Abstract Publication
More than 3,000 abstracts are published in this supplement. Abstracts are arranged by the abstract type**, then by presentation date* for orals, and then by chronological publication number. Abstracts with a “PUB” number will not be presented at the ASN Annual Meeting.

* TH = Thursday, FR = Friday, SA = Saturday
** OR = Oral, PO = Poster, PUB = Publication Only

The presenting author’s name is underlined.

Abstract Author Index
The Author Index lists all abstract authors in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day for orals (TH, FR, or SA), and then the chronological publication number.

Abstract Keyword Index
The Keyword Index lists major keywords from each abstract in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day for orals (TH, FR, or SA), and then the chronological publication number.

Abstract Reference Format
To cite abstracts in this publication, please use the following format: Author Names: Abstract Title [Abstract]. J Am Soc Nephrol 31, 2020: Page(s).

Roxadustat for the Treatment of Anemia in CKD Patients Not on Dialysis (NDD): A Phase 3, Randomized, Open-Label, Active-Controlled Study

Jonathan Barrett,1 Bransilav Andric,2 Avtandil Tatradze,3 Michael Schoemig,2 Michael Reusch,2 Udaya Valluri,1 Christopher R. Mariat.4 University of Leicester, Leicester, United Kingdom; 2Center of Diagnostics and Nephrology, Heidelberg, and Neckarwestheim, Germany; 3National Center of Urology, Tbilisi, Georgia; 4Health Center Krusevac, Krusevac, Serbia; 5Astellas Pharma Europe B.V., Leiden, Netherlands; 6CHU St Etienne, Service Nephrologie, Transplantation, St Etienne, France.

Background: Roxadustat is an orally administered hypoxia-inducible factor prolyl hydroxylase inhibitor to treat anemia in adult CKD patients (pts). Efficacy and safety of roxadustat versus darbepoetin alfa (DA) were assessed in NDD CKD pts in a randomized, open-label, controlled phase 3 study.

Methods: NDD CKD pts with anemia were randomized to roxadustat or DA for up to 2 years. Dose adjustments were permitted to correct and maintain hemoglobin (Hb) within 10–12 g/dL. The primary endpoint was Hb response, defined as Hb ≥11.0 g/dL and an increase of ≥2.0 g/dL with BL Hb >8.0 g/dL, during the first 24 weeks of treatment without rescue therapy. Noninferiority of roxadustat to DA was declared if the lower bound of the two-sided 95% confidence interval (CI) for the difference (roxadustat – DA) in proportion of responders was >0.15. Key secondary endpoints included change in low-density lipoprotein (LDL) cholesterol, time to first IV iron use, change in mean arterial pressure (MAP), and occurrence of hypertension. Treatment-emergent adverse events (TEAEs) were assessed.

Results: Of 616 randomized pts (roxadustat, 323; DA, 293), 424 completed 2 years of treatment (roxadustat, 215; DA, 209). Mean BL Hb was 9.55 g/dL in both groups. In the per protocol set, the proportion of pts who achieved Hb response during the first 24 weeks was 89.5% (roxadustat; n=256/286) and 78.0% (DA; n=213/273), with a difference of 11.5% (95% CI: 5.6%, 17.3%). Noninferiority of roxadustat to DA was demonstrated for MAP and time to occurrence of hypertension. Superiority of roxadustat to DA was demonstrated for decreasing LDL cholesterol (p<0.001) and increasing time to first IV iron use (p=0.004). The incidence of TEAEs was comparable between roxadustat (91.6%) and DA (92.5%). Common TEAEs in both groups were end-stage renal disease, hypertension, depression, eGFR, and peripheral edema.

Conclusions: Roxadustat was noninferior to DA for Hb response during the first 24 weeks of treatment in NDD CKD pts. Safety profiles were comparable between groups.

**Results:** In the NDD population, 4270 patients were randomized (roxadustat=2386, placebo=1884), corresponding to 3870.7 and 2323.2 patient-exposure years (PEY), respectively. Neoplasm-related AE rates were 2.5/100 PEY in both the roxadustat and placebo groups. Neoplasm-related SAE rates were 1.1/100 PEY and 1.3/100 PEY in the roxadustat and placebo groups. In the DD population, 3880 patients were randomized (roxadustat=1940, epoetin alfa=1940), corresponding to 3315.3 and 3743.6 PEY, respectively. Neoplasm-related AE rates were 2.7/100 PEY and 2.3/100 PEY in the roxadustat and epoetin alfa groups. Neoplasm-related SAE rates were 1.1/100 PEY and 1.2/100 PEY. In both the NDD- and DD-CKD populations, there were no between-treatment-group differences in neoplasm-related AE and SAE rates in the roxadustat phase 3 clinical trials.

**Conclusions:** There were no clinically meaningful between-treatment-group differences in neoplasm-related AE and SAE rates in the roxadustat clinical trials.

Roxadustat Treatment Results in Consistent Improvements in Hemoglobin (Hb) vs. Placebo: An Analysis of Three Multinational Randomized Clinical Trials in Patients with Non-Dialysis-Dependent CKD (NDD-CKD)

**Background:** Roxadustat is a hypoxia-inducible factor prolyl hydroxylase inhibitor that increases endogenous erythropoietin and enhances iron utilization. To evaluate the consistency of Hb increases across studies and global geographic regions, we analyzed data from three pivotal Phase 3 trials of roxadustat in patients with anemia and NDD-CKD.

**Methods:** While based on the same trial design, the studies were performed by different investigators and companies in differing global regions. Patients with baseline Hb <10 g/dL and eGFR <60 mL/min/1.73 m² not on dialysis were randomized to roxadustat or placebo (pbo) in the OLYMPUS (North and South America, Asia-Pacific, and Europe; N=2781, 1:1 ratio to pbo), ALPS (South America, Europe, and South Africa; N=597, 2:1 ratio to pbo), and ANDUS (North and South America, Asia-Pacific, and Australasia; N=922, 2:1 ratio to pbo) double-blind randomized controlled trials (RCTs). Oral iron was administered unrestricted; intravenous (IV) iron was limited to rescue therapy with roxadustat. Mean changes from baseline in Hb, hepcidin, and iron parameters were evaluated. Pooled results are reported.

**Results:** Significant (P<0.001) and consistent improvements in Hb were observed with roxadustat vs pbo across all studies (Figure) and were maintained over time. IV iron rescue therapy use was lower with roxadustat vs pbo (Figure). Overall safety of roxadustat with roxadustat vs pbo across all studies (Figure) and were maintained over time. IV iron rescue therapy use was lower with roxadustat vs pbo (Figure). Overall safety of roxadustat with roxadustat vs pbo across all studies (Figure) and were maintained over time.

**Conclusions:** Roxadustat consistently improved anemia in patients with NDD-CKD across the global roxadustat clinical program, in studies performed by different investigators and companies in varying global locations.

Hemoglobin (Hb) Correction with Roxadustat Is Associated with Improved Iron Homeostasis in Patients with Dialysis-Dependent CKD (DD-CKD)

**Background:** In the setting of chronic kidney disease (CKD), both decreasing enteral phosphate absorption and improving iron status could lower pathologically elevated FGF23 levels and indirectly improve kidney function. In a murine model of CKD, we assessed how FC (and iron status in general) affects FGF23 levels and kidney function.

**Methods:** Five-week-old Col6a2 knockout mice were placed on five-week diets containing low iron (4 ppm), standard iron (48 ppm), or standard iron supplemented with FC (48 ppm + 1% FC) (n = 15-20 mice per group). Mice were euthanized at ten weeks of age.

**Results:** Compared to the standard iron diet group, the mice on low iron diets developed iron deficiency anemia (lower liver iron, lower hemoglobin, lower mean corpuscular volume, and higher red cell distribution width); markedly worsened kidney function (higher serum urea nitrogen, creatinine, and phosphate); and markedly higher FGF23 levels (increased bone and marrow Fgf23 mRNA expression, and approximately ten-fold higher plasma intact FGF23 concentrations) (Figure). Conversely, compared to the standard iron diet group, the mice treated with FC had similar hemoglobin (with increases in liver and serum iron not reaching statistical significance), but decreased serum phosphate; decreased marrow Fgf23 mRNA expression; approximately ten-fold lower plasma intact FGF23 concentrations; decreased systemic inflammation; and markedly improved kidney function (decreased serum urea nitrogen, serum creatinine, urine albumin-to-creatinine ratio, and expression of renal fibrosis markers, along with increased kidney Klotho mRNA expression (Figure)).

**Conclusions:** In the setting of CKD, iron deficiency anemia is associated with markedly increased FGF23 levels and worsened kidney function. In this CKD model, compared to either iron-deficient or standard iron conditions, FC decreased serum phosphate, markedly decreased intact FGF23, and dramatically improved kidney function. These data support further human studies of how FC affects CKD progression.

Regional Variation of Erythropoietin-Stimulating Agent Hyporesponsiveness in the Global Dopadistol Dialysis Study (ASCEND-D)
Ajay K. Singh, Allison Blackkory, Borut Citzman, Alexander R. Cobitz, Sergio A. Godoy, Vivekanand Jha, Kirsten L. Johannsen, Gearoid M. McMahon, Amy M. Meadowcroft, Gregorio T. Obrador, Mah Geet Wong, Iain C. Macduffall, Brighten and Women’s Hospital, Boston, MA; 2George Institute for Global Health, Sydney, NSW, Australia; 3Hennepin Healthcare, Minneapolis, MN; 4Universidad Panamericana, Mexico, Mexico; 5Royal North Shore Hospital, St. Leonards, NSW, Australia; 6George Clinical, Pilar, Argentina; 7GlaxoSmithKline, Collegetville, PA; 8GlaxoSmithKline, Research Triangle Park, NC; 9King’s College Hospital, London, United Kingdom

Background: Hyporesponsiveness to erythropoiesis-stimulating agents (ESA) is present in 10%–15% of the prevalent dialysis population. We explored baseline characteristics and predictors of ESA hyporesponsiveness in a global randomized cardiovascular outcomes study comparing an investigational hypoixa-inducible factor prolyl hydroxylase inhibitor (HIF-PHI), dopadistol, with conventional ESA treatment.

Methods: ASCEND-D (NCT02879305) recruited 2964 prevalent dialysis patients receiving ESA treatment randomized to weekly intravenous (IV) epoetin or who were iron replete at baseline. Primary ESA hyporesponsiveness definition: ESA Resistance Index (ERI, ESA Units/kg/week/hemoglobin g/L) ≥ 2 or IV ESA equivalent dose ≤ 450 Units/kg/week. Predictors of ESA hyporesponsiveness were determined using a multivariable regression model. Alternate hyporesponder definitions were explored.

Results: Using the primary defined population, 342 (12%) patients were ESA hyporesponsive. Selected baseline characteristics in the overall population and by ESA responsiveness, along with the results from the multivariable analysis, are shown below. Additional predictors of ESA hyporesponsiveness include a history of heart failure (0.013), dialysis vintage (0.033), smoking status (0.046), aspirin use (0.039), and ACEI/ARB use (0.061).

Conclusions: This is the first global HIF-PHI study to report pre-defined predictions and predictors of ESA hyporesponsiveness. While most of the strong predictors identified in our study have been previously reported, geographic region stands out as an unexpected finding that requires further investigation.

Adverse Event Rates Are Higher Post-Transfusion vs. Overall Follow-Up and Independent of Background Anemia Treatment in Patients with CKD
Robert Provenzano, Carol A. Pollock, Roberto Pecois-Filho, Anjay Rastogi, Rachel Lai, Ming Zhong, Lynda Szczech, Wayne State University, Detroit, MI; 2The University of Sydney, Sydney, NSW, Australia; 3Arbor Research Collaborative for Health, Ann Arbor, MI; 4Pontificia Universidad Catolica do Parana Departamento de Medicina, Curitiba, Brazil; 5University of California Los Angeles, Los Angeles, CA; 6Fibrogen Inc, San Francisco, CA.

Background: The use of transfusion can treat anemia in the short term but may increase the risk of adverse events. Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor (HIF-PHI) that stimulates erythropoiesis and improves iron metabolism. Roxadustat has been shown to decrease the need for transfusions in patients with chronic kidney disease (CKD).

Methods: Data were pooled from three pivotal, phase 3 studies of roxadustat vs. placebo in patients with non-dialysis-dependent (NDD-CKD) and three pivotal phase 3 studies of roxadustat vs. epoetin alfa in patients with dialysis-dependent (DD) CKD. We evaluated rates of intravascular volume-related adverse events (AEs; reported from a predefined list [heart failure, pulmonary edema, respiratory failure]) as a direct cause of excess intravascular volume or as a potential symptom) and treatment-emergent adverse events (TEAEs) during the 14-day post-transfusion period and the overall follow-up period (last dose + 28 days) in patients who had a transfusion.

Results: Intravascular volume-related AE and TEAE rates were at least 9-fold higher during the 14-day post-transfusion period vs. the overall follow-up period across all subgroups (Table). Trends in overall TEAE rates were similar across treatment groups.

Conclusions: Intravascular volume-related AEs occurred at higher rates post-transfusion across all populations. The reduction in transfusions for patients taking roxadustat could lower patient risk and healthcare resource use in managing CKD-related anemia.

A Real-World Longitudinal Analysis of Anemia Treatment Prescriptions in Non-Dialysis-Dependent CKD Patients, a CKDopps Study
Marcelo Lopes, Charlotte Tu, Jancy Zee, Murilo B. Guedes, Ronald L. Pisani, Bruce M. Robinson, Katarina Hodman, Glen James, James A. Sloan, Ziad Massy, Antonio A. Lopes, Helmut Reichel, Sandra Wachter, Michelle M. Wong, Roberto Pecois-Filho. 1DOPPS; 2Arbor Research Collaborative for Health, Ann Arbor, MI; 3Pontificia Universidad Catolica do Parana, Curitiba, Brazil; 4AstraZeneca Pharmaceuticals LP, Wilmington, DE; 5Universite Paris-Saclay, Villejuif, France; 6Universidade Federal da Bahia, Salvador, Brazil; 7Nephrological Center, Fillingen Schwenningen, Germany; 8Vifor Pharma Ltd, Clatbrugg, Switzerland; 9The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada.

Background: Previously lacking in the literature, this analysis aims to comprehensively describe longitudinal patterns of anemia management, including prescriptions of ESA and iron replacement, for non-dialysis dependent chronic kidney disease (NDD-CKD) stage 3 to 5 patients under nephrologist care.

Methods: We analyzed data from a prospective cohort of 2455 NDD-CKD patients from Brazil, Germany and the US, who were not using anemia medications (oral iron, intravenous [IV] iron, or erythropoiesis stimulating agent [ESA]) at enrollment in the Chronic Kidney Disease Outcomes and Practice Patterns Study (CKDopps). We reported the cumulative incidence function (CIF) [HK1] of anemia treatment initiation, stratified by patient characteristics. For patients that started therapy, we report the frequency of medication type at the moment of initiation, as well as switches and discontinuation over 12 months.

Results: The CIF of any anemia treatment initiation at 12 months was 54% for patients with Hb <10 g/dL. For oral iron therapy, the CIF at 12 months was 26% (19%, 32%) for TSAT=20%, and 22% (17%, 28%) for ferritin <100. For IV iron use, CIF at 12 months was 6% (3%, 11%) for patients with TSAT<20% and 4% (2%, 7%) for patients with ferritin<100mg/mL. For ESA use, the CIF at 12 months was 38% (29%, 47%) for patients with Hb <10 g/dL, and 11% (8%, 14%) for Hb 10 to <12 g/dL. Medication types at initiation and longitudinal treatment patterns (switches and discontinuation) are shown in the figure.

Conclusions: In a period of 12 months, anemia medication is initiated in a limited number of NDD-CKD patients with clinical signs that would indicate to do so. This longitudinal analysis using data from the real-world setting, call attention to a sub-optimally management of anemia in the NDD CKD setting.

Results: Deletion of Hif1α delayed progression of CKD, as CPD mice showed reduced rate of bone loss of BUN-corrected age-matched Col4a3KO mice (p<0.05). CPD mice also showed lower Fgf23 levels (80% vs. Col4a3KO) and we obtained similar results in Col4a5KO mice administered with a HIF inhibitor (-30% FGF23, -30% BUN, vs. Ctrl. Col4a5KO). CPD mice also improved trabecular and cortical bone parameters (-50% trabecular bone volume, -20% cortical porosity vs. Col4a3KO). Finally, deletion of Hif1α increased alkaline phosphatase (ALP) positive colonies and mineral deposits in Hif1αKO cultures compared to Ctrl cells, and led to a 30% reduction in Fgf23 expression.

Conclusions: Our data suggest that osseous Hif1α stimulates Fgf23 production in CKD and is a negative regulator of osteoblast differentiation and function. Thus, inhibition of Hif1α in bone might represent a novel therapeutic strategy to improve bone and mineral outcomes in CKD.

Funding: NIDDK Support

Deletion of the Sodium-Hydrogen Exchanger Isoform 6 in Mice Is Associated with an Age-Dependent Loss of Bone Volume
Daniela Hanke,1,2 Giuseppe Albano,1,2 Manuel A. Andregg,1,2 Daniel G. Fuster,1,2 Department of Nephrology and Hypertension, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland; Department for BioMedical Research, University of Bern, Bern, Switzerland.

Background: The sodium/hydrogen exchanger isoform 6 (NHE6) localizes to recycling endosomes, where it mediates endosomal alkalization through K+/H+ exchange. NHE6 function in the endosome is essential for clathrin-mediated endocytosis, recycling of ligand and endosomal signaling. Mutations in the SLC9A6 gene encoding the NHE6 isoform cause severe X-linked mental retardation, epilepsy, autism and corticobasal degeneration in humans. Patients with SLC9A6 mutations exhibit skeletal malformations, and a previous study suggested a role of NHE6 in osteoblast-mediated mineralization. The goal of this study was to explore the role of NHE6 in bone homeostasis.

Methods: NHE6 expression, osteoclast differentiation and cell-mediated resorption were assessed in osteoclast precursor cells isolated from wild-type and NHE6 knock-out mice. In a next series of experiments, we used primary osteoblasts, extracted from calvariae of new-born mice, to study NHE6 expression, proliferation, and cell-mediated mineralization in vitro. To determine the impact of the in vivo findings on structural bone parameters, we performed high-resolution microcomputed tomography (µCT) studies on lumbar vertebrae of wild-type and NHE6 knock-out mice.

Results: NHE6 protein and transcript are expressed in both primary osteoclasts and osteoblasts. In two studies with osteosarcoma and osteoblasts derived from NHE6 knock-out mice demonstrated normal osteoclast differentiation and osteoblast proliferation. However, NHE6-deficient osteoblasts exhibited a repressive deficit, and the mineralization capacity was increased in osteoblasts lacking NHE6. Microcomputed tomography studies revealed a reduced bone volume at a single lumbar vertebral site (L4) but otherwise unaltered structural bone parameters in NHE6 knock-out mice compared to wild-type mice at 3 months of age. At 6 months of age, however, NHE6 knock-out mice displayed a significantly reduced bone volume and trabecular number as well as an increased trabecular space at all lumbar vertebral studied (L3-L5) compared to wild-type mice.

Conclusions: Thus, loss of NHE6 results in an age-dependent loss of bone volume in mice. The results of our in vitro studies argue against a direct bone cell-autonomous cause of the bone phenotype observed in NHE6 knock-out mice and suggest extraneous factors as likely mediators.

TH-OR14
Circadian PTH Secretion Is Entrained by Feeding, While the Internal Circadian Parathyroid Clock Is Independent but Affected by CKD
Sören Fugestrand,1,2 Anders Nordholm,1,2 Maria L. Mace,2 Marya Morevati,2 Klaus Olgaard,2 Ewa Lewin,1,2 Dept. of Nephrology, Herlev Hospital, Copenhagen, Denmark; 1Dept. of Nephrology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark.

Background: We have previously shown that an internal molecular circadian clock operates in the parathyroid gland. We now demonstrate that the circadian clock is entrained by a 24h rhythm of PTH secretion and whether it is impacted by feeding or CKD is unknown.

Methods: Rats were kept in 12h:12h light:dark cycle and fed ad libitum. Blood samples and parathyroid glands were harvested at 4h interval (N=38). Then feeding was restricted to the inactive period inverted to the parathyroid gland clock. Mice were then fed ad libitum. Blood samples and parathyroid glands were harvested at 4h interval (N=38)

Results: Circadian rhythm was found for PTH (p<0.0002), P, FGF23 (p<0.02), and urea (p<0.0001). Restricted feeding to the habitual inactive period inverted the acrophase timing of PTH (ZT9 = ZT23, P = ZT7 = ZT21), FGF23 (ZT7 to ZT4), and urea were measured. Parathyroid expression of core circadian clock genes was examined by qPCR.

Conclusions: There are several factors that can affect PTH secretion and whether it is impacted by feeding or CKD is unknown.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
significant rhythm of Per1 (p=0.02) was abolished. In CKD the best fitting period of rhythmicity was reduced to 20h as opposed to the normal 24h for Per1, Per2, Per3 and Cry2. Significant shifts in acrophase were found for Npas2, Per3 and Cry1, while amplitude of Rev-erba increased.

Conclusions: Feeding restricted to the inactive period inverted the acrophase of plasma Ca levels. We confirmed a clear dissociation between the phase of PTH secretion rhythm and the phase of the circadian clock in the parathyroid glands. In CKD the circadian rhythm of core clock genes were significantly interfered, affecting MESOR, phase, period, amplitude as well as rhythmicity.

Shensen Li, Wenwen Li, Qingqing Liu, Haiyan Shen, Binqugan Deng, Changchun Cao. Sir Run Run Hospital, Nanjing Medical University, Nanjing, China.

Background: Secondary hyperparathyroidism (SHPT) is one of the common complications in patients with chronic kidney disease. The development of SHPT is accompanied by the change of cell composition, while the exact cell type changes and mechanism are yet to be defined. Therefore, single cell sequencing was conducted to analysis the cell composition of parathyroid gland.

Methods: In current study, parathyroids from 3 SHPT patients were digested to obtain single cell suspension. A total of 21519 cells were obtained and the mRNA expression profiles were analyzed by single cell sequencing and bioinformatics. Furthermore, the development separation track of cell subpopulations was constructed by pseudotime analysis (Figure 1A).

Results: There may be 21 cell subpopulations in parathyroid, among which 6 subpopulations (clusters 0, 1, 2, 5, 11, 17) are high function subpopulations of parathyroid, which were indicated by high expression of gene (such as insulin-like growth factor 2, PTH (parathyroid hormone), Calr (calcium receptor) and KL (Klotho) genes) (Figure 1B-D). The results of pseudotime analysis in the 6 high function subpopulations show that cluster 0 is at the beginning of the main group separation track, cluster 1, 2, 5 are in the middle, while cluster 11 and 17 are at the end (Figure 1E). Multiple genes may play major role in the differentiation of cluster 0, including tspan1, park4, atp6v0c, rpl11, rps8 and hem (Figure 1F).

Conclusions: There are 6 subpopulations out of total 21 cell subpopulations of parathyroid cells with higher parathyroid hormone secretion and regulation function in SHPT patients. Among which, cluster 0 may be the initiation differentiation cell of high functional cells, because it may be a subpopulation with high proliferation and differentiation potential.

Calcium Isotopes: A Novel Biomarker of Bone Mineralization in CKD

Rukshana Shrof,1 Mary Fewtrell,1 Ana Kolevica,2 Alexander D. Lalayannis,1,3 Claus peter Schmit,2 Dagmar-Christian Fischer,2 Anton Eisenhauer,1 1University College London Great Ormond Street Institute of Child Health, London, UK; 2Department of Research, Kieler Klinik, Germany; 3Rostock University Medical Center, Rostock, Germany; 4Center for Pediatrics and Adolescent Medicine, Heidelberg, Heidelberg, Germany.

Background: Serum Ca, bone biomarkers and radiographic imaging do not allow accurate evaluation of bone mineral balance (BMB), a key determinant of bone mineral density (BMD) and fracture risk. Naturally occurring stable (non-radioactive) Ca isotopes, 44Ca and 43Ca, are absorbed from our diet and sequestered into different body compartments following kinetic principles of isotope fractionation. Isotopically light 44Ca is preferentially incorporated into bone, and heavier 43Ca excreted in urine and feces. Their ratio (δ44/43Ca) in serum and urine gives a direct measure of BMB; δ44/43Ca is higher during bone formation than bone resorption.

Methods: Ca isotopes were measured by plasma-ionization mass-spectrometry in blood, urine, feces and dialysate. The relationship between bone Ca gain and loss was calculated using a compartment model, and expressed as δ44/43Ca. In 124 children 1009 years old (10 years of age) were measured, bone biomarkers, DXA and tibial peripheral quantitative CT (pQCT), an accurate measure of cortical BMD.

