrificed 30 minutes after injection for immune-electron microscopy studies. We also performed intravital microscopy to visualize the transit of MNPs in Cx3cr1+ C57BL/6 mice with GFP-expressing renal macrophages. We also evaluated their therapeutic potential in a cisplatin-induced AKI (25 mg/kg IP) model. 24 hours following cisplatin, mice received edaravone-loaded MNPs or appropriate controls. Serum creatinine and histology were analyzed 24 hours following cisplatin.

Results: We found that MNPs localize to the proximal tubular epithelium via transcytosis from the peritubular capillaries. We observed MNPs flowing in these capillaries and in transit across the tubular interstitium. We also found that transcytosis of MNPs was not facilitated by macrophage uptake. Finally, we found that therapeutic MNPs use this mechanism to localize to the proximal tubules of mice with cisplatin-induced AKI (Figure).

Conclusions: These studies characterized transcytosis from the peritubular capillaries as the mechanism of particle localization to the kidneys and portend the development of additional therapeutic targeting tools for renal diseases.

PO0218
Role of the Exocyst, Cilia, and Mitochondria in AKI
Daria Ilatovskaya, Xiaofeng Zuo, Peifeng Deng, Wayne R. Fitzgibbon, Joshua H. Lipschutz. Medical University of South Carolina, Charleston, SC.

Background: AKI has high morbidity and mortality. Management consists of supportive care. Among the critical pathways in AKI are alterations of tubular mitochondrial metabolism, and, as recently suggested, disruption of primary ciliary homeostasis. Mitochondria are also involved in cilipathies. Here we tested if cilia acting via mitochondria are involved in AKI.

Methods: We previously showed that the exocyst trafficking complex is necessary for ciligenesis. Overexpression of Exoc5, a central exocyst component, protected renal tubule cells against H2O2-induced injury, whereas Exoc5 knockdown worsened it. In AKI, proximal tubules are most susceptible to injury. To determine the effect of Exoc5 loss, we crossed Exoc5fl/fl mice with mice expressing CreERT2 driven by the proximal tubule sodium-dependent inorganic phosphate transporter (SLC34a-CreERT2). Proximal tubule-specific Exoc5 knockout (KO) mice and littermate controls were subjected to bilateral ischemia reperfusion (IR) injury by clamping the renal arteries. In order to gain mechanistic insight, we evaluated mitochondrial function in Exoc5 overexpressing (OE), Exoc5 knockdown (KD), Exoc5 ciliary targeting sequence point mutant (cts-mut), and control Madin-Darby canine kidney tubule (MDCK) cells.

Results: Proximal tubule-specific Exoc5 KO mice had worse renal injury, and higher serum creatinine following IR injury compared to control mice (p<0.005). Seahorse assays revealed diminished spare respiratory capacity in Exoc5 KD and Exoc5 cts-mut cells, which was increased in Exoc5 OE cells, compared to control MDCK cells. Tetramethylrhodamine methyl ester was employed to measure mitochondrial membrane potential and we found mitochondrial uncoupling in Exoc5 KD and Exoc5 cts-mut as compared with control cells. Transmission electron microscopic imaging revealed healthy circular-shaped mitochondria with dense matrix in control and Exoc5 OE cells. Exoc5 KD cells exhibited mitochondrial damage and swelling consistent with the observed reduced respiration. Interestingly, Exoc5 cts-mut cells demonstrated formation of elongated mitochondria with pronounced cristae and large intracristae spaces, which could indicate less intensive bioenergetics, and would explain the reduced respiration.

Conclusions: For the first time we show that the exocyst and cilia are centrally involved in AKI and the effect may be mediated through mitochondria.

Ascending Vasa Recta Responsible for Medullary Vascular Congestion
Sarah C. Ray, Paul O’Connor. Augusta University Medical College of Georgia, Augusta, GA.

Background: Vascular congestion of the renal medulla is common in acute kidney injury and has been shown to prolong ischemia and promote injury. We have reported that pretreatment with low dose lipopolysaccharide (LPS) attenuates ischemia reperfusion (IR) induced congestion. The temporal localization of congestion during IR and how LPS prevents congestion remains unknown. We hypothesized that ‘vascular congestion

Pericyte and Macrophage C5aR1 Mediate Renal Fibrosis

University of Virginia, Charlottesville, VA; National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; Purdue University System, West Lafayette, IN.

Abstract: We reported that kidney injury (AKI) is widespread, identified in 30% of post-operative and 50% of ICU patients, and associated with increased rates of chronic kidney disease (CKD) and end stage renal failure. Peritubular capillary beds are significantly damaged, and it causes vascular rarefaction during many types of AKI. Vascular rarefaction is closely associated with post-AKI CKD progression. Vascular endothelial growth factor (VEGF) is a well defined angiogenic protein via its major receptor, VEGF receptor (VEGF-R2). However, prior work from other investigators demonstrated a role of VEGF-R2 as a negative regulator of pericyte function and vessel maturation. The functional implications of the VEGF-R2 signaling in renal stroma remains poorly understood.

Methods: We generated genetic mouse models for renal stromal cells (RSCs)-specific loss-of-function of VEGF-R2 with constitutively expressed Foxd1-Cre (C5aR1-/-) and tamoxifen inducible Foxd1-Cre (iC5aR1-/-). AKI/CKD models induced either by a renal ischemia/reperfusion injury (IRI) model or by low/dose repeated treatment of cisplatin were performed. Mice are monitored for the development of AKI and post-AKI CKD using serum chemistries and tissue analysis.

Results: cVEGF-R2-/- protects against ischemic AKI in male and female mice. Specifically, cVEGF-R2-/- reduces renal tubular injury and microvascular rarefaction. cVEGF-R2-/- also mitigates CKD progression post ischemic AKI. cVEGF-R2-/- reduces expression of kidney injury markers, HareV and Lcn2, in a cisplatin-AKI/CKD model. Interestingly, iVEGF-R2-/- demonstrates higher degree of protection against ischemic AKI as compared to cVEGF-R2-/- studies. We showed previously that iVEGF-R2-/- shows mild defects in kidney development. Our new data suggests that iVEGF-R2-/- decrease leakage of nephrin by the mutation during kidney development.

Conclusions: These data suggest that VEGF signaling in renal stroma cells exacerbates ischemic AKI and its post-AKI CKD progression as well as cisplatin AKI.

A Novel Renoprotective Strategy: Upregulation of PD-L1 Expression Mitigates Cisplatin-Induced AKI

**Jun Zhang, Shenwen V. Gu, Susu-Wei Hsu, Ching-Hsien Chen. University of California, Davis, Davis, CA.**

**Background:** Cisplatin is an effective chemotherapeutic agent against various types of cancers; however, the use of cisplatin is associated with a major side-effect of nephrotoxicity, resulting in acute kidney injury (AKI). Growing evidence suggests that programmed death-1 (PD-1) programmed death ligand (PD-L1) immune checkpoint signaling plays a critical role in mediating inflammatory responses and immune homeostasis. While PD-L1 has emerged as a promising target for immunotherapy, little is known regarding how PD-L1 is regulated. In this study, we aimed to determine the expression and contribution of PD-L1 in cisplatin-induced AKI.

**Methods:** PD-L1 expression in kidney cells and tissues were determined by immunohistochemistry (IHC), real-time polymerase chain reaction and western blot assays. PD-L1-containing lentiviruses were subcapsularly injected into the kidneys of mice. 7 days after the injection, mice were intraperitoneally treated with cisplatin for 3 days and subjected to kidney function tests. High-dimensional single-cell mass spectrometry was used to reveal immune profiling and discover the underlying immunological mechanisms of PD-L1 in an AKI mouse model. Results: IHC staining of PD-L1 showed a significantly lower intensity of staining and less stained proximal tubule epithelial cells in cisplatin-exposed mice tissues than that in the PBS controls. Next, we demonstrate that cisplatin exposure decreased mRNA expression and protein levels of PD-L1 in primary renal proximal tubular epithelial cells and in vivo inhibition appeared to be dose-dependent. Interestingly, we also find a decrease in PD-L1 expression with a concomitant increase in pro-inflammatory cytokines in response to cisplatin. Mass spectrometry analyses reveal cisplatin-induced multiple pro-inflammatory leukocytes infiltration in kidneys. Through genetically engineered kidney tissues in mice, ectopic expression PD-L1 in kidneys was able to suppress leukocytes infiltration and pro-inflammatory cytokines. In addition, both serum creatinine and blood urea nitrogen levels were significantly reduced in cisplatin-treated mice with PD-L1 overexpression.

**Conclusions:** Our data suggest a renoprotective effect of PD-L1 upregulation on cisplatin-induced AKI and also provide an alternative therapeutic strategy against nephrotoxicity.

Regulation of Renal Calbindin Expression During Cisplatin-Induced Kidney Injury

**Blessy George,1 John T. Szilagyi,1 Melanie S. Joy,2 Lauren Aleksunes,1**

1Rutgers The State University of New Jersey, Piscataway, NJ; 2University of Colorado Denver - Anschutz Medical Campus, Aurora, CO.

**Background:** Since the discovery of calbindin release into urine during renal injury, there has been growing interest in the utility of this calcium-binding protein as a biomarker of nephrotoxicity. However, little is known about the intrarenal regulation of calbindin during acute kidney injury. We sought to characterize the time-dependent expression and excretion of the distal tubule protein calbindin in comparison to the proximal tubule protein Kim-1 in a mouse model of cisplatin nephrotoxicity.

**Methods:** Male C57BL/6 mice were administered saline vehicle or 20 mg/kg of cisplatin i.p. Urine was collected in metabolic cages for 24 h periods on days 0 – 4. Blood and kidneys were collected between days 2 and 4. Kim-1 and calbindin proteins were measured in urine, kidneys, and blood. Kim-1 and calbindin (Calb1) mRNAs were quantified in kidneys by qPCR.

**Results:** SCr and BUN levels increased in cisplatin-treated mice by day 3, confirming development of acute kidney injury. Urinary concentrations of calbindin and Kim-1 were elevated by 11.6-fold and 2.5-fold, respectively by day 2. Time-dependent decreases in intrarenal calbindin protein to levels 60% of control were observed on days 3 and 4. A 200-fold up-regulation of Calb1 and Kim-1 mRNAs was seen on day 3. These data suggest that early loss of calbindin protein into the urine along with declines in renal calbindin protein initiate a compensatory induction of mRNA expression at later time points (days 3 and 4).

**Conclusions:** Understanding the regulation of calbindin during cisplatin nephrotoxicity further enhances its utility as a urinary biomarker of kidney damage. The results of the current study support the combined use of a proximal (Kim-1) and distal tubule (calbindin) marker to phenotype acute kidney injury secondary to cisplatin administration.

Neutral Ceramidase and Autophagy Play Diverse Roles in Cisplatin-Induced AKI and Fibrosis

**Sibo Jen Sears, Tess Dupre, Mark A. Doll, Parag P. Shah, Levi J. Beverley, Leah J. Siskind. University of Louisville School of Medicine, Louisville, KY.**

**Background:** Cisplatin (CDDP) is commonly used chemotherapeutic agent with a dose-limiting nephrotoxicity. 30% of patients given CDDP develop acute kidney injury (AKI), increasing risk of chronic kidney disease (CKD) development and mortality. Currently, there are no agents to treat or prevent CDDP-induced kidney injury. We believe this is due in part to a lack of clinically relevant animal models. In the past, only a single high-dose model has been used to study CDDP-induced AKI. Our lab and others have developed a repeated low dose model to analyze CDDP-induced AKI. To characterize renal outcomes in CDDP-induced AKI, we developed a) a high-dose model and b) a repeated low dose model.

**Results:** We assessed renal outcomes in nCDase knockout (KO) and wild type (WT) C57BL/6 mice in both the acute and chronic models of cisplatin treatment. Results: We demonstrated that nCDase KO provides protection from AKI in the high-dose model of CDDP-induced kidney injury. This protection was reversed when the autophagy-inhibitor chloroquine was co-administered. In the repeated low dose CDDP model, however, we found nCDase KO does not protect against development of renal fibrosis. We also observed that nCDase KO reduces induction of ER stress in the single high-dose model but not in the repeated low dose model.

**Funding:** This project is supported by grants from NIH CA072720, and CA046934.

Cisplatin-Induced MARCKS Phosphorylation Activates NF-κB Signaling and Contributes to AKI

Shenwen Liu, Jun Liu, Kuang-Yu Jen, Ching-Hsien Chen. University of California, Davis, Davis, CA, USA

**Background:** Cisplatin is widely used for cancer treatment but is known to induce nephrotoxicity with severe damage to the proximal tubules, leading to acute kidney injury (AKI). Although a major substrate of protein kinase C, MARCKS, was shown to be induced phosphorylation at Ser 159/163 (phospho-MARCKS) in response to cisplatin, the molecular mechanism underlying increased phospho-MARCKS and its functional consequence in AKI remain to be established. Herein, we investigated how phospho-MARCKS is regulated in proximal tubular cells, and its role in the context of cisplatin exposure.

**Methods:** The clinical relevance of phospho-MARCKS was first confirmed using immunohistochemistry. Next, we examined the effect of cisplatin exposure on phospho-MARCKS levels in kidney tubular epithelium. The MARCKS-interactome was identified by mass spectrometry. We also used genetic and pharmacological approaches to verify the functionality and molecular mechanism of cisplatin-induced phospho-MARCKS.

**Results:** In a screen of 75 renal biopsies from patients, we found that strong phospho-MARCKS expression was observed in kidney specimens from patients with acute renal tubular necrosis and was positively correlated. Western blot analyses demonstrate that an elevated abundance of phospho-MARCKS in cisplatin-exposed tubular epithelial cells and this increase appeared to be concentration–dependent. Mechanistically, we show that MARCKS protein directly binds to nuclear factor-kappa-B-activating protein (NKAP). Following cisplatin-induced phosphorylation at ser159 and ser163, the interaction of MARCKS with NKAP was inhibited, contributing to phosphorylation and NF-κB activation. Surprisingly, an elevation of phospho-MARCKS by cisplatin occurred in parallel with upregulation of inflammatory cytokines and markers of nephrotoxicity. Conversely, targeting of MARCKS phosphorylation with the MPS peptide, a novel MARCKS inhibitor, downregulated NF-κB signaling as well as suppressed levels of serum creatinine and blood urea nitrogen in cisplatin-treated mice.

**Conclusions:** Our results suggest that MARCKs phosphorylation is a novel NF-κB activator in cisplatin-induced proximal tubule damage and also present a proof of concept for the use of MPS peptide as a renal protection agent for AKI.

Decreased IFT88 Causes Cilia Shortening and Mitochondrial Dysfunction in Cisplatin-Induced Tubular Injury

Rie Fujii,2 Tsuyoshi Inoue,2 Sho Hasegawa,2 Kentaro Yoshioka,2 Masahito Nangaku,2 Reiko Inagi,2 Nagasaki University School of Medicine Graduate School of Biomedical Sciences, Nagasaki, Japan; 2The University of Tokyo Graduate School of Medicine, Bunkyo-ku, Japan

**Background:** Renal primary cilia are associated with the pathogenesis of various diseases, including acute kidney injury (AKI). The length of the primary cilia dynamically change during the progression of diseases: tubular primary cilia shortened in cisplatin-induced AKI mouse model. However, its relevance in kidney disease and the underlying mechanism are largely unknown. Tubular damage in AKI closely links to mitochondrial dysfunction. Thus, we investigated the interaction between primary cilia and mitochondria in cisplatin-induced tubular injury.

**Methods:** C57BL/6 mice with cisplatin-induced AKI were euthanized at 72 h after disease induction to collect blood and kidney samples. In vivo experiments, we used RPTEC/TERT1 cells, which are human proximal tubular epithelial cells that maintain the cilia length at high cell densities, and knocked down IFT88 (IFT88-KD), a cilia maintenance protein, by siRNA. Cisplatin-treated or IFT88-KD cells were assessed for the cellular phenotypic changes or mitochondrial metabolic function using the Flux Analyzer. We conclude loss of NHERF1 results in increased levels of GSSG, a modifier of thioredoxin and inhibitor of GSH synthesis in oxidizing conditions, and lower 72h post treatment in KO compared to WT.

**Results:** We found that the expression of protein IFT88 was decreased in damaged tubules of cisplatin-induced AKI mice. These data were consistent with that IFT88 expression decreased in the cisplatin of cisplatin-treated RPTEC/TERT1 at mRNA and protein levels in association with shortening of the primary cilia, suggesting the pathogenic link between tubular damage and IFT88-mediated cilia alteration. Interestingly, IFT88-KD cells significantly exhibited shorter cilia as compared to control siRNA-transfected cells and showed downregulation of mitochondrial oxidative phosphorylation capacity and decreased ATP production, indicating the contribution of IFT88 to mitochondrial homeostasis. Of note, such mitochondrial alteration linked to tubular inflammation. Our findings suggest that tubular mitochondrial dysfunction in cisplatin-induced AKI is mediated by a decreased IFT88 with shortening cilia, at least in part.

**Conclusions:** Tubular mitochondrial damage followed by tubular injury in AKI may occur by the alteration of IFT88 expression, and subsequent cilia shortening in the tubular epithelial cells.

chlorothiazide 500 mg twice daily. However, these large doses of intravenous diuretics failed to increase daily urine output above 1000 mL. After 20 hours of stable diuretic vasodilator therapy was initiated with low dose hydralazine 10 mg thrice daily. Within one day, her urine output more than doubled and, over the next 3 days of the stable therapy, it peaked at 4 liters. Her fraction Na excretion (FENa) was initially 0.1%; it increased to a maximum of 3.8% on the 5th day of IV continuous diuretic therapy but increased further to 3.8%-6.2% over 9 days after hydralazine was added to the diuretic regimen. After addition of hydralazine, her congestion dissipated, she lost 23 Kg and the diuretic regimen was reduced eventually to furosemide 80 mg BID and spironolactone 200 mg daily prior to her discharge with a serum creatinine of 1.3 mg/dL. At follow up after 3 months, her symptoms remained well controlled, her weight was reduced by a further 10 kg and her serum creatinine was 0.9 mg/dL.

Discussion: Hydralazine has been recommended to treat diuretic resistance in HF by increasing cardiac output, renal blood flow and renal diuretic delivery. However, our case suggests that hydralazine greatly improves renal tubular diuretic responsiveness as her FENa increased 3 fold. This is not likely due to better renal diuretic delivery since the patient received constant IV infusions of two diuretics at doses well above their ceiling. Further clinical trials and mechanistic studies of hydralazine-diuretic interaction are warranted.

PO0236
Carfilzomib-Induced Thrombotic Microangiopathy Effectively Treated with Eculizumab
Jorge M. Chancay rodriguez, Fadi Salem, Mohamed Rizwan Al Rasheed, Priya Deshpande. Mount Sinai Health System, New York, NY.

Introduction: Proteasome inhibitor (PI), Carfilzomib, have been associated with drug-induced microangiopathy (DITMA) in rare cases1. We present a patient with acute kidney injury (AKI) from Carfilzomib-induced DITMA who was successfully managed with Eculizumab, which is a monoclonal antibody that inhibits the alternate pathway of the complement cascade.

Case Description: A 56-year-old woman with refractory IgG Lambda Multiple Myeloma (MM) was admitted with fatigue and decreased oral intake one week after restarting Carfilzomib. She had been on Carfilzomib in the past and tolerated it well. On admission, she had no oliguric AKI with a serum creatinine (Scr) of 12mg/dL (one week prior to restarting Carfilzomib, her Scr = 0.8mg/dL). Peripheral smear revealed numerous with schistocytes and thrombocytopenia. Carfilzomib was immediately discontinued. Serologic work up, including ADAMS13, was within normal limits. Her free kappa/lambda ratio 0.41. She was dialyzed twice for clearance and underwent a renal biopsy. The renal biopsy showed diffuse thrombotic microangiopathy (TMA) with minimal tubulointerstitial fibrosis. Eculizumab 900mg weekly was started, and Scr declined to 1.6mg/dL over 3 weeks. She did not require further hemodialysis treatments. Currently, her Scr is 1.1mg/dL, and she is on Eculizumab 1200mg every two weeks.

Discussion: Our case is the fourth report using Eculizumab in Carfilzomib induced DITMA. The timing of our patient’s Carfilzomib exposure supports that DITMA caused her AKI (as opposed to MM-induced TMA). The first line of treatment requires immediate cessation of the drug. Interestingly, Bluitani et al, demonstrated the activation of the alternate complement pathway in a patient with Carfilzomib-induced TMA, indicated by elevated levels of fragment Bb and membrane attack complex (MAC)7. Portuguese et al, proposed that Carfilzomib may lower the gene expression of Complement factor level 3.6, which is a key regulator of TMA. Eculizumab 900mg weekly was started, and Scr declined to 1.6mg/dL over 3 weeks. She did not require further hemodialysis treatments. Currently, her Scr is 1.1mg/dL, and she is on Eculizumab 1200mg every two weeks.

PO0237
Tubulointerstitial Lupus Nephritis with Coexisting Renal Limited IgG4 Disease

Introduction: The classic pattern of Lupus Nephritis (LN) is an autoimmune condition limited to increased renal limited glomerulonephritis. Rare cases have been described with predominantly tubulointerstitial nephritis (TIN) with tubulointerstitial immune deposits in the absence of significant glomerular lesions. We describe a patient with such pattern of disease along with co-existing renal limited IgG4 related disease (IgG4 RD).

Case Description: 72 year old woman with a past medical history presented with fever, malaise and cough for 3 days. It was associated with occasional epistaxis and dyspnea. On examination, she had bilateral lower extremity edema. Vital signs included blood pressure 107/74 mmHg, without fever or respiratory distress. Laboratory workup showed creatinine (Scr) of 2.3 mg/dl (baseline 1.5 mg/dl), sodium 137 mg/dl, serum creatinine kinase (CK) levels of 170 U/L (38-174 U/L), thyroid secreting hormone levels (TSH) of 97.77 uIU/L. Her liver biochemistry was normal. She underwent a renal biopsy that showed immune complex mediated chronic active tubulointerstitial injury and interstitial fibrosis. Eculizumab 900mg weekly was started, and Scr declined to 1.6mg/dL over 3 weeks. She did not require further hemodialysis treatments. Currently, her Scr is 1.1mg/dL, and she is on Eculizumab 1200mg every two weeks.

Discussion: Our case is the fourth report using Eculizumab in Carfilzomib induced DITMA. The timing of our patient’s Carfilzomib exposure supports that DITMA caused her AKI (as opposed to MM-induced TMA). The first line of treatment requires immediate cessation of the drug. Interestingly, Bluitani et al, demonstrated the activation of the alternate complement pathway in a patient with Carfilzomib-induced TMA, indicated by elevated levels of fragment Bb and membrane attack complex (MAC)7. Portuguese et al, proposed that Carfilzomib may lower the gene expression of Complement factor level 3.6, which is a key regulator of TMA. Eculizumab 900mg weekly was started, and Scr declined to 1.6mg/dL over 3 weeks. She did not require further hemodialysis treatments. Currently, her Scr is 1.1mg/dL, and she is on Eculizumab 1200mg every two weeks.

Eculizumab 900mg weekly was started, and Scr declined to 1.6mg/dL over 3 weeks. She did not require further hemodialysis treatments. Currently, her Scr is 1.1mg/dL, and she is on Eculizumab 1200mg every two weeks.
with non-specific systemic illness. how renal biopsy and social history remain vital diagnostic tools in patients presenting a pauci-immune or immune complex pattern as with our patient. The case demonstrates association reported with ANCAs, particularly anti-PR3, which can demonstrate either particularly in the absence of overt clinical endocarditis. There has been a crossover and multiple scratches. Treatment focus shifted from immunosuppression to antibiosis. 1:1024 (normal <1:128). Bartonella PCR was negative. Both TTE and TEE were negative. Broader infectious workup was negative for ASO titers, Borrelia antibody, Quantiferon/A, HIV and Respiratory panel were negative. Renal cultures, assays for hepatitis B/C, HIV and Respiratory panel were negative. Renal biopsy showed an MPGN-pattern proliferative glomerulonephritis with necrotizing crescents. IF displayed global 3+ granular staining for both IgG and C3 as well as trace granular C1q. EM confirmed mixed mesangial (dominant), subendothelial, and a crescents. IF displayed global 3+ granular staining for both IgG and C3 as well as trace granular C1q. EM confirmed mixed mesangial (dominant), subendothelial, and a few distinct subepithelial hump-like deposits by EM, suggestive of an infection related hypoxia and blood-tinged sputum concerning for pulmonary/renal syndrome and was admitted for gastrointestinal bleed and AKI. He was given blood, intravenous fluids and right percutaneous nephrostomy. It is not identified, and instead a combination of dietary and pharmacologic factors are to be damaging calcium oxalate crystal deposition in the renal tubules and interstitium. It is an uncommon but severe cause of renal damage and leads to dialysis dependence in the majority of patients; thus, diagnostic index of suspicion must be high.

**Case Description:** Patient A was a 58 year old male with 2 prior renal stones but no history of gastric bypass, IBD, or other malabsorptive state who presented with vomiting, metallic taste, and behavior changes. Serum creatinine (Scr) on admission was 10.2 mg/dL (baseline 1.1 mg/dL). Basic workup including ANCA, A, dDNA, C3, C4, and C1q. EM confirmed mixed mesangial (dominant), subendothelial, and a few distinct subepithelial hump-like deposits by EM, suggestive of an infection related glomerulonephritis. With a biopsy suggesting an infectious process and BAL without evidence of alveolar hemorrhage, immunosuppression and PLEX were discontinued. Broader infectious workup was negative for ASO titers, Borrelia antibody, Quantiferon/AFB cultures, and BAL for fungal organisms. However, Bartonella IgG was positive at 1:1024 (normal <1:128). Bartonella PCR was negative. Both TEE and TEG were negative for valvular lesions. Additional patient history elucidated recent acquisition of a pet cat and multiple scratches. Treatment focus shifted from immunosuppression to antibiotics.

**Discussion:** Our case highlights an underappreciated entity associated with GN, particularly in the absence of overt clinical endocarditis. There has been a crossover association reported with ANCAs, particularly anti-PR3, which can demonstrate either a pauci-immune or immune complex pattern as with our patient. The case demonstrates how renal biopsy and social history remain vital diagnostic tools in patients presenting with non-specific systemic illness.

**Case Description:** An 84-year-old female presented with creatinine of 7.85mg/dl (baseline 0.81mg/dl) during a workup for painless hematuria. She developed progressive hypoxia and blood-tinged sputum concerning for pulmonary/renal syndrome and was treated with immunosuppression and plasma exchange. Serologic tests including ANA/ENA, anti-GBM, C-ANCA, P-ANCA, and MPO Ab were negative. However, PR3 Ab was elevated at 29.3 Units. Complement C3 and C4 levels were normal. Blood/urine cultures, assays for hepatitis B/C, HIV and Respiratory panel were negative. Renal biopsy showed an MPGN-pattern proliferative glomerulonephritis with necrotizing crescents. IF displayed global 3+ granular staining for both IgG and C3 as well as trace granular C1q. EM confirmed mixed mesangial (dominant), subendothelial, and a few distinct subepithelial hump-like deposits by EM, suggestive of an infection related glomerulonephritis. With a biopsy suggesting an infectious process and BAL without evidence of alveolar hemorrhage, immunosuppression and PLEX were discontinued. Broader infectious workup was negative for ASO titers, Borrelia antibody, Quantiferon/AFB cultures, and BAL for fungal organisms. However, Bartonella IgG was positive at 1:1024 (normal <1:128). Bartonella PCR was negative. Both TEE and TEG were negative for valvular lesions. Additional patient history elucidated recent acquisition of a pet cat and multiple scratches. Treatment focus shifted from immunosuppression to antibiotics.

most arteriolar walls and tubular basement membranes. There was no immune complex deposition and no immune deposits. This was indicative of severe, acute, subacute and chronic TMA involving all small arterial vessels with acute tubular necrosis. The patient required hemodialysis without renal recovery.

Discussion: TMA is reported in metastatic adenocarcinoma. Cancer treatment can also cause TMA. This was unlikely to be the TMA as it had not been present a few months since the last dose. There are no cases reported of radiation causing renal limited TMA which we thought could also be a potential cause. Hypertension and severe anemia with schistocytes were the only clues to a TMA process. The elevated laktoglobin and normal platelet count was unusual. The TMA is thought to be likely secondary to paraneoplastic syndrome or possibly from the radiation treatments.

Myeloid-Specific PKM2 Deletion Reduces Kidney Damage in Oxa-
lithiasis-Induced AKI
Orestes Foresto-Neto,1,2 Magaia A. Silva,1 Ingrid K. Watanabe,3 Tânia S. Honda,2 Marcos A. Ceneide,1 Meire I. Hiyama,1 Alvaro Pacheco-Nielsen,1 Niels O. Camara.1,2 Universidade Federal de Sao Paulo, Sao Paulo, Brazil; 3Universidade de Sao Paulo Instituto de Ciencias Biomedicas, Sao Paulo, Brazil.

Background: Reprogramming of immune cell metabolism has been associated with the development of kidney injury. The M2 isoform of pyruvate kinase (PKM2) catalyzes a critical stage of glycolysis, which was shown to be a crucial metabolic pathway for proinflammatory macrophage activation. We investigated whether deletion of PKM2 in myeloid cells exerts renoprotection in calcium oxalate (CaOx) crystal-induced acute kidney disease (AKI).

Methods: AKI was induced in myeloid-specific PKM2-knockout (PKM2 fl/fl Cre+) vs. wild-type (PKM2 fl/fl Cre−) mice. Mice were fed a diet containing either CaOx-nephrotoxic littersmates (PKM2+/-) by a single i.p. injection of calcium oxalate (NaOx, 100mg/kg) and 3% NaOx in drinking water for 24hr before sacrifice. Healthy controls received only vehicle. Serum creatinine and urine were evaluated as markers of renal function. CaOx crystal deposition (Pizzolato staining), IL-6, NGAL, and KIM-1 mRNA expression (quantitative PCR), Macrophage number/phenotype (FACS), and lactate levels were assessed in kidney tissue.

Results: In PKM2−/−, intrarenal CaOx deposition increased the serum levels of creatinine and urea, as well as the expression of IL-6, NGAL and KIM-1 in kidney tissue compared to healthy controls (p<0.01). Despite a similar deposition of crystals, loss of renal function and markers of renal inflammation/injury were reduced in PKM2−/− vs. PKM2+/- (p<0.05). FACS analysis indicated that the number of F4/80+ CD11b+ cells in kidneys were similarly elevated by CaOx in both PKM2−/− and PKM2+/-; Ly6M−/− mice. The macrophages with the pro-inflammatory phenotype Ly6C+CD206− were significantly reduced in PKM2−/− vs. PKM2+/- mice (p<0.01). In addition, PKM2 deletion also reduced renal levels of lactate (p<0.05).

Conclusions: The pro-inflammatory status of macrophages relays on glycolysis in CaOx nephropathy. Therefore, deletion of PKM2 in myeloid cells can reduce CaOx-induced renal inflammation and injury. FAPESP (2019/02893-9 and 2017/05264-7), CNPq and CAPES.

High-Content Imaging of Kidney Cell Function to Elucidate Mechanisms of Antiviral Drug Toxicity
Adam Pearson,1 Dominik Haenni,2 Andrew Hall.1,2 Universitat Zurich, Zurich, Switzerland; 1University Hospital Zurich, UniversitatsSpital Zurich, Zurich, Switzerland.

Background: Globally, millions of people live with HIV and hepatitis B virus (HBV). Toxicity from antiviral drugs is a major cause of kidney disease in these individuals. Tenofivir disoproxil fumarate (TDF) is a first line therapy for HIV and HBV; TDF induces functional proximal tubule (PT) defects for reasons that are unknown, partly due to a lack of appropriate experimental models. Clinically, TDF toxicity is characterized by two major phenotypes: isolated defects in PT solute transport; and severe tubular damage (Fanconi syndrome/acute kidney injury) associated with grossly enlarged mitochondria. The aim of our study was to establish realistic in vitro models of TDF toxicity, to investigate the underlying mechanisms.

Methods: Experiments were performed on monolayers of differentiated human-derived PT cells (RPTEC/TERT1). A high-content image analysis pipeline was established, using automated microscopy and machine learning, to quantify transport function, using dome formation as a readout. Metabolism was evaluated by antibody staining for mitochondrial morphology and autophagy.

Results: We screened numerous treatment regimens and generated phenotypes matching those observed in patients, including transport inhibition and mitochondrial hypertrophy. Further experiments using these models revealed that TDF caused a dose dependent decrease in ATP due to increased glycolysis and mtDNA content. Basal and ATP-linked respiration were decreased but maximal respiration was achieved, suggesting inhibition of complex V (ATP synthase). Metabolomic analysis confirmed that TDF was converted to the active antiviral metabolite Tenofivir diprophosphate (TFVpp), a structural analogue of ATP. Using an in vitro assay of complex V activity, we observed a dose dependent inhibition with TFVpp. Metabolomics revealed no major defects in the TCA cycle or beta-oxidation, but clear evidence of oxidative stress.

Conclusions: In summary, we have developed a high-content image analysis pipeline of human-derived PT cells to generate realistic in vitro models of functional TDF toxicity. Metabolic characterization of these revealed a clear phenotype consistent with ATP depletion and mitochondrial dysfunction, which might ultimately explain toxic effects in patients. As the PT solute transport is heavily dependent on aerobic respiration, ATP depletion might trigger compensatory mitochondrial biogenesis, leading to hypertrophy.

PO0245
Immunological Changes Following Cholinoic Anti-Inflammatory Pathway Stimulation
William Nash, Shini Tanaka, Mark D. Okusa. University of Virginia School of Medicine, Charlottesville, VA.

Background: The cholinergic anti-inflammatory pathway (CAP) protect mice from ischemia reperfusion injury (IRI). The interactions and mechanisms that regulate this protective response of great interest as targets for clinical intervention. Vagus nerve stimulation (VNS) induces neurotransmitter cascades that culminate in release of norepinephrine (NE) in the spleen. NE stimulates CD4+ T cells to produce acetylcholine via the choline acetyltransferase enzyme. Acetylcholine then stimulates anti-inflammatory via splenic immune cells that express the 67 nicotinic acetylcholine receptor (nAChR). Adaptive transfer of splenic cells from VNS-treated mice protects kidneys from IRI. However, the downstream effects on splenic structure and function that lead to protection are still not fully understood. The goal of this study is to profile immune cells following CAP stimulation and identify key downstream mechanisms.

Methods: VNS was performed on mice in vivo and nicotine stimulation on immune cells ex vivo. Vagus nerve stimulation was triggered optogenetically using blue light to target the vagus nerve of mice expressing channelrhodopsin-2 under control of the vascular glumatic transporter 2 promoter. Cells were collected from the spleen between 24- and 48-hours post-stimulation. A concentration of 50 μM nicotine in culture media was used to stimulate α7nAChR-expressing immune cells collected from the peritoneum of mice. Analysis of immune cell populations was performed with flow cytometry and single cell RNA sequencing.

Results: Overall, all optogenetic VNS led to a reduced number of CD45+ cells from the spleen. Within the CD45+ population, B1 cells and macrophages exhibited increased representations of ~30% and 60%, respectively. Monocyte and neutrophil representation remained relatively stable, but eosinophils displayed a marked reduction of ~60%. Single cell RNA sequencing showed increased novel gene expression in subpopulations of macrophages, including cell-cell adhesion genes (Sparc) and guanine nucleotide exchange factors (Arhgef5) that could regulate function.

Conclusions: Cholinergic stimulation triggers reorganization of immune cell populations in response to in vivo exposure. The downstream alterations in gene expression are likely important for regulating the inflammatory environment. Additional characterization and functional studies are currently underway to fully identify the importance of observed changes.

PO0246
Reduced Levels of Cyclic-GMP and Inhibition of cGMP-Dependent Protein Kinase Activate p21(127) and p27(127) and Lead to Renal Fibrosis and Dysfunction
Shobhit Das, Kandasamy Neelamgarm, Kailash N. Pandey. Tulane University Health Sciences Center School of Medicine, New Orleans, LA.

Background: Targeted-deletion of Npr1 (coding for guanylyl cyclase/natriuretic peptide A, GC-A/ANP) in extons VNS-treatment inhibits hyperplastic effects in target organs of Npr1 gene-knockout mice; however, the molecular mechanisms of these pathologies are poorly understood. Fibrosis and hypertrophy are regulated by p21(127) and p27(127), cell-cycle regulatory proteins that inhibit cyclin and cyclin-dependent kinase (cyclin-CDK) complex.

Methods: We examined the activation of CDK blocker (p21(127)/p27(127)) in Npr1 gene-knockout (0-copy); Npr1+/- mice and the GC inhibitor, AT7195-treated and CGMP-dependent protein kinase c(GIK) inhibitor, Rp-8-Br-cGMPs (Rp)-treated wild-type Npr1+/- and gene-duplicated 4-copy (Npr1+/-) gene using Western blot and quantitative real-time PCR. Systolic blood pressure (BP) was determined by non-invasive tail-cuff method.

Results: Renal cGMP levels and cGK activity were significantly decreased in 0-copy (p<0.01) compared with untreated control animals. Increased phosphorylation of p-Erk1/2 (3-fold), p-p38MAPK (4-fold), p21(127) (6-fold), p27(127) (5-fold) occurred in 0-copy, A7195-treated 2-copy mice, but only a small increase in 4-copy mice compared with untreated control animals. Increased phosphorylation of p-Erk1/2 (3-fold), p-p38MAPK (4-fold), p21(127) (6-fold), p27(127) (5-fold) occurred in 0-copy, A7195-treated 2-copy mice, but only a small increase in 4-copy mice compared with untreated control animals. Increased phosphorylation of p-Erk1/2 (3-fold), p-p38MAPK (4-fold), p21(127) (6-fold), p27(127) (5-fold) occurred in 0-copy, A7195-treated 2-copy mice, but only a small increase in 4-copy mice compared with untreated control animals.

Conclusions: The present results suggest that Npr1 has a pivotal role in inhibiting the renal fibrosis and pathology and exerts renal protective effects through the cGMP/cGK axis by repressing the CDK inhibitors, p21(127) and p27(127).

Incubation of Acetyl-CoA Carboxylase in Acutely Injured Tubular Cells Exacerbates DNA Damage and Mitochondria Fission in Diabetic Nephropathy
Xiaohuan Liu,1,2 Jiuhua Li,1 Shun-Yang Cheng,1 Guixia Li,1,3 Joseph V. Bonventre,1 Brigham and Women’s Hospital, Boston, MA; The Second Hospital, Checllos College of Medicine, Shandong University, Jinan, China; 3Shenzhen Third People’s Hospital, Shenzhen, China.

Background: Both diabetes and acute tubular injury (ATI) alter lipid metabolism of proximal tubules. Inhibiting lipogenesis causes G2/M cell cycle arrest, which can cause maladaptive tubular repair. Acetyl-CoA carboxylase (ACC) stimulates lipogenesis and inhibits fatty acid oxidation (FAO). Phosphorylation (p-ACC) inhibits ACC, which inhibits lipogenesis and promotes FAO. We hypothesized that p-ACC exacerbates DNA damage and mitochondria dysfunction in diabetic nephropathy (DN) after ATI.

Methods: Human DN samples were co-stained for p-ACC, KIM-1, and α-SMA. ATI was induced by a single deribeterin toxin (DT) injection in Akita mice in which the DT receptor (DTR) was introduced genetically into the kidney tubule (AkitaSIX2-DTR). Mice were fed a high-fat diet (HFD). The expression ratio of p-ACC/ACC was determined at 3 days after DT and markers for tubular injury and DNA damage (p-H2AX) were evaluated at 3 days and 4 months. Cisplatin-injured HK2 cells were treated with an ACC inhibitor, PF-05175157 (ACCi) or a carnitine palmitoyltransferase 1 inhibitor, etomoxir (CPT1i) and examined for DNA damage and mitochondria fission.

Results: P-ACC expression was increased and correlated with expression of tubular injury marker KIM-1 and myofibroblast marker α-SMA in human DN specimens. At day 3 after DT, ATI increased the p-ACC/ACC ratio in the Akita 3H2O mice on HFD and resulted in enhanced expression of p-H2AX in KIM-1 positive tubules and kidney fibrosis at 4 months. When cisplatin-injured HK2 cells were treated with ACCi, which allowed b-oxidation of acyl-CoA, there was an increase in mitochondrial fission (MFF) without a further increase of p-H2AX. Etomoxir, which blocked acylcarnitine entry into mitochondria, reduced MFF and p-H2AX expression.

Conclusions: Increased levels of p-ACC were associated with increased tubular injury and fibrosis in human DN. P-ACC in injured renal epithelial cells permitted b-oxidation of acyl-CoA in damaged mitochondria and enhanced mitochondrial fission resulting in DNA damage plausibly from reactive oxygen species. Prevention of mitochondrial overload of acyl-CoA is a potential therapeutic target to mitigate mitochondria damage and DNA damage after ATI in DN.

Funding: NIDDK Support

The Effect of ANG-3777 on In Vitro Cell Proliferation

Background: Hepatocyte growth factor (HGF) regulates tissue growth and development by inducing cell motility, proliferation and morphogenesis in multiple cell types including endothelial and epithelial cells. However, it has no effect on proliferation in fibroblasts. ANG-3777 is a novel molecule that exerts similar cytoprotective and regenerative effects as HGF. This study compared the effect of ANG-3777 with that of HGF in stimulating cell proliferation.

Methods: In vitro cell proliferation assays were conducted in triplicate using human umbilical vein endothelial cells (HUVECs), rat neuronal Schwann cells, and mouse fibroblasts. HUVECs and fibroblasts were exposed to 5 μM ANG-3777 or 25 ng/mL HGF for up to 24 hours. Schwann cells were exposed to increasing doses of ANG-3777 (up to 10 μM) or HGF (up to 100 ng/mL) for 16 to 24 hours to evaluate the effective concentration at 50% proliferative activity (EC50). Radiolabeled [3H]-thymidine incorporation was used as a measure of cell proliferation. An unpaired T-test was used to compare ANG-3777 or HGF versus vehicle (dimethyl sulfoxide) treatment.

Results: A statistically significant increase in cell proliferation (~3-fold) was observed in HUVECs exposed to ANG-3777 and HGF compared with vehicle (p<0.01; Figure 1). Similarly, Schwann cell proliferation increased in a concentration-dependent manner following exposure to ANG-3777 (EC50 0.012 μM) and HGF (EC50 6.5 ng/mL).

Conclusions: ANG-3777 is comparable to that of HGF in inducing cell proliferation in HUVECs and rat Schwann cells with neither agent stimulating proliferation in mouse fibroblasts.

A Combination of Contrast Media and Radiation Increases DNA Damage and Delays DNA Damage Repair in Mouse Kidneys
Shu Fujino, Shigehiro Doi, Toshiki Doi, Ayumu Nakashima, Takao Masaki. Department of Nephrology, Hiroshima University Hospital, Hiroshima, Japan.

Background: Contrast-induced nephropathy (CIN), resulting from contrast media (CM) administration, is a major complication of angiographic procedures. CIN may also be induced by exposure to radiation. However, the molecular mechanism of CIN has only been investigated using a CM-injected rodent model. Here, we examined the dual effect of CM and irradiation (IR) on DNA damage and repair in in vitro and in vivo.

Methods: Human renal tubular epithelium (HK)-2 cells were stimulated by medium containing 100 μg iodine/ml of iohexol (Ihx-HK2), 1 Gy of X-ray irradiation (IR-HK2), or both (Ihx+IR-HK2). Mannitol-treated cells were used as an experimental control (Man-HK2 or Man+IR-HK2). For the in vivo study, ischemic reperfusion injury (IRI)

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
was induced in mice after right kidney removal, then IRI mice were treated with 200 μL saline and/or 320 mg/kg/day γ-irradiation 24 h after injury. CN was performed without performing immunohistochemistry, immunofluorescence staining, and western blotting for DNA damage markers (γH2AX, PATM, 53BP1, and RAD51), an oxidative stress marker (8-OHdG), a macrophage marker (F4/80), and klotho.

Results: Immunofluorescence staining revealed increased expression of γH2AX, 53BP1, and RAD51 in Ihx+IR-HK2 compared with Ihx- or IR-HK2. These proteins remained highly expressed at 24 h in Ihx-IR-HK2, but not in Ihx- or IR-HK2. Cells positive for γH2AX, pATM, 53BP1, and RAD51 were significantly increased in IRI/CIN+IR mouse kidneys. As a result of DNA damage and delay DNA damage repair, which are accompanied by increased levels of oxidative stress and inflammation and downregulation of klotho expression.

Conclusions: Both CM administration and exposure to radiation induce DNA damage and delay DNA damage repair, which are accompanied by increased levels of oxidative stress and inflammation and downregulation of klotho expression.

PO0251
Whole-Transcriptome Sequencing of Proximal Tubule Cells Exposed to Free Light Chains
Rohit Unadkat,1 Vecchi Batuman,1,2 Tulane University School of Medicine, New Orleans, LA; 2SLFCHS, Southeast Louisiana Veterans Health Care System, New Orleans, LA.

Background: Despite medical advancements, molecular markers for early detection of kidney injury (KI) are limited. Serum creatinine, the only functional marker for KI, has poor predictive accuracy, particularly in the early stages of AKI due to free light chains in multiple myeloma (MM) patients. Identification of new markers would be highly useful in a select group of MM patients who do not present initially with a detectable rise in creatinine.

Methods: Human kidney proximal tubule cells (PTCs; RPTEC cell line) were exposed to κ or λ FLCs. Control/ treated cells were harvested, and total RNA (mRNA) was isolated following standard procedures for whole transcriptome analysis. Whole transcriptome sequencing by RNA sequencing for whole transcriptome was performed by using Illumina NextSeq 500 to generate ~60M paired-end 75bp reads per sample. After initial data quality checking by FastQC and RseqC, bioinformatics analysis was performed using TopHat, Samtools, and Picard. For further classification, annotation, and visualization were facilitated by Partek and R statistical packages. RNA sequencing data were validated through qPCR.

Results: Whole transcriptome RNA-Seq data suggested role of several genes involved in innate immunity (VNN1, MX1, OAS2, TLRs, IFI6, IFI27, IFIT1, ISG15, BS2) and ERK signaling (KCTD12, IF6, MAP3K, ERK1/2, JNK, p38), and inflammation (CXCL6, TNFA, IL6, CXCL8, IL8, IRAK1, IRAK4, TAFK6, NFKB, IKBA, IKK) as well as miRNAs (hsa-146a-5p, hsa-miR-574-3p, hsa-miR-331-3p, hsa-miR-125a-5p) in FLC induced tubular injury in MM patients. We also found a K1 mechanism involving cross-talk among innate immunity, ERK signaling, and the inflammatory pathway by different FLCS types.

Conclusions: Our results show differentially expressed genes and a mechanism of injury involving cross-talk between innate immunity and inflammatory pathways in PTCs exposed to FLCs.

Single-Cell Profiling of AKI in Mice Highlights Differential Immune Cellular Response Programs in Regeneration and Fibrosis
Michael S. Balzer,1,2 Yawen Yang,1 Ziyuan Mu,1,2 Rojesh Shrestha,1 Matthew Palmer,1 Katalin Susztak,1 Susztak Lab1 University of Pennsylvania, Perelman School of Medicine, Department of Medicine, Philadelphia, PA; 2University of Pennsylvania, Perelman School of Medicine, Institute for Diabetes, Obesity, and Metabolism, Philadelphia, PA; 3University of Pennsylvania, Perelman School of Medicine, Department of Pathology and Laboratory Medicine, Philadelphia, PA.

Background: After acute injury the kidney has the ability to regenerate and repair to a certain extent. On the other hand, maladaptive injury response leads to kidney fibrosis and chronic kidney disease. We are only beginning to understand the complex interactions of epithelial, stromal and immune cells involved in these adaptive processes.

Methods: Here we profiled gene expression changes at single cell resolution over time in acute injuries of mice subjected to mild and severe bilateral ischemia-reperfusion injury (IRI). Immune function, structure, bulk and single cell gene expression analysis was performed on day 1, 3 and 14. We used gene regulatory network and trajectory analyses to define key drivers of successful and failed regeneration.

Results: Gene expression resulted in similar kidney function decline as analyzied by serum BUN; however long ischemia led to severe kidney fibrosis, while mild ischemia prompted minimal structural changes. In total, we obtained scRNAseq data for >160,000 cells. IRI lead to very significant cell proportion changes including a decrease in renal tubule cells, progenitor cell clusters, and increased numbers of immune cells involved in innate and adaptive immune functions. Whole transcriptome sequencing for whole transcriptome was performed by using Illumina NextSeq 500 to generate ~60M paired-end 75bp reads per sample. After initial data quality checking by FastQC and RseqC, bioinformatics analysis was performed using TopHat, Samtools, and Picard. For further classification, annotation, and visualization were facilitated by Partek and R statistical packages. RNA sequencing data were validated through qPCR.

Results: Whole transcriptome RNA-Seq data suggested role of several genes involved in innate immunity (VNN1, MX1, OAS2, TLRs, IFI6, IFI27, IFIT1, ISG15, BS2) and ERK signaling (KCTD12, IF6, MAP3K, ERK1/2, JNK, p38), and inflammation (CXCL6, TNFA, IL6, CXCL8, IL8, IRAK1, IRAK4, TAFK6, NFKB, IKBA, IKK) as well as miRNAs (hsa-146a-5p, hsa-miR-574-3p, hsa-miR-331-3p, hsa-miR-125a-5p) in FLC induced tubular injury in MM patients. We also found a K1 mechanism involving cross-talk among innate immunity, ERK signaling, and the inflammatory pathway by different FLCS types.

Conclusions: Our results show differentially expressed genes and a mechanism of injury involving cross-talk between innate immunity and inflammatory pathways in PTCs exposed to FLCs.

PO0254
Long-Term Use of Ferric Citrate in the Treatment of Iron Deficiency Anemia in Patients with Non-Dialysis-Dependent CKD: The COMPASS Trial
Pablo E. Pergola,1 Diogo S. Belo,2 Paul W. Crawford,3 Moustafa A. Moustafa,2 Wenli Luo,4 Alex Goldfarb,5 Renal Associates PA, San Antonio, TX; 1California Center of Renal & Vascular Research, Clincs, El-Fayoum, CA; 2South Carolina Nephrology & Hypertension Center, Inc, Orangeburg, SC; 3Akebia Therapeutics, Inc, Cambridge, MA; 4Research by Design, Chicago, IL.

Background: Ferric citrate (FC) is an FDA-approved oral iron replacement for adults with iron deficiency anemia (IDA) and non-dialysis-dependent (NDD) CKD and as a phosphate binder in adults with dialysis-dependent CKD. For IDA, the recommended FC starting dose is 1 tablet (1 g, contains 210 mg ferric iron) 3 times daily (TID) titrated to maintain hemoglobin (Hb) goal. We studied the long-term efficacy and safety of various FC regimens for IDA treatment in adults with NDD-CKD (stages 3-5).

Methods: 48-wk, phase 4, randomized, open-label, multicenter study (NCT03236246). Patients received (1:1) FC 1 g tablet TID (1 g/day) or 2 tablets BID (4 g/day). At Wk 12, if Hb ≤10 g/dL or changed <0.5 g/dL from baseline (BL), dose was increased to 2 tablets TID (from 1 TID) or 3 tablets BID (from 2 BID). Primary endpoint was change in Hb from BL to Wk 24. Secondary endpoints included changes in transferrin saturation (TSAT), ferritin, and phosphate to Wk 48.

Results: This analysis included 183 of 206 randomized patients. Groups were well matched, with mean age 69.5±10.3 y and 54% with CKD due to diabetes. Mean BL sCr was 3.3±1.6 mg/dL (110±60 µmol/L). Hb was 9.6±1.5 g/dL and 80% of patients were Hb responders (>1.2 g/dL increase) at BL. At Wk 48, the percentage of responders was 73% in BID and 72% in TID groups. No significant differences were observed between groups in adverse events. The percentage of patients with a >10% increase in Hb from BL to Wk 24 was 50% in BID and 47% in TID. Incidence of serious AEs was 13.9% in BID and 17.3% in TID groups. Fewer deaths were reported, none deemed FC related by investigators.

Conclusions: Both FC regimens studied increased and maintained Hb through 48 wks in patients with NDD-CKD with IDA. Patients with lower baseline Hb and iron parameters had a higher increase in Hb with FC treatment. Serum phosphate remained within normal range over study duration. Mean changes in Hb, TSAT, ferritin, and phosphate were similar in the BID and TID and the 3 and 4 g/day dosing groups. These results support the potential for FC dosing flexibility in the long-term treatment of IDA.

**Triferic (Ferric Pyrophosphate Citrate, FPC) Maintains Hemoglobin and Reduces IV Iron: Results from a Single-Site 2-Year Observational Analysis**

Marc L. Hoffman,1 Richard Delvalle,2 Raymond D. Pratt,1 Rockwell Medical Inc, Wixom, MI; Center for Renal Replacement, LLC, Lincolnwood, IL

**Background:** Triferic (ferric pyrophosphate citrate, FPC) is approved as an iron (Fe) replacement product for anemia in hemoglobin (Hgb) in adult patients (pts) receiving chronic hemodialysis (HD). Trial data have demonstrated that FPC maintains Fe stores and Hgb while reducing IV Fe usage with a well-tolerated safety profile. We now report one clinic’s experience using FPC for all HD patients (pts) during a 2-year period.

**Methods:** FPC was added to centrally delivered liquid bicarbonate to provide 110 μg Fe/dialyze. All patients received FPC at each HD. Anonymized retrospective data from the electronic health record were collected between Sep 2016–Dec 2018. A recommended FPC Fe protocol was provided, but the clinic was allowed to adjust anemia management at their discretion. Supplemental Fe gluconate (IV Fe) was administered according to a protocol based on serum ferritin and TSAT values. All pts receiving IV Fe received single doses of 125 mg elemental Fe up to a max of 500 mg Fe/month when criteria for supplementation were met. During the first 4 months of FPC, the center converted pts from epoetin alfa (EPO) to darboepoetin alfa (INN), therefore INN equivalents were calculated using the published conversion guide (EPO dose/300). IV iron and ESA use were standardized and changes from pre-FPC were reported for Hgb, IV Fe and ESA usage. KDQoL data were available for the years 2016–2018.

**Results:** Within 3 months of initiation of FPC, Hgb increased by 0.3 g/dL and was maintained during the observation period. Total IV Fe dose was significantly reduced by 78.4%. Darboepoetin equivalent doses were reduced from pre-FPC by 31.5% by the end of the observation period. Compared to the first year of assessments (2016), post FPC assessments of QoL showed improvements in the Burden of Kidney Disease (KD), Symptoms and Problems of KD and Effects of KD on daily life scales. No adverse events related to FPC were reported.

**Conclusions:** This observational study demonstrates that FPC is a well-tolerated replacement for IV Fe when administered to all patients in a HD unit. The findings of this real-world observational study align with those of clinical trials in terms of reduction of IV Fe use and maintenance of Hgb. ESA was gradually reduced and the KDQoL showed improvements in the burden and symptoms of kidney disease.

**Funding:** Commercial Support - Rockwell Medical Inc.

**Roxadustat Lowers Risk of Red Blood Cell Transfusion in Patients with Anemia of CKD**

Steven Fishbane,1 Robert Provenzano,2 Anjay Rastogi,2 Daniel W. Coyne,1 Robetorio Pecoits-Filho,3 Chaim Charytan,1 Maksym Pola,2 Lona Poole,1 Gopal Sahni,2 Willis Chou,1 Tyson T. Lee,1 Kien-Hung F. Yu,1 Northwell Health, Great Neck, NY; 2Wayne State University, Detroit, MI; 3University of California Los Angeles, Los Angeles, CA; 4Washington University in Saint Louis School of Medicine, Saint Louis, MO; 5Arbor Research Collaborative for Health, Ann Arbor, MI; 6Nephrology Associates, PC, New Rochelle, NY; 7AstraZeneca, Warrikon, Poland; 8 FibroGen Inc., San Francisco, CA; 9Renal Associates PA, San Antonio, TX.

**Background:** RBC transfusions may cause reactions, lead to allo-sensitization, or increase the risk of blood-borne infections. Reducing the need for RBC transfusions is desirable. This analysis assessed whether roxadustat, an oral hypoxia-inducible factor prolyl hydroxylase inhibitor, treats anemia by enhancing erythropoietin synthesis and reducing transferrin synthesis and increasing iron availability via reducing hepcidin and increasing iron transport. We assessed the effect of roxadustat on iron parameters in patients with NDD-CKD.

**Methods:** Patients were randomized to double-blind roxadustat or placebo in 3 pivotal NDD-CKD trials. Oral iron was administered without restriction per discretion of the treating physician, and intravenous (IV) iron use was limited to rescue therapy. Mean changes from baseline (BL) in Hb, hepcidin, and iron parameters were evaluated. Pooled results are reported.

**Results:** Overall, 4277 patients were evaluated (roxadustat N=2391; placebo N=1886). Mean eGFR was 20 ml/min/1.73 m² in both groups. Roxadustat was superior to placebo in increasing mean Hb from BL (9.1 g/dL for both groups) averaged over Weeks 24–52: 1.9 vs 0.2 g/dL (P=0.0001). IV iron use was required in 2.1% of roxadustat vs 4.8% of placebo patients during the first 52 weeks after randomization. Roxadustat reduced hepcidin and increased both transferrin and serum iron (Figure). Reductions in ferritin and transferrin saturation occurred predominantly in patients with the highest BL values of hepatocyte nuclear factor-4α expression. Mean (±SD) baseline values were 785 (±382) ng/mL and 44 (±35)% for hepcidin and transferrin respectively. Roxadustat reduced mean % change from baseline at Week 24 in hepcidin vs placebo by 21% (−54.9% vs −33.6%, P<0.001) and in transferrin by 23% (−27.4% vs −4.9%, P=0.002). Reductions in transferrin and transferrin saturation were associated with a mean increase in serum iron of 7.4 μg/dL (P<0.001). In the 20% of patients with baseline serum ferritin >600 ng/mL, reductions in hepcidin and transferrin were even more pronounced.

**Conclusions:** Roxadustat increased both serum iron and iron-carrying capacity (transferrin) while simultaneously inducing erythropoietin and correcting anemia in patients with NDD-CKD, without the need for regular IV iron supplementation.

**Funding:** Commercial Support - AstraZeneca

Health-Related Quality of Life in Roxadustat-Treated Patients with Anemia and Non-Dialysis-Dependent CKD

Daniel W. Coyne,1 Roberto Manlio-Karim,2 Pablo E. Pergola,3 Carol A. Pollock,4 Roberto Pescitello-Filho,5,6 Tyson T. Lee,7 Elise Hardy,2 Kim-Hung P. Yu8 Washington University in Saint Louis School of Medicine, Saint Louis, MO; 9South Texas Kidney Specialists, P.A., McAllen, TX; 1Renal Associates PA, San Antonio, TX; 2The University of Sydney, Sydney, NSW, Australia; 3Arbor Research Collaborative for Health, Ann Arbor, MI; Pontificia Universidade Catolica do Parana Departamento de Medicina, Curitiba, Brazil; 4Fibrogen Inc, San Francisco, CA; 5AstraZeneca, Gaithersburg, MD.

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Anemia in CKD impacts health-related quality of life (HRQOL) by reducing physical capacity and energy levels. Studies have demonstrated a direct relationship between HRQOL scores and hemoglobin (Hb) levels in non-dialysis-dependent (NDD) and dialysis-dependent patients with CKD. We assessed the impact of roxadustat on HRQOL in patients with NDD-CKD.

Methods: Pooled data from three pivotal, phase 3, randomized, double-blind, placebo-controlled studies of roxadustat for the treatment of anemia in patients with NDD-CKD were assessed. Patients with data up to the time of dialysis treatment and who had pretreatment and post-treatment HRQOL measurement were included. Mean changes from baseline to Week 12 in HRQOL scores were compared between the treatment groups.

Results: Least-squares mean treatment differences favored the roxadustat group at Week 12 in the majority of measures analyzed (Table). Between-group differences were larger in subgroups with lower (ie, worse) baseline scores. p-values <0.05) in the majority of measures analyzed (Table). Between-group differences were larger in subgroups with lower (ie, worse) baseline scores.

Conclusions: Roxadustat demonstrated improvement in most HRQOL measures vs. placebo in patients with NDD-CKD.

Subgroup Analyses of Efficacy of Roxadustat for Treatment of Anemia in Patients with Incident Dialysis-Dependent CKD

Robert Provenzano,1 Jayant Kumar,2 Steven Fishbane,3 Anjay Rastogi,4 Lona Poole,5 Cameron S. Liu,6 Dustin J. Little,7 Kin-Hung P. Yu8 Washington University School of Medicine, Saint Louis, MO; 9Wayne State University, Detroit, MI; 10Renal Medicine Associates, Albuquerque, NM; 11Northwell Health, Great Neck, NY; 12University of California Los Angeles, Los Angeles, CA; 13Fibrogen Inc, San Francisco, CA; 14AstraZeneca, Gaithersburg, MD.

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism.

Methods: Data from three pivotal, phase 3, randomized, double-blind, placebo-controlled studies of roxadustat for the treatment of anemia in patients with non-dialysis-dependent (NDD) CKD were assessed. Data from prespecified, clinically relevant patient subgroups were analyzed for: mean change from baseline (CFB) in hemoglobin (Hb) averaged over weeks 28–52 regardless of rescue therapy (primary US efficacy endpoint) and patients (%) that received rescue therapy in the first 52 weeks.

Results: ROX (n=2390) vs. placebo-treated patients (n=1886) achieved a significantly larger mean (SD) CFB in Hb level (1.85 [0.94] vs. 0.13 [1.01]), corresponding to a least-squares mean (LSM) difference of 1.72 (95% CI: 1.65, 1.79) (p<0.0001). The results of all subgroup analyses were consistent with those for both the primary US efficacy endpoint and the percentage of patients requiring rescue therapy in the overall NDD population (Table). Significantly fewer patients required rescue therapy during roxadustat treatment vs. placebo (8.9% vs. 31.1%), corresponding to a hazard ratio of 0.19 (95% CI: 0.16, 0.23) (p=0.0001). The effect was consistent in all subgroups and especially pronounced in patients with baseline Hb <8.0 g/dL (18.1% vs. 59.3%) and those with baseline eGFR <100 mL/min/1.73m2 (14.8% vs. 48.3%).

Conclusions: The efficacy of roxadustat vs. placebo for a larger mean CFB in Hb and fewer patients that received rescue therapy was consistent across a wide range of prespecified subgroups in the NDD-CKD population.

PO0261
Risk of Transfusion in Patients with Non-Dialysis-Dependent CKD Increases with Hemoglobin Levels <10 g/dL vs. ≥10 g/dL: Pooled Results from Roxadustat Phase 3 Studies

Daniel W. Coyne,1 Roberto Pecottis-Filho,2 Anjay Rastogi,2 Lynda Szczecz,3 Tyson T. Lee,1 Maksym Pola,4 Kin-Hung P. Yu,3 Washington University in Saint Louis School of Medicine, Saint Louis, MO; "Arbor Research Parana Departamento de Medicina, Curitiba, Brazil; 4University of California

Background: Roxadustat is a novel, orally bioavailable, heterocyclic small molecule that reversibly inhibits inhibitory- inducible factor (IFHI) prolyl hydroxylase enzymes and activates HIF and transcription of HIF-responsive genes, including erythropoietin.

Methods: We analyzed data from a Phase 3, randomized, double-blind study (ANDES) comparing roxadustat to placebo for the treatment of anemia in NDD-CKD patients. 922 patients were randomized (2:1) to receive roxadustat (n=616) or placebo (n=306) thrice weekly with monthly dose titrations. Patients were encouraged to receive oral iron daily unless not tolerated. Change in Hb was compared to changes in key iron and red blood cell (RBC) parameters.

Results: All baseline (BL) parameters were comparable between the study arms. Roxadustat was superior to placebo in increasing mean Hb from BL over weeks (wks) 28-52: -2.02 g/dL (p<0.0001), respectively. The rate of transfusion was approximately 4 times higher in patients with Hb between 8.0 and <10.0 g/dL vs. those with Hb ≥10 g/dL. An initial decline in mean ferritin and TSAT was noted primarily in the higher BL quartiles, with little change in the 2 lower BL quartiles. Serum iron increased by 13.6 μg/dL at wk 20 from baseline. All initial changes in iron parameters plateaued by wks 16-20, and remained unchanged thereafter. Reticulocyte Hb content at wk 20 were at baseline level, and it was 2.4% at Weeks 28-52. Mean MCV was slightly increased by 1-4 fL at wk 4 before plateauing and stabilizing, while mean MCHC was unchanged.

Conclusions: Roxadustat lowered serum hepcidin, accompanied with initial decline in ferritin and TSAT in patients with high BL levels but little change in ferritin and TSAT in patients with low-normal BL levels despite active erythropoiesis. Maintenance of reticulocyte Hb content level during treatment reassures sufficient iron availability during erythropoiesis with roxadustat. These findings in iron parameters suggest that iron is efficiently absorbed and mobilized for erythropoiesis during anemia correction and Hb maintenance with roxadustat in NDD-CKD patients.

Roxadustat Increases Hemoglobin in Non-Dialysis-Dependent (NDD) CKD Patients Independent of Inflammation

Carol A. Pollock,1 Simon D. Roger,2 Roberto Manillo-Karim,3 Maksym Pola,4 Stefan Tham,5 Kin-Hung P. Yu,3 Mohamed A. El-Shahawy,7 The University of Sydney, Sydney, NSW, Australia; 2Renal Unit, Gosford Hospital, Gosford, NSW, Australia; 3 Gamma Medical Research, McAllen, TX; 4Clinical Research, AstraZeneca, Warsaw, Poland; 6Clinical Research, AstraZeneca, Gothenburg, Sweden; 7Fibrogen Inc., San Francisco, CA; 8Keck-USC School of Medicine, Los Angeles, CA.

Background: Inflammation is a common cause of decreased responsiveness to erythropoiesis-stimulating agents, Roxadustat, an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis by increasing endogenous erythropoietin and improving iron metabolism.

Methods: Data from three pivotal phase 3 randomized, placebo-controlled studies of roxadustat for the treatment of anemia in NDD patients were assessed. Patients were randomized to receive roxadustat or placebo with period dose evaluation/titratin. Transfusion was allowed at any time if it was deemed a medical necessity by the Investigator. The incidence rate of transfusion was calculated based on Hb level and it was maintained at Weeks 28-52. Mean MCV was slightly increased by 1-4 fL at wk 4 before plateauing and stabilizing, while mean MCHC was unchanged.

Conclusions: Roxadustat lowered serum hepcidin, accompanied with initial decline in ferritin and TSAT in patients with high BL levels but little change in ferritin and TSAT in patients with low-normal BL levels despite active erythropoiesis. Maintenance of reticulocyte Hb content level during treatment reassures sufficient iron availability during erythropoiesis with roxadustat. These findings in iron parameters suggest that iron is efficiently absorbed and mobilized for erythropoiesis during anemia correction and Hb maintenance with roxadustat in NDD-CKD patients.

Funding: Commercial Support - Fibrogen, Inc.; AstraZeneca plc; Astellas Pharma Inc.
similar across all hsCRP quintiles in roxadustat-treated patients (Figure). Mean weekly roxadustat doses at Week 24 for baseline hsCRP quintiles 1 through to 5 were comparable at 3.2, 2.9, 2.5, 3.0, and 3.0 mg/kg, respectively.

Conclusions: Roxadustat increased Hb in anemic NDD-CKD patients independent of inflammation.

Funding: Commercial Support - AstraZeneca

PO0265

Roxadustat Increases Hemoglobin in Anemic Dialysis-Dependent (DD) CKD Patients Independent of Inflammation
Mohamed A. El-Shahawy,1 Simon D. Roger,2 Roberto Manello-Karim,3 Maksym Pola,3 StefanTham,3 Lynda Szczezch,3 Carol A. Pollock,2 Keck-UCSC School of Medicine, Los Angeles, CA; 1Renal Research, Gosford, NSW, Australia; 2Gamma Medical Research, McAllen, TX; 3Clinical Research, AstraZeneca, Warsaw, Poland; 3Clinical Research, AstraZeneca, Gothenburg, Sweden; 4FibroGen Inc., San Francisco, CA; 5The University of Sydney, Sydney, NSW, Australia.

Background: Inflammation is a common cause of decreased responsiveness to erythropoiesis-stimulating agents. Roxadustat, an oral hypoxia-inducible factor prolyl hydroxylase inhibitor, treats anemia by inducing endogenous erythropoietin production and increasing iron utilization via reducing hepcidin. Roxadustat efficacy has been shown in those with inflammation, as defined by baseline (BL) elevation of high sensitivity C-reactive protein (hsCRP). This pooled analysis explored the efficacy of roxadustat in correcting Hb in DD-CKD patients across the spectrum of baseline hsCRP values.

Methods: Data from three randomized Phase 3 pivotal trials in anemic patients with DD-CKD were pooled and the efficacy of roxadustat in increasing hemoglobin (Hb) from BL was assessed. hsCRP concentration was used as a marker of inflammation; patients with hsCRP >5 mg/L were considered to have inflammation at BL. Mean Hb change from BL (CBF) to Weeks 28–52 was summarized by BL hsCRP quintile. Roxadustat dose requirements at Week 24 were based on mean weekly dose in mg per kg of mean BL weight.

Results: Overall, 1538 roxadustat-treated DD-CKD patients were assessed and had a mean BL Hb of 10.5 g/L. Mean BL Hb measures were similar across the hsCRP quintiles (range 9.5–9.7 g/dL). In patients with BL inflammation (n=723), mean Hb CFB to Weeks 28–52 was 1.2 g/dL with roxadustat. Mean Hb CBF to Weeks 28–52 was similar across all hsCRP quintiles in roxadustat-treated patients (Figure). Mean weekly roxadustat doses at Week 24 for BL hsCRP quintiles 1 through to 5 were comparable at 3.9, 3.4, 3.5, 3.3, and 3.6 mg/kg, respectively.

Conclusions: Roxadustat increased Hb in anemic DD-CKD patients independent of inflammation.

Funding: Commercial Support - AstraZeneca

PO0266

Effects of Roxadustat Treatment on Serum Parathyroid Hormone (PTH) in Hemodialysis Patients with Erythropoiesis-Stimulating Agent (ESA) Resistant Anemia
Iyunichiro Hashiguchi,1 Satoshi Funakoshi,1,2 Kenji Sawasz,1,2 Kanako Hayashi,1 Kosei Yamaguchi,1 Mineaki Kitamura,1 Takashi Harada,1 Tomoya Nishino,1 Nagasaki Kidney Center, Nagasaki, Japan; 2Nagasaki University Hospital, Nagasaki, Japan.

Background: Roxadustat, an oral HIF-prolyl hydroxylase inhibitor, is shown to stimulate erythropoiesis thereby improving iron metabolism. Of note, recent research suggests that iron utilization plays a role in bone turnover in hemodialysis patients.

Methods: A total of 64 hemodialysis patients with ESA-resistant anemia despite high-dose epoetin α (3000 units 3 times weekly) therapy participated in the study after giving informed consent. Patients were switched from intravenous epoetin α to oral roxadustat therapy (100 mg 3 times weekly), with no dose change in any of the iron supplements, calcimimetics or vitamin D formulations being used, and were assessed after 8 weeks of roxadustat therapy for improvements in anemia, as well as for changes in parameters related to iron metabolism and bone turnover.

Results: The study included 39 men and 25 women (age, 70.8 ± 11.8 years; Hb concentration, 10.3 ± 1.2 g/dL). After 8 weeks, the Hb concentration tended to be increased (P = 0.06). As shown in Table, the serum iron, ferritin concentration and TSAT significantly decreased (P<0.05), suggesting increased iron utilization. Again, the serum calcium concentration was significantly decreased from 8.54 to 8.36 mg/dL, while the intact-PTH (i-PTH) concentration was significantly decreased from 98.61 to 75.80 pg/mL (P < 0.001).

PO0267

Roxadustat Treatment Corrects Anemia to Hemoglobin (Hb) Values ≥10 g/dL in the Majority of Patients with Non-Dialysis-Dependent Chronic Kidney Disease (NDD-CKD)
Anjay Rastogi,1 Roberto Pectos-Filho,2 Steven Fishbane,3 Dustin J. Little,4 Elise Hardy,5 Kin-Hung P. Yu,2 Robert Provenzano,3 David Geffen School of Medicine at UCLA, Los Angeles, CA; 4Arbor Research Collaborative for Health, Ann Arbor, MI; 1Department of Medicine, Donald and Barbara Zucker School of Medicine at Hofstra/ Northwell, Great Neck, NY; 3Clinical Research, AstraZeneca, Gaithersburg, MD; 2FibroGen Inc., San Francisco, CA; 4Department of Nephrology, Hypertension & Transplantation St John Hospital & Medical Center, Detroit, MI.

Background: The KDIGO clinical practice guidelines recommend the treatment of anemia in NDD-CKD patients with Hb <10 g/dL to reduce associated symptoms and prevent the need for red blood cell transfusions. Roxadustat is a hypoxia-inducible factor prolyl hydroxylase inhibitor studied for the treatment of anemia in patients with CKD through increasing erythropoietin synthesis and enhancing iron utilization. We studied the percentage of patients with NDD-CKD treated with roxadustat achieving Hb ≥10 g/dL.

Methods: Patients with Hb <10 g/dL and eGFR <60 mL/min/1.73 m2 were randomized to roxadustat or placebo in 3 pivotal double-blind NDD-CKD trials (OLYMPUS, ANDES and ALPS). The cumulative percentage of patients with Hb ≥10 g/dL for at least 2 consecutive visits was analyzed monthly over 12 months of roxadustat treatment, using the number of patients remaining on roxadustat treatment at each time point as the denominator. Hb values were censored for 6 weeks following rescue therapy.

Results: In total, 2391 patients received roxadustat. Mean Hb at baseline was 9.1 g/dL and mean eGFR was 19.7 mL/min/1.73 m2. Among patients still on roxadustat treatment, the cumulative percentage of patients with Hb ≥10 g/dL for at least 2 consecutive visits was 38.3%, 75.5%, and 87.0% at months 1, 2, and 3, respectively, and 96.4% at month 6. Among patients still receiving roxadustat treatment at 12 months, the cumulative percentage with confirmed Hb ≥10 g/dL was 99.0%.

Conclusions: Roxadustat effectively raised Hb levels in NDD-CKD patients, with over 95% of patients achieving Hb ≥10 g/dL after 5 months of treatment.

Ophthalmological Effects of Roxadustat in the Treatment of Anemia in Dialysis-Dependent and Non-Dialysis-Dependent CKD Patients: Findings from Two Phase 3 Studies

Quan D. Nguyen, Yasir J. Sepah, Yusuke Yamaguchi, Tetsuro Otsuka, Yoshikatsu Majikawa, Michael Reusch, Tadao Akizawa, BYers Eye Institute, Stanford School of Medicine, Stanford, CA; 4Ocular Imaging Research and Reading Center, Sunnyvale, CA; 5Astellas Pharma, Inc., Tokyo, Japan; 6FibroGen Inc, San Francisco, CA; 7Showa University School of Medicine, Tokyo, Japan.

Background: Roxadustat is an orally active hypoxia-inducible factor prolyl hydroxylase inhibitor in late-stage development for the treatment of chronic kidney disease (CKD) anemia. Nonclinical data had suggested that hypoxia-inducible factor (HIF) stabilization was capable of promote angiogenesis, increasing the risk of retinal pathologies. We herein report the 24-week ophthalmological findings from two phase 3 studies of roxadustat in Japan.

Methods: Dialysis-dependent (DD) and non-dialysis-dependent (NDD) CKD patients (pts) with anemia were randomized to roxadustat (three times weekly) or darbepoetin alfa (DA; once weekly [DD]; once every two weeks [NDD]). Pts were titrated to maintain target hemoglobin. Ophthalmological assessments (funduscopic photograph, optical coherence tomography) were performed by centralized grading; vision acuity measurements were performed at baseline, week 18, and week 24. Results were compared between study groups using the Wilcoxon rank-sum test. Rates of emergent adverse events (AEs) were assessed.

Results: A total of 302 DD pts (150, roxadustat; 152, DA) and 262 NDD pts (131, roxadustat; 131, DA) were randomized and received ≥1 dose of study drug. Results from the ophthalmological funduscopic photograph assessments are reported in Table 1. No meaningful changes were observed in visual acuity or retinal thickness in the treatment groups of either study.

Conclusions: In DD and NDD CKD pts with anemia, the risk of developing ophthalmic abnormalities was comparable between roxadustat and DA.

PO0269

A Phase 3, Multicenter, Randomized, Open-Label, Active Comparator Conversion Study of Roxadustat in Non-Dialysis-Dependent (NDD) Patients with Anemia in CKD

Tadao Akizawa,1 Manabu Iwasaki,2 Tetsuro Otsuka,3 Yusuke Yamaguchi,4 Michael Reusch,3 AstraZeneca Japan, Tokyo, Japan; 1Yokohama City University, Yokohama, Japan; 2Astellas Pharma, Inc., Tokyo, Japan; 3Astellas Pharma Europe B.V., Leiden, Netherlands; 4Showa University School of Medicine, Tokyo, Japan.

Background: Roxadustat is an orally active hypoxia-inducible factor prolyl hydroxylase inhibitor for the treatment of anemia in CKD. Efficacy and long-term safety of roxadustat was assessed, following conversion from darbepoetin alfa (DA), recombinant human erythropoietin (rHuEPO), or epoetin beta pegol (EBP) to roxadustat, in NDD-CKD patients (pts) with anemia. Noninferiority of roxadustat efficacy against DA was evaluated.

Methods: This study enrolled adult Japanese NDD-CKD pts receiving DA, rHuEPO, or EBP for ≥8 weeks before prescreening. Patients who had used rHuEPO or DA were randomized to receive roxadustat or DA (comparative group [CG]). EBP-using pts were allocated to receive roxadustat (referential group [RG]). The primary endpoint was change in average hemoglobin (Hb) from baseline (BL) at Weeks 18-24. Roxadustat efficacy was confirmed if the 95% CI of average Hb at Weeks 18-24 was within 10-12 g/dL. Treatment-emergent adverse events (TEAEs) were assessed.

Results: A total of 262 pts were randomized to CGs and received ≥1 dose of roxadustat (n=131) or DA (n=131); 70 pts were allocated to RG and received ≥1 dose. The mean (95% CI) of average Hb at Weeks 18-24 in roxadustat (CG) was 11.14 (11.01, 11.27) g/dL, confirming the efficacy of roxadustat. The difference between roxadustat and DA (CGs) in the change in average Hb from BL at Weeks 18-24 was -0.75 g/dL; noninferiority of roxadustat efficacy against DA was evaluated.

Conclusions: This study confirmed the efficacy of roxadustat after conversion from DA, rHuEPO, or EBP, as well as its noninferiority to DA, in NDD-CKD pts with anemia. The safety profile of roxadustat was consistent with previous reports. A final analysis of this study (including 52-week data) will be presented at the congress.

PO0270

HIF Prolyl Hydroxylase Inhibitor Improves Exercise Endurance and Hardly Affects Instantaneous Force in Mice

Koiti Takeyama, Hiroshi Nishi, Takaaki Higashihara, Masaoi Nangaku. Tokyo Daigaku, Bunkyo-ku, Japan.

Background: Erythropoietin (EPO) and hypoxia-inducible factor (HIF) stabilizers (PH inhibitors) are efficient therapeutic modalities against anemia in CKD. Compared to EPO and EPO receptor system, extra-renal action of PH inhibitors has still not been fully understood. Previous reports caution us about the actual misuse of PH inhibitors in doped athletes, but nonhematopoietic effects of PH inhibitors on skeletal muscles remain controversial. Metabolic shift from oxidative phosphorylation toward glycolysis in myotubes in vitro was previously reported. Direct pharmacological effects of PH inhibitors on skeletal muscles and exercise performance were assessed in vivo.

Methods: Roxadustat, one of PH inhibitors, was administered via oral gavage to 8-week-old C57BL6 mice. Plasma EPO levels and HIF-targeted gene expression were measured.
Temporal Trends in Anemia Management and Major Clinical Outcomes in Diabetic Patients with CKD

Methods: The Canadian Organ Replacement Register was used to identify 35,945 adults who initiated hemodialysis or peritoneal dialysis from Jan 1, 2007 to Dec 31, 2015. Time at risk started on day 90 of dialysis and continued for a minimum of 12 months to capture outcomes via data linkage with hospital discharge diagnoses. Patients were categorized into 3 time periods anchored to landmark target hemoglobin trials and publications: Era 1 (Era 1 Jan 2007-Dec 2009); Era 2 (Jan 2010-Dec 2012); Era 3 (Jan 2013-Dec 2015). Cox proportional hazards regression models were used to investigate the association between era and the primary composite outcome (acute myocardial infarction (AMI), stroke or mortality).

Results: The mean hemoglobin at dialysis initiation decreased from 102.9 g/L in 2007 to 93.9 g/L in 2015 corresponding with a doubling in the prevalence of hemoglobin <80 g/L (8% to 17%) and a reduction in ESA use (49% to 44%). A total of 11,810 events were observed during 66,844 person years of follow-up. After multi-variable adjustment, Era 3 was associated with an 8% relative risk reduction in the primary outcome compared to Era 1 (hazard ratio (HR) 0.92, 95% confidence interval (CI) 0.88-0.96), driven by a decrease in all-cause mortality (HR 0.90, 95% CI 0.85-0.94) without a reduction in AMI or stroke. In a model without era, neither hemoglobin nor ESA use was an independent predictor of mortality.

Conclusions: There have been modest declines in average hemoglobin values and ESA use among incident dialysis patients in Canada. Unlike the US, there has been no temporal reduction in stroke. Patient survival has improved over time, likely for reasons other than anemia management. An increasing number of patients are starting dialysis with a hemoglobin <90 g/L, which represents a substantial shift in practice and merits further investigation in terms of patient-centered outcomes.

PO0274
Cost and Healthcare Resource Use in Patients with Anemia in CKD
Using Linked Us Claims and Electronic Health Records

Methods: This retrospective analysis of the integrated Limited Claims and Electronic Health Record (IBM Health, Armonk, NY) spanned Jan 1, 2012 to Sept 30, 2018. Patients were aged ≥18 years with ≥2 eGFR measures <60 mL/min/1.73 m² ≥90 days apart. Anemia was defined as any hemoglobin (Hb) value <10 g/dL observed within 6 months of confirmatory eGFR (baseline period). Total site- specific costs and selected healthcare resource utilization were analyzed and stratified by presence of baseline Hb range, CKD stage, sex, and insurance type.

Results: Of 22,720 patients (n = 228) had baseline anemia, 77% (17,437) did not; females accounted for 60% and 56% of the patients, mean ages ≥70 (SD) were 70 (14) and 70 (12) years, and median follow-up times were 2.9 and 3.8 years, respectively. Baseline anemia prevalence by CKD stage was 18% (stage 3a), 25% (3b), 41% (4), and 60% (5). Median per patient total costs were $49,012 and $31,667, total hospitalization costs were $334,797 and $226,925, and total ER costs were $2,232 and $1,891, respectively. Median annual number of transfusions doubled (2 vs 1) and annual transfusion cost was 50% greater in patients with vs without baseline anemia, respectively. Slightly increased

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
costs were associated with male sex and were markedly increased by advancing CKD stage (≥3a), baseline HB <10, and supplemental Medicare and non-capitated insurance coverage.

**Conclusions:** Anemia is associated with substantially added direct cost and healthcare resource utilization experienced by patients with non-dialysis CKD, in both early and advanced stages and with lower HB. Effective management of anemia in CKD offers an opportunity to address this ongoing burden.

**Funding:** Commercial Support - AstraZeneca

**Modelling the Clinical and Economic Burden of Anemia in Patients with CKD**

**Oliver T. Darlington,**1 David Booth,1 Peter D. Gabb,1 Myrleen Sanon,2 Efstathios N. Michalopoulous,2 Youssef M. Farag,1 Xinyu Wang,1 Philip McEwan,1,3 "Health Economics and Outcomes Research Ltd., Cardiff, United Kingdom; 2Otsuka Pharmaceutical Development and Commercialization, Inc., Princeton, NJ; 3Akebia Therapeutics, Inc., Cambridge, MA; 4Otsuka Pharmaceutical Europe Ltd., Slough, United Kingdom; 5Centre for Health Economics, Swansea University, Swansea, United Kingdom.

**Background:** Chronic Kidney Disease (CKD) imposes a significant societal burden. Anemia is a common complication of CKD and is independently associated with poorer patient outcomes, including CKD progression, cardiovascular (CV) events and death. The objective of this study was to develop a natural history model to characterize the consequences of anemia in patients with CKD.

**Methods:** A lifetime Markov model was developed to estimate the economic impact of anemia. Two cohorts aged 58 years with CKD stage 3b were modelled with and without anemia (Hb 9-10 g/dL and Hb ≥ 12 g/dL) to estimate differences in life expectancy (LE) and quality-adjusted life years (QALYs), and event incidence. Hb level was linked to CKD progression, CV hospitalization and mortality using published data. Published direct costs and utility estimates associated with CKD and event incidence were incorporated, and costs were inflated to 2019 US dollars. Costs associated with anemia treatment such as erythropoiesis-stimulating agents or supplemental iron were not considered. Future costs and benefits were discounted at 3.0% per annum.

**Results:** Predicted LE was 10.21 years in patients with anemia compared to 12.36 years in patients without anemia, or a reduction of 2.15 years. Decreased patient LE and reduced quality of life with anemia resulted in 2.18 fewer QALYs. Time to end stage renal disease was 10.4 years with anemia and 12.5 years without anemia. Patients with anemia experienced 25 additional CV-related hospitalizations per 1,000 patients. Total lifetime costs were higher in the non-anemic cohort due to improved LE ($342,867 vs. $316,510), however, annual costs were lower in patients with an undetected Hb level of $2,628 per year due to reduced CV event incidence and CKD management costs.

**Conclusions:** This analysis supports that those without anemia have increased LE and QALYs, and account for less costs to the healthcare system. Therefore, anemia management, aligned with clinical guidelines, has the potential for better outcomes for both the patient and the healthcare system.

**PO0276**

**Prevalence of Severe Anemia and Transfusion Risk in Medicare and Non-Medicare Populations with CKD Stages 3 and 4**

**Jill Davis,**2 Robert M. Perkins,2 Allison A. Pettrilla,1 Scott B. Robinson,1 Dakota C. Powell,1 Anne Murunga,1 Shamhambi Kumar,1 Kevin Dietz,1 Avaleere Health, Washington, DC; 2AstraZeneca, Wilmington, DE.

**Background:** While 30 million people in the United States have chronic kidney disease (CKD), real-world clinical burden of anemia in non-dialysis dependent (NDD) CKD patients is poorly documented, which we seek to address.

**Methods:** A retrospective cohort analysis was conducted using the 100% sample of Medicare Fee-For-Service (FFS) beneficiaries (parts A/B/D) and a convenience sample of Commercial (Com), Medicare Advantage (MA), and Managed Medicaid (MM) from Inovalon’s Medical Outcomes Research for Effectiveness and Economics (MORE®) Registry® linked to eGFR and hemoglobin (Hgb) values from Prognosis laboratory data. Patients with ≥2 consecutive eGFR tests with eGFR 15-59 mL/min/1.73m2 (≥90 days apart) and severe anemia (Hgb <9 g/dL; January 1, 2018) were retained for analysis; patients on maintenance dialysis were excluded. Severe anemia was defined as Hgb<10 g/dL, measured within 90 days of index eGFR. Red blood cell transfusion (RBCT) during a 12-month follow up was identified using procedure codes. A logistic regression model identified baseline factors associated with receiving RBCT.

**Results:** A total of 1,305,334 patients were identified from Medicare FFS and 154,163 from MORE®. Prevalence of severe anemia in the Medicare FFS cohort was 3.1% and 3.3% in the MORE® cohort (Table 1). Severe anemia was highest among stage 4 CKD patients at 11.3% in the FFS cohort and 13.5% in MORE® cohort, with prevalence among Medicare Advantage patients at 17.1%. High value, cancer, diabetes, liver disease, and hospitalizations were risk factors for RBCT. Within the MORE® cohort, the odds of receiving RBCT increased by 47% for each 1 g/dL decrease in hemoglobin.

**Conclusions:** The proportion of severe anemia increases with worsening CKD stage in both FFS and MORE® cohorts primarily in Medicare Advantage. Marginal clinical factors influence the odds of severely anemic NDD CKD patients receiving RBCT.

**Funding:** Commercial Support - AstraZeneca

Table reports percentages. Marginally-adjusted prevalence derived using logistic regression models (age, sex, education, marital status, income, health insurance, employment, smoking, alcohol use, vascular disease, chronic heart failure, coronary heart disease, angina pectoris, heart attack, stroke, arthritis, chronic obstructive pulmonary disease, body mass index, hypertension, diabetes, and hyperlipidemia).

**Association of Anemia with Activities of Daily Living in CKD: The National Health and Nutrition Examination Survey (NHANES), 1999-2016**

**Efstathios N. Michalopoulous,**1 Di Zhao,1 Youssef M. Farag,1 Myrleen Sanon,2 Fredric O. Finkelstein,1,2 Otsuka Pharmaceutical Development and Commercialization, Inc., Princeton, NJ; 3Johns Hopkins University, Baltimore, MD; 4Akebia Therapeutics, Inc., Cambridge, MA; 5Yale University, New Haven, CT.

**Background:** Anemia is a major contributor to clinical burden and may negatively impact patient outcomes in chronic kidney disease (CKD). We assessed the impact of anemia on activities of daily living (ADLs) among participants with CKD in the US population.

**Methods:** A cross-sectional study (n=33,300; aged ≥20 years) using NHANES data (1999-2016) was conducted. Estimated glomerular filtration rate (eGFR) was calculated using the CKD-EPI formula. Participants were classified as no CKD, CKD stage 1-2, and CKD stage 3-5 using KDIGO criteria. Anemia was defined using WHO criteria. ADL impairment was defined as "some difficulty" in performing ADL activity.

**Results:** Mean age of participants was 46.7 years; 51.0% were female. The percentage of participants with no CKD, CKD stage 1-2, and CKD stage 3-5 was 86.4%, 7.6%, and 6.0%, respectively. Anemia prevalence in each CKD category was 4.9%, 8.7%, and 18.6%, respectively. Multivariable-adjusted prevalence of impairment in ≥1 ADL, by CKD and anemia status, is presented along with covariates in the Table. Compared to participants with no anemia, the adjusted prevalence ratio for impairment in ≥1 ADL was 1.06 (95%C.I: 0.98-1.14; p=0.13) in no CKD, 1.14 (0.99-1.28; p=0.06) in CKD stage 1-2, and 1.20 (1.05-1.35; p=0.01) in CKD stage 3-5. The clinical implications of this association should be investigated further.

**Funding:** Commercial Support - Otsuka Pharmaceutical Development & Commercialization, Inc. & Akebia Therapeutics, Inc.

Adjusted prevalence (95%CI) of impairment in ≥1 ADL by CKD and anemia category

Table reports percentages. Marginally-adjusted prevalence derived using logistic regression models (age, sex, education, marital status, income, health insurance, employment, smoking, alcohol use, vascular disease, chronic heart failure, coronary heart disease, angina pectoris, heart attack, stroke, arthritis, chronic obstructive pulmonary disease, body mass index, hypertension, diabetes, and hyperlipidemia).

**Clinical Outcomes in Patients with Anemia in CKD Using Linked US Claims and Electronic Health Records**

**Eric T. Wittbrodt,**1 Glen James,2 Supriya R. Kumar,3 Juan Jose Garcia Sanchez,2 Hungta (tongy) Chen,3 James A. Slaoad,4 Kamyar Kalantar-Zadeh,4 1AstraZeneca, Wilmington, DE; 2Astrazeneca, Cambridge, United Kingdom; 3Astrazeneca, Gaithersburg, MD; 4University of California - Irvine, Irvine, CA.

**Background:** Anemia is common in pts with CKD, yet contemporary outcome data to understand the long-term clinical burden are scarce. This analysis describes selected cardiovascular and renal outcomes in non-dialysis CKD pts with and without anemia at baseline (BL) in US real-world practice.

**Methods:** This retrospective observational study evaluated the integrated Linked Claims and Electronic Health Record data (IBM Health, Armonk, NY). Pts were aged ≥18 with ≥2 eGFR measures ≥60 mL/min/1.73 m2 ≥90 days apart. Anemia was defined as the presence of any observed HB <10 g/dL within a 6 months period of confirmatory eGFR (anemia BL period). In addition, the BL period for disease history was defined as the start of pt data +6 months, and for lab measures and medications was defined as date of the second confirmatory eGFR +6 months. Pts with active bleeding, chronic dialysis, and tenofovir derivatives therapy were excluded. BL pt characteristics and clinical outcomes during follow-up were analyzed for the period from Jan 1, 2012 to Sep 30, 2017. Descriptive data were summarized; no inferential statistics were performed.
Results: Of the total study cohort (N=22,720), 23% (n=5283) had BL Hb <10 g/dL. The following results are for pts with and without anemia at BL, respectively. Females accounted for 60% and 57% and mean ages (±SD) were 70 (±14) and 71 (±12) y. Proportions by BL CKD stage were: 3a, 50% and 68%; 3b, 27% and 24%; 4, 15% and 7%; 5, 9% and 1%. Median follow-up times were 2.9 and 3.8 y. Acute coronary syndrome (ACS) events during follow-up occurred in 2.2% of pts with BL anemia and 2.3% of pts without BL anemia, heart failure hospitalizations (HFh) occurred in 5.9% and 3.7%, and stroke hospitalizations and emergency visits (S) occurred in 2.8% and 3.0% of pts. Incidence rates/100 pt-y were 0.8 and 0.7 for ACS, 1.6 and 0.8 for HFh, respectively, and 0.7 in both groups for S. The incidence of HFh in patients with TSAT <25% or 25-45% was 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories (G4 and G5) were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were 2.0%, 4.2%, 9.2%, 2.0280
Lower Transferrin Saturation (TSAT) Index Is Associated with Anemia-Independent Risk of Increased Mortality in Non-Dialysis (ND) CKD Patients
Murilo H. Guedes,1,2 Daniel G. Muenz,2 Jarcy Zee,2 Brian Bieber,2 Sandra Wachter,1 Benedicte Stengel,1 Ziad Massy,41 Helmut Reichel,2 David M. Charytan,3 Michelle M. Wong,4 Ronald L. Pisoni,2 Bruce M. Robinson,2 Roberto Pecoits-Filho,2,3 Pontificia Universidade Catolica do Parana, Curitiba, Brazil; 2Arbor Research Collaborative for Health, Ann Arbor, MI; 3Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; 4Division of Nephrology, Ambroise Paré University Hospital, APHP, Boulogne-Billancourt, France; 5The University of British Columbia, Vancouver, BC, Canada; 6NYU Langone Health, New York, NY; 7Nephrological Center, Villingen-Schwenningen, Germany; 8Vifor Pharma Ltd, Glattbrugg, Switzerland.

Background: Iron Deficiency (ID), defined by a TSAT index <20 %, is present in approximately half of ND-CKD patients, varying little by CKD stage. Distinct from approaches in conditions such as heart failure, the importance of iron reserves and the basis for iron therapy in CKD has focused primarily on supporting effective erythropoiesis. A comprehensive approach and design to estimate the impact of ID, independently from hemoglobin (Hb) levels, on mortality risk has not been explored in ND-CKD until the present.
Methods: 5144 patients from Brazil (N=294), France (N=2227), the US (N=494), and Germany (N=2129) enrolled in the Chronic Kidney Disease Outcomes and Practice Patterns Study (CKDopps) from 2013-2019 with available TSAT were included in the analysis. We categorized patients by first available TSAT at enrollment. Hb measurements at the same time as TSAT were used. Cox models were used to estimate hazard ratios (HR) of TSAT on mortality, censored at start of dialysis or kidney transplantation. Models were progressively adjusted including demographics, comorbidities, inflammation surrogates, treatment with erythropoietin stimulating-agents and Hb.
Results: Sample characteristics were: 59% male; 45% diabetes; and mean (SD) age 69 (±13) years, eGFR 28 (±11) mL/min, Hb 12 (±2) g/dL, TSAT 24 (±2) %, ferritin 196 (±214) ng/dL. TSAT levels below 25% were progressively associated with higher mortality risk, while patients with TSAT greater than 45% tended to have higher risks for mortality (Figure).
Conclusions: ID, as measured by the TSAT index, is associated with higher risk of all-cause mortality in ND-CKD patients, even after extensive adjustments for clinical, demographic and biochemical confounders, including Hb levels. Interventional studies evaluating the impact of iron supplementation and alternative targets on clinical outcomes in ND-CKD patients are needed to better inform ID management strategies.

PO0281
Lower Transferrin Saturation (TSAT) Is Associated with Worse Health-Related Quality of Life (HRQOL) in Non-Dialysis CKD Patients Independently from Hemoglobin (Hb) Levels
Murilo H. Guedes,1,2 Daniel G. Muenz,2 Jarcy Zee,2 Marcelo Lopes,2 Sandra Wachter,1 Benedicte Stengel,1 Ziad Massy,41 Elodie Speyer,4 Fredric O. Finkelstein,1 Ricardo Sesso,1 Ronald L. Pisoni,2 Bruce M. Robinson,2 Roberto Pecoits-Filho,2,3 Pontificia Universidade Catolica do Parana, Curitiba, Brazil; 2Arbor Research Collaborative for Health, Ann Arbor, MI; 3Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; 4Division of Nephrology, Ambroise Paré University Hospital, APHP, Boulogne-Billancourt, France.

Background: Iron Deficiency (ID) is a common condition in NDD-CKD patients that is associated with poorer outcomes. However, the effect of ID on HRQOL in this population is unknown. We analyzed real world data from a multinational cohort of NDD-CKD stage 3 to 5 patients to test the association between TSAT and ferritin with HRQOL.
Methods: Patients from Brazil (N=205), France (N=2015), and the US (N=293) in the Chronic Kidney Disease Outcomes and Practice Patterns Study (CKDopps, 2013 to 2019) with TSAT, ferritin, and HRQOL data were included. We grouped patients according to TSAT and ferritin levels closest to the HRQOL measurement. Our primary analyses evaluated the associations of TSAT and ferritin with mean differences in physical component summary (PCS) and mental component summary (MCS). Secondary analyses evaluated joint TSAT and ferritin categories, as well as additional pre-specified HRQOL measures. Linear mixed models were adjusted for potential confounders including Hb level.
Results: 2513 patients were included. In the primary analyses, TSAT ≤15% and both ferritin <50 ng/mL and 200-399 ng/mL were associated with worse PCS scores, while MCV was not directionally associated with iron parameters (Figure). Patients with the composite TSAT ≤15%/ferritin ≤300 ng/mL had lower functionality scores and worse PCS, compared to those with TSAT between 20-30% and ferritin 50-299 ng/mL. Adjustment for Hb only slightly attenuated the effects, and the results were similar for subgroups of patients with Hb <11.5 vs ≤11.5 g/dL.

Conclusions: Low TSAT levels, and both low and high ferritin levels, are associated with poorer physical HRQOL in ND-CKD patients, even after adjustment or stratification by Hb level. Intervention studies of iron therapy on HRQOL among ND-CKD individuals are needed to confirm these findings.

PO0283
A Novel, Fast-Acting Iron Sucrose Formulation for CKD Patients with Iron Deficiency Anemia
Charles M. Cook,1 Bhupinder Singh,2 Stacey Ruiz,1 Alvaro F. Guillen.1
1Renibus Therapeutics, Southlake, TX; 2‘University of California Irvine, University of California Irvine, Irvine, CA, US. Department of Medicine, Irvine, CA; 3CMC SQUARED, Southlake, TX.

Background: Intravenous (IV) iron is commonly used to treat iron deficiency anemia in patients with chronic kidney disease (CKD). We report the results of the physicochemical and safety profile of RBT-3, a novel iron sucrose formulation, which was assessed in a Phase 1b study conducted in healthy volunteers and subjects with chronic kidney disease (CKD) Stage 3 or 4.

Methods: Analytical testing was conducted to examine the physicochemical profile of RBT-3. Safety of RBT-3 was assessed in a Phase 1b study in healthy volunteers and subjects with CKD. RBT-3 was administered IV as a single dose of 120, 240, or 360 mg. Plasma and urine ferritin were measured at baseline, then 2 h (plasma) or 24 h (urine) after 168 h post-treatment to assess clinical response.

Results: RBT-3 particle size is similar to commercially available iron sucrose. However, RBT-3 has a lower molecular weight and higher water content than similar IV iron formulations, suggesting faster uptake and greater solubility, respectively. RBT-3 also has a negative Zeta potential, demonstrating low cytotoxic potential. Furthermore, Fe2+, which is associated with oxidative stress, is present in much lower quantities in RBT-3 (3.4%) compared to commercially available iron sucrose (15.8%). In this Phase 1b study of RBT-3, 18 subjects were enrolled; 6 subjects (3 healthy volunteers and 3 subjects with CKD) randomized to 3 cohorts received a single dose of RBT-3 at 120, 240, or 360 mg. Mean age was 60.3 years; 66.7% of the subjects were female. Dose-dependent increases in plasma ferritin were observed in all subjects within 2 h of treatment and reached statistical significance by 8-12 h. Urine levels were increased at 24 h. Both plasma and urine ferritin levels remained elevated through 168 h (7 days). No treatment-related adverse events (AEs) were observed, and no serious AEs (SAEs) were reported.

Conclusions: RBT-3 represents a novel iron sucrose formulation with desirable physicochemical characteristics that makes it a fast-acting mediator of iron hemodynamics. This is the first report of ferritin levels increases within only 2 h by an iron formulation. RBT-3 is safe and well tolerated in healthy volunteers and subjects with CKD at a single dose up to 360 mg.

Response to Oral Iron Therapy in Children with Anemia of CKD
Sharmi Biswas,1 Kelly Meza,2 Haneen Aljayyousi,1 Dmitry V. Samsomov,2 Sonia Solomon,2,3 Eduardo M. Perelson,2,3 Jubi Kumar,1 Oleh M. Akchurin.1
1Pediatric Nephrology; 2Weill Cornell Medicine, New York, NY; 3Westchester Medical Center, Valhalla, NY; 4‘Boston Children’s Hospital, Boston, MA; 5‘NewYork-Presbyterian Hospital/Weill Cornell Medical Center, New York, NY.

Background: Anemia is a common complication of chronic kidney disease (CKD). Current guidelines recommend oral iron therapy as the initial treatment of anemia in CKD. However, the efficacy of iron therapy in children with pre-dialysis CKD has not been evaluated. Factors determining the response to oral iron in pediatric CKD remain poorly understood.

Methods: An ongoing retrospective observational study. Data were abstracted from health records of children with pre-dialysis CKD at the time of iron therapy initiation and at the next clinic visit and compared using paired t-Test. Children receiving anemia-stimulating agents were excluded. Response to iron therapy was defined as improvement in both hemoglobin and hematocrit after iron therapy. Changes of serum iron were used as a surrogate measure of adherence to iron therapy. Data are presented as median (interquartile range).

Results: We identified 44 children (48% boys) who met the inclusion criteria. Median age was 11 (5-15) years, glomerular filtration rate (GFR) 46 (31-60) mL/min/1.73m². Ferrous sulfate was used in 86.4% of children. The interval between visits was 61 (31-120) days. Iron therapy resulted in a significant increase in transferrin saturation (14 (0-21%), p<0.01) and serum iron (45 to 65 μg/dL, p<0.01). While there was an overall improvement of hemoglobin (from 10.6 to 11.2 g/dL, p<0.02), 45% of children did not respond to iron therapy. Non-responders had a significantly smaller change in serum iron after iron therapy compared to responders (3 vs. 35 μg/dL, p=0.03), likely indicating low adherence to iron therapy by non-responders. Baseline age, GFR, hemoglobin, transferrin saturation, serum iron, and serum ferritin were not different between responders and non-responders. Baseline body weight and height Z scores were significantly lower in non-responders than in responders (-0.67 vs. 0.12, p=0.04 and -1.66 vs. -0.25, p=0.02, respectively), possibly representing differences in nutritional status.

Conclusions: This is the first study that systematically assesses response to oral iron therapy in children with pre-dialysis CKD after 2012 Kidney Disease Improving Global Outcomes (KDIGO) guidelines. Response to iron therapy may be related to medication adherence and baseline nutritional characteristics of study participants.
Improving Knowledge of Nephrologists Regarding an Emerging Class to Treat Anemia Associated with CKD

Background: As emerging therapies hold promise to improve treatment of anemia in patients with CKD, clinicians need to understand mechanisms of action in order to understand the potential place in therapy when available. We sought to determine if online continuing medical education (CME) could improve the clinical knowledge of nephrologist related to emerging Hypoxia-Inducible Factor Prolyl Hydroxylase Inhibitors (HIF-PHIs).

Methods: The effect of 2 online, 30-minute, CME-certified activities were analyzed. Multiple-choice knowledge and self-efficacy confidence questions were presented both before and immediately after each activity. A repeated pairs pre-/post-assessment study design was used and chi-square test (5% significance level, P <.05) assessed educational effect. Cramer’s V was used to calculate the effect size (0.00-0.15 is a noticeable effect, 0.16-0.26 considerable, and >0.26 extensive). The activity launched June 20, 2019 and data were collected through July 11, 2019.

Results: In total, 167 nephrologists were included in the study. Overall improvements were seen for both activities after participation: Activity 1: N=75, P=.001, V=.156; Activity 2: N=93, P=.001, V=.162 Individual question-level improvement was also demonstrated: 21% of nephrologists (N=75, P=.05; V=.169) improved at correctly identifying the mechanism of action of HIF-PHIs 20% of nephrologists (N=75, P=.05; V=.197) improved at recognizing clinical trial data for HIF-PHIs 33% of nephrologists (N=92, P=.05; V=.315) improved at recognizing clinical trial data for HIF-PHIs 21% of nephrologists (N=93, P=.05; V=.103) improved at recognizing CVOTS for HIF-PHIs 45% (N=75) and 47% (N=92) reported increased confidence in understanding HIF PHI clinical trial data Continued educational gaps: 55% (activity 2) and 59% (activity 1) of nephrologists did not recognize the mechanism of action of emerging HIF-PHIS 46% of nephrologists did not recognize clinical trial data for emerging HIF-PHIs

Conclusions: This study demonstrates the success of online, video-based CME on improving knowledge of nephrologists related to emerging treatments for anemia associated with CKD. Continued knowledge gaps were identified for future educational targets.

Funding: Commercial Support - AstraZeneca ad Fibrogen

Online CME Successful at Improving Nephrologist Understanding of Emerging Class to Treat Anemia Associated with CKD

Background: As emerging therapies hold promise to improve treatment of anemia in patients with CKD, clinicians need to understand mechanisms of action in order to understand the potential place in therapy when available. We sought to determine if online continuing medical education (CME) could improve the clinical knowledge of nephrologist related to emerging Hypoxia-Inducible Factor Prolyl Hydroxylase Inhibitors (HIF-PHIs).

Methods: The effect of an online, CME-certified, roundtable video discussion was analyzed to determine efficacy of online education. Three multiple-choice knowledge/competence questions and 1 self-efficacy confidence question were presented both before and immediately after each activity. A repeated pairs pre-/post-assessment study design was used and chi-square test (5% significance level, P <.05) assessed educational effect. Cramer’s V was used to calculate the effect size (0.00-0.15 is a noticeable effect, 0.16-0.26 considerable, and >0.26 extensive). The activity launched June 27, 2019 and data were collected through August 27, 2019.

Results: In total, 62 nephrologists answered all pre-/post-assessment questions and were included in the study. Overall improvements were seen after participation in both CME activities: 24% of nephrologists (P<.05; V=.216) improved at correctly identifying the mechanism of action of HIF-PHIS 11% of nephrologists (P=.72; V=.032) demonstrated improvement at selecting the recommended use of erythropoiesis stimulating agents (ESAs) in the treatment of anemia 21% of nephrologists (P<.05; V=.181) improved at recognizing clinical trial data of HIF-PHIS 47% reported increased confidence in understanding HIF-PHI clinical trial data Continued educational gaps: 52% of nephrologists did not recognize the mechanism of action of emerging HIF-PHIS 47% of nephrologists did not recognize the role of ESAs in the treatment of anemia 31% of nephrologists did not recognize clinical trial data for emerging HIF-PHIS

Conclusions: This study demonstrates the success of online, video-based roundtable discussion on improving knowledge of nephrologists related to emerging treatments for anemia associated with CKD. Continued knowledge gaps were identified for future educational targets.

Treatment Pathways of Non-Dialysis-Dependent CKD Patients with Anemia: A Report from the DISCOVER CKD Retrospective Cohort

Eric T. Wittbrodt,1 Juan J. Carrero,2 Glen James,3 Steven Fishbane,4 Supriya R. Kumar,4 Roberto Pecoits-Filho,5,6 Juan Jose Garcia Sanchez,7 Carol A. Pollock,8 James A. Slaad,9 Katarina Hedman,9 David C. Wheeler,9 AstraZeneca UK Ltd, Cambridge, United Kingdom; AstraZeneca, Gaithersburg, MD; Karolinska Institutet, Stockholm, Sweden; Norway, Manhasset, NY; Pontificia Universidad Catolica do Parauna, Curitiba, Brazil; Arbor Research Collaborative for Health, Ann Arbor, MI; University of Sydney, Sydney, NSW, Australia; AstraZeneca, Gothenburg, Sweden; University College London, London, United Kingdom.

Background: Anemia is a frequent complication of chronic kidney disease (CKD), yet most patients experiencing this problem remain untreated until the initiation of renal replacement therapy. We describe treatment pathways of key medications prescribed to non-dialysis dependent (NDD) CKD patients with anemia in DISCOVER CKD.

Methods: Patients included in this analysis were extracted from the Limited Claims and EHR (LCED) data. The study cohort included patients aged >18 years with 2 estimate glomerular filtration rate (eGFR) measures >60 mL/min/1.73m2 >90 days apart between January 2008 and September 2018. The index date was the first Hb measure <12 g/dL (females), <13 g/dL (males) per WHO criteria), or an anemia therapy (iron, ESA or blood transfusion) prescription after the 2nd eGFR measure. Exclusion criteria were: <1-year registration/medical history prior to index, active bleeding in the 30 days preceding and inclusive of index, an Hb value (only) within 30 days from transfusion or bleeding and no Hb measure within a year after CKD diagnosis. Oral iron was incompletely captured in LCED. Sankey Plots were used to visualize chronological treatment pathways (1st to 3rd line) post-index of key medications commonly prescribed to CKD patients with anemia including: oral iron, IV iron, ESA and blood transfusion.

Results: Preliminarily, 1446 (2.6% of anemia base cohort) patients were prescribed anemia therapies during follow-up, with IV iron (32.5%), transfusions (30.5%), ESA (21.6%), oral iron (12.2%) and ESA-IV Iron (2.7%) used as 1st-line therapies, Figure 1. Median times to 1st-line therapy initiation after index were: 108 days for oral iron, 194 days for ESA, 197 days for IV iron, and 244 days for blood transfusion.

Conclusions: In routine clinical care, anemia in NDD CKD is under treated and rescue therapies are used for anemia more often than preventive therapies.

Physician Attitudes Toward Diagnosis, Treatment Initiation, and Unmet Needs in the Management of Anemia due to CKD: Results from a Real-World Survey in Germany, Italy, and the United Kingdom

Madhusudan Kabra,1 Tim Hammond,2 Allison Fleetwood,2 Lewis Harrison,3 James Jackson,3 Sarah Clayton,3 Adelphi Real World, Bollington, United Kingdom; Otuska Pharmaceutical Europe Limited, Slough, United Kingdom.

Background: Anemia, a complication of chronic kidney disease (CKD), is often defined as serum hemoglobin (Hb) levels of <12 g/dL in women and <13 g/dL in men. Traditionally, primary care physicians (PCPs) have less involvement managing and treating patients with anemia due to CKD while nephrologists play a greater role in treatment decisions. We describe current physician perceptions towards the diagnosis and treatment of anemia due to CKD and unmet needs in anemia management, in a real-world setting.

Methods: Data were drawn from the Adelphi CKD Disease Specific Programme, a point-in-time study conducted between November 2019 and April 2020 with nephrologists and PCPs from Germany, Italy and the United Kingdom. Physicians completed an online survey providing information on their demographic characteristics, on the diagnosis and treatment of anemia, and the current unmet needs they believe exist in the management and treatment of anemia. Results were descriptively analyzed.

Results: A total of 200 physicians (n=140 nephrologists; n=60 PCPs) were included in the analysis. Among those who responded, the majority (98% nephrologists; 80% PCPs) used Hb levels to diagnose anemia in CKD patients. Over two thirds of physicians mentioned using ferritin to diagnose anemia and over half reported using transferrin saturation (TSAT) levels. Approximately 4 in 5 nephrologists and PCPs (78%
PO0289
Patient Preferences Study for Treatments of Anemia in CKD Patients Not on Dialysis (NDD)
Ana filipa Alexandre,1 Antonio Morga,2 Caitlin Thomas,3 Nicolas Krucien,3 Tommi Tervonen,2,3 Alina Jiletcovici,1 Kevin P. Marsh,1 Astellas Pharma Europe B.V., Leiden, Netherlands; 2Astellas Pharma Europe Ltd, Addlestone, United Kingdom; 3Evidera, London, United Kingdom; 4University Medical Center Groningen, Groningen, Netherlands; 5Astellas Pharma, Inc., Northbrook, IL.

Background: Erythropoietin analogues (EAs) are a mainstay of treatment of anemia in adult patients with CKD but they are associated with increased risk of cardiovascular (CV) events. Furthermore, their mode of administration (intravenous or subcutaneous [SC]) may represent a barrier to some patients. As such, the aim of this study was to understand patients’ valuation of attributes associated with CKD anemia treatments.

Methods: Adult (≥18 years) patients from UK, Spain, Germany, and France, who had NDD CKD anemia and were being treated with EAs, participated in this online discrete choice experiment (DCE). Patients were presented with choice tasks, each with two anemia treatment options described in terms of five attributes (mode of administration, need for iron supplementation, risk of gastrointestinal [GI] side effects, risk of major CV events, and impact on energy levels). A multinomial logit model with an error component was used to analyze participants’ choices and estimate their treatment preferences. Estimated preferences were used to determine maximum level of CV and GI risk that patients were willing to tolerate to improve other treatment features.

Results: Between November 2019 and March 2020, 209 eligible patients (53% male) completed the DCE survey. The mean (SD) age was 53.78 (12.73) years; patients had been diagnosed with CKD 6.02 (7.49) years prior, and with CKD anemia 3.45 (4.44) years prior. Patients were found, on average, to value each of the five attributes associated with the treatments of CKD anemia. Patients were willing to tolerate a 5.12% (95% CI: 1.99; 8.25) increase in the risk of a major CV event and an 11.73% (95% CI: 4.96; 18.50) increase in the risk of GI side effects to switch from an at-home SC injection administered once every 2 weeks to an at-home oral pill administered three times a week. Patients would be willing to tolerate a 20.31% increase in the risk of GI side effects and an 8.36% increase in the risk of a major CV event to move from sometimes having a lot of energy to always having a lot of energy.

Conclusions: Patients would be willing to tolerate increased risks of CV and GI events to obtain an oral treatment for NDD CKD anemia and to always have a lot of energy.

Funding: Commercial Support - Astellas Pharma, Inc.

PO0290

Background: We studied the effect of online education designed to improve the clinical performance of clinicians in the OB/Gyn and primary care setting related to iron deficiency anemia (IDA) management in women.

Methods: The continuing medical education (CME) activity was a 45-minute online text- and video-based activity focusing of different aspects of anemia management in the women’s health setting. The impact of the education on performance outcomes was measured with a follow-up Planned Change Assessment® (PCA) survey immediately post-education to assess planned changes in clinician practice. Survey participants were contacted 8 weeks later to assess reported actual changes in practice.

Results: In total, 1,239 clinicians completed the initial PCA questionnaire 275 OB/Gyn physicians, 142 OB/Gyn NPs and PAs, 446 PCPs, and 376 NP/PA in the primary care setting Of those, 1,171 (95%) indicated they planned to make changes 3,610 changes were planned, an average of 3.1 per complete PC of immediate PCA completers, 92 completed the follow-up PCA 89 completers (97%) made 331 changes in practice, an average of 3.1 per completer Of immediate PCA completers, 92 completed planned, an average of 3.1 per completer. As such, the aim of this study was to understand patients’ valuation of attributes associated with CKD anemia treatments.

Results: Between November 2019 and March 2020, 209 eligible patients (53% male) completed the DCE survey. The mean (SD) age was 53.78 (12.73) years; patients had been diagnosed with CKD 6.02 (7.49) years prior, and with CKD anemia 3.45 (4.44) years prior. Patients were found, on average, to value each of the five attributes associated with the treatments of CKD anemia. Patients were willing to tolerate a 5.12% (95% CI: 1.99; 8.25) increase in the risk of a major CV event and an 11.73% (95% CI: 4.96; 18.50) increase in the risk of GI side effects to switch from an at-home SC injection administered once every 2 weeks to an at-home oral pill administered three times a week. Patients would be willing to tolerate a 20.31% increase in the risk of GI side effects and an 8.36% increase in the risk of a major CV event to move from sometimes having a lot of energy to always having a lot of energy.

Conclusions: Patients would be willing to tolerate increased risks of CV and GI events to obtain an oral treatment for NDD CKD anemia and to always have a lot of energy.

Amelioration of CKD-Associated Anemia by Vadadustat in Mice Is Not Dependent on Erythropoferone
Mark R. Hanadel, Shirley Wong, Grace Jung, Bo Qiao, Victoria R. Gabayuan, Tomas Ganz. University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.

Background: Vadadustat is an investigational hypoxia inducible factor prolyl hydroxylase inhibitor that increases endogenous erythropoietin (EPO) production, and has been shown to decrease iron turnover, increase hepcidin levels, decrease iron status, and increase hemoglobin concentrations in anemic chronic kidney disease (CKD) patients. Increased EPO induces erythropoiesis secretion of erythropoiferone (ERF), which acts on the liver to suppress serum hepcidin production. To determine whether vadadustat mechanisms of action are dependent on ERF, we treated wild type (WT) and ERF knockout (EKO) mice, with and without diet-induced-CKD, with vadadustat.

Methods: 6-week-old male C57BL/6 WT and EKO mice were placed on 8-week diets that did or did not contain 0.2% adenine. For the last 3 weeks of the diets, the mice were treated with vadadustat (75 mg/kg/day via oral gavage) or vehicle solution. Mice were euthanized at 14 weeks of age (n=8 mice per group).

Results: Unlike the WT mice, EKO mice had undetectable spleen ERF mRNA, minimal marrow ERF mRNA, and no increase in ERF mRNA or protein in response to vadadustat. However, in both WT and EKO CKD models, vadadustat normalized hemoglobin concentrations (Fig 1a), increased expression of duodenal iron transporters, tended to lower serum hepcidin, and decreased tissue iron concentrations (consistent with increased iron mobilization), suggesting ERF-independent pro-erythropoietic effects. Vadadustat treatment was also associated with improved kidney function (Fig 1b) and decreased expression of renal fibrosis markers. Lastly, vadadustat affected FGF23 profiles: In non-CKD mice, vadadustat increased plasma total FGF23 out of proportion to intact FGF23, consistent with the known effects of HIF1α and EPO on FGF23 production and metabolism in adult patients with CKD but they are associated with increased risk of cardiovascular (CV) events. Furthermore, their mode of administration (intravenous or subcutaneous [SC]) may represent a barrier to some patients. As such, the aim of this study was to understand patients’ valuation of attributes associated with CKD anemia treatments.

Conclusions: Vadadustat ameliorates CKD-associated anemia independently of ERF, and also improves kidney function and lowers FGF23 in this CKD model. How vadadustat affects CKD progression in humans may warrant future studies.

Figure 1. Reactive oxygen species (ROS) and Heme Oxygenase-1 levels in red blood cells (RBC) from healthy controls (CON-RBC) and patients pre (PreHD-RBC) and post (Post/HD-RBC) hemodialysis. Data are shown as median and interquartile range of the Mean Fluorescence Intensity (MFI). ***p<0.001 and **p<0.01 represent the difference compared to CON-RBC. AP<0.001 represents the difference between pre- and post/HD-RBC.

PO0293
Daprodustat Interaction with Phosphate Binders Has Minimal Impact on Hemoglobin Values in Hemodialysis Population

Background: Daprodustat is a hypoxia-inducible factor prolyl hydroxylase inhibitor (PHI) in phase 3 development for the treatment of anemia of chronic kidney disease. Phosphate binders (PB) are widely prescribed for patients on hemodialysis (HD) to control hyperphosphatemia. PB may interfere with medication absorption; thus, concomitant use with a PHI may potentially impact the latter’s efficacy on hemoglobin (Hgb). The purpose of this analysis was to determine whether administration of daprodustat in subjects receiving PB has an impact on Hgb values in the HD population.

Methods: The 24-week GSK PHI11303 study (NCT01977482) included 216 subjects on maintenance HD previously treated with recombinant human erythropoietin (Clin Kidney J 2019;12:139-148). Target Hgb range was 10.0 g/dL to 11.5 g/dL. Baseline PB users were defined as a prespecified study subgroup. The difference in mean Hgb values at Week 24 between treatment groups was summarized overall and by subgroup. Comparisons were performed for the Week 24 Hgb (post loc), as well as the final dose of daprodustat, for those receiving/not receiving PB.

Results: The majority of HD subjects received PB at baseline; 136/177 (77%) of daprodustat and 33/39 (85%) of control subjects were taking PB, with comparable phosphate control at baseline (mean [s]PD phosphate: daprodustat 1.76 mmol/L [0.56]; control 1.67 mmol/L [0.44]). All subjects receiving PB at baseline, except two, continued throughout the study. No meaningful difference in Hgb change from baseline (CFIB) at Week 24 was noted between treatment groups. The final median dose for subjects on treatment changes was the same for those receiving and those not receiving PB (6 mg), with no meaningful difference in the Hgb at Week 24 (mean [s]PD: PB use=Yes 10.40 g/dL ±0.95; PB use=No 10.79 g/dL ±0.95).

Conclusions: These results suggest that PB use does not have a major impact on Hgb values during the 24-week study. Results of an ongoing, phase 3 dialysis study of daprodustat compared with conventional treatment are awaited to confirm these initial observations.

PO0295
Hemoglobin Requirements of Clinical Trials Involving Anemia in CKD and Implications on Future Work: A Systematic Literature Review

Background: Anemia is a common complication in patients with chronic kidney disease (CKD), contributing to reduced quality of life and increased risk of morbidity and mortality. Erythropoiesis-stimulating agents (ESAs) are the established standard of care for anemia management in CKD patients. This review examines hemoglobin (Hb) requirements in randomized controlled trials (RCTs) of ESAs as treatment of anemia in CKD.

Methods: Embase, Medline, and Cochrane Library were searched from 1946 to November 2019 for RCTs evaluating the safety and efficacy of ESAs as treatment for adults with anemia and CKD. Descriptive analyses were performed to assess between-trial differences with respect to baseline Hb and Hb target ranges. Studies were classified by dialysis status (non-dialysis-dependent [NDD] vs dialysis-dependent [DD]) vs renal transplant recipient (RTR)], and by treatment goal (correction vs conversion.

Results: Searches retrieved 3,482 records, from which 57 trials met the inclusion criteria. Forty-seven studies reported a Hb target, including 15 correction studies (NDD, 11; DD, 3; RTR, 1), 19 conversion studies (NDD, 2; DD, 16; RTR, 1) and 3 that were mixed/unclear (DD, 2; NDD/DD, 1). The unweighted medians (range) of the mean baseline Hb in correction and conversion studies were 10.1 g/dL (7.0-11.7) and 11.2 g/dL (9.1-11.1), respectively. There were 20 different Hb target ranges used to assess efficacy; 10-12 g/dL was utilized most often (n=8). Three of 37 RCTs used a singular Hb target threshold, whilst the remaining studies used a Hb target range, which varied from narrow (0.5 g/dL) to wide (5.0 g/dL) between the lower and upper limits. Target Hb ranges used an upper limit of >12 g/dL in 21/37 RCTs (correction, 13/15; conversion, 10/19); however, only 3/21 RCTs were published after 2012 (the last update of KDIGO Clinical Practice Guideline).

Conclusions: This systematic review shows that changing Hb requirements over time are a source of difference in RCTs of ESAs for treatment of anemia in CKD. Such differences may introduce bias when using quantitative synthesis methods (e.g. network meta-analysis) to assess the comparative efficacy and safety of ESAs relative to new treatment options.

PO0296
Excessive Decrease of Hematocrit After Discontinuation of Dapagliflozin Yoshiharu Wada,1 Yoshiyuki Hamamoto,3 Yoshishira Nakatani,3 Sachiko Honjo,1 Yamato Keida1, Yohei Seno,1 Kanako Iwasaki,1 Yorihiro Iwasaki,1 Jun Fujikawa,4 Hiroko Kakuta,1 Akihiro Hamaski,4 Tizuka Kofukai Medical Research Institute Kitano Hospital, Osaka, Japan; 2Kansai Electric Power Hospital, Osaka, Japan; 3Kindai University, Osaka, Japan.

Background: Recently, sodium-glucose cotransporter 2 (SGLT-2) inhibitors were indicated to have hematopoietic effect, but it is still unclear how long the effect continues after discontinuation. In this study, we investigated changes in hematocrit, urinary gravity and HbA1c after discontinuation of SGLT-2 inhibitor in patients with type 2 diabetes.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Methods: A total of 8 patients (male: n=4; age: 54.4±1.9 [mean±SD] years, BMI: 27.1±3.4 kg/m²; HbA1c: 9.2±1.2 %) with type 2 diabetes who were newly admitted 5mg per day of dapagliflozin from March 2015 to September 2019 and discontinued the drug due to adverse events or side effects which did not require admission were retrospectively identified. Changes in HbA1c, hematocrit and urine specific gravity levels between before the administration and after the discontinuation of the drugs were evaluated.

Results: The drug was discontinued 8.4±6.6 months after administration due to non-benefit on glycemic control (n=4), polyuria (n=2), weight loss (n=1) and genital infections (n=1). HbA1c and hematocrit (p=0.45) whereas urine specific gravity (0.014±0.009 g/mL; p=0.001) and hematocrit (1.63±1.99 %; p=0.04) were significantly increased at the time of discontinuation. Urine specific gravity (0.005±0.009 g/mL; p=0.12) and hematocrit (0.15±2.14 %; p=0.84) levels were returned to the levels of before drug administration 60 days after the discontinuation. After the 120 days of discontinuation, hematocrit was still decreased to continue to decrease the level of baseline (-1.29±1.70 %; p=0.05) whereas urine specific gravity was not.

Conclusions: Our data demonstrate that the increased urine specific gravity and hematocrit return to original levels within 60 days after the discontinuation of dapagliflozin, and that hematocrit may continue to decrease below the original level even after.

PO0297
Human Mesenchymal Stem Cells Cultured in a Hollow Fiber Bioreactor
Maintain Constant Levels of Exosomes in the Perfusion Medium: Relevance to the Simultaneous Production of Two Biotherapeutic Agents
Christof Westenfelder,1,2 Anna Gooch,1 Mikhail Skliar,2 Sabiba Sultana Chowdhury,1 Ping Zhang,1 Zhuma Hu,1 SymbioCellTech, LLC, Salt Lake City, UT, UT;1 University of Utah, Salt Lake City, UT.

Background: We have shown that the administration of allogeneic Mesenchymal Stem Cells (MSC) to patients at high risk for Acute Kidney Injury (AKI) following open-heart surgery prevents AKI and prolongs organ function (cardiac transplant). Treatment of rats with severe, progressive IRI AKI with MSC-derived exosomes affords significant survival benefits and rescues their renal function (see abstract this meeting). The current study examined the possibility to simultaneously collect MSC-derived exosomes while culturing human MSCs, both used for various therapies in renal and other diseases. This approach, if successful, would be cost saving, efficient and facilitate up-scaling of the production of both MSCs and their exosomes.

Methods: Human MSCs (20x10^6) were loaded into a hollow fiber Cell Expansion System (Quantum®, TERUMOBCR; pre-conditioned for cell adhesion with Fibronectin) and expanded using xMEM with 5% human Platelet Lysate (iPFL). The number of exosomes in aliquots of the perfusion medium were monitored (NanoSight instrument) throughout the course of cell expansion.

Results: MSCs reached ~ 90% confluence within 12 days, yielding 500x10^6 MSCs. The number of exosomes/nanoparticles derived from the 5% iPFL, per se was 4.1±10^11/mL. Post seeding of MSCs in the bioreactor, exosome numbers in the perfusate decreased and stabilized at 1.1±10^11/mL. The size of collected exosomes was between 60 and 100 nm.

Conclusions: The data from this pilot study demonstrate that iPFL-derived exosomes or nanoparticle are taken up by the expanding MSCs, which lowers their total number in the perfusion medium. However, exosome numbers stabilized during the subsequent cell expansion, indicating that growing MSCs release high numbers of exosomes. This conclusion will be confirmed by speciating hPL- and MSC-derived exosomes, using specific markers for each type of nanoparticle. Together, these observations show promise for the efficient generation of MSCs and their exosomes to be used for various clinical applications.

PO0298
Clinical Study Results Confirming a Novel Fluorescent Compound Is a Glomerular Filtration Rate (GFR) Tracer Agent in Humans

Background: A fluorescent GFR tracer agent for use in the clinic would enable a noninvasive transdermal continuous GFR detection method. This would make possible a point-of-care true GFR measurement for an individual, and possibly obviate the use of estimated GFR from ensemble equations. The plasma pharmacokinetics of the novel fluorescent compound MB-102, constructed to have the properties of a GFR tracer agent, is compared to that of iohexol, an established GFR tracer agent.

Methods: Intravenous administration of MB-102 followed immediately by iohexol (Omnipaque 300) was given to 120 subjects enrolled with estimated GFR in the range from normal to stage 4 CKD. Fifteen blood draws post-administration over 12 hours were used to investigate the plasma decay. Plasma was analyzed for both agent concentrations at each time point. Analysis of MB-102 in plasma used methodology developed internally, and analysis of iohexol used the standard multi-step method employing an internal standard, drying, and reconstitution.

Results: Plasma pharmacokinetic parameters, which includes GFR, were determined from the concentration vs. time data for each agent separately using standard pharmacokinetic software. For every subject, each agent exhibited a two-compartment model, the initial compartment being the vascular to tissue equilibrium, and the terminal compartment containing the slow metabolites. The terminal-compartment yield a single GFR value and was unperturbed over the approximate 10 hour time span for which the subjects were eating and taking their usual medications. The comparison of GFR from the MB-102 data to that of GFR from the iohexol data is shown in Figure 1.

Conclusions: The correlation of GFR from plasma MB-102 to that of plasma iohexol is excellent (rsquared = 0.99). Thus MB-102 is a fluorescent GFR tracer agent in humans. This result is the first step in the development of a noninvasive transdermal GFR measurement at the point-of-care.

Dialysate Exposure Does Not Compromise the Function of Bioengineered Proximal Tubules for Bioartificial Kidney
Rosalinde Masecorew,1 Silvia M. Mihaila,1 Dimitrios Stamatialis,2 Igor R. Middel,1 Marianne C. Verhaar,1 Karin G. Gerritsen,1,3 Universiteit Utrecht, Utrecht, The Netherlands; Universiteit Twente, Enschede, Netherlands;1 Universitair Medisch Centrum Utrecht, Utrecht, Netherlands.

Background: Protein-bound uremic toxins (PBUTs) accumulate in plasma of end-stage kidney disease patients and are associated with a wide range of comorbidities. Their removal by conventional hemodialysis is severely limited, warranting the development of novel renal replacement therapies such as the bioartificial kidney (BAK). Recently, we developed bioengineered kidney tubules as functional BAK units capable of active PBUTs secretion via organic anion transporter-1 (OAT1). To accelerate their application, a comprehensive assessment under clinical-like conditions is essential. Here, we assessed the extent to which exposure to dialysate and uremic plasma would affect the viability and function of the kidney tubules.

Methods: Human conditionally immortalized proximal tubule epithelial cells equilibrated with OAT1 (cPTEC-OAT1) exposed to 10-240min of dialysate and uremic plasma were evaluated for metabolic activity, membrane integrity (LDH release), inflammatory response (IL-6 and IL-8), oxidative stress (ROS) and OAT1 function (fluorescein uptake). Further, cPTECs grown on biofunctionalized hollow fiber membranes were extraluminally exposed to dialysate fluid, intraluminally perfused with human uremic plasma (30min) and assessed for PBUTs clearance (indoxyl sulfate (IS), kynurenic acid (KA), L-kynurenine (L-Kyn), hippuric acid (HA) and indole-3-acetic acid (IA3-AA)), determined by LC-MS/MS (n=7). Membrane integrity was evaluated by paracellular FITC-inulin leakage.

