Results: Subjects were started on another steroid-sparing agent. The study was discontinued due to apparent lack of effect. ManNAc supplementation showed a trend towards proteinuria reduction, possibly linked to the degree of glomerular hyposialylation. Baseline plasma ManNAc levels in nephrotic subjects with normal eGFR were similar to those in subjects with normal renal function, but baseline plasma free NeuAc levels were elevated in nephrotic subjects with lower eGFR. This is consistent with NeuAc having high glomerular permeability and little tubular reabsorption. Plasma ManNAc levels peaked 2-4 h after dosing and returned to baseline after ~12 h. Plasma free NeuAc levels peaked ~10 h after dosing, remained elevated beyond 48 h, and continued to increase during twice daily dosing, particularly in subjects with low eGFR. There was no adverse event related to the use of the drug. Frequent monitoring of lymphocyte subsets is advised, as lymphocytes are increased in inflammation and therefore regularly monitored in patients with frequent relapses.

Conclusions: Oral ManNAc was safe and well tolerated in glomerular disease subjects. ManNAc supplementation showed a trend towards proteinuria reduction, possibly linked to the degree of glomerular hyposialylation. A phase 2 study is planned to include assessment of longer-term pharmacokinetics, efficacy and safety.

Efficacy and Safety of ACE Inhibitor and ARB Therapies in Primary FSGS: A Systematic Review and Meta-Analysis
Kirk N. Campbell,1 Natali Pennese,2 Andrea Zaffalon,3 Barbara Magalhaes,4 Marina Faiella,5 Dawn J. Caster,1 Jai Radhakrishnan,1 Vladimir Tesar,3 Howard Trachtman,4 Mt Sinai School of Medicine, New York, NY, 1Lattitude Consulting, Geneva, Switzerland; 2University of Louisville School of Medicine, Louisville, KY; 3Columbia University Medical Center, New York, NY; 4Charles University, General University Hospital, Prague, Czechia; 5NYU School of Medicine, NYU Langone Medical Center, New York, NY.

Background: Use of ACEi and/or ARBs (RASi) as conservative management to control proteinuria in primary and genetic focal segmental glomerulosclerosis (FSGS) following guideline recommendations based on other proteinuria-related kidney diseases. There is lack of consensus about the efficacy and safety of RASi therapies in primary and genetic FSGS, thus this systematic review aims to assess the benefits and risks of RASi therapies on renal outcomes in these patients.

Methods: English-language studies were searched in MEDLINE, Embase and Cochrane Central Register of Controlled Trials, from inception to April 2019. Cohort studies assessing efficacy (response to treatment and indicators of renal function) and safety outcomes in primary and genetic FSGS were selected. Study results were summarized as Ratio of Means (ROM) between baseline and follow-up measurements, or as Hazard Ratio (HR) using random effects models.

Results: We selected 30 studies of which only 5 were controlled trials. Only 8 assessed RASi as monotherapy while the rest studied them in combination with other drugs, mainly immunosuppressants (IS). On average, a 32% reduction on proteinuria (ROM-0.68; 95% CI: 0.47-0.98) and no change on eCrCl (ROM-0.95; 95% CI: 0.77-1.16) from baseline to variable follow-up periods was observed in patients treated with RASI therapy alone. A reduction of 72% in proteinuria was observed when RASI were combined with other drugs, mainly IS (ROM-0.24, 95% CI: 0.08-0.55). Published data did not allow to evaluate the eGFR ROM between follow-up and baseline and the

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

586
effect on the risk of reaching ESRD of RASI therapy alone. Only one controlled study reported adverse effects of RASI as monotherapy. Overall, the available evidence exhibits considerable heterogeneity in cohort baseline characteristics and study design. 

Conclusions: This review supports the tendency to observe a reduction of proteinuria in patients treated with RASI, and demonstrates the lack of strong evidence to quantify their effect on eGFR and their long-term impact on renal survival. The current lack of properly controlled studies in primary FSGS stresses the need for larger and better designed clinical trials to better understand the effect of RASI.

PO1889

Efficacy and Safety of Immunosuppressive Therapy in Primary FSGS: A Systematic Review and Meta-Analysis

Dawn J. Castor, Barbara Magalhães, Natali Pennese, Andrea Zaffalon, Marra fatelea, Kirk N. Campbell, Jai Radhakrishnan, Vladimir Tsear, Howard Trachtmann, University of Louisville School of Medicine, Louisville, KY; Latch N Point Cosmetic, The Geneva, Switzerland; 12Luhn School of Medicine at Mount Sinai, New York, NY; 3Columbia University Medical Center, New York, NY; 4Charles University, General University Hospital, Prague, Czechia; 5NYU School of Medicine, NYU Langone Medical Center, New York, NY.

Background: Focal segmental glomerulosclerosis (FSGS) is a rare condition which can lead to decline in renal function and progression to ESRD. Immunosuppressants (IS) are often used to treat primary FSGS. However, their efficacy and safety is not clearly established. The aim of this work was to collect the current knowledge on the clinical effectiveness and safety of IS in the treatment of primary FSGS.

Methods: MEDLINE, EMBASE and Cochrane Central Register of Controlled Trials were searched for English-language studies on primary FSGS from inception to 2019. Clinical outcomes of interest were changes from baseline to post-treatment on renal survival, and effect on eGFR and their long-term impact on renal survival. The current lack of properly controlled studies in primary FSGS stresses the need for larger and better designed clinical trials to better understand the effect of RASI.

Conclusions: This systematic literature review supports that patients treated with IS have on average, a reduction in proteinuria between baseline and varying follow-up periods. Reported changes from baseline to follow-up in CrCl and eGFR are contrasting methods as Ratio of Means (ROM) between follow-up and baseline measurements or as Hazard Ratio (HR).

Results: We included 100 articles. Substantial heterogeneity was observed in patient baseline characteristics and study design. Most studies assessed treatment with corticosteroids alone or combined with other drugs, mainly other IS. On average, patients treated with IS showed a reduction of proteinuria (14 studies, ROM=0.34, 95% CI 0.25-0.46). Pooled studies showed a lower CrCl at the end of the follow-up compared to baseline (ROM=0.77; 95% CI 0.71-0.83). In contrast, eGFR measurements suggested no change from baseline to follow-up (16 studies, ROM=0.92; 95% CI 0.84-1.01). IS therapy had uncertain effect on reducing the risk of reaching ESRD (HR=0.79; 95% CI 0.4-1.2). Importantly, IS therapy was not monitored in most studies.

Conclusions: This review supports the beneficial effect of IS treatment on proteinuria and renal survival. Further studies with IS therapy are recommended as insufficient data exists to reliably assess the effect of IS in primary FSGS patients.

PO1890

The Epidemiological Comparison Between North American and Japanese FSGS/Minimal Change Disease Patients

Takafumi Nakano,1 Sho Sugiyama,1 Laura H. Mariani,1 University of Michigan, Ann Arbor, MI; 2Nagoya University Graduate School of Medicine, Nagoya, Japan.

Background: Few studies directly compared the presentation and treatment response of nephrotic syndrome (NS) considering the racial and ethnic differences of different countries.

Methods: NEPTUNE is a prospective cohort study of NS across 23 North American centers. Nagoya Kidney Disease Registry (N-KDR) is a Japanese retrospective cohort in Nagoya area. Nephrotic FSGS/MCD adults who received immunosuppressive therapy (IST) were included. Demographics and laboratory data of the patients were compared. Time to complete remission (CR: UPCR<0.3) from the start of IST were evaluated considering patient baseline characteristics and study design. Most studies assessed treatment with corticosteroids alone or combined with other drugs, mainly other IS. On average, patients treated with IS showed a reduction of proteinuria (14 studies, ROM=0.34, 95% CI 0.25-0.46). Pooled studies showed a lower CrCl at the end of the follow-up compared to baseline (ROM=0.77; 95% CI 0.71-0.83). In contrast, eGFR measurements suggested no change from baseline to follow-up (16 studies, ROM=0.92; 95% CI 0.84-1.01). IS therapy had uncertain effect on reducing the risk of reaching ESRD (HR=0.79; 95% CI 0.4-1.2). Importantly, IS therapy was not monitored in most studies.

Results: Eighty-eight NEPTUNE and 302 N-KDR cases were eligible. The median of patient follow-up was 6 years (range 0.2-11.8 years). Japanese patients had a higher rate of response to the IST. FSGS, hypertension, higher albumin, and lower eGFR were considered as shared predictors of poor treatment response between both cohorts.

Conclusions: Japanese FSGS/Minimal Change Disease Patients

PO1891

Long-Term Renal Outcomes in Focal Segmental Glomerulosclerosis

Benjamin M. Forster, Robert Nee, Stephen W. Olson. Walter Reed National Military Medical Center, Bethesda, MD.

Background: Focal Segmental Glomerulosclerosis (FSGS) is a glomerular disease defined by pathomonic histopathology but is caused by multiple mechanisms of disease, not all of which have been fully elucidated. Therefore, the reported renal prognosis, treatment strategies, and treatment response has varied significantly in previous small case series. We sought to analyze long term renal survival and associated risk factors in the largest cohort over the longest period of follow up described to date.

Methods: We performed a retrospective cohort study on all patients in the NEPTUNE database. Only patients with complete data were included. We searched for English-language studies from inception to 2019. Clinical outcomes of interest were changes from baseline in proteinuria, and renal function (eGFR or CrCl) and survival (ESRD, renal failure, doubling of creatinine, or death). We performed extensive data collection and analyzed using STATA 16.

Results: We identified 348 patients with biopsy proven FSGS with a mean follow up of 9.5 years. The majority were black, male, and under 40 years old. Progression to end stage kidney disease (ESKD) was 14%, 25%, and 35% at 5 years, 10 years, and 15 years after diagnosis, respectively. More patients with nephrotic range proteinuria progressed to ESKD (20%, 31%, and 49% at 5, 10, and 15 year follow up, respectively) compared to non-nephrotic range proteinuria (13%, 20%, and 31% at 5, 10, and 15 year follow up, respectively), and no significant proteinuria (6%, 14%, and 23% at 5, 10, and 15 year follow up, respectively) p=0.04. Overall progression to stage 3 chronic kidney disease (CKD3) was 32%, 40% and 50% at 5, 10, and 15 years after diagnosis, respectively. Full remission from initial treatment was associated with a substantial reduction in progression to ESKD (2%, 4%, and 7% at 5, 10, and 15 year follow up, respectively) compared to partial remission (12%, 21%, and 30%) and no remission (27%, 45%, 63%), p<0.001.

Conclusions: We present the largest cohort of biopsy proven FSGS cases over the longest follow up period to date. Approximately one third of all FSGS patients develop ESKD and half developed CKD3 within 15 years. Proteinuria significantly increased the risk of progression to ESKD. Achieving a full or partial remission after initial treatment significantly decreased the risk of progression to ESKD.

PO1892

Cellular Senescence Is Associated with Faster Progression of Renal Disease in Adults with Focal Segmental Glomerulosclerosis: A 6-Year Prospective Cohort Study

Elisa Russo,1 Wesley V. Veiga,2 Michelle Saio,1 Daniela Picciotto,1 Francesca Viazzi,1 Elisa Russo,1 Leda Cipriani,1 Annalisa Carta,1 Francesco Costiglioli,1 Gabriele Gaggero,2 Pasquale Esposito,1 Giacomo Garibotto,2 Laura Poggi,2 1Division of Nephrology, Dialysis and Transplantation, Department of Internal Medicine, University of Genova and IRCCS Ospedale Policlincio San Martino, Genova, Italy; 2Division of Pathology IRCCS Ospedale Pollicino San Martino, Genova, Italy.

Background: A current hypothesis is that an acceleration of cellular senescence, a state of irreversible cell cycle arrest mediated by cyclin-dependent kinase inhibitors, is an important impaired renal function in FSGS. The role of cellular senescence in patients with glomerular diseases is unknown and if senescence is really associated with more disease progression is still not understood.

Methods: The hypothesis that cell senescence represents a proximate mechanism by which the kidney is damaged in focal segmental glomerulosclerosis (FSGS) was investigated in 26 consecutive kidney biopsies from FSGS patients (Age 50 ± 3, M/F 12/14, eGFR 72 ± 3.7, proteinuria 2.3 ± 0.6) who were incident in a Northern Italy Nephrology Centre. All biopsies were classified as the not otherwise specified (NOS) FSGS subtype.

Results: Cell senescence (p16INK4A, SA-b-galactosidase stains) was upregulated both in glomeruli (mainly in podocytes) and tubule cells in FSGS as compared to controls (p=0.05-0.01). Tubular p16INK4A correlated with tubulointerstitial fibrosis. Similar relationship between eGFR and senescent fibrotic glomerulosclerosis (FSGS) was observed in 26 consecutive kidney biopsies from FSGS patients (Age 50 ± 3, M/F 12/14, eGFR 72 ± 3.7, proteinuria 2.3 ± 0.6) who were incident in a Northern Italy Nephrology Centre. All biopsies were classified as the not otherwise specified (NOS) FSGS subtype.

Results: Eighty-eight NEPTUNE and 302 N-KDR cases were eligible. The median of patient follow-up was 6 years (range 0.2-11.8 years). Japanese patients had a higher rate of response to the IST. FSGS, hypertension, higher albumin, and lower eGFR were considered as shared predictors of poor treatment response between both cohorts.
PO1893
Clinicopathological Characterization of Focal and Segmental Glomerulosclerosis in a Dominican Republic Sample
Eliana Dina-Batlle,1 Limber I. Rojas,2 Mirtha C. Almanzar,2 Hector A. Pantaleon,1 José J. Sánchez,3 Hôpital Metropolitano de Santiago, Santiago, Dominican Republic; 4Hospital General de la Plaza de la Salud, Santo Domingo, Dominican Republic; 5Pontificia Universidad Católica Madre y Maestra, Santiago de los Caballeros, Dominican Republic.

Background: There are limited recent epidemiological and clinicopathological behavior reports on FSGS in the Caribbean population. The aim is to identify clinical characteristic, epidemiological trend and treatment response of patients with diagnosed FSGS and their different variants in a Dominican Republic sample.

Methods: Cross-sectional study of performed transcutaneous native kidney biopsy taken in an interval date from years 2018-2019 of two separate nephrology consult from Dominican Republic. Diagnosed FSGS biopsy reports available and biochemical laboratories (creatinine, BUN, 24 Proteinuria, cholesterol, triglycerides, hematuria) within the date of biopsy were analyzed. Histopathological analysis of foot process effacement (FPE) degree reported and nephrotic syndrome (NS) presentation was correlated to primary or secondary cause of FSGS. Also, description of FSGS variants and response to the different treatments implemented at the time of data collection, overlapping comorbidities and serology were taken in notice.

Results: 49 biopsies were analyzed with FSGS. NOS variant was the most common (72%), tip lesion (8%) and collapsing (6%), with no reported perihilar or cellular variants and 10% reported as unclassified biopsy of FSGS. Biopsy with diffuse FPE (>90%) 24 presented with nephrotic syndrome and 8 did not (p=0.010). Remission in biopsy with described diffuse foot process effacement (DFPE) with unidentified cause 32% had complete remission (CR) (serum albumin >3.5g/dl or <300 mg/24h protein), 16% had partial remission (PR) (>50% reduction basal proteinuria, subnephrotic proteinuria), and 20% did not remitted at a 6 month period (p=0.921). Steroids and calcineurin inhibitors treatment were significantly associated with CR in FSGS with DFPE with unidentified cause (p=0.029, p=0.014 respectively).

Conclusions: Biopsies analyzed in a 2 year period presented NOS as the most common variant while perihilar or cellular variants were not reported. In the sample studied the degree of FPE was associated to NS presentation. The use of steroids and calcineurin inhibitors in suitable patients is significantly associated with remission of disease. The FPE degree, biopsy, clinical manifestations of patients and history represent the best tools for correct diagnose and treatment.

PO1894
Differentiating Focal and Segmental Glomerulosclerosis
Afonso Santos,1 Anna Lima,1 Ana Gaspar,1 Ana C. Brás,1 Pedro Pereira Campos,3 Rita Theias Manso,3 Karina Soto.1 1Nephrology Department, Hospital Professor Doutor Fernando Fonseca EPE, Lisboa, Portugal; 2Pathology Department, Hospital Professor Doutor Fernando Fonseca EPE, Lisboa, Portugal.

Background: FSGS is a histological pattern of kidney injury associated to broad causes and pathogenesis. FSGS can be primary, genetic or secondary to other conditions. Differentiating these subclasses is crucial for management and prognosis, but there is no consensus on the criteria that are not suitable.

Methods: In a retrospective analysis of 359 kidney biopsies were identified patients with FSGS histological diagnosis and secondary FSGS were identified based on clinical and histological data. Genetic FSGS was considered if they present at least one of the following:a) nephrotic syndrome (NS) resistant to corticosteroids; b)NIS with focal albuminuria/cNS with focal foot process effacement or d)non-nephrotic proteinuria with diffuse foot process effacement. Each group was divided in immunosuppression treatment (IST) or only supportive treatment (ST) groups. Renal and survival outcomes were assessed.

Results: Among 66 FSGS patients, 65% were males, 71% non-black, 74% had HTN; 26% diabetes; median eGFR 26.5±14.7mL/min/1.73m2 (IQR 13.5-48.1), 24-hr U-protein 4.4g (IQR 2.5-7.6). Globally, 38% (n=25) progressed to ESKD and mean time to RRT was longer in IST group (p=0.37). According to the applied criteria 52% (n=34) were classified as having secondary FSGS, 23% (n=15) primary and 25% (n=17) as genetic FSGS. Among primary FSGS patients 40% received IST. In ST group 25% progressed to ESKD in a median time to RRT of 24 months (SD±21.7) vs 13% in 66m (SD±31.3) in IST group. Among secondary FSGS, 17.6% received IST. Of them, 50% developed ESKD in 31.7m (SD±28.6) vs ST group with 46% progression to ESKD in 12m (SD±28.7). From the genetic group 59% were in IST group and 30% progressed to ESKD in 12m (SD±27.1) vs ST group with 29% ESKD in 42m (SD±27.1).

Conclusions: FSGS etiology is not straightforward in most patients. Since IST can be inappropriate and potentially harmful in some FSGS subclasses, it is crucial to identify patients that respond to the different treatments and are likely to benefit from IST.

PO1895
APOL1-High Risk Genotype Is Highly Prevalent Among Brazilian Patients with Collapsing Glomerulopathy, an Association That Manifests from Adolescence to Early Middle Adulthood
Priel D. Neves,1 Andrea Watanabe,1 Elices H. Watanabe,1 Lívia B. Cavalcante,1 Denise M. Malheiro,2 Lectícia Jorge,1 Matt G. Sampson,2 Luis D. Batllí,1 Universidade de Sao Paulo, Sao Paulo, Brazil; 2Boston Children’s Hospital, Boston, MA.

Background: Collapsing glomerulopathy (CG) is associated with fast progression to ESKD. CG has been linked to specific infections, drugs and immune disorders, the APOL1 high-risk genotype (HRG) and monogenic pathogenic variants.

Methods: 70 Brazilian patients of all ages with the diagnosis of idiopathic CG were submitted to PO1891 genotyping and 51 of them to broad genetic evaluation through whole exome sequencing, a 62-gene panel directed to glomerulopathies or Sanger sequencing. Based on retrospective analyses of medical records, the frequency and clinical impact of HRG were analyzed.

Results: Thirty-three (47.1%) patients harbored an HRG. Monogenic pathogenic or likely pathogenic variants were identified in 5 APOL1 high-risk genotype (LRG) individuals, affecting the COL4A5 (2 cases), COQ2, MYH9, and PLC1E1 genes. Gender distribution did not differ between the HRG and LRG groups. Patients with HRG were less often self-declared Caucasian than LRG individuals (36.4% vs 89.2%, p<0.001). While the age of disease onset was not significantly different between the HRG and LRG groups [21 (17-33) vs 25 (18-31) years, p=0.755], patients harboring HRG manifested the disease from adolescence to early middle adulthood (10-44 years) more frequently than LRG individuals (97% vs 70.3%; OR=13.54, CI 2.01-150.00; p=0.004). HRG patients presented more often family history of renal disease than individuals with LRG (36.4% vs 10.8%, p=0.01). HRG patients, however, did not differ from individuals with LRG or with monogenic/likely monogenic etiologies with respect to hematuria, hypertension and eGFR decline. The transplant rate did not differ between patients with HRG and patients with LRG with LRG without identified Mendelian disease, whereas the rate of disease relapse in the graft was significantly lower in the first group (0 vs 33.3%, p=0.02).

Conclusions: APOL1 HRG is highly prevalent among Brazilian patients with CG, suggesting a common role of side effects in genetic-environmental interaction in the pathogenesis of this glomerulopathy. Our findings strongly suggest that HRG-associated CG is a disease that manifests primarily from adolescence to early middle adulthood.

PO1896
Collapsing Glomerulopathy and Vascular Lesions
Mapes T., L. Lauriotti, Priel D. Neves, Cristiane B. Dias, Luis Yu, Leonardo Testagrossa, Denise M. Malheiro, Viktoria Woronik, Lectícia Jorge, Universidade de Sao Paulo, Sao Paulo, Brazil.

Background: Collapsing Glomerulopathy (CG) has usually been associated with rapidly progressive renal failure. Some authors have found that vascular injury could be associated with poor outcomes. The goal of the study was to compare patients with and without vascular lesion on renal biopsy.

Methods: A retrospective analysis was performed on all CG cases diagnosed by kidney biopsy between 1996 and 2019 at the University of Sao Paulo. Clinical and laboratory data were collected at baseline and at the end of follow up. We excluded cases of chronic viral infection(8 HIV, 4 HCV, 2 HBV) drugs, any suspected immune-mediated disease(4 SLE) and diabetes(3). We analyzed histological, clinical and follow-up data and compared patients with and without vascular lesions in biopsy.

Results: Clinical features of the groups with and without vascular lesions are summarized in Table 1. There was no significant difference in gender, albumin, proteinuria, among the two groups. Moreover, the immunofluorescence of the renal biopsies showed no difference in IgM and C3 deposits in glomeruli. Patients with vascular lesions were older and presented with worse renal function.

Conclusions: Vascular lesion in CG is associated with worse renal function and it is more prevalent in this glomerulopathy. Our findings strongly suggest that HRG-associated CG is a disease that manifests primarily from adolescence to early middle adulthood.
PO1897

The Dual Endothelin/Angiotensin II Receptor (ET, R/AT, R) Antagonist Sparsentan Slows Renal Disease, Improves Lifespan, and Attenuates Injury Loss in Alport Mice: Comparison with Losartan and Atrasentan

Dominic F. Cosgrove1, Brianna M. Dulfek1, Duane C. Delinomt,1 Daniel T. Meehan,2 Gina C. Samuelson,1 Jared Hartsook,2 Grady Phillips,2 Ruth Gill,2 James Hasson,2 Celia P. Jenkinson,1 Radko Komers,1 MichaelAnne Tam,2 Helen Rakesh R E R antagonist losartan (LS), and the ET(B)/AT(B) antagonist sparsentan (SP60, SP120) on lifespan and proteinuria, and of SP and LS on hearing loss and inner ear pathology.

Methods: Wild type (WT) and AS mice were gavaged daily with vehicle (V), 60 or 120 mg/kg of SP (SP60, SP120), LS (20 mg/kg; 3-4 W) or LS (10 mg/kg from 4 W), or ATR (7.5 mg/kg females or 10 mg/kg males) in the drinking water. Two studies were conducted: early intervention for hearing from 3-8.75 W (V, SP120 and LS), and for lifespan with treatment from 3 W (V or SP120, LS or ATR). Urinary protein/creatinine ratio (UP/C) was assessed weekly. The auditory brainstem response (ABR) was used to assess hearing ability and sensitivity to noise at 8-8.75 W. The cochleae were preserved and strial pathology determined by transmission electron microscopy.

Results: SP60 significantly (P<0.05) increased median lifespan compared to any other group (Figure 1). At 8 W, only SP120 significantly (P<0.05) attenuated the increase in UP/C compared to V (UP/C mg/mg creatinine day–1; 42±18 ATR, 39±18 SP60, 20±3 SP120). UP/C at 11 W in SP120 mice was significantly attenuated (P<0.05) vs. LS mice. SP120 significantly improved post-noise ABR thresholds at 16 kHz vs. V mice (P<0.05). LS had no effect. Dysmorphology of the stria vasularis was noted in LS but not in SP120-treated mice.

Conclusions: SP120 in AS mice extended lifespan beyond that of mice treated with SP60, LS, or ATR and attenuated noise-induced hearing loss compared to LS. Sparsentan may therefore offer a novel, dual-therapeutic approach in AS by reducing both renal injury and hearing loss.

PO1898

Long-Term Outcomes of Tacrolimus Treatment for Idiopathic Membranous Nephropathy

Aiakterini K. Nikolopoulou,1 Sarah Gleeson,1 Rakesh Duttani,1 Marie B. Condon,1 Tom Cairns,1 Jeremy B. Levy,1 Liz Lightstone,2 Stephen P. McAdoo,1 Frederick W. Tam,1 Charles D. Pusey,1 Megan Griffith,1 Imperial College Healthcare NHS Trust, London, United Kingdom; Imperial College London Faculty of Medicine, London, United Kingdom.

Background: Tacrolimus (TAC) is effective for the treatment of membranous nephropathy (MN).

Methods: Retrospective study of longterm outcomes of 111 patients (pts) with MN treated with TAC from January 2000 to June 2018.

Results: Demographics: Table 1. Treatment: 91/111 TAC monotherapy, 20/111 dual therapy with mycophenolate + TAC. All pretransplant treated with ACRU/ARB. Median follow up (FU) 68 months (IQR 33-115). 93/111 pts (84%) reached Partial Remission (pPR) reduction of proteinuria <50% and <300mg/mmol) at 5.1 months (median, IQR 2.11, 76/111 (69%) also reached Complete Remission (cPR <50mg/mmol) at 15.2 months (9.3-24). 18/111 (16%) did not respond to initial treatment with TAC and 3/111 progressed to ESRD rapidly, 9/18 were treated with Rituximab (RTX), 4/18 with cyclosphamide (CYP) and steroids. Only 4 achieved remission, all in the RTX group. 2 lost to FU. 48/83 (51%) of pts that achieved remission relapsed after 22 months (14-34) (Figure 1) following withdrawal of TAC with reduction of immunosuppression. 28/48 were retreated with TAC and all achieved remission, 15/48 treated with RTX, remission in 11/15. 3/48 treated with CYP and steroids (2/3 remission, 1 lost to FU). No treatment in 2, 11/28 cases retreated with tacrolimus and had a second relapse. At 3 months on TAC there was a reduction of eGFR from baseline (89±16 to 78±16 ml/min (48-99, 0.001). Figure 2). Renal function stabilised thereafter during the follow up period to 10 years. 10/9% pts reached ESRD and 5/10 within 12 months from diagnosis;these pts had a lower baseline eGFR 48ml/min (23-61).

Conclusions: TAC can be an effective treatment for MN with a relatively rapid response. Lack of response to TAC and low eGFR at presentation are associated with non-responders to treatment (immunosuppression and ESRD). Relapse is common necessitating repeat immunosuppression. Most pts maintain eGFR in the longterm.

Funding: Clinical Revenue Support

Noninvasive Diagnosis of Primary Membranous Nephropathy Using Anti-Phospholipase A2 Receptor (PLA2R) Antibodies: A Validation Study
Shane A. Bobart,1 Shahzad Tehrani,1 Cristiana Andrades Gómez,2 Sanjeet Sethi,1 Callen D. Giesen,1 John C. Liesek,1 An S. De Vries,2 Fernando C. Fervenza,11 Mayo Clinic Minnesota, Rochester, MN; 2Hospital Universitario Virgen del Rocio, Sevilla, Spain; 3AE Sant-Jan Brugge-Oostende AV, Brugge, Belgium.

Background: Kidney biopsy is the current gold standard to diagnose membranous nephropathy (MN). Approximately 70-80% of patients with primary MN have circulating anti-PLA2R antibodies. We sought to validate our previous work showing that in a proteinuric patient with preserved renal function (eGFR <60 ml/min/1.73m²) and no associated conditions (e.g. autoimmunity, malignancy, infection, drugs, paraproteinemia) a positive anti-PLA2R antibody test by simultaneous ELISA and IFA is a valid strategy to classify MN and guide clinical decision making.

Methods: The medical records of all Mayo Clinic patients with positive serum anti-PLA2R antibody tests by both ELISA and IFA between July 2018 and April 2020 were reviewed.

Results: A total of 1522 anti-PLA2R antibody tests were ordered in 1112 unique patients, yielding 128 positive results. We excluded previously reported patients (n=33), renal transplant recipients (n=5), no biopsy available (n=18), and pediatric cases (n=2). In all 70 remaining patients, the primary biopsy diagnosis was MN. Associated disease was identified in 28 cases (autoimmunity = 10, malignancy = 6, NSAID = 4, Hepatitis = 3, monoclonal protein = 5). Of the 42 patients with negative work up for secondary causes, 32 (76%) had preserved renal function. One patient had fibrin thrombi and neutrophils in the capillary loops, and one patient had 1 glomerulus with focal glomerular basement membrane necrosis. Of these findings, none met the criteria for diagnosis or management. Among the 10 patients with eGFR <60 ml/min/1.73m², additional findings that altered the treatment plan included acute interstitial nephritis (n=1) and superimposed diabetic nephropathy (n=1).

Conclusions: The study extends our previous observations that in patients with preserved renal function and no evidence of secondary causes or diabetes, a positive PLA2R test by simultaneous ELISA and IFA confirms the diagnosis of MN.

PO1902
Association Between Anti-Complement Factor H Antibodies and Renal Outcome in Primary Membranous Nephropathy
Yu Kagaya,1 Norifumi Hayashi, Keiji Fujimoto, Hiroki Adachi, Kengo Furuchi, Hitoshi Yokoyama. Department of Nephrology, School of Medicine, Kanazawa Medical University, Uchinada, Japan.

Background: The complement factor H (CFH) regulates activation of the alternative complement pathway. Autoantibodies against CFH have been involved in progressive renal dysfunction in a case with primary membranous nephropathy (MN) (Ronco P. et al. N Engl J Med 2018;379:1779-81). However, the prevalence and the roles of anti-CFH antibodies in the clinical outcome of MN remains unclear.

Methods: We investigated retrospectively 36 Japanese patients with primary MN (23 males, 13 females; age 64.5 [59-72] years old) and 18 healthy normal controls (8 males, 10 females, age 31 [27-38] years old). Serum anti-CFH antibody titers were measured by enzyme-linked immunosorbent assay (Vidia Vestatec, Czech Republic) to evaluate the association between anti-CFH antibody titers and the clinical outcome of MN patients.

Results: Anti-CFH antibody titers were significantly higher in MN patients as compared with normal controls [4.69 [3.60-6.38] RU/ml vs. 0.0 [0.0-0.0] RU/ml, p <0.001]. Twenty-eight patients were classified into the anti-CFH antibody positive group. The other 8 patients were classified into negative group. According to the Kaplan-Meier method, no significant difference was observed in the complete or incomplete remission rate of proteinuria, the incidence of renal dysfunction by the 30% reduction of estimated glomerular filtration rate (eGFR) and 50% elevation of serum creatinine (s-Cr) levels between the anti-CFH antibody positive group and the negative group of MN patients, however. In MN patients, anti-CFH antibody titer was selected an independent unfavorable predictor of renal dysfunction in Cox proportional hazards analysis adjusted by age, gender, sCr levels, proteinuria (g/24h), anti-CFH antibody titer and immunosuppressive therapy (adjusted hazard ratio (HR) 1.344, 95% confidence intervals (CI) 1.038 to 1.741, p=0.025 for 30% reduction of eGFR, adjusted HR 1.930, 95% CI 1.108 to 3.363, p=0.020 for 50% elevation of sCr).

Conclusions: These data suggested that anti-CFH antibodies may be involved in the deterioration of renal function in primary membranous nephropathy.

PO1903
Concurrent Anti-Glomerular Basement Membrane Nephritis and Membranous Nephropathy

Background: Anti-gbm nephritis is an uncommon entity with a rapidly progressive course. The concurrence of anti-gbm nephritis with membranous nephropathy (MN) is rare and poorly understood. We report a single center case series of this dual glomerulopathy with emphasis on presenting features, course, and outcome.

Methods: A total of 12 cases of combined anti-gbm nephritis and MN were identified from the archives of the Columbia Renal Pathology Laboratory over the past 18 years. Presenting clinical, histopathologic and laboratory data with follow up were obtained by chart review.

Results: The cohort of 12 cases included 7 men and 5 women with age range 18-81 years. The most common presenting feature was AKI (mean creatinine 9.3 mg/dl), with one patient having pulmonary symptoms. Positive anti-gbm serumology was available at presentation for 11 cases, 5 with titers > 100 au/mL, and all were ANCA negative. Of those tested the majority were PLA2R negative. Patients were predominantly Caucasian (N = 9). All patients required hemodialysis (HD) at presentation, and two patients, a 28-year-old woman and an 81-year-old woman had renal recovery with the latter having a stable creatinine of 2.0 mg/dl after 11 months later. Treatment regimens included the following: cyclophosphamide, plasmapheresis, and prednisone (N=9); cyclophosphamide and prednisone (N=1), prednisone and plasmapheresis (N=1) and rituximab alone (N=1).

Conclusions: Combined anti-gbm and MN is a rare entity presenting with severe AKI at presentation. Renal recovery is uncommon. High percentage of crescents are consistent with poor outcomes. Treatment and course are dominated by anti-gbm nephritis. The MN component is predominantly PLA2R negative, and further studies into pathogenesis are needed.

PO1904
Recurrent Membranous Post Transplantation: Histopathology, Treatment, and Outcomes
Sarah Gleeson,1 Aikaterini K. Nikolopoulou,2,8 Megan Griffith,2,8 Marina Loucaidou,1 Michelle Willcomb,1 Candice A. Roufosse,1 Imperial NHS Healthcare Trust, London, United Kingdom; Imperial College London Faculty of Medicine, London, United Kingdom.

Background: Membranous nephropathy (MN) recurs in 30-45% of transplants. Reported recurrence rates are higher in centres that perform surveillance biopsies. Optimal treatment is unknown. We examined recurrent MN in our cohort in terms of their histopathology, treatment and outcomes.

Methods: Patients with MN as the cause of their esrfr who were later transplanted were identified from an in-house database. Further data was collected from the electronic health record.

Results: 36 patients with a diagnosis of MN were transplanted. Mean follow up was 6.4 ± 4.2 years. 41.6% had a rejection episode (mean time from transplant 0.42±0.15 years). Overall there was 22% graft loss (mean time 6.5 ± 3.7 years), 11% deaths (8.6 ± 2.3 years from transplant) and 6% deaths with functioning grafts (mean time 6.9 ± 2.3 years). Mean eGFR at 3 months and 1 year were 48.1 ± 18.5 and 48.1±14.5 ml/min/1.73 m². 30/36 patients had at least one biopsy following transplantation. Of those whose biopsies did not show recurrence, the mean time to the most recent biopsy was 2.9±2.7 years (range 0.02-9.3). 8/36 patients (22%) had recurrent MN, 7 detected on indication biopsy and 1 on surveillance biopsy. The mean time to recurrence was 1.9±1 years (range 0.09-4.46 years). Granular C4d staining of the capillary wall was detected in 6/8 biopsies prompting immunofluorescence and electron microscopy, leading to the diagnosis of recurrent MN. Histological anti-PLA2R staining was positive in 3/8 biopsies. 2/8 patients had donor specific antibodies. In the 4 patients with clinically significant proteinuria rituximab was used to treat with a complete or partial response in all patients (mean time 22.5±16 months [range 4.4-3.8 months]). There are no significant differences in rejection, graft loss, death or death with functioning graft between those with recurrence and those without recurrence in our cohort.

Conclusions: Recurrent MN was frequent but not associated with increased allograft failure in our programme, with the use of rituximab in selected cases. Granular C4d staining of the glomerulus in transplant patients with MN could prompt further investigation with immunofluorescence and electron microscopy to look for recurrent disease.

Secondary Polycythemia Associated with Membranous Nephropathy
Rakameshrina Thotakura, Suman Siddanreddy, Sruithi Kanuru, Aditya Kadiyala, University of Arkansas for Medical Sciences, Little Rock, AR; Baptist Health, Little Rock, AR, University of Maryland Medical System Corporation, Baltimore, MD, Central Arkansas Veterans Healthcare System John L McClellan Memorial Veterans Hospital, Little Rock, AR.

Introduction: Polycythemia has been recognized as a common occurrence in certain renal diseases such as cystic diseases of the kidney, renal cancer, tuberous sclerosis and hyperephrinosis. However, polycythemia in association with membranous nephropathy has rarely been reported. Here we report a case of secondary polycythemia from membranous nephropathy. Although the mechanism of this phenomenon is unclear, decreased effective circulating volume leading to hypoxia and thereby polycythemia seems to be the most likely explanation.

Case Description: 37-year old white male with Hypertension, OSA using CPAP, tobacco use was admitted with 40-lb weight gain and anasarca. 24-hour urine collection revealed 17-gram protein excretion with serum albumin of 1.1 and marked hyperlipidemia. Kidney biopsy revealed membranous nephropathy. Staining for PLA2R and THSD7a were negative within the glomerular deposits. Evaluation for secondary causes of membranous nephropathy was negative for ANA, RPR/syphilis antibodies, Hepatitis, HIV, ANCA, Anti-GBM Ab and normal C3,C4 levels. CT of chest was negative for overt malignancy or hepatosplenomegaly. Patient’s hemoglobin ranged between 16.5 – 18.5 g/dl (ht 52-60%). Serum erythropoietin level was 12.3 IU/L (Normal 5-30IU/L) with corresponding Serum Ferritin levels were 1951 IU/L (Normal <300 IU/L). Serum hepcidin was 1.7 pmol/L (Normal<5 pmol/L). Patient was manifested with polyphagia, polydipsia and erythroblastopenia. He was referred for prophylactic anticoagulation. Follow up labs to evaluate response to therapy are currently pending. It is yet to be seen if polycythemia resolves with remission of membranous nephropathy.

Discussion: Polycythemia is seldom seen in patients with membranous nephropathy. We postulated that hypoxia induced by decreased renal perfusion is the main trigger for polycythemia. However, it is puzzling as to why more patients with membranous nephropathy are not polycythemic. This leads us to believe that there might be some unique processes leading to polycythemia in membranous nephropathy, as in this patient, where the hypoxia is augmented by a condition which was further enhancing the risk of thromboembolism in such patients whose risk of hypercoagulability is already high in setting of severe hypoalbuminemia. Hence, prophylactic anticoagulation should strongly be considered in these patients.

Glu...r Syndrome in African Americans

Andrew A. Moses, Syed A. Husain, Woon Ahn. Columbia University Irving Medical Center, New York, NY.

Introduction: Nephrotic syndrome caused by focal segmental glomerular sclerosis (FGS) in African Americans is known to have a poor prognosis and frequent treatment failure. Tip variant FSGS connotes good prognosis, usually responsive to calcineurin inhibitors (CNI) and steroid. We present a case of CNI-resistant tip lesion FSGS requiring plasma exchange (PLEX) and rituximab.

Case Description: A 25-year-old African-American male, initially presenting to outpatient clinic for edema associated with proteinuria. He had a past medical history of seizure disorder controlled with zonisamide. He trialed hydrochlorothiazide and an ACE inhibitor (CNI) and steroid. We present a case of CNI-resistant tip lesion FSGS requiring plasma exchange (PLEX) and rituximab.

Case Description: A 25-year-old African-American male, initially presenting to outpatient clinic for edema associated with proteinuria. He had a past medical history of seizure disorder controlled with zonisamide. He trialed hydrochlorothiazide and an ACE inhibitor (CNI) and steroid. We present a case of CNI-resistant tip lesion FSGS requiring plasma exchange (PLEX) and rituximab.

Discussion: Glomerular tip lesion is more common in European Americans and associated with a favorable outcome compared to other subtypes of FSGS. Resistance to immunosuppressive treatment is not always associated with resistance to other treatment modalities. PLEX and rituximab should be considered in glomerular tip lesion in African Americans.

PO1911

Utility of Immunofluorescent Intensity of IgG3 and Phospholipase A2 Receptor-to-IgG4 Ratio to Presume the Prognosis of Patients with Membranous Nephropathy

Takatsugu Iwashita, Kaoi Takayanagi, Maiko Yamasaki, Mai Aoyagi, Taisuke Shimizu, Hajime Hasegawa. Department of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan.

Background: Membranous nephropathy (MN) is likely to show the long-term course and is a frequent glomerulonephritis in the elderly. For this reason, effective use of immunosuppressive drugs in a short period of time is desirable. In this study, we aimed to investigate the factors that could predict treatment responsiveness, using the treatment outcome in a short period of time, and retrospectively analyzed patients with MN in our hospital.

Methods: We included 66 patients who underwent renal biopsy and were diagnosed with MN in our hospital between April 2009 and December 2017. The percentage reduction in proteinuria one month after initiation of steroids, immunosuppressants, and ARBs was set to the endpoint. Intensity of immunofluorescent staining (IF) was scored according to the criteria of Japanese Society of Nephrology. Hematuria was quantified by 7-grade scoring of RBC numbers in high powered microscopic field.

Results: The intensity of IF (IgG subclass, PLA2R, THSD7A) was numerically evaluated and used for the analysis. The mean age of the patients included in the analysis was 56.4 ± 11.7 years and baseline eGFR 63.9 ± 18.7 mL/min, baseline urine protein was 7.05 ± 5.45 g/gCr. Multiple parameters in high responder (HR, n=39) that resulted in less than 50% of urine protein after one month and low responder (LR, n=27) that remained proteinuria more than 50% were compared. Baseline urine protein and scored baseline hematuria were both higher in HR group (urine protein: 6.95 in HR vs 3.86 g/gCr in LR, p < 0.003; hematuria: 1.0 in HR vs 0.0 in LR, p=0.036), but there was no difference in baseline eGFR (70.5 in HR vs 60.4 mL/min in LR, p=0.087). The mean dose of prednisolone used was also not different between the two groups (18.6 in HR vs 14.0 mg/day in LR, p=0.451). In IF, significant differences were observed between the two groups in the scored staining intensity of IgG3 and the staining intensity ratio of PLA2G to IgG4 (PLA2R-to-IgG4 intensity ratio/PGR) were both lower in HR group (IgG3: 0.9 in HR vs 0.5 in LR, p=0.049; PGR: 0.58 in HR vs 1.00 in LR, p=0.029).

Conclusions: From the result of the present examination, staining intensity of IgG3 and intensity ratio of PLA2G to IgG4 might be helpful to predict better therapeutic responsiveness in addition to the baseline proteinuria and hematuria.

PO1912

Graves Disease and Nephrotic Syndrome

Sajid Mahmood, Alaleh Mazhari, Nicholas Emanuele, David J. Leehey. Loyola University Health System, Maywood, IL.

Introduction: Disorders of the thyroid and kidney may co-exist. Isolated case reports of Graves’ disease associated with various glomerular diseases, including membranous nephropathy, membranoproliferative GN, fibrillary GN, and minimal change disease have been published. A patient with membranous nephropathy and Graves’ disease who had improvement but not resolution of proteinuria after treatment with radioactive iodine has been described (Sasaki et al. CEN Case Rep. 2014; 3(1): 90-93). We report a case of nephrotic syndrome associated with Graves’ disease which completely resolved after treatment of the thyroid disease with radioactive iodine.

Case Description: A 33-year-old healthy female was seen for evaluation of proteinuria discovered during a routine life insurance evaluation. BP was normal, and she had trace–1+ lower extremity edema. Urinalysis showed 3+ protein, 1 red blood cell and 1 white blood cell per high power field. Urinary albumin/creatinine ratio was 4010 mg/g. Serum albumin was 2.7 g/dL. Renal function was normal. Tests for hepatitis B and C, HIV, RPR, ANA, C3, C4, cryoglobulins, immunofixation, and free light chains were normal. Renal biopsy was planned but the patient missed the biopsy date. Subsequently she returned to clinic complaining of neck swelling. Exam revealed tachycardia, palpable goiter, 1+ pedal edema, no tremor. She reported heat intolerance, occasional diarrhea, insomnia, diaphoresis, and weight loss for the past month. A thyroid panel showed TSH <0.01 UU/mL (0.40–4.60 UU/mL), free T3 = 2000 pg/dL (230-420), and free T4 10.6 ng/dL (4.8–1.7). TSH receptor and thyroid peroxidase antibodies were present. The patient was treated with methimazole and tapering steroids. She refused thyroid surgery and ultimately underwent two sessions of radioactive iodine treatment. After this treatment, nephrotic syndrome went into complete remission (Figure).

Discussion: Although relatively uncommon, Graves’ disease needs to be considered as a reversible cause of nephrotic syndrome.
PO1913
Treatment of Systemic Lupus Erythematosus with or Without Nephritis with the Immunoproteasome Inhibitor KZR-616: Initial Results of the MISSION Study
Mary K. Farmer,1 Samir V. Parikh,2 Richard Furie,3 Christopher Kirk,1 Ken Harvey,4 Darrin Bomba.5 Kezar Life Sciences, Inc, South San Francisco, CA; 5 The Ohio State University, Columbus, OH; 4 Northwell Health, Great Neck, NY.

Background: Immunoproteasome inhibition demonstrated therapeutic potential in preclinical models of systemic lupus erythematosus (SLE) and lupus nephritis (LN). KZR-616 is a first-in-class selective immunoproteasome inhibitor, which has been safe and well tolerated in early clinical trials. One hundred subjects across 2 healthy volunteer studies, with dosing of KZR-616 up to 75mg SC, achieved target levels of immunoproteasome inhibition at doses ≥30mg. Here we report safety, tolerability and exploratory efficacy data from the Phase 1b portion of MISSION (KZR-616-002; NCT: NCT03393013), a clinical trial in which KZR-616 was administered to patients with active SLE with or without LN.

Methods: In this open-label dose-escalation study, SLE patients (per SLICC classification criteria) with SLEDAI ≥4 despite stable background therapy received KZR-616 at doses of 45mg (Cohort 1), 60mg (Cohort 2), or 60mg following a step-up dose (Cohorts 2a, 2b, 2c) SC weekly through Week 13 (W13) with 12 weeks of follow-up.

Results: To date, 39 patients with SLE, including 2 patients with active proliferative LN, have enrolled in MISSION. The majority of TEAEs have been mild or moderate with injection site reactions the most common TEAE. Tolerability has improved with a step-up dosing regimen, subsequent doses and the introduction of a lyophilized formulation. To date, no patients have discontinued from cohorts after implementation of these protocol modifications. Multiple measures of disease activity improved from Baseline to W13 and persisted through W25; no patients worsened over 13 weeks. KZR-616 administration resulted in improvements in multiple serologic markers as well as reduced expression of inflammatory gene expression modules. Both patients with biopsy-proven active proliferative LN had reductions in proteinuria. Conclusions: KZR-616 has been safe and tolerated at a target dose of 60 mg weekly. Step-up dosing, use of select pre-medications, and/or introduction of a lyophilized preparation have increased its tolerability. The administration of KZR-616 resulted in improvement across multiple disease activity measures as well as serologic markers, including improvement in proteinuria in patients with active proliferative LN. MISSION is an on-going study now focused on patients with LN.

PO1914
Rituximab as Maintenance Therapy in Lupus Nephritis
Anushya Jeyabalan, Jillian Rosenthal, Reza Zonozi, Noah Huizenga, Karen A. Laliberte, John Niles. Massachusetts General Hospital, Boston, MA.

Background: Rituximab (RTX) has been shown to be effective in refractory lupus nephritis (LN) in some studies. Minimal literature exists on using RTX as maintenance therapy for LN.

Methods: We performed a retrospective review of 21 patients (pts) with biopsy-proven LN who received RTX. We analyzed clinical data at baseline (pre-RTX) and up to 36 months (mo) of follow-up.

Results: Of 21 pts, 7 received RTX as part of first-line treatment, 7 for refractory LN and 7 for relapsing LN. All continued RTX (1g q4-6 mo) as maintenance therapy. 15/21 (71%) pts were on RTX monotherapy (excluding prednisone and plaquenil) at 12 mo, 14/16 (88%) at 24 mo, and 11/13 (85%) at 36 mo. At 12 mo, 13/21 (62%) achieved complete or partial remission. Median uPCR (g/g) decreased from 2.95 at baseline to 0.61 at 12 mo, 0.42 at 24 mo and 0.21 at 36 mo. 16/21 (76%) pts were on prednisone ≤5mg/day at 12 mo, 13/16 (81%) at 24 mo, and 10/13 (77%) at 36 mo. Over 36 mo, 2 pts had LN relapses while on RTX alone, and later progressed to ESRD. 2 pts developed hypogammaglobulinemia.

Conclusions: RTX monotherapy appears promising as maintenance therapy in LN. Given favorable renal outcomes and steroid-sparing effect, larger studies studying this effect may be warranted.

PO1915
Therapeutic Effect of Belimumab in Lupus Nephritis with Impaired Renal Function
Miki Karube, Hiroko Uchida, Yoshinori Komagata, Shinya Kaname. Division of Nephrology and Rheumatology, Kyorin University School of Medicine, Tokyo, Japan.

Background: To investigate the nephroprotective effect of belimumab (BEL) in SLE with mildly impaired renal function and proteinuria.

Methods: We studied 28 patients in the maintenance phase of SLE who was treated with BEL for more than 6 months. The median duration of treatment was 14 months. The patients were divided into those with reduced eGFR less than 60 ml/min/1.73 m2 (n=5; R group) and those with normal renal function (n=23; N group), and the effects of BEL were compared 6 months after treatment. In addition, the effect of BEL on lupus nephritis was investigated in patients with urinary protein of 0.2 g/gCr or more.

Results: The patients consisted of 26 females and 2 males, and the median age was 41 years. After BEL treatment, urinary protein decreased in both groups, 0.45 to 0.20 g/gCr in N group and 0.32 to 0.17 g/gCr in R group. The eGFR changed from 88.6 to 87.7 and from 50.8 to 61.2, while dsDNA antibodies (IU/mL) decreased from 54.9 to 30.5 and from...
23.2 to 9.04, respectively. The doses of prednisolone (mg/day) decreased in both groups. The IgG level decreased from 1377 to 1204 (mg/dL) in N group and from 1009 to 865 in R group. In 18 patients with urinary protein of 0.2-2 g/gCr or more, proteinuria significantly decreased from 0.54 to 0.20 to 0.23 (g/gCr) and dsDNA antibody improved from 67 to 34 to 31.5 (U/mL) at 3 and 6 months after BCL therapy.

Conclusions: BCL may improve SLE activities and also renal function in patients with renal insufficiency as effectively as in those with normal renal function, although hypogammaglobulinemia comparably develops in both groups.

POI1916
A Multicenter Double-Blinded Preclinical Randomized Controlled Trial (pRCT) on Jak1/2 Inhibition in Lupus Nephritis
Yutian Lei,1 Bettina Sehnert,4 Reinhard E. Voll,4 Conxita Jacobs Cachá,4 Maria Jose Soler,1 María Dolores Sanchez-Nino,1 Alberto Ortiz,1 Roman D. Bülow,2 Peter Boor,2 Hans J. Anders.1 Division of Nephrology, Department of Medicine IV, University Hospital, LMU Munich, Munich, Germany; 1Institute of Pathology and Department of Nephrology, RWTH University of Aachen, Aachen, Germany; 4IIS-Fundación Jimenez Diaz, School of Medicine, Universidad Autonoma de Madrid, Fundacion Renal Iñigo Alvarez de Toledo-IRSN and REDINREN, Madrid, Spain; 3Nephrology Department, Hospital Universitari Vall d’Hebron, Universitat Autonoma de Barcelona, Nephrology Research Group, Vall d’Hebron Research Institute (VHIR) and REDINREN, Barcelona, Spain; 1Division of Nephropathy, Department of Medicine IV, University Hospital, LMU Munich, Munich, Germany; 2Department of Rheumatology and Clinical Immunology, Medical Center-University of Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, Germany.

Background: We conducted the first multicenter double-blinded pRCT in experimental lupus nephritis.

Methods: We conducted a pRCT at two Spanish and two German academic sites. One site included MRL/lpr mice from their own breeding colony and the other sites purchased MRL/lpr mice from the Jackson lab. Eligibility criteria included female and 13-14 weeks old. Mice were randomized at a 1:1 ratio and orally dosed with 20 mg/kg/d baricitinib or vehicle for 4 weeks. Samples were assembled for blinded analyses, including histology, which was assessed by an independent pathology institute. The primary endpoint was proteinuria.

Results: A total of 55 mice were randomly assigned to the vehicle (n=28) and baricitinib group (n=27). Baricitinib-treated mice showed a trend towards decreased proteinuria, but this did not reach statistical significance (p=0.104). In contrast, plasma total IgG and lymphadenopathy score were significantly improved in the baricitinib group. In the vehicle group, at the initiation of treatment, self-fed mice had less proteinuria, less plasma total IgG, and worse skin lesion compared to commercial-source mice.

Conclusions: In a pRCT, targeting Jak1/2 with baricitinib for 4 weeks had no significant effect on the primary end-point proteinuria in MRL/lpr mice, whereas total plasma IgG and lymphadenopathy score significantly improved. Mice of different origins had different lupus phenotypes and increased the variability. Placebo controlled multicenter trials are feasible in animal models of lupus, however, standard deviations may increase due to multiple factors, which requires higher numbers of animals.

POI1917
Management of Lupus Nephritis (LN) with Voclosporin: An Update from a Pooled Analysis of 534 Patients
Brad H. Rovin,1 Samir V. Parikh,1 Robert B. Huizinga,2 Neil Solomon,2 Simrat Randhawa.2 The Ohio State University Wexner Medical Center, Columbus, OH; 1Aurinia Pharmaceuticals Inc, Victoria, BC, Canada.

Background: Voclosporin (VCS) is a novel calcineurin inhibitor (CNI) with a favorable metabolic profile and a consistent, predictable dose response potentially eliminating the need for therapeutic drug monitoring. VCS significantly improved renal response (RR) in patients with LN in two pivotal trials. Compared to MMF (target dose 2g/day) and prednisone (rapid taper), the addition of VCS 23.7 mg BID increased renal response by 25% in the Phase 2 AURA-LV (OR: 3.21; 95% CI: 1.68, 6.13; p < 0.001) and 18% in the Phase 3 AURORA (OR: 2.65; 95% CI: 1.64, 4.27; p < 0.001) studies at one year. To provide more information on VCS treatment effect we analyzed an integrated data set from AURA-LV and AURORA.

Methods: The two pivotal trials were of similar design, conducted in comparable patient populations and defined similar key outcome measures. The integrated data set included an intent to treat (ITT) population of 266 control and 268 VCS 23.7 mg BID patients. Here we report key integrated data of interest including renal response, defined as: ● UPCR ≥ 0.5 mg/g ● eGFR ≥ 60 mL/min or no decline > 20% from baseline ● ≤ 10 mg prednisone 8 weeks prior to endpoint measurement ● No rescue medications.

Results: RR at one year was 43.7% for VCS vs 23.3% for control (OR 2.76, 95% CI: 1.88, 4.05; p < 0.0001), and at 6 months (VCS 31.7%; control 20.3%); [OR: 2.01; 95% CI: 1.34, 3.01; p < 0.0008]. In addition, 1-year RR for Hispanic patients was 37.9% in VCS vs 28.2% in control. To examine the largest estimated effect of VCS compared to control-treated patients occurred early at week 4, (-5.6 mL/min/1.73 M2) which decreased to -3.7 mL/min in week 52 (p = 0.0012). Mean change from baseline of eGFR in the VCS arm at week 52 was -1.0 mL/min [p<0.05]. Finally, serious adverse events were similar between groups (2.7% in VCS and 2.0% in control).

Conclusions: This integrated analysis provides further support to the efficacy of VCS seen in both AURA-LV and AURORA including in Hispanic patients, a high-risk LN patient population. Furthermore, VCS’ expected impact on mean eGFR as a CNI was mild over the course of one year.

Funding: Commercial Support - Aurinia Pharmaceuticals, Inc.

POI1918
Use of Therapeutic Drug Monitoring Does Not Add Clinical Value for Voclosporin in Patients with Lupus Nephritis
Teun van Gelder,2 Robert B. Huizinga,1 Jan Noukens,3 Laura J. Lisk,1 Neil Solomon.1,4Aurinia Pharmaceuticals Inc Victoria, Victoria, BC, Canada; 2Universiteit Leiden, Leiden, Netherlands; 4Curare Consulting, Leiden, Netherlands.

Background: In a phase III clinical trial in patients with active lupus nephritis (LN), patients treated with 23.7 mg voclosporin bid in combination with MMF, achieved renal response rates of 40.8% vs. 22.5% for the control arm (OR 2.65; p < 0.001). The dose of voclosporin (VCS) was adjusted in response to decreases in eGFR. The objective of the present analysis was to evaluate the potential added value for therapeutic drug monitoring (TDM) in the LN patient population.

Methods: Pharmacokinetic (PK) data was analyzed from patients with LN treated with VCS in a population PK model, the influence of various covariates on the disposition of voclosporin was evaluated. Calcineurin inhibition (CNI) was estimated using concentration data in the LN population and previously measured inhibition. Obtained exposure were put into perspective of renal response and the established safety margin.

Results: Sex, body weight, race, age, serum albumin, total bilirubin and eGFR demonstrated no significant or clinically relevant effect on the PK parameters. VCS has linear PK, and the goodness-of-fit plots (Figure 1 a-b) indicate that the model adequately describes observed and predicted concentrations of VCS. A strong correlation between VCS concentration and calcineurin inhibition is observed. VCS inhibits calcineurin in a dose-dependent manner up to maximum of 64 mg bid. In healthy subjects, a 96 mg bid dose was considered to be the upper limit of tolerability though did not present any safety concerns. At the 4-fold lower therapeutic dose of 23.7 mg bid, CNI was estimated to be 15.7% at Cmax and 58.1% at Cmin. In a quartile exposure analysis, no relationship with the odds ratio for renal response was observed and favored VCS in all quartiles.

Conclusions: At a therapeutic dose of 23.7 mg bid, sex, body weight, race, age, serum albumin, total bilirubin and eGFR demonstrated no clinically relevant effect on VCS PK parameters. The linear PK profile of VCS allows the use of a pharmacodynamic approach instead of a pharmacokinetic approach, in which the dose of VCS is adjusted in response to decreases in eGFR. These data suggest that TDM is unlikely to be of added benefit to patient management.

Clinical Outcomes in Lupus Nephritis by Renal Response Status: A Retrospective Analysis of the Hopkins Lupus Cohort
Michelle Petri,1 Qingfeng Fu,2 Yulia Green,3 Anuradha Madan,4 Daniel W. Goldman,1 Selin Cooper-Blenkinsop,5 Johns Hopkins University School of Medicine, Baltimore, MD; 2GlaxoSmithKline, Upper Providence, PA; 3GlaxoSmithKline, Uxbridge, United Kingdom; 4GlaxoSmithKline, Collegeville, PA; 5GlaxoSmithKline, Stevenage, United Kingdom.

Background: A retrospective analysis of the Hopkins Lupus Cohort (a prospective, longitudinal study of patients [pts] with systemic lupus erythematosus) reported that renal response (complete/partial/none) at 24 months post-diagnosis of lupus nephritis (LN) predicts long-term renal survival.1 Here, we compare long-term renal survival and chronic renal insufficiency-free survival in pts with and without a renal response (RR) to standard LN therapy, as defined by primary endpoint in the Phase 3 BLISS-LN study (GSK Study BEL114054, NCT01639339).

Methods: This retrospective analysis (GSK Study 213039) of the Hopkins Lupus Cohort included pts with biopsy-proven class III, IV, or V LN. Endpoints were: long-term renal survival (no end-stage renal disease [ESRD] and/or mortality) and long-term chronic renal insufficiency-free survival by RR status at 24 months post-biopsy, both assessed by Kaplan–Meier plots with log-rank test and Cox proportional hazards regression.

Results: 173 pts with LN were included; 91.3% were female and mean (SD) age at biopsy was 36.2 (11.8) years. At 24 months post-biopsy, 114 (65.9%) pts achieved RR. Pts with RR at 24 months were less likely to experience an ESRD/mortality event and chronic renal insufficiency (Figure), even after adjusting for covariates (HR [95% CI] 0.33 [0.13, 0.87], p=0.0255; and HR [95% CI] 0.26 [0.14, 0.47], p<0.0001, respectively).

Predictors of Doubling of Serum Creatinine at the Time of Biopsy in a Lupus Nephritis Cohort
Jaime (James) A. Vondenberg, Saeed K. Shaffi. University of New Mexico, Albuquerque, NM.

Background: Lupus nephritis is associated with significant morbidity and it is imperative to study the factors associated with renal survival. We study the determinants of doubling of serum creatinine in a predominantly Hispanic cohort.

Methods: We identified patients with biopsy-proven lupus nephritis from the biopsy registry that comprises of biopsies performed between 2002-2016. Demographic, clinical, and biochemical variables were obtained from the registry and electronic medical records. We studied the factors associated with the doubling of creatinine by performing a univariate and multivariate proportional hazard analysis. All significant associations (p <0.05) were studied in a multivariate Cox regression model. Patients were censored upon death or the last follow-up.

Results: Out of 62 patients with biopsy-proven lupus nephritis, 53 (85.5%) were female. Whites, Hispanics, and Native Americans comprised 35.5, 30.6, and 16.1% of the cohort, respectively while 56% of the participants identified ethnically as Hispanic. Mean biopsy age, serum creatinine, and spot urine Protein/Creatinine were 34.5 (SD 15.3) years, 1.34 (SD 0.83) mg/dl, and 4.2 (SD 4.3) g/g, respectively. Class IV (48.4%) and III (16.1%) were the most prevalent lupus classes. Median (IQR) follow-up was 474.5 (1170) days. On multivariate analysis, higher age at biopsy was associated with decreased risk of doubling of serum creatinine (Figure 1). A higher spot urine Protein/Creatinine and C4 level at the time of biopsy were associated with increased risk of doubling of serum Cr.

Conclusions: Previous studies have shown that biochemical markers at the time of kidney biopsy are a poor prognostic marker of renal outcomes in lupus nephritis. In this study, demographic, biochemical, and histological markers failed to predict doubling of serum creatinine. The age and the level of proteinuria at the time of kidney biopsy were associated with doubling of serum creatinine.

PO1921
Lupus-Related Renal Disease Increases Inpatient Mortality: Analysis of the National Inpatient Sample
Ehizogie Edigin,1 Precious Eseason,1 Augustine Manadan,2,3 University of Benin Teaching Hospital, Benin City, Nigeria; 2John H Stroger Hospital of Cook County, Chicago, IL; 3Rush University Medical Center, Chicago, IL.

Background: The aim of this study is to analyze the difference in outcomes of Systemic Lupus Erythematosus (SLE) with and without lupus-related renal disease. The primary outcome was inpatient mortality, while secondary outcomes were hospital length of stay (LOS) and total hospital charges.

Methods: Data were abstracted from the National Inpatient Sample (NIS) 2016 and 2017 Database. NIS is the largest inpatient admission database in the USA. The NIS was searched for adult SLE hospitalizations with and without lupus-related renal disease as principal or secondary diagnosis using ICD-10 codes. Multivariate logistic and linear regression analysis was used to adjust for confounders for the primary and secondary outcomes respectively. STATA software was used to analyze the data.

Results: There were over 71 million discharges included in the combined 2016 and 2017 NIS database. 355,740 hospitalizations were for adult patients, who had either a principal or secondary ICD-10 code for SLE: 51,875 (14.6%) and 303,865 (85.4%) of these hospitalizations were for SLE with and without lupus-related renal disease respectively. 7,060 adult SLE hospitalizations (2%) resulted in inpatient mortality. 1,110 (2.14%) of the deaths occurred in SLE with lupus-related renal disease vs 5950 (1.96%) without lupus-related renal disease (P=0.228). The adjusted odds ratio (AOR) for inpatient mortality for SLE with lupus-related renal disease compared to those without lupus-related renal disease was 1.38 (95% CI 1.17-1.63, P<0.0001). SLE with lupus-related renal disease hospitalizations had a mean increase in adjusted LOS of 1.14 days (95% CI 1.05-1.24, P<0.0001) compared to SLE without lupus-related renal disease. Hospitalizations for SLE with lupus-related renal disease had an increase in adjusted total hospital charges of $15,910 (95% CI 13,085-18,736, P<0.0001) compared to SLE without lupus-related renal disease.

Conclusions: Hospitalizations for SLE with lupus-related renal disease have increased inpatient mortality, LOS, and total hospital charges compared to those without lupus-related renal disease. SLE patients with lupus-related renal disease require a multidisciplinary approach involving the rheumatologist and nephrologist to optimize outcomes.

Analysis of Characteristics and Risk Factors of Sepsis in Patients with Lupus Nephritis

Zhenjian Xu,1 Meisheng Liang,2 Anqing Xu.1 Sun Yat-sen Memorial Hospital of Sun Yat-sen University, Guangzhou, China; 2The People’s Hospital of Guangxi Zhuang Autonomous Region, Nanning, China.

Background: Patients with lupus nephritis are at high risk of infection due to intrinsic immune dysregulation and treatment with glucocorticoids and immunosuppressants. Infection is a common complication in patients with lupus nephritis and is a major determinant of in-hospital mortality. Sepsis are the most frequent causes of infection-related mortality. In this research, we study the clinical characteristics and related risk factors of sepsis in patients with lupus nephritis according to a retrospective analysis.

Methods: A retrospective study was carried out for 322 hospitalized patients with lupus nephritis in Sun Yat-Sen Memorial Hospital from 2010 to 2019. The infected group consisted of 140 patients (The infected patients were subdivided into septic group and non-septic group according the sepsis criteria) while the non-infected group consisted of 182 patients without infection. Baseline data including sex, age, disease duration, hospitalization duration, associated organ involvement, use of glucocorticoid and immunosuppressants.

Results: Compared to the non-infected group, longer hospitalization duration (14 vs. 9 days, P<0.05), pulsed methylprednisolone treatment within 1 month (10.7% vs. 1.6%, P<0.05), cyclophosphamide (22.9% vs. 14.3%, P<0.05), and calcineurin inhibitors (18.6% vs. 10.4%, P=0.05) were seen in the infected group (P<0.05). Compared to the non-septic group, higher proportion of patients with a history of diabetes (56.9% vs. 30.0%, P=0.05), lower platelet count (91.7 vs. 145.6 K/μL, P<0.05), higher proportion of pancytopenia (12.0% vs. 8.0%, P=0.05) and erythrocyte sedimentation rate (60.0 vs. 45.5 mm/h, P<0.05) can be seen in the septic group (P<0.05). About the laboratory results, lower level of platelet(129.0 vs. 194.5×10^9/L, P<0.05) and lymphocyte(0.6 vs. 9.0×10^9/L, P<0.05), while higher level of serum creatinine(134.0 vs. 88.0μmol/L, P<0.05), C reactive protein(43.8 vs. 12.3mg/L, P<0.05) and erythrocyte sedimentation rate(60.0 vs. 45.5mm/h, P<0.05) can be seen in the septic multivariate Logistic regression analysis revealed that male and pulse methylprednisolone treatment within 1 month were independent risk factors of sepsis in patients with lupus nephritis (P<0.05).

Conclusions: Male and pulse methylprednisolone treatment within 1 month were independently associated with sepsis in patients with lupus nephritis.

PO1923

An Evaluation of Costs Associated with Overall and Renal-Specific Organ Damage in Patients with Systemic Lupus Erythematosus in the United States

Christopher F. Bell,1 Juliana Meyers,2 Mayank Ajmera,2 Benjamin Wu,1 Joan Von Feldt,1 GlassoSmithKline, Research Triangle, NC;3 RTI Health Solutions, Research Triangle Park, NC; 4GlassoSmithKline, Philadelphia, PA.

Background: Systemic lupus erythematosus (SLE) is a chronic, multisystem, inflammatory, autoimmune disease affecting multiple organ systems, and characterized by fluctuating disease activity (flares). The combination of flares and SLE treatment toxicity increases the risk of organ damage (OD), including renal OD. Despite the high prevalence of OD and the associated poor disease prognosis, real-world studies on the economic impact of OD, especially renal OD, in SLE are limited.

Methods: This retrospective analysis (GSK Study 208380) used the IQVIA PharMetrics Plus Database to identify patients with SLE and OD during 01/01/09–06/30/18. Patients with OD were identified using International Classification of Diseases (ICD)-9/10 codes derived from the Systemic Lupus International Collaborating Clinics/ American College of Rheumatology Damage Index.1 Inclusion criteria: all adults ≥18 years of age; continuous enrollment 12 months both pre and post index (index: date of first observed OD medical claim); a1 inpatient (IP) or a2 outpatient (OP) claims within 6 months for an OD diagnosis code; no IP or OP claims separated by ≥90 days for SLE (ICD-9: 710.0 or ICD-10: M32.X) prior to the index date. Patients with renal-specific OD at index were noted. Patient characteristics were identified in the 12-month pre-index period and all-cause healthcare costs (2018 US$) were reported in the 12-month pre- and post-index periods. Results were analyzed with descriptive statistics.

Results: A total of 8952 patients met OD criteria and 486 (5.4%) had renal-specific OD. Patients were 92% female, mean (standard deviation [SD]) age was 46.4 (12.2) years, and mean (SD) Charlson Comorbidity Index was 2.0 (1.1). Mean (SD) all-cause healthcare costs increased from $15,746 ($29,637) to $26,998 ($57,982) in pre- versus post-index periods, respectively. In patients with renal-specific OD, mean (SD) all-cause healthcare costs increased from $16,131 ($22,914) to $36,905 ($72,188) in pre- versus post-index periods, respectively.

Conclusions: In patients with SLE and OD, annual costs increased after OD diagnosis. A similar increase in annual costs was observed for patients with renal-specific OD at index. Gladman DD and Urowitz MB. Lupus. 1999;8:632–7.

Characteristics of Lupus Nephritis in a Cross-Sectional Study of Hispanic and Native American Patients in New Mexico

Jaime (James) A. Vondenberg, Sazed K. Shaffi. University of New Mexico, Albuquerque, NM.

Background: In patients with lupus, nephritis develops in ~50% of patients, and is associated with significant morbidity. Therefore, it is important to characterize the demographic and biochemical variables associated with lupus nephritis. In this cross-sectional study comprised of many Hispanics and Native Americans, we investigate the demographic and biochemical variables at the time of lupus nephritis diagnosis.

Methods: We identified 62 patients with lupus nephritis from the University of New Mexico kidney biopsy registry that contains biopsies from 2002-2016. Demographics, comorbidities, outcomes, therapies, and laboratory data typically followed in lupus patients (complements, spot urine protein/creatinine [P/Cr] ratio, urine RBCs, serologies, etc) were collected from the registry and medical charts.

Results: 62 patients were included, 53 females and 9 males. White, Hispanic, and Native American races accounted for 35.5%, 30.6%, and 16.1% of the cohort, while 56.6% of patients identified ethnically as Hispanic. 3 patients had no labs. Overall mean age at the time of renal biopsy was 34.5 (SD 15.3) years old. Laboratory data among ethnicities is shown in Figure 1. Class IV was the most common classification in the whole cohort (48.5%), for Hispanics (56.7%), and Non-Hispanics (30%). Antibody status was similar among all ethnicities: ANA positive (95%, 80% titer ≥ 1,80), anti-dsDNA positive (73%), anti-Smith positive (56%), and SS-A positive (56%). The most common comorbidities were hypertension (n=46) and depression (n=16). For induction therapy, most patients received low dose cyclophosphamide (CYC) (41%), and Non-Hispanics received mycophenolate mofetil (MMF) (35%). For maintenance therapy, both Hispanics (37%) and Non-Hispanics (35%) most often received MMF. 7 patients progressed to ESKD, by ethnicity: 5 Hispanic and 2 Unavailable (1 African American).

Conclusions: Lupus nephritis is a life-threatening complication of systemic lupus erythematosus. The 2003 pathological classification of LN by the International Society of Nephrology/Renal Pathology Society (ISN/RPS) was revised in 2016; it quantitatively evaluates the interstitium in addition to the glomeruli. To date, the clinical utility of the 2016 classification cannot be fully established.

Methods: We performed a retrospective multicenter cohort study and investigated the utility of the 2016 classification—including the activity index (AI), chronicity index (CI), and each pathological component to predict CR or renal function decline defined as >60% decline in serum creatinine from biopsy date. The results were compared with that of the 2003 classification. Adult patients with first-onset class III/IV LN who were newly prescribed any immunosuppressants were consecutively enrolled from January 2004 to December 2014 and observed until July 2016.

Results: We enrolled 91 patients (number of female, 65; median age [interquartile range: IQR], 47 [30–62] years old; median estimated glomerular filtration rate (eGFR), 64 [IQR: 45–84] mL/min/1.73 m²; median proteinuria, 1.9 [IQR: 0.9–4.6]) g/Cr). During the observation period (median, 51 [IQR: 23–77] months), 35 patients achieved CR, and 16 developed 1.5-fold increase in sCr. The A or A/C subclasses based on the 2003 classification were not associated with clinical outcomes. After adjustments for eGFR and urinary protein levels, higher CI and interstitial inflammation scores were associated with failure to achieve CR (adjusted hazard ratios (HR) [95% confident interval (CI)]: 0.75 [0.64–0.88], 0.39 [0.25–0.61], respectively). Similarly, higher CI and higher interstitial fibrosis and lower hyaline deposit scores were associated with renal functional decline (adjusted HR [95%CI]: 1.24 [1.01–1.53], 2.66 [1.43–4.93], 0.45 [0.21–0.97], respectively).

Conclusions: We demonstrated the utility of CI and importance of assessing interstitial regions in predicting renal prognosis. The 2016 classification may predict the clinical outcomes more precisely than the 2003 classification.

**Resolution of Immune Deposits in the Glomeruli of Patients with Lupus Nephritis (LN)**

Ana Malvar,1 Valeria G. Alberton,2 Karina Fayolle,2 Rocío A. Jones,2 Pedro J. Davila Terreros,2 Bruno J. Lococo,2 Brad H. Rovin,1 1The Ohio State University, Columbus, OH; 2Hospital Fernandez, Buenos Aires, Argentina.

**Background:** Patients with proliferative LN have severe glomerular immune injury that resolves over time with treatment. The extent of resolution has been assessed by the presence of immune deposits (CD163) in patients who have had a repeat kidney biopsy during maintenance immunosuppression, and many patients do achieve an AI=0, so-called histologic remission. The fate of glomerular immune complexes in treated LN patients has not yet been characterized. This study examined the immunofluorescence (IF) patterns in biopsies obtained during LN therapy.

**Methods:** A cohort of Hispanic LN patients (n=89) was studied. All patients had biopsy-proven (Bx1) proliferative (Class III, IVaV) LN, and were treated with corticosteroids plus cyclophosphamide or MMF for 6 months and then switched to MMF for maintenance therapy. After a median of 42 (range 30-52) months patients had a second protocol biopsy (Bx2) to determine if they had achieved histologic remission (AI=0) or had persistent histologic activity (AIa1). Kidney biopsies were evaluated by standard IF microscopy (IgG, IgA, IgM, C3, C1q), and semi-quantitatively graded on a scale of 0-3 (not present–bright).

**Results:** cyclophosphamide (48%). These patients had a median serum creatinine of 0.7 mg/dl (0.5-2.2) and proteinuria of 0.2 g/dl (0.0-8.5). The 26 patients who had persistent histologic activity at Bx2 had a median AI of 2 (1-6), serum creatinine of 0.75 mg/dl (0.6-1.1), and proteinuria of 0.2 g/dl (0.1-0.9) and about half had been treated with MMF. No residual IF was present in 30% of patients with an AI of 0, but was present in all patients who had an AI>1. IF for IgG became negative in 46% of patients with an AI=0 between Bx1 and Bx2, but in only 7.7% of patients with AI>1 (P=0.005). Similarly, IF for C3 became negative in 84% of patients with AI=0, compared to 31% of patients with AI>1 (P=0.0001). After a median of 23 months (11-39) 7 patients who had been in histologic remission suffered an LN flare. None of these patients had had complete resolution of IF on Bx2. In contrast, no patient with an AI=0 and an absence of IF on Bx3 has had an LN flare during the follow up (44 months, 19-105).

**Conclusions:** About one third of patients with LN can achieve histologic and immunologic remission kidney. These patients appear to have an outstanding long-term kidney prognosis.

**Funding:** Clinical Revenue Support

**Urine Epidermal Growth Factor Levels Are Associated with Kidney Prognosis in Lupus Nephritis**

Juan M. Mejia,1 John P. Shapiro,2 Xiaolian Zhang,2 Cristina Cruz,3 Grant R. Zimmerman,1 Rossa A. Méndez,2 Samir V. Parikh,2 Haikady N. Nagaraja,1 Luis E. Morales-Buenrostro,1 Brad H. Rovin,1 1Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubiran, Mexico City, Mexico; 2The Ohio State University Wexner Medical Center Dorothy M Davis Heart and Lung Research Institute, Columbus, OH; 3Department of Biostatistics, School of Public Health, The Ohio State University, Columbus, OH.

**Background:** Epidermal growth factor is a protein specifically synthesized in the kidneys. EGF urine levels have been associated with progressive chronic kidney disease. This study evaluated the role of urine epidermal growth factor (uEGF) as a biomarker of chronic kidney damage in lupus nephritis (LN).

**Methods:** Through a proteomic approach we identified uEGF as a biomarker of interest in an LN discovery cohort. The expression of uEGF was characterized in two large multiethnic LN cohorts, and the association between uEGF at flare and long-term outcomes assessed in a subset of 120 patients. The expression of uEGF over time was observed in two longitudinal LN cohorts in which serial urine samples were collected.

**Results:** The proteomic analysis showed lower uEGF in patients with active LN than in normal controls. The peptide sequence was consistent with the proEGF isoform, and this was confirmed by immunoblotting. These findings were verified by ELISA. Patients with active LN had a significantly lower levels of uEGF than patients with active non-renal lupus, patients with inactive lupus, and kidney donors. Urine EGF was inversely correlated with the kidney biopsy chronicity index (r=-0.67, P<0.001). Multivariate survival analysis showed that uEGF at flare was associated with the time to doubling of serum creatinine (HR 0.88, 95% CI 0.77-0.99, P=0.045). In patients who progressed to doubling of serum creatinine (Figure 1A) and end-stage kidney disease (Figure 1B), uEGF was lower at flare and then decreased over the 12 months following flare. A uEGF cutoff of 5 ng/ml identified all patients who progressed to end-stage kidney disease.

**Conclusions:** Urine EGF levels correlate with histologic kidney damage. Low uEGF levels at flare and decreasing uEGF levels over time are associated with adverse long-term kidney outcomes.

**Funding:** Other NIH Support - NIH - NIAMS

**Vasculopathy Associated with Lupus Nephritis (Severity and Outcomes)**

Marcel Torres, Muhammad Alqudsí, Juan Carlos Q. Velez, Murner Mohanmed. Ochsner Clinic Foundation, Ochsner Health System, New Orleans, LA.

**Background:** Lupus nephritis (LN) is common in patients with systemic lupus erythematosus. Classification, prognosis, and treatment considerations of LN rely mainly on kidney biopsy features. Although few observational studies showed LN with vasculopathy has more severe course, literature reviews are scarce and mostly from Asian populations. The goal of the study was to shed more light on severity and response to Immunosuppression (IS) therapy in this subgroup of LN.

**Methods:** This was a single center retrospective chart review of LN patients from 2010-2019. Inclusion criteria were adult patients with native kidney biopsy proven LN documented in chart. Patients with systemic thrombotic microangiopathy (TMA) or possible secondary cause of renal TMA (other than SLE) were excluded. Two groups were identified for comparison, LN without vasculopathy (WOV) and LN with vasculopathy (WV). Vasculopathy was defined from kidney biopsy as vascular sclerosis (at least 75%), which had been tracked in chart. Patients with systemic thrombotic microangiopathy (TMA) or possible secondary cause of renal TMA (other than SLE) were excluded. Patients with systemic thrombotic microangiopathy (TMA) or possible secondary cause of renal TMA (other than SLE) were excluded. Two groups were identified for comparison, LN without vasculopathy (WOV) and LN with vasculopathy (WV). Vasculopathy was defined from kidney biopsy as vascular sclerosis (at least 75%), which had been tracked in chart.

**Results:** There were 431 patients with LN, 65 patients qualified for the study, patients with LN-WOV (n=38), and LN-WV (n=27). Racial demographics: 49% black, 34.5% Hispanic, 11% Asian. Females 57% (88%). Median age 37 years. Average follow-up 3.5 years. Induction IS regimen for LN-WOV was mycophenolate mofetil (MMF) in 52%, Cyclophosphamide (CYC) in 11%, and Rituximab (RTX) in 15%. In LN-WV induction IS regimen was MMF in 52%, CYC in 23%. At baseline, median values of uEGF were 1.7 mg/dl. Abb 2.5 g/dl and UP CR 3.7 g/l for LN-WOV and LN-WV were similar (p=0.38, 0.37, 0.53, respectively). At 6 and 12 months of follow-up, mean values of uEGF, Cr, Alb, and UP CR remained similar (p=0.59, 0.49, and 0.64 for 6 months, and 0.34, 0.41, 0.53 for 12 months). No difference was found in ESRD events (7% (18%) in LN-WOV and 14% in LN-WV, p=0.86.

**Conclusions:** In our cohort, both groups of LN-WOV and LN-WV showed no statistical difference in the severity of presentation, nor in response to IS therapy assessed at 6 and 12 months follow-up of Cr, Alb, and UP CR, and ESRD. Hence, LN-WV was not associated with ominous outcomes or more resistance to IS.

**Idiopathic Hypokalemia in Lupus Nephritis: A Previously Unrecognized Entity**

Emmanuel A. Adomako,1 Saira Bilal,2 Yu-Lun Liu,1 Ayesha M. Malik,2 Kamalanathan K. Sambandam.1 1University of Texas Southwest Medical Center at Dallas, Dallas, TX; 2Agan Khan University, Karachi, Pakistan; 3George Washington University Medical Faculty Associates, Washington, DC.

**Background:** The lupus nephritis (LN) population at Parkland Hospital is among the largest in the country. During the course of usual care in this population, we encountered a phenomenon of unexplained hypokalemia that has never been previously described. Here we begin to phenotype this cohort by comparing it to a group of LN controls as well as LN with distal renal tubular acidosis (RTA).

**Methods:** From our population of 403 LN patients followed in the Parkland Health and Trauma System, we identified a cohort of 20 patients with idiopathic hypokalemia (HK). This cohort is compared to 90 LN controls (control) and 10 LN patients with distal RTA (RTA). In contrasting the three groups, the Chi-squared test or Fisher’s exact test were used for categorical data and the one-way ANOVA or Kruskal-Wallis test was used for continuous measures. For paired comparisons of continuous variables between the groups, the student’s t-test was employed.

**Results:** The HK cases had lower mean serum potassium compared to control and RTA (3.24 vs 4.06 and 3.75 mmol/L, respectively; P<0.001). The mean serum bicarbonate was normal in HK and control but lower in RTA (25.83 vs 25.20 and 21.98 mmol/L, respectively; P=0.001). The urine pH was abnormally high only in the RTA group (6.13 vs 6.22 vs 6.68; P<0.001). The mean serum magnesium was modestly lower in HK compared to control-nml and control-RTA (1.75 vs 1.97 vs 1.97 mg/dL; P=0.002). There were differences in serologic markers of autoimmunity. Compared with control, bilirubin and RTA were more common and the seropositive for anti-SSA (P=0.002 and 0.015, respectively). In contrast, compared to controls, only HK expressed a higher rate of anti-RNP seropositivity (P=0.002) and only control-RTA had a higher rate of anti-SSA positivity (P=0.044).

**Conclusions:** A syndrome of idiopathic hypokalemia was revealed in 20/403 (5%) of patients within our lupus nephritis population and is distinct from the RTA that is
PO1939
Outcomes of Lupus-Related Glomerular and Tubulointerstitial Disease: Analysis of the National Inpatient Sample

**Background:** The study aims to compare the differences in outcomes of hospitalizations for Systemic Lupus Erythematosus (SLE) with glomerular and tubulointerstitial related renal disease. The outcomes compared were inpatient mortality, hospital length of stay (LOS), and total hospital charges.

**Methods:** Data were abstracted from the National Inpatient Sample (NIS) 2016 and 2017 Database. NIS is the largest inpatient hospitalization database in the United States (U.S.). The NIS was searched for adult SLE hospitalizations with lupus-related glomerular and tubulointerstitial disease as principal or secondary diagnosis using ICD-10 codes. The analysis was done using STATA. Multivariate logistic and linear regression analysis was used accordingly to adjust for confounders for the outcomes.

**Results:** There were combined 71 million discharges included in the 2016 and 2017 NIS database. 51,875 hospitalizations were for adult patients, who had either a principal or secondary ICD-10 code for SLE with lupus-related renal disease. 51,525 (99.3%) and 350 (0.7%) of these hospitalizations were for SLE with lupus-related glomerular and tubulointerstitial disease respectively. The mean age for SLE with lupus-related glomerular disease was 40.6 vs 42.2 years for lupus-related tubulointerstitial disease (P<0.004). 7,060 adult SLE hospitalizations resulted in inpatient mortality, 1,110 (2.14%) of the deaths occurred in SLE with lupus-related glomerular disease. The number of deaths for lupus-related tubulointerstitial disease was less than 10, hence it was omitted during the analysis by STATA. SLE with lupus-related glomerular disease had similar LOS (6.8 vs 6.7 days, p=0.865) and total hospital charges ($79,718 vs $83,006, p=0.961) compared to those with tubulointerstitial disease.

**Conclusions:** SLE with glomerular disease makes up the vast majority of SLE with lupus-related renal hospitalization disease. Almost all in the in-hospital deaths of SLE patients with lupus-related renal disease occurred in SLE with glomerular disease. LOS and total hospital charges were similar between hospitalizations for SLE with lupus-related glomerular and tubulointerstitial diseases.

PO1931
Lupus Podocytopathy Systematic Review

Ivan L. Claudio-Gonzalez, Ajay S. Rajabalan, Jose E. Navarrete, Jason Cobb. Emory University Woodruff Health Sciences Center, Atlanta, GA.

**Background:** Patients with lupus, can present with a renal lesion distinct from the ones described by the ISN/RPS classification of lupus nephritis called lupus podocytopathy. Lupus podocytopathy has been described as minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) in patients with SLE with or without mesangial involvement but without proliferative or membranous lupus nephritis features. We have gathered the available data on lupus podocytopathy and analyzed it to provide a comprehensive report in this review.

**Methods:** We searched electronic databases including pubmed and google scholar, using keywords related to lupus podocytopathy and synonyms and treatment from inception to December 2019. Articles retrieved were screened for relevance, including reference list of retrieved. We included cohort studies, case series, and retrospective studies. Individual case reports were excluded.

**Results:** The search identified 8 studies, of which 6 were included with a total of 107 patients. The patients were predominantly female (88%). The average age was 35 years. Studies done outside of China had predominantly African-American patients 72.5%. The average serum creatinine was 2.06 mg/dL. The average proteinuria was 6.5 g/years.

**Conclusions:** When compared to those with tubulointerstitial disease, patients with lupus-related renal disease had similar LOS and total hospital charges were similar between hospitalizations for SLE with lupus-related glomerular and tubulointerstitial diseases.

PO1932
Extended Follow-Up of Patients Recruited to a Randomized, Controlled Trial of Rituximab vs Azathioprine, After Rituximab Remission Induction for Patients with Relapsing ANCA-Associated Vasculitis

Rona M. Smith,1,2 David R. Jayne,1,2 Peter A. Merkel.1 University of Cambridge, Cambridge, United Kingdom; 2Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; 3University of Pennsylvania, Philadelphia, PA.

**Background:** RTX is an effective remission induction therapy in AAV. However, the effect of RTX is not sustained, and relapse rates are high, especially in patients with a history of severe disease. The RITAVASC trial was an international, open-label, randomized, controlled trial of patients with AAV with relapsing disease comparing the efficacy, after induction of remission with RTX, of repeat dose RTX or AZA as relapse prevention strategy.

**Methods:** Patients with relapsing AAV received induction therapy with RTX and glucocorticoids (GC). If remission was achieved by month 4, patients were randomized 1:1 to receive RTX (1000 mg every 4 months for 5 doses) or AZA (2 mg/kg/day) as maintenance therapy for 24 months. Patients continued to be followed until at least 36 months after enrolment, with a primary outcome of time to disease relapse. The final patient reached month 36 in the trial in November 2019.

**Results:** 190 patients were enrolled and 170 randomized at month 4 (85 to RTX; 85 to AZA): median age = 59 years (range 19-89); prior disease duration = 5.3 years (0.4-38.5), 123/170 (72%) with anti-PR3 ANCA, 47/170 (28%) with anti-MPO ANCA; 161 (95%) enrolled after a severe relapse, 66-170 (39%) after a non-severe relapse; GC induction regimen: 48/170 (28%) higher-dose, 122/170 (72%) lower-dose; 114 (67%) patients had prior renal involvement. We previously presented the results demonstrating the superiority of rituximab over azathioprine during the maintenance treatment period. Results of the follow up phase of the study after discontinuation of maintenance therapy will be presented at the 2020 meeting.

**Conclusions:** The results of the extended phase of RITAVASC will examine the long-term impact of B cell depletion in patients with AAV on sustaining remission beyond the treatment period, clinical or biomarker factors associated with risk of relapse, and post-treatment safety of prolonged use of rituximab, including a focus on hypomimmoglobulinemia.

**funding:** Other NIH Support - The VCRC is funded through collaboration between NCAI and the National Institute of Arthritis and Musculoskeletal and Skin Diseases, and has received funding from the National Center for Research Resources (U54 RR019497), Commercial Support - Genentech/Roche

PO1933
Renal Disease During Maintenance Treatment in ANCA-Associated Vasculitis (AAV) Remains a Problem and Glucocorticoid Use Is High

Peter A. Rutherford, Dieter K. Goette. Vifor Pharma Ltd, Glattingburg, Switzerland.

**Background:** AAV is a relapsing remitting long term condition and patients are at risk of organ damage from active AAV and therapy in particular glucocorticoids (GC). The remission maintenance phase of AAV is critical for good long term renal outcomes. This retrospective study examined the pattern of renal disease during the maintenance phase in AAV patients managed in routine clinical practice.

**Methods:** 1478 AAV patients managed by 493 EU physicians (61% Nephrologists) who completed induction therapy for organ/life threatening AAV and initiated therapy between 2014-16 were studied. Data were collected from when maintenance was determined to begin by the physician and then after 6, 12, 18 and 36 months.

**Results:** 49% had GPA; mean age 54.2 years and 56% male. 49% had incident AAV and 51% were studied from relapse. 70% received cyclophosphamide/GC and 36% received rituximab/GC with 28% plasma exchange. Physicians defined time of start of maintenance as mean of 5.7 months from diagnosis. Over 36 months from maintenance start 38% patients had relapse (26% 1, 8% 2, 3% 3 and 1% 4). Only 22% had no comorbidity at diagnosis, hypertension and renal impairment were common. eGFR CKD stage changed over time - stage 5 (8% to 11%), stage 4 (12 to 8%), stage 3 (43 to 37%) and stage2/3 (38 to 46%) – mean at 36 months of 53.3 ml/min. Hypertension and renal impairment were frequent comorbidities and renal related AE’s were often reported. Many patients stayed on GCs and renal impairment and hypertension as well as active/ chronic vasculitis activity were more frequent in patients remaining on GCs throughout maintenance. Renal function worsened in 24% patients and 46% were still receiving steroids vs 35% and 37% of those with improved or unchanged renal function (<p= 0.05)

Cost-Effectiveness of Maintenance Therapy with Azathioprine vs. Rituximab (Tailored or Fixed-Schedule) in Adults with Generalized ANCA Vasculitis in Colombia
Katie Contreras, Viviana Orozco Ortiz, Eduardo J. Puche Carrascal, Paola García, Camilo A. Gonzalez, Patricia Rodriguez, Diego Rosselli. Hospital Universitario San Ignacio, Bogota, Colombia.

Background: Azathioprine has been the drug of choice for maintenance therapy in patients with generalized ANCA vasculitis. However, recent studies show that rituximab, a high-cost biological agent, which can be administered in two different schedules, might be more effective, so it is important to know the cost-effectiveness. Our goal was to compare the cost-effectiveness of the 3 maintenance schemes: standard therapy with azathioprine; fixed-dose rituximab and rituximab tailored according to CD19 lymphocyte level and ANCA titres, from the perspective of the Colombian healthcare system.

Methods: We designed a 5-year annual cycle Markov model with the following stages: remission, minor relapse, major relapse and death. Transition probabilities were obtained from a systematic review of the literature (Scopus and Pubmed). Following national guidelines for economic studies, costs, in 2018, USD = 2.956 Colombian pesos (COP), were estimated based on national drug registries, and official tariff manuals for procedures and other resources. Main outcome was quality-adjusted life years (QALY), using lupus nephropathy as a proxy; values were obtained from Tufts CEA Registry and validated by local expert panel through a modified Delphi technique. Cost-effectiveness threshold was three-times per capita GDP (USD 17253). Discount rate was 5%. Univariate and probabilistic sensitivity analyses were performed.

Results: Overall discounted 5-years costs were USD 1356 for azathioprine; USD 4750 for tailored rituximab and USD 6162 for fixed rituximab. QALY gains were 2.94, 3.63 and 3.64, respectively. Both tailored and fixed rituximab were cost-effective (cost per QALY gained: USD 4.919 and USD 6.865 respectively), but tailored dosing was preferable due to its lower cost. Sensitivity analyses did not modify these results significantly.

Conclusions: To our knowledge this is the first economic evaluation that compare azathioprine with tailored and fixed rituximab regimens as a vasculitis maintenance treatment in adults with ANCA generalized. Due to its lower effectiveness azathioprine should not be the first line of treatment. Tailored rituximab should be a better option than fixed schedule due to its lower cost with similar effectiveness.

PO1935
Use of Subcutaneous IgG to Treat Hypogammaglobulinemia in ANCA-Associated Vasculitis
Sam Kani, Antoine Azar, Eric J. Gapud, Duvuru Geetha. Johns Hopkins University School of Medicine, Baltimore, MD.

Background: Intravenous immunoglobulin (IVIG) has been used to treat ANCA vasculitis (AAV) patients with recurrent infections as a result of hypogammaglobulinemia induced by immunosuppressive treatment regimens. Subcutaneous immunoglobulin (SCIG) has a better safety and tolerability profile. We characterized the clinical features, treatment and outcomes of AAV patients treated with SCIG).

Methods: We conducted a retrospective chart analysis of 187 patients in our AAV database to identify patients with recurrent infections and hypogammaglobulinemia subsequently treated with SCIG. Patient demographics, clinical characteristics, treatment and immunological parameters were assessed.

Results: Of the 187 patients identified with AAV, 6 were treated with SCIG. All were Caucasian, PR3 positive and majority (n=4) were females. All patients had pulmonary involvement, and regimens of cyclophosphamide (CYC) and/or rituximab (RTX) were employed for induction and remission. Ig levels (IgG, IgM, IgA) were reduced in all patients. CD19/CD20 B cells were depleted, and CD3/CD8 and NK cells were preserved in all patients. The majority of patients (n=4) experienced recurrent URIs, 3 had shingles, in addition to other infections(table 1). All patients had no discernible IgG antibody response to pneumococcal vaccine. Mean duration between first rituximab administration and initiation of SCIG was 6.4 years. Four patients continued to receive RTX every 6 to 12 months while 2 patients remained in remission off RTX for over 2 yrs. IgG levels normalized and none of the patients had recurrence of infections after initiation of SCIG

Conclusions: These data, albeit preliminary, is one of the first series that demonstrates SCIG can be safe and reliable alternative to IVIG in AAV patients with recurrent infections secondary to hypogammaglobulinemia. Our data also suggest that SCIG may have immunomodulatory effects to maintain disease remission in AAV.

PO1936
Glucocorticoid Maintenance Therapy and Severe Infectious Complications in ANCA-Associated Vasculitis

Background: Although treatment and outcomes in anti-neutrophil cytoplasmic autoantibody associated vasculitis (AAV) have been improved over the last decades, intensified immunosuppressive burden is concurrently associated with life-threatening adverse effects which are the main cause of death during the first year after disease onset. Our study evaluates the impact of cyclophosphamide (CYC) induction dose and glucocorticoid maintenance dose and duration on patient outcomes with an emphasis on infectious complications.

Methods: A total of 130 AAV patients from two different German Vasculitis Centers diagnosed between 2004 and 2019 treated with CYC for induction therapy and glucocorticoids a mycophenolate mofetil or azathioprine for maintenance therapy were included in this study. We evaluated the impact of CYC dose for induction therapy and glucocorticoid dose and treatment duration for maintenance therapy on time to relapse, kidney function, infectious complications, irreversible physical damage and mortality. Patients were separated into four groups: <7.5mg versus ≥7.5mg cumulative CYC dose and <7.5mg after 6 months versus ≥7.5mg glucocorticoids after 6 months.

Results: The baseline demographic and disease characteristics were comparable between groups. Cumulative CYC dose had no impact on relapse rate, kidney function, infectious complications or mortality. Patients receiving ≥7.5mg glucocorticoids after 6 months had an increased rate of infectious episodes per patient (0.6 vs. 1.7; p=0.001). Urinary tract infection (p=0.007), pneumonia (p=0.003) as well as opportunistic pneumonia (p=0.022) and sepsis (p=0.008) appeared more frequently. Especially pneumonia during the first 24 months after disease onset (hazard ratio, 3.0 [95% confidence interval (CI), 1.5–6.1]) led to more death by infections (p=0.034). Patients ≥65 years with ≥7.5mg glucocorticoids after 6 months were at particular risk for infectious complications. Glucocorticoid maintenance therapy had no impact on relapse rate or kidney function after the last follow-up.

Conclusions: An extended glucocorticoid maintenance therapy may induce severe infectious complications leading to an increased frequency of death by infection, has no effect on time to relapse and should therefore be critically revised throughout the aftercare of AAV patients.

PO1937
Country Differences Exist in the Treatment of ANCA-Associated Vasculitis (AAV), but High-Dose and Prolonged Glucocorticoid Use Is Observed Across Europe
Peter A. Rutherford, Dieter K. Goette. Vifor Pharma Ltd, Glattbrugg, Switzerland.

Background: European AAV guidelines recommend remission induction therapy with combination of high dose glucocorticoids (GC) and rituximab (RTX) or cyclophosphamide (CYC) and maintenance therapy with either RTX or azathioprine (AZA). This retrospective study examined the pattern of prescribing, including the use of GCs, across Europe in AAV patients managed in routine clinical practice.

Methods: 1478 AAV patients managed by 493 expert centers in Switzerland, Germany, Italy, Spain and UK who completed induction therapy for organ or life threatening AAV (49%...
POI1938

Validation of a Clinical-Pathologic Renal Risk Score in ANCA-Associated Glomerulonephritis: The US Experience

Sam Kant,1 Silke R. Brix,2 Francesca Costigliolo,1 Paride Fenaroli,1 Avi Z. Rosenberg,1 Duvuru Geetha,1 Johns Hopkins University School of Medicine, Baltimore, MD; 3Manchester Royal Infirmary, Manchester, United Kingdom

Background: The prognostication of renal disease in the setting of ANCA associated vasculitis (AAV) continues to pose a significant clinical challenge given lack of validated clinical and pathologic correlates. A risk score has been developed by a German consortium (Brix et al Kidney International 2018), to stratify risk of AAV-related renal disease progression to ESKD. We applied this risk score in our cohort of AAV patients to ascertain its reproducibility.

Methods: A single center retrospective cohort study was performed reviewing 148 renal biopsies of patients with AAV GN. Data for score calculation was available of 119 patients with a median follow up of 58 months (IQR 28 – 97 months). Three parameters were used in the risk prediction score: (1) # of normal glomeruli (N0 >25%, N1 10-25%, N2 <10%), (2) tubular atrophy and interstitial fibrosis (T0 <25%, T1 >25%) and (3) eGFR at the time of diagnosis (G0 >15, G1 <15). A weighted assignment of points to each parameter was as follows: N1 [4], N2 [6], T1 [2], G1[3], and the resulting aggregate risk score used to classify predicted ESRD risk was low (0), intermediate (2 to 7), or high (8 to 11 points).

Results: In the cohort of 148 patients, median age was 62 years and mean eGFR at diagnosis was 27.7. Seventy-six were MPO, 57 were PR3 positive and 15 were ANCA negative. With regards to risk stratification, 34 were in low risk category, 59 in the medium risk category and 26 patients in the high-risk category. Overall, 23 patients (15.3%) progressed to ESKD with 2 (5.9%), 11 (18.6%), 10 (38.5%) in low, medium and high risk groups, respectively. A Kaplan-Meier survival curve (Figure1) demonstrates worsening of renal survival across the risk groups (p=0.0035).

Conclusions: This AAV renal risk score was able to reliably predict risk for progression to ESKD. A further analysis revalidating cut-offs and risk score points would likely refine the score improving its prediction accuracy.

Clinical Features and Outcomes of Anti-Neutrophil Cytoplasmic Autoantibody-Associated Vasculitis in Chinese Elderly and Very Elderly Patients

Ting Meng, Departments of Nephrology, Xiangya Hospital Central South University, Xiangya Hospital Central South University, Changsha, China.

Background: Anti-neutrophil cytoplasmic autoantibody-associated vasculitis (AAV) is predominantly a disease of the elderly, and the incidence increases with age. However, there are few data focusing on the clinical features in elderly-onset AAV, especially in very elderly-onset AAV in China. The aim of this study was to explore whether elderly-onset AAV shows any specific clinical features and outcomes in Chinese patients.

Methods: We performed a retrospective study in Xiangya Hospital, a mixed tertiary medical center in south China. A total of 177 patients presenting with AAV were included between January 1, 2010 and December 31, 2017. Patients were divided into younger group (age<65 years) and older group (age≥65 years) which was sub-divided into elderly group (age 65-74 years) and very elderly group (age≥75 years).

Results: We found patients in the very elderly group had more chest and cardiovascular involvement (P<0.033 and P<0.017). Elder AAV patients had less renal involvement and lower serum C4 level (P<0.013 and P<0.003). Very elderly AAV patients had lower platelet counts. Patients in the younger group had a higher level of BVAS among three groups (P<0.05 younger group vs. very elderly group; P<0.05 younger group vs. elderly group). There were no significantly difference in the proportion of ESRD patients among the three groups (P=0.473). Patients in the very elderly group had the poorest patient survival (P=0.002).

Conclusions: Older AAV patients had less renal involvement, lower serum C4 level and BVAS. The very elderly group got the most chest and cardiovascular involvement and had lower platelet counts. Older age is associated with higher mortality in AAV patients.

Validation of the Renal Risk Score for ANCA-Associated Glomerulonephritis in a National Irish Cohort

Jennifer Scott,1 Silke R. Brix,2 Laura M. Slattery,2 Michelle Clince,1 Mark A. Little.1 Trinity Health Kidney Centre, Trinity College Dublin, Ireland 1Trinity Health Kidney Centre, Dublin, Ireland; 2The University of Manchester, Manchester, United Kingdom.

Background: Histopathological examination is currently the gold standard for diagnosis of ANCA-associated glomerulonephritis (AAN). However, the commonly used Berden score is inconsistent at predicting renal outcomes across different cohorts. Furthermore, treatment related morbidity remains a major problem. Brix et al. recently published a clinicopathologic score to predict End-Stage Kidney Disease (ESKD), using 3 parameters to stratify patients into 3 risk groups. Parameters include: percentage normal glomeruli (N0 >25% = 0 points, N1 10 to 25% = 4, N2 <10% = 6), percentage tubular atrophy and interstitial fibrosis (T0 ≥25% = 0, T1 >25% = 2), and estimated glomerular filtration rate at the time of diagnosis (G0 >15 ml/min/1.73 m2 = 0, G1 ≤15 ml/min/1.73 m2 = 3). The ultimate aim is to use this to personalise treatment, enabling the optimal balance of toxic immunosuppression for every patient.

Methods: The Rare Disease Kidney (RDK) registry is an Irish national longitudinal, multi-centre, cohort study which includes 567 AAV patients, to date, diagnosed using the European Universities Medicine Agency Algorithm (1990-2019). Patients with Granulomatosis with Polyangiitis (GPA), Wegener’s Granulomatosis, Cryopyelonephritis, and other forms of vasculitis were included in the validation of the renal risk score.

Results: 248 patients, of whom 43 (17.3%) developed ESKD and 35 (14.1%) died, over a median follow up of 32 months (interquartile range, IQR 5 to 85 months), were identified. Outcome data and histology were available for 205 patients. Forty-five patients were in the lowest risk group (group 1) - (2.4%) of which developed ESKD. Eight (8.6%) of the 93 patients in the middle risk group (group 2) reached ESKD. Sixty-seven patients were in the highest risk group (group 3) and (41.9%) of them required permanent renal replacement therapy. Kaplan Meier survival analysis demonstrated a difference in renal outcome between the 3 risk groups (p <0.0001).

Conclusions: The proposed renal risk score accurately predicts ESKD in patients with AAV and is feasible in a national Irish cohort. The next step is to further refine the predictive cut-off values for the 3 clinico-pathologic parameters using a regression tree analysis.

PO1941

Hypocomplementemia Is Associated with More Severe Renal Disease and Worse Renal Outcomes in Patients with ANCA-Associated Vasculitis: A Retrospective Cohort Study

Aglaia Chalkia,1 Konstantinos Thomas,2 Panagiota E. Giannou,1 Zoe Alexakou,2 Athanasia Kapota,1 Christina Tsalapak,2 Dimitrios Vassilopoulos,2 Dimitrios I. Petras.1 1Nephrology Department Hippokration General Hospital, Athens, Greece; 2Pathology, Laiko Hospital, Athens, Greece.

Background: The complement system has been recently proposed to play an important role in the pathogenesis of ANCA associated vasculitis (AAV). Real life data assessing its predictive role in renal outcomes are limited. In this study, we evaluated the value of serum and kidney deposited C3 in predicting renal outcomes in patients with AAV.

Methods: In this retrospective study, patients with AAV were categorized according to their baseline serum C3 levels as hypo- or normocomplementemic and to those with positive or negative kidney biopsy immunofluorescence (IF) for C3. Clinical, serologic, treatment and histopathologic characteristics, as well as prognosis between the 2 groups were compared.

Results: Forty-seven patients (51% men) were enrolled with a mean age at diagnosis of 65 years and were followed up for a median period of 56 months. At baseline, 23% (11/47) of the patients were hypocomplementemic (C3 <75 mg/dL). These patients were older (74 vs 65 years, p=0.013), had higher creatinine levels (4.9 vs 2.2 mg/dL, p=0.006), were more often hemodialysis dependent (64% vs 19%, p<0.009) and progressed more often to ESRD (55% vs .11%, p=0.01) compared to normocomplementemic patients (n=36). On multivariate analysis, serum Cr at diagnosis (HR=16.8, 95% CI: 1.354-208.62, p=0.028) and low serum C3 (HR=2.492, 95% CI: 0.537-1.156, p=0.044) were independent predictors for ESRD. Among 25 patients with kidney biopsy data, those with positive IF staining for C3 (56%, n=14) had more often a mixed histological pattern (72% vs 27%, p=0.033), low serum C3 levels (42% vs 18%, p=0.001) and serious infections during follow-up (57% vs 18%, p=0.047) compared to those with negative (n=11) IF staining.

Conclusions: The subgroup of patients with AAV and low C3 levels at diagnosis (25%) have more severe renal disease and outcome (ESRD) compared to patients with normal C3 levels. This should be taken into account in therapeutic and monitoring strategies.

PO1942

Clinical Features and Treatment Outcomes of Patients with Pauci-Immune Vasculitis with and Without a Medical History of Autoimmune Disease

Sophia Lionaki,1 Smaragdi Marinaki,1 Sofia Fragioudaki,1 Emmanuel Kalaitzakis,1 Petros Kalogeropoulos,1 Georgios Lipiis,2 Athanasia Tszioufas,1 Ioannis Boletis.1 1Nephrology, Laiko Hospital, Athens, Greece; 2Pathology, Laiko Hospital, Athens, Greece.

Background: A proportion of patients with puauci-immune vasculitis (PIV) report a past medical history (PMH) of other autoimmune disorder prior to the diagnosis of vasculitis. The purpose of this study was to identify the differences, if any, between patients with PIV with or without a PMH of other autoimmune disease prior to the onset of vasculitis.

Methods: Among 304 patients with biopsy proven PIV at any site, detailed information regarding their PMH was available in 235 patients (77.3%). Of these, 60 (25.5%) reported a PMH of other autoimmune disorder including Sjogren syndrome, Crohn’s disease, autoimmune thyroiditis, psoriasis, rheumatoid arthritis, and scleroderma.

Results: The clinical characteristics and outcomes of the two groups are displayed in [table 1].

Conclusions: Patients with a PMH of other autoimmune disorder prior to the diagnosis of PIV were predominantly P/P-ANCA positive, had less impaired kidney function at presentation and a lower probability of relapse after achieving remission, compared to patients without a PMH of autoimmunity.

PO1943

Low Serum C3 at Diagnosis of Puauci-Immune Glomerulonephritis Is Associated with More Advanced Kidney Impairment and Worst Renal Prognosis

Sophia Lionaki,1 Smaragdi Marinaki,1 Emmanuel Kalaitzakis,1 Sofia Fragioudaki,1 Petros Kalogeropoulos,1 Georgios Lipiis,2 Athanasia Tszioufas,1 Ioannis Boletis.1 1Nephrology, Laiko Hospital, Athens, Greece; 2Pathology, Laiko Hospital, Athens, Greece.

Background: Recent evidence supports the notion that complement activation plays a critical role in puauci-immune (PI) vasculitis pathogenesis. The aim of this study was to investigate if the clinical, serological and laboratory characteristics and treatment outcomes of patients with PI glomerulonephritis (GN) with low serum complement levels at diagnosis differ from those of patients with complement values within the normal range.

Methods: In a retrospective design we studied patients with biopsy proven PI GN with available serum complement measurements at diagnosis, or during a relapse, prior to initiation of immunosuppressive therapy. All patients were tested for antineutrophil cytoplasmic antibodies (ANCA) at presentation. Fisher’s exact tests and Wilcoxon rank sum tests were used to compare the characteristics by serum C3.

Results: Of 96 patients included in the study, 22 (22.9%) had low serum C3 at diagnosis. Comparison of clinical, serological and laboratory characteristics and outcomes between the two groups is shown in [table 1].

Conclusions: Almost one quarter of patients with biopsy proven PI GN had low serum C3 at diagnosis in this cohort. These patients had more advanced renal impairment, required acute dialysis more frequently and were more likely to end up in end-stage kidney disease compared to patients with serum C3 within the normal range.

PO1944

Serum and Urinary Metabolites Discriminate Disease Activity in ANCA-Associated Glomerulonephritis

Sam Kant, Anne Le, Nabeel Attarwala, Durvuu Geetha. Johns Hopkins University School of Medicine, Baltimore, MD.

Background: Relapse of disease and treatment related morbidity due to lack of a reliable biomarker for disease activity continue to be a significant issue in patients with ANCA associated vasculitides (AAV). Renal biopsy is currently gold standard for reliable detection of active disease. Metabolomics have been used to successfully discern disease activity in a number of autoimmune diseases. We sought to investigate the use of serum and urinary metabolomics to discriminate disease activity in AAN associated GN.

Methods: Ten patients with AAV renal disease history: serum and urine supernatant sample collections during active and remission phases of disease. Active renal disease was defined by presence of hematuria >5 RBC/hpf, urinary RBC casts or an increase in serum creatinine >30% or < in eGFR by 25% or biopsy proven GN. The samples were then subjected to targeted metabolomics data acquisition using a Thermo scientific Q Exactive plus Orbitrap Mass Spectrometer Plus with a Vanquish UPLC at our metabolomics facility.

Results: The mean age in this cohort was 61 years, with 6 patients each being male and Caucasian. Nine patients had biopsy proven renal disease, with clinical diagnosis in one. Mean BVAS and mean GFR was 17 and 28 respectively. Intensities of urinary citrate and iso-citrate are significantly higher in the remission group compared to the active one. Mean BV AS and mean GFR was 17 and 28 respectively. Intensities of urinary citrate and iso-citrate levels in serum and urine samples compared to other metabolites of the TCA cycle implying involvement of additional metabolic pathways.

Conclusions: This study indicates that serum and urinary citrate and iso-citrate may be utilized to monitor disease activity in AAV and emerge as an alternative to kidney biopsy.

PO1945

Renal Involvement in Granulomatosis with Polyangiitis Does Not Increase Inpatient Mortality Compared with No Renal Involvement

Phizhog Edgin,1 Precious Eseaton,2 Augustine Manadan.2 1 John H Stroger Hospital of Cook County, Chicago, IL; 2 University of Benin Teaching Hospital, Ehizogie PO1945, University School of Medicine, Baltimore, MD.

Background: The aim of this study was to analyze the difference in outcomes of Granulomatosis with polyangiitis (GPA) with and without renal involvement. The primary outcome was inpatient mortality, while secondary outcomes were hospital length of stay (LOS) and total hospital charges.

Methods: Data were abstracted from the National Inpatient Sample (NIS) 2016 and 2017 Database. NIS is the largest inpatient admission database in the United States. The NIS was searched for adult GPA hospitalizations with and without renal involvement as the principal or secondary diagnosis using ICD-10 codes. Multivariate logistic and linear regression analysis was used to adjust for confounders for the primary and secondary outcomes respectively. STATA software was used to analyze the data.

Results: There were 71 million discharges included in the combined 2016 and 2017 NIS database. 23,670 hospitalizations were for adult patients, who had either a principal or secondary ICD-10 code for GPA. 8,265 (34.92%) and 15,405 (65.08%) of these hospitalizations were for GPA with renal and without renal involvement respectively. Inpatient mortality occurred in 4.0% (GPA) patients (5.1%) and 3.8% (without GPA) patients (p=0.0287). The adjusted odds ratio (AOR) of inpatient mortality for GPA with renal compared to without renal involvement was 1.14 (95% CI 0.84-1.56, p=0.406). GPA with renal involvement hospitalizations had a mean increase in adjusted mean LOS of 1.36 days (95% CI 0.82-1.91, p=0.0001) compared to GPA without renal involvement. GPA with renal involvement hospitalizations had an increase in adjusted total hospital charges of $18,723 compared to GPA without renal involvement (95% CI 9,595-27,852, p=0.0001).

Conclusions: There is no statistically significant difference in inpatient mortality for hospitalizations of GPA with and without renal involvement. However, LOS and total hospital charges in GPA with renal involvement were greater than those without renal involvement. Hence GPA with renal involvement has a greater burden to the healthcare system compared to without renal involvement.

PO1946

Immunological Indexes Both in Renal and Serum Were Associated with Relapse and Patient Outcome in Chinese Patients with Myeloperoxidase-ANCA-Associated Glomerulonephritis

Wei Lin, Zhong Yong. Department of Nephrology, Xiangya Hospital, Central South University, China, Changsha, China.

Background: Rapidly progressive glomerulonephritis (RGN) caused by antineutrophil cytoplasmic antibody (ANCA)–associated vasculitides (AAV) are typically characterized by few or no immune deposits in glomerulus which was defined as pauci-immune glomerulonephritis (GN). Immune complex (IC) deposits in glomerulus and abnormal complement (C3, C4) levels have also been reported in patients with AAV. Most patients with AAV in China are positive for anti-myeloperoxidase (MPO), which more frequently had renal involvement and developed RGN. Therefore, it is necessary to assess serum immunological indexes and the IC deposits in renal in MPO-ANCA-associated GN.

Methods: Clinical and histopathologic characteristics of patients with AA V in China are positive for anti-myeloperoxidase (MPO) were collected. This study included 398 patients with MPO-ANCA-Associated GN from 2016 to 2019. The patients were divided into 2 groups according to the presence of both the regimens.

Results: The patients whose sC3 level return to normal after a period of treatment, which was confirmed that both initial and continuously low sC3 can act as predictive indicators for renal outcome. IgG and complement C1q deposits associated with poorer renal and patient outcome, which can help to judge the prognosis of MPO-ANCA-associated GN to some extent.

PO1947

Rituximab vs. Cyclophosphamide in the Treatment of Anti-GBM Crescentic Glomerulonephritis: An Observational Study

Ajay Jarayal, Sanjay Vikrant. Indira Gandhi Medical College, Shimla, India.

Background: Anti glomerular basement membrane (GBM) crescentic glomerulonephritis (CGN) is a rare disease affecting kidneys and/or lungs. At present most of the evidence for its treatment is with use of plasmapheresis (PP), high dose steroids (HDS) and cyclophosphamide (CYC). The use of Rituximab (Rtx) in addition to PP and HDS is only anecdotal. Herein, we are describing our experience with the use of both regimens.

Methods: A retrospective analysis of all the patients with anti GBM CGN admitted in our hospital from September 2018 to November 2019 was done. Anti GBM CGN was diagnosed on the basis of ≥50% crescents on kidney biopsy and immunofluorescence showing IgG deposition along GBM and/or by the presence of anti GBM antibodies.

Results: 11 patients were admitted with anti GBM CGN, during this period (15 months). Kidney biopsy was done in 10 patients and in one anti GBM GN was diagnosed on the basis of raised anti GBM antibody titres. There were 8 females and three males (age range 37-72 years). The mean serum creatinine was 8.69 mg/dl. Out of 11 patients 2 refused for treatment and 2 were lost to follow up. 3 out of 7 patients had diffuse alveolar hemorrhage (DAH) and in all it succeeded renal involvement (one had diagnosis of usual interstitial pneumonia for 1 year). 4 out of 11 patients had concomitant urinary tract infection, 5 out of 7 (71.42%) were ANCA positive, 2 out 11 had type 2 diabetes mellitus, 5 out of 11 were oligoanuric and 7/11 (63.6%) were dialysis requiring at presentation. PP was given on alternate days. Both the patients who refused for treatment died on follow up. Among remaining 7 patients 5 had received PP+HDS + CYC and 2 had received PP+HDS+Rtx. In CYC group 4 (all 4 were dialysis dependent and 3 were oligoanuric) out of 5 patients died whereas in Rtx group both the patients survived (one was dialysis dependent and oligoanuric).
Conclusions: In our study most of the patients presented late to the hospital due to vague symptoms at the onset (mean 30 days) and few had co-existing UTI (this delayed the treatment). 63.6% were dialysis requiring at presentation and DAH was the most common cause of in-hospital death. Two out the three survivors achieved normal eGFR (one in CYC and one in RTx arm) whereas third one had no progressive decline in eGFR (RTx). The use of RTx along with HDI and PS showed favourable outcomes in our study.

Impact of Race on Hospitalization Outcomes for Goodpasture Syndrome

PO1948

Impact of Race on Hospitalization Outcomes for Goodpasture Syndrome in the United States

Janet A. Medrano,1 Charat Thongprayoon,2 Michael A. Mao,4 Boonaphaph Boonaphaph,3 Wisit Kaewput,2 Wisit Cheungsapitorn1.1 Division of Nephrology, Department of Internal Medicine, University of Mississippi Medical Center, Jackson, MS; 2Division of Nephrology and Hypertension, Department of Medicine, Mayo Clinic, Rochester, MN; 3Phramongkutklao College of Medicine, Bangkok, Thailand; 4Division of Medicine, Mayo Clinic, Jacksonville, FL; 5Department of Medicine, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA

Background: Goodpasture’s syndrome is a rare and life-threatening autoimmune disease. While Goodpasture’s syndrome is well described in Caucasian and Asian populations, its prevalence and outcomes among African American and Hispanic populations are unclear. We conducted this study to assess the impacts of race on hospital outcomes among patients with Goodpasture’s syndrome.

Methods: The National Inpatient Sample database was used to identify hospitalized patients with a principal diagnosis of Goodpasture’s syndrome from 2003-2014. Goodpasture’s syndrome patients were grouped based on their race. The differences in hospital treatments and outcomes between Caucasian, African American, and Hispanic Goodpasture’s syndrome patients were assessed using logistic regression analysis.

Results: 964 patients were hospitalized with a primarily diagnosis of Goodpasture’s syndrome. Of these, 786 were included in the analysis: 622 (65%) were Caucasian, 73 (8%) were African American, and 91 (9%) were Hispanic. The need for mechanical ventilation, non-invasive ventilation support, and renal replacement therapy in African American and Hispanic patients was higher compared to Caucasians. There was no significant difference in organ failure, sepsis, and in-hospital mortality between African Americans and Caucasians. In contrast, Hispanics had higher in-hospital mortality than Caucasians but similar risk of organ failure and sepsis.

Conclusions: African American and Hispanic populations account for 8% and 9% of hospitalizations for Goodpasture’s syndrome, respectively. While there is no significant difference in in-hospital mortality between African Americans and Caucasians, Hispanics with Goodpasture’s syndrome carry a higher in-hospital mortality compared to Caucasians.

PO1949

Overlap Syndrome of Antineutrophil Cytoplasmic Antibody-Associated Vasculitis and IgG4-Related Disease: Distinct Clinicopathologic Clues for Precise Diagnosis

Peifen Liang,2 Qiongqiong Yang,1 Wenfang Chen,2 Shuling Yue,3 Qianqian Han.1 Department of Nephrology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China; 2Department of Pathology, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; 3Guangzhou KingMed Center for Clinical Laboratory Co., Ltd, Guangzhou, China

Background: Both antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) and IgG4-related disease (IgG4-RD) are multi-system inflammatory disorders. The coexistence of both diseases presents the possibility of a new overlap syndrome which leads to different treatment and outcome. In this study, the symptomatic and pathological concurrence of AAV and IgG4-RD is investigated to explore the possibility and clinicopathologic clues to the diagnosis of this overlapped syndrome.

Methods: A case of a 67-year-old man in our hospital who exhibited the characteristics of both AAV and IgG4-RD was presented. The treatment response and outcome of the case were followed up for the next 15 months. Then, a systematic literature review of the overlap syndrome of AAV and IgG4-RD was performed on PUBMED database from 1976 until January 2020.

Results: Mild hematuria with rapid progressive renal failure of the patient was diagnostic of Goodpasture's syndrome. Four common clinicopathologic characteristics could be used as specific clues to the diagnosis of overlap syndrome.

Conclusions: AAV may overlap with IgG4-RD while presenting atypical manifestations. Four common clinicopathologic characteristics could be used as specific clues to the diagnosis of overlap syndrome.

Anti-IL-5 Therapy in Eosinophilic Granulomatosis with Polyangiitis (EGPA): An 18-Month Follow-Up Study of a Steroid-Sparing Therapeutic Approach

Allyson C. Fegan,1 Pasupathy Sivasothy,1 Robin B. Gore,1 Caroline M. Owen,1 Rachel B. Jones,1 Rona M. Smith,1 Lisa C. Willcocks,1 Stella M. Burns,1 David R. Jayne,2 Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; 2University of Cambridge, Cambridge, United Kingdom.

Background: EGPA is a small vessel vasculitis with protein renal manifestations including necrotizing glomerulonephritis, eosinophilic interstitial nephritis and obstructive uropathy. In the randomized, placebo-controlled MIRRA trial for relapsing and refractory EGPA, adjuvant therapy with 300mg anti-IL-5 mAb Mepolizumab (MEPO), accrued long times in remission, reduced steroid exposure and reduced relapse rates.

Methods: The aim of our study was to analyze the outcome for EGPA patients who received 100mg s/c of MEPO monthly for 18 months and beyond. This retrospective, descriptive study analyzed 13 patients with EGPA, who received 100mg s/c of MEPO therapy monthly. Time points of assessment included MEPO commencement [M0] and ≥ 18 months [>M18].

Results: This study demonstrates that anti-IL-5 therapy serves as a favorable model for steroid minimization in EGPA, with an overall 50% reduction in steroid dosage. Additional reduction in conventional immunosuppressants was also observed in 3 patients. ANCA positive serology normalized in all four patients. Well tolerated, it demonstrated considerable clinical benefit, with 12 patients [92.3%] continuing anti-IL-5 therapy beyond 18 months. Renal function was preserved. One patient had MEPO switched to Rituximab to treat both EGPA and new onset monoclonal gammopathy. Three patients were switched to alternative anti-IL5 therapies, belatacept (x2) and Reslizumab (x1).

Conclusions: The relapsing nature of EGPA places a potential dependency of therapy on steroids, underscoring the importance of targeted pathway specific biologics to minimize steroid exposure, prevent tissue damage and ensure early response to therapy. This results in a 50% reduction in steroid dosage in this study, with preserved renal function.

Pauci-Immun Lupus Nephritis: A Case Report

Bharath Suryadevara, Anvita Anne, Varun Kumar Bandi. Dr. Pinnamaneni Siddharth Institute of Medical Sciences & RF, Gannavaram, India

Introduction: Systemic lupus erythematosus (SLE) is an autoimmune disease with multisystem involvement, and Lupus nephritis (LN) typically shows immune deposits on biopsy. Pauci-immune LN is a rare entity.

Case Description: A 35-year-old female presented with pedal edema, reduced urine output & yellowish discoloration of eyes since 20 days. No vomiting, diarrhea, joint pains, rashes, or hematuria. She had similar episodes in 2011 and 2013 & was given blood transfusion and oral steroids. She is a hypertensive for 10 years and diabetic for 2 years. She had 2 normal vaginal deliveries with no obstetric complications. On examination she had pallor, icterus and generalized edema, blood pressure of 170/100mmHg. Rest of the examination was normal. She had severe anemia, renal failure, positive ANA, dsDNA and direct Coom’s test, with no normal complements. There was no evidence of autoimmune ANA. SLE with Anti-nucleic acid antibody (ANAs) and probable lupus nephritis (LN) was diagnosed. Steroid pulse was started with stabilization of renal function and hemoglobin. Renal biopsy showed necrotising crescentic glomerulonephritis with no endocapillary proliferation. Immunofluorescence did not show any immune deposits. A diagnosis of pauci immune LN was made, and was started on cyclophosphamide. She had partial renal recovery with creatinine of 1.5 mg/dl, no hematuria, no hemolysis.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Discussion: Renal biopsy in SLE patients can reveal varied pathologies like ANCA or lupus vasculitis etc. In our case, renal biopsy was similar to ANCA vasculitis, however systemic features favored SLE. With a diagnosis of SLE, and absence of endocapillary proliferation, a diagnosis of pauci-immune LN was made.

PO1952

Pulmonary Renal Connection: A Case of ANCA Vasculitis and Atypical Anti-GBM Antibody Associated with Vaping
Josephine Abraham, Larith Al-Rabadi, Monica P. Revelo Penafiel, Martin C. Gregory. University Of Utah University Of Utah Hospital, Salt Lake City, UT.

Introduction: The use of e cigarettes and vaping is linked to the development of lung injury (EVALI). We present a case of ANCA (antineurul cytoplasmic antibody) vasculitis with atypical Anti GBM (glomerular basement membrane) antibody in a patient with EVALI.

Case Description: A 17 year old male with a history of vaping presented with acute respiratory failure requiring mechanical ventilation. CT chest revealed diffuse bilateral consolidation. Evaluation for infection was negative. Nephrology was consulted for acute renal failure. Urine analysis was notable for hematuria and proteinuria. Urine microscopy identified dysmorphic erythrocytes. Renal biopsy showed pauci immune crescentic glomerulonephritis (panel A). ANCA with MPO (myeloperoxidase) specificity and Anti GBM antibody were positive. He was treated with methylprednisolone, therapeutic plasma exchange and oral cyclophosphamide initially and subsequently Rituximab. Four months later his creatinine was 1.2 mg/dL, improved from a peak level of 7.5mg/dL with plasma exchange and oral cyclophosphamide initially and subsequently Rituximab. Two other patients with vaping associated lung injury admitted to the intensive care unit were noted to have dysmorphic hematuria. Urine negative ANCA and Anti GBM titers. Two other patients with vaping associated lung injury (EV ALI). ANCA with MPO-ANCA levels >8.0 U, along with positive anti-histone antibodies and SCL-70 antibodies, but with negative anti-GBM and ds-DNA. Kidney biopsy showed pauci-immune crescentic GN with trace staining for IgA, IgM, C3, kappa and lambda. As she had been on HZ, the diagnosis of HZ-induced ANCA-associated vasculitis was made. Offending agent was held and cyclophosphamide was started. After 2 months, kidney function returned to baseline, with resolution of proteinuria and hematuria.

Discussion: In patients with HAV, unusually high titers of MPO are present and can be used to differentiate drug-associated and spontaneous cases. A minority of patients can also present with other positive antibodies, such as ds-DNA, anti-histone, or Scl-70. As HZ can also cause SLE-like pattern of injury, it can be difficult to obtain a diagnosis based on serologies alone; biopsy is essential for diagnosis and prognosis. The treatment of HAV involves not only removing the inciting agent, but also further immunosuppression, as HZ is thought to lead to increased expression of MPO and PR3 breaking neutrophils tolerance and leading to auto-antibody formation. When choosing a treatment strategy, guidelines for spontaneous ANCA should be followed; in this particular case, as she had severe lung involvement, cyclophosphamide was chosen.

PO1954

Isolated ANCA Renal Arteritis
Ishan Shah,1 Nidia C. Messias,2 Muhammad A. Siddiqui,1 Sara Combs,1 J Pedro Teixeira,1 1University of New Mexico Health Sciences Center, Albuquerque, NM; 2Arkana Laboratories, Little Rock, AR.

Introduction: Vasculitis associated with antineutrophil cytoplasmic antibodies (ANCA) usually causes acute kidney injury (AKI) through crescentic glomerulonephritis (GN). Renal ANCA arteritis without GN is often accompanied by prominent interstitial nephritis (IN). We present a case of AKI due to ANCA renal arteritis without significant GN or IN.

Case Description: An 84-year-old woman with hypertension, chronic kidney disease [baseline creatinine (Cr) 1.6 mg/dL], and prior right nephrectomy for renal cell carcinoma presented with nausea and anorexia. She was admitted the prior month for pyelonephritis and Cr of 1.9. Dysmorphic RBCs were seen in the urine sediment and proteinuria at 1.2g/g. Given concern for anti-GBM, she received IgG and plasma exchange followed by rituximab, but a week later she opted to stop dialysis and transition to comfort measures and she died 2 days later.

Discussion: Most patients with AKI from ANCA-associated vasculitis will have GN, often crescentic. Extraglomerular features on biopsy of ANCA disease are common and include IN and arteritis/arteriolitis, but often parallel the activity of glomerular disease. Prior case reports of ANCA renal disease without GN have featured prominent IN with or without arteritis/arteriolitis. This case of marked necrotizing arteritis, minimal IN, and absent GN represents a rare phenotype of ANCA renal disease.

PO1953

Sabotaged: Hydralazine-Induced ANCA Glomerulonephritis
Larissa Kruger Gomez, Esilida Sula Karrecci, Krishna A. Agarwal, Ruth Schulman, Jeffrey H. William, Stewart H. Lecker, Isaac E. Stillman. Beth Israel Deaconess Medical Center, Boston, MA.

Introduction: While usually well known to cause SLE-like syndrome, hydralazine (HZ) can also be involved in a different clinical scenario with ANCA vasculitis.

Case Description: 77y/o woman with hypertension and COPD presents with 2 days of hemoptysis and hematuria, requiring urgent intubation. CT scan reveals multifocal infiltrates and bronchoscopy shows diffuse alveolar hemorrhage. Labs showed Hb of 6.8 and Cr of 1.9. Dysmorphic RBCs were seen in the urine sediment and proteinuria at 1.2g/g. Given concern for anti-GBM, she received IgG and plasma exchange. ANA 1:1280 with MPO-ANCA levels >8.0 U, along with positive anti-histone casts. (b) IF 0 to trace IgG (C) EM Occasional electron dense deposits in mesangium only.

(a) Masson trichrome - Crescent with compression of capillary tuft. Tabules with RBC casts. (b) IF to trace IgG (C) EM Occasional electron dense deposits in mesangium only.

(b) IF 0 to trace IgG (C) EM Occasional electron dense deposits in mesangium only.

Acknowledgements: The use of e cigarettes and vaping is linked to the development of lung injury (EVALI).

Rare Case of Silicosis-Induced Pauci-Immune Glomerulonephritis

Sandheep Venkataraman, Matthew Ray, James F. Dylewski. University of Colorado, Denver, CO.

Introduction: Pauci-immune glomerulonephritis (GN) caused by ANCA was first described in 1982. Most cases are idiopathic, however, ANCA vasculitis may induced due to certain exposures. Here we report a case of ANCA vasculitis associated with pulmonary silicosis.

Case Description: A 37-year-old man with no prior history presented with anorexia, weight loss, fatigue, and arthralgias for 6 months. He was employed as a sandblaster, stonecutter, and as a mason. On initial exam he was found to have dactylitis and Raynaud’s phenomenon. His presenting creatinine (Cr) was 2.9 mg/dL with urinalysis showing 3+ blood and 1.2 gm proteinuria. Renal ultrasound demonstrated enlarged kidneys bilaterally. Notable serologies were ANA positive 1:1280, p-ANCA positive 1:2560, C3 77 mg/dL, C4 6 mg/dL, and MPO at 78 AU/mL. CT Chest revealed innumerable pulmonary nodules, extensive fibrosis, and mediastinal lymph nodes with eggshell calcifications. Infectious workup was negative. Transbronchial biopsy demonstrated collection of histiocytes containing black pigment without granulomas. Kidney biopsy showed necrotizing crescentic GN, with marked interstitial inflammation and focal intralobular vessel infiltrates. IF and EM was negative, consistent with pauci-immune ANCA vasculitis. Given his history and presentation, he was diagnosed with silica-induced ANCA vasculitis. He was treated with 3 days of IV methylprednisolone, followed by a rapid prednisone taper. He also received IV Rituximab 1 gm on days 0 and 14, plus IV cyclophosphamide 500 mg every 2 weeks for 6 doses starting on day 0. The patient responded well with Cr improving to 1.0 and decreased proteinuria. Unfortunately he relapsed 3 months after last rituximab dose.

Discussion: Silica exposure is most often associated with pulmonary disease but there have been case reports of RPGN associated with it too. The majority of these patients were MPO positive. T-cell dysregulation and endothelial damage from PMNL free radical generation is a proposed mechanism for this disease. Duration and intensity of silica exposure are known risk factors. In addition to pulmonary-renal symptoms, these patients may have systemic manifestations of lupus, rheumatoid arthritis, scleroderma, or dermatomyositis. More research is needed to further understand the management of these patients. This patient represents a rare case of silica-induced ANCA pulmonary-renal vasculitis.

PO1956

ANCA-Negative Small-Vessel Vasculitis with IgG4-Positive Plasma Cell Infiltration: A Case Report and Literature Review

Huipeng Ge, Cufiang Li, Qingjiong Yuan. Xiangya Hospital Central South University, Changsha, China.

Introduction: Although the histopathology was critically important for differential diagnosis between AAV and IgG4-RD, overlapping morphologies and clinical manifestations put the clinicians in a dilemma of diagnosis sometimes. Here, we described a case of ANCA negative PICG with IgG4-positive plasma cell infiltration.

Case Description: A 60-year-old male patient presented with cough for 3 months and progressive renal impairment for 8 days. He had elevated serum IgG level with absence of anti-neutrophil cytoplasmic antibodies (ANCA). Lung CT as shown in Figure 1. Renal biopsy showed severe tubulointerstitial nephritis (TIN) with extensive infiltration of IgG4-positive plasma cells, suggesting a diagnosis of IgG4-related kidney disease (Figure 2). However, the identification of necrotizing glomerulonephritis and crescents forming and the absence of storiiform fibrosis and obliteratorive phlebitis led to a diagnosis of ANCA negative renal small-vessel vasculitis. The condition was improved by using corticosteroids and cyclophosphamide at beginning.

Discussion: ANCA negative cannot exclude the diagnosis of AAV. The elevated serum IgG4 and/or abundant IgG4-positive cell infiltration can act as one of the manifestations in AAV. ANCA-negative pauci-immune crescentic glomerulonephritis (PICG) might represent an independent disease entity from ANCA positive PICG. Besides, IgG4-related disease (IgG4-RD) is an exclusive diagnosis and needs to be differentiated from vasculitis and other diseases. It is suggested that ANCA-negative PICG with elevated serum IgG4 and/or abundant IgG4-positive cell need to be further studied.

Figure 1. Lung CT in different periods.

Figure 2. Histological findings of the kidney.

PO1957

Adalimumab-Associated Pauci-Immune Glomerulonephritis: Coincidence or Causation Effect?

Nirav N. Patel, Emma Spangler, Pavan Annamaram. Johnston Memorial Hospital, Abingdon, VA.

Introduction: Adalimumab is a TNF-blocker used in the treatment of hidradenitis suppurativa (HS). Infections, lupus-like syndrome, and lymphoma are known safety concerns with TNF-blockers. We report a rare case of adalimumab associated pauci-immune crescentic GN (PICGN) in a patient with HS.

Case Description: A 19-yr-old male with a history of HS on adalimumab for 6 months was seen on 4/1/20 with a fever of 103°F, cough & epistaxis for 2 weeks. CT sinuses showed polyps and sinusitis. He was treated with antibiotics for sinusitis. CT chest nasal PCR for COVID-19, blood, and urine cultures were negative. By hospital day 8, he remained febrile and developed AKI [Creatinine (Cr) 9 mg/dL, baseline of 0.8 mg/dL]. Physical exam showed chronic scarred skin lesions on the chest and axilla with no signs of infection or rash. Hematuria and microalbuminuria were noted. Ultrasound showed renomegaly. Inflammatory markers were high (CRP 254 mg/L, Ferritin 1059 mg/mL). PR3-ANCA antibody was positive 530 IU/mL. A renal biopsy confirmed PICGN (Fig 1). Bone marrow biopsy showed no evidence of hemophagocytosis. The patient was treated with pulse doses of steroids and rituximab and plasma exchange (peak Cr 6.4 mg/dL). On a 3-week follow up creatinine improved to 1.8 mg/dL suggesting a favorable outcome. The patient never required dialysis.

Discussion: AKI, microscopic hematuria, and proteinuria can be seen in a febrile illness. However, epistaxis and renomegaly prompted us to check for ANCA serology. To our knowledge, this is the first case of adalimumab associated PICGN in a patient with HS. Interestingly, our patient is much younger compared to previously reported cases (mean 51.4 years). It is possible that adalimumab may be unrelated to the vasculitis; however, due to a strong temporal association, it was felt to be the culprit agent. Nephrologists must be aware of the renal side effects of this class of drugs.
PO1958
A Case of C-ANCA Associated Retroperitoneal Fibrosis and Periaortitis
Vinay Srinivasa. Darling Downs Health Service, QLD Australia Darling Downs Hospital and Health Service, Toowoomba, QLD, Australia.

Introduction: Granulomatosis with Polyangiitis (GPA) is a type of small vessel vasculitis that has prevalence rate of 25-160 cases per million population, and a incidental rate of 0.4 cases per 100,000 population per year. Clinical features of the disease involves respiratory and renal systems. However, large vessels such as the Aorta and retroperitoneal tissue are rarely involved.

Case Description: We present the case of a middle-aged male who presented with an obstructive nephropathy in which abdominal CT revealed a soft tissue mass encasing the Aorta and Inferior Vena Cava causing obstruction of the Left ureter. Despite ureteric stenting, serum creatinine failed to improve. Further urinanalysis demonstrated an active urinary sediment; hemoproteinuria. Serum c-ANCA and PR-3 antigen titres were positive. Renal biopsy was performed and confirmed pauci-immune vasculitis. The patient was induced with pulsed intravenous methylprednisolone and cyclophosphamide and as part of his maintenance treatment received prednisolone and oral cyclophosphamide. On follow up, partial remission has been achieved with his serum creatinine returning to baseline level and proteinuria reduced, though erythrocytes are still evident. Repeat abdominal imaging has revealed a reduction in the size of the soft tissue mass with treatment.

Discussion: Biopsy proven vasculitis has been shown in patients with retroperitoneal fibrosis. Few case reports and series have described this association, inferring a pathogenic role of ANCA in the development of retroperitoneal fibrosis. Moreover it has been suggested that retro peritoneal fibrosis may be an early clinical manifestation of ANCA associated vasculitis. Consequently, ANCA associated vasculitis should be considered in the differential diagnosis of any patient who has Retroperitoneal fibrosis and an active urinary sediment

PO1959
A Rare Case of ANCA-Negative Pauci-Immune Crescentic Glomerulonephritis in an Elderly Woman
Oscar A. Garcia Valencic, Eduardo Edelman Saul, Yanetzky Olivera Arenciña, Marte A. Sosa. University of Miami Jackson Memorial Hospital, Miami, FL.

Introduction: Acute kidney injury is usually multifactorial with a broad differential diagnosis. Of those, rapidly progressive glomerulonephritis (RPGN) requires special attention as it represents a true diagnostic and therapeutic emergency that can lead to irreversible kidney failure.

Case Description: A 92-year-old female with a history of Chronic Kidney Disease Stage III, Diabetes Mellitus type II, hypertension, and recurrent deep vein thrombosis sent to the ER for evaluation of rapidly worsening kidney function found on outpatient laboratories for assessment of poor oral intake and fatigue for 2 weeks. On arrival, BP was 133/79mmHg, HR 70rpm, temperature 36.9°C, RR 17 rpm and SO2 of 99%. Mental status was at baseline and physical exam was unremarkable. Laboratory data were remarkable for serum creatinine of 10.55 mg/dl from baseline of 1.8 mg/dl, potassium level of 6 mEq/L and bicarbonate of 17 mEq/L. Urinalysis showed proteinuria (3+), hematuria (344 RBCs/hpf) and leukocyturia (68 WBC/hpf). Urine protein creatinine ratio of 2.4. No acute EKG changes were present. Renal ultrasound demonstrated increased bilateral echodensity; otherwise unremarkable. Patient initially treated medically with no improvement requiring hemodialysis. Work up sent with ANCA panel, Anti-GBM, Serum protein electrophoresis, immunofluorescence, Free Light Chains, complement and Hepatitis panel all negative. Acutely worsening kidney function coupled with active sediment and proteinuria prompted a kidney biopsy which demonstrated pauci-immune crescentic glomerulonephritis. She was started on Methylprednisolone 500mg IV daily for 3 days, followed by prednisone 60mg qd and plasmapheresis every-other-day.

Discussion: PICG is a potentially life-threatening condition leading to renal failure within days or weeks and represents up to 80% of RPGN. The majority of cases (~90%) are ANCA positive and occur in younger patients. Here we present the clinical profile of a rare new diagnosis of ANCA negative PICG in an elderly lady. Renal damage is more severe and kidney survival poorer when compared to ANCA positive crescentic GN. Our patient received RRT throughout hospital stay showing signs of recovery on second week. She was discharged on oral Prednisone 30mg qd and Cyclophosphamide 50mg qd with close follow up.

PO1960
Anti-Glomerular Basement Membrane (GBM) Disease with Atypical Clinical and Histologic Features Precipitated by Parainfluenza
Fergal Foulhuy, Louise M. Burke, Nick Mayer, Michelle M. O'Shaughnessy, Cork University Hospital, Cork, Ireland.

Introduction: Anti-GBM disease typically presents with rapidly progressive glomerulonephritis (RPGN) and linear GBM staining for IgG1 or IgG3. We describe a case of anti-GBM disease with an initially indolent course that progressed to RPGN following parainfluenza infection. Serum anti-GBM antibodies were only mildly elevated and kidney biopsy showed linear GBM staining for IgG1.

Case Description: An otherwise healthy 23-year old male presented with a 2-week history of cough, dyspnea, and hemoptysis. He recently returned from China, where he smoked the respiratory and renal systems. Despite smoking heavily, Hematouria and proteinuria were not noted during a routine medical exam 2 months prior. Physical exam notable for BP 150/90mmHg, bibasilar chest crackles, and bipedal edema. Investigations: sCr 2.6mg/dL (1.5mg/dL 2 weeks prior); 3+ blood and 3+ protein by UA; negative/normal C3, C4, ANA, anti-dsDNA, ANCA; viral respiratory PCR positive for parainfluenza; serum anti-GBM 15mc/mL (<10mc/mL). CT Thorax showed bilateral pleural effusions and groundglass nodularity within the right middle and lower lobes. Kidney biopsy showed linear GBM staining for IgG4, with glomerular necrosis, crescents, and unusually prominent endocapillary proliferation (Figure). Treatment included diuretics, antibiotics, IV methylprednisolone, oral cyclophosphamide, and 8 plasma exchanges over 11 days. Serum anti-GBM was undetectable after 2 days. He progressed to dialysis-requiring ESRD over the next 6 weeks: a repeat kidney biopsy showed persistent crescentic GN with endocapillary proliferation and strong linear IgG4 staining, despite repeatedly negative serum anti-GBM.

Discussion: This case highlights complexities in the pathogenesis and diagnosis of anti-GBM disease. RPGN was likely triggered by parainfluenza infection, a rarely described association. Low anti-GBM antibody levels were likely explained by the poor sensitivity of ELISA to detect IgG4. Finally, prominent endocapillary proliferation is characteristic of “atypical anti-GBM disease”, yet serum anti-GBM was positive in this case.

PO1961
Seronegative Anti-GBM: A Spectrum of Disease
Alisa Ilescas,1 Michael B. Kuperman,2 Sara Combs,1 J Pedro Teixeira,3 1University of New Mexico Health Sciences Center, Albuquerque, NM; 2Arkana Laboratories, Little Rock, AR.

Introduction: Glomerulonephritis (GN) due to anti-GBM disease is usually associated with detectable antibodies against the NC1 domain of the type IV collagen alpha-3 chain [NC1-α3(IV)], but a subset of seronegative anti-GBM disease has been described with no lung involvement, non-crescentic GN on biopsy, and indolent course. We present a case of anti-GBM disease that is neither typical nor atypical.

Case Description: A 56-year-old woman with hypertension and obesity underwent renal biopsy after routine labs showed rise in creatinine (Cr) above baseline of 1.5 mg/dL 6 months prior and hemoproteinuria on UA. The results [Figure] prompted transfer to our center. On admit, she noted mild chronic dyspea but denied cough or hemoptysis. She had mild hypertension (146/80) and trace edema. Cr had risen to 4.5, urine protein was 3.4 g/g Cr, and chest x-ray was clear. She was started on IV corticosteroids and plasma exchange (PLEX). Anti-GBM IgG [multiplex bead assay, ARUP], drawn prior to PLEX, was negative (4 AU/mL, upper limit normal 19). She was treated with IV cyclophosphamide and 7 PLEX sessions over 2 weeks and her Cr stabilized at 3.5. She avoided dialysis and was discharged on prednisone with plans to continue monthly cyclophosphamide.

Discussion: Our patient exhibited an intermediate phenotype of anti-GBM disease with crescentic GN, subacute Cr rise, no lung involvement, and negative serology. Modern assays for anti-GBM antibody have a sensitivity of 94-100%. However, negative serology is also seen in rare cases of anti-GBM GN due to antibodies against epitopes of the GBM other than NC1-α3(IV). Our case illustrates that a negative anti-GBM antibody does not exclude anti-GBM disease which is ultimately a pathologic diagnosis. It also suggests a spectrum exists between classic and atypical anti-GBM disease, but favorable outcome is possible regardless with biopsy-directed therapy.

Biopsy yielded 35 glomeruli, 15 globally sclerotic and 12 with fibrinous necrosis, cellular crescents (panel A, PAS, 600x), or fibrocellular crescents. RBC casts and 50% interstitial fibrosis were seen. IF showed linear GBM staining with λ (3+), IgG1 (3+), and IgG4 (3+, panel B, 400x).

A Case of Lupus Podocytopathy (LP) with Focal Segmental Glomerulosclerosis (FSGS): Is It Time to Add LP to the Next Revision of the Classification of Lupus Nephritis?

Introduction: Lupus podocytopathy is not included in the commonly used International Society of Nephrology/Renal Pathology Society (ISN/RPS) classification of Lupus Nephritis (LN). It has been reported in literature for the last 20 years. LP can have pathologic transition with variable outcomes. We describe a case of LP with FSGS in a young male patient with subsequent relapse.

Case Description: 25 year old male with past history of lupus without nephritis and chronic immune mediated thrombocytopenia presented with generalized fatigue. Physical exam revealed diffuse rash and vital signs were within normal limits. Relevant laboratory findings included platelet count of 21000/microliter, acute kidney injury with creatinine (Cr) of 1.6 mg/dl (baseline Cr of 0.8 to 1.1 mg/dl), spot urine protein creatinine ratio of 4.3 g, 24 hour urine protein of 4.1 g, low C3 and C4, hemoglobin of 9.6 g/dl and WBC count of 3.6/microliter. Serology was positive for ANA, dsDNA and SSA indicating active lupus flare. Left kidney biopsy showed mild mesangial expansion, no endocapillary proliferation and subtotal (>80%) podocyte foot process effacement. No subendothelial or subepithelial deposits were seen. He was treated with pulse dose steroids followed by oral steroids and serum Cr came back to baseline. Subsequently he was treated with mycophenolate mofetil 2 g/day. At 2 weeks, proteinuria came down to 1.8 g/day and by 12 weeks he achieved remission. However at 6 months, he had urine protein of 8.5 g in 24 hours with increase in Cr to 2.4 from 1.6, suggesting relapse.

Discussion: The presence of minimal or no capillary wall immune deposits with or without mesangial proliferation and effacement of podocyte foot processes in the setting of nephrotic range proteinuria is collectively termed as LP. LP must be considered in patients with lupus presenting with NS (Nephrotic Syndrome). It is cardinal that we consider adding this distinct entity in the classification of lupus nephritis.

PO1964

Oliniguat Protects Renal Function and Podocytes in In Vivo and In Vitro Models of Podocytopathies

Emmanuel S. Buys, 1 Ehtesham Artif, 2 Suzana Marusic, 1 Deepak Nihalani, 2 Cyclerion, Cambridge, MA; 2Medical University of South Carolina, Charleston, SC; 1Hooke Laboratories, Lawrence, MA.

Background: The nitric oxide (NO) receptor soluble guanylate cyclase (sGC) is a signal-transduction enzyme producing the secondary messenger cGMP. Impaired NO–sGC–cGMP signaling is associated with renal dysfunction. sGC stimulators trigger NO production, inhibit apoptosis, and retard inflammatory and fibrotic processes important in renal injury.

Methods: We studied the reno-protective effects of oliniguat, a clinical-stage sGC stimulator, by studying in vitro and in vivo models of glomerular injury.

Results: In an acute focal segmental glomerulosclerosis (FSGS) model of glomerular injury induced by nephrotoxic serum (NTS), treatment with oliniguat attenuated proteinuria and kidney pathology when compared to vehicle-treated mice. Additionally, oliniguat treatment prevented NTS-induced mislocalization of the slit diaphragm proteins synaptopodin and nephrin. Ultrastructural analysis by transmission electron microscopy revealed that podocyte foot process morphology was preserved in mice treated with oliniguat. To further assess the protective effect of sGC stimulation on podocytes, human podocytes injured by exposure to proteasome-sulfate (PS) were treated with oliniguat. Oliniguat treatment restored PS-induced damage of podocyte actin cytoskeleton organization and the localization of podocyte cell membrane proteins. In the genetic MRL.Mpg-Fas-lpr/J mouse model of systemic lupus erythematosus (SLE), disease progression, as assessed by immunofluorescence for lupus nephritis, was attenuated in mice treated with the positive control cyclophosphamide or with oliniguat than in vehicle-treated mice. Fewer kidney lesions (interstitial infiltrates, tubular atrophy, tubular epithelium vacuolation, tubular and interstitial lesions, and glomerular lesions) were observed in mice treated with cyclophosphamide or oliniguat than in vehicle-treated mice. In contrast to cyclophosphamide, oliniguat treatment did not result in leukopenia, reduction in spleen weight, or lower anti-dsDNA antibody in serum, suggesting that oliniguat did not impact the auto-immune aspect of SLE.

Conclusions: In summary, oliniguat, an orally bioavailable sGC stimulator, exhibits significant reno-protective effects in nonclinical models and warrants further evaluation for the treatment of FSGS, other podocytopathies, or nephropathies associated with diseases such as sickle cell disease.

Urinary Rac1, a Novel Predictive Biomarker, Is Elevated in FSGS and Diabetic Nephropathy Patients and Reduced by TRPC5 Inhibition with GFB-887 in a Rat FSGS Model

Yossi Douzen, Hari Raghu, Tingting Ge, Liron Walsh, John F. Reilly, Goldfinch Bio Inc, Cambridge, MA

Background: Activation of Ras-related C3 botulinum toxin substrate 1 (Rac1) plays a key role in podocyte injury and dysfunction in focal segmental glomerulosclerosis (FSGS) and diabetic nephropathy (DN). In diseased podocytes, Rac1 activation is mediated by calcium influx through the transient receptor potential canonical 5 (TRPC5) ion channel. GFB-887 is a sub-type selective, small molecule inhibitor of TRPC5 that reduces albuminuria in deoxycorticosterone acetate (DOCA)-salt and ZIDSD rat models of FSGS and DN, respectively. Here, we aimed to develop a urinary biomarker to assess podocyte Rac1 activity in kidney disease and in response to GFB-887 treatment.

Methods: Using a sandwich ELISA, we measured Rac1 concentrations in sera and urine from patients with FSGS, DN, and Alport in response to treatment with GFB-887, and in urine from healthy volunteers, FSGS, DN and Alport patients.

Results: Rac1 was detected in extracellular vesicles (EV) isolated from podocyte culture supernatant and rat and human urine. GFB-887 treatment lowered urinary Rac1 concentrations in normal and DOCA-salt rats, and the decreased Rac1 was associated with decreased albuminuria in the DOCA-salt rats. Urinary Rac1 concentrations were markedly elevated in FSGS and DN but not in Alport patients. In a murine model of DN, the TRPC5 inhibitor GFB-887 reduces albuminuria and retards kidney injury. The decreased Rac1 was associated with decreased albuminuria in the DOCA-salt rats. Urinary Rac1 concentrations were markedly elevated in FSGS and DN compared to healthy subjects, but not elevated in Alport. GFB-887 is efficacious in rodent models of FSGS and DN, but not of Alport, suggesting that elevated urinary Rac1 is predictive of disease.

Conclusions: The TRPC5 inhibitor, GFB-887, targets the TRPC5-Rac1 pathway and suppresses urinary Rac1 associated with its therapeutic action in a rat model of FSGS. Rac1 urine concentrations are markedly higher in FSGS and DN compared to healthy subjects, but not elevated in Alport. GFB-887 is efficacious in rodent models of FSGS and DN, but not of Alport, suggesting that elevated urinary Rac1 is predictive of disease. Together, these data support the potential for clinical utilization of urinary Rac1 as a pharmacodynamic and predictive biomarker for GFB-887 treatment in FSGS and DN. GFB-887 is currently being studied in TRACTION®, a Phase 2 clinical trial in FSGS and DN, in which baseline and on-treatment urinary Rac1 measurements will support further development of the biomarker.

PO1966
A Novel In Vivo Approach to Capture the Podocyte Foot Process Proteome
Lori L. O'Brien, Gary F. Gerlach. University of North Carolina at Chapel Hill, Chapel Hill, NC.

Background: Podocytes are an extraordinary cell of the kidney filtration system with their tentacle-like foot processes flowing out from each cell body and interdigitating with neighboring processes. Proper kidney function relies on these cells and the complex architecture created by the interdigitating processes. They are the most critical component of the glomerular filter. Podocytes are injured and their integrity is compromised in the majority of kidney diseases leading to progressive proteinuria. However, we know little about the full complement of proteins localized to the foot process and how they change with disease.

Methods: We have developed a novel genetic mouse model capable of generating a spatially restricted, real-time, in vivo proteinome. Recently, proximity labeling techniques have been developed to provide snapshots of spatially localized proteomes. The BioID method utilizes a promiscuous bacterial biotin ligase flexibly linked to a target protein of interest to biotinylate proteins within the vicinity. We have adapted this approach to identify the podocyte foot process proteome. Using podocin as a handle, we have modified the Nphp2 (podocin) locus to link to the mutated, promiscuous Biotin ligase to podocin (Nphp2BioID). A flexible, 13x linker allows for a generous proximity around podocin, thereby capturing the broad proteome of the podocyte foot process.

Results: We have obtained viable Nphp2BioID animals. Utilizing immunostaining, we have confirmed the proper expression and localization of the podocin-BioID. The HA-tagged biotin ligase appended to podocin colocalized with podocin and other foot process proteins. To test it’s functionality, we injected biotin dialy for 7 days. This produced an increase of biotinylated proteins in Nphp2BioID podocytes versus wild type biotin injected controls or un.injected Nphp2BioID mice. We have affinity purified the biotinylated proteins from glomerular isolations and are currently performing proteomic analyses.

Conclusions: We have generated the first of it’s kind in vivo mouse model to specifically identify the spatially localized proteome of the podocyte foot process. Our proteomics results will provide unprecedented insights into the make-up of this highly specialized and critical structure.

Soluble RARRES1 Induces Apoptosis of Podocytes to Promote Progression of Kidney Disease
Anqun Chen,1,2 Ye Feng,1 Yu Li,1 Chengguo Wei,2 Tianjun Guan,1 Kyung Lee,2 John Ch. C.7 Division of Nephrology, Zhongshan Hospital, Xiamen University, Xiamen, China; 2Division of Nephrology, Department of Medicine, Icahn School of Medicine at Mount Sinai, NY, NY.

Background: Podocyte loss is a major event leading to the progression of focal segmental glomerulosclerosis (FSGS) and diabetic nephropathy (DN). Here, we found that retinoic acid receptor responder protein 1 (RARRES1) contributes to the podocyte loss in FSGS and DN.

Methods: We determined the role of RARRES1 in human and mouse with FSGS and DN. We investigated the mechanisms of RARRES1 in cultured human podocytes.

Results: The expression of RARRES1 increased in the glomeruli of patients with FSGS and DN and correlated with the eGFR. Single-cell RNA-sequencing of the kidney showed that RARRES1 is highly expressed in podocytes. Immunostaining confirmed that podocyte expression of RARRES1 increased in patients with DN and FSGS as compared to MCD. RARRES1 expression was strongly induced by TNF-α in cultured human podocytes. RNA-sequencing of podocytes with RARRES1 overexpression revealed genes enriched in apoptosis. RARRES1 was cleaved into a soluble RARRES1 and the cleavage site was mapped at the aa70. Overexpression of wild RARRES1 or adding soluble RARRES1 in cultured human podocytes induced apoptosis, while overexpression of RARRES1 cleavage mutant lost the apoptotic effect. Further, we showed that soluble RARRES1 underwent endocytosis to interact with intracellular RIOK1, leading to the activation of p53 and apoptosis in podocytes. In vivo, podocyte-specific overexpression of RARRES1 resulted in marked glomerular injury and albuminuria in mice, while the overexpression of RARRES1 cleavage mutant had no renal phenotype. Finally, knockdown of RARRES1 in podocytes ameliorated kidney injury in mice with adriamycin-induced nephropathy.

Conclusions: We demonstrate a new role and mechanism of RARRES1 in regulation of podocyte apoptosis in glomerular disease, as summarized in the Figure: TNF-α induces expression of RARRES1, which is cleaved, then undergoes endocytosis to interact with intracellular RIOK1, leading to the activation of p53 and apoptosis. High RARRES1 expression promotes the progression of FSGS and DKD.

The Glomerulus-on-a-Chip as a System to Unravel Novel Membrane Attack Complex (MAC)-Independent Role of Complement in Membranous Nephropathy
Stefano Da Sacco,1 Astigik Petrosoyan,2 Susan Hartzell,3 Valentina Villani,3 Charmi Dedhiya,2 Andrea Angeletti,4 Joaquin Manrique,5 Roger E. De Filippo,6 Laura Paola,7 Paolo Cravedi,5 Silvio de Chafu’s Hospital of Los Angeles, Los Angeles, CA; 6Complejo Hospitalario de Navarra, Pamplona, Spain; 7Università di Bologna, Bologna, Italy; 1Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Primary membranous nephropathy (MN) is a leading cause of nephrotic syndrome in adults worldwide due to the deposition of anti-podocyte-antibodies against in the glomerular subepithelial space. While complement deposition is thought to play a crucial pathogenic role, the exact effector mechanism of complement in MN is unclear due to the lack of in vitro and in vivo systems that recapitulate human disease. We have developed a novel glomerulus-on-a-chip system (GOAC) using human primary podocytes and human glomerular endothelial cells (GEC) in combination with OrganoidPlates and assessed the functional response to human MN serum and the role of MAC deposition and C3a/C3aR signaling in MN pathogenesis.

Methods: Glomerular chips were cultured with serum from anti-PLA2R+ MN patients or healthy individuals. Functional response was assessed by albumin permeability assay to evaluate selective-permeability. Role of MAC and C3a/C3aR signaling pathway in glomerular filtration barrier damage was assessed by immunofluorescence and functional analysis while mechanisms of action were explored by PCR arrays, Western Blotting and immunostaining. Results were confirmed in vitro using podocytes on which C3aR1 was silenced and in vivo using a C3aR1 KO mice model.

Results: Following exposure to sera from MN patients, we have confirmed deposition of human IgG on podocytes and formation of MAC complex, accompanied by albumin leakage. GOAC supplemented with C3aR1 antagonists as well as GOAC using podocytes in which C3aR1 was silenced were able to prevent glomerular filtration damage on the GOAC kidney confirmed by rescue of permeability efficiency, while inhibition of MAC formation by protein S (an inhibitor of MAC formation) did not significantly reduce GOAC permeability.

Conclusions: We have successfully developed a glomerulus-on-a-chip system that closely mimics the GFB structure and provides a powerful tool for studying renal regenerative and disease mechanisms in proteinuric diseases. Using this model, we showed that C3a/C3aR signaling plays a dominant role in complement-mediated MN pathogenesis.

PO1969
Dach1 Is Essential for Maintaining Normal Podocytes
Keiko Tanaka, Taiji Matusaka. Department of Basic Medicine, Tokai University School of Medicine, Isehara, Japan.

Background: Dach1 is a transcription factor, determining cell fates in various organs. Dach1 polymorphism has been reported to be associated with nephrotic syndrome and chronic kidney diseases. We previously found that Dach1 was highly expressed in normal primary podocytes and rapidly disappeared after induction of podocyte injury, similarly to WT1. We, therefore, aimed to elucidate the function of Dach1 in normal podocytes in vivo.

Methods: Podocyte-specific Dach1-knockout (KO) mice were generated by mating Dach1-Cre mice with Nphs1-Cre or Nphs2-CreERT2 mice. Podocyte injury was evaluated by urinary analysis (SDS-PAGE) and histology. In addition, we analyzed primary cultured podocytes of Dach1 overexpressing knock-in transgenic (K1) mice (n=9), in which Dach1 is expressed under the control of Rosa26 promoter.

Results: Although the efficiency of Cre-mediated recombination was not high, all of the congenital Dach1/KO mice (n=20, more than 4 weeks old) presented abnormal albuminuria. Seven out of the 11 (63%) mice histologically analyzed showed focal segmental glomerulosclerosis. Injured podocytes lacked Dach1 staining, whereas intact podocytes retained Dach1. When Dach1 KO was induced in adult mice, the mice showed abnormal albuminuria within two weeks. Immunostaining revealed that podocytes lacking Dach1 causes leakage of albumin, while retaining WT1 protein. Since endogenous Dach1...
Dysregulated Dynine-Mediated Vesicle Trafficking Is a New Mechanism of FSFG

Methods:

1. We demonstrated that INF2 limited dynine mediated retrograde trafficking of nephrin by binding to and sequestering Dynll1, a component essential for the integrity of dynine. 2. R218Q KI podocytes illustrated an impaired recycling of nephrin with enhanced recruitment of dynein components, which could be rescued by targeting dynein transport pathway using Cilobrevin D (Dynine inhibitor), dominant negative Dynacin 1, siRNA for Dynll1 or overexpression of wildtype INF2 (to sequester Dynll1). 3. PAN damage induced podocytes to switch from G0 to G1 phase, and rapamycin (a cell cycle regulator) compensated for their loss during CKD progression. Their only adaptive response to podocyte loss is an underlying mechanism of the disease.

Results:

1. We demonstrated that INF2 limited dynein mediated retrograde trafficking of nephrin by binding to and sequestering Dynll1, a component essential for the integrity of dynein. 2. R218Q KI podocytes illustrated an impaired recycling of nephrin with enhanced recruitment of dynein components, which could be rescued by targeting dynein transport pathway using Cilobrevin D (Dynine inhibitor), dominant negative Dynacin 1, siRNA for Dynll1 or overexpression of wildtype INF2 (to sequester Dynll1). 3. PAN damage induced podocytes to switch from G0 to G1 phase, and rapamycin (a cell cycle regulator) compensated for their loss during CKD progression. Their only adaptive response to podocyte loss is an underlying mechanism of the disease.

Conclusions:

Recognition of the dysregulated dynine mediated trafficking of SD has enlightened a new understanding and therapeutic targets for podocyte related pathology and FSFG.

RNA Sequencing and ATAC-Seq Reveal Gene Profiles in Injured Podocytes in Mice, and Podocyte-Specific Hypoxia Inducible Factor 2α Deletion Protects from Adriamycin-Induced Podocyte Injury

Xiaoyan Li,1,2 H. William Pachter,1,2,3 and Tomoko Hayashida.1,2

Northwestern University Feinberg School of Medicine, Chicago, IL; Ann and Robert H Lurie Children’s Hospital of Chicago, Chicago, IL.

Background: Roles for hypoxia-inducible factor (HIF) in kidney diseases have been controversial. Upregulation HIF expression is beneficial in protecting kidney from acute injury, while we and others showed that HIF aggravates chronic fibrosis. In podocytes, deletion of VEGFR caused progressive glomerular damage, prevented by overexpression of hypoxia inducible factor 2α. Here, using podocyte-specific HIF-2α deletion mice, we tested effects of HIF-2α deletion on gene profiles in injured podocytes.

Methods: HIF-1α−/− or HIF-2α−/− mice were crossed with either NPHS1 or 2-Cre mice. HIF-2α−/− or NPHS2-Cre mice were further crossed with Z/EG mice that express GFP under control of the ROSA26. In vivo, podocyte specific induction of NPHS2-Cre is sufficient to protect from TNF induced podocyte injury.

Results: Our results identify a new role of NPHS2-Cre in the uptake of fatty acids, the accumulation of TAGs, CE and formation of LDs. Further experiments to understand the exact mechanism by which NPHS2-Cre expression contributes to the progression of podocyte damage in FSFG are underway.

Shroom3-FYN Regulates Podometrics via LKB1-AMPK Signaling
Khadija Banu, John M. Basgen, Qisheng Lin, Arun Cumpelik, Lewis Kaufman, Marina Planoutene, Barbara T. Murphy, John C. He, Madhav C. Menon. Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Previously, we showed Shroom3–FYN interaction regulated podocyte cytoskeleton via FYN activation. Intriguingly, global Shroom3 knockdown mice (CAGS-TG/Shr3 Kd) displayed reduction in glomerular volume-VGlom, podocyte & endothelial fraction of VGlom vs NTGs [1].

Methods: To examine mechanism of podometrics regulation by Shr3, we used Shr3 & FYN Kd human podocytes (hPodo) to study cell protein content & growth regulatory pathways; performed unilateral nephrectomy examining Vpodo hypotrophy in remnant kidneys.

Results: At day-7, CAGS-TG mice showed restricted Vpodo hypotrophy with reduced expansion of PodoVf, Vpodo vs NTGs [1b]. We observed reduced hPodo volume (FSC), Protein:DNA ratios (n=3, P<0.01) & inhibited ribosomal biogenesis (18S RNA) in vitro & in vivo suggesting reduced protein synthesis and FYN will be downstream of Shr3 in regulating hPodo size. Notably, we observed increased AMPK activation, increased p-ERK & autophagy (high p-ULK1 and LC3II levels) downstream of AMPK, in vitro/in vivo by immunoblot (IB) & immunofluorescence (IF) [1c] suggesting negative regulation of protein synthesis. Next, we examined LKB1 localization (AMPK-kinase) by IB after subcellular fractionation & IF in Shr3/FYN Kd hPodo identifying increased LKB1 Cytosolic:Nuclear ratio, explaining AMPK activation due to increased cytosolic pool of active LKB1 [1d]. Finally, we used an AMPK inhibitor, Compound C in CAGS-TG mice and observed reversal of podometric changes-Vpodo, Vendo, induction of podocytopenia with AMPK-inhibition [1e].

Conclusions: Here, we show Shroom3-FYN interaction regulating podometrics via AMPK-signaling in podocytes. The protective morphometric effects have implications to disease models with podocyte/nephron loss requiring obligate Vpodo/Lpodectomy hypotrophy.

Knockout of the Neonatal Fe Receptor (FcRn) Alters Lysosomal Function in Podocytes
Judith Blaine,1 Madeline D. Ng,1 Pantipa Tonsawan,2 Linda Lewis,1 James F. Dylewski.1 1University of Colorado Denver School of Medicine, Aurora, CO; 2Khon Kaen University, Khon Kaen, Thailand.

Background: FcRn is a trafficking protein that diverts monomeric IgG from the lysosome but sorts multimeric IgG and immune complexes (ICs) to the lysosome for processing. FcRn is required in dendritic cells to traffic ICs to the lysosome for proteolytic processing and presentation on MHC II. Podocytes express FcRn and previous work had reported that podocytes can act as antigen presenting cells. Here we show that cultured podocytes are weak antigen presenting cells (APCs) and that knockout (KO) of FcRn in podocytes does not alter podocyte response to an immune stimulus but does result in significant downregulation of lysosomal function.

Methods: Cultured wild type (WT) and FcRn KO podocytes were treated with interferon gamma (IFNg) to simulate proinflammatory conditions. MHC II and costimulatory marker expression was assessed by flow cytometry. Antigen presentation was evaluated by examining T cell response when WT or FcRn KO podocytes were treated with ICs and used as APCs. Lysosomal size and cellular location in WT and FcRn KO podocytes were examined using confocal microscopy. WT or FcRn KO podocytes were treated with IFNg and ICs was quantitated. RNA-seq was used to examine lysosomal pathways.

Results: Both WT and FcRn KO podocytes upregulated MHC II after treatment with IFNg but there was no difference in expression levels between WT and KO. There was no change in CD80 expression between WT and KO after treatment with IFNg. CD86 and ICOSL expression levels in WT and FcRn KO were minimal at baseline and after treatment with IFNg. When used as APCs, WT podocytes induced a very modest amount of IL-2 production by T cells (a marker of T cell activation) whereas KO podocytes induced none. After treatment with ICs, lysosomes in WT podocytes were significantly larger and were also clustered around the nucleus, indicating lysosomal activation. In contrast, after IC treatment lysosomes in the KO were smaller and more peripherally located. Treatment with ICs also resulted in significantly greater colocalization between lysosomes and ICs in WT versus FcRn KO podocytes, demonstrating that ICs were not directed to the lysosome in the KO. RNA-seq showed significant downregulation of lysosomal pathways in KO podocytes compared to WT after treatment with ICs.

Conclusions: FcRn KO in podocytes alters lysosomal trafficking and function.

POI977
The Role of Opioid Receptor Signaling in Podocytes and Renal Damage in Dahl Salt-Sensitive Rats
Daria Golosova1, Oleg Palygin1, Vladimir Levenchenko1, Christine A. Klemens2, Ashraf El-Meanawy3, Alexander Staschenko1. 1Medical College of Wisconsin Department of Physiology, Milwaukee, WI; 2Medical College of Wisconsin Department of Medicine, Milwaukee, WI.

Background: The rise in opioid use underscores the urgent need to better understand the direct and indirect effects of opioids on renal function, especially in patients with chronic kidney disease (CKD) or hypertension. The extensive use of opioids is strongly correlated with poor cardiovascular outcomes. We hypothesize that stimulation of opioid receptors (ORs) elevates intracellular calcium level in podocytes leading to kidney damage and progression of hypertension.

Methods: Freshly isolated glomeruli from Dahl salt-sensitive (SS) rats, human kidneys and immortalized human podocytes were used to elucidate the contribution of specific ORs to podocyte calcium flux. Calcium response in the podocytes was analyzed via ratiometric confocal fluorescent microscopy. For chronic studies Dahl SS rats were on a 0.4% (LS) or 8% (HS) NaCl diets for 14 days with or without a daily intravenous bolus infusion of BRL52537, a potent and selective kappa-OR agonist.

Results: Stimulation of kappa-ORs, but not mu-ORs or delta-ORs, mediated calcium influx in podocytes through activation of TRPC6 channels in rat and human kidney. The effect of BRL52537 was completely abolished when we used the 0 mM calcium media or when SAR7334 (a TRPC6 channel inhibitor) was applied. Triggering the kappa-OR/ TRPC6 pathway induced podocyte cell shape changes via actin cytoskeleton remodeling. In vivo studies revealed that SS rats chronically treated with BRL52537 exhibited augmented blood pressure (MAP was 179 ± 15 mmHg vs. 151 ± 11 mmHg), nephrinuria, albuminuria, and elevation in podocyte calcium in BRL52537 treated Dahl SS rats.

Conclusions: Stimulation of kappa-OR modulates calcium influx in podocyte via TRPC6 channels. The opioid-induced increase in the calcium flux in podocytes is expected to contribute to podocyteopathy, proteinuria, kidney injury and progression of salt-induced hypertension. These findings are important to advance our knowledge of the pathogenesis of the development of CKD and hypertension in the context of pain management.

POI975
Apolipoprotein M as a Biomarker of Glomerular Lipotoxicity in Nephrotic Syndrome
Yelena R. Drexler, Judith T. Molina David, Sandra M. Merscher, Alessia Formoni. University of Miami Katz Family Division of Nephrology and Hypertension, Miami, FL.

Background: Dysregulation of intrarenal metabolic pathways involved in cholesterol efflux is implicated in lipid-induced podocyte injury in glomerular diseases. Among several genes that are involved in cholesterol efflux, we recently reported a significant downregulation of glomerular apolipoprotein M (APOM) expression in patients with FSGS. HDL-associated APOM facilitates reverse cholesterol transport and is the carrier for the bioactive sphingolipid sphingosine-1-phosphate (S1P). Mutations in S1P lyase, the enzyme responsible for S1P degradation, cause a familial form of FSGS. We hypothesize that glomerular APOM deficiency is a surrogate biomarker for lipid-induced kidney injury in NS.

Methods: Patients with FSGS, MN, and MCD enrolled in NEPTUNE, a multi-center, longitudinal cohort study of children and adults ≥18 NS, who were treated with prednisone 1 g/g at baseline were selected for analysis. RNA expression data were obtained from the

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster - Publication Only

610
glomerular compartment isolated from kidney biopsies and compared with living kidney samples. Linear regression analysis was used to correlate glomerular APOM expression with plasma and urinary levels of APOM to and to correlate glomerular APOM expression and plasma and urinary APOM levels with eGFR at baseline.

**Results:** Among 84 patients, 68% were male, mean age was 40 years, mean baseline eGFR was 80.6 mL/min/1.73m², and mean uPCR was 4.9 g/g. Glomerular APOM expression was decreased in patients with NS compared to healthy controls (p < 0.001), irrespective of histologic diagnosis. APOM expression was positively correlated with plasma and urinary APOM levels in the NS cohort (R² = 0.089, p = 0.003) and in the FSGS subgroup (R² = 0.189, p = 0.0218). Decreased APOM expression (p = 0.005) and decreased plasma APOM (p = 0.031) were associated with a lower eGFR at baseline. After adjustment for age, sex, and race, each unit decrease in APOM expression was associated with a 9.83 mL/min/1.73m² (95% CI, 3.72 to 15.93, p = 0.002) lower eGFR at baseline.

**Conclusions:** Glomerular APOM deficiency and decreased plasma APOM levels were associated with decreased kidney function at baseline in the NS cohort. These findings identify APOM as a potential biomarker of lipid-induced kidney injury in NS.

The Sensitivity of Podocytes to AP In Vivo Is Distinctly Lower than the Sensitivity of Glomerular Endothelial and Proximal Tubular Cells

Julia S.,1 Bernhard Scherner,1 Thomas Benzing,2 Matthias Hackl,1
1Department II of Internal Medicine and Center for Molecular Medicine Cologne, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany; 2CECAD, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany.

**Background:** ATP signaling is involved in a plethora of pathways, involving damage signaling. Cell culture models as well as experiments on isolated glomeruli indicate that podocytes respond to ATP with a calcium transient. To date a direct effect of ATP on podocytes in vivo in glomeruli has not been described.

**Methods:** In this study mice expressing GCaMP3 in podocytes (Pod:cre), proximal tubular cells (Pax8:cre) or endothelial cells (Tie2:cre) underwent multiphoton in vivo imaging of the kidneys. Mice were anesthetized, an arterial catheter was placed into the right carotid artery and aorta and the left kidney was exteriorized. The vascularculature was labelled with a 70-kDa dextrane. Different doses of ATP were injected as a bolus via the catheter and dose-dependent calcium transients were monitored.

**Results:** Our data indicates that even doses of 5 mg/kg ATP did not induce calcium transients in podocytes and proximal tubular cells via a cortical arterial catheter, while robust activation of calcium signaling was induced in endothelial and proximal tubular cells with 0.5 mg/kg ATP. Further increasing the ATP dose by injection via an abdominal aortic catheter resulted in a calcium transient in podocytes.

**Conclusions:** In contrast to endothelial cells and proximal tubular cells, podocytes show a low sensitivity to ATP-mediated calcium signaling. We therefore hypothesize, that the low sensitivity ATP of podocytes is a protection mechanism to avoid calcium signals from filtered ATP.

**Funding:** Government Support - Non-U.S.

Cytomegalovirus Viremia-Associated Collapsing FSGS in an Immunosuppressed Systemic Lupus Erythematosus Patient

Emily Daniel,1 Dominick Savarese,2 Andrew S. Bomback,1 Hilda E. Fernandez,3 Columbia University Irving Medical Center, New York, NY.

**Introduction:** Maintaining a broad differential in evaluating AKI in SLE patients with a history of lupus nephritis (LN) is important. We describe a patient with SLE and AKI progressing to dialysis dependence due to collapsing FSGS in the setting of CMV infection.

**Case Description:** A 23 yo African American F with a history of LN class IV + V (maintained on MMF; Ig BID) and APLS presented with one week history of nausia, vomiting and diarrhea. Admission labs were notable for a Cr of 10.5 mg/dl (baseline Cr 0.7), pancytopenia, with albumin of 1.7 mg/dl. Spot urine protein to creatinine ratio was >27 g/g. Serologies showed low C3 and C4, positive ANA, LDH 1437 and negative HIV test. Patient became anuric and required hemodialysis. Stress dose steroids were administered for presumed RPGN on LN. Renal biopsy on hospital day 8 demonstrated collapsing FSGS with 100% podocyte foot process effacement without significant IFTA and 4/9 globally sclerotic glomeruli. Testing revealed CMV viremia with viral load of 100,000 copies/mL. Both AKI progressing to dialysis and CMV viremia were presumed to be due to CMV infection.

**Results:** In vivo studies, administration of LMB2 caused leakage of co-introduced EGFP in podocytes, incorporation of propidium iodide in 37.1% ± 2.5% of hCD25-transfected cells, activation of caspase 3 in 19.6% ± 13.6% of hCD25 and EGFP expression plasmids and treated with a 1C6-D25-targeting immunotoxin, LMB2 (1nM). 24 hours later, EGFP, cleaved-caspase 3 (cCasp3) and TUNEL staining were imaged. In in vivo experiments, podocyte injury was induced by injecting LMB2 into NEP25 mice, which express hCD25 in podocytes. In some experiments, NEP25 mice carrying another transgene expressing EGFP in podocytes were used.

**Conclusions:** Apoptosis of podocytes has been widely reported in many in vitro studies, but definitive apoptosis has been rarely documented in vivo podocytes. To elucidate this discrepancy, we analyzed dying process in podocytes in vitro and in vivo. Podocytes are highly sensitive to ATP signaling as well as experiments on isolated glomeruli indicate that podocytes respond to ATP with a calcium transient. To date, a direct effect of ATP on podocytes in vivo in glomeruli has not been described.

**Methods:** In this study mice expressing GCaMP3 in podocytes (Pod:cre), proximal tubular cells (Pax8:cre) or endothelial cells (Tie2:cre) underwent multiphoton in vivo imaging of the kidney. Mice were anaesthetized, an arterial catheter was placed into the right carotid artery and aorta and the left kidney was exteriorized. The vascularculature was labelled with a 70-kDa dextrane. Different doses of ATP were injected as a bolus via the catheter and dose-dependent calcium transients were monitored.

**Results:** Our data indicates that even doses of 5 mg/kg ATP did not induce calcium transients in podocytes and proximal tubular cells via a cortical arterial catheter, while robust activation of calcium signaling was induced in endothelial and proximal tubular cells with 0.5 mg/kg ATP. Further increasing the ATP dose by injection via an abdominal aortic catheter resulted in a calcium transient in podocytes.

**Conclusions:** In contrast to endothelial cells and proximal tubular cells, podocytes show a low sensitivity to ATP-mediated calcium signaling. We therefore hypothesize, that the low sensitivity ATP of podocytes is a protection mechanism to avoid calcium signals from filtered ATP.

Transcriptional Reprogramming by WT1 Mediates a Repair Response During Podocyte Injury in Mice and Human Kidney Organoids

Sandrine S. Etou,1 Youngsook L. Jung,2 Tomoya Miyoshi,1 Ken Hiratsuka,1 Ryuji Morizane,3 Peter Park,4 Jordan A. Kreidberg,5 1Boston Children’s Hospital, Boston, MA; 2Harvard Medical School, Boston, MA; 3Massachusetts General Hospital, Boston, MA.

**Background:** We previously identified WT1 as one of the most upstream transcription factors regulating gene expression in podocytes, binding nearly all genes known to be crucial for maintenance of the glomerular filtration barrier. Here, we focus on understanding WT1 transcriptional mechanism in response to injury.

**Methods:** We used Adriaycin (ADR)-induced podocyte injury as a model for human Focal Segmental Glomerulosclerosis in mice and human kidney organoids, and a conditional WT1 inactivated mouse model to decipher the transcriptional mechanism through which WT1 regulates podocyte gene expression during injury, using transcriptomic approaches.

**Results:** After injury, we observed a transient increased expression of podocyte genes in mice and human kidney organoids. Transcriptional changes of podocytes isolated from mTgW-Nphp2cre mice during the course of injury revealed a transient increase in the expression of crucial podocyte genes, including Nphp2. Synpo and many others, reflecting a reparative response during the early stages of injury. ChIP-seq analyses demonstrated that WT1 binds nearly 50% of known genes in podocytes, and the vast majority of genes with expression changes during the response to injury. We identified de novo binding of WT1 that were only bound during the course of injury, and the expression of novel WT1 target genes. It appears that WT1 increases gene expression during injury through both the acquisition of novel binding sites, and increasing its binding intensity at sites that already harbored podocyte-specific motifs present before injury. Expression of other podocyte-specific transcription factors were highly enriched at sites where WT1 binding increased after injury. Since the DNA binding transcription factors is modulated by chromatin accessibility, we used FACS-isolated podocytes to study epigenetic reprogramming. Both ADR-meditated podocyte injury or inducible podocyte specific inactivation of WT1 resulted in the conversion of active to repressive histone marks at WT1-bound sites.

**Conclusions:** These results demonstrate that target gene binding of WT1 is highly dynamic in response to injury. WT1 directs the epigenetic regulation of gene expression, maintaining active chromatin marks at bound genes, that change to repressive marks in the absence of WT1.

Atypical Caspase 3-Dependent Death Process in Podocytes

Kazuyoshi Yamamoto,1 Masahiro Okabe,1 Takashi Yokoo,1 Taiji Matsusaka,2 1The Jikei University School of Medicine, Tokyo, Japan; 2Tokai University School of Medicine, Isehara, Japan.

**Background:** Apoptosis of podocytes has been widely reported in many in vitro studies, but definitive apoptosis has been rarely documented in vivo podocytes. To elucidate this discrepancy, we analyzed dying process in podocytes in vitro and in vivo. Podocytes are highly sensitive to ATP signaling as well as experiments on isolated glomeruli indicate that podocytes respond to ATP with a calcium transient. Systematic In Silico Exploration of the Kidney Rho-GTPase System Regulation in CKD

Background: It has become evident that dysregulation of the Rho-GTPase system would result in rearrangement of the actin cytoskeleton in the podocyte with resulting foot process effacement, a hallmark for glomerular diseases. To build further understanding how dysregulation in the Rho-GTPase system occurs in CKD, we performed a systematic mining of kidney transcriptional data to generate a full-perspective view and insights on complex interplay between the members of the large family of Rho-GTPases and their regulatory proteins, the Guanine Nucleotide Exchange Factors (GEFs) and the GTPase-activating proteins (GAPs).

Methods: A comprehensive list of 143 genes was compiled including the members of the three gene families according to HUGO Gene Nomenclature Committee (HGNC). Publicly available human transcriptomics data from healthy and CKD kidneys (microarray and RNA-seq, bulk-tissue and single-cell) were used for interrogation of gene expression patterns, including presence of detectable expression, its abundance, cell type specificity, modulation in disease, and co-expression structure. WGCNA and Cytoscape were used to correspondingly generate and visualize the gene co-expression network.

Results: All but one (142/143) genes were detectable in the human kidney, with 121 having robust levels >1TPM. The majority of genes were broadly expressed across the different tissues outside the kidney, however expression of several GEF and GAP members showed specific kidney enrichment. A number of GEFs and GAPs were modulated in CKD patient kidneys as compared to controls, predominantly with tendency for up-regulation and negative correlation with renal function, reflecting first time activation in potentially pathophysiologically or compensatory disease mechanisms. Hierarchical clustering of pairwise correlation values and WGCNA module analyses identified clusters of closely expressed genes that may implicate functional similarities.

Conclusions: To our knowledge, this is the first systematic evaluation of the Rho-GTPases, GEFs and GAPs kidney expression in the CKD context. Elucidation of the molecular interplay provides systems-level understanding and mechanistic insights that can lead to new biological hypotheses and therapeutic targets.

Bag3 as a Potential Mechanoprotector in Podocytes
Ingo Plaggmann,1 Markus M. Rinschen,1,2 Karim Heinlein,1,2 Jan C. Degenhardt,1,2 David Unnersjø-Jess,1,2 Sybille Kohler,4 Bernhard Schermer,1,2 Thomas Benzing,1,2 Department II of Internal Medicine and Center for Molecular Medicine, University of Cologne, Cologne, Germany; 3Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases (CECAD), University of Cologne, Cologne, Germany; 1The Scripps Research Institute, La Jolla, CA; 2The University of Edinburgh Centre for Discovery Brain Sciences, Edinburgh, United Kingdom.

Background: Podocyte loss is a hallmark of glomerular diseases leading to glomerulosclerosis and progression of kidney disease. Sitting on the outside of the glomerular tuft podocytes have to withstand extensive mechanical stress due to perfusion and filtration. Hypertension and hyperperfusion e.g. in disease states cause podocyte detachment when overheating their mechnomorphoprotective capacity, which start a vicious cycle of mounting strain on the remaining podocytes. Bag3 is an important mechanoprotector in many mechanical strained tissues and by inducing chaperone-assisted autophagy (CASA) maintains the protostasis of e.g. Filamin and Sypaptiopodin– indispensable for podocyte biology. Additionally Bag3 insufficiency renders susceptibility to diabetic nephropathy in a mouse model. These findings point toward Bag3 as a candidate for mechanical stress protection in podocytes.

Methods: Using immunohistochemistry, super-resolution-microscopy and mass-spectrometry we examined glomeruli and podocytes for Bag3/CASA expression and characterized the CASA-complex composition in podocytes by immunoprecipitation. The influence of mechanical clues was examined by stiff matrices and cyclic stretch. The role of Bag3 in vivo is being evaluated in different mouse lines (Bag3.F209L mutation, a conditional knockdown, fusion-protein).

Results: In the glomerulus the Bag3 and the entire CASA-complex is enriched in podocytes in mass-spectrometry. Bag3 staining localizes to the slit diaphragm protein nephrin in superresorolution microscopy. Importantly the co-chaperone Bag3 shows interaction with the essential actin-cytoskeleton regulators like Rock, Arp2 and Dynamin2 in co-immunoprecipitation. The expression of Bag3 and the CASA-complex in podocytes is regulated by mechanical clues. Knockdown of the Bag3 homologue starvin in drosophila nephrocytes displays a mild filtration disturbance. The dominant-negative Bag3.F209L mutation causes a mild proteinuria in a whole-body overexpression mouse line.

Conclusions: The data further emphasize the role of Bag3 and chaperone-assisted-selective-autophagy in podocyte mechanoprotection and maintenance of podocyte cytoskeleton architecture. Currently undergoing characterization of podocyte specific Bag3 genes and the Bag3/CASA lines and the mixed disease models will further help to understand the role of Bag3 at the kidney filtration barrier.

Knockout of the Neonatal Fc Receptor in Podocytes Ameliorates Nephritis by Reducing Glomerular Apoptosis
Judith Blaine,1 James F. Dylewski,1 Linda Lewis,1 Pantipa Tonsawan.2
1University of Colorado, Aurora, CO; 2Khon Kaen University, Khon Kaen, Thailand.

Background: There are few targeted treatments for immune mediated kidney diseases which can result in progressive renal failure. Podocytes express the neonatal Fc receptor (FcRn), a trafficking protein that sorts immune complexes (ICs) to the lysosome. In dendritic cells FcRn mediates trafficking of ICs to the lysosome is required for antigen processing and presentation on MHC II. We have found that podocyte specific knockout (KO) of FcRn ameliorates nephrotoxic serum (NTS) nephritis but that this protection occurs via a non-immune mediated mechanism. Here we show that KO of FcRn in podocytes results in a significant reduction in apoptosis both in vitro and in vivo after an immune challenge.

Methods: Wild type (WT) and FcRn KO podocytes were cultured in the presence or absence of ICs. The intrinsic and extrinsic apoptotic pathways were assayed by Western blot and ELISA. RNA-seq was performed to evaluate changes in apoptotic pathways. NTS nephritis was induced in control and podocyte specific FcRn KO (podFcRn KO) mice. Glomerulosclerosis and crescent formation were quantified on PAS sections. Flow cytometry was used to measure renal CD4+, CD8+ or FoxP3+ T cells. Glomerular apoptosis was assessed using the TUNEL assay.

Results: In vitro, after treatment with ICs, FcRn KO podocytes expressed significantly less caspase-3 and caspase-9 (intrinsic pathway caspases) and caspase-3 activity was significantly decreased in KO podocytes compared to WT. There was no difference in caspase-8 expression (a marker of extrinsic apoptosis) between WT and KO podocytes. RNA-seq analysis demonstrated significant downregulation of intrinsic apoptotic pathways in FcRn KO podocytes compared to WT. In vivo, after induction of nephrotoxic serum nephritis, there was no change in renal CD4+, CD8+ or FoxP3+ T cells in KO or control mice. KO mice had significantly less glomerulosclerosis and crescent formation. Podocyte-specific KO of FcRn also resulted in a significant reduction in the number of apoptotic cells within the glomerulus.

Conclusions: KO of FcRn reduces apoptosis via the intrinsic pathway in cultured podocytes after an immune challenge and ameliorates immune mediated nephritis in vivo by reducing glomerular apoptosis.

The African APOL1 E150 SNP and Cell Surface Expression Are Required for Kidney Risk-Variant (G1/G2)-Mediated Cytotoxicity in Podocytes

Background: Apolipoprotein L1 (APOL1) variants G1 and G2 protect against trypanosome infection, but homozygosity greatly increases the risk of chronic kidney diseases, purportedly by acting as surface cation channels in kidney podocytes. “Wild-type” APOL1-G0 exhibits various single nucleotide polymorphisms (SNPs), most commonly haplotype E150K, M228I and R255K (“KIK”), where the Reference Sequence is “EMR”), whereas G1 and G2 are only found in a single African haplotype background (“EIK”), also seen in some G0 Africans. Lannon et al (Kidney Int. 96: 1303) recently documented that differential cytotoxicity of APOL1-G1 and G2 variants versus G0 in HEK-293 cells depended on the haplotype. However, HEK-293 cells are unusually sensitive to APOL1, and podocytes are a more relevant cell type. Furthermore, only the small fraction of APOL1 that is transported to the cell surface (from its major expression site in the ER) is responsible for cytotoxicity and cell surface levels were not shown in that study. Since APOL1 residue 150 can differ in G0 Africans, we focused on comparing the cytotoxicities of E150 vs K150 SNPs in podocytes expressing equal surface levels of APOL1.

Methods: We generated podocytes stably expressing APOL1 G0, G1 or G2 under a doxycycline-inducible promoter and compared the effect of the African E150 (EIK) vs K150 (KIK) SNPs on cytotoxicity (by the Cyto-Tox Glo assay). Surface and total APOL1 were measured by FACS and Western blotting at increasing doxycycline levels. Budding was used to prevent APOL1 transport to the cell surface.

Results: Cell surface APOL1 levels increased in a doxycycline dose-dependent manner, but only the E150 G1 and G2 variants caused toxicity to podocytes as compared to E150 G0 at equal surface expression levels; K150 G0, G1 and G2 were not toxic. E150 G1 and G2 cytotoxicity was dose-dependent and required exit of APOL1 from the ER. Conclusion: Using a physiologically relevant podocyte cell line, we confirmed that the African haplotype (EIK) is required for APOL1 G1 and G2 to exert cytotoxicity. Non-natural KIK variants were not toxic. Additionally, APOL1 G0 was not toxic in either the KIK or EIK background. Furthermore, African (E150) G1 and G2 cytotoxicity required ER exit, supporting the surface cation channel hypothesis. Our data thus suggest two mutant pathways for APOL1 nephropathy.

Gliomerular Heterogeneity and Modulation of miR-93: The Role of Extracellular Vesicles

Laura Perin,1,2 Charmi Dedhia,3 Paola Aguilar,4 Roger E. De Filippis,5 Sargin Sedrakyan,6 1Children’s Hospital of Los Angeles, Los Angeles, CA; 2University of Southern California, Los Angeles, CA.

Background: Modulation of miRNA in podocytes and glomerular endothelial cells (GEC) has been associated with development of renal diseases. miR-93 is a potent regulator of pathways responsible for glomerular damage, like VEGF, TGFB and Mek2. We have evidence that miR-93 is altered in the glomeruli of mice with X-linked Alport syndrome (AS), carrying the Col4a5 mutation, and in glomeruli of AS patients. Here, we investigated the role of miR-93 in mesangial cells, podocytes and GEC from WT and AS mice. We also used extracellular vesicles (Eves) derived from human amniotic fluid stem cells (hAFSC) to assess their disease modifying activity in vitro and in vivo by regulation of miR-93.

Methods: miR-93 expression was evaluated by qRT-PCR in mesangial cells, podocytes and GEC sorted from glomeruli of male and female WT (C57BL/6J) and homozygous and heterozygous AS (Col4a5−/−) mice at different stages of disease (2m, 3.5m and 5.5m) and in biopsies of AS patients. Modulation of miR-93 by Eves was evaluated in vitro and EV therapeutic effect was evaluated in vivo by RNA-seq and qRT-PCR.

Results: miR-93 expression is different between male and female mice along disease progression. In AS males miR-93 level was significantly lower in GEC, but not in podocytes or mesangial cells vs WT cells. miR-93 expression was downregulated also in AS patients. Expression of WT in paracrine aminonucleoside damaged podocytes, and expression of fibroactin and VEGF in damaged GEC was restored by miR-93 hEve cargo transfer. In vivo, hEves showed therapeutic effect by ameliorating the level of proteinuria, which suggests pro-fibrotic activation in podocytes.

GDC-0879 Rescues Lipid Peroxidation and Podocyte Dysfunction in Coenzyme Q-Deficient Kidney Disease

Eriene-Heidi Sidhom,1 Choai Koim,2 Maria Alimina,2 May Theng Ting,4 Julian R. Avila-Pacheco,5 Andrew J. Watts,2 Katherine A. Vernon,2 Jamie L. Marshall,2 Astrid Weins,2 Jillian Shaw,2 Anna Greka,1 1Harvard Medical School, Boston, MA; 2Children’s Hospital, Boston, MA; 3Brigham and Women’s Hospital, Boston, MA; 4Columbia University Irving Medical Center, New York, NY.

Background: Mutations affecting mitochondrial coenzyme Q (CoQ) biosynthesis lead to kidney failure due to selective loss of essential cells of the kidney filtered called podocytes. Curiously, neighboring tubular epithelial cells are spared early in disease, despite their higher mitochondrial content. We therefore sought to illuminate new, cell-specific roles for CoQ, independent of its role in the electron transport chain (ETC).

Methods: Here we use CoQ deficiency caused by a monogenic disorder due to PDSS2 mutations as a model system with which to investigate the cell-specific mechanisms of disease. The resolution afforded by single nucleus RNA sequencing revealed podocyte-specific disease pathways in hexokinase (kidney disease) mice, the result of a spontaneous missense mutation in Pdes2 (V117M, Pdes2K150). We combine single nucleus transcriptomics with in vitro metabolomics and transcriptomics analyses to better understand the metabolic perturbations within this disease.

Results: Single nucleus RNA sequencing from kidneys of Pdes2K150 mice, characterized by nephronic syndrome and CoQ deficiency in all cells, identified a podocyte-specific perturbation of the Braf/Mplk pathway. Treatment with GDC-0879, a Braf/Mplk-targeting compound ameliorated kidney disease in Pdes2K150 mice. In vitro, mechanistic studies showed that depleted podocytes revealed a previously unknown perturbation in PUF metablism leading to lipid peroxidation. Ablation PUF metabolism was confirmed in vivo, where the abundance of Gpx4, an enzyme that protects cells from lipid peroxidation, was elevated in disease and restored after treatment with GDC-0879. We demonstrate broader human disease relevance of these findings by uncovering patterns of Gpx4 and Braf/Mplk pathway gene expression in tissue from patients with several kidney diseases.

Conclusions: Our studies reveal ETC-independent roles for CoQ in podocyte injury and point to Braf/Mplk as a conserved, podocyte-specific pathway for the treatment of kidney diseases.

Noncanonical PAR-1 Signalling Leads to Profibrotic Effects in Podocytes in Response to Steroid-Resistant Nephrotic Syndrome Disease Plasma

Nishita Chesor, Jack P. Tuffin, Carl J. May, Gavin I. Welsh, Moin Saleem. Bristol Renal University of Bristol, Bristol, United Kingdom.

Background: Post-transplant recurrence of steroid-resistant nephrotic syndrome (SRNS) is thought to be due to the presence of an unknown “circulating factor”, the identity of which has so far remained elusive. Our previous works suggest a role for protease-activated receptor-1 (PAR-1) involving an unknown circulating protease leading to increased podocyte motility. We have now further elaborated the signalling pathways downstream of PAR-1, which suggests pro-fibrotic activation in podocytes.

Methods: Conditionally immortalised human podocytes (ciPods) were treated with PAR-1 agonist peptide or post-transplant SRNS relapse plasma and paired-remission plasma without or with PAR-1 antagonists, RWJ 56110, SCH 79777, Vorapaxar, and FR17113. ciPods were also treated with TGF-β1 or SRNS plasma along with SB-43152, an effective TGF-β1 receptor inhibitor. A new 3D co-culture glomerular spheroid model was used to study both signalling pathways and podocyte loss.

Results: We found that PAR-1 agonist and patient relapse disease plasma, but not paired-remission plasma significantly induced the phosphorylation of VASP, JNK, and proteins involved in pro-fibrotic pathways. These changes were inhibited by co-incubation of ciPods with certain PAR-1 inhibitors, but not by TGFβ1 inhibitor. These four PAR-1 inhibitors demonstrated distinct antagonist properties and among 4 inhibitors, only FR17113 was effective in inhibiting effects of relapse plasma, suggesting a non-canonical agonism of PAR-1 by disease plasma. The phosphorylation of VASP and JNK on a 3D spheroid model corroborates the finding from a 2D ciPods model. Functionally, the circulating factor enhanced podocyte motility and podocyte loss.

Conclusions: We propose that the SRNS circulating factor acts as a pro-fibrotic effector that can activate PAR-1 leading to increased podocyte injury. A greater understanding of these signalling pathways will lead to the identification of novel therapeutic targets for this disease.

TRPC6 Is a Key Mediator of a PAR-1 Activation Pathway in Podocytes That Is Responsible for FSGS

Cari I. Mag, Musileha Chevor, Gavin I. Welsh, Moin Saleem. University of Bristol, Bristol, United Kingdom.

Background: There is good evidence for the role of a circulating factor in the pathogenesis of idiopathic nephrotic syndrome (NS). We have previously presented our work hypothesising the role of circulating plasma proteases. An active form of the protease activated receptor, PAR-1 expressed in the podocytes of SV129 mice (PAR-1α50) led to proteuria, sclerosis and death at 42 days. It was found that the signalling

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

613
response to PAR-1 agonist treatment of podocytes in vitro was also present in the kidney of mice from the PAR-1 KO, mouse, and in human podocytes treated with post-transplant recurrence plasma. This response includes the phosphorylation of VASP, JNK and Paxillin. We hypothesized that the downstream response to PAR-1 signaling involves activation of TRPC6.

Methods: Conditionally immortalised human WT podocytes and TRPC6 KO mouse podocytes were treated with a PAR-1 agonist (15 μM PAR-3931-PI Peptides International). The PAR-1 WT mouse was crossed with a TRPC6 KO on a C57 Bl6 background to develop the NPHS2 Cre PAR-1 KO, TRPC6 KO mouse. Biopsy tissue was obtained via the UK National Nephrosis Syndrome, Nephros, housed within the UK Renal Rare Disease Registry, RaDx.

Results: We present data confirming activation of the same signalling pathways in vitro in podocytes treated with a PAR-1 agonist, and in vivo in our NPHS2 Cre PAR-1 KO, mouse model with increased podocyte size and actin stress fibres, in contrast to the decreased actin stress fibres in the podocytes from the PAR-1 KO mouse. In human podocytes treated with PAR-1 agonist, the PAR-1 agonist treatment resulted in increased phosphorylation of VASP, JNK and Paxillin. When we crossed a TRPC6 KO mouse with our NPHS2 Cre PAR-1 Active mouse we saw significantly increased survival from a median of 40 days in the NPHS2 Cre PAR-1 Active mouse to 60 days when the TRPC6 was knocked out.

Conclusions: We have identified a common signalling response to PAR-1 activation in podocytes in vitro and in vivo, including in human disease. We identified TRPC6 as being a key player in the response, suggesting a unique role of this ion channel in modulating circulator factor disease, and a direct therapeutic target.

A Novel Insulin Sensitizer Targeting Nuclear Receptor PPARy Provides Beneficial Effects in a Glomerular Disease Model

Galen Rusk, Amanda P. Waller, Bryce A. Kerlin, Francisco R. Neves, Sherman Agawal, Virginia Weaver Research Institute at Nationwide Children’s Hospital, Columbus, OH; The Ohio State University, Columbus, OH; Universidade de Brasilia, Brasilia, Brazil.

Background: Thiazolidinediones (TZDs) are nuclear receptor peroxisome proliferator-activated receptor γ (PPARγ) agonists traditionally used to treat type 2 diabetes due to their insulin-sensitizing effects. These have recently been demonstrated to be beneficial in protecting podocytes and reducing proteinuria in glomerular disease. Since these FDA-approved drugs are associated with adverse effects such as weight gain, edema, and increased risk for heart failure, there is an urgent need for new therapeutic options that do not have these adverse effects. We have shown that TZD treatment ameliorates proteinuria in a murine model of collapsing glomerulosclerosis.

Methods: The studies were approved by the Institutional Animal Care and Use Committee at Nationwide Children’s Hospital. Proteinuria was induced in male Wistar rats by single intravenous puromycin aminonucleoside (PAN) injection, while the control group received saline. PAN-injected rats received sham vehicle, pioglitazone (Pio) or GQ-16 by oral gavage daily (n = 7/group). The rats were weighed daily, and urine samples were collected and analyzed for proteinuria. Plasma with sodium citrate and corn trypsin inhibitor was collected from the inferior vena cava. Endogenous thrombin potential was determined by thrombin generation assay.

Results: PAN induced robust proteinuria (P<0.009) on Day 11 and Pio reduced PAN-induced proteinuria significantly with 63.3% mean reduction (P<0.038). Interestingly, GQ-16 reduced proteinuria even further by 81.2% (P<0.008), and these were comparable to control (P>0.05). Furthermore, proteinuria reduction correlated with decreased proteinuria in healthy control levels (ns, P=0.66). Furthermore, proteinuria reduction correlated with endogenous thrombin potential. Endogenous thrombin potential was also present in the kidney organoids as a model to dissect the pathogenic process.

Conclusions: This study suggests roles for tropomyosin isoform changes in regulating podocyte shape in health and injury conditions. Funding: Private Foundation Support

IRE1α Is Essential for Podocyte Proteostasis and Mitochondrial Health

José R. Navarro-Betancourt, Joan Papillon, Jackie Guillemette, Takao Iwawaki, Andrey V. Cybulsky, Amanda P. Waller, Virginia Weaver Research Institute at Nationwide Children’s Hospital, Columbus, OH; The Ohio State University, Columbus, OH; Universidade de Brasilia, Brasilia, Brazil.

Background: Glomerular epithelial cell (GEC)/podocyte proteostasis is disrupted in glomerular diseases. To maintain proteostasis, the endoplasmic reticulum (ER) orchestrates the unfolded protein response (UPR), which includes upregulation of chaperones and clearance of misfolded proteins via autophagy. Insoluble requiring enzyme-α (IRE-1α) is activated in the UPR and is a direct therapeutic target. This study characterizes the mechanisms by which IRE1α regulates proteostasis in GECs.

Methods: GECs were cultured with podocyte-specific deletion of IRE1α (IRE1α KO) and were produced by breeding IRE1α flox/flox mice with mice expressing podocin-Cre recombinase. Nephrosis was induced with a single injection of adriamycin (ADR). GECs were cultured from glomerulus of IRE1α flox/flox mice and IRE1α was deleted by transduction of Cre recombinase. Cellular oxygen consumption rate (OCR) was quantified using the Seahorse mitochondrial stress test. Mitochondria were visualized using MitoTracker Red CMXROS or MitoTracker Green FM.

Results: Podocyte-specific IRE1α KO mice had greater ADR-induced albuminuria compared to control littermates. ADR increased expression of ER chaperones in glomeruli of control mice, but this upregulation was impaired in IRE1α KO mice. Autophagy induction was blunted in ADR-treated IRE1α KO animals, evidenced by reduced LC3-II and increased p62 levels, compared to treated controls. Electron microscopy showed prominent swelling of the ER and mitochondrial injury in podocytes of ADR-treated IRE1α KO mice. In cultured GECs incubated with tunicamycin (TM), deletion of IRE1α or chemical inhibition of the IRE1α/ERαnase with 4μC optimized upregulation of ER chaperones and LC3 lipidation compared to control. LC3 transcription and total LC3 protein levels were also reduced in TM-treated IRE1α KO GECs. Compared to control, IRE1α KO GECs showed decreased maximal and ATF-linked OCR. Mitochondrial membrane potential was lower in IRE1α KO GECs, and is a transduction of the UPR. This study characterizes the mechanisms by which IRE1α regulates proteostasis in GECs.

Conclusions: Stress-induced chaperone production, autophagy and mitochondrial dysfunction are compromised by IRE1α deletion. The IRE1α pathway is cytoprotective in glomerular disease associated with podocyte injury and ER stress.

Studying the Pathogenesis of Congenital Nephrotic Syndrome Using NPHS2 Mutant Kidney Organoids

Aude Dorison, Sara E. Howden, Thomas A. Forbes, Irene Ghobrial, Melissa H. Little. Kidney Development, Disease and Regeneration Murdoch Children’s Research Institute, Melbourne, VIC, Australia; ‘Department of Anatomy, Neuroscience and Physiology, University of Melbourne, VIC, Australia; ‘Department of Nephrology, Royal Children’s Hospital, Melbourne, VIC, Australia; ‘Department of Paediatrics, The University of Melbourne, Melbourne, VIC, Australia.

Background: Nephrotic syndrome (NS) is one of the most common forms of renal disease in children. NPHS2 mutations are the most common cause of congenital NS with missense NPHS2 mutations reported to result in misfolding and mistrafficking of the encoded slit-dihaphragm protein, Podocin. This study overexpresses mutant protein in immortalised podocyte and non-podocyte cell lines, which may not reflect the in vivo scenario.

Methods: We have simultaneously reprogrammed and CRISPR/Cas9 gene edited immortalised podocyte and non-podocyte cell lines, which may not reflect the in vivo scenario. Stress-induced chaperone production, autophagy and mitochondrial function were assessed by live cell imaging. NPHS2 KO mice had greater ADR-induced albuminuria compared to control littermates. ADR increased expression of ER chaperones in glomeruli of control mice, but this upregulation was impaired in IRE1α KO mice. Autophagy induction was blunted in ADR-treated IRE1α KO animals, evidenced by reduced LC3-II and increased p62 levels, compared to treated controls. Electron microscopy showed prominent swelling of the ER and mitochondrial injury in podocytes of ADR-treated IRE1α KO mice. In cultured GECs incubated with tunicamycin (TM), deletion of IRE1α or chemical inhibition of the IRE1α/ERαnase with 4μC optimized upregulation of ER chaperones and LC3 lipidation compared to control. LC3 transcription and total LC3 protein levels were also reduced in TM-treated IRE1α KO GECs. Compared to control, IRE1α KO GECs showed decreased maximal and ATF-linked OCR. Mitochondrial membrane potential was lower in IRE1α KO GECs, and is a transduction of the UPR. This study characterizes the mechanisms by which IRE1α regulates proteostasis in GECs.

Conclusions: Stress-induced chaperone production, autophagy and mitochondrial dysfunction are compromised by IRE1α deletion. The IRE1α pathway is cytoprotective in glomerular disease associated with podocyte injury and ER stress.

kidney organoids containing all nephron segments. Podocin localization was assessed using immunofluorescence together with known markers of cell components.

**Results:** Podocin protein was evident in the glomeruli of all organoids, however all mutant lines revealed a marked reduction of the Podocin protein. While the G92C deletion suppressed LPS-increased serum creatinine, but this difference was not statistically significant. G92C and OASIS CKO-LPS; 0.76

**Conclusions:** Suppression of in podocytes attenuated LPS-induced tubular injury in part by increased PRKCI secretion. Targeting OASIS-PRKCI signaling in podocytes could be therapeutic value in kidney diseases.

Pharmacologic Blockade of the Natriuretic Peptide Clearance Receptor

Ameliorates Glomerular Disease in an Animal Model of FSGS

Liang Yang1, Yingping Tang2, Robert Raper1,2, Robert Spurney1,2

**Background:** Glomerular podocytes play a key role in glomerular disease processes. Accumulating evidence suggests that cGMP signaling has podocyte protective effects in kidney diseases (J Am Soc Nephrol 28: 260, 2017). cGMP is produced by nitric oxide and attenuate glomerular injury.

**Methods:** We used 1×10⁵ EBV-immortalized cells isolated from peripheral blood from an anti-PLA2R seropositive MN patient to develop a protocol for the cloning and expression of recombinant IgG (rIgG) specific for PLA2R. A-Gplasmid containing H-tailed fragment of the IgG heavy (VH) and IgG (VL) chains were cloned into a single-cell workflow that allowed expression of rIgG for follow-up screening using an in-house ELISA to assess IgG binding to human PLA2R. Sera from anti-PLA2R seropositive MN patients and healthy controls served as positive and negative controls, respectively.

**Results:** Starting with 1×10⁵ EBV-immortalized cells isolated from peripheral blood from an anti-PLA2R seropositive MN patient with membrane IgG specifically reactive with non-reduced PLA2R. This subpopulation was next stained with FITC-conjugated N-terminal PLA2R peptide used to isolate B cells with antigen-specific B-cell receptor (membrane IgG) by FACS. Variable regions of IgG heavy (VH) and light (VL) chains were cloned through a single-cell workflow that allowed expression of rIgG for follow-up screening using an in-house ELISA to assess IgG binding to human PLA2R. Sera from anti-PLA2R seropositive MN patients and healthy controls served as positive and negative controls, respectively.

**Conclusions:** Blocking of NPRC would enhance local NP levels, promote cGMP signaling in podocytes and attenuate glomerular injury.

The Renal Risk Variants of Apolipoprotein L-1 Lead to an Influx of Sodium and Calcium That Drive Cytotoxicity

Joseph A. Guimazzo1, Russell P. Thomson1, Nailia Khalizova1, Patrick J. Zager2, Ryan Schreiner2, Jayne Rapel3, "Hunter College, New York, NY"; "Weill Cornell Medicine, New York, NY.

**Background:** Apolipoprotein L-1 (APOL1) is an innate immunity gene that protects against protozoan parasites. Recently evolved variants, G1 and G2, provide increased immunity against African trypanosomes while increasing the risk of chronic kidney disease. There is little consensus on how these renal risk variants (RRVs) lead to cell death or kidney disease, or which pathways to target for drug development. As APOL1 kills the parasites by forming cation channels, and because of the many pathways associated with the RRVs are linked to pore-forming toxins, we hypothesize that a similar mechanism is involved in kidney disease. In this study, we performed a series of experiments to delineate the events leading up to RRV-mediated cell death.

**Methods:** Stable segments of rRRVs and the non-risk G0 variant of APOL1. We also generated constructs using the retention using selective hooky system (RUSH) to control the trafficking of APOL1. Live-cell fluorescent microscopy was performed to measure the influx of cations Ca²⁺ and Na⁺ with GCaMP6F and FIIIC sensors, respectively. Anion exchange was performed to test the effect of G0 variant of APOL1 localization. Ion reduction experiments were performed to test the effect of each ion on cell death. Finally, planar lipid bilayers were used to test for APOL1 channel selectivity.

**Results:** We discovered that in addition to K⁺ and Na⁺, the APOL1 channel is permeable to Ca²⁺. The RRVs mediated cationic cell swelling and lysis by several hours. These events required RRV trafficking out of the ER and to the plasma membrane, where they localized prior to cation flux. Reduction of Ca²⁺ and Na⁺ in the media inhibited RRV-mediated cell death. We also found that the previously reported high Ca²⁺ gradient against a low Na⁺ gradient.

**Conclusions:** We report that the earliest event in RRV-mediated cytotoxicity is localization to the plasma membrane, followed by cation flux driven by Ca²⁺ and Na⁺. Because many of the proposed models of RRV cytotoxicity and kidney disease can be activated by pore-forming toxins, we propose that the cytoxic cation channels at the cell surface are the upstream even that links them together. Our data suggests that targeting RRV channel activity represents a promising avenue for drug development.

**Funding:** Government Support - Non-U.S.
Conclusions: These data suggest that: 1. Pharmacologic blockade NPRC may be a useful therapeutic strategy for treatment of proteinuric kidney disease, and 2. Treatment outcomes might be improved by optimizing blockade of the NPRC to more effectively inhibit clearance of NPs from the circulation.

Mitochondrial Damage in FSGS due to ANLN Mutation
Brandon M. Lane,1,2 Guanghong Wu,2 Megan Chryst-Stangl,2 Gentzon Hall,1,2 Rasheed A. Gbadegesin,1,2 Department of Pediatrics, Duke University School of Medicine, Durham, NC; 2Duke Molecular Physiology Institute, Durham, NC; 1Department of Medicine, Duke University School of Medicine, Durham, NC.

Background: We previously identified ANLN R431C as a cause of focal segmental glomerulosclerosis (FSGS). In addition to defects in actin bundling, targeted evaluation of this variant in cultured human podocytes identified disruption of AKT/mTOR signaling as a cause of ERF stress and reduced podocyte viability. Creation of the orthologous R431C point mutation in mice confirmed the increased podocyte ERF stress and identified mitochondrial damage as another possible feature of disease. To gain an unbiased view of the molecular mechanisms driving ANLN R431C induced disease, we used transcriptomic analysis and automated live cell imaging to interrogate cultured human podocytes.