Results: In healthy children the δ44/43CaBone and δ44/43CaSerum were higher in adults (p=0.001), reflecting avid Ca uptake during bone formation. Since urinary Ca excretion is impaired in CKD, δ44/43CaBone was higher and δ44/43CaSerum lower in CKD4-5D compared to controls (p=0.001 for both). In CKD2-5D δ44/43CaBone was positively correlated with cholecalciferol (p=0.01) and alfacalcidol (p=0.02) doses, implying increased bone Ca uptake when Ca bioavailability is increased. δ44/43CaSerum was inversely correlated with biomarkers of bone formation (ALK, p=0.05) and inversely with resorption markers (PTH, p=0.013; TRAP5b, p=0.01 and CTX, p=0.006). δ44/43CaBone correlated positively with cortical BMD-Z-score (p=0.006, R2=0.39), and DXA hip BMD-Z-score (p=0.02). Significant and independent predictors of cortical BMD-Z-score were δ44/43CaBone (p=0.068, p=0.006) and PTH (p=0.039, p=0.04), together predicting 67% of the variability in BMD.

Conclusions: Ca isotope ratios provide a novel, non-invasive method of assessing bone mineralization. Defining an accurate biomarker of BMB forms the basis of future studies investigating Ca dynamics in disease states and the impact of treatments that affect bone homeostasis.

Funding: Government Support - Non-U.S.

Secondary Hyperparathyroidism Is Associated with Weight Loss and Longer-Term Mortality Among Patients Undergoing Hemodialysis: Results from the Dialysis Outcomes and Practice Patterns Study

Hirohata Kobama,1,2 Junhai Zhuo,3 Suguru Yamamoto,3 Takeanobu Nomura,4 Douglas S. Fuller,5 Keith McCallough,6 Pieter Evenepoel,7,8 Anders Christenson,9 Jinxi Zhao,10 Mona Al Rakhiami,11 Fadwa M. Al-Al,12 Eric W. Young,1 Bruce M. Robinson,13 Masafumi Fukagawa,14 1Division of Nephrology, Endocrinology and Metabolism, Tokai University School of Medicine, Isehara, Japan; 2The Institute of Medical Sciences, Tokai University, Isehara, Japan; 3Arbor Research Collaborative for Health, Ann Arbor, MI; 4Division of Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; 5Department of Nephrology and Renal Transplantation, University Hospitals Leuven, Leuven, Belgium; 6Laboratory of Nephrology, Department of Microbiology and Immunology, KU Leuven, Leuven, Belgium; 7Department of Nephrology, Peking University People’s Hospital, Beijing, China; 8Fahad Bin Jassim Kidney Center, Department of Nephrology, Hamad General Hospital, Hamad Medical Corporation, Doha, Qatar; 9Medical Affairs Department, Kyowa Kirin, Tokyo, Japan; 10Department of Nephrology, Skåne University Hospital, Lund University, Malmö, Sweden; 11Department of Medicine, Dubai Medical College, Dubai, United Arab Emirates.

Background: Wasting is a common complication of kidney failure that leads to weight loss and poor outcomes. Recent experimental data identified parathyroid hormone (PTH) as a driver of adipose tissue browning and wasting, but little is known about the relations among secondary hyperparathyroidism (SHPT), weight loss, and risk of mortality in patients undergoing hemodialysis.

Methods: We included 42,319 participants receiving hemodialysis for at least one year in the DOPPS phases 2-6 (2002-2018). Linear mixed models were used to estimate the association between baseline PTH and percent weight change over 12 months, adjusting for country, demographics, comorbidities, and labs. Accelerated failure time models were used to assess 12-month weight loss as a mediator between baseline high PTH and mortality after 12 months.

Results: At baseline, mean (SD) body weight was 74 (22) kg and the median PTH level was 251 pg/mL (interquartile range [IQR], 131-444 pg/mL). Baseline PTH was inversely associated with 12-month weight change: 12-month weight loss >5% was observed in 21%, 18%, 18%, 17%, and 16%, and 14% of patients for PTH ≥600 pg/mL, 450-600, 300-450, 150-300, 50-150, and <50 pg/mL, respectively. In adjusted analysis, 12-month weight change compared to PTH 150-299 pg/mL was -0.60%, -0.12%, 0.10%, +0.15%, and +0.35% for PTH ≥600, 450-600, 300-450, 150-50, and <50 pg/mL, respectively (P<0.01). Interacting baseline PTH*appetite, high PTH was associated with weight loss only in persons with preserved appetite (P<0.01). During follow-up after the 12-month weight measure (median, 1.0 [IQR, 0.6-1.7] years; 6,127 deaths), patients with baseline PTH ≥600 pg/mL had 11% (95% CI, 9-13%) shorter lifespan, and 18% (95% CI,14-23%) of this effect was mediated through weight loss a 2.5%.

Conclusions: Our findings indicate that SHPT may be a novel mechanism of wasting in dialysis patients, corroborating experimental data, and that this pathway may be a mediator when elevated PTH levels and mortality. Future research should examine whether PTH-lowering therapy can limit or prevent weight loss and improve longer-term dialysis outcomes.

SNF472 Consistently Slows Progression of Coronary Artery Calcification Across Subgroups of Patients on Hemodialysis

Glenn M. Chertow,12 Paolo Raggi,1 Antonio Bellasi,2 David A. Bushinsky,3 Jordi Bover,4 Mariano Rodriguez,5 Markus Ketteler,6 Sneeta Sinha,7 Rekha Garg,8 Claire S. Pagdant,9 Joan Perello,10,11 Alex Gold,12 Mazankowski Alberta Heart Institute and University of Alberta, Edmonton, AB, Canada; 1Research, Innovation and Brand Reputation Unit, ASST Papa Giovanni XXIII, Bergamo, Italy; 2Department of Medicine, University of Rochester Medical Center, Rochester, NY; 3Department of Nephrology, Fundació Puigvert and Universitat Autònoma, IIB Sant Pau, REDinREN, Barcelona, Spain; 4Department of General Internal Medicine and Nephrology, Robert-Bosch-Krankenhaus, Stuttgart, Germany; 5Department of Renal Medicine, Salford Royal NHS Foundation Trust, Salford, United Kingdom; 6Research and Development, Sanifit (now with PharmaDRS Consulting), San Diego, CA; 7Research and Development, Sanifit, San Diego, CA; 8Research and Development, Sanifit, Palma, Spain; 9University of the Balearic Islands, Palma, Spain; 10Department of Medicine, Stanford University, Palo Alto, CA.

Background: In the CalLPSO study, SNF472 significantly attenuated progression of coronary artery calcium (CAC) volume score compared with placebo. This pre-specified analysis examined CAC progression in key subgroups.

Methods: Patients were randomized to SNF472 300 mg (n=92), SNF472 600 mg (n=91) or placebo (n=91) infused 3x/week during hemodialysis (HD) for 52 weeks on standard care therapy determined by each investigator. We examined change in log CAC volume score from baseline to week 52 in the combined SNF472 dose groups vs placebo for subgroups of age, sex, diabetes, dialysis vintage, arteriosclerotic cardiovascular disease (ASCVD), use of non-Ca phosphate binders, Ca-based phosphate binders, calcimimetics, activated vitamin D, warfarin, or statins in the modified ITT population (mITT, defined as subjects who received at least one dose of study drug and had an evaluable post-baseline CT scan).

Results: Baseline characteristics were similar across treatment groups: mean age was 64 y, 39% were female, 62% had diabetes, and 41% had prior ASCVD. Median HD vintage was 42 mo; 33% received HD for ≥5 years. Concomitant medications at baseline were: 62% non-Ca phosphate binders, 28% Ca-based phosphate binders, 31% calcimimetics, 51% activated vitamin D, 8% warfarin, and 64% statins. In the overall mITT, CAC progression volume was 11% in the combined SNF472 groups vs 20% in placebo (p=0.016). Treatment differences for CAC volume progression were similar across subgroups (Figure). All interaction p-values were non-significant and comparisons favored SNF472 vs placebo in each subgroup.

Conclusions: SNF472 treatment for 52 weeks attenuated CAC progression compared with placebo in all subgroups.

Pharmacodynamic (PD) Profiling of Reloxaliase in Patients with Severe Hyperoxaluria

Felix Knauf,2,3 Danica Grujec,1 Mira T. Keddis,4 Alicia Weeks,1 Annamaria T. Kausz,1 Allena Pharmaceuticals, Newton, MA; 2University Hospital Charite, Berlin, Germany; 3Mayo Clinic Hospital, Phoenix, AZ.

Background: Hyperoxaluria is a major risk factor for kidney stones and can lead to chronic kidney disease (CKD). With decreasing kidney function, plasma oxalate (POx) rises and oxalate may deposit in the kidneys and other tissues (systemic oxalosis) leading to ESRD. Reloxaliase (REL), a non-absorbed, oxalate specific oral enzyme therapy designed to degrade oxalate along the GI tract, may potentially reduce the systemic and renal oxalate burden in patients with enteric and primary hyperoxaluria (EH and PH). This study tested the PD of REL, and addressed questions regarding potential systemic accumulation (by-product of oxalate degradation) and systemic absorption of oxalate decarboxylase (OxDc, the active component of REL).

Methods: This 12-week, open label study enrolled subjects with EH, CKD and hyperoxalemia (UOx ≥40 μg/dL, eGFR <55 mL/min and POx>5μmol/L, n=10) and PH (UOx ≥40 μg/dL, n=5) who received 7,500u of REL 5x/day with meals/snacks. Parameters assessed at baseline, and weeks 4, 8 and 12 included POx and UOx (only if eGFR >15 mL/min), plasma formic acid (pre- and post-prandial/post-dose; Q' Solutions) and OxDc (specific ELISA, Absorption Systems).

Results: Reported adverse events (AEs) were mostly GI related; there were no related serious AEs. In EH, both POx and UOx decreased substantially; in PH, UOx did not change, and POx stayed normal at baseline and during treatment (Table). There was no systemic accumulation, as all samples were below or within normal range (1-9 mg/L). Similarly, there was no detectable absorption of REL, as all samples were below the limit of detection of the assay for OxDc (<0.0001% of the administered dose of 37,500 u/day).

Conclusions: Reloxaliase was well tolerated; the absence of formate accumulation further supports its safety. The lack of REL absorption, in addition to supporting low potential for systemic toxicity, confirms its site of action within the GI tract. This best aligns with the pathophysiology of EH as evidenced by the substantial reduction in both POx and UOx in EH subjects with CKD/ESRD.

Efficacy and Safety of Upacicalcet in Hemodialysis Patients with Secondary Hyperparathyroidism: A Phase 3 Study

Tadao Akizawa,1 Daisuke Honda,2 Masaki Taniguchi,3 Fumihiko Koiwa,4 Showa University School of Medicine, Tokyo, Japan; 2Sanwa Kagaku Kenkyusho Co., Ltd., Nagoya, Japan; 3Sanwa Kagaku Kenkyusho Co., Ltd., Nagoya, Japan; 4Showa University Fujigaku Hospital, Yokohama, Japan.

Background: Secondary hyperparathyroidism (SHPT) is a major complication of hemodialysis (HD) patients. Calcimimetics suppress the hyperfunction of parathyroid and reduce serum calcium and phosphorus levels, and are currently used for the treatment of SHPT. Upacicalcet (UPA) is a novel intravenous small molecule calcimimetic in late stage development in Japan to treat SHPT of HD patients. We report the efficacy and safety of UPA in HD patients.

Methods: This study was a phase 3, multicenter, randomized, double-blind, placebo-controlled, parallel-group study. UPA or placebo (PBO) was administered i.w. at the end of HD at an initial dose of 50 mcg or 25 mcg. The doses were subsequently adjusted to maintain serum intact PTH (iPTH) levels between 60-240 pg/ml (recommended level of Japanese guideline) every 3 weeks between 25 and 300 mcg during 24 weeks of treatment. The primary endpoint was the proportion of patients who achieved a mean iPTH level of 60-240 pg/ml in weeks 22 to 24.

Results: A total of 154 SHPT patients were enrolled, and randomly allocated to UPA group (n: 103) or PBO group (n: 51). The primary endpoint, percentage of patients achieving the target iPTH range was greater for UPA (67.0%) than for PBO (8.0%) (P<0.001). UPA significantly reduced iPTH and cCa levels compared with PBO (Fig.). Concerning phosphorus, no statistically significant difference between the groups was observed while it tended to decrease in the UPA group. In the safety assessment, treatment emergent adverse events (AE) occurred in 88 patients (85.4%) and 36 patients (72.0%) in the UPA and the PBO groups. The incidences of upper-gastrointestinal-related AE were 20.4% in the UPA and 18.0% in the PBO groups (P=0.8298). As an AE, hypocalcemia did not occur in either group.

Conclusions: This study demonstrates that UPA significantly decreases iPTH without increasing the incidence of upper-gastrointestinal symptoms as compared to PBO. It is suggested that UPA will be a promising calcimimetic agent capable of safe and appropriate management of SHPT.

Funding: Commercial Support - Sanwa Kagaku Kenkyusho Co., Ltd.
Background: The primary cilium is an organelle found on essentially all epithelial cells. Similarly, the glyocalyx is a matrix-like layer of proteoglycans, glycosaminoglycans (GAGs) and proteins covering the surface of all cells. In vascular endothelial cells, primary cilia and GAGs such as heparan sulfate and chondroitin sulfate mediate responses to the mechanical forces exerted by blood flow. In thick ascending limbs, increases in luminal flow enhance nitric oxide (NO) production, an important regulator of the kidney function including sodium reabsorption; however, the role of primary cilia and the glyocalyx in NO production by thick ascending limbs is unknown. We hypothesized that primary cilia and the glyocalyx act as flow sensors and thus mediate flow-induced NO production by thick ascending limbs.

Methods: We measured flow-induced NO in isolated rat thick ascending limbs using DAF-FM. Intracellular NO was first measured during the control period without and with luminal flow. NO was measured again during the experimental period after treating tubules for 15 min to deciliate cells or to degrade major glyocalyx GAGs. Dibucaine (0.1 mM) was used to remove cilia from cells. Heparinase III (0.2 or 0.4 U/ml) and chondroitinase ABC (0.2 U/ml) were used to degrade heparan sulfate and chondroitin sulfate, respectively.

Results: In untreated control tubules, flow-induced NO did not differ between the two periods, 4.3 ± 1.03 vs 4.68 ± 0.84 arbitrary units (AU)/min. Dibucaine decreased flow-induced NO from 4.25 ± 0.62 to 1.19 ± 0.65 AU/min (p < 0.002). Heparinase (0.2 U/ml) attenuated flow-induced NO from 4.02 ± 0.84 to 1.70 ± 0.74 AU/min (p < 0.04), a higher concentration (1.0 U/ml) caused a greater effect (0.96 ± 1.36 vs 0.41 ± 0.14 AU/min; p < 0.006). Heat inactivation of heparinase (0.2 U/ml) abolished its effect (3.01 ± 0.34 vs 2.83 ± 0.22 AU/min). Chondroitinase (0.2 U/ml) decreased flow-induced NO from 4.17 ± 0.96 to 2.45 ± 0.49 AU/min (p < 0.038).

Conclusions: We conclude that both primary cilia and the glyocalyx act as flow sensors in thick ascending limbs and transduce mechanical stimuli into chemical signals that ultimately result in NO production by this segment.

Cell-Autonomous Expression of Membrane Transport Proteins in Mammalian Distal Nephron

Background: Reabsorption of NaCl in kidney thick ascending limb (TAL) via NKCC2 involves the action of luminal (ROMK) and basolateral (Kır4.1/Kir5.1) multionis, potassium channels, a basolateral calcium sensing receptor (CaSR), and the claudin (Cldn) family of proteins. Morphological heterogeneity of TAL cells has been reported, as well as mosaic expression of ROMK and Kir.4.1. We hypothesized that this variability between TAL cells extends to other aspects of their function.

Methods: We studied TAL EM morphology, zonal and cell-autonomous heterogeneity of the transport proteins at steady state in mice, rats and humans, and under stimulation by vasopressin (AVP; V2R agonist dDAVP for 72 h) using AVP-deficient Brattleboro rats. NKCC2, phosphorylated (p) NKCC2, ROMK, Kir4.1, CaSR, Cldn-10 and Cldn-16 signals were induced by immunofluorescence, in situ hybridisation (ISH), EM and Western blot (WB).

Results: Between cortex and medullary kidney zones, TAL morphological cell heterogeneity was observed, but not at a cell-to-cell level within each zone. NKCC2 was continuously expressed in all TAL cells, while pNKCC2 signals were heterogeneous, increasing from inner stripe of outer medulla to cortex and varying between cells of each zone. ROMK and Kir.4.1 protein expression showed conspicuous heterogeneity in a mutually exclusive pattern, with stronger pNKCC2 expression in the ROMK-negative or Kir.1-positive cell type. CaSR and Cldn-16 signals were moderate to absent in ROMK-positive cells, but intensified in ROMK-negative cells, while Cldn-10 was strongly expressed only in ROMK-positive cells. ISH revealed no cell heterogeneity of ROMK mRNA. In Brattleboro rats, 72h dDAVP increased the number of ROMK- and Kir.1-positive cells and the overlap of both signals in mTAL, and stimulated NKCC2 ROMK mRNA. In Brattleboro rats, 72h dDAVP increased the number of ROMK- and Kir.1-positive cells and the overlap of both signals in mTAL, and stimulated NKCC2 ROMK mRNA.

Cldn-10 expression was induced in the outer stripe of outer medulla. Kir4.1-positive cells and the overlap of both signals in mTAL, and stimulated NKCC2 ROMK mRNA. In Brattleboro rats, 72h dDAVP increased the number of ROMK- and Kir.1-positive cells and the overlap of both signals in mTAL, and stimulated NKCC2 ROMK mRNA. In Brattleboro rats, 72h dDAVP increased the number of ROMK- and Kir.1-positive cells and the overlap of both signals in mTAL, and stimulated NKCC2 ROMK mRNA.

In Brattleboro rats, 72h dDAVP induced NO from 4.02 ± 0.84 to 1.54 ± 0.49 AU/min (p < 0.002). Heparinase (0.2 U/ml) attenuated flow-induced NO from 4.25 ± 0.62 to 1.19 ± 0.65 AU/min (p < 0.002). Heparinase (0.2 U/ml) attenuated flow-induced NO from 4.02 ± 0.84 to 1.70 ± 0.74 AU/min (p < 0.04), a higher concentration (1.0 U/ml) caused a greater effect (0.96 ± 1.36 vs 0.41 ± 0.14 AU/min; p < 0.006). Heat inactivation of heparinase (0.2 U/ml) abolished its effect (3.01 ± 0.34 vs 2.83 ± 0.22 AU/min). Cldn-10 (0.2 U/ml) decreased flow-induced NO from 4.17 ± 0.96 to 2.45 ± 0.49 AU/min (p < 0.038).

Conclusions: We conclude that both primary cilia and the glyocalyx act as flow sensors in thick ascending limbs and transduce mechanical stimuli into chemical signals that ultimately result in NO production by this segment.

Positive Allosteric Modulation of the Calcium-Sensing Receptor (CaSR) by Glucose or Fructose Induces Activation of the Sodium-Chloride Cotransporter (NCC)

Jessica P. Bahena-Lopez,1,4 Lorena L. Rojas,1 Silvana Bazzu-Valenti,1 Norma H. Vázquez,1 María Chavez-Canales,2 María Castañeda-Bueno,1 Magdalena Madero,1 Gerardo Gamba,1,4 Molecular Physiology Unit, INCMNSZ and IIB, UNAM, Mexico City, D.F., Mexico; 2Traslational Medicine Hospital RWTH, Aachen, Germany.

Background: The abundance of the distal convoluted tubule (DCT) thiazide-sensitive sodium chloride cotransporter (NCC) is greater in females than males. Because structural remodeling of the DCT is dependent on NCC activity, it has been generally assumed that there is a corresponding sexual dimorphism in DCT morphology. Until now, this has never been directly examined. Here, combining new optical clearing techniques with structural analyses of DCT segments, volumetric imaging we quantitatively assess DCT morphology in male and female mice and study DCT remodeling response to furosemide.

Methods: Male and Female (3-month-old) mice were treated with vehicle or Furosemide administered in the food (100 mg/kg per day) for seven days. Total NCC and phospho-active NCC abundance (pNCC) was evaluated by Western Blot in one kidney, the other kidney was perfused and fixed for imaging. Kidneys were cleared using the Clear, Unobstructed Brain/Body Imaging Cocktails and Computational Analysis (CUBIC) pipeline, co-stained with antibodies that label the early DCT (DCT1, paravalbumin) and the entire DCT (DCT2 & NCC), imaged using a high-speed spinning disc confocal microscope, and processed with 3D rendering and analysis software (IMARIS).

Results: We confirmed previous studies that females have greater NCC abundance in the basal state. Surprisingly, the length of the DCT was longer in males (~620 μm) than female mice (~560 μm). Furosemide treatment significantly increased the abundance of NCC and pNCC in both sexes. Furosemide delivery to the DCT was paralleled by an increase in DCT length and volume. The remodeling response to furosemide was more profound in females (~20% increase in DCT length and 50% in DCT1 volume) than males (~8% and 30%, respectively). The DCT extension of furosemide treatment in females stemmed largely from an increase in DCT1 length. Furosemide expanded the DCT2 significantly in males but not females.

Conclusions: Our study reveals a surprising sexual dimorphism of the DCT. The greater NCC density in a shorter structure may provide a means for females to protect sodium balance. Further work to unravel the DCT remodeling response to furosemide, but have larger reserve and remodeling capacity to adapt to unique physiological stresses.

**Cross-Talk Between Epithelial Sodium Channel and Basolateral Kir4.1/Kir5.1 Channels in the Cortical Collecting Duct**

Oleg Palgyin, Elena Isaeva, Vladimir Levenchuk, Jerod S. Denton, Alexander Staruschenko. 1Medical College of Wisconsin, Milwaukee, WI; 2Clement J. Zablocki VA Medical Center, Milwaukee, WI; 3Vanderbilt University Medical Center, Nashville, TN.

**Background:** The growing body of evidence suggest that inwardly rectifying K⁺ (Kir) channels located on the basolateral membrane of epithelial cells in the distal nephron play a crucial role in K⁺ handling and blood pressure control, making these channels attractive targets for the treatment of hypertension. The purpose of the present study was to determine how the inhibition of basolateral Kir4.1 homomeric or Kir4.1/Kir5.1 heteromeric K⁺ channels affects ENaC-mediated Na⁺ transport in the cortical collecting duct (CCD) principal cells.

**Methods:** Electrophysiological approaches were used to test the effect of fluoxetine, amitriptyline, and, recently developed Kir4.1 inhibitor, VU0134992, on the activity of Kir4.1, Kir4.1/Kir5.1, and ENaC. Channel activity was recorded in CHO cells transfected with respective channel subunits, cultured polarized epithelial mCCD cells, and native freshly isolated rat and human CCD tubules. To test the effect of pharmacological Kir4.1/Kir5.1 inhibition on electrolyte homeostasis in vivo, Dahl salt-sensitive rats were injected with amitriptyline (15 mg/kg/day).

**Results:** We found that inhibition of Kir 4.1/4.5, but not K⁺ 4.1 channel, substantially suppresses both amiloride-sensitive Iₘ₈ in mCCD cells and single-channel ENaC activity in principal cells of rat and human CCD tubules. Furthermore, we demonstrated that i.p. injection of Kir4.1/Kir5.1 antagonist for three days leads to a significant drop in plasma K⁺ level, triggering sodium excretion, and diuresis.

**Conclusions:** These data uncover a putative mechanism underlying a renal control of blood electrolytes mediated by Kir4.1/5.1 and introduce a new molecular target for the treatment of salt-sensitive hypertension.

**CIC-K2 Chloride Channel Determines Acid-Base Transport and Chloride Reabsorption in Intercalated Cells of the Collecting Duct**

Najmeh Hassanzadeh Khayat, Victor N. Tomilin, Oleg L. Zaika, Oleh Pochynyuk. University of Texas John P and Katherine G McGovern Medical School, Houston, TX.

**Background:** Intercalated cells (ICs) of the collecting duct (CD) play a critical role in regulation of systemic acid-base homeostasis. In addition, ICs are capable of performing trans-cellular Cl⁻ reabsorption particularly during volume depletion. While the major apical membrane transport systems are well characterized, little is known about mechanisms and contribution of the basolateral membrane in both processes. Kidney specific CIC-K2 is expressed in the basolateral membrane of the distal nephron segments, including the CD.

**Methods:** We generated CIC-K2 deficient mice using Cre-loxP strategy to investigate the role of the channel in acid-base and Cl⁻ transport. We combined BCECF-sensitive intracellular pH (pH) measurements with fluorescent AQPB2-based identification of principal cells (PCs) and ICs to assess CIC-K2-dependent pH changes in different cell types.