Results: Prolonged exposure (240min) of flat monolayers of cPTEC-OAT1 to dialysate slightly reduced the metabolic activity to 80±4% (p<0.001) and OAT1 function to 81±5% (p<0.001) and an increased LDH release (from 10±2% in controls to 15±3%, p<0.05), without inducing the release of IL-6 or IL-8. After 30min, a 3.6±0.9 fold increase in ROS production was noticed. Still, exposure of cPTEC-OAT1-containing hollow fiber membranes were extraluminally exposed to dialysate fluid, intraluminally perfused with human uremic plasma (30min) and assessed for PBUTs clearance (indoxyl sulfate (IS = 2980±1438; KA = 223±120; L-Kyn = 324±100; HA = 6547±1278 and I3-AA = 884±130 mmol/cm²; n=6-7), without compromising the membrane integrity as observed by FITC-inulin leakage (20±4% vs 25±5%).

Conclusions: The demonstrated functionality of bioengineered kidney tubules in PBUT clearance under clinical-like conditions advances the development of a BAK.

May the (Mechanical) Force Be with You: Modeling Shear Stress on the Glomerulus-On-a-Chip
Stefano Da Sacco,1 Owen Richfield,7 Valentina Villani,3 Geremy Clair,3 Roger E. De Filippo,1 Laura Perin,1 1Children’s Hospital of Los Angeles, Los Angeles, CA; 2Tulane University, New Orleans, LA; 3Pacific Northwest National Laboratory, Richland, WA.

Background: In the glomerulus, mechanical forces generated on glomerular endothelial cells (GEC) by the passage of blood in capillaries and by the flow of ultrafiltrate between adjacent podocytes play a critical role in regulating glomerular filtration. In vivo modeling of shear stress is difficult and traditional in vitro 2D systems are unable to faithfully replicate shear and tensile stress. We have recently developed a barrier-free glomerulus-on-a-chip (GOAC) system that closely mimics architecture, physiology and function of the GBM. In this work we have further modeled shear stress on the chip and assessed how changes in mechanical forces affect the barrier formation and function.

Methods: Mathematical modeling of the shear stress on the GOAC was performed and shear stress was calculated for standard GOAC culture conditions. Using model simulations, angle of inclination and rocking frequency of the GOAC were changed to modify shear stress, and results were assessed after 5 days. Phenotypal analysis by IF were performed and function was measured by albumin-leakage assay. Podocytes and GEC were separated by FACS and transcriptomics and proteomics analysis performed.

Results: Under standard culture conditions, time-averaged shear stress generated by rocking the GOAC is equal to 0.1Pa. By changing angle of the rocking platform, shear stress could be modulated from 0 to ~4Pa exerted on the GEC with each rocking motion. Proliferation was not significantly affected by different rocking angles (but was impaired under static conditions) after 5 days. Importantly, Gene and protein expression analysis on podocytes and GEC have identified important changes in cytoskeleton regulation, ECM-cell interaction, proliferation and transcription factors, suggesting that long-term modification of the shear stress might significantly impact phenotypical and functional cell activity.

Conclusions: The glomerulus-on-a-chip is an ideal system to model architecture and function of the glomerular filtration barrier, including mechanical forces. Changes in shear stress affect cellular gene and protein expression in the GFB and can have long-term effects on phenotype and function. The glomerulus-on-a-chip system can provide an important in vitro tool to study the role of shear stress in physiological and pathological conditions.

Chronic AMPK Activation Reprograms Glucose Metabolism and Oxygen Respiration in Renal Tubule Epithelial Cells
Kuniko Hunter,1 Rachel C. Evans,2 Harold D. Love,3 William H. Fissell.2 Vanderbilt University, Nashville, TN; 2Vanderbilt University Medical Center, Nashville, TN.

Background: In vitro human renal tubule epithelial cells (HREC) exhibit a glycolytic, differentially programmed phenotype that limits their use in bioartificial kidney development. We have identified AMP-activated protein kinase (AMPK) and Transforming Growth Factor-β (TGFβ) as critical modulators of HREC differentiation. Here we show that inhibition of AMPK and TGFβ signaling enhances increased respiration induced by activation of AMPK.

Methods: Primary HREC were seeded on polystyrene tissue culture plates (100,000 cells/cm²). After one week, cells were supplemented with AMPK activator Metformin (200μM), TGFβ receptor 1 inhibitor SB431542 (10μM), or both. After five weeks, cell oxygen consumption (OCR) and extracellular acidification rates (ECAR) were assessed using a Seahorse XF96 Analyzer and respiratory inhibitors oligomycin (2μM), CCCP (2μM), Rotenone (0.5μM), Antimycin A (0.5μM) and 2-deoxyglucose (50mM). Statistical differences were estimated by paired, two-tailed Student’s t-test in MatLab.

Results: Metformin and Combination treatments increased cell glycolytic capacity as shown in Fig 1A. Metformin and Combination treatments significantly decreased ATP-coupled respiration, while increasing maximal oxidative phosphorylation capacity and non-mitochondrial respiration capacity as shown by elevated OCR following injections of Oligomycin, CCCP, and Rotenone/Antimycin A, respectively, as shown in Fig 1B.

Conclusions: Concomitant increases in both glycolytic and oxidative phosphorylation capacity suggest AMPK activation and TGFβ inhibition modulate cell mitochondrial and non-mitochondrial metabolic activity.

PO0302

An In Vitro Model of the Glomerular Filtration Barrier Using Tissue-Derived Glomerular Basement Membrane
Dan Wang, Snehal Sante, Nicholas J. Ferrell. Vanderbilt University Medical Center, Nashville, TN.

Background: The glomerular filtration barrier consists of the glomerular basement membrane (GBM), podocytes and endothelial cells that regulate kidney permeability to macromolecules. Damage to podocytes increases albumin permeability, resulting in proteinuria. Interactions between podocytes and the GBM are important for regulating glomerular permeability and are not captured in standard in vitro cell culture systems. This work aims to investigate molecular permeability of the GBM and podocytes using a novel in vitro model that incorporates decellularized GBM.

Methods: GBM substrates were made by pressure compacting decellularized glomeruli from porcine kidneys against a Transwell membrane in a stirred cell. GBM alone provided a stringent barrier to diffusion of both albumin and Ficoll. Podocytes were plated on the GBM at low and high concentrations. Transepithelial electrical resistance (TEER) was measured before molecular permeability measurements. Podocytes on GBM were imaged by staining with phalloidin and DAPI. Permeability of the GBM with and without podocytes were analyzed by measuring FITC-BSA and FITC-Ficoll diffusion through the filtration barrier.

Results: GBM characterization showed that cells are efficiently removed from the glomeruli, and the GBM retains laminin and collagen IV after decellularization. GBM alone provided a stringent barrier to diffusion of both albumin and Ficoll. Podocytes attached and spread on the GBM to further restricted albumin diffusion. TEER showed an increased resistance of GBM with podocyte compared to GBM alone. Podocytes resulted in slightly lower permeability at high seeding concentration than low concentration.

Conclusions: Interactions between the GBM and podocytes are important for regulating the permeability of the glomerulus. We developed a new in vitro model of the glomerular filtration barrier that incorporates tissue derived GBM to support podocyte culture. GBM alone restricted albumin and Ficoll diffusion and incorporation of podocytes further restricted albumin diffusion. Future work will focus on co-culture of podocytes and endothelial cells on both sides of the GBM for evaluating the permeability of the filtration barrier and evaluate how podocyte and endothelial injury regulate permeability.

**Extraction of Escherichia coli in Urine by New Static Electricity Technique In Vitro**

Tokunori Yamamoto,1 Shoichi Maruyama,1 Satoshi Morita,2 Yoshikazu Wakizaka.3,4 Dept of nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan; 2AFI Corporation, Kyoto, Japan.

**Background:** The treatment results for sepsis are poor due to infectious diseases, and the mortality rate is over 25%. It is clinically significant that the detection identifies patient specimen primary causative organisms as promptly as possible to give appropriate antimicrobial treatment, and to save patients with serious infectious disease. However, it usually takes 2-3 days from the submission of the sample to the identification of the primary causative organism. We newly developed the device (PixeeMo™ approved by AOAC® Performance Tested™ Certificate No. 012002 in January 14, 2020) with quick extraction of bacteria in drinking water by static electricity technique. In this report, we evaluated the ability of PixeeMo™ to extract E. coli from urine.

**Methods:** Samples were prepared by adding Ecoli to artificial urine. 27 mL of a dedicated buffer was added to 3 mL of the sample, and after centrifugation (8000 xg, 20 min), 27 mL of the supernatant was removed. This operation was performed 3 times. After the preparation, E. coli was extracted from each sample using PixeeMo™ less than 0.5 hour. The number of bacteria in the sample prepared on the standard agar medium was measured by colony count.

**Results:** The table shows results of the experiments. The components of artificial urine and E. coli were separable and the extraction results by PixeeMo were consistent with the culture method. It was also suggested that the detection limit concentration is 10 cells/mL (Table).

**Conclusions:** The new technique could detect clinical pathological conc. of E. coli in short time less than 2.0 hour. Extremely useful possibility is suggested as the new measurement technology of sepsis to reflect a diagnosis and evaluation of treatment, curative effect, very quickly.

**PO0304**

**Kidney Segmentation with Deep Learning in MRI of 40,000 UK Biobank Subjects**

Taro Langner,1 Andreas Östling,1 Lukas Maldonis,2 Albin K. Karlsson,1 Daniel Olmo,1 Dag Lindgren,2 Andreas H. Wallin,2 Lowe Lundin,2 Robin Strand,1 Håkan Ahlström,1,2 Joel Kullberg,1,2 Uppsala Universitet, Uppsala, Sweden; Antarios Medical AB, Möln达尔, Sweden.

**Background:** Kidney volume and its association to several demographic and physiological parameters are subject of ongoing research. The UK Biobank (UKB) studies over half a million volunteers, examining blood samples, lifestyle, genetics, and body composition, including medical imaging for 100,000 participants, and 10,000 repeat scans. We have developed a system for automated kidney segmentation in 40,000 currently available MRI scans for image-based measurements of parenchymal kidney volume.

**Methods:** UKB neck-to-knee body MRI has been released for 40,264 participants (52% women), aged 44-82 (mean 64) years, with BMI 14-62 (mean 27). The kidneys are imaged in two 17s breath-hold stations with a Siemens 1.5T Aera device at (224 x 174 x 44) voxels of (2.23 x 2.23 x 4.5) mm. In this work, three operators marked cortex and medulla, excluding cysts, in 122 subjects (Fig a, b) for training and validation of a 2.5D U-Net with 40,000 repeat scans. We have developed a system for automated kidney segmentation in 40,000 currently available MRI scans for image-based measurements of parenchymal kidney volume.

**Results:** The network predictions matched the references in total kidney volume for a single patient at 5 treatments over a 3-week period. Model time constant and steady-state gain were obtained for a single patient at 5 treatments over a 3-week period.

**Conclusions:** The proposed system may ultimately provide measurements of left and right kidney volume for all imaged UKB subjects which can be analyzed and shared for further large-scale investigation of associations and longitudinal changes in kidney volume.

**PO0305**

**A Simplified Fluid Dynamics Model of Ultrafiltration**

Christopher R. Cardimino,1 Michael J. Germain,2 Yossi Chait,1 University of Massachusetts Amherst, Amherst, MA; 2Renal and Transplant Associates of New England, Springfield, MA.

**Background:** We recently presented a novel approach for the design of personalized ultrafiltration rate (UFR) profiles during hemodialysis (HD) treatments. The success of this approach depends on an accurate parameter estimation of a simplified fluid volume dynamics during ultrafiltration.

**Methods:** We used a simplified model derived from a validated fluid volume model during HD comprising intravascular and interstitial pools, microvascular refilling/filtration, and lymphatic flow. Input data used for parameter estimation are UFR profile and hematocrit (HCT) from CLIC obtained during actual HD treatments. Estimation was based on initial 30-min segment of the data and the model was validated based on the subsequent 30-min response. Model time constant and steady-state gain were obtained for a single patient at 5 treatments over a 3-week period.

**Results:** Estimation/validation results (Figure 1) demonstrate reasonable accuracy of the simplified fluid dynamics model. Underlying model parameters of a single patient exhibit significant variability between similar days of treatment and between treatment days (Figure 2). Both HCT response to same UFR profile (steady-state gain) and response time (time constant) vary by as much as 100%.

**Conclusions:** Successful estimation of fluid volume model parameters during HD is feasible which supports the concept of online design of personalized UFR profiles. A non-negligible variability of a patient’s model parameters may complicate the design of personalized UFR profiles.
PO0306

Human Amniotic Membrane as a Novel Scaffold for Induced Pluripotent Stem Cell-Derived Kidney Organoids

Maria Figetakis, Kevin J. James, Richard Torres, William G. Chang. Yale University, New Haven, CT.

Background: Human inducible pluripotent stem cells (hiPSCs) can be differentiated into kidney organoids that can be used to tissue-engineer functional renal tissue. However, there are several challenges to therapeutic implementation. Among these is how to elicit organoids in a manner that allows for both vascularization and filtrate outflow. Previous research has demonstrated in animal models, that kidney organoids can be perfused when implanted in the kidney subcapsular space. One limitation though is that there is no obvious filtrate outflow tract. Furthermore, in ESRD patients there would likely be significant fibrosis or even cystic disease that would prevent successful perfusion and filtrate outflow of kidney organoids implanted in a similar manner. Alternative heterotopic organoid implantation strategies should be considered. Examples include, but are not limited to, peritoneal implantation (with peritoneal dialysis catheter drainage) or tissue engineered tubular constructs for ureteral anastomoses. Here we describe a biomaterial, decellularized human amniotic membrane (dHAM), that could be used for differentiation of iPSC derived kidney organoids. Because kidney organoids will be exposed to mechanical forces in heterotopic implant locations, we examine the effects of mechanical stretch on the structure of kidney organoid tubules.

Methods: We decellularized dHAM with mild detergents, and differentiated kidney organoids in a manner previously described by the Little research group. We constructed a titanium stretch device that allowed for kidney organoid differentiation and uniaxial stretch of the dHAM acutely or over 10 days. We performed multiphoton microscopy to image the kidney organoids and then used 3D reconstructions to measure tubular volumes. Results: We have observed that dHAM can be differentiated on dHAM, and that uniaxial stretch of the dHAM elongates and increases tubular volumes within the kidney organoids, without tubular disruption or increased cell death.

Conclusions: dHAM is a promising scaffold for studying effects of mechanical forces on human kidney organoids in vitro. dHAMS could be used to facilitate the implantation of kidney organoids into the peritoneum or other heterotopic locations. The constructs have the flexibility to be used as a patch, modified into tubes after rolling, or form sac-like structures.

Renal Cell-Derived Extracellular Vesicles Improve Functional Phenotype of Kidney Tubuloids

Rafael S. Lindoso,1,2 Estela Mancheño Juncosa,1 Fjodor Yousef Yengej,1 Maarten B. Rookmaaker,1 Marianne C. Verhaar,1 Rosalinde Masereeuw,1 1Universiteit Utrecht, Utrecht, Netherlands; 2Universidade Federal do Rio de Janeiro Instituto de Biofisica Carlos Chagas Filho, Rio de Janeiro, Brazil; 3University Medical Center Utrecht, Utrecht, Netherlands; 4Utrecht Institute for Pharmaceutical Sciences, Utrecht, Netherlands.

Background: Kidney tubuloids (KT) are adult stem cell-derived organoid that hold great potential in translational bioartificial kidneys (BAK). However, reproducing complete cell maturation and function remains a challenge. Extracellular vesicles (EVs) are cell-derived structures that regulate several cellular processes. In the kidney, EVs mediate interorgan communication through the transfer of bioactive molecules. This study aimed to investigate the use of renal EVs as modulator of KT phenotype by increasing the levels of organic anion transport 1 (OAT1), involved in renal waste handling, and explore their use for BAK engineering.

Methods: EVs from conditionally immortalized proximal tubule epithelial cells overexpressing OAT1 (cPTEC-OAT1) were isolated with 100 K filters, quantified by nanoparticle tracking analysis and incubated with KT. The 24 h conditioned media (CM) of cPTEC-OAT1, depleted or not of EVs, were used as controls. Gene expression was determined by QPCR and Western blotting. For renal tubule engineering, KT were seeded on hollow fibers and were exposed to EVs or CM. Molecule integrity and cell polarity were analyzed by immunofluorescence and confocal microscopy.

Results: KT exposed to CM showed increased OAT1 levels (protein: 2.0±0.3-fold and mRNA: 2.8±0.5-fold). Moreover, EVs mimicked CM effects (2.6±0.4-fold), while CM EV depleted didn’t induce OAT1. EVs were shown to contain OAT1 protein and mRNA as cargo. Visual observations of KT seeded on hollow fibers with CM containing EVs, presented slightly improvement in 3D tubular structure organization with the expression of tight junction protein (ZO-1) and cell polarity (apical cell formation and Na+/K+-ATPase presence at the basolateral side) when compared with the control condition.

Conclusions: KT phenotype can be directed by renal EVs obtained from cPTEC-OAT1. In addition, renal EVs can support KT to form tight monolayersons on hollow fiber membranes. Further research is aimed at a full functional characterization of these bioengineered proximal tubules for application in BAK.

PO0308

Nitric Oxide (NO) Based Urinary Catheter Balloon Inflation Solution to Prevent Urinary Tract Infection

Alexander S. Yevzlin, Karthik Ramani, Faroug Suliman. University of Michigan, Ann Arbor, MI.

Background: UTI is the most common hospital acquired infection with indwelling catheters being a major risk factor and are difficult to treat due to the formation of bacterial biofilms which are resistant to systemic antibiotics. NO is an endogenously formed gas molecule known to play a key role in preventing infection by dispersing biofilm formed by a variety of bacterial strains. In this abstract, we describe the effectiveness of a novel urinary catheter balloon inflation fluid to effectively reduce catheter associated urinary tract infections (CAUTI) by providing up to 7 days of bactericidal effect via NO release.

Methods: Our innovative approach to prevent CAUTI involves employing a balloon inflation fluid being novel NO secreting materials based on using S-nitrosothiol type NO donors like S-nitrosoglutathione (GSNO) within the balloon of urinary catheters that slowly releases NO over a period of up to one week. The advantages of the use of NO in CAUTI prevention is its short half-life with a very low steady-state level immediately adjacent to the surface of the device required to achieve the desired anti-microbial effect with no risk of systemic effects when using NO secreting materials with fluxes that are near physiological levels.

Results: We performed in vitro studies using a Foley catheter placed in a long-necked flask with a shape resembling the urinary bladder and the urethra. (Fig 1) The Foley catheter retention balloon was filled with GSNO solution and the balloon was used to seal the neck of the flask. Then the flask was filled with synthetic urine inoculated with E. coli and incubated for seven days at 37 °C with horizontal shaking at 80 rpm. The results showed a significant reduction in planktonic bacterial growth (Fig 2) and a 3-log reduction in biofilm (Fig 3) of the GSNO Foley balloon solution compared to the control.

Conclusions: These data suggest that NO-based urinary catheter balloon fluid results in significant anti-microbial effects in our in vitro model of CAUTI.

PO0309

Feature-Rich Covalent Stains for Interrogation of Kidney Tissue

Chenxi Mao, Min Yen Lee, Joshua C. Vaughan. University of Washington, Seattle, WA.

Background: Fluorescence microscopy is a workhorse tool in biomedical imaging but often poses significant challenge to practitioners in achieving bright or uniform labeling. In addition, while antibodies are effective specific labels, they often suffer penetration in thick tissues, loose binding in heavily fixed or processed specimens (e.g., FFPE tissue), high cost, and inconsistent reproducibility or commercial availability. Thus, it would be highly useful to develop a simple yet robust labeling alternative that could rapidly produce even staining for thick tissues and be compatible with a wide range of simple processing or clearing methods.

Methods: We use conventional fluorescent dyes to covalently label abundant chemical functional groups on kidney tissues. These include the use of amine-reactive...

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
dyes for proteins and aldehyde-reactive dyes for carbohydrates. We term this approach Fluorescent Labeling of Abundant Reactive Entities (FLARE).

Results: We first showed FLARE’s utilities in freshly fixed mouse kidneys (≈100 μm) using super-resolution fluorescent microscopy. Within glomeruli, the carbohydrate stain specifically labeled the basement membranes of the capillary loops and the mesangial matrix, while the amine stain revealed mitochondria and brush border microvilli (Fig. A). Then we stained optically cleared FFPE human kidney tissues (≈50 μm) without performing antigen retrieval (Fig C), revealing more general features. Furthermore, FLARE does not perturb antigenicity, where immunolabeling of proteins can be easily integrated afterwards (data not shown).

Conclusions: We have shown that FLARE reveals abundant details in a wide range of kidney tissue processing methods using super-resolution and cleared-tissue microscopy, and is compatible with other staining modalities.

Ex Vivo Perfusion and Initial Function of a Recellularized Human-Scale Bioengineered Kidney
Joseph S. Uzarska,1 Emily C. Beck,1 Emily Russell,1 James Jaffe,1 Ron Shaprio,1 Sander Floroman,2 Dominique Davidow,3 Thomas Gilbert,4 Jeff Ross,1 Miromatrix Medical, Inc., Eden Prairie, MN; 2Mount Sinai Health System, New York, NY; 3Recanati/Miller Transplantation Institute at Mount Sinai, New York, NY.

Background: The need for more transplantable kidneys is greater than ever, with nearly 100,000 patients actively waiting for a kidney. To meet this growing demand, our team is developing a fully transplanta bilegenged engineered kidney (BEK) by seeding cells into perfusion-decellularized porcine kidney scaffolds. Previously, orthotopic transplantation of HUVEC-only BEKs in pigs resulted in 83.3% (n=5/6 pigs) renal perfusion at 7 days post in vivo implantation. Building on these results, the focus of the current study was to recellularize the glomerulus of a clinically relevant whole kidney matrix and then assess the preliminary filtration function.

Methods: Adult porcine kidneys were decellularized via detergent perfusion through the vasculature. Primary glomerular cells were isolated from fresh porcine kidneys or rejected human kidneys. The porcine matrix was then seeded with either human umbilical vein endothelial cells (HUVECs), HUVECs and porcine glomerular cells as a model system of HUVECs and human glomerular cells. The recellularized grafts were then cultured using a custom perfusion recellularization bioreactor until sufficient cellular coverage of the vasculature was obtained through nondestructive metabolic markers. Both HUVEC-only and co-culture BEKs were then implanted in an ex vivo blood loop for 30 minutes, where urine effluent was collected and analyzed for filtration function.

Results: Sufficient histological vascular coverage with endothelial cells and thromboresistance with vascular patency was found for grafts with a minimum glucose consumption rate of 20 mg/hr. From the ex vivo blood loop test, the ureter effluent hematocrit concentration in the co-culture BEK was found to be undetectable. In comparison, the endothelial-only BEK and the pig’s blood hematocrit levels were both 22%. Finally, the addition of glomerular cells in the BEK restored physiological flow rates of ureter effluent.

Conclusions: These results demonstrated human cellular engraftment and growth, long-term vascular patency, sustained hemoperfusion, removal of processed filtrate, and early signs of filtration and waste clearance in BEKs, which moves the field closer to an alternative for kidney transplantation.

PO0311
Stiffening of Decellularized Tubular Basement Membrane Regulations
Renal Tubular Epithelial Cell Function
Snigdha Sant, Dan Wang, Nicholas J. Ferrell. Vanderbilt University Medical Center, Nashville, TN.

Background: Damage to renal proximal tubular epithelial cells (RPTEC) plays an important role in chronic kidney disease. Epithelial cells are supported by a specialized extracellular matrix called the basement membrane (BM). The structure of the BM is altered in various kidney diseases such as diabetic nephropathy and may result in increased BM stiffness. We have developed a novel cell culture model that utilizes tissue derived tubular basement membrane (TBM) with tunable stiffness as a culture substrate for RPTEC. The aim of this study was to determine if TBM stiffening promotes activation of pro-fibrotic signaling pathways and/or regulates RPTEC differentiation.

Methods: TBM was isolated from decellularized porcine kidneys. TBM cell culture substrates were made by pressure compacting the TBM on Tenvorwell inserts. Conditionally immortalized mouse RTPEC were grown TBM substrates. To induce stiffening, TBM was treated with the chemical crosslinker genipin. Decellularized TBM was characterized by western blot and immunofluorescence staining. Viability of the matrix and morphology of RTPEC were confirmed by LIVE/DEAD Viability/Cytotoxicity Kit. Real-time PCR was performed on RTPEC to evaluate the effect of stiffness on multiple genes related to kidney fibrosis and RTPEC differentiation.

Results: Western blot analysis of decellularized TBM showed the presence of lamin and collagen I and absence of lamin B1 showing proper decellularization of TBM. Genipin treatments (0.05% and 0.5%) resulted in average stiffness of 2 kPa and 3.2 kPa respectively, compared to 0.5 kPa for untreated TBM. Neither decellularization nor genipin modification had a significant effect on cell viability. Pro-fibrotic downstream targets of YAP activation (CTGF, AREG, and ANKRD1) were upregulated on stiff TBM substrates. Additionally, stiffness regulated expression of cell-cell junction markers E-cadherin and N-cadherin.

Conclusions: A new cell culture model was developed using tissue derived TBM as a culture substrate for tubular epithelial cells. Stiffness of the TBM was tuned using genipin. Increased TBM stiffness upregulated pro-fibrotic targets of YAP activation and altered RTPEC cell differentiation. These data show that stiffness significantly affects renal tubal cell function and suggest that TBM stiffening in chronic kidney disease may play a role in disease progression.

HIF-PHI Improves Anemia and Controls Circulating FGF-23 in a CKD Model
Megan L. Noonan, Pu Ni, Rafiou Agoro, Elizabeth A. Swallow, Matthew R. Allen, Kenneth E. White. Indiana University School of Medicine, Indianapolis, IN.

Background: The phosphaturic hormone FGF23 is a critical factor in chronic kidney disease-mineral and bone disorder (CKD-MBD), with elevated levels in blood associated with increased odds for patient mortality (>6-fold). Anemia is a potent driver of FGF23 expression, and patients with CKD ultimately develop anemia as the kidneys lose the ability to produce erythropoietin (EPO), in concert with FGF23-mediated alterations in mineral metabolism. Our goal was to investigate a HIF-PHI (hypoxia-inducible factor prolyl hydroxylase inhibitor) for effects on anemia-dependent FGF23 levels and key outcomes in a mouse model of CKD.

Methods: Female C57Bl6 mice were fed a casein control or adenine-containing diet to induce CKD, which resulted in markedly elevated iFGF23 and BUN, hyperphosphatemia, and anemia. After 12 weeks of CKD induction, mice were treated with the HIF-PHI BAY 85-3934 (‘BAY’; Moldemutast) at a human equivalent dose over every other day for 3 weeks.

Results: Compared to saline controls, BAY elevated serum EPO and restored CBCs to normal levels in CKD mice. iFGF23 was significantly elevated in saline-treated CKD mice (120-fold, p<0.01). Importantly, circulating iFGF23 was significantly attenuated (>60%; p<0.05) in BAY-treated mice with CKD, coinciding with reduced renal Egr-1 expression (p<0.01). Renal 1,25D anabolic Cyp27b1 and catabolic Cyp24a1 mRNAs were up and downregulated, respectively, in BAY-treated CKD mice. This extended treatment resulted in decreased BUN (p<0.01) and reduced expression of renal fibrosis markers (p<0.01). The bone marrow EpoR, Transferrin receptor, and Erfe mRNAs were all upregulated (p<0.05-0.01), and liver hepcidin expression was downregulated in both control and CKD groups treated with BAY (p<0.05-0.01). HIF activation in osteoblasts/osteocytes is associated with increased bone mass, therefore we investigated femur trabecular parameters and cortical porosity, however saw no effect with BAY over this time course. Serum alkaline phosphatase was significantly elevated in CKD-BAY mice compared to CKD controls (p<0.01), suggesting increased osteoblast activity.

Conclusions: Collectively, these results support that resolving anemia using a HIF-PHI may improve kidney function and lower FGF23 during CKD, potentially providing modifiable outcomes beyond improving iron utilization for this patient population.

Second Harmonic Generation and Fluorescence Imaging Reveal Collagen Fibris and Cell Nuclei in Mature Randall Plaque
Victor Hugo Canela,1 Sharon B. Bledsoe,1 Seth Winfree,1 Angela R. Sabo,1 Elaine M. Worcester,2 Tarek M. El-Achkar,1 James C. Williams.1 Indiana University School of Medicine, Indianapolis, IN; 2University of Chicago, Chicago, IL.

Background: The formation of calcium oxalate (CaOx) stones on Randall’s plaque (RP) is a common phenomenon (perhaps 25% of CaOx stones), yet this mechanism of stone formation is still poorly understood. The objective of the study was to devise novel techniques to study RP structure.

Methods: Micro CT was used to orient RP stones for decalcification and sectioning. Sections were examined for collagen using Second Harmonic Generation (SHG)
signals with multiphoton excitation. Other sections were stained with the DNA marker 7-aminomethylnucleoside D (7-AAD).

**Results:** SHG showed collagen fibrils in the plaque but not in the CaOx overgrowth region. Demineralized RP displayed autofluorescence in the far-blue region, as we have previously described in mineralized RP. Staining of plaque sections with the DNA marker, 7-AAD, confirmed the presence of cell nuclei within mature RP.

**Conclusions:** Our results show that collagen fibrils and cell nuclei are present in RP. The nature of cells and their role in plaque formation are yet to be determined. Our data suggest that these cells contain normal nuclear morphology and were well-preserved within the mature plaque. The presence of cell nuclei in the plaque raises critical questions about the role of apoptosis/necrosis and survival in this mineralized environment. Future studies exploring organization of collagen and the nature of cells in plaque will be invaluable in understanding plaque and stone pathogenesis.

**Cell Cycle Acceleration in Parathyroid Glands Is Caused by the Suppression of LncRNA Gas5 Expression in the Presence of a High-Phosphorus Diet in an Adenine-Induced CKD Rat Model**

Taketo Uchiyama, Ichiro Ohkido, Yatsumu Saito, Akio Nakashima, Takashi Yokoo. Jikei University School of Medicine, Minato-ku, Japan.

**Background:** Chronic kidney disease (CKD), especially secondary hyperparathyroidism (SHPT), is strongly associated with systemic calcification, including that in blood vessels. Therefore, it is important to elucidate its underlying pathological mechanism. SHPT is characterized by an unusually increased proliferation of parathyroid cells. We analyzed the expression of multiple cyclins, cyclin-dependent kinases (CDks) and CDk inhibitors and demonstrated that the accelerated cell cycle in SHPT is caused by a reduction in CDK1B1 expression (ASN 2019). To investigate the mechanism underlying SHPT development, we analyzed factors regulating cell cycle in parathyroid glands using two-photon imaging.

**Methods:** CKD was induced by a diet containing 0.75% adenine. For 5 days, few rats in the CKD and control groups were fed a diet containing 0.9% phosphorus, and the remaining rats were fed a diet containing 1.3% phosphorus. We investigated the expression levels of approximately 20 miRNAs, such as mir-221, known to regulate cell cycle. We analyzed the expression of multiple cyclins, cyclin-dependent kinases (CDks) and CDk inhibitors and demonstrated that the accelerated cell cycle in SHPT is caused by a reduction in CDK1B1 expression (ASN 2019). To investigate the mechanism underlying SHPT development, we analyzed factors regulating cell cycle in parathyroid glands using two-photon imaging.

**Results:** There were no significant differences in miRNA expression levels among the four groups (Figure 1). Gas5, known to be downregulated in prostate cancer cell line, directly upregulates CDK1B1 expression and further interacts with E2F1, which binds and activates CDK1B1. This strengthens the binding between E2F1 and CDK1B1 stronger. It was observed that the expression of Gas5 was significantly decreased when the high-phosphorus diet was added to the CKD environment, and E2F1 expression did not change significantly (Figure 2).

**Conclusions:** These results suggest that parathyroid cell proliferation might be due to the suppression of Gas5 expression in response to the addition of the high-phosphorus diet to the CKD environment, with a subsequent reduction in CDK1B1 expression.

**Treatment with β,γ-Methylenedadenosine 5’-Triphosphate Prevents Arterial Media Calcification in a Warfarin Rat Model**

Britt Opdebeeck,1 Isabel Orriss,2 Jessal J. Patel,2 Geoffrey Van den bergh,1 Patrick D’Haese,1 Anja Verhulst.1 Universiteit Antwerpen Laboratorium voor Pathofysiologie, Wilrijk, Belgium; The Royal Veterinary College Department of Comparative Biomedical Sciences, London, United Kingdom.

**Background:** Arterial media calcification (AMC) is a severe complication in patients with chronic kidney disease, diabetes, and osteoporosis. In vitro studies showed that the synthetic PZK receptor agonist β,γ-ATP promotes vascular smooth muscle cell (VSMC) calcification. Here, we aimed to evaluate whether β,γ-ATP prevents the development of AMC in a rat model of warfarin-induced AMC.

**Methods:** To induce AMC, rats received a diet containing 0.30% warfarin + 0.15% vitK1 throughout the entire study and were subjected to daily i.p. treatments with vehicle (n=10) or 2 mg/kg/day β,γ-ATP (n=10) from start of the study until sacrifice at wk7. Four rats on a standard chow diet were included as a control group. Serum calcium (Ca) and phosphorus (P) levels were analyzed at sacrifice. To evaluate the bone-like switch of VSMCs, aortic mRNA expression of TNP and SOST were analyzed by qPCR. AMC was evaluated by analysis of total Ca content in the arteries and quantification of the area % calcification on Kossa stained aortic sections. To determine arterial stiffness, ultrasound-based pulse wave velocity (PWV) was evaluated in the abdominal aorta.

**Results:** Serum P levels were unchanged in all groups while serum Ca was significantly lower in rats treated with β,γ-ATP vs vehicle group. Exposure to warfarin induced distinct calcification in the aorta and peripheral arteries in vehicle treated rats which led to an increase in PWV score. Interestingly, daily treatment with β,γ-ATP significantly reduced the Ca content in the aorta (mean ± SEM; vehicle 1.49 ± 1.51 mg Ca/g wet tissue vs β,γ-ATP 0.38 ± 0.20 mg Ca/g wet tissue; p<0.05) and peripheral vessels which was further reinforced by a significant (p=0.01) reduction in aortic Von Kossa positive area % vs vehicle group. However, β,γ-ATP did not significantly affect PWV scores. Treatment with β,γ-ATP also did not alter the mRNA expression of bone-like marker genes.

**Conclusions:** β,γ-ATP significantly decreased AMC in the aorta and peripheral vessels of warfarin exposed rats, however, without affecting the bone-like switch of VSMCs suggesting that β,γ-ATP mediates its inhibitory effects on AMC probably by interfering with the formation of Ca-P crystals via its breakdown product methylene bisphosphonate. Further research will be conducted to evidence this hypothesis.

**Efficacy of Oxidative Stress Inhibitor Alone or Combined Therapy with a Calcimimetic in a Rat Model of CKD-MBD**

Neil X. Chen,1 Kalisha O’Neill,1 Shruthi Srinivasan,1 Corinne E. Metzger,1 Alexander J. Stacy,1 James M. Dominguez,1 Annabel Birueto,1 Matthew R. Allen,1 Keith G. Avin,2 Sharon M. Moe.1,12 Indiana University School of Medicine, Indianapolis, IN; 1Rodalebush Veterans Affairs Medical Center, Indianapolis, IN;

**Background:** We previously demonstrated the role of NADPH oxidase (NOX 1 & 4) and hyperparathyroidism in the pathogenesis of arterial calcification, a component of CKD-MBD. We hypothesized that the combination of reduced NOX activity and lower PTH would have additive benefit on CKD-MBD. To test this hypothesis, we evaluated the efficacy of the NOX 1/4 inhibitor GKT137831(GKT) alone or combination with the PTH-lowering calcimimetic KP-2326 (KP) on CKD-MBD in a slowly progressive rat model of CKD-MBD, the Cd 1/2 rat.

**Methods:** We compared five groups of animals: 1: Normal (NL); 2: CKD; 3:CKD+GKT (60mg/kg, s.q. daily); 4: CKD+ KP (0.6mg/kg i.p., 3x/wk) and 5: CKD+GKT+KP. Treatment began at 3 weeks of age (~60% NL kidney function) and ended at 28 weeks (~25% NL kidney function). Serum biochemistries, aorta and heart calcification and bone architecture were assessed. One Way ANOVA was used for statistical analysis.

**Results:** As expected, there was a decline in kidney function in all CKD groups compared to NL. There was no difference in serum phosphorus or calcium levels between NL and any of the CKD groups. PTH and FGF23 serum levels were elevated by 5 and 2.3 fold, respectively, in CKD rats; only KP treatment reduced PTH levels (p<0.003). Interestingly, GKT alone or combined with KP increased FGF23 levels by 2-fold in
PO0317
Comparison of the Effects of Ferric Citrate and Intravenous Iron on Markers of Mineral and Bone Disorder and Oxidative Stress in a Rat Model of CKD-MBD

Ahmad Asadi,1 Hui Wang,1 Neil X. Chen,1 Corinne E. Metzger,1 Alexander J. Stacy,1 Shruthi Srinivasan,1 Kalisha O’Neill,1 James M. Dominguez,1 Keith G. Avin,2 Matthew R. Allen,1,2 Sharon M. Moe,1,2 1Indiana University School of Medicine, Indianapolis, IN; 2Richard L Roudebush VA Medical Center, Indianapolis, IN.

Background: Anemia and chronic kidney disease-mineral and bone disorder (CKD-MBD) are common in CKD. Ferric citrate is an oral therapy approved as an oral iron replacement product in non-dialysis dependent CKD and as a phosphate binder for dialysis-dependent CKD patients. However, studies comparing the effects of ferric citrate vs. IV iron on markers of CKD-MBD and oxidative stress in moderate CKD are limited.

Methods: We compared four groups of male rats (n=11-14 rats/group): 1) Rats with CKD (CKD+); 2) CKD+ treated with ferric citrate (CKD+ + CIT); 3) CKD+ treated with IV iron sucrose (CKD+ + IV iron); and 4) CKD+ treated with IV iron sucrose and ferric citrate (CKD+ + IV iron + CIT). The rats were treated for 10 weeks. At sacrifice, the renal cortical tissue was collected for analysis.

Results: Ferric citrate changed markers of oxidative stress and bone metabolism compared to untreated CKD rats. Ferric citrate decreased oxidative stress markers and increased FGF23 levels in CKD rats.

Conclusions: Ferric citrate treatment improved oxidative stress and bone metabolism compared to untreated CKD rats.

PO0318
Upacicalcet, a Novel Non-Peptide Calcimimetic for the Treatment of Secondary Hyperparathyroidism, Has a Low Risk of Hypocalcemia

Go Nishimura,1 Yu Yamaguchi,1 Moritaka Goto,1 Daisuke Honda,2 Naoki Takahashi,1 Sanwa Kagaku Kenkyusho, Co., Ltd., Inabe, Japan; 2Sanwa Kagaku Kenkyusho, Co., Ltd., Nagoya, Japan.

Background: Calcimimetics are widely used for the treatment of secondary hyperparathyroidism (SHPT) in chronic renal failure patients. However, there are some problems with calcimimetics treatment. One of the biggest problems is hypocalcemia that leads to treatment interruption. Upacicalcet is expected to be a novel non-peptide calcimimetic that does not cause excessive hypocalcemia from the results of clinical studies. In the present study, we investigated the pharmacological characteristics of upacicalcet and effect on hypocalcemia in preclinical studies.

Methods: In vitro study was conducted using human CaSR-expressing (hCaSR) HEK-293T cells. In vivo study, upacicalcet was intravenously administered in a single dose to Double-Nephrectomized (Double-Nx) rats, an animal model of SHPT, and serum intact parathyroid hormone (iPTH) and Ca concentrations were measured.

Results: Upacicalcet increased the intracellular Ca2+ concentration in hCaSR-HEK-293T cells dose-dependently. Additionally, upacicalcet shifted the EC50 value for extracellular Ca2+ to lower concentrations in a dose dependent manner. In Double-Nx rats, 0.3, 3, and 30 mg/kg of upacicalcet dose-dependently reduced the serum iPTH level at 24h and 48h after administration, and the reductions were significantly greater than that in Control (P<0.01). Upacicalcet 0.3 mg/kg: 397±40 pg/mL vs. Control: 1306±80 pg/mL; P<0.001, 48h; upacicalcet 0.3 mg/kg: 795±91 pg/mL vs. Control: 1889±77 pg/mL; P<0.001.

Upacicalcet also significantly decreased the serum Ca level dose-dependently at 24h and 48h after administration. However, interestingly, it bottomed out without getting too low even with 30 mg/kg of upacicalcet, 100-fold higher than the efficacious dose (0.3 mg/kg) (Table 1).

Conclusions: These findings suggest upacicalcet is a novel non-peptide positive allosteric modulator on human CaSR with a low risk of hypocalcemia for the patients with SHPT.
Methods: Aortic valve leaflets from commercial pig hearts were dissected and randomly assigned to experimental groups. Whole leaflets were cultured in individual wells. Two growth media were used for cultivation: standard growth medium and an antimony/oligoblastic growth medium. The latter was employed to inhibit contraction of the leaflet into a ball-like structure. Calcification was induced in the growth media by supplementing with 10 nM 1α,25-(OH)2D3 (but not CDP) or 10 nM 1α,25-(OH)2D3 and 0.1 μM b-glycerophosphate. Leaflets were cultivated for four weeks and medium was changed every third day. To block calcification, SNF472 was used at concentrations between 1 and 100 μM. Calcium amount in leaflets after four weeks was measured by inductively coupled plasma optical emission spectroscopy.

Results: Osteodifferentiation with calcium accumulation was in principle absent when standard medium was used. However, when the antimony/oligoblastic medium was used, a strong calcium accumulation was induced (p=0.006 compared to controls), and this was blocked in a dose-dependent manner by the calcification inhibitor SNF472 (p<0.001 with EC50 of 3.3 μM).

Conclusions: Cultured whole leaflets of porcine aortic valves are a new in vitro model to study calcification of heart valves. This model will be useful for studying the basic mechanisms of valve calcification and to test pharmacological approaches to inhibit calcification. The latter was shown by SNF472, which strongly inhibited calcification in this model of aortic valve disease.

Funding: Commercial Support - Sanfilhi Therapeutics, Government Support - Non-U.S.

PO0321
Amelioration of Uremic Vascular Calcification After Experimental Aorta Transplantation
Maria L. Mace,1 Sören Egstrand,1 Anders Nordholm,1 Marya Morevati,1 Geert J. Behts,2 Patrick D’Haese,3 Klaus Olgaard,1 Ewa Lewin.3
1Rigshospitalet, Copenhagen, Denmark; 2Universiteit Antwerpen, Antwerpen, Belgium; 3Herlev Hospital, Herlev, Denmark.

Background: CKD causes a shift in phenotype of the vascular smooth muscle cell (VSMC) to a secretory cell and promotes vascular calcification (VC). Our aim was to study whether VC is reversed by transplantation of an uremic calcified aorta into a healthy recipient.

Methods: A novel model of isogenic aorta transplantation in the rat was used (ATx). VC was induced in inbred Dark Agouti rats by 5/6 nephrectomy, high phosphate diet and alfalfa/fenugreek treatment. The abdominal aorta of the uremic rat was transplanted into a normal rat (uremic ATx, n=16). Control groups were: ATx between normal rats (normal ATx, n=9) and age-matched rats (control, n=6). Four weeks after ATx, the aorta was analyzed for genes related to the osteochondrogenic transition by RT-qPCR. Data are presented as mean±SD. mRNA levels are normalized to stable housekeeping genes and expressed as the ratio to controls.

Results: The uremic donor rat had severe CKD with disturbed mineral and bone metabolism as well as severe aorta calcification with altered expression of genes related to the osteochondrogenic phenotype: ATx mitigated some of these genetic changes as indicated by a significant downregulation of the expression level of mineralization inhibitors and fibrosis matrix proteins. More specifically, mRNA levels of MGP (control 1.9±0.18 vs. uremic 3.74±0.18 vs. uremic ATx 1.67±0.61), Sfrp1 (control 1.0±0.2 vs. uremic 13.69±4.47 vs. uremic ATx 2.62±0.84), ANKH (control 1.6±0.5 vs. uremic 10.43±6.90 vs. uremic ATx 4.94±1.72), Posnt (control 1.0±0.34 vs. uremic 3.19±0.77 vs. uremic ATx 1.74±0.85), Fnt1 (control 1.0±0.25 vs. uremic 7.26±2.49 vs. 3.02±1.45), all p<0.01. No difference in expression of these genes between control and normal ATx was noticed. The VSMC markers ACTA2 & Eln were downregulated in uremic VC with no recovery through ATx. The upregulated Wnt inhibitor sclerostin showed a trend towards downregulation by ATx. Activins A & TGF-beta were highly upregulated in uremic VC with no reversibility. Plasma biochemistry did not differ between control, normal ATx and uremic ATx.

Conclusions: Our results for the first time show downregulation of genes related to mineralization and fibrosis, indicating amelioration of uremic vascular calcification after experimental aorta transplantation.

PO0322
Impaired Arterial Vitamin D Signaling Is Pathogenic in Vascular Calcification
Kenneth Lim,1 Guerman Molostvov,2 Maria A. Lubczanska-Hasdley,3 Simon Fletcher,2 Rosemary Bland,3 Thomas F. Hiemstra,3 Daniel Zhendner.3
1Indiana University School of Medicine, Indianapolis, IN; 2University of Birmingham, Birmingham, United Kingdom; 3University Hospital Coventry and Warwickshire, Coventry, United Kingdom; 4University of Warwick, Coventry, United Kingdom; 5University of Cambridge School of Clinical Medicine, Cambridge, United Kingdom; 6North Cumbria Integrated Care University Hospital NHS Trust, Carlisle, United Kingdom.

Background: Conflicting data exists as to whether vitamin D receptor agonists (VDRa) are protective of arterial calcification. This is confounded by inherent physiological differences between human and animal experimental models and conflicting published data. Herein, the study aims to address these problems by leveraging frontiers in human arterial organ culture models.

Methods: Human arteries were collected from 24 patients (healthy controls, n=12; end-stage CKD, n=12). Cross-sectional and interventional studies were performed using arterial segments with normal and calcified (containing 5mmol/L CaCl2 and 5mmol/L b-glycerophosphate) medium, ex vivo. To assess the role of VDRa therapy, arteries were treated with either calcitriol or paricalcitol.

Results: Human arteries express a functionally active vitamin D system, including VDR, 1α,25-hydroxylase and 24-hydroxylase (24-OHase) components and these were dysregulated in CKD arteries. Arteries from CKD patients exhibited reduced capacity to synthesize 1,25(OH)2D, increased basal expression and excessive induction of the vitamin D catabolic pathway in response to VDRa. VDRa therapy increased VDR expression in physiological conditions but reduced the 1α,25-OHase enzyme expression in patients with CKD.

Conclusions: Maladaptation of arterial vitamin D signaling components occurs in CKD. VDRA exposure can exert vasculo-protective effects and seems critical for the regulation of arterial health in CKD.

Analysis of Human Jackstone Protrusions Show a Protein-Rich Core, Suggesting That Proteins Drive Their Rapid and Linear Growth
Victor Hugo Canela,1 Sharon B. Bledsoe,2 Cornelius Dzien,2 Michael S. Borofsky,3 James E. Lingeman,1 Tarek M. El-Achkar,1 James C. Williams.3
1Indiana University School of Medicine, Indianapolis, IN; 2Medical-Center Innsbruck, Innsbruck, Austria; 3University of Minnesota, Minneapolis, MN.

Background: Jackstones are urinary stones that have arm-like extensions from the body of the stone. This morphology of stone has been long recognized but poorly studied.

Methods: Micro CT was used to analyze 96 jackstones from 47 different patient specimens. Additional analyses included infrared spectroscopy (IR), fluorescence microscopy, and immunohistochemistry for Tamm-Horsfall protein (THP)

Results: Jackstone cores consisted of an X-ray lucent core (high in protein by IR) and a tightly layered calcium oxalate monohydrate (COM) shell that matched the COM on the stone body. The layering in the shell region showed that the arms had grown at a more rapid pace way from the center of the stone than had the stone body. Microscopy studies showed brilliant autofluorescence in the core region but less in the COM shell. Immunno-staining showed that THP content was richer in the core region than in the shell.

Conclusions: We hypothesize that the protein-rich core of a jackstone arm preferentially binds more protein from the urine and resists deposition of COM, such that the arm tip grows rapidly, with the sides (shell) of the arm being covered with COM layers just like the body of the stone. This hypothesis suggests enrichment of growth-accelerating proteins in the core of the jack arm, which bind preferentially to the protein-rich tip but which bind less avidly to the COM surface of the stone. Identification of such proteins could provide clues as to how proteins modulate the deposition of mineral layers in kidney stone growth.

PO0324
Hyperphosphatemia Contributes to Inflammation, Iron Dysregulation, and Skeletal Muscle Wasting
Brian A. Czaya, Kylie Heitman, Isaac D. Campos, Christopher Yanucil, Dominik Kentrup, Christian Faust. University of Alabama at Birmingham, Birmingham, AL.

Background: Fibroblast growth factor (FGF) 23 is a phosphaturic hormone that promotes phosphate (Pi) excretion. In patients with chronic kidney disease (CKD), serum levels of Pi & FGF23 gradually rise as renal function declines & associates with various pathologies such as systemic inflammation, anemia, vascular calcification & muscle wasting. Our previous studies have shown FGF23 induces inflammatory cytokine expression by targeting hepatocytes via FGF receptor 4 (FGFR4). Other studies have shown Pi accelerates vascular calcification and other, whether Pi contributes to inflammation, anemia or skeletal muscle wasting remains unclear. Here we compare the
effects of Pi versus FGFR23 to determine their contributions towards these CKD-associated pathologies in different stone types. In an ANOVA of the mean LEU by patient adjusted for the number of stone removal procedures, LEU in Br SF was higher than in CaOx SF (p=0.01).

Conclusions: Dipstick LEU is informative in SF aside from predicting infection. Dipstick LEU was significantly higher in Br SF than in CaOx SF but NIT, indicating that Pi was not different between stone types. Adjusting for other indicators of infection, such as ammonia, BLO, and PRO as well as the number of stone removal procedures did not abolish this difference. Dipstick LEU may serve as a urine biomarker of the inflammatory activity and neutrophil infiltration that we have observed in the kidneys of Br SF and may reflect the papillary histopathology.

Heterogeneity of Mechanisms for Idiopathic Hypercalciuria in Calcium Stone Formers

George A. Helsing,1 Elane M. Worcester,1 Kristin J. Bergsland,1 Fredric L. Coe,1 2 University of Chicago, Chicago, IL; 3 Medical College of Wisconsin, Milwaukee, WI.

Background: In past research, we have found evidence that patterns of segmental nephron tubule calcium reabsorption differ between the sexes in calcium (Ca) stone formers (SF) demonstrating a different underlying mechanism of their hypercalciuria. Whether or not these mechanisms differ between calcium oxalate (CaOx) and calcium phosphate (CaP) SF is not known.

Methods: We studied 18 CaOx SF subjects (12 male), 17 CaP SF subjects (9 male), and 25 normal (N) subjects (13 male) in both the fasted and fed state. Subjects ate a diet consisting of three isocaloric meals with hourly blood and urine samples for 14 hours. We measured endogenous and dietary calcium reabsorption, which are accompanied by urinary events such as calcium and/or phosphate wasting. Outcomes are not alleviated in FGFR4 knockout mice. Furthermore, we study primary hepatocytes treated with FGF23 or Pi to examine movement of the expression levels of this gene is linked to extended lifespan in mice. The present comparative study aimed to establish the movement of this gene in extended lifespan in mice. The presence of this gene is linked to extended lifespan in mice.

Results: In the kidney, similar levels of Kl mRNA were observed between those two species by qPCR (RN: 0.9 ± 0.1 vs. NMR: 1.2 ± 0.2; n.s.). The expression of Kl was further examined in the lung, skin and liver of NMR, compared to VN. There was no expression of Kl in the lung and skin of NMR. In the liver of NMR, a high expression of Kl mRNA was observed (Cp: 25) by qPCR in contrast to RN, where no expression was detected. Sanger sequencing was performed to confirm that the gene expressed in the liver was Kl. In order to ensure that this was not a truncated form of Kl, which could be a target for mRNA decay, the predicted region for alternative splicing sites for Kl was sequenced in the RN. These results indicated that this was not the case, neither in the kidney nor in the liver.

Conclusions: This comparative study showed for the first time that α-klotho expression is significantly increased in the liver of NMR, while the gene is absent in the liver of RN. The higher levels of α-klotho were similar in kidneys of NMR and RN. Further experimental work is required to clarify whether the hepatic expression of α-klotho might contribute to the longevity of the NMR.

PO0328

Magnesium’s Roles in the Treatment of Hyperphosphatemia of CKD

Background: Hyperphosphatemia is causally related to atherosclerotic cardiovascular disease, the most important cause of death in all stages of renal failure and the single greatest threat to survival among ESRD patients undergoing dialysis. To meet the current KD/QO guideline, patients use cationic binders to bind phosphate (Pi) in the gastrointestinal and prevent its uptake. FDA-approved phosphate binders include lanthanum salts, sevelamer, and calcium carbonate. Combinations of calcium and magnesium salts have the potential both for phosphate binding with reduced calcium load and for reduction in oxidative stress, vascular calcification, and bone dysfunction.

Methods: Recent literature describing treatment of hyperphosphatemia with phosphate binders composed of calcium acetate/magnesium carbonate and calcium citrate/magnesium carbonate was analyzed. The results highlight aspects of magnesium’s roles in the treatment of hyperphosphatemia of Stage 4-5 CKD and illustrate the potential benefits of these combination therapies in treatment of hyperphosphatemia.

Results: Recent clinical data strongly suggest that combinations of calcium and magnesium salts exhibit pleiotropic benefits for hyperphosphatemic Stage 4-5 CKD patients. In addition to reducing the calcium load, magnesium appears to act in the following ways. (1) Treatment lowered serum phosphorus into the K/DOQI target range in all patients. (2) Although treatment increased serum magnesium concentrations, [Mg2+] was in the high normal range and comparable to the intracellular magnesium concentration. (3) Short-term treatment raised the Tp value. Since lower values are associated with accelerated conversion of soluble calcioprotein particles composed of

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.

150
amorphous calcium phosphate to secondary (insoluble) calciprotein particles containing negative calcium phosphate particles, higher magnesium appeared to beneficially slow the rate of conversion. (4) Analyses of bone turnover parameters suggested that higher magnesium may have supported more normal bone remodeling.

**Conclusions:** Clinical data from several sources suggest that combinations of calcium and magnesium citrates and propionates can be effectively and safely administered to 4-5 CKD patients of all ages. Additional preclinical studies are underway to confirm that calcium magnesium citrates and propriates can be effectively and safely administered to hyperphosphatemic ESRD patients.

**Vitamin D Deficiency, Investigating the Connection Between Osteoporosis and CKD**

Reena A. Dona, John M. Greally. Albert Einstein College of Medicine, Bronx, NY.

**Background:** Chronic kidney disease (CKD) is estimated to affect thirty-seven million people in the United States and leads to drastic alteration in bone and calcium metabolism. Metabolic bone disease is a common complication, resulting in skeletal consequences and CKD-associated osteoporosis. This occurs due to a combination of abnormalities in calcium, phosphorus, parathyroid hormone, vitamin D metabolism, and dysregulation in both bone formation, and bone resorption. One mechanism of the pathophysiology of age-associated osteoporosis is the shift in lineage commitment of mesenchymal stem cells (MSCs) towards adipogenesis at the expense of osteogenesis. Recent studies have implicated MSCs as mediators of osteoporosis due to the disrupted endochondral bone development and aging individuals, similar to individuals with CKD.

**Methods:** We performed a re-analysis of a published single cell transcriptomics dataset investigating differentiation of MSCs to osteoblasts and adipocytes. We applied a standard pipeline from the R package “Seurat” to examine transcriptional heterogeneity of undifferentiated mesenchymal stem cells. Additionally, we tested the effects of 1,25D on MSC differentiation towards the osteogenic lineage.

**Results:** Here, we demonstrate heterogeneity of bone-marrow derived MSCs at the transcriptional level, implying potential underlying functional heterogeneity. Using single cell transcriptomics, we characterize the subpopulations of MSCs, multipotent stem cells, and cells poised for differentiation. Once we confirmed this heterogeneity, we investigated stem cell priming with the vitamin D metabolite 1α,25-dihydroxyvitamin D3 (1,25D), testing the memory of a prior exposure to stem cells influences later lineage commitment choices. Vitamin D supplementation is a common therapeutic intervention for osteoporosis in postmenopausal women. In key for patients with CKD-associated osteoporosis, Vitamin D deficiency is prevalent in populations at-risk for developing osteoporosis and patients already diagnosed with CKD.

**Conclusions:** This project supports the commonly used treatment for development and prevention of osteoporosis, and demonstrates functional heterogeneity of MSCs. Further steps in this project will explore the response to vitamin D priming at a higher resolution by employing single cell RNA-sequencing.

**Dissecting Ferric Citrate- and FGF-23-Associated Mineral Metabolism During the Anemia of CKD**

Michael P. Lisen, 1,2 Megan L. Noonan, 1 Erica Clinkenbeard, 1 Pu Ni, 1 Raffion Agors, 3 Julia M. Hum, 1 Kenneth E. White. 1 White Laboratory Indiana University School of Medicine, Indianapolis, IN; 2Marvin University, Indianapolis, IN.

**Background:** Ferric citrate (FeC) is a dual therapy used in patients with chronic kidney disease (CKD). This drug is given as a phosphate (Pi) binder for dialysis-dependent CKD, and for iron deficiency anemia in non-dialysis CKD due to delivery of elemental iron. Elevated Pi and anemia both lead to increased FGF23 during CKD, however, the roles of iron and anemia on FGF23 pathways are unclear.

**Methods:** Iron and Pi utilization was tested in a mouse model of CKD receiving FeC, with and without osteocyte deletion of FGF23 (floxed-Fgf23/Dmp1-Cre). Male mice (n=4–7) with the genotype flox-Fgf23/Dmp1-Cre and -Cre were placed on a customized 0.2% adenine (AD)-containing diet for 6 weeks to induce FeC in the presence of or absence of 10 mg/kg of AD.

**Results:** After the diet regimen, iFGF23 increased significantly in all CKD mice (p=0.05-0.01), iFGF23 was lower in Cre+ mice fed FeC (p=0.01), with Cre+ AD-only mice following a similar trend, demonstrating that the Dmp1-Cre was effective in reducing FGF23. Bone DMP1 mRNA was reduced by 50% prior to the onset of proteinuria at 4 weeks of age and remained low at all time points throughout CKD progression; each p<0.05 vs. age-matched WT.

**Conclusions:** These data show that reduction in FGF23 expression occurs prior to major reductions in kidney function and precedes alterations in osteocyte metabolism, cortical bone loss, and FGF23 elevation in CKD. Although further studies are needed to identify the factors that suppress FGF23 expression in CKD, FGF23 administration might represent an effective therapeutic strategy to prevent alterations in bone and mineral metabolism in early CKD.

**A Role of FHL2 in the Pathogenesis of VOT and Calcification Induced by High Phosphate**

Xiaowen Huang, 1 Weichun He. 1 Center for Kidney Disease, 2nd Affiliated Hospital, Nanjing Medical University, Nanjing, China; 3Nanjing Medical University, Nanjing, China.

**Background:** Hyperphosphatemia is germane to the development and progression of arterial medial calcification (AMC) in patients with chronic kidney disease. Vascular smooth muscle cells (VSMCs) to osteoblast-like cells differentiation (VOT) induced by high phosphate is a crucial step in AMC. Either β-catenin or HIF-1α signal activated by high phosphate promotes VOT and calcification in VSMCs. As an adaptor protein, four-and-a-half LIM domains protein 2 (FHL2) has been demonstrated involving in β-catenin and HIF-1α signaling, respectively. However, the potential role and mechanism for FHL2 in high-phosphate-induced VOT and AMC remains to be clarified.

**Methods:** The regulation and function of FHL2 in high-phosphate-induced VOT and calcification were examined in cultured VSMCs. The expression of FHL2 in AMC induced by high phosphate was examined in cultured arterial rings. The regulation of FHL2 on β-catenin and HIF-1α signaling during VOT was also examined in VSMCs, respectively.

**Results:** The expression of FHL2 was induced in VSMCs and arterial rings cultured in a high phosphate environment. Knockdown of FHL2 suppressed high-phosphate-induced Rux2 and osteocalcin expression and calcium deposition, whereas ectopic expression of FHL2 was sufficient to induce the expression of Rux2 and osteocalcin in VSMCs. Downregulation of FHL2 partially inhibited the high-phosphate-induced upregulation of active β-catenin and β-catenin-mediated gene transcription, whereas ectopic expression of FHL2 was able to induce active β-catenin and β-catenin-mediated gene transcription. Similarly, downregulation of FHL2 partially inhibited the expression of HIF-1α induced by high phosphate, while ectopic expression of FHL2 enhanced HIF-1α-mediated gene transcription, although it didn’t significantly increase the expression of HIF-1α. Moreover, high phosphate induced physical interactions between FHL2 and β-catenin, FHL2 and HIF-1α, respectively, especially in the nucleus. Meanwhile, high phosphate also induced a combination of β-catenin and HIF-1α, suggesting that the high-phosphate-induced upregulation of FHL2 facilitates the formation of a FHL2/β-catenin/ HIF-1α ternary complex.

**Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only**

Underline represents presenting author.
Conclusions: Our results suggest that FHL2, through activating β-catenin and HIP-1α signaling, plays a notable role in regulating high-phosphate-induced VOT and could be a potential therapeutic target for AMC in patients with chronic kidney disease.

CKD Decreases Cardiac PGC-1α Through Activin A Disrupting Mitochondrial Function

Matthew J. Williams,1 Kishor B. Devalaraja-Narashimha,2 Keith A. Hruska,1 Washington University in Saint Louis School of Medicine, Saint Louis, MO; Regeneron Pharmaceuticals Inc, Tarrytown, NY

Background: The CKD-MBD syndrome is a cause of cardiac risk. Our hypothesis was that a new component of the cardiac receptor, activin A, is responsible for systemic activation of activin receptor (ActRII) signaling in kidney disease, and is a mechanism of cardiac disease.

Methods: Two models of CKD were employed, Col4A5 Alport Syndrome mice and ablative CKD in Rosα26 cre ERT+/inhbafl/fl mice. Inhibition of Activin A in CKD was accomplished by either knockdown in Rosα26 cre ERT+/inhbafl/fl CKD mice or by monoclonal antibody in Alport mice. PGC-1α, mitochondrial gene expression and oxidative phosphorylation were measured by PCR and western analysis. Cardiac mitochondrial respiration was measured by respirometry.

Results: In two kidney disease models, we show that activin A is the responsible ligand for cardiac and aortic ActRIIA activation in CKD. In untreated CKD mice, cardiac levels of pSmad2 and inhibin βa mRNA and preprotein (activin A monomer) were increased. Activin A inhibition, accomplished by either knockdown in Rosα26 cre ERT+/inhbafl/fl CKD mice or by monoclonal antibody in Alport mice, prevents CKD-induced cardiac ActRIIA activation and loss of PGC-1α, the master regulator of mitochondrial biogenesis and fatty acid oxidative phosphorylation. Mitochondrial gene expression and oxidative phosphorylation were decreased by CKD but prevented by activin A inhibition in CKD. Cardiac hypertrophy by echocardiography and heart weight was increased by CKD and prevented by activin A inhibition in the absence of vascular stiffness and without change in FGF23 levels.

Conclusions: We conclude that activation of cardiac activin/ActRIIA signaling by CKD induces mitochondrial dysfunction through decreased PGC-1α which contributes to compensated cardiac hypertrophy in the early stages of CKD associated cardiac disease.

PO0334

Response of Bone to Acid: Effect of Deletion of the Proton Receptor OGR1 in the Osteoblast

Nancy S. Krieger, Luojing Chen, Jennifer Becker, Michaela Chan, David A. Bushinsky. University of Rochester Medical Center Department of Medicine, Rochester, NY

Background: Metabolic acidosis induces bone resorption by inhibiting osteoblast (OB) bone formation and stimulating osteoclast (OC) bone resorption. Mice generate large amounts of endogenous acid and we have shown that OGR1 is the proton (H+) receptor in bone and is stimulated by this endogenous acid. Mice with a global deletion of OGR1 have increased bone density which appears due to increased bone formation. There is communication between OB and OC and OGR1 is present in both. To determine if the response of OGR1 in the OB is independent of a response in OC, we generated a conditional knockout with an osteoblast-specific deletion of OGR1 (OB-cKO).

Methods: OB-cKO mice were generated from a col1a-cre mouse and an OGR1flox/flox mouse. We examined bones from 3 month old female mice using micro-computed tomography (μCT) and immunohistochemistry. Bone marrow mesenchymal stem cells (BMSC) from femurs of OB-cKO and wild type (WT) mice were differentiated to OB. Mineralization was detected with alizarin red and gene expression was analyzed by QPCR. All indicated changes are significant (p<0.05).

Results: Immunofluorescent staining of OGR1 in differentiated OB from BMSC confirmed the absence of OGR1 in OB-cKO cells compared to WT. μCT demonstrated an increase in tibia cortical bone area (0.76±0.01 vs 0.71±0.01 mm²), but no change in femoral cortical bone in OB-cKO compared to WT. Femoral trabecular bone was decreased (8.64±1.03 vs 11.81±0.70 %BV/TV), but there was no change in tibia trabecular bone. Alizarin red staining of differentiated BMSC showed greater mineralization of OB from OB-cKO mice compared to WT (5.14±0.02 vs 4.39±0.03 relative intensity). Relative gene expression of col1a1 (1.53±0.15 vs 0.88±0.10), osteocalcin (1.79±0.05 vs 1.13±0.18) and Rankl (2.89±0.48 vs 1.11±0.21) was higher in differentiated BMSC from OB-cKO mice compared to WT cells.

Conclusions: Our results demonstrate that specific loss of OB OGR1 alters the response of bone to endogenous acid on bone content, in vitro mineralization and gene expression compared to WT, indicating that the response of OGR1 in the OB is independent of the response in OC. Characterization of the direct role of OGR1 in acid-induced bone resorption may assist in understanding bone loss associated with the metabolic acidosis in patients with chronic kidney disease.

Testing Patterns for CKD-MBD Abnormalities Before and After Treatment

James B. Wetmore,1 Yuanyuan Ji,2 Akhtar Ashfaq,1 David T. Gilbertson,2 Nicholas S. Roetker,1 Hennepin Healthcare, Minneapolis, MN; 1Chronic Disease Research Group, Minneapolis, MN; 2OPKO Health Inc, Miami, FL

Background: We examined patterns of testing, treatment, and retesting after treatment initiation in CKD-MBD to determine if they were concordant with KDIGO guidelines.

Methods: We utilized 2010-19 data from IBM Explorys, an electronic health database. We created cohorts of incident CKD stage 3, 4, and 5 patients using a diagnosis code for CKD stage and a confirmatory eGFR lab value. Patterns of lab test ordering for PTH, phosphorus, 25D, calcium, and ALP and drug prescribing for activated vitamin D compounds, nutritional vitamin D, and phosphate binders were assessed during follow-up. We estimated the cumulative incidence of lab retesting following treatment (with death as a competing risk). We used multivariable Cox regression to examine whether pre-treatment test result values predicted retesting.

Results: We identified 215,553 stage 3, 43,576 stage 4, and 11,407 stage 5 CKD patients; mean follow-up was 2.3, 1.7, and 0.6 years, respectively. Only 46% of stage 4 and 41% of stage 5 patients underwent a PTH test; only 74% and 73%, respectively, a test for phosphorus, and only 38% and 25%, respectively, a test for 25D. By one year after treatment with activated vitamin D compounds, only 50% (stage 3), 53% (stage 4), and 60% (stage 5) of patients had received retesting for PTH [Figure]. By one year after treatment with 25D, retesting of 25D occurred in 46% (stage 3), 49% (stage 4), and 55% (stage 5) of patients by one year. Pretreatment levels of PTH and 25D were not associated in a graded fashion with retesting after treatment commenced.

Conclusions: Frequency of initial testing and retesting following treatment initiation are suboptimal. Unexpectedly, patients with the highest and lowest pre-treatment levels of PTH and 25D, respectively, did not have the highest rate of retesting, suggesting room for improvement.

Using a Quantitative Systems Pharmacology Model of CKD-MBD to Guide Therapy Minimizing Calcium Flux from Bone and into Vasculature

Adam E. Gaweda,1 Michael E. Brier,1,2 Eleanor D. Lederer,1,4 1University of Louisville, Louisville, KY; 2Robley Rex VA Medical Center, Louisville, KY; 3University of Texas Southwestern Department of Internal Medicine, Dallas, TX; 4Dallas VA Medical Center, VA North Texas Health Care System, Dallas, TX.

Background: CKD-MBD is characterized by bone loss and vascular calcification. Pharmacologic treatment of CKD-MBD involves dosing of three agents to minimize these complications through optimal balance of Calcium (Ca), Phosphorus (P), and PTH. Having developed a Quantitative Systems Pharmacology (QSP) model of CKD-MBD, we test the hypothesis that an AI method called Deep QLearning (DQL) in conjunction with our model can be used to determine the impact of precision therapy on the mineralization defect in patients with End Stage Renal Disease (ESRD).

Methods: Applying a quantitative systems pharmacology (QSP) model of CKD-MBD to mimic disease progression, we trained a Deep Neural Network (virtual physician) to minimize the Ca bone efflux and the Ca vascular tissue influx regardless of achieved serum Ca, P, and PTH predicted by the model. The virtual physician observed Ca, P, PTH and adjusted the doses of P binder, vitamin D, and a calcimimetic. We evaluated a trained virtual physician through simulation of CKD-MBD treatment over 18 months on a population of 100 virtual ESRD patients with varying baseline Ca, P, PTH levels, P intake, and Ca sensing receptor sensitivity.

Results: Simulations produced an average 30% decrease in bone Ca efflux and a 20% decrease in Ca influx to vascular tissue over baseline values. Average P decreased from 7.4 to 5.1 mg/dL, average Ca increased from 8.5 to 9.2 mg/dL, median PTH decreased from 1650 to 315 pg/mL.

Conclusions: Using a QSP model of CKD-MBD, we trained an AI agent to minimize the Ca fluxes from the bone and into the vascular tissue by prioritizing optimization of Ca fluxes over the achievement of specific Ca, P, and PTH levels. Our approach demonstrates benefitting synergies of Systems Biology and AI in modeling complex processes.

Mineral Metabolism Changes in Renal Transplantation

Ana Carina Ferreira,1,2 Marco Mendes,1,3 Cecilia Silva,1 Patricia Cotovio,1 Ines Aires,1,3 David Navarro,1 Fernando C. Pereira,1 Rute M. Salvador,1 Bruna F. Correia,1 M. Guadalupe Cabral,2 Fernando E. Nolasco,1,2 Manuel A. Ferreira,1,2 1Hospital Curry Cabral, Lisboa, Portugal; 2Nova Medical School, Lisbon, Portugal.

Background: Successful renal transplant restores many physiologic abnormalities. The aim of this study was to analyse the evolution of CKD-MBD patients (alpha-klotho, fibroblast growth factor (FGF) 23, sclerostin, parathyroid hormone (PHT), bone alkaline phosphatase (BAP), calcitonin, vitamin D (vitD), phosphorus (Pi), Calcium (Ca) and Magnesium (Mg)) pre and post transplantation.

Methods: Prospective cohort study of de novo renal transplanted patients (pts). A inclusion and after 12 months (time 0 and 1) pts performed laboratory evaluation. The differences between values (time1 - time 0) is the delta value. Associations between variables were performed Wilcoxon matched-pairs test and Spearman correlation test. STATA software was used and p < 0.05 was considered statistically significant.

PO0338

Quantitative Systems Pharmacology Approach to the Treatment of CKD Metabolic Bone Disorder (CKD-MBD) Using Deep Learning

Adam E. Gaweda,1 Michael E. Brier,1,2 Eleanor D. Lederer,1,4 1University of Louisville, Louisville, KY; 2Robley Rex VA Medical Center, Louisville, KY; 3University of Texas Southwestern Department of Internal Medicine, Dallas, TX; 4VA North Texas Health Care System, Dallas, TX.

Background: CKD-MBD is a common comorbidity that leads to serious skeletal and cardiovascular complications. Using a Systems Biology model of CKD-MBD and Artificial Intelligence (AI) guided precision dosing approach, we tested the hypothesis that this approach can effectively achieve recommendations for Ca, P, and PTH by balancing the administration of vitamin D and a calcimimetic when faced with varying adherence to phosphate binder dosing.

Methods: Using a Quantitative Systems Pharmacology (QSP) approach to model the disease trajectory, we trained a Deep Neural Network AI-agent to adjust doses of a P binder, vitamin D, and a calcimimetic to drive Ca, P, and PTH to recommended targets. We evaluated the agent through treatment simulation in a cohort of 100 virtual patients (defined by dietary P and sensitivity of the Ca receptor) under 3 experimental conditions: 100%, 50%, and 0% adherence to P binder prescription. Using model derived doses of vitamin D and calcimimetic, we analysed the effect of P binder adherence on achieving the recommended Ca, P, and PTH target ranges. Drug doses were determined by simultaneously maximizing the percent in range of Ca, P, and PTH while minimizing the changes in bone Ca efflux and vascular Ca influx. Simulations were performed over 18 months.

Results: Results are shown in Table 1.

Conclusions: Using a QSP model of CKD-MBD, we trained an AI agent to guide precision dosing of a P binder, vitamin D, and calcimimetic. We validated the agent under three simulated scenarios of P binder adherence. Simulation results show that control of intestinal P absorption is paramount in treatment of CKD-MBD. Failure to control P level completely compromises the ability to control vascular tissue calcification even when Ca and PTH are controlled pharmacologically.

Funding: Veterans Affairs Support

PO0339

Differences in 25-Hydroxyvitamin D Clearance by eGFR and Race: A Pharmacokinetic Study

Simon Hsu, Leila R. Zelnick, Yvonne S. Lin, Cora M. Best, Bryan K. Kestenbaum, Lynn M. Rose, Andrew N. Hoofnagle, Ian H. de Boer.

University of Washington, Seattle, WA.

Background: 25-hydroxyvitamin D (25(OH)D) clearance is an essential yet often overlooked determinant of circulating 25(OH)D concentration, the prevailing marker of vitamin D status. Observational studies associate markers of low 25(OH)D clearance with poor clinical outcomes and suggest differences in 25(OH)D clearance by kidney function and race, but these potential variations have not been tested using gold-standard methods.

Methods: We administered intravenous deuterated 25(OH)D (d-25(OH)D) in a pharmacokinetic study of 87 adults with a wide range of kidney function, including normal estimated glomerular filtration rate (eGFR > 60 ml/min/1.73m², n=43), non-dialysis chronic kidney disease (CKD; eGFR < 60 ml/min/1.73m², n=24), and kidney failure treated with hemodialysis (n=20). We measured d-25(OH)D, and deuterated 24,25-dihydroxyvitamin D (25(OH)D), concentrations 5 minutes, 1, 2, 3, and 4, 7, 14, 21, 28, and 56 hours post-administration. We calculated 25(OH)D clearance using non-compartmental analysis of d-25(OH)D concentrations over time. We re-measured 25(OH)D clearance in a subset of participants after 12-16 weeks of 2000 IU/day of oral vitamin D3 (n=18).

Results: We recruited 85 pts in 29 months and included 69 pts in the study. Mean age 50.2±12.4 years, 48 men, 53 caucasian (78.8%), median BMI 24.5 (21.4 – 27.8), median dialysis vintage 55 (42 – 84). We observe a significant reduction on Pi, Mg, PTH, calcitoni, sclerostin, bAP and FGF23. Both Ca and alpha-klotho levels increased, with no significant changes in vitD levels. With restoring renal health (time 1) and comparing with time 0, PTH maintaining the negative correlation with sclerostin (ρ=-0.02) and the positive correlation with FGF23 (p=0.002); modify the correlation with Pi, becoming a negative correlation instead of positive (ρ=-0.001) and gain new correlations with Ca (ρ=-0.001) and vitD levels (ρ=0.03). Also, PTH correlated with the delta FGF23 (ρ=-0.4, p<0.003) and sclerostin correlated with delta PTH (ρ=0.01). FGF23 didn’t have statistical association with Pi or Ca levels after transplant, contrasting with positive associations in pre transplant (ρ=0.002, p<0.0001). On the contrary, sclerostin developed a new correlation with Pi (ρ=0.0004) and a negative correlation with Ca (ρ=0.01). We didn’t find correlations between these molecules and alpha-klotho.

Conclusions: It seems that sclerostin influences PTH levels and that PTH is the stimulus for the increase or decrease of FGF23 serum levels. Levels of Ca and Pi seemed to be directly influenced by the level of PTH in post transplant, and those minerals seemed to be key factors for sclerostin secretion.
Results: The mean age of the study cohort was 64 ± 11 years; 41% were female and
30% were black. Mean eGFR was 90 ± 23 ml/min/1.73m², 31% of participants
had CKD and 23% had CKD. In fully adjusted models, a doubling of VMR and
fracture risk did not reach statistical significance. A higher VMR was associated with a lower risk of fracture [HR 0.71 (95% CI 0.51, 0.97) per doubling of VMR],
but in those with CKD or kidney failure [p-for-interaction = 0.052], 25(OH)D
clearance did not differ compared with before vitamin D supplementation,
although lower 25(OH)D clearance was correlated with a larger increase in serum 25(OH)D
clearance following supplementation (r = -0.53).

Conclusions: Through pharmacokinetic measurements, these findings confirm
impaired 25(OH)D clearance as a feature of disorder mineral metabolism in CKD,
and may help understand racial differences in vitamin D metabolism. Surrogate measures of
25(OH)D clearance may allow clinicians to more accurately anticipate individual response
to vitamin D supplementation.

PO0340
The Vitamin D Metabolite Ratio and Change in Bone Density and Fracture Risk in Older Adults

Charles Ginsberg,1 Ronit Katz,2 Andrew N. Hoofnagle,1 Jan M. Hughes-Austin,1 Lindsay M. Miller,1 Jessica O. Becker,1 Stephen B. Kritchevsky,1 Michael Shlipak,1 Mark J. Sarnak,1 Joachim H. Ix,1 University of California San Francisco, San Francisco, CA; 2Wake Forest School of Medicine, Winston-Salem, NC.

Background: Recent studies have suggested that 25-hydroxyvitamin D [25(OH)D]
may be a poor biomarker of bone health. Higher concentrations of its catalytic product
24,25-dihydroxyvitamin D [24,25(OH)2D3] and a higher ratio of 24,25(OH)2D3 to 25(OH)D,
(d the vitamin D metabolite ratio [VMR]) may provide additional information on
vitamin D receptor activity and bone health.

Methods: We measured 24,25(OH)2D3, 25(OH)D3, 25(OH)2D3, and VDBP in
Seattle, WA; 1University of California San Francisco, San Francisco, CA; 2Tufts Medical Center, Boston, MA; 3Wake Forest University School of Medicine, Winston-Salem, NC.

Results: Study participants had mean age 75 ± 3 years, 49% were female, 42% were
black, and 23% had CKD. Lower VDBP concentrations were not associated with any of the BMD measurements. There were 194
fractures in follow-up. A higher VMR was associated with a lower risk of fracture [HR 0.71 (95% CI 0.51, 0.97) per doubling of VMR],
but in those with CKD or kidney failure [p-for-interaction = 0.052], 25(OH)D
clearance did not differ compared with before vitamin D supplementation,
although lower 25(OH)D clearance was correlated with a larger increase in serum 25(OH)D
clearance following supplementation (r = -0.53).

Conclusions: Through pharmacokinetic measurements, these findings confirm
impaired 25(OH)D clearance as a feature of disorder mineral metabolism in CKD,
and may help understand racial differences in vitamin D metabolism. Surrogate measures of
25(OH)D clearance may allow clinicians to more accurately anticipate individual response
to vitamin D supplementation.

PO0341
The Vitamin D Metabolite Ratio Is Independent of Vitamin D Binding Protein Concentration

Charles Ginsberg,1 Andrew N. Hoofnagle,1 Ronit Katz,2 Jessica O. Becker,1 Stephen B. Kritchevsky,1 Michael Shlipak,1 Mark J. Sarnak,1 Joachim H. Ix,1 University of California San Francisco, San Francisco, CA; 2Tufts Medical Center, Boston, MA; 3Wake Forest University School of Medicine, Winston-Salem, NC.

Background: 25-hydroxyvitamin D [25(OH)D] may be a poor marker of vitamin D status due to variability in vitamin D binding protein (VDBP) between individuals and
groups. The vitamin D metabolite ratio [VMR, the ratio of 24,25(OH)2D3 to 25(OH)D3] is a marker of vitamin D status that has been hypothesized to be independent of variability in
VDBP. This hypothesis has not been directly evaluated.

Methods: We measured 25(OH)D3, 24,25(OH)2D3, 1,25(OH)2D3, and VDBP in
377 community dwelling older adults that participated in the Health Aging and Body
Composition Study. 24,25(OH)2D3 and 25(OH)D3 were used to calculate the VMR.
We used linear regression to assess the relationship between VDBP with the VMR,
24,25(OH)2D3, 25(OH)D3, and 1,25(OH)2D3.

Results: Study participants had mean age 75+3/ years, 52% were female, 40% were
black, and 24% had CKD. Lower VDBP concentrations were associated with male sex,
lower serum albumin and Gc2/Gc2 VDBP phenotype in multivariable models. In
fully adjusted models, each 1% higher VDBP was associated with a 0.92%, 0.76% and
0.57% higher 24,25(OH)2D3, 25(OH)D3, and the 1,25(OH)2D3 (Table 1). The VMR was
independent of VDBP concentration, [0.16% (95% CI -0.11, 0.44)] higher VMR per
1 ml/min/1.73m² increase in VDBP, p = 0.247.

Conclusions: In diverse cohort of community dwelling older adults, the VMR was
independent of VDBP concentration whereas VDBP was strongly directly associated with
the individual vitamin D metabolite concentrations. The VMR may serve as an important biomarker of vitamin D status and clinical outcomes that can be utilized in populations
with a large spectrum of VDBP concentrations.

PO0342
Meta-Analyses of the Impacts of Supplementation with Nutritional Vitamin D on Mineral and Bone Markers in Non-Dialysis CKD

Noel Gunnarsson,1 Giuseppe Cianciolo,2 Rosa Lauppe,1 Philipp Csmor,3 Fei Zhao,2 Marcus Kaisser,3 Becco Soro,2 Jordi Bover1
1Quantum AB, Stockholm, Sweden; 2Vifor Pharma Ltd, Glattbrugg, Switzerland; 3Fundacio Puigvert, Barcelona, Spain; 4Universita di Bologna, Bologna, Italy.

Background: Secondary hyperparathyroidism (SHPT) is a critical component of
mineral and bone disorder in chronic kidney disease (CKD-MBD), characterized by
excessive parathyroid hormone (PTH) secretion and low levels of vitamin D. Nutritional
vitamin D (NVD) supplements are frequently used to treat SHPT, especially in early CKD. The objective of this meta-analysis (MA) was to evaluate the impact of NVD
supplements on PTH, vitamin D (25D), calcium (Ca), phosphate (P) and fibroblast growth factor 23 (FGF23).

Methods: Study level results were pooled using a fixed effect model with inverted-
variance weighting. The impact of the NVDs was measured in two ways: as change versus
placebo or ‘no treatment’ and as change within the NVD study arm (before versus after
NVD supplementation).

Results: Overall changes in PTH from NVD supplementation were small when measured
within the NVD study arms (pooled reduction of 10.53 pg/ml, 95 % confidence interval (CI): -16.33 to -4.73) but larger when compared to placebo/no treatment (reduction of 49.74 pg/ml, 95 % CI -70.17 to -29.3). NVDs tended to increase levels of 25D both within the NVD study arms (increase of 20.62 ng/ml, 95 % CI 19.58 to 21.65) and when compared to placebo/no treatment (increase of 26.87 ng/ml, 95 % CI 24.44 to 29.30). At the end of the study periods, average levels of 25D in the NVD study arms were -30 ng/ml in all but two RCTs and -50 ng/ml in only five of the included RCTs. Ca levels increased statistically significant from supplementation with NVDs versus placebo/no treatment (increase of 0.30 mg/dl, 95 % CI 0.24 to 0.36 mg/dl). Only small and
statistically non-significant impacts were observed on levels of P and FGF23.

Conclusions: Our results suggest that the magnitude of 25D increase caused by NVD may
be insufficient to efficiently and consistently lower PTH. While supplementation with NVDs can be used to correct vitamin D insufficiency, the potential of NVDs to actively reduce PTH in NVD patients with SHPT is limited.

PO0343
Fibroblast Growth Factor 23 (FGF23)-Calcification Propensity, and Heart Failure with Preserved Ejection Fraction (HFpEF) in Patients with CKD: The CRIC (Chronic Renal Insufficiency Cohort) Study
Alexander S. Leidner,1 Xuan Cai,1 Leila R. Zelnick,2 Nina Bansal,2 Andreas Pasch,1 Mayank Kansal,1 Jing Chen,1 Amanda H. Anderson,1 James H. Sondheimer,2 James P. Lash,2 Raymond R. Townsend,2 Alan S. Go,31 Raymond A. Isakson,1 Myles Wolf,1 Tamara Izakova,1 1Northwestern University Feinberg School of Medicine, Chicago, IL; 2University of Washington, Seattle, WA; 3University of California San Francisco, San Francisco, CA; 4Tufts Medical Center, Boston, MA; 5Wake Forest University School of Medicine, Winston-Salem, NC.

Background: HFpEF represents half of all HF events and is common in patients with
CKD. Given lack of treatments, identifying factors that impact HFpEF development is
critical. FGF23 is an osteocyte-derived hormone involved in phosphorus homeostasis and
is implicated in HF development. Calcification propensity (T50) is an in vitro
assessment of the time for secondary calciprotein particle formation.

Methods: Using multivariable adjusted Cox proportional hazards models, we investigated the associations of FGF23 and T50 with incident HFpEF. FGF23 and T50 were measured at the baseline and Year 1 visits, respectively. Incident HFpEF was
defined as ejection fraction > 50% on echocardiogram at the time of event or by a CRIC Study echocardiogram within 1 year. After excluding individuals with baseline HF and individuals with HF events prior to analyte measurement, we included 3502 and 3029 individuals for our FGF23 and T50 analyses, respectively.

Results: In the FGF23 cohort, 333 incident HFpEF events occurred over a median follow-up of 10.8 years. In the T50 cohort, 259 incident HFpEF events occurred over a median follow-up of 10.2 years. Individuals in the highest FGF23 and lowest T50 quartiles had the highest rates of incident HFpEF (Figure). When adjusted for demographics, cardiovascular risk factors and kidney function, elevated FGF23, but not T50, was independently associated with incident HFpEF (Table).

Conclusions: FGF23, but not T50, was associated with incident HFpEF in patients with CKD. These data are consistent with studies demonstrating cardiac toxicity of FGF23 and may inform future trials of HFpEF development in CKD.

PO0345
Renal Clearance of Intact and C-Terminal FGF-23 in Man
Joachim H. Is,1,2 Alfsion J. Houben,1 Abraham A. Kroon,1 Peter W. de Leeuw,1
Andrew N. Hoofnagle,1 Charles Ginsberg,1 Ronit Katz,4 Alexander Bullen,1
Shilpa Sharma,1,3 University of California San Diego, La Jolla, CA; 1VMER/VA San Diego Healthcare System, San Diego, CA; 1Maasticht Universitair Medisch Centrum+, Maastricht, Netherlands; 1University of Washington, Seattle, WA; 1University of California Los Angeles, Los Angeles, CA.

Background: The ratio of C-terminal (cFGF23) to Intact FGF23 (iFGF23) is higher in persons with higher eGFR. Mechanisms are unclear. Differential renal clearance is one possibility.

Methods: Patients were referred for clinically suspected renal artery stenosis (RAS), and maintained off BP meds for 21 days before angiography. This study includes those found without RAS (N=93). Blood was obtained from the aorta (Ao) and bilateral renal veins (RV), and renal blood flow (RBf) was measured using 133 Xenon washout. Single pass % reductions of each measure ([Ao – RV]/Ao*100) was calculated, left and right was averaged, and multiplied by RBf to provide renal clearance in ml/min/100g kidney tissue. To determine the relative renal clearance, we calculated the cFGF23/iFGF23 clearance ratio (C/I ratio) and evaluated its relationship with eGFR.

Results: Mean age was 52±11 years, 22% were women, all were white, eGFR was 77±26 ml/min/1.73m2 and directly measured Cr clearance was 72±42 ml/min/100g. Renal clearance of cFGF23 was similar to Cr, while ifGF23 was 37% higher (C/I ratio 0.73±0.10). The clearance of cFGF23 and iFGF23 were directly correlated to eGFR (r=0.31 and 0.35). However, their relative clearance was similar across the range of eGFR (r=0.01). Results were similar in models adjusted for age, sex, and BMI.

Conclusions: Renal cFGF23 clearances (which measures both iFGF23 and c-terminal fragments) is similar to Cr, whereas iFGF23 clearance is higher, suggesting that renal clearance of c-terminal fragment clearance is low. While renal cFGF and iFGF23 clearance were both reduced in persons with lower eGFR, the relative efficiency of clearance of cFGF23 vs. iFGF23 appeared similar across the range of eGFR.

PO0346
Association of Changes in Levels of eGFR and Fibroblast Growth Factor 23 from Midlife to Late Life with Risk of Mortality: The ARIC Study
Joseph B. Pike,1 Elvis A. Akwo, Loren Lipworth, Adriana Hung, Talat Alp Ikizler, Cassianne Robinson-Cohen. Vanderbilt University Medical Center, Nashville, TN.

Background: Observational studies suggest that elevated levels of circulating fibroblast growth factor-23 (FGF-23) contribute to the burden of cardiovascular disease, in the setting of chronic kidney disease and in the general population. These studies can suffer from confounding and reverse causation, limiting their ability to identify causal associations. Mendelian randomization (MR) has emerged as a powerful study design to provide evidence supporting or refuting causality by utilizing the genetic determinants of a risk factor. We used MR to evaluate whether genetically predicted higher FGF-23 levels are associated with the risk of coronary artery disease (CAD).

Methods: We performed two-sample MR of the relationship between FGF-23 and CAD with the use of summary statistics from the CARDioGRAMplusC4D consortium’s genome-wide association meta-analysis of 48 studies with a total of 60,801 CAD cases and 123,504 non-cases. We selected 5 single nucleotide polymorphisms (SNPs) robustly associated with FGF-23 at genome-wide significance among 16,624 individuals as instrumental variables.

Results: A genetic predisposition to higher FGF-23 levels was associated with CAD. In conventional MR analysis, the odds ratio of CAD was 1.44 (95% confidence interval 1.14 to 1.80) per 10-fold increase in genetically predicted FGF-23 levels. Results were consistent in sensitivity analyses using the weighted median and heterogeneity- penalized model averaging methods.

Conclusions: This study provides evidence that FGF-23 levels are causally associated with risk of CAD. Whether interventions to lower FGF-23 result in decreased risk of CAD remains to be determined but warrants investigation.

Factors Associated with Change in Fibroblast Growth Factor 23 Levels from Midlife to Late-Life: The ARIC Study
Junichi Ishigami,1 Yasuyuki Honda,1 Amy B. Karger,2 Elizabeth Selvin,1 Josef Coresh,3 Pamela L. Lutssey,2 Kunihiro Matsushita,1 Johns Hopkins University, Baltimore, MD;1 University of Minnesota, Minneapolis, MN.

Background: Factors associated with change in fibroblast growth factor 23 (FGF23) levels from midlife to late-life are not well-characterized in the general population.

Methods: Among 5,981 participants of the Atherosclerosis Risk in Communities Study who had serum level of FGF23 measured during midlife (visit 3, 1993-1995, mean age 58 years, 58% women, 23% black race) and late-life (visit 5, 2011-2013, mean age 76 years), we explored demographic and clinical factors associated with change in FGF23 levels. Change in FGF23 levels was regressed on pre-specified factors assessed at visit 3 of age (above vs. below median), sex, race, ever smoke, high BMI (as vs. <30 kg/m²), hypertension, diabetes, history of CVD, and reduced eGFR (a vs. <60 ml/min/1.73m²) using multivariable linear regression models.

Results: The mean FGF23 level increased by 21.0 (95%CI, 20.3-21.6) pg/mL from 39.7 at visit 3 to 60.6 pg/mL at visit 5. Reduced eGFR, diabetes, hypertension, female, older age, and white race were significantly associated with a greater increase in FGF23 levels (Table). Although history of CVD demonstrated a similar magnitude as race, the β coefficient was not significant. We also did not observe significant associations for BMI or smoking. The associations were strongest for reduced eGFR and diabetes with similar degrees of associations (AFCGF23, 6.7 [95%CI, 2.7 to 10.6] pg/mL for reduced eGFR and 6.7 [4.4 to 9.0] pg/mL for diabetes) independent of each other.

Conclusions: In addition to reduced eGFR, we identified diabetes, hypertension, female, older age, and white race as predictors of an increase in FGF23 levels from midlife to late-life. Among these, the strong association of diabetes of kidney function deserves future investigations.

Table: Factors associated with changes in FGF23 levels from midlife to late-life. Multivariable linear regression analysis unadjusted for chosen covariates.

Effects of Adjustment for Iron Parameters, Inflammation, and Kidney Function on the Associations of C-terminal and intact FGF23 with Mortality

PO0347
Intact and C-Terminal Fibroblast Growth Factor 23 Assays: Do Kidney Function, Inflammation, and Iron Deficiency Influence Relationships with Clinical Outcomes?
Shilpa Sharma,1 Ronit Katz,1 Alexander Bullen,2 Alions J. Houwen,4 Michael Shlipak,1 Joachim H. Ix,3,2 University of California Los Angeles, Los Angeles, CA;1 University of California San Diego, La Jolla, CA;3 University of California San Francisco, San Francisco, CA;4 Maastricht Universitair Medisch Centrum+ Interne Geneeskunde, Maastricht, Netherlands;1 University of Washington, Seattle, WA.

Background: Higher fibroblast growth factor-23 (FGF23) concentrations are associated with heart failure (HF) and mortality, but strengths of associations differ depending upon FGF23 assay type. We investigated whether iron deficiency, inflammation, and kidney function account for these differences.

Methods: In 844 Cardiovascular Health Study participants, using a case-cohort design, we examined associations of intact and C-terminal FGF23 with risk of mortality and HF, using modified Cox models to account for case-cohort design, adjusting sequentially by iron status, inflammation, kidney function or their combinations.

Results: C-terminal FGF23 more strongly correlated with ferritin (r = 0.26) and CRP (r = 0.21) than intact FGF23 (r = 0.04 & r = 0.07, respectively). The two FGF23 assays moderately correlated with one another (r = 0.47). During follow up, there were 658 deaths, and 220 incident HF events. FGF23 measured by either assay was associated with mortality in unadjusted analysis (intact FGF23 HR per two-fold higher 1.45; 1.25-1.68) to 1.16 (0.97, 1.38). Adjustment for iron deficiency and inflammation to 0.99 (0.76, 1.28) with eGFR and albuminuria adjustment, whereas C-FGF23 went from 1.45 (1.25, 1.68) to 1.16 (0.97, 1.38). Adjustment for iron deficiency and inflammation did not meaningfully influence the differential impacts of the two assays with either endpoint.

Conclusions: The associations of biologically active FGF23 with clinical endpoints may be weaker than previously thought.

PTH 1-84 and Bone Alkaline Phosphatase Are Independently Associated with Mortality, Whereas FGF-23 Predicts Dialysis Initiation in CKD Patients

Silvia M. Titan,1,2 Isabela M. Bengsonor,1 Pablo Lutufo,1 Rosa M. Moyes.1
1Universidade de Sao Paulo, Sao Paulo, Brazil; 2Tufts Medical Center, Boston, MA.

Background: Despite the fact that CKD-MBD is a risk factor for CKD morbidity and mortality, limited results of studies regarding the role of individual biomarkers are available. In addition, dimensionality reduction techniques have not been applied in CKD-MBD. The aim of our study was to evaluate a panel of CKD-MBD biomarkers, namely Ca, P, PTH 1-84, FGF-23, 25-vitamin D, 1,25-vitamin D, bone alkaline phosphatase (BAP) and sclerostin individually and collectively in relation to death and KRT.

Methods: Events of death and KRT in 454 participants of the Progredir Cohort (Sao Paulo, Brazil) with predominantly CKD G3 and G4 were ascertained after a median follow-up of 6 years. Those with missing values were excluded (n=25) and 4 were lost to follow-up. The association of individual CKD-MBD parameters (DiaSort® assays) and factors derived from factorial analysis was evaluated through Cox and Competitive Risk models (R package “compnr”).

Results: Mean age was 68(12)y, mean eGFR was 38(15) ml/min/1.73m², 63% were male and 56% diabetic. In univariable analysis, sclerostin, BAP, PTH, and factor 1 were associated with death and 1.25vitD, DM, MI, AUC, smoking. After adjustments, BAP, PTH, and factor 1 remained associated with death, and FGF-23 was associated with death and KRT (Table). The addition of BAP and PTH (with interaction) to a reference model significantly improved the model fit for death (p=0.01). The addition of FGF-23 with interaction with P significantly improved the model fit for KRT (p=0.0046).

Conclusions: PTH and BAP are positively associated with death and improved its prediction model. This finding suggests that BAP could be reflecting not only bone turnover but also vascular calcification. FGF-23 is associated with the risk of bone turnover but also vascular calcification. FGF-23 is associated with the risk of death, and FGF-23 remained associated with KRT (Table). The addition of BAP and PTH (with interaction) to a reference model significantly improved the model fit for death (p=0.01). The addition of FGF-23 with interaction with P significantly improved the model fit for KRT (p=0.0046).

Parathyroid Hormone Serum Levels and Mortality Among Hemodialysis Patients in the Gulf Cooperation Council Countries: Results from the DOPPS (2012-2018)

Isa M. Salmi,1 Mona Al Rukhaimi,1 Ali AlSahow,4 Faisa1 Al Shaheen,3 Sadeq Al-Ghandi,6 Jamal S. Al Wakee,5 Fadwa M. Al-Alisi,1 Ali Alaradi,3 Fayezy F. Alhejaili,4 Yaqoob A. Almaimani,2 Essam F. Abdelhamid,10 Brian Bieber,1 Bruce M. Robinson,1 Ronald L. Pisoni.1

On behalf of the GCC-DOPPS Study Group

Background: The prospective Dialysis Outcomes and Practice Patterns Study (DOPPS) has collected data since 2002 in all six Gulf Cooperation Council (GCC) countries (Bahrain, Kuwait, Oman, Qatar, Saudi Arabia, United Arab Emirates). Here, we report the relationship of PTH with mortality in the largest GCC hemodialysis (HD) patient cohort studied to date.

Methods: Data were from randomly-selected national samples of HD facilities in GCC DOPPS phases 5 and 6 (2012-2018). PTH descriptive findings and case-mix bias of events were reported. Mortality analyses were nested within these data. Hazard ratios (HRs) and 95% confidence intervals (CIs) were reported for PTH levels compared with normal, no adjustment or adjusted PTH levels compared with normal.

Results: Mean patient age was 65 (median age 65, IQR: 59-71) years, 59% male, and 56% diabetic. In univariable analysis, PTH levels were significantly associated with events but did not improve prediction. Mortality rates were highest in the highest PTH tertile, similar to previous analyses. The HRs were 1.39, 1.30, and 1.34 for tertiles 2, 3, and 4, respectively, compared with the lowest tertile. After adjustment for confounders, the highest tertile remained associated with death, and PTH remained associated with both death and KRT. After adjustment for confounders, PTH remained associated with death and KRT. After adjustment for confounders, PTH remained associated with death and KRT.

Conclusions: Secondary hyperparathyroidism is highly prevalent among GCC HD patients, with a strong U-shaped PTH/mortality relationship seen at PTH <300 and >450 pg/mL. Future studies are encouraged for further understanding this PTH/mortality pattern in relation to unique aspects of the GCC HD population.

Effect of PTH Dosing Frequency and Amplitude on Bone Health: From Anabolism to Catabolism

Alhajii Cherif1 Peter Kotanko.1,2 Renal Research Institute, New York, NY; 2Icahn School of Medicine at Mount Sinai, New York, NY.

Background: In patients with chronic kidney disease or primary hyperparathyroidism, chronically elevated parathyroid hormones (PTH) levels exert catabolic effects on the bone. In contrast, PTH cycling or daily application of teriparatide (TP) promotes bone formation. These responses have important clinical and therapeutic implications. Although the anabolic effects of PTH cycling are widely accepted, the underlying dynamics are not well understood.

Methods: We developed a physiology-based model quantitating the interrelations of osteoclasts, osteoblasts and osteocytes on bone remodeling (Cherif et al., NDT 33(1), 2018, i65-i6). Using the validated model, we explore the effect of altered PTH (TP) dosing (e.g., dosing frequency and amplitude) on bone catabolism and anabolism, respectively.

Results: The model accurately predicts differential responses of anabolic and catabolic effects of continuously and intermittently elevated PTH (TP) levels, respectively. We observe that intermittent dosing of PTH with a high frequency and amplitude induces bone catabolism similar to that seen with chronically elevated PTH. We see a more than 3-fold change from baseline in osteoclastic over osteoblastic activities, resulting in catabolism. Low PTH frequency with high dosing amplitude induces both osteoclastic and osteoblastic activities, but the net result is bone anabolism. Figure 1 shows a region where high osteoclastic activities exceed osteoclastic resorption. These findings suggest the existence of optimal PTH (TP) frequency-amplitude values that enhance anabolic gains, beyond which there can be a detrimental effect on bone.

Conclusions: Our results suggest that both frequency and amplitude of PTH (TP) cycling affect the balance of catabolic and anabolic effects. Understanding the underlying mechanism of differential responses induced by intermittent and continuous levels of PTH, respectively, may provide new therapeutic options for patients and minimize unintended, unforeseen consequences of intervention.

Illustrates regions with high osteoblastic and osteoclastic activities corresponding to anabolic gains and/or catabolic loss in bone health as a function of dosing frequency and amplitude.

Chemical Characterization and Quantitation of Circulating Intact Parathyroid Hormone and Parathyroid Hormone Fragments by High-Resolution Mass Spectrometry in Chronic Renal Failure
Kittrawee Kritmetapak,1 Louis A. Losbanos,2 Jolanne M. Hines,3 Katherine O’Grady,3 Candice Z. Ulmer,1 Hubert W. Vesper,3 Felicity T. Enders,1 Ravindra Sinha1,2 Rajiv K. Benner,2 Khon Kaen University, Khon Kaen, Thailand; ‘Centers for Disease Control and Prevention, Atlanta, GA; 3 Mayo Clinic, Rochester, MN.

Background: The precise concentrations of full-length parathyroid hormone (PTH 1-84) and the identity and concentrations of PTH fragments in patients with various stages of chronic renal failure (CRF) are unknown.

Methods: We developed a liquid chromatography-high resolution mass spectrometry (LC-HRMS) method to characterize and quantitate PTH 1-84 and PTH fragments in the serum of 221 patients with progressive renal dysfunction. Following capture by matrix-bound amino-terminal or carboxy-terminal region-specific antibodies and elution from matrix, full-length PTH and PTH fragments were identified and quantitated using LC-HRMS. PTH 1-84 was simultaneously measured using an intact PTH (iPTH) immunoassay.

Results: Full-length PTH 1-84 and eight PTH fragments (PTH 28-84, 34-77, 34-84, 37-77, 37-84, 38-77, 84-45, and 84-45) were unequivocally identified and were shown to increase significantly when the eGFR declined to less than 17-23 mL/min/1.73 m2. Serum concentrations of PTH 1-84 were similar when measured by LC-HRMS following capture by amino-terminal or carboxy-terminal immunocapture methods. Serum PTH 1-84 concentrations measured by LC-HRMS were significantly lower compared with PTH measured by an iPTH immunoassay in patients with eGFRs of less than 30 mL/min/1.73 m2. PTH 7-84 was below the lower limit of quantitation of the method (<50 pg/mL).

Conclusions: LC-HRMS accurately quantitates full-length PTH, carboxyl-terminal PTH fragments, and mid-region PTH fragments, in the serum of patients with progressive renal failure. Serum concentrations of PTH 1-84 and PTH fragments increase when eGFR decreases to less than 17-23 mL/min/1.73 m2. PTH values measured by LC-HRMS are lower than those obtained from an iPTH immunoassay in severe CRF.

Management of Secondary Hyperparathyroidism Among Patients Who Transition from Daily At-Home To Three-Times-Weekly Oral Cinacalcet Given In-Center
Steph Karpinski,1 Scott Sibbel,1 Adam G. Walker,1 Gilbert Marlowe,1 George R. Aronoff,2 Deborah A. Benner,1 Steven M. Brunclik,1 Frank R. Tenorini.1 Davita Clinical Research, Minneapolis, MN; 2 DaVita Inc, Denver, CO.

Background: Results of a small phase 1 clinical trial demonstrated the safety and potential utility of 3X weekly in-center administration of cinacalcet to control secondary hyperparathyroidism (SHP) in hemodialysis (HD) patients. Moreover, a larger prospective chart review of 195 in-center HD patients describes the safety and potential utility of 3X weekly in-center administration of cinacalcet to control secondary hyperparathyroidism (SHP) in hemodialysis (HD) patients. Moreover, a larger observational study demonstrated comparable control of SHPT among HD patients who initiated 3X weekly cinacalcet in-center to those who initiated cinacalcet at home. The present study assessed the effectiveness of 3X weekly in-center cinacalcet among HD patients who transitioned from cinacalcet administered daily at home in the management of SHPT.

Methods: Patients included in this analysis were a ≥8 years of age, receiving standard in-center HD, Medicare beneficiaries, and having a history of transition from daily at-home cinacalcet to cinacalcet given 3X weekly in-center (July 2018 to December 2019). Patients were followed forward in time for up to 9 months after transition to in-center cinacalcet or until loss to follow-up or end of study. Generalized linear modeled means and 95% confidence intervals (CIs) were calculated for parathyroid hormone (PTH), calcium (Ca), and phosphorus (Phos). Hypocalcemia events were defined as Ca <8.4 mg/dL.

Results: We identified 874 qualifying HD patients who transitioned from at-home to in-center, cinacalcet administration during the study period. Among patients with baseline PTH >800 pg/mL, PTH levels initially increased but stabilized after transition. Among patients with baseline PTH 800 to 1599 pg/mL and PTH >1600 pg/mL, PTH levels initially decreased but then stabilized following transition. Ca and Phos levels were generally stable for all patients following transition. Hypocalcemia was observed in approximately 25% to 38% of patients during follow-up.

Conclusions: These results suggest that SHPT can be stably maintained by patients transitioning from daily at-home cinacalcet to cinacalcet given in-center 3X per week. We postulate that increased prescription adherence is the likely factor mediating this effect.

PO0355
Real-World Experience with Etecalcitide in an Academic Dialysis Program
Dennis Hu, Benjamin Lobo, Brendan T. Bowman. University of Virginia Health System, Charlottesville, VA.

Background: High parathyroid hormone (PTH) levels may increase fracture risk, vascular calcification, and cardiovascular disease in end-stage kidney disease (ESKD) patients. Treatments include phosphorus binders, Vitamin D analogues, and cinacalcet.

Methods: We retrospectively reviewed PTH levels of ESKD patients with high PTH levels. Etecalcitide (ETC) is an injectable calcimimetic recently approved to treat hyperparathyroidism in ESKD. To date, few studies have described the safety and efficacy of ETC on calcium (Ca) and PTH levels in real world usage.

Results: This retrospective chart review of 195 in-center HD patients describes those who received a stable dose of ETC for at least 12 consecutive weeks. ETC dose, Ca, and PTH levels were obtained monthly x 3 months prior to ETC start and up to 9 months post. 23 patients were included for 2 or more doses of ETC. Overall and severe hypocalcemia were defined as corrected Ca <8.3 and <7.5 mg/dL, respectively.

Conclusions: ETC treatment was effective and well tolerated with no serious adverse events, although hypocalcemia was common. ETC was effective and well tolerated with no serious adverse events, although hypocalcemia was common. ETC was effective and well tolerated with no serious adverse events, although hypocalcemia was common. A Real-World Observational Study of Calcimimetic Use in Hemodialysis (HD) Patients with Secondary Hyperparathyroidism (SHPT) in Europe

Marco Joel

Indirect Comparison of Treatments for Secondary Hyperparathyroidism

Background: Calcium, oral cinacalcet (CIN) and intravenous etelcalcetide (ETEL), are approved for treating SHPT in adult patients on maintenance HD. Data on real-world use of calcimimetics are needed to provide guidance in clinical practice.

Methods: In this observational study, Chronic HD patients treated with calcimimetics for at least 3 months, and with serum calcium values within ±0.8 days following a calcimimetic initiation, were included. Data on demographics, clinical history, laboratory values and calcimimetic use were abstracted from medical charts.

Results: Interim data for 503 HD (96 CIN and 407 ETEL) patients from 57 sites across 6 countries were analyzed. Calcium levels had decreased by ≥5% and CIN use for 5 mg and 2.5 mg was recorded in ≥35% and ≥45% of CIN patients respectively. Table 1 summarizes median PTH and mean total calcium (Ca) and phosphate (P) levels. Among 341 ETEL and 79 CIN patients who had normal Ca at baseline, the cumulative incidence of hypocalcemia (<2.1 mmol/L) at 3 and 6 months was greater for CIN (47% and 58%) than ETEL (35% and 52%). As recorded in medical charts, nausea and vomiting rates at 12 months were similar for CIN (3.7% and 1.8%) and ETEL (3.6% and 1.9%). ETEL persistence (89.6%) was greater than CIN (71.8%) at 12 months. During follow-up, 13.5% switched from CIN to ETEL and 2.5% from ETEL to CIN. The proportion of patients achieving ≥30% reduction in PTH from baseline was greater for CIN than ETEL at 6 months (64% vs 54%) but similar at 12 months (73% vs 74%).

Conclusions: This is the largest real-world study on calcimimetics following 2016 approval of ETEL in Europe. There were marked reductions in PTH, Ca, and P levels. Gastrointestinal events did not differ between ETEL and CIN groups.

PO358

Indirect Comparison of Treatments for Secondary Hyperparathyroidism Through a Network Meta-Analysis

Joel Gunnarsson,1 Rosa Lauppe,2 Philipp Csomor,1 Astride Grava,1 Marco Soro.1

Yfir Pharma Ltd, Glattbrugg, Switzerland; 2Quantify Research Ltd, London, United Kingdom

Background: Secondary hyperparathyroidism (SHPT) is a complication of chronic kidney disease (CKD) affecting mineral and bone metabolism and characterized by excessive parathyroid hormone (PTH) production and parathyroid hyperplasia. Currently, the only 2 treatments indicated for the treatment of SHPT in non-dialysis CKD (ND CKD) are cinacalcet (CIN) and beta-calcimimetics (BCTs) to be included in a Network Meta-Analysis (NMA). In all the comparator groups, were considered being placebo. A quality assessment was done with the GRADE method. The treatment effects of ERC and PCT were compared using random effects in a frequentist setting, and a sensitivity analysis with a Bayesian approach performed using random effects model. Comparisons were made between the overall treatment effects of the drugs.

Results: Nine RCTs comprising a total of 1426 patients were included in the analyses. Compared to placebo, treatment with both ERC and PCT lowered levels of PTH in a statistically significant manner. No statistically significant differences in PTH reduction were found between ERC and PCT. Treatment with PCT significantly increased calcium levels compared to placebo (effect size: 0.30 mg/dl, 95% CI: 0.21 to 0.40 mg/dl), whereas a statistically significant effect for CIN (effect size: 0.10 mg/dl) was not significant (95% CI: 0.03 to 0.23 mg/dl). The calculated difference of effects between treatment with PCT and ERC shows that PCT significantly raises levels of calcium by 0.2 mg/dl (95% CI: -0.37 to -0.04 mg/dl).

Conclusions: These analyses using a well tolerated treatment option for the early management of SHPT in patients with ND CKD.

Parathyroideectomy Improves Muscular Function but Not Muscle Mass in Hemodialysis Patients with Severe Hyperparathyroidism

Eduardo J. de Sa C. Filho,1 Shirley F. Crispilho,2 Carla M. Avessani,3 Rosa M. Pereira,1 Vanda Jorgeti,4 Peter Stenvinkel,5 Bengt Lindholm,6 Rosilene M. Elias,3,2 Rosa M. Moysés,1 1Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil; 2Universidade de Novo de Juho, Sao Paulo, Brazil; 3Karolinska Institutet, Stockholm, Sweden.

Background: Increased levels of parathyroid hormone (PTH) are associated with a negative impact on the bone-muscle axis including sarcopenia and osteoporosis, and it has been hypothesized that treating hyperparathyroidism (HT) can ameliorate these disturbances. However, the effects of parathyroideectomy (PTX) on muscle mass, strength and performance have not been thoroughly investigated. This study aims to evaluate the impact of PTX on muscle mass, strength, performance, body fat and resting energy expenditure (REE) in patients with severe SHPT due to ossified parathyroid glands and parathyroid of dual x-ray absorptiometry, and REE was examined by indirect calorimetry. Participants completed the SARC-F questionnaire.

Results: At the 6 months after PTX, 20 patients who already completed the protocol, showed a significant drop in PTH [1510(1368-1885) vs. 91(38-260) pg/mL; p<0.01] and improvements of strength tests: HGS(27.4±14 vs 31.4±16 kg p=0.01); SP(26.5±15 vs 31.6±16 kg p=0.01) and LPC(24±2 vs 30±4 kg p<0.01). In addition, there was an improvement of SARC-F [10±1 vs 6±1 p=0.01] and BMI [30±7 vs 28±2 kg/m² p<0.01]. A significant increase in bone mineral content [1.81±0.22 vs 2.22±0.26 kg p=0.001], fat mass [21.8±4 vs 24.5±9 kg p<0.01] and visceral adipose tissue [530±287 vs 975±432 g] was seen. No change was noted in skeletal muscle index and in REE [1643±1573 kcal/d p=0.7). We noticed an increase in KIF-1B [199±201 u/ml p=0.04] and HOMA index [1.6±1.72 p=0.02], but no variation was found in serum albumin.

Conclusions: In hemodialysis patients with SHPT undergoing PTX, there were improvements of muscular function and bone mass, but not of muscle mass, at 6 months after PTX. Our findings suggest that PTH-associated sarcopenia is mediated not only by a decrease in muscle mass but also by muscle dysfunction.

Indications and Justification for Parathyroideectomy in Secondary Hyperparathyroidism

Aswin Srinivasan,1,2 Sangeeta Muturi,3 Shabbir Safri,1 Mahendra L. Agraharkar,1,2 University of Texas Medical Branch at Galveston, Galveston, TX; 1Bay College of Medicine, Houston, TX; 2HCA Gulf Coast Division, Houston, TX; 3University of Houston System, Houston, TX; 4Montefiore Medical Center, Bronx, NY; 5Crestview University, Omaha, NE.

Introduction: Hyperparathyroidism (HT) is a common complication of CKD, which is treated by diet, medications and surgery. Parathyroideectomy (PTEctomy) is reserved for patients with refractory HT. There are no guidelines for the timing or type of surgery. We describe five patients with HT, who were treated with different modalities with unsatisfactory outcomes.

Case Description: We present 5 patients in a table format. Patient 1 had total PTEctomy, which resulted in decalcification needing hospitalization. After 3 years, they remain hypocalcemic requiring high doses of Vit D and calcium. Selecting a suitable phosphate binder in this patient was difficult due to hypocalcemia. Patient 2 underwent total PTEctomy with autotransplantation which resulted in low calcium levels that resolved over time, but PTH levels remained very low. Patients 3 and 4 refused surgery and their PTH levels fluctuated significantly, failing to levels much below the acceptable level of 600 pg/ml. Patient 5 underwent partial PTEctomy and 2 enlarged PT glands were removed. This resulted in lower calcium and higher PTH levels than prior to surgery.

Discussion: The medical management for PHT in all patients failed. We opted for surgery when the PTH levels were in a range of 1300 to 4000 pg/mL. The surgeon decided the type of surgery. In patient 1, intraoperative PTH was measured that resulted in removal of only three glands. But within a very short time, the PTH bounced back to 2500 pg/L which was much higher than our surgical limit. Therefore, the parathyroideectomy was performed. We cannot recommend specific surgical modality based on this experience. Therefore, we strongly feel that there is a need for larger controlled studies to elucidate specific guidelines for treating refractory HT.
Palatal Brown Tumor in a Dialysis Patient

Nawal Habib, Scott Mullaney, Alexander Bullen, Danuta Trzebinska, Tamara T. Rubenzik. University of California San Diego, La Jolla, CA.

Introduction: Secondary hyperparathyroidism (SHPT) is a common complication of end stage kidney disease (ESKD) causing loss of bone density through increased osteoclastic activity. Imbalanced bone resorption and peri-trabecular fibrosis causes formation of hemosiderin-laden giant cell granulomas – brown tumors. Here is a case of palatal brown tumor in an ESKD patient which led to complications of hungry bone syndrome.

Case Description: A 57 yo F with ESKD on HD and SHPT presented with a growing palatal mass. She reported difficulty chewing and shortness of breath. A friable mass was located over the hard palate. Labs showed serum calcium (Ca) 9.5 mg/dL, PTH 4477 pg/mL, phosphate 5.1 mg/dL, and alkaline phosphatase (ALP) 1124 U/L. Parathyroid scan showed a focus of activity in the left thyroid bed. She underwent a mass resection and parathyroidectomy. Pathology revealed an atypical parathyroid adenoma without features of carcinoma. Her postoperative course was complicated by hungry bone syndrome with prolonged hypocalcemia, hypomagnesemia and hypophosphatemia which persisted despite aggressive Ca supplementation and high Ca dialysate. She was also started on teriparatide to stimulate osteoblast activity and bone formation. After a long hospital course, she was discharged on oral supplemental Ca and calcitriol with close follow-up.

Discussion: Despite the advent of effective management strategies for renal osteodystrophy, we must be mindful of brown tumors. Surgical excision with parathyroidectomy is the preferred treatment. Post-operatively, patients must be monitored for hungry bone syndrome. As bone formation increases, rising ALP levels can serve as a biomarker for increasing Ca requirements requiring escalating dosage of supplements. Teriparatide is a recombinant human PTH which can be used to augment bone density.

Etelcalcetide Effectively Treated with Cinacalcet Hydrochloride but Not with Etelcalcetide

Hironori Nakamura,1 Anayama Mariko,1 Yasushi Makino,1 Masaki Nagawa,2 Masanori Tokumoto,2 Department of Nephrology, Shinonoi General Hospital, Nagano, Japan; 2Department of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan.

Introduction: Although both cinacalcet hydrochloride and etelcalcetide are calcimimetics that directly inhibit the parathyroid hormone (PTH) secretion by activating the calcium (Ca)-sensing receptor, their binding sites are different.

Case Description: We report a rare case of a hemodialysis (HD) patient with secondary hyperparathyroidism, in whom cinacalcet was effective to reduce serum intact PTH (i-PTH) level but not etelcalcetide. A HD patient underwent total parathyroidectomy with autotransplantation to his right forearm 19 years ago. His i-PTH level had been almost controlled with 100 mg of cinacalcet. At a month after switching to etelcalcetide, serum i-PTH level increased from 269 pg/mL to 716 pg/mL. Although the dose of etelcalcetide was gradually increased to 45 mg/week, the maximal dose of etelcalcetide, serum i-PTH level increased to 919 pg/mL. Therefore, etelcalcetide was switched to 50 mg/day of cinacalcet, and his i-PTH level decreased to 208 pg/mL.

Discussion: Thus, the present case has resistance to etelcalcetide treatment but not cinacalcet, suggesting that his parathyroid gland might have partial deletion or mutation in the extracellular domain of the Ca-sensing receptor. Therefore, we should consider the possibility of resistance to etelcalcetide treatment while treating secondary hyperparathyroidism.

Hypercalcemia Resulting from Spindle Cell Tumor-Induced Calcitriol Production

Tejas Gopal,1,2 Pranu Neclam,1,2 Paul C. Nader,1,3 University of Texas at Austin, Austin, TX; 2Ascension Texas, Austin, TX; 3Austin Kidney Associates, Austin, TX.

Introduction: Less than 1% of cases of hypercalcemia of malignancy are caused by overproduction and release of 1,25-dihydroxy vitamin D (calcitriol) by tumor cells.1 Calcitriol excess has been identified most often in sarcoidosis, hematologic malignancy, and infancy.2,3 We present a patient who developed hypercalcemia and acute kidney injury as a result of spindle cell neoplasm-mediated calcitriol excess, with normalization of serum calcium and creatinine in response to treatment with prednisone.

Case Description: A 65yo man with a history of a large retroperitoneal mass presented with malaise. He was not taking calcium or vitamin D supplements. Initial lab showed serum calcium 15.7 mg/dL, 1,25-dihydroxy Vit. D 126 pg/mL (elevated), and creatinine 4.5 mg/dL. His PTH 8 pg/mL, PTHrP 0.8 pmol/L, and 25-hydroxy Vit. D 26 ng/mL were suppressed or normal. SPEP, UPEP, serum immunofixation, and serum free light chains were unremarkable. Pathology of the mass revealed a spindle cell neoplasm embedded within fibrous stroma. Prednisone was prescribed to suppress tumor-associated calcitriol production. His serum calcitriol level fell to 33.2 pg/mL, with a serum calcium of 10.9 mg/dL, after taking prednisone 40 mg/day for 2 weeks. His calcitriol 39.2 pg/mL, calcium 8.7 mg/dL, and creatinine 0.81 mg/dL levels were normal while on prednisone 20 mg/day at 76 days after starting corticosteroids and before any anti-tumor therapy or surgical debulking.

Discussion: The conversion of 25-hydroxy Vit. D to calcitriol is catalyzed by 1-alpha hydroxylase, a phenomenon that can occur in extra-renal tissues, such as within macrophages in sarcoid tissue.4 We hypothesize that elevated 1-alpha hydroxylase activity in spindle tumor cells or in activated macrophages within tumor stroma was responsible for excess calcitriol production and the resultant hypercalcemia. Corticosteroids inhibit the 1-alpha hydroxylase conversion of 25-hydroxy Vit. D to calcitriol and have been used successfully to reduce malignancy-induced calcitriol production.5-7 This case provides evidence of severe hypercalcemia due to endogenous production of calcitriol associated with a large spindle cell neoplasm, with rapid normalization of both serum calcium and calcitriol levels in response to treatment with prednisone, without anti-tumor therapy or surgical debulking.
Unexplained Persistent Hypercalcemia After Liver Transplantation
Luba Muaddi, Kalathil K. Sureshkumar, Bhavna Chopra. Allegheny General Hospital - Western Pennsylvania Hospital Medical Education Consortium, Pittsburgh, PA.

Introduction: Hypercalcemia has been reported as a sequela of chronic liver disease in association with hyperbilirubinemia. Previous reports of hypercalcemia post liver transplant were thought to be potential rare complication of altered bone metabolism under intense immunosuppression and from prolonged immobilization. However the pathogenesis of this rare phenomenon has not been clarified to this date. We present cases of unexplained severe persistent hypercalcemia in three liver transplant recipients.

Case Description: Hypercalcemia post liver transplant in 3 recipients described in Table 1 and calcium trends shown in Figure 1

Discussion: Extensive work up for hypercalcemia was negative in our patients. Although immobilization could be contributory, other unrecognized possibilities are plausible. Immunosuppression with steroids and other agents, especially cyclosporine, has been hypothesized to cause calcium imbalance by inhibiting T cell activation and transcription of interleukin-2 which are involved in bone turnover. Depletion of T cells upregulates osteoclastogenesis through prostaglandin production; by interfering with receptor activator of nuclear factor kappa ligand (RANK-L) and osteoprotegerin on osteoblasts. However, only one patient was on cyclosporine. Other, yet unidentified, factors modifying calcium metabolism could be involved. We would like to draw attention to this fascinating phenomenon in order to gain more insight. Low dialysate calcium, pharmacotherapy (Calcitromin, Pamidronate and Denusomab) along with improved mobility has successfully lowered serum calcium in these patients. One patient had hypocalcemia after Denusomab administration, hence needed careful monitoring.

Hypercalcemia cases post liver transplant.

Figure 1: Calcium trends and treatments.
Methods: Patient level data was collected via an online, HIPAA-compliant form in June 2019 as part of an independent chart audit. A total of 1,015 patient records (789 in-center HD, 200 PD, and 26 home HD) were submitted by 159 nephrologists. Patients had been on dialysis for at least six months (Mean: 26, Median: 15) and most were in LDO-affiliated units.

Results: Patients in the consistently high group had been on dialysis longer than those consistently in target or in the target-high variability group (36 months vs. 23 months) and were also younger on average (53 years vs. 61 years). Those in the consistently high and high-target group (CH/HT) had a 1.77 higher daily pill burden (from binders) than those consistently in target. Patients dialyzing in Fresenius units were the most likely to be consistently in target (27%). Compared to those consistently in target, those in the CH/HT group were significantly more likely to have diabetes, obesity, heart failure and coronary artery disease. They were also six times as likely to have poorly controlled hypertension. Ethnicity also was correlated with phosphate control with a disproportionate percent of non-white patients in the consistently high and high-target variability groups.

Conclusions: Not only is hyperphosphatemia rampant at any given time, but only a small minority of patients on phosphate binders (19%) are able to achieve consistent control; most patients fluctuate in and out of target. Increased phosphate binder dosing was not associated with better control and suggests that a new approach to the management of hyperphosphatemia is warranted.

PO0368

Hyperphosphatemia with Elevated Serum FGF-23 and PTH, Reduced Calcitriol, and Normal FGF7 Concentrations Characterizes Chronic Renal Failure in Humans

Kittrawee Krithipatak,1,2 Louis A. Losbanos,3 Taylor Berent,1 Susan L. Askarzadeh-Kian,1 Alicia Algeciras-Schimnick,1 Jolane M. Hines,1 Ravinder Singh,1 Rajiv Kumar.1 1Mayo Clinic Minnesota, Rochester, MN; 2Kohn Kaen University, Khon Kaen, Thailand.

Background: Fibroblast growth factor 23 (FGF23), a phosphatonin produced by osteocytes, regulates phosphate (Pi) homeostasis and is increased in CKD. A recent study showed that low serum (s) concentrations of FGF7 may contribute to hyperphosphatemia in patients with hyperphosphatasia, and are elevated in some patients with tumor-induced osteomalacia and hypophosphatemia. We hypothesized that FGF7 might play a role in compensating for elevated Pi concentrations in CKD.

Methods: We measured serum concentrations of intact FGF7 (iFGF7; R&D Systems), iFGF23 (Eagle Biosciences), intact parathyroid hormone (iPTH) by enzyme-linked immunosorbent assays and determined s Pi, and 1,25-dihydroxyvitamin D (1,25(OH)2D, by mass spectrometry) among 75 non-kidney transplant patients with varying estimated glomerular filtration rate (eGFR). Relationships between these parameters and eGFR were explored.

Results: For sFGF of 60 or more (n=29), 45-59 (n=14), 30-44 (n=9), 15-29 (n=13), and under 15 mL/min/1.73 m2 (n=10), the median (IQ25-75) iFGF23 concentrations were 46.1 (40.8-56.1), 43.1 (39.2-49.2), 45.4 (39.5-53.8), 47.7 (38.5-54.6), and 46.1 (40.8-54.6) pg/mL, respectively (P<0.01). At comparable eGFRs, median (IQ25-75) iFGF7 concentrations were 46.1 (40.8-56.1), 43.1 (39.2-49.2), 45.4 (38.5-53.8), 47.7 (38.5-54.6), and 46.1 (40.8-54.6) pg/mL, respectively (P=0.81). Negative correlations between Pi and s FGFR (r=-0.46; P<0.01), iPTH and s FGFR (r=-0.33; P<0.05), and a positive correlation between 1,25(OH)2D and eGFR (r=0.51; P<0.01) were demonstrated. Significant increases in iFGF23, iPTH, and Pi were observed at eGFRs of less than 33 (95% CI, 36.57-81.43). iFGF7 concentrations did not significantly correlate with Pi, iFGF23, iPTH, and 1,25(OH)2D.

Conclusions: Increases in serum concentrations of Pi, iFGF23, iPTH, but not iFGF7, and decreases in 1,25(OH)2D are observed as renal function declines in CKD.

PO0369

Effects of a Reduced Phosphorus Diet on the Circulating Metabolome in Healthy Adults

Shejuti Paul, Orlando M. Gutierrez. University of Alabama at Birmingham, Birmingham, AL.

Background: Excess phosphorus intake is linked to hypertension, heart failure, and disorders of bone and mineral metabolism. The reasons for these associations are unclear. Most prior work on the effects of diet phosphorus has focused on changes in specific endocrine factors in the blood. Less is known about the effects of nutritional phosphorus changes in specific analytes of note within each of these pathways are depicted in the Figure. Changes in specific analytes of note within each of these pathways are depicted in the Figure.

Conclusions: In healthy adults, a reduced phosphorus diet altered metabolites related to the microbiome, urea cycle, steroid hormones, energy and lipid metabolism.

Hospital Admission Rates Among Hemodialysis Patients with Persistent Hyperphosphatemia Who Were Prescribed Changes in Phosphate Binder Treatment: A Retrospective Analysis of Real-World Data

Sagar U. Nigwekar,1 Vidhya Parameswaran,2 Linda Ficociello,3 Claude Mullon,2 Michael S. Anger,2 Robert J. Kossmann,1 Massachusetts General Hospital, Boston, MA; 2Fresenius Medical Care Renal Therapies Group, Waltham, MA; 3Fresenius Medical Care North America, Waltham, MA.

Background: Phosphate binders (PB) may have different formulations, potency, and pill burden, however, there is limited data on hard outcomes to support decisions in PB therapy. The goal of this retrospective analysis is to determine the rate of all-cause hospital admissions of patients who, at baseline, remained hyperphosphatemic despite treatment with sevelamer carbonate (SC) and had prescriptions to either (1) switch to monotherapy sucroferic oxhydroxide (SO) or (2) switched to Non-SO binders [Calcium Acetate, Lanthanum Carbonate, or Ferric Citrate] or added one of these PBs to SC therapy.

Methods: Deidentified clinical and prescription data were retrospectively extracted from the Fresenius Kidney Care database and pharmacy records. All prescription changes were the result of routine clinical care. We aimed to control for selection bias by using Inverse Probability of Treatment Weighting (IPTW). This method was chosen due to its ability to balance baseline characteristics between the two groups and maintain adequate sample size.

Results: We identified 1,076 patients with baseline hyperphosphatemia despite SC prescription who switched PB therapy, including 319 patients with SO therapy and 757 patients with Non-SO therapy. Patients switched to SO had 27 fewer hospital admissions per 100 patient-years compared to patients with Non-SO therapy (Table 1).

Conclusions: In a retrospective database analysis of hemodialysis patients previously treated with sevelamer carbonate and switched to SO or Non-SO phosphate binder therapy, patients switched to SO monotherapy had a lower rate of hospital admissions than patients switched to other, non-SO phosphate binders.

An Observational Analysis of Hospital Admissions and Total Member Costs Associated with the Use of Various Pharmaceutical Binders Used in Dialysis Patients Included in ESRD Seamless Care Organizations
Kristian C. Lindemann,1 Christiana Ajala,1 Melissa M. Rosen,2 Claudy Mullon,2 Robert J. Kossmann,2 Terry L. Ketchersid,1 Linda Ficociello.1 Fresenius Medical Care Renal Therapies Group, Waltham, MA; 1Fresenius Medical Care North America, Waltham, MA; 2Fresenius Medical Care North America, Waltham, MA.

Background: A prior observational study using real world data and estimates of hospitalization costs based on national data, found patients continuing sucralfate oxyhydroxide (SO) therapy had fewer hospital admissions and expected lower healthcare costs when compared to patients switching to another phosphate binder (PB). End Stage Renal Disease (ESRD) Seamless Care Organizations (ESCOs) coordinate treatment for Medicare dialysis patients in the U.S. By providing quality care, ESCOs may control costs by avoiding unnecessary hospitalizations. The aim of this analysis was to assess hospitalizations and costs associated with various PBs prescribed to dialysis patients in ESCOs.