Methods: Conditionally immortalized human podocytes overexpressing wildtype ANLN or the R431C variant were evaluated by mRNA-Seq and smRNA-Seq analysis to identify differentially expressed genes and microRNAs, as well as the molecular pathways involved. Potential therapeutic strategies were examined by evaluating cultured podocyte cellular and organelle-specific viability using automated live cell imaging.

Results: The top differentially expressed genes encode molecules that interact with previously identified pathological mechanisms including F-actin bundling (SYNPO2L) and AKT/mTOR signaling (CAVIN3, KIT). Mitochondrial damage was identified via increased ER stress (APT39), with mTOR signaling identified as a pathway that was disrupted by the R431C mutation. We also performed targeted evaluation of improved mitochondrial viability through increased bioenergetic function (CAV1, CAV3, KIT, RAB35, or ANLN R431C).

Conclusion: Unbiased transcriptomic analysis confirmed that ANLN R431C disrupts AKT/mTOR signaling and actin cytoskeletal dynamics, resulting in increased ER stress and mitochondrial damage that reduce podocyte viability. Targeting various aspects of mitochondrial regulation may present viable alternative treatment strategies for FSGS caused by ANLN mutations.

PO2000
Prothrombin Modulates Podocyte Health and Function During Glomerular Proteinuria
Amanda P. Walker,1 Katelyn Wolfgang,1 Tasha K. Wilkie,1 Sagar Bhayana,1 Kyle A. Seip2 William E. Smoyer,2 Bryce A. Kerlin,1,2 Abigail Werner Research Institute at Nationwide Children’s Hospital, Columbus, OH; The Ohio State University College of Medicine, Columbus, OH.

Background: Ongoing podocyte injury is a known critical determinant of glomerular disease progression. Recent research suggests thrombin exerts beneficial effects in vitro podocyte injury, however, pharmacologic manipulation may cause both on- and off-target effects. Thus, the purpose of this study was to directly examine the effects of thrombin on glomerular proteinuria by manipulating its zymogen precursor, prothrombin (PT). We hypothesized that circulating PT would directly modulate both podocyte function and in situ survival in a rat model of nephrotic syndrome.

Methods: Purified PT (Sanofi-Aventis, background factor VIII assay less than 1% control) was administered by tail vein injection (500 ng/kg b.d. for 4 days in each of 6 IgAN patients). LncRNA-G2151 was significantly down-regulated in IgAN patients. The predicted target genes of lncRNA-G2151 are FCGR3, which encode family of Fc gamma receptors (FcγRs). S was observed in 12 IgAN patients (66.7%) and was positively correlated with lncRNA-G2151 relative expression (r=0.545, P=0.019), but had no correlation with proteinuria, blood pressure, mesangial hypercellularity(M), endocapillary proliferation(E), tubulointerstitial fibrosis (T) and crescent(C). The relative expression (fold change) of lncRNA-G2151 was significantly higher in S group than in S group (11.26±7.90(20.38) vs 7.04±13.19(11.00), P=0.025).

Results: 18 pairs of IgAN patients and their healthy first-degree relatives were enrolled in this study. The mean age was 29.71±6.06 years and urinary protein was 1.00±0.32 (g/24h) in these IgAN patients. LncRNA-G2151 was significantly down-regulated in IgAN patients. The predicted target genes of lncRNA-G2151 are FCGR3, which encode family of Fc gamma receptors (FcγRs). S was observed in 12 IgAN patients (66.7%) and was positively correlated with lncRNA-G2151 relative expression (r=0.545, P=0.019), but had no correlation with proteinuria, blood pressure, mesangial hypercellularity(M), endocapillary proliferation(E), tubulointerstitial fibrosis (T) and crescent(C). The relative expression (fold change) of lncRNA-G2151 was significantly higher in S group than in S group (11.26±7.90(20.38) vs 7.04±13.19(11.00), P=0.025).

Conclusions: 1) The relative expression of lncRNA-G2151 was significantly higher in S group than in S group (11.26±7.90(20.38) vs 7.04±13.19(11.00), P=0.025). 2) Treatment outcomes might be improved by optimizing blockade of the NPRC to more effectively inhibit clearance of NPs from the circulation.

Exosomal Long Non-Coding RNA-G21551 as a Potential Predictive Biomarker for Segmental Sclerosis Change in IgA Nephropathy
Qianqian Han,1 Jiajia Li, Xiaona Wei, Peifen Liang, Qiongqiong Yang. Sun Yat-Sen University Sun Yat-Sen Memorial Hospital, Guangzhou, China.

Background: Segmental sclerosis (S) is an independent pathological predictor for renal progression in IgAN patients, and is closely related to proteinuria. However, there is less invasive biomarker for pathological S change. We investigate the difference in expression profiles of exosomal long non-coding-RNAs (lncRNAs) in plasma from IgAN patients compared with their healthy first-degree relatives, then explore the possible lncRNA associated with S.

Methods: To isolate exosomes from the plasma of both IgAN patients and their healthy first-degree relatives, High-throughput RNA sequencing and real-time quantitative polymerase chain reaction (qRT-PCR) was used to validate lncRNA expression profiles. Target lncRNAs were selected by bioinformatics analysis. The relationship between target lncRNA and S was analyzed by Spearman correlation. ROC curve evaluated the area under curve (AUC) of the target lncRNA for diagnosis S and its predictive sensitivity and specificity.

Results: 18 pairs of IgAN patients and their healthy first-degree relatives were enrolled in this study. The mean age was 29.71±6.06 years and urinary protein was 1.00±0.32 (g/24h) in these IgAN patients. LncRNA-G2151 was significantly down-regulated in IgAN patients. The predicted target genes of lncRNA-G2151 are FCGR3, which encode family of Fc gamma receptors (FcγRs). S was observed in 12 IgAN patients (66.7%) and was positively correlated with lncRNA-G2151 relative expression (r=0.545, P=0.019), but had no correlation with proteinuria, blood pressure, mesangial hypercellularity(M), endocapillary proliferation(E), tubulointerstitial fibrosis (T) and crescent(C). The relative expression (fold change) of lncRNA-G2151 was significantly higher in S group than in S group (11.26±7.90(20.38) vs 7.04±13.19(11.00), P=0.025).

Conclusions: Exosomal lncRNA-G2151 was down-regulated in IgAN patients, but positively correlated with S change. Exosomal lncRNA-G2151 may be a potential independent predictor for S lesion in IgAN patients.

Analysis of the Relationship Between Proteasome and Autophagy in Podocytes Using Podocyte-Specific Proteasome Impairment Mice
Shinichi Makino,1 Hiroyuki Yamada,1 Ika N. Kadariswintaningsih,1 Maulara A. Emptia,1 Motoko Yanagita,1 Katsuhiko Asanuma,1 Chiua Daigaku Daigakusii Ikuu Kenkyuu Igakubu, Chiua, Japan; Kyoto Daigaku Daigakusii Ikuu Kenkyuu Igakubu, Kyoto, Japan.

Background: Ubiquitin-proteasome system and autophagy-lysosome system are major intracellular protein degradation mechanism. The relationship of these systems in podocyte has not well been understood.

Methods: In this study, we generated podocyte-specific proteasome impaired mice (Rpt3pKO) by deletion of Rpt3, which is essential for construction of 26S proteasome, using Cre-loxP system. Albuminuria and number of sclerotic glomeruli increased in the Rpt3pKO mice compared with Rpt3control mice. Oxidative stress and podocytes apoptosis were related to podocyte injury. To evaluated autophagic activity, LC3 dots

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

in podocytes were evaluated after administration of chloroquine, inhibitor of autophagic flux. In vivo and in vitro experiments, cultured podocytes were treated with bortezomib (BTZ), proteasome inhibitor, which lead to podocyte apoptosis. The expression of LC3 was evaluated in podocytes after administration of bortezomib in the presence of 64/Δp2 control. These results indicated autophagic activity was significantly lower in podocytes with proteasome impairment. LC3-II, which is a downstream of mTOR signal, was phosphorylated in podocytes with proteasome impairment, suggested that suppression of autophagic activity was associated with mTOR activation. Pre-treatment of rapamycin, inhibitor of mTOR, ameliorated podocyte apoptosis induced by BTZ in vivo and in vitro, the number of sclerotic glomeruli decreased in Rpt3/dKO mice with rapamycin administration compared with in Rpt3/dKO mice without rapamycin administration.

Conclusions: Impairment of proteasome suppressed autophagic activity associated with mTOR activation in podocytes. Activation of autophagy have the protective effect on podocyte injury due to proteasome impairment.

PO2003
Functionally Resolving WT1 Variants of Uncertain Significance in Nephrotic Syndrome
Jennifer Lai Yee,1 Xiaoyan Jia,1 V. Vega-Warner,2 Matt G. Sampson,2 Jacob O. Kitzman,1 1University of Michigan, Ann Arbor, MI; 2Boston Children’s Hospital, Boston, MA

Background: Patients with Mendelian forms of nephrotic syndrome (NS) are likely to progress to end stage kidney disease. Because of the increased availability and promise to guide clinical decision, genetic screening among affected patients is proliferating. However, accurate attribution of pathogenicity to rare variants found during genetic screening remains challenging. WT1 is the second most common gene causing NS.

Results: Wild-type and several bona fide pathogenic WT1 variants were tested for transcriptional activity in a standard dual-luciferase assay. Several cell lines including HeLa, HEK293, and HK2, were co-transfected with variant or wild-type WT1 and an NPHS1 promoter luciferase vector. Furthermore, potential WT1 targets gene specific to HEK cells were identified by analyzing differential gene expression in RNA-Seq data of WT1 over-expressing HEK293 cells, in order to identify additional WT1-responsive promoters for use as WT1 activity reporters.

Methods: Overexpression of wild-type WT1 in HEK cells and HEK cells increased expression of luciferase under the NPHS1 promoter by ~2-fold relative to truncated WT1. The luciferase activity of bona fide pathogenic WT1 variants was also significantly lower than the wild-type WT1 and bona fide benign WT1 variants (P<0.05). Overexpression of wild-type WT1 in HEK293 resulted in upregulation (log2 fold change=0.4, adjusted p<0.05) of IGFB1, EGF, TGFβ2. These candidates are being developed as WT1 responsive reporters.

Conclusions: Previous reports suggested NPHS1 promoter reporters as a model system to investigate WT1 function. However, the transcriptional effect of WT1 was so small it could be missed. Future work is needed to establish a robust WT1 reporter is ongoing using cloned IGFB1, EGF, TGFβ2 promoters.

PO2004
Sources of Variability in Podocyte Foot Process Width Measurements and Approaches to Mitigation
Molly Geraghty,1 Morgan P. Thompson,1 Donal Gorman,1 Hui Chen,1 Kondala R. Atkuri,2 Stephen Berasi,2 J. B. Copley,1 Joel M. Henderson,1 1Boston Medical Center, Boston, MA; 2Pfizer Inc, New York, NY

Background: Podocyte foot process (FP) morphology is used in the research setting to quantify podocyte injury and has the potential to be leveraged for diagnostic use. However, the impact of pre-analytic and analytic variables on these measurements are not well understood. We sought to identify these sources of variability and develop a robust method for podocyte foot process width (FPW) measurement within various kidney diseases.

Methods: We examined the impact of operator bias and sample size on FPW measurements comprehensively classify variants in this key NS gene.

Conclusions: Impairment of proteasome suppressed autophagic activity associated with mTOR activation in podocytes. Activation of autophagy have the protective effect on podocyte injury due to proteasome impairment.

PO2005
Glomerular Transcriptomic Analysis of Glucocorticoid- and Pioglitazone-Treated Nephrotic Syndrome
Sagar Bhavana, Shipra Agrawal, Melinda A. Chanley, Amanda P. Waller, Katelyn Wolfgang, Saranga Wijeratne, James Fitch, Bryce A. Kerlin, William E. Smoyer. Nationwide Children’s Hospital, Columbus, OH.

Background: Nephrotic Syndrome (NS) is among the most common glomerular diseases in children. Glucocorticoids (GC) are the primary treatment for NS, but 15-20% of children have or develop steroid resistant NS, creating an unmet need for novel therapeutics. Thiazolidinediones (TZDs) such as pioglitazone (Pio) have been shown in vitro and in vivo mechanistic studies provide new insights about podocyte pathways that can be useful for future therapies for NS, distinct from current immunosuppressive approaches.

Novel Podocyte Protective Compounds Identified Using Ultra-Miniaturized High-Content Screening (HCS) Assays
Manuel Noben,1 Danish Qavi,2 Shreyaa Khanna,1 Ha Won Lee,3 Mehmet M. Aliftans,1 Jochen Reiser,1 Susanne Heyen-Genel,1 Vineet Gupta,1 1Rush University Medical Center, Chicago, IL; 2Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA.

Background: Podocytes are specialized epithelial cells which are part of the filtration barrier in the kidney. Podocyte dysfunction is part of kidney pathology hallmarkied by proteinuria. Using a high-content imaging based assay, we have shown that podocytes can be used to identify novel therapeutic compounds.

Methods: Differentiated mouse podocytes were seeded on collagen-I coated multi-well plates. After 10-14 days of differentiation, cells were exposed to puromycin amincouleoside (PAN, podocyte injury inducing agent), with compounds from the screening library or newly identified targets, or DMSO as control, for 48 hours. After, cells were fixed with 4% paraformaldehyde and permeabilized with 0.1% Triton X-100. Cells were labeled with cytoplasmic stain HCS CellMask Green, and actin fibers were detected by using labeled phalloidin. Cell images were taken with using Opera High content screening (HCS) System. Columbus software was used to quantify morphology properties such as roundness, as well as the overall F-actin signal. We utilized commercial libraries containing >50k unique compounds to identify podocyte protective hits.

Results: Using PAN as a podocyte damaging agent, we noticed marked reduction in F-actin fiber numbers and intensity, and increased roundness in podocytes. Screening of a library of chemical compounds identified >25 hits which had favorable profiles.

Conclusions: Using our optimized podocytes high-throughput screening assay in 1536-well plates, we have identified a number of highly novel compounds. Further mechanistic validation of smaller set of compounds within these candidates followed. In vivo and in vitro mechanistic studies provide new insights about podocyte pathways that can be therapeutically targeted.

The Role of FNB1P in Podocytes
Qiaoqi Tang, Lu Ren, Hui Song, Zhang Sipan, Zheng Tang, Shaolin Shi. Jinling Hospital National Clinical Research Center of Kidney Diseases, Nanjing General Hospital of Nanjing Military Command Research Institute of Nephrology, Nanjing, China.

Background: Podocytes exhibit a complex cellular morphology characterized by the formation of foot processes. The normal structure of podocytes depends on their unique cytoskeleton, including actin microfilament network. Nuclearization of actin monomers is the rate limiting step in actin polymerization. There are two distinct nucleators for actin nucleus in podocytes, Arp2/3 complex and forms, which mediate branch and linear actin filament formations, respectively. Our previous study identified hundreds of genes expressed in every single podocyte, which were potential podocyte essential genes. Of them, FNB1P is known to be involved in Arp2/3 complex and forms activity in nucleus, supporting FNB1P’s essentiality for podocytes. Here, we test this hypothesis.

Methods: Cultured podocytes were used for this study. FNB1P was knocked down by siRNA, and immunostaining, immunoblotting, qPCR, wound healing assay, immunoprecipitation were performed to test FNB1P essentiality and mechanism.

Results: FNB1P was specifically expressed in podocytes in glomeruli, and its expression was decreased in purinycin anionucleosides-treated in podocytes, when FNB1P was knocked down, we found that the expression of WT1, SYNPO and CD2AP was decreased; that the migratory capability was impaired; that F-actin stress fibers were reduced and disorganized; and that focal adhesion number was decreased while their size increased as shown by p-FAK staining. Mechanistically, FNB1P regulated Arp2/3 complex and INF2 (a formin) actin nucleus activities. Co-IP and IF showed that FNB1P colocalized and interacted with CDC42 and N-WASP to facilitate interaction of N-WASP with Arp2/3 complex, thereby increasing the activity of Arp2/3 complex in actin nucleus. Podocytes with INF2 knocked down with INF2 and affected its localization in cytoplasm and its actin nucleus. Consistently, the reduction of FNB1P impaired the interaction between N-WASP and Arp2/3 complex and mis-localized INF2 in the cytoplasm.

Conclusions: FNB1P may regulate branched and linear actin filament polymers and podocyte morphology by regulating Arp2/3 complex and INF2 actin nucleus activities in podocytes, thereby maintaining podocyte normal structure and function. Reduction of FNB1P expression is involved in podocyte injury and targeting FNB1P may represent a novel therapeutic approach for podocytopeny.

Role of AT1 in Radiation-Induced Nephrotoxicity
Anis Ahmad,1 Cameron Bader,2 Saba Ansari,1 Jumana Afaqhani,1 Sandra M. Merscher,1 Alessia Fornoni,1 Yousef Zaidan,1,2 Robert B. Levy,1 Brian Marples,1 Radiation Oncology,1 Department of Radiation Oncology, University of Miami, Miller School of Medicine, Miami, FL; 2Department of Radiation Oncology, Anatomy, Cell Biology, and Physiology, American University of Beirut School of Medicine, Beirut, Lebanon; 3Peggy and Harold Katz Family Drug Discovery Center and Division of Nephrology, Department of Medicine, University of Miami, Miami, FL; 4Department of Oncology,1 Department of Biochemistry and Molecular Medicine,1 Department of Medicine and Dentistry, Rochester, NY; 5Department of Microbiology and Immunology, Miller School of Medicine, University of Miami, Miami, FL.

Background: Arginylation increases actin polymerization and supports cellular morphology. However, the effect of radiation therapy (RT) on arginylation is not known. This study investigated the impact of RT on arginyltransferase 1 (ATE1) and its role in podocyte morphology and kidney function.

Methods: Human podocytes were irradiated with 4 Gy, and preceded by rituximab mAb (100 μg/ml) or IgG (100 μg/ml) treatment, 30 min before RT. Additionally, 8- to 6-week-old C57BL/6 male and female mice were included at both (i) 1x14Gy bilateral kidney-only RT (ii) lethal-dose total body irradiation (TBI 10.5Gy) and rescued with infliximab (5 mg/kg) and affected its localization in cytoplasm and its actin nucleus. Consistently, the reduction of FNB1P impaired the interaction between N-WASP and Arp2/3 complex and mis-localized INF2 in the cytoplasm.

Results: FNB1P was specifically expressed in podocytes in glomeruli, and its expression was decreased in purinycin anionucleosides-treated in podocytes, when FNB1P was knocked down, we found that the expression of WT1, SYNPO and CD2AP was decreased; that the migratory capability was impaired; that F-actin stress fibers were reduced and disorganized; and that focal adhesion number was decreased while their size increased as shown by p-FAK staining. Mechanistically, FNB1P regulated Arp2/3 complex and INF2 (a formin) actin nucleus activities. Co-IP and IF showed that FNB1P colocalized and interacted with CDC42 and N-WASP to facilitate interaction of N-WASP with Arp2/3 complex, thereby increasing the activity of Arp2/3 complex in actin nucleus. Podocytes with INF2 knocked down with INF2 and affected its localization in cytoplasm and its actin nucleus. Consistently, the reduction of FNB1P impaired the interaction between N-WASP and Arp2/3 complex and mis-localized INF2 in the cytoplasm.

Conclusions: FNB1P may regulate branched and linear actin filament polymers and podocyte morphology by regulating Arp2/3 complex and INF2 actin nucleus activities in podocytes, thereby maintaining podocyte normal structure and function. Reduction of FNB1P expression is involved in podocyte injury and targeting FNB1P may represent a novel therapeutic approach for podocytopeny.

Podocyte Inflolding Glomerulopathy: New Disease or Pattern of Injury?
Sri Vibhavari Guntupalli, Suzanne G. Martin. Saint Vincent Hospital, Worcester, MA.

Introduction: Occasional podocyte infolding is reported in membranous nephropathy, but global and diffuse infolding is rare. Whether this is a new disease entity or a pattern of podocyte injury may influence therapy.

Case description: 52-year-old male with hypertension developed lower extremity edema, pleuritic chest pain and dyspnea. CT chest showed bilateral pulmonary emboli. Creatinine was 0.92 mg/dl, cholesterol 239 mg/dl, albumin 3.2 g/dl, urine protein:Cr ratio 32.647 mg/gCr. Renal biopsy showed immune complex deposition in a membranous pattern, and subepithelial deposits with targetoid microvesicular structures, suggesting a podocyte infolding glomerulopathy (PIG) [Fig.1 Electron microscopy showing PIG]. Immune deposits were dominantly reactive for IgG4, and also for other IgG subclasses, C3, IgM, and kappa and lambda light chains. Deposits were reactive for PL2AR. Serum PL2AR antibody and other serologies were negative. He was anticoagulated and treated for 6 months with the modified Ponticelli protocol. Creatinine remains normal, but hypoalbuminemia and proteinuria (190mg – 1.2g) persist 8 months after starting treatment.

Discussion: In 1985, Dales and Wallace [1] described massive deposits of spherical organellae in the subepithelial space of glomerular capillary walls in a patient with membranous nephropathy. In 2008, Jol et al [2] studied 25 Japanese patients with microspheres and microtubular structures associated with podocyte infolding, coming the term “podocyte infolding glomerulopathy.” Rare cases are reported in India, Latin America, and Europe. It is unclear whether PIG is a subtype of membranous nephropathy or a distinct glomerular lesion. Identification of PIG associated with vesiocularural reflux, myeloma, and autoimmune diseases, and the absence of immune complexes in many biopsies, suggest a distinct type of podocyte injury. Ultimately, the pathophysiology of PIG is not understood. Response to therapy and prognosis are not well-described. This patient was treated with the modified Ponticelli protocol, given findings of membranous nephropathy, with a reduction in proteinuria but not full remission. This may represent a partial response to therapy or may imply that podocyte infolding glomerulopathy is a separate disease entity not responsive to immunosuppression.

C2D Remodels Skeletal Muscle Metabolism Toward Carbohydrate Oxidation
Keith G. Avin,1,2 Neal X. Chen,3 Shruthi Srinivasan,3 Meghan C. Hughes,3 Thomas O’connell,2 Robert L. Bacallaio,3 Christopher G. Perry,3 Sharon M. Moe,1 Indiana University Purdue University at Indianapolis, Indianapolis, IN; 2Indiana University School of Medicine, Indianapolis, IN; 3York University, Toronto, ON, Canada.

Background: Skeletal muscle health progressively declines from chronic kidney disease (CKD). To test the hypothesis that exercise mitigates abnormal muscle metabolism in CKD, we utilized high-resolution mitochondrial respiration and metabolomics techniques for indices of skeletal muscle carbohydrate and fat metabolism in a progressive CKD rat model.

Methods: Animals. 1) Cy/+ (CKD) rats, 2) CKD + wheel running, and 3) normal littermates (NL) (N=12/gy). Running wheel was accessible 24 hr/day 25-35 weeks of age; normal (NL) were CKD rats removed at sacrifice. Functional, histopathological, and biochemical changes were studied by strain-donor hematopoietic stem cell transplantation (HSCT) or (iii) left untreated (SHAM).

Results: In the EDL, protein content of Complex 1 was reduced, but pyruvate-stimulated respiration increased with CKD wheel running. Metabolism analysis (MS) of the EDL supported this, as wheel running lowered long-chain fatty acids (C14-18; p<0.05). In the soleus, Complex 1 content decreased and pyruvate-stimulated respiration increased in both CKD and CKD running compared to NL (p<0.05). Soleus MS demonstrated lower long-chain fatty acids (C14-18; p<0.05). Serum NMR demonstrated increased pyruvate and reduced lactate concentrations suggesting greater re-direction of pyruvate to mitochondrial oxidative phosphorylation. Carnitine levels were low in serum and muscle, suggesting impaired transport of fatty acids to the mitochondria.

Conclusions: These intriguing results indicate C2D impairs skeletal muscle mitochondrial oxidative capacity despite increased pyruvate oxidation. In addition, metabolomics data suggests impaired fatty acid oxidation that worsened with wheel running due to low carnitine levels. These results suggest dual alterations in response to mild exercise in CKD: 1) impaired fatty acid oxidation from deficient carnitine; 2) enhanced pyruvate oxidation consistent with lower lactate production. These cellular metabolic reprogramming events suggests that skeletal muscle may shift away from fatty acid metabolism towards carbohydrates which may explain why patients with CKD do not experience the usual benefit of exercise.

Podocyte-Derived Testican 2 Promotes In Vitro Glomerular Angiogenesis
Donghai Wen,1 Debby Ngo,2 Benjamin D. Humphreys,3 Martin R. Pollak,3 Robert Gerzsten,4 James G. Wilson,1 Eugene P. Rhee,1 Massachusetts General Hospital, Boston, MA; 1Washington University in Saint Louis, Saint Louis, MO; 2Beth Israel Deaconess Medical Center, Boston, MA.

Background: In addition to their fundamental role in clearance, the kidneys release select molecules into the circulation, but whether any of these anabolic functions provides insight on kidney function is unknown.

Methods: Using aptamer-based proteomics, we characterized arteriolar (A) to renal venous (V) gradients for >1,300 proteins in 22 human individuals who underwent invasive sampling. To localize testican-2, immunohistochemistry, immunofluorescence, immunogold electron microscopy and single cell RNA sequencing in human kidney tissue were used. Functional effects of testican-2 were tested on cultured primary human glomerular endothelial cells (HGEC).

Results: Although most of the proteins that changed significantly decreased from A to V, consistent with renal clearance, several were found to increase, the most significant of which was testican-2 (V/A = 1.40, P = 1.5 x 10^-9). Imaging and single cell RNA sequencing demonstrated testican-2 expression in human podocytes. Testican-2 promoted angiogenesis and migration in cultured HGEC, but not proliferation. Further, testican-2 upregulated MMP-2/MMP-9 activity in the culture media of HGEC.

Conclusions: Testican-2 is a circulating protein that is synthesized in the human podocyte. Testican-2 promotes angiogenesis in cultured HGEC, which may be mediated by upregulating MMP-2/MMP-9 activity and increased endothelial cell migration.

Mitochondrial Quality Control Mechanisms in Renal Cortex During the Normoalbuminuric Stage of Diabetes Mellitus
Masato Ikenaga,4 Yoshifumi Ichikawa,1 Tsuneo Takenaka,3 Masato Katagiri,1 Kitasato University, Sagamihara, Japan; 1University of Nebraska Medical Center, Omaha, NE; 1International University of Health & Welfare, Minatoku, Japan; 2Seikai, Tochigi, Japan.

Background: Oxidative stress during the normoalbuminuric stage of type 1 diabetes mellitus (DM) damages renal cortical mitochondria. Because accumulation of damaged mitochondria can contribute to renal dysfunction, we aimed to determine if oxidative stress in DM triggers 1) mitochondrial fission or fusion, 2) increased fatty acid metabolism, and/or 3) mitophagy as quality control mechanisms.

Methods: Rats receiving i.p. injection of streptozotocin (STZ, 65 mg/kg) or vehicle (Sham) were either left untreated or treated with telmisartan (TLM, an angiotensin II receptor blocker; 10 mg/kg). Two weeks later, blood glucose levels (BG), blood pressure (BP), glomerular filtration rate, and urinary excretion of albumin and N-acetyl-β-D-glucosaminidase (NAG) were measured. The oxidative stress marker, 3-nitrotyrosine (3-NT), was detected by HPLC. Fission-, fusion-, and mitophagy-related proteins were quantified by Western blot. Levels of acetylcarinate, which transports fatty acids into mitochondria for β-oxidation, were calculated as the difference between total and free carnitine levels measured by the enzymic cycling method using commercial kits.

Results: TZ rats displayed hyperglycemia and hyperfiltration that were unaffected by TLM. BP, albumin excretion, and NAG excretion were similar in all groups. Renal cortical 3-NT levels were increased in STZ rats, a change that was prevented by TLM (STZ+TLM). Renal cortical acyl carnitine levels in STZ rats were more than double those of Sham rats (P<0.05) and were further elevated in STZ+TLM rats (P<0.05 vs STZ alone). Renal cortical fission and mitophagy-related proteins LC3-II and PINK1 (all P<0.05). Renal cortical Drp1 levels were 3-fold higher in STZ than in Sham, with STZ+TLM rats exhibiting intermediate levels of this fission marker. Levels of the fusion marker Mfn2, and mitophagy-related proteins BNIP3 (dimer) and p62 did not differ among groups.

Conclusions: During the normoalbuminuric stage of DM, renal cortical mitochondria undergo increased fatty metabolism, as well as enhanced fission and mitophagy that are blunted by TLM in association with its antioxidant effect and, thus, are likely quality control mechanisms triggered by oxidative damage.

Indoxyl Sulfate Modulates Expression of Myosin Heavy Chain Isoforms and induces Sarcopenic Phenotype in Mouse
Takaaki Higashihara, Hiroshi Nishi, Koji Takemura, Masaoimi Nangaku. Division of Nephrology and Endocrinology, Graduate School of Medicine, The University of Tokyo, Bunkyoku, Japan.

Background: In patients with chronic kidney disease, sarcopenia is frequently associated with decreased renal function and correlates with increased morbidity and mortality. However, the molecular mechanism to underlie uremic sarcopenia is not fully elucidated yet. We hypothesized that the accumulation of uremic toxin might have a direct negative effect on skeletal muscle, and investigated the mechanism of indoxyl sulfate (IS) induced toxicity on mouse skeletal muscle.

Methods: We conducted the in vivo experiments using C57BL/6J mice. After unilateral nephrectomy, vehicle (PBS) or high dose IS was intraperitoneally administered daily for 1 week, and evaluated exercise tolerance (treadmill fatigue test and four limbs grip test), skeletal muscle wet weight, cross-sectional area, and protein levels of myosin heavy chain isoforms.

Results: In mice treated with IS, exercise tolerance was deteriorated and gastrocnemius muscle wet weight were decreased compared to the control group. Intriguingly, IS administration also reduced a cross-sectional area of fast twitch myofiber and protein levels of fast twitch myosin heavy chain. Also, IS treatment tended to upregulated miRNA expression of muscle atrophy related genes (quantitative-PCR).

Conclusions: IS induces direct sarcopenic effect on mouse skeletal muscle and predominantly decreases on fast-twitch muscle fibers. In the future, we will further investigate the molecular mechanism of uremic toxic induced sarcopenia.

PO2014
Lnc-Gm43360 Regulates TCMK-1 Senescence by the miR-141/Sirt1 Pathway
Jie Li, Hongli Jiang, Lei Chen. The First Affiliated Hospital of Xi’an Jiaotong University, Xi’an, China.

Background: Aging is a complex process, which will lead to the gradual decline of physiological functions of all organ systems. The kidney, which is a metabolically active organ, is extremely susceptible to aging, but the mechanism of kidney aging is not clear. Long-chain non-coding RNA (lncRNA) is a non-coding RNA consisting of 200 nucleotides, which play an important role in kidney fibrosis and diabetic nephropathy, but there is no study on kidney senescence.

Methods: Detection of lnc-Gm43360 expression by qRT-PCR. Transfection with lnc-Gm43360 siRNA and overexpressed plasmid to measure the miR-141 and Sirt1 expression by qRT-PCR, and the p53, p21 and p16 expression by western blot, and SA-β-gal expression. Transfection with miR-141 mimic and inhibitor to measure Sirt1 expression by qRT-PCR, and p53, p21 and p16 expression by western blot, and SA-β-gal expression.

Results: Lnc-Gm43360 expression in 24-month-mouse lower than 3-month-mouse kidney tissue. The reduction of Lnc-Gm43360 expression significantly increases miR-141 expression, decrease Sirt1 expression on both the miRNA and protein level, and induces the SA-β-gal expression. miR-141 mimic and inhibitor decrease and increase Sirt1 expression. Lnc-Gm43360 negatively regulates miR-141 expression and positively negatively regulate Sirt1 expression at both the mRNA and protein level. The function of Lnc-Gm43360 in regulating Sirt1 expression depends on modulating miR-141 expression.

Conclusions: Lnc-Gm43360 can induce TCMK-1 senescence by miR-141/Sirt1 pathway.

PO2015
Modified Lipoproteins Modulate Renal Lymphatic Vessel Vasodynamics via NKCC1 on Lymphatic Endothelial Cells
Jianyong Zhong, Jing Liu, Elaine L. Shelton, Eric J. Delprie, Haichun Yang, Valentina Kon. Vanderbilt University Medical Center, Nashville, TN.

Background: In addition to its pivotal role in chloride transporting epithelia, the sodium–potassium–chloride cotransporter 1 (NKCC1) is increasingly recognized as a key modulator of vascular tone. We previously documented NKCC1 expression in renal lymphatic endothelial cells (LEC)s of rats and cultured human LECs. Ex vivo we showed that blocking NKCC1 by furosemide caused a dose-dependent dilation in renal lymphatic vessels, decreased amplitude, and decreased frequency of spontaneous contractions. Since lymphatic vessels clear interstitial lipids and kidney injury increases lipid peroxidation products including isolevuglandins (IsoLG) which modify lipoproteins (apoAI), we examined if IsoLG-modified apoAI can affect renal lymphatic vessel contractility through blocking NKCC1.

Methods: Purumycin nephropathy (PAN) was induced in Sprague Dawley rats, while non-injected rats served as controls (Cont). Renal lymphatic vessels were isolated and mounted in a perfusion chamber to assess vasoactivity. The effects of apoAI or IsoLG-apoAI on the NKCC1 signaling pathway were assessed in LECs.

Results: PAN rats had significantly higher renal lymph flow which contained significantly more IsoLG vs Cont. Ex vivo studies showed renal collecting lymphatic vessels from PAN were more dilated than Cont. Immunostaining revealed NKCC1 expression on LECs that was more prominent in PAN renal lymphatic vessels vs Cont.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
LECs (prox-1 positive cells) isolated from PAN kidneys also had more NKKC1 gene expression than cells from Control. In LECs, IsoLG-apoAI increased NKKC1 expression vs apoAI. Similarly, NKK1, OxsR1 and SPAK, upstream activators of NKKC1, were significantly increased in LECs exposed to IsoLG-apoAI vs unmodified apoAI, which was accompanied by increased eNOS expression. Ex vivo renal collecting lymphatic vessels significantly increased diameter, amplitude, and frequency of spontaneous contractions when exposed to IsoLG-apoAI vs with apoAI. Conclusions: ISOLG-apoAI change renal lymphatic vessel vasodynamics through the NKK1-OxsR1/SPAK-NKKC1 pathway on LECs which we propose is a novel target to improve lymphatic function in kidney disease. Funding: NIDDK Support

PO2016
Programin Deficiency Exacerbates High-Fat Diet-Induced Inflammation in Kidney
Maki Murakoshi, Tomohito Gohda, Yusuke Suzuki. Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan.

Background: Programin (PGRN) has been reported to bind to tumor necrosis factor receptor (TNFR) and inhibit TNFR signaling. Conversely, PGRN is a ‘bad’ adipokine that can contribute to insulin resistance in some metabolic diseases. We evaluated the effect of augmentation of TNFR signals by PGRN deficiency on the progression of kidney injury in high-fat diet-induced obesity model mice.

Methods: Eight-week-old PGRN knockout (KO) mice and their wild-type (WT) mice were fed a standard diet or high-fat diet (HFD) for 12 weeks. Mouse proximal tubule (mProx24) cells knocked down with PGRN siRNA were treated with TNFR stimulation.

Results: The body weight and albuminuria were significantly increased in WT-HFD group compared with WT-standard diet (SD) group. The body weight of KO-HFD group was significantly decreased compared with WT-HFD group. However, albuminuria and the expression of renal inflammatory markers including TNFR in KO-HFD group were increased than those in WT-HFD group. On the other hand, the WT-HFD mice showed vacuolar degeneration in the proximal tubule, but KO-HFD mice did not. Immunohistochemical analysis showed that vacuolar membranes were clearly positive for a lysosomal marker, LAMP-1, suggesting impairment in lysosomal function. The expression of megalin which plays a critical role in the reabsorption of protein in proximal tubules was found to be decreased in KO mice compared with WT mice, and also reduced in mProx24 stimulated with TNFR.

Conclusions: PGRN deficient exacerbated renal inflammation caused by high-fat diet, while the results also showed improvement in tubular vacuolization. Anti-inflammatory treatment with PGRN for kidney diseases should be considered based on the opposing function of PGRN.

Diets Has a Stronger Impact on the Gut Microbiota Than Kidney Function in Rats with Moderate CKD
Annabel Biruete,1 Tzu-Wen L. Cross,2 Stephen R. Lindemann,3 Kelly Swanson,3 Neal X. Chen,1 Sharon M. Moc,1 Indiana University School of Medicine, Indianapolis, IN; 2Purdue University, West Lafayette, IN; 3University of Illinois at Urbana-Champaign, Urbana, IL.

Background: Diet and CKD have been shown to alter the gut microbiota. However, whether diet or kidney function plays a stronger role in the gut microbiota in moderate CKD is not well established. We assessed the effects of two diets on the gut microbiota in rats with moderate CKD.

Methods: Cy/+ rats (CKD) and normal littermates (NL) consumed an autoclaved cellulose (Casein) until 28-wk-old (n=8-10 rats/group). DNA was extracted from cecal contents and isolated using QIAamp DNA Stool Mini Kit (Qiagen). DNA was sequenced via Illumina MiSeq, and data were analyzed using QIIME2 and LEfSe. Conclusions: Rats CKD rats fed the casein diet had a higher relative abundance of Akkermansia, Prevotella, and Bacteroides than NL rats, which has been suggested to drive the pathogenesis of inflammatory bowel disease. Additionally, the relative abundance of Faecalibacterium, Faecalibacterium, was increased in LECs exposed to IsoLG-apoAI vs unmodified apoAI, which was accompanied by increased eNOS expression. Ex vivo renal collecting lymphatic vessels significantly increased diameter, amplitude, and frequency of spontaneous contractions when exposed to IsoLG-apoAI vs with apoAI. Conclusions: ISOLG-apoAI change renal lymphatic vessel vasodynamics through the NKK1-OxsR1/SPAK-NKKC1 pathway on LECs which we propose is a novel target to improve lymphatic function in kidney disease. PO2018
Effect of High Fiber or Probiotics-Enriched Diets on Kidney Injury in Mice Model of Bilateral Ischemia Reperfusion
Shirin Pourafshar, Nabin Poudel, Nataliya Skrypnyk, Junlan Yao, Mark D. Okusa. University of Virginia Health System, Charlottesville, VA.

Background: Changes in dietary intake have a significant effect on the incidence and development of chronic kidney disease (CKD). The progressive decline in kidney function during CKD can lead to increased systemic chronic inflammation and worsening of kidney injury. Fibers and probiotics are used by gastrointestinal bacteria to produce metabolites with anti-inflammatory activities. The objective of our study was to investigate the role of fiber and probiotics in ameliorating kidney injury using bilateral ischemia reperfusion (IR) surgery as a CKD model in mice.

Methods: Thirty-six C57BL/6J wild type, male mice were purchased from the Jackson Laboratory (Bar Harbor, ME, USA). After co-housing for a week, they were then isolated and randomly assigned to a diet: normal chow (C); control, high fiber (HF; modified AIN-93G with increased Hi-Maize Corn), and probiotics (P; AIN-93G with added Bifidobacteria spp.). After 14 days, mice underwent sham surgery (5 per group) or IR surgery (7 per group) and then resumed assigned diet for 28 days. Blood and fecal samples were collected both before surgery and after surgery. Mice were euthanized after 42 days to collect kidneys, small intestine, colon, fecal, and blood samples. Measurements of plasma creatinine, markers of kidney injury, and tissue staining were performed. Fecal samples were further processed to assess diversity of gut microbiota. Two-way ANOVA with Tukey’s multiple comparisons was used for statistical analysis.

Results: On each diet, the IR increased serum creatinine compared to sham (p<0.05); confirming kidney injury. Transcripts of kidney injury markers, neutrophil gelatine-associated lipocalin (NGAL) and kidney injury molecule-1 (KIM1), were also higher with IR in all groups (p<0.05). However, NGAL and KIM1 were lower in HF and P compared to C, respectively (p<0.005). The histology sections in control group appeared to be more fibrotic compared to the other two groups. The sequencing of 16s rRNA gene was completed and is currently being used to assess the composition and diversity of gut microbiota in each group.

Conclusions: Supplementation with fiber or probiotics may reduce kidney injury after ischemia. Additional studies to identify specific changes in metabolites driving this protection are needed.

Nutritional Status and Oral Nutritional Supplement (ONS) Use Among Patients with Non-Dialysis CKD in British Columbia (BC)
Michelle M. Wong,1 Dani Renouf,2 Yuyan Zheng,3 Zainab Sheriff,1 Adcera Levin.2,3 The University of British Columbia, Vancouver, BC, Canada; St. Paul’s Hospital, Vancouver, BC, Canada; BC Provincial Renal Agency, Vancouver, BC, Canada.

Background: Malnutrition and protein-energy wasting are complications of advanced CKD that are associated with increased risk of mortality and morbidity. In BC, a government-funded Nutritional Supplement Policy stewarded by renal dietitians guides ONS prescription for CKD patients who meet weight or nutrient intake criteria.

Methods: We conducted a retrospective study of CKD-ND patients who entered multidisciplinary CKD clinics in BC during 2013-2018 (N=15859). We used Wilcoxon signed-rank test to compare baseline nutrition/immunological parameters among patients with any ONS prescription within 1 year of clinic entry and those not prescribed ONS. Longitudinal ONS prescription patterns over 3 years were described in the 2013-2015 entry cohort (N=7611). Results: 1389 patients (9%) were eligible for and prescribed ONS, with variation between health regions. Patients taking ONS had lower eGFR, BMI, bicarbonate, hemoglobin, and greater age, ferritin, phosphate, PTH, neutrophil-to-lymphocyte ratio compared to those who did not receive ONS (p<0.0001 for all comparisons). Overall ONS use during the first 3 years of follow-up remained stable, with 40% new ONS users and 60% previous ONS users during year 2 and 3 of follow-up. For patients prescribed ONS within the 1st year of clinic entry, 65% had ≥1 ONS prescriptions/year, and among those continuing follow-up in year 2, 38% discontinued ONS, 35% had ≥1 ONS prescriptions/year, and 27% had ≥3 ONS prescriptions/year (Figure).

Conclusions: This is the first Canadian study to describe ONS use among CKD-ND, which provides an estimate of incidence of undernutrition, as defined by dietitian assessment and corroborated by nutritional lab parameters. Among patients prescribed ONS, the majority have infrequent ONS use, while another subset has regular ONS use.
Dietary Fat Intake and Mortality Across Kidney Function in a Nationally Representative Cohort

Yoko Narasaki,1 Amy S. You,1 Tsuyoshi Miyagi,1 Yoshikazu Miyasato,1 Hiroshi Kimura,1 John Sy,1 Anna Jin,1 Csaba P. Kovacs,1 Danh V. Nguyen,1 Kamyar Kalantar-Zadeh,1 Connie Rhee,1 University of California Irvine, Irvine, CA; The University of Tennessee Health Science Center, Memphis, TN.

Background: In the general population, lower dietary intake of saturated fatty acids (SFA) and higher intake of polyunsaturated fatty acids (PUFA) are associated with greater survival. However, the optimal amount and type of dietary fat intake in patients with kidney disease is unknown. We assessed the relationship between dietary fat intake and mortality in a cohort of US adults with and without kidney disease.

Methods: We examined the association between dietary intake of fat subtypes (SFA, PUFA, monounsaturated fatty acids [MUFA]) ascertained by 24-hour dietary recall with presence of kidney dysfunction (eGFRs ≥60 vs <60 ml/min/1.73m2, respectively). Dietary fat intake was estimated as a proportion (%) of total energy intake, and associations with mortality in continuous NHANES adult participants (1999-2014) stratified by absence vs. presence of kidney dysfunction (eGFRs ≥60 vs. <60 ml/min/1.73m2, respectively). Dietary fat intake was estimated as a proportion (%) of total energy intake, and associations with all-cause mortality were estimated using adjusted Cox models.

Results: Among 37,155 participants who met eligibility criteria, 7% (N=2,677) had kidney dysfunction. In participants with normal kidney function, those with the highest tertile of SFA intake had higher death risk (ref. lowest tertile) (HRs [95%CI] 1.31 [1.04,1.67]), whereas those with the highest tertile of PUFA intake had better survival (HR [95%CI] 0.82 [0.76, 0.90]). In participants with kidney dysfunction, those in the second and third highest tertiles of SFA intake had significantly higher mortality risk and trended towards higher mortality, respectively: HRs (95%CI) 1.21 (1.04, 1.41) and 1.33 (0.97, 1.82), respectively; however, PUFA was not associated with survival. In participants with and without kidney dysfunction, MUFA intake was not associated with mortality.

Conclusions: Higher dietary SFA intake was associated with a higher mortality in US adults with and without kidney dysfunction, whereas higher PUFA intake was associated with greater survival in those with preserved kidney function only. Further studies are needed to elucidate mechanisms behind the association of dietary fat intake with mortality.

PO2021

Predictors of Healthy Behavior Engagement in CKD

Sarah J. Schrauben,1 Jesse Y. Hsu,1 Julie A. Wright Nunes,1 Ana C. Ricard,2 Michael J. Fischer,1 Raquel C. Greer,1 Cheryl A. Anderson,8 Madhumita J. Mohanty,9 Sankar D. Navaneethan,9 Jing Chen,9 Amanda H. Anderson,1 Laura M. Dember,1 Harold I. Feldman,1 University of Pittsburgh Perelman School of Medicine, Philadelphia, PA; University of Illinois at Chicago College of Medicine, Chicago, IL; Johns Hopkins University, Baltimore, MD; Baylor College of Medicine, Houston, TX; Tulane University School of Medicine, New Orleans, LA; Tulane University, New Orleans, LA; University of Michigan, Ann Arbor, MI; University of California San Diego School of Medicine, San Diego, CA; Wayne State University School of Medicine, Detroit, MI.

Background: Guidelines for chronic kidney disease (CKD) management recommend healthy behaviors to mitigate disease progression, but behavior engagement is low. Identifying predictors of behavior engagement could inform strategies to increase healthy behaviors.

Methods: Using data from the Chronic Renal Insufficiency Cohort Study, potential predictors of behavior engagement included demographics, clinical and psychosocial factors, and behaviors at baseline. We dichotomized behaviors (recommended vs. not): smoking (no vs. current), body mass index (BMI ≤18.5 or ≥30 kg/m2), physical activity (≥150 vs <150 minutes/week), diet (score of ≥2 vs 0-1), and hemoglobin A1c (<7 vs ≥7) if diabetes. Relationships between predictors and behaviors at 2 years were estimated by multivariable adjusted logistic regression models.

Results: Among 5,209 participants at baseline, mean age was 60 years, mean eGFR was 48 ml/min/m2, and 51% had diabetes. In multivariable analyses, baseline behaviors were most strongly associated with behaviors at 2 years (Table). Higher SF-12 physical component scores, which relate to better physical function and pain control, associated with recommended behaviors at 2 years. In models that did not adjust for baseline behaviors, smoking was associated with older age, female sex, and non-White race, but the other behavior associations were not notably changed.

Conclusions: Interventions to increase healthy behavior engagement should be implemented and tested to evaluate whether they improve physical function and pain control, and possibly mitigate CKD progression.

Funding: NIDDK Support

Impact of Participation in Food Assistance Programs Among NHANES Dialysis Patients from 2001-2016

Hannah Chen, Lea Borgi. Brigham and Women’s Hospital, Boston, MA.

Background: Food insecurity and malnutrition are recognized risk factors for poor outcomes and mortality among end-stage renal disease (ESRD) patients on dialysis. However, little is known about the effect(s) of participation in food assistance programs such as Supplemental Nutrition Assistance Program (SNAP) on outcomes among dialysis patients.

Methods: This study is a cross-sectional analysis of dialysis patients in the National Health and Nutrition Examination Survey (NHANES) cohorts from 2001-2016. Food assistance program participation was self-reported as part of the NHANES interview. Differences in baseline characteristics were determined through null hypothesis testing. Logistic and linear regressions were used to examine the association between food assistance program participation and outcomes including hospitalizations and albumin as
a marker of nutrition status. The analyses were adjusted for demographics, BMI, diabetes, hypertension, and hyperlipidemia.

Results: A total of 156 dialysis patients were analyzed across all NHANES cohorts. Dialysis patients receiving food assistance were more likely to report higher household income and lower levels of post-secondary education (p<0.05). These patients also reported significantly higher daily physical intake. Dialysis patients receiving food assistance were significantly more likely to report higher food security and less likely to report full food security. Specifically, they reported more concerns regarding food running out, food not lasting, and not being able to afford balanced meals. Approximately 30% of dialysis patients reported food insecurity but did not participate in food assistance programs. When adjusted to be representative of the non-institutionalized U.S. population, there was a non-significant trend towards increased hospitalization among dialysis patients on food assistance programs (OR 1.73 [95% CI: 0.42-7.12]). There was a non-significant trend away from increased hospitalization among dialysis patients who did not receive food assistance.

Conclusions: Food assistance programs are not widely used among dialysis patients, even when patients report food insecurity. Food assistance program participation among dialysis patients did not significantly impact hospitalizations and serum albumin.

Tameshige Banercie,1 Deidra C. Crews,1 Charles E. McCulloch,1 Nilka Rios Burrows,2 Karen R. Siegel,1 Rajiv Saran,2 Yuto Han,1 Neil R. Powe.1
1University of California San Francisco, San Francisco, CA; 2Johns Hopkins University, Baltimore, MD

Background: Food insecurity has been associated with CKD and its progression. Trends in food insecurity among adults with CKD have not been well characterized in the US population, particularly across racial/ethnic groups.

Methods: Data from NHANES from 2003-2016 were used to estimate the prevalence of food insecurity among individuals with CKD (defined by albuminuria or eGFR 15-59 ml/min/1.73 m²), overall and by racial/ethnic group. We included individuals aged ≥20 years and with a household income <400% of the federal poverty level (n=3180). Food insecurity was defined as ≥3 yes responses on the 18-item questionnaire. Racial/ethnic groups were defined as non-Hispanic white (NHW) and non-NHW. Survey years were collapsed into time periods 2003-2006, 2007-2010, and 2011-2016. Prevalence rates of food insecurity were estimated using the National Center for Health Statistics sample design.

Results: Overall prevalence of food insecurity in adults with CKD was 19.9%. During the period, the age-standardized prevalence of food insecurity increased from 5.7% to 32.8% among NHW and from 23.2% to 35.8% among non-NHW (p-trend=0.001). After adjusting for age, sex, education level of post-secondary education, annual household income, non-NHW had a significantly higher prevalence of food insecurity compared to NHW in 2007-2010 but not in 2003-2006 or 2011-2016 (Figure).

Conclusions: From 2003 to 2016, food insecurity among both NHW and non-NHW increased significantly among non-NHW compared to NHW during 2007-2010. One potential explanation may be the US economic recession during that period. Targeted interventions such as medically tailored meals for individuals with CKD and poverty may be evaluated for their impact on reducing healthcare utilization and costs and in reversing the increasing trend in food insecurity.

Approach to Nutritional Protein Intake in Hemodialysis Patients with Hyperphosphatemia: Associations with Mortality in the DOPPS

Suguru Yamamoto,2 Brian Bieber,3 Hikato Komabara,3 Hiroki Kitabayashi,3 Takanoou Nomura,3 Alex Cases,1 Christian Combe,4 Ronald L. Pisoni,1 Bruce M. Robinson,1 Masafumi Fukagawa.1 Arbor Research Collaborative for Health, Ann Arbor, MI; 2UMichigan Medical School, Graduate School of Medical and Dental Sciences, Niigata, Japan; 3Kyowa Kirin Co., Ltd., Tokyo, Japan; 4Tokai University School of Medicine, Isehara, Japan; 5Universitat de Barcelona, Barcelona, Spain; 6Université de Bordeaux, Bordeaux, France.

Background: Patients undergoing hemodialysis (HD) have poorer nutritional status than the general population, and worse nutritional status is associated with poor outcomes. Hyperphosphatemia is common in HD pts due to abnormal mineral and bone metabolism. Nephrologists manage hyperphosphatemia by prescribing phosphate binders and/or promoting dietary protein restriction; the latter may, however, adversely affect nutritional status. We address the hypothesis that, even in the presence of hyperphosphatemia, liberalizing dietary protein leads to better outcomes.

Methods: The analysis includes 11,628 HD pts in 12 countries in DOPPS phase 4 (2009-2016) from 254 facilities where the medical director reported facility practices. The primary exposure variable was response to the following question: “For pts with s. albumin 3.0 g/dL and phosphate 6.0 mg/dL, do you typically recommend to (A) increase or (B) not change/decrease dietary protein intake?” The primary outcome was all-cause mortality, analyzed by Cox regression. Linear regression was used to model associations between the exposure and intermediate nutrition markers. Models were adjusted for country, case-mix, and lab values.

Results: In the case scenario, 91% of medical directors in N. America recommended to increase protein intake compared to 58% in Europe (range=16-83% in 7 countries) and 56% in Japan. Advice to increase dietary protein intake was associated with 0.33 mg/dL higher s. creatinine levels (95% CI: 0.08-0.57) while clinically meaningful associations were not observed for s. albumin and phosphorus. Advice to increase dietary protein intake was weakly associated with lower mortality-HR (95% CI)=0.89 (0.77-1.03). The association with survival was stronger in pts with age 70+ yrs and for those without diabetes (p=0.08 and 0.20 for interaction).

Conclusions: In this large international cohort study, the medical director’s policy to recommend increase in dietary protein intake for HD pts with low albumin and high phosphorus levels was most common in N. America and associated with higher s. creatinine levels and potentially lower all-cause mortality. Further research into the possible benefits of protein intake liberalization for HD pts, even in the presence of hyperphosphatemia, is warranted.

Dietary Acid Load is Associated with the Risk of Mortality and Kidney Replacement Therapy in Diabetic CKD Patients but Not in Non-Diabetics

Alisson D. Machado,1 Dirce Marchioni,2 Paulo Lotufo,1 Isabelia M. Bensenor,1 Silvia M. Tain,2,3,4 Department of Nephrology, Hospital das Clínicas, Faculty of Medicine, University of São Paulo, São Paulo, Brazil; 2Department of Nutrition, School of Public Health, University of São Paulo, São Paulo, Brazil; 3Clinical Research Center, University Hospital, University of São Paulo, São Paulo, Brazil; 4Tufts Medical Center, Boston, MA.

Background: Dietary acid load (DAL) may be related to CKD progression but results are still conflicting. In addition, no studies have evaluated the association of DAL with mortality in CKD. The aim of this study was to evaluate two estimates of DAL, PRAL (potential renal acid load) and NEAP (net-endogenous acid production), in relation to events of mortality and kidney replacement therapy (KRT) in CKD.

Methods: Baseline clinical and dietary data (food frequency questionnaire) from the PROGRESSR Cohort (n=454), a CKD cohort based on Sao Paulo, Brazil, composed predominantly of older people with CKD G3 and G4 was used in this analysis. PRAL and NEAP were computed using previously validated formulas, and those with missing values were excluded (n=11). Events of death (n=190) and KRT (n=62) were ascertained after a median follow-up time of 6 years. Uni and multivariable Cox proportional hazards and Competing R. Risk models were computed.

Results: Mean age was 68 ± 12 y, mean eGFR was 38 ± 15 ml/min/1.73m², 63% were male and 56% were diabetic. Mean intake of PRAL and NEAP were 4.1 ± 18.5 and 51.9 ± 17.4 meq/d, respectively. Initially, neither PRAL nor NEAP were associated with mortality or KRT. However, after stratification for diabetes, both estimates were positively related to the risk of KRT and death in diabetics only, even after adjustments (Table). Competing risk analysis were consistent with the Cox findings. By entering interaction terms between diabetes and DAL estimates, which were significant, both PRAL and NEAP showed an inverse association with the risk of clinical events.

Conclusions: Our results suggest the existence of a relevant interaction between PRAL/NEAP and diabetes: whereas DAL estimates were associated with mortality and KRT in diabetics, this association was not observed in non-diabetics.

PO206
Mediterranean Diet and the Risk of CKD: A Systematic Review and Meta-Analysis
Panupong Hansrivijit,1 Sharad Oli,2 Resha Khanal,1 Nasrollah Ghahramani,2 Charnpak Chomprasertsop,1 Wisit Chomprasertsop,1 UPM-Phitak, Harrisburg, PA; 1Penn State College of Medicine, Hershey, PA; 2Mayo Clinic Florida, Rochester, MN; 4University of Mississippi Medical Center, Jackson, MS; 5Maimonides Medical Center, Brooklyn, NY.

Background: Mediterranean diet has been shown to be associated with lower risk for cardiovascular disease. However, its association with chronic kidney disease (CKD) remains inconclusive as the results were not consistent among population-based studies. Thus, this study aims to assess the association between Mediterranean diet adherence and CKD prevention.

Methods: Ovid MEDLINE, EMBASE, and the Cochrane Library were searched from database inception to March 2020 without language restrictions. We included studies describing the risk for CKD in community-dwelling subjects ≥18 years of age. CKD was defined by an eGFR < 60 mL/min/1.73m². Mediterranean diet adherence was assessed by standardized food frequency questionnaires. Meta-analysis and meta-regression analysis were used to evaluate the risk of CKD and the association between clinical factors and incidence of CKD, respectively.

Results: Of 168 citations, a total of ten (n = 19,151) and five studies (n = 9,099) were included in the systematic review and meta-analysis, respectively. Only studies adopting Mediterranean Diet Scale (MDS) were included in the meta-analysis. The mean score was 4.0 ± 0.1 points. The mean age was 53.1 ± 8.2 years. The mean eGFR was 77.3 ± 29.6 mL/min/1.73 m². The average total daily energy intake was 1,999 ± 258.0 kilocalories per day. Up to 50.4% were male, 7.1% were black, and 14.9% had a history of diabetes mellitus. With the mean follow-up duration of 11.5 ± 9.5 years, the pooled adjusted odds ratio (OR) for CKD was 0.897 (95% CI, 0.865-0.930; p = 0.005). By excluding kidney transplant patients, the adjusted OR for CKD was 0.901 (95% CI, 0.868-0.935; p < 0.0001). Both findings remained significant on sensitivity analysis. No publication bias was detected. The incidence of CKD was 0.028 events per person-year (95% CI, 0.012-0.044). From meta-regression analysis, male sex was associated with higher incidence of CKD in an adjusted model. There was no significant association between age, black race, eGFR, and total daily energy intake vs. CKD incidence.

Conclusions: Adherence to Mediterranean diet by a 1-point increment of MDS was associated with 10% lower risk of CKD. However, this only applies to healthy individuals without a history of pre-existing CKD, whether Mediterranean diet slows CKD progression is to be discovered.

PO207
Attitudes Toward Plant-Based Eating (PBE), Self-Reported Habits, and Nutritional Knowledge in Patients from CKD/ESKD Patients
Ahmad Saleh, Kingsley Cruickshank, Takisha Morancy, Iqra Nadeem, Mariana Markell. SUNY Downstate Health Sciences University, Brooklyn, NY.

Background: The benefits of a PBE dietary pattern are well described, yet there is scarcity in the literature on the attitudes of CKD/ESKD patients regarding PBE as well as their self-reported habits.

Methods: A face-to-face survey was conducted in a random convenience sample patients from CKD clinic (15), Transplant clinic (12), and the Dialysis Unit (4). Pts were asked to answer questions assessing their attitudes and understanding of PBE using a 5-point Likert scale, and to rate their daily vegetable intake. There was no difference noted in answers among the clinics so all data were analyzed together. All comparisons are by t-test unless noted.

Results: Mean age was 54.7 ± 1.7 years. There were 16 (53%) men and 14 (47%) women with 25 Black (81%). 12 people (40%) had an income < $20K, with 10 (33%) between $20K and 40K. 10 (33%) were employed. 64.5% (20) were interested in learning more about PBE; 35% had never heard of it. 22 (71%) reported consuming animal protein 1-3x/d or more. 20 (57%) reported consuming plant-based foods less <1/d or never. Pts who did not eat plant-based foods had a higher BMI than those who consumed plants (30.9 ± 8.6, p = 0.05), and higher systolic and diastolic BP (144.3 ± 29.1 vs 136.6 ± 28.5, p = 0.05) and 77.2 ± 13.5 vs 66.3 ± 4.1, p = 0.019). 46.4% thought they could not get all the proteins they need from plant-based foods without eating animal meat or products; 40.7% thought it would be hard to get all the vitamins and nutrients but 63.1% thought it would be easy to find recipes that taste good if they followed PBE.

Conclusions: In our population: 1. The majority of pts were interested in learning about PBE but ate few to no vegetables on a daily basis. 2. Possible obstacles to introducing PBE in these populations are misconceptions including the difficulty of affording food, getting enough protein and finding something to eat when eating out, believed by almost half of those surveyed. 3. Intensive educational programs targeted towards our population should be developed as pts who ate more vegetables had lower BMI and both systolic and diastolic BP and in general PBE has been shown beneficial for pts with CKD/ESKD.

PO208
Higher Estimation of Dietary Phosphorus Content with More Plant-Based Protein in Hemodialysis Patients Across Race/Ethnicity Using 3-Day Food Records with Interviews
Amanda R. Tortorici,1 Connie Rhee,1 Amy S. You,1 Elani Streja,1 Keith C. Norris,2 Kamyar Kalantar-Zadeh,1 3University of California Irvine, Orange, CA; 4University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.

Background: Dietary phosphorus (P) restrictions are commonly recommended based on the estimated phosphorus (P) content of foods, not accounting for P type or its absorbability. Whereas plant-based diets have important benefits, they are traditionally not recommended to dialysis patients given perceived higher P content in plant vs. animal-based proteins, although P is less absorbable in plant foods. We examined dietary differences across race/ethnicity in a population of hemodialysis (HD) patients from several dialysis centers in Southern California.

Methods: The self-administered 3-day diet diary with face-to-face interview was conducted by a trained dietitian among 80 in-center HD patients, and the data were entered into a diet software (Nutrition Data System for Research), and dietary components of the individuals and subgroups were obtained.

Results: Patients were 57 ± 15 years and included 25 Blacks, 36 Hispanics and 18% non-Hispanic Whites. Table shows dietary data across race/ethnicity. [Table] Figure shows the association of the phosphorus-to-protein ratio with the percentage of plant protein, correlation coefficient r was 0.58 (p = 0.001) for all including 0.28, 0.61 and 0.38 for Blacks, Hispanics and Whites, respectively.[figure]

Conclusions: Whereas estimated dietary potassium was not substantially different across race/ethnicity or different plant- vs. animal based protein proportions, dietary phosphorus content analyses may not account for varying phosphorus bioavailability across sources, which may lead to incorrect assumptions that higher plant-based protein for dialysis patients is associated with more phosphorus burden.

Benefits of Home-Delivered, Low-Sodium Meals in Hemodialysis Patients
Luis M. Perez, Hsin-Yu Fang, Brett Burrows, Alexis King, Sadia anjum Ashrafi, Kenneth R. Wilund. Renal and Cardiovascular Research Laboratory University of Illinois at Urbana-Champaign, Urbana, IL.

Background: Patients undergoing maintenance hemodialysis (HD) therapy are routinely counseled to reduce dietary sodium intake to reduce sodium retention, volume overload (VO), and hypertension. Unfortunately, low-sodium trials in HD are sparse and mostly indicate that dietary education and behavioral counseling alone are ineffective in reducing sodium intake. The purpose of this study is to determine if 4-weeks of a low-sodium home delivered meals intervention will reduce interdialytic weight gain (IDWG) and subsequent VO and hypertension in patients undergoing HD when compared to 4-weeks of a usual diet.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: We recruited 20 subjects (55±12 years, BMI 40.7±16.6 kg/m², 45% male, 65% 4MA, 70% DM, 50% CVVHD) from a HD clinic in central IL. Participants followed a usual-control diet for the first 4 weeks. PurFoods, LLC prepared and shipped 3 low-sodium kidney meals (<700 mg sodium, potassium, and phosphorus each) per day to patients in the following 4 weeks. We collected monthly IDWG, bioelectrical impedance, standardized blood pressure, 3 days (HD, non-HD, and weekend day) of dietary recalls, and blood at baseline (0M), after a usual diet (1M), and post-intervention meals (2M).

Results: Home-meal delivery significantly reduced both dietary sodium intake, IDWG, BP, and VO in HD patients. It will be important to determine if these changes can be sustained long-term with additional counseling and in larger sample sizes. The long-term benefits and cost-effectiveness of this approach also needs to be evaluated.

Performance of GLIM for Nutritional Assessment of Hemodialysis Patients: Comparison with Subjective Global Assessment (SGA) and Malnutrition-Inflammation Score (MIS)

Carla M. Avesani,1 Alice Sabattino,4 Alessandro Guerra,2 Juan J. Carrero,3 Giovanni maria Rossi,1 Peter Stenvinkel,1 Enrico Fiacchadore,4 Bengt Lindholm,1 Karolinska institutet Department of Clinical Sciences Intervention and Technology, Huddinge, Sweden; 3Università degli Studi di Genova, Genova, Italy; 4Parma University Hospital, Parma, Italy.

Background: There is a need for methods to identify and monitor malnutrition in maintenance hemodialysis (MHD) patients. We assessed GLIM (Global Leadership Initiative on Malnutrition) evaluated agreement and survival prediction of GLIM vs. SGA and MIS in MHD pts.

Methods: We investigated two cohorts, MHD Italy (121 adult pts from Italy; 67±16y, 65% men, BMI 25±4 kg/m²) and MHD Italy cohort (169 elderly (age≥60 y) pts) from Brazil; 71±7y, 66% men, BMI 25±4 kg/m²), followed for 40 (27; 46) and 17 (12; 31) months (median and 66% men, BMI 25±4 kg/m²), respectively. GLIM comprises: 1. Screening and 2. Confirming malnutrition by phenotypic and etiologic criteria. For 1., presence of >1 criteria from protein-energy and/or BMI and the percentage of body mass (1000 kcal had increased mortality risk compared to those in the highest quartile: adjusted HR=2.42; 95% CI=1.28 to 3.79; P=0.007) while in the MHD Italy cohort, only pts malnourished by MIS had higher risk for mortality (HR=2.42; 95% CI=1.28 to 4.59; P=0.007) and MIS (HR=2.24; 95% CI=1.20 to 4.16; P=0.01) had higher risk for mortality.

Conclusions: In MHD pts, GLIM showed low agreement with SGA and MIS, raising question on its validity and usefulness in renal care. Only malnutrition by MIS predicted mortality risk in MHD Italy cohort, but in the MHD Italy cohort, malnutrition by all three methods predicted higher mortality risk.

PO2031

Dietary Fiber Intake, Cardiovascular Risk Factors, and Kidney Function: A Mediation Analysis

Background: Higher fiber intake may be associated with higher eGFR but the mechanisms underlying this association are poorly understood. Considering that higher fiber intake is linked to improved cardiovascular (CV) risk factors, we hypothesize that the effect of fiber intake on eGFR could be mediated by these CV factors.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Protein Supplements and Proteinuria: A Case-Control Study in Military Candidates
Sofia H. Marques,1,2 Alberto Freitas,3 Hospital Militar Polo Porto, Porto, Portugal; 4Faculty of Medicine of the University of Porto, Porto, Portugal.

Background: Man has long wanted to improve both image and physical performance using supplements some of which include proteins. Low protein diets are recommended by guidelines to attenuate the progression of chronic kidney disease. In healthy individuals, however, protein intake does not seem a risk factor. This study addressed whether protein supplements could cause proteinuria in a healthy population.

Methods: We performed a case-control study at the Military Hospital of Oporto including 1541 military academy candidates who had urinalysis in 2017. Among them, 102 (6.6%) had proteinuria (diostick test ≥1+) and these were compared to a random sample of 106 non-proteinuric candidates. Telephone interviews collected data on comorbidities, exercise, smoke, alcohol habits, drugs, supplements, height and weight. Protein supplements were accessed as risk factors for proteinuria using the Pearson Qui-square test.

Results: Answers were obtained from 49 cases and 52 controls. Of these 101 candidates, 88 were males, had a median age of 19 and mean body mass index of 24.1±2.4 kg/m2. Most (97%) exercised for a mean weekly time of 6±3.7h: 40% practiced only resistance training; the rest both resistance and strength. Half used supplements at some point in time and 32 were current users. All used protein powder, mainly whey protein. Additional supplements (mostly amino acids) were used by 13. The weekly powder dose ranged from 3 to 14 scoops (20-30g/scoop). No significant association was found between the use of protein supplements and proteinuria (p=0.51). Similarly, no difference was found in creatinine, ura or other laboratory parameters. Supplements were significantly used more by those who practiced strength, as compared with resistance-training subjects.

Conclusions: One third of Portuguese military candidates used protein supplements. Increased use was noted in strength training most likely due to peer pressure. Proteinuria was found in 6.6%, similar to screenings in other healthy populations. No relation was found between protein supplements and proteinuria which could mean that the kidneys of healthy individuals are capable of dealing with a higher metabolic strain after increasing protein loads. However we acknowledge that proteinuria as a marker of disease has limitations and that the cumulative exposure and longterm impact of protein supplements was not considered and may be relevant.

Continuous Intradialytic Amino Acid Infusion from the Start of Dialysis Is Better to Avoid Catabolism under the High-Volume Pre-Dilution Online Hemodiafiltration
Motoko Kato,1 Yukie Kitajima,1 Kenichi Kubo,3 Toru Hyodo,4 Department of Clinical Engineering, Eijin Clinic, Hirasuka, Japan; 1Tokyo University of Technology School of Health Sciences, Setagaya, Japan; 1Allied Health Science, Kitasato University, Sagamihara, Japan; 4Dialysis Center, Eijin Clinic, Hirasuka, Japan.

Background: Amino acid infusion during dialysis is useful for improving nutritional status (Clin Nephrol 3:234,1975). Usually, amino acid is infused 60 to 90 minutes before the end of dialysis, but it is reported that continuous administration from the start of dialysis is better (Kidney Int 21: 500, 1982). Moreover, these effects are unclear in the high-volume pre-dilution on-line HDF (HVPO-HDF). The optimal administration method of amino acid infusion under the HVPO-HDF was analyzed.

Methods: The subjects were 10 patients receiving HVPO-HDF (7 males, 4 diabetics, mean age 57, ±5 years). We compared the pre- and post-dialysis plasma amino acid levels and the total amino acids amount in the waste fluid when the amino acids infusion was performed from the start of dialysis (Group A) and from 1 hour before the end of dialysis (Group B). The treatment time is 4 hours. The mean blood flow rate was 200 mL/min. The dialysate flow rate was 600 mL/min. The replacement fluid flow rate was 400 mL/min. The replacement fluid volume was 90. Hemodialyzer MF21Meco (Nipro, Ltd) was used.

Results: In pre-dialysis plasma levels of total amino acid (TAA), Group A and Group B showed the same level (247±267 mmol/mL and 262±319 mmol/mL, respectively). In the essential amino acid (EAA) and non-essential amino acid (NEAA), similar results were obtained (827±145 mmol/mL and 847±99 mmol/mL of EAA, 1644±216 mmol/mL and 1120±193 mmol/mL of NEAA, respectively). Moreover, the losses of amino acids were also similar (90±131 mmol/L and 880±924 mol/L of TAA, 880±9074 mol/L and 454±4534 mol/L of EAA, 402±644 mg/L and 434±9826 mg/L of NEAA, respectively). In Group A, post-dialysis plasma levels of amino acids were significantly lower than in Group B (206±6370 mmol/mL and 382±636 mmol/mL of TAA, 94±193 mmol/mL and 22±3539 mmol/mL of EAA, 1120±193 mmol/mL and 1577±260 mmol/mL of NEAA, respectively, p <0.01).

Conclusions: The result of high post-dialysis plasma levels despite the same loss of amino acids suggests more catabolism from muscle to blood in Group B. The continuous intradialytic amino acid infusion from the start of dialysis is better to avoid catabolism under HVPO-HDF.
yet attenuated relationship was observed among A2 patients. Odds of faster UACR slope was higher only in patients with LDL ≤ 160 mg/dL and with index UACR≤300 mg/g. For A3 patients, there was no association between LDL level and UACR slope.

**Conclusions:** Among patients with baseline UACR <300 mg/g, both low and very high LDL were associated with higher odds of having fast UACR change. Yet, among those with higher albuminuria, the relationship with LDL and UACR change was null. More studies are needed to delve into the mechanism between LDL and CKD progression.

**Lipidomic Markers for Cognitive Impairment in Maintenance Hemodialysis Patients**

Ke Zheng, Yujun Qian, Xuemei Li. Peking Union Medical College Hospital, Dongcheng-qu, China.

**Background:** Cognitive impairment (CI) was relatively common in maintenance hemodialysis patients. The pathophysiology of CI in this particular population was not well understood. Whether the classic lipid components that affect cognitive outcome in general population have similar effect in dialysis patients is not clear. In this study, we tried to get a better understanding of the pathogenesis CI in hemodialysis patients by lipidomic analysis and find potential lipid markers to predict cognitive decline.

**Methods:** From July 2013 to July 2019, we followed up the cognitive evaluation results of the hemodialysis patients in our dialysis center. The cognitive function was evaluation by the MMSE and MoCA at baseline and follow-up period. Plasma and hemocytes of enrolled patients were collected at baseline. Lipidomic analyses were performed on an Exxon LC-system coupled with a QTRAP 6500 PLUS system (Sciex). Principal component analysis and orthogonal project to late structures discriminant analysis, and t-test were used to analyze the differences in patients in cognitive decline group and cognitive retained group.

**Results:** At the baseline, plasma from 21 patients and hemocytes from 65 patients were collected for lipidomic analyses. 539 lipids were detected in plasma and 237 lipids were detected in hemocytes. In individuals with plasma lipids data, 10/21 suffered MMSE scores decrement and 16/21 showed MoCA decrement. In patients with hemocytes lipids files data, 29/65 of them suffered MoCA scores decrement and 43/65 of them suffered MMSE scores decrement. Compared with the reference group, the hazard ratios [HR (95% CI)] for all-cause mortality were 1.56 (1.24-1.98) for MIC−/low FS, 1.75 (1.32-2.32) for MIC+/ high FS, and 2.97 (2.31-3.82) for MIC+/low FS groups. The adjusted HRs for infection-related mortality were 1.57 (0.91, 2.71) for MIC−/low FS, 1.67 (0.84, 3.31) for MIC+/high FS, and 5.45 (3.15, 9.45) for MIC+/low FS groups.

**Conclusions:** The combination of MIC and low FS is a strong predictor of mortality, and infectious mortality in particular, in HD patients. Identification of patients with MIC and FS.

---

**PO2038**

**The Combination of Malnutrition Inflammation and Limitations in Functional Status Is Associated with a Very High Risk of Mortality in Hemodialysis Patients: Results from the DOPPS**

Marcelo Lopez,1 Eiichiro Kanda,2 Brian Bieber,1 Kazukhu Tsuuryu,2 Hideki Hirakata,1 Angelo Karaboyas,1 Stefan H. Jacobsson,1 Indranil Dasgupta,4 Bruce M. Robinson,1 Roberto Pecoits-Filho,1 DOPPS ‘Arbor Research Collaborative for Health, Ann Arbor, MI; ’Kawasaki I Daigaigu, Kurashiki, Japan; ’Nara-ken, Nara, Japan; ’Fukuoka Renal Clinic, Fukuoka, Japan; ’Karolinska Institute, Stockholm, Sweden; ’University of Warwick Warwick Medical School, Coventry, United Kingdom.

**Background:** The malnutrition-inflammation-complex (MIC) is a risk factor for mortality and lower quality of life in hemodialysis (HD) patients. The identification of MIC and its risk factors, which include the limited ability to perform functional status (FS), is key to improve the patient experience on HD. Our study investigates the association of MIC and FS combinations with mortality in HD patients.

**Methods:** We analyzed data from a cohort of 5465 HD patients from Australia, France, Germany, Italy, Japan, New Zealand, Spain, Sweden, and United Kingdom, enrolled in the Dialysis Outcomes and Practice Patterns Study phases 4 (2009-2011) and 5 (2012-2015). MIC syndrome was defined as low serum albumin (<3.8 g/dL) and high serum C-reactive protein (>3mg/L in Japan; >10 mg/L elsewhere). Poor functional status was defined as the sum of scores from the self-reported limitations in the Katz Index of Independence in Activities of Daily Living (0 to 5) and the Lawton-Brody Instrumental Activities of Daily Living Scale (score ranges from 0 to 8) less than 11. We investigated the association between combinations of MIC (+)/− and FS (low/high) with death, using Cox proportional hazards models adjusted for possible confounders including patient demographics, comorbidity history, catheter use, serum creatinine, phosphorus levels, WBC count, hemoglobin level, and time on dialysis therapy.

**Results:** The prevalence of different combinations were: MIC-/High FS 57%, MIC-/ Low FS 24%, MIC+/High FS 9%, and MIC+/Low FS 10%. Patients with MIC+/high FS were younger, better nourished, and had lower prevalence of comorbidities. Compared to the reference group, the hazard ratios [HR (95% CI)] for all-cause mortality were 1.56 (1.24-1.98) for MIC−/low FS, 1.75 (1.32-2.32) for MIC+/ high FS, and 2.97 (2.31-3.82) for MIC+/low FS groups. The adjusted HRs for infection-related mortality were 1.57 (0.91, 2.71) for MIC−/low FS, 1.67 (0.84, 3.31) for MIC+/high FS, and 5.45 (3.15, 9.45) for MIC+/low FS groups.

**Conclusions:** The combination of MIC and low FS is a strong predictor of mortality, and infectious mortality in particular, in HD patients. Identification of patients with MIC and FS.
Effects of RS supplementation or placebo on plasma TMAO, choline and betaine levels

Indoxyl Sulfate Reduces the Inducibility of NLRP3 Inflammasome in Hemodialysis Patients

Li-chun Ho,1,2 Chang Min-Yu,1,3 Yi-che Lee,1 Hsi-Hao Wang,1 Ching-fang Wu,1 Shih-Yuan Hung.1 1-I-Shou University, School of Medicine, Kaoshiung City, Taiwan; 2-E‘Da Hospital, Department of General Medicine, Yanchao, Taiwan; 3-E‘Da Hospital, Division of Nephrology, Department of Internal Medicine, Yanchao, Taiwan.

Background: The NLRP3 inflammasome is a cellular component of innate immunity responsible for the maturation of interleukin-1β (IL-1β). Studies have shown that the basal activity of the NLRP3 inflammasome is increased in the immune cells of hemodialysis (HD) patients, but the inducibility of the NLRP3 inflammasome upon canonical stimulation has not been studied.

Methods: Peripheral blood mononuclear cells (PBMCs) isolated from 13 HD patients and 18 volunteers without a history of chronic kidney disease (CKD) were treated with a combination of lipopolysaccharide (LPS) and nigericin to induce NLRP3 inflammasome activation. Likewise, THP-1 monocytic cell-derived macrophages, with or without indoxyl sulfate (IS) pretreatment, underwent the canonical NLRP3 inflammasome stimulus as well. The activity of the inflammasome was determined by immunoblot analysis.

Results: Despite the high plasma levels of IL-1β in HD patients, caspase-1 and IL-1β in the PBMCs of HD patients remained predominantly immature and were not stimulated in response to the canonical stimulus. Further investigations showed that while IS treatment alone facilitated the secretion of IL-1β from THP-1-derived macrophages, IS pretreatment reduced the inducibility of NLRP3 inflammasome in response to LPS and nigericin, characterized by the low mature rate of caspase-1. The PBMCs derived from the HD patients and the macrophages exposed to IS both had low expression levels of NLRP3 inflammasome components, suggesting insufficient supplies of inflammasome machinery.

Conclusions: The low induction response of the NLRP3 inflammasome attributed to indoxyl sulfate probably constitutes a breach of the immune defense system, which may explain the high infection risk in HD patients.

Prevalence and Risk Factors of High-Altitude Hyperuricemia in the Bai Ethnic Group

Chenni Gao, Xiaonong Chen. Shanghai Jiao Tong University Medical School Affiliated Ruijin Hospital Department of Nephrology, Shanghai, China.

Background: The Bai ethnic group is one of the 55 minorities in the People’s Republic of China. Hyperuricemia is not rare among this ethnic partly due to the chronic exposure to high altitude. However, the prevalence of hyperuricemia in the Bai ethnic group remains unclear.

Methods: We collected retrospectively the demographic characteristics and laboratory measurements of 1393 Bai ethnic adults undergoing annual medical examination during Jan 2019 to Dec 2019 in the People's Hospital of Jianchuan County (average altitude 2300m), Yunnan Province. We investigated the prevalence of hyperuricemia as well as its clinical features and risk factors.

Results: Of the 1393 participants enrolled in the study, the prevalence of hyperuricemia was 24.8%, and the prevalence was significantly higher in male gender (52.2% in men vs. 11.0% in women, P<0.001). The prevalence of hyperuricemia increased from 19.2% among participants aged 30-40 years to 30.1% among participants aged 50 years and older. Also, the prevalence elevated from 17.2% among participants with normal body mass index (BMI) to 35.5% among those who were overweight/obese. Interestingly, we found a positive correlation between hemoglobin level (HB) and serum uric acid (β=2.19, P<0.01). Logistic regression analysis revealed main risk factors for hyperuricemia in the Bai ethnic group included age, sex, BMI, systolic blood pressure (SBP) and Hb.

Conclusions: Hyperuricemia is common in the Bai ethnic group. Besides traditional risk factors such as age, sex and BMI, polycthemia secondary to chronic exposure to high altitude may also contribute to the hyperuricemia.
Dysbiosis of Gut Microbiota in Adult Idiopathic Membranous Nephropathy with Nephrotic Syndrome

Jian Zhang. Division of Nephrology, Department of medicine, Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.

Background: Gut bacterial microbiota is altered in patients with chronic kidney disease (CKD) and those on dialysis. However, it is not yet clear what bacterial composition changes occur in patients with idiopathic nephrotic syndrome. We present in this report the changes in gut bacterial microbiota in idiopathic nephrotic syndrome patients with membranous nephropathy.

Methods: A total of 158 individuals were recruited for this study. Of these, 80 were CKD3–5 stage patients without nephrotic syndrome, 48 patients had idiopathic nephrotic syndrome and pathological diagnosis of membranous nephropathy, and 30 were age- and sex-matched healthy controls. The gut microbiome composition was analyzed using a 16S ribosomal RNA gene-based sequencing protocol.

Results: The results indicated that the nephrotic syndrome (NS) patients had a significantly different alpha and beta diversity compared with the CKD3–5 group and healthy controls (p < 0.01). At the phylum level, the NS patients showed increased Faecalibacterium and Proteobacteria but reduced Firmicutes when compared with the healthy controls. At the genus level, Megamonas, Megaplexus, Akkermansia, and the butyrate-producing bacteria Lachnospiraceae, Rosearhabdus, and Flobacterium were more abundant in the controls (LDA score > 3) than the CKD3–5 and NS patients. Compared with the healthy controls, we found that Parabacteroides was increased in CKD3–5 and NS patients. In addition, Oscillospira and Ruminococcus were more abundant in CKD3–5 patients than in the other two groups (LDA score > 3). At the genus level, ten bacterial taxa were more prevalent in the healthy controls. Providencia and Microbacterium were more prevalent in NS patients.

Conclusions: Our findings highlight that, NS patients had a significantly different alpha and beta diversity and decreased gut microbiota-derived short-chain fatty acids, such as butyrate. However, large-scale prospective studies should be performed to identify the cause and effect factors of these changes in the microbiota in NS patients.

Effect of Intradialytic Oral Nutritional Supplementation with and Without Exercise on the Skeletal Muscle Quantity and Quality of Adult Hemodialysis Patients

Geovana Martin-Alemayh1, L. M. Perez-Navarro2, Angeles Espinosa-Cuevas2, Gloria G. Garcia Villalobos, Elba O. Medina, Miguel Angel Reyes Caldejas, Rafael Velazquez-Oritz1, Hospital General de Mexico, Dr. Eduardo Liceaga Ciudad de Mexico, Mexico; 1National Institute of Medical Science and Nutrition Salvador Zubirán, Ciudad de Mexico, Mexico.

Background: The muscle mass (MM) is one of the major tissues affected by the chronic kidney disease. Patients undergoing chronic hemodialysis (HD) have loss of MM due to many factors. Intradialytic oral nutritional supplementation (ONS) and exercise (EX) have been shown to improve the amount and quality of MM and physical function (PF).

Methods: Patients were randomized in two different groups: 1) ONS and 2) EX + ONS. Patient’s realized 30 minutes of aerobic EX using static bicycles and 30 minutes of resistance EX using Theraband Bands. Quantity and quality of MM were measured with anthropometrics and computed tomography (CT). PF was measured by short physical performance battery (SPPB), six-minute walk test (6 MWT) and handgrip strength (HGS). According to the data distribution Student t test or Mann-Whitney test were used to analyze the data.

Results: Twenty-three patients conclude the study. Both groups improve their weight (ONS: baseline, 53 ± 5.4 kg; final, 54.3 ± 4.9 kg; p = 0.020 and ONS + EX: baseline, 57.2 ± 9.2 kg; final: 59 ± 9.2 kg; p = 0.001) and the AMC (ONS: baseline, 227 ± 20 mm; final, 241 ± 19 mm; p = 0.040 and ONS + EX: baseline, 235 ± 27 mm; final: 250 ± 31; p = 0.047).

In the ONS group we observed decreases in the 6MWT; baseline: 417 ± 53.9 mm; final: 405 ± 52 mm; p = 0.016 and improvements in the SPPB; baseline: 10.8 ± 1.3, final: 11.2 ± 1.4, p = 0.005) with no change in the intramuscular lipolipid infiltration (baseline: 53.5 ± 5.8% final: 53.5 ± 5.9%); p = 0.8). The EX group had improvements in the 6MWT; HGS and in the SPPB; (baseline: 383 ± 58 mm; final: 425 ± 46 mm; p = 0.000; baseline: 22.6 ± 8.8 kg, final: 24.8 ± 8 kg, p = 0.000 and baseline: 10.2 ± 1.1, final: 10.8 ± 1.4, p = 0.801, respectively) with decreases in the intramuscular lipolipid infiltration (baseline: 53.1 ± 4.5H, final: 52.3 ± 4.8H; p = 0.093).

Conclusions: Exercise training for 6 months improves the MM composition of HD patients measured by CT and this was reflected with the improvements in the PF tests and no changes were observed in MM composition in the ONS group.

Muscle Mitochondrial Function and Physical Performance Are Associated with Branched-Chain Amino Acid Levels in Patients with CKD

Jorge Gamboa1, Berfu Korucu,1 Dungeng Peng,1 Baback Roshanravan,2 Talat Alp Ikizler, Vanderbilt University Medical Center, Nashville, TN; 1University of California Davis, Davis, CA.

Background: Muscle mitochondrial function and physical performance are impaired in patients with chronic kidney disease (CKD). Previous studies suggest that decreased branched-chain amino acids (BCAA) levels are associated with muscle catabolism in patients with CKD. We hypothesized that BCAA is lower in patients with CKD and associated with mitochondrial function and physical performance, critical components of protein-energy wasting observed in patients with CKD.

Methods: In a cross-sectional study, we evaluated 63 participants [20 with CKD stage 3-5, 20 with CKD stage 5 on maintenance hemodialysis (MHD), and 20 controls with no history of CKD]. Mitochondrial function was evaluated using 1H phosphorus magnetic resonance spectroscopy to evaluate the phosphocholine (PCr) recovery after exercise. A longer PCR recovery results in a greater time constant (τ), which indicates worsening mitochondrial function. Physical performance was measured using the six-minute walk test. BCAA levels were measured in plasma samples using nuclear magnetic resonance. Linear regression analysis was used to evaluate association and adjusting by age, race, sex, and body mass index (BMI).

Results: Groups were similar in terms of gender, BMI, and history of diabetes and hypertension. Patients on MHD were younger than patients with CKD stage 3-4 (47 ± 11.7 vs. 63.6 ± 9.0) but had similar age compared to controls (46 ± 9.5). BCAA levels were lower in patients with CKD and patients on MHD compared to controls (Figure 1A). Lower levels of BCAA, particularly leucine, were associated with worse mitochondrial function (higher time constant τ, Figure 1B) and lower physical performance (Figure 1C) in unadjusted and adjusted linear regression.

Conclusions: CKD is associated with lower levels of BCAA. Furthermore, low levels of BCAA are associated with impaired mitochondrial function and poor physical performance. Future studies should evaluate the effect of BCAA supplementation in mitochondrial function and physical performance in patients with CKD.

High Prevalence of Sleep Disordered Breathing and Its Association with Renal Function in Patients with CKD: A Cross-Sectional Study

Kanii Ota, Youseke Nakayama, Tomofumi Moriyama, Yusuke Kaida, Kei Fukami. Division of Nephrology, Department of Medicine, Kurume University, Kurume, Japan.

Background: Sleep disordered breathing (SBD) is known as a novel risk factor for cardiovascular disease, and one of five adults suffer from SBD in general population. In non-dialysis chronic kidney disease (CKD) and hemodialysis (HD) patients, a high prevalence of SBD has been reported due to the excess accumulation of extracellular fluid. However, precise prevalence and associated factors of SBD in patients with peritoneal dialysis (PD) has not been known. This cross-sectional study aimed to investigate the prevalence and determinants factors associated with SBD in patients with CKD.

Methods: This was a single-center retrospective cohort study recruited 334 patients with CKD stages 1-3a, 3b-5, HD, and PD enrolled from 2018 to 2020. All patients were hospitalized and received our CKD educational program, and did not have sleep complaints. The diagnosis and assessment of the severity of SBD were evaluated using PULSiox-Mc306 and SAS2000 systems. The 3% oxygen desaturation index and SpO2 were measured during sleep. SBD was defined as 3% oxygen desaturation index (ODI)>15.0 and SpO2<92% in this study.

Results: Proportion of the patients with CKD1-3a, CKD3b-5, HD, and PD were 28%, 53%, 11%, and 8%, respectively. 31% of the patients were diagnosed with SBD in all CKD patients. In a generalized linear model, 3% ODI>15.0 and SpO2<92% were significantly correlated with apnea hypopnea index (p<0.05, r=0.87 and p<0.05, r=0.45, respectively). Furthermore, it became clear that the proportion of 3%ODI>15 and SpO2<92% was significantly higher in PD patients (50%) than in other CKD patients. Furthermore, 3% ODI was significantly correlated with BMI and HDL cholesterol levels in PD patients (p<0.05, r=0.67 and p<0.05, r=0.54, respectively).

Conclusions: We reported for the first time that the prevalence of SBD was very high and that the severity of SBD was significantly associated with BMI in patients with PD. These findings suggest that the extracellular fluid overload and excess glucose exposure due to PD fluid might accelerate SBD in patients with PD. Further clinical studies are needed to determine whether PD-associated SBD might influence the development of cardiovascular disease in CKD patients.

Effects of Restorative Starch (RS) Type 2 Cookies on Gut Microbiota Profile in Hemodialysis (HD) Patients

Denise Mafra, Julie Ann Kemp, Marta Esгалhado, Bruna Paiva, Hugo E. de Jesus, Henrique F. Santos. Federal University Fluminense, Niterói, Brazil.

Background: Dysbiosis is recognized as a new cardiovascular risk factor in HD patients. In this context, nutritional strategies as the use of high amylose RS have been proposed to modulate the gut microbiota in HD patients. The aim of the present study was to evaluate the effects of RS supplementation on gut microbiota modulation in HD patients.

Methods: This double-blind, placebo-controlled clinical trial evaluated HD patients randomized in two groups, RS or placebo. They received 9 cookies/day (16g of RS - Hi-Maize 260, Ingredion®), in the HD days and 1 sachet/day in non-HD days for 4 weeks. The placebo group received manioc flour. Fecal bacteria composition and diversity were evaluated by high-throughput sequencing of 16S RNA gene.

Results: Twenty patients concluded the study: 10 in the RS group (3♂, 52 ± 12.3 yrs, BMI, 24.6 ± 3.9 Kg/m²) and 10 in the placebo group (8♂, 55.1 ± 11.1 yrs, BMI, 25.6 ± 4.9 Kg/m²). Microbial diversity (Shannon index) and richness (ACE) were similar in both groups at baseline. RS supplementation increased mainly the relative abundance of the genus Ruminococcus 2 and maintained genus Blautia, while the placebo group decreased both of these genera, as showed in the Fig 1. After RS supplementation the beta diversity (PCA) changed, increasing the short-chain fatty acid producers, which are related to benefits effects.

Conclusions: The RS supplementation was able to change the gut microbiota in HD patients. Linking these results with our previous studies, which RS was able to reduce related to benefits effects.

**Gut Dysbiosis and Mortality in Hemodialysis Patients**

Ting-yun Lin. Taipei Tzu Chi Hospital, Taipei, Taiwan.

**Background:** Persistent inflammation plays a pathogenic role in CKD-associated protein-energy wasting, cardiovascular disease, and mortality. Gut dysbiosis, characterized by decreased microbial diversity, promotes inflammation. The gut microbiota is markedly altered in patients with ESKD. Therefore, we aimed to determine the relationship between gut dysbiosis and mortality in an ESKD cohort.

**Methods:** In an observational study, we examined the associations between microbial diversity and mortality in ESKD patients undergoing maintenance hemodialysis (n=109) using Cox proportional hazards models. The gut microbiota was assessed by 16S rRNA sequencing. Microbial diversity was calculated using the Simpson index. Participants were stratified into higher- (above the median) and lower-diversity (below the median) groups and were followed up for a median of 2.1 years. Next, in a matched case-control study, we compared the microbial composition between nonsurvivors and survivors.

**Results:** Kaplan-Meier analyses revealed a significant association between higher diversity and a lower risk of death (P=0.015). After adjustment for patient characteristics and comorbidities, the risk of death among patients with higher diversity was 74% lower than that among patients with lower diversity (hazard ratio, 0.26; 95% CI, 0.07 to 0.95). Nonsurvivors and survivors were matched 1:4 for age and sex. We observed significantly lower values of microbial diversity and higher levels of proinflammatory cytokines (IL-6 and TNF-α) among nonsurvivors (n=114) than survivors (n=56). Notably, the relative abundance of Succinivibrio and Anaerostipes, two short-chain fatty acid-producing bacteria, was reduced in nonsurvivors compared with survivors.

**Conclusions:** A unique gut microbial composition is associated with an increased risk of mortality in patients with ESKD and may be used to identify subjects with a poor prognosis. Our findings need to be validated in a larger independent cohort.

**Insulin Resistance and Pancreatic Beta-Cell Function in Calcium Kidney Stone Formers**

Oliver W. Tang, Kevin Mitchell, Jie Tang. Johns Hopkins Medicine, Baltimore, MD; Alpert Medical School of Brown University, Providence, RI.

**Background:** Diabetes mellitus is common among individuals with kidney stones; however, the risk factors associated with glucose dysregulation in this population is unclear.

**Methods:** We characterized the independent associations between vitamin D, urinary measures of dietary intake (sodium, magnesium), and urinary ammonia and citrate with homeostasis model assessment of β-cell (HOMA-B) and insulin resistance (HOMA-IR) in prevalent calcium kidney stone formers without diabetes mellitus recruited from Lifespan Kidney Stone Clinic (N = 96). We used linear regression with adjustment for demographics, body mass index, hypertension, hyperlipidemia, parathyroid hormone, and serum uric acid.

**Results:** The study population had a mean age of 53 years, 48% were male, and 83% were Caucasian. The mean 25-hydroxy-vitamin D (25D) was 30 ng/ml, 1,25-dihydroxy-vitamin D (1,25D) was 55 pg/ml, 24-hour urine sodium was 145 mmol, urine ammonia was 30 mg, urine citrate was 590 mg, and urine magnesium was 102 mg. Mean HOMA-B was 172.1, and mean HOMA-IR was 5.4. Urine sodium was negatively associated with HOMA-B, but not HOMA-IR. Urine ammonia was positively associated with HOMA-IR, but not HOMA-B. Urine citrate was positively associated with both HOMA-B and HOMA-IR (Table).

**Conclusions:** In our cohort of calcium kidney stone formers, high salt intake and low urine citrate were associated with worse beta-cell function. High urine ammonia and citrate were associated with increased insulin resistance.

**Funding:** Clinical Revenue Support

**Time to Hyperkalemia Recurrence in 1 Year Among 103,155 US Veterans**

Jui-Ting Hsung, RuBee K. Israni, Cachet Wenziger, Nipun Atreja, Connie Ha, Deborah A. Anzalone, Kamyar Kalantar-Zadeh, Elani Streja. Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; AstraZeneca, Wilmington, DE.

**Background:** Elevated serum potassium (sK) is commonly asymptomatic, but in a subset of patients, hyperkalemia (HK) is associated with worse outcomes and frequent recurrence. Whether the initial HK event was captured during a hospitalization may be associated with time to recurrence. Further characterizing time to recurrence in inpatient (INPT) and outpatient (OPT) settings may improve HK monitoring and treatment.

---

**Fig.1:** Relative abundance at genus level from RS and Placebo group.

Kaplan-Meier analysis curves. Hemodialysis patients were stratified by the median of the Simpson index to assess the unadjusted risks for all-cause mortality.

---

**Key:** TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Methods: Among 3,958,837 US veterans that had a sK between 2004-2006, there were 559,019 that had an index HK event (sK >50 mL/eG/d) during this period where we could ascertain INPT/OPT status. We then identified patients who had a recurrent HK event 7-365 days after the index HK and had at least one normal sK ≤50 mL/eG in between events. We examined time to recurrence in 30-day intervals according to whether the index sK was INPT or OPT. Patients who’s INPT-OPT status at HK recurrence could not be ascertained were excluded.

Results: HK recurrence over one year occurred in 103,155/589,019 (17.5%) patients, or 17,215/51,262 (34%) and 85,940/53,757 (16%) of patients with index INPT and OPT events, respectively. The 103,155 patients with HK recurrence had a mean patient age of 68±11 years, consisted of 98% males, 14% African Americans, 56% diabetics, and 60% with estimated glomerular filtration rate <60 mL/min/1.73m². In patients with HK recurrence, 50% (n=5,165) developed this event 6 months after the initial HK (table). Among patients who had an OPT index HK, 56% developed recurrence 6 months after initial HK event. However, 51% of the patients who had an INPT index HK event developed recurrence within 60 days of the index HK.

Conclusions: A significant proportion of VA patients with HK developed another HK event within one year. Hospitalized patients with HK developed recurrence faster than patients in the OPT setting despite requiring 7 days between HK events and normalization of sK between events. This could be due to the fact that hospitalized patients are usually sicker or they were monitored more closely by the healthcare providers, therefore it is easier to catch HK recurrence in INPTs than OPTs.

PO2058
Effect of Exercise on Quality of Life and Functional Capacity in Patients with CKD

Vijay Kumar Bandi,1 Haneesha Kolli,2 Sreelakshmi Nimmagadda,2 Sandhya Komatla,2 *
1Dh Pinnamneni Siddhartha Institute of Medical Sciences & RF; Gannavaram, India; 2Kommaredy Venkata Sadasiva Rao Siddhartha College of Pharmaceutical Sciences, Vijayawada, India.

Background: Chronic kidney disease patients have lower activity levels when compared to normal population, compounded by sedentary lifestyle and is associated with increased mortality, which might reduce with exercise.

Methods: Patients with chronic kidney disease were evaluated for 12 weeks of supervised exercise program. The subjects were divided into 2 groups: Group I (CKD stage 3-5) and Group II (CKD on maintenance hemodialysis). Serum hemoglobin (Hb), calcium (Ca), phosphorous (Pi), and albumin (Alb) were done at baseline and at 12 weeks. Symptom burden was assessed using Functional Assessment of Chronic Illness Therapy-Fatigue Scale (FACT-F) and Leicester Uremic Symptom (LUS) Scale. Quality of life using SF-36 questionnaire, functional capacity using Duke Activity Status Index, Physical activity using Godin-Shephard Leisure time Exercise Questionnaire and Nutritional status using modified Subjective Global Assessment at baseline and at 12 weeks. Subjects in Group I were advised combined aerobic and resistance exercises at home, with once in 3 weeks hospital visit. Subjects in Group II underwent aerobic and resistance exercise in the predialytic and intra-dialytic period during each dialysis visit.

Results: Group I included 28 patients, while group II had 30 patients. At baseline, Hb and Albamum were significantly different between groups, while other parameters and scores were similar. At baseline, SF-36 and FACT-F significantly correlated positively with Hb, Alb, Ca and Pi, while SGA correlated significantly with Alb, Ca & Pi. At end of study, in group I there was a non-significant increase in SF-36 (p=0.41), and DUKES (p=0.17), with a non-significant decrease in LUS (p=0.36), FACT-F (p=0.83) and SGA (p=0.1136), while in group II there was a significant increase in SF-36 (p<0.001), with non-significant increase in Dukes (p=0.75), and a significant decrease in LUS (p=0.001), SGA (p=0.05) and FACT-F (p=0.001).

Conclusions: Exercise increased the quality of life and decreased symptom burden but there was an increase in fatigue perception in patients on dialysis. However, LUS reduced with reduced FACT-F which could mean decrease in symptom burden but persistence of fatigue. In patients not on dialysis there was no significant increase in quality of life or decrease in symptom burden.

PO2059
The Effect of Caloric Restriction and Aerobic Exercise on Serum FGF-23 in Patients with Moderate to Severe CKD

Elvis A. Akwo,1 Thomas G. Stewart,1 Cassianne Robinson-Cohen,1 Adriana Hung,1 Jonathan Hummelgard,1 Katherine R. Tuttle,1 Talat Alp Ikizler,1 2Vanderbilt University Medical Center, Nashville, TN; 3University of Washington Department of Medicine, Seattle, WA.

Background: Chronic kidney disease (CKD) is associated with elevated serum fibroblast growth factor 23 (FGF23) which correlates with increased cardiovascular risk. Prior data suggest serum FGF23 is also associated with increased adiposity. We tested the hypothesis that an intervention involving caloric restriction and aerobic exercise to reduce body weight would reduce serum FGF23 in patients with moderate to severe CKD.

Methods: We performed a secondary analysis of data from a 2X2 factorial randomized trial enrolling 103 participants randomized to receive combined caloric restriction and aerobic exercise, caloric restriction alone, aerobic exercise alone, or usual care. Enrollees were persons with a median estimated glomerular filtration rate (eGFR) of 40.5 ml/min/1.73m² (IQR: 30.3, 56.2). Measurements of Serum FGF23 (using C-terminal ELISA assay) and serum phosphate were obtained at baseline and month 4. Changes in serum FGF23 between baseline and month 4 across intervention arms were examined using analysis of covariance with robust standard errors.

Results: After adjustment for baseline differences, serum FGF23 levels fell by 20.6% [95%CI: 0.4, 36.7, p = 0.047] more in the combined intervention arm compared to usual care. Further adjustment for baseline serum phosphate attenuated the relative difference in serum FGF23 decline between the combined intervention arm and usual care [percent change = -18.6, 95% CI: -33.5, 2.9, p = 0.10]. Caloric restriction or exercise alone did not demonstrate significantly greater decline in serum FGF23 compared to usual care. The median values of change in serum phosphate between baseline and month 4 among participants in the combined intervention and diet-only arms were -0.15 and 0.05 mg/dl whereas the exercise and usual care arms experienced no change in serum phosphate. Neither intervention arm showed a significantly greater percent change in serum phosphate from baseline to month 4 compared to usual care.

Conclusions: A combined 4-month caloric restriction and aerobic exercise intervention led to significant reductions in serum FGF23. The magnitude of serum FGF23 reduction appeared to be influenced in part by baseline serum phosphate levels while the latter remained relatively unchanged at the end of the trial.

Changes in Body Composition, Muscle Strength, and Fat Distribution Following Renal Transplantation

Susan Ziockowski,1 Simin Goral,2 Jin Long,4 Joshua F. Baker,2 Justine Shults,6 Babette Zemel,3 Peter P. Reese,2 Francis P. Wilson,2 Mary B. Leonard,1 1Stanford University School of Medicine, Stanford, CA; 2University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 3The Children’s Hospital of Philadelphia, Philadelphia, PA; 4Lucile Packard Children’s Hospital at Stanford General Pediatrics, Palo Alto, CA; 5Yale University School of Medicine, New Haven, CT; 6University of Pennsylvania, Philadelphia, PA.

Background: The impact of renal transplantation on body composition and muscle quality has not been established. Low muscle mass relative to fat mass (relative sarcopenia) has been associated with mortality and disability but has not been examined following transplantation.

Methods: DXA measures of fat mass index (FMI) and appendicular lean mass index (ALMI; representing muscle mass), CT measures of muscle density (low density index (ALMIFMI), and leg muscle strength were assessed in 60 transplant recipients (ages 20-60 years) at transplantation, and 6, 12, and 24 months after transplantation. ALMI relative to FMI (ALMFMI) is an established index of relative sarcopenia. Measures were expressed as age, sex, and race-specific Z-scores and compared with 327 healthy controls.

Results: At transplantation, ALMI, ALMIFMI muscle strength and muscle density Z-scores were lower vs. controls (all p<0.001). Transplant recipients received glucocorticoids throughout. The prevalence of obesity increased from 18% to 45%. Although ALMI increased following transplantation (p=0.001) and was comparable to controls from 6 months onward, gains were outpaced by increases in FMI, resulting in persistent ALMIFMI deficits (mean Z-score -0.31 at 24 months, p=0.02 vs controls). Fat gains were disproportionately vital in distribution (p=0.05). Muscle strength improved but remained low compared with controls independent of ALMI (p=0.05). Exercise increased in the early months following transplantation (p=0.05) but remained lower than controls (p=0.02).

Conclusions: The two-year interval following renal transplantation was characterized by gains in muscle mass and strength that were outpaced by gains in fat mass resulting in persistent relative sarcopenia.

Home-Based Aerobic Exercise and Resistance Training in Pre-Dialysis Patients with Advanced CKD: A Randomized Controlled Trial
Kiyotaka Uchiyama, Keika Adachi, Shu Wakino, Hiroshi Itoh. Keio University School of Medicine, Shinjuku-ku, Japan.

Background: Muscle wasting, a common and progressive condition in patients with uraemia, is associated with increased risk for morbidity, lower health-related quality of life (HRQOL), and mortality. But, the potential effects of aerobic and resistance training in predialysis patients with advanced chronic kidney disease (CKD) have not been fully elucidated. This randomized controlled trial with a parallel-group design investigated the effects of a home-based exercise program on physical functioning and HRQOL in patients with stage 4 CKD.

Methods: A total of 46 patients (median age, 73 years; 33 males; estimated glomerular filtration rate, 23.2 ± 4.7 ml/min/1.73 m²) were randomly assigned to exercise (n = 23) and control (n = 23) groups. The exercise group performed aerobic exercise thrice weekly and resistance training twice weekly at home for 24 weeks. The control group received no specific intervention. Primary outcomes were distance in incremental shuttle walking test (ISWT) and HRQOL assessed by the Kidney Disease Quality of Life-Short Form questionnaire. Secondary outcomes were kidney function assessed by combined urea and creatinine clearance, urinary biomarkers, and anthropometric/biochemical parameters associated with CKD.

Results: ISWT distance was significantly improved in the exercise group than in the control group (34.5 ± 50.5 vs. −21.9 ± 48.2 m; P < 0.001). The intervention increased several HRQOL subscales including symptoms/problems, quality of interaction, sleep, kidney disease component summary, and mental health. Although the change in combined urea and creatinine clearance was not significantly different between the groups (P = 0.69), natural log-transformed (ln) urinary excretion of liver-type fatty acid-binding protein, ln serum C-reactive protein, and acylcarnitine/free carnitine ratio were significantly decreased in the exercise group compared to the control group (P = 0.02, 0.005, and 0.03, respectively). No adverse events associated with the intervention were reported.

Conclusions: The 24-week home-based exercise program improved aerobic capacity and HRQOL with possible beneficial effects on kidney function and CKD-related parameters, in patients with stage 4 CKD. The present trial demonstrated the multifaceted efficacy of home-based training in predialysis patients with advanced-stage CKD.

PO2062
Association of Self-Reported and Objective Measures of Physical Activity with Leg Muscle Mitochondrial Oxidative Capacity in CKD
Jorge Gamboa,2 Chenoa R. Vargas,3 Sophia Liu,3 Kushang V. Patel,2 Ian H. de Boer,4 Bryan R. Kestenbaum,4 Baback Roshanravan.3 University of California Davis, Davis, CA; Vanderbilt University Division of Medicine, Nashville, TN; University of Washington, Seattle, WA; University of California Davis Department of Internal Medicine, Sacramento, CA.

Background: Chronic kidney disease (CKD) is associated with skeletal muscle dysfunction leading to lower muscle mitochondrial oxidative capacity and decreased physical performance. However, the influence of physical activity (PA) on muscle mitochondrial function remains unknown.

Methods: We included participants from the CKD Mitochondrial Energetics and Dysfunction (CKD-MEND) study. Muscle mitochondrial oxidative capacity (ATPmax) in the leg muscle was measured using in vivo 31Phosphorus Magnetic Resonance Spectroscopy. We measured self-reported PA using the adjusted Human Activity Profile (HAP) score and objective PA using an Actigraph accelerometer. Linear regressions were used to test associations between CKD status and ATPmax adjusting for confounders.

Results: We included 36 participants with CKD (mean eGFR=38) and 19 controls. Mean age was 61±13 years, 51% male, and 25% had diabetes. Diabetes and CKD were independently associated with lower ATPmax (-0.12 mV/s, p<0.01 and -0.19 mV/s, p<0.01, respectively). Accelerometry counts per minute (r=0.58, p<0.01) was more strongly correlated with ATPmax than HAP scores (r=0.46, p<0.01) with no interaction by CKD status (p=9). Accelerometry counts explained 43% of the difference in ATPmax between CKD and controls and HAP scores 15% after adjustment.

Conclusions: Objective PA was more strongly associated with ATPmax and explained more of the differences in ATPmax between CKD and controls than self-reported PA. Further studies should demonstrate if exercise interventions can improve muscle ATPmax in CKD.

Metabolic Acidosis and Muscle Metabolic Health Are Important Determinants of Fatigue in Persons with CKD
Tae Youn Kim,1 Se Ri Bae,2 Jorge Gamboa,2 Chenoa R. Vargas,1 Sophia Liu,1 Kusliang V. Patel,1 Ian H. de Boer,2 Bryan R. Kestenbaum,2 Babac K. Roshanravan.1 1University of California Davis, Davis, CA; 2University of Washington, Seattle, WA.

Background: Chronic kidney disease (CKD) is associated with a high prevalence of physical frailty, reduced physical function and fatigue, contributing to increased morbidity, mortality risk, and poor quality of life. Impaired muscle mitochondrial oxidative capacity (ATPmax) underlies poor physical endurance in persons with CKD. Metabolic acidosis may mediate effects of CKD on ATPmax. Little is known about the relevance of metabolic acidosis and ATPmax on patient-reported fatigue in CKD.

Methods: We performed a cross-sectional analysis of 58 participants (39 CKD and 19 non-CKD) from the CKD Muscle Mitochondrial Energetics and Dysfunction (MEND). Muscle metabolic health of the tibialis anterior leg muscle was measured from the time course of phosphocreatine after exercise using 31P Magnetic Resonance Spectroscopy. Fatigue was measured using the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) scale. Metabolic acidosis (MA) was determined from serum bicarbonate (< 22 mmol/L). Linear regression was used to test associations adjusting for age, sex, body mass index (BMI), and diabetes.

Results: The cohort included 48% female and 29% diabetes with a mean age of 61±12 years and a mean BMI of 28.5. The mean eGFR was 39±19ml/min per 1.73m² in CKD and 98±15 in non-CKD. The mean ATPmax was 0.67±0.155mL/sec and mean FACIT-F score was 40±11.5. CKD was associated with increased fatigue (mean difference: 7.6, 95% CI [1.8, 13.5], p=0.02) compared to non-CKD after adjustment. Of those with CKD, each 1 SD (standard deviation) greater ATPmax was associated with a 5.4-point (95% CI [1.03, 9.7], p=0.017) reduction in fatigue after adjustment. Further adjustment for MA attenuated the estimated association by 38% (3.3 points, 95% CI [-1.1, 7.7], p=0.14). Of those with CKD, participants with MA (n=18) had a 10.0 points greater fatigue (95% CI [1.8,18.1], p=0.018) after adjustment compared to those without MA (n=21).

Conclusions: ATPmax is directly associated with fatigue. MA might play an important role in the association of muscle metabolic health with fatigue in CKD. Further research is needed to examine the impact of treating MA on improvement in muscle metabolic health, fatigue and quality of life in CKD.

Blood Pressure in Young Adults with CKD and Associations with Cardiovascular Events and CKD Progression
Alexander J. Kula,1,2 Nisha Bansal,2 David K. Prince,3 Joseph T. Flynn.1,2 1Seattle Children’s Hospital, Seattle, WA; 2University of Washington, Seattle, WA.

Background: Young adults (age 18-40yrs) with CKD are a poorly studied subset of CKD patients. Blood-pressure management for young adults with CKD relies on extrapolating findings from studies conducted in older adults or children. Our objective was to perform an observational study exclusively in young adults with CKD to test the association between BP and adverse outcomes.

Methods: Participants aged 21-40yrs of age enrolled in the Chronic Renal Insufficiency Cohort Study were included (n=317). Exposures included baseline systolic BP (SBP) category, <120, 120-120, ≥130, and per +10 higher baseline SBP. Outcomes included cardiovascular (CV) events, including heart failure, myocardial infarction, stroke, or all-cause death, and CKD progression, defined as 50% eGFR decline or ESRD. We used cox-proportional hazard models to test association between baseline SBP with outcomes. Adjusted models included age, race, eGFR, diabetes, with prevalent CV disease for CV event models and urine albumin to creatinine ratio for CKD progression.

Results: As seen in Figure 1, incidence rates for HF, death, CV events, and CKD progression were greatest in higher SBP categories. In adjusted models, a baseline SBP >130 was significantly associated with CV events (HR: 3.32, 95% CI: 1.53-7.20) and CKD progression (HR: 1.63, 95%CI: 1.02-2.59) compared with SBP<120. Every +10 in SBP was significantly associated with CKD progression (HR: 1.13, 95%CI: 1.02-1.26) in adjusted models.

Conclusions: There is a graded association of higher SBP with greater risk of CV events and CKD progression in young adults with CKD. Among those with SBP>130, 5.8% per year had a CV event and risk was 3-fold higher compared with SBP<120, and 20.7% per year had CKD progression and risk was nearly 2-fold higher. These data suggest that higher SBP is an important risk factor for adverse outcomes in young adults with CKD.

Angiotensin Converting Enzyme Inhibitor and Angiotensin Receptor Blocker Use Among Hypertensive US Adults by Albuminuria Status, 2013-2018
Chi-D. Chuy1, Neil R. Powe,1 Charles E. McCulloch,2 Tanushree Banerjee,1 Deidra C. Crews,4 Rajiv Saran,3 Jennifer L. Bragg-Gresham,3 Hal Morgenstern,2 Meda E. Pavlov,3 Sharon Saydah,3 Delphine S. Tuot,1 CDC CKD Surveillance Team1 University of California San Francisco, San Francisco, CA; 2University of Michigan, Ann Arbor, MI; 3Centers for Disease Control and Prevention, Atlanta, GA; 4Johns Hopkins University School of Medicine, Baltimore, MD.

Background: Since 2003, U.S. hypertension (HTN) guidelines have recommended angiotensin converting enzyme inhibitor (ACEi) or angiotensin receptor blocker (ARB) therapy for urine albumin/creatinine ratio (UACR) ≥30 mg/g. Our objective was to assess the prevalence of ACEi/ARB use for UACR ≥30 mg/g among adults with HTN and to examine the association between UACR and ACEi/ARB use.

Methods: We studied adults with HTN in the National Health and Nutrition Examination Surveys 2013-2018. Respondents were classified as having HTN if they had systolic blood pressure ≥140 mmHg or diastolic blood pressure ≥90 mmHg, were currently using anti-hypertensive medications, or reported being told by a clinician they had HTN. ACEi/ARB use was assessed by review of medication containers by study staff. Modified Poisson regression was used to estimate crude and adjusted prevalence ratios (PR) for the association between ACEi/ARB use and UACR. Adjustment was for sex, race/ethnicity, diabetes, systolic blood pressure (continuous), chronic kidney disease stage, and having a reported routine site for healthcare.

Results: Among 7,377 adults with HTN, 63.4% had UACR ≥30 mg/g, 13.5% had UACR 30-299 mg/g, and 3.2% had UACR ≥300 mg/g. ACEi/ARB use was 43%, 54%, and 48% in UACR categories ≥30, 30-299, and ≥300 mg/g, respectively. This represents approximately 1.5 million adults with UACR ≥30 mg/g who are not receiving ACEi/ARB therapy. Adjusted ACEi/ARB use was minimally associated with UACR ≥30 mg/g (PR = 1.09, 95% CI 1.03-1.17 for UACR 30-299 mg/g; PR = 0.96; 95% CI 0.83-1.10 for UACR ≥300 mg/g; reference ∼UACR 30 mg/g).

Conclusions: Nationally representative data indicate a large gap in guideline-concordant ACEi/ARB use among adults with HTN and UACR ≥30 mg/g. Improving uptake of ACEi/ARB therapy presents a substantial opportunity for prevention of cardiovascular disease and kidney disease progression for adults with HTN.

Increased Residual Cardiovascular Risk in US Veterans with Moderately Elevated Baseline Triglycerides, Well-Controlled LDL Cholesterol Levels on Statins, and Decreased Renal Function
Sarah Leatherman,1 Ryan E. Ferguson,1 Cynthia Hau,1 Craig B. Granowitz,2 Kelly M. Harrington,1 Sephy Philip,3 Peter P. Toth,3 Deepak L. Bhatt,2 William E. Boden.1 1VA Boston Healthcare System, Boston, MA; 2Amarin Corp, Bridgewater, NJ; 3Brigham and Women’s Hospital, Boston, MA.

Background: Recent studies have suggested a causal role for elevated triglycerides (TG) in incident cardiovascular (CV) events. Using a large cohort of U.S. veterans with statin-controlled LDL-C levels (40-100mg/dL), we explored whether increased residual CV risk existed in patients with elevated baseline TG levels versus those with normal TG levels in the subset who had reduced eGFR (<60 ml/min).

Methods: We identified veterans receiving a statin but not a TG-lowering agent from the VA Corporate Data Warehouse, a database of the VA electronic health record,
from 2010-2015. We compared CV event rates (nonfatal MI, stroke, unstable angina, or coronary revascularization) between the elevated TG (150-499 mg/dL) and normal TG (<150 mg/dL) groups. We calculated crude event rates, rate ratios, and 95% CI for both groups, and adjusted event rate ratios for age, sex, baseline blood pressure, glomerular filtration rate, and weight.

Results: We included 152,266 veterans (predominantly male and white) in the design of CDK and Subsequent Outcome Prediction in Community-Dwelling Individuals. Niall Cosgrave,1 John D. O’Connor,1 George S. Mellotte,1 Brenda Griffin,2 Conall M. O’Seaghdha,3 Scott Reule,2 Robert N. Foley,1 Silvin P. Knight,1 Mark A. Little,1,2 Donal J. Sexton,1,2 1University of Dublin Trinity College, Dublin, Ireland; 2Trinity Health Kidney Center, St James’s Hospital & Tallaght University Hospital, Dublin, Ireland; 3Beaumont Hospital, Dublin, Ireland; 4National Renal Office, Health Service Executive of Ireland, Dublin, Ireland; 5United States Renal Data System Coordinating Centre, Minneapolis, MN; 6Minnesota VA Health Care System, Minneapolis, MN; 7University of Minnesota System, Minneapolis, MN.

Background: Whether subtle abnormalities in cardiac function exist in community dwelling individuals and can be used toagnostically discern those with reduced kidney function and incident adverse outcomes over follow up is unknown.

Methods: The Irish Longitudinal Study on Ageing (TILDA) is a prospective nationally representative cohort study based on random sampling of the community-dwelling general population aged 50 years in Ireland. Wave 1 was performed between June 2009-June 2011. Participants underwent a detailed health assessment including blood tests, and an active stand test using the Finometer, which measures continuous blood pressure and heart rate for 10 mins while supine at rest, then throughout the standing test and for 2 mins thereafter. Cardiac function metrics are derived: left ventricular ejection time (LVET), cardiac output, and total peripheral resistance. CKD-EPI equation was used for eGFR. We analysed repeated measures data at 10 second intervals over the entire observation period using sequential neural networks with the categorical outcomes of coincident CKD, and incident mortality. Follow up was approximately 10 yrs. Python v 3.77 and TensorFlow v2.0.0 were used for the analysis.

Results: N=4388 TILDA participants were included. N=2013 were male, mean age was 62 (8) yrs, 647 died over follow up. Figure 1. A demonstrates profiles in LVET by eGFR category and A an ROC curve output from the Neural Network model predicting coincident CKD AUC = 0.81(resampled model: which included an input layer, 2 hidden layers and an output layer based on cardiac metrics, age and sex). AUC for mortality was 0.75 (resampled model).

Conclusions: Deep Learning analysis of repeated measures of derived cardiac function metrics discerned community dwelling individuals with CKD and subsequent outcomes. This method has potential for population level risk discrimination.

PO2069
Risk of Mortality, ESKD, and Hospitalization Among Medicare Beneficiaries with Pulmonary Hypertension and CKD
Sankar D. Navaneethan,1,3 Carl P. Walf ter,1 L. Parker Gregg,2 Wolfgang C. Winkelmayer,1 Vijay Namb i,1,3 Jingbo Niu.1,3 Baylor College of Medicine, Houston, TX; University of Texas Southwestern Medical Center at Dallas, Dallas, TX; Michael E DeBakey VA Medical Center, Houston, TX.

Background: Pulmonary hypertension (PH) is highly prevalent among patients with non-dialysis dependent CKD (~20%). We studied the risks of mortality, ESKD, cardiovascular (CV) and non-CV hospitalizations among those diagnosed with both PH and CKD.

Methods: Patients with PH (based on 2 claims within 2 years) were identified from a Medicare 5% sample (1995-2015). For each PH patient we randomly selected 5 persons diagnosed with the same CKD stage as the PH patient but without a PH diagnosis. We used Cox proportional hazards models to assess the association between PH and mortality, adjusting for age, sex, race, and comorbidities. We considered death as a competing event in Fine-Gray models to assess the association between PH and ESKD.

Results: We studied 41,478 patients with PH and CKD and 207,390 CKD stage-matched patients without diagnosed PH. Over 59% of the study population were >80 years, 12% were African American, 47% had diagnosed diabetes and 46% had COPD. The presence of diagnosed PH (vs. no PH diagnosis) was associated with increased risk of mortality, ESKD, and CV and non-CV hospitalizations at 1-, 3-, and 5-year follow-up (Table 1). Diabetes modified these associations with higher risk of all outcomes noted among those without diabetes.

Conclusions: Among older Medicare beneficiaries diagnosed with CKD, the presence of PH increased risk of mortality, ESKD, and hospitalization. Mechanistic understanding of these associations, especially the increased risk of ESKD, requires additional study.

Funding: NIDDK Support
Table 1. Associations of PH with mortality, ESKD, and cardiovascular and non-CV hospitalization in those with PH and CKD

PO2070
A Marginal Structural Model to Estimate Causal Effect of Time-Dependent Anemia Status on Renal and Cardiovascular Outcomes Among Community-Dwelling Japanese Subjects at Beginning of Impaired Renal Function
Satoshi Onozawa,1 Tomomi Kimura,2 Masataka Morita,1 Osamu Yamamoto,1 Tadao Akizawa.3,1 Astellas Pharma, Inc., Tokyo, Japan; 2Astellas Pharma, Inc., Northbrook, IL; 3Showa University School of Medicine, Tokyo, Japan.

Background: We investigated whether anemia increases the risk of renal and cardiovascular (CV) outcomes considering the changes of anemia status over time, using a marginal structural model.

Methods: We retrospectively analyzed data from a Japanese database (IMDC) consists of annual health checkup data linked to medical and pharmacy claims for over 3 million of beneficiaries. Subjects with consequent eGFR value of ≥60 and then <60 mL/min/1.73 m² within 2 years and during the period between 2008 and 2019 were included. The first date where the eGFR value became <60 was defined as the index date. Patients without serum creatinine (SCr) record within 38 months from the index date were excluded. Anemia status (yes/no) was defined by the age-sex specific hemoglobin value according to the Japanese guidelines. Renal outcomes (composite of ≥30% eGFR decline over 3 years, eGFR ≤15 mL/min/1.73m², SCr doubling, initiation of chronic dialysis and kidney transplantation), CV outcomes (myocardial infarction, stroke, unstable angina and heart failure) and mortality was assessed. In order to incorporate dynamic change of anemia status and covariates during the follow-up, a time-dependent standardized inverse probability weight at time x was estimated based on propensity score to either be or not be—anemia at time x. Weighted survival probability and weighted hazard ratio were estimated.

Results: 32,870 subjects were enrolled in the study cohort (median age 52, 73% male) and 4.2% of subjects had anemia at the baseline. Anemia treatment was rarely provided even in the anemia group (3.9%). During the average of 4.1-year of follow-up period, 210 renal outcomes and 1039 CV outcomes occurred. In 91% of the cases with the renal outcomes, eGFR decline occurred first. The weighted hazard ratios (95% confidence interval) for renal outcomes, CV outcomes and mortality were 2.6 (1.7-3.8), 1.6 (1.2-2.2), and 2.8 (1.8-4.3), respectively.
PO2071
Estimation of Sodium Consumption by Novel Formulas Derived from 12-Hour Urine Collection
Pitchaporn Sonuch, Surasak Kantachuesiri, Mahidol University Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand.

Background: 24-hour urine sodium excretion is the gold standard for estimating sodium intake. Several equations have been used to estimate 24-hour urine sodium excretion from spot urine samples. However, a validated formula for predicting 24-hour urine sodium excretion from 12-hour urine collection has not been established. This study aims to establish novel equations for predicting 24-hour urine sodium excretion from 12-hour urine collection and to also validate spot urine equations for predicting 24-hour urine sodium excretion.

Methods: 299 adults were recruited from hospital personnel. Participants were asked to perform a 12-hour daytime, nighttime, and a random spot urine collection in 1 day. Pearson correlation was used to compare measured 24-hour sodium excretion to the estimated values from three different methods. A multivariate linear regression analysis was performed to create novel equations. Bland-Altman method was used to estimate bias and agreement between the equations.

Results: The mean 24-hour urine sodium excretion was 4,055±1,712 mg/day (male 4,307±1,694 and female 3,882±1,710 mg/day, P=0.078). The 24-hour urine sodium excretion in non-healthcare workers was higher than in healthcare workers (4,442±1,865 and 3,617±1,406 mg/day respectively, P<0.001). Estimated urine sodium excretion from 3 different equations using spot urine samples showed moderate correlation with actual 24-hour urine sodium excretion (r=0.54, P=0.001 for Kawasaki; r=0.57, P=0.001 for Tanaka; r=0.66, P=0.001 for INTERSALT). Novel equations for predicting 24-hour urine sodium excretion was then developed using variables derived from 12-hour daytime urine collection, 12-hour nighttime urine collection, and random spot urine samples which showed strong correlation with actual measured values (r=0.88, P=0.001, r=0.83, P=0.001, r=0.67, P=0.001 respectively. Bland-Altman plots indicated good agreement between predicted values and actual 24-hour urine sodium excretion using the new equations, with biases for 12-hour daytime urine collection of ±0.28 mmol/day (95%CI: -0.59 to 0.53), for 12-hour nighttime urine collection of 0.85 mmol/day (95%CI: -4.86 to 6.56), and for random spot urine sample of 0.90 mmol/day (95%CI: -6.66 to 8.45).

Conclusions: The use of 12-hour urine collections can accurately predict 24-hour urine sodium excretion.

PO2072
Serum Magnesium, Blood Pressure, and Risk of Hypertension: Insights from the Chronic Renal Insufficiency Cohort (CRIC) Study
Simon Correa,1,2 Xavier E. Guerra Torres,3 Sushrut S. Waikar,4 Finninn R. McCausland,1,2 Brigham and Women’s Hospital, Boston, MA; 4Harvard Medical School, Boston, MA; 3Hospital Universitario Principe de Asturias, Alcalá de Henares, Spain; 2Boston Medical Center, Boston, MA.

Background: Magnesium (Mg) has been implicated in regulation of blood pressure (BP). Magnesium levels in serum Mg (sMg) are common in CKD and ESRD due to decreased intestinal absorption, impaired renal handling and diuretics use. Studies assessing the association of sMg and BP are scarce, and the association of sMg with the risk of developing hypertension (HTN) is unknown.

Methods: We analyzed data from 3,866 participants from CRIC. Adjusted linear regression models assessed the association of sMg with SBP and DBP at baseline and adjusted smoothing splines were fit. Adjusted logistic regression models explored the association of baseline sMg with baseline HTN (CRIC-defined HTN: SBP ≥140 or DBP ≥90 or anti-HTN drug use; AHA-defined HTN: SBP ≥130 or DBP ≥80 or anti-HTN drug use) and sub optimally controlled blood pressure (SBP ≥120 or DBP ≥80). Adjusted cox-proportional hazard models stratified by clinical site explored the association of baseline sMg with incident HTN. All models were adjusted for demographics, CV comorbidities, eGFR, proteinuria, serum albumin, GFR-23, calcium, phosphate, total PTH, Na, K, urine Na, and urine K.

Results: Median sMg was 2.0 mEq/L (25%-75th percentile 1.9 to 2.1 mEq/L). Higher sMg at baseline was associated with lower SBP (β=-2.63 mmHg, 95% CI -5.01 to -0.25, per 1 mEq/L) and lower DBP (β=-2.75 mmHg, 95% CI -4.16 to -1.34, per 1 mEq/L) (Fig 1A, 1B). Higher sMg was associated with a lower risk of AHA-defined HTN at baseline (aOR 0.25, 95% CI 0.12-0.55, per 1 mEq/L), a lower risk of sub optimally controlled BP (aOR 0.22, 95% CI 0.10-0.53, per 1 mEq/L) but not with a higher risk of CRIC-defined HTN (aOR 0.77, 95% CI 0.50-1.26, per 1 mEq/L). In time-to-event analyses, higher baseline sMg was associated with a numerically lower risk of incident CRIC-defined HTN (aHR 0.68, 95% CI 0.40-1.13, per 1 mEq/L).

Conclusions: Higher sMg is associated with lower SBP, lower DBP and a nominally lower risk of incident HTN. Monitoring and optimal control of sMg should be considered in patients with CKD for improved BP control.

PO2073
Cardiac Structure and Function and Long-Term Risk of ESKD in African Americans: The Atherosclerosis Risk in Communities (ARIC) Study
Manabu Hishida,1,2 Junichi Ishigami,1 Lena Mathews,1 Morgan Grams,1 Josef Core,1 Scott D. Solomon,1 Kunihiro Matsushita,1 Welch Center Johns Hopkins University, Baltimore, MD; 2Nagoya Daigaku Daigakuin Igakucei Kenkyukai Igakubu, Nagoya, Japan; 3Brigham and Women’s Hospital, Boston, MA.

Background: Cardiovascular disease and end-stage kidney disease (ESKD) disproportionally affect African Americans. Whether cardiac structure and function is associated with the risk of ESKD in this population is not well-characterized.

Methods: In 1,929 African American ARIC participants who underwent echocardiography between 1993-1995 (mean age 58.5 [SD 5.6] years, 36% male), we explored the association of left ventricular mass index (LVMI), fraction shortening (FS), left atrial diameter (LAD), and LV end-diastolic diameter (LVEDD) with the subsequent risk of ESKD using Kaplan-Meier method and multivariable Cox models.

Results: During a median follow-up of 22.3 years, 82 participants developed ESKD (incidence rate 3.0 per 1,000 person-years). The cumulative incidence of ESKD was highest in the top quartile (bottom quartile for FS) of all echo parameters (Figure), although the risk separation was most evident for LVMI. The association of LVMI with ESKD remained significant even after accounting for potential confounders like blood pressure and clinical history of cardiovascular disease (HR, 2.46 [1.13-5.38] in the top vs. bottom quartile). FS, LAD, or LVEDD were not independently associated with ESKD.

Conclusions: Among African Americans, higher LVMI was robustly and independently associated with the risk of ESKD. Our findings support the importance of LVMI or its pathophysiology in CKD progression in African Americans.

Myeloperoxidase and the Risk of Atrial Fibrillation in the Chronic Renal Insufficiency Cohort (CRIC) Study
Katherine Curtis,1,2 Simon Correa,1,2 Sushrut S. Waikar,3 Finninn R. McCausland,1,2 Me Causland Lab 1Brigham and Women’s Hospital, Boston, MA; 3Harvard Medical School, Boston, MA; 1Boston Medical Center, Boston, MA.

Background: Myeloperoxidase (MPO) catalyzes the formation of reactive oxygen intermediates and is associated with adverse CV outcomes and progression of chronic kidney disease (CKD). We wished to determine the association of MPO with hospitalization for atrial fibrillation (AFib) in patients with baseline CKD.

Methods: We evaluated 3,872 participants with MPO measured at baseline in the CRIC Study, a large prospective multicenter cohort of non-diagnosis dependent CKD. The association of MPO with hospitalization due to AFib was evaluated through adjusted Cox proportional hazard models in all study participants, and separately in subjects with and without AFib at baseline. Models were adjusted for age, sex, race, DM, SBP, coronary artery disease, CHF, eGFR (CKD-EPI), proteinuria, ACEi-ARB, beta-blocker and diuretic use.

Conclusions: Among African Americans, higher LVMI was robustly and independently associated with the risk of ESKD. Our findings support the importance of LVMI or its pathophysiology in CKD progression in African Americans.
PO2076
Temporal Trends of the Burden of CKD Among Hospitalized Aortic Stenosis Patients in the Province of Quebec, Canada
Nada Khelifi, 1 Denis Hamel, 2 Sonia Jean, 2,3 Claudia Blais, 2,4 Fabrice Mac- Way, 1 CHU de Quebec Research Center, Faculty of Medicine, Université Laval, Québec, QC, Canada; 2 Institut national de santé publique du Québec, Québec, QC, Canada; 3 Faculty of Medicine, Université Laval, Québec, QC, Canada.

Background: Aortic stenosis (AS) is associated with valvular calcifications which are highly prevalent in chronic kidney disease (CKD). The aim of this study was to describe the temporal trends of comorbid CKD status in patients hospitalized for AS and evaluate the impact of these two conditions on 1-year mortality in the province of Quebec, between 2000 and 2017.

Methods: Using the Quebec Integrated Chronic Disease Surveillance System, we identified patients a 20 years with incident AS using ICD-9 and ICD-10 codes, in the hospital discharge database. We then combined hospital discharges and physician billing claims databases to identify patients with comorbid CKD status in the two years prior to the AS diagnosis. Three subgroups of CKD status were considered: 1) non-CKD, 2) pre-dialysis and 3) dialysis. To allow comparison over time, direct adjustment using age distribution of the 2016-2017 AS population was used for proportion, 1-year all-cause and cardiovascular mortality.

Results: We included 108,780 patients with incident AS (Women: 51.8%; mean age (aSD): 76.4 ±11.7; non-CKD: 74.2% (n=80,768); pre-dialysis: 24.6% (n=26,809); dialysis: 1.1% (n=1,203)). During the study period, the age-adjusted proportion of AS patients with non-CKD comorbid status decreased by 14% (80.7% [95% CI 77.6-84.0] to 69.6% [95% CI 67.2-71.9]). Inversely, the age-adjusted proportion of AS patients with pre-dialysis and dialysis comorbid status increased by 58% (18.5% [95% CI 16.9-20.2] to 29.3% [95% CI 27.8-30.9]) and 46% (0.7% [95% CI 0.5-1.1] to 1.1% [95% CI 0.8-1.4]), respectively. Age-adjusted 1-year all-cause and cardiovascular mortality decreased over time but remained higher in patients with comorbid CKD. In 2015-2016, age-adjusted relative risk (RR) of 1-year all-cause mortality was significantly higher in pre-dialysis (RR=1.56 [95% CI 1.44, 1.69]) and dialysis (RR=2.04 [95% CI 1.62-2.61]) compared to non-CKD patients. Age-adjusted RR of 1-year cardiovascular mortality was also significantly higher in pre-dialysis (RR=1.83 [95% CI 1.66-2.03]) and dialysis (RR=2.28 [95% CI 1.68-3.09]) compared to non-CKD patients.

Conclusions: Proportion of patients with incident AS and comorbid CKD increased from 2000 to 2017. One-year all-cause and cardiovascular mortality improved over time but remained higher in AS patients with comorbid CKD.

PO2077
The Association Between Pre-Donation Hypertension and Early Post-Donation Systolic Blood Pressure Among Older Living Kidney Donors
Fawaz Al Ammary, Abimereki Muzzaalic, Daniel C. Brennan, Dorry L. Segev, Allan Massie. Johns Hopkins University School of Medicine, Baltimore, MD.

Background: One mechanism underlying pre donation hypertension in older (age≥50) living kidney donors is a reduced number of nephrons. The 50% nephron mass reduction associated with donor nephrectomy may exacerbate predonation, controlled hypertension. In light of evolving hypertension guidelines, we aimed to study systolic blood pressure (BP) trajectory in older donors with- vs. without hypertension.

Methods: We conducted a national registry study of 11,969 older living kidney donors from 2010-2018. We modeled the association between pre donation hypertension and postdonation systolic BP using a mixed linear model with donor-level random intercept adjusting for age, sex, race, predonation systolic BP, BMI, and year of donation. We modeled odds of having 6-month postdonation systolic BP >130 mmHg and >140 mmHg using multivariable logistic regression.

Results: 1,161 of 11,969 older donors (9.7%) had hypertension. Median (IQR) predonation systolic BP was 130 mmHg (122-140) among donors with hypertension vs. 124 mmHg (115-132) among those without (p<0.001). After adjustment for baseline characteristics including predonation systolic BP, hypertension was associated with a 2.4 ± mmHg increase in postdonation systolic BP (p<0.001). Hypertension was associated with 39% higher odds of having 6-month postdonation systolic BP >130 mmHg (OR=1.39, p<0.001) and 50% higher odds of having 6-month postdonation systolic BP >140 mmHg (OR=1.50, p<0.001).

Conclusions: Pre donation hypertension was associated with higher risk of uncontrolled 6-month postdonation systolic BP among older donors, even after adjusting for pre donation systolic BP. Our findings call for programs to monitor postdonation systolic BP in donors with hypertension to ensure adequate BP control following nephrectomy.

Troponin Level in Relation to Angiographic Coronary Artery Disease in CKD Patients
Sachin Butra, 1 Bhavin Chokshi, 1 Balaram Krishna J. Hanumanthu, 2 Belinda Jim, 1 Jacobi Medical Center, Bronx, NY; 2 Mount Sinai Beth Israel Hospital, New York, NY; 3 Wayne State University School of Medicine, Detroit, MI; 4 James J Peters VA Medical Center, Bronx, NY.

Background: An association between cardiac troponin I (cTNI) in the diagnosis of angiographic coronary artery disease(CAD) is unclear in the CKD population. We evaluated the association between cTNI to findings of angiographic significant CAD in CKD patients with traditional risk factors.

Methods: Data was collected from left cardiac catheterizations (LCCHs) performed between 2000-2017 at Jacobi Medical Center. CAD outcomes were defined as: none, mild (<50% stenosis), moderate (50-69% stenosis), severe (≥70% stenosis of any major epicardial artery). ROC characteristics of cTNI as biomarker for severe CAD was performed in patients with CKD stages 3-5. C-Statistic/AUC were used to compare pretest probabilities for severe CAD based on CAD risk factors (age, race, HTN, HLD, DM, smoking), abnormalities on ECHO and ECG, cTNI level, and CKD stage.

Results: 798 LCCHs were included. Figla shows that cTNI level is only significantly higher in severe CAD as compared to no CAD among CKD 1-2 patients. ROC showed cTNI=0.7 ng/mL displayed peak sensitivity (59%), specificity (62%). Multivariate analysis for predictors of severe CAD among 223 CKD patients was stratified by cTNI>0.3 and cTNI<0.3. Among cTNI<0.3 subgroup, age=63 (OR 4.6; 95% CI 1.49-12.79, p=0.012) and eGFR<30 (OR 2.92; 95% CI 0.94-9.00; p=0.06) were associated with severe CAD. Among cTNI>0.3 subgroup, none of the clinical factors were significantly associated with severe CAD. Figb shows that the addition of dichotomized cTNI > or = 0.3 to CAD risk factors did not significantly change the AUC value.

Conclusions: cTNI levels are not associated with different levels of CAD in patients with eGFR<60. The addition of cTNI>0.3 does not alter the predictive value of severe CAD when other cardiac risk factors are considered. It will be important to study if the change in cTNI during a cardiac event would be more predictive in the CKD population.
PO2078
Pediatric vs. Adult Ambulatory Blood Pressure Monitoring (ABPM) Criteria for the Diagnosis of Hypertension (HTN) and Detection of Left Ventricular Hypertrophy (LVH) in Adolescents

Kornell Merchant1, Paras P. Shah,2 Paula Singer,2 Laura J. Castellanos,1 Christine B. Settina,2,3 Cohen Children’s Medical Center, Queens, NY; Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.

Background: Normative values for clinic blood pressure (BP) measurements in adolescents were recently updated to align with adult HTN guidelines (CPG 2017). However, the most widely accepted pediatric normative values used to diagnose HTN by ABPM criteria have not been updated. The objective of this study was to compare pediatric ABPM criteria (pHTN) vs. adult ABPM criteria (aHTN) for the diagnosis of HTN and detection of LVH in adolescents. Methods: ABPM and ECHO reports from adolescents aged 13-21 years performed from 2015-2019 at a single center were analyzed. The concordance of HTN diagnosis based on pHTN (AHA 2014) was compared to aHTN from ACC/AHA 2017 (overall BP ≥125/75mmHg, wake BP ≥130/80mmHg, sleep BP ≥110/65mmHg) using Cohen’s kappa statistic. Logistic regression adjusted for body mass index (BMI) z-score and receiver operating curves (ROC) were used to compare the ability of pHTN vs. aHTN to detect LVH (left ventricular mass index [LVMI] >95th percentile reference values and LVMI >51g/m²). Results: Of 306 adolescents (15.9±1.86 years, 73.5% male), 140 (45.8%) had HTN based on pHTN compared to 228 (74.5%) based on aHTN. There was poor agreement in the diagnosis of HTN between pHTN and aHTN (95.3%, kappa 0.41). 1.0% (N=3) had HTN by pHTN only while 29.7% (N=91) had HTN by aHTN only. Although a higher prevalence of LVH was captured by aHTN only, 9.5% (6.6%) adolescents who had LVH >95th% did not have HTN by either criteria. In logistic regression, adjusted for BMI z-score, there were no significant differences between pHTN and aHTN in the detection of LVH >95th% (OR 1.24, CI 0.66-2.31, p=0.45) or >51g/m² (OR 1.06, CI 0.47-2.40, p=0.89). ROCs for pHTN were not significant for detecting LVH >95th% (0.50, p=0.91) or >51g/m² (0.55, p=0.45). However, the ROC for aHTN was significant for detecting LVH >95th% (0.59, p=0.045) but not >51g/m² (0.63, p=0.07). Conclusion: Pediatric ABPM criteria (pHTN) are less sensitive than adult ABPM criteria (aHTN) for the diagnosis of HTN in adolescents. aHTN appears to better predict LVH than pHTN, although neither criteria diagnosed all patients who had LVH. A consideration to align the ABPM criteria for the diagnosis of HTN in adolescents with adult guidelines is warranted.

PO2079
Effect of Psychiatric Diagnosis and Selective Serotonin Reuptake Inhibitors (SSRIs)/Serotonin Norepinephrine Reuptake Inhibitors (SNRIs) Use on BP Using 24-Hour Ambulatory Blood Pressure Monitoring (ABPM)

Nabeel A. Aslam1,2 Shohat H. Memon, Hani Wadi, Shehzad K. Niazi. Mayo Clinic, Jacksonville, FL.

Background: Hypertension (HTN) and psychiatric disorders frequently coexist. Psychiatric conditions and their treatment by SSRI/SNRIs affect serotonin & norepinephrine and may cause variation in blood pressure (BP). There is limited data to assess this variation by using ABPM. Methods: Subjects who underwent psychiatric evaluation & ABPM within six month of each other between 1/2012 to 12/2017 were identified. Demographics, comorbidities, medications, ABPM, lab data were retrospectively collected. Subjects were divided into group-subjects with no psychiatric diagnosis & no psychiatric medicine(Group 1), subjects with psychiatric diagnosis & on no medication(Group 2) and subjects with psychiatric diagnosis & on SSRI/SNRIs(Group 3). BP systolic & diastolic levels (daytime, nighttime) were compared between groups controlling for age, sex, race, HTN, DM and smoking. Single and multivariable linear regression models were used to analyze group differences.

Results: Of 475 subjects met inclusion criteria-Group 1=135, Group2=232, and Group3=108. First, Group 1 was compared with Group 2 for daytime systolic & diastolic, nighttime systolic & diastolic BP. In multivariable analysis adjusted for age, sex, race, HTN, DM, and smoking, subjects in Group 2 had higher nighttime systolic BP (122.7±110.5 mmHg; 8.36; 95%CI 4.21, 12.51;P<0.0001) and nighttime diastolic BP (68.2±63.4 mmHg; 4.6; 95%CI 2.7, 7.9;P<0.001) compared to Group 1. In adjusted model, there was no statistically significant difference between Group 1 & 3 for daytime systolic & diastolic BP suggesting higher nighttime BP in Group 2 was associated with SSRI/SNRIs use. Conclusions: In this single center retrospective study, use of SSRI/SNRIs was associated with significantly higher nocturnal systolic & diastolic BP among subjects with psychiatric disorders using ABPM criteria. This may be due to ongoing sympathetic activation during sleep with serotonin & norepinephrine with SSRI/SNRIs use. Further prospective studies using ABPM are needed to determine the risk of nocturnal hypertension with SSRI/SNRIs use that could adversely impact cardiovascular outcomes.

PO2080
Obesity-Related Renal Damage in Adolescent Women: Body Surface Area Matters
Dana Bielopolski1, Neha Singh1, Caroline S. Jiang1, Robert B. Macarthur1, Kimberly S. Vasquez1, Dena S. Mofth1, Rhonda Kost1, Jonathan N. Tobin1,2,3 The Rockefeller University, New York, NY; Clinical Directors Network Inc., New York, NY.

Background: Obesity is a potentially modifiable risk factor for the development and progression of kidney disease. In adults, obesity is strongly associated with increased kidney disease. However, the most widely accepted pediatric normative values used to diagnose HTN by ABPM criteria have not been updated. The objective of this study was to compare pediatric ABPM criteria (pHTN) vs. adult ABPM criteria (aHTN) for the diagnosis of HTN between pHTN and aHTN for the diagnosis of HTN in adolescents. aHTN appears to better predict LVH than pHTN, although neither criteria diagnosed all patients who had LVH. A consideration to align the ABPM criteria for the diagnosis of HTN in adolescents with adult guidelines is warranted.

Urinary Magnesium Predicts Risk of Cardiovascular Disease in Pre-Dialysis CKD Patients
Qiongqiong Yuan1, Hui Xu1, Jinwei Wang2, on behalf of the C-STRIDE study group; Yangguang Hospital Central South University, Changsha, China; 3Peking University First Hospital, Beijing, China.

Background: 24h Urinary magnesium concentration (24h UMG), an indicator of intestinal magnesium absorption, may provide a better insight in the connection of CKD progression.

Methods: We examined 3179 participants aged 18 to 74 years pre-dialysis patients in the Chinese Cohort Study of Chronic Kidney Disease (C-STRIDE) study. We performed a time-to-event analysis of the data using Kaplan-Meier Survival model, Cox proportional hazard and competing risks Fine and Gray subdistribution hazard models.

Results: During the median follow-up of 4.19 (IQR 3.42-5.09) years, lower incidence rate of ESRD events was observed with increases in 24h UMG (Figure 1). Higher incidence rate of CVD events was seen with increase in 24 h UMG (Figure 2). After adjustment for demographic and traditional ESRD risk factors, 24h UMG was strongly associated with risk of CVD (HR of 1.509 [95% CI 1.031-2.208](Table 1).

Conclusions: 24h UMG risk variants display a modest association with CVD in pre-dialysis CKD patients.

**Left Atrial Strain Measurements Are Associated with Cardiovascular Outcomes in Patients with ESRD**

Ruth F. Dubin,1 Amrita S. Ayer,2 Catherine L. Donovan,1 Lauren Nelson,3 Sanjiv Shah.4 University of California San Francisco, San Francisco, CA; 2University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; 3Northwestern University Feinberg School of Medicine, Chicago, IL.

**Background:** Left atrial (LA) strain is a marker of diastolic dysfunction, heart failure and atrial fibrillation that has been validated in populations without chronic kidney disease. There are few studies of LA strain in patients with end-stage renal disease (ESRD), among whom cardiovascular (CV) mortality is high and there are no accepted methods of CV risk stratification. We sought to examine associations of LA reservoir strain with CV hospitalization and mortality in a cohort of patients with ESRD on dialysis, and to investigate prognostic utility of strain measurements for CV outcomes.

**Methods:** 190 ambulatory participants with ESRD on dialysis in the Cardiac Endothelial Function and Arterial Stiffness in ESRD (CERES) study underwent 2D echocardiography at one study visit. The composite outcome, CV hospitalization or death, was adjudicated over a median of 2 years. Hospitalizations attributed to missing dialysis were not counted as events. LA and left ventricular (LV) structure and function were captured by a single technician, and de-identified images were read by a single reader using GE EchoPac software. Associations of LA reservoir strain with the composite outcome were analyzed with Cox survival analyses, adjusting for age, gender, comorbidities, and systolic blood pressure.

**Results:** Mean age was 56 years, 1/3 were women, and the median time since dialysis initiation was 3.5 years. 45% were diabetic and 14% had a history of heart failure. Participants were relatively euvolemic, based on well-controlled blood pressure and weight. Mean (SD) LA volume index was 40ml/m²(±12), mean LA reservoir strain was 24%±(6.9). There were 61 events: 40 hospitalizations and 21 deaths. In the adjusted model, HR (95%CI) per SD LA volume index was 1.4(1.04, 1.9); LA reservoir strain HR (95%CI) per SD was 0.67(0.47, 0.94). A risk model including age, LA reservoir strain and LV global longitudinal strain had a c-statistic(95%CI) of 0.72(0.63, 0.81) for the composite outcome.

**Conclusions:** Our results suggest that LA strain is independently associated with CV hospitalizations and deaths among patients with ESRD on dialysis. Strain measurements have the potential to contribute to CV risk stratification in this population. Larger studies are necessary to validate our findings.

**Under Diagnosis of Pediatric Hypertension**

Anoosh Moin, Craig B. Langman. Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL.

**Background:** Pediatric hypertension is associated with target organ damage in children and cardiovascular morbidity in adults. Therefore, prompt diagnosis and treatment are critical. Application of clinical practice guidelines is inconsistent.

**Methods:** Using electronic health record data (from 8 community centers), we evaluated the proportion of children (3-18 years) with elevated blood pressures (≥90th percentile) who were appropriately diagnosed as either hypertension or elevated blood pressure over 1 year (2016-17), and provided guideline directed follow-up; by age, sex, race/ethnicity and weight.

**Results:** The sample included 6233 children with elevated blood pressure, 15% were appropriately diagnosed. These children were more likely to be older, white, and obese. 55 children met criteria for hypertension with 23 being appropriately diagnosed, there was no difference by patient characteristics. Of children with blood pressure ≥95th percentile, 13% had follow-up within 1 month; they were more likely to be older, female, of Hispanic ethnicity or ‘other’ race. Of children with blood pressure ≥90th percentile, 41% had follow-up within 6 months, and were more likely to be older, of either white, Hispanic, Asian race or Hispanic ethnicity.

**Conclusions:** We found persistent under-diagnosis of pediatric hypertension and elevated blood pressure as well as disparities in the diagnosis of elevated blood pressure and guideline-directed follow-up among diverse children in a community setting. New strategies are needed to improve compliance with guidelines.

Associations of Blood Pressure Variability with Cardiovascular Events, Death, and ESKD in Patients with CKD
L. Parker Gregge,1,2 Susan Hedayati,1 Hui Yang,1,2 Peter N. Van Buren,1,2 Sankar D. Navaneethan,2,4 Salim S. Virani,1,2 Wolfgang C. Winkelmayer,1 Carlos A. Alvarez,3,4 University of Texas Southwestern Medical Center at Dallas, Dallas, TX; 2VA North Texas Health Care System, Dallas, TX; 3Baylor College of Medicine, Houston, TX; 4Michael E DeBakey VA Medical Center, Houston, TX; 5Texas Tech University Health Sciences Center School of Pharmacy, Dallas, TX, US, TX, TX.

Background: Visit-to-visit blood pressure variability (BPV) is associated with cardiovascular (CV) events in individuals with chronic kidney disease (CKD) stages 3-5. We examined the associations of BPV with CV events, death, and end-stage kidney disease (ESKD) among veterans with CKD stages 1-5 and hypertension, and if treatment with a thiazide or loop diuretic modified these associations.

Methods: In a matched cohort study, patients seen between 2010-2016 with non-dialysis CKD and hypertension on single-agent therapy with a non-diuretic were propensity matched 1:1 for initiation of a loop or thiazide diuretic vs. other antihypertensive class as their second agent. BPV, defined as the coefficient of variation of outpatient systolic blood pressure over 6 months after prescription of the second antihypertensive, was divided into quintiles. Cox proportional hazards regression measured associations of BPV with time to CV events (first among myocardial infarction [MI], hospitalization for heart failure, or ischemic stroke), each component of the primary outcome, all-cause death, and ESKD.

Results: We included 31,394 new users of diuretics and 31,394 patients initiating other agents. Over a median (IQR) follow up time of 939 (404-1,606) days, there were 7,326 CV events, 16,567 deaths, and 2,029 ESKD events. Higher BPV was associated with composite CV events (Figure). Diuretic exposure attenuated these associations at the fourth and fifth quintiles of BPV (interaction P<0.03 at the 4th and .04 at the 5th quintile). BPV was also associated with MI, heart failure, stroke, and death, but not with ESKD (Figure). Diuretic treatment did not modify these associations.

Conclusions: BPV was associated with CV events and all-cause death but not ESKD in patients with CKD and hypertension. Diuretic use attenuated the association of BPV with CV events at the highest quintiles of BPV. Future studies should test whether diuretics improve CV outcomes in those with high BPV.

Importance of Continuous Blood Pressure Monitoring in CKD
Andreea G. Andronesi,1,2 Cristina Cristache,1 Bogdan Obrisa,1,2 Bogdan M. Sorohan,1,2 Roxana A. Jurubita,1,2 Danut Andronesi,1 Gabriela Lupusoru,1,2 Mircea Lupusoru,1 Gener Ismail,1,2 Fundeni Clinical Institute, Bucharest, Romania; 3Carol Davila University of Medicine and Pharmacy, Nephrology Department, Bucharest, Romania; 4Carol Davila University of Medicine and Pharmacy, Physiology Department, Bucharest, Romania.

Background: A strong relationship exists between CKD and high blood pressure (BP), tight BP control is essential for delaying CKD progression and improving cardiovascular outcome. Automated blood pressure monitoring (ABPM) is associated with hypertension-related target-organ damage and cardiovascular outcomes compared with office-based BP in general population.

Methods: We performed a prospective study in CKD. Heart ultrasound and ABPM were performed at inclusion. Normative values for ABPM were defined according to AHA recommendation from 2019. Medical data were recorded for at least one year or until death. The aim was to analyze the correlation between ABPM and left ventricular (LV) changes and cardiovascular outcome.

Results: We included 339 pts (171F, mean age 60.1±14): 15.9% stage 1/2, 31.8% stage 3, 19.7% stage 4. 66 were in HD, 24 in PD. Prevalence of increased BP readings was higher in advanced CKD- 21.5% in stage 1/2, 56.7% in stage 5. Mean diastolic load was higher in LV hypertrophy (35.6±29 vs 19.7±19.6 mmHg, p<0.05). We found a negative correlation between mean arterial pressure (MAP) and GFR (r=-0.457, p<0.05). MAP was higher in PD compared to HD (109.1 ± 17.6 vs 98.9±3.3 mmHg, p<0.01). Serum albumin had a weak negative correlation (r=0.245, p<0.01) and fibrinogen a weak positive correlation (r=0.266, p=0.02) with mean systolic BP, and mean LDL-cholesterol (as an indirect marker of malnutrition) was lower in non-dipper (95.4±5.4 vs. 130.5±27.2 mg/dl, p<0.05), suggesting a negative influence on BP control of malnutrition and inflammation. 225 (72.8%) were non-dipper, with 56 being extreme non-dipper. Analysis (OR 4.5, p<0.001) and creatinine protein >10 mg/l (OR 3.7, p<0.001) induced a higher risk of non-dipper profile. We had 78 cardiovascular deaths (23.0%). Independent predictive factors for cardiovascular death were male gender, calcium x phosphate>55 mg/dl and extreme non-dipper.

Conclusions: This study demonstrates an increased prevalence of high BP readings and non-dipper profile especially in advanced CKD. Malnutrition and inflammation were associated with non-dipper pattern and extreme non-dipper was an independent risk factor for cardiovascular death. ABPM monitoring may be useful in optimizing BP control and improving cardiovascular outcome in CKD.
abnormalities. Left ventricular mass index (LVMi), relative wall thickness (RWT) and left ventricular ejection fraction were normal. Left ventricle was dilated in 1 patient. Obesity, dsDNA, proteinuria, use of steroids and antihypertensives did not differ significantly between the patients with and without BP abnormalities.

Conclusions: Masked HTN and blunted nocturnal dipping is common in adolescents with SLE and can be missed if ABPM is not applied in clinical practice. Additional studies are required to find risk factors and management strategy.

Results: A Pediatric Case Series

Methods: We report 2 adolescent cases of hypertension diagnosed by clinic BP and target organ damage but not confirmed by ABPM. Both patients had EST done as part of their evaluation because they were first seen by cardiologists at the study center who frequently employ EST as part of evaluation for hypertension. The cut-off value of 180mmHg for EESP was employed in this report as a previous study had identified 181 mmHg as the most discriminatory systolic BP threshold for predicting hypertension at follow-up. The discrepant results between the ABPM and EST BP in our patients with target organ damage may indicate that multiple diagnostic tools may be required to confirm the diagnosis of hypertension. Both tests could be viewed as complimentary as ABPM is not recommended during exercise which is a part of everyday life. Furthermore, a normal ABPM may not exclude a diagnosis of hypertension in patients with elevated clinic BP and target organ damage. Further studies are needed to confirm these findings in a larger population, and to better understand how these 2 tests may perhaps be used adjunctively to diagnose hypertension.

Case Description: See table below.

Discussion: We describe 2 adolescent cases of hypertension diagnosed by clinic BP and target organ damage but not confirmed by ABPM. Both patients had EST done as part of their evaluation because they were first seen by cardiologists at the study center who frequently employ EST as part of evaluation for hypertension. The cut-off value of 180mmHg for EESP was employed in this report as a previous study had identified 181 mmHg as the most discriminatory systolic BP threshold for predicting hypertension at follow-up. The discrepant results between the ABPM and EST BP in our patients with target organ damage may indicate that multiple diagnostic tools may be required to confirm the diagnosis of hypertension. Both tests could be viewed as complimentary as ABPM is not recommended during exercise which is a part of everyday life. Furthermore, a normal ABPM may not exclude a diagnosis of hypertension in patients with elevated clinic BP and target organ damage. Further studies are needed to confirm these findings in a larger population, and to better understand how these 2 tests may perhaps be used adjunctively to diagnose hypertension.

PO2089

Individualized Hypertension Management in CKD

Yossi Chai,1 Brian H. Nathanson,1 Barbara A. Greco,2 Michael J. Germain.2

1University of Massachusetts Amherst, Amherst, MA; 2Renal and Transplant Associates of New England, Springfield, MA; 3OpiStatim, LLC, Longmeadow, MA.

Background: The prevalence of hypertension (HTN) in chronic kidney disease (CKD) patients ranges from 60% to 90% with up to 50% having drug resistant hypertension.

Methods: We instituted a practice improvement project comparing hypertension Standard Care (Group B) to an Individualized Protocol (Group A) in non-dialysis CKD patients referred to our nephrology practice. The Individualized Protocol used noninvasive impedance cardiography (NICAS) and central arterial pressure waveform (SphygmoCor) to define the hemodynamic state: vasostenotonic, hyperdynamic, or mixed. Recommendations for pharmacologic interventions were guided by the hemodynamic state, however, choice of specific drugs was left to the nephrologist. Group A nephrologists were trained to use the Individualized Protocol, and hypertensive patients were assigned to groups A or B during an initial 6-month period, then followed for 6 months (endpoint).

Results: There were 90 and 21 patients in groups A and B, respectively. At baseline, demographics were similar in both groups (Table 1). At endpoint, Group A had more patients at targeted blood pressure (BP) (55.6% vs 33.4% at 140/90 mmHg; 21.1% vs 19% at 130/80 mmHg), and larger reduction in both brachial and central BP parameters (Table 2). The mean (SD) of number of office visits were 3.1(1.0) and 2.9(1.1), in Groups A and B, respectively. In Group A, mean aorta compliance was increased 23.3% and 1.7% in the subgroups that met and did not meet target BP, respectively. Mean number of medications at baseline/endpoint were 1.7/2.6 and 1.9/2.0 in groups A and B, respectively. At endpoint, Group B had negligible change in distribution of drug classes, while Group A had significant increased use of calcium channel blockers (dihydropyridine) and beta-blockers.

Conclusions: Impedance cardiography is a simple, noninvasive method for evaluating underlying hemodynamic drivers of HTN. Hypertension management is more effective when guided by hemodynamic state.

Associations of Diuretic Use with Cardiovascular Events and All-Cause Mortality in the Systolic BP Intervention Trial (SPRINT)

Shubhrajit Banerjee,1 Lincheng Shen,1 Guo Wei,1 Robert E. Boucher,2 Glenn M. Chertow,1 Paul K. Whelton,2 Alfred K. Cheung,3 Srinivasan Beddhu.3

1SPRINT Consortium 2Stanford University School of Medicine, Stanford, CA; 3Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; 4The University of Utah School of Medicine, Salt Lake City, UT; 5The University of Texas Health Science Center at San Antonio Joe R and Teresa Lozano Long School of Medicine, San Antonio, TX.

Background: It has been suggested that the beneficial effects of intensive compared to standard treatment of systolic BP (SBP) on the primary outcome of cardiovascular events (CVE) and all-cause mortality (ACM) in the SPRINT were due to increased diuretics use in the intensive arm.

Methods: In a post hoc analysis of SPRINT, we used time-dependent Cox analyses to examine if adjusting for diuretic use during follow-up attenuated the effects of intensive treatment on CVE and ACM. We also examined the interactions of diuretic use with the SBP interventions to assess the presence of effect modification.

Results: Figure 1 shows the percentage of intensive and standard treatment participants on diuretics over time. Intensive treatment resulted in lower CVE (HR 0.76,
Participants on diuretics over time.

PO2093
The Influence of Baseline Diastolic Blood Pressure on the Effects of Blood Pressure Lowering on Death and ESKD Outcome

Olesya Ilkun,1 Guo Wei,2,3 Robert E. Boucher,1 Srinivasan Beddhu,1,3 1Division of Nephrology & Hypertension, University of Utah School of Medicine, Salt Lake City, UT; 2Division of Biostatistics, University of Utah School of Medicine, Salt Lake City, UT; 3Medical Service, Veterans Affairs Salt Lake City Health Care System, Salt Lake City, UT.

Background: Intensive systolic blood pressure (SBP) lowering decreased the risk of death in SPRINT. However, there are concerns in those with low baseline diastolic blood pressure (DBP) that intensive BP lowering might adversely affect kidney perfusion and increase the risk for death/ESKD.

Methods: The African-American Study of Kidney Disease and Hypertension (AASK) trial examined the effects of two different BP goals (mean arterial pressure [MAP] < 92 vs <102-109) in African American men and women (N =1094) with kidney disease but no diabetes. We investigated whether the effects of BP intervention on the risk of death/ESKD was modified by baseline DBP.

Results: Mean baseline age was 55±11 yrs and DBP 95±14 mmHg. There were 264 death/ESKD events over 4714 years of follow-up. Compared to usual BP control, low BP goal resulted in lower levels of follow-up SBP, MAP and DBP across baseline DBP tertiles (Fig 1). Despite the lower follow-up MAP and DBP values, there was no evidence that low BP goal increased the risk of death/ESKD in those with low baseline DBP (Fig 2). Interaction of baseline DBP and BP intervention for death/ESKD was not significant (p = 0.22).

Conclusions: The effect of BP lowering on the risk of death/ESKD was not modified by low baseline DBP. Hence, low baseline DBP by itself should not be an impediment for intensive BP lowering in CKD.

Abstract Withdrawn

PO2092
The Influence of Baseline Diastolic Blood Pressure on the Effects of Intensive Blood Pressure Lowering on Incident Strokes in the SPS3 Trial

Robert E. Boucher,1 Guo Wei,1,2 Olesya Ilkun, Srinivasan Beddhu,1,3 1Division of Nephrology & Hypertension, University of Utah School of Medicine, Salt Lake City, UT; 2Division of Biostatistics, University of Utah School of Medicine, Salt Lake City, UT; 3Medical Service, Veterans Affairs Salt Lake City Health Care System, Salt Lake City, UT.

Background: In persons with low baseline diastolic blood pressure (DBP) and previous stroke, intensive systolic blood pressure (SBP) lowering might by decreasing cerebral perfusion increase the risk for recurrent stroke.

Methods: SPS3 was a 2x2 factorial RCT that examined the effects of intensive vs. standard (<130 vs. 130-149 mmHg) SBP control and combination versus aspirin alone in patients with previous stroke. We examined whether the effects of intensive SBP lowering on stroke were modified by baseline DBP using spline regression models.

Results: Mean age was 63±11 yrs, 63% male and 15% black. Mean baseline SBP was 143±19 mmHg and DBP was 78±11 mmHg. There were 267 strokes over 10725 person-years of follow-up. In spline regression models, those with lower baseline SBP were at higher risk for stroke (Fig 1, panel A) but stroke incidence was lower in intensive vs. standard SBP arm all three baseline DBP tertiles (Fig1, panel B). In a spline regression model, there was no evidence that intensive SBP lowering increased the risk of stroke in those with low baseline DBP (Fig 2). Repeating the analysis with a cardiovascular composite (MI, CHF, stroke, or cardiovascular death) showed similar results.

Conclusions: While observational analysis suggested higher risk of recurrent stroke with low baseline DBP, intensive SBP lowering did not increase recurrent stroke risk in those with low baseline DBP and previous stroke.

Early GFR Decline with Intensive BP Lowering and the Risk of Death and ESKD: Mediation Analysis of AASK Study

Srinivasan Beddhu,1,2 Jincheng Shen,3 Glenn M. Chertow,4 Paul K. Whelton,4 Guo Wei,5 Robert E. Boucher,6 Alfred K. Cheung,7 Tom Greene.7 Division of Nephrology & Hypertension, University of Utah School of Medicine; Salt Lake City, UT; 2Medical Service, Veterans Affairs Salt Lake City Health Care System, Salt Lake City, UT; 3Division of Biostatistics, University of Utah School of Medicine, Salt Lake City, UT; 4Division of Nephrology, Stanford University School of Medicine, Palo Alto, CA; 5Tulane University School of Public Health and Tropical Medicine, New Orleans, LA.

Background: Intensive BP lowering decreased the risk of death in CKD but there are concerns that its acute, hemodynamic kidney effects might increase ESKD risk.

Methods: AASK Study (N = 1094) was a RCT of low vs. usual mean arterial pressure (≥92 vs. 102 to 107 mmHg) on kidney outcomes. Using the change in measured iothalamate GFR from baseline to the average of months 3 and 6 (early GFR change), we examined the acute effect of the intervention on subsequent death/ESKD in a mediation analysis. We partitioned the total effect of BP intervention on death/ESKD that was mediated through early GFR change (indirect effect) and independent of early GFR change (direct effect). We also used SIMEX method to access the impact of measurement error in early GFR change on the findings.

Results: We included 976 AASK participants with GFR measurements at baseline, 3 and 6 months. Mean baseline GFR was 55±11 ml/min/1.73m². There were 223 deaths, 293 ESKD events and 445 death/ESKD events during an average of 7.2±3.3 years of follow-up. BP separation was maintained through the trial (Fig 1, panel A) with an early decline in GFR in the lower BP group but GFRs in the two arms that were similar at the end of the trial (Fig 1, panel B). After adjustment for covariates listed in the footnote to Fig 2, we observed a borderline significant beneficial total effect of the BP intervention on death/ESKD and a slightly stronger direct effect (Fig 2). The HR for the indirect effect was slightly > 1, consistent with the possibility of a small adverse effect of early GFR change.

Conclusions: Intensive BP lowering appears to have a largely beneficial direct effect and a small deleterious indirect effect on death/ESKD in CKD.

A Novel Marker of Resistant Hypertension in CKD

Guido Gembillo, Rossella Siligato, Valeria Cernaro, Domenico Santoro. Policlinico G. Martino, Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy.

Background: Inflammation, oxidative stress (OS), atherosclerosis and resistant hypertension (RH) are common features of chronic kidney disease (CKD) leading to higher risk of death from cardiovascular disease. These effects seem to be modulated by impaired anti-oxidant, anti-inflammatory and reverse cholesterol transport actions of high-density lipoprotein cholesterol (HDL). Recently, monocyt count to HDL-cholesterol ratio (MHR) has emerged as a potential marker of inflammation and OS, demonstrating to be relevant in CKD. Our research was aimed to assess, for the first time, its reliability in RH.

Renal Denervation (RDN) vs. Spironolactone in the Treatment of Resistant Hypertension (RH): A Meta-Analysis
Sherida N. Edding, Monica Therese Cating-Cabral, Brian Michael I. Cabral, St. Luke’s Medical Center - Global City, Taguig City, Philippines.

Background: Resistant hypertension (RH) is defined as blood pressure that remains above guideline-directed goal despite the concurrent use of at least three antihypertensive agents of different classes, one of which is a diuretic. Treatment of RH is focused on implementing appropriate treatment strategies.

Methods: A comprehensive literature search from the PubMed, Embase, Cochrane Library, and Ovid was performed with the following search terms: Resistant Hypertension, Denervation in patients with RH.

Results: Two trials comprising 130 patients were selected - 63 patients treated with RDN and 67 patients with Spironolactone. Pooled analysis of the 2 trials for 24H SBP and DBP showed an adjusted standardized mean difference of 0.55 mmHg (CI -0.72, 1.82; P = 0.39) and 0.32 mmHg (CI -0.72, 1.35; P = 0.55) with significant heterogeneity. No significant differences were also noted in terms of decline in eGFR (P = 0.07) and changes in serum potassium (p = 0.29) from baseline to 6 months.

Conclusions: Based on our results, RDN appears to be safe and effective treatment for RH. However, additional larger studies should be done including a cost-benefit analysis to explore that possibility of RDN as treatment alternative for those intolerant of spironolactone or as a possible 5th line of treatment for those already taking spironolactone.

PO2098

Primary Aldosteronism in CKD
Heather Wachtel,1 Jae Ermer,1 Angela C. Davio,2 Yuta Tczuka,3 Gregory L. Hundemer,2 Adina Turcu,1 Anand Vaidya,4 Debbie L. Cohen,1 1University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 2Ottawa Hospital, Ottawa, ON, Canada; 3University of Michigan, Ann Arbor, MI; 4Brigham and Women’s Hospital Department of Medicine, Boston, MA.

Background: Primary aldosteronism (PA) is a common cause of secondary hypertension, with unilateral causes of PA are potentially cured with adrenalectomy. Treatment of PA in CKD is often avoid for concerns of safety and efficacy.

Methods: We conducted a retrospective cohort study of patients with PA and CKD (eGFR <60 ml/min/1.73m2) at 3 institutions (2009-2019). eGFR was calculated using CKD-EPI. Statistical comparison utilized the student’s t-test, Chi-square test, and Wilcoxon rank-sum test.

Results: Of 250 patients included, mean age was 56.6 years (±10.5), and 64% were female. Median plasma aldosterone concentration was 29.0 ng/dl (IQR:20.3-47.4); median plasma renin activity was 0.2 ng/ml/hr (IQR:0.1-0.6) and aldosterone-renin ratio was 119 (ng/dl)/(ng/ml/hr) (IQR:63.5-240.0). Median eGFR on initial evaluation was 49.0 ml/min/1.73m2 (IQR:40.3-58.2). Adrenal vein sampling (AVS) was performed in all patients; unilateral PA was diagnosed in 66.6% (n=169). Adrenalectomy was performed in 163 subjects. Surgical pathology demonstrated adrenocortical adenomas in 66.9%, nodular hyperplasia in 4.9%, and nodular hyperplasia with a dominant nodule in 10.4%. The median tumor size was 1.2 cm (IQR:1.0-1.8). No differences were detected in baseline MAP, number of anti-hypertensive medications (AHHM), serum creatinine, or potassium levels between adrenalectomy patients and those medically managed. Adrenalectomy patients had significantly lower AHM requirements at 1 month (2.2 ± 4.5 vs. 4.5 ± 4.5 AHM requirements at 1 month (2.2 ± 4.5 vs. 4.5 ± 4.5 AHM requirements at 1 month). Median follow-up was 6 months (2.0 vs. 3.0, p=0.002) and 12 months after surgery (2.0 vs. 4.0, p<0.001) compared with medically managed patients. Adrenalectomy patients demonstrated stable eGFR from baseline to 12 months postoperatively, while medically managed patients had a statistically significant decrease in eGFR from baseline to 12 months (p<0.040). There was no difference between groups in cardiovascular outcomes.

Conclusions: Patients with CKD and unilateral PA experience significant and durable decrease in AHM requirement and demonstrate stabilization of eGFR after adrenalectomy when compared to medically managed patients. AVS was successful despite reduced GFR. This study demonstrates that patients with CKD and suspected PA should undergo adrenalectomy evaluation to determine whether they have surgically curable disease, as there is a clear benefit in medication reduction and stabilization of GFR at 12 months.

PO2099

Bilateral Nephrectomy in a Patient with Refractory Hypertension Prior to Development of ESKD
Anna M. Zenk,1 Alexander A. Hiepas,2 Martin Herl,3 Waleed Ali,1 Noga A. Roddy,4 George L. Bakris,1 1Department of Medicine, Division of Nephrology, Rush University Medical Center, Chicago, IL; 2Department of Medicine, Rush University Medical Center, Chicago, IL; 3Department of Medicine, Comprehensive Hypertension Center, University of Chicago Medicine, Chicago, IL; 4Department Transplant Surgery, Rush University Medical Center, Chicago, IL.

Introduction: Renal denervation (RDN) reduces increased sympathetic activation in refractory HTN (rHTN) while preserving kidney function, and trials in both the US and Europe demonstrate a 7-12 mmHg placebo subtracted reduction in systolic BP. Bilateral nephrectomy (BLN), originally performed in ESKD patients in the 1970s for rHTN is an effective treatment, but is reserved for ESKD pts. We present a case of life threatening rHTN in a pt with Stage 3b CKD that was unresponsive to open surgical renal denervation (OS RDN) but responded extremely well to BLN.

Case Description: A 43 y/o white woman with stage 3b CKD (eGFR 38 ml/min/1.73m2) presented with a resting SBP between 180-240 mmHg on maximal doses of 8 different antihypertensive medications including spironolactone and minoxidilll. She required frequent hospitalizations for symptomatic HTN with IV CCBs and beta blockers. Workup included an evaluation of all secondary causes including drug screening, urine metanephrines, renin MRI, and renin/aldosterone ratio. In an effort to avoid BLN, she initially underwent bilateral OS RDN by severing all neural tissue entering the kidney. Renal vein renin levels were 9.1, 7.8 ng/ml/hr pre OS RDN and 0.7, 1.4 ng/ml/hr post. Despite an initial drop in BP to 140/70 mmHg on only 2 medications, within 4 wks of OS RDN, her BP rose to 240/120 on 4 medications and she was symptomatic. At this point, BLN was performed as the only remaining option. Understanding of the need for RRT following BLN, the patient consented to proceed. Follow up BPs have been in the 130/80 mmHg range on a reduced dose 12.5mg bid alone.

Discussion: Neither OS RDN nor pre-ESKD BLN for rHTN have been previously reported. Advancements in endovascular RDN are becoming more effective, but still only lower systolic BP by 7-12 mmHg placebo subtracted. Our case failed to respond to OS RDN, where we were guaranteed completed resection of the nerves and surrounding connective tissue, and suggests the effects of any form of RDN may be limited. BLN for rHTN is the preferred option in the 1970s. Almost 50 yrs later, despite enormous improvements in medications, there is still a role for this procedure, and it emphasizes how little we still know about the etiology of rHTN. Requiring this in a patient pre-ESKD was extreme but we felt a life-saving requirement. She will be referred for transplantation.
Hypertension, Mayo Clinic, Rochester, MN; 2Department of Internal Medicine, University of Missouri Kansas city, Kansas city, MO, USA, Kansas City, MO; 3Department of Family Medicine, Creighton University, Omaha, NE.

Introduction: RfHTN is defined as uncontrolled HTN with BP >140/90 mmHg despite a5 different classes of maximally tolerated antihypertensive agents, including a diuretic and a mineralocorticoid receptor antagonist. RfHTN may be underdiagnosed.

Case Description: A 43-year-old female with a history of mitral valve prolapse, iron deficiency anemia, mild asthma and migraines presented for management of uncontrolled severe HTN. Her HTN became increasingly resistant following use of pheniramine and fenfluramine for two years and a recent hysterectomy, with persistently elevated blood pressure (BP) up to 250/100 mmHg. Her medications included: hydralazine, lopressor, procardia, demadex, accupril, diovan, catapres and aldactone. On physical exam, her BP was 230/136 mmHg with regular pulse of 96 beats/min and no papilledema or bruits. Renal function and aldosterone levels were normal. Renal ultrasound/doppler, captopril scan, and angiograms showed no renal artery stenosis or coarctation of the aorta, and 24-hour urine metanephrines were normal. Her echocardiogram showed concentric left ventricular hypertrophy with ejection fraction of 60%. Minoxidil was initiated and procardia and lopressor were maintained, with no effect on BP. A high-resolution brain MRI with spectroscopy showed a venous angioma in the right superior temporal lobe and CT angiogram showed irregularity of the basilar artery with outpouring at the left posterior communicating artery and right anterior choroidal artery. She was diagnosed with neurogenic arterial HTN from neurovascular compression (NVC) of the rostral ventrolateral (RVL) medulla. Left retro sigmoid craniotomy was performed for NVC decompression, but aborted eight hours later for fear of precipitating a massive stroke.

The patient continues to have RfHTN despite maximal medical therapy and has now developed complications including a cerebral ICA dissection, CKD stage 3, heart failure, and severe intractable disease.

Discussion: NVC is related to neurogenic HTN when occurring in the RVL medulla. This case highlights that brain MRI be performed in patients with intractable resistant HTN when all other secondary causes are ruled out.

PO2101
Adjuvant Mesenchymal Stem Infusion Boosts Recovery of GFR After Renal Revascularization for Atherosclerotic Renovascular Disease
Abdelrhim Abumoaawad,1,2 Ahmed Saad,1,2 Christopher M. Ferguson,1 Alfonso Eirin,1 Sandra Herrmann,1 LaTonya J. Hickson,2 Emily Bendel,2 Lilach O. Lerman,1 Stephen C. Tector1,2 (Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; 1Department of Internal Medicine, University of Missouri Kansas city, Kansas city, MO, USA, Kansas City, MO; 2Department of Radiology, Mayo Clinic, Rochester, MN; 3Department of Family Medicine, Creighton University, Omaha, NE.

Background: Atherosclerotic renovascular disease (ARVD) reduces renal blood flow RBF, GFR and accelerates poststenotic kidney (STK) tissue injury. Renal revascularization alone often fails to restore GFR in ARVD. Whether adjunctive infusion of autologous mesenchymal stem cells (MSC) can modify reparative processes during restoration of RBF is unknown.

Methods: We measured RBF (MDCT), GFR (ilohamurate clearance), systolic blood pressure (SBP), in 16 human subjects with ARVD, before and 3 mo after MSC delivery and stent PTRA. MSC were administered at 3 dose levels (1, 2.5 and 5.0x10^5 MSC/kg, n=7.5-4 patients each) into STK, after stent PTRA. A cohort with ARVD n=17 matched for age, SBP and GFR studied under identical protocol treated with stent PTRA alone served as controls.

Results: SBP decreased in MSC+ PTRA and PTRA alone groups 145±20 to 135±19, P=0.022, and 147±20 to 137±16 mmHg, p= 0.02. RBF increased in both MSC+ PTRA and PTRA alone treated groups following the three-month hiatus 23±121, to 29±178 ml/min, p=0.015 and 315±260, to 376±304 ml/min, p=0.017. By contrast, GFR increased in the MSC + PTRA group 64±29 to73±34 ml/min p=0.017 whereas GFR did not change in the PTRA group 63±7 to307±65.0±28.6, p =0.35. The increases in RBF and GFR were higher in the group treated with the highest MSC dose Fig1.

Conclusions: These data reinforce the dissociation between restoring RBF and recovery of GFR in ARVD. Adjunctive therapy with autologous MSC was associated with a dose-related increase in GFR after restoring blood flow, consistent with the ability of MSC to repair microvascular injury. Further clinical trials to characterize the durability and extent of these reparative pathways are warranted.

PO2102
Percutaneous Angioplasty of Renal Artery Stenosis Most Beneficial in Patients with AKI Requiring Acute Hemodialysis
Nabil H. Abu amoawad,1 Lesya Kukuy,1 Uri Rimon,1 Eliezer J. Holtzman,1 Pazit Beckerman,1 Dganit Dinour,1 Sheba Medical Center at Tel Hashomer; Tel Hashomer, Israel; 1Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, Israel.

Background: Treatment of atherosclerotic renal artery stenosis (RAS) is still controversial and several studies have shown that percutaneous transluminal renal angioplasty with stenting (PTSTRAs) is not superior to medical treatment, and the procedure is commonly reserved for malignant hypertension, flash pulmonary edema or deterioration of kidney function. The benefit of endovascular intervention among acute kidney injury (AKI) patients requiring hemodialysis secondary to severe RAS has not been studied. We studied the effects of PTSTRAs on patients with atherosclerotic RAS, specifically those who presented with AKI indicated for hemodialysis.

Methods: 109 PTSTRAs were performed in 92 patients with RAS from 2003 to 2019 in a tertiary hospital. Eleven patients presented with AKI secondary to high grade RAS and underwent PTSTRAs after starting acute hemodialysis. Data collected included demographic parameters, medical background, indication for intervention, technical procedure parameters and complications and long term data including dialysis treatment and mortality. Patients were categorized as responders or non-responders based on improvement in kidney function and discontinuation of dialysis.

Results: A total of 109 procedures were performed in 92 patients with severe renal artery stenosis. Eleven patients (12%) underwent PTSTRAs for severe high grade stenosis causing renal hyperperfusion and hemodialysis-dependent AKI. After PTSTRAs, 8 of 11 patients (73%) improved kidney function and discontinued dialysis. The average time on dialysis was 17 days (range 3-35 days) to PTSTRAs and 22 days (range 3-42 days) to recovery of kidney function, which occurred 6.5 days (range 1-24 days) after PTSTRAs. Two of the 8 patients later required long term hemodialysis. Only two cases were reported with mild complications.

Conclusions: In patients with hemodialysis dependent AKI, PTSTRAs should be considered as a rescue treatment as kidney function may recover even after prolonged time on dialysis.

PO2103
Outcomes of Cardiac Surgery in CKD Stage 3 vs. Stage 4 and 5
Aimen Liaquat,1 Elias Basil,1 Jonathan J. Taliercio,1 Ali Mehdi,1 Remy Daou,2 Susana Arrigain,3 Victoria Konig,1 Jesse D. Schold,1 Serge C. Harb,1 Per Wierup,1 Sevag Demirjian,1 Georges Nakhoul,1 Cleveland Clinic, Cleveland, OH; 1Universite Saint-Joseph, Beirut, Lebanon.

Background: Pre-operative kidney dysfunction is associated with worse outcomes following cardiac surgery. However, few studies have assessed the outcomes of advanced Stage 4 and 5 Chronic Kidney Disease (CKD) patients.

Methods: Using our Electronic CKD registry, we compared the outcomes of 988 patients with CKD stages 3 vs. 4 and 5 undergoing Coronary Artery Bypass Graft (CABG) and/or valvular cardiac surgery. We compared length of stay (LOS), ICU days, days on pressors, and days intubated as continuous values and as proportion above the 50th percentile using Kruskal-Wallis and Chi-square tests. We estimated Fine and Gray’s competing risks cumulative incidence function of days to post-operative AKI requiring
dialysis (AKI-D) with mortality as a competing risk during hospitalization. We also compared the proportion developing AKI-D with Chi-square test.

**Results:** Among 988 total patients with cardiac surgery, 115 (12%) had CKD stage 4/5 and 873 (88%) had CKD stage 3. Average age was 71.2 ± 9.5 and 590 (59.7%) were male. Patients with CKD 4/5 had a higher proportion of diabetes (60% vs. 37%). Compared to CKD 3 patients, CKD 4/5 patients required longer intubation (33% more than 2 days compared to 20%, P=0.003), more pressures (47% more than 3 days vs. 32%, P=0.003), longer ICU LOS (median of 5 days vs. 4 days, P=0.001), longer post-operative LOS (median 12 days vs. 9, P=0.001). 24 patients (20.9%) with CKD 4/5 developed post-operative AKI-D vs. 42 (4.8%) in the CKD 3 group (p < 0.001). The cumulative incidence of End-Stage-Kidney Disease (ESKD) with death as a competing risk at 15 days was 5% (95% CI, 4, 8) in CKD 3 group vs. 24% (15, 33) in CKD 4/5 group (p < 0.001).

**Conclusions:** Advanced CKD stages 4/5 is associated with worse outcomes following cardiac surgery including prolonged ICU stay, intubation duration, days on pressors, development of AKI-D and ESKD.

**Post-operative Outcomes in CKD Stage 3 Vs. Stage 4 and 5**

**Cardiovascular Events and Mortality in Adults with Kidney Failure after Major Noncardiac Surgery**

Tyrone Harrison,1 Paul E. Ronksley,1 James Wick,1 Shannon M. Ruzycki,1 Matthew T. James,1 Deirdre McCaughey,1 Kelly B. Zarnke,1 Brenda Hemmelgarn.2,1 University of Calgary Cumming School of Medicine, Calgary, AB, Canada; 1University of Alberta Faculty of Medicine and Dentistry, Edmonton, AB, Canada.

**Background:** People with kidney failure have a high incidence of major surgery. Despite this surgical exposure, there is a paucity of literature investigating postoperative CV events and death. We aimed to determine the risk of these outcomes based on surgery type.

**Methods:** This retrospective cohort study used administrative health data from Alberta, Canada from April 2005 to February 2017. Adults (≥18 years) with kidney failure (receipt of chronic dialysis or two outpatient eGFR measures <15 mL/min/1.73m²) admitted to hospital for a surgical procedure were included. Surgery type, categorized using ICD-10 codes from hospitalization data, was examined for association with acute myocardial infarction (AMI) and death within 30 days of surgery using multivariable logistic regression. We adjusted for demographics, comorbidities, preoperative laboratory measures, procedure urgency, and kidney disease specific variables.

**Results:** 3398 people with kidney failure had a major surgery (1905 hemodialysis; 903 peritoneal dialysis; 590 non-dialysis). Most of the cohort was male (61.0%), the median age was 61.5 years (IQR 50.0, 72.7), and over half of the procedures were urgent (56.9%). 198 people (5.8%) had an AMI or died within 30 days of major surgery. Kidney transplantation had the lowest frequency of the outcome and were the reference group. After adjustment, vascular, skin and soft tissue, intra-abdominal, musculoskeletal, retroperitoneal, anorectal, and neurosurgical procedures had statistically higher odds of AMI or death compared to kidney transplantation (Figure 1).

**Conclusions:** Major non-transplant surgery in people with kidney failure is associated with a high risk of AMI and death, which has implications for the direction of future perioperative research in this population.

**Race Differences in Cardiovascular Events After Percutaneous Coronary Intervention-Induced AKI**

Joseph Lumera,1 Robert M. Clare,2 Karen Chiswell,2 Julia J. Scialla,3 Patrick H. Pun,1,2 Kevin L. Thomas,1,3 Monique Starks,1,2 Clarissa J. Diamantidis,1 1Duke University School of Medicine, Durham, NC; 2Duke Clinical Research Institute, Durham, NC; 3University of Virginia School of Medicine, Charlottesville, VA.

**Background:** AKI portends a higher risk of subsequent cardiovascular disease (CVD). Although racial differences in AKI incidence have been found, it is unclear if the risk of CVD events following AKI also varies by race.

**Methods:** We quantified racial differences in the association of AKI with CVD events 1-year following percutaneous coronary intervention (PCI), using the Duke Databank for Cardiovascular Disease (DDCD). The DDCD captured all patients who underwent PCI at Duke between January 1, 2003 and December 31, 2013 with a combination of structured (forms) and electronic health record (EHR) data. Patients were followed prospectively for CVD events. AKI was defined as a 1.5-fold increase in serum creatinine from outpatient reference value before PCI to the peak value within 7 days post-PCI or a 0.3 mg/dl increase from the reference value within 48 hours. The primary outcome was a CVD composite including all-cause death, myocardial infarction, stroke, and revascularization. Cox models from date of AKI to outcome were adjusted for demographics, baseline cardiac comorbidities, medication use (RAAS inhibitors and NSAIIDs), indication and urgency of PCI, and BP at PCI and number of stents placed.

**Results:** Among 9432 patients (median age 63y; 33% women; 75% white, 20% black), 965 (9%) developed AKI. Among 6699 patients with follow-up, the cumulative incidence of CVD at 1-year was 21%. After adjustment, AKI vs no AKI was associated with 1.84 greater hazards for the composite CVD outcome [95% confidence interval (CI) 1.62 to 2.10]. Compared to whites, other race (HR 0.79, 95% CI 0.63 to 0.99) but not black race (HR 1.07, 95% CI 0.95 to 1.20) was associated with lower risk of subsequent CVD. There was no interaction between race and AKI (p-interaction 0.216). Results were similar with individual components of the outcome.

**Conclusions:** AKI vs. no AKI following PCI is associated with greater risk for CVD events, regardless of race. Efforts to offset long-term consequences of AKI should target all patients undergoing PCI.

PO2106
Frailty Is Associated with Higher Risk of Cardiovascular Events and Death in Adults with CKD: Findings from the Chronic Renal Insufficiency Cohort (CRIC) Study
Mary Hannan,1 Ana C. Ricardo,1 Julia Brown,1 Eunice Carmona,1 Zahraa Hajiri,1 Natalie Meza,1 Jinsong Chen,1 Mildred R. Saunders,1 James P. Lash,1 1University of Illinois at Chicago College of Medicine, Chicago, IL; 2UChicago Medicine, Chicago, IL.

Background: Frailty is common in individuals with chronic kidney disease (CKD). In the general population, frailty is associated with increased risk of cardiovascular events and mortality, but this association has not been fully examined in the CKD population. The objective of this study is to evaluate frailty status as a predictor of cardiovascular events and death in individuals with CKD.

Methods: Among 2,537 CRIC Study participants, frailty status was assessed using five criteria (slow gait speed, muscle weakness, low physical activity, exhaustion, and unintentional weight loss). Frailty was defined as meeting ≥3 criteria, pre-frailty as meeting 1-2 criteria, and non-frailty as meeting zero criteria. Cox proportional hazards models were used to evaluate associations with atherosclerotic events, incident heart failure, and death.

Results: Baseline age was 57.5 years, 45.5% were female, mean eGFR was 46.9 mL/min/1.73m², and median urine protein was 0.13 mg/day. Frailty was present in 21% of the participants and 66% were pre-frail. During a median follow-up of 12.5 years, there were 349 atherothrombotic events, 398 incident heart failure events, and 398 deaths. In multivariable analyses, frail individuals had a higher risk of each outcome compared to non-frail individuals. Pre-frail individuals had a higher risk of atherosclerotic events compared to non-frail individuals (Table).

Conclusions: In adults with CKD, frailty is associated with increased risk for cardiovascular events and death. Future studies are needed to evaluate the impact of interventions to reduce frailty in individuals with CKD.

PO2107
CKD Predicts Stroke Severity, Disability, and Early Recurrence in a Population-Based Cohort Study

Background: Chronic kidney disease (CKD) is associated with cerebrovascular disease and related mortality, and with under-utilisation of acute and preventive treatments, but any impact on initial event severity and recurrence risk is unclear. We aimed to determine whether CKD is associated with worse initial stroke severity and disability, and whether CKD is independently predictive of recurrent stroke and other vascular events.

Methods: In a population-based study of all TIA/stroke (Oxford Vascular Study), we studied initial stroke severity and disability using the National Institutes of Health Stroke Scale (NIHSS) and modified Rankin scale (mRS), respectively, in relation to CKD in all patients presenting with TIA and stroke from April 1, 2002 to March 31, 2017. Associations between CKD and event severity, and between CKD and risk of recurrent vascular events (stroke, myocardial infarction, and sudden cardiac death) were examined using ordinal and Cox regression models, respectively, adjusted for age, sex, and known vascular risk factors, and stratified by TOAST subtype.

Results: Among 3178 patients with TIA (n=1167), ischaemic stroke (n=1802), and intracerebral haemorrhage (n=209), 1267 (40%) had CKD. CKD was independently associated with greater risk of ischaemic stroke compared to TIA (adjusted OR=1.31, 95%CI=1.11-1.56, p=0.002) and with greater initial NIHSS (adjusted OR=1.28, 1.04-1.46; p=0.018), driven mostly by those with an estimated glomerular filtration rate (eGFR) < 30 mL/min/1.73m² (adjusted OR=2.59, 1.44-4.66; p=0.001 for ischaemic stroke; adjusted OR=4.06, 2.04-8.06; p=0.001 for initial NIHSS). Among patients with ischaemic stroke, CKD was also associated with higher one-month mRS scores (adjusted OR=1.40, 1.13-1.74; p=0.002), driven by those with an eGFR < 30 mL/min/1.73m² (Adjusted OR=6.51, 3.04-13.97; p=0.001). Risk of early (<90 days) recurrent stroke was increased with CKD (adjusted HR=1.60, 1.15-2.21; p=0.005) as was the risk of longer-term (0-15 years) composite vascular outcomes (adjusted HR=1.14, 1.05-1.46; p=0.01).

Conclusions: The consistent independent impact of CKD on initial event severity, early disability and recurrence risk suggests that there may be processes intrinsic to CKD leading to uniformly worse outcomes. Further research should determine whether there are CKD-specific treatments that may improve stroke outcomes.

PO2108
Control of Blood Pressure in Elderly Patients with Heart Failure and Risk of Mortality
Antoniou S. Dourou,1-3 Alice Schneider,1 Natalie Ebert,1 Martin K. Kuhlmann,2 Nina Mielke,1 Markus van der Giet,1 Elke Schuefner,1 1Charite Universitaetsmedizin Berlin, Berlin, Germany; 2Vivantes-Netzwerk für Geriatrie GmbH, Berlin, Germany; 3McGill University, Montreal, QC, Canada.

Background: Blood pressure (BP) targets in elderly patients with heart failure (HF) are unclear and guidelines are based on expert consensus and extrapolation from populations without HF. Thus, our population-based prospective cohort study assessed if BP control <140/90 mmHg is associated with a decreased risk of mortality in elderly HF patients.

Methods: We included participants of the Berlin Initiative Study, all ≥70 yrs, with HF and treated with antihypertensive drugs at baseline (2009-2011). Demographics, lifestyle factors, medication, and comorbidities were obtained in face-to-face interviews and linked with administrative healthcare data. BP status was defined as normalized BP (systolic BP <140 and diastolic BP <90 mmHg) or non-normalized BP (systolic BP ≥140 or diastolic BP ≥90 mmHg) and updated every 2 yrs, so that each patient could contribute person-time to both exposure categories during follow-up. Time-dependent Cox proportional hazards models estimated adjusted hazard ratios (HRs) with 95% confidence intervals (CIs) of cardiovascular death and all-cause mortality associated with normalized BP compared to non-normalized BP in HF patients. Analyses were repeated in non-HF patients.

Results: There were 544 HF patients treated with antihypertensive drugs (mean age 82.4 yrs; 45.4% female). During a median follow-up of 7.5 yrs and compared with non-normalized BP, normalized BP was associated with an increased risk of cardiovascular death (HR, 1.79; 95% CI, 1.23-2.61) and all-cause mortality (HR, 1.48; 95% CI, 1.15-1.90). No increased risks of cardiovascular death (HR, 1.23; 95% CI, 0.87-1.74) or all-cause mortality (HR, 1.19; CI 0.95-1.49) associated with normalized BP were observed among 1,079 non-HF patients.

Conclusions: BP <140/90 mmHg was not associated with a decreased risk of mortality in elderly HF patients. The increased risk requires further confirmation.

Funding: Private Foundation Support

Risk of cardiovascular death and all-cause mortality associated with normalized BP in older adults with HF

PO2109
Renal Outcomes of Sacubitril-Valsartan vs. ACE Inhibitors and Angiotensin Receptor Blockers in Heart Failure: A Systematic Review and Meta-Analysis

Background: Chronic kidney disease is an important comorbidity in heart failure patients through elevation in blood pressure and activation of the RAAS. Angiotensin converting enzyme inhibitors and angiotensin receptor blockers have been linked to beneficial effects on clinical outcomes of HF patients with CKD; however, they have been found to increase the risks for renal impairment. Clinical trials on the angiotensin receptor nephrilysin inhibitor, sacubitril-valsartan, have found that it causes kidney dysfunction less frequently. This study determined the effect of sacubitril-valsartan on renal outcomes among HF patients compared to ACEi and ARBs alone.

Methods: A comprehensive literature search was done through electronic databases and readings until November 2019. This analysis incorporated randomized controlled trials in which indicators of renal function of patients on sacubitril-valsartan were compared to those of patients on reference drugs—estimated glomerular filtration rate, eGFR, serum creatinine, and increase in serum potassium.

Results: Four RCTs were included with a total of 14,377 subjects for analysis. Two of the studies used an ACEi (enalapril), while the remaining 2 used an ARB (valsartan). Compared with ACEi and ARBs, there was a nonsignificant difference between decline in eGFR (RR 0.75, 95% CI 0.55 to 1.02; participants = 14377; studies = 4; I2 = 53%), but a significant difference between rise in serum potassium level (RR 0.90, 95% CI 0.84 to 0.96; participants = 14334; studies = 4; I2 = 66%), and elevation of serum creatinine level (RR 0.86, 95% CI 0.78 to 0.95; participants = 14070; studies = 3; I2 = 72%).

Conclusions: In HF patients, sacubitril-valsartan shows possible reduction of risks for renal impairment, and definite reduction of risks for both increasing serum creatinine and hyperkalemia, as compared to ACEi and ARBs.

The Accuracy of Current Ankle-Brachial Index and Toe-Brachial Index Diagnostic Criteria for Peripheral Artery Disease Among Patients with CKD
Jing Chen,1,2 Hua He,2 Charlton C. Starcke,2 Yajun Guo,2 Siyi Geng,2 Chongshuan Chen,2 Erin Mahone,2 Jodie R. Laurent,2 Christina W. Liggin,2 Praktiti Mehta,2 Paige R. Pielet,2 Vecchi Batuman,5 L. Lee Hamm,1 Jiang He,2 1Tulane University School of Medicine, New Orleans, LA; 2Tulane School of Public Health and Tropical Medicine, New Orleans, LA.
Background: Ankle-brachial index (ABI) less than or equal to 0.9 and toe-brachial index (TBI) less than or equal to 0.7 are used as diagnostic criteria for peripheral artery disease (PAD). The sensitivity and specificity of the ABI and TBI diagnostic criteria have not been evaluated in patients with chronic kidney disease (CKD).
Methods: We performed ABI, TBI, and doppler ultrasound among 100 patients with CKD using standard methods. Color doppler ultrasound, which has a high level of diagnostic performance with a sensitivity of 93% and a specificity of 95% for diagnosing PAD, was used as the reference standard. Doppler ultrasound diagnostic criteria were determined by multiple ultrasound features including reduction in luminal diameter, monophasic waveform, peak systolic velocity ratio (PSVR) >2, and presence of special broadcasting. Sensitivity greater than or equal to 50% based on doppler ultrasound imaging was used to diagnose PAD. Sensitivity, specificity, positive predictive value, and negative predictive value were estimated. The areas under the curve (AUCs) for ABI and TBI were calculated.
Results: Participants with PAD were older, and more likely to be male and have a history of cardiovascular disease. The average estimated glomerular filtration rate and proteinuria were similar among participants with and without PAD. The sensitivity, specificity, positive predictive value, and negative predictive value were 15.6%, 88.3%, 20.8%, and 9.4% for ABI and 44.8%, 93.3%, 54.2%, and 99.5% for TBI, respectively. AUCs for ABI and TBI were 0.71 and 0.73, respectively.
Conclusions: These data indicate that current ABI and TBI diagnostic criteria have suboptimal accuracy in diagnosing PAD in CKD. New ABI and TBI diagnostic criteria with higher sensitivity and specificity need to be developed.

PO2111
Efficacy and Safety of Roxadustat in Patients with Non-Dialysis-Dependent CKD, Anemia, and Heart Failure
Simon D. Roger,1 Steven Fishbane,2 Pablo E. Pergola,3 Willis Chou,4 Khali G. Saikali,4 Dustin J. Little,4 Kin-Hung P. Yu,4 1Renal Research, Gosford, NSW, Australia; 2Northwell Health, Great Neck, NY; 3Renal Associates PA, San Antonio, TX; 4Fibrogen Inc, San Francisco, CA; 4AstraZeneca, Gaithersburg, MD.
Background: Roxadustat is an oral hypoxia-inducible factor (HIF) prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Patients with heart failure (HF) represent an important clinical subgroup of patients with CKD.
Methods: Pooled data from three pivotal, phase 3, randomized, open-label, placebo-controlled studies of roxadustat for the treatment of anemia in patients with dialysis-dependent (DD) CKD were assessed in the subgroup of patients with a history of NYHA Class I or II HF recorded at baseline. Endpoints were: mean change in hemoglobin (Hb) observed in this patient subgroup.
Results: In the DD-CKD study population, 25% (991/3890) of patients had HF (roxadustat=49%; epoetin alfa=42%). Baseline characteristics were generally similar. Mean (SD) Hb levels (g/dL) at baseline were 9.59 (1.30) in the roxadustat group and 9.65 (1.29) in the epoetin alfa group. Patients achieved significantly larger least-squares means (LSM) [SEM] CFB in Hb levels (g/dL) with roxadustat vs. epoetin alfa (1.24 [0.04] vs. 0.94 [0.04]), corresponding to a LSM difference of 0.29 (95% CI: 0.18, 0.40) (p<0.0001). The hazard ratio for first blood/RBC transfusion during the treatment period in the roxadustat and epoetin alfa groups was 0.76 (95% CI: 0.54, 1.08); p=0.1274. Mean (SD) monthly IV iron (mg) use was lower in roxadustat- vs. epoetin alfa-treated patients: 55.8 (288.8) vs. 68.6 (142.7) (p=0.0001), TEAE rates were comparable between treatment groups and similar to those in the overall DD-CKD study population.
Conclusions: Roxadustat was efficacious vs. epoetin alfa for increasing Hb levels and reducing mean monthly IV iron use in DD-CKD patients with HF. The safety and tolerability profile was similar to the overall population and consistent with that observed in this patient subgroup.

Roxadustat Lowers Low-Density Lipoprotein Cholesterol in Patients with Anemia of CKD
Simon D. Roger,1 Mohamed A. El-Shalawy,1 Carol A. Pollock,2 Rosa H. Jimenez,2 Robert Leong,2 Maksym Pol,1 Kin-Hung P. Yu,4 1Renal Research, Gosford, NSW, Australia; 2The University of Sydney, Sydney, NSW, Australia; 3Fibrogen Inc, San Francisco, CA; 4AstraZeneca, Warsaw, Poland; 5University of Southern California Keck School of Medicine, Los Angeles, CA.
Background: Roxadustat is an oral hypoxia-inducible factor (HIF) prolyl hydroxylase inhibitor with positive safety and efficacy results in phase 3 studies in patients with anemia in CKD. The HIF pathway affects cholesterol metabolism; at high altitude, total and low-density lipoprotein cholesterol (LDL-C) decrease in healthy individuals. Roxadustat reduced LDL-C in phase 2 studies. We evaluated the effect of roxadustat on LDL-C in patients with anemia in non-dialysis-dependent (NDD) and dialysis-dependent (DD) CKD.
Methods: Data were pooled from three pivotal phase 3 studies in patients with NDD-CKD and three pivotal phase 3 studies in patients with DD-CKD, including the incident dialysis (ID; on dialysis <4 mo at randomization) population. Mean changes from baseline (CBF) in LDL-C (regardless of statin use) averaged over weeks 12–28 were analyzed using a mixed model of repeated measures and reported least-squares mean (LSM) treatment differences.
Results: In patients with NDD-CKD, there was a 17.2% reduction in LDL-C averaged over Weeks 12–28 in the roxadustat group (n=1984) and a 1.4% increase in the placebo group (n=1430). The LSM treatment difference was statistically significant (p<0.0001). In the patients with DD-CKD, there was an 8.5% reduction in the roxadustat group (n=1650) and a 1.7% reduction in the epoetin alfa group (n=1741). The LSM treatment difference was statistically significant (p<0.0001). In patients with ID-DD-CKD, there was a 21.5% reduction in the roxadustat group (n=680) and a 4.6% reduction in the epoetin alfa group (n=691). The LSM treatment difference was statistically significant (p<0.0001).
PO2114
Roxadustat vs. Placebo or Epoeitin Alfa Has No Clinically Meaningful Effect on Blood Pressure in Patients with Anemia of CKD
Tak Mao D. Chan,1 Roberto Pecoto-Filho,2 Anjay Rastogi,2 Pablo E. Pergola,3 Jacqueline G. Nolan,4 Ming Zhong,4 Lynda Szczecz,5 Kin-Hung P. Yu,5 University of Hong Kong, Queen Mary Hospital, Pok Fu Lam, Hong Kong SAR, China; 2Arbor Research Collaborative for Health, Ann Arbor, MI; 3Pontificia Universidade Catolica do Parana Departamento de Medicina, Curitiba, Brazil; 4University of California Los Angeles, Los Angeles, CA; 5Renal Associates PA, San Antonio, TX; 6FibroGen Inc, San Francisco, CA.

Background: Hypertension (HTN) is a leading cause of chronic kidney disease (CKD) and often worsens as CKD progresses. Erythropoiesis-stimulating agents have been associated with an increase in blood pressure (BP) and other cardiovascular risks. Roxadustat is an oral hypoxia–inducible factor prolyl hydroxylase inhibitor that stimulates hematopoiesis and has been shown to improve BP and other cardiovascular outcomes compared to epoetin alfa in DD patients.

Methods: Pooled data from three, phase 3, randomized, placebo-controlled trials in NDD patients (n=4270), and three pivotal phase 3 randomized, active-controlled trials in DD patients (n=3880), including incident-dialysis-dependent (ID-DD; on dialysis for ≥3 mo; n=1526) and stable dialysis-dependent (SDD; on dialysis for >3 mo; n=2354) patients, were assessed. All DD patients and NDD patients (data censored after dialysis initiation (NDD-NDD)) were included. Mean change from baseline (CBF) in mean arterial pressure (MAP) averaged over Weeks 20–28 (NDD-NDD, SDD) and over weeks 8–12 (ID-DD); time to first exacerbation of hypertension (SBP ≥170 mmHg or DBP ≥110 mmHg and an increase from baseline ≥20 mmHg [SBP] or ≥15 mmHg [DBP]); and adjudicated hypertensive emergency were analyzed.

Results: In NDD-NDD, the least squares mean (LSM) difference between roxadustat and placebo in MAP (mmHg) was 0.67 (0.30) [95% CI: 0.09, 1.25]. Values for ID-DD and SDD patients were −0.35 (0.66) [95% CI: −1.65, 0.95] and −0.06 (0.42) [95% CI: −0.88, 0.76]. Hazard ratios (95% CI) for HTN exacerbation in NDD-NDD, ID-DD, and SDD patients were 1.12 (0.95, 1.32), 1.02 (0.84, 1.25), and 1.06 (0.93, 1.21). Follow-up adjusted incidence rates [events/100 patient-exposure year] of adjudicated hypertensive emergency were 1.1 and 1.1 in roxadustat- and placebo-treated NDD-NDD, 2.2 and 2.5 in the overall roxadustat- and epoeitin-alfa treated DD, and 1.7 and 1.7 in the subgroup of ID-DD.

Conclusions: Pooled analyses of phase 3 data across a continuum of patients with CKD and anemia showed that roxadustat did not have any clinically meaningful effect on BP, HTN exacerbation, or hypertensive emergency vs. placebo in NDD-NDD patients and epoeitin alfa in ID-DD patients.

Rivaroxaban Reduces Major Cardiovascular and Limb Events in Patients with CKD and Peripheral Artery Disease with Recent Lower Extremity Revascularization: Insights from VOYAGER PAD
Judith Hsia,1,2 Mark R. Nehler,3 Sonia Anand,4 Manesh R. Patel,4 William R. Hiatt,5 Sebastian Debus,6 Connie Hess,4 Warren H. Capell,1 Lihong Diao,3 Scott D. Berkowitz,2 Eva Muehlfelder,4 Lloyd P. Haskell,4 Rupert M. Bauersachs,3 Marc P. Bonaca,6 1CPC Clinical Research, Aurora, CO; 2University of Colorado Denver School of Medicine, Aurora, CO; 3McMaster University, Hamilton, ON, Canada; 4Duke University, Durham, NC; 5University of Colorado Denver - Anschutz Medical Campus, Aurora, CO; 6Bayer Corp, Whippany, NJ; 7Janssen Global Services LLC, Raritan, NJ; 8Bayer AG, Leverkusen, Germany; 9Klinikum Darmstadt, Darmstadt, Germany; 10Universitaetsklinikum Hamburg Eppendorf, Universitaires Herzenzentrum Hamburg GmbH, Hamburg, Germany.

Background: In the VOYAGER PAD trial, rivaroxaban reduced cardiovascular (CV) and limb ischemic events (HR 0.85 vs placebo, 95% CI 0.76–0.96; p=0.009) in peripheral arterial disease (PAD) patients following lower extremity revascularization (LER). This analysis examines the prespecified subgroup of VOYAGER PAD patients with CKD.

Methods: VOYAGER PAD (NCT02504216) randomized 6564 PAD patients following LER to rivaroxaban 2.5 mg twice daily or placebo on a background of aspirin 100 mg daily. The primary endpoint was a composite of acute limb ischemia, major amputation for vascular cause, myocardial infarction, ischemic stroke or CV death. Intention-to-treat analyses utilized Kaplan Meier estimates and Cox proportional-hazards models.

Results: Mean baseline eGFR was 75±23 ml/min/1.72m² with 79, 20, 1 and <1% of patients with CKD stage ≥2, 3, 4 and 5 respectively. During 28-month median follow up, rates of major CV and limb events were higher among patients with more severe CKD (placebo group event rate: 7.4/100 patient-years for eGFR ≥60, 10.0 for eGFR 30–<60 and 9.8 for eGFR 15–30). Rivaroxaban reduced primary endpoint events with no heterogeneity by eGFR above or below 60 (mostly CKD stage 3)(Figure). Acute limb ischemia and major amputation were significantly reduced among patients with eGFR≤60 (HR 0.77, 95% CI 0.63, 0.94) and <60 (HR 0.55, 95% CI 0.36, 0.86). Major bleeding was infrequent with no heterogeneity by CKD category.

Conclusions: Rivaroxaban reduced CV and limb events in patients with CKD, PAD following LER, a particularly high-risk population.

Methods: We analyzed parameters related to volume status in these Phase 3 trials. Results: In these studies, 97% and 31% of pts, had HTN and CHF, respectively, and 193 pts were treated with veverimer or placebo for up to 52 weeks. Treatment with veverimer (v placebo) had no effect on weight, BP, urine Na/creatinine ratio, volume-related adverse events, or increased use of diuretics or antihypertensives (Table).

Conclusions: Veverimer, a novel non-absorbed HCl binder, effectively treats metabolic acidosis in CKD without adversely affecting BP or volume status.

Vilniaus Universiteto ligonines Santariskiu klinikos, Vilnius, Lithuania; 2Department of Internal Medicine, Alfried Krupp Krankenhaus, Essen, Germany; 3Department of Internal Medicine, Institute for Experimental Cardiology, University Hospital of Essen, Essen, Germany; 4Washington University School of Medicine, St. Louis, MO; 5University of Michigan School of Medicine, Ann Arbor, MI; 6National Heart Lung and Blood Institute, Bethesda, MD; 7New York University School of Medicine, New York, NY; 8Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 9University Hospitals Case Medical Center, Cleveland, OH; 10Johns Hopkins University School of Medicine, Baltimore, MD; 11Batra Hospital and Medical Research Centre, New Delhi, India; 12University of Leicester and NIHR Leicester Cardiovascular Biomedical Research Centre, Leicester, United Kingdom; 13Johns Hopkins University School of Medicine, Baltimore, MD.

Objective: To examine OMT goal attainment in patients with CKD on dialysis (CKD-D) and non-dialysis CKD (CKD-ND) in the ISCHEMIA-CKD trial.

Methods: OMT was recommended to all participants in ISCHEMIA-CKD. Longitudinal trajectories of individual OMT components (smoking cessation, systolic blood pressure (SBP) ≤140 mmHg, low density lipoprotein (LDL) cholesterol <70 mg/dL, high-intensity statin use, and aspirin use) were modeled over study follow-up. Covariate-related adverse events, or increased use of diuretics or antihypertensives (Table).

Conclusions: OMT improved over time in advanced CKD-ND and CKD-D. CKD-D achieved the SBP goal more than CKD-ND, yet CKD-D were less likely to be treated with high-intensity statin. Future studies should explore systemic and patient-related barriers to attainment of OMT in this high-risk cohort.

Cardiovascular Determinants of Physical Function in Patients with ESKD on Hemodialysis

Sherna F. Adenwalla,1 Gaurav S. Gulsin,1 Roseanne Billany,1,2 Daniel S. March,12 Robin Young,1 Alyshka Careless,1 Clare L. Tomlinson,1 Gerry P. McCann,1,3 James Burton,1,2 Matthew Graham-Brown,1,2 University of Leicester and NIHR Leicester Cardiovascular Biomedical Research Centre, Leicester, United Kingdom; 1Johns Hopkins University School of Medicine, Baltimore, MD; 1University of Glasgow Robertson Centre for Biostatistics, Glasgow, United Kingdom; 2NIHR Leicester Biomedical Research Centre, University Hospitals of Leicester NHS Trust, Leicester, United Kingdom.

Background: Patients with end-stage kidney disease (ESKD) are often sedentary and decreased functional capacity associates with mortality. The relationship between physical function and cardiovascular disease (CVD) has not been fully explored. Understanding the relationships between prognostically relevant measures of CVD and physical function and capacity may offer insight into whether exercise interventions could target specific elements of CVD.

Methods: 130 patients on haemodialysis underwent cardiorespiratory phenotyping with echocardiography (left ventricular (LV) structure and function, pulse wave velocity and native T1 mapping) and cardiac biomarker assessment. Participants completed the incremental shuttle walk test (ISWT) and sit-to-stand 60 (STS60) as field-tests of physical function and capacity. Separate linear regression analyses identified CV determinants of physical function measures. Multivariate models were adjusted for age, gender, BMI and diabetes.