**Results:** CIC-K2 inhibition with NPPB (100 µM) had no effect in PCs of WT mice, whereas it induced rapid intracellular acidification in B-type and alkalinization in A-type of ICs. NPPB failed to significantly affect pH in CD from CIC-K2 deficient mice. Extracellular Cl⁻ removal to drive basolateral Cl⁻ exit via CIC-K2 had no effect on pH in PCs, but caused alkalinization in B-type and acidification in A-type of ICs. Importantly, Cl⁻ removal did not induce pH changes in both A- and B-type of ICs from CIC-K2 deficient mice. This suggests that CIC-K2 mediates trans-cellular Cl⁻ reabsorption and determines apical acid-base transport by controlling intracellular Cl⁻ concentration. Moreover, application of Angiotensin II (Ang II, 500 nM) increased ClC-K2 single channel activity whereas it induced rapid intracellular acidification in B-type and alkalization in A-type of ICs. Importantly, Cl⁻ removal to drive basolateral Cl⁻ exit via ClC-K2 had no effect on pHi in different cell types.

**Conclusions:** Together, our results show that CIC-K2 is central for acid-base transport in the CD. CIC-K2 activity can be independently regulated in A- and B-type of ICs during different physiological conditions to allow fine tuning of renal acid-base handling.

TH-OR27

**Evolutionary Conserved TLDc Domain Defines a New Class of V-ATPase Interacting Proteins**

Amity F. Eaton, Dennis Brown, Maria Merkulova. Program in Membrane Biology Massachusetts General Hospital, Boston, MA.

**Background:** Kidney-specific V-ATPase regulates acid-base homeostasis, and its dysfunction causes distal renal tubular acidosis (dRTA). We recently found that nuclear receptor coactivator 7 (Ncoa7) interacts with kidney V-ATPase, and its deletion in mice resulted in dRTA. Ncoa7 belongs to a group of proteins playing a role in the oxidative stress response, that contain the evolutionarily conserved TLDc domain. We found that another of these proteins, Oxr1, also interacts with the V-ATPase. Here we asked if other proteins from this family, i.e. Tbc1d24, Tdcl and Tdcl2 interact with V-ATPase in kidney and if their TLDc domains mediate this interaction.

**Methods:** Interaction between endogenous Tbc1d24, Tdcl and Tdcl2 and V-ATPase was assessed by co-immunoprecipitation (co-IP) and western blotting of mouse kidney lysates. Interaction with the V-ATPase was also studied by GST pull-downs from kidney lysates using purified GST-tagged wild-type TLDc domains of Ncoa7, Oxr1, Tbc1d24, Tdcl and Tdcl2, or mutant TLDc domains of Ncoa7 (G802A, G815A, S817A, G845A, G889A, L926A, E938A) followed by western blotting for B1.

**Results:** In Co-IP studies of mouse kidney lysates we found that endogenous Tbc1d24 interacted with the B1 subunit isoform of V-ATPase, but not with the more ubiquitous B2 subunit isoform. However, we did not detect any interaction between V-ATPase and endogenous Tdcl or Tdcl2 in Co-IPs, possibly due to low sensitivity of the anti-Tdcl1 and anti-Tdcl2 antibodies. Additionally, we found that the purified TLDc domains of Ncoa7, Oxr1 and Tdcl2, but not Tbc1d24 or Tdcl1, interacted with V-ATPase in GST pull-downs. Finally, the G815A, G845A and G896A mutants in evolutionarily conserved regions of the Ncoa7 TLDc domain did not interact with V-ATPase, L926A and E938A mutations resulted in a decreased interaction, while S817A or the non-conserved G802A mutation (used as a positive control), did not decrease interaction at all.

**Conclusions:** In the kidney, Tbc1d24 and possibly Tdcl2, as well as Ncoa7 and Oxr1, interacted with V-ATPase and may play a role in the V-ATPase-dependent regulation of renal acid-base homeostasis. We conclude, that the Tdcl motif is a protein-protein interaction domain that defines a new class of V-ATPase interacting regulatory proteins. The evolutionary conserved amino acids within the TLDc domain of Ncoa7 are critical for its interaction with the V-ATPase.

TH-OR28

**Lysine Acetylation of Aquaporin 3 Affects Water Permeability of the Collecting Duct**

Kelly A. Hyndman, Parker R. Davis, Luciano D. Mendoza. The University of Alabama at Birmingham School of Medicine, Birmingham, AL.

**Background:** We recently reported that there are > 400 proteins in the inner medullary collecting duct (IMCD) that are post-translationally lysine acetylated (ac), including the basolateral water channel, aquaporin-3 (AQ3). The purpose of this study was to determine if lysine acetylated AQP3 (acAQP3) affects water permeability.

**Methods:** We developed an antibody to detect acAQP3 and found acAQP3 localized to the basolateral membrane of the cortical and outer medullary CD in mice and human kidney biopsies. In mice, following 24 h of water deprivation, acAQP3 was also found in the IMCD. Next, we developed acQP3 K point mutation plasmids; an acetylated mimetic K282Q (AQP3α), and a deacetylated mimetic K282R (AQP3β). These were stably expressed in vasopressin-responsive mouse cortical CD cells and loaded with a volume sensitive dye. Finally, using CRISPR/CAS we engineered whole body point mutation mice. The AQP3α, AQP3β and lattternate controls AQP3W1/W1 were placed on standard chow and: 1) ad lib water, 2) 5% sucrose water for hydration, or 3) 24 h water deprivation and urine flow measured.

**Results:** Following osmotic stimulus, we found AQP3α cells had the highest water permeability followed by the AQP3W1/W1 cells and the AQP3β cells. From our mutant mice, as adults, control and AQP3β mice had similar urine flow on all protocols. However, the AQP3α mice produced double the urine on protocols 1 and 2. Thus, maintenance of deacetylated AQP3 enhances fluid excretion under normal and hydrated conditions. To further determine whether the increased urine flow was due to impaired water permeability, we immunolocalized AQP2 and AQP3 under ad lib conditions. AQP3α mice had enhanced expression of AQP3 in the basolateral membrane, and reduced AQP2 expression in the apical membrane. In contrast, the AQP3β mice had diffuse AQP3 localization in the CD, with no obvious change in AQP2.

**Conclusions:** Together, these preliminary data suggest that acAQP3 promotes localization to the basolateral membrane of the CD and supports the hypothesis that acAQP3 could serve as an important regulator of CD function in fluid homeostasis.

**Funding:** NIDDK Support
Role of TRPC3 in the Control of Osmosensitivity and Renal Water Handling in the Mouse Collecting Duct

Víctor N. Tomlin,1 Mykola Mamenko,2 Naghem Hassanzadeh Khayyat,1 Oleg L. Zaika,1 Oleh Pochynyuk1
1University of Texas John P and Katherine G McGovern Medical School, Houston, TX; 2Austin University Medical College of Georgia, Augusta, GA.

Background: Kidney is central in the control of systemic water balance of the organism. A VP facilitates aquaporin 2 (AQP2) translocation to the apical membrane and regulates AVP-dependent water excretion.

Methods: The employed techniques include simultaneous measurement of [Ca2+]i, with Fura 2 and the rate of cell swelling as a readout of the AQP2-dependent water reabsorption in freshly isolated split-opened CD of wild type and TRPC3−/− mice; immunofluorescent detection of AQP2-induced AQP2 trafficking to the apical membrane and metabolic cage balance studies.

Results: TRPC3 is a Ca2+-permeable mechano-activated channel abundantly expressed in the CD. We found that TRPC3 deletion or pharmacological inhibition precluded [Ca2+]i elevations induced hypotonicity and severely slowed the rate of cell swelling indicative of diminished water transport in the CD. TRPC3−/− and WT mice had comparable serum and urine osmolality in control conditions, but exhibited a significantly greater bodyweight loss, and urine volume excretion after 24 h of water deprivation (WD) despite higher AQP levels when compared to WT. Furthermore, osmosensitive [Ca2+]i elevations were greatly increased in CD from WT but not TRPC3−/− animals after 24 h WD. Greatly accelerated rate of cell swelling was observed in WT, while it was only modestly increased in TRPC3−/− mice under the same condition. Using immunofluorescent microscopy, we found that AQP2 translocated to the apical plasma membrane in WT, while maintaining mostly cytosolic localization in TRPC3−/− after 24 h WD, which favors a significant role of TRPC3 in osmosensitivity and regulation of AVP-dependent AQP2 trafficking in the CD. TRPC3 deletion compromises systemic water balance producing an ND-like phenotype.

Distinct Cellular Osmoregulatory Response in the Skin of Patients with Disturbed Glycosaminoglycan Biosynthesis

Jlettja L Oppelaar,1 Elaine Wensing,1 Nietsje M. Rorije,1 Rik H. Olde Engberink2 Bert-jan van den born,1 Jan Aten, Liifert Vogt. Amsterdam UMC Locatie AMC, Amsterdam, Netherlands.

Background: Several studies have shown that during high Na+ diet (HSD) sodium content of the skin increases. Nuclear factor of activated T cells 5 (NFAT5) is a hypotonicity-induced transcription factor that is upregulated by the hypertonic conditions present in the skin. Sulfated glycosaminoglycans (GAGs) have been suggested to neutralize Na+-induced hypertonicity driven transcription factor responsive to environmental osmotic changes. Extracellular hypotonicity increases [Ca2+]i and causes cell swelling due to AQP2-driven water influx. The role of the osmosensitive [Ca2+]i signaling in renal water transport and urine concentration remains unknown.

Methods: The techniques used in this study included simultaneous measurement of [Ca2+]i dynamics with Fura 2 and the rate of cell swelling as a readout of the AQP2-dependent water reabsorption in freshly isolated split-opened CD of wild type and TRPC3−/− mice; immunofluorescent detection of AQP2-induced AQP2 trafficking to the apical membrane and metabolic cage balance studies.

Results: TRPC3 is a Ca2+-permeable mechano-activated channel abundantly expressed in the CD. We found that TRPC3 deletion or pharmacological inhibition precluded [Ca2+]i elevations induced hypotonicity and severely slowed the rate of cell swelling indicative of diminished water transport in the CD. TRPC3−/− and WT mice had comparable serum and urine osmolality in control conditions, but exhibited a significantly greater bodyweight loss, and urine volume excretion after 24 h of water deprivation (WD) despite higher AQP levels when compared to WT. Furthermore, osmosensitive [Ca2+]i elevations were greatly increased in CD from WT but not TRPC3−/− animals after 24 h WD. Greatly accelerated rate of cell swelling was observed in WT, while it was only modestly increased in TRPC3−/− mice under the same condition. Using immunofluorescent microscopy, we found that AQP2 translocated to the apical plasma membrane in WT, while maintaining mostly cytosolic localization in TRPC3−/− after 24 h WD, which favors a significant role of TRPC3 in osmosensitivity and regulation of AVP-dependent AQP2 trafficking in the CD. TRPC3 deletion compromises systemic water balance producing an ND-like phenotype.

Risk Factors for AKI During Autologous Stem Cell Transplantation in AL Amyloidosis

Ralf Meissner1 Stephanie S. Pavlovich,1 Avital Angel-Korman,1 Alexander Pogrebinsky,2 Georghe Doros,2 Hanni Menn-Joseph,3 Lauren D. Stern,1 Shayana Sarbraeck,1 Dana Brauneis,1 Vaiashan Sancharowala,1 Andrea Havasi,1 Boston University School of Medicine, Boston, MA; 2Boston University School of Public Health, Boston, MA; 3Boston Medical Center, Boston, MA.

Background: Acute kidney injury (AKI) is a common complication after high dose melphalan and autologous stem cell transplantation (HDM/SCT) in AL amyloidosis patients. However, its incidence, outcome, and risk factors are not well known.

Methods: This observational study included 173 AL amyloidosis patients who underwent HDM/SCT in the Amyloidosis Center at Boston University School of Medicine. Demographic, laboratory and clinical data were prospectively collected and analyzed retrospectively. AKI was defined as an increase in serum creatinine ≥1.5 times the baseline value and occurring within the first 30 days after HDM/SCT.

Results: The median age was 57 years (range 32-77). Fifty-nine percent of patients were male. Renal and cardiac involvement were present in 65.3% and 19.7% of patients, respectively. Median eGFR was 83 mL/min/1.73m2 (range 9-213) and median proteinuria was 2.503 mg/dL (range 0-19.996). The median time from diagnosis to SCT was 4 months (range 1-100). AKI occurred in 28.3% of patients. The causes of AKI were: ATN (27.9%), pre-renal injury (26.4%), melphalan-induced AKI (12.0%), cardio renal physiology (5.8%), ATN (2.9%), contrast-induced AKI (1.5%), obstructive nephropathy (1.5%), and no clear etiology (22.0%). AKI was associated with increased overall mortality with a hazard ratio of 4.78 (95% CI, 1.9-11.9, p=0.001). The 10-year overall survival was 87.5% for patients who did not have AKI versus 56.2% who had AKI. Baseline characteristics significantly associated with AKI development were: amyloid renal involvement, renal function, proteinuria, hypoalbuminemia, IVSD, atrial fibrillation, use of midodrine or diuretics. Sepsis in the post-transplant period, IV vancomycin use, and C. difficile infection were significantly associated with AKI. In terms of hematologic factors, anemia severity, and the need for red blood cell transfusion were significantly associated with AKI. Prolonged thrombocytopenia was associated with AKI; however, delayed WBC engraftment was not associated with AKI.

Conclusions: AKI occurs frequently after HDM/SCT in AL amyloidosis patients and is associated with several risk factors and an increased overall mortality. Prophylactic measures addressing some of these risk factors may reduce this risk.

Associations Between the Immunoglobulin Germline Gene Usage and the Tropism of Organ Involvement and Renal Amyloid Deposition Patterns in Immunoglobulin Light-Chain Amyloidosis by Mass Spectrometry

Dan Y. Li1 Dan Liu,2 Su-xia Wang,3 Ming Hui Zhao,1 Peking University First Hospital, Beijing, China; 2Peking University Health Science Center School of Foundational Education, Beijing, China.

Background: The goal of this study was to characterize the associations between the immunoglobulin light chain variable region (IGVL) germline gene usage and organ tropism, renal amyloid deposition patterns in Chinese patients with AL amyloidosis. Methods: 105 patients were selected randomly from an overall database of 310 patients with AL amyloidosis diagnosed by renal biopsies during 2000 to 2018. The clinical manifestation and organ involvement were assessed. The renal amyloid deposits on different compartments were evaluated and classified into three patterns: (1) glomerular dominant amyloid deposition pattern (G-AL, n=27); (2) vascular dominant deposition pattern (V-AL, n=32); (3) diffuse amyloid deposition pattern (D-AL, n=46). IGVL germline gene usage was identified based on proteomic analysis of renal amyloidotic tissue by mass spectrometry using a reference database supplemented with sequences of IGVL genes. AL amyloidosis. The association of IGVL genes with organ involvement, renal amyloid deposition patterns and survival were assessed.

Results: IGVL genes were successfully identified in 84.8% patients (89/105). LV 9-67 (31.2%) was the most common α IGVL gene identified among patients with AL amyloidosis, and KV 1-33 (50.0%) was predominant in x IGVL patients. When compared with patients with renal involvement, the frequency of LV 1-44 (12.1% vs 4.3%) was P=0.639

Treatment of AL Amyloidosis with Daratumumab Monotherapy

Riccardo Magli,1 Savioino Sciutito,1 Dario Roccatello. Nephrology and Dialysis Unit & CMD (Center of Research of Immunopathology and Rare Diseases), Coordinating Center of the Network for Rare Diseases of Piedmont and Aosta Valley, San Giovanni Bosco Hub Hospital of Turin, and Department of Clinical and Biological Sciences, University of Turin, Turin, Italy, Turin, Italy.

Background: Immunoglobulin light chain amyloidosis (AL) is characterized by poor outcome. Daratumumab (D) is a first in class anti CD38 human antibody (IgG1κ) which proved to be effective in combination with bortezomib in MM refractory to conventional bortezomib-based regimens. Its effectiveness and safety in the treatment of AL amyloidosis is under study. This study reports the experience of D monotherapy in a series of severe patients (pts) with AL amyloidosis and multorgan and biopsy-proven renal involvement.

Methods: Five pts, mean age 64 years were treated with D following antibody testing and extended RBC antigen phenotyping. Treatment protocol was as follows: 16 mg/kg D i.v. administered weekly for 8 weeks, then every 2 weeks (8 doses), and then monthly for 1 year.

Results: In pt #1, in dialysis, who was refractory to conventional therapies D administration resulted in normalization of the FLC ratio with disappearance of serum M-component and Bence-Jones (BJ) proteinuria. In pt #2 who had a relapsing disease, D treatment resulted in a rapid decrease of proteinuria and N-terminal propeptide (NT-proBNP) levels with disappearance of serum M-component and BJ proteinuria and normalization of the FLC ratio. Pt #3 was treated front-line. He had an impressive decrease of proteinuria and NT-proBNP levels with normalization of FLC ratio and disappearance of serum M-component. In pt #4, who was intolerant to conventional regimens, D therapy resulted in decrease in proteinuria, disappearance of serum M-component and improvement in the FLC ratio, which were paralleled by a reduction of NT-proBNP levels. Pt #5 had a relapsing disease. D achieved a decrease of proteinuria, a decrease of serum M-component with increase of FLC ratio. This was the only patient who experienced an infusion reaction during the first dose. The 4 pt with still preserved renal function also showed renal response with sCr improvement or stabilization and a decrease of serum M-component with increase of FLC ratio. Pt #5 had a relapsing disease. D achieved a decrease of proteinuria, and extended RBC antigen phenotyping. Treatment protocol was as follows: 16 mg/kg D i.v. administered weekly for 8 weeks, then every 2 weeks (8 doses), and then monthly for 1 year.

Conclusions: Daratumumab monotherapy resulted in the disappearance of M-proteinemia in every pt of D-Clin group normalized in 4 out of 5 subjects and impressive decrease of proteinuria and pro-BNP values proving to be an effective therapeutic option for pretreated/ naïve patients with severe AL with renal involvement.

Immune Checkpoint Inhibitor Use in Kidney Transplant Recipients: A Multicenter Study

Naoko Murakami,1 Leonardo V. Riella,1 Rimda Wanchoo,2 Vinay Nair,2 Kenar D. Jhavert.1 Immune Checkpoint Inhibitor in Solid Organ Transplant Consortium ‘Brigham and Women’s Hospital, Boston, MA; 2Northwell Health, Great Neck, NY.

Background: Immune checkpoint inhibitors (ICIs) significantly improved the survival in many cancers, but the data on survival benefit in KTxs recipients are lacking. ICIs are reported to be associated with higher acute rejection rate in KTxs recipients, but the risk factors of ICI-associated rejection are not fully understood.

Methods: We conducted a multicenter observational study to investigate the clinical characteristics of ICI-associated rejection and the survival outcomes of KTxs recipients treated with ICI. 66 KTxs patients with a functioning allograft at the time of ICI initiation were collected from 18 institutions. In addition, historical control groups of KTxs recipients with advanced stage melanoma (AACC stage III-IV, n=17) and cutaneous squamous cell carcinoma (cSCC, AACC stage III (unresectable)-IV, n=23), who could be considered as potential ICI candidates, were collected to compare the overall survival (OS).

Results: In ICI cohort, median age was 64, male dominant (83%) and transplant to ICI initiation was median 11 years. cSCC was the most frequent malignancy (n=22), followed by melanoma (n=28) patients (42.4%) experienced rejection, of which 19 (64.2%) lost allograft and returned to dialysis. Median time from ICI initiation to rejection was 26 days. In biopsy-proven rejection (n=13), both mixed acute cell and antibody-mediated rejection (n=7, 53%) and acute cell-mediated rejection (n=6, 47%) were seen. By Chi square test, mTOR inhibitor use (P=0.012) and the use of higher number of immunosuppressive drugs (P=0.06) were associated with higher risk of rejection. For both melanoma and cSCC cohort, ICI groups experienced higher rejection rate (57% and 40%, for melanoma and cSCC, respectively, compared to non-ICI control groups (12% and 4.3%), suggesting the higher rejection rate in ICI groups was not solely explained by reduction in immunosuppression. OS didn’t show statistical difference in melanoma cohort (log rank test P=0.22), but OS was significantly longer in cSCC cohort (log rank test P=0.015), when compared ICIS vs non-ICI control groups.

Conclusions: Our multi-center study provides a novel data on the survival benefit and the risk factors of rejection in KTxs recipients with ICI use compared to non-ICI control groups.

Daily Caffeine Consumption and Risk of AKI Related to Platinum-Salt Chemotherapy: A Prospective Cohort Study

Aubigue Hamroun,1 Decaestecker Antoine,1 David Blum,2 Christelle Cauffliez,2 François Glowacki,1 Centre Hospitalier Regional Universitaire de Lille, Lille, France; 1Université de Lille, Lille, France.

Background: Although their efficacy has been well-established in Oncology, the use of platinum salts remains limited due to the occurrence of acute kidney injury (AKI). Caffeine has been suggested as a potential pathophysiological actor of platinum salt-induced AKI, through its hemodynamic effects. This work aims to study the association between caffeine consumption and the risk of platinum salt-induced AKI.

Methods: We conducted a single-center prospective cohort study that has included 108 consecutive thoracic cancer patients receiving a first-line platinum-salt chemotherapy between January 2017 and December 2018. Before the first course of chemotherapy, they were all invited to fill in a previously validated auto-questionnaire, designed for a detailed evaluation of their daily caffeine consumption (mg/day). The association of daily caffeine consumption with the risk of platinum-salt induced AKI was estimated by cause-specific Cox proportional hazard model adjusted for several known confounders (baseline renal function and serum albumin level, nature and dose of platinum-salt, tobacco exposure, and Performans status).

Results: Overall, 34 patients (31.5%) (mean age 61.7 years, 65% men, 80% tobacco users) experienced a platinum salt-induced AKI (67% grade 1) and 47 (43.5%) died during follow-up (6.2 months [3.4; 8.4]). The group of high-caffeine consumption (a 386mg/day) had a twice higher risk of AKI (HR=2.12 [1.01; 4.45]) in the fully adjusted model. The cumulative incidence of AKI (considering the competing risk of death) was also significantly increased in the high-caffeine consumption group (p=0.03, see figure 1).

Conclusions: In a population of thoracic cancer patients, the group of high-caffeine consumption was exposed to a significantly higher risk of platinum salt-induced AKI.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Results: We identified 183 patients (98 gem-cis, 32 split and 53 gem/gem-cis). Median follow-up was 57 months (IQR: 64-73). Multivariate analysis showed a significant increase in risk of progressing to proteinuria of greater than 1.0 g/g, Age and hypertension were not associated with increased risk. Due to lack of randomization and incomplete data, further analysis is needed.

Conclusions: A presence of baseline P/Cr greater than 0.25 g/g, type 2 diabetes, and CKD III, all showed a significant increase in risk of progressing to proteinuria of greater than 1.0 g/g. Age and hypertension were not associated with increased risk. Despite the lack of long-term follow-up, the study provides important insights into the risk factors associated with proteinuria in patients receiving Bevacizumab.

CKD Prevalence, Patterns of Treatment, and Outcomes in Patients with Cancer: A Population-Based Cohort Study

Abigail Kitchi,1 Bin Luo,2 Nivethika Jayakumar,3 Amit X. Garg,4 Eitan Amir,5 Joseph Kim,1 Ron Wald.1 University Health Network, Toronto, ON, Canada; 2Institute for Clinical Evaluative Sciences, London, ON, Canada; 3London Health Sciences Centre, London, ON, Canada; 4St. Michael’s Hospital, Toronto, ON, Canada.

Background: Chronic kidney disease (CKD) may impede optimal cancer treatment and result in worse outcomes. There are limited data to assess receipt of systemic therapy, radiation, and palliative care in patients with cancer and CKD.

Methods: We conducted a population-based cohort study of all patients (≥18 years old) with a new cancer diagnosis in Ontario, Canada (2007-2015). We categorized patients according to CKD status at cancer diagnosis [estimated glomerular filtration rate (eGFR) ≥60 (referent group), 45-59, 30-44, 15-29, <15 mL/min/1.73m², dialysis and transplant recipients]. We used multivariable Fine and Gray proportional hazards models to assess overall survival, receipt of systemic therapy, radiation and palliative care (6-months prior to death) in the 5 most common solid cancers (bladder, breast, colon, prostate, lung) and kidney cancer.

Results: We identified 128,489 patients with a new cancer diagnosis, of whom 16% had pre-existing CKD (eGFR ≤60 mL/min/1.73m²). Patients with the 6 cancers of interest accounted for 73% (93,751). Kidney function at cancer diagnosis was associated with (progressively) worse overall survival in CKD stages 3a-5, dialysis, and transplant recipients (Figure a). Increasing CKD stage was associated with significantly reduced receipt of all treatment modalities [systemic therapy, radiation and palliative care (Figure b-d)]. Patients receiving dialysis had 2-fold increased mortality in bladder, breast and ovarian cancers, and 3-fold mortality in kidney cancer.

Conclusions: In patients with cancer, CKD is associated with reduced exposure to systemic, radiation and palliative treatments and worse overall survival. Strategies to improve cancer care in the CKD population are needed.