Methods: Patients included in the analysis had PBs prescribed during 2016-2018 in ESCOs along with parathyroid (PTH) levels <$000 pg/ml. Aggregated utilization and cost data from 24 ESCOs were used over 3 years. Total hospital admissions and member months (MM) were used to calculate hospital admission rates and rate ratios. The statements contained in this document are solely those of the authors and do not necessarily reflect the view or policies of CMS. The authors assume responsibility for the accuracy and completeness of the information contained in this document.

Results: Hospital admission rates were found to be lower for SO (Table). Compared to MM treated with SO, an increased hospital admission rate of 11%, 20%, 32%, and 42% was observed for MM treated with SEV, CaAC, FC, and LC, respectively. In addition, the total per member per month (PMPM) healthcare costs were lower for SO ($5670) compared to FC ($5908), CaAC ($6104), CaAC ($6303), and SEV ($6354), respectively.

Conclusions: Data from 24 ESCOs showed differences in hospital admission rates with the lowest rate in SO (7.97 per 100-member month (MM)) and the highest in CaAc (11.28 per 100-MM). In addition, total costs of care per MM where SO was prescribed were lower when compared to other PBs.

PO0372
Determining the Value of Pharmaceutical Treatment of Hyperphosphatemia with Phosphate Binders: A Systematic Review
Lindell, Christiana,1 Melissa M. Rosen,1 Michael S. Anger,1 Robert J. Kossmann,2 Claudy Mullon.2 Fresenius Medical Care Renal Therapies Group, Waltham, MA; 1Fresenius Medical Care North America, Waltham, MA; 2Fresenius Medical Care North America, Waltham, MA.

Background: Phosphate binders (PBs) are the primary therapeutic treatment for hyperphosphatemia in ESRD patients receiving dialysis. Medicare spending on PBs has been estimated to be over $1.5 billion. There is increased focus on value-based prescribing as a method to control rising healthcare spending in the U.S. However, guidance to support such decisions is limited. The purpose of this study was to review economic evaluations of PBs to understand if specific binders are associated with greater value to patients and payers.

Methods: We conducted a systematic literature review with results restricted to economic evaluations published in English in peer reviewed journals between January 1995 and May 2020. Studies included in the review reported cost-effectiveness outcomes. Results: After removing irrelevant articles and duplicates, 8 publications were found that met our inclusion criteria. Four (50%) studies compared either sevelamer carbonate (SEV) or lanthanum carbonate (LC) to calcium-based binders. SEV or LC was found to be cost-effective compared to calcium-based binders. Two studies focused on ferric citrate (FC) with one comparing FC to the standard of care (either calcium acetate, SEV, or LC), and the other to SEV or calcium acetate. The results favored FC based on differences in the use of erythropoiesis-stimulating agents and hospitalization risk. However, these studies did not examine the potential for unsafe levels of iron absorption associated with FC use. The remaining two studies evaluated sucralfate oxyhydroxide (SO). One study found SO to be cost-effective relative to SEV based on clinical trial data. The other analysis looked at patients prescribed SO for two years compared to those who discontinued use after 90 days and switched to another binder. This model estimated that SO use had the potential to be cost-saving based on reduced risk of hospitalization. We were unable to find an economic evaluation that compared the two iron-based binders, SO to FC.

Conclusions: This review demonstrates the need for more economic evaluations of phosphate binders. Our one cost-effectiveness analysis was found that compared two non-calcium binders (SO vs SEV) head-to-head. In addition to cost analyses, payers may benefit from reviewing real-world data to examine the clinical benefits of specific phosphate binders.

PO0373
Effect of Lanthanum Carbonate on Blood Pressure in CKD: The COMBINE TRIAL
Mitra Jamshidian,1 Brett Larive,1 Jennifer J. Gassman,1 Kalani L. Raphael,1 Michelle Chonchol,2 Joachim H. Ix,1 Charles Ginsberg,1 1Cleveland Clinic, Cleveland, OH; 2University of Colorado Denver School of Medicine, Aurora, CO.

Background: Higher serum phosphate concentrations are associated with vascular calcification, cardiovascular events, and all-cause mortality. Emerging data suggests that higher serum phosphate may also be associated with increased blood pressure (BP). The effect of phosphate-lowering medication on BP has not been studied in a chronic kidney disease (CKD) cohort.

Methods: We evaluated patients from the CKD Optimal Management with Binders and Nicotinamide (COMBINE) Trial, a randomized, double-blind, placebo-controlled trial of phosphate binders and/or nicotinamide in patients with eGFR 20-45 ml/min/1.73m2. Our primary end point for this analysis was 12-month change in systolic BP (SBP).

Results: 205 participants underwent randomization. The mean (± SD) baseline age was 59±12 years, eGFR was 32±7 ml/min per 1.73 m2, and SBP was 129±17 mmHg. Over the 12-month trial, compared to the non- lanthanum arms (N=102), SBP in the lanthanum arms (N=103) rose by 5 mm Hg (P value 0.0497) after adjusting for baseline BP, age, sex, baseline eGFR, clinical center and number of antihypertensives over time. Within the lanthanum arms SBP rose by 5 mm Hg (95% CI 1, 9 mm Hg) and diastolic BP rose by 2 mm Hg (95% CI 0.4, 4 mm Hg). BP did not change in the non-lanthanum carbonate arms. There was no association between 24-hour urine phosphate excretion and change in BP.

Conclusions: Among trial participants with moderate to severe CKD, randomization to lanthanum carbonate was associated with increased BP. Future studies should determine whether lanthanum carbonate influences absorption of anti-hypertensive medications.

PO0374
Efficacy of Tenapanor for the Control of Serum Phosphorus in Patients with CKD on Dialysis: Novel Mechanism of Action Allows for Both Monotherapy and Dual-Mechanism Approach
David P. Rosenbaum, Yang Yang, Areldy Inc, Fremont, CA.

Background: Tenapanor (TEN) is an investigational, first-in-class, non-binder, phosphate absorption inhibitor being developed to control serum phosphorus (sP) in patients with chronic kidney disease (CKD) on dialysis. It has a unique mechanism of action and acts locally in the gut to inhibit the sodium-hydrogen exchanger 3 (NHE3). This results in the tightening of epithelial cell junctions, reducing paracellular uptake of phosphate, the primary pathway of phosphate absorption, thereby reducing serum phosphorus concentrations.

Methods: Two Phase 3 studies were completed. An 8-week, double-blind (DB), randomized treatment period (RT) with a 4-week placebo (PBO)-controlled randomized withdrawal period (RW) examining the efficacy of TEN as monotherapy to treat hyperphosphatemia (HP) in patients with CKD on dialysis (NCT0342725) and a 4-week, randomized, DB, PBO-controlled study examining the efficacy of TEN administered with phosphate binders (BIND) using a dual mechanism approach to treat patients with uncontrolled HP (≥5.4 mg/dl) in patients with CKD on dialysis (NCT 03824587).

Results: In the monotherapy study, 219 patients were randomized to the RT, 164 patients (75%) completed the RT, and of these, 152 (93%) completed the RW. TEN achieved the primary endpoint with a LS mean difference of -0.8% (95% CI: -1.4, -0.2, p=0.01) in sP between TEN and PBO during the RW period. Approximately 50% of the patients treated with TEN achieved a mean sP reduction of 2.56 mg/dl from baseline to the end of the RT period. In the dual mechanism study, 236 patients were randomized to treatment. At week 4, the mean change in sP was significantly greater in the TEN+BIND arm (0.84 mg/dl v. -0.19 mg/dl in the PBO+BIND arm, p=0.0004). Twice as many patients achieved sP<5.4 mg/dl with TEN+BIND than with PBO+BIND (up to 49.1% v. up to 23.5%, p<0.01).

In both studies, the most common adverse event for patients treated with TEN was nausea which was less than 2% of patients treated with TEN.
**PO0375**

**Efficacy and Safety of Add-on Tenapanor to Phosphate Binders for Refractory Hyperphosphatemia in Japanese Patients on Hemodialysis:**

### Background:
Among hemodialysis (HD) patients, some patients have poorly controlled serum phosphorus levels, even when using phosphate binders (PB). Tenapanor is a novel agent, which reduces phosphate uptake by selectively inhibiting sodium/hydrogen exchanger isoform NHE3 on the apical surface of the enterocytes and thus decreasing paracellular phosphate permeability. The mechanism of action is different from conventional PB used to treat hyperphosphatemia. The additional treatment of tenapanor is expected to reduce serum phosphorus levels in HD patients with poorly managed serum phosphorus levels by PB. Here, we evaluated the efficacy and safety of adding tenapanor to PB for refractory hyperphosphatemia in patients on HD.

### Methods:
This was a multicenter, randomized, double-blind, placebo (PLA)-controlled, Phase 2 study. The study consisted of a screening period, a 2 or 3-week observation period, and a 6-week treatment period. Patients whose serum phosphorus level was ≥6.1 and ≤10.0 mg/dL with PB were randomized to either tenapanor+PB or PLA+PB group in a 1:1 ratio. Starting dose of tenapanor was 30 mg BID, which could be reduced in a stepwise manner (30, 20, 10, and 5 mg BID) at the investigator’s discretion, based on GI tolerability. The primary endpoint was the change in serum phosphorus level from baseline value at the end of treatment.

### Results:
Results: 47 subjects were randomized. Mean change in serum phosphorus level from baseline was −1.99 mg/dL in the tenapanor group and 0.08 mg/dL in the PLA group (95% CI: −2.89, −1.26 mg/dL; p<0.001). The achievement ratio of target serum phosphorus level (≤6.0 mg/dL) at the end of treatment was 87.0% in the tenapanor group and 74.2% in the PLA group. Diarrhea was the most frequent adverse event (tenapanor=65.2%; PLA=16.7%), all were of mild to moderate severity.

### Conclusions:
Tenapanor showed a significant decrease in serum phosphorus levels compared with PLA (p=0.001) under PB combination. This result suggests that combination of tenapanor with PB could be the utmost needs to better control serum phosphorus in HD patients with refractory hyperphosphatemia.

**PO0377**

**Changes in Serum Phosphorus Among Patients Who Switch from Sevelamer Carbonate to Sucroferric Oxyhydroxide or Other Phosphate Binders After Persistent Hyperphosphatemia**

**Background:** Despite being prescribed phosphate binders (PB), many HD patients have persistent hyperphosphatemia. The current analysis examines serum phosphorus (sP) and pill burden changes among patients who have 3 months of sP > 5.5 mg/dL despite prescription of sevelamer carbonate (SC) and switched to (1) sucroferric oxyhydroxide (SO) monotherapy, or (2) Non-SO binders [Calcium Acetate, Lanthanum Carbonate, or Ferric Citrate] monotherapy or added one of these PBs to SC therapy.

**Methods:** All deidentified clinical and prescription data were extracted retrospectively from the Fresenius Kidney Care database. Follow-up was divided into quarters (Q1-Q4) to determine mean sP and PB pills/day. We applied Propensity Score Matching (PSM), Coarsened Exact Matching (CEM), and Inverse Probability of Treatment Weighting (IPTW) to address potential confounding/selection bias. PSM and CEM were used to match patients using overall PSM or agreement with each variable (CEM), and IPTW used weights on all patients.

**Results:** We identified 1,076 SC patients with baseline hyperphosphatemia who switched to SO (319 patients) and Non-SO (757 patients) PB therapy. Results from IPTW method that allowed retention of the entire sample size (n=1,076) are presented in Table 1. All PSMs/CEMs and IPTWs identified 197 and 257 matches for SO patients, respectively and noted results comparable to IPTW.

**Conclusions:** In a retrospective database analysis of HD patients with persistent hyperphosphatemia despite being prescribed SC, patients switched to SO had a mean sP decrease of 1.1 mg/dL compared to 0.79 mg/dL decrease among patients prescribed non-SO PBs. The PB pills/day decreased by 6.3 for SO-treated and 2.2 for Non-SO-treated patients.

**Funding:** Commercial Support - Fresenius Medical Care Renal Therapies Group

**PO0378**

**The Effect of Phosphate Lowering Using Sucroferric Oxyhydroxide on Endogenous Calciprotein Particle Formation in Dialysis Patients:**

**Background:** We have recently demonstrated in a randomized, controlled, cross-over study in 39 chronic hemodialysis patients with hyperphosphatemia that high-dose phosphate binder therapy with 2000 mg/d of sucroferric oxyhydroxide (SO) over two weeks significantly reduces calcification propensity as determined by the T<sub>c</sub>-test compared with a two-week wash-out phase (Cejka, Kidney Week 2019, FR-PO149). Based on these results, we hypothesized that SO would influence endogenous calciprotein particle (CPP) formation and crystallization, i.e. conversion from primary to secondary CPP.

**Methods:** To test this hypothesis, we conducted post-hoc analyses of our RCT (74% men, mean age 65±27 years, median dialysis vintage 24, IQR 16–36 months). We compared native serum CPP levels (measured by a fluorescent probe-based flow cytometry assay) by Wilcoxon matched-pairs test and hydrodynamic radii (R<sub>c</sub>) of secondary CPP formed after enrichment with exogenous calcium and phosphate (measured by three-dimensional cross-correlation dynamic light scattering) by paired t-test between the phosphate binder washout and high-dose treatment phase.

**Results:** Upon SO therapy serum phosphate levels decreased from 2.28±0.5 mmol/L to 1.63±0.43 mmol/L (p<0.0001), coincident with a reduction (median, IQR) in primary

Changes in Serum Phosphorus and Pill Burden in Peritoneal Dialysis (PD) Patients Treated with Sucroferric Oxyhydroxide (SO) as Part of Routine Clinical Care: A Contemporary Cohort

Kamary Kalantar-Zadeh,1 Linda Ficociello,2 Meijiao Zhou,2 Vidhya Parameswaran,2 Claudy Mullon,2 Robert J. Kossmann,2 University of California Irvine, Orange, CA; 2Fresenius Medical Care Renal Therapies Group, Waltham, MA; 2Fresenius Medical Care North America, St. Gallen, Switzerland.

Background: Previous real-world analyses of SO in PD patients (pts) included pts first prescribed SO within the first 2 years of SO availability in the US (2014 Cohort: Kalantar 2018). A more contemporary cohort of pts prescribed SO may have different patient characteristics or treatment patterns than earlier SO pts. The current retrospective study assessed changes in serum phosphorus (sP) and phosphate binder (PB) pill burden in PD pts recently and previously prescribed SO.

Methods: Included were adult Fresenius Kidney Care PD pts first prescribed SO monotherapy during 5/2018- 5/2019 with PB monotherapy during a 3-month baseline (BL), and sP measured the month before SO start and in ≥5 months during SO therapy. The current retrospective study assessed changes in sP and phosphate binder (PB) pill burden in pts prescribed SO in managing sP among dialysis pts. Previous real-world analyses included HD pts prescribed SO within the first 2 years following SO availability in the US (2014 Cohort, Kalantar 2018). With greater physician experience with SO and increased availability, prescription patterns may have changed over time. The current retrospective study assessed changes in sP and phosphate binder (PB) pill burden in pts prescribed SO in managing sP among dialysis pts.

Results: At BL, the 2018 Cohort (n=201) included slightly older pts (52.3 vs 50.6 yrs) with shorter dialysis vintage (22 vs 29 months) and different BL PB: sevelamer (42 vs 63%), calcium acetate (33 vs 21%), lanthanum (3 vs 5%), ferric citrate (12 vs 0%), or switched PB (8 vs 11%) compared to 2014 cohort. Lower pill burden (7 vs 10) and sP (6.52 vs 6.59) at BL were observed in 2018 cohort. In the 2018 cohort, pts achieving sP≤5.5 mg/dL increased from 21.9% at -1M to 40.4-44.4% at follow-up and the pattern was similar in 2014 cohort (25.8% at -1 M to 35.3-44.4% at follow-up). Mean SO pill/day was higher (4.7) in 2018-2019 cohort than the 2014 cohort (4.3).

Conclusions: PD pts prescribed SO as part of routine care in 2018 and 2014 experienced significant reductions in sP, and PB pill burden, and an increase in pts with sP≤5.5mg/dL.

PO0380

Assessment of Serum Phosphorus Levels in Patients Following Administration of Ferric Pyrophosphate Citrate: A Retrospective Study

David M. Brooker,1 David R. Brooker,2 Ali M. Ayyash,3 Yossi Chait,4 Brian H. Nathanson,4 Michael J. Germain,4 Grace Hospital, Morgantown, NC; 2Brooker Kidney Care, Cranberry, PA; 3Div of Nephrology, Baystate Medical Center, Springfield, MA; 4Renal and Transplant Associates of New England, PC, Springfield, MA; 5University of Massachusetts Amherst Department of Mechanical and Industrial Engineering, Amherst, MA; 6OptiStatim, LLC, Longmeadow, MA.

Background: Iron deficiency is common among hemodialysis patients contributing to chronic anemia. Ferric pyrophosphate citrate (FPC) is FDA-approved to replace iron and maintain hemoglobin in adult hemodialysis patients by delivering iron directly and rapidly to transferrin. FPC is a mixed-ligand iron complex in which iron is bound to phosphates, vitamin C, and citrate. Phosphorus regulation in ESRD patients can be challenging thus administering products containing phosphates risks increasing serum phosphorus in addition to exacerbating underlying endocrine abnormalities. The objective of this study is to assess any changes in phosphorus levels in hemodialysis patients receiving FPC.

Methods: Retrospective data from patients at a single center hemodialysis clinic was realanalyzed looking at serum phosphorus level of hemodialysis patients receiving FPC over a one-year span of time. The data analyzed included serum phosphorus levels prior to initiating therapy compared to serum phosphorus levels after being administered FPC.

Results: Forty-nine patients were included in the study. Median serum phosphorus values were at pre-therapy (median 4.8), 1-month of FPC (median 4.7, p=0.56), 6-months of FPC (median 4.8, p=0.49), and 12-months of FPC (median 5.1, p=0.36) as represented in Figure 1.

Conclusions: After analysis of serum phosphorus levels in hemodialysis patients receiving ferric pyrophosphate citrate, the findings show that there was no difference in average sP among phosphorus levels before and after therapy. Clinicians who are prescribing this medication should be aware that there is no increase in serum phosphorus in patients while receiving this therapy considering how difficult it can be to regulate phosphorus along with managing the potential consequences of phosphorus abnormalities.

Figure 1

PO0381

Real-World Effectiveness of Sucroferric Oxyhydroxide (SO) in Lowering Serum Phosphorus (sP) Among a Contemporary Hemodialysis (HD) Cohort: A 6-Month Follow-Up

Daniel W. Coyne,1 Meijiao Zhou,2 Vidhya Parameswaran,1 Linda Ficociello,2 Claudy Mullon,2 Michael S. Anger,2 Stuart M. Sprague,2 Washington University in Saint Louis School of Medicine, Saint Louis, MO; 2Fresenius Medical Care Renal Therapies Group, Waltham, MA; 3NorthShore University HealthSystem, University of Chicago Pritzker School of Medicine, Evanston, IL, USA, Evanston, IL.

Background: Clinical trial and real-world data demonstrated the effectiveness of SO in managing sP among dialysis pts. Previous real-world analyses included HD pts prescribed SO within the first 2 years following SO availability in the US (2014 Cohort, Coyne 2017). With greater physician experience with SO and increased availability, prescription patterns may have changed over time. The current retrospective study assessed changes in sP and phosphate binder (PB) pill burden in pts prescribed SO in 2018-2019 (2018 Cohort) and compare these results to the 2014 Cohort findings.

Methods: We included adult Fresenius Kidney Care HD pts first prescribed SO monotherapy during 5/2018- 5/2019, on other PB monotherapy during a 3-month baseline (BL), and had sP measured the month before SO start and in ≥5 months during SO. We compared BL to quarterly (Q1, Q2) means, calculated using mixed-effects linear regression, for PB pill burden and lab measurements.
Results: Compared to the 2014 Cohort, the 2018 cohort (n=208) was larger (vs 424), older (56 vs 51 years with shorter dialysis vintage 11 vs 16 months), more likely prescribed calcium acetate (42 vs 22%) and less likely prescribed sevelamer (41 vs 63%). The 2018 Cohort had better BL sP control (25.7 vs 15.6% pts with sP 5.5 mg/dL), yet in both cohorts SO conversion was associated with significant reductions in sP (6.39 to 6.00 vs. 6.86 to 6.41) and PB pills/day (7.6 to 4.4 vs. 9.7 to 4.0). % pts with sP at 5.5 mg/dL increased from 15.6 to 30.4% in 2014 Cohort and 25.7 to 41.3% in Cohort 2018.

Conclusions: Similar to the 2014 Cohort, a contemporary cohort of HD pts converted to SO experienced improved in sP and achieving sP ≤ 5.5 mg/dL with fewer PB pills/day. Physicians are prescribing SO to a broader patient population with different distributions of baseline PB therapy.

PO0382
Dose-Response Efficacy and Tolerability of Tenapanor on Hyperphosphatemia in Japanese Hemodialysis Patients: Results of a Randomized Phase 2 Study

Daijo Inaguma,1 Yu Sato,2 Masayuki Takamuna,2 Hirohori Kanda,2 Masafumi Fukagawa,3 Tadao Akizawa,4 Fujita Health University School of Medicine, Aichi, Japan; 2Kyowa Kirin Co., Ltd., Tokyo, Japan; 3Tokai University School of Medicine, Kanagawa, Japan; 4Showa University School of Medicine, Tokyo, Japan.

Background: Tenapanor is a novel, non-binder, targeted therapy that reduces paracellular phosphate absorption in the gut by selectively inhibiting the intestinal sodium-hydrogen exchanger isoform NHE3. In a US clinical trial by Ardelyx, Inc, tenapanor significantly reduced serum phosphate levels in hemodialysis (HD) patients with hyperphosphatemia as compared to the placebo (PLA). The purpose of this study was to confirm the efficacy, dose-response and tolerability of tenapanor on hyperphosphatemia in Japanese HD patients.

Methods: This was a multicenter, randomized, double-blind, PLA-controlled, parallel-group and dose-finding Ph2 study. The study consisted of a screening, a 2 or 3-week 1st washout (WO) period, a 6-week treatment period, and a 3-week 2nd WO period. Patients were enrolled when screening serum phosphate level was 3.5–6.0 mg/dL and increased by ≥0.1 mg/dL to 6.1–9.9 mg/dL after 1st WO. Thereafter patients were randomized to one of 5 groups (PLA, tenapanor 5 mg, 10 mg, 30 mg or 30 mg down titration (DT) twice/day). 30 mg DT group could be down-titrated in a step-wise manner (PLA: 22.0%, tenapanor 5 mg: 57.1%, 10 mg: 65.9%, 30 mg: 76.2%, 30 mg DT: 70.7%). Most of the events were mild in severity, and, in each group). The mean change in serum phosphorus at the end of treatment from baseline was 6.0 mg/dL in the PLA group, -0.64 mg/dL in the 5 mg group, -0.93 mg/dL in the 10 mg group, -1.36 mg/dL in the 30 mg group and -1.99 mg/dL in the 30 mg DT group (p<0.001 in all tenapanor groups vs PLA). The major adverse event was diarrhea, which occurred in a dose-dependent manner (PLA: 22.0%, tenapanor 5 mg: 57.1%, 10 mg: 65.9%, 30 mg: 76.2%, 30 mg DT: 70.7%). Most of the events were mild in severity, and, in each tenapanor group, only 1 to 3 subjects were discontinued from the study due to diarrhea.

Conclusions: Tenapanor was well tolerated in Japanese HD patients and significantly decreased serum phosphate level in a dose-dependent manner compared with PLA (p<0.001).

PO0383
CKD and Vitamin D Status Alter Vitamin D Metabolism

Lauren E. Thompson,1 Stacey M. Tuoey,1 Linda Preblealla; Raymond E. West,2 Michel Chonchol,2 Nirav A. Shah,3 Thomas D. Nolin,4 Melanie S. Joy,5 University of Colorado Denver Skaggs School of Pharmacy and Pharmaceutical Sciences, Aurora, CO; 2University of Pittsburgh Department of Pharmacy and Therapeutics, Pittsburgh, PA; 3University of Colorado Denver Division of Renal Diseases and Hypertension, Aurora, CO; 4University of Pittsburgh Renal- Electrolyte Division, Pittsburgh, PA.

Background: Up to 90% of people with chronic kidney disease (CKD) are vitamin D (VitD) deficient. VitD is subsequently prescribed and has documented health benefits, including nephro-, cardio-, and immune- protection. This paired study sought to evaluate and compare VitD metabolism in CKD patients and healthy controls (HC) under both 25(OH)D3 daily for 12 weeks. At week 12 (Phase 2), participants received their final dose of D, after 25(OH)D was confirmed to be replete (≥30 ng/mL). Blood was collected at serial time points for up to 336 h at each phase for determination of D3, 25(OH)D3, 1,25(OH)2D3, and 24,25(OH)2D3. Metabolism ratios (MR) were defined by the area under the plasma concentration-time curve (AUC) of pre-cursor to a subsequent metabolite. Analyses for differences were assessed by ANOVA with a Tukey-Kramer post-hoc test.

Results: Metabolism was differentially altered by VitD status and CKD. Significant differences in assessment of MR were determined in both an immediate precursor to the next metabolite in the sequence and by the parent compound (D3) to the final metabolite in the metabolism sequence. The metabolism of D3 to 25(OH)D3 and of 25(OH)D3 to 1,25(OH)2D3 were significantly decreased by CKD severity, with differences more pronounced after VitD repletion.

Conclusions: CKD severity decreased metabolism by the cytochrome 2R1 and 2B13 pathways resulting in reductions in the D3 to 25(OH)D3 and 25(OH)D3 to 1,25(OH)2D3 respectively. Daily dosing leading to repletion appears to decrease the overall conversion of cholecalciferol to its metabolites in HC and CKD patients, possibly due to saturation of metabolism pathways. Future research will evaluate the influence of daily vs. intermittent dosing on metabolism efficiency.

PO0384
Long-Term Safety and Efficacy of Tenapanor for the Control of Serum Phosphorus in Patients with CKD on Dialysis

Glenn M. Chertow,1 Yang Yang,2 David P. Rosenberg,1 Ardelyx, Inc., Fremont, CA; Stanford Medicine, Stanford, CA.

Background: Tenapanor (TEN) is an investigational, first-in-class, non-binder therapy that targets the primary pathway of phosphate absorption, providing a novel approach to treating hyperphosphatemia. TEN blocks the paracellular absorption of phosphate in the GI tract by local inhibition of the sodium-hydrogen exchanger (NHE3) and is dosed as one small pill (<12x7 mm) twice daily. Two previously conducted pivotal trials of TEN met their primary efficacy endpoint. A 52-week study consisting of a 26-week, open-label, randomized treatment period (RT) with a 12-week placebo-controlled randomized withdrawal period (RW), followed by a 14-week open label safety extension period (SE). Patients on maintenance dialysis with serum phosphorus (sP) ≥6.0 mg/dL and ≤10.0 mg/dL and a 1.5 mg/dL increase in sP following washout were randomized 3:1 to receive one 30 mg TEN tablet BID or sevelamer carbonate (SEV); a safety control) dosed per package insert. At end of RT all patients in the TEN arm were re-randomized 1:1 to either TEN or placebo for the RW. Primary endpoint was the mean change in sP from the end of RT to the end of the RW and was compared between TEN and placebo for the efficacy analysis set, defined as patients demonstrating a 1.2 mg/dL decrease in sP at the end of RT.

Results: The study achieved its primary endpoint demonstrating a statistically significant difference in least squares (LS) mean sP change (-1.4 mg/dL, p<0.0001), between TEN and placebo. For the efficacy analysis set (n=131), the mean sP decreased from 7.7 mg/dL at baseline to 5.1 mg/dL at the end of the 26-week TEN treatment, with a mean reduction of 2.6 mg/dL. During the 26-week treatment period, 77% of TEN-treated patients in the intent-to-treat population (n=807) had a decrease in sP, with a mean reduction from baseline of 2.5 mg/dL. TEN was generally well tolerated; the only AE with incidence >5% during RT was loose stools/diarrhea (53.0%), the majority of which were mild-to-moderate and transient in nature. In the RT, 17.4% of tenapanor-treated patients compared to 23.4% of sevelamer-treated patients experienced a serious adverse event. Conclusion: The trial results suggest that among patients on maintenance dialysis with hyperphosphatemia, TEN dosed one tablet twice daily is safe and efficacious as monotherapy.

Acid-Base Status More Than Dietary Acid Intake Determines Urine Citrate Excretion in CKD
Nimrit Goraya,1,2 Nicolaos E. Madas,1,3 Abdullah A. Mamun,4 Jan Simoni,1 Donald E. Wesson,1,4 Baylor Scott and White Health and Wellness Center, Boston, MA; 1University of California Los Angeles, Los Angeles, CA; 2Texas A&M University System, College Station, TX; 3Tufts University School of Medicine, Boston, MA; 4Baylor Scott and White Health and Wellness Center, Dallas, TX; 5University of Texas Health Science Center, Lubbock, TX.

Background: Lower urine excretion of the pH-sensitive metabolite citrate (UcitV) might be a clinically useful biomarker of steady-state acid (H^+ retention) not evident by plasma acid-base parameters in patients with CKD. Ongoing dietary H^+ intake might also be an important determinant of UcitV and possibly confound its utility as a biomarker of underlying H^+ retention.

Methods: We examined the influence on 8-hour UcitV (UcitV), its plasma citrate concentration (Pcit) and kidney clearance (UcitV/Pcit) components, and 8-hour urinary net acid excretion (8h NAE) of 1) ongoing dietary acid addition assessed by potential renal acid load (PRAL) and 2) steady-state acid-base status assessed by plasma total CO2 (PTCO2) and by H^+ retention [estimated by comparing observed to expected PTCO2, increase in response to retained HCO3− (administered minus UHCO3−)] 2 hours after oral NaHCO3 and bovine (0.5 mmol/kg bw), assuming 50% body wt HCO3−, normal space of distribution] in 224 patients with CKD stages 1-3 due to macroalbuminuric, non-diabetic, hypertension-associated nephropathy.

Results: Because Pcit, UcitV, UcitV/Pcit, and PTCO2, each directly associated with eGFR [p<0.01] and because H^+ retention inversely associated with eGFR [p<0.01], we adjusted reported associations for eGFR. PRAL associated directly with 8h NAE [p<0.01, R²=0.05] and inversely with UcitV/Pcit [p=0.03, R²=0.13] but not with PTCO2 [p=0.15], H^+ retention [p=0.85, UcitV/p=0.21] or Pcit [p=0.49]. PTCO2 inversely associated with H^+ retention [p=0.02, R²=0.06] but not with 8h NAE [p=0.14], UcitV [p=0.59], Pcit [p=0.11] or with UcitV/Pcit [p=0.79]. By contrast, H^+ retention associated inversely with UcitV [p=0.01, R²=0.52] and UcitV/Pcit [p=0.01, R²=0.20] not with 8h NAE [p=0.12].

Conclusions: Ongoing dietary acid intake assessed by PRAL inversely associated with UcitV/Pcit, although quantitatively less than did H^+ retention [R²=0.13 vs. 0.20], but did not contribute with the remaining measures of acid-base status. By contrast, steady-state acid-base status associated with H^+ retention associated inversely with each measure of citrate homeostasis. The data show that steady-state acid-base status is a more important determinant of UcitV than dietary acid intake and support continued exploration of UcitV as a biomarker of underlying H^+ retention in CKD.
Vascular Calcifications in Renal Transplantation

Ana Carina Ferreira,1,2 Marco Mendes,1,2 Cecilia Silva,1 Patricia Cotovio,1 Ines Aires,1,2 David Navarro,1 Fernando C. Pereira,1,2 Rute M. Salvador,2 Bruna F. Correia,2 M. Guadalupe Cabral,2 Fernando E. Nolasco,1,2 Manuel A. Ferreim,1,2 Hospital Curry Cabral, Lisboa, Portugal; 2Novo Medical School, Lisboa, Portugal.

Background: The aim of this study was to analyse the progression of vascular calcifications (VC) in a cohort of renal transplanted patients.

Methods: Prospective cohort study of de novo renal transplant patients. All patients were submitted to X-ray of the pelvis and hands (Adragão score); bone biopsy; laboratory and echocardiographic evaluation at baseline and after 12 months (time 0 and 1). At the end of the study, bone densitometry and non-contrast cardiac CT (Agatston score) were performed. Associations between variables were performed using Wilcoxon rank sum test and Spearman correlation test. STATA software was used and p < 0.05 was considered statistically significant.

Results: We recruited 85 patients during 29 months and 69 were included in the study (6 patients refuse to perform the 2nd evaluation, 5 had primary non-function of the kidney graft, I had no sample on bone biopsy in time 0 and 4 patients died). Mean age 50.1 ± 12.7 years, 59 men (69.4%), 66 caucasian (77.6%), median BMI 25.1 ± 3.4. The median baseline and 12 months Adragão score had no differences. The median coronary artery calcium score (CACS) was 48.5 (0 – 535) and median percentile was 80 (0 – 92.5). Valvular calcifications were present in 15 and 16 patients at baseline and after 1 year (p=0.05). CACS were correlated with age (p=0.001), both Adragão score (p=0.001), presence of valvular calcification in time 1 (p=0.004), baseline calcium (p=0.02), baseline and 1-year sclerostin (p=0.01; p=0.04). CACS were higher in patients with highest values of FGF23 at baseline (p=0.04). Using a pairwise correlation, vitamin D levels (r=0.4; p=0.0004), iPTH (r=0.6; p<0.001) and total cholesterol levels (r=0.3, p=0.01) were correlated with the score. Coronary calcium percentile was correlated with Adragão score in the two time points (p=0.0001; p=0.002), with presence of valvular calcifications in time 1 evaluation (p=0.02), baseline and 1-year calcium levels (p=0.004; p=0.02) and baseline sclerostin (p=0.01).

Conclusions: VC stabilize after renal transplantation. Adragão score can assess VC in renal transplanted patients. Calcium and sclerostin correlated with Agatston scores.

Clinical Outcomes in Patients with Calcifications on Kidney Biopsy

Anna R. Gaddy,1 Ranjani N. Moorthi,1 Michael T. Eadon,1 Tae-Hwi Schwantes-An,1,2 Carrie L. Phillips,1 Sharon M. Moe.1,2 Indiana University School of Medicine, Indianapolis, IN; 2Regenstrief Institute Inc, Indianapolis, IN.

Background: Calcification is often noted on kidney biopsies, but the consequences of this finding is not known.

Methods: We searched a biobank for specimens with at least two years of linked clinical data and identified those which had calcification on report. Biopsy specimens were further classified to be described as calcium oxalate (CO), calcium phosphate/dystrophic (DC), or both. Linked clinical data was examined in 3 month intervals before and after index date of kidney biopsy. Cox proportional hazard analysis was performed using a split time model to evaluate relationships between presence of calcification, type of calcification, and clinical endpoints. Linked clinical data was examined in 3 month intervals before and after index date of kidney biopsy. Cox proportional hazard analysis was performed using a split time model to evaluate relationships between presence of calcification, type of calcification, and clinical endpoints.

Results: Patients with any calcification (n=429) vs. without (n=3936) were (p=0.05) older, more likely to be white, have diabetes, lower eGFR and higher AKI/ATN on kidney biopsy specimen (31 vs. 13%). Patients with COX (n=126) vs. DC (n=260) were older, less diabetes, lower eGFR, more likely to have malabsorption or gastric bypass, and used more vitamin D. By univariate analyses, patients with any calcification were more likely to have a decline in the slope of creatinine at 6 months, 1 year, and 2 years; these findings persisted even after adjusting for baseline eGFR, bmi, proteinuria, negative biopsy findings, CAD (for 1 year beta 0.029, p < 0.001). When adjusted for age, diabetes, and baseline eGFR, patients with any calcification were less likely than those without calcification to advance to ESKD (HR 0.59; 95%CI 0.38-0.89; p < 0.05) but not to meet the outcome of death.

Conclusions: The presence of calcification on kidney biopsy specimen is associated with lower progression to ESKD and decrease in rate of decline of eGFR over time at 6 months, 1 year, and 2 years. This paradoxical finding may be due to increased AKI with recovery, rather than progressive chronic disease but requires further analyses.

Urinary Phosphate Excretion and Microvascular Function in a Population-Based Cohort

Charles Ginsberg,1,2 Alfons J. Houwen,2 Rakesh Malhotra,2 Tos Berendschot,2 Jeroen Kooman,2 Carroll A. Webers,2 Coen Stehouwer,1 Joachim H. Ix,1,2 1University of California San Diego, La Jolla, CA; 2Universiteit Maastricht, Maastricht, Netherlands; 3VA San Diego Healthcare System, San Diego, CA.

Background: Higher serum phosphate is associated with cardiovascular events and all-cause mortality. While these associations have largely been attributed to an increased risk of large vessel calcification, our previous work demonstrated a higher morning serum phosphate is associated with microvascular dysfunction. However, the relationship between 24-hour urinary phosphate excretion ([UPE]) a surrogate for dietary phosphate and microvascular function has not been explored.

Methods: We performed a cross-sectional analysis of 3,116 community-living participants that underwent a 24-hour urine collection and skin capillaroscopy, laser-Doppler flowmetry, and flicker-light induced retinal vessel responses as part of the Maastricht Study. The primary outcome was post-oclusive finger skin capillary recruitment. Secondary outcomes included capillary recruitment during venous congestion, heat-induced skin hyperemic response, and flicker-light-induced retinal arteriolar and venular dilation.

Results: The mean age of the cohort was 60 years, 48% were women, 7% had an eGFR < 60 ml/min/1.73 m², and the mean serum phosphate concentration was 3.2mg/dl. The mean UPE was 874 ± 315 mg/dl. UPE was not associated with any of the microvascular outcomes (Table 1) and there were no significant interactions between UPE and sex, diabetes status or eGFR on any of the outcomes (P>0.43). We found an inverse relationship between UPE and serum phosphate (r=-0.26, p<0.001)

Conclusions: We found no relationship between UPE and microvascular function in community-living individuals predominately with normal kidney function. Relationships between urine phosphate, serum phosphate and microvascular function require further exploration.

Complete Resolution of Calciphylaxis in a Renal Transplant Patient with Calcifediol

Mohankumar Doraiswamy,1 Priyamvada Singh,1 Shumei Meng,2 Todd E. Pesavento.1 1Comprehensive Transplant Center, The Ohio State University Wexner Medical Center, Columbus, OH; 2Division of Endocrinology, The Ohio State University Medical Center, Columbus, OH.

Introduction: Calciphylaxis is a rare but lethal disorder (mortality 60-80%) characterized by occlusion of microvasculature in the subcutaneous adipose tissue and dermis, resulting in excruciating painful, ischemic skin lesions. It commonly occurs in dialysis patients but only few cases in transplants reported. Treatment options are meager, and a multidisciplinary approach (dermatology, nephrology, nutrition, pain, palliative medicine, plastic surgery, and wound care), with surgical debridement, antimicrobial therapy, optimization of calcium-phosphorus product, dialysis adequacy, sodium thiosulfate, and hyperbaric oxygen been suggested.

Case Description: A 62-year-old female with a LDLT (2008) complicated with CKD III, lupus nephritis, hypothyroidism, presented with painful, bilateral, medial calf ischemic ulcerations, which on punch biopsy revealed calciphylaxis. Her baseline iPTH, calcium, phosphorus, and 25-hydroxyvitamin D, was 372 pg/mL, 9.4 mg/dL, 3.8 mg/dL, and 17.4 mg/dL, respectively. She was on calcitriol 0.75 mg/daily, ergocalciferol 50,000 units weekly and cinacalcet 30 mg every other day. We started her on Calcifediol 30 mg, which increased to 60 mg daily. Her calcitriol and ergocalciferol doses were reduced slowly, while cinacalcet remained the same. This led to gradual increase in 25-hydroxyvitamin D and reduction in iPTH levels without effect on the calcium-phosphorus product. Over 1-year follow-up, her ulcers completely resolved as shown in the images with marked improvement in the pain.

Discussion: Treatment of hyperparathyroidism is limited as calcitriol and ergocalciferol worsen the calcium-phosphorus product while calcimimetics cause hypocalcemia, which hinders the attempt to lower calcitriol. Calcifediol is well tolerated and causes a progressive increase in serum 1,25-dihydroxy vitamin D and reductions in plasma iPTH without a significant effect of serum calcium and phosphorus levels. This led to remarkable clinical improvement with resolution of calciphylaxis in this case. Large clinical trials mandated to test these findings.

PO0394

Rapidly Growing “Calcified Cauliflower” in the Lung of an Orthotopic Heart Transplant (OHT) Recipient on Hemodialysis (HD)

Rui Song, Ali Arif, Chandra Dass, Iris J. Lee, Dina AbdelWahab. Lewis Katz School of Medicine at Temple University, Philadelphia, PA.

Introduction: Pulmonary calcinosis is commonly seen in ESRD patients but rarely in OHT recipients. We report a rare case of an OHT recipient who developed AKI requiring RRT. CT chest was noted for rapid progressive calcifications of lungs with both dystrophic and metastatic features.

Case Description: A 48-year old male with non-ischemic cardiomyopathy who underwent OHT. The post-transplant course was complicated by biventricular failure requiring VV/ECMO and IABP support, aortic anastomotic bleeding, multiple surgeries, recurrent bacterial and viral pneumonia dependent on mechanical ventilation, and ischemic acute tubular injury requiring CRRT then switched to HD. The imaging was noted for cardiac calcification, followed by rapidly progressive lung calcification. CT chest showed diffuse ground-glass opacity and “calcified cauliflower” signs with a mixture of dystrophic and metastatic lung calcifications. Work up for hyperparathyroidism, vitamin D toxicity, malignancy was negative. Contributing factors for pulmonary calcinosis included multiple surgeries, infections of the lungs, massive transfusion with subsequent IV calcium repletion, calcium concentration in replacement fluid of CRRT, use of calcium acetate. Subsequently, the patient was put on the lowest calcium bath and longer HD hours.

CT chest: cauliflower calcification bilaterally

Discussion: Dystrophic pulmonary calcification occurs in the injured lung due to inflammation, infection, or hemorrhage. While metastatic calcification is more common in ESRD patients, primary and secondary hyperparathyroidism, or malignancy. Our case report emphasizes the importance of bone mineral disease as an underlying etiology for pulmonary calcinosis in dialysis-dependent OHT patients. The supportive approach includes avoidance of massive transfusions, IV calcium infusion, and calcium-based phosphorus binder, use of low calcium bath in HD.

**Penile Calciphylaxis: Challenges in Its Diagnosis and Management**

Isabelle Dominique V. Tomas cruz, Carl Arenos, Sachiko S. Estreller, Blythe N. Ke, Shahara Abalos-Babaran, Elizabeth Montemayor. *Philippine General Hospital, Manila, Philippines.*

**Introduction:** Penile calciphylaxis is an uncommon presentation of a rare systemic disorder.

**Case Description:** We discuss 2 cases of penile calciphylaxis in patients with end stage kidney disease on hemodialysis presenting with painful ulcerations and eschar formation on their penile shaft. Diabetes mellitus, hyperphosphatemia and vascular calcifications on radiographs were common in both patients. A multidisciplinary approach to management involved wound care with irrigation followed by application of petrolatum-impregnated wet-to-dry dressing, antibiotic therapy, intensification of hemodialysis and use of intravenous sodium thiosulfate. Both patients showed good wound healing on discharge.

**Discussion:** Skin biopsy may aid in confirmation, but should be weighed against the risks of provoking nonhealing wounds & secondary infection. A high index of suspicion and multidisciplinary management are key components; but, prognosis is poor with survival rates reported to be less than a year upon diagnosis.
PO0397
High Turnover Bone Disease After Successful Parathyroidectomy in a Dialysis Patient
Yahya R. Ahmad, Katherine M. Donaldson, Matthew Shea, Florence Lima, Madhumathi Rao. University of Kentucky Department of Nephrology University of Kentucky, Lexington, KY.

Introduction: We report a patient with end stage renal disease (ESRD) on hemodialysis (HD) with history of successful near-total parathyroidectomy (PTX) and normal to low parathyroid hormone (PTH) levels, found to have high-turnover hyperparathyroid (HPT) bone disease, complicated by calciphylaxis treated with wound care and sodium thiosulfate. Patient also has history of focal segmental glomerular sclerosis of her native kidneys, gastric bypass, uterine cancer requiring radiation, and psoriatic arthritis and gout requiring steroids. Labs showed corrected calcium 9.4 mg/dL, serum phosphorus 7.9 mg/dL, 25-OH-vitamin D3 16.9 ng/mL, bone specific alkaline phosphatase 12.8 ug/L, intact PTH level 34 pg/mL (consistent with past values). PTH-(1-84)/(7-84) ratio 1.1 (Scantibodies CA). She was started on weekly ergocalciferol. Bone bx showed persistent high-turnover/HPT bone disease with normal mineralization and low bone volume (2019, Figure 1). Relative to her prior bx, however, there was a demonstrable decrease in bone turnover and volume.

Discussion: Bone bx studies showing the evolution of bone disease after PTX in ESRD patients are limited. Development of adynamic bone is often presumed, but not established. In this patient, osteoporosis was related to high bone turnover, despite near-total PTX in 2014 for secondary hyperparathyroidism and bx proven severe HPT bone disease, complicated by calciphylaxis treated with wound care and sodium thiosulfate. Patient also has history of focal segmental glomerular sclerosis of her native kidneys, gastric bypass, uterine cancer requiring radiation, and psoriatic arthritis and gout requiring steroids. Labs showed corrected calcium 9.4 mg/dL, serum phosphorus 7.9 mg/dL, 25-OH-vitamin D3 16.9 ng/mL, bone specific alkaline phosphatase 12.8 ug/L, intact PTH level 34 pg/mL (consistent with past values). PTH-(1-84)/(7-84) ratio 1.1 (Scantibodies CA). She was started on weekly ergocalciferol. Bone bx showed persistent high-turnover/HPT bone disease with normal mineralization and low bone volume (2019, Figure 1). Relative to her prior bx, however, there was a demonstrable decrease in bone turnover and volume.

Figure 1: Anterior iliac crest bone biopsy: 1A – Trichrome stain 10x showing osteoclastic activity with tunnelling in trabecular bone and increased osteoid volume and surface 1B – Fluorescent microscopy for tetracycline labelling 10x showing double labels and diffuse uptake in woven bone

PO0398
Successful Treatment of Severe Osteoporosis with Romosozumab in a Patient Undergoing Combined Peritoneal Dialysis and Hemodialysis: A Case Report
Hyeryong Lee, Kazuhiro Fukuoka, Shinya Kaname. Kyorin University School of Medicine, Department of Rheumatology and Nephrology Kyorin Daigaku, Mitaka, Japan.

Introduction: Recently osteoporosis is becoming a bigger problem as aging of population distribution increases. However, the use of anti-osteoporotic drugs is limited because of concerns for increased rates of adverse events associated with decreased drug clearance and comorbidities such as CKD-MBD in dialysis patients. Here we present a case of severe osteoporosis that was successfully treated with romosozumab.

Case Description: A 57-year-old woman ESKD patient due to lupus nephritis had been on peritoneal dialysis (PD) combined with hemodialysis for the last 4 years. She has been suffering from systematic lupus erythematosus and complicated by severe osteoporosis probably due to long-term use of glucocorticoids and renal dysfunction. Although she was treated with vitamin D3 analogues, bisphosphonates, and denosumab, severe pains continued and had pelvic bone and vertebral fractures, followed by repeated pathological bone fractures of the ribs. Thus, we decided to use romosozumab. After administration of romosozumab, bone pains dramatically improved and fragile bone fractures became less frequent, without progression of bone destruction. Four months later levels of tartrate-resistant acid phosphatase-5b decreased, total type I procollagen N-terminal propeptide increased, and bone mineral density significantly improved. Serum calcium and inorganic phosphate levels slightly decreased, and intact PTH slightly increased, but no overall adverse effects were noted.

Discussion: Romosozumab is a humanized anti-sclerostin monoclonal antibody that has recently been introduced for the treatment of osteoporosis. While it demonstrates strong effects on osteogenesis and bone reabsorption, it also raises concerns about increased cardiovascular events. Our case suggests that romosozumab can be safely and effectively used for the treatment of osteoporosis, at least for a short period, in patients undergoing dialysis, although further study is clearly required to evaluate the efficacy of the agent.

Ethnic Differences in the Association of Kidney Function and Low Bone Density
Joshua Chang, Malini Chandra, Jeanne A. Darbinian, Nirmala D. Ramalingam, Joan C. Lo, Stijie Zheng. Kaiser Permanente Oakland Medical Center; Oakland, CA.

Background: Chronic kidney disease (CKD) is an important risk factor for bone disease and fracture. Here, we examined the relationship between reduced kidney function (RKF) and bone mineral density (BMD) in women. We also examined PTH and calcium levels among a subset of patients with advanced CKD and low BMD (osteoporosis range).

Methods: We examined femoral neck BMD in 118,484 women age 60-79 with an ambulatory creatinine/eGFR within 1 year of the BMD scan and compared the proportion with low BMD (T-score ≤ -2.5) by kidney function. Presence of hyperparathyroidism (PTH > 65 and > 130 pg/mL) and hypercalcemia (Ca ≥ 10.5 mg/dL) was examined in a subset of 257 patients with low BMD and advanced CKD G3B (eGFR < 45) and G4/G5 (eGFR < 30) who had PTH, calcium, and confirmatory eGFR measured within 2 years of BMD scan.

Results: Among 118,484 women, 83% had eGFR ≥ 60, 12% had eGFR 59-45, 4% had eGFR 44-50, and 1% had eGFR < 40. Overall, 12% of women age 60-69 and 21% of women age 70-79 had low BMD, but this varied by race/ethnicity. Asians had the highest burden of low BMD. Within each race/ethnicity group, the burden of low BMD varied by RKF/eGFR (Figure). In the subset with low BMD, advanced CKD, and measured PTH and calcium, 9.7% of G3B and 5.4% of G4/G5 had PTH > 130 pg/mL (OR 95%CI 7.331 to infinity). Multivariable linear regression analysis showed the independent predictors of cortBMD Z-scores were PTH (β=0.21, p=0.005), which positively correlated with cortBMD. CortBMD Z-scores were negatively associated with PTH (r=-0.44, p<0.001) and alkaline phosphatase (ALP) (r=-0.22, p=0.03) and positively with calcium (r=0.33, p=0.001). None of the patients with PTH levels less than three times the upper limit of normal had a cortBMD Z-score below -2 SD (OR 95%CI 7.331 to infinity). Multivariable linear regression analysis showed the independent predictors of cortBMD Z-scores were PTH (β=0.35, p<0.001) and ALP (β=0.36, p<0.001) and serum calcium (β=0.21, p=0.005), which together predicted 57% of variability in cortBMD. DXA imaging did not improve this prediction.

Conclusions: The burden of low BMD and the association of RKF with low BMD varied by race/ethnicity. The majority of patients with advanced CKD and low BMD also had evidence of hyperparathyroidism when laboratory data were assessed. Our findings support guidelines for PTH and BMD screening in advanced CKD patients to optimize bone health.

Low Bone Turnover and Increasing Calcification with Lower Trabecular Bone Score in Early CKD Patients

Ammar E. Mohamed, Mohamed Ahmad, Michael Winkler, Habib Sour, Daniel Davenport, Marie-Claude M. Faugere, Hartmut H. Malicuie. University of Kentucky University of Kentucky, Lexington, KY.

Background: Little information is available on turnover abnormalities early during the development of loss of kidney function. Vascular calcifications may develop in association with bone turnover abnormalities. This study was designed to evaluate bone changes and cardiovascular calcification in early CKD patients without clinically known bone or cardiovascular disease.

Methods: This is a cross-sectional analysis of 32 adult volunteers with CKD stage 2-4. All patients underwent 1) dual energy x-ray absorptiometry including trabecular bone score (TBS). 2) Non-contrast CT for cardiovascular calcium scoring, and 3) anterior iliac crest bone biopsy after double tetracycline-labelling and mineralized bone histology with histomorphometry.

Results: The mean age of the patients was 61±11 years. Patients tended to be obese (75%), white (72%), and female (59%). The mean eGFR was 44±17 mL/min/1.73 m². On bone histology low turnover was found at the higher eGFR levels in 78% and normal or high turnover at lower eGFR levels. Mineralization was normal in all. Bone volume was normal in 75% and slightly low in the others. Correlation between bone parameters and cEGR are shown in Table 1. Coronary artery calcium (CAC) score was above 400 in 31%, between 100 and 400 in 24%, and less than 100 in 45% of patients. TBS correlated negatively with CAC-scores (R=0.43, p=0.02), and hip fractures (R=0.49, P=0.0001). The mean area of AGEs deposits in the cortical bone was 5.4±12.1%; cortical thickness were negatively correlated with serum pentosidine levels (R=-0.27; P=0.02) and age (R=-0.235; P=0.04); cortical porosity was positively correlated with serum pentosidine levels and correlated with their risk for osteoporotic fractures. Serum pentosidine levels were associated with low thickness of cortical bone. Cortical porosity was associated with serum glycosylated hemoglobin levels, SOST and RANKL mRNA expression. RANK was positively influenced by serum pentosidine levels. Together these data point to a direct relationship between AGEs and fractures in patients with CKD.

Bone-Derived Hormones, Mineral Metabolism, Cardiovascular Disease, and Patient Survival in ESRD

Ana Carolina Ferreira,1,2 Marco Mendes,1,2 Cecilia Silva,1 Patricia Cotovio,1 Ines Aires,1,2 David Navarro,1 Fernando C. Pereira,1,2 Rute M. Salvador,1 Bruna F. Corrêa,1 M. Guadalupe Cabral,2 Fernando E. Nolasco,1,2 Ana Carolina Ferreira,1,2,3 Diary Carri Cabral, Lisbon, Portugal; 1Nova Medical School, Lisbon, Portugal.

Background: The aim of this study was to analyse the associations between chronic kidney disease-mineral and bone disorder (CKD-MBD) players [alpha-klotho, fibroblast grow factor (FGF) 23, sclerostin, parathyroid hormone (PTH), bone alkaline phosphatase (bAP), vitamin D (vitD), phosphorus (Pi), Calcium (Ca) and Magnesium (Mg)], and echocardiographic findings [left ventricular mass index (LVMi) measured by Devereux formula (sclerotic calcifications), vascular calcifications and patient (pts) outcomes].

Methods: We performed a prospective cohort study of a sample of ESRD pts listed for renal transplant. All pts were submitted to renal transplant and were followed for 12 months. Patient and graft survival were recorded. At inclusion, demographic and clinical data were collected, laboratory evaluation, bone biopsy and X-ray of the pelvis and hands (Ardaglo score) were performed. Associations between variables were performed using Wilcoxon rank sum test and Spearman correlation test. STATA software was used and p < 0.05 was considered statistically significant.

Results: We included 85 pts. Mean age 50±12.7 years, 59 men (69.4%), 66 caucasian (77.6%). The mean LVMi was 108.5 (92 – 129) g/m², with 32 patients presenting LVH and 19 valvular calcifications. Median Adraglo score was 1 (0 – 2). At the end of 12 months, 4 pts died and 5 had graft failure (non-primary function). Alpha-klotho correlated with Pi (R=0.0061) and negatively with PTH and absence of valvular calcifications (p=0.05). FGF23 correlated with Pi (p=0.001), Ca (p=0.004), PTH (p=0.003), Mg (p=0.002), and inversely with bAP (p=0.003), and presented a marginal association with Adraglo score (p=0.06). We didn’t find correlations between FGF23 and alpha-klotho or dialysis vintage or echocardiographic characteristics. Sclerostin correlated negatively (p<0.007) and PTH (p=0.04). The 3rd sclerostin tertile was associated with high scores of vascular calcifications (p=0.02). Lower levels of sclerostin were associated with pt survival at the end of 12 months (p=0.02).

Conclusions: Sclerostin. A bone formation inhibitor, seems to act as a risk factor for vascular calcifications and worse outcomes.

PO0406

Bone Mineral Density Is Not Associated with Coronary Artery Calcification in Children and Young Adults with CKD

Alexander D. Lalavigni,1,2 Nicola J. Crabtree,3 Charles Ferro,10 Varvara Askiti,4 Andronachi Mitisoni,4 Lorenzo Biassoni,4 Aimir Kaur,4 Manish Sinha,4 David C. Wheeler,4 Neil D. Duncan,4 Joyce Popoola,11 Simon McGurk,4 Kristian H. Mortensen,4 David Milford,4 Jin Long,4 Mary B. Leonard,4 Mary Fewell12,5 Rukshana Shroff,12,13 Great Ormond Street Hospital For Children NHS Foundation Trust, London, United Kingdom; 1University College London, London, GB, London, United Kingdom; 2Imperial College Healthcare NHS Trust, London, United Kingdom; 3Birmingham Women’s and Children’s NHS Foundation Trust, Birmingham, United Kingdom; 4Children’s Hospital “P. & A. Kyriakou”, Athens, Greece; 5Evelina London Children’s Healthcare, London, United Kingdom; 6University College London, London, GB, London, United Kingdom; 7Imperial College Healthcare NHS Trust, London, United Kingdom; 8Stanford University, Stanford, CA; 9Manchester University NHS Foundation Trust, Manchester, Manchester, United Kingdom; 10University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; 11St Georges Healthcare Trust, London, United Kingdom.

Background: Coronary artery calcification(CAC) has been linked with bone demineralization in older adults with CKD, but there are no studies examining this relationship in children and young adults. We studied bone mineral density(BMD) by tibial peripheral quantitative CT(pQCT) and measures of vascular health to examine the association between bone demineralization and vascular calcification in a young CKD population.

Methods: Patients with CKD4-5 and on dialysis aged 5-30 years underwent tibial pQCT [for cortical(cortBMD) and trabecular BMD(trabBMD)], cardiac CT for CAC, ultrasound for carotid intima-media thickness(IMT), carotid-femoral pulse wave velocity(cPWV) and measurement of routine serum biomarkers. All measures were expressed as Z-scores and adjusted for age, and height. CAC was expressed as Agatston score (AS).

Results: One hundred participants [median 13.82 years(IQR 10.7 to 16.5), 20% above median (44% female 57%), BMI 61.2±3.1 kg/m², height 1.55±0.11 m, 59 (56%) were male, 41 (48%) Caucasian and 16 (19%) diabetics; dialysis vintage was 21 (10-44) months. Dialysis frequency was <2.0 AU, serum pentosidine 71 (44–121) pmol/mL and glycated hemoglobin 5.4 (5-6); cortical bone volume, thickness and porosity were 22.3±9.8 μm³, 619±213 μm and 1.55 (0.9-2.7); respectively, AGEs in skin were correlated with age (R=0.53; P=0.0001), risk for major osteoporotic fracture (R=0.56; P=0.0001) and hip fractures (R=0.49; P=0.0001). The mean area of AGEs deposits in the cortical bone was 5.4±12.1%; cortical thickness were negatively correlated with serum pentosidine levels (R=-0.27; P=0.02) and age (R=-0.235; P=0.04); cortical porosity was positively correlated with serum pentosidine levels and correlated with their risk for osteoporotic fractures. Serum pentosidine levels were associated with low thickness of cortical bone. Cortical porosity was associated with serum glycosylated hemoglobin levels, SOST and RANKL mRNA expression. RANK was positively influenced by serum pentosidine levels. Together these data point to a direct relationship between AGEs and fractures in patients with CKD.

Nephrolithiasis at Baseline Did Not Increase the Risk of Nephrocalciosis Progression After Long-Term Bursosumab Treatment in Adults and Children with X-Linked Hypophosphatemia (XLH)

Farzana Perwad,1 Angel Chen,2 Lin Zhang,3 Mary Scott Roberts,1 Anthony A. Portale,1 1Ultragenyx Pharmaceutical Inc., Novato, CA; 2University of California, San Francisco, San Francisco, CA.

Background: In patients with XLH, excess FGF23 induces hypophosphatemia, leading to musculoskeletal impairments. In two Phase 3 trials (NCT025526160, NCT02015705), bursosumab significantly improved serum phosphorus concentrations in adults and children with XLH. We examined subject characteristics and long-term safety of bursosumab by the absence or presence of nephrocalcinosis (NC) at baseline (BL) from these trials.

Methods: Adults were randomized (1:1) to bursosumab 1.0 mg/kg every 4 weeks or placebo for 24 weeks; after 24 weeks, adults received bursosumab through 96 weeks. Children were randomized (1:1) to bursosumab 0.8 mg/kg every 2 weeks or oral phosphate and active vitamin D (Pi/D) for 64 weeks. NC was defined at BL and during study by ultrasonography and graded by central readers from 0 (normal) to 4 (stone formation).

Results: In adults, NC was found in 73/134 patients (54%) at BL. Age, sex, and duration of treatment with Pi/D as adults did not differ by baseline NC group. Compared with adults without NC at BL, those with NC had longer duration of treatment with Pi/D during childhood (mean [SD] 13.2 [3.2] vs 11.3 [4.9] years) but not with D. After 96 weeks in adults, median 24-hr urine calcium increased by 35% overall but remained within the normal range. NC scores increased by 1 in 573 adults with NC at BL and 5/6 adults without NC at BL. In children, NC was found in 14/61 (23%) at BL. Compared with children without NC at BL, children with NC were older (7.6 [2.8] vs 5.7 [3.4] years), more likely to be male (71% vs 36%), treated longer with Pi/D pre-enrollment (4.8 [3.3] vs 3.6 [3.0] years), and had higher 24-hr urine calcium (4.4 [5.4] vs 2.3 [1.9] mg/kg/day [normal <4.0 mg/kg/day]). After 64 weeks in children, median urine calcium decreased by 50% overall. At week 64, NC scores did not increase in any child and decreased by 1 in 8 children. Serum creatinine and estimated GFR did not change in adults or children.

Conclusions: In adults and NC at BL was associated with longer duration of Pi during childhood. In children with XLH, NC at BL was associated with longer duration of Pi and D pre-enrollment and with BL hypercalciuria. With long-term bursosumab, the presence of NC at BL did not increase the risk of NC progression.

PO0409

Proton-Pump Inhibitors Are Associated with Decreased Urinary Citrate Excretion

Parth M. Patel,1 Alexander Kandabarov,2 Escosa Aiwerioghene,1 Enrique Blanco-Martinez,2 Spencer Hart,2 David J. Leehey,3 Ahner Farooq,1 Kristin Baldea,1 Thomas Turk.1 1Loyola University Health System, Maywood, IL; 2Edward Hines Jr. VA Hospital, Hines, IL.

Background: Proton-pump inhibitors (PPIs) may increase the risk of kidney stone formation, but the mechanism(s) has not been elucidated. PPI-associated hypomagnesemia is due to impaired intestinal magnesium absorption thought to result from changes in intestinal pH that decrease binding of magnesium to its transporters. Citrate is a tricarboxylic acid with pKa values of 2.9, 4.8, and 5.6. Since citrate is transported primarily in the divalent form (citrate2+), by the intestinal sodium dicarboxylate transporter (NaDC1), changes in intestinal pH by PPIs might decrease the amount of the divalent form, thus reducing intestinal absorption of citrate, thereby decreasing alkaline load and urinary citrate excretion.

Methods: We performed a retrospective review of nephrocalcinosis patients treated at our institution and compared patients who were taking PPIs or not at the time of their 24-hour urine collections. Patients taking PPIs were older and more likely to have medical comorbidities associated with metabolic syndrome such as hypertension, diabetes, and dyslipidemia (p<0.01). Controlling for these factors, patients taking PPIs were found to have lower 24-hour urine citrate excretion (p<0.012, ΔF=4.24, df=9,34). 24-hour urine magnesium excretion was numerically but not significantly lower in patients taking PPIs. There were no other differences in urinary composition between the groups.

Conclusions: Our findings suggest that patients who take PPIs regularly may be at risk for decreased urinary citrate excretion, which is a known risk factor for kidney stone formation. It is possible that the decrease in urinary citrate with PPIs may have clinical significance, particularly in patients with idiopathic hypercalciuria or other conditions associated with hyperparathyroidism such as genetic polymorphisms of the renal-sodium-citrate co-transporter, chronic metabolic acidosis, or the use of carbonic anhydrase inhibitors, high animal protein diet intake, and incomplete distal RTA.

PO0408

Roux-en-Y Gastric Bypass and Kidney Stones

Background: Roux-en-Y gastric bypass (RYGB) is a bariatric surgical procedure that is highly effective in the management of morbid obesity but also associated with higher risk of stone formation after surgery. It is not known why RYGB is associated with higher kidney stone risk but it may be due to changes in urine composition, such as high urine calcium oxalate supersaturation (CaOx SS) and calcium phosphate supersaturation (CaP SS). It is not known who is at risk for high urine CaOx SS after surgery. We examined 24-hour urine composition in 18 men and women before and after RYGB to look for predictors of urine high CaOx SS and CaP SS.

Methods: Patients were recruited from a bariatric surgery clinic prior to scheduled laparoscopic long-limb RYGB. Three consecutive 24-hour urine collections performed in a Clinical Research Center both before and 1 year after surgery. We performed Welch's 2-sample and paired t-tests to compare mean urinary values for pre- to post-RYGB collections and to compare men to women in the post-RYGB collections. We used linear regression to evaluate predictors of urine CaOx SS and CaP SS.

Results: Seven men and eleven women completed pre- and post-RYGB urine collections. Post-RYGB, women had a significantly higher urine CaOx SS (13.1 vs 4.6, p=0.002), CaP SS (5.9 vs 1.0, p=0.05), and lower urine oxalate (1.7 vs 2.7, p=0.001) compared with men. There were no differences by sex in CaOx SS or urine oxalate pre-RYGB. Both men and women had high oxalate in the pre- and post-RYGB collections. Urine volume was most strongly associated with urine CaOx SS and a difference in urine CaOx SS of -6.4 (8.7 to -4.0) for every 1 liter of urine volume excretion. Citrate was also associated with change in -0.01 (-0.01 to -0.002) mg/l citrate. Calcium and oxalate were not significantly associated. For CaP SS, high urinary phosphorus and pH (1.3 vs 0.8 to 1.7) were associated with higher CaP SS (Calcium 0.01mg, 0.008 to 0.12mg; pH 1.3 vs 0.8 to 1.7). Higher urine volume (-0.4 -0.6 to -0.1) was associated with lower CaP SS and citrate was not significant.

Conclusions: There are important differences in urinary parameters by sex that may contribute to differences in kidney stone risk after RYGB. Women may be at higher risk for kidney stone formation after RYGB compared with men.

PO0407

A Randomized, Double-Blind, Placebo-Controlled Trial Assessing Efficacy of Standard and Low-Dose Hydrochlorothiazide Treatment for Prevention of Recurrent Caleorous Nephrolithiasis (NOSTONE Trial)

Nasser Dhayat,3 Olivier Bonny,2 Beat Roth,2 Grazia M. Ceregatti,2 Davide Costantini,4 Francesca Barra,2 Marco Gavazzi,1 Paolo Chiaravalloti,1 Gianluca Serafini,1 Marco Mazza,5 Thomas W. Wehrli,2 1Inselspital Universitatsklinik Bern, Bern, Switzerland; 2University of Bern, CTU Bern, Switzerland; 3Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland.

Background: Nephrolithiasis is a global healthcare problem with a current lifetime risk of up to 18.8% in men and 9.4% in women. Without specific treatment, 5- and 20-year recurrence rates are 40% and 75%, respectively. Given the high cost of medical treatments and surgical interventions as well as the morbidity related to symptomatic stone disease, medical prophylaxis for stone recurrence is an attractive approach. Efficacy of thiazides for kidney stone prevention was tested in 11 trials in the past. However, all these trials had major methodological deficiencies. Nowadays, thiazides are widely used in the treatment of recurrent nephrolithiasis and arterial hypertension, but at significantly lower doses. In the case of recurrent nephrolithiasis, however, this practice is not supported by randomized evidence. Thus, evidence for benefits and harms of thiazides in the prevention of kidney stones remains unclear.

Methods: NOSTONE is a multicenter, randomized, placebo-controlled, double-blind, parallel-group trial with the purpose to assess the dose-response relationship for three different dosages of hydrochlorothiazide (placebo, 12.5mg, 25.0mg, 50.0mg) in kidney stone prevention. The primary outcome is incidence of stone recurrence (a composite of symptomatic or radiologic recurrence) at 3 years, a low-dose CT will be performed at the beginning and the end of the trial. Patients from 12 hospitals throughout Switzerland were included in the trial.

Results: NOSTONE received all necessary approvals by the end of February 2017. Recruitment started in Bern on the 9th of March 2017, all study sites are operative since June 10th 2017. A total of 416 patients randomized in the trial was reached and therefore recruitment stopped (www.nostone.ch). In March 2020 the first patient randomized in the trial completed the treatment phase. All patients are expected to reach end of treatment by the end of August 2021.

Conclusions: The results of this study will affect many patients currently treated with hydrochlorothiazide for the prevention of recurrent nephrolithiasis.

Dietary Intake and Risk of Incident and Recurrent Kidney Stones

Apichai Chewcharat,1 Eric N. Taylor,2 Charat Thongprayoon,1 Lisa E. Vaughan,1 Ramila A. Mehta,1 Felicity T. Enders,1 John C. Lieske,1 Andrew D. Rule.1 1Mayo Clinic Minnesota, Rochester, MN; 2VA Maine Healthcare System, Augusta, ME.

Background: Dietary factors associated with recurrent kidney stones (KS) may differ from those associated with incident KS.

Methods: We recruited adult incident symptomatic KS formers and controls from local residents surrounding the Mayo Clinics in Minnesota and Florida between 2009 and 2018. Participants were administered the Viocare Food Frequency Questionnaire, a KS survey, and completed a 24h urine chemistry evaluation at a baseline study visit. Medical records of stone formers were reviewed for symptomatic recurrence with a visit to a confirmed stone through May 2019. Analyses compared baseline dietary factors between incident symptomatic stone formers and controls and assessed whether these same dietary factors predicted symptomatic recurrence.

Results: There were 416 incident symptomatic KS formers (74 had a recurrence during follow-up) and 384 controls. Higher dietary potassium, calcium and phytate were associated with lower odds of an incident symptomatic KS adjusting for BMI, fluid and energy intake. Dietary calcium intake predicted a lower risk of symptomatic KS recurrence (Hazard ratio for highest tertile vs lowest tertile= 0.53, 95%CI [0.28, 0.99] and 2.09, 95%CI [1.18, 3.69], respectively) adjusting for BMI, fluid and energy intake, and Recurrence of Kidney Stone score. (Table)

Conclusions: Certain dietary factors may differ in their association with incident and recurrent KS. In particular, dietary oxalate intake may be more important for preventing recurrence than for preventing a first KS episode.

Funding: NIDDK Support, Private Foundation Support

Table of results

| Table 1: Table of results for the cross-sectional study of metabolic profiles and the association with kidney stone disease in the Nurses’ Health Studies I and II |
|---------------------------------|----------------|----------------|----------------|
| Nutrient                         | Adjusted odds ratio for incident KS formers (controls) | 95% confidence interval | P-value |
| Calcium                         | 0.53 (0.28, 0.99) | 2.09 (1.18, 3.69) | 0.01 |
| Phosphorus                      | 0.72 (0.48, 1.09) | 1.80 (1.30, 2.49) | 0.01 |
| Magnesium                       | 1.49 (0.99, 2.25) | 2.70 (1.54, 4.77) | 0.01 |

Type 3 Renal Tubular Acidosis in Association with a Pelvic Kidney

Introduction: The association of renal tubular acidosis (RTA) from carbonic anhydrase isoenzyme II (CA II) deficiency, cerebral calcifications and osteopetrosis is known as marble brain disease.

Case Description: 21-year-old woman with a medical history of multiple fractures since childhood, recurrent episodes of nephrolithiasis and, renal tubular acidosis (RTA), presented to establish care at our clinic. Genetic testing had revealed she had CA II gene mutation. Her brother had the same condition but her sisters were healthy. Her medication included potassium citrate and vitamin D3. Laboratory assessment revealed the following: serum Na+ 143 mmol/L, K+ 3.9 mmol/L, CI- 109 mmol/L, HCO3 21 mmol/L, creatinine 0.73 mg/dl, Ca2+ 9 mg/dl, PO43- 4.4 mg/dl, vitamin D 7.6 mg/dl. Urine pH was 6. CT urogram revealed a normal right kidney and an ectopic left kidney with numerous small stones. (Figure 1). Spine X rays showed osteoporosis of vertebral endplates and MRI brain showed calcifications in basal ganglia. Pycnolithotomy of the pelvic stone was performed and stone analysis revealed 90% calcium phosphate and 10% calcium oxalate. 24-hour urine showed a low urine citrate with low urine volume. Thus the findings were consistent for RTA with low urine bicarbonate, low urine citrate and calcium phosphate predominant stones.

Discussion: CA II deficiency syndrome is a rare autosomal recessive disorder that results in Type 3 RTA (combined proximal and distal RTA). Pelvic kidneys, which result from a failure of mesonephros to ascend normally during early gestation, are prone to urolithiasis due to poor urinary drainage. In our patient RTA, along with altered urine flow due to pelvic kidney predisposed to nephrolithiasis.

Incidence and Characteristics of Kidney Stones in Patients on a Ketogenic Diet: A Meta-Analysis

Prakriti C. Acharya,2 Juan A. Medaura,1 Chirag Acharya,3 Charat Thongprayoon,1 Wisit Cheungpasitporn.1 1University of Mississippi Medical Center, Jackson, MS; 2Texas Tech University Health Sciences Center El Paso, El Paso, TX; 3LCCF, Hobbs, NM; 4Mayo Clinic Minnesota, Rochester, MN.

Background: Very-low-carbohydrate diets or ketogenic diets have frequently been used for weight loss in adults and as a therapy for epilepsy in children. The incidence and characteristics of kidney stones in patients on ketogenic diets are not well studied.

Methods: A systematic literature search was performed using MEDLINE, EMBASE, and Cochrane Database of Systematic Reviews from the databases’ inception through April 2020. Observational studies or clinical trials that provide data on the incidence and/or types of kidney stones in patients on ketogenic diets were included. We applied a random-effects model to estimate the incidence of kidney stones.

Results: A total of 36 studies with 2,795 patients on ketogenic diets were enrolled. The estimated pooled incidence of kidney stones was 5.6% (95%CI, 4.4%-7.1%) in patients on ketogenic diets at mean follow-up time 3.7+-2.9 years. Subgroup analyses demonstrated the estimated pooled incidence of kidney stones of 5.6% (95%CI, 4.3%-7.2%) in children and 5.6% (95%CI, 2.3%-12.6%) in adults, respectively. Within reported studies, 48.7% (95%CI, 33.2%-64.6%) of kidney stones were uric stones, 36.5% (95%CI, 10.6%-73.6%) were calcium based (CaOx/CaP) stones, and 27.8% (95%CI, 12.1%-51.9%) were mixed uric acid and calcium based stones, respectively.

Conclusions: The estimated incidence of kidney stones in patients on ketogenic diets is 5.6%. Its incidence is comparable among adults and children. Uric acid stones are the most prevalent kidney stones on ketogenic diets followed by calcium based stones. These findings may impact the prevention and clinical management of kidney stones in patients on ketogenic diets.

Association of Urine Findings with Metabolic Syndrome (met-s) Traits in Patients with Nephrolithiasis

New York, NY; 2University of Vermont Medical Center, Burlington, VT; 3University of Vermont, Burlington, VT.

Background: Met-s is a health concern related to lifestyle habits including acidogenic and high protein diets. The odds of nephrolithiasis increases with an increasing number of met-s traits. Prior studies have shown relationships among the number of met-s traits and decreasing urine pH and other acid excretion markers. We evaluated associations of urine markers including acid excretion and stone composition with the number of met-s traits in a large cohort of stone-forming patients.

Methods: A retrospective review was performed of 24-hour urine studies (Litholink, Chicago, Il) from patients seen in Urology and Nephrology divisions, UVMMC July 2009 to December 2018. Patients <18 years and those with improper collections based on creatinine/kg were excluded. Patient variables, laboratory values, associated diagnoses, and medications were identified within 6 months of urine collection and 1 year of kidney stone composition. Four groups based on the number (0, 1, 2, 3-4) of met-s traits (hypertension, obesity, dyslipidemia, diabetes) were evaluated. Trends across groups were tested using linear contrasts in analysis of variance.

Results: 1250 unique patients, 49% F, 703 with stone composition met criteria for inclusion. Met-s groups n were 0=509, 1=381, 2=203, 3+4=157. There was no difference or trends among the groups for urine volume, calcium or citrate. There was a significant trend p<0.001 for increasing number of met-s traits with decreasing urine pH and SS calcium phosphate (CaP) and increasing age, weight, protein intake, urine uric acid (UA), SS UA, oxalate, sodium, potassium, phosphorus, urea nitrogen, chloride, estimated net acid excretion and high protein intake. P=0.05 for sulfates (S), ammonium, magnesium. When adjusted for age and protein intake the trend remained significant only for urine pH and a reversed trend for S. There was a significant trend for more UA and fewer predominately CaP stones in those with more met-s traits.

Conclusions: High protein intake accounted for most of the difference in urinary markers of stone risk except low urine pH. The latter facilitates more UA and less CaP contribution to stone composition. Future studies could determine if changing diet can reduce risk for stones in met-s.

Assessment of Blood Oxalate Concentrations in Patients with CKD

Anja C. Pfau,1 Monika Wytopoli,2 Kinsksha Chauhan,3 Martin Reiche,1 Steven G. Coca,4 Peter S. Aronson,4 Kai-Uwe Eckardt,2 Felix Knaut,1,4
1Charité Universitätsmedizin Berlin, Berlin, Germany; 2Universitätsklinikum Erlangen, Erlangen, Germany; 3Icahn School of Medicine at Mount Sinai, New York, NY; 4Yale University Department of Internal Medicine, New Haven, CT.

Background: Alterations in oxalate homeostasis are associated with kidney stone disease and progression of chronic kidney disease (CKD). However, accurate measurement of plasma oxalate (P_Ox) concentration is challenging as prompt processing and acidification of samples has been deemed necessary. In the present study we examined the effects of variations in sample handling on P_Ox results. Subsequently, a standardized analytical protocol was established, and P_Ox concentrations were measured in a large cohort of patients with CKD.

Methods: We tested the effects on P_Ox results of storage time at room temperature (RT), storage on dry ice and maintenance of samples at -80°C. P_Ox results of storage time at room temperature (RT), storage on dry ice and maintenance of samples at -80°C.

Results: P_Ox concentrations increased rapidly when samples were maintained at RT. This was most relevant for P_Ox < 10 μM as concentrations more than doubled within a few hours. Immediate freezing on dry ice and storage at -80°C provided stable results and allowed postponement of acidification for > 1 year. In the GCKD study, mean (SD) eGFR at the time of P_Ox measurement was 44.0 (17.9) ml/min/1.73 m². More than half of the patients had a P_Ox concentration below 2.0 μM. P_Ox correlated positively with urinary albumin to creatinine ratio and inversely with eGFR (P < 0.001). In the lowest eGFR quartile, median eGFR was 25.1 ml/min/1.73 m² (IQR 20.3 - 28.1) with a median P_Ox of 2.7 μM (IQR 1.9 – 4.2).

Conclusions: We conclude that immediate freezing and maintenance of plasma samples at -80°C facilitates the sample collection process and allows accurate P_Ox assessment in large patient cohorts. Our study presents a critical and useful modification of the complex preanalytical procedure. Moreover, we demonstrate that P_Ox concentrations in patients with CKD are substantially lower than previously reported. The present study may serve as a reference for sample handling to assess P_Ox in clinical trials and to determine its role in CKD progression.

Underline represents presenting author.
Methods: We created a 3-tiered in vitro VC model and an in vivo uremic rat model receiving high phosphate diet to mimic uremic VC. RNAs from the in vitro and in vivo models underwent miRNA and mRNA microarray, with results screened for differentially expressed miRNAs and their target genes as biomarkers. Findings were validated in all models and human cells, followed by functional assays of identified miRNAs, and tests of sera from end-stage renal disease (ESRD) and non-dialysis dependent chronic kidney disease (CKD) patients without and with VC.

Results: Totally 122 down-regulated and 119 up-regulated miRNAs during calcification progression were identified initially; further list-narrowing based on miRNA-mRNA pairing, anti-correlation, and functional enrichment left 16 and 14 differentially expressed miRNAs and mRNAs. Levels of 4 miRNAs (miR-10b-5p, miR-195, miR-125b-2-3p, and miR-378a-3p) were shown to decrease throughout all models tested, while 1 mRNA (SULF1) was noted to exhibit the opposite trend comparatively. Among 77 ESRD (88.3% with VC) (Figure A) and 59 CKD patients (61% with VC) (Figure B), serum miR-125b-2-3p and miR-378a-3p decreased with greater VC severity, while serum SULF1 levels increased. Adding serum miR-125b-2-3p, miR-378a-3p, and SULF1 into regression models for VC substantially improved performance compared to using clinical variables alone.

Conclusions: Using a translational approach, we discovered a novel panel of biomarkers for gauging the probability/severity of uremic VC based on miRNAs and their target proteins, which improved the diagnostic accuracy.

PO0421
Clinical Characteristics and eGFR and Urine Albumin-to-Creatinine Ratio Distribution According to the 2012 KDIGO CKD Classification
From a Report of the DISCOVER CKD International Retrospective Cohort
Juan Jose Garcia Sanchez,1 Juan I. Carrero,2 Supriya R. Kumar,2 Roberto Pecoisits-Filho,3,4 Glen James,5 Hildo J. Heerspink,6 Stephen Nolan,1 Lam S. Carolyn,7,8 Hungta (Tony) Chen,1 Eiichiro Kanda,4 Alyshah Abdul Sultana,9 Naoki Kashihara,9 Mikhail Kosiborod,10 Carol A. Pollack,11 David C. Wheeler,12 AstraZeneca, Cambridge, United Kingdom; Karolinska Institutet, Stockholm, Sweden; AstraZeneca, Gaithersburg, MD; Arbor Research Collaborative for Health, Ann Arbor, MI; Pontificia Universidade Catolica do Parana Escola de Medicina Campus Londrina, Londrina, Brazil; Rijksuniversiteit Groningen, Groningen, Netherlands; National Heart Centre Singapore, Singapore, Singapore; Duke-NUS Medical School, Singapore, Singapore; Kasawaki Ika Daigaku, Karashiki, Japan; Saint Luke’s Mid America Heart Institute, Kansas City, MO; Royal North Shore Hospital, St Leonards, NSW, Australia; University College London, London, United Kingdom.

Background: Contemporary studies describing the prevalence and characteristics of patients with CKD categorised according KDIGO 2012 are scarce. We describe patient characteristics and the prevalence of CKD according to the 2012 KDIGO categories in patients with CKD.

Methods: The DISCOVER-CKD retrospective cohort of patients was extracted using real-world data from the integrated Limited Claims and Electronic Health Record (LCLCRD) data in TriNetX. Patients were aged ≥18 years, with at least 1 UACR measure and ≥1 eGFR measure, and without first diagnostic coding of CKD (Stages 3A to ESRD) or two estimated glomerular filtration rate (eGFR) closest to index was used to categorise patients. Descriptive analyses were used to summarise prevalence and patient characteristics.

Results: Preliminarily, among 22229 included patients, 63.6% (n=10979, TriNetX) and 78.6% (n=3813, LCEC) had normal to mildly increased albuminuria, 26.6% (n=4581, TriNetX) and 17.9% (n=6889, LCEC) had moderately increased albuminuria and 9.8% (n=1694, TriNetX) and 5.5% (n=273, LCEC) had severely increased albuminuria (Figure 1). Hypertension and type 2 diabetes were the most common comorbidities (prevalence >60%) and their prevalence increased with albuminuria.

Conclusions: This study, utilising real-world data, fills an important knowledge gap regarding the characteristics of patients with CKD in different eGFR and UACR strata according to the KDIGO 2012 definitions.

PO0422
Tope Olufadé,1 Lois Lamerato,2 Juan Jose Garcia Sanchez,2 Like Jiang,1 Joanna C. Huang,1 Stephen Nolan,2 AstraZeneca, Wilmington, NC; AstraZeneca UK Ltd, Cambridge, United Kingdom; Henry Ford Health System, Detroit, MI.

Background: The DAPA-CKD Trial is the first SGLT-2i renal outcome trial to test the efficacy and safety of an SGLT-2i, dapagliflozin, in patients with diagnosed CKD and without T2D. To appropriately evaluate future results and aid clinical interpretation of the DAPA-CKD trial, the present study assessed the renal and CV outcomes of a “DAPA-CKD-like population” (eGFR 25-75ml/min/1.73m² and UACR 200-5000mg/g) in a contemporary US healthcare system.

Methods: Administrative data from the Henry Ford Health System was used to identify patients with CKD stages 2 through 4 between 2006 and 2016 based on eGFR lab reading (n=38,736). Exclusions included no confirmatory eGFR > 90 days from index date, death within 30 days, history of renal transplant, and evidence of renal replacement therapy, or progression to CKD stage 5 during the baseline period (6 months pre or post index date). Within that cohort, 17,742 had eGFR (25-75ml/min/1.73m²) and 9,177 had a UACR (0-5000 mg/g) within 12 months of index date. Additional exclusions were type 1 diabetes, lupus nephritis and polycystic kidney disease. Patients were followed through December 31, 2018.

Results: Of the 6,557 patients that met the eligibility criteria and were included in the study cohort, the mean age was 62.9 years and 46.2% were male. The population was stratified by UACR (0–30, 30–199, 200–5000mg/g). Across all outcomes assessed, incidences were highest in the DAPA-CKD-like cohort (UACR 200-5000mg/g) (HF 36.1%, MI 11.3%, Stroke 8.9%; ESKD 16.8%; Mortality 18.5%; see Table 1). The greatest increase was observed for renal outcomes particularly ESKD, increasing from 0.9% (UACR 0–30mg/g) to 3.4% (UACR 30-199mg/g) to 18.6% (UACR 200-5000mg/g).

Conclusions: In a contemporary US healthcare system, there remains significant and independent renal, CV and mortality outcomes among patients fitting the DAPA-CKD study inclusion criteria. These results highlight the unmet need existing for additional therapies to delay disease progression and improve outcomes and survival in this high risk population.

NSAID Use Is Not Associated with Kidney Injury or Dysfunction in Ambulatory Older Adults
Jonathan G. Amatruda,1,2 Harini Sarathy,1 Carmen A. Peralta,1,4 Michelle M. Estrella,2,7 Ronit Katz,1 Joachim H. Ix,1 Linda F. Fried,1 Chiara R. Parikh,1 Anne B. Newman,1 Mark J. Sarnak,1 Michael Shlipak.1,9
1University of California San Francisco, San Francisco, CA; 2Kidney Health Research Collaborative, UCSF, San Francisco, CA; 3University of Washington, Seattle, WA; 4VA Pittsburgh Healthcare System, Pittsburgh, PA; 5University of California San Diego, La Jolla, CA; 6Johns Hopkins University, Baltimore, MD; 7Tufts Medical Center, Boston, MA; 8Cricket Health, San Francisco, CA; 9University of Pittsburgh, Pittsburgh, PA.

Background: NSAIDs cause AKI and may worsen CKD, especially in vulnerable populations such as older adults. We hypothesized that NSAID use would be associated with markers of both tubular and glomerular damage in older adults.

Methods: In the multicenter Health ABC cohort of ambulatory older adults, prescription and OTC NSAID use was self-reported. Estimated GFR by cystatin C, and urine albumin to creatinine ratio (ACR), KIM-1, and IL-18 were measured in 2,999 participants; urine a1m, NGAL, PiNP, and UMOD were measured in a random subset of 500 participants. We evaluated cross-sectional associations between NSAID use and these biomarkers with separate linear regression models. The association between time-updated NSAID use and eGFR decline over 10 years was estimated with linear mixed models.

Results: Participants had a mean age of 74 years, 51% were female, and 41% were African-American. No eGFR differences were detected between NSAID users (n=655) and non-users (n=2344) at baseline (72 mL/min/1.73m2 in both groups). Compared to non-users, NSAID users had 33% (95% CI: 11%-49%) lower adjusted odds of having ACR >50 mg/mg and 11% (95% CI: 4%-18%) lower mean urine IL-18 concentration at baseline. Significant differences in baseline concentrations of the remaining urine biomarkers were detected. NSAID users and non-users did not differ significantly in the rate of eGFR decline (-2.2% vs. -2.3% per year).

Conclusions: Among ambulatory older adults, NSAID use was not associated with kidney dysfunction as measured upon eight markers of kidney health, and NSAIDs were associated with significantly lower urine albumin and IL-18 concentrations. These findings illustrate the potential for NSAID use without kidney harm, even in a presumably high-risk population.

PO0424
The Prevalence of CKD Among First-Degree Relatives of Saudi Hemodialysis Patients and Associated Factors
Dujair Alharbi,1,2 Ahmak Mohammadi,1,3 Mohammed A. Alhomrayn,1 Imad Helal,1 Fayeza F. Alhejaili. Diaverum Saudi Arabia Diaverum Renal Services Group, Riyadh, Saudi Arabia.

Background: In Saudi Arabia, there are currently over 20,000 patients on dialysis and 9810 patients followed up for functioning renal transplantation. The combined prevalence of renal replacement therapy (stage 5 CKD) in Saudi Arabia is estimated to be 1294.3 PMP. There are no local data or registry about stages 1 to 4 CKD in the Kingdom. Objective: To assess the prevalence of CKD among first degree relatives of Saudi hemodialysis patients and evaluate the associated characteristics.

Methods: 1° degree relatives of all hemodialysis patients in Diaverum clinics in Saudi Arabia were screened for CKD. Demographic data were collected as well as history of hypertension or diabetes mellitus. Serum creatinine, urinalysis and a single Blood pressure reading were measured. eGFR was calculated using EPI formula. For the index cases, the cause of CKD, age and gender were recorded. The prevalence rates of CKD stages among relatives were calculated and the association between different variables and CKD stages assessed.

Results: Out of 4550 dialysis patients, 20258 1° degree relatives were approached of whom 5177 responded. The cause of CKD among the index cases was DM in 52.5% followed by hypertension (20.6%). The eGFR was <90 mls/min in 39.6% and <60 mls/min in 5% of the screened cases. Proteinuria was present in 8%, making the combined prevalence of CKD of 13.8%. In the screened group, the prevalences of glycosuria, hematuria and proteinuria were 9.5%, 17.9% and 26.5% respectively and systolic hypertension (>130 mmHg) was observed in 28.1% and diastolic hypertension in 8.6%.

Conclusions: The combined prevalence of CKD was 13.8% and is highest in the Southern region of Saudi Arabia. The presence of CKD in the screened relatives was not associated with identifiable cause of CKD in the index cases or use of analgesics. Many relatives were discovered to have undiagnosed hypertension and undiagnosed diabetes.

Sex Differences in CKD Prevalence in Asia: A Systematic Review and Meta-Analysis
Carinna Hockham,1 Lexia Bao,1 Anushree Tiku,1 Sunil Badve,1,2 Martin P. Gallagher,1,2 Meg J. Jardine,1,3 Vivekanand Jha,1,4 Min Jun.1 The George Institute for Global Health, UNSW Sydney, Sydney, NSW, Australia; 2St. George Hospital, Sydney, NSW, Australia; 3Concord Repatriation General Hospital, Sydney, NSW, Australia; 4The George Institute for Global Health, University of Oxford, Oxford, United Kingdom

Background: Individual studies reporting sex-specific chronic kidney disease (CKD) prevalence in Asia have shown inconsistent sex differences in CKD prevalence. We sought to synthesize available sex-disaggregated data to better define and compare CKD prevalence in women and men in Asia.

Methods: We systematically searched the literature for observational studies of a 500 adults reporting sex-disaggregated CKD prevalence data in Asia. We calculated the women-to-men prevalence ratio (PR) for each study and pooled these using random-effects meta-analysis. Subgroup analyses were performed to explore potential sources of heterogeneity in the PR.

Results: Sex-disaggregated CKD prevalence data were available for 12 of the 26 Asian countries (109 studies; 1,452,308 women and 1,391,995 men). Most studies (83%) came from China, Taiwan, Japan and South Korea. Sex-specific CKD prevalence estimates varied substantially between studies (median [IQR] reported prevalence was 19% [9-35%] in women and 17% [8-28%] in men). Overall, CKD prevalence was higher in women compared to men (pooled PR 1.14; 95%CI 1.07-1.21), with evidence of significant heterogeneity (I²=99%). In subgroup analyses, prevalence was higher in women among studies with a younger mean age, a higher proportion of diabetes and that defined CKD using eGFR only (Table 1). The pooled PR varied considerably by country.

Conclusions: Existing sex-disaggregated data suggest a higher overall prevalence of CKD in women compared to men in Asia. However, adequate assessment of sex differences in CKD prevalence is limited by the absence of sex-disaggregated data for a large part of the region. Standardised reporting of sex-disaggregated CKD prevalence data in Asia is needed.
this region regarding APOL1 risk status is scarce. We aimed to determine APOL1 risk variants, plasma suPAR levels and estimate kidney function in HIV patients in Zambia.

Methods: We performed a cross-sectional study with 480 adult HIV infected persons on anti-retroviral treatment (ART) (women, 64.8%) in Lusaka, Zambia. APOL1 genotyping was done to determine the prevalence of the risk alleles; plasma suPAR levels were assayed and estimated GFR (eGFR) was calculated by CKD-EPI creatinine-based formula.

Results: Plasma suPAR levels were increased and were negatively correlated to eGFR, whether less than 60 or not (r=-0.15, p<0.001). Women while younger (42 vs 46 years old for men, p=0.0003), had higher suPAR than men (3.68 ng/mL vs 3.07 ng/mL, p<0.0001). Ten out of 480 patients (2.1%) had CKD, and their suPAR levels were higher than patients without CKD (5.6 mg/mL vs 3.44 ng/mL, p<0.0001). Fifty percent (10.4%) had 2 APOL1 risk alleles (35 for women vs 15 for men); among those, 3 (6%) developed CKD (p<0.007). No difference in suPAR levels or eGFR was observed between patients who carried 2 APOL1 risk alleles and those with 1 or 0 risk allele.

Conclusions: HIV infected persons in Zambia on ART have increased suPAR levels. The prevalence of two APOL1 risk alleles is similar as with AA HIV patients. A longitudinal study with a bigger cohort should reveal the relationship between suPAR, APOL1 risk alleles and kidney function.

Kidney Tubular Injury and Dysfunction Relate to Frailty and Cognitive Function in Persons with CKD in SPRINT

Lindsay S. Miller,1 Manjula Kurella Tamura,2 Nicholas M. Pajewski,3 Daniel E. Weiner,2 Dena E. Rifkin,1 Michael Shlipak,5,6 Joachim H. Ix,1 1University of California San Diego Division of Nephrology-Hypertension, San Diego, CA; 2Stanford University School of Medicine, Stanford, CA; 3Wake Forest University School of Medicine, Winston-Salem, NC; 4Tufts Medical Center, Boston, MA; 5Kidney Health Research Collaborative, San Francisco, CA; 6VAHCS/UCSF, San Francisco, CA

Background: The association of lower levels of eGFR and higher levels of albuminuria with poor cognition is well established. However, these markers do not specifically evaluate kidney tubule injury or dysfunction.

Methods: We measured 8 biomarkers of kidney tubule dysfunction and injury among 2,282 SPRINT participants with eGFR < 60 and evaluated their associations with frailty (Figure). Higher urine concentrations of MCP-1 & uromodulin [Umod], kidney injury molecule-1 [KIM-1], interleukin-18 [IL-18], uromodulin [Umod], and neutrophil gelatinase-associated lipocalin [NGAL]) among a random sample of 502 participants, and serum bicarbonate [sHCO3] among 2,288 community-living elders aged 70-79. We evaluated the cross-sectional associations with cognitive function using the Modified Mini-Mental State Exam (3MSE) and the Digit Symbol Substitution Test (DSST), where higher scores represent better cognitive function.

Results: None of the urine tubule marker biomarkers were associated with 3MSE, whereas higher urine NGAL was associated with lower DSST scores. Lower concentrations of sHCO3 were associated with lower scores of 3MSE but not DSST (table). These associations were independent of demographics, eGFR, and albuminuria.

Conclusions: Among urine markers of tubule injury and dysfunction, only higher NGAL was associated with lower cognitive function testing by DSST. Similarly sHCO3 was associated with worse cognitive function by 3MSE independent of eGFR, albuminuria, or other risk factors.

Cross-sectional association between biomarker of kidney tubule dysfunction with cognitive function.

PO0428
Association of Kidney Tubule Injury and Dysfunction with Cognitive Function in the Health, Aging and Body Composition Study

Lindsay S. Miller,1 O. Alison Potok,1 Dena E. Rifkin,3 Mark J. Sarnak,2 David A. Drew,2 Linda F. Fried,1 Michael Shlipak,5,6 Joachim H. Ix,1 1University of California San Diego Division of Nephrology-Hypertension, San Diego, CA; 2Stanford University School of Medicine, Stanford, CA; 3VA Pittsburgh Healthcare System, Pittsburgh, PA; 4Kidney Health Research Collaborative, San Francisco, CA; 5VAHCS/UCSF, San Francisco, CA

Background: The association of lower levels of eGFR and higher levels of albuminuria with poor cognition is well established. However, these markers do not specifically evaluate kidney tubule injury or dysfunction.

Methods: We measured 5 urinary biomarkers of kidney tubule injury and dysfunction (alpha-1 microglobulin [α1M], kidney injury molecule-1 [KIM-1], interleukin-18 [IL-18], uromodulin [Umod], and neutrophil gelatinase-associated lipocalin [NGAL]) among a random sample of 502 participants, and serum bicarbonate [sHCO3] among 2,288 community-living elders aged 70-79. We evaluated the cross-sectional associations with cognitive function using the Modified Mini-Mental State Exam (3MSE) and the Digit Symbol Substitution Test (DSST), where higher scores represent better cognitive function.

Results: None of the urine tubule marker biomarkers were associated with 3MSE, whereas higher urine NGAL was associated with lower DSST scores. Lower concentrations of sHCO3 were associated with lower scores of 3MSE but not DSST (table). These associations were independent of demographics, eGFR, and albuminuria.

Conclusions: Among urine markers of tubule injury and dysfunction, only higher NGAL was associated with lower cognitive function testing by DSST. Similarly sHCO3 was associated with worse cognitive function by 3MSE independent of eGFR, albuminuria, or other risk factors.

Funding: NIDDK Support, Other NIH Support - This research was supported by National Institute on Aging (NIA) contracts #N01-AI-6-2101; N01-AI-6-2103; N01-AI-6-2106; NIA grant R01-A0288050; NINR grant R01-RR012459, Veterans Affairs Support

Cross-sectional association between biomarker of kidney tubule dysfunction with cognitive function.

Figure. Multinomial regression showing the baseline association between biomarkers of kidney tubule dysfunction and injury with frailty compared with fit older adults (less fit group omitted). Models were adjusted for age, sex, race, BMI, alcohol use, years of education, SBP and DBP, smoking status, urine creatinine, eGFR, and albuminuria.
Conclusions: We observed that elevated TG were associated with higher risk of pneumonia hospitalization in non-CKD and CKD stage 3A-3B patients, but this relationship was not observed in late-stage CKD patients. While use of statins and cholesterol levels have been studied in the context of pneumonia and lung function, future studies are warranted to also investigate the role of triglycerides in pneumonia risk especially among early stage CKD patients.

PO0430

The Reference Interval and Risk Factors of NT-ProBNP in CKD Patients Without Heart Failure

Junzhe Chen, Ying Tang, Zhenjian Xu, Quyan Huang, Anping Xu. Department of Nephrology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China.

Background: N-terminal pro-B-type natriuretic peptide (NT-proBNP), a diagnostic marker of heart failure (HF), as well as the specific and sensitive biomarker of HF is been demonstrated to be affected by renal function. NT-proBNP is significantly associated with the severity of GFR loss. However, the reference interval (RI) of NT-proBNP in non-dialysis chronic kidney disease (CKD) patients without HF remains unclear. The aim of our study was to establish the threshold value of NT-proBNP which could help to early recognition, prevention and treatment for HF.

Methods: All patients diagnosed with CKD aged more than 18 years old in our hospital from Jan 01, 2014 to Dec 31, 2019 were recruited into this study. Individuals who diagnosed with HF were excluded. The RI for NT-proBNP was defined by nonparametric method and risk factors were analyzed by linear regression analysis.

Results: A total of 1260 CKD patients without HF were included in this study. Of them, 589(46.67%) were female. NT-proBNP were increased with the advanced stage of kidney function in CKD patients without HF. The median level of NT-proBNP in CKD stage 5 (non-dialysis) patients without HF were the highest, as 610.25 pg/ml. The RIs for NT-proBNP in CKD patients without HF with respect to kidney function stage (ranges of stage 1, stage 2, stage 3, stage 4, stage 5 ND) were 8.15-536.32, 12.38-2519.90, 16.62-1411.05, 33.14-2945.05, 88.58-5533.73pg/ml. We also demonstrated that NT-proBNP was significantly correlated with the serum levels of Hb (β=−0.174, P<0.001), Ca (β=−0.214, P<0.001), P (β=−0.111, P<0.001), hs-CRP (β=−0.140, P<0.001), and eGFR(β=−0.243, P<0.001).

Conclusions: Our study proved that NT-proBNP was increased with the advanced stage of GFR in CKD patients without HF. The RI of NT-proBNP varied among the different stages of CKD without HF and multiple factors contributed to NT-proBNP, which could help clinicians to prevent and take actions against the occurrence of HF.

Trends in the Transition to ESRD Among Native Hawaiians and Pacific Islanders Across the United States

Connie Rhee,1 Amy S. You,2 Keith C. Norris,3 Merle R. Kataoka-Yahiro,3 James Davis,4 Glen Hayashida,4 Victoria Page,3 Shihuh-Feng Cheng,4 Roland C. Ng,4 Linda L. Wong,4 Kamyar Kalantar-Zadeh,1 University of California Irvine, Irvine, CA; 2University of California Los Angeles, Los Angeles, CA; 3University of Hawaii Manoa, Honolulu, HI; 4John A. Burns School of Medicine, Honolulu, HI; 1National Kidney Foundation Hawaii, Honolulu, HI.

Background: Census data indicate there are >1.5 million Native Hawaiians and other Pacific Islanders (NHOPIs) in the US. While growing data show NHOPIs have a high prevalence of kidney disease risk factors (diabetes, obesity, hypertension, limited healthcare access), there are major knowledge gaps regarding the burden of end-stage renal disease (ESRD) in this population. We examined trends in the transition to ESRD in NHOPIs.

Methods: Using United States Renal Data System (USRDS) and Census Bureau data, we compared annual incident ESRD rates among NHOPI, African Americans (AA), and other racial subgroups over 2010-16. Rates were calculated as the observed incident ESRD count divided by the race-specific Census population size at that year. Multiple race designations were considered by utilizing Census categorizations that incorporated primary race in combination with one or more other races (alone or combination). We estimated crude rates and rates standardized to the age-sex distribution of 2011 race-specific Census population data.

Results: Over 2010-16, NHOPIs and AAs demonstrated the highest crude incident ESRD rates over time (Fig 1A). A similar pattern was observed for standardized incident ESRD rates (Fig 1B): 918, 638, 308, 226, and 162 incident ESRD patients per million (population/year) in 2016 for NHOPI, AA, Caucasian, Asian, and American Indian/Alaska Native subgroups, respectively. While standardized incident ESRD rates among AAs gradually declined, there was a steady rise in NHOPIs’ incident ESRD rates over time.

Conclusions: NHOPIs demonstrated the highest incident ESRD rates over time. Further studies are needed to determine sociodemographic, biologic/genetic, cultural, and health care related ESRD risk factors among NHOPIs to inform targeted interventions in this population.

PO0434
Association Between eGFR-Cystatin C/eGFR-Creatinine Ratio and Fat Weight
Agne Lauceyte-Cibulskiene,1,2 Anders Christenson.1,2 1Lunds Universitet Institutionen för Kliniska vetenskap i Lund, Lund, Sweden; 2Skane universitetssjukhus Malmo, Malmo, Sweden.

Background: The ratio of eGFR-cystatinC/eGFR-creatinine less than 0.7 is a condition that demonstrates different filtration for small and large molecules and is associated with accumulation of othersecretes/protecting proteins, higher cardiovascular event and mortality risk. Though, we hypothesize that this ratio could also be an indirect reflection of certain body composition. For example creatinine/cystatin C ratio has been used as a marker for sarcopenia, whereas cystatin C is highly expressed in human adipose tissue and might be increased in obesity. So the aim was to explore whether eGFR-cystatinC/eGFR-creatinine ratio is valid independently on body composition measures.

Methods: Data were extracted from the population based Malmö Diet and Cancer (MDC) study (n= 28 449) cardiovascular cohort (MDC_CC) that enrolled a random sample of study subjects invited to participate in carotid artery disease epidemiological analysis (n = 6 103) during the year 1991-1994. Our study sample consisted of 5061 subjects who had body composition measurements and cystatin C available. Estimated glomerular filtration rate (eGFR) according to Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) 2012 creatinine-cystatin C equation was calculated. Bioimpedance analysis of body composition was estimated by following procedures provided by manufacturer (BIA-103 RJL Systems, Detroit, MI, single frequency (50kHz)).

Results: In our study sample 11% (n=564) of subjects, mainly women (n=562), were classified as with eGFR-cystatinC/eGFR-creatinine ratio lower than 0.7. Therefore, we applied logistic regression analysis explicit in women and compared 2430 women without SPS with the rest of the 562. We found that the ratio adjusted for age was associated with obesity (OR 3.49, p<0.001) and in multivariate analysis only with fat weight (OR 1.91, p<0.001). Lower lean weight showed also significant relationship with lower eGFR-cystatinC/eGFR-creatinine ratio, but not after adjustment to other cofounders.

Conclusions: The ratio of eGFR-cystatinC/eGFR-creatinine lower than 0.7 is dependent on fat weight in females from population based study.

PO0435
Discovery of Obesity and Adiposity-Related CKD Subgroups and Preliminary Metabolomics Findings: The CRIC Study
Zihe Zheng,1 Hongzhe Li,1 Eugene P. Rhee,2 Wei Yang,1 Sushrut S. Waikar,3 Ryan Urbanowicz,1 Amanda H. Anderson,2 Dawei Xie,1 Harold I. Feldman,1 Chronic Renal Insufficiency Cohort Study 1University of Pennsylvania, Philadelphia, PA; 2Tulane University, New Orleans, LA; 3Massachusetts General Hospital, Boston, MA; *Boston Medical Center, Boston, MA.

Background: Obesity/adiposity perturbs the plasma metabolome, as does chronic kidney disease (CKD). Understanding the complex relationships across CKD patient subphenotypes, obesity, and the metabolome may shed light on finding novel risk factors and the mechanisms for CKD progression.

Methods: Among 1,529 participants in the Chronic Renal Insufficiency Cohort (CRIC) study (n = 634 known metabolites, after adjusting for demographics, health history, eGFR and UACR), we first generated consensus clustering with K-means on 20 baseline clinical adiposity-obesity-related attributes to identify patient subgroups. We individually examined the association of 634 known metabolites with the identified subgroups using separate multivariable linear models. Finally, Cox model was used to examine the prospective association of the adiposity-obesity subgroups (the biggest subgroup as reference) with CKD progression, ESRD, a composite cardiovascular disease outcome, and death.

Results: We identified four distinct adiposity-obesity-related CKD subgroups: Subgroup 1 (N=429) - favorable obesity/diabetes profiles and elevated lipid levels; Subgroup 2 (N=349) - favorable diabetes profiles, but slightly obese; Subgroup 3 (N=357) - less favorable diabetes profile, lower lipid levels and severe obesity; and Subgroup 4 (N=394) - less favorable diabetes profiles, but less obese. Among the 634 known metabolites, after adjusting for demographics, health history, eGFR and UACR, 260 were significantly associated with CKD subgroups at Bonferroni-adjusted p<7.9 x 10^-4. Survival analyses showed that compared to Subgroup 1 (ref), Subgroup 4 had the highest risk for CKD progression (HR 1.78, 95% CI 1.40, 2.26) and ESRD (HR 1.92, 95% CI 1.45, 2.52), and Subgroup 3 had the highest risk for the composite CVD outcome (HR 1.87, 95% CI 1.40, 2.50) and death (HR 1.51, 95% CI 1.09, 2.10).

Conclusions: With consensus clustering and metabolomics analysis, we discovered four distinct adiposity-obesity-related subgroups of CKD patients that were associated with numerous metabolites and different risks of clinical endpoints. Novel biomarkers that co-segregate with patient subgroups of high risk could reveal new insights into the obesity related biology of CKD progression and subsequent CVD events, and potentially suggest tailored therapeutic targets among CKD patients.

Defining the Excess Risk of Adverse Kidney Outcomes in CKD Patients with Type 2 Diabetes in the DISCOVER-CKD Cohort

Alyshah Abdul Sultan,1 Stephen Nolan,1 Juan J. Carrero,2 Zhuxin Jiang,3 Supriya R. Kumar,2 Roberto Pecore-Filho,4,6 Glen James,1 Juan Jose Garcia Sanchez,7 Lam S. Carolyn,2,10 Hungta (tong) Chen,2 Eishio Kanda,4 Naoki Kashihara,4 Mikhail Kasiborod,6 Carol A. Pollock,6 David C. Wheeler,3 Hiddo J. L. Heerspink,12 AstraZeneca, Cambridge, United Kingdom; 1 Karolinska Institute, Karolinska Institutet, Stockholm, Sweden; 2 AstraZeneca, Gaithersburg, MD; 3 Arbor Research Collaborative for Health, Ann Arbor, MI; 4 Pontificia Universidade Catolica do Parana Escola de Medicina Campus Londrina, Londrina, Brazil; 5 National Heart Centre Singapore, Singapore, Singapore; 6 Duke-NUS Medical School, Singapore; 7 Kawasaki Ika Daigaku, Kurashiki, Japan; 8 Saint Luke's Mid America Heart Institute, Kansas City, MO; 9 Royal North Shore Hospital, St Leonards, NSW, Australia; 10 University College London, London, United Kingdom; 11 Rijksuniversiteit Groningen, Groningen, Netherlands.

Background: Chronic Kidney Disease (CKD) patients with type 2 diabetes (T2D) are considered at a high risk of cardiovascular events. However, the excess risk of major kidney events in T2D patients compared to patients without T2D is unknown.

Methods: DISCOVER-CKD is an international observational study of patients with CKD that encompasses large retrospective electronic medical records (EMR) and claims data between 2008 and 2020. Preliminarily, data from US-based Limited Claims and Electronic Health Record (LCED) data (IBM Health, Armonk, NY) and TriNetX (historical EMR) were analysed. CKD patients (eGFR < 60 mL/min/1.73 m²) aged ≥18 years with a 1 record of urine albumin to creatinine ratio (UACR) were identified. T2D was ascertained any time before the index date (2 eGFR measurement). The risk of kidney outcomes (sustained ≥50% eGFR decline or end-stage kidney disease) was compared between patients with and without T2D at 5 years follow-up.

Results: Compared to non-T2D patients, T2D patients had a slightly higher incidence rate of adverse renal outcomes (LCED: 2.7% versus 2.3% per year; TriNetX: 1.8% versus 1.2% per year). After adjusting for all confounding factors (Figure 1) we observed an increased risk of adverse renal outcomes in T2D compared to non-T2D patients in LCED (hazard ratio (HR): 1.08; 95%CI 0.81-1.43) and a 34% increased risk in TriNetX database (HR: 1.34; 95%CI 1.11-1.62).

Conclusions: There is an excess risk of adverse renal outcomes in CKD patient with T2D compared to those without T2D. This is explained to a large extent by conventional risk markers in LCED but not completely in TriNetX. Both groups (T2D and non-T2D) should be managed proactively to reduce the risk of poor clinical outcomes.

PO0438

Assocation of the Creatinine-to-Cystatin C Ratio with Overall Survival with and Without CKD

Elam Sirova,1,3 Cachet Wenzinger,1 John Sy,1,2 Ekamol Tantisattamo,1 Ramy M. Hanna,1 Csbah P. Kovacsy,1 Susan T. Crowley,1 Kamyar Kalantar-Zadeh,1 Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; 2 The University of Tennessee Health Science Center, Memphis, TN; 3 VA Long Beach Healthcare System, Long Beach, CA; 4 Memphis VA Medical Center, Memphis, TN.

Background: Creatinine and Cystatin C are measured as glomerular filtration markers. Creatinine is highly correlated with skeletal muscle mass, whereas Cystatin C is not. We hypothesized that persons, in whom serum Cystatin C is lower than creatinine level, i.e. creatinine to Cystatin C ratio (CrCCR) >1.00 (regardless of measurement units) have incrementally greater survival chance, likely due to a larger muscle mass.

Methods: We examined a cohort of 7,849 Veterans with baseline measured Cystatin c and creatinine data between 2004-2015. Veterans were divided into 0.25 increments of CrCCR, i.e. <0.75, 0.75–1.01, 1.01–1.25, ≥1.25. They were further stratified into groups based on normal vs. low eGFR (<60 vs. ≤ 60 mL/min/1.73 m²), and the associations of CrCCR with survival across two eGFR strata were examined.

Results: The mean age (±SD) in the Veterans’ cohort was 69±12 years. There were 4% Black, 5% Asian, 57% white, and 15% African American. The median (IQR) range for cystatin C was 1.28 (0.99,1.71) mg/L, for creatinine 1.24 (0.92,1.68) mg/dl, and for the CrCCR 0.99 (0.81,1.17). Compared to the reference (CrCCR<1.25 and eGFR≥60 mL/min/1.73 m²) the multivariable adjusted model showed that those with a lower CrCCR ≥0.75 (indicating lowest muscle mass) had the highest mortality risk for both eGFR strata, with the normal eGFR group having higher death risk than the low eGFR group (HR (95%CI): 1.86 (1.49,2.31) and 2.13 (1.75,2.59), respectively). In the highest CrCCR group (≥1.25) indicating more muscle mass, the normal eGFR group had the overall survival lower than those with low eGFR (HR (95%CI): 0.45 (0.27,0.73)).

Conclusions: A lower CrCCR indicating higher cystatin C relative to creatinine levels are strongly associated with worse overall survival in Veterans regardless of kidney function level. Future studies should examine the clinical utility of this potential surrogate of muscle mass and overall health over creatinine or Cystatin C alone in evaluating risk stratification in patients with and without kidney disease.

Results: Among 3,930 patients, 1,374 were in PPI group, 119 were in H2 blocker group, and 2,347 had no medications. Average age was 72.8±11.1, and 42.5% male. Among PPI 28% had Coronary Artery Disease compared to 22% among H2B and 19% among no medication (P<0.001). Congestive Heart Failure was 13%, 8% and 7% for each group respectively (P=0.01). Overall mortality was not different amongst the three groups (PPI vs. none: HR 0.94, 95% CI: 0.80, 1.10, and PPI vs. H2B HR 0.80, 95% CI: 0.52, 1.24). The cumulative incidence of ESKD/eGFR<20 with death as a competing risk was also not different across groups in univariate (Fig 1) or adjusted models (PPI vs. none SHR 0.99, 95% CI: 0.74, 1.34, PPI vs. H2B SHR 1.82, 95% CI: 0.91, 3.63).

Conclusions: Use of PPI in a CKD population was not associated with increased mortality or CKD progression to ESKD when compared to the use of H2 blockers and to no acid suppressing therapy.

Elderly Patients Are Likely to Have Faster CKD Progression if Plasma Brain Natriuretic Peptide (BNP) Is Elevated
Shiho Morimoto, Hiroshi Tanaka. Mihara Red Cross Hospital, Mihara, Japan.

Background: Elderly CKD patients have been mostly believed that they have slower decline in eGFR than younger individuals. However, this is not the case, especially when the patient has well-known factor(s) that accelerate(s) CKD progression, such as cardiac dysfunction. Plasma concentration of brain natriuretic peptide (BNP) is often elevated in patients with cardiac dysfunction and is known to be associated with higher mortality. This study was conducted to find out whether plasma BNP level can be used to predict future decline in eGFR.

Methods: A hospital-wide study with all the laboratory data for a period of 4 years and 2 months was performed. Non-dialysis CKD patients (median eGFR <60 mL/min/1.73m2) with an eGFR slope in whom the eGFR slope was obtained over 731 days or more with BNP measured at least three times were retrieved. An eGFR slope per each patient was calculated and its relationship with plasma BNP level and other factors was assessed. Statistical analysis was done with R 3.6.0 on Ubuntu.

Results: A total of 339 patients (M:F = 154:185, age 65-102 (median 84) years) were included whose initial BNP was 130.0~184.2 (0.1641, median 75.76) pg/mL. A “random forest” analysis, one of the multivariate analyses, was performed using an R package (randomForest), in order to elucidate risk factors associated with faster decline in eGFR. Among the 339 patients, 12% of the eGFR slope was obtained over 731 days or more with BNP measured at least three times were retrieved. An eGFR slope per each patient was calculated and its relationship with plasma BNP level and other factors was assessed. Statistical analysis was done with R 3.6.0 on Ubuntu.

Conclusions: Elevated plasma BNP might predict faster decline in eGFR in the elderly CKD patients.

PO0441
Pump-Proton Inhibitors (PPIs) vs. H2 Blockers (H2B) Users and Overall Risk of CKD Progression
Linda Zhu,1 Tarek Ashour,2 Ali Mehdi,1 Jonathan J. Taliercio,1 Remy Daou,2 Susana Arreguin,1 Jesse D. Schold,1 Nazih L. Nahkoul,2 Georges Nahkoul,1 1Cleveland Clinic, Cleveland, OH; 2University Saint-Joseph, Beirut, Lebanon; Tulane University School of Medicine, New Orleans, LA.

Background: PPI use is associated with adverse kidney events. The relationship between PPI use and the development of acute interstitial nephritis (AIN) is well established. However, the relationship between PPI use and CKD progression is less clear. Notably, there is a lack of data regarding renal outcomes in established CKD patients. The aim of our study is to determine the risk of CKD progression among patients on PPI, H2B, or no anti-acid therapy.

Methods: Using our CKD registry, we evaluated the relationship between the use of PPI and H2B and CKD among patients with CKD stage 3 and 4 with at least 2 PCP visits in the year prior. We evaluated the relationship between medication group and overall mortality using a Cox proportional hazards model while adjusting for demographics and comorbidities, and the relationship between medication group and progression to eGFR<20 or ESKD with death as a competing risk using regression models as described by Fine and Gray.

Novel Fibrosis Biomarker Development and Validation in Human Kidney Disease

Insa M. Schmidt,1,2 Mia Colona,1,2 Bryan R. Kestenbaum,3 Leonidas G. Alexopoulos,4 Ragnar Palsson,5 Anand Srivastava,5 Jing Liu,6 Isaac E. Stillman,7 Helmut G. Rennek,8 Vishal S. Vaidya,9 Haojia Wu,9 Benjamin D. Humphreys,2 Sushrut S. Waikar,10 Boston University Medical Center, Boston, MA; 2Brigham and Women’s Hospital, Boston, MA; 3University of Washington, Seattle, WA; 4University of Washington School of Medicine, Seattle, WA; 5ProtATonce LTD, Athens, Greece.

Background: Biomarkers for non-invasive assessment of kidney fibrosis are not available. This study illustrates the characterization of five novel candidate biomarkers of kidney fibrosis—Cadherin-11 (CDH11), Sprectral-related modular calcium binding-2 (SMOC2), Pigment epithelium-derived factor (PEDF), Matrix-gla protein (MGP), and Thrombospondin-2 (THBS2)—which were selected from transcriptomic findings in animal models of fibrosis.

Methods: We developed Lumixem-based assays and measured proteins in plasma and urine samples of two independent prospective cohort studies, the Boston Kidney Biopsy Cohort (BKBC, n=881), a cohort of individuals with biopsy-confirmed semi-quantitative assessment of kidney fibrosis, and the Seattle Kidney Study (SKS, n=252). Ordinal logistic regression and Cox proportional hazard models tested associations of biomarkers with interstitial fibrosis and tubular atrophy (IFTA) in the BKBC and progression to end-stage kidney disease (ESKD) in both cohorts, respectively. snRNA datasets of human kidneys assessed cell-specific gene expression profiles.

Results: In the BKBC, higher levels of urinary PEDF and plasma and urinary SMOC2 and CDH11 were independently associated with more severe IFTA (Figure 1). In both cohort studies, higher levels of plasma and urinary SMOC2 and urinary CDH11 associated with progression to ESKD (HR-range 1.27 to 1.89) after adjustment for age, sex, race, proteinuria, and eGFR. Higher levels of urinary PEDF were associated with ESKD in the SKS (HR=1.29, 95% CI 1.14 to 1.45), with consistent signals in the BKBC, although the latter narrowly missed statistical significance. snRNA-sequencing data demonstrated expression of all biomarkers in human fibroblasts.

Conclusions: Novel plasma and urine biomarkers of kidney fibrosis, developed from animal models, are associated with higher levels of human kidney fibrosis and subsequent progression to ESKD.

Clinical Significance and Related Factors of GFR Slope in a Large Multicenter Observational Study in Japan
Yui Kamijo,1,2 Koji Hashimoto,1,2 Yosuke Yamada,1,2 Makoto Harada,1,2 Masatsugu Aida,1,2 Shitotomo Yamauchi,1,2 NKEA study group 'Shinshu University School of Medicine, Matsumoto, Japan; 2Nagano Kidney Function Association, Matsumoto, Japan; 1Ehime Co., Ltd., Chiyoda-ku, Japan.

Background: Recently, GFR slope has attracted attention as an important surrogate marker for the prognosis of CKD, with a reduction in slope of GFR decline by 0.75 mL/min/1.73 m² per year reported having clinical significance. This investigation addresses the clinical significance of GFR slope and its related factors on Japanese CKD patients.

Methods: CKD patients in 15 general hospitals between January and March 2014 were surveyed using medical records. The selection criteria were age ≥20 years, eGFR <60 mL/min/1.73 m², and receiving medical treatment for CKD. Baseline patient characteristics, eGFR changes, and hard endpoints (death or ESKD requiring RRT) were analyzed. We calculated GFR slope using eGFR data of 2 years by 2 calculation methods, the linear mixed model and least squares linear regression, and examined the relationship of GFR slope with the hazard ratio (HR) of the endpoints. The factors related to GFR slope were also assessed by multiple regression analysis.

Results: Among a total of 11233 patients, we analyzed the data of 7490 CKD G3 and G4 patients (60% male, mean age: 71 years, CKD G3A: 55%, G3B: 30%, G4: 15%, mean eGFR: 44 mL/min/1.73 m², urine protein positive: 51%, diabetes mellitus: 49%, use of RAS-I: 57%). The mean observation period was 1040 days. Hard endpoints after the GFR slope measurement period occurred in 301 subjects. The GFR slope of the cohort was -0.948 mL/min/1.73 m² per year (95% confidence interval [CI] -1.016, -0.880) in the linear mixed model and -0.982 mL/min/1.73 m² per year (95% CI -1.075, -0.889) according to least squares linear regression. Both calculated GFR slopes were significantly related to the HR of the composite hard endpoints. HR decreased by 0.85 (linear mixed model) and 0.9 (least squares linear regression) times in case of a reduction in slope of GFR decline by 0.75 mL/min/1.73 m² per year. Multiple regression analysis revealed strongly significant associations for GFR slope with urine protein and CKD stage and undetectable relationships for GFR slope with diabetes and age.

Conclusions: This study demonstrated the clinical significance of GFR slope as a surrogate marker for renal prognosis in Japanese CKD patients. In order to reduce slope of eGFR decline, active intervention for proteinuria before the progression to an advanced CKD stage appears to be effective.

PO0449
The Kidney Failure Risk Equation: Testing Previous eGFR Slopes, Clinical Variables, and Novel Populations
Morgan Grams, Nigel J. Brunskill, Angela Yee Moon Wang, Navdeep Tangri. CKD Prognosis Consortium CKD Prognosis Consortium, Baltimore, MD.

Background: The 4-variable kidney failure risk equation (KFRE) is a well-validated tool that accurately predicts the 2- and 5-year risk of kidney failure in patients with eGFR <60 mL/min/1.73 m² using baseline eGFR, ACR, age, and sex. The aim of this study was two-fold: to assess whether KFRE can be improved using previous eGFR slope or other variables; and to evaluate whether the KFRE can be used in patients with eGFR ≥60 mL/min/1.73 m².

Methods: We used 36 cohorts in development and 17 cohorts in validation to accomplish these aims; all cohorts participate in the CKD-Prognosis Consortium and had data on the four variables, previous 2-year eGFR slope, and at least 25 ESKD events.

Results: There were 205,004 participants with eGFR <60 mL/min/1.73 m² (12,794 CKD events) and 441,915 participants with eGFR ≥60 mL/min/1.73 m² (1,220 ESKD events). In the eGFR <60 group, previous 2-year eGFR loss >3 mL/min/1.73 m²/year was associated with ESKD (meta-analyzed HR 1.36, 95% CI: 1.19-1.56) with a small improvement over the 4-variable model (baseline c-statistic in validation cohorts, 0.87-0.88; meta-analyzed difference in c-statistic in validation cohorts when adding slope, 0.001, 95% CI: 0.000-0.002). Using previous 5-year slope resulted in slightly better c-statistic compared to the model using 2-year slope (meta-analyzed difference in c-statistic in validation cohorts, 0.003, 95% CI: 0.001-0.005). Other approaches, such as using 1-year or 2-year average eGFR as inputs in the 4-variable KFRE, or incorporating black race, heart failure, or atrial fibrillation, did not result in meaningful improvements. The KFRE had poor discrimination and calibration in the eGFR ≥60 mL/min/1.73 m² population. In a model that instead predicted 40% decline in eGFR and included age, sex, ACR, diabetes, hypertension, heart failure, and coronary heart disease, previous eGFR loss >3 mL/min/1.73 m²/year over 2- and 5-years were associated with greater risk (HR, 1.43, 95%CI: 1.19-1.70; 1.84, 95%CI: 1.40-2.42).

Conclusions: In summary, the KFRE was improved only slightly by the inclusion of previous eGFR slope. For populations with eGFR >60, a more relevant and predictable outcome may be percent eGFR decline.

Comparison of Predicted Risk of Renal Replacement Therapy vs. eGFR for Arteriovenous Fistula Placement in CKD: A Retrospective Analysis
Ken J. Park,1 Micah L. Thorp,2 Erin Keast,3 Jose G. Benuzillo,1 David Mosen,2 Eric S. Johnson.1 Kaiser Permanente Northwest, Portland, OR; Kaiser Permanente Center for Health Research Northwest Region, Portland, OR; Edwards Lifesciences Corp, Irvine, CA.

Background: The complexity in predicting which and when patients with chronic kidney disease (CKD) will progress to renal replacement therapy (RRT) contributes to 80% of patients starting hemodialysis without a functioning permanent access. Studies suggest AVF referral at eGFR of 15-20 ml/min increases the likelihood of starting dialysis with an AVF. We were interested in whether a prediction model developed at Kaiser Permanente Northwest better predicted progression to RRT at 1 year compared to eGFR.

Methods: We retrospectively followed 613 patients with stage 4 CKD between ages of 18 to 89 from May 2013 to May 2018 followed by nephrologist who had a nephropathy visit with an eGFR and a calculable 2-yr risk for 60 months before the start of follow up (defined as death, initiation of RRT, or 2 years from initial enrollment date). We calculated sensitivity, specificity, and area under the curve (AUC) based on a range of 2-yr risk for RRT (20%, 40%, 60%, and 80%) and compared them to eGFR threshold of 15 ml/min and 20 ml/min at the 12 month visit prior to end of follow up. We compared 2-yr risk for patients, eGFR, laboratory values, and imaging.

Results: At end of follow up, 12% had died and 14% had progressed to RRT (69% hemodialysis, 22% peritoneal dialysis, 9% transplant). Compared to eGFR threshold of 20 ml/min, specificity and specificity was greater at 2-yr RRT risk of 40% (73% and 49%) for eGFR threshold of 15 ml/min respectively compared to 83% and 54% respectively for 2-yr RRT risk of 80% (84% and 80%) compared to eGFR threshold of 15 ml/min/specificity and specificity was greater at 2-yr RRT risk of 80% (97% and 11%) for eGFR threshold of 15 ml/min respectively compared to 98% and 18% respectively for 2-yr RRT risk threshold of 80%). The AUC was greater between 2-yr RRT of 20% to 40% (0.73 to 0.70) compared to eGFR between 15 ml/min to 20 ml/min (0.54-0.61). Decision curve analysis showed better net benefit using 2-yr risk >40% compared to eGFR of 20 ml/min above a 1 year threshold of 25%.

Conclusions: In patients with CKD stage 4, 2-yr risk for RRT better predicted progression to RRT at 1 year compared to eGFR alone. Our study suggests that use of prediction model for RRT may be an important tool for determining optimal timing for AVF referral.
Background: Identifying the optimal measurement of proteinuria in clinical settings has been challenging. To determine the potential consequence of varied measures of proteinuria, we contrasted their clinical significance primarily in relation to renal events and secondarily to cardiovascular (CVD) and mortality events.

Methods: We compared the predictive ability of four measures of proteinuria and albuminuria, among 3592 CKD participants from the Chronic Renal Insufficiency Cohort (CRIC) Study, for incident renal events (halving of glomerular filtration rate [GFR] or end-stage renal disease), CVD events (myocardial infarction, congestive heart failure, stroke and peripheral arterial disease) and mortality over 3 years. The four measures included timed urinary albumin and protein excretion rates (AER, PER), albumin:creatinine ratios (ACR, PCR), albumin:protein:adjusted creatinine (accounting for creatinine production) (eAER, ePER), and lastly albuminuria/proteinuria indexed to GFR (ACR-G, PCR-G), as an estimation of glomerular permeability. We used Harrell’s C-Statistics to measure model discrimination.

Results: Predictive performance for renal events was lowest for AER and PER. Results were generally similar for ACR vs eAER and PCR vs ePER. Notably, PCR-G showed significant improvement in predicting renal outcomes and performed better than albuminuria-based measures. C-statistics for renal events were 0.831, 0.840, 0.841, 0.846 and 0.862 for AER, eAER, ACR, PCR and PCR-G, respectively. Trends were similar for CVD and mortality events, except that ACR performed better than PCR for CVD events, but not as well as PCR-G or ACR-G. Results were overall consistent across diabetes, gender and race strata, and were validated in an additional 1443 participants from the third phase of CRIC.

Conclusions: Indexing proteinuria to GFR is a simple and economical measure, compared to albuminuria, that significantly enhances the prediction of CKD progression and associated outcomes.

PO0456

Hypophosphatemia as a Surrogate Marker of Renal Outcome in Chronic Hepatitis B Patients Receiving Antiviral Therapy

Mee yeon Park, Junseok Jeon, Jung eun Lee, Wooseong Huh, Yoon-Goo Kim, Dae jong Kim, Hyun Suk Lee, Hye Ryoun Jung. Division of Nephrology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea Samsung Medical Center, Gangnam-gu, Seoul, Republic of Korea.

Background: Antiviral therapy is crucial for the treatment of chronic hepatitis B (CHB). Although hypophosphatemia has been known to be an important adverse effect of antiviral agents, the clinical significance is yet to be revealed. In this study using a large cohort of CHB patients, the incidence and clinical significant of hypophosphatemia was investigated.

Methods: CHB patients who started antiviral therapy between 2005 and 2015, and had received at least one year of therapy, were included after excluding liver cirrhosis, diabetes mellitus, hypertension, concomitant administration of diuretics, and ESRD. Hypophosphatemia was defined as serum phosphorous level ≤ 2.5mg/dL. The primary outcome was changes in renal function. Secondary outcomes included the incidence of infection and changes in serum potassium, uric acid, and total carbon dioxide (CO2)
Results: Of the 4,335 patients, hypophosphatemia developed in 75 patients (1.7%). When patients were categorized depending on serum phosphate level, median phosphate level of 728 patients (16%) decreased by more than 0.5mg/dL from the baseline. During the 2-year follow-up period, patients with hypophosphatemia showed lower eGFR compared to the control group. Also, patients whose serum phosphate level decreased by more than 0.5mg/dL showed significantly lower eGFR compared to the control group at all time points. The incidence of infection and changes in serum potassium, uric acid, and CO2 were similar between groups.

Conclusions: Hypophosphatemia was associated with renal function decline in CKD patients. The incidence of hypophosphatemia in CHB patients was 1.7%. 50% of patients had hypophosphatemia during antiviral therapy was relatively low, our results support the clinical significance of hypophosphatemia as a surrogate marker of adverse renal outcome in CHB patients.

PO0457
Dietary Phosphorus Restriction Improves Renal Function, Blood Pressure, FGF-23, and Klotho Levels in CKD Stages 1 and 2

Anita Saxena, Trisha Sachan, Amit Gupta, Anup Kumar, Sachin Sharma. Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.

Background: To evaluate impact of dietary education and intervention (phosphorus restriction) on creatinine, eGFR, FGF23, Klotho and blood pressure.