Results: Mean age was 57±15 years, 73% were male and median dialysis vintage was 1.3 years (0.5, 3.4). In multivariate models, NT pro-BNP and global native T1 were independent determinants of ISWT and STS60 performance. LV ejection fraction was also an independent determinant of ISWT distance. However, age, gender and diabetes had the strongest relationship with physical function. Cardiovascular markers that were significant in multivariate models are shown in Table 1.

Conclusions: Markers of CV health could be targeted in exercise interventions to improve outcomes in patients with ESKD. NT pro-BNP, global native T1 and LV ejection fraction were independent CV determinants of physical function. The influence of age and diabetes on performance had the strongest relationship. Improving strategies for prevention and management of diabetes may ameliorate deconditioning in these patients.

The Relationship of Cardiovascular Morbidity with Death and End-Stage Kidney Failure in Patients with Diabetes and CKD Receiving Specialist Renal Care

Conclusion: 
Ken Soon Tan, Eunice P. McDonald CKD.QLD 'The University of Queensland Faculty of Medicine, Herston, QLD, Australia; Griffith University School of Medicine, Gold Coast, QLD, Australia; 'Australia and New Zealand Dialysis and Transplant Registry, Adelaide, SA, Australia; 'The University of Adelaide Adelaide Medical School, Adelaide, SA, Australia.

Background: Patients with diabetes (DM) and CKD have worse cardiovascular, renal and mortality outcomes than those with neither and either condition alone. However, relationships between these 3 outcomes remain unclear, especially in patients receiving specialist renal care. Aims: To report the mortality and other outcomes at a single center, especially in patients with cardiovascular (CVD), hypertension (BP), and kidney diseases (CKD) receiving specialist renal care.

Results: A total of 1288 patients were included. Of 1122 patients who had CVD, 617 had BP, and 259 had CKD. The highest mortality was in patients with DM, CKD and CVD (25.2%). The most consistent predictors of outcome were age, gender, ethnicity, incident status, access to services, biosecurity, smoking, diabetes treatment, HbA1c, MACE prior to enrolment, movement of patient interstate/overseas, loss to follow-up or censor date of 31/12/2017, whichever occurred first. Competing risk analysis was performed with MACE, ESKF and death in turn as the primary outcome while the other 2 were competing risks. Covariates examined were age, gender, ethnicity, incident status, access to services, biosecurity, smoking, diabetes treatment, HbA1c, MACE prior to enrolment, eGFR, proteinuria, Hb, RAAS block and lipid lowering therapy.

The Combined Prognostic Significance of Red Blood Cell Distribution Width and Vascular Calcification in Patients with ESKD

Da won Kim, Dongryul Kim, Yeonhee Lee, Seok Joon Shin, Hye Eun Yoon. Catholic University of Korea School of Medicine, Seoul, Seoul, Republic of Korea.

Background: Red blood cell distribution width (RDW) is a simple parameter that reflects the degree of red blood cell volume variability. Recent evidence has shown that increased RDW is associated with adverse clinical outcomes in end-stage kidney disease (ESKD) patients. Vascular calcification (VC) is another major independent risk factor for mortality among ESKD patients. This study investigated the combined prognostic effect of RDW and VC in ESKD patients starting dialysis.

Methods: We conducted a retrospective observational cohort study of 582 ESKD patients treated at a single center from January 2006 to July 2017. VC was assessed by the aortic calcification index (ACI) using abdominal computed tomography. Patients were divided into four groups based on the median ACI (17.12) and serum RDW value (14.3) as low ACI-low RDW, low ACI-high RDW, high ACI-low RDW, or high ACI-high RDW. The association between RDW and VC on the composite of cardiovascular events (CVEs) and death was investigated.

Results: During a median follow-up of 3.1 years (range, 1.5-5.5 years), 165 (28.3%) CVEs and 126 deaths (21.4%) occurred. The Cox regression analyses showed that the patients with low ACI-high RDW (adjusted hazard ratio, 1.934; 95% confidence interval, 1.853-2.021) and low ACI low RDW (adjusted hazard ratio, 1.921; 95% confidence interval, 1.671-2.093) had a greater risk of the composite endpoint than patients with low ACI-low RDW. Patients with high ACI-high RDW had the greatest risk (adjusted hazard ratio, 2.367; 95% confidence interval, 1.465-3.824; P < 0.001). The interaction between ACI and RDW on CVEs and mortality was statistically significant (P = 0.008).

Conclusions: In ESKD patients starting dialysis, the combined effect of VC and high RDW was associated with a higher risk of CVEs and death. Also, high serum RDW amplified the risk associated with VC.
using her lower extremities since her mastectomy. Blood pressure measured with her right upper extremity was 116/68.

Discussion: Often patient after mastectomy with SNB or ALND avoids taking blood pressure on affected limb regardless of lymphedema in order to prevent lymphedema. Despite this, the evidence for this is sparse with most recent studies reporting blood pressure measurement in ipsilateral affected arm as not being risk factor for lymphedema.

Deformed stent (arrow) with severe in-stent restenosis

Effect of Dietary Salt Reduction on Blood Pressure in Kidney Transplant Patients: A Randomised Controlled Trial

Louise E. Ross,1 Rebecca Suckling,1 Mark E. Dockrell,1 Thomas Bailey,2 Pauline A. Swift.1 1Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom; 2University of Warwick, Coventry, United Kingdom.

Background: Cardiovascular morbidity and mortality are increased in kidney transplant patients. High blood pressure (BP) contributes significantly to this risk and is associated with shortened allograft survival. Dietary salt reduction is widely recommended as a strategy to lower BP in the general population and in chronic kidney disease. Due to a lack of evidence there is currently no consensus on dietary salt restriction in kidney transplant patients.

Methods: Sixty stable kidney transplant patients, a 6-months post-transplantation, with BP ≥120/80 mmHg, and sodium intake ≥80 mmol/24hrs, were randomised in this parallel-designed study to receive either a regular-salt diet (target 150 mmol/24hr) or a low-salt diet (target 80 mmol/24hr) for 8-weeks. The primary outcome measure was systolic and diastolic BP. Secondary outcome measures included 24-hour ambulatory BP (ABP) and proteinuria. Dietary salt intake was assessed by 24-hour urinary sodium excretion.

Results: At baseline, patients (72% men) were 56±11 years with estimated glomerular filtration rate (eGFR) 53±18 mL/min/1.73m², diastolic heart failure, and hypertension who presented with hypertension emergency (blood pressure (BP) 220/80 mmHg) and flash pulmonary edema.

Case Description: During her hospital stay, despite treatment with up to nine anti-hypertensive medications, her systolic BP remained 180-200 mmHg. Her Scr also increased to 3.92. Work-up showed normal kidney sizes and urine protein/creatinine ratio 1.26 g/g. Renal artery duplex revealed right renal artery peak systolic velocity 267 cm/sec, renal-to-aortic ratio 2.68, and resistive index 0.7-0.9, suggestive of right renal artery re-stenosis and some intrinsic damage. Due to progressive volume overload and worsening respiratory status, she required temporary hemodialysis. As her volume status improved, she underwent CO2 angiogram and was found to have 90% diffuse in-stent restenosis with marked deformity of the previous stent. She underwent re-stenting of the right renal artery with a proprietary FDA-approved Herculink Elite® renal stent with only 8 ml of contrast. Immediately post-intervention, her BP dramatically improved and after two months, her dialysis was stopped (new baseline SCr 1.5-1.9) and she only requires a low-salt diet and a regular oral medication regimen.

Discussion: This case highlights several important points. First, renal ultrasound should be considered in the work-up of patients with hypertensive emergency and history of renal stent due to the risk of re-stenosis. Second, it highlights the importance of using an appropriate FDA approved stent in the renal position as placement of coronary stents in the renal position might have a higher incidence of structural failure and re-stenosis.

Weight Gain Is a Risk Factor for the Progression of Coronary Artery Calcification in CKD: From the KNOW-CKD Study

Ji Hye Kim, Young Youl Hyun. Kangbuk Samsung Medical Center, Jongno-gu, Seoul, Republic of Korea.

Background: In chronic kidney disease (CKD), patients with high body mass index or weight gain have better survival. However, their cardiovascular risk is uncertain. The aim of this study was to investigate the relationship between weight changes and the progression of coronary artery calcification (CAC) in CKD.

Methods: This study analyzed 839 participants (Mean age 52.51±12.03, Males 41.12%) from the KNOW-CKD cohort. Changes in weight between baseline and 4 year follow-up period were categorized in tertiles: first tertile (T1) (-1kg to -1.1kg), second tertile (T2) (-1kg to 0.9kg) and third tertile (T3) (1kg to 30kg). The coronary artery calcium score (CACS) was assessed using cardiac computed tomography at baseline and 4 years after enrollment. The CAC progression was defined as increase of CACS after 4 years after enrolment.

Results: The study participants’ baseline median CACS was 0.0 (median) [0 (25th quartile)- 3.45(75th quartile)] and 387 (46.13%) participants had baseline CACS above 0. After 4 years, numbers of patients in each tertile was 247 (29.4%) in T1, 258 (30.8%) in T2 and 334 (39.8%) in T3. Median difference in CACS between baseline and follow-up was 2 [0 - 69.3] in T1, 0 [0 -47.2] in T2 and 6.4 [0 -64.77] in T3. (p=0.088) Multivariate adjusted odds ratios (OR) [95% confidence interval] (95% CI) for CAC progression in T1 and T3 group compared to T2 group were 1.21 [0.79-1.85] and 1.80 [1.20-2.70].

Conclusions: Third tertile group, which gained between 1 to 30kg after 4 years, was significantly and independently associated with CAC progression compared to weight stable second tertile group in Korean predialysis CKD patients. These results suggest that preventing excessive weight gain might help prevent cardiovascular complications in CKD.

PO2127

The Circadian Clock Provides Beneficial Effects Against the Endothelial Dysfunction to Promote Atherogenesis by Regulating Heme Oxygenase 1 Expression

Haejouk Nego,1,3 Harvard Medical School, Boston, MA; 2The Graduate School of Project Design, Tokyo, Japan, Japan.

Background: The circadian clock is a molecular machinery that confers 24 hour variations in gene expression and function to regulate number of physiological functions in humans. Disruption of the clock is associated with pathological remodeling in the arterial structure and vascular stiffness. Chronic circadian clock disruption is also associated with dysfunction in endothelial signaling and responses. Heme oxygenase-1 (HO-1) is an intracellular enzyme which catalyzes the oxidation of heme to generate ferrous iron, carbon monoxide, and biliverdin, which is subsequently converted to bilirubin. These products have anti-inflammatory, anti-apoptotic and anti-thrombotic properties. In this study, we observed if the deletion of Bmal1, a critical component of the circadian clock, can influence HO-1 which play an important part in the protection of vascular diseases.

Methods: Congenic 12- to 16-week-old male, wild-type and Bmal1-KO littermate mice were generated from heterozygote breedings to be used for these studies. We also knocked down Bmal1 to evaluate the protein levels of HO-1 expression in the knocked down cells.

Results: Endothelial function was reduced in aorta from Bmal1-KO mice. In aorta from Bmal1 KO mice, there was a reduction in HO-1 expression in mice with a dysfunctional circadian rhythm. Moreover, Bmal1 KO mice display pre-mature aging to have a dramatic proatherothrombotic phenotype. This phenotype is linked to changes in the regulation of key risk factors for cardiovascular disease. These include HO-1 which is significantly reduced in Bmal1 KO mice. We also confirmed that HO-1 levels follow a circadian pattern and this pattern was absent in Bmal1 KO mice.

Conclusions: These findings indicate that circadian clock provides beneficial effects against the endothelial dysfunction to promote atherogenesis by regulating HO-1 expression. This study establishes a mechanistic connection between Bmal1 and cardiovascular phenotype.

Modeling Endothelial Cell Dysfunction Using Human Induced Pluripotent Stem Cells Derived from Patients with ESRD

Suweon Hong,1 Sun Woo Lim,1 Yoo-Jin Shin,2 Eun jeong Ko,2 Byung ha Chung,1 Chul Woo Yang,1,3 Uijeongbu St. Mary’s Hospital, Uijeongbu, Republic of Korea; 2Seoul St. Mary’s Hospital, Seoul, Republic of Korea; 3Transplant research center, Seoul, Republic of Korea.

Background: Endothelial cell (EC) dysfunction is a frequent feature in end-stage renal disease (ESRD). The aim of this study was to generate human induced pluripotent stem cell-derived EC (hiPSC-ECs) from patients with ESRD as a model to investigate EC dysfunction.

Methods: hiPSCs were obtained using peripheral blood mononuclear cells of patients with ESRD and healthy controls (HC). Next, we generated hiPSC-ECs and the expression of endothelial markers was assessed by immunofluorescence. The differentiation efficacy, EC dysfunction, and molecular signatures of EC-related genes based on microarray were compared with HC-hiPSC-ECs.

Results: In both groups, hiPSCs and hiPSC-ECs were successfully obtained based on iPSC or EC marker expression. However, the efficiency of EC generation from hiPSC was lower in ESRD than HC. In addition, ESRD-hiPSC-ECs failed to form branching point networks, unlike HC-hiPSC-ECs in the tube formation assays. In a microarray analysis, transcripts associated with oxidative stress and inflammation were upregulated and transcripts associated with vascular development and basement membrane extracellular matrix components were downregulated in ESRD-hiPSC-ECs compared with HC-hiPSC-ECs.

Conclusions: In conclusion, ESRD-hiPSC-ECs showed a greater EC dysfunction based on functional assays and molecular profiles and it can be a useful disease model to investigate EC dysfunction in ESRD.

Funding: Government Support - Non-U.S.
Macrophage Neutrophil Gelatinase-Associated Lipocalin Has a Critical Role in Aldosterone-Induced Renal Fibrosis via the CCL5/IL4 Pathway

Background: Neutrophil Gelatinase-Associated Lipocalin (NGAL) is a neutrophil protease inhibitor in the cardiovascular system. NGAL is also described as an acute renal lesion biomarker and NGAL serum concentration is associated with the severity of renal damages patients with a chronic kidney disease (CKD). Lipocalin2 (Lcn2) gene invalidation in a CKD mouse model protects from proteinuria and renal lesions. We hypothesized that NGAL produced from macrophages promotes expression of chemotacticant molecules involved in renal lesions induced by mineralocorticoid excess.

Methods: The role of Lcn2 was analyzed using full Lcn2 knock out mice (NGAL KO) challenged with uni-Nephrectomy, Aldosterone 200 mg/kg/day, Salt 1% (NAS model) during 6 weeks. Assessment of CCL5/L4 in kidney fibrosis were studied using maravirus administration (50 mg/kg in chow diet) or by injections of anti-lL4 antibody (600 mg/kg).

Results: NAS induced a significant increase in the expression (relative values, mean±SEM, compared to 1 in the control samples, p<0.05) of extracellular matrix proteins such as collagen I (2.35±0.33), a-SMA (2.04±0.42) and fibronectin (3.38±0.42) in the kidney of WT mice associated with interstitial kidney fibrosis (6.49±0.70). This is fully prevented by Lcn2 deletion. Expression of macrophages markers F4/80, CD80 and CD68 was increased (5.11±0.46, 4.84±0.19 and 5.22±0.45 respectively) in WT NAS mice and partly prevented in Lcn2 KO mice. Macrophages isolated from Lcn2 KO or WT mice were co-treated with aldosterone (10^4 M) and NaCl (40Ml). In WT macrophages, expression of Lcn2 (2.81±0.30) and the CCL5 chemokine (2.48±0.32) was increased. The increase of CCL5 was blunted in Lcn2 KO macrophages. Similarly to Lcn2 inactivation, CCL5 receptor blockade improved renal fibrosis and reduced high levels of Th2 CD4+ cell markers induced by NAS. Neutralization of IL4, a Th2 cytokine, in NAS mice injected with anti-IL4 antibody blunted kidney fibrosis and overexpression of profibrotic proteins such as collagen I, a-SMA and fibronectin.

Conclusions: NGAL produced by macrophages plays a critical role in renal interstitial fibrosis through the CCL5/IL4 pathway in mice exposed to mineralocorticoid excess.

PO2129

Water Intake and Blood Pressure in Children: Results from the SPA Project

Background: The SPA Project studied blood pressure (BP) in relation to water (H2O) and Na intake with the working hypothesis that increased water intake can improve renal Na handling.

Methods: 339 healthy, non-overweight children (166 girls), 5.7 years old (IQR: 5.3–6.2) were characterized for: BP (using standardized multiple office BP measurement), Na and water intake (by means of urinary Na and creatinine from 4 samples taken in 4 different days). After categorizing subjects as low/high Na and low/high water intake (based on median value), BP was compared.

Results: Among children with higher Na intake, those introducing more water, showed a significantly (p=0.001) lower BP (both systolic and diastolic) compared to those who drink less (figure). This difference was not observed among children with lower Na intake.

Conclusions: Our findings support the hypothesis that an increased water intake, reduces high blood pressure in children. We speculate that this simple, highly acceptable, inexpensive and harmless measure might have a role in preventing and minimizing the epidemics of HPT and related morbidities.

654
expressed as % total gated kidney cells: Sham = 6±0.3%. ORX significantly decreased renal function, renal cortex area and volume in H&E images compared to sham group (p<0.001). The protein abundance of NCC (193.5±30) between renal CD81 and NCC, we treated mouse kidney distal tubule cells with LPS for 24h (n=4/group, same as below) and NCC (278.0±α) group) and urine protein (1185±35.0 vs 3550±180.0, μg/day, n=4-group) were higher in LPS group, but not significantly altered vs. sham despite having the lowest BP (ORX = 4±0.4%; HCTZ/Res = 5±3.0%; p=0.003). To begin to gain insight into the mechanisms mediating maturation-induced increases in nerosis, RIP3 and HMGB1 protein expression were measured in 5 and 15 wk old groups. Expression of RIP3 (1.9±0.1 vs 0.6±0.6, n=5-6; p=0.003) and HMGB1 (1.0±0.2 vs 0.7±0.1; P=0.005; n=5-6) were greater in 15 wk SIRPα interacts with the IGF-1 Receptor in CKD-Induced Cardiomyopathy
Jiao Wu,1 William E. Mitch,2 Sandhya S. Thomas,1,2 1Baylor College of Medicine, Houston, TX; 2US Department of Veterans Affairs, Houston, TX.
Background: A major consequence of chronic kidney disease (CKD) is associated with cardiomyopathy. Even at early stages of CKD with near normal GFR, and normal blood pressure, left ventricular hypertrophy (LVH) is present, which suggests an unidentified trigger unrelated to pressure overload. We now find that elevations of signal regulatory protein alpha (SIRPα), a substrate for tyrosine phosphorylases, in cardiac muscle adversely influences insulin signaling via the insulin-like growth factor-1 receptor (IGF-1R) in CKD.
Methods: SIRPα floxed (control) vs. muscle-specific (mSIRPα) KO mice were subjected to subtotal nephrectomy. The binding affinity between IGF-1R immunoprecipitate lysates and purified recombinant SIRPα was determined based on the association rate (ka) and the dissociation rate (kdis) constants using bio-layer interferometry (BLI; Octet RED384 systems). Finally, SIRPα vs. GFP plasmids were transfected into myotubes, and IGF-1R interactions were further validated using the BLI to assess protein quantities and characterization of kinetics. Specifically, IGF-1R was immunoprecipitated from cardiac muscle and the binding kinetics of Fc-tagged recombinant SIRPα (rSIRPα) to the IGF-1R was identified via BLI. We concluded that rSIRPα was bound to immunoprecipitated IGF-1R with a k of 147 μM, which further validate their interactions. Lastly, SIRPα plasmids were transfected into myotubes, which led to an upregulation of SIRPα and impaired activation of insulin signaling mediators (IGF-1R and pAKT) plus worsening muscle fibrosis when compared to control transfected cells.
Conclusions: SIRPα interacts with IGF-1R reducing receptor activities, confirming its role in regulating insulin/IGF-1 intracellular signaling in cardiac muscle while exacerbating cardiac muscle functions in CKD.

Increases in Renal CD81 and NCC Are Associated with Lipopolysaccharide-Induced Preeclampsia
Ping Wang,1 Gangyi Zhu,1 Yutao Jia,1 Yanting Yu,1 Xiaoyan Wang,1,2 1InQ Hospital of Nanjing Medical University, the Fourth Clinical Medical College, Nanjing, China; 2George Washington University, DC, WA.
Background: CD81, a member of the tetraspain superfamily, is an important component in the pathogenesis of pregnancy hypertension while the status of renal salt transport proteins plays an important role in blood pressure (BP) regulation. A rat model of pregnancy hypertension was built by injecting a small amount of LPS into the arterial wall. The development and cardiovascular events. Also, it is commonly observed in chronic kidney disease (CKD). The association between glomerular endothelial cell damage in diabetic nephropathy of KLF2 has been studied, but not in hypertensive nephropathy. Here, we present a role of KLF2 in hypertensive nephropathy.
Methods: Human primary glomerular endothelial cells were harvested and cultured under various duration, pressure condition by a rotational force device for mimic development of new therapeutics.
Conclusions: Our findings in vivo and in vitro suggest that LPS can cause an increase in protein abundance and mRNA expression of CD81 and up-regulate NCC in renal distal convoluted tubules, which could contribute to an increased blood pressure in pregnancy rats.

Neurogenic Tachykinin Mechanisms in Experimental Nephropathy of Rats
Kristina Rodionova,1 Tilmann Ditting,1,2 Gisa Tieg,3 Karl F. Hilgiers,1 Mario Schiffer,1 Christian Ott,1 Roland E. Schneider,1 Kerstin U. Amann,1 Roland Veelken,1,2 Friedrich-Alexander-Universitat Erlangen-Nurnberg, Nurnberg, Germany; Paracelsus Medizinische Privatuniversitat, Nuremberg, Germany; Universitatsklinikum Hamburg Eppendorf Zentrum für Experimentelle Medizin, Hamburg, Germany.
Background: We demonstrated earlier that renal afferent pathways combine very likely “classical” neural signal transduction to the central nervous system and a substance P (SP) dependent mechanism to control sympathetic activity. SP content of afferent sensory neurons is known to mediate neurogenic inflammation upon release. We tested the hypothesis that alterations in SP dependent mechanisms of renal innervation contribute to experimental nephritis.
Methods: Nephritis was induced by Ox-7 antibodies in rats, six days later instrumented for recording of blood pressure (BP), heart rate (HR), drug administration; intrarenal administration (IRA) of the TRPV1 agonist capsaicin to stimulate afferent renal nerve pathways containing SP and implantation of electrodes for renal sympathetic nerve activity (RSNA). The presence of the SP receptor NK-1 on renal immune cells was assessed by FACS.
Results: IRA: SP increased RSNA from 62±4±5 μV/sec to 21±6±1.5 μV/sec (p<0.003) in controls, a response impaired in nephritis. Suppressed RSNA in nephritic rats and controls transiently after systemic administration of a neurokinin 1 (NK1-R) blocker. NK-1 receptors occurred mainly on CD11+ dendritic cells (DCs). An enhanced frequency of CD11c+ NK1R+ cell, NK-1 receptor+ macrophages and DCs were assessed in nephritis. Administration of the NK-1 antagonist aprepitant during nephritis reduced CD11c+ NK1R+ cell, macrophage infiltration, renal expression of chemokines and markers of sclerosis.
Conclusions: Hence, SP promoted renal inflammation by weakening sympathoinhibitory mechanisms while at the same time substance SP released intraurally from afferent nerve fibers aggregated immunological processes i.e. by the recruitment of DCs.

Renoprotective Effect of KLF2 on Glomerular Endothelial Dysfunction in Hypertensive Nephropathy
Eunjin Baeg,1 Mi-yeon Yoo,1 Ji Eun Kim,1 Yong Kyun Do,1 Joon moo Jung,1,2 Dong Jun Park,1 Young Su Kim,1 Seung Hee Yang,1 Gyeongsang National University College of Medicine, Seoul, Republic of Korea; 2Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; 3Korea University Guro Hospital, Seoul, Republic of Korea; 4Ulsan University Hospital, Ulsan, Republic of Korea; 5Seoul National University College of Medicine, Seoul, Republic of Korea; 6Hanyang University Guri Hospital, Guri, Republic of Korea.
Background: KLF2 is a transcription factor, which regulates endothelial cell metabolism. KLF2 plays a role in maintaining normal vascular integrity by proinflammatory, anti-thrombotic, anti-angiogenic effects in endothelial cells. Endothelial dysfunction is associated with hypertension, and is a predictor of atherosclerosis development and cardiovascular events. Also, it is commonly observed in chronic kidney disease (CKD). The association between glomerular endothelial cell damage in diabetic nephropathy of KLF2 has been studied, but not in hypertensive nephropathy. Here, we present a role of KLF2 in hypertensive nephropathy.
Methods: Human primary glomerular endothelial cells were harvested and cultured under various duration, pressure condition by a rotational force device for mimic hypertensive nephropathy. We established the appropriate culture environment by rotate the cells on a rotating disk for 4mmHg pressure for 48hr in human primary glomerular endothelial cells, expression of KLF2 mRNA was decreased, while eSMA mRNA was increased and KLF4 mRNA was similar compared to control. 5/6 nephrectomy in rats resulted in increased blood pressure, decreased kidney function, as well as decreased KLF2 expression of glomerular endothelial cells. These findings suggest a new role for KLF2 in hypertensive nephropathy, which may be the basis for the development of new therapeutics.

Substance P: Differential Influences on Action Potential Production in Afferent Neurons of the Kidney?

Kristina Rodionova,1 Tilman Ditting,1 Christian Ott,2 Roland E. Schmieder,1 Mario Schiffer,1 Kerstin U. Amann,1 Roland Veelken,1,2 Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany; 3 Paracelsus Medizinische Privatuniversität, Nuremberg, Germany.

Background: Afferent nerve fibers of the kidney play a role in controlling sympathetic activity in hypertension and cardiovascular diseases. Proinflammatory substances influence the action potential production of these neurons. Therefore, we tested the hypothesis that proinflammatory substance P (SP) released from afferent nerves inhibits the action potential production in neurons with renal afferents.

Methods: Cultured dorsal root ganglion neurons (DRG TH1-L2) of rats with renal afferents were investigated in current clamp mode to assess action potential generation during both current injections and TRPV1 stimulation with protons (pH 6) with and without exposure to SP (0.5 μmol) or CGRP (0.5 μmol). Neuronal classification as tonic (high AP generation under stimulation) and phasic (AP ≤ 5 upon stimulation). Additional experiments were performed in voltage clamp mode to fully assess electrophysiological properties of the neurons.

Results: Renal neurons were stimulated with current injection (14.4±1.5 APs/600ms, p<0.05, mean±/SEM) and protons (9.6±1.9 APs/10s of stimulation with pH6). The co-stimulation of renal neurons with SP and pH decreased the number of action potentials in tonic neurons (15.2±2.1 APs/600ms vs. 10.1±1.6 APs/600ms, p<0.05, mean±/SEM), however superfusion of renal neurons with both protons (pH6) and SP increased (9.6±1.9 APs/60s vs. 16.9±2.3 APs/60s, p<0.05, mean±/SEM).

Conclusions: The proinflammatory SP but not CGRP was without significant effect under any circumstances.

Tonic Inhibition of Sodium Reabsorption by Na/K’-ATPase in the Renal Proximal Tubule

Shreya T. Mukherji,1 Luca Brambilla,1 Isabella Mayes,1 Laura C. Kutz,1 Jeff P. Mcclermont,2 Steven T. Haller,1 Michael F. Romero,1 Jiang Liu,3 Joseph I. Shapiro,2 Gustavo Blanco,3 Zi-jián Xic,1 Sandrine V. Pierre,1 1Marshall Institute for Interdisciplinary Research, Huntington, WV; 2Joan C Edwards School of Medicine at Marshall University, Huntington, WV; 3University of Toledo College of Medicine and Life Sciences, Toledo, OH.

Background: The renal proximal tubule (PT), Na/K’-ATPase (NKA) is exclusively located in the basolateral domain. Through its classic ATP-dependent ion-pumping function, NKA generates the Na+ gradient that drives apical Na’ reabsorption, mostly through Na/H’ exchanger (NHE3). Accordingly, activation of NKA-mediated ion transport decreases natriuresis through activation of basolateral (NKA) and apical (NCC) reabsorption (NHE3). In contrast, activation of the more recently discovered NKA/Src signaling is not only physiologically relevant, it is functionally dominant over NKA ion-pumping in the control of PT Na reabsorption. NKA signaling therefore provides a long sought-after mechanism for the natriuretic action of endogenous NKA ligands such as cardioselective steroids.

NPFFR2 in the Kidney via Novel Transcriptional and Posttranslational Mechanisms Triggers Molecular Responses to Salt

Laurenano D. Asico,1 Selim Rozveye,1 Jessica Hunt,1 Ron Jakob D. Domingo,4 Ines Armando,2 Pedro A. Jose,1 The George Washington University School of Medicine and Health Sciences, Washington, DC; 2Children’s National Health System, Washington, DC; 1University of Maryland at College Park, College Park, MD.

Background: Hypertension and salt sensitivity is dependent on NaCl intake. The kidney maintains sodium (Na) balance and blood pressure homeostasis. Neuropeptide FF (NPFF), is involved in nociception, hormonal modulation, and body temperature control. NPFF and its receptors, NPFFR1 and NPFFR2, are found in the kidney and have prohypertensive properties.

Methods: Renal restricted bolus or chronic infusion of NPFF raised blood pressure and reduced Na excretion (n=4) in C57Bl/6 mice. Silencing NPFFR1 had no effect but, silencing NPFFR2 raised UNaV (3 fold). NPFFR2 with the D1 dopamine receptor interacts. Both commonprecipitated (colp) and colocalized in human renal proximal tubule cells (bRPTCs) and whole kidney. NPFF and the D1R/D1R against fenoldopam (FEN) antagonized aCAMP production (2.5±0.1 pmol/mg/min for FEN vs. 1.23±0.2 for vehicle). Administration of 50 pmol of NaCl and Na transport (1.7±0.1 fold with FEN, 1±0.1 fold for vehicle, and 1.1±0.2 fold for both, n=4) in bRPTCs. Mice fed a 4% NaCl diet increased (~2.5 fold) the cAMP between renal NPFFR2 and D1R, enabling the D1R to limit NPFFR2 effects. A normal (145 μM) to low (90 μM) NaCl raised both promoter activity (~2.5 fold, n=3), mRNA and protein expression (n=4; 0.8-9 hr). A normal to high (175 μM) Na concentration reduced promoter activity (~0.5 fold), mRNA and protein expression of NPFFR2 (0-8 hr). The increased cAMP by prohypertensive NPFFR2 and antihypertensive D1R, resulted in an increased receptor antagonism to cAMP response and Na transport (vs FEN or NPFF treatment [1 mM/30 min], n=4).

PO2110

Age-Dependent Regulation of the NCC and the Development of Salt-Sensitive Hypertension

Kiyoun Kim, Franco J. Puleo, Alissa Frame, Mohammed Z. Ferdaus, Richard D. Wainford, Boston University School of Medicine, Boston, MA.

Background: The prevalence of hypertension (HTN) increases with age, and age-dependent HTN is associated with increased sympathetic tone and blood pressure (BP). Dietary sodium intake is a major risk factor for HTN as excessive dietary sodium intake leads to increases in BP in individuals that demonstrate the salt sensitivity of BP to evoke salt sensitive HTN (SSH). We have previously demonstrated excessive release of norepinephrine upregulates the activity of the renal sodium chloride cotransporter (NCC) to promote sodium reabsorption and salt sensitive hypertension. However, the regulation of the NCC with age remain unclear. Thus, we tested the hypotheses that 1) upregulation of NCC contributes to age-dependent HTN, and 2) aged rats develop SSH.

Methods: Three different age groups (5, 8, 16 month old (MO)) of male Sprague-Dawley (SD) rats were fed a normal salt (NS; 0.6% NaCl) or HS (4% NaCl) diet for 21 days respectively. On day 21, basal MAP and NCC activity (peak natriuresis to IV hydrochlorothiazide (2mg/kg) infusion) were measured in vivo. The expression of total NCC, phosphorylated NCC, with-no-lysine [K] kinases (WNK) 1, WNK4, STE20/SPS1-related proline-alanine-rich protein kinase (SPAK), oxidative stress responsive kinase 1 (OsxSR1), and phosphorylated SPAP/OsxSR1 were assessed via immunoblotting (N=6/gp).

Results: Male SD rats develop age-dependent HTN with increased NCC activity and expression, and increased WNK1 expression. Aged male SD rats developed SSH, impaired dietary salt evoked suppression of NCC activity, phosphorylation, and the expression of kinases SPAP and OsxSR1.

Conclusions: These data suggest that the NCC contributes to the development of age-dependent HTN. Moreover, dysregulation of the NCC may play a pivotal role in the development of age-dependent SSH.
Ang II infusion caused a greater rise in MAP (+30 ± 3% ; P < 0.05) and RVR (+190 ± 5%; P < 0.05) compared to CVR. All Ang II-stimulated responses (7 ± 5%; NS) were observed. **Conclusions:** Basal RVR and CVR depend on PG-dependent NO generation. Whereas CVR is entirely protected from vasoconstriction with Ang II, the increase in RVR with Ang II is moderated by PG-dependent NO generation. Thus, PGs and NO exert distinct action in the renal and cerebral vasculature.

**PO2143**

**The Intrarenal Ras Uregulates SGLT2 Expression and SGLT2 Inhibitors Attenuate Angiotensin-II Induced Hypertensive Kidney Injury in Mice**

Kana N. Miyata,1 Chao-Sheng Lo,1 Shuiling Zhao,1 Junzhen Peng,1 Matthias Kretzler,2 Janos G. Filep,3 Julie R. Ingeffinger,4 Shao-Ling Zhang,5 John S. Chan.6 1Centre Hospitalier de l’Université de Montreal Centre de Recherche, Montreal, QC, Canada; 2University of Michigan, Ann Arbor, MI; 3Hospital Massoneuve-Rosemont, Montreal, QC, Canada; 4Massachusetts General Hospital, Boston, MA.

**Background:** Clinical trials have shown that SGLT2 inhibitors (SGLT2i) improve both cardiac and renal outcome in several diseases. However, the mechanisms underlying regulation of SGLT2 gene expression remain unclear. Here, we studied whether the intrarenal renin-angiotensin-system (RAS) modulates SGLT2 expression and SGLT2i efficacy.

**Methods:** We analyzed the association between RAS-related genes and SGLT2 gene expression in the tubulointerstitial compartment of the kidneys of adult non-diabetic patients in the Nephrotic Syndrome Study Network (NEPTUNE). We compared SGLT2 expression in transgenic mice overexpressing angiotensinogen (Agt) in their renal proximal tubular cells (RPTCs) and Agt-Tg as a RAS blockers, and wild-type (WT) mice. We administered angiotensin II (AngII, 1000 ng/kg/min subcutaneously) in WT mice and a canagliflozin (Cana, 15mg/kg/day in drinking water for 4 weeks). We also studied human immortalized RPTCs (HK2) as an in vitro model.

**Results:** In human kidney samples (N=183 patients), SGLT2 mRNA was significantly correlated with Agt (r=0.55, P<0.001), Renin (r=0.46, P<0.001), ACE (r=0.47, P<0.001), and ATIR (r=-0.28, P<0.001), but not with AT2R. SGLT2-immunopositive staining was higher in RPTCs of Agt-Tg mice than in WT mice and this was attenuated by losartan treatment. Ang II infusion in WT mice significantly increased blood pressure, which was not reversed by Cana co-treatment. Ang II caused glomerulosclerosis, tubulointerstitial fibrosis, and albuminuria, which were all abated by Cana. Fractional glucose excretion was significantly higher in Ang II+Canan than in WT+Cana. In vitro, Ang II dose-dependently stimulated SGLT2 mRNA in HK2 cells, and these were inhibited by losartan.

**Conclusions:** Our data demonstrate that the intrarenal RAS upregulates SGLT2 expression and show that SGLT2i ameliorate AngII-induced kidney injury independent of blood pressure.

**Loss of Soluble (Pro)renin Receptor Attenuates DOCA-Salt Hypertension**

Nirupama Ramkumar,1 Deborah Stuart, Caitlin S. Peterson, William Wheatley, Donald E. Kohan. University of Utah Health, Salt Lake City, UT.

**Background:** Cleavage of the extra-cellular domain of the (pro)renin receptor (Prr) yields a soluble fragment (sPrr), which may be involved in mediating hypertension.

We recently developed a mouse model with mutation in the cleavage site of the Prr using CRISPR/Cas9 such that sPrr is not generated and showed that absence of sPrr attenuated angiotensin-II induced hypertension and kidney damage. In this study, we examined if sPrr alters blood pressure (BP) in angiotensin-II independent hypertension using deoxycorticosterone acetate (DOCA)-salt treatment.

**Methods:** Mutant sPrr mice and littermate controls were treated with DOCA (50 mg/kg) and high Na+ diet for 3 weeks. BP was monitored by radio-telemetry and metabolic balance studies performed on Day 17-18 of DOCA-salt treatment. Only male mice were studied as the Prr gene is on the X-chromosome.

**Results:** Compared to control male sPrr mice, female markedly lower sPrr levels (control: 21.5 ± 2.5 vs mutant 0.2 ± 0.3 ng/ml) and baseline BP (systolic control: 122 ± 3 vs mutant 114 ± 3; diastolic control: 94 ± 5 vs mutant 82 ± 3 mm Hg). BP remained low in mutant sPrr mice relative to controls following 12 days of DOCA-salt treatment (systolic control: 141 ± 2 vs mutant 132 ± 5; diastolic control: 110 ± 4 vs mutant 95 ± 5 mm Hg). Mutant sPrr mice had lower body weight but similar food intake and urinary albumin excretion compared to controls (Table 1). Mutant mice had lower urine volume, water intake and urinary K but not Na excretion. No differences in renal histology were noted between control and mutant sPrr mice.

**Conclusions:** Loss of sPrr attenuates DOCA-salt mediated hypertension. The mechanisms by which sPrr might regulate BP and water/Na homeostasis in DOCA-salt hypertension are currently being investigated.

Underline represents presenting author.
Hypertension, Saitama Medical Center, Saitama Medical University, Kawaoe, Japan, Paracelsus Medizinische Privatuniversität, Nuremberg, Germany.

**Results:** No significant difference in mean blood pressure was seen between two groups (NMD: 97.8±7.6 mmHg vs HMD: 94.2±9.0 mmHg, n=4), and serum Mg was elevated in HMD group (NMD: 1.5±0.13 mM/L vs HMD: 1.7±0.15 mM/L, n=4).

**Conclusions:** Hypertension nephroclerosis is one of the major causes of end-stage renal failure, and its suppression is important. It was confirmed that the outermedullary fibrosis was inhibited by high Mg diet, while there was no change in the blood pressure, indicating that anti-fibrotic effect of high Mg diet seemed to be an independent mechanism from the blood pressure. We report that claudin-16 expression is reduced and Mg excretion is increased in the interstitial fibrosis model (Shimizu, Magnesium Res 2018). These results suggest that high Mg diet has an inhibitory effect on fibrogenesis through suppressing the increased Mg-excretion.

**Effect of Dietary Magnesium Supplementation on Tubulointerstitial Damages in Angiotensin II-Induced Hypertensive Rats**

Kaori Takayanagi,1,2 Taiske Shizumizutama,1 Takatsugu Ishii,1 Hiroaki Harayama,2 Akira Kurosawatama,3 Masaaki Terao,2 Hajime Hasegawatama,1 Iikshika Kinokawai,1 Kawagoe Ekmia Clinic, Kawagoe, Japan.1 Department of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawaoe, Japan.

**Background:** Recently, it has been epidemiologically suggested that Mg deficiency promotes progressive renal damage, and conversely, it has been reported that Mg load to Cyclosporine A-induced renal damage models attenuates renal impairment. This study aimed to investigate the ameliorating effect of high Mg diet on the renal impairment by use of hypertensive nephroclerosis model.

**Methods:** Eight-week-old SD rats were subjected to continuous infusion of Angiotensin II by subcutaneously placed osmotic mini-pumps for 2 weeks (435 ng/kg/min) and then housed for 6 weeks. The food for animals was normal Mg diet (NMD): 4% NaCl+0.05% Mg or high Mg diet (HMD): 4% NaCl+0.5% Mg. PicroSirius Red staining was used to assess fibrosis, and immunostaining of Claudin-16, which is known to be down-regulated in the renal interstitial damage, was also performed.

**Results:** No significant difference in mean blood pressure was seen between two groups (NMD: 97.8±7.6 mmHg vs HMD: 94.2±9.0 mmHg, n=4), and serum Mg was elevated in HMD group (NMD: 1.5±0.13 mM/L vs HMD: 1.7±0.15 mM/L, n=4).

**Conclusions:** Hypertensive nephroclerosis is one of the major causes of end-stage renal failure, and its suppression is important. It was confirmed that the outermedullary fibrosis was inhibited by high Mg diet, while there was no change in the blood pressure, indicating that anti-fibrotic effect of high Mg diet seemed to be an independent mechanism from the blood pressure. We report that claudin-16 expression is reduced and Mg excretion is increased in the interstitial fibrosis model (Shimizu, Magnesium Res 2018). These results suggest that high Mg diet has an inhibitory effect on fibrogenesis through suppressing the increased Mg-excretion.

**Pharmacological Sympathetic Denervation of the Kidney with Angiotensin II Receptor Blockade?**

Kristina Seidelin,1,2 Dominik Ditting,1,2 Karl F. Hilgers,1 Christian Ott,1,2 Roland E. Schneider,1,2 Mario Schiffer,1 Kerstin U. Amann,1 Roland Veelken,1,2 Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany.1 Paracelsus Medizinische Privatuniversität, Nuremberg, Germany.

**Background:** A putative interaction between angiotensin II (Ang II) and the renal sympathetic nervous system has been described. We tested the hypothesis that the angiotensin II receptor inhibitor candesartan mimicks a functional renal sympathetic denervation not distinguishable from surgical renal nerve ablation.

**Methods:** Measurement of arterial blood pressure (MAP), heart rate (HR), renal sympathetic nerve activity (RSNA), glomerular filtration (GFR), renal plasma flow (RPF), urine volume and urinary sodium. To assess neural control of volume homeostasis, 21 days after the induction of congestive heart failure (CHF) via myocardial infarction rats underwent volume expansion (0.9% NaCl, 10% body weight) to decrease RSNA. CHF rat and controls with or without renal denervation (DNX) or pretreated with the angiotensin II type 1 receptor antagonist candesartan (0.5 ug i.v.) were studied.

**Results:** CHF rats excreted only 68.5% of the volume load in 90 min. CHF rats pretreated with candesartan or after DNX excerted from 92% to 103% like controls. Decrease of RSNA induced by volume expansion were impared in CHF rats but unaffected by candesartan pointing to an intrarenal drug effect. GFR and RPF were not significantly different in controls or CHF rendering mere hemodynamic effects on sodium and water excretion unlikely. 0.5 mg candesartan did not inhibit the pressor response to i.v. Ang II as compared to higher blood pressure lowering doses.

**Conclusions:** The prominent function of increased RSNA – retaining salt and water – could no longer be observed after renal Ang II receptor blockade in CHF rats mimicking renal nerve ablation. Since inhibitors of the renin-angiotensin system are nowadays standard treatment of patients with CHF and hypertension, the role of efficient sympathetic denervation in these patients needs further meticulous scrutiny.

**Atrial Natriuretic Peptide Deficiency Alters Mitochondrial Bioenergetics in Dahl Salt-Sensitivity Rats**

Mark Dandona, Regina F. Sultanova, Ryan Schibalski, Daria Ilatovskaya. Medical University of South Carolina, Charleston, SC, US, Charleston, SC.

**Background:** In the heart and fat tissue, Atrial Natriuretic Peptide (ANP) is known to affect mitochondrial bioenergetics. However, little is known about the effects of ANP on mitochondria in the kidney, especially in the context of salt-sensitivity (SS).

We hypothesized that in SS hypertension ANP deficiency causes renal mitochondrial dysfunction and contributes to end-organ damage.

**Methods:** Hypertension was induced in male SS Nppa−/− (Nppa encoding for ANP) knockout in Dahl SS background and SS WT (wild type Dahl SS) rats by a 21-day long high salt diet challenge (HS, 4% NaCl). Normal salt diet (NS, 0.4% NaCl) was given to age-matched control animals. A combination of in vitro techniques and studies on isolated renal mitochondria (seahorse respiration and spectrofluorometry assays) were used to test the role of ANP knockout in mitochondrial bioenergetics.

**Results:** SS Nppa−/− rats exhibit exacerbated salt-sensitivity of blood pressure and kidney injury when challenged with a HS diet. In order to test mitochondrial function in this model, we measured membrane potential and levels of superoxide and H2O2 in renal cortical mitochondria. TMRM, Amplex Red and MCLA were used to detect mitochondrial calcium leakage within the ETC. A Western analysis revealed that in SS WT rats SOD2 levels are increased in the knockout rats on HS, while in HS fed SS WT rats SOD2 was down-regulated.

**Conclusions:** Lack of circulating ANP results in changes of mitochondrial bioenergetics in the renal tissue via effects on calcium uptake, and alters respiratory chain activity leading to changes in ROS production. Further studies will advance the understanding of the mitochondria-mediated mechanisms affecting renal damage susceptibility in SS hypertension.

Inhibition of Mineralocorticoid Receptor Ameliorates Salt-Sensitive Hypertension After Ischemic-Reperfusion Injury in Rats

Takumi Ito,1 Shigehiro Doi,1 Ayumu Nakashima,1 Takao Masaki.1
1Department of Nephrology, Hiroshima University Hospital, Hiroshima, Japan; 2Department of Stem Cell Biology and Medicine, Graduate School of Biomedical & Health Sciences, Hiroshima University, Hiroshima, Japan.

Background: The transition from acute kidney injury (AKI) to chronic kidney diseases (CKD) is a major pathway for progression to end-stage kidney disease. Although hypertension is reported to be associated with the clinical progression of chronic kidney disease, the mechanism by which AKI induces hypertension remains elusive. Previous studies have demonstrated that salt-sensitive hypertension occurs in rats after ischemic-reperfusion injury. In the present study, we investigated a rodent model of AKI, and that distal nephrons play an important role in the development of salt-sensitive hypertension. Herein, we investigated the role of the mineralocorticoid receptor (MR) in the progression of IRI-induced salt-sensitive hypertension in rats.

Methods: Seven days after right nephrectomy, IRI was induced by clamping of the left renal artery for 45 min in 8-week-old male Syrian-Dawley rats. Rats were sacrificed at 7 days after IRI, and expression of MR examined. IRI rats were also given drinking water with 1% sodium chloride (IRI/NaCl), or were implanted with an osmotic mini-pump to infuse aldosterone (IRI/Aldo). Esaxerenone (3 mg/kg/day; a non-steroidal MR antagonist [MRA]), or vehicle were administrated in IRI/NaCl and IRI/Aldo rats for 6 weeks. Blood pressure and urinary protein level were measured weekly during the study period. Protein expression in renal tissues was examined by immunoblotting and/or immunohistochemistry.

Results: MR expression was increased at 7 days after IRI. Further, blood pressure and urinary protein excretion increased in IRI/NaCl and IRI/Aldo rats over the 6-week observation period, whereas these effects were negated by MRA administration. Similarly, MRA ameliorated the expression of α-ENaC and γ-ENaC, and fibrotic markers, but not β-ENaC or NaCl cotransporter channel in both IRI/NaCl and IRI/Aldo rats.

Conclusions: Upregulation of MR, β-ENaC, and γ-ENaC may play a pivotal role in the development of salt-sensitive hypertension in rats after IRI.

The Effect of Epidermal Growth Factor Inhibition on Salt Sensitivity in Mice

Keyona King,1,2 Robert S. Hoover.1,2 Emory University School of Medicine, Atlanta, GA; 3Veterans Affairs Health Care System Atlanta, Atlanta, GA.

Background: Every year in the United States, more than 3 million adults are determined to have high blood pressure. Studies have shown that the epidermal growth factor (EGF) decreases the open probability of the epithelial-Na+ channel (ENaC) along the apical surface of the kidney cortical collecting duct (CCD). Yet, it is unknown whether EGF influences renal Na+ transport via the Na+-Cl- cotransporter (NCC). Our laboratory has investigated whether EGF regulates NCC. We performed various in vitro experiments using mouse distal convoluted (mDCT-15) cells and found that EGF decreases NCC protein expression in renal tissues was examined by immunoblotting and/or immunohistochemistry.

Methods: Using radio-telemetry, we collected the systolic blood pressure (SBP) measurements in five male mice ages 7 weeks old. These animals received a low salt (LS) diet (0.4% Na chow) for 6 days and high salt (HS) diet (4% Na chow) for 8 days. Over a period of two weeks, only the experimental (E) group (n=3) received gefitinib (an EGF receptor tyrosine kinase inhibitor) at a regimen of 100 mg/kg/d given orally while the control (C) group (n=2) received a placebo.

Results: The results showed the E group had less of a decrease in their SBP during the C group (E group: -9.7 ± 0.066 vs. C group: -14.4 ± 0.33 mmHg, p<0.001; delta = 4.7 mmHg, p<0.001). When increasing the dietary Na+ intake by giving the HS diet, once again the E group demonstrated an attenuation of their ability to lower their SBP during rest compared to the C group (E group: -7.3 ± 0.18 vs. C group: -13.5 ± 0.001; delta = 6.1 mmHg, p<0.001), which shows that the C group maintained a greater decrease in their resting SBP compared to the E group.

Conclusions: Overall, our results suggest that inhibition of EGF leads to decreased dipping in SBP regardless of the dietary Na+ intake and this effect is greater with a high dietary Na+ intake. Therefore, our data is the first to suggest that EGF may play a role in the nocturnal dipping of BP, which could have potential implications for managing HTN-related cardiovascular disease.

Aetiological Subtypes of Transient Ischemic Attack and Ischaemic Stroke in CKD: A Population-Based Study

Dearbhla Kelly,1,2 Peter M. Rothwell.1,2 Oxford Vascular Study Wolfson Centre for the Prevention of Stroke and Dementia, Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, United Kingdom.

Background: Chronic kidney disease (CKD) is strongly associated with stroke risk but the mechanisms underlying this association are unclear, and might be informed by aetiological subtypes (AS). However, few studies have reported stroke subtypes in CKD according to established classification systems such as the Trial of ORG 10172 in Acute Stroke Treatment (TOAST) criteria. We therefore aimed to determine which transient ischaemic attack (TIA) and ischaemic stroke subtypes using the TOAST classification occurred most frequently in patients with CKD.

Methods: In a population-based study of all TIA and stroke (Oxford Vascular Study; 2002-2017), all ischaemic events were classified by TOAST subtypes (cardioembolism, large artery disease, small vessel disease, undetermined, multiple, other aetiology, or undetermined (not investigated). Logistic regression was used to determine the relationship between CKD (defined as an estimated glomerular filtration rate [eGFR] < 60 ml/min/1.73m2) and TIA/stroke subtypes adjusted for age, sex, and hypertension, and then stratified by age and eGFR category.

Results: Among 3178 patients with TIA (n=1167), ischaemic stroke (n=1802), and intracerebral haemorrhage (n=209), 1267 (40%) had CKD. Although there was a greater prevalence of cardioembolic events (31.8 vs. 21.2; p<0.001) in patients with CKD, this association was lost after adjustment for age, sex, and hypertension (Adjusted
Identification of Novel Biomarkers and Pathways for Coronary Artery Calcification in Non-Diabetic Patients on Hemodialysis Using Metabolomic Profiling

Wei Chen,1,2 Jessica Fitzpatrick,2 Stephen M. Sozio,3 Bernard G. Jaar,3 Michelle M. Estrella,4 Dario F. Rioscios-Bernal,5 Tong tong Wu,6 Yunping Ou,7 Irwin J. Kurland,8 Ruth F. Dubin,9 Yabin Chen,8 Rulan S. Parekh,10 David A. Bushinsky,11 Nicholas Sibiga,12 PACEMonterey Medical Center, Bronx, NY; 2Hospital for Sick Children, Toronto, ON, Canada; 3Johns Hopkins University, Baltimore, MD; 4San Francisco VA Medical Center, San Francisco, CA; 5University of California San Francisco, San Francisco, CA; 6University of Rochester Medical Center, Rochester, NY; 7Yeshiva University Albert Einstein College of Medicine, Bronx, NY; 8University of Alabama at Birmingham, Birmingham, AL.

Background: A better understanding of pathophysiology involving coronary artery calcification (CAC) in hemodialysis (HD) patients will help to develop new therapies. We sought to identify the differences in metabolomics profiles between HD patients with and without CAC.

Methods: This is a case-control study nested within a cohort of 568 incident HD patients from the Predictors of Arteriographic and Cardiovascular Risk in ESRD (PACE) study. Cases were non-diabetics with a CAC score >100 (n=51), and controls were non-diabetics with a CAC score of 0 (n=48). We measured 452 serum metabolites in each participant using liquid chromatography–mass spectrometry. Metabolites and pathway scores were compared using Mann–Whitney U tests, partial least squares-discriminant analyses, and pathway enrichment analyses. Multiple logistic regression was used to examine associations between metabolites and presence of CAC.

Results: Cases had a median CAC score of 466 (IQR 246-981). Compared to controls, cases were older (64.13 vs. 42.12 years) and were less likely to be African American (51% vs. 94%). We identified three metabolites in bile acid synthesis (chenodeoxycholic, deoxycholic, and glycolithocholic acids) and one metabolic pathway (arginine/proline metabolism) that were associated with CAC. After adjusting for demographic factors, higher levels of chenodeoxycholic, deoxycholic, and glycolithocholic acids were associated with higher odds of having CAC. Comparing the third with the first tertile of each bile acid, the adjusted OR (95% CI) was 6.34 (1.23–36.06), 6.73 (2.10–21.37), and 8.83 (1.50–48.49), respectively. Using the first principal component (P1) score, arginine/proline metabolism was associated with CAC after adjusting for demographic factors [OR: 1.83 (95% CI: 1.06-3.15) per 1 unit higher in P1 score], and the association remained significant after additional adjustment.

Conclusions: Among HD patients without diabetes mellitus, chenodeoxycholic, deoxycholic, and glycolithocholic acids may be potential biomarkers for CAC, and arginine/proline metabolism may emerge as a new pathway in the pathogenesis of CAC and could be a potential treatment target.

NaRE: A Novel “Salt Response Element” in the NPFFR2 Gene Promoter and Antagonist of the D1 Dopamine Receptor

Selin Rozvyev,1,2 Lauraneo D. Asico,3 Jessica Hunt,2 Pedro A. Jose,3 Van Anthony M. Villar,2 Children’s National Hospital, Washington, DC, 4The George Washington University School of Medicine and Health Sciences, Washington, DC.

Background: The neuropeptide FF receptor R2 (NPFFR2) is one of two receptors that correspond to a low sodium diet (<0.04 g sodium/day) and reduced further the decreased systolic blood pressure caused by the low sodium diet (65±50 mm Hg vs. 83±3.1±3, P=0.05). We then studied a mechanism by which NPFFR2 dynamically interacts with the D1 receptor (NPFFR2 and D1 co-immunoprecipitated and colocalized in both kidney and brain tissue). As a proof of concept, we used the established rat model of renal hypertension and demonstrate that NPFFR2 and D1, thus increasing the ability of NPFFR2 to antagonize the D1 effects.

Conclusions: Our data are the first to identify NaRE and demonstrate novel transcriptional and post-translational mechanisms by which mammalian genes respond to sodium.

Discovery and Characterization of Small-Molecule Potentiators of K+1.5.1

Samantha J. Mcclenahan, Jerod S. Denton, Vanderbilt University Medical Center, Nashville, TN.

Background: Heterotetrameric inward rectifier potassium (Kir) channels composed of Kir4.1 (KCNJ10) and Kir5.1 (KCNJ16) play key roles in regulation of sodium, potassium, and water balance by the distal convoluted tubule of the renal tubule. Loss-of-function mutations in KCNJ10 lead to EAST syndrome, which is characterized by renal salt wasting and neurological dysfunction. Here we describe the discovery and characterization of small-molecule potentiators of Kir4.1/5.1 that could potentially be used to rescue the function of EAST syndrome mutant channels.

Methods: We established a monoclonal HEK-293 cell line that stably expresses human Kir4.1 and Kir5.1 from a bicistronic vector, and developed and validated a fluorescence-based thallium-flux assay of Kir4.1/5.1 channel function in 384-well format. This assay was used to screen small-molecules from the Vanderbilt Chemical Library and confirmed with whole-cell electrophysiology.

Results: To date, we have screened more than 60,000 compounds using this assay and identified 420 putative inhibitors and 354 putative potentiators of Kir4.1/5.1. Forty-five of these potentiators increase Kir4.1/5.1-mediated thallium flux by greater than 50% and are selective for Kir4.1/5.1 over homomeric Kir4.1 channels. Fourteen (14) potentiators are active at low single micromolar concentrations with EC50 values of 0.1±0.5 μM, while six (6) compounds appear to be highly efficacious and increase Kir4.1/5.1-mediated thallium flux by more than 100%. Importantly, we have also verified with patch clamp electrophysiology the activity of one of the first-in-class activator of Kir4.1/5.1, termed VU206. In thallium flux assays, VU206 potentiates thallium flux dose-dependently with an EC50 of 1.9 μM and maximal efficacy of ~50% above baseline between 10-30 μM. In whole-cell patch clamp experiments, VU206 led to maximal activation of whole-cell currents at 10 μM, complementing the thallium assay. Analysis of current-voltage relationships showed robust activation at both negative and positive test potentials without a depolarizing shift in the reversal potential suggesting VU206 potentiates Kir4.1/5.1 activity without affecting ion selectivity.

Conclusions: Findings from this study provide a novel pharmacological tool for exploring renal Kir4.1/5.1 channel integrative physiology and therapeutic potential of Kir4.1/5.1 potentiators for the treatment of EAST syndrome.

Improvement in Albuminuria and Hypertension in Renin Transgenic Mice by a Novel Filterable Form of Angiotensin-Converting-Enzyme 2 with Prolonged Half-Life

Jan Wysoczynski,1 Arndt Schulze,2 Gvaneta Gulaia,3 Minghao Ye,4 Daniel Batle,1 Northwestern University Feinberg School of Medicine, Chicago, IL, 2Charite Universitaetsmedizin Berlin, Berlin, Germany.

Background: ACE2 is a monocarbboxypeptidase that converts angiotensin (Ang) II to Ang 1-7. Its large molecular size precludes it from being filtered by the kidneys. We have developed smaller, filterable forms of ACE2 (VU206) and human renin-binding protein (rPBP) but, like the native ACE2, have a short (hours) half-life in vivo. We bioengineered a fusion protein using an albumin binding domain (ABD) and tested its long-lasting effects in mice transgenic for an unregulated secretion of Renin/Ren TMG.

Methods: Short soluble mouse(m) and human(h) ACE2 variants were fused with Albumin-Binding Domain(ABD). In vivo pharmacokinetic was determined after i.v. and i.p. injection followed by repeated measurement of plasma ACE2 activity. Subsequently, m and h rACE2-ABD(2 mg/kg) were injected every 2-3 days s.p. to Ren TMG mice. The undepolymerized included urinary albumin and blood pressure were determined.

Results: Administration of 619-ABD to ACEZKO mice resulted in detectability of urinary ACE2 activity which at the baseline was not detectable. Blocking proximal tubule (PT) reabsorption with L-lysine, further increased urinary ACE2 activity suggesting that the ABZ-attached ACE2 undergoes uromeric filtration and is taken up by PT. In WT mice, augmentation of plasma ACE2 activity could still be shown a week after administration. In Ren TMG mice, both m and h ACE2-ABD markedly reduced SBP and ACR(Figure). Conclusions: A shorter soluble ACE2 variant fused with ABD exhibits a prolonged half-life and maintaining ACE2 activity which is filterable and re-absorbable by the proximal tubule, thereby providing increased kidney ACE2 activity
as well as circulating plasma ACE2 activity. Its efficacy was documented by reduced BP and ACR in Ren TgMK, a hypertensive model due to RAS activation. Thus, this novel ACE2 variant with extended half-life offers potential for treatment of kidney disease and hypertension.

**Title:** Fibroblast Growth Factor 23 Induces Ventricular Arrhythmias and Prolongs QTc Interval in Mice In Vivo Mediated Through FGF Receptor 4

**Authors:** Julian Vallejo, 1 Derek Wang, 1 Jonah M. Graves, 1 Christian Faul, 2 Michael J. Wacker. 1

1. Department of Biomedical Sciences, School of Medicine, University of Missouri-Kansas City, Kansas City, MO; 2. Division of Nephrology, Department of Medicine, The University of Alabama at Birmingham, Birmingham, AL.

**Background:** Sudden cardiac death and arrhythmias are leading causes of mortality in those with compromised renal function, such as in chronic kidney disease (CKD). Fibroblast growth factor 23 (FGF23) is a phosphaturic hormone released by osteocytes, which becomes markedly elevated in CKD. Previously, we found that FGF23 increases intracellular Ca²⁺ in cardiomyocytes and alters contractility in mouse ventricles ex vivo via stimulation of FGF receptor 4 (FGFR4). Since FGF23 could disrupt Ca²⁺ homeostasis, we hypothesized that FGF23 at pathological levels would alter depolarization/repolarization of the heart and induce arrhythmias in vivo via a mechanism involving FGFR4.

**Methods:** To assess our hypothesis, CD-1 male mice (3 months old) were anesthetized and electrocardiogram (ECG) needle electrodes were inserted into the limbs. The jugular vein was cannulated for infusion of vehicle or FGF23 (9ng/ml total blood volume) with and without pretreatment with an FGFR4-specific blocking antibody (anti-FGFR4; U3 Pharm). Lead II ECG and arrhythmias were monitored at baseline and then for 30 minutes post injection.

**Results:** FGF23 induced premature ventricular contractions (PVCs) in 5 out of 11 mice (P=0.038 vs vehicle) with an average maximal rate of PVCs in these mice of 10.2 ± 5.2 PVCs/minute (P=0.01 vs vehicle). Vehicle (n=9) and FGF23/anti-FGFR4 treated (n=8) mice did not exhibit PVCs. Treatment with Isoproteonol (0.1mg/kg) after FGF23 further augmented arrhythmias to a maximal rate of 25.0 ± 21.1 PVCs/minute (P=0.05 vs vehicle) and 2 out of 8 mice displayed ventricular tachycardia. Upon examination of ECG intervals, FGF23 prolonged QTc within 30 minutes (P=0.05, n=8) compared to vehicle treatment (n=9), whereas no effect was found for PR interval or QRS duration. FGFR4 blockade abrogated the FGF23 prolonging effects of FGF23 (n=8).

**Conclusions:** We conclude that FGF23/FGFR4 signaling in the heart may contribute to ventricular arrhythmogenesis and repolarization disturbances commonly observed in patients with CKD and may be an important therapeutic target to reduce cardiac mortality in CKD.

**Title:** Use of Immune Checkpoint Inhibitors in ESKD

**Authors:** Rimirul Wanchoe, Jia Hwei Ng, Jamie S. Hirsch, Rushang Parikh, Yurii Khanin, Kenzar D. Jhaveri. Northwell Health, Great Neck, NY.

**Background:** Use of immune checkpoint inhibitors (ICI) in ESKD patients is limited. We describe our single-center experience of ICI use in ESKD patients and summarize the current literature.

**Methods:** Using an analytics database, we identified all patients with a minimum of one ESKD diagnosis code who received ICI therapy at our health system. Charts were reviewed manually to confirm that patients were on HD or PD during the ICI therapy. Clinical details such as demographics, comorbidities, cancer type, immune-related adverse events (irAEs), cancer disease status, and patient survival were reviewed. Further literature search was performed for all published cases of ICI use in ESKD patients and was summarized as part of the methods.

**Results:** In total, 5 patients with ESKD were initiated on ICI. A variety of malignancies were identified. Four patients received pembrolizumab, two received nivolumab, one received both ipilimumab and nivolumab, and the last received PD-1 inhibitor. Eight patients were receiving protease inhibitors. The mean duration on dialysis (dialysis vintage) prior to ICI therapy was 15.8 months (range: 3-60 months). Two patients had an immunotherapy-related adverse event. In both cases, the physicians discontinued the offending ICI agent and started the patients on systemic steroid therapy. Both patients subsequently suffered from kidney transplant rejection.

**Conclusions:** Our series and previously published literature review, the rate of adverse events appear similar to non-ESKD patients (15-25%). ESKD may not be a contraindication to the use of ICI therapy.

**Title:** AKI as a Risk Factor for Mortality in Oncological Patients Receiving Immunotherapy

**Authors:** Clar García-Caro, 1 Mónica Bolufer, 1 Roxana Bury, 1 Eva Muñoz, 2 Fernando Ferrer, 2 Alejandra Gabaldon, 1 María Jose Careyza, 1 Daniel Serón, 1 María Jose Soler. 2

1. Hospital Vall d’Hebron, Nephrology Department, Barcelona, Spain; 2. Hospital Vall d’Hebron, Neoplastic Department, Barcelona, Spain; 2. Hospital Vall d’Hebron, Pharmacy Department, Barcelona, Spain.

**Background:** Checkpoint inhibitors (CI) are used to treat cancer by promoting immune-mediated elimination of tumor. CPI-associated AKI (CPI-AKI) is an adverse effect and its incidence is 13-29%. The effect of CPI-AKI on patient survival is unknown. Our aim was to evaluate if CPI-AKI is a risk factor for mortality in patients with cancer under immunotherapy.

**Methods:** We evaluated data of all patients under CPI at our centre between March 2018-May 2019 and followed-up until April 2020. We divided them into 2 groups according to the development of CPI-AKI. Kaplan-Meier and Cox survival analysis comparing patients who developed CPI-AKI with those who did not were performed.

**Results:** 821 patients received CPI during the study period. Mean age was 62.03 years and 59.2% men. Malignancies: lung 30.3%, urogenital 20.5%, melanoma 10.8%, others 34.3%. 54.34% patients received antiPDL1, 28% antiPDL1, 1.6% antiCTLA4, 4.4% other drug, 11.7% two CPI. Mean baseline creatinine was 0.85±0.30 mg/dl. 125 patients (15.2%) developed CPI-AKI. 790 patients completed follow up and were included in the survival analysis, including all with CPI-AKI. Mean time of follow up 13.20months. 50.8% patients had died at the end of follow up, mean time after starting CPI 8.60 months.

**Conclusions:** Based on our series and previously published literature review, the rate of adverse events appear similar to non-ESKD patients (15-25%). ESKD may not be a contraindication to the use of ICI therapy.

**Title:** A Single-Center Cohort Study of Nephrotoxicity due to Immune Checkpoint Inhibitors

**Authors:** Craig T. Irwin, Jennifer Panic, Fahad A. Lodhi, Joshua T. Lee, Sabri E. Elkhidir, Connie M. Folz, Soumya Pulipati, Adam M. Bissonnette, Zefi Fatima, Rebecca Blonsky, Chady A. Leon, Siddhartha Kattamanchi. Marshfield Clinic Health System, Marshfield, WI.

**Background:** Previous studies and case reports have demonstrated an increased risk of nephrotoxicity in patients receiving immunotherapy inhibitors (CI) compared to clinical trials. The primary objective of this study was to contribute to the existing data regarding the frequency, causes of, and risk factors for CPI-induced AKI.

**Methods:** This was a retrospective cohort study of patients receiving at least one dose of a CPI at a health system in Central Wisconsin from 2013 to 2019. Baseline serum creatinine, defined as the average of all values obtained within 6 months of the CPI start date, was compared to the average serum creatinine minimum during CPI therapy and through 60 days after the last CPI dose. Patients developing an AKI of at least three day duration were further assessed to determine the likely cause of AKI, with the incidence of potentially CPI-induced AKI being our primary outcome.

**Results:** A total of 936 patients were included at least one dose of a CPI at MCHS during the study period. After applying exclusion criteria, a total of 910 patients were included in the analysis. A total of 8.4% of patients (76 of 910) were on CPI therapy (ipilimumab)
AKI is acute interstitial nephritis. The risk appears to be increased if a patient has already had AKI. In our population, it occurred at an incidence of 3.2% and sometimes occurred even after the last dose of CPI. The etiology of AKI in almost all cases of biopsy-proven CPI-induced AKI is acute interstitial nephritis.

Background: The percentage of cancer patients eligible for checkpoint inhibitor (CPI) therapy has increased rapidly over the past few years and approaches 45%. As a result, more cases of CPI-related nephrotoxicity, including AKI, are being reported. To elucidate the clinical presentation of CPI-associated vasculitis with kidney involvement and its possible mechanisms, treatment options, and prognosis, we describe the cases from a comprehensive cancer center and reviewed the literature for similar cases.

Methods: We retrospectively reviewed the charts of all cancer patients from 2014 to 2020 who were diagnosed with CPI-related nephrotoxicity and underwent a kidney biopsy.

Results: We identified 5 cases of vasculitis with kidney involvement: 3 patients were diagnosed with renal vasculitis, 1 case with ANCA vasculitis, and 1 case with Immunoglobulin A (IgA) vasculitis. Of these cases, 4 patients were receiving nivolumab, and 1 patient was receiving tremelimumab. All patients had microscopic hematuria, four out of five had negative anti-neutrophil cytoplasmic antibodies (ANCA) serology, one patient had concurrent lung involvement and positive ANCA serology, and all had severe acute kidney injury with creatinine > 4.50 mg/dL upon diagnosis. All patients were treated by discontinuing CPI and initiating corticosteroids and rituximab. Three patients received plasmapheresis; 2 of these required renal replacement therapy (RRT) including the patient with lung involvement. All patients after rituximab had partial or complete renal response. Two patients died within 8 months of diagnosis due to malignancy progression. None of the patients had a relapse of vasculitis.

Conclusions: We demonstrated that CPI can be associated with different types of vasculitis with kidney involvement that are predominantly ANCA negative and manifest as severe acute kidney injury. Despite the lack of strong evidence, treatment similar to that of primary ANCA vasculitis with corticosteroids and rituximab is well tolerated with favorable renal outcomes.

**Immune Checkpoint Inhibitor–Associated Glomerular Disease: A Systematic Review and Meta-Analysis**

Abhijit Kitchlu, Kenar D. Shaveri, Shikha Wadhwani, Priya Deshpande, Ziv Harad, Tetsuko Kishibe, Kammi J. Henrikson, Rimda Wanchoo, University Health Network, Toronto, ON, Canada; 1Northwestern University Feinberg School of Medicine, Chicago, IL; 2Icahn School of Medicine at Mount Sinai, New York, NY; 3St. Michael’s Hospital, Toronto, ON, Canada; 4Columbus, OH

**Background:** Immune checkpoint inhibitors (ICI) are associated with acute interstitial nephritis (AIN). However, as their use continues to increase, we observe other renal manifestations being described. Distal renal tubular acidosis (dRTA) has been described, but the mechanism is not clear to date.

**Methods:** We performed a systematic review and meta-analysis of all biopsy-proven cases of glomerular pathology associated with ICI therapy. We searched the MEDLINE, EMBASE and Cochrane Central databases from inception to February 2020. We abstracted patient-level data, including demographics, cancer and ICI therapy details, and characteristics of kidney injury. We performed exploratory univariate logistic regression analysis for predictors of end-stage kidney disease (ESKD) or death.

**Results:** After screening, 27 manuscripts with 45 cases of biopsy-confirmed ICI-associated glomerular disease were identified. Several types of lesions were observed, with the most frequent being pauci-immune glomerulonephritis and renal vasculitis (27%), minimal change disease (MCD) (20%), and C3 glomerulonephritis (11%). Concomitant AIN was reported in 41% of cases. The majority of patients had ICI discontinued (88%), and nearly all received corticosteroids (98%). Complete or partial remission of proteinuria was achieved in 45% and 38%, respectively. Most patients had full (31%) or partial (42%) recovery from AKI although 19% required dialysis and approximately one-third of patients died. In exploratory univariate logistic regression for predictors of end-stage kidney disease (ESKD) or death, glomerular lesion, ICI class, peak level of ICI therapy, and line of therapy remained significant in multivariate analysis (p=0.009) and line of therapy (p=0.033) were all associated with development of AKI, and RCC, BMI, and line of therapy remained significant in multivariate analysis (p=0.0125). Overall survival (OS) was 12.2 months in absence of AKI vs 10.7 months with AKI (p=0.0125). Statin use (p=0.007) and RCC diagnosis (p=0.012) were significantly associated with RirAE with a trend to higher rates in combination immunotherapy (p=0.064). These three variables were also significant in multivariate analysis. OS was not different in the RirAE group (10.8 months) vs no RirAE group (11.8 months).

**Conclusions:** Patients undergoing ICI therapy can develop AKI as well as RirAE. However, outcomes are worse for AKI. Survival for pts who develop RirAE does not appear to differ from patients without RirAE. AKI and RirAE share an independent risk factor in RCC. However, statin use and combination ICI therapy appear to be unique risk factors for RirAE. Further studies are needed to verify the finding regarding statin use, a drug with widespread use.

PO2166

**Statin Use, Renal Cell Carcinoma, and Combination Immunotherapy: Increase Risk of Checkpoint Inhibitor-Induced Nephritis: A Single-Center Database Study**

Jason Prosek, Dwight Owen, Marium Husain, Lai Wei, Gabrielle A. Lopez, Songhua Zhao, The Ohio State University Wexner Medical Center, Columbus, OH.

**Background:** Immune checkpoint inhibitors (ICI) are associated with improved cancer outcomes, however immune related adverse events (irAE) develop and are poorly understood. Renal irAE (RirAE) are less common but may jeopardize effective cancer therapy, and no reliable risk factors for RirAE have been identified. Concomitant medications have been shown to play a role in response to ICI but the impact on toxicity is unknown. We report risk factors and clinical outcomes of patients who develop RirAE.

**Methods:** We queried a patient database with advanced cancer treated with ICI between 2010 and 2017 at Ohio State Univ for pts who developed AKI (defined as a doubling of creatinine after initiation of ICI) irAEs were reviewed by nephrologist and oncologist. Overall survival (OS) was calculated from date of initiation of ICI to death from any cause or date of last follow-up. Associations between irAE incidence and categorical outcomes were studied using chi-square or Fisher’s exact test. The Wilcoxon test was used for continuous outcomes. Survival outcomes were studied using log-rank test or cox regression model.

**Results:** Of 1,091 pts treated with ICI, 160 (14.7%) developed AKI of any cause and 30 (2.74%) developed RirAE. PPI use (p=0.032), renal cell carcinoma (RCC) diagnosis (p=0.009) and line of therapy (p=0.033) were all associated with development of AKI, and RCC, BMI, and line of therapy remained significant in multivariate analysis (p=0.0125). Overall survival (OS) was 12.2 months in absence of AKI vs 10.7 months with AKI (p=0.0125). Statin use (p=0.007) and RCC diagnosis (p=0.012) were significantly associated with RirAE with a trend to higher rates in combination immunotherapy (p=0.064). These three variables were also significant in multivariate analysis. OS was not different in the RirAE group (10.8 months) vs no RirAE group (11.8 months).

**Conclusions:** Patients undergoing ICI therapy can develop AKI as well as RirAE. However, outcomes are worse for AKI. Survival for pts who develop RirAE does not appear to differ from patients without RirAE. AKI and RirAE share an independent risk factor in RCC. However, statin use and combination ICI therapy appear to be unique risk factors for RirAE. Further studies are needed to verify the finding regarding statin use, a drug with widespread use.

**A Potential Mechanism of Distal Renal Tubular Acidosis in Patients Treated with Immune Checkpoint Inhibitors**

Sandra Herrmann,1 Mariam P. Alexander,1 Michael F. Romero,1 Ladan Zand,2 Mayo Foundation for Medical Education and Research, Rochester, MN; 2University of Minnesota, Minneapolis, MN.

**Background:** The main cause of acute kidney injury in patients on immune checkpoint inhibitors (ICI) is acute interstitial nephritis (AIN). However, as their use continues to increase, we observe other renal manifestations being described. Distal renal tubular acidosis (dRTA) has been described, but the mechanism is not clear to date. We hypothesized that an alteration of H⁺-ATPase or anion exchanger (AE-1) in alpha intercalated cells (α-IC) in collecting duct is affected.

**Methods:** We present two patients with AIN and dRTA secondary to ICI. Patient #1 with metastatic adenocarcinoma of lung and patient #2 with metastatic melanoma, both treated with anti-PD1/anti-PD-L1 antibodies ( pembrolizumab/nivolumab). They had prominent intercalated cell abnormalities consistent with dRTA (Figure 1A). Kidney biopsy was performed in each patient which showed diffuse AIN with negative routine immunofluorescence (IF) staining. Both patients had received PPI in addition to ICI therapy and had improvement in their kidney function following steroid therapy and with discontinuation of the drugs. In order to investigate the potential mechanism for developing dRTA, the kidney biopsy frozen sections from patients #1 and #2 were further stained by indirect IF for acid-base transporters in α-IC (α4 and B1) subunits of the vacuolar H⁺-ATPase (V-ATPase) and the AE-1.

**Results:** In order to quantify the staining, data were normalized to a T0 allograft biopsy as control.

**Conclusions:** α-IC cell markers were decreased in both patients compared to the control as shown in Figure 1B. Quantification of AE1, B1-V-ATPase and A4-V-ATPase were all reduced compared to control biopsy, however, staining for other markers of α-IC (α4 and B1) subunits were not significantly different. This suggests a more targeted reduction in V-ATPase subunits that may be immune-mediated.

PO2168
Clinical Features of AKI in Patients Receiving Tisagenlecleucel (CAR-T Therapy)
Meghan Lee,1 Ian A. Strohbehn,1 Harish Shanthanu Seethapathy,1 Nifasha Rusibamayila,1 Keagan S. Casey,1 Shruti Gupta,1 David E. Leaf,2 Matthew Frigaud,1 Meghan E. Sise.1 Massachusetts General Hospital, Boston, MA;2Brigham and Women’s Hospital, Boston, MA.

Background: CAR-T therapy uses genetically engineered T cells to target tumor antigens, which can lead to cytokine release syndrome (CRS), neurotoxicity, and in severe cases, AKI. Prior series demonstrated 20% incidence of AKI after axicabtagene ciloleucel (Yescarta), a CD28 costimulatory domain CAR-T. Tisagenlecleucel (Kymriah) is a 41IB CAR-T that targets CD19 on B cells but has delayed toxicities, slower expansion kinetics, longer persistence, and is associated with lower rates of severe CRS. We determined incidence and clinical features of AKI in patients receiving tisagenlecleucel.

Methods: We performed a retrospective review of adults with diffuse large B cell lymphoma treated with tisagenlecleucel at our institution between Jan 2019–Apr 2020. Baseline demographics, laboratory data, and clinical outcomes were obtained from electronic health records. The primary outcome, AKI, was defined as a ≥1.5-fold rise in creatinine from pre-CAR-T baseline and staged using KDIGO criteria.

Results: Overall, 37 patients received tisagenlecleucel: average age was 60 (SD 18), 65% male, 86% white. CRS occurred in 51% (no severe CRS); neurotoxicity occurred in 24%. Thirteen (35%) required steroids, 8 (22%) received tocilizumab, and 8 (22%) received anakinra to treat CRS/neurotoxicity. AKI occurred in 2 (5%) patients; both had stage 3 AKI. One had acute tubular necrosis due to septic shock starting post-infusion day 1. The other had AKI with new-onset nephrotic range proteinuria (5-6g/d) concurrent with a hemophagocytic lymphohistiocytosis-like syndrome beginning day +8. The patient was also receiving anphoteracinc and acyclovir. Both patients with AKI died (days 4 and 28, respectively). Among patients without AKI, the 30-day mortality was 8.6%. Clinically significant electrolyte disorders were also common (Table).

Conclusions: Compared to prior reports, we found lower rates of CRS and AKI in patients receiving tisagenlecleucel. We report a case of new-onset nephrotic-range proteinuria and AKI following CAR-T.

PO2169
Dabrafenib-Induced Acute Interstitial Nephritis (AIN) and AKI in Patients with Cancer
Meghan Lee, Harish Shanthanu Seethapathy, Orhan Efe, Ian A. Strohbehn, Nifasha Rusibamayila, Ivy Rosales, Robert B. Colvin, Donald F. Chute, Meghan E. Sise. Massachusetts General Hospital, Boston, MA.

Background: BRAF inhibitors (vemurafenib, dabrafenib, encorafenib) commonly used to treat BRAF mutated cancers have been associated with AKI. Cases of acute and chronic tubular injury and AIN have been reported with dabrafenib. We aimed to define the incidence and clinical features of AIN in patients on dabrafenib.

Methods: We conducted a retrospective cohort of patients receiving dabrafenib from 2010-2018 in a large healthcare system. Baseline comorbidities and medication use was determined by chart review. The primary outcome was AKI (≥1.5-fold increase in baseline creatinine) within 12 months. AKI etiology was reviewed by 2 nephrologists. Multivariable modeling was used to determine predictors of AKI.

Results: Overall, 199 patients were included; mean age was 59 (SD 16) years, 56% were male, and 94% were white. 96% received trametinib (a MEK inhibitor) concurrently. Mean baseline creatinine was 0.9 (SD 0.2) mg/dl (20% had baseline eGFR 60-90 mL/min/1.73m2), and 42 patients (21%) experienced AKI at a mean of 141 (SD 116) days after starting dabrafenib. In multivariable modeling, only baseline liver disease predicted AKI. Etiology and stage of AKI are shown in Fig 1A; clear alternative causes for AKI were found in 32 of 42 cases. Ten patients (5% of total cohort, 24% of AKI) experienced AIN at a mean of 141 (SD 116) days after starting dabrafenib. In multivariable modeling, only baseline liver disease predicted AIN. Etiology and stage of AIN are shown in Fig 1A; clear alternative causes for AIN were found in 32 of 42 cases. Ten patients (5% of total cohort, 24% of AKI) experienced AIN at a mean of 141 (SD 116) days after starting dabrafenib. In multivariable modeling, only baseline liver disease predicted AIN.

Conclusions: AIN is common in patients on dabrafenib (21%). A febrile systemic response or CRS after dabrafenib may explain up to 24% of AKI; we report another case of AIN after dabrafenib.

PO2170
Temporal Trends of Palliative Care Use Among Hospitalized Patients with Metastatic Renal Cell Carcinoma
Si Li,1 Yichen Wang,1 Min Zhou,2 Qiyu O. Wang,2 Nasha Elavía,1 Nishant Sharma,1 Bojana Milekic,1*The Wright Center for Graduate Medical Education, Scranton, PA;2Cook County Health and Hospitals system, Chicago, IL;1Beth Israel Deaconess Medical Center, Boston, MA.

Background: Patients with metastatic renal cell carcinoma have a poor prognosis and they may suffer from hypercalcemia, venous thromboembolism, anorexia-cachexia syndrome. Little is known about the trends in the utilization of palliative care in this patient population.

Methods: We conducted a retrospective cohort study using data from 2004 to 2014, which were extracted from the National Inpatient Sample. ICD-9-CM was used to identify all diagnosis variables. We compared the baseline demographics. We assessed the annual trend over time in palliative care utilization rates. Statistical analysis was performed using STATA 16.0. We considered a two-tailed P value of <0.05 as statistically significant.

Results: We identified 181,199 hospitalizations with metastatic renal cell carcinoma from 2004 through 2014, of which 16,390 (9.0%) involved palliative care services. Inpatient palliative care utilization increased from 2.8% in 2004 to 16.3% in 2014 (p=0.001). Compared with patients discharged from non-teaching hospitals, we noticed a significantly higher rate of palliative care utilization in patients discharged from teaching hospitals [aOR 1.46; 95% CI 1.29 to 1.65]. There were higher odds of receiving palliative care in patients with private insurance [aOR 1.26; 95% CI 1.11 to 1.42]. We also observed lower odds of receiving palliative care in Hispanic patients [aOR 0.83; 95% CI 0.70 to 0.98, p=0.03].

Conclusions: The rate of inpatient palliative care use in metastatic renal cell carcinoma patients sharply increased between 2004 and 2014. Our findings demonstrated improving adherence to the National comprehensive cancer network (NCCN) guidelines, which is highly encouraging. Patients from teaching hospitals and using private insurance and were more likely to receive palliative care.

PO2171
AKI Secondary to Multiple Myeloma: Complications of Treatment with High Cut-Off Filters

Background: Acute kidney injury is a frequent complication of MM that can affect 18 to 56% of patients and more than 10% end up needing dialysis. One of the drawbacks associated with the technique is attributed to the albumin loss. The other complications are related with the dialysis technique itself, especially infections.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: We have performed 28 treatments of hemodialysis with High cut off filters (HD-HCO). The HD-HCO protocol includes daily dialysis session of 6 hours during the first 6 days to subsequently switch to dialysis every other day until free light chains levels below 500 mg/L, or until the recovery of renal function allows the independence of dialysis. All these patients have a chemotherapy regimen based on Bortezomib (25 mg/m² on days 1, 4, 8 and 11) and dexamethasone (28 treatment days - retrospective analysis) of the 28 treatments that are performed with HD-HCO after 8 years of experience (July 2011 to May 2019) to demonstrate the presence of the same complications as the conventional HD.

Results: Our findings indicate that the HD-HCO has the same safety profile as the conventional HD. There is no serious infectious complications in our patients despite of the fact that all of them are immunosuppressed patients (AKI secondary to Multiple Myeloma in patients treated with chemotherapy).

PO2172

Acute Myeloid Leukemia Worsens Sepsis-Induced AKI

Takayuki Tsuji, Naoko Tsuji, Tetsushi Yamashita, Xuzhen Hu, Peter S. Yuen, Robert A. Star. Renal Diagnostics and Therapeutics Unit National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.

Background: Patients with hematological malignancies are at high risk for acute kidney injury (AKI), which is associated with high morbidity and mortality. Sepsis is the main cause of AKI in ICU patients with hematologic malignancies. However, the contributions that host or cancer cells make to systemic inflammation during sepsis-induced AKI is not known.

Methods: We created a mouse xenograft model of acute myelogenous leukemia (AML) associated sepsis AKI. Human leukemia HL-60 cells were injected into the tail vein of 6-week-old male NOD/SCID/IL-2Rγ−/−N(SGO) mice. After engraftment 2 weeks later, eliciting leptospirosis and puncture (CLP) was performed to induce sepsis (n=12 per group). Tumor engraftment in the bone marrow (BM) and blood tumor burden were measured by flow cytometry of human CD33 and human CD45 double positive cells. Multiple organ damage, and both mouse and human systemic cytokines were evaluated at 24 h after CLP or sham surgery.

Results: AML-intensified sepsis-induced AKI. Both BUN and LDH were significantly higher in AML+CLP than CLP alone (AML+CLP+vehicle vs CLP+CLP, BUN 74.5±25.4 vs 42.7±25.3 mg/dL, LDH 3,969±1,720 vs 1,863±661 mg/dL, p<0.05). CLP dramatically increased the percentage of circulating leukemia cells (pre CLP vs post CLP, 2.2±1.3 % vs 20.6±13.3 %, p<0.05). Tumor burden in either BM or blood did not correlate with AKI severity. Systemic mouse IL-6 in AML+CLP at 24 hours after CLP was significantly higher than CLP alone (45.9±2.4 vs 15.1±4.2 ng/mL, p<0.05). Systemic human IL-6 in AML+CLP was higher, but not significantly, than vehicle-CLP. There was no correlation between human cytokines and severity of AKI, although human cytokines (IL-6 and TNFα) significantly correlated with tumor burden in both BM and blood at 24 hours after CLP.

Conclusions: We established a clinically relevant mouse xenograft model of human leukemia associated sepsis AKI. Leukemia intensifies sepsis-induced AKI, and sepsis intensifies sepsis-induced AKI. Whereas malignant cells do not produce circulating cytokines that directly drive the systemic immune response to subsequent sepsis-induced AKI, cell-cell interactions in the BM niche may impact systemic inflammation indirectly, possibly through mouse IL-6.

PO2173

Acute Acquired Fanconi Syndrome (FS) in Multiple Myeloma (MM) After Autologous Hematopoietic Stem Cell Transplantation (HCT): A Case Series

Janina Paula T. Sy-Go, Nelson Leung, Mayo Clinic Minnesota, Rochester, MN.

Background: Proximal tubular dysfunction can occur in patients with MM. The main clinical presentation is electrolyte abnormalities indicative of FS. The objective of the study was to describe and identify the rate and clinical predictors of developing acute acquired FS in adult patients with MM after autologous HCT.

Methods: We identified 2515 adult MM patients who underwent autologous HCT at Mayo Clinic between 2000 and December 31, 2018. 45 without research authorization were excluded. 13 patients were identified after searching for “Fanconi,” “Fanconi’s,” and “Fanconi’s” in the EMR. 6 patients did not have FS. 4 patients were diagnosed with FS prior to HCT. The remaining 3 patients (0.12% of cohort) were clinically evaluated to have FS based on features indicative of FS: hypokalemia, hypophosphatemia, hypouricemia, proximal renal tubular acidosis, and normoglycemia - within 14 days after HCT. Of note, these patients did not have features of PO or IV prior to HCT.

Results: The median age of the cohort was 65 years (range: 53-75). All were Caucasians. 2 were women and 1 was a man. Medical comorbidities included hypertension, dyslipidemia, CKD, hypothyroidism, and kidney stone. All had kappa-restricted light chain MM with a median M-spike of 1.2 g/dL (range: 0.4-2.2). All received dexamethasone while 2 received bortezomib and 1 each for cyclophosphamide and lenalidomide. They underwent HCT about 8.3 months after MM diagnosis and were clinically diagnosed with FS about 14.6 days after HCT. None underwent a kidney biopsy. All had hypokalemia, hypophosphatemia, and hypomagnesemia (≤3.5, ≤2.5, and ≤1.7 respectively). 2/3 patients had AKI (≥1.5-fold increase in serum creatinine) and normoglycemia glycosuria. 1/3 had hypouricemia (low range of normal: 2.7-6.1) and proximal renal tubular acidosis (<22 and urine pH <5.3). Aminonuciduria was not checked. All received electrolyte replacement, whether PO or IV, and 2/3 received amiloride to help maintain normokalemia.

Conclusions: Although rare, severe electrolyte depletion after HCT in kappa MM patients could occur and should raise the suspicion for FS. Lenalidomide has been reported to induce FS. Concurrent GI symptoms could exacerbate these electrolyte losses, which concurrent AKI, conversely, could help correct. Timely electrolyte repletion and close monitoring are required.

PO2174

Hyponatremia Is Common After Indwelling Catheter Drainage of Malignant Ascites

Shruti Gupta,1 Maria Clarissa Tio,2 Emily D. Gutowsky,1 Michael S. Stecker,1 Ashish Verma,1 Shweta S. Motwani,2 David B. Mount,1 Gearoid M. McMahon,1 Sushrut S. Waikar1,4 Brigham and Women’s Hospital, Boston, MA; 2Harvard Medical School, Boston, MA; 1Dana-Farber/Children’s Hospital Cancer Center, Boston, MA; 3Boston Medical Center, Boston, MA.

Background: Indwelling peritoneal catheters (IPC) are frequently used to drain tense, symptomatic, malignancy-related ascites. Large-volume drainage may lead to hyponatremia due to massive salt depletion. To date, no studies have examined the epidemiology of hyponatremia after IPC placement.

Methods: We retrospectively reviewed the charts of 461 patients who had IPCs placed between 2006 and 2016 at a tertiary care hospital. Among the 309 patients with labs available pre- and post-catheter, we studied the incidence of hyponatremia and its risk factors. We also examined the management of hyponatremia and its association with mortality.

Results: The overall incidence of hyponatremia post-IPC placement was 85%, of whom 8% had severe hyponatremia with a serum sodium (sNa) ≤120 mEq/L. The mean decline in sNa pre-versus post-catheter was 5 mEq/L (+/- 5.1) and fell by ≥10 mEq/L, among 52 patients (16.8%). Patients with hyponatremia prior to catheter placement had an 8-fold (95% CI, 2.9-21.7) higher adjusted odds of having persistent hyponatremia post-catheter (Table 1). Patients with hepato-pancreatic-biliary malignancies and lower BMI also had a higher adjusted odds of hyponatremia. Hyponatremia was either unrecognized or untreated in 61% of patients. Patients who had sNa ≤120 mEq/L had shorter median survival compared with those with a post-IPC sNa>120 mEq/L. (8 versus 17 days, log-rank p value = 0.03) (Figure 1).

Conclusions: Though IPC placement is often a palliative measure, hyponatremia is common, and severe hyponatremia may be associated with shorter survival. These patients may warrant closer monitoring post-catheter placement.

Funding: Other NIH Support - NIDCD F32DC017342

Table 1: Predictors of Hyponatremia Post-IPC
Selinexor-Associated Hyponatremia: Single-Center Real-World Data
Omar Mamoulk,1 Kenar D. Jhaveri,2 Jaya Kala.3 1University of Texas MD Anderson Cancer Center; Houston, TX; 2Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; 3University of Texas John P and Katherine G McGovern Medical School, Houston, TX.

Background: Introduction: Hyponatremia is a commonly reported side effect in recent clinical trials evaluating the efficacy and safety of selinexor in treatment of refractory multiple myeloma (MM). With incidence ranging 7-47%, the hyponatremia was reported to be generally asymptomatic, transient, and highly responsive to medication dose reduction and sodium. The etiology for hyponatremia is not yet completely understood and speculated to be multifactorial, hypovolemic, diarrhea, poor solute intake, or pseudohyponatremia from high M protein level.

Methods: We retrospectively reviewed the medical records of all relapsed MM patients at our cancer institute. The study was approved by the institutional review board. We reviewed data relevant to hyponatremia in patients’ clinical presentation, medication history, comorbid conditions, physical examination, and laboratory review.

Results: Hyponatremia was seen in 13/17 patients within 5 weeks of therapy, 8 of whom required hospitalization. Three of these hospitalized patients had grade 3 hyponatremia (serum sodium 120 to ≤130 meq/l) with severe symptoms including fall and altered mental status. Both groups of patients received antihyponatremics, anti-depressants and diuretics that included thiazides. Cancer related pain was observed in both groups but the hyponatremic group was on higher dose selinexor and more likely to have more gastrointestinal side effects, sepsis, hypotension. Nephrology was consulted on only 4 out of 13 patients. These 4 patients were elderly patients with serological and urinary studies done high urine osmolality and high urine sodium concentration that along with euvolemia favored SIAD diuretics in 3 out of these 4 patients.

Conclusions: Our observations suggest that hyponatremia is multifactorial, as the patients receiving higher dose selinexor, and selinexor side effects (hypovolemia, nausea and possible unidentified factor) may contribute to hyponatremia. It is possibly dose dependent, more likely to occur with patients who had gastrointestinal side effects, sepsis and hypotension. We recommend discontinuation of medications associated with hyponatremia prior to starting/during selinexor therapy, obtaining basic hyponatremia investigations, and early referral to nephrology to prevent potential serious symptoms

PO2175

Antiemetic Drugs and the Risk of Cisplatin-Induced AKI
Roman A. Shinguargy,1 Andrea Knezevic,1 Sheron Latcha,1 Melanie S. Joy,2 Lauren Aleksunes,1 Edgar A. Jaime,1 1Memorial Sloan Kettering Cancer Center, New York, NY; 2University of Colorado, Denver, CO; 3Rutgers, Rutgers The State University of New Jersey, New Brunswick, NJ.

Background: Cisplatin (CIS) is an effective first line therapy for a variety of cancers. Acute kidney injury (AKI) is a common side effect of CIS seen in up to 30% of patients (Latcha et al CJASN, 2016). AKI results from the selective uptake and accumulation of CIS in proximal tubules. CIS is a highly emetogenic and fluid loss can also contribute to AKI. This retrospective study evaluated whether anti-emetics modify the risk of AKI.

Methods: The medical records of adult cancer patients who received CIS between Jan 1, 2010 and Dec 31, 2016 (n=6,889) were reviewed. The association between use of anti-emetics and development of AKI (50% increase in serum creatinine (sCr)) was evaluated. Inclusion criteria were adults, baseline sCr, CIS dose and administration of anti-emetics. Fisher’s exact test was used for univariable associations between categorical values and logistic regression analyzed multivariable associations with AKI at p<0.05.

Results: Out of ~8700 patients, 6889 met search criteria. A total of 3,881 (56.3%) patients received antiemetics. AKI developed after cisplatin in 1,666 (24.2 %) patients. Of those with AKI (n=1666), patients who received any antiemetic represented 52.6% (n=877), while patients who did not document antiemetic use represented 47.4% (n=789).

Of patients without AKI (n=5223), patients who received any antiemetic represented 51.8% whereas AKI alone was 13.6%. Risk factors for AKI included chemotherapy (odds ratio [OR]=3.245, P=0.024), robotic RC (OR=2.437, P=0.029) and operation time (OR=1.005,P=0.012). Of 150 patients without CKD history, CKD developed in 62.5% of patients with AKD,33.3% with AKI alone and 30.6% with NDKD during the 30 months follow up (p=0.013). K-M analysis showed AKD patients had the highest AKI incidence(Fig.1). Cox model also identified AKD (HR=2.224,p=0.012) but not AKI alone, was independent risk factor predicting CKD, along with age.

Conclusions: The incidence of AKD was higher than AKI alone after microinvasive RC compared with No-AKD. This persistent or repetitive injury is significantly associated with CKD.Hence, interventions for AKD are needed to improve outcomes.

PO2176

Acute Kidney Disease After Microvascular Radical Cystectomy for Bladder Cancer Is Associated with CKD
Shengnan Ge, Ying Tang, Junzhe Chen, Sha Fu, Qiyuan Huang, Wenshan Yu, Anping Xu. Sun Yat-Sen University Sun Yat-Sen Memorial Hospital, Guangzhou, China.

Background: Acute kidney disease (AKD) proposed in 2012 by KDIGO is getting more and more attention for its vital role in acute kidney injury (AKI) to chronic kidney disease (CKD) transition. However, no study has explored the incidence, risk factors of AKD and its impact on new-onset CKD after microvascular radical cystectomy (RC).

Methods: The medical records of 308 patients at our hospital between January 2014 and May 2019 were reviewed. We excluded 29 patients from the study due to missing sCr preoperatively or postoperatively. AKD was diagnosed as a ≥5% decrease in eGFR or ≥50% increase in sCr between 7-90 days after surgery. AKI alone was defined by the 2012 KDIGO classification but failed to meet AKD criteria after 7 days. No kidney disease (NDKD) was defined if patients didn’t meet either criteria.

Logistic regression model was used to explore risk factors of AKD, while its significance for CKD was assessed using Kaplan-Meier analysis and Cox model.

Results: We evaluated 279 bladder cancer patients, including 168 for Robotic-assisted Laparoscopic RC and 111 for Laparoscopic RC. The incidence of AKD was 14.7% whereas AKI alone was 13.6%. Risk factors for AKD included chemotherapy (odds ratio [OR]=3.245,P=0.024), robotic RC(OR=2.437,P=0.029) and operation time (OR=1.005,P=0.012). Of 150 patients without CKD history, CKD developed in 62.5% of patients with AKD,33.3% with AKI alone and 30.6% with NDKD during the 30 months follow up (p=0.013). K-M analysis showed AKD patients had the highest CKD incidence(Fig.1). Cox model also identified AKD (HR=2.224,p=0.012) but not AKI alone, was independent risk factor predicting CKD, along with age.

Conclusions: The incidence of AKD was higher than AKI alone after microvascular RC compared with No-AKD. This persistent or repetitive injury is significantly associated with CKD. Hence, interventions for AKD are needed to improve outcomes.

Figure 1. Kaplan–Meier analysis

PO2177

Comparative Analysis of Characteristics and Survival Outcomes of Clear Cell and Sarcomatoid Subtypes of Renal Cell Carcinoma: Results from the SEER Database 2000-2017
Dona Attia,1 Tapas Ranjan Behera,1 Sara A. Attia.1 1Taussig Cancer Institute, Cleveland, OH; 2Northeastern University, Boston, MA; 3Cleveland Clinic, Cleveland, OH.

Background: Renal cell carcinoma (RCC) accounts for more than 90% of kidney cancers. Clear cell RCC (cRCC) is the commonest type, while sarcomatoid RCC (sRCC) is rare and constitutes 5% of all RCCs. sRCC is known for aggressive clinical course and poor prognosis. In this study, we sought to compare the epidemiological features and survival trends of cRCC with sRCC, using SEER dataset 2000-2017.

Methods: The Surveillance, Epidemiology and End Results (SEER) database was used to identify all adult patients (a18 years) diagnosed with cRCC and sRCC between 2000 and 2017. Variables included age, sex, ethnicity, laterality, staging, histological grade, and nephrectomy. Overall survival was estimated using the Kaplan-Meier method, and compared using the Log-Rank test. Multivariable covariate-adjust Cox models were used for adjusted survival analyses.

Results: A retrospective cohort study of 20248 patients (19398 cRCC, 850 sRCC) with overall survival rate of 38% (40% cRCC and 16.2% sRCC). Although the two subtypes share similar demographic characteristics, including mean age (66.3 ± 13.7 for cRCC vs 62.9 ± 12 for sRCC), there were female ratio (7.1:1 vs 2:3), and using caucasian race more affected (79% vs 82%), sRCC had a significantly worse prognosis in univariate analysis with median overall survival of 7 months vs 30 months for cRCC. Caucasian male patients were more affected in both types. But neither sex nor race significantly affected survival in sRCC (P =0.814, 0.794 respectively), however, black americans have worse outcomes in cRCC (HR 1.123,[1.083-1.163], P < 0.001). On multivariate
regression analysis, advanced stage, high histological grade, and older age 65+ years (HR 1.002, 95% CI [1.001-1.003], P < 0.001) were associated with worse outcomes. Patients with cancer-related death had significantly shorter survival time in both RCCs (P<0.001). Nephrectomy was associated with better survival outcomes (HR 0.486 [0.459-0.514], P<0.001). Elevated levels of albumin at the time of AKI conferred a better prognosis (HR 0.63, 95% CI 0.42 – 0.95; P=0.027).

Conclusions: Our model showed that HM patients with AKI are at high risk of sepsis and IMV, and resulting in elevated in-hospital death. Elevated levels of albumin at the time of AKI correlated with a better one-year survival, while LNH, cancer progression and IMV were risk factors for death.

PO2179

Acid-Based Biomarkers and Cancer Mortality
Ashish Verma,1 Sonu Subudhi,2 Ankit B. Patel,1 Maria Clarissa Tio,1 Sushrut S. Waikar,3 Brigham and Women’s Hospital, Boston, MA; 1Massachusetts General Hospital, Boston, MA; 2Boston University Medical Campus, Boston, MA.

Background: Acidosis in the tumor microenvironment is associated with cancer progression in animal models. We explored the association of serum bicarbonate and anion gap – measures of acid-base balance -- with cancer mortality in community-dwelling adults.

Methods: We conducted a prospective cohort study using the National Health and Nutrition Examination Survey (NHANES), a nationally representative cross-sectional survey of the US non-institutionalized population. Anion gap (mEq/L) was calculated as serum sodium (mEq/L) – (serum chloride (mEq/L) + serum bicarbonate (mEq/L)). We used weighted Cox proportional hazards models to assess the associations between serum bicarbonate and anion gap with cancer-specific mortality, as recorded by the National Death Index. Multivariable models were adjusted for demographics data, BMI, smoking status, diabetes, systolic blood pressure, cardiovascular disease history, ACE/ARB diuretics, HIV drugs, metformin, serum albumin, total cholesterol, total protein, total calorie intake, hemoglobin, cancer diagnosis, eGFR and urine albumin to creatinine ratio.

Results: This study included total 39,137 participants [mean (SD) age, 46.83(19.25) years, 20,162(51.5%) females, 18,119 (46.3%) white]. During 4,433,277 person-years of follow up, 964 (2.46%) participants died secondary to cancer. A history of cancer at the time of enrollment was reported in 3186 (8.8%). Table 1 shows the associations between serum bicarbonate and anion gap in tertiles with cancer-related mortality. In analyses restricted to those with a history of cancer, results were 78% increased risk for cancer mortality in highest tertile compared to lowest tertile [HR 1.78; 95% CI (1.11,2.87)].

Conclusions: Increased anion gap may be a risk factor for cancer mortality. The reasons driving this association deserve further examination.

Risk of cancer mortality according to bicarbonate and anion gap as tertiles (method – weighted survey cox regression)

PO2180

In-Hospital and 1-Year Mortality Among Patients with AKI and Haematological Malignancies
Indra Patel,1 Teresa Chua,2 Hugo Ferreira,3 Ana M. Paiva,2 José M. Costa,2 1Hospital Amato Lusitano, Castelo Branco, Portugal; 2Instituto Portugues de Oncologia do Porto Francisco Gentil EPE, Porto, Portugal.

Background: Patients with haematological malignancies (HIM) are at high risk for acute kidney injury (AKI), which is associated with high morbidity and mortality. The aim of this study was to identify the prognostic factors for in-hospital mortality and one-year mortality in this population.

Methods: We conducted a single centre, retrospective, observational cohort study of 101 in-hospital patients with AKI and HIM between 1 January 2015 and 31 December 2019. We recorded essential demographic, clinical and laboratory data at baseline, 1 and 12 months. We classified AKI according to the KDIGO definition. Cox proportional hazard model was applied to investigate the one-year mortality, and logistic regression analysis was used to assess the in-hospital mortality.

Results: The study population included 64 males and 37 females, with a mean age of 58.7 ± 16.8 years. Multiple myeloma was present in 30.7% (n=31) of the patients, followed by non-Hodgkin lymphoma (LNH) in 27.7% (n=28), 51.5% (n=52) were admitted to intensive care unit (ICU). 60.4% (n=61) needed renal support therapy (RST). Basal GFR, one-month GFR and one-year GFR were, respectively, 65.7 ± 28.9 mL/min/1.73m², 57.1 ± 28.5 mL/min/1.73m² and 54.9 ± 28.1 mL/min/1.73m². Mean length of in-hospital stay was 16 days (IQR 1-88). In-hospital death was 52.5% and after one year only 26 patients were alive. In multivariate analysis, the independent predictors for in-hospital mortality were invasive mechanical ventilation (IMV) (OR 49.53; 95% CI:19.17 – 267.57; p<0.001) and sepsis (OR 5.09; 95% CI:1.18 – 21.89; p=0.029).

PO2181

Renal Recovery from AKI After Hematopoietic Stem Cell Transplant: A Systematic Review and Meta-Analysis
Karathik Kovuru1, Swetha Rani Kanduri,1 Wisit Cheungpasitporn,2 Charat Thongprayoon,2 Juan A. Medinaura,1 Kianoush Kashiani,3 1University of Mississippi Medical Center, Jackson, MS; 2Mayo Clinic, Rochester, MN.

Background: Patients with the recovery of renal function after an episode of acute kidney injury (AKI) have better outcomes compared to those without recovery. The current systematic review is conducted to assess the rates of kidney function recovery among patients with AKI or severe AKI requiring RRT within 100 days after hematopoietic stem cell transplant (HSCT).

Methods: Ovid MEDLINE, EMBASE, and the Cochrane Databases were systematically searched from database inception through August 2019 to identify studies reporting the rates of recovery from AKI after HSCT. Random-effects and generic inverse variance method of DerSimonian-Laird were used to combine the effect estimates obtained from individual studies.

Results: A total of 458 patients from 8 cohort studies with AKI after HSCT were enrolled. Overall, the pooled estimated rates of AKI recovery among patients with AKI and severe AKI requiring RRT within 100 days were 58% (95% CI: 37%-78%) and 10% (95% CI: 2%-4%), respectively. Among patients with AKI recovery, the pooled estimated rates of complete and partial AKI recovery were 60% (95% CI: 39%-78%) and 29% (95% CI: 10%-61%), respectively. There was no clear correlation between study year and the rate of AKI recovery (p =0.26).

Conclusions: The rate of recovery from AKI after HSCT depends on the severity of AKI. While recovery is common, complete recovery is reported in about two-thirds of all AKI patients. The rate of recovery among those with AKI requiring RRT is substantially lower.
Methods: We performed a retrospective analysis of 50 AL Amyloidosis patients who underwent kidney biopsy. Patients with renal involvement who achieved a hematologic response were included. Renal response was defined prior to transplant, according to consensus guidelines, as partial response (PR, > 30% decrease in proteinuria) or stable disease (SD, ≤ 30% proteinuria reduction). Primary endpoints were progression free survival (PFS) and overall survival (OS). PFS and OS were defined as the time from transplantation to day of progression or death, respectively. Kaplan-Meier survival function estimated the PFS and OS. The log-rank test tested the equality of survivor functions between different groups of patients.

Results: Following ASCT, 16 patients (32%) achieved hematological VGPR/CR after ASCT. All had renal involvement. Baseline and 1-year post-transplant proteinuria and serum creatinine (SCr) levels are shown in the Table. In the group of pts achieving VGPR/CR as hematological response PFS and OS were similar for patients having PR and SD as renal response (p=0.89 and p=0.44, respectively). No patients required hemodialysis. Median follow up for PFS was 4.1 years and for OS was 5.6 years (PR) and 11.9 years (SD).

Conclusions: Hematological response is important in AL amyloidosis and survival improves similarly with VGPR and CR. In patients with renal involvement, this study shows similar outcomes to patients who achieved a PR or SD as renal response prior to ASCT. However, our study has a small sample size and we would recommend a larger study.

PO2183

High-Dose Methotrexate (HDMTX) and Nephrotoxicity: Effect on Subsequent Dosing

Background: HDMTX is an important part of various chemotherapeutic protocols due to its central nervous system penetration. A key complication of HDMTX is nephrotoxicity as this leads to delayed MTX excretion and further morbidity. Nephrotoxicity in a previous cycle of HDMTX leads to an increased risk of future toxicity. Our aim was to establish how nephrotoxicity affected clinical decision making with regards to future dosing.

Methods: A retrospective review of the electronic medical record was performed to identify patients who developed nephrotoxicity post HDMTX from 1/1/02 to 12/31/18. Patients were stratified into those who received a subsequent dose, those who did not, and those who did not receive subsequent dose due to its central nervous system penetrance. A key complication of HDMTX due to its central nervous system penetrance.

Results: A monocentric retrospective study was carried out enrolling 23 patients with biopsy-proven acute myeloma kidney and sFLC levels >1000 mg/l. Patients received Bortezomib-based chemotherapy and extracorporeal treatment for sFLC removal. For each session 2 dialyzers of the same kind were used and the dialytic dose was only related to the SFLC removal. The dialyzers had high absorptive properties: PMMA (poly(methylmethacrylate); Filtryzer BK-F 2.1 m2 cut-off 20 kDa); PEPA (poly ester polymer alloy; FDX or FYD 210-GW 2.1 m2, cut-off undisclosed).

Results: The factors that have been found to be significantly and independently associated with higher survival rate were: baseline serum albumin, reduction of sFLC at day 12 and day 30, reduction of sFLC at day 30 above 50%, number of session and dialysis independence.

Conclusions: Our analysis highlights the importance of the early treatment for removal of sFLC in AKI for MM. In fact the variable associated with higher survival rate are the reduction of sFLC at day 12 and at day 30 and number of session and dialysis independence. These results indicate that the early removal of sFLC can guarantee a better outcome. Baseline serum albumin is also associated with survival rate and it demonstrates that it still carries a prognostic value in the population with AKI. This finding suggests the importance of albumin-sparing extracorporeal treatments. In fact alternative techniques, as HD-HCO, have been proposed for sFLC removal but they present high costs and albumin leakage.

PO2186

Daratumumab for Management of Bortezomib-Resistant Monoclonal Gammapathy of Renal Significance

Salem Almaani, Samir V. Parikh, Naresh Bummia, Nidhi Sharma, Yvonne A. Efebera, Isabelle Ayoub. The Ohio State University Wexner Medical Center, Columbus, OH.

Background: The management of monoclonal gammapathy of renal significance (MGRS) is challenging. In our center, MGRS patients are initially treated with a bortezomib-based regimen. Patients who do not respond have very limited therapeutic options. Daratumumab is an anti-CD38 monoclonal antibody that is being increasingly used in patients with multiple myeloma with a favorable adverse effect profile, and represents a potential therapeutic option for patients with MGRS.

Methods: Retrospective review of the use of daratumumab in management of patients with bortezomib-resistant MGRS.

Results: Five patients were treated with daratumumab after receiving a variety of immunomodulatory therapies (Table 1). All received bortezomib with no response. One patient had a dramatic improvement in proteinuria with a stable renal function. One patient had resolution of glomerular monoclonal protein deposits but had persistent proteinuria due to significant damage to the glomerular basement membrane. One patient suffered from an acute kidney injury due to acute tubular necrosis (noted on biopsy) and became dialysis dependent. Two patients were started on daratumumab recently and had limited follow up, however both demonstrated a reduction in proteinuria. Daratumumab was well-tolerated and no patients required hospitalization due to adverse effects.

Conclusions: Our experience in using daratumumab for management of bortezomib-resistant MGRS suggests good tolerability and short-term response rates.

PO2187

Diffuse Background Monoclonal Light Chain Staining in Kidney Biopsies, Without Electron Dense Deposits: Is It Relevant?

Isabelle Ayoub, Tibor Nadasy. 1The Ohio State University, Columbus, OH; 2Marshall University, Huntington, WV.

Background: Pathologic diagnosis of monoclonal gammapathy (Mlg)-associated kidney disease requires specific morphologic and immunofluorescence (IF) findings with deposits on electron microscopy. We have encountered kidney biopsies showing only diffuse “background” monoclonal light chain staining the renal parenchyma, without characteristic lesions of Mlg-associated kidney disease or organized/non-organized deposits on ultrastructural examination. Such staining is either overlooked if weak, or can be over-diagnosed as Mlg-associated kidney disease if strong, causing dilemma over the need for immediate clone-directed therapy. We performed a clinicopathologic study to better understand its significance.

Methods: Database search over 12-year period revealed such 32 cases. Clinical and laboratory data was retrieved along with a mean follow-up of 13 months.

Results: Out of the 32 patients, 15 (47%) had active myeloma by hematologic criteria (despite absence of myeloma casts on kidney biopsy) warranting immediate clone-directed therapy; but 11 (34%) did not have/develop myeloma-defining events till the end of follow-up period; 3 (9%) did not have detectable paraprotein; and 3 (9%) were lost to follow-up. The mean staining intensity of background monoclonal light chain was significantly higher in myeloma patients as compared to the non-myeloma patients (2.2 vs 1.5, p=0.03), but strong (2 or 3+) intensity of staining was seen in 36% (5/14) of the cases without active myeloma (Fig. 1).

Conclusions: It is important to recognize and document this isolated background monoclonal light chain staining in the biopsy report, but by itself, should not be classified as Mlg-associated kidney disease. It does warrant a thorough hematologic work-up. It can help to unmask (previously unsuspected) underlying active myeloma which many patients. But it is important to note that there is a subset of patients that do not have active myeloma despite the strong background staining. Care must be taken to avoid inadvertent immediate clone-directed therapy in these patients, but periodic monitoring with hematologic and renal parameters to watch for possible malignant transformation is important.

PO2188

Immune Checkpoint Inhibitor-Induced p-ANCA Multigranular Vasculitis

Marelle Montanez,1,2 Jamie Lin,2 Omar Mamlok,1,2 Ala Abudayyech,2 William F. Glass.1 1University of Texas Health Science Center at Houston, Houston, TX; 2University of Texas MD Anderson Cancer Center, Houston, TX.

Introduction: Use of immune checkpoint inhibitors (ICIs) has led to improved mortality in melanoma, lung cancer, and lymphoma. ICIs augment immunologic reaction against tumor cells via blockade of cytotoxic T-lymphocyte antigen-4 (CTLA-4), programmed cell death-protein 1 (PD-1), or programmed death-ligand 1 (PD-L1). Renal complications from ICI use are uncommon but can involve development of glomerular diseases and interstitial nephritis. Below we present a case of p-ANCA vasculitis in a patient on ICI therapy.

Case Description: A 52-year-old female with adenocarcinoma of the right lung (T2N2) s/p right lower lobectomy, cisplatin/vinorelbine, radiation therapy, and durvalumab was hospitalized for evaluation of new onset oral blisters, fevers, hemoptysis, skin lesions, and acute kidney injury. Her creatinine rose to 3.2 mg/dl (baseline of 0.5 mg/dl). Urinalysis revealed >180 RBCs and 17 WBCs per high power field with a urine protein to creatinine ratio (UPCR) of 2.63 g/g. ANCA titers were positive for PR-3 antibody of 4.6 units. Patient underwent renal biopsy, which revealed evidence of renal vasculitis involving all glomeruli and crescents in 4 out of 20 glomeruli. There was concern for endocarditis with vegetation seen on echocardiogram; however, with negative blood cultures the etiology was attributed to autoimmunity (vasculitis) rather than infection. The patient was aggressively treated for ANCA vasculitis with pulse steroids, plasmapheresis, and rituximab (1g given 2 weeks apart). She had a dramatic improvement in her skin lesions, hemoptysis, cardiac and renal function. Two months following her last rituximab infusion, she has not had further hematuria, her UPCR remains < 0.5 g/day, and creatinine is stable at 1.2 mg/dl. PET/CT continues to demonstrate clinical remission of her underlying cancer.

Discussion: With the dramatic cancer responses seen in patients receiving immune checkpoint therapy, there has also increased understanding associated toxicities. Although reports of ANCA positive vasculitis from ICI has been reported; this case is unique due to the multigranular involvement of her vasculitis including the heart valves. Aggressive treatment with steroids, plasmapheresis, and rituximab has proven effective due to hindering her tumor response.

PO2189

IgA Nephropathy in the Setting of Dual Immune Checkpoint Inhibitor Use

Lorenz Leuprecht,1 Steven Salvatore,2 Victoria Gutgarts,2 Ilya Glezerman,2,3 1University of Texas Health Science Center at Houston, Houston, TX; 2Memorial Sloan Kettering Cancer Center, New York, NY.

Introduction: Acute kidney injury (AKI) is a recognized side effect of immune checkpoint inhibitors (ICPs), with acute tubulointerstitial nephritis (AIN) as the most common pathologic finding. Risk of AKI is higher with use of proton pump inhibitors (PPIs) and dual ICPi use. Glomerular disease with ICPi is infrequently found on kidney biopsy. We report a case of concomitant IgA nephropathy and AIN associated with dual ICPi blockade.

Case Description: 62-year-old male with metastatic sarcoma recently initiated on Ipitumumab and Nivolumab presented with dark colored urine for 2 days. He was recently hospitalized for neutropenic fevers with a negative infectious work up. On admission his blood pressure was 181/94 and he was afebrile. Physical exam was notable for hypertension. The patient was aggressively treated for ANCA vasculitis with pulse steroids, mycophenolate was added to his treatment regimen while undergoing steroid taper. His creatinine improved to 2.7mg/dl, though he developed several steroid related side effects. Due to inability to tolerate higher doses of steroids, mycophenolate was stopped. No additional doses of immunotherapy were administered. His serum creatinine improved to 1.6mg/dl after 1 week, with plan for outpatient steroid taper. At 10mg prednisone daily, his creatinine increased to 4.5mg/dl prompting pulse steroids due to concern for ongoing interstitial inflammation versus worsening IgA nephropathy. One week later creatinine improved to 2.7mg/dl, though he developed several steroid related side effects. Due to inability to tolerate higher doses of steroids, mycophenolate was added to his treatment regimen while undergoing steroid taper.

Discussion: This case underscores the importance of considering acute glomerulonephritis as a cause for AKI in patients recently started on ICPi therapy. Risk of AKI in this patient was higher given use of PPI and dual ICPi therapy. This case is unique as the renal biopsy showed both AIN and IgA nephropathy. These findings had important implications for the treatment plan since the patient was unable to successfully stop prednisone and required a second immunosuppressive agent.
Hypercalcemia Associated with Immune Checkpoint Inhibitors

Eshetu L. Obelog, Isabelle Ayoub. The Ohio State University Wexner Medical Center, Columbus, OH.

Introduction: Immune checkpoint inhibitors revolutionized treatment of many cancers with marked improvement in prognosis. They target CTLA-4, PD-1/PD-L1 pathways. However, immune related adverse events complicate their use. Here we present the case of hypercalcemia as a result of immune checkpoint inhibitors.

Case Description: A 68-year-old man with metastatic renal cell carcinoma underwent right nephrectomy followed by immunotherapy with ipilimumab and nivolumab. Two weeks after his second cycle of immunotherapy, he presented with inflammatory arthritis and pruritis. Workup was significant for sCa 12.8 mg/dL and Scr 3.6 mg/dL. Hypercalcemia was suspected to be malignancy related from bone metastasis or humoral stimulation. He received fluids, calcitriol and Zoledronic acid. Further investigations showed a suppressed iPTH-6.3 pg/ml, normal PTP, low TSH 0.04 uU/ml, free T4 1.91, normal 25 OH Vitamin D 62 pg/ml and normal renal function tests.

No monoclonal proteins were detected in serum. CRP and interleukin 6 were elevated to 80 mg/dL and 176 pg/ml respectively. PET scan showed diffuse hypermetabolic lymph nodes in mediastinum, neck, and abdomen. Transbronchial needle aspiration was negative for malignancy. Inflammatory arthritis, pruritis, hyperlymphocytosis, nonmalignant diffuse lymphadenopathy, and 1.25 dihydroxyvitamin D induced hypercalcemia are suggestive of immune related adverse effects rather than disease progression. Patient was started on prednisone 1mg/kg/d. Hypercalcemia, AKI, pruritis and inflammatory arthritis resolved. Repeat 1.25 dihydroxy vitamin D and CRP levels were back to normal.

Discussion: Hypercalcemia related to checkpoint inhibitors was previously described in setting of increased PTP. Our patient had hypercalcemia directly related to immunotherapy likely through increased alpha hydroxylas.

PO2190

Double Trouble with Pembrolizumab: Immune Checkpoint Inhibitor-Induced Type I Renal Tubular Acidosis and Secondary Adrenal Insufficiency

Dayvan M. Adoor, Hafia Tariq, Arash Rashidi. University Hospitals, Cleveland, OH.

Introduction: Pembrolizumab is a novel immune checkpoint inhibitor (ICI) that targets programmed cell death protein (PD-1) signaling. Checkpoint inhibitor associated nephropathy toxicity is an immune-mediated process that can manifest with a variety of clinical presentations. Here, we report a unique case of Pembrolizumab induced distal renal tubular acidosis (RTA) and secondary adrenal insufficiency (AI) which was successfully treated with steroids.

Case Description: A 72-year-old male with a history of stage IIIC malignant melanoma, who had recently completed 3 cycles of therapy with Pembrolizumab was admitted with generalized fatigue, weakness, and anorexia. Initial work up was notable for severe hyponatremia and a non-anion gap metabolic acidosis (NAGMA); (Na: 120 mmol/L, Cl: 89 mmol/L, K: 3.8 mmol/L, HCO3: 20 mmol/L and Creatinine 0.67mg/dL). Urine anion gap was positive at 8meq/L, urine osmolar gap was low at 57 mosm/kg and urine pH was 6.0. Subsequent laboratory work up was notable for AM cortisol of 1.0 ug/dL, and 17-hydroxyprogesterone at 12 ng/dL. Other pituitary hormones including LH, TSH and ACTH were normal. An MRI of the sella was negative for hypophyhsitis. CT scan of the abdomen showed no adrenal hemorrhage or necrosis. Exergetic serologic work-up including serum ANA, ANCA, anti-SSA/SSB, Hepatitis B, Hepatitis C, and C4 levels were all unrevealing. A presumptive diagnosis of immune mediated central AI and distal RTA was made. An AM cortisol of 1.0 ug/dL and urine osmolar gap (<150mosm/kg) in the setting of NAGMA was highly suggestive of a distal RTA. Although this condition is associated with hypokalemia, simultaneous AI could have offset this finding. He was admitted with generalized fatigue, weakness, and anorexia. Initial work up was notable for severe hyponatremia, and a non-anion gap metabolic acidosis (NAGMA); (Na: 120 mmol/L, Cl: 89 mmol/L, K: 3.8 mmol/L, HCO3: 20 mmol/L and Creatinine 0.67mg/dL).

Discussion: Recent studies have shown that acute interstitial nephritis is the most common type of Pembrolizumab associated nephrotoxicity. We report a novel case of Pembrolizumab toxicity, where distal RTA concurrently manifests with secondary AI.

PO2193

Immune Checkpoint Inhibitor Therapy-Related Graft Intolerance Syndrome in a Failed Kidney Transplant Recipient on Hemodialysis

Christina Irene Mejia, Adam M. Frank, Pooja Singh, Anju Yadav. Thomas Jefferson University, Philadelphia, PA.

Introduction: Immune check-point inhibitors (ICPIs) are monoclonal antibodies against inhibitory receptors on T-cells resulting in anti-cancer activity. The use of ICPIs among kidney transplant (KT) recipients with cancer is controversial, as ICPIs increase the risk of acute rejection and are associated with a higher risk of rejection in functioning allografts. In failed allografts, the effects of ICPIs are unknown. We present a unique case of a patient with a failed KT on maintenance hemodialysis (HD) who developed graft intolerance syndrome (GIS) after ICPI therapy for metastatic renal cell carcinoma (RCC).

Case Description: Our patient is a 66-year-old male with a history of diabetes, RCC and left nephrectomy in 1996. He developed end-stage kidney disease and had a deceased donor KT in 2012. His graft failed 6 years post KT, due to biopsy-proven recurrent diabetic nephroclerosis. He was started on HD in 2018 and immunosuppression was tapered off. In 2019, he was diagnosed with renal and urethral cell cancer in the right native kidney and underwent nephrectomy. Ten months later, distant metastasis was detected, and he was started on Nivolumab and Ipilimumab. Twenty-eight days after his 1st cycle of immunotherapy, he had good oncologic response, but developed gross hematuria, pain over his allograft, malaise, and anemia consistent with GIS. Urine culture and cytoscopy were normal. A computed tomography scan of the abdomen revealed an enlarged allograft with patchy enhancement and perinephric stranding consistent with GIS. After a multidisciplinary discussion, he underwent transplant nephrectomy.

Discussion: Although acute graft rejection from ICPI therapy has been documented, this is the first known report of GIS developing with ICPI therapy in a failed allograft. GIS typically occurs within 6-12 months of graft failure. Meanwhile, in functioning allografts, rejection occurs around 24 days after ICPI initiation. The temporal relation of GIS to ICPI initiation in our patient suggests the potential role of the latter as a trigger for GIS. As ICPI use becomes more prevalent in cancer management, we need to be aware of the potential complications with its use among KT recipients even with failed allografts, which requires multidisciplinary management.

PO2194

Crescentic Glomerulonephritis and Phospholipase A2 Receptor-Positive Membranous Nephropathy in a Lung Cancer Patient on an Immune Checkpoint Inhibitor

Matthew Abramson,1 Surya V. Seshan,2 Insarra Jaffer Sathick.1 1Memorial Sloan Kettering Cancer Center, New York, NY; 2Weill Cornell Medicine, New York, NY.

Introduction: Hypercalcemia associated with pembrolizumab toxicity, where distal RTA concurrently manifests with secondary AI.

Case Description: A 72-year-old male with a history of stage IIIC malignant melanoma, who had recently completed 3 cycles of therapy with Pembrolizumab was admitted with generalized fatigue, weakness, and anorexia. Initial work up was notable for severe hyponatremia and a non-anion gap metabolic acidosis (NAGMA); (Na: 120 mmol/L, Cl: 89 mmol/L, K: 3.8 mmol/L, HCO3: 20 mmol/L and Creatinine 0.67mg/dL).

Discussion: Recent studies have shown that acute interstitial nephritis is the most common type of Pembrolizumab associated nephrotoxicity. We report a novel case of Pembrolizumab toxicity, where distal RTA concurrently manifests with secondary AI.

PO2192

Immune Checkpoint Inhibitor-Associated Reactivation of Primary Membranous Nephropathy Responsive to Rituximab

Jamie Lin,1 Daniel Y. Wang,2 Omar Mamlouk,1 William F. Glass,3 Ala Abduyaeh.1 1University of Texas MD Anderson Cancer Center, Houston, TX; 2Baylor College of Medicine, Houston, TX; 3University of Texas Health Science Center at Houston, Houston, TX.

Introduction: The same mechanisms that mediate immune checkpoint inhibitor (ICI) anti-tumor efficacy also increases the activity of the immune system and can lead to ICI-related adverse events (iAEs). Those with preexisting autoimmune disease are particularly vulnerable. We report the first case of ICI associated reactivation of primary membranous nephropathy (MN) responsive to rituximab in a patient with mesothelioma and successful continued ICI treatment.

Case Description: A 37-year-old male with primary MN was diagnosed with stage IA malignant pleural mesothelioma (MMP) in September 2018. Shortly after receiving nivolumab his proteinuria began to increase and his nephrologist recommended continued nivolumab. In May 2019, the patient came to our clinic at MD Anderson Cancer Center for a second opinion. Notable labs included: albumin 1.9 g/ dl, creatinine (Cr) 1.25 mg/dl (baseline Cr 0.82-0.91 mg/dl), and a 24-hour urine protein 13.4 g/day (<1.0 g/day prior to Nivolumab). Due to concern for reactivation of primary MN vs other causes, he underwent a renal biopsy which directed chronic reactivated primary MN with strong positive PLA2R stain. Consideration of immunosuppressive treatment options were discussed, and the patient was initiated on rituximab (1 g IV on Day 1 and 15), a monoclonal antibody binding specifically to CD20 on B cells. Labs one month later showed decrease in proteinuria by >50% (4.8 g/day), and improved albumin to 2.9 g/dl. The patient restarted nivolumab in January 2020 and has stable to improved kidney function five months later. PET/CT imaging continues to demonstrate complete metabolic response and no new sites of increased FDG activity.

Discussion: It is unknown how the immunosuppressive effect of rituximab in our patient affects the anti-tumor effectiveness of ICI therapy. Whether the role(s) of B cells as pro- or anti-tumoral mediators in cancer and ICI is unknown, understanding B cell role(s) could be beneficial for those with autoimmune disease – allowing for split treatment should iAEs occur. Therapy for autoimmune reactivation should be directed by immunosuppressive mechanism in concert with goals of cancer treatment.
PO2195

Diffuse Large B-Cell Lymphoma Presenting with Light Chain Cast Nephropathy: A Case Report
Sheng-Li Cho,1 Hao-Yu Wu,1 Tai-Chung Huang,1 Tzong-Shinn Chu,1 Taomin Huang,1,2 Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan; 2Department of Epidemiology and Preventive Medicine, National Taiwan University College of Public Health, Taipei, Taiwan.

Introduction: Light chain cast nephropathy is caused by filtration of excessive amounts of free light chains into the renal tubules, leading to acute kidney injury (AKI). The most common associated malignancy is multiple myeloma (MM). No adequate case of cast nephropathy associated with diffuse large B-cell lymphoma (DLBCL) was reported

Case Description: A 55-year-old previously healthy man presented with foamy urine for 3 months and exercise intolerance. Physical exam showed pale conjunctiva, multiple neck masses, and no edema. His serum creatinine (Scr) was 7.6 and 15.2 mg/dL initially and on admission 4 weeks later, whereas baseline Scr had been normal one year ago. His hemoglobin level was 7.9 g/dL, and white blood cell count was 8750/μL with eosinophilia. No active urine sediments were found. A UPCR was 7250 mg/g, and a UACR 500 mg/g. Ultrasound showed decreased kidney sizes (R 9.0, L 9.7 cm). Immunoelectrophoresis detected monoclonal λ light chain in both his serum and urine, and a serum λ free light chain level was 8830 mg/L, with a k:λ-t ratio of 0.0024. Following a diagnosis of DLBCL (Lugano stage IV) by neck mass biopsy, a renal biopsy disclosed diffuse aggregation of amorphous eosinophilic proteinaceous casts in the tubules, with a normal glomerular compartment and mild arteriosclerosis, findings consistent with IgG-dominant light chain cast nephropathy. He was treated with 4 courses of R-CHOP, hemodialysis, and a short course of plasmapheresis. A λ free light chain decrease was to 2830 mg/L after plasmapheresis. A complete response for DLBCL was achieved 6 months later but he remained on hemodialysis.

Discussion: This is, in the literature, the first adult DLBCL patient presenting with proteinuria and renal deterioration proving to be light chain cast nephropathy. Standard lymphoma treatments were given, and based on limited evidence, plasmapheresis was given to reduce the light chain load (Median serum free light chain level was 6590 mg/L in MM patients as reported by Bridoux in JAMA 2017). Decreasing plasma light chain concentration leading to improvement in AKI has been reported for MM. However, this case remained dialysis-dependent despite a decline in light chain levels. To conclude, we provide a unique case of DLBCL with cast nephropathy. Clinicians could take this into consideration and treatment may be tailored for better outcomes.

PO2196

A Case of Mixed Cryoglobulinemia Type II with Monoclonal Gammaopathy in a Patient with Chronic Hepatitis B
Hui Zhan Tan, Chandramouli Nagarajan, Alwin Hwai Liang Loh, Ricce Koniman, Jason Choo Chon Jun. Singapore General Hospital, Singapore, Singapore.

Introduction: Non-Hepatitis C related mixed cryoglobulinemia Type II (MCT2) is rare. Causes include lymphoproliferative disorders, chronic infections like Hepatitis B and autoimmune.

Case Description: A 68-year-old Chinese male presented with livedo reticularis and rapidly progressive glomerulonephritis requiring dialysis, on a background of chronic Hepatitis B (HBV) infection. Investigations showed a uPCR of 9.75g/L and serum creatinine (Scr) of 407 μmol/L (baseline Scr 72 μmol/L). Rheumatoid factor was positive (>650/μL). Both C3/C4 were low. HBV viral load was detected at 479, 452 copies/μL while HCV, HIV and autoimmune screen were negative. A IgM kappa monoclonal band (3g/L) was detected on serum protein electrophoresis and immunofixation. Renal biopsy revealed MPGN with 28% crescents, capillary luminal hyaline thrombi, and IgM Kappa deposits. Findings were consistent with MCT2 despite negative serum cryoglobulins. Bone marrow aspiration and biopsy revealed a small clonal B-cell population confirmed on flow cytometry. Pulsed methylprednisolone followed by high-dose prednisolone, Rituximab and plasmapheresis were initiated for organ-threatening disease. Meanwhile, together with entecavir: HBV viral suppression was observed after 1 month. Partial remission was achieved (Scr 140 μmol/L; uPCR 2.39g/g) after 4 months. Development of sepsis and CMV reactivation prompted withdrawal of steroids, resulting in progressive deterioration of renal function (Scr 302μmol/L; uPCR 10.62 g/g). Commencement of Bortezomib and dexamethasone resulted in gradual improvement of renal function (Scr 107 μmol/L; uPCR 4.71 g/g) after 3 cycles.

Discussion: MCT2 observed in our patient was possibly contributed by chronic HBV. However, suboptimal response despite HBV viral suppression prompted further treatment of the underlying lymphoproliferative disease causing monoclonal gammapathy of renal significance (MGRS). Clinical improvement of MCT2 is not established, although immunosuppression consisting of corticosteroids with Rituximab or cyclophosphamide is required in severe renal involvement. We demonstrated a favourable outcome with Bortezomib-based clone directed therapy after achieving a non-sustained response with Rituximab/prednisolone. Long-term monitoring of the underlying low grade non-Hodgkin’s lymphoma (NHL) is necessary.

PO2197

Myeloma Cast Nephropathy with Diffuse Amyloid Casts: Two Case Reports and Literature Review
Zhao Yong,1,2 Xiaoyuan,1 Su-xia Wang,1 Ming Hui Zhao.3 Revan Division, Department of Medicine, Peking University First Hospital; Institute of Nephrology, Peking University; Pathology Center, Peking University First Hospital; 3Pathological Centre, Peking University First Hospital, Beijing, China; 4Peking-Tsinghua Center for Life Sciences, Beijing, China.

Introduction: Multiple myeloma (MM) is a plasma cell derived hematologic malignant disease. The proliferating plasma cells can secrete massive monoclonal immunoglobulins which can cause various pathologic types of renal injury. Myeloma cast nephropathy (MCN) is the most common pathologic lesion with the worst renal prognosis. Rarely, the free light chains in the protein casts can form amyloid fibrils. Here we report two rare cases of cast nephropathy with amyloid deposits.

Case Description: Case 1: A 54-year-old Chinese man presented with a 4-year history of multiple myeloma, proteinuria and hematuria. He had Monoclonal IgA, plus free λ, spike in both serum and urine. He was treated with chemotherapy. His serum creatinine was normal until 11 months before admission, and he was on hemodialysis 3 months before admission. Renal biopsy showed diffuse amyloid casts in the tubular lumens, and he had no obvious amyloid deposits in other kidney compartments and no sign of extra-renal amyloidosis. The amyloid fibrils formed around mononuclear cells which were CD68 positive. The patient was maintained on chemotherapy and hemodialysis, and he died 8 months after renal biopsy. Case 2: A 58-year-old Chinese man presented with a one-and-a-half-year history of proteinuria and slowly rising serum creatinine. He had Monoclonal IgD, spike in both serum and urine. Amyloid casts were observed in the tubular lumens and in the centre of some casts were mononuclear cells. There were no amyloid deposits in other kidney compartment and no sign of systemic amyloidosis. The patient also had fine granular deposits along the tubular basement membrane with linear staining along tubular basement membrane suggestive light chain deposition disease. Renal biopsy was treated with both MM and amyloidosis-based chemotherapy and achieved very good partial remission (VGPR). After twenty-seven months of follow-up, the patient still had no sign of systemic amyloidosis.

Discussion: These 2 cases of MCN with diffuse amyloid casts have different pathologic characteristics from the usual myeloma casts and tubular epithelial cells may play important roles in the pathogenesis.

PO2198

Masked Light Chain Proximal Tubulopathy (LCTP) and Focal Segmental Glomerulosclerosis (FSGS) in Multiple Myeloma (MM)
Matthew Abramson,1 Surya V. Seshan,2 Carlos D. Flombaum,1 3Memorial Sloan Kettering Cancer Center, New York, NY; 2Weill Cornell Medicine, New York, NY.

Introduction: Patients with MM often do not have a myeloma-defining disease, and delayed recognition/treatment of a monoclonal gammapathy of renal significance (MGRS) may confer worse renal outcome. Here we report 3 patients with “masked” LCTP (one also had FSGS) and a 4th patient with both FSGS and LCTP. None had cryoglobulin deposits. All 4 patients had a history of untreated, smoldering MM and the initial kidney biopsy interpretation in 3 of the cases reported no evidence of MGRS. Treatment of the underlying MM resulted in improvement of renal parameters in all, suggesting MM as the etiology for the renal disease.

Case description: 73 y/o, worsening renal function (WRF), albuminuria and monoclonal proteinuria (MP). Biopsy: FSGS. Initial immunofluorescence (IF) was negative. Re-examination after protease digestion 6 months later: LCTP. Therapy for MM resulted in decreasing FLCs, improvement of renal function and a marked decrease in MP.

Discussion: MCN attributed to MM. Therapy for MM resulted in decrease in FLCs, stabilization of albuminuria and complete disappearance of MP. The malignant proliferating plasma cells can secrete massive monoclonal immunoglobulins which can cause various pathologic types of renal injury.
kidney biopsies of patients with monoclonal gammopathies. In addition, detailed EM examination of the tubules is essential to identify the lysosomal abnormalities typical of LCPT.

PO2199

CKD After 225Ac-PSMA617 Therapy in Patients with Advanced Metastatic Prostate Cancer: A Report of Two Cases

Karyne Pelletier, Gabrielle Côté, Abhijat Kitchlu. University Health Network, University of Toronto, Toronto, ON, Canada.

Introduction: A promising therapeutic efficacy has been demonstrated with targeted radionuclide therapy (TRNT) using 225Ac-PSMA617 in patients with advanced metastatic castration-resistant prostate cancer (mCRPC). However, these novel agents may be associated with significant toxicity. As seen in animal models, the multiple alpha particles generated in the decay chain of 225Ac may accumulate in the renal tubular cells, resulting in nephropathy. We report our experience with 225Ac-PSMA617 therapy in 2 patients with advanced mCRPC who developed kidney injury.

Case Description: Patient 1: a 68-year-old man with widely metastatic mCRPC despite multiple lines of therapy and secondary chronic hydropnephrosis with bilateral nephrostomy tubes. He received 3 rounds of 225Ac-PSMA617 in 2-month intervals. Baseline serum creatinine was 1.6 mg/dL (eGFR 44 mL/min/1.73m²) and it increased up to 3.3 mg/dL (eGFR 18 mL/min/1.73m²) after 225Ac-PSMA617 therapy. A kidney biopsy was obtained and revealed severe interstitial fibrosis with ongoing tubular injury and interstitial inflammation. A trial of corticosteroids therapy was attempted with no improvement in kidney function. 225Ac-PSMA617 therapy was discontinued because of related kidney failure. Patient 2 is a 67-year-old man with mCRPC with progression on multiple prior therapies. He first initiated Lu177-PSMA and one year later this was combined with 225Ac-PSMA617 in 2-month intervals. He received 5 rounds of 225Ac-PSMA617 in total, the last round being complicated with grade 3 cytopenias leading to cessation of treatment. Baseline serum creatinine at initiation of TRNT was 1.0 mg/dL (eGFR 82 mL/min/1.73m²). He subsequently developed progressive CKD and serum creatinine was 1.7 mg/dL (eGFR 40 mL/min/1.73m²) on last follow-up.

Discussion: We report 2 cases of progressive kidney disease in the setting of 225Ac-PSMA617 therapy for patients with advanced mCRPC. One underwent kidney biopsy showing tubulointerstitial injury, consistent with 225Ac-PSMA617-related tubular accumulation of toxic nuclides seen in animal models. This kidney injury was not responsive to corticosteroids therapy. Our case studies emphasized the need for careful assessment and monitoring of kidney function in patients receiving these novel agents.

PO2200

Successful Management of Chronic Ifosfamide Nephrotoxicity with Immunosuppression: A Case Series

Sankalp Malhotra, Jason Prosek.1,2 The Ohio State University, Department of Internal Medicine, Columbus, OH; 1The Ohio State University, Division of Nephrology, Columbus, OH.

Introduction: Ifosfamide is an alkylating chemotherapeutic agent that causes both acute and chronic kidney injury. Ifosfamide-induced chronic tubulointerstitial nephropathy is characterized by delayed diagnosis and treatment. Here, we describe three cases of chronic ifosfamide nephrotoxicity, wherein the time-course and outcomes suggest that earlier recognition and initiation of immunosuppression may benefit these patients.

Case Description: Three adult patients with distinct malignancies, status-post at least 3 cycles of ifosfamide chemotherapy, presented to our onco-nephrology clinic for worsening renal function. On average, the patients were referred to our clinic ~8 months after their last dose of ifosfamide. In this period, their serum creatinine (Scr) had risen to a peak ~2.5mg/dL from ~1mg/dL. The patients reported occasional frothy urine but were otherwise asymptomatic. Urine analysis and microscopy was significant for mild glucosuria/proteinuria, sterile pyuria, and granular casts, with urine protein/creatinine ratio of ~1.2. Autoimmune serologies, complement levels, protein electrophoresis, and renal ultrasound were unremarkable. Kidney biopsies, performed 10 months after the last ifosfamide cycle, demonstrated tubulointerstitial nephritis with moderately advanced interstitial fibrosis. Cyto logical atypia of the tubular epithelium was consistent with karyomegalic interstitial nephritis (KIN), previously documented in cases of ifosfamide toxicity. In cases, prednisone therapy led to improvement and plateau of Scr ~2.1. Curiously, multiple attempts to wean corticosteroids led to worsening Scr and active urinary sediment. In 2 patients, addition of mycophenolate mofetil enabled dose reduction but not cessation of corticosteroids. In all cases, Scr remained stable at ~2.1 after 1 year of follow-up.

Discussion: These cases illustrate the latent presentation and challenging management of chronic tubulointerstitial nephritis secondary to ifosfamide. On average, prednisone was started ~10 months after the last ifosfamide dose, when significant interstitial fibrosis had already developed. This delay in therapy and ongoing inflammation may have also contributed to the failure to stop corticosteroids. Overall, early surveillance, prompt recognition, and long-term immunosuppression is likely important in these patients to stabilize and maintain renal function.

PO2201

Hyperphosphatemia in the Setting of Fibroblast Growth Factor Receptor Inhibitors

Shahroz Zonozi,1 Bader Kfouri,2 Abdallah Sassine Gearsa.1 Philadelphia Hospital, Philadelphia, PA; 1Hospital of the University of Pennsylvania, Philadelphia, PA.

Introduction: Fibroblast growth factor (FGF)-23 is a phosphaturic hormone which works by reducing apical membrane expression of sodium-phosphate co-transporters in the proximal renal tubule and thus decreasing phosphate re-absorption. Fibroblast growth factor receptors (FGFR) are ubiquitously expressed in different tissues and become altered in various types of cancer. TAS-120 is one of several pan-FGFR inhibitors currently in clinical trials for use in patients with cholangiocarcinoma. Hyperphosphatemia is seen in more than 70% of patients on this therapy.

Case Description: A 44-year-old female with metastatic intrahepatic cholangiocarcinoma with progressive disease despite conventional therapy was started on TAS-120. Fifteen days into treatment she developed pain in knees and hips and was noted to be hyperphosphatemic to 7 mg/dL. She was initiated on sevelamer but given persistent hyperphosphatemia to 6.4 mg/dL, acalzolamide, calcitonin and phytodnadoine were added. Despite this, phosphorus remained elevated at 5.8 mg/dL; addition of alendronate 35mg weekly alongside dose reduction of TAS-120 led to sustained improvement in serum phosphorus levels. A 49-year-old male with a history of cholangiocarcinoma was started on TAS-120. Four days into treatment he developed calf pain and was noted to be hyperphosphatemic to 7.3 mg/dL. The medication was briefly stopped and he was initiated on sevelamer with improvement in phosphorus to 2.7 mg/dL. Resumption of TAS-120 led to recurrent hyperphosphatemia for which acalzolamide was initiated.

Three months after initiation of TAS-120 he had ongoing hyperphosphatemia; following dose reduction of TAS-120 and starting phytodnadoine, protencb and calcitonin, serum phosphorus levels remained within normal limits.

Discussion: FGFR-induced hyperphosphatemia has a similar clinical presentation as hyperphosphaticemic familial tumoral calcinosis (HFTC) with debilitating joint pain and tissue calcification. The current management of hyperphosphatemia relies mainly on dietary modification and gastrointestinal phosphate binding that were insufficient for our patients. The hyperphosphatemia and calciphylaxis pain was successfully treated with phosphaturtic medications (acalzolamide, calcitonin) and alendronate. Phytodnadoine (vitamin K) interferes with matrix Gla protein, a tissue inhibitor of calcification.
Treatment with immunosuppressive therapy is crucial. Early diagnosis with renal and bone marrow biopsy and subsequent complications. Autopsies have shown that 90% of CLL patients have renal infiltration; CD20 positive lymphocytic renal interstitial infiltrate.

**PO2203**

**Attack of the Clones: Leukemia and Myeloma**

Sara Wang, Shreya Patel, Elizabeth A. Alaimo, Shanaz Azad, Pankaj Jain, Tauseef A. Sargurdu. *Francis Health Inc, Mishawaka, IN.*

**Introduction:** Chronic lymphocytic leukemia (CLL) and multiple myeloma (MM) are both neoplastic diseases that are monoclonal tumors of differentiated B-cells that rarely occur simultaneously. There is disagreement and conflicting evidence as to whether these seemingly distinct disorders may arise from identical clones. In some cases MM may be diagnosed up to 15 years after the established diagnosis of CLL. We describe a rare case of a patient with renal failure and nephrotic range proteinuria where both CLL and MM were diagnosed concomitantly from a single renal biopsy.

**Case Description:** 59 y/o Indian male with COPD, DM-type 2, HTN, recent pseudomonas aeruginosa pneumonia presented with bilateral temporal headaches and fevers. Work-up revealed creatinine: 1.7mg/dl, UPCR: 6.6 g/g, free kappa/lambda ratio of 0.25 and mildly depressed C3 and C4. Renal biopsy showed diffuse proliferative and crescentic glomerulonephritis with IgG lambda light chain restriction, CD-20 positive lymphocytic interstitial infiltrate, ATN and diabetic glomerulopathy. EM also revealed subepithelial hump-shaped deposits and abundant glomerular neutrophils suggesting a component of post-infectious GN. Both flow cytometry and bone marrow biopsy revealed monotypic B-lymphocyte population with aberrant expression of CD5 and CD23 consistent with the diagnosis of CLL. The patient was treated with cyclophosphamide and dexamethasone and is currently stable on Brutinib with a creatinine of 1.3mg/dl.

**Discussion:** CLL is a common hematologic malignancy that has many systemic complications. Autopsies have shown that 90% of CLL patients have renal infiltration; however there is seldom renal impairment. This is a rare case of renal C. J. L. infiltration causing type-I cryoglobulinemia with IgG lambda monoclonal gammapathy of renal significance. Early diagnosis with renal and bone marrow biopsy and subsequent treatment with immunosuppressive therapy is crucial.

**PO2204**

**Should We Give the Green Light to Green Top Tube? Reverse Pseudohyperkalemia in Leukemia Patient**

Ming-Jen Chan, Chuang Gong Memorial Hospital, Taoyuan, Taiwan.

**Introduction:** Here we described a 69-year-old woman presented with hyperleukocytosis with reverse pseudohyperkalemia. This is also the first case of reverse pseudohyperkalemia in Philadelphia chromosome positive acute lymphoblastocytic leukemia.

**Case Description:** The 69-year-old woman was rushed to our emergency department due to progression of dyspnea for one week. Upon lab examination, hyperleukocytosis (> 500000/ul) with blasts that suggestive of acute leukemia. Notably, marked hyperkalemia (11.6 mEq/L) with normal renal function was noted but there is no typical electrocardiogram change. High LDH (3393 U/L) and low haptoglobin (<7.88 mg/dL) also noted. After clarification, the blood tube that had result of hyperkalemia is sodium heparin reagent. We retested potassium by using serum separate tube with 5 minutes of 3000 revolutions per minute, revealing serum potassium level 3.8 mEq/L. Reverse pseudohyperkalemia was impressed. She received leukopheresis and chemotherapy for leukostasis. The bone marrow biopsy later confirmed Philadelphia chromosome positive acute lymphoblastocytic leukemia. Reverse pseudohyperkalemia resolved after leucocyte return to normal level.

**Discussion:** Pseudohyperkalemia is suspected when the measured potassium is high but the patient does not manifest signs of hyperkalemia, such as abnormal electrocardiogram. Pseudohyperkalemia is falsely elevated of serum potassium levels without elevation of plasma potassium levels, commonly occurred in patients with hematological disease. Heparin anticoagulated plasma samples provide more accurate measurement of the true potassium level in these patients and sodium heparin (green top) tube is widely used. However, in reverse pseudohyperkalemia, serum potassium is within normal range, and plasma potassium falsely elevated, such as in our patients. The heparin in the plasma collection tube causes damage to the cell membrane during processing and centrifugation in the context of fragile cells of hematologic malignancy. Reverse pseudohyperkalemia had been reported in chronic lymphocytic leukemia patient. To our knowledge, this is the first case report of reverse pseudohyperkalemia in Philadelphia chromosome positive acute lymphoblastocytic leukemia patient. This case reminds us that potassium obtained using heparin tube is not panacea to get accurate level, and reverse pseudohyperkalemia is a must-known phenomenon for clinicians.

**PO2205**

**A Rare Case of Composite Lymphoma with Kidney Infiltration of Nodal Marginal Zone B Cell Lymphoma and Three Different Types of Cast Nephropathy**

Tianjun Guan, Yu Li, Anqun Chen. Division of Nephrology, Zhongshan Hospital, Xiamen University, Xiamen, China.

**Introduction:** We present an interesting case of composite lymphoma (nodal marginal zone B-cell lymphoma and multiple myeloma) characterized by the rare kidney invasion of the nodal marginal zone B-cell lymphoma and three different types of cast nephropathy present simultaneously in patient with multiple myeloma.

**Case Description:** A 57-year-old Chinese male was admitted to hospital for proteinuria. He reported foam urine, abdominal distension, fatigue, and weight loss of 5 kg within one month. Laboratory tests demonstrated hemoglobin 108 g/L, blood urea nitrogen 27.1 mmol/L, serum creatinine 639.1 umol/L and urine acid 547 umol/L. The 24-hour urinary protein and microalbumin was 3193.3mg and 42.3mg, respectively. Immunofixation electrophoresis (IFE) showed IgD-Lambda monoclonal protein. MRI narrow aspiration osteosclerotic lesions. Bone marrow biopsy demonstrated a hypercellular marrow with extensive plasma cell infiltration. Besides, multiple lymphadenopathies in both axillary and bilateral Inguinal lymph nodes were noticed. Lymph node biopsy suggested a nodal marginal zone B-cell lymphoma. To explore the involvement of kidney injury, we performed a kidney biopsy. Surprisingly, we found three types of nephropathy (myeloma casts, light chain crystal structure and light chain amyloidosis). At the same time, we also found focal lymphocyte infiltration, which are confirmed of nodal marginal zone B-cell lymphoma by immunohistochemistry with various molecule markers. To further explore the relationship between the two tumors, we performed the whole genome exon sequencing of the bone marrow and lymph nodes, surprisingly we found the similar mutation sites (V1982I of ARID1A gene) in both tissues, suggesting that the two tumors might originated from the same mutation. After BCT chemotherapy and PAD-T chemotherapy, urea nitrogen and blood creatinine decreased, the patients get rid of hemodialysis.

**Discussion:** Nodal marginal zone B-cell lymphoma infiltrate kidney only is very rare. Also three kinds of nephropathy (myeloma casts, light chain crystal structure and light chain amyloidosis), present simultaneously is also very rare. And the sequencing of the genome exon suggested that nodal marginal zone B-cell lymphoma might developed in to multiple myeloma in bone marrow micro-environment.

**PO2206**

**Breast Cancer-Associated Podocytopathy**

**Introduction:** Podocytopathies such as FSGS have not been classically associated with solid malignancy. Here we present a case of a female with a diagnosis of FSGS and its association bilateral lobular carcinoma in situ of the breast.
Case Description: A 52 year old Sri Lankan female with history of DM2 (with no prior known history of proteinuria) was referred for sudden onset of proteinuria. The patient first reported foamy urine in October 2017 with workup significant for sub-nephrotic proteinuria of 2 gram with normal serum creatinine and albumin. A kidney sonogram was unremarkable. Further workup was negative for infectious, autoimmune, vasculitis and para-protein etiologies. The patient was started on Lisinopril 10mg, however proteinuria worsened to 12.6 grams thereby switch to losartan (100mg daily) with slight improvement in proteinuria. A kidney biopsy was performed which showed focal global glomerulosclerosis secondary to adaptive changes with minimal fibrosis with no diabetic nephropathy related changes seen. Light microscopy showed globally sclerosis (9%) and IFTA (5-10%). Immunofluorescence microscopy showed no evidence of primary podocyte disease, immune complex-mediated disease or para-protein deposition disease.

Discussion: Our case demonstrates a potential link of the diagnosis of lobular ductal cancer of the breast with a diagnosis of FSGS. Interestingly, the FSGS diagnosis preceded the diagnosis of the breast cancer. While the proteinuria came into partial remission with conservative management, a dramatic resolution of FSGS was noted post-surgery and hormonal therapy for the breast cancer.

PO2028
A Patient with Hyper-Warburgism Successfully Treated with Peritoneal Dialysis
Surasath Isaranuwatchai, Thatchanan Porntharukchareon,
Chayapa Thiokhomme. Chulabhorn Hospital, Bangkok, Thailand.

Introduction: The combination of hypoglycemia and lactic acidosis in cancer patients is usually known as hyper-warburgism.

Case Description: A 74-year-old Thai man presented to our hospital with symptomatic hypoglycemia. He was previously healthy, no history of diabetes. Further investigation revealed hyperbilirubinemia, hepatosplenomegaly and first-diagnosed HIV infection. Computerized tomography of abdomen showed large liver mass with multiple intraabdominal lymphadenopathy. Liver mass biopsy showed round cell neoplasm with immunohistochemistry staining compatible with Burkitt lymphoma: positive for CD20, Bcl-6, CD10, C-myc, Ki67 100%, and negative for Bcl-2. His lymphoma was initially treated with high-dose dexamethasone. During investigation and initial treatment, our patient developed acute kidney injury (AKI) with severe lactic acidosis. Hypoglycemia persisted even he received intravenous glucose 18 g/hour. Serum ketone, insulin and c-peptide were normal. We suspected that he had hyper-warburgism due to Burkitt lymphoma, which was not respond to dexamethasone. Due to HIV seropositive status, we chose automated peritoneal dialysis (PD) for AKI and severe metabolic acidosis in this patient. PD dose in this patient was 19 liters per day. After PD initiation, the patient gradually recovered, with serum lactate dramatically decreased and intravenous glucose could be stopped. Clinical and laboratory parameters, including major clinical events, were shown in figure 1. After lactic acidosis resolved, we decided to treat this patient with chemotheraphy. Unfortunately, this patient died later due to fungemia, neutropenia and septic shock.

Discussion: Hypercatabolic state such as hyper-warburgism was usually treated with continuous renal replacement therapy (CRRT). Here, we presented a case of hyper-warburgism successfully treated with PD. We hoped this report might offer alternative treatment in patients unable to undergo CRRT.
Discussion: Nesiritide is a human monoclonal antibody that inhibits mammalian
decay-accelerating factor (MAD-Fc) which is an essential enzyme in the complement system leading to
pathway can ameliorates proteinuria induced kidney injury. However she did not have
in their platelet count, LDH and C3b9 levels. Further studies are ongoing
(Phase 3 trials in IgA nephropathy and HSC-TMA) to evaluate such renal benefits.

PO2210
The Histopathologic Spectrum of Kidney Biopsies in Patients with
Thymoma, Myasthenia Gravis, or Both: A Report of 24 Cases from a
Single Institution
Akira Takahashi, Takamasa Miyashita, Michifumi Yamashita. Cedars-Sinai Medical Center, Los Angeles, CA.

Introduction: Nephropathy in patients (Pts) with thymic diseases such as thymoma and
myasthenia gravis (MG) is rare and has been the subject of case reports. Previously, 93
cases have been reported from multiple institutions, and of these, common diseases are
minimal change disease (MCD; 45.2 %), membranous nephropathy (MN; 19.4 %),
primary focal segmental glomerulosclerosis (FSGS; 9.7 %). Here we characterize the
spectrum of kidney biopsy findings in 24 cases from a single institution.

Case Description: Total 40,268 renal biopsy cases from 2005 through 2019 at Cedars-Sinai Medical Center were reviewed. 24 cases (0.0596 %) of Pts have history of
thymoma and/or MG. Main pathological findings are following: MCD (10 cases; 41.7 %),
Tubulointerstitial nephritis (TIN; 3 cases; 12.5 %), Immune complex-mediated
glomerulonephritis (ICGN; 2 cases; 8.3 %), Diabetic glomerulosclerosis (2 cases; 8.3 %)
acute tubular necrosis/necrosis (ATN/ATN) with myoglobin casts (2 cases; 8.3 %), ATN/ATN (1 case; 4.2 %), IgA nephropathy (1 case; 4.2 %), MN (1 case; 4.2 %), secondary FSGS (1 case; 4.2 %), and Monoclonal Ig deposition disease (1 case; 4.2 %).

Discussion: Consistent with previous report, MCD is the most common renal lesion in Pts with thymic diseases. However, we experienced only one case of MN and no primary FSGS, the 2nd and 3rd common diseases in the reports. We, instead, observed kidney diseases that haven’t been reported before: TIN, and ATN/ATN with myoglobin casts. Of TIN cases, 1 showed granulomatous interstitial inflammation without infection and 1 case showed acute tubulitis with immune complex deposits both in mesangium and along tubular basement membranes. In addition, 40 % of MCD cases showed a atypical feature: IgC deposits in mesangial area. The possible mechanisms of thymic disease-associated nephropathy include T cell dysregulation, IC formation containing tumor antigen, and effects of tumor-releasing lymphokines. In conclusion, this is the largest and the unique case series of nephropathy in Pts with thymic disease from a single institution.

PO2211
Erdheim-Chester Disease: A Rare Cause of Bilateral Renal Artery
Stenosis and AKI
Mieke B., Ng Ni, Saw Yu Mon,,1 Rachael O’Rourke,4,5 Nileg Mott,3 Touraj Tabel.,2,6,7 Kirk Morris,1 Pedro H. Gois,1,3,4,5,11 Kidney Health Service, Royal Brisbane and Women’s Hospital, Brisbane, QLD, Australia; 2Faculty of Medicine and Institute for Molecular Bioscience, University of Queensland, Brisbane, QLD, Australia; 3Medical Imaging, Royal Brisbane and Women’s Hospital, Brisbane, QLD, Australia; 4Medical Imaging, Prince Charles Hospital, Brisbane, QLD, Australia; 5Faculty of Medicine, University of Queensland, Brisbane, QLD, Australia; 6Pediatogy Queensland, Royal Brisbane and Women’s Hospital, Brisbane, QLD, Australia; 7Department of Cancer Services, Royal Brisbane and Women’s Hospital, Brisbane, QLD, Australia.

Introduction: Erdheim-Chester disease (ECD) is a rare, non-Langerhans cell
histiocytosis affecting multiple organ systems. We report a case of ECD with bone
stenting, anti-hypertensive requirement reduced to 2 agents and renal function improved
to better than pre-AKI levels. She is receiving peg-interferon-g2a and prednisolone for
ECD.

Discussion: The disease affects renal arteries in 18-27% cases and should be considered as cause of renal artery stenosis in older patients with multisystem anomalies. Renal stenting in this subset can improve hypertension and renal outcomes. The disease has characteristic radiological findings and the diagnosis is frequently reliant on imaging. Histological examination is often not sufficient to confirm the diagnosis. ECD diagnosis is essential for treatment of the underlying disease process.

PO2212
Renal Involvement as Initial Presentation of mantle Cell Lymphoma: A Case Series
Ibrahim El Halabi,1 Natachia Righal Soler,1 Elvira O. Gososanov,2 Swati Mehta, Andrea R. Lightle,1 Terry H. Salzman,2 and Mauricio Monroy,1,31 Albany Medical Center, Albany, NY; 22 Albany Stratton VA Medical Center, Albany, NY.

Introduction: Mantle cell lymphoma (MCL) rarely affects kidneys. We present 2 cases with different spectrum of kidney involvement in MCL.

Case Description: The 1st case was a 63-yr old male with incidental finding of serum creatinine (SCr) of 10mg/dL. Chronic lymphocytic leukemia was diagnosed 2 weeks prior via peripheral blood analysis & flow cytometry (FC) done due to constitutional symptoms and headaches for which he was using daily ibuprofen for several months. On exam he had elevated blood pressure but no signs of volume overload. Initial supportive treatment did not improve kidney function and hemodialysis was initiated due to worsening azotemia and persistent nausea and vomiting suspicious for uremia. Renal biopsy showed diffuse acute on chronic interstitial nephritis with peryverosal lymphoid aggregates of monoclonal CD 20+ B-cells positive for CD5 and Cyclin-D1 consistent with MCL. No significant immunostaining was found. Bone marrow biopsy confirmed renal biopsy findings and diagnosis of MCL. Until last follow up, the patient refused chemotherapy and remained in stable condition. The 2nd case was a 73-yr old male with incidental finding of SCr of 1.9mg/dL in association with glomerular hematuria and grade A3 proteinuria. He had no constitutional symptoms and had normal physical exam except for presence of diffuse lymph node (ENL) enlargement. Renal biopsy was obtained and showed MPGN-pattern with 25% crescents on light microscopy, presence of all immunoglobulin classes with c-light chain (KLC) predominance in glomeruli and lymphoid infiltration with KLC in the interstitium on immunostaining. MCL was confirmed with FC and excisional LN biopsy. Prednisone/Rituxin/Bendamustine therapy led to improvement in kidney function and proteinuria.

Discussion: MCL can cause differential kidney involvement from direct tumor infiltration to MCL-associated glomerulonephritis. Therefore, correct diagnosis with renal biopsy and prospective registries are needed to generate data about differences in outcomes in MCL with various kidney involvement.

PO2213
Cystatin C Measurement Improves Renal Function Estimation with Selpercatinib Use
Victoria Gutgarts,1,2 Dazhi Liu,1 Lauren A. Kaplanis,1 Alexander Drilon,1,2 1Memorial Sloan Kettering Cancer Center, New York, NY; 2Weill Cornell Medicine, New York, NY.

Introduction: Selpercatinib (LOXO-292) is a selective RET inhibitor that is approved for the treatment of RET-dependent lung and thyroid cancers. In the LIBRETTO-001 trial of selpercatinib, a treatment-emergent increase in serum creatinine was noted in ~18% of patients. Creatinine is mainly excreted by glomerular filtration and is partly secreted via renal tubules as MATE1/2B-dependent transport. Inhibition of selpercatinib, can reduce creatinine clearance leading to an incorrect diagnosis of drug related kidney injury. Cystatin C is an alternative marker that is freely filtered, completely reabsorbed and not secreted like creatinine. It is therefore not affected by transporter inhibitors and may be a better marker of kidney injury in patients receiving Selpercatinib. We present a patient on Selpercatinib with significant difference in kidney function by creatinine and cystatin C.

Case Description: 58-year-old male with metastatic RET fusion-positive lung cancer who progressed on cabozantinib started selpercatinib. His pre-treatment creatinine was 0.9 mg/dL which increased to 1.3 mg/dL in 3 months with no significant proteinuria. Renal sonogram showed right sided hydronephrosis which prompted placement of ureteral stent. Creatinine did not improve with persistent hydropnephrosis prompting conversion to a nephroureterectomy tube one year later. Serum creatinine remained elevated at 1.9mg/dL despite resolving hydropnephrosis. Cystatin C levels were measured and showed significant discrepancy with serum creatinine as shown in Table below. This finding highlighted that although the patient did have chronic kidney disease, the extent was less than estimated by solely creatinine.

Discussion: This case highlights the benefit of checking both creatinine and cystatin C in patients on selpercatinib. Despite urological intervention, the persistence in elevated

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
creatinine is likely attributed to the drug inhibitory effect on creatinine secretion. Cystatin C may be a better measure of renal function in patients receiving MATE-1 inhibitors such as selpercatinib.

Discrepancy in Serum Creatinine and Cystatin C Trends

PO2214
ALECT 2 and Hepatocellular Carcinoma: An Intriguing Association
Janelle K. Kottee, Niraj K. Yadav, Josephine Abraham. University of Utah Health, Salt Lake City, UT.

Introduction: Amyloidosis derived from leukocyte chemotactic factor 2 (ALECT2) is the third most common type of renal amyloidosis in the United States. The incidence of ALECT2 is highest among Hispanics and there is a predilection for involvement of the kidney and liver with sparing of the heart. We report a case of hepatocellular carcinoma (HCC) in a patient with ALECT2.

Case Description: A 69-year-old Hispanic man with chronic kidney disease secondary to ALECT2 and monoclonal gammonaphy of undetermined significance was admitted for constipation and distended abdomen. Creatinine on admission was 1mg/dL and he was initiated on dialysis. Imaging revealed cirrhosis, ascites and two liver masses involving the portal vein. Alpha fetoprotein was 7123 ng/mL and he was diagnosed with large multifocal HCC. Evaluation for hepatitis, autoimmune disease and other etiologies for chronic liver disease was negative and cirrhosis was presumed to be secondary to ALECT2. Based on the Barcelona Clinic Liver Cancer staging, he was given a stage D3.

His functional status precluded any liver directed therapies or systemic chemotherapy and he died due to cancer progression 3 months later. Figure 1 summarizes his treatment and laboratory course.

Discussion: ALECT2 is a recently described form of systemic amyloidosis that has quickly emerged as a common and possibly underdiagnosed cause of systemic amyloidosis particularly in patients of Hispanic ancestry. ALECT2 can involve various organs but usually spares the heart and brain. ALECT2 in association with HCC has not been reported to date. Interestingly in one study, expression of LECT2 in human organs but usually spares the heart and brain. ALECT2 in association with HCC has not been reported to date. Interestingly in one study, expression of LECT2 in human organs but usually spares the heart and brain. ALECT2 in association with HCC has not been reported to date. PO2216
Eculizumab for Treatment and Prevention of Recurrent Gemcitabine-Induced Atypical Hemolytic Uremic Syndrome After Gemcitabine Rechallenge: A Case Report
Orhan Ergin,1,2 John Niles,1 Reza Zonoz.1 Massachusetts General Hospital, Boston, MA; 2Brigham and Women’s Hospital, Boston, MA.

Introduction: Atypical hemolytic uremic syndrome (aHUS) is a rare side effect of gemcitabine. Here, we report a case of gemcitabine-induced aHUS successfully treated with eculizumab, with subsequent use of eculizumab to prevent recurrence of aHUS after reinitiating gemcitabine.

Case Description: A 29-year-old male with intrathoracic cholangiocarcinoma on gemcitabine and cisplatin was admitted with AKI. On presentation, he was newly hypertensive to 162/108 mmHg and edematous. His labs were notable for a serum creatinine (Scr) of 1.19 mg/dL (baseline 0.6 mg/dL), hemoglobin 8.8 g/dL (baseline of 12.6 g/dL) with reticulocytosis, platelet count 190 K/µL, LDH 635 U/L, haptoglobin <10 mg/dL, schistocytes on blood smear, and a normal ADAMS13 level. Urine studies revealed hematuria, proteinuria, and granular casts. Gemcitabine and cisplatin were discontinued, yet his SCR continued to rise to 2.12 mg/dL, LDH to 1222 U/L and platelet count fell to 77 K/µL. Eculizumab was initiated and his creatinine improved to 1.14 mg/dL, and his LDH, platelet count, and haptoglobin normalized. Eculizumab was stopped after 2 months without subsequent recurrence. He was reinitiated on dose-reduced gemcitabine and cisplatin due to progression of his cancer despite multiple alternative chemotherapies. Eculizumab was reinitiated concurrently with gemcitabine and continued b iweekly. His blood pressure, Scr, haptoglobin, LDH and platelet count remained stable. Unfortunately, he died due to cancer progression 3 months later. Figure 1 summarizes his treatment and laboratory course.

Discussion: We report a case of successfully utilizing eculizumab to prevent recurrence of gemcitabine-induced aHUS after gemcitabine reinitiation, which has not been previously reported to our knowledge. There are scarce reports of gemcitabine reinitiation without eculizumab, most of which resulted in recurrent renal toxicity. There may be utility in the use of eculizumab in patients who need to reinitiate gemcitabine. Larger studies evaluating this approach are warranted.

PO2217
A Case of Lupus Nephritis Improved by Molecular Targeted Drug Therapy for Multiple Intrapulmonary Metastasis of ROS-1 Gene-Positive Lung Cancer
Miho Karube, Hiroko Uchida, Yoshinori Komagata, Shinya Kaname. Division of Nephrology and Rheumatology, Kyorin University School of Medicine, Tokyo, Japan.

Introduction: Systemic lupus erythematosus is a multisystemic disease associated with genetic, environmental and epigenetic factors. The effect of tyrosine kinase inhibitors has only been reported in SLE model mice for imatinib. Here we report a case in which lupus nephritis was improved by a molecular targeted drug for multiple intrapulmonary metastases of ROS-1 gene-positive lung cancer.

Case Description: Thirty-one-year-old woman, who was diagnosed with SLE at the age of 14 years, had been treated with immunosuppressive agents including corticosteroids, cyclophosphamide and mycophenolate mofetil, with frequent relapses. At the age of 30 years, she was admitted to our hospital due to development of systemic erythema, which was diagnosed as drug-induced eruption with increased SLE activities. She was treated with prednisolone (PSL) 50 mg/day and remission was achieved for

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
SLE, however, during the systemic screening, lung adenocarcinoma was accidentally detected, and thoracoscopic right middle lobeectomy was performed. Seven months after surgery, she had an exacerbation of erythema on the face and bilateral arms, arthralgia and urinary proteins, with elevated anti-ds-DNA antibodies and decreased serum complement levels. The dose of PSL was increased, but the symptoms did not improve, when multiple intrapulmonary metastases were detected, indicating recurrence of lung adenocarcinoma. The previous lung specimens revealed a high expression of PD-L1 and positive ROS-1 fusion gene, thus tyrosine kinase inhibitor (crizotinib) was selected as the anti-cancer therapy instead of anti-PD-L1 antibodies. Interestingly, urine protein and erythema/ arthritis improved, and the size of lung tumor reduced.

Discussion: Crizotinib is a molecular targeting agent with non-receptor-type tyrosine kinase inhibitor action that competitively binds to the ATP binding site of EML4-ALK tyrosine kinase, resulting in signal transduction inhibition. In this case, the molecular targeting drug induced improvement of lupus nephritis along with regression of lung cancer, suggesting that tyrosine kinase inhibition may be effective for lupus nephritis.

Paraneoplastic Minimal Change Disease Associated with High-Grade Neuroendocrine Tumor

Mohankumar Doraiswamy, Jessamyn S. Carter, Sethu M. Madhavan, Jason Prosek. The Ohio State University Wexner Medical Center, Columbus, OH.

Introduction: Minimal Change Disease (MCD) is usually associated with Lymphoma. Leukemia and solid tumors like Lung Cancer, Renal Cell Carcinoma and Thymanoma but data on incidence of paraneoplastic glomerular disease are lacking. To our knowledge, only two cases of neuroendocrine tumor (NET) presenting with Paraneoplastic MCD reported in literature. Herein we report a 47 year-old woman with diabetics and diagnosed with nephrotic syndrome and renal biopsy was suggestive of minimal change disease.

Case Description: A 47 year-old-man with history of well-differentiated metastatic NET (not on therapy) and HTN admitted for dyspepsia and anasarca for two weeks. His labs were: Hgb 9.3; Urea 3.9 mg/dl, Creatinine 1.9 mg/dl, sodium 145 mmol/L, potassium 4.3 g/l, and Na 118 mmol/L. IV diuretics with albumin infusion initiated, which improved his kidney function. Serologies and proteinuria workup - negative. Renal biopsy performed for nephrotic syndrome, showed prominent podocyte foot process effacement with mild acute tubular necrosis and mild membranous nephropathy. Diagnosis with paraneoplastic MCD from metastatic NET and treatment with steroids initiated. Chemotherapy not started because of the overall decline in his clinical status and increased tumor burden. One week after steroids, his proteinuria was 42 g/day, and steroid doses were increased. Three weeks later, proteinuria decreased to 6 g/day and his symptoms improving. Unfortunately, he suffered further kidney injury because of hypotension and hemodialysis initiated one month later.

Discussion: The most common paraneoplastic glomerular disease is membranous glomerulopathy in tumour patients, but MCD should be kept on the differential as well. Like membranous nephropathy, remission of MCD was reported on ablation of the tumor, suggesting a paraneoplastic process, though the precise mechanisms are not fully understood. In our case, since the patient did not qualify for chemotherapy because of increased tumor burden, steroids were initiated which helped in part to reduce symptoms. The etiology of glomerulopathy in cancer does not appear to be related to tumor burden, by the lymphomatous infiltrates impeding tubule function and peritubular capillary blood flow. Our patient’s biopsy supports this mechanism. Her AKI resolved with urgent corticosteroids and chemotherapy. Further reporting is needed on the prevalence of this condition and nephrologists should consider renal lymphomatous invasion when evaluating AKI in those with cutaneous T-cell lymphoma.

**PO2220**

Sezary Syndrome with Renal Involvement

Sheikh B. Khald,1,2 J. Charles Jennette,1 Monica L. Reynolds,1 Obaijula Kanu,1 Vikas Singh.1 University of North Carolina at Chapel Hill, Chapel Hill, NC, 2Shaheed Khanum Memorial Cancer Hospital and Research Centre, Lahore, Pakistan.

Introduction: Sezary Syndrome is a cutaneous T-cell lymphoma that presents with erythroderma, lymphadenopathy, and circulating malignant T cells. While involvement of the spleen, liver, bone marrow and lung are well documented, kidney involvement is rare. We present a case of acute kidney injury (AKI) due to biopsy-proven T cell lymphoma invasion of the kidneys

Case Description: A 69-year-old female with a history of cutaneous T-cell lymphoma was admitted to the oncology service with AKI. Serum creatinine (sCr) 3.3mg/dl (baseline 0.6mg/dl), urine protein-to-creatinine ratio 2.5g/g, urine sediment bland and renal ultrasound unremarkable. A PET scan, performed to evaluate systemic disease burden, revealed diffuse kidney enlargement with high FDG uptake throughout the renal parenchyma. A kidney biopsy was performed Light microscopy showed diffuse interstitial infiltration by atypical small lymphoid cells and prominent focal apoptosis with apoptotic bodies and focal interstitial hemorrhage. The lymphoid cells had the same immunophenotype as the cutaneous T cell lymphoma. The glomerulus had slight segmental wrinkling of capillaries and glomerular basement membranes, and segmental podocyte swelling. She also had leptomeningeal involvement. Treatment included dexamethasone, systemic and intrathecal doxorubicin, melphalan, and cytarabine. sCr returned to baseline, but unfortunately, however, her course was complicated by severe mucositis, neutropenic fever, gastrointestinal hemorrhage and refractory shock. The patient was stabilized and opted to return home with hospice

Discussion: AKI caused by kidney involvement in Sezary syndrome has only been reported via case reports. The mechanism of AKI is thought to be tubular compression by the lymphomatous infiltrates impeding tubule function and peritubular capillary blood flow. Our patient’s biopsy supports this mechanism. Her AKI resolved with urgent corticosteroids and chemotherapy. Further reporting is needed on the prevalence of this condition and nephrologists should consider renal lymphomatous invasion when evaluating AKI in those with cutaneous T-cell lymphoma.

Management of IgA Nephropathy and Comorbid Breast Cancer

Victoria Gutierrez,1,2 Steven Salvatore,1,2 Roman A. Shingarev,1,2 Memorial Sloan Kettering Cancer Center, New York, NY; 1Weill Cornell Medicine, New York, NY.

Introduction: Immunoglobulin A nephropathy (IgAN) is the most common glomerulonephritis worldwide. Although treatment guidelines have been established, there is little known about the management of IgAN in the setting of solid malignancy.

Herein we describe two cases of IgAN and breast cancer diagnosed at our center.

Case Description: Case 1: 42-year-old female with newly diagnosed breast cancer 3 months ago presents to the renal clinic for acute kidney injury (AKI) (Cr) 3.5mg/dl from baseline 1.1-1.3mg/dl. Chemotherapy was started because of the overall decline in his clinical status and increased tumor burden. MCD from metastatic NET and treatment with steroids initiated. Chemotherapy not started because of the overall decline in his clinical status and increased tumor burden. One week after steroids, his proteinuria was 42 g/day, and steroid doses were increased. Three weeks later, proteinuria decreased to 6 g/day and his symptoms improving. Unfortunately, he suffered further kidney injury because of hypotension and hemodialysis initiated one month later.

Discussion: The most common paraneoplastic glomerular disease is membranous glomerulopathy in tumour patients, but MCD should be kept on the differential as well. Like membranous nephropathy, remission of MCD was reported on ablation of the tumor, suggesting a paraneoplastic process, though the precise mechanisms are not fully understood. In our case, since the patient did not qualify for chemotherapy because of increased tumor burden, steroids were initiated which helped in part to reduce symptoms. The etiology of glomerulopathy in cancer does not appear to be related to tumor burden, by the lymphomatous infiltrates impeding tubule function and peritubular capillary blood flow. Our patient’s biopsy supports this mechanism. Her AKI resolved with urgent corticosteroids and chemotherapy. Further reporting is needed on the prevalence of this condition and nephrologists should consider renal lymphomatous invasion when evaluating AKI in those with cutaneous T-cell lymphoma.

Belatacept-Induced Post-Transplant Lymphoproliferative Disorder of the Spleen That Spontaneously Resolved on Withdrawal of the Agent

Alexander Pennekamp,1 Karl B. Pernub,2 The Christ Hospital, Cincinnati, OH; 1The Kidney and Hypertension Center, Cincinnati, OH.

Introduction: PTLD (Post-Transplant Lymphoproliferative Disorder) is a dreaded and serious complication of allograft transplant. Compared to CNIs, allograft rejection prophylaxis with Belatacept is less nephrotoxic, but carries a higher risk of PTLD. B-cell proliferation in PTLD is linked to EBV, and while use of Belatacept is limited to those that are EBV+ pre-transplant, prior EBV infection does not completely ensure that a patient will not develop PTLD. Patients with active PTLD characteristically show B symptoms and an increase in EBV RNA due to active viral replication. Prompt PET, BMB and blood testing must be pursued to determine a potential site of proliferation.

Case Description: A 64 year AAM 2 years status-post deceased-donor transplant was admitted for altered mental status, nausea, vomiting, fever of unknown origin, and weight loss. He was found to have splenomegaly on CT without other evidence of adenopathy. LDH was elevated. Patient underwent brain MRI, PET scanning, BMB and LP; all of which were normal. A full ID work-up including CMV, EBV RNA, BK were all negative. Core biopsy of the spleen demonstrated CD20+/CD5+ cells with tissue effacement, suggesting a diffuse large B-cell lymphoma. While involvement of the spleen, liver, bone marrow and lung are well documented, kidney involvement is rare. We present a case of acute kidney injury (AKI) due to biopsy-proven T cell lymphoma invasion of the kidneys

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Discussion: Even in EBV recipient-positive patients, there is still a risk to develop PTLD post-transplant. Our case demonstrated PTLD which resolved spontaneously when withdrawing Belatacept. This suggests that overly aggressive immune suppression, rather than induction of dysregulated proliferation, was the culprit. The fact that the patient did not show an acute increase in EBV RNA, and EBV by ISH on core biopsy of the spleen was negative, suggests that pre-transplant seroconversion based on EBV seropositivity may not be sufficient to predict risk for developing PTLD. The patient had complete resolution of AMS and B symptoms with discontinuation of Belatacept, with no subsequent recurrence of PTLD after switching to sirolimus/mycophenolate.

PO2222

Heterogeneous Manifestations of Post-Renal Transplant Lymphoma

Rujuta R. Patil,1 M. Abouljoud,2 Anita K. Patel,1 1Wayne State University School of Medicine, Detroit, MI; 2Henry Ford Hospital, Detroit, MI

Introduction: Post-transplant lymphoproliferative disorder (PTLD) is a serious complication occurring in 1-3% of adult renal transplant recipients (RTR). PTLD is often associated with Epstein-Barr Virus (EBV) and over immunosuppression (IS). A majority of PTLD is of B-cell origin. PTLD has a heterogeneous presentation, involving the allograft, GI tract, and nervous system. We present a case series of 16 RTR who demonstrate a variety of PTLD manifestations.

Case Description: 50% of RTR were Caucasian and 38% African American. 62% of RTR received a deceased donor and 38% a living donor. 62% received Thymoglobulin induction and 38% Simulect. Maintenance IS was Prednisone, Tacrolimus, and Mycophenolate Mofetil (MMF). RTR presented with GI symptoms, abdominal pain, B symptoms, and neurological deficits. At diagnosis, average time from transplantation was 96.8 months. 13 out of 16 RTR were male and 44% were >61 years old. 31% were EBV mismatched and 12.5% were Cytomegalovirus mismatched. PTLD involved a single site in 44% and multiple sites in 56%. PTLD localized to the GI tract (10), lymph nodes (9), CNS (4), bone marrow (3), lungs (2), mediastium (2), skin (2), retroperitoneum (1), and native kidney/ureter (2). 6 RTR had purely extranodal involvement. PTLD was EBV+ (8), monomorphic monoclonal (14), and of B-cell lineage (13). Diffuse Large B Cell Lymphoma in 11. Non-Hodgkin’s Lymphoma was diagnosed in 7. 3 RTR had T-cell PTLD. IS agents (MMF, Tacrolimus) were discontinued in all 16 RTR at diagnosis; maintained on steroid monotherapy. Treatment was chemotherapy either alone or in combination with radiation (2), resection (2), and salvage therapy (1). Post treatment, all RTR remained on steroid monotherapy or with Everolimus (3), Tacrolimus (1), or Azathioprine/Rituximab (1). Treatment was complicated by Tuberculosis, Lymphosarcoma (1) infections. 50% of RTR developed renal insufficiency and 31% received dialysis. The mortality rate was 44%, 4 years after diagnosis.

Discussion: PTLD that was EBV-, had T-cell involvement, and localized to the CNS/ bone marrow presented with aggressive disease and a higher mortality. Thymoglobulin induction, deceased donor, and donor EBV+ status are potential contributing risk factors for PTLD development; further analysis is still being conducted. Physicians should be aware of the various PTLD manifestations and assure in management of renal transplant recipients.

PO2223

Richter Transformation (RT): A Rare Complication in Renal Transplant

Introduction: RT is conversion of B-cell chronic lymphocytic leukemia (CLL) into diffuse large B-cell lymphoma (DLBCL). We present a rare case of RT in a renal allograft.

Case Description: A 68 year old male was admitted for a syncopal episode and acute renal failure. He had significant medical history of ESRD secondary to diabetes and hypertensive nephrosclerosis, deceased donor renal transplant in 2015 on Mycophenolate and Tacrolimus, DCLL diagnosed in 2017 on Ibrutinib, Stage III CKD of allograft with baseline creatinine 15 mg/dl. Initial work up revealed orthostatic hypotension and AKI with creatinine of 3.3 mg/dl. Urine analysis and microscopy was negative for proteinuria, hematuria, pyuria casts or crystals. Renal ultrasound showed the size of transplant kidney was 10.7 x 5.8 x 4.3 cm with normal renal cortex and no demonstrated mass, cyst or hydro nephrosis. Administration of IV NS and holding antihypertensive medications to correct orthostasis failed to improve renal function with creatinine rising up to 4.02 mg/ dl. Transplant renal biopsy was done. Pathology results revealed no evidence of allograft rejection but extensive infiltration of renal parenchyma with atypical lymphocytes with high Ki-67 expression suggesting transformation to DLBCL in a patient with a known history of CLL. Lymphocytes retained their positivity for CD5 and CD23 which supported high Ki-67 expression suggesting transformation to DLBCL in a patient with a known history of CLL. Treatment was chemotherapy either alone or in combination with radiation (2), resection (2), and salvage therapy (1). Post treatment, all RTR remained on steroid monotherapy or with Everolimus (3), Tacrolimus (1), or Azathioprine/Rituximab (1). Treatment was complicated by Tuberculosis, Lymphosarcoma (1) infections. 50% of RTR developed renal insufficiency and 31% received dialysis. The mortality rate was 44%, 4 years after diagnosis.

Discussion: RT is conversion of B-cell chronic lymphocytic leukemia (CLL) into diffuse large B-cell lymphoma (DLBCL). We present a rare case of RT in a renal allograft.

PO2242

Longitudinal Assessment of Unilateral Ureteral Obstruction Kidney Injury by Relaxometry and Spin-Lock Exchange MRI

Feng Wang, Tadashi Otsuka, Keiko Takahashi, Raymond C. Harris, Takamune Takahashi. Vanderbilt University Medical Center, Nashville, TN.

Background: Non-invasive imaging technique allows longitudinal and repetitive assessment of renal disease progression. In this study, we assessed the utility of a new MRI technique, quantitative relaxometry and Spin-lock exchange MRI, in detecting renal pathology in unilateral ureteral obstruction (UUO) kidneys, focusing on destructive tubular injury (dilatation) and renal fibrosis, the pathological changes commonly observed in progressive kidney disease.

Methods: BALB/c mice (n=6-8) were imaged before and after (day 5, 10 and 15) UUO surgery at 7T magnet. Spin-lock images were acquired in a transverse plane using a fast spin echo sequence preceded by a preparatory spin-lock cluster. The dispersion of R2, with locking frequency was fit to Chopra model. The fits provided regional values of transverse relaxation rates R2, in arbitrary spin-lock frequency (R2), and an exchange rate-weighted parameter S. Since cortex and outer stripe of outer medulla (OSOM) were clearly identified with T2-weighted image, even with UUO kidneys, these regions were selected for analysis. Paraffin tissue sections were stained using picrosirius red or anti-collagen I antibody. Histological scores for tubular dilatation and fibrosis, based on renal space and positive fibrotic areas in sections, were computationally measured and the correlation between MRI parameters and histological scores were assessed.

Results: In histology, evident tubular enlargement was observed at UUO day 5 while tubulointerstitial fibrosis was mild at this stage. Both histological changes became more evident by UUO day 10 and fibrosis showed larger increases from day 5 to day 15 (tubular dilatation~25% increase, fibrosis~3 fold increase). Relaxation rates R2, R2 and R2 were progressively dropped (25-50%) in UUO kidneys. Interestingly, S showed the highest sensitivity to tubular dilatation, while S showed the highest correlation with renal fibrosis.

Conclusions: Relaxation parameters showed high detectability to tubular dilatation and overall changes in UUO progression. S best detected fibrotic changes. This would be because it depends mainly on the average exchange rate between water and collagen. If response to shaft reductions is used as amplitude modulations from these accumulations. These new MRI parameters could be used for the assessment of kidney disease progression.

PO2225

Kidney-Specific Landscape of Aging Mitochondrial DNA Mutations by Duplex Sequencing

Mariya T. Sweetwyne, Monica Y. Sanchez-Contreras, Kristine A. Tsantilas, Jeremy A. Whiston, Matthew D. Campbell, David J. Marcinek, Peter S. Rabionitch, Scott R. Kennedy. University of Washington School of Medicine, Seattle, WA.

Background: Accumulation of mutations in the mitochondrial genome (mtDNA) is a potential mechanism of aging in the mitochondrial rich kidney, where mtDNA damage also increases with diabetes, CKD and AKI. Accurately detecting low level somatic mtDNA mutations within the cellular complexity of the kidney was previously confounded by variable levels of mtDNA heteroplasmy. Using ultra-sensitive Duplex Sequencing (DS), a modified next-gen sequencing (NGS) technique, we decreased the error rate relative to conventional NGS by >10^4, allowing us to accurately characterize mtDNA mutation patterns unique to the aging kidney relative to other organs.

Methods: We compared mtDNA mutations in kidneys from cohorts of aged (26-28 m.o.) and young (5-m.o.) NIA C57Bl/6j mice to multiple organs with high mitochondrial content (heart, eye, liver, skeletal muscle and brain). In both ages, kidney carried the highest burden of mtDNA point mutations. Mutation spectrum analysis showed that mtDNA point mutations in the kidney increased significantly with age and were primarily G>A/C>T, indicative of polymerase error (2.5x10^-5 p > 0.0001 relative to all other tissues) and G>T/C>A, mutations indicative of oxidative damage, the second most common type. Aged kidneys were further separated into glomeruli and tubule-rich whole cortex fractions to determine regional mutation burden.

Results: Glomeruli had ~25% fewer total mtDNA mutations (p = 0.002) and specifically~80% fewer oxidative lesions (G>T/C>A, G>C/C>G, p = 0.02). Furthermore, differential accumulation of mtDNA mutation between kidney fractions does not appear to be randomly distributed across the genome but is instead gene-specific as demonstrated by target enrichment of reduced mutations in glomeruli of mtRNA gene mRn1 but not mRn2, and of Complex IV gene mt-Co2, but not mt-Co1 or 3. Finally, we sequenced kidneys from aged mice treated systemically for 8 weeks with SS-31, a mitochondrial therapeutic peptide that reduces oxidative stress in the kidney, and found that mutations stemming from oxidation, but not polymerase error, were significantly reduced.

Conclusions: These data suggest that renal mtDNA mutation is cell specific and that even in old age, accumulation of some mutations is tractable with therapeutic intervention.

**Integrated Analysis of the DNA Methyelome, Transcriptome, and Proteome in Human Glomerular and Tubulointerstitial Compartments**

Samir V. Parikh,1 Kimberly S. Collins,1 Ricardo Melo ferreira,1 Yinghua Cheng,1 Daria Barwinska,1 Michael J. Ferkowicz,2 Ken Dunn,1 Katherine J. Kelly,1 Timothy A. Sutton,1 John P. Shapiro,2 Brad H. Rovin,7 Pierre C. Dogher,1 Tarek M. El-Achkar,1 Michael T. Eadon1, Indiana University School of Medicine, Indianapolis, IN; 2The Ohio State University Wexner Medical Center, Columbus, OH.

**Background:** The interplay between the human DNA methylome, transcriptome, and proteome in the kidney glomerulus and tubulointerstitium is incompletely understood. Promoter sequence methylation is often thought to contribute to gene and protein expression regulation. We hypothesized that promoter sequence methylation would explain differential protein expression between the glomerulus and tubulointerstitium.

**Methods:** Nine reference nephrectomies underwent laser microdissection of the glomeruli and tubulointerstitium. DNA methylation sequencing, RNA sequencing, and mass spectrometry quantification of peptides was completed for both compartments in the samples. Datasets were dimensionally reduced to match expressed proteins (N=4600). Regions of hypermethylation in promoter sequences, introns, and exons were assessed and compared to corresponding protein and mRNA expression.

**Results:** At least three patterns of hypermethylation were observed across the methylome: promoter sequence, intrinsic, and exonic methylation. In many cases, promoter sequence or exonic methylation of the tubulointerstitium correlated with a higher glomerular to tubulointerstitial protein and mRNA expression ratio. Likewise, increased tubulointerstitial protein or mRNA expression was associated with glomerular hypermethylation of promoter or exonic regions. For example, Uromodulin (UMOD) protein and mRNA expression were higher in the tubulointerstitium than the glomerulus. The strongest regions of uromodulin hypermethylation were observed in exons 9 and 10 of the glomerular compartment, although hypermethylation was also observed in the promoter sequence and two intronic regions of the tubulointerstitium. In contrast, regions of hypomethylation of Apolipoprotein L1 (APOL1) were exclusively confined to the tubulointerstitium, distributed in all three patterns.

**Conclusions:** Promoter sequence methylation alone does not explain differential expression patterns between the glomerular and tubulointerstitial compartments. Hypermethylation of exonic regions also contributes to expression regulation.

**Single-Cell Transcriptomics of the Peripheral Blood Revealed Inflammation and Infection Were Associated with IgAN**

Changwei Wu, Guisen Li, Li Wang. Renal Department and Nephrology Institute, Sichuan Provincial People’s Hospital, School of Medicine, University of Electronic Science and Technology of China, Chengdu, China.

**Background:** Immunoglobulin A nephropathy (IgAN) is the most common primary glomerular disease worldwide. Due to the diverse clinical manifestations and the complex pathological features, IgAN patients have different response to therapy, and the optimal treatment for IgAN remains controversial. Our study investigated the pathogenesis of IgAN by single-cell transcriptome sequencing.

**Methods:** Single-cell transcriptome sequencing was performed on peripheral blood monocytes derived from 3 IgAN patients and 1 healthy control, and differential gene expression profiles of peripheral blood single-cell were established. Functional analysis was performed to explore the pathogenesis of IgAN. Meanwhile, RT-PCR was used to validate the differential expression of mRNA and mRNAs.

**Results:** According to quality control and cell selection, we characterized 21739 cells using unbiased single-cell RNA sequencing. 3 IgAN patients included 7847, 5389 and 6609 cells, respectively, and the healthy control included 1894 cells. We used unsupervised clustering to cluster cell clusters. In addition, cells were divided into 14 cell groups, including B lymphocytes and T lymphocytes, based on cell markers (Figure 1). Functional analysis revealed that differential genes were extensively enriched in inflammation / infection-related pathways in each cell type (Figure 2), and the EBV infection pathway focused on antigen presentation (Figure 3). RT-PCR of B lymphocytes demonstrated that SPI1, MXD1 and S100A9 mRNA levels were higher in IgAN patients than controls (Figure 4), which showed the reults of single-cell transcriptome sequencing was available.

**Conclusions:** Differential gene expression profiles of IgAN in peripheral blood single cells were successfully established, and it demonstrated that the inflammation/ infection pathway was associated with IgAN.
PO2228

Analysis of Urinary Exosomal RNAs After Treatment of Rats with an Nrf2 Activator
Ayae Tanaka, Hiroko Sonoda, Yui Sakaguchi, Masahiro Ikeda. Veterinary Pharmacology, University of Miyazaki, Miyazaki, Japan.

Background: Renal NF-E2-related factor 2 (Nrf2) is known to be increased in the presence of oxidative stress. Administration of an Nrf2 activator has also been reported to lessen the degree of renal damage. However, biomarkers for detection of Nrf2 activation in the kidney are largely unknown. Urinary exosomes, a subset of extracellular vesicles released by renal epithelial cells, contain RNA molecules that are expected to be biomarkers for renal disease. Thus we analyzed urinary exosomal RNAs after administration of bardoxolone methyl (BARD), an Nrf2 activator, in rats.

Methods: Male Sprague-Dawley rats were randomly divided into two groups; the BARD group, intraperitoneally receiving 10 mg/kg BARD, and the control group, receiving only vehicle (100% DMSO). The urine was obtained for 6 hours just after administration, and exosomes were isolated from the urine. At 6 hours after administration, rats were sacrificed and the kidneys were removed. Thereafter RNAs were extracted from the kidneys and urinary exosomes. The RNAs (27,012 mRNAs and 1,218 miRNAs) were analyzed with microarrays.

Results: BARD altered expression of 98 renal mRNAs and 357 urinary exosomal mRNAs with more than 2.0-fold relative to the control. BARD also changed expression of 15 renal miRNAs and 3 urinary exosomal miRNAs. The correlation coefficients between renal and urinary exosomal mRNAs as well as miRNAs were both less than 0.1. mRNAs that were commonly changed in both the kidney and urinary exosomes were 13. Among them, 8 genes are known to be targets of Nrf2 including Akr1b8, Akt1, Tshb1, Hmox1, Pir, Scl4a1 and Ugdh. Of 8 genes, Akr1b8 and Pir were increased more than 10-fold in the kidney and more than 4.0-fold in urinary exosomes. For miRNA, only miR-877 was changed in both the kidney and urinary exosomes.

Conclusions: The correlation coefficients between renal and exosomal RNAs were less than 0.1, suggesting that specific RNAs were selectively loaded into exosomes. In addition, Akr1b8 and Pir expression was dramatically increased in both kidney and urinary exosomes. Therefore, they could be potential biomarkers to detect their renal expression changes by renal Nrf2 activation.

PO2229

Urinary Excretion of Extracellular Vesicles in 24 Hours: Time Point Collection and Normalization Strategy
Luka Moseatic, Sabrina La saliva, Uta Erdbreugger. University of Virginia Health System, Charlottesville, VA.

Background: Urinary extracellular vesicles (uEVs) are an ideal source of biomarkers for kidney diseases. Despite the interest generated, little is known about collection time and normalization approach. The majority of the studies on uEVs focus on spot urine collection based on the assumption that it accurately reflects the renal function. However, the practice to collect spot urine does not allow for calculating and standardizing the uEV excretion rate and then assessing the renal function. Moreover, no research has been done to compare it with 24 hour collection.

Methods: Each single spot void urine was collected and 20% of the volume was used to create the 24 hours collection. uEVs were enriched by differential centrifugation. Transmission electron microscopy (TEM), western blot (WB), nanoparticle tracking analysis (NTA), tunable resistive pulse sensing (TRPS), imaging flow cytometry (IFC) and miRNA (miR16 and miR200b) quantitation by qPCR were used to quantify uEVs markers variation during the 24 hour. Creatinine, urinary osmolality and particle concentration (NTA, TRPS) were used to normalize the analytes.

Results: TEM showed a homogeneous population of EVs and WB confirmed the presence of EVs marker (TSG101, ALIX and CD9). RNA was extracted by a column-based method (miRNA extraction kit Qiagen) and cel-39 miRNA was spiked in each sample. A multiparametric detection of nephron markers podocalyxin (PODXL1), aquaporin-2 (AQP2) and uEVs pan tetraspanins (CD9 + DC63 + CD81) was performed in imaging flow cytometry. Whereas the uEV composition of did not change across the 24 hours analysis, the quantity of uEVs and related markers (miRNA and protein) fluctuated during the day depending on the hydration and excretion rate. Creatinine, urinary osmolality and particle count normalization failed to normalize “outliers”.

Conclusions: In conclusion, this study represents the very first report which compares single void urine versus 24 hour uEV analysis. We concluded that the 24 hour collection is the preferred choice for a robust and rigorous assessment of uEVs and its associated markers.

PO2230

Ultra-Fast Clearing Protocol for 3D Optical Renal Pathology
David Ummersiö-Jesu, Linus Butt, Martin Höhne, Anna Wittas, Lucas Kuehne, Peter Hoyer, Jaakko Patrakka, Paul T. Brinkkoeft, Annika Wernerson, Bernhard Schermer, Thomas Benzing, Lena Scott, Hjalmar Brismar, Hans Blom. Karolinska Institutet, Huddinge, Huddinge, Sweden; Department II of Internal Medicine and Center for Molecular Medicine Cologne (CMMC), University of Cologne, Cologne, Germany; Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases (CECAD), University of Cologne, Cologne, Germany; Pediatric Nephrology, Pediatrics II, University of Duisburg-Essen, Essen, Germany; Science for Life Laboratory, Dept. of Women’s and Children’s Health, Karolinska Institutet, Solna, Sweden, Solna, Sweden; Science for Life Laboratory, Dept. of Applied Physics, Royal Institute of Technology, Solna, Sweden.

Background: Kidney pathology involves three separate microscopy workflows. Histology, typically carried out on paraffin-embedded sections, used to optically visualize large-scale renal morphology. Immunofluorescence, used for mapping presence of specific molecular variations, carried out on paraffin-embedded or fresh-frozen thin sections. To visualize renal ultrastructures, electron microscopy is applied, with elaborate preparation protocols on ultra-thin slices.

Methods: We have modified published protocols in order to simplify and speed up the workflow of routine optical kidney imaging. The presented protocol induces a slight swelling of a cleared sample, and increase effective resolution enough for 3-D confocal visualization of filtration barrier structures. The duration of the protocol is only 5 hours from harvesting the tissue until full image acquisition.

Results: Our simple and fast protocol can resolve foot processes in mouse and human tissue using standard lab equipment and conventional 3-D confocal microscopy. Importantly, the protocol can be used to visualize various large-scale histopathological features as well as immune deposits in human patient material too. Compared to others, our tissue protocol is simpler and faster, and allow better 3-D in situ imaging capabilities.

Conclusions: We conclude that our simple and fast protocol, allow researchers and pathologists to use a single preparation and microscopy technique, to visualize both renal ultrastructure, histology and protein expression. Our protocol has the potential of, not just to complement, but also merging workflows used today while adding accessing to in situ depth information on all scales.

A Novel Model of CKD and Heart Failure with Preserved Ejection Fraction
Alejandro R. Chade, Maxx Williams, Jason E. Engel, Michael Hall. University of Mississippi Medical Center, Jackson, MS.

Background: Chronic kidney disease (CKD) has high cardiovascular mortality. We developed a model of CKD that shows major pathological features: low GFR (+/- 60 ml/min), renal inflammation, fibrosis, microvascular disease, and hypertension. We aim to define the cardiac phenotype of the model and, if present, the pathological traits involved in the development of HFpEF.

Methods: CKD was induced in 6 pigs (bilateral renorenal renovascular disease and dyslipidemia) and observed for 14 weeks. Renal hemodynamics (RBF, GFR) were quantified by multi-detector C, cardiac morphology and function by echocardiography, and mean arterial pressure (MAP) by telemetry. Blood was collected to measure circulating inflammatory cytokines (TNF-α, MCP-1), markers of inflammation (C-reactive protein), and biomarkers of heart failure (ANP, BNP, NT-proBNP). Pigs were then euthanized and kidneys and hearts collected for ex vivo studies. Normal pigs were used as time-matched controls.

Results: Loss of renal function was accompanied by left ventricular hypertrophy, left atrial dilatation, diastolic dysfunction (E/A ratio with preserved ejection fraction (pEF), elevated ANP, BNP, and NT-proBNP, and hypertension (MAP of 131.2 mm/Hg, p=0.05 vs. normal). CKD also increased renal (but not cardiac) mRNA expression of TNF-α, MCP-1, and IL-6, accompanied by increased circulating inflammatory cytokines (Figure).

Conclusions: CKD leads to cardiac abnormalities that meet the criteria of heart failure with pEF (HFpEF). Our data suggest that hypertension and inflammatory mediators (possibly from kidney origin) target the heart and may contribute to HFpEF.

PO2232

Pathophysiological Insight of the Liver by Gadolinium-Based Contrast Agent Treatment

Joshua Deaugago,1 Tamara A. Howard,1 Brent Wagner,1,2 G. P. Escobar,1,2 Kidney Institute of New Mexico; University of New Mexico Health Sciences Center, Albuquerque, NM; 1; New Mexico VA Health Care System, Albuquerque, NM.

**Background:** The advent and overuse of gadolinium-based contrast agents (GBCAs) lead to consequent iatrogenic systemic fibrosis. Gadolinium may accumulate in tissues in every organ. GBCA treatment induces dyslipidemia and insulin resistance (Do C et al, Toxicol Appl Pharmacol 2019 Jul 15;375: 32-45). Therefore, the impact of gadolinium on its added value to the model.

**Methods:** Wild-type male and female C57/BL6 mice were randomized by age and weight to untreated (n = 20) or GBCA-treatment (n = 20) (Omniscan, 2.5mmol/kg, intraperitoneally, 20 doses over 4 weeks). Tissue were isolated, specimens fixed in formalin, weighed, and processed. Electrophoresis mass spectrometry (Human Metabolome Technologies, Japan).

**Results:** Liver from the GBCA group demonstrated ballooned hepatocytes, lipid-laden vacuoles, and reduction in glycogen. Furthermore, GBCA treatment promoted hepatic steatosis. Gadolinium reduced expression of lipid metabolism and transport metabolites g-butyrobetaine, prostanandin E2, O-acetylcarnitine, malonylcarnitine, isobutyryl CoA and hexanoic acid, lauroylcarnitine, and decanoic acid (P < 0.05). GBCA treatment alters metabolite expression of metabolites from other pathways, including glycolysis, histidine metabolism, and purine metabolism. Furthermore, gadolinium treatment altered the urea cycle.

**Conclusions:** GBCA treatment alters several metabolic pathways, particularly lipid metabolism and lipid transport pathway intermediates. GBCA treatment induces ultrastructural and metabolic disruptions that mimic nonalcoholic fatty liver disease. These studies are the first to demonstrate GBCA mediates metabolic perturbations in the liver. GBCAs are not biologically inert.

Expression of Immunoglobulin G in Human Proximal Tubule Epithelial Cell and Its Role in Epithelial Mesenchymal Transformation

Zhenling Deng, Song Wang, Yue Wang. Peking University Third Hospital, Beijing, China.

**Background:** Our previous studies showed that human mesangial cells and podocytes can synthesize and secrete IgA and IgG respectively, participating in cell viability and adhesion. Proximal tubular epithelial cells (PTECs) mediate transcytosis of IgG through neonatal Fc receptor (Fcr). Whether PTECs express IgG has not been reported. The aim of this study was to explore whether PTECs express immunoglobulins.

**Methods:** Kidney cortical tissues were obtained from four patients undergoing nephrectomy as a result of renal carcinoma. Immunohistochemical (IHC) staining was used to assay the IgG expression in PTECs. Single PTECs were sorted by FACS from the cell suspension of the cortices. 10Genomics and nested PCR combined with Sanger sequencing were used to detect the transcripts and repertoire of IgG in single PTECs. An immortalized PTEC cell line (HK-2) was used to detect IgG protein expression and potential roles in tubular epithelial mesenchymal transformation.

**Results:** IHC showed positive staining of IgG but not other IgGs in PTECs of kidney cortex. High throughput single cell RNA sequencing by 10xGenomics only detected IgG transcripts in < 5% of PTECs without V(D)J rearrangements. Nested PCR amplified IgG transcripts in 8% (9/111) manually picked single PTECs. Sanger sequencing showed that the IgG-derived IgG variable region displayed classic VDJ rearrangements but predominant VH1-24/DH2-15/HJ4 sequence, biased VH usage and less diversity than other B cells derived IgG. Western blot and immunofluorescence staining demonstrated IgG (including IgG4, IgGκ and IgGλ, in HK-2, RP215, which specifically recognizes non-B cell-derived IgG, can identify the IgG in HK-2. The IgG was upregulated by TGF-β1 and accompanied by the up-regulation of α-smooth muscle actin and the down-regulation of E-cadherin. In addition, the transcripts of recombination activating gene 1/2 (RAG1/2, essential for V(D)J rearrangement) and activation-induced cycline deaminase (AID, essential for class switch recombination) were detected in HK-2.

**Conclusions:** Our study suggests that PTECs can express IgG in a similar way as B cells. TGF-β1 can upregulate the expression of IgG in PTECs. PTEC-derived IgG may be involved in tubular epithelial mesenchymal transformation and interstitial fibrosis.

Long-Term Mitochondrial Protection Reduces Proteinaemia in Obese Aged Mice

Marilyn T. Sweetney, Rene Coig, Ruby Sue M. Mangalindan, John Morton, Jeremy A. Whitson, Peter S. Rabinovitch, Warren C. Ladiges. University of Washington School of Medicine, Seattle, WA.

Background: In humans, obesity is associated with higher rates of kidney disease, which is compounded by aging. As an energetically demanding tissue, it has been proposed that preventing mitochondrial dysfunction is one key to reducing renal decline. Previously, we showed that an 8-week systemic treatment of aged 24-month-old (m.o.) mice with a mitochondrial targeted protective tetrapeptide, SS-31, significantly reduced the burden of age-induced glomerulosclerosis by 26-m.o. and preserved podocyte integrity.

Methods: To determine if SS-31 aging protection also applied with a comorbidity of obesity, 18-m.o. male NIA C57Bl/6j mice were fed regular chow (RC) or a high fat, high sucrose diet (HFHS) for 10 months and treated with SS-31 injected 5x/wk (3 mg/kg) or saline vehicle (n= 20/group).

Results: Mice were weighed weekly. RC mice averaged 33g with no change from age or treatment. HFHS mice gained weight in the first month but by 5 mo. of diet, SS-31+HFHS mice weighed significantly less relative to HFHS untreated mice (40 g vs. 45.9 g p= 0.047). Spot urine was collected monthly for albumin/creatinine ratio (ACR, μg/g). At 18-m.o. baseline, ACR averaged 48μg/mg. In RC mice, ACR increased modestly, and not significantly, with age although SS-31 RC mice had lower ACR at endpoint (28-m.o. control 125.9 vs. SS-31 31.0). HFHS untreated mice displayed more renal pathology with a 75% increase in ACR (RC: CR = 32.6 vs HFHS = 243.2, p = 0.003), climbing significantly to an average of 519.8 μg/mg at 28-m.o. ACR increased in SS-31 HFHS mice but levelled off by 23-m.o. (5 mo. treat.), averaging 146.1 μg/mg with no significant increase by 28-m.o. By 9 mo. of treatment, ACR was significantly lower in HFHS+SS-31 treated mice. Proximal tubule quantification of podocytes by p57 nuclear stain and PAS counter stain (n=4-7) showed that HFHS mice, regardless of treatment, had a 30% decrease in podocyte density relative to RC mice. Control HFHS mice tended to higher tuft volume (glomerular hypertrophy) than in SS-31 HFHS mice. However, results were not significant in the small sample size.

Conclusions: Combined with improved ACR our results suggest that podocyte integrity, if not number, may be preserved in mice fed a Western diet by SS-31 intervention and that long-term mitochondrial protection is a potential therapeutic target to preserve renal function with aging.

Bacterial and Fungal Communities Entombed Within Calcium Oxalate, Struvite, and Brushite Human Kidney Stones

Elena M. Wilson,1,2 Jessica J. Saw,1,2 Mayandi Sivaguru,1 Dirk Lange,1 Yiran Dong,3,4 Robert A. Sanford,1,2 Christopher J. Fields,1 Melissa Cregger,4,1 William J. Bruce,3,1 Annette Merkel,3 John J. Cieske,3 Amy E. Krambeck,1,2 Marcelino E. Rivera,3 Tim Large,5 Nicholas L. Chia,3 Michael F. Romero,3 Joseph R. Weber,3,4 Bruce W. Fouke,3,4 Carl R. Woese Institute for Genomic Biology, University of Illinois at Urbana-Champaign, Urbana, IL; University of Illinois at Urbana-Champaign, Urbana, IL; Mayo Clinic School of Medicine, Rochester, MN; Oak Ridge National Laboratory, Oak Ridge, TN; Mayo Clinic Minnesota, Rochester, MN; Indiana University School of Medicine, Indianapolis, IN; Jackson Bell Research Centre, Vancouver, BC, Canada; Roy J. Carver Biotechnology Center, University of Illinois at Urbana-Champaign, Urbana, IL; China University of Geosciences, Wuhan, China.

Background: Mechanisms of human kidney stone formation are poorly understood. More than 70% of stones are composed of calcium phosphate or oxalate. Recent studies have shown that kidney stone formation follows a continuum of complex biogeochemical transitions and is strongly influenced by the presence of human host and microbial organic material.

Methods: Kidney stones, removed via percutaneous nephrolithotomy, were prepared as 1 cm thick doubly polished petrographic thin sections and analyzed using brightfield, confocal and super-resolution autofocus microscopy. DNA was extracted from 18 calcium oxalate stones, 1 struvite stone, and 1 brushite stone for Fluidigm™ PCR amplification. Pair-end sequencing of bacterial 16S rRNA gene sequences and fungal 18S rRNA gene sequences was completed using Illumina® MiSeq. Reads were correlated with patient metadata and analyzed using DADA2, phyloseq v1.22.3 and R software.

Results: A 153-amplicon sequence variant (ASV) fungal community, dominated by A. niger (92% of total reads), was present in 11 of 20 total sequenced stones and correlated with higher patient urine calcium excretion (335 ± 131 vs 175 ± 108 mg/day, p=0.01). Petrophytography of 30 stones documented entombed coecoidal and rod-shaped bacterial cells in the struvite stone and well-preserved fungal borings and hyphae in one calcium oxalate stone. Most bacterial sequences were closely affiliated with Cutibacterium, Acinetobacter and Bacillus. The brushite stone microbiome contained Cutanocytophaga and Humibacter and the struvite stone microbiome included Pseudomonas and Staphylococcus.

Conclusions: This paper presents the first evidence of a low-diversity fungal and bacterial microbiome community entombed and preserved within calcium oxalate, struvite, and brushite human kidney stones. The macromolecules secreted by the fungal and bacterial communities may play crucial roles in human kidney stone growth, dissolution, and recrystallization, similar to processes that have been documented in natural geologic stone growth.

Targeting of Factor D in Cfh/-/- Mice Does Not Relieve C3 Glomerulopathy due to the Action of C3(H2O)

Yuzhou Zhang,1 Adam C. Keenan,1 Dao-Fu Dai,2 Kristofer S. May,1 Gabriella R. Pitcher,1 Ronald P. Taylor,1 Richard J. Smith.1 Molecular Otolaryngology and Renal Research Laboratories, University of Iowa, Iowa City, IA; Department of Pathology, University of Iowa, Iowa City, IA; 1University of Virginia School of Medicine, Charlottesville, VA.

Background: C3 glomerulopathy (C3G) is an ultra-rare kidney disease defined by underlying complement dysregulation and characterized by complement C3 deposition on glomerular basement membrane. Dysregulation of the alternative pathway (AP) is fundamental to disease expression, although terminal pathway dysregulation is also common. Treatment of C3G with eculizumab is unsuccessful in the majority of patients, consistent with the fact that complement C3 deposition on the terminal complement cascade while leaving up-stream C3 complement dysregulation untouched. Of up-stream targets, factor D (FD) is appealing because it circulates in the plasma at low concentrations and has a single function, to cleave its substrate, factor B, to generate C3 convertases of the alternative complement pathway. Mice with a targeted deletion of factor H (FH; Cfh/-/-) mice develop features of C3 glomerulopathy (C3G).