TH-OR38

Characterizing the Risk of Development of Proteinuria with Bevacizumab Therapy

Tomás L. Guerrero Nunez, Abigail B. Shoben, Jason Prosek. The Ohio State University Wexner Medical Center, Columbus, OH.

Background: Bevacizumab is a well-known cause of proteinuria. There are multiple hypotheses regarding mechanism that involve the VEGF receptor, nitric oxide metabolism and increased arterial glomerular pressure. The most accepted explanation is that Bevacizumab induces thrombomicroangiopathy. However, there is no current model or description of potential risk factors to identify at-risk patients who may need closer follow-up. Although CKD has been described as a risk factor, there exists no proven therapy for mitigating or reversing the proteinuria. Current guidelines advise that therapy be either discontinued or completely stopped depending on the level or proteinuria that develops. Some authors have proposed RAAS inhibition, but no data is available to support that therapy.

Methods: 1224 patients on Bevacizumab were sampled, with 714 having at least one P/Cr value needed for analysis. The time frame in which data was collected was 600 days. Data sampled included, age, baseline P/Cr, status of type 2 diabetes, chronic kidney disease stage 3, hypertension, use of Angiotensin Converting Enzyme inhibition, and sequential P/Cr values. Cox proportional hazard models were used to assess differences in the instantaneous risk of the event by categories, no violations of proportional hazard models were observed. The primary endpoint was defined as a P/Cr of 1.0 g/g, indicative of progression of proteinuria.

Results: A baseline P/Cr above 0.25 (HR 5.83, p < 0.001), Type 2 Diabetes (HR 1.69, p = 0.074), and CKD III (HR 3.25, p = 0.007) were associated with an increased risk of developing proteinuria, while age, hypertension (HR 1.11, p = 0.86), a baseline P/Cr < 0.25 (HR 1.04, CI 0.53,2.04, p = 0.001) were not. ACE inhibitors had the following association: (Losinopril; 10 mg, 20 mg, > 20mg), HR (1.47, 1.76, 1.67), p=0.67. Treatment duration was also shown to increase risk of the primary endpoint. The cumulative incidence was 23% after 600 days of treatment.

Conclusions: The risk factors for nephropathy with high-dose methotrexate (HDMTX) in haematological malignancies, and the role of age, hypertension and urinary alkalisation are emphasized in this study, but despite these measures, nephrotoxicity remains 2-12%. Determination of risk factors is key in order to further stratiﬁcation and ameliorate the risk of acute kidney injury.

Methods: A retrospective review of the electronic medical record was conducted to identify patients with leukaemia or lymphoma who received HDMTX from 1/1/2002 to 12/31/2015. We characterised the incidence of AKI using the acute kidney injury network criteria, and the time to AKI. We assessed key baseline demographics, underlying malignancy, delivered MTX dose, and previous nephrotoxicity. Significant factors on univariate analysis were further assessed on Multivariate analysis. Analysis was performed on Minitab.

Results: We identified 3091 cycles of HDMTX with lymphoma accounting for 90.7% of cases. The incidence of AKI was 19.1% in the lymphoma cohort and 13.6% in the leukaemia cohort (p=0.023). The median time to AKI grade shortened with higher severity of AKI (p<0.001). In those with AKI N3, creatinine increased to this level in a median time of 1 day. All patients requiring dialysis (n=7) developed an AKI at day 1 post HDMTX. Univariate analysis revealed age (p=0.022), Gender (p=0.001), higher BSA (p=0.001), type of malignancy (p=0.023), nephrotoxicity on previous dose (p=0.001), cycle number (p=0.001), GFR by Cockcroft-Gault (p=0.016) and 48-hour MTX level (p=0.001). There was no association between AKI and MTX dose (p=0.225), or GFR by MDRD (p=0.497). Multivariate analysis revealed increased age (p=0.001), male Gender (p=0.001), Lymphoma (p=0.002), previous AKI (p=0.001), cycle number (p=0.032), and 48-hour MTX level (p=0.001) to be significant risk factors for nephrotoxicity.

Conclusions: Nephrotoxicity remains a significant complication with HDMTX despite current measure standards. High grade AKI occurs early post HDMTX and therefore, risk stratiﬁcation is vital. Our study identiﬁed key risk factors as older, male, AKI on previous dose, diagnosis of lymphoma, elevated 48-hour MTX level and earlier cycle.
is less influenced by muscle mass or nutritional status, and eGFR using both markers (eGFRcr-cys) is more accurate than either eGFRcr or eGFRcys, but not as widely assessed in cancer patients. Our aim is to compare the performance of eGFR equations (Table) in cancer patients compared to mGFR.

**Methods:** This analysis is a cross-sectional evaluation of a prospective cohort of cancer patients in treatment at the ICESP. mGFR was determined by plasma clearance of 

\( \text{Cr-EDTA} \) indexed for body surface area.

**Results:** A group of 1,200 patients recruited between April 2015 and September 2017. Patients were 60 (51 – 68) y, 50.8% male. The most common cancer sites were breast (22.6%), prostate (19.8%) and gastrointestinal (13.4%). All eGFRcr equations overestimated mGFR with varying bias. CG had the lowest precision and was least accurate. eGFRcys underestimated mGFR and eGFRcr-cys had minimal bias and was the most accurate of all equations (Table).

**Conclusions:** All eGFRcr equations overestimated mGFR in our study. CG was the least accurate and should not be preferred over CKD-EPI. eGFRcr-cys is more accurate and can be used as a confirmatory test.

**Spatial Transcriptomics (ST): Integrating Molecular Profiles with Histomorphology in Kidney Tissue Sections**

Arti M. Raghubar,1 Duy T. Pham,2 Xiao Tan,2 Laura F. Grice,1 Pui Yeng Lam,1 Joanna Crawford,1 Stacey Andersen,2 Sohyo Yoon,1 Samuel E. Holland,1 Leo Francis,1 Alexander N. Combes,2 Andrew J. Kassianos,2 Helen G. Healy,1 Quan Nguyen,1 Andrew J. Malliet,2 1The University of Queensland, Saint Lucia, QLD, Australia; 2Monash University Monash Biomedicine Discovery Institute, Clayton, VIC, Australia; 3Royal Brisbane and Women’s Hospital, Herston, QLD, Australia; 4The University of Queensland Institute for Molecular Bioscience, Saint Lucia, QLD, Australia.

**Background:** Advances in sequencing methods have increased available molecular information on dissociated cells and tissues. Spatially linking this molecular information with histomorphology is needed to understand a complex organ like the kidney, in both health and disease.

**Methods:** Here we used the commercially available 10x Genomics ST platform to investigate the spatially resolved transcriptome expressions in fetal (n=2), adult male (n=3) and female (n=3) mouse kidney and a healthy human cortical frozen kidney tissue sections. We utilized Space Ranger (10x Genomics), Seurat and stLearn analysis pipelines to explore the spatial transcriptome expression within the kidney tissue sections. Furthermore, we confirmed the robustness of our ST data against matched publicly available mouse and human kidney scRNA-seq data.

**Results:** We identified a unique transcriptome plasticity in fetal and adult mouse kidneys, and healthy human cortical kidney tissue. Further dimensional reduction identified transcriptome clusters which correlated with distinct developing kidney structures in fetal mouse kidney tissue, functional cortical and medulla regions in adult mouse kidney tissue, and scarred and non-scarred regions in human cortical kidney tissue.

**Conclusions:** ST is a non-dissociative sequencing and imaging method which allows molecular profiles to be integrated with histomorphology of frozen kidney tissue sections. This provides a novel opportunity to inform physiological and non-physiological conditions at the cell, nephron and tissue levels.

**Funding:** Government Support - Non-U.S.
Sudhir Perincheri, Randy L. Luciano, Gilbert W. Moeckel, Richard Torres.
Yale University School of Medicine, New Haven, CT.

**Background:** Digitization of clinical renal biopsy histology is motivated by the importance of early intervention in acute kidney conditions, assessment by remotely-based experienced nephropathologists, and application of emerging computerized quantitative evaluation tools. Despite the interest, image quality and workflow impact are concerns for digital renal pathology. A newly developed tool for rapid, slide-free microscopic image preparation called clearing histology with MultiPhotonic Microscopy (CHIMP) has demonstrated high efficiency and high quality morphology for diagnostic review in renal disease in a research environment. We sought to commence clinical validation of CHIMP for remote review using effects on downstream traditional special stains and ability to detect a broad range of clinically relevant pathological lesions in renal biopsies.

**Methods:** Kidney core biopsies were procured from 50 consented individuals undergoing renal biopsy for any reason and CHIMP processing was integrated into the routine clinical workflow, using previously-described methods. Images were obtained through entire core biopsies with a prototype fast, high resolution, multiphoton microscopy system (Applitek Technologies, Washington, DC) and visualized with web-based software. Samples were subsequently processed using standard methods for clinical interpretation under transmitted-light microscopy, including special stains. A subset of 20 core biopsies underwent detailed morphologic feature analysis and quantitative lesion comparison.

**Results:** Diagnostic quality remotely-reviewable renal images of 10-16 digital slices were available within ~3 hours of receipt. CHIMP detected morphologic findings were equally detectable in digital images compared to physical, paraffin-embedded sections including cases showing tubular injury, proliferative glomerulonephritis, glomerular deposition disease, and interstitial nephritis. No significant negative effects on downstream processing were identified.

**Conclusions:** CHIMP can be used in rapid morphologic evaluation of kidney biopsies integrated into clinical work enabling rapid rendering of preliminary diagnoses while simultaneously making digital images available for remote expert evaluation and digital analysis. Continuing validation will test ability to augment detection of rare lesions and quantitative precision.

A Deep-Learning Approach to Kidney Biopsy Frozen Sections

Richard Davis,1,2 Xiang Li,1 Nao Souma,1 Zehan Wang,2 Yuewei Xu,2 G. Sotolongo,3 Jonathan Bell, Matthew J. Ellis, David N. Howell,1 Xiaoyang Shen,1 Kyle LD Li, Laura Barisoni,1 Duke University School of Medicine, Durham, NC; 2Duke University Health System, Durham, NC; 3Duke University, Durham, NC; 4Nanjing University Medical School Affiliated Nanjing Drum Tower Hospital, Nanjing, China.

**Background:** Pre-implant assessment of donor kidney biopsies to determine allograft viability is often performed by non-renal pathologists, and carries limited accuracy and reproducibility. The purpose of this work is to develop a deep learning (DL) method for the classification of relevant histologic primitives from donor biopsies as an aid to pathologists. In this article, we report the development and validation of a deep learning system that allows for the recognition of histologic primitives in kidney biopsies.

**Methods:** A total of 268 frozen sections stained with hematoxylin and eosin (H&E) from cadaveric donor kidney biopsies (128 performed at Duke and 140 at outside institutions) were scanned into whole slide images (WSI) at 40x (Leica Biosystems AT2 iScan). The WSIs were divided into the training, validation, and test datasets (0.8:0.1:0.1). Mallory trichrome stained sections were used as ground-truth for training and validation cohorts. The DL algorithms reduced the time required for atubular glomeruli assessment, provided data correlating well with human manual-based assessment, and correlated well with relevant morphology data. This methodology can be extended to 3D glomerular phenotype analysis.

Kidney Biopsy Transcript Patterns Offer a Novel Approach to Distinguishing Etiologies of Acute Interstitial Nephritis

Ivy Rosales,1 Kristen Tomaszewski,2 Ellen Acehampong,1 Astrid Weins,3 Rebecca Smith,1 Meghan E. Sisson,1 Robert B. Colvin,1 Massachusetts General Hospital, Boston, MA; 2Brigham and Women’s Hospital, Boston, MA.

**Background:** One of the challenges in renal pathology is distinguishing causes of acute interstitial nephritis (AIN). Based on encouraging results from renal allografts, we sought mRNA transcript profiles of checkpoint inhibitor associated AIN (CPI), drug induced AIN (Drug), AIN in diabetes (DM), IgG4-related renal disease (IgG4) and T cell rejection type 1 (TCMR1).

**Methods:** Three 20 um sections were obtained from 65 FFPE blocks: 9 controls, 46 AIN types (10 CPI, 13 DM, 14 Drug, 9 IgG4 and 10 TCMR1). mRNA was extracted and hybridized with NanoString HOT Panel of 770 probes and analyzed on an nCounter Max instrument. The gene list is available at nanostring.com. Pathway analysis, differential expression and cell type scores were analyzed from normalized mRNA counts using nSolver.

**Results:** Similarities were found across AIN however each had one or more distinct patterns of transcripts. CPI AIN was distinguished from the other causes of AIN by higher IFNγ signaling pathway scores (Fig 1). CPI AIN had more exhausted CD8 cells (p<0.05) and NK cells (p<0.001) than drug induced AIN. DM AIN differed from histologically indistinguishable Drug AIN by several genes (e.g. higher TGFβ2, p=0.007). IgG4 AIN showed the highest levels of B cell receptor signaling, MAPK and mTOR pathways, and highest Th17 and Treg differentiation scores. TCMR1 had lower scores for TGFβ and TNF pathways and lower Treg scores compared with the other causes of AIN. TCMR1 had the most favorable scores for AKI and pathways related to outcome (eGFR later, GoCAR progression).

**Conclusions:** Our initial findings suggest that once extended to customized algorithms and validated, this approach may prove fruitful in distinguishing the underlying diagnosis and pathogenesis of diverse causes of AIN.

of histopathologic lesions. We tested the associations of each biomarker with clinicopathologic diagnoses, histopathologic lesions, and the risks of kidney disease progression (a ≥40% decline in estimated glomerular filtration rate (eGFR) or end-stage kidney disease) and death.

Results: After multivariable adjustment and correction for multiple testing, 39 proteins were independently associated with clinicopathologic diagnoses and 53 with different histopathologic lesions. Kidney-injury molecule-1 (KIM-1) associated with diabetic nephropathy and glomerular and tubulointerstitial diseases. The top performing markers for acute tubular injury and interstitial fibrosis and tubular atrophy were KIM-1 and tumor necrosis factor receptor superfamily member-9 (TNFRSF-9), respectively. Thirty proteins were significantly associated with kidney disease progression and 35 with death (Figure 1 A, B). The top performing markers for kidney disease progression were placental growth factor (PGF; HR 5.4, 95% CI 3.4 to 8.7) and BMP and Activin Membrane Bound Inhibitor (BAMBI; HR 3.0, 95% CI 2.1 to 4.2); the top performing markers for death were TRAIL-receptor-2 (TRAIL-R2; HR 2.9, 95% CI 2.0 to 4.0) and CUB Domain Containing Protein-1 (CDCP1; HR 2.4, 95% CI 1.8, 3.3). Five proteins were significantly associated with decreased risks of death (Figure 1 B).

Conclusions: We identified several biomarkers of kidney disease histology, pathology, and prognosis—many of which have not been reported previously and may represent important avenues for future research.

Terlipressin Improves Renal Replacement Therapy–Free Survival in Hepatorenal Syndrome Type 1
Juan Carlos Q. Velez,1 Alex Befek,1 Ira Kurtz,2 Juan F. Gallegos-Orozco,3 Hugo E. Vargas,3 John M. Vierling,2 S. Chris Pappas,2 Kharram Jani.2
1Ochsner Health System, New Orleans, LA; 2Malinckrodt Pharmaceuticals Speciality Brands Principal Office, Bedford, NJ; 3Mayo Clinic, Phoenix, AZ; 4Saint Louis University, Saint Louis, MO; 5University of Utah Health, Salt Lake City, UT; 6Orphan Therapeutics, Lebanon, NJ; 7Baylor College of Medicine, Houston, TX; 8UCAL Medical Center, Los Angeles, CA.

Background: Hepatorenal syndrome type 1 (HRS-1) is an ominous form of acute kidney injury in patients with cirrhosis. Recently, the results of the randomized placebo (PBO)-controlled trial (CONFIRM) demonstrated that terlipressin (TERLI) is effective in reversing HRS-1 and in reducing the cumulative need for renal replacement therapy (RRT). However, whether TERLI reduces the need for RRT among survivors has not been determined.

Methods: CONFIRM (NCT02770716) was a North American RCT (n=300) that compared HRS-1 reversal rates between patients treated with albumin plus TERLI (n=199) or albumin plus PBO (n=101) (2:1). We conducted a post hoc intention-to-treat analysis to assess the incidence of RRT among CONFIRM survivors. We also conducted a pooled analysis of the 3 TERLI RCTs in HRS-1 (OT-0401 [NCT00089570], REVERSE [NCT01143246], and CONFIRM) to examine 90-day RRT-free survival rates.

Results: In CONFIRM, the cumulative incidences of need for RRT for TERLI at day 14, 30, and 90 were 23%, 26%, and 29% compared with 35%, 36%, and 39% for patients assigned to PBO (P=0.03, 0.07, and 0.1, respectively). Among survivors, significantly fewer TERLI-treated patients remained dependent on RRT at day 14, 30, and 90 (22%, 26%, and 30%, respectively) compared with PBO (39%, 43%, and 46%; P=0.01, P=0.03, and P=0.05, respectively). The 90-day RRT-free survival rate was 35% in the TERLI group vs 30% in the PBO group (P=0.08), with a numerically longer median number of days in the TERLI group (20 vs 11). Pooled analysis of the 3 RCTs revealed a greater 90-day RRT-free survival rate for TERLI-treated (n=352) compared with PBO-treated (n=256) patients (37% vs 29%, P=0.03; OR [95% CI], 1.47 [1.04, 2.07]).

Conclusions: Treatment with TERLI added to albumin decreased the rate of RRT and improved RRT-free survival in patients with HRS-1. This is the first pharmacological intervention proven to reduce the need for RRT in patients with HRS-1. Because of the significant impact of RRT on quality of life, this observation expands the clinical benefit of TERLI and enhances the reported efficacy of TERLI in inducing HRS-1 reversal.

Immunotactoid Glomerulopathy: A Rare Entity with Monoclonal and Polyclonal Variants
Sanath H. Nasr,1 Satoru Kudose,2 Samar M. Said,1 Dominick Santoriello,2 Sanjeev Sethi,1 Mary E. Fidler,2 Nelson Leung,1 Vivette D’Agati,2 Glen S. Markowitz,3 Mayo Foundation for Medical Education and Research, Rochester, MN; 2Columbia University Medical Center, New York, NY.

Background: Immunotactoid glomerulopathy (ITG) is a rare disease currently classified as an MGRS lesion for which our understanding is limited.

Methods: 73 patients with ITG were identified by retrospective review of all native renal biopsies received at two large renal pathology laboratories from 1993-2019.

Results: ITG biopsy incidence was 0.04%. Median age at diagnosis was 61 years, 86% were Caucasian, and there was no gender predilection. Patients presented with proteinuria (median 6.6 g/day, 58% with full nephrotic syndrome), hematuria (86%), and renal insufficiency (median creatinine 1.6 mg/dl). Hematologic disorders were classified as an MGRS lesion for which our understanding is limited.

As compared to polyclonal ITG, monoclonal ITG had a higher incidence of lymphoma (11% vs. 6%), multiple myeloma (8% vs. 0), and MGRS (22% vs. 0). On follow up (median 47 months), 31% had complete remission, 11% partial remission, 35% persistent renal dysfunction, and 24% progressed to ESRD. The median survival (not reaching a plateau) was 123 months. Monoclonal ITG was more commonly treated with immunosuppression, and 24% progressed to ESRD. The median survival (not reaching a plateau) was 123 months. Monoclonal ITG was more commonly treated with immunosuppression, and 24% progressed to ESRD (53% vs. 11%), multiple myeloma (8% vs. 0), and MGRS (22% vs. 0). On follow up (median 47 months), 31% had complete remission, 11% partial remission, 35% persistent renal dysfunction, and 24% progressed to ESRD. The median survival (not reaching a plateau) was 123 months. Monoclonal ITG was more commonly treated with immunosuppression, and 24% progressed to ESRD.

Conclusions: As compared to polyclonal ITG, monoclonal ITG had a higher incidence of lymphoma (11% vs. 6%), multiple myeloma (8% vs. 0), and MGRS (22% vs. 0). On follow up (median 47 months), 31% had complete remission, 11% partial remission, 35% persistent renal dysfunction, and 24% progressed to ESRD. The median survival (not reaching a plateau) was 123 months. Monoclonal ITG was more commonly treated with immunosuppression, and 24% progressed to ESRD.

A Parsimonious Model for Diagnosis of Biopsy-Proven Acute Intestinal Nephritis Using Electronic Health Record Data
Dennis G. Moledina,1,2 Yu Yamamoto,1 Chirag R. Parikh,3 Francis P. Wilson,1,2 Yale University School of Medicine, New Haven, CT; 3Clinical and Translational Research Accelerator, New Haven, CT; 1Johns Hopkins Medicine, Baltimore, MD.

Background: Due to its atypical clinical features and difficulty in establishing diagnosis without a biopsy, acute intestinal nephritis (AIN) diagnosis is delayed or missed. We developed a predictive model for AIN using clinical data from all patients who underwent a kidney biopsy available through the electronic health record.

Methods: We obtained data on all patients who underwent a native kidney biopsy at two centers between 2013-18 and obtained corresponding information of demographics, comorbidities, and all laboratory tests collected up to one year before biopsy. We used least absolute shrinkage and selection operator (LASSO) method to select features associated with AIN and performed area under received operating characteristics curve (AUC) analysis in temporally-split training (70%) and test (30%) sets. We also applied this model to a separate cohort of kidney biopsies with AIN diagnosis adjudicated by 3 pathologists and compared it to the clinician’s prebiopsy impression of AIN obtained through chart review.

Results: Among 551 patients who underwent native kidney biopsies, 60 (11%) had AIN on clinical pathology diagnosis. We evaluated 163 potential features for their association with AIN. The five features with the highest AUC were last creatinine at the time of biopsy (AUC, 0.73), BUN to creatinine ratio (0.70), urine specific gravity before biopsy (0.67), serum bicarbonate (0.62), and urine protein (0.62). The top 4 variables picked using LASSO had an AUC of 0.76 in the test set (table). Applying this model to a separate cohort of participants with adjudicated AIN, we noted an AUC of 0.80 (0.73, 0.87), which was higher than the clinician’s pre-biopsy impression of AIN (0.61 (0.52, 0.70), P=0.001).

Conclusions: We noted four variables associated with AIN and the model containing these showed a modest AUC but was an improvement on clinician’s pre-biopsy impression of AIN.

Development and Validation of a Convolutional Neural Network Model for Intensive Care Unit AKI Prediction
Jacob Calvert,1 Angier O. Allen,1 Sidney H. Le,1 Paul M. Palevsky,2 Gregory L. Breden,1 Shariad Patel,1 Emily Pellegrini,1 Abigail Green-Saxena,1 Jana Hoffman,1 Ritanark Das,1 Dascena, Oakland, CA; 2VA Pittsburgh Healthcare System, Pittsburgh, PA; 1Baystate Medical Center, Springfield, MA; 3Cooper University Health Care, Camden, NJ.

Background: Acute kidney injury (AKI) is common among hospitalized patients and has a significant impact on morbidity and mortality. While early prediction of AKI has the potential to reduce adverse patient outcomes, it remains a difficult condition to predict and diagnose. The purpose of this study was to evaluate the ability of a machine learning algorithm to predict for AKI KDIGO Stage 2 or 3 up to 72 hours in advance of onset using convolutional recurrent neural nets (CNN) and patient Electronic Health Record (EHR) data.

Methods: A CNN prediction system was developed to continuously and automatically monitor for incipient AKI. 7122 patient encounters were retrospectively analyzed from the Medical Information Mart for Intensive Care III (MIMIC-III) database. The CNN machine learning-based AKI prediction model was compared to an established XGBoost AKI prediction model and the Sequential Organ Failure Assessment (SOFA) scoring system. AKI onset was used for the outcome. The model was trained on routinely-collected patient EHR data.

Results: On a hold-out test set, the algorithm attained an Area Under the Receiver Operating Characteristic (AUROC) of 0.85 and PPV of 0.25, relative to a cohort AKI prevalence of 5.21%, for long-horizon AKI prediction at a 72-hour window prior to onset. The ROC curve comparison of 72-hour prediction on the 10% hold-out test set is shown in Figure 1. The CNN model, which was provided text data through Doc2Vec input, outperformed the XGBoost model and the SOFA score.

Conclusions: A CNN and autotagging-based AKI prediction model outperforms XGBoost and the SOFA scoring system, demonstrating superior performance in predicting acute kidney injury 72 hours prior to onset, without reliance on changes in serum creatinine.

Outcomes from the Use of the Selective Cytopheretic Device (SCD) in Critically Ill Children Receiving CRRT: A Report of the Multicenter Pediatric SCD (pSCD) Study
Stuart Goldstein,1 Kelli A. Krallman,1 Cassie L. Kirby,1 David J. Askernazi,2 Rajit K. Basu,1 David T. Selewski,1 H. David Humes1 Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 3The University of Alabama at Birmingham, Birmingham, AL; 4Children’s Healthcare of Atlanta Inc, Atlanta, GA; 5Medical University of South Carolina, Charleston, SC; 6University of Michigan, Ann Arbor, MI.