Methods: 105 subjects (CKD stages 1, 2 N 70; 3Controls) evaluated for eGFR, creatinine, phosphorus, calcium, FGF-23, soluble o-Klotho, iPTH FGF 23, blood pressure and 3 days dietary intake, using standard methodology on first visit, 6 and 12 months. CKD patients were grouped based on dietary phosphorus intake:Group 1 (n 42): phosphorus intake <1000mg/day and Group 2 (n=37; 17 in CKD 1; 20 CKD 2): high phosphorus intake (>1000mg/d). Patients in Group 2 were counselled for low phosphorus diet.

Results: Parameters of controls and CKD patients differed significantly. Dietary, serum and urinary phosphorus (0.001) had significant association. Systolic and diastolic BP, protein intake, dietary phosphorus, iPTH, FGF23 were significantly high (p 0.001) and Klotho significantly low (p 0.001) in Group 2 compared to Group 1. Impact of dietary intervention was seen at 6 and 12 months as reduction in protein intake from 0.64±0.35 to 0.58±0.11 (CKD 1) and 0.71±0.074 to 0.64±0.095 (p 0.012 CKD 2); decline in creatinine from 1.13±0.14 to 1.07±0.14 (CKD 1) and 1.06±0.56 (p 0.009 CKD 1); serum phosphorus from 3.57±0.19 to 3.22±0.58 (CKD 1) and 4.32±0.42 to 3.35±0.85 mg/dL (p 0.001 CKD 2); FGF-23 from 55.01±1.65. to 51.27±11.17 (CKD 1); 65.42±4.80 to 56.60±11.23 (p 0.010 CKD 2); systolic BP from 127.95±3.14 to 121.05±4.40 (CKD 1); 134.22±3.54 to 118.38±9.08 (p 0.001 CKD 2) and diastolic BP from 85.14±3.80 to 83.29±8.03 (CKD 1); 89.11±4.74 to 80.33±6.02 (p 0.003 CKD 2) and a significant increase in eGFR ml/min from 95.17±5.50 to 97.75±20.26 (CKD 1); 109.82±8.56 to 74.04±11.07 (p 0.019 CKD 2) was observed. sKlotho increased from 700.79±27.82 to 879.39±18.87 (p 0.001 CKD 1); from 633.52±56.03 to 823.37±15.67 (p 0.001 CKD 2). Ca x P product declined from 36.10±8.41 to 29.48±7.63 (p 0.001). eGFR can predicted using dietary protein, creatinine systolic BP, haemoglobin, cholesterol (r 0.808).

Conclusions: Dietary counselling had significant effect on all the parameters in early and late stages of CKD. Dietary intervention can prevent decline in FGF23, reduce blood pressure and prevent decline in renal function as demonstrated by significant increase in eGFR with phosphorus restriction in early stages of CKD.

PO0459
The Effects of Intermittent Fasting on the Progression of CKD

Deepthi Venkatesan, Buthayana A. Dinay,1,2 Fairview Hospital, Cleveland, OH; 1,2 University Hospitals, Cleveland, OH; 1 Cleveland Clinic, Cleveland, OH.

Background: Intermittent fasting (IF) refers to the practice of restricting food intake to a specific period of the day alternating with a prolonged period of fasting. Preclinical and clinical trials have shown that IF has broad-spectrum benefits for many health conditions, such as obesity, diabetes mellitus, cardiovascular disease, cancers, and neurologic disorders. There are currently few studies suggesting a decrease in the progression of chronic kidney disease (CKD) with IF.

Methods: Retrospective chart review was done on patients from outpatient nephrology clinic with CKD stage I to IV who were self-reported to practice intermittent fasting. Patients with ESRD on dialysis, hospital admission during the study period, and reported poor compliance with fasting regimens were excluded. The primary outcome was the change in eGFR at the end of the period of intermittent fasting.

Results: Here we report current findings from 16 patients practicing IF regimen with continued ongoing enrollment. 75% of these patients were diabetic. Duration of the IF regimen ranged from 4 months to 12 months. 50% of patients had completed 12 months of IF regimen. 62.5% of patients were found to have an improvement in eGFR at the end of the period of IF. The change in eGFR was found to range from 0.4 mg/dl/1.73 m2 to 38.8 mg/dl/1.73 m2 (1.4-76.5%). The median increase in eGFR was 6.5 ml/min/1.73 m2 (18.1%) during an average period of 8 months of IF (p-value = 0.04). There was no significant correlation between change in eGFR and change in weight or hemoglobin A1C during this period.

Conclusions: A significant increase in eGFR was seen in a small population of patients with CKD practicing intermittent fasting for four months or more. Previous studies report an average annual decline in GFR of 1.5-2 ml/min/1.73 m2 in the general CKD population, with a more rapid decline in certain subsets. Intermittent fasting as a preventive measure for the progression of CKD needs to be studied further.
Future intervention trials should investigate whether a diet enriched in fibers would
with cardiovascular outcomes or kidney disease progression in individuals with
CKD. (≥45 ml/min/1.73 m²), and proteinuria.

dietary fiber intake and kidney and cardiovascular disease outcomes. Results were similar
compared to those in the highest fiber tertile (HR [95%CI], 1.18 [1.01, 1.38], p =0.04
adjustments, individuals in the middle and low fiber tertiles were at greater risk of death
4.5 years, there was an inverse association between
changes in dietary protein intake and outcomes among patients

Changes in Dietary Protein Intake and Outcomes Among Patients
with CKD

Memphis, TN; 2Memphis VA Medical Center, Memphis, TN

Background: Protein energy wasting is common and associated with poor outcomes
in CKD while low protein diet is recommended to delay the development of ESRD.
However, the clinical relevance of the temporal change in dietary protein intake (DPI) in
real-world data remains unclear in this population.

Methods: We performed repeated collections of morning spot urine in a prospective
cohort of non-dialysis dependent veterans with CKD at a single institution. We assessed
urine urea nitrogen-to-creatinine ratio to estimate 24-hour urine urea excretion and then
estimated DPI using the Maroni formula. Among 345 patients who had data on DPI
between 6-12 months from the initial measurement, we estimated the slope of DPI in
mixed effects models and examined its association with subsequent ESRD and all-cause
mortality in cause-specific hazard models with adjustment for demographics, Charlson
Comorbidity Index, eGFR, urinary protein, smoking status, body mass index, and
baseline DPI.

Results: Patients were 68±10 years old, 97% were male, 36% were African American,
and their baseline eGFR was 34±12 ml/min/1.73 m². Baseline DPI was median 0.55 (IQR,
0.45–0.67) g/kg/day and its slope was 0.01±0.04 g/kg/day per year. During a median
follow-up of 4.2 years, 129 died (104/1000 PY) and 87 developed ESRD (83/1000 PY).
Decrease in DPI was associated with lower risk of ESRD (HR 0.94 [95%CI, 0.89-0.99]
per 0.01 g/kg/day per year; p=0.025), but not with mortality risk (p=0.84). Non-linear
regression models confirmed these findings (Figure). Compared to patients who had no
change in DPI, the hazard ratio (95%CI) of death and ESRD in those with a change of
-0.03 g/kg/day per year were 1.12 (0.95-1.47) and 0.71 (0.52-0.98), respectively.

Conclusions: In patients with CKD, DPI showed a relatively small intra-individual
temporal variation, but decrease in DPI was significantly associated with lower risk of
ESRD, without an association with mortality.

Effect of Zinc Deficiency on CKD Progression and Effect Modification
by Hypoalbuminemia
Atsuyuki Tokuyama,1 Eiichiro Kanda,2 Seji Itano,1 Megumi Kondo,1
Yoshihisa Wada,1 Hiroyuki Kadosya,1 Kengo Kidokoro,1 Hajime Nagasu,1
Tamaki Sasaki,1 Naoki Kashihiara,1 1Department of Nephrology and
Hypertension, Kawasaki Medical School, Kurashiki, Japan; 2Department of
Medical Science, Kawasaki Medical School, Kurashiki, Japan.

Background: Serum zinc (Zn) levels tend to be low in chronic kidney disease (CKD)
patients. However, it has not been shown whether zinc deficiency itself leads to poor renal
prognosis. The purpose of this study was to investigate the relationship between zinc
deficiency and CKD progression.

Methods: This is a retrospective cohort study using the CKD patient database of
electronic medical records (n=325). The study patients were classified into two groups: Zn
levels<60μg/dl (low-Zn group, n=165) and Zn levels≥60μg/dl (high-Zn group, n=162).
The primary outcome was defined as end-stage kidney disease (ESKD) or death, and the
observation period was one year. The relationship between low Zn levels and the outcome
was assessed using Cox proportional hazard model and by competitive risk analysis.
Furthermore, the propensity score-matched analysis for low Zn level was also conducted.

Results: Among the subjects, 51.7% were male; mean age, 69.3 years; mean Zn
level, 59.9μg/dl; and median eGFR, 20.4ml/min/1.73 m². The incidence of the primary
outcome was higher in the low-Zn group than in the high-Zn group (42.3% vs 19.1%,
mean±9.6). The average dietary fiber intake was 17.3±9.6

Conclusions: Dietary fiber intake may be associated with the risk of death, but not
with cardiovascular outcomes or kidney disease progression in individuals with CKD.
Future intervention trials should investigate whether a diet enriched in fibers would
influence mortality and other clinical outcomes.

Changes in Dietary Protein Intake and Outcomes Among Patients
with CKD
Yoshitsugu Ohi,1 Mahmoud M. Mohamed,1 Waleed Hassan,1 Hisham N. Abu
Farsak,1 Abbisheke J. Patel,1 Jawed Akhtar,1 Mahmoud A. Mahmoud,1
Keiichi Sumida,1 Miklos Z. Molnar,1 Barry M. Wall,1,2 Csaba P. Kovessy,1,2
1The University of Tennessee Health Science Center College of Medicine,
Memphis, TN; 2Memphis VA Medical Center, Memphis, TN

Background: Standard dietary interventions for individuals with chronic kidney
disease (CKD) consist of reductions in salt, phosphorus, potassium, and protein intake,
with no specific guidance regarding dietary fiber intake. In animal models of kidney
disease, a diet high in amylose resistant starch has been found to trigger a reduction
in inflammation and CKD progression. It is unclear whether low dietary fiber intake is
associated with a higher risk of incident kidney disease progression, cardiovascular
disease, and overall mortality in individuals with CKD.

Methods: A total of 3791 participants with chronic kidney disease and information
on dietary fiber intake at the baseline visit in the Chronic Renal Insufficiency Cohort
(CRIC) Study were included in the analyses. Cox proportional hazards models adjusted
for sociodemographic, comorbidities, medications and laboratory data, including eGFR
and proteinuria were used to analyze the association between dietary fiber intake and
clinical outcomes.

Results: The mean age was 59±11 years, 46% were female, 47% had diabetes, and the
average eGFR was 48±17 ml/min/1.73 m². The average dietary fiber intake was 17.3±9.6
g. After a median follow up of 8.8±4.5 years, there was an inverse association between
the crude death rates and baseline dietary fiber intake: increasing from 3.1 per 100 person-
years (PY) for the highest to 3.4 per 100 PY for the lowest fiber tertile. After multivariable
adjustments, individuals in the middle and low fiber tertiles were at greater risk of death
compared to those in the highest fiber tertile (HR[95%CI], 1.18 [1.01, 1.38], p =0.04
and 1.10 [0.94, 1.29], 0.24, respectively). We found no significant association between
dietary fiber intake and kidney and cardiovascular disease outcomes. Results were similar
in sensitivity analyses by subgroups defined by age, gender, ethnicity, diabetes, eGFR
(< and ≥) 45 ml/min/1.73 m²), and proteinuria.

Conclusions: Dietary fiber intake may be associated with the risk of death, but not
with cardiovascular outcomes or kidney disease progression in individuals with CKD.
Future intervention trials should investigate whether a diet enriched in fibers would
influence mortality and other clinical outcomes.

Association of Plasma Selenium with Renal Function in Hypertensives: Modification by Folate

Youbaou Li, Xianhui Qin, Jing Nie, Min Liang, Fan Fan Hou. Division of Nephrology, Nanfang Hospital, Southern Medical University; National Clinical Research Center for Kidney Disease; State Key Laboratory of Organ Failure Research, Guangdong Provincial Institute of Nephrology, Guangzhou, China.

Background: We aimed to investigate the association between plasma selenium (Se) and renal function decline in adults with hypertension and to explore the possible modifying role of folate.

Methods: This was a prospective study, including a total of 935 hypertensive adults from a folate intervention trial (CSPPFT) with baseline plasma Se measurements and renal outcome data available. The primary outcome was rapid decline in renal function, defined as an average decline in eGFR ≥5 mL/min/1.73m² per year.

Results: Over a median follow-up of 4.4 years, the primary outcome occurred in 72 participants. After multivariate-adjusted, there was an inverse association between plasma Se and rapid decline in renal function (per 10-unit increment: OR, 0.90; 95% CI: 0.85, 0.95). Consistently, compared to the lowest tertile of baseline plasma Se (≤7.4 μg/L), the highest tertile (89.4−150 μg/L) was significantly associated with a 60% (0.40; 0.21, 0.79) reduction in the odds of the outcome. A stronger inverse plasma Se-renal function decline association was observed in those received folate acid treatment (per 10-unit increment: OR, 0.97; 95% CI: 0.94, 1.00; P-interaction=0.036) or with a higher baseline folate concentration (≥90 ng/mL: 0.59; 0.43, 0.82; P-interaction=0.004).

Conclusions: In China hypertensives with plasma Se <150 μg/L, there was an inverse relationship of plasma Se with the renal function decline, especially in those with folate acid supplementation or a higher folate level.

Funding: Government Support - Non-U.S.

Association between plasma Se and the outcome

Relationship of Serum Triglycerides with Incident Albuminuria Among 114,817 US Veterans

Melissa Soohoo,1 Jui-Ting Hsiung,2,3 Maria V. Marroquin,4 Csaba P. Kovessy,2 Kamyr Kalantar-Zadeh,2,3 Elani Streja.2,3 1The University of Tennessee Health Science Center, Memphis, TN; 2VA Long Beach Healthcare System, Long Beach, CA; 3Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; 4Memphis VA Medical Center, Memphis, TN.

Background: The association of metabolic syndrome (MetS) components of impaired glucose, obesity, low high-density lipoprotein, hypertension, and serum triglycerides (TG), with renal endpoints such as incident chronic kidney disease (CKD) have been previously studied individually. Urine albumin to creatinine ratio (UACR) remains an integral part of CKD staging and incidence, yet it remains understudied. Thus, we sought to examine the relationship of TG with incident albuminuria among normal UACR patients with consideration for other MetS components.

Methods: Our cohort comprised 114,817 veterans with albuminuria stage A1 (<30 mg/g) and data on TG and MetS components. Incident albuminuria was defined as at least two UACR measurements of >30 mg/g at least 90 days apart. We used Cox proportional hazards models to evaluate the association of TG with incident albuminuria, adjusted for case-mix characteristics, laboratory values and individual MetS components, as well as stratified by s2 and a3 MetS components.

Results: The meansSD age was 65±11, with a median [IQR] of TG, UACR and eGFR of 144[97, 214] mg/dL, 7[4, 13] mg/g, and 75[61, 89] mL/min/1.73m², respectively, and 70% had at least 3 MetS components. We observed a linear association between TG and incident albuminuria, adjusted for case-mix characteristics, laboratory values and individual MetS components, as well as stratified by s2 and a3 MetS components. The association of TG with incident albuminuria was attenuated (Figure A). Moreover, stratification by number of MetS components showed similar linear associations between TG and incident albuminuria, especially in patients with ≥5 MetS components. In patients with ≥5 MetS components, the linear relationship of TG and incident albuminuria was attenuated (Figure B).

Conclusions: Higher TG are associated with incident albuminuria independent of other components of MetS. Further study is needed to understand the drivers of this association, with a specific focus of how to best manage TG levels in at-risk populations.

PO0466

Short-Term Associations of Triglycerides with Atherosclerotic and Non-Atherosclerotic Cardiovascular Disease Hospitalizations Across CKD Stages

Melissa Soocho,1,1 Jui-Ting Hsing,1,1 Csaba P. Kovesdy,1,2 Kaymarr Kalantar- Zadeh,1,2 Elani Streja,1,3 Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; 1The University of Tennessee Health Science Center, Memphis, TN; 2VA Long Beach Healthcare System, Long Beach, CA; 3Memphis VA Medical Center, Memphis, TN.

Background: In chronic kidney disease (CKD) patients, we showed that the risk of atherosclerotic cardiovascular disease (ASCVD) and non-ASCVD events with high baseline triglycerides (TG) incrementally attenuated across worse CKD stages, where high TG was associated with lower risk of non-ASCVD events in late-stage CKD. TG levels can change with CKD progression, but associations of time-varying TG with ASCVD or non-ASCVD hospitalizations is unknown.

Methods: We examined time-varying TG with time to first ASCVD or non-ASCVD hospitalization in 2,963,176 US veterans who received care in 2004-2006 (baseline) and were followed to 2014. Events were classified by primary ICD-9 codes. Using time-varying Cox models, we evaluated associations of time-varying TG with first ASCVD or non-ASCVD events stratified by baseline CKD stage, with adjustment for demographics, and time-varying comorbidities and laboratory values.

Results: The cohort was 63±14 years old with a mean [IQR] TG 72[49,127] mg/dL and 23% had CKD 3A or higher at baseline. TG <80 mg/dL was associated with a lower risk of time to first ASCVD event (ref: TG 120–<160 mg/dL) for all baseline CKD stages (Fig A). There was a linear association between time-varying TG and ASCVD events. High TG (≥240 mg/dL had the highest risks for ASCVD, for baseline non-CKD, and CKD 3A-3B. Among late-stage CKD patients, the association of high TG and ASCVD was null. We observed an inverse association between time-varying TG with time to non-ASCVD event (Fig B). Patients with low TG had faster times to first non-ASCVD event for non-CKD and CKD 3A-4, while high TG were associated with slower times in all stages. CKD stages 5 and stage renal disease patients with TG ≥240 mg/dL had the lowest risk of non-ASCVD event.

Conclusions: Short-term risk of higher TG with ASCVD or non-ASCVD events incrementally decreased across CKD stages, where risk was lower to null in late stage patients. High TG were associated with lower risks of non-ASCVD across all CKD stages. Investigation is needed to evaluate the pathways involving TG and cardiac events as CKD severity progresses in order to best manage health.

PO0468

Relationship Between Metabolic Acidosis and CKD Progression Is Evident Across US Racial and Ethnic Groups

Navdeep Tangri,1 Vandana S. Mathur,2 Nancy L. Reaven,1 Susan E. Funk,2 Donald E. Wesson,3 1University of Manitoba, Winnipeg, MB, Canada; 2MathurConsulting, Woodside, CA; 3Strategic Health Resources, La Canada, CA; 4Baylor Scott & White Health and Wellness Center, Dallas, TX.

Background: Metabolic acidosis is a known risk factor for CKD progression, but little is known about the impact of race and ethnicity on this relationship. We used a large electronic medical record (EMR) database of >100 million patients from all 50 states and insurance types to evaluate the relationship between metabolic acidosis and adverse renal outcomes and death by race and ethnicity.

Methods: De-identified electronic medical records (Optum® EMR), 2007–2019 were queried to identify patients with non-dialysis CKD Stages 3-5, ≥2 years of post-index data or death within 2 years, and grouped by baseline metabolic acidosis (12 to < 22 mEq/L) vs normal serum bicarbonate (22 to ≤ 30 mEq/L). Patients (N = 136,067) were classified as Asian (N=1,328), Black (N=15,248), Hispanic (N=4,137), White (N=111,953) or Other (N=3,401). The primary endpoint was the composite outcome of death, kidney dialysis or transplant, or 40% decline in eGFR from baseline (DD40). Cox proportional hazards models examined the impact of serum bicarbonate on DD40 within each racial/ethnic group, adjusted for age, sex, eGFR, log albumin-to-creatinine ratio, diabetes, hypertension, heart failure, Charlson Comorbidity Score.

Results: Overall, 47,032 patients (34.6%) experienced DD40 events within 2 years: Asian, 35%; Black, 44%; Hispanic, 48%; White, 32%; Other, 48%. Serum bicarbonate independently predicted DD40 in all racial/ethnic groups. Adjusted Hazard Ratios for DD40 per 1 mEq/L increase in serum bicarbonate (median 4.2 yrs, max 11.5 yrs follow-up) were as follows: Asian, 0.942 (CI: 0.917-0.968); Black, 0.976 (CI: 0.969-0.983); Hispanic, 0.970 (CI: 0.956-0.984); White, 0.960 (CI: 0.957-0.963); P< 0.0001 for all groups.

Conclusions: In a large community-dwelling US population, serum bicarbonate was independently associated with adverse kidney outcomes and death in Asians, Blacks, Hispanics and Whites with CKD. Since race and ethnicity are associated with other sociodemographic factors that affect health, further exploration of the potential reasons for the observed range of hazards across racial/ethnic groups is warranted.

PO0469

Metabolic Acidosis Is Associated with CKD Progression: A Longitudinal Analysis of >100,000 US Community-Based Patients

Vandana S. Mathur,1 Nancy L. Reaven,2 Susan E. Funk,2 Navdeep Tangri,3 1University of Manitoba, Winnipeg, MB, Canada; 2MathurConsulting, Woodside, CA; 3Strategic Health Resources, La Canada, CA; 4University of Manitoba, Winnipeg, MB, Canada.

Background: To delay the progression of CKD, it is imperative to identify modifiable risk factors and then evaluate efficacy of interventions. Here we assess the role of metabolic acidosis as an independent risk factor for CKD progression in patients (pts) with non-dialysis-dependent CKD Stages 3-5.

Methods: De-identified electronic medical records (Optum® EMR), 2007–2019 were queried to identify pts with non-dialysis CKD Stages 3-5, (2 consecutive eGFR values ≥10 and <60 mL/min/1.73m2 90-365 days apart) followed by 2 consecutive serum bicarbonate values ≥28-365 days apart) followed by 2 consecutive serum bicarbonate values ≥90-365 days apart) followed by 2 consecutive serum bicarbonate values 28-365 days apart, a2 <22 mEq/L (metabolic acidosis) or 22 to <30 mEq/L (normal serum bicarbonate) and a2 yrs of post-index data or death within 2 yrs. Pts (N = 136,067) were followed for up to 11.5 yrs for evidence of CKD progression, measured as a ≥40% decline in eGFR from baseline and as progression of a ≥1 CKD stage from baseline using laboratory data. We describe outcomes at 2 yrs and used Cox proportional hazards models over the entire follow-up period to examine potential confounders: age, sex, race/ethnicity, eGFR, log albumin-to-creatinine ratio, diabetes, hypertension, heart failure, and weighted Charlson Comorbidity Index.

Results: 75,127 pts (55%) progressed 1 or more CKD stages within 2 yrs. The incidence of CKD progression within 2 years was significantly higher in pts with metabolic acidosis compared to pts with normal serum bicarbonate, irrespective of the endpoint (≥40% decline in eGFR: 38.3% vs. 20.4%, P< 0.0001; progression of a ≥1 CKD stage from baseline vs. 54.5%, P< 0.0001). During the up to 11.5 yrs of follow-up (median 4.2 yrs), serum bicarbonate was independently associated with CKD progression; hazard ratios per 1 mEq/L increase in serum bicarbonate were 0.969, CI: 0.965-0.973 for a ≥40% decline in eGFR and 0.975, CI: 0.972-0.977 for progression of a ≥1 CKD stage.

Conclusions: In pts with non-dialysis CKD, serum bicarbonate levels below 22 mEq/L were independently associated with increased risk of CKD progression. Large randomized trials targeting treatment of metabolic acidosis to slow CKD progression are needed. There was a 2.5–3.0% risk reduction for a ≥40% decrease in eGFR or progression by a ≥1 CKD stage for every 1 mEq/L increase in serum bicarbonate.

Funding: Commercial Support - Tricida, Inc.

Lower Urine Citrate Excretion Associated with Advanced CKD Stage Is Mediated by Reduced Plasma Citrate and Decreased Kidney Citrate Clearance

Nimrit Goraya,1 Nicolaos E. Madias,2 Abdullah A. Mamun,3 Jan Simoni,1 Donald E. Wesson,1,3 Texas A&M University College Station, College Station, TX; Baylor Scott and White Health and Wellness Center, Dallas, TX; Tufts University School of Medicine, Boston, MA; Surgery, Texas Tech University HSC, Lubbock, TX.

Background: Lower urine citrate excretion (UcitV) might be a biomarker of covert acid (H+) retention in patients with CKD but with metabolic acidosis and so mechanisms that mediate UcitV differences among patients with CKD would help assessment of its biomarker utility. Because longitudinal eGFR decreases in patients with CKD associated with decreasing UcitV (Goraya, et al. AJP 317:F502, 2019), we examined cross-sectional differences in UcitV across CKD stages and mechanisms that mediate such differences.

Methods: We measured 8-hour UcitV (8h UcitV), plasma citrate concentration (Pcit), and kidney citrate clearance (citrate (UcitV)/Pcit) in 52 patients with CKD 1 (eGFR=99.5±7.7 ml/min/1.73 m²), 120 with CKD 2 (eGFR=73.4±6.1 ml/min/1.73 m²), and 52 with CKD 3 (eGFR=40.1±7.6 ml/min/1.73 m²) with macroalbuminuria, non-diabetic, hypertension-associated nephropathy. We assessed ongoing dietary H+ intake as potential renal acid load (PRAL) and steady-state acid-base status with plasma total CO2 (PTCO2) and H+ retention, the latter estimated by comparing observed to expected PTCO2, increase in response to retained HCO3 (administered minus UHCO3V) 2 hours after oral NaHCO3, bolus (0.5 mmol/kg bw), assuming 50% body weight HCO3 apparent space of distribution.

Results: Although PRAL was not different among CKD 1, CKD 2, and CKD 3 groups (62.4±11.9, 62.9±14.7, and 65.2±7.9 mmol/day, respectively, p=0.47), PTCO2 was progressively lower (26.4±0.7, 25.9±0.6, and 21.6±1.9 mM, respectively, p<0.01) and H+ retention progressively higher (3.9±1.2, 18.2±1.0, and 25.1±13.4 mM, respectively, p<0.01) with advancing CKD stage. 8h UcitV was progressively lower with advancing CKD stage (1.14±0.03, 1.00±0.25, and 0.86±0.10 mmol/1.73 m², respectively, p<0.01) as was Pcit (0.16±0.01, 0.15±0.02, and 0.14±0.01 mM, respectively, p<0.01) and UcitV/Pcit (0.015±0.001, 0.014±0.003, and 0.013±0.001 mm/1.73 m², respectively, p<0.01).

Conclusions: Cross-sectional advanced CKD stage was associated with greater H+ retention and lower UcitV, the latter mediated by lower Pcit and lower UcitV/Pcit. The data support that reduced UcitV associated with decreased eGFR reflects underlying H+ retention with reduced body citrate stores and increased citrate conservation through reduced kidney citrate clearance.

Urinary Calcium Excretion and Risk of CKD Progression: The CRIC Study

Jing Liu,1,2 Maria Clarissa Tio,3 Titilayo O. Ilori,1 Ashish Verma,3 Insa M. Schmidt,1,3 Sushrut S. Wailer,3,1 Renal Section, Department of Medicine, Boston University Medical Center, Boston, MA; 2Division of Nephrology, Kidney Research Institute, West China Hospital of Sichuan University, Chengdu, China; 3Renal Division, Brigham & Women’s Hospital, Harvard Medical School, Boston, MA.

Background: Hypercalcuria is implicated in nephrolithiasis and nephrocalcinosis, conditions associated with chronic kidney disease (CKD). We aimed to study the determinants of urinary calcium excretion (UCAe) and its association with adverse clinical outcomes in CKD.

Methods: 24-hour UCAe was measured in 3,768 Chronic Renal Insufficiency Cohort (CRIC) participants. We used multivariable linear regression models to determine independent predictors of UCAe in CKD 2 (CONSORT). Weighted Cox regression analyses tested the associations of UCAe with incident end stage kidney disease (ESKD), CKD progression (50% eGFR decline or incident ESKD), atherosclerotic cardiovascular disease (ASCVD) events, and death.

Results: Estimated glomerular filtration rate (eGFR) correlated most strongly with UCAe (r=0.417, p<0.001). In both males and females, determinants of UCAe included eGFR, African American race, iPTH, 24-hour urine sodium and phosphate, serum albumin and the use of diuretics and angiotensin receptor blockers (Figure 1). Certain predictors of UCAe differed between sexes: systolic blood pressure and alcohol drinker were associated with UCAe in males, while serum calcium and vitamin D intakes were significantly associated with UCAe in females. Higher UCAe was significantly associated with lower risk of ESKD, CKD progression, death and ASCVD events in unadjusted models. These associations were attenuated after adjusting for baseline characteristics, and for most outcomes the associations became insignificant after adjusting for eGFR.

Conclusions: Predictors of UCAe in CKD differed between males and females. eGFR is extremely strongly associated with UCAe and greatly confounds the associations between UCAe and all the outcomes.
Methods: We utilized electronic health record (EHR) data of patients seen at a healthcare system in the 7-county metropolitan area in Minnesota and linked census tract data. Census tract measures (median value of owner occupied housing units (wealth), percentage of residents >25 years with a Bachelor’s degree (education), and median household income (income)] and individual level insurance status (≥65 years: Medicare vs. other insurance; <65 years: Medicare vs. supplemental insurance plan) were obtained from the American Community Survey (2008-2012) and the EHR, respectively. A patient was considered to be living in low and high SES tracts if they belong to the first and fourth quartile of each SES measures. CKD prevalence was defined as having an estimated glomerular filtration rate (eGFR) <60 mL/min/1.73m2 or proteinuria. We used a multilevel Poisson regression with robust error variance with a random intercept at the census tract level to estimate the association between tract SES [low (first quartile) vs. high (fourth quartile)], insurance, and CKD.

Results: We included 185,269 patients. Tract SES (wealth and education) and insurance are independently associated with CKD prevalence. After adjusting for demographic and clinical characteristics, patients (<65 and a 65 years) living in low vs. high SES tracts had higher CKD prevalence (Prevalence Ratio, PR, 95%CI of low vs. high tract SES for education among patients >65 years: 1.11 [1.05, 1.18] and 1.08 [1.04, 1.12] for women and 1.26 [1.17, 1.36] and 1.24 [1.15, 1.33] for men). Patients (<65 years) on Medicare vs. other insurance had higher CKD prevalence (PR, 95%CI: 1.51 [1.43, 1.60]). For patients ≥65 years, insurance type was not associated with prevalence of CKD in the fully adjusted model.

Conclusions: In conclusion, we found that patients from low SES tracts and Medicare recipients (among patients <65 years) have greater rates of CKD compared to patients from high SES tracts and patients with other insurance. These may be two of several socioeconomic and individual factors influencing the complexity of identification, management, and treatment of CKD.

Social Determinants of CKD in the Military Health System
Jenna M. Norton, Lindsay Grunwald, Cara H. Olsen, Eric S. Marks, Tracey L. Koehlmoos. Uniformed Services University of the Health Sciences, Bethesda, MD.

Background: A growing body of evidence suggests that negative social determinants of health—or social risks—contribute to socioeconomic and racial disparities in chronic kidney disease (CKD). One mechanism through which social risks appear to produce disease is by impeding access to healthcare. The Military Health System (MHS) provides an opportunity to assess CKD disparities in the context of universal healthcare.

Methods: We identified all MHS beneficiaries aged 18 to 64 who received care through the MHS from October 1, 2015 to September 30, 2018. CKD was identified by ICD-10 code and/or a validated laboratory value-based electronic phenotype for CKD. Directed acyclic graphs were developed to understand potential confounding or mediating roles of covariates. Multivariable logistic regression models were used to compare the prevalence of CKD by race, rank, zip code level median household income, and marital status, controlling separately for suspected confounders (age, sex, active duty status, service branch, and depression) and mediators (hypertension, diabetes, HIV and BMI). For family beneficiaries, the sponsor’s rank and zip code were used.

Results: Of the 3,330,893 MHS beneficiaries in this analysis, 105,504 (3.2%) were identified as having CKD. In confounder-adjusted models, CKD prevalence was statistically elevated in beneficiaries of black vs white race, lower vs higher income, and married vs single status (p <0.001). As expected, associations were partially or fully mitigated when further adjusting for suspected mediators, indicating the mediators may indeed be on the causal pathway between social risks and CKD.

Conclusions: Racial and socioeconomic disparities persist in CKD under the context of universal healthcare coverage provided by the MHS. While racial disparities may result in part from underlying genetic differences, the presence of disparities by rank and area income suggest social factors remain pertinent despite access to universal healthcare coverage.

Low Documentation of Social Determinants of Health Among US Veterans and Medicare Patients with CKD
Yuh Bin Maggie Hira1, Diane Steffick,1 Alvin Wyncott,1 Jennifer L. Bragg-Gresham,1 Kara Zivin,2 Nilka Rios Burrows,4 Carla I. Mercado,4 Delphine S. Tuot,5 Neil R. Powe,6,74 Rajiv Saran.1 1University of Michigan Division of Nephrology, Ann Arbor, MI; 2University of Michigan, Ann Arbor, MI; 3US Department of Veterans Affairs, Ann Arbor, MI; 4Centers for Disease Control and Prevention, Atlanta, GA; 5University of California San Francisco, San Francisco, CA; 6Zuckerberg San Francisco General Hospital and Trauma Center, San Francisco, CA; 7University of California, San Francisco.

Background: The implementation of ICD-10 codes in 2015 included new codes to identify social determinants of health (SDOH). We sought to identify differences in SDOH-related Z-code (SDOH-ZC) utilization in Veterans Health Administration (VHA) and Medicare patients identifying differences in SDOH-ZC utilization in those with and without chronic kidney disease (CKD).

Methods: We used 5% sample of Medicare claims data (2015-2018) and 100% VA health data (2015-2019). A list of SDOH-ZCs were grouped into 17 categories (education and literacy, employment status, occupational risk factors, housing, economic circumstances, lifestyle factors, etc.). Proportion of claims assigned a SDOH-ZC were measured quarterly across different healthcare encounters and described by patient characteristics including age, sex, race, and hypertension, diabetes, and CKD. Use of SDOH-ZC were compared between those with and without CKD.

Results: SDOH-ZCs appeared more frequently in the VA health system than in Medicare data (Fig 1.a-b). Tobacco use was the most common SDOH-ZC in both the VA and VA data. More SDOH-ZCs were evident in the VA employment, environment, housing and economic, and family circumstances. Compared to those without CKD, use of SDOH-ZC was higher in individuals with CKD in outpatient settings but lower among those with inpatient visits, observation stays, and emergency department visits (Fig 1.c-d).

Conclusions: We observed lower recording of SDOH overall and among those with CKD in health care settings. Additional efforts might consider increasing SDOH documentation to help assess need for social services, which could potentially reduce disparities in health outcomes by socioeconomic status.

PO0476

Association of Health-Related Social Needs with Kidney Protective Measures in an Urban Population
Tessa K. Novick,1 Dingfen Han,2 Elizabeth A. Jacobs,3 Michele K. Evans,3 Alan B. Zonderman,1 Deidra C. Crews.1 1University of Texas at Austin Dell Medical School, Austin, TX; 2Johns Hopkins University, Baltimore, MD; 3National Institute on Aging, Bethesda, MD.

Background: Health-related social needs are individual-level social determinants of health, such as food insecurity and housing insecurity. Maintaining blood pressure ≤130/80 mmHg, hemoglobin a1c ~7%, sodium intake <2 g/day, regular physical activity, BMI 20-25 kg/m2, and smoking cessation reduce risk of CKD and CKD progression. We evaluated whether having unmet needs was associated with achieving kidney protective measures.

Methods: We performed a cross-sectional analysis of data from the Healthy Aging in Neighborhoods of Diversity Across the Life Span (HANDLS) study (Baltimore, MD) during study visit 4. We used multivariable regression to quantify associations between having and least one unmet social need (food insecurity or housing insecurity), and the number of protective measures (BP ≤130/80 mmHg, a1c ≤7%, sodium intake <2 g/day, regular physical activity, BMI 20-25 kg/m2, and smoking cessation) relative to those with no unmet needs.

Results: Among 1805 HANDLS participants, 899 (49.8%) reported at least one unmet health-related social need. Compared to those without unmet needs, those with unmet needs were younger (mean age 55.0 versus 57.8 years), more likely to be black (63.7% versus 38.5%), report income <125% of federal poverty level (46.8% versus 31.9%), and had higher eGFR (mean 90.0 versus 85.8 mL/min/1.73m2). The likelihood of achieving a higher number of protective measures was significantly lower for those with unmet needs compared to those without unmet needs (Table). Having unmet needs was significantly associated with lower likelihood of being a non-smoker and engaging in physical activity.

Conclusions: Individuals with unmet social needs may be less likely to achieve measures to prevent incident CKD and CKD progression.
**Association Between Air Pollution and Renal Outcomes: A Systematic Review and Meta-Analysis**

Aghiles Hamroun,1,2 Aurore Camier,1 Jean Joel Bigna,1 François Glowacki,1
1Centre Hospitalier Regional Universitaire de Lille, Lille, France; 2Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France;
INSERM, UMR1153 Center for Research in Epidemiology and Statistics (CRESS), Research Team on Early Life Origins of Health (EAROH), Paris, France; 1Centre Pasteur, Yaounde, Cameroon.

**Background:** Although several risk factors of chronic kidney disease (CKD) have been well-established, mainly diabetes and hypertension, many remain less studied, such as chronic exposure to air pollution. Our purpose is to exhaustively summarize the current evidence on the association between air pollution and various renal outcomes.

**Methods:** We searched EMBASE, Pubmed, Web of Science, Cochrane library, and CINAHL database, for relevant records using a combination of keywords related to the type of exposure (O3, CO, NO2, NOx, SO2, PM2.5, PM10, and PM1) and outcome (CKD, end-stage renal disease-ESRD, proteinuria/albuminuria, renal function, kidney transplant failure, nephrotic syndrome, and kidney cancer). Using random-effects meta-analyses, we pooled summary statistics (hazard ratios, odds ratios, or beta-coefficients with their respective 95% confidence intervals) associated with a standardized increased level of each pollutant and presented the results by air pollutant and outcome. Heterogeneity has been assessed using the y2 test on Cochran’s Q statistic and quantified I2 calculation.

**Results:** Within 1214 eligible studies, 42 articles fulfilling the selection criteria were included in this work (11 cross-sectional, 15 prospective, and 16 retrospective cohort studies). The most significant associations are for PM10 exposure and higher risks of CKD, ESRD, and kidney cancer incidence; PM2.5 exposure and higher risks of CKD and ESRD incidence; PM2.5/PM10 exposure and higher CKD prevalence, as well as lower renal function (see details in Figure 1). These results should however be interpreted with caution, due to significant between-studies heterogeneity and risks of methodological bias.

**Conclusions:** Chronic exposure to particulate matter and nitrate dioxide seems to be associated with poorer renal outcomes. Further studies are warranted to confirm these results.

**PO0479**

**Prevalence and Severity of Hyperkalemia in Patients Referred to Nephrology Consultation: Epidemiologic Data from 1106 Mexican Patients at a National Reference Hospital**

Mayra Aviles,1 L. M. Perez-Navaarro,1 Samantha Escorza Valdivia,1 Alberto Sigfrido Benitez Renteria,2 Rafael Valdez-Ortiz,1 3Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico; 3AstraZeneca, Ciudad de Mexico, Mexico.

**Background:** Hyperkalemia (HK, serum K+ > 5 mEq/L) is an electrolyte disorder that occurs frequently in patients with chronic kidney disease (CKD), heart failure. In CKD, the ability to excrete K+ is reduced, impairing quality of life and increasing morbidity and mortality.

**Methods:** Cross-sectional retrospective, observational study. Records of adult patients who attended an outpatient Nephrology consultation in the period from February 2019 to February 2020 were included, with laboratory reports from the last 15 days prior to the date of the medical consultation. Descriptive statistics were performed, with a 95% CI and a p-value ≤ 0.05.

**Results:** 1106 patient records were included. 51% (563) were women. The mean age was 55.8 ± 15.6 years. 47% of the population had Diabetes mellitus and/or hypertension as their main comorbidity and 61% were overweight or obese. HK was identified in 29% of the study population. Figure 1 shows the frequency of HK by stage of CKD. 13% of the patients who entered the study were on renal replacement therapy, of which 54% had HK. 54% of the subjects with HK were diabetic, 56% hypertensive, 25% consumed ACE inhibitors and 13% consumed NSAIDs on a regular basis and 48% had proteinuria.

**Conclusions:** The presence of HK is a risk factor that increases the risk for cardiovascular complications and accelerates the progression to more advanced stages of CKD. It is important to intentionally search for this alteration in all stages of CKD and implement measures that help correct and mitigate its impact on patients with CKD.

Serum Potassium and Survival Among Advanced CKD Patients

Transplanting to Dialysis

Yoko Narasaki,1 Kamyr Kalantar-Zadeh,1 Antony J. Ferrey,1 Ekamol Tantisattamanoi,1 Amy S. You,1 Elani Streja,1 Kaushik Ivaturi,1 Cachet Wenziger,1 Jui-Ting Hsiung,1 Danh V. Nguyen,2 Csaba P. Kovesdy,2 Connie Rhee.1 University of California Irvine, Irvine, CA; 2iThe University of Tennessee Health Science Center, Memphis, TN.

Background: Most laboratories designate a wide reference range for “normal” serum potassium levels (3.5–5.5 mEq/L), yet the precise concentrations associated with favorable outcomes in chronic kidney disease (CKD) remain uncertain. While dietary potassium is commonly restricted in CKD patients to mitigate hyperkalemia, there may be ill effects of this strategy by restricting healthy potassium-rich foods (fruits, vegetables).

We hypothesized that high-normal serum potassium levels are associated with better long-term survival in advanced non-dialysis dependent (NDD) CKD patients transitioning to dialysis.

Methods: Among 43,798 US Veterans with NDD-CKD transitioning to end-stage renal disease (ESRD) (mean age: 60.2 yrs, 10/2007-3/2015) an electronic health record cohort study was linked to United States Renal Disease System data. Associations of serum potassium levels (categorized as <3.5, 3.5–<4.0, 4.0–<4.5, 4.5–<5.0, and 5.0–5.5 mEq/L) with all-cause mortality were estimated using adjusted Cox models.

Results: In adjusted Cox analyses, high-normal serum potassium levels ranging from 5.0–5.5 mEq/L were associated with greater survival (HR: 1.07, 95% CI 1.04-1.10). In contrast, serum potassium concentrations at or below normal range were associated with higher death risk (OR 1.16, 95% CI 1.06-1.27). These findings are compatible with the hypothesis that within the normal range, high serum potassium levels may benefit survival among advanced CKD patients transitioning to dialysis.

Conclusions: Our study confirms that high-normal serum potassium levels is associated with improved long-term survival among advanced CKD patients transitioning to dialysis.

PO0482

High Serum Alkaline Phosphatase Predicts CKD Progression: Effect Modification by GFR

Francesca Mallama,1,2 Grazzella D’Arrigo,1 Francesco Marino,2 Grazzella Caridi,1 Giovanna Parlongo,1 Daniela Leonardi,1 Patrizia Pizzini,1 Sebastiano Cutrupi,1 Anna Pisano,1 Giovanni Tripepi,1 Carmine Zoccali,1 CNR-IFC, Reggio Calabria, Italy; 2Nephrology, Dialysis and Transplantation Unit, Reggio Calabria, Italy.

Background: In the post-hoc analyses of SUSTAIN/ASSURE trials, Apabetalone, an epigenetic modulator which lowers alkaline phosphatase (AlkPhos), stabilized the GFR in patients with CV disease and GFR <60 ml/min/1.73 m². Analyzing the relationship between AlkPhos and renal outcomes in patients with CKD is useful to explore the biological hypothesis that AlkPhos is implicated in CKD progression.

Methods: We investigated the relationship between AlkPhos and the risk of a combined end-point (30% GFR loss or dialysis/renal transplantation) in 609 stage 3-5 CKD patients (mean GFR: 34±12 ml/min/1.73 m²).

Results: Median AlkPhos was 91 IU/L and in the majority of patients had values below 147 IU/L (the upper limit of the normal range). Over a median follow up of 3 yrs, 290 patients had the combined end-point. In an unadjusted analysis, 1 ln increase in AlkPhos entailed a 49% risk excess for the renal end-point (HR:1.49, 95% CI 1.11-2.01, P=0.008). Adjusting for age, gender, smoking, diabetes, cholesterol, BMI, systolic BP, CV comorbidities, hemoglobin, albumin, phosphate, and hs-CRP, did not modify this association (HR:1.48, 95% CI 1.08-2.02, P=0.016). In a fully adjusted analysis testing the GFR as an effect modifier of the AlkPhos - combined renal end-point link showed a GFR-by-AlkPhos interaction (p=0.007). Adjusted for age, gender, smoking, diabetes, cholesterol, BMI, systolic BP, CV comorbidities, hemoglobin, albumin, phosphate, and hs-CRP, did not modify this association.

Conclusions: In stage 3-5 CKD patients, AlkPhos within the normal range is associated with the progression to ESRD and the GFR is an effect modifier of this relationship. These findings are compatible with the hypothesis that within the normal range of this biomarker, the risk for CKD progression by AlkPhos is amplified by CKD severity. These data are in keeping with post-hoc analyses of SUSTAIN/ASSURE trials and support the hypothesis that interventions lowering AlkPhos may mitigate CKD progression.

PO0481

Hyperkalemia, CKD, and RAAS Inhibition: A Triad with a Fine Balance to Prevent Mortality

Luis F. Goncalves, Mario R. Raimundo. Hospital Beatriz Angelo, Loures, Portugal.

Background: Hyperkalemia (HK) is a common and dangerous complication of CKD. HK is also a complication of beneficial therapeutic agents acting on the RAAS. Our goal was to investigate incidence, prevalence and clinical outcomes of at least one episode of HK in a CKD population outpatient setting. Additionally, we investigated the association of HK with changes in RAAS inhibition and mortality.

Methods: Retrospective analysis of all adult patients referred to a nephrology clinic over a 6 years period. We included CKD stage 3 patients with at least 24 months of follow up and 3 or more serum potassium determinations. The prevalence of HK at first consultation and incidence during follow up were assessed. Patients were split in two groups prior to analysis: A) Patients without any HK episode and B) Patients with at least one HK episode.

Results: Out of the 3008 patients referred, 575 (19.1%) met the inclusion criteria (mean age: 70.4 years; 63.7% male and 94.0% white color). Mean follow-up was 4.1±1.8 years. The prevalence of HK at first consultation was 8.7% and follow up incidence 21.7%. From this cohort, 164 (28.5%) had at least on episode of HK (Group B) and 101 (17.6%) died. During the follow up, RAAS inhibition drugs was removed or not started in 200 (34.8%) and diuretic was initiated in 165 (26.8%). At least one HK episode was associated with Diabetes (65.9 vs 42.3%, p<0.001), Heart failure (36.6 vs 28.0%, p=0.007), Macroalbuminuria (34.1 vs 21.2%, p=0.001), CKD progression (33.5 vs 16.3, p=0.001) higher frequency of diuretic initiation (38.4 vs 24.8%, p<0.001) and higher mortality (27.6 vs 13.7%, p=0.001). The independent predictors of mortality were: At least one HK episode (OR 1.82, 95% CI 1.08-3.04); Heart Failure (OR 1.97, 95% CI 1.16-3.35); Older age (OR per 1 year increase 1.04, 95% CI 1.02-1.07); CKD progression (OR 4.18, 95% CI 2.43-7.19); Patients who maintained RAAS inhibition during follow up (OR 0.50, 95% CI 0.26-0.96); Patients who started RAAS inhibition during follow up (OR 0.38, 95% CI 0.16-0.88).

Conclusions: Our study confirms that RAAS inhibition had and protector and independent impact in mortality when prescribed in CKD early stages. Patients with at least one episode of HK have a higher risk of mortality. All efforts should be made to maintain these therapeutic agents, looking for other ways to control hyperkalemia rather than stop it.

The Association Between Fibroblast Growth Factor 23 (FGF-23) and Pulse Pressure (PP) in CKD Stage G5 Patients

Cristian Rodelo-Haad,1,2 Isabel López-López,3 Rafael Santamaría,1,2 Juan R. Munoz-Castaneda,2,4 Sagrario Soriano,1,2 Mariano Rodriguez Portillo,5 Alejandro Martín-Malo,1,2 Instituto Maimonides de Investigacion Biomedica de Cordoba, Cordoba, Spain; 1Hospital Universitario Reina Sofia, Cordoba, Spain.

Background: FGF23 is associated with increased cardiovascular events and mortality in CKD patients. Non-classical biological effects of FGF23, such as left ventricular hypertrophy and vascular remodeling, may potentially explain this association. Experimental models suggest that FGF23 stimulates renal tubular sodium reabsorption and volume overload. It is plausible that FGF23 also increases blood pressure. The linking of FGF23 increment with blood pressure control may help identify novel risk factors of mortality in CKD patients. Therefore, we aimed to evaluate the relationship between FGF23, blood pressure control, and indirect signs of arterial stiffness in subjects with CKD G5.

Methods: Clinical and analytical variables were analyzed in 159 CKD G5 patients immediately before starting kidney replacement therapy. The association between these variables and the levels of intact FGF23 (iFGF23) was evaluated with linear regression models. PMI was used as an indirect surrogate of arterial stiffness. Statistics were performed using R 3.6.2.

Results: The mean SBP was 158.8 ± 16.1 years (mean ± standard deviation), and 60.8% were male. The eGFR was 44.4 ± 23.5 mL/min/1.73m². The median glomerulosclerosis index (GS) was 18.3 (interquartile range, 4.7-44.4) %, and the tubular injury index was 17.5 (5.0-36.3) %. The PMI was 0.94 ± 0.23, the PMP was 21.6 ± 7.3 x 10⁶, and the BMI was 22.9 ± 4.7 kg/m². Both PMI and PMP were positively associated with GS, HbA1c, and triglycerides, whereas negatively associated with eGFR (P < 0.02 and 0.004, respectively), CKD stages (P = 0.04 and 0.02, respectively) and HDL. Of note, each parameter such as BMI, HbA1c, and blood pressure was not correlated with either eGFR or CKD stages.

Conclusions: We observed correlations between both PMI and PMP and kidney function. This study indicates that PMI and PMP may be possible makers of the relative risk of unhealthy obesity with CKD.

Table 1. Determinants of SBP, DBP, and PP. SBP: Systolic Blood Pressure; DBP: Diastolic Blood Pressure. PP: Pulse Pressure. * Model adjusted by serum phosphate, serum calcium, parathyroid hormone, and C-reactive protein.

PO0484

Pulse Mass Index and Pulse Mass Pressure Product in CKD Patients

Rina Oba, Go Kanzaki, Kotaro Haruhara, Takaya Sasaki, Yusuke Okabayashi, Kentaro Koike, Nobuo Tsuboi, Takashi Yokoo. The Jikei University School of Medicine, Division of Nephrology and Hypertension, Department of Internal Medicine., 3-25-8 Nishi-Shimbashi, Minato-ku, Japan.

Background: Recent studies have conflicting findings on the association between obesity and the risk of chronic kidney disease (CKD). The body mass index (BMI) by itself is an imperfect marker of metabolically unhealthy obesity. The pulse mass index (PMI) and the pulse mass pressure product (PMP) show strong correlations with the risk of cardiovascular disease and may reflect an individual’s metabolic energy state. However, it is still unclear whether PMI and PMP can be useful parameters for the risk of CKD.

Methods: We retrospectively identified 51 subjects who underwent ambulatory blood pressure monitoring and kidney biopsy simultaneously at the Jikei University Hospital, Tokyo, from 2017 to 2019. All subjects were diagnosed as primary or secondary glomerular diseases by kidney biopsy. The PMI and the PMP were calculated from the following formula: PMI = BMI x resting heart rate (RHR) /1730. PMP = BMI x RHR x systolic blood pressure. We evaluated the clinicopathological findings associated with PMI and PMP.

Results: Of 51 subjects, the age was 50.3 ± 16.1 years (mean ± standard deviation), and 60.8% were male. The eGFR was 44.4 ± 23.5 mL/min/1.73m². The median glomerulosclerosis index (GS) was 18.3 (interquartile range, 4.7-44.4) %, and the tubular injury index was 17.5 (5.0-36.3) %. The eGFR was 0.94 ± 0.23, the PMP was 21.6 ± 7.3 x 10⁶, and the BMI was 22.9 ± 4.7 kg/m². Both PMI and PMP were positively associated with GS, HbA1c, and triglycerides, whereas negatively associated with eGFR (P < 0.02 and 0.004, respectively), CKD stages (P = 0.04 and 0.02, respectively) and HDL. Of note, each parameter such as BMI, HbA1c, and blood pressure was not correlated with either eGFR or CKD stages.

Conclusions: We observed correlations between both PMI and PMP and kidney function. This study indicates that PMI and PMP may be possible makers of the relative risk of unhealthy obesity with CKD.
PO0486

Baseline Characteristics of Non-Dialysis CKD Patients with and Without Anemia: A Report from the Retrospective Cohort from DISCOVER CKD

Eric T. Witthoft,1 Juan J. Carrero,2 Glen James,3 Steven Fishbane,4 Supriya R. Kumar,1 Roberto Pecois-Filho,5,6 Juan Jose Garcia Sanchez,7 Carol A. Pollock,7 James A. Sloand,1 Katarina Hedman,1 David C. Wheeler,3 AstraZeneca UK Ltd, Cambridge, United Kingdom; Northwell Health, Manhasset, NY; University of Sydney, Sydney, NSW, Australia; University College London, London, United Kingdom.

Background: Anemia is a frequent complication of chronic kidney disease (CKD), associated with adverse clinical outcomes and reduced quality of life. This analysis describes baseline characteristics of non-dialysis dependent (NDD) CKD patients with and without anemia in DISCOVER CKD.

Methods: The DISCOVER CKD retrospective cohort of patients in this analysis were extracted from the Trinetx health research network, Japan Medical Data Vision (JMDV) and integrated Limited Claims and EHR (LCED) databases. Patients were aged ≥18 years with 2 estimated glomerular filtration rate (eGFR) measures <60 ml/min/1.73m² ≥90 days apart between January 2008 and March 2020. The index date was the first Hb measure (regardless of value) or anemia therapy (iron, ESA or blood transfusion) prescription after the 2nd eGFR measure. Exclusion criteria included: <1-year registration/medical history prior to index, active bleeding, a Hb value (only) within 30 days from transfusion or bleeding and no Hb measure within a year after CKD diagnosis. Anemia was defined as ≥12 g/dL [females] or ≥14 g/dL [males] per WHO criteria. Baseline characteristics were summarized and stratified by presence of anemia.

Results: Preliminarily, of 709183 CKD patients meeting our I/E criteria, 67% were not anemic at baseline. In patients with anemia (33%), 191451 (81%) had a baseline Hb of 10-12 (female) 10-13 (male) g/dL, 36889 (16%) 8-10 g/dL and 6906 (3%) <8 g/dL. Compared to patients without anemia: patients with anemia were older, more likely to be female, to have more advanced CKD, and more likely to have comorbidities.

Conclusions: In routine clinical care, the presence and severity of anemia increases as CKD advances and is associated with a higher comorbidity burden.

PO0487

Incidence of and Risk Factors for Incident eGFR <60 in the Reasons for Geographic and Racial Differences in Stroke Study

Katharine L. Cheung,1 Mary Cushman,1 Deidra C. Crews,2 Suzanne E. Judd,3 David G. Warnock,3 Orlando M. Gutierrez,3 The University of Vermont Larner College of Medicine, Burlington, VT; 2John Hopkins University School of Medicine, Baltimore, MD; 3The University of Alabama at Birmingham School of Public Health, Birmingham, AL.

Background: Few contemporary US cohorts examined the incidence of and risk factors for developing a low estimated glomerular filtration rate (eGFR) or whether these factors vary by race, sex or region of US residence.

Methods: We studied 11,814 black or white participants with an eGFR ≥ 60 ml/min/1.73m² at baseline and who had 10-year follow-up eGFR. Low eGFR was defined as incident eGFR < 60 ml/min/1.73m² at the second visit and ≥40% decline from baseline. Incidence rates were calculated overall and by age, sex and race groups. We used Poisson regression to calculate the risk of incident low eGFR, adjusting for demographics, socioeconomic status and clinical factors, and across race, sex and region strata.

Results: At baseline, mean age was 62 (±8.1) years, 54% were female, 36% black and 56% resided in the US stroke belt. The overall incidence of low eGFR was 9% and ranged from 4% in those aged 45-54 to 18% in those 75 years and older. Age, systolic blood pressure, diabetes, heart disease, BMI, smoking, lower income, higher education, and residence in the US stroke belt were independent risk factors for incident low eGFR. Blacks had higher risk, accounting for socioeconomic risk factors, but this was fully attenuated after adjusting for clinical factors. Low eGFR risk factors did not differ substantially by race, sex or region.

Conclusions: The higher incidence of low eGFR in black compared to white participants was accounted for by modifiable clinical risk factors. Residence in the US stroke belt was independently associated with incident low eGFR in REGARDS participants.

Risk factors for incident low eGFR (Relative risk and 95% confidence interval)

Based on the provided textual content, it appears that the document contains research findings related to chronic kidney disease (CKD), anemia, and risk factors for low eGFR. The studies were conducted in various settings and countries, with a focus on understanding the prevalence and factors associated with CKD and anemia. The research was aimed at improving clinical care and enhancing awareness of these conditions, particularly among certain populations such as individuals living with HIV. Various methods, including case-control studies and prospective cohort analyses, were employed to examine the incidence and risk factors for CKD, anemia, and low eGFR. The findings highlight the importance of addressing these conditions, as they are associated with adverse clinical outcomes and reduced quality of life.
Oxygen Kinetics and Microvascular Function in CKD

Natalie J. Bohmke,1 Meghan G. Ramick,2,3 David G. Edwards,2 Danielle L. Kirkman,1,3 Virginia Commonwealth University; Richmond, VA; 2University of Delaware, Newark, DE; 3West��University of Pennsylvania, West Chester, PA

Background: Patients with chronic kidney disease (CKD) have reduced cardiorespiratory fitness levels that are associated with reduced quality of life and mortality. Impaired oxygen uptake kinetics create a larger oxygen deficit that promotes fatigue. CKD related microvascular dysfunction may contribute to impaired oxygen uptake kinetics by hampering oxygen delivery to the working muscle. The purpose of this study is to investigate the relationship between oxygen kinetics and a measure of microvascular function in CKD.

Methods: 13 patients with stage 3-5 CKD (Mean±SD, Age 60±14 years; eGFR 48.5±10.3 ml/min/1.73m²) were included in the analysis. Peak oxygen consumption (VO₂peak) was measured via breath by breath expired gas analysis during a symptom limited graded cycle ergometry test. Oxygen kinetics were quantified as mean response time (MRT), the exponential time constant to reach 63% of steady state VO₂peak. Microvascular function was assessed as cutaneous vasodilation during local heating coupled with intradermal microdialysis, measured by laser Doppler flowmetry.

Results: VO₂peak was 20.36±8.7 ml/kg/min. A moderate inverse correlation was observed between oxygen uptake kinetics and microvascular function (Figure 1; p=0.056, p=0.02). Microvascular dysfunction may contribute to a larger oxygen deficit in CKD patients. Following further studies, microvascular function could serve as a potential treatment target to improve exercise tolerance in these patients.

Funding: Other NIH Support - Grant number: 1R01DK122343

Conclusions: Microvascular dysfunction may contribute to a larger oxygen deficit in CKD patients. Following further studies, microvascular function could serve as a potential treatment target to improve exercise tolerance in these patients.

Evaluating the Longitudinal Association of Marijuana Use and Adverse Kidney Outcomes

Flor Alvarado,1 Alan B. Zonderman,1 Michele K. Evans,2 Deidra C. Crews,3 Johns Hopkins University School of Medicine, Baltimore, MD; 2National Institutes of Health/National Institute on Aging, Baltimore, MD; 3Intramural Research Program, NIA, NIH, Baltimore, MD

Background: Marijuana use has increased for recreational and medicinal purposes, however, its long-term effects on the kidneys remain uncertain. We examined the longitudinal association of marijuana use and adverse kidney outcomes among adults living in Baltimore, MD.

Methods: We used data from the prospective Healthy Aging in Neighborhoods of Diversity across the Life Span study. Baseline exposure, defined as self-reported never, former, or current marijuana use, and covariates were obtained between 2004 and 2009. The primary outcome was measured using an eGFR <60 ml/min/1.73m². Rapid kidney function decline (defined as a ≥33% eGFR decline per year) among those with a baseline eGFR ≥15 and incident albuminuria (albumin-to-creatinine ratio [ACR] ≥30 mg/g) at follow-up was also assessed. Participant characteristics were evaluated using ANOVA or χ² tests. Multivariable-adjusted logistic regression was used to evaluate associations of marijuana use with kidney outcomes. Covariates included baseline eGFR, age, sex, race, education, poverty status; current cigarette, opiate, cocaine use; hypertension, diabetes, and body mass index (BMI).

Results: Among 1,529 participants, 54.5%, 31.8% and 13.7% reported never, former, or current marijuana use, respectively. Participants with current marijuana use were more likely to be younger, male, American, have lower BMI and concurrently use cigarettes, opiates and/or cocaine; but were less likely to have hypertension or diabetes. Mean follow-up time was 8.6 ± 0.9 years. Rapid kidney function decline occurred in 5% of the cohort, but there was no significant difference in deaths between marijuana exposure groups (Pearson χ², p=0.524). After adjustment, marijuana use was not significantly associated with incident reduced kidney function (OR 1.08 [95% CI, 0.49-2.36] among those with current use, and OR 0.90 [95% CI, 0.49-1.61] for former use). Marijuana use was not significantly associated with rapid kidney function decline (OR 0.73 [95% CI, 0.42-1.27] for current use) or incident albuminuria (OR 0.63 [95% CI, 0.11-4.83] for current use).

Conclusions: In this Baltimore-based cohort, there was no independent association of marijuana use and longitudinal adverse kidney outcomes.

Life’s Simple 7 and CKD Progression: Results from the Mexico Chronic Renal Insufficiency Cohort (MCRIC) Study

Magdalen Madero,1 Ana P. Hernandez Martinez,2 Ana K. Fernandez Yepiz,2 Jinsong Chen,1 Claire T. Larkin,1 Natalie Meza,1 Eunice Carmona,1 Christopher G. Viamonte,1 Carlos L. Morales Cruz,1 Zuleyma T. Vasquez Vasquez,1 Tania J. Ramos Estrada,2 Areli d. Avalos Galicia,1 Bernardo Moguel,2 Carlos Linares Kolofon,1 Ana C. Ricardo,1 James P. Lash.1 University of Illinois at Chicago, Chicago, IL; 2Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico

Background: The American Heart Association developed the Life’s Simple 7 metric to promote cardiovascular health. We evaluated the association of this metric with chronic kidney disease (CKD) progression among individuals with CKD living in Mexico.

Methods: MCRIC is an ongoing, prospective observational cohort study of adults with CKD recruited in Mexico City, with entry estimated glomerular filtration rate (eGFR) ≥30 ml/min/1.73 m². Using data from 1,731 participants, we conducted a proportional hazards regression analysis to evaluate the association between Life’s Simple 7 (score range 0-14) and CKD progression (30% decline in eGFR from baseline).
Ideal cardiovascular health was defined as nonsmoker; body mass index ≤ 25 kg/m²; ≥ 150 minutes/week of physical activity; healthy dietary pattern (high in fruits and vegetables, fish, and fiber-rich whole grains; low in sodium and sugar-sweetened beverages); total cholesterol < 200 mg/dL; blood pressure <120/80 mm Hg; and fasting blood glucose <100 mg/dL.

(Po0493) Facilitators and Barriers to Self-Management of CKD
Sarah J. Schrauben,1 Eleanor Rivera,1 Sandra Amaral,2,1 Laura M. Dember,1 Harold I. Feldman,1 Frances K. Barg,1 1University of Pennsylvania, Philadelphia, PA, 2The Children’s Hospital of Philadelphia, Philadelphia, PA.

Background: Self-management is integral for the prevention and management of chronic kidney disease (CKD). Despite low adherence to self-management behaviors, few studies provide insight into barriers and facilitators of self-management from the perspective of patients. Methods: Semi-structured interviews were conducted with 30 participants who were purposively recruited for representation by CKD stage (3 or 4), age (≥65, 65 yrs), race (white, non-white), and sex. Interviews focused on patient experiences with CKD and efforts to follow treatment recommendations. They were recorded, transcribed, and entered into NVivo 12.0 for coding and analysis. Transcripts were coded inductively and analyzed thematically.

Results: We identified three key phases of CKD self-management behavior: prioritization, participation, and maintenance. Facilitators and barriers were organized according to these phases. Participants needed to prioritize the behavior to consider engagement, which was favorably influenced by optimism, stress management, and effective patient-provider communication. Prioritization was impeded by fatalism and competing priorities. One of the most widely reported impediments to behavior was presence of comorbid conditions that caused treatment burden and adverse symptoms. Notable facilitators of behavior performance included the presence of motivating factors, self-efficacy, social support, low cost, and convenience. For maintenance, participants’ ability to integrate and sustain behaviors in their lives was influenced by the aforementioned behavior performance factors, but also by behavior-specific factors, such as pets and physical therapy (for physical activity) and pharmacy assistance (for medication adherence). Key elements of effective maintenance included the use of memory aids, goal-setting, self-monitoring, and proactive preparation.

Conclusion: Individuals who adhered to CKD self-management behaviors viewed them as a priority, and developed strategies that fit their lifestyle to allow for behavior performance and maintenance. To increase self-management behavior prioritization, performance, and maintenance, we need to assess patients’ attitudes and beliefs, improve patient-provider communication, help patients overcome barriers such as high costs and conflicting treatment regimens, and leverage facilitators such as memory aids and goal-setting.

PO0496 Critical Care Resource Use in CKD in the Safety-Net Setting
Jefferson L. Triozzi, Jingbo Niu, Sankar D. Navaneethan. Baylor College of Medicine, Houston, TX.

Background: Chronic kidney disease (CKD) is associated with adverse outcomes among patients with critical illness. There is limited data on the extent of critical care resource use among patients with CKD in safety-net settings.

Methods: We conducted a retrospective cohort study of patients in a safety-net healthcare system with non-dialysis-dependent CKD and critical illness, defined as admission or transfer to the intensive or intermediate care unit. Poison regression was used to identify risk factors for critical illness based on sociodemographic factors, comorbidities, and baseline stage of CKD. Critical care resource use was extracted from the medical record, including dialysis initiation, ventilatory support, blood products, and vasopressors. Results were stratified by CKD stage.

Results: Out of 1,208 patients with CKD who were hospitalized during a three-year period (stage 3a= 43%, stage 3b= 35%, stage 4- 22%), 495 patients required intermediate or intensive care. In the multi-adjusted model [IRR (95% CI)], critical illness was associated with stage of CKD [stage 3a- 1 (referent), stage 3b- 1.24 (1.01, 1.49), stage 4- 1.99 (1.72, 2.30)]. Hypertension and non-Hispanic black race, congestive heart failure, and moderate/severe anemia were also associated with risk of receiving critical care (Table 1).

Conclusions: We report a high burden of hospitalizations requiring critical care resources in a safety-net setting. Notably, a third of patients with CKD stage 4 and critical illness required hemodialysis initiation. Further research is needed to prevent critical illness and the need for critical care resources in patients with CKD.

PO0497

Usual Source of Care and Clinical Outcomes in Adults with CKD: Findings from the Chronic Renal Insufficiency Cohort (CRIC) Study

Stephanie M. Toth-Manikowski,1 Jesse Y. Hsu,1 Michael J. Fischer,1 Jordana B. Cohen,2 Claudia M. Lora,1 Thilda C. Tan,1 Jiang He,4 Raquel J. Green,1 Matthew R. Weir,1 Sarah J. Schrauben,1 Mildra S. Saunders,2 Ana C. Ricardo,1 James P. Lash,1 University of Illinois at Chicago, Chicago, IL; 2University of Pennsylvania, Philadelphia, PA; 3Kaiser Permanente, Northern California, Oakland, CA; 4Tulane School of Public Health and Tropical Medicine, New Orleans, LA; 5Johns Hopkins Medicine, Baltimore, MD; 6University of Maryland School of Medicine, Baltimore, MD; 7University of Chicago, Chicago, IL;

Background: In general populations, having a usual source of care (USOC) increases use of preventive care and is associated with higher survival. However, there are limited data in adults with chronic kidney disease (CKD).

Methods: In the CRIC Study, we categorized participants’ self-reported USOC as follows: 1) clinic/doctor’s office, 2) emergency room (ER)/urgent care, and 3) other. Using multivariable regression analyses, we evaluated the association between USOC and incident end stage renal disease (ESRD), cardiovascular events (myocardial infarction, heart failure, stroke and peripheral arterial disease), hospitalizations, and all-cause death.

Results: Among 3,140 participants, mean age was 65 years, 45% were non-Hispanic white, 43% non-Hispanic black, 9% Hispanic, and mean estimated glomerular filtration rate (eGFR) was 50 mL/min/1.73m². 90% identified clinic/doctor’s office as USOC, 9% ER/urgent care, and 1% other. Over a median follow-up time of 3.6 years, there were 288 deaths, 181 incident ESRD events, 444 cardiovascular events, and 7,957 hospitalizations. In multivariable analyses, compared to clinic/doctor’s office as USOC, ER/urgent care was associated with higher risk for death and hospitalizations (Table). No significant association was seen with incident ESRD or cardiovascular events.

Conclusions: ER/urgent care as USOC was associated with higher risk for adverse outcomes in this large and diverse adult cohort with CKD. Further studies are needed to identify barriers to accessing appropriate preventive care to reduce negative health outcomes in this population.

Healthcare Resource Utilization and Costs of CKD According to the 2012 KDIGO CKD Classification: A Report from the DISCOVER CKD Retrospective Cohort

Juan Jose Garcia Sanchez,1 Juan J. Carrero,2 Supriya R. Kumar,2 Hiddo J. L Heerspink,3 Glen James,4 Stephen Nolan,1 Lam S. Carolyn,1,5 Hungta (Tony) Choi,2 Alyshah Abdul Sultan,1 Carol A. Pollock,5 Roberto Pocsik-Filho,6 1AstraZeneca, Cambridge, United Kingdom; 2Karolinska Institutet, Stockholm, Sweden; 3AstraZeneca, Gaithersburg, MD; 4Rijksuniversiteit Groningen, Groningen, Netherlands; 5National Heart Centre Singapore, Singapore, Singapore; 6Duke-NUS Medical School, Singapore, Singapore; 7Royal North Shore Hospital, St Leonards, NSW, Australia; 8Pontificia Universidade Catolica do Parana Escola de Medicina Campus Londrina, Londrina, Brazil; 9Arbor Research Collaborative for Health, Ann Arbor, MI;

Background: The DAPA-CKD trial finished early due to overwhelming efficacy. Real-world data reporting healthcare resource utilization (HCRU) and cost associated with CKD categorized according to the 2012 KDIGO recommendations are scarce. We assessed HCRU and costs in a “DAPA-CKD-like population” (eGFR 25-75/ml/min/1.73m² and UACR 200-5000mg/g) compared to patients categorized according to KDIGO 2012 recommendations.

Methods: DISCOVER CKD is an observational study in patients with CKD, data was extracted using the integrated Limited Claims and Electronic Health Record data. Patients were aged ≥18 years, with ≥1 UACR measure and ≥2 eGFR measures of 0-75/ml/min/1.73m² recorded at least 90 days apart between January 2008 and September 2018. Index date was 2nd eGFR. We calculated total and annualized number of encounters and estimated annualized per-patient and total costs. Incidence rates per 100 person-years (PY) were estimated for outpatient and hospitalization events.

Results: Preliminarily, 6,270 patients met the KDGO 2012 definition (mean[SD] age 64.0(10.9) years, 51.0% female) and 383 patients met the DAPA-CKD-like criteria (mean[SD] age 64.0(11.9) years, 38.9% female). The rate of hospitalizations almost doubled for the DAPA-CKD-like population vs the KDGO 2012 defined population (Rate 100-PY[95%CI] 59.0[53.7-64.8] vs 26.4[25.5-27.3]) and mean length of stay was also higher (Mean[SD] 6.5[9.4] vs 5.4[6.6] days). The DAPA-CKD-like population incurred substantially higher annualized per patient hospitalization costs (mean[SD] USD39782[78572] vs USD25717[60019]); Figure 1.

Conclusions: This analysis demonstrated that the DAPA-CKD-like population is associated with a higher HCRU and cost burden. These results highlight the need for innovative therapies to improve patient outcomes in this population.

Figure 1. Summary of annual healthcare resource use and cost (US$)

PO0499

Tope Olatunde,1 Lois Lamerato,1 Juan Jose Garcia Sanchez,2 Like Jiang,1 Joanna C. Huang,1 Stephen Nolan,1 1AstraZeneca, Wilmington, NC; 2AstraZeneca UK Ltd, Cambridge, United Kingdom; 3Henry Ford Health System, Detroit, MI;

Background: The DAPA-CKD Trial is the first SGLT-2i renal outcome trial to test the efficacy and safety of an SGLT-2i, dapagliflozin, in patients with diagnosed CKD with and without T2D. The objective of this study is to assess the healthcare resource utilization and cost in a "DAPA-CKD-like population" (eGFR 25-75/ml/min/1.73m² and UACR 200-5000mg/g) using a contemporary US healthcare system.

Methods: Data from the Henry Ford Health System (HFHS) were used to identify patients with CKD stages 2 through 4 between 2006 and 2016 (based on eGFR labs) and patients were followed through 2018. Patients with no confirmatory eGFR > 90 days from index date, death within 30 days, history of renal transplant, and evidence of renal replacement therapy, or progression to CKD stage 5 during the baseline period (6 months pre or post index date) were excluded. Cumulative primary and secondary utilization was evaluated for all patients during the follow-up time. Annual utilization rates are the total observed utilization divided by follow-up time. Billing records with HFHS were used to estimate costs.

Results: 6,557 patients (mean age 62.9 years, 46.2% male) met the eligibility criteria and are included in the study cohort. The population was stratified by UACR (0<50, 30–199, 200–5,000mg/g). The FR (CDR=200-5,000mg/g) population was categorized with significantly higher annualized per-patient healthcare costs, $39,222/yr (UACR 0–50mg/g) to $63,236/yr (UACR 200-5,000mg/g).
200-5000mg/g) vs. $19,547/yr (UACR <30mg/g). Persons in the highest UACR category were almost three times more likely to have a hospital admission compared to the lowest (rates 0.55/year vs. 0.20/year, respectively; see Table 1).

Conclusions: This analysis of a contemporary US healthcare system demonstrated that there exists a high disease burden in the DAPA-CKD-like population as seen by the substantial increase in healthcare resource utilization and costs compared to other cohorts of patients with a lower UACR. These results highlight the need for innovative therapies to improve patient outcomes in this high risk population.

Understanding Patterns of Medical Spend Informs Design of Upstream Intervention in CKD

Title: Srinivas. University Hospitals, Cleveland, OH.

Background: Despite ease of diagnosis based on laboratory testing, CKD is often unrecognized and comorbid decompensation results in delayed diagnosis in acute care settings. The purpose of our inquiry was to inform the design of systems of care that would prevent escalation of total cost of care (TCOC) of CKD through minimization of acute care spend.

Methods: Unrecognized CKD was defined as CKD that was evident by laboratory data in the EHR but not captured by an ICD10 code or DRG for chronic kidney disease. Recognized CKD or ESRD had both ICD10 and DRG data and laboratory evidence of CKD. We then compared inpatient and total medical spends as well as the density of preventive measures such as wellness visits among these groups. The data repository was built on the MS Power BI platform and machine learning and high throughput analyses were conducted using Alteryx utilities.

Results: A total of 217,125 patients were included that had eGFR and spend data in 2019. Annual wellness visits occurred on average among 38 percent (n=142,373) of those with no CKD diagnosed or evident by lab values vs. 19.1 percent of those with unrecognized Stage 3b to 4 CKD (n=31,435) vs. 18 percent among those with recognized Stage 3-5 CKD or ESRD (n=52,242; P < 0.001). No statistical difference was observed between wellness rates and stage 1 and stage 2 unrecognized CKD cohorts. Of annual spend in 2019, those with recognized CKD/ESRD, incurred 61.9 percent of spend in the inpatient setting vs. 25 percent among those with unrecognized CKD. The number of chronic condition increased from an average of 3.5 among those with Stage 3-5 unrecognized CKD to 10 among those with recognized CKD/ESRD. Average 12 mo spend was $ 6500 among those with unrecognized CKD stage 3b-5 and $ 22,978 among those with recognized CKD/ESRD (p<0.0001). A diagnosis of CHF was recorded in 13.1 %, 20.5 %, and 24.3 % of those with undiagnosed CKD stage 3a-5 vs. 46.9 percent of those with diagnosed CKD/ESRD (Chi square for trend <0.001).

Conclusions: CKD is often unrecognized clinically despite eGFR support of its existence in the medical record. Decompensation of unrecognized heart disease likely contributes to increased inpatient utilization and costs with clinical recognition of CKD. Wellness measures are unfortunately deficient in this population and systems of care triggered by eGFR values could inform care upstream of CKD decompensation to capture value.

Treatment Pathways of CKD Patients Defined by the 2012 KDIGO CKD Classification: A Report from the DISCOVER CKD Retrospective Cohort

Juan Jose Garcia Sanchez, 1 Juan J. Carrero, 2 Supriya R. Kumar, 3 Roberto Pecoiots-Filho, 4,5 Glen James, 1 Hiddo J. L. Heerspink, 1 Stephen Nolan, 1 Lam S. Carolyn, 6,7 Hungta (Tony) Chen, 1 Eiichiro Kanda, 1 Alyshah Abdul Sultan, 6 Naoki Kashiura, 6 Mikhail Kosiborod, 8,9 David C. Wheeler, 9,10 Carol A. Pollock, 10,11 AstraZeneca, Cambridge, United Kingdom; 1 Karolinska Institutet, Stockholm, Sweden; 2 AstraZeneca, Gothenburg, MD; 3 Arbor Research Collaborative for Health, Ann Arbor, MI; 4 Pontificia Universidade Catolica do Parana Escola de Medicina Campus Londrina, Londrina, Brazil; 5 Rijksuniversiteit Groningen, Groningen, Netherlands; 6 National Heart Centre Singapore, Singapore, Singapore; 7 Duke-NUS Medical School, Singapore, Singapore; 8 Kawasaki Ika Daigaku, Kurashiki, Japan; 9 Saint Luke’s Mid America Heart Institute, Kansas City, MO; 10 University College London, London, United Kingdom; 11 Royal North Shore Hospital, St Leonards, NSW, Australia.

Background: Treatment strategies to delay the progression of CKD focus on use of RAASi, anti-hypertensive and, for patients with type 2 diabetes, anti-diabetic therapy. Data describing treatment pathways in patients defined according to the 2012 KDIGO classification are scarce.

Methods: The DISCOVER CKD retrospective cohort of patients was extracted using the integrated Limited Claims and EHR data. Patients were aged ≥18 years, with at least 2 years of follow-up, UACR measure and two measures of eGFR 0-75 mL/min/1.73 m² recorded at least 90 days apart between 2008-2018. Sankey Plots were used to visualize chronological treatment pathways (1st-3rd line) post-index, of key treatments commonly prescribed to these CKD patients including: RAASi, anti-diabetic therapy, beta-blockers and anticoagulants. We also describe median time to 1st line therapy initiation.

Results: Preliminarily, 4283 patients were prescribed key treatments during follow-up with anti-hyperglycaemic therapy and RAASi therapy being the most common 1st line therapy, Figure 1. Median time to 1st-line therapy initiation was: 34 days for anti-diabetic therapy, 45 days for beta-blockers, 49 days for RAASi therapy and 50 days for anticoagulants. Anti-diabetic therapy and RAASi therapy accounted for the highest proportion of time in which treated patients remained on therapy during follow-up (68% and 61%, respectively).

Conclusions: We observed a high proportion of time on therapy for key pharmacological treatments during the follow-up period. However, it is well established that a substantial residual risk and unmet need exists with current standard of care.

Background: Chronic kidney disease (CKD) is a global health problem associated with clinical complications. Gaps exist in real-world data to understand treatment pathways of CKD patients. We describe treatment pathways of key medications prescribed to CKD patients in DISCOVER CKD.

Methods: The DISCOVER CKD retrospective cohort of patients were extracted using Japan Medical Data Vision (JMDV) and integrated Limited Claims and EHR (LCED) data. The study included patients aged ≥18 years with a diagnostic CKD code (stage 3A through end stage renal disease or renal replacement therapy) or 2 estimate glomerular filtration rate (eGFR) measures <75 mL/min/1.73m² at least 90 days apart between January 2008 and October 2018. The index date was the date of first diagnostic code or 2nd eGFR. Sankey Plots were used to visualize chronological treatment pathways (1st to 3rd line) post-index of key treatments (including combinations) commonly prescribed to at least 500 CKD patients including: RAAS, statins, diuretics and anti-hypertensives. We also described median time to first line therapy initiation.

Results: Preliminary, in the study cohort (N=159849) anti-hypertensives were the most common first-line therapy prescribed. Median time to first-line therapy initiation for LCED and JMDV data was: 48 days and 168 days for anti-hypertensives, 39 days and 89 days for diuretics, 51 days and 259 days for RAAS and 56 days and 133 days for statins, respectively. In both databases patients remained on anti-hypertensives the most (33.7%) during their time on therapy.

Conclusions: Patients with CKD have high therapy burden, with varying time to initiation of therapies.

PO0505

Albuminuria Testing and Prevalence and Incidence of Elevated Albuminuria in the DISCOVER CKD Retrospective Cohort

Jung-Im Shin, Alex R. Chang, Yingteng Sang, Ron T. Gansevoort, CKD Prognosis Consortium

Background: Guidelines recommend an annual evaluation of urine albumin creatinine ratio (ACR) in patients with diabetes (DM) or hypertension (HTN) for early identification and close monitoring of kidney damage. The aim of this study was to inform ACR testing strategies by 1) evaluating the frequency of ACR testing, 2) determining the prevalence and incidence of ACR≥30 mg/g, and 3) developing and validating a risk prediction model for incident ACR≥30 mg/g.

Methods: We analyzed 28 cohorts from the CKD Prognosis Consortium including 1,909,350 persons with DM or HTN from 5 countries. Analysis was performed separately for persons with DM and those with HTN but without DM. We selected a two-year baseline period for administrative cohorts and used the baseline visit for research cohorts to assess frequency of testing and prevalence of a single ACR≥30 mg/g. Confirmed incident ACR≥30 mg/g (elevated twice) was assessed 5 years after baseline in those with baseline ACR<30 mg/g. Development of prediction models for incident ACR≥30 mg/g used logistic regression and age, sex, baseline systolic blood pressure, HTN and DM medication use, coronary heart disease, heart failure, BMI, A1c, and eGFR as covariates. Models were validated in 5 DM cohorts and 4 HTN only cohorts.

Results: The median frequency of ACR testing across administrative cohorts was 48.9% (IQ: 32.5-58.3%) and 4.3% (IQ: 3.2-7.1%) in DM and HTN only. Among those tested at baseline, the median prevalence of ACR≥30 mg/g was 32.7% (IQ: 28.4-37.0%) and 21.9% (IQ: 18.6-29.6%) in DM and HTN only. Among 107,754 persons with DM and 15,676 persons with HTN only who had baseline ACR<30 mg/g, the median incidence of ACR≥30 mg/g at 5 years was 23.3% (IQ: 18.6-28.5%) and 21.7% (IQ: 15.7-26.3%) in DM and HTN only. Risk prediction models for 5 year incidence of ACR≥30 mg/g had only modest accuracy in DM (median C statistic: development cohorts 0.629, IQ: 0.600-0.655, validation cohorts 0.635, IQ: 0.619-0.641) and in HTN only (median C statistic: development cohorts 0.649, IQ: 0.621-0.695, validation cohorts 0.665, IQ: 0.638-0.671).

Conclusions: ACR testing in DM or HTN is low in clinical practice. The risk prediction models for incident ACR≥30 mg/g performed only modestly, suggesting focused efforts based on risk stratification may not improve clinical utility. Universal albuminuria testing for individuals with DM or HTN is likely necessary.

Urine Albumin and Serum Creatinine Dual Testing in US Veterans: Trends and Associations with Subspecialty Care

Nicolle M. Bhave,¹ Yun Han,¹ Diane Steffick,¹ Jennifer L. Bragg-Gresham,¹ Kara Zivin,¹ Nilka Rios Burros,² Meda E. Pavkov,² Delphine S. Tuot,² Neil R. Powe,² Ravjiv Saran,³ "University of Michigan, Ann Arbor, MI; "US Department of Veterans Affairs, Ann Arbor, MI; "Centers for Disease Control and Prevention, Atlanta, GA; "University of California San Francisco, San Francisco, CA; "Zuckerberg San Francisco General Hospital and Trauma Center, San Francisco, CA.

Background: Urine albumin and serum creatinine (Scr) help define chronic kidney disease (CKD). Despite the fact that urine albumin and Scr are multiplicatively associated with cardiovascular and all-cause mortality, dual testing remains limited. We sought to characterize trends in dual testing in all veterans and those seen by nephrologists.

Methods: We used Veterans Health Administration (VA) data (2009-18). VA patients with any inpatient or outpatient visit in a given calendar year were included. Time trend of dual testing and patient characteristics including age, sex, race, hypertension, diabetes, CKD, and cardiovascular diseases (CVD) were noted.

Dipstick Urinalysis Can Identify Patients with Early CKD Who Lack a Quantified Proteinuria Measurement
Meredith McAdams, Duwayne L. Willett, Yu-Lun Liu, Vaishnavi Kannan, L Parker Gregg, Susan Hedayati.
University of Texas Southwestern Medical Center at Dallas, Dallas, TX.

Background: Urine protein-to-creatinine ratio (UPCR)>0.15 g/g or albumin-to-creatinine ratio (UACR)>30 mg/g is the gold standard for identifying patients with stages 1-2 CKD with eGFR>60 mL/min/1.73m^2, but are not routinely obtained. Dipstick urinalysis semi-quantitative protein (DSP) is widely available and commonly measured.

Methods: To develop a pragmatic EHR tool to identify patients with stages 1-2 CKD, we investigated diagnostic utility of various DSP cutoffs (negative/trace, 30, 100, 300, or >500 mg/dl) against gold-standard proteinuria (UPCR>0.15 g/g or UACR>30 mg/g) using logistic regression. We also investigated whether addition of SG improved the diagnostic utility of DSP by comparing areas under the receiver-operating characteristic curves (AUC) for DSP with and without addition of SG. DSP was obtained from the EHR in 3,897 individuals with UPCR or UACR measured on the same date. A development model was created in a random sample of 2,728 (70%) using a bootstrap method and validated in the remaining 1,169 individuals.

Results: Mean age was 57±16.9 years, 51.7% were female, 25.6% Black, and 42.8% had an eGFR>60 mL/min/1.73m^2. Gold-standard proteinuria was present in 1,775 (45.5%). DSP cutoff=30 had specificity 81.1 (95% CI 79.0, 83.1), +LR=2.43 (95% CI 2.15, 2.75), -LR=0.67 (95% CI 0.63, 0.71). The combination of DSP and SG, taken continuously, performed better than DSP alone (Figure A). When including SG, a DSP cutoff of 30 had the best diagnostic accuracy vs. other cutoffs (Figure B). In the validation cohort, addition of SG to DSP also yielded a higher AUC than DSP alone, P=0.03. For DSP p>30 as a screening test, an SG of at least a 1.025 is needed. A more dilute urine, with a SG of 1.020, would be allowed if DSP p>100. A DSP cutoff of 30 had an AUC of 0.652 (0.621, 0.684), P<0.001, vs. a cutoff of 300 or 500. Using DSPs>30 identified an additional 141 individuals with CKD than use of eGFR≥60 alone.

Conclusions: Combining DSP and SG from a dipstick urinalysis can identify patients with early CKD who do not have a measured UPCR or UACR.

Funding: NIDDK Support

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Conclusions: Proteinuria was detected and CKD was recognized in half of the at-risk Veterans. Co-morbidities and health care visits other than primary care associated with increased screening and recognition suggest utility of initiatives at primary care level to educate the need for CKD detection and awareness.

PO0510
Spatial Distribution of Newly Detected CKD Among US Veterans, 2009-2018
Jennifer L. Brage-Gresham,1 Brenda W. Gillespie,2 Yun Han,1 Xiaosong Zhang,1 Diane Steffick,1 William Weitzel,1 Susan T. Crowley,1 Rajiv Saran,1,3 1University of Michigan Medical School, Ann Arbor, MI; 2University of Michigan, Ann Arbor, MI; 3Veterans Health Administration, West Haven, CT; 4Veterans Health Administration, Ann Arbor, MI.

Background: While the rate of new end stage renal disease (ESRD) cases has slowed in recent years, less is known about trends in the incidence of pre-ESRD CKD. Using national data from the Veterans Health Administration (VHA) we examined the rates and spatial distribution of newly detected cases of CKD using laboratory measures.

Methods: Using data from 8.5+ million US Veterans over a decade (2009-18), in the VHA system during the previous 3 years with no indication of kidney disease, rates of newly detected kidney disease were calculated by year. Three measures of kidney disease were assessed by laboratory reports: 1) eGFR < 60 ml/min/1.73m², 2) albuminuria, and 3) either low eGFR or albuminuria. Spatial maps contain 3-year incidence rates (2016-18) by county, based on patient residence.

Results: Rates of newly detected low eGFR were steady from 2011 forward (~30/1,000 PY), after a drop from 55 to 31 cases between 2009 and 2011, a time when standardization of creatinine calibration to IDMS became mandatory and may explain the change in rates. Rates of newly detected albuminuria showed little variability (~10/1,000 PY). Areas of high incidence of low eGFR were present in northern Michigan, northern Indiana, central Illinois, and western North Carolina. Newly detected albuminuria was highest in coastal North Carolina, northern Idaho, northeastern Indiana, and on the border of Washington and Oregon.

Conclusions: Rates of newly detected disease reflect a combination of the true incidence rate as it presents to a health system, but is also influenced by the rate of testing for the disease in question. Despite this limitation, these findings are important for both individual and population health management, early detection, management and prevention.

PO0511
Defining Criteria for CKD Stage 3 Patients Nephrology Referral: An Analysis Focused on CKD Progression and Mortality Risk
Luis F. Goncalves, Adriana Fernandes, Mario R. Raimundo. Hospital Beatriz Angelo, Loures, Portugal.

Background: The high prevalence of CKD and its increasing awareness by primary care clinicians. While the referral of CKD stage 4 and 5 to a nephrology clinic is undisputable, the need for stage 3 patients referral is still subject to debate. Our objective was to investigate baseline characteristics of CKD stage 3 patients associated with subsequent CKD progression, in order to help determine which patients should be referred at this stage.

Methods: Retrospective analysis of all patients referred to a nephrology clinic over 6 years. We included CKD stage 3 patients with at least 36 months of follow-up or 24 of follow up with more than 3 serum creatinine determinations. CKD progression was defined by one of the following: 1) an eGFR decline superior to 5ml/min/year; 2) creatinine duplication; 3) The need for chronic RRT. Baseline covariates included demographics, comorbid conditions and laboratory values. Univariate and multivariate analysis were employed to determine independent predictors of CKD progression and mortality.

Results: Out of the 3008 patients 594 (19.8%) met the inclusion criteria (median age: 71.9 years; 63.8% male). Median follow-up was 4.9 years (IQR 2.2). 133 (22.4%) met the criteria for CKD progression and 110 (18.6%) died. CKD progression was associated with higher proteinuria (405.7 vs 65.5 mg/gr, p=0.001), Diabetes (60.9 vs 45.3%, p=0.002), CHF (40.6 vs 28.7%, p=0.009), Anemia (68.0 vs 44.7%, p<0.001), higher diuretic use (48.9 vs 34.1%, p=0.002) and mortality (40.9 vs 12.2%, p<0.001) Albuminuria over 300 mg/gr [Odds ratio (OR) 3.57, 95% CI 2.20 - 5.80] and Anemia (OR 1.97, 95% CI 1.03 - 3.62) were associated with CKD progression. The independent predictors of mortality were: CKD progression (OR 4.49, 95% CI 2.69-7.50), Older age (OR per 1 year increase 1.03, 95% CI 1.01-1.05), presence of CHF (OR 1.75, 95% CI 1.03-2.98), presence of Hyperkalemia at first consultation (OR 2.12, 95% CI 1.00 - 4.52) and Anemia (OR 1.93, 95% CI 1.03 - 3.62).

Conclusions: Patients with macroalbuminuria and anemia at first consultation are at increased risk for rapid CKD stage 3 progression. In this group, patients with CHF, anemia and hyperkalemia (even at first consultation) have a higher risk of mortality. This study may be useful and help us in guiding which CKD stage 3 patients should be referred to a nephrology clinic.
PO0512

Laboratory-Based Potential Indicators vs. Risk-Based Triage for Nephropathy Referrals in the Veterans Affairs Health System

Vishal Duggal,1,2 Maria E. Montez-Rath,1,2 Chun Thomas,1,2 Mary K. Goldstein,1 Manjula Kurella Tamura,3,4 VA Palo Alto Health Care System, Palo Alto, CA; 3Stanford University Stanford Health Policy, Stanford, CA; 4Stanford University School of Medicine, Stanford, CA; 1VA Palo Alto Geriatric Research Education and Clinical Center, Palo Alto, CA.

Background: Clinical decision support tools may facilitate identification of chronic kidney disease (CKD) and timely nephrology referral. Little is known about the potential effects they might have on the volume of nephrology referrals. We sought to estimate how the implementation of a CKD decision support tool could affect potential nephropathy referral volume based on U.S. Veterans Affairs Health System (VA)/Department of Defense (DoD) guidelines, and the risk profile of referred patients.

Methods: In a retrospective cohort study of 434,735 patients with CKD, we determined the number of patients who met laboratory-based potential indications for nephropathy referral based on VA/DoD guidelines. We used the Kidney Failure Risk Equation to estimate end-stage kidney disease (ESKD) risk and to determine how incorporating ESKD risk thresholds would modify referral volume.

Results: Among 70,972 patients meeting potential indications for referral who had not visited a nephrologist in 2013, 12,008 (16.9%) were referred in 2014. The two-year risk of ESKD was low in both groups, 2.9% [9.9-8.6%] in the referred group, compared to 1.3% [0.3-3.9%] in the unreferral group (P < 0.001). The number of patients meeting potential indications for referral was approximately equivalent to the number of patients with a two-year risk of ESKD exceeding 1%, or N=81,132. Among potential indications for referral, rapid eGFR decline accounted for 37.6% of eligible unreferred patients and was associated with the lowest two-year ESKD risk.

Conclusions: Laboratory-based potential indications for referral identify a large number of patients at low risk of ESKD. Further study is needed to determine the value of nephrology care for these populations.

PO0513

Variation in Kidney Failure Risk Across Health Organizations Among Adults with CKD in Nephrology Ambulatory Care

Chi D. Chu,1,2 Neil R. Powe,1,4 Michael Shlipak,1,3 Rebecca Scherzer,1,3 Sri Lekha Tummalapalli,1 Michelle M. Estrella,1,5 Delphine S. Tuo,1,4 1University of California, San Francisco, San Francisco, CA; 2Optum Labs Visiting Scholar, Cambridge, MA; 3San Francisco VA Medical Center, San Francisco, CA; 4University of California San Francisco General Hospital and Trauma Center, San Francisco, CA.

Background: Since most adults with chronic kidney disease (CKD) have low risk for end-stage kidney disease (ESKD) progression, subspecialty nephrology care should focus on patients at highest risk of progression. To optimize utilization of nephrology care, a threshold of 3% risk of ESKD at 5 years based on the Kidney Failure Risk Equation (KFRE) has been proposed for nephropathy referral. To understand how application of this threshold in practice could impact CKD care delivery and subspecialty referral, we examined variation in 5-year ESKD risk distributions of patients in nephrology ambulatory care across U.S. healthcare organizations.

Methods: In 22 healthcare organizations, we identified patients age ≥18 years, with eGFR <60 mL/min/1.73 m² and concurrently measured serum albumin/creatinine ratio, who had an ambulatory encounter with a nephrologist from 1/1/2017-12/31/2018 using the Optum Labs® Data Warehouse, a longitudinal, real-world data asset with de-identified administrative claims and electronic health record data. We compared the distribution of patient-derived KFRE 5-year risk across health care organizations with ≥500 patients in nephrology care.

Results: Among 45,145 patients with CKD in nephrology care, the overall median 5-year ESKD risk was 2.4%. However, between organizations, the median 5-year ESKD risk varied widely, ranging from 0.8% to 6.7% (Figure). 54.3% of patients were below the 3% recommended referral threshold risk of ESKD.

Conclusions: There is substantial heterogeneity of ESKD risk across healthcare organizations in the population receiving ambulatory nephrology care. A greater understanding of the patient population and delivery system characteristics is needed to explain this heterogeneity, and associated health outcomes could inform recommended risk thresholds for referral and ongoing nephrology care.

PO0514

Prevalence of Comorbid Conditions at CKD Onset Among US Veterans

Media E. Pavkov,1 Devasmita Choudhury,1,2 Wei Yu,3 Nilka Rios Burrows,2 Robert Nee,5 Alfred K. Cheung,1,4 Keith C. Norris,1 Guofen Yan,3 Centers for Disease Control and Prevention, Atlanta, GA; 2Salem VA Medical Center, Salem, VA; 3University of Virginia, Charlottesville, VA; 4Walter Reed National Military Medical Center, Bethesda, MD; 5University of Utah Health, Salt Lake City, UT; 6VA Salt Lake City Health Care System, Salt Lake City, UT; 7University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.

Background: Comorbid conditions such as hypertension (HTN) and diabetes increase risk of adverse outcomes among patients with CKD. It is less clear whether such conditions develop prior to CKD onset or subsequently emerge as the disease progresses. Using a newly constructed national incident CKD cohort, we examined the prevalence of major comorbidities at the time of CKD onset by demographic groups.

Methods: The cohort included 1,074,238 subjects with new-onset CKD between 2002 and 2017 in the U.S. Veterans Health Administration (VHA). CKD onset was defined as the first time when estimated GFR (eGFR; CKD-EPI equation) decreased to a value ≤60 mL/min/1.73 m² for ≥3 months. We excluded subjects in VHA for <2 years prior to first eGFR ≤60, or with CKD stage 4 or 5, or end-stage kidney disease (ESKD) when first identified. Thus, the first time identified was close to the onset of CKD stage 3. Comorbidities at CKD onset were ascertained from ICD-9/ICD-10 codes during any time before onset and through 6 months after onset.

Results: All subgroups (age, gender, race and ethnicity) had similar mean eGFRs at onset (51 mL/min/1.73m²). The percentage with age at onset ≥65 years was greater in males (74%) than females (43%), greater in Black (48%) than in American Indian or Alaska Native (39%), Asian or Pacific Islander (33%), and Hispanic (30%), which in turn were greater than Whites (23%). At CKD onset, HTN was highly prevalent, varying from 83% in females to 96% in Blacks; diabetes ranged from 36% in females to 61% in Hispanics; more than two-thirds had cardiovascular disease (CVD); and 19-28% had cancer across subgroups (Table).

Conclusions: This finding suggests that many veterans at the time of CKD onset had already developed some major comorbidities, which could make them particularly susceptible to death before ESKD.

Funding: NIDDK Support, Other U.S. Government Support

Percentages of patients with the individual comorbidity at CKD onset

PO0515
Classification of Cause of CKD Using ICD-9 and ICD-10 Codes
Jennifer Chen,1 Matthew F. Blum,1 Aditya L. Surapaneni,2 Yingying Sang,2 Alex R. Chang,2 Josef Coresh,2 Morgan Grams,1,2 Johns Hopkins University School of Medicine, Baltimore, MD; 3Johns Hopkins School of Public Health, Baltimore, MD; 4Geisinger Health, Danville, PA.

Background: Current KDIGO guidelines classify CKD using three parameters: glomerular filtration rate (GFR), albuminuria, and cause of disease. While prognosis based on estimated GFR and albuminuria have been studied, less is known about the prevalence of disease etiology in CKD patients. We sought to classify various causes of CKD using billing codes for better assessment of the prevalence and risk implications of disease etiology in CKD staging.

Methods: We categorized cause of CKD with 18 potential etiologies and assigned relevant International Classification of Diseases (ICD) 9th and 10th revision Clinical Modification codes pertaining to each etiology. We applied the algorithm to two study populations, Johns Hopkins Medicine and Geisinger Health, to assess the prevalence of different etiologies of CKD in large health systems. To validate our CKD classification system, we determined CKD cause among 101 outpatients treated within Johns Hopkins Medicine through internal chart reviews and compared our findings to the classification algorithm generated CKD etiology.

Results: 43.3% and 26.4% of patients with eGFR <60 ml/min/1.73 m2 in 2016 in the Geisinger and Johns Hopkins study population, respectively, had a billing code used in our classification algorithm. The most prevalent etiologies of CKD in patients with available billing codes at Geisinger were hypertensive nephrosclerosis (27%), diabetic nephropathy (13.6%), obstructive nephropathy (5.2%), and nephritic syndrome (4.9%). In contrast, the most common causes of CKD in the Johns Hopkins cohort were miscellaneous (12%), obstructive nephropathy (6.3%), and non-PKD hereditary disease (3.2%). Chart review revealed 56% concordance between cause of CKD determined by chart review and that determined by our classification algorithm. The most prevalent etiologies of CKD in patients with available ICD codes using electronic medical record data; however, validation suggests varying degrees of accuracy across different CKD etiologies.

Conclusions: We developed an algorithm for classifying CKD cause by ICD-9 and ICD-10 codes using electronic medical record data; however, validation suggests varying degrees of accuracy across different CKD etiologies.

PO0516
Epidemiology of Patients with High-Risk CKD: A Demographic Evaluation of Patients Who Had Indications for SGLT2 Inhibitors and GLP-1
Huiwen Chen,1,2 Melanie R. Weltman,1 Manqi Cai,1 Jonathan Yabes,1 Thomas D. Nolin,1 Manisha Jhamb,1,2 Khaled Abdel-Kader.1 University of Pittsburgh, Pittsburgh, PA; 2University of Pittsburgh Medical Center, Pittsburgh, PA; 3Vanderbilt University Medical Center, Nashville, TN.

Background: The emerging evidence of the favorable effects of sodium-glucose co-transporter-2 inhibitors (SGLT2is) and glucagon-like peptide 1 receptor agonists (GLP-1) on renal function has brought hope and excitement to the nephrology communities in the US. However, many patients with high risk CKD and indications for SGLT2is and GLP-1 are not on the medication. We would like to identify the features of these patients and their primary care providers to offer targeted recommendations regarding concerns for initiating SGLT2is and GLP-1.

Methods: This is a preliminary analysis of data obtained from the Kidney Coordinated Health Management Partnership (K-CHAMP) study (NCT03832595), an ongoing, NIH funded pragmatic randomized control trial testing an electronic health record-based population health management approach to improve CKD care. The studied populations include patients with high risk CKD and indications for SGLT2is and GLP-1, who were not on the medication. We would like to identify the features of these patients and their primary care providers to offer targeted recommendations regarding concerns for initiating SGLT2is and GLP-1.

Results: Baseline demographics such as median age, gender, race, and BMI were compared. Comorbidities, the presence of endocrinology referral, laboratory values and whether or not patients have been on angiotensin-converting enzyme inhibitors (ACEIs) and angiotensin receptor blockers (ARBs) were also compared. Clinicians’ characteristics were compared as well. Patients who had the indications for SGLT2is but were not on them were more likely to be older in age, had low GFR (around low 30 ml/min) and low hemoglobin A1C. Patients who had the indications for GLP-1 but not on them were likely to have high A1C and likely to have already been on insulin.

Conclusions: Identification of features of high risk patients who had clinical indications for SGLT2is and GLP-1 but were not on the medication would be helpful in finding better ways to provide nephrology recommendations regarding SGLT2is and GLP-1.

PO0517
Disparities in CKD Progression by Medicare Advantage Enrollees Clarissa J. Diamantidis,1 Lindsay Zepel,1 Virginia Wang,2 Valerie A. Smith,2 Sarah H. Scholle,4 Loida A. Tamayo,1 Matthew L. Maciejewski,1,2 Duke University School of Medicine, Durham, NC; 3HSRD, Durham VA HCS, Durham, NC; 4OptumLabs Visiting Fellow, Minnetonka, MN; National Committee for Quality Assurance, Washington, DC; Centers for Medicare and Medicaid Services, Baltimore, MD.

Background: The prevalence of chronic kidney disease (CKD) in Medicare beneficiaries has quadrupled in the past two decades, but little is known about risk factors affecting the progression of CKD. This abstract aims to understand the progression of CKD up to five years after study entry in a large cohort of Medicare Advantage (MA) enrollees and whether it differs by provider recognition of CKD, race, ethnicity, or geographic location.

Methods: In a cohort of 1,002,388 MA enrollees with CKD stages 1-4 based on 2013-2018 labs, progression was estimated using a mixed-effects model that adjusted for demographics, urbanicity, comorbidity, urine albumin-to-creatinine ratio, clinical recognition via diagnosis of CKD, and time fixed effects. Race and ethnicity, geographic location, or clinical recognition of CKD were interacted with time in three separate regression models.

Results: Mean (median) follow-up was 3.1 (3.0) years. At study entry, Black and Hispanic MA enrollees had greater kidney function at study entry than other beneficiaries, but their kidney function declined faster compared to non-Hispanic Whites. At study entry, MA enrollees with clinically recognized CKD had estimated glomerular filtration rate levels that were 18.6 units (95% confidence interval: 18.5-18.7) lower than levels of unrecognized patients, but kidney function declined more slowly in enrollees with clinical recognition of CKD. There were no differences in CKD progression by metropolitan or non-metropolitan areas.

Conclusions: These results suggest that patients with clinically recognized CKD and racial and ethnic minorities merit closer surveillance and management to reduce their risk of faster progression.

PO0518
Impact of the Race Multiplier in the Estimated Glomerular Filtration Rate Equation on Care Delivery Among African-American CKD Patients
Saliman Ahmad, Mallika L. Mendu. Brigham and Women's Hospital, Boston, MA.

Background: African-American patients with chronic kidney disease (CKD) have poorer outcomes, including in dialysis access placement and transplantation. Estimated glomerular filtration rate (eGFR) equations, which assign higher eGFR values to African-American patients, may be an inadvertent mechanism for inequitable outcomes. Electronic health record-based registries enable population-based examination of care across racial groups.

Methods: Cross-sectional study at two large academic medical centers and affiliated community primary care and specialty practices.

Results: Of 2225 African-American patients, 743 (33.4%) would hypothetically be reclassified to a more severe CKD stage if the race multiplier were removed from the eGFR equation. Similarly, 167 of 687 (24.3%) would be reclassified from stage 3B to stage 4. Finally, 64 of 2069 patients (3.1%) would be reclassified from eGFR > 20 ml/min/1.73m2 to eGFR ≤ 20 ml/min/1.73m2, meeting the criterion for accumulating kidney transplant priority. Zero of 64 African-American patients with an eGFR <20 ml/min/1.73m2 after the race multiplier was removed were referred, evaluated or waitlisted for kidney transplant, compared to 19.2% of African-American patients with eGFR<20 ml/min/1.73m2 with default CKD-EPI equation.

Conclusions: Our study reveals a meaningful impact of race-adjusted eGFR on the care provided to the African-American CKD patient population.

PO0519
Prevalence of Diabetes, Hypertension, Anemia, and Hyperkalemia as Frequent Comorbidities in Patients with CKD Regardless of their KDIGO Staging
L. M. Perez-Navarro,1 Samantha Escoza Valdivia, Alberto Sigfrido Benitez Rentería,2 Rafael Valdez-Ortiz,1 Hospital General de Mexico De Eduardo Liceaga, Ciudad de Mexico, Mexico; 2AstraZeneca, Ciudad de Mexico, Mexico.

Background: Chronic kidney disease (CKD) is a worldwide public health problem. Currently in Mexico, the prevalence of CKD is only an estimate, based primarily on records of advanced stages of the disease. It is necessary to identify comorbidities and thus establish strategies to delay its progression and reduce morbimortality associated with CKD. Objective: To know the prevalence of comorbidities associated with CKD at different stages in an outpatient population who attended a 3rd level hospital.

Methods: This is a cross-sectional retrospective study. Records of adult patients who attended an outpatient nephrology consultation in the period from February 2019 to February 2020 were included, with laboratory reports from 15 days prior to the inclusion date. Descriptive statistics were performed, with a 95% CI and a value of p=0.05.

Results: 1772 patient records were included. 51% (907) were women, the mean age was 42 ± 24.2 years. 12% were on renal replacement therapy, 11% hemodialysis and 1% peritoneal dialysis. 87% (1546) lacked family history of CKD; 11% (192) were smokers. Regarding body mass index, 2% (32) presented low weight, 37% (562) normal weight, 53% (804) overweight and 8% (122) obesity. Figure 1 shows the distribution by CKD stage and main comorbidities. The prevalence of proteinuria was 39% (693); 53% (826) had anemia. The prevalence of hyperkalemia (HK; K+≥5) was 29% (325). The prevalence of serum albumin <3.5 was 26%; 44% of the population had glycemia < 100 mg/dL; 53% with triglyceride >150 mg/dL and 29% with total cholesterol ≥200 mg/dL.

Conclusions: A high prevalence of CKD comorbid risk factors such as diabetes, hypertension, anemia and HK were identified regardless of CKD staging, increasing in proportion in later stages.

PO0520
Cystatin C Use in Clinical Practice
Jennifer Torres,1 Jennifer L. Ennis,2 Rita L. McGill,1 ‘University of Chicago, Chicago, IL’; 2Laboratory Corporation of America, Burlington, NC; 3DaVita Inc, Denver, CO.

Background: Cystatin C is a filtration biomarker that can be used as an alternative for serum creatinine. The 2012 KDIGO guidelines advocate for the use of cystatin C to confirm the diagnosis of chronic kidney disease (CKD), but 9 years later it is not clear how this test is being used in clinical practice.

Methods: We examined 87,803 cystatin C levels obtained among 55,360 patients between 11/2011-6/2018 in the database of Laboratory Corporation of America Holdings (LabCorp®). The CKD-EPI cystatin equation was used to calculate the estimated GFR for each level. Descriptive analyses of patient age, sex, and ordering provider were provided, and relationships between serum cystatin C and creatinine levels were examined with correlation analysis and linear regression.

Results: We examined 87,803 cystatin C levels obtained among 55,360 patients, 51% (907) were women, the mean age was 50.2±11.5 years. 12% were on renal replacement therapy, 5% hemodialysis and 1% peritoneal dialysis. 87% (487) lacked family history of CKD; 11% (192) were smokers. Regarding body mass index, 2% (32) presented low weight, 37% (562) normal weight, 53% (804) overweight and 8% (122) obesity. Figure 1 shows the distribution by CKD stage and main comorbidities. The prevalence of proteinuria was 39% (693); 53% (826) had anemia. The prevalence of hyperkalemia (HK; K+≥5) was 29% (325). The prevalence of serum albumin <3.5 was 26%; 44% of the population had glycemia < 100 mg/dL; 53% with triglyceride >150 mg/dL and 29% with total cholesterol ≥200 mg/dL.

Conclusions: A high prevalence of CKD comorbid risk factors such as diabetes, hypertension, anemia and HK were identified regardless of CKD staging, increasing in proportion in later stages.

Appropriate Interval Between Two eGFR Measurements for the Evaluation of the Association of eGFR Slope with Incidence of Renal Events
Maiko Kokubu,1 Masaru Matsui,2 Takayuki Uemura,1 Kazuhiko Tsuynaru.2 1Nara-ken Sogo Iryo Center, Nara, Japan; 2Nara Keijuitsu Iku Daigaku, Kashihara, Japan.

Background: In recent years, growing evidence has shown the prognostic utility of eGFR slope for the risk of ESRD. Previous observational studies have assessed the association between renal events and eGFR slopes estimated by two measurements of eGFR but had great differences in the interval between two eGFR measurements. In this study, we thus aimed to determine the appropriate interval between two eGFR measurements to evaluate the association of eGFR slope with incidence of renal events.

Methods: This is a retrospective cohort study in 203 CKD patients who visited Nara Prefecture General Medical Center, Japan between 1 January 2013 and 31 December 2016 and in whom two or more than two measurements of eGFR levels were confirmed in medical records. eGFR slopes were estimated by using two measurements of eGFR at baseline and at 0.5, 1, 1.5, 2, or 3 years. We excluded patients with acute kidney injury, urologic malignancies, nephritic syndrome with steroid treatment or collagen diseases. Outcome was renal events defined as a composite of ESRD and eGFR decline of > 30%. C statistics were used to evaluate the association between eGFR slope and incidence of renal events.

Results: The median age of study participants was 67 (56-77) years and 71 (37%) were male. The median levels of baseline eGFR were 34 (21-48) mL/min/1.73m² and diabetes was present in 80 (39%) participants. During the median follow-up period of 38 months, renal events occurred in 52 participants. Medial levels of eGFR slopes were 1.5, 1, 0.5, 2 and 3yr for renal events were 0.622, 0.691, 0.797, 0.858, 0.806, respectively, and that of eGFR slope 1yr was significantly higher than that of eGFR slope 2yr. C-statistics of renal events when considering baseline eGFR alone was 0.853 but combination use of baseline eGFR and eGFR slope 1yr significantly increased c-statistics, to 0.913 (p=0.01). In stratified analysis, eGFR slope 1yr had higher prognostic ability of renal events in patients with versus without diabetes, advanced CKD and proteinuria. C-statistics of renal events when considering baseline eGFR alone was 0.853 but combination use of baseline eGFR and eGFR slope 1yr significantly increased c-statistics, to 0.913 (p=0.01).

Conclusions: eGFR slope for high prognostic ability of renal events may be needed to be calculated by at least 1.5-year interval between two eGFR measurements.

PO0522
Rates of Clinical Events in Patients with CKD: A UK Population-Based Cohort Study
Alyshah Abdul Sultan,1 Ping Sun,1 Katarina Hedman,2 Xia Wang,3 Mark T. Houser,1 Dustin J. Little,2 Glen James.1 1AstraZeneca, Cambridge, United Kingdom; 2AstraZeneca, Gothenburg, Sweden; 3AstraZeneca, Gaithersburg, MD.

Background: Epidemiology of clinical event rates in patients with chronic kidney disease (CKD) is limited and can impede the ability of dialysis organizations, government agencies, other institutions, and payers to counsel patients and assess quality of care.

Methods: The Clinical Practice Research Datalink (CPRD) is a large, longitudinal UK-based primary care database that covers 6% (~4 million people) of the population. CPRD is linked to Hospital Episode Statistics (HES), which contains information on all hospital admissions in England. We identified CKD patients with eGFR <60 ml/ min/1.73m² in CPRD between 2004 and 2017. Adverse clinical events were identified using ICD-10 and READ codes. Non-dialysis dependent (NDD) patients were staged by eGFR. Dialysis dependent (DD) patients were identified using Classification of Interventions and Procedures (OPCS) and READ codes. Clinical events were identified by ICD10 and READ codes. Incidence rates per 100 person-years (PY) were calculated for selected adverse event stratified by dialysis status and CKD stage.
Results: We identified 310362 NDD and 5248 DD patients with a mean (standard deviation [SD]) age of 75.5 (10.2) years and a median (interquartile range [IQR]) follow-up of 87.5 (46.5-130.9) months. Among NDD patients 96%, 3%, and 1% of patient-years came from CKD 3, 4, and 5, respectively. Most event rates were consistently higher in DD CKD patients, compared to NDD CKD patients; and higher among CKD 4-5 compared to CKD 3 patients (Table 1).

Conclusions: Our results help establish baseline rates of specific clinical events and provide additional evidence of increased morbidity for DD vs. NDD patients, and for NDD patients with more severe vs. less severe kidney disease.

Estimating the Future Burden of CKD Through Microsimulation Methods
Lise Retal,1 Michael Xu,1 Laura Webber,1 Claudia S. Cabrera,2 Elisabeth SØrstadius,2 Stephen Nolan,2 Juan Jose Garcia Sanchez,2 HealthLumen, London, United Kingdom; 3AstraZeneca AB, Soderatle, Sweden; 4AstraZeneca PLC, Cambridge, United Kingdom.

Background: Chronic kidney disease (CKD) is a debilitating and costly condition, impacting over 10% of people globally. Early diagnosis and proactive management could potentially mitigate the rates of progression to end stage renal disease. Understanding the future trajectory of CKD prevalence, progression, outcomes and the related economic burden are important considerations for public health and policy planning. This study estimated the epidemiological and cost burden of CKD with an emphasis on high-risk populations with macroalbuminuria, type 2 diabetes (T2D) and/or heart failure (HF), from 2020 to 2025.

Methods: A patient-level microsimulation was developed to estimate the epidemiological and economic burden of CKD in the UK. KDIGO 2012 recommendations were used to categorise patients according to eGFR and albuminuria using the Health Survey of England extrapolated to the UK population. The future prevalence and healthcare costs for the CKD population, as well as for subpopulations – macroalbuminuria, T2D, HF were estimated. Finally, “current practice” management scenario was compared to an early detection and proactive scenario.

Results: By 2025, CKD prevalence in the UK is expected to grow by 11% from ~9.1M to 10.2M corresponding to a £4B (18%) increase in annual cost from £18B, of which, £0.58B is incurred due to macroalbuminuria where prevalence is projected to reach 860,000 by 2025. Within the macroalbuminuria population, costs were comparable between patients with (390,000; £0.31B) and without (465,000; £0.27B) T2D. However, costs for patients with macroalbuminuria were 3-times higher than for CKD patients with HF (£0.11B, 140,000). Early identification and proactive management of patients with CKD and macroalbuminuria resulted in a cumulative £0.65B direct healthcare cost saving by 2025.

Conclusions: This model predicts that CKD poses a serious public health threat. The overall epidemiological burden for patients with macroalbuminuria was comparable with patients with and without T2D. Early detection along with proactive treatment may reduce CKD progression and more directly improve patients’ quality of life while also reducing the long-term economic burden of CKD.

Identifying and Clustering CKD Progression Trajectories Using Machine Learning
Alvash Abdul Sultan,1 Kirsty Rhodes,1 Michail Doulos,2 Irena Brookes-Smith,3 Joshua S. Faria,1 Jose D. Salazar,2 Glen James,1 Iain MacPhee,2 Robert J. Unwin,1 David Wright,1 Mishal Patel,1 Paul D. Metcalfe,1 Lutz Jermutus,1 1AstraZeneca, Cambridge, United Kingdom; 2AstraZeneca, Gothenburg, Sweden.

Background: There is evidence suggesting that estimated glomerular filtration rate (eGFR) slope can be used as a surrogate clinical endpoint in renal clinical trials. However, there are limited data on the characteristics of fast and slow progressors based on eGFR slope from large population-based studies.

Methods: We identified CKD patients (based on two consecutive eGFRs of ≥75ml/min/1.73m² recorded more than 90 days apart) aged ≥18 years from the UK Clinical Practice Research Datalink (CPRD) between 2004 and 2019. Estimated GFR measurements over a 3-year observation period post-index date (date of 2nd eGFR measurement) were extracted. Patients were clustered based on their eGFR trajectories using statistical (linear mixed effect models (LMM)) and machine learning techniques (unsupervised machine learning and Bayesian approaches). Association between trajectory clusters and all-cause mortality was assessed using Cox regression analysis.

Results: Preliminarily, 407,108 patients with 1.8 million eGFR measurements (median 4 (IQR: 2-6) eGFR measurements per patient) were identified. Using LMM, we found 5% of patients declined rapidly with an average rate of eGFR change per year ≤-4.78 (95%CI: -9.40 to -3.28) whereas the majority (95%) remain stable or progressed slowly. A distinct fast progressing cluster was also detected using unsupervised machine learning and Bayesian methods which showed broadly linear patterns. Overall, there was an agreement between all three clustering approaches. These findings were replicated in the validation dataset showing consistent findings. Compared to stable/slow progressors, fast progressing patients were 3 times more likely (Hazard Ratio (HR)=2.95; 95%CI:2.75-3.10) to die following the 3-year observation period.

Conclusions: A clear fast progressing cluster was identified with an average eGFR decline of ≥3 ml/min/1.73m² per year with a higher risk of all-cause mortality compared to other clusters. Whilst Bayesian and unsupervised machine learning methods can detect non-linear patterns, we found broadly linear trajectories.

Using Autoencoders for Imputing Missing Data in eGFR Decline Trajectories of Patients with CKD

Davina J. Zamanzadeh,1 Panayiotis Petousis, Tyler A. Davis,1 Anders O. Garlid,1 Xiaoyan Wang,1 Keith C. Norris,1 Obidiugwu Duru,1 Katherine R. Tuttle,1 Alex Bui,1 Susanne B. Nicholas.1 CURE-CKD Registry Study Team 1University of California Los Angeles, Los Angeles, CA; 2Providence St Joseph Health, Spokane, WA.

Background: Using machine learning (ML) approaches to impute missing data has not been explored in CKD progression. We investigated the utility of a data-driven imputation to improve downstream classifier prediction of rapid eGFR decline in the CURE-CKD registry.

Methods: We analyzed CKD patients at UCLA (N=13,206) over a 2-year period. We used: 1) the dataset with missing data; and 2) a censored subset with no missing data. We introduced 33% and 66% missingness by removing values by removing values either missing completely at random (MCAR); missing at random (MAR); or missing not at random (MNAR). We included: eGFR, hemoglobin (HbA1c), systolic blood pressure (SBP), number of ambulatory and inpatient visits, age, sex, ethnicity, rurality status, diagnosis of hypertension, diabetes mellitus (DM), pre-DM, and use of renin angiotensin aldosterone system inhibitors. We introduced missingness on SBP and HbA1c to mirror the original dataset. We imputed missing values using an autoencoder ML model. To predict a 40% eGFR decline over 2 years, we developed random forest models using the full and resultant imputed datasets.

Results: On the full subset, the MNAR imputation method achieved a root mean squared error (RMSE) of 0. The MAR method achieved RMSE of 3.8 at 33% missingness and 5.4 at 66%. MCAR achieved RMSE of 38.5 at 33% missingness and 56.4 at 66%. Using the random forest model to predict rapid decline on the fully observed subset without removing and imputing data achieved a receiver operating characteristic (ROC) area under the curve (AUC) mean of 80.8±1.1 and precision/recall (PR)-AUC mean of 23.9±1.5; the same as our methodology on MNAR, which is explained by the RMSE of 0, shown in Table 1.

Conclusions: Our method accurately imputes clinical data values while accounting for uncertainty caused by missing values.

Machine Learning Prediction of ESKD and Death in CKD Patients: Electronic Medical Record-Based Cohort Study

Eijihiro Kando,1 Atsuyaiki Tokuyama, Seiji Itano, Hajime Nagasu, Naruki Kashihara. Kawasaki Medical School, Kurashiki, Japan.

Background: Chronic kidney disease (CKD) is a risk factor for end-stage kidney disease (ESKD) and death. An accurate prediction of these risks is required to improve their prognosis. We developed the new machine learning models for the prediction of CKD progression and death using the electronic-medical-record-based-CKD-patient big database in Japan (n=3,714, 66,981 claim data).

Methods: We developed 20 risk prediction models with 45 variables for the classification of the patients on the basis of their outcomes (ESKD and death) over 1 to 3 years using random forest (RF), Gradient Boosting Decision Tree (GB), eXtreme Gradient Boosting (XG), support vector machine, and multivariate logistic regression models using validation datasets including baseline or time-series datasets. The performance characteristics of the models were compared with those of the laboratory indices, and the kidney failure risk equation (KFRE) using the area under the prediction curves (AUCs)

Results: The RF models based on time-series data showed the highest AUCs: 0.924 (95% CI 0.895, 0.953) (Fig. A). These three models also demonstrated the significantly higher AUCs for the prediction of outcomes than KFRE 0.782 (0.682, 0.881), and the RF, GB, and XG models based on time-series data showed the highest AUCs: 0.924 (95% CI 0.895, 0.953) (Fig. A).

Conclusions: Using machine learning (ML) approaches to impute missing data has not been explored in CKD progression. We investigated the utility of a data-driven imputation to improve downstream classifier prediction of rapid eGFR decline in the CURE-CKD registry.

Funding: Other NIH Support - NIMHD

PO0528

Predicting Rapid eGFR Decline Using Electronic Health Record (EHR) Data Despite High Missingness in the CURE-CKD Registry

Tyler A. Davis,1 Panayiotis Petousis, Davina J. Zamanzadeh,1 Xiaoyan Wang,1 Keith C. Norris,1 Obidiugwu Duru,1 Katherine R. Tuttle,1 Alex Bui,1 Susanne B. Nicholas.1 CURE-CKD Registry Study Team 1University of California Los Angeles, Los Angeles, CA; 2Providence St Joseph Health, Spokane, WA.

Background: Patients with rapid eGFR decline tend to progress to kidney failure. Automated tools can identify individuals at risk of severe renal function decline and facilitate disease mitigation. We describe a deep neural network (DNN) for predicting the risk of rapid eGFR decline (~40% decrease in eGFR over 2 years) and identifies patients at higher risk of rapid decline using the CURE-CKD Registry.

Methods: Variables include: age, sex, race/ethnicity, ACE inhibitor/ARB use, eGFR, systolic blood pressure (SBP), hemoglobin (Hb), and the diagnosis of hypertension, diabetes, and CKD. We selected patients with CKD (N=93,567) and at-risk for CKD (N=913,289) with eGFR > 140 mmol/L (72%), age 45-66 years (56%), DM (52%), and AIC > 8 (50%).

Conclusions: Using machine learning (ML) approaches to impute missing data has not been explored in CKD progression. We investigated the utility of a data-driven imputation to improve downstream classifier prediction of rapid eGFR decline in the CURE-CKD registry.

PO0629

A Machine Learning-Based Prediction Model for Trajectory of GFR in CKD Patients with Rapid Decline of GFR by Using a Big Database

Dajo Inaguma,1 Akimitsu Kitagawa,1 Ryosuke Yanagiya,1 Akira Koseki,2 Tomoyuki Fujimori,1 Michiharu Kudo,1 Shingo Fukuma,1 Naotake Tsuibo,1 Yukio Yuzawa,1 Fujita Health University School of Medicine, Department of Nephrology, Toyoake, Japan; 2IBM Research, Tokyo, Japan; 3Fujita Health University Bantane Hospital, Department of Nephrology, Nagoya, Japan; 4Fujita Health University, Division of Medical Information System, Toyoake, Japan; 5Kyo University Graduate School of Medicine, Human Health Sciences, Kyoto, Japan.

Background: There are various patterns of GFR trajectories in patients with chronic kidney disease (CKD), even among those with rapid declines in GFR. We sought to create a machine learning-based predictive model for extremely rapid decline of GFR in patients with CKD using a single hospital database.

Methods: We used a database, which included the electronic medical records of 286,494 patients. We selected patients with CKD and rapid decline in kidney function, which was defined as an estimated GFR (eGFR) decline of 30% or more within two years. We used longitudinal statistics using data extracted from baseline, 90-, 180-, and 360-day windows prior to baseline and exponentially weighted averages (ESAs) where the weight was calculated as 0.95^days/deay parameter). The random forest algorithm and python code from the scikit-learn library (https://scikit-learn.org/) were used for model creation.

Results: Patients were automatically classified, using machine learning, into three groups according to eGFR at baseline (G1: high GFR, G2: intermediate GFR, G3: low GFR) and nine subgroups according to the slope of eGFR decline. The subgroup with the

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

210
fastest GFR decline exhibited the steepest slope (Figure 1). The area under the curves for predicting the steepest (fastest) GFR decline by random forest model among the G1, G2, and G3 were 0.68, 0.72 and 0.81, respectively. Regarding feature importance, in the G1 group, hemoglobin of the 7-day ESAs and measures obtained 90 days prior to baseline ranked within the top five. Meanwhile, serum albumin and CRP at baseline ranked within the top seven in the G3 group.

Conclusions: The random forest model identified patients with extremely rapid GFR decline. Anemia in patients with higher eGFR, and nutritional status in patients with lower eGFR, emerged as strong risk factors.

PO0530

Automation of Renal Blood Flow Analysis from Dynamic Phase-Contrast MRI with Deep Learning
Andrés Martínez-Mora,1,2 Dag Lindgren,1 Camilla Englund,1 Lars Johansson,1 Paul Hockings,1 Joel Kullberg,1 1Antares Medical, Möln达尔, Sweden; 2Uppsala University, Department of Surgical Sciences, Radiology, Uppsala, Sweden; 3Kungliga Tekniska Högskolan Skolan för kemi bioteknologi och halsa, Stockholm, Sweden.

Background: Phase-contrast magnetic resonance imaging (PC-MRI) allows to assess renal blood flow (RBF), an important parameter in the development of chronic kidney disease (CKD). RBF assessments require time-consuming and observer-dependent delineations of the renal arteries. Thus, we have developed and evaluated a fully-automated deep learning model for renal artery segmentation.

Methods: PC-MRI data came from 131 subjects, four studies, three MRI vendors and a range of velocity encodings. The deep learning model (DL) was a deeply-supervised attention U-Net with residuals with the result re-introduced in a second iteration. Flow was estimated by integrating the flow values in the segmentations. Segmentation and flow results were compared for cross-validation (CV, 73 subjects) against manual delineations and reference flow measurements from external software. The remaining data (Extra) only had reference flow measurements, being only evaluated for flow.

Results: In 4-fold CV, a segmentation accuracy of Dice 0.71 ± 0.21 was obtained. Although most segmentations were relatively accurate, the model failed in ten out of 144 arteries. Flow measurements were relatively highly correlated in CV with no significant deviation from the reference: (r=0.84, DL: 5.8±3.0 ml/s vs Ref: 5.8±3.0 ml/s, p=0.98). The Extra set provided a high correlation and no significant deviation (r=0.94, DL: 6.4±2.8 ml/s vs Ref: 6.7±2.9 ml/s, p=0.11).

Conclusions: The method promises to support RBF measurements from PC-MRI. It may save analysis time and increase objectivity in the future. More high quality and representative training data are likely to improve accuracy and generalizability.

Mortality Following New Onset of CKD Among Veterans by Comorbid Conditions: Results from a US Large Incident CKD Population

Nikla Rios Burrows,1 Devasmita Choudhury,2 Wei Yu,1 Meda E. Pavkov,1 Robert Nee,2 Alfred K. Cheung,1,3 Keith C. Norris,4 Guofen Yan,5 Centers for Disease Control and Prevention, Atlanta, GA; 2 Salem VA Medical Center, Salem, VA; 3 University of Virginia, Charlottesville, VA; 4 Walter Reed National Military Medical Center, Bethesda, MD; 5 University of Utah Health, Salt Lake City, UT; 6 University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; 7 VA Salt Lake City Health Care System, Salt Lake City, UT.

Background: Data on mortality rates after CKD onset are scarce. Using a recently constructed national incident CKD cohort, we examined mortality rates following new-onset CKD for various subgroups with or without comorbidities.

Methods: We identified 1,074,238 individuals with new-onset CKD between 2002 and 2017 in the US Veterans Health Administration (VHA). CKD onset was defined as the first time when estimated GFR (eGFR, CKD-EPI equation) decreased to <60 mL/min/1.73 m² for >3 months. Individuals excluded were those in the VHA for <2 years prior to first eGFR <60, or had CKD stage 4 or 5, or end-stage kidney disease when first identified. Thus, the first time identified was close to the onset of CKD stage 3. Comorbidities at CKD onset were ascertained from ICD-9/ICD-10 codes during any time before onset and through 6 months after onset. All individuals were followed for death status from onset through June 30, 2018.

Results: CKD patients with and without comorbidities had similar mean eGFRs at onset (51 mL/min/1.73m²). Most (97%) were male and mean age at onset was 72 years. Hypertension (HTN) (90%), cardiovascular disease (CVD) (75%), and diabetes (46%) were the three most common comorbidities. For each comorbidity, mortality rate was substantially greater among those with compared to those without (Table). After adjustment for age, sex, race, ethnicity, and onset eGFR, mortality risks remained substantially greater among those with than those without the comorbidities, ranging from 12% greater with HTN to 100% greater with liver disease.

Conclusions: At time of CKD onset, mortality risk is greater in veterans with the presence of comorbidities. Intervention trials to examine the management and treatment of comorbidities on mortality in an incident CKD population might be warranted.

PO0535

Impact of Variability in Estimated Glomerular Filtration Rate on Major Clinical Outcomes: A Nationwide Population-Based Study

Sooin Lee,1 Yeonhee Lee,1 Schoon Park,1 Yaerim Kim,2 Min woo Kang,1 Semin Cho,1 Yong Chul Kim,3 Kwon Wook Joo,1 Chun Soo Lim,2 Yong Su Kim,2 Dong Ki Kim.1 Seoul National University College of Medicine, Seoul, Republic of Korea; 2Keimyung University, Daegu, Republic of Korea; 3Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea.