Methods: To assess the impact of FD inhibition, we studied Cfh/-/-/Cfd/-/- mice. After crossing the Cfd/-/- and Cfh/-/- mice, Cfh/-/-/Cfd/-/-/-/- progeny were backcrossed to C57BL/6 for 10 generations. Littermates of Cfh/-/-, Cfd/-/-, Cfh/-/-/Cfd/-/- and wildtype were used for assessing complement dysregulation and renal pathology.

Results: The C3G phenotype in the Cfh/-/- mouse is not rescued by removing FD. Instead, Cfh/-/-/Cfd/-/- mice develop a subtype of C3G and nephrogenic diabetes insipidus. We used serum from the Cfh/-/-/Cfd/-/- mouse to show that residual AP function is present in these mice. FD and FH are both required that hemolytic activity is increased in vivo and in vitro due to the action of C3(H2O). Therefore, uncontrolled tick-over leads to slow activation of the AP in the Cfh/-/-/Cfd/-/- mouse. While a tiny amount of FD suffices to activate complement, a minimal threshold of FH is needed to prevent tissue deposition of C3 in the absence of FD.

Conclusions: These findings suggest that efforts to block AP activity by targeting FD may lead to unanticipated outcomes in subgroups of C3G patients. Sustained complete and persistent FD blockade may be difficult to maintain, and due to the action of C3(H2O), may not completely suppress complement activation. Substantial break through complement activation may then occur as even minuscule amounts of free FD become available.

A Mutation in Complement Factor D Causing Massive Fluid-Phase Dysregulation of the Alternative Complement Pathway Can Result in Atypical Hemolytic Uremic Syndrome

Yuzhou Zhang,1 Robin A. Kremsdorf,2 John Sperati,1 Kammi J. Henriksen,1 Mari Mori,3 Renex X. Goodfellow,1 Gabriella R. Pitcher,1 Nicolo Ghiiringhelli Borsa,1 Ronald P. Taylor,1 Carla M. Nester,1 Richard J. Smith.1 Molecular Otolaryngology and Renal Research Laboratories, University of Iowa, Iowa City, IA; Department of Pediatrics, Warren Alpert Medical School of Brown University, Providence, RI; Division of Nephrology, Johns Hopkins University School of Medicine, Baltimore, MD; Department of Pathology, University of Chicago, Chicago, IL; Division of Genetic and Genomic Medicine, Nationwide Children’s Hospital, Columbus, OH; Department of Pediatrics, College of Medicine, The Ohio State University, Columbus, OH; University of Virginia School of Medicine, Charlottesville, VA.

Introduction: Atypical hemolytic uremic syndrome (aHUS) is an ultra-rare disease characterized by microangiopathic hemolytic anemia, thrombocytopenia and acute kidney injury. Pathogenesis is driven most frequently by dysregulated cell-surface control of the alternative pathway (AP) of complement secondary to inherited and/or acquired factors.

Case Description: We present two unrelated aHUS patients (a 5-year-old female and a 55-year-old female) who presented with the classic signs of thrombotic microangiopathy associated with renal failure with the additional finding of an undetectable C3 level. Circulating levels of C5 and properdin were also low, consistent with over-activity of both the alternative and the terminal pathways of complement. Genetic testing identified a heterozygous novel variant in the complement factor B gene (CFB c.1101 C>A, p.Ser367Arg). Functional studies demonstrated strong fluid-phase C3 cleavage when membrane-bound serum was mixed. Cell-surface C3 cleavage was strongly preserved when patient serum was supplemented with C3. In vitro control of C3 conversion activity could be restored with increased concentrations of factor H.

Discussion: CFB p.Ser367Arg is a gain-of-function pathogenic variant that leads to dysregulation of the AP in the fluid-phase and increased C3 deposition on cell surfaces. This report highlights the complexities of complement-mediated diseases like aHUS and illustrates the importance of functional studies to characterize variants of unknown significance and to gain insight into the disease phenotype.

Efficacy of Low-Intensity Pulsed Ultrasound on CKD-Associated Cachexia and Muscle Wasting Prevention in a Mouse Model

Shing-Hwa Liu,1 Kuan-Yu Hung,1,4 Chih-Khang Chang,1,2 Institute of Toxicology, National Taiwan University, Taipei, Taiwan; 1Department of Integrated Diagnostics & Therapeutics, National Taiwan University Hospital, Taipei, Taiwan; 2Superintendent Office, National Taiwan University Hospital Hein-Chu Branch, Hsinchu, Taiwan; 3Department of Internal Medicine, College of Medicine, National Taiwan University, Taipei, Taiwan.

Background: Low-intensity pulsed ultrasound (LIPUS), a therapeutic ultrasound, is recognized to elevate the bone fracture repair process and help in some soft tissue healing. Here, we tested the prevention of chronic kidney disease (CKD)-associated cachexia and sarcopenia by LIPUS in a renal ischemia/reperfusion injury (IRI) mouse model.

Methods: Adult C57BL/6J male mice were used. A model of unilateral IRI with nephrectomy of the contralateral kidney was performed without and with LIPUS treatment. IRI was induced via three cycles of 30 minutes of ischemia followed by 4 hours of reperfusion. LIPUS treatment (3 MHz, 0.1 W/cm², 20 minutes/day) 5 days before and 14 days after surgery was performed. The CKD-related cachexia/muscle wasting in mice was evaluated. Mice were euthanized 14 days after IRI.

Results: LIPUS treatment significantly alleviated the decrease in the serum albumin/globulin (A/G) ratio and the increase in the serum levels of blood urea nitrogen (BUN), creatinine, cystatin C, and fibroblast growth factor (FGF)-23, and the renal pathological changes and fibrosis in CKD mice (p<0.05, n=6; for A/G ratio and FGF-23). The development of epithelial-mesenchymal transition and the induction of senescence-related molecular signals and decreased protein expressions of α-Klotho and endogenous antioxidant enzymes in the kidneys of CKD mice were significantly alleviated by LIPUS treatment (p<0.05, n=6). LIPUS treatment could also significantly reverse the decreased muscle mass, grip strength, and cross-section areas (CSA) of muscle fibers (p<0.05, n=6; for soleus muscle weight, hindlimb grip strength), and the increased muscular protein expressions of atrogin1 and MuRF1, and phosphorylated AMP-activated protein kinase (AMPK), and the decreased muscular protein expressions of phosphorylated Akt, peroxisome proliferator-activated receptor-γ coactivator 1α (PGC-1α), and mitochondrially encoded cytochrome c oxidase I (MT-CO1) in CKD mice (p<0.05, n=6 or 6).

Conclusions: LIPUS treatment showed the benefits for renal and muscular protection in a CKD mouse model via inhibition of renal fibrosis, restoration of antioxidant enzymes, and attenuation renal senescence/aging, and muscle mass loss via prevention of muscular mitochondrial dysfunction, AMPK activation, and Akt downregulation. LIPUS treatment may be potentially applied to an alternative non-invasive therapeutic intervention on CKD-associated cachexia/muscle wasting therapy.

**PO2240**

Mechanisms of Suppressed Autophagic Flux in the Kidney Caused by Sham Surgery and Unilateral Nephrectomy

Carolyn N. Brown,1,2 Daniel Atwood, Deepak Pohlkril, Chris Altmann, Sarah Faubel, Charles L. Edelstein. Univ Colorado, Aurora, CO.

Background: Compensatory renal hypertrophy resulting from loss of nephron mass has been implicated in promoting further nephron damage. Unilateral nephrectomy (UNX) is a model of compensatory hypertrophy in the remaining kidney. We previously reported that in the remaining mouse kidney that both sham surgery (SS) and UNX vs. normal kidney (N) resulted in increased mTORC1/2, decreased lysosomal function, suppressed autophagic flux. p62/SQSTM1, is an autophagy receptor that links cargo proteins with the autophagosome membrane. p62 is destroyed by the lysosome and is a marker of autophagic flux, a decrease usually indicating increased autophagic flux. The aim of the study was to measure p62 and other potential mechanisms of suppressed autophagy caused by SS and UNX.

Methods: C57BL6 mice. p62 and ERK was measured by quantitative immunoblot analysis. Cytokines were measured by MesoScale. Mice were treated with the MEK1/2 inhibitor Trametinib (T) (1 mg/kg/d for 3 days) that is a potent ERK1/2 inhibitor.

Results: There was an increase in p62 in SS and UNX kidneys, p62/GAPDH (densitometry units) was 0.6 in N, 1.0 in SS (P<0.05 vs N) and 1.0 in UNX kidneys (P<0.05 vs N). p62 is known to modulate pro-inflammatory cytokines. In the serum, there were increases (fold) in IL-1β (50), IL-4 (10), IL-6 (100), IL-8 (5), IL-12 (5), GMCSF (2), IL-10 (100), TNFα (0) in SS and UNX vs N. Pro-inflammatory cytokines can activate ERK1/2, a known autophagy suppressor. There was a large increase in ERK1/2 in SS and UNX kidneys. Phospho/total ERK (densitometry units) was 0.2 in N, 1.4 in SS (P<0.001 vs N) and 2.0 in UNX kidneys (P<0.001 vs N). Trametinib blocked the increase in pERK in sham surgery and UNX kidneys and resulted in a significant decrease in p62. Phospho/total ERK (densitometry units) was 1.0 in N, 0 in SS+T (P<0.001 vs N) and 0 in UNX+T kidneys (P<0.001 vs N). p62/GAPDH (densitometry units) was 1.6 in N, 0.4 in SS+T (P<0.05 vs N) and 0.4 in UNX+T kidneys (P<0.05 vs N).

Conclusions: The mechanism of suppressed autophagy with SS and UNX may be mediated by uPA-independent mechanisms. Expression of the anti-aging gene klotho has been shown in acute kidney injury (AKI), but few is known about chronic kidney disease (CKD). The mechanism of suppressed autophagy with SS and UNX may be potentially applied to an alternative non-invasive therapeutic intervention on CKD-associated cachexia/muscle wasting therapy.

Differential Role of NAD⁺ Deficiency in Acute and Chronic Kidney Disease

Anna Faivre,1,2 Elena Katsyuba,3 Thomas Verissimo,1 Carolyn Heckemeyer,1 David Legouis,1,2 Sophie M. De Seigneux,1,2 Université de Geneve, Geneva, Switzerland; Hopitaux Universitaires de Geneve, Geneve, Switzerland; École Polytechnique Federale de Lausanne, Lausanne, Switzerland.

Background: Nicotinamide adenine dinucleotide (NAD⁺) is a ubiquitous coenzyme involved in electron transport and a co-substrate for many important NAD⁺-deficiency has been shown in acute kidney injury (AKI), but few is known about chronic kidney disease (CKD).

Methods: We studied the expression of key NAD⁺ biosynthesis enzymes in kidney biopsies from allograft patients undergoing reperfusion, mimicking AKI, and in patients with CKD at different stages. We used ischemia-reperfusion injury (IRI) and cisplatin injection to model AKI, unilateral ureteral obstruction (UO) and tubulointerstitial fibrosis induced by proteinuria (Pod-Attac) to investigate CKD in mice. Then we assessed the effect of a potent NAD⁺-replenishment therapy, the nicotinamide riboside (NR), in both AKI and CKD models.

Results: RNA-sequencing analysis of human kidney allograft biopsies during reperfusion showed that the NAD⁺ of de novo synthesis is impaired in the immediate post-transplantation period. This decrease in de novo NAD⁺ synthesis was confirmed in two mouse models of IRI where NR supplementation prevented plasma urea and creatine elevation and tubular injury. In biopsies from CKD patients, the NAD⁺ of de novo synthesis was impaired according to CKD stage, with better preservation of the salvage pathway (Figure 1). Similar alterations in gene expression were observed in UO and Pod-Attac mouse models. NR supplementation did not prevent CKD progression in contrast to its efficacy in AKI.

Conclusions: Impairment of NAD⁺ synthesis seems to be a hallmark of AKI and CKD. An oral NR supplementation showed protective effects on AKI but had no effect on CKD in mouse models. This study shows the dual role of NAD⁺ deficiency in AKI and CKD and the potential of NAD⁺-replenishment therapies as a preventive strategy for human AKI.

PO2243
Pericutaneous Renal Biopsy Using an 18-Gauge Automated Needle Is Not Optimal
George Sousanieh, William L. Whitber, Roger A. Rodby, Vasil Pece, Stephen M. Korbet. Rush University Medical Center, Chicago, IL.

Background: As percutaneous renal biopsies (PRB) are increasingly performed by interventional radiologists, an increase in the use of the smaller 18-gauge automated biopsy needle has been observed. The use of smaller gauge needles stands to compromise adequacy, ideally ~20 glomeruli per biopsy. We compare the adequacy and safety of PRB with a 14, 16, and 18-gauge automated needles.

Methods: PRB of 592 native (N) and 1023 transplant (T) kidneys were performed by a nephrologist or a supervised nephrology fellow at Rush University Medical Center from 1/2002 to 12/2019 using real-time ultrasound guidance. Baseline clinical and laboratory data, biopsy sample data (number of cores, total glomeruli per biopsy (glomeruli on light × immunofluorescence screening + electron microscopy) and total glomerular per core) and outcome data (hematoma on renal US 1-hr post-PRB and complications requiring a transfusion or procedure post-PRB) were collected prospectively. PRB with N14g (n=337) vs N16g (n=255) and T16g (n=892) vs T18g (n=131) needles were compared. A P value of ≤0.05 was significant.

Results: PRB with an 18g needle yielded the lowest number of total glomeruli per biopsy (N16g vs N16g: 33±13 vs 29±12, P<0.01 and T16g vs T18g: 34±16 vs 21±11, P<0.001 and N16g vs T18g: P<0.001). PRBs with 18g needle were also less likely to have ≥20 total glomeruli per biopsy (N16g vs N16g: 83% vs 82%, P=0.4 and T16g vs T18g: 83% vs 46%, P<0.0001). The number of cores per biopsy was: N14g-2.3±0.7, N16g-2.2±0.6, T16g-2.8±0.7 and T18g-2.2±0.6. Adjusting for the number of cores obtained, the total glomeruli per core was significantly less with 18g needle (N14g vs N16g: 15±8 vs 14±7, P=0.01 and T16g vs T18g: 15±6 vs 10±2, P<0.001 and N16g vs T16g, P=0.001). A hematoma by routine screening renal US 1-hr post-PRB was significant for native (14g-35% vs 16g-29%, P=0.2), and transplant biopsies (16g-10% vs 18g-9%, P=0.9) irrespective of needle size. The complication rate for native (14g-18.9% vs 16g-17.1%, P<0.5), and transplant biopsies (16g-4.6% vs 18g-1.3%, P=0.2) as well as the transfusion rate for native (14g-7.7% vs 16g-5.8%, P=0.4), and transplant biopsies (16g-3.8% vs 18g-0.8%, P=0.1) were not significantly different irrespective of needle size.

Conclusions: The use of the smaller, 18g biopsy needle compromises the adequacy and thus, quality of the PRB while not enhancing safety.

PO2244
Deep Neural Network Facilitated Immunofluorescence Assessment of Glomerular Diseases: A Preliminary Report
Peng Li1,2, Yuheh Wu1, Wen Xuesong Zhao,1 Hua Zheng,1 Xuemei Li1, Fei Ren,2 Limeng Chen.1 1Nephrology Division, Peking Union Medical College Hospital, Beijing, China; 2Institute of Computing Technology, Chinese Academy of Sciences, Beijing, China.

Background: Immunofluorescence (IF) tests of renal tissue are important in diagnosing glomerular diseases. Deep neural network were used to facilitate analysis of pathologic images recently, but not in IF assessment. We proposed a novel Convolutional Residual Dense Network (CR-DenseNet) to facilitate IF assessment of glomerular diseases.

Methods: A dataset with 614 IF images of glomeruli, including IgA Nephropathy, IgAN (n=319), Idiopathic Membranous Nephropathy, IMN (n=211) and Secondary Membranous Nephropathy, SMN (n=84) from Peking Union Medical College Hospital, PUMCH were used for training of CR-DenseNet. Additional 78 IF images from PUMCH (35 IgAN, 15 IMN and 28 SMN) and 98 IF images (36 IgAN, 34 IMN and 28 SMN) from other 3 hospitals were used for validation and human tests. These images were annotated by two nephropathologists independently. Convolutional residual dense blocks were introduced. Each of them consisted of a dense block with a convolutional skip connection block. The DenseNet was trained using the training dataset (35 IgAN, 15 IMN and 28 SMN) and 98 IF images (36 IgAN, 34 IMN and 28 SMN) from other 3 hospitals were used for validation and human tests. These images were annotated by two nephropathologists independently. Convolutional residual dense blocks were

Conclusions: The adoption of an -omics style analysis for renal histology may be feasible to mine prognostically significant morphometric information.

Prognostic Glomerular Morphometric Phenotype Discovery via Clustering Across Large Datasets
Brandon Ginley,1 Kuang-Yu Jen,2 Avi Z. Rosenberg,3 Pinaki Sarder.1 1University at Buffalo - The State University of New York, Buffalo, NY; 2University of California Davis, Davis, CA; 3Johns Hopkins University, Baltimore, MD.

Background: Microscopic glomerular assessment is diagnostic and prognostic for a diverse array of renal parenchymal disorders. Digital renal pathology enables complex morphometric studies that may identify prognostic information imperceptible to the human eye. We use clustering and feature enrichment to discover morphometric phenotypes that may relate to patient prognosis.

Methods: A convolutional network extracted glomeruli from 29 Periodic acid-Schiff stained transplant biopsies. 315 features were calculated on each glomerulus and clustered with a modularity-based community detection algorithm available in Seurat. Clusters were compared with patient outcome (eGFR decline at 1 year). A Wilcoxon rank sum test identified features enriching each cluster. Uniform manifold approximation and projection (UMAP) was used to visualize the clusters in low dimension.

Results: Clustering revealed 5 glomerular populations (Fig. 1A), and glomeruli of different patients were well admixed across clusters (Simpson’s Diversity Index: 0.78 – 1.0 = diversity, 1 = infinite). Patients were separated in two classes (eGFRa5 or <5 mL/min/year), and these labels were projected into the cluster space (Fig. 1B). We observed that clusters show different frequencies of glomeruli from patients with higher eGFR decline. Two of the clusters (2 and 4) had >90% of their morphometrically similar glomeruli solely from slower eGFR decline patients. The distribution of two example features (glomerular area and total nuclei) per cluster are shown in Figs. 1C & D, though the full analysis revealed hundreds of significant features enriching each cluster.

Conclusions: The an -omics style analysis for renal histology may be feasible to mine prognostically significant morphometric information.

IgA Staining Patterns Differentiate Between IgA Nephropathy and IgA-Dominant Infection-Associated Glomerulonephritis

Sergey V. Brodsky, Clarissa A. Cassol, Anjali A. Satoskar, Tibor Nadasy. The Ohio State University Medical Center, The Ohio State University Wexner Medical Center, Columbus, OH.

Background: Differential diagnosis of primary IgA nephropathy (IgAN) and IgA-dominant infection-related glomerulonephritis, particularly Staphylococcus infection-associated glomerulonephritis (SAGN), on a kidney biopsy can be challenging because of similar morphologic findings by light microscopy, immunofluorescence and electron microscopy. Clinical management approach however, is very different. Immunosuppressive therapy is contraindicated in SAGN because it can lead to sepsis and even death. Antibiotics constitute the first line of therapy. In contrast to that, primary IgAN is treated either with conservative management or with immunosuppression. There are no specific biomarkers to distinguish between these two diseases.

Methods: Kidney biopsies from patients with IgAN or SAGN were analyzed. Immunofluorescence with an antibody to IgA was performed on sections of frozen and paraffin embedded tissue.

Results: In total, 75 biopsies (45 with IgAN and 30 with SAGN) were evaluated. All 75 biopsies showed distinct granular staining for IgA in the non-sclerotic glomeruli (Figure 1). Globally sclerosed glomeruli were identified in 47 biopsies (29 with IgAN and 18 with SAGN). Among the 29 biopsies of IgAN, 20 (69%) had positive granular staining for IgA in the globally sclerosed glomeruli and 9 (31%) cases did not. Among the 18 kidney biopsies with SAGN, only one case (5.6%) showed positive staining for IgA in globally sclerosed glomeruli, whereas the remaining 17 (94.4%) did not (Table 1). The sensitivity of positive IgA staining in globally sclerosed glomeruli for kidney biopsies with IgAN was 68.97%, specificity was 94.44%.

Conclusions: Evaluation of IgA staining in sclerosed glomeruli can help to differentiate between primary IgAN and SAGN in the right clinical context, and aid in patient management in most cases.

Clinical Context and Outcomes of Kidney Biopsy in Pregnant Women: An Institutional Review

Anna B. Gaddy, Karen Trevino, Carrie L. Phillips, Elizabeth Taber-Hight. Indiana University School of Medicine, Indianapolis, IN.

Background: Kidney biopsy is an excellent method of gaining insight to causes of renal decline but is not without risk, particularly in pregnant patients. While we await the era of biomarkers which enhance our ability to diagnose diseases of pregnancy, biopsy remains the most inclusive way of reaching a diagnosis. Clinical manifestations warranting biopsy include gross deterioration in renal function, de novo development of nephrotic syndrome, or suspicion for glomerulonephritis. A recent metaanalysis found that the risk of complications during pregnancy was 7% and should be limited to patients in whom the diagnosis would warrant urgent therapy. We sought to explore indications for biopsy and histopathology in patients evaluated at our institution.

Methods: Our surgical pathology database was searched for renal biopsy specimens interpreted from 2008 to mid-2020. Patients were either pregnant at the time of biopsy or within 3 months postpartum. Indiana University IRB approved the study. A chart review was completed to obtain lab data at the time of biopsy and post procedure.

Results: We identified biopsy specimens from 38 women who were pregnant during the specified time period. Histopathologic diagnoses included lupus nephritis (n=4), FSGS (8), diabetic kidney disease (3), allergic interstitial nephritis (1), IgA (10) and minimal change disease (3). Chart information was available for 19 women including 15 Caucasian and 4 African American patients, with a mean age of 28.6 years. Eight specimens were obtained during pregnancy and 11 during the postpartum period. Proteinuria was present in 17 patients with a mean value of 3.5g/d. Hematuria was also present in 14 of the patients. Mean serum creatinine was 2.6mg/dl.

Conclusions: Renal biopsy is a procedure with high risk and morbidity for pregnant women. At our institution, biopsy was performed for either worsening renal function or proteinuria. Our population showed diverse diagnoses which justified need for biopsy, including requiring urgent intervention. Our study highlights the need of judicious biopsy in pregnant women. Further studies can be done to determine long term kidney outcomes in pregnant women.

Prevalence and Risk Factors Associated with Nephrosclerosis in Renal Parenchyma Specimens of Patients Undergoing Partial or Radical Nephrectomy

Juan D. Salcedo, Betancourt,1 Kenny A. Goodrich,1 Olekssi Iakymenko,1 Jhoan B. Rozas,1 Ragi Phillips,1 Gabriel Contreras,2 Alessia Fornoni,1 Laura Barisoni,3 Jorge A. Florindez,4 David B. Thomas,1 Jair Munoz Mendoza,5 1University of Miami School of Medicine, Miami, FL; 2Duke University School of Medicine, Durham, NC; 3YM Health Financial Services, PLLC, Charlotte, NC.

Background: Evaluation of non-neoplastic renal parenchyma in nephrectomies is part of the College of American Pathologists (CAP) Cancer Protocols. We evaluated the prevalence of histological nephrosclerosis and its association with clinical factors in patients undergoing nephrectomy for any cause at our institution.
**PO2250**

**Evaluation of Preexisting Renal Disease in Nephrectomies**

Juan D. Salcedo Betancourt,1 Oleksei Iakymenko,2 Kenny A. Goodrich,1 Jhioan B. Rozas,3 Ragi Philips,1 Alessia Fornoni,1 Gabriel Contreras,3 Dinesh Prakash,1 Laura Barisoni,2 Jorge Beshay,2 Jair Munoz Mendoza.1 1University of Miami School of Medicine, Miami, FL; 2Duke University School of Medicine, Durham, NC; 3IYM Health Financial Management, Honda, NC.

**Background:** Evaluation of non-neoplastic renal parenchyma in nephrectomies is part of the College of American Pathologists (CAP) Cancer Protocols. We aimed to determine the prevalence of pre-existing renal diseases in all patients who underwent nephrectomy for any cause in our center.

**Methods:** The surgical pathology protocol for nephrectomies was modified with a) additional sampling of non-tumoral renal parenchyma, b) Hematoxylin and eosin, Periodic acid-Schiff, trichrome and silver stains, and c) addition of the expanded checklist for reporting nephrectomy from the Renal Pathology Society recommendations. All samples were reviewed by nephropathologists (NP) (total of 813 nephrectomies, 49% partial and 51% radical) performed between 2013 and 2017 and were evaluated and included in the study. Reasons for nephrectomies were malignancy in 645 (79%) of patients, of which 528 (82%) had renal cell carcinoma, 100 (16%) urothelial carcinoma, and 168 (21%) benign lesions (42 oncocytomas, 34 pyelonephritis, 13 trauma, and 168 nephrotheliomis). Clinical, demographic, and pathological data were collected by chart review.

**Results:** The mean age was 60 ± 14 years. 62% were male and 44% Hispanics, 59% had hypertension, 22% had diabetes mellitus, and 24% had a history of smoking. Baseline eGFR was 73 ± 27 ml/min/1.73m2 and 31% had an eGFR < 60 ml/min/1.73m2. Only 41 patients (5%) had a documented pre-operative consult to nephrology. 296 (36%) patients had at least one renal disease diagnosis and only 62 (8%) had a single diagnosis. 37 nephropathological lesions were reported including focal segmental glomerulosclerosis (FSGS) (157), mostly NOS variant (88%), diabetic glomerulosclerosis (57), interstitial nephritis (66), arterionephrosclerosis (39), pyelonephritis (36), acute tubular injury (10), chronic sclerosing glomerulonephritis (4), amyloidosis (1) and atheoemphal renal disease (4).

**Conclusions:** Pre-existing renal disease are frequently identified in nephrectomy specimens. FSGS was the most common diagnosis. A collaborative effort involving nephrologists, urologists and pathologists is warranted to improve the care of patients undergoing surgical nephrectomy.

**Examining Accuracy and Reproducibility of Novel Creatinine and Urea Rapid Measurements in Human Saliva**

Manal Beshay,1 Kamyar Kalantar-Zadeh,2 Trong D. Nguyen,1 Maria Ortega,2 Danh V. Nguyen,1 Connie Rhee,1 University of California Irvine, Irvine, CA; 2Intelligent Optical Systems, Inc., Torrance, CA.

**Background:** Rapid and frequent point-of-care kidney filtration markers that do not require laborious blood specimen draws-processing can improve CKD patient care. The use of saliva as a non-invasive biofluid for monitoring kidney function biomarkers such as Creatinine (Cr) and Urea, addresses a clinical need in support of telemedicine.

**Methods:** We developed novel Enhanced Enzyme and Immunoassay-based Linear Flow (ELF) assays to quantify measurement of 2 kidney filtration markers in human saliva using highly selective reagents for optimum specificity. We used healthy donor saliva samples spiked with known levels of Cr and Urea. Standard calibration curves (SCCs) for each marker was established with nonlinear 4-parameter logistic curve fitting in triplicate at each spiked level. Accuracy/fit of the SCC was assessed using the coefficient of determination (R2).

**Results:** SCC fitted to relative optical intensities (ratio of test to control lines vs. spiked CySC (0-14 ng/ml) was excellent (R2=0.991) and provided accurate estimates of spiked true CySC levels (R2=0.994). Assessment of intra-assay variation showed that repeatability is very good with CV <10% throughout the dynamic range of measurements. Assessment of inter-assay variation (measurements over 8 days) showed that reproducibility is acceptable with CV <13% throughout most of the dynamic range. Preliminary assessment of long-term reproducibility (stability) out to 258 days indicated similar performance. [figure]

**Conclusions:** We demonstrated feasibility of CySC measurements in human saliva samples with acceptable ELF assay characteristics including accuracy, repeatability, reproducibility, and long-term stability. Validation studies are ongoing to optimize the saliva testing framework for kidney function markers.

Comparison of Creatinine-Based Estimated Glomerular Filtration Rate Equations with DTPA GFR in Healthy Adults
Varun kumar Bandi, Sroopith Ramineni. Dr. Pinnamaneni Siddhartha Institute of Medical Sciences & RF, Vijayawada, India.

- Measurement of glomerular filtration rate (GFR) is a reliable technique but is expensive and cumbersome for routine use. GFR is routinely estimated (eGFR) with serum creatinine. These equations are not widely validated in Indian populations.
- The cross-sectional study was done on live kidney donors. DTPA was used to measure GFR, 24 hour creatinine clearance (CcI) was measured and creatinine based eGFR was calculated using Cockcroft-Gault (CG), Modification of Diet in Renal Disease-(MDRD)-4, Modification of Diet in Renal Disease-5 variable (MDRD-5) and Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equations.
- Results: 88 subjects were included, of whom 29.5% were male, with a mean age of 46.8 yrs, and BMI of 25.7 kg/m2. Mean GFR (a standard deviation) obtained by CKD-EPI, MDRD-4, MDRD-5, CG, CcI, and DTPA GFR were 99.8 (±15.2), 96.2 (±17.9), 100.1 (±20.2), 83.1(±38.7), 89.3(±26.9) and 98.4(±11.7) cc/min/1.73m2 respectively. The mean absolute difference in GFR and percentage variation between calculated and measured GFR for CKD-EPI, MDRD-4, MDRD-5, CG, CcI and DTPA GFR were 99.8 (±15.2), 96.2 (±17.9), 16.2 (17.9%), 19.8 (22.2%), 32.0 (36.5%), and 23.6(25.7%) respectively. Percentage of values within 20% of DTPA GFR in each equations were CKD-EPI - 69.32%, MDRD-4 - 70.45%, MDRD-5 - 54.55%, CG - 38.64% and CcI - 45.45%. There was no significant co-relation between the measured GFRs and eGFR using any of the above equations.
- Conclusions: All the equations used (CKD-EPI, MDRD4, MDRD5, CG) and CcI did not correlate significantly with the measured GFR. Among the equations, CKD-EPI had the least variation with about 69% confirming within 20% of DTPA GFR, and about 86% and 97% confirming within 30% and 50% of DTPA GFR.

Fecal Calprotectin Correlates with Serum Albumin in Patients with CKD
Yura Chag, Eun Sil Koh, Jongho Son, Sunjin Chung. The Catholic University of Korea, Seoul, Republic of Korea.

- Background: Persistent inflammation, a characteristic feature in chronic kidney disease, contributes to decreased serum albumin levels and plays a central role in the Malnutrition, Inflammation and Atherosclerosis (MIA) syndrome, which is associated with poor clinical outcomes. Altered bowel habit is also a frequently high status among patients with chronic kidney disease potentially due to their low fiber and fluid intake, medications, multiple comorbidities and dysbiosis of the gut microbiota. In this study, we have explored whether measurement of fecal calprotectin, a commonly used marker for increased neutrophil infiltration and local inflammation in gastrointestinal diseases, could reflect a state of low serum albumin in patients with chronic kidney disease.

- Methods: Clinical and biochemical data including stool samples for calprotectin were collected from 579 cases of patients with no history of inflammatory bowel disease.

- Results: Fecal calprotectin was not different according to estimated glomerular filtration rate, degree of proteinuria and medication of polystyrene sulfonate and ferric sulfate. However, it was significantly and negatively correlated with serum albumin in patients (r=-0.107, p=0.010). Patients with higher tertile of fecal calprotectin were older and had lower hematocrit. Multivariable linear regression analysis showed that elevated fecal calprotectin was significantly correlated with serum albumin (β=-0.107, P=0.010).

- Conclusions: These observations that serum albumin were significantly correlated with fecal calprotectin in patients with chronic kidney disease, suggest that the bowel inflammatory response may be another contributing factor.

PO2255
A Case of Sevelamer-Induced Colon Perforation
Venkata R. Manchala, Rajendra Mandalapu, Soumya P. Thumma, Nithin Karakala. University of Arkansas for Medical Sciences, Little Rock, AR.

- Introduction: Sevelamer is an anion exchange resin used to treat hyperphosphatemia in patients with chronic kidney disease. It does not cause hypercalcemia or vascular calcification associated calcium based phosphate binders. Common adverse effects include nausea, vomiting, diarrhea, dyspepsia and constipation 1. Case reports of sevelamer associated bowel perforation have been reported in the literature 2,3. Here we report a case of sevelamer induced colon perforation.

- Case Description: 61 year old Caucasian male with history of ESRD from diabetic nephropathy on automated peritoneal dialysis presented to the emergency department with abdominal pain. Physical exam was notable for epigastric tenderness. Labs were unremarkable except for hyperglycemia of 427 mg/dL. CT scan abdomen showed calcification in the pelvis consistent with multiple right renal infarcts. Subsequently a CT angiogram was obtained. During renal arteriography, the right renal artery developed dissection with minimal catherizer manipulation suggestive of significant underlying abnormality. The procedure was aborted given risk for further complications including renal infarction and hemorrhage. Radiology reported findings consistent with medium vessel vasculitis. Autoimmune workup showed positive ANA, Sc 70 and rheumatoid factor, supporting suspicion for systemic vasculitis such as PAN. However, mesenteric vessels were normal. She was advised to continue on prednisone while additional workup was completed. Carotid dopplers were obtained and demonstrated partial dissection of the mid right internal carotid artery, with subsequent CT angiogram of the head and neck showing findings consistent with FMD throughout vertebral arteries and left internal carotid artery. Initial renal CT angiogram was evaluated by Radiology, with renal artery scan abdomen which revealed large pneumoperitoneum with possible colon perforation. Patient was emergently taken to the operating room laparotomy requiring right hemicolectomy with ileocolic anastomosis. Pathohistological exam of the resected colon showed scattered yellow esinophilic, acellular crystalline material with “fish scale” morphology within the lumen suggestive of sevelamer resin. Patient was on sevelamer 800mg TID for several years. Patient improved with appropriate medical management. Sevelamer was discontinued prior to discharge.

- Discussion: Sevelamer is composed of a non-absorbable hydrogel with ammonia on the hydroxide (Renagel) or the carbonate (Renvela). In the acid milieu of stomach, these complexes dissociate into their respective cations to bind phosphate to the intestine 4. The exact pathogenesis of intestinal perforation remains unclear. It is hypothesized that presence of sevelamer crystals in the gastrointestinal tract was associated with mucosal abnormalities including inflammation, ischemia and necrosis. The formation of characteristic sevelamer crystals (typically seen as bright pink linear accretions with a rusty yellow background and irregularly spaced fish-scales) on pathology along with the supporting clinical history clinches the diagnosis. It is important for clinicians to be aware of this rare but a serious potential complication of bowel perforation associated with sevelamer.

PO2256
Case of Pulmonary-Renal Syndrome Involving Goodpasture Disease and Granulomatosis with Polyangiitis
Shatabh Khan. AU-UGA Internal Medicine, Athens, GA.

- Introduction: Wegner’s granulomatosis and Goodpasture’s disease are two rare causes of pulmonary-renal syndromes syndromes. Both have similar presentation and different mortality. Both are crucial for cardiology and nephrology. WG is a systemic vasculitis that affects the respiratory and renal systems and associated with C-ANCA (PR3) antibodies. Goodpasture’s disease is an autoimmune condition that is characterized by rapidly progressive glomerulonephritis (RPGN) and severe alveolar hemorrhage. It is most often related to ANCA antibodies against proteinase-3 and renal basement membrane antigens. It is noted that 5% of all ANCA + patients are also positive for anti-GBM and all of the anti-GBM about 1/3rd also have ANCA but that does not always correlate with active clinical disease. This leads to a significantly poor prognosis and worse renal outcomes than either disease process alone.

- Case Description: We present a 59-year-old female with initial complaint of weakness, lethargy and sinus congestion. She had a history of untreated hypertension. She was noted to be hypoxic and had rales and rhonchi bilaterally. Labs revealed WBC of 35, Hg 5.6, Hct 15.5 and platelets 594. She had sodium of 98, Potassium 5.8, Bicarbonate 18, BUN of 58 and Creatinine of 8.5. Chest x-rays showed bilateral opacities resembling CAP. Further hypoxemia prompted intubation, revealing copious amounts of alveolar hemorrhage. Vasculitis was in the differential given alveolar hemorrhage and renal failure. She was then started on plasmapheresis, high dose IV steroids as well as cyclophosphamide. Complement levels and immunofixation were normal as were studies for lupus and hepatitis B and C. She had + ANA, Anti-GBM and c-ANCA antibodies. Renal biopsy showed predominant sclerosis and >90% focal necrotizing crescent GN and severe interstitial scarring. Immunofluorescence (IF) demonstrated linear staining of glomerular BM as well as ANCA mediated changes. However, the patient improved on prednisone while additional workup was completed. Carotid dopplers were obtained and demonstrated partial dissection of the mid right internal carotid artery, with subsequent CT angiogram of the head and neck showing findings consistent with FMD throughout vertebral arteries and left internal carotid artery. Initial renal CT angiogram was evaluated by Radiology, with renal artery
PO2258
Asymptomatic Spurious Hyperuricemia Related to Waldenstrom Macroglobulinemia
Pankaj Goyal,1 Prakash S. Gudsoorkar,1 Charuhas V. Thakar,1,2 University of Cincinnati Academic Health Center, Cincinnati, OH; 2Cincinnati VA Medical Center, Cincinnati, OH.
Introduction: Increased IgM has been shown to result in underestimation of uric acid levels and pseudo-hypouricemia; however, there are no reported cases of hyperuricemia in the setting of paraproteinemia. We present a case of Waldenstrom’s Macroglobulinemia (WM) resulting in marked elevation of uric acid level in the absence of tumor lysis syndrome (TLS).
Case Description: A 73-year-old man with history of WM was incidentally noticed to have very high uric acid level of 37.2 mg/dL. He had no history of crystal arthropathy or chronic kidney disease. He was started on Acalabrutinib because of high serum viscosity and elevated IgM level. After 30 days of treatment, his serum viscosity and uric acid levels improved significantly, however, the treatment had to be discontinued due to development of potential drug related adverse events. After discontinuation of Acalabrutinib, his serum viscosity and uric acid level gradually increased back to the previous level. Laboratory parameters were not suggestive of TLS and potassium, calcium and phosphorus were all normal. 24-hour uric acid excretion was noticed to be low normal (341 mg/24 hours). He was treated with allopurinol and monitored in clinic with serial uric acid checks. He continued to remain asymptomatic despite of having a uric acid level consistently above 35 mg/dL. He was not treated with Rasburicase due to lack of symptoms and potential false elevation of uric acid in the setting of paraproteinemia.
Discussion: Paraproteins often cause factitious biochemical measurements by forming opaque precipitates with the test reagents and interfering with various automated assays. Such interferences may be difficult to anticipate as they are intermittent and patient specific. Ultrafiltration of paraproteins, dilution or depolymerization of the samples can sometimes help correct these measuring errors. WM and other paraproteinemia may cause true hyperuricemia in the setting of TLS. However, the absence of other cytotoxic drugs and patients should raise suspicion of factitious results. An observant clinician should be aware of these findings in order to avoid unwarranted concomitant laboratory abnormalities should raise a suspicion of factitious results. An unexplained increase in uric acid in the setting of paraproteinemia could be due to the presence of Tamm-Horsfall protein (THP) which is a normal constituent of normal urine and can be the primary constituent of many urinary casts. The phenomenon of THP polyp formation in obstructive uropathy first appears in the literature about 1978. The polyps are described in these reports as being located in renal veins or sometimes lymphatics. Our case is the first to confirm the location of a THP polyp by immunohistochemical (IHC) analysis.
Case Description: A 64-year-old Caucasian male presented with bilateral flank pain and persistent gross hematuria. On admission, he had mildly elevated BUN (26.0 mg/dL) and serum creatinine (3.2 mg/dL). Urine analysis showed red blood cells > 182 /hpf with negative leukocyte esterase and negative nitrates. He developed azotemia during the hospitalization with the highest creatinine of 7.4 mg/dL on day 3 of admission. Renal ultrasound indicated mild-moderate hydronephrosis with a collapsed bladder. Renal biopsy was performed given lack of proper explanation for his presentation. Biopsy showed Periodic acid-Schiff (PAS) positive THP with no cellular or granuloma. The polyp formation distended the markedly dilated tubules (confirmed by positive Pan-cytokeratin and negative CD31 immunohistochemical (IHC) stains). The THP polyp also contains delicate elongate-appearing endothelial cells. There was diffuse interstitial edema with mild fibrosis without tubular atrophy, and mild to moderate to focally intense inflammation with numerous eosinophils surrounding the involved tubules. The walls of the inflamed tubules are densely infiltrated by inflammatory cells and has focal fibrinoid necrosis. No significant glomeruli or vascular pathologic changes were identified. The renal pathology findings of acute and subacute tubulointerstitial nephritis with THP polyps consistent with obstructive uropathy.
Discussion: There were a total of four cases of intravenous THP polyps identified in the patients with obstructive uropathy and persistent gross hematuria. It was theorized that acute or subacute progression increases the intratubular pressure, with extravasation of THP into the veins forming tubulovenous communications. However, our study suggests that this theory may not be true due to the misidentification of the markedly distended renal tubules as renal veins.

Vedolizumab-Induced Acute Interstitial Nephritis and Acute Tubular Necrosis
Abdulrahman Muzib, Rushang Parikh, Vanessa Bijol, Nupur N. Uppal, Malia Sachdeva. Donald and Barbara Zucker School of Medicine at Hofstra/ Northwell, Great Neck, NY.
Introduction: Vedolizumab is a humanized monoclonal antibody used in the treatment of ulcerative colitis. To date there has been no reported case of vedolizumab associated acute interstitial nephritis (AIN) and acute tubular necrosis (ATN). We report the first such case.
Case Description: A 58 year old female with history of ulcerative colitis on vedolizumab for one year, primary hyperparathyroidism and calcium oxalate nephro lithiasis presents due to acute kidney injury. Patient received her last dose of vedolizumab two months prior. She had been receiving 300mg IV every eight weeks, making her last dose her seventh dose. Her pre-medication creatinine (Cr) was 0.9mg/dL. Approximately one week prior to admission she was found to have a Cr of 2.0 mg/dL. She denied any history of NSAIDs, PPI, antibiotics or herbal use. Her past medical history was unremarkable. Her admission labs were notable for a Cr 2.25mg/dL, potassium 3.1mmol/L, bicarbonate 15mmol/L, phosphorus 2.2mg/dL, uric acid 1.3 mg/dL, urinalysis specific gravity 1.011, pH 6.5, glucose 500mg/dL, small blood, protein 30 mg/dL, negative leukocyte esterase, nitrite negative, 2 RBC, 4 WBC, negative urine culture, and spot protein/creatinine ratio. 1.1. Further workup revealed urine electrolytes: Cr 39mg/dL, sodium 77mmol/L, potassium 20mmol/L and phosphorus 22.9mg/dL. Fe/Phos was 61% suggesting renal wasting. Serologic workup was negative for ANA, ANCA, cl v c3, c4 and spep. Renal sonogram showed normal sized kidneys with two nonobstructing calculi in each kidney. Renal biopsy revealed focal degenerative changes in the tubules with flattening of the epithelium consistent with mild ATN. The interstitium had diffuse inflammation with mononuclear cells and frequent eosinophils consistent with AIN. EM showed tubuloreticular inclusions. She was started on prednisone which was tapered over 8 weeks. Creatinine downtrended to 1.1mg/dL. She was discharged off prednisone with serum creatinine 1.4mg/dL.
Discussion: Vedolizumab reported AIN and mild ATN has not thus far been reported. Here we report the first case which seemed to have a cumulative dose response. Whether this patient has a mild proximal RTA due to this medication remains to be elucidated, as the phosphorus wasting could have been due to her primary hyperparathyroidism. Clinicians should be made aware of such reported associations so that both a timely renal biopsy and therapy could be instituted without delay.

PO2261
An Unusual Case of Granulomatous Interstitial Nephritis (GIN)
Charis E. Whitney, Ronald L. Mars. University of Florida Health Science Center-Jacksonville, Jacksonville, FL.
Introduction: A 28 Y/O man was admitted with stage 5 CKD. He was entirely asymptomatic with a negative PMH except for recent HTN & proteinuria. Entire proteinuria w/u was negative. PE was unremarkable. Kidney biopsy showed advanced glomerulosclerosis with chronic non-casting GIN. Ectokine was uncertain except for history of BCG vaccination. BCG induced GIN was proposed. He was given a trial of ACE-I’s, but ultimately required long term hemodialysis (HD).
Case Description: A 28 Y/O Hispanic male with 1 yr PMH of untreated HTN & proteinuria presented with BUN 88, Cr 7.85. 1 day after foot surgery Cr increased to 18.4 A 2-wk hemodialysis was performed. 1 year ago he was diagnosed with HTN & proteinuria. He never received f/u or treatment. PMH was negative. FH was significant for a cousin with ESRD s/p kidney transplant & an uncle with diabetes. Full proteinuria w/u was (-). Renal US revealed normal size kidneys & increased cortical echogenicity c/w medical renal disease. GIN was considered for biopsy. Despite improvement in BUN, Cr and proteinuria, a repeat renal biopsy was done. Renal biopsy function & was then started on HD. Kidney biopsy revealed acute tubular injury without regeneration changes, acute & chronic interstitial nephritis with a few granulomas, 75% global glomerulosclerosis, mild tubular atrophy & interstitial fibrosis. GMS & AFB stains were negative for fungus & mycobacteria. No electron dense deposits (EDD’s) were seen on electron microscopy. Further discussion with patient revealed he received BCG vaccine when 2 weeks old.
Discussion: Bacillus Calmette-Guerin (BCG) vaccine is a live but attenuated strain of Mycobacterium bovis used to protect against TB in many countries with a high prevalence of TB. BCG has been implicated in the development of granulomatous disease in multiple organs, but rarely in the kidneys. Our patient received an intra-dermal BCG injection 2 wks after birth & had no sequelae or side effects. The historical (-) PMH, absence of new infections or infectious process, (-) serologic w/u, (-) history of environmental exposures made the incidental discovery of asymptomatic stage 5 CKD with proteinuria all the more surprising. The unexpected finding of GIN raised the consideration for stimulated immunity & granuloma formation from latent BCG vaccine. While literature documents granuloma formation in other organs, an occurrence in kidneys & potential contribution to progressive CKD seems less common, but should not to be overlooked.

PO2262
An Unusual Case of Aki
Taher Khordadian, Cynthia Miracle, Haiyan Zhang. University of California San Diego, La Jolla, CA.
Introduction: New-onset nephritic syndrome often requires kidney biopsy for diagnosis. Pathology is at times insufficient.
Case Description: An 81-year-old Hispanic female with HTN, CKD stage III presented with rash, fever, peripheral eosinophilia, AKI and diagnosed with DRESS
syndrome due to allopurinol started 3 weeks ago. Urinalysis showed pyuria, hematuria. Spot urine PrCr was 3.8 with serum albumin 2.5g/dL. Admission creatinine was 4.1mg/dL, increased to 6.5mg/dL prior to starting dialysis. Serologic findings shown below. Steroids were started for DRESS and suspected AIN. Genetic testing for HLA-B*5801, seen in severe cutaneous adverse reactions to allopurinol, was positive. Skeletal survey demonstrated no lesions. Blood counts revealed anemia and thrombocytopenia. Bone marrow biopsy did not show a plasma cell dyscrasia. Kidney biopsy noted amyloidosis (Congo red positive deposits in glomeruli, vessels, interstitium) with 56% global glomerulosclerosis and >60% severe IFTA. Mild interstitial infiltration with occasional eosinophils suggested resolving AIN. Severe findings of hypertensive sequelae noted. Immunofluorescence was 2+ for IgG and kappa. Electron microscopy showed 10nm fibrils and severe podocyte foot process effacement. Mass spectrometry diagnosed ALECT2 amyloidosis.

Discussion: Our case is unusual in having three simultaneous pathologies, namely AIN and ALECT2 amyloidosis superimposed on a background of hypertensive changes; the recognition of disproportionate proteinuria was essential to question the diagnosis and avoid early closure on AIN. Concurrent renal pathologies are a common finding in patients with ALECT2 amyloidosis, underscoring the utility of kidney biopsy in these patients who often have mixed clinical pictures. Circumstances leading to this case raise suspicion for preceding immune dysregulation, in the form of DRESS/steroids, that may have triggered amyloidogenesis. A prior case report describes a patient who developed ALECT2 amyloid after steroids for allergic symptoms. This potential interplay between genetic and environmental factors requires further investigation.

PO2263
ALECT2 Amyloidosis with Cardiac Involvement Complicating Renal Transplantation

Introduction: ALECT2 amyloidosis may be associated with slowly progressive renal failure that is clinically unsuspected at the time of transplantation. While this is typically not clinically significant, we report a case with extensive systemic ALECT2 amyloidosis that also involved the myocardium, contributing to perioperative death post renal transplantation.

Case Description: A 72-year-old Hispanic woman presented for renal transplantation due to ESRD from hypertension. She was bradycardic on admission. Cardiac workup prior to transplantation had not identified an infiltrative process. Post-transplant hypotensive bradycardic arrests lead to multiorgan failure, anoxic brain injury and death. Autopsy revealed massive amyloid deposition in the native kidneys, adrenals, spleen, and less extensive infiltration of liver and myocardium. Cardiac intramural vasculature from venules to capillaries, arterioles and arteries showed amyloid deposition. Mass spectrometry revealed ALECT2 as the amyloidogenic protein.

Discussion: ALECT2 is a systemic amyloidosis that typically involves kidneys, adrenals, spleen and liver. It may be clinically unsuspected at the time of renal transplantation and should be considered in older patients, especially from higher ALECT2 amyloid prevalence populations. Complications related to systemic disease may add to morbidity or mortality post-transplantation. Cardiac involvement in ALECT2 amyloidosis has not been previously identified as a significant clinical or autopsy finding, but our case demonstrates that the cardiovascular system may indeed rarely be involved by ALECT2 amyloidosis and be associated with clinical sequelae.

Model of ALECT2 amyloidosis in native kidneys, adrenals and involving vasculature of the myocardium.

Persistent Coagulation Abnormalities in ESRD After 1 Year of Follow-Up
Emily Rontekog, Vinod K. Bansal, Fakihah Siddiqui, Debra Hoppensteadt, Jawed Farreed. Loyola University Medical Center, Maywood, IL

Background: Common to end-stage renal disease (ESRD), coagulation abnormalities can lead to severe bleeding events or excessive thrombin formation and generate increased morbidity and mortality in this population. Repeated heparin administration to ESRD patients during maintenance hemodialysis may also contribute to changes in the coagulation system. Thus, profiling coagulation parameters in ESRD patients over 1-year may provide insight to long-term coagulation dysfunction in this population.

Methods: Blood samples were collected at baseline and 1-year from ESRD patients undergoing maintenance hemodialysis (n=95) 48-hours post-dialysis. Plasma samples were analyzed using clot-based methods including activated partial thromboplastin time (aPTT), prothrombin time (PT), and thrombin time (TT). Chromogenic assays measured heparin levels by anti-Xa and anti-IIa methods. Patients were categorized by heparin administration during dialysis (n=44) and compared via statistical method and percent change.

Results: In the clotting and chromatographic assays, all parameters were elevated in the baseline and 1-year ESRD cohorts compared to controls, as shown on Figure 1. Only anti-IIa levels demonstrated a significant difference in ESRD patients after 1-year (p<0.0001). Heparin administration varied in aPTT, TT, and anti-Xa (p<0.05).

Conclusions: These results suggest ESRD patients on dialysis exhibit a long-term, hypo-coagulable state as shown by prolonged aPTT and TT. Elevated parameters maintained over 1-year suggests persistent dysregulation of clotting factors in ESRD patients. Circulating levels of heparin, as evidenced by anti-Xa and anti-IIa assays may be due to impaired clearance of heparin components via dialysis.

PO2267
Using Skin Biopsies to Measure Target Occupancy of a Renal Anti-fibrotic Monoclonal Antibody (mAb) in a Phase 1 Clinical Study
Rowann Boweust,1 Geoffrey I. Johnston,1 Linghong Huang,2 James Z. Song,3 Ting S. Schmidt,1 Alison L. Bigley,4 Graham Oggi,1 Eric Wong,1 Elizabeth S. Thomson,1 Jane Y. Chan,3 Anastasia Raiveska,1 Timothy S. Johnson,1 UCB Pharma, Slough, United Kingdom; 2Prisys Biotechnologie, Shanghai, China; 3OracleBio, Chapelhill, United Kingdom; 4University of Oxford, Oxford, United Kingdom; 5University of Cincinnati, Cincinnati, Ohio.

Background: Defining the optimal dose of drug required to bind to its mechanistic target (target occupancy, TO) and affect a measurable distal event (target engagement, TE) in damaged kidney is a challenge in the development of anti-fibrotic therapies for chronic kidney disease (CKD). We aimed to identify an accessible surrogate human tissue to predict TO in the kidney, prior to application in a Phase 1 study.

Methods: We developed a ‘biopsy-on-biopsy’ approach in skin: a 3mm biopsy initiated from biopsy at the same site, up to 6 days later, provided tissue where active healing/fibrotic processes were ongoing. This method was used to measure the TO of zampilimab, a humanized mAb specific for human transglutaminase 2 (TG2), in development for fibrosis in CKD. Primate skin TO was correlated with kidney TO and TE in a translational kinetic observation (TOKO) model, before application in a single dose Phase 1 study (NCT02879877). Following dosing of zamilpimab, TO in skin biopsies and kidney was measured using a competitive immunofluorescence assay on cryosections. A TRITC-labeled mouse parent of zamilpimab (DC1) and a FITC-labeled anti-TG2 antibody binding a distant epitope (DH2) were used. TO was measured by comparing the relative binding of DC1 (competitively inhibited by zamilpimab administered in vivo) to DH2 in skin and a TG2 in-situ activity assay.

Results: In a primate UO-CKD model treated prophylactically with zamilpimab, the ‘biopsy-on-biopsy’ method showed excellent correlation between TO in the kidney and healing skin (3 days post first biopsy). Importantly, TO and TG2 inhibition (TE) in the kidney were also highly correlated. Subsequent use in the zamilpimab Phase 1 study generated data directly comparable to the preclinical model.

Conclusions: Our ‘biopsy-on-biopsy’ approach allows early identification of a dose range in Phase 1 studies where the target organ is inaccessible, and is applicable to other therapeutic mAbs intended for treatment of fibrotic kidney disease. A Phase 1/2 study of zamilpimab in patients with post-renal transplant fibrosis is ongoing (NCT04355578).

PO2268
Standardized Grading of Chronicity in Native Renal Biopsies: A Single-Center Experience
Yuan Huang, Paul J. Lee, Diping Wang. University of Cincinnati, Cincinnati, OH.

Background: Chronic changes in native kidney biopsies are important in predicting prognosis and guiding treatment. In this retrospective single-center study, we investigated the applicability of histological chronicity grading in native kidney biopsies, using a newly proposed standardized grading system by Sethi et al. and with modifications.

Methods: 52 consecutive patients (46.8 ± 1.6 yrs, 53.8% F) from January 2017 to December 2019 were recruited and 44 cases were deemed adequate. 9 categories of histopathology were evaluated and scored independently and blindly by two renal pathologists. From 4 summed scores (Sum1), a single score was generated. The other 5 categories were included to provide additional histopathologic information, which generated Sum2 score (Figure). Inter-rater agreement was measured by kappa statistics. eGFR levels both at the time of biopsy and at the end of 12 to 18-month follow-up were obtained from electronic medical records. The correlations between the calculated total scores and continuous variables were determined by bivariate correlation analysis.

Results: Inter-rater agreement was almost perfect based on the Landis and Koch scale with a kappa value 0.89. Among the 44 analyzed cases, mean baseline eGFR was 39.6 ± 29.7 mL/min/1.73m². The at end of follow-up, eGFR was 47.8 ± 29.5 mL/min/1.73m². Sum1 and Sum2 scores were significantly correlated with baseline eGFR levels (R=0.34, p<0.05, and R=0.44, p<0.01, respectively) and those at the end of follow-up (R=0.56, p<0.01 and R=0.44, p<0.01, respectively).

Conclusions: We demonstrated that the modified criteria were comparable to the original criteria; both had good interrater agreement and correlated well with eGFR levels. The modified criteria could provide standardized grading of additionally relevant histopathology. Application of standardized chronicity grading will benefit prognosis evaluation and clinical management in renal diseases.

PO2269
Inadequate Tissue for Renal Biopsy Analysis Has Significantly Increased Since the Switch to Interventional Radiology (IR)
Patrick D. Kelleg,1 Vanessa Moreno,2 Caleb Nissen.3 'Arkana Laboratories, Little Rock, AR; 2University of Arkansas for Medical Sciences, Little Rock, AR.

Background: The aim of this study was to determine the incidence of inadequate native renal biopsy (Bx) samples in our laboratory over time.

Methods: A retrospective study of native kidney biopsy adequacy from 2004 through the first month of 2020 was done. Adequacy was defined by the number of glomeruli for light microscopy (LM) as follows: 1. Ideal ≥ 20; 2 Adequate 10-19; Limited 4-9; Miss 0-3. An in-depth study of kidney biopsies received in 2004 and August-October of 2018 was conducted in comparison with Bx's performed prior to IR intervention. In 2004, there were 1,535 native Bx's: Neph 1,489 (97%); IR 46 (3%). In the 20-week 2018 study, there were 5,134 native needle Bx's: Neph 250 (5%); IR 4,884 (95%).

Results: The mean miss rate changed from 2% in 2004-2008 to 7% in 2009 through 2018 (figure). This correlates with the change from Neph to IR as operators. The miss rate deep (medulla) v miss rate shallow (peri-renal tissue) also significantly changed from Neph ≤ 2% to IR 7%.

Conclusions: The availability of advanced tissue analysis techniques and more importantly, the increase in therapeutic options has made the renal biopsy an even more

Morphologic Evidence of Excretory Function in Human Mesonephros
PO2271
Hemorrhagic Complications
Value of Immediate Post-Kidney Biopsy Ultrasound in Excluding Major Hemorrhagic Complications
Albalas, Anmar Almehni, Sloan Almehni, Michael Allan. The University of Alabama at Birmingham, Birmingham, AL.
Background: Hemorrhage is the most serious potential complication of percutaneous kidney biopsy. Patients are typically observed for at least 6-8 hours after a kidney biopsy, with serial measurements of vital signs and hemoglobin to monitor for major hemorrhage. This study assessed whether an immediate post-biopsy ultrasound can reliably predict major hemorrhage.
Methods: Retrospectively evaluated the clinical outcomes in 147 patients undergoing an outpatient native kidney biopsy at a large medical center during a 2.5 year period (January 2017 to June 2019). All patients underwent a standardized post-biopsy ultrasound. We extracted from the medical records vital signs and hemoglobin values obtained before the biopsy and at 2, 4, and 6 hours after it, and ascertained whether the patient developed a major hemorrhage requiring hospitalization.
Results: Each patient underwent 2 or 3 biopsy passes. The mean patient age was 48±17 years, 49% were female, 37% were black, 53% had hypertension and 16% had diabetes. Five patients had evidence of a perinephric hematoma on the ultrasound and were hospitalized. The remaining 142 patients had no evidence of bleeding on ultrasound. Their blood pressure, heart rate, and hemoglobin remained stable during 6 hours of observation. All were discharged after 6 hours, and none had a late bleeding complication.
Conclusions: If the immediate post-kidney biopsy ultrasound does not show hemorrhage, the patient is extremely unlikely to develop a major hemorrhagic complication (negative predictive value, 100%). Such patients can be discharged home safely after a 2-hour observation, thereby simplifying their management.

PO2271
Morphologic Evidence of Excretory Function in Human Mesonephros
Ping L. Zhang.1 Joseph V. Bonventre.2 Beaumont Health, Royal Oak, MI; ‘Brigham and Women’s Hospital, Boston, MA.
Background: Human mesonephros develops at 4 weeks of gestation and regresses at approximately 16 weeks of gestation. It is not clear if the human mesonephros has excretory function. Our goal was to assess morphologic evidence of primordial glomeruli, and renal tubules suggestive of excretory function using special staining and immunohistochemical staining methods.
Methods: Five mesonephric kidneys from human embryos found in miscarriage (missed abortion) or ectopic pregnancy specimens were studied. They were obtained from 4 weeks to 10 weeks gestation. In addition, 8 early metanephric kidneys from 10 weeks to 21 weeks of gestation were identified from our surgical pathology and autopsy cases for comparison with mesonephric specimens. Beside routine hematoxylin and eosin staining, the sections were stained for Periodic Acid Schiff (PAS) to detect proximal tubules (PT) brush borders and glomerular basement membranes (GBM). Furthermore, mesonephros and metanephros sections were immunohistochemically stained for CD133 for progenitor cells, GATA3 for mesangial cells and distal tubules, P504S for proximal tubules, and kidney injury molecule-1 (KIM-1) for PT injury.
Results: CD133 was positive in mesonephric glomerular and tubular structures at 4 weeks but this expression disappeared in the mesonephros from 5 weeks to 10 weeks, implying gradual maturation. GATA3 staining was positive in Wolffian duct, mesangial cells of primordial glomeruli (at 7 weeks the GBM was PAS+) and distal tubules, but not in PT. PT were positively stained for P504S. PT of mesonephric kidneys revealed brush borders on PAS stained sections from 7 to 10 weeks suggestive of reabsorbptive activity. The PT of mesonephros at 7 weeks stained positively for KIM-1, suggestive of acute tubular injury during apoptosis processes. The metanephros showed expression of markers in respective renal compartments, similar to those in mesonephros.
Conclusions: Human mesonephros can have GATA3+ mesangial cells in the glomeruli (although structures are simplified (no loop of Henle and collecting ducts), the human mesonephric nephrons include primitive glomeruli, PT showing brush borders and distal tubules, having morphological features similar to those of advanced metanephric stages with excretory function. They have react to injury, at least during 7 to 10 weeks of gestation based on identification of brush borders and KIM-1 expression in PT.

PO2272
Monogenic Causes of Nephrolithiasis or Nephrocalcinosis in Korean Children
Jeong yeon Kim.1 Beomhee Lee,2 Heeyeon Cho.1 Department of Pediatrics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; 2Department of Pediatrics, Asan Medical Center Children’s Hospital, University of Ulsan College of Medicine, Seoul, Republic of Korea.
Background: Nephrolithiasis (NL) or nephrocalcinosis (NC) can be the early manifestation of hereditary nephropathy in children and early detection of hereditary nephropathy gives us chance to provide therapeutic and preventative intervention. In this study, we present genetic characteristics of NL/NC in pediatric patients who were treated in tertiary medical center in Korea.
Methods: The medical records of pediatric patients (age of 0-18 year) who had NC/NL and underwent genetic test under suspicion of hereditary nephropathy from March of 2013 to January of 2020 in Samsung Medical Center in Korea were reviewed. When specific disease was suspected, the sanger sequencing was done. The whole exome sequencing was performed when suspected mutations were not detected in sanger sequencing or when the disease could not be specified. DNA was extracted from whole blood or saliva. The novel mutations were evaluated by clinical findings and bioinformatics analysis such as in silico prediction.
Results: Total 20 patients underwent genetic test and two of them were sibling. The median age at the time of NC/NL detection was 4.8 year and male was predominant (M/F=2:3). Genetic diagnosis was done at the median age of 5.5 year. Three patients had family history of NC/NL (15%). Total 13 pathogenic gene mutations were detected in 16 patients (80%): 5 genes (SLC34A1, GRIN2A, CLCN5, OCLR1, CLCNKB) were known to cause monogenic forms of NL/NC and 8 genes (PA2X, PKD1, HNF1B, SCN11A, SLC36A2, BUB1B, VPS33B, PHEx) were not. Three pathogenic autosomal recessive mutations were detected in 3 individuals; BUB1B (n=1), GRIN2A (n=1), VPS33B (n=1). We also detected pathogenic mutations in 6 autosomal dominant genes in 7 individuals; CLCNKB (n=1), SLC34A1 (n=1), SLC34A2 (n=1), HNF1B (n=2), SCN11A (n=1), PKD1 (n=1), SLC36A2 (n=1). Two X-linked recessive genes were detected in 5 individuals; CLCN5 (n=4), OCLR1 (n=1). In one patient, X-linked dominant gene was detected; PHEx. Eight of 16 detected mutations (50%) were novel mutation that have not been previously reported in database of human disease causing mutation.
Conclusions: In conclusion, NL/NC can be the clue to detect monogenic cause of hereditary nephropathy in children. Further large population study is needed to evaluate NL/NC as indicator for genetic analysis to detect monogenic hereditary nephropathy in children.

PO2273
Trans IL-6 Signaling Does Not Distinguish Between Pediatric Patients with and Without Scarring After Febrile Urinary Tract Infection
Sudipti Gupta, Sara E. Lautzenhiser, John D. Spencer, Brian Becknell, Christina B. Ching. Nationwide Children’s Hospital, Columbus, OH.
Background: The inflammatory response generated in response to infection is believed to be largely responsible for the development of renal scarring after UTI. IL-6 is a cytokine known to be induced during UTI with a pro-inflammatory pathway, known as trans signaling. We hypothesized there would be differences in markers of trans IL-6 signaling between patients with a history of febrile urinary tract infection (UTI) who had subsequent renal scarring as compared to those with a history of febrile UTI who did not develop renal scarring.
Methods: Urine samples were collected on consenting/assenting pediatric patients with a history of febrile (≥38°C) UTI (urine culture ≥10^5 CFU/mL or documented presence or absence of renal scarring on imaging). Patients were not actively infected at time of sample collection. Enzyme-linked immunosorbent assays were performed on samples for markers of trans IL-6 signaling: IL-6, soluble (s)IL-6 receptor (R), and soluble
(s)gpl130, a buffer in trans-IL-6 signaling. Values were normalized to urine creatinine. Retains were analyzed by t-test or Mann-Whitney U. Spearmann rank correlation was used. A p-value of <0.05 was considered significant.

Results: 50 urines from patients with a history of febrile UTI were collected: 23 with and 27 without scarring. The groups were not significantly different in age or gender. Urine IL-6 were not significantly different between those with and without renal scarring. While IL-6 values significantly correlated with sgp130 values (p=0.0004) in those without renal scarring, the values did not correlate in those with scarring (p>0.05). Ratios of IL-6/sgp130 and sIL-6R/sgp130 were not different between groups.

Conclusions: The expression of trans IL-6 signaling in those with renal scarring compared to those without due to a lack of correlation of sgp130 with IL-6 in those with scarring. The absolute values and ratios of these markers of trans IL-6-signaling, however, are not significantly different between individuals with a history of febrile UTI with and without renal scarring in the non-acute setting.

PO2274

Markers of Trans-IL-6 Signaling Are Not Differentially Induced During Febrile and Afebrile Urinary Tract Infection

Sudipti Gupta, Sara E. Lautzenhiser, John D. Spencer, Brian Becknell, Christina B. Ching. Nationwide Children’s Hospital, Columbus, OH.

Background: Febrile urinary tract infections (UTIs) are generally thought to be evidence of tissue inflammation such as pyelonephritis as compared to afebrile UTIs which are thought to be more localized to the bladder. As such, generally the concern for renal damage is more in those with febrile UTI and thought to be a result of the inflammatory response generated. IL-6 is a known mediator of inflammation, particularly through its trans signaling pathway. We hypothesized there would be differences in markers of trans IL-6 signaling in the urine of children with febrile compared to afebrile UTI.

Methods: Pediatric patients with signs of active UTI were consented/assented for participation. Urine was collected at time of evaluation for active UTI in the urology or nephrology office or at hospitalization and were divided into those with a fever (38°C) compared to those without (<38°C). Patients were included for analysis if they had a positive urine culture (>50K CFU of a uropathogen) and for those without a fever if they had a urinary incontinence. Those with fever were termed a febrile UTI and those without a fever were termed afebrile UTI. Enzyme-linked immunosorbent assays were performed on samples for markers of trans IL-6-signaling: IL-6, soluble (s)IL-6 receptor (R), and soluble (s) gp 130. Results were normalized to urine creatinine. Results were analyzed by Mann-Whitney U. A p-value of <0.05 was considered significant.

Results: 17 patients with febrile UTI and 23 patients with afebrile UTI were included. Two of the patients with febrile UTI were male while all of the afebrile UTI patients were female (p=0.1258). The groups did not differ significantly based on age (p=0.6218). While we found that those with a febrile UTI had a higher IL-6 in their urine at the time of collection (p=0.0479), there was no significant difference in expression of sIL-6R or sgp130. Ratios of these markers also were not significantly different.

Conclusions: Markers of trans IL-6 signaling, either as absolute values or ratios, are not different between individuals at the time of febrile or afebrile UTI.

Human Neutrophil Peptide 1-3 Protects the Urinary Tract from Uropathogenic Escherichia coli Infection in Humanized Mouse Model

Jorge J. Canas, Jenaya Hooks, Sam W. Arregui, Andrew L. Schwaderer, David S. Hains. Division of Pediatric Nephrology, Department of Pediatrics, Indiana University School of Medicine, Indianapolis, IN.

Background: Urinary tract infection (UTI) susceptibility is defined by heritable genetic differences associated with the innate immune system development and efficiency. DNA copy number variations in the alpha-defense DEF41A1 locus are associated with UTI susceptibility in children with VUR. In humans, DEF41A3 is expressed in neutrophils as well as in the kidney. However, how DEF41A1 protects the urinary tract in some individuals is unknown. We hypothesized that Defa-1−/− humanized mouse would be resistant to experimental UPEC infection.

Methods: We induced UTI with two uropathogenic E. coli (UPEC) strains in wild-type (WT) C57Bl/6J and Defa−/− transgenic mice, which express human DEF41A3. Bacterial suspension was inoculated with a catheter transurethrally. To assess the colony-forming unit (CFU) burden, kidneys and bladders were homogenized and colony forming units and clearance were determined by quantifying the plated serial dilutions grown overnight on LB plates at various time points.

Results: Results are presented in Figure 1: Comparing the Defa−/− mouse to WT (n=8 for each group), at 6-hours post infection, bacterial burdens were lower in the Defa−/− mice kidneys for both UPEC strains (A). At 24-hours after inoculum, the bladder total bacterial load (CFU/g) was significantly lower in the Defa−/− mouse in comparison to the C57Bl/6J group (B).

Conclusions: Our findings support the early protective role of DEF41A3 from UPEC challenge in the humanized mouse kidney and bladder when compared to the absence of the antimicrobial peptide in the wild-type mouse. Further investigation is needed to determine whether renal or extra-renal expression of DEFA1A3 is critical in shielding and clearing UPEC UTIs.

Bacterial Cystitis and Pyelonephritis

Hanna H. Cortado, Birol Li, Ashley R. Jackson, Sudipti Gupta, Christina B. Ching, John D. Spencer, Brian Becknell. Nephrology and Urology Research Affinity Group Nationwide Children’s Hospital, Columbus, OH.

Background: Bacterial urine infection (BNI) is a highly conserved cationic peptide activity toward uropathogenic Escherichia coli (UPEC) in vitro. Here, we determined the cellular sources of RNase 6 along with the consequences of its gain and loss of function during experimental urinary tract infection (UTI).

Methods: We generated female mice with a Rnase6CreERT knock-in allele, human RNAse6 transgenic, or controls on a C57Bl/6J genetic background. We identified cellular sources of RNase6 by flow cytometry and microscopy. We transurethrally inoculated Rnase6CreERT, RNAse6 transgenic, and control mice with UPEC strain CFT073 and enumerated bacterial burden. The role of RNase6 during intracellular killing of UPEC was investigated in bone marrow derived macrophages (BMDM) by gentamicin protection assay.

Results: RNase6 is expressed by tissue resident macrophages and circulating monocytes that are recruited to the infected bladder and kidney within hours of UPEC inoculation. Rnase6 deficiency leads to increased renal UPEC burden relative to controls, whereas RNAse6 transgenic mice exhibit reduced UPEC burden. RNAse6 macrophages localize within the urethra and its underlying stroma at baseline and during UTI. RNase6 is not secreted by macrophages; instead, it is retained intracellularly within the endolysosomal system. RNAse6 over-expression in macrophages leads to increased killing of phagocytosed UPEC.

Conclusions: RNAse6 is a monocyte/macrophage derived antimicrobial peptide that acts intracellularly to kill phagocytosed UPEC and limit bacterial UTI.

Risk Factors for Urinary Tract Infection Caused by Extended-Spectrum Beta-Lactamase Gram-Negative Bacteria in Infants

Yo Han Ahn, Ji hyun Kim, Juyoung Lee, Seonhee Lim, Hee Gyang Kang, Ji Young Lee, Yoonhee Kim, Ji hyun Kim, Jiuyoung Lee, Seonhee Lim, Hee Gyang Kang. Seoul National University Children's Hospital, Seoul, Republic of Korea; Seoul National University Bundang Hospital, Seongnam, Republic of Korea; Inha University Hospital, Incheon, Republic of Korea.

Background: Community-acquired extended-spectrum beta-lactamase (ESBL) producing bacterial infections are an evolving public health problem. Urinary tract infections (UTIs) due to ESBL-producing bacteria are increasing even in infants rarely exposed to antibiotics. We aimed to identify risk factors for UTI caused by ESBL-positive bacteria in infants.

Methods: We retrospectively analyzed the medical records of hospitalized infants with the first episode of UTI from 2018 to 2019. Data includes demographic characteristics, birth history, previous use of antibiotics, female event, urinalysis results, and urine isolated organisms. Multivariable regression analysis was used to quantify independent risks associated with ESBL-positive UTI.

Results: Patients were diagnosed in 266 patients at a median age of 3.6 (interquartile range: (IQR) 2.3-5.4) months. Among the two (30.4%) patients were diagnosed with UTI caused by ESBL-producing bacteria. When we divided patients according to ESBL status, there was no difference in gender, age, birth history, milk type, and use of postpartum care centers. Maternal use of antibiotics during pregnancy (odds ratio (OR), 3.817; 95% confidence interval (CI) 1.812-8.040, P <0.001), previous antibiotic exposure to patients was higher in the ESBL-positive group than in the ESBL-negative group (32.3% vs. 10.3%, P <0.001, and 22.6% vs. 12.3%, P =0.044, respectively). Klebsiella species was more frequently identified in the ESBL-positive group than in the ESBL-negative group (19.4% vs. 4.9%, P <0.002). In multivariable analysis, maternal use of antibiotic during pregnancy (odds ratio (OR), 3.817; 95% confidence interval (CI) 1.812-8.040, P <0.001), previous antibiotic exposure to patients (OR 2.418; 95% CI 1.071-5.661, P =0.034), and Klebsiella species as a causative organism (OR 6.222; 95% CI 2.396-16.158, P <0.001) were associated with ESBL positivity. In a comparison of clinical courses of patients, the ESBL-positive group showed severe leukocytosis (WBC 16,795 (µL vs. WBC 14,620 (µL, P =0.04), and stayed longer in hospital than the ESBL-negative group (7.0 days vs. 4.5 days, P <0.001).

Conclusions: In this study, the high rate of ESBL positivity was detected in infantile UTI. Antibiotics exposure on both parents of patients was associated with UTI caused by ESBL producing bacteria. Identification of underlying risk factors could improve treatment and preventive strategies.

PO2278

Urinary Sodium to Potassium Molar Ratio in Pediatric Stone Patients

Vimal Master sankar raj, University of Illinois College of Medicine at Peoria, Peoria, IL.

Background: The incidence of pediatric stone disease is on the rise. Dietary elements including high salt intake and reduced water consumption remain the major risk factors for stone formation. Urinary stone profile in pediatric literature remains limited. The purpose of this study is to get data on 24 hr urinary mineral excretion in pediatric stone formers with particular emphasis on these two research questions 1. How does urinary sodium/potassium (Na/K) molar ratio in pediatric stone patients compare to the national average intake data in USA? 2. How does risk factors of stone formation such as hypercalcuric correlates with dietary risk factors in pediatric stone formers?

Methods: This retrospective cohort study included all Pediatric stone patients who attended outpatient Nephrology clinic from 03/1/2014 to 10/1/2018. Children with known metabolic/genetic causes for stone disease, incomplete 24 hr urinary collection or on medications that affect mineral excretions were excluded from the study.

Results: 150 patient charts were screened and 89 included in the study. Average age of the study population was 12.7 years with 58% females and 42% males. Mean Na/K molar ratio in pediatric stone patient was 3.7, statistically significantly higher than the national average of 2.5 using one sample t test (P < 0.001). Urinary calcium excretion showed a strong linear correlation with sodium excretion (r = 0.545, P < 0.001). Multiple regression model using urinary calcium excretion as the dependent variable showed correlation with Urinary sodium excretion (P < 0.0004), urinary volume (P < 0.0001) and urinary Ph (P = 0.001)

Conclusions: 24 hr urinary sodium potassium molar ratio is significantly higher in stone formers indicating a higher salt and lower potassium consumption when compared to national average intake. Water intake, salt consumption and alteration of urinary Ph remains the main dietary modality to alter calcium excretion and hence reduce risk of stone formation

PO2279

Keratin 5+ Urothelial Cells Are Developmental and Tissue Repair Progenitors in the Bladder

Ashley R. Jackson,1 Birong Li,1 Brian Becknell,1,2 1Center for Clinical and Translational Research, Abigail Wexner Research Institute at Nationwide Children’s Hospital, Columbus, OH; 2Division of Pediatric Nephrology, Nationwide Children’s Hospital, Columbus, OH.

Background: Urothelium is nearly quiescent during homeostasis, but injury engages a robust regenerative capacity. Several progenitor cell candidates have been implicated, but prevailing models demonstrate conflicting roles discrete urothelial subpopulations. We recently demonstrated that Keratin 5 (K5)-expressing UCs are temporally restricted renal urothelium progenitors. It is unclear whether similar temporal restrictions are imposed on bladder K5-UCs, and whether an investigation into the temporality of the K5-UC progenitor may clarify bladder progenitor models. The objective of this study was to determine temporal progenitor-progeny relationships responsible for bladder urothelium generation and regeneration.

Methods: Using Ker5+CreERT2,Rosa26tg mice, K5-UCs were inducibly and permanently labeled with tdTomato (tdT). Tamoxifen (TMX) was administered at postnatal day (P)1, P7, P14, P21 or P41. Mice were sacrificed (SAC) at P42 or subjected to a single round of acute adult bladder injury (CUS) and 69% (TMX P7 -SAC) and 23.5% (TMX P7 -SAC) of umbrella cells expressed tdT K5 (tdT K5+;K5-;Upk+;K20+) (P<0.01). CYS-c was significantly higher in infants with HF (1.6 ± 0.3 mg/L vs 1.4 ± 0.3 mg/L, p < 0.001). Linear regression analysis corrected for confounders (type of feeding, delivery mode, weight loss velocity) confirmed that paternal hypertension was the only variable significantly associated with high Cys-c level (mean difference 0.2 mg/L, IC 95% 0.1-0.3 in, p < 0.001).

Conclusions: Our results support the key role of nephron endowment in the pathogenesis of AH and suggest the possibility of identifying at-risk subjects at birth. This opportunity opens up specific and targeted preventive health measures very early in life.

PO2280

Perinatal Cystatin C as Biomarker of Nephron Endowment

Beatrice L. Crippa,1 Stefano Ghirardello,1 Valentina Capone,2 Gianluigi Ardissino.1 1NICU, Fondazione IRCCS Ca’ Granda, Ospedale Maggiore Policlinico, Milano, Italy; 2Pediatric Nephrology, Dialysis and Transplantation, Fondazione IRCCS Ca’ Granda, Ospedale Maggiore Policlinico, Milano, Italy.

Background: Nephron endowment has a wide individual variability and plays a crucial role in drug toxicity, outcome of kidney diseases and pathogenesis of arterial hypertension (AH), but nephrons count is technically impossible in vivo. During acute dehydrathion, subject with reduced nephron mass (unilateral renal agenesis or renal hypoplasia) exhibit increased levels of biomarkers of renal function compared to healthy subjects. We hypothesized that healthy newborns with reduced nephron endowment will have high levels of cystatin C (Cys-c) during perinatal dehydration. The aim of the study was to compare Cys-c level during physiological perinatal dehydration in healthy term infants with hypertensive fathers (HF) and normotensive fathers (NF).

Methods: Healthy, Caucasian, newborns were enrolled: infants with fathers on antihypertensive therapy were compared to infants with normotensive fathers > 40 yo. Enrolled infants underwent Cys-c capillary determination at time of expanded newborn screening.

Results: We enrolled 40 infants with HF and 80 infants with NF. Basic characteristics were not different between the two groups except for the number of hypertensive grandparents, that was higher among infants with HF. Cys-c levels was determined at a median of 62.5 hours of life (IQR 55-71) without any difference between groups. Cys-c was significantly higher in infants with HF (1.6 ± 0.3 mg/L vs 1.4 ± 0.3 mg/L, p < 0.001). Linear regression analysis corrected for confounders (type of feeding, delivery mode, weight loss velocity) confirmed that paternal hypertension was the only variable significantly associated with high Cys-c level (mean difference 0.2 mg/L, IC 95% 0.1-0.3 in, p < 0.001).

Conclusions: Our results support the key role of nephron endowment in the pathogenesis of AH and suggest the possibility of identifying at-risk subjects at birth. This opportunity opens up specific and targeted preventive health measures very early in life.

Elevated Urinary Neutrophil Gelatinase-Associated Lipocalin Predicts Postoperative AKI

Cara L. Slagle, Hailey W. Gavigan, James A. Rowe, Brenda Pinto, Kelli A. Kraliman, Alexandra Schmerge, Chunyan Liu, Shelby Ehrlich, Meera Kotagal, Stuart Goldstein. Cincinnati Children’s Hospital Medical Center, Cincinnati, OH.

Background: Post-operative acute kidney injury (AKI) in neonates remains understudied despite occurring frequently. Urinary neutrophil gelatinase-associated lipocalin (uNGAL) offers promise as a novel predictive biomarker for AKI, yet clinical utilization lags behind in neonatology.

Methods: Infants undergoing a general surgical procedure, excluding gastric tube placement alone, were prospectively enrolled. uNGAL samples were obtained prior to surgery and over post-operative days (POD) 0-3 at six time points. AKI was defined by the 2014 neonatal modified Kidney Diseases: Improving Global Outcomes (KDIGO) definition. Samples were processed using The NGAL Test® (BioPorto, Denmark). Generalized additive mixed effect model (GAMM) was utilized to study the longitudinal trajectory of log transformed uNGAL values. The ability to predict AKI was assessed using receiver operating characteristic curves (AUC-ROC).

**AKI in Neonatal Congenital Diaphragmatic Hernia**

Briania M. Libario,1,2 Katja M. Gist,1,2 John T. Brinton,3 Danielle Soranno,1,2 Megan J. Kirkley,2,4 Jason Gien,2,4 Children’s Hospital Colorado, Aurora, CO; 1University of Colorado, Denver, CO; 2Denver Health Medical Center, Denver, CO

**Background:** Acute kidney injury (AKI) occurs in about 30% of hospitalized neonates and is independently associated with mortality. Infants with congenital diaphragmatic hernia (CDH) are frequently exposed to nephrotoxins and predictive fluid shifts, surgery, cardiopulmonary compromise, and extracorporeal life support (ECLS). As such, they are cited to have an increased AKI incidence. We sought to determine prenatal characteristics and postnatal exposures associated with an increased risk of AKI in neonates with CDH during the first 30 days of life, as well as the impact of AKI on selected long-term outcomes.

**Methods:** We performed a single-center retrospective review of neonates with CDH from 2009 to 2017. AKI was defined by the modified neonatal Kidney Disease Improving Global Outcomes (KDIGO) criteria. Demographics, patient demographics, and long-term outcomes were assessed between those with and without AKI. We used longitudinal models with and without lagged predictions to determine associations between postnatal exposures and AKI.

**Results:** 90 infants with CDH were included. In the cohort, median gestational age was 38 weeks [IQR: 36, 38], median birthweight was 2.89 kilograms [IQR: 2.5, 3.19], 56% were male, and 50% were born outborn. AKI occurred in 34 (37.8%) infants during the first 30 days of life. Specifically, 15 (44%) had stage 1, 10 (29%) had stage 2, 9 (26%) had stage 3 AKI. CDH patients who required CRRT at some point had lower estimates of lung volume (percent predicted lung volume, total lung volume; lung to head ratio, observed to expected lung to head ratio) and higher occurrences of liver up. Postnatally, ECLS, nephrotoxin exposure, CDH repair, abdominal closure, and 10% fluid overload significantly increased the odds of AKI development at varying time-points in the lagged predictions model. Those with AKI had increased mortality and almost two times greater length of stay and duration of mechanical ventilation.

**Conclusions:** AKI is common among neonates with CDH. In our cohort, greater CDH severity assessed antenatally conferred greater odds of AKI, and those with AKI had worse long-term outcomes. Attention to kidney function should be paid to neonates with fluid overload, on ECLS, exposed to nephrotoxins, or in the post-operative period, given the increased odds of AKI in such situations.

**PO2283**

**Modification of the Renal Angina Index for Identifying Need for Renal Replacement Therapy in Critically Ill Pediatric Patients**

Erik K. Stenson,1,2 Danielle Soranno,1,2 John T. Brinton,1,2 Katja M. Gist,1,2 Children’s Hospital Colorado, Aurora, CO; 1University of Colorado Denver School of Medicine, Aurora, CO

**Background:** Severe acute kidney injury (AKI) is a common and serious problem affecting critically ill children that lacks effective treatment options. Currently, there are no treatment options for AKI other than supportive care. Continuous renal replacement therapy (CRRT) is employed to reduce fluid overload (FO) burden and treat metabolic disturbances in AKI. Identifying patients upon admission who may require CRRT has potential clinical care implications.

**Methods:** The analytic cohort consisted of patients who required CRRT and illness severity score matched controls who did not require CRRT at a single center. Patients who required CRRT had higher mortality rates, length of stay, and use of ventilatory and inotropic support. Test characteristics assessed and compared the discriminatory accuracy of three scores: 1) the renal angina index (RAI), 2) serum-creatinine based AKI on day 0 (Day0AKI) and 3) modified RAI created with an additional RAI injury tranche that corresponded to stage 3 AKI serum creatinine (SCr) elevation.

| Table 1: Comparison of predicted uNGAL values (95% CI) following Emergent and Routine Procedures |
| Procedure | Emergent (n=69) | Routine (n=121) |
| Preoperatively (preCP) | 60.2 (50.4, 71.1) | 65.8 (59.2, 72.3) |
| 12 hour post | 200.2 (184.3, 216.3) | 197.8 (184.7, 210.9) |
| 24 hour post | 328.8 (314.0, 344.1) | 317.7 (305.0, 330.8) |
| 36 hour post | 460.4 (440.0, 480.8) | 461.5 (442.5, 480.4) |
| 48 hour post | 604.5 (584.0, 625.1) | 608.7 (588.8, 628.5) |
| 72 hour post | 760.4 (734.2, 786.7) | 756.7 (730.7, 782.6) |
| 96 hour post | 926.8 (895.4, 958.2) | 925.6 (894.9, 956.1) |

**Results:** The optimal cutoff for creatinine-based Day0AKI was found to be stage 3; the optimal cutoff for RAI was 0.8 (200). Infants with AKI were more likely to have undergone an emergent procedure (63% vs 31%, p<0.001) and had higher unNGAL levels (Table 1). Pre-op uNGAL did not differ between AKI and no AKI patients (26ng/mL vs 59ng/mL, p=0.12). uNGAL levels were higher at all post-op time points even when controlled for pre-operative AKI (p<0.001 to 0.0356). The AUC-ROC for predictability of post-operative AKI using uNGAL at 24 hours was 0.8 (95% CI: 0.71, 0.88).

**Conclusions:** Post-op uNGAL predicts AKI. In patients undergoing emergent procedures, careful monitoring of renal function should be performed and uNGAL offers clinical utility. Identifying patients with post-operative AKI trends could allow clinicians and families to better understand renal injury in real time and adjust treatment plans and/or avoid or restart nephrotoxic medications.

**Funding:** NIDDK Support, Private Foundation Support

**Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only**
post-op FO and no FO groups were evaluated by Mann-Whitney U tests. Ability to predict FO was assessed by receiver operating characteristic curves (AUC-ROC).

**Results:** A total of 141 infants underwent 192 procedures. FO occurred after 46% (88/192) procedures (mean %FO = 27±10). Previous medical history of FO was associated with development of post-op FO (35% vs. 14%, p=0.001). Development of post-op AKI was also associated with FO even when controlled for pre-op AKI (69% vs. 31%, p=0.005). When SCr was adjusted for FO, AKI increased from 35 to 38 events and stage of AKI increased in 8 events. In FO patients, elevations in uNGAL were higher at all time points (Table 1). The AUC-ROC for uNGAL to predict post-op FO was 0.7 (95% CI: 0.63-0.78).

**Conclusions:** FO is an indicator of reduced renal function and is associated with AKI. uNGAL offers utility as an additional biomarker to assist in prediction of post-op FO and inability to maintain acceptable fluid balance. Post-op FO should be monitored closely for all surgical patients, and particularly patients with a previous history of AKI.

**Funding:** NIDDK, Private Foundation Support

**Use of B-Type Natriuretic Peptide as a Quantitative Marker of Fluid Overload in Neonatal Renal Replacement Therapy**

Nouroeddin D. Nourbakhsh,1,2 Nadine M. Benador,1,2 Comprehensive Kidney Care Center, Rady Children’s Hospital, San Diego 1Rady Children’s Hospital San Diego, San Diego, CA; 2University of California San Diego, La Jolla, CA.

**Introduction:** Neonatal renal replacement therapy (RRT) remains one of the most challenging dialysis scenarios in Pediatric Nephrology. Evaluation of dry weight can be particularly difficult as fluid overload may be mistaken for adequate nutritional weight gain. Physical exam is insensitive in assessing hypervolemia until significant fluid overload develops. Non-invasive BP measurements are often difficult to obtain as upper extremities are typically used for IV access and the patient’s lack of cooperation alters measurement. B-type natriuretic peptide (BNP) has long been used in the evaluation of heart failure and has been reported to be a marker of fluid overload in adult hemodialysis patients. In this study, we evaluate the role of BNP as a quantitative marker of fluid overload in a neonate with ESRD.

**Case Description:** A 3 week old child with bilateral renal agenesis required emergent RRT. Following the failure of peritoneal dialysis in this 2.19 kg child, RRT modality was converted to hemodialysis (HD). Although HD is the gold standard for renal replacement therapy, it is associated with significant complications including hypotension, hypoxia, and increased risk of hospitalization. In the present case, HD was initiated in a patient with a known history of heart failure. To better understand the role of BNP in the management of fluid overload in neonates, we evaluated the association between BNP levels and fluid overload in this patient.

**Discussion:** Providing successful dialysis in infants is more problematic than in older patients. To assess fluid overload in children on dialysis, traditional tools include clinical assessment, serial weights and measuring blood pressure. In this infant, measurement of serial BNP levels allowed for an objective assessment of volume status, which was helpful in maintaining dry weight and lead to successful dialysis.

**PO2287**

**Comparison of Nafamostat Mesylate and Regional Citrate Anticoagulation for Anticoagulation in Pediatric CRRT**

Mai J. Miyai,1,2 Kelli A. Krallman,1 Kentaro Ide,1 Stuart Goldstein,1 1Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 2National Center for Child Health and Development, Kokuritsu Kenkyu Kaihatsu Hojin Kokuritsu Seiiku Iryo Kenkyu Center, Setagaya-ku, Japan.

**Background:** Regional Citrate Anticoagulation (RCA) is the preferred anticoagulant for CRRT in the US in children. Nafamostat Mesylate (NM), a synthetic serine protease, has been widely used for CRRT anticoagulation in Japan and Korea. While NM is considered safe and effective, there is a paucity of evidence in pediatric literature. We describe the safety and efficacy of NM compared to RCA for pediatric CRRT.

**Methods:** Using one children’s hospital in Japan and one in the US, medical records of patients ≥21 years who received CRRT between 2017-2019 were reviewed. Patients receiving CRRT concurrently with ECOM were excluded. Basic demographics, CRRT characteristics, and outcomes were analyzed between the RCA and NM groups. Filter life (FL), defined as the number of hours a single CRRT filter was in use, was the primary efficacy outcome of efficacy. For Kaplan Meier analysis, circuits were censored for elective filter discontinuation. Safety was assessed by anticoagulation complications. Results: 28 pts (100 filters) received RCA and 36 pts (90 filters) received NM. Baseline Table1. There was no difference in median FL (42.6h in RCA vs 42h in NM, p=0.17). Kaplan-Meier curves of time to spontaneous filter failure shown in Fig1. The mortality and bleeding rate did not differ between the groups.

**Conclusions:** NM provides similar efficacy compared to RCA for FL. No significant difference in safety was observed between the two groups.

**Renal Replacement Therapy and Mortality Rates for Children with Posterior Urethral Valves and Prune Belly Syndrome**

Emily J. Stonebrook,1 Yuri V. Sebastião,1 Brian Becknell,1,2 Christina B. Chung,1,2 Daryl J. McLeod,1,3 Nationwide Children’s Hospital, Columbus, OH; 1Center For Clinical and Translational Research, The Research Institute at Nationwide Children’s Hospital, Columbus, OH; 2Center for Surgical Outcomes Research, The Research Institute at Nationwide Children’s Hospital, Columbus, OH.

**Background:** Posterior Urethral Valves (PUV) and Prune Belly Syndrome (PBS) cause congenital obstructive uropathy and dysplasia in infants. Resulting chronic kidney disease and pulmonary hypoplasia may lead to renal replacement therapy (RRT), mechanical ventilation and death.

**Methods:** This retrospective cohort study queried The Pediatric Health Information System (PHIS) database to identify patients with PUV or PBS who were born at or transferred to a PHIS hospital by 3 months of age between 1/1/2006 and 9/20/2016. Ethnicity, race and insurance were investigated as predictor variables for time to RRT or in-hospital mortality. Prematurity and mechanical ventilation were evaluated as predictors of in-hospital mortality.

**Results:** 1673 PUV and 236 PBS patients met inclusion criteria. There was no difference in time to RRT or mortality based on ethnicity, race, or insurance. 212 patients (11.1%) required RRT by 2 years of age. There was no difference in RRT requirement between the PUV and PBS groups. 130 patients (6.8%) died during the initial admission:

<table>
<thead>
<tr>

**Fig. 1 Kaplan-Meier curves of time to spontaneous filter failure (p=0.085)**
98 PUV patients (5.9%) and 32 PBS patients (13.6%), with a median time to death of 6.5 days and 2.5 days, respectively. PBS patients had an increased risk of death (Adjusted Relative Risk (ARR) 2.12, p < .0001). The difference in median time to death was not significant. Of 381 (20%) premature patients, 72 (18.9%) died prior to discharge. 696 patients (36.5%) required mechanical ventilation, and of these, 118 (17%) died. Prematurity and mechanical ventilation were associated with an increased risk of death (ARR 2.3, p < .0001 and ARR 9.9; p < .0001 respectively).

**Conclusions:** The severity of the sequelae associated with PUV and PBS is affirmed by the 11.1% risk of early RRT and 6.8% in-hospital mortality. PBS patients did have an increased mortality rate compared to PUV patients. Prematurity or the requirement of mechanical ventilation was associated with an increased mortality rate. Future large, prospective studies will enable investigation of early morbidity and mortality associated with PUV and PBS, as well as long-term outcomes.

**PO2289**

**Preterm Birth in Mice Results in Differential Gene Expression and Premature Cessation of Nephrogenesis**

**Alesandra Cwieck, Kimberly Deronde, Masako Suzuki, Kimberly J. Reidy, Jennifer R. Charlton, Albert Einstein College of Medicine, Department of Genetics and Development, New York, NY; Children’s Hospital at Montefiore, Department of Pediatrics, Division of Nephrology, New York, NY; University of Virginia, Department of Pediatrics, Division of Nephrology, Charlottesville, VA.**

**Background:** Neonates born preterm are at risk of developing chronic kidney disease (CKD). In humans, nephron development is completed by 36 weeks’ gestation and the successful formation of nephrons is dependent on self-renewing niches of cells which reside directly under the kidney capsule in the nephrogenic zone (NZ). Little is known about the fate of these progenitor cells or the other compartments of the kidney following premature birth. The objective of this study was to characterize the effect of premature birth on kidney development in murine model of prematurity. We hypothesize that preterm mice will have a shorter period of postnatal nephrogenesis and gene expression profiles will reflect premature differentiation.

**Methods:** Timed pregnant CD-1 dams were stratified into 2 cohorts. The preterm group was comprised of 59 pups born by Cesarean section at 18 days post-conception (dpc) and the term group contained 79 pups delivered vaginally at 20 dpc. The mice were euthanized on 20-27 dpc. The presence of the nephrogenic zone was determined on histological sections. Genome-wide expression profiles of 20 dpc mice kidneys were evaluated with RNA-seq in both preterm and term groups (n=3 per group).

**Results:** At 25-27 dpc, kidney to body weight ratios were significantly lower in preterm cohort. In the kidney, the cap mesenchyme was not detectable in the preterm mice a full day (25 dpc) prior to its cessation in the term mice (24 dpc). The expression profiles of 20 dpc kidneys in the preterm group showed distinct alterations compared to the term group. The differentially expressed genes were enriched in a fat-soluble vitamin (including vitamin A and D) metabolic process related pathways.

**Conclusions:** In a mouse model of prematurity, there is an early differential expression of genes that may be important in nephrogenesis. The shortened window of nephrogenesis may result in a lower nephron number and future risk for CKD in neonates born preterm.

**PO2290**

**Gestational Age (GA) Affects Urine Biomarkers by Postnatal Age but Most Converge by 34 Weeks Post-Menstrual Age (PMA)**

**David J. Askenazi, Brian A. Halloran, Robert Schmicker, Patrick J. Heagerty, Sandra Jaul, Stuart Goldstein, Sangeeta R. Hingorani, PENUT Investigators. The University of Alabama at Birmingham School of Medicine, Birmingham, AL; University of Washington, Seattle, WA; Cincinnati Children’s Hospital Medical Center, Cincinnati, OH.**

**Background:** Urine biomarkers may improve our understanding of kidney development and disease in premature neonates. We evaluate how 1-week differences in GA impact 11 biomarkers by postnatal age and PMA.

**Methods:** Neoneates were grouped by GA. Urine was collected on postnatal days 1, 3, 5, 7, 9, 14, 28; on PMA of 30 and 34 weeks; and discharge in 750 neonates without stage 2/3 AKI. Neutrophil-gelatinase associated lipocalin (NGAL), Clusterin, kidney injury molecule 1 (KIM-1), alpha glutathione S-Transferase (a-GST), albumin, beta-2-microglobulin (B2M), cystatin c, epithelial growth factor (EGF), osteopontin (OPN), uromodulin (UMOD), and Creatinine were evaluated by electrochemiluminescence; creatinine by mass spectrometer. Biomarkers are displayed as 7-day rolling mean (day X ± **16** 17) over the first 30 postnatal days. Most biomarkers converge and are not significantly different by 34 weeks PMA.

**Results:** Figure: Left side plot biomarkers by postnatal age; right side plot biomarkers by PMA. When exploring the values by postnatal age, the most premature neonates have higher NGAL, clusterin, KIM-1, a-GST, albumin, B2M, Cystatin C, OPN, and lower EGF, UMOD, and Creatinine (p<0.05; ** in Figure) after adjusting for day. The association of biomarker and time is significantly modified by GA for a-GST, Albumin, B2M, Creatinine and Cystatin C (interaction term p<0.05; ** in Figure) over the first 30 postnatal days. Only B2M and OPN diverge by GA at 34 weeks PMA (p<0.05; *** in Figure).

**Conclusions:** Urine biomarkers differ and are modified by GA during first 30 postnatal days. Most biomarkers converge and are not significantly different by 34 weeks PMA.

PO2291

The Association Between Infantile Pulmonary Hypertension, Sildenafil, and AKI During Hospitalization

Emily E. Zangla, Emily L. Joyce. University Hospitals, Rainbow Babies and Children’s Hospital, Department of Nephrology, Cleveland, OH.

Background: Pulmonary hypertension (pHTN) is a nidus for poor organ perfusion, and is an understudied potential risk factor for acute kidney injury (AKI) in infants. Neither the association between pHTN and AKI, nor treatment with phosphodiesterase-5 inhibitors (i.e. sildenafil) on renal recovery have been elucidated. We sought to describe AKI in a cohort of hospitalized infants with pHTN.

Methods: A retrospective chart review was performed on 18 infants (less than 1 year of age) during the initial hospitalization for diagnosis of pHTN over one year at a single institution. Adapted neonatal KDIGO criteria was utilized to determine presence of AKI during the hospitalization for each patient.

Results: Out of 18 infants with pHTN, 50% developed AKI during hospitalization. Those who developed AKI were older at the age of diagnosis of pHTN (p = 0.04) and more likely to be treated with sildenafil (p = 0.02). Within the cohort, 7 (39%) were treated with sildenafil. On univariate analysis, treatment with sildenafil was associated with increased odds of developing AKI (OR 6.7, 95% CI 0.81-55.0). Of those treated with sildenafil who developed AKI, 80% (4/5) developed AKI before initiation of treatment and 20% (1/5) developed AKI after initiation of treatment.

Conclusions: AKI is prevalent in infants diagnosed with pHTN. The increased odds of developing AKI in patients treated with sildenafil is likely a reflection of severity of illness, as most patients developed AKI prior to initiation of treatment. Further research is needed to evaluate the association between pHTN and AKI, as well as determine the role of sildenafil treatment in preventing AKI or promoting renal recovery.

Baby NINJA (Nephrotoxic Injury Negated by Just-in-Time Action) Transfusion Rates

Halev W. Gavigan, Cara L. Slagle, Kelli A. Kralllman, Brenda Poindexter, David K. Hooper, Stuart Goldstein. Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

Background: Acute kidney injury (AKI) is associated with poor outcomes in neonates. Nephrotoxic medication (NTM) exposure is a common cause of AKI. Nephrotoxic Injury Negated by Just-in-time Action (NINJA) identifies patients with high NTM burden and recommends daily creatinine (Cr) screening. In neonates, concern for iatrogenic anemia decreases AKI screening. We monitored transfusion rates in our project modeled off the neonatal NINJA adaptation, Baby NINJA.

Methods: Critically ill neonates with high NTM exposure initially received modified Cr monitoring (only with routine labs) before transitioning to standard daily Cr monitoring. Patients transfused 3 days into & up to 7 days after Baby NINJA exposure periods counted as an associated transfusion. Statistical process control methods were used to detect changes from baseline. X̄ and Poisson regression analyses were used to compare metrics between SCr monitoring eras.

Results: Figure 1 shows an increase in transfusions 15 weeks before an increase in Cr compliance. A decrease in transfusions was sustained through the standard Cr era where the highest rate of Cr compliance was seen. The rate of NINJA-associated transfusions was unchanged. Table 1 shows that Cr compliance increased during each era, transfusions decreased between modified & standard Cr eras, NINJA-associated transfusions remained stable, and transfusion rate changes were independent of NINJA-associated transfusions.

Conclusions: There was no association between transfusion rates and daily Cr testing with Baby NINJA implementation; therefore, critically ill neonates with high risk NTM exposure can safely be screened for NTM associated AKI.

Children with a Low Birth Weight (LBW) Show Greater Reduction in Kidney Function Than Previously Described Using the Updated Schwartz Equation

Kaye E. Brathwaite,1 Rebecca Levy,1 Harini Sarathy,2 Ilir Agalli,2 Tanya S. Johns,2 Kimberly J. Reidy,3,2 Frederick J. Kaskel,1,2 Michael L. Melamed,1,2 Children’s Hospital of Philadelphia, Philadelphia, PA; 3Montefiore Medical Center, Bronx, NY; 4University of California San Francisco, San Francisco, CA.

**Background:** There is a higher risk of reduced kidney function in adults born with LBW (birthweight<2500g). A study using the Counahan-Barrat (CB) eGFR estimation is shown to model a modest risk increase in adolescents with LBW. However the CB equation is only validated in children with CKD and underestimates the burden of CKD. Utilizing the updated Schwartz equation, a more sensitive calculation of eGFR validated in healthy children, we sought to assess the prevalence of reduced kidney function in adolescents born with LBW.

**Methods:** We performed a cross sectional analysis of children aged 12-15 from the National Health and Nutrition Examination Survey 1999-2016. Reduced kidney function was defined as eGFR <90mL/min/1.73m². Participant characteristics were described as weighted sample means and proportions. We constructed logistic regression models adjusted for important sociodemographic factors to evaluate the association of LBW with reduced kidney function.

**Results:** A total of 6345 individuals were analyzed and proportions, representing 13,760,132 adolescents of whom 8% had a history of LBW. Of those born with LBW, the median age was 13.6 years, 49% were males, 49% were white, 25% were black, 19% were Mexican-American, and 5% were other races. A higher percentage of children with LBW was seen in worse poverty groups. Mean eGFRs in those born LBW were 103 and 107mL/min/1.73m² using the updated Schwartz and CB equation, respectively. The prevalence of reduced kidney function in those born LBW was greater using the updated Schwartz equation compared to the CB equation, 30% vs 21.4%. A higher prevalence of reduced kidney function was found in higher poverty groups. Mean eGFRs in those born LBW were 103 and 107mL/min/1.73m² using the updated Schwartz equation compared to the CB equation, OR 1.51 (95% CI 1.16-1.97) compared to the CB equation, OR 1.44 (95% CI 1.06-1.96). In an adjusted analysis, the odds of reduced kidney function in adolescents with LBW remained significant OR 1.46 (95% CI 1.12-1.97) using Schwartz but not the CB equation.

**Conclusions:** A higher prevalence of reduced kidney function was seen in children born with LBW utilizing updated Schwartz compared to the CB equation. The higher risk was sustained in adjusted analyses. These findings may support development of guidelines for CKD screening during long term follow up in the pediatric population with LBW.

FCGG Renal Biopsy Network: First Epidemiological Report on Pediatric Renal Disease

Noel Koops,1 Johan M. De Meester,1 Amélie Dendooven,2 Wim Laurens,1 Ben Sprangers,3 Elena L. Nevtschenko,1,*AZ Nikolaas, Sint-Niklaas, Belgium; *Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven Campus Gasthuisberg, Leuven, Belgium; Universitair Ziekenhuis Gent, Gent, Belgium.

**Background:** In 2017 and 2018, 92 renal biopsies were performed in pediatric patients (age = 0-17 years) or 3.6 per 100,000 pediatric inhabitants per year. For the first time, reliable estimates of pediatric renal disease spectrum were presented. Its major goal is to describe the findings of a pilot study obtained in the first three schools.

**Methods:** Following informed consent and in compliance with GDPR, data registration consists of basic patient and categorical renal data, semi-structured medical information of renal disease, structured information of renal histopathology, and the clinical renal disease.

**Results:** In 2017 and 2018, 92 renal biopsies were performed in pediatric patients (age = 0-17 years) or 3.6 per 100,000 pediatric inhabitants per year. Three clinical patterns were included: patients with normal renal function, patients with glomerulonephritis and of nephrotic syndrome of childhood. Patients with a Caucasian background (age ≤ 17 years) or 3.6 per 100,000 pediatric inhabitants per year. For the first time, reliable estimates of pediatric renal disease spectrum were presented. Its major goal is to describe the findings of a pilot study obtained in the first three schools.

**Conclusions:** In 2017 and 2018, 92 renal biopsies were performed in pediatric patients (age = 0-17 years) or 3.6 per 100,000 pediatric inhabitants per year. Three clinical patterns were included: patients with normal renal function, patients with glomerulonephritis and of nephrotic syndrome of childhood. Patients with a Caucasian background (age ≤ 17 years) or 3.6 per 100,000 pediatric inhabitants per year. For the first time, reliable estimates of pediatric renal disease spectrum were presented. Its major goal is to describe the findings of a pilot study obtained in the first three schools.

**Factors Related to Significant Albuminuria or Low Glomerular Filtration Rate in Adolescents from a Population with a High Prevalence of CKD of Unknown Origin**

Jose M. Arceola Guerra, Cesar M. Gutierrez, Itzel Ovalle, Mariana J. Macias, Andrea L. Garcia Diaz. Centenario Hospital Miguel Hidalgo, Aguascalientes, Mexico.

**Background:** Chronic kidney disease (CKD) of unknown origin has been recognized as the leading cause of kidney disease in young adults in some underdeveloped countries. In Aguascalientes Mexico we report a high prevalence of treated CKD (1997 ppm), with more than half (54%) of unknown cause. The peak of prevalence is between 20 - 30 years (45%), biniing in that group 73% CKD of unknown origin. For this reason, a CKD screening study was designed in high school students in the state. The aim of this report is to describe the findings of a pilot study obtained in the first three schools.

**Methods:** Cross-sectional study of high school students. Determination of albumin/creatinine ratio was performed in isolated urine sample and standardized serum creatinine to calculate eGFR with Schwartz formula, an abnormal albumin/creatinine ratio >30 mg/g and GFR<75 mL/min were defined as CKD. Students and parents were questioned about potentially risk factors. For the multivariate analysis, only students with complete questioning were included.

**Results:** During March 2020, three high schools in the municipality of Calivello (Aguascalientes) were visited, accepting entry to the study 187 students out of 260 (72%). The average age was 13.3 years (IQR 12-14) with a predominance of males (n = 109, 58.2%). 33 students with pb CKD were detected (17.6%), 32 of which were due to the presence of normal albumin/creatinine ratio. Only two patients had low GFR, one with 43 mL/min and the other with 75 mL/min. Four patients presented macro albuminuria, the rest microalbuminuria. In the multivariate analysis, next variables remainad significant: economic income less than 4,000 Mx$, (OR 4.4, 95% CI, 1.3 - 14.7), frequent NSAID intake (OR 3.8 95% CI 1.16 - 13, p= 0.02), a greater association of LBW and reduced kidney function OR 1.51 (95% CI 1.16-1.97) using Schwartz and CB equation, respectively. The prevalence of reduced kidney function of unknown cause has been recognized as the leading cause of kidney disease in young adults in some underdeveloped countries. In Aguascalientes Mexico we report a high prevalence of treated CKD (1997 ppm), with more than half (54%) of unknown cause. The peak of prevalence is between 20 - 30 years (45%), biniing in that group 73% CKD of unknown origin. For this reason, a CKD screening study was designed in high school students in the state. The aim of this report is to describe the findings of a pilot study obtained in the first three schools.

Measurement of GFR and Vasoactive Substances in Children with Sickle Cell Anemia
Oluwadamilola Ejike,1 George J. Schwartz,2 Susan Logan,3 Amy M. Becker,4 Raymond P. Quigley,1 Baylor Medical Center, San Antonio, TX; 2University of Rochester Medical Center, Rochester, NY; 3University of Rochester Medical Center, Rochester, NY; 4University of Texas Southwestern Medical Center at Dallas, Dallas, TX; 5Dresslcar Children’s Hospital, Corpus Christi, TX.

Background: Patients with sickle cell anemia (SCA) have a high risk of developing renal disease. Sickle cell nephropathy is thought to begin in childhood with higher than normal glomerular filtration rates (GFRs) known as hyperfiltration that can lead to proteinuria, sclerosis of the glomeruli, decreased GFR, and eventual renal failure. This model of sickle cell nephropathy has not been validated in clinical studies. This study measured directly the GFRs of patients with sickle cell anemia and age matched control patients. In addition, urinary vasoactive substances were measured to correlate with the GFR.

Methods: Children with sickle cell anemia (SCA) and sickle-β0-thalassemia (HBSS0) were recruited for the study from the Sickle Cell Clinic at Children’s Medical Center of Dallas. These sickle cell disease genotypes are phenotypically similar and are the most severe. Healthy siblings of children seen in the Pediatric Nephrology Clinic at Children’s Medical Center of Dallas were recruited to serve as controls. GFR was measured directly from isohem clearance. Urine was obtained to measure vasoactive substances.

Results: A total of 14 families were enrolled. 12 of 14 (86%) of children with SCA were in the SCA group and 93% of children with normal GFR. The intrenal angiotensinogen system appears to play a role in this hyperfiltration. Further studies are needed to continue to understand this phenomenon.

Urine Angiotensinogen / urine creatinine

HbSS urine angiotensinogen/creatinine was significantly lower than control (p=0.005).

PO2299

Food Insecurity During COVID-19 in Children with ESKD: The Second Wave?
Melvin Chan, Amy C. Wilson, Neha D. Pottanat, Michelle C. Starr. Indiana University School of Medicine, Indianapolis, IN.

Background: Food insecurity (FI) affects 1 in 6 children in the US and has increased three-fold during the COVID pandemic. Children with end-stage kidney disease (ESKD) may be at even higher risk of FI due to complex care needs, medication burden and dietary restrictions. A pre-COVID study assessing FI in pediatric hemodialysis (HD) patients described 70% prevalence. No data exists describing the effects of the COVID pandemic restrictions. A pre-COVID study assessing FI in pediatric hemodialysis (HD) patients (pts) to support preference of either agent.

Methods: In conclusion, we have shown that although the GFR in patients with SCA might not be elevated, there appears to be a population of SCA patients with higher than normal GFR. The intrenal renin-angiotensin system appears to play a role in this hyperfiltration. Further studies are needed to continue to understand this phenomenon.

FP301

Incidence of Hypercalcemia with Calcitriol Compared with Paricalcitol in Pediatric Patients Receiving Hemodialysis
Rohan Dwivedi, Jennifer L. Morris, Jessica Geer, Poyyapkakam Srivaths, Sarah J. Swartz. Texas Children’s Hospital, Houston, TX.

Background: At our institution, both calcitriol and paricalcitol are available for use. Paricalcitol is generally used when adverse effects of calcitriol are observed or during times of calcitriol shortage. There are limited data on the efficacy and safety of vitamin D analogs in pediatric (ped) hemodialysis (HD) patients (pts) to support preference of either agent. This study evaluated the incidence of hypercalcemia in ped HD pts receiving calcitriol compared to paricalcitol.

Methods: Single-center, retrospective review of ped pts on HD treated between January 2012 – December 2018 who received in-center doses of calcitriol or paricalcitol. Pts were excluded if they received in-center doses of both paricalcitol and calcitriol or if they had an active prescription for oral calcitriol for home. Data were collected for 6-months from the date of the first in-center calcitriol or paricalcitol dose. The primary objective was to evaluate the incidence of hypercalcemia in those receiving calcitriol compared to paricalcitol. Secondary objectives included the incidence of hyperphosphatemia, high calcium-phosphorus product, and hyperparathyroidism (IPTH). Data were evaluated using descriptive statistics, Mann-Whitney-U and Fisher’s Exact test.

Results: 34 pts met the criteria for the study (calcitriol group=15, paricalcitol group=19).

The groups had no statistically significant differences at baseline. Patients in the paricalcitol group received an average weekly dose of 14 ± 7 mcg, equivalent to 4.67 ± 2.33 mcg of calcitriol compared to 2.36 ± 1.51 mcg in the calcitriol group (p=0.002). There were no differences between the time averaged serum calcium, phosphorous, calcium-phosphorus product, and IPTH between the two groups. Between the paricalcitol and calcitriol groups the incidence of hypercalcemia events per patient (EPP) was 2.6 and 2.67 (p=0.20) and high IPTH EPP was 2.63 and 2.2 (p=0.38).

Conclusions: The incidence of hypercalcemia in patients receiving paricalcitol compared to calcitriol was high but did not reach statistical significance. There is no clear advantage seen with the use of paricalcitol when compared to the calcitriol group in ped population.

PO2301

Associations Between Short Stature, Emotional-Behavioral Functioning, and Adaptive Skills in Children with CKD
Rebecca J. Johnson, Lyndsay Harshman,1 Matthew Matheson,2 Arlene C. Gerson,1 Bradley A. Wurady,1 Susan L. Furth,1 Stephen R. Hooper,1 Children’s Mercy Kansas City, Kansas City, MO; 2The University of Iowa Stead Family Children’s Hospital, Iowa City, IA; 3Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; 4Johns Hopkins Medical Institute, Baltimore, MD; 5The Children’s Hospital of Philadelphia, Philadelphia, PA; 6University of North Carolina School of Medicine, Chapel Hill, NC.

Background: Short stature impacts quality of life (QOL) for children with chronic kidney disease (CKD). Little is known about how short stature impacts emotional-behavioral functioning and adaptive skills in this group of children.

Methods: Baseline and longitudinal data from the Chronic Kidney Disease in Children study were used to evaluate associations between emotional-behavioral functioning, adaptive skills, and short stature (height z score <−2) in children with mild to moderate CKD ages 10+ years. Linear mixed models were used to determine if short stature predicted emotional-behavioral outcomes, using data from both the parent- and self-report BASC2 rating scales. Models were adjusted for sociodemographic and disease-related covariates.

Results: Baseline parent-report data were available for 737 participants (61% male; median age 13 [IQR=11-16]; 32% glomerular CKD; median eGFR 52 ml/min/1.73m2 [IQR=39-66]; 10% short stature; 8% growth hormone use). BASC2 self-report was available for 229 participants. For BASC2 parent-report, short stature was not associated with the summary scales of internalizing symptoms (e.g., anxiety, sad mood), p=1.46.
**PO2302**

Urine Biomarkers of CKD Progression in Children

Jason H. Greenberg,1 Alison G. Abraham,2 Yunwen Xu,3 Jeffrey R. Schelling,3 Harold I. Feldman,4 Venkata Sabbisetti,5 Joachim H. Ix,6 Bradley A. Warady,4 Paul L. Kimmel,3 Joseph V. Bonventre,7 Michelle Denburg,1 Chirag R. Parikh,3 Susan L. Furth,3 CKD Biomarker Consortium 1Yale University School of Medicine, New Haven, CT; 2Johns Hopkins University, Baltimore, MD; 3Case Western Reserve University, Cleveland, OH; 4University of Pennsylvania, Philadelphia, PA; 5Children’s Mercy Hospitals and Clinics, Kansas City, MO; 6National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; 7Emmani Kennedy Shriver National Institute of Child Health and Human Development, and the National Heart, Lung, and Blood Institute

**Background:** Biomarkers of tubular injury, repair, and inflammation may improve the ability to identify children at high risk of rapid kidney function decline and help elucidate the pathophysiology of CKD progression. In this study, we investigated whether the urinary biomarkers EGF, KIM1, MCP1, YKL-40, and alphal microglobulin are prognostic of CKD progression in children.

**Methods:** In the prospective CKiD study, children aged 6 months to 16 years old with an eGFR of 30-90 were enrolled and eGFR was assessed annually. We measured urine biomarkers collected 5 months after study enrollment. Urine biomarkers were indexed to an eGFR of 30-90 and alpha microglobulin are prognostic of CKD progression in children.

**Results:** Of the 375 children included, median age was 12 years [IQR, 8-15], 227 (61%) were male, and baseline eGFR was 44 [IQR, 35-56]. Overall, 187 children (50%) reached the primary outcome over a median follow-up time of 6.2 years [IQR, 3.0–10.3]. All biomarker levels were higher in children with CKD progression, except for EGF which was lower in those with CKD progression (p for all <0.05). After adjustment for confounders, children with urine EGF concentrations in the highest quartile were at a significantly lower risk of CKD progression compared to those with EGF in the lowest quartile [EGF aHR; 0.51 (95% CI: 0.31, 0.85); p=0.01]. There was a marginal, but nonsignificant, association with the depression subscale (β=−1.33, CI=−0.99, 3.54; p=0.8). Similar findings were obtained for the other subscales and summary scores of the BASC2 self-report ratings.

**Conclusion:** For most measures of emotional-behavioral functioning and adaptive skills, short stature was not associated with an increase in parent- or self-reported internalizing or externalizing symptoms or adaptive skills. Short stature was associated with parent-reported, but not self-reported, somatization. The present findings offer some reassurance that while short stature may be related to poorer QOL and somatization, preliminary findings suggest that it is not associated with more significant psychopathology or concerns regarding adaptive skills.

**Funding:** This work was supported by the National Heart, Lung, and Blood Institute.

**PO2303**

Effect of Cholecalciferol Supplementation on FGF-23 in Children with CKD

Stephanie M. Chu, Meredith A. Atkinson. Johns Hopkins University, Baltimore, MD.

**Background:** Cholecalciferol increases total vitamin D levels in children with chronic kidney disease (CKD), but by increasing serum phosphate levels may also increase levels of fibroblast growth factor 23 (FGF23), which is associated with adverse outcomes in both adults and children with CKD. Our objective was to quantify changes in FGF23, α-klotho and vitamin D binding protein (VDBP) in children participating in a vitamin D supplementation trial.

**Methods:** We utilized stored serum samples from a 4-week pilot randomized controlled trial of supplementation with 4000 (high dose) vs. 400 (DRI) IU per day of cholecalciferol in children with mild-to-moderate CKD. Intact and C-terminal FGF23, soluble α-klotho, and VDBP were measured using commercially-available ELISAs in the Johns Hopkins Institute for Clinical and Translational Research Core Laboratory. Statistical analyses conducted using Stata 14.

**Results:** Thirty-four children were included in the analysis; 17 received the intervention dose of 4000 IU/day of cholecalciferol, and 17 received the control dose of 400 IU/day of cholecalciferol. The mean (SD) age of the cohort was 10.9 (5.8) years, 26.5% female, 23.5% black, 58.8% white, and 17.7% other race. Mean (SD) GFR at baseline was 60 (17.6) ml/min/1.73m2. Median (IQR) baseline total vitamin D level was 29 (20, 34) ng/ml in the control arm and 32 (23, 39) ng/ml in the intervention arm. Total vitamin D level did not change significantly after 4 weeks of supplementation in the control arm, but was increased to 38.5 (31, 50) in the intervention arm (p<0.001). The table compares baseline and 4-week FGF23, α-klotho, and VDBP levels in the control and intervention arms, and no significant differences were noted between the groups who received DRI vs. high dose cholecalciferol.

**Conclusions:** Cholecalciferol supplementation of 4000 IU/day in children with CKD was not associated with significant differences in FGF23, α-klotho, or VDBP levels compared to children who received only the DRI.

Improving Metabolic Acidosis in Patients with CKD

**Background:** Pediatric chronic kidney disease (CKD) is characterized by multiple metabolic derangements including metabolic acidosis. Untreated acidosis is associated with bone disease, increased mortality, and CKD progression1-3. Current guidelines

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Recommend bicarbonate supplementation for CKD patients with serum bicarbonate < 22mEq/L. Review of our nephrology division’s clinical practice in the past year found that 36% of patients with CKD stage 3-5 were acidic, although only 25% of these received an intervention to address the acidosis. Our aim is to increase the percentage of interventions for acidosis in this population from 25% to 50% by June 30, 2020.

Methods: Monthly alerts were generated for patients with CKD stage 3-5 and acidosis in the nephrology clinic. Our outcome measure is the percentage of acidic patients. Process measures include the percentage of acidosis recognition, appropriate intervention, and patients on bicarbonate treatment. The balancing measure is patients with alkalosis (bicarbonate > 28mEq/L) while on supplementation. A multidisciplinary team identified multiple root causes and baseline data identified that lack of provider recognition of mild acidosis (bicarbonate 20-22) was the primary driver why treatment was not initiated. Countermeasures were developed to address this gap.

Results: Using PDSA cycles, we have implemented 2 countermeasures. Initially, we utilized provider directed feedback to notify those who had patients with untreated acidosis in the past month. Then, an education session was completed in March 2020. Our goal of increasing interventions for acidosis to 50% was exceeded by March 2020 (75%). There was also an increase in the number of acidic patients, increase in provider recognition and bicarbonate treatment, with no increase in patients with alkalosis (Figure 1).

Conclusions: Utilizing provider directed feedback along with educational sessions have effectively increased the percentage of CKD stage 3-5 patients who are appropriately treated for acidosis. Further interventions are ongoing.

PO2305
Factors Influencing Duration of Dialysis in Children with Shiga Toxin-Producing Escherichia coli-Associated Hemolytic Uremic Syndrome (STEC-HUS) at a Single Center
Mydha Khalid, Neha D. Potatnatt, Chloe Miller, Sharon P. Andreoli. Indiana University School of Medicine, Indianapolis, IN.

Background: More than half the children with STEC-HUS require renal replacement therapy. Several factors influence the duration of dialysis.

Methods: We performed a retrospective cohort analysis using electronic medical records and chart review of 67 patients with STEC-HUS identified through billing data from July 1st 2008 to August 30th 2015. Cases of atypical hemolytic uremic syndrome (HUS), Streptococcus pneumoniae associated HUS were excluded.

Results: The mean age at presentation with STEC-HUS was 4.9 years (range 0.99-17.16yrs). 44 (66%) were females compared to 23 (34%) males. Data on intravenous fluids (IVF) administration prior to diagnosis of HUS was available in 54 subjects of which 39 (72%) received IVF anytime during four days prior to presentation, and 15 (28%) did not. Of the patients receiving IVF, 22 (56%) required dialysis for an average duration of 11.4 days whereas in subjects without IVF, the average dialysis duration was 14.7 days. In subjects without NVAF exposure, we also evaluated patients on antibiotic exposure before and after the diagnosis of HUS. In 30 (53%) subjects without any antibiotic exposure the average duration on dialysis was 9.8 days. For 11 (19%) subjects receiving antibiotics before the diagnosis of HUS average duration of dialysis was 13.6 days.

Conclusions: To our knowledge our study is first to evaluate the impact of NSAIDs on the severity of HUS, and demonstrates that the use of NSAIDS in STEC-HUS increases the duration of dialysis significantly. Confirming previous literature, the use of antibiotics results in prolongation of dialysis regardless of the timing of administration. We also note that IVF administration in the first 4 days prior to the diagnosis of HUS may result in a shorter time on dialysis.

PO2306
Determining the Optimal Dose of Cholecalciferol Supplementation for Children with CKD (C, Trial): An Open-Label Multicentre Randomized Controlled Trial
Arpana A. Iyengar,1 Nivedita Kamath,1 Hansa V.; Susan Uthup;2 Jyoti Sharma,3 Jyoti S. Singhal,5 Sudha Ekambaram,3 Mandy Wan,4 Rukshana Shroff;3 St John’s Medical College Hospital, Bangalore, India; 5Great Ormond Hospital for Children, London, United Kingdom.

Background: The optimal treatment regimen for correcting 25-hydroxyvitamin D (25OHD) deficiency in children with CKD has not been established. We studied oral cholecalciferol treatment regimens that achieve and maintain 25OHD levels above 30ng/ml in children with CKD stages 2-4.

Methods: We performed an open label, multicentre randomized controlled trial in children with 25OHD <30ng/ml, randomized 1:1:1 to oral cholecalciferol as 3000IU daily, 25,000IU weekly or 100,000IU monthly for 3months intensive phase therapy. A maximum of 3 courses of intensive phase treatment were allowed if 25OHD was <30ng/ml. Patients achieving normal 25OHD entered maintenance phase with 1000 IU cholecalciferol daily for 9 months. Primary outcome was achieving 25OHD levels ≥30 ng/ml at end of intensive phase therapy.

Results: Of the 150 children screened, 90 were 25OHD deficient and randomised to daily=30), weekly(n=29) or monthly(n=31) treatment arms. Age, gender, renal disease, eGFR and baseline 25OHD were comparable between treatment arms. At end of the intensive phase 68.8% achieved 25OHD ≥30ng/ml with comparable levels between arms(mean 44.3 39.4 and 39.3 ng/ml p=0.24) on daily, weekly, monthly regimens respectively. The time taken to achieve 25OHD ≥30 ng/ml was comparable between treatment arms (p=0.28) with 7.7% not achieving normal 25OHD after 3 courses. Irrespective of treatment arm, median 25OHD were lower in children with glomerular disease than non-glomerular disease [25.8 ± 41.8ng/ml; p<0.007]. There was no significant difference in 25OHD between treatment arms at end of intensive phase (p=0.24) or maintenance phase therapy (p=0.05)[Figure]. There was no hypercalcaemia or hypercalciuria.

Conclusions: Intensive phase therapy with oral cholecalciferol as daily, weekly or monthly regimens achieved similar 25OHD levels without toxicity. Children with glomerular disease require higher doses of cholecalciferol compared to non-glomerular disease.

PO2307
ESRD Risk in Type 1 vs. Type 2 Childhood-Onset Diabetes Mellitus
Oren Pleneau,3,1 Gilad Twig,4 Tomer Erlich,2 Lilat Keinan Boker,4 Karl Skorecki,1 Ronit Calderon-margarit,1 Asaf Vivante,2 Pediatric Stem Cell Research Institute, Sheba Medical Center, Tel Hashomer, Ramat Gan, Israel; 2Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, Israel; 3Rambam Health Care Campus, Haifa, Israel; 4Israel Defense Forces, Tel Aviv, Israel; 5University of Haifa School of Public Health, Haifa, Israel; 6Hebrew University of Jerusalem; Braun School of Public Health and Community Medicine, Jerusalem, Israel.

Background: Diabetic kidney disease (DKD) is becoming increasingly common among children. We aimed to estimate the risk of end-stage renal disease (ESRD) and mortality among adolescents with type 1 diabetes mellitus (T1DM) or type 2 diabetes mellitus (T2DM) and normal renal function compared to non-diabetics. We hypothesized that childhood onset T1DM vs T2DM would be associated with a different risk profile for developing ESRD and its complications.

Methods: A nationwide, population-based, retrospective cohort study, including 1,500,522 adolescents examined for military service between 1967-1997, which were classified according to the presence and type of diabetes. Data were linked to the Israeli ESRD registry. Cox proportional-hazards models were used to estimate the hazard ratio (HR) for ESRD.

Results: At study enrolment, 1,183 adolescents had T1DM and 196 had T2DM. ESRD developed in 2,386 non-diabetic individuals (0.2%) compared to 72 individuals (6.6%) with T1DM, and 8 individuals (4.1%) with T2DM. Participants with T1DM were younger at ESRD onset than participants with T2DM (median age: 36.0 vs. 40.5 years, P<0.05). In a multivariate model adjusted for age, sex, paternal origin, enrollment year, BMI, and blood pressure, T1DM and T2DM were associated with HR of 36.4 (95% CI,
PO2309
Clinical Relevance of Fluid Volume Status Assessment by Bioimpedance Spectroscopy in Children on Maintenance Dialysis
Jesu Min,1 Peong Gang Park,1 Ji hyun Kim,2 Yo Han Ahn,2 IL-Soo Ha,2 Hee Gyung Kang,1,2 Seoul National University Children's Hospital, Seoul, Republic of Korea; 1Seoul National University College of Medicine, Seoul, Republic of Korea; 2Seoul National University Bundang Hospital, Seongnam, Republic of Korea.

Background: Bioimpedance spectroscopy (BIS) has been used as a noninvasive method to evaluate body fluid volume status in dialysis patients. However, reports in pediatric dialysis patients about the effectiveness of this method are rare. We asked if there is a correlation in the results of BIS and clinical characteristics, and if there is a subsequent change of cardiovascular characteristics in patients whose dialysis prescription was modified based on BIS.

Methods: Medical records of children on maintenance dialysis who were evaluated by multifrequency BIS between January 2016 and December 2019 were reviewed. Their first result of BIS was assessed and fluid overload status was correlated with hypertension, number of oral antihypertensive medications and echocardiography results. In patients with fluid overload, change of dialysis prescription and clinical characteristics over time were reviewed.

Results: Among the 47 patients (male:female 28:19, hemodialysis/peritoneal dialysis 17:30) with a median age of 13.5 years, 13 children were overhydrated with the proportional overhydration relative to extracellular water more than 15%. Majority of children (76.9%) with fluid overload were taking two or more oral antihypertensive medications, while less than half of those without fluid overload were. 11 out of 13 overhydrated children changed their dialysis prescription to reduce their target body weights. Subsequent BIS in overhydrated children revealed a significantly decreased amount of fluid overload (initial: median 22.9%, follow-up: median 13.4%). However, their mean blood pressure (initial: 89.8 mmHg, follow-up: 84 mmHg) and the number of antihypertensive medications (initial: median 2 (0-4), follow-up: median 2 (0-3)) did not significantly change. Also, none of the children initially overhydrated had their left ventricle hypertrophy changed.

Conclusions: While BIS might be a useful and noninvasive method to assess fluid status, implementation of this tool did not lead to clinically meaningful improvement of cardiovascular characteristics in the children on maintenance dialysis. Long-term follow-up of a larger population and correlation with a more objective clinical indicator of fluid overload such as serum brain natriuretic peptide would be necessary to verify the clinical effectiveness of BIS in pediatric dialysis patients.

PO2310
Variants of SLC34A1, SLC34A3, and AGXT in an Infant with Nephrocalcinosis and Hypercalcemia
Marijah L. Wright, John D. Mahan, Tahagod Mohamed.
Nationwide Children’s Hospital, Columbus, OH.

Introduction: Idiopathic infantile hypercalcemia (IIH) is a rare genetic disorder that can lead to neonatal nephrocalcinosis. It is typically caused by loss of function mutations in CYP24A1 or less commonly in SLC34A1. SLC34A1 encodes the NaPi-IIa transporter which aids in phosphate reabsorption in the renal proximal tubules. Defects in AGXT are responsible for primary hyperoxaluria type 1 (PH1). Defects in either AGXT or SLC34A1 can lead to infantile nephrocalcinosis and subsequent renal damage.

Case Description: A term male infant had bilateral hyperchoeic kidneys on prenatal ultrasound. Postnatal labs showed hypercalcemia, hypophosphatemia, high 1,25 dihydroxyvitamin D3 and acute kidney injury. The patient was treated with fluids, furosemide, and calcitonin without significant change in serum calcium. Pamidronate was given which decreased serum calcium and worsened hypophosphatemia. Phosphate supplementation was initiated. Whole exome sequencing revealed two variants in SLC34A1, one of which was pathogenic, and a variant in SLC34A3 of unknown significance. Incidentally, this patient was compound heterozygous for three variants in AGXT: one pathogenic and two benign. After these results, patient was found to have generalized aminoaciduria and mild hyperoxaluria for age. Serum calcium decreased with maintenance of adequate plasma phosphate levels.

Discussion: Compound heterozygous mutations of SLC34A1 can cause IIH type II, and the variant in SLC34A3 could be contributing to this patient’s clinical phenotype in a unique triallelic pattern. The pathologic AGXT gene variants could cause this patient to develop PH1. The combined effects of IIH and PH1 could significantly impact the clinical course of this patient. Mutations in both AGXT and SLC34A1 have not been previously described in the literature. During acute severe hypercalcemia, it might be necessary to use pamidronate to lower serum calcium to levels that are safe for the administration of phosphate supplements.
PO2311
Dent Disease Phenotype Caused by Immunodysregulation Polycystin-1 Mutations
Raja Dandamudi, Keith A. Hruska. Washington University in Saint Louis School of Medicine, Saint Louis, MO.

Introduction: Immunodysregulation, polycystinopathy, enteropathy, X-linked (IPEX) recessive disorder caused by loss-of-function mutations forkhed box protein 3 gene (FOXH3) transcription factor affecting the function of circulating regulatory T cells. Previously described renal manifestations were immune complex deposition in a membranous- pattern and interstitial nephritis. Here we report novel renal manifestations of IPEX syndrome.

Case Description: 5-year-old male presented at the end of the first month of life, with type 1 diabetes mellitus, hypothyroidism, and chronic diarrhea and diagnosed by IPEX syndrome by c.434C>T; p. Ala 145Val mutations in the FOXJ3 gene. He underwent stem cell transplant at 6 months of age from a fully matched unrelated donor. Post stem cell transplant he had raised chimerism with low but relatively stable donor T cells. He remained relatively stable until 4 years of age when he presented with the clinical picture of Dent’s disease: nephrocalcinosis, tubular proteinuria, Fanconi syndrome (proximal RTA, phosphaturia, calciumuria, glycosuria and aminoaciduria) and renal insufficiency. No disease-causing mutations in CLCN5 gene or the OCRL1 gene were identified on genetic testing. Renal biopsy demonstrated non-sclerotic glomeruli with no capillary loop spike formation, no crescent formation, no endocapillary proliferation, or segmental necrosis. Immunofluorescence showed tubular basement membranes stain with IgG, C3, kappa and lambda. Glomerular basement membranes were negative. Tubular basement membranes show extensive small electron dense deposits without substructure.

Discussion: In this case report we presented child with confirmed IPEX syndrome with nephritic-range tubular proteinuria, proximal RTA, phosphaturia, calciumuria, medullary nephrocalcinosis, and renal insufficiency, in addition to the classical triad of enteropathy, dermatitis and polycystinopathy. Our report is the first to document the anti-tubular basement disease clinically manifesting as the Dent’s disease phenotype in association with IPEX syndrome.

PO2312
Severe Hyperkalemia in a 4-Month-Old Female due to Cullin-3 Mutation
Grace C. Yu,1 Faris Q. Hashim,2 Christian Hanna.1 Mayo Clinic Minnesota, Rochester, MN; 1Baylor Scott and White Central Texas, Temple, TX.

Introduction: Pseudohypoparathyroidism (PHA) type II, also known as familial hyperparathyroidism, is a rare autosomal-dominant disorder that causes renal tubular acidosis (RTA) type 4, characterized by late-onset hyperparathyroidism, hyperkalemia, non-gast metabolic acidosis, and low or low-normal plasma renin and aldosterone levels. We present a case of a female infant with PHA type II who presented with asymptomatic severe hyperkalemia due to Cullin-3 Mutation. Treatment with thiazide diuretics resulted in rapid correction of her hyperkalemia.

Case Description: A 4-month-old female infant with an unremarkable past medical history presented for management of right neck abscess. Family history was significant for an unspecified seizure and movement disorder in her older sister. She had appropriate growth for her age, with weight, length, and head circumference all measuring around the 20th percentile. Vital signs including blood pressure were normal. Admission laboratories revealed high potassium level of 8.4 mEq/L, low bicarbonate level of 16 mEq/L (normal for age is 19–24), high chloride level of 116 mEq/L (normal for age is 97–108). Anion gap was normal at 10 mEq/L. No electrocardiogram changes were noted. Additional studies revealed positive urine anion gap of 40 mEq/L, a normal serum aldosterone level of 22 ng/dL and a low renin activity of 0.2 ng/mL/hr (normal for age is 2–27). She received intravenous calcium gluconate, sodium acetate, and polyethylene sulfonate for hyperkalemia management. Whole exome sequencing revealed a de novo heterozygous c.1376A>T (p.K459M) mutation in the Cullin 3 (CUL3) gene consistent with PHA type II. She was treated with thiazide diuretics, which quickly corrected her metabolic abnormalities.

Discussion: Our case of PHA type II with a CUL3 pathogenic variant is exceptionally rare, especially given the patient’s age at presentation and the negative family history. Her diagnosis could have been easily missed were she not hospitalized for her neck abscess. Without genetic evaluation and prompt initiation of thiazide diuretic treatment, she may have eventually suffered from failure to thrive and hypertension at a later point in life because of chronic hyperkalemia and metabolic acidosis. Primary care physicians and nephrologists should consider the possibility of PHA type II in any child who presents with hyperkalemia and metabolic acidosis with or without hypertension.

PO2313
A Rare Pediatric Case of Karyomegalic Tubulointerstitial Nephritis
Carlos C. Berceril romero.1,2 Sasha R. Kapil.1,2 April Rahrig.1,2 Carrie L. Phillips.1,2 David S. Hains.1,2 Jodi L. Skiles.1,2 Sushil Gupta.1,2,1 Indiana University School of Medicine, Indianapolis, IN; 1Indiana University Health, Indianapolis, IN.

Introduction: Karyomegalic tubulointerstitial nephritis (KIN) is a rare type of interstitial nephritis that often progresses to chronic kidney disease. The pathogenesis is unclear but speculated to result from disruptions to tubular epithelial cell division by genetic predisposition or external insults. Only 6 pediatric cases have been reported and perhaps this condition is underdiagnosed.

Case Description: A 2-year-old male with history of refractory AML received a matched unrelated donor stem-cell transplant following busulfan, fludarabine, and single fraction total body irradiation. His post-transplant course was complicated by engraftment syndrome, hyperacute graft versus host disease (GVHD), thrombotic microangiopathy, and acute kidney injury. He required ICU stay, treatment with eculizumab and two weeks of renal replacement therapy. His kidney function improved but serum creatinine stayed higher than baseline (picture). Four months post-transplant, he was treated with cefepime, acyclovir, ibuprofen for enterococcus bacteremia and pericardial effusion. Seven months post-transplant, while off all immunosuppression, he developed eosinophilia, renal tubular dysfunction with increased serum creatinine. Eosinophilia resolved spontaneously. Bone marrow was negative for leukemia and infectious workup was negative. Eight months post-transplant, he developed GVHD, diagnosed with skin biopsy. He also had persistent high serum creatinine with normal urinalysis. Ultrasound showed echogenic kidneys. Kidney biopsy was performed because of unexplained high serum creatinine. Specimen tissue showed tubulointerstitial nephritis with widespread karyomegaly in medullary tubules. Glomeruli were unaffected. Some cortical tubules showed ultrastructural myelinosomes. His renal function improved with steroids.

Discussion: Our case highlights that KIN can develop in children after chemotherapy. Diagnosis requires high index of suspicion and thorough pathological examination of kidney biopsy specimen. A trial of corticosteroid therapy may be considered.

PO2314
Rescue Therapy with Eculizumab for Catastrophic Antiphospholipid Syndrome in Juvenile Systemic Lupus Erythematosus
Patricia A. Arrovo Parejo Drayer, Malek Al Barabi, Marissa J. Defreitas,1,2 Elyse P. Katsoulis, Jayanthi Chandramani,1 Corlyn L. Abitbol, Wacharee Secherunvong. University of Miami School of Medicine, Miami, FL.

Introduction: Catastrophic antiphospholipid syndrome (CAPS) is a life-threatening condition, and is associated with acute multiorgan failure, small vessels thromboembolism, and elevated markers of antiphospholipid syndrome (APS). Early recognition and prompt treatment can improve the outcome. We present a case of juvenile systemic lupus erythematosus (SLE), who presented with CAPS, refractory to conventional treatment, but rescue with Eculizumab.

Case Description: The patient is a 10y female, previously diagnosis with systemic lupus erythematosus (SLE) without renal involvement and treated with hydroxychloroquine and low dose steroid, who presented with acute kidney injury and hypertensive crisis. On exam, her weight was 31.3 Kg, height 133 cm. Her BP was 185/127 mmHg and pulse 118/ min. Initial investigation showed hemoglobin of 7.2 g/dl, platelet count of 182/12l, BUN 99 mg/dL, Cr 7.86 mg/dL, haptoglobin < 10 mg/dL. Urine protein to creatinine ratio was 5 mg/mg. Serum complements were low and had positive serology for Anti-DSDNA, Lupus anticoagulant, Anti-beta2 glycoprotein, and anticardiolipin. The presumptive diagnosis was CAPS associated with SLE and thrombotic microangiopathy (TMA) which was confirmed by kidney biopsy. She underwent Methylprednisone, therapeutic plasma exchange (TPE), renal replacement therapy and Nicardipine infusion. After 7 sessions of TPE, Methylprednisone, Rituximab, and Mycophenolate Mofetil, her renal function improved and was taken off hemodialysis. Blood pressure was still uncontrolled. She had evidence of on-going hemolysis with undetectable haptoglobin and elevated LDH. Repeat TPE did not control her BP or hemolysis, thus Eculizumab was administered as rescue treatment.
a rescue therapy for TMA associated with CAPS. After 2 weekly doses Eculizumab, her renal function, blood pressure and hemolytic markers were much improved. Currently, her serum creatinine was 1 mg/dL, without significant proteinuria. She remained on 3 antihypertensive medications with good BP control

Discussion: This is a rare but challenging case of juvenile SLE, complicated with CAPS and TMA, who responded partially to conventional treatment. Eculizumab served as a rescue therapy with good result. Our case supports the use of Eculizumab for refractory CAPS in SLE.

PO2315
Hypertensive Crisis in an Infant: The Mass Effect
Jonathan S. Chawla,1 David Manning,2 Isa Ashoor,1,2 ‘Louisiana State University Health Sciences Center, New Orleans, LA; ‘Children’s Hospital New Orleans, New Orleans, LA.

Introduction: It is unusual for congenital hydronephrosis to present with a hypertensive crisis. Recognition of this etiology and prompt urologic intervention to relieve the acute mass effect is critical to prevent further morbidity and mortality.

Case Description: A 3 month-old male with known, mild, right-sided hydronephrosis secondary to ureteropelvic junction obstruction (UPJO) presented to the ED with one week of poor feeding, emesis, and abdominal distension. His recent urine output had been normal. Right upper extremity blood pressure (BP) was recorded as 140/79 mmHg in the ED. Labs were unremarkable with a normal urinalysis and serum creatinine of 0.3 mg/dL. Abdominal ultrasound revealed massive pelvocaliectasis of the right kidney with the kidney parenchyma stretched and thinned over the massively dilated central collecting system. Findings were confirmed on abdominal CT which also revealed profound mass effect on abdominal organs and vessels, specifically compressing and displacing the aorta and inferior vena cava. He was admitted to the pediatric ICU for BP management, which was controlled with IV hydralazine. Pediatric urology placed a percutaneous nephrostomy tube and drained over one liter of urine from the right collecting system. At discharge, the patient was normotensive off medications. A right pyeloplasty was completed shortly following discharge.

Discussion: UPJO is the most common cause of antenatally detected hydronephrosis. The renal pelvis of infants exhibits increased compliance and can accommodate large urine volumes. Kidney function may be preserved or could undergo deterioration depending on UPJO severity. If missed prenatally, infants with UPJO may present with a palpable abdominal mass, urinary tract infection, hematuria, or failure to thrive. Kidney failure and hypertensive crises are rare presentations but are indications for prompt surgical intervention to prevent permanent damage and reduce blood pressure. Infants with preserved function can be monitored conservatively with serial imaging.

PO2316
Missed Diagnosis: A Case of Asymptomatic Isolated Orthostatic Proteinuria from Nutcracker Phenomenon
Anna R. Gaddy, Ranjani N. Moorhi. Indiana University School of Medicine, Indianapolis, IN.

Introduction: In children, proteinuria which exceeds 100 mg/m2 per day or 150 mg per day is considered abnormal. Isolated proteinuria is relatively common, but persistent proteinuria is abnormal and should be investigated. Persistent proteinuria can be further divided into orthostatic subtype if the recumbent Pt-Cr is ~0.2mg/mg but this rises to abnormal (~2.0mg/mg) after standing. One cause of orthostatic proteinuria is entrapment of the left renal vein, which is known as the Nutcracker Syndrome. Orthostatic proteinuria, isolated hematuria and pelvic congestion pain are the most common manifestations, however Nutcracker Syndrome is highly heterogeneous and frequently missed.

Case Description: We present an 18 year-old female with intermittent proteinuria, hematuria and occasional flank pain for nine years. The patient had proteinuria on dipstick at age eight. At age 15, she again was noted to have proteinuria on serial urinalyses with up to 500mg/dL protein. ANA, anti-dsDNA, C3, and C4 were normal. Renal ultrasound was performed with unremarkable kidneys and urinary bladder. For several years, proteinuria was mild and intermittently negative and no further workup was done. Split urine collection demonstrated minimal protein on first morning void but over 1g/g Pr/Cr by afternoon. We ordered renal ultrasound with Doppler, which demonstrated Doppler ultrasonogram showed the left renal vein had significantly increased flow velocity and appeared to be compressed between the AO and SMA.

Discussion: Differential for etiology of orthostatic proteinuria should include Nutcracker Syndrome as this diagnosis requires a high degree of suspicion. Nutcracker Syndrome can involve proteinuria as well as hematuria but also pelvic pain, back pain, and pelvic congestion symptoms.

PO2317
Rare Presentation of Nephrotic Syndrome in 10-Year-Old Male
Ellen Cody, Katherine A. Vanderheuvel, Mark Mitsnefes. Cincinnati Children’s Hospital Medical Center, Cincinnati, OH.

Introduction: Review nephrotic syndrome 2/2 amyloidosis due to genetic mutation

Case Description: A 10 year male w/ mild proteinuria, progressed to UPC of 4mg/mg over months, Cr 0.4, alt 2.5. Got strep, treated w/ amoxicillin & motrin, after 3 days developed periorbital edema, poor PO, fatigue, admitted. Labs Cr 4.1, alb 1.1, UPC 31 mg/mg, no blood. RUS b/l enlarged, echogenic kidneys. Biopsy w/ glomeruli expanded by amorphous, acellular proteinaceous material in mesangium, walls of arteries and arterioles (Image 1), congophilic on Congo red stain (Image 2), apple green on light birefringence, & tubular injury, final read: amyloidosis and AIN. Completed 3 days of IV steroids for AIN, started colchicine for amyloidosis. Genetics w/ pathogenic Cys59Arg variant of TNFRSF1A, c/w TNF Receptor-Associated Periodic Syndrome (TRAPS). Started canakinumab, human monoclonal anti-IL-1 Ab. After 3 months, Cr baseline, no edema, still nephrotic range proteinuria, low alb. MOC w/ ESRD as teen, required dialysis, transplant. Last both kidney and liver failure, died at 31. Diagnosed w/ Familial Mediterranean Fever, as was MGF.

Discussion: Autoinflammatory disease usually presents as intermittent fever, abdominal & joint pain. Second most common is renal involvement, which starts w/ proteinuria, progresses to nephrotic syndrome, renal dysfunction. Diagnosis of amyloidosis based on amyloid fibrils in biopsy of involved tissue, stain positive w/ congo red, apple green birefringence to polarized light. No clear relationship between extent of amyloid deposition & severity of clinical manifestations of renal disease. TRAPS treated w/ directed therapy (IL-1 inhibitor), but difficult to track response to therapy as serum amyloid A not available. Use inflammatory markers (i.e. CRP) given autoinflammatory syndrome.
PO2318

Cyanotic Nephropathy (CN) in Pre-Fontan Congenital Cyanotic Heart Disease (CCHD) with Solitary Kidney

Kimmy T. Vuong,1,2 Katayoon Shayan,1 Caitlin E. Carter,1,2 Rady Children’s Hospital San Diego, San Diego, CA; 1University of California San Diego, La Jolla, CA.

Introduction: CN is a glomerulopathy seen in patients with CCHD. Chronic hypoxia leads to proteinuria and reduced GFR through tubular and glomerular injury. Case Description: Patient was a single kidney and pre-Fontan CCHD presented with hematuria and proteinuria on cardiac transplant evaluation. He had 6 months of symptomatic hypoxia requiring increased supplemental O2, but no other recent illness. Exam was notable for 3/6 pansystolic murmur, tachypnea with clear lung fields, hepatoplenomegaly, cyanotic nailbeds with marked clubbing, but no peripheral edema. 24 hour urine protein measured 4.1 g (normal <0.2g), 38% was albumin. Serum albumin was 3.5 g/dL (normal) and eGFR by Cystatin C was 72 mL/min/1.73m2. Hemoglobin was elevated at 20.1 (normal 12.5-16.1 g/dL). C3, C4, ANA, dsDNA, ANCA were normal. Ultrasound showed solitary left kidney with nephromegaly (12.5cm, 1000mH2O) and a large cystic mass. Renal biopsy showed class III lupus nephritis and multifocal arterial and arteriolar thrombosis. Given our patient’s clinical improvement with these therapies, we conclude that more research is needed to define their role in treatment of patients with lupus vasculopathy.

Discussion: Prior case reports have documented effective treatment of lupus vasculopathy with rituximab. To our knowledge, no data exists on ecilizumab for treatment of lupus vasculopathy. Given our patient’s clinical improvement with these therapies, we conclude that more research is needed to define their role in treatment of patients with lupus vasculopathy.

PO2320

Nephrotic Syndrome Relapse due to Bee Sting in Steroid-Resistant Nephrotic Syndrome

Russell S. Whelan,1,2 Roberto Gordillo,1 Seattle Children’s Hospital, Seattle, WA; 1University of Washington, Seattle, WA.

Introduction: Initial and relapsing presentations of nephrotic syndrome are known to be commonly precipitated by acute illness such as upper respiratory infections and urinary tract infections. Rarely, bee stings can cause development of nephrotic syndrome relapses, particularly in patients with reports of relapses secondary to insect stings being even more sparsely reported. Here we report a patient with steroid-resistant nephrotic syndrome who developed a nephrotic flare after being stung by a bee, and the clinical course to achieve remission.

Case Description: A 14 month old unvaccinated male presented with rapid weight gain due to edema and proteinuria, and was diagnosed with nephrotic syndrome with renal biopsy consistent with minimal change disease. An initial 60mg/m2 course of prednisolone failed to achieve remission. Mycophenolate mofetil (MMF) treatment was then initiated, which resulted in rapid remission. Two months after initial remission, the patient sustained several bee stings, with initially minimal localized swelling. Several days later he was noted to have edema, proteinuria and weight gain, and was diagnosed with a relapse of his nephrotic syndrome. Spontaneous remission did not occur after 2 weeks of expectant management, and a subsequent increase in dosing of MMF also provided insufficient clinical benefit. The patient’s anemia, thrombocytopenia and elevated creatinine, was attributed to acute kidney injury status-post nephrectomy that has since improved. Pathology report came back and confirmed clear cell renal cell carcinoma. Cytogenetic screen showed a translocation of large intimal complex deposits with endothelial cell necrosis, consistent with a diagnosis of lupus vasculopathy. He received 6 sessions of plasmapheresis without improvement. Based on renal biopsy, he was treated with cyclophosphamide per Euro Lupus protocol. Eculizumab was started for treatment of lupus vasculopathy. His anemia, thrombocytopenia, and proteinuria improved after initiation of eculizumab, but he remained dialysis dependent. Eculizumab was discontinued after 6 weeks of therapy, but he again developed thrombocytopenia, hemolytic anemia, worsening proteinuria and hypertension. These improved after restarting eculizumab. Due to ongoing evidence of lupus activity, rituximab was given after completion of cyclophosphamide. Hemodialysis was discontinued one month after his first rituximab dose with B-cell depletion. He remains on eculizumab therapy and has stable chronic kidney disease stage 2 despite B-cell repopulation.

Discussion: Prior case reports have documented effective treatment of lupus vasculopathy with rituximab. To our knowledge, no data exists on ecilizumab for treatment of lupus vasculopathy. Given our patient’s clinical improvement with these therapies, we conclude that more research is needed to define their role in treatment of patients with lupus vasculopathy.

PO2321

Managing Pediatric Renal Cell Carcinoma in Jehovah’s Witness Patient Yineng Zhang, Joanna Luty. Baystate Medical Center, Springfield, MA.

Introduction: Pediatric Renal Cell Carcinoma (pRCC) is rare in children and adolescents and only account for about 5% of all pediatric renal neoplasms. The driver mutation of the majority of these tumors is due to cytogenetic translocations involving the Mit family of transcription factors. Surgical resection of the mass is the main treatment and depending on the advancement of the cancer, can result in a complete nephrectomy. Due to complexity of surgery and the risk of blood loss, treatment can be complicated by a patient’s religion that decline blood product transfusions, such as Jehovah’s Witness. This case describes an already rare cancer requiring a unique medical management due to a family’s religious belief.

Case Description: A previously healthy 14-year-old male presented complaining of left flank pain. Patient was normotensive to the 120s, and initial labs including pRCC, thus a complete nephrectomy was decided to be the best course of treatment. Due to family’s religious background of Jehovah’s Witness a multi-disciplinary approach was considered to reduce the need for blood transfusions. Patient received daily erythropoietin injections and iron supplementation about three weeks prior to nephrectomy to stimulate red blood cell production post-operatively. Additionally, on the day of his procedure, interventional radiology (IR) first emphasized the left renal artery leading to tumor followed immediately by a left radical nephrectomy. Patient tolerated the procedure well with minimal blood loss and only had mild anemia. He required no blood products intraoperatively and subsequently developed grade 1 renal injury status-post nephrectomy that has since improved. Pathology report came back and confirmed clear cell renal cell carcinoma. Cytogenetic screen showed a translocation of

IgG4-Related Disease: Nephropathy and Bone Marrow Failure in a 2-Year-Old Child

Eduardo La Porta,1,2 Isabella Pisani,1 Maura Faraci,1 Francesco P. Pilato,3 Luca Lanino,4 Daniela Verzoła,4 Giacomo Garibotto,4 Angela R. Sementa,5 Letizia Gnetti,1 Enrico E. Verrina,1 Istituto Giannina Gaslini, Genova, Italy; Istituto Clinico Ligure di Alta Specialita, Rapallo, Italy; Ospedale Universitario, Parma, Italy; Ospedale Policlinico San Martino, Genova, Italy.

Introduction: IgG4 related disease (IgG4 RD) is a systemic immune-mediated disorder that can potentially affect every organ. It is characterized by fibro-inflammatory tissue damage, IgG4 positive plasma cells, and often by elevated serum IgG4. Renal involvement can include tubulointerstitial nephritis (TIN), membranous glomerulopathy (MGP), and retroperitoneal fibrosis. The disease is more frequent over 50 years of age and only a few cases of IgG4 RD are reported in children.

Case Description: A 2-year-old child was diagnosed with a trilobine bone marrow failure. Bone marrow biopsy showed poor and dyshomogeneus cellularity and lymphoplasmacytic infiltrate organized in follicular structures. Hematologic DNA analyses were negative. IgG subclass analysis showed elevated serum levels of IgG4 subclass (353 mg/dL). Kidney failure was also found (creatinine 1.3 mg/dL, PO2323

Proteinuria and Dipping on 24-Hour Ambulatory Blood Pressure Monitoring in Children

Chahmesty Y. Bakhoum,1,2,3 Kimmy T. Vuong,1,2 Caitlin E. Carter,1,2 Pranav S. Garimella,4 Joachim H. Ix,5 1Rady Children’s Hospital San Diego, San Diego, CA; 2University of California San Diego, La Jolla, CA; 3Maura Pisani,5 Angela R. Sementa,5 Letizia Gnetti,1 Enrico E. Verrina,1 Istituto Giannina Gaslini, Genova, Italy; Istituto Clinico Ligure di Alta Specialita, Rapallo, Italy; Ospedale Universitario, Parma, Italy; Ospedale Policlinico San Martino, Genova, Italy.

Background: Absence of nocturnal blood pressure dipping is associated with adverse cardiovascular outcomes in adults. Risk factors for non-dipping in adults include obesity and proteinuria. In children, risk factors for non-dipping have not been well established.

Methods: We identified consecutive patients aged 5 to 19 years who underwent 24-hour ambulatory blood pressure monitoring (ABPM) at Rady Children’s Hospital from August 2018 to January 2019 and had a spot urine protein to creatinine ratio (PCR) measurement within one year of their ABPM. Dipping was defined as a 10% reduction in systolic and diastolic blood pressure from day to night. Multivariable logistic and linear regression models evaluated the association of proteinuria with dipping, employing backwards selection models to retain important confounders.

Results: Seventy-seven children had ABPM and urine PCR assessments during the study period, among whom 27 (35.1%) were non-dippers. Non-dippers had a higher left ventricular mass index as compared to dippers (mean difference 6.9 g/m2.7, 95% CI 1.6 to 12.2). Doubling of urine PCR was associated with 38% higher odds of non-dipping in the multivariable model (Table). Doubling of urine PCR was also associated with a lower diastolic dipping percent by 1.33 (95% CI 0.31 to 2.34), after adjusting for age, body mass index, and estimated glomerular filtration rate.

Conclusions: Proteinuria is significantly associated with non-dipping in children.

Is a Single Static Cut Point Useful to Define Ambulatory Hypertension in Youth? The SHIP AHOY Study

Ghilad Hamdani,1 Michael A. Ferguson,2 Marc Lande,3 Kevin E. Meyers,3 Mark Mitsnefes,1 Joshua A. Samuels,1 Joseph T. Flynn,1 Elaine M. Urbina,1 The SHIP AHOY Investigators 1Schneider Children’s Medical Center of Israel, Petah Tikva, Israel; 2University of Rochester Medical Center, Rochester, NY; 3Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 4Seattle Children’s Hospital, Seattle, WA; 5The Children’s Hospital of Philadelphia, Philadelphia, PA; 6Boston Children’s Hospital, Boston, MA; 7University of Texas Health Science Center at Houston, Houston, TX.

Background: Ambulatory blood pressure monitoring (ABPM) is increasingly utilized for the diagnosis of hypertension (HTN). While adult guidelines use absolute blood pressure (BP) cut points to define ambulatory HTN, current pediatric guidelines utilize for 24-hour and wake ABPM are lower than those for adults but may be used to define ambulatory HTN in this population.

PO2325
Association of Environmental Tobacco Exposure with Blood Pressure in US Children
Rebecca Levy,1 Kaye E. Brathwaite,1 Harini Sarathy,1 Kimberly J. Reidy,1 Frederick J. Kaskel,2 Michal L. Melamed,1,2 Albert Einstein College of Medicine, Bronx, NY; 1University of California San Francisco, San Francisco, CA.

Background: Hypertension is a leading cause of cardiovascular and kidney disease in adults, and there is evidence that pathologic sequelae begin in childhood and young adulthood. Nicotine and other tobacco compounds have a variety of toxic effects, but to date their associations with chronic hypertension is unclear, especially in pediatric populations.

Methods: We examined the association between tobacco exposure and high blood pressure (HBP) in children who participated the National Health And Nutrition Examination Survey (NHANES) during 2008-2016. Children were classified as having tobacco exposure if they had blood cotinine levels >0.05ng/dl or reported living with a smoker or smoking themselves. High blood pressure was classified according to the 2017 AAP Clinical Practice Guidelines. Analysis was conducted by logistic regression with adjustment for baseline demographics, income and other possible confounders. Subgroup and sensitivity analyses were conducted.

Results: There was a positive association of high blood pressure with tobacco exposure in the study population. After adjustment for demographics, the odds of having high blood pressure was 1.39 (95% Confidence Interval (CI) 1.04, 1.87) for any tobacco exposure compared to no smoking exposure. The association was similar across participant subgroups. The association remained significant by sensitivity analysis using cotinine exposure as a continuous variable. Separately, the odds of having high blood pressure for passive smokers was 1.35 (CI 0.98, 1.85) while the odds for active smokers was 1.71 (CI 1.14, 2.54) compared to participants with no tobacco exposure.

Conclusions: Tobacco exposure is associated with high blood pressure in US children and adolescents.

PO2326
Hypertension and CKD at 7 Years After Surgical Repair of Congenital Heart Disease in Children
Jason H. Greenberg,1 Michael Zappetti,2 Heather Thiessen Philbrook,3 Yaqi Jia,1 Prasad Devarajan,4 Chirag R. Parikh.5 TRIBE-AKI Consortium Yale University, New Haven, CT; 2Hospital for Sick Children, Toronto, ON, Canada; 3Johns Hopkins University, Baltimore, MD; 4Cincinnati Children’s Hospital Medical Center Division of Child and Adolescent Psychiatry, Cincinnati, OH.

Background: We previously determined that children who require surgery for congenital heart disease (CHD) are at an increased risk for hypertension and CKD 5 years after cardiac surgery. This study assessed the long-term risk of hypertension and CKD after cardiac surgery and if these outcomes are sustained.

Methods: We prospectively enrolled children from 1 month to 18 years old, undergoing cardiopulmonary bypass at three centers. Children who survived their surgical hospitalization had blood pressure, urine albumin to creatinine ratio, and serum creatinine measured at two-person follow-up visits (median 5.4 years and 7.4 years after surgery). Hypertension was defined using the American Academy of Pediatrics 2017 Hypertension guidelines. Estimated glomerular filtration rate (eGFR) was calculated using the CKD equation. CKD was defined as the presence of low eGFR (<90 ml/min/1.73m²) or microalbuminuria. We compared the risk of hypertension and CKD status at the 5 and 7-year visits using the McNemar test.

Results: Of 131 children with a follow-up visit 5 years after cardiac surgery, 88 (67%) children participated in the 7-year follow-up visit. The median age of the cohort at the 7-year follow-up visit was 10.7 (IQR: 7.8-13.0) years and 47% were female. 32 children had previously had a septal defect repair, 15 an inflow/outflow tract or valve procedure, 34 had a combined procedure, and 7 were not defined. Hypertension, microalbuminuria, eGFR<90, and eGFR<60 was 15%, 8%, 9%, and 1% respectively, at the 5-year visit and 17%, 4%, 19%, and 1%, respectively, at the 7-year visit. CKD was present in 16% and 18% of children at the 5-year and 7-year visit, respectively, with no statistically significant change in risk at the two visits (p=0.35). Between the 5-year and 7-year visits, hypertension and CKD were sustained in 8 (62%) and 4 (29%) patients, respectively.

Conclusions: The long-term risk of hypertension and CKD were common at the 7-year visit. Compared to the five-year visit, hypertension was sustained in the majority of children. Although CKD was not sustained, there was an increased incidence of new children with GFR<90 at the 7-year visit. The risk factors for sustained hypertension and kidney disease should be further studied in children with congenital heart disease.

PO2327
Evaluating the Role of the Kidneys in Posterior Reversible Encephalopathy Syndrome in Pediatric Patients
Shruti Shah, Andrew M. South. Wake Forest University School of Medicine, Winston-Salem, NC.

Background: Kidney disease is a known risk factor for posterior reversible encephalopathy syndrome (PRES), but the specific markers of kidney function that are relevant to PRES are undescribed. The objective was to investigate the associations of various markers of kidney function with PRES.

Methods: In a case-control study of high-risk children, we recorded most-recent blood urea nitrogen (BUN), documentation of acute kidney injury (AKI), serum creatinine, serum albumin, and hemoglobin level and calculated the estimated glomerular filtration rate (eGFR). PRES cases were confirmed clinically and radiologically. We applied multivariable regression models to estimate the associations of the exposures with PRES. We utilized directed graphical to inform the following model adjustments: 1) history of kidney disease and nephrotoxic medication exposure for the kidney function models; 2) history of kidney disease, eGFR, and albumin treatment for the serum albumin model; and 3) age, sex, history of kidney disease, eGFR, fluid overload, and nephrotoxic medication exposure for the hemoglobin model.

Results: The mean age of the study population was 9.5 years (±4.9) and 51% were female. Of that population, 29% had a history of kidney disease, 67% had exposure to nephrotoxic medications, and 29% had AKI prior to the onset of PRES. BUN [adjusted OR (aOR) 1.03 per 1 mg/dl increase, 95% CI 0.99-1.07, p=0.09] and AKI (aOR 3.78, 0.68-21.13, p=0.13) were modestly associated with PRES. eGFR (aOR 1.0 per 1 ml/min/1.73 m² increase, 0.99-1.02, p=0.02) and albumin (aOR 1.71 per 1 g/dl increase, 0.73-3.93, p<0.001) and hemoglobin (aOR 1.12 per 1 g/dl increase, 0.81-1.56, p=0.48) were not associated with PRES.

Conclusions: In a case-control study of children at high risk for PRES, we determined that among several markers of kidney function, BUN and AKI were modestly associated with PRES. Further prospective studies with larger sample sizes and higher power are necessary to fully evaluate the role of kidney function in the development of PRES.

PO2328
Effect of Hypertension on Childhood-Onset Systemic Lupus Erythematosus in a Tertiary Medical Center in Korea
Jeong yeon Kim, Heeyeon Cho. Department of Pediatrics, Samsung Medical Center; Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.

Background: Hypertension (HTN) is prevalent in childhood-onset systemic lupus erythematosus (cSLE) and affected either by disease activity itself, cSLE medication or both. The purpose of this study is to evaluate the prevalence, clinical characteristics and long-term clinical effect of HTN in Korean cSLE patients treated in tertiary medical center in Korea.

Methods: The medical records of cSLE patients, diagnosed by 2019 SLE European League Against Rheumatism/American College of Rheumatology (EULAR/ACR) classification criteria, who visited Samsung Medical Center from January 2009 to May 2019 were reviewed retrospectively. The disease activity was evaluated by Modified Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) and renal activity (renal SLEDAI) was measured by scores from SLDEA-2K. The long-term damage was evaluated by The Pediatric Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (Ped-SDI). The sex-, age- and height-blood pressure standards recommended by AAP 2017 guideline was used to define HTN. Left ventricular hypertrophy (LVH) was defined by sex, age specific left ventricular mass index (LVMI) at 95th percentile.

Results: Total 32 patients were enrolled in this study. The median follow-up duration was 7.3 year and female was predominant. Median age at SLE and HTN diagnosis were 14.2 and 14.3 year, respectively. Initial renal involvement was detected in 12.5%. The highest mean LN was detected in 84.4% (n=28) and 37.5% of them were class IV (n=12). The prevalence of HTN, including 2 transient HTN, was 34.4% (n=11) and stage 2 HTN was prevalent (n=9). The median dose of steroids, converted to prednisolone, at diagnosis of SLE and HTN was 1.0mg/kg/day and 0.5mg/kg/day. Among cSLE patients with HTN, 13 patients had 3 episodes of posterior reversible encephalopathy syndrome. LVH was detected in 2 patients with HTN. In the cSLE patients with persistent HTN (n=9), lower eGFR (OR=0.9, p=0.031) and higher BMI (OR 1.4, p=0.047) were shown at the time of SLE diagnosis. Every patient with HTN - including transient HTN - in cSLE (n=11) showed lower eGFR at the time of SLE diagnosis (OR 0.9, p=0.029) and higher Ped-SDI (OR 1.8, p=0.047) at last visit.

Conclusions: In conclusion, HTN in cSLE is associated with BMI and renal function at SLE diagnosis. Also, HTN affect long term damage accumulation in cSLE.

Hemodiafiltration Maintains a Sustained Improvement in BP Compared with Conventional Hemodialysis in Children: The HDF, Heart and Height (3H) Study

Francesca De Zan,1 Colette J. Smith,2 Aysun Bayazit,3 Karolis Azukaitis,4 Sevcan A. Bakkaloglu,1 Fabio Pagliolona,1 Mohan Shennoy,1 Manish Sinha,1 Branko B. Spasojevic,6 Claus Peter Schaefer,10 Franz S. Schaefer,10 Enrico Vidal,11 Rukshana Shroff.12 1UCL Institute of Global Health, London, United Kingdom; 2Cukurova University, Adana, Turkey; 3Clinic of Pediatrics, Vinluin University, Vinluin, Lithuania; 4Gazi University Hospital, Ankara, Turkey; 5Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, Italy; 6Royal Manchester Children’s Hospital, Manchester, United Kingdom; 7Evelina Children’s Hospital, London, United Kingdom; 8University Children’s Hospital, Belgrade, Serbia; 9Center for Pediatrics and Adolescent Medicine, Heidelberg, Germany; 10Division of Pediatrics, Department of Medicine, University of Udine, Udine, Italy; 11Great Ormond Street Hospital for Children NHS Foundation Trust, and University College London Institute of Child Health, London, United Kingdom.

Background: Hypertension is prevalent in children on dialysis and associated with left ventricular hypertrophy, cardiovascular disease, and mortality. We studied the blood pressure (BP) trends as well as risk factors associated with the evolution of BP over 1-year in children on conventional hemodialysis (HDV) vs hemodiafiltration (HDF).

Methods: This is a post-hoc analysis of the “3H - HDF-Hearts-Height” dataset, a multicenter, non-randomized, parallel-arm observational study. Mean arterial pressure (MAP) derived from 24-hour ambulatory BP monitoring was calculated and hypertensive defined as 24-hour MAP standard deviation score (SDS) ≥95th percentile.

Results: 78 children on HD and 55 on HDF were followed-up for 1-year and had three ABPM measures included. MAP-SDS was under-estimated by pre-dialysis systolic BP-SDS (mean difference -0.6; 95% LoA +4.9 to 3.8). At baseline 82% on HD and 44% on HDF were hypertensive, with uncontrolled hypertension (BP-95th centile on medications) in 88% vs 25% respectively; p<0.001. At 12-months children on HDF had lower MAP-SDS compared to those on HD in all age groups (p<0.001). Over the one-year follow-up, the HD group had a mean MAP-SDS increase of +0.98 (95%CI 0.77 to 1.20; p<0.0001), whereas the HDF group had a non-significant increase of +0.15% (95%CI -0.10 to 0.40; p=0.23). Significant and independent predictors of MAP-SDS were dialysis modality (β=0.83 [95%CI 0.51 to 1.15] SDS for HD vs HDF, p<0.0001) and higher IDWG% (β=0.13 [95%CI 0.06 to 0.19] p<0.0003).

Conclusions: Children on HD had a significant and sustained increase in BP over the 1-year study period compared to an attenuated and non-significant increase in HDF. Volume overload with higher IDWG%, but not anti-hypertensive medications, was associated with a higher MAP-SDS in both groups.

PO2330

Novel Nephrin Protein/HLA Class II Complexes: A New Mechanism of Steroid-Sensitive Nephrotic Syndrome

Tomoko Horinouchi,2 Yuya Aoto,2 Shinya Ishiko,2 Nana Sakakibara,2 China Nagano,2 Tomohiko Yamamura,2 Takeshi Ninchoji,2 Kandai Nozu,2 Kazumo Iijima,2 1Department of Immunocchemistry, Research Institute for Microbial Disease, Osaka University, Suita, Japan; 2Department of Pediatrics, Kobe University Graduate School of Medicine, Kobe, Japan.

Background: We have recently identified the risk allele (HLA-DRB1*07:02) and the protective allele (HLA-DRB1*13:02) in the development of childhood steroid-sensitive nephrotic syndrome (SSNS) in a Japanese population (JASN 2018). HLA-DRB1*07:01-DQA1*0201-DQB1*0201 was also identified as a risk haplotype in other populations. In addition, we found that NPHS1, coding nephrin, which is a key component of podocytes, was associated with susceptibility to childhood SSNS (Kidney Int 2020). HLA class II genes are associated with susceptibility to many kinds of autoimmune diseases, with one of the mechanisms being misfolded protein/HLA class II complexes that are aberrantly transported to the cell surface inducing immune responses (Jim, Arase et al. PNAS 2014). Therefore, we investigated the relationship between each HLA allele and nephrin, based on the hypothesis that nephrin protein/HLA class II complexes might be involved in the development of SSNS.

Methods: Nephrin lacking the transmembrane domain (Nephmis) was used as a model of misfolded protein that is not expressed on the cell surface. We co-transfected Nephrmis and HLA-DR to HEK293T cells and assessed the expression patterns by flow cytometry and immunoprecipitation.

Results: Nephrmis was detected on the cell surface in the presence of HLA-DR, which was more intense in the risk alleles than in the protective allele (DRB1*07:01-DRB1*08:02-DRB1*13:02). While Nephrmis communoprecipitated with HLA-DR, Nephrmis was not detected in the absence of HLA-DR. [Discussion] Podocytes are sometimes considered as a key component professional antigen presenting cells because they present antigens on the cell surface via HLA class II and stimulate immune signaling. We showed that the risk HLA DR allele tended to present Nephrmis stronger than the protective allele, suggesting that an immune response could be more easily induced in the risk alleles than in the protective allele. Although there are a variety of possible mechanisms by which HLA polymorphisms could be associated with SSNS, the binding of specific molecules, such as nephrin or Nephmis, and their presentation may provide new insights into the pathogenesis of SSNS.

Conclusions: Our results suggest that nephrin protein/HLA class II complexes can be involved in the pathogenesis of childhood SSNS.

PO2331

Efficacy and Safety of Ravulizumab in Pediatric Patients with Atypical Hemolytic Uremic Syndrome Previously Treated with Eculizumab: 26-Week and 1-Year Data

Larry A. Greenbaum,1 Novaya Fujita,1 Brigitte V. Adams,1 Álvaro Madrid Aris,2 Masayo Ogawa,1 Stephan Ortiz,2 Marc Vallec,1 Kazuki Tanaka,2 1Emory University School of Medicine and Children’s Healthcare of Atlanta, Atlanta, GA; 2Aichi Shoni Hoken Iryo Sogo Center, Obu, Japan; 3Alexion Pharmaceuticals Inc, Boston, MA; 4Queen Fabiola Children’s Hospital, Brussels, Belgium; 5Children’s Nephrology and Renal Transplantation Service, Children’s Maternity Hospital Sant Joan de Déu, University of Barcelona, Barcelona, Spain.

Background: The complement C5 inhibitor eculizumab improves outcomes of atypical hemolytic uremic syndrome (aHUS) but must be administered every 2–3 weeks. Ravulizumab, engineered from eculizumab for a longer half-life, is efficacious and safe in adults with 8-week dosing intervals. This analysis was in eculizumab-treated children with aHUS.

Methods: ALXN1210-aHUS-312 (NCT03131219) is a phase 3, single–arm trial in complement inhibitor-naïve children (Cohort 1; reported separately) and children who were receiving treatment with eculizumab without thrombocytopenia microangiopathy (TMA; Cohort 2; reported here). This analysis assessed TMA activity, and the pharmacodynamic measure serum free C5 levels after patients switched from eculizumab to ravulizumab treatment. Patients received loading doses then maintenance treatment with ravulizumab every 4 or 8 weeks, dependent on weight, for 26 weeks. An extension phase is ongoing; here we report data on efficacy through 1 year and safety from all available follow up (median 50.2 weeks).

Results: Ten patients (mean [SD] age 11 [5.0] years) were enrolled into Cohort 2; all completed the 26-week initial evaluation period and entered the extension. Mean eGFR, hematologic outcomes (platelet, lactate dehydrogenase and hemoglobin normalization), and fatigue measures remained stable during both trial periods. At 1-year, the mean (SD) changes from baseline were: eGFR, -3.9 (8.3) mL/min/1.73m²; platelets, -17.8 (54.6) ×10^10/L; LDH, -10.7 (19.2) U/L; hemoglobin, +4.5 (7.1) g/L. All patients were in the same eGFR category at 1 year as recorded at baseline (eGFR mL/min/1.73m² ≤90, n=8; 60–90, n=1; 49–59, n=1). No patients required dialysis. Despite the increased dosing interval, serum free C5 levels were maintained below the threshold of 0.5 mg/mL. All patients experienced adverse events (AEs) but none discontinued the trial. No meningococcal infections occurred. One patient experienced serious AEs due to a respiratory tract infection.

Conclusions: Continued efficacy, no additional safety concerns and the benefit of reduced dosing frequency was demonstrated in pediatric patients with aHUS who were stable on eculizumab and switched to ravulizumab.

PO2332

Typical Hemolytic Uremic Syndrome in Children: A Single-Center Experience

Siddharth A. Shah, University of Louisville, Prospect, KY.

Background: Typical hemolytic-uremic syndrome (HUS) associated with diarrhea can be a fatal disease in children. Diarrhea and blood-stained stools are early symptoms. Oliguria and renal failure can occur anywhere from 3–7 days after onset of diarrhea. Intravenous (iv) fluids in the initial timeline of disease presentation may decrease the need for dialysis. Oligo-anuria at admission and leukocytosis is associated with poor outcomes during hospitalization. After recovery, there is a risk of long-term renal complications such as hypertension, proteinuria, and chronic kidney disease (CKD).

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Methods: We performed a retrospective analysis of 43 children admitted with diarrhea associated with HUS at our center in the last ten years. The ‘late presentation’ defined as serum creatinine >1 mg/dl, oliguria, or anuria at admission. The primary outcome was the presence of long-term renal sequelae. It included proteinuria, hypertension, or chronic kidney disease (CKD) (eGFR <75 ml/min/1.73m2) after one year of disease-onset. The Chi-square and correlation analysis performed on the SPSS platform.

Results: Overall, 32/43 presented late in the disease course, 30/43 required dialysis (median: 8 d), and 8/43 had a strong correlation with days of hospitalization. 10/43 children were lost to follow up. 33/43 children showed renal sequelae (includes 3 with CKD and 1 with ESRD who required kidney transplant) after having an initial diagnosis of HUS in our center. We counted >2000 cells/mm3 (at p<0.001) and duration of dialysis-14 days at (p<0.002) were associated significantly with the primary outcome. 6/43 children were un-immunized. There was no mortality. Conclusions: High peak WBC count may be a useful prognostic marker to evaluate the risk of long-term renal complications. These children need monitoring periodically after discharge and recovery. Early diagnosis and iv fluids before the onset of renal failure may help to prevent dialysis-related morbidity at the time of admission. More awareness is needed to discourage the use of NSAIDs following initial symptoms of HUS.

PO2333

Targeting Bloody Diarrhea to Fight Shiga Toxin-Producing Escherichia coli-Hemolytic Uremic Syndrome in Children: The Experience of the ItaKid HUS Network

Gianluigi Ardissino,1 Rosaria Colombo,2 Laura Daprai,2 Valentina Capone,1 Antonella Dodaro,2 Sara Testa,2 Fabio Pagliola,1 Chiara Vagnati,2 Carla Vignati,2 Francesca Tel,1 Ilaria Pontini,1 Giovanni Montini,1 Pediatric Nephrology, Dialysis and Transplantation, Fondazione IRCCS Ca’ Granda, Ospedale Maggiore Policlinico, Milano, Italy; 2Microbiology Unit, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milano, Italy; 1Pediatric Department, Vittore Buzzi Children’s Hospital, Università degli Studi di Milano, Milano, Italy.

Background: Bloody diarrhea (BD) is often the first distinctive sign of hemolytic uremic syndrome (eHUS), the leading cause of acute kidney injury in infants, caused by shiga toxin (Stx)-producing Escherichia coli (STEC) infection. The few days prior to the development of the renal complication, when bloody diarrhea is the only symptom, represent a window for better understanding, preventing or mitigating HUS. The present study aims at identifying patients at risk for HUS early and at evaluating the rate of BD associated with STEC infection.

Methods: This multicenter case series study was performed between 2010 and 2019 in Pediatric emergency departments and clinics belonging to a network of 63 pediatric hospitals in Northern Italy (referral population: 12 million general population; 2.3 million children). 4767 children (<20 yo) presenting with BD were enrolled. Stool samples were centrally screened for the presence of Stx genes (1 and 2) using a Reverse Dot blot assays (Genotype EHEC - Arimika) until 2018 and Real Time PCR (RIDA Gene-Relab) thereafter. Stx-positive cases were further investigated for E.coli serogroups. Children positive for Stx genes were monitored for hemoglobinuria, blood tests to rule in or out the diagnosis of STEC-HUS were done if urine dipstick turned positive for hemoglobinuria.

Results: Out of the 4767 screened samples, 214 (4.5%) turned out to be positive for either Stx1 (n: 62; 29.0%) or Stx2 (n: 97; 45.3%) or both (n: 55; 25.7%). 34 patients out of the 214 (16%) and 84 (20%) respectively were found to be infected with eHUS (0.71% of BDs). Patients infected with STEC producing Stx2 alone were at higher risk for eHUS compared with Stx1 (23.7 vs. 12.7%) while Stx1 alone was only exceptionally associated with eHUS (1.1%). The most frequent serogroup found in patients with Stx+BD was the O157 while in patients with eHUS the O26 was the most (36.5% of cases), followed by O157 (20%). Conclusions: STEC is still a rare cause of BD in children thus the screening for Stx of BD is recommended. We also suggest to monitor patients carrying Stx2 closely with urine dipstick for hemoglobinuria every 12 hours for the early detection of eHUS together with providing them with generous fluid infusion.

PO2334

Hemoglobinuria for the Early Identification of STEC-HUS in High-Risk Children

Valentina Capone,1 Gianluigi Ardissino, Maria Cristina Mancuso, Giovanna Montini,1 Pediatric Nephrology, Dialysis and Transplantation, Fondazione IRCCS Ca’ Granda, Ospedale Maggiore Policlinico, Milano, Italy.

Background: Shigatoxin-producing Escherichia coli – associated hemolytic uremic syndrome (STEC-HUS) represents one of the main causes of acute kidney injury in children and can be associated with several extrarenal complications. Its management is entirely based on supportive care, which includes generous fluid infusions, since-delayed patients have been described to have a worse outcome compared with previously, underhydrated patients. The present study aims at validating urine dipstick/urinalysis for hemoglobinuria as a early test to screen patients at high risk for the development of STEC-HUS.

Methods: Since 2010, a network 63 pediatric units (the ItaKid-HUS Network) has been developed in Northern Italy, with the aim of the early identification and management of STEC infections and STEC-HUS. Once a patient with bloody diarrhea (BD) is identified as Stx positive, he/she is rehydrated as appropriate and followed up with urine dipstick/urinalysis for hemoglobinuria until HUS develops or diarrhoea resolves. We here reviewed all the urine dipstick/urinalysis results from pediatric patients with Stx positivity either with BD only (Group 1) or with ongoing HUS (Group 2) from 2010 to 2019.

Results: A total of 100 children were eligible for the study. In Group 1, 22/63 patients had or developed hemoglobinuria while the remaining 41/63 were and remained negative. In 15/22 positive cases, blood tests ruled in a ongoing HUS, while in the remaining 7 the diagnosis was excluded. Among the 41 negative patients no one developed HUS. As expected, 37 children in Group 2 (already ongoing HUS) all had hemoglobinuria at admission.

Conclusions: Hemoglobinuria shows a sensitivity of 100% (95% CI 93-100%) and a specificity of 85% (95% CI 74-93%), with positive predictive value of 68% and negative predictive value of 100% in diagnosing ongoing HUS. Thus, urine dipstick or urinalysis for the detection of hemoglobinuria can be proposed as an easy, fast, inexpensive and repeatable test to screen patients at high risk for the development of STEC-HUS and to start supportive treatment as soon as possible.

PO2335

Hemoglobinuria for the Early Identification of Atypical Hemolytic Uremic Syndrome Relapse: Data from the ItaKid-HUS Network

Gianluigi Ardissino, Marta Brambilla, Fabio Pagliola, Sara Testa, Valentina Capone, Antonio Vergori, Donata C. Cresseri, Giovanni Montini. Ospedale Maggiore Policlinico, Milano, Italy.

Background: Atypical hemolytic uremic syndrome (aHUS) is at risk of relapse any time, thus patients require lifelong monitoring. We suggested that patients could be monitored for relapses, with hemoglobinuria (twice weekly and during intercurrent diseases) based on the hypothesis that a thrombotic microangiopathy involving the glomerulus, cannot take place without hematuria. However this assumption has not been validated.

Methods: The aim of the study is to analyze our experience with the mentioned approach in patients with aHUS who have never been treated (group 1), on treatment (group 2) and who have discontinued C5 inhibition (group 3). The records of all aHUS patients managed or referred to our Center from January 2009 to March 2020 were included and the analysis for the presence of hemoglobinuria was restricted to the period following primary remission with the aim of validating this biomarker as a reliable one for the early identification of relapses. Patients with persistent hemoglobinuria, although in documented TMA remission, were excluded. A positive test was defined as hemoglobin ≥ 1+. Patients reporting positive urine dipstick were addressed to laboratory investigations to rule in or out, the diagnosis of aHUS relapse.

Results: 84 patients with aHUS (50% females) were included with 1517 determinations of hemoglobinuria during a cumulative observation period of 261 patient-years (Figure). Hemoglobinuria for the early diagnosis of ongoing aHUS relapse shows a sensitivity of 100% and a specificity of 87.4% with a PPV of 10.5% and NPV of 100%.

Conclusions: Hemoglobinuria is a very sensitive and acceptably specific marker of aHUS relapse. This finding and its validation may have an important positive impact both on patient’s quality of life and on the outcome of disease via an early diagnosis of relapses.

Extensive Complement Analysis in a C3 Glomerulopathy Cohort of Dutch Children with Benign Outcome

Kiaa L. Wijnsma,1 Marloes Michels,1 Roel Kureurs,1 Joanna Van Wijk,2 Antonia Bouts,3 Valentina Gracchi,2 Flore Horuz-Engels,3 Mandy G. Keijzer-Veen,3 Eiske Dorrestein,3 Elena Volokhina,3 Lambertus P. Van den heuvel,4 Niki van der De Car,5 on behalf of the COMBATE consortium 6Amsterdam Children’s Hospital, Radboudumc, Nijmegen, Netherlands; 2Emma Children’s Hospital, Kobe, Japan; 4Clinical Research Center, Takatsuki General Hospital, Kobe, Children’s Hospital, University Medical Center Utrecht, Utrecht, Netherlands; 5University Hospitals Leuven, Leuven, Belgium; 6Wilhelmina Children’s Hospital, University Medical Center Utrecht, Utrecht, Netherlands; 7Maastricht University Medical Center, Maastricht, Netherlands.

Background: C3 glomerulopathy (C3G) is a rare renal disorder driven by dysregulation of the complement alternative pathway (AP) and characterized by predominant C3 depositions in the glomerulus. C3G can be subdivided in dense deposit disease (DDD) and C3 glomerulonephritis (C3GN). Patient cohort studies including clinical features offer important data in rare renal diseases. Moreover, biomarkers are increasingly used to select patients for clinical trials with novel complement-targeted therapies. This retrospective study describes complement biomarker profiles and outcome of 29 Dutch children.

Methods: Patients with a C3G diagnosis from 5 Dutch university medical centers (1992-2014) were included. Clinical, genetic, and laboratory findings were retrieved from patient files. Specialized biochemical assays were used to detect complement-directed autoantibodies and complement biomarkers.

Results: A total of 29 patients with DDD (n=19) and C3GN (n=10) were included. Median (IQR) follow-up was 51 months (26-90). Patients presented with proteinuria and hematuria (>90%) and low serum C3 levels (84%). Ten patients (35%, 8 DDD, 3 C3GN) presented with an impaired glomerular filtration rate (GFR). DDD patients presented at younger age and with a lower GFR (P<0.05). C3 nephritic factors were found in 10 patients (35%). 3 patients carried rare genetic variants in AP genes. Elevated levels of the complement activation markers C3d, C3bBbP, and C5b-9, combined with lowered C3 and C5 levels, indicated AP activation in the acute phase. Taking longitudinal data into account, a linear mixed model showed that C3GN patients had higher C5b-9 and low C3 levels than DDD patients (P<0.05). During follow-up, 13 (45%) patients experienced a relapse. No significant differences in clinical or laboratory features were observed between patients with and without a relapse and persistent renal sequelae. At last follow-up, only 4 patients (14%; all DDD) had a GFR below 60 ml/min/1.73m².

Conclusions: We present the extensive description of clinical, genetic, and biochemical complement features of a large pediatric C3G cohort. In most patients AP abnormalities were found. Overall, the outcome of the patients we described was relatively benign.

PO2337

Comparison of Clinicopathological Findings Between Childhood IgA Nephropathy and IgA Vasculitis Nephritis Using Oxford Classification

Yuko Shima,1 Koichi Nakashiki,1 Hironobu Mukaiyama,1 Yu Tanaka,1 Takuo Wada,1 Kandai Nozu,1 Ryojiyo Tanaka,1 Kazumoto Iijima,1 Norito Yoshikawa,2 Noriyuki Watanuki,1 Wataru Obanai,1 Ryo Fujii,1 Yuko Tani,1 Isao Kimura,1 Takasuna Ono,1 Takanori Okinawa, Japan; 2Pediatrics, Graduate School of Medicine, University of the Ryukyus, Okinawa, Japan; 3Pediatrics, Graduate School of Medicine, Kobe University, Kobe, Japan; 4Clinical Research Center, Takatsuki General Hospital, Kobe, Japan; 5Pediatric Nephrology, Hyogo Prefectural Kobe Children’s Hospital, Kobe, Japan.

Background: IgA nephropathy (IgAN) and IgA vasculitis nephritis (IgAVN) are nephritis with a common pathological feature of significant mesangial IgA deposition, but it remains controversial whether they are the same disease.

Methods: We compared clinical and pathological findings between 67 patients with IgAN and 100 patients with IgAVN who underwent renal biopsy from April 2000 to April 2019 to clarify the differences.

Results: Clinical findings showed significant differences in onset age (IgAVN vs IgAN 11.6±7.0 years vs 9.5±3.5 years, p=0.10). Electron microscopic findings showed significant differences in the frequency of mesangial IgA deposition (9.5 vs 3.5%, p=0.10). Electron microscopic findings showed significant differences in the frequency of mesangial IgA deposition (9.5 vs 3.5%, p=0.10). Electron microscopic findings showed significant differences in the frequency of mesangial IgA deposition (9.5 vs 3.5%, p=0.10). Electron microscopic findings showed significant differences in the frequency of mesangial IgA deposition (9.5 vs 3.5%, p=0.10). Electron microscopic findings showed significant differences in the frequency of mesangial IgA deposition (9.5 vs 3.5%, p=0.10).

Conclusions: IgAN has higher frequency of M1 lesion regardless of degree of proteinuria. The frequency of chronic lesions such as S, T, and G, and higher frequency of acute lesions such as M and C compared with IgAN. Although IgAN had some pathological similarities to that of IgAN, there seems to be differences which cannot be explained by the timing of renal biopsy.

PO2338

Race and Age at Onset of ESRD in Patients with Alport Syndrome

Sarah J. Kizibash, Blanche M. Chavers, Clifford E. Kaskan. University of Minnesota Academic Health Center, Minneapolis, MN.

Background: Angiotensin-converting enzyme (ACE) inhibitors have been shown to delay the onset of end-stage renal disease (ESRD) in both animal models and humans with Alport syndrome. In 2013, expert guidelines recommended the use of ACE inhibitors to delay onset of ESRD. We examined temporal changes in the age at onset of end-stage renal disease (ESRD) and interaction between race and age at ESRD for patients with Alport syndrome.

Methods: We used the Scientific Registry of Transplant Recipients to identify all patients who received a kidney transplant in the United States for Alport syndrome between 1987 and 2017. We divided the study period into three equal eras (era 1, 1987-1997; era 2, 1998-2007; and era 3, 2008-2017) to assess changes in age at ESRD using a linear regression model adjusting for race and gender. Age at ESRD was defined as the earlier of the age at dialysis or the age at kidney transplant.

Results: Between 1987 and 2017, 4105 Alport patients received a kidney transplant in the United States. Of these patients, 3,115 (75.9%) were male and 3176 (77.4%) were white. Pre-emptive transplants were performed in 962 (23.4%) patients. Table 1 demonstrates temporal changes in median age at ESRD, demographic and clinical characteristics for patients with Alport syndrome. After adjusting for race and gender, the age at ESRD increased by a mean of 2.7 years (SE 0.51, p <0.01) for era 2 and 4.4 years (SE 0.51, p<0.01) for era 3 compared with era 1. We also observed that age at ESRD was significantly lower for black (6.3 years, p <0.01), Hispanic (6.4 years, p <0.01), and others at age at death<50 (5.9 years, p <0.01) versus the black race (Table 2).

Conclusions: The age at ESRD for patients with Alport syndrome has progressively increased over the last 30 years. White patients have delayed onset of ESRD compared with patients of other races.

Temporal changes in ESRD and transplant characteristics

PO2339

Risk of Rituximab-Associated Severe Adverse Events Increases with Young Age in Children with Nephrotic Syndrome

Camille Laroché,1 Dominique Lemieux,2 Anne-Laure Lapeyraque,2 Adrien Flahaut,1 1Centre Hospitalier Universitaire Sainte-Justine Centre de Recherche, Montreal, QC, Canada; 2Centre Hospitalier Universitaire Sainte-Justine, Montreal, QC, Canada.

Background: Rituximab prevents relapse in steroid-dependent frequently relapsing nephrotic syndrome (SDFRNS). We aimed to assess the safety of rituximab in children with steroid-resistant nephrotic syndrome (SRNS) or SDFRNS.

Methods: This single-center retrospective study included all children with SRNS/ SDFRNS treated with rituximab since 2007 at our institution. All information concerning adverse events (AE) were obtained from medical records. Severity of adverse events was graded according to the Common Terminology Criteria for Adverse Events. We performed a Cox proportional hazards analysis and log-rank tests or proportional hazards models to determine hazard ratios (HR) with 95% confidence intervals (CI) of risk factors associated with severe AE (SAE).

Results: Of the 38 children included in this study, most had a SDFRNS (n=36, 96%). Median age at diagnostic was 3.4 (interquartile range, 2.4-6.2) years and median age at rituximab initiation was 9.0 (6.8-11.6) years. Median [95% CI] time to relapse was 1.4 [1.16-2.27] years. Median follow-up time was 3.7 (2.2-4.9) years. No patient died during follow-up. Fourteen SAE occurred in 12 (32%) patients, including one case of Pneumocystis jiroveci pneumonia, 6 cases of severe neutropenia and 2 cases of inflammatory colitis. Rituximab initiation before 10 years of age was associated with a higher risk of SAE (HR [95%CI], 11.3 [1.44, 88.6], Figure 1) and all SAE occurred in children aged <10 years except for anaphylactic reactions. The occurrence of a SAE was not associated with an increased risk of relapse.

Conclusions: A young age at rituximab initiation for SRNS/SDFRNS is associated with an increased risk of SAE. Rituximab should be used with particular caution in children under 10 years old.

Evaluating Nephrotic Syndrome Response to Rituximab in Children

Anna E. Williams, Katherine Tombley, Annabelle N. Chu,
Rasheed A. Gabdegeasin
Duke University, Durham, NC; Medical University of South Carolina, Charleston, SC.

Background: Nephrotic syndrome (NS) is the most common cause of glomerular disease in the pediatric population. In children, 80% of cases are steroid sensitive (SSNS) & 20% are steroid resistant (SRNS). Rituximab (RTX) has been identified as a steroid-sparing therapy with minimal nephrotoxic side effects. The determinants of clinical response to rituximab is not completely known.

Methods: A retrospective review of patients aged 0-21 years with idiopathic NS who received at least 2 doses of RTX therapy over 6 years. Data collected included gender, race, ethnicity, age at diagnosis, steroid response, number of RTX doses, CD20 levels post therapy & outcomes. Outcome was defined as complete remission, CR (urine protein < 0.2), partial remission, PR (UPCR 0.3-1.9) & no response, NR (UPCR ≥ 2). Data were compared by Fisher's exact & Wilcoxon Rank Sum tests.

Results: 48 patients met the inclusion criteria for the study comprising of 23 (48%) with SSNS & 25 (52%) with SRNS. There was no difference in race or age of onset between the patients with SSNS & SRNS. At 12/26 (62%) of patients who had CD20 lymphocyte levels measured following treatment achieved therapeutic end point of CD20 lymphocyte depletion. There was no difference in the proportion of patients who achieved this therapeutic end point between the patients with SSNS & SRNS (46% vs. 72%). Overall, 72% of patients achieved partial or complete remission. The remission rate was significantly higher in the SSNS group compared with the SRNS group (87% vs. 58%, p=0.001); however, there was no difference in remission rate between patients who achieved the therapeutic end point of CD20 lymphocyte depletion & those who did not in the entire cohort (56% vs 55%, p=1.0) as well as in subgroup of patients with SSNS & SRNS.

Conclusions: Children with both SSNS & SRNS achieved the desired therapeutic effect of CD20 lymphocyte depletion following treatment with RTX; however, disease remission rate was higher in children with SSNS. This data suggests that RTX can be administered at any phase of the disease (relapse or remission) without jeopardizing clinical response.
PO2343
Caregiver Perspectives of Pre-Transplant Evaluation for Children
Eloise Salmon,1 Laura Barr,2 Douglas Hill,1 Sandra Amaral,1 1Children's Hospital of Philadelphia, Philadelphia, PA; 2University of Pennsylvania, Philadelphia, PA.

Background: Pre-transplant evaluation is mandated by Centers for Medicare and Medicaid Services, but there is institutional variation in implementation. The family experience of this process also is incompletely understood. Current literature largely focuses on adult transplant recipients. Our interview study aims to fill the knowledge gap about family experience of the evaluation for children.

Methods: Interviews took place 07/2019 - 02/2020 with caregivers of children referred for kidney transplant at our center 07/2017 - 12/2018. The interview guide focuses on adult transplant recipients. Our interview study aims to fill the knowledge gap about family experience of the evaluation for children.

Results: Our team interviewed caregivers of 19 children; demographics in Fig. 1. Prominent themes included (1) the pre-transplant evaluation is overwhelming and emotional, (2) prior experiences and background knowledge are influential and (3) frustration with communication among teams was common. Fig. 2 highlights representative quotations from caregivers.

Conclusions: These findings are relevant to nephrologists to optimize delivery of information about transplant and other complex topics. The data highlight the importance of (1) acknowledging the scope of content and continually reevaluating accessibility of delivery (2) recognizing the influence of prior experiences and tailoring elements accordingly for increased family-centeredness and (3) making concerted efforts to define roles and set expectations, especially when multiple teams are involved in care.

PO2345
Vaccination Status in Pediatric Kidney Transplants: An Integrated Pediatric Transplant Research Database Study
Jaya S. Parulekar,1 Eric J. McGrath,2 Amrish Jain.1 1Wayne State University School of Medicine, Detroit, MI; 2Division of Pediatric Nephrology, Children’s Hospital of Michigan, Detroit, MI; 3Division of Pediatric Infectious Disease, Children’s Hospital of Michigan, Detroit, MI.

Background: The American Society of Transplant recommends candidates be immunized before transplantation. However, there is limited data on pre/post-transplant vaccination status for children with kidney transplants. Our study evaluates vaccination rates & an approach to increasing vaccination in our kidney transplant program.

Methods: Pediatric kidney transplant recipients at Children’s Hospital of Michigan from 2013-2019 were included. Official immunization records were obtained from the State of Michigan’s Michigan Care Improvement Registry. During the pre-transplant period, age-based catch-up or accelerated immunization was performed at primary care provider’s or at the in-house immunization center. Demographic, clinical & serology data were entered into an integrated database created through RedCap and analyzed with SPSS Version 26.

Results: Included were 58 children with mean age at transplant of 11.9±5.7 yrs, 66% Male, 52% African-American, 31% Caucasian, 76% deceased donor transplants & 10% re-transplants. Median duration of follow-up was 3 yrs. Pre-transplant vaccination rates of ≥95% were achieved for all vaccines, except PCV13 (69%), PCV23 (62%) & HPV4/9 (96%). Pre-transplant serology for HepA, HepB and Varicella showed immunogenicity of 95%, 93%, 88% respectively. Catch-up & accelerated immunization increased the vaccination rate to 100% from 53% (Varicella); 57% (HepA); 73% (MCV); 72% (MMR). Post transplant vaccination series was a 95% complete for all vaccines except PCV23 (43%); HPV4/9 (37%); MCV (30%).
Conclusions: A systematic approach using catch-up & accelerated immunization improves vaccination rates. Regular monitoring of immunization record post-transplant is required to maintain up-to-date status.

PO2346

Decreased CD28 Expression in Memory CD4+ T Cells in Children Awaiting Kidney Transplant Is Associated with Increased Expression of Senescence Markers

Charlotte Duneton,1 Roshan P. George,1,2 Mandy L. Ford,1 Pamela D. Winterberg1, Emory University, Atlanta, GA; 1Children’s Healthcare of Atlanta Egleston Hospital, Atlanta, GA.

Background: Despite improved patient and graft outcomes with CD28-CD80/86 costimulation blockade, increased early acute rejection has hindered the widespread use of CTLA-4Ig (belatacept) for kidney transplant. Our group has previously reported lower pre-transplant frequencies of CD28+ effector memory helper T cells (CD4+TEM) among recipients of belatacept.

Methods: We analyzed existing flow cytometry data of unstimulated blood cells collected from children on dialysis (n=30) or healthy children (n=18) and examined expression of markers of costimulation (CD28), senescence (CD57, PD1), activation (CD38) and cytotoxicity (Perforin, Granzyme B) on memory CD4+ T cells.

Results: None of the children had CD28+CD4+ TEM frequencies as low as those we have previously observed in adults that were rejection-free on belatacept. However, 8 children on dialysis (27%) had CD28-CD4+TEM frequencies below the minimum value observed in healthy children (Fig1A-B). Patients with this “stable-like” T cell phenotype had higher frequency of CD4+TEM cells bearing senescence markers (CD57+ Fig1C) and cytolytic effectors (Granzyme B, Perforin, Fig1D) but decreased activation markers (CD38- Fig1E).

Conclusions: Despite their young age and limited antigen experience, a subset of children on dialysis accumulate CD4+TEM cells that have lost CD28 expression and bear markers suggestive of impaired function, a phenotype reminiscent of adults with decreased risk for early rejection on belatacept. The functional capacity of these cell populations in children needs further study.

PO2347

Predicting Allograft Survival in Young Pediatric Kidney Transplant Recipients

Florian Manca Barayre,1 Jerome Hambant,1 Amelia Le Page,4 Stephen D. Marks,2 Chanel Prestidge,6 Matthew P. Sypek,7 Stephen P. McDonald,1 Rachel E. Patzer,1 Julien Hogan,1,2 1Emory University School of Medicine, Atlanta, GA; 2Robert-Debré Hospital, APHP, Paris, France; 3Bordeaux University Hospital, Bordeaux, France; 4Monash University Faculty of Medicine Nursing and Health Sciences, Clayton, VIC, Australia; 5Great Ormond Street Hospital For Children NHS Foundation Trust, London, United Kingdom; 6Starship Children’s Health, Newmarket, New Zealand; 7Australia and New Zealand Dialysis and Transplant Registry, Adelaide, SA, Australia.

Background: Kidney transplantation (kTx) presents specific challenges in younger recipients. There are no predictive model of renal allograft loss in young pediatric recipients to inform donor selection. We aimed to develop and validate a predictive model of graft loss in an international cohort of young kTx recipients.

Methods: We included first-time kTx recipients under 5 years of age in the USA, Australia, New Zealand, UK and France between 2005 and 2018. A multivariate Cox regression was used to develop a predictive model of graft loss or death on the US cohort. Model discrimination (C-statistics) and calibration were assessed internally and externally on the non-US cohort.

Results: 2543 kTx in children <5 years old were included. 10-year overall graft survival rate was 80.0% [95% CI = 77.7% – 82.2%]. Given the interaction between some predictors and recipient’s age, we developed two models stratified on recipient age and 0.65 (95% CI = 0.59 – 0.71) and the models were well calibrated. Figure 1 presents the discrimination of the models at different time horizons and the calibration at 10 years on the validation cohort.

Conclusions: We confirm the overall good renal allograft survival in children transplanted under the age of 5. We developed and validated predictive models of graft loss or death based on pre-transplant factors in this population that may be used to inform donor selection.

PO2348

Safety and Efficacy of Low-Dose Rabbit Antithymocyte Globulin in Pediatric Renal Transplant Recipients

Vaka K. Sigurjonsdottir,1,2 Paul C. Grimm,3 Abanti Chaudhuri,1 Landspitali, Reykjavik, Iceland; 2Stanford University, Stanford, CA.

Background: Currently there is no consensus among pediatric kidney transplant centers regarding the use and regimen for immunosuppressive induction therapy. The safety and effectiveness of reduced Rabbit Antithymocyte Globulin (ATG) ≤ 3.5 mg/kg cumulative dosing as induction therapy in low risk pediatric kidney transplant recipients is unknown.

Methods: Pediatric renal transplant recipients transplanted 1/1/2013-5/1/2018 were considered for inclusion. Recipients of deceased or living donor organs and with least 12-month follow-up were included. “High risk” was defined by a repeat transplant, African-American race. Maintenance immunosuppression protocol was tacrolimus, steroid free unless high risk. Outcomes were de novo DSA (dnDSA) formation, graft survival, biopsy proved rejection (BPR) and EBV/CMV/BK viremia infection during the first 12 months. DSAAs were routinely screened at 3-6 and 12 months. Protocol biopsies were done at 6 and 12 months and graded with Banff criteria. Subclinical/borderline findings were included with or without treatment. Additional DSA testing and/or biopsies were done if there was a clinical concern. Group 1: low risk patients, ATG dose of ≤ 3.5 mg/kg; Group 2: low risk patients receiving dose of >3.5 mg/kg and Group 3: high risk patients.

Results: A total of 181 patients met inclusion criteria. Age of patients was 11 years (11 mo-21 y), median (range), 21% received a living donor transplant and 49% were female. Graft loss at 12 months was a rare event with 99.5% graft survival and patient survival was 100%. Patients outcomes based on groups is shown in the table.

Conclusions: Reduced ATG dosing (≤ 3.5 mg/kg) when compared with higher dosing (>3.5 mg/kg) is safe and effective. Reduced ATG dose was associated with lower rates of BK viremia and BK nephropathy without increasing risk of dnDSA or BPR.

PO2350

Reduced 1-Year Allograft Function in Pediatric Renal Transplant Patients: Role of Subclinical Viral Replications

Raja Dandamudi, Stanley P. Hmiel, Vikas R. Dharmidharka. Washington University in Saint Louis School of Medicine, Saint Louis, MO.

Background: BK virus (BKV) and Epstein-Barr virus (EBV) subclinical viral replications (SVR) are common after renal transplant. The effects of SVR on the GF in pediatric kidney transplant (pKTx) recipients is not well defined and was the purpose of this study.

Methods: This retrospective study was done in our hospital from Jan 2012 to Dec 2018. 480 serum and urine samples from 39 pKTx were analyzed for viral load by quantitative PCR through the first post-transplantation year. Clinical characteristics, including GF by estimated glomerular filtration rate (eGFR) via bedside Schwartz formula were collected simultaneously. Analysis of differences between GF in patients with and without SVR was performed with t test and differences of P < 0.05 was significant.

Results: SVR occurred in 23/39 (59%) of pKTx. EBV SVR occurred in 13/39 (33%) pKTx at a mean (M) 95.8 days after transplantation (range(R) 14 to 220 days). M EBV level was 918 copies/ml (R 2K to 109K copies/ml). BK viremia occurred in 10 pKTx at a M 132 days after transplantation (R 11 to 276 days) with a M level 22,339 copies/ml (R 2K to 1,610K copies/ml). BK viruria occurred in 18 pKTx at a M 83 days after transplantation with a M level 49769 copies/ml (R 2K to 1,610K copies/ml). There was a significant difference in GF decline in patients with any SVR (M 21.97, SD 26.29) compared to patients without SVR was performed with t test and differences of P < 0.05 was significant.

Conclusions: Our adaptation of the KDPI demonstrated a higher accuracy to predict graft loss in young recipients of deceased donors. Furthermore, our SP-LKDPI model may allow direct comparison of living versus deceased donors offered to the youngest recipients.
PO2352

Variability in Surveillance Monitoring and Management of Donor-Specific Antibodies Among Pediatric Transplant Programs Participating in the Improving Renal Outcomes Collaborative (IROC)

Lyndsay Harshman,1 Hiren P. Patel,2 Gina-Marie Barletta,2 David K. Hooper,4 Rouba Garo,6,7 The University of Iowa Stead Family Department of Pediatrics, Iowa City, IA; 4,7Nationwide Children’s Hospital, Columbus, OH; 3Phoenix Children’s Hospital, Phoenix, AZ; 5Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 6Emory University, Atlanta, GA; 7Children’s Healthcare of Atlanta, Atlanta, GA.

Background: There have been few advancements in long-term outcome of pediatric kidney transplant (KT) recipients who develop rejection. Many centers perform surveillance monitoring for donor specific antibodies (DSA) to diagnose and treat subclinical rejection. Despite the existence of guidelines, there is variability in monitoring and management of DSA post-pediatric KT.

Methods: An IRB approved survey was distributed using REDCap among pediatric KT programs participating in IROC to evaluate practice patterns in monitoring and management of DSA post KT.

Results: Twenty-nine of 33 (88%) IROC centers completed the survey. Twenty-five of 29 (86%) centers perform surveillance DSA monitoring. Of those 25 centers, 20 (69%) check DSA twice or more in one year post KT. Nineteen (65%) check once in the second year and annually thereafter. Ten (33%) centers check DSA only by indication after year two post KT. Twenty-eight (97%) utilize MFI trend in interpreting DSA results and 10 (34%) centers use C1q complement fixing antibody assay to guide management. Management of patients with +DSA, stable creatinine and no evidence of antibody mediated rejection (AMR) on biopsy varies across centers from monitoring (15%), to intensifying immunosuppression (34%) or to intensifying immunosuppression (10%, baseline immunosuppression (9%, 66%). Very few centers reported giving IVIG alone (3/29, 10%) or IVIG and rituximab (3/29, 10%). Only 34% of centers (10/29) give kidney biopsy if DSA develops with stable creatinine. When rituximab is used for treatment of DSA+ AMR, 11/29 (41%) centers use one dose (1/5, 20%) and 12/29 (41%) use 2 doses with variable frequency. Center’s use C1q as monitoring for treatment of DSA+ AMR, 12/20 (60%) use 1 g/kg/dose and 6/20 (30%) use 2 g/kg/dose. The frequency of IVIG dosing is monthly in 16/20 (80%). The number of IVIG doses is variable ranging from 1 to 6.

Conclusions: There is significant variability in surveillance monitoring and management of DSA post-KT across pediatric centers. Large, multicenter studies should be considered to evaluate the ideal post-KT surveillance DSA monitoring strategy and to determine the effect of different treatment approaches on long-term outcomes in pediatric KT recipients.

PO2353

Assessment of Pediatric Nephrology Programs’ Readiness to Participate in Prospective Clinical Trials

Shyamne Harlely,1 Israel Howard,1 H. William Schnaper,2 William E. Smoyer,3 Katherine M. Dell,4 Coleman Gross,2 Katherine Twombly,2 Tetyana L. Vasylyeva,4 Scott E. Wenderfer,4 Texas Tech University Health Sciences Center School of Medicine, Amarillo, TX; 2Northwestern University Feinberg School of Medicine, Chicago, IL; 4Nationwide Children’s Hospital, Columbus, OH; 3Cleveland Clinic, Cleveland, OH; 2Relypsa Inc, Redwood City, CA; 1Medical University of South Carolina, Charleston, SC; 2Baylor College of Medicine, Houston, TX.

Background: Currently, there is a limited availability of effective, FDA-approved drugs for children with kidney disease in the United States; therefore, there is an increased need for clinical trials to evaluate drug effectiveness and safety for pediatric usage. Implementation and conduction of clinical trials is complex process, which requires a team approach, involves multiple inter-dependent steps, research infrastructure support, legal policies/procedures, equipment, and access to a regulatory oversight board. The conduct of clinical trials in small pediatric subspecialties (i.e. pediatric nephrology) may be hampered by provider clinical demands and small numbers of patients available for such studies. The goal of this survey was to assess the readiness to conduct clinical trials by pediatric nephrologists in institutions of different sizes. As a result, we would give consideration to the sites for prospective trials and educate the programs about steps needed in clinical research.

Methods: The survey was designed and tested by a small group of pediatric nephrology experts. Qualtrics Online Survey Platform and Statistical analysis were used. The survey was distributed to members of ASPN (60 sites in 30 U.S states and 2 Canadian Provinces). Respondents were asked to complete the survey on behalf of the institution/practice, not their individual preferences. There was a total of 17 survey questions, which assessed the respondent’s institution’s participation/interest in conduction of clinical research, availability of a clinical research coordinator/IRB, and access to equipment for trial execution (dry ice, centrifuges, freezers).

Results: Currently, we have recorded 68 survey responses. Two of the responding institutions had no interest in conducting clinical trials (2.9%). Notably, more respondents practiced at Academic Centers/Universities (91%) than in private practices (8.3%). We noted no major differences in access to clinical trial resources between large and small institutions.

Conclusions: Clinical trials remain vital to finding better treatments and cures for pediatric patients with renal diseases. Overall, pediatric nephrology programs have good infrastructure and readiness to conduct clinical trials independently of the size of the institution.
Methods: Clinical parameters were collected. All participants were genotyped for Apolipoprotein-L1 (APOL1) G1 (rs73855319, rs66910145) and G2 (rs71785313) variants, and for Heme oxygenase 1 (HMOX1) GT dinucleotide repeats (rs3043732). APOL1 high-risk genotype (HRG) was defined by the presence of 2 risk variants (G1/G1, G1/G2, and G1/G2) and low risk genotype (LRG) if 0 or 1 risk variants were present. APOL1 GT dinucleotide repeats were categorized into two allele classes (<25 repeats as short and >25 repeats as long). As the main outcomes, albuminuria was defined as albumin-to-creatinine ratio (ACR) a 30mg/g, reduced kidney function (eGFR <60 ml/ min per 1.73 m²) and glomerular hyperfiltration (eGFR >130 and 140 ml/min/1.73 m² for female and male, respectively).