Background: Critically ill children who develop acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT) are at increased risk of death. The SCD promotes an immunomodulatory effect in a hypocalcemic environment (ionized Ca (ionCa) < 0.4 mmol/L) in animal models of inflammation. In a randomized trial, adult ICU patients on CRRT treated with the SCD, who maintained CRRT ionCa < 0.4 mmol/L, had improved survival/dialysis independence. We conducted an FDA grant sponsored safety evaluation (adverse and serious adverse events) of the SCD in 16 critically ill children.

Methods: 4 center US study of the SCD in children (<15 kg, ±22 years) with AKI and multigener failure receiving CRRT. The SCD was integrated post CRRT membrane, changed daily, and circuit ionCa maintained <0.4 mmol/L. Pts received SCD treatment for up to 7 days or CRRT discontinuation.

Results: 16 pts (8F/8M) completed the study from 12/2016 thru 2/2020. Mean pt age was 12 yr (range 4-21 yr), weight was 53 kg (range 19-111 kg) and PRISM 2 score was 7 (range 2-19). Two pts received ECMO. The most common ICU diagnosis was shock. Circuit ionCa were maintained at <0.4 mmol/L for 90.2% of assessments. Median SCD duration was 6 days (range 1 to 7). 15/16 pts survived SCD therapy, 12/16 patients survived to ICU discharge. All 12 ICU survivors were dialysis independent at 60 days. No SCD related adverse events were noted.

Conclusions: Our data suggest the SCD is safe in critically ill children who require CRRT. While we cannot make efficacy claims, the 7% survival rate and 100% renal recovery rate in surviving children suggest a favorable benefit to risk ratio.

Funding: Other U.S. Government Support

Nicotinamide Riboside with Pterostilbene Increases NAD+ in Patients with AKI: A Randomized, Double-Blind, Placebo-Controlled, Stepwise Safety Study of NRPT in Patients with AKI
Petra Simic,1 Xavier F. Parada,1 Samir M. Parikh,2 Ryan Dellinger,3 Leonard P. Guarente,4,5 Eugene P. Rhee.1 1Massachusetts General Hospital, Boston, MA; 2Beth Israel Deaconess Medical Center, Boston, MA; 3Elysium Inc, New York, NY; 4Massachusetts Institute of Technology, Cambridge, MA.

Background: Preclinical studies have identified both NAD+ and sirtuin augmentation as potential strategies for the prevention and treatment of AKI. Nicotinamide riboside (NR) is a NAD+ precursor vitamin and pterostilbene (PT) is potent sirtuin activator found in blueberries. Here, we tested the effect of combined NR and PT (NRPT) on whole blood NAD+ levels and safety parameters in patients with AKI.

Methods: We conducted a randomized, double-blind, placebo-controlled study of escalating doses of NRPT in 24 hospitalized patients with AKI. The study was comprised of four Steps during which NRPT (5 subjects) or placebo (1 subject) was given twice a day for two days. NRPT dosing was increased in each Step: Step 1 250/50mg, Step 2 500/100mg, Step 3 750/150mg and Step 4 1000/200mg. Blood NAD+ levels were measured by liquid chromatography-mass spectrometry and safety was assessed by history, physical exam, and clinical laboratory testing.

Results: AKI resulted in a 50% reduction in whole blood NAD+ levels at 48 hr compared to 0 hr in patients receiving placebo (p=0.05). There was a trend for increase in NAD+ levels in all NRPT Steps individually at 48 hr compared to 0 hr, but only the change in Step 2 reached statistical significance (47%, p=0.04), and there was considerable interindividual variability in the NAD+ response to treatment. Considering all Steps together, NRPT treatment increased NAD+ levels by 37% at 48hr compared to 0hr (p=0.002). All safety laboratory tests were unchanged by NRPT treatment, including creatinine, estimated glomerular filtration rate (eGFR), electrolytes, liver function tests, and blood counts. Three of 20 patients receiving NRPT reported minor gastrointestinal side effects.

Conclusions: NRPT increases whole blood NAD+ levels in hospitalized patients with AKI. In addition, NRPT up to a dose of 1000mg/200mg twice a day for two days is safe and well tolerated in these patients. Further studies to assess the potential therapeutic benefit of NRPT in AKI are warranted.

Role of Angiopoietins in CKD Progression After Hospitalization
Sherry Mansour,1 Steven G. Coca,2 Yaqi Jia,2 Vernon M. Chinchilli,4 Wassim Obeid,6 Francis P. Wilson,1 Samir M. Parikh,6 Edward D. Siew,2 Talat Alp Ikizler,7 Jonathan Himmelfarb,2 Paul L. Kimmel,1 Chirag R. Parikh.3
ASSESS-AKI Consortium 1Yale University School of Medicine, New Haven, CT; 2Icahn School of Medicine at Mount Sinai, New York, NY; 3John Hopkins University, Baltimore, MD; 4Pennsylvania State University, University Park, PA; 1Beth Israel Deaconess Medical Center, Boston, MA; 6University of Texas Southwestern Medical Center at Dallas, Dallas, TX; 7Vanderbilt University Medical Center, Nashville, TN.

Background: The factors determining chronic kidney disease (CKD) progression after an episode of acute kidney injury (AKI) are poorly understood. Angiopoietins play a role in vessel remodeling after AKI, where Angiopoietin-1 (Angpt-1) maintains vessel stability and Angiopoietin-2 (Angpt-2) destabilizes quiescent vessels. We investigated whether the balance of Angpt-1 and -2 was prognostic of CKD and mortality after hospitalization in patients with and without AKI.

Methods: Using plasma samples from ASSESS-AKI, we measured Angiopoietins 3 months after hospitalization. We assessed the ratio of Angpt-1:Angpt-2 with CKD progression (composite of incident and progression of CKD, and end stage kidney disease), and all-cause mortality.

Results: Angiopoietins were measured in 1503 hospitalized patients, among whom 746 (49.6%) had AKI. Median (IQR) age was 65.8 (56.6, 73.9) years, 555 (37%) were female, and 196 (13%) were black. Median times to CKD progression, and all-cause mortality were 4.4 (2.5, 5.7), and 4.9 (3.6, 6.0) years, respectively. CKD progression developed in 293 (19%) and mortality in 314 (21%) participants. The highest quartile of Angpt-1:Angpt-2 ratio was independently associated with 50% reduced risk of CKD progression and 77% reduced risk of mortality as compared to the lowest quartile. Stratified analyses by AKI status revealed stronger associations between Angpt-1:Angpt-2 ratio and both outcomes in the AKI group (Figure).

Conclusions: A higher Angpt-1:Angpt-2 ratio was strongly associated with lower risk of CKD progression and mortality after hospitalization, particularly in patients with AKI. Angiopoietins may help risk stratify patients with AKI after discharge for those in need of close follow-up and CKD management.

FR-OR07
Determinants of Major Adverse Kidney Events (MAKE) in Extra Corporeal Membrane Oxygenation (ECMO) Survivors
Animesh Bobba,1 Christy Costanian,2 Sola A. Bahous,2 Fadi Tohme.1,2
Washington University in Saint Louis School of Medicine, Saint Louis, MO; 1Lebanese American University School of Medicine, Byblos, Lebanon.

Background: The majority of ECMO patients develop acute kidney injury (AKI) and 40-60% require renal replacement therapy (RRT). Little is known about the effects of AKI on long-term renal outcomes after ECMO. The aim of this study was to examine the determinants of MAKE in ECMO survivors.

Methods: Patients who were admitted to a single-center between 2008 and 2017, were on ECMO for more than 24 hours & survived to hospital discharge were included. MAKE was defined as either doubling of serum creatinine (Scr), incident ESRD or death. USRDS and NDI databases were used to obtain information about ESRD and death. AKI was defined as KDIGO stages 2-3. Complete AKI recovery was defined as a return to 50% of baseline Scr and partial recovery as an improvement in the AKI stage without a return to 50% of baseline Scr. Survival analysis plots & Cox regression models were fitted to examine the associations of AKI status, AKI recovery and other factors with MAKE.

Results: Among 188 ECMO patients who survived until hospital discharge, 63% had AKI, and 41% required RRT. The mean follow-up time was 3.4 years. Patients with AKI were more likely to be on ECMO for a cardiac rather than respiratory indication and had a longer length of stay compared to patients with no AKI. Kaplan-Meier survival curves showed that patients with no/partial recovery from AKI had a higher rate of MAKE compared to those with no AKI (Figure 1). Results of the unadjusted analysis showed that ECMO type and timing of initiation of RRT were associated with MAKE. Multivariate analysis showed that AKI [aHR=1.79 (95%CI=1.00-3.21)], no/partial recovery from AKI [aHR=2.94 (95%CI=1.46-5.92)] and initiation of RRT after ECMO [aHR 5.4 (95%CI=1.14-25.6)] were significant determinants of MAKE after adjustment for potential confounders.

Conclusions: AKI, AKI recovery status, and timing of initiation of RRT are determinants of major adverse kidney events in patients who received ECMO.

FR-OR08
AKI Among African Americans with Sickle Cell Trait and Disease
Kabir O. Olaniran,1,2 Andrew S. Allegretti,1 Sophia Zhao,1 Sagar U. Nigwekar,1 Sahir Kalim.1,2 Massachusetts General Hospital, Boston, MA; 1University of Texas Southwestern Medical Center at Dallas, Dallas, TX.

Background: Sickle cell trait (SCT) and disease (SCD) are independent risk factors for estimated glomerular filtration rate (eGFR) decline among African Americans (AA). However, our understanding of the risk for acute kidney injury (AKI) and the role of AKI in eGFR decline in patients with SCT/D remains limited. We aimed to describe the relative risk for AKI in SCT/D and the effect of AKI on eGFR decline in patients with SCT/D.

Methods: We performed a multi-center observational study of adult AA patients with a baseline eGFR ≥ 15 ml/min, and ≥ 1 year follow-up between 2005-2018. The presence of SCT/D (exposure) and normal hemoglobin phenotype (reference) was determined by hemoglobin electrophoresis. Outcomes of interest (incident All AKI [Kidney Disease: Improving Global Outcomes criteria], incident Severe AKI [doubling of baseline creatinine] and incident Sustained AKI [AKI persisting for ≥ 2 hours]) were adjudicated by chart review and evaluated by Cox regression. Only first AKI events were used. The effect of All AKI on eGFR decline (mixed linear models) was also investigated. Models were adjusted for predictors of AKI.

Results: We identified 8868 reference, 1279 SCT, and 254 SCD patients with a median follow-up of 7.6 years and mean serum creatinine of 0.8 mg/dl. SCT was associated with Sustained AKI (adjusted hazard ratio [aHR] 1.42; 95% CI, 1.08-1.88) compared to the reference. SCD was associated with All AKI (aHR 3.13; 95% CI, 2.33-4.21), Severe AKI (aHR 3.04; 95% CI, 1.90-4.87) and Sustained AKI (aHR 2.10; 95% CI, 1.24-3.53) compared to the reference. Effect of AKI on eGFR is shown in Figure 1.
**Conclusions:** The risk for AKI is increased in both SCT (Sustained) and SCD (all forms) and may contribute to faster eGFR decline in SCD/T. Further studies are needed to understand the mechanisms of AKI in SCT/D. Such studies will inform best practices that will help attenuate the burden of kidney disease in SCT/D.

**Assessment of Kidney Proximal Tubular Secretion in Critical Illness**

Pavan K. Bhathala,1, Edward D. Siew,2 Jonathan Himmelfarb,1 Andrew N. Hoofnagle,1 Mark M. Wurfel,1 Bryan R. Kestenbaum.1,4 University of Washington, Seattle, WA. 4Division of Nephrology and Hypertension. Vanderbilt University, Nashville, TN.

**Background:** Serum creatinine concentrations (SCr) are used to determine the presence and severity of acute kidney injury. SCr is primarily eliminated by glomerular filtration; however, most mechanisms of kidney injury in critical illness involve kidney proximal tubules, where tubular secretion occurs. Proximal tubular secretion is thought to currently measured in the ICU. To estimate the kidney clearance of solute clearance in critically ill adults.

**Methods:** We collected matched blood and spot urine samples from 170 ICU patients and from a comparison group of 70 adults with normal kidney function. We measured seven endogenously produced solutes using liquid chromatography-tandem mass spectrometry. We computed a composite secretion score incorporating all seven endogenously produced solutes using liquid chromatography-tandem mass spectrometry. We computed a composite secretion score incorporating all seven endogenously produced solutes using liquid chromatography-tandem mass spectrometry.

**Results:** The urine/plasma ratio of six of seven secretory solutes were lower in critically ill patients compared with normal individuals after adjustment for SCr. The composite secretion score was moderately correlated with SCr and cystatin C (r = -0.53, r = 0.53, respectively). Each standard deviation higher composite secretion score was associated with a 52% lower risk of MAKE and albuminuria (P = 0.004) and albuminuria (P = 0.007) remained in the final model for the non-AKI group. In the AKI group, PRO-C6 had a stronger association with mortality than eGFR, as only age (P = 0.005), albuminuria (P = 0.04) and PRO-C6 (P = 0.004) remained in the final model. When stratified into tertiles, patients with higher levels of PRO-C6 at year 1 were significantly more likely to die (P = 0.009).

**Conclusions:** In this study, we compared levels of PRO-C6 in patients with and without AKI, and show that PRO-C6 levels measured in plasma can predict mortality in patients with AKI. Our findings may indicate that PRO-C6 identifies patients with active fibrogenesis after AKI, suggesting that long-term renal injury after AKI is important for patient outcome.

**Endotrophin, Released During Collagen Type VI Formation, Predicts Long-Term Mortality After AKI**

Nadja Sparding,1,2 Daniel Guldager Kring Rasmussen,3 Federica Genovese,1 Morten A. Karsdal,1 Rebecca A. Packington,3 Nicholas M. Selby,3 Fibrosis, Renal and Cardiovascular Research. Nordic Bioscience, Herlev, Denmark; 2Faculty of Health and Medical Science, University of Copenhagen, Copenhagen, Denmark; 3Centre for Kidney Research and Innovation, University of Nottingham, Nottingham, United Kingdom.

**Background:** Acute kidney injury (AKI) is defined as a rapid decrease in kidney function which may be associated to structural damage. Early markers predicting AKI are emerging, but tools to monitor patients subsequent to AKI are still lacking. The novel biomarker PRO-C6 reflects formation of collagen type VI (COL6) and levels of endotrophin, a bioactive molecule derived from COL6. Here we evaluated the potential of PRO-C6 as a biomarker of mortality in AKI patients.

**Methods:** We measured PRO-C6 in plasma samples collected 1 year after the episode of AKI, using a novel ELISA in 801 patients from the AKI Risk in Derby (ARID) study, who were then followed prospectively until year three. 393 of the patients had been hospitalized for an episode of AKI, and 408 patients who did not sustain AKI were included as controls (non-AKI). The groups were matched for age, baseline renal function and diabetes.

**Results:** PRO-C6 levels were significantly higher in the AKI compared to the non-AKI group (median (m): 10.85 vs 9.23 ng/mL, P < 0.0001). By year 3, a total of 70 patients died; 43 in the AKI group and 27 in the control group. In the AKI group, patients who died had significantly higher PRO-C6 levels than the patients who did not die (m: 12.66 vs 10.68 ng/mL, P < 0.004), whereas there was no difference between patients who died and did not die in the non-AKI group (m: 9.97 vs 9.21 ng/mL, P = 0.234). In a Multivariable Cox regression analysis with backwards elimination including age, gender, baseline CKD and diabetes status, albuminuria, serum creatinine, eGFR and PRO-C6, only age (P = 0.04) and albuminuria (P = 0.007) remained in the final model for the non-AKI group. In the AKI group, PRO-C6 had a stronger association with mortality than eGFR, as only age (P = 0.005), albuminuria (P = 0.04) and PRO-C6 (P = 0.004) remained in the final model. When stratified into tertiles, patients with higher levels of PRO-C6 at year 1 were significantly more likely to die (P = 0.009).

**Conclusions:** In this study, we compared levels of PRO-C6 in patients with and without AKI, and show that PRO-C6 levels measured in plasma can predict mortality in patients with AKI. Our findings may indicate that PRO-C6 identifies patients with active fibrogenesis after AKI, suggesting that long-term renal injury after AKI is important for patient outcome.

**Association of Use of Kidney Disease Education Benefit with ESKD-Related Outcomes**

**Background:** ESKD onset in the US is marked by poor outcomes, including little use of home dialysis, widespread catheter dependence among patients on hemodialysis, and high mortality. Consequently, in 2010, the Centers for Medicare and Medicaid Services (CMS) initiated a new kidney disease education (KDE) benefit to ensure that beneficiaries with stage 4 CKD are informed about the effects and treatment of kidney disease, diet and nutrition, transplantation, dialysis modalities, and vascular access. Following the US president’s Executive Order on Advancing American Kidney Health in 2019, CMS plans to expand KDE. However, the current use and efficacy of KDE have not been examined.

**Methods:** We used USRDS data to identify eligible patients and to ascertain KDE and ESKD outcomes. We examined use of KDE in the 2 years prior to ESKD onset in 2013-2017 among 106,465 individuals aged ≥67 years who had CKD stage 4. We compared use and ESKD outcomes. We examined use of KDE in the 2 years prior to ESKD onset in 2013-2017 among 106,465 individuals aged ≥67 years who had CKD stage 4. We examined use and ESKD outcomes among patients with stage 4 CKD are informed about the effects and treatment of kidney disease, diet and nutrition, transplantation, dialysis modalities, and vascular access. Following the US president’s Executive Order on Advancing American Kidney Health in 2019, CMS plans to expand KDE. However, the current use and efficacy of KDE have not been examined.

**Results:** 3171 patients (3%) received KDE, 56% of whom received a single session. 49.5% of KDE sessions were delivered by nephrologists and 42% by physician extenders. Younger patients, men, and non-Hispanics were more likely to receive KDE. There was substantial regional variation in KDE utilization, and rural residents were less likely to receive KDE. In the matched cohort, receipt of KDE was associated with higher odds of transplant waiting before dialysis initiation, pre-emptive transplantation, home dialysis, or pre-center HD initiation with an AVF or AVG (vs. catheter, Table). Can be sustainably relevant to structural damage. Early markers predicting AKI are emerging, but tools to monitor patients subsequent to AKI are still lacking.

**Conclusions:** A very small percentage of eligible patients reaching dialysis receive Medicare-reimbursed KDE within the previous 2 years. KDE was associated with favorable outcomes, at least among those who advanced to ESKD.

Correlation Between Patient Activation and Quality of Life Among Patients with CKD
Penn State College of Medicine, Hershey, PA.

Background: Quality of Life (QOL) is an important outcome in patients with chronic kidney disease (CKD). We have previously demonstrated that online peer mentoring (PM) improves patient activation and QOL. In this study, we evaluate the correlation between patient activation and QOL among patients with CKD who received online PM.

Methods: We randomized 155 patients with stage 4 or stage 5 CKD to one of 3 groups: online PM, face-to-face (FTF) PM, or usual care. Participants in all 3 groups received a book that contained detailed information about kidney disease. Participants assigned to intervention groups received 6 months of PM, either FTF or through a secure online platform. At baseline and at 18 months, the participants completed the Patient Activation Measure® (PAM) and the Kidney Disease QOL-36 (KDQOL-36) instrument. We used linear mixed effect models to estimate the slope of change of PAM and subsets of KDQOL over time. Then we calculated the correlation between PAM and individual subscales of KDQOL by Pearson’s Correlation Coefficient. We used SAS, version 9.4 (SAS Institute Inc., Cary, NC) for data analysis.

Results: Baseline KDQOL-36 and PAM scores, as well as demographic characteristics were similar among the 3 groups. Among the online PM group, there was a statistically significant improvement in: 1. The mean PAM score between baseline and 18 months (Slope estimate [SE]: 5.65, 95% confidence interval [CI]: 2.75, 8.52; P= 0.0001). 2. The following components of the KDQOL-36 score: Effects of Kidney Disease (EKD) (SE: 4.13; CI: 3.67, 4.56; P= 0.01); Burden of Kidney Disease (BKD) (SE: 5.44; CI: 4.29, 6.59; P= 0.01); Symptoms and Problems of Kidney Disease (SPKD) (SE: 6.00; CI: 3.09, 8.91; p= 0.006); SF-12 Physical Composite Score (PCS) (SE: 2.50; CI: 0.95, 4.06; P= 0.002); SF-12 Mental Composite Score (MCS) (SE: 3.46; CI: 1.78, 5.13; P=0.0001). Among the online PM group, the improvement in PAM was correlated with improvements in 4 components of the KDQOL-36: EKD (Pearson Coefficient [PC]: 0.36; P=0.04); BKD (PC: 0.44; p=0.01); SPKD (PC: 0.47; P=0.005); PCS (PC: 0.35; p=0.04). There was no correlation between PAM and MCS.

Conclusions: Among CKD patients who receive online PM, there is a correlation between the improvements in PAM and KDQOL, suggesting that improved QOL may be a result of improved activation. Funding: PCORI

FR-OR13
Breath Ammonia Is a Useful Biomarker Predicting Kidney Function in CKD Patients
Ya-chung Tian, Linkou Chang Gung Kidney Research Center and Department of Nephrology, Gueishan, Taoyuan, TW, Taoyuan, Taiwan.

Background: Chronic kidney disease (CKD) is a public health problem and its prevalence has increased worldwide; patients are commonly unaware of the condition. Early identification and immediate intervention are crucial to delay CKD progression. Finding a tool to predict kidney function without visiting hospitals is an attractive method for CKD monitoring in COVID-19 pandemic. The present study aimed to investigate whether exhaled breath ammonia measurement could be used for rapid CKD screening.

Methods: CKD patients (n=121), including CKD stage 1-5 patients, were enrolled and breath ammonia was detected. Correlation between breath ammonia and blood urea nitrogen (BUN) levels, serum creatinine levels, estimated glomerular filtration rate (eGFR) were determined. The predictive value of breath ammonia for the presence of CKD was assessed.

Results: Correlation analysis demonstrated a good correlation between breath ammonia and blood urea nitrogen levels (R=0.756, p<0.0001), serum creatinine levels (R=0.735, p<0.0001), eGFR (R=-0.535, p<0.0001) and inversed eGFR (R=-0.685, p<0.0001). Breath ammonia concentration was significantly elevated with increased CKD stage compared with the previous stage (CKD stage 1/2:34/4: 636±54; 102±120; 1943±326, 442±1042; 1278±1807 ppb, p<0.05). The receiver operating characteristic curve analysis showed an area under curve (AUC) of 0.835 (p<0.0001) for distinguishing CKD stage 1 from other CKD stages at 974 ppb (sensitivity, 69%; specificity, 95%, positive predictive value [PPV] 0.99; negative predictive value [NPV], 0.36). The AUC was 0.831 (p<0.0001) for distinguishing between patients with/without eGFR ≥60 mL/min/1.73 m2 (cut-off 1187 ppb: sensitivity, 71%; specificity, 78%; PPV, 0.84; NPV, 0.61). At 886 ppb, the sensitivity increased to 80% but the specificity decreased to 69%. For a non-life threatening and non-serious CKD, breath ammonia at a cut-off concentration of 886 ppm is a good screening tool for detection of patients with potential CKD and suitable for kidney function monitoring.

Conclusions: Because CKD is non-life threatening and breath ammonia detection was conducted in real-time, inexpensive, easy to administer, and had an acceptable diagnostic accuracy, breath ammonia can be used as a good surrogate for kidney function and a reliable tool for CKD screening.

Estimated Glomerular Filtration Rate Equations: Do We Need to Use the Ethnicity Correction Factor in People of African Ancestry Outside of the United States?
Rouvik Gama, Amanda Clery, Kieran R. Palmer, Henry A. Kibble, Hugh Cairns, Claire C. Sharpe, Adrien M. Peters, Neil Heraghthy, Kate Bramham, King’s College Hospital, London, United Kingdom; King’s College London, London, United Kingdom.

Background: Recent African studies suggest ethnicity factors in estimated glomerular filtration rate (eGFR) equations is not required.

Methods: To assess accuracy of eGFR equations, with and without ethnicity factors compared with gold standard 4Cr-ethylenediaminetetraacetic acid (4Cr-EDTA) clearance assays. Patients with albumin <30g/dl, hepatology referrals, <18 years old, non-white or black, mixed ethnicities were excluded. Accuracy of CKD-EPI and MDRD eGFR compared to 4Cr-EDTA GFR were assessed with and without correction factor.

Results: 2,776 4Cr-EDTA studies were identified (Mean age: 54yrs; 43% female; 12% Black ethnicity). In Black patients, CKD-EPI and MDRD eGFR equations significantly overestimated GFR compared to White (p<0.001) but without ethnicity correction factor estimates were considerably improved (p<0.001)(Table 1). Accuracy was superior for GFRs60ml/min/1.73m2 compared to <60ml/min/1.73m2 using CKD-EPI equation for both White and Black patients (p=0.001).