Background: The estimated glomerular filtration rate (eGFR), commonly estimated using the serum creatinine value, often fluctuates throughout the serial measurement. The clinical significance of GFR variation among the general population with normal renal function has not yet been demonstrated. Thus, we explored the impact of GFR variability on adverse clinical outcomes.

Methods: A nationwide retrospective cohort study using the Korean National Health Insurance System database was performed. National health screening examinees who underwent creatinine measurement ≥3 times between 2012 and 2016 were considered. Those with eGFR under 60 mL/min/m² were excluded. The fluctuation of eGFR was represented with variability independent of the mean (VIM) value, which was calculated by the standard deviation divided by the exponent of the regression coefficient of the mean. Then, the risks of myocardial infarction (MI), stroke, and death were assessed according to the quartiles of the VIM.

Results: Of total 3,538,500 participants, 0.29% of myocardial infarction (MI), 0.14% of stroke, 0.36% of deaths were observed during the median follow up of 3.27 years. Participants with the highest VIM index, which represents the highest eGFR variability, were significantly associated with an increased risk of MI (hazard ratio [HR]: 1.10, 95% confidence interval [95% CI]: 1.04-1.16), stroke (HR: 1.16; 95% CI 1.09-1.23), and death (HR: 1.18; 95% CI 1.12-1.24). (Figure 1)

Conclusions: Increased eGFR variability exhibited an association with major clinical outcomes, indicating that monitoring eGFR variability might be a useful parameter for predicting the adverse outcomes.

PO0536

Development and Internal Validation of a Mortality Risk Prediction Model in Older Adults with Advanced Non-Dialysis-Dependent (NDD) CKD

David Y. Li,1 Heather L. Prigmore,2 Thomas G. Stewart,2 Khaled Abdel-Kader.1 Vanderbilt University Medical Center, Nashville, TN; 2Vanderbilt University, Nashville, TN.

Background: Older adults with CKD expect practitioners to share prognostic estimates to inform decision-making regarding future care. The availability of useful mortality prediction models in NDD-CKD could reduce prognostic uncertainty and aid in identifying patients who would benefit from advance care planning (independent of dialysis initiation).

Methods: 699 patients with NDD-CKD stages 4-5 and age ≥60 were enrolled and followed between 2014 and 2019. Cox proportional hazards regression was used to model the risk of 1-year mortality. Candidate predictor variables included age, gender, race, Charlson Comorbidity Index (CCI), common labs and the provider’s response to the Surprise Question (“Would you be surprised if this patient died in the next 12 months?”), SQ, recorded using binary and 5-point Likert response scales. Optimism-corrected measures of model performance were calculated with bootstrap resampling. Model calibration was assessed visually.

Results: In the derivation cohort, age, CCI, hemoglobin values and the provider’s Likert scale response to the SQ were predictive of 1-year mortality (Table 1). The C-statistic in the derivation sample was 0.76 and the optimism corrected C-statistic obtained by bootstrap resampling was 0.73. Visual examination of model calibration demonstrated good calibration.

Conclusions: A 1-year mortality risk prediction model in older adults with advanced NDD-CKD performed reasonably well and was well calibrated. Studies are needed to understand how to best leverage information on mortality risk to enhance patient-provider communication and ensure that future care delivered to patients is aligned with their priorities.

PO0538
Association of eGFR Index Category and Annual Slope with Adverse Clinical Outcomes in Japan
Ling Zhang,1 Moe H. Kyaw,1 Yasuhisa Ono,2 Sibylle J. Hauske,1,4 Boehringer Ingelheim USA, Ridgefield, CT; 2Nippon Boehringer Ingelheim, Tokyo, Japan; 3Boehringer Ingelheim Germany, Ingelheim, Germany; 45th Medical Center, University of Heidelberg, Germany, Heidelberg, Germany.

Background: The relationship between the slope of eGFR with adverse clinical events has not been evaluated extensively. The objective of the study was to assess the association between eGFR and clinical outcomes.

Methods: The study population included persons with 3 or more eGFR values in the MDV database between January 1, 2014 and September 31, 2019. Patients were stratified into 5 index eGFR categories (TABLE). Least square regression model was used to examine the association between eGFR and its slope vs. study outcomes. Patients were stratified into 5 index eGFR categories (TABLE). Least square regression model was used to calculate the annual rate of eGFR change to stratify into 6 categories. Cox proportional hazard model was applied to examine the association between eGFR and its slope vs. study outcomes.

Results: 57,692 patients met the study criteria, and were grouped by index eGFR and its slope (TABLE). The mean age ranged from 56.69 to 74.21 in the index eGFR and from 65.3 to 67.2 in the slope categories. The risk of all-cause mortality or hospitalization, CV death, and any CV or renal outcomes were higher among the low and high index eGFR compared to the reference groups (grade 3 eGFR and 1~1+1 slope), as well as those with rapidly declining or increasing eGFR.

Conclusions: Our study showed that those with the highest or lowest categories in index eGFR and eGFR slope had a higher risk for adverse clinical outcomes. Further studies are needed to confirm the findings and explore potential reasons why high eGFR and rapid increase are associated with mortality, CV and renal events.

Sex-Specific Differences in Clinical Outcomes Among Patients with CKD: Results from CKDops
Manfred Hecking,1 Charlotte Tu,2 Jarcy Zee,2 Brian Bieber,2 Sebastian Hödlmoser,3 Benedicte Stengel,4 Helmut Reichel,5 Kunihiro Yamagata,6 Ricardo Sesso,7 Friedrich K. Port,2 Bruce M. Robinson,2 Roberto Pecoto-Filho.8 On behalf of CKDops and CKD REIN investigators 1Medical University of Innsbruck, Division of Internal Medicine, Innsbruck, Austria; 2Arbor Research Collaborative for Health, Ann Arbor, MI; 3Medical University of Vienna, Department of Epidemiology, Vienna, Austria; 4CESP, Insern U104, Kidney and Heart Team, Villejuif, France; 5Nephrologisches Zentrum Villingen-Schwenningen, Villingen-Schwenningen, Germany; 6University of Tsukuba, Ibaraki, Japan; 7Escola Paulista De Medicina, Unifesp, Sao Paulo, Brazil.

Background: Women have more chronic kidney disease (CKD) than men, but are under-represented in the dialysis population. We aimed to assess sex-specific differences in clinical outcomes among CKD Outcomes and Practice Patterns Study (CKDops) participants.

Methods: Using data of 5682 CKDops stage 3-5 patients from Brazil, Germany and the US, we reported cumulative incidence of pre-dialysis death, dialysis, and transplantation, by sex and CKD stage at CKDops entry. We used Fine & Gray models to assess the effect of sex on the time to events, stratified by CKD stage. Models were adjusted for age and race, and then for eGFR slope in the first 6 months after enrolment, but not for case mix variables as men and women are biologically different.

Results: There were more men than women at baseline (54 vs 46%). Men were more likely on the transplant waitlist (13 vs 10%) and had higher median eGFR at dialysis initiation (5.2 vs 10.6 mL/min/1.73m²). Over a median follow-up of 1.75 years, the crude cumulative incidence of dialysis was higher in men while that of death was similar (Figure). The age- and race-adjusted hazard ratio (HR) (95% CI) between men vs women was 1.59 (1.40-1.82) for dialysis, 1.24 (1.04-1.49) for death and 1.80 (0.83-3.80) for transplantation. After adjustment for eGFR slope, the HR for dialysis was 1.72 (1.46-2.01), but the HR for the other two outcomes remained similar.

Conclusions: Despite higher CKD prevalence in women, more men received treatment at nephrologist-run clinics in our study. Men had a higher chance of commencing dialysis before death, unexplained by CKD progression. This finding helps interpret the preponderance of men in the dialysis population.

Evaluation of Thromboelastometry and Multiple Electrode Aggregometry in ESRD

Alvina Abdelmaquid,1,2 Lara N. Roberts,3 Jennifer R. Joslin,4 Kiran H. Parmar,1 Kate Bramham,1,3 ’King’s Kidney Care, King’s College Hospital, London, United Kingdom; 2Alexandra University, Medical Research Institute, Alexandria, Egypt; 3King’s Thrombosis Centre, Department of Haematological Medicine, King’s College Hospital NHS Foundation Trust, London, United Kingdom; 4Thrombosis and Haemostasis Centre, Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom; 5Department of Women and Children’s Health, King’s College London, London, United Kingdom.

Background: Bleeding and thrombosis rates are paradoxically increased in chronic kidney disease (CKD), but risk assessment for both is not possible with routine laboratory tests. We aimed to evaluate haemostatic changes in CKD stage 5 patients with modern techniques; using thromboelastometry (TEM), multiple electrode aggregometry (MEA), markers of thrombogenesis, fibrinolysis and endothelial activation.

Methods: TEM, MEA, thrombin antithrombin (TAT), alpha-2 antiplasmin, d-dimer and Interacellular Adhesion Molecule-1 (ICAM-1) were quantified in 50 CKD Stage 5 patients (including 20 haemodialysis patients) and 30 healthy controls. Patients taking antiplatelet agents were excluded from MEA analysis.

Results: TEM parameters showed hypercoagulability, with increased maximal clot firmness (MCF) & shorter clot formation time (CFT); and D-dimer, TAT and ICAM-concentrations were also increased in CKD Stage 5 patients compared to HC (Table 1).

Conclusions: Our study shows that the prothrombotic changes in CKD Stage 5 are due to increased coagulation and endothelial activation. Bleeding tendency may relate to platelet dysfunction and possibly increased fibrinolytic activation.

Table 1: Comparison of TEM, MEA, Alpha-2 Antiplasmin, D-dimer, Thrombin Antithrombin and ICAM-1 between Healthy Controls and CKD Stage 5 (Median and Interquartile Range (IQR))

PO0543

During P2Y_12 Antiplatelet Therapy, Treatment of Anemia Was More Frequent Among Peripheral Artery Disease Patients with Lower eGFR: The EUCLID Trial

Judith Hsia,1,3 Sarah T. Kavanagh,1 Charles W. Hoptie,2 Marc P. Bonaca,1,3 William R. Hiatt,1,3 CPC Clinical Research, Aurora, CO; 2Dartmouth College, Hanover, NH; 3University of Colorado School of Medicine, Aurora, CO.

Background: Anemia independently predicts amputation and mortality among patients with peripheral artery disease (PAD). In the EUCLID trial, minor bleeding was more frequent among PAD patients with baseline eGFR<60 vs ≥60 mL/min/1.73m^2 (adjusted HR 1.51, 95% CI 1.07-2.15; p=0.02 for TIMI minor bleeding; HR 1.21, 95% CI 0.89-1.64; p=0.22 for TIMI major bleeding). We evaluated the impact of eGFR on hemoglobin (Hb) levels and anemia treatment.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Methods: EUCLID (NCT01732822) randomized symptomatic PAD patients to monotherapy with ticagrelor or clopidogrel for 30 months (median); treatment groups were combined for analysis. Independent predictors of Hb change from baseline were evaluated in a multivariable model including baseline Hb and eGFR, sex, age, and post-randomization revascularization procedures, myocardial infarction and anemia treatment.

Results: At baseline, 9025, 1870 and 1000 patients had eGFR ≥60, 45-59 and <45 ml/min/1.73m², respectively. Patients with lower eGFR were older, more often male and had higher prevalence of diabetes and hypertension. Mean Hb at baseline was 14.2, 13.5 and 12.7 g/dL for the 3 eGFR categories. Mean fall in Hb during the trial was 0.5±1.7 g/dL and did not differ by baseline eGFR category. On-study treatment with iron, erythropoietin and/or red blood cell transfusion was reported for 479 (5.3%), 163 (8.8%) and 129 (12.9%) patients, respectively (Figure, p<0.0001 across eGFR categories). In multivariable analysis, even after adjustment for baseline and post-randomization effects, baseline Hb was a significant independent predictor of Hb fall; anemia treatment was a significant independent predictor of Hb rise.

Conclusions: Among patients with PAD taking antiplatelet therapy in the EUCLID trial, those with lower eGFR were more often treated for anemia.

The Ratio and Difference of Urine Protein-to-Creatinine Ratio and Albumin-to-Creatinine Ratio Facilitate Risk Prediction of All-Cause Mortality: A Retrospective Cohort Study

David R. Chang,1 Hung chieh Yeh,1 Pei-Lun Cha,2 Chin-Chi Kuo,1 1China Medical University Hospital, Taichung, Taiwan; 2Fu Jen Catholic University Hospital, New Taipei City, Taiwan.

Background: The difference and ratio of albuminuria (defined by urine albumin-to-creatinine ratio, uACR) and proteinuria (defined by urine protein-to-creatinine ratio, uPCR) has not been systematically evaluated with relevant clinical outcomes. We aimed to assess the prognostic performance between the difference and ratio of uACR and uPCR with all-cause mortality.

Methods: This retrospective cohort study identified 2904 adult patients with concurrently measured uACR and uPCR from the same urine specimen in a tertiary medical center in Central Taiwan between January 2003 and June 2017. Urinary albumin-to-protein ratio (uAPR) was derived by dividing uACR by uPCR. Urinary non-albumin protein (uNAP) was calculated by subtracting uACR from uPCR. Conventional severity categories of uACR and uPCR were used to develop a risk matrix. We evaluated all-cause mortality based on uAPR and uNAP on a continuous scale using the multivariable Cox proportional hazards model.

Results: For each doubling increase in uPCR, uACR, and uNAP, the adjusted hazard ratios (aHRs) of all-cause mortality were 1.29 (95% confidence interval [CI]:1.24-1.35), 1.12 (1.09-1.16), and 1.41 (1.34-1.49), respectively. Linear dose-response association with all-cause mortality was only observed with uPCR and uNAP. The 3 x 3 risk matrices revealed that patients with severe proteinuria and minimal albuminuria had the highest risk of all-cause mortality (aHR 5.25, 95% CI: 1.88, 14.63). uNAP significantly improved the discriminative performance compared to that of uPCR (c-statistics: 0.834 vs. 0.828, p=0.05).

Conclusions: uNAP provides better mortality prognostic assessment than uPCR and uACR.

Magnetic Resonance Imaging-Based Renal Function Estimation Using a Machine Learning Approach

Daichi Fukaya,1 Tsutomu Inoue,1 Eito Kozawa,2 Masahiro Ishikawa,3 Yusuke Watanabe,2 Hiroaki Arano,3 Naoki Kobayashi,2 Mamoru Niitsu,2 Hirokazu Okada.1 Department of Nephrology, Faculty of Medicine, Saitama Medical University, Iruma-gun, Japan; 2School of Clinical Engineering, Faculty of Health and Medical Care, Saitama Medical University, Hidaka-shi, Japan; 3Division of Dialysis Center and Department of Nephrology, Saitama Medical University International Medical Center, Hidaka-shi, Japan.

**Background:** In patients with deterioration of GFR with an unknown clinical course, it is quite difficult to determine whether the renal dysfunction is caused by a hemodynamic alteration or changes in the renal parenchyma, even when using kidney imaging. Therefore, to estimate renal function quantitatively based on the morphology of the renal parenchyma, we performed an advanced image analysis of renal magnetic resonance imaging (MRI) using machine learning (ML).

**Methods:** We used coronal Dixon water-dominant images obtained from a 3.0T MR device and a deep ML convolutional neural network (CNN) to evaluate renal function (eGFRcre). K-fold cross-validation (k = 5) was performed for the assessment of accuracy and generalization performance. The study protocol was approved by the IRB of our institute.

**Results:** A total of 196 patients (age, 57.9 ± 16.9 years; 128 males; CKD stage, G1 (n = 18), G2 (39), G3a (43), G3b (45), G4 (35), and G5 (16) were included. After optimization of the CNN model, the accuracy, precision, recall, and F1-score of the confusion matrix, as well as the AUC of the ROC curve at thresholds of eGFRcre of 60, 45, and 30 were 0.80, 0.83, 0.87, 0.86, 0.75, 0.71, 0.84, 0.77, 0.83, and 0.76, 0.80, 0.90, 0.85, 0.83, respectively. The output value of the CNN model also showed a significant positive correlation with the normalized eGFRcre of the subjects (R² = 0.46, P < 0.01). When the difference in signal intensity between the renal cortex and medulla, as measured based on the region of interest method, was used as a diagnostic index, the accuracy was the same as that of ML if the threshold was eGFRcre 30 (AUC of the ROC curve, 0.84). Conversely, when the threshold was set at eGFRcre 45 or 60, the accuracy deteriorated gradually (AUC 0.80 and 0.73, respectively).

**Conclusions:** Compared with the classical method, in which only the signal intensity is used, the ML approach was able to quantitatively evaluate differences in renal morphology regarding a wide range of renal functions. Our results may have clinical applications for assessing the cause of changes in kidney function in the conditions in which renal function and morphology diverge, e.g., in the early stages of acute kidney injury, renovascular hypertension, and therapeutic interventions that cause hemodynamic alterations.

Inflammation Mediates the Association of Depression Severity with Selective Serotonin Reuptake Inhibitor Treatment Response in Patients with CKD

Salvatore Torres Rodriquez,1 L Parker Gregg,1,2 Thomas Carmody,1 Madhukar Trivedi,3 Susan Hedaya,1 1University of Texas Southwestern Medical Center at Dallas, Dallas, TX; 2VA North Texas Health Care System, Dallas, TX.

**Background:** Patients with chronic kidney disease (CKD) are at high risk for depression, which is associated with inflammation in patients with chronic diseases. We investigated whether depression severity is associated with response to treatment with selective serotonin reuptake inhibitors (SSRIs) in patients with chronic kidney disease.

**Methods:** We conducted a prospective study of patient-reported outcomes pre and post ERA for RKP. Baseline & subsequent pain questionnaires (McGill Pain (MPQ), Brief Pain Inventory (BPI), Opioid oral morphine milligrams equivalent (MME)) & QOL (LASA-6, PHQ-9 & SF-8) were obtained. The Wilcoxon test was used. ERA using an open irrigation ablation catheter was performed in a spiral manner distal to proximal renal arterial ostium. Power was titrated between 5-30 watts guided by change in impedance.

**Results:** We performed 24 ERA (3 bilateral, 21 unilateral; 4 redos) in 20 patients, with female:males, 14:6; median age 40y. 12 patients (60%) had Loin Pain Hematuria Syndrome (LPHS), 4 (20%) ADPKD, and others 4 (20%). 17 of 20 have completed the baseline questionnaires & 9 of 17 patients have 6mo data. All nine experienced variable or complete reductions in pain & QOL from baseline to 6mo (Table1). A median of 8mo pain relief was reported. After their first ERA, responders (pain relief >6mo) median 8.5m (n=12/20;60%) while 4 (20%) reported pain relief <6mo (non-responders) median 2mo. 3 (15%) had no relief, and 1 was lost to FU. In the redo era, there was no relief in 2; in 1 pain relief lasted 4mo (non-responder), and in the other, relief was 8mo (responder).

**Conclusions:** Among patients with RKP undergoing ERA, half achieved objective improvement in pain & QOL at 6mo. Prospective randomized studies with careful patient selection are required to assess the role of ERA for palliation of pain.

**Assessments of Pain & QOL**

Prospective Study of Patient-Reported Outcomes After Endovascular Renal Ablation in Individuals with Chronic Kidney Pain and Opiate Use

Vitor A. Lopez,1 Ablisheek Deshmukh,2 Rajiv Gulati,1 Paul Novotny,3 Marie C. Hogan,3 Mayo Clinic Minnesota, Rochester, MN; 1Mayo Clinic Dpt of Neph & HTN Research, Rochester, MN; 3Mayo Clinic Biomedical Statistics and Informatics, Rochester, MN; 4 Mayo Clinic Dpt of Cardiovascular Medicine, Rochester, MN.

**Background:** Endovascular renal ablation (ERA) may be useful for palliating and in some instances relieving refractory kidney pain (RKP) but is not widely available. We report our experience of ERA in 20 patients with RKP.

**Methods:** We conducted a prospective study of patient-reported outcomes pre and post ERA for RKP. Brief pain inventory (BPI), opioid oral morphine milligrams equivalent (MME) & QOL (LASA-6, PHQ-9 & SF-8) were obtained. The Wilcoxon test was used. ERA using an open irrigated ablation catheter was performed in a spiral manner distal to proximal renal arterial ostium. Power was titrated between 5-30 watts guided by change in impedance.

**Results:** We performed 24 ERA (3 bilateral, 21 unilateral; 4 redos) in 20 patients, with female:male; 14:6; median age 40y. 12 patients (60%) had Loin Pain Hematuria Syndrome (LPHS), 4 (20%) ADPKD, and others 4 (20%). 17 of 20 have completed the baseline questionnaires & 9 of 17 patients have 6mo data. Clinical Impact of Body Muscle Mass for Kidney Function Evaluation: New eGFR Formula Based on Serum Creatinine and Body Muscle Mass

Kazunori Goto, Yosinori Yasuda, Sawako Kato, Shoichi Maruyama, Nagoya University, Nagoya, Japan.

**Background:** Kidney function is globally evaluated by estimated glomerular filtration ratio (eGFR) based on serum creatinine (Crea). Since Crea is influenced by body muscle mass, there is serious concern of overestimation of eGFR among elderly people with higher muscle volume due to frailty. In this study, eGFR based on Crea (eGFRc) and Crea×(fat mass of the Crea×fat mass of the body) were analyzed in association with psoas muscle mass index (PMI) by CT image among CKD patients whose kidney function was accurately evaluated by measured GFR (eGFRc) computed from inulin clearance (Cin).

**Methods:** Study design: Single-center, cross-sectional retrospective study. Study subjects were consecutive 184 CKD patients (123 males) at Nagoya university hospital whose Crea and abdominal CT were examined within 1 year between 2009 and 2013. New eGFR formula based on Crea and PMI (eGFRc×PMI) were developed in 122 patients and validated in 62 patients, which were randomly determined to each cohort. 20%
accuracy for Cini was analyzed by eGFRcreat and eGFRcys calculated by eGFR formulae for Japanese. The performance of eGFRcreat-PMI was assessed by means of bias (eGFRcys/mGFR), accuracy (percentage of estimates within 20% of mGFR), root mean square error, and correlation coefficient. In PMI tertile subgroups and GFR(Cini) subgroups (<30, 30-60, >60%), the performance of each formulae was assessed.

Results: Patients’ characteristics (n=184, mean±SD) or median[Q1,Q3] were: age: 62 [50, 70], eGFRcreat: 58.5 (25.5), eGFRcys: 59.4 (25.9), Cini: 55.0 (25.0) and PMI: 7.29 [6.18, 9.11]. Log-PMI was significantly associated with age, gender, log-BMI, log-Cre and logCys in univariate analyses, and with age, gender and log-BMI in multivariate analysis. New eGFR formula (eGFRcreat-PMI) was well correlated with Cini. 20% accuracies for Cini was the highest in eGFRcreat-PMI (74.5%), compared to eGFRcreats (67.9%) and eGFRcreat (68.5%), which was more prominent among low PMI tertile group (77.4% in eGFRcreat-PMI, 67.7% in eGFRcys, and 71.0% in eGFRcreat) and high PMI tertile group (73.8% in eGFRcreat-PMI, 59.0% in eGFRcys, and 67.7% in eGFRcreat).

Conclusions: Body muscle mass seriously influences accuracy of kidney function evaluation, and new GFR formula based on PMI and Cre would be useful for accurate evaluation of kidney function, especially among patients with low and high body muscle mass.

PO0550
Incidence and Predictors of Non-Alcoholic Fatty Liver Disease in CKD
Sankar D. Navaneethan,1-3 L. Parker Gregg,2 Peter Richardson.1,2 Baylor College of Medicine, Houston, TX; 1Michael E DeBakey VA Medical Center, Houston, TX; 2The University of Texas Southwestern Medical Center, Dallas, TX.

Background: The prevalence of non-alcoholic fatty liver disease (NAFLD) is increasing due to global epidemics of obesity and diabetes mellitus, which are commonly seen in CKD. We studied the incidence and predictors of NAFLD in those with CKD.

Methods: We conducted a retrospective cohort study of patients with incident CKD (eGFRcreat <60 ml/min/1.73 m2) a median follow-up time of 4.7 years in the Veterans Health Administration from 2005-2016. Patients with no NAFLD at the time of CKD diagnosis were followed for a primary outcome of NAFLD, defined as development of sustained elevated alanine aminotransferase levels in the absence of hepatitis B or C virus infection or alcoholic liver disease, identified by laboratory values and diagnosis codes. We calculated incidence rates for NAFLD for the entire study population and by CKD stage. Predictors of NAFLD were evaluated using Cox proportional hazards regression, considering death and ESKD as competing risks.

Results: Of 1,155,901 veterans with CKD but no NAFLD in 2005, 51,584 (4.4%) developed NAFLD at a rate of 0.86 (0.85-0.87) per 100 person-years during 4.7 years follow-up. A total of 3.9% developed ESKD at a rate of 0.76 (0.75-0.77) per 100 person-years, and 33% died at a rate of 6.5 (6.5-6.5) per 100 person-years during the same time period. In a multivariable model, age >50 (vs. 40-49 years) (HR 0.72, 95% CI 0.67, 0.77), women, blacks and veterans with advanced CKD were less likely to develop NAFLD; however, presence of diabetes, higher BMI, anemia, CHF, and hypertension were associated with higher risk of developing NAFLD (Table).

Conclusions: Patients with CKD have a high incidence of NAFLD, which was associated with diabetes, BMI, and CHF. Future studies should determine if interventions targeting these factors may reduce NAFLD risk.

Factors associated with incident NAFLD in CKD

PO0551
Alterations of Gray Matter Volumes and Connectivity in Patients with CKD Compared to Healthy Subjects
Jie Wang, Dongmoo Kim, Yoo min Lee, Siyuhang Park, Bongsoo Park, Eunjung Youn. Research Hospital, Inje University College of Medicine, Busan, Republic of Korea.

Background: Our previous study demonstrated that patients in End stage renal disease had decreased structural and functional brain connectivity, and there was significant association between brain connectivity and cognitive function. The aim of this study was to evaluate the alterations of structural and functional connectivity using graph theoretical analysis in the neurologically asymptomatic patients with relatively early stage chronic kidney disease (CKD).

Methods: We prospectively enrolled neurologically asymptomatic 20 patients with CKD stage 3 and 20 healthy controls, and all of the subjects underwent diffusion tensor imaging (DTI) and resting state functional MRI (rs-fMRI). Using data from the structural and functional connectivity matrix built on DTI and rs-fMRI, we calculated network measures, including global efficiency, local efficiency, mean clustering coefficient, characteristic path length, and small-worldness index, and investigated the differences between patients with CKD and healthy controls.

Results: The patients with CKD had altered global structural connectivity and preserved functional connectivity compared to healthy controls. All of the measures of global structural connectivity were significantly different between the patients with CKD and healthy controls. However, all of the measures of global functional connectivity in the CKD patients were not different from those in healthy participants. In the CKD patients, the functional betweenness centrality of the right insular cortex, right occipital pole, and right thalamus was significantly different from that in healthy subjects. The structural betweenness centrality of the left hippocampus, right posterior cingulum was significantly different from that in healthy subjects.

Conclusions: There were significant alterations of global structural connectivity between patients with CKD and control. However, functional connectivity of brain network was preserved in contrast to ESRD patients.

PO0552
CKD and Metabolic Risk Factors: A Cross-Sectional Study Based on 398,120 Adults in China
Lingling Xu, Jun Liu, Yang Zhou, Junwei Yang. Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.

Background: Chronic kidney disease (CKD) has become a worldwide health problem. The prevalence of CKD varied within countries by different socio-demographic characteristics and economic status. Elderly people are particularly susceptible to kidney damage from age-related decline in glomerular filtration and chronic disease states, such as diabetes mellitus (DM) and hypertension (HTN). It is necessary to understand the epidemiological features and the association risk factors of CKD in adults, especially in these elderly populations.

Methods: We did a cross-sectional survey based on the records of universal health examinations of the residents in Binhai county of China in 2018. A total of 398,120 participants aged a 18 years in this study had underwent blood test, body measurements and routine urinalysis. Those 51.6% of subjects who aged ≥65 years (n=37,533) were randomly selected to complete the routine urinalysis. Chronic renal insufficient (CRI) was defined by eGFR < 60 ml/min/1.73 m2(CKD-EPI), while CKD was defined by CRI or presence of proteinuria. We analyzed the epidemiological features and the association between CKD and relevant covariates by logistic regression models in the general and elderly population.

Results: The age- and gender- standardized prevalence of CRI was estimated to be 1.10% (95% CI, 1.07%-1.13%) in Chinese adult population. It was 0.86% among men (95% CI, 0.82%-0.90%) and 1.34% among women (95% CI, 1.29%-1.39%). Female, aging, central obesity, elevated triglycerides, systolic blood pressure, fasting blood glucose (FBG) and heart rate were independent risk factors for CRI in the general adults. Rates of CRI increased significantly by age, especially when people aged ≥60 years. Furthermore, the prevalence of CKD was 17.7% (95% CI, 17.5%-18.1%) in the elderly. Aging, HTN, elevated triglyceride and FBG were still found to be independent risk factors for CKD in this subgroup. Elevated FBG had the strongest correlation with CKD, gender was no longer association with CKD in the elderly.

Are There Any Further Modalities for Prediction of Subclinical Volume Overload in Advanced Stages of CKD?
Ahmed H. Bakri, Hazem Mansour. Ain Shams University Faculty of Medicine, Cairo, Egypt.

Background: Subclinical volume overload is commonly seen in our daily practice which represents a debatable issue. These patients respond favorably to diuretics despite lacking clinical signs of volume overload. Therefore a proper assessment of the volume status in Chronic Kidney Disease (CKD) patients leads to a better control of their medical condition and prevents further deterioration of their clinical situation into the well-known sequelae. Although many tools were used to detect volume overload in such patients as biomarkers, ultrasonography, bio-impedance, echo, and blood viscosity, many non-specific results were due to presence of concomitant comorbidities. The use of Bio Impedance Spectroscopy (BIS) is a recent tool increasingly used due to its appealing features that make it non-invasive. BIS is an objective fluid status assessment method, which is shown superior to classical methods such as BP monitoring and weight control in many studies. Combining some of these tools may improve their accuracy and specificity. Inferior vena cava collapsibility index (IVCVC) with Brain Natriuretic Peptide (BNP) can be considered for more specificity and assessment.

Methods: To assess the usage of combined IVCVC and BNP level in CKD patients to predict subclinical volume overload, 110 patients with CKD (stage 4&5) & not on dialysis and having normal LV systolic function were included with exclusion of the following: 1) patients who suffered other causes of raised BNP than volume overload (i.e. anemia and heart failure). 2) Patients on diuretics. Complete history, clinical examination and basic laboratory were done for all included patients. IVCVC, BNP serum level were evaluated. By using BIS, we estimated Fluid overload (FO) and extracellular water (ECW). The patients were subdivided a FO >15% were considered as volume overloaded.

Results: Among the 110 cases, we found that 26 patients (23.6%) had subclinical hyperervolemia as diagnosed by FO/ECW ratio >15. IVCVC ≥38% had higher diagnostic
performance than BNP ≥24 pg/mL. Combining both IVCCI ≥38% and BNP ≥24pg/mL increased the specificity and negative predictive value for detection of subclinical hyperparathyroidism.

Conclusions: Combined elevated BNP level and decreased IVCCI could be more precise tools for subclinical volume overload detection in CKD patients.

PO0554
Sensitivity of Urinary N-Terminal Osteopontin-to-Creatinine Ratio in Predicting Renal Function Loss
Ling Sun,1 Satyesh K. Sinha,1 Aldons J. Lusis,1 Susanne B. Nicholas.1
Metabolic Syndrome In Men (METSIM) | UCLA, University of California Los Angeles, Los Angeles, CA, 2Xiazhou City Centre Hospital, Xiazhou, China.

Background: Osteopontin (OPN) is a multifunctional protein that gets cleaved to create N-terminal OPN (ntOPN). ntOPN has been reported in urine in kidney diseases but little is known about the sensitivity of ntOPN to creatinine ratio (ntOCR) as a urinary biomarker compared to the urinary albumin-to-creatinine ratio (UACR). This study is aimed to explore the prognostic value of ntOCR regarding renal function loss in a subset of the metabolic syndrome in men (METSIM) study with a high incidence of diabetes mellitus.

Methods: The METSIM study recruited 10,197 Finnish men between 2005 and 2010 and reexamined participants at two 5-year follow-ups. We performed a prospective observational study of a METSIM cohort of 137 participants, 45-72 years old at entry, with available urine at baseline and the first follow-up period, after 3.8±1.4 years. Serum and urinary levels of the ntOPN were quantified by ELISA. Using estimated glomerular filtration rate (eGFR), UACR and urine albumin excretion (UAE) of progressors and non-progressors, data were analyzed by paired t-test and Wilcoxon matched-pairs signed-rank test. The area under the receiver-operating characteristics (ROC) curve (AUC) was used to assess the sensitivity/specificity of variables in predicting the progression of CKD. Pearson correlation coefficient was performed to detect the relationships between the values of variables.

Results: Compared to the CKD non-progressors, the progressors had significantly higher eGFR at baseline (96.95 vs. 87.75 mL/min/1.73 m², p=0.00) and lower eGFR at follow-up (86.11 vs. 91.40 mL/min/1.73 m², p=0.01). The baseline urine levels of ntOCR were higher in progressors than non-progressors (6.83 vs 3.68 pmol/mg, p=0.05). There were no differences in the UAE, UACR, or serum ntOPN between the two groups. However, baseline urinary ntOCR predicted renal function loss with an AUC of 0.60 (p=0.05), and the change between baseline and follow-up had a higher AUC of 0.63 (p=0.01).

Conclusions: Our study suggests that urinary ntOCR might be a promising predictive biomarker for renal function loss in a population with high rates of metabolic syndrome and diabetes. Measurements at the second METSIM follow-up may confirm this observation. Further studies are needed in females, larger size populations, and long-term follow-up.

PO0555
Effect of Renin-Angiotensin System Blockade in Immunoglobulin A Nephropathy Only with Persistent Hematuria
Hui Xu, Department of Nephrology, Xiangya Hospital, Central South University, Changsha, China.

Background: Recent guideline recommended that long-term renin-angiotensin system blockade (RASB) should be used in immunoglobulin A nephropathy (IgAN) when proteinuria > 1g/d. If proteinuria is 0.5–1g/d, RASB is also suggested. We tried to investigate whether IgAN patients only with persistent hematuria and without proteinuria can benefit from RASB.

Methods: IgAN patients only with persistent hematuria initially from January 2013 to December 2018 from four centers were included. We divided patients into treatment and untreated group according to the use of RASB. The primary outcome was the appearance of proteinuria, the secondary outcome was the decreased percentage of hematuria and the rate of estimated glomerular filtration rate (eGFR) decline. Effect of RASB on the outcomes was assessed by multivariate Cox regression models and a propensity score matching.

Results: 110 eligible patients were included and 44 (41.9%) received RASB. Patients in the treatment groups had higher diastolic pressure. The unadjusted primary outcome of RASB treated patients was better than the untreated individuals. The multivariate Cox regression revealed that RASB lowered the risk of primary outcome, besides, RASB decreased more percentage of hematuria. No obvious difference was found in the rate of eGFR decline between two groups.

Conclusions: RASB decreased the risk of proteinuria appearance and increased the remission of hematuria in IgAN only with persistent hematuria initially, but it did not obviously impact the blood pressure of patients without hypertension and the rate of eGFR decline.

PO0556
Fibrates and CKD Patients: A Controversial Issue
Aber H. Bakr, John Zarif. Ain Shams University Faculty of Medicine, Cairo, Egypt.

Background: Fenofibrates were not previously known to affect renal function tests until some reports indicated that these drugs may lead to a decrease in renal function. Likewise, the nephrotoxic effect of fibrates remains to be vague and unclear Fenofibrate’s safety in patients with renal insufficiency is an issue because it may increase plasma creatinine. Furthermore, guidelines regarding fenofibrate dosing in renal impairment vary internationally. We investigated fenofibrates’ effects on cardiovascular and on advanced CKD, according to eGFR. The multiple incidents of elevated kidney function tests for patients on fibrates have led us to make this study to review our experience as well as literature on this matter.

Methods: A prospective cohort study over 6 months with a total of 80 patients on fibrates divided into 2 groups, 40 of which received statins and the other 40 continued on fibrates. All our patients were subjected to full history, clinical examination and complete baseline labs. The kidney function tests including serum creatinine and eGFR were measured at 0.1, 2 and 6 months’ intervals and lipid profile at 0.3,6 months serially in both groups.

Results: Out of the baseline values of the kidney function tests that were recorded on previous fibrate therapy, the statin group (n=40) showed a significant decrease in all kidney function values including serum creatinine by (0.9mg/dL, P=0.001) and an increase in eGFR (8.9 mL/min/1.73 m2, P=0.001). Whilst in the other 40 patients who continued to receive fibrates the kidney function tests continued to rise as serum creatinine showed a significant increase in their mean serum Cr levels (by 0.9 mg/dL or 20%, P=0.001), and a significant decrease in their mean eGFR values by (8.2 mL/min/1.73 m2 or 20.55%, P=0.001). On the other hand total and LDL Cholesterol were significantly lower in Statin group at all follow up intervals. Also triglycerides were significantly higher in Statin group at the end of month-6 from baseline.

Conclusions: In our study fibrates administration showed a short term state of renal insufficiency. The long term effects of fibrates versus variable renal derangement are yet to be identified. As to lipid profile, shifting from fibrates to statins led to a stastically significant rise in triglyceride but it’s clinical impact is yet to be investigated, so established guidelines might need a revision regarding clinical benefits of fibrates versus it’s renal injury.

PO0557
Calciphylaxis: An Uncommon Skin Manifestation in Non-Dialysis CKD Patients
Rubab Sarwar,1 Ujala Zubair,2 Wanzwarat Ananthapanyasut,1 Skagit Regional Health, Mount Vernon, WA; 2Jinnah Sindh Medical University, Karachi, Pakistan.

Introduction: Calciphylaxis is a rare but fatal skin disorder seen in 1-4% of dialysis patients. It is characterized by ischemia and necrosis of the skin tissue due to the deposition of calcium in the arterioles and subcutaneous tissues. The risk of infection is increased, and once ulceration develops, the mortality rate can be above 80%. Risk factors include diabetes, warfarin, vitamin D, obesity, female, white race and mineral-bone disorder. The skin findings ranging from livedo reticularis to nodules, plaques, or deep ulcerations. The treatment is focused on supportive care. To date, there is no strong studies to suggest that sodium thiosulfate (STS), bisphosphonates, or calcimimetics are curative. However, STS is commonly used despite the lack of strong supporting data.

219
Case Description: We report a case of a 76-year-old Caucasian woman with a history of stage G4/A3 chronic kidney disease, insulin-dependent diabetes, hypertension, secondary hyperparathyroidism, and obesity, who presented with severe pain and redness on both legs. The skin lesions had progressed to the painful ulcerations and eschars on both shins one month after the initial visit. A skin biopsy was performed and histopathology was consistent with calciphylaxis. She was started on STS 25 mg intravenously (IV) twice a week and cinacalcet 30 mg by oral route (PO) thrice a week. The patient showed improvement within one month of the treatment.

Discussion: Calciphylaxis in non-dialysis patients is uncommon; however, it should be considered in those with predilection factors. The skin biopsy is crucial for the diagnosis, which can lead to proper management of such a rare yet lethal disease. STS is the most common drug used to treat calciphylaxis. It acts as a calcium chelator with some antoxidative and vasodilation properties leading to recovery.

PO0558
Calciphylaxis: Clinical Features, Therapeutic Options, and Outcomes
José Agapito Fonseca, Maria Sanches, Inês C. Duarte, Joana Gameiro, Cristina B. Outurco, Hugo Silva, Sofia C. Jorge, Jose A. Lopes, Estela Nogueira. Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Lisboa, Portugal.

Background: Calciphylaxis is characterized by microvascular disease with calcification of the middle layer of the arteriolar walls, internal hyperplasia and thrombotic occlusion, conditioning areas of ischemia and skin necrosis. Given the rarity of this pathology, there is a lack in literature regarding clinical presentation, diagnostic approach and therapeutic management. We performed a descriptive analysis of clinical, epidemiologic, laboratory characteristics, treatment options and outcomes in a population of patients with calciphylaxis.

Methods: Retrospective analysis of all calciphylaxis diagnosed in a single-center between January 2003 and December 2019.

Results: The diagnosis of calciphylaxis was made in 9 patients, 7 of whom were female, with a mean age of 63.4±10.9 years. Eight patients were on renal replacement therapy (hemodialysis) at the time of diagnosis, with a dialysis vintage of 66.4±82.4 months and one patient had no chronic kidney disease. Six patients were taking warfarin, with an average of 46 months on anticoagulation. The mean pre-diagnostic serum calcium product was 42 mg^2/dL^2 with an average of 46 months on anticoagulation. The mean pre-diagnostic serum calcium product was 42 mg^2/dL^2 with an average of 46 months on anticoagulation.

Conclusions: More than 60% of patients were under warfarin, reinforcing the role of vitamin K antagonists in the pathogenesis. Mean time on dialysis was highly variable, from the 1st to the 216th month since the beginning of the technique. The standard of treatment varied according to the drugs available and the clinical evidence that supported its use at the time of diagnosis. The registered deaths corresponded to patients diagnosed later in the course of the disease, reinforcing the importance of a high clinical suspicion regarding the appearance of trophic skin lesions in this population as a form of early diagnosis to prevent mortality.

PO0559
Role of Adipose Tissue-Derived Mesenchymal Stem Cells in CKD: A Phase 1 Study Assessing Safety and Clinical Feasibility
Zheng Cai-Mei. Taipei Medical University College of Medicine, Taipei, Taiwan.

Background: Chronic kidney disease (CKD) is a most common progressive disorder associated with high mortality and huge socio-economic burden globally. We hypothesize that allogeneic adipose tissue mesenchymal stem cells (hASCs) are renotrophic and may retard CKD progression through anti-apoptotic, anti-fibrotic, and anti-inflammatory effects. In this study, we will assess the safety and tolerability of a hASCs infusion in CKD patients with various underlying etiologies.

Methods: We performed a single-arm phase I clinical trial with a 6-month follow-up. This study enrolled 12 eligible CKD patients with an estimated glomerular filtration rate (eGFR) of 15-44 mL/min/1.73m^2 (mL/min). Patients were allocated to receive low, moderate, or high dose of allogeneic cultured hASCs infusion. We investigated the safety issues and kidney function during the follow-up visit.

Results: There was no patient lost to follow-up. We observed two treatment related adverse events (AE) in high dose group. One subject experienced grade 1 slow speech immediately after hASCs infusion, which was resolved on the next day and completely normal afterwards. The AE was considered possibly related to study treatment and met dose-limiting toxicity (DLT). Another subject experienced grade 1 bradynia after the infusion, and the situation was resolved during the following 9 days, however, this AE was not considered as DLT. One SAE was reported in moderate dose group, who was hospitalized for persistent heavy proteinuria, and later proved as diabetic nephropathy stage 4 by renal biopsy. No significant reduction in mean systolic blood pressure was observed in all treated patients, and specifically an improvement in eGFR was noted among those with baseline eGFR<30mL/min. No significant reduction in proteinuria was noted.

Conclusions: This trial demonstrated the safety and tolerability of allogeneic hASCs infusions in various stages CKD patients. Patients with reserved renal function (e.g. Backlund, S., Hoffstedt, J., Smid, E.F., et al. J Am Soc Nephrol 31: 2020

PO0605
Pegunigalsidase Alfa, Novel Pegylated Enzyme Replacement Therapy, Evaluated in Fabry Patients with Progressing Kidney Disease: A Randomized Clinical Trial Study Design
David G. Warnock,1 Derrylam Hughes,2 Sari Alon,3 Raul Cherkoff,3 Einat Almon,3 Raphael Schifflmann,4 UAB Medicine, Birmingham, AL; 2LSDU, Institute of Immunity and Transplantation, Royal Free London NHS Foundation Trust, London, United Kingdom; 3Protalix Biotherapeutics, Carmiel, Israel; 4Baylor Institute of Metabolic Diseases, Baylor University Medical Center, Dallas, TX.

Background: Fabry disease (FD) is an X-linked multisystem lysosomal storage disorder, affecting males and females caused by the deficient of α-galactosidase-A (α-Gal-A) activity. Long-term disease manifestations include progressive renal failure, hypertrophic cardiomyopathy, cardiac rhythm disturbances, stroke, and death. Two enzyme replacement therapies (ERT) and oral chaperon therapy are commercially available. The clinical benefit of available treatments may not be as robust as anticipated, especially in the subset of males with ‘classic’ Fabry disease. In the context of ERT, a combination of factors including dose, dosing interval, presence of anti-drug antibodies, estimated glomerular filtration rate (eGFR), and age at the time of ERT initiation, and proteinuria could explain the less than optimal responses achieved by the currently available ERT. Pegunigalsidase alfa is a novel PEGylated homo-dimer ERT which is more stable, has a favorable safety profile, potentially less development of anti-drug antibodies, and enhanced pharmacokinetic profile (~80 hours half-life and higher AUC) compared to other available ERT.

Methods: Adult FD patients (males and females) deteriorating in kidney function with annualized eGFR < -2 mL/min/1.73 m^2/year while on agalsidase beta have been enrolled into BALANCE, a phase-III double-blind active control study (NCT02795676), and were randomized (2:1 ratio) to pegunigalsidase alfa or continue agalsidase beta for 2 years at 1 mg/kg every other week. The primary outcome is the difference in the mean annualized slope of eGFR between the study between the two groups.

Results: Description of the baseline characteristics for approximately 75 patients enrolled at 29 US and European study sites by: age, sex, enzymatic activity, genetic mutations, FD symptoms, previous FD treatment length, kidney function (eGFR, eGFR slope and UPCR), Lyso-Gb3, and anti-drug antibodies pre-treatment status.

Conclusions: This trial demonstrated the safety and tolerability of allogeneic hASCs infusion in various stages CKD patients. Patients with reserved renal function (e.g. Backlund, S., Hoffstedt, J., Smid, E.F., et al. J Am Soc Nephrol 31: 2020

PO0561 Pegunigalsidase Alfa, PEGylated α-Galactosidase-A Enzyme in Development for the Treatment of Fabry Disease, Shows a Correlation Between Renal Gb3 Inclusion Clearance and Reduction of Plasma Lyso-Gb3
Ahmad M. Tufaha1, Derrynna Hughes,2 Sineon Boyce,3 Pilar Giradlo,4 Malin Holila,5 Mohamed G. Atta,6 Ozlem Goker-Alpan,7 Kathleen M. Nicholls,8 Raphael Schiffman,9 Gustavo Maegaard,10 Laura Barisoni,11 Robert B. Colvin,11 James J. Jennette,12 Sari Alon,13 Mali Szafler,14 Einat Almon,15 Raoul Chertkoff,16 'Kansas University Medical Center, Kansas City, KS; ‘LSDU, Institute of Immunity and Transplantation, Royal Free London NHS Foundation Trust, London, United Kingdom; ‘Hospital de Dia Quirón, Zaragoza, Spain; ‘University of Iowa Hospitals and Clinics, Iowa City, Iowa, USA; ‘Division of Medical Genetics and Genomics, Johns Hopkins, Johns Hopkins University School of Medicine, Baltimore, MD; ‘Nephrology Department, the Royal Melbourne Hospital, Melbourne, VIC, Australia; ‘Baylor Institute of Metabolic Diseases, Baylor University Medical Center, Dallas, TX; ‘Duke University, Durham, NC; ‘Massachusetts General Hospital, Harvard Medical School, Department of Pathology, Boston, MA; ‘University of North Carolina, Department of Pathology, Chapel Hill, NC; ‘Protalix Biotherapeutics, Carmiel, Israel; ‘University of Florida Department of Pediatrics/Genetics & Metabolism, Gainesville, FL; ‘Q&O Alpan LLC, Fairfax, VA; ‘Department of Pediatrics, Section of Genetics, MIND Institute, UC Davis Medical Center, Sacramento, CA.

Background: Fabry disease (FD) is caused by the loss of function of the lysosomal enzyme α-Galactosidase-A leading to the accumulation of globotriasylceramide (Gb3). Reduction in histological Gb3 burden in renal peritubular capillaries (PTCs) is considered an indicator of treatment efficacy and patients with severe renal involvement are likely to benefit the most. Previous studies demonstrated that treatment with PEGylated α-Galactosidase-A significantly reduced renal lyso-Gb3 burden.

Methods: The phase I/II (NCT01678898) dose-ranging studies (0.2mg/kg; 1 mg/kg; 2mg/kg) were designed to evaluate the safety (primary objective), pharmacokinetics and efficacy (secondary objective) of pegunigalsidase-alfa administered IV every 2 weeks in adult symptomatic FD treatment naïve male and female patients. The Barisoni Lipid Inclusion Scoring System (BLISS) was adopted to quantitively assess patients' renal involvement, and was reduced to a mean of 0.83 after 6 months (-67.8% in the three dose groups. Mean BLISS score at baseline was 4.23, proving an important indicative of clinical improvement.

Results: Renal biopsies were available and evaluated in 13 out of 16 patients allocated to the highest tolerable dose of angiotensin-converting enzyme inhibitor (ACEI) or angiotensin II receptor blocker (ARB) for at least 8 weeks. They received amiodarone 5 mg twice daily or triamterene 50 mg twice daily for 8 weeks. All the patients then entered a washout phase for 4 weeks, followed by a crossover to the other trial drug for 8 weeks. Weight, blood pressure, metabolic panel, urine studies, and 24-hour urine protein excretion were frequently monitored. Patients with serum potassium >5.5 or an increase in serum Cr >30% one week after the treatment were withdrawn.

Conclusions: These results show a potential benefit of pegunigalsidase-alfa on renal function for FD patients currently treated with agalsidase alfa, to be confirmed by long-term data.

PO0563 Tolerance for Potassium Supplementation in Patients with CKD
Martin George1, Stanley M. Yeung,2 Rosa D. Wong,3 Liffert Vogt,4 Martin H. De Borst,2 Joris I. Rotmans,5 Ewout J. Hoorn,6 Erasmus MC, Rotterdam, Netherlands; 7Universitair Medisch Centrum Groningen, Groningen, Netherlands; 8Amsterdam Universitair Medisch Centra, Amsterdam, Netherlands; 9Leids Universitair Medisch Centrum, Leiden, Netherlands.

Background: Recent studies have shown an association between higher potassium (K+) intake and better kidney outcomes in patients with chronic kidney disease (CKD). However, K+ supplementation in CKD may be limited by the risk of hyperkalemia (>5.5 mEq/L). The primary aim of this study was to patients with CKD with the aim of determining whether it is safe to use Potassium supplementation in patients with progressive CKD and hypertension.

Methods: In 151 patients (67±11 years, 74% males, eGFR 32±9 mL/min/1.73 m2, 83% on renin-angiotensin inhibitors), K+ supplementation (40 mEq/day) increased urinary K+ excretion from 73±24 to 106±28 mEq/day, WKBI from 4.3±0.5 to 4.7±0.5 mEq/L, and plasma aldosterone from 294 (210-447) to 366 (271-504) pg/mL (P<0.001 for all). The majority of patients (n=138, 91%) remained normokalemic upon K+ supplementation, despite the use of renin-angiotensin inhibitors. K+ supplementation increased renin-angiotensin system activity (156±62 to 155±68 mEq/day, systolic blood pressure (132±15 to 132±15 mmHg), or eGFR (32.9±32.8 mL/min/1.73 m2).

Conclusions: This short-term study illustrates the feasibility of investigating the renoprotective potential of K+ supplementation in patients with CKD and provides the characteristics of patients in whom K+ is safe.

PO0656 The Effect of Amiloride and Triamterene on Proteinuria in Patients with Proteinuric Kidney Diseases
Mohammed Alshehri,1 Wen Shen,2 Sameer Y. Desale,3 ‘MedStar Georgetown University Hospital, Washington, DC; ‘Medstar Health Research Institute, Hyattsville, MD.

Background: Proteinuric kidney diseases are associated with a significant risk of developing stage renal failure. Treatment options after maximizing the renin-angiotensin-aldosterone system (RAAS) inhibition are limited. Amiloride, a diuretic inhibiting epithelial sodium channel (ENaC), has been reported to have antiproteinuric effects in animal studies independent of its action on ENaC. This study was designed to specifically examine the effect of Amiloride and triamterene in patients with significant proteinuria.

Methods: It is a cross-over pilot trial where each patient acted as his/her own control. Patients with proteinuria more than 1.0g/day, eGFR >30mL/min/1.73m2, and on the drug of interest was given one of angiotensin-converting enzyme (ACE) or angiotensin receptor blocker (ARB) for at least 8 weeks. They received amiodarone 5 mg twice daily or triamterene 50 mg twice daily for 8 weeks. All the patients then entered a washout phase for 4 weeks, followed by a crossover to the other trial drug for 8 weeks. Weight, blood pressure, metabolic panel, urine studies, and 24-hour urine protein excretion were frequently monitored. Patients with serum potassium >5.5 or an increase in serum Cr >30% one week after the treatment were withdrawn.

Results: A total of 12 patients were enrolled and completed the study. Amiloride reduced 24-hour urine protein by 25.4% (P=0.00435), UPCr by 31.6% (P=0.0104), UACR

Hyperparathyroidism (SHPT) in CKD
Comparison of Extended-Release Calcifediol (ERC), Immediate-Release Calcifediol, Cholecalciferol, and Paricalcitol for Treating Secondary Hyperparathyroidism (SHPT) in CKD

Background: Total 25-hydroxyvitamin D (25D) levels above 50.8 ng/mL are required to produce meaningful and progressive reductions in plasma intact parathyroid hormone (iPTH) in patients with stages 3 or 4 CKD [Strugnell et al 2019]. The current study compared the abilities of four treatment regimens to increase serum 25D to this level and to reduce iPTH in this population.

Methods: Subjects with stage 3 or 4 CKD, SHPT (iPTH ≥ 150 pg/mL), and vitamin D insufficiency (25D <30 ng/mL) underwent an 8-week washout from previous vitamin D therapies and were randomized to 60 days of open-label treatment with: 1) ERC 60 mcg/day; 2) immediate-release calcifediol (IRC) 266 mcg/month; 3) high-dose cholecalciferol (HDC) 300,000 IU/month; or 4) paricalcitol plus low-dose cholecalciferol (PLDC) 1 mcg and 800 IU/day. Paricalcitol was increased to 2 mcg/day after 30 days if iPTH was not reduced by 30% and safety parameters allowed. Subjects were monitored for changes in serum 25D, calcium (Ca), and phosphorus (P), and plasma iPTH.

Results: Mean (SD) post-washout/pre-treatment baseline levels for 25D and iPTH in the per-protocol population were 20.6 (6.8) ng/mL and 154 (99) pg/mL, respectively. No differences were observed at baseline between treatment groups (14-17 subjects each). The mean change in serum 25D (ng/mL) increased to 82.9 (17.0) with ERC (P <0.05), 30.8 (11.6) with HDC (P <0.05), 26.3 (6.8) with IRC and 24.2 (7.3) with PLDC. All subjects treated with ERC attained 25D levels ≥30 ng/mL vs. only 44% with HDC (P <0.001), 20% with IRC and 14% with PLDC. Most ERC subjects (94%) attained 25D levels >50.8 ng/mL. The proportion of subjects who achieved at least a 20% reduction in iPTH were 71% with ERC, 38% with HDC, 20% with IRC and 79% with PLDC. No changes from baseline were observed in mean Ca or P in any treatment group, but one instance of hypercalcemia (>10.3 mg/dL) was observed with PLDC treatment.

Conclusions: ERC was safe and more effective at increasing serum 25D and decreasing plasma iPTH than IRC, HDC or PLDC in patients with SHPT, vitamin D insufficiency, and stage 3 or 4 CKD.

Renoprotective Effects of Febuxostat and Allopurinol in Patients with Hyperuricemia and CKD: A Meta-Analysis

Background: Hyperuricemia is associated with rapid deterioration of renal function in patients with chronic kidney disease (CKD). The two most common urate-lowering drugs available are allopurinol and febuxostat. Randomized controlled trials and observational studies have shown that the individual drugs have potential to slow down deterioration of renal function in CKD patients. However, it is unclear which drug is more effective because of insufficient direct comparison between the two. Hence, our study aims to perform a meta-analysis to assess the renoprotective and urate-lowering effects between the two drugs in patients with CKD and hyperuricemia.

Methods: A comprehensive literature search using PubMed was performed with the following search terms: febuxostat, allopurinol, chronic kidney disease, renoprotection. Five relevant studies were selected and analyzed using Cochrane Revman v5.3. Outcomes assessed were changes in estimated glomerular filtration rate, serum creatinine, level of proteinuria and/or albuminuria and change in serum uric acid levels.

Results: Five studies comprising 606 patients were selected – 304 treated with febuxostat and 302 with allopurinol. No significant differences were found in the changes in serum creatinine (mean difference (MD) -0.02; CI -0.07, 0.03; P = 0.39) and eGFR (MD 2.09; CI 0.67, 1.75; P = 0.0003) from baseline to 3 months between the two groups. Significant difference in the change in eGFR favoring Febuxostat, was observed after 6 months (MD 4.94; CI 2.25, 7.64; P = 0.0003). Significant decrease in proteinuria (MD -0.24; CI -0.42, -0.07, P = 0.007) and albuminuria (MD -80.47; CI -149.29, -11.64, P = 0.02) were observed more in the febuxostat group after 3 months; however these changes were not significant after 6 months. Serum uric acid levels were significantly more reduced in the febuxostat group both after 3 (MD -0.90; CI -1.14, -0.67, P = 0.00001) and 6-months (MD -1.50; CI -1.70, -1.30, P < 0.00001).

Conclusions: Our study showed that febuxostat might be more renoprotective (as measured by eGFR change in 6 months) and offers a better anti-proteinuric and urate-lowering effect. However, more studies are needed to assess its efficacy across the spectrum of CKD, including those requiring hemodialysis and post-transplant patients.

CKD Is Associated with Attenuated Plasma Metabolome Response to Oral Glucose Tolerance Testing

Background: Chronic kidney disease (CKD) is associated with decreased anabolic response to insulin contributing to protein-energy wasting. Targeted metabolic profiling of the response to oral glucose tolerance testing (OGTT) may help identify metabolic pathways contributing to disruption in incretin response.

Methods: Using targeted metabolic profiling, we examined the plasma metabolome in 58 moderate to severe non-diabetic CKD patients with estimated glomerular filtration rate (eGFR) >60 ml/min per 1.73 m² and 37 healthy controls with normal eGFR before and after 2h of 75g oral glucose challenge. We used linear mixed effect models adjusting for potential confounders of age, sex, race, and body weight to determine the interaction of eGFR and change in metabolites in response to OGTT by CKD status. Pathway analyses were performed using MetaboAnalyst.

Results: CKD patients had lower eGFR compared to healthy control (37.3 ± 12.5 Vs. 89.3 ± 17.1 ml/min per 1.73m²). Oral glucose challenge was associated with a marked reduction in a wide array of metabolites, predominantly amino acids, TCA cycle intermediates, and bile acids. CKD status was associated with attenuated OGTT induced prominent changes in pathways of taurome metabolism, phenylalanine, tyrosine and cryptoporphyrin biosynthesis, nicotinamide metabolism, and TCA cycle (Figure 1).

Conclusions: Targeted plasma metabolic profiling in response to OGTT suggests a broad disruption of amino acid and mitochondrial energy metabolism in CKD patients. These findings motivate further investigation into incretin response in patients with CKD and the impact of incretin mimetics such as GLP-1 receptor agonists.

The Effects of Allopurinol on the Progression of CKD According to Baseline Serum Urate Level: Results from Post Hoc Analyses of the CKD-FIX Trial

Background: Allopurinol did not slow decline in estimated glomerular filtration rate (eGFR) over 2 years in patients with chronic kidney disease (CKD) at risk of progression in the CKD-FIX trial. We assessed the effect of allopurinol on eGFR slope by baseline serum urate level.

Methods: In this trial, 369 adults with stage 3 or 4 CKD, without history of gout, and either urate-to-creatinine ratio ≥2.50 mg/g or eGFR decrease ≥0.90 mL/min/1.73 m² in the preceding year, were randomized to allopurinol or placebo. The primary outcome was change in eGFR up to 104 weeks using the CKD-EPI creatinine equation. This post hoc subgroup analysis describes outcomes in 352 participants according to baseline serum urate level (normouricemia and hyperuricemia [urate >6 mg/dL in women and >7 mg/dL in men], and tertiles of baseline serum urate level).

Results: At baseline, 65 (18.5%) and 287 (81.5%) participants had normouricemia and hyperuricemia, respectively. The mean serum urate level in the normouricemic group was 5.9 mg/dL (4.8 mg/dL for women, 6.1 mg/dL for men), and mean serum urate in the hyperuricemic group was 8.7 mg/dL (8.3 mg/dL for women and 8.9 mg/dL for men). There were no significant differences in change in eGFR between allopurinol and placebo in normouricemic (mean difference [MD] 0.35, 95% CI -2.72 to 3.42 mL/min/1.73 m²/year) and hyperuricemic (MD -0.06, 95% CI -1.20 to 1.08 mL/min/1.73 m²/year) groups.

Conclusions: In CKD patients at risk of progression, the effect of allopurinol on eGFR decline was not modified by baseline serum urate.

CKD Progression End Points as Potential Surrogates for Kidney Failure: Findings from the CKDopps

Jacee Zee, Daniel G. Muenz, Keith McCullough, Brian Bieber, Marie Metzger, Natalia Alencar de Pinho, Antonio A. Lopes, Danilo Fiser, Bruce M. Robinson, Eric W. Young, Ronald L. Pisoni, Benedicte Stengel, Roberto Peiro-Filho, 1 Arbor Research Collaborative for Health, Ann Arbor, MI; 2. French Institute of Health and Medical Research (INSERM), Villejuif, France; 3. Department of Internal Medicine, Federal University of Bahia, Salvador, Brazil; 4. Universitätsklinikum des Saarlandes und Medizinische Fakultät der Universität des Saarlandes, Homburg, Germany.

Background: Many potential surrogate endpoints for kidney failure (KF) have been used in clinical trials and observational studies of chronic kidney disease (CKD). Individual and composite surrogate endpoints must be compared to ensure accurate research that maximizes power and facilitates harmonization across studies, particularly among an international sample of advanced CKD patients.

Methods: Using data from CKD stage 3-5 patients from Brazil, France, Germany, and the US enrolled in the CKD Outcomes and Practice Patterns Study (CKDopps), we defined potential individual and composite KF endpoints based on reaching (1) eGFR-15 mL/min/1.73 m² and (2) eGFR decline of ≥40%, and composite surrogate endpoints that combine (1) and (2) with and without kidney replacement therapy (KRT, dialysis or transplant). We used each individual and composite endpoint as a time-varying indicator in a modified Cox model to predict time from study entry to the hard outcome of KRT. Potential surrogate endpoints were compared by number of events and prediction accuracy (integrated area under the time-varying receiver operating curve [AUC]).

Results: N = 5242 patients had median (IQR) baseline eGFR of 26.8 (20.7-35.5) and 1448 KRT events over a median (IQR) follow-up time of 2.7 (1.2-3.0) years. Potential surrogate endpoints that included eGFR-15 had higher prediction discrimination compared with those that only included eGFR decline (Figure, AUCs of 0.83-0.84 vs. 0.73-0.73). Composite endpoints had higher event counts than non-composite endpoints (Ns of 1622-1878 vs. 1144-1556, see Figure x-axis).

Conclusions: A composite KF endpoint defined by the earliest occurrence of either KRT, eGFR-15, or eGFR decline of ≥40%, had the highest prediction discrimination for KRT and the highest number of events among a cohort enrolled at low eGFR. This endpoint should be further evaluated and considered for clinical research studies to optimize power while sufficiently capturing KF.

Treatment for CKD: A Systematic Literature Review and Population Comparison

Juan Jose Garcia Sanchez,1 Juliette C. Thompson,2 David A. Scott,2 Naven Rao,1 Elisabeth Sörstadus,1 Glen James,1 Stephen Nolan,1 Eric T. Wittbrodt,1 Alyoshah Abdul Sultan,1 Bergur V. Stefansson,1 Dan Jackson,1 Neil S. Hawkins,1 Keith R. Abrams,2 1BioPharmaceuticals Medical, AstraZeneca, Cambridge, United Kingdom; 2Visible Analytics, Oxford, United Kingdom; 3BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; 4BioPharmaceuticals Medical, AstraZeneca, Gaithersburg, MD.

Background: DAPA-CKD is the first renal outcomes trial assessing the efficacy and safety of a sodium–glucose cotransporter-2 inhibitor, dapagliflozin, vs placebo, added to standard of care in patients with chronic kidney disease (CKD) with/without type 2 diabetes (T2D). Several other agents have been or are currently under investigation for their effect on renal and cardiovascular outcomes in CKD; however, comparisons of efficacy are challenging, due to differences in study design, duration, patients and endpoint definitions. We conducted a systematic literature review of randomized controlled trials (RCTs) in CKD, with the aim of assessing inter-study comparability.

Methods: Searches of MEDLINE, Embase, the Cochrane Central Register of Controlled Trials and grey literature sources were conducted to identify phase 3–4 RCTs of adults (≥18 years) with albuminuric CKD with/without T2D, published in English between 1990 and March 25, 2020. Studies of ≥12 weeks duration that reported clinical outcomes, adverse events, quality of life or patient-reported outcomes for pharmacologic CKD treatments were eligible for inclusion.

Results: Preliminarily, 13,451 unique citations were identified, and 204 full-text manuscripts were included after abstract screening (Figure). Data from 81 RCTs were included: 24, 39 and 18 in patients with CKD with/without T2D, CKD with T2D and CKD without T2D, respectively.

Conclusions: As anticipated, differences in the inclusion of patients with/without T2D between studies make comparisons difficult. Future work will compare additional relevant study characteristics, with further insights available in October 2020.

A New Vision for Nephrology Trials in Canada
Alicia Murdoch, 1 Francois Madore, 1 Dwight Sparkes, 1 Karthik K. Tennanoke, 1 Arris H. Vorster, 1 Ritu Suri. 1

Universite de Montreal, Montreal, QC, Canada; 2 Can-SOLVE CKD Network, Vancouver, BC, Canada; 3 Dalhousie University, Halifax, NS, Canada; 4 McGill University, Montreal, QC, Canada.

Background: The Canadian Nephrology Trials Network (CNTN) was established in 2014 to improve the quantity and quality of clinical trials in nephrology in Canada. With inception of the Canadians Seeking Solutions and Innovations to Overcome Chronic Kidney Disease (Can-SOLVE CKD) Network in 2016, CNTN received additional funding to expand its mandate. We surveyed and assembled a broad cross-section of Canadian kidney patients, nephrology researchers, and other relevant stakeholders in order to establish an expanded new vision for CNTN.

Methods: In July-August 2018, we administered two separate surveys – one to patient members of Can-SOLVE CKD and the second to members of CNTN and other Canadian nephrology investigators. We then conducted a two-day visioning workshop in September 2018 to discuss how best to support nephrology research in Canada. Over 40 stakeholders participated, including 10 patients, 22 researchers, and members of the Can-SOLVE CKD Operations Team.

Results: Through the survey, we identified two issues that were at least moderately challenging: inability to facilitate multi-site trials (81%) and lack of engagement with community sites (74%). Three key themes emerged from the visioning exercise: peer review, training, and engagement. A summary report captured workshop discussions and was used to inform revisions to CNTN’s structure and governance. Three new working committees were created: Capacity Building; Communication and Engagement; and Scientific Operations; as well as a governing Executive Committee. Each committee is co-chaired by a nephrologist and patient, who take turns leading the Executive Committee.

Conclusions: With its new vision and committee structure, CNTN aims to promote a culture of collaboration within the Canadian kidney community and integrate patients into research. The network offers resources to enhance nephrology researchers’ ability to conduct clinical trials, directly involve patients in designing studies, and motivate change in patient care based on patient priorities through increased peer review, engagement, and training.

Implementation of Surprise Question Assessments Using the Electronic Health Record in Older Adults with Advanced CKD
Natalie C. Erneuoff 1, Khaled Abdel-Kader 2, Manej Cai 1, Jonathan Yabes 1, Jane O. Schell 1, Manisha Jambh 1. 1 University of Pittsburgh School of Medicine, Pittsburgh, PA; 2 Vanderbilt University, Nashville, TN.

Background: The Surprise Question (SQ; “Would you be surprised if this patient died in the next 12 months?”) is a validated prognostic tool for mortality and hospitalization among patients with advanced CKD. Yet, barriers in clinical workflow have slowed SQ implementation into practice. We sought (1) To evaluate implementation outcomes following use of electronic health record (EHR) decision support to automate collection of the SQ, and (2) To assess the prognostic utility of the SQ for mortality and hospitalization/emergency room (ER) visit.

Methods: We developed and implemented a synchronous decision support [best practice alert (BPA)] algorithm in the electronic health record (EHR) to identify patients attending an outpatient nephrology follow-up visit who were ≥ 60 years of age with an eGFR<30. At the time of the visit, a ‘pop-up’ BPA was triggered, prompting the physician to answer the SQ (dichotomized). To evaluate implementation, we assessed provider response rate, and efficiency of responses. We assessed the SQ’s prognostic utility in survival and time-to-hospital encounter (hospitalization/ER visit) analyses. We abstracted EHR data on patient sociodemographics and clinical characteristics. Physicians provided their demographic and clinical practice characteristics.

Results: Among 510 unique patients for whom the BPA triggered, 95 had the SQ completed (18.6%) by 16 unique providers. Among those patients with completed SQ, nearly all providers (97.9%) completed the SQ on the clinic appointment day, and 61 (64.2%) the first time the BPA fired. Providers answered “No” for 27 (28.4%) and “Yes” for 68 (71.6%) patients. By 12 months, 6 (6.3%) “No” patients died; 3 (3.2%) “Yes” patients died (age-adjusted hazards ratio [HR] 0.35, CI[0.13, 0.94]). About 40% of “No” patients and 25% of “Yes” patients had a hospital encounter by 12 months (HR 1.85, CI[0.927, 3.689]).

Conclusions: We successfully integrated the SQ into the EHR for routine collection to aid in clinical practice. Our response rate indicates additional implementation efforts are needed to encourage further integration of the SQ in clinical practice. Consistent with prior research, the SQ has reasonable prognostic utility for mortality and future hospital encounters.

Telehealth for Adults with CKD: A Systematic Review and Meta-Analysis
Li Luo, Min Zhang, Dingjun Zhang, Huifen Chen, La Zhang, Bingqing Xin, Jiaoqiang Tan, Chendi Dong, Yannin Xu, Xiusheng Liu, Yifan Wu. 1 The Second Clinical College, Guangzhou University of Chinese Medicine, Guangzhou, China; 2 Renal Division, Beijing University of Chinese Medicine Shenzhen Hospital, Guangzhou, China; 3 Renal Division, the Second Affiliated Hospital of Guangzhou University of Chinese Medicine (Guangdong Provincial Hospital of Chinese Medicine), Guangzhou, China.

Background: Evidence has supported improved quality of CKD care when assisted with telehealth, while these results were predominantly based on cohort observation or small-scale randomized controlled trials (RCTs). Moreover, robust findings regarding its effects on endpoints were still limited. This study thus aimed to evaluate impacts of telehealth on non-dialysis CKD patients.

Methods: This study was conducted and reported according to PRISMA statement. We searched databases including MEDLINE, EMBASE, Cochrane Central Register of Controlled Trials (CENTRAL), Chinese Biomediicine Database (CBM), Chinese National Knowledge Infrastructure (CNKI), Wanfang Database and VIP Database until 2019 April. Relevant studies regarding telehealth for non-dialysis CKD population were screened, reviewed, selected and assessed of quality for systematic review and meta-analysis. The protocol was registered at PROSPERO (CRD42017073665).

Results: Eighteen trials involving 4749 patients were included for systematic review and 4 for further meta-analysis. The qualitative study summarized different study population, telehealth intervention type (consultation, education, monitoring) and variable results of outcomes measured (endpoints, surrogate values, patient-centered outcomes). The quantitative analysis comparing the telehealth and control group detected no significant difference in systolic blood pressure (SBP), diastolic blood pressure (DBP) and serum creatinine (SCr) at 12 months, but found significantly lower SCr level at 6 months, preserved estimated glomerular filtration rate (eGFR) at 6 months and at 12 months in telehealth group.

Conclusions: This study detected advantages of telehealth on delaying CKD progression but uncertain impacts on decreasing endpoint incidence.

Funding: Government Support - Non-U.S.

PO0574

Telenephrology Care for Veterans in the COVID-19 Pandemic
Juan D. Salcedo Betancourt,1 Carlos A. Torres,1 Yanetesy Olivera Arenchiba,1 Vasuki N. Venkat,1,2 Daniel J. Soderen,1,2 Marco A. Ladino Avellaneda,1,2
1 University of Miami School of Medicine, Miami, FL; 2 Miami VA Healthcare System, Miami, FL.

Background: Chronic kidney disease (CKD) affects 37 million adults in the United States. Since 2013 our Nephrology section has carried out a telenephrology clinic and implemented electronic consults (E-consults). During the COVID-19 pandemic, we implemented changes to evaluate patients with kidney disease. The aim of this study is to report our experience.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Methods: This is a single-center, retrospective chart review study, which evaluated the outcomes of our telenephrology clinic (video-on-demand and telemedicine clinic visits), as well as E-consults. Between January 2013 and 2020, 410 patients were seen at telemedicine clinic visits, and 1020 E-consults were evaluated. During the COVID-19 pandemic, between March 2020 and May 2020, 40 patients were assessed through video-on-demand.

Results: For telemedicine, a total of 169 patients were included, 99.4% were males, and 87% were white. The mean age was 66 ± 10 years, 92% had hypertension, and 41% diabetes mellitus. The baseline eGFR was 45 ± 14 mL/min/1.73m2. A one-way analysis of variance showed a statistically significant difference on the systolic (SBP) and diastolic (DBP) blood pressure (p-value < 0.000), and improvement in potassium and bicarbonate levels (p-value = 0.000). Phosphorus levels did not show a significant difference (p-value 0.37). There was a significant association between attendance to ≥3 telenephrology visits and SBP control (p-value=0.027), DBP control (p-value=0.002) and potassium improvement (p-value=0.013). The overall decrease in GFR was 1.2 ± 1.1 mL/ min/1.73 m2 (95% CI -0.41 to 2.95), lower than the reported natural progression of CKD (1.03 mL/min/1.73 m2/year). A survey for the video-on-demand patients showed 100% satisfaction, reflecting that patients felt their renal care needs were fulfilled. E-consults were covered in less than 24 hours, with 100% satisfaction from primary care physicians.

Conclusions: This is the first study evaluating the use of telenephrology in patients with kidney disease during the COVID-19 pandemic. In our cohort, telenephrology interventions improved SBP, DBP, bicarbonate, and potassium control. All three options improved health outcomes and guaranteed safety during the COVID-19 pandemic, at a reduced cost for the patient and the institution.

PO0575
Telenephrology: A Feasible Option for Inmates
Maxwell Butler, Laura J. Maursetter. University of Wisconsin-Madison, Madison, WI.

Background: Socioeconomic and racial disparities are factors that contribute to the disproportionately high burden of chronic disease amongst the incarcerated population in the United States. Access to care can be compromised because of the burden of cost to a facility, lack of staff to transport patients and physical distance from specialists. Telenephrology as been shown to be a feasible option in the correctional setting for specialties such as mental health, infectious disease, cardiology, and primary care, but has not been studied in nephrology. In this quality improvement study, we showed telenephrology is a feasible option that can be implemented for CKD and hypertension management.

Methods: Using quality improvement methodology, data was collected from the electronic medical record for all telenephrology appointments from January 2015 to June 2019. Demographic data, comorbidities, appointment compliance, and clinical data were recorded. Data on blood pressure control was collected. Data for patients seen over a period of at least 3 years were included in the CKD progression portion and those seen at least 4 times for the blood pressure management.

Results: There were 871 appointments schedule over the 4.5 year period with 86% completed. Technology limited 3.5% of the cancelled appointments. The population was predominantly men (96%) of black race (51.9%) with hypertension (78%) and CKD (75.2%) being the most common comorbidities. There were 214 patients included in the analysis for management of CKD that showed an average annual change in eGFR of -1.57 mL/min/1.73 m2 (CI -2.87 to -0.27). There were 79 included in the hypertension analysis with 19.0% achieving a goal BP of 130/80 mm Hg and 63.3% achieving a BP of ≤140/90 mm Hg.

Conclusions: Telenephrology can be successfully carried out in the correctional facility setting with a low number of cancellations due to technology. The study sample showed mild-to-moderate CKD progression consistent with previously reported population rates of eGFR decline suggesting comparable management. The smaller sample showed mild-to-moderate CKD progression consistent with previously reported 10 years, 92% had hypertension, and 41% diabetes mellitus. The baseline eGFR was 45 ± 14 mL/min/1.73 m2. A one-way analysis of variance showed a statistically significant difference on the systolic (SBP) and diastolic (DBP) blood pressure (p-value < 0.000), and improvement in potassium and bicarbonate levels (p-value = 0.000). Phosphorus levels did not show a significant difference (p-value 0.37). There was a significant association between attendance to ≥3 telenephrology visits and SBP control (p-value=0.027), DBP control (p-value=0.002) and potassium improvement (p-value=0.013). The overall decrease in GFR was 1.2 ± 1.1 mL/ min/1.73 m2 (95% CI -0.41 to 2.95), lower than the reported natural progression of CKD (1.03 mL/min/1.73 m2/year). A survey for the video-on-demand patients showed 100% satisfaction, reflecting that patients felt their renal care needs were fulfilled. E-consults were covered in less than 24 hours, with 100% satisfaction from primary care physicians.

Conclusions: This is the first study evaluating the use of telenephrology in patients with kidney disease during the COVID-19 pandemic. In our cohort, telenephrology interventions improved SBP, DBP, bicarbonate, and potassium control. All three options improved health outcomes and guaranteed safety during the COVID-19 pandemic, at a reduced cost for the patient and the institution.

PO0576
Nephrology eConsultation: The “Curb Side” Consult for the 21st Century
David Levy, Rickinder Grewal, Scott E. Liebman, Thu H. Le. University of Rochester School of Medicine and Dentistry, Rochester, NY.

Background: The Nephrology Division at the University of Rochester receives on average 120 new outpatient referrals per month. While every effort is made to see new referrals promptly, this demand exceeds the capacity to evaluate these patients in a timely manner. To decrease waiting time and increase efficiency, we developed a Nephrology eConsultation program. Here we report our experience with time and value-based metrics as well as primary care provider (PCP) satisfaction.

Methods: After a year-long pilot phase, in September 2019 we expanded the eConsult program to provide telenephrology care via videoconferencing to PCPs across the University health system for renal-related issues such as mild to moderate acute kidney injury, CKD, electrolyte disturbances, and proteinuria.

Results: Within the first 8 months of the expanded program, 110 eConsult requests were received. Of these, 62 were deemed medically appropriate and completed, with 46 (74.2%) related to acute kidney injury, CKD, or azotemia, 6 (9.7%) related to electrolyte imbalances, and 4 (6.5%) related to proteinuria. The mean time for a nephrologist to complete an eConsult was 18.3 minutes (Table 1). Of the 48 deemed inappropriate for eConsults, 36 (75%) were converted to in-person visits due to complexity (Table 2). All eConsults were completed within 67 hours (mean time 15.5 hours). Survey of PCP satisfaction showed that 68% of PCPs were very satisfied and 32% were satisfied with the nephrology eConsult program.

Conclusions: eConsultation in Nephrology has the potential to provide timely, cost effective, and remote guidance to PCPs for more straightforward questions, while prioritizing the limited resource of face-to-face nephrology consultation for patients with more complex diseases. This also offers financial advantages, as the work relative value units (wRVUs) for eConsult is 0.7, or up to 2.8 wRVUs per hour in our model. eConsultation in Nephrology could also be integrated with the rapidly evolving field of telemedicine to improve delivery of care remotely and increase provider and potentially patient satisfaction.

PO0577
Development of a Global CKD Personal Impact Index (CKD-PII) Assessing the Reality of Living with CKD
Mary F. James,1 Corey Windett,2 Jillian K. Guigliotto.1 1WZO, San Francisco, CA;2AstraZeneca, Wilmington, DE.

Background: CKD affects >700M people globally, but its full burden and personal impact attributes (PIA)—impact on instrumental activities of daily living—are under-recognized. Qualify of life (QoL) measures fail to show the full patient experience. A Global CKD-PII uncovering the direct and indirect daily impact of CKD on patients may improve understanding of disease burden and secondary complications. The development of the CKD-PII using a geographically diverse cohort of CKD patient-reported aggregate data is described.

Methods: A multiphase approach was used to develop CKD-PII. In Phase 1, social media landscape audit and qualitative interviews determined PIA to understand disease burden. Patient conversations within online communities gauged the social, economic and physical impact of CKD. Each attribute was assigned as high, medium or low impact based on the lexicon, overall sentiment and self-reported impact on patient’s QoL. Qualitative, moderated phone interviews followed an engagement model, whereby key PIA and language and characterization of attributes were further explored. Findings of Phase 1 informed Phase 2, a quantitative survey. Data from both phases will culminate in the development of CKD-PII.

Results: Phase 1: Social media landscape analysis leveraged 12 months of relevant patient dialogues (n=156) and shortlisted 11 key PIA from >200M internet sources. Among the key PIA identified, dietary impacts (19%), time lost to appointments/dialysis (45%) and mental health implications (44%) were rated as high impact. Qualitative interviews (n=15) uncovered key PIA identified consistently. Phase 2: An online survey questionnaire was administered to quantify the extent of patients’ experience of PIA. The CKD-PII synthesizes data from all research phases into an insights and perspectives report evaluating global perspectives.

Conclusions: Uniquely, CKD-PII will use metrics to showcase the real-life impact of CKD, beyond QoL, providing insights into the patient experience that other studies do not typically address. The social media data facilitates understanding of critical issues and patient conversations within online communities gauged the social, economic and physical impact of CKD. Each attribute was assigned as high, medium or low impact based on the lexicon, overall sentiment and self-reported impact on patient’s QoL. Qualitative, moderated phone interviews followed an engagement model, whereby key PIA and language and characterization of attributes were further explored. Findings of Phase 1 informed Phase 2, a quantitative survey. Data from both phases will culminate in the development of CKD-PII.

Lowering Mortality in CKD Stage 3B and CKD Stage 4 with Increased Outpatient Nephrology Visits
Stephanie S. Cheung, Michael Shen, Hui Xue. Kaiser Permanente San Diego Medical Center, San Diego, CA; Kaiser Permanente Department of Research and Evaluation, Pasadena, CA; Kaiser Permanente Orange County, Anaheim, CA; Kaiser Permanente Orange County, Business Intelligence & Transformation, Santa Ana, CA.

Background: Management of Chronic Kidney Disease (CKD) is complex requiring comprehensive evaluation of multiple organ systems. We hypothesized that more frequent outpatient nephrology visits is associated with lower mortality in advanced CKD patients.

Methods: CKD3B & CKD4 patients at Kaiser Permanente Southern California Orange County were followed from 2012 to 2018. Patients were divided into 4 groups based on initial eGFR per MDRD equation; eGFR 30-44, 25-29, 20-24, and 15-19. Each eGFR group was further divided by the number of annual nephrology visits (0, 1, 2, 3, and 4+). Patients who transitioned to dialysis, kidney transplant, or lost to follow up during the 7 years were excluded. Annual all-cause mortality was analyzed based on the number of nephrology visit in each eGFR category using ANOVA.

Results: The cohort consisted of 2943 individuals, 59% female, 41% male, mean age 77.4. 42% of patients were diabetic and 89% had hypertension. Lower starting eGFR had increased mortality over time while renal function stayed fairly stable. Increased outpatient visit was seen with lower eGFR during the follow up period, Figure 1. All CKD3B and CKD4 patients gained a statistically significant reduction in mortality when seen at least twice in nephrology clinic annually, p<0.04, in Figure 2. For eGFR ≤42, the mortality benefit was observed with 1 or more nephrology visit, p<0.005. Patients who transitioned to dialysis, kidney transplant, or lost to follow up during the 7 years were excluded. Annual all-cause mortality was analyzed based on the number of nephrology visit in each eGFR category using ANOVA.

Conclusions: CKD stage 3B and 4 patients seen in nephrology clinic at least twice a year had improved survival. More frequent follow up was associated with lower eGFR. The relationship between the lower eGFR and the improved survival warrants further investigation.

Uptake of Evidence-Based Recommendations to Improve Care for CKD Patients in the Kidney Coordinated Health Management Partnership (Kidney CHAMP) Study
Melanie R. Weltman, Huiwen Chen, Jonathan Yabes, Manqi Cai, Khaled Abdel-Kader, Manisha Jhamm, Thomas D. Nolin. University of Pittsburgh School of Pharmacy, Pittsburgh, PA; University of Pittsburgh Renal-Electrolyte Division, Pittsburgh, PA; University of Pittsburgh Department of Medicine, Pittsburgh, PA; University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA; Yanderbilt University Division of Nephrology and Hypertension, Nashville, TN.

Background: Medication therapy in patients with chronic kidney disease (CKD) is focused on slowing CKD progression, managing causes of CKD, and preventing cardiovascular morbidity and mortality. The aim of this project was to assess the uptake of evidence-based medication recommendations (recs) provided to primary care providers (PCP) of patients with high-risk CKD by an interdisciplinary nephrology team.

Methods: This project is part of Kidney CHAMP, an ongoing NIH funded, pragmatic randomized controlled trial testing an electronic health record (EHR)–based population health management (PHM) approach to improve CKD care. Eligible patients are 18-85 years with CKD who have a high risk of progression to ESKD and are not being followed by a nephrologist. Patients in the intervention arm receive a nephrologist-led electronic consult and pharmacist-led telephonic medication therapy management (MTM). Recs are provided in the EHR for the PCP to review and order at the upcoming office visit. We focused on medication recs related to the progression of CKD and prevention of cardiovascular disease, which included use of RAAS inhibitors, SGLT2 inhibitors, GLP-1 receptor agonists, and HMG-CoA reductase inhibitors (statins).

Results: From July 1, 2019 to January 31, 2020, 125 patients received an e-consult and 121 patients received MTM. A total of 83 recs were provided to PCPs. Uptake of recs for initiation or dose escalation of RAAS inhibitors was the highest, with 19 of 46 recs (41%) being implemented. Two of eight recs regarding GLP-1 receptor agonists were implemented (25%) and two of 24 recs for SGLT2 inhibitor initiation were implemented (8%). Five recs for statin initiation were made and none were implemented; however, baseline statin use was high at >75%.

Conclusions: Many patients with high risk CKD receive suboptimal care, which can be effectively identified by interdisciplinary nephrology teams using an EHR-based PHM platform. Uptake of RAAS inhibitor recs was highest. However, initiation of medications with recent FDA approved indications for CKD management remained poor. Future research is needed to identify barriers and strategies to increase uptake of evidence-based CKD recs and thereby improve patient care.

PO0580
Interdisciplinary Care Improves Patient Preparedness for ESRD in a High-Risk Patient Population with CKD
Kalvan Prudvil, Kaltrina Sedalia, Michelle M. Estrella, L. Ebony Boulware, Michal L. Melamed, Tanya S. Johns, Albert Einstein College of Medicine, Bronx, NY; Montefiore Medical Center, Bronx, NY; San Francisco VA Medical Center, San Francisco, CA; Duke University School of Medicine, Durham, NC.

Background: The Kidney Care Choice initiative has made improving the quality of care for patients with late-stage CKD a national priority. Interdisciplinary care (IDC), including nurse practitioner (NP) driven care coordination, is an intervention that may improve health outcomes in patients with CKD. Few studies have evaluated this model of healthcare delivery in racial-ethnic minorities.

Methods: We compared incident ESRD patients who received NP care coordination as part of our IDC clinic (n=84) to a contemporaneous cohort of incident ESRD patients (n=245) who received usual nephrology care alone at Montefiore Medical Center from 10/1/2013 – 10/31/2017. Clinical data were extracted using Clinical Looking Glass™, and chart reviews were done for validation. Patients included in our study had established care for CKD stage 4.5 and had at least one nephrology clinic visit within 3 months preceding their progression to ESRD. All patients were eligible for IDC, but receipt of IDC was limited by resource availability.

Results: Of the 329 incident ESRD patients included in our study, the mean age was 59.6 years (SD 13.3), 47% were female, and 86% were African American or Hispanic. The baseline characteristics were similar between the groups, except the IDC group had a lower prevalence of hypertension (60% vs 77%). The mean eGFR was 8 ml/min/1.73m² at dialysis initiation. Fifty percent of patients had an arteriovenous (AV) access prior to developing ESRD. However, compared to the usual care group, patients in IDC group were more likely to have a mature AV access at HD initiation (41% vs 33%); start HD as an outpatient (30% vs 19%); receive a preemptive transplant (4% vs 2%); do peritoneal dialysis (7% vs 4%); and be listed for kidney transplant (44% vs 15%) prior to developing ESRD. Receipt of IDC was associated with a higher odds (OR 3.9 [95% CI 2.0 – 7.8]; P<.0001) of kidney transplant listing compared to usual care alone after adjusting for sociodemographic and clinical factors. Other outcomes also favored IDC but were not statistically significant.

Conclusions: Interdisciplinary care is associated with better ESRD preparedness compared to usual nephrology care alone in racial-ethnic minorities. Larger randomized controlled studies are needed to determine the effectiveness of IDC among patients with advanced CKD.

Patient Outcomes Following Discharge from a CKD Clinic

Michael Che, Susan J. Thanabalasingam, Eduard A. Iliescu, Christine A. White. Queen’s University Department of Medicine, Kingston, ON, Canada.

Background: In Ontario, Canada multidisciplinary care for patients with advanced chronic kidney disease (CKD) is delivered in Multi-Care-Kidney-Clinic (MCKC) operated by Regional Programs funded through a provincial network based on the number of eligible patients. These eligibility criteria were progressively revised between 2016 and 2018 from an absolute estimated glomerular filtration rate (eGFR) less than 30 ml/min/1.73m² to less than 15 ml/min/1.73m² or a two-year risk of end-stage kidney disease, calculated by the Kidney Failure Risk Equation (KFRE), greater than 10%. The objective of this study was to ascertain the outcomes of existing MCKC patients who were discharged as these criteria were implemented.

Methods: This is a retrospective cohort study of prevalent CKD patients in MCKC in 2015 in the region of South Eastern Ontario, followed to January 2020. The outcomes were discharge from MCKC, re-referral, initiation of kidney replacement therapy (KRT), and death. Data were extracted from electronic medical record. Death was ascertained through Ontario’s Office of the Registrar General. Patients’ 2 and 5-year KFRE scores were calculated using the 4-variable KFRE.

Results: Of the 643 MCKC patients in 2013 with available data, 470 (73%) continued follow-up in MCKC, while 142 (22%) and 31 (5%) were discharged to primary care and general nephrology respectively. Of those discharged to primary care, 52 (37%) died, while 15 (11%) were re-referred to nephrology, and 8 (6%) initiated KRT within median (IQR) times of 982 (560) and 850 (1411) days from discharge respectively. Five (63%) of the 8 discharged patients who required KRT did so for unforeseen acute illness rather than progressive CKD.

Conclusions: The results of this study suggest that gradually moving MCKC funding eligibility criteria from absolute eGFR level to one based on both eGFR, and the KFRE prediction model resulted in the discharge of a significant number of patients. Notably, few of the discharged patients ultimately required KRT that could have been prevented. This study offers a regional perspective with low loss to follow-up as there is only one Renal Program in the region. The results may not be generalizable to different populations, health care systems, or predictive models. Further research is needed to establish the optimal KFRE criterion upon which MCKC funding eligibility can be based.

Association of CKD with Early Heart Failure Readmissions in Adults

Si Li, Yichen Wang, Nasha Elavia, Bojana Mlickic. The Wright Center for Graduate Medical Education, Scranton, PA.

Background: Heart failure is a complex chronic disease with multiple comorbidities that contribute to frequent hospitalization. We aimed to examine the impact of chronic kidney disease on the 30-day readmission rate among patients hospitalized with heart failure.

Methods: We performed a retrospective analysis of the National Readmission Database (NRD) 2016-2017. We identified adult patients with a primary hospital diagnosis of heart failure. We compared baseline demographics and calculated all-cause 30-day readmission rates. Multivariate survey logistic regression was used to identify predictors of readmission.

Results: We identified a total of 865,328 patients admitted with heart failure. Of these patients, 839,625 patients were discharged alive. Among which 181,130 (21.5%) had at least one readmission within 30 days. The in-hospital mortality of index admissions and readmissions was 2.9% and 6.5%, respectively. The 30-day inpatient mortality was 4.0%. The mean length of stay of index admission and readmissions was 5.3 days and 6.4 days, respectively. The most common reasons for all-cause readmissions were acute on chronic disease, calculated by the Kidney Failure Risk Equation (KFRE), greater than 10%. The disease, calculated by the Kidney Failure Risk Equation (KFRE), greater than 10%.

Conclusions: Further prospective studies with focus on multilevel interventions are needed to help reduce early readmission associated significant morbidity and resource utilization for this high-risk population.
A Medication Use Evaluation of Patiromer in a Clinical Practice Setting at a Veteran’s Affairs Medical Center

Daniele N. Cooney,2 Emily M. Fox,2 Mary Beth Low,2 Niraj Desai,1,2 Case Western Reserve University, Cleveland, OH; 3Louis Stokes VA Medical Center, Cleveland, OH.

Background: Patiromer is cation exchange polymer approved for treatment of hyperkalemia. There is limited data regarding the utility, adverse effects, frequency of laboratory monitoring and discontinuation rate of Patiromer in a clinical practice setting.

Methods: We performed a retrospective, observational review of veterans prescribed one or more doses of patiromer between 10/2015 and 11/2019 at the Veterans Affairs Northeast Ohio Hospital System (VANEOHS), to evaluate changes to RAAS inhibitor therapy, adverse effects resulting in patiromer discontinuation, and monitoring of serum potassium level. Patiromer prescription characteristics, concomitant medications, laboratory characteristics and adverse effects were collected for each veteran over the study time period. Baseline characteristics are reported as means; relative frequency of outcomes are reported as percentages.

Results: 69 Veterans with hyperkalemia were included for analysis. Mean age was 70 years, African-American race 29%, diabetes 90%, chronic kidney disease 91%, 17% ESRD on dialysis, and heart failure 36%. The most common patiromer dose was 8.4 g daily (78%), prescribed for a mean 209 (SD 3-1597) days. 21% of patients had repeat labs within 2 weeks and 54% within 4 weeks of patiromer initiation. 77% of patients achieved normokalemia (K= 5.0 meq/L) by the first follow up lab draw. Amongst 52 veterans with chronic, continuous patiromer use, 22 (41%) were taking RAAS inhibitors at baseline; 15 (29%) of these had either increased RAAS inhibitor dose over the study period. 28 (54%) discontinued patiromer with 7 (25%) veterans doing so due to GI complaints.

Conclusions: In a clinical setting at a Veteran’s Affairs hospital, patiromer therapy preserved RAAS inhibitor use and improved serum potassium levels, but was discontinued at a high rate due to adverse effects.

The Practical Patterns of Medication and the Association Between CKD Stage and Polypharmacy: The Fukuoka Kidney Disease Registry Study

Masatoshi Tanaka,2 Kumiko Torisu,3 Masanori Tokumoto,1 Kazuhiro Tsunuma,1 Hirosi Odoishi,1 Toshiki Nakano,2 Takahiro Kizazono,2 1Department of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan, 2Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan, 3Department of Nephrology, Nara Medical University, Kashihara, Japan.

Background: Polypharmacy has emerged as one of the important medical and socioeconomic problems in an aging society. Chronic kidney disease (CKD) is also one of the important medical problems for older people. However, the extent to which CKD is involved in polypharmacy still has not been fully explored yet.

Methods: We examined 3,968 Japanese CKD patients using baseline data from a multicenter prospective cohort study in a cross-sectional manner. We used the baseline data of prescribed medicines on medical records. We evaluated the association between CKD stage and polypharmacy (defined as ≥6 medications). We performed logistic regression analyses with adjustment for potential confounding factors.

Results: At baseline, the prescribed medicines varied between 0 and 17, and the median (interquartile range) was 5 (3–7). Among 3,968 CKD patients, 1,540 (38.8 %) patients showed polypharmacy. The multivariable-adjusted odds ratios for polypharmacy were 1.42 [95% confidence interval, 0.77–2.61] for G2, 1.44 [0.78–2.65] for G3a, 4.06 [2.17–7.37] for G4 and 8.44 [4.53–16.5] for G5, respectively, compared with patients in the lowest category (G1) as the reference value. In the higher glomerular filtration rate (GFR) category (>G3b), many drugs, including angiotensin-2 receptor blockers, calcium channel blockers, uric acid synthesis inhibitors, proton pump inhibitors, aspirins, loop diuretics, and cation exchange resins were prescribed more frequently than those in the lower GFR category (≤G3a). In addition, aldosterone blockers, biguanides, fibrates, non-steroidal anti-inflammatory drugs, and sulfonylureas were continuously prescribed despite decreased GFR.

Conclusions: The higher GFR categories were independently associated with higher odds of polypharmacy. This might reflect the increasing prescription for managing to control symptoms caused by decreased GFR. We also have more to pay attention to prescribe medicines according to renal function.

A Pilot and Feasibility Randomized Controlled Trial Targeting Sedentary Behavior in CKD: Sit Less, Interact, and Move More (SLIMM) Study

Robert E. Boucher,1 Guo Wei,2,3 Tom Greene,3 Srinivasas Beddhu,2,12 Division of Nephrology, Hypertension, and Perfusion, University of Utah School of Medicine, Salt Lake City, UT, 2Medical Service, Veterans Affairs Salt Lake City Health Care System, Salt Lake City, UT, 3Division of Biostatistics, University of Utah School of Medicine, Salt Lake City, UT.

Background: Sedentary behavior (engaging in activities in the seated/lying position) is highly prevalent and associated with mortality in CKD.

Methods: In a 24-week pilot and feasibility RCT, we tested the feasibility of a ‘Sit Less, Interact, Move (SLIMM)’ intervention to replace sedentary activities with casual stepping activities in CKD. Participants wore an accelerometer for 7 days before randomization and for increased RAAS inhibitor dose over the study period. 15 (29%) veterans either maintained or increased RAAS inhibitor dose over the study period. 228 veterans with hyperkalemia were included for analysis. Mean age was 69 ± 13 years, 42% were women. 5%, 38%, 43% and 14% had CKD stages 2, 3A, 3B/4 and ESKD, respectively. Sedentary and stepping durations did not change in the SOC group. In the SLIMM group, the maximum decrease in sedentary duration, increase in stepping duration, and the number of steps per day were observed at week 20 but attenuated at week 24 (Fig1). In separate linear mixed effects models (Table 1), overall treatment effects of the intervention on sedentary duration, stepping duration and the number of steps were not significant. The SLIMM intervention significantly reduced baseline sedentary duration by 14% at week 24.

Conclusions: It is feasible to reduce sedentary duration and increase stepping duration in CKD but additional measures along with SLIMM intervention may be needed to sustain its effect on sedentary behavior.

The Effects of Allopurinol on the Progression of CKD According to Baseline Kidney Function: Prespecified Analyses of the CKD-FIX Trial

Anshuree Tiku,1 Elaine Pascoe,2 Neil Boudville,3 Alan Cass,4 Nicola Dalbeth,5 Richard O. Day,3 Janak de Zoysa,6 Bettina Douglas,7 Randall Faul,8 David Harris,9 Carmel Hawley,9 Graham R. Jones,10 John Kandall,5 Suetonia Palmer,11 Vlad Perkovic,12 Gopi Rangan,13 Donna Reindell,14 Robert J. Walker,15 Giles Walters,15 David W. Johnson,3 Sunil Badve.16 George Institute for Global Health, Sydney, NSW, Australia; 2The University of Queensland, Saint Lucia, QLD, Australia; 3The University of Western Australia, Perth, WA, Australia; 4Menzies School of Health Research, Casuarina, NT, Australia; 5The University of Auckland Faculty of Medical and Health Sciences, Auckland, New Zealand; 6Sir Vincent’s Health Australia Ltd, Bondi Junction, NSW, Australia; 7The University of Adelaide Faculty of Health and Medical Sciences, Adelaide, SA, Australia; 8The University of Sydney, Sydney, NSW, Australia; 9University of New South Wales, Sydney, NSW, Australia; 10Monash University, Clayton, VIC, Australia; 11University of Orago, Dunedin, New Zealand; 12Westmead Hospital, Westmead, NSW, Australia; 13Australian National University, Canberra, ACT, Australia.

Background: The CKD-FIX trial showed that allopurinol did not slow the decline of estimated glomerular filtration rate in patients with CKD stage 3 or 4, no history of gout, and who were at risk of progression (identified by urinary albumin-to-creatinine ratio ≥265 mg/g or eGFR decrease ≥3.0 mL/min/1.73 m² in the preceding year) were randomized to receive allopurinol or placebo. Primary outcome was rate of change in eGFR up to 104 weeks using the CKD-EPI creatinine equation. This pre-specified subgroup analysis describes outcomes in patients with CKD stage 3 and ≥4.

Methods: At baseline, 1,982 (23%) patients had CKD stage 3 (mean eGFR 41 mL/min/1.73 m², mean serum urate 7.9 mg/dL) and 185 (51%) patients had CKD stage 4 (mean eGFR 23.1 mL/min/1.73 m², mean serum urate 8.4 mg/dL). In patients with CKD stage 3, change in eGFR did not differ between the allopurinol (-0.33 mL/min/1.73 m²/year, 95% CI -1.18 to 0.11) and placebo (-0.76 mL/min/1.73 m²/year, 95% CI -1.18 to 0.17). The interaction P value for subgroup analysis was 0.87.
Conclusions: In CKD patients at risk of progression, the effect of allopurinol on eGFR decline was not modified by baseline kidney function.

PO0588
Effects of the SGLT2 Inhibitor Dapagliflozin on Proteinuria in Non-Diabetic Patients with CKD (DIAMOND): A Randomized Double-Blind Cross-Over Trial
Hiddo J. L. Heerspink,1 Claire Dekkers,1 David Cherney,2 Department of Clinical Pharmacy and Pharmacology, University Medical Centre Groningen, Groningen, Netherlands; 2Department of Medicine, Division of Nephrology, University Health Network and University of Toronto, Toronto, ON, Canada.

Background: Sodium glucose co-transporter 2 (SGLT2) inhibition decreases albuminuria and reduces the risk of kidney disease progression in patients with type 2 diabetes. These benefits are unlikely mediated by improvements in glycemic control alone. We therefore examined the renal effects of the SGLT2 inhibitor dapagliflozin in patients with proteinuric kidney disease without diabetes.

Methods: A multicenter double-blind placebo controlled 6-week crossover study was performed in six hospitals in the Netherlands, Canada, and Malaysia. Patients (18-75 years old), without diagnosis of diabetes, 24-h urinary protein excretion >500 and 3500 mg/24h and estimated glomerular filtration rate (eGFR) 30 to 90 mL/min/1.73 m2 on stable renin angiotensin system blockade were included. Participants were randomly assigned to one of the two consecutive treatment periods of first placebo and then dapagliflozin 10 mg/day or vice versa. The primary outcome was proteinuria change from baseline to week 8. The main secondary outcome was change in inoxel measured GFR (mGFR).

Results: Fifty-eight patients were screened of whom 53 patients were randomized. Median baseline proteinuria was 1110 mg/24h (IQR 730, 1560) mg/24h; mean mGFR was 58.3 (SD 23) mL/min/1.73 m2 on stable renin angiotensin system blockade were included. Participants were randomly assigned to one of the two consecutive treatment periods of first placebo and then dapagliflozin 10 mg/day or vice versa. The primary outcome was proteinuria change from baseline to week 8. The main secondary outcome was change in inoxel measured GFR (mGFR).

Conclusions: Six week treatment with dapagliflozin does not affect proteinuria in patients with chronic kidney disease without diabetes, but did induce acute and reversible decrease in mGFR, body weight reduction, and increased hemoconcentration.

PO0589
The Impact of Decline in Renal Function on the Clinical and Economic Burden of CKD: An Application of the DAPA-CKD Cost-Effectiveness Model
Philip McEwan,1 Juan Jose García Sanchez,1 Klas Bergenheim,1 Oliver T. Darlington,1 David C. Wheeler,1 Hiddo J. L. Heerspink.2 AstraZeneca, Cambridge, United Kingdom; 2University of Groningen, Groningen, Netherlands; 3Health Economics and Outcomes Research Ltd, Cardiff, United Kingdom; 4University College London, London, United Kingdom; 5AstraZeneca, Gothenburg, Sweden.

Background: The efficacy of dapagliflozin for the treatment of chronic kidney disease (CKD) was assessed in DAPA-CKD, which was stopped early for overwhelming efficacy. Cost-effectiveness analysis of new treatments plays an important role in the effective allocation of healthcare resources. The objective of this study was to develop a model for evaluating the cost-effectiveness of dapagliflozin based on the pending results of DAPA-CKD, and to demonstrate its functionality by characterizing the health economic burden of CKD progression from a UK payer perspective.

Methods: A lifetime microsimulation model was developed to estimate health economic outcomes in patients with CKD. Disease progression was modelled based on a hypothetical cohort of similar demographic and chronic kidney disease characteristics. Outcomes were measured as cumulative CKD stages with standard eGFR decline (<0.5 mL/min/1.73 m2 annually) and one with rapid eGFR decline (4.20). Models were populated using best available literature. Results: CKD patients with rapid eGFR decline had a reduced life expectancy of 9.1 years compared with 6.4 years in those with standard mGFR decline. Patients with rapid eGFR decline experienced an additional 326 CV events per 1,000 patients and spent an additional 0.4 years receiving RRT. Reduced life expectancy, increased rates of CKD progression and CV event incidence translated to 2.4 fewer quality adjusted life years with dapagliflozin in patients with eGFR decline (5.5 versus 7.9) and an additional 493.7% of direct healthcare expenditure.

Conclusions: The DAPA-CKD cost-effectiveness model is capable of estimating health economic outcomes in patients with CKD, projecting health benefits and costs consistent with previous published studies. The improved diagnosis thresholds of CKD may reduce the burden imposed by CKD on both patients and healthcare systems.

PO0590
Development of a CKD Model in Cynomolgus Monkeys and Its Application to Test Zampilimab, a Monoclonal Antibody (mAb) Specific for Human Transglutaminase 2 (TG2)
Linhong Huang,1 James L. Song,2 Timothy S. Johnson.1 1UCB Pharma, Slough, United Kingdom; 2Prisys Biotechnology, Shanghai, China.

Background: TG2, a crosslinking enzyme involved in wound healing, is linked to the development of renal fibrosis. TG2 irreversibly crosslinks proteins via ε-(glutamyl) lysine dipeptide bonds, including extracellular matrix (ECM) proteins. TG2 accelerates ECM deposition and renders the matrix resistant to ECM proteases, forcing ECM homeostasis towards accumulation. TG2 also crosslinks large latent TGFβ1 into the ECM, releasing the active pro-fibrotic TGFβ1 dimer. Zamilpimab (IC50 0.2nM, Kd 120pm), a humanized mAb specific for human TG2, is under investigation for the treatment of fibrosis. Application of zamilpimab in a primary human cell model of renal fibrosis had positive results; however due to human specificity, zamilpimab efficacy cannot be tested in rodent in vivo models.

Methods: A unilateral ureteric occlusion model of CKD was developed in aged cynomolgus monkeys. Zamilpimab was applied prophylactically immediately following model induction. TG2 activity was measured using an in-situ activity assay, and zamilpimab target occupancy determined by competitive immunofluorescence. Renal fibrosis was measured by computerized image analysis and histopathological scoring of Masson’s trichrome, Picosirius red and H&E stained slides with hydroxyproline measured by amino acid analysis.

Results: Ligation of the left ureter led to development of severe tubulointerstitial fibrosis that correlated to an increased TGFβ1 dimer, leading to end-stage renal failure. At this time point, zamilpimab intervention in a 4-week study, 7 days post final dose, TG2 activity and TGFβ1 dimer were completely inhibited at a high dose level of 3 mg/kg. At 6 months post final dose, at a low dose. However, both zamilpimab doses ameliorated the level of renal fibrosis by pathology score, computerized determination of fibrin index and hydroxyproline.

Conclusions: Our primate model of CKD demonstrated that zamilpimab can effectively block TG2 activity and prevent renal fibrosis. A Phase 1/2 study of zamilpimab for the treatment of post-renal transplant fibrosis is ongoing (NCT04335578).

PO0591
Conditional Deletion of Myeloid-Specific Mitofusin 2 Promotes Kidney Fibrosis
Divya Bhartia, Allyson M. Capilli, Kiichi Nakahira, Thangamani Muthukumar, Augustine M. Choi, Oleh M. Akchurin, Mary E. Choi. Well Cornell Medicine, New York, NY.

Background: Mitochondrial dysfunction is implicated in the pathogenesis of CKD. Mitochondrial dynamics regulate macrophage mitochondrial stress responses; we hypothesize that their impairment leads to kidney fibrosis. We determined the role of myeloid-specific mitochondrial fusion proteins (MFN1) and MFN2 in PINK1-mediated mitophagy in experimental and human kidney fibrosis.

Methods: Pnk-1−/−, myeloid-specific Mfn1 (LysM-Cre−/−Mfn1fl/fl), Mfn2 (LysM-Cre−/−Mfn2fl/fl) null mice and corresponding controls were subjected to unilateral ureteral obstruction (UUO) (17, 20 days) or adenine diet (AD, 28 days). Kidneys, renal macrophages (MRMs), bone marrow-derived macrophages (BMDMs), PBMCs, and plasma were analyzed by western blot, qPCR, Mito stress test, ELISA, immunohistochemistry, flow cytometry, confocal and electron microscopy. Patients with renal biopsy-proven interstitial fibrosis & tubular atrophy (IFTA, n=6) and severe CKD (GFR 30 mL/min, n=15) were compared to controls (no IFTA, n=9) and mild/moderate CKD (GFR >30 mL/min, n=8).

Results: MFN1 and MFN2 expression decreased in kidneys after UUO or AD, and BMDMactivated TGF-β1 treatment AD-fed LysM-Cre−/−Mfn1fl/fl/but not LysM-Cre−/−Mfn2fl/fl mice displayed increased renal expression of CD11b+F4/80+ macrophages than AD-fed controls. Increases in fibronectin, CD206, galectin-3, and TGF-β expression in the kidneys and RMs were higher in AD-fed LysM-Cre−/−Mfn1fl/fl mice than AD-fed controls. TGF-β1-induced inhibition of mitophagy and increases in mitochondrial mass, size, and superoxide levels were greater in LysM-Cre−/−Mfn2fl/fl RMs and BMDMs than LysM-Cre−/−Mfn1fl/fl and controls. The reduction in colocalization of MFN2 but not MFN1 with renal mitochondria after UUO was higher in Pnk-1−/− mice. PBMCs from patients with severe CKD showed higher superoxide levels and lower MFN2 expression than mild/moderate CKD. IFTA was associated with lower renal expression of MFN1 and MFN2 and higher circulating CCL2 levels than controls. Decreased MFN2 and PINK1 expression in IFTA-treated human RMs was associated with increased fibrotic response.

Conclusions: This study is the first to suggest that myeloid-specific MFN2 but not MFN1 by regulating renal macrophage mitophagy biogenesis and mitophagy prevents fibrosis. Mitophagy inducers may attenuate macrophage superoxide production and progression of kidney fibrosis.

**EZH2 Mediates Renal Fibrosis and Links Activation of Notch Signaling and Suppression of Klotho and BMP-7 Expression**

Shougang Zhuang,1,2 Shanghai East Hospital, Shanghai, China; 1Rhode Island Hospital, Brown University, Providence, RI; 2Shanghai East Hospital, Shanghai Tongji University, Shanghai, China.

**Background:** Our previous studies have shown that pharmaceutical blocking EZH2 (Enhancer of Zeste Homolog 2), a histone H3 lysine 27 histone methyltransferase, attenuates renal fibrosis in a murine model of renal fibrosis, but the underlying mechanism in this process remain undefined.

**Methods:** In this study, we used two highly selective EZH2 inhibitors and conditional knockout mice to evaluate the effect of EZH2 inhibition on renal fibrosis and activation of profibrotic signaling pathways and expression of renoprotective proteins in two in vivo models of chronic kidney disease (CKD) induced by UUO and 5/6 nephrectomy (SNx).

**Results:** Global inhibition of EZH2 by administration of gambogic acid or GSK-126 and conditional depletion of EZH2 in pericytes suppressed renal fibroblast activation and fibrogenesis in the kidney with UUO and SNx. Treatment with these inhibitors or EZH2 siRNA also inhibited serum- and TGF-β1-induced activation of renal fibroblasts in vitro. Moreover, pharmacological and genetic inhibition of EZH2 suppressed expression of Notch-1, Notch-3, Jagged-1 and HES-1 and HEV-2 in vivo and in vitro. Similarly, inhibition of EZH2 was effective in inhibiting phosphorylation of extracellular signal-regulated kinase 1/2, AKT and NF-κB as well as expression of multiple profibrogenic cytokines/chemokines and renal macrophtage infiltration. In contrast, EZH2 inhibitors prevented injury-induced downregulation of Klotho and BMP-7, two anti-fibrotic proteins in the kidney.

**Conclusions:** These results revealed that EZH2 may promote renal fibrosis and activation of renal fibroblasts by activation of Notch signaling, downregulation of Klotho and BMP-7 and induction of inflammation in the injured kidney. Targeting EZH2 may be a novel therapeutic strategy to treat CKD.

**Kidney Targeted Renalase Agonist Peptide Rescues Severe Model of Cisplatin-Induced AKI and CKD**

Xiaojia Guo,1 Leyuan Xu,1 Heino Velazquez,1,2 Tian-Min Chen,1 Ryan Williams,1,4 Daniel A. Heller,1 Robert L. Safirstein,1 Gary V. Desir,1,2 Yale University School of Medicine, New Haven, CT; 3VAMC, West Haven, CT, 4Sloan-Kettering Institute, New York, NY; 5The City College of New York Division of Science, New York, NY.

**Background:** Cisplatin (CP) causes Chronic Kidney Disease (CKD) upon repeated doses and limits its chemotherapeutic use. Renalase (RNL5) is a protein that activates kinases linked to survival and attenuates acute ischemic and CP-induced kidney injury. We now seek to target delivery of RNL5 specifically to kidney to prevent CP-induced CKD.

**Methods:** CKD was induced in RNLS knockout (KO) (severe) and wild type (WT) mice by 2 doses of CP 15 mg/kg 2 weeks apart. The RNLS agonist peptide RP81 was synthesized and encapsulated in mesoscale nanoparticles (MNP) that target the kidney. Its cytoprotective activity was tested in vitro using TKPTS proximal tubule cells and in vivo using RNLS KO mice. RP181MNP or empty MNP was administered weekly for 4 weeks. Reduced renal cell death was evaluated by immunohistochemistry and plasmacytoid (Cr). The mechanism of action of RP181MNP was investigated using single cell RNA sequencing (scRNAseq) of whole kidney cells.

**Results:** MNP were retained intracellularly by TKPTS cells and were localized to proximal tubules in vivo. RP181MNP protected TKPTS cells from CP-induced cytoxicity: cell viability was enhanced 3.5-fold, n=6, p<.05, compared to empty MNP. Naked RP81 increased cell viability 1.72-fold, n=6, p<.05 over BSA control. Compared to WT, CP in KO caused more severe AKI (Cr: 0.61 mg/dl ± 0.05 vs. 0.13±0.03 in WT, n=3, p<.05), higher mortality (45% death at 4 weeks vs. 20%, p<.005), and more severe CKD (Cr: 0.16 ± 0.02 mg/dl ± 0.1 ± 0.05, n=5, p<.05). In KO given CP, RP181MNP ameliorated AKI (Cr: 0.30 ± 0.05 mg/dl vs. 0.64 ± 0.14 in control, n=5, p<.05) and CKD (increased kidney weight: 176% ± 7.0 vs. 145± 2.4, decreased plasma Cr: 0.10± 0.01 vs 0.16±0.02, and KiM:1-124.3±15.1 pg/ml vs 227±23.4). RP181MNP significantly reduced plasma cytokines IL-1β, IL-2, IL-6, KC, and TNFα and inhibited regulated necrosis. SCRNAsseq revealed that RP181MNP preserved tubule and vasculature cell mass and decreased infiltrated immune cells caused by CP.

**Conclusions:** We conclude that RP181MNP attenuates CP-induced CKD by diminishing cell death pathways and inflammation activation by CP. These data suggest that RP181MNP may be an effective therapeutic agent to prevent CKD in patients treated with repeated doses of cisplatin.

**Pyruvate Kinase M2 in Renal Tubular Cells Is a Key Regulator of Kidney Repair After Ischemic Injury**

Qingwei Wei,1 Zheng Dong,1,2 Augustana University, Augustus, GA; 3Augusta VA Medical Center, Augusta, GA.

**Background:** Tissue injury and repair is associated with changes of metabolism. In kidneys, metabolic changes including mitochondrial dysfunction and induction of glycolysis have been reported in renal fibrosis and chronic kidney disease. It remains unclear whether and how the metabolic changes contribute to kidney injury and repair. We have examined the effects of glycolysis inhibitors and the ablation of pyruvate kinase M2 (PKM2, an enzyme in glycolysis) in kidney tubules. Glycolysis inhibitors (including PKM2 inhibitor shikim) suppressed renal fibrosis in the mouse model of unilateral ureter obstruction (UUO). Interestingly, in vitro the inhibitors suppressed fibrogenic gene expression (e.g. fibronectin and a-SMA) in fibroblasts, but not in cultured renal tubular cells.

**Methods:** To further understand the role of glycolysis in renal tubular cells in vivo, we established a mouse model in which PKM2 ablation in renal tubule cells can be induced by doxycycline. To this end, PKM2-flox mice were bred with Pax8-xT/A1C CRE recombinase mice to create an inducible renal tubule-specific PKM2 knockout (iRT-PKM2-KO) mouse model. Exposure to doxycycline for 5-7 days induced PKM2 ablation in all renal tubules in iRT-PKM2-KO mice, but not in wild-type littermates. These mice were subjected to 30 minutes of unilateral renal ischemia-reperfusion one day after initial doxycycline treatment, and kidneys were collected at 2 weeks later for histology, immunoblot analysis, and fibrosis staining.

**Results:** Wild-type mice showed increased expression of collagen I, collagen IV, vimentin and a-SMA in kidney tissues. The increase of collagen I was significantly attenuated in iRT-PKM2-KO mice, while collagen IV and vimentin induction was marginally inhibited and no inhibition for fibronectin and a-SMA in these mice. Wild-type and iRT-PKM2-KO kidney tissues had similar levels of Sirius red staining of collagen fibrils. We further examined Lotus Tetragonolobus lectin (LTL) staining of proximal tubules, which detected obviously more intact proximal tubules in iRT-PKM2-KO mice than in wild-type littermates.

**Conclusions:** Together, these results indicate a pathogenic role of glycolysis in maladaptive kidney repair. Importantly, PKM2 and associated metabolism contribute to the degeneration of renal tubules after acute kidney injury.

**Proximal Tubule-Specific DPP4 Deletion Slows Kidney Disease Progression in Obese Mice**

Ravi Nistala,1 Jing Ren,1 Jingzhong An,2 Tammy L. Srawn,1 Suryanshi Rawat,1 Priyanka Patel,1 Adam Whaley-Connell.1 University of Missouri, Columbia, MO; 1Souch Municipal Hospital, Souchina, China.

**Background:** Obesity is a major risk factor for Chronic Kidney Disease progression to End Stage Renal Disease and/or Dialysis. Increased absorption of fats and/or sugars from Western Diet (WD) likely leads to kidney tubular injury in obesity. We observed that whole body dipeptidyl peptidase 4 (DPP4) deletion as well as inhibition in WD-fed mice results in decreased kidney injury which, in turn was associated with a decrease in proximal tubule DPP4. Therefore, we hypothesized that proximal tubule (PT) DPP4 activation leads to injury and progression of kidney disease.

**Methods:** PT-KO and WT littermates were fed a WD starting 4-6 weeks of age and continued for 2 years. GFR and albuminuria were monitored periodically. Tissue histology was performed at select intervals. GeLC-MS was used to separate kidney peptides and Scaffold 4/Pathway guide used to analyze the Proteomics data.

**Results:** WD-fed WT mice gained 150-200% weight of chow-fed (CD) mice and had a greater decline in GFR than CD-fed animals over 2 years (50% vs. 20%, p<0.05). WD-fed PT-KO mice had a lesser decline (~35%) when compared to WT mice. This was true for both male and female mice. Concomitantly, there was an increase in albuminuria in WD-fed WT mice that was mitigated in PT-KO mice. PAS/PSR stained sections showed worsening fibrosis, tubular dilatation and glomerulomegaly, tubular vacuolization in WD-fed WT mice that was mitigated in PT-KO mice. Oil Red O staining showed increased fat accumulation in glomeruli and tubules of WD-fed WT mice that was mitigated in KO mice. Proteomics analysis followed by immunoblots showed that WD-feeding led to an increase in cell adhesion proteins and ribosomal machinery that was significantly suppressed by KO. In addition, there was a shift towards reduction in gluconeogenesis and improved fatty acid oxidation in KO mice.

**Conclusions:** Obesity without diabetes can lead to rapid decline in GFR in both male and female mice. DPP4 inhibition may slow decline if started early in the course of developing obesity and/or insulin resistance.

The PAR-1 Antagonist Vorapaxar Protects Against AKI to CKD Transition

Sarah W.Y. Lok,1 Wai Han Yiu,1 Loretta Y.Y. Chan,1 Joseph C K Leung,1 Kar Neng Lai,1 Sydney C. Tang.1 The University of Hong Kong, Queen Mary Hospital, Hong Kong. Hong Kong; 2The University of Hong Kong, Hong Kong, Hong Kong.

Background: Protease-activated receptor-1 (PAR-1) has been reported as a key regulator in the pathophysiology of AKI. Beyond its normal function in haemostasis, aberrant PAR-1 signaling may lead to the development of tubulointerstitial fibrosis, and subsequently CKD.

Methods: We investigated whether the administration of PAR-1 antagonist vorapaxar, an FDA-approved drug for reducing thrombotic cardiovascular events, has any renoprotective effect in a robust AKI mouse model following unilateral ischemia reperfusion injury (UIRI), as well as in hypoxia-induced cultured rat proximal tubular epithelial cells (NRK-52E).

Results: Vorapaxar reduced morphological abnormalities and the expression of tubular injury marker kidney injury marker-1 (KIM-1) in UIRI kidneys. Mice treated with vorapaxar showed less intrarenal accumulation of ECM proteins including fibronectin, α-smooth muscle actin and collagen I via TGF-β1/Smad signaling after UIRI. IR-induced endothelial dysfunction and macropage infiltration were also decreased by vorapaxar treatment. In NRK-52E cells, PAR-1 expression was activated under a hypoxia milieu associated with upregulation of TGF-β-induced ECM protein accumulation.

Conclusions: Vorapaxar diminishes renal fibrosis through TGF-β1/Smad signaling in UIRI model, and protects against tubular injury during AKI to CKD transition. A PAR-1 targeted strategy by vorapaxar as a therapeutic approach in human CKD warrants further. Funding: Health and Medical Research Fund (HMRF) of Hong Kong (grant no. 05163596), Research Grants Council of Hong Kong (Collaborative Research Fund, grant no. C7081-16C), and Hong Kong Society of Nephrology/ HK Foundation for Research Grant 2018.

Sphingosine Kinase 2 in Kidney Perivascular Cells Promotes Inflammation and Fibrosis Through S1PR1 Signaling

Shinji Anaka1, Yugesh Kharel,2 Shuqiu Zheng,1 Jonathan E. Lipsey,1 Diane L. Rosin,1 Kevin Lynch,2 Mark D. Okusa.1 Division of Nephrology and Center for Immunology, Inflammation and Regenerative Medicine, University of Virginia, Charlottesville, VA; 2Department of Pharmacology, University of Virginia, Charlottesville, VA.

Background: Sphingosine 1-phosphate (SIP) is a sphingolipid, which is produced by two different kinases, sphingosine kinase (SphK) 1 and 2. SIP is exported through Sphn2 or Mfn2d, and then reacts with SIP receptors (SIPR1-5) to affect various cell functions. We recently showed that SphK2–/– mice were protected from renal fibrosis when compared to wild type or Sphk1–/– mice (PMID: 27799486). We hypothesized that Sphk2 deletion in renal perivascular cells confers the protection from progressive kidney fibrosis.

Methods: Male Fosl/Cre Sphk2fl/fl and Fosl/Cre Sphk2fl/fl (control) mice were used. For unilateral ischemia-reperfusion injury (IRI), left kidney was clamped for 30 min; right nephrectomy was performed at day 13. For bilateral IRI, both kidneys were clamped for 30 min. Mice were euthanized at day 14 to evaluate kidney fibrosis (unilateral IRI) and at day 1 to evaluate the extent of acute kidney injury (bilateral IRI). Primary kidney perivascular cells were isolated from kidneys of Fosl1Cre Sphk2fl/fl and control mice.

Results: In the unilateral IRI model, Fosl1Cre Sphk2fl/fl mice demonstrated better kidney function (plasma creatinine, less kidney fibrosis (histology)) with less macropage infiltration, and suppressed expression of fibrosis-related genes (Acta2, Colla1, Col3a1) in the kidneys compared with control mice but there was no difference in plasma SIP between the groups. In contrast, in the bilateral IRI model, there was no difference between the groups in kidney function, kidney Haver1/En2 expression, and histology at day 1. In vitro studies, Sphk2-deficient perivascular cells expressed less inflammatory cytokines, such as Ccl2, Itgav, Clec11, after LPS stimulation compared with control perivascular cells. Sphk2-deficient and control perivascular cells robustly expressed Smad2, but not Mfn2d, and S1pr1-3 among the five SIP receptor subtypes. Among S1pr1-3, only knockdown of S1pr1 resulted in suppressed expression of inflammatory cytokines after LPS stimulation.

Conclusions: Sphk2 deletion in renal perivascular cells was protective against kidney fibrosis. In vitro studies suggested that SIP production by Sphk2 is exported through Sphn2 and reacts with S1PR1 to enhance the inflammatory signal in these cells, leading to immune cell infiltration and subsequent fibrosis in the kidneys.

Histone Demethylase JMJD3 Protects Against Renal Fibrosis by Suppressing TGF-β and Notch Signaling

Chao Yu,1 Shougang Zhuang,2,3,4,5 Shanghai East Hospital, Shanghai Tongji University; 2Rhode Island Hospital, Brown University, Providence, RI; 3Shanghai East Hospital, Shanghai Tongji University, Shanghai, China.

Background: The Jumonji domain-containing 3 (JMJD3), a specific histone demethylase for trimethylation on histone H3 lysine 27 (H3K27me3), is associated with the pathogenesis of many diseases, but its role in renal fibrosis remains unexplored. Here, we examined the role of JMJD3 and mechanisms involved in the activation of renal fibroblasts and development of renal fibrosis.

Methods: Murine models of 5/6 nephrectomy (SNx) and ureteral unilateral obstruction (UUO) were used to assess the effect of a specific JMJD3 inhibitor, GSKJ4, and genetic deletion of JMJD3 from FOXD1 stroma-derived renal interstitial cells on the development of renal fibrosis and activation of renal interstitial fibroblasts. Cultured rat renal interstitial fibroblasts (RRK-48F) and mouse renal epithelial (mTECs) cells were also used to examine JMJD3-mediated activation of profibrotic signaling.

Results: JMJD3 and H3K27me3 expression levels were upregulated in the kidney of mice subjected to SNx, UUO and UUO. Pharmacological inhibition of JMJD3 with GSKJ4 completely blocked the expression of JMJD3 led to worsening of renal dysfunction as well as increased deposition of extracellular matrix proteins and activation of renal interstitial fibroblasts in the injured kidney. This was coincident with decreased expression of Smad7 and enhanced expression of H3K27me3, transforming growth factor β1 (TGFB1), Smad3, Notch1, Notch3 and Jagged1. Inhibition of JMJD3 by GSKJ4 or specific siRNA also resulted in the similar responses in cultured NRK-49F and mTECs exposed to serum or TGFB1. Moreover, JMJD3 inhibition augmented phosphorylation of AKT and ERK1/2 in vivo and in vitro.

Conclusions: These results indicate that JMJD3 confers anti-fibrotic effects by limiting activation of multiple profibrotic signaling pathways and suggest that JMJD3 modulation may have therapeutic effects for chronic kidney disease.

Induction of CKD by Gene Deletion of Canonical Transient Receptor Potential 1 (TRPC1) Channels Independent of Hypertension and Nepheromalgy Despite Diabetes and Metabolic Syndrome

Muhammad Mubeen Anwar, Usman A. Khan, Bonnie Eby, Kai Lau. The University of Oklahoma Health Sciences Center, Oklahoma City, OK.

Background: TRPC1 gene on chromosome 3q22-24 is in the linkage region for diabetic nephropathy. Despite reduced expression in diabetes, no causal relationships has been established. Since null mice are obese, hyperterylyceridemic and diabetic with fatty liver, we evaluated potential renal phenotypes, testing the hypothesis of impaired Ca signaling, as we found reduced cell free Ca in bone, renal, and parathyroid cells.

Methods: From 3rd to 22nd mon, metabolic, cardiac & abdominal ultrasound (US) & clearance (CI) studies were done in age- & sex-matched littermates of TRPC1 +/+, +/-, & -/- mice. Creatinine (Cr) was analyzed by creatininase or HPLC; glomerular filtration rate (GFR) by inulin Cr. Systolic (S) & diastolic (D) BP was measured by arterial (A) cannulation.

Results: Null mice were hyperglycemic from the 3rd mon & developed diabetes in 6 to 22 mon by standard IP glucose tolerance test. Nepheromalgy was absent in null mice since kidney volume by US (0.38 vs. 0.46 at 7 mon & 0.4 vs 0.5 ct at 11-20 mon) was 16% smaller & kidney (K) to body (B) weight (W) (1.2 vs 1.5 7 at 7 mon & 1.1 vs 1.5 % at 11-20 mon) was lighter by 17-28%. Chronic injury & scarring were suggested by 37% increase in echogenicity at 20 mon, though normal at 7 or 11 mon. Urine albumin/Cr ratio in null mice rose barely (64-71%). At 17 mon, CrCl fell by 30% (p<0.01) in null & by 46% (p<0.01) in null vs. GFR at 22 mon corroborated stage III CKD as inulin C1 fell by 45-48%, whether expressed per mouse, per g KW, or per 100 g BW. Haploid TRPC1 deletion reduced CrCl by 40% (p<0.05) at 16 mon vs 44% by diplodip deletion (p<0.02). TRPC1 deletion significantly reduced, not raised, mean SBP (113 vs 131 torr), DBP (77 vs 86 torr), & MABP (89 vs 98 torr). Since TRPC1 was implicated in cardiac hypertory signaling, smooth muscle proliferation & mesangial cell contraction, we did cardiac US & found 33% reduced cardiac output in -/- mice (14 vs 21 ml/min) & 14% smaller heart mass, corroborated by 20% lower weights measured at 22 mon.

Conclusions: 1. TRPC1 deficiency impairs Ca signaling, retards renal & heart dysfunction, compromises homodynamics and produces hypohypertensive nephropathy.

2. Null mice provide an excellent model to study progressive CKD independent of hypertension and heavy proteinuria.

The Novel Soluble Guanylyl Cyclase (sGC) Activator Runcaciguat Induced Renal Vasodilation and Reduced Kidney Damage in a Rat CKD Model

Anne Marie Benardaud,1 Michael G. Hahn,1 Michael Gerisch,1 Michaela Meyer,1 Dzianis Menshhyak,2 Terence Hetzel,1 Jan Schliender,1 Elke Hartmann,2 Tobias Rensing,1 Andrea Patzak,1 Frank Schweda,1 Jan F. Kräsländer,1 Peter Sandner,1 Frank Ettmayer1 2Bayer AG, Leverkusen, Germany; 2Universität Regensburg, Regensburg, Germany; 3Charité Universitätsmedizin Berlin, Berlin, Germany.

Background: CKD progression is associated with impaired NO/sGC/cGMP-signaling, low cGMP production and increased oxidative stress. Oxidative stress modifies the native sGC to oxidized, heme-free apo-sGC which cannot be activated by NO anymore. Runcaciguat is a novel potent and selective sGC activator that binds and activates heme-free sGC independently of NO and restores NO/sGC/GMP signaling. We investigated the effects of Runcaciguat on intrarenal hemodynamics and in a rat model of T2D-associated CKD.