Results: From 361 participants enrolled, 73 (20.2%) presented with albuminuria, 104 (28.8%) with hyperfiltration and 19 (5.26%) had reduced kidney function. Logistic regression analysis revealed that blood transfusions (> 9 per year) were significantly associated with albuminuria (P = 0.036); age (P = 0.015) and diastolic hypertension (P = 0.0099) were significantly associated with hyperfiltration. APOL1 HRG emerged as the main genetic factor associated with both albuminuria (odds ratio [OR]: 3.70, 95% confidence interval [CI]: 0.0307–22.55; P = 0.041) and hyperfiltration (OR: 21.84, 95% CI: 1.51–5.20; P < 0.001), while no association was found with HMOX1 GT repeats.

Conclusions: Kidney disease is highly prevalent in children with SCA in the DRC. APOL1 HRG is the main determinant associated with the risk of developing SCN.

PO2356
Disparities in Kidney Failure Care for Children: A Global Survey
Rowena Lalji,1,2 Anna Francis,1,3 Germaine Wong,1,2 David W. Johnson,1 on behalf of the Pediatric GKH Atlas Working Group 1The University of Queensland Faculty of Medicine, Herston, QLD, Australia; 2Princess Alexandra Hospital, Woolloongabba, QLD, Australia; 3The University of Sydney, Sydney, NSW, Australia 1Wesmead Institute Research, Westmead, NSW, Australia; 2Queensland Children’s Hospital, South Brisbane, QLD, Australia.

Background: Globally, the capacity to access and deliver kidney replacement therapies (KRT - dialysis and transplantation) to children has never previously been described. The present study reports current disparities in access to kidney care between children and adults worldwide based on the results of the 2018 International Society of Nephrology Global Kidney Health Atlas (GKH Atlas) survey.

Methods: A mixed methods analysis of pediatric-specific data from the 2018 GKH survey were used. Respondents were from countries categorized as low (LIC), lower-middle (LMIC), upper-middle (UMIC) or high income (HIC) according to 2018 World Bank income classification. Descriptive statistics were used for the population-based analysis of health expenditure across different world bank countries. Open text responses were thematically analyzed using HyperRESEARCH.

Results: Responses were received from 160 (88%) of 182 countries, including LIC (n=26, 16%), LMIC (n=36, 23%), UMIC (n=39, 24%) and HIC (n=59, 37%). Child access to end stage kidney disease care (ESKD) and KRT differed from adults in 29% and 23% of countries, respectively. Lower income countries were associated with graded increases in disparate access to ESKD (LIC 62%, LMIC 38%, UMIC 18%, HIC 9%) and KRT care (LIC 58%, UMIC 33%, UMIC 13%, HIC 9%). Five themes explained access disparities for children: inadequate resources for KRT; kidney failure care is expensive and incurs lifelong costs; priority and access based on a country’s economic status; a lack of child-specific resources; and longer travel distances for children.

Conclusions: There are significant disparities worldwide in care for children with kidney failure when compared with adults, particularly in low resource settings. Future policy and advocacy efforts are needed to promote universal, equitable kidney care for children globally.

PO2357
Clinical and Biopsy Characteristics in a Pediatric Cohort of C3 Glomerulopathy (C3G) and Immune Complex Membranoproliferative Glomerulonephritis (IC-MPGN)
Bradley P. Dixon,1,2 Amy Goodwin Davies,3 Hanieh Razaghi,4 Sherin Meloni,3 Melissa E. Thomas,3 Joseph T. Flynn,5 Donna J. Claes,6 Mark Mitsnefes,5 Brian R. Stoller,7 Vikas R. Dhamidharka,8 Caroline A. Gluck,8 Joshua Zaritsky,9 Michael J. Somers,9 Mahmoud Kallahsh,10 William E. Smoyer,11 Susan L. Furth,12 Christopher B. Forrest,12 Benjamin L. Laskin,12 Michelle Denburg,13 Renal Section, Department of Pediatrics, University of Colorado School of Medicine, Aurora, CO; 2Children’s Hospital Colorado, Aurora, CO; 3The Children’s Hospital of Philadelphia, Philadelphia, PA; 4Seattle Children’s Hospital, Seattle, WA; 5Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 6Washington University in Saint Louis School of Medicine, Saint Louis, MO; 7Nationwide Children’s Hospital, Columbus, OH.

Background: C3G and IC-MPGN are rare diseases. The ability to identify and phenotype children with C3G and IC-MPGN using electronic health records (EHR) would aid description of natural history and prognosticate therapeutic response.

Methods: Using a computable phenotype algorithm, a pediatric cohort of children with glomerular disorders was identified in PEDSnet, a national network of pediatric health systems with aggregated EHR data, and refined using MPGN-specific SNOMED-CT codes to identify C3G and IC-MPGN patients at 6 centers. Discrete data elements were captured from electronic health records, and additional clinical data were extracted by standardized chart review. Biopsy diagnosis was classified as C3G or IC-MPGN by applying an automated algorithm to immunofluorescence data.

Results: Of 285 identified patients, 173 were true cases of C3G or IC-MPGN. Of 285 identified patients, 173 were true cases of C3G or IC-MPGN. Of those, 35 were C3G and 138 were IC-MPGN. Median age at diagnosis was lower in C3G compared to IC-MPGN (p = 0.005). There were no significant differences in light microscopic injury pattern or ultrastructure between C3G and IC-MPGN biopsies, but C3 intensity was higher in C3G compared to IC-MPGN (p = 0.006) (Table 3).

Conclusions: Patients with C3G and IC-MPGN can be identified and characterized by the use of a computable phenotype, allowing the creation of robust databases to define clinical predictors of treatment response. This may prove to be a vital asset for recruitment into clinical trials of complement-targeted agents likely beneficial to this patient population.

Efficacy and Safety of Ravulizumab in Pediatric Patients with Atypical Hemolytic Uremic Syndrome Naïve to Complement Inhibitor Treatment: 26-Week and 1-Year Data
Gema Ariete,1 Bradley P. Dixon,2 Seong Heon Kim,3 Gaurav Kapur,4 Teri Jo Mauch,5 Stephan Ortiz,6 Marc Vallee,6 Andrew E. Denker,7 Hee Gyu Kang,8 Larry A. Greenbaum,9 Hospital Vall d’Hebron, Barcelona, Spain; 1University of Colorado School of Medicine, Aurora, CO; 2Children’s National University Children’s Hospital, Seoul, Republic of Korea; 3Children’s Hospital of Michigan, Detroit, MI; 4University of Nebraska Medical Center, Omaha, NE; 5Aexion Pharmaceuticals Inc, Boston, MA; 6Emory University School of Medicine and Children’s Healthcare of Atlanta, Atlanta, GA; 7Seoul National University College of Medicine, Seoul, Republic of Korea.

Background: Ravulizumab is a complement C5 inhibitor derived from eculizumab, with an increased half-life extending the maintenance dosing schedule from every 2–3 to every 4–8 weeks. We evaluated the efficacy and safety of ravulizumab to resolve active thrombotic microangiopathy (TMA) in children with atypical hemolytic uremic syndrome (aHUS) naïve to complement inhibitors.

Methods: ALXN1210-aHUS-S12 (NCT03131219) is a phase 3, single-arm trial in children with TMA due to aHUS. Patients received ravulizumab every 4–8 weeks, depending on bodyweight. The primary endpoint was complete TMA response (platelet count and lactate dehydrogenase normalization and ≤25% improvement in serum creatinine at baseline to ≥28 days apart) through 26 weeks. Key secondary endpoints included eGFR and dialysis requirement. Patients were then followed in an ongoing extension period. Here we report efficacy outcomes through 1 year and safety from all available follow-up (median 82.6 weeks).

Results: Eighteen patients (mean [SD] age 6.4 [4.5] years; 55.6% female) were enrolled; 14 (77.8%) achieved complete TMA response by 26 weeks, and 3 more patients (94.4%) by 50 weeks. Further improvements in TMA parameters occurred with longer-term treatment (Table). Mean (SD) increase in eGFR from baseline was 85.4 (54.3) mL/min/1.73m2 at 26 weeks, and 94.1 (50.7) at 50 weeks. Of 6 patients on dialysis at baseline, 5 (83.3%) discontinued dialysis by week 26, and the last patient by week 50. Complete free C5 inhibition was sustained throughout the trial. No unexpected adverse events, deaths, or meningococcal infections occurred.

A Pharmacologic “Stress Test” for Assessing Select Antioxidant Defenses in Patients with CKD
Richard A. Zager,1,2 Ali C. Johnson,1 Alvaya F. Guilm,1 Donald J. Keyser,3 Bhupinder Singh,4 Fred Hutchinson Cancer Research Center, Seattle, WA; 1University of Washington Department of Medicine, Seattle, WA; 2Renibus Therapeutics, Southlake, TX; 3University of California Irvine, University of California Irvine, Irvine, CA, US; Department of Medicine, Irvine, CA.

Background: Oxidative stress is a hallmark and mediator of CKD. Diminished antioxidant defenses are thought to be partly responsible. However, there is currently no way to prospectively assess antioxidant defenses in humans. RBT-6 (N-acetyl-L-cysteine, NAC) or protoporphyrin; SnPP) induces mild, transient oxidant stress in animal models, triggering increased expression of select antioxidant proteins (e.g., heme oxygenase 1 [HO-1], NAD[P]H dehydrogenase [quinone] 1 [NQO1], ferritin, p21). Hence, we tested the hypothesis that RBT-6 can also variably increase these proteins in humans and can thus serve as a pharmacologic “stress test” for gauging generic responsiveness and antioxidant reserves.

Methods: A total of 18 healthy volunteers and 24 participants with stage 3 CKD (n=12; eGFR 30–59 ml/min per 1.73m2) or stage 4 CKD (n=12; eGFR 15–29 ml/min per 1.73m2) received a single dose of RBT-6 at 9, 27, or 90 mg administered intravenously. Plasma and/or urinary antioxidant proteins were measured at baseline and for up to 4 days post-dosing. Kidney safety was assessed by serial measurements of BUN, creatinine, eGFR, albuminuria, and urinary AKI biomarkers (kidney injury molecule 1, neutrophil gelatinase associated lipocalin, cystatin C, and N-acetyl glucosaminidase).

Results: Plasma HO-1, ferritin, p21, and urine NQO1 were all elevated at baseline in CKD participants. Plasma HO-1 and urine NQO1 levels each inversely correlated with eGFR (r=0.85 to -0.95). All four proteins manifested statistically significant dose- and time-dependent elevations after RBT-6 infusion. However, marked inter-subject differences were observed. p21 responses to high-dose RBT-6 and HO-1 responses to low-dose RBT-6 were significantly suppressed in participants with CKD versus healthy volunteers. RBT-6 was well tolerated by all participants, and no evidence of nephrotoxicity was observed.

Conclusions: RBT-6 can be safely administered and, after its infusion, the resulting changes in plasma HO-1, NQO1, ferritin, and p21 concentrations can provide information as to antioxidant gene responsiveness/reserves in subjects with and without kidney disease. Additionally, baseline values of these markers may also be indicative of oxidative stress at baseline, especially in patients in CKD.

PO2360
Prediction of Kidney Drug Clearance: A Comparison of Tubular Secretory Clearance and GFR
Yan Chen,2,10 Leila R. Zelnick,2,10 Andrew N. Hoofnagle,4,24 Catherine K. Yeung,1,2 Laura M. Shireman,1 Calder C. Brauchla,1 Ian H. de Boer,1 Jonathan Himmelfarb,2,10 Bryan R. Kestenbaum,2,10 University of Washington Department of Epidemiology, Seattle, WA; 1Kidney Research Institute, Seattle, WA; 2University of Washington Department of Medicine, Seattle, WA; 3University of Washington Department of Laboratory Medicine, Seattle, WA; 4University of Washington Department of Pharmacy, Seattle, WA.

Background: Tubular secretion is the primary mechanism of kidney drug elimination. Few studies have empirically evaluated the role of tubular secretion on the kidney elimination of administered drugs.

Methods: We evaluated 54 participants with and without chronic kidney disease. We administered a single dose of isohexyl, furosemide, and famciclovir at the start of the study visit. We used LC-MS/MS to measure furosemide, penciclovir (the active form of famciclovir), and secretory solutes in sequential timed plasma samples and timed urine collections. We compared isohexyl GFR (iGFR) with the kidney clearances of secretory solutes in predicting kidney drug clearance using mean absolute errors (MAE) derived from linear regression and leave-one-out cross-validation.

Results: Participants were characterized by a mean age of 55 years and a median iGFR of 73 ml/min/1.73m2. Using iGFR as a single predictor, the MAE between model-predicted and measured furosemide and penciclovir clearance was 40.1 and 64.1 ml/ min, respectively. The MAEs for models of individual secretory solute clearances were statistically similar to that of the iGFR model. The addition of kynurenine, pyridoxic acid, isovalerylglucose, and tiglyglyclate clearances individually improved the predictive accuracy of penciclovir clearance compared with the iGFR model.

Conclusions: The kidney clearance of secretory solutes and iGFR showed similar accuracy for predicting the clearances of furosemide and penciclovir, with some improvement from combining both measures. These findings provide cautious optimism that measurements of secretory clearances may improve kidney drug dosing.

PO2361
Reduction in Proximal Tubular Secretion Precedes Reduction in Glomerular Filtration Rate in the Adenine-Induced CKD Model
Eleni Kougioumtzidou, Tasso Miliotis, Anna Granqvist, Magnus Soderberg, Astrazeneca, Gothenburg, Sweden.

Background: Glomerular filtration rate (GFR) is frequently used to instruct dose levels of renally cleared drugs in patients with renal disease. This is based on the assumption that proximal tubule secretory clearance declines equally to GFR during disease progression. We tested this hypothesis in adenine-induced CKD mouse model.

Methods: C57BL/6 mice were fed either control or 0.2% adenine diet to induce progressive kidney damage. Body weight, urinary output, GFR and tubular secretion were monitored and histological analysis performed to assess disease progression at 1 and 3 weeks. Tubular secretion was estimated by measuring renal clearance of the endogenous secretory solutes indoxyl sulfate (IS), hippuric acid (HA) and cinnamoylglycine (CMG) using liquid chromatography couple to mass spectrometry. GFR was estimated by transcutaneous measurements.

Results: Mice on adenine diet developed kidney disease, indicated by progressive GFR decline. Histological assessment showed normal glomeruli throughout the study and a moderate tubular damage at 1 week which progressed to severe at 3 weeks. However, the maximum urinary albumin-creatinine ratio was reached already at 1 week of treatment, as was Kim-1, an early tubular injury marker, suggesting extensive early tubular injury and functional damage preceding structural damage. Likewise, when tubular secretion was assessed directly, a profound decrease in renal clearance of IS was detected already after 1 week on adenine diet with only a small further decrease by the 3rd week. Similar trends were observed for HA and CMG. In direct comparison, the decline in GFR versus tubular secretion over time revealed that at 1 week GFR was decreased by 30% whereas tubular secretion was decreased by >65%, suggesting earlier impact on the latter. Immunohistological analysis revealed a reduction in Oat1 transporter expression, to an extent not fully accounting for the reduction in function. This suggests a component of Oat1 inhibition and/or involvement of other transporters.

Conclusions: Our results indicate that tubular secretory function can be dissociated from glomerular filtration. Thus, assessment of tubular function based on GFR alone can be misleading, which has implications for dosing of renally excreted drugs to patients with kidney disease.

PO2362

The Influence of Vitamin D Status and CKD on the CYP3A Metabolism Substrate Midazolam
Stacey M. Taeu,1 Linda Prebehalia,2 Michael F. Wempe,1 Michel Chonchol,3 Nirav A. Shah,4 Thomas D. Nolinc,4 Melanie S. Joy,1,2 University of Colorado, Skaggs School of Pharmacy and Pharmaceutical Sciences, Aurora, CO; 1University of Colorado, Division of Renal Diseases and Hypertension, Aurora, CO; 2University of Pittsburgh, Department of Pharmacy & Therapeutics, Pittsburgh, PA; 3University of Pittsburgh, Department of Medicine Renal Electrolyte Division, Pittsburgh, PA.

Background: Patients with chronic kidney disease (CKD) have a high prevalence of vitamin D (VitD) deficiency. Given its widespread use and knowledge of CYP gene induction, there is a paucity of data on how the pharmacokinetics (PK) of CYP3A substrates may be impacted by VitD in CKD. This study sought to investigate the role of VitD status (deficient or replete) on CYP3A metabolism in CKD and healthy control (HC) subjects using midazolam (MDZ) as a prototypical probe substrate.

Methods: CKD (n=19) and HC (n=6) subjects with VitD deficiency (25(OH)D < 30ng/mL) were enrolled in a 2-phase study. Phase 1, subjects were given one dose of oral cholecalciferol (D3, 5000 IU) and oral MDZ (2 mg). In Phase 2, subjects received D3, 5000 IU daily for up to 14 weeks to repletion (25(OH)D >30 ng/mL) and were again given one dose of oral D3, 5000 IU and MDZ 2 mg. Blood was serially collected for up to 48 h at each phase. MDZ plasma concentrations were measured by LC-MS/MS. Population PK analysis was performed using Phoenix NLME (v.8.2, Certara®).

Results: A 2-compartment model with delayed absorption and a mixed ratio residual error model was fit to the observed MDZ plasma concentration data. Glomerular filtration rate (GFR) and phase study were included as covariates in the model. MDZ population parameter estimates (%RSE) were: central volume of distribution (Vc/F) 95.6 L (26.8%), peripheral volume of distribution (Vp/F) 213 L (25.0%), clearance (CL/F) 31.1 L/h (25.0%), and rate (GFR) and study phase were included as covariates in the model. MDZ population analysis was performed using Phoenix NLME (v.8.2, Certara®).

Conclusions: The FEX data suggest that nonrenal transporter function (likely intestinal P-gp and/or hepatic OATP) is decreased in VitD deficient CKD patients and repletion, but no differences were statistically significant.

CYP3A and Drug Transporter Activity Changes in Thai Elderly with CKD Assessed using a Microdose Cocktail
Punyabandhu Rattanachew,2 Wonngarn Kittanamontholchakai,1 Natavudh Townnamchai,1 Suwasin Udomkaranun,2 Kearakit Pratdoponsilpa,2 Stephen J. Kerr,3 Thanusondorn Thanussawanansk,2 Udorn Udommoliboon,2 Natavudh Townnamchai,1 Boonsri Ongparphet1,3

Background: Chronic kidney disease (CKD) may influences cytochrome P450 (CYP) enzymes and drug transporters activity, resulting in the change of pharmacokinetics. This study investigated the effect of age and renal function on activity of CYP3A and various drug transporters in healthy Thai elderly and CKD patients using a validated microdose probe substrate cocktail.

Methods: Fifty three subjects were studied [healthy young subjects (Gr1, n=20), healthy elderly (Gr2, n=16) and elderly CKD patients (Gr3, n=17)]. Each subject was given a single dose of the microdose cocktail consisting of midazolam (M; for CYP3A), dabigatran etexilate (D; for gut P-gp), pitavastatin (P; for OATP1B), rosuvastatin (R; for OATP1B, BCRP, P-gp), and atorvastatin (A; for OATP1B, BCRP, P-gp, CYP3A). Plasma samples were collected at 0, 0.33, 0.67, 1, 1.5, 2, 3, 4, 6, 8, 10, 12, 24, 36 and 48 hours after dosing. All plasma drug concentrations were measured using a fully validated LC/MS/MS. Area under the concentration-time curve (AUC) were calculated by the trapezoidal rule.

Results: No side effect was observed. Multivariate analysis, adjusted for body mass index, co-morbidity and liver functions) showed negative effects of ageing and CKD on drug transporters activity. AUC0-last and maximum plasma drug concentration (Cmax) were increased in elderly compared to healthy young (OATP: A 2.28 and 4.22 folds). AUC0-last and maximum plasma drug concentration (Cmax) were increased in elderly compared to healthy young (OATP: A 2.28 and 4.22 folds). AUC0-last and maximum plasma drug concentration (Cmax) were increased in elderly compared to healthy young (OATP: A 2.28 and 4.22 folds). AUC0-last and maximum plasma drug concentration (Cmax) were increased in elderly compared to healthy young (OATP: A 2.28 and 4.22 folds). AUC0-last and maximum plasma drug concentration (Cmax) were increased in elderly compared to healthy young (OATP: A 2.28 and 4.22 folds). AUC0-last and maximum plasma drug concentration (Cmax) were increased in elderly compared to healthy young (OATP: A 2.28 and 4.22 folds).

Conclusions: Independent of age, CKD itself further reduces the activity of drug transporters, suggesting that this information has to be taken into account when drugs that pass through these transporters are prescribed to CKD patients.

Funding: Government Support - Non-U.S.

Tacrolimus and Mycophenolic Acid Pharmacokinetics in Young, Middle-Aged, and Elderly Stable Renal Transplant Recipients
Kathleen M. Tornatore,1,2 Kris Attwood,1,2 Transplantation Immunosuppressive Pharmacology Research Program 1University at Buffalo - The State University of New York, Buffalo, NY; 2Erie County Medical Center, Buffalo, NY; 3Roswell Park Comprehensive Cancer Center, Buffalo, NY.

Background: Tacrolimus (TAC) and mycophenolic acid (MPA) comprise a critical maintenance immunosuppressive regimen. Limited pharmacokinetic data are available comparing age-related differences of these immunosuppressive drugs which is an important factor considering the increase in renal transplants in older patients. This analysis compared TAC and MPA pharmacokinetics among young, middle age and elderly stable renal transplant recipients (RTR).

Methods: Twelve-hour TAC and MPA pharmacokinetic studies were conducted in 67 stable RTR at least 1-year post renal transplant. Tacrolimus dose regimens were adjusted to troughs (4 to 10 ng/mL) based upon time post-transplant. MPA regimens were adjusted using clinical responses only. Patients were categorized as: young: >21 & ≤40 years; middle age: >40 & ≤60 years and elderly-60 years. Non-compartmental pharmacokinetic analysis determined area under the concentration-time curve 0-12h (AUC0-12).
AUC4/12-AUC0-12 (to define MPA entericophetic recirculation), apparent clearance (CL) normalized to body weight (CL/BMI) and 0 hour troughs. Univariate ANOVA was conducted using SAS V 9.4.

Results: Table 1 summarizes the results. No group differences were noted for estimated glomerular filtration rate, MPA and TAC doses. Enteropheretic recirculation and MPA troughs were reduced in elderly compared to young. For MPA target AUC0-12hr of 30 to 60 mg·hr/L, 34.3% of RTR achieved this range with 56.7% above this therapeutic exposure. There were 52.2% of RTR within the therapeutic tacrolimus AUC0-12hr target of 120-200 ng·hr/ml with 46.1% below this range with no age relationship. Reduced tacrolimus CL/BMI was noted in elderly compared to middle age.

Conclusions: Tacrolimus and mycophenolic acid pharmacokinetics demonstrates age-related differences with lower clearances or exposures in the elderly. Tacrolimus and mycophenolic acid immunosuppression may require age-adjusted individualization to achieve therapeutic exposure.

Tacrolimus and Mycophenolic Acid Pharmacokinetics by Age

PO2366
A Single Time Point Plasma Concentration of Mycophenolic Acid Predicts Enteric-Coated Mycophenolate Sodium Exposure in Thai Renal Transplant Recipients

Napatssan Tananithipuwarat,1,2 Pajaree Chariyavilaskul,1,2 NATAVUDH TOWNMAHAT,2 SUPEecha Wittayalertpanya,1,2 CLINICAL PHARMACOKINETICS

Background: Enteric-coated mycophenolate sodium (EC-MPS) is a salt form of mycophenolate widely used in renal transplantation. The area under the concentration-time curve (AUC) of an active form of EC-MPS, mycophenolic acid (MPA) of ≥20 μg/L is highly associated with drug efficacy. However, this technique is impractical in clinical setting. Little is known regarding metabolites' AUC. This study determined the relationships of a single time point of plasma MPA level and the ratio of optimum MPA AUC and assessed the cut-off plasma level of that single time point to predict AUC. The full profile of active (7-O-MPA-glucuronide; MPAG) and inactive (acyl mycophenolic acid glucuronide; AcMPAG) metabolites, both free and total form are also measured and related to its AUC.

Methods: Twenty renal transplant recipients with EC-MPS were studied. On day 3 post transplantation, plasma samples were collected at 0, 0.5, 1, 1.5, 2, 2.5, 3, 3.5, 4, 6, 8, 10, and 12 hours post dose. Total and free form levels of MPA and metabolites were measured using a fully validated LC-MS/MS. Receiver operating curve (ROC) was carried out.

Results: The AUC of the MPA total form moderately correlated with a single time point plasma MPA concentration at C (r2 = 0.50) with the concentration cut of 2.5 μg/ ml (sensitivity 87%, specificity 80%, area ROC = 0.83). The AUC of the MPA free form poorly correlated with a single time point concentration. The AUCs of total and free forms of MPAG and AcMPAG highly correlated with a single time point concentration of C (r2 = 0.97) and C (r2 = 0.95) for MPAG and C (r2 = 0.59) and C (r2 = 0.81) for AcMPAG. High variability in metabolites concentrations were observed, suggesting inter-individual variability in drug metabolizing enzyme activity.

Conclusions: At the early stage post transplantation, in renal transplant recipients who received EC-MPS, a single time point of the total form plasma MPA concentration is best monitored at 4 hours post dose. The MPA level of 2.5 μg/ml that time point predicts optimum AUC. Further studies required for the use of metabolites' AUCs to assess drug effect and to evaluate the point concentration that predicts drug exposure.

Preclinical Characterization of MAU868, a Novel Neutralizing Antibody Targeting BK Virus

Atul Sathe,1 Mark Knapp,2 Lihong Zhao,2 Peter Kim,2 Andreas Hein,4 Meike Scharenberg,4 Jacob Shaul,2 Kelly A. Wong,2 Steven J. Kovacs,2 Elisabella Traggiai,3 Amy Patick,2 Johanna R. Abend.1,2 Novartis Institutes for BioMedical Research East Hanover, East Hanover, NJ; 3Novartis Institutes for BioMedical Research Emeryville, Emeryville, CA; 4Amplex Pharmaceuticals, Inc. San Diego, CA; 5Novartis Institutes for BioMedical Research Basel, Basel, Switzerland.

Background: Reactivation of BK virus (BKV) can cause significant kidney and bladder disease in immunocompromised patients. There are currently no effective or BKV-specific therapies. MAU868 is a novel human monoclonal IgG1 that binds to the BKV major capsid protein VP1. Its binding affinity, antiviral activity, and resistance profile were investigated in vitro.

Methods: Binding affinity was determined using a solution equilibrium titration assay.

Results: Neutralization of BKV infection in primary renal proximal tubule epithelial (RPTE) cells was evaluated by quantitating Tag-expressing cells using an immunofluorescence-based assay. The AUC of BKV neutralization was calculated. MAU868 had a μM binding affinity and sub-nM neutralizing activity against the 4 major BKV genotypes, with EC50 and EC90 values ranging from 0.009 to 0.093 μg/ml (0.062 to 0.645 nM) and 0.102 to 4.160 μg/ml (0.708 to 28.865 nM). No cytotoxicity was observed at the highest concentration tested 500 μg/ml. MAU868 also potently neutralized BKV variants constructed to contain VP1 sequences from clinical isolates or highly prevalent VP1 polymorphisms, and JC virus, a related polyomavirus. No RAVs were identified following serial passage of BKV in the presence of MAU868 for up to 182 days. The crystal structure of MAU868 in complex with the VP1 pentamer at 2.6 Å resolution identified a conserved structural information comprising 3 contact residues in VP1 (Y169, R170, K172) that are strictly conserved across BKV isolates. BKV variants with double or triple alanine substitutions at residues Y169, R170, or K172 were non-viable.

Conclusions: The strict conservation of the contact residues within the conformational epitope of VP1 may explain the broad-spectrum antiviral activity of MAU868 and its high in vitro barrier-to-resistance, ideal characteristics for a potential first-in-class therapeutic agent for the treatment or prevention of BKV disease.

PO2368
Pharmacokinetic Evaluation of Drug Interactions Between Vadadustat and HMG-CoA Reductase Inhibitors (Statins)

Ajit B. Chavan,1 Rishikesh Sawant,1 Leontia Burke,2 Susan K. Paulson,1 Akemia Therapeutics Inc, Cambridge, MA; 1AGTC, Cambridge, MA.

Background: Cardiovascular disease is the most common cause of mortality in patients with chronic kidney disease (CKD). Vadadustat is an oral hypoxia-inducible factor (HIF) prodrug that inhibits the HIF prolyl hydroxylase inhibitor (PHI) in late-stage development for the treatment of anemia due to CKD. The prevalence of dyslipidemia in CKD is very high, and nearly 50% of patients have been prescribed statins to decrease cholesterol levels. The disposition of most statins is dependent on metabolic enzymes and transporters. This study evaluated the drug interaction potential for statins when co-administered with vadadustat.

Methods: In this 3-part study (NCT03801733), 108 healthy adults were enrolled for vadadustat-statin pharmacokinetic (PK) evaluation. Vadadustat (600 mg daily) was administered concomitantly with either rosuvastatin (20 mg; n=43), pravastatin (40 mg; n=44), or atorvastatin (10 mg; n=33). Plasma samples were collected at 0, 0.5, 1, 1.5, 2, 2.5, 3, 3.5, 4, 6, 8, 10, and 12 hours post dose. Total and free form levels of MPA and metabolites were measured using a fully validated LC-MS/MS. Receiver operating curve (ROC) was carried out.

Results: No group differences were noted for exposure (AUC and Cmax) to rosuvastatin, a BCRP and OATP1B1 substrate, increased 2- to 3-fold in the presence of vadadustat. No change in exposure to pravastatin (an OATP1B1 substrate) was observed. The AUC for atorvastatin (a BCRP and OATP1B1 substrate) increased 1.4-fold, although no change in Cmax was noted; for simvastatin (a BCRP and OATP1B1 substrate), the AUC increased 2-fold and Cmax increased ≥50% of patients have been prescribed statins to decrease cholesterol levels. The disposition of most statins is dependent on metabolic enzymes and transporters. This study evaluated the drug interaction potential for statins when co-administered with vadadustat.

Conclusions: There were no clinically significant interactions with pravastatin or atorvastatin, suggesting that vadadustat has a low likelihood for OATP1B1-mediated drug interactions. Increases in exposures to rosuvastatin and simvastatin are possibly due to BCRP inhibition. In summary, these results provide information to aid in the management of concomitant administration of vadadustat with statins. Funded by: Akemia Therapeutics, Inc.

PO2369
Impact of Renal Impairment and Dialysis on the Pharmacokinetics and Pharmacodynamics of Roxadustat

Dorien Groenendaal-van de Meent,1 Virginie Kerpuch,2 Rudiger Kaspera,1 Maria Barroso,1 Piergiorgio Galletti,1 Gernot Klein,1 Martin den Adel.1

1Astellas Pharma Europe B. V., Leiden, Netherlands; 2Pharmakspire, Wijchen, Netherlands; 3APEX GmbH, Munich, Germany.

Background: Roxadustat is an orally active hypoxia-inducible factor prolyl hydroxylase inhibitor for the treatment of CKD anemia. The objective was to evaluate the pharmacokinetics (PK), metabolic profile, pharmacodynamics, and safety of roxadustat in patients (pts) with varying degrees of renal function (RF).

Methods: In this phase 1, open-label study (EudraCT: 2015-002565-28), 16 pts were enrolled. An initial dose of 40 mg for group of normal RF; EGfr <90 mL/min/1.73 m2; severe end-stage renal disease (ESRD) on continuous ambulatory or automated peritoneal dialysis (CAPD/APD); or ESRD on hemodialysis or hemofiltration (HD/HDF). Patients in the NRF, SIRF, and CAPD/APD groups received a single dose of 100-mg oral roxadustat on Day 1. Two treatment periods (P1/P2), separated by a washout period, were used for HD/HDF

PO2370
A Genotype-Guided Antihypertensive Therapy and CKD Care Precision Health Initiative
Judith Maddatu, Ranjani N. Moothut, Katherine M. Speich, Nehal Sheth, Michael T. Eadon. Indiana University School of Medicine, Indianapolis, IN.

Background: A precision health initiative was implemented, wherein pharmacogenomic predictors of antihypertensive response and genomic predictors of chronic kidney disease (CKD) were provided to clinicians caring for nephropathy patients.

Methods: This is a prospective cohort study of 580 individuals who presented to outpatient nephrology clinics. Subjects were genotyped for 60 antihypertensive response variants and 10 chronic kidney disease (CKD) predictors. Predictors included variants of CYP2D6 for metoprolol dosing and CYP2C9 for angiotensin receptor blocker dosing. Variants in APOLI, UMOD, and SHROOM3 were markers of CKD risk prediction. Subjects were followed to ascertain utilization of the genetic information by nephrologists.

Results: Subjects were followed for a median of 26 months. A majority of patients (297/580; 52%) were identified with actionable genotypes. The primary nephrologist was surveyed for each subject. In the 143 subjects who completed follow-up, nephrologists reported a change in diagnosis in 44% of their patients and a change in management in 28.0% based on genotype. Clinicians discussed the genetic testing results with their patients in 83.9% of cases.

Conclusions: Nephrologists utilized a genetic testing panel of up to 60 variants in the routine care of their CKD patients. Pharmacogenomics predicts of disease response may prove to be very valuable the care of patients with chronic kidney disease.

PO2371
KBP-5074, a Nonsteroidal Mineralocorticoid Receptor Antagonist, Reduces Urine Albumin-to-Creatinine Ratio and the Risk of Hyperkalemia in a Novel Animal Model of Chronic Kidney Disease
Frederic Jossier,1 Liu Jinrong,2 Shuangshuang Chi,2 Ping Wang,2 Judy Tan,2 Vincent Benn,1 Y. Fred Yang,1 Jay Zhang.1 KBP Biosciences Inc USA Inc; KBP Biosciences Inc USA Inc, Princeton, NJ; 2Khp Biosciences Co Ltd, Jinan, China; 1Centre de Recherche des Cordeliers, Paris, France.

Background: KBP-5074 is a novel non-steroidal mineralocorticoid receptor antagonist (MRA) being developed for uncontrolled hypertension and advanced chronic kidney disease. The primary objective of this study was to evaluate KBP-5074's ability to prevent hyperkalemia in a rat model of nephropathy.

Methods: KBP-5074 was formulated with 27% hydroxypropyl methylcellulose (HPMC) and 73% KHB. Study rats received saline or the vehicle (control) and KBP-5074 at 5, 15, and 50 mg/kg/day for 28 days. On day 21, rats received a single dose of 3.0 mg/kg of KBP-5074 and their urine was collected for 24 hours. Results: KBP-5074 reduced UACR by 40% and 99% respectively on day 26. PK/PD analysis of Urinary Na +/K+ ratio showed a significant effect with a reduction in the ratio for KBP-5074 treated rats compared to vehicle.

Conclusions: KBP-5074 demonstrated a significant effect on UACR reduction with less risk for hyperkalemia compared to eplerenone in a rat model of nephropathy.

PO2372
Pharmacological Inhibition of Vanin 1 Is Not Protective in Models of Acute and Chronic Kidney Disease

Background: Dysregulated oxidative stress handling is a hallmark of acute and chronic kidney diseases. The pantetheinase Vanin-1 is highly expressed in tubular cells and is known to contribute to renal dysfunction by inhibiting the replenishment of cellular anti-oxidative glutathione stores. The aim of this study was to elucidate whether pharmacological inhibition of Vanin-1 protects mice from acute or chronic kidney injury.

Methods: C57B16 mice undergoing ischemia reperfusion injury and Col4a3/- (Alport syndrome) mice were treated orally for 1d and 3wk, respectively, with a potent and selective Vanin-1 inhibitor or placebo. In vitro oxidative stress insult was mimicked in human renal proximal tubular epithelial cells either chemically or by hypoxia/ reoxygenation. Kidney function was assessed by serum urea and urinary creatinine as well as serum urea and urinary albumin. Furthermore, mRNA and protein expression, Vanin-1 activity, oxidative stress level and tubular apoptosis were monitored.

Results: Oxidative stress levels were elevated in all models. Treatment with the Vanin-1 inhibitor resulted in ameliorated systemic compound exposure and full inhibition of Vanin-1 activity in kidney tissue in vivo. However, this did not translate to a relevant reduction of oxidative stress level. Moreover, kidney function (serum Crea, blood urea, albuminuria), fibrosis marker gene expression and tubular cell apoptosis were not improved in Vanin-1 inhibition.

Conclusions: Pharmacological inhibition of Vanin-1 is insufficient to protect kidneys from oxidative stress insult contributing to acute and chronic kidney injury. The biological relevance of pharmacological Vanin-1 inhibition for the treatment of kidney diseases remains to be proven.

PO2373
Evaluation of Veverimer Drug Interaction Potential in Healthy Subjects
Elizabeth Down Parsell,1 Robert Guttedorff,2 Vick Sen Wu,1 Lillian Tsao,1 Tan,2 Vincent Benn,1 Y. Fred Yang,1 Angela Lee,1 Kalpesh N. Bhatia,1 Gerrit Klaerner.1 Tricida, Inc, South San Francisco, CA; 2Aclairo Pharmacetical Development Group, Vienna, VA; 3Unaffiliated, Burlingame, CA.

Background: Veverimer is an orally administered HCl binder for treatment of metabolic acids in CKD. We assessed its potential for drug-drug interactions (DDIs) using a strategy based on its physicochemical characteristics. Since veverimer is a non-absorbed polymer, potential DDIs are limited to effects on absorption of other oral drugs via (1) direct binding or (2) increases in gastric pH resulting from HCl binding.

Methods: Features important for binding to veverimer were determined in vitro. A set of anionic probes and a panel of 16 drugs were used to define characteristics required for binding. Test drugs covered a broad range of size, charge, solubility and permeability characteristics across 14 drug classes. The magnitude and duration of veverimer’s effect on gastric pH was determined in fed and fasting healthy subjects via 22-h monitoring with an intragastric pH probe. Results from binding and gastric pH studies informed selection of drugs for human DDI studies.

Results: In vitro studies showed the most important determinant for binding to veverimer is negative charge, with small size as a secondary determinant. Veverimer did not bind any positively charged, neutral or zwitterionic drugs. Negatively charged drugs (~30 kDa) did not bind; the presence of chloride reduced or eliminated binding. The 2 drugs showing the most binding to veverimer in vitro (furosemide, aspirin) were chosen for human DDI studies. Veverimer increased gastric pH by ~3.0 (fasted) and 1.5 (fed) pH units. The gastric pH increase was transient, peaking by 1 h after dosing and returning to baseline after 1.5 (fasting) and 3 (fed) hours. Based on these results, 2 drugs with pH-dependent solubility (warfarin, dabigatran) were chosen for human DDI studies. In human DDI studies, no clinically meaningful changes in bioavailability were observed for furosemide, aspirin, dabigatran, or warfarin when coadministered with veverimer.

Conclusions: We observed: 1) no effect of veverimer on the bioavailability of drugs most susceptible to binding to the polymer; 2) modest, transient effects of veverimer on gastric pH; 3) no effect on bioavailability of drugs with pH-sensitive solubility. We conclude that there is a negligible risk of clinically significant veverimer DDIs.

PO2374
Action of Veverimer on Gastrointestinal Acid Binding Is Not Affected by Omeprazole
J. Michael Klaerner,1 Robert Guttedorff,2 Y. Fred Yang,1 Elizabeth Li,1 Gerrit Klaerner,1 Vandana S. Mathur.1 Tricida, Inc, South San Francisco, CA; 2Aclairo Pharmacetical Development Group, Vienna, VA; 3PharmaStat LLC, Fremont, CA; 4MathurConsulting, Woodside, CA.

Background: Veverimer, an orally administered, non-absorbed polymer that selectively binds and removes hydrochloric acid (HCl) from the gastrointestinal tract, has been shown to correct metabolic acidosis in patients with CKD. Unlike proton pump inhibitors (PPIs), which do not affect systemic acid-base status, the removal of HCl

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
from the gastrointestinal tract by veverimer leads to a net increase in blood bicarbonate. Veverimer was designed to bind HCl across a wide range of intraluminal pH, but the effect of veverimer on acid binding in the presence of PPIs has not been previously described.

**Methods:** To evaluate the effect of veverimer on gastric pH, we conducted a Phase 1, open-label, 2-stage study in which subjects (N=46) were randomized 1:1:1 to receive 1 of 4 drug treatments (water fasted; water fed; veverimer fasted; veverimer fed) in the presence and absence of a steady-state level of omeprazole. Gastric pH was measured continuously for 22 hours (hrs) using a microelectrode pH probe positioned in the gastric fundus.

**Results:** Ingestion of veverimer caused a modest, transient increase in gastric pH that peaked within 1 hr post-dose. In the absence and presence of food, the median (distribution-free 95% CI) times to peak pH after veverimer administration was 0.25 (0.17, 1.00) and 0.71 (0.25, 1.17) hrs, respectively. Peak pH after veverimer administration was ~3 and ~1.5 pH units greater than that observed after water control in the fasted and fed states, respectively. The magnitudes of these increases were in the same range in the presence of omeprazole. Gastric pH returned to baseline after ~1.5 hrs under fasting conditions and after ~3 hrs under fed conditions. In the presence of omeprazole, the veverimer-induced gastric pH increase dissipated by 4 hrs post-dose or shortly after initiation of the subsequent meal.

**Conclusions:** The effect of veverimer on gastric pH is transient and similar in the presence or absence of omeprazole. The magnitude of the individual effects of food, veverimer, and omeprazole on gastric pH were similar (increase of 2–4 pH units). These findings are consistent with prior studies in patients with CKD in which the magnitude of efficacy of veverimer was unaffected by use of H2-receptor antagonists and PPIs (Wesson et al. Lancet, 2019).

**PO2376**

Circulating Heparin and Its Relevance to Thrombin Generation Profile in ESRD Patients Undergoing Maintenance Hemodialysis

Fahika Siddiqui, Emily Bontecoe, Debra Hoppensteadt, Walter Jeske, Vinod K. Bansal, Jawed Fareed. Loyola University Medical Center, Maywood, IL.

**Background:** End stage renal disease (ESRD) is a complex pathophysiological syndrome which results in vascular disorders and hemostatic disturbance. Despite the use of heparin during maintenance hemodialysis some of these patients exhibit hypercoagulable state. The purpose of this study was to characterize the thrombin generation (TG) profile in ESRD patients in relation to circulating heparin levels.

**Methods:** Citrated blood samples from 95 patients with ESRD undergoing maintenance hemodialysis were collected. NHP was prepared for referencing purposes. Individual samples were supplemented with heparinase. TG was assessed using a kinetic fluorogenic substrate method. TG parameters such as peak thrombin, lag time and area under the curve (AUC) were compiled. Circulating heparin levels were determined using activated partial thromboplastin time (aPTT) and chromogenic anti-Xa and IIa assays. The ESRD cohort was stratified into heparinized and heparin naïve groups.

**Results:** ESRD group showed decrease in peak thrombin (107.1 ± 163.5 μM) and AUC (589.8 vs 815.7 nM·min) with increase in lag time (2.9 vs 2.2 min) compared to NHP. Heparinase supplementation increase the lag time (3.4 min, p value <0.0001), while decrease the peak thrombin (100.0 nM, p value 0.0245) and AUC (503.4 nM·min, p value <0.0001). Such parameters as aPTT (43.2 vs 31.1 sec), anti Xa (0.21 vs 0.14 U/mL) and anti-IIa (0.27 vs 0.15 U/mL) decreased with heparinase treatment. Heparin naïve group showed decreased peak thrombin and AUC values whereas the lag time was increased. Simultaneously aPTT, anti-Xa and anti-IIa levels were decreased in this group. Heparinized patients did not show any difference in peak thrombin, decrease in AUC values and an increase in lag time. However, the aPTT, anti-Xa and anti-IIa levels were decreased in this group.

**Conclusions:** These studies showed that heparinase treatment of plasma samples from ESRD patients resulted in the decrease in the aPTT, anti-Xa and IIa levels suggesting the digestion of heparin. However, contrary to these results, TG parameters such as peak thrombin and AUC were decreased whereas lag time was increased suggesting that the depolymerized heparin fragments possessed thrombin generation inhibitory properties.

**PO2377**

Clinically Apparent AKI Secondary to Suspected Vancomycin Toxicity: A Cellular Kinetic Analysis

Ryan P. Flood, Matthew Ray, Judith Blaine, Anip Bansal. University of Colorado Denver School of Medicine, Aurora, CO.

**Background:** The use of antimicrobial therapies for treatment of hospitalized patients is abundant. While the usage rate of antibiotics has remained stable over the last decade, however, with the emergence of methicillin-resistant staphylococcus aureus, vancomycin usage has increased during that same time period. Although vancomycin induced AKI or vancomycin associated nephrotoxicity (VAN) has been a topic of debate for the patient analysis, IRB approval was obtained to evaluate the cases of possible VAN on the renal consult service.

**Results:** Creatinine secretion through the cellular epithelium was not affected by transporters does not cause creatinine elevation in concentrations used clinically. The patient cohort analysis identified 12 cases of clinically apparent vancomycin associated nephrotoxicity (VAN) has been a topic of debate since its generalization use approximately 50 years ago, the proposed mechanism of VAN is an on-going focus of research. The current study aims to answer whether proximal tubular creatinine secretion, which can account for upwards of 20% of creatinine clearance, is impacted by vancomycin dosing, and whether vancomycin trough levels seen in clinical practice alter this relationship.

**Methods:** For the cellular kinetic analysis, we took immunomized human proximal tubule epithelial cells, and after allowing them to epithelialize on a semi-permeable membrane, evaluated creatinine secretion in the presence of varying concentrations of both vancomycin and vancomycin, while measuring eliminated levels for up to 24 hours. For the patient analysis, IRB approval was obtained to evaluate the cases of possible VAN on the renal consult service.

**Conclusions:** These studies showed that heparinase treatment of plasma samples from ESRD patients resulted in the decrease in the aPTT, anti-Xa and IIa levels suggesting the digestion of heparin. However, contrary to these results, TG parameters such as peak thrombin and AUC were decreased whereas lag time was increased suggesting that the depolymerized heparin fragments possessed thrombin generation inhibitory properties.
traditionally not been associated with systemic vancomycin toxicity. We report here an incidence of vancomycin nephrotoxicity secondary to a sternal vancomycin slurry that required dialysis.

**Case Description:** A 62-year-old 91 kg man with Marfan’s Syndrome and total aortic arch replacement presented with mediastinal abscess and recurrent sternal osteomyelitis. A transplant surgeon and an on-call vascular surgeon echoed a circumferential fluid collection around the aortic graft. He underwent a “redo” aortic arch replacement and a trans-sternal incision revealed a 45 to 22 mL/min decrease in renal function. Heightened awareness about medication toxicity developing in renal insufficiency is underrecognized. In this case report, the patient with AKI only was saline, naloxone, and intravenous. Carazol. Despite these, she became progressively confused and developed cr to 2.77 mg/dL. Urine output improved to 1200 mL/day. He was dialyzed after 5 rounds of dialysis, serum vancomycin concentration lowered to 8 mg/L and P. 6.45mg/dL. 

**Discussion:** There can be substantial unaccounted systemic absorption from vancomycin slurry. The POD4 serum level was 48 mg/dL and he was dialyzed 14 hours later under operating conditions such that the level should be reduced by at least one-third. The post dialysis level was 47 mg/dL, so by conservative estimation his predialysis level was about 70 mg/L, suggesting that there was a substantial contribution of vancomycin to the serum level in that 17-hour interval from sternal slurry.

**Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.**

**PO2381**

**Gabapentin Toxicity in Existing and Developing Renal Failure**

**Introduction:** Gabapentin is a medication used to treat partial onset seizures, neuropathic pain caused by diabetic neuropathy, postherpetic neuralgia, & central neuropathic pain. This medication is nearly completely excreted by the kidneys. It is recommended as one of a number of first-line medications for the treatment of pain.

**Case Description:** Here we report two cases of potential Gabapentin toxicity across the spectrum of renal insufficiency. The first case was a 48-year-old female with a history of ESRD (HD X 3 times/week), HCV, DM, HTN and spinal abscess presented with new onset seizure, body stiffening with head and eye deviation, confusion, fall and hypertensive emergency while awaiting for dialysis. She had a second seizure while in the ED and was started on anti-seizure medication Levetiracetam. Home medications included Gabapentin (800 mg TID). Head CT was unremarkable. The second case was a 69-year-old female patient with a history of DM, peripheral vascular disease, coronary artery disease & atrial fibrillation who presented with non-healing left heel ulcer. Home medications included Gabapentin (300 mg 3 times daily). The patient developed contrast-induced AKI due to a CT angiogram procedure on admission. Following the development of AKI, the patient became confused without evidence of significant azotemia (BUN 33). Both the cases were found to be arousable and GCS of 12/15, intact strength & sensation of both extremities, no ataxia, dysarthria, hemigemite or signs of pronator drift. In both cases, Gabapentin toxicity was suspected and the dosage of Gabapentin was reduced to 100 mg orally at night. There was a drastic improvement of confusion and other symptoms within 2 to 3 days post dosage adjustment in both patients.

**Discussion:** Renal insufficiency predisposes patients to increased risk of gabapentin induced toxicity due to reduced clearance. Advanced age and other comorbidities may further accelerate the risk. The range of Gabapentin toxicity across the spectrum of renal insufficiency is underrecognized. In this case report, a patient with AKI only was confused and the patient with ESRD had myoclonus and seizure in addition to confusion. There seems to be a graded increase in toxicity with the corresponding deterioration of renal function. Heightened awareness about medication toxicity developing in renal failure is important to prevent significant adverse effects.

---

**PO2382**

**Gabapentin-Induced Edema Masquerading as Treatment-Resistant Heart Failure**

Muhammad Shahzad, Ankur Shah. Warren Alpert Medical School of Brown University, Providence, RI.

**Introduction:** Gabapentin is widely used in the management of neuropathic pain but has multiple well-known side effects but less recognized is edema. We describe a case of gabapentin induced edema, which was misdiagnosed as CHF exacerbation, resulting in significant diuretic use and stage 3 AKI.

---

**PO2380**

**Extracorporeal Removal of Valproic Acid in Overdose: A Case Report**

Jessie Beaulieu, Andréanne Côté, Marc Ghannoun. CHU de Québec-Université Laval, Quebec, QC, Canada; Cité internationale universitaire de sante et de services sociaux du Nord-de-l’Île-de-Montreal du Quebec, Montreal, QC, Canada.

**Introduction:** Valproic acid (VPA) is considered not dialyzable at therapeutic concentration and dialyzable at supratherapeutic concentration because of saturable protein binding which increases its free fraction (from 10% to 90%).

**Case Description:** We report a case of a 53-year old 50kg woman admitted for suicidal polydrug intoxication. She had ingested 15g of VPA, 300mg of atorvastatin, 3g of quetiapine, and 750mg of naltrexone 3 hours prior to admission. Her vital signs were stable on admission and she was somnolent but arousable. Blood analyses for ethanol, acetaminophen, and salicylates were negative. Biochemistry, blood gases, and complete blood count were unremarkable. She was initially treated with intravenous
Case Description: An 85-year-old male with a past medical history of stage 4 chronic kidney disease secondary to diabetic nephropathy (baseline serum creatinine 2.2.5mg/dl). Type 2 Diabetes Mellitus, diabetic neuropathy, and hypertension, presented to clinic for worsening of serum creatinine. Pertinent home medications included bumetanide 3 mg BID, metolazone 2.5 mg daily and gabapentin 600 mg TID. Bumetanide and metolazone were up titrated for worsening bilateral lower extremity edema over last 3 months with 20-pound weight gain. Exam was notable for 2+ LE edema. His serum creatinine progressively increased from 2.4 to 4 mg/dl in the setting of aggressive diuresis. A recent TTE showed only grade 1 diastolic dysfunction. The presumed diagnosis was heart failure with reduced ejection fraction. Urine sediment was bland. After identification of gabapentin as potential culprit agent for his edema, both gabapentin as well as his diuretics were discontinued with a resultant significant drop in his weight and serum creatinine to 218lbs and 2.7mg/dl respectively over next one month and complete resolution of his edema.

Discussion: Incidence of gabapentin induced edema varies from 2% to 8% and has been correlated to dosage. Exact mechanism is unknown but possibly related to loss of venoarteriolar reflex leading to increased capillary hydrostatic pressure and hence increased net capillary fluid filtration into the interstitium. Gabapentin induced edema, just like calcium channel blockers induced edema, is not associated with salt and water retention and hence diuretics are ineffective. Physicians, especially nephrologists, should be mindful of uncommon side effect of this commonly prescribed medication as distinguishing this early can prevent a lot of unnecessary work up and potentially prevent harm to the patient.

PO2384
Glomerular Changes in Transplant Glomerulopathy
Samir Husami, Dina Hammad, Jeffrey H. Miner, Tarek Alhamad, Hani Suleiman. Washington University in Saint Louis Department of Medicine, Saint Louis, MO.

Background: Transplant glomerulopathy (TG) affects 20% of transplanted kidneys 5 years post transplantation. It carries an important significance due to its correlation with decreased graft survival. Repeated endothelial cell injury by chronic active antibody mediated rejection (CAMR) leads to glomerular basement membrane (GBM) reduplication and thickening, the hallmark finding of TG. Based on our previous molecular mapping of the GBM, we aim to define the composition of the thickened GBM in TG using super-resolution microscopy.

Methods: Two super-resolution microscopy techniques, STORM (Stochastic optical reconstruction microscopy) and Airyscan, were used to image confirmed TG and control biopsies. For STORM, fresh frozen, 200 nm sections were imaged. While for Airyscan, 1-3 microns, formalin fixed paraffin embedded (FFPE) sections were used. Samples were labeled with antibodies for Laminin α5, Integrin α8, Myosin IIA, Vimentin, Synaptopodin, Integrin b1, Fibronectin, and several Collagen IV chains.

Results: STORM TG samples showed increased distance between Integrin b1 labeled membranes, indicating thickening of the GBM. Collagen α3α4α5(IV) did not change, while Collagen α1α2α(V) was increased at the GBM's endothelial aspect. There was an increase in Fibronectin, suggesting a role for the TGfβ pathway. Airyscan TG images showed Vimentin- and Integrin αIIa positive areas inside the GBM, indicating cellular protrusions extending into the GBM. Since these markers stain mesangial as well as endothelial cells, this suggests differentiation of endothelial cells and transition to mesenchymal cells. We detected alternating Myosin IIA and Synaptopodin labeling in the form of "Sarcomere-like structures".

Conclusions: Our data revealed increased Collagen α1α2α(V) secreted from the endothelial side, while Collagen α3α4α5(IV) was unchanged at the GBM's endothelial aspect.

PO2385
Calcineurin Inhibitor Cyclosporine A but Not Tacrolimus Induces Proapoptotic Endoplasmic Reticulum Stress in Kidney Epithelial Cells
Duygu E. Yilmaz,1 Karin M. Kirshner,1 Hasan Demirci,1 Sebastian Bachmann,1 Kerim Mutlu,2* Charlie Universitätsmedizin Berlin, Berlin, Germany; 1L.M. Sеченov First Moscow State Medical University (Sеченov University), Moskva, Russia.

Background: Current immunosuppressive strategies in solid organ transplantation rely on the calcineurin inhibitors (CNI), cyclosporine A (CsA) or tacrolimus (Tac). Their nephrotoxicity is a major limitation for long-term usage. We hypothesized that CsA compared to Tac exerts more pronounced toxic side effects at the cellular level, with endoplasmic reticulum (ER)-stress and maladaptive unfolded protein response (UPR) as the most prominent landmarks.

Methods: To test this hypothesis we treated human embryonic kidney (HEK293) cells with CsA (10 μM) or Tac (10 μM) for 6h. The established ER stress-inducing agent, thapsigargin, served as positive control. To study the molecular mechanisms of CNI-induced cell toxicity we studied genetically-modified HEK293 cells lacking the crucial UPR elements, PERK or ATF6. Abundances of the ER-stress sensor IRE1α, adaptive transcription factor XBP1, and proapoptotic transcription factor CHOP were evaluated as endpoints.

Results: Treatment of native HEK293 cells with CsA or Tac equally increased phosphorylation of the known calcineurin substrate, NFAT, verifying the treatment protocols. CsA increased levels of activating IRE1α phosphorylation (pIREA) and stimulated both CHOP and spliced XBP1 (sXBP1) products. In contrast, Tac enhanced pIREA1a abundance only. CsA but not Tac significantly increased the number of cleaved caspase 3-positive cells suggesting enhanced apoptosis rate. Treatment with the chemical chaperone, TUDCA, partially abolished the CsA-induced increases of CHOP but did not affect sXBP1, suggesting alleviation of ER-stress. Knockdown of CsA binding partners, cyclophilin A and B, by siRNA reduced their expression approximately by half and increased CHOP expression suggesting that suppression of cyclophilins may contribute to CsA-induced cellular toxicity. PERK- or ATF6-deficiency blunted the increases of CHOP and sXBP1 in response to CsA, suggesting an implication of these pathways in CsA-induced ER-stress and UPR.

Conclusions: In summary, CsA but not Tac induces pronounced ER-stress and proapoptotic UPR. Pharmacological modulation of UPR bears the potential to alleviate CNI nephrotoxicity.

Tubular Cell Binding of β-Catenin to TCF1 or FoxO1 Associates with Chronic Fibrosis and Adverse Outcomes in Transplanted Kidneys

Guoping Zhou,1 Ying Yang,1,2 Brian J. Nankivell,1 Padmashree Rao,1 Xiaojun Ren,2,3 Hong Yu,4 Titi Chen,5 Qi Cao,5 Tiping Wang,5,2,6 Vincent W. Lee,7 Stephen I. Alexander,7 Natasha M. Rogers,7 David Harris,3 1University of Sydney, Sydney, NSW, Australia; 2Children’s Hospital at Westmead, Westmead, NSW, Australia; 3Shanshi Medical University, Taiyuan, China; 4Shansi Bethune Hospital, Taiyuan, China; 5Westmead Institute for Medical Research, Westmead, NSW, Australia.

Background: β-catenin is a key transcription factor via which multiple fibrogenic pathways converge. Importantly, it binds to multiple transcription co-factors mediating diverse signaling pathways. Its role in kidney transplantation is unknown.

Methods: A proximal tubular protein binding of β-catenin within renal tubular epithelial cells to transcription factors, TCF1 and FoxO1, in 240 transplanted kidneys. Their correlation with pathological and clinical outcomes was evaluated.

Results: β-catenin-FoxO1 binding in 1-month protocol biopsies inversely correlated with contemporaneous chronic fibrosis, and subsequent inflammation and inflammatory fibrosis (P < 0.001). The relative binding of β-catenin-TCF1 versus β-catenin-FoxO1 (TF ratio) was the optimal prognostic biomarker compared with individual components, and abnormal in a diverse range of fibrotic transplant diseases. A high 1-month TF ratio was followed by greater tubular atrophy and interstitial fibrosis scores, cortical inflammation, renal impairment, and proteinuria at one year (n = 131, all P < 0.001). TF ratio predicted reduced eGFR (AUC 0.817), mild fibrosis (AUC 0.717) and moderate fibrosis (AUC 0.769) using receiver-operating-characteristic analysis, exceeding conventional clinical and predictors including baseline fibrosis. An independent validation cohort (n = 76; confirmed 1-month TF was associated with 12-month moderate fibrosis (15.8% versus 2.6%, P = 0.047), but not with 10-year graft survival.

Conclusions: In conclusion, differential binding of β-catenin to TCF1 rather than FoxO1 is predictive of fibrogenic response in transplanted kidneys.

Immunosuppression by Cyclosporine A Affects Proximal Tubular Homeostasis via Endoplasmic Reticulum Stress

Suncica Popovic,1 Junda Hu,2 Hasan Demirci,1 Duygu E. Yilmaz,1 Carsten Dittmann,1 Yan Xu,1 Martin N. Thomson,1 Kerim Mutig,1,2 Sebastian Bachmann,1 1Charite Universitaetsmedizin Berlin, Berlin, Germany; 2Peryvyi Moskovskij gosudarstvennyj medicinskij universitet imen i M Sechenova, Moskva, Russian Federation.

Background: Calcineurin inhibitors (CNI) such as cyclosporine A (Csa) or tacrolimus are first-line immunosuppressive drugs used after solid organ transplantation. However, renal side effects such as vascular and tubulo-interstitial malformations regularly occur in their long-term usage, especially in patients with renal allografts. Measures to reduce CNI nephrotoxicity by RAS inhibition or calcium antagonism had regularly occur in their long-term usage, especially in patients with renal allografts. Measures to reduce CNI nephrotoxicity by RAS inhibition or calcium antagonism had limited success. Dysfunctions in renal epithelial proteinuria is suggested CNI-induced drainage system and malfunctions of tubuloglomerular feedback (TGF) responses.

Methods: We have established a rat model for chronic CNI nephotoxicity to test whether epithelial pathology and loss of functioning nephrons are related to ER stress and TGF dysfunctions and malfunctions of tubuloglomerular feedback (TGF) responses. Methods: We have established a rat model for chronic CNI nephotoxicity to test whether epithelial pathology and loss of functioning nephrons are related to ER stress and TGF dysfunctions and malfunctions of tubuloglomerular feedback (TGF) responses.

Results: Rats with Csa displayed a stimulated RAS and increased distal NaCl transporter activity along with decreased urine volume, GFR, FE Na, and COX-2 expression. Pathological changes in vasculature and glomeruli were inconspicuous, whereas early proximal tubular segments (S1, S2) revealed large lysosomal vacuoles with granular content, their abundance correlating with epithelial dedifferentiation, basement membrane thickening, and subepithelial collagen I accumulation. Protein endocytosis was diminished. Changes in UPR included enhanced pERK2a, pPERK, CHOP, and BiP levels. Parallel studies in cultured cells indicated sensitivity to chemical chaperones ameliorating proteinuria.

Conclusions: These results suggest a so far unrecognized role of proximal tubular homeostasis in long term Csa-induced nephrotoxicity. Addressing UPR failure and restitution of proteinuria in proximal tubule may, therefore, have renoprotective potential.

Fibroblast culture from CABMR patients were cultured to purity and to mimic this condition fibroblast were pre stimulated with IL-6 (20ng/μL), IL-17 (50ng/μL), IL-6 plus IL-17 for 24 hrs and culture supernatant were collected for IL-6 ELISA to see synergistic activation. Serum IL-6 levels of CABMR and Non-CABMR patients were measured by ELISA. mRNA expression of pro-fibrotic genes; COL1A1, FN1, ASMA1, and anti-fibrotic gene; MMP2/TIMP was analyzed by real-time PCR. Student’s t-test was used for statistical analysis in SPSS 17 software.

Results: IL-6 in sera of CABMR patients was significantly higher (p<0.001) than non-rejection patients. In comparison to IL-6 and IL-17 alone these cytokines synergistically induced IL-6 production from renal fibroblasts(Fig 1). Together IL-6+IL-17 significantly increased the expression of COL1A1, ASMA1, Fibronectin and synergistically induced more IL-6 production from renal fibroblasts(Fig 1). Together than non-rejection patients. In comparison to IL-6 and IL-17 and untreated fibroblasts.

Conclusions: CABMR is perpetuated by inflammation amplifier or synergistic induction of IL-6 and IL-17 which results in chronic inflammation and Allograft rejection. Anti-IL-6 may attenuate the CABMR related injury.

**B-Cell Maturation Phenotypes and Time Post-Transplant**

Alcino Gama, Olivier Despy, Stephanie Beland, François Bouchard-Boivin, Sacha A. De Serres. CHU de Quebec-Universite Laval, Quebec, QC, Canada.

**Background:** Over the past decade, B cell participation in allograft response has been progressively elucidated. Beside the occurrence of DSA (donor-specific alloantibodies), different patterns of B cell phenotypes are also being related to graft outcome. Loss of naive B cells and appearance of memory B cells have been linked to chronic rejection and ultimately to graft loss. Here we show the impact of time post-transplant on phenotypic B cell changes, particularly regarding different distributions of naive B cells.

**Methods:** Single-center, observational cohort of 82 kidney transplant recipients (KTr), adults and clinically stable. Blood samples were collected between January 2015 and November 2018. Peripheral blood mononuclear cells (PBMCs) were isolated and analyzed on flow cytometry. B cells (CD19+) were stained for CD38 and IgD and classified according to Bm classification (IgD vs CD38).

**Results:** The median time post-transplant was 2.9 [0.9-9.89] years and the mean age was 54±13 years. 63% of the patients were males and mean eGFR was 49±17mL/min. B cells absolute counts were lower in later phases post-transplant (R=-0.4, p<0.01). Among all B cell subtypes, Bm2 compartment (comprised mainly by naive B cells) had the most significant reduction in both absolute counts (R =-0.62, p<0.01) and relative percentage (R =-0.58, p<0.01) over time. The opposite, mature B cells (both Bm5 and early Bm6 compartments) absolute counts did not differ over time (R =-0.04 and 0.11 respectively, p=0.05) whereas the percentages of them were positively correlated with time post-transplant (R =0.40 and 0.56 respectively, p<0.01). Linear regression model showed that the absolute reduction in Bm2 cell compartment (i.e naive B cells) was independent of age, sex, graft function and immunosuppression scheme.

**Conclusions:** Patients with longer time post-transplant have fewer circulating peripheral B cells. Phenotypic analysis of B cells subsets reveals that this reduction is due to an absolute decrease in naive B cells counts. Mature B cell absolute numbers, on the other hand, did not change significantly. Either exhaustion due to long-term immunosuppression or immunologic accommodation due to chronic allograft exposure could explain these observations.

**Donor Derived Cell-Free DNA in Renal Transplants, Allosure vs. Prospera**

Ali Khalil,1 Salmon Khan,1 Erica Kalu,1 Muhammad Sain,1 Mark J. Lerman,1 Medical City Dallas Kidney Transplant 1Medical City Dallas Hospital, Dallas, TX; 2Dallas Nephrology Associates, Dallas, TX.

**Background:** The risk for allograft loss remains high due to rejection. Measuring donor cell free DNA has recently become an important noninvasive test for renal allograft injury and rejection. Two of the commercially available tests to measure dd-cfDNA, are Allosure(AS) and Prospera.

**Methods:** We measured dd-cfDNA in 44 post kidney transplants simultaneously using both tests. Patients were 3 to 50 months post kidney transplant and all samples were drawn for cause. Eleven of the 44 patients had allograft biopsies, see table. All patients had routine labs including trough CNI levels and in some cases DSA and/or BK PCR.

**Results:** 44 patients had side by side dd-cfDNA done using AS and Prospera for cause. There were 5 patients with either ACR 1a or 1b or AMR on biopsy. 6 patients had no rejection on biopsy. Please see image for statistical analysis.

**Conclusions:** There was no statistical difference between dd-cfDNA as measured by both commercial tests in all 44 patients, including 5 with ACR or AMR and 6 without rejection by biopsy. We acknowledge the number of patients who underwent biopsies were small. Prospera demonstrated larger measurements of dd-cfDNA in comparison to AS, but this was not statistically significant p=0.27. Side by side analysis showed AS had marginally better AUC but no significant differences between diagnostic test characteristics observed. AS had better specificity, PPV, and NPV, but this did not reach statistical significance.

**Donor-Derived Cell-Free DNA Kinetics After Kidney Transplant Biopsy**

Yousuf Kyeso,1 Anshul Bhalla,2 Alyssa P. Smith,1 Safa Alakhdhair,1 Mohammad Abuzeinich,1, Daniel C. Brennan,1 Sami Alasfar,1 ’Johns Hopkins Medicine, Baltimore, MD; 2Methodist University Hospital, Memphis, TN.

**Background:** Donor-derived cell-free DNA (dd-cfDNA) has generated interest as a potential biomarker for kidney transplant (KT) rejection. It is possible that the KT biopsy procedure itself can cause the release of dd-cfDNA in the blood stream, therefore affecting the reliability of this assay in the post biopsy period. In this study we evaluated the effect of KT biopsy on the level dd-cfDNA and assessed the magnitude and duration of this effect.

**Methods:** We conducted a single arm prospective study. Samples were collected from 16 adult KT recipients undergoing renal allograft biopsy. All participants had samples drawn within eight hours prior to the biopsy (pre-biopsy), within 20 minutes (hour 0), 2 hours after (hour 2), and 24-48 hours (hours 24-48) after the biopsy.

**Results:** Mean age at the time of biopsy was 50.6 ± 7.02 years. Most participants were men and Caucasian. Mean serum creatinine at the time of biopsy was 2.24 ± 0.42 mg/dL. The most common reason for obtaining biopsy was rise in serum creatinine, while 4 patients had the biopsy due to elevation in dd-cfDNA. The pre-biopsy time point was compared against all remaining time points. At hour 0 and hour 2, there was a significantly larger log dd-cfDNA mean scores compared to pre-biopsy time point (0.37 vs -0.44, p=0.006), (0.35 vs -0.44, p=0.03) respectively. By 24-28 hours post biopsy there was no significant difference in log dd-cfDNA mean score compared to the pre-biopsy score.

**Conclusions:** KT biopsy leads to an increase in dd-cfDNA percentage after the procedure, however, this rise is transient and resolves by 24-48 hour after the biopsy. Providers can obtain dd-cfDNA level as soon as 48 hours post biopsy with high confidence that the levels have not been affected by the biopsy.

**Funding:** Commercial Support - This study was an investigator initiated study supported by CardEx, Inc., Brisbane, CA.
Results: Of 208 biopsies done at a median of 5.8 months post-transplant, 108(52%) were done for allograft dysfunction; 74(36%) for surrogates to DSA) and 26(12%) for post-rejection treatment surveillance. There were significant discrepancies between Hx and MMDx; with MMDx(92; 44%) identifying a higher number of rejection cases vs Hx(79; 38%). While MMDx identified a higher number of antibody-mediated rejection cases(65; 31%) than Hx(43; 21%); the opposite was true for T-cell mediated rejection[TCMR; Hx:27(13%) vs MMDx: 13 (6%); AUC Curves for cDNA concentration and prediction of rejection were more robustly correlated with MMDx(AUC=0.830; p<0.001) than with Hx(AUC=0.75; p<0.001). The median cDNA levels increased significantly to rejection treatment(median 0.94 to 0.29; p=0.015) vs non-responders(0.76 to 0.82; p=0.25)

Conclusions: In this single-center study, for the first time we describe the calibration of dd-cfDNA with simultaneous assessment of kidney transplant biopsy with traditional histology and MMDx. We confirmed and expanded on the data from the DART study where a cut-off<1% was highly sensitive and specific for ruling-in rejection. We report the correlation of cfDNA with response to rejection therapy. We propose that the combination of tissue gene expression using the molecular microscope and blood-based ddcfDNA may add precision to traditional histology and could change future practice and treatment paradigms

PO2396
Elevated Donor-Derived Cell-Free DNA (dd-cfDNA) Associated to Antibodies Type I Receptor Receptors (AT1R-Ab) in Renal Re-Transplantation
Howard H. Coké,1 Matthew Van Norman,1 Akshata Pai,2 Aleksandra De Golovine,2 Angelina Edwards,2 1University of Texas McGovern Medical School, University of Texas John P and Katherine G McGovern Medical School, Houston, TX; 2Memorial Hermann Texas Medical Center, Houston, TX.

Introduction: Complications of renal transplants include graft rejection and failure. Noninvasive dd-cfDNA values greater than 1% detect renal allograft injury and rejection, prior to changes in creatinine. Although antibody mediated rejection (AMR) typically involves donor specific antibodies (DSA) to human leukocyte antigens (HLA), non-HLA antibodies may also impact allograft outcomes. This series of re-transplantation patients with graft injury from AT1R-Ab (>10 U/mL) shows improvement in dd-cfDNA levels with treatment of an ARB.

Case Description: Case #1: 23 year-old man with history of CKD IV due to hypoplastic kidneys. First transplant living unrelated donor failed due to renal vein thrombosis. Received 2nd deceased donor transplant (DDRT) with thymoglobulin induction. Combined panel reactive antibodies (cPRA) was 99%, with no DSA. Post-transplant allograft function was excellent with nadir creat of 1.0mg/dL. Losartan was initiated with a sustained decrease in dd-cfDNA to <0.3% and stable creatinine levels. Case #2: 63 year-old woman with ESRD from hypertension. Prior living donor transplant failed due to chronic allograft nephropathy. Received 2nd DDRT with thymoglobulin induction given cPRA of 98%, with no DSA. Post-transplant allograft function was excellent with nadir creatinine of 0.8 mg/dL. Non-invasive allograft injury surveillance showed an acute rise in dd-cfDNA to 3.9% on post-operative week 5. Despite stable creatinine, a renal biopsy showed C4D-negative, mild antibody mediated rejection with peritubular capillaritis (ptc 2) and glomerulitis(g1). Antibody assessment showed no DSA but positive AT1R at 16 U/mL. Following Losartan initiation, dd-cfDNA decreased to <1%, with continued excellent graft function.

Discussion: AT1R-Ab may be more prevalent in the re-transplant population and is a causative factor for accelerated allograft injury, chronic fibrosis, and graft loss. Detection of injury via dd-cfDNA, prompt assessment of AT1R-Ab, and initiation of ARB therapy may lead to preserved allograft function, particularly in high immunologic risk patients.

PO2397
Class II Donor-Specific Anti-HLA Antibody Level Is the Major Determinant of Elevated Donor-Derived Cell-Free DNA in Renal Allograft Recipients
Maria Batia,1 Bogdan Obregon,1 Ramasamy Bakhavatsalam,1 Kelly D. Smith,1 Iris C. De Castro,1 Christopher D. Blosser,1 Lena Shibulesky,1 Catherine Kling,1 Gener Ismail,1 Bogdan M. Sorohan,2 Nicolae Leca,1 1University of Washington, Seattle, WA; 2Fundeni Clinical Institute, Bucharest, Romania.

Background: Dd-cfDNA is a biomarker of allograft injury used for rejection risk monitoring. We sought to analyze the relationship between dd-cfDNA and DSA. We included all kidney transplant recipients (n=171) who underwent DDA and dd-cfDNA testing as part of their clinical care between 9/17-12/19 at our center. We aimed to identify independent predictors of high dd-cfDNA (at a cut-off of 1%).

Methods: We included all kidney transplant recipients (n=171) who underwent DDA and dd-cfDNA testing as part of their clinical care between 9/17-12/19 at our center. We aimed to identify independent predictors of high dd-cfDNA (at a cut-off of 1%).

Results: Table 1 outlines clinical characteristics. There was a strong association between absolute dd-cfDNA level and DSA MFI category (Figure 1). In multivariate logistic regression analysis, DSA MFI was an independent predictor of high dd-cfDNA (Figure 2).

Conclusions: dd-cfDNA is strongly associated with class II DSAs and MFI level. Variability observed identifies dd-cfDNA as a potential biomarker for monitoring allograft injury status in patients with DSA.

Case Series: Systemic Infection Alters Background Cell-Free DNA and Influences Results of Donor-Derived Cell-Free DNA Transplant Rejection Assays

Suthaphum Bunnapradist,1 Philippe M. Gauthier,2 Hossein Tabriziani,2 Ryan Swenerton,3 Ebad Ahmed,3 Trudy McKenna,3 Paul R. Billings,3 1University of California Los Angeles, Los Angeles, CA; 2Natera, Inc, San Carlos, CA.

Introduction: Donor-derived cell-free DNA (dd-cfDNA), a biomarker for kidney transplant rejection, is reported as a percentage of background cfDNA. Various factors affect total cfDNA levels (3,4). We present 3 cases with elevated background cfDNA where dd-cfDNA was assayed for rejection assessment.

Case Description: 1: A 78 year old man with end-stage renal disease (ESRD) underwent a kidney transplant. A biopsy at +6 months (m, all time points relative transplant date) due to an elevated creatinine level indicated an acute T cell-mediated rejection (TCMR). At +7m, the patient tested positive for BK viremia, and was treated. He was admitted for nephrectomy of his native kidney at +14m and tested positive for herpetic and cytomegalovirus (CMV) esophagitis and treated. A cfDNA analysis was negative for rejection with background cfDNA ~10,326 Arbitrary units (AU)/mL (~21X median cfDNA). Banff chronic active cellular rejection was confirmed from a subsequent biopsy. 2: A 62 year old woman with ESRD who underwent a kidney transplant had a cfDNA assay at +3 years, that was reported as a negative result. However, the background was elevated at 3,466 AU/mL (~7X median). She had a biopsy that showed BK virus-associated nephropathy and TCMR. 3: A 53 year old woman with ESRD had a kidney transplant from an ABO incompatible donor. A month later, she was diagnosed with dengue fever followed by acute allograft dysfunction. A biopsy at +6m showed active antibody-mediated rejection (ABMR). On a cfDNA assay at +7m indicated a negative result; however with an elevated background (6344 AU/mL, ~13X median). A biopsy showed resolution of ABMR and border line acute cellular rejection.

PO2399

Donor-Derived Cell-Free DNA Identifies Patients with Antibody-Mediated Rejection and Strongly Correlates Histologically with Microvascular Inflammation

Bogdan Obrisa,1 Maria Buti,1 Ramsamy Bakhavatsalam,1 Kelly D. Smith,1 Iris C. De Castro,1 Christopher D. Blosser,1 Lena Sibuleysa,1 Catherine Kling,1 Gener Ismail,2 Bogdan M. Sorohan,2 Nicolae Leca,1 1University of Washington, Seattle, WA; 2Fundeni Clinical Institute, Bucharest, Romania.

Background: Accurate and timely detection of rejection is central to improving long-term kidney transplant outcomes. We sought to characterize the association of dd-cfDNA level with rejection status and histological lesions.

Methods: We included all patients (n=54) that underwent a kidney transplant biopsy for suspicion of rejection at our center between 9/17-12/19. Concurrent dd-cfDNA andDSA testing was obtained. Rejection type (Banff 2017) and histological lesions were tested for association with dd-cfDNA level.

Results: 18 patients had ABMR (6 mixed ABMR/TCMR), while 12 patients had TCMR alone. Of those with ABMR, 94.4% had a dd-cfDNA level >1%, compared to 16.6% of those with TCMR alone (p<0.001). Of those with a high dd-cfDNA (>1%), 76.2% had both DSA and ABMR. In multivariate logistic regression analysis, a high dd-cfDNA was a more important predictor of ABMR than a DSA MFI level over 2500 (Fig1). A high dd-cfDNA accurately discriminates ABMR (AUC=0.96; 95%CI, 0.92 to 1.00; p<0.001), with a positive and negative predictive value of 80.9% and 96.9%, respectively. Dd-cfDNA level showed a strong correlation with microvascular inflammation (Fig2), but not with tubulitis or interstitial inflammation.

Conclusions: Our study confirms the high diagnostic accuracy of dd-cfDNA for ABMR, while the strong association with elementary lesions of microvascular inflammation supports the specificity of this test for antibody-mediated allograft injury.

PO2400
Impact of Body Mass Index on Baseline Donor-Derived Cell-Free DNA in Kidney Transplant Recipients

Background: Donor derived cell free DNA (dd-cfDNA) is useful in predicting acute rejection in renal allografts. The technology uses next generation sequencing and does not require donor genotyping. dd-cfDNA is expressed as a percentage of the total (including self and non-self) circulating DNA fragments. Since self-portion of cell free DNA can vary according to body size, we aimed to test the hypothesis that expressed percent of baseline dd-cfDNA can vary by the recipient’s body mass index (BMI).

Methods: Our center has been doing for-cause as well as surveillance (for high immunologic risk) dd-cfDNA in kidney transplant recipients (KTRs) using AlloSure (CareDx, Brisbane, CA). We identified patients who underwent kidney transplantation between September 2017 and June 2019 and had serial dd-cfDNA levels. A dd-cfDNA value ≥1% prompted allograft biopsy. KTR with biopsy evidence for rejection or other injuries were excluded from the analysis. Study subjects were divided into BMI (kg/m²) groups as follows: <25, 25-29.9, 30. Baseline dd-cfDNA values were compared between BMI groups.

Results: There were 88 (81 first-time and 7 repeat) KTRs during the study period who had dd-cfDNA measurements and available BMI. We excluded 16 first-time and 3 repeat KTRs from the analysis due to biopsy evidence of rejection. The remaining 69 patients had 227 dd-cfDNA levels available for analysis. Patients were divided based on BMI categories with stratification of baseline dd-cfDNA values as shown in table 1. There were no significant differences in baseline dd-cfDNA values for BMI groups <25 vs. 25-29.9 vs. ≥30 (0.63 ± 0.63% vs. 0.41 ± 0.27%, p=0.16) and BMI groups 25-29.9 vs. ≥30 (0.41 ± 0.27% vs. 0.33 ± 0.16%, p= 0.22). However, there was a trend towards significantly higher baseline dd-cfDNA values in BMI group ≥30 vs. <25 (0.63 ± 0.63% vs. 0.33 ± 0.16%, p= 0.06).

Conclusions: Our study showed a trend towards significant differences in dd-cfDNA values between extremes of BMI groups. These differences could become significant with larger patient studies. Our findings point towards the need for normalization of dd-cfDNA values with respect to body size for reporting purposes.

Protocol-Based Donor-Derived Cell-Free DNA Surveillance in Kidney Transplant Recipients: A Single-Center Experience
Pipachan Nissaisorakorn, Het Patel, Martha Pavlakis, Amtul Aala, Nikhil Agrawal. Beth Israel Deaconess Medical Center, Boston, MA.

Background: Kidney biopsy is invasive and has limited utility when used as a surveillance test post-transplant. Donor-derived cell-free DNA (dd-cfDNA) surveillance testing has never been studied in comparison with other routinely performed surveillance tests.

Methods: Our transplant center implemented the dd-cfDNA (AllSure) surveillance protocol in 2019 which is a 3-month post-op in-kidney transplant recipients starting July 2018, in addition to our existing protocol measurements of serum Cr, proteinuria and DSA. We retrospectively reviewed all kidney alone transplant recipients transplanted between July 2018- April 2020. Data collection was done at time points within 3 months of baseline. A Kaplan-Meier analysis was used to depict survival.

Results: 385 screening dd-cfDNA test results were reviewed from 84 patients. There were 136 positive dd-cfDNA tests in 8/4 patients. 5 of the 8 patients underwent a kidney biopsy which showed: 4 rejections (2 humoral, 2 cellular) for 1 patient who had cellular rejection, dd-cfDNA test was the only surveillance test that was positive) and 1 ATN (dd-cfDNA test was borderline positive at 1.0%). The remaining 3 patients did not undergo a biopsy and repeat dd-cfDNA testing improved without intervention. In the 353/366 negative dd-cfDNA tests in 76 patients: 8 patients underwent a biopsy: 2 patients who had increased Cr showed borderline acute cellular rejection, 3 had recurrent disease (MPGN, DM, IgAN) and 3 showed ATN/Vascular disease/ITFA. In the 2 patients with borderline acute cellular rejection dd-cfDNA was <0.7%.

Conclusions: We found that the addition of surveillance dd-cfDNA testing to current testing algorithm was able to identify rejection in 1 patient, when others surveillance tests were negative. A negative result may obviate the need for biopsy, including protocol biopsies in centers who perform them.

Successful Transplantation Outcomes Using Deceased Donors with AKI
Amy L. Harshman, Luke Prezewski, Meghan Muldoon, Giselle Guerra. Miami Transplant Institute, Miami, FL.

Background: Kidneys from deceased donors with acute kidney injury (AKI) are discarded at a higher rate than those without AKI, exacerbating the organ shortage. This paper reviews outcomes of kidneys from deceased donors with AKI over a four-year period at a single transplant center.

Methods: We analyzed 1119 consecutive deceased donor kidney adult recipients transplanted from 2016 through 2019 at our center. Donors were classified using AKIN criteria for AKI based on increase of terminal serum creatinine (SCr) over initial SCr.

Results: 911 recipients received kidneys from donors with no AKI (Stage 0). 208 (18.6%) received kidneys from donors with AKI. 45 (4.02%) had Stage 1 AKI, 59 (5.27%) had Stage 2 AKI, and 104 (9.29%) had Stage 3 AKI. There were no significant differences between the AKI and non-AKI groups in recipient age, gender, ethnicity, or Estimated Post-Transplant Survival score. Using a Cox Proportional Hazards Model, death-censored graft survival at 1 year was not distinguishable between recipients whose donor had any stage of AKI versus donors without AKI (HR 0.94, p=0.854) nor among AKI stages (Figure 1). Mean eGFR by MDRD formula for recipients alive and with followup at 1 year was 60.0 (SD 23.2) in recipients with non-AKI donors and 61.9 (SD 26.1) in recipients with AKI donors, which was of no statistical significance (p=0.4384).

Conclusions: Our study showed a trend towards significant differences in dd-cfDNA values with respect to body size for reporting purposes.

Combined Impact of Presensitization and Delayed Graft Function on Allograft Outcome in Deceased Donor Kidney Transplantation: Nationwide Cohort Study
Byung ha Chung,1 Haebi Lee,1 Yohan Park,1 Tae Hyun Ban,2 Sang Heon Song,3 Jaeceok Yang,4 Curie Ahn,1 Chul Woo Yang.1 Korean Organ Transplantation Registry Study group,1 Seoul Saint Mary's Hospital, Seocho-gu, Seoul, Republic of Korea; 2Eunpyeong St. Mary's hospital, Seoul, Republic of Korea; 3Pusan National University Hospital, Busan, Republic of Korea; 4Seoul National University College of Medicine Department of Internal Medicine, Seoul, Republic of Korea.

Background: Pre-sensitization to HLA has detrimental effect on allograft rejection, worse allograft function and survival. Delayed graft function (DGF) can be associated with poor allograft outcome by ischemia-reperfusion injury. We undertook analysis to determine combined association of presensitization to HLA and DGF on allograft outcome in deceased donor kidney transplantation (DDKT) and whether there is a synergistic effect.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

729
**Methods:** In our prospective cohort study, between May 2014 and June 2019, 137 deceased donor kidney transplants were assigned into 2 groups: pre-sensitized and non-pre-sensitized. Each group was divided into 2 subgroups according to DGF. Pre-sensitization was defined as the presence of donor specific antibodies (DSA) or the presence of panel-reactive antibody (PRA), combination with crossmatch positive. DGF was defined as the need for dialysis before discharge. We compared the clinical outcomes including allograft rejection, the change of allograft function, infectious and toxic complication and allograft survival.

**Results:** Pre-sensitization group were 137 (10.0%) patients and others (n=1233, 90.0%) were assigned to non-pre-sensitized group. Pre-sensitization-DGF subgroup was 21 (15.3%) and pre-sensitization-non-DGF group was 116 (84.7%). Non-pre-sensitization-DGF subgroup was 133 (9.7%) and non-pre-sensitization-non-DGF group was 1100 (80.3%). In both pre-sensitization and non-pre-sensitization groups, allograft function using eGFR by CKD-EPI equation (mL/min/1.73m^2^) was lower in DGF subgroup than non-DGF subgroup. In contrast, allograft rejection rate showed no significant difference between DGF and non-DGF subgroup within non-pre-sensitization group (15.0% vs 12.9%, p=0.493). There was no significant difference between DGF and non-DGF subgroups in both groups in regard to allograft survival and patient survival.

**Conclusions:** DGF combined with pre-sensitization had much worse effect on allograft outcome in terms of allograft rejection. Therefore, we suggest more careful monitoring or surveillance for allograft rejection when DGF occurred in DDKT with pre-sensitization to HLA.

The Clinical Significance of Preformed C1q-Binding Donor-Specific HLA Antibodies in Kidney Transplantation

**Sun Lee,1 Byeong Ha Chung,2 Chul Woo Yang.2 Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; 2Catholic University of Korea, Seoul, Republic of Korea.**

**Background:** The anti-human leukocyte antigen (HLA) antibodies are well known for risk factor of rejection or allograft loss in kidney transplantation (KT). De novo complement component 1q-binding donor-specific anti-HLA antibodies (C1q-binding DSAs) are already reported to be associated with an increased risk of acute allograft rejection in KT. This study investigated the clinical significance of identification of preformed C1q-binding DSAs for predicting graft outcomes in KT.

**Methods:** From December 2016 to December 2018, 323 recipients underwent KT at Seoul St. Mary’s Hospital. If the results of panel reactive antibodies (PRA) were positive in the pre-transplant examination, DSAs and C1q-binding DSAs were performed using Luminex Single Antigen Bead Assay (SAB) at the same time. Graft outcomes in term as Chronic Kidney Disease-Epidemiology Collaboration estimated Glomerular Filtration Rate, biopsy proven acute rejection and graft survival were compared between recipients with preformed C1q-binding DSAs and recipients without preformed C1q-binding DSAs.

**Results:** Eighty-two of 323 recipients (25.4%) were evaluated DSAs and C1q-binding DSAs before transplantation. Among them, 40 recipients (48.8%) had preformed DSAs and 8 recipients (9.9%) had preformed C1q-binding DSAs. The higher MFI values of DSAs had higher prevalence of C1q-binding DSAs (9263.9 ± 3670.3 vs. 5955.3 ± 5245.5; p = 0.050). There was a strong correlation between the presence of DSAs against Class II and C1q-binding DSAs (p = 0.007; CI 95%, OR 9.333). Five of 21 patients (23.8%) with positive at least one of complement-dependent cytotoxicity (CDC) or flow cytometry crossmatch (FCXM) had preformed C1q-binding DSAs. There was a discrepancy between positivity of crossmatch and preformed C1q-binding DSAs (p = 0.024; CI 95%, OR 6.042). Four of 8 recipients (50%) in C1q-binding DSAs(+) group were confirmed acute antibody mediated rejection. C1q-binding DSAs(+ ) group had higher incidence of acute antibody mediated rejection than C1q-binding DSAs(-) group (p=0.044; CI95% OR 4.236).

**Conclusions:** The identification of preformed C1q-binding DSAs may be important in predicting acute antibody mediated rejection. Therefore, the surveillance such as protocol allograft biopsy is required for early detection of acute antibody mediated rejection after transplantation in patients with preformed C1q-binding DSAs.

**PO2405**

Potential Combined Use of Kidney Donor Profile Index (KDPI) and Estimated Post-Transplant Survival (EPTS) Scales to Predict eGFR Decline in Deceased Donor Kidneys

**Pablo Magrini,1 Sergio Hernández-Estrada,1 Odette Del Carmen Diaz Avendaño,1 Christian P. Flores,2 Benjamín Gomez-Navarro,3 María Guadalupe R. Ramírez,1 José H. Cano,1 María Concepcion Osegueda-Vizcaíno,1 Daniel F. Ovando-Morga,1 Mayra M. Matías Carmona,1 1Renal Transplant Unit, National Medical Center “20 de Noviembre”, Mexico City, Mexico; 2Renal Transplant Unit, Hospital Civil de Guadalajara Fray Antonio Alfonso belonvedor de Guadalajara; 3Mexico; 3Centro Medico Nacional de Occidente, Guadalajara, Mexico.**

**Background:** Utility of the sum of EPTS and KDPI scales to predict the decline of eGFR in patients who received a cadaveric donor transplant. Assess the reproducibility of the Organ Assignment System of the USA in our country.

**Methods:** 128 deceased-donor kidney transplant recipients at two National Mexican Hospitals between 2015 – 2017, retrospective, observational cohort study over 36 months following transplant. We include age, gender, primary renal disease, sensitization events, peak panel-reactive antibody, cold ischemia time, dialysis type and vintage, KDPI and EPTS, DGF, PTDM, Acute rejection, eGFR and cause of graft failure P. outcome: Relationship between a decrease >30% eGFR and the different combined scores of the KDPI and EPTS scales.

**Results:** The sum of the scores of the EPTS and KDPI scales >81% had a sens. 76% and a spec. 84% to predict a >30% decline in eGFR. AUC 80.8% (95% [CI] 0.022 to 0.005; p < 0.001). Multivariable Cox proportional hazard model: the sum of EPTS and KDPI scores >81% was associated with a 9.9-fold increase in losing more than 30% eGFR over the 36-months follow-up [adjHR] 9.9; 95% [CI] 1.85 to 53.6, p = 0.007).

Acute rejection was associated with a 3.1-fold increase in losing more than 30% eGFR ([adjHR] 3.1; 95% [CI] 1.15 to 8.72, p = 0.02).

**Conclusions:** Observing the donor and the recipient as a sum can be a new tool that helps us to predict the decline of eGFR in Deceased Donor Kidneys transplants.
**PO2407**

**Differences in Urinary Inflammatory Profiles in Donor-Recipient Pairs**

Elizabeth Spiwak, Corina Nailescu, Andrew L. Schwaderer. Riley Hospital for Children at Indiana University Health, Indianapolis, IN.

**Background:** Renal transplant is the most common type of transplant performed in the US. Immunosuppressants are used in transplant recipients to prevent rejection. Kidney transplant recipients are at a higher risk for infection in the pre- and post-transplant state. Urine inflammatory profiles may lend insight to this balance between infection and rejection. Since donor and recipient urine is generated by genetically identical kidneys, it represents an ideal biosample for paired analysis.

**Methods:** Urine samples were obtained from stable children > 2 months post-transplant along with their donors (n=6) and another 8 recipient-donor-recipient pairs (adult and children) that were collected for longitudinal samples; of which a pretransplant sample has been obtained. Using the VPLEX Human Cytokine Panel (Mesoscale Discovery, Rockville MD) urine inflammatory mediators were quantified. The paired T-test or Wilcoxon test for parametric and nonparametric data respectively

**Results:** Interleukin (IL)7, IL15, Monocyte chemoattractant protein-1 (MCP-1) and Granulocyte-macrophage colony-stimulating factor (GM-CSF) were elevated in the pediatric post-transplant recipients compared to their donors P values of 0.017, 0.037, 0.046 and 0.031 respectively. IL-9 was higher in recipient urine in pre-transplant patients (p=0.004) compared to donors.

**Conclusions:** Transplant patients have an elevated urine inflammatory mediator profile. Pretransplant patients have elevated IL-9 compared to their donors. Reasons for this altered inflammatory profile include immunologic, hemodynamic or physiologic changes intrinsic to the transplant procedure versus medications used to manage transplant patients.

**PO2408**

**LIMS1 Gene Mismatching and Risk of Rejection in Kidney Transplant Recipients**

Yasar Caliskan,1 Safak Miroglu,2 Halil Yazici,2 Ahmet B. Dirim,2 Erol Demir,2 Ozgur A. Oto,2 John C. Edwards,1 Rosemary Ousph,1 Aydin Turkmen,2 Krista L. Lentine,1 'Saint Louis University, Saint Louis, MO; Istanbul University, Istanbul, Turkey.

**Background:** Recent advances in precision medicine have provided new insights into the pathogenesis of kidney transplant (KTx) rejection such as the potential role of genetic risk variants in LIM Zinc Finger Domain Containing 1 (LIMS1). We aimed to evaluate the relationship between donor and recipient LIMS1 genotype matching status and allograft rejection and survival.

**Methods:** We genotyped 41 prevalent living KTx recipient [24 (59%) males; mean age 34±13 years] and donor [15 (37%) males; mean age 47±13 years] and donor recipient LIMS1 mismatching status for the rs893043 variant by Sanger sequencing in order to assess their impact on rejection and graft failure.

**Results:** There were no differences between recipients with risk LIMS1 mismatching (n=5) and recipients without risk LIMS1 mismatching (n=36) regarding demographic factors, duration of dialysis, pretransplant PRA, HLA mismatching, immunosuppressive protocols and follow up time. After a median post-KTx follow up of 10.5 (IQR 8.7-12.6) years recipients with risk LIMS1 mismatching had significantly higher risk of allograft rejection (40%; median 1 month) compared to recipients without risk LIMS1 mismatching (13.9%; median 72 months) (HR=4.32, 95%CI: 1.46-12.76, p=0.015). TCMR was higher in recipients with risk LIMS1 (40%) compared to recipients without risk LIMS1 mismatching (11.1%) (p=0.087). There were no significant differences found between patients with and without risk LIMS1 mismatching regarding risk of post-KTx DSA, ABMR and allograft failure. The mean eGFR levels at last follow up were also similar among recipients with and without risk LIMS1 mismatching.

**Conclusions:** Genomic mismatching at LIMS1 gene appears to impact risk of TCMR. LIMS1 may be a potential minor histocompatibility antigen and pre-transplant genetic testing may have clinical implications for the prediction and clinical management of KTx rejection.

Monitoring of Gene Expression in Tacrolimus-Treated De Novo Renal Allograft Recipients Facilitates Individualized Immunosuppression: Results of the IMAGEN Study

Claudia Sommerger,1 Merce Brunet,2 Klemens Budde,3 Olga Millan,2 Luis Guirado,4 Petra Glander,5 Stefan Meuer,5 Martin G. Zeier,5 Thomas Giese,5
1Nephrology, University Hospital Heidelberg, Heidelberg, Germany; 2Pharmacology and Toxicology Laboratory, Barcelona, Spain; 3Nephrology, University Hospital Charite, Berlin, Germany; 4Renal Transplant Unit, Nephrology Department, Fundació Puigvert Barcelona, Barcelona, Spain; 5Immunology, University Hospital Heidelberg, Heidelberg, Germany.

Background: The expression of nuclear factor of activated T-cells (NFAT)-regulated genes in the peripheral blood has been suggested as a potentially useful immune monitoring tool to individualize tacrolimus (Tac) therapy. The aim of the present study was to characterize the possibility and clinical utility of monitoring of residual NFAT-regulated gene expression in renal allograft recipients in a multicenter approach.

Methods: The IMAGEN study enrolled 64 de novo renal transplant recipients from three European centers. All patients were treated with Tac, mycophenolic acid, and corticosteroids. NFAT-regulated gene expression (NFAT-RGE; IL-2, IFN-g, GM-CSF) was evaluated by quantitative real-time PCR in whole blood samples at day 7, month 1, 2, 3, and 6 after transplantation.

Results: Altogether, 60 patients could be evaluated. Tac concentrations (C0 and C1.5) correlated inversely with gene expression (p<0.001). NFAT-RGE showed a high interindividual variability (1 to 61%). RGE increased in the first two months from 16±4% to 34±21%. Patients (n=20) with high residual gene expression (NFAT-RGE>30%) were at the increased risk of acute rejection in the following months (35% vs 5%, p=0.002), whereas patients (n=40) with low residual gene expression (NFAT-RGE<30%) showed a higher incidence of viral complications, especially cytomegalovirus and BK virus replication (52.5% vs 10%, p=0.001).

Conclusions: NFAT-RGE was confirmed as a potential non-invasive early predictive pharmacodynamic marker in the immediate post-transplant period for the risk of acute rejection and infections complications in Tac-treated renal allograft recipients. Monitoring of NFAT-RGE may provide additional useful information for physicians to achieve individualized treatment adjustments based on the immunomodulatory effect of Tac, thus preventing serious clinical events. The method of NFAT-RGE measurements can be applied in trials with multicenter approach.

PO2410

The Role and Inducers of Nonclassical HLA-G in Renal Transplanted Allografts

Sho Kimano,1 Keiji Fujimoto, Hiroki Adachi, Kengo Furuchi, Hitoshi Yokoyama. Department of Nephrology, Kanazawa Medical University School of Medicine, Uchinada, Ishikawa, Japan, Katsukun, Japan.

Background: Non-classical class I molecule HLA-G has a high potential to modulate immune response. However, the mechanism of HLA-G induction was still unknown. In this study, the expression of HLA-G on proximal tubular epithelial cells (pTECs) and the inducer of HLA-G were investigated.

Methods: Our subjects comprised 40 adult Japanese subjects whose allograft had survived for at least 1 year (35 patients from a living donor, 5 patients from a deceased donor). They were evaluated for HLA-G1/5 expression using an immunofluorescence method. We investigated inducer of HLA-G using primary cultured human pTECs treated with cytokines and immunosuppressants.

Results: In renal biopsy tissues, 2 to 4 weeks or 1 year following the transplantation, HLA-G expression was noted in the perinuclear region or on the basement membrane side of pTECs in 12 of 40 cases (30 %). Further, for median 8.8 years, the time taken for a 30 % reduction in eGFR was longer in the HLA-G-positive group than in the HLA-G-negative group (p=0.016, Figure). HLA-G1/5 expression on pTECs was also found to be an independent predictor of the improvement in renal allograft function by Cox’s proportional hazard model (p=0.030). In vitro study, interferon-beta (IFN-β) was the strongest inducer of HLA-G expression, while immunosuppressants (everolimus, tacrolimus, cyclosporin, and dexamethasone) did not induce expression.

Conclusions: The study showed that HLA-G1/5 expression on pTECs was an independent improving predictor of renal allografts. Furthermore, the strongest HLA-G1/5 inducer was IFN-β, but not the immunosuppressive agents. These results suggested the possibility that acquired expression of HLA-G exhibits a long-term renal preservation effect, different from the effect of immunosuppressants.

PO2411

The Clinical Impact of Preformed HLA-DQ Donor-Specific Antibodies on Graft Outcomes in Kidney Transplantation

Sua Lee,1 Chul Woo Yang,2 Byung ha Chung.1 Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; 2Catholic University of Korea, Seoul, Republic of Korea.

Background: De novo HLA-DQ donor-specific antibody (DSA) has been identified as a risk factor for graft rejection and loss in kidney transplantation (KT). Recently, the impact of preformed HLA-DQA DSA has been discussed. This study aimed to investigate the clinical impact of preformed HLA-DQA DSA on graft outcomes.

Methods: We evaluated 990 recipients who underwent kidney transplantation at Seoul St. Mary’s Hospital from January 2010 to July 2019. According to the result of DSA using lumines single antigen bead assay, recipients were classified as no DSA, only DQ, non-DQ, and DQ + non-DQ. Primary outcomes were the incidence of biopsy-proven acute rejection and the rate of death-censored graft loss.

Results: In total cohort, 611 recipients (61.7%) and 379 recipients (38.3%) underwent living-donor KT and deceased-donor KT, respectively. Recipients were classified as no DSA (909 recipients, 91.8%), only DQ (18 recipients, 1.8 %), non-DQ (57 recipients, 6.3%), and DQ + non-DQ (6 recipients, 0.7%). The overall incidence of acute rejection and acute antibody-mediated rejection (AMR) were 20.3% and 7.5%. Only DQ, non-DQ, and DQ + non-DQ group had significantly higher the incidence of acute AMR compared to no DSA group (p<0.05, respectively). There was no significant difference in the incidence of acute AMR between sensitized groups. There was no difference in the rate of death-censored graft loss between groups. In univariate Cox regression analysis, all of 3 groups with DSA were associated with high risk of acute AMR (Only DQ: HR 5.051; CI 95%, p < 0.002, non-DQ: HR 6.005; CI 95%, p < 0.001, DQ + non-DQ: HR 7.748; CI 95%, p < 0.005, respectively). HLA-DQA DSA and other DSAs (HLA-A, HLA-B, HLA-C) had a tendency to interact with acute AMR, although no statistical significance (p=0.055).

Conclusions: Preformed HLA-DQA DSA is associated with the development of acute rejection, especially acute AMR. Therefore, the identification of preformed HLA-DQA DSA may be necessary to improve graft outcomes.

PO2412

Outcomes of High Kidney Donor Profile Index Kidneys at a Large Center

Background: Kidneys from donors with high Kidney Donor Profile Index (KDIPI) are often discarded due to concerns about outcomes. Despite decreased survival, the survival benefit of receiving a transplant and avoiding time on dialysis is beneficial, especially for selected patients.

Methods: We increased use of high KDIPI (KDIPI>85) deceased donor kidneys (DDKT) over several years. We performed a single-center analysis of 1119 consecutive adult DDKT from 2016-2019. Our endpoints were Kaplan-Meier death-censored
Results: 1119 patients were transplanted: 205 (18.3%) received a kidney from a donor with KDPI > 85% vs. 914 (81.7%) from a donor with a KDPI of <=85%. As expected, the high KDPI group had a higher mean age (66.5 ± 5.3 years) and KDPI (85-100) than the low KDPI group (63.8 ± 5.0 years). The mean eGFR by MDRD equation at 3, 6, and 12 months post-transplant. Mean eGFR was compared for graft survival (HR calculated by the Cox Proportional Hazards model) and eGFR by MDRD equation at 3, 6, and 12 months for recipients of KDPI <=85 (0) vs. KDPI > 85 (1). The eGFR was consistently lower, but provided good function to those recipients. Utilizing high KDPI kidneys in well-selected recipients is an important aspect of reducing waiting time and morbidity and mortality of dialysis.

**PO2413**

**Could Individually Measured Creatinine Clearances Decrease the Discard Rate of High Kidney Donor Profile Index (86-100) Deceased Donor Kidneys?**

Adnan A. Khan, Robert W. Steiner, Hannah L. Turner, Charles K. Wainaina, Ashley S. Hahn. University of California San Diego, La Jolla, CA.

**Background:** The Kidney Donor Profile Index (KDPI) guides center acceptance and allocation of deceased donor kidneys (DDKs). It uses donor factors such as serum creatinine (sCr), diabetes mellitus and hypertension to predict organ quality and corresponding longevity. Due to this higher KDPI kidneys are often discarded. KDPI offers “only moderate predictability” of long-term transplant function with a c statistic of 0.64.

**Methods:** As an unexplored, but direct measure of deceased donor kidney quality, we determined pre-recovery creatinine clearances (CrCls) in 260 deceased donor candidates as that defines acceptable kidney function for living kidney donor candidates. Donor creatinine production rates were 17.9 ± 4.1 mg/kg/day, within population expectations. UNOS denial codes for high KDPI organ offers were mostly donor age or quality or organ specific donor issue.

**Conclusions:** Despite reduced graft survival, high KDPI kidneys offered renal function to those recipients. Utilizing high KDPI kidneys in well-selected recipients is an important aspect of reducing waiting time and morbidity and mortality of dialysis.

**Funding:** Clinical Revenue Support

**PO2414**

**Glomerular Blood Flow in Living Donor Kidney Transplant Recipients**

Gio Kanazaki, Takaya Sasaki, Kotaro Harahara, Rina Oba, Yusuke Okabayashi, Kentaro Koike, Akimitsu Kobayashi, Izumi Yamamoto, Nobuo Tsuibo, Takashi Yokoo. The Jikei University School of Medicine, Minato-ku, Japan.

**Background:** Renal graft hemodynamics may be a valuable predictor of graft survival and long-term outcomes. Although several studies have reported that renal blood flow was correlated with graft function and decreased remarkably during acute rejection episode, the glomerular hemodynamic changes during kidney transplantation are lacking because there is no method of measuring nephron number in vivo. In this study, we calculate glomerular blood flow (GBF) by estimating the nephron number and investigate changes in GBF after kidney transplantation and their clinicopathological relationship.

**Methods:** We performed a retrospective analysis of 42 patients who underwent living donor kidney transplantation. The number of glomeruli (Nglomeruli) was calculated as the cortical volume of both kidneys as assessed on computed tomography times the 1-hour posttransplant renal biopsy-determined glomerular density. Effective renal plasma flow (ERPF) was assessed as 90mTc-MAG3 clearance. GBF was calculated as follows: GBF (ml/min) = ERPF/Nglomeruli x (1-hematocrit/100) x 10. We analyzed the GBF before and during a 1-month observation period after transplantation. The GBF ratio as a marker of change in GBF was calculated as follows: (GBF one-month post-transplantation) / (GBF before transplantation in donors).

**Results:** Prior to transplantation, the GBF in donors was 55.7±25.7 ml/min, whereas the GBF in recipients on day 2 post-transplantation was decreased to 502.6±317.4 ml/min. After successful transplantation, the GBF one-month post-transplantation has settled down to 491.9±291.1 ml/min, while the eGFR progressively rose (48.7±18.4 ml/min/1.73m2) together with the hematocrit (31.1±3.9 %). The GBF at one month was positively associated with eGFR at one month (p<0.05). Of note, the GBF ratio was correlated with the eGFR and urinary protein excretion at one month and urinary protein excretion at one year but was not correlated with eGFR at 1 yr.

**Conclusions:** We first reported the GBF in kidney transplant recipients before and after kidney transplantation. Our findings suggest that abnormal change in GBF may be considered predictive indices for short-term allograft outcomes.

**PO2415**

**Characteristics of Anonymous Living Donors and Their Recipients and Outcomes: Appropriate Use of a Rare and Valuable Gift**

Muhammad Y. Jan, Muhammad S. Yaqub, Oluwafisayo O. Adebiyi, Tim E. Taber, Asif A. Shariffuddin. Indiana University School of Medicine, Indianapolis, IN.

**Background:** Anonymous Living Donors are a special select set of donors. We review the trends and the characteristics and utilization of such donors nationally.

**Methods:** All Living Donors (code=10 “Anonymous”) and their recipients who were recorded in the UNOS database from Oct 1997 through Sep 2017 were reviewed for demographics and recipient outcomes.

**Results:** There were a total of 2286 such donors during the study period. There was an increasing trend of the donors over the time period. Demographics and Outcomes are shown in the Table. DCGS was significantly superior when donor was 20 years or more younger than the Recipient (p=0.019) and significantly inferior when the 20 years older than the recipient (p<0.005). There was no difference in cumulative graft survival between adult and pediatric graft survival (p=0.055), although DCGS was superior in the adults (p=0.021).

**Conclusions:** To our knowledge, this is the first comprehensive report on the characteristics of Anonymous Living Kidney Donors and their Recipients and outcomes. Better characteristics matching in a minority of such transplants may improve further longevity from such donors.

Duration of Delayed Graft Function Predicts Kidney Allograft Function and Survival
Sanjana Kapoor, Nawras Alshoubaki, Chethan M. Puttarajappa, Sundaram Haririhan. University of Pittsburgh Medical Center, Pittsburgh, PA.

Background: The current study evaluated the duration of DGF as a measure of severity of ischemic injury to kidney transplant outcome.

Methods: This single center study evaluated DD kidney transplant recipients with DGF between Jan 2014 and Dec 2019. DGF was defined as the need for dialysis within 7 days post-transplant & were divided into three groups according to post transplant dialysis duration. Group I: dialysis ≤7 days, Group II: dialysis 8-14 days and Group III: dialysis >14 days.

Results: A total of 132 DD KT recipients with DGF were identified: Group I: n=84 (64%), Group II: n=24 (18%) & Group III: n=24 (18%). The recipient/donor demographics and Donor (KDPJ) & Transplant variables were similar across groups. Figure 1 (left) shows significantly lower eGFR values over time using linear mixed model among patients who needed dialysis for >14 days (Gr III vs I&II, P=0.006). Figure 1 (right) shows significantly lower composite end point (combination of patient loss, graft loss and impending graft loss) for among patients who needed dialysis for >14 days (P=0.0002).

Conclusions: In conclusion, we found a strong association between prolonged DGF>14 days with lower GFR values and survival outcomes. No differences in eGFR at survival rates were noted among patients with DGF patients < 7 days vs 7-14 days.

Funding: Clinical Revenue Support

PO2416

Outcomes of Delayed Graft Function: A Systematic Review and Meta-Analysis
Vanessa Sandra,1 Navin Sanichar,1 Emily Daniel,1 Miah T. Li,1 Kristen L. King,1 Jacob Stevens,2 Syed A. Husain,1 Tracy J. Mayne,2 Sumit Mohan.1 Columbia University, New York, NY; 2Angion BioMedica, San Francisco, CA.

Background: Delayed Graft Function (DGF) is a frequent complication of kidney transplantation, but its impact on long and short-term outcomes remain uncertain.

Methods: We conducted a literature search for studies investigating the association of DGF on subsequent outcomes from 2007-2020. Outcomes were abstracted and used to create cumulative forest plots with pooled odds ratios, stratifying our analysis between center-studies and registry-studies and follow-up time where possible. The outcomes analyzed were graft failure (GF), acute rejection (AR), patient survival, and renal function.

Results: Of the 1464 articles reviewed, 27 were included. In single center-studies, DGF patients experienced higher GF at 1 year (OR 2.45, 95% CI 1.79-4.29, p=0.001), 3 years (OR 1.70, 95% CI 1.01-2.86, p=0.001), increased AR 1-year post-transplant (OR 1.48, 95% CI 1.79-4.28, p=0.001), and decreased 1-year patient survival (OR 0.46, 95% CI 0.26-0.77, p=0.0001). Registry-studies showed a similar significant association with GF at 1 year (OR 2.76, 95% CI 1.79-4.28, p=0.001) and 3 years (OR 1.70, 95% CI 1.01-2.86, p=0.046), with AR within 1 year (OR 1.48, 95% CI 1.45-8.67, p=0.005) and 3-years (OR 0.54, 95% CI 0.41-0.72, p=0.001), and 1-year survival (OR 0.45, 95% CI 0.26-0.77, p=0.0001). Qualitative analysis showed that DGF had significant effect on eGFR and creatinine levels, though studies conflict on timeframe. Few studies investigated outcomes stratifying DGF severity or KDPI.

Conclusion: DGF was associated with increased risk of GF, AR, and mortality, although effects were largest within 1 year post-transplant. Our analysis indicated a need for a standardized method to measure DGF severity and further studies on DGF outcomes on varying KDPI. These results should inform the selection process, treatment, and monitoring of transplanted kidneys at high risk for DGF.
PO2419
Clinical Outcomes of Kidney Transplant Recipients Living Away from Their Home Country

Background: Many people leave their home country looking for better job opportunities and among those are kidney transplant recipients. However, taking care of such recipients might be challenging especially when information regarding induction immunosuppression, donor HLA typing, donor-specific antibodies, crossmatch and/or infections are not available. The aim of this study was to compare clinical outcomes of kidney recipients transplanted in their home country with kidney recipients transplanted locally.

Methods: In this retrospective cohort, we included all adult recipients transplanted between 2005 and 2016 and followed at our transplant clinics within their first year of transplant. Patients were categorized into two groups; local group including recipients transplanted at our center and abroad group including recipients transplanted in their home country.

Results: There were 111 patients in local group and 110 patients in abroad group. The mean age at transplant in local and abroad groups were 48 and 42 year-old, respectively. 63% of recipients in local group were from the Middle East, while 53% of patients transplanted abroad were from South Asia. Deceased donation was higher in local group (41% vs. 4%, p=0.0001). There was no difference in recipient sex, native kidney disease, pretransplant drug disruption or preoperative transplants. Most patients were on CNI and steroid immunosuppression, donor HLA typing, donor-specific antibodies, crossmatch and/or infections.

Conclusions: Transition of care between countries carry its risks as it may be related to drug disruption or incomplete medical record. Kidney recipients transplanted abroad are at increased risk of acute cellular rejection; however, patient and graft survival rates remain excellent.

PO2420
Factors Associated with the Use of Hypothermic Machine Perfusion in Kidney Transplant Recipients

Nadir Goulamhossenni,1 Lawrence Slapoffa,2 Dana Baran,3 Isabelle Houde,4 Anne Boucher,3 Martin Albert,1 Pierre Marsolais,1 Heloïse Cardinal,2 Josec Bouchard.1 Hôpital du Sacré-Cœur de Montréal, Montréal, QC, Canada; 2McGill University, Montréal, QC, Canada; 3Hôpital Maisonneuve-Rosemont, Montréal, QC, Canada; 4CHU Québec, Québec, QC, Canada; 5Centre Hospitalier de l’Université de Montréal, Montréal, QC, Canada.

Background: Delayed graft function (DGF) is associated with an increased risk of graft loss. The use of cold hypothermic machine perfusion (HMP) has been shown to reduce the incidence of DGF in kidney transplant recipients (KTRs), especially when extended-criteria donors (ECDs) are used. However, there is a paucity of data on the determinants of HMP use in real-life setting.

Methods: We aimed to determine the factors associated with the use of HMP in a cohort of donors and KTRs. We collected data on consecutive brain-dead donors admitted between January 2013 and recipients transplanted at our center and abroad group including recipients transplanted in their home country.

Results: The cohort included 159 deceased donors and their 281 KTRs. Thirty-three percent of donors were ECDs, and 59% of KTRs received organs placed on HMP. The median cold ischemia time (CIT) was 12.4 (IQR 7.9-16.2) hours. There were no differences in the use of HMP. The reasons underlying the differences in practice between centers should be explored in further studies.

PO2421
Microvascular Inflammation Is the Main Determinant of Elevated Donor-Derived Cell-Free DNA in Kidney Transplantation

Bogdan Obrissa,1 Maria Buti,2 Ramasamy Bakhvatsalam,3 Kelly D. Smith,2 Iris C. De Castro,2 Christopher D. Blosser,1 Lena Sibulesky,2 Catherine Kling,2 Gener Ismail,1 Bogdan M. Sorohan,1 Nicolae Leca.2 Fundeni Clinical Institute, Bucharest, Romania; 3University of Washington, Seattle, WA.

Background: Microvascular inflammation (Mi) is the main histological lesion for ABMR. Mi may occur separate from other ABMR criteria, earlier in the injury process, and may not be captured by the current Banff criteria. Donor-derived cell-free DNA (dd-cfDNA) has the potential to identify early allograft injury and supplement the current diagnostic criteria for rejection.

Methods: We included all patients (n=54) who underwent a kidney transplant biopsy for suspicion of rejection at our center from 9/17-12/19. Determinants of a biopsy were renal dysfunction, elevated dd-cfDNA, or presence of DSAx.

Results: dd-cfDNA correlated strongly with the presence of ABMR, Class II DSA>2500, and histological lesions of ABMR. The strongest association was with Mi lesions (OR 192.95%CI: 18.6, 1984, p<0.001). Of the 18 patients with Mi, 2 did not meet the criteria for ABMR and had a dd-cfDNA level of 0.32% and 1.9%. All patients with Mi that met the criteria for ABMR had a dd-cfDNA over 1%. There was no association with renal function or histological lesions of tubulitis or interstitial inflammation (Fig 2).

Conclusions: dd-cfDNA has the potential to identify early allograft injury and allow for early and less aggressive interventions that can benefit favorably long term outcomes of kidney transplant recipients.

Point-of-Care Creatinine Self-Testing in Renal Transplant Patients: An Assessment of Accuracy, Precision, and Patient Experience
Fabiana Fernandes da Costa,1 Michelle Willcombe,1,2 Kate Bramham,3 Clare B. Kelly.1 1Imperial College NHS TRUST, London, United Kingdom; 2Imperial College London, London, United Kingdom; 3Department of Women and Children’s Health, King’s College London, London, United Kingdom.

Background: During the Covid-19 pandemic it has become increasingly important to provide virtual care for patients with CKD. Point-of-Care testing of capillary creatinine (POC-Cr) is now available and has demonstrated validity, ease of use, improved efficiency and cost-efficiency. We aimed to determine patients’ desire to self-monitoring of POC-Cr and their characteristics.

Methods: Renal transplant patients were shown how to perform self-POC-Cr testing with a NovaBio StatSensor®XPress device, then undertook a test independently and answered survey questions about their attitude to self-testing of POC-Cr.

Results: All patients (N=189; Median age 52 years (IQR 40,64); 44 (23%) English as a second language; 128 (68%) male; Median eGFR 49 mls/min/1.73m2 (IQR 34,64) successfully performed a POC-Cr test and 110/120 (91%) of patients who completed the survey reported they would like to self-monitor POC-Cr. Most patients wished to reduce their clinic attendance and the majority were willing to have telephone consultations. Characteristics of the cohort are described in Table 1.

Conclusions: All transplant patients successfully performed a POC-Cr test with written instructions and a demonstration. Most patients would like to self-monitor POC-Cr and reduce clinic attendance. Limitations include the single-centre design, number of participants and language barrier. Virtual care including patient self-monitoring using POC-Cr should be explored.

Characteristics of patients who would and would not like to self-monitor POC-Cr at home

PO2423
Short-Term Variability in Graft Function Is Associated with Long-Term Mortality but Not Allograft Survival in Kidney Transplant Recipients
Reini Lyv, Didier A. Mandelbrot, Arjang Djamali, Brad C. Astor. University of Wisconsin-Madison School of Medicine and Public Health, Madison, WI.

Background: It is critical to identify kidney transplant recipients (KTR) at highest risk of graft failure and death to focus on monitoring and interventions to improve long-term outcomes. Variability in native kidney function is associated with the risk of mortality and hospitalization in chronic kidney disease, but it remains uncertain whether such associations exist in KTR. We examined the hypothesis that short-term graft function variability is associated with long-term outcomes in KTRs.

Methods: Using the Wisconsin Allorgraft Recipient Database (WisARD), we identified 2919 KTRs who had a functioning allograft at least 2 years after transplantation and at least 3 outpatient estimated glomerular filtration rate (eGFR) measurements from 1 to 2 years post-transplant. Graft function variability was defined for each patient as the coefficient of variation based on a linear regression of eGFR from 1 to 2 years. Associations between eGFR variability and total graft loss, death and graft failure were estimated in competing risk models.

Results: Patients with greater variability were more likely to be female, have more comorbidities, and have more prior hospitalization events and use beta-blockers. Compared to the lowest quintile, the highest quintile of eGFR variability was associated with a higher risk of total graft loss (adjusted HR 1.51, 95% CI: 1.11-2.06) and a higher risk of death (adjusted HR 1.85, 95% CI: 1.23-2.76), but not with a higher risk of graft failure (subHR 1.08, 95% CI: 0.64-1.83 in competing risk analysis), independent of eGFR and slope of eGFR. The associations remained consistent across strata of acute rejection, diabetes, peripheral arterial disease, baseline eGFR, history of cardiovascular disease, baseline hospitalization, and with all variability indicators and modeling approaches.

Conclusions: Short-term eGFR variability is associated with long-term death but not graft failure. Variability in eGFR provides independent prognostic information on transplantation outcomes and may be an indicator to differentiate the risk of death and graft failure.
PO2425
Composite Events Associated with Increased Expected Post-Transplant Survival Scores
Yasmeen Dhandia,1 Nakul N. Datta,2,3 Piyavadee Homkrailas,1 Suphamai Bunnapradist,4,5 Erik L. Lum,1,2 *University of California Los Angeles, Los Angeles, CA; 1University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.

Background: Kidney transplant candidates on the waiting list are assigned an expected post transplant survival score (EPTS) score. This score is used to determine allocation of kidneys in the kidney allocation system (KAS). The outcomes of candidates with an EPTS >95% at the time of listing is limited.

Methods: UCLA kidney Transplant Program data of waiting list with EPTS > 80% from January 2015 – December 2018 were included. Median follow up time of waiting list was 885 days. The outcomes included kidney transplant rate, 3 year death censored graft survival and patient survival in candidates with EPTS > 95% compared with EPTS < 95%.

Results: A total of 124 patients were identified with an EPTS score > 95% at the time of the study period. Of these 23 patients received a kidney transplant during the specified time frame (transplant rate of 16.9%). Recipients of kidney transplant had a longer dialysis vintage (2368.6 days vs. 9881 days, P<0.0001) and were more sensitized at the time of listing (34.8% vs. 11.8%, P=0.018). Compared to a group with an EPTS between 80-94% at time of listing (n=170) there were no differences in mortality (4.35% vs. 4.55%, P=0.969), graft failure (14.3% vs. 6.4%, P=0.254), or 3 year death censored graft survival (70.0% vs. 84.5%, P=0.517). The EPTS > 95% group was older, had a longer dialysis vintage, had a higher proportion of candidates with diabetes as a cause of ESRD, and was less likely to undergo transplantation. Candidates with an EPTS >95% who did not receive a transplant had a mortality rate of 7.9% and waitlist removal rate 16.9%.

Conclusions: Kidney transplantation in candidates with an EPTS > 95% provides comparable outcomes to candidates with an EPTS between 80-94%, which was superior to remaining on dialysis. Despite this benefit, the transplantation rate of this group was low and a quarter of those not transplanted either died or were removed from the waitlist. Strategies are needed to improve transplantation rates in this population.

PO2426
Transition of Renal Transplant Care from Pediatrics to Adolescence and Young Adulthood: Retrospective Study Comparing Serum Creatinine-Based GFR Estimating Equations
Rade-Dandamudi, Stanley P. Hmiel, Vikas R. Dhamidharka. Washington University in Saint Louis School of Medicine, Saint Louis, MO.

Background: The evaluation of graft function is vital in the management of pediatric kidney transplant (pKTx) recipients. Measured GFR (mGFR) using exogenous markers, is very accurate, but not suitable for daily use. Estimated glomerular filtration rate (eGFR) using Serum creatinine (Scr) is the easiest way and equations are categorized as either pediatric or adult specific. None of the equations were formally compared in adolescents and young adults with renal transplants. The aim of study was to assess the performance of creatinine-based formulas in a cohort of pKTx in pediatric, adolescents and young adult age groups.

Methods: This retrospective study was conducted at our hospital from January 2000 to March 2019 from 125 pKTx recipients. We compared 415 mGFR values to 5 different Scr-based eGFR formulae (original Schwartz(OS), BS, Pottel, Modification of Diet in Renal Disease (MDRD), CKD-EPI, and average of BS and CKD EPI). Basing on the age at which the GFR was measured we divided the cohort in to 3 categories (children <12 ys, Adolescents 12.1-17.9 y and young adults >18-21 y). We used Bland-Altman analysis to evaluate the bias, precision and accuracy between eGFR and mGFR.

Results: Pottel and BS performed well across pediatric and adolescent age groups with high 30% accuracy(figure). MDRD and CKD EPI performance improved in young adults >18 years. Average of BS and CKD EPI outperformed other equations in young adults and provides an overall unbiased estimate of GFR.

PO2427
A Comparison of the Associations of Urine Markers with the Rate of Decline in Kidney Allograft Function
Yoshitsugu Obu,1,2 Naotsugu Ichimaru,1,2 Yoshitaka Isaka,1 Takayuki Hamano,1,2 The CANDLE-KIT Trial Investigators ‘Ohi Clinic, Osaka, Japan; ‘The University of Tennessee Health Science Center College of Medicine, Memphis, TN; ‘Osaka Daigaku Daigakusen Igakukan Kenkyuka Igakusha, Suita, Japan; ‘Ippan Zaidan Hojin Sumitomo Byoin, Osaka, Japan; ‘Nagoya Shitsuru Daigaku Igakukan Kenkyuka Igakusha, Nagoya, Japan.

Background: Various urine markers are proposed to predict renal outcomes. However, there are few head-to-head comparison studies comparing their clinical relevance among kidney transplant recipients (KTRs). Methods: In a prospective clinical trial, we enrolled 153 KTRs with anemia and >1-year history of transplantation across 23 facilities and followed them for 2 years. The annual change in eGFR was estimated based on mixed effects model. We then selected 102 patients who had baseline urine data on total protein, beta-2-microglobulin (β2M), N-acetyl-beta-D-glucosaminidase (NAG), and L-type fatty acid binding protein (L-FABP). Total protein, NAG, and L-FABP were standardized according to urine creatinine concentration. We then compared the associations of the quintiles of each urine marker with annual decline in eGFR using univariate and multivariable linear regression models.

Results: Patients were 51±12 years-old and 54% were male. The median (IQR) of transplant vintage was 8 (5, 12) years, and the baseline eGFR levels were 31±11 mL/min per 1.73 m². The annual eGFR change was -1.6±2.0 mL/min per 1.73 m²/ year. The median (IQR) urine levels of total protein, β2M, NAG, and L-FABP at baseline were 0.3 (0.1-1.1) g/g Cr, 1535 (238-4780) μg/L, 0.06 (0.04-0.12) IU/L, and 16.7 (4.2-42.1) μg/g Cr, respectively. The higher levels of L-FABP and total protein were significantly associated with more rapid annual eGFR decline (P for trend <0.001 for both; Figure) while there was no significant association for β2M or NAG. R² was 0.10 (P=0.03) and 0.18 (P<0.001) for L-FABP and total protein, respectively. After adjustment for age, gender, mean arterial blood pressure, and baseline eGFR, the association remained significant for total protein but not for L-FABP (Figure).

Conclusions: Among urine markers of total protein, L-FABP, NAG, and β2M, total protein appears to have greatest predictive value for eGFR decline among KTRs.

PO2428
Chronic Graft vs. Host Disease in Pancreas After Kidney Transplant Recipient: An Unrecognized Entity
Prince Singh, Aleksandra Kukla. Mayo Clinic Minnesota, Rochester, MN.

Introduction: Graft-versus-host disease (GVHD), a common complication after allogeneic bone marrow transplantation is rarely seen after solid organ transplants (SOT). Reports of acute GVHD (maculopapular rash, diarrhea and cholestatic liver disease) described after SOT invariably happened in the early post-transplant period (days to months). In contrast, reports of SOT recipients with clinical features more consistent with chronic GVHD (cGVHD) (resembling autoimmune disease with chronic inflammation/ fibrosis) are lacking. We present a case of cGVHD in pancreas after kidney transplant (PRT) recipient diagnosed at 42 months post transplant.

Case Description: A 43 year old man received a HLA 5/6 mismatch, CMV mismatch (donor positive, recipient negative) deceased donor pancreas transplant two years after receiving a HLA 5/6 mismatch living unrelated kidney transplant. Anti-thymocyte

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
globulin induction was given along with a maintenance immunosuppression - tacrolimus, mycophenolate mofetil and prednisone. Post-transplant course was complicated by multiple opportunistic infections (Figure 1) leading to immunosuppression reduction. At 42 months post transplant, he developed dry eyes, arthralgia, anorexia, elevated alkaline phosphatase, dyspepsia on exertion, lichen simplex chronicus dermatitis, and severe pancytopenia. GVHD was suspected which lead to peripheral blood chromosome testing revealing 90% pancreas donor-derived DNA in CD3-positive fraction of T cells. Patient passed away.

**Discussion:** The infections may have represented the immune dysfunction associated with GVHD. Do-escalation of immunosuppression could have led to an unopposed activation of donor cytotoxic T-lymphocytes resulting in worsening GVHD. Donor-derived T lymphocytes received during pancreas transplant may have targeted the bone marrow, causing severe pancytopenia, hence compounding the dysregulated immune state. Transplant professionals should be aware of the possibility of the rare but challenging diagnosis of GVH in PAK recipients and hence identify it appropriately.

**Results:** There were a total of 2,886 IT recorded from 1990 through Sep 2017. There were a total of 190 (6.6%) Kidney transplants recorded of which 54 (28.4%) were KAIT while the remaining 136 (71.6%) where Combined (CIKT). The Median Duration from Intestinal Transplant to Kidney transplant was 5.6 years (Range 0.47 to 18.9). One year KAIT graft survival was 87% as compared to CIKT 52%. 3 year graft survival was 74% vs 36%. Death censored KAIT graft survival at 1 year was 98% vs 87% and 5 years 83% vs 74%.overall unadjusted kidney graft survival was significantly lower in CIKT as compared to KAIT p=0.009.

**Conclusion:** Our data shows that isolated kidney transplant after any prior Multi-organ or isolated Intestinal transplant has higher graft survival as compared to combined Intestinal Kidney Transplant. Higher CNI tough levels may be one common factor leading to lower graft survival.
death increases up to a rate of decline of 10 ml/min/1.73m²/yr. DM as cause of ESKD was associated with an almost 2-fold increase in risk of death after graft loss compared to non-DM (HR 1.95, 95% CI 1.27-2.96).

**Conclusions:** In this single-center cohort of kidney transplant recipients with DCGL, a faster rate of eGFR decline in the 2y prior to graft loss was not associated with a higher risk of death after graft loss after adjustment for important clinical variables.

**PO2432**

**Renal Recovery After Liver Transplantation Alone in Patients with Liver Cirrhosis and Severe CKD with Normal Kidney Size**

Suvra Junger, Asan Medical Center, Songpa-gu, Seoul, Republic of Korea.

**Background:** Most guidelines recommend simultaneous liver-kidney transplantation (SLKT) in patients with liver cirrhosis (LC) and severe chronic kidney disease (CKD) over liver transplantation alone (LTA). CKD, however, is not irreversible. This study evaluates the reversibility of kidney disease after LTA based on kidney size.

**Methods:** In this single-center retrospective study, we classified 90 patients with LC and severe CKD into 3 groups: normal kidney-LTA (NK-LTA, n=39), small kidney [both <9cm]-LTA (SK-LTA, n=40), and small kidney-SLKT (SK-SLKT, n=11). Baseline characteristics and renal recovery and survival outcomes were compared among 3 groups.

**Results:** The NK-LTA group had a lower percentage of hepatocellular carcinoma, a higher pre-LT eGFR, and a shorter duration of eGFR at <60 ml/min and pre-LT dialysis. This group, however, was older, received livers from a higher percentage of deceased donors and had a higher Child-Pugh score. Renal recovery, defined as no hemodialysis (HD) after LTA, was found in 79% of those in the NK-LTA group, which was higher than 7.5% of those in the SK-LTA group. Renal survival, defined as patient survival without progression to HD or kidney transplantation was found in 56% of patients in the NK-LTA group, which was higher than 2.5% of those of the SK-LTA group.

**Conclusions:** Patients with LC and severe CKD with normal kidney size may experience reversible kidney disease after LTA. Therefore, kidney after liver transplantation is recommended over SLKT for these patients.

**Funding:** Private Foundation Support

**PO2433**

**Immediate Allograft Function After Liver Transplant (LT) Modifies the Effect of Pre-LT Renal Dysfunction (RD) on Post-LT Survival**

Hani Wadi, Shennen Mao, Martin L. Mai, Naheel Aslam, Kristopher Croome. Mayo Clinic’s Campus in Florida, Jacksonville, FL.

**Background:** Pre-LT RD is associated with higher post-LT mortality. It is unclear if immediate liver allograft function modifies this risk.

**Methods:** We retrospectively reviewed data on 2,856 primary LT performed in our center from 1998 to 2018. Pre-LT RD was defined as Cr >1.5 mg/dl or on dialysis at LT. Immediate liver allograft function was defined using the validated early allograft dysfunction (EAD) criteria (bilirubina10 mg/dl, INR ≥1.6 or ALT/AST ≥2000IU/mL on POD 7). Pre-LT RD was present in 591(21%), of these 429 patients had Cr >1.5 and 165 were on dialysis. EAD developed in 784(27%). The cohort was divided into 4 groups according to pre-LT RD and EAD. Group 1 (n=1,617): No RD and no EAD, Group 2 (n=643): No RD but had EAD, Group 3 (n=451): had RD and no EAD, Group 4 (n=140): had both RD and EAD. The unadjusted and adjusted post-LT survival was compared between the 4 groups.

**Results:** Results are presented in Figure. Group 1 had the best outcome with 1,3 and 5 year survival of 95%, 89% and 82%, respectively, and group 4 had the worst outcome with 1, 3 and 5 year survival of 79%, 70% and 60%, respectively, P<0.001. Group 2 and 3 had comparable survival and comparable (P=0.5 between group 2&3) outcomes. Survival was better in group 2&3 compared to those in group 4 (P<0.001) but was worse than group 1 (P=0.02). After adjusting for recipient age, female gender, DM, MELD score, cause of ESLD and DRL, group 4 had the highest risk of death (aHR 2.33, CI:1.69-3.21, P<0.001). Patients in group 2 (aHR 1.16, CI:0.95-1.41, P=0.3) and group 3 (aHR 1.23; CI: 0.96-1.58, P=0.09) had comparable adjusted risk of death to group 1 patients.

**Conclusions:** LT recipients with pre-LT RD who enjoy immediate liver allograft function have comparable adjusted survival to those with normal renal function at LT. Our results indicate that livers at higher risk of EAD should be avoided in LT recipients with RD.

---

**PO2434**

**Sex and Equity in Pediatric Kidney Transplantation**

**Background:** Mortality in pediatric kidney failure (ESRD) is higher in girls than in boys, in contrast to the general population. In a recent report, correcting for access to transplantation partially ameliorated this risk, prompting an examination of equity in pediatric kidney transplantation.

**Methods:** USRDS files were used to examine incidence of pediatric ESRD (ages 18) and initial Rx modalities from 2000-15. UNOS data were used to evaluate pediatric kidney recipients between 2000-2019. Logistic regression was used to calculate an odds ratio (OR) for receiving a living donor kidney (LD). Hazard ratios (HR) of death, graft failure and death-censored graft failure (dcGF) were obtained in Cox models stratified for LD/deceased-donor (DD). Models were adjusted for age, sex, and year of transplant and reported with 95% CI.

**Results:** Among 17,366 incident pediatric ESRD patients in USRDS, 42.8% were female. Mean and median age did not differ. Initial kidney treatment was transplantation in 17.9% of girls and 23.8% of boys, with more hemodialysis in girls (46.0 vs 40.5%, P<0.001). Among 16,811 UNOS recipients, 41.0% were female. Changes in allocation policy were associated with a shift from parental donors to deceased-donors, which was more marked in female recipients (figure). 42.8% of boys and 39.7% of girls received LD (P<0.001); adjusted OR of receiving LD was 0.91 (0.85, 0.98, P=0.007) for girls. Compared to boys, girls had inferior outcomes with DD, with HRs: death 1.51 [1.30, 1.76], graft failure 1.31 [1.21, 1.46], and dcGF 1.30 [1.20,1.40, P<0.001 for all]. LD outcomes did not differ by sex.

**Conclusions:** Female children have fewer early transplants and higher odds of receiving DD kidney transplants that are associated with inferior outcomes than their male counterparts. Attention to sex-specific disparities may improve ESRD outcomes in girls.
PO2435

Outcomes of Emergency Department Visits of Children After Kidney Transplantation

Christian Hanna,1 Ashish Shah,2 Mark G. Roback,4 Priya S. Vergese,3 Ronald A. Furnival,1 1Mayo Clinic Minnesota, Rochester, MN; 2Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 3University of Minnesota, Minneapolis, MN; 4University of Colorado, Denver, CO; 5Northwestern University - Chicago, Chicago, IL.

Background: Systematic data evaluating the postoperative Emergency Department (ED) care and outcomes of Pediatric Kidney Transplant (PKTx) recipients is limited. Our study objective is to identify the risk factors, disposition, and outcomes of PKTx recipients presenting to the ED.

Methods: We retrospectively reviewed the medical records of PKTx patients (<18 years of age) who presented to our University Children’s Hospital ED from 04/01/2011 to 06/30/2015. Data pertaining to patient demographics, chief complaint, evaluation, interventions, results, length of stay (LOS) and disposition were abstracted. Multiple logistic regression analysis was used to study the associations between admission, the presence of bacteriaemia, and multiple risk factors.

Results: During the study period, 60 of the 85 PKTx recipients (71%) presented to the ED for acute care (total of 210 visits, range 1-20; mean 3.5 per recipient). The majority (148/210, 70%) of the visits occurred in the first year following transplant. Fever (44%) and gastrointestinal complaints (27%) were the most frequent presentations. Mean ED LOS was 3.5 hours (range 0.22-10.8 hours). Most (109/210, 52%) visits resulted in hospital admission, for a mean inpatient LOS of 4 days (range 1-55 days). After adjusting for age and sex, the following risk factors were significantly predictive of hospital admission: shorter time since transplant (p=0.003), presence of fever (p<0.001), higher heart rate (p=0.001), higher white blood cell count (p=0.004), and presence of Systemic Inflammatory Response Status (SIRS) (p=0.001). Age adjusted systolic and diastolic blood pressure, type of transplant (deceased vs living donor), underlying primary kidney disease, the presence of a central line, or the number of immunosuppressant drugs were not predictive of hospital admission. Multivariate analysis of all significant risk factors found that shorter time since transplant and presence of SIRS were the only factors significantly associated with hospital admission (p=0.05). Only presence of SIRS was significantly associated with positive blood cultures (p=0.03).

Conclusions: Nearly-three quarters of all PKTx recipients presented to ED most frequently in the first postoperative year, with over half requiring hospital admission. Shorter time since transplant and presence of SIRS were significantly predictive of hospital admission.

PO2436

The First Increase in Live Kidney Donation in the United States in 15 Years

Fawaz Al Ammary,1 Allan Massie, Deidra C. Crews, Dorry L. Segev, Abimereki Muzzaale. Johns Hopkins University School of Medicine, Baltimore, MD.

Background: After more than a decade of decline, the first sustained increase in live kidney donation was observed in the US from 2017 to 2019. Understanding these trends in donation may provide opportunities to effectively sustain or even enhance this recent increase in donation.

Methods: We conducted a national registry study of 35,900 donors (70.3% white, 14.5% Hispanic, 9.3% black, 4.4% Asian) to understand the increase in 2017-2019 vs. 2014-2016 using Poisson regression stratified by donor-recipient relationship (biologically related, unrelated, and kidney paired donors).

Results: Among biologically related donors aged <35, 35-49, and ≥50 years, the number of donors did not change across race/ethnicity but increased by 38% and 29% for Hispanic and black ≥50. Among unrelated donors <35, 35-49, and ≥50, white donors increased by 18%, 14%, and 27%; Hispanic donors <35 did not change but increased by 22% and 35% for 35-49 and ≥50; black donors <35 declined by 23% and did not change for 35-49 and ≥50; Asian donors did not change. Among kidney paired donors <35, 35-49, and ≥50, white donors increased by 42%, 50%, and 68%; Hispanic donors <35 and 35-49 increased by 36% and 55% and did not change for ≥50; black donors did not change; Asian donors <35 did not change but increased by 107% and 85% for 35-49 and ≥50.

Conclusions: The increase in live kidney donation was driven predominantly by unrelated and paired white donors. Donation among unrelated black individuals should be promoted.

PO2438

Demographic Variability of Kidney Function in Live Donors: A Single-Centre Analysis
Tina Thomson, Andreas Kousios, Rawya Charif, Honeylet Orr, Harvinder K. Dulku, Marina Loucaidou. Imperial College London Department of Medicine, London, United Kingdom.

Background: Live donation is encouraged as better outcomes in transplant recipients. Donor assessment requires thorough evaluation but kidney function varies with demographics. We compare mGFR with the performance of eGFR formulas and creatinine clearances.

Methods: Analysis of 997 live donors between February 1995 and October 2019. Using pre-donation measured GFR(TE EDTA-GFR) as the gold standard, we compared the performance of CKD-MDRD, CKD-EPI (CrCl(g/ml/min)), 24-hour creatinine clearance(CrCl) and Creatinine clearance by Cockcroft Gault((CrCl)(C-G)(g/ml/min)) between age, ethnicity, and gender. We also calculated the relative bias(mGFR-eGFR/mGFR), root mean square error and the accuracy(P30(eGFR between ±30%mGFR) of different eGFR equations.

Results: 422/42.32% males. 616/62% Caucasian, 228/23% South Asian. 114/11% Afro Caribbean and 39/4% of other ethnic groups. The Tc EDTA-GFR was 100.08(SD 10.87). Mean mGFR for males and females were 95.77 vs 96.27, respectively(p=0.05). 63(6.5%) donors were ≥65 years. Mean mGFR comparing young and ≥65 years old donors were 103.44 ± 82.27, respectively(p=0.0028). As predicted, there is a linear decline in mGFR with increasing age. Cr Cl-C has a tendency towards underestimating function in healthy living donors over 65 years old. GFR calculated by CKD-EPI formula was comparable to mGFR amongst all age groups, genders and ethnically diverse living donors. CKD-EPI performed better in terms of least bias and highest accuracy compared to MDRD for all donor subgroups.

Conclusions: mGFR declines with age and healthy older donors have significantly lower mGFR compared to younger donors. Cr Cl-C overestimates kidney function and should be used with caution. eGFR by CKD EPI comes closest compared to mGFR in all groups. It could be reliably used as first screening tool for assessing function of living donors pre donation, irrespective of age, gender or ethnicity.

Demographics & Comparative performances

PO2439

Assessment of Kidney Function at 3 and 6 Months in Kidney Donors with Cardio-Metabolic Risk Factors
Jesus D. Lima lusco, Rafael Valdez-Ortiz, L. M. Perez-Navarro, Ana G. Ortega, Ernesto C. Lopez, Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico; Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico.

Background: Cardio-metabolic risk factors (CRFs) in kidney donors contribute to further deterioration of kidney function after donation, increase their post-donation cardiovascular risk. Objective: To assess the renal function of kidney donors with CRFs at 3 and 6 months after donation.

Methods: Cross-sectional, descriptive study, which included kidney donors who were admitted to the National Medical Center “Dr. Antonio Fraga Moure” during the period January 2015 to 2019. Descriptive statistics were made, ANOVA with a 95% CI and a value of p < 0.05. The CRFs dyslipidemia, hypertension, hyperglycemia, body mass index (BMI) and hyperuricemia were evaluated.

Results: 153 donors were admitted, 34% with social security, 59% women, with a mean age of 42.7 ± 10.7 years. The clinical and biochemical characteristics at hospital admission were: mean SBP/DBP was 106 ± 6.02/72.9 ± 5.4, BMI, 26.3 ± 3.2, proteinuria 12.4 ± 13.4, hematocrit 44.6 ± 4.9, albumin 4.1 ± 0.4, K 4.1 ± 0.4, Ca 9.2 ± 0.6, Uric acid 5.4 ± 1.2, Total cholesterol 185.6 ± 34.4, triglycerides 156.5 ± 91.7, fasting glucose 91.6 ± 15.2, Creatinine 0.78 ± 0.14. The mean bleeding during surgery was 263.66 ± 447 ml, creatinine after surgery was 1.21 ± 1.8, upon release from hospital it was 1.13 ± 0.72. 72% of donors presented acute kidney injury (AKI) after surgery, with an average of 1.56 ± 1.8 days with AKI, 56% of donors released from hospital with AKI. More than 25% of kidney donors had 2, 3 and 4 CRFs. Figure 1 presents the comparison between groups (AKI vs No AKI) of creatinines at baseline, 3 months and 6 months.

Conclusions: A higher presence of CRFs is associated with higher AKI events after kidney donation. AKI patients during renal donation show a further deterioration of renal function at 3 and 6 months of follow-up. Timely interventions prior to donation could improve the evolution of this group of patients.
considered as HCV positive. The outcome of kidneys from HCVAb positive but NAT negative donors are unknown.

Methods: A national-registry-based retrospective cohort study was conducted using the SRTR data set. We identified all HCV negative recipients between April 1°, 2015 and March 2°, 2018, who received kidney transplant from HCV Ab positive and NAT negative (D-HCVAb(+)/NAT(-) n=166) and HCV Ab negative and NAT positive (D-HCVAb(-)/NAT(+); n=25,574) donor kidneys. We then compared recipients’ estimated glomerular filtration rate (eGFR) at 6 months in matched cohorts, using combined exact matching (based on KDPI) and propensity score matching. We created two separate matched cohorts to examine differences in outcomes based on how HCV positive status is defined: for the first cohort, we used the allocation KDPI (where HCV is considered positive in D-HCVAb(+)/NAT(-) patients), while for the second cohort we used a modified KDPI, where the HCV component of KDPI was considered negative in D-HCVAb(+)/NAT(-) patients.

Results: The mean±SD age of the allocation KDPI matched cohort at baseline was 59±10 years, 69% were male, 61% and 30% of the patients were white and African American, respectively. The baseline characteristics of the recipients were well-balanced in both matched cohorts. Recipients’ eGFR at 6 months after transplantation was significantly higher in the D-HCV Ab(+)/NAT(-) group compared to the D-HCV Ab(-)/NAT(-) patients. The baseline characteristics of the recipients were well-balanced in both matched cohorts. Recipients’ eGFR at 6 months after transplantation was significantly higher in the D-HCV Ab(+)/NAT(-) group compared to the D-HCV Ab(-)/NAT(-) group (61.1±17.9 versus 55.6±18.8 mL/min/1.73m², p=0.011) in the allocation KDPI matched cohort, while it was similar (61.8±19.5 vs. 62.1±20.1 mL/min/1.73m², p=0.9) in the modified KDPI matched cohort.

Conclusions: Recipients who received HCVAb positive, but NAT negative donor kidneys did not experience worse 6-month eGFR than correctly matched D-HCVAb(+)/NAT(-) recipients. HCVAb positive, but NAT negative donor kidneys should not be allocated as HCV positive kidneys.

PO2443
Hepatitis C NAT-Positive Kidney Transplant into Hepatitis C-Negative Recipients: A Single-Center Experience

Background: Direct-acting antivirals (DAAs) for Hepatitis (Hep) C have a 96-100% sustained viral remission (SVR) rate. This makes transplant of Hep C nucleic acid amplification testing (NAT) positive kidneys and treatment post-transplant feasible. We performed a prospective IBB approved trial at our center to validate the use and challenges of this approach.

Methods: Informed consent from eligible patients was obtained. Patients with chronic liver disease, dual organ transplants, HIV and active Hep B infection were excluded. Post-transplant, viral load was tested on day 3-5 and 7-10 and weekly thereafter until viremia was confirmed. All pts. were treated by hepatologist based genotype and insurance company preference. Standard of care immunosuppression protocols was used.

Results: 51 pts. got Hep C NAT+ kidney. The median age of the recipients was 58 years (range 29-72) and the mean wait time was 802 days (range 68-3073). Mean KDPI was 58.8 (range 27-94) with a median donor age of 38 years (range 21-56). Out of 16 implant biopsies, 13/16 (81%) had <5% of sclerotic glomeruli, 14/16 (88%) had minimal interstitial fibrosis, and 15/16 (94%) had no arteriosclerosis. There was a 100% transmission rate of Hep C. As of now, 46/51 (90%) have completed a 12-week course of DAA, and 45/46 (98%) have become RNA negative with 34/46 (74%) achieving SVR. So far, there had been no insurance denials of DAA coverage. Among 18 for cause allograft biopsies, 1 showed tubuloreticular inclusion thought to be Hep C related and another showed recurrent CSGN thought to be triggered by Hep C and Hep B.

Conclusions: Transplantation of HepC NAT+ kidneys to Hep C negative recipients followed by treatment with DAA is a feasible option as a standard of care outside trials. Recipients should be monitored for Hep C related complications.
rejection; IV methylprednisone and anti-thymocyte globulin were administered. Repeat biopsy for JCV nephropathy and replacement of the allograft issue with Kidney biopsy revealed metastatic KS. Immunosuppression was discontinued and he underwent allograft nephrectomy. He died at home 2 months later. Retroactive testing of samples prior to transplantation revealed the donor was HHV-8 PCR positive at the time of death and both recipients were HHV-8 antibody and PCR negative.

**Discussion:** We describe donor-to-recipient transmission of HHV-8 during kidney transplantation. HHV-8 associated post-transplant KS is well described but rare in the US. Post-transplant KS typically presents with classic skin lesions and kidney allograft involvement with a time of 7-10 years. In this report, there were only 7 reported cases Public Health Service (PHS) increased risk donors may represent a subset of donors at especially high risk for HHV-8 transmission. Future investigation is needed into this population to determine if post-transplant HHV-8 PCR monitoring or adjustments in immunosuppression are needed for kidney transplant recipients of PHS increased risk organ.

PO2445

**John Cunningham Virus (JCV) in Renal Allograft Recipients (RAR)**

*Bushra Z. Saleem, Sonitka Pur, Zahidul H. Mondal. Rutgers The State University of New Jersey, New Brunswick, NJ.*

**Introduction:** Both JCV and BK virus belong to Polyoma virus (PV) family and can lead to opportunistic infection in RAR. BK nephritis in RAR is well described in literature (incidence 1-10%) in contrast to JCV nephropathy (JCVN) which is a rare entity. Here we describe two cases of JCV in RARs.

**Case Description:** Case 1: 44-year-old woman with PMH of HTN and ESRD received her first renal transplant in 2009 followed by antibody mediated rejection (AMR) resulting in graft dysfunction. She received preemptive second renal transplant in 12/2015 followed by multiple RA biopsies within first few months due to elevated serum creatinine (s.cr). The biopsies showed borderline CMRs, acute AMRs and eventually chronic active AMR. Treatment regimen included steroids, rituximab, IVIG and plasmapheresis. Despite repeated treatments, her s.cr remained elevated leading to another biopsy in 6/2016 showing viral cytopathic changes suspicious for PVN. SV40 stain was negative as was serum BK titer. Immunosuppression (IS) was reduced and a biopsy was repeated in 8/2016 that stained positive for SV40. Given repeatedly negative serum BK, serum JCV titer was sent, which was positive and peaked at 350699 copies/ml on 9/2016. Titer improved to 66153 after 2 doses of Cidofovir however, later deteriorated to 33420. She had no neurologic involvement. Despite Cidofovir, her renal function deteriorated rapidly requiring bilateral RA nephrectomies with pathology showing JCVN. IS was discontinued following which JCV titer became undetectable. Case 2: 59-year-old man with PMH of HTN and ESRD who received renal transplant in 4/2013 followed by baseline s.c.r of 1.6 mg/dl. He was on Myfortic, Sirolimus and Prednisone for IS. He presented with rising s.c.r in 9/2019 (2.1mg/dl). He underwent RA biopsy in 11/2019 showing viral cytopathic changes, positive SV40 consistent with PVN. BK by PCR resulted negative s.2 but JCV titer returned at 3896 copies/ml. Myfortic was discontinued. Repeat JCV titer trended down to 2603 in 3/2020. Further follow up was delayed due to COVID-19 pandemic.

**Discussion:** The diagnosis of JCVN is challenging and easy to miss. Index of suspicion should be high with positive viral cytopathic changes (+/- SV40 stain) on nephrectomy. He died at home 2 months later. Retroactive testing of samples prior to transplantation revealed the donor was HHV-8 PCR positive at the time of death and both recipients were HHV-8 antibody and PCR negative.

PO2446

**Disseminated Adenovirus Treated with Brincidofovir in a Kidney Transplant Recipient**

*Tiffany Truong, Than Cao, Santhi Voora, Thin Thin Maw. University of Southern California, Los Angeles, CA.*

**Introduction:** Adenovirus is a common viral infection, with which immunocompromised patients have an increased risk of disseminated disease. It is less frequently described in solid organ transplant recipients and the optimal therapy for disseminated disease is unknown. We present a case of disseminated adenovirus in a kidney transplant recipient who was treated successfully with brincidofovir.

**Case Description:** A 56 year old female with ESRD received her second kidney transplant from a deceased donor 2 years ago with thymoglobulin immunosuppression in the treatment of adenovirus infection is cidofovir. However, cidofovir is nephrotoxic and renally cleared. This may limit its use, particularly in kidney transplant recipients. Cidofovir is nephrotoxic and renally cleared. This may limit its use, particularly in kidney transplant recipients. We report a case of well tolerated brincidofovir treatment of disseminated adenovirus infection in a kidney transplant recipient who demonstrated clearance of infection and improvement in kidney function.

**PO2447**

**Early Ganciclovir-Resistant Cytomegalovirus Infection in a Kidney Transplant Recipient: Could We Avoid It?**

*Kaushik Ivaturi, Ekamol Tantisattamo. University of California Irvine, Irvine, CA.*

**Introduction:** Although uncommon, ganciclovir-resistant cytomegalovirus (GMV) infection can lead to a therapeutic challenge given drug nephrotoxicity. Here we report a case of GMV infection during early post-kidney transplant (KT).

**Case Description:** A 41-year-old woman with ESRD received the second KT in February 2019 with rATG induction. She also received rituximab one dose for pre-KT donor specific HLA antibodies. Maintenance immunosuppression are tacrolimus, mycophenolate sodium (MPS), and prednisone. Serum creatinine slowly trended down to the baseline of 1.3mg/dl at 3 month post-KT. CMV IgG serostatus was D+R-. She received a 6-month CMV prophylaxis with a renally-adjusted dose of valganciclovir 450 mg twice weekly for 1 month, which was increased to 450 mg twice daily for 5 more months. 4 months after the CMV prophylaxis was completed, she developed asymptomatic CMV viremia with a titer up to peak of 47,643 IU/ml. Valganciclovir 900 mg twice daily started and MPS was decreased. CMV PCR slowly decreased to 440 IU/ml after 1 month of therapy. Despite continuation of valganciclovir, CMV PCR became rapidly increased to 3,349 IU/ml [Figure]. A CMV genetic resistance test revealed a UL97, but not UL54 gene mutation. Foscarnet was started and CMV PCR was decreased. Allograft function has been at the baseline.

**Discussion:** Our patient has several risk factors for GMV including high-risk CMV serostatus, prolonged exposure to low-dose oral valganciclovir prophylaxis, and intensified immunosuppression including rituximab. Given current treatment for GR-CMV remains limited with drug toxicity, adequate dose of CMV prophylaxis is critical to avoid GR-CMV. Pattern of CMV PCR after initiation of therapy should also raise a suspicion for GR-CMV and genetic CMV resistance testing is of paramount in early diagnosis. Novel preventive and therapeutic options may mitigate the risk of GR-CMV and drug-induced renal allograft toxicity.

PO2448

**A Case of Cytomegalovirus Infection with Spleenic Infarction in a Renal Transplant Patient**

*Mita Zahir E. Co, Rafael Villicana, Rungwasee Ratnavanich. Loma Linda University, Loma Linda, CA.*

**Introduction:** Cytomegalovirus (CMV) infection is common after kidney transplant (KT) but it is not known to be associated with splenic infarction.

**Case Description:** A 67-year-old female living-related KT recipient for end stage renal disease from systemic lupus erythematosus presented with acute fever, left flank pain, and diarrhea. Her medications included tacrolimus, mycophenolate mofetil (MMF), and prednisone. Examination was significant for fever (101.8°F) and abdominal tenderness. Labs revealed normal blood counts, metabolic profile (creatinine 0.9 mg/dL) and urinalysis. Stool study was negative for Clostridium difficile. Quantitative CMV DNA PCR was elevated at 126,000 IU/ml. Sigmodoscopy with biopsy also showed CMV colitis. CT abdomen and pelvis with contrast (Fig 1A) showed multiple wedge-shaped hypodense foci in the spleen consistent with splenic infarction and a splenic artery that was widely patent. Further investigations including Doppler ultrasound of the lower extremities, lung V/Q scan and hypercoagulable studies were all negative. CMV was suspected to be the cause of the splenic infarct. Thus, the patient was started on ganciclovir and anticoagulation. CMV was discontinued. On her 3-month follow-up, she was found to have improved symptoms, undetectable consecutive CMV titers and with interval radiographic resolution of her splenic infarctions (Fig 1B).
BK Polyomavirus Nephropathy After Kidney Transplantation from HCV-Infected Donor to HCV-Uninfected Recipient
Faisal Abdulameer,1 Hisham N. Abu Farsak,1 Barry M. Wall,1,2 Miklos Z. Molnar,1 1The University of Tennessee Health Science Center; Memphis, TN; 2VA Medical Center, Memphis, TN.

Introduction: BK polyomavirus (BKVpY) is an important cause of renal allograft dysfunction. We previously published the potential association of an increased risk of BKpY DNAemia/nephropathy in kidney transplant recipients receiving Hepatitis C (HCV) infected donor transplantation. Here, we report severe BKpY DNAemia/nephropathy in a recipient who received HCV infected donor transplantation, which was temporally associated with initial HCV treatment failure.

Case Description: 62-year-old HCV negative African American male received a cadaveric kidney transplant from an HCV infected donor in January 2019, with immediate graft function. Laboratory results 4 weeks later indicated HCV PCR of 9,310,000 IU/mL, serum creatinine 1.62 mg/dL, and BKpY DNAemia was negative. He received glicaprevir and pibrentasvir (March 2019) for a total of 12 wk. At completion of treatment, HCV PCR was negative. Evaluation 4 weeks later revealed HCV PCR level of 482,446 IU/mL, indicating initial treatment failure. While waiting for insurance approval for coverage of secondary direct acting antiviral (DAA) regimen, he developed acute kidney injury 6 wk after HCV viremia, with serum creatinine peaking at 3.3 mg/dL along with a rapidly rising BKpY DNAemia to >3,000,000 copies/mL. His immunosuppressive regimen was decreased. Allograft biopsy showed BKpYpY nephropathy and proliferative glomerulonephritis (GN) with monoclonal IgG deposits. He was started on cidofovir, levofloxacin and intravenous immunoglobulin, followed by a course of sofosbuvir/velpatasvir/voxilaprevir and ribavirin for a total of 12 wk, achieving SVR at 12 wk. His BKpY DNAemia slowly responded with 1,257,789 copies/mL at 6 weeks of DAA coverage of secondary DAA regimen, he developed acute kidney injury 6 wk after HCV viremia, with serum creatinine peaking at 3.3 mg/dL along with a rapidly rising BKpY DNAemia to >3,000,000 copies/mL. His immunosuppressive regimen was decreased. Allograft biopsy showed BKpYpY nephropathy and proliferative glomerulonephritis (GN) with monoclonal IgG deposits. He was started on cidofovir, levofloxacin and intravenous immunoglobulin, followed by a course of sofosbuvir/velpatasvir/voxilaprevir and ribavirin for a total of 12 wk, achieving SVR at 12 wk. His BKpY DNAemia slowly responded with 1,257,789 copies/mL at 6 weeks of DAA treatment and 7,378 copies/mL at 12 wk. Serum creatinine gradually improved to 2.04 mg/dL. His 1 year protocol biopsy still showed tubulointerstitial inflammation, rare positive SV40 staining, proliferative GN with improving monoclonal IgG deposits, indicating Banff borderline acute cellular rejection. His immunosuppressive regimen was intensified and graft function has remained stable.

Discussion: Our case report with close proximity of HCV treatment failure and severe BKpY DNAemia/nephropathy supports the previous finding that transplantation from HCV infected donor kidneys to uninfected recipients may be a risk factor of BKpY DNAemia/nephropathy.

Cytomegalovirus-Associated Collapsing Glomerulopathy in a Renal Transplant Recipient
Chirag Lavani, Alexander J. Gallan. Division of Nephrology Medical College of Wisconsin, Milwaukee, WI.

Introduction: Cytomegalovirus-associated collapsing glomerulopathy (CG) is a glomerular disease presenting with nephrotic syndrome and acute kidney injury (AKI), and showing collapse and sclerosis of glomerular capillaries with hypertrophic and injured podocytes on kidney biopsy. CG is most often seen in association with HIV infection and APOL1 nephropathy; however, CG can be associated with non-HIV viral infections. We describe a case of CMV-associated CG in a renal transplant patient.

Case Description: A 73 year old Caucasian male with history of ERSD due to collapsing glomerulopathy (CG) in a glomerular disease presenting with nephrotic syndrome and acute kidney injury (AKI), and showing collapse and sclerosis of glomerular capillaries with hypertrophic and injured podocytes on kidney biopsy. CG is most often seen in association with HIV infection and APOL1 nephropathy; however, CG can be associated with non-HIV viral infections. We describe a case of CMV-associated CG in a renal transplant patient.

Case Description: A 73 year old Caucasian male with history of ERSD due to collapsing glomerulopathy (CG) in a glomerular disease presenting with nephrotic syndrome and acute kidney injury (AKI), and showing collapse and sclerosis of glomerular capillaries with hypertrophic and injured podocytes on kidney biopsy. PO2452
Early Increase in Urinary Exosomal BK Virus MicroRNA as a Predictive Marker of BK Virus Nephropathy: A Prospective Kidney Transplantation Cohort
Won-Hee Lee,1 Su Woon Jung,1 Ju young Moon,1 Yang yun Kim,2 Kyung hwan Jeong,2 Sangho Lee,2 Kyung Hee University Hospital at Gangdong Department of Orthopedic Surgery, Seoul, Republic of Korea; 2Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea.

Background: Urinary exosomal bkv-miR-B1-5p was associated with BK virus (BKV) nephropathy (BKVN) in a cross-sectional study. However, its time-dependent post-transplantation changes and predictive value for BKVN have not been investigated.

Methods: We carried out a multicenter prospective cohort from which 83 kidney transplant recipients (KRTs) in South Korea (biopsy-proven BKVN [n=10], presumptive BKVN [n=12], and non-BKVN patients [n=61]) were selected for the measurement of urinary exosomal bkv-miR-B1-5p levels at 0.5, 3, 6, and 12 months posttransplant.

Results: At 2 weeks posttransplant, urinary exosomal bkv-miR-B1-5p levels showed an increasing trend (non-BKVN < presumptive BKVN < biopsy-proven BKVN), while plasma BKV DNA levels were undetectable in all groups. Thereafter, both urinary exosomal bkv-miR-B1-5p and plasma BKV DNA levels peaked at 3 months posttransplant and then decreased. Multivariable-adjusted Cox regression showed that urinary exosomal bkv-miR-B1-5p levels at 0.5, 3, 6, and 12 months posttransplant independently predicted biopsy-proven BKVN development. In particular, the early increase in urinary exosomal bkv-miR-B1-5p makes its predictive ability for biopsy-proven BKVN superior to that of plasma BKV DNA at 2 weeks posttransplant.

Conclusions: Our results suggest that urinary exosomal bkv-miR-B1-5p can be used to identify the KRTs at high risk for BKVN at earlier time than plasma BKV DNA loads, enabling earlier intervention.

Polyomavirus Nephropathy with Crescent Formation
Laura Binari, Meghan E. Kapp, Heidi M. Schaefer, Beatrice P. Concepcion. Vanderbilt University Medical Center, Nashville, TN.

Introduction: Polyomavirus reactivation in an immunosuppressed transplant patient may cause polyomavirus nephropathy (PVN). Classically seen as a pleomorphic tubulointerstitial inflammatory reaction to the virally infected tubular epithelial cells, there are few reports of glomerular viral tropism. We present unique histopathologic findings of PVN including crescent formation with ultrastructural and immunohistochemical evidence of viral infection of glomerular epithelial cells in a kidney transplant recipient with acute kidney injury.

Case Description: A 52 y/o man s/p DDKT with well-controlled HIV presented with 2 weeks of worsening cough. He was diagnosed with multifocal pneumonia and disseminated CMV and VZV infection. His serum creatinine (SCr) and BK virus PCR were elevated to 3mg/dl (baseline 1.4-2.0 mg/dL) and 3.8M copy/mL respectively. He received ganciclovir and his immunosuppression was reduced. His pneumonia improved, but his BK PCR increased to 13.6M copy/mL and SCr remained elevated at 2.4 mg/dL. A renal biopsy showed a diffuse plasma cell-rich pleomorphic interstitial inflammatory infiltrate, tubulitis, and acute tubular injury. Viral cytopathic effect was evident and SV40 immunostain was positive in 60-70% tubular profiles, as well as parietal and visceral epithelial cells. EM revealed viral particles measuring 30 nm in diameter in tubular epithelial cells and a parietal epithelial cell. In addition, 7 of 21 total glomeruli had crescent formation with no GBM breaks or fibrinoid necrosis. There was no evidence of concomitant cellular or antibody-mediated rejection or CMV infection. These findings were indicative of PVN, with the rare finding of frequent crescents with glomerular epithelial cell infection.

Discussion: PVN is rarely described as having crescentic glomerular lesions, and if present, only one glomerulus per biopsy was affected. There are no reported cases of rapidly progressive glomerulonephritis in PVN. In our case, we found crescent formation more frequently in 33% of glomeruli. Additionally, viral cytopathic changes uncommonly affect glomeruli, typically only involving parietal epithelial cells when present. We demonstrated viral infection of both parietal and visceral epithelial cells. Our case highlights a pattern of kidney injury not commonly seen in PVN and supports that crescent formation can be caused by viral infection of the parietal epithelial cells.

PO2454
Risk Factors for Detrimental Progression in Kidney Transplant Recipients with BK Viremia
Abish Kharel, Arjanga Djamali, Margaret R. Jorgenson, Beyann Alzoubi, Kurtis J. Swanson, Neetika Garg, Fahad Aziz, Maha A. Mohamed, Didier A. Mandelbrot, Sandesh Parajuli. University of Wisconsin School of Medicine and Public Health, Madison, WI.

Background: The only effective management for BK viremia (BKV) among kidney transplant recipients (KTR) is regular monitoring and adjustment of immunosuppression. With this strategy, the majority of patients will clear BK or have low-level persistent BKV (Group A). However, few will transition toward over-immunosuppression [BKV level > 5 log10 copies/ml or BK nephropathy (BKVN) (Group B)], or under-immunosuppression [de novo DSA (dnDSA) or acute rejection (AR) (Group C)]. In this study, we sought to find those characteristics of patients who progress to group B or group C.

Methods: It was a prospective study among KTR transplanted at our University hospital between 01/2015 and 12/2017. All KTR who developed BKV (> 3 log10 copies/ml) within 2 years of transplant were included in the study. Patients were followed up to 2 years of transplant and were divided into 3 groups as above, based on the BK levels or other diagnoses. Those patients with persistent BK > 5 log10 copies/ml on BKV along with dnDSA or AR, were assigned to the Group B or Group C, whichever event occurred first.

Results: A total of 224 KTR fulfilled our selection criteria, of which 118 (53%) remained in group A, while 64 (28%) and 42 (19%) transitioned to groups B and C, respectively. Compared to group A, in multivariate analysis, female (HR 2.05, 95% CI: 1.08-3.90, p = .02), rejection before BKV (HR 2.90, 95% CI: 1.04-8.12, p = .04) and interval from transplant to first BKV (HR 0.81, 95% CI: 0.72-0.90, p = 0.001) were associated with transition to group B. Conversely, basiliximab induction (HR 2.06, 95% CI: 1:03-4.11, p = .03), HLA mismatch > 3 (HR 2.27, 95% CI: 1:01-5.06, p = .04) and DGF (HR 4.14, 95% CI: 1.12-15.3, p = .03), were associated with progression to group C. At 2 years, graft failure rates were similar between the groups. However, among those with functional graft, group A had significantly better graft function with eGFR of 62 ml/min compared to 46 for group B and 50 for group C.

Conclusions: Our study suggests that in KTR with BK viremia, nearly 50% progress unfavorably toward a state of under-immunosuppression (AR) or over-immunosuppression (worsening BK). Modifiable risk factors including history of rejection, induction therapy, HLA mismatch, and DGF could help preventing untoward disease progression.
PO2455

**A First-in-Human Study of MAU868, a Novel Neutralizing Antibody Against BK Virus**

Steven J. Kovacs,2 Johanna R. Abend,3 Xiaoying Xu,4 Sachin Desai,5 Amanda Nguyen,6 Laura M. Sterling,7 Michael R. Hodges,8 Peter Pertel,9 Novartis Institutes for BioMedical Research Emeryville, Emeryville, CA; 9Novartis Institutes for BioMedical Research East Hanover, East Hanover, NJ; 1Celerion Inc, Lincoln, NE; 2Amphylx Pharmaceuticals, Inc, San Diego, CA.

**Background:** Reactivation of BK virus (BKV) infection can cause significant kidney and bladder disease in immunocompromised patients. BKV nephropathy is a leading cause of allograft loss in kidney transplant recipients. There are currently no effective or BKV-specific therapies. MAU868 is a novel monoclonal human IgG1 that binds to the BKV major capsid protein (VP1) with potent in vitro neutralizing activity against the 4 major BKV genotypes (IC50 ranging from 0.009 to 0.093 μg/ml).

**Methods:** MAU868 was administered i.v. (1, 3, 10, 30, and 100 mg/kg) or s.c. (3 mg/kg) to healthy adults in a randomized, placebo-controlled, blinded, single ascending dose design. Each i.v. cohort was 5 subjects (4 MAU868:1 placebo); the s.c. cohort was 8 subjects (6 MAU868:2 placebo). Subjects were observed for 24 h and followed for 100 d with routine safety monitoring and PK assessments. *Ex vivo* neutralizing activity of serum was measured before and 4 w after dosing. The range of doses included and exceeded the predicted clinically efficacious dose.

**Results:** 33 subjects completed the study. Adverse events were mild and infrequent; those occurring in more than 1 subject included nasal congestion (3, 9.1%), oropharyngeal pain (3, 9.1%), and injection site hemorrhage (ecchymosis after s.c. injection; 2, 6.1%). There were no infusion reactions. No subject discontinued the study due to an adverse event or developed anti-drug antibodies. MAU868 PK was typical of a human IgG with a half-life of 23 to 30 d. AUC and Cmax were dose-proportional, ranging from 9880 to 106000 μg*h/ml and 24.7 to 2740 μg/ml (ie, no evidence of FcRn saturation). Day 29 plasma MAU868 concentrations, adjusted for extravascular distribution to estimate parenchymal exposure, were approximately 7- to 751-fold higher than the highest in vitro EC50 (0.093 μg/ml). Maximum *ex vivo* neutralizing activity of serum was achieved for doses ≥10 mg/kg. Bioavailability after s.c. injection was 57.6%.

**Conclusions:** MAU868 was safe and well tolerated with PK typical for a human IgG. The *ex vivo* neutralizing activity suggests where the therapeutic range may be for the treatment or prevention of BKV disease. These results warrant further clinical investigation of MAU868 in patients with or at risk for BKV disease.

**Funding:** Commercial Support - Novartis

PO2456

**Induction with Alemtuzumab and Thymoglobulin in Kidney Transplant and the Risks of Leukopenia, Cytomegalovirus Infection, and BK Virus Nephropathy**

Ali Nephropathy and the Risks of Leukopenia, Cytomegalovirus Infection, and BK Virus.

**Poster**

**Background:** Reactivation of BK virus (BKV) infection can cause significant kidney and bladder disease in immunocompromised patients. BKV nephropathy is a leading cause of allograft loss in kidney transplant recipients. There are currently no effective or BKV-specific therapies. MAU868 is a novel monoclonal human IgG1 that binds to the BKV major capsid protein (VP1) with potent in vitro neutralizing activity against the 4 major BKV genotypes (IC50 ranging from 0.009 to 0.093 μg/ml).

**Effects of Early Conversion to mTOR Inhibitors on Viral Infections in Renal Transplant Recipients: Eight-Year Single-Center Experience**

Waled Hassan,1 Hisham Mostafa,2 'The University of Tennessee Health Science Center College of Medicine, Memphis, TN; 2'Minia Nephrology and Urology University Hospital, Minia, Egypt.

**Background:** Mammalian target of rapamycin inhibitors (mTORis) may decrease cytomegalovirus (CMV) and BK virus infection in renal transplant recipient. long-term effect of rejection rate follows up.

**Methods:** This is a retrospective analysis of all patients who underwent living unrelated donor kidney transplant at Nasr City Insurance and Nile Badrawy Hospitals from 2011 to 2018, panel reactive antibody zero and no donor specific antibody. Uni- and multi-variate analysis were done to compare between mTORis based regimen and cyclosporin inhibitors (CNI)-based regimen.

**Results:** We identified 1458 patients who underwent living unrelated kidney transplant with intermediate risk for CMV. All patients received Induction with anti-thymocyte globulin then were maintained on mycophenolate mofetil (MMF)-CNI-prednisone for at least 6 months. They were classified into two groups: * Group I: 658 patients on mTORis (sirolimus or everolimus), who were shifted from CNI to mTOR-I due to different causes. Group II: 800 patients on CNI (cyclosporin or tacrolimus). The overall incidence of CMV infection and BK infection (Table 1) were statistically significant lower in nTORis group compared to CNI group with no statistical differences in incidence of rejection in the first 36 month but late higher rate of BPAR (Table 2).

**Conclusions:** mTORis/MMF is associated with low incidence of CMV and BK infection with no significant difference in rejection rate in the first 36 months. However, further regiment modification is required to reduce late rejections.

PO2458

**The Utility of Procalcitonin in the Management of Kidney and Pancreas Transplant Recipients with Suspected Infection**

Sarah Gilligan,1 Faud S. Shihab,2 Divya Raghvan,3 Laith Al-Rabadi,4 Joseph Abraham,5 Isaac E. Hall. University of Utah Health, Salt Lake City, UT.

**Background:** Procalcitonin is used to differentiate between bacterial and viral infections to guide judicious use of antibiotics. It has, however, been well studied in renal and pancreas transplant recipients. These patients are frequently exposed to antibiotics and are at risk for developing resistant infections. Thus, there is a need for reliable markers of bacterial infection. The purpose of this study was to compare procalcitonin levels in patients with and without bacterial infection to determine whether procalcitonin is a reliable marker of bacterial infection in the transplant population.

**Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only**

Underline represents presenting author.

746
Methods: Serum procalcitonin levels were measured on admission on all patients admitted to the Transplant Nephrology service with suspected infection as determined clinically by the on-call physician. We obtained all study data via chart review.

Results: Procalcitonin was measured in 154 patients. Demographics are included in the table. Forty-two patients (27%) had a positive bacterial culture. Mean procalcitonin for those with positive cultures was 5.36 ng/ml vs. 3.35 ng/ml in those without positive cultures, however this was not statistically significant (t=0.642, p=0.522). Patients with positive cultures were more likely to have procalcitonin levels >0.5 mg/ml (p=0.003). Procalcitonin had a modest but significant correlation with WBC count (r=0.249, p=0.002). Receiver operating characteristic analysis demonstrated an area under the curve (AUC) of 0.679 (95% confidence interval: 0.590-0.768, p=0.001) for predicting positive cultures with procalcitonin compared with an AUC of 0.584 (95% confidence interval: 0.474-0.694, p=0.110) for WBC count.

Conclusions: In this cohort of hospitalized kidney and pancreas transplant recipients, serum procalcitonin concentration was associated with bacterial infection and was found to be a better predictor than WBC count. More information is needed to determine the utility of procalcitonin measurements in clinical decision making in this patient population.

Infection Rate at 1 Year of Deceased Donor Kidney Transplant in the Elderly

Wina Yousman, Nicole Low, Wei Xiang Wong, Venkatesh Kumar Aiyamuthu, Bekir Tanriover. The University of Arizona, Tucson, AZ.

Background: There is limited publications about infection incidence rate in deceased donor kidney transplant (DDKT) recipients older than 65 years of age. The objective of this study is to examine our center specific infection incidence rate within one year of DDKT.

Methods: Retrospective chart review of DDKT (N=176) from July 2016 to December 2019 at Banner Medical Center in Tucson, AZ. Primary outcome was the infection incidence rate among recipients older than 65 year-old, including Cytomegalovirus (CMV) viremia and BK viremia (screened by monthly plasma PCR testing), or urinary tract infection (UTI) (diagnosed with positive urine culture and urinary symptoms within 2 weeks of symptom onset).

Results: The characteristics of the study cohort was shown in Table 1. Out of 176 patients, 63 patients (35.8%) were older than 65 years old. There was no significant difference in the incidence rate of total infection, CMV viremia, BK viremia, and UTI in patients older than 65 years versus non-elderly patients (6.5% vs 6.7%, p=0.98; 14.8% vs 14.0%, p=0.79; 20.0% vs 19.0%, p=0.94). There was a trend of higher incidence rate in patients older than 65 years old compared to younger patients, however this was not statistically significant (t=0.452, p=0.654). The multivariable logistic regression analysis (adjusted for ethnicity, KDPI, EPTS, cPRA, and CMV mismatch) did not show increased odds of all type of infections among older recipients.

Conclusions: The infection rate of elderly versus non-elderly who received DDKT were similar.

PO2460

Two Deaths of Acute Transplant Patients from Strongyloides Hyperinfection Syndrome (SHS): Can We Prevent Harm with Screening and Prophylaxis at the Time of Transplantation?

Background: A 59 year old Vietnamese man presented with non-specific abdominal pain 8 weeks after a deceased donor kidney transplant. He was thoroughly investigated and no cause for the pain identified. On day three of the admission he became febrile and hypoxic. He died with multi-organ failure. Within three months a patient of Congolese origin presented nine weeks post transplant with abdominal pain. He became febrile with gram positive bacteraemia and was admitted to the ICU with type 1 respiratory failure where he unfortunately died. Autopsy findings revealed SHS. These cases were patients at a transplant centre in a non-endemic area albeit with an ethnically diverse population. A survey of other UK transplant centres showed that none did pre-transplant screening for strongyloides infection.

Methods: As a result of these cases we implemented and evaluated a program to screen for and prophylactically treat Strongyloides infection: Live donor patients were screened with Strongyloides serology in advance of transplantation. All recipients of deceased donor transplants were screened on admission for their transplant unless they had never travelled to an endemic area. At induction recipients received a weight adjusted dose of ivermectin pending serology results. If positive a second prophylactic dose was administered at day 14.

Results: Between July 2019 and March 2020, 135 patients were transplanted at our unit. Of those 125 had strongyloides serology testing; eight were positive at time of transplantation. Of these patients reported as “borderline”, one further patient tested positive on a previous admission for a transplant which was cancelled; but was negative on the admission of the successful transplant. This indicates that at least 8% of our transplant listed patients are positive for strongyloides infection. By May 2020 there were no recorded deaths due to SHS, or morbidity associated with strongyloides infection in this group.

Conclusions: We have demonstrated that there is a significant level of sero-positivity within our pre-transplant population and that a relatively low-cost strategy may help prevent the potentially fatal Strongyloides Hyperinfection Syndrome.

PO2461

Infectious Complications and Malignancy After Kidney Transplant in the Elderly Population

Luz F. Liriano-Ward, Yorg Al Azzi, Cindy T. Pynadath, Maria Ajaimy, Pablo Leverte Campos, Purna Bindu Nandigam, Enver Akalin. Montefiore Medical Center, Bronx, NY.

Background: Kidney transplantation improves quality of life and survival in all patients regardless of age. However, older patients are prone to development of side effects related to immunosuppressive medications including infections and malignancy. We aim to evaluate clinical outcomes in recipients >65 years of age.

Methods: We retrospectively reviewed all patients over the age of 18 who received an isolated renal transplant at our center from January 2013 to June 2017. We compared clinical outcomes including allograft and patient survival, as well as the development of infections and malignancy in patients > 65 compared to younger patients.

Results: Of 624 patients analyzed, 148 (24%) were > 65 years of age. There was no difference in terms of gender, race, immunosuppressive or induction therapy between the two groups. Older patients were more likely to receive a deceased donor kidney transplant (92% vs. 81%, p=0.009). During a median 48 months (28, 70) of follow-up, as expected mortality was higher in older patients (16% vs. 6.5%, p<0.0001) but there was
no difference in terms of death-censored graft loss (10.8% to 9%, p=0.52) compared to younger patients. Detailed analysis of infections revealed that there was no difference in terms of BKV and CMV viremia, pneumonia, bacteremia, influenza and c. diff between the two groups. However, older patients had more fungal and urinary tract infections and malignancy. The most common infection in the elderly was PJP pneumonia (4%), candidemia (3%), and cryptococcal infection (2%). The most common malignancy in the elderly was skin cancer (6%) followed by prostate (2%), lung (1%), and colon (1%).

Conclusions: Recipients older than 65 had similar graft survival compared to younger patients, but had a higher incidence of fungal and urinary tract infections and malignancies.

PO2462
Risk of Active Tuberculosis Infection in Kidney Transplantation Recipients: A Matched Comparative Nationwide Cohort Study
Sehoon Park,1 Ji Eun Kim,2 Mi-yeon Yu,3 Yong Chul Kim,2 Dong Ki Kim,3 Kwun Wook Joo,1 Yun Su Kim,1 Kyungdo Han,1 Hajeong Lee.3 Armed Forces Capital Hospital, Seongnam, Gyeonggi-do, Republic of Korea; 2Soongsil University, Dongjak-gu, Seoul, Republic of Korea; 3Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; 4Yonsei University Guri Hospital, Gyeonggi-do, Republic of Korea; 5Korea University Guro Hospital, Seoul, Republic of Korea.

Background: Although the risk of mycobacterium tuberculosis (TB) infection is high in both kidney transplantation (KT) recipients and dialysis patients, a large-scale evidence comparing the risk between the two groups in a nation with moderate or higher TB prevalence was rare.

Methods: We performed a nationwide retrospective cohort study based on the claims database of South Korea where moderate TB prevalence is reported. We included incident KT recipients from 2011 to 2015 and compared their active-TB risks with matched controls. The 1:1 matched general population group was matched for age, sex, and era, while the dialysis group was matched for age, sex, era, underlying hypertension, and diabetes. We excluded the matched pairs with age < 20 years old, a previous TB history, and those matched to a multi-organ transplantation case. The incident active-TB risk was assessed by the multivariable Cox regression analysis. Within KT group, associations between active-TB, as a time-dependent variable, and post-transplant death or death-censored graft failure was investigated.

Results: The number of matched 7,462 subjects (total 22,386) were included to each of the study groups. During median 3.57 years of follow-up duration, the incidence rate for active-TB was 3.92/1,000, 4.38/1,000, and 0.67/1,000 person-years in the KT, dialysis, and general population groups, respectively. The KT group showed a significantly higher risk of active-TB than the general population group [adjusted HR 3.39 (1.88-6.12)] but a similar to the dialysis group [adjusted HR 0.98 (0.73-1.31)]. Active-TB was a significant risk factor for death [adjusted HR 2.24 (1.19-4.42)] or death-censored graft failure [adjusted HR 2.21 (1.36-3.58)] in the KT patients.

Conclusions: In Korea with moderate TB prevalence and active surveillance strategies, KT patients may not have to burden additional risk of active-TB when compared to dialysis patients. Still, clinical attention for active-TB complication should not be overlooked in end-stage kidney disease patients, particularly for KT patients as active-TB was associated with worse post-transplant prognosis.

PO2463
Hydroxychloroquine as an Alternative or Adjunctive Antimetabolite in Kidney Transplant Recipients: Analysis of Linked US Registry and Claims Data
Krista L. Lentine,1 Tarek Alhamad,2 Huiling Xiao,3 Mark Schnitzler,1 Su-Hsin Chang,2 Yasar Caliskan,3 David Axelrod,3 Daniel C. Brennan.1 Saint Louis University, St Louis, MO; 2Washington University in Saint Louis, Saint Louis, MO; 3University Iowa, Iowa City, IA; 4Johns Hopkins University, Baltimore, MD.

Background: Hydroxychloroquine (HCQ) is an antimalarial drug with immunomodulatory effects in patients with systemic lupus erythematosus (SLE) and scleroderma. The potential anti-viral effects of HCQ have raised attention in the context of the COVID-19 pandemic, although safety is controversial.

Methods: We examined a novel database linking national transplant registry identifiers for kidney transplant recipients (KTxs) to records from a large U.S. pharmacological claims database (2008–2017) and Medicare claims to study HCQ use among Medicare beneficiaries with kidney failure due to SLE or scleroderma (N=2,550). We compared 3 groups based on immunosuppressive regimen 7–12 mos. post-KTx: 1) tacrolimus (Tac) + mycophenolic acid (MPA) + prednisone (Pred) – Reference; 2) Tac+HCQ+Pred; or 3) Tac+HCQ+MPA+Pred. Associations of regimen with graft failure, death and clinical cardiovascular complications captured in Medicare claims >1-to-3 yrs post-KTx were examined with multivariate Cox regression, adjusted for baseline factors in the registry.

Results: Among the study sample, 18.3% received Tac+HCQ+MPA+Pred 7–12 mos. post-KTx, while 1.7% received Tac+HCQ+Pred. Use of HCQ containing regimens was more common in women (vs men), and Black and Hispanic (vs white) recipients; use of Tac+HCQ+MPA+Pred was more common in younger patients (vs older) patients (Table). The unadjusted incidence of adverse events did not differ across the 3 groups (Fig A); risks also did not differ with covariate adjustment (Fig B).

Conclusions: HCQ is an inexpensive immunomodulatory agent that may be used safely in selected KTx recipients as an alternative or adjunct to standard immunosuppression.

PO2464
Bacillary Angiomatosis in a Kidney Transplant Recipient
Mohamed Hassanein, Bushra Syed, Jose Morillas, Jessica B. Kocher, A. M. Lum, A. Fatica. Cleveland Clinic, Cleveland, OH.

Introduction: Bacillary angiomatosis (BA) is a vascular proliferative manifestation of Bartonella henselae (BH) or Bartonella quintana (BQ) that usually affects immunocompromised hosts. It usually involves the skin but may affect other organs. Few cases of BA in kidney transplant (KT) recipients have been reported, with most cases presenting years after KT. We describe a case of BA in a KT recipient that occurred early post-transplant.

Case Description: A 67-year-old male KT recipient from a deceased donor developed fevers, night sweats, and fatigue 1-month post-KT. He received antihypocyt
globulin induction, and maintenance tacrolimus, mycophenolate, and prednisone. Two months later, he presented with diffuse violaceous papules (Figure 1A). Biopsy of a papule with Warthin-Starry stain showed clusters of bacteria suggestive for BA (Figure 1B). Diagnosis was confirmed with a positive serum Bartonella polymerase chain reaction (PCR). He was treated with doxycycline with resolution of symptoms. BH and BO Immunoglobulin G (IgG) were equivocal. A few weeks later, IgG for BH was 1:256 (reference range <1:128). Echocardiogram, abdominal computed tomography, and kidney biopsy were unremarkable. Recipient Bartonella PCR and antibodies on the day of transplant were negative. Donor Bartonella PCR and BH IgG were negative. Donor BQ IgG was equivocal. The recipient had a cat 8 years prior to KT without recent exposure. Allograft function remains intact, and the rash completely resolved. Bartonella PCR 6 months on treatment was negative.

Discussion: Our patient developed signs of BA with positive seroconversion within the first 3 months of KT which is rare. BA should be considered in the differential diagnosis of fever and cutaneous angioi-milia-like lesions in KT recipients, even in the absence of exposures. Combined serology and molecular testing (PCR) is useful in diagnosing BA as serology alone may be unreliable. Early empiric treatment should be considered in transplant recipients while waiting for confirmatory results.

Figure 1. (A) Violaceous papules on the trunk. (B) Warthin–Starry stain showing bacteria (arrow).

PO2465
Isavuconazole as Consolidation Therapy for Disseminated Histoplasmosis in a Kidney Transplant Recipient
Samar A. Medani, Michael Kessler, Sandesh Parajuli. University of Wisconsin-Madison, Madison, WI.

Introduction: The diagnosis of systemic fungal infection may be elusive and requires a high index of suspicion with prompt evaluation, directed laboratory and radiological work-up and if necessary, histological examination. To our knowledge, this is the first case report of isavuconazole use as consolidation therapy for disseminated fungal infection in a kidney transplant recipient.

Case Description: A 76-year-old female with polycystic kidney disease presented 8 years post kidney transplantation with a painful tongue ulcer, anorexia, weight loss, progressive anemia and severe de-conditioning. She was on maintenance mycophenolate, prednisone and tacrolimus. A midline fissure on the dorsal tongue surface (image 1- left), and two non tender nodular masses in the left forearm and right buttock were noted. A diagnosis of disseminated histoplasmosis was made by biopsy of the tongue ulcer, and cultures of blood, tongue tissue and forearm nodule aspirate. Blood and urine histoplasma antigens were positive. The patient was treated with amphotericin for two weeks before transitioning to itraconazole then to Isavuconazole due to QT prolongation. Mycophenolate was stopped. An outstanding clinical response with healing of the tongue ulcer (image 1 - right), shrinking of the subcutaneous lesions, and substantial functional progress to prior independence was seen within 3 months. Histoplasma urinary and plasma antigen levels declined to undetectable levels. Isavuconazole was continued for a year with no adverse side effects reported.

Discussion: Infections with Histoplasma capsulatum are largely asymptomatic but progressive disseminated mycosis can occur in the immunocompromised. There is no specified agent selectively approved for second line maintenance therapy when itraconazole is not tolerated or is ineffective. Limited experience has been reported with other azoles, and even less so with isavuconazole. This case demonstrates an excellent outcome of treating disseminated histoplasmosis with isavuconazole in a kidney transplant recipient.

Ulcereated median sulcus of the tongue, before (left) and 8 months after (right) starting antifungal therapy.

PO2466
The Diagnostic Dilemma of Diffuse Lymphadenopathy in a Kidney Transplant Recipient
Michael C. Krouse, Priyamvada Singh, Tomas I. Guerrero Nunez. The Ohio State University Wexner Medical Center, Columbus, OH.

Introduction: Immunological balance is critical for transplant recipients. An optimum amount of immunosuppression prevents rejection while avoiding infection and cancers. Constitutional symptoms and lymphadenopathy could be present in both scenarios and could pose a diagnostic challenge.

Case Description: A 36-year-old male immigrant from India (ten years ago) with PMH of ESRD secondary to IgAN received a DDKT (9/2019, EBV D+/R+, on tacrolimus and myfortic). He was admitted with extensive retroperitoneal and mesenteric lymphadenopathy and a hypodense structure in the left upper abdomen (3.8 x 5.1 cm) on CT scan along with constitutional symptoms of fevers, constipation, and abdominal pain for ten days duration three months after transplant. Vitals signs and physical examination were unremarkable except for low-grade fever. Aside from mild anemia (Hb 10 mg/dL), laboratory analysis was normal. PET scan revealed hypermetabolic lymphadenopathy in the neck, abdomen, and pelvis and consolidative changes in the left lung base and a right-sided loculated pleural effusion. Extensive workup - CMV PCR, pan-culture, fungal infections, and flow cytometry – was negative. CT-guided retroperitoneal lymph node biopsy, incisional biopsy of the mesenteric mass, and an endobronchial ultrasound-guided transbronchial needle aspiration of subcarinal LN were non-diagnostic. Finally, exploratory laparotomy and resection of the mesenteric mass revealed granuloma formation with multifoculated giant cells concerning for TB. The AFB culture grew mycobacterium tuberculosis on day 24. He is currently on antitubercular treatment.

Discussion: Our case highlights the importance of a high degree of clinical suspicion for infectious etiology in transplant recipients, especially those from countries with a high prevalence of TB. Our patient bore a distant immigration history and a negative tuberculin test and did not have a history of exposure. Still, he was at increased risk of activation of latent TB due to his immunocompromised state. Extra-abdominal TB, like abdominal TB, poses a diagnostic challenge as the presentation can be non-specific and the AFB stain and culture can be non-diagnostic. Thus, a tissue biopsy becomes key to diagnosis. PTLD was high on differential given the PET-avid LAP. PET-avid lesions imply a hypemetabolic state which can happen in both malignancies and infections.

PO2467
Post-Transplant Lymphoproliferative Disorder: Recurrence at an Unusual Site
Aditi Saha, Sohaib Tariq, Lalitha Thirunavukarasur Murugan, Sunil Sapru, Miguel Conde. Saint Barnabas Medical Center, Livingston, NJ.

Introduction: PTLD includes a spectrum of clinical presentations due to lymphoid proliferation ranging from benign hyperplasia to aggressive lymphomas that occur after either a HT or HSCT. PTLD can involve extra nodal sites like gaint tissue, GI tract, lungs, and skin. Soft tissue involvement is very rare. We report a patient with PTLD who had relapsed with axillary lymphadenopathy and a soft tissue mass on the arm.

Case Description: A 59-year-old male was diagnosed with EBV negative PTLD involving retroperitoneal, mediastinal and supraclavicular lymph node, one year after renal transplant. He was treated R-CEOP (Rituximab, Cyclophosphamide, Etoposide, Vincristine, Prednisone). After 6 cycles of chemotherapy repeat PET scan confirmed complete remission. 3 months later, he presented with LUE pain and swelling. Labs were significant for high LDH and Beta-2 microglobulin. CT LUE revealed 4.8 cm mass over left anterior arm and left axillary adenopathy. Biopsy and flow cytometry of axillary lymph node confirmed relapse. Immunohistochemical stains showed tumor cells positive for CD20, PAX5, BCL2, MUM1, BCL6 with Ki67 of 80-90%. Patient developed compartment syndrome and had to undergo fasciotomy. Patient was started on modified regimen with Rituximab, Gemcitabine and Oxa-platin (R-GEMOX) for poor performance status.

Discussion: The incidence of PTLD ranges from 1 to 25% with 90% of cases being EBV-associated, CD 20 positive, B cell neoplasms. EBV negative PTLD occurs in 5-10% cases, appears late with worse prognosis than EBV positive PTLD. EBV negative PTLD is assumed to be related to Tp35 mutation caused by immunosuppressive agents like azathioprine or tacrolimus. Skin and subcutaneous lesions are extremely rare as sites of extra nodal presentation and may take the form of solitary or multiple papules, nodules, plaques with ulceration, comedo-like lesions, follicular keratotic papules, or localized alopecia. Our patient is interesting as he had a relapse of EBV negative PTLD in the form of a soft tissue fibro-adipose mass in the upper extremity. To the best of our knowledge, there have been three cases of PTLD presenting as soft tissue masses on head reported in the literature. Biopsy remains the gold standard for diagnosis. Treatment is includes reduction of immunosuppression and rituximab with additional chemotherapy.

PO2468
Post-Transplant Lymphoproliferative Disorder (PTLD) Presenting as Solitary CNS Lymphoma: A Rare Occurrence
Aditi Saha, Sohaib Tariq, Lalitha Thirunavukarasur Murugan, Sunil Sapru, Israel R. Grossman. Saint Barnabas Medical Center, Livingston, NJ.

Introduction: PTLD associated lymphoma is the second most common malignancy in patients receiving SOT or HSCT with an incidence rate of 1%-3%. CNS involvement occurs in 7%-15% of all PTLD cases. We present a case of isolated PCNS lymphoma two years after renal transplant.
Case Description: A 57-year-old woman with PMH of ESRD s/p kidney transplant (D/R EBV+) with chronic CCI of 30-40% presented with paresthesia and numbness over the right side of her body with mild ataxia 2 years post transplant. Physical exam revealed only numbness over the right side of body. MRI with contrast revealed a left thalamic lesion with moderate vasogenic edema, and MR spectroscopy confirmed high grade neoplasm involving left thalamus. Stereotactic biopsy showed polymorphic CD-20 and EBV positive PTLD. EBV PCR were elevated. Further evaluation ruled out systemic PTLD. Myelofibrosis was stopped and oral steroids started with mild improvement in symptoms. Choice of systemic chemotherapy was limited due to reduced CCl and risk of graft failure. She received modified regimen with newly adjusted high dose Methotrexate, Vincristine and Rituximab for 6 cycles with partial remission and then Tenofovir for 7 cycles with complete remission.

Discussion: The incidence of PTLD ranges from 1 to 25% with 90% of cases being EBV+/EBV+ with chronic CCI of 30-40% cell neoplasms. PCNS-PTLD has a higher incidence in renal SOT, occurs late and is usually monomorphic unlike our patient. Median time of occurrence is 4-5 years after transplant. Risk factors include age, intensity of immunosuppression, time to transplant and EBV status of donor and recipient. Common presenting features include neurological deficits, seizure, and raised intracranial pressure. MRI with contrast preferred imaging and shows multifocal, ill defined, ring enhancing lesions usually in supratentorial and lobar regions. Positive EBV PCR is highly suggestive but biopsy remains the gold standard for diagnosis. Treatment modalities include reduction of immunosuppression, rituximab, high dose methotrexate, cytarabine and cranial radiotherapy. Use of high dose methotrexate has shown improved outcomes with median survival of 26-47 months. Lack of response to first line therapy is considered the dominant prognostic factor. Early recognition and diagnosis remain crucial for improving outcome.

PO2469
National Trends in Kidney Transplantation Among Patients with ESKD from Plasma Cell Dyscrasias
Jia Hwee Ng,1,2 Stephanie Izard,1 Kenar D. Jhaveri,1,2 Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; 1Northwell Health, Great Neck, NY.

Background: Due to relapses and kidney involvement, plasma cell dyscrasias have been a relative contraindication for kidney transplantation. With newer medications and improved prognosis of plasma cell dyscrasias, kidney transplantation in this population is becoming more common. We aimed to describe national trends in the proportion of kidney transplants among patients who had ESKD from plasma cell dyscrasias (multiple myeloma, amyloidosis, and monoclonal gammopathy of renal significance).

Methods: We used data from the United Network for Organ Sharing/ Organ Procurement and Transplantation Network (UNOS/OPTN) database. Patients 18 years or older, BMI >15 or <45 kg/m², received a first kidney transplant between January 1, 2006 to December 31, 2017 were eligible. Recipients of more than one organ transplant were excluded.

Results: A total of 160,966 patients received a first kidney transplant. Among these, 487 (0.3%) had ESKD from plasma cell dyscrasias, kidney transplantation in this population is becoming more common. We aimed to describe national trends in the proportion of kidney transplants among patients who had ESKD from plasma cell dyscrasias (multiple myeloma, amyloidosis, and monoclonal gammopathy of renal significance).

Discussion: Despite improvement in the treatment of plasma cell dyscrasias, national trends show only a small rise in the proportion of kidney transplantation for recipients with ESKD from plasma cell dyscrasias. Additional analyses are needed to assess the outcomes of these kidney transplant recipients.

PO2471
Secondary Malignancy in Kidney Transplant Recipients: University of Southern California Experience
Alexandra K. Wong, Tiffany Truong, Poorva Vaidya, Gino In, Thin Thanh Mai, Keck Hospital of USC, Los Angeles, CA.

Background: Kidney transplant recipients (KTR) on immunosuppressive therapy are at higher risk of developing secondary malignancy (SM). Although previous studies have demonstrated this increased risk, much remains to be elucidated regarding the spectrum of SM and the contributing factors to morbidity and mortality.

Methods: We conducted a retrospective review of all KTR from April 2005 to December 2017 at our institution. We then selected only those patients with SM, and collected demographics, variables related to kidney transplant, malignancy, and outcomes.

Results: Among 1414 KTR, 84 patients (6%) had post-tx SM. Forty-five percent of pts were Hispanic, 35% Caucasian, 11% Asian and 6% African American. Twenty four pts (28%), 11 pts (13%), and 51 pts (59%) developed cutaneous malignancy, hematological malignancy and solid organ malignancy (SOM) respectively. One patient developed both a secondary cutaneous and SOM, while another pt developed 2 different SOM. 46 (55%) pts were deceased by 1/1/20: 25 pts died from malignancy and 9 pts died from infection. Among those 46 pt, 37 pts (80%) had intact graft function at death. Eleven pts (13%) had malignancy prior to tx. The induction was rATG (36%) and basiliximab (41%). 20 pts had biopsy-proven acute rejection; of these 75% was prior to and 25% was post cancer diagnosis. 18 pts were switched to mTOR inhibitor from tacrolimus and cellcept was stopped in 22 pts.

Conclusions: We describe a wide range of SM among a diverse population of KTR, with nearly half of our patients being Hispanic. This highlights the need for further investigation of the impact of ethnicity on SM. Among our KTR, SM was the cause of death for 25 pts and infection was for 9 pts. Regardless of etiology, the majority of pts (80%) had intact graft function at death. Our findings illustrate the need for vigilant cancer screening and additional strategies to decrease cancer risk and death in KTR.

PO2470
A Retropertoneal Cyst of Pancreatic Origin in a Renal Transplant Recipient: Expect the Unexpected
Muhammad O. Saleem,1 Ambreen Chughtai,2 Imran Y. Gani,1 Muhammad I. Saeed,1 Rajan Kapoor.1 1Augusta University, Augusta, GA; 2FMH College of Medicine and Dentistry, Lahore, Pakistan.

Introduction: The immunosuppression required to maintain a renal allograft function puts the recipient at a higher risk of malignancy. We report a rare case that presented a diagnostic dilemma with a retropertoneal heteromorphic cystic mass turned out to be an adenocarcinoma of pancreaticobiliary origin.

Case Description: 43-year-old female with a history of End Stage Renal Disease due to Nephropathy and two renal transplantsations, first in 1999 from her sister and second in 2005 from a deceased donor, presented with complaint of left sided abdominal pain and distention for one month. Her graft function was stable with creatinine of 1.8mg/dl on immunosuppression with tacrolimus, mycophenolic acid, and prednisone. Abdominal CT scan showed a large a well-circumscribed cystic mass in her left renal fossa which subsequently underwent exploratory laparotomy which revealed a retropertoneal 1.7L cystic hematoma with no association to native or transplant kidneys. The histopathology showed adenocarcinoma with mucinous and enteric features. Based on the morphology and immunoprofile, the differential diagnosis included an ovarian, gastrointestinal or peritoneal primary. Tumor markers showed elevated CA19-9, but normal CEA and CA-125. Given the positivity for both CK 7 and CK 20, colonic origin was unlikely but could not be completely excluded. Negative EGD and colonoscopy ruled out GI malignancy. Given the size, location and consistency of the cystic mass, it was presumed to be a cystic neoplasm originating from the pancreas. PET scan was unremarkable. Molecular analysis predicted 90% probability of pancreaticobiliary adenocarcinoma. Subsequently patient was started on adjuvant chemotherapy with Gemcitabine. She failed first and second lines of chemotherapy with progression of cancer. Then she received PD-L1 inhibitor, Nivolumab which could not prevent progression of disease but resulted in renal graft failure. Per last reports, patient was on palliative chemotherapy and in terminal phase of her life.

Discussion: Post-transplant malignancy is one of the most feared complications. It is the third leading cause of mortality and accounts for 8-10% of all deaths in United States and 30% in Australia in kidney transplant recipients. Compared with general population, the risk is increased 2-3 folds and mortality rates are higher. The occurrence of pancreatic cancer is high too. But finding a pancreaticobiliary cancer from a retropertoneal cyst with negative pancreas imaging is rare. 

PO2472
Spectrum and Consistency of Cancer Outcomes in Randomized Trials in Kidney Transplant Recipients: A Systematic Review
Eric H. Au,1 Allison Thorpe,2 Gemeline Wong,1 Jonathan C. Craig,1 1The University of Sydney Faculty of Medicine and Health, Sydney, NSW, Australia; 2Children’s Hospital at Westmead Centre for Kidney Research, Sydney, NSW, Australia; 3Flinders University College of Medicine and Public Health, Bedford Park, SA, Australia.

Background: Cancer is an important cause of morbidity and mortality in kidney transplant recipients. Despite being established as a critically important outcome by patients, caregivers and health professionals, inconsistency in how cancer outcomes are defined and reported in trials involving kidney transplant recipients may limit decision-making. The aim of this study was to assess the spectrum and consistency of cancer outcomes in trials involving kidney transplant recipients.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Malignancy treatment with immunotherapy in renal transplant recipients is complicated by a very high risk of rejection. Immune checkpoint inhibitors have been shown to be effective treatments for certain malignancies (melanoma, renal cell carcinoma). However, they can cause acute rejection and graft loss in transplant recipients. Though PD-1 inhibition has been a major scientific breakthrough in late-stage cancer treatment, its impact on kidney transplant recipients due to high risk of rejection has not been fully examined. We present a case of graft failure due to rejection within a week of starting immunotherapy.

Case Description: 73-year-old female with a history of end-stage renal disease attributed to hypertensive nephrosclerosis underwent live unrelated kidney donor transplant and presented 6 months post-transplant with a right foot lesion and was diagnosed with stage IIIIC malignant melanoma. Her maintenance immunosuppression was decreased from tacrolimus/prednisone to prednisone monotherapy and the lesion was excised. 14 months later, disease surveillance via PET scan revealed metastatic disease. No measurement metric was specified in 18 (21%) cancer outcome measures.

Conclusions: Cancer is one of the most important outcomes for patients post-transplantation, but cancer outcomes are very poorly defined and highly variable in RCTs. A core outcome for cancer for all trials in kidney transplant recipients should be developed that is consistent and meaningful to patients and clinicians.

PO2473

Acute Rejection and Graft Failure in a Kidney Transplant Recipient with Malignant Melanoma and Treated with Pembrolizumab: A Case Report

Annalise M. Pantchofer, Kurtis J. Swanson, Didier A. Mandelbrot, Neetika Garg. University of Wisconsin School of Medicine and Public Health, Madison, WI.

Introduction: Malignancy treatment with immunotherapy in renal transplant recipients is complicated by a very high risk of rejection. Immune checkpoint inhibitors have been shown to be effective treatments for certain malignancies (melanoma, renal cell carcinoma). However, they can cause acute rejection and graft loss in transplant recipients. Though PD-1 inhibition has been a major scientific breakthrough in late-stage cancer treatment, its impact on kidney transplant recipients due to high risk of rejection has not been fully examined. We present a case of graft failure due to rejection within a week of starting immunotherapy.

Case Description: 73-year-old female with a history of end-stage renal disease attributed to hypertensive nephrosclerosis underwent live unrelated kidney donor transplant and presented 6 months post-transplant with a right foot lesion and was diagnosed with stage IIIIC malignant melanoma. Her maintenance immunosuppression was decreased from tacrolimus/prednisone to prednisone monotherapy and the lesion was excised. 14 months later, disease surveillance via PET scan revealed metastatic disease. No measurement metric was specified in 18 (21%) cancer outcome measures.

Conclusions: Cancer is one of the most important outcomes for patients post-transplantation, but cancer outcomes are very poorly defined and highly variable in RCTs. A core outcome for cancer for all trials in kidney transplant recipients should be developed that is consistent and meaningful to patients and clinicians.

PO2474

Renal Transplant Recipients Suffer Significantly More Complications After Breast Cancer Surgery but Benefit from Treatment at Transplant Centers

Ankur P. Choube,1 Afshin Parsikia,2 Maria Castaldi,2 Rifat Latifi,3 Jorge Ortiz.1
1The University of Toledo Medical Center, Toledo, OH; 2Westchester Medical Center, Valhalla, NY.

Background: Breast Carcinoma has the highest incidence of any cancer in adult females. The impact of kidney transplant (KT) on breast cancer surgery has not been examined. Our objective was to evaluate the influence of a previous KT on the short-term outcomes of mastectomy or lumpectomy.

Methods: A retrospective analysis was conducted using Nationwide Inpatient Sample (NIS) data between 2005 and 2014. Population included adult females with kidney transplantation surgically treated for breast malignancy. Weighted multivariate regression models were employed to compare outcomes at transplant and non-transplant centers.

Results: 398 women met the inclusion criteria. There was a greater proportion of African-American (p < 0.001), and Hispanic women (p < 0.01) compared to the cohort. KT recipients had more comorbidities and higher Elixhauser Comorbidity Index scores (p < 0.001). We noted longer length of stay (p < 0.001), higher expenditure (p < 0.001), and complications (p < 0.001). Specifically, rates of hematomas (p = 0.041), acute renal failure (p = 0.001), blood transfusion (p = 0.001), fresh frozen plasma transfusion (p < 0.001), cardiovascular (p < 0.001), and other complications (p = 0.012) were increased. There was no mortality among transplant recipients. Weighted multivariate analyses highlight that rates of complication (p = 0.048), and length of stay (p = 0.001) are lower at transplant centers.

Conclusions: History of kidney transplant has a significant impact on the outcomes of mastectomy or lumpectomy. These patients suffer more post-operative adverse events. However, KT recipients experience superior outcomes at transplant centers.

PO2475

Local Renal Graft Irradiation as Salvage Therapy for Renal Graft Rejection

Introduction: Graft rejection after treatment for malignancies with checkpoint inhibitors targeting the CTLA-4 and the PD-L1 pathways has been a growing interest in recent years since the rates of graft rejection are high as 33.3% with a median time to rejection of 8 days. To the best of our knowledge, there are no prior case reports of a renal transplant patient with stage IV gastric adenocarcinoma treated with pembrolizumab (a PD-1 inhibitor) who developed graft rejection and required local irradiation.

Case Description: This is a 65-year-old male with history of ESRD secondary to IgA nephropathy, chronic Hepatitis B and related donor kidney transplant who was diagnosed with gastric malignancy with peritoneal carcinomatosis and outlet obstruction after 12 years of transplantation. Gastric adenocarcinoma was HER2 equivocal, FISH negative, MMR deficient, PDL1 positive. Initial therapy included discontinuation of Tacrolimus, steroid monotherapy. Initial chemotherapy included 2 cycles of FLOT followed by ramucirumab. After finding disease progression at 6 months, he received a salvage chemotherapy with pembrolizumab. Two weeks after, presented to the ED with anuric AKI. A Mag-3 scan demonstrated good perfusion and a kidney biopsy showed cortex coagulative necrosis. High dose steroids and sirolimus were given with no response and required initiation of hemodialysis. In the following weeks, presented to the ED complaining of gross hematuria and clots. Cystoscopy with bladder biopsy was performed and showed no bladder origin and normal mucosa. The hematuria was found to be secondary to kidney graft rejection and he was started on high dose of steroids with mild improvement. Nephrectomy was not an option due to poor nutritional status and overall health condition. Palliative radiation therapy to the kidney was the only option for immunosuppression. He received local graft irradiation of 7.5 Gy in 5 fractions with resolution of hematuria.

Discussion: The case illustrates first, that the use of checkpoint inhibitors in patients with gastric malignancy with peritoneal carcinomatosis and outlet obstructionafter 12 years of transplantation. Gastric adenocarcinoma was HER2 equivocal, FISH negative, MMR deficient, PDL1 positive. Initial therapy included discontinuation of Tacrolimus, steroid monotherapy. Initial chemotherapy included 2 cycles of FLOT followed by ramucirumab. After finding disease progression at 6 months, he received a salvage chemotherapy with pembrolizumab. Two weeks after, presented to the ED with anuric AKI. A Mag-3 scan demonstrated good perfusion and a kidney biopsy showed cortex coagulative necrosis. High dose steroids and sirolimus were given with no response and required initiation of hemodialysis. In the following weeks, presented to the ED complaining of gross hematuria and clots. Cystoscopy with bladder biopsy was performed and showed no bladder origin and normal mucosa. The hematuria was found to be secondary to kidney graft rejection and he was started on high dose of steroids with mild improvement. Nephrectomy was not an option due to poor nutritional status and overall health condition. Palliative radiation therapy to the kidney was the only option for immunosuppression. He received local graft irradiation of 7.5 Gy in 5 fractions with resolution of hematuria.

Discussion: The case illustrates first, that the use of checkpoint inhibitors in patients with kidney transplant conveys a high risk of severe irreversible allograft rejection and can occur after only one dose. Second, the viability of palliative radiation as a non-surgical option for acute kidney graft rejection causing symptomatic hematuria resistant to conventional immunosuppressant therapy.

PO2476

A Rare Presentation of Disseminated Nocardia in a Kidney Transplant Recipient
Ruchi H. Naik, Saed Shawar, Heidi M. Schaefer. Vanderbilt University Medical Center, Nashville, TN.

Introduction: Nocardiosis is a very rare infection caused by the Nocardia asteroides bacterium. It most commonly involves the lungs but can spread to other areas of the body and is more likely to infect immunosuppressed patients. We report a case of a kidney transplant patient who presented with a tender lump of his right shoulder.

Case Description: Patient is a 58 year old African American male with a history ESRD due to hypertension and a renal mass status post right radical nephrectomy for renal cell carcinoma in 2001. He underwent deceased donor kidney transplant in May 2017 after being on dialysis for 13 years. He received alemtuzumab and methylprednisolone prednisone for induction followed by maintenance immunosuppression with Tacrolimus, mycophenolate mofetil and prednisone. In January 2020, he presented to the orthopedic clinic with a 10-day history of pain in a soft tissue mass of the right scapula and was diagnosed with a paraspinal muscle tear. One week later he presented to an outside hospital with fevers and CT of chest showing pulmonary nodule with satellite lesions in the RUL concerning for malignancy. He was transferred to our hospital where PET CT scan showed multiple intensely FDG avid masses in the lungs, brain, cecum and soft tissue inferior to the right scapula concerning for malignancy. Core tissue biopsy from the right scapular region was negative for bacterial or acid-fast bacilli stain but showed gram positive beaded rods identified as Nocardia. He was initially treated with intravenous sulfamethoxazole/trimethoprim and intravenous meropenem and then based on susceptibility transitioned to intravenous ceftazidime and oral sulfamethoxazole/trimethoprim. A follow-up MRI two months from diagnosis showed marked improvement in all lesions and he was transitioned to oral doxycycline to complete at least 12 months of therapy.

Discussion: Nocardiosis can present in unusual fashion in transplant recipients and one should have a high suspicion in patients who present with fever and disseminated lesions on imaging with plan for biopsy and culture of tissue early. In most cases, Nocardia can be treated successfully with appropriate antibiotics.

PO2478

Hypercalcemia: A Prodromal Feature of Pneumocystis jirovecii Pneumonia in Kidney Transplant Recipients
Joy C. Chen, Johann N. Isaac, Raviprasanna K. Parasuraman. University of Michigan, Ann Arbor, MI.

Introduction: Hypercalcemia in transplant recipients (KTRs) is frequently caused by persisting hyperparathyroidism. However, hypercalcemia can also be a prodromal feature of serious underlying infections and malignancy. We present 2 cases of parathyroid hormone (PHTH) independent hypercalcemia that preceded Pneumocystis jirovecii pneumonia (PJP) diagnosis.