Conclusions: Overestimation of measured GFR with eGFR equations using ethnicity correction factors identified in this study may lead to reduced rates of CKD diagnosis and under-recognition of CKD severity in people of Black ethnicity in the UK. These findings require prospective validation in other countries.

Table 1: Estimated Glomerular Filtration Equations bias, precision and accuracy compared with 4Cr-EDTA clearance for people of Black and White ethnicities according to 4Cr-EDTA GFR categories

FR-OR15
Mechanism of Higher Incidence of ESKD Among Blacks and Hispanics vs. Whites in the United States
Guofen Yan, Keith C. Norris, Robert Nec, Julia J. Scialla, Wei Yu, Tom Greene, Alfred K. Cheung, University of Virginia, Charlottesville, VA; University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; Walter Reed National Military Medical Center, Bethesda, MD; University of Utah, Salt Lake City, UT; VA Salt Lake City Health Care System, Salt Lake City, UT.

Background: In the U.S., Blacks and Hispanics have higher incidence of ESKD than Whites. Whether this is driven by lower mortality prior to ESKD or inherently faster progression to ESKD has not been clearly determined because most studies used prevalent cohorts that created survival bias. We examined this issue using a newly constructed national cohort of patients with new-onset CKD.

Methods: We identified 834,270 individuals with new-onset CKD in the US Veterans Health Administration (VHA) between 2002 and 2015, followed through 2016. CKD onset was defined as the first occurrence when there were two eGFR values (CKD-EPI equation) <60 mL/min/1.73 m2 that were >90 days apart, not in ESKD. We excluded patients in VHA for <2 years follow-up. The time of study entry should be close to the CKD onset for each individual. We examined jointly the cause-specific (CS) hazards ratios for two competing events, occurrence of ESKD and pre-ESKD death.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Results: Upon study entry, 704,557 Whites, 98,082 Blacks, and 31,631 Hispanics had similar mean eGFRs (49.50 ml/min/1.73m²). Ten years after CKD onset, fractions of patients entering ESKD were 1.3-2.5 times greater for Blacks and Hispanics vs. Whites across six age groups (Table). CS hazards for ESKD was 2.1-2.9 times greater for Blacks and 1.2-2.7 times greater for Hispanics vs. Whites. CS hazards for pre-ESKD death were similar for Blacks and only modestly lower for Hispanics vs. Whites across ages.

Conclusions: More Blacks and Hispanics to ESKD were driven by their greater hazards for ESKD due to more rapid decline in kidney function, not through lower mortality prior to ESKD. Delineation and elimination of the causes of faster kidney function declines are therefore the appropriate strategies to improve clinical outcomes in Blacks and Hispanics with CKD, instead of attributing the higher incidence to pre-ESKD survival bias.

Incidence of CKD and Environmental Inequities: An Integration of Ecological and Spatial Approaches in US Veterans
Yun Han,1 Jennifer L. Bragg-Gresham,1 Diane Steffick,1 Xiaosong Zhang,1 April Wyncott,1 Tiffany C. Veint,2 V. G. Vinod Vydiswaran,2 Brenda W. Gillespie,2 William Weitzel,1 Karandeep Singh,1 Susan T. Crowley,4 Rajiv Saran,1 1University of Michigan Medical School, Ann Arbor, MI; 2University of Michigan, Ann Arbor, MI; 3Veterans Health Administration, Ann Arbor, MI; 4Veterans Health Administration, West Haven, CT.

Background: Disparities in chronic kidney disease (CKD) can be linked to social and environmental determinants of health, which vary geographically across the US. We assessed geographic variation and the impact of environmental factors on incident CKD in US veterans.

Methods: We used a linked dataset from Veterans Health Administration (2014-18), the American Community Survey (2018); National Environmental Public Health Tracking Network (2018); EPA(2019) and Reference USA(2017). Incident cases of CKD were assessed geographic variation and the impact of environmental factors on incident CKD and environmental determinants of health, which vary geographically across the US. We applied to investigate the relationship between environmental factors and incidence rate of CKD.

Results: Average of incident rate of CKD was 34.8/1000 person-years (SD=12.3, n=2,718). Incident rate was higher in the rust-belt area and Appalachian region (Fig 1.b). PM2.5 was associated with higher incident rate (Fig 1.c).

Conclusions: Different environmental factors were associated with incident CKD in US counties. This highlights the potential importance of allocating resources for varied approaches to preventing and slowing the progression of CKD based on residence.

FR-OR17
Chlorthalidone and Bumetanide in Advanced CKD: HEBE Trial
Fabio Solis-Jime涅z, L. M. Perez-Navarro, Rafael Valdez-Ortiz. Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.

Background: Current treatment for hypertension and volume overload in chronic kidney disease consists of loop diuretics, nevertheless, chronic use leads to adaptive changes at the distal nephron, which in turn decreases their efficacy. The use of thiazide diuretics could be another treatment option in these patients, notwithstanding, there’s not enough evidence to justify their use in this population.

Methods: To evaluate the efficacy and safety of treatment with bumetanide plus chlorthalidone in patients with advanced chronic kidney disease a double-blind randomized controlled trial was conducted.

Results: Thirty-two patients with hypertension, chronic kidney disease stage IV/V, and chronic loop diuretic use where divided in two groups. The dual treatment group received bumetanide (2 mg BID) plus chlorthalidone (50 mg BID), while the control group was given chlorthalidone (2 mg BID) plus placebo, both for twenty-eight days. There was a decrease of systemic blood pressure in the dual treatment group when compared with the control group; systolic blood pressure -26.1±15.3 vs. -10±23.3 mmHg (p=0.028), diastolic blood pressure -13.5±10.7 vs. -3.4±11.9 mmHg (p=0.018), and mean arterial pressure -18.1±8.7 vs. -5.4±14.3 mmHg (p=0.006). There was also a decrease of volume overload in the dual treatment group when compared to the control group: total body water -4.3±3.29 vs. -0.7±0.78 liters (p=0.001), extracellular water -2.5±1.1 vs. -0.15±1.2 liters (p=0.001), and extracellular water to total body water ratio -2.9±2.76 vs. -0.24±2.42 (p=0.039).

Conclusions: In advanced chronic kidney disease plus hypertension patients whose treatment with loop diuretics is insufficient, combined use of bumetanide plus chlorthalidone can be useful for systemic blood pressure and volume overload control.

Benefits of Icosapent Ethyl Across a Range of Baseline Renal Function in Patients with Established Cardiovascular Disease or Diabetes: Results of REDUCE-IT RENAL
Arjun Maithia,1 Deepak L. BHATT,2 Allan N. Friedman,2 Michael Miller,3 Philippe Gabriel Sieg,4 Eliot A. Brinton,5 Terry A. Jacobson,6 Stephen B. Ketchum,7 Rebecca A. Kettula,5 Licia Jiao,8 Ralph T. Doyle,9 Craig B. Granowitz,10 Matthew J. Badoff,10 Preston Mason,10 Jean-Claude Tardif,10 William E. Boden,4 Christie Ballantyne.4 REDUCE-IT Investigators 1Brigham and Women’s Hospital, Boston, MA; 2Indiana University School of Medicine, Indianapolis, IN; 3University of Maryland School of Medicine, Baltimore, MD; 4Hopital Bichat - Claude-Bernard, Paris, France; 5University of California Los Angeles, Los Angeles, CA; 6Baylor College of Medicine, Houston, TX; 7VA Puget Sound Health Care System, Seattle, WA; 8Rigshospitalet - Copenhagen University Hospital, Copenhagen, Denmark; 9VA Boston Healthcare System, West Roxbury, MA; 10Amarin Pharma Inc, Cambridge, MA.

Background: Chronic kidney disease is associated with adverse outcomes among patients with established cardiovascular disease (CVD) or diabetes. Medications for treatment of CVD among patients with low estimated glomerular filtration rate (eGFR) may be ineffective.

Methods: The Reduction of Cardiovascular Events with Icosapent Ethyl-Intervention Trial (REDUCE-IT) randomized patients with CVD or diabetes and one additional risk factor to treatment with icosapent ethyl or placebo. Patients from REDUCE-IT were categorized by prespecified eGFR categories for analysis of the effect of icosapent ethyl (IPE) on the primary endpoint (composite of cardiovascular (CV) death, nonfatal myocardial infarction (MI), nonfatal stroke, coronary revascularization, or unstable angina) and key secondary endpoint (a composite of CV death, nonfatal MI, or nonfatal stroke). In post hoc analysis, patients were categorized by additional eGFR cutoffs consistent with current medical guidelines.

Results: Among the 8179 REDUCE-IT patients, median baseline eGFR was 75 mL/min/1.73m² (range: 17 to 123 mL/min/1.73m²). There were no meaningful changes in median eGFR for IPE versus placebo across study visits. IPE benefit was consistent across baseline eGFR for the primary (Figure) and key secondary endpoints. The numerical reduction in CV death was greatest in the eGFR <60 mL/min/1.73m² group (IPE: 7.6%; placebo: 10.6%; HR 0.70, 95%CI 0.51, 0.95, p=0.02). The rate of microalbuminuria in adverse event reporting was lower among IPE-treated patients (0.1% versus 3.3%, p=0.01).

Conclusions: In REDUCE-IT, icosapent ethyl reduced fatal and nonfatal ischemic events across the broad range of baseline eGFR categories.

Dapagliflozin Reduces the Risk of Hyperkalaemia in Patients with Heart Failure and Reduced Ejection Fraction: A Secondary Analysis from DAPA-HF
Soren L. Kristensen,1 Kieran F. Docherty,1 Pardeep Hundi,1 Olof Bengtsson,1 Silvio E. Inzucchi,1 Mikhail Kosiborod,2 Anna Maria Langikilde,2 Felipe Martinez,2 Piotr Poniowski,3 Marc S. Sabatine,4 Mikaela Sjostrand,2 Scott D. Solomon,3 John McMurray,11 BHF Cardiovascular Research Centre, University of Glasgow, Glasgow, United Kingdom; 2AstraZeneca, Gothenburg, Sweden; 3Wroclaw Medical University, Wroclaw, Poland; 4Yale University, New Haven, CT; 5St Lukes Mid America Heart Institute, Kansas City, KS; 6National University of Cordoba, Cordoba, Argentina; 7Brigham and Women’s Hospital, Boston, MA; 8Rigshospitalet - Copenhagen University Hospital, Copenhagen, Denmark.

Background: Hyperkalaemia often limits the use of mineralocorticoid receptor antagonists (MRAs) in patients with heart failure and reduced ejection fraction (HFrEF), denying these patients a life-saving therapy.

Methods: In a double-blinded randomized trial (NCT02252081), 50 patients with DAPA Stage 3, and MS and/or pre-diabetes, received either metformin or placebo for 16 weeks. Dosing was initiated at 500 mg and up-titrated over 7-14 days based on GI tolerance up to 1500 mg/day in CKD Stage 3a and 1000 mg/day in CKD 3b. Co-therapies for optimal CV risk reduction were continued. The co-primary outcomes included change in brachial artery flow-mediated dilation (FMD), aortic pulse-wave velocity (aPWV), and carotid intima-media thickness (CIMT) in common (CCA) and internal (ICA) carotid arteries, at 16 weeks. Lactic acid was obtained throughout the study for safety.

Results: Participants were 65 ± 10 years old and 80% were men. Mean (SD): BMI 31.4 ± 5.1 kg/m²; SBP 130.5 ± 16 mmHg; DBP 74 ± 9 mmHg; HDL 46.4 ± 15 mg/dl; fasting glucose (FG) 92.3 ± 10.3 mg/dl; Hba1c 5.7 ± 0.24%; HOBA-IR 2.4±1.5, and eGFR was 50 ± 7 ml/min/1.73 m². There were 18 patients (16%) in CKD Stage 3b, 3 in the metformin and 5 in the placebo group. Compared with placebo, metformin improved FMDbaseline (6.24% ± 4.5% [mean±SD], 16 weeks: 12.06% ± 8.4% [mean±SD]) with metformin and baseline: 6.12% ± 3.34% [mean±SD], 16 weeks: 7.6% ± 4.6% [mean±SD] with placebo, P=0.03 (Fig 1), without changing aPWV (P=0.84) or CIMT: R CAA (P=0.01) L CCA (P=0.96) R ICA (P=0.74) L ICA(P=0.44).

Conclusions: Treatment with metformin improved FMDbaseline but not aPWV or CIMT in patients with CKD and IR. Studies of larger sample size and longer duration are required to further evaluate the effects on cardiovascular outcomes.

Metformin Improves Vascular Function in CDK Patients with Metabolic Syndrome
Everly Ramos,1 Melis Sahinoz,1 Carlos O. Pena,2 Elvis A. Akwo,2 Christianne Romaine,2 Zhihong Yu,1 Edward D. Siew,2 Talat Alp Ikizler,2 Adriana Hung,2,3 Vanderbilt University Medical Center, Nashville, TN, 2Tennessee Valley Healthcare System, Nashville, TN, 3Universidad Central de Venezuela, Caracas, Venezuela, Bolivarian Republic of.

Background: Cardiovascular (CV) risk is increased in CKD. Insulin resistance (IR), highly prevalent in CKD patients, contributes to endothelial dysfunction and arterial stiffness, leading to poor CV outcomes. It remains unknown if insulin sensitization with metformin improves CV risk, in patients with CKD Stage 3-4 and metabolic syndrome (MS).

Methods: In a double-blinded randomized trial (NCT02252081), 50 patients with CKD Stage 3, and MS and/or pre-diabetes, received either metformin or placebo for 16 weeks. Dosing was initiated at 500 mg and up-titrated over 7-14 days based on GI tolerance up to 1500 mg/day in CKD Stage 3a and 1000 mg/day in CKD 3b. Co-therapies for optimal CV risk reduction were continued. The co-primary outcomes included change in brachial artery flow-mediated dilation (FMD), aortic pulse-wave velocity (aPWV), and carotid intima-media thickness (CIMT) in common (CCA) and internal (ICA) carotid arteries, at 16 weeks. Lactic acid was obtained throughout the study for safety.

Results: Participants were 65 ± 10 years old and 80% were men. Mean (SD): BMI 31.4 ± 5.1 kg/m²; SBP 130.5 ± 16 mmHg; DBP 74 ± 9 mmHg; HDL 46.4 ± 15 mg/dl; fasting glucose (FG) 92.3 ± 10.3 mg/dl; Hba1c 5.7 ± 0.24%; HOBA-IR 2.4±1.5, and eGFR was 50 ± 7 ml/min/1.73 m². There were 18 patients (16%) in CKD Stage 3b, 3 in the metformin and 5 in the placebo group. Compared with placebo, metformin improved FMDbaseline (6.24% ± 4.5% [mean±SD], 16 weeks: 12.06% ± 8.4% [mean±SD]) with metformin and baseline: 6.12% ± 3.34% [mean±SD], 16 weeks: 7.6% ± 4.6% [mean±SD] with placebo, P=0.03 (Fig 1), without changing aPWV (P=0.84) or CIMT: R CAA (P=0.01) L CCA (P=0.96) R ICA (P=0.74) L ICA(P=0.44).

Conclusions: Treatment with metformin improved FMDbaseline but not aPWV or CIMT in patients with CKD and IR. Studies of larger sample size and longer duration are required to further evaluate the effects on cardiovascular outcomes.

Associations Between Enrollment in ESRD Special Needs Plans and Outcomes
Bryan N. Becker,1 Jiacong Luo,2 Kathryn S. Gray,3 Carey Colson,4 Dena E. Cohen,1 Stephen D. McMurry,1 Bryan W. Gregory,1 Nathan Lohmeyer,5 Steven M. Brunelli,2 DaVita Integrated Kidney Care, Denver, CO; 2DaVita Clinical Research, Minneapolis, MN; 3DaVita Inc, Denver, CO.

Background: Chronic condition special needs plans (C-SPNs) are Medicare Advantage plans that offer care coordination and specialized services for patients with conditions such as end-stage renal disease (ESRD) via specific benefits packages and provider networks. Although ESRD C-SPNs have been offered for over 10 years, an understanding of their impact on patient outcomes is lacking.

Methods: This observational study considered dialysis patients receiving care at a large dialysis organization who enrolled in a C-SPN from January 2013 to September 2017; study data were derived from deidentified medical records. As of C-SPN enrollment date (or matched date for controls), enrollees and controls were matched on the basis of index month, sex, race, etiology, and dialysis modality, as well as a propensity score. Eligible controls were patients who (1) did not enter into the same facility as the C-SPN patient but had not enrolled in the C-SPN, (2) dialyzed in counties with no C-SPN but that were otherwise socio-demographically similar to C-SPN counties. Outcomes were evaluated from enrollment date through the first of study end (31 Dec 2018) or censoring for death, insurance change, or loss to follow-up. Within each matched cohort, outcomes were compared using generalized linear or Fine and Gray subdistribution hazard models.

Results: Hospitalization rates were 10% to 24% lower among C-SPN enrollees compared to controls, with an incidence rate ratio of 0.90 (95% confidence interval [CI] 0.84, 0.97) for patients in the same facility and 0.76 (95% CI 0.70, 0.83) for patients in similar counties. The mortality rate for C-SPN enrollees was approximately 23% lower than that of controls, with a hazard ratio of 0.77 (0.68, 0.88) for patients in the same facility and 0.77 (0.68, 0.88) for patients in similar counties. No meaningful differences were observed between groups with respect to serum calcium, phosphate, potassium, parathyroid hormone levels, or Kidney Disease Quality of Life scores.

Conclusions: C-SPN enrollment is associated with markedly lower rates of hospitalization and mortality, compared to non-enrollment.

FR-OR22
Organizational Characteristics Associated with High Performance in Medicare’s ESRD Seamless Care Organizations
Kelsey M. Dreyer1, Amal Trivedi,2 Adam S. Wilk,3 Emory University, Atlanta, GA; 4Brown University, Providence, RI.

Background: In 2016, the 1% of beneficiaries with end-stage renal disease (ESRD) constituted >7% of Medicare spending ($35 billion). To improve the value of care for the ESRD population, CMS implemented an alternative payment model (APM) for ESRD care, the ESRD Seamless Care Organization (ESCO), which shares savings with provider groups that reduce spending for ESRD patients below a defined benchmark. This study evaluated the relationship between key organizational, provider, and community characteristics, and ESCO performance.

Methods: We constructed a novel ESCO-level dataset capturing key information for Wave 2 (2017) ESCOs using data from CMS reports, the National Provider Identification registry, and the Area Health Resource File. After describing all 37 ESCOs, we performed bivariate comparisons of high- and low-performing (above vs below median) ESCOs based on gross savings/losses, composite quality score, and standardized mortality ratio (SMR). We then estimated generalized logistic regression models of ESCO performance as a function of organizational, provider, and community characteristics.

Results: ESCO composition and performance were highly varied (ranges: savings/losses −3.9 to 10.2%; quality 76.4-100%; SMR 0.75-1.14). Bivariate analysis showed that ESCOs with above (vs below) median savings had more aligned physicians (58 vs 29, p<0.006), fewer dialysis facilities (8.7 vs 17, p=0.07), a smaller non-Hispanic Black population (14% vs 22%, p<0.006), and a higher median household income ($55k vs $49k, p<0.001). Facilities reporting a quality score of 100% (vs <100%) had fewer practices (22 vs 43, p=0.05) and smaller non-Hispanic Black (16% vs 21%, p=0.06) and Medicaid eligible (6.5% vs 8.9%, p=0.14) populations. Low (vs above-median) SMR was associated with a higher median household income ($58k vs $46k, p<0.001). Regression model results were consistent with these findings, though small sample size prevented statistically significant estimates.

Conclusions: Our findings offer the first evidence of the impact of organizational composition and social disparities on ESCO performance. We show that the diversity in ESCO composition and settings partially explained the high variation in performance. This study provides crucial evidence that will inform the design and implementation of APMs in nephrology and the decisions of providers considering participation.

Progress in Preventing Bloodstream Infections in Hemodialysis: Data from the National Healthcare Safety Network, 2014-2018
Shannon Novosad, Lucy V. Fike, Minn Soe, Shunte Moon, Preeti Ravindranith, Erika J. Woolfolk, Lauren Moccia, Duc B. Nguyen, Priti R. Patel. Centers for Disease Control and Prevention, Atlanta, GA.

Background: Patients on hemodialysis are at high risk of bloodstream infections (BSIs) and associated morbidity and mortality. National prevention efforts have resulted in widespread practice changes, including central venous catheter (CVC) care. We analyzed Dialysis Event Surveillance data submitted to the National Healthcare Safety Network (NHSN) to describe BSI rates among hemodialysis outpatients from 2014 to 2018.

Methods: Outpatient hemodialysis facilities report BSIs (positive blood cultures collected in the outpatient setting or within 1 day after hospital admission) and the number of hemodialysis patients treated during the first 2 working days of each month to NHSN. For each BSI, the suspected source and vascular access type [e.g., CVC, arteriovenous fistula (AVF) or arteriovenous graft (AVG)] are indicated. Pooled mean rates (per 100 patient-months) were calculated. Annual BSI rate trends were evaluated using a negative binomial regression model including access type, year, and an access-year interaction variable.

Results: More than 6,000 outpatient hemodialysis hemodialysis facilities reported 134,961 BSIs from 2014 to 2018. Of these BSIs, 102,505 (76%) were categorized as access-related. Pooled mean BSI rates decreased 27% from 0.64 to 0.47 per 100 patient-months. Significant decreases in rates occurred across vascular access strata (Table); the reduction was most pronounced among patients with CVCs. BSI rates in patients with CVCs decreased 32% from 2.16 per 100 patient-months to 1.46 (annual average decrease 9.5%).

Conclusions: Substantial reductions in BSI rates among hemodialysis patients occurred during this 5-year period. Improvements in infection prevention practices, including CVC care, have likely contributed. Efforts to increase uptake of known prevention practices and implementation of new strategies might contribute to continued decreases in infections.

Funding: Other U.S. Government Support

BSI rates per 100 patient-months and annual trends, by access type, NHSN 2014-2018

Efficacy and Safety of Difelikefalin for Moderate-to-Severe CKD-Associated Pruritus: A Global Phase 3 Study in Hemodialysis Patients (KALM-2)
Thomas D. Wooldridge1, Kieran McCafferty2, Michael Schoemig3, Botond Szabolcs Csky3, Rafael Zwiech,4 Warren Wen,5 Catherine Munera,6 Frederique Menzaghi,7 Nephrology and Hypertension Associates, Ltd., Tupelo, MS; 2The Royal London Hospital - Barts Health NHS Trust, London, United Kingdom; 3Diabeteszentrum Heilbronn, Heilbronn, Germany; 4Norbert Barlacki Memorial Teaching Hospital No. 1 of the Medical University of Lodz, Lodz, Poland; 5Cara Therapeutics, Stamford, CT; 6FMC Szatellita Dialysis Center Pecs, Pecs, Hungary.

Background: Chronic kidney disease (CKD)-associated pruritus (CKD-aP) is a common and distressing condition in CKD patients (pts) and has a serious negative impact on quality of life (QoL). Difelikefalin (DFK), a novel, peripherally restricted and selective kappa opioid receptor agonist, demonstrated efficacy in a US phase 3 study (KALM-1) in hemodialysis (HD) pts with CKD-aP. Here we report primary results from the global phase 3 study of DFK in HD pts with CKD-aP (KALM-2; NCT03632609).

Methods: HD pts with CKD-aP were randomized to receive intravenous DFK 0.5 mg/kg (N=237) or placebo (PBO; N=236) after dialysis sessions. The primary endpoint was the proportion of pts who achieved a ≥3-point improvement from baseline (BL) in the weekly mean of the daily Worst Itching Intensity Numerical Rating Scale (WI-NRS) score at wk 12. Secondary endpoints were the proportion of pts who achieved an ≥4-point improvement in WI-NRS score and mean change in itch-related QoL scores (5-D Itch and Skinindex-10) from BL to wk 12.

Results: BL mean weekly WI-NRS scores were 7.3 and 7.1 in the DFK and PBO groups. The primary endpoint was met, with 54% of pts who received DFK achieving ≥3-point improvement from baseline (BL) in the weekly mean of the daily Worst Itching Intensity Numerical Rating Scale (WI-NRS) score at wk 12. Secondary endpoints were the proportion of pts who achieved an ≥4-point improvement in WI-NRS score and mean change in itch-related QoL scores (5-D Itch and Skinindex-10) from BL to wk 12.

Results: BL mean weekly WI-NRS scores were 7.3 and 7.1 in the DFK and PBO groups. The primary endpoint was met, with 54% of pts who received DFK achieving ≥3-point improvement from baseline (BL) in the weekly mean of the daily Worst Itching Intensity Numerical Rating Scale (WI-NRS) score at wk 12. Secondary endpoints were the proportion of pts who achieved an ≥4-point improvement in WI-NRS score and mean change in itch-related QoL scores (5-D Itch and Skinindex-10) from BL to wk 12.