Methods: Hemodynamic effects were analyzed ex vivo in isolated renal afferent/effluent arterioles and in perfused kidneys. Effect of Runcaciguat on kidney protein expression was evaluated in diabetic and proteinuric rats. ZSF1 rats (12w, male, n=6/gp) were implanted with telemetry systems and treated daily orally for up to 12 weeks with Runcaciguat, Enalapril or placebo. Key parameters included proteinuria, kidney structural changes, biomarkers, kidney gene expression, systemic hemodynamics, and substance plasma exposures.

Results: Runcaciguat dilated renal afferent/effluent arterioles under NO depletion and increased blood flow, GFR and cGMP production in NO-depleted, isolated perfused kidney slices under ZSF1 rat conditions dose-dependently reduced proteinuria (~17%, ~50%, ~85% (p < 1, 3.10 mg/kg/bid) without changing mean arterial pressure at steady-state. The reduction of proteinuria was significantly higher than with Enalapril (-39%, -63% (p < 0.2, 60 mg/kg/d) at doses significantly reducing systemic blood pressure. Runcaciguat reduced kidney injury parameters, albuminuria and liver and kidney weight. Runcaciguat restored reduced whole blood hemoglobin and plasma triglycerides while Enalapril did not. Metabolic improvement was accompanied by gene expression changes suggesting improvement of vascular and endothelial functions independently of interaction with the Renin-Angiotensin-Aldosterone system. Runcaciguat plasma concentration was dose-proportional after acute and chronic dosing.

Conclusions: Runcaciguat prevented further decline in kidney function and structure independent of blood pressure in CKD rats. Our data suggest that the novel sGC activator Runcaciguat represents a promising treatment option for CKD patients.

Funding: Private Foundation Support

Inhibition of KIM-1-Mediated Fatty Acid Uptake by a Novel Inhibitor Attenuates Pro-Fibrotic Responses in Multiple Models of Human Primary Kidney Epithelial Cells Including Kidney Tubuloids

Yutaro Mori,1 Amrendra K. Ajay,1 Ankit B. Patel,1 Andrew M. Siedlecki,1 Seiji Kishi,2 Takaharu Ichimura,3 Joseph V. Bonventre.1 1Division of Renal Medicine, Department of Medicine, Brigham and Women’s Hospital, Harvard Medical School, Boston, MA; 2Department of Nephrology, Tokushima University Hospital, Tokushima, Japan.

Background: Tubulointerstitial damage is strongly associated with many forms of kidney injury including diabetic kidney disease. Kidney Injury Molecule-1 (KIM-1), a surface-exposed, high-afﬁnity receptor for tubular lipid uptake, is upregulated in response to kidney injury. We hypothesized that KIM-1-mediated uptake of fatty acids (FAs) contributes to tubulointerstitial damage.

Methods: Human DKD renal biopsy samples were analyzed. Human primary epithelial cells were cultured from the non-tumor kidney tissue removed from patients with a renal mass. To grow human renal tubuloids, primary cells were cultured on ultra-low attachment plates for several days. Cells were transferred into media containing multiple growth factors and 5% fetal bovine serum. Cells and tubuloids were treated with palmitic acid with certain groups having siRNA knockdown of KIM-1. Conditioned media from FA-treated human primary cells and tubuloids were applied to mouse primary kidney fibroblasts. An inhibitor for KIM-1-mediated FA uptake was identiﬁed from >14,000 compounds and tested for its anti-fibrotic ability.

Results: KIM-1 expression in DKD patients was positively correlated with tubulointerstitial inﬁltration and ﬁbrosis. FA-BSA uptake was markedly reduced in cells depleted of KIM-1 indicating the relative importance of KIM-1 to proximal tubule FA uptake. High-dose FA treatment increased cell death. FA treatment increasedH2AX expression, a marker for DNA damage response. FA also increased the number of cells in the G2/M phase without an increase of those in S phase by cell cycle analysis, indicating that cells are likely arrested in G2/M phase. Our newly identiﬁed inhibitor for KIM-1, JB1, prevented FA uptake at least in part by inhibiting the direct binding of FA to KIM-1. JB1 reduced the pro-fibrotic effect of conditioned media from FA-treated human primary cells and tubuloids.

Conclusions: KIM-1 enhances the proximal tubular uptake of FA, leading to proximal tubule damage, pro-fibrotic responses and increase in cell death. Our ﬁndings support KIM-1 as a therapeutic target for chronic kidney disease including DKD and our work introduces a new candidate therapeutic agent.

Histone Deacetylase 6 Inhibition Mitigates Renal Fibrosis by Suppressing TGF-β/SMAD3 and eGFR Signaling Pathways

Xingyin Chen,1 Shougang Zhang,1,2 Shanghai East Hospital /Shanghai East Hospital, Shanghai Tongji University, Shanghai, China; 2Rhone Island Hospital, Brown University, Providence, RI.

Background: We have recently shown that histone deacetylase 6 (HDAC6) is critically involved in the pathogenesis of acute kidney injury, however, its role in renal fibrosis remains unclear.

Methods: In this study, we examined the effect of ricolinostat (ACY-1215), a selective inhibitor of HDAC6, on the development of renal fibrosis in a murine model induced by unilateral ureteral obstruction (UUO).

Results: HDAC6 was highly expressed in the kidney following UUO injury, which was coincident with deposition of collagen fibrils and expression of α-smooth muscle actin, fibronectin, and collagen III. Administration of ACY-1215 reduced these fibrotic changes and inhibited UUO-induced expression of transforming growth factor β1 and proliferation of Smad3, Smad7, and Smad7. ACY-1215 treatment also suppressed phosphorylation of epidermal growth factor receptor and several signaling molecules associated with renal fibrogenesis, including Akt, signal transducer and activator of transcription 3 and NF-kB in the injured kidney. Furthermore, ACY-1215 was effective in inhibiting differentiation of renal fibroblasts to myofibroblasts in cultured renal interstitial fibroblasts.

Conclusions: Collectively, these results indicate that HDAC6 inhibition can attenuate renal fibrosis development by suppression of TGFβ/β1 and eGFR signaling.

Critical Role of STAT6 Signaling in Renal Fibrosis

Baihai Jiao,1 Changlong An,1 Yanlin Wang,1,2 University of Connecticut School of Medicine, Farmington, CT; 2VA Connecticut Health System, West Haven, CT.

Background: Kidney fibrosis is a pathologic characteristic of chronic kidney disease, resulting in progressive loss of kidney function to end-stage kidney failure. We have recently demonstrated that bone marrow-derived fibroblasts contribute to the pathogenesis of kidney fibrosis. In this study, we investigated the role of STAT6 in activation of bone marrow-derived fibroblasts and development of renal fibrosis in folic acid nephropathy.

Methods: To investigate the role of STAT6 in myofibroblast activation and kidney fibrosis, we used STAT6 knockout mice or treated wild-type mice with AS1517499, a STAT6 inhibitor. Wild-type mice treated with vehicle were used as controls. Folic acid was administered at 250 mg/kg intraperitoneally to induce kidney fibrosis. Kidneys were harvested 2 weeks after folic acid injection.

Results: Folic acid injury led to activation of STAT6 in the interstitial cells of the kidney, which was abolished by treatment with AS1517499. Wild-type mice treated with AS1517499 accumulated fewer bone marrow-derived fibroblasts compared with vehicle-treated mice. AS1517499 treatment significantly inhibited myofibroblast activation, reduced total collagen deposition, and suppressed expression of extracellular matrix proteins with folic acid injury. Compared with wild-type mice, mice with STAT6 deficiency exhibited fewer myofibroblast and myofibroblasts and expressed less α-SMA protein in the kidneys following folic acid injury. Furthermore, genetic deletion of STAT6 significantly reduced total collagen deposition and ECM protein production in the kidneys with folic acid nephropathy.

Conclusions: Our results demonstrate that STAT6 signaling plays an important role in the development of bone marrow-derived fibroblasts during the development of renal fibrosis in folic acid nephropathy.

The Role of HNF4α in CKD Progression

Marta Martinez-Calle,1 Guillaume Courbon,1 Xueyan Wang,2 Bridget Hunt-Tobey,1 Jadeah J. Spindler,1 Emily P. Lynch,1 Aline Martin,1 Valentin David1 NorthWestern University Feinberg School of Medicine, Chicago, IL. 1

Background: Acquired kidney mitochondrial dysfunction is a prominent feature of Chronic Kidney Disease (CKD), and is associated with onset and progression of CKD. HNF4α is a transcription factor highly expressed in proximal tubules which controls the expression of genes involved in critical metabolic pathways. As a result, mutations in HNF4α are associated with mitochondrial defects. We previously found that Hnf4α is reduced in the kidneys of Col4α3KO mice with progressive CKD and it correlated with hyperphosphatemia. Here, we tested the hypothesis that kidney Hnf4α is reduced in response to hyperphosphatemia and that Hnf4α decline in CKD contributes to mitochondrial dysfunction and CKD progression.

Methods: We fed WT mice a control (Ctl) and a high phosphate diet (HPi) for 6 weeks. We confirmed that phosphate intake was reduced in the kidneys Col4α3KO mice by RT-PCR and next performed RNA sequencing (RNAseq) to identify genes and molecular pathways affected by HNF4α reduction in CKD. Finally, to further evaluate the causal role of Hnf4α reduction in CKD progression, we treated Col4α3KO mice with a daily dose of 30mg/g of I.P. IEs4α (700mg/kg) for 5 days.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underlines represent presenting author.
Results: WT mice fed a HPI diet showed a significant 70% reduction in kidney HNF4α mRNA and protein expression, suggesting that hyperphosphatemia, a hallmark of progressive CKD, contributes to HNF4α downregulation in the kidney. Kidney molecular profiling by RNAseq of Col4a3 KO mice showed increased acquired mitochondrial dysfunction and reduced oxidative phosphorylation, suggesting that impaired mitochondrial function strongly contributes to CKD progression. Downstream pathway analyzes showed that the vast majority of these genes (~30%) are regulated by HNF4α. Pharmacological inhibition or HNF4α in Col4a3 KO mice led to an accelerated decline in kidney function (200% increase in BUN), demonstrating the crucial role of HNF4α in CKD progression.

Conclusions: These results suggest that HNF4α is a master regulator of mitochondrial function in kidney and might represent a novel therapeutic target to improve outcomes in CKD.

An In Vitro Model to Elucidate the Synthesis of Extracellular Matrix Proteins Involved in Renal Interstitial Fibrosis
Alexandra L. Meier,1 Alexander L. Reese-Petersen,1 Daniel Guldager Kring-Rasmussen,1 Federica Genovese,1 Morten A. Karsdal,1 Fibrosis, Renal and Cardiovascular Research 1Nordic Bioscience, Herlev, Denmark; 2Biomedical Sciences, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark.

Background: Accumulation of extracellular matrix (ECM) proteins is a hallmark of renal fibrosis, which can lead to altered tissue homeostasis, kidney failure, and ultimately death. Many different cell types are involved in this process, but fibroblasts are the main source of ECM proteins such as fibrocollagen, collagen type I (COL I), III (COL III), and VI (COL VI). Recently it was suggested that a fragment of COL VI released during collagen maturation is, in fact, a bioactive molecule (endotrophin; ETP) with signaling potential, indicating that collagens are not just passive structural proteins. In this study, we investigated the effect of transforming growth factor (TGF)-β and ETP on the synthesis of different ECM proteins by human renal fibroblasts in the scar-in-a-jar (SiaJ) cell model.

Methods: Cells were seeded in 48-well plates at 30,000 cells/well and incubated for 24h in DMEM + 10% FBS for adherence. Cells were starved by incubating them for further 24h in DMEM + 0.4% FBS. Fresh medium was added at day 0 with 225/150 mg/mL Ficol 70/400 and 1% ascorbic acid, containing 0.02 nM TGF-β or either 12 or 30 nM ETP. Medium was changed and collected on days 3, 6, 10, and 13. Biomarkers of ECM formation, COL I (PRO-C1), III (PRO-C3), VI (PRO-C6), and fibronectin (FBN-C) formation were assessed in the medium by enzyme-linked immunosorbent assays developed at Nordic Bioscience.

Results: Stimulating renal fibroblasts with 0.02 nM TGF-β significantly increased the formation of COL I (P<0.0001), III (P<0.0001), and fibronectin (P<0.0001) compared to unstimulated cells. Interestingly, TGF-β treatment suppressed the formation of COL VI and ETP significantly increased the formation of COL I (P<0.0001) and III (P<0.0001) compared to unstimulated cells. 12 nM ETP significantly increased the synthesis of fibrocollagen compared to unstimulated cells (P<0.0001).

Conclusions: Different growth factors induce different protein expression profiles in fibroblasts. Interestingly, ETP, which originates from the ECM, drives renal fibrosis through increasing COL I and III as well as fibrocollagen. This SiaJ model, combined with the investigated biomarkers of ECM formation, could be used to elucidate the mechanisms behind acute and sustained matrix production profiles.

FoxM1 Inhibition Ameliorates Renal Interstitial Fibrosis (RIF) by Decreasing Extracellular Matrix and Epithelial-to-Mesenchymal Transition
Wang Y. Hui,1,2 Qiaoling Zhou,1 1Xiagang Hospital, Central South University, Changsha, China; 2Department of Geriatrics, Guangzhou First People’s Hospital, School of Medicine, South China University of Technology, Guangzhou, China.

Background: FoxM1 is a transcriptional regulator involved in tumor development, pulmonary fibrosis, and cardiac fibrosis. However, its role in RIF has yet to be elucidated.

Methods: We established a TGF-β-stimulated human proximal tubular epithelial cell (HK-2) model in vitro and a unilateral ureteral obstruction (UUO)-induced rat RIF model in vivo. FoxM1 inhibition was achieved by siRNA interference in vitro and by injecting thiostrepton into UUO-induced RIF rats in vivo. The degree of renal damage and fibrosis were determined by pathological assessment via hematoxylin and eosin staining. Immunohistochemistry, western blots, and qPCR were used to determine the expression levels of FoxM1, Collagen I, E-cadherin, α-SMA, and Snail1.

Results: FoxM1 inhibition could ameliorate RIF and reduce the deposition of Collagen I. H&E staining revealed that renal structural damage, inflammatory cell infiltration, and ECM deposition were significantly attenuated by thiostrepton treatment in the UUO rats. FoxM1 downregulation significantly suppressed EMT, as evidenced by decreased protein and mRNA expression levels of α-SMA and Snail1 and a significant increase in protein and mRNA expression levels of E-cadherin.

Conclusions: FoxM1 inhibition could be a novel therapeutic strategy for the treatment of RIF.

PO0607
The Macrophage Recruitment in the Unilateral Ureteral Obstruction Is Associated with the Raise of MCP-1 and Is Dependent of Lipocalin 2 Expression
Stefanny M. Figueroa,1 Mauricio A. Lozano, Carolina A. Lobos, Javier I. Reyes Osorio, Patricio A. Araos, Cristian A. Amador. Laboratory of Renal Physiopathology Universidad Autonoma de Chile - Campus El Llano Suburbano, Santiago, Chile.

Background: The persistent renal inflammation has been proposed as a crucial mechanism at the early stages of renal disease. The macrophages recruitment, as part of the pathogenic events, depends of the monocyte chemotactarctant protein-1 (MCP-1) raise. In addition, studies in patients have demonstrated that neutrophil gelatinase-associated lipocalin (NGAL, also called Lipocalin-2), it is overexpressed during early stages of renal lesion. However, whether NGAL is relevant for macrophages recruitment at renal level, and if this is related to the increase of MCP-1, remains unknown. Our objective was to determine whether NGAL promotes the pro-inflammatory status during the unilateral ureteral obstruction (UUO), characterized by the macrophages recruitment and the increase of MCP-1.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Methods: Male C3HBL/6 Wild type (WT) y Nyal-KO mice (8-12 weeks) were used for experiments. Male Sham surgery (control group) or sham surgery (control group) was performed to determine the effect of CaSR in the development of fibrosis in UUO. The effect of CaSR activation and upregulation by Cinacalcet was limited, however, it restored the progression of fibrosis and impairment of Mgl reabsorption. CaSR may play a key role for the mg loss-related renal fibrosis.

PO0610
Fibroblast-Specific LRP-1 Promotes Renal Fibrosis
Ling Lin, Kebin Hu. Penn State University College of Medicine, Hershey, PA.

Background: LRP-1, a scavenger receptor up-regulated during obstructive nephrathy, has been shown to mediate the actions of multiple profibrotic factors including αIPα, TGF-β1, and CTGF. However, in the vivo role of LRP-1 in kidney fibrosis remains largely unknown.

Methods: We generated a novel fibroblast-specific LRP-1 knockout mouse (LRP-1+/−) and induced the unilateral ureteral obstruction (UUO), a classic model of chronic kidney disease (CKD), in these mice to investigate the in vivo role of LRP-1 in kidney fibrosis.

Results: It was found that LRP-1+/− mice had similar phenotype as their littermate controls (LRP-1+/+). However, after UUO injury, LRP-1−/− mice displayed significantly decreased fibrosis, as demonstrated by reduced renal collagen content and FSP-1 abundance, in comparison with their littermates. We further found that obstruction-induced epithelial damage was alleviated in LRP-1−/− mice. After UUO, LRP-1+/− mice displayed decreased E-cadherin and increased vimentin expression, suggesting that the podo-mesenchymal transition (EMT) was induced in the obstructed kidneys.

Intriguingly, LRP-1−/− mice showed significantly reduced EMT as demonstrated by restoration of E-cadherin and elimination of vimentin induction.

Conclusions: Thus, it is clear that fibroblast LRP-1 promotes kidney fibrosis through EMT.

PO0611
Essential Renal Tubular Proteins Are Lost by Excretion Within Novel Large Extracellular Vesicles During Chronic Renal Insufficiency
Ryan J. Adam, Mark Paterson, Brian R. Hoffmann, Alison J. Kriegel. Medical College of Wisconsin, Milwaukee, WI.

Background: Within weeks of surgery, the 5/6 nephrectomy (5/6Nx) rat spontaneously develops renal disease including tubular damage, brush border loss, and the production of very large extracellular vesicles present in the tubule lumen. These large renal tubule extracellular vesicles (LRT-EVs) are too large to be microsomes or exosomes, and lack markers of apoptotic bodies, and thus may represent an undescribed vesicle. We hypothesized that formation and excretion of these vesicles represents a pathological mechanism by which important tubule proteins are lost in chronic renal insufficiency.

Methods: We performed a longitudinal, histologic examination for the presence of LRT-EVs in renal tubules of 5/6Nx rats at all measured time points and stained for the presence of kidney fibrosis and the production of very large extracellular vesicles present in the tubule lumen. These large renal tubule extracellular vesicles (LRT-EVs) are too large to be microsomes or exosomes, and lack markers of apoptotic bodies, and thus may represent an undescribed vesicle. We hypothesized that formation and excretion of these vesicles represents a pathological mechanism by which important tubule proteins are lost in chronic renal insufficiency.

Results: Histologic examination revealed virtually no LRT-EVs in sham-operated rat tubules at any time point. LRT-EVs were present in 5/6Nx rat tubules at all measured time points including 2, 4, 5, 7, and 13 weeks following surgery, and exhibited a marked increase in percentage of tubule presence between week 5 (7.0 ± 2.7%) and week 7 (51.1 ± 6.5%). This increase temporally corresponds to a time of rapid progression of renal disease. Median LRT-EV diameter upon microscopic image analysis was 2.5 μm. Protopic analysis of isolated LRT-EVs revealed them to contain a wide array of functionally essential tubule proteins including but not limited to basolateral Na+/K+ ATPase subunits, sodium-glucose co-transporters, aquaporin 1, megalin, cubilin, and mitochondrial VDAC.

Conclusions: Loss of important tubule proteins through production and urine excretion of previously unidentified LRT-EVs may represent a hitherto unappreciated aspect of chronic renal insufficiency.

PO0612
Indoleamine-2, 3-Dioxygenase Activates Wnt/B-Catenin to Induce Kidney Fibrosis
Binbin Pan1, Changchun Cao1, Xin Fan2, Nanjing Medical University, Sir Run Run Hospital, Nanjing, China; 1Nanjing First Hospital, Nanjing Medical University, Nanjing, China.

Background: Dysorder of tryptophan metabolism catalyzed by indoleamine-2, 3-dioxygenase (IDO) is common in chronic kidney disease which manifests as increased kidney fibrosis. In addition, IDO is also reported to be involved in fibrosis of other organs while little is known about correlations of IDO and fibrosis in kidney disease.

Methods: Wild type (WT) mice and IDO−/− mice were employed. Mice in Sham group underwent exposure of renal artery while mice in AKI group received unique renal artery occlusion. Two weeks after surgery, and exhibited a marked increase in percentage of tubule presence between week 5 (7.0 ± 2.7%) and week 7 (51.1 ± 6.5%). This increase temporally corresponds to a time of rapid progression of renal disease. Median LRT-EV diameter upon microscopic image analysis was 2.5 μm. Protopic analysis of isolated LRT-EVs revealed them to contain a wide array of functionally essential tubule proteins including but not limited to basolateral Na+/K+ ATPase subunits, sodium-glucose co-transporters, aquaporin 1, megalin, cubilin, and mitochondrial VDAC.

Conclusions: Loss of important tubule proteins through production and urine excretion of previously unidentified LRT-EVs may represent a hitherto unappreciated aspect of chronic renal insufficiency.

PO0608
Enabled ICOS-RTE-Tresps Proliferation Is Involved in the Pathogenesis of Active Systemic Lupus Erythematosus (SLE)

Kathleen Kälble, Christian Nusshag, Frida Steinborn-Kroehl.1 Christian Steinborn-Kroehl.2

Background: Dysfunction of CD4+ regulatory T-cells (Treg) and CD4+responder T-cells (Tresps) is an important trigger in the development of active systemic lupus erythematosus. But decreased in active SLE patients compared to healthy control patients. In contrast, proliferation of ICOS+RTE-Tresps is medically inhibited in SLE but increased differentiation of ICOS+RTE-Tregs via resting MN-Tregs into CD31−recent RTE-Tresps is not inhibited but enabled in SLE.

Methods: To determine differences in the differentiation of inducible costimulatory molecule (ICOS)− and ICOS+Tregs/Tresps, their percentages of CD45RA CD3− recent thymic emigrant (RTE)-Treg/Tresps and CD45RA/CD3+ mature naive (MN)-Treg/Tresps as well as CD45RA CD3+ and CD45RA/CD3− memory-Treg/Tresps (CD3+ and CD3−-memory Tregs) within total Tregs/Tresps were calculated. Additionally, subsets were stained for the proliferation marker Ki67. 124 healthy control patients and 234 SLE patients in remission show an increased differentiation of ICOS−RTE-Tregs and ICOS−RTE-Tresps via resting MN-Tregs into CD31−memory Tregs compared to healthy control patients. In contrast, proliferation of ICOS−RTE-Tresps into CD31−memory-Tresps is inhibited. Similarly, active SLE patients show an increased differentiation of ICOS+RTE-Tregs and ICOS+RTE-Tresps via resting MN-Tregs. Moreover, proliferation ability of ICOS−RTE-Tresps is not inhibited but enhanced in these patients. Both SLE patients in remission and active SLE patients show an impaired ICOS−RTE-Tresps differentiation compared to healthy control patients. Therefore, the ratio of ICOS−Tregs/ICOS−Tresps within CD4−T-cells is significantly increased in both SLE remission and active SLE patients compared to healthy control patients. In contrast, the ratio of ICOS−Tregs/ICOS−Tresps is significantly increased in SLE remission patients, but decreased in active SLE patients compared to healthy control patients.

Conclusions: Proliferation of ICOS−RTE-Tresps is medically inhibited in SLE remission patients. In active SLE patients, proliferation is enabled decreasing the ICOS+Tregs/ICOS−Tresps ratio.

PO0609
Involvement of Calcium-Sensing Receptor in the Development of Interstitial Fibrosis
Akira Kurosawa, Kaori Takayanagi, Taisuke erao, Taisuke akayanagi. Department of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan.

Background: Physiological and pathophysiological role of renal Ca sensing receptor (CaSR) have not been well understood. We have reported the down regulation of CaSR in the development of renal interstitial fibrosis along with the down regulation of Myo-transporting molecules, suggesting that CaSR plays an important role in the development of renal damage associated with Mg deficiency. We report here an analysis of the effects of calcimimetics administration on renal fibrosis models.

Methods: The left kidneys of 8-week-old SD rats were ligated to create unilateral ureteral obstruction (UUO) model and studied after 7 days. Cinacalcet 1.0 mg/day, a calcimetics, was administered to a part of UUO animals. Experiments were performed in three groups of sham group, UUO group and UUO+Cinacalcet group (n=5). Fibrosis was evaluated by the Trichrome and analysis of the histopathological fibrosis-related molecules. We also studied on mRNA expression of Mg-transporting molecules. Results: It was confirmed from immunohistochemistry and gene expression that CaSR expression was remarkably decreased by UUO (RT-PCR: sham 1.01±0.09 vs UUO 0.04±0.03, n=5). Cinacalcet treatment partially rescued the expression in the remaining 30-50% compared to UUO group. In Azan staining, an increase in the fibrosis area and a decrease in the non-damaged tubules were apparent in UUO, however, Cinacalcet treatment partially rescued. mRNA expression of TGF-beta and MCP-1 was not significantly decreased by Cinacalcet treatment as compared to UUO group.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only. Underline represents presenting author.
calculated by the ratio of kynurenine and tryptophan. Correlations between indicators were analyzed. The ROC curve was also performed.

**Results:** WT AKI mice revealed elevated expression of IDO and worse kidney function. PAS staining exhibited less loss of tubular epithelial cells and atrophy tubules in IDO−/− AKI mice. Additionally, fibrosis markers, including α-SMA, fibronectin and vimentin, were more severer in WT AKI mice. GSK-3β and β-catenin were significantly decline in IDO−/− AKI mice. On top of that, PGE2 administration revealed reduced IDO expression and decreased levels of GSK-3β and β-catenin resulting in lower expressions of α-SMA, fibronectin and vimentin in WT AKI mice. In patients, IDO had negative correlations with eGFR (r=−0.742, p<0.001). Further, the linear regression showed IDO was an independent influence factor of eGFR. ROC curve showed the area under the ROC curve was 0.825 for IDO.

**Conclusions:** IDO could activate Wnt/β-catenin pathway to induce kidney fibrosis. PGE2 could ameliorate kidney fibrosis via inhibiting IDO expression.

**Human Induced Pluripotent Stem Cell-Derived Kidney Micro-Organoids for High Throughput Disease Modeling in Drug Discovery**

Santhosh V. Kumar,1 Anna Jonebring,2 Pernille B. Laerkegaard Hansen,3 Ryan Hicks,2 Kevin Woollard.1 AZ Kidney-organoids 2 Bioscience Renal, Research and Early Development Cardiovascular, Renal and Metabolism (CVRM) BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; 3 Translational Genomics, Discovery Sciences, R&D, AstraZeneca, Gothenburg, Sweden.

**Background:** Human kidney contains around 1 million nephrons, more than 2 dozen different cell types. Reproducing physiological kidney cell types in vitro is limited. Recent advancements in human iPSCs differentiation provide an opportunity to culture and utilize multicellular kidney structures “kidney-organoids”. We have employed a kidney micro-organoid in suspension culture this method eventually accelerates kidney organoids to the industrial scale and differentiates from traditional low throughput transplant well organoids. This method involves differentiation of iPSCs to intermediate mesoderm using CHIR and FGF9 and spontaneous aggregation in the swirler culture leads to mature to kidney organoids, this can be used to study kidney disease in a high-throughput manner.

**Methods:** We aimed to model human kidney inflammatory and genetic disease in vitro using kidney micro-organoids, treatment with different insults to reproduce CKD microenvironment eg. IL-1β, TGFβ, Angiotsensin-II and prostate sulphate.

**Results:** After 24h of stimulation, we noted significant upregulation of kidney injury biomarkers including KIM1 and inflammatory cytokines. Reproducing genetic diseases like PKD is very challenging in vitro, we show treatment of cultured micro-organoids with forskolin (to elevate intracellular cAMP) altered the transportation of ciliary proteins and promoted cyst formation, resembling human PKD. This observations clearly demonstrate the use of micro-kidney organoids to study renal diseases in vitro for drug discovery applications with human translatable functional biomarkers.

**Conclusions:** Impact statement: Kidney micro-organoids provide a platform for high throughput modeling of human kidney diseases related fibrosis, inflammation and genetic disease like polycystic kidney disease with human translatable biomarkers in drug discovery.

**CKD of Unknown Origin (CKDu): Is the Problem Dehydration, Water Contamination, or Both?**

Vito M. Campese,1 Alessia Fornoni,2 Yan Zhong,1 Keck School of Medicine of USC, Los Angeles, CA; 2University of Miami, Miami, FL.

**Background:** An increasing number of people of Central America develop CKDu. The disease is characterized by chronic tubulo-interstitial nephritis. Occasionally, it presents as an acute kidney injury (AKI). The cause(s) remain unknown. Some sustain that dehydration is responsible. Others believe the disease is caused by water contaminated with heavy minerals or agrochemicals. To prevent dehydration, workers in these regions ingest 8-12L of water/day. Hence, even if concentrations of toxins are in “acceptable range”, the cumulative intake may reach toxic levels. If this hypothesis is correct, purified water should reduce the incidence of the disease. In 2017 a Nicaraguan sugarcane factory (SER) adhered to the Adelante initiative, consisting of reducing working hours, exposure to heat and dehydration. In 2017-18, these measures had no impact on the incidence of AKIuo.

**Methods:** During the 2019 season, SER adopted the policy of providing highly purified drinking water > 6000 workers (11/hour during working hours). The effects on AKIuo were monitored. Comparisons were made of the monthly incidence of AKIuo during years 2017, 2018 and 2019, by One-way ANOVA.

**Results:** With the introduction of purified water, the incidence of AKI decreased from 4.0±1.3 cases in 2017 and 3.4±2.1 in 2018 to 2.0±1.5 cases/1000 workers/month in 2019 (P< 0.02).(Fig.1)

**Conclusions:** Although preliminary, these data support the hypothesis that contaminated water may play a major role in AKIuo. This raises enormous public health issues. If dehydration is responsible, the remedies are hydration and less heat exposure. If toxins and agrochemical are responsible, the remedy is providing highly purified water to those at risk. The potential impact of these measures on CKDu remains to be determined.

**Effects of Chronic Intermittent Hypoxia on umod-/- Rats’ Model Link to Alterations of Gut Microbiota**

Na Wang, Yuqing Chen. Renal division, Peking University First Hospital, Beijing, China.

**Background:** Previous studies showed that both obstructive sleep apnea and uromodulin (UMOD) were associated with gut microbiota regulation. Here we explored the interaction effects of chronic intermittent hypoxia (CIH) and UOMD expression on variation of gut microbiota and association with phenotype.

**Methods:** umod−/− and wild type (WT) Sprague Dawley rats were attributed into 4 groups (N=10 in each group), umod−/− and WT under CIH, umod−/− and WT under normal air. All four groups were fed with same chaw for 10 weeks. All rats were anesthetized to collect fecal samples from large intestine directly and blood at the end of weeks feeding. The bacterial composition was analyzed based on 16S ribosomal DNA pyrosequencing. Bioinformatics tools, including sequence alignment, abundance, and taxonomic diversity, were used in microbiome data analyses. Correlation analysis between differential genera and changed biochemical indicators were measured.

**PO0616**
Results: Under normoxia, the serum phosphorus (P*) tend to be lower in umod\(^{-}\) group compared with WT group (1.9±0.2 vs 2.1±0.2mmol/L, P=0.04). Under normoxia environment, the α-diversity of gut microbiota decreased in umod\(^{-}\) group compared with WT group (Chao1 index, 301.8±30.2 vs 374.3±55.3, P=0.005), and the composition of microbiota was clearly separated between two groups (PCoA, P<0.001). The abundance of g-Lactobacillus (P=0.002) and g-Phascolarctobacterium (P=0.026) increased and g-Ruminococcus (P=0.023) decreased in umod\(^{-}\) group compared with WT group. g-Ruminococcus showed positive relationship with serum phosphorus (R=0.511, P=0.043). When CIH was added as an environment condition, the serum phosphorus (P*) increased in umod\(^{-}\) group obviously (2.3±0.3 vs 1.8±0.2 mmol/L, P=0.002). Gut composition in umod\(^{-}\) were still clearly separated from WT (PCoA, P<0.001). The abundance of g-Lactobacillus, g-Phascolarctobacterium and g-Ruminococcus showed no difference. The abundance of g-Blautia (P=0.008), g-Sutterella (P=0.008), g-Anaerotruncus (P=0.008) increased and g-Flavonifractor (P=0.008) and g-Anaerostipes (P=0.008) decreased in umod\(^{-}\) CIH group compared with wild type CIH group. G-Sutterella showed positive relationship with Phosphorus (R=0.831, P=0.001).

Conclusions: Chronic intermittent hypoxia can interact with uromodulin to affect serum phosphorus in umod\(^{-}\) rats. These changes were strongly linked to the alterations in gut microbiota.

PO0616

Influence of Colonic Dialysis on the Distribution of Gut Microbiome in CKD Stage 3-5 Patients

Hui Xu, Department of Nephrology, Xiangya Hospital, Central South University, Changsha, China.

Background: Chronic kidney disease (CKD) becomes a major public health challenge given high incidence rates in the world. Colonic dialysis (CD) has been used in pre-dialysis CKD patients (CKD3-5) in many hospitals of China because of its advantages of simple operation, low price and few complications. The gut microbiome is a potential cause of CKD progression and serve as a promising therapeutic target. We raise the question that whether CD improve renal function by affecting intestinal microbiome in CKD3-5 patients. Improving the imbalance of intestinal microbiome is considered a potential therapeutic target to decline chronic kidney disease(CKD) progression. We aimed to investigate the influence of colonic dialysis(CD) on the distribution of gut microbiome in CKD3-5 patients.

Methods: We studied gut microbiota in 50 patients with CKD, 25 CD patients, 25 outpatients(OP), and compared to 34 healthy subjects(HS). The gut microbiome composition was analyzed by a 16S ribosomalRNA(16S rRNA) gene-based sequencing protocol.

Results: we found that there was no significant difference in the richness of intestinal microbiota between CD and HS, but the richness of bacterial in OP decreased significantly (HS VS. OP, p = 0.002). CD can increase the abundance of some short chain fatty acid(SCFA) producing bacteria and decrease the abundance of some enteric toxin producing bacteria. CD also can increase the abundance of some anaerobic bacteria in intestine. Compared with OP, the profile of intestinal microbiota in CD group and HS group was more similarity.

Conclusions: Our study reveals CD treatment alters microbiome profile and increases microbiome richness in CKD3-5.

PO0617

Asymptomatic Hyperuricemia, a Regulator of Innate Immunity in CKD

Stefanie Steiger,1 Qiuyue Ma,1 Paola Romagnani,2 Hans J. Anders.1 1Division of Nephrology, Department of Medicine IV; LMU Hospital, Munich, Germany; 2Department of Biomedical Experimental and Clinical Sciences Maria Serio, University of Florence, Florence, Italy.

Background: Asymptomatic hyperuricemia (HU) is common in patients with chronic kidney disease (CKD) but the causative role of HU on CKD progression remains controversial. Two large multi-center randomized controlled trials, CKD-FIX and PERL study, have now disproven a causal relation. On the other hand, a causative role of HU exists with gout but a rapid correction of HU with urate lowering therapy can also elicit acute gout attacks. This suggests a more complex role of HU in this context. Hence, we hypothesized that soluble uric acid (sUA) has immunomodulatory effects on neutrophil function during the immune response to monosodium urate (MSU) crystals.

Methods: Alb-creERT2;Glut9lox/lox and Glut9loxlox control mice were injected with tamoxifen and placed either on a chow or acidogenic diet with inosine to induce HU with or without CKD. After 3 weeks, MSU crystals or vehicle were injected into air pouches or postcapillary venules in the cremaster muscle of transgenic mice. Leukocyte infiltration and the extent of inflammation were assessed by flow cytometry, intravital microscopy, and ELISA. Blood neutrophils were isolated from CKD stage G2-4 and G5D patients or healthy individuals and neutrophil transwell migration assays performed.

Results: We found that HU impaired leukocyte recruitment into MSU crystal-injected air pouches of mice with or without CKD. Intravital microscopy revealed that HU specifically reduced leukocyte adhesion, extravasation, and tissue inflammation. The CKD-mediated attenuation of MSU crystal-induced inflammation was fully reversible by treating HU with urate lowering therapy. In neutrophils isolated from healthy individuals, sUA diminished β2 integrin activation and expression, and hence impaired neutrophil migration in vitro. This process was dependent on the intracellular uptake of sUA via the urate transporter SLC2A9/GLUT9. An impaired migratory capability was also observed in neutrophils from CKD patients.

Conclusions: We identify sUA as an endogenous modulator of innate immunity. HU modulates neutrophil migration by altering efficient β2 integrin activation via SLC2A9 in gouty arthritis related or unrelated to CKD. This process provides a molecular explanation for several previously unexplained clinical phenomena in the context of gout and renal failure.

PO0618

Serum Lysyl Oxidase Is a Potential Diagnostic Biomarker for Kidney Fibrosis
Xiaojin Zhang, Chen Yu. Department of Nephrology, Tongji Hospital, Tongji University, Shanghai, China, China.

Background: Kidney fibrosis is the ultimate consequence of advanced stages of chronic kidney disease (CKD); however, there are currently no reliable biomarkers or noninvasive diagnostic tests available for the detection of kidney fibrosis. Lysyl oxidase (LOX) promotes collagen crosslinking, and serum LOX levels have been shown to be elevated in patients with fibrosis of the heart, lungs and liver. However, serum LOX levels have not been reported in patients with kidney fibrosis. We explored whether serum LOX levels are associated with kidney fibrosis.

Methods: Overall, 202 patients with kidney disease underwent renal biopsy, scoring of kidney fibrosis and determination of the area of kidney fibrosis. LOX levels were measured in serum and in kidney tissues. We analyzed the association of circulating LOX and tissue LOX levels with the scores and areas of kidney fibrosis. LOX expression was also investigated in vitro and in vivo in kidney fibrosis models.

Results: Serum LOX levels were higher in patients with kidney fibrosis than in those without fibrosis (p<0.001) and higher in patients with moderate-severe kidney fibrosis than in patients with mild kidney fibrosis (p<0.001). Both serum LOX and renal tissue LOX levels correlated with the area of kidney fibrosis (r=0.44, p<0.001) and the prediction of kidney fibrosis (5.06, p<0.001). ROC curve analysis of serum LOX showed an AUC of 0.80 (95% CI 0.74 to 0.86). The optimal serum LOX level cutoff point was 253.34 µg/ml for the prediction of kidney fibrosis and 306.36 µg/ml for the prediction of moderate-severe renal fibrosis. LOX expression was significantly upregulated (2.3-2.6-fold and 6-fold, respectively) in vitro and in vivo in interstitial fibrosis models.

Conclusions: Both serum LOX and tissue LOX levels correlated with the presence and degree of kidney fibrosis in patients with CKD. These results suggest that serum LOX level has potential to be a noninvasive diagnostic biomarker for kidney fibrosis and may further potentially serve as a stratified biomarker for the identification of mild and moderate-severe kidney fibrosis.

Tubulointerstitial Fibrosis and Markers of Kidney Tubule Secretion
Pranav S. Garimella,1 Ronit Katz,2 Sushrut S. Waiker, Anand Srivastava,3 Insa M. Schmidt,4 Andrew N. Hoofnagle,5 Isaac E. Stillman,5 Ragnar Palsson,5 Helmut G. Rennke,5 Ke Wang,6 Bryan R. Kestenbaum,7 Joachim H. Is.,8 John M. Mawhinney,9 Diego, La Jolla, CA;1 University of Washington, Seattle, WA;2 Boston Medical Center, Boston, MA;3 Northwestern University, Evanston, IL;4 Beth Israel Deaconess Medical Center, Boston, MA;5 Landspitali, Reykjavik, Iceland;6 Brigham and Women's Hospital, Boston, MA.

Background: Tubular secretion plays an important role in the efficient elimination of endogenous solutes and medications, and lower secretory clearance is associated with risk of kidney function decline. We evaluated whether the biopsy measurement of tubular secretory clearance even after adjusting for eGFR and albuminuria.

Methods: Among 418 persons, the mean age was 53 years, 51% were women, 64% were White and 18% were African American. The mean eGFR was 50 ml/min/1.73m² and median album/creatinine ratio was 890 mg/g. Compared to individuals with no IFTA, those with IFTA had a 15% lower eGFR (p<0.001), 27 to 76% lower UPR for the all 9 solute markers (p<0.001, respectively). ROC curve analysis of serum LOX showed an AUC of 0.80 (95% CI 0.74 to 0.86). The optimal serum LOX level cutoff point was 253.34 µg/ml for the prediction of kidney fibrosis and 306.36 µg/ml for the prediction of moderate-severe renal fibrosis. LOX expression was significantly upregulated (2.3-2.6-fold and 6-fold, respectively) in vitro and in vivo in interstitial fibrosis models.

Results: Serum LOX levels were higher in patients with kidney fibrosis than in those without fibrosis (p<0.001) and higher in patients with moderate-severe kidney fibrosis than in patients with mild kidney fibrosis (p<0.001). Both serum LOX and renal tissue LOX levels correlated with the area of kidney fibrosis (r=0.44, p<0.001) and the prediction of kidney fibrosis (5.06, p<0.001). ROC curve analysis of serum LOX showed an AUC of 0.80 (95% CI 0.74 to 0.86). The optimal serum LOX level cutoff point was 253.34 µg/ml for the prediction of kidney fibrosis and 306.36 µg/ml for the prediction of moderate-severe renal fibrosis. LOX expression was significantly upregulated (2.3-2.6-fold and 6-fold, respectively) in vitro and in vivo in interstitial fibrosis models.

Conclusions: Both serum LOX and tissue LOX levels correlated with the presence and degree of kidney fibrosis in patients with CKD. These results suggest that serum LOX level has potential to be a noninvasive diagnostic biomarker for kidney fibrosis and may further potentially serve as a stratified biomarker for the identification of mild and moderate-severe kidney fibrosis.

Proximal Tubule Albumin Uptake: Potential Role for Endothelin System in Sickle Cell Disease Patients
Malgorzata Kasztan, David M. Pollock. University of Alabama at Birmingham, Birmingham, AL.

Background: Elevated plasma endothelin-1 (ET-1) reported in sickle cell disease (SCD) patients correlate with microalbuminuria, a major mortality risk factor in SCD. ET-1 contributes to glomerular and tubular injury in SCD, as evidenced by increased glomerular permeability to albumin and urinary excretion of tubular injury markers. Although selective ET<sub>α</sub> receptor antagonism reduces albuminuria in humanized sickle cell (HbSS) mice, the mechanism of this action remains unclear. The aim of the study was to determine whether selective ET<sub>α</sub> receptor antagonism preserves albuminuria by preserving the expression of proximal tubular albumin-associated transporters in proximal tubule (PT) cells.

Methods: Male C57BL/6 and HbSS and genetic control (HbAA) mice were used to determine the effect of ET-1 on the expression of proximal tubule albumin trafficking mediators, such as megalin and NHE-3.

Results: Exposure of primary mouse PT cells to ET-1 (50µM) for 8 decreased megalin (53% reduction) and doubled NHE-3 expression. Pre-treatment with the ET<sub>α</sub> antagonist, BQ123 (1 µM), preserved megalin expression and had no effect on NHE-3. Moreover, selective ET<sub>α</sub> receptor blockade (BQ788, 1 µM) prevented ET-1-mediated increase in NHE-3 expression. Primary PT cells isolated from HbSS mice showed decreased megalin mRNA expression as well as protein abundance relative to HbAA PT controls. Ten-week treatment with selective ET<sub>α</sub> receptor antagonist (10mg/kg/day) preserved expression of megalin at control levels. There were no differences in NHE-3 mRNA expression in HbSS PT cells regardless the treatment. Interestingly, PT cells from HbSS cultured with HbSS plasma and ET-1 (10µM) had decreased NHE-3 protein abundance compared to non-treated cells.

Conclusions: These results potentially uncover a novel role for ET-1 in PT albumin trafficking. We suggest that PT ET-1 receptor signaling contributes to albuminuria in SCD.

APOL1 Risk Variants Mediate Increased Oxidative Phosphorylation Complexes Biogenesis and Mitochondrial Dysfunction

Mengyuan Ge,1 Gloria Michelle Ducasa,1 Shamroop Kumar Mallela,1 Shaoyi Liu,2 Hazel H. Szeto,2 Jeffrey B. Kopp,2 Flavia Fontanesi,3 Sandra M. Merscher,2 Alessia Fornoni,4 Katz Family Division of Nephropathy and Hypertension/ Drug Discovery Center, University of Miami, Miami, FL;5 Social Profit Network Research Lab, Alexandria LaunchLabs, New York, NY;6 Kidney Disease Section, NIDDK, NIH, Bethesda, MD;7 Department of Biochemistry and Molecular Biology, University of Miami, Miami, FL.

Background: Susceptibility to focal segmental glomerulosclerosis (FSGS) in African Americans is associated with genetic variants of the Apolipoprotein L1 gene (APOL1) named G1 and G2. APOL1 risk variants (RV) are a major driver of mitochondrial dysfunction. The mitochondrial specific lipid cardiolipin (CL) interacts with oxidative phosphorylation (OXPHOS) complexes and plays an important role in the biogenesis of OXPHOS complexes. While APOL1 functionality was assessed in targeted and overexpressed systems, studies evaluating the functions of endogenous APOL1 protein are missing.

Methods: We studied mitochondrial function using human urinary podocyte-like epithelial cells (HUPECs) established from patients with FSGS carrying different APOL1 alleles. Protein and mRNA levels were measured by WB and quantitative PCR respectively. TEM was performed to study mitochondrial morphology. OXPHOS complexes were studied by BN-PAGE analysis followed by WB. To study how APOL1 RV contributes to mitochondrial dysfunction, we purified APOL1-6xHis protein using HeLa cells infected with lentivirus carrying the APOL1 G0, G1 under the CMV promoter, followed by protein-lipid overlay assay.

Results: The expression of endogenous APOL1 was decreased in HUPECs carrying RVs (G1/G2 HEUPECs) when compared to G0/G0 carrying HEUPECs. We observed reduced mitochondrial function in the presence of increased OXPHOS complexes in G1/G2 HEUPECs. Using TEM, reduced mitochondrial matrix density and increased mitochondrial area were detected in G1/G2 HEUPECs. Hyperbranched mitochondria in G1/G2 HEUPECs were identified by the mRNA levels of mitochondrial fission and fusion proteins FIS1 and MFN1. The affinity of APOL1 G1 to CL was significantly higher than the affinity of APOL1 G0 to CL, when normalized to 6xHis tagged APOL1 expression. We found the mRNA level of cardiolipin synthase (CRLS1) was significantly increased in G1/G2 HEUPECs, which is consistent with the overexpression of OXPHOS complexes in G1/G2 HEUPECs.

Conclusions: Our findings indicate that endogenous APOL1 RV expression in human podocytes is associated with mitochondrial dysfunction in the presence of increased OXPHOS complexes, and that APOL1 RVs interact with CL thus interfering with CL function in mitochondria.

Uncovering Genomic Alterations in DOCA-Salt Nephropathy Rats Treated with Finerenone

Junnan Wu,1 Ziyuan Ma,1 Hana Cernecka,2 Ralf Leschke,1 Peter Kolkhoz,1 Katalin Susztak,1 University of Pennsylvania, Philadelphia, PA;1 Bayer AG, Leverkusen, Germany.

Background: The aldosterone antagonist spironolactone has antibiotic effects but its clinical use is limited due hyperkalemia, especially in patients with kidney disease. The cellular mechanism behind mineralocorticoid action and interrelated function has recently been developed with pronounced antibiotic activity at doses which have only limited effect on the potassium homeostasis. The exact molecular transcriptional targets of spironolactone and finerenone, however, remain unknown. Since there are more than 20 different receptor subtypes in vivo, single cell RNA and single cell epigenome (ATAC) analysis can help to define transcriptional targets.

Methods: We treated uninephrectomized, Sprague-Dawley rats injected with DOCA and spironolactone group. Single-nuclei open chromatin and gene expression analysis highlighted transcriptional targets of aldosterone, spironolactone and finerenone.

Funding: NIDDK Support, Commercial Support - Bayer AG

Cell Type-Specific Chromatin Architecture Reveals Target Genes for Kidney Disease Risk Variants

Jingping Yang,1,2 Aiping Duan,1 Zhihong Liu,2 1National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing, China;2 Nanjing University, Nanjing, China.

Background: Although GWAS studies have identified hundreds of genetic variants associated with kidney diseases, the identification of causal variants and their target genes are rather limited. Most of disease-associated variants locate in non-coding elements. The roles of these elements are cell type-specific. Additionally, due to the non-linear regulation of the elements, the identification of causal variants as well as their target genes is even more challenging.

Methods: In order to understand the genetic risk of kidney diseases, we generated a cell type-specific set of epigenomic landscape including transcription-centered 3D chromatin organization, histone modifications distribution and transcriptome with HiChIP, ChIP-seq and RNA-seq respectively, in kidney tubule cells. We integrated the epigenetic annotation to identify causal variants and target genes which were further tested by CRISP techniques in zebrafish.

Results: We identified genome-wide functional elements and thousands of interactions between the distal elements and target genes. The results revealed that risk variants for renal tumor and chronic kidney disease were enriched in kidney tubule cells. We further pinpointed the target genes for the variants and validated two target genes by CRISP techniques in zebrafish, demonstrating that SLC24A1 and MTX1 were indispensable genes to maintain kidney function.

Conclusions: Our results produce valuable multi-omic resource and establish a bioinformatic pipeline in dissecting functions of kidney diseases-associated variants based on cell type-specific epigenetic landscape.

A Comprehensive Transcriptome Profiling of Adipocyte Na-K-ATPase Signaling in Uremic Cardiomyopathy by RNA Sequencing Analysis

Komal Sodhi, Joan C Edwards School of Medicine at Marshall University, Huntington, WV.

Background: Oxidant stress plays a key role in the development and progression of uremic cardiomypathy. We have recently demonstrated that adipocyte dysfunction and uremic cardiomyopathy developed in partial nephrectomy mouse model, were significantly ameliorated by adipocyte-specific expression of NaKtide, an antagonist of Na-K-ATPase signaling. Hence, to better characterize the cellular transcriptome that are involved in various biological pathways associated with adipocyte function, we aim to explore the genomic approach in the present study, through RNAseq analysis.

Methods: For in vitro studies, mouse adipocytes were subjected to oxidized LDL (oxLDL) or index suflate (IS) with or without pNaKtide treatments. Partial nephrectomy was performed in C57Bl6 mice in order to produce experimental uremic cardiomyopathy. Specific expression of NaKtide in adipocytes was achieved using a lentivirus construct driven by an adiponectin promoter. A complete RNAseq analysis was performed using DESeq2 R package in combination with packages to perform over-representation analysis (ORA) and gene set enrichment analysis (GSEA).

Results: Several gene subsets corresponding to various biological processes and molecular phenotype were differentially expressed in adipocytes with in vitro oxLDL-IS treatments and in vivo PNX model. These genes, compared using GSEA analysis, showed that more than 75% of the Kegg pathways were similar among the in vitro treatments and in vivo model. The pathways that were common between in vitro and in vivo treatments, including adipogenesis, ROS signaling, inflammatory response and drug-induced apoptosis and drug metabolism contribute the profound impact on the pathogenesis of uremic cardiomyopathy. The overall analysis showed a widespread normalization of gene expression by pNaKtide/adipose specific NaKtide treatments that were altered in uremic cardiomyopathy.

Conclusions: The study provides a detailed genome-wide molecular information about adipocyte function in relation to uremic cardiomyopathys pathogenesis. These data provide deeper insight into the activation of pathways associated with adipocyte Na-K-ATPase signaling, which may be a viable clinical target for the prevention and treatment of uremic cardiomyopathy.

Transcriptomic Profiling Identifies Potential Mediators of Tubular Injury Sensitization of Glomeruli to Subsequent Second Hits

Janka Babickova,1,2 Xin Li,1 Haiunch Yang,1 Agnes B. Fogo,1 1Vanderbilt University Medical Center, Nashville, TN;1 Universitetet i Bergen, Bergen, Norway;3 Shanghai Jiao Tong University, Shanghai, China.

Background: Previous studies have shown that even isolated mild tubular injury leads to more severe glomerular damage in response to subsequent injury. The responsible mediators for this sensitization are unknown.

Methods: Double transgenic male mice, Nep25/DTR: 1 expressing human CD25 receptor on podocytes and Diphtheria toxin receptor on proximal tubular cells) and Nep25/DTR (n=5 per group) were used. Tubular injury was induced by injecting diphtheria toxin, followed by uninephrectomy (Nx) 4 weeks later and induction of glomerular injury

Funding: Private Foundation Support
by LMB2 toxin (CD25 ligand) one week after Nx. Mice were sacrificed 4 weeks after LMB2. Glomeruli and tubules from Nx were separated by sieving technique, RNA was isolated from tubules and next generation RNA sequencing was performed.

Results: Histopathological analysis and urinary Kim-1 at Nx and sacrifice confirmed mild tubulointerstitial fibrosis at Nx in Nep25/DTR+ but not Nep25/DTR- mice, and more severe glomerulosclerosis and albuminuria at sacrifice after LMB2 in Nep25/DTR+ vs Nep25/DTR- mice. RNA sequencing revealed 283 differentially expressed genes between the groups, with 93 over-represented and 190 under-represented in Nep25/DTR+ vs Nep25/DTR-. GO of biological processes showed involvement in 13 processes, with the highest amount of genes involved in cellular processes, biological regulation, and metabolic processes. STRING analysis of protein-protein interactions (PPI) based on cellular processes detected interactions between the Serpin family members: plasminogen activator inhibitor PAI-1 (Serpine1), alpha-1-antitrypsin 1-2 (Serpin1b), protein Z-dependent protease inhibitor (Serpine10) and complement C4b (C4b).

In addition, members of the non-canonical Wnt signalling pathway Wnt-9a (Wnt9a) and Wnt-10a (Wnt10a) and their interactors latent transforming growth factor beta binding protein 2 (Ltbp2) and VANGL planar cell polarity protein 2 (Vangl2) were over-represented and PPI of these genes was found. Quantitative real-time PCR confirmed numerically higher expression of all above-mentioned genes in Nep25/DTR+

Conclusions: High-throughput RNA sequencing of isolated tubules with mild injury revealed potential novel mediators of glomerular sensitization to a subsequent injury. Further experimental validation of the effects of the identified molecules on glomerular injury are warranted.

A Novel Short ACE2 Variant Causes ACE Suppression and Fosters Ang 1-7 Formation in a Murine Model of CKD
Gvantača Guluc,1,2 Jan Wysocki,1 Arndt Schulze,1,2 Minghao Ye,1 Chad R. Haney,1 Ming Zhao,1 Zheng J. Zhang,1 Daniel Batlle,1 Northwestern University Feinberg School of Medicine, Chicago, IL; 2Charite Universitätsmedizin Berlin, Berlin, Germany.

Background: ACE2 is a monocarboxypeptidase that cleaves Ang II to form Ang-(1-7). It is a large molecule the administration of which leads to increased enzyme activity in plasma, but not in the urine or kidney tissue. We have developed a truncated form of ACE2 that has a longer half-life by fusing it with an Albumin-binding domain (ABD) and is still short enough to be filtered by the kidney. In this study we examined the impact of this novel variant of ACE2 on kidney RAS in a model of CKD.

Methods: We used a 5/6 Nephrectomy model in CD-1 mice. The ACE2-ABD was given 3 days post-ablation surgery and thereafter every 3-4 days (3 ug/g BW) for 5 weeks. Afterwards, mice were euthanized and kidneys collected for analyses of RAS components.

Results: Administration of ACE2-ABD resulted in increased plasma ACE2 activity (768 vs. 12 RFU/ug/hr, p<0.0001). In kidney lysates there was also an increase in ACE2 activity (32 vs. 22 RFU/ug protein/hr, p=0.03) and a decrease in ACE activity (7187 vs. 4006 RFU/ug protein/hr, p=0.0014) without a significant change in Ang II levels (272 vs. 299 fmol/mg protein). To verify the kidney uptake of our ACE2 variant SPECT/Micro-CT imaging was performed. After the injection of radiolabeled ACE2-ABD kidney uptake was clearly seen (red) (Figure).

Conclusions: A long-acting form of a short ACE2 variant fused with ABD given every 3-4 days resulted in sustained plasma ACE2 activity and an increase in kidney ACE2 activity associated with suppressed kidney ACE activity. These enzymatic changes provide a favorable kidney RAS profile with increased Ang-(1-7), which overall should be renoprotective.

Disruption of the H3K4 Methyltransferase MLL-1/Menin Complex Attenuates Renal Fibrosis Development by Inhibiting Epithelial-Mesenchymal Transition and Fibroblast Activation
Jianan Zou, Shougang Zhuang. Rhode Island Hospital, Brown University Rhode Island Hospital, Brown University, Providence, China.

Background: The MLL-1/menin was disrupted by MI-503 and/or siRNA in a murine model of renal fibrosis induced by unilateral ureteral obstruction (UUO), cultured mouse proximal tubular cells and fibroblasts exposed to serum and transforming growth factor β1 (TGFβ1). Protein expression or activation was determined by immunofluorescent microscopy and immunoblot analysis.

Methods: The MLL-1/menin was disrupted by MI-503 and/or siRNA in a murine model of renal fibrosis induced by unilateral ureteral obstruction (UUO), cultured mouse proximal tubular cells and fibroblasts exposed to serum and transforming growth factor β1 (TGFβ1). Protein expression or activation was determined by immunofluorescent microscopy and immunoblot analysis.

Results: Injury to the kidney increased MLL1 and menin expression and H3K4 monomethylation (H3K4me1) in renal tubular epithelial cells and fibroblasts. Administration of MI-503, a highly selective inhibitor of the MLL1/menin complex, attenuated renal fibrosis and expression of α-smooth muscle actin, fibronectin and collagen I. Treatment with MI-503, MLL1 siRNA or menin siRNA also inhibited TGFβ1 and serum-induced activation of epithelial-mesenchymal transition (EMT) in vitro. Moreover, UUO injury induced epithelial expression of phospho-histone 3 at Serine 10 and expression of profibrotic factors, TGFβ1 and connective tissue growth factor; and blocking the MLL1/menin complex with MI-503 inhibited these responses. Finally, MLL1 inhibition reduced expression of snail and twist, two transcription factors involved in the development of EMT and renal fibrosis and the expression of proliferating cell nuclear antigen, cyclin D1 and p27 in fibroblasts.

Conclusions: Our data suggest that targeting disruption of the MLL1/menin complex can attenuate renal fibrosis through inhibition of EMT and fibroblast activation/proliferation.

Transcriptomic Profiling of Thick Ascending Limb Cells In Vivo Reveals the Complex Network of Genes Regulated by Uromodulin

Kaice A. LaFavers, Sheh naz Khan, Nida A. Khan, Laura Apple, Radmila Micanovic, Tarek M. El-Achkar. Indiana University School of Medicine, Indianapolis, IN.

Background: Tamm-Horsfall Protein (THP or Uromodulin, gene: Umod) is a protein uniquely made in the kidney by cells of the thick ascending limbs (TAL) of the loop of Henle. We previously established that THP has protective biological functions. Furthermore, THP production is decreased with chronic kidney disease (CKD). It was suggested that the promoter region of the Umod can regulate other genes. THP deficiency itself could alter the expression of other genes. Here, we used an unbiased approach to study the effect of a deletion in the Umod promoter/gene and the resultant THP deficiency on the transcriptomic profile of TAL cells in vivo.

Methods: THP- mice resultant from deletion of exons 1-4 and part of the Umod promoter were used, along with THP+ controls. Immuno-fluorescence guided laser microdissection was performed to isolate TAL cells from the medulla of kidneys of THP- and THP+ mice. After RNA extraction, next generation RNA sequencing and transcriptomic analysis was performed.

Results: The transcriptomic profile of medullary TAL cells was comprehensively defined in vivo. 85% of the top 250 expressed genes were common between THP- and THP+ TAL cells. Overall, 33 protein-coding genes, including Umod, were differentially expressed (FDR<0.05). These encompassed genes with a variety of functions such as immunomodulation (Erdj1, Gp2), cytoskeletal/extracellular matrix fibers (Lamal, Ctnbp2) and signal transduction (Camkb2, Ppren2). One down-regulated gene was a direct neighbor to the Umod locus (Gp2) on chromosome 7. However, many other affected genes were on different chromosomes. Bioinformatic analysis revealed that THP deficiency is associated with significant clustering of genes involved in connective tissue formation and activation or dysfunction of molecular mechanisms that could lead to fibrosis.

Conclusions: We delineated a comprehensive transcriptomic profile of TAL cells in vivo from mouse kidneys. Although highly expressed genes in TAL may not be altered by THP deficiency, many close and distant genes are regulated by the Umod locus or altered by the absence of THP. The absence of THP may also prime the TALs cells towards a fibrosis program. These findings may contribute to understanding the pathogenesis of CKD progression.

Lipid Metabolic Profiling of Ex Vivo Isolated Glomeruli as a Screening Platform for Modelling Glomerular Metabolic Dysfunction During Renal Disease

Simone Roncoli,1 Lynn N. Krause,2 J’homiliton, L. Griffin,2 Pernille B. Laerkegaard Hansen,1 Kevin Woollard.1 Renal Bioscience ex-vivo glomerular team 1Bioscience Renal, Research and Early Development, Cardiovascular, Renal and Metabolism (CYRM), BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; 2University of Cambridge Department of Biochemistry, Cambridge, United Kingdom.

Background: Dysregulated renal metabolism is a hallmark of loss of function in CKD. It is established that changes in tubular metabolism impact tubular functionality during progression of CKD. However, lipid metabolism in the glomerulus during CKD remain poorly described. Here, we use Isolated Glomeruli (IRG) to study lipid metabolism for metabolic drug discovery in kidney diseases.

Methods: Sprague Dawley rat glomeruli were isolated by differential sieving. We used retrobulbar anaesthesia with ADR and AngII for 24h. To probe metabolic activity, we used an LC-MS approach to quantify uptake and excretion rates of relevant metabolites in culture media, and to measure intracellular metabolites and lipids.

Results: We developed a new cultivation protocol for IRG, using organoids media and shaking platform to maximizing the biological activity. Metabolic and lipidomic profiles of IRG were monitored up to 150h. We saw significant metabolic activity for a wide range of metabolites: Uptake and excretion rates changed during the first 24h of culture, after which they declined. Metabolic rates for glutamate, glutamate and alanine were comparatively stable. Following treatment with AngII or ADR glomeruli exhibited metabolic changes after 24h: AngII reduced asparagine uptake, and induced trends towards lower substrate uptake consistent with reduced metabolic activity. Both ADR and AngII perturbed intracellular metabolic levels: nucleosides adenosine (+159%), and inosine (+171%), increases in 1,3-BPG (+194%), and changes in NAD (+209%), which suggest alterations in pentose phosphate pathway. Multivariate analysis revealed differentially responding lipid clusters: specifically, significant abundance and saturation ratio increases of intracellular FFA, including stearate (+34%), oleate (+102%) and arachidonate (+107%), as well as the depletion of several phosphatidylethanolamine species following AngII, which have been implicated as renal injury markers and/or relevant to renal injury protection.

Conclusions: Our results show alterations in lipid metabolism after IRG stimulation with AngII and ADR after 24h. We propose IRG lipid metabolome as a novel platform tool for understanding lipid signalling and improving CKD drug discovery.

Angiotensin II Type 1a Receptor Loss Ameliorates Chronic Tubulointerstitial Damage After Renal Ischemia Reperfusion

Yoko Fujita, Takeshi Sugaya, Daisuke Ichikawa, Jun Tanabe, Kenjiro Kimura, Yugo Shibagaki, Atsuko Ikemori, Division of Nephrology and Hypertension, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan; 2JCTO Tokyo Takanawa Hospital, Tokyo, Japan; 3Department of Anatomy, St. Marianna University School of Medicine, Kawasaki, Japan.

Background: Although angiotensin II (Ang II) type 1 receptor blocker was reported to attenuate chronic tubulointerstitial damage (TID) after renal ischemia reperfusion (IR), its effect is limited. The aim of this study is to reveal whether suppressed activation of Angiotensin II type 1a receptor (AT1a) ameliorates severe chronic tubulointerstitial damage (TID) after renal ischemia reperfusion (IR).

Methods: To induce severe chronic TID after IR, unilateral renal ischemia for 45 min was performed via clamping of right renal pedicle using cerebral aneurysm clip in AT1a knockout homo (AT1a−/−) male mice and wild type (AT1a+/+) male mice. Right and left kidneys were removed at 3, 28 and 70 days postischemia. Left kidneys were used as control. Furthermore, another AT1a−/− mice were administered hydralazine to maintain the same levels of systolic blood pressure (SBP) as the AT1a+/+ mice because the SBP levels of the AT1a−/− mice were significantly lower compared to the AT1a+/+ mice.

Results: Acute tubular necrosis in IR-kidneys of both AT1a−/− mice and AT1a+/+ mice was observed at 3 days postischemia, and the degree was significantly more severe in the IR-kidneys of AT1a−/− mice than in the IR-kidneys of AT1a+/+ mice. Conversely, the degrees of both interstitial fibrosis at 28 and 70 days postischemia and proximal tubular loss at 70 days postischemia were significantly attenuated in the IR-kidneys of AT1a−/− mice compared to the AT1a+/+ mice. While marked renal atrophy at 70 days postischemia was induced in the AT1a+/+ mice, such a development was not provoked in the AT1a−/− mice. Although the administration of hydralazine in the AT1a−/− mice mildly attenuated the degree of TID at 70 days postischemia, the degree of the AT1a−/− mice was significantly greater compared to the AT1a+/+ mice.

Conclusions: Early administration of Ang II type 1 receptor blocker in recovery phase after AKI may be useful for prevention of AKI-to-CKD transition.

Anti-Interleukin 22 Antibody Relieves Angiotensin II-Induced Renal Injury in Mice Through Inhibiting NLRP3 Inflammasome Activation

Rong Tang, Xiaoying Hospital Central South University, Changsha, China.

Background: Interleukin-22 (IL-22) is considered as a proinflammatory cytokine and participates in the pathogenesis of autoimmune and inflammatory diseases. Previously, we found that serum IL-22 increased significantly in hypertensive renal damage patients, and IL-22 was positively correlated with renal damage. The aim of this study was to investigate whether anti-IL-22 antibody exerts renoprotective effect via inhibiting NLRP3 inflammasome activation in angiotensin II (Ang II) induced hypertensive renal damage in mice.

Methods: Ang II was infused subcutaneously at a rate of 1.5 mg/kg/d to C57BL/6 mice for 28 days to establish the hypertensive model. One day after modeling, mice were injected intraperitoneally every other day with saline, recombinant mouse IL-22 (rIL-22; 20 μg/kg), mouse anti-IL-22 monoclonal antibody (anti-IL-22 mAb; 1.25 μg/mouse) or isotype IgG. So mice were divided into 5 groups: control, Ang II, Ang II+rIL-22, Ang II-anti-IL-22, Ang II-IgG. 28 d after Ang II infusion, all mice were euthanized. Blood pressure, urinary albumin/creatinine ratio, serum creatinine (Scr) and renal histopathology were measured. NLRP3, cleaved caspase-1 and IL-1β in kidney were detected by western blot. Renal inflammatory factors were detected by ELISA, IL-22 and IL-22R1 in kidney were detected by western blot.

Results: IL-22 and IL-22R1 Levels were elevated in kidney of Ang II-induced mice. Anti-IL-22 mAb therapy ameliorated proteinuria excretion, Scr and renal pathological damage in mice with established hypertensive renal injury. Blood pressure in Ang II-infused mice was also decreased after the treatment of anti-IL-22 mAb. In addition, anti-IL-22 mAb reduced NLRP3, cleaved caspase-1, IL-1β, TNF-α and IL-6 expression in kidney, along with inhibition of renal fibrotic related factors expression.

Conclusions: Anti-IL-22 antibody can reduce renal inflammation and fibrosis in Ang II-induced hypertensive mice, which may be through suppression of NLRP3/caspase-1/IL-1β pathway, suggesting it might exert therapeutic potential for the treatment of hypertensive renal injury.

**Soluble Uric Acid, a Negative Regulator of Monocyte Activation in Innate Immunity**

Stefanie Steigig, Qiuyue Ma, Maja Lindenmeyer, Paola Romagnani, Hans J. Anders. Division of Nephrology, Department of Medicine IV, LMU Hospital, Munchen, Germany; Department of Medicine III, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; Department of Biomedical Experimental and Clinical Sciences Maria Serio, University of Florence, Florence, Italy.

**Background:** While monosodium urate (MSU) crystals are known to trigger acute inflammation in gouty arthritis, soluble uric acid (sUA) in this context is discrepant. We hypothesized that diverse sUA preparation methods account for this discrepancy and that a novel animal model with clinically relevant levels of asymptomatic hyperuricemia (HU) and gouty arthritis can ultimately clarify this issue.

**Methods:** Soluble UA was prepared either by pre-warming or solubilized with NaOH. THP-1 cells or CD14+ monocytes from patients with HU and healthy individuals were pre-incubated with sUA prior to stimulation with MSU crystals or LPS. Intracellular sUA uptake via urate transporters was quantified using siRNA technology. In vitro, Alb-creERT2; Glut9lox/lox and Glut9creERT2; Alb-creERT2; Glut9lox/lox control mice were injected with tamoxifen and placed on a Chow diet with no sUA to induce HU. After 3 weeks, MSU crystals or vehicle were injected into air pouches, and leukocyte infiltration and the extent of inflammation were assessed by flow cytometry, RT-PCR, ELISA.

**Results:** We found that pre-warmed UA created erroneous results because of microrystal contaminants triggering IL-1β release. Solubilizing UA with NaOH avoided such artifact. This microrystal-free preparation suppressed LPS- or MSU crystal-induced monocyte activation, a process dependent on the intracellular uptake of sUA via the urate transporter SLC2A9/GLUT9. CD14+ monocytes isolated from HU patients were less responsive to inflammatory stimuli compared to monocytes from healthy individuals. Treatment with plasma from HU patients impaired the inflammatory function of CD14+ monocytes, an effect fully reversible by removing sUA from HU plasma with rasburicase. Moreover, Alb-creERT2; Glut9lox/lox mice with HU (serum UA of 9-11mg/dL) showed a suppressed inflammatory response to MSU crystals compared to Glut9lox/lox controls without HU.

**Conclusions:** We unravel a technical explanation for discrepancies in the published literature on monocyte responses of sUA and identify HU as an intrinsic suppressor of innate immunity, where sUA modulates the capacity of monocytes to respond to danger signals. Thus, sUA is not only a substrate for the formation of MSU crystals but also an inhibitor without HU.

**PP2A Increases Macrophage Accumulation and Activation to Accelerate Tubular Cell Death and Kidney Fibrosis Through Regulating Rap1 and TNFα Production**

Yun Liang, Chunsun Dai. Nanjing Medical University, Nanjing, China.

**Background:** Macrophage accumulation and activation play an essential role for kidney fibrosis, the underlying mechanisms remain to be explored.

**Methods:** Analyzing the kidneys of patients and animal models with kidney fibrosis. Generating the mice with macrophage PP2ACre ablation.

**Results:** We observed a significantly increased induction of PP2Acre in macrophages. We then generated mice with macrophage-specific deletion of PP2Acre. These mice developed less renal fibrosis as indicated by less macrophage accumulation, tubular atrophy or extracellular matrix deposition. In cultured cells, the deficiency of PP2Acre in macrophages resulted in decreased cell motility by inhibiting the activity of Rap1. Furthermore, TNFα production was downregulated in macrophages with PP2Acre-deficiency and co-culture of PP2Acre-deficient macrophages and renal tubular cells resulted in less tubular cell death, which was due to decreased TNFα production via phosphorylation of STAT3 in macrophages.

**Conclusions:** This study shows that PP2A promotes macrophage accumulation and activation, hence accelerating tubular cell death and kidney fibrosis through regulating Rap1 and TNFα production.

**Funding:** Government Support - Non-U.S.

**Investigating LOX and Its Role in AT1R-β-Arrestin Biased Signaling Pathway-Induced Renal Interstitial Fibrosis**

Xiaojin Zhang, Chen Yu. Tongji University, Shanghai, China Department of Nephrology, Tongji Hospital, Tongji University, Shanghai, China, Shanghai, China.

**Background:** We studied the downstream and mechanism of β-arrestins signaling in renal fibrosis process and the role of lysyl oxidase (LOX) in the AT1R-β-arrestin pathway. Moreover, in normal rat kidney tubule epithelial cells (NRK-52E) treated with SII in vitro, inhibition of JMD3 activity reduced EC proliferation and migration. Suppression of JMD3 enhanced the level of histone H3K27me3 promoting its binding to the promoter of EC markers (VE-cadherin and eNOS). These responses resulted in EndMT and VSMC proliferation. Moreover, the expression of JMD3 is reduced through TGFβ1/β-arrestin-1 signaling pathway. In AVFs from ESRD patients, the decreased expression of JMD3 in ESRD patients was associated with endothelial dysfunction, EndMT, and ECM deposition plus neointimal hyperplasia. Remarkably, endothelial expression of Hes1 in AVFs from ESRD patients was correlated with the decreased JMJD3 level.

**Conclusions:** These findings demonstrate that TGFβ1/β-arrestin-1/JMD3 signaling exist in AVFs which epigenetically regulates EC differentiation and barrier function leading to neointimal hyperplasia of AVF in CKD.

Renal Macrophage Infiltration Precedes Macrophage to Myofibroblast Transition and T-Cell Recruitment Following Repeated Low-Dose Cisplatin Treatment

Sophia M. Sears, Mark A. Doll, Levi J. Beverly, Leah J. Siskind. University of Louisville School of Medicine, Louisville, KY.

**Background:** Cisplatin is a commonly used chemotherapeutic agent with dose-limiting nephrotoxicity. 30% of patients who receive cisplatin develop acute kidney injury (AKI), which significantly increases the risk of developing renal fibrosis and chronic kidney disease (CKD). There are currently no therapies approved to prevent or treat cisplatin-induced kidney injury (CDDP-KI) and fibrosis. Other models of renal fibrosis have demonstrated that macrophages can play a pro-fibrogenic role by differentiating into myofibroblasts, the main effector of fibrotic development. Macrophage to myofibroblast transition (MPT) is proposed to occur when bone marrow derived M2 macrophages undergo chronic TGFβ stimulation. We hypothesize that cisplatin promotes fibrosis and CKD development through stimulating macrophage activity and MPT in the kidney.

**Methods:** We used a clinically relevant, repeated low dose model of CDDP-KI to characterize the immune response and MPT in the kidney following cisplatin treatment.

**Results:** Flow cytometric analysis revealed significantly increased numbers of renal infiltrating CD68+ inflammatory monocytes and F4/80+ infiltrating macrophages after four doses of cisplatin. These populations remained elevated above vehicle treated controls after a 6-month age out. At the four dose timepoint, we observed an increase in CD206+ F4/80+ cells and Arg-1 mRNA, indicating M2 polarization. We also identified a population of F4/80+ CD286+ eSMA+ cells present in the kidney, suggesting MMT is occurring. Interestingly, at the 6-month timepoint renal CD4+ and CD8+ T cell populations remained significantly elevated in cisplatin-treated mice compared to vehicle treated controls.

**Conclusions:** These studies provide insight on how the immune response to CDDP-KI can promote CKD via infiltration of bone marrow derived macrophages and subsequent M2 polarization and MPT. These early events orchestrate an immune response that continues up to 6-months after cisplatin treatment. Therefore, targeting macrophages could be a potential strategy for preventing the AKI to CKD transition triggered by cisplatin.

Microvascular Loss and Remodeling in Human Kidneys Distal to Severe Atherosclerotic Renovascular Disease

Nattawat Klomjit,1 Alfonso Eirin,1 Xiang yang Zhu,1 Aditya S. Pawar,1 Anruthesh S. Puranik,2 Christopher M. Ferguson,1 Seo Rin Kim,1 Kyra L. Jordan,1 Hui Tang,2 Amir Lerman,2 Stephen C. Textor,2 Lilach O. Lerman.1

**Division of Nephrology and Hypertension, Department of Medicine, Mayo Clinic, Rochester, MN; 1Langone Health, New York University, New York, NY; 2Department of Cardiovascular Disease, Mayo Clinic, Rochester, MN.

**Background:** Renovascular disease (RVD) may induce hypertension and kidney injury, but its effect on the microcirculation of the post-stenotic human kidney remains unclear.

**Methods:** Kidneys were collected from patients with RVD undergoing unilateral nephrectomy due to refractory hypertension (n=5) and deceased donor kidneys (DK) discarded due to incompatibility (n=7). Renal microvasculature (MV) was studied in vitro using micro CT after infusing contrast agent into the renal artery. Kidneys were also compared for angiogenic gene and protein expression.

**Results:** Age and sex were comparable between RVD and DK. RVD had reduced density of medium-sized (0.2-0.3mm) MV vs. donor kidneys (Fig. A-B, p=0.04), whereas density of small (0.02-0.2mm) and large (0.3-0.5 mm) MV was similar. Vascular tortuosity ratio was higher in RVD vs DK (Fig. C, p=0.05). The number/tubule of peritubular capillaries (PTC) was significantly lower in RVD, as was CD31+ area, whereas numbers of new angiogenic vessels (β3 integrin+, Fig. D) and pericytes were higher. Renal fibrosis and MV remodeling (media/lumen) were greater in RVD, as were oxidative stress and angioptin-1 expression, whereas VEGF (-p=0.9) and FLK-1 (p=0.2) protein or gene expression were unchanged.

**Conclusions:** Human RVD kidneys develop marked MV remodeling and loss, particularly of PTC and medium-size MV. Angioptin-1 upregulation may promote new PTC formation, but fails to offset overwhelming MV loss distal to severe RVD. These findings underscore the major component of microvascular injury in the development of ischemic kidney disease.

Novel Small Molecule Inducers of ABCA1-Dependent Cholesterol Efflux Preserve Renal Function in Mouse Models of FSGS and Alport Syndrome
Javier T. Varona Santos,1,2 Matthew B. Wright,3 Christian Kemmer,1 Cyrille Maugueais,4 Jean-Philippe Carralot,5 Stephan Roever,6 Judith T. Molina David7,8 Gloria Michelle Ducasa,9,10 Alla Mitrofanova,11,12 Alexis I. Sloan,13 Jeffrey D. Merscher,18 Marco Prunotto,19 Alessia Fornoni,1,2 University of Miami, Kat Family Division of Nephrology and Hypertension, Miami, FL; 1University of Miami, Peggy and Harold Katz Family Drug Discovery Center; Miller School of Medicine, Miami, FL; 7University of Genova, School of Pharmaceutical Sciences, Genova, Switzerland; 8Pharmacy Research and Early Development (pRED), Roche Innovation Center Basel, F. Hoffmann-La Roche Ltd., Basel, Switzerland; 9University of Miami Department of Pathology, Miller School of Medicine, Miami, FL; 10University of Miami, Miller School of Medicine, Diabetes Research Institute, Miami, FL; 11Institute for Research in Biomedicine, Universita della Svizzera Italiana, Bellinzona, Switzerland; 12Swiss Institute of Bioinformatics, Lausanne, Switzerland.

Background: Pathological accumulation of cholesterol in podocytes is associated with the progression of kidney disease. Depletion of podocyte cholesterol by non-specific means, with agents such as cyclodextrin, or by specific upregulation of ABCA1-mediated cholesterol efflux, have shown promise in renal disease models, but have not progressed in clinical development.

Results: The effects of novel compounds (Cpd A and G) that induce ABCA1-mediated cholesterol efflux were evaluated in comparison to LXR agonists in differentiated human podocytes in vitro. In vivo efficacy studies of Cpd A & G were conducted in mouse models of proteinuric kidney disease (Adriamycin-induced nephrapathy and Alport Syndrome).

Results: ABCA1-mediated cholesterol efflux was significantly increased in podocytes by all agents. While an LXR agonist resulted in accumulation of ABCA1 at the plasma membrane, it also induced significant accumulation in microsomal fractions. In contrast, Cpd A & G induced the redistribution of ABCA1 from intracellular sites to the plasma membrane. In ADP and progammed ADR challenged mice, Cpd A and G reduced ACR by 8% and 30-fold, respectively, compared to controls. In Col4A3 knockout mice, Cpd G significantly reduced ACR, serum creatinine and blood urea nitrogen, as well as prevented weight loss and mortality vs. control mice. We found that increased accumulation of cholesterol esters in the kidney cortex of ADR challenged mice strongly correlated with albuminuria. In both the FSGS and Alport mouse models, Cpd G significantly reduced proteinuria, kidney histology, kidney and heart biomarkers and kidney gene expression.

Conclusions: In summary, we describe the effects of novel small molecule drugs in renal disease models that induce ABCA1-mediated cholesterol efflux independently of LXR. This may represent a promising new therapeutic strategy for the treatment of kidney diseases and disorders of cellular cholesterol homeostasis.

PO0644
Metformin Therapy Is able to Halt the Progression of Established CKD in Rats
Raphaëlle Corremans, Ellen Neven, Patrick D’Haeze, Benjamin A. Vervaet, Anja Verhulst, Universiteit Antwerpen, Antwerpen, Belgium.

Background: Metformin, first-line drug for type-2 diabetes, exerts benign pleiotropic actions beyond its prescribed use and emerging data show protective effects against the development/progression of renal impairment. Current treatment strategies for chronic kidney disease (CKD) mainly focus on controlling important risk factors, while effective treatment directly targeting the kidney is lacking. However, in 2019, the FDA approved the use of the sodium-glucose co-transporter-2 (SGLT2) inhibitor, canagliflozin, to treat diabetic nephropathy. Here, the ability of metformin to attenuate the progression of established, non-diabetic CKD was investigated and compared to canagliflozin.

Methods: Adipin-induced CKD rats (n=86) were assigned to different treatment groups to receive 200 mg/kg metformin, 4 or 5 weeks after the start of the adömine diet (0.25%), i.e. after CKD had developed, or 25 mg/kg canagliflozin 4 weeks after the start of the diet, by daily oral gavage, during 4 weeks. Each treatment group was compared to a vehicle (1% carboxymethylcellulose) group.

Results: Serum creatinine levels dramatically rose in vehicle-treated CKD rats: from 0.7 ± 0.1 mg/dl (week 0) to 1.5 ± 0.1 mg/dl (week 4), 2.6 ± 1.2 mg/dl (week 5) and further to 6.0 ± 0.3 mg/dl (week 7) and 4.8 ± 1.1 mg/dl (week 9). Canagliflozin treatment did not alter the increase in serum creatinine as indicated by serum creatinine levels at week 9 (5.8 ± 0.4 mg/dl). In contrast, metformin treatment almost completely prevented the increase from week 4 or 5 on, as indicated by the serum creatinine levels after 9 (2.0 ± 0.5 mg/dl) and 9 (2.9 ± 0.5 mg/dl) weeks (p<0.05 vs. vehicle). Canagliflozin treatment did not alter the tubulointerstitial area percentage, while this parameter was 33% lower at week 9 and 23% lower at week 9 in metformin-treated CKD rats compared to vehicle treatment (p<0.05 vs. vehicle). Further histological examination revealed more tubular proliferation (PCNA positive cells) and less interstitial inflammation (CD45 positive cells) in metformin-treated rats compared to vehicle-treated animals.

Conclusions: In conclusion, metformin is able to attenuate the progression of pre-existing kidney-induced CKD. Our data do not present new evidence for a beneficial effect of canagliflozin on progression of non-diabetic CKD.

The Novel Soluble Guanylyl Cyclase (sGC) Activator Runcaciguat Attenuates Hypertensive Cardiorenal Rat Diseases
Aymes M. Benardeau, Johannes-Peter Stasch, Michael G. Hahn, Jutta Meyer, Jan R. Krueckl, Frank Eitner, Peter Sandner. Bayer AG, Leverkusen, Germany.

Background: Chronic kidney disease (CKD) is often associated with arterial hypertension, leading to the development of hypertensive nephropathy and ultimately kidney failure that is poorly prevented by current treatment options. Hypertension and nephropathy are associated with impaired NO/sGC/cGMP signaling, low cGMP production and increased oxidative stress. Runcaciguat is a novel potent and selective, NO- and heme-independent sGC activator. Here we investigated the therapeutic potential of Runcaciguat in rat models of hypertension associated chronic kidney disease.

Methods: Hypertensive rats (Sprague Dawley, 12-13 weeks old, n=13/group, angiotensin II (ANG) minipumps, 450mg/kg/min) were treated orally twice daily for 2 weeks with Runcaciguat (0.3, 1 or 3 mg/kg), losartan (30 mg/kg) or placebo. In a second study, male Renin-transgenic rats (mRen2/27, 8 weeks old, L-NNAME 30-50 mg/L, n=18-24/group) were treated twice daily orally for up to 8 weeks with Runcaciguat (1, 3 or 10 mg/kg) or placebo. Key outcome parameters included mortality, blood pressure (BP), proteinuria, kidney histology, kidney and heart biomarkers and kidney gene expression.

Results: In the 2-week-treated ANG-rats, Runcaciguat dose-dependently and significantly reduced proteinuria without changing BP. Losartan significantly decreased proteinuria. Runcaciguat reduced kidney LCN2 (NGAL) expression. In the 8-week-treated Renin-transgenic rats, Runcaciguat significantly and dose-dependently improved mortality from 58% (placebo) to 56%, 39% and 28% (@ 1, 3, 10 mg/kg). At all tested doses, Runcaciguat significantly reduced kidney and heart hypertrophy and increased creatinine clearance. At the highest dose, Runcaciguat also significantly reduced BP and proteinuria.

Conclusions: The novel oral sGC activator Runcaciguat exhibits cardiorenal protection and improved survival in hypertensive rat models. Our data strongly suggest that Runcaciguat represents a promising treatment option for hypertensive kidney disease patients.

The Novel Nonsteroidal and Selective Mineralocorticoid Receptor Antagonist Finerenone Differentiates from SGLT2 Inhibitor Empagliflozin by Anti-Fibrotic Effects in a Progressive Mouse Kidney Fibrosis Model
Karoline Droebner, Mia Pavkovic, Manuel Grundmann, Elke Hartmann, Laura Goea, Johannes Nordlohne, Frank Eitner, Peter Kolkhof. Bayer AG, Wuppertal, Germany.

Background: Finerenone and SGLT2 inhibitors have demonstrated clinical benefits in CKD patients with T2D. Cellular and molecular mechanisms responsible for these benefits are incompletely understood. MR-signaling has been linked to fibrosis pathways. Finerenone has direct anti-fibrotic properties resulting in reduced kidney fibrosis in vitro as well as in vivo. Here, we investigated potential effects and mechanisms in a relevant preclinical mouse kidney fibrosis model.

Methods: Kidney fibrosis was induced in mice via unilateral ureteral obstruction. In a series of experiments, mice (C57Bl/6j, 8 weeks old male, n=10-12/group) were treated orally for 10 days with the MR antagonist finerenone (3 and 10 mg/kg), the SGLT2 inhibitor empagliflozin (10 and 30 mg/kg), or in a direct comparison of both drugs. Intersitial myofibroblast accumulation was quantified via alpha-smooth muscle actin (αSMA) and interstitial collagen deposition via Sirius red fast green staining. Secondary analyses included kidney mRNA expression of inflammatory and fibrotic markers and pathways.

Results: Myofibroblast accumulation was dose-dependently reduced in finerenone-treated mice (-22% @ 3 mg/kg, p=0.1; -41% @ 10 mg/kg, p=0.002) as well as collagen deposition (-22% @ 3 mg/kg, p=0.1; -44% @ 10 mg/kg, p=0.001). These anti-fibrotic effects of finerenone on protein level were matched on mRNA expression level (including collagens type III and IV). In contrast, treatment with SGLT2 inhibitor strongly increased urinary glucose excretion but had neither significant effects on kidney myofibroblasts (0% @ 10 mg/kg, p=0.7; -10% @ 30 mg/kg, p=0.99) nor on collagen deposition (-6% @ 10 mg/kg, p=0.9; -9% @ 30 mg/kg, p=0.8). In finerenone-treated mice reduced kidney fibrosis was parallelly by reduced kidney PAI-1 expression (-19% @ 3mg/kg, p=0.3; -41% @ 10 mg/kg, p=0.002).

Conclusions: Finerenone has direct anti-fibrotic properties resulting in reduced myofibroblast and collagen deposition in a mouse model of progressive kidney fibrosis.

The Novel Potent and Selective Vasopressin V1a Antagonist BAY237949 Blocks Arginine Vasopressin-Mediated Decline of Renal Blood Flow and Tissue Oxygenation

Hana Cernecka, Karoline Drobner, Hanna Tinel, Elisabeth Pook, Chantal Fuerstner, Marie-Pierre L. Collin, Peter Hein, Frank Eitner, Peter Kolkhof, Bay AG, Research & Development, Pharmaceuticals, Wuppertal, Germany.

Background: Hypoxia is a major contributor to kidney disease progression. Arginine vasopressin (AVP) potentially induces renal medullary vasoconstriction via vaso-vascular receptors resulting in reduced renal blood flow (RBF). Here we characterized the kidney-protective properties of a recently identified, potent and selective V1a receptor antagonist.

Methods: BAY237949 was characterized in Chinese hamster ovary cells expressing recombinant human and rat V1a and V2 receptors. Vasodilatory effects were investigated on isolated A. renalis rings from male Wistar rats (n=10). RBF and intrarenal tissue oxygenation were studied in isolated perfused rat kidneys and in anesthetized rats (n=5-8 per group) via Laser Doppler Flowmetry.

Results: In vitro receptor profiling showed high potency and selectivity of BAY237949 for human V1a receptor (IC50 1:1.2 nM, IC50 1:170 nM). BAY237949 mediated dose-dependent relaxation (IC50 = 3.1 nM) of isolated rat A. renalis vessel rings precontracted by AVP. BAY237949 improved the AVP-mediated reduction of perfusate venous flow (figure) without affecting urinary volume. In vivo, infusion of AVP significantly increased mean arterial pressure (CON: 97±1, AQP: 135±12, means±SD) which was normalized by BAY237949 in a dose-dependent manner (90±5; p<0.0001). Infusion of AVP reduced both renal perfusion (CON: 1008±8, AQP: 758±107) and tissue oxygenation (CON: 27±4, AQP: 17±4). BAY237949 dose-dependently restored RBF (960±30; p<0.0001) and increased pO2 (25±4; p<0.0001).

Conclusions: BAY237949 is a novel potent and selective vasopressin V1a receptor antagonist blocking the detrimental effects of elevated vasopressin levels on renal perfusion and oxygenation in rats, suggesting potential benefit for patients with cardiorenal diseases.

PO0648
Apabetalone, an Inhibitor of BET Proteins, Downregulates Alkaline Phosphatase and Improves Cardiovascular Risk

Dean Gilchrist, Laura Tsujiwaka, Li Fu, Sylvia Wasilk, Christopher Halliday, Chris Saroson, Phoebe S. Ho, Stephanie Stotz, Brooke D. Rakai, Kenneth E. Lebioda, Ravi Jahagirdar, Michael Sweeney, Jan O. Johansson, Norman C. Wong, Kamary Kalantar-Zadeh, Mathias Haahrus, Ewelina Kulikowski, Resverlogix, Calgary, AB, Canada; Resverlogix, San Francisco, CA; University of California Irvine, Irvine, CA; Karolinska University Hospital, Stockholm, Sweden.

Background: Elevated serum alkaline phosphatase (ALP) predicts major adverse cardiac events (MACE). ALP is associated with vascular calcification (VC), inflammation & endothelial dysfunction in patients with cardiovascular disease (CVD) & chronic kidney disease (CKD). Apabetalone is an inhibitor of BET proteins - epigenetic readers modulating gene expression in pathological VC & inflammation. We studied apabetalone’s impact on tissue non-specific ALP (TNALP) expression in cell culture, then analyzed serum ALP in phase 2 trials.

Methods: Expression of TNALP (gene symbol APLP) was measured in primary hepatocytes, HepaRG, HepG2, primary mesangial cells (MC), vascular smooth muscle cells (VSMC) & vascular endothelial cells by q-PCR. TNALP was assessed by immunoblot & flow cytometry, ALP activity by enzymatic assays. Serum ALP was measured in CVD patients in phase 2 trials (ASSERT, SUSTAIN & ASSURE). Subpopulations had CKD (eGFR<60).

Results: Apabetalone downregulated ALP expression in liver cells by 60-80%, HepG2s had lower TNALP protein ~55%, enzyme activity ~40% & TNALP positive cells 15-30%; renal MCs had ~90% decreases in ALP expression & TNALP enzyme activity (p<0.001). ALP was suppressed 50-70% in 3 vascular endothelial cell types with apabetalone. In VSMCs, apabetalone lowered ALP expression, TNALP protein, enzyme activity & extracellular calcium deposition. In ASSERT, apabetalone dose dependently reduced serum ALP (p<0.001). In combined phase 2 analysis, apabetalone lowered ALP (-0.001), in reducing patients in the CKD subgroup (p<0.001). Notably, the apabetalone-mediated decreases in serum ALP in phase 2 correlated with reduced MACE at 12-14 weeks (HR 0.64 per 1-SD in ALP, 95% CI 0.46-0.90 p<0.0091-13DUL); similar associations were observed at 24-26 weeks (HR 0.66 per 1-SD ALP 95% CI 0.43-0.99 p=0.045, 1-SD=14UL).

Conclusions: Apabetalone lowers serum ALP, consistent with reduced hepatic, renal & vascular TNALP production. Modulation of ALP by apabetalone may affect pathogenic processes to lower cardiovascular risk. This study provides insight to MACE reductions in phase 2 clinical trials.

PO0649
Renal Expression of L-Type Fatty Acid Binding Protein in Addition to Angiotensin II Type 1a Receptor Loss Ameliorates Chronic Tubulointerstitial Damage After Renal Ischemia Reperfusion

Yoko Fujita, Takeshi Sugaya, Daisuke Ichikawa, Jun Tanabe, Kenjiro Kimura, Yugo Shibagaki, Atsuko Ikemori. Division of Nephrology and Hypertension, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan; JCHO Tokyo Takanawa Hospital, Tokyo, Japan; Department of Anatomy, St. Marianna University School of Medicine, Kawasaki, Japan.

Background: Although angiotensin II (Ang II) type 1 receptor blocker was reported to attenuate chronic tubulointerstitial damage (TID) after renal ischemia reperfusion (IR), its effect is limited. We had revealed the importance of renal l-type fatty acid binding protein (L-FABP) with antioxidative effect in various renal disease models. Therefore, the aim of this study is to elucidate the renoprotective effect of renal L-FABP and Ang II type 1a receptor (AT1a) loss against chronic TID after renal IR.

Methods: To induce severe chronic TID after renal IR, unilateral renal ischemia and reperfusion for 60 min was performed via clamping of right renal pedicle using four types of male mice; wild type mice (hL-FABP+/+AT1a+), human L-FABP chromosomal transgenic mice (hL-FABP+/+AT1a+), AT1a knockout homo mice (hL-FABP+/+AT1a−), and generated hL-FABP+/+AT1a− mice. Right and left kidneys were removed at 10 weeks after IR.

Results: While marked renal atrophy and progressive TID were found in each IR-kidney of hL-FABP+/+AT1a+, hL-FABP+/+AT1a− and hL-FABP−/− AT1a− mice, the degrees of both atrophy and TID were significantly ameliorated in the IR-kidneys of the hL-FABP+/+AT1a+ mice. Systolic blood pressure levels in the hL-FABP−/− AT1a− mice were similar to the h-L-FABP+/+AT1a− mice. These results suggested that antioxidative effect of L-FABP in addition to AT1a loss may be related to suppression of chronic TID after IR.

Conclusions: Increased expression of renal L-FABP in addition to suppressed activity of AT1a may be a useful strategy for prevention of AKI-to-CKD transition.

PO0650
Development of a Synthetic Biotic, SYNB8802, for the Treatment of Enteric Hyperoxaluria

Lauren Renaud, David Lubkowicz, Pip Reeder, Chris Bergeron, Zhbin C. Chen, Michael J. James, Pasquale Cantarella, Mark Charbonneau, Ron Shmueli, Jr Gao, Vincent Isabella, Mylene Perreault. Synlogic, Cambridge, MA.

Background: Enteric hyperoxaluria (EH) is a metabolic disease that results from excessive absorption of oxalate from dietary sources. Increased oxalate levels can lead to the formation of kidney stones and, ultimately, to kidney failure. EH occurs most frequently in patients with underlying gastrointestinal disorders, including inflammatory bowel disease, short bowel syndrome, or individuals who have undergone bariatric surgery. There is a high unmet need for new EH therapies, as a low oxalate diet is the only option currently available to patients. Synlogic is developing a novel Synthetic Biotic (SB) medicine for the treatment of EH, designated as SYNB8802.

Methods: SYNB8802 is an engineered bacteria derived from Escherichia coli Nissle 1917 (EcN) that has been engineered to metabolize oxalate to formate and CO2 in vivo.

Results: Inoculation of SYNB8802 into minimal media showed significant consumption of oxalate and production of formate as compared to un-engineered (EcN) bacterial strain. When administered concomitantly with “C-oxalate to healthy mice, SYNB8802 decreased the urinary recovery of “C-oxalate, indicative of its ability to consume oxalate in vivo. In healthy non-human primates (NHP) administered approximately 400 mg of dietary oxalate, SYNB8802 lowered the urinary recovery of oxalate and “C-oxalate in a dose dependent manner by up to 75% as compared to vehicle. In addition, Synlogic has developed a mathematical model that predicts clinically meaningful reductions in urinary oxalate in EH patients.

Conclusions: Overall, SYNB8802 represents a promising new approach for the treatment of enteric hyperoxaluria.
A Novel Small Molecule Modulating the Mitochondrial NEET Proteins Improves Inflammation and Fibrosis in Kidneys of Nonalcoholic Steatohepatitis Mice

Background: Non-alcoholic steatohepatitis (NASH) is a disease characterized by excessive fat accumulation, inflammation, and ballooning degeneration of hepatocytes, with or without fibrosis in the liver. It is now reported that NASH not only affects the liver but is also associated with chronic kidney disease (CKD). However, the morphological appearance of NASH kidneys has been poorly characterized. These observations highlight the need for a treatment that targets both conditions. Here, we assessed the effect of a novel chemistry that regulates the function of 3 mitochondrial proteins called the NEET proteins, previously reported to be important in metabolic diseases, on a diet-induced NASH model in mice.

Methods: Mice were fed with a high fat diet for 30 weeks prior treatment with ENYO’s molecule for 8 weeks. The kidneys and livers were collected at sacrifice and sections were stained with H&E, PAS and picrosirisin red staining to analyze their morphology. Specific immunostainings and qRT-PCR were performed to quantify the extent of inflammation (CD3, MAC1 and F4/80) and fibrosis (Col1a1, Col3a1, fibronectin).

Results: NASH mice displayed severe renal lesions such as glomerulosclerosis, tubular casts, tubular lipid accumulation and interstitial fibrosis. Mononuclear cell infiltration was also massively increased, in particular in the perivascular areas. Quantitative RT-PCR revealed a significant increase of the expression of several fibrosis and inflammation markers. Therapeutic administration of ENYO’s molecule was shown to resolve these lesions with a return back to normal regarding fibrosis, and a 50% and 35% decrease in lymphocyte and macrophage accumulation, respectively. In the liver, inflammation and fibrosis were also attenuated, specifically in the peritubular zone that has been shown to be correlated with the severity of the disease. Interestingly, the most significant responders in the liver were also the best responders in the kidneys.

Conclusions: We have shown that NASH mice developed CKD, recapitulating the phenotypes observed in humans. Moreover, we have identified a new treatment, that by targeting NEET proteins, protects mice from the development of both liver and renal lesions.

PO0653

Empagliflozin Restores CKD-Induced Impairment of Endothelial Regulation of Cardiomyocyte Relaxation and Contraction

Rio P. Juni, Rushid Al-Shama, Diederik W. Kuster, Jolanda Van der velden, Henrike M. Hamer, Marc G. Vervoort, Etto C. Eringa, Pieter Koolwijk, Victor van Hinsbergh. Amsterdam University Medical Centres, Amsterdam Universitair Medisch Centra, Amsterdam, Netherlands.

Background: Chronic kidney disease (CKD) promotes development of cardiac abnormalities and is highly prevalent in patients with heart failure (HF), particularly HF with preserved ejection fraction (HFpEF). CKD and HF are associated with endothelial dysfunction and have been shown to benefit from a sodium-glucose co-transporter 2 inhibitor, empagliflozin. We hypothesized that uric acid from CKD patients impairs cardiomyocyte (CM) relaxation and contraction by inducing endothelial cell dysfunction and that empagliflozin protects against this effect.

Methods: Co-culture system of human cardiac microvascular endothelial cells (CMECs) with adult rat ventricular cardiomyocytes (CMs).

Results: We showed that CMECs promote CM relaxation (return velocity, Fig. A) and contraction (sarcomere shortening, Fig. B). Serum from CKD patients impaired endothelial enhancement of CM function which was rescued by empagliflozin (Fig. A-B). Exposure to uric acid serum reduced nitric oxide (NO) bioavailability in CMECs and increased mitochondrial reactive oxygen species (ROS) and 3-nitrotyrosine level, indicating NO scavenging by ROS. Empagliflozin restored endothelial enhancement of NO level in CMs by restoring endothelial NO bioavailability and reducing endothelial mitochondrial ROS, an effect that was largely independent of sodium-hydrogen exchange.

Conclusions: Serum from CKD patients impairs CM relaxation and contraction through induction of endothelial dysfunction driven by an increase in mitochondrial ROS production. Empagliflozin restores the enhancement effect of CMECs on CM function by reducing mitochondrial oxidative damage, leading to reduced ROS accumulation and increased endothelial NO bioavailability.

PO0652

SIRT3 Deacetylates PDH1α to Regulated Mitochondria Metabolism in Tubular Epithelial Cells During Renal Fibrosis

Yu Zhang, Yang Zhou, Lei Jiang, Junwei Yang. Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.

Background: Abnormal energy metabolism is considered to be related to renal interstitial fibrosis. Pyruvate dehydrogenase α (PDH1α) is the main catalytic enzyme of pyruvate dehydrogenase complex (PDHC) linking glycolysis to the TCA cycle. N-lysine acetylation is an important post-translational modification involves in energy metabolism. SIRT3 is a mitochondrial deacetylase that mediates the activity many metabolic enzymes.

Methods: Unilateral ureteral obstruction (UUO) or ischemia-reperfusion (IR) were used to induce renal fibrosis in C57BL/6j mice or SIRT3 knockout mice. Primary tubular epithelial cells (PTCs) were stimulated by TGF-β1. Protein array and the acetylation array by LC-MS/MS were performed on tubules separated from sham or UUO-operated mice. K149R, K267R, K385R mutations in PDH1α were transfected into PTCs.

Results: Acetylation showed that the majority of proteins were hyper-acetylation after UUO. GO enrichment analysis revealed that PDH1a was the most obviously enriched GO term. Immunoprecipitation analysis confirmed that PDH1α acetylation was enhanced after UUO or IR operation. Activation of SIRT3 by HKL could block the hyper-acetylation of PDH1α, restored PDH enzyme activity, and inhibited the phosphorylation of PDH1α in mice with UUO or IR. On the contrary, Sirt3 KO mice had more acetylated PDH1α, more phosphorylated PDH1α and defective PDH enzyme activity. In vitro, increased PDH1α acetylation was accompanied by reduced PDH enzyme activity and increased PDH1α phosphorylation in PTCs after TGF-β1 stimulation. Activation of SIRT3 by HKL repressed the effect of TGF-β1. Inhibition SIRT3 activity by 3-TYP or SIRT3 siRNA transfaction have the same effect as TGF-β1. K149, K267, K385 were identified as the main potentially lysine acetylated sites in PDH1α.

Conclusions: In summary, our data showed that mitochondrial proteins involved in regulating energy metabolism were acetylated and targeted by SIRT3 in PTCs. The deacetylation of PDH1α at lysine 385 by SIRT3 plays a key role in metabolic reprogramming in renal fibrosis.

Funding: Government Support - Non-U.S.
differences in whole kidney analysis of inflammatory cytokine qPCR between them, renal macrophage CD148KO mice showed high expression of inflammatory cytokine expression (TNF-α, IL-1β, IL-6). Peritoneal macrophages derived from CD148KO mice showed higher inflammatory cytokine expression (TNF-α, IL-1β, IL-6) to LPS, accompanied by higher phosphorylation of Erk. In addition, Erk inhibitor, U0126 diminished the difference between WT and CD148KO macrophages.

Conclusions: Our data suggests that CD148 negatively regulates macrophage M1 polarization through Erk and its deficiency accelerates macrophage inflammation in uUO kidneys, leading to advanced tubular injury and renal fibrosis.

LRG1 Promotes Renal Fibrosis by Enhancing TGF-β-Induced Smad3 Pathway
Quan Hong,1,2 Hong Cai,1,2 Lu Zhang,1,3 Zhaoqi Ni,2 Guangyuan Cai,1 Xiaoning Chen,1 John C. He,1,4 Kyung Lee,1 Ichab School of Medicine at Mount Sinai, New York, NY; Chinese PLA General Hospital, Beijing, China; 1Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Shanghai, China; 2James J Peters VA Medical Center, Bronx, NY; 3The First Affiliated Hospital of Xiamen University, Xiamen, China.

Background: Renal fibrosis is a final convergent pathway for CKD progression, but effective fibrosis therapy is lacking. We recently showed that leucine-rich alpha-2 glycoprotein-1 (LRG1), a secreted glycoprotein, is highly upregulated in diabetic kidneys and potentiates the endothelial TGF-β signaling, mediated by ALK1 receptor and Smad1/5 activation, to increase angiogenesis and worsen DKD progression. However, increased LRG1 expression was not limited to the endothelial cells in the diabetic kidneys, but also found in the renal tubular epithelial cells (RTECs). Therefore, we examined whether the LRG1 expression to the TGF-β signaling in RTECs leading to renal fibrosis progression.

Methods: We examined the expression of LRG1 in the tubulointerstitial RNAseq datasets of human CKD. We explored the potential mechanism in LRG1 upregulation in cultured RTECs and examined the specific TGF-β-Smad signaling pathway mediated by LRG1 using shRNA-knockdown. We examined the effects of LRG1 ablation in unilateral ureteral obstruction (UUO) and aristolochic acid nephropathy (AAN) models of renal fibrosis. We also examined the effects of RTEC-specific overexpression of LRG1 in renal fibrosis in vivo. We further compared the activation of Smad proteins in the RTECs of control, Lrp1−/−, and Pan-LRG1−/− mice with UUO.

Results: We found that the LRG1 mRNA transcript was markedly increased in the microdissected tubulointerstitial of human CKD. In cultured RTECs, LRG1 expression was upregulated by a pro-inflammatory cytokine TNF-α, and chromatin IP assay confirmed the binding of NF-κB to the LRG1 promoter region. Importantly, LRG1 enhanced the TGF-β-induced Smad3 activation, but not of Smad1/5, and the expression of pro-fibrotic genes in RTECs. The global knockout of Lrg1 attenuated renal fibrosis in mice with UUO or AAN. In AAN mice, Lrg1 ablation also improved renal function. In contrast, the RTEC-specific overexpression of LRG1 markedly heightened the renal fibrosis in vivo. The level of Smad3 phosphorylation in RTECs in the obstructed kidneys was directly associated with the loss or gain of LRG1 expression.

Conclusions: Our current study attributes a previously undescribed role of LRG1 as a key modulator of the canonical TGF-β-Smad3 signal transduction in RTECs and suggests that the targeting of LRG1 may be an effective approach against renal fibrosis.

Single-Nucleus RNA Sequencing Identifies New Classes of Renal Proximal Tubular Epithelial Cell in Kidney Fibrosis
Yuehan Lu,1,2 Chie-ta Liao,1 Rachel Raybould,1 Bnar Talabani,1 Barbara Szomolyay,1 Timothy Bowen,1 Robert Andrews,1 Philip R. Taylor,1 Donald Fraser,2 Wales Kidney Research Unit 1Cardiff University, Cardiff, United Kingdom; 2Chang Gang Memorial Hospital, Taoyuan, Taiwan.

Background: Proximal tubular cells (PTC) play a central role in nephron recovery versus fibrosis following renal injury. PTC heterogeneity is well-documented but poorly-understood in single-cell sequencing data. Here we have determined PTC phenotype in renal fibrosis by single-nucleus RNA sequencing (snRNA-seq).

Methods: Kidneys were harvested from naïve mice and mice with renal fibrosis induced by chronic aristolochic acid administration. Nuclei were isolated using Nuclei Extraction kit (Cellular Dynamics). The purified nuclei were microdissected in the proximal tubular segments and used for snRNA-seq. The sequencing libraries were generated using Illumina NextSeq 550. Downstream bioinformatics analyses used Seurat.

Results: A total of 23,885 nuclei were analyzed. PTC’s were found in five abundant clusters, mapping to S1, S1-2, S2-cortical S3, and medullary S3 segments. Additional cell clusters were present (“new PTC clusters”) at low abundance in normal kidney and in increased number in kidneys undergoing regeneration/fibrosis following injury. These clusters exhibited clear molecular phenotypes, permitting labeling as, proliferating, dedifferentiated-intermediate, dedifferentiated-regenerating, and (present only following injury) differentiated-senescent. Each of these clusters exhibited a unique gene expression signature, including multiple genes associated with renal injury response and fibrosis progression. Comprehensive pathway analyses revealed metabolic reprogramming, enrichment of cellular communication and cell motility, and various immune processes in new PTC clusters. In ligand-receptor analysis, new PTC clusters promoted fibrotic signaling to fibroblasts and inflammatory activation to macrophages.

Conclusions: SnRNA-seq permits the dissection of cell-type and cell-subtype-specific responses. We identified previously unknown, injury-associated PTC clusters. These exhibit highly specific and restricted gene signatures, including canonical PTC injury responses, and suggest potential therapeutic targets in specific cellular populations in renal fibrosis.

Artificial Intelligence-Driven Target Identification in CKD
Chanchal Kumar,1 Lisa Buvall,2 Maria Ryaboshapka,1 Kevin Woolard,3 Julie Williams,2 Natalie Kurbatova,2 Anna Reznichenko,1 Iain MacPhee,1 Mohammad Booholy,1 Dirk S. Paul,1 James Dunbar,1 Andrea Taddei,1 Mark Davies,1 Siobhan McMahon,1 Andres Mori,2 Regina Fritsche-Danielson,2 Claus BendtSEN,2 Pernille B. Laerkgaard Hansen,2 1Translational Science and Experimental Medicine, Renal, Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; 2Bioscience Renal, Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; 3CVRM, AstraZeneca, Gothenburg, Sweden; 4Centre for Genomic Research, Research and Early Development, Discovery Sciences, BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; 5Centre for Genomic Research, Research and Early Development, Discovery Sciences, BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; 6Centre for Genomic Research, Research and Early Development, Discovery Sciences, BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; 7Centre for Genomic Research, Research and Early Development, Discovery Sciences, BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; 8Centre for Genomic Research, Research and Early Development, Discovery Sciences, BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; 9Centre for Genomic Research, Research and Early Development, Discovery Sciences, BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; 10Centre for Genomic Research, Research and Early Development, Discovery Sciences, BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; 11Centre for Genomic Research, Research and Early Development, Discovery Sciences, BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom.

Background: Involvement of multiple pathways and complex pathophysiology are few of the hallmarks of Chronic Kidney Disease (CKD). These reasons contribute to the challenge for drug discovery in CKD, which is a major contributor to global disease burden. Availability of a wealth of CKD omics data has opened avenues for novel insight generation through unbiased integrative analysis. In a pioneering effort AstraZeneca and BenevolentAI initiated a collaboration to leverage the potential of artificial intelligence (AI) to generate novel hypotheses for drug targets in CKD.

Methods: We have created a CKD knowledge graph (CKD-KG) - a knowledge base of biological and chemical entities (genes, small molecules, etc) and their relationships (gene-disease associations, therapeutic drugs, biological processes, etc) and augmented with CKD specific information derived from both public and AstraZeneca proprietary datasets. The CKD-KG was constructed by aggregating information from structured biomedical databases, machine learning (ML)-based extraction from unstructured sources, and patient-centric omics datasets (unstructured: 140M documents, 1B relationships, (ii) structured: 56M relationships, 3B omics data points, (iii) 35 licensed data sources, and (iv) 53 CKD omics datasets. The CKD-KG was used as input to BenevolentAI’s relational inference and causal reasoning ML models to produce target hypotheses for CKD.

Results: The fleet of models identified 295 potential targets that were triaged down to 69 targets. These 69 targets have been further prioritized based on an in-house human target validation pipeline, and additional criteria such as safety and drugability, in line with AstraZeneca’s 5R framework. We are undertaking in vitro studies via genetic modification in selected cell types to generate target-specific CKD-linked readouts. Subsequently, we will employ in vivo studies to confirm the mechanism of action for targets that had shown successful in vitro readouts. Eventually, we will progress targets with compelling novel biology within our renal portfolio.

Conclusions: CKD-KG enables a transformative approach to generating novel target hypotheses with the potential of improving health outcomes for CKD patients.

Twist1 in T Lymphocytes Exaggerates Kidney Fibrosis After Ureteral Obstruction
Jiafa Ren, Jamie Privratsky, Steven D. Crowley. Duke University School of Medicine, Durham, NC.

Background: T cells play a critical role in directing kidney fibrogenesis. The transcription factor Twist1 limits pro-inflammatory cytokine production in T cells, but the role of T cell-derived cytokine mediators regulated by Twist1 in kidney damage has not been fully elucidated. To explore the role of T cell Twist1 in kidney scar formation, we subjected mice with Twist1 lymphocyte-specific deletion ("TKO") of Twist1 and controls to the UUO.

Methods: 129/SvEv mice with a floxed allele for the gene encoding Twist1 or TNFα were bred with CD4-Cre mice to yield Twist1 TKO or TNFα TKO mice with robust but selective deletion of Twist1 mRNA >90% vs. WTs in CD4- T cells, and >85% vs. WTs in CD8+ T cells (p < 0.0001) or TNFα mRNA in T cells (published), respectively. Twist1 TKO, TNFα TKO, and WT controls underwent UUO with assessment of kidney fibrosis and T cell phenotype at 14 days.

Results: 2 weeks after UUO, Twist1 TKO mice developed less kidney fibrosis compared to WTs as quantitated by western blot for Col1 (0.75 ± 0.06 vs 1.0 ± 0.05; p = 0.02) and αSMA (0.65 ± 0.01 vs 1.0 ± 0.08; p = 0.01) and by RT-PCR for Col1 (0.69 ± 0.08 vs 1.0 ± 0.10; p = 0.048), fibronectin (0.76 ± 0.07 vs 1.0 ± 0.06; p = 0.03), TGFβ1 (0.73 ± 0.08 vs 1.00 ± 0.04; p = 0.004) and PAI-1 (0.47 ± 0.06 vs 1.0 ± 0.09; p = 0.001).

Twist1 TKO mice also showed attenuated kidney injury as indicated by NGAL mRNA expression (0.55 ± 0.06 vs 1.0 ± 0.16; p = 0.04). Twist1 can suppress pro-inflammatory mediators such as TNFα and IL17A in T cells, and expression of these cytokines was significantly lower in Twist1 TKO kidneys compared to WTs.

Conclusions: Twist1 in T cells drives fibrosis in the injured kidney, possibly by limiting TNFα production.

PO0659
Evaluation of the Effects of a Resistant Starch Diet and Metaproteomics Study of Microbiome-Host Interactions in a 5/6 Nephrectomy Murine Model of CKD
Oleg K. Karaduta,1 Galina V. Glazko,2 Zeljko Dvansajcik,1 Yasir Rahmatallah,1 Samuel G. Mackintosh,1 John M. Arthur,1 Boris Zybailov,1 University of Arkansas System, Little Rock, AR; 2Arkana Laboratories, Little Rock, AR.

Background: Chronic kidney disease (CKD), a progressive decline in kidney function, is a growing health problem: 13% of adults in the US have CKD. In 40% of cases, CKD leads to irreversible loss of kidney function, end-stage renal disease. Pre-biotic bacterial Resistant Starch (RS) changes gut flora and alleviates CKD. However, mechanisms of RS action remain unclear.

Methods: Male mice (n=8) were used to reduce renal mass and to induce CKD. 8 mice served as healthy controls. Each of the two groups was further split in two sub-groups (n=4, each), either supplemented with RS or regular diet. PEAKS was used to identify peptides via de novo sequencing in cecal content. To better understand the differences between CKD, CKDRS, HRS and H phenotypes we combined all bacteria that were differentially abundant in six comparisons to infer bacterial co-abundance (BCoA) network. Histopathological evaluation was used for kidney damage comparison.

Results: Histopathological evaluation showed that CKDRS mice had less kidney damage compared to CKD group. Using metaproteomics we found that the most abundant bacterium in HRS phenotype is indole-producing Oscillibacter sp. 1-3, confirming the result of BlaszGZO that indole metabolism is upregulated in HRS phenotype as compared to CKDRS and CKD. The most connected network hub Firmicutes bacterium ASF500 is significantly overrepresented in CKDRS as compared to CKD and is not significantly different between HRS and H. Firmicutes bacterium ASF500 belongs to 20 bacterial strains from human intestine that can induce Th17 cells in the mouse. The pathway of indole metabolism and have immunostimulatory effects. Experiments to validate effect of Lactobacillus in germ-free mice are underway.

Conclusions: Resistant starch slows down the progression of chronic kidney disease in 5/6 nephrectomy model. For the first time we demonstrate decrease in kidney fibrosis during RS supplementation. Metaproteomics allows to discover molecular mechanisms and bacterial species responsible for beneficial effects of RS. MST2 analysis allows for clear visualization of the most important connections within the bacterial co-abundance network.

Sex Differences in Renal Mitochondrial Function of Young Healthy Rats
Ryan Schibalski,1 Regina F. Tulvanova,2,3 Mark Donnordon,1 Allison N. Mericimon,1 Kristzian Stadler,1 Darja Ilatosvaya,1 1Medical University of South Carolina, Charleston, SC, USA; 2,3 St. Petersburg Chemical Pharmaceutical University, St. Petersburg, Russian Federation; 1University of South Carolina, Charleston, SC; 2Pennington Biomedical Research Center, Baton Rouge, LA, US; Baton Rouge, LA.

Background: Sex differences in mitochondrial function have been linked to many pathologies. Premenopausal females are typically less prone to cardiovascular damage than males. Differences in the ability to manage oxidative stress, calcium uptake, fission/fusion cycles, and respiratory performance in mitochondria can affect the onset and progression of the diseases. While characteristic sex-related dissimilarities have been reported in renal function, nothing is known with regards to how sex may affect the performance of renal mitochondria. The goal of this study was to compare renal mitochondrial function in young healthy male vs female rats.

Methods: Mitochondria were isolated from the kidneys of Sprague Dawley (SD) rats (10-11 weeks). Mitochondrial membrane potential, superoxide and H2O2 levels were measured with luminescent (MCLA) or fluorescent (TMRM, Amplex Red) dyes, and seahorse analysis was performed. Antioxidant capacity was measured with a Trolox-based assay. Lipid peroxide radicals were detected using with spin resonance spectroscopy (ESR) with in vivo spin trapping.

Results: Kidneys from SD male (SDM) and female rats (SDF) were divided into cortex (SDM c and cortex (SDM c and medulla (SDM m) and medulla (SDM m). First, we report significantly higher membrane potential in SDM compared to SDF (p < 0.001). H2O2 levels were elevated in both the cortex (SDM c) and medulla (SDM m) mitochondria compared to SDF (p < 0.01). Interestingly, mitochondrial superoxide production was increased in the medulla compared to the cortex for both SDM c and SDM m, while SOD2 expression was lower (p < 0.001). Antioxidant capacity was lower in SDM c tissues compared to all other groups, which is consistent with higher H2O2 levels (58 ± 7 vs. 35 ± 1 pg/mg protein, p < 0.001). Ex vivo analysis showed similar lipid peroxide radical levels in males and females, but detected different renal adducts – an amine or amino acid-centered radical – in the medulla.

Conclusions: We report sex-related differences in mitochondrial function in the kidneys of young healthy rats. Further studies are needed to establish the mechanisms that may affect the predisposition to kidney disease development later in life.

PO0661
Renal Involvement in Coronavirus Disease 2019 (RECORD): A Systematic Review and Meta‐Analysis
Kam‐ Chan,1 Kam Yan Y1, Pak Wing Lee,2 Sydney C. Tang,1 1Department of Medicine, The University of Hong Kong, Hong Kong, Hong Kong; 2London School of Hygiene and Tropical Medicine Faculty of Epidemiology and Population Health, London, United Kingdom.

Background: COVID-19 caused substantial casualty worldwide. As the reported renal involvement varied across regions, we sought to review the global prevalence of renal manifestations among COVID-19 patients and determine the risk factors associated with AKI.

Methods: We systematically searched 6 databases for peer-reviewed reports and 7 data portals for grey literature for all trials, cohorts, case-control studies and case-series that reported the prevalence of renal manifestations including AKI, RRT, proteinuria and hematuria, and their associated risk factors. All papers were screened, assessed and extracted by at least 2 researchers independently. Quality was assessed according to NIH assessment tools. To avoid duplicate of patient data, we matched the location, institution and time period, and only included the largest data source if studies overlapped. Prevalence of renal manifestations was pooled from studies that consecutively recruited patients from the general population, and with clear definition of outcome. This review was prospectively registered at PROSPERO (CRD42020184621).

Results: 36 studies from 8 countries and over 50 cities with a total of 14,712 patients were identified. 34 and 2 were cohorts and case-control studies respectively. 24, 7 and 5 studies reported COVID-19 patients from the general population, severe / critical patients and patients with history of RRT. AKI occurred in 14.5% of all COVID-19 cases and was highest in New York City. 4.7% of hospitalized COVID-19 patients underwent RRT. Proteinuria and hematuria were present in 42.5% and 26.7% of all COVID-19 cases. The odds of mortality among COVID-19 patients who developed AKI was 15 times higher than non-AKI COVID-19 patients (pooled OR=16.85, 95% CI: 10.06 to 28.23, 2 cities, 6 studies, 9,297 patients) and was higher in Hubei. Such effect was not observed among kidney transplant patients (pooled OR=0.95, 95% CI: 0.12 to 7.22, 2 studies, 30 patients). Higher C-reactive protein, leukocyte count, serum lactate dehydrogenase and creatinine levels on admission were associated with mortality. The odds of mortality among AKI patients varied significantly between cities, which could be associated with differences in healthcare infrastructure and delayed hospitalization and treatment initiation.
Forecasting Continuous Renal Replacement Therapy Shortages During the COVID-19 Pandemic in the United States
Yuvaram N. Reddy,1,2 Rochelle P. Walensky,3,2 Krishna P. Reddy,2,4 Renal Division, Brigham and Women’s Hospital, Boston, MA; 1Medical Practice Evaluation Center, Massachusetts General Hospital, Boston, MA; 4Division of Pulmonary and Critical Care Medicine, Massachusetts General Hospital, Boston, MA.

Background: The coronavirus disease 2019 (COVID-19) pandemic has increased continuous renal replacement therapy (CRRT) demand in the US, however total CRRT demand and capacity remain unclear. Our objective was to project national and statewide CRRT demand and capacity during the COVID-19 pandemic.

Methods: We analyzed the available literature to develop a national model of CRRT demand and capacity to estimate shortage. In sensitivity analysis, we varied parameters influencing CRRT demand and capacity. To estimate non-COVID-19 CRRT demand, we applied the prevalence of acute kidney injury (AKI) requiring CRRT, and the AKI incidence among other ICU patients of 8.8%. We assumed capacity would be double this demand and that this demand would decrease to 25% during the pandemic. We compared CRRT demand and capacity to estimate shortage. In sensitivity analysis, we varied parameters influencing CRRT demand and capacity.

Results: We estimated a national CRRT shortage of 1529 (95% uncertainty interval 1264-3837) machines with a capacity of 9375 machines, and shortages in 8 states during the COVID-19 pandemic (Table 1 and Figure 1).

Conclusions: Several US states are projected to have CRRT shortages during the COVID-19 pandemic. A national strategy, such as the creation of a federal stockpile, is needed to mitigate CRRT shortages during this pandemic and future healthcare crises.

Funding: NIDDK Support

Model-generated results for 8 states with CRRT shortages

Acute Tubular Injury in Patients with Severe COVID-19 Infection
Yasuji Fukao, Hajime Nagasawa, Yoshitoho Nihei, Seiji Ueda, Masao Kihara, Tomohito Gohda, Yosuke Suzuki. Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan.

Background: Novel coronavirus, severe acute syndrome coronavirus 2 (SARS-CoV-2), has rapidly spread all over the world. SARS-CoV-2 enters host target via angiotensin-converting enzyme-2 which are ubiquitously expressed in many organs including proximal tubules in kidney. Indeed, autopsy cases with coronavirus disease-2019 (COVID-19) revealed the existence of coronavirus particles in the renal tubules. However, involvement of SARS-CoV-2 in acute kidney injury (AKI), however involvements of SARS-CoV2 in tubular injury has not been fully understood. Here, we evaluated tubular injury in patients with severe and non-severe COVID19.

Methods: We investigated the relationship between urinary levels of tubule markers (NAG, FDNB, α1-MG, and L-FABP) and laboratory markers in 17 COVID-19 patients without chronic kidney disease on admission. We also analyzed the relationship between the laboratory markers and respiratory status in severe (n=7) or non-severe (n=10) COVID-19 patients which were defined by requirements of supplemental oxygen.

Results: Although only 2 patients developed AKI in severe cases, serum Interleukin-6 (IL-6) level significantly increased in all of severe patients and correlated with levels of proteinuria (R2=0.37, p=0.01), NAG (R2=0.41, p=0.006), α1-MG (R2=0.47, p=0.007), L-FABP (R2=0.57, p=0.001) on admission. In addition, severe patients had significantly higher levels of proteinuria (0.37 vs non-severe: 0.14g/gCr), α1-MG (33.3 vs 10.1U/L), β2MG (17134.4 vs 1168.5ug/L), α1-MG (63.6 vs 12.4mg/L), L-FABP (57.9 vs 7.5ug/gCr) as compared to non-severe cases. Proteinuria and elevated tubular markers were observed only in 2 and 6 cases respectively in non-severe patients, despite those were found in all severe cases.

Conclusions: We found that acute tubular injury was associated with the severity of COVID-19 infection. Since the pathophysiological hallmark of COVID-19 is severe systemic inflammation, it remains obscure whether progressive damage of tubules in SARS-CoV-2 is the result of direct viral infection, ischemic injury, or exposure of any humoral factors. Further large scaled studies focusing on tubular damage should be needed to elucidate underlying mechanisms of renal complication in COVID-19 infection.
0.067 mcg/kg/min (95% CI 0.047-0.101). Intradialytic hypotension (SBP decrease ≥20 mmHg) occurred in 10 (9.7%) of 104 PIRRT procedures, and 13/101 (13%) PIRRT were discontinued due to severe hypotensive episodes, with 2 patients switched to CRRT. System clotting was a frequent event during the first three weeks of March (7 events in the first 30 PIRRT procedures) until concomitant enoxaparin (0.5 mg/kg/day) and regional anticoagulation (unfractionated heparin 500 U/h) were employed. During follow-up, 3 patients (36%) recovered from AKI and respiratory failure, 3 (21%) died, and 6 (43%) are still hospitalized at the time of this report. In those who recovered renal function (9/14), the median number of PIRRT sessions was 6 [IQR 5-8]. Table shows changes in our PIRRT protocols during the COVID-19 outbreak.

Conclusions: PIRRT therapy was feasible and appropriate in most patients who exhibited an exuberant inflammatory response, severe hemodynamic instability, and hypercoagulability.

PO0666
COVID-19 AKI: Risk Factors and Markers of Disease from a Large UK Cohort
Thomas Phillips,1 Gary Leggett,1 Matt Stammers,1 Kirsty Armstrong,1 Simon D. Fraser,2 Becky Bonfield,1 Kristin Veighy.1 1University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom; 2University of Southampton, Southampton, United Kingdom.

Background: Acute kidney injury (AKI) is a significant complication of COVID-19 infection. UK NICE guidelines have been developed. Aim: to examine our local patient-level COVID-19 Hospitalisation in England Surveillance System (CHESS) database to elucidate potential risk factors for AKI vs guidelines.

Methods: 564 COVID positive admissions between 7 March-24 May 2020 at University Hospital Southampton were examined using Python (Anaconda distribution) and SPSS. AKI was staged by RIFLE and AKIN criteria consistent with NICE guidance. A test, Mann-Whitney U-test and logistic regression were used to analyse the data.

Results: AKI was present in 177 patients (31%). At peak, 108 (61%) stage 1; 42 (24%) stage 2; 27 (15%) stage 3. There were no significant differences in cohorts with respect to white vs non-white ethnicity, gender, obesity or anti-COVID-19 treatment. 44% of patients with AKI died vs 19% in the non-AKI group, increasing with stage of AKI (p<0.001). AKI was associated with ICU admission (27% vs 10% p<0.001), requirement of non-invasive ventilation (14% vs 4%) (both p<0.001). Prior diabetes (18% vs 8%), hypertension and thrombotic microangiopathy as a cause of AKI in COVID-19 patients. Additional studies are needed to explore this potential mechanism of AKI in COVID-19.

Conclusions: Elevated lactate dehydrogenase levels and microscopic hematuria on presentation are independently associated with 50% probability of moderate to severe AKI. Our findings suggest a possible pathogenic mechanism of endothelial cell injury and thrombotic microangiopathy as a cause of AKI in COVID-19 patients. Additional studies are needed to explore this potential mechanism of AKI in COVID-19.

PO0667
High C-Reactive Protein and D-Dimer on Admission Predict the Development of AKI in Patients Hospitalized with COVID-19
Sandeep Venkataraman, Zhiying You, Jessica B. Kendrick. University of Colorado Denver School of Medicine, Aurora, CO.

Background: COVID-19 infection is characterized by an acute respiratory syndrome that causes severe symptoms in some patients including a high incidence of acute kidney injury (AKI), which is associated with poor prognosis. COVID-19 infection results in a complex host response including a cytokine storm and severe inflammation. We aimed to identify whether high inflammatory markers on admission predict the development of AKI.

Methods: We performed a cohort study utilizing data from 430 patients admitted to the COVID-19 to the University of Colorado Hospital. We excluded patients with a known diagnosis of end stage kidney disease or chronic kidney disease or with missing data. A total of 203 patients were included in this analysis. The primary predictors were initial serum C-reactive protein (hsCRP) >100 mg/L and D-dimer >1000 ng/mL FEU on admission to the hospital. The primary outcome was AKI, defined by KDIGO definition of AKI based on serum creatinine levels. AKI diagnosis was confirmed by chart review. Multivariable logistic regression analysis was used to examine the association between CRP and D-dimer on admission and development of AKI.

Results: The mean age and body mass index of patients was 53.7 (16.9) years and 31.5 (8.4) kg/m², respectively. Ninety-five percent of patients were male, 40% were Hispanic and 22.7% were Black. 44.3% had hypertension, 35.0% had diabetes and 23% had underlying respiratory disease. Twenty-seven (13.3%) patients developed AKI. After adjustment for age, gender, race/ethnicity, diabetes, hypertension, respiratory disease, cardiovascular disease and ACE/ARB use, admission CRP level >100 mg/L was associated with nearly a 4-fold increased odds of developing AKI (OR 3.8, 95% CI 1.4-9.8). After full adjustment, admission D-dimer level greater than 1000 ng/mL FEU was associated with a 5-fold increased odds of AKI (OR 5.0, 95% CI 1.8 to 13.5).

Conclusions: High CRP and D-dimer on admission were associated with a significantly higher risk of developing AKI, independent of underlying comorbidities. Thus, high CRP and D-dimer on admission should trigger due deliberation and avoidance of nephrotoxic medications and close monitoring for the development of AKI.

PO0668
Hematuria and Elevated Lactate Dehydrogenase Are Associated with AKI in Hospitalized COVID-19 Patients
George Thomas, Georges Nakhoul, Jonathan J. Taliercio, Tushar J. Vachharajani, Sevag Demirjian. Cleveland Clinic, Cleveland, OH.

Background: Acute kidney injury (AKI) can be a severe complication of COVID-19, particularly in those who require intensive care. Its relationship to the incidence of proteinuria, hematuria, and elevated inflammatory markers has not been well characterized. Our objective is to describe the incidence of AKI in COVID-19, and its association with inflammatory markers.