Case Description: Case1. A 21 y.o. male with end-stage kidney disease (ESKD) from FSGS presented with 3 weeks of dyspnea and cough 8 months after transplant (Tx). Chest x-ray (CXR) showed interstitial opacities. Lab revealed acute kidney injury and severe hypercalcemia (Table 1). He was treated with IV fluid and calcitonin, and hypercalcemia improved (Figure 1). Workup showed significant elevation in 1,25 dihydroxyvitamin D (1,25(OH)2 VitD) and low PTH level, and his sputum was positive for PJP by DNA PCR. Case2. A 26 y.o. male with ESKD from nephronophthisis presented with 2 weeks of cough and dyspnea 10 yrs after Tx. He had severe hypercalcemia, and CXR showed nodular interstitial opacities. He was diagnosed with PJP by sputum DNA PCR. His hypercalcemia workup also revealed elevated 1,25(OH)2 VitD and low PTH.

Discussion: PJP occurs in 5–15% of KTRs without prophylaxis with significant morbidity and mortality. A timely diagnosis is challenging given its indolent presentation. Since hypercalcemia can occur in 20–30% of cases during early stages of PJP from increased production of 1,25(OH)2 VitD via 1-α-hydroxylase from alveolar macrophages, its presence should alert clinicians of its diagnosis. In 2019, 2 out of 5 PJP cases at our center had hypercalcemia at least 2 weeks prior to PJP diagnosis with high 1,25(OH)2 VitD and low PTH. In both cases, hypercalcemia resolved after treatment of PJP. These 2 cases illustrate hypercalcemia could be a prodromal feature in PJP. Early recognition with appropriate treatment would significantly reduce its morbidity and mortality.

PO2479

Hypercalcemia Associated with Pneumocystis jirovecii Pneumonia in Renal Transplant Patients

Introduction: Pneumocystis jirovecii pneumonia (PJP) is a common complication following solid organ transplantation with an estimated incidence of 5–15%. Although previously reported, hypercalcemia is not classically a sign of PJP. In the past 6 months at our institution, there have been six cases of PJP presenting with varying degrees of hypercalcemia.

Case Description: All patients in the table below presented with signs and symptoms concerning for pneumonia and were diagnosed with PJP by DFA and/or PCR from induced sputum or bronchoscopy. Patient demographics, labs, and calcium trends are outlined in the table. All patients were treated with Bactrim and prednisone for PJP (some later converted to alternative therapy); patients 1 and 2 were also given intravenous fluids to aid 1-alpha hydroxylase in alveolar macrophages. Recognition of hypercalcemia in patients presenting with clinical features concerning for PJP can aid in early diagnosis and treatment.
PO2479
Effect of UNOS Kidney Allocation System on Transplantation Rates for Veterans Waitlisted at Veterans Affairs Transplant Centers
Nidhi Aggarwal,1,2 Sankar D. Navaneethan,1 Jingbo Niu,2 Jenny S. Pan,1,2 Chandan Vangala,1,2 Ronald T. Cotton,1,2 Venkat RamanaNathan,1 Michael E DeBakey VA Medical Center, Houston, TX; 2Baylor College of Medicine, Houston, TX.

Background: Impact of new Kidney Allocation System (KAS) on kidney transplantation (KT) rates for Veterans waitlisted at Veterans Affairs Transplant Centers (VATC) is unknown. This study compares effect of KAS on waitlisted patients at VATC and non-VATC.

Methods: UNOS data on adult patients waitlisted for KT during January 2009 to December 2016 were obtained. Logistic regression was used to assess association between center type (VATC vs. Non-VATC), time period (pre-KAS 2009-2014 vs. post-KAS 2015-2016), and outcomes (receiving KT or death on waitlist) within 2 years of waitlisting. Odds ratio (OR) was calculated adjusting for demographic factors, comorbidities, calculated Panel Reactive Antibodies (cPRA) and Estimated Post-Transplant Survival (EPS) score.

Results: During study period, a total of 263,410 patients were listed on non-VATC (75% pre-KAS, 25% post-KAS) and 3,150 at VATC (68% pre-KAS, 32% post-KAS). VATC patients were significantly older (58.3 vs. 51.7 years), diabetics (55.4% vs. 42.5%), had lower cPRA, higher EPS (53 vs.39%) and longer duration of dialysis (762 vs. 727 days). Within 2 years of waitlisting, Veterans listed at VATC did not benefit from the new KAS like patients in non-VATC centers. Overall, independent of the era, Veterans tend to be transplanted less in this early waitlisting period. But wait time was 29% lower in VATC patients. (Results are shown in the table.)

Conclusions: Benefit of new KAS did not extend to Veterans listed at VATC who are older, less immunogenic and have higher EPS score. Early benefit of KAS seen in non-VATC's could be due to “bunch effect” from transplantation of younger, highly sensitized patients. However, risk of death is significantly lower in VATC waitlisted patients.

Outcomes of patients within 2 years of waitlisting for kidney transplantation

PO2480
Lend Me Your Ear: An Unusual Presentation of a Transplant Complication
Meredith McAdams, Kruti Yagnik, Swee-Ling Leva, Jeffrey Tessier, Reuben J. Arasaratam. University of Texas Southwestern Medical School, Dallas, TX.

Introduction: Infections are a major complication in solid organ transplant (SOT) patients due to need for life-long immunosuppression. Incidence of fungal infections following solid organ transplants ranges from 5-20%. Cryptococcus is an invasive fungal infection that can cause several types of infections including meningoitis, pulmonary, cutaneous, and disseminated disease.

Case Description: A 66 year old female with past medical history of ESRD on hemodialysis (HD) for 5 years underwent transplant to her son 15 months ago. She presented to the transplant clinic with right ear pain for the past 4 weeks after being evaluated in the emergency room. Her past medical history included renal transplant 15 months ago, DM, HTN presented to renal transplant clinic with kidney transplant. She was transitioned to oral fluconazole. Skin biopsy showed cyryptococcus. Patient was admitted to the hospital.

Discussion: Usually, cryptococcal infection is the third most common invasive fungal infection in SOT patients and typically presents later in kidney transplant patients, 16-21 months, compared to other transplanted organs. Risk factors include type of immunosuppressive agent and comorbid conditions such as diabetes. The majority of transplant patients with cryptococcus present with CNS manifestations or disseminated disease, cutaneous involvement is less common. Our patient had risk factors including diabetes, older age, and use of induction immunosuppression. Initial presentation with skin lesions is atypical for cryptococcal infection. It is important to have a high suspicion for fungal infections in immunosuppressed patients even those with atypical presentations.

PO2481
Pegloticase for Uncontrolled Gout in Kidney Transplant Recipients: Early Data Report of a Multicenter, Open-Label Efficacy and Safety Study
Abdul A. Abdellatif,1 Lia Zhao,2 Paul M. Peloso,2 Katya Cherny,2 Brad A. Marder,2 John D. Scandling,2 Kenneth G. Saag,2 Baylor College of Medicine, Division of Nephrology, Houston, TX; 3Horizon Therapeutics plc, Lake Forest, IL; 4Stanford School of Medicine, Division of Nephrology, Stanford, CA; 5University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, AL.

Background: Gout is common and more severe in US kidney transplant (KT) recipients, with prevalence >10% higher than in non-transplant patients. The management of gout can be challenging in KT patients due to decreased urate lowering therapy (ULT) clearance and drug-drug interactions. Recent reports suggest that pegloticase, a pegylated uricase approved for treating uncontrolled gout, has improved efficacy and safety when co-administered with immunosuppressive medications (IMM). We conducted the PROTECT trial (NCT04087720) to examine pegloticase use in KT recipients.

Methods: Patients with uncontrolled gout (sUA ≥7 mg/dL, intolerence of or contraindication to ULT, and a of the following: tophi, chronic gouty arthritis, a2 flares in past yr) and functioning KT graft (eGFR ≥15 mL/min/1.73m3) are included (KT≥1 yr earlier). Pegloticase (8 mg q2w for 24 wks) safety and efficacy are examined. Primary endpoint is ≥5% pegloticase responders during Month 6 (sUA <6 mg/dL for ≥80% of time).

Results: 7 patients were enrolled by Apr 30, 2020 (age: 52.0±11.2 yrs, KT 15.3±5.0 yrs ago, sUA: 10.0±1.4 mg/dL, gout duration: 5.9±4.3 yrs; all on stable doses of 2 IMM) and received 2-12 infusions. 1 patient discontinued. In the 1 completed and 5 ongoing patients, all central lab sUA levels were <1 mg/dL, indicating treatment response; no infusion reactions occurred. No notable eGFR changes were observed; 2 patients with baseline albuminuria of >300 mg/g showed >35% reduction in UACR by wk 14. 2 SAEs (stomach ulcer, cellulitis) unrelated to pegloticase were reported.

Conclusions: Early data from ongoing clinical trial are promising and suggest pegloticase is safe and effective for treating uncontrolled gout in KT recipients. Additional efficacy and safety data are planned.

Serum uric acid (sUA) and kidney function parameters

PO2482
Minoxidil-Induced Chylous Ascites in a Renal Transplant Recipient
Vivek Pathak, Kovai Medical Center and Hospital, Coimbatore, India.

Introduction: Chylous ascites is generally associated with malignancies and surgical trauma and rarely secondary to administration of drugs such as amiodarone, minoxidil, lithium, and calcium channel blockers. Recently, we encountered a case of minoxidil-induced chylous ascites.

Case Description: This patient is a 64 years old diabetic and hypertensive male who underwent kidney transplantation on 09.06.2009. He was HBsAg positive for last 9 years. He was taking multiple medications namely carvedilol, amlopidine, lasix, minoxidil, prebdilinose, MMF, Tacrolimus, insulin, metformin and Linaclipitin and Entocavicr. He came in May 2019 with ascites. Investigation revealed normal kidney function and ultrasound guided ascitic fluid tapping was done and it was found to be chylous. He underwent abdominal paracentesis and about 4lt of ascitic fluid was drained but he came back within 10 days with ascites again. Portal hypertension was ruled out by transjugular hepatic venous pressure gradient measurement and liver biopsy did not show any evidence of chronic liver disease. An upper GI endoscopy and duodenoscopy including duodenal biopsy were normal. Whole body PET scan did not show any active infection or disease. Meanwhile literature review suggested association of amiodarone with chylous ascites and it was stopped but he continued to develop recurrent ascites. An abdominal CT lymphangiogram was done which did not show any lymphatic leak.
He also underwent diagnostic laparoscopy which also ruled out TB or any malignancy. This recurrent chylous ascites continued for 6 months then we decided to discontinue minoxidil as it is known to cause fluid accumulation including pleural and pericardial. He showed immediate improvement after stopping minoxidil and never developed ascites again. He was fine even 6 months later on follow up.

Discussion: Minoxidil causes vasodilatation like calcium channel blockers though by a different mechanism so the mechanism of chylous ascites formation could be the same that it is also a lipophilic drug allowing it to pass rapidly into the lymphatic system and causes relaxation of smooth muscles of lymphatic vessels, interferes with lymphatic drainage, and increases the hydrostatic pressure in lymph vessels and causing it to leak in the peritoneum. Minoxidil must be considered as a probable cause of atramatic drug induced chylous ascites.

PO2483
COVID-19 in Kidney Transplant Recipients: Experience from a Large Health System in Louisiana
Aldo E. Torres Ortiz, Joseph B. Walker, Juan Carlos Q. Velez, Jorge C. Garces. Ochsner Nephrology Ochsner Health System, New Orleans, LA.

Background: Infections are an important cause of morbidity and mortality among kidney transplant recipients. The novel Coronavirus Disease 2019 (COVID-19) has affected all kinds of populations world-wide. However, the role of immunosuppression in the outcomes of these patients is not well understood.

Methods: We conducted a retrospective study in kidney transplant recipients from a single health system that were diagnosed with COVID-19 based on a positive real-time reverse transcription polymerase chain reaction test for SARS-CoV-2 RNA between March 2020 and February 2021. We compared them with age and sex-matched controls without a kidney transplant and without any kind of immunosuppressive medication (control). We examined the rates of hospitalization, intensive-care unit (ICU) admission, acute kidney injury (AKI) and mortality as outcome measures.

Results: A total of 8473 patients were diagnosed with COVID-19 within our Health System within the study period. Thirty-three (0.4%) were kidney transplant recipients. Sixteen of the 33 (48%) were admitted to the hospital (median age of 56, 68% males, 93% African American) vs 2201 admissions (25%) for the control group (median age 66, 48% males, 65% African-American), i.e., a significantly greater risk for hospitalization for transplant recipients (p = 0.002). Percentage of patients with hypertension in the transplant group was numerically higher (93% vs 80%, p = 0.06), as well as the number of ICU admissions (43% vs 28%, p = 0.055). AKI was more common in transplant patients (81% vs 33.8% p<0.0001). No difference in mortality was observed (31 vs 24%, p = 0.34). Among transplant patients, those hospitalized were more likely to be on prednisone (75% vs 35%, p = 0.025) and had a post-transplant graft life of 7.9 years compared to 5.5 years for those not hospitalized, p(0.08).

Conclusions: Kidney transplant recipients affected with COVID-19 exhibited a greater incidence of hospitalization, AKI and a trend for more ICU admissions. Use of immunosuppression with prednisone was associated with greater risk for hospitalization.

PO2484
Recurrent Anemia due to Chronic Parvovirus B19 Infection in a Kidney Transplant Recipient: Can Everolimus Make a Difference?
Diana Rodriguez-Espinoza, Nuriia Esforzado, Fritz Dickmann, Ignacio Revuelta. Hospital Clinico de Barcelona, Hospital Clinico de Barcelona, Barcelona, Spain.

Introduction: Parvovirus B19 (PB19) is a common infection among transplant recipients. Usually, it is asymptomatic, but some patients may suffer severe infections, often presenting with recurrent flares despite standard treatment. Relapses are usually managed by reducing immunosuppressive treatment (IST), potentially increasing graft rejection risk.

Case Description: 45-year-old woman with ESKD due to ADPKD, received a living-related kidney transplant on May 2013. Maintenance IST consisted of mycophenolate mofetil (MMF), prednisone and tacrolimus. A month after transplantation, she presented with fever and anemia. A bone marrow aspirate revealed pure red blood cell aplasia (PRCA) which was attributed to PB19 after positive serum qualitative PCR. She was treated intravenous immunoglobulin (IVIG) at 2g/kg and MMF was stopped with good response. However, 3 new relapses occurred (anemia and fatigue with viral loads for PB19 over a million copies). A monthly prophylactic dose of IVIG was initiated to control the infection. In spite of this, episodes of anemia and a high PB19 viral load (over a half million copies) continued to happen at least 3 times per year. Finally, given the potential anti-viral properties of mTOR inhibitors (mTORi), conversion from tacrolimus to everolimus was decided. Since November 2017 her maintenance IST consists of everolimus and prednisone alone, her last prophylactic IVIG was on December 2017, and since then she has been non-anemic with serum viral loads below 1000 copies, and without IVIG treatment.

Discussion: Incidence of symptomatic PB19 infection is highest during the 1st year after transplantation, like in the case presented. Standard therapy consists of IVIG. However, early KTR, often relapse after the IVIG effect wears off. In such cases, reduction of IST is needed to control the infection and avoid reurrences. There are multiple studies indicating that mTORi have anti-viral properties although their effect on PB19 has not been specifically studied. In conclusion, conversion from tacrolimus to an mTORi, could be an interesting approach in difficult-to-manage cases similar to ours, moderating the reduction of IST and minimizing the risk of rejection. Further studies are needed to establish this approach as “treatment of choice” in relapsing PB19 infection.

PO2485
Adjusted Donor Age Score: Validity and Influence on Deceased Donor Offer Decisions

Background: Although a number of donor factors are known to affect outcome following deceased donor kidney transplantation, many units have no clear criteria for acceptance. Existing donor scoring systems, such as KDRI, perform poorly in the modern comorbid donor pool, and are difficult for patients to understand. Adjusted Donor Age (ADA) is a patient-friendly scoring system in which donor age is modified according to the presence or absence of a number of risk factors, categorised by ADA decade (using cut-offs at 50, 60, 70 and 80 years) into quintiles (A – E) representing increasing donor risk (A – C, favourable, D, marginal, and E, unfavourable).

Methods: All deceased-donor kidney offers at a single centre were analysed over a 3 month period (beginning after the September change in UK organ allocation) during which ADA was optionally available to clinicians at the time of considering the offer. The effect of ADA on acceptance decisions and outcome in those transplanted were analysed.

Results: Out of 230 offers median(IQR) ADA was 67(56-76). Kidneys were accepted in 24%, declined due to concern over donor risk in 44%, with recipient and other factors responsible for non-transplantation in 32%. In those identified as favourable by ADA (quintiles E - C, without exclusion factors), organs were rejected due to donor risk in 28/104 offers (27%), compared to 50/186 (27%) in the 2018 cohort. In those identified as unfavourable by ADA (quintile E) organs were transplanted in 0/38 offers (0%), compared to 10/66 (15%) in the 2018 cohort. At 1 month post-transplantation (N=55, from quintiles A – D only, since no organs from quintile E were accepted) one recipient remained dialysis dependent (from quintile D). In those with functioning transplants (N=54) recipient GFR was strongly correlated with ADA (R=0.52, p<0.001) and was seen to reduce across quintiles A – D (74, 55, 43 and 33/ml/min). Conclusion: ADA is a patient-friendly score, calculated from donor age but adjusted for 12 potential risk factors, which can be used to guide acceptance decisions. At this early stage of familiarity, clinicians appear to be more persuaded by an unfavourable ADA quintile, than a favourable one. In this validation cohort, ADA strongly predicts early post-transplant outcome.
PO2487
Racial-Ethnic Disparities in Preemptive Kidney Transplantation Among Incident ESKD Adult Patients, 2006 to 2018

Naayla Baranal,1 Rebecca Thorness,2 Shailender Swaminathan,2,3 Rachel E. Patzer,4 Rajnish Mehrotra,4 Amal Trivedi,2,3 Brown University Warren Alpert Medical School, Providence, RI; 2Brown University School of Public Health, Providence, RI; 3Providence VA Medical Center, Providence, RI; 4Harborview Medical Center, Seattle, WA; 5Division of Transplantation, Department of Surgery, Emory University School of Medicine, Atlanta, GA.

Background: Preemptive kidney transplantation (PKT) is the preferred treatment for ESKD. Among kidney transplant recipients, black and Hispanics are less likely to receive PKT than whites, but less is known about disparities in PKT among the entire incident ESKD population. This is a critical gap in knowledge given the Advancing American Kidney Health goal of 80% of all new ESKD patients receiving transplant or home dialysis by 2025. This study assessed racial/ethnic disparities in initial treatment with PKT vs. dialysis among all incident ESKD failure patients aged 19-74 from 2006 to 2018.

Methods: Treatment modality for incident ESKD patients was identified using the CMS Medical Evidence Report Form. Linear regression models estimated PKT rates for white, blacks, Hispanics and Asians, adjusting for clinical, geographic, socioeconomic, and access factors.

Results: Among 1,133,326 incident ESKD adult patients, the age/sex adjusted PKT rate declined from 3.0% in 2006 to 2.5% in 2018, with varied trends in each racial/ethnic group (white: 5.0% to 4.0%, black: 0.5% to 0.7%, Hispanic: 1.3% to 1.3%, and Asian: 2.4 to 2.9%) (Figure). In age-sex adjusted analyses, whites had 3.9, 3.2, and 1.7 percentage points lower than blacks, Hispanics, and Asians, respectively. These differences persisted after adjusting for clinical, geographic, SES, and pre-ESKD nephrology care (Table). Among patients aged 19-44, whites had 8.0, 6.3, and 3.3 higher rates of PKT, compared to blacks, Hispanics, and Asians.

Conclusions: Among incident ESKD adult patients, racial/ethnic disparities in receipt of PKT are substantial, persistent, and not explained by differences in observed clinical factors and socioeconomic status. Efforts to increase preemptive transplantation must address disparities in access to this preferred treatment for ESKD.

PO2488
Lower Prevalence of Kidney Transplant Waitinglist in Micropolitan Areas, Small Towns, and Rural Areas

Eric D. Weinhandl,1,2 H. E. Hamilton,1 Lorien S. Dalrymple,1 Fresenius Medical Care, Waltham, Anguilla; 2Chronic Disease Research Group, Minneapolis, MN.

Background: The Percentage of Prevalent Patients Waitlisted (PPPW) measures the percentage of patients at a dialysis facility who are on the kidney or kidney-pancreas transplant waitlist. This measure joined the End Stage Renal Disease Quality Incentive Program in performance year 2020, with a weight of 4%. PPPW is adjusted for age, but not for other factors. Physical distance between residence and transplant center may influence PPPW. As an indirect test of this hypothesis, we assessed whether PPPW was associated with rural-urban commuting area (RUCA) levels.

Methods: We analyzed data in Dialysis Facility Compare (DFC), as of October 30, 2019. DFC included PPPW values that quantified waitlisting prevalence during 2018. According to ZIP code, we classified the location of each dialysis facility as metropolitan (RUCA values, 1-3), micropolitan (4-6), small town (7-9), or rural (10). We estimated weighted mean PPPW values in each location class, with the weight of each facility equal to the number of patients contributing to PPPW. We fit a linear regression model to test differences in PPPW values between the location classes.

Results: PPPW values were reported in 7086 (94%) of 7566 dialysis facilities, and RUCA values were identified in 6999 (99%) of 7086 facilities. The weighted mean PPPW value among all facilities was 17.5%. There were 5363 (77%) facilities in metropolitan areas, 954 (14%) in micropolitan areas, 550 (8%) in small towns, and 132 (2%) in rural areas. By location class, weighted mean PPPW values were 18.5% in metropolitan areas, 12.8% in micropolitan areas, 12.1% in small towns, and 10.8% in rural areas. Relative to the mean PPPW value in metropolitan areas, mean PPPW values were 5.8, 6.5, and 7.7 percentage points lower in micropolitan areas, small towns, and rural areas, respectively (P < 0.01 for each).

Conclusions: The PPPW measure takes significantly lower values in dialysis facilities located in micropolitan areas, small towns, and rural areas, relative to metropolitan areas. The physical distance between residence and transplant center may preclude many patients in non-metropolitan areas from completing the process of kidney transplant evaluation. New processes are needed to improve access to transplantation in outlying areas.

PO2489
Demonstrating Charitable Premium Assistance as a Mechanism for Overcoming the Cost Barrier to Transplant for Low-Income Patients in the United States

Michael Spigler,1 Morenike Bello,1 Melanie Paris,1 Lisa Vo,1 Silas Norman,2 American Kidney Fund, Rockville, MD; 2University of Michigan Transplant Center, Ann Arbor, MI.

Background: The optimal treatment for patients with end-stage renal disease (ESRD) is kidney transplantation. Adequate insurance coverage is one requirement for transplant eligibility. Many low-income ESRD patients cannot afford insurance coverage. Patients on dialysis are eligible for Medicare. Because Medicare covers only 80% of healthcare costs, most patients require supplemental insurance, often Medigap. Although Medigap

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

755
plans reduce out-of-pocket spending on healthcare services by almost 50%, spending on healthcare costs for KT candidates more than doubles compared to Medicare premiums alone. For low-income patients who cannot afford such premiums, inadequate insurance coverage can become an insurmountable barrier to qualifying for a kidney transplant (KT). We evaluated a premium assistance program designed to help low-income ESRD patients maintain their insurance and the impact on KT access.

Methods: We performed a descriptive analysis of self-reported patient data collected from paper and digital applications submitted to American kidney Fund’s (AKF) Health Improvement Program (HIPP) between November 15, 2018 and December 31, 2019.

Results: HIPP provided financial assistance grants to 1,357 (5.8%) of all kidney patients transplanted in the United States during the study period so they could maintain their health coverage in 2019. Of the 1,357 grants, 36% of grants issued helped patients pay for their insurance premiums, recipients who were enrolled in Medicare Advantage plans were more likely to be 65 (20%), African American (38% vs. 34%), and had lower median income ($23,622 vs. $27,168 respectively) compared to the overall transplant population.

Conclusions: KT candidates face financial barriers to transplantation. Premium assistance significantly reduced the barrier to transplant among KT candidates who rely on Medicaid for ensuring adequate coverage.

PO2490

“Some Person Behind a Desk Is Going to Be Looking at My File”: Thematic Analysis of the Health Records of a National Sample of Patients with Advanced Kidney Disease Evaluated for Kidney Transplant

Catherine Butler,1 Aaron G. Wightman,1 Janelle S. Taylor,2 Claire Richards,1 Chuan-fen Liu,2,3 Ann M. O’Hare,1,4 1University of Washington, Seattle, WA; 2VA Puget Sound Health Care System, Seattle, WA; 3Seattle Children’s Hospital, Seattle, WA; 4University of Toronto, ON, Canada.

Background: To be considered for kidney transplant, patients with advanced kidney disease must participate in a formal evaluation and selection process. Little is known about how this process unfolds in real-world clinical settings.

Methods: We conducted a thematic analysis of clinician documentation related to the kidney transplant evaluation in the VA-wide electronic medical records of patients who were referred to a transplant center among a random sample of 4,000 adults with advanced kidney disease between 2004 and 2014 who were followed through 2019.

Results: We identified 211 patients (5.2%) who were referred to a VA transplant center during follow-up. Four dominant themes emerged from qualitative analysis of clinician documentation in the electronic medical records of these patients: 1) far-reaching and intrusive and placed substantial demands on patients’ family members; 3) surveillance over compliance: clinicians monitored patients’ adherence to a wide range of medical recommendations; 4) disenrollment and lack of transparency: patients had a strong desire to receive a transplant, but neither they nor their local clinicians had a clear understanding of what to expect from the evaluation process or the rationale for selection decisions, which left patients and their clinicians with little choice but to adhere to the transplant center’s recommendations.

Conclusions: To be considered for kidney transplant, patients had little choice but to engage in a rigid, demanding, and opaque evaluation process over which neither they nor the surgeon who had evaluated the patient was significantly associated with a greater likelihood of the candidate being listed. We conducted a thematic analysis of clinician documentation related to the kidney transplant evaluation process.

PO2491

Implicit Bias in Recipient Selection

Yousef Swedish,1 Christine Mayuga,1 Kenneth Chaviv,1 Titte Srinivas,1 Aparna Padiyar,1 1University Hospitals Cleveland Medical Center Department of Medicine, Cleveland, OH; 2University Hospitals Cleveland Medical Center Department of Surgery, Cleveland, OH.

Background: The decision to place or exclude a candidate from the waitlist is not exclusively based on medical criteria. Scant literature exists regarding the intergroup dynamics within selection committees that influence decision making. This study attempts to clarify how the composition of selection committee meetings may affect listing outcome of kidney transplant candidates.

Methods: We performed a single-center retrospective study of kidney transplant selection committee attendance sheets and minutes from January 2012 to December 2015. We sought to determine if candidates who were evaluated by the same providers in attendance at selection committee are more likely to be listed for kidney transplant.

Results: 5205 (48.4%) of 6630 donor and recipient candidates presented during 91 selection meetings from 2012 to 2015 were listed. 8 nephrologists, 9 surgeons and 3 social workers comprised the clinicians that both evaluated potential candidates and attended recipient selection meetings. Table 1 describes the frequency with which clinicians who were in attendance at selection meetings had previously evaluated the candidates being discussed. Using binary logistic regression, the presence of the nephrologist on the surgeon who had evaluated the patient was significantly associated with a greater likelihood of the candidate being listed. We conducted a thematic analysis of clinician documentation related to the kidney transplant evaluation process.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

PO2494
Patient Barriers to Kidney Transplantation on the Mexican American Border

Background: Hispanics are the largest minority group in the United States and are more likely to develop end-stage renal disease (ESRD) compared to non-Hispanic whites. However, Hispanics with ESRD are less likely to receive a deceased donor kidney transplant. We reviewed data from clinics on the Mexican American border to evaluate barriers to transplantation.

Methods: We gathered data from three dialysis clinics in Laredo, Texas, a city on the Mexican American border. It has a population of approximately 250,000 inhabitants of which 80% is Hispanic. The number of patients referred for living donor transplantation was evaluated. We also determined the number of patients that were referred but not listed and those that were not referred at all and investigated reasons for non-referral.

Results: A total of 285 patients were included in the analysis. 52 patients (18.2%) were waitlisted or scheduled for living donor transplantation. An additional 91 patients (31.9%) were referred but not yet waitlisted or scheduled for living donor transplantation. A total of 140 (49.1%) were not referred. Of those not referred, the most common reasons included: advanced age (25.2%), weight (4.2%), malignancy (2.8%), cardiovascular (4.2%), peripheral vascular disease (3.57%), functional status (5.71%), noncompliance (5.71%), transportation (10.71%), and immigration status (7.14%).

Conclusions: Nearly half of ESRD patients were not referred for transplant evaluation and less than half of those referred were waitlisted or scheduled for living donor transplantation. This is lower than previous studies showing a greater percentage of referred patients as waitlisted (up to 66% in some studies). Major barriers to referral included age, immigration status, and transportation limitations. The last two barriers are likely more of a factor in a Mexican American border town than in other areas of the United States. Identifying these barriers highlight areas for improvement in access to renal transplantation for Hispanics.

PO2495
The Strength of Weak Ties and Living Donor Offers: A Multi-Site Social Network Analysis of Hemodialysis Patients
Ayrum Gillespie,1 Jonathan Daw,2 Riley Brown,3 Jamie Cappiello,1 Edward L. Fink,4 Heather M. Gardiner,5 Crystal A. Gadgebeku,6 Peter P. Reese,5 Zoran Obradovic,1 Temple University, Philadelphia, PA; 2Pennsylvania State University, University Park, PA; 3University of Pennsylvania, Philadelphia, PA.

Background: Increasing the rate of living donor kidney transplantation is crucial. Little is known about hemodialysis patients’ social networks and the members who offer to donate yet are never evaluated.

Methods: We administered a REDCap social network survey in an urban (Philadelphia) and suburban (North Brunswick) hemodialysis clinic. We asked participants to identify the top five network members, who offered to donate, whose offers were accepted, and who got tested. We analyzed the associations between living donor offers and the size and strength of the connections in the networks. Strongly connected members are those connected to greater than 2/3 of the other network members.

Results: A total of 105 patients participated. Their mean age was 60 ± 13 years. Half (54%) identified as male and 75% identified as black. Half were on the waiting list or undergoing testing (50%). The mean size of the networks was 5 members (SD, range 1-10). Half (53%) of the participants received a living donor offer; 27% received one offer and 26% had 2 or more offers. Those with larger networks received more donation offers (r = 0.39; p < 0.01). Of the total 527 network members identified, 113 offered to donate, 43 of these offers were accepted with 12 being evaluated for donation. Most (83%) network members were strongly interconnected within the participants network, however, there was greater proportion of weakly connected network members offered a kidney donation compared to strongly connected members (31% vs. 19%, p = 0.02). Participants accepted a greater proportion of offers from weakly connected members than strongly connected members (56% vs 33%; p = 0.03). Although a greater proportion of strongly connected members were evaluated compared to weakly connected members this was not significantly different (36% vs. 17%, p = 0.16).

Conclusions: Weakly connected social network members tend to offer to be living kidney donors more often than strongly connected members and a greater proportion of weakly connected members offer to donate never make it to the transplant center. Future interventions should focus on patients accepting living donor offers as well as identify methods to increase testing of interested donors especially those weakly connected in the network.

PO2496
Association of SNAP Benefit Use by Inner-City Kidney Transplant Recipients with Poorer Graft Function, Lower Fruit and Vegetable Intake, and Increased Psychosocial Stress
Elizabeth G. Kasparov, Kingsley Cruickshank, Ahmad Saleh, Soyeon Pak, Mariana Markell. SUNY Downstate Health Sciences University, Brooklyn, NY.

Background: Longterm graft survival may be affected by factors other than biologic, including social determinants of health such as food scarcity and psychosocial stress.

Methods: A face-to-face survey was conducted in a random convenience sample of 31 pts in transplant clinic. The Stress and Social Support survey and the Perceived Stress Scale were used. Dietary intake was assessed using 24-hr recall and analyzed with ASFA-24 software. All comparisons are by Chi square or t-test.

Results: There were 11 women(36%), 20 men(65%), 22 Black(71%). Mean age was 55.2±1.9 yrs, time since transplant 63.9±14.1 mos. 24 (77%) reported income <$40K, with 12 (39%)<$20K. 12 (39%) received SNAP benefits (SNAP+). Income or employment rate did not differ for SNAP+ vs SNAP-. SNAP+ had significantly worse kidney function(creatinine 2.17±0.24 vs 1.44±0.11 mg/dL=0.014) and eGFR 37.9±3.8 vs 55.2±13.6 mg/dL (p<0.05). In our cohort gender, race, BMI, tacrolimus level or age. SNAP+ also were more likely to disagree with the statement “I feel I am in control of my health and it doesn’t control me” (33% vs 0%, p=0.017), to report never or almost never feeling confident about handling personal problems(6% vs 16%, p=0.018), and to be unable to control irritations in their lives(67% vs 16%, p=0.043, p=0.043). No difference in caloric or macrominutient intake existed, but SNAP- ate less fruit (11.1±1.3 vs 16.7±1.8 gmp=0.023)and fewer servings of fruits/vegetables(1.5±0.28 vs 3.75±0.85, p=0.021). When asked about missed medication they did not report more missed doses.

Conclusions: In our patient population: 1. Pts receiving SNAP had worse kidney function than those who did not despite similar time since transplant, tacrolimus level, income, and employment status. 2. They ate less fiber and fewer servings of fruits/vegetables despite similar caloric intake, which should be investigated further as higher intake of fruit/vegetables is associated with delayed progression of kidney disease in non-transplant pts. 4. They also reported feeling less control over their health and less ability to handle daily stress. 4. These finding suggests that special attention should be paid to this population who have issues with social determinants that may affect kidney function.

PO2497
Impact of Ethnicity Matching on Kidney Transplant Outcomes Among African Americans: A Mate Kidney Analysis
Kalaniya Sureshsharma, Bhavna Chopra, Rita L. McGill. 1Allegheny General Hospital, Pittsburgh, PA; 2University of Chicago, Chicago, IL.

Background: Transplantation of kidneys from African American (AA) donors is associated with poorer convalescence and higher rates of rejection compared to transplants from white Americans. Unmeasured variables such as APOL1 renal risk variants and sickle cell trait could contribute to the heightened risk. We used a mate kidney model to test the hypothesis that ethnic-matching could improve outcomes.

Methods: We identified AA deceased donors in OPTN/UNOS database from 2000 to September 2019 in which both kidneys were transplanted into first-time kidney-olone recipients, and both recipients received induction therapy followed by tacrolimus/mycophenolic acid maintenance. Marginal models for hazards of graft failure, death censored graft failure (DCGF) and death were constructed, with adjustments for recipient and transplant variables. Outcomes of AA, Hispanic, and Asian recipients were compared, using white American recipients as reference. Results were compared to a parallel analysis of 41,886 recipients of white American donor kidneys.

Results: Median follow up of the study was 3.3 (IQR 1.1-6.5) years among 8194 paired recipients of AA donor kidneys. Despite donor ethnicity matching, DCGF was higher mortality lower among AA recipients. Graft failure did not differ. Hispanic and Asian recipients had lower hazards of most unfavorable outcomes (table 1). In the parallel analysis, DCGF was again inferior for AA recipient of white American donor kidney (HR 1.37, 95% CI 1.28-1.47, p<0.001).

Conclusions: Our data indicate an increased risk of DCGF in AA recipients of AA donor kidneys, despite the potential benefits of favorable immunologic matching and does not support an ethnicity-matching strategy to improve outcomes and reduce disparities. Our observations suggest that other recipient factors predominantly influence graft outcomes. Improved outcomes in Hispanic and Asian patients merit further study.

Cardio-Metabolic Risk Factors in Kidney Donors at a Third-Level Hospital of Care in Mexico

Dilcia I. Lara, Ana G. Ortega, Rafael Valdez-Ortiz, L. M. Perez-Navarro, Ernesto C. Lopez, Hospital General de Mexico De Eduardo Liceaga, Ciudad de Mexico, Mexico; Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico.

Background: Living donor kidney transplantation is the treatment of choice for chronic terminal kidney disease. A high prevalence of cardio-metabolic risk factors (CRFs) in the general population implies challenges when choosing the best candidate for kidney donation. Knowing the frequency of CRFs will allow us to make timely interventions in order to reduce cardiovascular complications after donation.

Methods: Cross-sectional, descriptive study, which included kidney donors who were admitted to the National Medical Center “Dr. Antonio Fraga Mouret” during the period from 2015 to 2019. Descriptive statistics were made, with a 95% CI. CRFs were included; systolic hypertension (SBP) higher than 120mmHg, diastolic hypertension (DBP) higher than 80mmHg, anemia hemoglobin less than 13 g/dl in men and less than 12 g/dl in women; impaired fasting glucose> 110 mg/dl, body mass index (BMI)> 25.

Results: 163 donors were included, 59% were women, 33% were siblings and 31% were the patient’s mother; 34% had no social security. The mean age was 42 ± 7.0 years; the mean BMI 26.3 ± 5.4, with a mean GFR 101.9 ± 13.4 (61.6-133) ml/min/1.73 m². 28% of donors smoked, 7% had SBP risk and 27% DBP risk, 30% had HbA1C> 8.0%, 25% had anemia and 13% hypercholesterolemia; 10% with impaired fasting glucose. Figure 1 shows the prevalence of CRF. More than 25% of kidney donors had 2, 3 and 4 CRFs across 23 facilities in Japan and conducted a multicenter, two-by-two factorial, open-label, randomized clinical trial. 72% presented acute kidney injury (AKI) after surgery, none required renal replacement therapy. The highest AKI frequency was observed in subjects who had from 1 to 3 CRFs with frequencies to 126.34%.

Conclusions: A BMI higher than 25 was the most prevalent CRFs; associated with AKI when more than 1 CRF was observed. Timely detection of CRFs will allow for timely interventions that will reduce post-donation cardiovascular risk and decrease the risk of AKI.

PO2499

The Effect of Anemia Correction with ESA and Cholecalciferol Supplementation on Post-Transplant Malignancy Among Kidney Transplant Recipients: A Prespecified Analysis of a Randomized Clinical Trial

Yoshitsugu Ohi,1,2 Naotsugu Ichimaru,1,4 Yoshihata Isaka,1 Takayuki Hamano,1,3 The CANDLES-KID Trial Investigators,1 The University of Tennessee Health Science Center College of Medicine, Memphis, TN;2 Obi Clinic, Osaka, Japan;3 Osaka Daigaku Daigakuin Igakuka Kenkyuka Igakuka, Suita, Japan;4 Jpan Zaidan Hoin Samitomo Byoin, Osaka, Japan;5 Nagoya Shitru Daigaku Daigakuin Igakuka Kenkyuka Igakuka, Nagoya, Japan.

Background: Kidney transplant recipients (KTRs) are at increased risk of cancer, and post-transplant malignancy (PTM) is among the leading causes of death with functioning allograft. Aggressive anemia correction with ESA shows the rate of decline in kidney allograft function but may increase the incidence of PTM. Vitamin D is proposed to exert pleiotropic effects including anti-cancer properties and may prevent the development of PTM.

Methods: We enrolled 153 KTRs with anemia and ≥1-year history of transplantation in KTRs. Brain functioning requires energy, for which iron is essential at the level of oxygen delivery and mitochondrial function. Iron deficiency (ID) has been linked to compromised cognitive functioning in premenopausal women. We aimed to investigate whether ID could be a potentially modifiable risk factor for cognitive function impairment in KTRs.

Results: Seven hundred and twenty-six patients were included in the study, of whom 219 (30.2%) had serum ferritin above 500 ng/dl. Patients with high serum ferritin were older with more diabetes mellitus (DM) and heart disease and tended to have deceased donor transplantation delayed graft function. By univariate Cox analysis, ferritin level above 500 ng/ml was associated with increased risk of death and graft loss (Hazard Ratio (HR) 2.38, 95% Confidence Interval (CI) 1.69-3.35, p<0.001). By extensive multivariate model ferritin was still highly associated with increased rate of graft loss (HR 1.87, 95% CI 1.29-2.72, p=0.001). High ferritin was also associated with increased risk of the secondary outcome of death censored graft loss (HR 2.09, 95% CI 1.26-3.48, p=0.005).

PO2500

Association Between Elevated Ferritin and Graft Survival During the First Year After Kidney Transplant

Benyu Rozen-zi1, Amir Schechter,2 Ruth Rahamimov,1,2 Anat Gafner1,2,3 Batob Medical Center, Petah Tikva, Israel; 1Tel Aviv University-Sackler Faculty of Medicine, Tel Aviv, Israel.

Background: Both iron deficiency and iron overload are associated with adverse outcomes in patients with end stage kidney disease on chronic hemodialysis. In contrast, the effect of iron metabolism markers on post-transplantation have not been thoroughly evaluated. In this study we aimed to evaluate the association between serum ferritin and transferrin saturation during the first year post transplantation on patients and graft survival.

Methods: Retrospective cohort study, using the Rabin Medical Center (RMC) kidney transplant registry. We included adults (>18 years) patients transplanted between 1/1/2006 and 31/12/2017 that had at least one available iron, transferrin and ferritin value during the first year post transplantation. Ferritin and transferrin were log transformed and serum ferritin was also analyzed as a dichotomous variable with 500 ng/ml as a cutoff value. Primary outcome was the composite of graft and patients’ survival. Secondary outcomes included death censored graft loss. Univariate and multivariate Cox models were used for the primary composite outcome of patients’ and graft survival.

Results: Seven hundred and sixty-two patients were included in the study, of whom 219 (30.2%) had serum ferritin above 500 mg/dl. Patients with high serum ferritin were older with more diabetes mellitus (DM) and heart disease and tended to have deceased donor transplantation delayed graft function. By univariate Cox analysis, ferritin level above 500 ng/ml was associated with increased risk of death and graft loss (Hazard Ratio (HR) 2.38, 95% Confidence Interval (CI) 1.69-3.35, p<0.001). By extensive multivariate model ferritin was still highly associated with increased rate of graft loss (HR 1.87, 95% CI 1.29-2.72, p=0.001). High ferritin was also associated with increased risk of the secondary outcome of death censored graft loss (HR 2.09, 95% CI 1.26-3.48, p=0.005).

PO2501

Iron Deficiency in Kidney Transplant Recipients: Impact on Cognitive Functioning

Joanna Sophia J. Vinka,1 Aaltje L. Ziegen,2 Lisanne van Sonderen,2 Antonio W. Gomes Neto,2 Anne Buunk,1 Stefan P. Berger,1 Stephan J. Bakker,2 Michele F. Eisenga,1 Martin H. De Borst,1 1University Medical Center Groningen, Department of Nephrology, Groningen, Netherlands, 1University Medical Center Groningen, Department of Neuropsychology, Groningen, Netherlands.

Background: Cognitive function impairment is common in kidney transplant recipients (KTRs). Brain functioning requires energy, for which iron is essential at the level of oxygen delivery and mitochondrial function. Iron deficiency (ID) has been linked to compromised cognitive functioning in premenopausal women. We aimed to investigate whether ID could be a potentially modifiable risk factor for cognitive function impairment in KTRs.

Methods: In a prospective study among KTRs participating in the TransplantLines Biobank and Cohort study, we analyzed KTRs >1 yr post-transplantation with data on iron status. All participants underwent neurocognitive testing to measure memory (Digit Span Forward and Delayed Recall of the 15 Word Test), attention and mental speed (Symbol Digit Modalities Test, Trail Making Test-A) and executive functioning (Trail Making Test-B, Digit Span Backward),” attention and mental speed; Symbol Digit Modalities Test, Trail Making Test-A) and executive functioning (Trail Making Test-B, Digit Span Backward). ID was defined as ferritin <100 μg/L or 100-299 μg/mL with transferrin saturation (TST) ≤20%. We used multivariable linear regression to analyze associations between ID and neurocognitive outcomes. Analyses were adjusted for hemoglobin, CRP, age, sex, eGFR, BML, smoking, alcohol intake, time since transplantation, dialysis duration, donor type, educational level and immunosuppressives.

Results: We included 398 KTRs (age 56±14 yrs, 62% male, eGFR 52±14 mL/min/1.73 m²). The results were similar when ferritin was evaluated as continuous variable. In contrast, transferrin saturation was not associated with overall and death censored graft survival. Furthermore, there was a significant decrease in both patients’ and graft survival. Further research is needed to evaluate whether this association is due to inflammation, iron overload or combination of the two.
mental speed and attention in KTRs, independent of hemoglobin and other potential confounders. Future studies should address whether ID correction restores cognitive function.

Discussion: SV use may have more serious GI adverse effects in CKD patients than noted in the original clinical trials. Preexisting GI disease and/or abnormalities may increase the risk of adverse GI effects related to SV. Recent use of SV prior to kidney transplantation or use of SV for control of hyperphosphatemia in the context of DGF can be associated with GI morbidity in the early post transplant setting. Need for higher doses of phosphate binders and severity of hyperparathyroidism may be contributing factors to this risk.

PO2504
C-Terminal and Intact FGF-23 in Kidney Transplant Recipients and Their Associations with Kidney Transplant Loss and Mortality
Chang Chu,1 Shufei Ying,2 Yingqian Xiong,2 Ahmed A. Hasan,3 Bernhard K. Krämer,2 Berthold Hocher,2 1Charité - Universitätsmedizin Berlin, Campus Mitte, Berlin, Germany; 2Fifth Department of Medicine (Nephrology/ Endocrinology/ Rheumatology), University Medical Centre Mannheim, University of Heidelberg, Germany; 3Manne Portal, Germany; 4Institute of Nutritional Science, University of Potsdam, Potsdam, Germany.

Background: Increased fibroblast growth factor 23 (FGF23) is a risk factor for mortality, cardiovascular disease, and progression of chronic kidney disease. Limited data exist comparing the association of either c-terminal FGF23 (cFGF23) or intact FGF23 (iFGF23) in kidney transplant at recipients (KTRs) with graft loss and all-cause mortality.

Methods: We conducted a prospective observational cohort study in 562 stable kidney transplant recipients. Patients were followed for graft loss and all-cause mortality for a follow-up of 48 months.

Results: During a median follow-up of 48 months, 94 patients had adverse outcome (graft loss or death). Both cFGF23 and iFGF23 concentrations were significantly higher in patients who had adverse outcome than those without adverse outcome (24.59 [11.43-87.82] vs 10.67 [5.99-22.73] pg/ml; P=0.007 and 45.24 [18.65-119.0] vs 29.04 [15.23-60.65] pg/ml; P=0.002 for cFGF23 and iFGF23, respectively). cFGF23 and iFGF23 measurements correlated well (rho=0.54, p<0.0001). ROC analysis of cFGF23 and iFGF23 yielded AUC of 0.69 (p<0.0001) and 0.61 (p=0.002) for prediction of the composite endpoint, respectively. Cox regression analyses adjusted for confounding factors, showed that cFGF23 (HR for one unit increase of log transformed cFGF23: 1.35; 95% CI, 1.03-1.77; p=0.028) but not iFGF23 (HR for one unit increase of log transformed iFGF23: 1.03; 95% CI, 0.81-1.31; p=0.827) was associated with the composite endpoint.

Conclusions: Elevated cFGF23 levels at baseline are independently associated with an increased risk all-cause mortality or graft loss. iFGF23 measurements were not independently associated with the study endpoint. The iFGF23 ELISA might detect bioactive FGF23 fragments that are not detected by the iFGF23 ELISA.

PO2505
The Time Is Now: Reducing Waiting Times in Minority Populations

Background: A significant limiting factor to transplantation resides on waiting time based on blood type. Historically candidates in blood groups B and O experience higher waiting times for kidney transplantation. Our center has worked to increase the rate of acceptance in kidneys that would have previously been discarded to try to maximize the donor pool for these blood groups.

Methods: We retrospectively analyzed 1287 consecutive deceased donor kidney transplants from 2015 to 2019. This cohort was chosen to ensure baseline was after allocation system changes, so the change is a result of change in practice at our center.

Average waiting time to transplantation and renal transplantation rates were analyzed after allocation system changes, so the change is a result of change in practice at our center.

Results: We observed a decrease in waiting time across all blood types (Figure 1) over the 5 year period of this study. There was a substantial benefit in blood type B recipients with a 6.4 year decrease in average waiting time from 2015 to 2019. Waiting time in

Figure 1. Multivariable-adjusted Cox regression analyses of composite endpoint: graft loss or all-cause mortality. Model 1: for cFGF; Model 2: for iFGF; Model 3: for age, sex, race, primary disease, donor age, donor race, donor sex, donor smoking status, recipient D-dimer, recipient weight, recipient height, recipient albumin, recipient creatinine, recipient dialysis vintage, recipient insurance status, recipient history of diabetes, recipient hypertension.

Underline represents presenting author.
blood type O recipients decreased by 3.4 years from 2015-2019 (Figure 1). We observed a decrease in disparity between African Americans and Hispanics versus Caucasians, with average waiting times decreasing from 2.5 years to 1.2 years and 1.6 years to 0.5 years, respectively. There were no type B recipients who received A2 donors in this cohort.

**Conclusions:** Waiting time at our center decreased significantly across all blood types with a disproportional benefit in blood group B recipients despite not utilizing the benefit of A2 donors transplanted into B. This, thus, reflects our increase in volumes by utilizing extended criteria donors such as acute kidney injury and high kidney profile index donors (KDPJ). These efforts have reduced the disparities in waiting time particularly in African-American and Hispanic populations.

**Ethnic Disparities in Hospitalization After Deceased Donor Kidney Transplantation**

Shahidul Islam,1 Sumit Mohan,2,4 William M. Brown,4 Stephen O. Pastan,4 Ajay K. Israni,1,2 Robert S. Gislon,3 Alejandro Mena-Gutierrez,1 Amber M. Reeves-Daniel,4 Bruce A. Julian,3 Barry L. Freedman,1 Jasmin Divers,1 1Division of Health Services Research, Department of Foundations of Medicine, NYU Long Island School of Medicine, Mineola, NY; 2Winthrop Research Institute, NYU Long Island School of Medicine, Mineola, NY; 3Division of Nephrology, Department of Medicine, Columbia University College of Physicians & Surgeons, New York, NY; 4Department of Epidemiology, Mailman School of Public Health, Columbia University, New York, NY; 6Renal Division, Department of Medicine, Emory University School of Medicine, Atlanta, GA; 7Division of Nephrology, Department of Medicine, Hennepin County Medical Center, University of Minnesota, Minneapolis, MN; 8Minneapolis Medical Research Foundation, Minneapolis, MN; 9Department of Internal Medicine, Section on Nephrology, Wake Forest School of Medicine, Winston-Salem, NC; 1Department of Nephrology, Department of Medicine, University of Alabama at Birmingham School of Medicine, Birmingham, AL.

**Background:** African American (AA) recipients of deceased-donor (DD) kidney transplants have shorter allograft survival than recipients of other racial/ethnic groups. However, it remains unclear whether similar patterns are observed for healthcare utilization. Hospitalization rates (HR) for recipients of kidneys from 2,639 AA and 12,043 European American (EA) DDs who had one kidney transplanted into an AA and one into an EA recipient were analyzed. Four donorrecipient pairs (DRPs) were studied: AA/AA, AA/EA, EA/AA and EA/EA using data from the Scientific Registry of Transplant Recipients for transplantations performed between January 1, 2001 and June 30, 2016.

**Methods:** All reported hospitalizations for the duration of the kidney allograft were counted. Negative binomial models were fitted to compare post-transplantation HRs with other racial/ethnic groups. The adjusted HR was higher for recipients with Medicaid insurance 62.0% (16.4%, 125.5%), or DGF 25.9% (18.7%, 33.5%), but compared to those performed during 2001-2005. HRs were also higher for recipients assigned to a Vitamin D (cholecalciferol, 4000 IU / day) group or a placebo group in a 1:1 ratio. A prespecified secondary endpoints in this study included a percent (%) change in handgrip strength (HGS), and leg strength (LS) for skeletal muscle strength, and skeletal muscle index (SMI) for skeletal muscle mass.

**Results:** A total of 193 KTRs were randomized, but 6 KTRs were lost before taking the medication. We analyzed 92 KTRs in Vitamin D group and 95 in Placebo group. Dropout during this study were 3 KTRs in Vitamin D group and 2 in Placebo group. In Vitamin D group, at baseline the mean age was 52.2 ± 12.5 years old and the number of males was 28 (30.4%), and in Placebo group, 53.7 ± 11.4 years old and 30 (31.5%), respectively. The mean changes in serum 25-hydroxyvitamin D levels from baseline to the end of this study were 11.2 ± 4.1 to 39.8 ± 13.0 ng/ml in Vitamin D group (p < 0.001) and 11.2 ± 4.1 to 14.5 ± 5.0 ng/ml in Placebo group (p < 0.001). In this study, there was no difference in % changes in HGS, LS, or SMI between those groups, respectively.

**Conclusions:** Vitamin D supplementation alone appears not to be effective in improving skeletal muscle weakness and loss among KTRs early post-transplantation. Larger-scale trials are warranted to confirm these findings.

**PO2508**

**Effects of Arteriovenous Fistulas on Outcomes of Kidney Transplant Recipients**

Yasar Caliskan,1 Ahmet B. Dirim,2 Safak Mirioglu,2 Ozgur A. Oto,3 Halil Yazi,2 Erol Demir,2 Sedat Safak,2 Nurana Guller,2 Mehmet S. Sever,2 Krista L. Lentine,1 1Saint Louis University, Saint Louis, MO; 2Istanbul School of Medicine, Istanbul, Turkey.

**Background:** Arteriovenous fistulas (AVFs) may exacerbate cardiovascular events (CVE) after kidney transplantation (KTx). We aimed to investigate the long-term effects of AVFs on KTx outcomes.

**Methods:** Prevalent 168 recipients were categorized at median 2yr. after KTx: recipients with functioning AVF (nAFV=73), recipients with non-functioning AVF (nNAVF=62) and recipients without AVFs (nNoAVF=33) pred-KTx peritoneal dialysis or underwent preemptive KTx. Baseline characteristics, echo findings and endothelial function were compared. During a median 11yr. follow-up after enrollment, CVE were defined as acute coronary syndromes or cerebrovascular accidents; additional outcomes included eGFRs at baseline and end of follow up, graft failure and death.

**Results:** Demographic, clinical, laboratory and echo characteristics and endothelial function at enrollment were not significantly different across all groups (Table 1). During follow up, CVE occurred in 9 (12.3%), 5 (8%), and 4 (12.1%) patients in nAFV, nNAVF and nNoAVF groups, respectively (p=0.70). Groups were comparable regarding graft and patient survival rates (p=0.13 and p=0.87, respectively). During follow-up, functioning AVFs thrombosed in 5 (7%) and were surgically closed in 20 (27%) patients in nAVF group. CVE rate was similar in patients with thrombosed (20%), closed (5%) and still functioning (75%) AVFs (p=0.47). Patient and graft survival rates were significantly lower in recipients with still functioning AVFs (77% and 73%, respectively) compared to nAVF patients with thrombosed (100% and 100%, respectively) and closed (100% and 95%, respectively) AVFs (p=0.05 and p=0.03, respectively).

**Conclusions:** Long-term CVE rate is similar in KTx recipients with and without patent AVFs. In a subgroup of KTx recipients with functioning AVFs, closure and thrombosis of AVFs may be associated with higher rates of patient and graft survival.
PO2509

Recurrent Cardiovascular Events After Kidney Transplant Are Associated with Increased Risk for Graft Failure and Mortality

Levton Galapia,1 John C. Lieske,2 Nan Zhang,1 Richard J. Butterfield,1 Mira T. Keddis.1 Mayo Clinic, Scottsdale, AZ; 2Mayo Clinic, Rochester, MN.

Background: Cardiovascular (CV) disease is prevalent after kidney transplant (KTx). The objective of this study was to describe patients with recurrent CV events in association with allograft function and mortality.

Methods: 1148 consecutive adults that received a KTx between 2011-2013 at a single center were evaluated. CV events were defined as: cardiac: myocardial infarction, heart failure, cardiac arrest requiring resuscitation, and vascular, any stroke, or peripheral vascular disease requiring intervention. Recurrent events were defined as more than one event (either cardiac or vascular).

Results: Mean age was 56.0years (SD14.2), 500(44%) were female, 403(35%) had diabetes, 1083(94%) had hypertension, 127(11%) had prior history of CV events, 603(52%) had dialysis, and 867(76%) received living donor KTx. After a median follow-up of 74 months there were 229(20%) deaths and 217(19%) CV events, of which 92(42%) were cardiac, 86(40%) were vascular, 39(18%) had both. 119 patients had an isolated CV event and 98 had recurrent CV events (median 3 (range 2,4)). Multivariate analysis revealed the following independent significant predictors of CV events: older age, prior history of CV event, diabetes, hypoalbuminemia and measured GFR. Compared to recipients with no CV events and those with an isolated event, recipients with recurrent CV events had increased: mortality (15% vs 38% vs 45%,p<0.0001) and graft failure (14% vs 26% vs 40%,p<0.0001). Hazard ratio for mortality associated with isolated CV events was 2.66 (1.90-3.73) compared to a HR 3.06 (2.18-4.29) for recurrent CV events, p<0.0001.[Figure 1]. Predictors of multiple CV events included measured GFR and increased c-reactive protein; on multivariate analysis only measured GFR was predictive. Compared to recipients of a KTx between 2011-2013 at a single center were evaluated. CV events were defined as: cardiac: myocardial infarction, heart failure, cardiac arrest requiring resuscitation, and vascular, any stroke, or peripheral vascular disease requiring intervention. Recurrent events were defined as more than one event (either cardiac or vascular).

PO2510

Mitral Regurgitation and Aortic Stenosis After Kidney Transplantation

Yuusuf Kyeso, Hashim Abbas, Daniel C. Brennan, Sami Alasfar. Johns Hopkins Hospital, Baltimore, MD.

Background: Valvular heart disease (VHD) is highly prevalent in patients with end stage kidney disease and has been associated with poor outcomes. The 5-year mortality rate among patients with at least mild aortic stenosis (AS) or mitral regurgitation (MR) is more than 50% greater than in persons without kidney disease (Samad et al, JAHA 2017). Current knowledge of VHD in patients after kidney transplantation (KT) is scarce.

Methods: This is an ongoing single center retrospective study. In our center, all KT recipients have echocardiograms within one year prior to KT. We included KT recipients at our institution between Jan 2016 and Dec 2016 who had underlying MR and/or AS of any severity. Participants had to have an echocardiogram (Echo) around one year post KT. Our primary objective was to compare the severity of MR and AS at one year post KT to the baseline severity. The secondary objective was to describe changes in left ventricle hypertrophy (LVH).

Results: Two hundred subjects were initially screened. The number of patients who met our inclusion criteria was 22 (Table 1). Mild MR was present in 10 recipients pre KT. MR improved in 4, remained stable in 4, and worsened in 2 out of these 10 recipients at one year post KT. Moderate MR was present in 7 recipients pre KT and all 7 had improvement in severity of MR at one year post KT. Two and three recipients had mild AS and moderate AS respectively pre KT and all of them were observed to have worsening of aortic valve area (AVA) at one year post KT (mean AVA 1.96 versus 1.15 cm2, p<0.01). Nine out of the total 22 recipients included had mild LVH pre KT and all the 9 continued to have mild LVH post KT.

Conclusions: Our study showed that most KT recipients with pre-existing MR had improvement in the severity of MR at one year post KT. However, recipients with AS prior to KT were observed to have worsening in severity of AS at one year post KT. Larger studies are needed to confirm these findings and identify factors that influence progression.

Table 1. Clinical Characteristics

</table>

Conclusions: Prevalence of recurrent CV events after KTx was 8.5%. Patients with recurrent CV events are at increased risk for mortality and graft failure. Decreased graft function was the primary predictor of recurrent CV events.

PO2511

A Retrospective Analysis of Post-Transplant Erythrocytosis: The Experience of a Tertiary Kidney Transplant Unit

Background: Post-transplant erythrocytosis (PTE) defined as persistently raised haemoglobin and haematocrit levels for over 6 months following kidney transplantation reportedly occurs in up to 20% of transplants and can influence physical and mental wellbeing. Reported complications include stroke, hypertension, NODAT and chronic fatigue. Our aim was to investigate the prevalence and potential risk factors of PTE in patients transplanted in our unit between 2013 and 2018.

Methods: We conducted a retrospective study of patients receiving a Kidney or Kidney-pancreas Transplant between 2013 and 2018 and followed up in our local clinic. We collected information on donor and recipient demographics, original kidney
Utility of the 6-Minute Walk Test in Coronary Artery Disease Screening Before Kidney Transplant

Xinxing Cheng,1 Daniel J. Waid,1 Hiyoriyuki Arashi,1,2 Jane C. Tan,1 William F. Feazell1,2 (1Stanford University School of Medicine, Stanford, CA; 2Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan).

Background: Coronary artery disease (CAD) screening is a cornerstone of kidney transplant (KTx) evaluation, but existing approaches result in excess testing and low intervention rate. We hypothesized that aerobic performance, based on a simple office test (the 6-minute walk test, 6MWT), may help risk stratify KTx candidates.

Methods: We performed 6MWT in waitlisted patients who were nearing KTx. Recipients were used for frailty counselling and not for cardiac evaluation. CAD screening was done according to our center protocol: invasive angiogram for patients with long-standing diabetes mellitus (DM) and non-invasive testing for other patients with risk factors and at the evaluating transplant nephrologist’s discretion. We used subdistribution Cox regression and time-dependent receiver operator curve to evaluate time to CAD event (revascularization, myocardial infarction, waitlist removal for CAD, or cardiac death), treating waitlist removal for non-CAD and non-cardiac death as competing events.

Results: Of the 360 patients, 200 and 161 patients had 6MWT results <400 meters and >=400 meters (~4 metabolic equivalents), respectively. Patients with lower 6MWT results were older (59±10 vs 50±12 years) and more likely to be female (54% vs 34%), have DM (61% vs 33%) or known atherosclerotic disease (44% vs 22%), and have had prior cardiac evaluation (72% vs 61%). They were also more likely to exhibit cardiac symptom during 6MWT (36% vs 6%) and more likely to be censored due to waitlist removal for non-CAD reasons (follow-up 391±337 vs 541±277 days). 6MWT was not associated with CAD event (subdistribution hazard ratio 1.00 [0.90-1.10], 1-year area under the curve [AUC] 0.54). 196 patients had invasive (52%) or non-invasive (48%) CAD testing within 6 months of 6MWT. 6MWT did not predict the CAD test result (odds ratio 0.96 [0.81-1.14], AUC 0.54). Of the 94 patients who had concurrent non-CAD invasive testing, the 1-year AUC of 6MWT, symptom (at rest or during 6MWT), AST guidelines, or non-invasive testing for CAD event were 0.64, 0.52, 0.46 and 0.46 respectively.

Conclusions: The 6MWT did not perform better in risk stratification for CAD events compared to a symptom- or risk factor-based approach.

PO2515

A Devastating Complication of Encapsulating Peritoneal Sclerosis (EPS) In Two Renal Transplant Recipients

Benjamin Lawson, Zar Chan, Lilly M. Barba. Renal Transplant Program Los Angeles County Harbor-UCLA Medical Center, Torrance, CA.

Introduction: EPS is a rare complication of peritoneal dialysis (PD) which carries great morbidity and mortality. The risk of EPS may be higher in PD patients who undergo renal transplantation as compared to PD patients who do not receive a transplant. Pre-transplant EPS, progressive peritoneal remodeling, cessation of PD and use of calcineurin inhibitors are potential etiologies. We present two unique cases of post-transplant EPS requiring surgical intervention with devastating outcomes.

Case Description: Case #1 A 47-year-old female with end stage renal disease due to congenital kidney disease on PD for 8 years transitioned to hemodialysis due to peritonitis, underwent a deceased donor kidney transplant (DDRT) presented 4 weeks postoperatively with nausea, vomiting, and abdominal pain. Imaging showed dilated loops of small bowel concerning for partial small bowel obstruction treated non-operatively with bowel rest. One month later she presented with similar symptoms and small bowel obstruction. Due to failure to improve, she was taken to surgery and was found to have a frozen abdomen with dense adhesions. Lysis of adhesions was complicated by enterotomies and small bowel resection. Multiple enterocutaneous fistulas prohibited wound closure. She is being evaluated for a small bowel transplant and remains on parenteral nutritional support. Case #2 A 39-year-old African female with history of ESRD secondary to Lupus on PD for 11 years received a DDRT. Eighteen months post-transplant, she presented with nausea, vomiting and abdominal pain. Imaging showed a small bowel obstruction treated non-operatively with bowel rest. Three weeks later she required emergent surgery for an acute abdomen undergoing lysis of adhesions, bowel resection and end ileostomy. She required parenteral nutrition for five months.

Discussion: We report two cases of EPS after DDRT who required surgical intervention with devastating outcomes. Fluid and nutritional support have complicated management and affected quality of life. Given the multifactorial etiologies and potential devastating outcomes of EPS, the pre-transplant evaluation should include a detailed assessment. Furthermore, long term PD patients and those with a history peritonitis should be monitored closely post-transplant.
PO2516
When a Peritoneal Dialysis Catheter Should Be Removed Post-Kidney Transplantation?

Background: Approximately 15% of patients on the kidney transplant (KT) waiting list in the US receive peritoneal dialysis (PD), a growing home dialysis therapy for end stage renal disease (ESRD) patients. European guidelines recommend keeping the peritoneal dialysis catheter (PDC) in-situ during KT, due to the potential risk for delayed graft function (DGF). With this approach, a 10% risk for post-transplant PDC exit-site infections has been reported. In the US guidelines for 1 PDC removal timing are lacking, and determine by transplant center and operating surgeon’s preferences.

Methods: We retrospectively reviewed the electronic medical records of all patients transplanted between 4/2017-7/2019 at our kidney transplant center. We studied basic donor and recipient characteristics, presence of DGF (defined as dialysis in the first week following KT), time interval between KT and PDC removal, and wound related complications.

Results: Of 259 patients received a KT during the study period, 28 were on PD prior to KT. Of those 10 patients underwent a living donor transplant, 16had a deceased donor, and 2and went a simultaneous kidney-pancreas transplant. Sixteen were female, 9were non-Hispanic blacks, and 4were aged >65 years. Three received induction with basiliximab (per center’s protocol for recipients aged ≥70 years) and the rest received antithymocyte globulin. PDC was removed at time of KT in 17 patients while in the other 11 recipients PDC was removed 22 days (median) post transplantation. For patients developed DGF, with modality switched to hemodialysis. Three of these had their PDC removed at the time of KT. The 4th patient with DGF who had his PD catheter left in place, received hemodialysis due to hemodynamic instability. Readmission rates (excluding unplanned hospitalization for PDC removal) and wound infections were similar between those who had their PDC removed at surgery, and those who did not.

Conclusions: Kidney transplant centers that do not routinely use PD for DGF should remove the PDC at time of kidney transplant to reduce costs and prevent patient and healthcare provider burden of additional surgery. As the prevalence of PD and KT is expected to grow in the near future with the new kidney health initiatives, kidney transplant centers should consider a protocol for optimal care for PDC removal.

PO2517
Could Targeting Dry Weight on Hemodialysis Patients Before Kidney Transplantation Leave Them Too Dry?
Hayam H. Al Dohan,1,2 Eduard A. Iliescu,1,2 Frances Macleod,1 M. Khaled Shamseddin.3,4 Queen’s University, Kingston, ON, Canada; 1,2 Kingston Health Sciences Centre, Kingston, ON, Canada.

Background: Delayed graft function (DGF) after transplantation is associated with inferior kidney and patient outcomes. Studies suggest that avoidance of hypovolemia peri-kidney transplantation is associated with a reduced risk of DGF. Hemodialysis (HD) patients that have HD prior to transplant targeting their usual dry weight may be volume contracted pre-transplant and at increased risk for DGF. By definition the dry weight is the state of near maximal volume contraction for most HD patients. The objective of this study is to examine the proportion of HD patients who have a pre-transplant post-HD weight at or below their usual dry weight.

Methods: This is a retrospective study of sequential kidney transplant candidates in HD patients at our center from Jan 2015 to Dec 2019. The primary outcome was the proportion of patients who had an HD session before transplantation that resulted in a post-HD weight equal to or less than their prevalent set target dry weight. Data was extracted from the electronic medical record and chart review. Recipients on home therapies and pre-emptive transplanted were excluded.

Results: Of 68 kidney transplants done in the study period, 40 were in-center HD patients with available HD data. They were mean age 54.8±14.5 years, 12 (30%) female, and majority were Caucasian. Twenty-five (62.5%) patients had a pre-transplant post-HD weight equal to or less than their prevalent set target dry weight (mean ± 0.26±0.25 kg). The other 15 (37.5%) patients achieved post-HD weights higher than their usual targets (+0.72±0.41 Kg).

Conclusions: The results of this study suggest that a high proportion of HD patients are at below dry weight after their dialysis and may be hypovolemic before kidney transplantation. This may represent at potentially avoidable increased risk for DGF. Further studies are planned to examine possible associations of achieved post-HD weight prior to transplant with perioperative central venous pressure, IV fluid administration, and graft function. There may be strategies to optimize volume status pre-transplantation to mitigate this risk of DGF including targeting a higher weight on HD or administration of IV fluid to raise weight above the prevalent set target dry weight before transplantation when feasible.

PO2518
Trends in Time to Graft Loss by Dialysis Exposure
Patrick Ahearn, Colin R. Lenihan, John D. Scandling. Stanford University School of Medicine, Stanford, CA.

Background: Preemptive transplantation is believed superior to transplantation after dialysis initiation, and transplantation after shorter dialysis exposure is better than with longer exposure. Considering recent registry reports of improved survival on dialysis, we examined temporal trends of graft loss by time on dialysis prior to kidney transplantation.

Methods: Using the US Renal Data System, we identified adults who underwent first kidney transplant between January 1, 1995 and July 31, 2017. We excluded recipients of simultaneous multiorgan transplants. We used an adjusted Cox model to examine the association between dialysis exposure prior to transplantation (categorized as preemptive, <6 months, 6 months-1 year, 1-3 years, 3-5 years, and >5 years) and graft failure within 3 years of transplant. Our model was adjusted for donor and recipient demographic factors, donor type, cause of ESKD, BMI, panel reactive antibodies, diabetes status, and cardiovascular disease status. We organized patients into the following transplant era groupings: 1995-2001, 2002-2006, 2007-2011, and 2012-2017.

Results: A total of 277,158 transplant recipients were studied and 38,364 had graft loss within 3 years. In each era, the hazard ratio for graft loss was lower for preemptive transplant recipients (referent group) compared to all other dialysis exposures except for the group that received less than 6 months of dialysis in the 2012-2017 era (HR 1.06 (95% CI 0.91-1.24)). Those exposed to more than 5 years of dialysis exposure had the highest risk for graft loss within 3 years in all eras, with over 2 times the hazard compared to the referent group in the most recent eras (figure).

Conclusions: Although preemptive transplantation offers the best graft survival across the study period, those transplanted within 6 months of dialysis initiation had similar 3-year graft survival to those transplanted preemptively in the most recent era. The negative association between the longest duration of pre-transplant dialysis and post-transplant survival persists.

PO2519
Does the Timing of Dialysis Initiation Affect Peak Calculated Panel Reactive Antibody in Waitlisted Kidney Transplant Candidates?
Adam Price, Mohamed A. Mohamed Ahmed, Zemin Su, Maria Aurora C. Posadas, Karim M. Soliman, Vinaya Rao, Michael Casey. Medical University of South Carolina, Charleston, SC.

Background: Higher calculated panel reactive antibody (cPRA) restricts access to kidney transplantation, but it’s unclear how the timing of dialysis initiation after listing might affect cPRA. We hypothesized that patients with earlier dialysis initiation would have higher cPRA scores.

Methods: This was a retrospective SRTR database study of adults listed for a solitary kidney transplant from 10/1/09 to 11/30/18. Waitlisted patients were stratified by dialysis initiation: prelist, 0-1 year after listing, 1-2 years after listing, or no dialysis within 2 years after listing. The outcomes studied were mean peak Cpra at 0-1 year and 0-2 years after listing. One-way ANOVA was used for statistical analysis.

Results: A total of 173,964 patients were identified who were waitlisted for 1-2 years. With later dialysis initiation, there was a stepwise decline in mean peak CPRA between those who initiated dialysis prelist, 0-1 year after listing, and 1-2 years after listing (Figure 1). There was no difference in mean peak CPRA between the dialysis initiation groups “1-2 years after listing” and “no dialysis 2 years after listing.” A similar stepwise decline in mean peak CPRA was seen with patients who were waitlisted for 0-1 year (Table 1).

Conclusions: Our data suggest that waitlisted patients with earlier dialysis initiation may be at risk for developing higher cPRA scores. If verified with further studies, then this may be an incentive for early predialysis referrals for transplant evaluation.

Variations in Practice Patterns in Eligibility Assessments Across Kidney Transplant Programs in the United States

Adrian Whelan, Brian K. Lee, Deborah B. Aday, Dhiraj Nallapothula, Elaine Ku. University of California San Francisco, San Francisco, CA.

Background: Kidney transplant programs are known to vary in terms of their practice patterns given lack of consensus surrounding many aspects of pre-transplant workup. The differences in national practice patterns related to transplant eligibility assessments have not been well described in the contemporary era.

Methods: We conducted a survey of kidney transplant programs in the US to assess current practice patterns as it relates to criteria for prioritizing transplant referrals, candidate evaluation, and determination of eligibility for kidney transplantation. We distributed our survey to 171 adult kidney transplant programs in the US.

Results: 89 (52%) of programs invited to participate in the survey completed it, 45% of which were completed by the Medical Director, 48% by a Transplant Nephrologist, and 7% by other providers. The majority of programs (58%) screened referrals for contraindications to transplantation before scheduling an in-person evaluation (Figure 1). 52% of programs did not prioritize the evaluation of patients with a self-identified living donor candidate when scheduling patients referred for eligibility assessments (Figure 1). Centers differed in the kidney function threshold at which transplant evaluation was begun, and age and body mass index limits for transplantation also varied considerably (Figure 1).

Conclusions: There is wide variation across transplant programs in the assessment of eligibility for kidney transplantation. Further studies are needed to understand how these variations may be associated with access to transplantation and post-transplantation outcomes.

PO2520

Post-Transplant Diabetes Mellitus in a Single Pediatric Kidney Transplant Center: Risk Factors, Outcomes, and Characterization of Clinical Course

Auli Khanna, Jee-Young N. Ham, Margret Kamel, Kathryn M. Ngo, Amanda S. Thomas, Rochelle Liverman, Rouba Garro. Emory University School of Public Health, Atlanta, GA; Children’s Healthcare of Atlanta Egleston Hospital, Atlanta, GA; Emory University School of Medicine, Atlanta, GA.

Background: The prevalence and outcomes of post-transplant diabetes mellitus (PTDM) in pediatric kidney transplant (KT) recipients vary among studies due to the lack of a consistent definition. Risk factors for and pathogenesis of pediatric PTDM are incompletely understood.

Methods: PTDM prevalence, risk factors and disease course was evaluated at a high volume, tertiary care pediatric hospital. We performed a retrospective review of pediatric KT recipients between 2006-2016 to evaluate PTDM prevalence. PTDM was defined as persistent hyperglycemia with serum glucose ≥ 200 mg/dl, HbA1C ≥ 6.5%, and requiring antihyperglycemic treatment for a 30 days. Full data were available on all patients transplanted between 2010-2016 and were used to compare demographic and clinical characteristics between PTDM (n=9) and non-PTDM patients (n=173) using Chi-square and Wilcoxon rank sum tests.

Results: Between 2006-2016, 312 patients received KT. Five patients with pre-existing DM were excluded. Fifteen developed PTDM with a prevalence estimate of 4.89 % (95% CI: 3% - 8%). Median time from transplant to DM was 17.6 months (25%-75%: 3 – 83). The majority of PTDM patients had a family history of DM in 1st degree relatives (81%) and were maintained on tacrolimus at diagnosis (67%). PTDM diagnosis and insulin initiation occurred in the context of active rejection episode in only two patients. Despite a more stringent definition of PTDM, insulin therapy was discontinued in 3/15 (20%) patients who continued to be normoglycemic. Comparing patients with and without PTDM during the period 2010-2016 revealed that PTDM patients had higher BMI-Z scores at transplant (p=0.053) and higher average blood glucose during the first week post KT (p=0.095), with no difference in age, gender, race, donor status, or dialysis modality.

Conclusions: A more consistent definition of PTDM and larger studies are warranted to better understand the prevalence, risk factors, and pathogenesis of hyperglycemia and PTDM in children. Detailed patient-level data can provide nuance that may be missed with larger registry studies.

PO2522

Diabetic Nephropathy: Is It All About Hyperglycemia?

Iyad Alabdul Bazzaz, Lois J. Arend, Sami Alasfar. Alfaisal University, Riyadh, Saudi Arabia; Johns Hopkins University, Baltimore, MD.

Introduction: Diabetic nephropathy (DN) is the most common cause of end stage renal disease (ESRD). Hyperglycemia has been suggested to be necessary for the development and maintenance of DN. Simultaneous pancreas and kidney transplantation (SPK) has revolutionized the treatment of type 1 diabetic patients with end-stage renal disease (ESRD), and prevention of recurrent DN is one of the main proposed benefits. We present a case of recurrence of DN after SPK despite normal endocrine pancreas allograft function.

Case Description: A 47-year-old man with past medical history of ESRD due to diabetes type I who underwent a SPK transplant from a deceased donor in December 2003. His nadir serum Creatinine was 1.5 mg/dl and baseline urine protein creatinine ratio (UPC) is 110-250 mg/g. Maintenance immunosuppression consisted of tacrolimus, mycophenolate, and prednisone. His home medications also included benazepril for hypertension. Sixteen years after transplant, he was noted to have increase in UPC (p<0.001) to 392.6. Trough tacrolimus levels were not available. 6 months ranged between 4.8 and 10.9 mg/dL. Donor specific antibodies were negative. He underwent renal allograft biopsy which showed early nodular mesangial matrix expansion and thickened glomerular basement membranes on electron microscopy.

consistent with diabetic nephropathy (Figure 1), early chronic transplant glomerulopathy, and severe arteriolar hyalinosis. Additional laboratory findings showed serum lipase 34 (Normal 7-60 U/L), amylase 103 (Normal 21-101 U/L), fasting glucose 79 (Normal 65-99 mg/dL), hemoglobin A1c 5.3, and C peptide was 2.03 (Normal 0.80 - 3.85 ng/mL). Despite increasing Benazepril dose to 40 mg daily, UPC and Cr continued to increase but stabilized in a range of 3800-4500 mg/g and 2.5 mg/dL respectively.

Discussion: Our case suggests that development of DN can be linked to mechanisms independent of hyperglycemia and the usual metabolic disturbances seen in patients with diabetes. A comprehensive restudying of the pathophysiology of DN could further enhance our existing knowledge of the factors implicated in DN, and possibly our ability to develop a more targeted therapy.

PO2523
Use of Weight-Altering Diabetes Medications to Address Obesity as a Barrier to Kidney Transplant Evaluation in Patients with Type 2 Diabetes Mellitus and Stage 4-5 CKD or ESKD
Kirnan Chintam, Prince Mohan, Jamie A. Green, Alex R. Chang. Geisinger Health, Danville, PA.

Background: Many patients with type 2 diabetes mellitus (T2DM) and chronic kidney disease (CKD) are ineligible for kidney transplant due to high body mass index (BMI). Some medication classes are associated with weight loss (glucagon-like peptide-1 receptor agonists [GLP1-RAs]), neutral-weight (dipeptidyl peptidase-4 inhibitors [DPP4i]), or weight gain (sulfonylureas and insulin).

Methods: We examined the relationship between BMI and use of weight-altering diabetes medications in patients with type 2 diabetes mellitus and stage 4-5 CKD or dialysis-dependent ESKD at Geisinger (1/18-3/20). In addition, we examined whether access to kidney transplant evaluation varied by BMI in patients on dialysis.

Results: Out of 4200 patients with T2DM and stage 4-5 CKD or ESKD, 30% had BMI≥35 kg/m² and 15% had BMI≥40 kg/m². Overall, use of T2DM medications with favorable weight effects was low, similar to use of sulfonylureas (Table). Patients with severe obesity had higher GLP1-RA use (BMI ≥ 35 vs. <35 kg/m²: 11%, 5%), higher insulin use (69%, 53%), and lower DPP4i use (9%, 13%). Similar findings were noted in the subset of patients on dialysis: GLP1-RAs (BMI ≥ 35 vs. <35 kg/m²: 6% vs. 2%), DPP4i (3% vs. 6%), sulfonylureas (5% vs. 8%), insulin (77%, 74%). In an adjusted analysis, transplant clinic attendance was highest in ESKD patients with BMI 30-34.9 kg/m² (23%), followed by BMI 35-39.9 (17%), BMI 25-29.9 (15%), BMI 18.5-24.9 (13%), BMI ≥ 35 vs. <35 kg/m²: 11%, 5%)

Conclusions: The vast majority of patients with T2DM and advanced CKD are taking obesogenic rather than weight loss-promoting diabetes medications. Those with BMI ≥ 40 kg/m² were 3.6x less likely to have been evaluated in transplant clinic than those with class I obesity (BMI 30-34.9 kg/m²). Consideration of the differential impact of certain diabetes medication classes on weight may help improve access to kidney transplantation and long-term outcomes.

Efficacy and Safety of SGLT-2 Inhibitors for Treatment of Diabetes Mellitus Among Kidney Transplant Patients: A Systematic Review and Meta-Analysis
Api Chewcharat,1,2 Narut Prasitlumkum,2 Charut Thongprayoon,2 Wisit Cheungpasitporn.1 Mount Auburn Hospital, Cambridge, MA; Mayo Clinic Minnesota, Rochester, MN; 1University of Hawai’i’s System, Honolulu, HI; 2University of Mississippi Medical Center, Jackson, MS.

Background: The objective of this systematic review was to evaluate the efficacy and safety profiles of sodium glucose co-transporter 2 (SGLT-2) inhibitors for treatment of diabetes mellitus (DM) among kidney transplant (KT) recipients.

Methods: We conducted electronic searches in Medline, Embase, Scopus, and Cochrane databases from inception through April 2020 to identify studies that investigated efficacy and safety of SGLT-2 inhibitors in KT patients with DM. Study results were pooled and analyzed utilizing random-effects model.

Results: Eight studies with 132 patients [baseline estimated glomerular filtration rate (eGFR) of 64.5±19.9 mL/min/1.73m²] treated with SGLT-2 inhibitors were included in our meta-analysis. SGLT-2 inhibitors demonstrated a significantly lower HbA1C (WMD = -0.56% [95CI: -0.97, -0.16]; p<0.007) and body weight (WMD = -2.16 kg [95CI: -3.08, -1.24]; p<0.001) at end of study compared to baseline level. There were no significant changes in eGFR, serum creatinine, urine protein creatinine ratio, and blood pressure. By subgroup analysis, empagliflozin demonstrated a significant reduction in BMI and body weight. Canagliflozin revealed a significant decrease in Hba1C and systolic blood pressure. In terms of safety profiles, 14 patients had urinary tract infection. Only 1 had genital mycosis, 1 had acute kidney injury, and 1 had cellulitis. There were no reported cases of euglycemic ketoacidosis or acute rejection during the treatment.

Conclusions: Among KT recipients with excellent kidney function, SGLT-2 inhibitors for treatment of DM are effective in lowering HbA1C, reducing body weight, and preserving kidney function without reporting of serious adverse events, including euglycemic ketoacidosis and acute rejection.

Health System Encounters in Kidney Transplant Recipients Converted from Immediate-Release Tacrolimus Capsules to Extended-Release Tacrolimus Tablets

Yoonhee P. Ha,1 Jamal Rashid,2 Mary Putt,3 Yu Bin Na,3 Chelsea Sammons,3 Maxwell Norris,2 Gregory Malat,1,3 Brendan Steiner,1 John H. Holmes,4 Roy D. Bloom,3 Peter P. Reese,1,3 Jennifer Trofe-Clark,3,21 Department of Epidemiology, Biostatistics and Informatics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 2Department of Pharmacy, Hospital of the University of Pennsylvania, Philadelphia, PA; 3Renal Electrolyte and Hypertension Division, Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 4Drexel College of Medicine, Philadelphia, PA.

Background: Kidney transplant recipients (KTRs) converted from immediate-release tacrolimus capsules (IR-TAC) to extended-release tacrolimus tablets (ER-TAC) may benefit from reduced dosing frequency and improved bioavailability. However, few studies have characterized health system encounters in these KTRs. Study aims were to determine if conversion to ER-TAC decreased number of dose changes, TAC troughs, and clinic visits during the 90-day post- and post-conversion periods.

Methods: Retrospective review of KTRs at our center transplanted between 2/2010-3/2019, on IR-TAC for ≥90 days, and converted to ER-TAC for ≤90 days. Random-coefficient Poisson regression was used to compare number of dose changes, troughs, and clinic visits during the 90-day pre- and post-conversion periods.

Results: 64 KTRs met inclusion criteria. Mean (SD) age was 52.8 (13.7) years, 38 (59%) were male, 28 (44%) were Black, and 8 (13%) were in an ER-TAC financial assistance program. Median (IQR) time since transplant was 333 (211-1,483) days. KTRs were converted from IR-TAC for tacrofor 52 (81%) non-adherence, 12 (19%) high IR-TAC dose, 21%, sub-therapeutic troughs, 2 (3%); and other/unknown, 22 (34%). The incidence rate of dose changes but not troughs or clinic visits decreased significantly post-conversion. For baseline (IR-TAC) vs. post-conversion (ER-TAC) number of dose changes was 2 (0-3) and days to achieve two consecutive therapeutic troughs was 33.5 (23.5-63).

Conclusions: The incidence rate of dose changes decreased significantly under ER-TAC, but most KTRs did not achieve two consecutive therapeutic troughs within 90 days of conversion. Closely follow up may be beneficial for these KTRs. Future research should determine if reasons for conversion resolved with use of ER-TAC.

PO2526

Looking Beyond the Allograft Survival: Long-Term, Five-Year Renal Outcomes in Lung Transplant Recipients

Mohankumar Doraiswamy,1 Eshetu L. Obole, Priyamvada Singh, Todd E. Pesavento. Comprehensive Transplant Center, The Ohio State University Wexner Medical Center, Columbus, OH.

Background: With the increase in incidence and overall survival of lung transplant recipients, the risk for chronic sequelae in terms of CKD is on the rise. However, the data on the long-term effect on kidneys in this population is scarce. Our study is the first to assess the five-year renal outcomes in lung transplant recipients.

Methods: We did a retrospective chart review of 171 adults with lung transplants performed between 1 January 2014 - 1 January 2019 and meeting inclusion/exclusion criteria. Primary outcomes were: the prevalence of CKD/ESRD (requiring RRT), risk of development of CKD in patients with AKI during index hospitalization, and all-cause mortality in recipients with CKD when compared to the non-CKD group. Secondary outcomes were calculation of the frequency of utilization of modalities for CKD (urinalysis, renal USG, biopsy, nephrology consults).

Results: 66% of patients were white, with a median age of 61 years, median BMI 27.3 kg/m² and 60% were males. Hypertension was present in 55% of recipients at baseline. COPD and IPF were the commonest etiology for lung failure, and 66% received a double lung transplant. Baseline median creatinine and eGFR were 0.8mg/dL and 54mL/min/1.73 m² respectively. 6% (n=117), 60% (n=161), 67% (n=155), 79% (n=47), and 86% (n=77) had CKD at baseline, 6, 12, 36, 60 months respectively. Eight percent received dialysis during the index hospitalization. The odds ratio of development of CKD in patients with an AKI episode during index hospitalization versus no AKI was 6.22 (2.87 to 13.06, p = 0.0001). Whereas, the odds ratio of all causes mortality in patients with CKD when compared to no-CKD was 3.84 (1.44 to 8.64, p = 0.005). Hematological and proteinuria parameters were measured infrequently. Renal biopsy done in 1.1% with renal USG abnormal in 22%, normal in 21% and never performed in 57%. Sixteen percent of recipients were on dialysis, 3% received a renal transplant, and 27% of mortality noted over a five-year follow up period.

Conclusions: There is a high prevalence of CKD in lung transplant recipients, and increased in the patients who had an AKI during index hospitalization. With increased lung transplant nowadays, early involvement of nephrologists is prudent to prevent and manage CKD effectively in the future. Large prospective trials to delineate the problem is warranted.

PO2527

Incidence, Risk Factors, and Outcomes of Post-Transplant Erythrocytosis After Kidney Transplantation

Beyann Alzjubi,1 Abish khare, Fauzia Osman, Fahad Aziz, Neetika Garg, Mahi A. Mohamed, Arjung Djamali, Didier A. Mandebrot, Sandesh Parajuli. University of Wisconsin School of Medicine and Public Health, Madison, WI.

Background: Post-transplant erythrocytosis(PTE) is a common condition after kidney transplantation. PTE is known to increase the risk of stroke, pulmonary embolism, and deep vein thrombosis, commonly called vascular thromboembolism(VTE). In the current era of immunosuppressive medication and management, the incidence, risk factors, and outcomes of PTE among kidney transplant recipients(KTR) is unknown.

Methods: This was a retrospective study among all adult KTRs transplanted at our university hospital between 01/2001 and 12/2016. All recipients in the PTE group had at least 2 consecutive Hct levels of >51 within the first 2 years of transplant. Controls were selected in a ratio of 5:1 using event density sampling. Patient survival, graft survival, and VTE incidence were outcomes of interest.

Results: Of 4317 kidney transplants during the study period, 214(5%) had PTE and were compared with 1035 controls. While comparing baseline characteristics between PTE and control, KTRs in the PTE group were more likely to be younger, male, have lower BMI, higher prevalence of diabetes as the cause of ESRD and receive a non-heart-beating transplant. Similarly, looking at donor characteristics, the PTE group was likely to receive the kidney from a younger donor and have lower KDPI. The median interval from transplant to the diagnosis of PTE was 9.9 months (IQR 5.89). 13 (6.1%) in the PTE group and 71(6.9%) in control had VTE events. In the multivariable analysis, patients with older age (HR: 0.98, 95% CI 0.97-0.99), higher BMI (HR: 0.97, 95% CI 0.93-0.99, p=0.05) were less likely to develop PTE, while non-preemptive transplant (HR: 3.95, 95% CI 1.74-8.39, p<0.001) was significantly associated with increased risk of PTE. After adjustment for the multiple confounding factors, PTE was not associated with patient mortality (HR: 1.0, 95% CI 0.70-1.43, p=0.899), graft failure (HR: 1.13, 95% CI 0.69-1.83, p=0.61) or VTE (HR: 1.07, 95% CI 0.59-1.96, p=0.81). In a subgroup analysis among PTE with Hct >55 (n=39) compared with controls, similar findings were observed.

Conclusions: In this era, the prevalence of PTE is lower at 5% compared to around 15% in various previous studies. Similarly, there were no detrimental effects of PTE on patient survival, graft survival, or the risk of VTE in the current era.

PO2528

Post-Transplant Outcomes Among Kidney Transplant Recipients with Intentional and Unintentional Weight Loss

Meera N. Harhay,1 Xiaomeng Chen,2 Nadia M. Chu,2 Mara McAdams-DeMarco.2 Drexel University, Philadelphia, PA; 2Johns Hopkins University, Baltimore, MD.

Background: Research has shown that kidney transplant (KT) recipients who lose weight before KT are at increased risk for post-KT weight gain, all-cause graft loss (ACGL), and mortality. No studies have examined whether these associations differ between recipients with intentional and unintentional weight loss.

Methods: Among 366 KT recipients from a prospective cohort study of frailty and KT, we used adjusted mixed effects models to estimate differences in post-KT BMI trajectories, ACGL, and mortality by 1-year pre-KT weight change, defined as stable weight, intentional weight loss, unintentional weight loss, and weight gain.

Results: Mean age was 53 years, 39% were black, and 39% were female. The majority (64%) had stable pre-KT weight, 12% had weight gain, 14% had unintentional weight loss, and 10% had intentional weight loss. By 3 years post-KT, BMI increased by 0.05 kg/m² (95% CI 0.02, 0.08 kg/m²) among those with stable pre-KT weight, the increase was similar among those with pre-KT weight gain and intentional weight loss. Those with pre-KT weight loss had greater increases in post-KT BMI than those with stable BMI (BMI change difference +0.15 kg/m² [0.04, 0.25 kg/m²], p<0.01). Unadjusted cumulative incidence of mortality was similar across weight change categories (Figure). Adjusted for age, sex, race, BMI, and donor type, only unintentional weight loss was associated with higher mortality (aHR 2.31 [1.24,3.41], p=0.008) and ACGL (aHR 2.62 [1.24,3.31], p=0.005) relative to stable weight.

Conclusions: In this study, pre-KT unintentional weight loss was associated with higher post-KT BMI increases, ACGL and mortality than pre-KT intentional weight loss, stable weight, and weight gain. These results suggest that unintentional weight loss should be identified and addressed in KT candidates, independent of BMI.

PO2529

Obesity and Poorer Renal Allograft Function: Analysis of Longitudinal Data

Ekamol Tantisattamo,1,2 Busara Songtanin,2 Natmicha Leelaviwat,1 Sakyda Sarawapa,2 Possawat Vuthikraivit,1 Chawit Lopimiphat,1 Nutchara Polphichai,1 1Division of Nephrology, Hypertension and Kidney Transplantation, Department of Medicine, University of California Irvine School of Medicine, Orange, CA; 2Multi-Organ Transplant Center, Section of Nephrology, Department of Internal Medicine, William Beaumont Hospital, Oakland University William Beaumont School of Medicine, Royal Oak, MI

Background: Obesity is associated with worsened allograft function, but its effect on allograft function after established baseline allograft function at a 12-week post-kidney transplant (KT) is unclear.

Methods: All 105 KT recipients were divided into obese (BMI ≥ 30 kg/m²) and non-obese groups. Longitudinal data were analyzed by linear mixed model to examine association between obesity and eGFR during the 1st year post-KT.

Results: Mean age was 54±11 years and 64 patients (61%) were female. Seventy-one patients (68%) were obese. Generalized estimating equation revealed that eGFR increased 0.16 ml/min/1.73 m² (95% CI: 0.09 to 0.23) for every 1 week after KT. Excluding eGFR at 4-week post-KT when baseline allograft function is generally not established, mean eGFR at 12-week post-KT was the lowest and assigned as the baseline allograft function. Given unequal spreading of time when eGFR were measured, a 1-year graphical representation was categorized into every 4 and 12 weeks if eGFR were measured before and after a 12-week post-KT, respectively. Spline interaction term was created at the 12-week post-KT as well as categorized time-spline interaction term. By using a linear mixed model and after adjusted for age, gender, type of KT (deceased vs living donor KT), obesity category and its interaction team with categorized time and spline interaction term, obese group had a higher rate of eGFR decline of 2.9 ml/min/1.73 m² every 4 weeks prior to 12-week post-KT, and the rate declined to 1.1 ml/min/1.73 m² every 12 weeks after 12-week post-KT. At the 12-week post when baseline eGFR was established, eGFR were 74.1±30.5 and 78.0±30.5 ml/min/1.73 m² for obese and non-obese groups, respectively (random intercept); whereas, rate of increase in eGFR of those corresponding groups were 69.3±30.5 and 78.0±30.5 ml/min/1.73 m² every 12 weeks (random slope).

Conclusions: Although population-based estimated eGFR was significantly increased overtime, obese KT recipients had lower baseline eGFR at the 12-week post-KT and rate of eGFR change were taken into the consideration. Pre-KT obesity remains one of the associated factors of poor allograft outcomes, which may be mitigated by pre-KT weight loss.

PO2530

A Call to Action: Finding the Right Kidney for All Potential Recipients

Background: The burden of dialysis among ESRD patients is a huge driver of morbidity, mortality, and cost. Thousands of deceased-donor (DD) kidneys that almost certainly have better outcomes than dialysis are discarded each year. Our center sought to find and transplant kidneys that would reduce waiting time for our patients while preserving post-transplant outcomes consistent with nationally expected results.

Methods: We reviewed 1119 consecutive DDKT recipients transplanted between 1/1/2016 and 12/31/2019 at our center. Endpoints were eGFR by MDRD death-censored graft survival using Kaplan-Meier survival estimation and the Cox Proportional Hazards Model. We reviewed on additional year (2015) for waiting time impact.

Results: DD KT volumes doubled from 2016 to 2019 (191 vs. 384). Growth was attributable to increased acceptance of hard-to-place imported kidneys, including kidneys with AKI (413% increase) and KDPI > 85 (296% increase). In 2016, 46.6% of DD kidneys were imported from outside our DSA and by 2019, 77.3% were imported. Overall one-year patient survival was 96.6% (CI: 95.4-97.6%) and death-censored one-year graft survival was 95.8% (CI: 94.4-97.6%). Recipients with any stage of AKI saw no additional risk vs. donors without AKI (HR 0.94, p=0.854) while death-censored graft survival at one year was 91.9% for recipients of kidneys with KDPI >85 vs 96.7% with KDPI <85, representing significant additional risk (HR: 1.91; p=0.017). This significantly decreased waiting time at transplant across all blood types (6 years in 2015 to 3.9 years in 2019). This benefit was even greater for blood group B (10.7 to 4.3), and significantly reduced the disparity in accrued waiting times for African-American and Hispanic populations. Kidney function was good at 1 year in all groups among those surviving with followup. Mean eGFR by MDRD formula was 60.0 (SD 23.2) in recipients with non-AKI donors and 61.9 (SD 26.1) in recipients with AKI donors (p=0.4384). Mean eGFR 49.0 in the KDPI > 85% group vs 62.3 in the <= 85% KDPI group (p=0.0001).

Conclusions: Transplant centers can answer the growing demands of patients enduring dialysis to better utilize kidneys that have previously been discarded. Our center demonstrated that it is possible to reduce waiting time, and maintain outcomes using kidneys previously discarded.

PO2532

Association Between Post-Transplant Visit-to-Visit Pulse Pressure Variability and Late Transplant Systolic Blood Pressure in Non-Elderly Kidney Transplant Recipients

Eknalom Tantisattame,1,2 Natnicha Leelavivat,1 Busara Songtanin,3 Sakditha Sawapana,1 Possawut Vuthikraivit,1 Chawit Lopipmsuth,1 Natchaya Polpichai,1 Division of Nephrology, Hypertension and Kidney Transplantation, Department of Medicine, University of California Irvine School of Medicine, Orange, CA; 2Multi-Organ Transplant Center, Section of Nephrology, Department of Internal Medicine, William Beaumont Hospital, Oakland University William Beaumont School of Medicine, Royal Oak, MI; 3Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; 4Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; 5Phramongkutklao College of Medicine, Mahidol University, Bangkok, Thailand; 6Faculty of Medicine Songklanagarin Hospital, Prince of Songkla University, Songkhla, Thailand.

Background: Visit-to-visit blood pressure variability is associated with vascular stiffness and cardiovascular outcomes, particularly in elderly. Association between visit-to-visit pulse pressure variability (VVPPV), which takes SBP and DBP into account, and late post-kidney transplant (KT) blood pressure (BP) in different age groups is unknown.

Methods: VVPPV was examined by average successive variability (ASV), which is the average absolute difference between successive BP measured at 4, 12, and 24 weeks post-KT. Since the slope of the linear plot between VVPPV and SBP at 48 weeks post-KT abruptly changed when VVPPV was 15 mmHg, VVPPV was then categorized into <15 and ≥15 mmHg (Figure 1A). Association between the categorized VVPPV and systolic and diastolic hypertension (SHTN, DHTN) at 48 weeks defined by SBP and DBP ≥130 and ≥80 mmHg, respectively, was examined by multiple logistic regression and stratified into age <60 and age ≥60 years old.

Results: Of all 105 KT recipients from a single KT center, mean age was 54±12 years and 64 patients (61%) were female. Mean VVPPV was 13.9± (range: 2 to 50). Mean post-KT SBP and DBP at 48 weeks post-KT were 133±16 and 77±11 mmHg, respectively. In the whole population study adjusted by gender, donor type (deceased vs. living), and types of induction immunosuppressive medications, patients with VVPPV ≥15 mmHg had 3.36 times higher risk of developing SHTN (OR: 3.36, P=0.02, 95%CI: 1.17, 9.65). However, after additional adjustment by age and interaction term between age and ASV, the association was persist only in patients whose age ≥60 years old (OR: 3.80, P=0.04, 95%CI: 1.04, 13.91 vs. OR<60: 2.18, P=0.40, 95%CI: 0.36, 13.31 (Figure 1B)). There was no association between VVPPV and DHTN in the whole study and age-stratified populations.

Conclusions: Higher VVPPV is associated with late post-KT SHTN in younger age group (<60 years old), but not in elderly. Further studies are required to elucidate the mechanisms.

PO2534

Middle Cerebral Artery Hemodynamics Is Blunted in Kidney Transplant Recipients

Andrew J. Juergensen,1 Jaimie Ward,2 Allegra Morton,2 Andrew P. Geise,2 Sandra Billinger,2 Aditi Gupta,1 University of Kansas Medical Center Division of Nephrology, Kansas City, KS; 1University of Kansas Medical Center Department of Physical Therapy and Rehabilitation, Kansas City, KS.

Background: Kidney transplant (KT) recipients have a higher risk of dementia and cerebrovascular events than the general population. Cerebrovascular hemodynamic response (CVR) to constant-load moderate-intensity exercise marks the ability of the brain to respond to increased oxygen requirements with exercise. Blunted CVR seen with vascular disease and aging can increase risk of dementia and stroke. We evaluated the middle cerebral artery blood velocity (MCrAV) dynamic response in KT recipients and compared it to age matched non-CRDK controls.

Methods: 35 KT recipients and 35 healthy controls completed a 90-second rest followed by a 6-minute moderate intensity exercise on a recumbent stepper at a prescribed step rate and workload. We used transcranial doppler (TCD) monitoring for MCAV while continuously monitoring heart rate and beat-to-beat mean blood pressure during rest and exercise. Baseline resting MCAV and steady state response during exercise were recorded. Outcome measures included resting MCAV and MCAV (during steady state exercise – baseline MCAV) and workload needed to achieve target heart rate. Statistical analysis employed independent t-test.

Results: KT recipients were 52±1.7 years old, 74.3% male, 91.4% white, 22.9% with diabetes, and 91.4% with hypertension. Controls were 54±2.0 years old, 74.3% male, 308% white, without diabetes, and 14.3% with hypertension. Baseline MCAV was similar in the two groups, but the response during moderate intensity exercise differed, CVR for KT recipients was 8.1±2.8 cm/s compared to 12.9±1.4 cm/s for controls (p=0.003) and target workload for KT recipients was 84.1±2.8 watts compared to 123.1±5.3 for controls (p=0.001) (Table 1).

Conclusions: KT recipients have a blunted middle cerebral artery hemodynamic response to exercise compared to healthy controls. This may be due to vascular disease and can explain the higher white matter disease, dementia, and stroke in this population.

PO2535

Longitudinal Physical Performance Following Kidney Transplant

Khin N. Chan,1,2 Daniel J. Watford,1 Xingxing S. Cheng,1 Jonathan N. Myers,2 Jane C. Tan.1 Stanford Medicine, Stanford, CA; 1Veterans Affairs Palo Alto Health Care System, Palo Alto, CA

Background: Frailty and poor physical performance are strongly associated with poor outcomes in kidney transplantation (KTx). However, the effect of KTx on physical performance remains poorly understood.

Methods: We measured 6-minute walk test (6MWT), meters and 1-minute sit-to-stand test (STS, number of repetitions from standing to sitting position) performances within 1 year prior to KTx. Physical performance indices were re-measured at 3 and 6-months, and 1-year post-KTx. Multivariable linear regression was used to assess which baseline characteristics were associated with 6MWT and STS. Trajectories of 6MWT and STS were assessed by baseline performance using a generalized estimating equation.

Results: Among 85 patients who performed baseline assessments, 39, 33 and 40 completed 3, 6, and 12-month evaluations, respectively. Average age was 53 and average dialysis vintage was 7 years. 49% had diabetes mellitus, 18% had coronary artery disease, 5% had cerebrovascular disease, and 10% had peripheral arterial disease (PAD).

In the multivariate model, age, female sex, and the presence of PAD were associated with lower 6MWT and STS. Median baseline characteristics were associated with 6MWT and STS. Trajectories of 6MWT and STS were assessed by baseline performance using a generalized estimating equation.

Conclusions: Walking ability did not improve appreciably after KTx. STS, a measure of lower body strength, improved progressively post-KTx, but was mostly observed in patients with higher baseline STS. Results must be interpreted with caution, since all patients, even those with lower physical performance, were selected to proceed with KTx.

PO2536

Outcomes of Kidney Transplantation in Fabry Disease: A Meta-Analysis

Maria Lourdes Gonzalez Suarez,1 Charrat Thongprayoon,2 Michael A, Mao,3 Juan A. Medura,1 Wisit Cheungpasitporn.1 University of Mississippi Medical Center, Jackson, MS; 2Mayo Clinic, Rochester, MN; 3Mayo Clinic, Jacksonville, FL

Background: Fabry disease (FD) is a rare X-linked lysosomal storage disorder with progressive systemic deposition of globotriaosylceramide, leading to life-threatening cardiac, central nervous system, and kidney disease. Current therapies involve symptomatic medical management, enzyme replacement therapy (ERT), dialysis, kidney transplantation, and more recently gene therapy. The aim of this systematic review was to assess outcomes of kidney transplantation among patients with FD.

Methods: Comprehensive literature review was conducted utilizing MEDLINE, EMBASE and Cochrane Database, from inception through February 28, 2020 to identify studies that evaluate outcomes of kidney transplantation including patient and allograft survival among kidney transplant patients with FD. Effect estimates from each study were extracted and combined using the random-effects, generic inverse variance method of DerSimonian and Laird.

Results: Eleven studies including 424 kidney transplant recipients with FD were enrolled. The post-transplant median follow-up time ranged from 3 to 11.5 years. Overall, the pooled estimated rates of all-cause graft failure, graft failure before death, and allograft rejection were 32.5% (95% CI: 23.9%-42.5%), 14.5% (95% CI: 8.4%-23.7%), and 20.2% (95% CI: 15.4%-25.9%), respectively. A sensitivity analysis limited only to the recent studies (year 2001 or newer when ERT became available), the pooled estimated rates of all-cause graft failure, graft failure before death, and allograft rejection were 28.1% (95% CI: 20.5%-37.3%), 11.7% (95% CI: 8.4%-16.0%), and 20.2% (95% CI: 15.5%-26.0%), respectively. The pooled estimated rate of biopsy proven FD recurrence was 11.1% (95% CI: 3.6%-29.4%), respectively. There was no significant difference in the risk of all-cause graft failure (P = 0.01) nor mortality (0.48) among recipients with vs. without FD.

Conclusions: Despite possible FD recurrence after transplantation of 11.1%, allograft and patient survival are similar among kidney transplant recipients with vs. without FD.

PO2537

Urinary Supersaturation in Patients with Kidney Transplant Nephrolithiasis

Erin E. Bolen, Mitchell Humphreys, Karen L. Stern, Todd Leavitt, Nan Zhang, Mira T. Keddis. Mayo Clinic Arizona, Scottsdale, AZ.

Background: Urine supersaturation (US) has not been reported for kidney transplant (KTx) recipients with de novo transplant-derived nephrolithiasis. The objective of this study was to assess outcomes on transplant recipients, treatment, and stone and allograft outcomes in KTx recipients with allograft nephrolithiasis.

Methods: Retrospective review from 2009-2019 of KTx recipients with nephrolithiasis at Mayo Clinic was completed. Stone event was defined as radiologic evidence.

Results: Fifty six transplant nephrolithiasis cases were identified. Mean transplant age was 56.5 (±12.1) years, 32 (57.1%) were male, 46 (82.1%) receiving first KTx, 41 (75.9%) required dialysis, and 17 (30.9%) had stone event prior to KTx. Twenty one (37.5%) had at least 2 stones in the allograft, median stone size was 6 mm, and most common location was the lower pole (n=20 [41.7%]). Median time from KTx to stone event was 1 year. Thirty four (60.7%) had a 24-hour US study at a median of 2 years after KTx. Select results are shown in Table 1. Of the 34, 14 (41.2%) had a stone event prior to KTx, and 6 (17.6%) had de novo derived stone. Thirty one (91.2%) had increased SS of calcium oxalate, 17 (50%) calcium phosphate, and 9 (26.5%) uric acid. Thirty two (94.1%) had urine citrate <450mg/24hrs. Management of the initial 56 included potassium citrate in 13 (23.2%), calcium citrate in 10 (17.6%), and dietician referral in 18 (32.1%). Forty five (80.4%) were seen by urology, 28 (50%) needed surgical management, and 14 (27.5%) passed the stone. At median follow-up of 4 years after KTx, 37 (66.1%) had persistent stone disease in the allograft, 3 (5.4%) had graft failure, and 2 (3.6%) had died.

Conclusions: This is the first study of urine SS in patients with transplant-derived nephrolithiasis. Profound hypocitraturia was the most prevalent risk, and increased supersaturation for calcium oxalate crystals predominated. Allograft stone clearance was rare, and many required surgical intervention.

PO2538

Exposure to Tacrolimus Trough Levels Below 6 ng/mL During the First Year Is Associated with Inferior Kidney Graft Survival

Tinna Agur,1,2 Ruth Rahamimov,1 Benaya Rozen-avi,1 1Department of Nephrology and Hypertension, Rabin Medical Center Israel, Petah Tikva, Israel; 2Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Israel.

Background: Accumulating data indicates that sub-therapeutic levels of calcineurin inhibitors are associated with long-term graft loss. However, while tacrolimus (TAC) was shown to provide adequate immunosuppression with lower acute rejection rate, its optimal maintenance dose for long term graft survival is still unknown. The aim of our study was to determine the minimal TAC trough level, which is associated with improved kidney graft survival.

Methods: We conducted a retrospective cohort study based on the RMC registry. We defined five TAC trough level intervals: 3-4, 4-5, 5-6, 6-7, and 7-8ng/ml. We calculated the exposure time for each drug level interval during the first year following transplantation, defined as the cumulative number of days at each interval. This measure

High Intrapatient Variability of Tacrolimus in Pediatric and Adolescent Renal Transplant Recipients Is Associated with Worse Graft Outcomes

**PO2539**

**High Inpatient Variability of Tacrolimus in Pediatric and Adolescent Renal Transplant Recipients Is Associated with Worse Graft Outcomes**

When stratified by age subgroups of 0-12 yr, 13-24 yr, and >24 yr, patients who formed C1q+ dDSA were identified by routine screening or at investigation of allograft dysfunction. Tacrolimus IPV was determined using the mean coefficient of variation (CV) over the immediate 6-month time period prior to each TAC level. All available TAC levels were included in the analysis. Mean CV was calculated using CV from 10 months post-transplant until end of follow-up. Patients were followed until 01/03/2019 or until graft loss.

**Results:**

225 pediatric kidney transplant patients met inclusion criteria. Median age was 12.5 years (range 15 mo.-21 yrs.). 46% were female, and 24% received a living donor transplant.

**Conclusions:**

High tacrolimus IPV was associated with C1q+ dDSA formation and graft loss. Tacrolimus IPV is a potential prognostic tool for optimizing transplantation outcomes.

Impact of Renal Transplantation on Functional Status in Tacrolimus Era

**PO2540**

**Impact of Renal Transplantation on Functional Status in Tacrolimus Era**

Mahmoud M. Mohamed,1 Karim M. Soliman,4 Hatem Ali,2 Ahmed Daoud,3 Tibor Fulop,1,2 Vinaya Rao,4 Maria Aurora C. Posadas,4 Michael Casey,4 Ahmed Halawa,4 Ingzi Elsayed.4

1 The University of Tennessee Health Science Center, Memphis, TN; 2 University hospitals of Birmingham, UK, Birmingham, United Kingdom; 3 Cairo University Kasr Alainy Faculty of Medicine, Cairo, Egypt; 4 Medical University of South Carolina, Charleston, SC; 5 Ralph H. Johnson VA Medical Center, Charleston, SC, United States, Charleston, SC; 6 Institute of Medical Sciences, Faculty of Medicine, University of Liverpool, Liverpool, UK, Liverpool, United Kingdom; 7 Royal Stoke University Hospital, Stoke-on-Trent, United Kingdom.

**Background:** Despite a large body of literature describing survival’s outcome after renal transplantation, little is known about the progress of functional capacity post-transplantation. Our aim is to assess the effect of renal transplantation and various factors on functional capacity.

**Methods:** From the United States Organ Procurement and Transplantation Network files, we identified a total of 19,704 renal transplant recipients (RTR) maintained on tacrolimus-based immunotherapy, who had Kernofsky Performance Status Scale (KPSS) defined functional capacity assessment at the time of transplantation evaluation with five-years data follow up. Age, gender, ethnicity, functional status, diabetes, body mass index, cold ischemia time, number of previous transplants, panel reactive antibodies, donor type, donor age, HLA-mismatches, number of acute rejection episodes, induction therapies, renal allograft immunotherapy, and CNI were collected. According to KPSS, RTRs were categorized into four groups at time of transplantation evaluation were divided into 3 groups (A: 13,701 RTRs with mild impairment: 80-89%; B: 5,557 RTRs with moderate impairment: 40-80%; C: 446 RTRs with severe impairment: <40%). The outcome measured was KPSS functional status five years post-transplant.

**Results:** In group A, 86.45% of patients showed improvement in functional capacity, 65.5% in group B, while 88.56% improved in group C (64.57% improved from severe to mild and 23.99% improved from severe to moderate functional capacity).

Furthermore, multiple logistic regression analysis showed that steroid withdrawal protocol was associated with significant improvement in functional capacity (OR=1.28, 95% CI: 1.1. - 1.49, P=0.007), while dialysis duration before transplantation was associated with abnormal functional capacity post-transplant (OR=0.74, 95% CI: 0.61 - 0.89, P<0.003).

**Conclusions:** Renal transplantation is associated with substantial improvement in all stages of functional capacity in RTRs. Steroid withdrawal as well as the duration of dialysis is an important novel determinant factors of functional capacity post-transplant and merit considerations during transplant selection and subsequent immunosuppressive therapeutic planning.

Calcineurin Inhibitor-Based Immunosuppression Has Negligible Negative Effects on Pregnancy Outcomes After Renal Transplantation in the Netherlands

**PO2541**

**Calcineurin Inhibitor-Based Immunosuppression Has Negligible Negative Effects on Pregnancy Outcomes After Renal Transplantation in the Netherlands**

Lisaaline M. Koener,1 Jildau R. Meindert,d,² Olivier W. van der Heijden,² Titta Lely,2 Margriet de Jong,3 Renate G. van der Molen,1 Henk W. Van Hunen,2 Pregnancy After Renal Transplant OUTCOMES (PARTOUT) Network1 Radboudumc, Nijmegen, Netherlands; 2 Universitair Medisch Centrum Utrecht, Utrecht, Netherlands; 3 Universitair Medisch Centrum Groningen, Groningen, Netherlands.

**Background:**

Pregnancy among renal transplant recipients (RTR) has increased over the past years, also in patients with compromised renal function and/or proteinuria. Immunosuppressive regimens may influence pregnancy outcomes and it is not yet clear whether replacing a calcineurin inhibitor (CNI) by a CNI-free (CNI-) regimen has a favorable effect.

**Methods:** We therefore retrospectively compared the effect of CNI-based (CNI+) and CNI- immunosuppression in the first trimester of pregnancy on maternal and fetal outcomes in Dutch pregnancies between 1986-2017 in RTR.

**Results:** We identified 129 CNI+ and 125 CNI- singleton pregnancies. Demographics did not differ except for higher BMI in CNI+ (median 25.3 vs 23.7 kg/m², p<0.01), year of renal transplantation (2000 in CNI+ vs 1989 in CNI-, p<0.01), year of pregnancy (2006 in CNI+ vs 1998 in CNI-, p<0.01) and interval of transplantation to pregnancy (69 in CNI+ vs 28 in CNI-, p<0.01). In the third trimester creatinine levels were significantly higher in CNI+ (127 vs 105 μmol/L in CNI-, p<0.01) but this difference had disappeared 6-18 months postpartum. The percental change in creatinine from preconception to the third trimester level was slightly different (+3.1% in CNI+ vs 2.2% in CNI-, p<0.05).

In both groups, a postpartum 11-12% creatinine increase from preconceptional level was observed (p=0.92). Regarding fetal outcomes, a trend in increased incidence of birthweight (<2500 grams was seen in CNI+ (52% vs 40%, p=0.07) and in both groups there was a high rate of preterm delivery (<37 weeks (49% vs 45% in CNI+; p<0.05).

**Conclusions:** Our data indicate that CNI do not negatively influence the course of renal function up to 18 months postpartum, but only lead to a more pronounced increase in serum creatinine levels towards the end of pregnancy. However, the substantial short term loss of renal function and the high rates of premature birth rate and low birthweight classify them as high risk pregnancies that should be followed carefully in tertiary obstetric/nephrologic care programs. Our data do not exclude possible long term negative effects of CNI on overall health, renal function or hypertension in the offspring of these women.
PO2542
The Natural History of Waitlist Candidates in the United States
Allan Massig, Dorry L. Segev. Johns Hopkins University School of Medicine, Baltimore, MD.

Background: Estimates of time to deceased-donor transplantation (DDKT) generally fail to take into account the competing risks of mortality. Understanding the natural history of KT registrants - their chance of DDKT/LDKT/death based on individual characteristics - can inform referrals for transplantation, counseling for transplant candidates, and allocation policy.

Methods: Using SRTR data on 186,174 waitlist registrants 12/2014-12/2019, we modeled time to DDKT, LDKT, or waitlist mortality in a competing-risks framework, overall and for clinically relevant subgroups of patients (based on candidate age, sex, race, ABO blood type, PRA). Competing-risks regression was used to model individual n-year chance of DDKT/LDKT/mortality based on candidate characteristics.

Results: Among all candidates, 5-year cumulative incidence of LDKT/DDKT/mortality/other removal DDKT was 17.3%/34.4%/15.7%/8.1% respectively. 85% of LDKT recipients received LDKT within 2 years of listing. Pediatric registrants had substantially higher incidence of DDKT than waitlist mortality (61.7% vs 1.1%), but adults had higher combined of waitlist mortality/other removal DDKT, particularly patients above age 65 (44.4% vs 32.3%) (Figure). Center-level 5-year incidence of LDKT (DDKT) 1.3%/44.8% (4.4%-82.6%) (Figure 2).

Conclusions: Despite a focus in the transplant community on small differences in one-year posttransplant outcomes and a reluctance to transplant kidneys with slightly worse expected outcomes, most adult patients wait >5 years for a kidney, incurring substantial waitlist mortality risk. High incidence of waitlist mortality will only be remedied through aggressive efforts to increase the living and deceased donor organ pool.

PO2543
Unusual Cause of Calcium Oxalate Nephropathy in a Renal Allograft
JoBeth McCoy, Anthony J. Langone. Vanderbilt University Medical Center; Nashville, TN.

Introduction: Crystal nephropathy is a well-known cause of acute kidney injury that is often overlooked. We present a case of oxalate nephropathy in a renal allograft that led to a rare diagnosis.

Case Description: A 63-year-old female with a kidney transplant for end-stage kidney disease (ESKD) caused by acute interstitial nephritis (AIN) presented with acute kidney injury. Her creatinine on presentation was 2.0mg/dL from her baseline of 1.0mg/dL and increased to around 3.0mg/dL despite hydration. It was decided that she would benefit from allograft biopsy. The biopsy was devoid of any rejection but did have many foci of calcium oxalate crystal deposition with tubular injury. She was planned for a 24-hour urine collection for stone evaluation that showed an elevated urinary oxalate level, 140mg. She changed her diet and the 24-hour urine collection was repeated in 3 months with no change. With the continued elevation, genetic testing was sent for primary hyperoxaluria which revealed that she has homozygote mutation in the AGXT gene, confirming that she has type 1 primary hyperoxaluria. Reevaluation of her biopsy diagnosing AIN before transplant was found to have interstitial multinuclear infiltrate with some crystallization consistent with oxalate crystal deposition. Her fat-soluble vitamins were increased to 3g/day. Her phosphorus was dropped to 2.5mg/dL. Her calcium was decreased to 8mg/dL with chelation. She changed her diet with oxalate decrease and her urinary oxalate was 10mg/24hr. Her urinary calcium was decreased to <300mg/24hr.

Disclosures: None

PO2544
Secondary Oxalosis with Enteric Oxalate Nephropathy in a Transplant Recipient: Is Mycophenolate the Culprit?
Himmat S. Brar, Nihal M. Ali, Franco H. Cabeza Rivera. University of Mississippi Medical Center; Jackson, MS.

Introduction: Secondary oxalosis causing acute kidney injury has been widely reported in native kidneys but its occurrence in allograft kidneys is relatively uncommon. Intestinal malabsorption can be present in transplant recipients as a result of factors from the general population such as immunosuppressive medications and some enteral infections. We present a case of enteric oxalate nephropathy as a result of mycophenolate toxicity.

Case Description: A 66-year-old male status post kidney transplant 3 years back for ESKD due to DM and HTN with a baseline creatinine of 1.5 mg/dL presented with a 2-month history of GI symptoms of vomiting, diarrhea and 22 lbs weight loss. He was on tacrolimus, mycophenolate and prednisone for immunosuppression. The patient denied any recent infection or antibiotic use, any medication change, supplements or OTC drug use. The vitals and the physical examination on admission was unremarkable. Lab findings showed Na 139, K 5.5, Cl 117, Bicarb 11, AG 22, Ca 9.6, BUN 71 and creatinine 3.5. Lactate and serum osmolar gap were normal. Lipase, amylase, Vit B1 and B6 were normal. UA showed trace ketones and blood with no protein or bacteria. Serology for CMV and BK virus was negative. Nephrotoxic level was at goal. MPA level was noted to be elevated at 9ug/ml at an office visit 1 month prior to admission with no recent adjustment in dosing. Plasma oxalate was elevated at 3.9. The stools studies and GI panel were negative. CT scan showed a 3mm non-obstructing stone. The renal biopsy showed interstitial fibrosis, tubular atrophy and calcium oxalate deposits with birefringence within the tubules. Oxalate was confirmed by thin-layer chromatography. The MMF metabolites indirectly affect the oxalate transport, resulting in increased oxalate excretion. The MMF was discontinued. The patient was given iv fluids and citrate to alkalize the urine. At discharge, his Cr improved with resolution of symptoms.

Discussion: Medication-induced malabsorption should be considered among potential causes of secondary oxalosis. The MMF metabolites indirectly affect the oxalate transport, resulting in increased oxalate excretion. The MMF was discontinued. The patient was given iv fluids and citrate to alkalize the urine. At discharge, his Cr improved with resolution of symptoms.

PO2545
Prophylactic Use of Eculizumab and Graft Loss in Kidney Transplant Recipients due to Hemolytic Uremic Syndrome in the United States
Richard A. Plass,1,2 Stephen W. Olson,1,2 Christina M. Yuan,1,2 Lawrence Agodoa,1,2 Kevin C. Abbott,1,2 Robert Nee,1,2 Walter Reed National Military Medical Center, Bethesda, MD; 1Uniformed Services University of the Health Sciences F Edward Hebert School of Medicine, Bethesda, MD; 1National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.

Background: Among kidney transplant recipients (KTRs) with end-stage kidney disease (ESKD) due to hemolytic uremic syndrome (HUS), recurrence is associated with poor allograft outcomes. We examined the prophylactic use of eculizumab, a monoclonal antibody that binds complement protein C5, and graft loss among HUS KTRs.

Methods: We conducted a retrospective cohort study using the United States Renal Data System. Out of 123,624 ESKD patients transplanted between January 1, 2008 and June 1, 2016, we identified 348 (0.28%) patients who had HUS as the primary cause of ESKD. We then linked these HUS patients to datasets containing the Healthcare Common Procedure Coding System (HCPCS) code for eculizumab infusion. We calculated crude incidence rates of overall graft loss and death-censored graft loss and conducted exact logistic regression, adjusted for recipient age and sex. Patients who received eculizumab prior to or within 30 days of transplant represented the exposure group.

Results: Our final study cohort included 335 HUS KTRs (23 received eculizumab, 312 did not). There were no significant differences in baseline demographic and clinical characteristics between the eculizumab vs. non-eculizumab group. For those who received eculizumab, the median number of infusions per patient was 42 (IQR 16, 66). The median payment amount per patient was $706,518 (IQR 241,237, 1,306,453). Eculizumab was discontinued in 9 out of 23 patients (39%), after a median prophylactic duration of 329 days (IQR 127, 791). As shown in the Table, the eculizumab group had no graft loss vs. 20% in the non-eculizumab group, with an adjusted odds ratio of 0.13.

Conclusions: Prophylactic use of eculizumab in HUS KTRs was significantly associated with a lower risk of graft loss. Given the high cost of eculizumab, randomized controlled trials are much-needed to guide prophylactic strategies to prevent graft loss.
Clinic’s Campus in Florida, Jacksonville, FL and Early Allograft Recurrence
A Case of Subretinal IgA Deposition in a Patient with IgA Nephropathy.

J Am Soc Nephrol 31: 2020
Transplant Complications: Glomerular Disease and Genetics

edema. However, renal function declined 2 months later, with persistently elevated

of creatinine. 4 months later, repeat OCT showed improved retinopathy and ocular

pigment deposits with central foveal sparing, consistent with IgA maculopathy. Post-

Coherence Tomography (OCT) had revealed bilateral macular edema and subretinal

neuropathy with recent decline in visual acuity, underwent living related donor renal

secondary to a 10 year history of IgAN complicated by retinal detachment and optic

Background: Hypomagnesemia is common in kidney transplant recipients (KTR),

likely due, at least in part, to renal magnesium (Mg) wasting related to calcitriulin-

inhibitor (CNI) use. The association of serum Mg levels and KTR outcomes may provide

insight into the optimal serum Mg levels in this population.

Methods: KTRs between 01/2000 and 12/2016 at a large US transplant center who

were alive with a functioning graft at 6 months post-transplant were included. Mean of

the outpatient serum Mg levels in the baseline period, i.e. 6 to 18 months post-transplant, was

used. Cox proportional-hazards regression was used to analyze the association between Mg

and all-cause mortality, cause-specific mortality, and risk of new-onset cardiovascular

events post-transplant.

Results: 2,131 KTRs met our inclusion criteria. Mean number of Mg measurements per

patient in the baseline period was 2.76. A U-shaped association between the mean

baseline Mg level and all-cause mortality was observed in both unadjusted analysis and

after adjusting for baseline characteristics, including eGFR and CNI levels. A mean Mg of

1.5 - 1.8 mg/dL was associated with the lowest incidence of death (Figure). Compared with

Mg of 1.5 - 1.8 mg/dL, Mg level ≤ 1.5 mg/dL was also associated with higher incidence of

mortality due to infection and arrhythmia but not ischemic heart disease or heart failure.

Conclusions: The relationship between serum Mg levels and mortality in KTRs is

U-shaped. Interestingly, the risk is lowest with Mg levels 1.5 - 1.8 mg/dL; which

represents the lower end of normal (1.6 - 2.6 mg/dL). Mg supplements for levels ≤ 1.5

mg/dL may be beneficial, but may cause increased renal wasting and diarrhea. Further

studies are needed to understand why Mg > 1.8 mg/dL but within the normal range

was associated with higher risk despite adjustment for eGFR.

Funding: Private Foundation Support

Post-Kidney Transplant Serum Magnesium Exhibits a U-Shaped Association with Subsequent Mortality
Annalise M. Panthofer, Beini Lyu, Brad C. Astor, Tripti Singh, Fahad Aziz, Didier A. Mandelbrot, Sandesh Parajuli, Maha A. Mohamed, Arijang Djamali, Neetika Garg. University of Wisconsin School of Medicine and Public Health, Madison, WI.

PO2547
A Case of Subretinal IgA Deposition in a Patient with IgA Nephropathy and Early Allograft Recurrence
Mahnoor M. Khan, Lyle W. Baker, Sarah T. Sulliman, Martin L. Mai. Mayo Clinic’s Campus in Florida, Jacksonville, FL.

Introduction: IgA Nephropathy (IgAN) has variable clinical manifestations and a 30% recurrence, which is typically a late complication in renal transplant recipients. Occult involvement in patients with IgAN is extremely rare. Thus, eye findings as a predictor of worse prognosis, including higher risk of recurrence, remains unexplored.

Case Description: A 66 year old Caucasian male with end-stage renal disease secondary to a 10 year history of IgAN complicated by retinal detachment and optic neuropathy with recent decline in visual acuity, underwent living related donor renal transplantation from his twin sister with Basiliximab induction. A month prior, Optical Coherence Tomography (OCT) had revealed bilateral macular edema and subretinal pigment deposits with central foveal sparing, consistent with IgA maculopathy. Post-

operative course was uneventful with immediate allograft function and normalization of creatinine. 4 months later, repeat OCT showed improved retinopathy and ocular edema. However, renal function declined 2 months later, with persistently elevated

Creatinine between 1.4-1.5 mg/dL. Allograft biopsy showed hypercellular endocapillary proliferation, glomerulitis and granular mesangial staining for IgA, IgM, Kappa and Lambda on Immunofluorescence, consistent with recurrent IgAN. Pulse-dose steroids were subsequently initiated.

Discussion: The pivotal role of the complement system has been implicated in IgA deposition between the retinal pigment epithelium (RPE) and Bruch’s membrane, a complex exposed to circulating immune complexes similar to glomerular basement membrane. To our knowledge, this is the first reported case of IgA maculopathy involving subretinal deposition with recurrence of primary disease in the renal allograft within 1 year. Given the lack of non-invasive testing and dynamic clinical features encompassed by IgAN, the link between ocular pathology and patient-specific morbidity including recurrence, despite clinical improvement in initial eye disease, needs exploration.

PO2548
Virtual Reality, a New Vision Becoming Our New Actuality: A Retrospective Study Comparing Virtual Crossmatch vs. Physical Crossmatch at Tampa General Hospital
Fernando Moran,1 Timothy M. Chow,2 Martin Aldana,3,4 John Lunz.4 Division of Nephrology University of South Florida, Tampa, FL; 2Nephrology and Transplantation University of South Florida, Tampa, FL; 3Division of Internal Medicine University of South Florida, Tampa, FL; 4LifeLink Foundation Transplantation Immunology Laboratory, Tampa, FL; 5Florida Kidney Physicians, Tampa, FL.

Background: A crossmatch (XM) is required prior to kidney transplantation to

ensure immunological compatibility between recipient and donor. This test is prone to

false positive reactivity and can increase cold ischemic time (CIT) especially for organs

procured outside the region of the transplanting hospital. Advances in HLA antibody
testing and donor HLA antigen typing facilitate the use of a virtual XM (VXM) based on

pre-transplant testing results to accurately predict a physical XM (PXM) result. Frequent

antibody screening and an accurate history of sensitizing events further ensures that

the VXM can predict immunological compatibility, even without retrospective PXM.

Methods: We compared the 6 mo. clinical outcomes of kidney recipients who

proceeded to transplant with only a VXM (without retrospective PXM) to those receiving

a PXM. 182 recipients with 6 mo. follow-up were reviewed for biopsy data, serum Cr

and UPCR. Patients were grouped according to the transplant type (living donor (LD) vs.
deceased donor (DD) and XM type (VXM vs. PXM). LD recipients had a PXM (n=42).

Patients with a VXM (n=76) were donor-specific antibody (DSA)-free and had a current

tested sample within 30 days. DD recipients had PXM (n=64) due to the presence of DSA

current or historic) or the absence of a current tested sample within 30 days. All patients

with PXM had an acceptable flow cytometric XM.

Results: Patients proceeding to transplant with a VXM tended to be less sensitized

(32% with PRA >0%) compared to DD-PXM (66%) and LD-PXM (49%). For DD

recipients, CIT was significantly reduced in patients receiving a VXM (727 vs 871 min; p=0.011). Within the first 6 mo. of follow-up, 67 for cause biopsies were performed. Rejection (T-cell or antibody mediated) was observed in 15 patients (7 DD-VXM, 6 DD-
PXM and 3 LD-PXM). Interestingly, antibody mediated rejection was only observed in

DD-PXM (n=3) or LD-PXM (n=1) groups.

Conclusions: In our cohort, kidney transplantation with an acceptable VXM

was beneficial in reducing CIT and rejection was similar to DD recipients needing

a PXM within the first 6 mo. post-transplant. Utilizing VXM helps facilitate kidney

transplantation, permits entertaining offers from greater distances, and reduces laboratory

burden with similar outcomes to when a PXM is performed.

PO2549
Reassessing Renal Transplantation in Light-Chain Deposition Disease

Background: Light chain deposition disease (LCDD) is a systemic rare condition that

usually leads to end stage renal disease. Treatment with a bortezomib-based regimen, followed by autologous stem cell transplantation (ASCT) has been increasingly used with improvements in the response rates and the renal graft outcomes in kidney transplant recipients.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: Retrospective study of 6 patients diagnosed of LCDD with complete response but not renal response after hematologic treatment that underwent kidney transplant in our institution between 2010 and 2019.

Results: A total of 6 patients (5 women) were analyzed, with mean age at diagnosis of 47 years, mean eGFR of 18 mL/minute and mean proteinuria of 5.5 g. Deposit was kappa type except in 1 case (heavy and light lambda type chains). In all of them there was an absence of monoclonal component in blood and urine but positive immunofixation in 5 cases (2 only in urine). 3 started chronic hemodialysis during admission and the others at 3, 5 and 44 months after diagnosis. As hematological treatment, all received bortezomib followed by ASCT, being under complete hematological response at the time of kidney transplant, which was performed at 28 months on average from ASCT. Mean kappa/lambda ratio was 2.6. 3 patients received induction with thymoglobulin and 3 with basiliximab, followed by triple therapy with tacrolimus+prednisone+mTOR inhibitor (4 patients) or mycophenolate (2 patients). After 36 months of mean follow-up after kidney transplant, 3 patients have suffered an hematological relapse, one of them including kidney involvement with graft loss at 46 months post-transplant. The remaining 5 continue with a functional graft with a mean creatinine of 1.54 mg/dL.

Conclusions: When sustained complete hematologic response is achieved but renal impairment with dialysis requirement persists, patients could benefit from a kidney transplant with good results.

PO2550
Granulomatous Interstitial Nephritis and Allograft Failure Secondary to Adenovirus Reactivation

Introduction: With an incidence of about 4% in renal transplant recipients, the typically self-limited adenovirus renders an infrequent propensity to cause allograft failure and life-threatening opportunistic infection in severe cases.

Case Description: A 29 year old female with history of living donor kidney transplant due to Henoch Schonlein Purpura (HSP) Glomerulonephritis with subsequent allograft failure underwent deceased donor re-transplantation with Anti-Thymocyte globulin induction. Post-op course was uneventful. Creatinine was 0.8 mg/dL on 4 month follow up. 6 months post-transplant, patient developed gross hematuria with clots, fever and acute kidney injury with creatinine of 2.82 mg/dL. Biopsy revealed granulomatous tubulointerstitial nephritis, extensive intra-nuclear viral inclusions with positive adenovirus immunohistochemistry (IHC). Mycophenolate Mofetil was discontinued and creatinine improved to 1.1 mg/dL. 3 months later, she was admitted for renal failure with creatinine of 7.2 mg/dL. Adenovirus was detected in the serum and urine. Repeat biopsy revealed markedly reactive tubular epithelium, widespread viral inclusions with negative adenovirus IHC, consistent with adenovirus nephropathy. Following a decrease in immunosuppression with improvement in renal function, adenovirus viral load became undetectable in both plasma and urine. The use of Cidofovir was considered for treatment; however, given risk of nephrotoxicity, was ultimately deferred after response became undetectable in both plasma and urine. The use of Cidofovir was considered for conservative treatment.

Discussion: Recurrence of HSP was in the broad differential given the initial presentation. Given its rarity, a paucity of cases and epidemiologic literature exists in illustrating allograft failure due to adenovirus nephropathy. Further research is not only needed to expand awareness of its presenting features and characteristic biopsy findings, but also, to limit more familiar culprits in masquerading as the elusive adenovirus infection, particularly in light of indeterminate therapeutic modalities.

PO2551
Phospholipase A2 Receptor Antibody Level Directed Management of Membranous Glomerulopathy After Transplant
Irfan Agha,1,2 Amna Ilahi,1,2 Silvi Simon,1,3 Rama Nadella,1,2 Diana Mahbod,1 Richard Dickerman.1 1Dallas Renal Group, Dallas, TX; 2Medical City Dallas Hospital, Dallas, TX; 3Methodist Dallas Medical Center, Dallas, TX.

Introduction: MN can recur after transplantation. Patients with high PLA2R Ab are at higher risk. There is equipoise on how to manage these patients. We present two cases to highlight PLA2R Ab level directed approach to management.

Case Description: Case 1: 35 YO AA female with MN diagnosed in 2013. Failed cytotoxic therapy and started RRT. Received a DD kidney transplant in Sep 2018. Given Thymoglobulin, tacrolimus, mycophenolate and prednisone. Pretransplant PLA2R titer 1:2560 by IIF. Titer serially monitored. After an initial decline, titer increase with precipitation of proteinuria noted. Biopsy confirmed early recurrent MN. Treated with 2 doses of Rituximab. Subsequent titers dropped with complete remission. Case 2: 65 YO W male with biopsy demonstrated MN (2015), on RRT since 2017 underwent DD kidney transplant in May 2019. Given Thymoglobulin and maintained on tacrolimus, mycophenolate and prednisone. Pretransplant PLA2 R Ab level was 164 RU/ml by EIA with 3.5 g/g of protein. His PLA2R Ab levels dropped and proteinuria rapidly & durably resolved after transplant. One year out, his PLA2R Ab is at 24 RU/ml with 0.11 g/g protein in the urine and a creatinine of 1.2 mg/dL.

Discussion: High PLA2 R Ab at the time of transplant is a significant risk factor for recurrent MN. PLA2R Ab levels should be monitored to direct care: decreasing PLA2R Ab should be followed conservatively. If Ab levels increase or proteinuria develops, perform biopsy to confirm diagnosis and initiate therapy expeditiously. PLA2R Ab levels should be monitored post transplant to ensure resolution. This approach allows stratification and directed therapy of patients with MN undergoing transplantation and avoids overt treatment.
PO2552

De Novo Membranous Nephropathy and Donor-Specific Allotubodies: A Path to the Pathophysiology?

Megan A. Tierney, Pradeep Vaitla, Wisit Cheungsapithorn, Franco H. Cabeza Rivera. University of Mississippi Medical Center, Jackson, MS.

Introduction: While pathophysiology of post-transplant membranous nephropathy due to recurrence of primary disease is established, less is known about the development of primary de novo membranous nephropathy (dnMN). We report a case of dnMN associated with antibody-mediated rejection in a transplant recipient with end-stage kidney disease secondary to focal segmental glomerulosclerosis (FSGS).

Case Description: A 20-year-old African American female with FSGS status-post deceased donor transplant eight years ago presented with acute lower extremity edema and acute kidney injury concerning for acute rejection. She has no history of prior rejection or medication non-adherence. Ultrason showed mild hydronephrosis. Biopsy showed Banff Type IB acute cellular mediated rejection (2, 2) and Stage 1 membranous glomerulopathy. Serum phospholipase A2 receptor (anti-PLA2R) antibodies were negative. Donor specific antibodies (DSA) testing revealed the presence of DQ5, DQ7, and DRB*10:01. Diagnosis of coexistence of Banff Type IB acute-cell mediated rejection, positive de novo DSA, and dnMN was made. She was treated with five doses of antithymocyte globulin (1.5 mg/kg/dose) and plasma exchange (PLEX) followed by IV immune globulin (IV Ig). Repeat DSA after fifth session of PLEX showed clearance of DRB*01:03 and reduced DQ antibody levels; after seventh session of PLEX, however, DQ antibodies had plateaued. Biopsy performed after PLEX and antithymocyte globulin showed chronic active T-cell mediated rejection Grade IB (i3, t3, and I-IFTA2) and persistent Stage 1 membranous glomerulopathy; in the setting of persistent DQ antibodies, this suggested failure of transplanted organ within the next 6-12 months. The patient was prepared for this eventuality, received a final session of PLEX and IV Ig and discharged in otherwise stable condition.

Discussion: Only one case of dnMN associated with HLA-DQ7 DSA has been previously reported (El Kossi Clin Transplant 2008). This case not only reports the unique occurrence of two glomerulonephropathies in one patient, but also provides support that post-transplant dnMN can be seen in the context of humoral alloreactivity, and DSA might play some roles for the pathogenesis in some patients with dnMN after kidney transplantation (Honda Clin Transplant 2011).

PO2553

Histological Predictors of Graft Failure in Kidney Transplant Recipients

Maria Ajaime, Yong AI Azzi, Purna Bindu Nandigam, Pablo Loarte Campos, Cindy T. Pynadath, Luz E. Liriano-Ward, Enver Akalin. Montefiore Medical Center, Bronx, NY.

Background: We aimed to identify the predictors of allograft failure in a large cohort of kidney recipients who underwent clinically indicated graft biopsies. We aimed to explore the importance of interstitial inflammation in biopsies with interstitial fibrosis and tubular atrophy (IFTA).

Methods: We retrospectively evaluated 516 patients who underwent transplant biopsy between 1/2009 and 1/2018. Acute and chronic allograft injury scores of Banff classification were used. We sub grouped the patients with chronic allograft injury score ≥ 3 or < 3 and sub grouped per interstitial inflammation (i score=0 and > 0) and compared to biopsies with both ≥ i score=0 and i=0.

Results: Biopsies were done at a median 12.5 months after kidney transplantation. The histopathological diagnosis were as following: acute antibody-mediated rejection (AMR) (6%), acute T-cell mediated rejection (9.3%), chronic AMR (6.7%), transplant glomerulopathy without donor-specific antibody (DSA) (10.2%), recurrent/de novo glomerular disease (10.8%), BKV nephropathy (2.5%), and the rest 54.2% had other diagnosis (normal, acute tubular necrosis, or non-specific IFTA). During a median follow up of 59.3 months after kidney biopsy, 36 %patients lost their graft. In univariate analysis, the following factors were significant for graft loss: Black race (p=0.005), previous rejection (p=0.0001), DSA at the time of biopsy (p=0.014), c1+c2+c3 ≥ 3 (p=0.0485), c1+c2+c3 ≥ 3 with interstitial inflammation ≥ 0 (p=0.0001), microvascular inflammation (p=0.0052), C4d positivity (p=0.008), serum creatinine at time of the biopsy

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

PO2554

A Case of Antibody-Mediated Rejection (ABMR) After Withdrawal of Etanercept in a Renal Transplant Recipient

Iris Jill E. Uy, Mohammad Abuzaineh, Sami Alasfar, Fizza F. Naqvi, Brandon L. Tollerling. Johns Hopkins Medicine, Baltimore, MD.

Introduction: Etanercept is a tumor necrosis factor (TNF) receptor fusion protein that is used to manage several forms of inflammatory arthritis and psoriasis. Herein, we present a renal transplant recipient who was concomitantly treated with Etanercept for psoriasis and subsequently developed two episodes of ABMR after the drug’s withdrawal.

Case Description: A 41-year-old man with history of psoriasis and end stage renal disease due to hypertensive nephrosclerosis and interstitial nephritis who underwent living related kidney transplant from his brother in December 2008. He was being treated for psoriasis with Etanercept which was withdrawn in September 2012. Subsequently he was being using serum creatinine (Cr) from baseline of 1.3-1.6 mg/dl and developed de-novo donor specific antibodies (DSA) to DR11 and DQ7 with positive cytotoxicity crossmatch. Renal allograft biopsy showed evidence of Banff 2A acute cellular rejection, ABMR, chronic glomerulonephritis and interstitial nephritis. He was treated with high dose steroids, 10 sessions of plasmapheresis with intravenous immunoglobulin (IVIG), and Rituximab. His Cr improved to 1.2 mg/dL but DSA remained positive. Later on he was restarted on Etanercept which was withdrawn again in March 2019. Accordingly, in September 2019, he developed acute kidney injury with Cr up to 1.7 from baseline of 1.3-1.5 mg/dl associated with nephrotic range proteinuria. He had a rise in DSA to DQ7, and developed new DSA to A2 and B60 with positive cytotoxicity crossmatch. Donor derived cell free DNA was elevated at 4.4%. Allograft biopsy showed glomerulitis, peritubular capillaritis with positive c4d, consistent with ABMR. He was treated with high dose steroids, 10 sessions of plasmapheresis with IVIG and Rituximab. Repeat DSA showed reduction in A2, but no change in DQ7. His serum Cr improved but his proteinuria remained at nephrotic range.

Discussion: Despite the use of Etanercept in the treatment of graft versus host disease among transplant recipients, it hasn’t been studied as a potential immunosuppressive drug. In our patient, Etanercept seemed to provide anti-rejection effect as shown by two episodes of ABMR with de-novo DSA after the drug’s withdrawal. Close monitoring of renal function and DSA may be warranted once Etanercept or other TNF inhibitors are withdrawn in transplant recipients.

PO2556

Molecular Analysis of Renal Graft Biopsies: Comparing the Edmonton Molecular Microscope with the NanoString Human Organ Transplant Panel

Jessica Schmitz, Helge Stark, Stephan Bartels, Danny Jonigk, Philip F. Halloran, Gunilla Eincecke, Jan H. Braesens, Hannover Medical School, Institute of Pathology, Hannover, Germany; Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH), Hannover, Germany; Hannover Medical School, Institute of Pathology, Molecular Pathology, Hannover, Germany; University of Alberta, Edmonton, AB, Canada; Alberta Transplant Applied Genomics Center, Edmonton, AB, Canada; Hannover Medical School, Department of Nephrology and Hypertension, Hannover, Germany.

Background: The renal transplant biopsy is the diagnostic gold standard and usually evaluated with the continuously expanded and updated Banff classification which is based on descriptive, empirically-derived criteria and thus lacks precision. High-resolution determination of the graft biology by NanoString analysis, which was developed for formalin-fixed paraffin-embedded-derived (FFPE) RNA, should be a sufficient approach for objective molecular diagnosis of renal transplant biopsies and may improve our understanding of graft biology.

Methods: We used well-annotated surveillance and indication biopsies from 63 patients whose time-matched second biopsy core had been frozen and analyzed by microarray in the INTERCOM/INTERCOMEX study. After reevaluation according to recent Banff consensus, RNA isolation of the FFPE biopsy was performed and led to a total of 102 RNA yields in 53 samples which were further processed for NanoString analysis using the nCounter Human Organ Transplant Panel.

Results: Morphologically, of the 53 samples analyzed (samples from 2011/12 and 2015), twenty-five patients showed no signs of rejection, twelve had borderline rejection, (p<0.0001), and spot urine protein/creatinine (<0.0001). In the multivariate analysis c1+c2+c3 ≥ 3 with i=0 has a hazard ratio followed by c1+c2+c3 ≥ 3 with i=0, black race, creatinine, and proteinuria.

Conclusions: Interstitial inflammation is the best predictor for allograft loss after clinically indicated kidney biopsy regardless of the severity of chronic allograft injury.
four showed cellular rejection, seven had humoral rejection, and five presented with combined rejection. Preliminary analysis of gene expression by T-distributed Stochastic Neighborhood Embedding (t-SNE), Random Forest and Principal Component Analysis (PCA) showed clear differences between samples with rejection (humoral and cellular) and without rejection. Rejection samples revealed high expression of chemokine ligands compared to rejection-free tissues. A common pattern of samples without rejection and borderline rejection was observed. Our results displayed good correlation with the former molecular microarray-based diagnosis from the INTERCOM/INTERCOMEX study.

**Conclusions:** Molecular diagnostic approach using the NanoString platform may supplement morphological diagnosis of renal grafts especially in unclear cases and thus enhance precision diagnostics with small tissue requirement. Morphological and molecular evaluation in the same biopsy core from FFPE tissue enables direct histological-molecular correlation. Additionally, this technology also improves our understanding of pathophysiology in renal and other transplants.

**Donor Biopsy and Kidney Transplant Outcomes in Pediatric Recipients**  
Ahmad Mashmoushi,1 Christine S. Hwang,2 Malcolm Maccomnara,3,4  
1University of Texas Southwestern Department of Surgery, Dallas, TX;  
2University of Texas Southwestern Medical Center, Division of Surgical Transplantation, Department of Surgery, Dallas, TX;  
3University of Texas Southwestern Medical Center, Division of Pediatric Nephrology, Department of Pediatrics, Dallas, TX;  
4Children’s Medical Center, Division of Pediatric Transplantation, Dallas, TX.

**Background:** Deceased Donor (DD) kidney biopsies are routinely used in the context of clinical concerns about donor quality in adult kidney transplants. We sought to examine the use of DD kidney biopsies in pediatric transplants. We aim to evaluate prognostic utility of glomerulosclerosis GS level in predicting graft outcomes.

**Methods:** Data was used from recipients who received kidney transplant between 1994 and 2018 documented in the Scientific Registry of Transplant Recipients database. Pediatric recipients were defined as recipients < 18 years who received DD kidney transplant excluding multi-organ transplants. The recipients were further stratified according to degree of donor kidney GS into 0-5% and > 5% categories. Demographic and outcome data were examined and graft survival was evaluated using STATA 16.

**Results:** 10,045 pediatric recipients received DD KT during this period. 644 had left and/or right DD kidney biopsies, 548 biopsies had 0-5% GS, 96 biopsies had > 5% GS. Biopsies were mostly performed on kidneys harvested from higher risk donors. There was a significant difference in the number of biopsies performed across regions (region 5 lowest at 2.6% and region 9 highest at 17.5%). There was no significant difference among share characteristics or transplant center volume. Allograft survival was significantly worse for donor kidneys with GS-5% compared to 0-5% group and no biopsy group. There was no significant difference in the incidence of DGF, acute rejection, or chronic rejection.

**Conclusions:** Although the biopsied kidneys are mostly from higher risk donors, the majority of biopsies have GS level 0-5%. At this level of GS there is no difference in allograft survival compared to DD kidneys without biopsies. Thus utilizing kidneys with GS 0-5% can expand the DD kidney pool and should be strongly considered for use in pediatric population.

**Predictors and Impact of Nephrocalcinosis in Renal Transplant Population: A Monocenter Retrospective Study**  
Jessie Beaulieu,1 Léa Thérien,1 Julie Riopel,1 Eva Latulippe,2 David Simonoyan,2 Isabelle Hourde,1 Mohsen Agharazi,1 Fabrice Mac-Way,1 1CHU de Quebec-Université Laval, CHU de Quebec-Université Laval, Quebec, QC, Canada;  
2Centre de recherche du CHUQ, Quebec, QC, Canada.

**Background:** Persistence of bone and mineral anomalies in post-transplant population has been suggested as contributing factors to nephrocalcinosis (NC) that could lead to graft dysfunction. However, adequate characterization of calcium deposits in biopsies from renal transplant patients are lacking. We thus aimed to determine: 1) the prevalence of NC in renal transplant patients, 2) the factors associated with NC and 3) the impact of NC on renal graft function.

**Methods:** This is a monocenter retrospective study using a protocolized renal biopsy from CHU de Quebec, l’Hôpital-Dieu de Quebec hospital from 2016-2018. All renal biopsies performed in 2016 at renal transplantation, at 6 and 24 months post-transplant were qualitatively and quantitatively analyzed for NC. Demographic, comorbidities and biochemical parameters were collected from patients’ records. Appropriate statistical analyses (Pearson’s chi-squared, Wilcoxon-Mann-Whitney, Spearman’s correlation and logistic regression) were performed to assess factors associated with NC and its impact on graft function.

**Results:** We included 53 patients (mean age of 52±13 years, 55% of men, 94% with hypertension, 23% with peripheral arterial disease and 19% with prior parathyroidectomy). Forty-nine patients (92%) were on chronic dialysis treatment before transplant for a mean duration of 34±29 months. The presence of NC was observed in 14% at baseline, 37% at 6 months and 50% at 24 months. The severity of NC as assessed by the number of calcified foci in the tubulointerstitial compartment also tended to increase over time. Analyses showed the prevalence of NC at 6 months was associated with male sex, presence of NC at baseline and high PTH levels (> 600 ng/L) at the time of transplant. Presence of NC at 24 months was also associated with prior NC and male sex. Interestingly, the presence of NC at 6 months was associated with use of phosphate supplements immediately after engraftment and with active vitamin D treatment at 6 months. Finally, NC at 24 months was correlated with the level of graft function as expected.

**Conclusions:** This study reveals that uncontrolled mineral and bone metabolism parameters before renal transplant are associated with development of NC in the post-transplant period that may contribute to deterioration of renal graft function.

**PO2559**

**Outcomes of Biopsy-Proven Acute Rejection (BPAR) in ABO-Incompatible Kidney Transplants (ABOi KTxs) Compared with a Propensity-Matched Cohort of ABO-Compatible Transplant Recipients (ABOc KTxs)**  

**Background:** Although available outcome data is equivocal for its non-inferiority compared to ABOc KTxs, the data on graft survival after an BPAR episode are scarce in ABOi KTxs.

**Methods:** Single centre, retrospective study. ESRD patients transplanted between 2014 and 2019 were included. Among 100 ABOi KTxs, 37 had BPAR and were included. A matched cohort of 37 ABOc KTxs with BPAR were identified as controls from 680 ABOc KTxs by propensity score matching (nearest neighbour matching) using recipient age and sex, donor age and sex, donor GFR, HLA match and induction agent used as matching covariates. Rejection rates, BANFF score, response to antirejection treatment, overall graft survival, post rejection graft survival were compared between both the groups.

**Results:** The hazard ratio for BPAR was 1.4 in ABOi KTxs, compared with ABOc KTxs. Overall graft survival at 1, 3 and 5 years were 86%, 72% and 50% in ABOi KTxs; 97%, 91% and 79% in ABOc KTxs, respectively. The post BPAR graft survival at 1 and 3 years were 80% and 63% in ABOi KTxs; 92% in both 1 and 3 years in ABOc KTxs. ABMR was more common in early period in ABOi KTxs and ACR was predominant in late period in both the groups. The response to anti-rejection therapy were similar between two groups, no response group (NR) in the ABOi KTxs had the poorest graft outcome, complete response group (CR) in the ABOc KTxs had the best graft survival. Between CR, PR (partial response) and NR groups, no histopathological parameters were found significant in ABOi KTxs, whereas in ABOc KTxs, T1 scores were higher in PR compared to NR group.

**Conclusions:** The graft survival after an acute rejection depends upon response to antirejection therapy. After an episode of acute rejection, the overall post rejection graft survival was inferior in ABOi compared to ABOc KTxs.

Kaplan-Meier curve of 5-year allograft survival for pediatric kidney transplant patients by donor kidney glomerular sclerosis (GS)
PO2560
Antiphospholipid Antibody Syndrome Causing Thrombotic Microangiopathy in the Immediate Post-Transplant Patient: A Case Report
Anna R. Gaddy, Muhammad S. Yaqub. Indiana University School of Medicine, Indianapolis, IN.

Introduction: Differential diagnosis of thrombotic microangiopathy on kidney biopsy specimen includes infection, hypertension, malignancy, or inherited complement disorders. In the the post-transplant period the differential also includes calcineurin inhibitor toxicity and rejection.

Case Description: A 29 year-old AA female with ESRD disease due to lupus nephritis and HTN. Her care was provided in another state until 2011- she had a stroke in the past which she reports was secondary to uncontrolled HTN. No h/o blood clot, never been pregnant. Native kidney biopsy in 2015 showed lupus: class V membranous GN, focal segmental and diffuse glomerular sclerosis with collapsing features, and focal acute thrombotic microangiopathy. In 2019, she underwent deceased donor kidney transplant. On post-op day 4, Sr Cr began to increase and biopsy demonstrated thrombotic microangiopathy. Chart review revealed increased aPTT prior to surgery. DsDNA was negative. Tacrolimus troughs were low, donor-specific antibodies were negative. She was treated empirically with high-dose steroids and plasma exchange. Workup revealed positive anti-cardiolipin IgG (46 GPL units/mL) and positive anti-beta-2 glycoprotein IgG (532 units/mL). She recalled being on warfarin following her CV A in 2010, for inhibitor toxicity and rejection.

Discussion: This case highlights the importance of a complete serological workup to rule out APLs in the pre-transplant patient, even in the presence of alternate explanatory diagnoses. Patients with APLs should be treated with lifelong anticoagulation to prevent further embolic complications, including loss of transplanted organs.

PO2561
Impact of Out-of-Hospital Organ Donor Cardiac Arrest and Cardiopulmonary Resuscitation on Donor Kidney Histology and Function
Samia A. Akram, Claudia G. Olano, Nehemiaa A. Guevara, Lilly M. Babra. Kidney Transplantation Group Harbor-UCLA Medical Center Department of Internal Medicine, Torrance, CA.

Background: The mortality rate of patients listed for kidney transplantation (KT) is 5 per 100-patient years. Due to an organ shortage crisis, expansion of KD pool (KDP) is critical (1). Kidney donors (KD) with out-of-hospital cardiac arrest (OHUS-CA) and cardiopulmonary resuscitation (CPR) have low acceptance rate due to presumed longer duration of CPR greater was the residual KF (Fig 1).

Results: TSC and ATDS prior to KT were evaluated as surrogates for KF post engraftment and there was no difference between OHUS-CA and No-CA (standard) donors. Effect of ischemic preconditioning was noted in OHUS-CA group (Table). Longer the duration of CPR greater was the residual KF post KT. We did a nested cohort study to study the impact of OHUS-CA and CPR of KDs on KF and KH.

Discussion: No KA (0.175) 0.72% (0.17%, P vlt 0.02) 100 477

PO2562
Living Donor-Derived APOL1-Associated Collapsing FSGS in a Kidney Transplant Recipient
Irfan Agha,1,2 Amna Ilahchi,1,3 Silvia Simon,,1,2 Rama Nadella,1,2 Diana Mahbod,1,3 Richard Dickerman.1 1Dallas Renal Group, Dallas, TX; 2Medical City Dallas Hospital, Dallas, TX; 3Methodist Dallas Medical Center, Dallas, TX.

Introduction: Homozygous high risk APOL1 mutations in donors can drive disease in recipients. We present a living kidney recipient with de-novo collapsing FSGS. His donor was homozygous for high risk mutations.

Case Description: 47 YO AA male with CKD due to biopsy proven diabetic nephropathy s/p LUKT in May 2018. Got thyglogobulin (5 mg/kg) with tacrolimus, mycophenolate sodium and prednisone. High risk for CMV (D+ / R-). EBV IgG +. Donor was his 35 years old AA wife. We were not testing APOL1 on AA donors at the time. At 1 month CR 1.4 mg/dl, Ur Pr/Cr of 0.22 g/g. Valganciclovir stopped. Two weeks later, Ur Pr/Cr 2.92 g/g. CMV PCR + 276 copies / ml and EBV PCR + 492 copies / ml PCR for Parvo Virus B-19 as well as DSA negative. Given steroids, plasmapheresis (X3) and IV ganciclovir. Biopsy C/W collapsing FSGS. IF negative, including CMV and C4d. Donor tested for and found to be homozygous for APOL1 G1 mutations confirming donor derived APOL1 gene associated collapsing FSGS, presenting as an acute diffuse podocytopathy. Trends in his renal function, CMV, EBV and proteinuria are tabulated in Figure 1. Treated with RAAS blockade, antivirals & immunosuppression. He cleared his CMV Viremia promptly. However, EBV viremia worsened. Eventually, in May 2019, received Rituximab with resolution of EBV viremia. He is 18 months out from his CMV Viremia promptly. However, EBV viremia worsened. Eventually, in May 2019, received Rituximab with resolution of EBV viremia. He is 18 months out from his CMV Viremia promptly. However, EBV viremia worsened. Eventually, in May 2019, received Rituximab with resolution of EBV viremia. He is 18 months out from his CMV Viremia promptly. However, EBV viremia worsened.

Discussion: APOL1 mutations place recipients of these kidneys at risk for adverse outcomes. Few instances of APOL1 mutation driven kidney disease in recipients from...

Pre-transplant Genetic Testing of Living Related Donor in a Case of

Clinical Course

PO2563

Pediatric Donor Glomerulopathy in Pediatric En-Bloc Kidney Transplants

Background: Use of pediatric en-bloc kidneys (EBK) have equivalent outcomes to standard deceased donor kidneys and has helped expand the pool of donor kidneys. The size mismatch related hyperfiltration injury in pediatric EBK and pediatric single kidney allografts is associated with pediatric donor glomerulopathy whose effect on allograft outcomes is not well documented.

Methods: We retrospectively reviewed for cause biopsies of pediatric EBK from 1/2015 to 1/2020. Our center performed 37 transplants using pediatric EBK. Recipient weight criteria was ≤ 75 kg to minimize donor-recipient size mismatch. One recipient died of a functioning graft at 4 months; one graft failed due to fungal infection of the vascular anastomosis requiring nephrectomy at 1 month.

Results: Fourteen biopsies were performed in 10 patients between 1 to 24 months after transplantation. Indications for biopsy were: graft dysfunction (10; 3 with proteinuria), proteinuria alone (2), BK viremia with proteinuria (1), and de novo donor specific antibody (DSA) (1). Biopsies from 5 EBK recipients demonstrated pediatric donor glomerulopathy represented by the presence of glomerular abnormalities including subepithelial multilayering/remodeling of the basement membrane, segmental glomerulosclerosis, mesangial hypercellularity, mesangial sclerosis, podocyte hypertrophy, and/or segmental mild podocyte foot processes effacement. Ten biopsies also showed thin basement membranes (BM) on EM consistent with the age of the donor kidney. Other diagnostic findings among the entire biopsy cohort were acute cellular rejection (ACR), antibody mediated rejection (AMR), or mixed ACR and AMR (5), acute tubular necrosis (ATN) (3), and pyelonephritis (1). Biopsies with pediatric donor glomerulopathy were performed early after transplantation and were associated with proteinuria. Semiquantitative proteinuria in the 5 recipients at the time of biopsy was 1-3+; 1.2-9.5 g/day in 4. Follow up 4-39 months post-transplant (mean 17 months) in patients with pediatric donor glomerulopathy showed serum creatinine 0.55-2.07 mg/dL (mean 1.1) and urine protein 0.4 to 1.2 g/day (mean 0.73).

Conclusions: Overall, pediatric donor glomerulopathy seen early post transplant period did not appear to negatively affect long-term graft function; this outcome may be related to growth of these kidneys occurring early post transplant.

PO2564

Pre-Transplant Genetic Testing of Living Related Donor in a Case of Atypical Hemolytic Uremic Syndrome

Meghna Kurup, Didier A. Mandelbrot, Tripti Singh. University of Wisconsin SMPH, Madison, WI.

Introduction: Atypical HUS (aHUS) is a rare thrombotic microangiopathy caused by dysregulation of the alternative complement pathway either through mutations in regulatory genes or autoantibodies directed against regulatory proteins. Here we report a case of genetic testing pre-transplant in a patient who developed aHUS with variants in the CFH and PLG genes and her living related donor.

Case Description: A 27-year-old female presented to the hospital with diarrhea, abdominal pain, AKI, and microangiopathic hemolytic anemia requiring dialysis. She was initiated on eculizumab but progressed to ESRD. Renal biopsy showed TMA with focal crescents and severe interstitial fibrosis and tubular atrophy. Workup revealed aHUS with complement dysfunction—low C3 and C4, normal CD46 and Factors H, I, and B, and no autoantibodies to CFH. Genetic testing showed mutation on exon 9 (SCRF7) of CFH that has been shown to cause aHUS as well as another variant on exon 7 of PLG, which is present in 0.3% of European Americans and may be pathogenic but is of uncertain significance for her. Ten months later, she was evaluated for living related renal transplant from her brother. Since she had a mutation known to cause aHUS, genetic testing was done for her brother as part of donor evaluation. He was found to have the same mutation in CFH but not PLG, despite being asymptomatic with no hemolytic anemia, normal kidney function. The transplant was cancelled because of increased risk of disease in the future in the brother. Genetic counseling was provided to brother about his possible risk of aHUS.

Discussion: Mutations in CFH are associated with aHUS; however, it is thought that a trigger—e.g. infection or additional acquired genetic variant leads to progression to aHUS in carriers of complement gene mutations. Genetic testing is recommended for patients with aHUS to determine cause and inform long-term treatment. This patient had a combination of a variant in the complement pathway gene CFH and coagulation pathway gene PLG, while her brother, a candidate for living related donor, had the same variant in CFH. We recommend genetic testing for a living related donor if any mutation is found in the index case to minimize posttransplant recurrence or precipitation of aHUS in the donor.

PO2565

Trouble Brui-ing: A Case of Doppler Discovery

Brandon M. Fairless,1 Anil S. Paramesh,2 Isa Ashoori.1,2 Louisiana State University Health Science Centers, New Orleans, LA; Tulane University School of Medicine, New Orleans, LA.

Introduction: This case highlights the clinical presentation and management of an uncommon kidney transplant biopsy complication.

Case Description: A 19 year old male with ESKD, now status-post second deceased donor kidney transplant, presented to clinic with hypertension. Post transplant course included 3 prior normal surveillance kidney transplant biopsies. Graft function was stable (creatinine 1 mg/dL), and tacrolimus trough level was therapeutic. His blood pressure was 130/85. Exam showed a palpable thrill with audible bruit over the graft site. Ultrasound showed a sonolucent lesion in the lower pole of the transplant kidney, which was not present on prior imaging. Doppler revealed turbulent flow concerning for an arteriovenous malformation (AVM). Renal angiography confirmed the diagnosis, and he underwent endovascular embolization with coil [Image]. Graft function and blood pressure readings remain normal on most recent follow-up.

Teaching Points: Ultrasound with Doppler assesses for the presence of AVM. Symptoms of post-biopsy AVM include hypertension, renal graft dysfunction, and gross hematuria. Transplant patients are at increased risk for post-biopsy AVM.

PO2566

Renal Transplant Artery Stenosis and Kinking: An Unusual Association

Haridjan Sosa Barrios,1 Victor Burguera,1 Ester Casillas,1 Daniel E. Vella,1 Sara Jimenez Alvaro,1 Irene Martin Capon,1 Milagros Fernandez-Lucas,2 Maite Rivera.1,2 Hospital Universitario Ramon y Cajal, Madrid, Spain; 2Universidad de Alcalá de Henares, Madrid, Spain.

Introduction: Renal artery stenosis of the kidney graft associated with kinking is not a frequent finding. As a correctable cause of graft dysfunction it is important to diagnose it as soon as possible to avoid further graft damage.

Case Description: A 62 year-old woman with ESRD due to ADPKD had a deceased donor kidney transplant (KTx) in her right iliac fossa (1 vein/1 artery) anastomosed to external iliac vessels. Immunosuppression:basiliximab, tacrolimus, everolimus and steroids. Creatinine drop halted 2 weeks post-op. Blood pressure was normal, CMV load : undetectable. Tacrolimus level:7-9 ng/mL. A KTx US was done, showing high velocities within KTx renal artery close to the anastomosis, increasing near a kinking image adjacent to the hilum (image 1), not present on Doppler US 1 day post-op. A CT angiography confirmed renal artery stenosis at anastomosis level and kinking of the graft renal artery (image 2). Endovascular angioplasty of the stenotic area without stenting was performed, but unsuccessful. Open surgery vascular reconstruction was carried out a week after angioplasty: renal artery was shortened and reimplanted. Within a week, graft function improved and Doppler US was normal.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Discussion: Renal artery stenosis is a correctable cause of hypertension and graft dysfunction in KTxs. Graft renal artery kinking is rare, even more in association with stenosis, worsening its prognosis as kinking renders angioplasty less effective. Complete Doppler US mapping of the graft’s arteries is essential to make an early diagnosis and nephrologists could do this examination promptly.

PO2567

Proliferative Glomerulonephritis Monoclonal Immunoglobulin Deposits (PGNMID) in a Kidney Allograft Successfully Treated with Rituximab

Rasha Alawieh, Mohankumar Doraiswamy, Seth Schetz, Anjali A. Satoskar, Todd E. Pesavento, Priyamvada Singh. The Ohio State University, Columbus, OH.

Introduction: PGNMID is a rare distinct form of glomerulonephritis (GN) characterized by glomerular monoclonal immunoglobulin deposits. There is no definite treatment for this condition. We present a case of PGNMID in a recurrent renal transplant patient who responded well to rituximab.

Case Description: A 43-year-old male with ESRD secondary to MPGN s/p 3rd renal transplant complicated with failure of previous transplants due to rejections (on cyclosporine and everolimus) presented with worsening pain at the graft site and AKI. Creatinine 5.6 mg/dL (baseline 2.5 mg/dL), UPC 1.5 gm/dL, RBC, and RBC casts on microscopy. Detailed serological, immunological, and infectious workup was negative. Renal biopsy showed mesangial, subepithelial, and subendothelial proliferation with electron dense deposits of IgG1 and IgG3 with kappa predominance most consistent with PGNMID. Monoclonal workup was negative and bone marrow biopsy showed no clear evidence of hematologic malignancy. He received two doses of rituximab in addition to home immunosuppression. Renal function improved to baseline (creatinine 2.5 mg/dL, negative blood, UPC 0.5) and has been stable for past year.

Discussion: GN recurrence in kidney allografts is responsible for around 24% of kidney graft losses. Approximately 70% of PGNMID patients have no detectable monoclonal proteins in serum or urine. Multiple regimens have been used for the treatment of PGNMID after renal transplant, including RAAS blockers, steroids, rituximab, bortezomib and plasmapheresis. Few reported cases of PGNMID responded well to rituximab, and a large prospective multicenter controlled study is warranted to better understand this rare disease.

PO2568

Rituximab or Plasmapheresis for Prevention of Focal Segmental Glomerulosclerosis Recurrence After Kidney Transplantation: A Meta-Analysis

Boonphiphop Boonpheng,1 Charat Thongprayoon,2 Wisit Cheungpasitporn.3 1University of California Los Angeles, Los Angeles, CA; 2Mayo Clinic Minnesota, Rochester, MN; 3University of Mississippi Medical Center, Jackson, MS.

Background: Focal segmental glomerulosclerosis (FSGS) can recur after kidney transplantation. Prevention of FSGS recurrence with rituximab and/or plasmapheresis has been evaluated in multiple small studies with conflicting results. We performed this meta-analysis to assess the post-transplant recurrence risk of FSGS with prophylactic rituximab and/or plasmapheresis in addition to standard immunosuppression.

Methods: A systematic review was conducted in MEDLINE, EMBASE, Cochrane databases from inception through April 2020 to identify studies that evaluated the risks of post-transplant FSGS after rituximab with or without plasmapheresis or plasmapheresis alone compared to controls. Effect estimates from the individual study were extracted and combined using random-effects model.

Results: 10 studies with a total of 381 FSGS patients undergoing kidney transplantation evaluated rituximab with or without rituximab and 11 studies with a total of 520 kidney transplant recipients with FSGS evaluated plasmapheresis alone. There was no significant difference in recurrence between the group that received rituximab with or without plasmapheresis and the standard treatment group, with a pooled risk ratio of 0.84 (95% CI, 0.47-1.48, I² = 67%). Plasmapheresis alone was also not associated with any significant difference in FSGS recurrence compared to no plasmapheresis with a pooled risk ratio of 0.94 (95% CI, 0.65-1.37, I² = 20%). Subgroup analysis in the pediatric or adult group did not yield significant recurrence risk difference.

Conclusions: Rituximab with or without plasmapheresis or plasmapheresis alone was not associated with lower risk of FSGS recurrence after kidney transplantation.
Case Study of Repository Corticotropin Injection (RCI) Prophylaxis for FSGS Recurrence in Kidney Transplant
Sandheep Venkataraman,1 Barrett R. Crowther,2,3 Monica Grafals,1,2 1University of Colorado, Denver, CO; 2University of Colorado Health, Aurora, CO.

Introduction: Idiopathic FSGS recurs post-transplant in one third of cases and is associated with a five-fold higher risk of graft loss.1

Case Description: In this single center pilot case study, 8 patients with biopsy-proven FSGS were treated with RCI prophylaxis 80 units subcutaneously twice a week for 6 months from day of kidney Tx, compared with a group of 6 patients who were treated with RCI later after the diagnosis of FSGS recurrence.

Discussion: All patients received rATG as induction and were on standard immunosuppression with FK, MMF, and prednisone. Patients in the control group were diagnosed with recurrent FSGS between 5-63 days post Tx. There were 3 patients in the study group that developed recurrent FSGS, 2 of them required plex. Patient 1 in the study group had DGF after a live donor kidney Tx from recurrent FSGS. Her protocol biopsy performed one year after transplant and still shows foot process effacement but no fibrosis or sclerosis in light microscopy. All but one patient in the control group have still functioning allografts. Conclusions: This is a small pilot study, but its findings suggest that use of RCI at time of kidney transplant surgery in patients with FSGS decreases the severity of the disease with less fibrosis in follow up biopsies despite the presence of foot process effacement. There may also be a decreased need for plex in the study group, however, further studies are needed to confirm this.

Does Therapeutic Plasma Exchange Improve Kidney Function in Renal Transplant-Associated Thrombotic Microangiopathy?
Karen A. Nahmod, Barbara J. Bryant, Sean G. Yates, Marjan Afrouzian. University of Texas Medical Branch at Galveston, Galveston, TX.

Background: Therapeutic plasma exchange (TPE) is performed in patients with renal transplant thrombotic microangiopathy (t-TMA) to improve the kidney function. The goal of our study is to evaluate the short-term efficacy of TPE in patients with renal t-TMA.

Methods: We retrospectively compared the outcome of TPE-treated vs. non-TPE-treated patients with biopsy-proven diagnosis of t-TMA. Histologic criteria for diagnosis of t-TMA included presence of thrombi in the artery/arteriole/glomeruli, mesangiolysis & double contours, and electron microscopic evidence endothelial cell injury including subendothelial rarefaction/ accumulation of fluffy material and mesangial interposition. Both groups received concomitantly other modalities of treatment. Creatinine and creatinine clearance levels were determined at the time of biopsy (T0) and after 1, 3 and 6-months (T1, T3, T6 respectively).

Results: In 13 TPE-treated and 9 non-TPE-treated patients, the mean creatinine levels at 6 months decreased 32.5% and 45% respectively over baseline, while the creatinine clearance increased by 68% and 65% respectively, although not statistically significant (p>0.05) Graph 1.

Conclusions: No significant differences were noted in creatinine or creatinine clearance levels within and between either groups at any time point. Our study suggest that no significant benefit in renal function is associated with performing TPE in patients with renal t-TMA. Larger studies are needed to confirm our data.
PO2571

Patient and Graft Outcomes of Kidney Transplant Recipients with Anti-Human Neutrophil Antigen Antibodies

Background: Antibody mediated rejection (AMR) is a well-established cause of poor graft outcomes in kidney transplant recipients (KTR). While the most common targets are human leukocyte antigen (HLA) antibodies (abs), there are data implicating some non-HLA abs in the process of AMR. Human neutrophil antigens (HNA) are glycoproteins expressed on neutrophil surfaces. Anti-HNA abs have been associated with transfusion-related acute lung injury but their role in AMR in KTR is unclear. The aim of our study was to examine the outcomes of KTR with anti-HNA abs at our center.

Methods: We retrospectively reviewed the medical records of KTR with non-HLA abs between 1/2008-5/2020. Relevant clinical and graft outcome data were obtained. Descriptive statistics were expressed as absolute numbers (%) for categorical data and as medians with interquartile range (IQR) for skewed distribution.

Results: There were 6 KTR with non-HLA abs during the study period, all anti-HNA abs. Three patients (pts) were male (50%), 5 white (83%), and 4 had polycystic kidney disease (PKCD) as primary disease (66%). Median age at KT was 46 (29.75-57). Pts’ characteristics, clinical course and outcomes are detailed in Table 1. Five pts developed biopsy-proven AMR at a median of 32 months (13.8-68.2) from KT. During follow-up (Fu), 3 pts had graft loss, 1 of which was re-transplanted while 2 are re-listed but dialysis-dependent. Mean creatinine of the 4 pts with working allografts is 1.21mg/dl(1.14-1.27) at median Fu of 68 months(52-105).

Conclusions: We observed varied clinical courses and graft outcomes in our pts, partly due to our small cohort. Although majorly developed AMR, it was not necessarily associated to graft loss or shortened graft survival. Of note, PKCD was the primary kidney disease in the majority of pts, similarly observed in one other case series. More studies are needed to determine the specific significance of anti-HNA abs in KTR.

Table 1. Patient and donor characteristics and allograft outcomes.

PO2572

Transplant Outcomes in Children with Lupus Nephritis
Vimal Chaladia,1 Heather W. Wass,1 Shirley Galbani,2 Meredith A. Atkinson,2 Bradley A. Wardy.1 Children’s Mercy, Kansas City, MO; 2Johns Hopkins University, Baltimore, MD; 1The Emesse Company LLC, Rockville, MD; 2State University of New York Upstate Medical University, Syracuse, NY.

Background: Children receiving dialysis for end stage kidney disease secondary to lupus nephritis (LN) have decreased survival and a lower likelihood of kidney transplantation compared to children with non-lupus glomerular diseases (NLGN). Whereas a previous North American Pediatric Renal Trials and Collaborative Studies (NAPRTCS) analysis reported equivalent patient and graft survival for LN patients when compared to matched controls, a comparison of recent transplant outcomes in children with LN and NLGN has not been conducted.

Methods: Retrospective analysis of the NAPRTCS registry data of subjects <21 years old who received a kidney transplant between 1987-2018. Outcomes for LN patients (n=191) were compared to NLGN patients (n=8675) during pre & post 2000 eras. Statistical analyses included Kaplan-Meier curves and multivariable logistic and Cox regression models.

Results: After adjusting for race, LN patients were less likely (p=0.001) to receive a preemptive transplant (OR=0.12). There was also a trend for LN patients being less likely to receive a living donor (LD) transplant (OR=0.8). When comparing pre- and post-2000 eras, time to 1st rejection and graft survival improved for both LN and NLGN groups, although the graft survival benefit in LN group was not sustained after 3.5 years of follow-up. Time to 1st rejection and graft survival for LN patients remained inferior to NLGN group during both eras (Figure 1 & 2).

Conclusions: LN patients are less likely to receive a preemptive, and possibly a LD transplant. Overall, outcomes for both LN and NLGN transplant patients improved after 2000, but the outcomes of the LN group were inferior to those of the NLGN group during both time periods.

PO2573

Effect of Rituximab Dose on Induction Therapy in ABO-Incompatible Living Kidney Transplantation: A Network Meta-Analysis
Seon Deok Hwang,1 Joon Ho Song,1 Kipyo Kim,1 Woo Yeong Park,2 Seoung woo Lee.1 Inha University, Incheon, Incheon, Republic of Korea; 2Keimyung University Dongsan Medical Center, Daegu, Republic of Korea.

Background: Rituximab is an induction immunosuppressant essential for ABO-incompatible kidney transplantation, but studies on its dosing, which differs between countries and transplant centers, are lacking we retrospectively investigated this phenomenon.

Methods: we retrospectively investigated this phenomenon by including five groups: ABO compatible; placebo; and rituximab 200 mg, 200–500 mg, and 500 mg. Publications were retrieved using CENTRAL, MEDLINE, EMBASE, and Science Citation Index Expanded databases from 1970 to February 2020 and analyzed. Reviews, observational studies, and clinical trials with unclearly defined outcomes or omitted graft failure as an outcome were excluded. We performed direct and indirect network meta-analyses using Bayesian models and ranked different rituximab doses using generation mixed treatment comparison. The GRADE of network meta-analysis approach specified four levels of certainty for a given result: high, moderate, low, and very low. The outcomes were patient survival, graft failure, and infections including bacterial and viral.

Results: Twenty-one trials with 4,256 subjects were analyzed for glomerular filtration rates, graft loss, antibody-mediated rejection, T-cell mediated rejection, fungal infection (Candida), and patient survival rates, which did not differ among four groups. However, incidence of sepsis and cytomegalovirus infection (0.728 and 0.855, 95% confidence interval: 0.572–0.926 and 0.724–0.921, respectively) were significantly lower in rituximab 200-mg group than in other groups.

Conclusions: In conclusion, in ABO-incompatible kidney transplantation, low-dose rituximab is more efficacious than higher doses and reduces serious infection risks. Future studies of large-scale, long-term data and further discussions on using lower rituximab doses are necessary.

PO2574

Delayed Diagnosis of Renal Allograft Uroenteric Fistula in a Pediatric Transplant Patient
Malek Al Barbandi, Patricia A. Arroyo Parejo Drayer, Juan C. Infante, George W. Burke, Jayanti Chandar, Marissa I. Defreitas, Chryso P. Katsoulis, Wacharee Seeherunvong, Carolyn L. Abitbol. University of Miami School of Medicine, Miami, FL.

Introduction: The diagnosis of uroenteric fistulae can be challenging and is often delayed for several months after symptoms begin. Here, we describe a rare case of a pediatric patient post en bloc kidney transplant who developed a urinoma post biopsy with a ureteral fistula into the small bowel resulting in profound acidosis and deceptive watery diarrhea.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

780
Case Description: The patient is an 8 year old girl with end stage kidney disease secondary to steroid resistant nephrotic syndrome and focal segmental glomerulosclerosis (FSGS). She underwent a right native nephrectomy and a deceased donor “en bloc” kidney transplant with two separate ureters. She had a renal allograft biopsy for suspected rejection. A few days after the biopsy, she began experiencing watery diarrhea and metabolic acidosis. A comprehensive screening for diarrhea produced inconclusive findings. She was maintained on parenteral nutrition with no oral intake to try to slow the diarrhea. However, the watery diarrhea increased while urine output decreased. Throughout this period, the patient maintained normal kidney function. The watery stool and bladder urine were analyzed for solutes, pH and creatinine. An MRI with contrast was performed which demonstrated fistulization of the distal transplanted ureters into the small bowel. She underwent corrective surgery which identified the fistulous tract which was resected and the ureters were re-implanted. The surgery went well without complications. The diarrhea resolved and she was discharged 2 weeks later with normal renal function.

Discussion: This is a perplexing case of the development of a uroenteric fistula in a pediatric transplant patient that went undiagnosed for almost 3 weeks due to the deceptive nature of the watery diarrhea which was actually urine. An important aspect of the uroenteric fistula is the severe acidosis that results when urine is diverted into the intestinal tract. This occurs in some cases of bladder augmentations that use the intestine. Another important diagnostic tool is the solute excretion in the diarrhea. Despite the watery nature of the diarrhea, the stool was not hyperosmolar and did not contain reducing substances. This made osmotic diarrhea unlikely and a fistula more likely.

Effect of Therapeutic Plasma Exchange on Glomerular Filtration Rate in Patients with Antibody-Mediated Rejection

Miguel Maza Moreno, Sergio Hernández-Estrada, Jose H. Cano, Odette Del Carmen Diaz Avendaño, Diana Maldonado Tapia. Nephrology and Transplant Division National Medical Center 20 de Noviembre, Mexico City, Mexico.

Background: AMR is the main risk factor for graft loss, especially after the first post-transplant year. Up to 80% of patients achieve response with immunosuppressive treatment and TPE, although the response is lower in patients with late AMR. The objective was to determine the effect of TPE on GFR at 0, 1, and 3 months postTPE.

Methods: Retrospective study that included patients with a renal transplant of the CMN-November 20 in Mexico City, from 2016 to 2019, undergoing membrane TPE for AMR. Analysis was performed using student’s t or MannWhitney U, repeated measures analysis, and Spearman or Pearson test. Significant p was less than 0.05.

Results: 25 patients with AMR who received TPE were evaluated. Age:32±11.6 years, 72% from living donor, 52% received basiliximab. 87% received tacrolimus. 80% of AMR were late. Prevalence of HLA class II DSA (66%), specifically vs DQnDR (57.2% and 28.8%). There was a significant difference between preTPE GFR and at the end of treatment (p=0.015, r=0.53), and no significant differences between preTPE GFR, with 1/3 month GFR (p=0.38; p=0.36). When evaluating IFTA or histological score (g+ptc), no difference was detected in the GFR at 1 or 3 months post-TPE. When comparing the effect of the AMR temporality on the GFR, difference was found at 1 and 3 months (p=0.022; p=0.01) postTPE, with lower recovery of GFR in patients with early AMR. There was a moderate correlation between GFR at the time of diagnosis of rejection and GFR at 3 months postTPE (r=0.68; p=0.01), Fig. 1.

Conclusions: Significant difference was demonstrated between the preTPE GFR and immediate postTPE GFR. In our study patients with early AMR presented a poor response to treatment. The GFR upon admission correlated positively with the GFR detected at 3 months postTPE. This suggests a beneficial effect of TPE over GFR fall during the first 3 months after diagnosis.
PO2577

Single-Dose Rituximab and Antithymocyte Globulin (ATG) in Hypersensitized Kidney Transplant Recipients

Aileen Wang, Uercia K. Wang, Megan L. Troxell, Stephan Busque, Colin R. Lenihan. Stanford University School of Medicine, Stanford, CA.

Background: Hypersensitized kidney transplant recipients (cPRA ≥ 98%), may represent a population at high risk of posttransplant immunologic events. Their optimal induction regimen so far remain uncertain. The goal of this study was to compare 1-year outcomes of patients receiving rituximab and ATG as induction, the majority of whom were hypersensitized, with highly sensitized recipients (cPRA ≥ 80%) who received ATG alone.

Methods: All patients ≥ 18 years received a flow cross-match compatible kidney transplant between December 2014 and May 2020. We excluded patients who underwent pretransplant desensitization, simultaneous multi-organ transplantation, or received 0-HLA antigen mismatched organ. The exposure of interest was receipt of single dose rituximab (500mg) at induction. The 1-year outcomes were 1) patient and death censored graft survival, 2) glomerular filtration rate (GFR), 3) de novo DSA formation, 4) biopsy proven T-cell or antibody mediated rejection, 5) the composite of dNSA and rejection, 6) BK viremia, and 7) CMV viremia.

Results: 70 patients received rituximab and ATG (Ritux) and 39 received ATG alone (Control). The Ritux group were (numerically) younger, more sensitized, received kidneys with a longer cold ischemia time, and lower kidney donor profile index. ATG doses were similar. The majority were deceased donor transplants. 1-year patient and death censored graft survival, mean GFR, incidences of BK viremia and CMV viremia were similar for Ritux and Control. 2 patients with primary graft non-function (1 in each group) and 1 patient with early posttransplant death (in Ritux) were excluded from the remaining outcome analyses (Table 1).

Conclusions: The addition of rituximab to ATG as induction for hypersensitized patients appears to be safe and is associated with excellent 1-year outcomes in patients with highly sensitized kidneys and death censored graft survival. Rituximab at induction was associated with reduced incidence of dNSA formation and/or rejection at 1-year post transplant. Our observations warrant further evaluation of anti-B cell therapy induction for hypersensitized kidney transplant recipients.

Table 1

PO2578

Risk Factors and Outcomes of Acute and Chronic Antibody-Mediated Rejection

Allyson Hart,1 David P. Schladt,2 Robbin F. Itzler,1 Ajay K. Israni,1 Bertram L. Kasiskie,1 Hennepin Healthcare, Minneapolis, MN; 2Chronic Disease Research Group, Minneapolis, MN; 3CISL Behring, King of Prussia, PA.

Background: Major gaps remain in our understanding of antibody-mediated rejection (AMR) after kidney transplantation. We examined incidence, risk factors, response to treatment, and effects on outcomes of locally-managed AMR at 7 transplant programs in the Long-Term Deterioration of Kidney Allograft Function (DeKAF) prospective study cohort.

Methods: Consecutive kidney or kidney-pancreas transplant recipients were enrolled in the DeKAF study from October 2005 through April 15, 2011. To determine the effect of AMR on death censored graft failure (DCGF), we performed Cox proportional hazards analyses including AMR as a time-dependent covariate.

Results: Among 3313 kidney and kidney-pancreas transplant recipients, there were 194 with a first AMR episode during a mean 4.85±1.86 years of follow-up for the entire cohort. Mean time to first AMR was 0.97±1.86 years post-transplant. After adjusting for other risk factors, patients with AMR had 10 times the risk of DCGF compared to patients with no AMR (aHR 10.1, 95% CI 6.5-15.7). Among the 50 (25.8%) patients whose AMR was refractory to treatment, defined as 2nd AMR diagnosis within 100 days or no improvement in eGFR by 42 days, the HR for DCGF was 7.5 (2.2-25.6, P=0.0013) in the first 180 days post biopsy; 3.8 (1.4-9.8, P=0.007) in the 1st year post biopsy, and 1.6 (0.9-3.0, P=0.11) at any time during follow-up compared to patients whose AMR responded to treatment.

Conclusions: Patients with AMR had substantially greater risk of DCGF compared to patients without AMR. While patients with refractory AMR were more likely to lose their graft compared to non-refractory cases in the first year following the AMR diagnosis, the likelihood of graft survival after that year was the same regardless of response to treatment.

PO2579

Allograft Loss and Patient Death Among Kidney Transplant Recipients: Is Therapy Nonadherence the Underlying Perpetrator?

Kartik Kaira, Puneet Sood, Rajil B. Mehta, Chethan M. Puttajarappa, Christine Wu, Sundaram Hariharan, Nirav A. Shah. University of Pittsburgh Medical Center, Pittsburgh, PA.

Background: To ascertain causes of allograft dysfunction, loss and death in a cohort of kidney transplant patients.

Methods: Retrospective cohort study, 943 patients with isolated kidney transplants between years 2013-17 were analyzed for the following transplant outcomes: 1. Death-censored allograft loss 2. Graft dysfunction 3. Death.

Results: 80 of 943 (9%) patients died while 63 (7%) lost their graft and 38 (4%) had prior biopsy proven T-Cell Mediated Rejection (TCMR) in 1st post-transplant year. Graft Loss- In this cohort TCMR (39%) was the most widespread factor contributing to allograft loss. While Infection (17%) and surgical causes (14%) were the next common associations, donor related disease accounted for 2% of graft losses. Graft Dysfunction- TCMR (42%) was strongly associated with allograft dysfunction in our patient cohort. The other factors associated with Allograft Dysfunction included a). Infection (21%) b). Donor Related causes (11%) and c). Other Causes (15%). Surprisingly ABMR was only noted in 11% of patients with allograft decline. Rejection and Non-Adherence- As TCMR was a common contributing factor to all the three hard outcomes in our study cohort, we examined the factors associated with TCMR. 40% of patients with TCMR were found to be non-adherent (defined by > 3 consecutive sub- therapeutic CNI levels, clinic no shows and poor adherence to regular lab draws). Importantly, patients who were non-adherent were significantly younger (mean age 38 ± 5.5 year; p<0.0001) and a greater proportion of them were of African American (47% vs 22%; p=0.055) compared to those who were adherent to therapy.

Conclusions: While the causes of death, early allograft loss and dysfunction were diverse, TCMR was the most dominant contributor. Non-Adherence was strongly associated with TCMR and was more common in younger patients and those with African American ethnicity. Addressing non adherence in this cohort of patients early with novel interventions could be a key to optimizing patient outcomes in this high risk cohort.

PO2580

Identifying the Causes for Kidney Allograft Failure

Background: Since it has been proposed that several causes (C) can contribute to graft loss (GL), we analyzed transplant (Tx) recipients in our center and attributed a C to each persistent decline in renal function, finally leading to GL.

Methods: We retrospectively analyzed 1477 Tx, transplanted between 1997 and 2017 in a single center, of which 303 progressed to GL. An adjudication committee consisting of 3 physicians evaluated biopsies, laboratory data and medical history. Nonreversible decreases in renal function were attributed to primary and secondary C.

Results: Overall graft survival for all patients is 93.7% for 1 year, 80% for 5 years and 66.6% for 10 years. The most frequent C leading to GL were intercurrent medical events in 36.3%, followed by T-cell mediated rejection (TCMR) in 34% and antibody-mediated rejection (ABMR) in 30.7% (table1). For primary C, ABMR (21.5%) was the leading C, followed by medical events (21.1%) and TCMR (12.9%). As expected, we observed an increasing relevance of ABMR in late GL (figure 1). Over 50% of GL had >1 C.

Conclusions: Analyzing GL, we observed that >50% were multifactorial. Our results show a significant role of TCMR in GL. Additionally, we were able to attribute medical events to GL in 36.3% of Tx and to highlight the role of ABMR in late GL.
PO2581
Assessing Cumulative Immunosuppressive Drug Exposure: Metrics, Outcomes, and Implications for Kidney and Non-Kidney Transplant Patients
Cavizhajan Skanthan, Emily Nguyen, Lakindu Somaweera, Madhumitha Rabiudranath, Olusegun Famure, Joseph Kim. University Health Network, Toronto, ON, Canada.

Background: Immunosuppressive drugs are used in the long-term management of post-transplant patients to prevent rejection of transplanted organs. Lacking prior qualitative systematic review on this topic, we aimed to characterize the metrics used to measure cumulative immunosuppressant exposure and their associated outcomes in kidney and non-kidney transplant patients.

Methods: We conducted a literature search using search terms related to immunosuppressants and cumulative exposure in Ovid MEDLINE, Ovid EMBASE, Cochrane CENTRAL, and Cochrane Database of Systematic Reviews. No date restrictions were applied. An additional search was performed on Google Scholar and references of studies included in the primary search were screened. Studies were limited to the English language with adult human transplant patient populations. Study risk of bias was assessed using the Quality in Prognostic Studies Tool where each domain was rated as low, medium, or high risk of bias.

Results: A total of 29 articles were included in our qualitative synthesis. Kidney transplant populations account for 12 (41%) of the studies in our analyses. Fifteen of the articles (51%) calculated the total dose of immunosuppression over the treatment period while 9 (31%) used long term area-under-the-curve (LT-AUC) of trough level concentrations to quantify cumulative immunosuppression exposure. Nine articles found certain cumulative exposure metrics to be predictive of adverse outcomes such as decreased kidney function, cancer recurrence, and bone fractures. Furthermore, an adequate mycophenolic acid LT-AUC was associated with a decreased risk of allograft rejection, while cumulative corticosteroid exposure was not associated with allograft rejection.

Conclusions: This review analyzed a comprehensive set of articles and metrics that predict long-term outcomes of immunosuppressants in transplant patients. The wide variety of metrics studied highlight the lack of agreement on the best measures of drug exposure in transplant patients. Although certain metrics may demonstrate an association with outcomes, future studies should investigate the predictive power and validation of these metrics.

PO2582
Fludrocortisone Corrects Tacrolimus-Associated Hyperkalemia in Renal Transplant Patients
Rouvick Gang, Virginia A. Quan, Mysore K. Phanish. Epsom and Saint Helier University Hospitals NHS Trust, London, United Kingdom.

Background: Hyperkalemic metabolic acidosis is commonly observed following kidney transplantation. This is often due to calcineurin inhibitors which are known to cause type 4 renal tubular acidosis either due to hyporeninemic hypoaldosteronism or due to direct effect on aldosterone responsive potassium secretion in the distal nephron.

Methods: We report 5 post-renal transplant patients (5 males) on tacrolimus with hyperkalemia treated with daily doses of either 50 mcg (n=3) or 100 mcg (n=2) of fludrocortisone. We retrospectively collected data at 3 time points before and after fludrocortisone on serum concentrations of sodium, potassium, bicarbonate, creatinine and tacrolimus as well as eGFR and blood pressure (BP). We recorded emergency admissions and length of stay (LoS) for treatment related to hyperkalemia. Data are presented as mean +/-SD and analysed with a paired students t-test.

Results: Pre and post-fludrocortisone serum concentrations for potassium was 6.3 ± 0.3 mmol/L and 5.1 ± 0.3 mmol/L (p=0.002); venous bicarbonate 18.4 ± 1.8 mmol/L and 20.4 ± 2.0 mmol/L (p=0.108); sodium 135 ± 1.6 mmol/L and 135 ± 2.2 mmol/L (p=0.873); creatinine 184 ± 12.2 mmol/L and 155 ± 10.6 mmol/L (p=0.058); eGFR 39 ± 3.4 ml/min and 47 ± 4.2 ml/min (p=0.035); blood tacrolimus levels 9.8 ± 2.1 ng/ml and 11.2 ± 1 ng/ml; BP was 133/69 ± 12/9 mmHg and 129/70 ± 8/6 mmHg before and after fludrocortisone respectively. We were able to either reduce or stop sodium bicarbonate after starting fludrocortisone due to increase in serum bicarbonate levels. Prior to fludrocortisone there were 6 episodes of serum potassium greater than 6.5 mmol/L, of which 3 patients required admission for hyperkalemia management, with LoS 1-3 days. The majority occurred with tacrolimus levels in target range. Reduction in potassium levels to ‘safe levels’ were noted within 24-48 hours of starting fludrocortisone.

Conclusions: Treatment of hyperkalemic metabolic acidosis with fludrocortisone resulted in rapid normalization of serum potassium. There were no adverse effects on BP, serum sodium levels or clinical evidence of fluid retention. Instigation of fludrocortisone prevented emergency admissions for treatment of hyperkalemia and allowed the clinicians to run adequate tacrolimus levels. Fludrocortisone can be a cheap, safe and effective option for the treatment of hyperkalemia in renal transplant patients on tacrolimus.
Changes in Serum Klotho in Kidney Transplant Recipients and Prognostic Marker for Allograft Function: A Systematic Review and Meta-Analysis

Juan A. Medrano,1 Charat Thongprayoon,2 Napat Leepatmon,3 Javier A. Neyra,1 Pradeep Vaitla,1 Franco H. Cabeza Rivera,1 Michael A. Mao,1 William C. Android1, Department of Internal Medicine, University of Mississippi Medical Center, Jackson, MS; 2Division of Nephrology and Hypertension, Department of Medicine, Mayo Clinic, Rochester, MN; 3Department of Medicine, Mayo Clinic, Jacksonville, FL; 4Division of Nephrology, Department of Medicine, University of Kentucky College of Medicine, Lexington, KY; 5Renal Transplant Program, University of Missouri-Kansas City School of Medicine/Saint Luke’s Health System, Kansas City, MO.

Background: α-Klotho protein is a well-known anti-aging factor that regulates systemic phosphate metabolism. Mutation of klotho in mice can lead to phenotypes resembling human aging. Since klotho expression is highest in the kidney, patients with advanced chronic kidney disease have progressive decline in klotho levels. However, changes in serum klotho levels in kidney transplant (KTx) patients and its prognostic significance on allograft function remain unclear.

Methods: A literature search was conducted using MEDLINE, EMBASE and Cochrane Database from inception through October 2019 to identify studies evaluating 1) change in serum klotho levels after KTx, 2) klotho levels among KTx vs non-KTx patients, and 3) prognostic significance of klotho levels on allograft function after KTx. Study results were pooled and analyzed utilizing random-effects model.

Results: 10 cohort studies with a total of 431 KTx patients were identified. After KTx, there was significant increase in serum klotho levels (at 4 to 13 months post-KTx) with mean difference (MD) of 243.11 (3 studies; 95%CI 67.41 to 416.81). Although KTx patients had lower serum klotho level with MD of = -234.50 (5 studies; 95%CI -444.84 to -24.16) compared to healthy volunteers, a study demonstrated comparable klotho level between KTx patients and eGFR-matched controls. Two studies demonstrated high serum klotho levels in deceased donors as prognostic marker for good allograft function within 1 year after KTx (p<0.05).

Conclusions: There is a significant increase in serum klotho levels after KTx. There is potential role of klotho levels as prognostic marker for renal allograft function.

Braving the Storm: Cytokine Release Syndrome with Rabbit Antithymocyte Globulin Therapy after Kidney Transplant

Himmat S. Brar, Franco H. Cabeza Rivera. University of Mississippi Medical Center, Jackson, MS.

Introduction: Cytokine release syndrome (CRS) is an acute systemic inflammatory syndrome associated with chimeric antigen receptor (CAR) T cell therapy or therapeutic antibodies. CRS can present with a variety of symptoms ranging from mild flu to severe life-threatening manifestations of shock, vascular leakage, DIC and multi-organ failure. We present a case of a CRS following rATG induction.

Case Description: A 29-year-old female with a history of T1 DM s/p kidney/pancreas transplantation 12 years ago experienced the rejection of transplanted kidney 1 year back. Her home immunosuppression included Tacrolimus, MMF and Prednisone. She underwent a kidney retransplant from a living donor. The induction immunosuppression consisted of rabbit anti-thymocyte globulin (ATG), methylprednisolone and MMF. Two hours after the rATG infusion (1.5 mg/kg) on day 1 of transplant; she developed breathing difficulty; temp of 102.7° R, RR of 25, HR of 160 and fall in BP to 108/55 mmHg. Lab work showed a drop of Hb from 11.4 to 9, platelets from 187 to 126 and WBC from 17 to 9.8. CXR was unremarkable. ECHO showed normal cardiac function. LE Doppler was negative for DVT. The patient was quickly diagnosed to have CRS and instead of giving fluids and causing pulmonary decompensation, she was given Solumedrol, Benadryl and Tylenol. rATG was discontinued. Cultures were obtained that resulted negative.

She improved within a couple of hours with stabilization of vital signs. We suspect that the CRS following ATG infusion caused the patient’s acute decompensation, given the temporal concordance. We believe that had we been more familiar with this presentation of CRS, we would have improved her outcomes.

Discussion: CRS is an inflammatory cascade that develops within minutes to hours after immunotherapy. The case emphasizes the successful rapid recognition and proper management of CRS in preventing the patient decompensation. The massive cytokine release triggers an inflammatory response leading to capillary leakage, severe hypotension and respiratory failure. The management differs from usual shock as the aggressive fluid lead to pulmonary edema. Steroids and pressors are the mainstay of therapy and should be administered early. The treatment is largely supportive with ventilation for respiratory failure and steroids for inflammation.

Proton Pump Inhibitor Prevalence and Documented Indication in a Small Kidney Transplant Program

Abdulrahman Alkandari, Frances Macleod, M. Khaled Shamseddin. Queen’s University, Kingston, ON, Canada.

Background: Proton pump inhibitors (PPIs) are commonly prescribed post kidney transplantation, and their use was prevalent in 44-48% of recipients. Prolonged exposure to PPIs could be associated with renal and non-renal adverse outcomes, including hyperkalemia and hip fracture (OR: 1.39, 95% CI: 1.04-1.84). The objective of this report is to evaluate the prevalence and the documented indication of PPI use in our kidney transplant program, while exploring the potential PPI withdrawal and GERD recurrence in a future Quality Improvement (QI) project.

Methods: This is a retrospective study to assess the prevalence and the documented indications of PPI use among all of kidney transplant recipients in our program by March 31st, 2020. The primary variables were the prevalence of PPI use and the percentage of patients with documented indication of PPI use in our Health Information System (HIS).

Results: Out of 202 kidney transplant recipients, 113 (55.9%) patients were on PPIs (Mean age 58 years, Male 68 (60.2%), mean post-transplant longevity 106 months), compared with 12 (5.9%) patients on H2 blockers. Thirty three (29.2%) patients who used to be on H2 blockers were switched to PPI in late 2019 due to contaminated and backordered ranitidine resulting in an adjusted prevalence of PPI use of 39.3% (Figure 1).

The indication of PPI use was documented in our HIS as gastro-esophageal reflux disease (GERD) in 53 (46.9%) patients, and as peptic ulcer disease (PUD) in 9 (8%) patients, while its indication was undocumented in 51 (45.1%) patients.

Conclusions: PPI use was prevalent among our kidney transplant recipients similar to other studies. Due to its association with multiple adverse outcomes, better documentation of its indication in the medical record is required. Consideration to withdraw PPI in our kidney transplant recipients and to reassess the risk of GERD recurrence will be assessed in a future QI project.
A Case of Porphyria Cutanea Tarda After Kidney Transplant

The University of Utah School of Medicine, Salt Lake City, UT.

Introduction: Porphyria cutanea tarda (PCT) is the most common subtype of porphyria and can be associated with kidney failure with reports of kidney transplantation curing the disease. We report the case of a patient who had previously undergone kidney transplantation and developed PCT after transplant.

Case Description: A 40-year-old man with end stage renal disease due to unknown chronic glomerulonephritis status post kidney transplant 4.5 years ago was admitted with non-healing blisters on both hands. Patient initially presented one month earlier with similar symptoms and was diagnosed with bullous impetigo due to methicillin resistance staphylococcus aureus. At that time, he was treated with vancomycin followed by trimethoprim-sulfamethoxazole (TMP-SMX) for a total of 14 days. He was also noted to have cysteineglucar violina which was treated with valganciclovir. Patient reported ongoing development of lesions despite antibiotic treatment and presented for follow-up where he was noted to have an acute kidney injury and hyperkalemia. At presentation his medications included mycophenolate sodium, tacrolimus, prednisone, triamcinolone cream and mupirocin ointment. There was no family history of skin disease and he did not drink alcohol. He underwent skin biopsy which was consistent with porphyria or pseudoporphyrhia. Urine and plasma porphyrins were checked showing elevated uroporphyrin and also elevate heptacarboxyl, hexacarboxyl and pentacarboxyl porphyrins with normal coproporphyrin I and III consistent with PCT. Additional workup was notable for a ferritin of 978 ng/mL, hepatitis A, B and C titers inconsistent with current or past infection and HFE gene testing showing the absence of mutations C282Y, H63D and S65C. Patient’s kidney injury resolved with cessation of TMP-SMX and fluid resuscitation. Patient was treated with therapeutic phlebotomy and erythropoiesis stimulating agents along with counseling on sunscreen use and wearing sun protective clothing.

Discussion: PCT is the most common form of porphyria and is associated with hepatitis C, iron overload, estrogen administration and alcohol use. It has also been associated with hemodialysis often with resolution at the time of kidney transplantation. However, elevated iron stores are often present in kidney transplant patients and PCT can be misdiagnosed as bullous impetigo as it was in this case.

PO2587

Recurrent Focal Segmental Glomerulosclerosis After Kidney Transplantation: A Single-Center Experience

Muhammad Ajmal Panezai, Priya Yenebere, John K. Guirguis, Dennis P. Mishler, Oluwafisayo O. Adebiyi, Muhammad S. Yaqub, Tim E. Taber, Asif A. Sharifuddin.
Indiana University School of Medicine, Indianapolis, IN.

Background: Recurrent FSGS (rFSGS) after Kidney Transplantation has a high risk of graft loss. However, the natural history, clinical predictors, and response to treatment remain unclear.

Methods: We retrospectively reviewed all transplant patients at our institution from 2000-2019 with a diagnosis of FSGS and identified and sub-analyzed all cases of recurrent FSGS cases (r-FSGS).

Results: Out of 198 transplants, there were 22 (11.1%) events of biopsy proven r-FSGS. Demographics of the rFSGS cases are described in the Table. 27% of cases had recurrence within 1 month of transplant. Treatments given for r-FSGS included ACE/ARB (100%), Therapeutic Plasma Exchange (40.9%), Rituximab (36.3%), conversion to Cyclosporin (36.3%) and Steroids (27.2%). 65% of cases had either a partial or complete remission. Mean proteinuria decreased by 75% in those who responded. 31.8% of patients were re-transplanted after initial graft loss (p<0.05). Over a median follow up period of 4.6 years, there was a 59% graft remission. Mean proteinuria decreased and mean eGFR was improved at 1 year of follow up (p<0.05).

Conclusion: r-FSGS continues to be a high risk for graft loss despite a high rate of remission. Recurrence risk is increased with r-FSGS in kidney transplant patients and should be closely monitored with follow up for recurrence.

PO2588

What Is the Safe Anti-A2 Titer for a Successful A2-Incompatible Kidney Transplantation?

Montefiore Medical Center, Bronx, NY.

Background: The new kidney allocation system implemented in December 2014 allowed for use of A2/AB donors to B recipients. However there is no mandate by UNOS regarding what anti-A2 titers are acceptable. We aimed to investigate the safety of kidney transplant in patients with anti-A2 titers equal or less than 1/16.

Methods: We performed 41 A2-incompatible kidney transplants at our institution if pre transplant anti-A2 titers are equal or less than 1/16. All patients received anti-thymocyte globulin induction. Patients with donor-specific-anti-HLA-antibodies (DSA) received intravenous immunoglobulins.

Results: Of the 41 recipients, 85% were male, 48% African-American, with a median age of 53 (20-73) years. There were 38 deceased donor renal transplants and 3 living related. Median donor age was 42 (16-65) and median KDPI was 52 (2-86). Twenty-one patients had PRA 0% and 8 had pre transplant DSA. Pretransplant anti-A2 titers were 1/2 in 16, 1/4 in 9, 1/8 in 6, and 1/16 in 5 and too weak to titer in 5 recipients. During a median follow-up of 33 months (6-57) patient and graft survival were 100% and 90.2% respectively. Twelve patients underwent a clinically indicated kidney biopsy at a median 28 days post transplant (6-190). There was one case of acute T cell mediated rejection type IIA, and one chronic antibody-mediated rejection which was due to non-compliance leading to graft loss. Interestingly C4d positivity was seen in 9 biopsies, of which 8 did not have any findings of antibody mediated rejection and no microvascular inflammation. Median serum creatinine level at last follow up was 1.3 mg/dL (0.6-3.2) and only 3 patients had spot urine protein/creatinine more than 1 g/day.

Conclusions: A2-incompatible transplant appears to be safe in patients with anti-A2 titers equal or less than 1/16 with or without DSAs and excellent short-term kidney allograft outcomes. C4d positivity is frequent in allograft biopsies without acute rejection suggesting accommodation to the allograft.

PO2589

Post-Transplant Outcomes for Highly Sensitized Kidney Transplant Recipients with Non-Highly Sensitized Recipients in the Era of the New Kidney Allocation System: A Single-Center Case-Control Comparison

Gaurav Agarwal,1,2 Darnell Mompoint-Williams,1,2 Song C. Ong,1,2 Jayme E. Locke,1,2 Viniceta Kumar,1 University of Alabama at Birmingham
1The University of Alabama at Birmingham, Birmingham, AL; 2The University of Alabama at Birmingham Comprehensive Transplant Institute, Birmingham, AL.

Background: The new UNOS kidney allocation system (KAS) of December 2014, gives substantial priority points to highly sensitized (HS) adult kidney transplant recipients (KTR) with cPRA of 99% or higher. There is a concern of worse post-transplant outcomes in HS KTR compared to non-HS KTR. When comparing pre-KAS to post KAS, similar 3-year patient and graft survival has been reported in HS KTR. The comparative outcomes of HS KTR to non-HS KTR in the post KAS era are unknown.

Methods: We studied outcomes in HS adult kidney transplant recipients (KTR) and compared them to non-HS KTR in the post KAS era. We included all recipients of deceased donor kidney transplant at the University of Alabama at Birmingham, from December 2014 to March 2020. HS patients were defined as those with cPRA 99% or higher. The HS patients were matched 1:2 with non-HS patients on age, sex, and time of transplant. A Kaplan Meier analysis was performed for patient survival and the combined endpoint of graft and patient survival.

Results: A total of 717 deceased donor kidney transplants were performed during the study period, of which 106 HS KTR were identified. There is a concern of worse post-transplant outcomes in HS KTR compared to non-HS KTR. When comparing pre-KAS to post KAS, similar 3-year patient and graft survival has been reported in HS KTR. The comparative outcomes of HS KTR to non-HS KTR in the post KAS era are unknown.

PO2590

Deceased Donor Kidney Transplantation: A Single-Center Experience

Montefiore Medical Center, Bronx, NY.

Background: The new kidney allocation system implemented in December 2014 allowed for use of A2/AB donors to B recipients. However there is no mandate by UNOS regarding what anti-A2 titers are acceptable. We aimed to investigate the safety of kidney transplant in patients with anti-A2 titers equal or less than 1/16.

Methods: We performed 41 A2-incompatible kidney transplants at our institution if pre transplant anti-A2 titers are equal or less than 1/16. All patients received anti-thymocyte globulin induction. Patients with donor-specific-anti-HLA-antibodies (DSA) received intravenous immunoglobulins.

Results: Of the 41 recipients, 85% were male, 48% African-American, with a median age of 53 (20-73) years. There were 38 deceased donor renal transplants and 3 living related. Median donor age was 42 (16-65) and median KDPI was 52 (2-86). Twenty-one patients had PRA 0% and 8 had pre transplant DSA. Pretransplant anti-A2 titers were 1/2 in 16, 1/4 in 9, 1/8 in 6, and 1/16 in 5 and too weak to titer in 5 recipients. During a median follow-up of 33 months (6-57) patient and graft survival were 100% and 90.2% respectively. Twelve patients underwent a clinically indicated kidney biopsy at a median 28 days post transplant (6-190). There was one case of acute T cell mediated rejection type IIA, and one chronic antibody-mediated rejection which was due to non-compliance leading to graft loss. Interestingly C4d positivity was seen in 9 biopsies, of which 8 did not have any findings of antibody mediated rejection and no microvascular inflammation. Median serum creatinine level at last follow up was 1.3 mg/dL (0.6-3.2) and only 3 patients had spot urine protein/creatinine more than 1 g/day.

Conclusions: A2-incompatible transplant appears to be safe in patients with anti-A2 titers equal or less than 1/16 with or without DSAs and excellent short-term kidney allograft outcomes. C4d positivity is frequent in allograft biopsies without acute rejection suggesting accommodation to the allograft.
The matched controls had a median cPRA of 0% (IQR 0-29.5%). There was no difference in death (p=0.17) or combined endpoint of death or graft survival (p=0.35) in the two groups (figure 1).

**Conclusions:** HS patients have similar mortality and graft survival as compared with non-HS controls. The results of our study support continuing to give HS patients priority in organ allocation.

**PO2591**

**Who Is at Risk for a Transplant Nephrectomy After Graft Loss?**

Peter E. Thorne, Everly Ramos, Laura Binari, Gunnet S. Kochar, Thomas G. Stewart, Rachel C. Forbes, Saed Shawar, Anthony J. Langone, Khaled Abdel-Kader, Beatrice P. Concepcion. Vanderbilt University Medical Center, Nashville, TN.

**Background:** Patients with failed kidney transplants who subsequently develop clinical symptoms such as fever, allograft pain and gross hematuria usually require a transplant nephrectomy to alleviate symptoms. Identifying patients at risk for a nephrectomy after graft loss may aid clinical decision-making and care at time of, and after graft loss.

**Methods:** We retrospectively reviewed all patients with death-censored graft loss (DCGL) from 1/1/2000 to 6/2018 at a single center. We collected baseline demographic and clinical characteristics at time of transplant, at time of, and after DCGL by manual chart abstraction. Data were analyzed using summary statistics. Predictors for nephrectomy were determined a priori. A Cox proportional hazards model was used to quantify the association of age, race, gender, body mass index (BMI) at time of graft loss, diabetes, acute rejection as cause of graft loss, and use of prednisone with the risk of nephrectomy.

**Results:** The study included 333 patients with DCGL of whom 75 (23%) underwent a transplant nephrectomy. Median (IQR) time from graft loss to nephrectomy was 135 (70, 267) days. Among 292 patients without missing data, baseline and transplant characteristics were as follows: age at transplantation 45 (36, 57), 59% male, 40% black, 20% diabetic, 53% with a deceased donor, 83% on calcineurin-based immunosuppression (CNIs), 71% on prednisone. Twenty-four percent and 69% of patients lost their graft due to acute rejection and chronic allograft nephropathy, respectively. At the time of DCGL: BMI was 25.9 kg/m² (22.7, 31.4), SCR 7.5 mg/dl (5.6, 9.6), albumin 3.3 (3.0, 3.8), 86% on CNIs, 91% on prednisone. In the Cox model, black race was associated with more than twice greater risk of nephrectomy compared to non-blacks (HR 2.4, 95% CI 1.3-4.3, p=0.01). Older age had a trend for decreased risk of nephrectomy (HR 0.98, 95% CI 0.951-1.0, p=0.06) but this did not reach statistical significance.

**Conclusions:** Transplant nephrectomies are common after graft loss and black race is associated with increased risk. Closer monitoring of these patients after graft loss may be warranted. Strategies and interventions to reduce the need for nephrectomy warrant further study.