22
a ≥3-point improvement in WI-NRS score vs 42% in the PBO group (P < 0.020). The proportion of pts who achieved a ≥4-point improvement in WI-NRS score was also significantly greater with DFK vs PBO (41 vs 28%, P < 0.010). Itch reduction was evident at wk 1 and was sustained through wk 12. Improvement in itch-related QoL assessed by 5-D Itch and SkinIndex-10 was observed. Treatment-emergent AEs ≥5% in DFK vs PBO were generally similar: 8.1% vs 5.5%, fall (6.6% vs 5.1%), dizziness (5.5% vs 5.1%), vomiting (6.4% vs 5.9%), and nausea (6.4% vs 4.2%). The incidence of serious AEs was similar across the groups.

Conclusions: In this phase 2 study, IV DFK demonstrated rapid and sustained itch reduction in HD pts with CKD-aP in multiple regions of the world. DFK was generally well tolerated, safety was consistent with findings in prior studies. With no approved therapies for CKD-aP in the US or Europe, DFK is a potential therapeutic that may address this unmet need.

Efficacy and Safety of Roxadustat in Patients with Dialysis-Dependent CKD and Anemia on Hemodialysis

Robert Provenzano,1 Jayant Kumar,2 Pablo E. Pergola,1 Bui Pham van,4 Geoffrey Thach,3 Ho Chi Minh, Viet Nam; 5FibroGen Inc, San Francisco, CA; 6AstraZeneca, Gaithersburg, MD

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Dialysis modality in patients with ESRD may impact clinical outcomes and survival. Thus, evaluation of safety and efficacy of roxadustat in patients on hemodialysis (HD) is of clinical importance.

Methods: Pooled data from three pivotal, phase 3, randomized, open-label, epoetin alfa-controlled studies of roxadustat for the treatment of anemia in patients with dialysis-dependent CKD were assessed in the subgroup of patients on HD. Endpoint evaluations were: mean change from baseline (CBF) in hemoglobin (Hb) averaged over Weeks 28–52 regardless of rescue therapy and Hb CBF averaged over Weeks 28–36 for all adverse events (TEAEs).

Results: In the DD-CKD study population, 90% (3515/3887) of patients were on HD (roxadustat=1761, epoetin alfa=1754). Baseline characteristics were generally similar between treatment groups. Mean (SD) Hb levels (mg/dL) at baseline were 9.64 (1.31) in the roxadustat (SD) CKD group and 9.3 (1.31) in the epoetin alfa group. Patients achieved a larger mean (SD) CBF to Weeks 28–52 in HD with roxadustat vs. epoetin alfa (1.27 [1.49] vs. 0.98 [1.51]), corresponding to a least-squares mean (LSM) difference of 0.25 (95% CI: 0.16, 0.33) (p<0.0001). TEAE rates were comparable between treatment groups.

Conclusions: Roxadustat was efficacious vs. epoetin alfa for increasing and maintaining Hb levels in patients with HD on CKD on HD. The safety and tolerability profiles were similar to the overall population and consistent with that observed in this patient subgroup.

Stroke and Bleeding Risk Among US Veterans with Preexisting Atrial Fibrillation Transitioning to ESRD

Cachet Wenzinger,5 John Sy,1 Maria V. Marroquin,1 Kammy Kalantar-Zadeh,1 Csaba P. Kovesdy,5 Elani Streja,1 Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; 2The University of Tennessee Health Science Center, Memphis, TN; 3VA Long Beach Healthcare System, Long Beach, CA; 4Memphis VA Medical Center, Memphis, TN

Background: Anticoagulation has been the mainstay of stroke prevention in patients with atrial fibrillation (AF). However, end stage renal disease (ESRD) patients on hemodialysis are at higher risk of bleeding and stroke outcomes, even without anticoagulation. It is unclear if patients should be continued on anticoagulation at the time of transition to ESRD.

Methods: We retrospectively examined a cohort consisting of 29,054 pre-dialysis US veterans that had a diagnosis of AF prior to transition to ESRD without a history of anticoagulation. It is unclear if patients should be continued on anticoagulation at the time of transition to ESRD. Incidence Rate Ratios (IRR) for stroke and bleeding outcomes among other ESRD patients with AF transitioning to dialysis regardless of CHA2DS2-VASC and HAS-BLED scores.

Methods: We specified the US ESKD population in Dec. 2018 and used Markov chain Monte Carlo methods to randomly assign patients to a dialytic modality, transplant, or death each month until Dec. 2030, according to parameters that regulate the inflow and outflow of each state. Incident ESKD patients entered the cohort each month and were subject to the same transition parameters. We assessed how changing transition parameters affects projected dialytic modality distributions.

Results: By prevailing conditions, the simulation projects home dialysis will comprise 12% of the dialysis population in 2025. Increasing home hemodialysis (HD) and peritoneal dialysis (PD) utilization among incident ESKD patients from rates of 0.3% to 7.5% and from 11.5% to 37.5%, respectively, by 2025 results in home dialysis utilization of 25% in 2025 and 29% in 2030. Concurrently increasing the rate of conversion from in-center HD to home dialysis from 3.0 to 15.0 events per 100 patient-years by 2025 results in home dialysis utilization of 37% in 2025 and 44% in 2030, as displayed. Decreasing home dialysis attrition rates has a smaller effect on home dialysis utilization.

Conclusions: Substantial growth of home dialysis utilization in the next decade will require a two-pronged approach to inflow: higher utilization of home dialysis in incident patients, emphasizing PD, and increased conversion of patients from in-center HD to home dialysis.

Funding: Commercial Support - Fresenius Medical Care
The absolute number of hospitalizations for each day of the week was reported for each treatment type and differences in the distribution of hospitalizations were compared using the Chi-Square test.

**Results:** The cohort consisted of 36,334 individuals. Median age was 67 and 61% were of male sex. A total of 81% of patients were receiving hemodialysis at dialysis initiation and the cause of end-stage kidney disease was secondary to diabetes in 37%. Overall, there were 119,466 hospitalizations over the observation period. The cumulative number of hospitalizations was highest for conventional in-center HD (92,707) and lowest for conventional home HD (701). Day of the week the admissions for each treatment type are noted in Table 1 (P<0.001). Hospitalizations were least frequent on Saturday and Sunday for all groups. The proportion of admissions was highest on Monday or Tuesday for conventional HD (regardless of location) and frequent in-center HD. In contrast, frequent home HD had a higher proportion of admissions on Wednesday.

**Conclusions:** There are daily variations in hospitalization comparing dialysis modalities. Future planned analyses will evaluate whether there are adjusted differences in day of the week hospitalization across modalities accounting for differences in patient characteristics.

Improving Supportive Care of Seriously Ill Dialysis Patients with Goals-of-Care Conversations

Alvin H. Moss,1 Annette Aldous,2 Glenda Harbert,3 Amanda C. Nicklas,3 Louis Diamond,4 Nancy Armstrong,5 Dale Lupu6 3 West Virginia University Health Sciences Center, Morgantown, WV; 2George Washington University School of Public Health and Health Services, The George Washington University Milken Institute of Public Health, Washington, DC; 1The George Washington University School of Nursing, Ashburn, VA.

**Background:** Dialysis patients are frequently known to receive unwanted high intensity end-of-life care. Families rate the quality of this care lower than families of patients with other chronic diseases. The purpose of this study was to test the feasibility of a supportive care intervention—the Pathways Project, an evidence-based change package of best practices—to identify seriously ill patients (SI), engage them in goals of care discussions, and track outcomes for patient goal concordance.

**Methods:** Pathways researchers recruited 10 dialysis centers with 1,546 patients. Dialysis staff screened patients with the surprise question (SQ): “Would you be surprised if this patient died in the next 6-12 months?” to identify those who were SI and recorded patient outcomes including the number screened, SI, goals of care conversations, hospitalizations, referred to hospice, death, and place of death. An odds ratio was calculated for the odds of SI dying versus those who were not SI, and one-sided Cochran-Armitage trend tests were used to assess for increasing goals of care conversations and deaths at home. The study was interrupted at 9 months due to COVID-19.

**Results:** On average, 98.8% of patients were screened monthly, and 18.4% were identified as SI. Of 114 patients who died, the SI constituted 66% of deaths though only 18.4% of patients. The mortality for the SI was 27% versus 3% for those who were not, and the odds ratio for SI dying was 11.22 (95% CI 7.42 to 16.98, P < .0001). Dialysis interdisciplinary teams implemented site-specific approaches to adding goals of care conversations into usual workflow; the number conducting conversations with SI within 30 days of hospital discharge increased from 30% to 80% (P = .02). The proportion of the patients who died at home in the last 2 months was higher than baseline (32.6% vs 18.8%), but a trend was not yet evident (P = .12).

**Conclusions:** The Pathways intervention is feasible to implement supportive care best practices into existing workflow of dialysis centers. It takes time for teams to get comfortable with new processes and communication approaches; after 9 months more centers were conducting goals of care conversations and more patients were dying at home. Future research is needed to determine if the Pathways intervention results in outcomes more aligned with patient preferences.

Implementation of a Decision Aid for Recognition and Correction of Volume Alterations (Recova®) in Hemodialysis

Jenny Stenberg,1 Magnus Lindberg,2 Hans Furuland,1 1 Uppsala University Department of Medical Sciences, Uppsala universitet Institutionen for medicinska vetenskap, Uppsala, Sweden; 2Uppsala University Department of Public Health and Caring Sciences, Uppsala universitet Institutionen for folkhals- och vardvetenskap, Uppsala, Sweden; 3Hogskolan i Gävle, Gävle, Sweden.

**Background:** Chronic fluid overload is an independent predictor of mortality in hemodialysis. Clinical assessment of fluid status is subjective and unprecise, and 30% of the patients remain fluid overloaded at dry weight. This study evaluates the effects of implementing a recently developed decision aid, Recova®, which combines a systematized fluid status procedure with bioimpedance spectroscopy, for individualized dry weight determination in hemodialysis.

**Methods:** The study was a prospective implementation intervention carried out at two hemodialysis units. The impact of the intervention was measured as the proportion of participants at an adequate dry weight at the end of the study, assessed as change in symptoms, hydration status, and N-terminal pro-brain natriuretic peptide (NT-proBNP). Hemodialysis nurses were instructed to use Recova® every two weeks, assessing the study participants’ fluid status and adjusting their dry weights as appropriate. The process of the intervention was measured as frequencies of fluid status assessments, bioimpedance measurements, and dry weight adjustments.

**Results:** Forty-nine patients were enrolled. In participants with fluid overload (n = 10), both bioimpedance-measured overhydration and fluid overload symptom score decreased. In fluid-depleted participants (n = 20), dry weight adjustment frequency and dry weight increased. The post-dialytic negative overhydration was reduced, but NT-proBNP increased. In the remaining 19 participants, with low volume status scores, no significant changes were observed.

**Conclusions:** Recova® defines how and when dry weight should be evaluated in hemodialysis patients. Its purpose is to provide the multidisciplinary team with a common language, and thereby facilitate early recognition and appropriate response to fluid alterations. Implementation of Recova® in hemodialysis care increased the monthly frequencies of bioimpedance measurements and dry weight adjustments, and contributed to symptom reduction.

Development of Alport-Syndrome-on-a-Chip to Study the Glomerular Filtration Barrier Pathophysiology

Laura Perin,1 Valentina Villani,1 Astigk Petrosoyan,1 Charmi Dedhia,1 Geremy Clair,2 Roger E. De Filippo,1 Stefano Da Sacco,1 Children’s Hospital of Los Angeles, Los Angeles, CA; 1Pacific Northwest National Laboratory, Richland, WA.

**Background:** Alport Syndrome (AS) is a genetic disorder in which podocytes fail to correctly assemble the COL4a3c4a4c5 trimer, a major constituent of the GBM. Disruption of the GBM network leads to podocyte depletion and progressive kidney failure. While important advances in our understanding of AS progression have been made possible by animal models, we still lack an efficient and faithful in vitro model that can mimic the human AS disease. We have recently developed a glomerulus-on-a-chip system (GOAC) that replicates the features of the glomerular filtration barrier and generated AS chips by combining this novel tool with COL4-defective podocytes.

**Methods:** Podocytes derived from amniotic fluid of patients affected by AS (APD) were seeded with human glomerular endothelial cells (hGEC) on Organoplates in a barrier-free system to generate AS-GOAC. The system was assayed by confocal microscopy, WB, proteomics and RNA-seq. Permeability was assessed by measuring albumin leakage. Transcriptomics studies were performed on podocytes by RNA-seq and qPCR and results confirmed in vivo in a mouse model of AS. Primary human podocytes were used as control.

**Results:** We confirmed AS phenotype in AS-POD by RNA-seq and WB. GOAC generated with AS-POD show absence of COL4A3-4-5 confirmed by WB. AS-GOAC
present impaired permeability to albumin, due to a dysfunctional assembly of the GBM, typically with high-grade vesicoureteral reflux (VUR). Our research has identified key targets known to target key players in AS and CKD like WT1, osteopontin, vinculin as well as VEGF and TGFβ pathways. Results were confirmed in vivo in glomeruli of AS mice, further validating the AS-GOAC as an efficient tool for AS studies. Proteomics analysis of the filtrate and the collected urinary proteins showed a distinct signature in AS-GOAC, including presence of apolipoprotein A, α1-antitrypsin and β2-glycoprotein I.

Conclusions: We have successfully developed an Alport-on-a-chip system that closely mimics the GBM structure and provides a powerful tool for studying the effect of AS on the GBM at the molecular level. We have also identified some specific AS proteins, indicative of disease manifestation. This system has the potential to improve our knowledge on AS pathophysiology, allowing novel therapeutic targets and a transformative tool, thus ultimately benefiting patients affected by renal failure.

Development of a Personalized Medicine Platform for Non-stop RTD Therapy in Alport Syndrome

Kohel Omachi,1 Hirofumi Kai,2 Jeffrey H. Minor,1 1Washington University in Saint Louis, Saint Louis, MO; 2Kumamoto University Graduate School of Pharmaceutical Sciences, Kumamoto, Japan, Kumamoto, Japan.

Background: Alport syndrome (AS) is characterized by glomerular basement membrane (GBM) abnormalities leading to progressive glomerulosclerosis. Mutations in the COL4A3, COL4A4 or COL4A5 genes encoding type IV collagen α3(α4)5α5(α5) are responsible for AS. Nonsense mutations resulting in premature termination codons (PTCs) account for about 65% of AS cases. Type IV collagen chains have a C-terminal NC1 domain, which is essential for assembly of GBM and for network formation in the GBM. Truncated α3(α4)5α5 chains without an intact NC1 domain due to PTCs cannot assemble in the GBM. Therefore, achieving full-length protein expression is a potential therapy for AS due to nonsense mutations. Small compound-based nonsense readthrough therapies have been studied in other genetic diseases, but whether nonsense readthrough therapy is applicable to Alport syndrome is unexplored.

Methods: To investigate the feasibility of PTC readthrough in AS, we made a C-terminal NanoLuc-fusion COL4A5 reporter cDNA to monitor full-length translation. The full-length COL4A5-NLuc produces luminescence, but truncated forms do not. To screen for COL4A5 nonsense mutants susceptible to PTC readthrough therapy, we introduced 49 nonsense mutations found in X-linked AS patients into the COL4A5-NLuc gene. We transfected these individually into HEK293 cells and measured luminescence in individual wells. The GBM in the New Zealand Golden (NZ) rat is known to have high residual activity.

Results: The COL4A5-NLuc gene produced luminescence when wild type, but not when carrying COL4A5 nonsense mutations. Among 49 nonsense mutants, we found that 11 were susceptible to PTC readthrough. The efficacy of readthrough was higher for UGA nonsense codons than for UAG and UAA. Gentiamicin also induced readthrough of these same 11 PTCs.

Conclusions: We found 11 nonsense mutations in COL4A5 susceptible to PTC readthrough drugs. This luciferase-based COL4A5 translation reporter system will contribute to the development of PTC readthrough therapy in a personalized medicine approach to treating AS.

A ROBO2 Fusion Protein (PF-06730512) Traps SLIT Ligands and Therapeutically Ameliorates Podocyte Injury

Stephen Bera,1 Janet E. Buhlmann,1 Michael Shamshak,1 Matthew V. Russo,2 Hongying Yang,1 Kelly M. Knowlton,1 Nathan Higginson-Scott,1 Hank Lin,1 Catharine Andresen,1 Rhys Jones,1 Xueping Fan,2 Sudhir Kumar,2 Aneesha Pydi,3 David J. Salant,4 Weining Lu,5 Pfizer Inc, Cambridge, MA; 2Boston University Medical School, Boston, MA.

Background: ROBO2/SLIT2 signaling negatively regulates nephrin-induced actin polymerization and destabilizes podocyte focal attachments and adherence to the glomerular basement membrane (GBM) by inhibiting non-muscle myosin II A. Lack of ROBO2 in podocytes are protected from podocyte injury. Based on these findings we hypothesized that blocking this pathway might have therapeutic potential in podocyte pathologies. Here, we present preliminary evidence to support our hypothesis from a case with a genetic defect in ROBO2 and a rodent model of podocyte injury.

Methods: We investigated a patient with a chromosomal translocation that disrupted the ROBO2 gene, produced transcripts encoding dominant negative proteins, and caused high-grade vescoureteral reflux (VUR). We designed a novel therapeutic ROBO2 fusion protein (ROBO2-Fc, PF-06730512) that inhibits the ROBO2/SLIT2 pathway. In vivo efficacy of ROBO2-Fc was tested in the rat Passive Heymann Nephritis (PHN) model. We also studied the molecular and cellular functions of SLIT2 in kidney glomeruli.

Results: In contrast to most adults with long-standing VUR that develop focal segmental glomerulosclerosis (FSGS) and proteinuria, the patient with a disrupted ROBO2 gene had stable renal function without proteinuria. In vitro, ROBO2-Fc bound to SLIT ligands with high affinity and dose-dependently inhibited SLIT binding to cell surface ROBO2, and it inhibited ROBO2-dependent cell migration ex vivo. ROBO2-Fc has a 35% half-life of about 8 hours in rats and 5 days in monkey. Treatment with ROBO2-Fc reduced proteinuria, shortened podocyte foot process width, and increased slit-diaphragm density in the rat PHN model. Mechanistically, we found that SLIT2 is localized to the GBM and binds to COL4A3/4 laminin to inhibit podocyte adhesion.

Conclusions: We have generated a novel therapeutic ROBO2 fusion protein that functions as a SLIT ligand trap to treat podocyte injury in a clinical model. Inhibiting the ROBO2/SLIT2 pathway therapeutically reduces proteinuria and improves podocyte ultrastructure. A phase 2 clinical trial to evaluate the safety and efficacy of ROBO2-Fc (PF-06730512) in patients with FSGS is currently ongoing (NCT03448692).

Semaphorin 3B-Associated Membranous Nephropathy

Sanjeev Sethi,1 Hanna Debies,2 Benjamin J. Madden,2 Marina Vivarelli,4 Cristine Charlesworth,1 Aishwarya Ravindran,1 Loaun Gross,1 David Buob,3 Cheryl L. Tran,1 Francesco Emma,4 Francesca Diomendi-Camasselli,4 Fernando C. Fervenza,1 Pierre M. Ronco,2,3 Mayo Clinic, Rochester, MN; 2Sorbonne Universite, Paris, France; 3Tenon Hospital, Paris, France; 4Ospedale Pediatrico Bambino Gesu, Roma, Italy.

Background: Membranous nephropathy (MN) results from subepithelial anti-β3 integrin complex deposition along the glomerular basement membrane (GBM). Although PLA2R, THSD7A, and NELL1 account for a majority (approximately 80%) of the target antigens, the target antigen in the remaining MN is not known.

Methods: We performed laser microdissection and mass spectrometry (MS) of glomeruli in kidney biopsies of 70 cases of PLA2R-negative MN. We detected high spectral counts of a unique protein Semaphorin 3B (Sema3B) in 3 cases. Immunohistochemistry (IHC) for Sema3B was then performed to confirm MS results. Next, we analyzed 332 Sema3B-positive cases and 118 PLA2R-negative MN cases by immunofluorescence microscopy (IF). Confocal microscopy studies were done to confirm colocalization of IgG and Sema3B along the GBM. Next, serum antibodies were detected by Western blotting (WB).

Results: MS identified a unique protein, Sema3B in 3 cases of PLA2R-negative MN. MS failed to detect Sema3B in the remaining 67 PLA2R-negative MN, in 23 PLA2R-associated MN, and 88 controls that included IgA nephropathy, diabetes, FSGS and undefined chronic disease. Semaphorin 3B antibody levels were significantly higher for Sema3B-positive cases compared to PLA2R-negative MN.

Conclusions: Semaphorin 3B-associated MN is a distinct type of MN, and is predominantly present in pediatric patients.

Figure 1 shows bright granular capillary wall staining for Sema3B in 3 cases of Sema3B-associated MN.

High Temperature Recombinant Protein A1 (HTRA1): A Novel Antigen in Membranous Nephropathy

Laith Al-Rabadi,1 Tiffany Caza,2 Claire Avillach,3 Aylin R. Rodan,4 B. Williams,1 Josephine Abraham,1 Monica P. Revelo Penafiel,1 Nicole K. Andeen,1 I. Kawai,1 Frederic Clayton,1 Timothy Cummings,2 Michael Merchant,3 Jon B. Klein,4 Christopher P. Larsen,4 Laurence H. Beck.4 (HICO) for Sema3B-associated MN were pediatric cases. In 5 of the 8 children, the disease started below the age of 2 years.

Conclusions: Semaphorin 3B-associated MN is a distinct type of MN, and is predominantly present in pediatric patients.

Methods: We present a multi-approach approach using traditional and modern technologies to converge on a novel target antigen. Instead of a case-vs-control design, we capitalized on the temporal variation in autoantibody titer for our biomarker discovery. Western blotting (WB) of human glomerular extract (HGE) proteins followed by differential immunoprecipitation and mass spectrometry analysis was complemented by laser-capture microdissection / mass spectrometry as well as autoimmune profiling on a protein expressed sequence tag microarray. Commercial antibodies to the candidate antigen were used for immunostaining MN biopsies, and reactivity of patient sera with a recombinant HTRA1 (HTRA1) by WB and ELISA was assessed.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only; Underline represents presenting author.
Glomerular Diseases: Charting New Territory

Protocadherin 7-Associated Membranous Nephropathy

of PCDH7-associated MN, and negative staining in a case (D) of PLA2R-negative MN. Figure 1 shows bright granular capillary wall staining for PCDH7 in 3 cases (A, B, C) of PCDH7-associated MN, and negative staining in a case (D) of PLA2R-negative MN.

Results: Using these combined approaches, we identified HTRA1 as a novel antigen in a subset of patients with primary MN. Serum from these patients reacted with WB with a 51 kDa protein in non-reduced HGE as well as HTRA1, which correlated with clinical disease activity.(Fig A and B) Consistent with PLA2R and THSD7A, anti-HTRA1 antibodies were predominantly IgG4. HTRA1 specifically was detected in a capillary loop fine granular pattern. (Fig C) and colociliated with IgG4. Whole-proteome peptide microarrays detected significantly higher titer (6.9 SD) of anti-HTRA1 antibody in the active stage as opposed to the remission stage which was informative of its candidacy as a podocyte targeted protein. We have 3 confirmed cases of HTRA1-associated MN and are currently screening several large biopsy cohorts of MN that are negative for PLA2R, THSD7A, and NELL-1 to better assess the prevalence of this novel form of MN.

Conclusions: This report demonstrates the convergence of conventional with more modern techniques to identify HTRA1 as a target podocyte antigen in MN.

Protocadherin 7-Associated Membranous Nephropathy
Sanjeev Sethi,1 Benjamin J. Madden,1 Louann Gross,1 Vivian C. Negron,1 Cristine Charlesworth,1 Hanna Debiec,2 Pierre M. Ronco,2 Fernando C. Ferravanti,3 Mayo Clinic, Rochester, MN; 3 Sorbonne Université, Paris, France; 4 Tenon Hospital, Paris, France.

Background: Membranous nephropathy (MN) results from subepithelial antigen-antibody complex deposition along the glomerular basement membrane (GBM). Although PLA2R, THSD7A, and NELL-1 account for a majority (approximately 80%) of the target antigens, the target antigen in the remaining MN is not known.

Methods: We performed laser microdissection and mass spectrometry (MS) of glomeruli in kidney biopsies of 85 cases of PLA2R-negative MN. We detected high spectral counts of a unique protein Protocadherin 7 (PCDH7) in 8 cases. Immunohistochemistry (IHC) for PCDH7 was then performed to confirm MS results.