Methods: Retrospective cohort study of adult patients hospitalized at the Cleveland Clinic with COVID-19. SARS-CoV-2 infection was confirmed by virus detection in respiratory specimens using RT-PCR. AKI was diagnosed per KDIGO serum creatinine-based classification. We selected stage 2 and higher as our primary endpoint for the study. Baseline creatinine was defined as the most recent pre-admission level available within 3 months of presentation. Acute lung injury was defined by the need for mechanical ventilation.

Results: The incidence of AKI was 14% in 621 hospitalized COVID-19 patients, with half requiring kidney replacement therapy (KRT). The incidence of proteinuria and microscopic hematuria were high in these patients (83% and 77% respectively). Seventy five percent of patients with AKI needed mechanical ventilation, and timing of KRT overlapped with time of mechanical ventilation. Inflammatory markers and acute phase reactants, including LDH, ferritin, and C reactive protein were significantly higher in patients with AKI compared to those with no AKI. On adjusted analysis, hematuria and elevated LDH levels were significantly associated with AKI (Figure).

Conclusions: Elevated lactate dehydrogenase levels and microscopic hematuria on presentation are independently associated with 50% probability of moderate to severe AKI. Our findings suggest a possible pathogenic mechanism of endothelial cell injury and thrombotic microangiopathy as a cause of AKI in COVID-19 patients. Additional studies are needed to explore this potential mechanism of AKI in COVID-19.
patient had BMI greater than 35 kg/m² and a history of appendectomy. Median duration of
follow-up from time of PD catheter placement was 37 days (IQR 32-37.5), death-censored
median follow up was 35 days (IQR 30-37.5). The median time from AKI to death was
17 days (IQR 14-22). Median time from AKI to renal recovery was 34 days (IQR 21-40).

Conclusions: In our AKI-PD cohort, the mortality rate was noted to be 36% and 45%
for patients with renal recovery observed. Two of our patients converted from CRRT to PD due to repeated filter
clogging. We did not observe any bleeding complications in our cohort. We hypothesize
that hypercoagulable COVID-19 patients may be excellent candidates for PD potentially
due to lower risk of bleeding complications.

Table 1.

Introduction: In developed countries such as the United States, intermittent
hemodialysis (IHD) or continuous renal replacement therapy (CRRT) are the primary
mode of renal replacement therapy (RRT) for the management of AKI. However,
during the COVID-19 pandemic, the ability to provide HD in our hospital system was
overwhelmed due to the surge in the number of patients with AKI requiring RRT combined
with severe personnel shortages related to illness. Studies have shown no difference in
clinical outcomes between HD and PD for AKI. We describe our rapid adoption of an
acute PD program during the COVID-19 surge.

Case Description: At Montefiore Medical Center (MMC), in Bronx, NY, the first patient with COVID-19 was admitted on March 11, 2020. As the number of patients with AKI rose, we initiated an acute PD program starting on March 25th. As of April 13th, there were 2,015 patients with COVID-19 admitted to MMC. From April 1st to April 22nd, 30 patients were initiated on PD with the help of surgery and interventional radiology who placed Trenchhoff catheters at bedside and under fluoroscopy, respectively. Of those 30 patients, 14 died, 8 were discharged, and 8 were still hospitalized as of May 14, 2020. Of the 8 patients discharged, 3 were still on PD and 5 had renal recovery (all were able to stop dialysis and 4 returned to baseline creatinine). Of the 8 patients still hospitalized, 4 patients were switched to IHD (3 due to fluid retention and 1 due to PD catheter malfunction), and 4 patients had renal recovery and were able to stop dialysis. Challenges to this program included lack of nurse training, difficulty securing supplies and irregular therapy provision and underdosining due to staffing shortages. Patients on medical wards received more frequent exchanges and did not have significant volume overload and metabolic derangements like those patients requiring intensive care.

Discussion: Despite challenges, we demonstrate the feasibility of acute PD as an
alternative to HD in patients with COVID-19-associated AKI. In this single-center experience, we found that acute PD was more effective for stable patients on the wards than for patients with severe illness requiring intensive care.
Results: The 20 patients initiated early RRT after 6.4±3.6 days from ICU admission. The median time of renal pathology was 50±42.2 hours, the net ultrafiltration rate was 65.5±65.2 ml/h. One patient in control group also received RRT after ICU admission due to AKI. No statistical difference was found in the two subgroups in baseline. 61.3% patients died during hospitalization. The median survival time was 12 days and the average observation time was 19 days. Kaplan-Meier analysis showed that the cumulative risk of death of early RRT patients was lower than control group (50.5% vs 66.7%, p=0.040). Univariate analysis and Cox proportional hazard regression also confirmed that early initiation of RRT was an independent risk factor (HR 0.21, 95% CI 0.06-0.74, p=0.014) for in-hospital all-cause death of severe Covid-19 after adjusting by SpO2, lymphocyte proportion, albumin, LogNT-proBNP, LogInterleukin-6, mechanical ventilation and use of glucocorticoid. A figure that shows the course of disease indicates that early initiation of blood purification may decrease the death without multiple organs injury (39% vs 0%, p=0.037).

Conclusions: Early initiation of blood purification could probably reduce the mortality of severe Covid-19. It was implied that it could delay occurs and reduce degrees of target organs injuries by cutting the peak load of cytokine storm. Further research in basic and clinical were needed to clarify the mechanism of blood purification in cytokine storm-related diseases.

PO0673
Incidence of New-Onset Proteinuria in AKI Associated with COVID-19
Is Not Greater Than It Is in AKI from Other Causes

Vincent Zago M.D.,1 Juan Carlos Q. Velez.2 Ochsner Nephrology 1Ochsner Clinical School - University of Queensland, New Orleans, LA; 2Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA.

Background: Early reports of acute kidney injury (AKI) associated with COVID-19 have claimed high incidence of proteinuria. If so, it may suggest an AKI pathogenesis not solely related to ischemic acute tubular injury (ATI). We hypothesized that those claims result from observation bias. Therefore, we sought to investigate the rate of de novo proteinuria in AKI associated with COVID-19 (CoV-AKI) compared to that of AKI in the pre-COVID-19 era (non-CoV-AKI).

Methods: Hospitalized patients with CoV-AKI entered the cohort (n=161). As a control-CoV-AKI group (n=186), we accessed a database of patients with AKI who underwent urinary sediment microscopy due to suspicion of an intrinsic cause of AKI (Sedi-AKI cohort, 2017-2019). We examined the incidence of proteinuria of any degree (S umoji ≥1+ dipstick), significant [urine protein-to-creatinine ratio (UPCR) ≥0.5-3.0 g/g or ≥3+ dipstick] or overt [UPCR ≥3.0 g/g + 3+ dipstick].

Results: In CoV-AKI and non-CoV-AKI, respectively, Women were 62% and 63% (p=0.56). Black race was more common in CoV-AKI (75% vs. 35%; p=0.0001). ATI (ischemic and/or toxic) was the presumed cause of AKI in 75% and 71% of CoV-AKI and non-CoV-AKI, respectively. Incidence of de novo significant or overt proteinuria were 123/148 (83%) vs. 8/186 (4.3%), respectively. Incidence of any, significant or overt proteinuria were 123/148 (83%) vs. 37/186 (20%) respectively.

Conclusions: Early initiation of blood purification may decrease the death without multiple organs injury (39% vs 0%, p=0.037).

PO0675
AKI due to COVID-19 in the Intensive Care Unit: Analysis of a Brazilian Center

Background: The kidney may be affected by coronavirus (COVID-19) in the setting of acute kidney injury (AKI) or glomerular diseases. Data about AKI in Intensive Care Unit (ICU) patients of Latin-America are scarce. The aim of this study is evaluate the risk of AKI, dialysis (HD) and death in ICU patients diagnosed with COVID-19 in a brazilian center.

Methods: Analysis from medical records of ICU patients with diagnosis of COVID-19 pneumonia in a brazilian single-center. AKI was defined according to KDIGO criteria.

Results: During the period of February 2nd to May 4th, 95 ICU patients diagnosed with COVID-19 were analyzed. There was predominance of male (64.2%), median age of 66.3 years. The previous diagnosis of hypertension, diabetes, smoking, high cholesterol, and 30.5% respectively. AKI was diagnosed in 54 (56.8%) patients and 32 (59.2%) of them required HD. Mortality rate was 17.9%. Patients with AKI, compared to no-AKI were statistically significant more frequently hypertensive and diabetic, worse SAPS3 and SOFA scores and need for organ support therapies. Laboratory tests depicted more anemia, lymphopenia, and higher levels of inflammatory markers as well as longer length of stay in ICU, hospital and death. Similar findings were seen in those one's who required HD compared to those with conservator treatment. Comparing patients who undergone death to survivors, they were older, more frequently diabetic, worse SAPS3 and SOFA scores and need for organ support therapies. AKI and dialysis. Multinomial logistic regression predicted that hypertension (p=0.01), mechanical ventilation (p=0.01) and use of hydroxychloroquine (p=0.009) were independent risk factors for AKI; hypertension (p=0.05), mechanical ventilation (p=0.01), use of vasopressor (p=0.04), and use of hydroxychloroquine (p=0.009) for HD patients; and age >65 years (p=0.03) and AKI (p=0.04) for death.

Conclusions: In our study, AKI was a common complication of ICU COVID-19 patients, it was related to hypertension, support therapies and use of hydroxychloroquine. As well as age >65 years, AKI was an independent risk factor to death.

PO0674
AKI Perspectives and Practices in Latin America (LA) During COVID-19: Analysis from GlomCon Latin America Working Group

Javier Soto-Vargas,1 Desiree Garcia Anton,2 Diana Aguirre, Denisse Arellano-Mendez,3 Franco H. Cabeza Rivera,4 Julio A. Gutierrez-Prieto,5 Blanca Martinez-Chagolla,6 Sonia Rodriguez Ramirez,7 Carmen Velasco-Casado,8 GlomCon Latin America Working Group 1Especialidad de Nefrologia, Hospital General Regional 46, Guadalajara, Mexico; 2University of Mississippi Medical Center, Jackson, MS; 3Hospital General de Mexico, Mexico; 4Unidad Medica de Atencion Ambulatoria 254, IMSS, Morelia, Mexico; 5Hospital Central del Estado de Chihuahua, Chihuahua, Mexico; 6Hospital General "Dr. Miguel Silvia ", Morelia, Mexico; 7Multi-Organ Transplant Program, University Health Network, Toronto, ON, Canada; 8Pathology Department, University Health Network, Toronto, ON, Canada.

Background: The epidemiology, clinical presentation, management and outcomes of COVID-19 comes from early reports from China and Europe with AKI prevalence ranging widely from 0.5% to 29%. However, knowledge about this pandemic is still evolving. Between May 20-27, 2020 from sixteen Spanish speaking Latin American countries divided into 6 categories. We present the results for the AKI category.

Results: 430 responses were obtained of which 360 (84%) were considered for analysis. Of the participants, 54% reported the prevalence of AKI to be <5%, while 32% estimated it at 6-10%. The majority of AKI in these patients was stage 3 according to 31% of the respondents. Roughly half of the nephrologists witnessed new onset proteinuria which was almost exclusively (96%) sub-nephrotic. The majority (64%) reported no hematuria. Half of the participants (59%) reported that renal replacement therapy (RRT) was never or rarely required. Intermittent hemodialysis was the main RRT used reported by 88% of those surveyed followed by continuous renal replacement therapy (33%), peritoneal dialysis (24%) and prolonged intermittent hemodialysis (19%). The most common complications during RRT were hypotension (60.3%) and circuit clotting (36.6%). Over one third of the participants (35%) estimated the mortality of patients with AKI and COVID to be <20%.

Conclusions: Our survey highlights potential differences in the presentation, management and outcomes of AKI in patients with COVID-19 in LA; among those, a lower prevalence, higher need for RRT and lower mortality. More studies are warranted to better understand AKI in hispanic COVID-19 patients as well as its distinct characteristics compared to the rest of the world.

AKI In People Living with HIV Hospitalized with COVID-19

Molly Fisher,1,2 Melissa Fazzani,2 David B. Hanna,2 Viraj V. Patel,1,2 Uriel R. Felsen,1,2 Mindy Ginsberg,2 Kathryn Anastasi,1,2 Michael J. Ross,1,2 Montefiore Medical Center, Bronx, NY

**Background:** People living with HIV (PLWH) have an increased burden of kidney disease and any increase in risk factors places them at increased risk for acute kidney injury (AKI) in the setting of COVID-19. The aim of our study was to characterize the incidence, risk factors and outcomes of AKI among hospitalized PLWH with COVID-19.

**Methods:** We performed a retrospective study of adult PLWH hospitalized with laboratory-confirmed COVID-19 in a large healthcare system in Bronx, New York, from March 10-May 11, 2020. Data collected included demographics, comorbidities, antiretroviral therapy (ART), initial laboratory data, and preadmission CD4 count and HIV viral load. AKI was defined and staged using KDIGO criteria. Fisher and Wilcoxon tests were used to compare differences in those with and without AKI.

**Results:** During the study period, 77 PLWH were hospitalized with COVID-19. The majority were Black or Hispanic, 50% were men, 53% had hypertension, 31% diabetes mellitus, 22% chronic kidney disease (CKD) and 14% end-stage kidney disease (ESKD). Mean age was 47 years and 83% had a suppressed HIV viral load (<40 copies/mL). After excluding 11 with ESKD, AKI incidence was 50%. Those with AKI were older (63 [SD 9.5] vs 55 [SD 13] years, p=0.005), more were black (56% vs 37%, p=0.01) and more had CKD (42% vs 9%, p=0.001) compared to those without AKI. There were no significant differences in CD4 count, HIV viral load, or use of tenofovir-containing ART between those with and without AKI. By AKI severity, 11/33 (33%) were stage 1, 4/33 (12%) stage 2 and 18/33 (55%) stage 3. Mechanical ventilation (33% vs 0%, p=0.0004) and in-hospital mortality (42% vs 3%, p=0.0002) were more common in those with AKI. Of 6 patients who required renal replacement therapy, 4 died and 2 remained RRT dependent. Admission white blood cell count, neutrophil/lymphocyte ratio, D-dimer, ferritin, C-reactive protein and lactate dehydrogenase levels were significantly higher in those with AKI.

**Conclusions:** The incidence of AKI in PLWH hospitalized with COVID-19 was high and associated with poor outcomes. We did not identify HIV-specific risk factors for AKI in the setting of COVID-19. Admission inflammatory markers may be predictive of AKI in PLWH with COVID-19.

**PO0678**

AKI Is Related to Mortality in COVID-19 Patients Without Underlying Kidney Disease

Yue Yu, Huipeng Ge, Xifen Wang, Lijian Tao, Zhangzhe Peng, Xiangcheng Xiao. Xiangya Hospital Central South University, Changsha, China.

**Background:** Due to its high infectivity and mortality, coronavirus disease 2019 (COVID-19) has become a global public health issue. The kidneys act as critical metabolic organs, therefore, whether COVID-19 can induce renal damage is of utmost importance but the evidence about the etiology of COVID-19 encountering acute kidney injury (AKI) is unknown. Moreover, the efficacy of different treatments that COVID-19 patients undergo needs to be explored. In this study, we aimed to explore these questions.

**Methods:** A single-center, retrospective study was conducted in which 96 patients with COVID-19 were enrolled. Epidemiological, clinical, and laboratory characteristics, as well as treatments and patient outcomes were described. Characteristics were compared between severe cases and critical cases. Relevant factors of AKI were filtrated, and the treatment efficacy was also evaluated. Results: A total of 6 patients (6.3%) died during hospitalization. Four patients (4.2%) developed AKI, among which 3 patients (75%) died. Statistical analysis indicated that AKI was not common in COVID-19 patients without underlying kidney disease, but was related to mortality. Age, severity of disease, procalcitonin, C-reactive protein and interleukin-6 were correlated with AKI onset in COVID-19 patients, while lymphocyte count and estimated glomerular filtration rate at admission were inversely related to the development of AKI.

**Conclusions:** In conclusion, AKI is not common in COVID-19 patients without underlying kidney disease but related to mortality.

**Funding:** Government Support - Non-U.S.

**PO0679**

Acute Peritoneal Dialysis with Percutaneous Catheter Insertion for COVID-19-Associated AKI in Intensive Care: Experience from a UK Tertiary Centre

Dandisobra B. Braidie-Azikiwe, Elaine Bowes, Kate Bramham, Caroline Tuley, Eirini Lioudaki, Hugh Cairns, Claire C. Sharpe. King’s College Hospital, London, United Kingdom.

**Background:** During the COVID-19 pandemic in 2020, high rates of acute kidney injury (AKI) in critically unwell patients are being reported, leading to increased demand for renal replacement therapies (RRT). There are considerable challenges providing RRT for large numbers of patients with COVID-19 and alternatives to continuous veno-venous hemodiafiltration therapies (CVVHFD) in intensive care units (ICU) are needed in both high and low-resource settings. Peritoneal dialysis (PD) can be initiated immediately after percutaneous insertion of the catheter, but there are concerns about impact on ventilation and RRT efficacy. We describe our recent experience of percutaneous catheter insertion and peritoneal dialysis in patients in ICU with COVID-19 infection.

**Methods:** Patients were selected according to local protocol and catheters inserted percutaneously using Seldinger technique by two experienced operators. Sequential Organ Failure Assessment score (SOFA) and ventilation requirements were recorded at time of insertion, and at 24 hours after insertion. Procedure complications, proportion of RRT provided by PD, renal recovery and RRT parameters during PD were assessed.

**Results:** Percutaneous PD catheters were successfully inserted in 32/39 (82.1%) patients after median of 10.0 (IQR 13.0, 19.0) days on ICU. No adverse events following insertion were reported, SOFA scores and ventilation requirements were comparable before and after insertion and adequate RRT parameters were achieved. Median proportion of RRT provided by PD following percutaneous insertion was 90.2% (IQR 77.5, 100).

**Conclusions:** PD provides a safe and effective alternative to CVVHFD in selected patients with AKI and COVID-19 infection requiring ventilation on intensive care.

**Clinical Parameters of Patients Prior to and after Peritoneal Dialysis Catheter Insertion**

- IQR: interquartile range; PD: Peritoneal Dialysis; PaO2 : FiO2 ratio (arterial oxygen partial pressure (PaO2 in mmHg) to fractional inspired oxygen (FiO2 expressed as a fraction)); SOFA: Sequential Organ Failure Assessment

Adding Heparin to Citrate in Continuous Renal Replacement Therapy May Extend Filter Lifespan in COVID-Related AKI

**Background:** COVID may predispose patients to thrombosis and lower filter lifespan. Association between D-dimer level and DD. There are considerable challenges providing RRT for large numbers of patients with COVID-19 and alternatives to continuous veno-venous hemodiafiltration therapies (CVVHFD) in intensive care units (ICU) are needed in both high and low-resource settings. Peritoneal dialysis (PD) can be initiated immediately after percutaneous insertion of the catheter, but there are concerns about impact on ventilation and RRT efficacy. We describe our recent experience of percutaneous catheter insertion and peritoneal dialysis in patients in ICU with COVID-19 infection.

**Methods:** Patients were selected according to local protocol and catheters inserted percutaneously using Seldinger technique by two experienced operators. Sequential Organ Failure Assessment score (SOFA) and ventilation requirements were recorded at time of insertion, and at 24 hours after insertion. Procedure complications, proportion of RRT provided by PD, renal recovery and RRT parameters during PD were assessed.

**Results:** Percutaneous PD catheters were successfully inserted in 32/39 (82.1%) patients after median of 10.0 (IQR 13.0, 19.0) days on ICU. No adverse events following insertion were reported, SOFA scores and ventilation requirements were comparable before and after insertion and adequate RRT parameters were achieved. Median proportion of RRT provided by PD following percutaneous insertion was 90.2% (IQR 77.5, 100).

**Conclusions:** PD provides a safe and effective alternative to CVVHFD in selected patients with AKI and COVID-19 infection requiring ventilation on intensive care.

**Clinical Parameters of Patients Prior to and after Peritoneal Dialysis Catheter Insertion**

253
filter clotting per patient-day. ACD/Hep also presented less clotting than ACD group (ACD:Hep: 41% vs ACD 106% p < 0.05). In COVID patients, median TFC was 33.5 h [17.0;72.0]. ACD:Hep [0.90 [13.68-65.5], ACD:Hep: 40.0 h [17.0;62.0], p: NS]. Clotting time from obese patients did not differ from non obese patients (obese: 31.0 h [18.5;57.2] vs non-obese: 36.0 h [16.8;72.0], p: ns). Median DD in all COVID patients was 3.519 [1420-13.883]. Patients with DD below median (<3,500) had higher TFC (ACD high DD: 19.0 h [9.0;27.5], ACD/Hep high DD: 34.0 h [17.0;62.0], ACD low DD: 57.0 h [27.0;68.0], ACD/Hep low DD: 67.0 h [26.0;72.0]). Figure 1. There was statistically significant correlation in between DD and TFC in ACD patients, but not in ACD/Hep group.

Conclusions: Hemox may extend filter lifespan in CRRT, and this benefit seems to be greater in high DD patients.

PO0683
Association of Ventilatory Time and AKI in a Bronx Cohort of COVID-19 Patients
Abhinav Bansal,
1 Diene Liu,
1 Molly Fisher,
1 Ladan Golestanech;2
1 Eran V. Bellin;2 Kim J. Reidy1;
2 Children’s Hospital at Montefiore, Bronx, NY; 3 Montefiore Medical Center, Bronx, NY.

Background: The relationship of lung-kidney interactions in COVID19 has not been well described. AKI has been associated with increased mechanical ventilation times. Recent publications have shown a strong association of COVID19-AKI with mortality and a high incidence of AKI occurring peri-intubation. We hypothesized that mechanical ventilation (MV) time would be increased in patients with COVID19-AKI and longer in those with more severe AKI.

Methods: We analyzed a cohort of incident COVID19 patients who required MV. Patients with end stage renal disease were excluded. AKI was defined using KDIGO criteria (0.3 mg/dL increase in creatinine from within 48 hours). AKI stage was defined by KDIGO criteria (0.3 mg/dL increase in creatinine from baseline). Total MV time was measured from initiation to extubation/continuous renal replacement therapy. Ventilator days were calculated using Hospital Episode Submission Data. AKI was defined per KDIGO criteria (0.3 mg/dL increase or greater than a 50% increase from the baseline Cr) between the current and baseline Cr. AKI stage was defined as per KDIGO criteria (0.3 mg/dL increase). AKI stage was defined by KDIGO criteria (0.3 mg/dL increase or greater than a 50% increase from the baseline Cr) between the current and baseline Cr. AKI stage was defined as per KDIGO criteria (0.3 mg/dL increase). AKI stage was defined by KDIGO criteria (0.3 mg/dL increase or greater than a 50% increase from the baseline Cr) between the current and baseline Cr. AKI stage was defined as per KDIGO criteria (0.3 mg/dL increase or greater than a 50% increase from the baseline Cr).

Results: Over 5000 AKI alerts were generated for this period for 4390 unique admissions. AKI occurred in 89% (N=283) of the cohort. Stage 3 AKI developed in over 50% (N=161) of patients. In models adjusted for age, hypertension, diabetes and disease related group weight, patients with AKI had 3.46 more days of MV, however this finding did not reach statistical significance (95%CI 0.92-6.00). This association however was significant and increased linearly with stage of AKI (p for trend <0.001).

Conclusions: We analyzed 318 patients. 62% were male, 37% were black/African American and 33% were Hispanic/Latino. Hypertension was prevalent in the cohort (N=212) and over 50% were obese. Median MV time was 4.67 days (IQR 1.76, 9.95). AKI occurred in 89% (N=283) of the cohort. Stage 3 AKI developed in over 50% (N=161) of patients. In models adjusted for age, hypertension, diabetes and disease related group weight, patients with AKI had 3.46 more days of MV, however this finding did not reach statistical significance (95%CI 0.92-6.00). This association however was significant and increased linearly with stage of AKI (p for trend <0.001).

PO0684
Can the AKI Alert Staging Tool Help Manage Patients Admitted During the COVID Pandemic?
Baraa Mohdin,1 Devndran A. Chatterjee, Gurminder S. Khamba, Georgia W. Winnett, Kidney Medicine, Basildon & Thurrock University Hospital Mid and South Essex University Hospitals Group, Basildon, United Kingdom.

Background: Basildon & Thurrock University Hospital has the second highest rate of hospital admissions with AKI stage 3 in the United Kingdom based on Renal Registry Hospital Episode Submission Data. Acute kidney injury (AKI) is common in hospitalized patients and carries a high risk of mortality. Given the limitations of resources both personnel and equipment, a retrospective study was done to see if the AKI alert staging tool could help predict and direct resources to those patients who would benefit most from specialist intervention.

Methods: Data was reviewed from January - May 2020. This corresponded to the peak of admissions and by the end of the period, the hospital was on course to running to pandemic activity. Relevant data including admission laboratory tests and imaging was collected. The admission stay was analysed for duration, the need for transfer to an intensive care environment to receive ventilator support and/or renal replacement therapy. Discharge destination was reviewed and whether the patient was discharged home, to another facility or did not survive the admission. For comparison we looked at the same period in the preceding year as this would represent the most matched population.

Results: Over 5000 AKI alerts were generated for this period for 4390 unique admissions. This compares to 3910 AKI alerts for 1098 unique admissions for the identical period in the previous year. The vast majority were for AKI stage 1 alerts none of which were in COVID positive patients. A significant proportion of patients with AKI Stage 2 and 3 alerts were positive for COVID. Those that were admitted to Intensive Care with Stage 3 AKI almost always required intubation and renal replacement therapy. Mortality was higher in this group.

PO0685

Characteristics and Outcome of AKI Needing Dialysis with COVID-19 Infection

Background: COVID-19 infection has varying grades of mortality worldwide. Multi-organ injury, not uncommonly associated with AKI, portends a poor outcome. We studied AKI needing hemodialysis (HD) in the context of COVID-19 infection.

Methods: From March 15th to May 25th 2020, for consecutive COVID-19 infections AKI needing HD in a large dialysis network age, gender, payer type, days:admission to HD start, urine output, S. Cr, comorbidities, other organ injuries, length of stay & outcome, dialysis session details: blood flow rate(BFR), dialysis flow rate(DFR), ultrasound volume were reviewed. We compared survivors and non survivors using Mann Whitney/ Wilcoxon 2 sample test for medians and Fisher exact 2 tailed for association.

Conclusions: AKI needing HD in COVID-19 infection is associated with significant multiorgan injury and high mortality, making management difficult. No significant clinical characteristics were predictive of survival in a sample size

Comparison of survivors and non survivors of COVID-AKI needing HD

PO0686

Circuit Clotting on Continuous Venovenous Hemofiltration in COVID-19 Patients at New England’s Largest Health Safety-Net Hospital

Claire Avillach, Megan E. Feeney, Mohamed T. Hassan Kamel, Hassan Mahmoud, Aileen W. Zhen, Natasha Awais, Sandeep Ghai. Boston Medical Center, Boston, MA.

Background: The pandemic of COVID19 led to a surge in critically ill patients with severe kidney failure requiring continuous renal replacement therapy (CRRT). Primary reports rapidly showed a hypercoagulable state associated with cytokine storm representing a challenge to conduct CRRT. We report our experience to face clotting on continuous venovenous hemofiltration (CVVH) with COVID19 patients.

Methods: We reviewed data on all admitted patients with COVID19 diagnosis and requiring CVVH at Boston Medical Center between March, 15th and May 7th, 2020. The study was approved by the institutional IRB.

Results: Twenty six patients were admitted to ICU with COVID19 disease and developed acute kidney injury requiring CRRT. The majority of patients were males (73%), and mean age was 64.3 ± 15.9 years. During the study period, patients showed markers of inflammation with a median CRP of 239.6 (IQR 123-391.5), fibrinogen 609mg/dl (431-693), d-dimer 4.036 ng/ml (1.777-15.558), CVVH was conducted in predilution mode, with a median therapy rate of 3L/h (2.5-3.1) and a mean blood flow of 280 mL/min. The median cartridge half-life from CVVH initiation was 11.8 hours (3.5-20). Ten patients (46%) experienced CVVH circuit clotting within the first 2 hours, including 6 patients (23%) with severe recurring clotting. Curative systemic anticoagulation by heparin was used in 12 patients (46%) based on hospital protocol. Its use was associated with mild improvement in cartridge half-life: 15h with curative heparin vs 11.25h with no low dose preventive anticoagulation (non-significant). Of note, heparin was held prior to CRRT initiation for dialysis catheter placement and was reinstituted without bolus, which could lead to early coagulization of the filter in patients with hypercoagulable state. The fatality rate was 76.9% with a median time of 22.5 days (1-87 days).

Conclusions: Conducting CRRT in patients with multiorgan failure secondary to COVID19 is challenging. Our experience suggests only a mild non significant improvement of clotting prevention with heparin anticoagulation at the time of cvvh initiation. Further studies are warranted to determine the optimal anticoagulation regimen.

PO0687

Clinical Characteristics and Short-Term Outcomes of Severe AKI in COVID-19 in Bronx, New York

Milagros Yunes,1 Emad Alahari,1 Ryan Mocerino,1 Kalyan Prudhvii,1 Ladan Golestan,1,2 Molly Fisher.1,2 *Montefiore Medical Center, Bronx, NY; 1Albert Einstein College of Medicine, Bronx, NY.

Background: After the first reported case of COVID-19 in the U.S., New York City quickly became the epicenter of the pandemic. AKI has been reported in patients with severe COVID-19. The Bronx consists of a predominantly minority population with a high burden of comorbidities that may be at increased risk for AKI in the setting of COVID-19. We aimed to characterize risk factors and short term outcomes in patients hospitalized with COVID-19 and severe AKI.

Methods: We performed a retrospective study of 113 adults hospitalized with COVID-19 in a large healthcare system in the Bronx who required nephrology consultation for AKI from March 11-March 30, 2020. We extracted data on demographics, comorbidities, admissions vital signs and labs, need for mechanical ventilation, renal replacement therapy (RRT), in-hospital death and discharge. AKI was defined by KDIGO criteria. Chi-square analyses and Wilcoxon tests were used. Data was censored on April 19, 2020. All patients had >14 days of follow up.

Results: Mean age was 63 (SD 12) years old; 69% were men and 33% were Black and 23% were Hispanic. Forty-five patients (39.8%) had chronic kidney disease, 58(51%) had diabetes mellitus and 87(77%) had hypertension. The majority presented with AKI within 24 hours of admission, and 75% had Stage 3 AKI. Ninety-two (81%) patients had proteinuria and 53(47%) had hematuria. Intensive care unit (ICU) was required in 62(55%), 64(57%) required mechanical ventilation, 56(49%) required RRT and 18(16%) were not candidates for RRT. In-hospital death occurred in 68(60%) and 22% were discharged. Of those who required RRT, in-hospital death occurred in 56(62%) and only 6 patients were discharged, 5 of whom remained RRT dependent. Heavy proteinuria (3+) or urinary protein were initial C-reactive protein (CRP) were higher in those with AKI who died (21.1 [IQR 14.3-29.6] versus 6.6 [3.2-16.3], p<0.001). Conclusions: Severe AKI in the setting of COVID-19 is associated with increased utilization of ICU, mechanical ventilation, and RRT. Outcomes are poor in those with Stage 3 AKI, underscoring the need for palliative care involvement and early goals of care discussions. Elevated initial CRP and heavy proteinuria may be useful to risk stratify patients with COVID-19 and severe AKI at increased risk for mortality.

PO0688

Clinical Factors Associated with AKI in Patients with COVID-19 from a University Hospital in Brazil

Daniela Ribeiro Chilaça,1 Isabelia S. Maltoni,1 Felipe F. Sanches,1 Mariana R. Coletti,1 Caio C. Delfino,1 Isabelia G. Almeida,1 Letícia C. Albeny,1 Gabriel N. Araujo,2 Renata G. Rozim,1 Giovanna M. Zavadzki,1 Miguel Angelo Goes,1 1Universidade Federal de Sao Paulo, Sao Paulo, Brazil; 2Unisa, Sao Paulo, Brazil.

Background: Critically ill patients with COVID-19 frequently presents Acute kidney Injury (AKI) associated with increased mortality. However, there is paucity of data from Brazil. So, we analyzed factors in associated with AKI patients in a university hospital.

Methods: We conducted an observation with frequencies and association with binary logistic regression study in patients with COVID-19 hospitalized at Hospital Sao Paulo-Federal University of Sao Paulo. Diagnosis and classification of acute kidney injury (AKI) were by KDIGO. We examined the rates of renal function, mechanical ventilation (MV), renal replacement therapy (RRT), medications and in-hospital mortality.

Results: We observed a total of 172 in-patients with COVID-19. Patients were predominantly male (61.5%). We observed hypertension in 55%, diabetes 34%, smokers 27%, obesity (19%). Eighty-nine (52%) patients needed intensive care unit (ICU), 70 (99.4%) cases of AKI were in ICU (31% of general ward admissions, p=0.001). In the ICU there were 78% needed mechanical ventilation, 36% in RRT, anemia 62.5% and mortality in 48%. AKI patients were older (61.15 ± 55.15; p<0.01), higher creatinine in admission (2.6 ± 1.6, 1.3 ± 0.7; p<0.002), higher RDRW (14.7 ± 1.3, 13.3 ± 1.6; p<0.08), need of MV (88%) and vasopressive anine (90%), RRT (88%) and higher mortality (87%). We used serum creatinine, BFR, RDW, mechanical ventilation and vasopressor anine in model of regression. We observed that MV (OR 10.26 [CI95%, 1009-1038; p<0.001) and age (OR 1030 [CI95%, 1004-1056; p=0.002) were independently associated with AKI.

Conclusions: AKI is associated with high rates of RRT and death. Higher age and need of mechanical ventilation were associated with AKI in COVID19 patients.

Funding: Government Support - Non-U.S.
Rigoberto with severe COVID-19 disease and associated multiorgan failure. Although more comorbidities were present in CA-AKI, outcomes were better for CA-AKI. Among patients with AKI, 92 (56%) died, 49% in the CA-AKI vs. 63% in the HA-AKI therapy. Recovery from AKI was more frequent in the CA-AKI group 66% vs 44% for RRT initiation. In general, AKI was associated with higher severity of COVID-19 Stage 3. Stage 3 was more frequently observed in HA-AKI (p<0.001). RRT was provided parametric ANOVA.

Background: AKI is a frequent complication of COVID-19. We describe characteristics of patients with COVID-19 who developed both, community-acquired AKI (CA-AKI) and hospital-acquired AKI (HA-AKI) in a Mexico City reference COVID-19 center.

Methods: We included data from all consecutive patients hospitalized between March 16th - May 29th 2020, with pneumonia and positive SARS-CoV-2 by RT-PCR test. Only data from patients who finished follow-up (n=636) was analyzed. AKI was defined according to KDIGO and ESKD patients (n=6) were excluded. Clinical and demographic characteristics of those with CA-AKI, HA-AKI, and non-AKI were compared by non-parametric ANOVA.

Results: Of 630 COVID-19, AKI was detected in 164 (26%), 81 (49%) CA-AKI, and 83 (51%) HA-AKI. Among AKI, 84 (51%) were Stage 1, 38 (23%) Stage 2, and 42 (26%) Stage 3. Stage 3 was more frequently observed in HA-AKI (p<0.001). RRT was provided to 15 (9.1%) at a median 3 days from diagnosis. Fluid overload was the main indication for RRT initiation. In general, AKI was associated with higher severity of COVID-19 evidenced by several risk scores, ICU admission, mechanical ventilation, and vasopressor therapy. Recovery from AKI was more frequent in the CA-AKI group 66% vs 44% (p<0.001), and 37% of patients associated to volume depletion were rehospitalized 26 Among patients with AKI, 92 (56%) died, 49% in the CA-AKI vs. 63% in the HA-AKI group (p<0.001). There were no differences in RAAS inhibitor use between groups.

Conclusions: CA-AKI and HA-AKI are frequent renal manifestations in COVID-19. AKI is associated with more severe COVID-19 and significantly higher mortality. Although more comorbidities were present in CA-AKI, outcomes were better for CA-AKI vs. HA-AKI, in spite the latter group being younger, as it represents ICU patients with severe COVID-19 disease and associated multiorgan failure.

Is AKI in COVID-19 Patients Associated with Increased Mortality? Vasantha Muthuppalanappan, Jennifer Ng, Phoebe Sharratt, Kristi Sun, Mark Harber. Whittington Hospital, London, United Kingdom.

Background: Acute kidney injury(AKI) affects 22% of hospitalised patients and is associated with a 21.9% increased risk of mortality in non COVID-19 admissions. Based on reports from China the rate of AKI in patients hospitalised with COVID-19 is 3-9%. The study’s objective was to identify AKI prevalence in COVID-19 patients and associated adverse outcomes.

Methods: This is a retrospective observational cohort study of patients admitted to hospital with positive COVID-19 PCR testing from 14th February to 7th May 2020. Demographic data, past medical history and blood results were obtained from health records. AKI was defined according to KDIGO criteria.

Results: 383 patients (220 Male) were included in the final analysis, with an age range of 18-99 yrs (median 69 yrs). AKI occurred in 153(39.9%) patients (103 male), with a median age of 74 years. 111(72.5%) patients had AKI on admission, 42(27.5%) developed AKI while hospitalised. Average clinical conditions were more (CFs) in the CA-AKI group was 4. Median creatinine kinase in the AKI group was 231u/L (IQR 149-1260). Of all 153 AKI patients,100(65.4%) were in Stage 1, 29(19%) in Stage 2 and 24(15.7%) in Stage 3. 140(92%) patients required renal replacement therapy (RRT) with 7(30%) becoming dependent on dialysis. 3 patients died associated to COVID-19 and 4 deaths occurred among specialist units for treatment whilst on RRT. Mean peak serum creatinine of 246mmol/L was observed on Day 5 of admission and Day 11 of symptoms on average. 90/153(58.5%) patients had recovery of renal function. 40/76(53%) patients who required CPAP or mechanical ventilation respiratory support had evidence of AKI compared to 113/304(37%) of non-ventilated patients. Of all 153 AKI patients, 65(43%) deaths occurred compared to 43/228(19%) in the non-AKI group. This difference was significant, p<0.01, OR = 2.89 (95% CI: 1.81, 4.58) suggesting that patients with AKI had a 74% chance of increased death. Univariate analysis showed that age, males, baseline eGFR, albumin, CFS and Charlson comorbidity index were predictors of AKI. Multivariable analysis showed that independent predictors of AKI included males, Black and Asian race, baseline eGFR and albumin. An increase in baseline eGFR by 1ml/min in COVID-19 patients was associated with a 2.4% risk reduction in death, p<0.01, OR = 0.976 (95% CI: 1.02, 1.03).

Conclusions: AKI is a common finding and a poor prognosticator in patients with COVID-19.
Background: Acute Kidney Injury (AKI) occurs in 3-37% of COVID patients; recovery is poorly described.

Methods: All patients who recovered from AKI in Clinics Hospital (Sao Paulo, Brazil) during April 2020 (COVID related-AKI (COV+), n=35) and September 2019 (COVID unrelated-AKI (COV-), n=25) were studied for 1.5 month each. Recovery was assessed by spontaneous serum creatinine (sCr) drop in patients not submitted to dialysis, or by withdrawal of dialysis in those who needed the therapy. Serum creatinine, urea (sU), sodium (sNa), bicarbonate (bic), and fluid balance (FB) were analyzed during the first five days of recovery (5-Dr). Data are expressed in mean ± SD. Repeated measures ANOVA was used to compare different days on each parameter, and t test was used to compare groups. Categorical data were analyzed using Fisher’s test.

Results: Among 88 COV- patients, 25 recovered from AKI, while 35 in 102 COV+ patients recovered during the time studied (80% COV+ were in KDIGO 3 classification). In COV+ group, COVID-AKI time was predictive of AKI duration: earlier AKI (≤ 2 days from COVID symptoms) lasted 5.6 ± 4.0 days (vs 11.9 ± 9.2 days in later AKI presentation, p = 0.05). Both COV+ and COV- patients showed sCr and sU drop during 5-Dr, except for diuretic users, who presented sCr drop without sU drop. COV+ patients presented negative overall FB during 5-Dr, while COV- patients presented positive FB (516.2 ± 2730 vs 225.5 ± 5868 ml/24h). In COV+, sNa rose through 5-Dr (p = 0.05), and in COV- it did not. Among diuretic users, the same pattern of FB was seen between groups (-194.9 ± 3163 in COV+ vs 163.5 ± 1080 ml/24h in COV-), and COV- showed increased sNa through 5-Dr (p<0.05), while COV- reduced sNa through 5-Dr (p = 0.05). Diuretic users had bicarbonate increase in COV+ (from 24.3 ± 3.6 to 27.0 ± 4.9 mmol/L, p<0.05), but not in COV-. In diuretic non-users, both groups have risen sNa through 5-Dr, but only COV+ reached statistical significance. Diuretic use at AKI-recovery was higher in COV+ patients (57% vs 28%, p = 0.05).

Conclusions: Later-onset COVID-related AKI seems to be more prolonged. Diuretics should be carefully used in AKI-recovering COV+ patients, once hypernatremia and metabolic alkalosis are more common than in other AKI etiologies.

PO0695
Filter Clotting, Anticoagulation, and Duration of Sustained Low-Efficiency Dialysis in Patients with COVID-19 and AKI
Yuanfeng Wang,1 Jason R. Ledoux,1 Akanksh Sumanand,1,2 Kevin Scharwath,1 Destiny A. Mundy,1 Muner Mohamed,1 Ivo Lukitsch,1 Juan Carlos Q. Yelez,1 Ochsner Nephrology 1Department of Nephrology, Ochsner Health System, New Orleans, LA, 2Ochsner Clinical School- The University of Queensland, New Orleans, LA.

Background: There have been anecdotal accounts of shortened duration of renal replacement therapy (RRT) due to filter clotting in patients with COVID-19 and acute kidney injury (AKI) (CoV-AKI) requiring RRT (AKI-RRT). Thus, we examined the duration of runs of RRT in patients with CoV-AKI as well as in patients with AKI-RRT in the pre-COVID-19 era.

Methods: Among 161 patients with CoV-AKI, we identified patients with CoV-AKI who underwent RRT by sustained low efficiency dialysis (SLED) for 2 days (n = 52) (March-April 2020). As a control, we included patients with AKI without COVID-19 diagnosis who underwent SLED (n = 24) (non-CoV-AKI) in December of 2019, pre-COVID-19 era. We quantified the duration of RRT under various protocols of anticoagulation (AC) [no AC, citrate (CIT), regional heparin (rH), minimally intensive heparin (mIH), systemic low intensity heparin (sLH), systemic high intensity heparin (sHH), and sHH plus CIT (sHH+CIT)] by computing the duration (hours) of each SLED session (hrs of SLED/start) and the percentage of short SLED runs (< 6 hours).

Results: In CoV-AKI, the median hrs of SLED/start under each AC protocol were 6.1 for no AC, 5.4 for CIT, 10.6 for rH, 11.6 for mIH, 11.4 for sHH, and 14.6 for sHH+CIT. As the AC intensified, the duration of SLED increased (ohrs for trend, p = 0.014). Pre-COVID-19, standard AC for non-CoV-AKI were no AC or CIT and had a median longer RRT duration compared to CoV-AKI under either no AC or CIT (10.2 vs 5.5 hrs of SLED/start, for non-CoV-AKI vs CoV-AKI, respectively, p = 0.021). Similarly, the proportion of patients with short runs was greater in CoV-AKI (under no AC or CIT) vs non-CoV-AKI (55% vs 19%, p = 0.01). When comparing the 3 more aggressive AC protocols (sLH, sHH and sHH+CIT) in CoV-AKI with non-CoV-AKI, the duration of RRT was similar (12.2 vs 10.2 hrs of SLED/start, p = 0.11) and the percentage of short SLED runs were also similar (10% vs 19%, p = 0.25).

Conclusions: RRT in CoV-AKI was associated with shorter duration of SLED compared to non-CoV-AKI, likely driven by increased filter and/or catheter clotting. Aggressive AC protocols with sHH with or without CIT in CoV-AKI were successful in restoring the duration of RRT back to that observed in patients with AKI-RRT in the pre-COVID-19 era.
Impact of Renal Replacement Therapy Modality on Prognosis of SARS-CoV2 Infection

Yannis Lombardi,1,2 Hafedh Fessi,1,2 Hélène François,1,2 Pierre A. Michel,1,2 Camille Petit-Hoang,1,2 Eric Rondeau,1,2 ‘Hôpital Tenon, Paris, France; ‘Sorbonne Université, Paris, France.

Background: Prognosis of SARS-CoV2 infection among patients with Chronic Kidney Disease (CKD) is poorly known. In particular, the impact of renal replacement therapy (RRT) modality on prognosis is undetermined. Patients with kidney transplant exhibit treatment-induced immunodepression, while patients on dialysis are usually older and exhibit higher frailty. We aim to determine the impact of RRT modality on the prognosis of SARS-CoV2 infection among patient with advanced CKD.

Methods: We conducted a retrospective cohort study using our institution’s Clinical Data Warehouse. Health records of all patients with at least one hospitalization or consultation in our nephrology department were screened based on ICD-10 codes. Inclusion criteria were: hospitalization in any of our institution’s hospitals for SARS-CoV2 infection (national Public Health agency criteria). Patients were divided into two groups: ‘active kidney transplants’ and ‘dialysis’. A Cox model stratifying on age and medical history of coronary artery disease was used to determine adjusted Hazard Ratio (HR) for death or intensive care unit (ICU) admission.

Results: We included 72 patients: 47 in the ‘transplant’ group and 25 in the ‘dialysis’ group. First hospitalization was on 20/02/28 and last hospitalization on 20/05/19. Median follow-up was 21.5 days. Death or ICU admission occurred in 21 (29%) patients (‘transplant’ group: 15 (32%), ‘dialysis’ group: 6 (24%), p=0.45). In multivariate analysis, adjusted HR for death or ICU admission was 1.70 [95% CI: 0.59-4.86] for transplant vs. dialysis (p=0.32).

Conclusions: In our study, among patients hospitalized for SARS-CoV2 infection, no significant difference in risk for ICU hospitalization or death was found between CKD patients on dialysis or with active kidney transplant. A trend for higher risk was noted among patients with active kidney transplant. Further studies are required to confirm these findings.

Lombardi, Priya, enebere, S., Sher, Katherine J. Kelly. Indiana University School of Medicine, Indianapolis, IN.

Low-Molecular-Weight Heparin Is a Superior Anticoagulant to Unfractionated Heparin for Renal Replacement Therapy in Patients with AKI due to Coronavirus Disease 2019

Neelakand Maricudu, Benjamin German, Casey N. Gashiti, Payal K. Gurnani, Roger A. Rodby, William L. Whittier. Rush University Medical Center, Chicago, IL.

Background: Severe coronavirus disease 2019 (COVID-19) not only causes acute pulmonary pathology leading to acute respiratory distress syndrome needing intubation, but also leads to acute kidney injury (AKI) requiring renal replacement therapy (RRT). Due to hemodynamic instability, these patients (pts) often need either continuous RRT (CRRT) or prolonged intermittent RRT (PIRRT). Accelerated Veno-Venous Hemodialysis (AVVHD), a form of PIRRT with typically 40-50 liter of dialysate used over 8-10 hours has been successfully used to treat hemodynamically unstable patients. In the past, we have published extracorporeal circuit clotting (ECC) to be low (5%) even without anticoagulation. However as hypercoagulability is extreme with COVID-19, we noticed a marked increase in ECC. Unfractionated heparin (UFH) was the initial anticoagulation of choice during the early phase of the pandemic but was unreliable in preventing ECC, prompting a trial of low molecular weight heparin (LMWH).

Methods: We conducted a single-center retrospective study to evaluate the efficacy and safety of LMWH vs UFH in preventing ECC in pts with AKI due to COVID-19 who received AVVHD from 3/25/20 through 4/30/20 at a large academic medical center. Data collected included pt demographics, type of anticoagulation and thrombolytic use, treatment characteristics including clotting frequency as well as bleeding complications. ECC was defined as any event that required an unexpected interruption in treatment or the use of thrombolytics.

Results: A total of 58 pts received 408 AVVHD treatments. The average pt age was 58 years, 65% were male, 66% were black and 69% were obese with body mass index >30 kg/m2. 188/408 (46%) of AVVHD treatments received anticoagulation with UFH while 165/408 (40%) of treatments received LMWH. ECC occurred in 30% of AVVHD treatments who received UFH vs 15% in the LMWH group, a relative risk reduction of 50% (P<0.001). 47.1% pts who were on UFH had ECC on the first RRT treatment compared to 13.6% on LMWH (P<0.01). 1 pt experienced a major bleeding event in the UFH group and none with LMWH.

Conclusions: Anticoagulation with LMWH is superior to UFH in reducing ECC in pts receiving AVVHD for AKI due to COVID-19 without an increased risk of bleeding.

PO0697

Lower Continuous Venovenous Hemodialysis Replacement Rate and Its Effect on Patient Outcome in the COVID Crisis Time

John K. Gurguis, Priya Yenebere, S. J. Sher, Katherine J. Kelly. Indiana University School of Medicine, Indianapolis, IN.

Background: Acute kidney injury (AKI) is a common problem encountered in COVID positive patients with incidence close to 23% and mortality close to 60% in this cohort of patients. Continuous Veno-Venous Hemodialysis (CVVHD) plays a primary role in management of these patients. Nephrologists nationwide have been facing a compelling supply/demand mismatch dilemma. Lowering the rate of replacement fluid flow rate (RFRF) is one strategy that was used by our practice to mitigate this issue in selected patients. We hypothesize there is no difference in clinical outcome between the patients receiving high RFRF vs low RFRF.

Methods: This is a retrospective observational study from a single center experience. We analyzed data from March 2020 till the end of May 2020. We included patients with confirmed coronavirus disease 2019 (COVID-19) who required CVVH during their hospitalization. Patients were divided into two groups i.e Group 1 (=20ml/kg/hr RFRF) vs Group 2 (<20ml/kg/hr RFRF). Patients 18 years or older with at least 3 days of CVVH during their hospital stay were included. We compared percentage drop of blood urea nitrogen (BUN) and phosphorus as well as hospital stay and mortality between the 2 groups. We used ANOVA, t-test and Chi square for analysis, as appropriate.

Results: We enrolled 36 patients in the study, 20 in group 1 and 16 in group 2. Eighty percent of the patients enrolled were men. Mean weight was 100 ±8 kg in group 1 vs 107 ±8 kg in group 2. There was no statistically significant difference in percentage reduction of blood urea nitrogen (BUN) or phosphorus (P0) >0.2k & 0.5 respectively (Means 25.4 vs 21.7 & 18.4 vs 17.1). Mean filtration fraction was similar between the two groups (17.9% vs 17%). Frequency of line clotting events was compared in the two groups using Chi square with P value 0.8. Mortality was not significantly different between groups, although it was actually lower in the groups treated with the lower RFRF.

Conclusions: Although our data analysis is still evolving, we found no difference in mortality, toxin clearance and frequency of line clotting between the two studied groups. No randomized control trial has assessed using a lower than 20ml/kg/hr RFRF in CVVH. Our study, thus far, showed no difference between the two groups. This finding needs to be further validated in a randomized control study.

PO0698

Markers of Inflammation and Risk for AKI and Need for Dialysis in Patients with COVID-19

Background: Acute kidney injury (AKI) is a reported manifestation of COVID-19 (CoV-AKI). Release of inflammatory cytokines has been recognized as a characteristic feature of SARS-CoV-2 and is linked to severity of illness. However, it has not been clearly determined if levels of serum markers of inflammation are associated with risk for development of AKI or its severity.

Methods: We conducted an observational study in patients hospitalized at Ochsner Medical Center over 1-month period with COVID-19 and diagnosis of AKI. We examined the relationship between the blood level of ferritin, C-reactive protein (CRP), procalcitonin (proCal), D-dimer and lactate dehydrogenase (LDH) and the incidence of AKI, as well as AKI requiring renal replacement therapy (AKI-RRT), by assessing comparison of means and safety of LMWH vs UFH in preventing ECC, during their hospital stay were included. We compared percentage drop of blood urea nitrogen (BUN) or phosphorus as well as hospital stay and mortality between the 2 groups. We used ANOVA, t-test and Chi square for analysis, as appropriate.

Conclusions: Although our data analysis is still evolving, we found no difference in mortality, toxin clearance and frequency of line clotting between the two studied groups. No randomized control trial has assessed using a lower than 20ml/kg/hr RFRF in CVVH. Our study, thus far, showed no difference between the two groups. This finding needs to be further validated in a randomized control study.
Morbid Obesity, Hypertension, and Male Sex Are Associated with Greater Risk for AKI in Patients with COVID-19

Ivo Lukitsch,1 Aldo E. Torres Ortiz,2 Alaa E. Mohammed,1 Joseph B. Walker,2 Muna Mohammed,1 Juan Carlos Q. Velez1,2
1Department of Nephrology, Ochsner Health System, New Orleans, LA; 2Ochsner Clinical School, The University of Queensland, Brisbane, QLD, Australia.

Background: Acute kidney injury (AKI) is a manifestation of COVID-19 (CoV-AKI). However, there is paucity of data from United States, particularly in a predominantly African American (AA) population. We report the phenotype and outcomes of AKI at an academic hospital in New Orleans.

Methods: We conducted an observational study in patients hospitalized at Ochsner Medical Center over 1-month period with COVID-19 and diagnosis of AKI by KDIGO. We examined the rates of renal replacement therapy (RRT) and in-hospital mortality as outcome measures. Adjudication of cause of AKI was independently performed via manual chart review by 3 study team members.

Results: Of 644 admissions with COVID-19, 69 were excluded due to ESRD or kidney transplant. Thus, 575 patients entered the cohort (173 [28%] to an intensive care unit (ICU). Patients were predominantly AA (71%). AKI was diagnosed in 161 patients (28% overall, 61% of ICU admissions), median age 65 (34 – 96), predominantly male (62%) and hypertensive (83%). Median follow up was 25 days. Vasopressors and/or mechanical ventilation was required in 105 (65%) of them. In-hospital mortality rate for those with AKI was 50% (80/161). De novo AKI was diagnosed in 65%, whereas AKI over preexisting chronic kidney disease occurred in 35% of the cohort. Ninety-one (57%) patients arrived with AKI, whereas the remaining 43% acquired AKI during the hospitalization [median hospital day of AKI onset: 4 (2 – 10)]. RRT was required in 89/161 (55%) and 77/105 (73%) patients for all AKI cases and the ICU subset, respectively. The mortality rate for those with AKI-RRT was 72% (64/91). Hemodynamic instability leading to ischemic acute tubular injury (ATI) and rhabdomyolysis accounted for 66% and 7% of the etiology, respectively. Reversible prerenal azotemia occurred in 9%. In 13%, no obvious cause of AKI was identified aside from the COVID-19 diagnosis. Three (1.8%) patients had de novo collapsing glomerulopathy.

Conclusions: CoV-AKI is associated with high rates of RRT, ICU care and death. Hemodynamic instability leading to ischemic ATI is the predominant cause of AKI in this setting, but other etiologies contribute to the overall AKI burden.

COVID-19: AKI and Outcomes

Refractoriness of Hyperkalemia and Hyperphosphatemia in Dialysis-Dependent AKI Associated with COVID-19
Akanksha Nath,1 Ramanand A.,1 Vinip Varghese,1 Yung Wen,2 Muner Mohamed,2 Juan Carlos Q. Veliz,2 Ochsner Nephrology, 1Ochsner Clinical School- The University of Queensland, New Orleans, LA; 2Department of Nephrology, Ochsner Health System, New Orleans, LA.

Background: There have been anecdotal accounts of an unusual incidence of persistent hyperkalemia (hyperK) and hyperphosphatemia (hyperP) in patients with COVID-19 and acute kidney injury (AKI) (CoV-AKI) despite renal replacement therapy (RRT). However, an observation bias could not be discarded. Thus, we examined the rate and severity of hyperK and hyperP in patients with CoV-AKI actively treated with RRT. Methods: Among 161 patients with CoV-AKI, we selected those who underwent RRT by sustained low efficiency dialysis (SLED) for ≥2 days (n=64). A database of patients with AKI on SLED who underwent urinary sediment microscopy (Sedi-AKI cohort, 2017-2019, n=60) served as control (non-CoV-AKI). We examined the rate of hyperP [serum phosphate (sP) ≥ 4.5 mg/dL], moderate hyperP [sP ≥ 10.0 mg/dL] and severe hyperP [sP ≥ 15.0 mg/dL] and severe hyperK [sK > 5.5 mEq/L], moderate hyperK [sK > 6.5 mEq/L], hyperK [sK ≥ 7.5 mEq/L], as % SLED-days, and by severity of hyperK and hyperP refractory to RRT (by SLED) were more frequent in CoV-AKI compared to other forms of AKI in the pre-COVID-19 era. Because of the correlation of sK and sP with higher LDH and shorter SLED runs, intracellular ion release correlated with sK and sP correlated with higher LDH and shorter SLED runs, intracellular ion release from cell injury due to cytokine “storm” and RRT interruptions may play a role.

PO0705
Risk Factors for AKI in Patients Hospitalized with COVID-19
Mridula Nadamuni, Yu-Lun Liu, Sadaf S. Khan, Shani Shastri, Duwayne L. Willett, Nilum Rajora, Catherine Chen, Susan Hedaya. The University of Texas Southwestern Medical Center, Dallas, TX.

Background: We evaluated risk factors and prevalence associated with AKI in our early experiences with patients hospitalized with COVID-19, 32% of whom required ICU level care, at the University of Texas Southwestern and Parkland Hospitals in Dallas, Texas from 3/13/20-5/7/20.

Methods: Patients admitted with COVID-19 confirmed by SARS-CoV2 PCR test were screened for AKI. Univariate and multivariate logistic regression was used to identify our risk factors associated with AKI.

Results: COVID-19 was confirmed in 145 patients, of whom 62 (43%) had AKI. Patients with AKI were older, mean (SD) age (17) ± 15 (15) years without AKI, p=0.03, and were more likely to have hypertension, 74% vs. 47%, p=0.002, and diabetes mellitus, 6% vs. 31%, p<0.001. CKD was present in 42% of those with AKI vs. 7% of those without, p<0.001. Race, ethnicity, and ACE/ARB use did not differ between groups. Patients with AKI had higher CRP, median (IQR) 102 (44-161) vs. 59 (21-116) mg/L, p=0.009, and LDH on presentation, 365 (265-493) vs. 317 (228-385) U/L, p=0.04. Ferritin, IL-6, and D-dimer was similar between groups. A higher percent with AKI had received steroids, 42% ± 16%, p=0.001. Ticloplatinum was administered in 15% of AKI vs. 5% of non-AKI groups, p=0.08 while rates of hydroxycytroloquin and remdesivir use did not differ. Renal replacement therapy was required in 8 patients with AKI, of whom 7 received CVVHD and 1 HD. There were 8 (13%) deaths in those with AKI vs. 5% (6%) in those without. Factors associated with AKI are listed (Table 1).

Conclusions: During the first weeks of COVID-19 outbreak at our hospitals, 43% of patients had AKI. Underlying CKD, diabetes, steroid use and illness severity were independently associated with AKI. Follow-up is needed to determine the long-term impact on kidney function and recovery.

PO0706
The Impact of COVID on CRRT Filter Lifespan
Lewis Mann, Mony Fraer, Sarat C. Kuppachi, Lama A. Nourreddine, Lisa M. Antes, Sreedevi kopissetti Jenigiri, Maria T. Story, Mecnakshi Sambharthi, Jayesh B. Patel, Kandi O’Connor, Benjamin R. Griffin. University of Iowa, Iowa City, IA.

Background: Patients with COVID are more likely to have systemic thrombotic events. Although it has been theorized that those on CRRT also have an increased rate of filter loss due to clotting. If COVID-positive patients are more likely to clot their filter than other patients on CRRT, a more aggressive anticoagulation strategy may be worthwhile. This could result in longer filter lifespan, less circuit down time, which would result in improved clearance, lower costs, less risk of iatrogenic blood loss, and less wasted nursing time. If there is no difference in filter lifespan between COVID positive and negative patients, then more aggressive anticoagulation would result only in added risk without a clear benefit.

Methods: We analyzed COVID data on patients in a related unblinded prospective randomized trial, in which patients are assigned to either pre-filter CVVH or CVVHD. The standard treatment protocol at the University of Iowa is to use citrate anticoagulation with a blood flow rate of 200 mL/min and a dose of 25 mL/kg/hr. The primary outcome is average filter life, and secondary outcomes are mortality, intensive care unit LOS, hospital LOS, and renal recovery.

Results: A total 30 patients using a total of 90 filters from March 25 to May 20, 2020 were evaluated (Table 1). The average filter life in COVID-positive patients was 37.4 ± 35.8 compared to 33.1 ± 26.7 in COVID-negative patients (p = 0.55). However, COVID-19 patients were more likely to receive heparin anticoagulation in addition to citrate.

Conclusions: Contrary to other reports, in this retrospective, unadjusted analysis of CRRT patients, the presence of COVID-19 did not decrease average filter life. Further research is needed regarding the appropriate anticoagulation strategy in COVID-19 positive patients.

Table 1: Patient characteristics

PO0707
Single-Center Experience of AKI in COVID-19-Infected Patients in West Kent Hospital, United Kingdom
Matthew James, Tord H. Hogsand, Kieran Jankowski, Jeetendra R. Rathod, Nihal Chitalia, Jonathan Kwan. Darent Valley Hospital, Dartford, United Kingdom.

Background: The outcome of renal function and in COVID-19 positive patients is unclear. We studied the epidemiology of acute kidney injury (AKI) in the COVID-19 positive patients.

Methods: Between 9th March 2020 and 26th April 2020 data was prospectively collected on 253 adult COVID-19 positive inpatients who died and 253 adult COVID-19 positive inpatients who died. We analyzed COVID data on patients in a related unblinded prospective randomized trial, in which patients are assigned to either pre-filter CVVH or CVVHD. The standard treatment protocol at the University of Iowa is to use citrate anticoagulation with a blood flow rate of 200 mL/min and a dose of 25 mL/kg/hr. The primary outcome is average filter life, and secondary outcomes are mortality, intensive care unit LOS, hospital LOS, and renal recovery.

Results: A total 30 patients using a total of 90 filters from March 25 to May 20, 2020 were evaluated (Table 1). The average filter life in COVID-positive patients was 37.4 ± 35.8 compared to 33.1 ± 26.7 in COVID-negative patients (p = 0.55). However, COVID-19 patients were more likely to receive heparin anticoagulation in addition to citrate.

Conclusions: Contrary to other reports, in this retrospective, unadjusted analysis of CRRT patients, the presence of COVID-19 did not decrease average filter life. Further research is needed regarding the appropriate anticoagulation strategy in COVID-19 positive patients.

Table 1: Patient characteristics
wise AKI mortality was AKI1 25.7% (27), AKI2 10.4% (11) and AKI3 20% (21). 66.6% haemorrhage patients 23% (25) AKI patients died with non-renal creatinine. Mortality in CKD patients as co-morbidity was 64%. All renal transplant patients survived without having AKI. 7.7% (19) patients required continuous positive airway pressure, 42.1% (8) patients developed AKI of these 75% (6) patients with CPAP died. A further 24 (9.75%) required mechanical ventilation with 62.5% (15) of these developed AKI with mortality of 80% (12).

Conclusions: Elderly patients were most commonly infected with COVID-19 infection. AKI was seen in 42.6% patients with COVID-19 infection. More than 60% COVID-19 infected patients died if they had AKI and were on any form of mechanical ventilatory support or had CKD as co-morbidity.

PO0708
Severe AKI in SARS-COV-19 Patients from a Tertiary Hospital in Rhode Island
Harshitha Kota,1,2 Mitchel,1,2 Brown University, Providence, RI; 2University Medicine Foundation Inc, Providence, RI.

Background: The clinical features & outcomes of COVID-19 patients who developed severe AKI are still being elucidated.

Methods: 42 patients with COVID-19 infection who developed KDOQI stage 3 AKI were identified from March 1 to May 15, 2020, at Rhode Island Hospital, a large tertiary teaching hospital. Their clinical presentations and outcomes are presented. The data in table 1 were presented as mean (± SD), median (IQR), or # (%).

Results: The baseline characteristics are outlined in table 1. Among them, 88% were admitted to ICU, 83% were intubated and needed pressor support. 71% received renal replacement therapy (RRT) on CVVHDF. The mean duration of RRT and ICU stay were 6 and 14 days, respectively, 33 participants received treatment for COVID-19, among them 14 (33%) received Remdesivir(RDV), 6 (14%) received convalescent plasma(CP), 4 (10%) received hydroxychloroquine(HCQ), and 25 (60%) also received azithromycin. The mortality rates were 15% in the RDG group, 67% in the CP group, and 75% in the HCQ group. The mortality was 67% in those without any treatment. At the 60-day follow-up, 11 (26%) were discharged alive, 21 (50%) died. Those who died were older (mean age 71 vs. 61), having higher Charlson Comorbidity Index (4.7 vs 3.0), more likely to have diabetes (71% vs. 61%) and coronary artery disease (38% vs. 24%).

Conclusions: The mortality rate of SARS-COV-19 patients who developed severe AKI is high in our cohort. Future larger scale studies are needed to elucidate the causes of this high mortality.

PO0709
The Clinical Presentation of AKI Complicating COVID-19: Observations from Elmhurst Hospital, New York City
Nasser M Alzahrani,1 Demetrios Papademetriou,2 George N. Cortisidis, Payal Ram, Ellena A. Linden, Aaron S. Stern. Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Early in March, NYC Hospitals became inundated, especially safety net public hospitals. The physicians at Elmhurst Hospital Center (EHC) encountered countless cases of respiratory failure often accompanied by AKI. Autopsy studies from China described an interstitial nephritis, with macrophage infiltrates and complement deposition along with fibrotic changes. We report our experience with COVID-19 and AKI.

Methods: We reviewed the charts of 137 SARS-CoV-2 positive patients (PCR of a nasopharyngeal sample) admitted to EHC 3/7/2020 - 4/7/2020. We categorized patients as having KDOQI defined AKI vs no AKI within the first seven days of admission. Co-morbidities, renal associated markers and inflammatory markers were anaylzed. Clinical outcomes were assessed. Exclusion criteria: <18 years old, pregnant, ESRD, mortality prior to day 7 of hospitalization. Welch T test and Chi square were used for AKI vs non-AKI.

Results: Age was similar in both groups as was gender (male 74% vs 79%) and incidence of diabetes. Early AKI developed in 35% of whom 55% needed RRT; 85% of the AKI patients required mechanical ventilation vs 11.2% of the non-AKI group. Inflammatory markers (WBC, CRP, LDH); urine protein and urine white cells (but not CKP) were significantly higher in the AKI group. Procalcitonin and D-dimers as maximum levels became significant. We found that 20% of those not with early AKI developed late-onset AKI. Mortality was 76.7% in the AKI and 17.9% in the non-AKI group.

Conclusions: Early AKI developing in the first week of hospitalization was associated with overwhelming respiratory failure. The accompanying higher inflammatory markers, elevated urine WBCs and protein could implicate interstitial nephritis as an underlying pathology as described earlier.

PO0710
Incidence of AKI in Hospitalized Patients with COVID-19
Lili Chan, Kumandeep Chaudhary, Aparna Saha, Kinsuk Chauhan, Akhil Vaid, Barbara T. Murphy, John C. He, Girish N. Naddkar, Steven G. Coca. Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Preliminary reports indicate that acute kidney injury (AKI) is common in coronavirus disease (COVID-19) patients and is associated with worse outcomes. AKI in hospitalized COVID-19 patients in the United States is not well-described.

Methods: This is a retrospective observational study of patients aged ≥18 years with laboratory confirmed COVID-19 admitted to the Mount Sinai Health System between February 27 and April 15, 2020. We describe the frequency of AKI and dialysis requirement, AKI recovery, and adjusted odds ratios (aOR) for mortality while adjusting for age, gender, race, comorbidities, and admission labs and vital signs.

Results: Of 3,235 hospitalized patients with COVID-19, AKI occurred in 1406 (46%) patients and 280 (20%) with AKI required dialysis. The proportion with stages 1, 2, and 3 AKI overall was 35%, 20%, 45%, and 20% received dialysis (Figure 1A). In the 815 patients admitted to the intensive care unit (ICU), 553 (68%) had AKI and 34% required dialysis. The median peak serum creatinine was 2.2 (IQR 1.6-3.7) mg/dL in those that did not receive dialysis and was 8.6 (IQR 6.5-11.4) mg/dL in those that did receive dialysis. Urine studies were available for 581 (18%) patients of whom 338 (60%) patients had AKI. 538 (96%) of all patients had any urinary abnormalities of proteinuria, hematuria, or leukocyturia. Independent predictors of severe AKI were chronic kidney disease, systolic blood pressure, and potassium at baseline. In-hospital mortality in patients with AKI was 41%. The aOR for mortality for AKI was 9.6 (95% CI 7.4-12.3) and 56% of patients with AKI who were discharged recovered kidney function back to baseline (Figure 1B).

Conclusions: AKI is common in patients hospitalized with COVID-19, associated with worse mortality, and nearly half of patients do not recover kidney function.

Methods: From 2/17 to 5/29, 2020, Dialysis Clinic Inc. had identified 422 COVID+ patients from 98 clinics in 20 states. We compared their characteristics relative to the uninfected source clinic population (N=6,993) and tracked outcomes over the 15-week period.

Results: Comparative characteristics are shown in the table (*p<0.05). Hospitalization occurred in 295 (70%) with 75 deaths, 159 discharges and 61 still hospitalized. Ten patients died <30 days post-discharge. Another 11 deaths occurred in 116 non-hospitalized patients. Overall, 96 of 422 died (22.7%). While more black patients were infected, death rates were higher in white than black dialysis patients (31.5% vs. 18.8%, p=0.008).

Conclusions: Chronic dialysis patients with COVID have higher death rates than the general population. Infected patients tended to be older, with more comorbidity, particularly DM/CVD, and utilized respiratory inhalers/assistance. Group home residents were overrepresented with COVID while home dialysis patients were disproportionately spared.

PO0713

Trends in Fever and Respiratory Illness in Hemodialysis Patients During the COVID-19 Pandemic
Sheetal Chaushri,1 Hao Han,1 John W. Larkin,1 Len A. Usvyat,1 Dinesh K. Chattoo,1 Jeffrey L. Hymes,2 Michael A. Kraus,2 Allan J. Collins,2 Franklin W. Maddux,3 1Fresenius Medical Care, Global Medical Office, Waltham, MA; 2Fresenius Medical Care, North America, Waltham, MA; 3Fresenius Medical Care AG und Co KGaA, Bad Homburg, Germany

Background: Hemodialysis (HD) patients are vulnerable to the 2019 coronavirus disease (COVID-19) due to older age and common coexistence of comorbidities. Fever and respiratory illness (RI) are common symptoms of COVID-19. In order to create a disease surveillance tool and anticipate areas of COVID-19 outbreak, we aimed to assess the trends in fever and RI symptoms in HD patients treated at a national dialysis provider network in the United States during the pandemic.

Methods: We used data from HD patients actively treated between Jan 1 2018 ad May 16 2020 at a national dialysis provider network of large integrated health care company. If the body temperature of the patient either before or after the treatment was greater than 100 degrees Fahrenheit, then the patient was identified as exhibiting the symptom of fever. If the patient complained of shortness of breath, wheezing, runny nose, bloody cough, dry cough or purulent cough, then in this analysis the patient was identified as exhibiting the symptom of RI.

Results: The total patients count ranged from 196,774 to 209,475 per week while the total count of HD treatments ranged from 413,477 to 454,215. For the year 2020, a clear increase in trend for number of patients was observed after week 11 (03/08-03/14/2020) for RI as well as fever. Both increasing trends spike at the week 15 (04/05-04/11/2020) and decline thereafter. At the end of the study period (May 16 2020) the trends in RI symptoms significantly increased while for fever such increase was observed post-week 11.

Conclusions: HD patients appear to exhibit a different trend in RI and fever symptoms during the year 2020 compared to concurrent periods in 2018 and 2019. Both increasing trends spike at the week 15 (04/05-04/11/2020) and decline thereafter. Surveillance of dialysis patients may allow early identification of COVID-19 outbreaks.

Implementation of Strategies for Prevention and Control of SARS-CoV-2 Infection at Dialysis Units in Latin America: Experience from GlomCon Latin America Working Group (L.GlomCon) 

Denisse Arellano-Mendez,1 Julio A. Gutierrez-Prieto,2 Javier Soto-Vargas,3 Blanca Martinez-Chagolla,4 Franco H. Cabeza Rivera,5 Desiree Garcia Antonio,6 Diana B. Sepulveda,7 Sonia Ramirez-Avila,8 Carmen Avila-Casado,9 GlomCon Latin America Working Group 1Unidad Medica de Atencion Ambulatoria 254, IMSS, Morelia, Mexico; 2Hospital Central del Estado de Chihuahua, Chihuahua, Mexico; 3Hospital General Regional 46, IMSS, Guadalajara, Mexico; 4Hospital General “Dr. Miguel Silva”, Morelia, Mexico; 5University of Mississippi Medical Center, Jackson, MS; 6Hospital General de Mexico, Mexico; 7Mexico City; 8Multi-Organ Transplant Program, University Health Network, Toronto, ON, Canada; 9Pathology Department, University Health Network, Toronto, ON, Canada.

Background: Patients on dialysis belong to the high-risk group to develop severe COVID-19 infection due to their multiple comorbidities. International societies have issued recommendations for the control and prevention of SARS-CoV-2 infection at dialysis units but implementing them may not always be feasible as many healthcare systems in Latin America (LA) have limited resources. This study aims to reflect the experience of nephrologists in LA at taking care of these patients and if the recommendations were adopted in their practices.

Methods: Descriptive analysis extracted from an online survey carried out among nephrologists, renal pathologists and other health workers treating kidney diseases between May 26 and June 20, 2020. Answers from 866 Spanish-speaking LA countries divided into 6 categories. We present the results for the ESRD category.

Results: 430 responses were obtained, 360 were considered for analysis. 276 (86.5%) of the participants were nephrologists and 178 (64%) of them practiced in dialysis units. 163 (92.6%) already implemented strategies to control and prevent COVID-19 in their units. 125 (71%) received training on it and 128 (72.7%) reported personal protective equipment availability. The most common implemented strategies were: education sessions about COVID-19 for patients and caregivers (68.5%), designated isolation areas (77.8%) or shifts (68.7%) for patients with suspected or confirmed COVID-19 and a 7-feet separation between hemodialysis (HD) machines (61.9%). 49 (28%) of the nephrologists reported an outbreak among patients and 60 (34.2%) among medical staff. Patient absenteeism to their HD sessions due to fear of infection, a decrease in the frequency and a shortening of the time of the sessions was reported in 41.7%, 30.2% and 36%, respectively. 29 (16.5%) of the respondents considered that those practices were associated with patient mortality.

Conclusions: Most dialysis units in LA are partially implementing the recommended strategies for control and prevention of COVID-19 but this seems to be insufficient since at least one third of them already faced outbreaks among patients and medical staff.

PO0715

Implementing COVID-19 Infection Control Procedures in Outpatient Dialysis in an Urban US Population

Ibironke W. Apata, Jason Cobb, Jose E. Navarrete, Janice P. Lea. Emory University School of Medicine, Atlanta, GA.

Background: Emerging data reveal disparities in the burden and severity of disease among racial and ethnic minorities in the US. Emory Dialysis consists of 4 outpatient dialysis facilities, serving an older, urban and predominantly African-American population. These facilities are in counties with the highest number of COVID-19 cases in Georgia. We describe infection control measures implemented to prevent COVID-19 transmission, and the clinical characteristics of patients with COVID-19 in the facilities.

Methods: Based on CDC’s recommended guidance, we implemented the following infection control procedure between February and April 2020: 1) screening; triaging all patients, and separating patients with symptoms of COVID-19; 2) monitoring staff for COVID-19 symptoms; 3) limiting healthcare personnel in the facilities; 4) universal masking in the dialysis units; 5) conducting PPE re-trainings; 6) assessing facility preparedness; 7) separating high risk patients (nursing home residents); and 8) cohousing patients with COVID-19 to a dedicated dialysis shift.

Results: Of the 745 patients followed at the Emory dialysis facilities, 18 (2.4%) were diagnosed COVID-19 between March 25—May 7, 2020. Among the 18 patients, 17 were receiving in-center hemodialysis and 1 was on peritoneal dialysis. The median age was 66.8 years (range 43–84) and 11 (61.1%) were female. Nine (50%) were residents of a skilled nursing facility. Sixteen (88.9%) patients had a diagnosis of hypertension, 10 (55.6%) had diabetes, and 10 (55.6%) had cardiac disease. Eight patients (44.4%) required hospitalization and 4 patients (22.2%) died from COVID-19 related complications. Two patients (11%) only were dialyzing at adjacent dialysis stations and the timing of their symptoms suggested possible transmission in the dialysis facility. In response, education, infection control audits and PPE re-trainings were conducted to bolster infection control practices.

Conclusions: In a high-risk patient dialysis population, we successfully implemented recommended infection control measures to mitigate the spread of SARS-COV-2 in our facilities. Dialysis facilities must stay vigilant and monitor for possible transmission of COVID-19. Regular audits of infection control practices remains critical.
Clinical Characteristics and Outcomes in ESKD Patients with COVID-19 Infection in an Urban Community Hospital in Brooklyn, New York, During the Global Pandemic
Carlos M. Zapata, Yariana E. Rodriguez, Olawale Akande, Laurie Ward, Premila Bhat. Wyckoff Heights Medical Center, Brooklyn, NY.

Background: The impact of coronavirus disease 2019 (COVID-19) on individuals with End Stage Kidney Disease (ESKD) receiving maintenance hemodialysis (MHD) is unknown. This study aims to describe clinical characteristics and outcomes in a cohort of patients with ESKD receiving MHD hospitalized with confirmed COVID-19 infection in an urban community hospital during the New York City peak of the global COVID19 pandemic.

Methods: Cases with a diagnosis of ESKD and COVID-19 based on positive PCR testing results were identified from retrospective review of electronic health records for patients hospitalized between March 4, 2020 and April 30, 2020. Electronic health records were reviewed in order to obtain demographic data, presenting symptoms, laboratory values, medical management, and outcomes.

Results: 29 patients with ESKD on MHD with confirmed COVID-19 infection were identified. 16/29 (55%) were over age 60 years, 20 (69%) were male and 14 (48%) were Hispanic. 18 (62%) had Diabetes and 26 (89%) were overweight or obese (BMI >25). All had hypertension. 68% were on Statin and 40% on ACE inhibitor orARB at the time of admission. 25/29 (86%) were dialyzed via arteriovenous fistula or graft. The most common presenting symptoms were dyspnea (85%), cough (60%) and fever (28%). All initial chest radiographs showed abnormalities, with diffuse infiltrates on 21 (72.4%) and focal infiltrates on the remainder. All patients who required renal replacement therapy during hospitalization received conventional HD. 10 patients required mechanical ventilation during hospitalization (34%); all of these patients died. Overall, 13 patients (45%) died and 16 patients (55%) were discharged after a median of 6 and 7 days hospitalization, respectively. 13 patients (10%) were readmitted during the period of observation. 

Conclusions: The observed lack of increased mortality in ESKD does not align with the outcomes of significance of serum ferritin in ESKD has to be done with caution. Furthermore, the rate was seen despite higher levels of ferritin, suggesting that the interpretation of the similar mortality to non-ESKD [2125 vs 633 ng/mL, p = 0.0019). p = 0.65]. Median serum ferritin level was significantly more elevated in ESKD compared to non-ESKD (BMI) were 32 vs 27 kg/m2 (p = 0.11) for those admitted to ICU vs wards, respectively. Cases with a diagnosis of ESKD and COVID-19 based on positive PCR testing results were identified from retrospective review of electronic health records for patients hospitalized between March 4, 2020 and April 30, 2020. Electronic health records were reviewed in order to obtain demographic data, presenting symptoms, laboratory values, medical management, and outcomes.

Results: 29 patients with ESKD on MHD with confirmed COVID-19 infection were identified. 16/29 (55%) were over age 60 years, 20 (69%) were male and 14 (48%) were Hispanic. 18 (62%) had Diabetes and 26 (89%) were overweight or obese (BMI >25). All had hypertension. 68% were on Statin and 40% on ACE inhibitor orARB at the time of admission. 25/29 (86%) were dialyzed via arteriovenous fistula or graft. The most common presenting symptoms were dyspnea (85%), cough (60%) and fever (28%). All initial chest radiographs showed abnormalities, with diffuse infiltrates on 21 (72.4%) and focal infiltrates on the remainder. All patients who required renal replacement therapy during hospitalization received conventional HD. 10 patients required mechanical ventilation during hospitalization (34%); all of these patients died. Overall, 13 patients (45%) died and 16 patients (55%) were discharged after a median of 6 and 7 days hospitalization, respectively. 13 patients (10%) were readmitted during the period of observation. 

Conclusions: The observed lack of increased mortality in ESKD does not align with the outcomes of significance of serum ferritin in ESKD has to be done with caution. Furthermore, the rate was seen despite higher levels of ferritin, suggesting that the interpretation of the similar mortality to non-ESKD [2125 vs 633 ng/mL, p = 0.0019). p = 0.65]. Median serum ferritin level was significantly more elevated in ESKD compared to non-ESKD [2125 vs 633 ng/mL, p = 0.0019). p = 0.65]. Median serum ferritin level was significantly more elevated in ESKD compared to non-ESKD [2125 vs 633 ng/mL, p = 0.0019). p = 0.65]. Median serum ferritin level was significantly more elevated in ESKD compared to non-ESKD [2125 vs 633 ng/mL, p = 0.0019). p = 0.65]. Median serum ferritin level was significantly more elevated in ESKD compared to non-ESKD [2125 vs 633 ng/mL, p = 0.0019). p = 0.65].
COVID-19: Dialysis Patients

PO0722
COVID-19 Incidence and Outcomes in Hemodialysis Patients in Mexico
Juan M. Ardavin Iturrate, Alicia Pineira, Juan Carlos Rodriguez. Medica Santa Carmen Staff Nephrologists Medica Santa Carmen, Mexico, Mexico.

Background: HD pts are at high risk for COVID-19. High incidence and death rate were reported in China and Europe with more than 20% of asymptomatics. We report incidence, features and outcomes of COVID-19 in HD patients in a network of 8 clinics in Mexico. A protocol was started on Mar 15 with hygiene measures; symptoms triangle; separation by age; use of PPE and isolation of suspected cases. We use a more inclusive case definition, different from Mexico Health Ministry’s(SSA). All cases are referred for PCR but most aren’t tested.

Methods: Retrospective analysis of cases (suspect or PCR(+) from mar 15 to may 22 2020 compared to controls. T-test and Chi’ were used. Hospitalization, IMV and deaths were registered. Overall mortality from mar - may 2020 compared to same period of 2019. We compared the number of cases using our case definition with that using the SSA’s. Incidence of COVID-19 in staff was also analyzed.

Results: Total 1276 pts; Of 102 suspects 25 (24%) had PCR and 16 (64%) were(-), 13 (12%) -test were not discarded based on alternative dx. 2 pts with (-) PCR were cases based on Ct. Total 75 cases (10 (+)PCR; 65 w/o test) were analyzed and compared to controls. No differences in HD vintage, DM, CVD, HD session length, VA, BUN or Kt/V. Less age, fem gender, HTN, more sessions/wk, ACEi/ARB and lower Hb were found in the cases. 7 (9%) hospitalized and 2 (3%) required IMV. There were 6 (8%) deaths, only 1 (1.3%) attributed to COVID-19. Overall mortality minimally higher than that of the same period of 2019 (1.35% vs 1.30%). 31% of cases had only 1 symptom. Only 1 PCR (+) and 14 PCR(+) cases fulfilled SSA’s case definition. Among 231 staff members, 31 (13.8%), 11 (35%) PCR(+) and 20 non tested.

Conclusions: Incidence of probable or confirmed COVID-19 was 5.9%; probably overestimated suggested by scarce testing and low mortality. ACEi/ARB use more frequent in cases, adjusted for HTN and age. Our protocol helps prevent in-clinic contagion. A more comprehensive probable case definition appears more useful for HD patients.

PO0723
COVID-19 Infection in Patients with ESRD Requiring Hemodialysis
Anna Anisimova,1, Valeria Ripa,2 Biruk Almaz,1 Nirav Mistry,2 Fariborz Rezaei,2 1St. George’s University School of Medicine, True Blue, Grenada; 2Saint Barnabas Medical Center, Livingston, NJ.

Background: This case series assesses characteristics and outcomes of patients with confirmed novel coronavirus (SARS-CoV-2) COVID-19 infection and end stage renal disease (ESRD) requiring hemodialysis during the COVID-19 pandemic.

Methods: This is a single center retrospective study of 24 ESRD patients on hemodialysis who were admitted to Saint Barnabas Medical Center, a 597-bed acute care hospital in Livingston, New Jersey, and with a confirmed COVID-19 diagnosis between February 1st to April 5th, 2020. The characteristics, clinical course, and outcome were assessed and compared. In addition, a subgroup analysis was made between patients who expired (n=8) versus those who lived (n=16).

Results: The overall mortality rate was 33.3% vs. 21% in the general population with COVID-19. Among the 4 (16%) patients who required ICU admission and prolonged pressor support and invasive mechanical ventilation, 2 (50%) patients were successfully extubated and discharged from the hospital while the other 2 (50%) patients died. There were no statistical differences in laboratory values between patients who survived versus patients who died except C-reactive protein (CRP), p=0.002.

Conclusions: We report a mortality rate of 33.3% in our case series of 24 patients with ESRD on dialysis with concurrent COVID-19 infection. There was a statistical difference in CRP value between patients who died versus survived. Fifty percent of intubated patients were successfully extubated and discharged.

PO0724
COVID-19 Infection Patterns in an Academic Inner City Dialysis Unit

Background: COVID-19 remains a major public health emergency and in-center dialysis providers have multiple opportunities for its spread. Elderly immune-impaired hosts pose a significant risk for infection as well as poor outcomes. We present a retrospective analysis of COVID-19 cases in our dialysis unit.

Methods: Retrospective analysis was done as a part of a quality improvement project using unidentified patient data including: demographics, distributions of dialysis shift, patient zip code, transportation mode (self, ride share or public transport), residence type (home, long term care facility or homeless shelter), etiology of ESRD and dialysis vintage. T-test and multivariate analysis (including logistic regression for binary and categorical data) were conducted using SPSS v23.

Results: There were 70 patients in the unit and 10 became positive for COVID-19. 65 (92.9%) of all patients were African American. Between COVID-19 positive and negative patients, there was no significant difference in age (62±15 vs 63±14 years p=0.2), dialysis vintage (7.6±8.7 vs 5.2±4.7 years p=0.31), male gender (7/10 (70%) vs 40/70 (58%) p=0.31), 5/10 (50%) of the positive patients were MWF (24h) shift. On multivariate analysis, this effect approached significance (p=0.051); however, there was no interaction of COVID-19 positive status with demographic characteristics, dialysis vintage, residence type, zip code distribution, or transportation modality. Of note, universal masking and temperature screening were implemented on March 5, 2020 in this unit and no new cases were noted after May 2, 2020.

Conclusions: Our analysis did not show any clear factor associated with COVID-19 infection among our dialysis patients although clustering approached statistical significance. Small sample size and demographic distribution are shortcomings of our study; larger scale epidemiological studies and data analysis are required for better understanding the risk of COVID-19 infection amongst in-center dialysis patients.

Chronological Distribution of COVID-19 Cases

PO0725
COVID-19 Infections in a Small Dialysis Organization in New York City
Jeffrey I. Silberweiz,1,2 Tarek Barbak,2 Yao Liu,1,2 Kwan Kim,1,2 Thomas Parker,1,2 Daniel M. Levine,1,2 1The Rogosin Institute, New York, NY; 2Weill Cornell Medicine, New York, NY.

Background: COVID-19 infected more than 1.6 million Americans (0.48%) and more than 15,000 of the 500,000 (3%) Americans with chronic kidney disease treated by dialysis. The Rogosin Institute operates nine dialysis centers in New York City (NYC), the epicenter of the COVID-19 US Public Health Emergency (PHE). We followed guidance from the Centers for Disease Control and Prevention and the New York State Department of Health throughout the PHE. We screened all patients and staff for signs and symptoms of COVID-19 by measuring temperature and inquiring about symptoms on presentation to the dialysis centers. Infected patients who did not require hospitalization were treated in our centers on a dedicated shift by dedicated staff. We used a symptom-based approach to discontinuing isolation.

Methods: We created a COVID-19 tool in REDCap to track the spread of Coronavirus. We surveyed our Electronic Health Record weekly using a direct data connection and automated scripting to identify patients infected with COVID-19. We reviewed demographic and clinical data for each infected patient. We used descriptive statistics to analyze our population of infected patients.

Results: On February 28, 2020, 1,559 patients received dialysis at our centers. By May 11, 241 (15.5%) had been infected. Our mortality rate was 22.8% compared to general populations in NYC (10-12%), US (6.0%) and worldwide (6.5%) and rates for dialysis patients reported between 7-20%. We had a disproportionate occurrence of COVID-19 among residents of Brooklyn (49% of infections, 44% of patients) and Queens (29%; 25%). Most of the infected patients were male (53%) and Black (51%). Common co-morbidities included hypertension (98%), diabetes mellitus (60%), heart failure (25%) and coronary artery disease (25%). Common outpatient medications included statins (64%) ACE inhibitors/ARBs (80%) and calcium channel blockers (65%). Fever was the only common presenting symptom (94% of patients). A significant proportion (12%) of patients were in the hospital within 14 days prior to diagnosis of COVID-19 infection.

Conclusions: COVID-19 infection was common and associated with high mortality rate in our NYC population of dialysis patients despite adherence to governmental guidelines for control of disease spread. We hypothesize community spread was common in our patients residing in the epicenter of the US COVID-19 PHE.

COVID-19 Outbreak and Experience in a Dialysis Unit in the Philippines
Ma. Anna Angelica PO0726

Background: Patients on regular dialysis are at an increased risk to COVID-19 due to their multiple comorbidities and exposure in the health care setting. The risk for virus transmission within a dialysis unit is also high emphasizing the importance of implementing infection control measures. The objective of this report is to describe the COVID-19 outbreak in a dialysis unit including interventions done.

Methods: Review of the epidemic course with contact tracing was done from March 14 to May 14, 2020 in the dialysis unit of a tertiary hospital in the Philippines. Results: Of 167 patients, 20 became COVID-19 suspects. Eight were positive -3 were exposed from the first confirmed case, 2 were handled by a COVID-19 infected healthcare worker (HCW) who was asymptomatic at time of contact while 2 asymptomatic patients tested positive during mass testing. Two of 67 HCWs tested positive were exposed to patients. Key interventions are (a) enhanced screening by mass testing using NPS/OPSI-PCR of patients and HCWs after identifying 6 patients and 2 HCWs infected with COVID-19 (b) instead of cohort, dialysis of COVID-19 confirmed and suspected cases was done in isolation rooms separate from the dialysis unit (c) adequate personal disinfection especially in the waiting area with strict social distancing and daily screening.

Conclusions: The infection control and preventive actions done halted the increase in cases. Maintaining these strategies for the duration of the pandemic allowed further decline in the rate of infection.

COVID-19 Suspects, Cases and Interventions

Contact Tracing in the Unit

PO0727

Demographic and Clinical Characteristics of Patients with CKD and SARS-CoV-2 Undergoing Hemodialysis Treatment
Laura C. Fuentes-Mendez, Angela M. Cordoba Hurtado, L. M. Perez-Navarro, Rafael Valdez-Ortiz, Maribel Merino. Hospital General of Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.

Background: Patients on HD or PD are likely to be at increased risk of COVID-19 and its complications because they have multiple comorbid conditions. There is a lack of evidence about the optimal management and even clinical manifestations because clinical presentation is highly variable. The delayed diagnosis is because it’s not recognized by the treating centers and the confusion with patients with fluid overload or uremic syndrome can be fatal in this population.

Methods: Retrospective, observational, single-center study in Mexico. We analyzed the clinical manifestations and outcomes of all maintenance HD patients hospitalized with COVID-19 from April 9th to May 31st, 2020 as confirmed by real-time polymerase chain reaction.

Results: 20 patients followed in our hospital with median age of 45.2±13.8 years, 50% were men. All the patients have HTA (100%), DM (50%), the most common symptoms at admission were asthenia (75%), dyspnea (65%), cough (55%) followed by myalgias (50%) and fever (45%). Poor oxygen saturation (<95%) breathing room air was observed in 18 patients (90%) with mean oxygen saturation of 77±9%. Lung abnormalities on initial chest X-ray were observed in all patients. Peripheral ground-glass opacities, the typical radiologic pattern, were bilateral in 13 patients and unilateral in 7. Laboratory studies with lymphopenia in 85% of patients with a mean of 0.7±0.38. There were no differences baseline leukocyte or lymphocyte from patients who survived vs from those who died. The mortality rate (40%) was much higher than that observed in the general population (8%). Mortality was higher in women.

Conclusions: The impact of this virus on patients with CKD is poorly understood. The evaluation of the nephrologist must be very detailed, most of the patients had mild dyspnea, however on physical examination, desaturation and radiological images were suggestive of infection by SARS-CoV2. The current situation provides a unique opportunity to gather vital information to process and learn from the experience worldwide. These results will allow us to treat them in a timely manner and reduce lethality in dialysis patients.

Effect of COVID-19 on Dialysis Practices on the Ground: Early Results from an International DOPPS Program Survey
Murilo H. Guedes,1 Brian Bieber,2 Patricia De Sequera,3 Pablo A. Urena Torres,1 Giuliano Brunori,1 Xinling Liang,4 Li Zuo,5 Michel Y. Jacoble,2 Roberto Pecoits-Filho,2 Jeffrey Perl,2 Ronald L. Pisoni,1 Bruce M. Robinson,2 1Pontificia Universidade Catolica do Parana, Curitiba, Brazil; 2Arbor Research Collaborative for Health, Ann Arbor, MI; 3University Hospital Infanta Leonor, Madrid, Spain; 4AURA Nord Saint Ouen, Paris, France; 5Ospedale S. Chiara, Trento, Italy; 6Guangdong Provincial People's Hospital, Guangzhou, China; 7Peking University People's Hospital, Beijing, China; 8Cliniques Saint-Luc, University of Louvain Medical School, Brussels, Belgium; 9St. Michael's Hospital, University of Toronto, Toronto, ON, Canada.

Background: The COVID-19 pandemic caused unprecedented disruption to dialysis patient care globally. Facility surveys were distributed to assess the impact of COVID-19 pandemic on hemodialysis (HD) and peritoneal dialysis (PD) practices.

Methods: Medical Director (MD) and Nurse Manager (NM) Surveys (MDs, NMS) are being distributed in May/June 2020 to 723 clinics enrolled in the Dialysis (in-center HD, DOPPS, PD), Peritoneal (PDOPPS) Dialysis Outcomes and Practice Pattern Study in Canada, China, Japan, the United States, 7 European countries, 5 Gulf Cooperative Council countries, and China metropolitan areas (Beijing, Guangzhou, Shanghai). Surveys content includes the number of COVID-19 cases, testing, and clinical management, screening, infection control, staffing, patient transportation, and psychological support.

Results: As of 27 May 2020, we have 80 MDS (China, Europe, US = 33, 38, 5) and 101 NMS (45, 46, 9) responses from DOPPS sites. The following percentages are presented sequentially for China, Europe, and US. Among MDs, 0%, 6%, 67% reported at least one confirmed COVID-19 case among dialysis patients, and 85% reported being on the late phase of the COVID-19 curve. 40%, 23%, 100% of MDs were more likely to recommend home dialysis; 19%, 5%, 29% reported an increase in missed dialysis treatments; 30%, 24%, 50% were more likely to prescribe potassium binders; and 75%, 60%, 83% had greater challenges obtaining vascular access interventions. Among NMs, 30%, 9%, 40% reported current limitations in access to COVID-19 testing; and 61%, 51%, 29% reported having, or risk of, shortage in staffing.

Conclusions: Early results indicate many clinics in Europe and US have had COVID-19 cases, but sites in the three DOPPS-China cities have avoided COVID-19 to date. In all regions, shortages of human and medical resources were common, as were changes to dialysis delivery/practice including more skipped sessions, greater use of potassium binders, and preferentially recommending home dialysis. Over the next month, we expect hundreds more responses, and will compare approaches in PD and HD clinics. These data will inform guidance for dialysis care as the COVID-19 pandemic ensues.

PO0729
Factors Associated with SARS-CoV-2 Infection (COVID) Severity and Mortality in Chronic Dialysis Patients
Eduardo K. Lacson,1,2 Gideon N. Aweh,1 Vladimir Ladić,1 Harold J. Manley,1 Carol Stewart,1 Doug Johnson,1 Dialysis Clinic Inc., Nashville, TN; 1Tufts University School of Medicine, Boston, MA.

Background: From 2/17 to 5/29, 2020, Dialysis Clinic Inc. had 422 maintenance dialysis patients diagnosed with COVID from 90 clinics in 20 states. While prognostic factors in the general population have been reported, there is limited information regarding the US dialysis population.

Methods: Over a 15 week period of observation, 96 patients died (22.7%) and 116 (27.5%) were not hospitalized (for up to 30 days post-COVID diagnosis), likely with milder illness. We compiled univariable associations with p<0.1 into stepwise logistic regression models (forcing in age, sex, race) to determine factors associated with 1) Death from COVID; and 2) Moderate/severe illness (hospitalized or died without hospitalization <30 days post-COVID diagnosis).

Results: Candidate variables are listed in the table, with retained significant factors marked (a or b at p<0.05). Notably, 42% of all deaths occurred at age >75 years, increasing to 74% of all deaths at age >65 years. Wheelchair use also associated with higher death risk.

Conclusions: Dialysis patients with low albumin and vintage ≥1 year associated with increased illness severity. It was surprising that a history of pneumonia vaccine associated with more severe illness - whether this reflects “treatment by indication” bias vs. pulmonary immune activation by vaccination vs. chance finding is unclear. PVD also tended to increase illness severity but more importantly, was significantly associated with risk of death, independent of older age.

PO0730
Fighting COVID-19: Experience from a Chinese Hemodialysis Center
Qian Zhang, Mengjing Wang, Jing Chen. Huashan Hospital Fudan University, Shanghai, China.

Background: COVID-19 has ravaged China and spread throughout the rest of the world. Since there is no effective treatment available at present time, patients with ESRD feel anxious and uncomfortable to come to dialysis center and receive dialysis treatments.

Methods: To help the patients deal with their anxiety without interrupting their treatments, we developed emergency response plans and offered following instructions during the pandemic of COVID-19.

Results: 1) We have immediately adopted a comprehensive epidemiological screening and symptom evaluation for all hemodialysis patients, family members and medical staff. Confirmed and suspected COVID-19 patients will be quarantined in the designated places for 14 days after they are cured and discharged from hospitals. 2) We emphasize scientific education and teach our patients about the scientific evidence-based protection measures. 3) Patients shall wear masks throughout the treatment and avoid gathering and talking. They are trained how to wash hands in the correct way. They are required to wash their hands before entering the hemodialysis center and after returning home. 4) Before entering the hemodialysis center, everyone shall scan the QR code and register his or her health information. Medical staff will screen patients and perform the risk stratifications as seen in figure 1. Medical staff will check the patients’ temperature before, during and after dialysis treatment. 5) The environmental cleaning and disinfection measures will be strengthened for hemodialysis facility. The spaces between dialysis stations will be increased and the isolation curtains will be installed to keep social distance. Isolation treatment area will be set up to reserve for suspected COVID-19 hemodialysis patients.

Conclusions: Since we adopted above-mentioned instructions, we have zero infection case during the pandemic of COVID-19.
PO0732
Impact of Undertaking Safeguards to Limit Exposure and Prevent COVID-19 Infection in Ambulatory Dialysis: A Single-Center Experience
Abdullah L. Hamad, Musab Elgaali, Essa Abulelaqia, Mohamad M. Alkadi, Muftah Othman, Mohamed A. Elesnawi, Tarek A. Ghonimi, Hassan A. Al-Malki. Hamad Medical Corporation, Doha, Qatar.

Background: Dialysis patients are considered at high risk to develop serious COVID19 complications. Taking extreme measures are necessary to prevent COVID19 transmission at the dialysis center. We are presenting outcomes of our COVID19 prevention project from our largest dialysis center in Qatar.

Methods: Our project was done at FBKC (largest dialysis center in Qatar with about 60% of all hemodialysis (HD) and 90% of all peritoneal dialysis (PD patients in Qatar)) between March 1st and May 25th 2020. We gradually implemented a bundle of measures and algorithm (attached) to properly triage and limit COVID19 exposure inside the center. New infection control protocol with specifications to COVID19 were implemented, including a new policy for reusing N95 masks in high risk areas. We tracked number of patients and staff who were infected during that period and source of infection.

Results: Our dialysis census during that period was 480 HD and 170 PD patients. Only 6 HD patients turned positive for COVID19 (0.9%) and 2 PD patients (1.2%) (compared to 1.3% general population in Qatar by May 25th). We had 3 dialysis staff infected out of 114 (2.6%). Our investigation showed that all cases of COVID19 (both in patients and staff) were likely contracted outside the center. All staff and patients exposed to positive cases of COVID19 inside the center turned out negative. Our infection control classified most exposures at low risk, especially after we fully implemented our precautions.

Conclusions: Preventive actions implemented inside a large dialysis center led to prevention of COVID19 transmission. Increase positive COVID19 cases (in staff and patients) were related to countrywide growth of infection.

PO0734
Outcomes of ESKD Patients Hospitalized with COVID-19
Jia Hwei Ng, Jamie S. Hirsch, Rimda Wanchoo, Mala Sachdeva, Susana Hong, Vipulbhai Sakhya, Kenar D. Jhaveri, Steven Fishbane. on Behalf of Northwell Nephrology Covid-19 Research Consortium Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.

Background: Patients with ESKD have a dysregulated immune system and a higher annual mortality rate compared with the general population. We aimed to describe the clinical characteristics and compare the outcomes of patients with and without ESKD, among those hospitalized with COVID-19 disease.

Methods: We reviewed the health records for all patients hospitalized with Covid-19 between March 1, 2020 and April 27, 2020 from 13 hospitals in New York. Patients < 18 years or admitted to inpatient obstetrics service were excluded. ESKD diagnosis was defined using ICD-10 code and manual adjudication. Patients were followed up through May 27, 2020.

Results: Of 10,482 patients admitted with COVID-19, 419 (4.0%) had ESKD. Among patients with ESKD, 408 (97.4%) were on hemodialysis and 11 (2.6%) were on peritoneal dialysis. When comparing baseline characteristics of the two groups, patients with ESKD were older, were predominately of Black race, and had greater proportions of comorbid conditions. The primary outcome was that patients with ESKD had a higher odds of in-hospital death than those without ESKD (rates, 31.7% vs 25.4%; OR 1.4, 95% CI 1.1 - 1.7). After adjusting for age, sex, race/ethnicity, the odds of
in-hospital death remained higher in the ESKD group (adjusted OR 1.5, 95% CI 1.2 - 1.8). The ESKD group did not have a significantly higher odds of needing mechanical ventilation than the non-ESKD group in both the crude analysis and after adjustment for age, sex, race/ethnicity. The odds of having a length of stay of >7 days was higher in the ESKD group compared to the non-ESKD group, in both the crude analysis and the adjusted analysis (OR 1.62, 95% CI 1.3 - 2.1; adjusted OR 1.6, 95% CI 1.3 - 2.1). The independent predictors for death for non ESKD patients were age, male gender, cancer, CHF, elevated BUN, low albumin and being on a ventilator. The independent predictors of death for ESKD patients were age, lymphopenia, low albumin and being on a ventilator. Black race was associated with lower risk of death.

Conclusions: ESKD patients had a higher rate of mortality compared to non-ESKD patients hospitalized with COVID-19. Black race was associated with a lower risk of death.

PO0735

Outcome of Hospitalized ESRD-COVID-19 (C19) Infected Patients

Jose E. Navarrete, Darya Hossein, Harold A. Aranch, Frederic F. Rabbari-Oskoui, Michael J. Connor, Janice P. Lea. Emory University, Atlanta, GA.

Background: Emory University affiliated hospitals serve the metro Atlanta area, where a significant number of C19 cases have occurred. In this report we describe the outcomes of AKI and ESRD patients with confirmed C19 admitted to our health-system.

Methods: All patients seen by Emory Nephrology at 2 tertiary referral and one county hospital were categorized as ESRD if they required dialysis prior to C19 infection, or AKI if they developed acute kidney injury as a result of C19 infection. Outcomes of interest included patient survival and discharge from the hospital. Admission to Intensive care unit and use of mechanical ventilation were recorded. Comorbid conditions and outpatient use of medications were analyzed.

Results: From 3/1/20 to 5/26/20, 474 consecutive patients were seen in COVID-19 related consultation. 287 patients were considered PU and eventually tested positive for C19. The remaining 187 patients were C19 positive by nasopharyngeal or tracheal aspirate and represent the study population for this report. There were 43 ESRD (23%) and 144 AKI (77%) patients. Age (64 vs 63 years), gender (63 vs 66% males) ethnicity (86 vs 82% African-americans) and comorbid conditions were similar in AKI and ESRD patients. AKI patients were more likely to be admitted to ICU (83 vs 35%) and to require mechanical ventilation (73 vs 20%) compared to ESRD patients (p<0.05). Figure 1 presents the outcomes based on the type of renal disease at presentation. The eGFR of AKI patients at time of admission was 30a34 ml/kg/m'. 84 AKI patients required dialysis during their hospitalization (53%).

Conclusions: Patients with ESRD C19+ were less likely to require ICU admission or mechanical ventilation. Mortality of ESRD patients was 14% compared with 42% of AKI patients, (p<0.002). ESRD patients with C19 were also more likely to be discharged from the hospital compared to those with AKI. Despite similar demographics and comorbidities, hospitalized C19 AKI patients had worse mortality than those receiving chronic dialysis.

PO0736

Non-Hospitalized Maintenance Hemodialysis Patients with COVID-19 Have Elevated Inflammatory Markers

Akhil Hegde, Jennifer E. Flythe, Cynthia J. Denu-Ciocca, Kawan A. Swain, Raven A. Voora, Heather J. Anseade, Gerald A. Hladik, Peter Kotanko, Prabir Roy-Chaudhury, Abhijit V. Kshirsagar. 1 UNC Kidney Center, Chapel Hill, NC; 2 Renal Research Institute, New York, NY.

Background: In addition to an aggressive pneumonia, patients hospitalized with COVID-19 have marked inflammatory and hypercoagulable states, with downstream cardiovascular and thrombotic events. Hemodialysis patients have baseline increases in inflammation and hypercoagulability. However, to our knowledge, little is known about the level of inflammation and hypercoagulability among non-hospitalized in-center hemodialysis patients with COVID-19. We collected inflammatory and coagulation markers from hemodialysis patients with COVID-19 who were managed as outpatients. Methods: Patients in our dialysis program with one positive nasopharyngeal swab PCR for SARS-CoV-2 were consecutively admitted to an outpatient COVID-19 hemodialysis shift. While receiving their usual dialysis prescription, the patients also had weekly measurements of D-Dimer, Fibrinogen, C-reactive protein (CRP), and Serum Ferritin, until they tested negative x 2 for SARS-CoV-2.

Results: 16 consecutive patients were admitted to the COVID-19 isolation shift over 30 days. Their average age was 60 yr, 56% were Black, 25% Hispanic, and 44% female. Causes of ESKD included diabetes (75%), glomerular diseases (19%), and hypertension (6%). No patients received intravenous iron supplementation while on the isolation shift. Table 1 displays the inflammatory marker levels in this group. Note, the 4-fold (D-Dimer), 6-fold (Ferritin) and 21-fold (CRP) increase in these biomarkers from normal levels.

Conclusions: Our initial, unique data show an increase in inflammatory markers in a group of non-hospitalized COVID-19 hemodialysis patients. Such an increase may be from the pro-inflammatory impact of COVID-19 in a group with pre-existing high levels of inflammation from uremia and oxidative stress. Additional investigation as to whether these elevated markers associate with cardiovascular and thrombotic events (dialysis circuit and vascular access clotting, sudden cardiac death) is needed.

Funding: NIDDK Support, Clinical Revenue Support

PO0737

Network Analysis of In-Center Spread of COVID-19: A Single Dialysis Center Experience

Lemuel Rivera Fuentes,1 Hanjie Zhang,1 Alhaji Cherif,2 Peter Kotanko.1,2

1 Renal Research Institute, New York, NY; 2 Icahn School of Medicine at Mount Sinai, New York, NY.

Background: The need to continue in-center hemodialysis (HD) during COVID-19 pandemic presents a risk of transmission for patients and staff members. The present study aimed to determine if the periodic interactions among patients and staff resulted in spread of COVID-19 in a HD center during a period of 2 months.

Methods: This is a retrospective analysis on a HD center in New York City (172 patients, 32 staff members, 26 chairs, MWF and TTS schedules, and 4 shifts/day). From March 24th to April 24th we recorded every HD treatment (chair, patient, and staff member involved in care). We kept dated records for positive COVID-19 cases (patients and staff). To estimate the patient-to-patient interaction, we obtained the location coordinates of each dialysis chair, calculated the Euclidean distance between them and weighted the interaction by proximity between chairs. We conducted network analysis to assess these interactions.

Results: During the study period, 16 patients and 2 staff members became COVID-19 positive. As shown in Figure 1(a), there were 3 chairs (2, 24, and 25) that had more than 1 positive patient. Clusters in chairs 2 and 25 were ruled out based on a lack of direct contact between the involved patients (at least 2 shifts separating them at all times; no in-between patients became positive); chair 2 had a nonviable temporal direction of transmission. Based on schedule, shift, and a 14-day incubation period, the cluster in chair 24 was dismissed. This was corroborated by network analysis (Fig. 1b) where the purple dots represent the COVID-19 positive patients, the blue dots represent negative patients (same shift/schedule), and the edges represent the weighted patient-to-patient interaction.

We reasoned that more exposed patients would have had a higher chance of becoming infected. Similar information was found for staff-to-patient interaction.

Conclusions: Based on our analysis we consider that for patient-to-patient, staff-to-patient, and staff-to-staff interactions, in-center spread of COVID-19 was unlikely.

Outcomes of Patients on Chronic Dialysis Hospitalized with COVID-19

Lili Chan, Suraj K. Jaladangi, Lewis Kaufman, Shuchita Sharma, Staci A. Leisman, John C. He, Barbara T. Murphy, Steven G. Cooa, Girish N. Nadkarni. Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Preliminary reports find that patients with end stage renal disease (ESRD) on dialysis who test positive for SARS-CoV-2 have fewer symptoms and require less intensive care than expected. However, there are no reports regarding the outcomes of ESRD patients who are hospitalized with coronavirus disease 2019 (COVID-19).

Figure 1(a) infection history; (b) network analysis patient interaction
**Methods:** This is a retrospective observational study of patients aged ≥18 years with laboratory confirmed COVID-19 admitted to the Mount Sinai Health System between February 27 and May 20, 2020. ESRD patients were identified by International Classification of Disease codes for ESRD. ESRD patients were propensity matched (5:1) to non-ESRD patients by age, gender, race/ethnicity, comorbidities, body mass index, and facility and ward of hospital admission. Multivariate analysis was performed to test the association of ESRD with mortality after adjustment for age, diabetes, hyperlipidemia, stroke, coronary artery disease, and congestive heart failure.

**Results:** 122 ESRD patients were included in this study. ESRD patients had higher prevalence of diabetes (55% vs 43%, P<0.02) and hypertension (66% vs. 55%, P=0.03). ESRD patients had higher inflammatory markers of ferritin and procalcitonin. There was a significant difference in d-dimer, fibrinogen, C reactive protein, or interleukin-6 (Figure 1A). ESRD patients were significantly less likely to receive mechanical ventilation (3% vs. 10%, P<0.01) or be admitted to the intensive care unit (9% vs. 21%), and had similar in-hospital mortality (9% vs 15%, P<0.5). ESRD status was associated with lower odds of initiation and intensive care admission, but not significantly associated with mortality after adjustments for age and comorbidities (Figure 1B).

**Conclusions:** While ESRD patients had a higher prevalence of comorbidities and higher inflammatory markers, they had similar in-hospital mortality as matched non-ESRD patients.

**PO0739**

Outpatient Hemodialysis Unit Preparedness During COVID-19 Pandemic in Several Dialysis Units in New York State

**Errol Carter, Duarry R. Sainvilien, Braham A. Mohamed, Jamrose K. Durran, John D. Wagner, Angelika C. Gruesser, Subodh J. Saggi. SUNY Downstate Health Sciences University, Brooklyn, NY.**

**Background:** HD units are clustered close contact environments where prolonged exposure to blood borne pathogens occurs. Weeks into the CoVID-19 pandemic, wide disparities in rates of death and exposure of staff and patients amongst HD units in the same zip code of an epicenter in New York regions emerged.

**Methods:** Random HD units surveyed as to when and what infection control measures they implemented. Direct input into RedCap and SAS 9.0 analysis of the data conducted.

**Results:** 15 HD units (average census 18-240) responded. Survey compiled exposure rates from 3/1/20 - 4/30/20. The 1st reported case of CoVID-19 by a facility was 3/2/20. Most facilities reported outbreaks (4-30 cases per facility) by 3/21/20. Missed HD sessions due to CoVID varied from 2-100, hospital stays for such patients varied from 2-20 days and death rates from 0-15 per facility. 20% of personal protective equipment (PPE) were unavailable in 13% of facilities, staff, and housekeeping. HD units in the same zip code of an epicenter in New York regions emerged.

**Conclusions:** These data suggest that during current COVID-19 pandemic, half of HD units have significantly increased their adherence to hemodialysis prescription in order to fear of contacting the SARS-CoV-2 virus. Retrospective studies have suggested that patients are avoiding seeking medical care due to fear of contracting COVID-19. We therefore evaluated the effects of the COVID-19 pandemic on patient adherence to their dialysis prescription.

**PO0740**

Outpatient Initiation of Dialysis for AKI Requiring Dialysis Following Diagnosis of COVID-19

**Kristine Kubisiak, Lorien S. Dalrymple, Norma J. Olshuhn, Yuping Sun, Franklin W. Maddux, Robert J. Kossman, Jeffrey L. Hymes. Fresenius Medical Care, Waltham, MA.**

**Background:** COVID-19 has been associated with the development of AKI, and the incidence of AKI-D may be as high as 3-5% in patients hospitalized with COVID-19. We examined the initiation of outpatient (OP) dialysis for AKI-D following a diagnosis of COVID-19.
Accuracy of Lower Temperature Thresholds in Detecting COVID-19 in Hemodialysis Patients
Remi Goupil,1 Annie-Claire Nadeau-Fredette,2 William Beaubois-Souligny,3 Francois Madore,1 Rita Suri,2 for the Réseau Rénal Québécois3 Hospital du Sacré-Cœur de Montreal, Montreal, QC, Canada;4 Centre Hospitalier de l’Université de Montreal, Montreal, QC, Canada; ‘McGill University, Montreal, QC, Canada.

Background: Patients receiving in-center hemodialysis (HD) are uniquely vulnerable to COVID-19 yet identifying infected individuals may be challenging. They may not present with typical symptoms and low basal body temperature may impair detection of fever. We studied the accuracy of temperature thresholds in detecting COVID-19 in HD patients.

Methods: We retrospectively studied all patients between March 24-May 14, 2020 from a single HD unit (Hôpital du Sacré-Cœur) in Montreal, Canada, where COVID-19 is highly prevalent. All patients who presented with symptoms or contact exposure were tested by nasopharyngeal swabs. Prompted by an outbreak, systematic testing of all HD patients was started on April 18th. Basal temperature was defined as the average pre-dialysis temperature from weeks -1 to -3 before testing. Diagnostic performance was determined for various temperature thresholds defined a priori.

Results: Of 205 in-center HD patients, 34 developed COVID-19 during the study period. Of these, 21 (61%) were hospitalised, 4 (11%) required intensive care and 9 (25%) died. Baseline characteristics are presented in Table 1. Less than a third had typical symptoms. Thresholds of 37.3°C and “basal temperature +0.5°C” had similar moderate sensitivity and high specificity in predicting COVID-19 (Table 2). Combining symptoms and either of these thresholds improved sensitivity to 85%.

Conclusions: Less than one third of HD patients have typical symptoms of COVID-19 or fever >38.0°C. Pre-dialysis temperature >37.3°C or 0.5°C above basal temperature markedly improves sensitivity for detection of COVID-19 in asymptomatic HD patients. A screening strategy combining symptom questionnaires and pre-dialysis temperature monitoring should be used in HD units in regions of high COVID-19 prevalence.

Assessment of a Laboratory-Based SARS-CoV-2 Antibody Test Among Hemodialysis Patients: A Quality Improvement Initiative
Dena E. Cohen,1 Gilbert Marlowe,2 Gabriel Contreras,3 Marie A. Sosa,7 Jair Munoz Mendoza,2 Oliver Lenza,2 Zain Mithani,2 Jorge L. Posada,6 Julio A. Fernandez-Bombino,2 Luis Garcia-Mayol,2 Michael T. Lemont,2 Anne Marie McVey,4 PA 1,2 Steven Zeig,2 Mara M. Teixeiro,2 Nery Quijada,6 Jean S. Jeanty,6 Katie Swanzny,7 Misha J. Palecek,7 Mahesh Krishnan,7 Jeffrey A. Giuliani,7 Steven M. Brunelli,7 Davita Clinical Research, Minneapolis, MN; 2University of Miami, Coral Gables, FL; 3Kendall Regional Medical Center, Miami, FL; 4Hialeah Hospital, Hialeah, FL; 5Kidney and Hypertension Specialists, Miami, FL; 6Memorial Healthcare System, Hollywood, FL; 7DaVita Inc, Denver, CO.

Background: The coronavirus disease 2019 (COVID-19) pandemic is caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection. Assessment of newly developed anti-SARS-CoV-2 antibody tests in hemodialysis patients is needed.

Methods: As part of a quality improvement (QI) initiative, nasopharyngeal swabs and predialysis blood samples were collected on the same day from adults receiving routine dialysis care at clinics managed by a large dialysis organization in the Miami, Florida, region (April 23-30, 2020). Polymerase chain reaction (PCR) tests for SARS-CoV-2 (Fulgent Genetics, Temple City, California) and chemiluminescence immunoassays (Diazyme Laboratories, Inc, Poway, California) were performed according to manufacturer protocols. For antibody tests (IgM and IgG), a reading of >1 arbitrary unit/ml was scored as positive.

Results: Of 715 participants in the QI initiative, 38 had symptoms consistent with COVID-19 prior to or during the initiative. Among these, COVID-19 was confirmed in 14 and ruled out in 20, with 4 being inconclusive. Among the 34 patients with known COVID-19 status, the sensitivity and specificity of the antibody test were 57.1% and 85.0%, respectively, when both IgM and IgG were considered. The remaining 677 patients had no record of symptoms consistent with COVID-19 or any known exposure. Of these, 38 (5.6%) tested positive for anti-SARS-CoV-2 antibodies; none of the antibody-positive patients with available PCR results (N=33) tested positive for SARS-CoV-2 infection.

Conclusions: The operational characteristics of the laboratory-based antibody test make it sufficient to rule in, but not rule out, SARS-CoV-2 infection in the appropriate clinical circumstance. A substantial proportion of dialysis patients may have had asymptomatic SARS-CoV-2 infection.

PO0743

Clinical and Psychosocial Impact in Mexican Hemodialfiltration Population During the COVID-19 Pandemic, Twice Weekly Sessions: Is This Safe?
Jose S. Lopez Gil, Hector Alejandro P. Garza, Magdalena Madero, Daniela Xavier. Division of Nephrology Instituto Nacional de Cardiologia Dr Ignacio Chavez, Mexico City, Mexico.

Background: There is evidence that in patients with residual kidney function (RKF) could benefit switch thrice to twice weekly sessions. In patients without RKF, the evidence is limited. We studied the clinical and psychosocial impact of the Covid-19 pandemic in Mexico City.

Methods: At the beginning of the Covid-19 pandemic, the on-line posdilutional hemodiafiltration (OL-HDF) sessions were adjusted from 3 to 2 times per week. 2 months later, we determine hemoglobin, urea, serum creatinine, sodium, potassium, calcium, phosphate, albumin, ferritin and C reactive protein. Likewise psychological evaluation using Hamilton test were carried out and characteristic of sessions were collected. We do not two groups according to thrice versus twice weekly schedule.

Results: 25 patients were evaluated, 16 (64%) were female, mean age was 42.04±18.02 years, 21 (84%) did not have RKF. The length session between thrice vs twice were 181.74±9.94 vs 196 ± 9.19 (p=0.001). When we analyzed the anuric patients we found a significant difference in post-session systolic and diastolic blood pressure when compared between groups (p = 0.014). We did not find difference in dry weight (p = 0.5). We found significant difference between total substitution volume between groups (24.43±10.91 vs 26.5± 12.48 L, p=0.042) and no difference in Kt/V (1.67 ± 0.25 vs 1.73 ± 0.34, p=0.35). We found significance difference between groups in serum creatinine (8.68±3.55 vs 10.04±2.94, p=0.03) in the rest of molecules we did not find difference. 32 and 44% of the patients developed depression and anxiety, respectively. 36% of patients lost their jobs and 80% use public transport. There was a moderate correlation between anxiety episodes and economic limitation due to Covid-19 (r = 0.40 p = 0.04). There was no significant inverse correlation between pharmacological adherence and economic limitation (r = -0.29 p = 0.29).

Conclusions: Change of the schedule in patients without RKF did not show significant differences in terms of biochemical parameters, on the other hand, improvement in replacement volumes. We considered a safe strategy to reduce the risk of transmission among our population. Pharmacological and attending adherence to sessions was not modified despite the psychological findings due to the Covid-19 pandemic.

PO0745
Clotting of Hemodialysis Catheters in Patients with Renal Failure with COVID-19
Mary C. Mallappalli, Jie Ouyang, Sabu John, John D. Wagner, Mariah W. Thaxton, Emie Yap, Siddhartha D. Bajracharya; Health and hospital corporation New York City - Kings County Hospital, New York, NY; State University of New York at Downstate Medical Center, Brooklyn, NY.

Background: We are an inner-city hospital in New York that had a surge of patients diagnosed with COVID-19. Many of these patients had acute kidney injury (AKI) and required renal replacement therapy (RRT). NYC Health + Hospitals/Kings County has 40 adult intensive care unit (ICU) beds. ICU capacity expanded to a potential of 150 beds during the COVID-19 surge. The surge included patients transferred from other NY inner-city hospitals for critical care and RRT. Sequential obstacles were faced in providing hemodialysis (HD) to this expanded pool of AKI patients. Additional machines, supplies, staffing and organization were helpful. Clinicians noted that COVID-19 complications included hypercoagulability and we observed an increased frequency of clotting of hemodialysis catheters (HDC).

Methods: We examined the percentage COVID-19 tested renal failure patients with clotting of HDC access during the period March 1, 2020 to May 15, 2020. We collected data on 146 patients during the above period who had HD. We then compared those who were COVID-19+ positive confirmed by testing to those who were not COVID-19+ by testing. HDC clotting was identified by the use of alteplase. We compared our findings of the two groups to historical controls during a similar time period prior to the COVID-19 surge, between January 1 to February 29, 2020.

Results: We had 3,665 admissions between March 1 and May 15, 2020, of which 1,075 patients had a confirmed COVID+ test during the admission. Of these, 773 patients were noted to have AKI from diagnosis codes in the electronic medical record. Of the 146 patients who needed HD (including patients with AKI and CKD) 97 were COVID-19+ and 49 were negative. HDC clotting identified by the use of alteplase was noted in 27% of those who were COVID-19+ compared to 10% of those who were COVID-19 negative. (P value = 0.02 by Chi-square using SPSS Version 24). The percentage of patients with clotting of catheters in the non-COVID-19 group was comparable to historical controls.

Conclusions: Significantly more COVID-19+ patients had HD catheter clotting compared to COVID-19 patients. Increased clotting was noted as a barrier to providing optimal HD therapy. For this and other reasons, we initiated an urgent start acute peritoneal dialysis program to mitigate the challenges in delivering HD to COVID-19 patients.

PO0746
Contingency Planning for COVID-19: Feasibility of Twice Weekly Hemodialysis in a Large Canadian Cohort
David Clark, Kenneth A. West, Karthik K. Tennankore. Dalhousie University Faculty of Medicine, Halifax, NS, Canada.

Background: Reducing hemodialysis treatments from three times weekly to twice weekly is a potential strategy to lessen potential exposure/transmission of COVID-19 while allowing hemodialysis units to operate with fixed/reduced resources. As part of contingency planning at a large Canadian center, all facility-based hemodialysis patients were reviewed in advance for candidacy of a reduced “twice weekly” schedule.

Methods: All prevalent patients receiving at least thrice weekly, facility-based hemodialysis - affiliated with the QEII Halifax, Nova Scotia, Canada - were systematically reviewed in a stepwise manner, using accepted criteria for implementing twice weekly hemodialysis. We examined the percentage COVID-19 tested renal failure patients with clotting of twice weekly hemodialysis patients for candidacy of twice weekly hemodialysis (N=473). Patients who fulfilled interdialytic fluid gain and serum potassium criteria were assessed by the primary nephrologist for eligibility using each of: III. good nutritional status, IV. no co-morbid conditions (cardiovascular and pulmonary).

Results: Of 473 patients assessed, only 18 (4%) fulfilled criteria for twice weekly hemodialysis (Fig 1.) Of these patients, average age was 63 ± 12 (SD) years, 61% were diabetic, 95% Caucasian; and at least 67% receiving dialysis for 6+ months prior to the surge, between January 1 to February 29, 2020.

Figure 1. Stepwise approach and selection criteria to review all facility-based hemodialysis patients for candidacy of twice weekly hemodialysis (N=473).

Conclusions: Although feasible, a twice weekly hemodialysis strategy applied to a small proportion of our patient population, potentially reflecting an ‘intention to defer’ strategy for initiating dialysis.

PO0747
Impact of the COVID-19 Pandemic on Virtual Care in Home Dialysis
Martin J. Schreiber, Adam J. Weinstein, Mahesh Krishnan, Brooke Bowblly, Mike Gonzales, Liz Mooney, Michelle Cassin. DaVita Inc, Denver, CO.

Background: While almost every provider and the majority of patients in the United States (US) possess the technology needed to conduct a telemedicine visit, prior to the current pandemic utilization in home dialysis was relatively low. The current study examined trends in telehealth utilization before and during the COVID-19 pandemic in US home dialysis patients treated by a large dialysis organization in the US.

Methods: Telehealth was delivered using a proprietary multiparty, video, secure messaging (HIPAA compliant), scheduling, and educational resource telehealth platform DaVita Care Connect™ (DCC™) application. IT systems data were utilized to develop ongoing reports depicting patient, facility, and physician adoption rates across 1750 home dialysis programs. Data were segmented by geographic areas (9) and by time of COVID-19 dissemination within localities.

Results: A meaningful increase in telehealth utilization was observed since the start of the pandemic (prior to March 2020). Among 28,500 home dialysis patients treated, the DCC™ application was installed on 18,300 patient cell phones (65.3%). Overall, 16,000 peritoneal dialysis (PD) patients and 2,200 home hemodialysis (HHD) patients participated in a telehealth visit. Fifteen thousand visits were performed in April 2020. There were 18,000 messages sent between the care team and patient and 6000 educational resources viewed by patients at home since the COVID-19 pandemic (mid-March). The numbers of social worker and dietician visits and interdisciplinary team rounds also increased over time. There was significant variation DCC™ app download and utilization across geographic regions.

Conclusions: The COVID-19 pandemic has dramatically increased the use of telehealth management for home dialysis patients in the US. Examining the impact of virtual visits on patient outcomes going forward will be critical in designing post-COVID care. Balancing the integration of telehealth visits and face-to-face visits to optimize care will necessitate advancing a new care model for patients with end-stage kidney disease.
COVID-19: Dialysis Patients

Abstract Withdrawn

PO0749

Mental Health Status During the COVID-19 Pandemic of Hemodialysis Patients

Ernesto Sabath,1,2 Edgar Morales-Montes,1 1Servicios de Salud del Estado de Queretaro, Santiago de Queretaro, Mexico; 2Universidad Autonoma de Queretaro Faculty of Ciencias Naturales, Queretaro, Mexico.

Background: Patients receiving hemodialysis (HD) treatment are a particularly vulnerable population as previous studies have shown that they are at higher risk to develop anxiety, depression, and diminished health-related quality of life. During the COVID-19 pandemic patients and health professionals are under insurmountable psychological pressure which may lead to various psychological problems. The aim of this study was to assess the effect of this pandemic on mental health and quality of life in low-income HD patients.

Methods: Observational, cross-sectional study done in low-income HD patients and matched healthy controls from March-April 2020. The survey collected basic demographic and laboratory data. To assess mental status 3 different scales were used: Generalized Anxiety Disorder (GAD-7), Insomnia Severity Index (ISI), and the Kidney Disease Quality of Life (KDQOL-36). An evaluation of media interest was added.

Results: 152 HD patients and 33 control subjects were included. The median age was similar in both groups (HD 51±17 vs 48±10 yrs p=NS). Literacy was significantly higher in the control group. The control group showed significantly higher interest media (p=0.03); 60.5% of HD patients showed none or low emotional impact with this pandemic (42% in control group p=0.02). Severe anxiety was more prevalent in the control group (22.6 vs 8% p=0.01). The ISI scale showed also significantly higher sleep impairment in control subjects (42.6 vs 20.5% p=0.04). In the HD group, the prevalence of GAD symptoms was higher in females than men (p<0.005), and one of the most influential factors associated with GAD symptoms was to live in a rented home. Patients ≥50 years had significantly higher GAD symptoms (0.01). Unemployed HD patients showed the lowest KDQOL scores.

Conclusions: HD patients had less emotional impact, lower GAD-7 and ISI scores symptoms than healthy controls. To live in a rented home and unemployment were important risk factors associated with a higher prevalence of anxiety and sleep disorders.

PO0750

Monitoring Trends of COVID-19 Among ESKD Patients in a Large Dialysis Organization

Kristine Kubis,1 Eric D. Weinhandl,1 Norma J. Ofsthun,1 Jeffrey L. Hymes,1 Robert J. Kossmann,1 Lorien S. Dalrymple,1 Fresenius Medical Care, Waltham, MA; 2Chronic Disease Research Group, Minneapolis, MN.

Background: Monitoring real-time acceleration, plateaus, and deceleration of infection rates is important for healthcare planning during a pandemic. We implemented methodology to continuously monitor daily cases and changes of COVID-19 case rates among individuals with ESKD receiving care in a large dialysis organization.

Methods: We identified patients with ESKD receiving dialysis in a Fresenius Medical Care North America (FMCNA) dialysis facility who tested positive for COVID-19. We fit a loess curve to the daily cumulative number of identified cases and computed the first and second derivative of the fitted curve to assess rate of change and change in rate of change, respectively, over time. We used these visualization techniques to monitor trends in case rates at the national and state levels.

Results: By May 15, 2020, there were 5,513 confirmed COVID-19 cases among patients receiving dialysis in an FMCNA facility. Mean age was 63.6 years, 57% were male, and 71% of confirmed cases had diabetes. Nationally, during the peak infection period in early April, new cases routinely exceeded 150 per day and there was a steady acceleration in growth of cases until the second week of April. As of May 15, 2020, among states with sufficient data, 2 states demonstrated continued acceleration, 10 demonstrated deceleration, and 13 plateaued in rate of growth.

Conclusions: The timing of the acceleration in growth of COVID-19 cases among individuals with ESKD followed national trends in the general population. Varying patterns of plateauing and deceleration of cases at the state level were observed in the ESKD population. Real-time monitoring of disease rates in high-risk populations, such as individuals with ESKD, is needed to plan for continuously changing healthcare demands during a pandemic.

PO0751

Psychological Impact of COVID-19 and Implementability of Prevention and Control Measures in Hemodialysis Centers: A Provincial Questionnaire Survey in China

Lingxiang Zhang,1 Yizhuang Chen,1 Yanhua Wu,1 Penghua Hu,1 Guangzhou Provincial People’s Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China; 2Guangdong Provincial People’s Hospital, Guangdong Academy of Medical Sciences, Guangdong Provincial Geriatrics Institute, Guangzhou, China.

Background: This study investigated the psychological status of patients and staff and implementability of prevention measures in hemodialysis centers in Guangdong Province of China during the Coronavirus disease 2019 (COVID-19) pandemic.