---

**PO2593**

**Evaluation of Reproductive Care Provided to Adolescent Patients in Pediatric Nephrology Clinics**

Shyanne Helley,1 Noel Howard,1 Salem Almamani,1 Isabelle Ayoub,1 Michelle A. Hladunewich,1 Michelle M. OSaughnessy,3 Shikha Wadhwani,4 Jarcy Zee,5 William E. Snoyer,2 Scott E. Wenderfer,4 Katherine Twombley,5 Tetyana L. Vasilyeva,1 Texas Tech University Health Sciences Center, Amarillo, TX;1The Ohio State University Wexner Medical Center, Columbus, OH;1University of Toronto, Toronto, ON, Canada;3University College Cork National University of Ireland, Cork, Ireland;4Northwestern University Feinberg School of Medicine, Chicago, IL;5Arbor Research Collaborative for Health, Ann Arbor, MI;1Nationwide Children’s Hospital, Columbus, OH;1Baylor College of Medicine, Houston, TX;5Medical University of South Carolina, Charleston, SC.

**Background:** An increasing number of adolescents are living with end-stage renal disease (ESRD) or chronic kidney disease (CKD) in the US. Therefore; it is important that nephrologists can manage reproductive and women’s health issues in adolescents with CKD. In this study, we aimed to determine the confidence levels of nephrologists in the US in managing women’s health issues in adolescent females with CKD.

**Methods:** Using Qualtrics Online Survey Platform, a survey was distributed by email to members of the Pediatric Nephrology Research Consortium. The survey contained 19 questions pertaining to provider demographics, training, current practice, frequency of documenting and/or discussing women’s health issues, and level of confidence in managing women’s health issues in adolescent female patients.

**Results:** Seventy-five nephrologists participated, with a majority practicing in academic centers (88%). For most providers, adolescents comprised 25-74% of all patients. Ninety-eight percent denied formal training in women’s health or obstetric nephrology. History of pregnancy termination/loss, last menstrual period (LMP), contraceptive use, sexual activity, number of sexual partners, and history of sexually transmitted infections were infrequently documented. Most providers documented discussions about risks of teratogenicity with use of ACEi/ARBs or mycophenolate and risks of infertility and fertility-preserving options with use of cyclophosphamide. Most providers weren’t comfortable managing pregnant adolescents and referred them to adult nephrologists. Most were uncomfortable discussing fetal risks with pregnancy in CKD. While most were confident discussing barrier methods, they were much less confident discussing oral contraceptives and long-acting reversible contraceptives (LARC’s).

**Conclusions:** Sexual development and pregnancy appear not to be a focus of nephrologists caring for adolescent females with CKD. Providers also appeared to have a low level of confidence in discussing and managing fertility and pregnancy-related issues in adolescents. Nephrology training needs to incorporate focused women’s health content to improve healthcare delivery to adolescent girls.
PO2594
Reproductive Health in Kidney Transplant Recipients
Andrea G. Kattah, Fernando G. Cosio, Vesna D. Garovic. Mayo Clinic Minnesota, Rochester, MN.

Background: Women with advanced chronic kidney disease develop menstrual irregularities and infertility that can improve after kidney transplant. However, some women do not have menstrual cycles return after transplant and pregnancy rates are lower than in the general population, which could be due to a combination of biologic and social factors.

Methods: We sent a survey on reproductive health to all women aged 18 to 44 at the time of transplant at all 3 Mayo Clinic sites between 1996 and 2014. We sent a second survey to all non-respondents from the first mailing and then called all remaining women to ask for their participation. We included questions on menstrual cycles, pregnancy, and menopause. Parity at the time of transplant was determined by chart review.

Results: There were 816 unique women, aged 18 to 44 at the time of transplant, in the period from 1996 to 2014. After excluding women who had passed away (n=10), there were 715 eligible women and 190 responded (26.6% response rate). Respondents were more likely to be white and to have had a pregnancy post-transplant. Only 10% of women reported a pregnancy post-transplant, though 14.2% reported actively pursuing pregnancy post-transplant. Nearly half (42.1%) of women said they were advised not to get pregnant, most often by a nephrologist. There were 61 pregnancies post-transplant, of which 80.1% were planned pregnancies. The majority of pregnancies resulted in livebirths (57%), and miscarriage occurred in 39% of pregnancies. Amnionrhea occurred in 34.2% of women pre-transplant, and 23% of these women did not have cycles return after transplant. The median (interquartile range) age of menopause was 44.5 (36-49) years.

Conclusions: While only 14.2% of respondents reported actively pursuing pregnancy after transplant, nearly half said they were advised not to pursue pregnancy, often by their nephrologists, which could in part explain low pregnancy rates in the kidney transplant population. While amnionrhea prior to transplant occurred in the minority of women, 23% of these women did not have menstrual cycles return post-transplant. Furthermore, the median age of menopause was much earlier than the general population. These findings suggest that kidney disease and/or transplantation itself may impact long-term gonadal function, which should be a target of future study.

PO2595
Menstrual Irregularities and Subfertility in Women with Glomerular Disease

Background: Women with CKD are known to have high rates of irregular menses and subfertility (an extended period of unwanted non-conception). Those with glomerular disease and/or vasculitis had high rates of menstrual irregularities and infertility that can improve after kidney transplant. However, some women do not have menstrual cycles return after transplant and pregnancy rates are lower than in the general population, which could be due to a combination of biologic and social factors.

Methods: A women’s health survey was distributed to women ages 18-65 in the Glomerular Disease Collaborative Network, a longitudinal research registry in the southeastern United States. Descriptive statistics were employed to assess responses.

Results: The survey was completed by 192 women (response rate 16%) with median age 48 (34-57 interquartile range(IQR)) and BMI 28 (24-35 IQR). The most common diseases were IgA nephropathy/vasculitis (22%), Lupus nephritis (20%), ANCA vasculitis (18%) and FSGS (16%). At the time of the survey, 17% had a kidney transplant or required dialysis. Table 1 describes self-reported menstrual cycle length and permanent cessation of menses by age group. Of those over age 45, 41% reported permanent cessation of menses had occurred at a 44 years old. Cyclophosphamide use was reported by 63 of 192 (33%), and their fertility preservation methods included leuprolide (6, 10%), and oocyte cryopreservation (1, < 2%). One in four women (50/192, 26%) reported a history of attempting to conceive for > 6 months without success. To aid conception, 26% (13/50) reported use of a medication (e.g. clomiphene) and 16% (8/50) underwent intrauterine insemination, in vitro fertilization, or received egg/sperm donation.

Conclusions: Women with glomerular disease and/or vasculitis had high rates of irregular menstruation and early menopause which may contribute to subfertility. Our data is limited as we do not know GFR, nor the timing or amount of cyclophosphamide prescribed. Response bias from women with a positive history may have also played a role. Future efforts should elucidate reproductive endocrinology utilization and success in this population.

Buffy Coat Methylation Is Representative of Methylation Patterns in White Blood Cell Types in Normal Pregnancy
Ronanie Ghamrawi,1 Natasa Milic,1,2 Sonja Suvakovic,1 Wendy White,1 Vesna D. Garovic.1 Mayo Clinic Minnesota, Rochester, MN; 2Medicinski fakultet Univerzitet u Beogradu, Belgrad, Serbia.

Background: Epigenetic changes through DNA methylation are increasingly identified in renal diseases and hypertensive disorders. Our previous studies identified an altered methylation pattern in preeclampsia compared to normotensive pregnancies. Epigenetic studies typically use buffy coat- a heterogenous cell population- that varies throughout pregnancy and could potentially interfere with DNA methylation results. The objective of the current study was to assess to what extent the buffy coat methylation is representative of the distinct cell types that it contains namely polymorphonuclear leukocytes(PMN) and lymphocytes(LYM) in normotensive pregnant women.

Methods: We performed a pairwise comparison of the differential methylation in the buffy coat, the polymorphonuclear fraction and the lymphocytic fraction drawn from the same individual in normotensive pregnant women (n=29) within the 24 hours prior to delivery. We analyzed 412481 cytosine-guanine (CpG) sites using an Illumina Human Methylation450 BeadChip.

Results: The three pairwise comparisons yielded a small number of probes that are differentially methylated. After multiple testing corrections, the smallest number of differentially methylated probes was found when comparing the buffy coat to the polymorphonuclear group (2.96%). Pathway analysis of the differentially methylated probes identified a matched process involved in leukocyte lineage. The differentially methylated CpG sites preferentially affected the open seas and shelf regions that have little effect on epigenetic regulation.

Conclusions: The buffy coat DNA methylation profile is representative of the PMN and LYM fractions on an Illumina Human Methylation450 BeadChip. The use of buffy coat is an acceptable approach for DNA sampling in DNA methylation studies and separation is only needed when studying lineage specific diseases.

PO2597
Pregnancy Outcomes in Women with AKI
Silvy Shah, Kathleen Harrison, Annette Christianson. University of Cincinnati, Cincinnati, OH.

Background: Acute kidney injury (AKI) during pregnancy is a public health problem and is associated with maternal and fetal morbidity and mortality. Literature concerning pregnancy outcomes in women with AKI is scarce.

Methods: We evaluated a retrospective single-center cohort of all women who delivered infants between 2012-2019 at our center (N=21,038) to assess the AKI rate and whether the history of AKI during pregnancy was associated with adverse maternal and fetal outcomes. Using multivariate logistic regression models, we determined factors associated with AKI, and associations between AKI and pregnancy outcomes.

Results: Overall, 109 deliveries were identified with AKI during pregnancy. AKI rate was 0.5%. The mean age of women was 28 years, 55% were black, and 36% were white: 25% had a history of diabetes and 24% had a history of hypertension. With regards to maternal outcomes, 46% had preeclampsia, 27% had gestational diabetes, 40% had gestational hypertension, and 57% had cesarean section deliveries. Maternal mortality was 4%. With regards to fetal outcomes, among women with AKI during pregnancy, 19% had preterm deliveries, the live birth rate was 85%, the stillbirth rate was 5%, and neonatal mortality was 5%. Diabetes and hypertension were associated with a higher adjusted likelihood of AKI during pregnancy (OR, 4.85; 95% CI, 2.87-7.50 and OR, 5.97; 95% CI, 3.63-9.80 respectively). In the adjusted model, AKI during pregnancy was associated with a 5.6-fold higher likelihood of preeclampsia (OR, 5.57; 95% CI, 3.70-8.39), 2.2-fold higher likelihood of cesarean section (OR, 2.21; 95% CI, 1.50-3.27), 2-fold higher...
likelyhood of preterm births (OR, 1.97; 95% CI, 1.22-3.16), 4-fold higher likelihood of stillbirths, & 43% term with 43% pre-term (5 born <34 weeks). 18 women (37%) had a rejection episode - mean time of 38.6±5.2 years. The physical exam, serum and urine studies suggested 3+ generalized edema. Her blood pressure improved with conservative treatment.

PO2600
Prepartum 1,3-Butanediol Supplementation Does Not Prevent Onset of Superimposed Preeclampsia in the Dahl S Rat
Jeanne A. Ishimwe, Michael R. Garrett, Jennifer M. Sassett. University of Mississippi Medical Center, Jackson, MS.

Background: Chronic hypertension increases the risk of developing superimposed preeclampsia (PE). Previous reports showed that 1,3-Butanediol (BD) lowers blood pressure (BP) in male Dahl salt sensitive (S) rats and female S SHR(S1). The goal of this study was to test if attenuating hypertension before pregnancy through the placentaion period via BD prevents the onset of PE and improves kidney function.

Methods: Female Dahl S rats (a spontaenous model of superimposed PE, 11-16 weeks old) were divided into two groups: BD treated (20% via drinking water) and control (ad libitum water). Animals received BD for 7 weeks, baseline BP measurements (telemetry) were taken, and both groups were then mated. On gestation day (GD) 12, treatment was stopped because pilot studies showed that treatment reduced water intake during late pregnancy. Both groups were maintained on normal rodent chow (Teklad 7014, 0.3% sodium; n-6 group). At GD18 (late pregnancy), urine antiproteinuric resistance index (UARI) was measured via Doppler ultrasound, 24h urine was collected on GD19, and tissues were harvested on GD20. Statistical comparisons between groups were done by Student t-test and repeated measures ANOVA used for BP analysis.

Results: Mean arterial pressure was lower in the treated group at baseline (141.9±4.0 vs. 165.7±4.53 mmHg, p=0.0076), early (135.9±3.42 vs. 168.9±4.55 mmHg, p=0.0003), mid (142.0±5.16 vs. 170.8±4.61, p=0.0048) but not late pregnancy (144.9±5.87 vs. 161.9±4.52 mmHg, p=0.1650). Treated dams had a lower UARI (0.71±0.02 vs. 0.81±0.02, p=0.0473), less frequent proteinuria (1.12±0.29 vs. 2.25±0.41, p=0.0343) but no differences in pug weight were observed (2.199±0.049 vs. 2.199±0.086, p=0.9938).

Proteinuria (39±8 vs. 32±7 mg/day, p=0.5401), blood urea nitrogen (21.0±7.5 vs. 22.7±0.78 mg/dL, p=0.2239), creatinine clearance (1.66±0.30 vs. 1.60±0.21 ml/min, p=0.9702), and renal fibrosis were similar (0.55±0.89 vs. 0.75±0.08 %, p=0.1382) were unaffected.

Conclusions: In this study, we observed slightly improved placental perfusion and lower fetal demise following prepartum BD treatment; however, the antihypertensive effects of BD were not maintained during late pregnancy when supplementation was stopped at mid-pregnancy. No improvements in renal function were noted.

PO2601
Low Nephrin Expression and Pregnancy-Related Renal Maladaptation in the Pathogenesis of Preeclampsia
Sara Cortiglio,1 Alessandra Bisti1,2 Giulia Genzono,1 Eugenio Ragazzi,1 Valentina Capone,1 Erich Cosmi,1 Gianluigi Ardissino,1 Pediatric Nephrology, Dialysis and Transplantation, Fondazione IRCCS Ca’ Granda, Ospedale Maggiore Policlinico, Milano, Italy; 2Dept. of Woman’s and Child’s Health, Obstetrical and Gynecological Clinic, University of Padova, Padova, Italy; 1Dept. of Pharmaceutical and Pharmacological Sciences, University of Padova, Padova, Italy.

Background: Pre-eclampsia (PE), whose pathogenesis is still unclear, complicates 2-8% of pregnancies and is responsible of significant maternal and/or perinatal morbidity and mortality. Given the following premises: 1.the high frequency of PE in renal patients of developing hypertension and CKD later in life; 5.the association between PE and chronic kidney disease, the goal of this study was to test if attenuating hypertension before pregnancy through the placentaion period via BD prevents the onset of PE and improves kidney function.

Methods: The authors reviewed data from pregnancies with delivery between January 1, 2015 and December 31, 2019. Potential pregnancies were identified with diagnostic codes for pregnancies and then included patients who had diagnostic codes for chronic kidney disease and proteinuria. Pregnancies that ended prior to 12 weeks of gestation, or were in the absence of documented proteinuria (3+ or 2+ urine protein) were excluded. Conception that resulted in termination of pregnancy were also excluded. Results: 39 women delivered 52 pregnancies. The mean age at delivery was 35.7 years (range 22-42 years). 36% of the women were nulliparous (34% pre-term born & 43% pre-term born). 18 women (37%) developed preeclampsia. There was one intrauterine death. 66% delivered by caesarean section. The mean birth weight was 2400±588 g, 24% were <10 percentile. Conclusions: Pregnancy outcomes in patients with transplants are better compared with those with dialysis(PMID. 27083278). However, complications still occur. The rate of preeclampsia (56%) is representative of the current literature & much higher than for women without transplants. Diagnosing preeclampsia in patients with pre-existing hypertension & proteinuria, as for many of our patients, remains challenging. In our experience, reflected here, there are relatively low rates of rejection & graft loss but high rates of obstetric complications. We believe these patients are ideally managed in a joint renal obstetric clinic.

PO2599
Does Nephrologist Involvement Improve Aspirin Prescribing in Pregnant Women with CKD?
Chritin M. Giordano McAlufife,1 Shelby A. Crants,1 Lynsa Nguyen,1 Lisa Zuckerverse,1 Anna M. Burgen,1 Vanderbilt University Medical Center, Nashville, TN; 1Vanderbilt University School of Medicine, Nashville, TN.

Background: Since 2014, the U.S. Preventive Services Task Force has recommended the use of aspirin beginning at 12 weeks gestation in women at high risk of developing preeclampsia including solitary kidney (CKD). A prior study at the authors’ institution revealed overall low prescribing rates for women with CKD with only 50.5% taking aspirin according to the recommended guidelines. The authors hypothesized that having a nephrologist involved in patient care would result in higher aspirin prescribing rates.

Methods: The authors reviewed data from pregnancies with delivery between January 1, 2015 and December 31, 2019. Potential pregnancies were identified with diagnostic codes for pregnancies and then included patients who had diagnostic codes for chronic kidney disease and proteinuria. Pregnancies that ended prior to 12 weeks were excluded. Mean age was 34±7.4 years. Mean parity was 1.6±0.9. Mean deviations, medians, and interquartile ranges were used for continuous variables and frequency. Proportions were used for categorical variables.

Results: In total, 91 pregnancies were included. The mean age at due date was 29.7 (std 5.3) with 20.9% being of advanced maternal age. The majority were obese (54.9%), with an overall mean BMI of 31.6 (std dev 8.8). During pregnancy, 64.8% (59/91) of patients with known CKD saw a nephrologist. In addition, 20.3% (12/59) of those with known CKD who had previously seen a nephrologist did not see one during pregnancy. Of those who saw a nephrologist during pregnancy, 50.8% (30/59) were prescribed aspirin. In patients who saw a nephrologist at any time before or after pregnancy, 52.1% were prescribed aspirin while of those who did not see nephrologist during pregnancy, 45% were prescribed aspirin. The odds ratio of receiving aspirin if seen by a nephrologist of 2.33 (6.09-7.89) was not statistically significant.

Conclusions: Nearly two-thirds of pregnant women with CKD saw a nephrologist during pregnancy. The involvement of a nephrologist did not significantly increase aspirin prescribing rates among pregnant women with CKD. Further studies should be done to assess attitudes and knowledge of nephrologists and obstetricians to better understand the reasoning for the low prescribing rates and to assess how to improve aspirin prescribing for preeclampsia risk reduction in pregnant women with CKD.

PO2602
Hyponatremia in Preeclampsia: A Diagnostic and Therapeutic Challenge
Nay Serif, Anand Srivastava. Northwestern University Feinberg School of Medicine, Chicago, IL.

Introduction: A 32-year-old female at 35-weeks gestation with twin pregnancy was admitted for hypertension, proteimuria, and hyponatremia (Figure 1A).

Case Description: She complained of nausea, blurred vision, and pain. Physical exam revealed 3+ generalized edema. Her blood pressure improved with conservative management, and medications controlled her nausea and pain. Figure 1B shows her hospital serum sodium trend. The physical exam, serum and urine studies suggested
Proteinuria in Early Pregnancy: Role of sFLT-1:PlGF Ratio

Nay Seif, Carla L. Ellis, Shikha Wadhwani. Northwestern University Feinberg School of Medicine, Chicago, IL.

Introduction: A 32-year-old nulliparous woman at 20 7/7 weeks gestation by in vitro fertilization was admitted for hypertension (HTN), proteinuria, and acute kidney injury. Exam was notable only for trace leg edema. Given nephrotic syndrome early in pregnancy and unremarkable hemolysis work-up (Figure 1A), there was concern for acute glomerulonephritis (GN). Renal biopsy showed signs of thrombotic microangiopathy (TMA) (Figure 1B) without evidence of immune-complex mediated GN. As Atypical hemolytic uremic syndrome (aHUS) and Preeclampsia (PEC) were both on the differential, serum was tested for sFLT-1 and PlGF. Based on emerging evidence of alternative complement pathway activation in PEC, Eculizumab use was discussed but not pursued due to uncertain fetal viability, even with pregnancy prolongation. Ultimately, patient chose to terminate the pregnancy and subsequent pathology review revealed maternal vascular malperfusion and early intrauterine fetal demise. Levels of sFLT-1 (95,228 pg/ml), PlGF (139.3 pg/ml), and sFLt-1: PlGF ratio (683.6) were all consistent with severe PEC (Figure 1C). At 2-month follow-up, proteinuria had resolved and HTN was controlled with Nifedipine.

Discussion: Patients presenting with nephrotic syndrome and hypertension ≥ 20 weeks gestation pose a diagnostic dilemma. Renal biopsy is necessary to distinguish PEC from GN but pathological diagnosis of TMA can lead to persistent diagnostic uncertainty. Measurement of circulating angiogenic factors can be useful, with sFLT-1:PlGF ratio > 38 supporting a diagnosis of PEC. Further validation and widespread availability of such testing is needed to assist in management of early pregnancy complications.

Hyponatremia in pregnancy may be due to antidiuretic hormone (ADH)- dependent factors, such as “reset” osmostat, diffuse vasodilatation, nausea, and pain. Administration of oxytocin, which is structurally similar to ADH, can also reduce serum sodium. In preeclampsia, hyponatremia may occur due to decreased effective circulating volume secondary to antiangiogenic factors or nephrotic syndrome, non-osmotic release of ADH with consequent water retention, or SIADH. Worsening hypertension with end organ damage are severe features of preeclampsia often requiring emergent delivery, but severe hyponatremia is often overlooked as a severe feature. This case illustrates that patients with preeclampsia may develop severe hyponatremia, which improves after delivery. Refined guidelines should consider severe hyponatremia and its management in preeclampsia.

Hypertension: Treatment of Severe Hypertension

PO2604

Hyperemesis Gravidarum-Induced Acute Tubular Necrosis: A Case with More Than Fivelfold Rise in Serum Lipase Level Above the Upper Limit of Normal

Samira Z. Chandra,1 Bruna Taveras Garcia,2 Belinda Jim,2 Bangladesh College of Physicians and Surgeons, Dhaka, Bangladesh; 2Jacobi Medical Center, Bronx, NY; 3Dhaka Medical College and Hospital, Dhaka, Bangladesh.

Introduction: Hyperemesis gravidarum (HG) occurs in 0.3 to 10 percent of pregnancies with only 0.8 percent requiring hospitalization. HG usually starts in 4th to 6th week of gestation, peaks around 9th week and fades away between 16th to 20th gestational weeks. In some cases, HG may last until the third trimester. Here we are reporting such a case which was associated with serious complication like acute renal failure. Co-incidentally the patient was also found to have serum lipase level 5 times above the upper limit of normal (ULN). Since HG exerts multisystemic manifestations, the unusual pattern of raised serum lipase is often due to associated renal impairment. Case Description: A 25-year-old primigravida at 16th week of gestation was admitted for severe dehydration and acute kidney injury (S. Creatinine 5.1 mg/dl). She was suffering from HG since the beginning of her pregnancy. A month prior to this admission, the patient was hospitalized on multiple occasions for extreme nausea and blood-tinted vomiting. Her initial labs were suggestive of high anion gap metabolic acidosis (anion gap 31.9mmol/L). Urine electrolytes (Na+<20mEq/day, K + 29mEq/day, Cl - <20mEq/day) with FeNa+ > 3% and S. creatinine >5 mg/dl. Patient’s HG persisted until 34th week of gestation when symptom subsided completely without medication. Discussion: In acute pancreatitis, the sensitivity and specificity of serum lipase above the ULN range 64%-100% and 99%-100% respectively. More than 3-folds rise of serum lipase above the ULN can also be seen in a variety of other conditions including renal failure. Even in 15% cases of HG with normal renal function, serum Lipase can rise by 5-folds. Therefore, clinical and biochemical co-relation is necessary to rule out acute pancreatitis in pregnancy.
PO2605
Outcomes of Delivery Hospitalizations Among Pregnant Women with Kidney Transplant in the United States

Api Chewcharat, Andrea G. Kattah, Charat Thongprayoon, Wistis Cheungpasitporn, Booniphop Boonpheng, Maria Lourdes Gonzalez Suarez, Jasmina Craici, Vesna D. Garovic, Mayo Clinic Minnesota, Rochester, MN; Mount Auburn Hospital, Cambridge, MA; University of Mississippi Medical Center, Jackson, MS; University of California Los Angeles, Los Angeles, CA.

Background: Outcomes of delivery hospitalizations, including acute kidney injury, obstetric and fetal events among pregnant women with kidney transplants (KT) compared to those with no known kidney disease and chronic kidney disease (CKD) stage 3-5 are unclear.

Methods: Hospitalizations for delivery were identified using the enhanced delivery identification method in the National Inpatient Sample dataset from the years 2009 to 2014. Diagnoses of CKD stage 3-5, KT along with obstetric events, delivery methods, and fetal events were identified using ICD-9-CM diagnosis and procedure codes. Logistic regression accounting for the survey weights and matched regression were conducted to investigate the risk of maternal and fetal complications in women with KT as compared to women with no kidney-related diagnosis and compared to women with CKD stage 3-5.

Results: A total of 5,408,215 hospitalizations resulting in delivery were identified, including 405 women with CKD stage 3-5, 295 women with functioning KT, and 5,405,499 women with no kidney diagnosis. Pregnant KT recipients were at higher odds of pregnancy-induced hypertension (OR = 3.11, 95%CI [2.26, 4.28]), preeclampsia/eclampsia/HELLP syndrome (OR = 3.42, 95%CI [2.54, 4.60]), preterm delivery (OR = 2.46, 95%CI[1.75, 3.45]), fetal growth restriction (OR = 1.74, 95%CI [1.01, 3.00]), and acute kidney injury (OR = 10.46, 95%CI [5.33, 20.56]) as compared to women with no kidney-related diagnosis. There were no significant differences in rates of gestational diabetes and cesarean section. Pregnant women with KT had 1.30-time longer length of stay and 1.28-time higher cost of hospitalization. However, pregnant women with CKD stage 3-5 were at higher odds of AKI, preeclampsia/eclampsia/HELLP syndrome and fetal death, and had longer hospital stay and cost of hospitalization compared to pregnant women with KT.

Conclusions: Pregnant women with KT were more likely to experience adverse events during delivery when compared to women with no known kidney disease. However, pregnant women with advanced CKD were more likely to experience serious complications than KT recipients. Women with advanced CKD who wish to conceive might consider conception after transplantation for better pregnancy-related outcomes.

PO2606
Successful Pregnancy in a Patient with Congenital Renal Dysplasia After Initiation of Dialysis

Jennifer C. Tang, Annika K. Khine, University of Southern California Keck School of Medicine, Los Angeles, CA; Los Angeles County University of Southern California Medical Center, Los Angeles, CA.

Introduction: Chronic kidney disease (CKD) is a well-known risk factor for adverse maternal and fetal outcomes including preeclampsia and fetal growth restriction. For those on dialysis, increasing the frequency and duration of dialysis has shown to optimize outcomes. However, it remains unclear if and when pregnant patients with CKD should start dialysis to improve outcomes. We present a patient with congenital renal dysplasia who successfully gave birth after starting dialysis.

Case Description: A forty-one-year-old female with an intrauterine pregnancy of 25 weeks and a history of two miscarriages, preeclampsia, and congenital renal dysplasia presented to nephrology clinic. Patient was unaware of her kidney dysfunction and had residual renal function with a creatinine of 3.76 and urine pr/cr ratio of 1.18. A fetal ultrasound revealed a fetal weight in the 12th percentile, head circumference in the 2nd percentile, and biparietal diameter (BPD) in the 33rd percentile. Therefore, the patient started daily dialysis with longer sessions to optimize fetal outcomes. A repeat ultrasound two weeks later revealed interval growth with a fetal weight in the 24th percentile and BPD in the 45th percentile but with abnormal umbilical artery Doppler findings, confirming the diagnosis. In addition to dialysis, the patient underwent plasmapheresis and immunosuppression with pulse dose steroids followed by a steroid taper as well as azathioprine and tacrolimus. The patient remained inpatient receiving daily hemodialysis until 26 weeks 0 days when the patient developed uncontrollable hypertension requiring an emergent cesarean section. The patient gave birth to a live male weighing 1.1 kg. Her post-partum course was uncomplicated, though the patient remains dialysis dependent.

Discussion: Initiation of dialysis resulted in significant interval fetal growth and this patient’s first viable infant. Further research is warranted to assess if starting dialysis earlier in pregnant patients with CKD may improve fetal outcomes.

PO2607
The Ethics of Caring for Pregnant Patients with CKD: A Scoping Review

Elizabeth M. Hendren, Michelle A. Hladunewich, Ariel Lefkowitz, University of Toronto, Toronto, ON, Canada.

Background: Physicians must consider many ethical principles when managing patients with chronic disease before and during pregnancy. An ethical framework could guide joint decision making between physicians and their patients, but does not currently exist.

Methods: We performed a scoping literature review to explore the ethical considerations associated with pregnancy in patients with chronic disease. We searched for articles published between 1975 and 2019 using the terms “Ethics” and “High risk Pregnancy/Pregnancy” along with 29 chronic disease-specific MeSH terms (e.g. scleroderma, diabetes, cystic fibrosis).

Results: We identified 968 articles and excluded 947 based on their title or abstract. 12 full text articles were included in the final scoping review representing discussions, case reports, and literature reviews on the ethics of high-risk pregnancy in 8 chronic diseases. The extracted data were examined and integrated into analyses of clinical cases in order to develop recommendations for ethically caring for this patient population.

Conclusions: Physicians have an ethical duty to their patients to facilitate autonomous decision-making and informed consent. Secondary, they have a duty to protect the fetus and to use resources judiciously as long as it does not negatively impact the care they provide to their patient.

PO2608
Anti-Glomerular Basement Membrane Disease in Pregnancy

Fahad A. Lodhi, Peter E. Umukoro, Syed Sajjad, Rebecca Blonsky, Marshfield Clinic Health System, Marshfield, WI; Indiana University School of Medicine, Indianapolis, IN.

Introduction: Anti-glomerular basement membrane antibody (anti-GBM) disease is a rare cause of renal failure due to the production of IgG antibodies against type IV collagen. Its occurrence during pregnancy is even less common and can lead to poor maternal and fetal outcomes.

Case Description: A 23-year-old female with history of depression presented at 15 weeks 3 days gestation with weakness, nausea and vomiting for one week and anuria for 24 hours. Labs were significant for a creatinine of 19.8 mg/dL, BUN 113 mg/dL and potassium 7.1 mmol/L. Labs six months prior were normal. Nephrology was consulted and the patient was transferred to the intensive care unit for urgent hemodialysis. Further serologic investigation revealed elevated anti-GBM antibodies. A kidney biopsy was performed which demonstrated 100% cellular crescents on light microscopy and linear deposits on immunofluorescence, confirming the diagnosis. In addition to daily hemodialysis, the patient underwent plasmapheresis and immunosuppression with pulse dose steroids followed by a steroid taper as well as azathioprine and tacrolimus. The patient returned to the hospital with hypoxic respiratory failure due to parainfluenza virus further complicated by pre-term premature rupture of membranes at 24 weeks 4 days. As the patient had no signs of renal recovery, her immunosuppression was discontinued. The patient remained inpatient receiving daily hemodialysis until 28 weeks 0 days when the patient developed uncontrollable hypertension requiring an emergent cesarean section. The patient gave birth to a live male weighing 1.1 kg. Her post-partum course was uncomplicated, though the patient remains dialysis dependent.

Discussion: The treatment of choice in anti-GBM disease is plasmapheresis to remove circulating antibodies and immunosuppression to reduce antibody production. However, pregnancy presents a unique challenge in choosing immunosuppressive agents as both maternal and fetal effects need to be considered. The involvement of high risk obstetricians as well as nephrologists in the care of these patients is imperative to ensure the best possible outcomes.
PO2609
Identification of Renal Disease in Women with Hypertensive Pregnancies
Hayley Martin,1 Henry A. Kibble,2 Kieran R. Palmer,1 Emmanueln2 Kountouris,3
Amelia M. Holloway,1 Kate Bramham,1,2 Katherine R. Clark.1,2 1King’s College
Hospital NHS Foundation Trust, London, United Kingdom; 2King’s College
London School of Lifecourse Sciences, London, United Kingdom.

Background: Hypertension in pregnancy can be associated with renal injury, which
may be masked by gestational change. Additionally, pregnancy affords an opportunity
to diagnose asymptomatic renal disease. Postpartum assessment enables detection of
on going renal abnormalities. We aimed to determine prevalence of renal disease in
postpartum women with chronic hypertension, pregnancy induced hypertension or pre-
eclampsia in a previous or current pregnancy.

Methods: Women with singleton pregnancies seen in a specialist clinic for
hypertension with estimated GFR (CKD-EPI) below 90mls/min/1.73m2 and/or proteinuria
at six-weeks postpartum were offered specialist renal midwifery clinic follow-up.

Results: 143/341 women offered follow-up attended renal clinic (Median 185 (IQR
246.25) days after delivery). 82 (57.3%) women had proteinuria and/or low eGFR.

Conclusions: Over half of women with proteinuria and/or reduced eGFR at six weeks
postpartum had sustained evidence of renal disease regardless of hypertensive diagnosis.
Postpartum assessment may afford an opportunity to detect renal disease.

Senescence Markers in Women with Preeclampsia Pregnancies
Sonja Suwak,1 Ranine Ghamrawi,1 Hailoa Tu,2 Wendy White,1 Natasa Milic,1
Joseph P. Grande,1 Vesna D. Garovic.1 1 Mayo Clinic Minnesota, Rochester, MN; 2 The First Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China.

Background: Preeclampsia, a hypertensive disorder of pregnancy, is characterized by increased angiogenesis and inflammation. Data indicate that preeclampsia is mechanistically related to cellular senescence, an irreversible cell arrest mechanism which has been increasingly associated with accelerated aging. The aim of this study was to determine if senescence plays a role in the pathophysiology of preeclampsia. To that end, we compared SASP components in blood and fat tissue sections between preeclamptic and normotensive patients.

Methods: Blood samples from preeclamptic and normotensive patients at the time of delivery were used to study circulating senesence-associated secretory phenotype (SASP) components. Plasma SASP components were tested using Luminex 200 system. Fat and kidney tissue samples.

Results: Significant increase of senescence markers were found in blood of preeclamptic pregnancies for NGF (1.30±0.82 vs. 0.77±0.19, p=0.032), MCP1 (3169.5±163.95 vs. 207.53±84.78, p=0.047), TNFa (2.79±1.08 vs. 2.06±0.64, p=0.043) and Pai1 (58.03±18.85 vs. 38.12±20.86, p=0.023). Similarly, significant increase in senescence markers was found in preeclamptic pregnancies for MCP1 and TNFalpha. Expression of p16 was significantly increased in fat tissue, whereas the difference in p21 expression between preeclamptic and normotensive patients was not observed. Expression of p16 in preeclamptic renal sections was significantly higher (p=0.02) than in sections from normotensive pregnancies.

Conclusions: Women with preeclampsia have higher senescent burden compared to normotensive pregnant women at the time of delivery. Senolytic agents that target senescence may offer the opportunity for mechanism-based therapies.

PO2611
Sexual Dimorphism and Hard Outcomes in AKI: Is Female Sex Protective? The Jury Is Still Out
Maria Isabel Acosta-Ochoa, Armando Coca, Jimmy R. Sanchez Gil, Alicia Mendiluce. Hospital Clinico Universitario de Valladolid, Valladolid, Spain.

Background: Many studies focus on sex dimorphism and it’s influence on hard outcomes when suffering an AKI episode. Some report that women, while others report that men are protected against adverse clinical events. In a real world cohort of individuals suffering from AKI, we compared hard outcomes between sexes with a novel approach: paired-match study.

Methods: Retrospective paired-match study of in-patients with AKI diagnosis; cases were matched based on sex, age and Charlson’s Index. We used KDIGO-2012 criteria to define AKI, analyzed clinical variables, and compared the hard outcomes: length of hospital stay, need for acute HD, HD dependence at discharge, and in-hospital mortality.

Results: We included 438-paired matches. Male individuals suffered from peripheral arterial disease and COPD, and were hospitalized in surgical wards more frequently than women. We found no statistically significant difference between groups regarding to the prevalence of common comorbidities and admission to ICU (Table 1A). The distribution in global KDIGO-AKI Stages was similar, but when analyzing every sub-criterion of the classification we found that women fulfilled the serum creatinine (SCr) increment a1.5-1.9x more frequently, and men fulfilled reaching a SCr >4 mg/dl more commonly. We found no statically significant differences in hospital stay, need for acute HD, HD dependence at discharge, and in-hospital mortality (Table 1B).

Conclusions: To our knowledge, a paired-match designed research topic to this has not been previously published. Although experimental studies find differences in clinical outcomes between sexes when suffering an AKI episode, in this real world study, we did not observe a clear distinction in the incidence of adverse outcomes between sexes. We conclude that sex (either female or male) may not be protective against AKI’s hard outcomes.
PO2612
Effects of Veverimer on Serum Bicarbonate and Physical Function in Women with CKD: A Subgroup Analysis from a Randomized Controlled Trial
Vandana S. Mathur,1 Donald E. Wesson,2 Navdeep Tangri,1 Yuri Stasiv,1 Dawn Parsell,1 Elizabeth Li,1 Gerrit Klaerner,1 David A. Bushinsky,1 Mathur Consulting, Woodside, CA; 2Baylor Scott & White Health and Wellness Center, Dallas, TX; 3University of Manitoba, Winnipeg, MB, Canada; 4Tricia, Inc., South San Francisco, CA; 5PharmaStat LLC, Fremont, CA; 6University of Rochester Medical Center, Rochester, NY.

Background: More women than men have CKD. However, women have been under-represented in clinical trials. Veverimer is an orally administered, non-absorbed polymer that treats metabolic acidosis by binding and removing HCl from the GI tract. In Phase 3 randomized, double-blind, placebo-controlled trials, veverimer significantly increased serum bicarbonate and improved physical function in acidic patients with CKD (Wesson et al. Lancet, 2019). Here we analyzed efficacy and safety among the women in these studies of up to one year.

Methods: Physical function was assessed using the Kidney Disease and Quality of Life Physical Function Domain (KDQOL-PFD) which quantifies limitations on daily activities and by performance on the repeated chair stand (RCS) test.

Results: Of the 217 pts randomized, 83 (32%) were women, of whom 81% were post-menopausal (≥55 yrs). Select comorbidities included hypertension (95%), diabetes (64%), and congestive heart failure (30%). At Baseline, mean eGFR in women was 28.4 mL/min/1.73m² and mean serum bicarbonate was 17.3 mEq/L. More women receiving veverimer met the primary study endpoint, had a significant increase in serum bicarbonate and improved both KDQOL-PFD scores and RCS time (Table) compared with placebo. The effects of veverimer exceeded the minimal clinically important difference for both KDQOL-PFD (+3 to +5 points) and RCS (-1.7 seconds). Rates of serious, non-serious and GI adverse events were similar in the groups; none required treatment discontinuation.

Conclusions: Given their lower bone and muscle mass, women with CKD may be particularly vulnerable to the adverse effects of metabolic acidosis. We found that in women with CKD and metabolic acidosis, treatment with veverimer significantly improved how women felt and functioned. The safety of veverimer was similar to placebo.

P-values are vs. placebo; An ANCOVA rank-based method was used for physical function endpoints

*Based on evaluable patients enrolled in controlled extension study (placebo, n=31; veverimer, n=46)

PO2613
Dietary Intake Trace, Risk of Kidney Stone, and Survival in the Women’s Health Initiative (WHI)
Harshitha Kota,1 Xuerong Wen,2 Chao Chen,3 Jie Tang,1,4 Brown University, Providence, RI; 2University of Rhode Island, Kingston, RI; 3University of Florida, Gainesville, FL; 4Brown Urology Brown Physicians Inc, Providence, RI.

Background: The effect of dietary intake (DMI) on the risk of stone is controversial, and its effect on survival among kidney stone formers is unknown.

Methods: We examined participants enrolled in WHI, a prospective, longitudinal, multicenter study investigating the health of postmenopausal women, and used Cox regression analyses to determine the independent effects of DMI on the risk of incident kidney stone and survival amongst the stone formers.

Results: 145,942 participants were identified free of kidney stone history at baseline. 83% were Caucasian, mean age was 63. Among them, 6024 (4%) developed incident kidney stone during 1,601,750 person-years of follow up. The mean daily DMI was 318 mg, with 26% in tertile 1 (241 mg), 41% in tertile 2 (241-348 mg) and 33% in tertile 3 (>348 mg). The incidence of kidney stone disease was 3.1, 3.3, and 3.9 per 1000 person-year in high, moderate and low DMI groups, respectively. The corresponding multivariable-adjusted hazard ratios were 0.82 (95% CI: 0.71-0.94) for high vs low DMI when dietary oxalate intake (DOI) is high, and 1.01 (95% CI: 0.81-1.26) for high vs low DMI when DOI is low. Among incident stone formers, 82% were Caucasian, 23% were above age 70. Mean daily DMI was 304 mg, 32% in tertile 1, 38% in tertile 2, and 30% in tertile 3. Subsequently, 1346 (22%) died. Older age, histories of hypertension, diabetes and heart disease, low serum vitamin D, cigarette smoking; and hormone replacement association significantly with mortality, p<0.05. However, DMI had no impact on mortality after adjusting for demographics and potential confounding factors, hazard ratio (HR) 0.91, 95% CI 0.73-1.14, p=0.4 when compared high DMI vs low DMI groups, HR 0.90, 95% CI 0.73-1.11, p=0.3 when compared medium DMI vs low DMI groups.

Conclusion: Our study suggests that higher DMI is associated with lower risk of incident kidney stone disease and this effect is modified by DOI. DMI does not appear to affect survival among post-menopausal women with incident kidney stone disease.

PHUB001
Consequences of Improper Interpretation of ANCA
Aswin Srinivasan,1 Sanjeeta Mutnuri,1 Shabbir Safri,2 Mahendra L. Agraharkar,2,12 University of Texas Medical Branch at Galveston, Galveston, TX; 2Baylor College of Medicine, Houston, TX; 1University of Houston, Houston, TX; 2HCA Gulf Coast Division, Houston, TX; 3Montefiore Hospital and Medical Center, Montefiore Medical Center, Bronx, NY; 4Creighton University, Omaha, NE.

Introduction: Antineutrophil cytoplasmic antibodies (ANCA) is important in suspected vasculitis. False positive or atypical ANCA (A-ANCA) can lead to erroneous interpretation of immunofluorescence (IF) causing disastrous consequences. We present a patient who was initially reported as Perinuclear-ANCA (P-ANCA) positive and was therefore treated with steroids, presented to the ER with dizziness, bradycardia and hypotension. He was weak, fatigued, and unarousable. In the ER, he was started on vasopressors and methylprednisolone. His creatinine rose from 2.6 to 3.1 mg/dL. RPGN was suspected and kidney biopsy was performed that demonstrated diffuse membranous glomerulopathy, due to presence of neutrophils and fibrin clumps. His AM cortisol level was 3 ug/dL (10-20). Because of hypotension, polyuria and natriuresis, hydrocortisone and fludrocortisone were started. His serum K level decreased and fludrocortisone was stopped. Over next few days, he became normotensive and his hemoglobin improved with increased dose of hydrocortisone. Hypokalemia slowly resolved with potassium supplements.

Discussion: ANCA are a group of antibodies that bind to antigens of neutrophils, causing systemic vascular inflammation. These autoantibodies can be found in the serum of patients with systemic, systemic, small vessel vasculitis and is a biomarker for ANCA-associated vasculitis. A positive staining of ANCA can be classified as: Cytoplasmic, Perinuclear, and Atypical, based on the pattern of IF. In cases with C-ANCA, the staining is diffuse throughout the cytoplasm and the cause of staining is due to antibodies directed against Proteinase 3 (PR3). In cases with P-ANCA, the staining is around the nucleus and it is due to antibodies directed against myeloperoxidase (MPO). A-ANCA can be found in conditions other than vasculitis and does not require immunosuppressive steroids for treatment. A-ANCA can be reported erroneously as P-ANCA or C-ANCA and patients can receive aggressive treatment with high dose steroids. Therefore, we suggest to confirm the ANCA results with MPO or PR3 before initiating aggressive therapy for vasculitis to avoid disastrous consequences.

PHUB002
Lymphoma of a Normal Kidney Size
Lavath Al Attar, Taqii Khaja, Jingjin Yan. Baylor College of Medicine, Houston, TX.

Introduction: Renal injury has been reported in the setting of hematopoietic neoplasms. The kidneys can be affected by a variety of mechanisms such as acute tubular necrosis (ATN), paraneoplastic glomerulopathy, and lymphocytic infiltration of kidney parenchyma (LKP). Diagnostic evaluation is important in differentiating mechanism of kidney injury, which will affect management and prognosis. LKP is suggested with clinical findings of bilateral kidney enlargement, acute kidney failure (AKI), or proteinuria.

Case Description: 50-year-old male with new diagnosis of high-grade lymphoma found to have severe kidney failure. Initial work up was unable to explain the underlying process of kidney failure. The patient was managed with volume replacement to alleviate the pre-renal component. Kidney ultrasound had no evidence of enlargement. Kidney function worsened over days and a decision to initiated dialysis was determined. After establishing dialysis access, kidney function demonstrated an improvement trend without dialysis initiation. Kidney biopsy revealed infiltration by atypical lymphoid cells consistent with the Double-Hit Diffuse Large B-Cell Lymphoma (DLBCL). Patient’s kidney function spontaneously recovered. Patient was discharged with plan to start chemotherapy as an outpatient.

Discussion: Our patient was diagnosed with DLBCL. This type of lymphoma accounts for approximately 25 percent of all Non-Hodgkin Lymphomas in the developed world. Clinical presentation of renal involvement includes AKI, proteinuria, or enlarged kidneys on imaging studies. Location of lymphocytic infiltration determines the extent of renal injury and whether interstitial or glomerular. Renal involvement incidence is 2% at time of diagnosis. Extramedullary renal involvement is diagnosed either by biopsy or imaging. Renal involvement can be diagnosed by imaging in 65% of patients. Cases presenting with AKI of interstitial type of lymphomatous infiltration show bilaterally enlarged kidneys about 65% of patients. Renal involvement with non-Hodgkin’s lymphoma remains uncommon. The presence of acute renal failure, proteinuria, or enlarged kidneys should be suspicious of lymphocytic infiltrate of the kidneys. Nevertheless, absence of radiologic changes or proteinuria, similar to our patient, should not rule out kidney involvement. We recommend a low threshold for kidney biopsy to assist in the diagnosis of renal lymphocytic infiltration.
Eventually decreased to 30 mg/dl and Cr to 1.26 mg/dl. Including bicarbonate and her cognitive function improved without dialysis. Her BUN normal bilateral kidney sizes. Patient was aggressively resuscitated with intravenous fluid usage was present. Laboratory results were significant for BUN of 298 mg/dl, Creatinine (Cr) of 13.5 mg/dl, serum potassium of 5.4 mEq/L, phosphate of 6.1 mEq/L and severe hyperlipidemia, alcohol use disorder, chronic kidney disease (CKD) with baseline high BUN in acute kidney injury. Treatment for uremia. However, there is no consensus on when to initiate the dialysis for other causes and is confirmed with a renal biopsy. Measures to prevent AKI include using sucrose-free IVlg or amino-acid-stabilized formulations, adequate hydration, avoiding other nephrotoxins and diuretics, reductions in dose, concentration (<5%), and/or rate of administration (<3mg sucrose/kg/min) of IVlg.

**Case Description:** A 64-year female with history of hypertension, hypothyroid, hyperlipidemia, alcohol use disorder, chronic kidney disease (CKD) with baseline creatinine of 1.5 mg/dl was admitted for head trauma after fall. Patient had poor intake and was confused and unresponsive to medical therapy or gradually enlarging hematoma with worsening hypertension associated with Page kidney. Persistently elevated blood pressure unresponsive to medical therapy or gradually enlarging hematoma with worsening renal functions might require percutaneous drainage, capsulotomy or even nephrectomy. Optimal medical management of Page kidney includes medications targeting the RAS pathway.

**Introduction:** Metabolic Encephalopathy due to AKI in a Patient with Recent Infusion of Intravenous Immunoglobulins (IVlg) Sheikh Raza Shalzad, Kelly H. Beers. Albany Medical Center, Albany, NY.

**Introduction:** IVlg induced AKI is extremely rare (1% of cases). We present a case of AKI requiring hemodialysis secondary to recent IVlg administration.

**Case Description:** A 61-year-old woman presented with acute onset altered mental status (AMS) for 2 days. Her past medical history included CKD G3, HTN, COPD, PVD, and CAD. A week prior, she received 3 doses of sucrose-containing IVlg for chronic inflammatory demyelinating polyneuropathy. Shortly thereafter, the patient developed a facial rash, poor oral intake, low urine output, and AMS. Labs showed BUN 71 mg/dL, SCr 10.62 mg/dL, baseline Scr 2.6 mg/dL. ABG showed pH 7.07, pCO2 30 mm Hg and HCO3 8 mmol/L. Toxicology screen was negative, CPK and lactic acid were normal. No NSAIDs use was reported. She required only 1 session of hemodialysis with the recovery of renal function and mental status. AIN due to IVlg and/or IVlg induced osmotic nephropathy to be the culprit for her presentation.

**Discussion:** IVlg can produce adverse reactions thought to be caused by activation of the complement cascade by the aggregation of IgG. To avoid this, a variety of stabilizing agents, including sucrose, are used. Sucrose is absorbed into proximal convoluted tubular cells and is followed by water due to the changed osmotic pressure. This results in cytoplasmic vacuolization and degeneration of the proximal cells. CKD, HTN, DM, advanced age, dehydration, hyperviscosity, use of sucrose stabilizers, high dose IVlg therapy (400–2000 mg/kg), high rate of IVlg administration, or treatment with other nephrotoxic medications increase the risk of AKI. About 30% of cases require dialysis. The mortality rate is 10%. Adverse renal outcomes usually occur within 10 days of initiation of IVlg, and the duration of renal failure lasts between 3 and 45 days. Most cases resolve spontaneously. Early recovery of renal function can be achieved by dialytic removal of sucrose from the circulation. To make a diagnosis of AIN, a renal association protocol should be established with the administration of IVlg. A clinical diagnosis is made after ruling out other causes and is confirmed with a renal biopsy. Measures to prevent AKI include using sucrose-free IVlg or amino-acid-stabilized formulations, adequate hydration, avoiding other nephrotoxins and diuretics, reductions in dose, concentration (<5%), and/or rate of administration (<3mg sucrose/kg/min) of IVlg. 

**A Patient with a Record High Blood Urea Nitrogen Value Surviving Without Dialysis** Hay Me Me, Urvashi Hooda, Aditi A. Sen, Amol Mittal, Michael Connery. Westchester Medical Center, Valhalla, NY.

**Introduction:** The blood urea nitrogen (BUN) has limited value as an index of glomerular filtration rate to access kidney function. It can be increased not only in the setting of acute or chronic renal failure but also in hypovolemic state, gastrointestinal tract bleeding, high catabolic states, and by certain medications. Dialysis is the effective treatment for uremia. However, there is no consensus on when to initiate the dialysis for high BUN in acute kidney injury.

**Case Description:** A 64-year female with history of hypertension, hyperthyroidism, DM, COPD, PVD. She had been on 3 doses of a sucrose-containing IVlg for chronic inflammatory demyelinating polyneuropathy. Shortly thereafter, the patient developed a facial rash, poor oral intake, low urine output, and AMS. Labs showed BUN 71 mg/dL, SCr 10.62 mg/dL, baseline Scr 2.6 mg/dL. ABG showed pH 7.07, pCO2 30 mm Hg and HCO3 8 mmol/L. Toxicology screen was negative, CPK and lactic acid were normal. No NSAIDs use was reported. She required only 1 session of hemodialysis with the recovery of renal function and mental status. AIN due to IVlg and/or IVlg induced osmotic nephropathy to be the culprit for her presentation.

**Discussion:** IVlg can produce adverse reactions thought to be caused by activation of the complement cascade by the aggregation of IgG. To avoid this, a variety of stabilizing agents, including sucrose, are used. Sucrose is absorbed into proximal convoluted tubular cells and is followed by water due to the changed osmotic pressure. This results in cytoplasmic vacuolization and degeneration of the proximal cells. CKD, HTN, DM, advanced age, dehydration, hyperviscosity, use of sucrose stabilizers, high dose IVlg therapy (400–2000 mg/kg), high rate of IVlg administration, or treatment with other nephrotoxic medications increase the risk of AKI. About 30% of cases require dialysis. The mortality rate is 10%. Adverse renal outcomes usually occur within 10 days of initiation of IVlg, and the duration of renal failure lasts between 3 and 45 days. Most cases resolve spontaneously. Early recovery of renal function can be achieved by dialytic removal of sucrose from the circulation. To make a diagnosis of AIN, a renal association protocol should be established with the administration of IVlg. A clinical diagnosis is made after ruling out other causes and is confirmed with a renal biopsy. Measures to prevent AKI include using sucrose-free IVlg or amino-acid-stabilized formulations, adequate hydration, avoiding other nephrotoxins and diuretics, reductions in dose, concentration (<5%), and/or rate of administration (<3mg sucrose/kg/min) of IVlg.

**Transient Anuric AKI Secondary to Parkinson Disease** Sabine Karam, Saint George Hospital University Medical Center, Beirut, Lebanon.

**Introduction:** Parkinson’s disease is a progressive neurodegenerative disease with diverse motor and neuropsychiatric manifestations. At the urological system level, it can cause neurologic dysfunction of the bladder but to our knowledge, no dysfunction of the upper collecting system has been described so far.

**Case Description:** A 67-year-old Lebanese female with a PMH of Parkinson’s disease, HTN, DL, DM II, HF, CKD (1.7), Hypothyroidism, recurrent pyelonephritis and nephrolithiasis was admitted on multiple occasions with a chief complaint of “decreased urination”. Physical examination showed no general abnormalities & the patient was afebrile. Upon each admission, a Foley catheter was inserted but with no urine output as she had an empty bladder. Adequate IV fluid hydration did not improve her urine output.

The anuria would resolve after a few days with no clear explanation. Renal Scintigraphy using MAG3 technique along with furosemide was performed twice, seven days apart, the first away from an anuric episode and the second during. The first study showed slow cortical emptying into the collecting system but with complete emptying after furosemide while the second study showed accumulation of the tracer in the cortex with minimal spontaneous excretion into the collecting system even after addition of furosemide. There was no evidence of mechanical obstruction or vascular etiology in both studies.

An abdominal CT showed no hydronephrosis or evidence of obstructive uropathy. An abdominal MRI showed third spacing and small atrophic kidneys with cortical scarring but no hydronephrosis, calculi, masses, or retroperitoneal fibrosis. The patient had her PD medications optimized and the frequent, mild severity of the anuria resolved.

**Discussion:** Our findings allow us to speculate that Parkinson’s disease could cause neurogenic dysfunction of the upper collecting system that manifests by episodes of intermittent anuria leading to acute kidney injury.

**Introduction:** Page kidney or Page phenomenon refers to compression of the renal parenchyma by subcapsular hematoma. Here we report the first case of spontaneous Page phenomenon in a native pelvic kidney.

**Case Description:** A 64-year-old male with a diagnosis of diabetes mellitus, essential hypertension, chronic kidney disease stage 3b, stage 3 obesity with a body mass index of 53, congenital right-sided pelvic kidney, presented to the emergency room with acute onset, severe right lower quadrant abdominal pain. Patient denied having any recent trauma and had no urinary or gastrointestinal complaints. He was not on any antplatelet or anticoagulation medications. CT angiogram of the abdomen and pelvis was performed which demonstrated a subcapsular hematoma around the right pelvic kidney. He had AKI with a peak creatinine of 4.2 mg/dl, from a baseline of 2.2 mg/dl. He remained non-oliguric, with gradual improvement of his renal functions and never required renal replacement therapy or any intervention for Page kidney. He presented with markedly elevated blood pressure of 190/110 mmHg and his hospital course was significant for sustained elevated blood pressure requiring addition of four new anti-hypertensive medications by discharge. Subsequent imaging showed marked decrease in the subcapsular hematoma in a week.

**Discussion:** Page phenomenon is a rare but potentially fatal condition that can result from trauma, tumor, vasculitis, renal cyst rupture, or procedures like kidney biopsy. External compression of renal parenchyma can result in intrastitial edema, tubulointerstitial nephritis and compression of intrarenal vessels thus activation of renin angiotensin system (RAS), resulting in AKI and hypertension associated with Page kidney. Persistently elevated blood pressure unresponsive to medical therapy or gradually enlarging hematoma with worsening renal functions might require percutaneous drainage, capsulotomy or even nephrectomy. Optimal medical management of Page kidney includes medications targeting the RAS pathway.

**Cholesterol Crystal Embolism with End-Stage Renal Failure and Refractory Gastric Ulcers After Abdominal Angiography** Naoki Yamamoto, Koichi Sato, Hisayuki Ogura, Taro Miyagawa, Shinji Kitajima, Tadashi Toyama, Akinori Hara, Yasunori Iwata, Norihiko Sakai, Miho Shimizu, Takashi Wada. Department of Nephrology and Laboratory Medicine, Kanazawa University, Kanazawa, Japan.

**Introduction:** Cholesterol crystal embolism is a systemic disease with various clinical manifestations after intraarterial interventions and vascular surgeries. Here we report a case complicated with acute kidney injury requiring hemodialysis and refractory gastric ulcers after transfemoral angiography of celiac and superior mesenteric arteries.

**Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only** Underline represents presenting author.
Case Description: A 78-year-old male with coronary artery disease, hypertension, hypercholesterolemia, and sleep apnea developed acute respiratory distress syndrome caused by septic shock. He underwent urgent tracheostomy, hemodialysis, and mechanical ventilation due to worsening respiratory failure. His hospital course was complicated by the development of hypertension, hyperglycemia, and sepsis. On the 10th day of hospitalization, he underwent tracheostomy and was weaned off ventilator support. His condition improved, and he was discharged home with follow-up appointments scheduled.

Discussion: This case highlights the importance of early recognition and aggressive management of sepsis in elderly patients with multiple comorbidities. Early use of antibiotics, timely initiation of mechanical ventilation, and close monitoring of vital signs and laboratory parameters are crucial in improving outcomes. Further research is needed to develop more effective strategies for managing elderly patients with sepsis.
The classic triad of rash, fever, and eosinophilia occurs in <10% of patients, and onset acute interstitial nephritis (DI-AIN) represents 20% of patients with unexplained AKI. Hematological disorders, autoimmune diseases and cancer in <5% of cases. Drug-induced vessel vasculitis with dapsone being the drug of choice. EED has been associated with 2VA Greater Los Angeles Healthcare System, Los Angeles, CA

AKI in a Patient with Erythema Elevatum Diutinum
Mrunalini Sarkar,1,2 1University of California Los Angeles, Los Angeles, CA; 2VA Greater Los Angeles Healthcare System, Los Angeles, CA.

Introduction: Erythema elevatum diutinum (EDD) is a rare cutaneous small vessel vasculitis with dapsone being the drug of choice. EED has been associated with hematological disorders, autoimmune diseases and cancer in <5% of cases. Drug-induced acute interstitial nephritis (DI-AIN) represents 20% of patients with unexplained AKI. The classic triad of rash, fever, and eosinophilia occurs in <10% of patients, and onset may be delayed by weeks or months after drug initiation.

Case Description: 55-year-old male with history of EDD admitted for infected lower extremity lesions. Vital signs and remainder of physical exam was normal. Patient was on dapsone in the past for over 10 years, however, in the last 6 months was not taking any medications. Vancomycin, zosyn and dapsone 200mg BID were started on admission. By day 3 only dapsone was continued as imaging was without evidence of deep infection. On day 4 he developed AKI, creatinine (Cr) 4.44mg/dL from 0.7mg/dL on admission. Labs also included Hb of 8.8g/dL, WBC 9.2 k/uL with 5% eosinophils, ESR 118mm/hr. Urinalysis with 3 wbc/hpf, UPCr of 0.18 and urine microscopy showed 1-2 WBC casts/LPF. Serum immunofixation revealed IgA-kappa in the beta region and a faint IgA- kappa monoclonal protein in the gamma region. Autoimmune and infectious serologic work-up negative. Dapsone was stopped on day 5 and renal biopsy was performed due to ongoing rise in Cr on day 8. Biopsy confirmed diffuse interstitial nephritis with prominent eosinophilic inflammation along with low grade membranous nephropathy favoring secondary, PLA2R negative. Patient started on IV solumedrol followed by oral prednisone taper over 6 weeks. Creatinine improved to 1mg/dL at 3 month follow-up.

Discussion: DI-AIN was attributed to dapsone. Despite withholding this medication, the CRI continued to rise prompting renal biopsy. Studies suggest that early corticosteroid initiation is associated with better outcomes and be considered in patients with no prior kidney dysfunction. In patients with suspected DI-AIN where a biopsy cannot be performed, a trial of empiric steroid therapy may be considered. The finding of secondary membranous nephropathy (MN) was unexpected as to date there has not been any reports of renal disease and EDD. We report a case of secondary MN in a patient with EDD now undergoing a full malignancy investigation.

PUB014

AKI from Tubular Bleeding from Rivaroxaban (XARELTO)
Aamir Zuberi,1 Fatima Zuberi,2 Nahia A. Syed,3 Mariessa L. Henderson,1 Safi Ahmad,4 Hafsa Zuberi,5 1Aamir Zuberi MD PA, Decatur, TX; 2University of Texas at Austin, Austin, TX; 3University of Texas Southwestern Medical Center at Dallas, Dallas, TX; 4Wake Forest University, Winston-Salem, NC; 5Texas Tech University System, Lubbock, TX.

Introduction: Anticoagulation induced acute kidney injury

Case Description: 68-year-old male with history of 7kg weight gain in the preceding 3-4 wks & fatigue. History of CAD, COPD and Pulmonary Embolism treated with Rivaroxaban Exam essentially negative except for edema Creatinine 8.4, ultrasound negative, previous creatinine normal, UA positive for blood & protein Dialysis initiated. All serologies negative IVF filter was placed, anticoagulation stopped, and kidney biopsy performed Biopsy showed diffuse intratubular red blood cells, red cells casts, acute tubular epithelial injury, mild interstitial fibrosis, few eosinophils and negative for crescents or vasculitis (images shown below) On follow-up, Pt regained kidney function in 2 months and creatinine remained normal at 1 year

Discussion: Warfarin related nephropathy is a rare but well-recognized phenomenon, which has also been reported with other anti-coagulation like Dabigatran (Pradaxa), however has not been reported with Rivaroxaban (Xarelto). Warfarin related nephropathy (WRN) and acute kidney injury is sometimes caused by excessive anticoagulation. A biopsy is needed to confirm this condition. Pathogenesis of anticoagulant related nephropathy is glomerular injury, obstruction of renal tubules by RBC casts, and tubular epithelial injury. Histologically, WRN and the biopsy from the patient receiving Rivaroxaban appeared very similar.
PUB015
Misleading Serologies in Thrombotic Microangiopathy due to Malignant Hypertension
tauqif khaja, rajevegh rathavan, william f. glass, carl p. walther. 'baylor college of medicine, houston, tx; university of texas health science center at houston, houston, tx.

introduction: nephrologists use autoimmune panels to screen for glomerular disease. some of these markers cause false positives in other systemic diseases which leads to misdiagnosis. we report a rare case of false positive mpd-anca and ana in patient with thrombotic microangiopathy (tma) due malignant hypertension.

case description: a 65 year old african american patient with a history of hypertension, breast cancer s/p right mastectomy, and ckd with baseline creatinine of 1 was admitted hypertensive urgency with pressures of 239/123. she had acute kidney injury with creatinine of 6.6 and her work-up revealed new pericardial effusion, thrombocytopenia (platelets of 90), and anemia (hemoglobin of 9). autoimmune panel was positive for ana (1:520, speckled) and positive rnp (>8). the presumptive diagnosis was mixed connective tissue disease. pericarditis was negative for malignancy and infections. she began dialysis but her renal function never improved. she was discharged dialysis dependent. the patient refused outpatient dialysis and her medications. she was re-admitted few weeks later with uremia and hypertensive urgency with pressures of 299/104. a repeat evaluation showed a newly positive mpd-anca (13.4), ana (1:640, speckled), and a low c3 (72.8). given the concern for vasculitis, a kidney biopsy was performed. her biopsy was significant for global glomerulosclerosis, interstitial nephritis, and severe interstitial fibrosis with tubular atrophy. there was extensive arteriolar onion skin intimal fibroplasia with red blood cell fragments. based on her clinical history, patient had tma secondary to hypertension. her biopsy lacked findings of vasculitis due to an absence of necrotizing crescentic glomerulonephritis and negative immunofluorescent stains. the patient was maintained on hemodialysis and hypertension medications.

discussion: diseases associated with tma can have false positive autoimmune markers and they require early recognition. there are cases that show thrombotic thrombocytopenic purpura can produce mpd-anca and anti-dna markers. the markers were correlated to intensity of the disease because the patients with active disease had higher titers. these markers are created secondary to immune dysfunction during tma. this case also emphasizes the importance of kidney biopsy in order to distinguish between active vasculitis and non-vasculitis diseases.

PUB016
AKI, Diplopia, and Altered Psyche: One Rare Case of Extrapolmonary Sarcoidosis
hillary derose-caldag, western reserve health education, youngstown, oh.

introduction: sarcoid is a multi-organ system disease primarily affecting the lungs. pathological diagnosis requires the presence of non-caseating granulomas. sarcoidosis is a genetic associated autoimmune disease more prevalent in african americans. renal sarcoidosis manifests in about 5-20% of patients with hypercalcemia, hypercalciuria, and nephrocalcinosis on normal screening. renal parenchymal involvement is typically granulomatous tubulointerstitial nephritis. neuro-sarcoid also occurs in about 1% of patients, affecting primarily the cranial nerves. cns involvement can present with visual and occasionally behavioral changes. ocular sarcoid presentations include uveitis and retinal lesions.

case description: 63-year-old white male with a history of rheumatoid arthritis, pulmonary nodules, glaucoma, presented with one year of blurry vision and weird psyche. he was referred to nephrology after an ophthalmologist found intermittent diplopia, transient optic disc swelling and intraretinal hemorrhage. abnormal labs from 5/2019 to 11/2018 in parenthesis: scr 2.73 (1.51 mg/dl), bun 27 (22), egfr nna 28 (49ml/min), ser calcium 8.6 (9.2 mg/dl) ace7 3/u/l, alce 5.4. given the worsening ckd fi, the following were drawn: ana-ifa: positive, speckled pat 1:640, ua ibd 10, fgran cast: 0-5, crs gran cast 0-5, ur prot rad 24. renal biopsy demonstrated noncaseating granulomatous interstitial nephritis, numerous noncaseating granulomas with giant cells. he was referred to cleveland clinic sarcoid clinic and started on 40mg prednisone for renal sarcoid. cxr with prior nodules, no hilar or parenchymal changes. cc ophthalmology clinic’s fundus exam revealed peripheral hypo-pigmented lesions possibly consistent with ocular sarcoid. vision had resolved. at 1 month, steroids were tapered with plans to start azathioprine. the patient’s ser improved on tapering steroids.

discussion: less than one in ten patients present solely with extrapolmonary sarcoidosis. this case demonstrates a rare presentation of neuro-ocular and renal sarcoidosis in the absence of lung findings. sarcoidosis ought to be considered in akI or new chronic kidney disease, particularly if a patient presents with other atypical findings such as retinal or optic nerve changes representing a syndrome of multi-organ involvement. multiple system involvement is a predictor of progression to esrd. glucocorticoids are first-line therapy. most cases respond to steroids.

PUB017
Dynamics of Tissue Injury mRNA Expression to Bilateral Renal Ischemia-Reperfusion Injury
samuel j. pfaff, toni l. richards, kenneth minor, yan zhong, craig f. plato, kristopher kuchenbecker. 'silver creek pharmaceuticals, san francisco, ca; 'plato bio/pharma, inc., westminster, co.

background: acute kidney injury (aki) secondary to acute renal ischemia is associated with high morbidity and mortality with few effective treatments. the bilateral renal ischemia-reperfusion injury (bri) model is commonly employed in rodent studies of akI. while disease progression is well characterized at the organism level, the dynamics of the molecular responses are less well understood. to improve the translational potential of compounds, the current study sought to temporally and mechanistically define the tissue a expression profiles following discrete durations of iri.

methods: rats underwent sham or warm, bilateral renal ischemia (30’ or 40’) surgery using pbi’s proprietary vascular clamps. subsets of rats were sacrificed at 8 timepoints following reperfusion (0-48hr), with blood and kidneys harvested at each timepoint for subsequent analyses. plasma was prepared and stored for the measurement of cytokines via clinical chemistry. the expression of 100 mRNA transcripts surveying genes across apoptosis, kidney injury, and inflammation/bibrosis pathways were measured by quanitgene.

results: plasma creatinine, the classical index of renal dysfunction in aki was ischemia- and reperfusion time-dependently increased upon inception of reperfusion. concomitantly, kidney injury and inflammation genes were upregulated early (~4hr) and remained elevated compared to shams throughout study duration. upregulation of pro-apoptotic genes occurred adhr post-reperfusion, indicating the initiation of programme cell death. last, pro-fibrotic genes were upregulated 24-48hr post-reperfusion indicating onset of remodeling. the information content provided by each mRNA expression profile and clinical parameter was determined using a novel statistical framework to identify measures best able to distinguish disease state over 48hr of reperfusion.

conclusions: this study demonstrated the temporal dynamics of response to renal irI in rats. the early injury phase (~4hr) was defined by mild, but significantly increased plasma creatinine indicating promptly reduced renal function along with upregulated injury response genes. induction of pro-apoptotic and pro-fibrotic genes occurred during the late phase, in line with biphasic changes in exacerbated renal function. our novel statistical method identified “high information” genes/parameters that can serve as reliable, mechanistic indicators of akI in future studies.

PUB018
Antioxidant Ameliorates Pulmonary Renal Injury in an Experimental Model of COVID-19 Organ Failure
firoozeh farahmand, saint louis university, saint louis, mo.

background: since the outbreak and rapid global spread of COVID-19 multi-organ involvement has largely influenced progression and severe akI has been an ominous clinical predictor with high mortality. the hyperinflammatory response of the body, associated with oxidative stress is a key player in mechanism of multiple organ failure.

methods: in an experimental model of multiple organ failure of Covid 19 similar to human disease with single injection of Toxoid (TOX) rats were treated with antioxidant curcudodil started daily 1wk pre-TOX-injection and continued for 1 wk post-TOX-injection. At 1-week post-injection in both TOX+ antioxidant and TOX groups lungs wet/dry weight ratios were measured to assess edema and lungs and kidneys from both group were analyzed for antioxidant enzyme activities including superoxide dismutase, glutathione peroxidase, catalase and oxidative stress. after sacrificing the animals, kidney and lung were removed for histology.

results: antioxidant treatment attenuated TOX induced lung and kidney injury and there was histopathological evidence of its beneficial effects. this was associated with decreased oxidative stress and increased activities of SOD and GSHPs in the lung and the kidney.

conclusions: in this experimental model that mimics human Covid 19 multiorgan failure, antioxidant improved survival, lung and kidney injury and also oxidative stress in the kidney. this suggest the beneficial effects of antioxidant as a kidney–lung protective strategy in patients with COVID-19.

PUB019
SRP14 Regulated Renal Tubular Apoptosis Induced by Ischemia-Reperfusion Injury via Interaction with RPS7
yun tang, yanniei wang, guisen li, li wang, yi li. department of nephrology, school of medicine, sichuan academy of medical science and sichuan provincial people’s hospital, university of electronic science and technology of china, chengdu, china.

background: akI could easily progress to CkD with increased incidence and mortality. due to the complex pathogenesis, there is a lack of effective early warning to intervene in akI.

methods: we performed lFQ proteomic analysis in Hk, renal tubular epithelial cells after H2O2 exposure and find SRP14 as a novel target to prevent akI upon apoptosis in renal tubular epithelial cells. this study will further study the role and mechanism of SRP14 in regulating MDM2-p53 pathway in apoptosis of renal tubular epithelial cells in akI. then analyze the clinical correlation of SRP14 in akI and explore the possibility of SRP14 as a potential therapeutic target for akI.
Results: We identified that SRP14 could be involved in apoptosis of renal tubular epithelial cells independent of SRP12; SRP14 could mediate the MDM2-p53 loop through RP57 in renal tubular epithelial cells to regulate apoptosis of renal tubular epithelial cells induced by IR. The AUC value of SRP14 (AUC_5% of baseline - 0.774) was close to serum creatinine (AUC_5% of baseline = 0.796), suggesting the potential prognostic value of serum SRP14.

Conclusions: This study found that SRP14 regulated renal tubular apoptosis induced by ischemia-reperfusion injury via interaction with RP57 involving MDM2-p53 loop. This finding could provide some novel targets and ideas for AKI control in the future.

PUB020
A Case of Masked AKI
Sitalakshmi T,1,2 Clay A. Block,3,4 NYU Langone Health, New York, NY; 2VA New York Harbor Healthcare System, Manhattan, NY; 3Dartmouth College Geisel School of Medicine, Hanover, NH.

Introduction: Despite wide recognition of pitfalls, changes in serum creatinine (Cr) and/or a decline in urine output (UO) remain the mainstay of AKI diagnosis. We report a patient whose extremely low Cr and preserved UO demonstrate the problem in reliance on these parameters.

Case Description: 57 F was admitted for respiratory failure due to COVID-19. Her management included tocilizumab, mechanical ventilation, vasopressors, ECMO, and antibiotics. On entry she weighed 54kg and Cr was 0.5 mg/dL. After 3 days, Cr nadir at 0.1 then gradually rose to 0.6 where it remained (day 15). Net fluid balance was 20L. By Cr, her eGFR was 110 ml/min/1.73m² but by cystatin C (CysC) it was 56.

Discussion: AKIN defines AKI by an absolute rise in Cr <0.3mg/dl within 48 hrs, a relative decrease in UO within 1 week, or reduction in Cr to <50% of baseline in UO to <0.5L/kg/hr for at least 6 hrs. Cr is a flawed AKI biomarker due to uncertainty of the baseline, variability in rate of generation, and elimination by secretion and filtration. Cr generation falls rapidly with critical illness. The impact of volume expansion resulting in hyperfiltration or hemodilution are underrecognized. Antibiotics, diuretics, glucose, ketones and bilirubin may interfere with measurement. Too low is flawed since oliguria may occur in the absence of AKI due to antidiuretic hormone or conversely, UO may be maintained despite AKI due to osmotic diuresis, failure of tubular function or diuretic use. The choice of baseline Cr influences our patient’s diagnosis. If 0.5 is chosen, she fails to meet AKIN criteria, but based on nadir Cr, she has severe stage III AKI. AKI can also be demonstrated by adjusting Cr for volume expansion: measured Cr x (initial total body water [TBW] + cumulative fluid gain) + initial TBW = 1.4 in our patient. Our patient received tube feeds, suffered hyperglycemia resulting in high osmolar load driving an osmotic diuresis. Also, periodic furosemide was given to mitigate her positive fluid balance. Below normal Cr is generally seen in myopathies, cirrhosis or with drug interference, but hyperfiltration can occur with volume expansion contributing to low Cr. In our case, we believe a baseline small muscle mass, critical illness sarcopenia, and marked volume expansion conspired to mask significant AKI in our patient. Documentation of AKI by measuring CysC led to adjustments in drug dosing.

PUB021
Online Medical Education Significantly Improves Nephrologists’ Knowledge and Confidence for Intravenous (IV) Iron Use in Patients with Iron-Deficiency Anemia (IDA) in CKD
George Boutsalis,1 Siggi A. Trier,2 Chris Allen,3 Jay B. Wish.1 Medscape LLC, New York, NY; 1Indiana University School of Medicine, Indianapolis, IN.

Background: Purpose: To determine if online medical education for nephrologists (Neph) could improve their evidence-based knowledge and confidence to use iv iron to treat IDA in non-dialysis (ND) and dialysis dependent CKD patients

Methods: Participants completed a 3-item questionnaire plus confidence assessment before and after watching a 30-minute online video series of 4 expert interviews with slides. A matched pair design was used pre-/post-assessment, with scores compared to assess changes in the proportion of correct responses. A chi-square test assessed statistical significance at the P < 0.05 level. Launch 01/29/20; data through 04/13/20. Total Neph learners (n=572), Neph assessment complers (n=122)

Results: At baseline, 20% of Neph (n=122) answered all 3 questions correctly, increasing to 61% (P < .001) post-assessment. An average of 61% of all responses were correct. For questions related to IDA in ND, 71%, 65%, and 63% of the predictions, respectively, lie within ±250 pg/mL of the actual PTH value. The MAE for the 1-, 2-, and 3-month calciotropic predictions is 0.410, 0.458, and 0.496 mg/dL, respectively. In addition, for the 1-, 2-, and 3-month predictions, 71%, 65%, and 63% of the predictions, respectively, lie within ±0.5 mg/dL of the actual calcium value.

Conclusions: The error distribution of the predictions is such that they 1) may be clinically meaningful as part of an effort to better control PTH, while potentially reducing excessive up-titration of etelcalcetide (and thus cost) and 2) may serve as a benchmark for future modeling efforts. Limitations include: a relatively small data set which precluded the use of other models (e.g., recurrent neural networks) and the dialysis program’s strict criteria for receiving etelcalcetide which led to a study population with significantly higher PTH values than may be encountered in the general dialysis population.

PUB022
Predicting PTH and Calcium Trajectories for ESKD Patients on Intravenous Calcimimetics
Benjamin Lobo,1 Dennis Hu,2 Brendan T. Bowman.2 University of Virginia School of Engineering and Applied Science, Charlottesville, VA; 2University of Virginia School of Medicine, Charlottesville, VA.

Background: Patients with End-Stage Kidney Disease (ESKD) often experience secondary and tertiary hyperparathyroidism leading to increased fracture risk, vascular calcification, and increased cardiovascular risk. Traditional pharmacotherapy includes phosphorus binders, Vitamin D analogues, and oral calcimimetics. Despite this, many ESKD patients still have elevated parathyroid hormone (PTH) levels. Ectelcalcetide is an intravenously delivered calcimimetic approved to treat hyperparathyroidism. Advantages include a long half-life and IV administration which guarantees drug delivery. Despite this, response of PTH and calcium levels to etelcalcetide remains difficult to predict. A predictive algorithm could assist clinicians in assessing the potential effect of a given dose. As a first step in developing a dosing decision support tool, we present a predictive model that forecasts the 1-, 2-, and 3-month PTH and calcium values for patients receiving etelcalcetide.

Methods: We used tree ensemble (RandomForest) models for their ability to model the data non-lineairities. Model inputs were historic data (calcimimetic dosing, labs, dialysis records, demographics, and phosphorus binder orders) and future calcimimetic dosing.

Results: The Mean Absolute Error (MAE) was 205, 227, and 249 pg/mL for the 1-, 2-, and 3-month PTH predictions, respectively. In addition, for the 1-, 2-, and 3-month calcium predictions, 70%, 65%, and 59% of the predictions, respectively, lie within ±250 pg/mL of the actual PTH value. The MAE for the 1-, 2-, and 3-month calcium predictions is 0.410, 0.458, and 0.496 mg/dL, respectively. In addition, for the 1-, 2-, and 3-month predictions, 71%, 65%, and 63% of the predictions, respectively, lie within ±0.5 mg/dL of the actual calcium value.

Conclusions: This study found that SRP14 regulated renal tubular apoptosis induced by ischemia-reperfusion injury via interaction with RP57 involving MDM2-p53 loop through increase in confidence using iv iron therapies to manage IDA. The activity significantly increased knowledge on the differences between iv and oral iron in delaying the need for erythropoiesis-stimulating agents when treating IDA in ND-CKD patients (pre: 64%, post: 85%, P < .001) and using a proactive dose iv iron strategy in CKD patients on dialysis to reduce cardiovascular risk versus a low dose approach (pre: 29%, post: 71% P < .001). Neph already chose to start iv iron therapy in an IDA patient on hemodialysis currently on ESA but not meeting their hemoglobin goals in adherence to KDIGO guidelines (pre: 91%, post: 93% P = .641). Polling showed 1 in 4 Neph started IDA treatment with iv iron in <50% of CKD patients.

Conclusions: Online medical education can significantly improve data recall from pivotal clinical trials on iv iron therapy to treat IDA in CKD patients with or without dialysis. This activity was also successful to facilitate application of such evidence into clinical practice and boost confidence using iv iron therapies, specifically with regards to iron repletion before ESA initiation in ND-CKD patients and using higher iv iron doses to mitigate cardiovascular risk in HD-CKD patients. Further nephrologist education on iv iron use in earlier IDA stages could be helpful to optimize patient outcomes.

PUB023
A Rare Case of Staghorn Calculi Complicated by Bilateral Xanthogranulomatous Pyelonephritis
Michael Chang, Gary Dellacerra, Deep Sharma, Joshua M. Stern, Peter Nauka, Wei Chen. Montefiore Medical Center, Bronx, NY.

Introduction: Staghorn calculi are usually unilateral and typically occur in women. Chronic obstruction and infection of staghorn calculi can cause xanthogranulomatous pyelonephritis (XGPN), a rare destructive granulomatous process of renal parenchyma. We describe a case of bilateral staghorn calculi in a man complicated with XGPN and worsening renal function.

Case Description: A 64-year-old man with bilateral staghorn calculi and chronic kidney disease (CKD) stage 4 was admitted for fatigue and worsening renal function. He tested positive for COVID-19 by nucleic acid-based test. Serum creatinine increased from 3.5 (2 months ago) to 6.2 mg/dL. Renal ultrasound showed dilated left calyces and large shadowing calculi without hydronephrosis. History was notable for persistently alkaline urine (pH > 6.5), 100% carbonate apatite (dahlite) on stone analysis, and urinary tract infection with Proteus mirabilis. CT imaging revealed bilateral staghorn calculi with “bear paw” signs (left > right), a typical appearance of XGPN [Figure]. Compared to a CT scan completed 10 months ago, the left kidney was enlarged with greater low-attenuating spaces indicating worsened XGPN; the right kidney decreased in size with less stone burden corresponding to the right percutaneous nephrolithotomy performed 7 months prior. AKI was thought to be related to COVID-19, and surgical intervention was deemed unnecessary. Bilateral XGPN likely increased his risk of AKI and hampered renal recovery, and he was subsequently initiated on hemodialysis.

Discussion: In this rare case of staghorn calculi progressed to bilateral XGPN, we observed the detrimental effects of staghorn calculi on the kidneys. More research on staghorn calculi is needed to improve the high morbidity and mortality associated with this disease.
Factors Associated with Serum Concentrations of 25-Hydroxyvitamin D (25D) and 1,25-Dihydroxyvitamin D (1,25D) in Stable Hemodialysis Patients

Eiji Ishimura, Takahiro Fujimoto, Kazunori Masutani, Kazunari Higashimoto, Nobuya Murakami, Shuko Ueda, Nobuyuki Kuwamura, Akihiro Tsuda, Shinya Nakatani, Katuhito Mori, Senji Okuno, Ruusuke Kakiya, Manasari Emoto, Meijibashi Hospital, Osaka, Japan; Osaka City University Graduate School of Medicine, Osaka, Japan; Shirasagi Hospital, Osaka, Japan.

Background: Serum 1,25D, an active form synthesized from 25D, is present in CKD patients (Ishimura, Kidney Int 1999; Wolf, Kidney Int 2007). However, factors associated with 1,25D and 25D are not well known. The aim of the present study is to examine the relationship between 1,25D, 25D and clinical parameters in hemodialysis patients.

Methods: Serum 1,25D and 25D were measured by a RIA2-Ab method and an ECLA method, respectively, in 108 stable maintenance hemodialysis patients (72 ± 10 years, 64 males, hemodialysis duration: 6.9 ± 7.5 years, 45 diabetics) from December 2019 to February 2020, i.e., in the winter.

Results: Serum 1,25D were 14.6 ± 8.0 pg/ml, demonstrating that 77 patients showed values less than reference ranges of healthy subjects (30-60 pg/ml). Serum 25D were 12.0 ± 8.4 ng/ml, demonstrating that 101 patients showed vitamin D deficiency of < 20 ng/ml. There was no significant correlation between serum 1,25D and 25D in maintenance dialysis patients in the present study, although 1,25D and 25D had been reported to show significant, positive correlations both in pre-dialysis CKD patients (Ishimura, Kidney Int 1999) and in incident dialysis patients (Wolf, Kidney Int 2007). There were no significant correlations between 25D and clinical parameters. However, there were significant, negative correlations between 1,25D and intact PTH (r = -0.344, p < 0.001) and between 1,25D and ALP (r = -0.309, p < 0.02), although no significant correlations were seen between 1,25D and other parameters, such as Ca and P. In multiple regression analyses, 1,25D was significantly, independently associated with intact PTH and with ALP after adjustments of several clinical parameters (R² = 0.345, p < 0.001; R² = 0.256, p < 0.001, respectively).

Conclusions: In maintenance hemodialysis patients, all patients showed hypovitaminosis D, in terms of serum 25D. 1,25D, even in low serum levels, correlated significantly and negatively with intact PTH and ALP. These results indicated that even low levels of serum active vitamin D, 1,25D, affect the status of CKD-MBD. The results may further indicate that the metabolism of vitamin D should be considered in the pathogenesis and treatment of CKD-MBD.

A Case of Parathyroid Hyperplasia with Single Explosive Growth

Bei Hou, Bing Tang, Yong Xu, Yuanning Li, Xinxin Liu, Xiayi yijia Doctor Group, Jinhui Hospital, Changsha, China; Xiangya Hospital Central South University, Changsha, China.

Introduction: Exploration of parathyroid hyperplasia with single explosive growth

Case Description: A 46-YO Asian man with ESRD has been undergoing regular hemodialysis for 20 years due to glomerulonephritis. The patient has had bone and joint pain for 10 years. In 2018, the measurement of his serum iPTH was elevated and the value was over 1000pg/ml (no data about serum calcium and phosphates levels), and he didn't have regular treatment. Serum calcium, phosphate and alkaline phosphatase were 2.46mmol/L, 2.4mmol/L and 380μmol/L respectively, and serum iPTH was 2205pg/ml in this admission examination. The ultrasonography showed two hyperplastic parathyroid glands. They are 13*5mm on the right lower side of thyroid gland and 43*16mm on the left lower side. Parathyroid needle scanning showed three hyperplastic parathyroid glands. That is located in bilateral hypothyroidism and left upper sternum, consider parathyroid development, Total parathyroidectomy was successfully carried out with total parathyroidectomy in May 2015, 2020. Four parathyroids were excised, which were 0.6*0.5cm in the upper left, 4.9*3.0cm in the lower left, 0.8*0.5cm in the upper right, and 1.5*1.0cm in the lower right (the maximum diameter and length). Pathological diagnosis showed that there was parathyroid nodular hyperplasia in the upper left, lower left, upper right and lower right. PTH values a week after surgery was less than 1.2pg/ml, serum calcium 2.13mmol/L, phosphate was 0.85mmol/L. Patient bone pain disappeared. Patient has been discharged and will be close followed up.

Discussion: Total parathyroidectomy is effective in uremic patients with secondary hyperparathyroidism which has explosive hyperplasia with parathyroid glands.
Conclusions: Our results show that in subjects with end-stage kidney disease a meal with high phosphorus content has only a negligible effect on plasma phosphate compared to a meal with low phosphorus content. Thus, large increases in plasma phosphate cannot be accounted for by a high intake of phosphorus in the hours prior to blood sampling.

A Rare Case of Severe J Secondary Hyperparathyroidism in a Patient with ESRD
Jose S. Reyes Oliva, Iritza Hasan, Zaiyara A. Rivera, Ljubomir M. Ilic.
University of Florida College of Medicine - Jacksonville, Jacksonville, FL.

Introduction: Refractory secondary hyperparathyroidism is defined as severe, persistent & progressive elevation of PTH which cannot be lowered by medical management & associated hypercalcemia, hyperphosphatemia, bone/joint pain and/or fracture, extra skeletal calcification, calciphylaxis & pruritus.

Case Description: A 43-year-old undocumented Hispanic male with PMH of uncontrolled DM, HTN, ESRD (HDX 3/week) & persistent tertiary hyperparathyroidism (on Cinacalcet) presented with multiple bone fractures, bilateral leg weakness, soft tissue calcification & severe renal osteodystrophy. Significant lab findings included PTH 3519pg/mL, phos 6.7mg/dL, Ca++ 10.9mg/dL & ak phos 804 IU/L were all above goal. X-ray of lower ext. revealed diffuse osteopenia with chronic fracture in distal fibula, midfoot, distal tibia & dislocation of talonavicular joint as well as extensive atherosclerotic vascular calcification & multiple punctate soft tissue calcification. CT spine reported demineralized appearance of vertebral bodies & sacrum, wide erosion of sacroiliac joints bilaterally & calcified atherosclerotic disease of abdominal aorta & bilateral interstitialar arteries. Patient was diagnosed as refractory tertiary hyperparathyroidism & treated with doxercalciferol, phosphate binders & advised for parathyroidectomy on multiple previous encounters but was unable to do due to health care access issue.

Discussion: Parathyroidectomy which has mortality benefit is indicated in the setting of severe & sustained PTH value above 800-1000 pg/mL, refractory to medical treatment & associated to others indicators like hypercalcemia, refractory hyperphosphatemia, bone pain/fractures & our case has majority of the above mentioned indications. Various other factors including immigration, insurance issues and post-operative intensive care requirements complicated the potential for parathyroidectomy in this patient. Although with advancement of medical field, the symptoms of severe hyperparathyroidism are rarely observed but the manifestations are real if not treated on time as per guideline recommendations.

Progression of CKD Stage G3a Among African Americans
Yelvzyaeva Pryvazhnyuk, Isha Puri, Jie Ouyang, Ernie Yap. SUNY Downstate Health Sciences University, Brooklyn, NY.

Background: Chronic kidney disease (CKD) stage 3 represents the most of all CKD patients. Stage G3 is divided into G3a (GFR 45–59 ml/min/1.73m²) and G3b (30–44 ml/min/1.73 m²) based on findings that showed differential kidney outcomes. Stage G3a has several unresolved paradigms. Firstly, it does not always imply kidney damage. It is recommended that cystatin C be used to confirm in people without manifesting signs of kidney damage to avoid over-diagnosis. Secondly, it primarily comprises of the elderly, and most will not progress to advanced CKD before succumbing to other causes of death. Thirdly, in people with manifestations of kidney damage, stage G3a becomes an important predictor of disease progression. The influence of ethnicity on eGFR in delineating these aberrances in CKD G3a is unclear. In this study, we sought to analyze the progression of CKD G3a patients in a predominantly African American cohort.

Methods: We performed retrospective chart reviews of patients at our CKD clinic. GFR was estimated based on the MDRD formula. Continuous variables are presented as means±SD. Comparison of continuous variables were performed using one-way ANOVA. Univariate and age and body mass index (BMI)-adjustment analyses was performed by SPSS. Results: We performed retrospective chart reviews of patients at our CKD clinic. GFR was estimated based on the MDRD formula. Continuous variables are presented as means±SD. Comparison of continuous variables were performed using one-way ANOVA. Univariate and age and body mass index (BMI)-adjustment analyses was performed by SPSS.

799
northern regions. At 46.6021° N latitude, Yakima is closer to the North Pole than other areas where CKDs have been documented. With increasing global temperatures, agricultural workers are on the frontline of climate-related health issues. Further study is necessary to develop awareness, earlier risk factor detection, and effective interventions for these essential and vulnerable members of our communities.

The Correlation Among Management of the Comorbidities and Progression of Renal Dysfunction or Adverse Events for CKD Patients

Takahiro Kuragano, Takeshi Nakamichi. Hyogo college of Medicine Kidney and dialysis, Nishinomiya, Japan.

**Background:** It is well established that several factors including anemia, hypertension, hyperuricemia, metabolic acidosis, and CKD-MBD are associated with progression of CKD or adverse events of these patients. However, the significant factors which associated with progression of CKD or adverse events under the condition of appropriate control which according to guidelines have not been cleared.

**Methods:** The study was an observational study in a single center for a period of 3 years. In 88 patients with various stages of CKD (not on dialysis) who were treated by nephrologists, Hb, ferritin, iron and albumin and high sensitive C reactive protein (hsCRP), f2microglobulin (MG), HCO3, and intact-parathyroid hormone (iPTH), in addition to urinary sodium, potassium, calcium, phosphorus protein, and f2MG levels, were measured. All patients were treated according to the clinical practice guideline for CKD. A time-dependent Cox hazard model was applied to evaluate the association between clinical parameters and adverse events.

**Results:** In multiple regression analysis, baseline of lower Hb (β=0.497, P<0.001) and vitamin D 125 (β=0.258, P=0.006), and higher int-PTH (β=0.334, P<0.001), urinary phosphorus (β=0.328, P<0.001), urinary f2MG (β=0.225, P=0.031) and urinary protein (β=0.280, P=0.02) levels were selected as significant predictors of decline of estimated glomerular filtration rate (eGFR) or 1/creatinine(Cr) at the end of the study. In the Cox hazard model, low calcium (HR: 0.37, P=0.026), high phosphate (HR:5.90, P<0.001), low 125 vitamin D (HR: 0.94, P=0.013), high int-PTH (HR:1.02, P<0.001) level, use of a phosphate binder (HR: 4.95, P=0.012), and use of vitamin D analogs (HR:3.75, P=0.014) are selected as risks for adverse event including initiation of dialysis.

**Conclusions:** In this study, we found that among several factors, anemia and CKD-MBD related factors (phosphate, calcium, vitamin D, int-PTH) were selected as significant predictors for the progression of renal dysfunction. Furthermore, although phosphate binder or vitamin D analogs were administered appropriately, CKD-MBD factors were associated with progression and adverse events of these patients. From these results, we presumed that the early intervention or strict control for CKD-MBD factors might attenuate the risk for adverse events of CKD patients.

**PUB032**

Association of Anion Gap with the Risk of CKD Progression

Ashish Verma,1 Jing Liu,2 Maria Clarissa Tio,1 Ankit B. Patel,1 Sushrut S. Waikar.1,2 Brigham and Women’s Hospital, Boston, MA; 1Boston University Medical Campus, Boston, MA.

**Background:** Increased anion gap is a marker of acid retention most reflected in patients with CKD. This study’s objective is to assess whether a higher anion gap is a risk factor for CKD progression.

**Methods:** This prospective cohort study assessed 4131 participants with CKD stage 2 to 4, who enrolled in a chronic renal insufficiency cohort study. Three types of anion gap were used as exposures, traditional anion gap (AG1), Albumin corrected anion gap(AG2), full anion gap(AG3). Multivariable adjusted Cox proportional hazard models were built using the lowest tertile as the reference of all three anion gaps for the composite outcome (50% decline in eGFR or ESRD) and ESRD. Models were adjusted for relevant covariates and baseline eGFR.

**Results:** This study included 4131 participants [mean (SD) age, 60.48(10.21) years; 1788 (43.28%) female]. During 26673.46 person years of follow up, 805 participants reached ESRD and 1138 participants reached a composite outcome of a 50% decline in GFR or ESRD. In a multivariable adjusted model each SD increase in AG1, AG2 and AG3 were independently associated with 10%, 10% and 12% increased risk for CKD progression: hazard ratio (HR) 1.10; 95% CI (1.01-1.21); HR 1.10; 95% CI (1.02-1.20), HR 1.12; 95% CI (1.03-1.21)], however each SD increased in AG2 and AG3 was independently associated with a 11% increased risk for ESRD [HR 1.11; 95% CI (1.02-1.21), HR 1.11; 95% CI (1.02-1.22)]. In multivariable adjusted models compared to tertile 3 (>12) those in tertile 1 (<10) had a 33% and 41% higher risk for CKD progression [HR 1.33;95% CI (1.09-1.62), HR 1.41;95% CI (1.16-1.71)] and 32% and 60% higher risk for ESRD [HR 1.32; 95% CI (1.06-1.64), HR 1.60;95% CI(1.28-2.01)].

**Conclusions:** Higher albumin corrected and full anion gap may be a risk factor for CKD progression and ESRD.

Therapeutic Interventions to Assess Outcomes and Disparities in Chronic Kidney Disease Among Veterans (TRI-CKD)

Keichi Sumida,1 Ankur A. Dashputre,1 Praveen Kumar Potukuchi,1 Friddjof Thomas,1 Jun Ling Lu,1 Miklos Z. Molnar,1 Cachet Wenziger,1 Elani Streja,1 Kamyar Kalantar-Zadeh,1 Csaba P. Kovessy,1 1The University of Tennessee Health Science Center, Memphis, TN, 2University of California Irvine, Irvine, CA.

Background: There continues to be a large unmet need in the management of CKD, due in part to a lack of effective intervention strategies to prevent CKD progression or decrease morbidity/mortality in patients with CKD. There is also a lack of race-specific application of clinical interventions, despite evidence suggesting racial differences in response to various therapies. High quality, large observational studies are essential to provide preliminary results in support of future clinical trials, and to offer large-scale, widely applicable evidence to inform clinical practice in this population when clinical trials are not feasible.

Methods: We established a cohort of 3,565,367 individuals with stable eGFR ≥60 mL/min/1.73m² during October 1, 2004-September 30, 2006, using an algorithm based on repeated serum creatinine measurements. Data about patients’ demographics, socioeconomic characteristics, comorbid conditions, administered medications, labs, vital signs, vital status, incident CKD and ESRD outcomes were obtained from various VA databases, from Centers for Medicare & Medicaid Services, and from USRDS.

Results: The mean (SD) age of the cohort is 59 (14) years; 93% are male; 16% are African-American; and 24% are diabetic. The mean baseline eGFR is 84 mL/min/1.73m². Individuals are followed longitudinally for up to 13 years. Overall, the crude rates of all-cause death and ESRD are 51 and 0.63 per 1000 patient-years (Figure).

Conclusions: We established a large nationwide cohort of US veterans with normal eGFR. Studies from this cohort will generate a wealth of information to examine therapeutic interventions used to treat various conditions associated with poor outcomes in patients with all levels of kidney function, potentially providing significant clinical, social, and policy implications for the care of US veterans and also for patients with kidney diseases in general.

A Double-Blind, Randomized, Placebo-Controlled with an Open-Label Rollover Extension Phase 2/3 Clinical Trial to Evaluate Safety and Efficacy of US-APR2020 in Subjects with CKD Stage IV

Naratanakorn Ranganathan,1 Usha N. Vyas,1 Pari Ranganathan,1 Anthony Irvin,1 Alan D. Weinberg,2 1Kibow Biotech, Newtown Square, PA, 2Mount Sinai Health System, New York, NY.

Background: CKD patients experience poor quality of life due to high levels of uric acids in the blood. Renal®, a Pro/Prebiotic dietary supplement has been shown in the market since 2010. It is proven to reduce several uric acids in 3 pilot clinical trials with no adverse outcomes. The product is now awaiting FDA-IND approval for a drug trial. This will be a large scale 12-month RCT to validate US-APR2020 as a Live Bio-Therapeutic drug product (LBP) under CBER guidelines.

Methods: (A) 6-month randomized placebo-controlled parallel design in an outpatient setting followed by (B) 6 month Open-Label Rollover Extension which will enroll all patients from study A.

Results: Study end points: As compared to placebo; Primary: 1. Less than 10% adverse event in the study population. 2. Arrest the decline of eGFR as per NKF-USFDA guidelines. Secondary: 1. Improvement in any of the basic blood uric acid metabolic markers. 2. Improvement in any of the biochemical blood parameters. 3: Reduction in C-Reactive Protein (CRP) levels. 4. Percent change from baseline in rating scale (Modified SF36 QOL questionnaire) at the end of 6 and 12 month. Tertiary (IN FEW SELECTED SITES): Blood levels of Kidney Injury Molecule (KIM-1), Neutrophil Gelatinase Associated Lipocalin (NGAL), glomerulonephritis related uric acid toxins: Indoxyl Sulfate (IS), para-cresyl sulfate (pCS) and Trimethylamine-N-Oxide (TMAO).

Conclusions: This is the first-ever clinical trial proposed using Pre/probiotics US-APR2020 as a Live Bio-Therapeutic drug product (LBP) for CKD IV patients. Being non-intervention the intervention avoids any possible infection. The addition of US-APR2020 with standard care of therapy may possess excellent potential towards CKD applications worldwide. Formal IND process under CBER/US FDA in progress. Seriously interested clinical PI’s please contact: rangan@kibowbiotech.com

Treatment Response in Patients with Uncontrolled Gout Co-Treated with Pegloticase and Leflunomide

Karin R. Masi,1 Kevin W. Winterling,2 Brian LaMoreux,2 1Ben Secours Rheumatology Center, Richmond, VA, 2Horizon Therapeutics, Lake Forest, IL.

Background: Many patients with CKD develop gout with a prevalence ≥36% in later stage disease. Though oral urate-lowering therapies are used in CKD patients, some may not respond to or cannot tolerate them. Uncontrolled (refractory) gout can be treated with pegloticase (PEGylated uricase enzyme), however, anti-drug antibodies (ADAs) can cause loss of therapeutic efficacy. Compared with pegloticase alone, recent case series show markedly higher response rates with methotrexate/pegloticase co-treatment (42% vs. 80-100%). However, certain considerations with methotrexate use including significant renal or hepatic disease may not be as restricting with leflunomide. This study examined pegloticase response rate in patients co-treated with pegloticase and leflunomide.

Methods: This chart review included uncontrolled gout patients treated with pegloticase (biweekly 8 mg infusions) and oral leflunomide (20 mg/day). Patient, disease, and treatment parameters were examined, along with safety data. Patients receiving ≥12 pegloticase infusions with a serum uric acid level (sUA) < 6 mg/dL at infusion 12 were considered responders.

Results: 10 patients were identified and included (5 men, 72±12.5 years, pre-therapy sUA: 7.1±2.4 mg/dL). Common comorbidities were CKD (90%), hypertension (70%), diabetes mellitus (60%), obesity (60%), congestive heart failure (50%), and coronary artery disease (20%). 7 patients (70%) met responder criteria (26.6±14.0 infusions, sUA at infusion 12: 6.9±1.5 mg/dL). 3 patients were lost to follow-up or discontinued therapy. Gout flare (1 patient, 3 flares), weight gain/loss of consciousness (1 patient; before pegloticase infusion, deemed unrelated treated), worsening of kidney/cardiac issues (1 patient, deemed unrelated to treatment), and mild, transient ALT/AST increases (2 episodes, 1 patient) were observed. All treatment-related AEs were known effects of pegloticase or leflunomide.

Conclusions: These findings suggest that leflunomide/pegloticase co-treatment can increase the proportion of pegloticase responders, likely due to attenuation of ADAs. While methotrexate has been shown to increase pegloticase response rates, many gout patients have advanced CKD and leflunomide potentially represents an alternative option for minimizing ADAs.

New-Onset Nephrotic Syndrome in a Child Associated with COVID-19 Infection
Siddharth A. Shah, University of Louisville, Louisville, KY.

Introduction: The COVID-19 outbreak has turned into worldwide public health emergency. The renal histo-pathological features of acute tubular necrosis or thrombotic microangiopathy are reported in adults previously with severe COVID-19 infections. In children, the renal manifestations associated with COVID-19 infection are not widely reported. Here, we describe a case report of a child with new onset nephrotic syndrome associated with COVID-19 infection.

Case Description: A 8-year-old boy with no previous significant medical history presented with bilateral eye and facial swelling soon after his parents were-diagnosed with COVID-19 infection. He had diarreha but no fever or shortness of breath. One week after onset of swelling, the boy was also tested positive for COVID-19 infection. Based on clinical findings of significant proteinuria (Urine protein and creatinine ratio of 11.4), hyperaobuminemia (serum albumin of 2 g/dl), and hypercholesterolemia (Total Cholesterol of 384 mg/dl), he was diagnosed having nephrotic syndrome. He responded well to standard-dose prednisone treatment for necrotic syndrome. In one week of starting prednisone treatment, he went into clinical remission. Lymphopenia continued to be present for 2 weeks after onset of symptoms. There were no complications related to clot formation or secondary infections with this presentation.

Discussion: This is the first case report to our knowledge of pediatric patient presenting with new-onset nephrotic syndrome associated with COVID-19 infection. Although, the burden of disease from COVID-19 is less severe in children, they can present with immune system related kidney disease like necrotic syndrome. The patient responded well to standard-dose prednisone treatment used typically for new onset nephrotic syndrome.

Recurrent Arteriovenous Graft Thrombosis in COVID-19
Namrata Singhania, 1 Saurabh Bansal, 1 Gishir Singhania. 2
1 CHI Saint Vincent Health System, Little Rock, AR; 2 Mount Carmel East, Columbus, OH; 1University of Illinois at Peoria, Peoria, IL.

Introduction: COVID-19 has been associated with increased risk of hypercoagulability. We report a case of COVID-19-associated coagulopathy leading to recurrent arteriovenous (AV) graft thrombosis in an end-stage renal dialysis (ESRD) patient.

Case Description: 84 yo African American female with ESRD on dialysis via lower extremity AV graft, diabetes and atrial fibrillation on warfarin who was diagnosed with COVID-19 came back again 1 week later and was admitted due to hypoxemia. COVID-19 PCR was again positive. INR was 1.4, D-dimer 3.28mg/mL, platelet count 114K/mm2, mildly prolonged PT, aPTT. She had elevated venous pressures during dialysis. Doppler suggested AV graft thrombosis. Heparin drip was started. Angiography and intravascular ultrasound (IVUS) showed thrombosed AV graft. (Figure 1a,1b) Thrombectomy was successful (Figure 1c,1d) with uneventful hemodialysis afterwards. She was discharged. Next day, she came back again with diarreha. Coronavirus PCR was still positive. INR was 1.9. She again had high venous pressures. Doppler found recurrent thrombosis. Heparin drip was started. Vascular surgery placed dialysis catheter and held thrombectomy till her coronavirus PCR turns negative.

Discussion: Incidence of venous thromboembolism (VTE) can be as high as 58% in patients with COVID-19. All categories of ‘Virchow’s triad’ are involved, endothelial injury (increased cytokines and complements), stasis (immobilization) and hypercoagulable state (changes in prothrombotic factors). Risk factors are males, obesity, heart disease, hypertension, diabetes and ESRD. High D-dimer, mildly prolonged PT, aPTT and thrombocytopenia are common. Full-dose anticoagulation is recommended for documented VTE.

Manage a Peritoneal Dialysis Unit During the COVID-19 Pandemic

Background: Peritoneal Dialysis (PD) patients are special, as they are mainly independent in a “life-support technique” but susceptible to various potential complications related. This pandemic brought new challenges and PD Units had to be reorganized considering their specific population, human and material resources. We aimed to understand the impact of our restructuration and discuss some lessons learned.

Methods: We retrospectively reviewed the activity and intercurrences at our Unit during the COVID-19 state of emergency declared by our Government, from 19th March to 2nd May (6 weeks), and compared it to the correspondent past two years (table 1). In a normal period, most of our patients are evaluated in a monthly basis. Simple descriptive and Student’s paired T-test analysis were performed.

Results: We managed 34 patients in the correspondent period of 2018, 36 in 2019 and 38 in 2020. Clinical appointments in this 2020 period were realized by phone. Necessary dislocations to the Unit in 2020 included peritonitis, exit-site infections and catheter malfunctioning. No dropouts occurred. There were no positive cases of COVID-19. Student’s paired T-test analysis between 2020 and 2019, plus 2020 and 2018, showed no statistically significant differences in every evaluated phenomenon (except for non-presential appointments; this discrepancy is justified by the Unit’s dynamic, without clinical implications).

Conclusions: Despite the restructuring, we were able to provide more teleassistance and the mean of complications/hospital admissions weren’t statistically worse. Some activities were postponed, but its true impact isn’t yet clear. Will suboptimal care bring long-term complications? Nonetheless, PD technique stands out for favorably, mainly if all the necessary support from medical and nurse staff is guarantee.

Activity and intercurrences at our PD Unit.

Exploration on Renal Protective Compounds and COVID-19-Induced Renal Injuries Based on Network Pharmacology and Molecular Docking

Yue-Yu Gu,1,2 Min Zhang,1,2 Yifan Wu,1,2 Xusheng Liu,1,2 1Department of Nephrology, Guangdong Provincial Hospital of Chinese Medicine, Second Affiliated Hospital, Guangzhou, China; 2Guangzhou University of Traditional Chinese Medicine, Guangzhou, China.

Background: The fullscreen of COVID-19 is getting revealed as some of the infected patients had developed severe renal complications. Natural compounds may have protective effects against COVID-19-induced renal injuries. The aim of this study is to explore the interactions and underlying mechanisms between active compounds and COVID-19-induced renal injuries.

Methods: The interaction network of 8 collected natural compounds (Hederagenin, β-sitosterol, Luteolin, Quercetin, Kaempferol, Jaranol, Formononetin and Calycosin) and COVID-19-related target proteins was established by using the pharmacological database. GO and KEGG pathways were also analyzed. Molecular docking was run by AutoDockTools and Discovery Studio.

Results: 259 target genes are potentially related to COVID-19, AKI and CKD. Active compounds may improve COVID-19-induced renal injuries by alleviating the inflammatory response, vascular abnormal changes, cell apoptosis and necrosis in kidneys. The docking results had indicated that 8 compounds may show great possibilities to interact with SARS-CoV-2 main protease 3CL and ACE2 by showing significant binding energy.

Conclusions: Our study may provide molecular evidence and support on compounds from herbal medicines or dietary supplements may serve as potential perspective drugs to protect kidneys from COVID-19-induced renal injuries.

Funding: Government Support - Non-U.S.
Underline represents presenting author.

**Case Description:** 49 year old African American male presented to the emergency department with 3-4 days of nausea and vomiting. He was diagnosed 10 days prior with COVID-19. His past medical history is significant for pulmonary interstitial fibrosis, lupus nephritis diagnosed in 2017 with baseline serum creatinine of 3 mg/dL, and hypertension. His outpatient medications included lisinopril and hydrochloroquine. On admission his serum creatinine was 230 mg/dL, blood urea nitrogen with 333 mg/dL, K 7.4 mg/dL, Bicarb 11 mg/dL, Cl 96 mg/dL, and albumin 2.9 g/dL. His serum aldosterone 2.3 ng/dL, ACE 6 U/L, procalcitonin 1.29 ng/mL, and D-Miner 2055. His urine dipstick showed 500mg/dl protein with moderate blood. On arterial blood gas, he had a compensated metabolic acidosis, a partial pressure of oxygen of 92.6 mm Hg on room air, and no respiratory distress. No hypotension was observed. CXR showed hazy patchy bilateral opacities, most pronounced in the lower lungs. A dialysis catheter was placed, and the patient dialedyzed. The patient’s pulse oximeter remained between 96-100% on room air; D-Miner 2055-2061, and procalcitonin < 1.29 ng/mL during his 12 day hospitalization. He was discharged on TIW hemodialysis with 14% of patients tested. Mortality was 24%. Deceased patients were older, had a higher BMI (29 vs 26), more likely to be diabetics (mortality 23%). Patients that tested positive were older (65±13 vs 60±13±14y-o), mainly African-Americans (90%) with a higher BMI (29 vs 26), more likely to be diabetics (51% vs 44%) and to reside in a Nursing Home (20 vs 10%), with higher prevalence of cardiovascular disease (45 vs 30%). Dialysis-related parameters (albumin, hemoglobin, phosphorus, PTH, Kt/V and blood pressure) were similar between those that tested positive vs negative. 4% (31 patients) of our entire dialysis population resides in Nursing Homes.

**Conclusions:** In our dialysis population the incidence of COVID-19 infection was 2.9% with 14% of patients tested. Mortality was 24%. Deceased patients were older, had a higher BMI and were on dialysis for longer time compared to those that survived. We did not observe an increase rate of hospitalizations or deaths compared to previous months (Figure 1).

**Discussion:** Our case is unique of having both influenza and COVID-19 infection and suggests a renal specific disease due to SARS-CoV2. This report describe the clinical outcomes related to these interventions.

**Results:** Until May 30/2020, 106 patients had been tested (14%). 22 patients were positive for C19 (2.9%) of which 20 were on HD and 2 on PD. Five C19+ patients died (mortality 23%). Patients that tested positive were older (65±13 vs 60±13±y-o), mainly African-Americans (90%) with a higher BMI (29 vs 26), more likely to be diabetics (51% vs 44%) and to reside in a Nursing Home (20 vs 10%), with higher prevalence of cardiovascular disease (45 vs 30%). Dialysis-related parameters (albumin, hemoglobin, phosphorus, PTH, Kt/V and blood pressure) were similar between those that tested positive vs negative. 4% (31 patients) of our entire dialysis population resides in Nursing Homes. 12 of them have been tested and 8 were C19+ (26%). The dialysis patients that expired were older (69 ±57y), all were African-Americans and had higher BMI (30 ±26) and time on dialysis (12.3 ±5.6 y) than those that survived. We did not observe an increase frequency of hospitalizations or deaths compared to previous months (Figure 1).

**Conclusion:** In our dialysis population the incidence of C19 infection was 2.9% with 14% of patients tested. Mortality was 24%. Deceased patients were older, had a higher BMI and were on dialysis for longer time compared to those that survived. We did not observe an increase rate of hospitalizations or deaths during initial 3 months of the pandemic.

**AKI with Minimal Pulmonary Pathology in SARS-CoV2 Infection**

**Yasnowski, Frank** 1Rajeev Rohatgi. 1Northport VA Medical Center, Northport, NY; Stony Brook University School of Medicine, Stony Brook, NY.

**Introduction:** SARS-CoV2 transmission occurs through infection of the upper airway epithelial cells. Though many cases are asymptomatic or mild, a significant fraction require hospitalization that is associated with morbidity and mortality. Primarily a pulmonary illness causing hypoxia and an acute respiratory distress syndrome (ARDS), SARS-CoV2 is also associated with AKI and other life-threatening systemic disorders. Generally, AKI occurs late in the course of SARS-CoV2 infection after severe pulmonary manifestations.

**Case Description:** A 43 year-old African American male presented to the emergency department with 3-4 days of nausea and vomiting. He was diagnosed 10 days prior with COVID-19 infection without acute kidney injury (AKI).

**Case Description:** A 43 year-old African American male with a history of medication-induced rhabdomyolysis 6 years ago, renal cell carcinoma status post partial right nephrectomy, hypertension, type 2 diabetes, and morbid obesity presented to emergency department with upper respiratory symptoms, myalgia and dyspnea for one week. He reported taking atorvastatin and diltiazem for a long time but has never...
developed myalgia. There was no family history of myopathies, or binge alcohol intake beforehand. On physical examination, patient was hypertensive, euvoelemic, and afebrile, with normal oxygenation. Chest x-ray showed subtle increased interstitial reticulation in the perihilar regions and COVID-19 rapid test returned positive. Laboratory data showed very high creatine kinase (CK) (208,456 U/L). Urinalysis showed trace proteinuria, large blood but only few red blood cells and confirmed myoglobinuria. However, his creatinine was normal (0.8 mg/dl), as well as serum calcium (8.4 mg/dl), phosphate (3.9 mg/dl), and uric acid (5.2mg/dl) levels. Patient was admitted for treatment of assumed severe rhabdomyolysis. COVID-19 was treated conservatively with oxygen supplementation. Atorvastatin and diltiazem were held, and normal saline and isotonic sodium bicarbonate fluids were administered. CK continued to rise with a peak of 499,020 U/L on day 3, but decreased steadily to 58,745 U/L on day 7. Renal function remained stable all the time during the treatment (serum Cr 0.68 – 0.82 mg/dl), with maintained urine output and well-preserved electrolytes and uric acid levels throughout.

**Discussion:** There are increasing number of reports of COVID-19-associated rhabdomyolysis, but risk factors and characteristics are fairly known. The clinical and laboratory manifestations are suggestive of COVID-19 associated rhabdomyolysis rather than statin-induced. We are not aware of any other reports documenting such extreme CK values – with a proper rise and fall of CK – without impacting renal function. As far as we know, this is the first case of COVID-19 associated rhabdomyolysis with peak CK of 499,020 U/L, without AKI and concurrent electrolyte abnormalities. The relationship to COVID-19 vs. individual genetic susceptibility remains to be explored.

**PUB048**

**CKD Patients on Hemodialysis (HD) with COVID-19 Infection: Characteristics and Outcome**

**Background:** The COVID-19 pandemic has special significance for Chronic Kidney Disease patients on HD. Clinical characteristics and outcome from low resource settings are not well known.

**Methods:** From March 15 2020 until May 20, 2020, quality managers reviewed all patients with confirmed COVID-19 infections in 200 HD centres among MHD patients. For patients with COVID-19 infections: age, gender, geographical zone, type of Insurance, continuity of care was noted, HD characteristics and outcome were reviewed. Comparison of median was done with Mann Whitney-Wilcoxon 2 sample test and proportion with Fisher exact test. All patients were transferred to public hospital for regulatory compliance limiting follow up of HD sessions.

**Discussion:** Maintenance HD patients have increased mortality as compared to reports in normal population and is associated with need for intensive care, steroid use and ventilatory support.

**Comparison of survivors and non-survivors in HD patients with COVID-19 infection**

**PUB049**

**Starvation-Induced Metabolic Acidosis in a COVID-19-Infected Pregnant Patient**

Muhammad R. Mustafa, Stony Brook University, Stony Brook, NY.

**Introduction:** Suffolk County in NY was hardest hit with COVID 19. We present a case of a pregnant female with COVID 19 infection and high anion gap acidosis.

**Case Description:** 34 yo female, 33 weeks twin pregnancy, a/w fever, SOB and polyuria. Her oral intake was poor. She was positive for COVID 19. Her T - 100 F,O2 saturation with 02 by NC at 2 L. She had bibasilar crackles. Both babies were moving. CXR showed multifocal pneumonia. Nephrology was consulted for metabolic acidosis. A diagnosis of starvation ketosis of pregnancy was made due to anion gap acidosis, high serum beta-hydroxybutyrate and ketonemia. Dextrose 5% with sodium bicarbonate was given. She had C section, remained intubated for 24 hours, recovered well and was discharged on hospital day 7.

**Discussion:** Almost 15% of pregnant patients develop server COVID 19, Pregnant patients with COVID infection are a higher risk group.
Kidney Transplantation in the United States During the Coronavirus Disease 2019 Pandemic: An Interrupted Time Series Analysis

Fkamol Tantissattanond,1,2 Natnitka Leelaviwattanat,3 Kadikhet Saowapat,3 Natchaya Polpichai,3 Busara Songtanin,3 Possawat Vuthikraivit,3 Chawit Lopipisuth.1 Division of Nephrology, Hypertension and Kidney Transplantation, Department of Medicine, University of California, Los Angeles School of Medicine, Orange, CA; 2Multi-Organ Transplant Center, Section of Nephrology, Department of Internal Medicine, William Beaumont Hospital, Oakland University William Beaumont School of Medicine, Royal Oak, MI; 3Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; 4Faculty of Medicine Songkla Ramathibodi Hospital, Prince of Songkla University, Songkla, Thailand; 5Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; 6Phramongkutklao College of Medicine, Mahidol University, Bangkok, Thailand.

Background: The number of kidney transplant (KT) in the United States (US) has decreased during COVID-19 pandemic; however, the magnitude of this impact is unclear. Methods: A period from January 5 to April 18, 2020 was divided into pre- and post-COVID-19 periods by assigning March 1, 2020 as the first day of the post-COVID-19 outbreak in the US. The number of waitlist candidates (WLC) and new KT every 7 days were obtained from OPTN/SRTR. An interrupted time series analysis was performed to examine an incidence rate ratio (IRR) between pre- and post-COVID-19 period by using multiple Poisson regression. Results: Compared to pre-COVID-19 period, the average number of new KT during post-COVID-19 period decreased (479±33 vs 318±119 cases/week, mean differenceSEM 161±44, 95%CI 67, 255). The number of WLC was relatively stable (mean±SEM 65,937±959 cases/week); whereas, it decreased during post-COVID-19 period (61,759±2033 cases/week). Mean incidence rates (IR) of new KT during pre- and post-COVID-19 periods were 727±58 and 511±176 cases/105 WLC-week, respectively (Figure 1). The IR of new KT during post-COVID-19 period was 29% lower than those during pre-COVID-19 period (IRR 0.71, 95%CI 0.96, 2.11) and each one additional week was associated with a 4% decrease in the new KT (IRR 0.96, 95%CI 2.60, 2.63). After adjusted by age group, transplant areas, and time-study period interaction term, the IR of new KT was 3% increase for every one more week during pre-COVID-19 period (IRR 1.03); whereas, there were 12% decrease for every one more week after March 1, 2020 (IRR 0.88). Compared to pre-COVID-19 period, the IR of new KT during post-COVID-19 period was 9% lower for every additional week for each corresponding period (IRR 0.91). Conclusions: COVID-19 outbreak in the US since March 2020 is an independent factor of a significant decline in the number of new KT. Further information regarding ability of control COVID-19 may direct KT.

Spectrum of AKI in Patients with COVID-19 Infection

Introduction: With the gradual unfolding of the full spectrum of COVID 19 manifestations, Acute Kidney Injury (AKI) is emerging as a frequent association & a predictor of disease severity & mortality. We present 3 cases of AKI in COVID19 patients & illustrate the clinical course, management & outcome. Case Description: The first case was a 50-yr old male with DM, HTN, & obesity, admitted with pneumonia, dyspnea & diarrhea, developed hypotension, arrhythmia, & required intubation on day 31 of admission. The next case was a hypertensive, obese 57-yr old female, admitted with pneumonia, worsening dyspnea & respiratory failure without hypotension, was intubated on day 30 of admission. Both of the cases developed AKI with oliguria & progressed to anuria 2hrs post-intubation. Case 3 was a 72-yr old female with hypertension admitted with pneumonia, dyspnea, diarrhea, & AKI, was intubated on day 12. All cases had bilateral pneumonia on chest radiograph & significantly raised inflammatory markers (CRP, LDH, Procalcitonin, Ferritin, ALT/AST, d-Dimer, & INR). Peak S. Creat. was 4.1, 6.6, & 3.07 for cases 1, 2, & 3 respectively. Urinalysis for all cases revealed proteinuria, hematuria, plus 4+ budding yeast & signs of d-Dimer, & INR. Peak S. Creat. was 4.1, 6.6, & 3.07 for cases 1, 2, & 3 respectively. Case 1 was intubated on day 12. All cases had bilateral pneumonia on chest radiograph & progressed to anuria 24 hrs post-intubation. Case 3 was a 72-yr old female, without hypotension, was intubated on day 30 of admission. Both of the cases developed manifestations, Acute Kidney Injury (AKI) is emerging as a frequent association & a predictor of disease severity & mortality.

COVID-19 Infection in Renal Transplant Patients

Azn U. Hussain, Kasif Eqbal, Rafiea Shah, Mary Dutton, Mirmay Berry. University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom.

Background: The SARS CoV-2 pandemic has disproportionately affected vulnerable patient populations including kidney transplant recipients (KTR). Methods: Our transplant centre covers a large multi-ethnic urban population with high rates of co-morbidity and social deprivation, and provides follow-up care for approximately 1500 kidney transplant recipients. In line with national guidance, COVID-19 testing was largely restricted to those patients presenting to secondary care. When COVID-19 was confirmed or suspected, anti- proliferative drugs were stopped, maintenance corticosteroids increased, and calcineurin inhibitor was stopped in patients requiring admission. We performed a retrospective analysis of clinical presentations and outcomes in kidney transplant recipients with confirmed COVID-19 between 20th March and 20th June 2020. Results: 25 patients (approximately 1.6%) had confirmed COVID-19. 11 (44%) were female and 14 (56%) male. The median age was 61 years (range 33 – 84 years). 11 (44%) were White - British, 12 (48%) Asian and 2 (8%) Afro-Caribbean. Median time post-transplant was 84 months (range 6 – 360), and more recently transplanted patients were not at increased risk. Respiratory symptoms were the predominant presenting complaint in 19 patients (76%) followed by GI symptoms in 4 (16%). Acute kidney injury (stages 1-3) occurred in 15 patients (60%) with 7 patients (28% of whole population 46% of patients with AKI) requiring renal replacement therapy. 6 patients (40%) recovered renal function at a median follow up of 26 days (range 7 – 51). 4 (16%) were admitted to ITU for ventilation. 10 patients (40%) died (although one death was not related to COVID-19). Among the patients who died, median age was 65 years and 6 (60%) were male with ethnicity proportionate to the study population. Conclusions: The strategy of performing COVID-19 testing only in patients requiring secondary care likely i) underestimates the incidence and ii) overestimates the disease severity. However, our data show that COVID-19 confers significant morbidity and mortality in kidney transplant recipients despite prompt reduction of immunosuppression. These data will inform a revised consent process for those patients awaiting kidney transplantation. Follow up studies are required to assess longer term outcomes, and potential complications in KTRs who have recovered from COVID-19.
Conclusions: While respiratory symptoms of COVID are often stressed we noted few symptoms other than fever and cough. While less than 50% of pts had COVID COV, this was associated with a significant decrease in albumin and increase in Ferritin consistent with inflammation and malnutrition. On average it took ~4 weeks for pts to test negative once infected. With good infection control practice and PPE, nurses and COVID - pts remained free of COVID in our facility.

PUB055
AKI in Hospitalized Patients with COVID-19: A Mexican Population
Victor H. Gomez Johnson,1 Gina C. Gonzalez-Calderon,1 Antonio Camiro Zúñiga,2 José A. García Gordillo,1 Adolfo Díaz Cabral,1 Alfredo Fonseca Chávez,1 Julio C. Arriaga,1 Jose S. Lopez Gil,1 Javier Zúñiga-Varga,1 Juan Pablo Herrera Felix.1 1Centro Medico ABC, Mexico City, Mexico; 2Instituto Nacional de Cardiología Ignacio Chavez, Mexico, Mexico.

Background: Although severe acute respiratory syndrome coronavirus (SARS-CoV-2) infection is primarily a respiratory disease, other organs are also affected. Several pathological studies confirm that SARS-CoV-2 invades kidney tissue causing endothelial damage, glomerular and vascular changes, extensive acute tubular injury and podocyte viral infection. AKI in COVID-19 appears to be frequent, with an AKI incidence of up to 46%, and a 20% requirement for renal replacement therapy (RRT). Patients with AKI show a trend towards worse outcomes and increased mortality. Information on Latin-American population is scarce.

Methods: We created a cohort to describe the incidence, risk factors, and outcomes associated with AKI in hospitalized patients with COVID-19 in Mexico City, excluding patients with a known chronic kidney disease. AKI was defined and classified according to KDIGO guidelines.

Results: We included 127 patients. 11 patients (8.66%) met the criteria for severe COVID-19, and were more likely to have AKI (81.82% vs. 54.31%, p=0.078). Of the 72 (56.69%) patients that had AKI, 48% were diagnosed at the time of admission. Patients with AKI were more likely to be men (61.7% vs. 42.2%, p=0.043) and older (55.68 years vs. 48.89 years, p=0.018). With regards disease severity, 72% of them had a grade 1 AKI. 7 patients (9.72%) had grade 3 AKI, 4 of which needed renal replacement therapy. Overall length of stay was longer in patients with AKI (12 days vs. 7 days, p=0.003). A nonsignificant trend towards stay in critical care units was observed. 3 out of 127 patients died, all 3 had AKI.

Conclusions: Amongst our studied population, AKI was associated with a longer length of stay and with a trend towards a more use of critical care services. The lack of association of AKI with mortality could be due to the low overall in-hospital mortality of COVID-19 patients (2.40%).

PUB056
AKI Lingering in a Patient with Novel Coronavirus
Marc Saad, Brandon Kirshner, Reuben K. Ellis. Mercer University, Macon, GA.

Introduction: Renal manifestations of the novel Coronavirus infection has been reported during the actual pandemic. While the renal injury was more pronounced in critically ill patients, the levels of AKI, proteinuria and hematuria predicted the severity of the infection. We are reporting a severe case of AKI and proteinuria in SARS-CoV-2 infected out of proportion of its clinical manifestation.

Case Description: This is a 55 year old African American male patient with PMH of hypertension, aortic valve replacement on Warfarin anticoagulation and CKDIII-b (56.69%) patients that had AKI, 48% were diagnosed at the time of admission. Patients with AKI were more likely to be men (61.7% vs. 42.2%, p=0.043) and older (55.68 years vs. 48.89 years, p=0.018). With regards disease severity, 72% of them had a grade 1 AKI. 7 patients (9.72%) had grade 3 AKI, 4 of which needed renal replacement therapy. Overall length of stay was longer in patients with AKI (12 days vs. 7 days, p=0.003). A nonsignificant trend towards stay in critical care units was observed. 3 out of 127 patients died, all 3 had AKI.

Conclusions: Amongst our studied population, AKI was associated with a longer length of stay and with a trend towards a more use of critical care services. The lack of association of AKI with mortality could be due to the low overall in-hospital mortality of COVID-19 patients (2.40%).

Background: Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection is primarily a respiratory disease, other organs are also affected. Several pathological studies confirm that SARS-CoV-2 invades kidney tissue causing endothelial damage, glomerular and vascular changes, extensive acute tubular injury and podocyte viral infection. AKI in COVID-19 appears to be frequent, with an AKI incidence of up to 46%, and a 20% requirement for renal replacement therapy (RRT). Patients with AKI show a trend towards worse outcomes and increased mortality. Information on Latin-American population is scarce.

Methods: We created a cohort to describe the incidence, risk factors, and outcomes associated with AKI in hospitalized patients with COVID-19 in Mexico City, excluding patients with a known chronic kidney disease. AKI was defined and classified according to KDIGO guidelines.

Results: We included 127 patients. 11 patients (8.66%) met the criteria for severe COVID-19, and were more likely to have AKI (81.82% vs. 54.31%, p=0.078). Of the 72 (56.69%) patients that had AKI, 48% were diagnosed at the time of admission. Patients with AKI were more likely to be men (61.7% vs. 42.2%, p=0.043) and older (55.68 years vs. 48.89 years, p=0.018). With regards disease severity, 72% of them had a grade 1 AKI. 7 patients (9.72%) had grade 3 AKI, 4 of which needed renal replacement therapy. Overall length of stay was longer in patients with AKI (12 days vs. 7 days, p=0.003). A nonsignificant trend towards stay in critical care units was observed. 3 out of 127 patients died, all 3 had AKI.

Conclusions: Amongst our studied population, AKI was associated with a longer length of stay and with a trend towards a more use of critical care services. The lack of association of AKI with mortality could be due to the low overall in-hospital mortality of COVID-19 patients (2.40%).

Discussion: Variable histopathological lesions (FSGS, collapsing glomerulopathy, podocytopathy and tubular interstitial disease) has been described in the renal manifestations of the novel coronavirus. While its physiopathological mechanisms remain unclear, the severity of proteinuria and renal injury observed in this clinically asymptomatic patient highlight an unusual infection-driven mechanism.

PUB057
Patients with COVID-19 and Kidney Disease: Who Fared Best?
Miciela Antonius, David Jackson, Sadananda V. Aithal, Michael T. Shiel, Huw Davies. Swansea Bay University Health Board, Swansea, United Kingdom.

Background: COVID-19 poses the greatest global challenge in modern day healthcare. Chronic Kidney Disease (CKD) patients are classed as ‘high risk’ in terms of the morbidity and mortality associated with COVID-19. We present data from a large centre encompassing a 24-bed inpatient renal ward, 2 in-centre haemodialysis (HD) units and a large ITU. We aim to compare and contrast clinical outcomes for COVID-19 patients with renal disease.

Methods: Observational analysis was performed on 61 patients (mean age 65y), all positive for COVID-19. Patients were stratified according to their renal status at the point of contacting the virus (table 1).

Results: Acute Kidney Injury (AKI) (n=24; mean age 67y) – 23 of 24 patients were intubated and ventilated in ITU. 18 died. 4 remain on haemofiltration (1 patient transferred for Extracorporeal Membrane Oxygenation). Only 1 patient required ventilatory support and survived with resolution of the AKI. 1 patient requiring invasive ventilation survived with recovery of renal function. Chronic HD (n=28; mean age 68y) – 20 prevalent adult HD patients tested positive for COVID-19. 10 recovered and were discharged. 10 died. Kidney Transplant Recipients (KTR) (n=4; mean age 59y) – 3 were managed as outpatients and have recovered with functioning grafts. 1 died.

Conclusions: AKI patients had the poorest outcomes in terms of need for ventilatory support and mortality. 50% of chronic HD patients with COVID-19 died. Despite immunosuppressants, only 4 KTRs (total cohort of 352) contracted COVID-19. The introduction of virtual transplant clinics, minimisation of face-to-face contact and efficient shielding may have played a role in preventing this. These data aim to reinforce the international collaborative against this global pandemic.

PUB058
COVID-19: Angiotensin Receptor Blocker to the Rescue?
Srikanth Thiruvadudurai, Theesitha Srikanth.1 Lewis Katz School of Medicine at Temple University, Philadelphia, PA; 2Sichuan University West China Hospital, Chengdu, China.

Background: An unusual suspect has been incriminated in the Coronavirus outbreak, Renin-angiotensin-aldosterone system (RAAS). RAAS is an intriguing system that holds many mysteries that are still waiting to be unraveled and explored.

Methods: Angiotensin-II (Ang II) is well known for its proliferative and vasodilatory effects and will inhibit ACE. This paper presents ACE2 (ACE2) to prevent Ang II formation and angiotensin receptor blockers (ARB) for inhibition of Ang II receptor binding. Angiotensin-1-2 (Ang I-2) along with ACE2, in the other hand, proven to have vasodilatory, antiproliferative and overall protective effects. Given the beneficial effects of ACE2 and Ang 1-7, it would make sense to potentiates this pathway for our sake, especially in the setting of lung injury.

Results: In the recent years, it’s been shown that Coronavirus is not only using the ACE2 to enter the cell, but also decreasing ACE2 expression at the same time. This is detrimental. ACE2 expression seems to be decreased in elderly and elevated in obese. It is very interesting to see that COVID severity varied among these individuals, likely due to the precarious balance between the amount of viral entry and activity of ACE2/ Ang I-7. If we can upregulate the expression of ACE2 by some mechanism, this would in turn increase the production of beneficial Ang 1-7. But with upregulated ACE2, one must make sure that there is a competitive substrate for ACE2, in order to make the Coronavirus binding of ACE2 difficult. A suitable candidate for that substrate, is Ang II, ARB, as opposed to ACE1, would seem to increase the levels of Ang II, while upregulating the expression of ACE2. Theoretically, we can reap the benefits of enhanced ACE2 expression while competitively inhibiting Coronavirus binding to ACE2, by the increased levels of Ang II. Titrating up ARB dosing as tolerated by the patient, will be necessary for the above mechanism to work effectively.

Conclusions: Increasing ACE2 and Ang 1-7 receptor binding, will determine the degree of benefit of ARBs in diminishing Coronavirus infectivity and severity. Tolerability to ARBs, will also be a limiting factor when treating the patients. Studying ACE2 levels, Ang I-7/Mas receptor activity in different patient populations and the correlation between Coronavirus infection and outcome, would be of value in the foreseeable future in patients worldwide.
COVID-19 Financial Ramifications on the Pediatric Nephrology Workforce

Darcy K. Weidemann,1,2 Allison C. Redpath,4 Isa Ashoor,1 Children's Mercy Hospitals and Clinics, Kansas City, MO; 3University of Missouri Kansas City, Kansas City, MO; 4LSU Health New Orleans, New Orleans, LA; 1University of Wisconsin System, Madison, WI.

Background: The adverse impact of the COVID-19 pandemic on state and federal budgets, coupled with widespread lockdown measures, and reduced non-COVID-19 clinical volume has forced healthcare and academic organizations to adapt to declining revenues. We examined the financial ramifications of the pandemic on the pediatric nephrology workforce.

Methods: Online survey distributed to active members of the American Society of Pediatric Nephrology (n=997) over 2 weeks in May 2020.

Results: Response rate was 16% (n=144). Most respondents (34%) were 35-44 years old, followed by 45-54 years old (24%). Most were White (65%) followed by Asians (24%). Respondents resided in the South (31%) followed by the Northeast (29%) and Midwest (22%). Most were faculty (92%) in early career stage (Assistant Professor, 31%), affiliated with a free-standing children’s hospital (55%) or a children’s hospital within an adult hospital (36%), working full time (79%) with an average of 60% effort dedicated to clinical activities. Most acknowledged feeling worried about the long-term financial ramifications of COVID-19 on their employer (88%) and their own financial future (75%). Figure 1 summarizes the financial repercussions reported. The majority (47%) were unclear whether they will be expected to assume increased clinical duties once stay-at-home orders are lifted, however, 44% reported new childcare or eldercare responsibilities.

Conclusions: Overwhelming concern regarding employee and employer financial security exists among practicing pediatric nephrologists in the context of the COVID-19 pandemic. Uncertainty, institutional hiring freezes, compensation reduction, and increased duties in one’s personal life all pose additional threats to a specialty with an already looming workforce shortage. Comprehensive strategies to prevent attrition and burnout are required to sustain the pediatric nephrology workforce during recovery from the COVID-19 pandemic.

Not All Coronavirus Patients Are Dying from Broncho-Pneumonia: Most Might Be Dying from Cerebro-Neurovascular Vascular Diseases and Cardiovascular Complications

Yahya Saglikier,1,2 Hassan S. Saglikier,1,2 Piril Saglikier Ozkanay,1,2 Nuray Paylar,1,2 Sagliker Nephrology and Hypertension Unit Çukurova Universitesi Tip Fakultesi, Adana, Turkey; 3Sagliker Nephrology and Hypertension Unit, Adana, Turkey; 4Ceyhan State Hospital, Ceyhan, Turkey; 5Karaisali Community Health Center, Adana, Turkey.

Introduction: Acute bronchopneumonia is not sufficient to explain deaths. Lungs, brain-nerves - heart- cardiovascular system might be playing for key roles. Three are playing together. In last days, lungs and brain and heart suddenly are stopping.

Case Description: Key places are neurological conjunction systems between brain, lungs and cardiovascular systems. All organs are being regulated by last two systems. All mentioned activities are being regulated in those systems. All decisions and functions of human are giving there.

Discussion: A neurologist and a cardiologist must be involved in treatment in late stages. This is vital. 1-Pulmonologists are following lungs. 2-Pulmonary-toracal surgeons are giving there organs are being regulated by last two systems. All lungs and cardiological systems. All o...
The role of treating severe COVID-19 patients with MHD. Cardiovascular disease is the leading cause of death in ESRD patients. The cardiovascular events of this patient might be combined with COVID-19-associated lung injury and worsening of pre-existing CHD. We suggested lack of family support during quarantine might be a reason of psychiatric symptoms. In conclusion, personalized immunomodulation therapies might be helpful in treating severe COVID-19 patients with MHD. Cardiovascular events were associated with poor outcome.

### PUB062

#### Clinical Presentation of Hemodialysis Patients with COVID-19: A Single-Center Study with 18 Patients

Eliana Dina-Battle, Hector A. Pantaleon, Mirtha C. Almanzar, Noemi Acevedo Rodriguez.

**Background:** SARS-CoV-2 has affected every nation around the world. The 1st case in the Dominican Republic was reported in early March, with the most affected being the elderly and patients with comorbidities like cardiovascular diseases. Most hemodialysis patients share these comorbidities, in addition to a weaker immune system and health care facility exposure, it is thought to be a vulnerable population. The aim is to describe the clinical manifestation, main laboratory abnormalities, imaging findings at the moment of presentation, and the clinical course of patients on hemodialysis diagnosed with COVID-19.

**Methods:** Exploratory study on 18 dialysis patients with Covid-19 in a renal replacement therapy facility. Demographics, symptoms, laboratories, CT scan, hospital course, ventilation requirement, treatment and complications were described.

**Results:** With a population of 204 patients, 18 were diagnosed with Covid-19 in the first 2 months of the outbreak in our facility. 77.8% were males, mean age was 60 years, and 44% had known contact with infected people outside the facility. All patients had cardiovascular disease and 12 had diabetes. Cough was the most common manifestation 77.8%, dyspnea 66.7%, fever 55.6%, and malaise 44.4%, among others manifestations. Oxygen therapy was required in 66.7%, with 11% needing mechanical ventilation. All presented abnormal CT scan findings, 60% with a COVID-RADS grade 3. Three patients were positive and asymptomatic on a round RT-PCR test taken for all facilities patients, 2 of them with CT scan graded COVID-RADS 3. Only symptomatic patients were admitted, 3 were directly admitted to the ICU, and 2 were later transferred from inpatient floor to ICU. The mean duration of hospitalization was 11 days and just 1 lethal outcome. At the moment of admission, 22.2% presented negative results on RT-PCR but had clinical and imaging findings consistent with Covid-19, with serologic conversion later.

**Conclusions:** Even with the increased risk of exposure, some comorbidities, and a weaker immune system, these didn’t necessarily determine a higher probability of infection. We have found a high incidence of respiratory symptoms, in contrast to other case reports. Asymptomatic cases had imaging with COVID-RADS grade 3, this made us consider that the COVID-RADS grade on CT scan is a helpful tool for diagnosis of Covid-19.

### PUB063

#### Pink Urine in a Patient with COVID-19

Mengqing Ma, Sir Run Run Hospital, Nanjing Medical University, Nanjing, China.

**Introduction:** Pink urine syndrome has been reported as a rare symptom described after surgery and propofol anesthesia. COVID-19 is not only manifested as a respiratory disease characterized by viral pneumonia, but also damage such as kidney, heart, blood and nervous system especially in severely ill patients.

**Case Description:** A 56-year-old man was diagnosed as severe COVID-19. He was admitted to ICU and underwent the tracheal intubation. During this treatment, propofol was used to sedate. He suddenly excreted cloudy pink urine on that day (Figure 1). There were some pink crystals in the urine bag and pink sediment at the bottom of the urine bag (Figure 2, Figure 3). His urine dipstick showed a specific gravity of 1.02, pH 5.5, blood (1+) and protein (1+). He had no urinary tract symptoms and his urine cultures were normal. His blood gas analysis showed pH was 7.3. His colour of urine gradually returned to normal when the patient was given intravenous Sodium bicarbonate injection.

**Discussion:** Pink urine syndrome is a phenomenon in which uric acid precipitates into the urine due to reduced urinary pH. Propofol can increase the excretion of uric acid in the urine. Lower urine pH will reduce the solubility of uric acid, promoting the formation of amorphous uric acid crystals, which exhibit a characteristic pink color. At the same time, metabolic acidosis may aggravate this phenomenon. COVID-19 has been reported to invade cells mainly through ACE2 receptors, ACE2 receptor is strongly expressed in the proximal tubule of the kidney, causing acute tubular necrosis. It has suggested that the kidney is one of the main targets of COVID-19. While considering the pink urine syndrome might caused by propofol, we speculate that COVID-19 could damage the renal tubule which affect its reabsorption of uric acid, which may worsen the uric acid crystalinity.

### PUB064

#### Telemedicine in the Care of Kidney Transplant Recipients with COVID-19

Fawaz Al Ammary, Mohammad Abuzeineh, Abimerki Muzaale, Deidra C. Crews, Robin K. Avery, Daniel C. Brennan, Dorry L. Segev. Johns Hopkins University School of Medicine, Baltimore, MD.

**Introduction:** Kidney transplant (KT) recipients with COVID-19 symptoms are bringing challenges to providers given the risk of COVID-19 exposure to health care workers, patients, and the public.

**Case Description:** Three KT recipients with COVID-19 were managed using telemedicine via synchronous video visits integrated with an electronic medical records system, from home to inpatient settings (Figure 1-2). Patient 1 is a 53-year-old male s/p KT in 2012; Patient 2 is a 56-year-old female s/p KT in 2019; and Patient 3 is a 53-year-old female s/p simultaneous liver-kidney transplant in 2014. Patients 1 and 3 had follow-up COVID-19 NAT testing: Patient 1 converted to be negative at 24 & 28 days, whereas Patient 2 converted to be negative at 45 & 48 days.

**Discussion:** Telemedicine helped assess, diagnose, triage, and treat patients with COVID-19 while avoiding an ER or outpatient clinic visit. We highlight the value of telemedicine in the maintenance of uninterrupted follow-up care for immunosuppressed patients with prolonged viral shedding.
Table 1: Patients 1 and 2 laboratory test results during hospitalization. Patient 3 was not hospitalized.

Table 2: Clinical course of the three patients with COVID-19 who were managed via telemedicine

**PUB065**

**Urinary Abnormalities and Urinary Sediment Findings in COVID-19 Patients**

**Background:** Coronavirus disease 2019 (COVID-19) is a new disease of pandemic proportions. There are only a few reports about urinary abnormalities in this disease, and to our knowledge there are no reports about the usefulness of urinary sediment on prognosis. Our aim was to describe the urinary abnormalities in COVID-19 and to assess the utility of urinary sediment on prognosis in COVID-19.

**Methods:** Prospective, single-center study, in patients diagnosed with COVID-19 (with a positive RT-PCR test), who were admitted in our hospital, from April 2020 to date, and whose urine sample could be obtained at admission to the isolation wing.

**Results:** 22 patients were included: 17 (77.3%) had proteinuria, 12 (54.5%) had microscopic hematuria, and 9 (40.9%) had leukocyturia. Granular casts (with a Chwla cast scoring index greater than 3) were present in 8 (36.4%) patients. Of the 8 patients with granular cast, 6 developed an AKI (75%), 2 required hemodialysis (25%) and 3 died (37.5%). Of the 14 patients whose urinary sediment was classified as bland, 5 developed a bland urinary sediment and a sediment showing granular casts for the need of hemodialysis or death (p=0.02), with a positive LR of 3.5.

**Conclusions:** The urinary sediment is a cheap, available tool for the prognosis of need for hemodialysis or death in patients diagnosed with COVID-19, and should be taken into consideration in the assessment of these patients by the Nephrology department.

**PUB066**

**Repurposing Baby Monitors in COVID-19**

Sobia N. Khan, Sandeep K. Mallipattu. Stony Brook University, Stony Brook, NY.

**Introduction:** As of May 2, total of 1,130,075 confirmed cases resulting in 65,605 deaths were reported in US. Nearly 3.2% of individuals with COVID-19 develop AKI and have been reported to require dialysis. Initial reports from Wuhan, the burden of acute kidney injury was relatively low, about 3% -9%, subsequent analysis have demonstrated increase in the incidence to 15%.

**Case Description:** In February, 376 hemodialysis and 59 CRRT while in March, 273 hemodialysis and 30 CRRT offered in our hospital. During pandemic bed capacity doubled from 650 to 1317 beds. Physical space gained by converting ambulatory surgical center and ambulatory locations. In April, observed 1,811 COVID-19 patients admitted to the hospital with 50 chronic hemodialysis patients, 30 were COVID positive. 334 kidney injury was relatively low, about 3% -9%, subsequent analysis have demonstrated increase in the incidence to 15%.

**Discussion:** To minimize the risk of exposure in COVID-19 isolation rooms we implemented telemonitoring strategy. We identified baby monitors could serve “read-to-go” telemonitoring. VTech Baby Monitor model display. HD camera uses WiFi connection to capture movements and sounds which helps in monitoring the patients in real-time. The camera ability to pan 360 degrees, tilts 82-degrees and zooms ten times to enable viewing of the dialysis monitor and patient. Two-way voice communication allows easy communication between patient and nursing. Before hemodialysis nurse sets up camera by the patient’s bedside (1 camera facing the dialysis monitor other camera facing patient and the dialysis access). Dialysis nurse visualize through the handheld monitor. Telemonitoring system COVID19 patients undergoing hemodialysis we observed zero positive COVID-19 dialysis staff.
PUB067

Impact of Ethnicity on COVID-19 Infection and Mortality Amongst In-Centre Haemodialysis Patients
Gregor D. Young, Noam Roth, Kieran McCallerty, Suzanne H. Forbes, Andrea Cove-smith. Royal London Hospital, London, United Kingdom.

Background: It is reported that patients of BAME origin are at greater risk of infection and death due to COVID-19. We describe outcomes in an inner city, ethnically diverse in-centre haemodialysis (HD) population during the pandemic.

Methods: A total of 1253 patient electronic records were analysed retrospectively. 207 infections were recorded -197 patients tested positive for Sars-Cov-2 on validated nasopharyngeal PCR analysis and 10 patients included due to high clinical suspicion. Ethnicity data is self-reported. All COVID-19 positive patients were isolated for subsequent dialysis sessions. Whole-cohort screening confirmed the rates of infection.

Results: Overall rate of infection amongst the group was 16.5% (n=207), hospitalisation 7.5% (n=94) and death 3.5% (n=44). Within COVID-19 infections, hospitalization rate was 45% and mortality 21%. Seven patients received critical care and two were intubated. Ethnicity data are shown in table 1: There was no significant difference in rates of COVID infection between ethnic groups. The risk of infection in BAME patients was not significantly greater than in white patients (p=0.24, OR 0.79, 95%CI 0.55-1.14). The mean age of those who died from COVID did not differ from the entire cohort (62 vs 63.2 years). Males made up the majority of both the baseline cohort (61.2%) and those infected with COVID (58.5%). 71% of those who died were male. Body mass index did not differ between the group as a whole and those infected with COVID. Rates of diabetes mellitus did not differ significantly between those infected with COVID and those who died.

Conclusions: We have defined COVID infections and outcomes within a real-life, large haemodialysis population. Hospitalisation and mortality rates were high, and patients self-reporting as black or Asian were over-represented in the infected group compared to the baseline prevalent HD population. Higher rates of death were observed in black and asian groups but conclusions are limited by small numbers. Larger collaborative studies are required to expand on these findings.

Ethnic breakdown of HD cohort and COVID cases

PUB068

COVID-19 Management in New York City Kidney Transplant Recipients: Before and After the Apex

Background: Kidney graft recipients receiving immunosuppressive therapy may be at heightened risk for Covid-19 and adverse outcomes. We aimed to study how practice patterns and outcomes changed before and after the peak incidence of cases in New York City.

Methods: We reviewed 68 consecutive adult kidney graft recipients from our center diagnosed with SARS-CoV-2 from March 13, 2020 to May 25, 2020. We compared outcomes of those treated from March 13 until the apex of infections on April 14 (Phase 1), and those treated from April 15 to May 25, 2020 (Phase 2).

Results: Characteristics of both Phase 1 and Phase 2 patients are described in Table 1. Inflammatory markers were lower in the second phase as was patient mortality. Changes in management strategies between the two phases are highlighted in Figure 2. Graft loss occurred in 4 patients (6%) and there were 5 deaths (7%).

Conclusions: Data from our study suggest that management strategies of immunosuppressed patients changed over the course of the Covid-19 Pandemic in New York City, including less use of hydroxychloroquine, and increased use of novel agents such as remdesivir. Additional data are needed to better understand if the decrease in patient mortality during the second phase is attributable to better management or lower inflammatory response in the setting of Covid-19 illness.
**Effect of COVID-19 Infection in Three Patients Treated with Rituximab**

**Anushya Jeyabalani, Reza Zonozi, Jillian Rosenthal, Karen A. Laliberte, John Niles. Massachusetts General Hospital, Boston, MA.**

**Background:** Rituximab (RTX), a monoclonal antibody against the CD20 antigen found on B lymphocytes, is widely used for glomerular diseases. It may be advantageous in COVID19 given the exaggerated immune response and cytokine storm elicited by Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) or could be detrimental given the impaired response to infections in immunocompromised patients.

**Methods:** We examined the clinical presentation and outcomes of 3 patients undergoing treatment with RTX who were infected with SARS-CoV-2.

**Results:** 2/3 patients had complication of severe hypoxemia with evidence of pulmonary infiltrates on imaging. Both had underlying ANCA vasculitis with a history of pulmonary involvement. Both were treated with remdesivir and one received convalescent plasma. The patient who received convalescent plasma was SARS-CoV-2 RNA negative at 3 weeks. The patient who received remdesivir but not plasma remained positive for SARS-CoV-2 RNA at 7 weeks and was negative for IgM and IgG antibodies at 4 weeks. The third patient recovered without hospitalization and had a first negative RNA test at 3 weeks and was positive for IgG antibodies when tested at 7 weeks despite a confirmed zero B cells by flow cytometry.

**Conclusions:** 3 out of 3 patients who developed SARS-CoV-2 infections while on RTX recovered. A larger review of individuals on RTX therapy infected with SARS-CoV-2 should be examined to study the association between B cell depletion and COVID19.

**AKI Following Hemolysis Related to Hydroxychloroquine Treatment for COVID-19 in a G6PD-Deficient Patient**

**PUB070**

**Introduction:** COVID-19 is associated with significant morbidity and mortality. As a potential treatment, Hydroxychloroquine (HCQ) is actually widely used. Concern has arisen about side effects of HCQ. Here, we describe severe AKI following HCQ administration for COVID-19.

**Case Description:** A 65-year-old patient has been admitted for fatigue. His treatment was glazide, lereadimine for T2DM and arterial hypertension. Initial evaluation revealed: SpO2 91%. Blood tests were detailed in the table1. COVID-19 pneumonia was diagnosed. HCQ and azithromycin were given, including a loading dose of HCQ. Patient developed severe acute hemolytic anemia (AHA) and AKI (table1, Day 7). Blood tests were consistent with acute hemolytic anemia (AHA). Glucose-6-phosphate dehydrogenase (G6PD) activity showed <0.2IU/g hgb (7.0-17.0) consistent with AHA triggered by HCQ in a G6PD deficient patient, and further complicated with AKI. Given the ongoing oliguria, hemodialysis was commenced. 23 days later, recovery of kidney function allowed him to stop dialysis. There remains a slight impairment of kidney function tests (table1, Day 72).

**Discussion:** The residual enzyme activity of G6PD deficiency determines the severity of clinical manifestations which are usually triggered either by fava bean ingestion or drugs, and are dose-dependent. This patient had a severe deficiency and he received a loading dose of an at-risk drug. Both induced hemolysis crisis. AKI is a rare complication of AHA related to G6PD deficiency. The need for renal replacement therapy seems exceptional. Renal recovery could be incomplete. Severe G6PD deficiency can manifest late in life. HCQ should be used with caution given potential severe side effects. We then recommend early monitoring of hemolysis parameters.

**COVID-19 in Kidney Transplant Recipients**

**PUB072**

Rachana Marathi, Paul W. Davis, Franco H. Cabeza Rivera, Wisit Cheungsapastorn, Swetha Rani Kanduri, Karthik Kovvuru, Pradeep Vaitla. University of Mississippi Medical Center, Jackson, MS.

**Background:** Coronavirus disease 2019 (COVID-19) is caused by Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). Kidney transplant recipients are at a higher risk for complications due to comorbid conditions and concurrent immunosuppression. We like to describe a small cohort of kidney transplant recipients with COVID-19.

**Methods:** A single-center, retrospective observational cohort study describing short term outcomes of COVID-19 infection in kidney transplant recipients.

**Results:** A total of 8 kidney transplant recipients were diagnosed with COVID-19 with a mean age of 58 yrs (26-78), predominantly African American (7/8), mean duration...
from transplant 3.5 yrs (1.5-11 yrs). All patients have HTN (8/8), half the patients have Diabetes Mellitus-2 (4/8). Common presenting symptoms are fever and shortness of breath. 6/8 patients required hospitalization. 8/8 patients were managed with a reduction of immunosuppression, primarily by decreasing the dose or holding the anti-proliferative agent. 1/8 patients died, 4/6 discharged from hospital, 1/6 still admitted to the hospital with resolution of clinical features. 6/6 patients required supplemental oxygen. 2/6 patients required ICU stay and 1/6 required mechanical ventilation and renal replacement therapy. 3/6 hospitalized patients received hydroxychloroquine/ Azithromycin combination and 1/6 received Remdesivir. Median hospital stay is 5 days with a mean of 9 days. The patient who required mechanical ventilation and renal replacement is the only recipient who died from COVID-19 at our transplant center.

Conclusions: COVID-19 is a novel infection primarily presenting with fever and shortness of breath. The course of illness appears to be severe with the majority of patients requiring supplemental oxygen and a third of hospital admitted patients required ICU stay. Reduction of immunosuppression appears to be helpful, however, no control group available. COVID-19 affected population is predominantly African American (7/8) and older recipients with age > 50 yrs (7/8).

Introduction: Patients with COVID-19 typically present with respiratory illness. AKI is a common complication of COVID-19. Although the etiology of AKI remains unclear, it is thought to be secondary to hemodynamic changes, cytokine release, and/or direct viral (SARS-CoV-2) cytotoxicity. The following case describes a patient who presented only with GI symptoms, which led to the diagnosis of COVID-19 and AKI.

Case Description: 71 year-old white male, a nursing home resident, has DM2, HTN, CAD, chronic 3 and dementia/cognitive impairment. His baseline serum Cr was 1.49 mg/dL in 2019. He was brought to our hospital for a new diagnosis of AKI and COVID-19. Three days ago, he started to have nausea/vomiting, and was treated with Zofran. No improvement the next day. Bp 96/63, P 107, Temp 97.7. COVID-19 test was positive. On the following day he was brought to a local ER after 3 large projectile emesis. Labs revealed BUN/Cr 80/9.4. He was given 1 liter IVF and was transferred to our hospital. He had watery brown-greenish stools, although he denies diarrhea or abdominal pain. Meds included Insulin, statins, heparin, SSRI, and donepezil. At our ER, the patient was awake, alert, oriented to self and year. T 98.3, BP 119/71, P 119, RR 18, SpO2 95% on RA, PE was unremarkable. Blader scan: 150 mL. Lab: WBC 10.9, Hb 13.3, Plt 207. Na 130, K 4.0, Cr 79, bicarb 17, BUN 85, Cr 8.6, Ca 7.3, Phos 6.6, Alb 3.2. LFT was normal. FeNa = 1.5%. UA: pH 5, prot 1+; Glu 50, RBC 4, WBC 4, with amorphous sediments. CXR: lungs were clear. Renal ultrasound: kidneys normal in size and echogenicity. No obstruction. Patient was admitted to the COVID ward. Patient’s nausea and vomiting stopped upon his admission, although his watery stools lingered. He was treated with iv fluid to optimize his hemodynamics. Over the next 5 days patient’s serum Cr decreased to 4.9mg/dL.

Discussion: Since the COVID-19 pandemic, GI symptoms and AKI are often regarded as complications of the overall respiratory illnesses. Patients with only GI symptoms were often not suspected for COVID-19. The causes of this patient’s AKI include immunologically mediated ATN/ possible cytokine release. Regarding direct viral cytotoxicity, postmortem data has shown the presence of coronavirus-like particles in podocytes and tubule cells. While the direct viral effect to the kidneys is still not understood, treatment with conventional approaches may significantly improve renal outcome.

Results: He was discharged on Apixaban.

PUB075
A COVID-19 Patient with AKI
Jinhua Zhao.1,2 Louis Stokes VA Medical Center, Cleveland, OH; ‘Case Western Reserve University School of Medicine, Cleveland, OH.

Introduction: Patients with COVID-19 typically present with respiratory illness. AKI is a common complication of COVID-19. Although the etiology of AKI remains unclear, it is thought to be secondary to hemodynamic changes, cytokine release, and/or direct viral (SARS-CoV-2) cytotoxicity. The following case describes a patient who presented only with GI symptoms, which led to the diagnosis of COVID-19 and AKI.

Case Description: 71 year-old white male, a nursing home resident, has DM2, HTN, CAD, chronic 3 and dementia/cognitive impairment. His baseline serum Cr was 1.49 mg/dL in 2019. He was brought to our hospital for a new diagnosis of AKI and COVID-19. Three days ago, he started to have nausea/vomiting, and was treated with Zofran. No improvement the next day. Bp 96/63, P 107, Temp 97.7. COVID-19 test was positive. On the following day he was brought to a local ER after 3 large projectile emesis. Labs revealed BUN/Cr 80/9.4. He was given 1 liter IVF and was transferred to our hospital. He had watery brown-greenish stools, although he denies diarrhea or abdominal pain. Comparative Evaluation of Orthostatic Hypotension in Patients with Diabetic Nephropathy

Gamze Aytes, Rumeyza Kazancioglu, Omer C. Elioglu, Meltem Gursu, Serra Aran, Aysegul Yabaci. Bezmialem Vakif Universitesi Tip Fakultesi, Istanbul, Turkey.

Background: Orthostatic Hypotension (OH) affects 5-20% of population. Our study investigated the presence of OH in diabetic nephropathy patients (DNP) and the factors affecting OH in comparison with other chronic kidney disease patients (CKDP).

Methods: Patients presented to the nephrology clinic and consented were included in the study. DNP were defined by renal biopsy and/or clinical criteria. CKDP of same sex, age and eGFR were matched to DNP. Demographic parameters and medications were obtained from the records. OH was determined by mayo clinic criteria. Same researcher used the electronic device to measure the blood pressures (BP). All samples were taken and analyzed the same day for biochemical and hematological parameters and albuminuria.

Results: 112(51F,61M, mean age:62.56±9.35 years) DNP and 94(40F,54M, mean age:62.23±10.08 years) CKDP were included. 70.5% DNP vs 61.7% CKDP had OH (p=0.181). The mean change in systolic BP in DNP was 21.50±16.10mmHg and it was 16.25±10.50mmHg in diastolic BP. In CKDP mean change in systolic BP was 22.1±13.90mmHg and it was 5.96±6.80mmHg in diastolic BP. There was no difference between the groups in systolic BP (p=0.797), but it was present for diastolic BP (p=0.025). 60.0% and 74.7% M patients had OH (p=0.028). Uric acid levels were 7.18mg/dl in OH patients and 6.36mg/dl in non-OH (p=0.017). Blood albumin level was not different in two groups (p=0.902). 73.7% of patients on calcium channel blockers developed OH (p=0.015) and OH developed in 80.6% of 36 patients on alpha blockers (p=0.049).

Conclusions: Our study demonstrated OH is frequent among DNP and there was no difference compared to CKDP. It is important to check OH in all CKDP as it is more common than thought.

Clinical Practice Gap Analysis of CKD in Type 2 Diabetes from Identification to Diagnosis to Management

Amy Larkin,1 Kelly L. Hanley,2 George L. Bakris.3 1Medscapes LLC, New York, NY; 2UCHicago Medicine, Chicago, IL.

Background: Understanding clinical practice gaps in the identification, diagnosis and management of CKD in patients with T2D can inform development of tools to improve physician practices.

Methods: A survey instrument of 25 multiple choice, knowledge- and case-based questions allowed participants to assess their knowledge, attitudes, and confidence with regard to CKD in T2D. The survey was available online to physicians across the globe without monetary compensation or charge. Respondent confidentiality was maintained and responses were de-identified and aggregated prior to analyses. Initial data collection occurred from February 26, 2020, to April 20, 2020.

Results: To date, 193 nephrologists completed the full assessment. Physicians demonstrated gaps in the following areas. When asked how satisfied nephrologists were with current treatment approaches for managing CKD in patients with T2D, 10% selected very satisfied, 74% selected moderately-mostly satisfied, and 16% slightly-not satisfied.

Conclusions: This educational research on assessment of physicians’ clinical practices yielded important insights into clinical gaps related to identification, screening, diagnosis, and management of CKD in patients with T2D. Further studies are planned to assess the effect of medical education on decreasing these clinical practice gaps.

A Study on an Early Marker of Renal Damage in Known Diabetics Living in an Urban Slum of Hyderabad, India

Raghav K. Ranga,1 Mahesh Kumar Mummidhi,2 Rhonda Dzakpasu.1 1Georgetown University, Washington, DC; 2National Institute of Nutrition, Hyderabad, India.

Background: India is the nation with the second largest prevalence of type 2 diabetes mellitus in the world, with an estimated 69.2 million people having the condition as of 2015. In the surrounding as a whole, 78.3 million people live with type 2 diabetes, out of which 52.1% are undiagnosed. 44% of all cases of nephropathy are caused by type 2 diabetes mellitus.

Methods: There are two goals for this cross-sectional study: i) to measure the prevalence of microalbuminuria and albuminuria in type 2 diabetic patients and ii) to determine associated factors that elevate a diabetic’s risk for kidney disease. The study was done with 100 type 2 diabetics from Adda Guuta, Hyderabad, India. We performed urinalyses to measure urinary albumin, and gave a modified WHO STEPS questionnaire to assess lifestyle risks.

Results: 42 of the 100 patients surveyed were normoalbuminuric, 46 were microalbuminuric, and 12 were albuminuric. Significant risk factors were: being older than 44, having type 2 diabetes for longer than 6 years, drinking alcohol, and smoking.

Conclusions: The prevalence of microalbuminuria in type 2 diabetic people is quite a bit higher than it was in previous studies. Primary prevention needs to be emphasized in this population so that future generations don’t get type 2 diabetes mellitus. If patients get their serum creatinine checked, then should nephropathy arise, then it will be detected earlier, and treatment could start earlier. Future studies could ask questions regarding stress on the questionnaires, as well as check the patients’ serum creatinine, blood pressure, and lipid profiles.

PUB081
The Miraculous Shrinking Kidney

Introduction: Glomerular hyperfiltration is common in conditions such as diabetes and obesity and can result in glomerular hypertrophy and organ growth as well as corresponding GFR increase. When hyperfiltration results in proteinuria this is a poor prognostic sign for ckd progression and needs to be managed appropriately. With this case report, we document dynamic progressive reduction in sizes of almost 18 and 16 cm, kidneys, associated with resolution in proteinuria, after weight loss.

Case Description: A 70-year-old man with type II diabetes mellitus with retinopathy, hypertension and morbid obesity was referred to nephrology for very enlarged kidneys and proteinuria. Of note, two weeks prior he had undergone a gastric bypass surgery. Prior to gastric surgery his BMI had been as high as 41.6 kg/m2. Kidneys measured 17.7 cm on the right and 15.9 cm on the left. His spot protein to creatinine ratio pre-gastric bypass was 2,388 mg/g. Due to the significant growth of the kidneys, concern was initially for an infiltrative process and kidney biopsy was considered. However, the patient had just been on a diet and exercise program and weight loss and dietary changes, within six months, the patient had lost sixty pounds and decreased his BMI to 32.5 kg/m2. His A1c had decreased from 8.1 to 6.9. He was able to stop insulin and was maintained on metformin 1000mg bid and sitagliptin 100mg. His urine protein to creatinine ratio dramatically reduced from around 2388 mg/dl to normal level of 78 mg/g.

Twenty-nine months post-surgery he has lost roughly ninety pounds and his BMI has decreased to 30. Remarkably his kidneys have decreased in size to 14.7 and 13 cm in size.

Discussion: This case illustrates dynamic change in kidney size by imaging with large weight loss as well as successful remission of sub-nephrotic range proteinuria following gastric sleeve surgery, extensive weight loss and glucose control.

PUB082
Multiple Targets on Sodium Excretion with SGLT2 Inhibitors, Furosemide, and Spironolactone Improves Diuretic Resistance in Patients with Diabetic Nephropathy on CKD Stage 3-4: A Pilot Study
Wei Liang, Renmin Hospital of Wuhan University, Wuhan, China.

Background: At stage 3-4 of chronic renal disease, patients with diabetic-induced renal dysfunction are not sensitive to the conventional diuretic therapy based on loop diuretics and thiazide diuretics, leading to the earlier renal replacement at stage CKD 3-4. The lower sodium excretion could contribute to the development of diuretic resistance. The protective effects of SGLT2 inhibitors on cardiovascular is contributed by metabolic regulation and osmotic diuretic effect of glucose due to extra excretion of Glucose. The present study aims to investigate the efficacy and safety of SGLT2 inhibitors on the diuretic resistance of diabetic nephropathy at CKD 3-4 stage.

Methods: Patients with Diabetic nephropathy at CKD3-4 stage were administered with furosemide + hydrochlorothiazide for 3 days with urine volume <1000ml, sodium excretion <90mmol followed by Dapagliflozin/Canagliflozin once a day for 7 days.

Results: 3 male and 7 female patients with diabetic nephropathy were included, aged 51-80 years, with eGFR 60-4.6ml/min, and 3 patients presented with cardiac insufficiency. Urine volume was 800±300mL in 4 hours before treatment and 2000±500mL in 24 hours after treatment. Sodium excretion in urine was 80±20mmol/24 hours before treatment and 150±50mmol/24 hours before treatment. The average net weight change was -3.5±2.2kg. The Scr increased by 30%±5% before and after treatment, and the renal function in 2 patients increased by >30% after 7 days of treatment, and returned to the level of Scr before treatment after 7 days of withdrawal of Dapagliflozin/ Canagliflozin. Electrolyte levels were comparable before and after treatment.

Conclusions: The diuretic regimen based on SGLT2 could significantly improve the resistance of diabetic nephropathy patients to loop diuretics, increase urinary sodium excretion, and slightly elevate renal function in the short term without affecting blood electrolyte level. The efficacy and safety of long-term use of SGLT2 in diabetic nephropathy patients at CKD3-4 stage need further investigate in larger sample size.

PUB083
Peripheral Neuropathy in a Hemodialysis Patient with a Normal Serum Vitamin B12 Level: Possible Vitamin B12 Deficiency in Target Tissues
Yadanar M. Lej,1 Thinn E. San,1,2 Hun M. Aung,1,3 Aye M. Thida,1 Myat E. Mon,1 Kyaw M. Thein,1,3 Kyaw Hla,1 Alexander M. Swan,1,6 1Nephrology Hypertension Renal Transplant & Renal Therapy, LLC, Avend, NJ; 2Icahn School of Medicine at Mount Sinai Elmhurst Hospital Center, Elmhurst, NY; 3Interfaith Medical Center, Brooklyn, NY; 4Woodhull Medical and Mental Health Center, Brooklyn, NY; 5South East Regional Health Authority, Kingston, Jamaica; 6Rutgers New Jersey Medical School, Newark, NJ.

Introduction: Many hemodialysis patients suffer from vitamin B12 deficiency, usually due to inadequate nutritional intake. Besides, food sources of vitamin B12 contain high concentrations of electrolytes, which are harmful to these patients. Thus, they are restricted to foods with low vitamin B12 content. Moreover, high-flux dialyzers remove vitamin B12 molecules from circulation, leading to vitamin B12 deficiency. We report a hemodialysis patient presenting with peripheral neuropathy and a normal serum vitamin B12 level whose symptoms improved with monthly vitamin B12 injections after excluding other differential diagnoses of peripheral neuropathy.

Case Description: An 86-year-old man with a history of ESRD on hemodialysis for 3 years along with HTN and CAD presented with fatigue, muscle weakness, and numbness of his extremities for 3 weeks. He was taking aspirin, dipyridamole, finasteride, tamsulosin, and pravastatin. His dietary history was significant for poor nutritional intake. Laboratory findings showed Hb 10.6 g/dL, MCV 102 fL, RBS 87 mg/dL, potassium 4.6 mmol/L, and BUN 42 mg/dL. Common causes of peripheral neuropathy in ESRD patients, such as uremic neuropathy, diabetic neuropathy, and hyperkalemia were excluded. Further evaluation revealed a normal serum vitamin B12 level of 421 pg/dL and a normal folic acid level of 11.4 ng/mL. Given his risk factors for possible vitamin B12 deficiency in target tissues, he was treated with monthly vitamin B12 1000 mcg injections and followed up regularly. His symptoms improved significantly after four months of injections.

Discussion: In hemodialysis patients, chronic inflammation impairs uptake of circulating vitamin B12 by peripheral tissues leading to decreased production of transcobalamin II, increased synthesis of transcobalamins I and III with further accumulation of vitamin B12 in blood. In addition, despite normal or high serum vitamin B12 levels, these patients may suffer from vitamin B12 deficiency in target tissue and show symptoms such as fatigue and peripheral neuropathy. Therefore, it seems reasonable to consider vitamin B12 supplementation in these patients after excluding other causes of peripheral neuropathy. Further studies are highly recommended.

PUB084
Hemodialysis Prescription in Ethylene Glycerol Overdose: A Mathematical Approach
Muhammad T. Shakoor, Tie Jang. Warren Alpert Medical School of Brown University, Providence, RI.

Introduction: The timely management of Ethylene glycol (EG) overdose is essential. Hemodialysis (HD) is indicated for rapid elimination of its toxic metabolites. We introduce a case diagnosed shortly after presentation prior to the availability of the blood EG level and share calculations that were used to precisely and accurately estimate the clearance of EG through HD.

Case Description: A 61-year-old male presented with unresponsiveness. Labs were notable for anion positive metabolic acidosis with anion gap 28, osmolal gap 57, along with stage 2 AKI. His whole blood lactate was >171 meq/L, with a venous lactate of 0.5 meq/L. EG intoxication was diagnosed based on high lactate gap (16.6) and calcium oxalate monohydrate crystals in his urine sediment. He was given fomepizole and seven HDs in total. HD prescription was based on the simple calculation which we have been using reliably to calculate HD duration and post HD EG level. His predialysis EG level was 71 mg/dL. To calculate the EG removal via HD, we need patient’s weight and EG clearance (Cl_{eg}) for specific filters used in HD. Our patient weighed 98kg (TBW 59L) and Cl_{eg} for the F200 filter under Q800 m/min and Q4 800 m/min is 147 m/min. We decided to dialyze him for 4 hours. His post HD EG level was estimated to be: K1 of EG = 240 - 200 (HD time) x 147 m/min \times Cl_{eg} and K2 of EG = 35 L/KV of EG = 35 L/KV x 59% x 98 kg x Cl_{eg} Post HD EG level = 71 mg/dL (pre-HD EG level) x (1-59%) = 29 mg/dL After HD was completed, the post HD EG level was 30 mg/dL.

Discussion: Generally, the diagnosis of EG intoxication is delayed and calculation of HD prescription remains a challenge due to lag in obtaining serial EG assays in clinically useful time frame. We present a case of EG toxicity that we were able to diagnose promptly with a single aliquot to wait for EG blood levels, and we present a simplified approach to determine the duration of HD based on a single EG assay. This calculation can be used to individualize HD treatments and avoid over or undertreatment of intoxication.
The Estimation Formula of Phosphorous, Potassium, and Salt Amounts Excreted into Urine in Hemodialysis Patients

Momoko Fukazawa,1 Shinichiro Urabe,2 Motoko Kato,3 Yukie Kitajima,2 Akihiro C. Yamashita,4 Toru Hyodo.5 Eijn Clinic, Hirsutaka, Japan; 2Tokyo University of Technology School of Health Sciences, Shinagawa, Japan; 3Hosei University, Koganei, Japan.

**Background:** We elucidated the contribution of residual renal function (RRF) to the phosphorous, potassium and salt excretion and established the estimation formula of these amounts which are excreted into urine by RRF of hemodialysis patients.

**Methods:** We collected the 24 hour urine from 22 hemodialysis patients (mean age: 73.1±12.1 years old, dialysis history: 31.1±29.3 months, 15 males, 12 diabetics). The urine volume, phosphorous, potassium and salt amounts in the 24 hours urine and creatinine clearance were determined. The correlation coefficients among the urine volume, amounts of phosphorous, potassium and salt, and creatinine clearance (Ccr) were calculated.

**Results:** The mean urine volume was 662±421 mL/day. The mean phosphorous amounts in the urine was 114.5±55.9 mg/day, potassium 418.2±212.4 mg/day, and salt 4.7±2.6 g/day. Ccr was 3.7±1.8 mL/min. There was a significant positive correlation: urine volume vs phosphorous amounts (r=0.759, p<0.001), urine volume vs potassium amounts (r=0.662, p<0.001) (Phosphorous amounts in the urine=101±4.7 mg/day, and salt amounts of phosphorous, potassium and salt, creatinine clearance were determined. The correlation coefficients among the urine volume, amounts of phosphorous, potassium and salt, and creatinine clearance (Ccr) were calculated.

**Conclusions:** For as phosphorous and potassium, if 24 hours urine volume is known, the amount of urinary excretion of phosphorous and potassium can be roughly estimated. As for salt, if 24 hours urine volume is known, the amounts of urinary excretion of salt can be estimated with 84% accuracy. Measuring urine volume in hemodialysis patients can estimate solute excretion roughly.

Survival Analysis of Hemodialysis Patients: Impact of Uremic Toxins

Mari Sargsyan,1 Juan Robles bausa,2 Sheila Cabello Pelegrin,3 Joana M. Ferrer,4 Miguel Uriol Rivera,1 Juan Rey Valeriano,1 Sonia Jimenez,1 Cristina Egea,1 Tanja Villagrasa,1 Gonzalo Gomez marques,1,2 Bernardino Barcelo,1,2 Joan M. Gasco.2,5 Hospital Universitari Son Espases, Palma de Mallorca, Spain; 3Universitat de les Illes Balears, Palma de Mallorca, Spain.

**Background:** HEMO study showed that β₂M serum level over time was predictive of mortality in hemodialysis (HD) patients (p). The aim of the study was to analyse β₂M and indoxyl sulfate (IS) as predictor factors of mortality.

**Methods:** 5 years follow-up of 60 prevalent HD patients. Baseline midweek pre-HD serum β₂M by nephelometry and total IS levels by HPLC connected to a UV detector. High serum β₂M group (≥27.5 mg/L). As to IS, p were divided into quartiles (1q <9.7 mg/L, 2-3q a9.7-26.5 mg/L, 4q ≥26.5 mg/L). Kaplan–Meier analysis at 1.2, 5 and 5 years in univariate analysis for albumin (≥38 g/L or lower), β₂M, and total IS groups. Multivariate analysis by proportional hazards Cox’s model.

**Results:** 60 prevalent p with mean vintage of 46.8 months (range 3-299 months). 60±20 years. Females 46.6%, 35% diabetic. 51.6% HD, 48.3% post-dilution haemodialfiltration, with mean convective volume of 23.8±2.8 L. Mean eCtV, 1.67±0.4, mean nPCR 1.0±0.27g/kg/day. 8.3% of p had urine volume>500cc/24 hours. Mean β₂M level 5.6±1.9mg/L (X±SE). Mean total IS level 18.9±6.9mg/L. Overall mortality at 5 years was 57%. Albuminemia lower than 38g/L was associated with mortality at 2, 3, and 5 years in univariate analysis ( Cox’s F test p=0.03, figure). No difference in survival rate between p with high or low serum β₂M levels at 3 or 5 years analysis (Cox’s F test p=0.27). At 2 years analysis, p in the lower β₂M group had better survival (Cox’s F test p=0.04, figure). There was no statistically significant association between albumin, β₂M, IS level and mortality on multivariate analysis. We observe no statistically significant associated between IS levels and all-cause mortality.

**Conclusions:** β₂M <27.5 mg/l was associated with better survival at 2 years univariate analysis. IS had no statistically significant association with all-cause mortality in our cohort.

Treatment of Uremic Tumoral Calcification in Maintenance Hemodialysis Patients

Guibiao Ke, Fengxia Zhang, Xueqin Chen, Hong Zhang, Shuai C. Dou, Zhiwen Liang, Shi Wei, Xinling Liang, Shuangxin Liu. Department of Nephrology, Guangdong Provincial People’s Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China.

**Background:** Uremic tumoral calcification (UTC) is a rare disease with metastatic tissue calcification in maintenance hemodialysis (HD) patients. However, limited data are available on treatment of UTC in HD patients. This article mainly discusses the diagnostic performance and follow-up results. Parathyroidectomy (PTX) or drug treatment were determined based on intact parathyroid hormone (iPTH) levels and clinical symptoms.

**Methods:** A retrospective analysis was conducted on the data of 13 cases of UTC, including their clinical features, biochemical indicators, imaging findings, diagnosis, therapeutic methods and follow-up results. Parathyroidectomy (PTX) or drug treatment were determined based on intact parathyroid hormone (iPTH) levels and clinical symptoms.

**Results:** Of all 13 patients were diagnosed as UTC definitely by imaging examination. The predominant areas involved were the buttocks (4 cases, 30.77%), shoulders (4 cases, 30.77%), and elbows (3 cases, 23.08%). Based on the levels of iPTH, while drug treatment group (lanthanum carbonate or sevelamer with STS) (4 cases, 30.77%), and elbows (3 cases, 23.08%). Based on the levels of iPTH, cases were categorized into two different groups: PTX treatment group was associated with high levels of iPTH, while drug treatment group (lanthanum carbonate or sevelamer with STS) was lower iPTH. After PTX treatment, there was a significant decrease in serum iPTH, calcium (Ca), phosphate (P) and alkaline phosphatase (ALP) levels (p<0.05). In drug treatment group, the serum P levels was decreased significantly, along with a finding that hemoglobin levels was increased (p<0.05). The UTC had lessened or even disappeared after treatment 4 to 6 months.

**Conclusions:** Although most UTC patients have an increased iPTH, a small number had lower iPTH levels. Based on iPTH levels and clinical symptoms, the patients were treated with PTX or drug therapy. With proper treatment, UTC disappeared without the need for surgery to remove calcification tissue.

**Funding:** Government Support - Non-U.S.
Conclusions: It has been demonstrated that flow balance error and fluid removal attainable with SC™ lies well within the acceptable standards permitted for haemodialysis machines, demonstrated across a range of clinically relevant parameters at dialysate flow rates of up to 500mL/min.

Clinical Performance of the Optiflux® F160NR Dialyzer
Jill M. Meyer,1 Dylan Steen,2 Lisa A. Weber,2 Mayuri Thakuria,4 Chiang-Hong Ho,6 Claudia Mullon,7 Robert J. Kossmann,9 California Institute of Renal Research, Chula Vista, CA, 1California Institute of Renal Research, San Diego, CA; 2Research Management Inc./ Kansas Nephrology Research, Wichita, KS; 3 Fresenius Medical Care North America, Waltham, MA.

Background: Subjects in the clinical trial (NCT# 0356663), An Open-Label Clinical Study to Assess the Performance of the Dialyzer with Exendin26 in End-Stage Renal Disease Subjects, were dialyzed with the Optiflux® F160NR dialyzer, followed by the new dialyzer with Endexo. This sub-analysis reports the safety and performance of the Optiflux® F160NR dialyzer.

Methods: Subjects prescribed thrice-weekly HD for at least 30 days at three US study sites were enrolled in the study. The Optiflux F160NR dialyzer study period included 12 HD treatments. Performance and safety assessments included URR, spKt/V, serum albumin and β-2-microglobulin levels with removal rates measured pre and post HD, complement activation, and Adverse Events (AEs).

Results: Twenty-six subjects were screened. Twenty-three subjects were enrolled in the study (median age 64 years, females 73.91% and white 73.91%) and completed 268 HD treatments with the Optiflux F160NR dialyzer. Four subjects discontinued the study due to missed visits, not related to adverse events. 19 subjects completed all 12 HD treatments per protocol (n = 228 dialysis sessions). Delivered HD treatments are presented in Table 1. No SAEs were reported during the study. Four subjects reported at least one adverse event not device related. Mean (SD) reported for enrolled subjects were: 80.5% (4.5) for URR, 1.9 (0.3) for spKt/V, 47.1% (7.4) for corrected β-2-microglobulin removal rate and an increase of 8.3% (8.2) post HD for serum albumin. Complement activation was measured Pre HD and 30 min Post HD start and showed no overt activation for C3a, C5a and sC5b-9.

Conclusions: HD treatments were well tolerated and URR and spKt/V were high with the Optiflux® F160NR dialyzer. Serum albumin levels increased post HD. Complements showed no overt activation.

PUB090
Dialysis Disequilibrium Syndrome: Severe Irreversible Brain Injury Following Hemodialysis
Fatima Ballout, Pravir V. Baxi, Roger A. Rodby, Rush University Medical Center, Chicago, IL.

Introduction: Dialysis disequilibrium syndrome (DDS) is a clinical complication of hemodialysis characterized by neurological symptoms attributed to cerebral edema that rarely occurs in ESKD patients following their first HD treatment. Treatment is primarily preventative, aimed at decreasing the rate of urea clearance to reduce subsequent osmotic fluid shifts. We describe a case of DDS with severe neurological sequelae in a patient with acute on chronic kidney disease.

Case Description: A 39 yo man with CKD 4 presented with dyspnea, lethargy and confusion. Initial labs showed a Na 133 mmol/L, K 7.9 mmol/L, BUN 281 mg/dL and creatinine 38.6 mg/dL. HD was initiated for treatment of uremia and hyperkalemia. Two hours after the start of HD, the patient had a tonic-clonic seizure followed by cardiopulmonary arrest. Lab data post-arrest showed a Na 133 mmol/L and BUN of 112 mg/dL (Fig 1). In the subsequent days, the patient remained in a comatose state. MRI of the brain revealed cortical restricted diffusion in both cerebral hemispheres and bilateral basal ganglia, concerning for hypoxic-ischemic injury. His clinical status did not improve over 3 months. He required a tracheostomy and PEG tube placement with HD dependency on discharge.

Discussion: DDS remains a rare clinical phenomenon which typically occurs with initiation of HD in those with severe azotemia and advanced CKD. Risk factors include pre-existing neurological conditions, hyponatremia, and higher starting BUN levels. While the pathogenesis remains debated, DDS is believed to be due to a reverse osmotic effect that occurs due to a faster decline of urea within the blood versus the brain creating osmotic disequilibrium with subsequent movement of water into the brain causing cerebral edema. Idiogenic osmole may also be involved. Recognition of patients at high risk is crucial as it provides an opportunity to implement preventative strategies including reduced HD treatment time with lower blood flows aimed at more gradual clearance of urea.

PUB091
Sustained High-Dose Chronic CRRT Fails to Attenuate Severe Lactic Acidosis in an Immunotherapy-Resistant Case of Malignant Melanoma with Liver Visceral Crisis
Mabel S. Tan, Han K. Tan. Singapore General Hospital, Department of Renal Medicine, Singapore, Singapore.

Introduction: Lactic acidosis is the most common cause of metabolic acidosis in hospitalized patients. Though of little proven benefit, continuous renal replacement therapy (CRRT) has been suggested as treatment in some patients. We describe a rare case of a patient with lactic acidosis who received nineteen days of high dose CRRT.

Case Description: A 60-kg, young Chinese female with melanoma and extensive liver metastasis presented in a visceral crisis. She was given combination of nivolumab and ipilimumab which was projected to take 1 month to work. She had severe lactic acidosis with serum lactate of 17mmol/L on admission despite normal renal function. After a failed trial of medical therapy, CRRT was started purely for lactic acidosis. A spot measurement of effluent lactate was 15mmol/L while the corresponding plasma lactate was 16.3mmol/L, suggesting sieving coefficient of 0.92. Switching to a lactate free dialysate fluid multilic did not help. Despite uninterrupted CRRT for 19 days, and repeated increase of effluent dose to peak of 5L/hour, giving lactate clearance of 76.7ml per minute, there was no improvement. She eventually demise 4 days after cessation of CRRT.

Discussion: We describe an unfortunate case where 2 specialties tried hard to save this young patient from the fatal complications of her aggressive tumor. Type B lactic acidosis is better described in hematological malignancies but there are increasing reports in solid organ tumors, most with extensive hepatic involvement. We present the first case of melanoma causing lactic acidosis reported in literature till date. While CRRT, convective therapies, bicarbonate-based dialysis fluids have been suggested as treatment for lactic acidosis, there is little proven benefit. In our case, we combined all 3 strategies, persisted at high dose for 19 days with no success. 2 learning points: Firstly, lactic acidosis in the absence of hypoperfusion (Type B) is not uncommon and equally dangerous. Secondly, while dialysis removes lactate to some extent, it is at best a temporizing measure. Addressing the underlying cause takes priority. Dialysis, regardless of dose, modality and timing is less likely to affect outcome.

PUB092
Primary Caregiver Burden in a Hemodialysis Clinic in Mexico: Prevalence and Caregiver-Related Risk Factors
Edgar Solis, Joselyn Rivera, Juan M. Ardavin Inuarte. Medica Santa Carmen, San Miguel de Allende, Mexico.

Background: Dialysis treatment is defined as a family disease. Primary caregiver is the main person who takes the responsibility for and supports the patient; caregiver burden can be defined as the strain or load borne by a person who cares for a chronically ill family member. The Zarit survey is a psychometric instrument designed to grade caregiver burden, recommended and validated among caregivers of patients in hemodialysis.

Methods: A descriptive study was conducted among primary hemodialysis caregivers from a dialysis clinic in Guanajuato, Mexico. Zarit Scale (A validated 22-item questionnaire with five item ranged from 0—never to 4—always) was applied in order to identify presence and level of caregiver burden. Caregivers of patients less than 3 months were excluded. Social and demographic data related were also collected. Data was analyzed for descriptive statistics using T-test and Chi square for comparison between groups.

Results: A total of 86 primary dialysis caregivers answered the survey via personal interview with one of the investigators. Most responders were female (77%) with a mean age of 47±15 years old. Seventy seven percent were married and almost all had an occupation (95%): homemaker (43%) was the most common. We found that couples take care of patients in 42% of cases, followed by parents (27%). Interestingly, 46% of responders did not take own recreational time and some of them (38%) were diagnosed with some chronic illness. More than half (56%) usually take care of 1 to 3 more persons along with the patient and meantime of life spent caring was 2 years. Any level of caregiver burden was identified in 67%, most of them (86%) in a slight level. There were not statistical differences between groups with none and any burden.

Conclusions: ESRD affects not only patients but also the people who takes care of them. Caregivers burden is prevalent in our clinic. Caregivers are predominantly female.

Within-Patient Relationships Between Ultrafiltration and Fluid Gains in Haemodialysis Patients

Background: Despite the now-widespread use of haemodialysis treatment, optimal fluid management in long-term dialysis patients remains challenging. Whilst the between-patient factors affecting target weight and ultrafiltration have been well studied, little is known regarding the within-patient factors affecting these relationships.

Methods: Dialysis data for a group of stable haemodialysis patients, from 4 dialysis units, were analysed over a period of one year. All weights and volumes are expressed as percentage of target weight.

Results: From 100 patients (aged 28–89, mean 65.4, 54% male) observed over a year, complete data were available for 15530 dialysis sessions, and 13027 combinations of dialysis session plus the following inter-dialytic interval. Mean arterial pressure dropped from 103.21±0.0% after a 3-day gap and 102.5±0.0% after a 2-day gap, with this difference being significant (p=0.05) in 87 patients. However, fluid gain was non-linear, diminishing during longer inter-dialytic intervals; mean(±se) fluid gain was 1.3(0.38)% during the 3-day gap vs 1.21(0.53)% during the 2-day gap (p<0.05 in 36 patients), implying that at least a third of patients consume less fluid during the 3rd post-dialysis day.

Conclusions: Inter-dialytic fluid gain is strongly dependent on ultrafiltration during the previous dialysis session, and diminishes during the inter-dialytic interval. Large ultrafiltration volumes, which have historically been perceived as the inevitable result of large fluid intakes, are actually a cause of thirst and large fluid intakes in haemodialysis patients. These data, derived from within-patient analyses, strongly challenge our conventional understanding of dialytic fluid management.

Medical Waste Management: How Industry Can Help Us Protect the Environment and Money

Jacek Malyszko, Tomasz R. Prystańcki, Wojciech Marcinkowski, Jolanta Malyzkod, Fresenius Medical Care Polska S.A., Poznan, Poland, Fresenius NephroCare Polska Sp zoo, Poznan, Poland, Warsaw Medical University, Warszawa, Poland.

Background: The global climate change and its consequences force us to remodel dialysis facility operations can create barriers between stakeholders. We aimed to assess the conduct of sponsored trials has no association with dialysis facility clinical quality outcomes.

Methods: We used data from adult (age ≥18 years) hemodialysis patients treated at 18 years) hemodialysis patients treated at Frenova Renal Research, Waltham, MA; Fresenius Medical Care, Global Medical Office, Waltham, MA; Fresenius Medical Care North America, Waltham, MA; Fresenius Medical Care AG & Co. KGaA, Global Medical Office, Bad Homburg, Germany.

Background: There is a paucity of clinical trials conducted in nephrology vis-à-vis other fields (Baigent, et al. 2017). The lack of knowledge on impacts of trial conduct on dialysis facility operations can create barriers between stakeholders. We aimed to assess the conduct of sponsored trials has no association with dialysis facility clinical quality outcomes.

Methods: We used data from adult (age ≥18 years) hemodialysis patients treated at a dialysis provider network in the United States during 2017 to 2018. Facilities that did not participate in trials were matched to research facilities using 1:1 matching on logit of propensity score for patient years of follow-up, years of certification, % of Medicare patients, % of ESCO facilities and geographical region. We cross-sectionally compared mean facility-level quality metrics for: anesthesia (% Hgb a10 & <10g/dL), mineral bone disorder (% calcium ≤10.0mg/dL, % phosphate >6.5mg/dL, % PTH >150 and <600pg/dL), and event outcomes (% catherter exposure >90 days, % treatment non-adherence, 30 day readmission rates, hospital days/patient year).

Results: We found no significant differences between mean facility-level quality metrics in dialysis facilities that conducted trials versus matched facilities not involved in research (Figure 1).

Conclusions: We found the conduct of trials in dialysis facilities had no association with achievement of quality targets, as compared to matched facilities not participating in trials. These insights are of importance to providers and stakeholders participating in considering nephrology research activities that are necessary for advancing the state of the art.

The Kt/V Measurement Provides Little Useful Information to Help Manage a Patient
Jack Rubin, Medicine and Nephrology of Los Alamitos California Medicine and Nephrology Associates, Los Alamitos, CA

Background: We measure Kt/V monthly but to what purpose? Does this reflect adequate dialysis? Can one predict needed information such as albumin, calcium phosphorus product or potassium?

Methods: To this end we reviewed our monthly May 2020 dialysis laboratory studies to see if there was any meaningful relationship with the standard pooled Kt/V measurement. We indexed albumin, calcium phosphorus product and whether the parameters correlated with Kt/V.

Results: Our population consisted of 106 patients of which 61 were males with an average age of 64 ± 12 years and on dialysis an average of 1785 ± 1713 days and 45 females of average age 65 ± 17 years on dialysis 1137 ± 979 days. The median time on dialysis was 842 days for males and 846 days for females. The mean albumin was 3.7 ± 0.3 g/100 ml. The mean hemoglobin was 9.6 ± 1.0 mg/dl. Th mean calcium phosphorus product was 48 ± 16. Th calcium averaged 9.2 ± 0.7 mg/100 ml and phosphorus 5.3 ± 1.7 mg/100 ml. The mean Kt/V was 1.48 ± 0.30. Using Excel a correlation coefficient was calculated between albumin and Kt/V = 0.28, hemoglobin versus Kt/V = -0.03, calcium and potassium product versus Kt/V = -0.19 and potassium versus Kt/V = 0.05. Vintage of dialysis correlated poorly with albumin = 0.09 and with potassium 0.09.

Conclusions: In summary Kt/V as a standalone measurement has minimal if any relationship to the parameters investigated and its continued use should be reconsidered.

Impact of Major Surgical Operations on Clinical Outcome in Dialysis Patients
Rezzan Eren Sadioglu, Gizem Kumru, Sim Kutlay, Sule Sengul, Kenan Keven, Gokhan Nergizoglu, Kenan Ates, Nebal Duman, Selcuvur Erturk. Ankara University Faculty of Health, Ankara, Turkey.

Background: We aimed to study the impact of major surgical operations on clinical outcome in patients with haemodialysis (HD) or peritoneal dialysis (PD).

Methods: We retrospectively evaluated the records of all patients on HD and PD, who had been treated for at least 3 months at our outpatient clinics between January 1, 2014 and December 31, 2018. In addition to clinical and laboratory parameters, data on all major surgical operations were recorded.

Results: Among the 202 patients, 133 (66%) were on HD and 69 (34%) on PD. The mean age (±SD) was 58.3±14.5 years, 48% were female and 28% had diabetes mellitus. Forty-seven patients (23%) had a major surgical operation. The operation types were cardiovascular in 14 patients, orthopaedic in 11, gastrointestinal in 8, gynecological in 6, parathyroidectomy in 2 and brain, lung, and breast in 1 patient each. Operations were emergent in 10 patients (21%) and elective in the others (79%). Among the whole study population, 59 patients (29%) died during the study period. In Kaplan-Meier analysis (Figure), mean (±SE) survival time in operated patients was 43 months (±7 to 49 months), while it was 94 months (46 to 52 months) in the others (p<0.001). Fifteen out of 23 deaths (65%) among the operated patients occurred in the first month after surgery. Severe perioperative complications (arrhythmias, hypervolemia, hypotension, bleeding, acute coronary syndrome, respiratory failure and cerebrovascular event) were recorded in 17 (36%) of the operated patients, of whom 16 died (p=0.001). Although did not reach a significant level, mortality rate tended to be higher after emergent operations than that after elective operations. Cox regression analyses revealed that age (RR 1.053, 95% CI 1.010-1.077, p=0.005), diabetes (RR 2.581, 95% CI 1.474-4.521, p=0.001), preoperative C-reactive protein level (RR 1.005, 95% CI 1.002-1.007, p<0.001) and having a major surgical operation (RR 1.868, 95% CI 1.068-3.268, p=0.028) were the independent predictors of mortality.

Conclusions: Although prospective studies with a higher patient number are needed to confirm, our study shows that, in addition to age, diabetes and inflammatory status, having a major surgical operation is an independent risk factor for mortality in dialysis patients.

Outcomes of Ceftolozane/Tazobactam Recommended Doses in Treating Multi-drug-Resistant Bacteria in Critically Ill Patients Using Renal Replacement Therapy
Wesam El Nekidy,1,2 Leen Oyoun Alsooud,1 Nizar M. Attallah,1 Laila Riekh,1 Fadi A. Hijazi,1 Ahmad R. Nusair,1 Jihad Mallat,1 Islam Ghazi.1 1Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates; 2Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, OH. University of the Sciences in Philadelphia, Philadelphia, PA; Trillium Health Partners, Mississauga, ON, Canada.

Background: Ceftolozane/tazobactam (CEF/TAZ) is a new broad spectrum cephalosporin effective against Multi-drug Resistant (MDR) bacteria. The clinical outcomes of the recommended dose of CEF/TAZ in patients utilizing renal replacement therapies are lacking. The purpose of this study was to evaluate the clinical and microbiological efficacy of CEF/TAZ in treating MDR in patients utilizing continuous venovenous hemofiltration (CVVH) and intermittent hemodialysis (IHD).

Methods: A retrospective cohort study was conducted at our quaternary care hospital between May 2015 and December 2019. We reviewed all hospitalized adults who had MDR Pseudomonas aeruginosa or MDR enterobacteriaceae treated with CEF/TAZ while utilizing CVVH or IHD

Results: We identified 11 patients who met the inclusion criteria with a mean age of 63.0 ± 17.8 years and a mean weight of 63.8 ± 15.7 kg. All patients were critically ill, needed mechanical ventilation, and used vasopressors. All 11 patients had pneumonia, one of them developed secondary bacteremia and two had decubitus ulcer. Nine patients had MDR pseudomonas aeruginosa while two had MDR E. coli and Klebsiella Pneumonia. Six patients were on IHD, while the remaining 5 patients were on CVVH. The most commonly used dose for CVVH was 450 or 750 mg intravenous (IV) every 8 hours (only one received 1500 mg at the same frequency). For IHD, the common dose was 450 mg IV every 8 hours. Of the 7 patients who had repeated cultures, three had microbiological cure and four had clinical cure. Two patients expired within 30 days and 3 more expired within 90 days. Two of the patients who had clinical cure, had recurrence within 4 weeks.

Conclusions: The efficacy of the recommended CEF/TAZ dose in patients utilizing RRT is uncertain. Pharmacokinetics and pharmacodynamics studies are urgently needed to determine the adequacy of CEF/AVI dosing in this population.

Does Dialyzer Surface Area Alone Adjusted to Body Surface Area Have Any Clinical Impact on Adequacy: A Single-Center Observation Study in Saudi Arabia
Najlaa Almalki,1 Ahmad S. Ghanem, Azharuddin Mohammed. Armed Forces Hospitals Administration in Taif Region, Taif, Saudi Arabia.

Background: Dialysis adequacy using sp Kv is a standard KPI in HD units, determined by dialyzer clearance(K), Volume of distribution urea(V) and treatment time(t). Increase in larger dialyzer size (t, V being constant) is a norm to improve Kt/V during HD as the patients gradually lose residual kidney function. However initial and subsequent dialyzer prescription using Body Surface Area(BSA) instead of Weight(V) is less well studied. We looked into effect of BSA and DSA on Kv.

Methods: 163(n=) patients receiving in-center HD on Gambro dialyzers (Polyflux, Revoluear) studied. Demographic and clinical data collected. Patients were stratified into 4 groups based on their dialyzer surface area (DSA) as 1.4, 1.7, 1.8 and 2.1 m². For each group, we then calculated BSA(Bois method), HD vintage, treatment time(hours), Access type, sp Kv (Douglas) and % pts with inadequate sp Kv, <1.2. Hemoglobin for each group was compared too.

Results: Our patients were representative of any HD center in terms of demographics; age 57.8 ±18.3, 50.9% Males, 28.2% DM, vintage 59.3±51.2 m, BMI 25.1±6.2, BSA 1.7±0.3 and Kv 1.7±0.4. The use of dialyzer with DASA’s 1.4, 1.7, 1.8 and 2.1 were 63.2%, 5.5%, 8.6% and 22.1 %. Among 4 groups, there was no significant difference in terms of age, treatment time, vascular access and hemoglobin, Image 1. But when DSA and BSA were stratified for adequacy, there was a modest linear trend of decreasing Kv with increasing BSA among 4 increasing DSA groups. Although all met the minimum sp Kv of 1.2, the proportion of patients with inadequate Kv were increasing despite their increasing dialyzer sizes. Factorizing for equilibrated Kv, adequacy could just be borderline for larger patients.

Conclusions: Dialyzer size change in itself may not be effective in achieving target Kv as BSA increases; attention must be paid to increasing dialysis time. Dialyzer prescription, adjusting for BSA may be more appropriate, particularly in large patients.
PUB101

High Ultrafiltration Rate: Is It Bad? A Case Report of a Patient on Hemodialysis for 29 Years with High Ultrafiltration Rate
Aziz U. Saeed, Diwerjson, Riyadh, Saudi Arabia.

Introduction: High ultrafiltration on Hemodialysis stresses cardiovascular and could have negative effect on survival. This is the notion of many studies done in line with High ultrafiltration rate. However, dismissing the other side of coin, cumulated effect of their load on cardiovascular system.

Case Description: We present a case 60 year male develop protein urea lost follow up, presented with CKD 5, started on hemodialysis which he is on for 29 years now. He was hypertensive to start with later became normotensive. His intradialytic weight gain is 4.5 to 5.5 liters, which he tolerates well without any episode of intradialytic hypotension.

Discussion: Except Carpal, tunnel Syndrome for which he had surgery, clinically stable, normal biochemical parameters and acceptable cardiovascular status with this entire very remarkable journey.

PUB102

The Influence of Different Hemodialysis Frequency on Maintenance Hemodialysis Patients
Hua H. U., the first affiliated hospital of Xi’an Jiaotong University, Xi’an, China.

Background: To investigate the effects of different dialysis frequencies on anemia, nutritional status, calcium and phosphorus metabolism, renal function indicators in patients.

Methods: The general data of MHD patients in our center from 2017 to 2019 and annual laboratory monitoring indicators (including HGB, SF, Bun, Scr, Ca, P, PTH, ALP, ALB), urine volume and eGFR, were used to compare in patients with different hemodialysis frequency groups (Group A: 2 times/week, B: 3 times/2 weeks, C: 3 times/week).

Results: There were 269 patients (163 males, 106 females), with an average age of 52.650 ± 14.982 years. There were statistical differences among HGB, Ca and ALB, but no statistical differences among SF, P, PTH, ALP, Bun and Scr. The three-year overall compliance rate evaluation found that the overall compliance rate of HBG and Ca significantly increased. It was found that the compliance rates of HGB and Ca at the dialysis frequency of 2 times a week were significantly lower than those of the other two groups, but there is no difference for P, PTH and ALB.

Conclusions: Different from western countries or developed areas, the the frequency less than 3 times is more than two-thirds in the western region in China. In this study, the average of HGB and Ca in patients with dialysis 3 times a week is significantly higher than other groups with low-frequency, and the compliance rate of HGB and Ca in group with the dialysis 3 times a week increased significantly. The results suggested that the higher frequency group was better in anemia and calcium correction.

PUB103

Achromobacter Xylosoxidans, Subspecies Denitrificans, Exit Site Infection, and Aeromonas Hydrophilia Peritonitis: Rare Infections in Peritoneal Dialysis Patients

Background: Achromobacter xylosoxidans, subspecies denitrificans, exit site infection in peritoneal dialysis patient is rare and will be reported. A second case of rare peritoneal infection caused by Aeromonas hydrophila peritonitis will also be reported. Both are gram negative microorganisms and are usually found in wet environments and are rarely found in peritoneal dialysis patients, causing infections in immunocompromised patients. Both cases occurred in the same rural city and in the same dialysis facility.

Methods: The cases involved conducting interviews with patients and documenting each visit. All observations and visitations were assessed in the dialysis center of a rural area. Previous data of cases with similar rare pathogen caused peritonitis were also analyzed.

Results: The patient with exit site infection, Achromobacter xylosoxidans, was treated with oral ciprofloxacin for 3 weeks resulting in a slow improvement of the exit site. During the treatment the patient experienced erythema, discomfort, and discharge. At the end of the treatment, repeat cultures drawn from the exit site were negative. The patient with Aeromonas hydrophila peritonitis is currently being treated with intraperitoneal Gentamicin.

Conclusions: Achromobacter xylosoxidans and Aeromonas hydrophila are both rare bacterial infections that have a history of causing infections in immunocompromised individuals exhibiting multiple risk factors. We reported exit site infections and peritonitis in end stage kidney disease patients. Both infections have been treated without any adverse effects or removal of peritoneal dialysis catheters.

PUB104

Bicarbonate-Rich Peritoneal Dialysis as Salvage Therapy for Metabolic Acidosis
Eli L. Stephenson, Ryan A. Carver, Jessica R. Burgess, Thomas R. McCune. Eastern Virginia Medical School, Norfolk, VA.

Introduction: Use of peritoneal dialysis (PD) in ICUs in developed nations is limited. The need for emergent dialysis is often considered a contraindication for peritoneal dialysis and the large peritoneal surface area is often neglected in the resuscitation of critically ill patients. We report a case of successful emergent PD with high bicarb dialysate in an actively dying patient not tolerating standard renal replacement therapies.

Case Description: A 36 yo male with no medical history sustained multiple gunshot wounds. He was found to have multiple injuries in the small bowel including the duodenum. Two 15-french drains were placed at the time of surgery. While initially stable, he gradually developed worsening acidosis and anemia requiring a bedside blood transfusion every 48 hours. His pH worsened (pH 6.97) with bicarb 6mmol/L and lactate (LA) 26.9mmol/L. Family said their goodbyes and he was made DNR. Methylene blue was given without hemodynamic change. Given his young age, inability to tolerate CRRT and intraperitoneal access already available, decision was made for emergent PD as a final effort to control refractory acidosis. Approximately 1L of 1.5% peritoneal dialysate with an additional 300 mL sodium bicarb/2L bag was instilled for a 30 minute dwell time. Within an hour, his labs showed pH 7.12, bicarb 15mmol/L, LA 16mmol/L and his vasopressor requirements decreased. After four exchanges, CRRT was initiated. His acidosis resolved within 24 hours and he was vasopressor free by 36 hours. He was extubated, dialysis dependent and continues to recuperate.

Discussion: PD in developed nations is often a forgotten modality for acute renal failure. We found only 2 published reports since 1980 using PD in the ICU for metabolic control. Our case describes successful use of high bicarbonate PD in the ICU to control refractory acidosis and achieve hemodynamic control. Data is lacking on the use of emergent PD in trauma patients and within ICUs despite its relative case and low cost. High bicarbonate PD is an option for refractory acidosis in the critically ill.

PUB105

Myoclonic Seizures and Altered Mental Status in a Patient on Peritoneal Dialysis Treated with Piperazine
Jimenez Acosta,1 Gustavo A. Guzman,2,3 Daniel F. Arroyo Ariza,2,3 1Universidad de los Andes, Bogota, Colombia; 2Hospital Universitario Fundacion Santa Fe de Bogotá, Bogota, Colombia; 3Healthy Medical Center, Zipaquira, Colombia.

Introduction: Here we present the case of a man on automated peritoneal dialysis (APD) with altered mental status and myoclonus after the self-administration of piperazine an hypnotic. This case illustrates how dangerous self-medication can be in patients with chronic kidney disease. Additionally, it shows that neither peritoneal dialysis nor hemodialysis appear effective methods for piperazine clearance in patients on renal replacement therapy (RRT).

Case Description: A 66-year-old man was brought unresponsive and with myoclonus to verbal commands. Myoclonus predominantly in his left arm was noticed. Initially we
suspected bacterial infection as the cause of the altered mental status, empirical antibiotic treatment was initiated. However, the patient’s symptoms persisted, requiring care at the ICU and intubation. Further interrogation of the patient’s family revealed that he had self-administered a full bottle of piperazine hexahydrate. An infectious cause was ruled out and no clinical improvement was achieved with anti-epileptics. At this point piperazine intoxication was the most likely diagnosis. After a week of APD we decided to switch RRT to sustained low efficiency hemodialysis (SLED). He received two sessions. Gradually the patient’s mental status improved and was discharged with his usual APD.

Discussion: The most common symptoms of piperazine intoxication are myoclonus, decreased level of consciousness and ataxia. Few data is available regarding the dialyzability of this medication, and neither PD nor HD seem effective treatment options. Hemoperfusion seems a suitable alternative. Clinical improvement in this case may be due drug metabolism, independent of treatment. We want to highlight the importance of education in renal patients, especially in the dangers of self-medication. Fortunately, our patient had a full recovery. But that may not be the case of other patients who inadvertently poison themselves with “safe” medications, like piperazine.

Two-Year Follow-Up of Quality Indicator Compliance in a Large International Peritoneal Dialysis Institution

Belen Marron, Suzanne H. Pearce, Charlotta Wolffheim, Carlos Lucas, Marietta Török, Israel P. Silva, Filiz Akdeniz, Fernando Macario. *Diaverum Renal Services. Corporate Medical Office, Hylie, Malmö, Sweden*

**Background:** Peritoneal dialysis (PD) practice is not universally homogeneous, best clinical practices are not completely understood as reference values are often obtained from small sized populations and/or frequently based on chronic kidney disease (CKD) and/or hemodialysis data. **Objectives:** To evaluate two years of follow up of compliance with PD-related quality indicators (QIs) following definition of new targets in an international PD network.

**Methods:** All English and Spanish language CKD and PD guidelines were reviewed. Twelve QIs were considered being of significant relevance and targets for these QIs were defined (see table). Retrospective data analysis

**Results:** Achievement of QI targets for years 2017-2018 is shown in table (image). Variability among countries not shown.

**Conclusions:** There was a significant increase in Q6 achievement in 2018 vs. 2017. 87% of patients met the target for the following variables: total weekly Kt/Vurea, 24 h fluid removal, mean arterial blood pressure and serum albumin. Peritonitis rates are clearly over international objectives and were improving. Due to the lack of referral source data, these series may help to understand PD practice and outcomes in a global setting.

**PUB107**

Acyclovir-Induced Encephalopathy in a Patient on Peritoneal Dialysis

Aileen Kate M. Kuan, Shamir Hasan, Yuriy Khanin, Hugo Andrade paz, Nupur N. Uppal, Mala Sachdeva. *Northwell Health, Great Neck, NY.*

**Introduction:** Acyclovir is an antiviral agent that is used for treatment of diverse viral pathologies. The regular pharmacokinetics for acyclovir is altered with kidney dysfunction. At present, our knowledge regarding treatment of acyclovir neurotoxicity in patients undergoing peritoneal dialysis (PD) is limited, as only few case reports have been published. We describe a case of acyclovir induced encephalopathy in a PD patient that was successfully treated with hemodialysis.

**Case Description:** 34F with a history of systemic erythematous lupus (on prednisone, celecoxib and plaquenil), ESKD on peritoneal dialysis (PD), subclinical hypothyroidism, anemia and hypertension was admitted for her lips and right eyelid. She was initiated on intravenous acyclovir at a dose of 500mg daily. 24 hours later, she developed acute confusion which progressed to include myoclonus, lethargy and coma. Labs on admission revealed hemoglobin 10, Na 137, K 4.6, Cl 92, CO2 22, BUN 64, Cr 20.85. CT head was negative. EEG did not reveal any epileptiform activity. Lumbar puncture and brain MRI did not show any evidence of viral encephalitis. Acyclovir neurotoxicity was considered as the etiology for her severe encephalopathy. Acyclovir was held and her CC PD prescription was increased but she continued to remain encephalopathic. A decision to initiate hemodialysis (HD) was made. After the first HD session, her mentation slightly improved. She received a total of 3 HD sessions, after which her mental status completely returned to baseline. Given that she improved after discontinuation of acyclovir and with HD this confirmed her diagnosis of acyclovir induced neurotoxicity. She was switched back to PD after recovery.

**Discussion:** Dose adjustment for acyclovir is recommended in patients with ESKD. Even when the acyclovir dose is adjusted for these patients, it can still cause neurotoxicity. This complication seems to be more common in those on PD likely due to the slower removal of the medication with PD. Clinicians need to be aware of this potential adverse event, as this diagnosis needs prompt recognition and treatment. Clearance of acyclovir with PD is not completely understood and in fact PD was not adequate to help with clearance in our patient despite increasing her prescription. The modality of choice for clearance of acyclovir in toxicity is hemodialysis.

**PUB108**

The Analysis of Risk Factors for the Patients with Venous Needle Dislodgment and Bleeding During Hemodialysis

Hsuan Ming Lin,1 Wen H. Wu,2 Hsiang Wei Hu,3,4 ‘1An Nan Hospital, China Medical University, Tainan, Taiwan, Tainan City, Taiwan; 2Department of Healthcare Administration of J-Shou University, Taiwan, Kaohsiung, Kaohsiung, Taiwan; 3National Cheng Kang University, Tainan, Taiwan; 4Acusense Biomedical Corp., Tainan City, Taiwan.

**Background:** A puncture of vascular access is commonly used in clinical treatment, such as hemodialysis or central venous catheters. Leakage or infection associated with Venous needle dislodgement (VND) is a high risk of fatality. However, only a few studies are focusing on patient disease, medication, and other risk assessments. Therefore, this study aims to explore the risk factors of patients with venous needle dislodgement and bleeding and hope to establish the risk classification.

**Methods:** This study was a prospective study conducted in the hemodialysis unit of Tainan Regional Hospital. During the three months from July 2019 to Sep 2019, we collected clinical data, including patient sex, gender, diseases, records of dialysis access leakage, anti-coagulant dose, and a risk assessment form. We compared the data between the two groups of patients who have at least one risk in the risk assessment form. We analyzed the data with STAT™. P<0.05 was defined as significant.

**Results:** In the study period, seventy-one patients were included in this study, with an average age of 63.0 (± 1.19 years) and 46 males (64.79%). The patients with any risk in the risk assessment form were considered the high-risk group. There were 72 venous needle dislodgement and bleeding in 32 patients during the study period. In the below feature, gender, high-risk group or not, diabetes, high blood pressure, exposure to Benzodiazepine, the experience of Intradialytic hypotension, exposure to warfarin, or dosage of anti-coagulant, there was no statistic significant between the patients experienced at least one episode of VND and others.

**Conclusions:** Between patients experience VND or not, we did not find any significant association in not only conventional factors or other factors. However, this study provides a reference for future research.

**PUB109**

**Catheter Malposition: Unacceptable Reason for Access Dysfunction**

**Yuliya Sharakova, Mohamed Hassanein, Evamaria Anvari, Tushar J. Vachharajani, Cleveland Clinic, Cleveland, OH.**

**Introduction:** In 2017, 80% incident and 20% prevalent patients in the US received hemodialysis (HD) with a catheter (CVC). CVC placement with ultrasonography and fluoroscopy guidance (FG) is an accepted standard of care to avoid early mechanical complications. Early dysfunctional CVC (dCVC), defined as malfunction in <1 week of insertion, is often due to a malpositioned tip leading to inadequate HD and a higher risk of bacteremia. We present a series of early dCVC, a preventable complication.

**Case Description:** Case 1: A 42 y/o male had left IJ non-tunneled CVC placed for continuous dialysis therapy. Encountered multiple episodes of circuit clotting soon after initiation of therapy despite heparinization. The dCVC tip was found to be abutting against the innominate vein wall preventing adequate blood flows. An attempt to place a tunneled right subclavian vein catheter at bedside, without fluoroscopy was unsuccessful. Chest XR showed the CVC tip in the left IJ. Case 2: A 30 y/o male with a pre-existing right portacath presented with several episodes of non-sustained ventricular tachycardia, 2 days after a newly placed left dialysis CVC. Chest XR showed portacath had disconnected and migrated to the right ventricle. Removal of the dislodged portacath led to resolution of arrhythmia. Dialysis CVC was preserved. Case 3: A 49 y/o obese female had poor blood flows (300 ml/min) in catheter and frequent alarms that failed to improve despite iPA and port reversal. dCVC resulted from tip retraction from right atrium into SVC requiring replacing with a longer CVC. Case 4: A 65 y/o female with left IJ tunneled CVC, placed under FG, had poor blood return 2 days after placement. The CVC tip had migrated to the right innominate vein. Catheter was replaced successfully. Case 5: A 70 y/o male encountered clotting of the continuous dialysis circuit soon after initiation with a left IJ CVC, requiring replacement of circuit to continue with therapy. Evaluation showed a short CVC with tip abutting against superior vena cava (SVC) wall and required replacing with a longer CVC.

**Discussion:** Recognizing and troubleshooting early dCVC is an essential learning milestone for a nephrology trainee. Evaluation of a dCVC includes chest XR, forceful saline flush and appropriate use of iPA. Most of these mechanical complications are preventable with proper training and utilizing imaging tools during the procedure.

**PUB110**

**Percutaneous Transluminal Angioplasty in Arteriovenous Fistula**

**Dysfunction Secondary to Vascular Stenosis**

**Mohammed Sheeb Ahmed Khan, Vinod Kumar. Aster Medcity Aster Medcity, Kochi, India.**

**Background:** Arterio-venous fistula (AVF) is the lifetime of a hemodialysis patient and the number of vascular accesses in a hybrid is a major factor. Vascular stenosis necessitates vascular intervention or creation of a “de novo” AVF. In this study we aimed to evaluate the outcome of percutaneous transluminal angioplasty (PTA) in arterio-venous fistula due to vascular stenosis.

**Methods:** This is a prospective study of two years (02.05.17 to 02.05.19). Records of patients admitted to our hospital were obtained from hospital archives and images from the hospital radiology and angiography system. Demographic characteristics, duration of dialysis, stenosis or occlusion level, patency rates of AVF were evaluated. All procedures were performed by interventional radiologists in a hybrid in a patient in supine position. A antegrade, retrograde, or both antegrade and retrograde punctures were used, depending on the site of the stenosis as depicted on preoperative ultrasound. A complete angiogram from the proximal arteriovenous anastomosis to the central venous outflow was performed in all cases. A successful percutaneous balloon angioplasty was defined when there was no more than 30% residual stenosis (KDOQI). AVF patency rates were assessed at six months and one year.

**Results:** Total number of patients studied were 16. The average age was 66.6 years. All were hypertensive and diabetics comprised 75% of study group. Coronary artery disease was established in 81.25%, and two patients were known to have chronic liver disease. Most common type of AVF was the left brachio-cephalic (62.5%), followed by radio-cephalic (37.5%). Average dialysis vintage of AVF at the time of procedure was one year. Previously failed AVF was present in two patients. There were 18 vascular stenosis in 16 patients. The most common site of stenosis was the venous cannulation zone (62.5%), followed by anastomotic site stenosis (31.2%) and central vein stenosis (18.75%). Successful PTA was done in 12 patients. There were no complications; however, AVF closure was resumed within the first 2 months. The AVF occlusion rate at 2 months was 100%, six months was 75% and at one year it was 37.5%. Four patients were lost to follow up. Mean follow up was 941 ± 67.9 months. None underwent a repeat PTA.

**Conclusions:** Percutaneous transluminal angioplasty is effective for salvaging arterio-venous fistula in majority of hemodialysis patients.

**PUB111**

**A Tale of Two Accesses: The “Less Is More”**

**Sherif Metwalli, Anil K. Agarwal, Khaled Boubes. The Ohio State University, Columbus, OH.**

**Introduction:** Well-functioning dialysis access is of utmost importance as the lifetime of those with end stage kidney disease (ESKD). We present 2 patients with ‘imperfect’ accesses where a conservative approach avoided potentially problematic interventions.

**Case Description:** Case 1: A 24 year old man started hemodialysis (HD) in 1992 due to IgA nephropathy. He received a kidney transplant in 2000 which failed in 2005 requiring resumption of HD. His vascular access history is complex, involving multiple bilateral failed arteriovenous (AV) fistulae and AV grafts requiring numerous access interventions including tunneled HD catheter placements, angioplasties, and thrombectomies. He has also developed severe contrast allergy, making any further access interventions difficult. Since 2005 he has been dialyzing through a right upper extremity AVF complicated by central venous occlusion causing mild right arm swelling. Last resort vascular access options including a femoral AVG and a HeRO graft were contemplated. However, clinical decision making based on the presence of extensive collateral circulation, we opted for a conservative approach instead utilizing low blood flow rates. He has been doing well on this prescription for the last 3 years with adequate dialysis and swelling resolution. Case 2: A 67 year old woman with ESKD started peritoneal dialysis (PD) 2 years ago. PD was complicated by recurrent malpositioning of PD catheter with the catheter tip repeatedly migrating to the right upper quadrant. Changing the catheter insertion site and suturing it to the bladder wall did not prevent tip migration. Transition to HD was contemplated but she was able to continue with PD albeit with position changes to allow for complete drainage of PD fluid. Despite occasional sluggish drainage of PD fluid, the patient continued on PD for a total of 15 months before receiving a kidney transplant.

**Discussion:** These 2 cases illustrate the importance of dialysis access function as well as the dilemma of both the patient and provider when it becomes dysfunctional. The cases, however, also demonstrate that anatomical perfection is not always necessary to achieve adequate function. In both cases, a conservative approach allowed the patient to optimize dialysis through their existing ‘malfunctioning’ access and avoided further interventions that could result in worse complications, proving the adage ‘Less is More’ still true for dialysis access.

**PUB112**

**What Are Nephrologists’ Preferences Related to Continuing Medical Education?**

**Amy Larkin, Donald Blatherwick. Medscape LLC, New York, NY.**

**Background:** Understanding how clinicians prefer to learn and participate in continuing medical education (CME) can help providers of such education design more engaging and effective activities that can potentially further improve nephrologists’ clinical performance.

**Methods:** Medscape conducted a 10 question, online, incentivized survey in November 2018. Respondents’ confidentiality was maintained and responses were de-identified and aggregated prior to analysis.

**Results:** Most preferred duration for a CME activity: 30 minutes (51%) Followed by 15 minutes (31%) Most preferred format for a CME activity: online (70%) Followed by live events at a medical conference (13%) Most preferred format for an online CME activity: video and text (45%) Most preferred instructional design format: case-based (56%) Most important factors in selecting which symposia to attend at a scientific congress were content (69%), format (61%), and time (46%). Most preferred format for a CME activity: online (70%) Followed by video (22%).

**Discussion:** Understanding how clinicians prefer to learn and participate in continuing medical education (CME) can help providers of such education design more engaging and effective activities that can potentially further improve nephrologists’ clinical performance.

**Conclusions:** CME activities have an impact on changing clinician practices. Learner preferences for nephrologists related to live and online CME were identified. Most prefer participation in multiple activities that are online, 15-30 minutes, case-based, video and text description, learning objectives, and faculty play an important role in learner participation. These data should inform development of future CME activities that are engaging and impactful.
Online Education Effectively Improves Nephrologists' Knowledge, Competence, and Confidence Related to Hyperkalemia Management

**Background:** To improve outcomes for patients, clinicians must be able to implement evolving standards of care and apply relevant data on hyperkalemia management. We sought to determine if an online continuing medical education (CME) curriculum could improve hyperkalemia management.

**Methods:** The online CME curriculum consisted of 4 activities. Of these, 3 were 30-minute video panel discussions. A repeated pairs pre-/post-assessment study design was used and McNemar’s test assessed educational effect for each activity. The last activity comprised two patients presenting in a VPS platform that allows learners to order lab tests, make diagnoses, and prescribe treatments in a manner matching the scope and depth of actual practice. Tailored clinical guidance (CG), based on current evidence and expert recommendation, was provided following each decision, followed by the opportunity for the learner to modify their decisions. Decisions were collected post-CG and compared with each user’s baseline (pre-CG) decisions using a 2-tailed paired t-test to determine P values. The activities launched in 2019 and data were collected for 4-12 weeks.

**Results:** Education significantly improved physicians’ knowledge, competence, and performance managing and treating hyperkalemia. A 40% relative increase was observed among nephrologists related to knowledge of clinical trial data related to hyperkalemia. Nephrologists also significantly improved their knowledge and competence regarding the use of therapies in practice, with a relative increase of 16% observed. Case based simulation had a strong and significant positive impact on physicians’ performance in the treatment of hyperkalemia. The % of physicians who decided to start preferred potassium-binder more than tripled after education.

**Conclusions:** Some gaps still remain after education. Over 40% physicians are still not equipped with the right information regarding clinical trial data and the use of therapies in practice. In addition, an average of 40% physicians are still not making the right decision to start preferred potassium-binder. As such, further education needed in these areas.

**Funding:** Commercial Support - independent educational grant from Astrazeneca and Fibrogen.

Renal Clinic Quality Improvement Education Initiative

Rui Song,1 Iryna Danylyuk,1 Colleen Rabbit,1 Diane Y. Woodford,1 Wayne A. Satz,2 Mark G. Weiner,3 Soma Prakash.1 1Lewis Katz School of Medicine at Temple University, Philadelphia, PA; 2Weill Cornell Medicine, New York, NY.

**Background:** Benefits of timely CKD modality education include increased knowledge and home dialysis. At our centre, attendance of scheduled CKD 4/5 patients to education sessions was low. This quality improvement study was initiated and aims to increase the prevalent percentage of CKD 4/5 patients who received CKD modality education from 40% to 55% over one year.

**Methods:** Outcome measure was prevalent weekly percentage of CKD 4/5 patients who completed education sessions. Process measures were 1) weekly percentage of scheduled patient education attendance and 2) weekly number of incident CKD 4/5 patients education referrals by nephrologists. Ishikawa diagram was utilized to determine system gaps and develop changes to test in plan-do-study-act (PDSA) cycles. Changes tested were: a) NPs tracking weekly class attendance, b) NP reminder calls, c) information letter mailed to patients, d) referral data presented to nephrologists, e) reminder emails to nephrologists on education eligible patients. Discussion with primary care colleagues and 5-why’s tool resulted in developing an information webpage for patient education including NPs’ zoom recorded sessions. Median outcome and processes were calculated and plotted on run charts.

**Results:** Prevalent percentage of CKD 4/5 patients educated decreased from 40.6% to 29.4%. All referred patients had not yet been educated due to COVID19 and number of new patients increased over time. Median weekly session attendance increased from 60-67% with PDSA cycles (Figure 1). Monthly incident education referral numbers increased from 5-18/month.

**Conclusions:** Weekly session attendance and incident education referrals increased. Prevalent percent patients educated decreased but number of incident referrals increased. To provide a virtual information option for patients with barriers to attending sessions and for use during COVID19 pandemic, the webpage described is a helpful resource developed as a result this project. We anticipate this tool will increase the outcome and both process measures over time.

---

Optimizing On-the-Go Learning Utilizing Short Modules on Topics Related to Nephrology

Kiran Munir, Farah Daccueil. Stony Brook University Hospital, Stony Brook, NY.

**Background:** Residents and medical students are expected to formulate evidence-based treatment plans by keeping up with the most recent guidelines but that can be difficult given our schedules. In such circumstances, it is ideal to learn bite-sized pieces on the go.

**Methods:** We created two modules about Phosphorus Binders and Oral Hypoglycemic Agents using a friendly graphic interface called Prezi. These modules were estimated to take 10-15 minutes and were accompanied by a total of seven content related questions that were compiled from Uworld Step 3 Question Bank, John Hopkins Primary Modules, and hospital courses of patients seen at Stony Brook. Survey monkey was utilized to create the pre and posttest. The modules were sent to third and fourth year medical students. Data was collected for 10 days.

**Results:** Wilcoxon signed rank test was utilized to evaluate the effectiveness of the modules. Unfortunately, only six students completed the hypoglycemic module of which two had no improvement in scores, so no statistical significance was achieved. However, four of the six students had improvement in posttest scores by at least one point. Improvement in the posttest scores for the phosphorus module was significant as of the nine students who completed the phosphorus module, eight had an improvement by at least 1 point (W 36, p=0.008).

**Conclusions:** The observation of improved posttest scores for the phosphorus module supports the use of short lessons using a friendly graphic interface such as Prezi.

Wabishki Bizhiko Skaanj: A Learning Pathway to Foster Better Indigenous Cultural Competence Within Canadian Kidney Research

Helen Robinson-Settee, Craig Settee. Can-SOLVE CKD Network, Vancouver, BC, Canada.

**Background:** Can-SOLVE CKD is a kidney research network in Canada within which Indigenous patients, caregivers, researchers, and community leaders have created an Indigenous Peoples’ Engagement and Research Council (IPERC). A key component of IPERC’s work is the creation of a new learning pathway, Wabishki Bizhiko Skaanj (“White Horse” in Anishinaabemowin), that will help researchers build respectful partnerships with Indigenous peoples within the health research setting. Wabishki Bizhiko Skaanj aims to enhance researchers’ knowledge of racial biases, Indigenous voices and stories, the impact of colonization, and culturally safe health research practices.

**Methods:** A working group including members of the Can-SOLVE CKD Network, Diabetes Action Canada, First Nations Health Authority (BC), Provincial Health Services Authority (BC), and First Nations Health and Social Secretariat of Manitoba is leading the pathway’s development. Two in-person workshops were held in October 2017 and March 2018 to develop the concept and identity of the curriculum, which consists of interactive learning exercises, facilitated online modules, and webinars. Several components of the pathway have been piloted and feedback is being gathered via surveys, pledges, and stories.

**Results:** The pathway’s content is designed to help participants understand, recognize, and correct the racism that occurs in health care and research, in some cases caused by their own conscious and unconscious biases. Through enhanced knowledge, self-awareness and strengthened cultural competency, Wabishki Bizhiko Skaanj aims to support all partners in health care and research to close the gaps in health outcomes between Indigenous and non-Indigenous communities.

**Conclusions:** Wabishki Bizhiko Skaanj represents a novel learning platform for Indigenous cultural safety in Canadian health research. While Wabishki Bizhiko Skaanj was developed in the context of kidney health, the learning pathway can be adopted by networks and institutions across Canada, to help reduce and ultimately eliminate the racism that Indigenous people face within the health care system.

Ethylene Glycol Poisoning with Near-Normal Osmolar Gap: A Diagnostic Challenge

Moeed Ahmad, Cliff Janikowski, Aiza Ahmad, Lee E. Morrow. Creighton University School of Medicine, Omaha, NE.

Introduction: Ethylene glycol poisoning is classically associated with a high anion gap metabolic acidosis (HAGMA). Neurological and gastrointestinal symptoms predominate early while renal failure and death occur if not diagnosed and treated promptly. The diagnosis is usually suggested by HAGMA and an elevated serum osmolal gap in the setting of a suspected ingestion. Rarely, the serum osmolal gap may be close to normal which can delay the diagnosis or lead to a misdiagnosis. We report a case of ethylene glycol ingestion with near-normal serum osmolal gap.

Case Description: An 85-year-old man with a past medical history of Dementia presented to the Emergency Department with altered mental status, restlessness, and hypotension. Laboratory workup revealed HAGMA (anion gap = 21 mEq/L, arterial blood pH = 7.26, serum bicarbonate = 9.3 mmol/L, lactic acid = 2.2 mmol/L) with a near-normal serum osmolal gap (12 mOsm/kg). Urinalysis, urine drug screen, blood ethanol, beta-hydroxybutyrate, acetaminophen and salicylate levels were normal. Given a high clinical suspicion for toxic alcohol ingestion, the patient was treated with IV fluids and fomepizole. Over the next few days, his mental status improved, and repeat laboratory workup demonstrated correction of the anion gap which normalized.

Discussion: The workup for a HAGMA should include evaluation of the serum osmolal gap in the setting of a suspected toxic alcohol ingestion. Although uncommon, the absence of an elevated serum osmolal gap should not prohibit treatment for toxic alcohol ingestion when the clinical suspicion is sufficiently high.

Pyroglutamic Acidosis: A Painful Gap in the MUPDILE

Introduction: Pyroglutamic acid (5-exopeptide) is a rare cause of metabolic acidosis most often associated with sub-acute or chronic acetaminophen intake in the presence of unique risk factors.

Case Description: A 25-year old female with Crohn’s disease presented with one month of worsening abdominal pain, diarrhea, and anorexia with reported 20 kg weight loss. She developed septic shock secondary to sigmoid colon perforation and underwent sub-total colectomy and end ileostomy. Her hospital course was complicated by stage 2 acute kidney injury (AKI) secondary to acute tubular necrosis with a peak creatinine of 0.8 mg/dl from baseline of 0.3 mg/dl. Her AKI gradually resolved with supportive treatment. Over a 10-day period, she received a total of 20 g of acacetaminophen with a total daily dose of 2.5-4 g. On day 10, a persistent 24-hour high-anion gap metabolic acidosis developed with serum bicarbonate levels as low as 11 mmol/L and a corrected anion gap of 26 mmol/L. Further laboratory data showed normal serum osmolality, blood urea nitrogen, beta-hydroxybutyrate, L-lactate, D-lactate, acetaminophen, and salicylate levels.

Discussion: Pyroglutamic acidosis is an often underrecognized condition requiring a high index of clinical suspicion for diagnosis. Urine or serum 5-exopeptide levels are needed for diagnosis, which may not always be readily available. Chronic acetaminophen use depletes intracellular glutathione resulting in increased levels of 5-exopeptide. Patients, like the one reported here, who malnutrition, female gender, sepsis, and kidney dysfunction are expected to be at higher risk. They may be more vulnerable to faster 5-exopeptide accumulation despite standard dosing of acetaminophen. Prompt recognition is essential for treatment with acetaminophen cessation and bicarbonate supplementation. The use of acetaminophen as an analgesic alternative to opioids is growing, especially in post-operative and critical care settings. Clinical awareness of predisposing conditions and close monitoring of patient’s acid-base and kidney status can help us mitigate this underrecognized complication of acetaminophen use.

Amphotericin B Lipid Complex Inducing Distal Renal Tubular Acidosis

Introduction: Amphotericin B is the drug of choice for most life-threatening fungal infections. Nephrotoxicity is a common adverse reaction of this medication and its lipid complex formulation is an alternative to ameliorate this risk. Renal Tubular Acidosis (RTA) is an uncommon but major complication that can occur, and close monitoring should be performed for rapid identification and management. We hereby present the case of a patient who developed distal RTA secondary to amphotericin B lipid complex.

Case Description: A 59-year-old male patient without known medical history was admitted to Hematology-Oncology Ward with acute Myeloid Leukemia. Chemotherapy with cytarabine and idarubicin was initiated. The patient developed pancytopenia and potassium and bicarbonate were replaced. Treatment led to resolution of azotemia, acidosis of 21.4 mEq/L. Noted findings were consistent with distal RTA and high anion gap metabolic acidosis developed with serum bicarbonate levels as low as 11 mmol/L and a corrected anion gap of 26 mmol/L. Further laboratory data showed normal serum osmolality, blood urea nitrogen, beta-hydroxybutyrate, L-lactate, D-lactate, acetaminophen, and salicylate levels.

Discussion: Nephrotoxicity is induced after amphotericin B inserts into tubular cell membranes and creates pores that increase permeability, leading to kalurexia and back diffusion of secreted hydrogen ions. Although this effect is less common with liposomal amphotericin, it has been described in the literature. In addition, the risk increases in the presence of other nephrotoxic agents or non-modifiable risks such as critical illness. This case highlights the importance of prompt recognition of distal RTA in the at-risk population as it can lead to an early adequate management and prevention of further deterioration.

Treatment Pattern of Hyperkalemia Among Patients Presenting Emergency Department in China

Introduction: Hyperkalemia (HK) is a common complication among patients presenting emergency department (ED) that is not well described.

Methods: Data containing hospital information system (HIS) records of 157 hospitals covering 30 provinces in China were extracted from Beijing Data Center for Rational Use of Drugs. Patients (aged ≥18 years old) in ED with record(s) of HK, defined as serum potassium (S-K) ≥5 mmol/L, were included. The diagnosis rate was defined as the proportion of HK episodes that have diagnoses records. Treatment rate was defined as the proportion of HK episodes that have records of any HK treatment including diuretics, glucose injection + insulin (G+I), calcium injection, sodium bicarbonate, potassium binder or dialysis. Retesting rate was defined as the proportion of HK records that have potassium retest record(s) within 1 day.

Results: A total of 36.615 HK episodes were included. The overall HK diagnosis rate was 9.2%. Diagnosis rates increased by the severity of HK, patients with S-K ≥7 mmol/L showed the highest diagnosis rate of 31%. The overall treatment rate within 2 days was 45.2%, treatment rates increased by the severity of HK. Analyzing the HK episodes with HK treatment, G+I (used in 72.4% of HK episodes), loop diuretics injection (used in 50.36% of HK episodes) were most commonly used, while oral potassium binders, including sodium polystyrene sulfonate and calcium polystyrene calcium, were used in only 0.2% of HK episodes. Combined treatments were observed, among which a combination of G+I and loop diuretics injection was used in 10.4% of episodes and a combination of G+I, diuretics injection, calcium injection and sodium bicarbonate was used in 7.4% of episodes. Subgroup analysis of HK treatment in patients with chronic kidney disease showed that, G+I (used in 71.7% of episodes), loop diuretics injection (used in 61.2% of episodes) were most commonly used. The overall retesting rate within 1 day was 19.36%. Patients with S-K 5.0-5.5 mmol/L were retested less frequently (15%) than those with S-K ≥5.5 mmol/L (22.4-30.6%).

Conclusions: In China, the diagnosis and retesting rates of HK in ED patients was relatively low. Glucose injection + insulin was commonly used to treat HK in ED, while oral potassium binders were rarely used. Combination of treatments was common.
IgA (anionic), will cause deviations in SAG. In IgG myeloma, the combination of cationic IgG accumulation as well as hyperparacrina and hypobuminemia can lead to a low or negative SAG. We report a patient who presented with an unrelated chief complaint and was found to have a myriad of electrolyte abnormalities causing a negative SAG, eventually leading to a diagnosis of multiple myeloma.

Introduction

A 56 year old woman presented with right knee pain due to septic arthritis. Her admission labs were notable for a sodium of 124 mEq/L, Cr 4.76 mg/dL. Her anion gap was -3 and her serum osmolality was measured as 316 mOsm/kg with a 50 mOsm/kg osmolar gap. Her total protein was noted to be 12.6 g/dL, albumin 2.1 g/dL, with a total bilirubin of 11.1 mg/dL. Her Lactate was 137 mg/dL consistent with pseudohyponatremia. UAC and UPC were 187 mg/mg and 780 mg/g respectively. SIEP and UIEP ultimately demonstrated monoclonal IgG Kappa. Her total protein increased to 13.7 g/dL; she subsequently became lethargic and developed 

Discussion

This case illustrates the myriad presenting electrolyte derangements of multiple myeloma. The combination of pseudohyponatremia, negative SAG, increased osmolar gap, and high protein gap raised the suspicion of a cationic hyperproteinemia, which eventually led to the diagnosis of IgG multiple myeloma. The hypercalcemia and AKI were also classic features of her myeloma. Her mental status changes, which were thought to be from hyperviscosity, were indications to treat with plasmapheresis. A negative SAG is rare and has a limited differential diagnosis, with IgG myeloma as perhaps its most significant clinical etiology.

PUB126

A Surprising Complication Following Steroid Therapy: Tumor Lysis Syndrome

Jesus D. Vega Colon, Stephen Barry, Dev Boodoosingh. Saint Luke Episcopal Hospital, Ponce; PR.

Case Description: We report a 76-year-old female with Past Medical History of Hypertension, Diabetes Mellitus Type-II and Chronic Kidney Disease that came to our hospital complaining of pleuritic chest pain since 3 days. Vital signs and physical exam were unremarkable. Labs results were remarkable for hemoglobin 7.8 g/dl and serum creatinine 1.60 mg/dl. No evidence of leukemia, electrolytes disorders or positive cardiac markers were present. Patient was admitted with diagnosis of symptomatic anemia. During blood transfusion, patient developed an acute allergic reaction evidenced by generalized urtica and bronchospasam. Single dose intravenous steroid therapy (methylprednisolone 20 mg) was given. After 48 hours post transfusion clinical condition continued to worsen. New labs showed leukocytosis (49.7 x10^3/L) and lactic acidosis (8.5mmol/L).

Severe hypotension led the patient to developed acute respiratory failure requiring mechanical ventilation and vasopressors therapy. Further labs revealed typical findings of TLS including hyperuricemia (158 mg/dl), hyperkalemia, hyperphosphatemia, hypocalcemia and acute renal failure. Few cases have been able to demonstrate the occurrence of TLS following steroid therapy alone in the absence of chemotherapy or radiotherapy.

Discussion: This report highlights that recent use of corticosteroids can be associated with TLS. We should be aware of potential complications of steroid therapy. 

PUB127

Laxative Use in Acute Hyperkalemia

Faisal Abdulameer, Barry M. Wall, C. Sabaa P. Kovesdy, The University of Tennessee Health Science Center College of Medicine, Memphis, TN; 1VA Medical Center, Memphis, TN.

Introduction: The most effective treatment of severe hyperkalemia is hemodialysis. Treatment options for patients who are not candidates for renal replacement therapy are limited. Oral potassium binders, available for treatment of chronic hyperkalemia, are not approved for acute hyperkalemia. We describe a stage 5 CKD patient with severe hyperkalemia who was not a hemodialysis candidate in whom lactulose was used after other measures failed to lower serum potassium (K+).

Case Description: 66 year old female with stage 5 CKD who was not a candidate for renal replacement therapy due to severe schizophrenia was being managed medically. Her serum K+ was controlled with patiromer 8.4 mg/day during the previous year. She was presented with volume overload and uric acid encephalopathy with hyperkalemia (K+ 5.7 mEq/L), high anion gap metabolic acidosis (serum CO2 9 mmol/L) and serum creatinine, 20 mg/dL. She received 10 units of insulin with D50, 150 mg of IV bicarbonate, furosemide 60 mg IV daily, and patiromer 8.4 g/day. Her serum K+ decreased to 5.3 mEq/l after 24 hr, but increased to 7.0 mEq/l after 72 hr. Patiromer dose was doubled to 16.8 g/day, and sodium bicarbonate was added. Serum K+ initially decreased to 6.7 mEq/l, but subsequently progressively increased despite improvement of metabolic acidosis, repeated administration of insulin+D50 and albuterol, patient, and use of high dose loop diuretics, peaking at 9.3 mg/dL on day 11. Daily lactulose dose of 17 g daily was added, resulting in diarrhea and gradual decline in serum K+ at an average rate of 0.7 mEq/L/day, reaching a nadir of 6.9 mEq/L after 72 hr. The patient unfortunately passed away on that day due to other uremic complications.

Discussion: Use of laxatives can be considered as a means to control hyperkalemia in patients who are not candidates for renal replacement therapy.

PUB128

Battling Warburg: Type B Lactic Acidosis in a Patient with Diffuse Large B-Cell Lymphoma

Stephen P. Regis, Roberto L. Collazo-Maldonado. Methodist Health System; Methodist Health System, Dallas, TX; Dallas Nephrology Associates, Dallas, TX.

Introduction: The Warburg effect is a rare paraneoplastic syndrome seen in patients with hematologic malignancy. The metabolism of cancerous cells converts to aerobic glycolysis and results in type B lactic acidosis.

Case Description: The patient is a 62-year-old man with diffuse large B-cell lymphoma and prior hemophagocytic syndrome (HS) diagnosed 6 months prior, on chemotherapy. He presented with several weeks of fever and respiratory symptoms. Clinical and diagnostic workup did not reveal a source of sepsis. Chest radiography and CT chest were without infiltrates. COVID-19 PCR was negative. Labs- WBC 1,500/mm3, Hemoglobin 8.8 g/dL, Platelets 63,000/mm3, creatinine 1.1 mg/dL, lactate 2.6 mmol/L, ferritin 417 ng/mL, serum triglycerides 349 mg/dL. Patient was placed on vancomycin and cefepime and volume expanded, but continued febrile with persistent lactic acidosis. Abdominal CT revealed splenomegaly with focal hypodensities, mild descending and sigmoid diverticulosis without diverticulitis. CT mesenteric angiography revealed moderate narrowing of celiac artery and severe narrowing of the inferior mesenteric artery origin. For suspected ischemic colitis, the patient was taken emergently for exploratory laparotomy, but findings did not support ischemia. Creatinine trended up to 2.0 mg/dL with increasing lactate of 11 mmol/L, bicarbonate 13 mmol/L, and serum pH of 7.0. At this point, without septic or ischemic processes identified, the lactate production was ascribed to DLBCL, and not HS as ferritin was not substantially elevated. CRRT was initiated for anuria. AKI. Lactate continued to trend up to 21.7 mmol/L with bicarbonate 6 mmol/L. Family discussions were held, and the patient was transitioned to palliative care.

Discussion: Type B lactic acidosis should be considered in the differential diagnosis in patients with increased anion gap metabolic acidosis and malignancy. One rare and potentially fatal Type B lactic acidosis is due to the Warburg effect, a rare and potentially lethal paraneoplastic syndrome of hematologic malignancies.
was started on IV hydration, dexamethasone, rasburicase, and allopurinol. On the fifth hospital day, hypothermia was started, and white blood cell count decreased by approximately 50 thousand/μL. Two days after, laboratory values were remarkable for hyperkalemia of 6.1 mmol/L, blood urea nitrogen of 66.2 mg/dL, creatinine of 2.61 mg/dL, hyperphosphatemia of 8.5 mg/dL, and a corrected calcium of 7.1 mg/dL. These findings were suggestive of TLS following chemotherapy, along with the development of a non-oliguric stage three acute kidney injury. The next day, the patient had adequate urine output, stable blood pressures, no signs of volume overload or uremia, but laboratory values revealed worsening renal parameters and an increased calcium-phosphate product above 70 mg2/dL. Consequently, hemodialysis was performed with good tolerance and response to treatment.

Discussion: The criteria for hemodialysis in this case of a non-oliguric euvolmic patient with acute renal failure secondary to TLS was founded on an elevated calcium-phosphate product as an indication for renal replacement therapy in the setting of tumor lysis syndrome.

PUB130

Hypomagnesemia and Proton Pump Inhibitors
Pooja Kalantri,1 Jasleen Kaur,1 Sumanta Sengupta,2 Rochester, NY
1Saint Vincent Hospital, Worcester, MA; 2Mass Memorial Medical Center University Campus, Worcester, MA; 1UMass Memorial Marlborough Hospital, Marlborough, MA.

Introduction: Proton pump inhibitors (PPIs) are commonly used for GERD. They are associated with acute interstitial nephritis, B12 deficiency, Closstridium difficile infection, gastric malignancy, atrophic gastritis, bone fractures, and rarely, hypomagnesemia. We present a case of hypomagnesemia manifesting with unexplained hypocalcemia, refractory hypokalemia, and neuromuscular disturbances. Two months ago, an old male with GERD and prostate cancer (scheduled for prostatectomy), was found to have abnormal electrolyte values on routine preoperative evaluation. Two months ago, they were all normal. He had carpopedal spasms, facial twitching, frequency and weak urine stream for two months. He denied diarrhea, nausea, vomiting, fever, chills, medication changes or use of supplements. He drank alcohol socially. Trousseau sign was positive. Labs showed potassium 2.8 mmol/L, bicarbonate 8.87 mmol/L, calcium 6.1 mg/dL, albumin 4 mg/ dL, magnesium 0.9 mg/dL, and phosphorus 3.2 mg/dL. 25-OH vitamin D was 9 ng/mL, with normal 1, 25 (OH)2 vitamin D. FTH was elevated at 122 pg/mL. Fractional excretion of magnesium (measured after changing his PPI to an H2-receptor antagonist) was 2.5%. It was suspected that PPI use may have driven hypomagnesemia (which accelerated renal K+ losses), with associated PTH resistance and vitamin D deficiency (causing hypocalcemia). Symptoms resolved with electrolyte supplementation.

Discussion: Hypomagnesemia can result from gastrointestinal or renal losses. The presumed mechanism for PPI-induced hypomagnesemia involves impaired absorption of magnesium by intestinal epithelial cells caused by PPI-induced inhibition of transient receptor potential melastatin-6 (TRPM6) and melastatin-7 (TRPM7) channels. The aim of this study was to review the literature and present a case of PPI-induced hypomagnesemia. Our case is unique, as he developed the abnormalities so acutely. He was restarted back on his PPI, along with magnesium supplements, and repeat electrolytes over the ensuing 4 months have been normal.

PUB131

Rising from Death: A Case of Life-Threatening Hyperkalemia
Sonali Gupta, Jeremy G. Taylor. University of Rochester Medical Center; Rochester, NY.

Introduction: Hyperkalemia affects the cardiac conduction and can result in fatal consequences. We describe a rare case of life threatening hyperkalemia presenting in setting of hyperglycemia, sepsis and shock and manifesting as new ST elevation in anterior leads, which resolved with correction of hyperkalemia.

Case Description: A 63-year-old male with intellectual disability and diabetes presented in state of shock after refusing his medications for last 5 days. His vitals on arrival were BP 90/39 mm Hg, pulse 96 beats/day, respiratory rate 24 breaths/min, Glasgow Coma Scale of 5. Cardiovascular and abdominal examination were unremarkable. Laboratory study revealed arterial pH of 6.9, serum potassium [K+] of 11.1 mmol/L, serum bicarbonate level of <6 mmol/L, serum phosphorus of 11.8 mg/dL, serum creatinine of 2.4 mg/dL (baseline 0.6 mg/dL), blood glucose of 1100mg/dL and serum sodium [Na+] of 129mg/dL. Chest radiograph showed cardiac enlargement and electrocardiography (EKG) revealed absent P waves, prolonged QRS intervals, ST elevation in anterior leads, marked left axis deviation and tented T waves. Creatine kinase (CK) levels were normal but troponin T high sensitivity were elevated. He was treated with intravenous fluids, sodium bicarbonate, calcium gluconate, insulin drip, broad-spectrum antibiotics and norepinephrine. The blood glucose, potassium and bicarbonate levels improved with conservative management without need for renal replacement therapy. EKG showed improvement and the patient made full recovery.

Discussion: Severe hyperkalemia is dangerous and can result in cardiac arrest. Our patient presented with very high potassium levels, however hyperthermic state might have reduced the acute toxic effects and prevented immediate cardiac arrest. Hyperkalemia in setting of uncontrolled hyperglycemia usually responds to medical management if the patient is not anuric. Moreover, pseudo infarction as seen in this case is a rare manifestation of hyperkalemia. With the recent emphasis on reducing door-to-balloon times in setting of myocardial infarction, it is important to be aware of its association with hyperkalemia as it usually resolves with reduction of the serum potassium levels.

PUB132

Analysis by Bioimpedanciometria of Three Cohorts with Expanded Extracellular Volume: Critically Ill, Nephrotic, and Hemodialysis Patients
Waldo Bernales,1 Patricio Vargas,2 Gonzalo Correa,3 Maria E. Sanhueza,4 Fernando Gonzalez.2 1Hospital de Coyhaique, Coyhaique, Chile; 2Clinica Alemana de Santiago SA, Vitacura, Chile; 3Hospital Del Salvador, Santiago, Chile; 4Hospital Clínico Universidad de Chile, Santiago, Chile.

Background: By applying, bioimpedanciometry provides information on body composition, estimating total body water (TBW) and extracellular water (ECW) with formulas. However, these estimates are imprecise in edematous patients. Fortunately, there are variables that are directly measured: resistance (R), reactance (Xc) and phase angle (AF), which in theory reflect the cells’ ability to maintain adequate function. In our work, we mainly wanted to analyze this second group of variables in patients with increased ECV and additionally compare them with a group of healthy volunteers.

Methods: Using a multifrequency bioimpedanciometry, we performed measurements on edematous patients in the ICU, edematous patients with nephrotic syndrome (NS), and anuric patients on hemodialysis (HD) before starting a random session. The control group were healthy volunteers (V) of the same age as the studied patients. A t-test was performed to compare each group against V and a pearson’s correlation test was performed to assess correlation between variables.

Results: During 6 weeks measurements were made getting data of 14 V, 11 HD, 13 SN and 11 ICU. When comparing against V, significant differences were obtained in R, Xc and AF (p<0.05) in all groups except R in the HD group. When comparing among them the most edematous groups (ICU and NS), surprisingly no differences were obtained (p=0.05). In the estimated variables related to water distribution (ECW, TBW and ECW/TBW), the 3 groups show significant differences compared to V, except in TECW and TECW/TBW. Finally, when comparing for a correlation between measured and estimated variables, we found that Xc has a high negative correlation (r: -0.75) with ECW; AF has a high negative correlation (r: -0.83) with ECW/TBW, while R has a moderate negative correlation (r: -0.67) with ECW and TBW.

Conclusions: Our results show, the studied groups have differences in measured and estimated variables compared to V, theoretically reflecting a state of cellular malfunction in addition to the expansion of the ECV. Surprisingly, patients with NS and ICU are “electrically” the same, despite their very different clinical contexts. However, we cannot rule out that it is only due to expansion of the ECV of a similar amount since the measured variables depend to some degree on the estimated variables.

PUB133

Intractable Hyponatremia, Polydipsia, and the Reset Osmostat: A Case Report
Mohamed T. Hassan Kamel, Ashish Upadhyay, Steven C. Borkan. Boston Medical Center, Boston, MA.

Introduction: Water intake in excess of water excretion results in hyponatremia, the most common electrolyte abnormality in clinical practice. Typically, ADH secretion fluctuates to maintain a physiologic serum osmolality, the so called “ADH osmostat”. This threshold can be altered by multiple physiologic and pathologic stimuli. For example, with diabetes insipidus, a patient with pituitary stalk compression results in inappropriately high ADH levels, leading to a syndrome of inappropriate antidiuresis (SIADH). Such patients may present with a spectrum of fluid accumulation ranging from hyponatremia and polyuria to more severe clinical entities such as pulmonary edema and cerebral edema. Hyponatremia can also be a manifestation of acute neurological injury, with a recent report describing a patient with hypovolemic shock and severe hyponatremia who developed acute renal failure. In this report, we present a case of symptomatic hyponatremia associated with polydipsia in an elderly patient with psychiatric comorbidities and chronic hyponatremia. We describe the accompanying laboratory findings that support the diagnosis of reset osmostat. We postulate that chronic hyponatremia secondary to polydipsia related to psychiatric illness could have reset this patient’s osmostat and discuss potential therapeutic strategies.
An Unusual Cause of Rhabdomyolysis

Esilda Sala Karroci, Larissa Kruger gomes, Ruth Schulman, Krishna A. Agarwal, Amar Pandit, Bradley M. Denker, Beth Israel Deaconess BIDMC, Beth Israel Deaconess Medical Center, Boston, MA.

Introduction: Rhabdomyolysis results from muscle cell injury and often leads to AKI. Common causes include trauma, medications, electrolyte abnormalities, and metabolic myopathies. The clinical presentation includes muscle pain, dark urine, and possibly oliguria. Here, we present an unusual etiology of rhabdomyolysis resulting from sustained hyperosmolarity due to severe hyperglycemia and hypernatremia.

Case Description: 23-year-old male with no significant medical history presented with fatigue two years ago. He denied fever, nausea, vomiting, pain, or diarrhea. Despite drinking large amounts of fluids, he felt thirsty, with frequent urination. Family history: diabetes. Social history: no alcohol, smoking or drug use. No pain, diarrhea, or abnormal bowel movements. He developed weakness and difficulty getting up but no muscle soreness. He developed a Na+ level of 172 with a free water deficit 10 L. Initially given 3 L NS bolus followed by 1/2 NS NS. Urine was glucosuria and ketones, sediment was bland. He was started on an insulin drip. Corrected rate of 110-120 beats/min. He appeared lethargic. Physical exam showed dry mucous membranes and tachycardia, otherwise unremarkable. Initial laboratory values showed blood glucose of 1132 mg/dL, Cr 3.5 mg/dL, Na+ 147 mmol/L (see table). Urine showed glucosuria and ketones, sediment was bland. He was started on an insulin drip. Corrected Na+ was 172 with a free water deficit 10 L. Initially given 3 L NS bolus followed by 2 NSNS to correct hypernatremia, with goal correction of 10-12 mEq/L in the first 24 hours. On day 3, he complained of weakness and difficulty getting up but no muscle soreness. He developed a temperature of 101°F and his exam was unremarkable. Creatinine and Na+ improved (see table), however, ALT/AST continued to rise. Right upper quadrant US showed hepatic steatosis. Repeat UA showed large blood, but no red blood cells on sediment. CPK returned at 111850 IU/L, and peaked at 195380 IU/L on day 5. He was given isotonic fluids at 500 cc/h. He remained tachycardic with low grade fever and on day 9, CTA showed bilateral pulmonary emboli.

Discussion: This case highlights an unusual cause of rhabdomyolysis caused by hyperosmolarity in HHS. Although, the literature suggests that rhabdomyolysis may be present in up to 50% of HHS cases, this is an extreme case and highlights the importance of looking for rhabdomyolysis in HHS. It is unclear why our patient showed such a severe hyperosmolarity. It is possible that the patient had undiagnosed diabetes mellitus.

An Atypical Case of Hypocalcemia Associated with the Use of Patiromer

Muhammad T. Baig, Estheli L. Obole, Jason Prosek, Khaled Boube, The Ohio State University, Columbus, OH.

Introduction: Novel potassium (K) binders were approved a few years ago and introduced to the market. With their increased use, more side effects are surfacing. We report an atypical case of hypocalcemia that was associated with the use of patiromer.

Case Description: An 86 year-old male with stage 3 chronic kidney disease secondary to left radical nephrectomy from urothelial cancer, who was on patiromer for secondary to left radical nephrectomy from urothelial cancer, who was on patiromer for 23 years. He was discharged from the hospital with close outpatient follow up. He reported an atypical case of hypocalcemia that was associated with the use of patiromer. In this unique case, hypocalcemia was an indirect side effect attributed to patiromer use. In this unique case, hypocalcemia was an indirect side effect attributed to patiromer use. In this unique case, hypocalcemia was an indirect side effect attributed to patiromer use. In this unique case, hypocalcemia was an indirect side effect attributed to patiromer use.
A Novel Frameshift Mutation of COL4A5 Identified by Whole-Exome Sequencing in a Chinese Family with Alport Syndrome

Jun Zhang, Wenyua Gong, Xiaxia Xiong, Hui-qun Li. Division of Nephrology, Department of medicine, Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.

Background: Alport syndrome is an inherited kidney disease caused by the defects in type IV collagen, approximately 80% of which is caused by X-linked mutations in the COL4A5 gene. This study explores a novel frameshift mutation of COL4A5 responsible for renal disorder in a 3-generation Han Chinese pedigree.

Methods: We enrolled the proband and his family members from a village in Shichuan province, and collected the family history and clinical data. Clinical examinations were performed to evaluate the phenotypes of the family. Blood samples from the proband and the other eight family members were collected for genetic screen. Whole exome sequencing (WES) was applied in the proband to find out the potential genetic variants, and then the variant within the family was verified by Sanger sequencing.

Results: The 31-year-old male proband and his elder brother had ESRD, bilateral sensorineural hearing loss and ocular lesions. Further, his three male cousins received hemodialysis and all died from ESRD between 18 and 25 years old. The 90-year-old maternal grandmother, one maternal aunt and one female cousin had only microscopic hematuria without gross hematuria, proteinuria, impaired kidney function or extrarenal symptoms. Genetic analysis identified a novel deletion mutation (c.422-428del) in exon 7 of COL4A5 gene which located on the X chromosome in the proband. The c.422_428del variant was also detected in the proband’s grandmother and four other affected family members. The proband’s father and three unaffected family members had not found this variant. This mutation was results into frameshift followed by formation of a truncated COL4A5 protein product with only 152 amino acids including an aberrant 10 residues. This mutation was not present neither in the Exome Variant Server of the NHLBI-ESP database, ExAC database or in the 1000 Genomes database. According to the variant interpretation guidelines of American College of Medical Genetics and Genomics (ACMG), this novel variant was classified as “likely pathogenic” variant for Alport syndrome in this pedigree.

Conclusions: Our study identified a novel COL4A5 frameshift mutation in a Chinese family with Alport syndrome, expanding the mutational spectra of COL4A5 gene, which were significant for screening and genetic diagnosis for Alport syndrome.

Elevated Ambulatory Blood Pressure Is Associated with a Progressive Form of Fabry Disease

Federica Rossi,1 Einar Svarstad,2 Hassan O. Elsaid,3 Agnese Binaglia,4 Letizia Roggero,1 Sara Auricchio,1 Hans-Peter Marti,1,2 Federico Pieruzzi,1,4 1Department of Medicine and Surgery, University of Milano-Bicocca, Monza, Italy; 2Department of Clinical Medicine, University of Bergen, Bergen, Norway; 3Department of Medicine, Haukeland University Hospital, Bergen, Norway; 4Nephrology and Dialysis Unit, ASST-Monza, San Gerardo Hospital, Monza, Italy.

Background: Published data on hypertension incidence and management in Fabry Disease (FD) are scanty and it remains to be shown how much high blood pressure (BP) contributes to organ damage in these patients. Therefore, we have assessed BP values and their correlations with clinical findings in a cohort of FD patients.

Methods: Between January 2015 and May 2019, all adult FD patients (n=32) referred to our institute were enrolled; they were Caucasians (n=24) and females (n=8, males) with an average age of 50±12.2 years. Data regarding hypertension were obtained by ambulatory BP monitoring (ABPM), home self-monitoring and office measurements. Patients were defined as hypertensive according to 2018 ESC/ESH Guidelines. The severity and the stability of FD were assessed with the Fabry Stabilization Index (FASTEX). Organ involvement and hypertension risk factors were also evaluated.

Results: The ABPM revealed elevated BP in 18.75% (n=6) of the FD population and 50% (n=3) of this group was diagnosed with masked hypertension. All these patients were females with an average age of 58±9.9 years. They presented a lower (p=0.046) glomerular filtration rate compared with the normotensive patients (77±17.7 and 89.3±21.4 ml/min/1.73m², respectively) and a more advanced cardiac hypertrophy with a higher LVPWd (p=0.044) and LVMi (p=0.033). Four of them (66.7%) were classified as progressive by the FASTEX score while the majority of the normotensives (84.6%) were stable (Figure 1). No correlation (p=0.428) was found between the category of GLA mutation and the development of hypertension.

Conclusions: Newly detected hypertension is found in a restricted portion of stable FD patients, while it becomes more prevalent in clinically progressive cases. The use of ABPM is of paramount importance to reveal masked hypertension which can contribute to the progressive worsening of the organ failure. We recommend a standardised ambulatory long-term BP monitoring program and timely antihypertensive intervention to improve the outcome of FD patients.

Non-Compliance and Acute Dehydration Are Main Reasons for Acute Kidney Failure in Patients with Non-Infantile Primary Hyperoxaluria Type 1

Cristina Martin Higueras,1 Bodo B. Beck,2 Bernd Hoppe.3
1Dept. Ciencias Medicas Basicas, Fac. Medicina, Universidad de la Laguna, Tenerife, Spain; 2Institute of Human Genetics, University Hospital Cologne, Cologne, Germany; 3German Hyperoxaluria Center, Bons, Germany.

Background: Patients with primary hyperoxaluria type 1 (PH1) have an increased risk of acute or chronic kidney failure (AKF/CKF). There are two risk groups: infantile oxalosis or patients with an unremarkable family history and adult patients with only an oligosymptomatic course (minor stone events), who get into end-stage renal disease (ESRD) due to oxalate-induced chronic inflammatory processes in the kidney. We were interested in the prevalence of acute kidney failure in patients with non-infantile PH1 seen in our Hyperoxaluria Center over the last 10 years.

Methods: We retrospectively analyzed the database of the German Hyperoxaluria Center for patients being seen in our outpatient clinic for AKF. AKF was defined as a sudden onset of kidney failure and the necessity of dialysis installment in patients, but a documented stable kidney function (no worse than stage 2-3 CKD) prior to onset of AKF.

Results: There were 117 PH1 patients in the center, of whom 6 had infantile oxalosis and thus early ESRD, 8 patients are currently on dialysis, and 6 patients have died. Transplantations were performed in 35 patients with PH1 (liver & kidney in 28 patients, liver-only in 4 patients, and kidney-only in 3 patients). Currently, we routinely follow up (3-4 times a year) 49 of 117 PH1 patients. Out of these 49 patients, AKF was diagnosed in 8 patients aged 11-56 years (1 pediatric patient, 3 patients 18-19 years old, and 4 patients 28-56 years old), which led to CKF and subsequently, maintenance hemodialysis in 7 patients and death in 1 patient. Non-compliance regarding medication or recommended fluid intake was the reason for AKF in 6 of the 8 patients. Acute massive diarrea without adequate fluid substitution led to AKF in the other 2 patients.

Conclusions: AKF is not uncommon in patients with PH1. It is frequently related to either non-compliance or to situations of severe fluid losses with inadequate fluid substitution and not based on already extremely altered renal function. Therefore, interruption of medication or lack of fluid intake, even for short periods of time, can lead to severe clinical consequences in these patients.

Findings of Whole-Exome Sequencing in a Tunisian Man with Congenital Anomalies of Kidney and Ureteral Tract and Dilated Cardiomyopathy

Sabra Aloui,1 Majdi Nagara,1 Salima Ltaief,1 Ahmed Letaief,1 Manel Ben salah,1 Mouna Hamouda,1 Meriem Ben salem,1 Habib Shkiri,1 Ridha Mrad,2 Sonia Abdelhak.1
1Department of Nephrology, Monastir University, Monastir, Tunisia; 2Department of Human Genetics, Charles Nicolle Hospital, Tunis, Tunisia; 3Laboratory of Biomedical Genomics and Oncogenetics, Institut Pasteur de Tunis, Tunis, Tunisia.

Background: Congenital Anomalies of Kidney and Ureteral Tract (CAKUT) is a paediatric concern but can be diagnosed in adults adding challenges in the identification of CAKUT’s etiology. To date, there are more than 50 single-gene disorders known to underlie CAKUT. Furthermore, a substantial number of CAKUT causes are extremely rare in the general population. Whole exome sequencing (WES) has been proposed as the solution in some cases.

Methods: Whole exome sequencing and case study of an adult with CAKUT, cardiomyopathy, factor? and other anomalies

Results: It is about a 30-years-old Tunisian man. He was referred to our unit for renal failure. His parents are second degree consanguine. He was hospitalized at age 2 years for dehydration. He had a brother with Parkinson disease started early at age of 20 years. He was hospitalised at age 29 in cardiology unit for heart failure. Examinations revealed dilated cardiomyopathy (DCM) and an elevated plasmatic creatinine. Physical examination showed a peculiar facies with crying facial expression when laughing, dental anomalies, mild mental retardation, strabismus, large prominent earlobes, brachydactylia, right cryptorchidism and normal blood pressure. Laboratory exams confirmed kidney failure: creatinine at 900μmol/L without proteinuria or haematuria. Prothrombin level showed a single right kidney of reduced size. We concluded at chronic renal failure due to tubulointerstitial nephritis associated with urofacial syndrome, DCM and factor VII deficiency. Several studies have suggested that ANCA-negative PICGN has a lower incidence of extra-renal involvement, a poorer prognosis, and often dialysis dependent. Unfortunately given our limited understanding of the pathophysiology of ANCA-negative PICGN, current therapy is similar to ANCA-positive despite its worse prognosis.

Case Description: 60-year-old female presented for hypertension emergency. She had an elevated creatinine (Cr) of 1.48; baseline was 1.29 two weeks ago. Her Cr worsened to 2.05 and nephrology was consulted. Initial differential included acute drop in BP from restarting medications. UA showed 2+ protein, quantified 2 grams/gCr and RBC > 100. Findings of proteinuria and hematuria suggested PICGN however testing for ANCA, Anti-GBM, HIV, Hepatitis B and C, ANA, C3, C4 were negative. AKI due to ATN from infection was included in the differential for MDRO UTI. Despite treatment for infection and liberalized BP control, Cr continued to worsen and she became oliguric, acidic and was started on dialysis. Given infiltrates seen on Chest CT, she had bronchoscopy with biopsy suggestive of bleeding that raised the possibility of pulmonary-renal syndrome. A renal biopsy was performed which showed pauci immune ANCA negative crescentic GN. Pathology showed almost 100% of glomeruli involved with global scarring and fibrinoid necrosis. She was started on steroids and Cytoxan. Six months later, she is off both medications but still on dialysis.

Discussion: Since patients with ANCA-negative PICGN have few extra-renal manifestations, they are often dialysis dependent and have a worse prognosis, early recognition is crucial. The diagnosis primarily relies on performing a kidney biopsy rather than serological testing, otherwise the diagnosis may be missed. Early initiation of empiric therapy is imperative to minimize the degree of irreversible injury and delay dialysis initiation. The development of sclerotic fibrotic lesions in renal biopsy may predict treatment response. ANCA negative PICGN is a rare diagnosis; this case highlights why it is important to keep this diagnosis in the differential and why novel treatment options are needed.

ANCA-Negative Pauci-Immune Crescentic Glomerulonephritis: A Positively Rare Cause of RPGN

Aarni Noorayan, Wafa Dawahri, Paru P. Kathapalia. Mercy Hospital Medical Center, Chicago, IL.

Introduction: Pauci-immune crescentic necrotizing glomerulonephritis (PICGN) is the most common subset of RPGN. Most cases of PICGN are antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis; however, about 10-30% of patients are ANCA negative. Several studies have suggested that ANCA-negative PICGN has a lower incidence of extra-renal involvement, a poorer prognosis, and often dialysis dependent. Unfortunately given our limited understanding of the pathophysiology of ANCA-negative PICGN, current therapy is similar to ANCA-positive despite its worse prognosis.

Patients with primary hyperoxaluria type 1 (PH1) have an increased risk of acute or chronic kidney failure (AKF/CKF). There are two risk groups: infantile oxalosis or patients with an unremarkable family history and adult patients with only an oligosymptomatic course (minor stone events), who get into end-stage renal disease (ESRD) due to oxalate-induced chronic inflammatory processes in the kidney. We were interested in the prevalence of acute kidney failure in patients with non-infantile PH1 seen in our Hyperoxaluria Center over the last 10 years. We retrospectively analyzed the database of the German Hyperoxaluria Center for patients being seen in our outpatient clinic for AKF. AKF was defined as a sudden onset of kidney failure and the necessity of dialysis installment in patients, but a documented stable kidney function (no worse than stage 2-3 CKD) prior to onset of AKF. Out of these 49 patients, AKF was diagnosed in 8 patients aged 11-56 years (1 pediatric patient, 3 patients 18-19 years old, and 4 patients 28-56 years old), which led to CKF and subsequently, maintenance hemodialysis in 7 patients and death in 1 patient. Non-compliance regarding medication or recommended fluid intake was the reason for AKF in 6 of the 8 patients. Acute massive diarrea without adequate fluid substitution led to AKF in the other 2 patients. The diagnosis primarily relies on performing a kidney biopsy rather than serological testing, otherwise the diagnosis may be missed. Early initiation of empiric therapy is imperative to minimize the degree of irreversible injury and delay dialysis initiation. The development of sclerotic fibrotic lesions in renal biopsy may predict treatment response. ANCA negative PICGN is a rare diagnosis; this case highlights why it is important to keep this diagnosis in the differential and why novel treatment options are needed.

Collapsing Focal Segmental Glomerulosclerosis Associated with Parvovirus B19 Infection

Mandeep K. Babbra, Paul S. Bhamrah, Phani P. Morisetti. Ochsner-LSU Health Sciences Center, Shreveport, LA.

Introduction: Focal segmental glomerulosclerosis (FSGS) can be subdivided based upon its histologic classification. The collapsing subtype of FSGS is not only of the rarer forms of FSGS, but also carries the worst prognosis. We present a case of collapsing FSGS secondary to Parvovirus B19 infection in a patient with a relatively unremarkable past medical history.
Case Description: A 32-year-old female with prior history of gestational hypertension presented to our hospital in her third trimester with a three-day history of bilateral lower extremity edema and periorbital swelling. On exam, profound periorbital edema and 2+ pitting edema up to the knees bilaterally was noted. Labs were consistent with a creatinine level of 5.0 mg/dL up from her baseline of 0.5 mg/dL three months prior. Urinalysis and random urine testing confirmed proteinuria of almost 19 grams per day. Renal ultrasound was obtained showing normal sized kidneys with increased echogenicity. Kidney biopsy was obtained and results were consistent with collapsing FSGS. Secondary workup for etiology of FSGS came back positive for Parvovirus B19 infection. Along with diuresis, decision was made to start IVIG kidney protection therapy. Initially, patient had improvement in kidney function post treatment and patient was followed up in clinic. However, required hemodialysis for one month.

Discussion: FSGS is commonly associated with nephrotic syndrome and stems from podocyte abnormalities. Podocyte detachment and death lead to segmental sclerosis, which is the hallmark pathophysiology of FSGS. Kidney biopsy is used to diagnose FSGS and characterized by the presence of sclerosis of at least one glomerulus on histologic examination. Histologically there are five classifications of FSGS with collapsing carrying the worst prognosis. Treatment is typically aimed at controlling proteinuria, edema, and cholesterol. In our patient with Parvovirus B19 induced FSGS, we used IVIG with prednisone therapy but no improvement. Further research is needed to find treatments for Parvovirus B19 induced FSGS for better outcome.

Case 1: A 49-year-old man presented with 4-5 days of fevers, chills, nausea, vomiting and diarrhea. Labs revealed mild thrombocytopenia, proteinuria, microscopic hematuria and a low C3 level. Blood cultures revealed Streptococcus pyogenes. His hospital course was marked by rapidly progressive pancytopenia and hemodialysis-requiring acute renal failure. He received a single dose of ecilizumab empirically due to concern for atypical HUS, but platelet counts improved too rapidly.
to be consistent with eculizumab benefit. Kidney biopsy revealed acute tubular injury with PMN and EM did not have detectable monosocial serum protein. Like other reported cases, he responded well to a bortezomib based regimen.

**PUB151**

A Challenging Case of Renal-Limited Vasculitis

Moein Ahmed, Bashar Ramirez, Eric Magliulo, Dongpo M. Salas, Jocelyn A. Taylor, Khalid Bashir. Creighton University School of Medicine, Omaha, NE.

**Introduction:** Anti-neutrophil cytoplasmatic autoantibody (ANCA)-Associated Vasculitis (AAV) is an autoimmune disease that causes inflammation of blood vessels and has a wide spectrum of clinical presentation. It can present as multisystem or renal-limited disease. The typical renal presentations that of a rapidly progressive glomerulonephritis (RPGN). We present an interesting case of renal-limited vasculitis with atypical features.

**Case Description:** A 76 year old male with a past medical history of Hypertension (treated with hydrochlorizine) and CKD Stage 3 presented with weakness and shortness of breath for about two weeks. Physical exam and vitals were unremarkable. Laboratory workup showed elevated AKI with creatinine of 6.5 mg/dl. Urinalysis revealed microscopcic hematuria and proteinuria (urine protein/creatinine ratio of 0.9). Renal ultrasound was unremarkable. Serologic workup including ANA, C3, C4, anti-GBM Ab, HBsAg, HBsAb and HBeAb was unremarkable. However, p-ANCA titer was high (1:160). He was treated with IV fluids. Interestingly, he continued to have good urine output as well as improvement in serum creatinine to 4.8 mg/dl and was discharged from the hospital.

Follow-up renal function panel in two weeks showed worsening serum creatinine of 6.8 mg/dl. The patient was readmitted to the hospital. Repeat serologic workup revealed p-ANCA, titers of 1:320 and elevated MPO IgG of 78 U/mL. Renal biopsy revealed pauci-immune glomerulonephritis. Steroids and rituximab were initiated as treatment. Due to worsening kidney function, patient was started on hemodialysis. He remained dialysis dependent with no significant renal recovery. Given atypical features of disease presentation, hydrochlorizine was considered to be an etiologic agent hence, and was discontinued.

**Discussion:** We present a case of renal-limited vasculitis with atypical features making the diagnosis very challenging. Firstly, the patient remained normoligic throughout the first hospital course. Secondly, his serum creatinine improved with supportive treatment leading to his discharge with presumptive diagnosis of ATN. In summary, ANCA associated GN may present with nonoliguria as well as waxing and waning renal function. Atypical features of AAV should raise concern for drug-induced etiology.

**PUB182**

Collapsing Focal and Segmental Glomerulosclerosis with Thrombotic Microangiopathy Found on Renal Biopsy in a Patient Receiving Intravitreal Aflibercept for Age-Related Macular Degeneration

Ramy M. Hanna,1 Gautam M. Phadke,2 Kenar D. Jhaveri,3 Ira Kurtz,4 Kanytar Kalantar-Zadeh.1 UC Irvine, University of California Irvine, Orange, CA.1 University of California Los Angeles, Los Angeles, CA. 2Northwell Health, Great Neck, NY. 3University of North Dakota, Columbus, OH.

**Introduction:** Intravitreal Vascular Endothelial Growth Factor (VEGF) Receptor blocker has been used for a variety of retinal pathologies. These include age related macular degeneration (AMD), diabetic macular edema (DME), and central retinal vein obstruction (CRVO). Reports of absorption of intravitreal agents into systemic circulation have increased in number, and confirmation of depletion of VEGF has been confirmed. Increasingly there are studies and case reports showing worsening hypertension, proteinuria, renal dysfunction, and glomerular disease. The pathognomonic findings of systemic VEGF blockade, thrombotic microangiopathies (TMA) are also being increasingly reported. One variant of TMA that has been described is collapsing focal and segmental glomerulosclerosis (cFSGS). cFSGS has been postulated to occur due to TMA induced chronic glomerular hypoxia. We present the third reported case of cFSGS in the setting of intravitreal VEGF blockade, a chronic TMA component was crucially found on biopsy.

**Case Description:** This patient is a 74-year-old non-diabetic male receiving aflibercept for AMD. Of the two prior cases of cFSGS in setting of VEGF blockade, one had AMD and the other had DME.

**Discussion:** This case solidifies the finding of cFSGS and its association with chronic TMA as a lesion that may be frequently encountered in patients receiving intravitreal VEGF inhibitors.

A Case of IgA Vasculitis in Liver Cirrhosis

Javesh B. Patel, Swe Zin Mar Winhtutuo, Dainelle G. Holanda, Lama A. Noureddine. University of Iowa Hospitals and Clinics, Iowa City, IA.

Introduction: IgA vasculitis (previously termed Henoch-Schönlein purpura) is a systemic immune-complex mediated condition characterized by predominant IgA1 deposition in microvessels. We present a case of biopsy-proven IgA vasculitis involving skin and kidney in a patient with known liver cirrhosis.

Case Description: A 71-year-old man with liver cirrhosis due to chronic ETOH use presented to ER with an 1-month history of progressive rash and pedal edema. He denied arthralgias, melena, hematemesis, abdominal pain, or fever. Diffuse, erythematous, palpable, non-pruritic petechial lesions were noticed on bilateral thighs, arms, and anterior abdominal wall with few lesions coalescing to purpura. Laboratory evaluation revealed an elevated creatinine at 1.7 mg/dL. Urinalysis showed dysmorphic erythrocytes, leukocytes, and proteinuria. ANA was positive (1:320), C3 slightly low with normal C4, Cryoglobulin, RA factor, SPEP, ANCA, anti-dsDNA, HBsAg, antibodies to HCV, HCV, rickettsia, and syphilis were negative. Peritoneal fluid culture was sterile. Kidney biopsy revealed dense perivascular neutrophilic infiltration with fibrin deposition and erythrocyte extravasation consistent with leukocytoclastic vasculitis. He was diagnosed with IgA vasculitis and treated with pulse IV steroids followed by oral taper along with monthly IV cyclophosphamide infusions. Petechial lesions improved markedly, but renal function was unchanged at 4-month follow-up. Unfortunately, the patient died 5 months after initial presentation due to complications of underlying liver disease and secondary infection.

Discussion: IgA vasculitis, more commonly observed among children than adults, manifests clinically as palpable, blanching purpura, arthritis, intussusception, and kidney injury. Adults commonly develop ESRD in one-third of cases. Similar to crescentic GN, children with IgA vasculitis are at risk of immune complex formation and deposition.

A Remission Case with Obsolete IgA Nephropathy in Aspirin Plus Eicosapentaenoic Acid

Shinichiro Koga, Section for Nephrology and Hypertension, Department of Medicine, Tokyo Metropolitan Police Hospital, Tokyo 1686541, Japan.

Introduction: In case of evading immunosuppression therapy to IgA nephropathy, ACEI, ARB, or both has statistically improved renal prognosis evaluated in urine protein (UP). Eicosapentaenoic acid (EPA) on IgA nephropathy has documented alternative effects and side effects to steroids.1,2

Case Description: A 68-year-old woman was referred to nephrologist with complaint of bilateral leg edema accompanied with proteinuria and microscopic hematuria. She had been diagnosed on diabetes mellitus with hyper-tension for 2 years. She had already pointed out that urine abnormality at 2 years ago. Her BP was 177/93mmHg, body weight 61 Kg, O2B(3+), urine RBC 10-30/HF, URF 2.2g/day, serum Cr 0.63mg/dL, Hba1c 7.6%, IgA 331mg/dl, and IgG 1,059mg/dl, on 20mg valsartan. After 4 years, she required emergent hemodialysis (HD). Those authors speculated that ASA superimposed on EPA to reduce UP.5 Daily salt intake was restricted to 6g. After 4 years, T/Cr/0B, urine RBC has normalized(Table).

Discussion: This case is diagnosed as chronic IgA nephropathy; this pathology might illustrate why her UP had not reduced with valsartan. On the other hand, acute lesion such as necrotized, or cellular or fibrocellular crescents was not detected. This finding gave us discussion on alternative medication which could evacuate from steroids and immunosuppressants. In addition to EPA 900-1,800mg per day on ARB, EPA on ASAs5 has reported to significantly reduce UP. Those authors speculated that ASA superimposed physical beneficial effect on antiplatelet agent in the case of long-term chronic IgA nephropathy has been normalized urinedistick findings by means of ASA plus
hypothyroidism and BMI 54 kg/m^2, sought care for 3 months of dyspnea, bilateral leg edema, and severe shortness of breath. She was admitted to the hospital on dialysis.

Discussion: TMA can occur with autoimmune diseases. Although the mechanism remains unclear, there is evidence of complement activation leading to injury. For these cases, there is no evidence that treating TMA itself changes outcomes. It is important to distinguish between the causes of TMA as treatment differs between primary and secondary. There are current ongoing trials of the use of eculizumab in lupus nephritis, to distinguish between the causes of TMA as treatment differs between primary and secondary. There are current ongoing trials of the use of eculizumab in lupus nephritis, however current guidelines recommend induction treatment using cyclophosphamide and steroids. The cause of her heart failure remained unclear, thought was secondary to NS which has been recognized since the 1970s.

Given the concern for thrombotic thrombocytopenic purpura (TTP), an ADAMST13 level was drawn and plasmapheresis was initiated. Despite therapy, her kidney function worsened. As there were no overt causes of TMA, such as anti-phospholipid syndrome, infection, malignancy, or drugs, we strongly suspected autoIM and administered one dose of eculizumab. On hospital day 4, a kidney biopsy was performed which revealed an immune complex deposition driven glomerulonephritis with significant TMA as well as membranoproliferative changes consistent with class IV/V lupus nephritis. Eculizumab was discontinued and she was started on cyclophosphamide and pulse dose steroids. Her kidney function continued to decline and she eventually required hemodialysis. Serial echocardiograms revealed improvement in cardiac function and she was discharged from the hospital on dialysis.

Introduction: TMA can occur with autoimmune diseases. Although the mechanism remains unclear, there is evidence of complement activation leading to injury. For these cases, there is no evidence that treating TMA itself changes outcomes. It is important to distinguish between the causes of TMA as treatment differs between primary and secondary. There are current ongoing trials of the use of eculizumab in lupus nephritis, however current guidelines recommend induction treatment using cyclophosphamide and steroids. The cause of her heart failure remained unclear, thought was secondary to microvascular coronary damage from SLE.

Background: There is a lack of published evidence on patient perspectives in IgAN; a rare condition that can progress to end stage renal disease (ESRD). The objective of this study was to understand the patient journey, disease perceptions and burden of disease from the patients’ perspective.

Methods: This qualitative study was conducted after review board approval through a moderated online bulletin board platform and by telephone interviews, to allow comprehensive answering of pre-defined questions. Participants were recruited via physician referral and were screened to ensure eligibility and willingness to participate. Analysis was conducted using a combination of various qualitative analytical tools.

Results: Eight participants with a confirmed diagnosis of IgAN from North America and Europe, aged 29–58 years participated. Diagnosis was often incidental as symptoms were underestimated or unnoticed. Participants were overwhelmed to learn they were diagnosed with a chronic disease and many did not understand the seriousness of the outcomes associated with the same. Post diagnosis, participants were referred to a nutritionist to discuss diet changes and received blood pressure medications. Some participants also received steroids and immunosuppressants. Frequency of monitoring visits varied and created anxiety among participants. Lack of standard procedures for early screening and diagnosis along with the absence of adequate information in patient friendly language and counselling were some of their needs. Additionally, participants expressed the need for a support mechanism with similar peers to learn to live with the disease and to counteract feelings of being alone.

Conclusions: This study provides insights into how differently IgAN patients perceive and live with their disease. The insights obtained can be used to inform drug development and include what matters most to patients. Finally, this study highlights that a comprehensive education program for patients and caregivers is needed.

Retinal Drusen in Antibody-Mediated and Pauci-Immune Glomerulonephritis

Philip A. Harraka,1 Heather G. Mack,2,3 Deb J. Colville,1 David Barin,1 David Langford,1 Timothy J. Pianta,1 Judith A. Savige,1 The University of Melbourne Department of Medicine, Northern Health, Melbourne, VIC, Australia; 2The University of Melbourne Department of Surgery (Ophthalmology), Melbourne, VIC, Australia; 3Department of Ophthalmology, Melbourne Health, Melbourne, VIC, Australia.

Background: Membranous and anti-glomerular basement membrane (GBM) glomerulonephritis are autoantibody-mediated diseases, where the antigens (PLA2R, THSS4, collagen IV α3 respectively) are also expressed in the retina. Drusen are retinal deposits caused by complement activation and lipid debris in Bruch’s membrane. Drusen have been described in one individual with membranous nephropathy and linear IgG deposits in Bruch’s membrane of another with anti-GBM disease. In contrast, pauci-immune disease does not produce glomerular immune deposits. This study examined individuals with antibody-mediated or pauci-immune glomerulonephritis to determine how often drusen occurred in each group.

Methods: This was a cross-sectional observational case-series of individuals with antibody-mediated (n=15, membranous n=9, anti-GBM disease n=6) or pauci-immune (n=16, granulomatosis with polyangiitis n=7, microscopic polyangiitis n=7, eosinophilic granulomatosis with polyangiitis n=2) glomerulonephritis recruited from a general and an Australian tertiary-care hospital. Two-field colour fundus images were obtained with a non-mydriatic camera (CANON, Japan). Images were coded and assessed for drusen count, location and size by two trained graders using the Wisconsin Age-Related Maculopathy Grading Grid. Central drusen counts a 10 were considered abnormal.

Results: Four (27%) individuals with antibody-mediated disease (membranous n=2, anti-GBM disease n=2) but only one (6%) with a pauci-immune vasculitis had ≥10 central drusen. Gender, mean age and disease duration were not different between the two groups.

Conclusions: These results suggest that retinal disease occurs together with glomerular disease when the target antigen is found in both locations. Retinal drusen may be a useful biomarker for some forms of glomerulonephritis, and drusen pathogenesis may explain in part the pathogenesis of glomerular immune deposits. In addition, treatments that target retinal drusen may also be useful in antibody-mediated glomerulonephritis.

The Masquerading Diagnosis of Secondary Thrombotic Microangiopathy

Janany I. Sabescumar, Justin Komisarof, David Levy, Bruce Goldman. University of Rochester Medical Center, Rochester, NY.

Introduction: Thrombotic microangiopathy (TMA) is an umbrella term defined by hemolytic anemia, thrombocytopenia and end organ damage secondary to microvascular thrombi. TMA is subclassified as either inherited or acquired (i.e lupus). We report a case of secondary TMA initially masquerading as atypical HUS.

Case Description: A 27 year old female with no significant medical history presented with shortness of breath for one month. She was noted to have acute kidney injury and new onset congestive heart failure. An echocardiogram revealed a dilated left ventricle and a severely reduced ejection fraction (10%). Her admission labs were notable for elevated creatinine of 7.4 mg/dL and antibodies on peripheral blood smear. Given the concern for thrombotic thrombocytopenic purpura (TTP), an ADAMST13 level was drawn and plasmapheresis was initiated. Despite therapy, her kidney function worsened. As there were no overt causes of TMA, such as anti-phospholipid syndrome, infection, malignancy, or drugs, we strongly suspected autoIM and administered one dose of eculizumab. On hospital day 4, a kidney biopsy was performed which revealed an immune complex deposition driven glomerulonephritis with significant TMA as well as membranoproliferative changes consistent with class IV/V lupus nephritis. Eculizumab was discontinued and she was started on cyclophosphamide and pulse dose steroids. Her kidney function continued to decline and she eventually required hemodialysis. Serial echocardiograms revealed improvement in cardiac function and she was discharged from the hospital on dialysis.

Discussion: TMA can occur with autoimmune diseases. Although the mechanism remains unclear, there is evidence of complement activation leading to injury. For these cases, there is no evidence that treating TMA itself changes outcomes. It is important to distinguish between the causes of TMA as treatment differs between primary and secondary. There are current ongoing trials of the use of eculizumab in lupus nephritis, however current guidelines recommend induction treatment using cyclophosphamide and steroids. The cause of her heart failure remained unclear, thought was secondary to microvascular coronary damage from SLE.

Membranous Nephropathy and Autoimmune Thyroid Disease

Brandon Bates,1 Maria T. Story,1 Kathleen Robinson,2 Jeydith Gutierrez,3 Roy J. and Lucille A. Carver College of Medicine, Iowa City, IA; 1The University of Iowa Hospitals and Clinics, Iowa City, IA.

Introduction: The relationship between thyroid dysfunction and nephrotic syndrome (NS) has been recognized since the 1970s, yet the mechanisms connecting them are poorly understood. Here we present a patient with profound hypothyroidism and idiopathic membranous nephropathy (iMN).

Case Description: 54-year-old Caucasian female with a 32-year history of hypothyroidism and BMI 54 kg/m^2, sought care for 3 months of dyspnea, bilateral leg edema and a 30 kg weight gain. She was admitted to her local hospital and had workup for anasarca. Physical exam: Vitals: BP 145/71 mmHg, pulse: 86 bpm and SpO2 of 98%. Thyroid was normal size, morbid obesity and anasarca noted. Labs: creatinine 1.2 mg/dL, albumin 0.9 g/dL, and a thyroid stimulating hormone (TSH) 97.55 mU/L. Urine protein/creatinine ratio of 12.6 g/g. A kidney biopsy demonstrated MN with phospholipase A2 receptor (PLA2R) positive antibody staining. Supportive treatment for iMN was initiated and she sought a second opinion at our institution. Additional testing revealed elevated anti-thyroid peroxidase antibodies (TPO), consistent with Hashimoto’s Thyroiditis (HT). Treatment with the modified Ponticelli protocol and 200 mcg of levothyroxine daily was initiated.

Discussion: An association between HT and iMN has been described, but the underlying mechanism connecting these conditions remains poorly understood. Hypothyroidism can increase serum creatinine, decreased glomerular filtration rate and higher risk of chronic kidney disease. Similarly, nephrotic patients with thyroid dysfunction have increased proteinuria and lower albumin levels compared to those without thyroid disease. In addition, loss of TSH and thyroid binding globulins due to hypothyroidism can cause or exacerbate hypothyroidism. Interestingly, a recent study reports the presence of elevated anti-PLA2R antibodies in patients with isolated HT, raising the question of an autoimmune phenomenon affecting both organs. Although we cannot definitively determine that the same autoimmune process was affecting both organs in our patient, it is an intriguing question based on new evidence. Certainly, her undergoing hypothyroidism was worsened by the development of NS. Nephrologists should consider screening for hypothyroidism when diagnosing NS, as treatment has the potential to significantly improve patient symptoms.
Long-Term Therapeutic Plasma Exchange (TPE) in Management of Focal Segmental Glomerulosclerosis (FSGS) in Native Kidneys

Northwestern University Feinberg School of Medicine, Chicago, IL.

Introduction: Circulating permeability factors (CPF) may be involved in the pathogenesis of some forms of FSGS that are non-responsive to intensified immunosuppression and exhibit a rapidly progressive course. The role of CPF-mediated FSGS is indicated by the post-transplant recurrence of proteinuria and its response to TPE. Moreover, experimental animals injected with plasma from patients with FSGS can develop proteinuria. While TPE in patients with post-transplant recurrence can prevent graft failure, evidence to support its use in resistant FSGS in native kidneys is lacking.

Methods: A 62-year-old Caucasian female presented with anasarca and nephrotic-range proteinuria (5.0 g/day) in March 2018. Kidney biopsy revealed minimal change disease. The first 14 months of her course were complicated by steroid resistance, side effects of high-dose steroids and calcineurin inhibitors (CNI), recurrent AKI, CNI/ ARB-induced hypertension, and worsening of proteinuria with CNI reduction. She received 4 doses of rituximab (375 mg/m²) during that period. Genetic testing for the steroid-resistant nephrotic syndrome was negative. In June 2019, a trial of 10 TPE sessions resulted in a significant improvement in proteinuria (UPCR= 1.8-2.0), which worsened over the following 4 months after discontinuation of TPE (UPCR= 4.0). Repeat kidney biopsy revealed FSGS. Given the previous response to TPE, a central-venous port was placed for long-term TPE in December 2019. The patient received TPE twice a week for the first 6 weeks. With improved proteinuria, TPE was tapered to twice a month with maintenance removal (UPCR= 1.5) for the last 5 months. The patient is on ARB, on a minimal dose of CNI. The symptoms associated with nephrotic state and the side-effects of multiple drugs have resolved.

Discussion: This case highlights the dilemma of therapeutic decision-making in patients with resistant FSGS. Long-Term TPE successfully maintained symptom-free sustained PR and stabilized renal function. TPE has become the preferred choice of our patient to avoid the toxic effects of long-term intensive immunosuppression. More studies are required to study the efficacy and safety of TPE in patients with native kidney FSGS resistant to therapy.

Association Between Anti-GBM Titers and Kidney Inflammation with a New Activity Score

Northwestern University Feinberg School of Medicine, Chicago, IL.

Introduction: Anti-glomerular basement membrane (anti-GBM) disease is a rare glomerulopathy characterized by rapidly progressive loss of kidney function, leading to end stage kidney disease in a significant amount of cases. The main objective of our study is to determine whether anti-GBM titer correlate with rate of activity in renal biopsy and long-term kidney survival in patients with anti-GBM, hence identifying patients who would potentially benefit from more intensive treatments.

Methods: A retrospective analysis was performed on anti-GBM cases from 2007 to 2018 with both positive biopsy and serology. Anti-GBM levels and kidney function at admission, discharge, treatment, and kidney biopsy findings were collected. All biopsies were reevaluated by a single, blinded pathologist. Based on a recent study by Van Daalen et al, we developed an activity score. The score was divided in a glomerular and interstitial section. In the glomerular section, a sclerotic pattern (>50% of glomeruli) was given 0 pts in activity and 3 in chronicity, a mixed pattern was given 1 pt in activity and chronicity, and a crescentic pattern (>50% with cellular crescents) was given 3 pts in activity and 0 in chronicity. In the interstitial section, the presence of fibrosis and atrophy was given between 0 and 3 pts in chronicity and the presence of tubulitis or interstitial infiltrate with neutrophils were given points in activity (0 to 3 respectively). Spearman correlation was performed between anti-GBM levels, our biopsy score, and kidney survival at follow-up.

Results: Twelve cases were identified, 9 were males, mean age was 54. Anti-GBM at admission ranged from 40 to 1517 mg/mL. Ten patients were treated with cyclophosphamide, 1 with rituximab plus cyclophosphamide and 1 with only rituximab. The median number of therapeutic plasma exchange sessions was 8 (range 6-12). High antibody titers correlated with greater activity on biopsy (r 0.6, p= 0.04) and lesser survival at follow-up (35 months) was 92%.

Conclusions: These results suggest that patients with higher titers have more acute inflammation, and therefore could benefit from more intensive treatment. It would be interesting to study this score in larger cohorts in order to produce more definitive conclusions.

Syntheticetase Syndrome and Nephrotic Syndrome

Noe Martinez murillo, Jorge J. Font, Jonathan Chavez, Joana G. Navarro gallardo, Jose A. Torres, Christian P. Flores.
Universidad de Guadalajara, Guadalajara, Mexico.

Introduction: The presence of anti-synactem syndrome and IgA nephropathy is unusual. Similar symptoms to other diseases that affect the connective tissue: Lupus, Rheumatoid Arthritis and others.

Case Description: A 39-year-old female with Acute Renal Failure of Unclear Etiology

Kalirina Sedaliu, Samuel Rednot. Montefiore Medical Center, Bronx, NY.

Introduction: Rapidly progressive glomerulonephritis, or RPGN, is a disorder of the kidney with accelerated loss of kidney function that manifests histologically by glomerular crescent formation. This rare entity may be caused by pauci-immune crescentic glomerulonephritis, which is strongly associated with antineutrophil cytoplasmic antibody (ANCA) vasculitis. Nevertheless, a small portion of patients lack ANCA. There is limited literature on the comparison of ANCA positive and ANCA negative patients. We present the case of a 39 year old female presenting with shortness of breath, hypoxic respiratory failure, acute renal failure. Her lack of ANCA rendered her disease entity mystifying and puzzled providers in terms of how to proceed with treatment.

Case Description: A 39-year-old Caucasian female was admitted to the hospital with a one day history of shortness of breath. Her admission was complicated by multiple progressive hypoxemia, hypotension, respiratory failure, warm and dry oral mucosa, and subcutaneous edema with venous extracorporeal membrane oxygenation. Labs showed acute kidney injury (AKI) with a serum creatinine of 3.70 mg/dL. Urinalysis demonstrated
large blood, 4–10 red blood cells, and proteinuria > 1000 mg/dL. Urine protein creatinine ratio was 3.895 mg/g. She developed bloody endotracheal tube secretions, warranting performance of bronchoscopy that was consistent with diffuse alveolar hemorrhage. Given that serological work up, including ANCA, returned unremarkable, the etiology of her renal failure was unclear. Her AKI became oliguric and she was initiated on continuous venovenous hemodialysis (CVVHD). Given the uncertainty regarding the etiology of her renal failure, and therefore how to proceed with treatment, despite her hemodynamic instability, renal biopsy was performed. Findings were consistent with segmental sclerosing pauci-immune glomerulonephritis with small cellular crescents.

Discussion: Studies on the characteristics of patients with ANCA negative pauci-immune GN, as well as prognosis, are vital, as up to 30% of patients with pauci-immune glomerulonephritis lack ANCA. Prompt recognition and appropriate treatment has proved essential to preservation of renal function. Additional literature regarding ANCA negative pauci-immune GN may ameliorate the need for renal biopsy in unstable patients, and may guide more timely treatment.

Bloody Tubules: Is It the Warfarin?  
Hira Younas,1 Jenny Bhatt,1 Muhammad H. Wadud,1 Emma Horton,3 Sumil Patel,1 Tauseef A. Sargurth.1  
1Franciscan Health Inc, Mishawaka, IN; 2Midwestern University - Downers Grove Campus, Downers Grove, IL.

Introduction: Acute kidney injury(AKI) with gross hematuria can have a myriad of urological and glomerular etiologies. Anticoagulation related nephropathy is one of them and has been known to cause AKI in the setting of warfarin use. This is a case of a patient with primary biliary cirrhosis(PBC) on warfarin that presented with persistent hematuria and AKI requiring hemodialysis. Her renal biopsy revealed warfarin nephrotoxicity with secondary IgA nephropathy from liver disease.

Case Description: 72 year old Hispanic female with history of PBC and osteoarthritis underwent a right knee arthroplasty and was started on warfarin for DVT prophylaxis by orthopedics for a month. She subsequently developed persistent gross hematuria and underwent a cystoscopy that was unremarkable. Labs showed creatinine 5.5mg/dl, UPCR: 581.1g/g and INR: 1.0 as the patient by then had stopped taking warfarin. Serologies were all negative and a renal biopsy was performed that revealed acute tubular necrosis with numerous intratubular red blood cell casts suggestive of warfarin nephrotoxicity. The biopsy also showed mesangial, subendothelial and capillary wall IgA deposits likely secondary to her underlying liver disease(PBC).

Discussion: Previously known as warfarin induced nephropathy; this renal etiology is now recognized as anticoagulation related nephropathy as it is seen with other anticoagulants as well. Characteristic histology shows tubular injury and occlusive red blood cell casts that lead to ischemia and hemorrhage into the tubules and bowmans capsule. Risk factors include supratherapeutic INR and underlying chronic kidney disease. Our case report is unique as her undiagnosed secondary IgA nephropathy from primary biliary cirrhosis precipitated the warfarin nephrotoxicity. The patient is currently stable on bi-weekly hemadialysis.

PUB167

Staphylococcal Infection-Associated Glomerulonephritis and Nephrotic Syndrome in an Intravenous Drug User with Hepatitis C: A Challenging Clinical Scenario  
Ghanshay Das, Harris Mobeen, Syed H. Bukhari. State University of New York Upstate Medical University, Syracuse, NY.

Introduction: Renal disease in intravenous drug users, especially those with Hepatitis C, can present with challenging clinical scenarios and biopsy findings. We describe a case of a 46-year-old male who presented with shortness of breath, chest pain and acute kidney injury.

Case Description: A 46-year-old male with a history of Intravenous (IV) drug use and Hepatitis C presented with shortness of breath and chest pain. Patient was found to have Methylcellulose Resistant Staphylococcal bacteremia and tricuspid valve endocarditis. Physical examination was positive for bilateral leg edema and pain systolic murmur over left lateral sternal border. Initial serum creatinine was 1.54 mg/dl (baseline 0.3 1.9 mg/dl). Urine microscopic examination revealed proteinuria, hematuria and the sediment was consistent with isomorphic WBCs and RBCs with many granular casts. Renal US revealed right kidney 11.6 cm and left kidney 13.5 cm in maximum dimension with no hydronephrosis. All serology tests were negative except for a low C3 and positive complement C4. We tested negative MBG and PR3 levels. A percutaneous renal biopsy showed proliferative GN (diffuse proliferative GN) with focal MPGN pattern in few glomeruli and rare crescent (in one glomerulus), full house immunofluorescence (IF) with IgA co-dominance and both capillary wall and mesangial staining (IgA 3+, IgG1-2+, IgM 2+, C3 3+, C1q 1+ and lambda 3+) and small subepithelial (hump-like) and both small and large subendothelial deposits on ultramicroscopy. Final biopsy diagnosis was given as IgA-codominant staphylococcal infection-associated glomerulonephritis (SAGN). Patient was treated with eight weeks of IV antibiotics and underwent supportive hemodialysis during hospitalization. He was discharged home off hemodialysis and followed up in outpatient clinic for Chronic Kidney Disease stage IV.

Discussion: The presence of nephrotic syndrome in this patient presents a challenging scenario and MPGN secondary to hepatitis C may be considered a differential here although SAGN is a stronger contender based on clinical and biopsy findings and steroid-range proteinuria, though not common, has been described in SAGN and endocarditis-associated GN cases in variable percentages, ranging from 6-48%.

PUB168

Unmasking of Pancreatobiliary Carcinoma in a Patient with Fibrillary Glomerulonephritis  
Avneek Singh Sandhu,1 Harold J. Duarte,1 Natallia Maroz.1  
1Kettering Health Network, Dayton, OH; 2Wright State University, Dayton, OH.

Introduction: Fibrillary Glomerulonephritis (FGN) is a rare disease with known malignancy correlation. Cancer can be discovered simultaneously with the diagnosis of FGN or later in the course of the disease. As per our knowledge, this case is a first description of rapidly progressing pancreatobiliary carcinoma (PBC) associated with FGN.

Case Description: 49 y/o white woman presented to the nephrology office with proteinuria of 1.3 g/day and hematuria. She had a past medical history of smoking (>20 years) and hysterectomy for endometriosis. Serologic workup and urology evaluation were unrevealing. Kidney biopsy reported FGN with minimal interstitial scarring. Oncology referral was made to rule out hidden malignancy. She had an unremarkable CT scan of the chest and abdomen, PAP smear, mammogram, colonoscopy as well as normal chemical evaluation and ultrasound of thyroid. Patient quit smoking and had conservative management for the first 11 months. Introduction of ACE-I led to reduction in proteinuria of 0.6 g/day. Unfortunately, she had decline in creatinine from 0.6 to 1.0 mg/dl, and worsening of proteinuria to 1.3 g/day associated with edema and weight gain. Therapy with Achatar® injections was initiated at the dose of 80 units thrice weekly. Patient had rapid improvement in proteinuria and swelling, and after 12 months of therapy, Achatar® dose was reduced to 40 units twice weekly. Creatinine remained stable. 24 months after the initial presentation and 13 months from Achatar® therapy initiation, she developed acute pancreatitis. Imaging studies showed pancreatic pseudocyst. Unfortunately, her pain did not improve. During the second hospitalization, a month later, HDNA scan and FGS performed without revealing results. She was managed with pain medications and Achatar® therapy was uninterrupted. Patient underwent MRCP 3 months after the initial presentation, which showed pancreatic mass and multiple liver lesions. Biopsy of the liver lesions demonstrated poorly differentiated adenocarcinoma. Palliative chemotherapeutic PBC was discussed but was not tolerated by the patient. Patient deceased 4 months after the development of pain symptoms.

Discussion: Consideration of a hidden malignancy is a part of FGN management. PBC is a devastating cancer with dismal survival. Conducting an aggressive and repetitive work up for malignancy in patients with a new diagnosis of FGN may improve outcomes.

PUB169

A Case of Proliferative Glomerulonephritis with Monoclonal IgG Deposits Following Influenza Infection  
Merve Postalcioglu.1,2 1Kent Hospital, Warwick, RI; 2Brown University Department of Medicine, Providence, RI.

Introduction: Proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMID) is a relatively new entity. It is a form of monoclonal gammopathy with renal significance. Our patient is presented with this rare disease triggered by very common illness, influenza infection.

Case Description: A 1-year-old female with a past medical history of chronic kidney disease stage IIIIB, and type 2 diabetes mellitus presented to the hospital with gross hematuria for 1 week and right-sided flank pain started within last 24 hours. The patient was diagnosed with influenza A infection 10-days before her hospital admission and treated with Oseltamivir. She was started on ciprofloxacin after 1 week from presentation, which showed pancreatic mass and multiple liver lesions. Biopsy of the liver lesions demonstrated poorly differentiated adenocarcinoma. Palliative chemotherapeutic PBC was discussed but was not tolerated by the patient. Patient deceased 4 months after the development of pain symptoms.

Discussion: Consideration of a hidden malignancy is a part of FGN management. PBC is a devastating cancer with dismal survival. Conducting an aggressive and repetitive work up for malignancy in patients with a new diagnosis of FGN may improve outcomes.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
urolithiasis or hydronephrosis. Urine albumin/creatinine ratio was 470.8 mg/g in a spot urine sample which was 104 mg/g before admission. Serum C3 level was normal at 134 mg/dl (reference: 88-201), anti-streptolysin O antibody (ab), c-ANCA (antineutrophil cytoplasmic antibody), p-ANCA, anti-glomerular basement membrane ab were negative. Her immunoglobulin G level elevated to 1,740 mg/dl (reference 649-1618), kappa level elevated to 1,470 mg/dl (reference 269-638), and lambda level elevated to 774 mg/dl (reference 269-638). Serum electrophoresis did not show M-spike and serum immunofixation test was negative for monoclonal gammopathy. Kidney biopsy was recommended by nephrology which revealed endocapillary-proliferative glomerulonephritis with linear glomerular capillary wall staining for IgG1-kappa. She did not receive any immunosuppressive treatment as her kidney function returned to baseline without intervention. Discussion: PGNMID is a rare form of glomerulonephritis which can mimic immune-complex glomerulonephritis especially in a patient with an infection. Therefore, considering renal biopsy with light-chain and IgG staining is crucial for proper diagnosis.

PUB170

Dual Positive Myeloperoxidase and Proteinase 3 Antibodies and Class V Lupus Nephritis in an Elderly Female with Cocaine Use

Anirudh R. Gone,1 Molly Fisher,2 Daniel Schwartz,2 Mary J. Dominguez,2 James M. Pullman,2 Montefiore Medical Center, and Mount Sinai Medical Center, Bronx, NY; 1Montefiore Medical Center, Bronx, NY.

Introduction: Cocaine contaminated with levamisole is a reported cause of dual positive ANCA vasculitis and rarely has been associated with lupus nephritis. We present a case of an elderly female who presented with unexplained acute kidney injury (AKI) and chronic cocaine use and was found to have dual positive ANCA and Class V lupus nephritis.

Case Description: A 70-year-old female with a history of hypertension, coronary artery disease, atrial fibrillation on warfarin, pre-diabetes, remote history of breast cancer status post lumpectomy, baseline serum creatinine (SCr) 0.8 mg/dl was sent to the emergency room after being found to have a SCr 6.0 mg/dl on outpatient labs. Urgent renal biopsy was significant for glomerulonephritis and microscopic hematuria. Urine protein: creatinine ratio was 2.7 g/g. Workup revealed positive anti-nuclear antibody titer of >1:320, double-stranded DNA antibody titer 270 IU, myeloperoxidase (MPO) antibody of 5.1 and Proteinase 3 (PR3) antibody of 1.0. Serum complement 3 was 149 mg/dl and complement 4 was 31 mg/dL. She had no clinical symptoms of systemic erythematous lupus (SLE) or systemic vasculitis. Urine toxicology was positive for cocaine. She was pulsed with steroids due to concern for a rapidly progressing glomerulonephritis and then underwent kidney biopsy, which demonstrated full house immunofluorescence with IgG predominant subepithelial deposits, few mesangial deposits and mild acute tubular injury. No proliferative glomerular lesions or crescents were observed. She was initiated on mycophenolate mofetil with improvement in Scr to 3.8 mg/dl and proteinuria to 1.2 g/g.

Discussion: Dual positive (MPO and PR3) ANCs have been reported in patients with lupus nephritis, but rarely in the setting of class V lupus nephritis. Although our patient’s history of cocaine use may explain positive MPO and PR3 antibodies, she did not have the pauci-immune crescentic glomerulonephritis often seen with ANCA, but rather an immune complex, non-inflammatory glomerulopathy. Given her unusual manifestation of late-onset lupus nephritis, we hypothesized that chronic cocaine use may have led to an altered immune response and autoimmune disease, as rarely described for SLE in young men with chronic cocaine use.

PUB171

Collapsing Glomerulopathy due to Hemophagocytic Lymphohistiocytosis: A Case Report

Introduction: Collapsing glomerulopathy (cFSGS) is most commonly seen in association with Human Immunodeficiency Virus infection (HIV) and can also occur in association with viral and non-viral infections, autoimmune diseases, malignancy and drug exposure. Patients typically present with rapidly worsening renal function and nephrotic syndrome. We report a case of cFSGS due to Hemophagocytic lymphohistiocytosis (HLH).

Case Description: A 41-year-old man with acute myeloid leukemia and allogenic hematopoetic stem cell transplant with graft-versus-host disease on Ruxolitinib was admitted for hypervolemia, respiratory failure, rapidly rising creatinine and nephrotic syndrome. We report a case of cFSGS complicating HLH is rare. Excessive immune activation with release of pro-inflammatory cytokines targeting the podocytes is hypothesized to cause cFSGS in HLH. Renal prognosis appears to be poor despite therapy and most patients remain dialysis dependent. HLH has been reported post stem cell transplant and should be considered in the differential diagnosis of cFSGS.

PUB172

Epidemiology of Glomerular Diseases in Minia Governorate: A 5-Year Single-Center Experience

Waleed Hassan,1 Hisham Mostafa.2 1The University of Tennessee Health Science Center College of Medicine, Memphis, TN; 2Minia Nephrology and Urology University Hospital, Minia, Egypt.

Background: Studying the pattern of glomerular diseases gives an important insights about factors associated with its development or progression.

Methods: This is a retrospective study includes 312 patients underwent kidney biopsy at Minia university hospital between 2014 to 2019. The aim of this study was to highlight the histopathological patterns of glomerular disease in Minia governorate.

Results: A total of 312 biopsy-proven glomerular diseases were reported. The mean age was 31.65±13.77 years, 61.5% were females Table (1). The most common clinical presentation was nephrotic Syndrome (39.4%). Lupus Nephritis contributed 27.9%, followed by Membranoproliferative glomerulonephritis (15.4%) Focal segmental glomerulosclerosis (13.5%), IgA nephropathy (11.5%), amyloidosis (7.7%), Crescentic glomerulonephritis (5.8%), Thrombotic microangiopathy (4.8%), Vascular nephropathies (3.8%), Minimal change disease (3.8%), Membranous nephropathy (2.9%), Postinfectious glomerulonephritis (1.9%) and Diabetic nephropathy (0.96%). Table (2). Eighteen patients (62.1%) of lupus nephritis belonged to ISN/RPS class IV, seven patients belonged to class III, and four patients belonged to class V.

Conclusions: Histopathological patterns of glomerular disease may indicate regional and ethnic variations that could point towards genetic or environmental influence. This might help in effectively managing this disease by identifying the predisposing factors.

A for Amyloidosis

Muhammad Y. Jan, Simit Doshi. Indiana University School of Medicine, Indianapolis, IN.

Introduction: We present a case of osteomyelitis related amyloidosis presenting as acute injury (AKI) with nephrotic range proteinuria.

Case Description: A 62 years old male with type 2 diabetes mellitus and hepatitis C (treated) was admitted with complaints of bilateral foot pain of 3 weeks duration leading to inability to ambulate. Work up revealed pedal wounds with drainage and imaging was consistent with osteomyelitis. Blood cultures were positive for methicillin sensitive staphylococcus aureus (MSSA) which was treated with IV antibiotics. Baseline serum creatinine (Scr) was 2.0 mg/dL and Scr on admission was 3.85 mg/dL, which was thought to be from acute tubular necrosis related to sepsis from osteomyelitis. Work up of AKI revealed nephrotic range proteinuria of 4.7g, hematuria without dysmorphic red blood cells and monoclonal kappa IgM spike on serum protein electrophoresis. Kappa/Lambda ratio was 3.86:1. Total protein was 8.5 g/dl with serum albumin of 1.9 g/dl. Hemoglobin A1c level was 4.6%. Left below knee amputation was performed and patient was transitioned to 4 weeks of oral cephalexin. Scr on discharge was 2.9. On clinic follow up, repeat labs showed non-resolution of AKI as well as nephrotic range proteinuria of 6.8g and a kidney biopsy was obtained. His wound was healing slowly and antibiotic duration was extended. Kidney biopsy showed no glomerular obsolescence or hypercellularity. Mesangial and glomerular capillary walls showed Congo Red Positive deposits. Thickening of glomeruli was noted with segmental duplication. Tubular atrophy and interstitial fibrosis was 20%. Staining was positive for serum amyloid A (AA) in glomeruli, arterioles, and tubular basement membranes. Immunofluorescent staining was negative. Electron microscopy showed mesangial expansion with randomly arrayed extracellular fibrils with solid cores and a mean diameter of 9.8 nanometer.

Discussion: Patient completed extended oral antibiotic therapy for osteomyelitis with resolution of M spike on SPEP and improvement of creatinine to baseline. Deposition of serum amyloid A (SAA) protein, an acute phase reactant is a potential complication of chronic inflammatory conditions. Most commonly involved organ is the kidney presenting as nephrotic syndrome. Clinical evaluation for secondary amyloidosis is important in the setting of infection. Unusual causes for nephrotic syndrome includes less common causes even in presence of comorbidities such as diabetes and hepatitis C.

Factors Related to Clinical Efficacy of Corticosterone Combined with Tonsillectomy for IgA Nephropathy

Ryo Yamamoto, Yuta Kogure, Mai Aoyagi, Kaori Takayangi, Minoru Hatano, Takatsugu Iwashita, Hajime Hasagawa. Department of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan.

Background: IgA nephropathy (IgAN) is the most frequent primary glomerulonephritis in Japan. Treatment combining tonsillectomy with intermittent intravenous methyl prednisolone (PSL) and alternate-day oral PSL (TSP therapy) may be sometimes chosen, and results from multiple prospective multicentered studies have been reported for its clinical usefulness. However, the treatment selection criterion has not been cleared. We retrospectively analyzed the patients who underwent TSP therapy in our faculty, and investigated the factors associated with efficacy of this therapy.

Methods: Subjects are 63 patients with IgAN who underwent TSP therapy in our hospital from April 2012 to July 2019. Intravenous methyl PSL 500 mg/day was administered for 3 days in the first 2 weeks after tonsillectomy, followed by oral PSL 30 mg every other day. The protocol was repeated 3-times every 2 months, then PSL was tapered off. Treatment every 2 months was performed 6 months after initiation of the therapy. When urinary protein was 0.5 g/gCr or less or decreased by 50% or more, and the urine red blood cell count was less than 20 per microscopic field, the treatment was considered to be effective.

Results: The mean age of enrolled patients was 36.2 ± 13.5 years, at an onset age of 33.8 ± 11.7 years. The mean age at the start of TSP therapy was 37.4 ± 9.9 years. The mean age at the end of follow-up (mean ± standard deviation; 58.2 ± 13.5 years) was significantly higher than the onset age (p < 0.05). The mean duration of follow-up since the start of TSP therapy was 18.9 ± 11.2 years. The mean duration of follow-up since the start of TSP therapy among responders was 22.7 ± 13.0 years, whereas it was 15.8 ± 8.9 years among non-responders (p = 0.033). The median follow-up duration was 6 years (range: 6 months to 26.8 years) in responders and 4 months (range: 6 months to 12 years) in non-responders. Changes in proteinuria at baseline and at the end of follow-up (mean ± standard deviation) were not significantly different among responders and non-responders (p > 0.05).

Conclusions: Serum IgA levels may be a reference for predicting the efficacy of TSP therapy by ROC-analysis.

An Elusive Case of Renal Failure in a Patient with Atypical Hemolytic Uremic Syndrome

Frank A. Portugal, Ayasha Ahmed. Robert Wood Johnson University Hospital, New Brunswick, NJ.

Introduction: AHUS is microangiopathic hemolysis, thrombocytopenia, and AKI with normal ADAMTS13 and absence of STEC. It involves activation of complement via alternative pathway causing TMA with end-organ involvement. Causes can be complement regulation deficits, infections, and drugs. Here is a rare case of AHUS after a Ca difficile infection, requiring dialysis.

Case Description: 19-year-old man with OSA, ADHD, and obesity had a 3-week course of diarrhea and fever. Cr was 2.15, platelet 143, and tested + for C.diff and was on po vanco then flagyl. Given worsening symptoms, he went to the ER and Hb was 13.9, platelets 24, WBC 14.8, BUN 130 and Cr 8.4. He had low complements (C4 = 7.9, C3 46.2), few schistocytes on peripheral smear, mildly elevated LDH and high-normal haptoglobin. He began dialysis, plasmapheresis and had a renal biopsy. Imaging showed splenomegaly (15-20 cm) and lymphadenopathy (negative BM and lymph node biopsy). ADAM13 level was 50 and plasmapheresis was stopped. Further infections and autoimmune workup was negative. Renal biopsy showed a TMA process and C5b-9 staining was positive in the glomerulus and arteriolar vessels. Serum C5b-9 level was elevated (343). A genetics panel showed no variant associated with AHUS nor predisposition to poor response to eculizumab. He was discharged with eculizumab maintenance and dialysis. Recently, his labs improved with a Cr of 1.5 and platelets of 163.

Discussion: Here, typical features of hemolysis were missing, and diagnosis was made on renal biopsy with findings of TMA and + C5b-9 stain. Ongoing understanding of causes for AHUS include hereditary (complement and DOCK18 gene mutations) and acquired (infection, autoantibodies to complement, drug toxicity and autoimmune). Although genetic panel was negative, it cannot be ruled out as genetic mutations are only identified in 50-70% of cases. Shiga-toxin and pneumococcal-HUS are causes, but here we found rare C difficile-induced cause. Patient was successfully treated with eculizumab. Thus, AHUS is elusive and clinically challenging in diagnosis.
Sudden Explosive Onset of Collapsing FSGS in the Setting of Influenza: A Unusual Presentation

Amaresh R. Vanga, Varun Malhotra. Eastern Virginia Medical School, Norfolk, VA.

Introduction: Collapsing FSGS (Focal Segmental Glomerulosclerosis) is often seen in the setting of HIV, pamlidrome use, parvovirus infections. Here we present a case that was explosive in onset and was associated with influenza.

Case Description: Elderly African American male in his 60s presents with flu-like symptoms. His influenza swab was positive. His past medical history was significant for occasional cocaine use, hypertension, parathyroid adenoma, hypercalcemia, prostate cancer. His vitals revealed BP 107/64, Pulse 61 | Temp 97.2 °F (36.2 °C) | Resp 16 | SpO2 97%. Physical examination was benign. His creatinine was 6.9. His baseline creatinine was 1.8 (for the past few years) and thought to be related to his hypertension. Other labs indicated corrected calcium of 11, potassium of 5.9, Co2 of 8 with normal platelets, and WBC. USG(Ultrasound) of kidneys revealed obstructing 3mm left UVJ stone with hydronephrosis. UA revealed 3 plus protein with moderate blood, 10-20 RBC per HPF, bacteria. He was started on antibiotics and a double JJ stent was placed. His stone disease is probably a manifestation of parathyroid adenoma. He was awaiting parathyroidectomy and was maintained on saprisyn in the interim. His creatinine continued to increase and peaked at 7.5 mg/dl. However repeat urinalysis revealed significant proteinuria and on quantification, it was 17g with albumin of 2. He also had lower extremity edema indicative of nephrotic syndrome. Of note, he did not have proteinuria a week before his hospital admission. At this point, a renal biopsy was undertaken and was noted to have collapsing glomerulopathy with 80-90 percent effacement of foot processes. The patient continued to improve to creatinine of 2.4 with improvement in urine output at which point he was discharged on ACE-I.

Discussion: Collapsing FSGS in probably related to complex interplay of multiple factors like infection, acute kidney injury due to other etiologies, genetic risk factors such as APOL1. Recent cases of COVID-19 related AKI point towards the possibility of collapsing FSGS as the etiological mechanism, especially with APOL1 association. Though it is traditionally described in the setting of infections like parvovirus and HIV, there could underlying common mechanisms for infections that may not be exclusive to these and may expand to other infectious etiologies like influenza, COVID.

Renal Response and Its Predictive Factors of Lupus Nephritis: A Two-Year Cohort of 77 Hospital-Based Patients

Zhiming Lin,1 Junmei Feng,2 Jun Zhang,2 Changlin Zhao,3 Zhen Wu.3
1Department of Rheumatology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China; 2Department of Nephrology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China; 3Department of Vasculocardiology, The Third Affiliated Hospital of Sun Yat Sen University, Guangzhou, China.

Background: To evaluate the renal response rates of lupus nephritis (LN) patients undergoing standard treatment during a two-year follow-up and investigate its predictive factors.

Methods: A prospective cohort study enrolled 77 clinically diagnosed LN patients who were carried out. All patients underwent standard treatment according to Joint European League Against Rheumatism and European Renal Association-European Dialysis and Transplant Association (EULAR/ERA-EDTA) recommendations or American College of Rheumatology (ACR) guidelines for the management of LN. Regular visits were performed every 6 months until 2 years. Data on renal response and clinical characteristics were collected and analyzed.

Results: Among 77 patients, 41(53.2%) and 15(19.5%) patients achieved complete response (CR) and partial response (PR) at 6 months after induction therapy, respectively. With every 6-months visit, 53(68.8%) patients completed the whole 2-year follow-up. 38(71.7%) and 5(9.4%) patients developed CR and PR at 2 years. During follow-up, serum creatinine (SCr) and Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) score showed a significant decrease as compared to baseline data, while estimated glomerular filtration rate (eGFR) and C3 level gradually elevated. In multivariate regression model, immunological disorder (OR 4.73, 95%CI 1.00-22.40, p<0.05), eGFR (OR 1.04, 95%CI 1.02-1.07, p=0.001) and SLEDAI (OR 1.21, 95%CI 1.05-1.40, p<0.05) at baseline were found to be associated with CR/PR at 6 months as compared to non-responders.

Conclusions: Nearly 70% LN patients achieved renal response after 6-months standard induction therapy, and the renal response rates were higher after 2 years. Renal function and disease activity showed a significant improvement during follow-up. Besides, immunological disorder, higher baseline eGFR and SLEDAI were predictive factors for renal response.

An A-Tip-ical Side Effect of Lithium

Casie James, Randall Craver, Isla Ashoor. Louisiana State University Health Sciences Center, New Orleans, LA.

Introduction: Lithium is a mood stabilizer approved for bipolar disorder treatment in children as young as 12 years. Though effective in the pediatric population, lithium requires close monitoring for toxicity and adverse effects.

Case Description: An 18 year old male with Hashimoto’s thyroiditis, bipolar 1 disorder, and anxiety presented with 10 days of edema, weight gain, progressive abdominal pain, emesis, diarrhea, and decreased urine output with frothy urine. Medications included levothyroxine, Risperdal, and lithium. Creatinine was 1.2 mg/dl, up from baseline of 0.8 mg/dl. There was nephrotic-range proteinuria, with spot urine protein/creatinine ratio of 3.12 and 24-hour urine protein of 3.5 gm/day. A lipid panel showed a cholesterol of 391 and a LDL of 292. Serologies for hepatitis B and hepatitis C were negative. Complement levels were normal and no monoclonal protein was seen on serum/urine electrophoresis. A serum PLA2-R was negative. He underwent a kidney biopsy that demonstrated subepithelial glomerular, mesangial, and tubular basement membrane deposits consistent with secondary membranous nephropathy. Staining for PLA2-R was positive. He was started on Rituximab and continued treatment as an outpatient.

Discussion: Here we describe a case of nephrotic syndrome in which the degree of hypoaalbuminemia was not consistent with the amount of proteinuria. This discordance represents a defect in the homeostasis of albumin typically seen in nephrotic syndrome. At a steady state, albumin synthesis is balanced by albumin catabolism and urinary loss. In nephrotic syndrome, catabolism is decreased while synthesis and urinary loss increases. The patient’s history of diarrhea and dysphagia suggested that he had either increased catabolism from non-renal GI losses or decreased synthesis due to poor intake. This case highlights alternative laboratory findings in membranous nephropathy and a framework for understanding the differences.
Serum creatinine results during 40 months of follow up

AKI After Eculizumab Interruption in a Case of C3 Glomerulopathy
Mostafa F. Elshirbeny, Mohammed E. Hussain, Essa Abuhelaiaq, Awais Nauman. Hamad Medical Corporation, Doha, Qatar.

Introduction: C3 glomerulopathy (C3G) is a newly recognized rare disease characterized by predominantly glomerular deposition of complement C3. Treatment with the C5 complement inhibitor eculizumab may be a therapeutic option but due to rarity of the disease, predicting tools of the outcomes remain largely unknown.

Case Description: Here we report 25-year old female patient who was referred to nephrology clinic with renal impairment, hematuria, and proteinuria. Kidney biopsy results revealed membranoproliferative changes with predominant C3 deposits, suggestive of C3 glomerulopathy. Genetic testing revealed two unrelated mutation in C3 gene, likely not related to C3G. Patient was responding well to oral steroid and MMF with remission of proteinuria and normalized serum creatinine. She was relapsed again, 1 year later with hematuria and nephrotic proteinuria. Steroids and MMF were resumed with no response then started on eculizumab, after which she achieved partial remission with reduction in serum creatinine and urine protein. During next 2 years, patient missed eculizumab in 2 occasions. The first, when she missed one dose followed by mild rise in serum creatinine which improved after eculizumab resuming and few months later she missed two doses then presented with severe AKI requiring dialysis. Was started on steroids and eculizumab was resumed with no improvement in kidney function and patient still dialysis dependent.

Discussion: Despite looks like safe and valuable therapeutic option in patients with C3G but the response to eculizumab is heterogeneous and when to discontinue the therapy still unsolved problem as transient interruption of the therapy sometimes complicated with AKI which may be severe enough to end with ESRD like this case.

Pathological Features and Clinical Course of IgA Nephropathy Patients with Isolated Hematuria
Yusuko Fukao,1 Hitoshi Suzuki,2 Toshiki Kano,1 Yuko Makita,1 Maiko Nakayama,1 Mingfeng Lee,2 Rina Kato,1 Yusuke Suzuki,1 Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; 2Department of Nephrology, Juntendo University Faculty of Medicine, Chiba, Japan.

Background: Microscopic hematuria is the most common manifestation of IgA nephropathy (IgAN). There are a few studies identifying the remission rate of microscopic hematuria as an important clinical predictor of deterioration of renal function. Microscopic hematuria caused by glomerular microvasculitis may have clinical significance. Renal biopsy was performed rarely in case with isolated hematuria. Renal pathological features and the renal prognosis of IgAN patients with isolated hematuria are unclear. Thus, there are no established treatments guides. In present study, we evaluated the pathological features and clinical course in IgAN patients with isolated hematuria in our cohort.

Methods: We retrospectively recruited 47 biopsy proven patients with IgA nephropathy who showed isolated hematuria at real biopsy from 2012 to 2017. We evaluated renal pathological findings in those patients. Moreover, we analyzed clinical course during 24 months from the diagnosis. Thirty of these patients were treated with steroid pulse therapy combined with tonsillectomy (TSP group) and the others were conservatively treated (CT group). In CT group, only three patients were treated with renin-angiotensin system inhibitor. We analyzed clinical parameters, such as, levels of urinary red blood cells, onset of proteinuria, eGFR and serum IgA.

Results: Although age, sex and degree of hematuria at the time of renal biopsy were not significantly different between the TSP and CT group, baseline eGFR was significantly lower in TSP group (88.7 versus 105.9 mL/min/1.73 m2). Of note, 51% of patients showed crescent or endocapillary proliferation. At the end of observation period,
remission rate of hematuria in TSP group (100%) was much higher than that in CT group (50%). Moreover, immunosuppression therapy was effective to prevent significant decline in kidney function.

Conclusions: We clarified that more than half of patients with isolated hematuria showed crescent or endocapillary proliferation in present study. Immunosuppression therapy is effective for those lesions. Thus, even in the patients with isolated hematuria, conservative treatment can be a risk for deterioration of renal function.

**PUB184**

**IgG4-Related Disease Presenting with Membranous Nephropathy**

Elizabeth Peper*1, Jalal E. Hakemi,2 and Edward Via College of Osteopathic Medicine - Carolinas Campus, Spartanburg, SC; 2Palmetto Nephrology, Orangeburg, SC.

**Introduction:** Pauci-immune glomerulonephritis (PIGN) is most commonly associated with a rapidly progressive course towards renal failure, although rarely, an indolent course may be observed. PIGN has a frequent association with either MPO- or PR3-antibodies and is associated with extra-renal manifestations. We report a patient with slowly developing renal function over the course of two years that had a renal-limited MPO-antibody associated pauci-immune glomerulonephritis.

**Case Description:** A 61 year old Caucasian female with controlled hypertension, hypercholesterolemia, and prediabetes without complaints was noted by her PCP to have a slowly rising creatinine over two years. A nephrology referral was made with new onset 1+ pitting edema in the bilateral, distal lower extremities and a creatinine of 1.7mg/dL. Urinalysis at this point showed a sediment and 2g/g of creatinine to protein. A renal ultrasound showed structurally sound kidneys. Common infectious causes of renal disease as well as antinuclear antibodies (ANA), C and HIV were negative, and MPO-PR3-ANCA were negative. MPO-PR3-ANCA were negative and C4 were seen to be if there was an autoimmune cause. A positive MPO prompted a renal biopsy which yielded a sample of 50 glomeruli with 15 completely sclerosed, 4 with crescent formation, and moderate to severe interstitial fibrosis and tubular atrophy. This confirmed the diagnosis of MPO-associated PIGN. Immunosuppression was begun with a rituximab based therapy, but the second dose of rituximab was interrupted due to severe back pain combined with nausea and vomiting. Creatinine was elevated at 3.6mg/dL from 2.2mg/dL the day before. Methylprednisolone was tapered and further infusions were not pursued due to development of deranged liver function tests, hospitalization for diverticulitis, development of uncontrolled DM, and severe psychological symptoms.

Over the following two months, the patient’s creatinine has trended down to 1.5 mg/dL.

**Discussion:** Her consistently rising creatinine was the main driver to begin immunosuppressive therapy despite having moderate to severe interstitial fibrosis and tubular atrophy. Rituximab based therapy was shown in the RAVE trial to be non-inferior to cyclophosphamide for induction of remission in ANCA associated disease. This combination may also have superior relapse rates and a better safety profile in comparison with cyclophosphamide. Her improving creatinine suggests that even an incomplete regimen might have conferred some benefit.

**PUB185**

**IgG4-Related Disease Presenting with Membranous Nephropathy**

Elena Zakhareva1, City Clinical Hospital n.a. S.P. Botkin, Moscow, Russian Federation; 1Medical University of Innsbruck, Innsbruck, Austria; 2Department of medicine II - nephrology/urology professional'nogo obrazovania, Moscow, Russian Federation.

**Introduction:** Immunoglobulin G4-related disease (IgG4-RD) is a condition, affecting multiple organs. Retroperitoneal fibrosis with obstructive nephropathy and interstitial nephritis are most typical kidney damage. Rare cases of glomerular disease, including membranous nephropathy (MN), had been described. Search for IgG4-RD cases in the database of our nephrology unit found 11 patients, in three cases kidney biopsy showed MN, and we present one of them.

**Case Description:** 73 years old Caucasian female with a history of arterial hypertension, diabetes, skin patchy hyperpigmentation, asthma and nasal polypsy manifested in 2016 with the weight loss and skin rush. 9 months later, at admission, she was undernourished, with multiple skin scratches, pedal edema, and otherwise unremarkable physical exam; her blood pressure was 150/90 mm Hg, vital signs were normal. Work up demonstrated nephrotic syndrome and marked eosinophilia (32.6% - 2.6*10³/μL). Her blood chemistry tests, serum and urine immunocomplex, p and c ANCA were positive, and anti-CEA-PR3-ANCA were within normal limits. Kidney biopsy showed MN with IgG, C3, kappa and lambda fine granular deposits on the capillary loops periphery. Her anti-PLAR2 antibodies titer was <1:10; kidneys, abdomen, neck and pelvis ultrasound, chest CT, gastroscopy and colonoscopy were unremarkable. Tests for parasitic infections and mycoid hypersincommune syndrome markers (FIP1LI, PDGFRα and ETV6-PDGFRβ) were negative. IgG4 level was 1.9 lg/L (0.81-1.4) – 29.2% (4.0-5.0). We diagnosed IgG4-RD and started her on oral prednisone 40 mg daily. Her skin rush resolved immediately, in a month her eosinophil count became normal, two months later we achieved partial remission of nephrotic syndrome. We added cyclosporin A and slowly tapered prednisone. At the latest follow-up visit January 2020, she was doing well, with the complete remission of nephrotic syndrome, preserved kidney function and normal IgG4 level.

**Discussion:** Clinical presentation was suggestive for ANCA-associated vasculitis or systemic sclerosis, not confirmed by serology and kidney pathology findings. The search for the hypersincomimmune syndrome causes was negative, and only IgG4 testing gave a clue to the diagnosis. Steroids allowed controlling hypersincomimmune symptoms, but no kidney biopsy showed MN, and we present one of them.

We conclude that IgG4-RD should be considered in differential diagnostics of membranous nephropathy.
AA Amyloidosis and CKD in a Patient with Coexisting Hepatitis C Infection and Crohn Disease

Arteen Pirverdian, Monica E. Corral, Grace McNutt, Julio P. Zavala Geoffrino.
University of the Incarnate Word, San Antonio, TX.

Introduction: AA amyloidosis is in the differential diagnosis of patients with proteinuria and may lead to chronic kidney disease (CKD). It is usually associated with chronic inflammatory conditions like rheumatoid arthritis which is implicated in 40% of cases. Crohn’s disease (CD) is also recognized as an underlying etiology. We present a patient with chronic Hepatitis C infection (HCV) and CD who developed proteinuria and CKD in a relatively short period of time.

Case Description: 33-year-old man with a past medical history of CD, HCV, and cocaine/heroin abuse with frequent IV drug use presented to the ED with complaints of bilateral lower extremity swelling and tenderness. Initial laboratory studies were significant for a creatinine of 4.56 and nephrotic range proteinuria. On review, his creatinine had been trending up from 0.75 mg/dL to 4.09 mg/dL in the last year. Secondary work-up for proteinuria including: ANA, RPR, RF, ANCA, C3, C4, Cryoglobulin with reflex, ds DNA Ab, UPEP, and SPEP w/ immunofixation screenings all yielded negative results. S. cerevisiae Ab IgA was 51.5, a positive confirmation of patient’s CD. HCV antibody test was positive with a positive HCV RNA. Renal biopsy was performed and revealed AA amyloidosis with severe interstitial fibrosis and tubular atrophy.

Discussion: AA amyloidosis is a disorder characterized by the overproduction of extracellular proteins that deposit and subsequently cause organ and tissue impairment. It is often attributed to chronic inflammatory/infectious diseases. Though literature about the incidence of AA amyloidosis in people afflicted with HCV is limited, incidence in individuals afflicted with CD has been reported to be between 0.5%-8%. AA amyloidosis has also been found to be a major cause of CKD in IV drug users. One UK study found that up to 35% of these patients have associated HCV. There are reports of increased CD “flares” in patients undergoing treatment for chronic HCV, which may suggest that the coexistence of both diseases may lead to worse morbidity. Our case is unique due to the coexistence of two chronic diseases that lead to inflammatory/infections processes known to be involved in the pathophysiology of AA amyloidosis. This co-existence may lead to a faster progression of CKD and overall worsening outcomes.

Awareness of Association of ANCA Vasculitis and Aortic Aneurysm Can Improve Survival
Sonalika Agarwal, Jitendra Kumar. QRG Hospital, Faridabad, India.

Introduction: ANCA vasculitis is a small-medium vessel vasculitis which is characterized by systemic necrotizing inflammation of blood vessels. Aortic aneurysm is a very rare complication of ANCA vasculitis. We describe a case of such association and highlight the need for guidelines for its screening in patients diagnosed with ANCA vasculitis.

Case Description: 40 year old man with no known medical history presented with renal failure and was started on dialysis. Kidney biopsy showed pauci immune crescentic glomerulonephritis. As per KDIGO guidelines, he was treated with steroids, cyclophosphamide and plasmapheresis after which he recovered from dialysis. 3 months later, he presented with hematemesis and shock. Due to worsening hematemesis and shock, upper endoscopy was done which revealed aorto-esophageal fistula and patient died of shock with no time for surgical intervention. On retrospective analysis, we found that unfolding of aorta seen on chest xray 3 months ago was likely aortic aneurysm which had increased in size and ruptured.

Discussion: To the best of our knowledge, this is the first case reported from India. The reason we think ANCA vasculitis is associated with aortic aneurysm is because it has been proven by biopsy in case reports in the past and in few of them, aneurysm had even decreased in size with chemotherapy. Also, it is surprising that such degenerative condition would occur without any risk factor like smoking, atherosclerosis, history of hypertension, or family history of connective tissue disorders in such a young patient. Since both ANCA vasculitis and aortic aneurysm are rare pathologies, it is reasonable to consider that they are related when occurring together. Again, its rapid expansion and rupture within a span of 3 months favors an underlying association. This case highlights that nephrologists should be aware of such association, screen the patient on presentation and then at intervals likely earlier than recommended for aortic aneurysm of other etiologies.

Atypical Presentation of Microscopic Polyangiitis

Introduction: MPA is an uncommon disease, more common in men, in white and Asian populations and whose incidence increases with age. We describe an atypical presentation of MPA.

Case Description: 48-year-old female patient, no relevant past medical history, who came to the ER with a 2-week history of bradyphoria, gait disturbances, arthralgia, lower limb pain. On PE non-blanching red-purple papules were noted. A lab panel showed increased creatinine at 5.79 mg/dL (baseline Cr was 1.09), microscopic hematuria and sub-nephrotic proteinuria. Kidney ultrasound was normal, urinary sediment showed dysmorphic RBC with RBC casts She was placed an acute catheter for HD prior biopsy. Immunological panel showed positive ANCA, specificity for PR3 antigen; C3 and C4 levels were normal; the rest of the panel and HIV, HBB and HCV serologies were negative. CT showed maxillary sinusitis, lungs were normal Skin biopsy showed a leukocytoclastic vasculitis and kidney biopsy showed a pauci-immune necrotizing glomerulonephritis, with diffuse extra-capillary proliferative lesions, mild interstitial fibrosis; no granulomas. Patient was diagnosed with a MPA, and treatment was started with IV GC and RTX. Patient was discharged to continue treatment in the out-patient clinic and currently has received a second dose of rituximab, with no need for hemodialysis and a creatinine of 2.5 mg/dL (7 days after starting treatment)

Discussion: MPA is a rare disease with unknown frequency in Mexico. Our case was atypical since it presented in a Hispanic female younger patient, with a histopathological phenotype of MPA but positive to PR3, with no respiratory involvement and no upper airway destructive lesions
C3 Glomerulonephritis: Can Therapy Be Individualized?

**Case Description:** 76-year-old male with T2DM, cirrhosis, HTN & MM in remission, on diltiazem, propranolol, insulin, presented to an outside hospital with 10-days of weakness, nausea, vomiting, diarrhea, and low urine output. He has a history of cirrhosis secondary to diltiazem. Antihistone Ab (AHA) was sent & diltiazem stopped. Electron microscopy noted subendothelial deposits & intracellular macroglobulins suggestive of SLE. AHA was positive with negative cryoglobulin. Diagnosis of drug induced SLE from diltiazem with p-ANCA positive RPGN was made. He was discharged on prednisone 60mg daily with slow taper & Roxizubam. Cr at discharge was 3.6mg/dl.

**Discussion:** Treatment involves prompt diagnosis & cessation of the offending agent & immunosuppression, with improved prognosis compared to PAAV.

---

Kidney Aging and Estimation Equations for GFR in Beijing

**Background:** When evaluating renal function, eGFR data show significant variation across different equations, particularly in elderly patients. Here, we investigated how age affected renal function in healthy subjects in Beijing and compared different eGFR equations for the evaluation of renal function.

**Methods:** We recruited all patients undergoing routine assessment in our hospital between January 2012 and December 2014. For each patient, we recorded age, gender, and eGFR. Kidney function was evaluated by five equations: CKD-EPI, MDRD, MDRDc, FAS and BIS.

**Results:** A total of 46,713 subjects were enrolled. Subjects were 16 - 100 years-old of age and were followed-up for 3 years. All subjects showed an increase in sCr and decrease in eGFR with increasing age. For males, there was a more obvious and significant reduction of eGFR in the elderly; but in older females, eGFR did not tend to change. Different equations showed good consistency (the intraclass correlation coefficients (ICC) was 0.849 for males, and 0.817 for females). The CKD-EPI equation yielded higher eGFR than the MDRD equation, which was indicative of more advanced CKD (according to sCr levels). There was no obvious trend for age-related change in the 3-year mean rate of eGFR change when compared across age groups. For subjects aged over 70 years, the MDRD and MDRDc equations yielded significantly higher eGFR data than the BIS produced the lowest eGFR values.

**Conclusions:** The annual rate of GFR change was not associated with age. Different eGFR equations yielded data that varied across different populations of patients and sCr levels. We were unable to identify a specific equation for use in the elderly Chinese population.

---

Kidney Changes: Stop That Drug!

**Introduction:** Drug associated antineutrophil cytoplasmic antibody (ANCA) associated vasculitis (DAV) with rapidly progressive glomerulonephritis (RPGN) is rare. Historically linked to antithyroid drugs, new evidence implicates almost every pharmacologic class. DAV, it is catastrophic. Prompt diagnosis & cessation of the offending agent is paramount. This is a case of DAV-RPGN secondary to diltiazem.
A Workplace Wellness Program Results in Improvements in Physical Activity and Blood Pressure in the Staff of a Hemodialysis Clinic 

Alexis King,1 Alana P. Harris,1 Luis M. Perez,2 Kenneth R. Wilund.1,2
1University of Illinois at Urbana-Champaign, Department of Kinesiology and Community Health, Urbana, IL; 2University of Illinois at Urbana-Champaign, Division of Nutritional Sciences, Urbana, IL.

Background: Evidence indicates that health and wellness programs in the workplace provide numerous benefits with respect to altering indices of health. The purpose of this study was to assess the feasibility of a workplace wellness program (WOW) as a means of improving blood pressure by participation in habitual physical activity (PA) and improving dietary choices among the staff at a hemodialysis clinic.

Methods: 26-staff members (age:46.5±12.2;BMI: 28.7±5.6 kg/m2) from a hemodialysis clinic (nurses, technicians, social workers, dietitians, and administrative staff) participated in the 12-week WOW program that consisted of weekly counseling sessions, the provision of educational resources, PA incentive challenges, and healthy dietary choices challenges. Body weight(kg), height(cm), blood pressure, BMI, 24-hr dietary recalls, PA behaviors (IPAQ), andwaist/hip circumference(cm) were collected at weeks 0(baseline), 6, and 12 following the conclusion of the intervention. Statistical analysis was performed using SPSS24. All primary and secondary outcomes were assessed by one-way Analysis of Variance (ANOVA) comparing values at the different testing time points, with significance at (p<0.05). Paired sample t-test was used to test the questionnaire (IPAQ) data that was collected at baseline and post intervention.

Results: The program also resulted in improvements in several health related metrics. This included reductions in body weight (1.07±kg±21.4; p<0.05), body mass index (p<0.05), waist circumference cm (96.9±14.8; p<0.05), and hip circumference cm (111.7±13.6;p<0.05). Systolic blood pressure change was non-significant but trending toward significance (p=0.08), while diastolic blood pressure was reduced (p<0.05). There were significant changes in PA behavior, specifically walking behavior (p<0.05), as indicated by the IPAQ.

Conclusions: The WOW program demonstrated increased measures in the staff’s PA. As a result, this led to the improved health outcomes which included body weight reductions, BMI improvements, lowered hip and waist circumference, and improved diastolic blood pressures values. The study suggests that a workplace wellness program has the potential to improve health indices of the staff of hemodialysis clinics and may positively impact the health behaviors in the hemodialysis patients under their care.

Fragility Changes in Patients on Hemodialysis After an 8-Week Exercise Intervention 

Rick Ward, Wise Health System Dialysis Center Wise Health System, Decatur, TX.

Background: The Fried frailty phenotype defines frailty as having at least 3 of the following: unintentional weight loss, decreased grip strength, slow gait speed, exhaustion, and decreased physical activity. The vulnerability inherent in frailty is exacerbated in people with end-stage renal disease, but frailty assessments are typically not used.

Methods: 11 patients from the Wise Health System Dialysis Center in Decatur, TX (6 in the experimental group, 5 in the control group). The experimental group received a supervised elastic band resistance and cycling ergometer program 3 days per week for 8 weeks during dialysis. The resistance component included: ankle dorsiflexion and plantarflexion, knee flexion and extension, and hip abduction. A repeated measures 2-way ANOVA was conducted on the dependent variables of: frailty scores, gait speed, grip strength, 2-Minute Step Test, exhaustion, Timed Up and Go, and 30-second Sit to Stand Test.

Results: There was a significant difference in pre- to post-test frailty scores [F(1, 9) =6.14, p =0.035, η2 = .41]. Specifically, the exercise group’s frailty score dropped from 3.67 to 2.67 while the control group’s score did not change. This change in frailty scores was influenced by the change in the exhaustion component of the frailty score from a mean of 1.00 to 0.17 [F(1, 9) =16.05, p =0.003, η2 = .64]. There were no significant differences found in the other dependent variables. There were no adverse reactions to the exercise intervention.

Conclusions: The results of this feasibility study support the hypothesis that an exercise program during dialysis can change frailty scores in people with ESRD, as the differences found in the other dependent variables. There were no adverse reactions to the interventions conducted at 4 institutions. Frailty was evaluated with the Tilburg Frailty Indicator (TFI) and it was used as the self-reported questionnaire. Anxiety symptoms was assessed by the Self-Rating Anxiety Scale(SAS), depressive symptoms was assessed by the Self-Rating Depressive Scale(SDS). We collect sociodemographic and clinical characteristics the patients who complete the scale. Statistical analysis was performed using SPSS20.0 for Windows.

Results: Of the 623 patients visiting each institution, 300 were enrolled in this study. The mean age was 61.9±13.64 years, with mean duration of HD 30.7 (43.39±2.36) months.116 patients (38.7%) were female and 133 (44.3%) had diabetic kidney disease. In total, there were 225 patients (73%) were evaluated as frailty. The prevalence of frailty increased steadily with age and was more prevalent in the diabetes mellitus patients. A multivariate logistic regression analysis revealed that the factors independently associated with frailty were the following: age, Charlson comorbidity index, DMSAS, SDS. There was no relationship between the duration of HD and frailty status. Anxiety and depressive symptoms by SAS and SDS were identified in 52.6% and 72.0% of MHD patients. MHD patients with both anxiety and depression generally had higher frailty score. The coexisting frailty and psychological disorder were present in 45.0% patients. There was an additive effect of psychological disorders and frailty on nutritional status. For the groups with frail and psychological conditions and no frail and no psychological conditions, both serum albumin and creatinine decreased.

Conclusions: This study demonstrated that anxiety and depressive symptoms are associated with prevalent frailty in Southern Chinese MHD patients. Older age, diabetes mellitus, CCI and lower serum albumin were associated with frailty among patients on MHD. Anxiety and depressive symptoms are independent risk factors of frailty.

**Scope and Consistency of Physical Fitness Outcome Measures in CKD: A Systematic Review**

**Methods:** A systematic review of randomized trials reporting physical fitness outcomes in adults with CKD (not requiring kidney replacement therapy), receiving hemodialysis or peritoneal dialysis, and kidney transplant recipients was conducted. Studies were identified from MEDLINE, Embase and the Cochrane Library from 2000 to 2019. The scope, frequency and characteristics of outcome measures were reported in trials in CKD.

**Results:** From 112 trials and 6,047 participants, 87 tests/measurements were used to evaluate 30 outcomes measures that reported on 23 outcomes, categorized into five domains of physical fitness: neuromuscular fitness (reported in 76% of trials), exercise capacity (50%), body composition (30%) and cardiorespiratory fitness (30%).

**Conclusions:** There is large heterogeneity in the reporting of physical fitness outcomes, with inconsistencies in the use of validated and patient-important outcome measures. Standardization in the assessment of physical fitness is required to improve the comparability of trial outcomes and enhance clinical recommendations.

**Time to Revisit Contemporary Heart Failure Risk Prediction Models:**

**Methods:** Articles cited in the PubMed database using keywords “heart failure”, “prognostic model” were searched. Available data from clinical trials performed between January 1995 and December 2019 were included. The studies were selected if they prognosticated outcomes in the HF population through a predictive model that consisted of at least 2 factors. Pertinent data on clinical and laboratory parameters (e.g. hemoglobin, albumin and hemoglobin) were extracted.

**Results:** A total of 15 studies with 82,706 participants were included, of which 5 validated a model derived from equations predicting the risk of mortality and morbidity.

---

**Low Inflammation Vaccination Rates and Patient Misconceptions in Inner-City CKD and Kidney Transplant (KTR) Patients**

**Methods:** A face-to-face survey was conducted in a random convenience sample of 30 patients with CKD attending clinic (30) and Transplant clinic (45). Pts were asked if they refused or accepted the influenza vaccine and associations between beliefs about vaccines and cause of vaccine refusal examined.

**Results:** There were 37 (49.3%) women and 38 (50.7%) men with 60 black (80%). 40 (40%) did not attend any college. 17 (22.7%) were employed. Mean age was 58.6±1.4 yrs. 34 (45.3%) reported having had influenza with more TTP pts (63% vs 31%, p<0.001) and more men (62% vs 37%, p=0.035) in the group by Chi-square. 18.36% (50%) of the patients did not believe in the previous evidence between CKD and KTRs. Reasons were believing that they were not at risk (28%), experience with side effects (33%), fear related to 3rd party information (22%) and other. Pts who did not think illness prevented by vaccines were severely agreed they should question shots (r=0.58, p<0.0001), felt knowledgeable about vaccines (r=0.77, p<0.0001) but less so if the establishment of a nutritional care process adapted to the chronic kidney disease, improve patients quality of life. The main objective of this survey will be to evaluate 30 outcomes measures that reported on 23 outcomes, categorized into five domains of physical fitness: neuromuscular fitness (reported in 76% of trials), exercise capacity (50%), body composition (30%) and cardiorespiratory fitness (30%).

**Conclusions:** There is large heterogeneity in the reporting of physical fitness outcomes, with inconsistencies in the use of validated and patient-important outcome measures. Standardization in the assessment of physical fitness is required to improve the comparability of trial outcomes and enhance clinical recommendations.
a variety of HF populations (e.g. acute, chronic, carrying mechanical circulatory device) and the median number of included parameters was 7. There was substantial variation across models in the reporting of the kidney related parameters as well as the studied outcomes. While no study included eGFR, serum creatinine and BUN were included in only 6 and 4 studies respectively. Interestingly, serum chloride level was included in none of the included models, while it contains data for serum sodium level.

Conclusions: The emerging clinical evidence on the paramount prognostic value of hypochloremia for adverse outcomes in HF is in keeping with distinctive physiologic mechanisms relating it to renin secretion and modulation of renal tubular sodium transport. Moreover, we found that there is still a lag in its integration into contemporary predictive models of HF. This observation highlights the need for revisiting these models in backdrop of emerging data and explore whether incorporation of hypochloremia, or replacing hyponatremia by hypochloremia, would add to their predictive value.

PUB204

Long-Term Ambient PM2.5 Exposure Associated with Major Cardiovascular Risk Factors in a Large Chinese Population-Based Study

Jianfeng Lin, Hua Zheng, Peng Xia, Limeng Chen. Peking Union Medical College Hospital, Dongcheng-qu, China.

Background: The association between long-term exposure to ambient air pollution and hyperlipidemia or overweight is still controversial. We aimed to investigate the relationship between long-term exposure of PM2.5 and cardiovascular risk factors in a large multi-provincial and multi-ethnic Chinese adult sample.

Methods: We recruited 19,236 adult participants from 2007 to 2010 in 6 provinces of China (Chinese Physiological Constant and Health Condition Study, CPHC). A questionnaire, physical examination, and biochemical tests were performed. The PM2.5 data used were derived from aerosol optical depth with the GWR model and GEOSChem method.

Results: The average age of the participants 42.7±16.12 years and nearly half were male (47.0%). Annual average PM2.5 exposure 1-year before the CPHC study was 33.4±14.63 μg/m3. Multiple linear regression showed that each 10 μg/m3 increment of PM2.5 was associated with 0.025% (95%CI: 0.011%, 0.040%) decrease of cholesterol and 0.098% (95%CI: 0.083%, 0.113%) decline of BMI. Adjusted by age, sex, education, ethnicity, physical activity, and smoking, logistic regression indicated that PM2.5 exposure still associated with the prevalence of hyperlipidemia (OR = 0.958, 95%CI: 0.942, 0.974) and overweight (OR = 0.925, 95% CI: 0.911, 0.939). PM2.5 exposure was also corresponded to elevated SBP (0.048%, 95%CI: 0.034%, 0.063%) and an increased prevalence of hypertension (OR=1.020, 95% CI: 1.001, 1.039).

Conclusions: Long-term PM2.5 exposure was associated with an increased prevalence of hypertension, decreased prevalence of hyperlipidemia and overweight.

Predictive Models for Prognosis of Cardiovascular Events (in 5 Years) in Asian Patients with CKD

Wentao Hu, Xin Liu, Shaomin Li. the Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

Background: Chronic kidney disease (CKD) is viewed as a major health problem worldwide. However, independent influencing factors related to the prognosis of CKD patients (especially in cardiovascular events) is still potential to be exploited, and few researches on predictive models for individualized prognosis in CKD patients were published, especially in Asian area. Therefore, we are willing to evaluate independent influencing factors in regard to prognosis of CKD patients and build predictive models for individualized prognosis in CKD patients.

Methods: 1246 participants were included in this cross-sectional study. All data were used in univariate Cox proportional hazards regression models and multivariable Cox regression analyses (P<0.05). Then, 1246 participant were divided into two cohorts (development cohort and validation cohort). We will establish one best predictive model by the means of CINDEX, AIC, NRI, IDI.

Results: In the Cox regression analysis of cardiovascular events, we found that HGB, K, Pre-albumin, APOB, Heart failure, CKD progression are independent risk factors. In the development cohorts, we found that the model (K, Pre-albumin, HGB, HF, CKD) is the best prediction model of cardiovascular events (P=0.088e (1.93584*APOB + 0.00356*pre-albumin + 0.00679*HGB +1.11488*heart failure - 0.22131*K - 0.10215*CKD progression) is the best prediction model of cardiovascular events.

Conclusions: Lower HGB is independent protective factor of cardiovascular events, and higher K, Pre-albumin, APOB, Heart failure, CKD progression are independent risk factors of it. And we establish the best prediction model (P=0.088e (1.93584*APOB + 0.00356*pre-albumin + 0.00679*HGB +1.11488*heart failure - 0.22131*K - 0.10215*CKD progression)) of cardiovascular events (in 5 years).

PUB206

Epidemiology of Cardiovascular Risk Factors in Hemodialysis Patients in a Tertiary Care Hospital

Muntazir Ali Sayed,1 Navneet K. Guru,4 Adil A. Akbani,1 Ali Hamza,1 Sadiq Ali Sayed,2 Farhin N. Sayyad,2 Sayed Mohd Tahir Rizvi,3 Desi Doctors1 Avicenna Medical College, Lahore, Pakistan; 2National Pirogov Memorial Medical University, Vinnytsya, Ukraine; 3Rajiv Gandhi Medical College and CPR Hospital, Kolhapur, India; 4Government Medical College, Patiala, India; 5J K Somaiya College of Engineering, Mumbai, India.

Background: Cardiovascular events remains the leading cause of mortality in patients with end stage renal disease (ESRD) and the risk of cardiovascular events is 10 to 20 times higher in ESRD as compared to general population. The main objective of this study was to evaluate the prevalence of traditional cardiovascular risk factors in the population of ESRD outpatients on chronic hemodialysis in a tertiary care center in Kolhapur city of Western India.

Methods: All patients undergoing regular hemodialysis for ESRD in the tertiary care center of CPR Hospital were considered for inclusion in the retrospective study. Clinical and demographic data were obtained from the medical records, whereas laboratory records were obtained as the most recent result in the six preceding months. Adequate statistical tests were carried out and for all tests, a p-value <0.05 was considered statistically significant.

Results: A total of 1937 patients were included from the data of 2 years from May 2018 to April 2020 at our institute. Their average age was 61.3 years old, 69.3% were males. The prevalence of cardiovascular risk factors observed was 89.3% for hypertension, 83.9% for dyslipidemia, 75.3% for sedentary lifestyle, 49.7% for tobacco use, and 43.5% for diabetes. In a multivariate adjusted analysis, we found that sedentary lifestyle (p = 0.041, PR 1.15 – 95%CI: 1.09 - 1.17), dyslipidemia (p = 0.021, PR 1.05 – 95%CI: 1.01 - 1.11), and obesity (p < 0.0001, PR 1.88 – 95%CI: 1.59 - 2.95) were more frequent in women; and hypertension (p = 0.019, PR 1.03 – 95%CI: 1.01-1.17) and tobacco use (p = 0.009, PR 3.1 – 95%CI: 1.97 - 4.67) were more often found among patients under 65 years old. Sedentary lifestyle was independently associated with time in dialysis less than 12 months (p < 0.001, PR 1.33 – 95%CI: 1.19 - 1.43).

Conclusions: The population in chronic hemodialysis in the city of Kolhapur presents a high prevalence of cardiovascular risk factors. These findings confirm the high-risk cardiovascular profile of hemodialysis patients. Prospective studies and clinical trials are needed to further clarify interventions that can be transformed in public health strategies to prevent cardiovascular death in hemodialysis patients.

PUB207

Prevalence and Associated Risk Factors of Pre-Hypertension and Hypertension Among University Students in Bahrain

Amjad E. El Agroudy. Arabian Gulf University, Manama, Bahrain.

Background: The increase of hypertension in the developing countries may be connected with the economic transition within those countries. This study aimed to assess the prevalence of prehypertension and hypertension among university students and their associated risk factors.

Methods: The study used a cross-sectional design. Data were collected from February 2019 to May 2019 at the Arabian Gulf University Campus in Bahrain. A total of 411, randomly selected students aged 17 to 24 years (196 males, 215 females) were included in the study. The data were obtained through a self-completed structured questionnaire, which included data about nutritional lifestyle, sleep, exercises, family history and smoking pattern. In addition, blood pressure and body mass index were measured. Systolic and diastolic blood pressure measurements were taken by trained personnel.

Results: The mean age was 19 ± 1.9 years. Normotensive cases constituted 61.3% (n = 252), prehypertensives formed 30.7% (n = 126), and hypertensive students comprised of 8% (n = 33). The overall proportions of hypertension and prehypertension were higher among male students (81.8 and 69.8%) than female students (18.2 and 30.2%), respectively.
Higher body mass index was associated with significantly higher prevalence of hypertension (36.1%), pre-hypertension (33.3%), and obesity (9.4%) but not with pre-hypertension (normal weight 47.6%, overweight 32.5%, and obesity 17.5%). The Univariate analysis showed an association between hypertension and age, sex, body mass index (BMI), nutritional lifestyle, sleep duration, physical activity, smoking pattern and family history.

Conclusions: The findings of this present study highlighted the prevalence of hypertension (8%) and prehypertension (30.7%) among university students in Bahrain. This study showed a significant association with age and age-related factors (age, sex, body mass index, smoking, sleep duration, physical activity and family history of hypertension). The results of this study recommended that periodic screening and monitoring of students for hypertension should be done to the university students.

PUB208
A Combined Effect of Sacubitril/Valsartan and Evolocumab on Chronic Heart Failure in an ESRD Patient
Hun M. Aung,1,2 Aye M. Thida,1,2 Myat E. Mon,1 Phyio Wai Khine,3 May T. Zin,4 Banya M. Win,4 Kyaw Hla,1 Alexander M. Swan.1,2 Interfaith Medical Center, Brooklyn, NY; 1Nephrology Hypertension Renal Transplant & Renal Therapy, LLC, Avenel, NJ; 2Woodland Medical and Mental Health Center, Brooklyn, NY; 3Rutgers New Jersey Medical School, Newark, NJ.

Introduction: End-stage renal disease (ESRD) patients generally have underlying risk factors for coronary artery disease and heart failure (HF) such as hypertension and diabetes mellitus. In fact, chronic HF is highly prevalent and is one of the leading causes of death in these patients. We report a combined effect of sacubitril/valsartan and evolocumab on chronic HF in an ESRD patient.

Case Description: A 63-year-old man with a history of chronic HF for 3 years, along with hypertension, diabetes mellitus, hypercholesterolemia, coronary artery disease, status post coronary artery bypass graft with multiple stents, and ESRD on hemodialysis, presented with worsening dyspnea over 2 months (NYHA Class IV). His medication list included enalapril, valsartan, carvedilol, clonidine, amlopidine, hydralazine, isosorbide, mononitrate, ranolazine, aspirin, warfarin, amiodarone, erythropoietin, rosvastatin, sevelamer, lanaglipin, and insulin. An echocardiogram revealed an ejection fraction (EF) of 15%. He was placed on a cardiac transplant waiting list after receiving an implantable cardioverter defibrillator. Meanwhile, enalapril and valsartan were replaced by sacubitril/valsartan for chronic HF, and evolocumab was added to reduce the risk of myocardial infarction. During an initial follow-up for 10 months, his dyspnic symptoms improved significantly to NYHA Class I. An echocardiogram later revealed an EF of 60%. He was followed up for 4 years, with only a few hospitalizations, worsening of HF, or side effects of the medications such as hypotension, hyperkalemia, and nasopharyngitis.

Discussion: Sacubitril/valsartan, an angiotensin receptor-neprilysin inhibitor, has multiple mechanisms of action and is known to reduce the risk of cardiovascular death and HF hospitalization in patients with chronic HF with reduced EF. Besides evolocumab, a PCSK9-inhibitor antibody, is known to promote plaque regression and stabilization. The combined use of sacubitril/valsartan and evolocumab in our patient for 10 months resulted in an improvement of his EF from 15% to 60%, most likely due to a significant improvement of coronary blood flow with a recovery of hibernating ischemic myocardium. Therefore, additional studies are highly recommended to explore the beneficial effect of these medications used in combination.

PUB209
Fanconi Syndrome and Acute Interstitial Nephritis: A Toxic Combination Associated With Ifosfamide
Hafsa Tarig, Nimreen El Fadawy, Miroslav Sekulic, Arash Rashidi. University Hospitals, Cleveland, OH.

Introduction: Ifosfamide is an alkylating chemotherapeutic agent used in the treatment of various soft tissue tumors. Nephrotoxicity associated with ifosfamide is less frequently reported in adults. We describe a patient with Ewing sarcoma, who presented with AKI and Fanconi syndrome. Worsening renal function prompted renal biopsy which showed acute interstitial nephritis. AIN associated with ifosfamide may portend a bad prognosis due to lack of response to steroids.

Case Description: 33-year-old female with chest wall Ewing Sarcoma presented with AKI and AKIN. She was started on CyBorD therapy. Worsening of renal function prompted CyBorD withdrawal. She was volume resuscitated and started on treatment with CyBorD therapy. She was transfused 2 units of packed red blood cells and labwork showed creatinine of 10.79mg/dL, BUN 94mg/dL, bicarbonate 16mmol/L, potassium 5.9 mmol/L, phosphorous 10mg/dL calcium 7.5mg/dL, and urinalysis with <30 mg/dL albumin. She was volume resuscitated and nephrology consulted for acute kidney injury. Further workup for urinary protein of 404 mg/dL and 43mg/dL creatinine, with urine pro/cre ratio of 9.3. 24 hour urine collection showed 24 hour total protein of 4.8g. FLC assay showed Lambda load of 3694mg/dL, kappa 341mg/dL. Kidney biopsy revealed interstitial fibrosis and tubular atrophy in 20-50% and glomerulosclerosis 30-40% with strong lambda staining casts present. Hematology consulted and performed bone marrow biopsy which revealed over 90% plasma cells, confirming MM. Patient was started on hemodialysis for metabolic complications, and started on treatment with CyBorD therapy.

Discussion: Our patient presented with an extremely high light chain burden, and was treated aggressively with hemodialysis and immediate chemotherapy. The fairly recent development of the free light chain assay provides a tool to screen for MM and measuring serum light chain quantitatively. Currently, there are conflicting results as to whether there is an overall light chain burden/hazard correlation and impact on tail kidney survival and salvageability. Further testing and meta-analyses are needed to determine if this can be used as a prognostic tool.
AKI Associated with Immune-Checkpoint Inhibitors: Management Challenges and Dilemmas Without Renal Biopsy
Hui Zhan Tan, Jason Choo Chun Jun. Singapore General Hospital, Singapore, Singapore.

Introduction: There is much to be learnt about renal lesions seen in patients with acute kidney injury (AKI) associated with the use of immune-checkpoint inhibitors (ICIs). Acute tubulo-interstitial nephritis is the most common, with glomerulonephritis (GN) being increasingly recognized.

Case Description: A 61 Chinese male presented with generalised arthritis and AKI with nephritic-nephrotic syndrome on a background of Stage IV metastatic clear cell RCC and left radical nephrectomy. At presentation, he was on treatment with pembrolizumab (PD-1 inhibitor) and axitinib (VEGF receptor TKI). Investigations revealed 24hr TUP of 8.26g/day and peak serum creatinine (Scr) of 605 μmol/L (CTCAE G3; baseline Scr 117 μmol/L). Autoimmune markers and complements were negative. Patient was counselled for but refused a high-risk renal biopsy. Pembrolizumab was discontinued. High dose prednisolone was initiated for renal and rheumatological IRAE. Scr improved to 220 μmol/L at 3 months but his nephritic-nephrotic state persisted. Risks and benefits of empiric mycophenolate mofetil were discussed extensively and patient opted to continue with corticosteroid (CS) monotherapy. His subsequent clinical course was complicated by community acquired pneumonia and herpes simplex viral oral mucositis, before eventually succumbing to polymicrobial sepsis from acute cholecystitis despite optimal management.

Discussion: The clinical presentation of our patient is highly suggestive of an underlying GN. In view of concurrent rheumatological IRAE, we postulated that his AKI was related to ICI use. Empiric use of high-dose CS resulted in partial improvement in renal function but persistence of nephritic-nephrotic state, suggesting that CS monotherapy is suboptimal. Without histological data, directed therapy was not possible. However, given the rarity and heterogeneity of ICI associated GN, success of previously tried agents was limited to case reports and optimal treatment remains unknown. In view of this uncertainty, hesitancy with the empiric use of immunosuppressants beyond CS is understandable. While we await further research, in-depth discussion of treatment risk and benefits, especially infective complications, during shared decision making remains a key element in the optimal care of this unique population with advanced malignancies and often, limited life expectancy.

PUB213
Aibratere-Inuced Rhabdomyolysis as an Unusual Cause of AKI Requiring Hemodialysis
Juan Carlos Garcia Yanez,1,2 1Hospital Aranda de la Parra, Leon, Mexico; 2Universidad de Guanajuato - Campus Leon, Leon de los Aldama, Mexico.

Introduction: A 86-year-old male diagnosed with metastatic, castration-resistant prostate cancer (mCRPC) treated with abiraterone (Zitaiga) for 3 months was admitted to the emergency department due to hypoxemia, worsening fatigue and leathargy.

Case Description: After being diagnosed with prostate cancer, the patient had been subject to a radical prostatectomy 10 years prior to admission; 12 months prior to admission he developed deep-vein thrombosis that required endovascular treatment. The patient was prescribed daily 10mgivarosiran and 5mgprednisone for 1 year. For over 4 years, the patient had an irregular consumption of esomeprazole, atorvastatin and risperidone. Upon admission to the emergency department laboratory analysis revealed a dialytic emergency: serum creatinine of 6.1mg/dL, urea 295 mg/dL, BUN 138mg/dL and potassium of 7.3mEq/L. The patient refused renal replacement therapy. Aggressive hydration and treatment with calcium gluconate, IV insulin and beta-agonist micronebulizations were prescribed to treat hyperkalemia. 24 hours later the patient persisted with serum creatinine 5.8, urea 276, BUN 128 and potassium of 7.0 despite optimal hydration management and potassium-lowering measures. As the clinical status didn’t improve wrongly the previously described measures, the patient agreed to hemodialysis. Neurological symptoms improved, but the patient persisted with localized muscle pain in both legs, and it was decided to measure myolysis enzymes, with the following results: CPK 425 CPK-MB 92 and Myoglobin of 500 ng/mL. (7 times over the reference value). The patient was subject to three additional hemodialysis sessions, until creatinine, urea, BUN, K, CPK, and myoglobin levels were at reference parameters.

Discussion: There are only a few case reports that describe an association between abiraterone and rhabdomyolysis requiring renal replacement therapy. In Mexico, this is the first reported case. Rhabdomyolysis is an important lesson, particularly in an oncologic hospital, as this unusual cause of acute kidney injury may be under-recognized in patients with prostate cancer undergoing treatment with this medication.

PUB214
A Unique Case of CKD with Multiple Primary Genitourinary Tumors
Shreyan Arora,1 Aiman Haider.2 1University of North Carolina at Chapel Hill, Chapel Hill, NC; 2University College London, London, United Kingdom.

Introduction: Studies in pre and post dialysis chronic kidney disease (CKD) patients have shown a high risk for urinary system malignancy. There is a 44% higher risk of malignancy in patients with eGFRs less than 45 mL/min/1.73 m. Renal cell carcinoma (RCC) represents 3% of all adult cancers. Primary penile melanoma is rare with an incidence less than 0.2% of all melanomas. Multiple primary genitourinary tumors are uncommon. Here we highlight an unusual case of a CKD patient with bilateral RCC and penile melanoma.

Case Description: We present a 78-year-old man with history of gout, osteoarthritis, and hypertension who underwent radical left nephrectomy for an incidental RCC (Fuhrman grade 2, pT1a). He went on to develop a spindle cell penile melanoma (pT3b). He was treated with a glansectomy and received a neoadjuvant. Moreover, he was diagnosed with stage 3 CKD. He subsequently developed RCC (Fuhrman grade 2-3, pT3b) in the right kidney and was treated with cryoablation. Serum creatinine ranged from 136-185 μmol/L, GFR from 31-45 mL/min/1.73m², urea from 14.8-17.4 mmol/L and potassium from 4.5-4.7 mmol/L. Unfortunately, his melanoma progressed with multiple recurrences and he subsequently passed away.

There is a risk factor for malignancies in the genitourinary tract, particularly in older men. As the prevalence of CKD in the aging population increases globally, the importance of the recognition of CKD as a risk factor for genitourinary cancers must also increase. Our case highlights the association of CKD with multiple genitourinary tumors. There is a need for assessing the impact of CKD on treatment and prognosis of genitourinary cancers.

Bilateral Renal Burkitt Lymphoma Presenting with Persistent Lactic Acidosis in an HIV-Negative Patient
Oscar A. Garcia Valencia,1,2 Juan D. Salcedo Betancourt,1,2 Victor G. Becerra-Gonzalez,1,2 Karla G. Carias martínez,1,2 Marco A. LadinoAvellaneda,1,2 1Jackson Memorial Hospital, Miami, FL; 2University of Miami, Coral Gables, FL; 3Miami VA Healthcare System, Miami, FL.

Introduction: Burkitt lymphoma is an uncommon and aggressive B-Cell lymphoma accounting for <1% of adult Non-Hodgkin Lymphomas. The ileococcal region is the most common affected area, but it can involve extra nodal sites including the kidney. Renal involvement is usually asymptomatic and requires a high degree of suspicion to prevent early complications.

Case Description: 63 years old non-smoker, HIV negative male with a history of an incidentally found left medial upper pole exophytic perinephric hematoma on CT 2 months prior to presentation, presented to the ED complaining of acute on chronic lumbar back pain. Noted asfetile, BP 86/52 mmHg with orthostatic changes, HR 92bpm, RR 20rpm and SO2 96% on RA sonnentel but arousable, pale, no abdominal, spinal or costovertebral tenderness. Laboratory showed Hb 8.2 (14.7 a month prior), WBC 17,000, Na 126, Sodium bicarbonate 16, Anion gap of 22, Lactic acid 5.0 and SCR 1.5 (baseline 0.8). UA unremarkable. CT-CAP w/o contrast with interval increase of perinephric hematoma and rectus abdominis hematoma. Urology recommended no surgical intervention. He was resuscitated with isonicotic IV fluids, with resolution of shock. Subsequent MRA showed no evidence of enhancing left renal hematoma but multiple rounded hypo enhancing lesions in the renal parenchyma bilaterally. He remained with persistent anion gap metabolic acidosis with increasing lactic acid up to 14.5. A kidney biopsy was planned but aborted as patient became hypotensive and confused with a drop in hemoglobin to 5.6. Patient endorsed dark stools so, when hemodynamically stable, EGD was performed and gastric biopsies showed aggressive Burkitt’s lymphoma. Discussion: Lactic acidosis (LA) can occur in the presence or absence of tissue hypoxia (type A and type-B LA respectively). Persistent LA without identifiable causes of tissue hypoxia should prompt clinicians to suspect non-hypoxic etiologies, including occult high-grade malignancies. Hematological malignancies constitute and uncommon cause of type-B LA, carrying a poor prognosis.

Oxalaplavin-Induced Hypomagnesemia
Yury Khanin, Mala Sachdeva, Nupur N. Uppal. Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.

Introduction: Platinum based chemotherapy is used in the treatment of several malignancies including lung, colorectal, ovarian, breast, head/neck, bladder and testicular cancers. We present a case of profound electrolyte disturbances in the setting of oxalaplavin therapy.

Case Description: 78-year-old Caucasian male diagnosed with pancreatic cancer three months prior to admission, on oxalaplavin therapy, presented to emergency room with new onset atrial fibrillation. He was afebrile, hemodynamically stable, EGD was performed and gastric biopsies showed aggressive Burkitt’s lymphoma.
admission. Laboratory analysis revealed hypokalemia: 2.9 mmol/L, hypomagnesemia: 0.8 mmol/dL, hypocreatinine: 6.2 mmol/L, with ionized calcium of 0.8 mmol/L. Urine magnesium (Mg) was 10.2 mg/dL, and urinary fractional excretion of Mg was calculated to be 2.75%, consistent with renal Mg wasting. The atrial fibrillation resolved after adequate repletion of electrolytes, and he was transitioned from intravenous to oral supplements. He was discharged on drugs for hypomagnesemia, magnesium chloride, and potassium chloride supplements. Repeat labs one week post hospitalization showed stable potassium of 4.2 mmol/L and calcium 9.3 mmol/dL, however hypomagnesemia persisted to 1.3 mg/dL, requiring an increase in Mg supplementation.

Discussion: Due to chemotherapy including cisplatin and to a lesser extent carboplatin have been known to cause electrolyte disturbances, in particular hypomagnesemia. However, case reports of oxaliplatin associated magnesium wasting are limited. This can be partially explained by the fact that oxaliplatin is protein bound and cannot readily accumulate in the kidney tubules to mediate nephrotoxicity, as is the case with carboplatin which is not protein bound. Magnesium deficiency is an under recognized entity, however it can precipitate potentially fatal cardiovascular dysfunction. Clinicians need to be aware of this potential adverse effect related to oxaliplatin therapy, as its prompt diagnosis and treatment can prevent the associated complications.

**PUB217**

**Immune Checkpoint Inhibitor-Induced Renal and Cardiac Sarcoidosis**

**Jamie Lin,1 Nicolas L. Palaska,2 Omar Mamlouk,1 William F. Glass,2 Louis M. Buja,3 Ala Abudayyeh,1 University of Texas MD Anderson Cancer Center, Houston, TX; 4University of Texas Health Science Center at Houston, Houston, TX.

**Introduction:** Immune related adverse events (irAEs) associated with immune checkpoint inhibitors (ICIs) represent an incidence of 6% with increasing incidence due to the side effect of having patients receiving this therapy. Sarcoid-like / granulomatous lesions from ICIs are reported to be as high as 5% based on case series and registries. In all reported cases, patients presented with lymph node, skin, or lung involvement. We present the first case of sarcoid lesions in the heart in a patient treated with immune checkpoint therapy.

**Case Description:** A 62-year-old male with stage IV metastatic melanoma received two cycles of pembrolizumab in November 2019 followed by three cycles of ipilimumab and nivolumab. In March 2020 he was admitted with acute kidney injury, creatinine peaked at 2.85 mg/dL (baseline 0.88-0.94 mg/dL). Urinalysis and serologies were unremarkable. A kidney biopsy was obtained and revealed granulomatous tubulointerstitial nephritis with focal necroting granuloma. Acid-Fast Bacilli (AFB) and Grocott methenamine silver (GMS) stains were negative. Incidentally, the patient was noted to have increased shortness of breath. Echo revealed new-onset cardiomyopathy with ejection fraction (EF) of 22% and SVT. Cardiac catherization was negative for coronary artery disease, but endomyocardial biopsy revealed lymphohistiocytic infiltrate with granulomatous myocarditis consistent with cardiac sarcoidosis. He was initiated on pulse IV steroids with improvement of both his cardiac and renal function. EF improved to 46% and creatinine improved to 1.0 mg/dL. Follow-up PET/CT imaging showed small inginal nodes that could be sarcoidosis otherwise no indication of melanoma.

**Discussion:** Use of ICI has dramatically improved patient survival; however, there is a growing appreciation for adverse events that can be associated with increased morbidity.

To our knowledge, this is the first case of sarcoid involvement in both the kidney and heart. Our case highlights the need for aggressive approach to ICI toxicity when clinical work-up is unrevealing. The timely manner that both kidney and heart biopsies were performed allowed for definitive diagnosis and guided treatment. Despite receiving ICI therapy to treat his irAEs, he continues to have cancer response from checkpoint therapy. Further follow-up is needed to determine long-term outcomes of both irAEs and ICI therapy.

**Gemcitabine-Induced Thrombotic Microangiopathy in Breast Cancer**

**Arun Rajasekaran, Ashita J. Tolwani. The University of Alabama at Birmingham, Birmingham, AL.

**Introduction:** Thrombotic microangiopathies (TMA) are potentially life-threatening conditions caused by small-vessel platelet microthrombi and are characterized by microangiopathic hemolytic anemia, kidney injury, and thrombocytopenia. TMA associated toxicity to gemcitabine therapy (GTMA) is extremely rare and is associated with a poor prognosis, with nearly 50% of cases progressing to end stage kidney disease. The mainstay of management is withdrawal of the offending drug and supportive care.

**Case Description:** A 65-year-old Black female with a history of metastatic invasive ductal breast cancer on gemcitabine therapy, well-controlled hypertension, well-controlled type 2 diabetes mellitus without proteinuria, and normal baseline kidney function presented with a 1 month history of poor oral intake, worsening hypertension, and progressive decline in kidney function. She was receiving 1250 mg/m2/week of gemcitabine for 3 weeks/month for 1 year. She had no previous co-morbidities or risk factors prior to presentation. On admission, BP was 210/110 mm Hg, serum creatinine 2.7 mg/dL (baseline creatinine 0.9 mg/dL), serum albumin 2.6 g/dL (4 g/dL a month ago), new onset anemia (hemoglobin 6.9 g/dL) and thrombocytopenia (platelet count 51,000/mm3), serum urea 928 IU/L, and had schistocytes on blood film. Urinalysis revealed numerous acanthocytes and RBC casts. 24 hour urine protein was 1.8 g. Testing for ANA, ANCA, and hepatitis B and C serologies were negative and complements within normal range. Renal ultrasound was unremarkable. A diagnosis of GTMA was suspected.

**Discussion:** GTMA is a desoxyxurydin analogue antimitabolite, is a commonly used chemotherapeutic agent for cancers of the pancreas, breast, lung, and ovaries. GTMA is a very rare and highly fatal condition with mortality rates ranging from 50 to 70%. It is thought to be immune and non-immune mediated. Physicians should have a high index of suspicion to diagnose GTMA early in the course of the disease. Mainstay of management is discontinuation of gemcitabine therapy, supportive care, and treatment of kidney injury with dialysis if necessary.

**Recurrent Mesenteric Cyst in an ESRD Patient on Maintenance Hemodialysis**

**Muhammad Awais,1 Saloman O. Khokhar,1 Muhammad F. Akhtar,1 Fateh S. Chattah,1 Syed Rizwan A. Bokhari,2 1Prince Sultan Military Medical City, Riyadh, Saudi Arabia; 2Bassett Healthcare, Cooperstown, NY.

**Introduction:** Mesenteric cyst is a rare tumor reported with an incidence of 1:100,000 in normal population. Here we report a case of recurrent mesenteric cyst in hemodialysis (HD) patients.

**Case Description:** We chronicle a case of 47 years old male on hemodialysis for last 15 years with an unknown primary cause of end stage renal disease (ESRD). He never underwent peritoneal dialysis and had no prior history of abdominal surgery. He presented with gradual onset of abdominal pain and altered bowel habits. CT scan of abdomen and pelvis revealed encysted fluid in mesentery, measuring 10 x 5 cm, located behind the anterior abdominal wall. Patient refused enucleation procedure. Later, aspiration was done, which drained three liters transudative fluid. Cytology was negative for malignant cells, Histopathology demonstrated cuboidal epithelial cells of enteric origin and was not suggestive of mesothelial or glandular origin. One month after aspiration, patient presented with re-accumulation of cystic fluid and underwent second session of aspiration. Patient presented with worsening symptoms of abdominal distension and pain within two months of last aspiration. Repeat CT scan showed large intra-abdominal cystic lesion measuring 10 x 20 cm in mid- abdominal region, pushing all the adjacent abdominal viscera to the left side. At this time, cystic mass was surgically removed. Abdominal ultrasound and CT scan were negative for cirrhosis or Budd chiari malformation. Hepatobiliary system was also unremarkable. It re-demonstrated large mesenteric cyst 13 x 10.3 x 14.1 cm, located in the small bowel mesentery around the ligament of Treitz, extending down and exerting mass effects on the adjacent bowel loops. The extensive workup for causes of ascites, including liver disease, hepatitis panel, Tuberculosis, Brucellosis, Hydatid cyst and malignancy screening with markers namely CEA, CA 125, CA 19-9, CA 15-3, were all unremarkable. Erythrocyte Sedimentation Rate (ESR) was mildly elevated at 35 mm/ hour.

**Discussion:** This is the first reported case of recurrent mesenteric cyst in ESRD patient from KSA. Recurrent mesenteric cysts are extremely rare and are very difficult to manage. Enucleation and aspiration, both are ineffective modalities for such cysts.
**Phospholipase A2 receptor antibodies (Anti PLA2R)** show tubular injury/necrosis with swollen mitochondria. Ifosfamide enters proximal tubule and diffuses to the interstitium. It causes proximal tubular injury and Fanconi syndrome due to ifosfamide nephrotoxicity. He was managed with supportive care including repletion of deficient electrolytes and renal replacement therapy if indicated. Possible long term complications include permanent proximal tubulopathy, renal phosphaturia, and drainage of 500 ml of urine, and nephrogenic diabetes insipidus.

Aneesh A. G. and Anusha A. R.

**Fanconi syndrome due to Ifosfamide Nephrotoxicity**

**Introduction:** Ifosfamide is an alkalyting agent that is used in treatment of lymphoma, leukemia, medullary carcinoma (RMC).

**Case Description:** An 89-year-old man with a history of chronic kidney disease, hypertension, chronic lymphocytic leukaemia. She also reported cocaine use. On presentation, her blood pressure was 160/100, pulse 80, respiratory rate 20, temperature 37.2°C. She was noted to have anemia, thrombocytopenia and AKI with nephrotic-range proteinuria.

**Other remarkable labs included a low haptoglobin and a high LDH. Urinalysis revealed dysmorphic red blood cells, and peripheral smear showed schistocytes. An autoimmune process was suspected; thus, pulse steroids was initiated. A renal biopsy was suggestive of thrombotic microangiopathy (TMA). A full immunological work-up eventually resulted in a diagnosis of thrombotic microangiopathy.

**Discussion:** Although a rare disease with features that overlap with other autoimmune processes, aHUS can cause rapid decline in renal function, thus requiring early recognition and treatment. CHF-CFHR5 mutation can be negative in ~40% of the patients. In the presence of the dysregulated complement cascade, microangiopathic process and renal failure, early treatment with eculizumab is crucial in renal recovery, but the renal response to treatment can be delayed compared to the hematologic response.

**Conclusion:** We present a case of aHUS-induced acute renal failure with skin ulcerations as an unusual presenting feature. This case report serves as a reminder that aHUS can present with unusual and atypical manifestations.
Effect of Gemfibrozil on Kynurenine Aminotransferases Activity and Kynurenic Acid Production in Rat Kidney

Izabela N. Zakrocka,1 Katarzyna M. Targowska-Duda,2 Artur Wnorowski,2 Tomasz Kocki,2 Krzysztof Jozwiak,2 Waldemar Turski,1 Wojciech T. Zaluska,1
1Department of Nephrology, Medical University of Lublin, Lublin, Poland; 2Department of Biopharmacy, Medical University of Lublin, Lublin, Poland; 3Department of Experimental and Clinical Pharmacology, Medical University of Lublin, Lublin, Poland.

Background: Hypertigrylceridemia is the most common lipid disorder in chronic kidney disease. A tryptophan metabolite, kynurenic acid (KYNA), is produced from L- kynurenic (L-KYN) by kynurenine aminotransferases (KATs). KAT I and KAT II isoenzymes are the best analyzed KATs. KYNA acts predominantly as a nonseselective antagonist of ionotropic glutamatergic receptors. Diet rich in fatty acids was reported to elevate central and peripheral KYNA level. The goal of presented study was to analyze the influence of gemfibrozil, on KYNA production and the activity of KAT I and KAT II in rat kidney in vitro. Additionally, the molecular docking of gemfibrozil to KAT I and KAT II structures was performed. On the final step the microarray datamining was carried out to investigate if gemfibrozil affects the expression of KAT coding genes.

Methods: The effect of gemfibrozil on KYNA synthesis together with KAT I and KAT II activity was tested in rat kidney homogenates in vitro after 2 hours incubation in the presence of L-KYN and gemfibrozil. The drug was examined at the concentration of 1 μM, 10 μM, 50 μM, 100 μM, 500 μM and 1 mM. Production of KYNA was analyzed using the high performance liquid chromatography (HPLC) with fluorometric detector.

Results: Gemfibrozil at 100 μM, 500 μM and 1 mM decreased KYNA production in kidney homogenates in vitro to 66% (P < 0.05), 58% (P < 0.01) and 41% (P < 0.01) of control value, respectively. At 100 μM, 500 μM and 1 mM concentration gemfibrozil lowered renal KAT I activity in vitro to 68% (P < 0.05), 56% (P < 0.01) and 52% (P < 0.01) of control value, respectively. Moreover, gemfibrozil at 500 μM and 1 mM concentration decreased kidney KAT II activity in vitro to 47% (P < 0.001) and 26% (P < 0.001) of control value, respectively. Results of the molecular docking suggested that gemfibrozil may affect the active site of both KAT I and KAT II. Publically available microarray datasets suggested that the expression of KAT-coding genes does not change after gemfibrozil administration.

Conclusions: Gemfibrozil decreases KYNA production in rat kidney in vitro through inhibition of KAT I and KAT II isoenzymes. Presented results indicate a novel mechanism of gemfibrozil’s action in the kidney. Its potential role in nephrotoxicity needs verification in upcoming studies.

Outcomes in Kidney Transplantation from Increased-Risk Donor Organs: A Single-Center Experience

Maria L. Safar-Boueri, 1,2 Jean M. Francis, 3 Northwestern University Feinberg School of Medicine, Chicago, IL; 2Boston University, Boston, MA.

Background: Despite their lower Kidney Donor Profile Index (KDPI) score and demonstrated survival benefit of transplantation as compared with remain on dialysis, Public Health Service increased-risk donor (IRD) organs continue an underutilized source for transplantation.

Methods: This is a single-center retrospective cohort conducted at Boston Medical Center. Patients receiving IRD organs from 2016 and 2019 were evaluated. Baseline characteristics and outcomes one year after transplantation were described.

Results: We included 41 patients receiving IRD organs. Donors tended to be younger, with lower KDPI scores and good kidney function. Most common cause of death was anoxia from drug intoxication. Patients receiving IRD organs had stable kidney function at one year, with >70% having an estimated glomerular filtration rate (eGFR) of >60 mL/min (Table 1). None of the patients became positive for HBV, HCV or HIV.

Conclusions: Patients receiving IRD organs did not show a higher risk of infection or poor renal outcomes in this single-center population.

Prospective longitudinal study, 39 patients transplanted were analyzed, they were followed up daily until their discharge, they were divided into three groups according to their serum phosphorus (p) levels after transplantation; (Group A: $p<2.5$, B: $p=2.6$ to 4.5, C: $p>4.6$ mg/dL), the data were obtained on the days of hospitalization after his kidney transplant, obtaining this variables gender, age, type of donor, cold ischemia, days of hospitalization, urea, creatinine and GFR dayle until discharge, data are shown in numbers, percentages, mean, ANOVA test and ROC curve.
Results: A total of 39 patients, 30(76.9%) patients were male, a mean age(29.5), 38(97.4%) had a history of dialysis, 21(53.8%) they were transplanted by a living donor, cold ischemia an average of 127/min, days in hospital an average of 5.3, serum phosphorous prior kidney transplant an average 5.7(2.3) mg/dl, in the ANOVA analysis a mean serum creatinine (Group A=0.9, B=2.2, C=2.1 mg/dl), a mean GFR (Group A=100, B=65, C=48.7 ml/min), a mean urea (Group A=4423, B=3027, C=1865 ml/day) at discharge were compared; A vs B urea P=0.03 IC=1219/3913, creatinine at discharge P=0.01 IC=26.0/2.0, GFR discharge P=0.03 IC=-9.71, A vs C urea P=0.07 IC=256/5372, creatinine at discharge P=0.01 IC=4.2/0.4, GFR at discharge P=0.01 IC=8.5/9.7, AUC of 0.9, with a cutoff value of 3.65mg/dl have a TFG >/=60ml/min P=0.001.

Conclusions: Patients who decrease serum phosphorus to normal or inclusive ranges of hypophosphatemia after immediate kidney transplantation, have better renal function than those who have hyperphosphatemia at discharge, serum phosphorus may be a predictor of optimal GFR in this patients.

Baseline characteristic, ANOVA test, ROC curve.

PUB236
Routine Monitoring of Donor-Specific Antibodies During the First Year of Kidney Transplant: Is It Underrated?

Background: Kidney transplant (KT) recipients with de novo donor-specific antibodies (DSA) are at risk of graft loss. DSA could lead to a decline in kidney function due to antibody-mediated rejection (ABMR), or be asymptomatic. Efficacy and cost-effectiveness of routine DSA monitoring are not known. Confirmation of ABMR with kidney biopsy is advised. We aim to study the utility of routine DSA monitoring (RDM) in predicting rejection in asymptomatic pediatric KT recipients.

Methods: A retrospective chart review of patients who had RDM were done. Patients with clinical suspicion of rejection were excluded from the study. Demographic data and clinical features were analyzed using descriptive statistics. Continuous and categorical variables were analyzed using the student’s t-test and Fisher’s exact test respectively. A p-value <0.05 was considered statistically significant.

Results: Four out of 17 (24%) patients were tested positive for de novo DSA. There were no significant differences in age, gender, race, type of transplant, or serum creatinine between patients with positive and negative DSA. Three out of four (75%) patients had positive DSA at 4-6 months that persisted till the end of the year (1 had ABMR, 1 had T cell-mediated rejection and 1 had no rejection on biopsy), and one (25%) had positive DSA at 10-12 months with ABMR on biopsy. All patients with biopsy-proven rejection (BPR) received steroids, anti-thymocyte globulin, plasmapheresis, intravenous immunoglobulin, and/or rituximab based on the type of rejection.

Conclusions: In our small cohort, we found that for every 5.7 asymptomatic patients who underwent routine DSA testing, one had de novo DSA with BPR. Larger, controlled studies are required to further evaluate the efficacy of RDM.

PUB237
De Novo Thrombotic Microangiopathy Associated with Cytomegalovirus Infection and Alloreactivity: A Fork in the Road of Immunomodulation
Samar A. Mezquita, Karim M. Soliman, Michael Casey, Maria Aurora C. Posadas, Vinuya Rao. Medical University of South Carolina, Charleston, SC.

Introduction: De novo thrombotic microangiopathy (TMA) may yield cross-roads of diverging therapeutic approaches, not well delineated. We describe such a nephropathy in the setting of Cytomegalovirus (CMV) viremia and suspected rejection.

Case Description: A 52-year-old female with presumed hypertensive nephropathy received a deceased donor kidney transplant (KDPI 73%) complicated by progressive allograft dysfunction after 6 months. Anti-thymocyte globulin was used for induction, tacrolimus, mycophenolate mofetil and prednisone. The maintenance of immunosuppression. With step-wise rise in serum creatinine (baseline 1.7 mg/dL) to 2.5, 3.4 and 5.7 mg/dL at 6, 8, and 9 months post-transplant respectively, three allograft biopsies were obtained. Secondary focal segmental glomerulosclerosis, moderate-severe interstitial fibrosis and tubular atrophy, and a mild tubulitis were seen in all biopsies; mild glomerulitis and peritubular capillaritis in the last two, and TMA in the last biopsy. Cyclosporine (Cyd) and HLA DSA were consistently negative. Despite methylprednisone given at month 8, creatinine continued to rise to 7 mg/dl by month 9. The course was complicated by leukopenia, brief thrombocytopenia (platelet count ~ 100 K/mm), progressive anemia (Hemoglobin 11.5 to 6.8 g/dl) and diarrhea in the setting of newly diagnosed CMV viremia (CMV DNA 1164 to 9177 IU/mL at months 8 and 9 respectively). Lactate dehydrogenase increased to 841 U/L with a normal haptoglobin and no reticulocytosis. Schistocytes were seen on a peripheral blood smear. ADAMTS-13, cold agglutinins, antibodies to H, I, B, C, and C4, and stool pathogen panel were unremarkable. FK506 was switched to Cyclosporin (Cyc) after diagnosing TMA. After clearance of CMV viremia and stopping valganciclovir, neutropenia resolved. Creatinine fell from 7 to averagely 5.8 mg/dL at month 10-11. Plasmapheresis (PP) and IVIG were initiated for suspected non-HLA antibody mediated rejection (AMR) with TMA.

Discussion: The constellation of TMA, CMV viremia, tubulitis, microvascular inflammation and myelosuppression, poses dilemmas in balancing management as FK506, CMV and AMR may all be contributory, in isolation or combination to TMA. We elected to maintain a calcineurin inhibitor and mycophenolate regimen in face of TMA and CMV due to the risk of florid rejection, and initiated PP with IVIG.

PUB238
Hypofibrinogenemia as a Risk Factor of Bleeding After Plasmapheresis with Centrifuge in Renal Transplantations with Active Humoral Rejection
Mayra M. Matias Carmona,1,2 Sergio Hernández-Estrada,1,2 Jose H. Cano,1 Odette Del Carmen Diaz Avendano. 1Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico; 2Universidad Nacional Autónoma de México Facultad de Medicina, Universidad Nacional Autonoma de Mexico Facultad de Medicina, Mexico, Mexico.

Background: Humoral rejection represents an important cause of graft loss, multiple therapies have been implemented, therapeutic plasma exchange (TPE) is one of them, however one of its main complications is hypofibrinogenemia due to the risk of bleeding, which represents a challenge due to the risk of immunization in the event of a transfusion and even limiting the continuity of treatment due to the risk of bleeding imminent due to low values of fibrinogen. In the face of low figures during the passage of the session, for determination if hypofibrinogenemia(<100 mg/dl)after sessions of TPE with centrifuge is an absolute risk factor for bleeding that warrants the need for transfusion or cessation of therapy.

Methods: In the period from June 2017-May 2019, 25 Mexican kidney transplant patients with diagnosis of active humoral rejection, without previous coagulation abnormalities, were submitted to TPE; a total of 5 sessions per patient were granted in an average of 10±2 days, with measurement of fibrinogen levels before and after each session; as well as daily clinical evaluation of active bleeding.

Results: The age range was 21-35 years, 44% were female, the causes of ERTC up to 52% were not reported, cadaveric donor transplantation predominated in 52%, The initial average fibrinogen value was 397mg/dl, after the 1st session a reduction of 33% was observed, with an average value of 133mg/dl. The lowest level was 43mg/dl, the most important bleeding event was documented during the 4th session. Only 1 major bleeding event was documented due to epistaxis that required transfusion. This event was after the 3rd session, with fibrinogen of 79mg/dl. At the end of TPE treatment, fibrinogen levels normalized in all patients, with no further bleeding events.

Conclusions: Despite the strong association of hypofibrinogenemia and bleeding, only one major bleeding event was reported in our population. There were no other events despite having level as low as<50mg/dl, therefore we consider close surveillance as the main measure during TPE; leaving the transfusion only in the context of active bleeding. The blood tissue is rich in immunoglobulins and therefore favors the host’s immune response; is paradoxical to remove antibodies and grant new ones with transfusions. Hypofibrinogenemia did not limit the continuity of treatment, concluding its treatment in a timely manner.

PUB239
Kidney Transplant Recipients Suffer Fewer Complications After Adrenal Surgery
Ankur P. Choubye,1 Darren Abbas,1 Jonathan Demeter,1 Afshin Parsiakia,2 Jorge Ortiz.1 1The University of Toledo Medical Center, Toledo, OH; 2Westchester Medical Center, Valhalla, NY.

Background: Chronic immunosuppression after kidney transplant (KT) is a known risk factor for developing a malignancy. While occurrences of other cancers have been well documented, there is a paucity of data regarding the incidence and effects of adrenal tumors after renal transplantation. The aim of this study is to evaluate the differences in short-term outcomes between renal allograft recipients and the general population undergoing adrenal surgery.

Methods: A retrospective analysis was conducted using Nationwide Inpatient Sample (NIS) data between 2005 and 2014. The population of interest was adults with a kidney transplant undergoing adrenal surgery. ICD-9 codes were used to identify the procedures. Sample mean with standard deviations, and Student’s t tests were calculated for categorical variables. Odds ratios were computed using weighted data. Multivariable linear regressions were utilized to compare outcomes at transplant and non-transplant centers.

Granulomatous Tubulointerstitial Nephritis in a Kidney Transplant Recipient

Mohamed Hassanein, Leal C. Herlitz, Cyndee Miranda, Aimen Liaqat, Richard A. Fatica. Cleveland Clinic, Cleveland, OH.

Introduction: Granulomatous tubulointerstitial nephritis (GTIN) is a rare pathological diagnosis accounting for 6% of all causes of tubulointerstitial nephritis (TIN). Causes of GTIN include fungal and tuberculous infections, sarcoidosis, and medications. We describe a case of GTIN in a kidney transplant recipient (KTR).

Case Description: A 65-year-old male with a history of diabetes mellitus, hypertension, active pulmonary and ocular tuberculosis (TB), and a deceased donor kidney transplant 8 years prior was admitted for acute kidney injury (AKI). Medications included metformin, rifampin, carvedilol, insulin, and tacrolimus. Serum labs showed: creatinine (Cr) 2.65 mg/dL (baseline Cr 1.3 mg/dL), corrected calcium 13.2 mg/dL, and tacrolimus trough level 7.6 ng/mL. Urine sediment examination and kidney ultrasound were unremarkable. Further workup for hypercalcemia revealed: parathormone (PTH) 7 pg/mL, 1-25 dihydroxy-vitamin D 54.3 pg/mL, PTH related peptide <2 pg/mL, and angiotensin-converting enzyme 47 U/L. Kidney biopsy showed TIN and non-caseating granulomas (figure A) with negative acid-fast bacilli (AFB) staining, bacterial, and fungal polymerase chain reaction. He was treated with prednisone taper over 6 weeks with complete resolution of AKI and hypercalcemia.

Discussion: GTIN in KTRs is rare, with an incidence of <1% in transplanted kidney biopsies. AKI and PTH-independent hypercalcemia with a negative workup for other causes of AKI should prompt a kidney biopsy. Granulomas with multinucleated giant cells can help differentiate GTIN from acute rejection – the most common cause of TIN in KTRs. Despite negative DAB staining of the biopsy tissue sample, it was impossible to exclude tuberculous GTIN in our patient who was on anti-tuberculous therapy. Cautious initiation of steroid therapy can be effective in these cases.

Kidney Transplants from Deceased Donor After 11 Days of Hemodialysis

Ankur P. Choubye, Obi Ekwekwa, Michael Rees, Jorge Ortiz. The University of Toledo Medical Center, Toledo, OH.

Introduction: There is little consensus on the use of organs from donors with acute kidney injury (AKI) for kidney transplantation. Previously published work has supported use of AKI donor kidneys with lower ischemic time but without associated results.

Case Description: The aorta and renal arteries were ligated 11 days after the car accident in a 65-year-old male with severe AKI from rhabdomyolysis requiring 11 days of hemodialysis and DCD donor, procurement was possible because AKI due to rhabdomyolysis is transient and resolves within weeks. AKI donor-recipient matching is an individualized process. Clinician decision-making with rigorous donor and recipient selection is paramount in transplanting AKI organ.

Results: 54 patients met the inclusion criteria. KT recipients were older (p=0.001), more likely to be African American (p=0.001), and had higher Elixhauser Comorbidity Index scores (p<0.001). We noted shorter length of stay (p=0.011), lower rates of any complications (p=0.001), and fewer packed RBC transfusion (p=0.039) compared to the non-transplant cohort. There was no mortality among transplant recipients. Weighted multivariate analyses highlight that total expenditures were lower for renal allograft recipients treated at transplant centers (p=0.021).

Conclusions: Previous publications have demonstrated that history of kidney transplant has deleterious effects on surgical outcomes. In the largest national cohort analysis of adrenal surgery after KT, we discovered that despite higher age and more comorbidities, renal transplant recipients benefitted from fewer post-operative adverse events. There was additional benefit from seeking treatment at transplant centers.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
treatment: 3 were submitted to radiotherapy (RT), 1 to chemotherapy (CT) and 2 had both RT and CT. The patient developed severe RLN that was unresponsive to treatment.

Conclusions: Despite the scarcity of published series on KTR, the experience of KS in our center is in line with the literature, since it’s more common in man, the incidence is higher in the first 2 years after transplant and cutaneous lesions were the main presentation. In our series, a lower incidence of KS in the last decade has been reported. However, thorough surveillance in higher-risk groups, as HIV patients, should not be forgotten.

PUB244

Rapid Renal Allograft Failure Following Recurrence of Lupus Nephritis 12 Years After Renal Transplant

University of Iowa, Iowa City, IA.

Introduction: End stage kidney disease (ESRD) secondary to lupus nephritis (LN) is an important complication of systemic lupus erythematosus (SLE) for which the treatment of choice is to undergo a kidney transplant (KT). Following a KT, patients rarely develop recurrent lupus nephritis (RLN), but when they do, most events of recurrence occur within a few years after KT. We describe the case of a young Caucasian lady who underwent a living related KT for LN and maintained stable renal function for 12 years, and then developed severe RLN that was unresponsive to treatment.

Case Description: A 39-year-old developed severe RLN and her kidney biopsy (KB) demonstrated global sclerosis with immune complex glomerulonephritis with positive serum antimembranous (ANA) and antinuclear antibodies (ACAs) in 2006. She received living related KT in 2007. Her post-transplant course was complicated with the development of Banff grade IIa acute cellular rejection 1-month later, which was treated with steroids. She responded to treatment and remained on a baseline creatinine (C) measuring 1.2 to 1.3 mg/dL. She was maintained on tacrolimus, mycophenolate mofetil (MMF) and prednisone. Her MMF was replaced with azathioprine in an uneventful pregnancy in 2011. She had a slight increase in her baseline C over the years but maintained a stable C measuring 1.4-1.6 mg/dL. In 7/2019, the C suddenly increased to 3.9 mg/dL with proteinuria and microscopic hematuria. Her platelet counts, complement, ANA, ANCA and double stranded DNA levels were normal. A KB demonstrated features of thrombotic microangiopathy, diffuse proliferative GN with focally crescentic LN and full house pattern on IF. Despite treatment with intravenous steroids and cyclophosphamide her renal allograft function deteriorated, she required dialysis by 11/2019.

Discussion: Even patients with stable renal function maintained on standard immunosuppressive medications many years after transplantation are at risk of RLN. Our case demonstrates that RLN can manifest suddenly, and with a lack of usual laboratory features characteristic of a lupus flare. Further studies are necessary to better identify reasons for lupus recurrence in patients with long standing stable renal function.

PUB245

Simultaneous Disseminated Adenovirus Infection and Rejection in a Kidney Transplant Patient

Augusta University, Augusta, GA.

Introduction: Adenovirus can lead to serious conditions in the immunocompromised transplant recipients. It infects urothelium and causes acute hemorrhagic cystitis and either nephritis or acute rejection causing functional deterioration of transplanted kidney.

Case Description: A 52-year-old male with history of ESRD on hemodialysis received a deceased donor renal transplant. After induction with steroids and Thymoglobulin, he was maintained on mycophenolate mofetil (MMF), tacrolimus and prednisone with stable creatinine of 1.1-1.3 mg/dL. After 6 months, he presented with right lower quadrant abdominal pain, hematuria, dysuria, productive cough, fever, conjunctivitis, sore throat and diarrhea. Labs showed mild elevation of creatinine (1.5 mg/dL). Urine microscopy showed non-deformed RBCs without glomerular casts. Chest x-ray and ultrasound of transplant kidney were normal. Patient was started on intravenous fluids, ampicillin and ceftriaxone. The RPP along with the Respiratory pathogen panel (RPP) was negative for any pathogen. Urine culture had no growth. Cystoscopy was unremarkable. Patient had worsening leukopenia and proteinuria of 3.3 grams. A repeat RPP was positive for adenovirus and serum Adenovirus PCR was 28,600 copies/mL. Biopsy of transplant kidney showed mild tubulo-interstitial rejection with transplant glomerulitis and negative for adenovirus nephritis. Due to simultaneous occurrence of infection and acute transplant rejection, MMF was reduced to 250mg BID and pulse steroids were started for 5 days. Serum adenovirus PCR was decreased to 1200 copies/mL in 1 day. Day 2 of the treatment, patient had increased in Adenovirus PCR to 1900 copies/mL. Decreasing immunosuppression was avoided given recent rejection episode. Patient’s IgG level was low at 549 mg/dL and a dose of 300 mg/kg IVIG was administered. Repeat urinalysis showed resolution of hematuria and proteinuria. Serum Adenovirus PCR was undetectable at 2, 3 and 4 months follow up.

Discussion: Disseminated adenovirus infection after renal transplantation is becoming more prevalent. The treatment includes reducing the immunosuppressive therapy, IVIG infusions, anti-viral agents, or combination of these therapies. The approach to therapy is based on the guidelines for selection, timing and efficacy of treatment modalities, which requires further investigation.

PUB246

A Case Report of Transplant Renal Artery Stenosis Presenting as Acute Encephalopathy and Cardiac Arrhythmia in a 28-Year-Old Man

Neilbert Jay B. Olivares, Davao Medical School Foundation Hospital, Inc.
Davao Medical School Foundation, Davao Medical School Foundation Hospital, Davao City, PH, Davao City, Philippines.

Introduction: Transplant renal artery stenosis (TRAS), defined as narrowing of the transplanted renal artery, is one of the most serious vascular complications post kidney transplantation. TRAS presents as hypertension and allograft dysfunction at 3 to 12 months after transplantation. Unique to this case is the early presentation with behavior changes and cardiac arrhythmia. No report of such has been published as of this writing, especially in a third world setting.

Case Description: This is a case of a 28-year-old filipino male patient with post kidney transplantation one month prior to admission. Donor and recipient matching revealed low immunologic risk for rejection with four HLA matched. Transplantation was unremarkable. He presented at the ER with behavioral changes, incoherence and SVT on ECG. Medical cardioversion with adenosine and verapamil was done. He was immediately dialyzed and noted resolution of symptoms. Course in the ward was unremarkable except for the persistence of hypertension and elevated creatinine. Doppler ultrasound is suggestive of TRAS on main renal artery allograft. Renal CT angiography confirmed 50-60% stenosis of right renal artery graft. He was given amloidpine 10mg/day and eventually underwent renal angioplasty as the definitive procedure to correct stenosis. Post angioplasty blood pressure was normal and remained on this level for the following days. Serum Creatinine lowered down to 110 umol/L. Repeat Doppler scan showed an angioplasty stent in the right renal artery allograft. On his follow-up check up, his serum creatinine and BP remained on normal levels.

Discussion: The case proves that although TRAS usually presents at 3 to 12 month post kidney transplant, it may occur earlier and unusually with encephalopathy and cardiac arrhythmia. Doppler ultrasonography is essential in early detection, however, Renal CT angiogram is the imaging of choice for the confirmatory diagnosis. TRAS is catastrophic but early diagnosis and prompt medical-surgical intervention with amloidpine and renal angioplasty can lead to improved allograft survival and good prognosis for the patient.

PUB247

Management of Kidney Transplant Waiting List in Belarus

Aleksandr Kalachyv, Minsk Scientific and Practical Center of Surgery Transplantology and Hematology, Minsk, Belarus.

Background: The reasons for establishing an automated waiting list system were as follows: the main clinical information about patients was available only on paper, there was an optimal problem of choice from the list of compatible donor-recipient pairs based on a large number of factors, there were difficulties with information transfer rate, security and reliability.

Methods: The project was implemented as a web-application. The program’s interface includes several parts: Unit “file-cabinet” that contains patients’ passport data and contact information Unit “Clinical information” includes immunological and clinical data of recipients Units “Examination” and “Conclusion of the consilium” is based on examination results and determines the suitability waiting list Unit “Recipient selection” Unit “Calculation of graft function”.

Results: Web application helps to allocate donor organs by medical and social principles of selection. The social principles are: priority of patients who waited kidney transplant longer considering of donor and recipient territorial compatibility increased chances for kidney transplant patients with “incomplete” phenotype (homozygotes) priority for highly sensitized patients priority for children priority for patients who needed multiple-organ transplantation Medical principles: balance between the potential kidney transplant and recipient survival stratified accounting of histocompatibility degree between donor and recipient reduction of kidney transplant cold preservation time creation of transplantation priority conditions for patients who needed urgent kidney transplantation initial kidney graft function prognosis accounting Scoring system is based on the fact that the main feature of social justice (maximum waiting period) is equated domain medical principle of effectiveness (maximum compatibility degree). The allocation of organs accounts the risk of early graft dysfunction (automatic kidney graft function calculator based on multifactor analysis of donor - and recipient-dependent risk factors is integrated). The final result is a prioritized list of recipients with a score of each factor and to perform the final selection of the council of physicians.

Conclusions: The software application allows to keep records, make statistical data analysis of potential recipient, distribute the organs anytime, anywhere in the world where the Internet is available.

Late-Onset Recurrent Granulomatous Interstitial Nephritis in Transplanted Kidney with Successful Treatment: A Case Report
Fatmah Yanami,1 Miroslav Sekulic,1,2 Arkasarapuk Jittirat,1,2 1Case Western Reserve University, Cleveland, OH; 2University Hospitals Cleveland Medical Center, Cleveland, OH.

Introduction: End stage renal disease (ESRD) secondary renal sarcoidosis is rare and likely due to hypercalcemic nephropathy. There is limited data on recurrent renal sarcoidosis post kidney transplant. We report a case of unusually late onset, recurrent sarcoidosis in transplanted kidney with successful treatment.

Case Description: A 65 year-old female with history of pulmonary sarcoidosis and ESRD due to sarcoidosis related granulomatous interstitial nephritis (GIN) received a renal transplant in 2008. She was maintained on tacrolimus, mycophenolate(MMF) and prednisone. Baseline serum creatinine (SCr) had been 1.5 mg/dL. In 2017, patient was diagnosed with recurrent metastatic colorectal cancer. In 2019, her SCr increased to 3 mg/dL. A transplant kidney biopsy showed non-necrotizing GIN. She was treated with prednisone 40 mg daily. SCr decreased to 2.3 mg/dL. 3 months later, a repeat transplant kidney biopsy showed resolution of GIN. Prednisone dosage was tapered.

Discussion: GIN related to sarcoidosis has an overall estimated occurrence at 0.18 % of native kidney biopsies. GIN in transplanted kidney due to recurrent sarcoidosis has been reported ~17%. Risk factors for recurrence include primary renal disease related to sarcoidosis and a shorter delay between the last sarcoidosis flare and renal transplantation. Recurrence typically occurred shortly after transplantation, averaging 13 months after transplantation. More studies on treatment of recurrent renal sarcoidosis are warranted. We report a case of late onset recurrent GIN, occurring 11 years after transplantation with successful treatment.

Native kidney biopsy showed prominent, non-necrotizing GIN (A). Transplant kidney biopsy showed non-necrotizing GIN, similar to that of the native kidney biopsy (B). Immunoperoxidase staining for CD68 highlighted the interstitial histiocytes (C). Repeat allograft kidney biopsy did not show previously identified non-necrotizing GIN (D).

Elevated Donor-Derived Cell-Free DNA as an Indication for Kidney Transplant Biopsy
Aileen Wang, John D. Scandling, Colin R. Lenihan. Stanford University School of Medicine, Stanford, CA.

Background: Donor derived cell-free DNA testing (dd cf-DNA) is increasingly employed for post-kidney transplant monitoring and may influence the decision to proceed with indication biopsy. The goal of this study was to identify those patients in whom the finding of an elevated dd cf-DNA was a key factor in the decision to obtain a kidney biopsy and to review 1) their biopsy findings and 2) any resulting treatment.

Methods: We reviewed the charts of 73 patients who underwent kidney transplant biopsy and had at least 1 dd cf-DNA (AlloSure) test performed. Ten patients underwent biopsy prompted primarily by an elevated dd cf-DNA level. Biopsy findings and resultant therapeutic interventions were abstracted.

Results: The median time from transplant to biopsy was 25.5 months. 2/10 patients had a normal biopsy. 5/10 had histological findings consistent with antibody mediated rejection (ABMR) with or without concurrent T-cell mediated rejection (TCMR). 2/10 had TCMR and 1/10 had recurrent glomerulonephritis. Of those with ABMR, 1/5 had a de novo HLA donor specific antibody (DSA) and 3/5 had positive non-HLA antibody (AT1 receptor antibody (AT1R)). 8/10 patients had a therapeutic intervention following biopsy. Dd cf-DNA decreased following treatment in 4/7 patients and did not change or worsened in 3/7 patients with available follow-up dd cf-DNA testing.

Conclusions: Kidney transplant biopsies in patients with an elevated dd cf-DNA frequently yield findings that warrant therapeutic intervention. Kidney transplant biopsy should be considered in patients with elevated dd cf-DNA, even if otherwise stable. Our observations warrant further examination on the utilization of long term dd cf-DNA monitoring, particularly in immunologically high risk kidney transplant recipients.

Disseminated Nocardiosis in Renal Transplant Recipient
Mohamedanwar M. Ghandour, Mareena S. Zachariah. Wayne State University School of Medicine, Detroit, MI.

Introduction: Nocardiosis is an uncommon opportunistic Gram-positive bacterial infection caused by aerobic actinomycetes in the genus Nocardia. Nocardia can cause localized or systemic suppurative diseases involving eyes, kidneys, skin, lungs, bone, and Central nervous system. Disseminated Nocardiosis is a rare condition, seen among immunocompromised patients.

Case Description: We report the case of a 55-year-old African American kidney transplant recipient on maintenance immunosuppression who was diagnosed with cutaneous and pulmonary Nocardiosis. Presenting symptoms were shortness of breath, bilateral lower extremities pain and swelling. Tissue culture grew gram-positive bacilli specified as Nocardia farcinica from thigh and gluteal abscesses (figure 1). CT thorax showed bilateral reticulonodular opacities (figure 2). Patient was managed with immunosuppression reduction and specific treatment with high dose Bactrim in conjunction with linezolid. Combination antibiotics were continued for four weeks, thereafter Bactrim alone was continued for twelve months, at which point all lesions had healed.

Discussion: Nocardiosis with systemic involvement carries a poor prognosis. The reported patient had disseminated Nocardiosis involving lungs and skin, though lungs were thought to be the primary source of infection. However, early diagnosis and appropriate antibiotic coverage, had a favorable outcome, in a renal transplant recipient. Recommended treatment duration is 6 to 12 months with frequent imaging.
Kidney Cytomegalovirus Nephritis

Sandyia Bindrap, Paul D. Killen, Mona D. Doshi. University of Michigan, Ann Arbor, MI.

Introduction: Cytomegalovirus (CMV) is the most common opportunistic infection in solid organ transplant (SOT) recipients and is estimated to affect 15-30% of high-risk SOT recipients. Typical manifestations of CMV end-organ disease includes colitis, esophagitis, pneumonia, hepatitis, and chorioretinitis. However, late-onset CMV nephritis is rare, reported in less than 1% of renal biopsies. We present a case of CMV nephritis in a high risk renal transplant recipient who completed six months of CMV prophylaxis four weeks prior to presentation.

Case Description: A 66-year-old man with history of liver transplantation was hospitalized on post-transplant day 230 for worsening kidney function (serum creatinine 4.40 mg/dL, baseline 2.0 mg/dL) and fatigability. The patient’s history was notable for cryptogenic cirrhosis and hepatitis-re谈. Nephrology. Immune mediated injury was thought to be the cause of the persistent renal failure, a renal biopsy was performed, revealing acute tubular injury and focal severe interstitial nephritis. CMV intra-nuclear and cytoplasmic inclusions were visualized and confirmed by immunohistochemical staining. Plasma CMV DNA levels by quantitative PCR were 40662 IU/mL. Treatment consisted of IV ganciclovir at induction doses adjusted for renal clearance, followed by maintenance dose ganciclovir. His renal function improved.

Discussion: We report a rare manifestation of CMV disease with evidence of CMV in native kidney. Clinicians should have a high suspicion for late onset CMV diseases as a diagnosis in at-risk SOT recipients with signs and symptoms of genitourinary tract.

Incidence and Risk Factors in Mexican Patients with Diarrhea After Kidney Transplantation

Background: Diarrhea is one of the most frequent complications after kidney transplantation. Leads to dehydration, alteration of immunosuppressants serum levels, kidney function deterioration and graft loss. The prevalence of diarrhea varies from 20-50% globally. Focusing treatment on guidelines or recommendations, without considering local microbiology, may lead to mistakes in the management of this patients.

Methods: Cohort, analytical, retrospective study, were included kidney transplant patients from January 2014 to December 2018 in the Nephrology and Kidney Transplant Department at the Centro Medico Nacional 20 de Noviembre in Mexico City. Annual cumulative incidence and risk factors were performed. A stepwise logistic regression was used for the evaluation of risk factors. Survival analysis made by Kaplan-Meier curves.

Results: 92 patients were evaluated. Thirty two diarrhea episodes were recorded in 28 patients. 25% of the cases were in the first month after transplant, 40.6% of the episodes occurred after the first year, and authors posited 34.4% more than 6 months post-transplant. 19% of the cases were infectious etiology suspected, but only 45.8% had microbiological isolation. The most frequently isolated microorganism was Entamoeba histolytica in 45.5% of the cases. The cumulative incidence was 34%. There was no difference in graft survival in patients who developed diarrhea and those who did not (p = 0.17). Thymoglobulin induction increases up to 5 times the probability of developing post-transplant diarrhea (HR 5.98 p=0.01).

Conclusions: In our center, the cumulative incidence of diarrhea after transplantation is similar to reported in international series. The microbiology of diarrhea events, unlike that described in developed countries, is mainly associated with parasites. The impact of this complication on graft survival and accumulated survival is the same in patients who developed it versus in those who did not. Limited epidemiological data exist in our country and Latin America, fortunately an approach to rare causes of diarrhea around the world was to increase epidemiological information and thereby improve therapeutics options for this patients.

Unusual Presentation of Ramsay-Hunt Syndrome in a Kidney Transplant Recipient

Daniael Via Reque Cortes, Géssica S. Braga Barbosa, Marcelo P. Menezes filho, Tomas D. Ferreira, Jose O. Reusing, Elias David-Neto. Universidade de Sao Paulo Hospital das Clínicas, Sao Paulo, Brazil.

Introduction: Herpes-virus reactivation has long been recognized as occurring more frequently in immunocompromised individuals. There are only a few cases of Ramsay-Hunt Syndrome described after transplantation. We report a case of a kidney transplant recipient (KTR) with an atypical course due to multiple cranial nerve involvement.

Case Description: After treatment of esophageal candidiasis, a 50yo male KTR presented with persistent orofacial dysphagia, dysphonia, fever, hiccups, otalgia and vesicular lesions in the external left auditory canal, compatible with Herpes Zoster Oticus. He had undergone a deceased-donor kidney transplant ten years before, and maintained on mycophenolate mofetil (1.5 g/d), tacrolimus (2 mg/d) and prednisone (7.5 mg/d). The patient denied any recent upper respiratory infection. A naso-fibrolaringoscopy showed unilateral paralysis of the left vocal cord with saliva aspiration. Computed tomography scan of cranium, neck and thorax excluded expansive lesions. Blood polymere chain reaction test detected Varicella-Zoster Virus (VZV). Due to severe dysphagia with significant weight loss, reaching 35 kg, he received enteral nutrition through a nasogastric feeding tube during 12 weeks. He gradually recovered motor function of the 7th and 10th cranial nerves. Six months after the onset of symptoms, the patient is under full immunosuppressive therapy and feeding through mouth with occasional choking to some solids.

Discussion: Reactivation of pre-existing VZV in cranial sensory ganglia causes Herpes Zoster, which is characterized by a painful erythematous rash in the affected dermatome. Ramsay-Hunt Syndrome occurs when VZV affects neurons of the geniculate ganglion. When it occurs unusually with multiple cranial neuropathies it leads to a potential missed diagnosis and delayed treatment.

Tacrolimus: A Worth-Considering Culprit for Post-Transplant Anemia Sequelae to Parvovirus B19

Movt T. Ave, Arvind Singh. University Hospitals of Plymouth NHS Trust, Plymouth, United Kingdom.

Introduction: Haematological side effects of tacrolimus seem to be rare and their aetiology is unclear. Parvovirus B19 is an uncommon yet clinically significant infection that manifests as refractory anaemia in post-transplant patient. The exact mechanism by which tacrolimus can aggravate pure red cell aplasia (PRCA) is still unclear. Here we report a case of post-transplant anaemia where withdrawal of tacrolimus demonstrated significant improvement in chronic transfusion dependent anaemia.

Case Description: A 66-year-old male with end stage renal failure due to accelerated hypertension had a deceased donor transplantation in 2018. Before receiving his transplant, his peripheral blood counts were relatively normal. Patient was discharged nine days after operation with haemoglobin of 82 g/dL. Approximately five weeks following transplantation, the patient was found to have profound anaemia with haemoglobin level falling to 57 g/dL but white cell and platelet count remained normal. Following investigations, patient was found to have parvovirus B19 with positive DNA titre. Since then patient was transfusion dependent with two weekly red cell transfusion. Patient had two courses of IVIG, however, showed only transient improvement in viral DNA titre with no haematological improvement. Finally, tacrolimus was switched to cyclosporin A and showed rapid improvement within two weeks.

Discussion: Persistent parvovirus B19 infection can occur in immunocompromised host due to impairment of the neutralizing antibody response and/or cellular immunity thus failure to clear the virus. Tacrolimus, on the other hand, is believed to be an immunosuppressive agent without significant potential for myelosuppression. In this case, temporal relation of withdrawal of tacrolimus with improvement of anaemia suggests an etiological role of tacrolimus. The close inverse relationship between viral DNA PCR titre and erythropoietic activity reflected by the improvement of refractory anaemia showed that the direct cause of red cell aplasia was viral infection, rather than direct drug effect. Parvovirus B19 DNA copy number is generally lower than 10^8 copies and the patients is aggravated by the use of tacrolimus through impairment of its clearance by tacrolimus, which cannot be simply explained by a state of heightened immunosuppression.
Infections in the Early Period After Kidney Transplantation

Andrea A. Berchet,1 Bogdan M. Sorohan,2 Bogdan Obrisca,2 Andreea G. Andronescu,1,2 Genesc Imaiel.1,2 1Fundeni Clinical Institute, Bucharest, Romania; 2Carol Davila University of Medicine and Pharmacy, Bucharest, Romania.

Background: Infectious complications remain an important cause of morbidity and mortality in kidney transplant recipients, especially in the first year after kidney transplantation (KT). The aim of our study was to evaluate incidence, type of infectious complications and also, to identify risk factors and graft survival impact of these infections in the first 90 days after KT.

Methods: We performed a prospective cohort study, which included 67 adult patients (age ≥ 18 years), transplanted in our center between the 1st of October 2018 to the 1st of October 2019. Demographics data, recipient, donor, transplant, treatment and infections parameters were analyzed.

Results: Among the 67 patients, the mean age was 41.3 ± 10.5 years, male was the predominant recipient gender (59.7%) and 65.7% received a graft from a cadaveric donor. During the first 90 days after KT, 26 infectious episodes occurred in 22 kidney recipients (32.8%). The majority of patients (68%) developed infection in the first 30 days after KT. The most common infections with the highest infection rate 53.8% were urinary tract infections.

Discussion: We showed that infections in the early period after KT remain a common complication with negative impact on graft function, specially urinary tract infections. Likewise, induction therapy with ATG, DGF and donor age were independent risk factors for infectious complications.

AKI in Kidney Transplant Patients: A Single-Center Experience

Hay Me Me, Neha Deval, Aditi A. Sen, Shruti Kore, Sanjeet Gupta, Daniel Glick,1,2 Westchester Medical Center, Valhalla, NY.

Background: The incidence of acute kidney injury (AKI) after kidney transplantation varies depending on the centers but it is a significant risk factor for graft failure. Kidney transplantation recipients have various risk factors for AKI according to the time after transplantation, most commonly being infection, ischemia-perfusion injury, volume depletion, calcineurin induced nephropathy and acute rejection. We present the common causes of acute kidney injury in our center and the related outcomes.

Methods: A retrospective study was conducted and gathered the information from their first episode of acute kidney injury event starting from January 2011. Out of 180 patients, 65 patients were excluded due to the lack of detailed documentation. We looked up the reasons of acute kidney injury from biopsy reports and serology data and the subsequent renal outcomes.

Results: Among 115 patients, 105 patients (88%) had non-oliguric AKI and 10 patients (8%) developed oliguric AKI. Biopsy results revealed the most common cause of AKI being the transplant glomerulopathy (chronic rejection) at 23% in non-oliguric groups and 66% in oliguric groups. Only a few patients (9.5%) recovered and most of them developed chronic kidney disease with 41% in non-oliguric group. Acute cellular mediated rejection was found in 18% patients in non-oliguric group. Dialysis was needed in 13% of the oliguric patients.

Conclusions: Our data shows that non-oliguric AKI is the most common presentation in kidney transplant patients and had poor outcome. Surprisingly, the most common etiology of AKI is chronic rejection in our center. Close follow up and early detection with biopsy might help to prevent chronic kidney disease due to chronic rejection.
Magnesium Intake, Bone Mineral Density, and the Risks of Falls and Fractures in Post-Menopausal Women with Kidney Stone

Harshitha Kota,1 Xuerong Wen,2 Chao Chen,3 Jie Tang.1,4 Brown University, Providence, RI; 2University of Rhode Island, Kingston, RI; 3University of Florida, Gainesville, FL; 4University Medicine Foundation Inc, Providence, RI.

Background: Kidney stone formers are a unique patient population at high risk for fall and fractures due to dysregulated calcium homeostasis and early bone loss. Magnesium is an important component of bone, but its relation to falls and fractures among stone formers is unclear.

Methods: We performed regression analyses to determine the independent effect of dietary magnesium intake (DMI) on bone mineral density (BMD), and risks of fall and bone fracture among incident stone formers identified in the Women’s Health Initiative (WHI), a prospective longitudinal multicenter study investigating the health of post-menopausal women.

Results: Out of a total of 145,942 WHI participants free of kidney stone history at baseline, 6024 developed kidney stone after 1,601,750 patient years of follow up. Among these incident stone formers, 82% were Caucasian, 23% were above age 70. Mean DMI was 304 mg/day, 30% had high DMI defined as >348 mg/day, 38% had medium DMI defined as 241–348 mg/day and 32% had low DMI defined as <241 mg/day. A total of 238 (4%) and 2581 (43%) incident stone formers had low BMD and new falls or fractures, respectively. Both low dietary calcium intake and active smoking associated with reduced BMD (p<0.05), but DMI did not affect BMD in the multivariate regression analysis, \( \beta = 1.6, p=0.4 \). Older age, black race, history of diabetes, history of either parent having broken bones after age 40 all associated strongly with risks of fall and bone fracture (p<0.05). However, DMI again did not have such significant association after adjustment for demographics and potential confounding factors, \( \beta = 1.7, p=0.4 \).

Conclusions: DMI does not appear to affect BMD and the risk of fall or bone fracture among post-menopausal women.