Methods: An electronic questionnaire survey was performed in an anonymous manner between March 28 and April 3, 2020. Two questionnaires were designed to investigate the psychological status for hemodialysis patients and general staff (doctors, nurses, technicians, and other staff), respectively. An additional questionnaire for administrators (directors or head nurses) of hemodialysis centers was designed to address the implementability of prevention measures, including strengthened patient triage management, restricting caregiver visits to patients during dialysis, strengthened prevention amongst staff, and improved patient education and protection. All the 516 hemodialysis centers registered in Guangdong Province were voluntarily invited to join the survey.

Results: Total 1,782 patients, 3,400 staff, and 420 administrators responded for this survey. Patients living in rural areas reported a higher incidence of severe anxiety compared to those living in other areas. Medical staff reported better mental health than non-medical staff. With respect to implementability of prevention measures, hemodialysis centers in general hospitals outperformed independent blood purification centers, and tertiary hospitals outperformed other level hospitals. However, restricting acceptance of non-resident patients was lower in tertiary hospitals than that in other hospitals. Under this condition, only one patient imported from Hubei Province was diagnosed with COVID-19.

Conclusions: The outbreak did not significantly affect the psychological status of most patients and medical staff. Due to the successful implementation of comprehensive prevention measures, the COVID-19 epidemic was controlled effectively. This provincial survey may provide experience for other countries and regions with similar epidemic.

PO0752

Persistent Viral Shedding and Antibody Response to the SARS-CoV-2 Virus in Chronic Hemodialysis Patients

Aisha Shankh,1,2 Ett J Zeldis,1 Kirk N. Campbell,2 Lili Chen,2 James J. Peters VA Medical Center, Bronx, NY; 2Icahn School of Medicine at Mount Sinai, New York, NY.

Background: The duration of SARS-CoV-2 viral RNA shedding and antibody response of chronic HD patients to the SARS-CoV-2 virus is currently unknown.

Methods: This is a retrospective case series of chronic HD patients who tested positive for severe acute respiratory syndrome corona virus 2 (SARS-CoV-2 RNA) on nasal or nasopharyngeal specimen between March 20 and May 28, 2020 at the James J. Peters VA Hospital. Patients were tested at varying intervals to document clearance of virus or for surveillance purposes. SARS-CoV-2 Virus IgG Antibody (Ab) testing was performed on all HD patients with COVID-19 (using the Abbott IgG nucleocapsid antibody test and i2000SR machine, Ref. range of the Ab titer: >1.39 positive).
Results: Of 834 chronic HD patients, 26% (222) were diagnosed with COVID-19. Mean age of those with COVID-19 was 72±9 years old, 86% were Black, 77% had diabetes and all had hypertension. Of these patients, 59% (13/22) required hospitalization and 18% (4/22) died. IgG Ab testing was performed on 19 out of 22 COVID-19 patients. All 19 patients tested positive for IgG Ab with an average Ab titer of 7±1.2. 20 days after the first SARS-CoV-2 RNA positive test, 68% (13/19) patients remained positive on repeat RNA testing. 3 patients tested positive for SARS-CoV-2 RNA on repeat surveillance testing, despite testing negative on 2 prior consecutive nasal or nasopharyngeal specimens (Fig. 1). None of these 3 patients were symptomatic at the time their repeat swabs were positive for SARS-CoV-2 RNA.

Conclusions: All HD patients with a confirmed diagnosis of COVID-19 developed IgG Ab to the SARS-CoV-2 virus, but the SARS-CoV-2 RNA was detectable in the swab specimen for a prolonged duration of time. In a few cases, the SARS-CoV-2 RNA became detectable after 2 consecutive negative RNA specimens. It is unknown if the IgG antibodies confer immunity against the SARS-CoV-2 virus. Additionally, the significance of persistent viral RNA shedding in patients who have recovered from COVID-19 remains to be elucidated.
Enhanced Sentinel Surveillance System for COVID-19 Outbreak Prediction in a European Dialysis Clinics Network

Francesco Belloccchio,1 Paola Carioni,1 Mario Garbelli,1 Francisco Martinez-Martinez,1 John W. Larkin,2 Len A. Usvyat,2 Franklin W. Maddux,2 Stefano Stuard,1 Luca Neri.1 Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; 2Fresenius Medical Care North America, Waltham, MA, 3Fresenius Medical Care Italia SpA, Palazzo Pignano, Italy.

Background: Accurate predictions of epidemic dynamics may enable timely organizational interventions in high risk regions. We exploited the interconnection of the EMEA Fresenius Medical Care (FMC) dialysis clinic network to establish a sentinel surveillance system where the occurrence of new cases in a clinic propagates distance-weighted risk estimates to proximal dialysis units. The surveillance system is embedded in an artificial intelligence model which predicts COVID-19 outbreak occurrence in HD clinics from trends in clinical practice patterns and regional COVID-19 epidemic metrics. The system stratifies clinics by their risk of new local outbreak.

Methods: The risk prediction model is computed considering a cohort of 640 clinics belonging to the FMC network. We trained a model to predict outbreak in each clinic in a 2-week prediction horizon (i.e. two or more COVID-19 cases). In addition to sentinel distance-weighted risk estimates, the model included 73 variables (i.e. regional-level epidemic data from open source datasets and clinical practice data from the EuChDi® database). We generated the training set on data available on 04/01/2020 and tested prediction accuracy at 4/15/2020 and 4/20/2020.

Results: In the training set there were 58 (9.1%) clinics with two or more patients with COVID-19 infection in the two-week prediction window. In the validation samples there were 27 (4.2%) and 12 (1.9%) clinics with two or more patients with COVID-19 infection during the two-week prediction window. The performance of the model was suitable in both testing windows (AUC=0.86 and 0.80 respectively). The model is used to construct risk maps highlighting geographical clusters of clinics at risk (figure).

Conclusions: A sentinel surveillance system together with the wealth of information collected in EuChDi® and state of the art modeling strategies allows prompt risk assessment and timely response to COVID-19 epidemic challenges throughout networked European clinics.

Funding: Commercial Support - Fresenius Medical Care

Figure 1: Trajectories of Clinical and Laboratory Characteristics Before COVID-19 Diagnosis in Hemodialysis Patients

Yue Jiao,1 John W. Larkin,1 Caitlin Monaghan,1 Anke Winter,1 Jochen G. Raimann,2 Luca Neri,1 Peter Kotanko,2 Jeffrey L. Hymes,1 Sangho Lee,1 Len A. Usvyat,1 Franklin W. Maddux,2,3 Fresenius Medical Care Global Medical Office, Waltham, MA; 2 Renal Research Institute, New York, NY; 3 Fresenius Medical Care Deutschland GmbH, EMEA Medical Office, Bad Homburg, Germany; 4 Fresenius Medical Care North America, Waltham, MA; 5 Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea; 6 Loyola University Medical Center, Maywood, IL.

Background: The frequency of evaluations in hemodialysis (HD) care affords opportunities to assess profiles that may characterize onset of the 2019 coronavirus disease (COVID-19). We aimed to characterize the trajectories of clinical/laboratory assessments before COVID-19 diagnosis in HD patients.

Methods: We assessed data from HD patients with known COVID-19 dialyzed at Fresenius Kidney Care in the United States between 02 Mar and 09 Apr 2020. We computed mean daily values for 40 variables 90 days before a positive rRT-PCR test (COVID-19+). Nonparametric smoothing splines were used to fit data of individual trajectories and estimate the mean change over time.

Results: There were 1294 HD patients with COVID-19 (mean age 64±14 years, 60% male, 47% white race, 69% had diabetes, and 24% had coronary artery disease). Mean pre-HD body temperature (primarily oral) increased by about 1°F over 10 days before COVID-19+ test and approached 99°F at diagnosis (Fig 1A). Mean interdialytic weight gain decreased by about 0.75 kg (Fig 1B) over 14 days before COVID-19+ test; concurrent decreases of about 20 minutes were seen in HD treatment time. Mean neutrophil-to-lymphocyte ratio had mild increases (Fig 1C), while mean platelet counts decreased by about 40x10^9/L over 14 days before COVID-19+ test (Fig 1D).

Conclusions: The trajectories of several clinical/laboratory parameters appeared to change before COVID-19 diagnosis in HD patients. Many changes were small and may not be independently useful in identifying onset of COVID-19. Mean pre-HD body temperature before SARS-CoV-2 infection was 97.4°F and should be considered in screening. Findings may have utility in prediction model development. Further comparisons to patients without COVID-19 are needed.
Methods: This prospective, observational, multi-centre study collected data on SARS-CoV-2 infected HD patients between 29/02/2020 and 15/05/2020. Data was collected on demographics, comorbidities, WHO performance status, clinical symptoms, laboratory parameters, hospital management and outcomes. Treatment was predominantly supportive, unless patients were part of an approved clinical trial. The study was approved by the NHS Research Ethics Committee 20/SW/0077 and Health Research Authority IRAS 283130.

Results: Of 1737 HD patients at the 3 renal centres, 224 (13%) were COVID-19 positive over the study period. The characteristics of the COVID-19 HD patients were: mean age 65.8; 59% male; 38% Caucasian; 81% hypertension; 54% diabetes; 25% chronic lung disease; 29% ischaemic heart disease and 22% cerebrovascular disease. The most common symptoms at presentation were fever (62%) and cough (53%). About 143 (64%) patients were managed as an inpatient and 81 (36%) as an outpatient. Of 9 patients that required mechanical ventilation: 6 died, 1 patient was discharged and 2 are still under clinical care. Overall 51 patients died (23%), 154 (69%) were discharged alive and 19 (8%) were still under clinical care as of 15/05/2020. Preliminary analyses suggested that those that died were significantly older (p=0.0028), more likely to have ischaemic heart disease (p=0.003), cerebrovascular disease (p=0.019), smoking history (p=0.006), WHO performance status 3-4 (p=0.004), higher neutrophil:lymphocyte ratio at presentation (p=0.0001) and higher CRP at presentation (p=0.0021).

Conclusions: This large cohort of COVID-19 positive haemodialysis demonstrates a high case fatality ratio, which increased significantly with age, cardiovascular disease, smoking history, frailty and markers of inflammation.

PO0761
COVID-19 Infection in Kidney Transplant Recipients: A Single-Center Experience
Tyler Andrea, Bhavna Chopra, Sabihah M. Hussain, Kalathil K. Sureshkumar, Allegheny Health Network, Pittsburgh, PA.

Introduction: The SARS-CoV-2 (COVID-19) pandemic presents significant challenges to kidney transplant recipients (KTRs) with risk for higher mortality yet sparse available data. We present our single center experience of COVID-19 infection in KTRs.

Case Description: Methods We reviewed the electronic health records of KTRs with confirmed COVID-19 infection using rt-PCR testing via nasopharyngeal swabs, at our transplant center. Results We identified four KTRs with diagnosed COVID-19 infection in our institution. Details of individual cases are summarized in Table 1. Patient A died of complications while patients B, C and D fully recovered. Patient A initially recovered from COVID-19 pneumonia but then was readmitted three weeks later and developed features closely resembling macrophage activation syndrome (MAS) and hemophagocytic lymphohistiocytosis (HLH) leading to death despite treatment with dexamethasone, IV immunoglobulin and anakinra. Patient C had minimal symptoms without cytokine storm possibly related to complement blockade from revulizumab, a C5 inhibitor, which was being used for treatment of aHUS.

Discussion: Our single center case series of COVID-19 infections in KTRs is small but highlights two important aspects: 1) development of MAS/HLH like features in patient A which to our knowledge has not been described in the setting of COVID-19 infection in KTRs, 2) development of minimal symptoms without cytokine storm in patient C likely related to use of C5 blocking agent revulizumab. Further studies are needed to shed light on these phenomenon.

Case series of varied clinical manifestation of COVID 19 infection at our center

Seifert,2,3 Improving Renal Outcomes Collaborative (Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; University of Cincinnati, Cincinnati, OH; The University of Alabama at Birmingham, Birmingham, AL; St. Jude Children’s Hospital, Memphis, TN; Stanford University School of Medicine, Stanford, CA; Lucile Packard Children’s Hospital at Stanford, Palo Alto, CA; Emory University School of Medicine, Atlanta, GA; Bennington Russell Hospital for Children, Birmingham, AL; Children’s Healthcare of Atlanta Inc, Atlanta, GA; Alfred I DuPont Hospital for Children, Wilmington, DE; Nemours Children’s Health System, The Nemours Foundation, Jacksonville, FL; Children’s Hospital Colorado, Aurora, CO; University of Colorado Denver School of Medicine, Aurora, CO; Riley Hospital for Children at Indiana University Health, Indianapolis, IN; Indiana University School of Medicine, Indianapolis, IN; Nationwide Children’s Hospital, Columbus, OH; The Ohio State University College of Medicine, Columbus, OH; Johns Hopkins University School of Medicine, Baltimore, MD; Seattle Children’s Hospital, Seattle, WA; University of Washington School of Medicine, Seattle, WA; Mattel Children’s Hospital UCLA, Los Angeles, CA; University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; SSM Health Cardinal Glennon Children’s Hospital, Saint Louis, MO; Saint Louis University School of Medicine, Saint Louis, MO; Ann and Robert H Lurie Children’s Hospital of Chicago, Chicago, IL; Northwestern University Feinberg School of Medicine, Chicago, IL; Children’s Hospital of Pittsburgh of UPMC, Pittsburgh, PA; University of Pittsburgh School of Medicine, Pittsburgh, PA; Boston Children’s Hospital, Boston, MA; Harvard Medical School, Boston, MA; Children’s Mercy Hospitals and Clinics, Kansas City, MO; University of Missouri Kansas City, Kansas City, MO; The University of Iowa Stead Family Children’s Hospital, Iowa City, IA; The University of Iowa Stead Family Department of Pediatrics, Iowa City, IA.

Background: The incidence of COVID-19 disease on previously healthy children has been minimal, yet there is limited data on the impact of COVID-19 on children and adolescents with kidney transplants.

Methods: We used the existing infrastructure of the Improving Renal Outcomes Collaborative (IROC) learning health system to develop and rapidly implement a web-based registry for collecting clinical and outcomes data about COVID-19 disease in pediatric transplant recipients. We distributed the registry to 32 U.S. pediatric kidney transplant centers and requested clinical and outcomes data from all recipients suspected of having COVID-19 disease. Here, we present an interim analysis of the first 6 weeks of registry data.

Results: Between April 6 and May 27, 2020, 18 IROC centers entered data on 99 pediatric kidney transplant recipients who had PCR based testing for COVID-19. 54 patients were tested due to symptoms of COVID-19 (most commonly fever and cough), 7 asymptomatic patients had a known COVID exposure. 34 patients were tested per hospital policy (e.g. pre-anesthesia), and 4 did not have a reported testing indication. Overall, 10 (10%) tested positive for COVID-19, 6 of whom had any symptoms, 3 had a known exposure with a COVID+ individual, and 1 was diagnosed by a pre-anesthesia screen. Thus far, the clinical course and outcomes are known in 8/10 COVID+ patients: 5 received outpatient supportive care alone, 2 were admitted to intensive care and 1 was admitted to a mechanical ventilation support unit. Transplant outcomes were excellent in all COVID+ patients. There were no cases with respiratory failure, acute kidney injury, or allograft rejection/failure. There were no deaths due to COVID-19 disease.

Conclusions: In this interim analysis of the IROC learning health system, pediatric kidney transplant recipients had a relatively low incidence of COVID-19 disease and excellent short-term outcomes.

PO0764

Clinical Outcomes of Hospitalized Kidney Transplant Recipients with COVID-19 in a Predominantly Minority Population

Background: COVID-19 has been associated with increased morbidity in kidney transplant recipients. We aimed to identify risk factors for mortality in hospitalized kidney transplant recipients with COVID-19

Methods: We retrospectively reviewed the medical records of 75 kidney transplant recipients admitted for COVID-19 at our institution.

Results: Among the 75 patients, 28 (37%) died at a median 8 days (range, 1-36) after admission to the hospital. The Table summarizes the demographics and initial labs values of both groups. Most of our patients were Hispanic (54%) and African American (32%) and 97% had hypertension and 65% had diabetes mellitus. There was no difference between the two groups in terms of sex, type of transplant, time from transplant, immunosuppressive medications, medical comorbidities, presenting symptoms, temperature, or pulse oximetry values on admission. Non-survivors were older and had higher BMI. On admission most patients were lymphopenic, had low CD3/CD4/CD8 counts and had higher inflammatory markers (ferritin, d-dimer, CRP, procalcitonin, interleukine-6 levels). Non-survivors had statistically significant higher procalcitonin, IL-6 and pro-BNP levels on admission. More non-survivors required ICU stay (64% vs. 13%, p=0.001), intubation (57% vs. 11%, p<0.001) and renal replacement therapy (32% vs. 17%, p=0.17) compared to survivors. There was no difference in secondary bacterial infections, CMV viremia, DVT or stroke between the two groups. In a multivariate analysis, BMI (OR 4.16, 1.09-18.87, p=0.046) and proBNP levels (OR 1.017, 1.002-1.034, p=0.039, per 100 unit increase) on admission were associated with increased mortality.

Conclusions: COVID-19 is associated with increased mortality (37%) in our kidney transplant recipients and higher BMI, procalcitonin and proBNP levels at admission are associated with mortality.
PO0765
COVID-19 and Kidney Transplantation: Results from the TANGO International Transplant Consortium
Leonardo V. Riella,1 Suraj Sarvode mothi,4 Enver Akalin,2 Paolo Cravedi,3 TANGO Consortium 1Massachusetts General Hospital, Boston, MA; 2Montefiore Medical Center, Bronx, NY; 3Mount Sinai Health System, New York, NY; 4B Brigham and Women’s Hospital, Boston, MA.

Background: Chronic immunosuppression and comorbidities may expose kidney transplant recipients to an increased risk of developing critical coronavirus disease 2019 (COVID-19), but data in transplantation have been limited so far to single centers. To determine the clinical presentation, outcomes, and mortality risk factors in transplant patients with COVID-19, we analyzed retrospective data from a large international transplant consortium (TANGO Study).

Methods: Retrospective cohort study included kidney transplant recipients admitted with COVID-19 in 11 centers participating in the international TANGO consortium. We included all adult (≥18 years) kidney transplant recipients with a functioning kidney allograft who were admitted to a hospital between March-April, 2020. Epidemiological, demographic, clinical, laboratory, treatment, and outcome data were extracted from electronic medical records using an ad hoc designed data collection form.

Results: Among 9,697 kidney transplant recipients followed at 11 transplant centers, 145 (1.5%) were hospitalized due to COVID-19. 65% were male and more than half were over 60 years old (55%). Median time since transplant was 5 years (2-10) and only 16% were transplanted less than one year from the presentation. Prevalent comorbidities included hypertension (95%), obesity (41%), heart disease (25%) and lung disease (19%). Common symptoms at the onset of illness were fever and dyspnea (71%), followed by myalgia (54%) and diarrhea (33%). Management of anti-rejection therapy varied across centers: antihypertensives were withdrawn in 69% of patients and calcineurin inhibitor in 26%. Other treatments used during hospitalization included hydroxychloroquine (83%), antibiotics (76%), tocilizumab (13%) and antivirals (10%). During a median follow-up of 13 days (IQR: 7 - 21) after diagnosis of COVID-19, mortality was 30% and occurred at a median 10 (5-16) days after admission. Acute kidney injury (AKI) occurred in 46% and respiratory failure requiring intubation in 29% of cases. No rejection events were observed.

Conclusions: Our large international consortium indicates that kidney transplant recipients with COVID-19 have increased mortality (30%) upon hospitalization compared to the general population with a high rate of AKI (46%) and significant respiratory failure (29%).

PO0766
Atypical Clinical Presentation of COVID-19 in a Kidney Transplant Recipient with Tacrolimus Toxicity
Michael J. Chau,1 Irsam K. Almokyad,1 Ping Li,2 1The George Washington University Milken Institute of Public Health, Washington, DC; 2US Department of Veterans Affairs, Washington, DC.

Introduction: Kidney transplant recipients represent a unique challenge to manage amidst the Coronavirus disease 2019 (COVID-19) pandemic as they have reduced innate ability to fight the viral infection due to immunosuppression. However, calcineurin inhibitors such as tacrolimus, may offer an advantage in reducing the effects of cytokine storms in transplant patients with viral pneumonia. We present an atypical case of COVID-19 in a kidney transplant recipient with toxic levels of tacrolimus due to SARS-CoV-2 infection on its metabolism, as well as preventing toxic levels, which further reduces the body’s innate immunity and may indirectly worsen cytokine storm.

Case Description: A 76-year old African American male kidney transplant recipient presented to the Emergency Department (ED) after five days of fever (temperature of 101.8°F), nausea, vomiting, diarrhea and urinary frequency on March 27, 2020. His vitals were noted with a temperature of 96.9°F, respiratory rate of 40/ min, and heart rate of 166 beats/min, blood pressure of 110/75 mmHg and pulse oxygen saturation was 85% at ambient air. Admission labs were significant for a rise of serum creatinine to 3.1 mg/dL from a baseline of 1.5 mg/dL, lactic acid of 4.4 mmol/ L, and a tacrolimus level of 26.9 mcg/L. He was transferred to the ICU following increased oxygen demands and elective intubation for impending respiratory failure on hospital day 2. His blood pressure transiently improved with a decrease in lactic acid to 1.4 mmol/L and serum creatinine down to 1.6 mg/dL following IV fluid resuscitation. On hospital day 4, he continued to require high ventilator support and initiated on vasoconstricting agents for hemodynamic support. His serum tacrolimus level continued to increase to 32.9 mcg/L with concordant increase of serum creatinine to 2.1 mg/dL with oliguria. Tacrolimus levels sustained super therapeutic levels >8 mcg/L despite cessation of the drug.

Discussion: It is possible that Severe Acute Respiratory Syndrome coronavirus 2 (SARS-CoV-2) infection may cause hepatic dysfunction and diarrhea, which reduced drug metabolism and lead to toxic levels of tacrolimus—perpetuating cytokine storm. It is important that in this particular transplant patient population to closely monitor drug levels due to SARS-CoV-2 infection on its metabolism, as well as preventing toxic levels, which further reduces the body’s innate immunity and may indirectly worsen cytokine storm.

PO0768
Risk Factors for Mortality in Kidney Transplant Recipients with COVID-19

Background: There is limited information on the presentation and risk factors for poor outcome in kidney transplant recipients with COVID-19.

Methods: We reviewed data of admitted kidney transplant recipients at 12 system hospitals with COVID-19 between March 1, 2020, and April 30th, 2020. We analyzed risk factors for mortality.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
**Results:** 31 patients were identified, 30 were admitted. Median age was 58 (IQR 53–68) years, male, 32% Caucasian, 29% African American, 29% multiracial, and 6% Asian. Median time from transplant to COVID-19 testing was 1178 days (IQR 252-2897). The most common symptom was cough, followed by fever, shortness of breath and fatigue. Chest X-ray/CT revealed multifocal patchy opacities. Ten patients required mechanical ventilation. Laboratory markers can be seen in the table. Acute kidney injury occurred in 39% of patients. The majority of patients were on triple immunosuppression (94% on tacrolimus, 90% on mycophenolate, and 74% on prednisone). During the hospital course 87% had the antineutrophilic antibody (ANA) and 84% had anti-double-stranded DNA antibodies. During hospitalization mortality was also higher in patients with higher peak serum creatinine (3.2 mg/dl vs 1.5 mg/dl, p=0.013), or if requiring intubated (70% vs 14%, p<0.001). Increase in inflammatory markers including peak D-dimer, peak CRP, ferritin and procalcitonin were also predictive of mortality.

**Conclusions:** Kidney transplant recipients with COVID-19 should be monitored closely in a transplant center. Mortality is high, particularly in patients presenting with lymphopenia and hypoxemia.

**Introduction:** AKI in patients with COVID-19 may be due to ATN from hemodynamic instability or inflammatory responses. We present two cases of CSG and ATI in patients admitted for COVID-19.

**Case Description:** Case 1 25-year-old black obese female admitted with fever, cough, dyspnea and serum creatinine of 1.4 mg/dL, discharged next day with home quarantine. Re-admitted 26 days later due to nausea, fatigue, and bilateral foot swelling. Serum creatinine 28 mg/dL and urine protein to creatinine ratio (uPCR) of 10.4 g/g. Case 2 42-year-old black female with hypertension, diabetes mellitus admitted with fever, dyspnea, cough, and diarrhea. Patient found to have diabetic ketoacidosis, serum creatinine 12.7 mg/dL. She developed deep vein thrombosis and pulmonary embolism and uPCR 15.4 g/g. She was started on hemodialysis Kidney biopsy showed global and segmental capillary collapse with a variable degree of sclerosis and severe renal tubules injury. Electron microscopy showed structural changes in the podocytes, endothelial cells, and tubular epithelium similar to Coronavirus particles.

**Discussion:** Our experience above is part of a growing literature describing the direct visualization of SARS-CoV-2 in causing ATN and CSG. Pathogenic pathways remain to be elucidated.

**PO0769**

**Living Donor Kidney Transplant Practice in the COVID-19 Era: A Survey of U.S. Transplant Programs**

**Krista L. Lentine,1 Luke S. Vest,1 Mark Schnitzler,1 Roslyn B. Mannon,2 Vineeta Kumar,3 Mona D. Doshi,4 Matthew Cooper,4 Didier A. Mandelbrot,5 Meera N. Harhay,5 Michelle A. Josephson,5 Bertram L. Kasicek,5 Yasar Caliskan,6 David Axelrod.7 Saint Louis University, Saint Louis, MO; 2University of Nebraska Omaha, Omaha, NE; 3The University of Alabama at Birmingham, Birmingham, AL; 4University of Michigan, Ann Arbor, MI; 5MedStar Georgetown University Hospital, Washington, DC; 6University of Wisconsin-Madison, Madison, WI; 7Drexel University, Philadelphia, PA; 8University of Chicago, Chicago, IL; 9Hennepin County, Minneapolis, MN; 10University of Iowa, Iowa City, IA.**

**Background:** We surveyed U.S. transplant programs to assess practices, strategies and barriers related to living donor kidney transplantation (LDKT) in the context of the COVID-19 pandemic.

**Methods:** After IRB approval, the survey was launched 5/29/20 by email and postings to professional society list-servers, using the Qualtrics platform. Data are reported through 5/27/20, and examined by state COVID-19 prevalence.

**Results:** Staff at 117 unique centers responded, representing 58% of U.S. living donor recovery centers and 75% of LDKT volume in the year before pandemic declaration. Overall, 66% reported LDKT surgery was on hold (82% in high vs. 50% in low prevalence states). 36% reported that evaluation of new donor candidates had paused, although timeframe and modalities vary.

**Conclusions:** COVID-19 has created many barriers to LDKT, especially in areas of highest prevalence. Transplant centers are planning to restart LDKT cautiously. Consensus-building is needed to reduce barriers, guide optimal practice, and facilitate safe restoration of LDKT across centers.
Results: Presenting symptoms and hospitalization rates were similar in waitlisted ESKD and kidney transplant patients with COVID-19. Azithromycin and dexamethasone use was similar in both groups. Hydroxychloroquine use was more frequent in kidney transplant patients (62% vs 36%), as were other experimental therapies. Mortality was greater in waitlisted ESKD compared to kidney transplant patients (29% vs 13). Of the waitlisted ESKD patients who died, most were male, Black or Hispanic, and 81% had T2DM and/or HTN as the cause of their ESKD. None of the non-hospitalized patients died in either group.

Conclusions: Waitlisted ESKD patients on dialysis with Covid-19 are comparatively at higher risk for mortality compared to kidney transplant recipients with Covid-19 despite similar demographics and similar burden of comorbidities. Whether the ability of immunosuppressive therapy to prevent the cytokine storm contributed to better survival among kidney transplant recipients remains to be determined.

PO0773
Kidney Transplant Practices in Latin America During the COVID-19 Pandemic: Analysis from GlomCon Latin America Working Group (LGComCon)
Sonia Rodriguez Ramirez,1 Franco H. Cabeza Rivera,2 Julio A. Gutierrez-Prieto,3 Javier Soto-Vargas,4 Blanca Martínez-Chagolla,5 Denisse Arellano-Mendez,6 Diana Aguirre,7 Desiree Garcia Anton,8 Carmen Avila-Casado,9 GlomCon Latin America Working Group (LGomCom)1 University Health Network, Toronto, ON, Canada; 2University of Mississippi Medical Center, Jackson, MS; 3Hospital Central del Estado de Chihuahua, Chihuahua, Mexico; 4Hospital General Regional 46, Guadalajara, Mexico; 5Hospital General “Dr. Miguel Silva”, Morelia, Mexico; 6Unidad Medica de Atencion Ambulatoria 254, IMSS, Morelia, Mexico; 7Hospital General de Mexicali, Mexicali, Mexico.

Background: Latin America (LA) is the current epicenter of a global pandemic that has never been seen in the era of transplantation and immunotherapy. We aimed to describe their nephrologists’ practices and experiences regarding kidney transplant (KT) management in the context of COVID-19 pandemic.

Methods: Descriptive analysis extracted from an online survey carried out among nephrologists, renal pathologists and other health workers treating kidney diseases at centers that perform KT in LA countries. 139 (49%) respondents routinely participate in the care of transplant patients and have been involved in the management of COVID-19 patients in their respective centers. Respondents were asked about the demographic data of centers as well as the practices and experiences they encounter in their routine practice and the management of COVID-19 patients.

Results: 430 responses were obtained of which 360 (84%) were considered for analysis. 139 (49%) respondents routinely participate in the care of transplant patients and have been involved in the management of COVID-19 patients in their respective centers. 43 centers reported that up to 50% of their patients experienced a mechanical ventilation or vasopressor/suppressors, 46% of their centers continued their transplant activity during the COVID-19 pandemic.

Conclusions: The results of the survey indicate that the majority of LA centers have not changed their clinical practices for the management of COVID-19 patients.

PO0774
ESKD Patients with COVID-19 vs. Kidney Transplant Recipients with COVID-19

Background: The Covid-19 pandemic has had significant impact on the ESKD population with reduction in kidney transplantation due to decreased organ availability and temporary cessation of transplant procedures. To better understand the impact on patients with ESKD, we compared the outcomes of Covid-19 positive patients on the waitlist with those with a functioning kidney transplant.

Methods: Our center developed a dashboard and active surveillance of Waitlisted and Kidney transplant recipients tested for SARS-CoV-2. From 3/13/20 to 5/20/20, we identified 55 Waitlisted patients who tested positive for SARS-CoV-2, and compared their clinical characteristics and outcomes with those who received a kidney transplant. Primary outcomes included hospitalization and mortality rates.

Results: A total of 51 patients tested positive (1.05% of the 1,195 CNI recipients, 21 tested positive (1.76%) of the 1,195 CNI recipients, 21 tested positive (1.76%) of the 3,949 patients with no record of CNI treatment, 33 tested positive (0.84%). Given an age distribution difference between the two cohorts (CNI cohort median 58; non-CNI cohort median 66). We therefore calculated an age-adjusted positive test rates of any coronavirus strain in those receiving CNIs to those not receiving CNIs.

Conclusions: Based on the data, as far as we can tell being on a CNI does not offer protection from a symptomatic coronavirus infection. It remains to be seen if it decreases anti-cytokine-storm effects and compared the occurrence of positive coronavirus test rates in a population receiving a CNI and non-CNI treatment population. This is of high importance as CNIs are being trialed as a treatment for severe acute respiratory syndrome coronavirus 2 (COVID-19) immune response (NCT04343508). Transplant nephrologists recommend continuing CNIs through the COVID-19 pandemic.

PO0775
What Do Data Tell Us About Patients Receiving Calcineurin Inhibitors (CNIs) and Contracting a Coronavirus
Jung Hoon Son,1 Ollie Fielding,1 Xiaoyang Wang,1 Chris Kipers,1 Jeffrey I. Silberzweig,2 Frank Liu.1 The PEAK team ‘pulseData, New York, NY; 2The Rogosin Institute, New York, NY.

Background: We hypothesized that patients taking CNIs, cyclosporine and tacrolimus would be less susceptible to coronavirus infections because of antiviral and anti-cytokine-storm effects and compared the occurrence of positive coronavirus test rates in a population receiving a CNI and non-CNI treatment population. This is of high importance as CNIs are being trialed as a treatment for severe acute respiratory syndrome coronavirus 2 (COVID-19) immune response (NCT04343508). Transplant nephrologists recommend continuing CNIs through the COVID-19 pandemic.

Methods: We analyzed longitudinal EHR system data from the Rogosin Institute’s nephrology clinic to identify a population of 5,144 patients with a record of respiratory viral panel (RVP) testing for any coronavirus strain between December 2012 and May 2020. We identified 1,195 patients receiving cyclosporine or tacrolimus and compared positive test rates of any coronavirus strain in those receiving CNIs to those not receiving CNIs.

Results: A total of 51 patients tested positive (1.05%) Of the 1,195 CNI recipients, 21 tested positive (1.76%); of 3,949 patients with no record of CNI treatment, 33 tested positive (0.84%). Given an age distribution difference between the two cohorts (CNI cohort median 58; non-CNI cohort median 66). We therefore calculated an age-adjusted positive test rates of any coronavirus strain in those receiving CNIs to those not receiving CNIs.

Conclusions: Based on the data, as far as we can tell being on a CNI does not offer protection from a symptomatic coronavirus infection. It remains to be seen if it decreases severity of the illness because of the potential for cytokine storm effects.

A Machine Learning-Based Predictive Model for Outcome of COVID-19 in Kidney Transplant Recipients
Ignacio Revuelta,1,2 Francisco-Javier Santos-Artega,1 Enrique Montagud-Marrabí,1 Pedro Ventura-Aguirar,1,2 Debra Di Caprio,1 David Cucchiari,1 Beatriz Bayés,1 Esteban Poch,1 Federico Oppenheimer,1 Fritz Diekmann,1,2 1Department of Nephrology and Kidney Transplant. Hospital Clinic, Barcelona, Spain; 2Institut d’Investigacions Biomediques August Pi i Sunyer, Barcelona, Spain; 3Faculty of Economics and Management. Free University of Bolzano, Bolzano, Italy; 4Department of Economics and Management. University of Trento, Trento, Italy.

Background: Health systems need tools to deal with COVID-19, especially for high-risk population, such as transplant recipients. Predictive models are necessary to improve management of patients and optimize resources.

Methods: A retrospective study of hospitalized transplant patients due to COVID-19 was evaluated (March 3-April 24, 2020). Admission data were integrated to develop a prediction model to evaluate a composite-event defined as Intensive Care Unit admission or immunosuppression treatment with antiinflammatory agents. Predictions were made using a Data Envelopment Analysis(DEF)-Artificial Neural Network(ANN) hybrid, whose accuracy relative to several alternative configurations has been validated through a battery of clustering techniques.

Results: Of 1006 recipients with a planned or an unscheduled visit during the observation period, thirty-eight were admitted due to COVID-19. Twenty-five patients(63.2%) exhibited poor clinical course(mortality rate:13.2%), within a mean of 12 days of admission stay. Cough as a presenting symptom(P=0.000), pneumonia(P=0.011), and levels of LDH(P=0.031) were admission factors associated with poor outcomes. The prediction hybrid model working with a set of 17 input variables displays an accuracy of 96.3%, outperforming any competing model, such as logistic regression(65.5%) and Random forest(denoted by Bagged Trees, 44.8%). Moreover, the prediction model allows us to categorize the evolution of patients through the values at hospital admission.

Conclusions: The prediction model based in Data Envelopment Analysis-Artificial Neural Network hybrid forecasts the progression towards severe COVID-19 disease with an accuracy of 96.3%, and may help to guide COVID-19 management by identification of key predictors that permit a sustainable distribution of resources in a patient-centered model.

PO0775
Outcomes of COVID-19-Positive Kidney Transplant Recipients

Background: Kidney transplant recipients (KTR) are at increased risk of infections due to immunosuppression (IS). COVID-19 has posed unique challenges due to its evolving symptomatology and lack of effective treatment options. Current data published about the impact of COVID-19 in KTR comes from severely impacted areas. The aim of our study was to review course and outcomes of KTR at our center.

Methods: Retrospective chart review of KTR diagnosed with COVID-19. Descriptive statistics were summarized as absolute numbers for categorical data and as median with interquartile range (IQR) for skewed distribution.

Results: We had 20 KTR diagnosed with COVID-19. Median age of 53.5 years(47-63), 10 males, and 12 blacks. Median time from KT to presentation was 70.7 months(17.25-158.75), with 1 pt in 1st year post KT. Thirteen (65%) pts were obese with BMI≥30kg/m², 2 pts had chronic obstructive pulmonary disease, and 5 had cardiac disease. Most common presenting symptom was cough in 14 pts, followed by fever-13 pts, shortness of breath-9, and diarrhea-6pts. During the study, 15 pts were hospitalized, and 9 of them had chest x-ray findings of bilateral opacities consistent with pneumonia. Inflammatory markers were elevated in all pts but did not correlate with disease outcome. Acute kidney injury was seen in 9 pts, with 3 requiring continuous renal replacement therapy. Four pts required mechanical ventilation. Ten pts had reduction of their IS. Hydroxychloroquine was used in 11 pts, and azithromycin in 4. Four hospitalized pts received convalescent plasma as part of an ongoing COVID-19 trial in our center. Donors were 4-6 weeks post recovery from confirmed severe acute respiratory syndrome coronavirus 2 infection. Enrollment was offered to pts at high risk of progression to severe disease. We had 3 deaths, 2 pts remain hospitalized, and the remaining 15 were either discharged or managed as outpatients. Median follow up time from presentation was 25 days(13-38) for the entire cohort.

Conclusions: In our cohort, 45% of patients presented with acute allograft dysfunction highlighting impact of SARS-CoV-2 infection on kidney function. Our center utilized investigational convalescent plasma in 4 pts successfully while the clinical trial outcomes are awaited. Ultimately, the development of a safe and efficacious vaccine targeting SARS-CoV-2 may better equip us to fight this pandemic.

PO0776
COVID-19 in Kidney Transplant Recipients at New England’s Largest Safety-Net Hospital
Hassan Mahmoud, Sandeep Ghai, Jean M. Francis. Boston University, Boston, MA.

Background: The coronavirus disease 2019 (COVID-19) has led to a global pandemic as announced by the World Health Organization. Kidney transplant patients are thought to constitute a unique high risk group for severe COVID19 infection. Furthermore, disparities in health care have led to COVID-19 disproportionately affecting minory groups including African Americans and Hispanics.

Methods: We identified adult kidney transplant recipients who were admitted with COVID-19 between March, 15th and May 1st, 2020. We evaluated the demographic, clinical and laboratory data of all admitted patients. We also evaluated the presence of co-infections as well as decisions regarding immunosuppressant management.

Results: 23 kidney transplant recipients who were hospitalized for COVID-19 were evaluated. 91% of our patients were of minority groups. 35% of patients required ICU admission, and 30% required mechanical ventilation. 40% of patients had associated co-infections in addition to COVID19. 87% of patients had variable degrees of AKI, 26% of patients with AKI required renal replacement therapy. Mortality rate in our population was 22%. Upon admission to the hospital, our immunosuppressant therapeutic approach included stopping the antimetabolites and continuing with the calcineurin inhibitors (targeting trough level of 4 to 6 ng/dl for tacrolimus and 50 ng/dl for cyclosporine), and prednisone if patients were on steroids.

Conclusions: This report demonstrates higher rate of AKI, coinfection and mortality in kidney transplant patients in the setting of COVID19 as compared to general population.
PO0777

**Identifying Scenarios of Benefit or Harm from Kidney Transplantation During the COVID-19 Pandemic: A Simulation Study**

**Allan Massie,1 Brian J. Boyarsky,1 William A. Werbel,1 Sunjae Bac,1 Eric Chow,2 Robin K. Averly,1 Daniel C. Brennan,1 Jacqueline Garonzik wang,3 Dorry L. Segev,1 Johns Hopkins University School of Medicine, Baltimore, MD; 2Rosalind Franklin University of Medicine and Science Chicago Medical School, North Chicago, IL.**

**Background:** Clinical decision-making in kidney transplantation (KT) during the COVID-19 pandemic is a challenge: both candidates and recipients may face increased acquisition risks and case fatality rates (CFRs). Given our poor understanding of these risks, many centers have paused or reduced KT activity, yet data to inform such decisions are lacking.

**Methods:** To quantify the benefit/harm of KT in this context, we conducted a Markov simulation study of immediate-KT vs delay-until-after-pandemic for different patient phenotypes under a variety of potential COVID-19 scenarios (Figure 1), simulating a scenario study of immediate-KT vs delay-until-after-pandemic for different patient risks, many centers have paused or reduced KT activity, yet data to inform such decisions are lacking.

**Results:** Characteristics of the pandemic (acquisition risk, CFR) and length of delay (length of pandemic, waitlist priority for DDKT) had greatest influence on benefit/harm (Figure 2). In most scenarios of COVID-19 dynamics and patient characteristics, immediate-KT provided survival benefit; KT only began showing evidence of harm in scenarios where CFRRs were substantially higher for KT recipients (e.g. ≥50% fatality) than for waitlist registrants.

**Conclusions:** Our simulations suggest that KT remains beneficial under COVID-19 in many scenarios. Our calculator can help identify patients who would benefit most. As the pandemic evolves, our calculator can update these predictions.

**COVID-19 in Patients with CKD in New York City**

Oleh M. Akchurin,1,2 Sharmi Biswas,1 Michaela Greenbaum,1,2 Alexandra Licana,1,2 Justin J. Choi,1,2 Mary E. Choi,1,2 Weill Cornell Medicine, New York, NY; 3NewYork-Presbyterian Healthcare System Inc, New York, NY.

**Background:** Coronavirus disease 2019 (COVID-19) has affected millions of people, and several chronic medical conditions appeared to increase the risk of severe COVID-19. However, limited data are available about the outcomes of COVID-19 in people with chronic kidney disease (CKD).

**Methods:** This was an observational study of patients with CKD at three affiliated hospitals in New York City who were diagnosed with COVID-19 by reverse-transcriptase polymerase chain reaction of nasopharyngeal swab specimens collected in the emergency departments between March 3rd and April 21st, 2020. We stratified patients into three groups: pre-dialysis CKD, dialysis, and transplant. Data are shown as median (interquartile range). Logistic regression was used to identify CKD characteristics associated with non-survival.

**Results:** Of the 372 confirmed COVID-19 patients with CKD, 182 were pre-dialysis, 149 were on dialysis, and 41 had functional kidney transplant. The median age of the pre-dialysis group was 75 (63-85) years, dialysis group 66 (58-74) years, and transplant group 63 (48-71) years. Men comprised 62.4% of the cohort. Baseline serum creatinine was 1.5 (1.2-2.2) mg/dL in the pre-dialysis group. By the end of the observation period, 78.5% of patients were discharged or had died. Of these patients, mortality was highest in the pre-dialysis group (26.9%), followed by dialysis (24.2%), then transplant (9.8%) groups. Almost half of the cohort was receiving ACE-inhibitors or ARBs pre-COVID-19, which was not associated with non-survival. In patients with pre-dialysis CKD, the other group phosphorus was associated with non-survival (OR 1.5 per each 1.0 mg/dL of increase in serum phosphorus). Anemia, defined as hemoglobin <10 g/dL, was also associated with non-survival (OR 3.1) in that group. Body mass index (BMI)≥25 kg/m2 was paradoxically associated with non-survival (OR 2.7) in patients with pre-dialysis CKD.

**Conclusions:** Our data demonstrate that mortality in this cohort, particularly in patients with pre-dialysis CKD, was substantially higher than in the general population in New York City. Poorly controlled CKD complications, including CKD-mineral and bone disorder and anemia, as well as low BMI were associated with mortality. Ongoing control of CKD complications may serve as an opportunity to improve outcomes of COVID-19 in patients with CKD.

**PO0779**

**COVID-19 in CKD: Retrospective, Propensity Score-Matched Cohort Study**

Ahmet B. Dirim,1 Erol Demir,1 Serap Yadigar,2 Sedal Safak,1 Ergün Parmakoz,1 Nurana Guller,1 Alpay Medetaliyeyoglu,1 Ozgur A. Oto,1 Kubra Aydin Bahat,1 Meric Oruc,1 Seniha Basaran,1 Günseli Orhun,1 Halli Yaziçi,1 Aydin Turkmen.1 Istanbul Universitesi Istanbul Tip Fakultesi, Istanbul, Turkey; 2Dr Lütfi Kirdar Kartal Eğitim ve Araştırma Hastanesi, Istanbul, Turkey.

**Background:** The prognostic factors for COVID-19 in patients with chronic kidney disease (CKD) are uncertain. We conducted a propensity score-matched study to compare clinical and prognostic features between hospitalized COVID-19 patients with and without CKD.

**Methods:** Patients with estimated creatinine clearance below 60 ml/min/1.73 m² for more than three months, were included in the CKD group. Fifty-six patients and the propensity score-matched fifty-six control patients were followed-up at least 15 days or until death after diagnosis of COVID-19. All demographic data and diagnostic and therapeutic methods were evaluated. The endpoints were all-cause mortality and acute kidney injury (AKI).

**Results:** Patient and control groups were reviewed retrospectively over a median follow-up of 44 days (IQR, 36-52 days) after diagnosis of COVID-19. Patients in the CKD group had higher intensive care unit follow-up and mortality rates than the other group, but these results did not reach statistical significance (16 [28.6%] vs. 19 [33.9%]; p=0.54 and 11 [19.6%] vs. 16 [28.6%]; p=0.269, respectively). The frequency of AKI was significantly higher in pre-dialysis patients with CKD compared to the other group (8 [14.3%] vs. 5 [45.5%]; p<0.001), but there was no significant difference between the groups in terms of cytokine release syndrome and respiratory failure (13 [23.2%] vs. 8 [14.2%]; p=0.226, 25 [44.6%] vs. 22 [39.3%]; p=0.566, respectively). Multivariate logistic regression analysis revealed that respiratory failure (30.283 [95% CI 7.296 to 211.519; P<0.001) and AKI (10.961 [95% CI 1.688 to 71.186; P=0.012) were independent risk factors for the mortality.

**Conclusions:** The prognosis of COVID-19 in patients with CKD is worse than non-uremic patients. Also, AKI and respiratory failure are independent risk factors for mortality.

Kidney and Clinical Outcomes of COVID-19 in the Mexican Population

Background: Coronavirus Disease 2019 (COVID-19) is a new disease of pandemic proportions. Currently, there are no reports about kidney involvement and the association with mortality in Mexico. Our aim was to describe the characteristics in our population, clinical course, and renal outcomes.

Methods: Prospective, descriptive, single-center study in patients diagnosed with COVID-19 (positive RT-PCR tests), admitted to our hospital from April 2020 to date.

Results: 48 patients (60.4% men) with an average age of 54.33 years were included. 23 (47.9%) had a previous diagnosis of hypertension, 11 (22.9%) had obesity (>30 kg/m²), 10 (20.8%) had neurological diseases, 4 (6.3%) had heart disease, 3 (6.3%) had malignancies and 1 (2.0%) had liver disease. 9.18% (5) patients had a history of smoking. At admission, the mean oxygen saturation was 85.76%. The main reason for consultation was dyspnea in 35 patients (72.9%). Regarding symptoms, 81.3% (39) had dyspnea, 87.5% (42) fever, 54.2% (26) headache, 72.9% (35) cough and, to a lesser extent, odynophagia, myalgia and malaise in 33.3% (16), 45.8% (22) and 41.7% (20) respectively. The mean creatinine, urea and bicarbonate was 1.34 mg/dl, 56.69 mg/dl and 18.49 mmol/l respectively. 25% of the patients required ICU admission and 27.1% mechanical ventilation. During the study period, 19 patients (39.6%) developed AKI, 20.8% classified as KDIGO stage 1 and 15.6% stage 2. 3 patients required RRT, with a total of 13 deaths (68.4%). There was a statistically significant difference in mortality between patients with AKI vs patients with normal kidney function (p=0.002), with a RR of 3.47.

Conclusion: This study showed a higher prevalence of AKI in the Mexican population compared to reports from other countries, with a significantly higher risk for death. Special attention should be paid to this outcome and as nephrologists, we must take an active role in the care of these patients.

Association Between Kidney Dysfunction at Admission and Outcomes in Hospitalized Patients with COVID-19

Imran Chaudhri,1 Farrukh M. Koraishy,1 Olena Bolotova,1 Jeanwoo Yoo,1 Simrat Dhaliwal,2 Raji Reddy Amadi,2 Minh Hoai Nguyen,2 Sandeep K. Mallipattu,1,4 Stony Brook University Hospital, Stony Brook, NY,1 Stony Brook University Renaissance School of Medicine, Stony Brook, NY,1 Northport VA Medical Center, Northport, NY.

Background: AKI is a major predictor of mortality in patients with coronavirus disease 2019 (COVID-19). Data regarding association of renal dysfunction (AKI, hematuria and proteinuria) at the time of admission with hospital outcomes is limited. We aim to assess if renal dysfunction on day one of hospital admission is associated with increased mortality risk of patients with severe COVID-19 infection.

Methods: In this retrospective single-center study, we analyzed electronic medical records data on 300 patients admitted with COVID-19 infection. AKI data collection included history of comorbidities, medications, vital signs, and admission and peak laboratory values. Outcomes included inflammatory burden (calculated using composite scores for multiple markers of inflammation), AKI during hospitalization, admission to the intensive care unit (ICU), need for invasive and non-invasive mechanical ventilation, mortality and length of stay. For multivariate analysis, a pre-specified genotype and clinical algorithm was used. The study cohort was divided into groups based on serum creatinine level on day one of hospital admission. Group 1 included patients with normal serum creatinine (SCr) < 1.10 mg/dl while group 2 included patients with high SCr > 1.10 mg/dl. The primary outcome was mortality. Secondary outcomes were the need for renal replacement therapy (RRT), duration of RRT, development of adult respiratory distress syndrome (ARDS) and need for mechanical ventilation. Comparisons between groups were done using Mann-Whitney U-tests for continuous variables and chi-square tests for categorical variables. Mortality was evaluated with a Kaplan-Meier Survival Analysis.

Results: A total of 77 in group 1 and 20 in group 2. Patients in group 2 compared to group 1 were older (67 vs. 56, p=0.04), more frequently African Americans (11% vs 45%, p=0.002), hypertensives (80% vs 52%, p=0.05) with chronic kidney disease (25% vs 0%, p=0.01), without significant differences sex, diabetes, smoking status, and exposure to renin angiotensin system blockers. In group 2 and 3 patients in group 1 died, with significant difference in cumulative survival (Figure 1). Need for RRT (55% vs 41%, p=0.33), duration of RRT (6 vs 3 days, p=0.08), development of ARDS (85% vs 81%, p=0.75) and need for mechanical ventilation (65% vs 61%, p=0.89) were not significantly different between groups 2 and 1.

Conclusions: The presence of renal dysfunction on the day of hospital admission is associated with increased hospital mortality in patients with severe COVID-19 infection.

COVID-19 in CKD Patients: Lessons from 553 CKD Patients with Biopsy-Proven Kidney Disease

Juan León Román, Clara García-Caro, Nestor Toapanta, Irina Torres, Roxana Bury, Cinthia Baldallo, Daniel Serón, Maria Jose Soler. Hospital Vall d’Hebron. Nephrology Department, Barcelona, Spain.

Background: COVID-19 is a novel coronavirus currently at the centre of a global pandemic, and patients with cardiovascular risk factors such as hypertension and diabetes are at risk of a serious complication such as hospitalization and death. Chronic kidney disease (CKD) increased cardiovascular risk and ~90% of CKD patients presented hospitalization. The prognosis and lethality of COVID-19 in patients with biopsy-proven kidney disease has not been previously studied.

Methods: Data included patients who underwent a kidney biopsy at the Vall d’Hebron Hospital between January 2013 and February 2020 with diagnostic confirmation and those with high clinical suspicion of SARS-CoV-2 infection during the period from March to May 2020.

Results: Of 553 patients, 39% were diagnosed with SARS-CoV2 infection. The mean age was 63+4±15 years. 48.7% were male, 31 hypertension, 19 diabetic, 12 obese and 19 African American. In-hospital mortality was 17.6% (99/553). Of these, 47.4% died with AKI, 41% had need for invasive ventilation, and 47.4% were treated with RRT. 59 patients were confirmed with COVID-19 infection at hospital admission [average hospital stay was 16 days±11], of which 4 in the ICU and 6 (15%) developed acute respiratory distress syndrome. 23 patients, 4 patients, 20 patients, 104 patients, 9 patients, 3 patients had blood transfusions, 9 patients, 10 patients, 9 patients, 28 patients, 29 patients, 12 patients, 8 patients, 9 patients, and 8 patients with hydroxychloroquine; 6 patients, tocilizumab; 9 patients, intravenous corticosteroids. 11 patients presented impaired renal function, of which 3 were transplanted and 8 with CKD. CKD patients under RAS blockade had less mortality than patients without RAS blockade treatment. The use of hydroxychloroquine was statistically associated with increased in-hospital mortality in patients with COVID-19 infection, suggesting that they should not be withdrawn.

Conclusion: COVID-19 was diagnosed in 7% of our CKD patients with kidney biopsy. The mortality was 15%, lower than the reported in hemodialysis patients. RAS blockade is not exerting a deleterious effect in our CKD patients with COVID-19 infection, suggesting that they should not be withdrawn.

COVID-19: CKD and Transplant Patients

PO0780

PO0781
Involvement and Outcome of COVID-19 Patients Admitted from a Federal Medical Facility

Yahya R. Ahmad,1 Matthew Shea,1 Mohamed M. Abdalbary,2 Elijah Kakani,1 Javier A. Neyra,2 Amr E. Mohamed,1 1University of Kentucky Medical Center; Lexington, KY; Mansoura University, Mansoura, Egypt.

Background: Correctional facilities face unique challenges with the COVID-19 pandemic. A COVID-19 outbreak was reported in the Federal Medical Center (FMC) in Lexington, Kentucky, a prison for inmates requiring medical and/or mental health care. We aimed to compare clinical characteristics and kidney-related outcomes in inmates from this FMC to other COVID-19 hospitalized patients.

Methods: A total of 86 COVID-19 patients were admitted to our hospital between March 1st and June 1st, 2020. Among those, 37 patients were from the same FMC. We examined demographics, clinical and laboratory characteristics, along with the outcomes of this cohort and compared it to other COVID-19 non-prisoners. AKI was determined by KDIGO criteria.

Results: All inmates were men and their mean age was 59.8 ± 10.6 years. The majority of them were white (60%) and required ICU admission (54%), while 39% of patients required mechanical ventilation. The prevalent comorbidities were hypertension (81%), obesity (62%), diabetes (41%) and coronary artery disease (CAD) (58%). Stage 3 CKD was present in 22% of inmates. The mean eGFR was 56 ± 26 ml/min/1.73m² at time of admission. Significant hematuria and proteinuria were found in 17% and 25% of patients, respectively. Hypertension, heart failure, CAD, COPD, hepatitis C infection, and AKI were more prevalent in the FMC cohort (P = 0.030, 0.001, 0.024, 0.001, 0.017, and 0.011, respectively). The difference in mortality rates was not statistically significant between groups (12% for inmates vs. 13% for non-inmates, P = 0.520). Incident AKI was higher in inmates vs. non-inmates (68% vs. 38%, P = 0.006) and there was no difference in acute dialysis need (14% vs 12%, respectively). The overall mortality rates were higher in patients that required dialysis (80% vs. 6% for those who did not, P = 0.001). The need for acute dialysis was independently associated with mortality in multivariable models.

Conclusions: Incidence of AKI was higher in hospitalized inmates with COVID-19 vs. non-inmates. The need for acute dialysis was strongly associated with mortality in overall COVID-19 hospitalized patients.

Urinary Biomarkers Predict Severity of COVID-19: A Preliminary Study

Dorukche Katagiri, Eisei Noiri, Masahiro Ishikane, Yusuke Asai, Noriko Kinoshita, Norio Ohmagara, Fumihiko Hinoshita, National Center for Global Health and Medicine, Shinjuku-ku, Japan.

Background: Early detection of coronavirus disease COVID-19 in patients likely to develop severe manifestations enables appropriate interventions, including rapid intensive care unit admission. This study was conducted to determine whether non-invasive urine biomarkers can predict the clinical severity of COVID-19.

Methods: Design A retrospective case series. Setting Single-center study, national center hospital designated for infectious disease. Patients Fifty-eight patients who tested positive for SARS-CoV-2 in respiratory specimens through real-time reverse transcription-polymerase chain reaction (RT-PCR) were retrospectively studied.

Measurements and main results Urinary β2-microglobulin (β2MG), liver-type fatty acid binding protein (L-FABP) were serially measured. Sensitivity y and monoclonal chromatometric protein-1 were also evaluated.

Results: The 58 patients were assigned into three groups. Patients requiring intensive care were assigned to the severe group (N = 12). Patients treated with oxygen were assigned to the moderate group (N = 11). Other patients were assigned to the mild group (N = 33). Urine tests revealed that low β2MG and L-FABP levels on admission were associated with mild disease, whereas high levels were associated with severe disease. In severe cases, L-FABP tended to be persistently high. The resulting cutoff values were β2MG: Severe vs. Moderate: Mild ≥ 2457 pg/ml (Specificity 76.9% and Sensitivity 90.0%, AUC 85.9%), L-FABP: Severe vs. Moderate: Mild ≥ 22.0 μg/gCr (Specificity 84.6% and Sensitivity 90.0%, AUC 91.8%). Urinary β2MG and serum IFN-γ/MCP-1 showed a similar trend.

Conclusions: Evaluating urinary biomarkers such as β2MG and L-FABP may allow determination of COVID-19 patients with active cytokines and recognition of patients likely to become critically ill and requiring careful observation and early intervention.

Management of COVID-19 in kidney transplant recipients (KTR) should include treatment of infection and regulation of immunosuppression but there is no consensus on this issue yet. In this study, we aimed to describe our experience in KTR with COVID-19.

Results: Forty patients (20 female) were reviewed over a median follow-up of 32 days (IQR, 14-51 days) after COVID-19. 5 patients died during the follow-up. The frequency of graft dysfunction was similar between groups (n = 12 and n = 2; p = 0.615, respectively).

Conclusions: MicrExUrSed in CoV-AKI was comparable to that demonstrated in other forms of AKI.

Infection in Kidney Transplant Recipients: A Multicenter Experience in Istanbul

Erol Demir,1 Murathan Uyar,1 Ergin Parmaksiz,2 A. Sinangil,1 Bengin Yalçın,1 Ahmet B. Dirim,1 Halil Yazıcı,1 Aydin Turkmen,1 İstanbul Üniversitesi Tip Fakültesi, İstanbul, Turkey; İstanbul Bilim Üniversitesi Tip Fakültesi, İstanbul, Turkey; Koç Universitesi, İstanbul, Turkey; "Dr Lutfi Kirdar Kartal Eğitim ve Araştırma Hastanesi, İstanbul, Turkey; 'Yeni Yazılı Üniversitesi, İstanbul, Turkey.

Background: Management of COVID-19 in kidney transplant recipients (KTR) should include treatment of infection and regulation of immunosuppression but there is no consensus on this issue yet. In this study, we aimed to describe our experience in KTR with COVID-19.

Results: Among 161 cases of AKI, MicrExUrSed was performed in 20 (12.4%). Amnira and contact precautions were barriers to obtain specimens. GC were found in 17 (85%) of which 16 (80%) had "muddy" brown GC (MBGC). A median 5 MBGC per LPF (1-20) were found in a median 40% (10-95%) of LPFs. WC were found in 10 (50%) cases with a median 2 (1-5) per LPF, all of whom had MBGC also present. TCREC were found in 3 (15%) cases with a median 1 (1-4) per LPF. Altogether, ATI score was assigned to 17 (85%) patients, of which 12 (60%) had AKI either after a hemodynamic/ischemic insult (9) or after a toxic insult (3) (rhabdomyolysis, vancomycin, contrast) and 3 (15%) had biopsy-proven ATI along with collapsing glomerulopathy; for a total of 15 (75%) patients with either clinical or histological evidence on ATI matching the MicrExUrSed findings. Ten (50%) and 5 (25%) had WBCC and RBCs, respectively. Acanthocytes were found in 1 (5%) patient with presumptive proliferative endocapillary glomerulonephritis.

Conclusions: MicrExUrSed in most patients with CoV-AKI showed overt evidence of ATI with an abundance of MBGC and WC, including in cases of coexisting glomerulopathy. Pyuria was observed in half. The diagnostic utility of MicrExUrSed in CoV-AKI was comparable to that demonstrated in other forms of AKI.
COVID-19 and Kidney Transplant Outcomes

Background: Recent publications report great variations in the clinical course and mortality of COVID-19 in solid organ transplant (SOT) recipients. It is unclear whether these differences are related to study methods, treatments, choices, or variables associated with patient populations.

Methods: We reviewed and summarized 9 published articles of COVID-19 in solid organ transplant recipients. We contrasted difference between study design and compared outcomes.

Results: All studies included kidney transplant recipients while study 6 and 8 included non-renal SOT. Four come from the United States. Results can be seen in the attached table. Most studies had a median age in the 50’s, with hypertension and diabetes being common comorbidities. Tacrolimus, mycophenolate analogs and prednisone was the most common immunosuppression regimen. Presenting symptoms were usually fever, cough, dyspnea, and diarrhea. Immunosuppression was either reduced or discontinued in all studies. The majority of patients received hydroxychloroquine. Azithromycin, remdesivir, leronlimab, lopinavir/ritonavir, darunavir, oseltamivir, and tocilizumab were also used. Mortality ranged from 0% to 30%. All studies described hospitalized patients. A third of reports also included outpatients. The median follow-up was approximately 3 weeks for most studies (range of 7 to 29 days). All but one series with reported patient deaths under 20% either did not include or had follow-up periods of less than 10 days.

Conclusions: Presentation of COVID-19 and immunosuppression strategies are similar among transplant centers. Differing outcomes may be related to small number of cases, potentially varying acuities of illness and follow up periods. Given that cytokine storm occurs late in the course of COVID-19, it is plausible that mortality may increase in studies with long follow up. When excluding short or missing follow up, mortality appears to be between 20-30%, which suggests that transplant recipients have a higher mortality than their non-immunocompromised peers.

Renal Artery Thrombosis with Infarction in a Patient with Mild COVID-19
Ryan Mocerino, Neelja D. Kumar. Montefiore Medical Center, Bronx, NY.

Introduction: There has been increased focus on the microvascular and macrovascular complications of COVID-19. Here we present a case of renal arterial thrombosis in a woman with mild symptoms of COVID-19.

Case Description: A 69 year old female with diabetes, hypertension, coronary artery disease, and acute embolic cerebrovascular event post cardiac catheterization in 2016 presented to the emergency department with acute diffuse intermittent abdominal pain and nonbloody emesis. Prior to this, she had been evaluated for cough, shortness of breath and myalgias which were conservatively managed with improvement. Her medications included aspirin, clopidogrel, furosemide, and insulin. Examination was significant for diffuse nonsegmental abdominal tenderness without rebound or guarding. Laboratory assessment revealed preserved renal function with creatinine of 1.10 mg/dL and PCR positive for SARS-CoV-2. A computed tomography of the abdomen and pelvis with intravenous contrast revealed a non-occlusive thrombus in the left renal artery with several large wedge-shaped areas of decreased enhancement consistent with multiple left renal infarctions. On interdisciplinary discussion, the patient was managed conservatively with anticoagulation without acute intervention and was discharged home on aspirin.

Discussion: To our knowledge, this is the first description of renal artery thrombosis with renal infarction in the setting of COVID-19 infection. Patients who present with a COVID-19 infection, regardless of disease severity, should be evaluated for coagulopathy and development of thrombosis as these may potentially contribute to infarction and end-organ damage. Although it requires a high index of suspicion, renal infarction should be considered part of the differential when evaluating a patient with COVID-19 infection presenting with abdominal pain or acute kidney injury. Initiation of anticoagulation should be considered with consideration of risks involved.

PO0790

Thrombotic Microangiopathy (TMA) in a Patient with COVID-19
Bessy Suzin Flores Chang, Rushang Parikh, Rinda Wanchao, Vanessa Bijol, Kenar D. Jhaveri. Donald and Barbara Zucker School of Medicine at Hofstra Northwell, Hempstead, NY.

Introduction: We describe a patient with COVID-19 and clinically significant kidney biopsy proven TMA

Case Description: 69-year-old Caucasian female with medical history of asthma came to the ED with productive cough, fever and dyspnea for 2 weeks. She was afebrile, tachypneic and hypoxic. Initial laboratories showed a normal WBC, hemoglobin level and platelet count. Inflammatory markers were elevated. SARS-CoV-2 infection was confirmed by PCR assay. CXR showed bilateral diffuse patchy opacities. Treated with hydroxychloroquine, enoxaparin and oxygen was started. Patient received anakinra and tocilizumab. On day 12, the patient developed thrombocytopenia, anemia and worsening kidney function concerning for microangiopathic hemolytic anemia. Due to worsening hypoxemia, patient received convalescent plasma. On day 17, she was intubated due to worsening respiratory failure. Findings suggestive of hemolysis were present. Urinalysis showed hematuria and proteinuria. Patient’s kidney function worsened requiring initiation of CRRT. On day 20, the patient underwent a kidney biopsy that revealed severe acute TMA with cortical necrosis. Beta 2 glycoprotein-1 IgM levels were elevated, anti-phospholipid antibodies were absent. A disintegrin and ADAMTS13 level were not low. C3,C4 were in normal range. Heparin induced antibody testing was negative. Coagulation parameters were normal. Kidney doppler was unremarkable. No other systemic findings of macro thrombi were found. Low factor H complement antigen, elevated plasma C3b complement and plasma SC5b-9 complement levels suggesting an activation of the alternative complement pathway were found. Genetic testing was not done. Plasma exchange was not performed, but received a single dose of eculizumab on day 21. Unfortunately, she died on day 23.

Discussion: Coagulopathy associated with SARS-CoV-2 has been widely reported. Profound hypoxia, inflammation, disseminated intravascular coagulation(DIC) and platelet count have all been implicated as potential causes, but were not present in our patient. To the best of our knowledge, we report the first case of TMA associated with SARS-CoV-2 with presence of diffuse cortical necrosis and widespread microthrombi in kidney biopsy. It is not clear if the virus played a direct pathogenic role or unmasked a latent complement defect leading to widespread endothelial damage and micro thrombi.

Renal Artery Thrombosis with Infarction in a Patient with Mild COVID-19
Ryan Mocerino, Neelja D. Kumar. Montefiore Medical Center, Bronx, NY.

Introduction: There has been increased focus on the microvascular and macrovascular complications of COVID-19. Here we present a case of renal arterial thrombosis in a woman with mild symptoms of COVID-19.

Case Description: A 69 year old female with diabetes, hypertension, coronary artery disease, and acute embolic cerebrovascular event post cardiac catheterization in 2016 presented to the emergency department with acute diffuse intermittent abdominal pain and nonbloody emesis. A Case of Severe Thrombocytopenia in a Patient with COVID-19
Receiving Continuous Venovenous Hemodialysis
Hay Me, Zhou Zheng, Jennifer Griffthls, Anjani K. Dubey, Savneek S. Chugh. Westchester Medical Center Westchester Medical Center, Valhalla, NY.

Introduction: Thrombocytopenia is a rare complication of renal replacement therapy with most of the cases reported in intermittent hemodialysis patients. There is limited data regarding the incidence of thrombocytopenia caused by continuous renal replacement therapy (CRRT). We report a case of thrombocytopenia in patient treated with CRRT for severe AKI from COVID-19 sepsis unrelated to heparin.

Case Description: A 73-year female with history of type 2 diabetes mellitus was admitted for Coronavirus Disease 2019 (COVID-19) pneumonia. Patient developed acute hyperoxic respiratory failure requiring mechanical ventilation despite treatment with hydroxychloroquine, azithromycin and convalescent plasma. Hospital course was complicated by septic shock and acute kidney injury with serum creatinine rising from a baseline of 0.8 mg/dL. Continuous venovenous hemodialysis (CVVHD) without any anticoagulation was initiated due to severe fluid overload. Significant thrombocytopenia below 50,000/mm3 was noted 2 days after CVVHD treatment. Patient received multiple antibiotics and heparin drip before CVVHD and platelet counts were above 150,000/mm3. Heparin induced thrombocytopenia (HIT) was ruled out with negative serotonin release assay and platelet counts remain low despite the discontinuation of all potential agents. Disseminated intravascular coagulopathy was excluded based on coagulation tests. Platelet counts finally went up to 160,000/mm3 on subsequent CVVHD holidays and again dropped to 70,000/mm3 after CVVHD was resumed.

285
Discussion: The rate of rise in platelet count more than 150,000/mm3 in 2 days after cessation of CVVHD supports the diagnosis of thrombocytopenia caused by CVVHD. Although the exact mechanisms remain unclear, previous studies suggested that the mechanical destruction of platelets by the hemofilter or allergic reaction to dialyzer membrane as some of the reasons. Some studies have found that severe decline (more than 50%) of platelet count was associated with increased mortality and decreased rate of renal recovery. Thrombocytopenia on CVVHD unrelated to HIT is an under-acknowledged complication. Understanding the multiple etiologies of thrombocytopenia will help prevent the excessive use of blood products, fluid overload state and the potential clotting issue of CVVHD due to transfusion.

PO0794 Rhabdomyolysis as a Complication of COVID-19: A Report of Five Cases

Miguel Maza Moreno,1,2 Vanessa C. Garcia Macas,1,2 Jose L. Herrera,1 Gandhy T. Fonseca,1 Jose H. Cano,1 Juvenal Torres Pastrana.1 CMN 20 de Noviembre Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico; Mexico; Nefrologia y Extercorporal Membrane Therapy Department, Mexico City, Mexico.

Introduction: COVID-19 virus pandemic has caused more than 5 million infected and 330 thousand deaths worldwide. The incidence of acute kidney injury (AKI) is variable, from 0.5% to 29.8%. Rhabdomyolysis (Rb) is a life-threatening emergency, usually manifesting as myalgia, fatigue, pigmenturia, and AKI. One of its leading non-traumatic causes are viral infections. We report 5 cases of Rb associated with COVID-19.

Case Description: Of a total of 460 positive cases of COVID-19 infection (real-timePCR), at the NationalMedicalCenter20deNoviembre in MexicoCity,5were diagnosed with Rb and associated AKI(Cr< 0.5,000µI/uL and KIDIGO AKIcriteria). Characteristics of patients are presented in Fig.1. Age range was from 29 to 64 years, only one female, all with BMI<25 kg/m2, time from admission-diagnosis of Rb was on average one week. Most common symptoms were fever, cough, and dyspnea(5/3), as well as abdominal pain(4/3). Only(1/3) was oliguric at diagnosis. Average Cr at diagnosis was 7845 (18-165 µg/L) and all cases had high levels of interleukin-6. They were managed with aggressive hydration, 20% of them required renal replacement. At the time of this report, 2 had been discharged, 2 remained hospitalised(on one still on RRT), and one died.

Discussion: COVID-19 patients can develop AKI primarily due to low oral intake, sepsis, and anticoagulation. Patients with COVID-19 have multiple risk factors for Rb development: viral muscle cytotoxicity, continuous hyperthermia, and anticoagulation among others. This results in a high risk of AKI via 3 mechanisms: renal vasoconstriction, tubular obstruction and direct tubular toxicity. Of note, in the described cases, abdominal pain was a common symptom and only one was oliguric. Early identification allowed managing patients as for AKI, which underscores the importance of having a high index of suspicion. Further observations will be needed to understand the full spectrum of association between COVID-19 and Rb, but is clear that these patients are at high risk for developing AKI by these mechanisms.

as any preexisting risk factors for calciphylaxis, must be kept in mind. Atypical presentations of COVID-19 due to a combination of procoagulant state, as COVID-19 caused a so-called "second hit" resulting in clinically apparent disease. Calciphylaxis given risk factors of secondary hyperparathyroidism and an additional insult of interventional care. We hypothesize that our patient had an underlying predisposition for evident. Management of calciphylaxis in PD patients is difficult under current intervention. Examination revealed tender, indurated retiform dusky plaques on thighs and bilateral leg pain and edema for 4 weeks. She had recently been started on peritoneal dialysis. The patient is a 21-year-old man with VATER Syndrome who transitioned to intermittent hemodialysis and started on intravenous sodium thiosulfate and management challenges for nephrologists. We report an atypical manifestation of Retiform Purpura in a peritoneal dialysis patient. The Coronavirus disease (COVID-19) pandemic has posed diagnostic and management challenges for nephrologists. We report an atypical manifestation of COVID-19 presenting as a case of Calciphylaxis and COVID-19 Associated Thrombotic Retiform Purpura in a peritoneal dialysis patient. Case Description: A 62-year-old female presented to the emergency room with leg pain and edema for 4 weeks. She had recently been started on peritoneal dialysis. Examination revealed tender, indurated retiform dusky plaques on thighs and bilateral lower legs (Figure 1). Laboratory findings are summarised in Table1. Her SARS-CoV-2-RT-PCR was positive. Imaging revealed no evidence of thrombosis. Skin biopsy showed severe ischemic dermopathy syndrome consistent with an overlap of COVID-associated thrombotic retiform purpura and calciphylaxis (Figure 2). The SARS-CoV-2 envelope protein was seen in endothelial cells within dermal blood vessels. The patient was transitioned to intermittent hemodialysis and started on intravenous sodium thiosulfate 25 grains three times weekly. Discussion: In COVID-19 era, coagulation abnormalities are becoming increasingly evident. Management of calciphylaxis in PD patients is difficult under current circumstances due to limitations in the ability to provide regular infusions and multi-interventional care. We hypothesize that our patient had an underlying predisposition for calciphylaxis given risk factors of secondary hyperparathyroidism and an additional insult (COVID-19) caused a so-called “second hit” resulting in clinically apparent disease. Atypical presentations of COVID-19 due to a combination of procoagulant state, as well as any preexisting risk factors for calciphylaxis, must be kept in mind.

### Case Description: Remote Peritoneal Dialysis Training in a COVID-19-Positive Patient

**Aditya V. Jain, Tina S. Samuel, Leslie A. Jansto, Erwin E. Morales, Cybele Ghossein. Northwestern University Feinberg School of Medicine, Chicago, IL.**

**Introduction:** Training patients in peritoneal dialysis (PD) traditionally requires up to fourteen in-person clinic visits to cover all aspects of care. The COVID-19 crisis has created an unprecedented challenge in educating patients to perform PD safely while minimizing exposure to staff. Telemedicine has been well-received by staff and patients in other aspects of PD care. We present a case of a COVID-19 positive patient who was fully trained in PD using telemedicine.

**Case Description:** The patient is a 21-year-old man with VATER Syndrome who progressed to ESRD with uremic symptoms. He chose PD as his dialysis modality while awaiting a kidney transplant. Prior to his PD catheter insertion, he tested positive for COVID-19. He was deemed an ideal candidate for PD training via telemedicine and agreed to proceed. For the first two training sessions, he presented to the PD clinic and was placed in a designated isolation room with his personal computer. His PD nurse was in an adjoining room and trained him via video conferencing with the option to enter his room if needed. The patient quickly mastered the procedure in this monitored environment. He completed the remainder of the required education remotely in his home via telemedicine. Currently, he is fully trained and has initiated his full PD prescription.

**Discussion:** There are several advantages of telehealth in COVID-19 patients. The risk of viral exposure to healthcare staff and other patients is reduced by limiting trips to the PD clinic. Additionally, reducing the burden of travel saves time and expense for the patient. Patient selection for telehealth learning is critical: the ideal patient must be motivated and technologically savvy. The patient, PD nurse, and nephrologist must jointly determine whether proceeding with tele-learning is feasible and safe. Although remote videoconferencing is not the conventional or optimal method for PD education, it can be used successfully to train patients while minimizing exposure of COVID-19 to staff.
Severe Hyponatremia as an Untintended Consequence of COVID-19-Related Social Distancing

Mahmoud M. Mohamed,1 Stacy A. Johnson,1 Barry M. Wall.2,† The University of Tennessee Health Science Center, Memphis, TN; 2Memphis VA Medical Center, Memphis, TN.

Introduction: COVID-19 is primarily a respiratory infection which can have adverse effects on multiple organ systems. There is limited information concerning the harmful effects of social distancing on patients with chronic diseases who avoid seeking medical attention due to fear of contracting the novel COVID-19 disease.

Case Description: A 64-year-old African American female with a past history of HIV-related dementia and seizure disorder was residing with family members, requiring assistance provided by daily living. She was antihypertensive but needed assistance with hygiene and meals. The family reported that over the past 7-10 days, she had become less interactive, remaining bedbound and resisting oral intake. There was an initial reluctance to bring her to the Medical Center due to the fear of contracting COVID-19 infection, given the patient's history. Despite the family being told to provide social distancing and home care, mental status progressively worsened, prompting presentation to the emergency department. The patient had a GCS of 10. The patient was nonresponsive, did not follow commands, and only withdrew from noxious stimuli. Vital signs were prominent for fever 37.7°C and blood pressure was 94/64 mmHg. Pertinent laboratory results included: serum sodium, 201 mEq/L; plasma osmolality, 431 mOsm/kg; BUN 107 mg/dL; and creatinine of 4.8 mg/dL. CT head showed no acute intracranial pathology. Her condition required ICU care, including mechanical ventilation. COVID-19 screening was negative to 37.7% of cases. Here we report a case of a woman with COVID-19 presenting with rhabdomyolysis and AKI.

Case Description: A 48 y/o Hispanic woman with history of HTN, hyperlipidemia and DM type 2 who presented to the ED complaining of shortness of breath, fever, cough, and hypoxia four days before presentation she had been diagnosed with COVID-19 and was self-isolating at home. Her symptoms worsened prompting her visit to the ED. Vital signs showed fever of 103.1°F, pulse 86, respiratory 37, blood pressure 106/58 and O2 Sat 85% at room air, 95% with nasal canula at 4 L. PE was normal except for the chest which was clear. On lung auscultation her breath sounds were clear. Admission labs were remarkable for AKI and rhabdomyolysis. Serum creatinine was 3.61, BUN, and total 106,193. U/A with blood, 5-10 RBC, 5-10 WBC and many bacteria. FeNa was 0.3%. Toxicology panel was negative. Respiratory viral panel was negative. Inflammation A and B were negative. She initially received 2 L bolus of IV NS then continued with balanced crystalloid solutions for volume expansion over the next 3 days. She received treatment with hydroxychloroquine, azithromycin and ceftriaxone for COVID-19 pneumonia. Her symptoms improved and serum creatinine and CK gradually decreased until back to normal levels.

Discussion: Rhabdomyolysis can be seen associated with viral infections. We presented a patient with COVID-19 and rhabdomyolysis. There are no studies establishing a mechanism for COVID-19 induced rhabdomyolysis. Patients with COVID-19 pneumonia are generally kept with negative fluid balance to avoid overload and worsening of ARDS. On the other hand, volume expansion is mainstay management for rhabdomyolysis. Clinicians should have a high suspicion for rhabdomyolysis in patients with COVID-19 presenting with myalgias and AKI. Early recognition of and appropriate treatment is crucial to improve outcomes.

Bilateral Renal Artery Thrombosis in a COVID-19 Patient with Anuric AKI

Nitzy N. Munoz Casablanca, Osama El Shamy, Steven G. Coca, Jaime Uribarri, Shuchitra Sharma. Icahn School of Medicine at Mount Sinai, New York, NY.

Introduction: AKI is common in COVID-19. Hypercoagulability has been described. We present the case of a COVID-19 patient with anuric AKI who was found to have bilateral renal artery thrombosis (RAT) while on systemic anticoagulation.

Case Description: A 66-year-old woman with a past medical history of paroxysmal atrial fibrillation on apixaban (continued on admission), hypertension, and heart failure presented with 2 days of shortness of breath and a productive cough. She was found to be in hypoxic respiratory failure in the setting of COVID-19 pneumonia. Admission laboratory evaluation was significant for a white blood cell count of 36.8 x 10^3/μL, creatinine 6.04 mg/dL, and lactate dehydrogenase 2,600 U/L. The patient was intubated and mechanical ventilation was initiated. Her baseline serum sodium improved to 146 mEq/L, and serum creatinine improved to 0.7 mg/dL over a 10 day period. The patient was subsequently transferred to a rehabilitation unit.

Discussion: Despite the pivotal role of social distancing in preventing the spread of the novel Coronavirus, reluctance in seeking medical attention can lead to serious and even life threatening consequences.

A Case of Severe Hyponatremia in a Patient with COVID-19

Napur N. Upal, Bessy Suin Flores Chang, Hugo Andrade paz, Mala Sachdeva. Northwell Health, Manhasset, NY.

Introduction: Hyponatremia is a common electrolyte disturbance seen in association with conditions such as malignancy and infections. In the recent literature, hyponatremia has been linked to SARS-CoV-2 infection. To date, the most likely reported etiology of hyponatremia in setting of COVID-19 has been SIADH. We describe a severe case of hyponatremia, not due to SIADH, seen in a patient with COVID-19.

Case Description: 49-year-old male with history of hypertension, hyperlipidemia, positive novel coronavirus nasopharyngeal swab done as outpatient, presented to the emergency department with fever, cough and dyspnea for a week. On admission, he was afebrile with respiratory rate of 18 and oxygen saturation of 84% on ambient air. His BP was 166/105 and heart rate 105 beats per minute. Portable chest X-ray revealed rales bilaterally. Initial laboratory test showed serum sodium of 104 mEq/L and serum creatinine of 0.58 mg/dL. Additionally, C-reactive protein was elevated to 7.19, serum ferritin elevated at 1798 and D-Dimer was 158. CXR showed bilateral infiltrates. Serum lactate was low at 217, and urine studies showed elevated urine osmolality (328) and low urine sodium (< 35), suggestive for diagnosis of hypotonic hyponatremia from volume depletion. He received treatment with 3% hypertonic saline with a subsequent

Extracorporeal Cytokine Reduction Using Oxiris Blood Purification in COVID-19
Spencer Hodgins,1 Marat Abdullin,2 Mark A. Tidswell,1 Daniel L. Landry,1
1Baystate Medical Center, Springfield, MA; 2Kidney Care and Transplant Services of New England, Springfield, MA.

Introduction: Severe COVID-19 infection can cause “cytokine storm” and end-organ dysfunction. OXIRIS, a blood-purification filter, was recently approved by the FDA under emergency use authorization for this indication due to its ability to remove cytokines and endotoxin through its AN-69ST membrane. We describe our experience with the first two cases treated at our institution.

Case Description: Case 1: 58 year-old female patient with a baseline creatinine of 0.8 mg/dL & history of hemoglobin SC disease was admitted with respiratory failure due to COVID-19 infection. She deteriorated on hospital day (HD) 6 and was intubated. She received broad-spectrum antibiotics and convalescent plasma. On HD 15 she had increasing vasopressor requirement, anuric AKI and was started on continuous renal replacement therapy (CRRT). Due to worsening clinical status on HD18 she was started on the OXIRIS hemofilter through the CRRT circuit for 48 hours. Oxygenation improved and there was some improvement in inflammatory markers (IM) (table 1), however, the family withdrew care on HD 20. Case 2: 29-year-old male with no prior past medical history except for morbid obesity presented with fever and dry cough in the setting of recent COVID-19 exposure. He was found to be COVID-19 positive and rapidly deteriorated with resultant intubation on HD4. He received hydroxychloroquine, doxycycline, remdesivir and convalescent plasma. OXIRIS hemoperfusion was initiated on HD8 due to worsening hypoxia despite high FiO2. Oxygenation improved by HD10 (table 1) and he was successfully extubated on HD16.

Discussion: We present our first 2 cases using the OXIRIS hemofilter. We treated the patients for 48 hours with a scheduled filter exchange at 24 hours. We used a blood flow of 250 ml/min and dialysate flow of 25 ml/kg/hour with either systemic heparin or regional citrate anticoagulation along with 1L/hr of pre-filter saline. For hemoperfusion we used the same parameters without dialyse. We observed rapid improvements in oxygenation (Figure 1). The findings are hypothesis generating though more data is needed to determine optimal timing and efficacy of this filter.

Table 1: Inflammatory and Respiratory Parameters.

PO0805

Rhabdomyolysis as a Late Complication of COVID-19 Infection
Benjamin Lindgard, Ann M. O’Hare, Sarah F. Sanghavi, Bessie A. Young.
University of Washington, Seattle, WA.

Introduction: The 2019 novel Coronavirus (COVID-19) is a betacoronavirus which typically presents with fever, cough, myalgia, and fatigue and can be associated with acute kidney injury (AKI). Recently, several cases of rhabdomyolysis (with and without AKI) have been reported with COVID-19 infection. We present a case of a patient with COVID-19 infection who developed rhabdomyolysis on hospital day 22.

Case Description: A 74-year-old man presented with several weeks of progressive malaise, dyspnea, fatigue, and nausea. He was hypoxic to 87%, febrile (38.8 C) and had diffuse bilateral infiltrates on chest x-ray [Figure 1]. He was intubated on hospital day 1. Testing for COVID-19 by PCR was positive. Creatinine improved from 1.6 to 0.9 mg/dL with 2L of IV fluids. He did not require vasopressors. On hospital day 22, while still intubated, his creatinine increased from 1.4 to 3.8 mg/dL. The level of creatinine phosphokinase (CPK) had was 7393 U/L from 118U/L on admission, and his plasma free myoglobin was 34,640 mcg/L. Urinalysis was positive for 3+ occult blood, few red blood cells, and many granular casts. His serum creatinine peaked at 6.67 mg/dL on hospital day 26 and subsequently declined to 1.6 by hospital day 33.

Discussion: Rhabdomyolysis is an infrequent complication of COVID-19 infection. While observed, rhabdomyolysis is typically present on admission. This is, to our knowledge, the latest that rhabdomyolysis has been observed in COVID infection. The patient’s inflammatory markers were not re-checked at the time of this event, though worsening inflammation may have provoked this event. Their troponin was mildly elevated on ITT. PCP was not performed. No bed sores were observed, and the patient had no access to illicit substances. No medications known to cause rhabdomyolysis were given prior to this development. This case report suggests that rhabdomyolysis-related AKI may be a late complication of COVID-19 infection.

Case Description: Case 1, a 28 years old African American female and Case 2, a 58 years old African American male with baseline CKD III, admitted with COVID-19 infection and had acute kidney injury with significant proteinuria with hypoaalbuminemia. Patients had kidney biopsies. Please see table for all the details.

Discussion: Possible etiologies of acute kidney injury in COVID 19 are tubular injury due to cytokine storm, direct cytotoxic effect and immune mediated glomerulonephritis. Both the patients had collapsing FSGS in addition to tubular injury suggesting injury to the podocytes. Viral particles were not seen on both the biopsies, and hence direct cytopathic effect was not considered to be the mechanism of renal injury, although viral level below the detection threshold could not be excluded. Collapsing FSGS has been seen with other viral infections including Parvo-virus infection, Cytomegalovirus infection and HIV. Variant of apolipoprotein L1 (APOL1) gene in African Americans have been shown to be associated with FSGS. These two patients had genetic susceptibility due to APOL1 and COVID infection caused interferon surge leading to a second hit. Teaching Points: Renal biopsy should be considered in patients with COVID-19 and Nephrotic range proteinuria. APOL1 testing should be done in patients with African American descent.

Demographic, clinical, laboratory, biopsy findings and follow up.

PO0807

Attenuation of Circuit Longevity in COVID-19 Critical Illness with AKI on Continuous Venovenous Hemodiafiltration Despite the Use of Regional Citrate Anticoagulation (RCA) and Heparin-Bonded AN 69 (Oxiris®) Filter

Tung Lin Lee, Zhong Hong Liew, Manish Kaushik, Li Cho Michelle Ng, Jiunn Tung Lin, Hui-Lin Chuong, Han K. Tan. Singapore General Hospital, Singapore, Singapore.

Introduction: Critical illness in SARS-CoV-2 (COVID-19) infection can result in acute kidney injury (AKI). Continuous renal replacement therapy (CRRT) is part of the overall supportive ICU management.

Case Description: CRRT was delivered as Continuous Veno-venous Haemodiafiltration (CVVHDF) using the Prismaflex (Baxter Inc.) system with heparin-bonded filter (Oxiris®). The filters were electronically changed every 12 hours for first 5 days to augment cytokine adsorptive capacity. Regional citrate anticoagulation (RCA) was used to ensure filter longevity. Initial citrate dose was prescribed at 3.0 mmol/L. All 3 consecutive patients were male aged 66.7 ± 6.02 years. APACHE II score was 32.7 ± 6.51 and predicted mortality was 71%. Mean initial creatinine was 264.7 ± 60.7 μmol/L, and urine output was 6.7 mL/hour. All patients were on vasopressor support, broad spectrum antimicrobials and mechanical ventilation. 30 Oxiris filters were studied in the 3 patients. 6/30 (20%) filters clotted spontaneously before scheduled change. Mean filter lifespan (2430) was 689.6 ± 42.3 min before elective change. For the filters that clotted, mean circuit longevity was 515.7 ± 126.2 min. The observed difference was significant, p = 0.002. Importantly, filter clotting occurred despite adequate citrate dose of 3.0 mmol/L and mean post-filter ionized calcium of 0.34 ± 0.06 mmol/L. Vascular access issues were excluded by reviewing access site, return pressures. Citrate dose was increased to 3.2 mmol/L for all patients and this reduced the frequency of filter clotting subsequently. Two patients were extubated and had full renal recovery - mean duration of CRRT dependence was 9.5 days. However, the third patient remained CRRT dependent until demise on the 28th day of ICU stay.

Discussion: Attenuation of circuit lifespan was observed despite adequately dosed RCA and heparin bonded Oxiris filters. We theorise that this could be due to a pro-coagulant state induced by the SARS-CoV-2 infection. Possibly, higher citrate dose to target even lower post-filter ionized calcium may be required to optimise anticoagulation and filter lifespan, thereby ensuring optimal effluent dose and solute clearance, for critically ill COVID-19 patients.

PO0808

SARS-CoV-2 Infection in the Early Post-Transplant Period After a Living Donor Kidney Transplant

Introduction: Coronavirus disease 2019 (COVID-19) pandemic presented multiple challenges for living and deceased donor kidney transplant programs with the likelihood of exposure to severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). We report the course of COVID-19 and immunosuppression in 3 months of living donor kidne y transplant (LDKT) which has not been described previously.

Case Description: Three LDKT recipients developed COVID-19 in the early post-transplant period and were detected positive for SARS-CoV-2 at day 7, day 19 and 2 months post-transplant. Patients 1 and 2 had received 1 mg/kg of anti-thymocyte globulin (ATG) as induction and patient 3 had received no induction at the time of transplant. Patients 1 and 2 had minimal symptoms at diagnosis, whereas patient 3 had high grade fever, cough and shortness of breath. All 3 patients had lymphopenia at diagnosis and none required supplemental oxygen or intensive care unit monitoring. All 3 patients received hydroxychloroquine and hydroxychloroquine. Mycophenolate mofetil dose was reduced in patient 1 and was stopped in patients 2 and 3. Patient 3 developed acute kidney injury with a peak serum creatinine of 2.4 mg/dL, whereas other 2 patients did not develop kidney allograft dysfunction. All 3 patients recovered from SARS-CoV-2 infection with normal renal function at discharge.

Discussion: Limited experience of SARS-CoV-2 infection in early post-transplant period is available in deceased donor kidney transplant (DDKT) which has not been described previously.

PO0809

COVID-19-Related Collapsing Focal Segmental Glomerulosclerosis and Apolipoprotein L1: A Report of Two Cases

Sandeeep Magoon, Varun Malhotra, Prasad B. Bichu. Eastern Virginia Medical School, Norfolk, VA; Nephrology Associates of Tidewater, Norfolk, VA.

Introduction: Acute kidney injury has been seen in approximately 15% of the patient with COVID-19 infection. Acute tubular injury was presumed to be the most common cause of AKI, but it did not explain significant proteinuria and hematuria. We present the case report of 2 patients with collapsing focal segmental glomerulopathy with COVID-19.
PO0811
Low-Sodium Disorders and the 2019 Novel Coronavirus Disease (COVID-19)
Jaameet Gill,1 Xunxi S. Guo,2 Akinwande A. Akinfolarin,2 Ankit Mehta,1 1Baylor University Medical Center at Dallas, Dallas, TX; 2Dallas Nephrology Associates, Dallas, TX.

Introduction: COVID-19 have been well characterized with hallmarks of pneumonia and respiratory failure. Hyponatremia is a well reported finding in patients with COVID-19. However, very few reports or cases of hypomagnesemia have been directly attributable to the disease. We report three different presentations of hyponatremia in COVID19 patients.

Case Description: 1. 70 year old man with hypertension, diabetes presented with dyspnea. He was clinically euovolemic. Chest X-ray (CXR) showed bilateral interstitial and airspace opacities. Laboratory data revealed, serum sodium 122 mEq/L, serum osmolality 264 mosm/kg, urine osmolality 579 mosm/kg and urine sodium 153 mEq/L. A diagnosis of hyponatremia secondary to the Syndrome of inappropriate Antidiuretic Hormone (SIADH) was made and the patient was treated with oral urea and fluid restriction. 2. 50 year old man with chronic alcohol abuse presented with bilateral calf soreness. CXR revealed increased interstitial markings. Laboratory data showed serum sodium 113 mEq/L, serum osmolality 251 mosm/kg, urine osmolality 426 mosm/kg and urine sodium 14 mEq/L. Hyponatremia was attributed to a low solute state. Serum sodium improved with normal saline infusion. 3. 69 year old female with hypertension admitted with vomiting and diarrhea. CXR showed diffuse pulmonary infiltrates. Initial laboratory data revealed serum sodium of 126 mEq/L, serum osmolality 260 mosm/kg. Serum sodium recovered as diarrhea resolved. However, eight days after starting therapy with Selinexor, a nuclear transport inhibitor, serum Na declined to 128 meq/L, serum osmolality 260 mosm/kg. SIADH was attributed to Selinexor therapy. Sodium improved with oral sodium chloride therapy and fluid restriction.

Discussion: Incidence of Hyponatremia due to SIADH in community acquired pneumonia is 8-31% in adult patients. To the best of our knowledge, there have only been two case reports of SIADH in COVID-19 disease from Switzerland. Hence, it is unclear if SIADH is the predominant presentation of hyponatremia with COVID-19. The etiology of hyponatremia could be multifactorial as seen in the cases above. Clinical assessment of volume status and urine studies including osmolality and sodium with a thorough review of medications is the key to differentiating causes of hyponatremia and determining adequate management.

PO0812
COVID-19 Short-Term Outcomes of AKI and Chronic Hemodialysis
Jessica Smolander,1 Annette Bruchfeld,1,2 Dandyders Sjubas AB, Stockholm, Sweden; 1Karolinska Universitetssjukhuset, Stockholm, Sweden; 2Linköpings universitet, Linköping, Sweden.

Introduction: Acute kidney injury (AKI), albuminuria and hematuria are common and in patients with COVID-19 in addition to viral pneumonia, hypercoagulability and hyperinflammation. We present short-term outcomes of 21 COVID-19 patients with AKI and CRRT and the clinical course of 40 chronic hemodialysis (HD) patients with Covid-19.

Case Description: Twenty-one non-CKD Covid-19 infected patients with AKI required mechanical ventilation and CRRT at the ICU, 20 were males, average age was 59.7 years (y), average BMI 29 kg/m2, 33 % had diabetes. The typical scenario was a normal/slightly elevated creatinine level at admission, normalizing after few fluids, but rising creatinine from day 3-4 and start of CRRT on day 8 (median). Urinary analysis was available in eight patients, of which seven had albuminuria and/or hematuria. So far eight patients (38 %) have died. Dialysis has been discontinued in nine patients (43 %), median time 17 days in dialysis (range 1-35 days), follow up of 1-4 weeks. Patients 3-4 weeks on CRRT (median time 39 days) with a creation(Cr) of 7.87mg/dL. Urinalysis revealed active sediments with 55 RBC/bhp, 65 WBC/bhp, and nephritic range proteinuria: 5 g/gm of creatinine. We initiated on renal replacement therapy and received convalescent plasma along with Tocilizumab for the treatment of COVID-19. Serologic testing revealed a positive perinuclear (p)-ANCA (1:320), myeloperoxidase (32.5). Kidney biopsy was consistent with a pauci immune glomerulonephritis; cellular crescent present in 40% of glomeruli. He received pulse dose steroids and Rituximab. The patient had a good clinical response and was able to discontinue hemodialysis and serum Cr decreased to 3.5mg/dL. Case Two: 46 year old South Asian male presented with rash from leukocytoclastic vasculitis and was diagnosed with COVID-19. He had an AKI, serum Cr peaked at 4.0mg/dl with proteinuria, leukocyturia, and microhematuria on urinalysis. Cryoplasma(c)-ANCA and proteinase-3(PR-3) were positive. A kidney biopsy was performed which revealed a necrotizing glomerulonephritis. He was treated with steroids and Rituximab with a positive response, Cr decreased to 2.0mg/dL.

Discussion: It is now well known that SARS-CoV-2 affects organs outside of the respiratory system, with the kidneys being a usual target. The most commonly reported presentation of COVID-19 and the kidneys is AKI, the etiology of which is predominantly acute tubular necrosis (ATN). ATN is by far the most described glomerular lesion. Clinicians should be aware of AVF with GN as another potential pathology, and concurrent use of immunosuppression with treatment of infection, can lead to favorable clinical outcomes.
Case Description: 58-year-old African American male with past medical history of hypertension presented with cough, dyspnea and fever. On admission, he had a temperature of 104°F, BP of 149/90 mmHg, HR of 104 bpm, and oxygen saturation of 92%. Physical examination was remarkable for diminished and diffuse coarse breath sounds. Lab work-up showed serum creatinine of 2.99 mg/dL (baseline 1.19 mg/dL) with an estimated GFR of 26 mL/min. Urinalysis revealed protein > 500 mg/dL, RBC 25, and presence of coarse granular casts. Urine protein-creatinine ratio was 3.2. Serology was negative for ANA, ANCA, and anti-proteinase antibodies, as well as hepatitis and HIV panels. Serum C3 and C4 levels were within normal limits. Viral PCR of nasopharyngeal aspirate was positive for SARS-CoV-2. Home medications lisinopril and hydrochlorothiazide were held on admission, and he was started on intravenous fluids, azithromycin, and hydroxychloroquine. On day 4, serum creatinine trended up to 3.29 mg/dL and potassium was 4.0 mmol/L but since the patient was oliguric, hemodialysis (HD) was started. Serum creatinine then trended to a high of 15 mg/dL, urea nitrogen to 102 mg/dL and serum potassium level to 6.9 mmol/L despite multiple HD sessions. Meanwhile, his oxygen requirement also increased to 15L. After 10 days of daily HD sessions, serum potassium came down to 4.3 mmol/L but he ultimately required HD post discharge.

Discussion: Previous literature has discussed SARS-CoV-2 association with renal dysfunction. A clear viral cytopathic effect of SARS-CoV-2 on proximal tubular cells causing hypokalemia. In the case setting, a direct viral induced cytopathic effect, which we believe held true for our patient. As viremia cleared, the kidney function improved though it did not return to baseline. In our case, development of hyperkalemia despite hemodialysis makes it more interesting, but it remains unclear how.

Rhabdomyolysis in COVID-19 Patient Requiring RRT
Muhammad usama shah Hamdani, Jeremy Carlson, Hasan Zahid. University of Florida College of Medicine, Gainesville, FL.

Introduction: Rhabdomyolysis is characterized by the release of intracellular muscle contents into the circulation. Of the 1099 patients affected by Covid-19 in China, only 0.2% had rhabdomyolysis. The case setting is a direct viral induced cytopathic effect, which we believe held true for our patient. As viremia cleared, the kidney function improved though it did not return to baseline. In our case, development of hyperkalemia despite hemodialysis makes it more interesting, but it remains unclear how.

Case Description: A 52 year old African American female with past medical history of Diabetes and hypertension presented to the ER with 7 days of worsening fever, chills, myalgias, nausea, vomiting, dyspnea, loss of sense of taste and smell. Her home medications included metformin and Candesartan-HCTZ, however, she had been off these medications for the last seven days. She was not on statins. She was a healthcare worker at a nursing home that had a recent outbreak of the novel Coronavirus with 51 positive cases. In ER, she was febrile, tachypneic with WBCs of 11.8 thousands/mm3, Creatinine of 6.88 mg/dL, BUN 78mg/dL, and creatinine kinase (CK) of 167,770 U/L. Urinalysis showed large amount of blood with 17 RBCs. Chest X-ray significant for mild patchy airspace opacity in the Lingula. She also tested positive for COVID-19. She was adequately volume resuscitated and alkalinized. Due to her severe AKI, she did not meet criteria for Hydroxychloroquine and Azithromycin. Sarilumab was contraindicated due to transaminis. Patient was started on hemodialysis on day 3 of admission as her creatinine continued to rise. On the 10th day after admission, her transaminis improved and Sarilumab was administered. Repeat Covid-19 test before administering Sarilumab was positive. Her IL-6 levels checked before initiating the drug were <5 pg/mL. Her CK levels had started to trend down and were at 4880 U/L the day before starting Sarilumab. She remained oliguric and on hemodialysis with no signs of renal recovery at the time of discharge.

Discussion: Coronavirus has a huge range of presentation from asymptomatic to severe ARDS. Our goal is to highlight one of the complications of the novel corona virus leading to acute renal failure requiring hemodialysis.

Severe AKI from Thrombotic Microangiopathy and Acute Tubular Necrosis in a Patient with COVID-19 and Gemicitabine Chemotherapy Use

Introduction: Thrombotic microangiopathy (TMA) is a known but rare complication of gemcitabine therapy. However, gemcitabine-associated TMA has not been reported in a patient with concurrent COVID-19. Here, we present an interesting patient with COVID-19 who developed severe acute kidney injury (AKI) from acute TMA and acute tubular necrosis (ATN) following gemcitabine therapy.

Case Description: 45-year-old AA female with history of recurrent metastatic cervical cancer, peritoneal carcinomatosis, small bowel resection, coloso-valvulostomy, colostomy and bilateral nephrostomy tubes was hospitalized for severe symptomatic anemia, fever and AKI. A week prior to hospitalization, patient had received her third outpatient dose of gemcitabine. Four weeks prior to presentation, serum creatinine (Scr) was 0.77. On admission labs, Scr was elevated at 7.36 and hemoglobin was low at 4.8. Patient also tested positive for COVID-19 on admission labs. There was no evidence of hydrenephrosis on CT scan. Patient found to have clinical and labs findings of TMA (hypertension, thrombocytopenia, elevated lactate dehydrogenase and low haptoglobin) during hospital stay. Peripheral smear showed multiple schistocytes. Urinalysis was significant for microscopic hematuria and proteinuria. Spot urine total protein to creatinine ratio was 4.6. Complement C3 and C4 were not low. Patient was Coombs IgG positive and was initiated on high dose intravenous corticosteroids. Our patient also received one dose of rituximab therapy as per inpatient oncology team. Patient was initiated on hemodialysis for uremic symptoms. Kidney biopsy subsequently performed during hospital stay showed acute TMA and acute tubular injury with focal tubular necrosis.

Discussion: Our patient developed severe AKI in the setting of gemcitabine chemotherapy use and COVID-19. Kidney biopsy showed findings of both TMA and ATN. While the kidney biopsy findings are very interesting, it is unknown if either gemcitabine or COVID-19 or both were responsible for the severe AKI seen in our patient. Our patient remains oliguric and dialysis dependent.
First US Case Series: Continuous Renal Replacement Therapy with Adsorbent Oxiris Filter in the Setting of COVID-19 Infection

Introduction: Many COVID-19 hospitalized patients sustain acute kidney injury (AKI) requiring CRRT. Multisystem inflammatory response plays a large role in their infection leading to enhanced morbidity and filter clotting. Oxiris filters have been used in Europe in septic patients due to their properties of reducing cytokines and inflammatory mediators but have not been available in the United States until late April 2020. Use of these filters in COVID-19 patients has been very limited, and has not yet been reported. We report the first U.S. experience in 3 COVID-19 patients requiring mechanical ventilatory support and continuous venous to venous hemodiafiltration (CVVHDF) using oxiris dialyzers for their AKI.

Case Description: Case 1: A 73 year old male with laboratory tests revealing: creatinine 1.79mg/dl, C-Reactive Protein 1.01mg/dl, D-dimer 397, ferritin 13,000 ng/ml. He was started on CRRT on the ICU day of admission using CVVHDF with an oxiris filter and then switched to oxiris filter. He remained on oxiris CVVHDF for 9 days with no reported clotting events, a decline in ferritin by 90% to 1437ng/ml and a decline in IL-6 levels to 73 pg/ml. Case 2: A 55 year old male on CVVHDF with the M150 filter had a serum ferritin level progressively increasing to 2377 ng/ml and multiple clotting events. The dialyzer was switched to oxiris. He had no clotting events while on CVVHDF for six days and his serum ferritin level decreased to 1759 ng/ml. Case 3: A 40 year old male on extracorporeal membrane oxygenation (ECMO). He was initiated on CVVHDF to the ECMO circuit using a M150 filter for 7 days and was switched to oxiris filter with no reported clotting events thereafter.

Discussion: The COVID-19 cytokine storm leads to activation of pro-inflammatory mediators leading to severe morbidity including coagulopathic events. Optimal treatment is still unknown. ECMO and CVVHDF with oxiris dialyzer in critical COVID-19 infection may play a role in decreasing inflammatory markers, which confers overall clinical improvement. Once switched to oxiris, our patients showed improvement in inflammatory markers and had no clotting of their dialyzers. In these patients, convective clearances (CVVHDF) may be more beneficial than diffusive therapies (CVVHD).

Pre-Filter Argatroban for Coronavirus Disease 2019
Pablo Villanueva-Meyer,1 Sandhya S. Thomas,2,3 Baylor College of Medicine, Houston, TX;1 Michael E DeBakey VA Medical Center, Houston, TX.

Introduction: Coronavirus disease – 2019 (Covid-19) has been implicated in a pro-thrombotic state. This has been well documented in numerous articles and has posed to be a clinical obstacle for those caring for Covid-19 positive patients. This has been particularly challenging for Nephrologists managing patients on continuous renal replacement therapies (CRRT). Amongst other things, filter clotting has been associated with an increased number of transfusions and interruptions in sustained therapy, as well as increased costs to the healthcare systems and patients.

Case Description: We present the case of a 73-year-old African American male with a past medical history of underlying chronic kidney disease, hypertension, diabetes mellitus, heart failure, and atrial fibrillation who was admitted from his nursing facility for respiratory failure and stage 3 AKI. Although MetHb is linked to severe illness including sepsis, little is known about its association with COVID-19 positive patients. Our report highlights the importance of considering alternative diagnoses of very high MetHb levels such as G6PD deficiency in COVID-19 patients. This is of particular relevance as Hydroxychloroquine has been used as experimental treatment for COVID-19 and in the current climate, G6PD deficiency could be an important issue in patients with AKI due to haemolytic anaemia and significantly elevated MetHb, particularly in those from regions of high prevalence and those treated with known triggers such as Hydroxychloroquine.

Pre-Filter Argatroban for Coronavirus Disease 2019
Viviam Tainaka, Aulio, Aromma Kapoor, St Helier Hospital, London, United Kingdom.

Introduction: Patients with COVID-19 can be asymptomatic or have severe illness. Oxidative stress may be a cause of increased severity and mortality in COVID-19 patients. Methaemoglobinemia (MetHb) and haemolysis can occur as a result of oxidative stress. MetHb is associated with sepsis, exposure to drugs and inborn errors of metabolism. Glucose-6-phosphate dehydrogenase (G6PD) deficiency may also manifest with MetHb and haemolysis.

Case Description: A 31-year-old man, originally from West Africa, with no comorbidities, presented with dyspnea, cough, anemia, and oligo-anuria. He had type 1 respiratory failure and stage 3 AKI, which led to critical care admission for ventilation and haemolysis. COVID-19 pneumonia was confirmed by nasopharyngeal swab and radiological imaging. He developed haemolytic anaemia. The MetHb was 3.5% (normal <1.5%). It rose to a peak of 10.7% with persisting anaemia and further investigations showed G6PD deficiency. He had no exposure to medications known to trigger haemolytic crises, such as Hydroxychloroquine. He was treated with supportive management including red cell transfusions and also with Ticlopidine for COVID-19. He was extubated after 15 days and recovered renal function. Data on 9 other patients admitted during this period to the ITU with COVID-19 and AKI showed 7 had normal MetHb levels and 2 had modest elevations (~3%).

Discussion: Triggers of G6PD deficiency include stress from infections, fava beans, or drugs e.g. Hydroxychloroquine. It typically presents as haemolytic anaemia, jaundice and AKI. Although MetHb is linked to severe illness including sepsis, little is known about its association with COVID-19 positive patients. Our report highlights the importance of considering alternative diagnoses of very high MetHb levels such as G6PD deficiency in COVID-19 patients. This is of particular relevance as Hydroxychloroquine has been used as experimental treatment for COVID-19 and in the current climate, G6PD deficiency could be an important issue in patients with AKI due to haemolytic anaemia and significantly elevated MetHb, particularly in those from regions of high prevalence and those treated with known triggers such as Hydroxychloroquine.

Rhabdomyolysis and Methaemoglobinemia
Nafees Naifee, Rouvick Gama, David Makanjuola, Virginia A. Quan.

Introduction: Covid-19-associated rhabdomyolysis has not been clearly established; therefore, clinicians might have low clinical suspicion for rhabdomyolysis.

Case Description: We are presenting five cases where Covid-19 patients became very catabolic and developed rhabdomyolysis, with AKI. One day later they were intubated for tachypnea and worsening oxygen saturation. They were admitted to the intensive care units and were treated with intravenous hydration. All the patients eventually required pressor support. AKI developed 10 days after onset of the symptoms and it was attributed to cytokine storm, ischemic acute tubular necrosis, and rhabdomyolysis. Intravenous furosemide was attempted with poor response. Renal replacement therapy (RRT) was needed approximately three days after development of AKI. Continues renal replacement therapy (CRRT) was the modality used. After 3 days of interrupted therapy due to clotting, there was no improvement and overall high mortality.

Discussion: Rhabdomyolysis has been associated with many infectious diseases, including viral infections. The direct viral invasion and circulating viral toxins may directly destroy muscle cell membranes leading to rhabdomyolysis. However the
Severe Hypertriglyceridemia Leading to CRRT Malfunction in a COVID-19 Patient

Richard Parikh, Richard L. Barnett. Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.

Introduction: Continuous renal replacement therapy (CRRT) is a therapy used in critically ill patients and is of particular importance with COVID-19. We present a patient with COVID-19 on propofol for sedation with persistent filter clotting issues found to have severe hypertriglyceridemia (SHT) corrected with lipopheresis. This case highlights the importance of managing all aspects of CRRT, the highly inflammatory state of COVID-19 and supply chain management during high utilization periods.

Case Description: A 41-year-old male with severe obesity and T2DM presented to the hospital with shortness of breath and fevers found to have COVID-19. The patient was intubated on presentation due to hypoxic respiratory failure and admitted to the ICU. The patient was placed on Propofol for sedation. The patient presented with normal kidney function but peri-intubation had a rapid rise in creatinine to 4.00 mg/dL and was started on CRRT. It was noted that the CRRT circuit was continuously clotting within 30 minutes of initiation. The patient was also noted to have rising CPK levels and a concern for Propofol Infusion Syndrome (PRIS) was raised. A triglyceride level was checked and found to be 3286 mg/dL. The patient was initiated on insulin and heparin drips however due to CRRT issues and inadequate clearance a decision was made to perform lipopheresis to rapidly correct SHT. Patient underwent lipopheresis and the triglycerides dropped to 426 mg/dL. The heparin drip was continued and filter life greatly improved. The patient was continued on CRRT and adequate clearance was achieved.

Discussion: This case highlights important points for CRRT, COVID-19 and supply chain management. This patient was found to have PRIS however COVID-19 on propofol for sedation may help to improve the vital prognosis of COVID-19.

COVAN, COVID-Associated Nephropathy: An Evolving Epidemic of Kidney Disease

Aneesa A. Shetty, Ibrahim Tawhari, Maria L. Safar-Boueri, Nay Seif, Ameen S. Alahmad, Vikram Aggarwal, Richard Gargiulo, Yashpal S. Kanwar, Susan E. Quaggin. Northwestern University Feinberg School of Medicine, Chicago, IL.

Introduction: We highlight COVID-19 related renal characteristics in 6 African American patients with positive nasopharyngeal RT-PCR for SARS-COV-2 infection, presenting without severe respiratory symptoms but with acute kidney injury and nephrotic range proteinuria.

Case Description: One of the patients was a transplant recipient. None required mechanical ventilation and no COVID-19 specific therapy was prescribed. All underwent a renal biopsy that showed varying combinations of collapsing glomerulopathy, podocyteopathy and protein overload tubulopathy (Fig 1A). Additionally, tubulo-vascular inclusions and virions (suspected to be SARS-COV-2 virions) were seen in electron micrographs (Fig 1B). APOL1 genotype was tested in 3 patients who were all found to carry high-risk genotypes, suggesting possible susceptibility of patients with high-risk APOL1 alleles to kidney involvement in SARS-Cov-2 (Fig 1C)

Discussion: There was discordance between the high risk G1/G1 genotype of the transplant recipient and the low risk G1/G0 donor kidney genotype, suggesting the important possibility of a systemic APOL1-related mechanism in kidney injury. In conclusion, these 6 cases draw attention to proteinuric kidney disease in COVID-19 infection, possibly associated with a milder form of respiratory disease and high risk APOL1 genotype, emphasizing the need for ongoing vigilance and further investigation into this phenomenon.

Figure 1: 1A: Demographic and Clinical features of the Six Cases. 1B: Biopsy findings.

PO0826

AKI and Purpuric Rash in a COVID Patient

Zakir Shaik, Rui Song, Jared Hassler, Iris J. Lee, Dina Abdelwahab, Avrum Gillespie. Temple University, Philadelphia, PA.

Introduction: AKI in COVID-19 patients are reported in several studies with an incidence of 23%. We report a case of COVID-19 pneumonia with AKI and purpuric rash.

Case Description: A 54 y/o female with hypertension, CKD stage 3, with a COVID+ swab, presented with CT chest findings consistent with COVID-19 pneumonia, purpura of the lower limbs concerning for leukocytoclastic vasculitis and non-oliguric AKI. Creatinine on admission was 8.5mg/dL (baseline of 1.6mg/dL), CBC showed a wbc 26.9, Hb 6.9, platelets 196 and eosinophilia. Serologies were notable for elevated direct coomb, low haptoglobin, low C3/C4, and rheumatoid factor of 26. UA had no hematuria, UPUR 0.75 mg/mg. Home medication, naproxen was stopped one month ago. Renal biopsy showed severe acute tubular injury (ATI), coarse vacuolization of tubular epithelial cells, severe leukocytic infiltration of lymphocytes, neutrophils, eosinophils, severe vascular hyalinosis, global glomerular sclerosis (11 out of 30 glomeruli), severe (60%) interstitial fibrosis & tubular atrophy. Per institutional protocol, Immunofluorescence could not be performed in COVID+ patients. Renal function improved significantly after a 5 day course with IV steroids alone and patient remained stable with a creatinine of 3.4 mg/dl.

Discussion: This case features multiple potential mechanisms for AKI in a COVID-19 patient. Viral effects include, acute interstitial nephritis (AIN), severe ATI, and endothelial inflammation leading to vasculitis and purpuric rash. Recently, vasculitis similar to Kawasaki disease has been described in COVID-19 patients. Our case suggests that immune deregulation from COVID infection may result in autoimmune findings such as elevated RF and hemolytic anemia. AKI improved in our patient after steroids, suggesting that a biopsy with features of AIN should be treated and could change the course of the disease.
PO0827

Kevin S. Ha, Rasha Alawieh, Khaled Boubes. The Ohio State University, Columbus, OH.

Introduction: Well-functioning dialysis access is of utmost importance as the lifeline of those with end stage kidney disease (ESKD). With the evolution of COVID-19 pandemic, elective procedures were placed on hold. The American Society of Diagnostic and Interventional Nephrology (ASDIN) and Vascular Access Society of the Americas (VASA) issued a joint position statement on March 24, 2020, designating dialysis vascular access procedures to be “essential.” We present a case with a series of complications that could have been prevented had the patient undergone a timely thrombectomy procedure.

Case Description: A 62 year old woman with ESKD undergoing hemodialysis through an upper arm arteriovenous fistula (AVF) presented with a thrombosed AVF in early March 2020 (before the ASDIN statement was issued). She was evaluated by the surgical team; however, due to restrictions to surgical procedures at the time, she did not undergo a thrombectomy and had a right internal jugular tunneled dialysis catheter (TDC) inserted instead. This was complicated by a superior vena cava thrombosis a few weeks later. The TDC was then removed and she had a right femoral TDC placed. She was started on anticoagulation. Her right femoral TDC was complicated by tunnel infection, necessitating its removal and subsequent placement of a left femoral TDC.

Discussion: This case illustrates the complexity of dialysis vascular access and some of the potential complications that are associated with it. It also highlights the importance of timely action to rescue any failed access. As outlined by the statement of ASDIN and VASA, dialysis vascular access should always be treated as a priority, and procedures to salvage it ought to be considered essential. This should also be the case in any future unforeseen restrictions to surgical procedures, such as pandemics or natural disasters.

PO0828

Does Cyclophosphamide Exposure in Patients with Vasculitides Lead to Better COVID-19 Outcomes?

Sayed mohammed fazzan M. Zabiullah,1,2 Arie Gunarsa,1 Ashok P. Chandhari.1 Metropolitan Hospital Center, New York, NY; 2New York Medical College, Valhalla, NY.

Introduction: COVID 19 is a pandemic disease caused by novel coronavirus called SARS-CoV-2. End Stage Renal Disease patients are at high risk for developing severe manifestations of the disease often associated with high morbidity and mortality. Excessive and uncontrolled immune response is thought to be one of the important underlying mechanism for severity of the disease. We present 3 ESRD patients with underlying vasculitides who were admitted with respiratory distress due to COVID 19.

Case Description: 3 patients with COVID 19 infection were treated. A 37-year-old male with ANCA-PR3 related vasculitides resulting in ESRD, on hemodialysis. He had been treated with Cyclophosphamide and prednisone induction. The third patient is a 43-year-old female with SLE; ESRD secondary to lupus nephritis. She had been treated with cyclophosphamide and prednisone induction. The patient started on anticoagulation. Her right femoral TDC was complicated by tunnel infection, necessitating its removal and subsequent placement of a left femoral TDC.

Discussion: This case illustrates the complexity of dialysis vascular access and some of the potential complications that are associated with it. It also highlights the importance of timely action to rescue any failed access. As outlined by the statement of ASDIN and VASA, dialysis vascular access should always be treated as a priority, and procedures to salvage it ought to be considered essential. This should also be the case in any future unforeseen restrictions to surgical procedures, such as pandemics or natural disasters.

PO0829

Renal Biopsy Findings in Patients with COVID-19 Infection

Tuvet Hong T. Tran, Ming Wu. NYU Langone Health, New York, NY.

Introduction: COVID-19 infection is caused by severe acute respiratory syndrome-2 (SARS-CoV-2). SARS-CoV-2, using its Spike protein, interacts with angiotensin converting enzyme-II (ACE2) protein expressed in human kidneys. Upon internalization, host cells may go through pyroptosis, a process characterized by membranous pore formation, cytokine storm and cell death. We report light microscopy (LM), immunofluorescence microscopy (IF), and electron microscopy (EM) findings in renal biopsies of patients with COVID-19 to further understand the pathological process.

Case Description: 10 patients were biopsied, age range 25-63 years. 7 were confirmed by reverse transcriptase polymerase chain reaction (PCR) via nasopharyngeal swab. 3 patients were suspected, but PCR-negative. Common comorbidities include hypertension, hyperlipidemia, and obesity. Patients had AKI with creatinine range 1.2 to 13.48 mg/dL. Kidney ultrasound showed enlargement and increased echogenicity. Biopsies were performed 9 to 71 days from symptom onset of such as fever, cough, and diarrhea. Tissue was fixed in formalin and processed for LM. Fresh frozen tissue was utilized for IF. Tissue was fixed in paraffin-embedded and processed for EM. All had acute tubular injury and viral particles on EM (Figure). Patients received supportive care. None required ventilation, but 4 required hemodialysis. Survival rate is 100% (8-12 weeks).

Discussion: Renal biopsies were evaluated in 7 confirmed and 3 suspected COVID-19 patients. Although PCR is the gold standard, it is known to have a 15% false negative rate. This may be due to low viral loads and antibody testing may be warranted in suspected PCR-negative patients. Coronavirus particles are reported to measure 50-200 nm, and SARS-CoV-2 50-140 nm. Viral particles were seen in all 10 patients. The particles are contained in vesicles or sacs, and can be found in podocytes, endothelial, and tubular epithelial cells. This may contribute to intrinsic injury resulting in AKI seen in patients.

AKI in the Setting of COVID-19: Histopathologic and Ultrastructural Findings in Postmortem Kidney Biopsy

Pounch Golmai,1 Christopher P. Larsen,2 Maria V. DeVita,1 Samuel J. Wahl,1 Astrid Weins,1 Helmut G. Rennek,1 Vanessa Bijol,1 Jordan L. Rosenstock.1 1Lenox Hill Hospital, New York, New York; 2Arkana Laboratories, Little Rock, Arkansas, USA; Little Rock, AR; Brigham and Women’s Hospital, Boston, MA; Hofstra Northwell School of Medicine at Hofstra University, Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.

Background: COVID-19 has been associated with a very high risk of AKI. The pathophysiology of the AKI is unclear with conflicting reports regarding the presence of direct infection of the kidney with SARS-CoV2.

Methods: Postmortem kidney biopsy was performed in adult patients with confirmed COVID-19 and stage 2/3 AKI. Biopsies were examined using light and electron microscopy. Immunohistochemistry and RNA in situ hybridization were performed for SARS-CoV2.

Results: 12 patients (83% male) with mean age of 70±13 years underwent biopsy. Mean baseline and peak creatinine were 1.0 and 5.3 mg/dL, respectively. Renal replacement therapy was required in 8 (67%) patients (Table 1). All 12 patients had a pathologic diagnosis of acute tubular injury with focal acute tubular necrosis (Table 2). There was no glomerulitis, vasculitis, or thrombotic microangiopathy. There were no characteristic viral particles on electron microscopy and there was no evidence of SARS-CoV-2 on immunohistochemistry or in situ hybridization.

Conclusions: AKI in patients with COVID-19 infection was associated with acute tubular injury and focal epithelial necrosis in all patients. There was no evidence of direct viral infection. It appears unlikely that SARS-CoV-2 causes renal injury by direct infection.
Methods: Liposomal nanoparticles displaying the SARS-CoV-2 spike protein trimer (S1 and S2) on their surface (virosmes) were generated. We evaluated spike protein and virosmes uptake by human KIM-1 expressing kidney epithelial cells and human kidney tubuloids, 3D structures of kidney epithelial cells. KIM-1-mediated uptake was compared to uptake by ACE2, a well-known receptor for SARS-CoV-2. Our recently discovered specific KIM-1 spike inhibitor, JB-1 was tested in its ability to block virosmes uptake by KIM-1 expressing cells. KIM-1 expression was augmented in the tubuloids by infection with adenovirus vector carrying human KIM-1 cDNA to examine if the virosmes uptake was enhanced. Protein-protein interaction characteristics between purified SARS-CoV-2 spike protein and S1 binding domain and purified KIM-1 were determined using microscale thermophoresis.

Results: KIM-1 expression on kidney epithelial cells markedly enhanced virosmes uptake, despite no change in ACE2 expression. This KIM-1 specific uptake was inhibited by JB-1. Human kidney tubuloids also endocytosed virosmes, and tubuloids with enhanced KIM-1 expression secondary to infection of KIM-1-adenovirus had increased uptake of virosmes. Using microscale thermophoresis the Kd for interaction between KIM-1 and SARS-CoV-2 spike protein and the receptor binding domain were 56.2±28.8 nM and 0.95±0.310 nM respectively.

Conclusions: KIM-1 is a receptor for SARS-CoV-2. KIM-1 specific uptake of the SARS-CoV-2 virosmes suggests that KIM-1 confers efficient SARS-CoV-2 binding in kidney epithelial cells when these cells are expressing KIM-1. The KIM-1 dependent virosmes uptake by 3D tubuloids indicates that this can be a valuable human cell model for studying SARS-CoV-2 interactions and testing for inhibitors. KIM-1 inhibitors, such as JB-1, can be potential therapeutics SARS-CoV-2 for COVID-19. Kidney tubular intraluminal and systemic circulating levels of KIM-1 ectodomain may be protective by acting as decoy receptor for the virus.

Morphological Evidence Suggests That Kidney Injury Molecule 1 May Serve as a Proximal Tubule Receptor for SARS-CoV-2

Ping L. Zhang,1 Mustafa M. Deequaljaj,1 Joseph Fullmer,2 Takaharu Ichimura,2 Misutl B. Amin,1 Joseph V. Bonventre1 2 Beaumont Health System, Royal Oak, MI; 1Brigham and Women’s Hospital, Boston, MA.

Background: Kidney injury molecule-1 (KIM-1), a type-1 transmembrane glycoprotein, has been well studied as a specific injury marker for proximal tubules (PT). KIM-1 functions as a receptor for apoptotic fragments through a phagocytic process. KIM-1 (also called TIM-1) serves as a receptor for hepatitis A virus and Ebola virus, and possibly for severe respiratory syndrome-coronavirus (SARS-CoV-1). During the pandemic spread of coronavirus disease 2019 (COVID-19), many patients have suffered from acute kidney injury (AKI) as well as lung damage, Viral uptake has been attributed to interactions with ACE2, a receptor for the virus. The goal of this study was to investigate whether there is kidney histological data that KIM-1 may also serve as a receptor for SARS-CoV-2 to infect the PT.

Methods: Two patients (one adult and one child) who died of COVID19 and 10 patients with AKI but no COVID19 (control group) were included in the study. All kidney tissue sections were stained for KIM-1 (monoclonal AKG7 antibody) and scored from 0 to 3+. Electron microscopy was used for examining uptake of virosomes. The results were analyzed using the Wilcoxon rank-sum test.

Results: Both COVID19+ patients had normal pre-mortem levels of serum creatinine (sCr) (adult 0.63 and child 0.17 mg/dl), whereas the control cases all had elevated sCr (1.9 to 7.0 mg/dl). Control renal biopsies revealed positive KIM-1 staining ranging from 1+ to 3+ along the surface of PT in a patchy pattern involving 20 to 80% of the cortex; no cytoplasmic granular materials were identified. By contrast, the KIM-1 staining in COVID19+ kidneys revealed spotty granular staining in the cytoplasm and diffuse 1+ to 3+ granular staining in the PT cytoplasm as well. The KIM-1 staining in COVID19+ kidneys was significantly lower than in the control kidneys, indicating active regulation in response to injury.

Conclusions: Proteinuria is common in COVID-19 infected patients and we studied serum-exposure, as a model of glomerular dysfunction and subsequent proximal tubule responses in our kidney MPS. Serum induces the expression and secretion of IL6 and IL8, suggesting a localized, pro-inflammatory tubule response. Our epigenetic studies validated the observed differences. Our study is one of the first to show KIM-1 expression in COVID+ kidneys revealed spotty granular staining in the cytoplasm and diffuse 1+ to 3+ granular staining in the PT cytoplasm as well. The KIM-1 staining in COVID19+ kidneys was significantly lower than in the control kidneys, indicating active regulation in response to injury.

Kidney Injury Molecule 1 Is a Receptor for SARS-CoV-2

Takaharu Ichimura,1 Mahmoud L. Nasr,1 Samuel Mon-Wei Yu,2 Yutaro Mori,1 Joseph V. Bonventre,1 1Brigham and Women’s Hospital, Departments of Medicine, Boston, MA; 2Harvard Medical School, Boston, MA.

Background: Acute kidney injury (AKI) is a common feature of Coronavirus disease 2019 (COVID-19) caused by SARS-CoV-2. Kidney Injury Molecule-1 (KIM-1) has been reported to be a receptor for Hepatitis A virus, and KIM-1 is a scavenger receptor in kidney epithelial cells. We hypothesized that KIM-1 is a receptor for SARS-CoV-2 and may play an important role in COVID-19-associated AKI.

also decreased (38 % of the WT, p<0.01). In kidney membranes from mice that received captopril or telmisartan for 2 weeks there was a reduction in ACE2 protein to the level of 37%, p<0.01 and 76%, p<0.05 of that of vehicle control mice, respectively. In lung membranes the expression of ACE2 was very low and not detected by western blotting but no significant differences in terms of ACE2 activity could be detected in mice treated with captopril (118% of control) or telmisartan (93% of control).

**Conclusions:** Genetic kidney ACE deficiency, suppressed ACE enzyme activity by Captopril or blockade of the AT1 receptor with telmisartan are all associated with a decrease in ACE2 expression in kidney membranes. These findings altogether suggest that ACE2 protein abundance at two potential target sites for SARS-CoV-2 infection is decreased or unaffected by RAS blockers. Since these medications do not increase ACE2 expression in lung or kidney epithelia, we conclude that they likely would not pose a risk for increased susceptibility to COVID-19.

**Noninvasive Mapping of the Cellular Response to COVID-19 via Urine Single-Cell RNA Sequencing (scRNAseq)**

Jennifer A. Schaub, Rynan Sohaney, Abhijit S. Naik, Rajasree Menon, Edgar A. Otto, Laura H. Mariani, Celine C. Berthier, Matthias Ketelzter, University of Michigan Health System, Ann Arbor, MI.

**Background:** COVID-19 is associated with a high incidence of AKI. Mapping the transcriptional profiles of kidney and urinary tract derived single cell populations can establish a framework to assess renal molecular response to COVID-19 and emerging treatment strategies.

**Methods:** Patients throughout the COVID-19 disease course were recruited to the study. A modification of our protocol (Arazi et al. Nat Immunol) allowed for immediate isolation of urinary cell pellets followed by 10X Genomics Chromium based scRNAseq.

**Results:** Urine scRNAseq data sets were generated from 13 COVID patients: age 50/+17, 7 males; 7 African Americans; urine sampling 11 days post SARS-CoV-2 diagnosis (IQR 5-29) with 8 in AKI at time of sampling. 25,994 single cell profiles passed QC with a median of 433 cells per sample [IQR 271 to 718]). Cellular clusters were annotated to immune (9780 cells, Fig: cluster 3-7), renal epithelial (4364, cluster 1) and bladder cells (4151, cluster 2). The SARS-CoV-2 receptor ACE2 was found in epithelial cells and co-expressed with CPEB3. The COVID-19 therapeutic target IL-6 was robustly detected in both myeloid and epithelial cells with co-expression networks linking IL-6 expression in proximal tubular epithelial cells to HMG1, VEGF and HIF signaling and to viral response networks in myeloid cells.

**Conclusions:** Urine single cells contain a spectrum of epithelial and immune cells expressing viral receptors of SARS-CoV-2 and therapeutic targets of emerging COVID-19 therapies offering a window to monitor renal cellular responses in COVID-19 trials.

**Stimulus and Cell-Specific Responses to Volume Depletion, Ischemia, and COVID-19**

Katherine Xu, Tian Shen, Jacob Stauber, Krzysztof Kiryluk, Vivette D. Agati, Jonathan M. Barasch. Columbia University Irving Medical Center, New York, NY.

**Background:** A stimulus-response map of the injured kidney might reflect a common response of the injured kidney (Rossa-Donati et al. J Am Soc Nephrol 31: 2020). Emerging COVID-19 therapies offering a window to monitor renal cellular responses in immune cells expressing viral receptors of SARS-CoV-2 and therapeutic targets of SARS-CoV-2 infection. Therefore, we investigated the gene expression profile of a broad range of immune cells using single-cell RNA sequencing (scRNAseq).

**Methods:** We developed a novel protocol (Arazi et al. Nat Immunol) allowing for immediate isolation of urine cells by lysis into a cell pellet followed by a 10X Chromium-based scRNAseq. We generated 25,994 single cell profiles from 13 COVID patients: age 50/+17, 7 males; 7 African Americans; urine sampling 11 days post SARS-CoV-2 diagnosis (IQR 5-29) with 8 in AKI at time of sampling. 25,994 single cell profiles passed QC with a median of 433 cells per sample [IQR 271 to 718]). Cellular clusters were annotated to immune (9780 cells, Fig: cluster 3-7), renal epithelial (4364, cluster 1) and bladder cells (4151, cluster 2). The SARS-CoV-2 receptor ACE2 was found in epithelial cells and co-expressed with CPEB3. The COVID-19 therapeutic target IL-6 was robustly detected in both myeloid and epithelial cells with co-expression networks linking IL-6 expression in proximal tubular epithelial cells to HMG1, VEGF and HIF signaling and to viral response networks in myeloid cells.

**Conclusions:** Urine single cells contain a spectrum of epithelial and immune cells expressing viral receptors of SARS-CoV-2 and therapeutic targets of emerging COVID-19 therapies offering a window to monitor renal cellular responses in COVID-19 trials.