Results: MS identified a unique protein, PCDH7 in 8 cases (9.4%) of PLA2R-negative MN. MS failed to detect PCDH7 in remaining 77 PLA2R-negative MN, 23 PLA2R-positive MN, and 88 controls that included IgA nephropathy, diabetes, FSGS and minimal change disease. Among the 77 PLA2R-negative MN, MS detected NELL1 (14 cases), EXT1/EXT2 (6 cases), PLA2R (4 cases labeled PLA2R-negative on IF), Sema3B (3 cases), THSD7A (2 cases), and DNAJH9 (4 cases of fibrillary GN, misdiagnosed as MN as EM was not done). PCDH7 localized as granular deposits along the GBM by IHC (Figure 1). Kidney biopsy showed a grade II MN in 6 cases, grade I in 1 and grade III in 1 case. Immunofluorescence microscopy showed GBM staining for IgG and C3 in all cases. IgG subtyping done in 2 cases showed IgG4 in both. The mean age was 64 years (+/-11) and 7 of the 8 patients were males. The average serum creatinine and proteinuria was 1.28 mg/dL (+/-0.3) and 4.9 gm/L (+/-3.0), respectively. Interestingly, 3 of 8 cases had associated malignancies. Further studies including evaluation for circulating antibodies are ongoing.

Conclusions: Protocadherin 7-associated MN may represent distinct type of MN.

FR-OR37
Nefecon® (Budesonide) Selectively Reduces Circulating Levels of BAFF (BLYS) and Soluble BCMA and TACI in IgA Nephropathy
Karen Molyneux, Jonathan Barratt, David H. Wimbury. Mayer IgA Nephropathy Laboratory, University of Leicester, UK, Leicester, United Kingdom.

Background: Evidence supports a pivotal role for gut-associated lymphoid tissue (GALT) as a major source of poorly O-galactosylated immunoglobulin A (IgA) 1 in patients with IgA nephropathy (IgAN). IgA synthesis in GALT is regulated by B-cell activating factor (BAFF) [B-lymphocyte stimulator (BLYS)] and APRIL, a proliferation-inducing ligand (APRIL). BAFF and APRIL bind to specific cell-surface receptors: transmembrane activator and calcium modulator and cyclophilin-Ligand (TACI), B-cell maturation antigen (BCMA), and the BAFF receptor. Elevated levels of BAFF and APRIL have been linked to worse clinical outcomes in IgAN. The therapeutic potential of targeting GALT was demonstrated in the NEFIGAN trial (NCT01738035), which assessed the efficacy of a novel targeted-receptor formulation of budesonide (Nefecon®), designed to deliver budesonide to the GALT-rich distal ileum in patients with IgAN. The trial comprised 6-month run-in, 9-month treatment, and 3-month follow-up phases: 48 patients received Nefecon® 16 mg/day, 51 patients received Nefecon® 8 mg/day, and 50 patients received placebo. As a result, Nefecon® 16 mg/day, added to optimised renin–angiotensin system blockade, reduced proteinuria and stabilized estimated glomerular filtration rate in patients with IgAN. This study investigated whether Nefecon® treatment altered serum levels of BAFF and APRIL and their receptors.

Methods: Serum levels of BAFF, APRIL, BCMA, and TACI were measured using Luminex technology. Changes in the levels of BAFF and APRIL were compared using a one-way analysis of variance. Significance was set as p<0.05.

Results: A significant, dose-dependent reduction in serum BAFF levels was seen with Nefecon®, which reversed on cessation of Nefecon®. There were similar significant reductions in the levels of soluble BCMA and TACI with treatment, but no effect was seen on circulating levels of APRIL. These changes were mirrored by parallel changes in soluble CD27 levels and were consistent with our previous reports on dose-dependent reductions in circulating IgA-IgG immune complexes, secretory IgA, and galactose-deficient IgA-IgG levels with Nefecon®.

Conclusions: Delivering budesonide to the GALT-rich distal ileum modules key regulators of GALT B-cell maturation and IgA class switch recombination in patients with IgAN.

Tony Muchamuel, Rong A. Fan, Janet L. Anderl, Henry Johnson, Dustin L. Memmin, Brian Tuch, Christopher Kirk. Kezar Life Sciences Inc, South San Francisco, CA.

Background: Selective inhibition of the immunoproteasome blocks progression of nephritis in a mouse model of systemic lupus erythematosus (SLE). Here we describe the effects of KZR-616 in this model and in patients from MISSION (KZR-616-002; NCT03393013), an open-label study of KZR-616 in patients with SLE with and without nephritis.

Methods: 24-week old NZB/W mice were treated weekly with subcutaneous administration of 5 mg/kg KZR-616 for 11 weeks. SLE patients with active disease and stable background medication (N=34) were dosed subcutaneously with KZR-616 at 30, 45 or 60 mg weekly for 13 weeks with a 12-week follow-up. Clinical samples were evaluated for proteasome subunit binding, and immune cell profile was evaluated by flow cytometry. Gene expression analysis was performed by RNaseq in mouse tissue (whole blood, spleen, and kidneys) and patient (whole blood) samples.

Results: KZR-616 treatment resulted in complete resolution of proteinuria, prevention of glomerular damage, and absence of renal IgG deposition. Depletion of splenic activated T- and B-cells and short and long-lived plasma cells in treated animals was noted and correlated with decreased gene expression associated with inflammation, T helper (Th) 1 and Th17 pathways, interferon signaling, antibody secreting cells, and differentiation of plasma cells (PC). KZR-616 reduced kidney tissue transcripts associated with inflammation, cell and myeloid glomerulus trafficking and renal genes implicated in LN pathogenesis. In SLE patients, KZR-616 treatment was determined to be safe and tolerated at all dose levels and reductions in disease activity parameters were noted. KZR-616 treatment was associated with a reduction in class-switched memory B cells and PC in peripheral blood. Decreased expression of gene modules for PC, T-cell activation, inflammation, neutrophil, and type I IFN responses were seen in response to treatment.

Conclusions: KZR-616 resolves nephritis in a mouse model of SLE/LN by regulating immunoproteasome subunit gene expression and glomerular injury. In SLE patients, KZR-616 demonstrated broad anti-inflammatory activity across T, B, and innate immune effector cells. These results support further clinical evaluation of KZR-616 in patients with LN.

NCAM1 Is an Autoantigen in Membranous Lupus Nephritis
Tiffany Caza,1 Samar Hassen,1 Michael B. Kuperman,1 Ricky Edmondson,2 Christian Herzog,2 Aaron J. Storey,2 John M. Arthur,2 Zeljko Dvanjacsek,3 Shree G. Sharma,1 Daniel J. Kenan,1 Laith Al-Rabadi,1 Christopher P. Larsen.1
1Arkana Laboratories, Little Rock, AR; 2University of Arkansas for Medical Sciences, Little Rock, AR; 3University of Utah Health Hospitals and Clinics, Salt Lake City, UT.

Background: Membranous lupus nephritis is a frequent cause of proteinuria in patients with systemic lupus erythematosus. In patients with membranous lupus nephritis, the target autoantigens are largely unknown. Determination of a target autoantigen can have diagnostic significance, inform prognosis, and enable non-invasive monitoring of disease activity. We utilized mass spectrometry to identify target autoantigens in membranous lupus nephritis and report cell neural adhesion molecule-1 (NCAM1) as a novel target podocyte antigen.

Methods: We utilized mass spectrometry for antigen discovery of laser capture microdissected (LCMD) glomeruli and protein G immunoprecipitation studies to interrogate immune complexes. Confocal microscopy was used to examine co-localization with IgG within glomerular immune deposits. Case series of biopsies from PLA2R-negative membranous nephropathy patients (n=101) and patients with membranous lupus nephritis (n=212) were used to determine the overall frequency of these antigens. Western blotting detecting patient sera against recombinant NCAM1 protein was used to detect circulating anti-NCAM1 antibodies.

Results: NCAM1 was uniquely identified in a subset of patients with membranous lupus nephritis in LCMD glomeruli and protein G immunoprecipitations by mass spectrometry. NCAM1 was co-localized with IgG within glomerular immune deposits. The prevalence of NCAM1 positivity by immunofluorescence was 6.1% of cases of membranous lupus nephritis and 2.0% of idiopathic membranous nephropathy cases. Additionally, serum from NCAM1 patients showed reactivity to NCAM1 recombinant protein, demonstrating the presence of circulating autoantibodies.

Conclusions: We propose that NCAM1, a cytoskeleton-linked transmembrane protein, is a target autoantigen in a subset of patients with membranous lupus nephritis and within rare cases of idiopathic membranous nephropathy. The presence of anti-NCAM1 antibodies in urine could allow for non-invasive monitoring.

Alpha1-Antitrypsin Diminishes Neutrophil Activation by PR3-ANCA
Ralph Kettritz,1 Uwe Jerke,1 Claudia Eulenberg-Gustavus,1 Dieter E. Jenne.1
1Experimental and Clinical Research Center, Charité, Max Delbrück Center for Molecular Medicine in the Helmholtz Association, Berlin, Germany; 2Charité Universitätsmedizin Berlin, Berlin, Germany; 3German Center for Lung Research, Helmholtz Zentrum München, Munich, Germany.

Background: Neutrophil serine proteases (NSPs) contribute to ANCA-associated vasculitis (AAV). PR3 is a unique NSF family member because it is both a proteolytic enzyme and an ANCA antigen. Alpha1-antitrypsin (AAT) is the major natural NSP inhibitor. We hypothesized that AAT protects from ANCA-induced neutrophil activation and neutrophil-mediated glomerular endothelial cell injury.

Methods: We produced wild-type (wt) AAT and a mutant (μm) form that does not inhibit proteolytic NSP activity. We used flow cytometry to study membrane PR3 (mPR3) and MPO (mMPO), ferricchiochrome C assay for superoxide release, FRET assays for proteolytic NSP activity, human neutrophils and glomerular microvascular endothelial cells (gMVEC) for transcriptional and electron microscopy, and assessed ECs by phallodin staining and gene expression.

Results: Wt-AAT reduced mPR3 on TNF-primed neutrophils dose-dependently from 0.1 to 10 μM (n=3). Five μM wt-AAT, but not μm-AAT, reduced neutrophil mPR3 in suspension, on fibronectin, and on an EC monolayer to approximately 25% (n=3). Parallel comparisons in neutrophil-EC co-cultures using antibodies to different PR3 epitopes showed that 5 μM AAT reduced mPR3 but not mMPO. Importantly, reduced mPR3 by AAT resulted in significantly less superoxide release by TNFα-primed neutrophils that activated with PR3-, but not with MPO-ANCA IgG from AA V patients (n=4). Next, we studied the NSP transfer from activated neutrophils to gMVEC and found that gMVEC increased NSP concentrations, exemplified by PR3 from both cell-free supernatants (cf-SN) and under neutrophil-EC co-culture conditions. Importantly, wt-, but not μm-AAT abrogated the PR3 transfer from cf-SN. In contrast, AAT did not inhibit the PR3 transfer under neutrophil-EC co-culture conditions. Finally, we observed by RT-PCR that cf-SN from activated neutrophils increased two NF-kB dependent genes in gMVEC, namely IkBα and IL-8. This effect was reduced by wt-, but not by μm-AAT suggesting an NSF-dependent activation mechanism.

Conclusions: AAT has protective effects by reducing neutrophil activation in response to PR3-ANCA, and NSF-mediated glomerular microvascular endothelial cell injury. Disturbances of the AAT-NSP balance possibly contribute to neutrophil-mediated vascular injury in AAV, particularly, but not exclusively, in patients with PR3-ANCA.

Harnessing Expressed Single-Nucleotide Variation and Single-Cell RNA Sequencing to Define Immune Cell Chimerism in the Rejecting Kidney Transplant
Andrew F. Malone, Haojia Wu, Joseph Gauto, Benjamin D. Humphreys. Washington University in Saint Louis, Saint Louis, MO.

Background: In solid organ transplantation, donor derived immune cells are assumed to decline with time after surgery. Whether donor leukocytes persist within kidney transplants or play any role in rejection is unknown, however, in part because of limited techniques for distinguishing recipient and donor cells.

Methods: We performed paired whole exome sequencing of donor and recipient DNA and single cell RNA sequencing (scRNA-seq) of human kidney transplant biopsy cores. Exome sequences were used to define single nucleotide variants (SNV) across all samples.

Results: By analyzing expressed SNVs in the scRNA-seq dataset we could define recipient vs. donor cell origin for all 81,139 cells. The leukocyte donor to recipient ratio varied with rejection status for macrophages and with time post-transplant for lymphocytes. Recipient macrophages were characterized by inflammatory activation and donor macrophages by antigen presentation and complement signaling. Recipient origin T cells expressed cytotoxic and pro-inflammatory genes consistent with an effector cell phenotype whereas donor origin T cells are likely quiescent expressing oxidative phosphorylation genes relative to recipient T cells. Finally, both donor and recipient T cell clones were present within the rejecting kidney, suggesting lymphoid aggregation. Our results indicate that donor origin macrophages and T cells have distinct transcriptional profiles compared to their recipient counterparts and donor macrophages can persist for years post transplantation.

Conclusions: This study demonstrates the power of this approach to accurately define leukocyte chimerism in a complex tissue such as the kidney transplant coupled with the ability to examine transcriptional profiles at single cell resolution.

Results: We found 107 glomerular and 112 tubulointerstitial proteins significantly differentially expressed in AMR vs ACR (p<0.05). Similarly, 112 (glomerular) and 124 (tubulointerstitial) proteins were altered in AMR vs ATN. Basement membrane and extracellular matrix (ECM) proteins were decreased in both compartments in AMR, compared to ACR and ATN. We verified decreased glomerular and tubulointerstitial LAMA proteins expression, and decreased glomerular NPHS1 and PTPRO expression in AMR. Cathepsin-V (CTSV) was predicted to cleave ECM-proteins in the AMR glomeruli. We identified galectin-1, an immunomodulatory protein increased in AMR glomeruli and linked to the ECM. An external dataset (GSE36039) also demonstrated increased galectin-1 expression in anti-HLA class-I antibodies induced inflammation and significantly increased CTSV expression, and galectin-1 expression and secretion, in human glomerular endothelial cells. We also studied GSTO1, an ECM-modifying enzyme, increased in the AMR tubulointerstitium. GSTO1 expression was significantly increased in TGF-treated proximal tubular epithelial cells.

Conclusions: Baseline remodelling are often remodeled in chronic AMR, and we demonstrated that this remodelling begins early in glomeruli and tubulointerstitium. ECM-remodelling in AMR may represent a new therapeutic target.

Interim Update of the MDR-101-MLK Phase 3 Trial: MERCURY Study

Dixon Kaufman,1 Mark D. Segall,2 Ethan P. Marin,3 Ahmed O. Gaber,4 Titte Srinivas,5 Erik Stites,6 Stephan Busque,7 Martin L. Mai,8 Matthew Cooper,9 Suzanne Crowley,10 James B. Piper,11 Ashish P. Shah,12 Sanjeev Akkina,13 Kenneth Chavin,4 Mercury Study Group1 University of Wisconsin System, Madison, WI; 2Mayo Clinic Minnesota, Rochester, MN; 3Yale University Department of Internal Medicine, New Haven, CT; 4Houston Methodist, Houston, TX; 5University of Colorado, Denver, CO; 6Stanford University School of Medicine, Stanford, CA; 7Mayo Clinic’s Campus in Florida, Jacksonville, FL; 8MedStar Georgetown University Hospital, Washington, DC; 9University Hospitals, Cleveland, OH; 10Medore Therapeutic, South San Francisco, CA; 11Inova Health Systems, Falls Church, VA; 12Jefferson Health, Wayne, Pa; 13Loyola University Health System, Maywood, IL.

Methods: Eligible adult pairs (donor/recipient) of a first kidney allograft from an ABO-compatible donor were randomized to receive ATG conditioning, low-dose total lymphoid irradiation (TLI) over 10 days and IS followed by 5 days before undergoing apheresis (1 or 2 cycles). IA recipients receive ATG (IA; n=20) or Control Arm (CA; n=10). Donors in the IA received G-CSF mobilization conditioning, low-dose total lymphoid irradiation (TLI) over 10 days and IS followed by 5 days before undergoing apheresis (1 or 2 cycles). IA recipients receive ATG

Conclusions: Administration of MDR-101 in HLA-identical LD Ktxp recipients eliminated the lifelong need for immunosuppressive (IS) drugs and to prevent graft loss due to rejection or drug toxicity. MDR-101 is a novel cellular immunotherapy, to produce persistent mixed chimerism without graft versus host disease (GvHD) to allow elimination of all IS therapy without rejection, and, thus, to produce operational tolerance. The randomized study evaluated the need for chronic IS therapy in recipients of HLA-matched living donor (LD) kidney transplants as compared to standard of care (SOC) (NCT03363945).

FR-OR44

Single-Cell RNA-sequencing Analysis of Kidney Transplant Biopsies Demonstrates a Proinflammatory Role for Renal Tubular Cells in Rejection

Andrew F. Maloney, Aidan Leckie-Harre, Haojia Wu, Benjamin D. Humphreys.

Washington University in Saint Louis, Saint Louis, MO.

Background: Antibody mediated rejection (AMR) remains one of the major causes of allograft failure and our understanding of this disease process is poor. CXCL12 is thought to contribute to allograft rejection through T cell recruitment and a CXCL12 promoter variant is associated with worse graft outcomes. We performed single cell RNAseq on biopsies from transplant patients to examine ligand expression in kidney cells.

Methods: The 10X Genomics platform was used to make libraries which were sequenced to a depth of ~50k reads/cell. Gene-cell matrices were obtained from CellRanger and the downstream analysis (clustering, integration analysis, expression analyses) were done using R and Seurat. This study had IRB approval.

Results: 81139 cells in total (avg = 1124 genes/cell) from 5 kidney transplant biopsy samples (2 non-rejecting, 3 ABMR) were included in the final integrated analysis using UMAP. All major kidney cell types were identified as well as macrophages, B cells and T cells. Renal epithelial cells from rejection samples differentially expressed ligands with cognate receptors found on immune cells. All renal tubular cell types increase HLA gene expression allowing allowing for ligation of macrophage and T cell cognate receptors LIRL and CD3, respectively. Interestingly, only loop of Henle cells increased expression of CXCL12 whereas stromal cells decreased CXCL12 expression in rejection samples.

Conclusions: Comprehensive single cell RNAseq of human kidney transplant biopsies suggests a role for loop of Henle cells in rejection though expression of CXCL12. We also demonstrate that stromal cells, known to express CXCL12, downregulate CXCL12 expression in rejection. These data suggest a pro-inflammatory role for tubular cells in rejection.

Modulated Immune Cell Infusion in Kidney Transplantation
Christian Morath,1 Matthias Schauer,1 Eman H. Ibrahim,1 Lei Wang,1 Christian Kleist,1 Gerhard Opelz,1 Caner Süsäl,1 Mostafa G. Aly,1 Claudius Speer,1 Florian Käuble,1 Christian Nußthag,1 Luiza Pego Silva,2 Claudia Sommerer,1 Angela Hückelhoven-Krauss,1 Arianeb Mehrabi, Carsten Mueller-Tidow,1 Jochen Reiser,2 Martin G. Zeier,1 Michael Schmitt,2 Peter Terness,1 Anita Schmitt,1 Volker Daniel,11 Ruprecht Karls Universität Heidelberg, Heidelberg, Germany; 2Rush University Medical Center, Chicago, IL.

Background: We have shown that donor blood cells, modified in vitro by an alkylating agent (MIC, modified immune cells), induced specific immunosuppression against the allogeneic donor when administered prior to transplantation. An additional finding was an up to 60-fold increase in the frequency of immunosuppressive CD19CD24CD38hi Bregs compared to transplanted controls without MIC infusions. The question arises whether donor-specific immunosuppression and increased regulatory B lymphocytes (Breg) are permanently detectable in MIC-treated patients.

Methods: Four patients from a phase-I trial who had received 1.5x10^8 MIC per kg b.w. on day -7 before living donor kidney transplantation and who were not on immunosuppression were compared to 12 transplanted control patients without MIC infusions.

Results: MIC-treated patients showed an excellent clinical course with no donor-specific HLA antibodies or rejection. On day 1080 after transplantation, median serum creatinine was 1.59 mg/dL. Patients had absent in vitro lymphocyte reactivity against stimulatory donor blood cells while reactivity against third party cells was preserved as an indication of continued donor-specific unresponsiveness. CD19CD24CD38+ and CD10+CD19CD24CD38+ Breg were with 2.2 ± 0.84 and 1.0 ± 0.50 μL respectively, strikingly higher than the 0.0 ± 0.01 and 0.0 ± 0.01 μL (P<0.001) in transplanted controls and in the range of the numbers of healthy individuals (N=34, P=0.73 and P=0.60). In addition, significantly higher Breg numbers were found for CD1D CD19CD24CD38+ (P=0.0071), CD19CD25+CD73CD71 (P=0.0077), CD19CD25CD73CD71 (P=0.013), CD19CD25CD73CD71 (P=0.0011), CD19CD24CD27+ memory (P=0.029), and IL10+CD19CD24CD27+ memory Breg (P=0.042). No such differences were observed for CD4+CD25CD27FoxP3+ Treg (P=0.08) or different Treg subsets when comparing the four MIC-treated patients to transplanted controls without MIC infusions.

Conclusions: Donor-specific immunosuppression after MIC infusion is long-lasting and is associated with a striking increase in Breg at various stages of B cell development, including memory Breg.

Normothermic Ex Vivo Kidney Perfusion in a Porcine Auto-Transplantation Model Preserves the Expression of Key Mitochondrial Proteins: An Unbiased Proteomics Analysis
Caitriona M. McEvoy,1,2 Sergi CLoett Freixas,1 Tomas Tokar,1 Chiara Pastrello,3 Shelby Reid,4 Ilor Batruch,4 Adrien A. RaoPeters,4 Peter Urbanellis,5 Sofia Farkona,5 Julie Anh Dung Van,5 Brad Urquhart,6 Rohan John,6 Lisa Robinson,6 Markus Selzner,5 Ana Konvalinka,1 Barcelona HiP,6 Toronto General Hospital, University Health Network, Toronto, ON, Canada; 1Krembil Research Institute, Toronto Western Hospital, University Health Network, Toronto, ON, Canada; 2Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada; 3Department of Surgery, University of Toronto, Toronto, ON, Canada; 4Department of Surgery, University of Toronto, Toronto, ON, Canada; 5Department of Surgery, University of Toronto, Toronto, ON, Canada; 6Division of Nephrology, The Hospital for Sick Children, Toronto, ON, Canada.

Background: Normothermic ex-vivo kidney perfusion (NEVKP) results in significantly improved graft function in porcine auto-transplant models of DCD injury compared to cold storage of the organ (CS). However, the molecular mechanisms underlying these beneficial effects remain unclear.

Methods: We performed an unbiased proteomics analysis of 28 kidney biopsies obtained at 3 timepoints from pig kidneys subjected to 30-minutes of warm ischemia, followed by 9 hours of NEVKP or CS, and auto-transplantation.

Results: Of 6593 proteins quantified, 70 were differentially expressed between NEVKP and CS groups (2-way ANOVA, q<0.05). Proteins increased in NEVKP mediated key metabolic processes including fatty acid β-oxidation, the TCA cycle and oxidative phosphorylation; expression of our findings with external datasets of ischemia-reperfusion, and other models of kidney injury confirmed that 47 of our proteins represent a common signature of kidney injury reversed or attenuated by NEVKP. We validated key metabolic proteins (ETFB, CPT2) by immunoblotting. Integrated transcription factor databases identified PPARC1A, PPARG/D and RXRA/B as the upstream regulators of our dataset, and we confirmed their increased expression in NEVKP with RT-PCR.

Conclusions: The proteome-level changes observed in NEVKP mediate critical metabolic pathways that may explain improved graft function with NEVKP compared to CS. These effects may be coordinated by PPAR-family transcription factors, and may represent novel therapeutic targets in ischemia-reperfusion injury.

FR-OR48
Cyclosporine-Induced Endothelial Injury and Complement Activation Is Caused by Impaired Complement Factor H Binding to the Glycoalkyly Chia Wei Teo,1 Carolina Ortiz,1 Magdalena Riedl Khursigara,2 Valentina Bruno, Lisa Robinson, Christoph Licht. The Hospital for Sick Children, Toronto, ON, Canada.

Background: Calcineurin inhibitors are associated with nephropotoxicity, endothelial cell (EC) dysfunction and thrombotic microangiopathy. Evolving evidence suggests a central role for complement dysregulation in the pathogenesis of CNI-induced thrombotic microangiopathy. However, the exact mechanism of calcineurin-induced complement-mediated injury remains unknown.

Methods: In an in-vitro model utilising Blood Outgrowth EC (BOEC) from healthy donors, we evaluated the effects of cyclosporine (CsA) on EC injury, complement activation (C3a, C9) and regulation (CD46, CD55 and complement factor H [CFH]) on EC surfaces, and on the EC glycoalkyly, utilising flow cytometry, Western blot, and immunofluorescence imaging. Functional activity of CFH was assessed via CFH co-factor assay. Co-immunosuppression of Angiopoietin-2 (Angpt-2), Angiopoietin-1 (Angpt-1) and Tie2 was assessed by Western blot.

Results: CSa resulted in a dose and time dependent enhancement of EC complement deposition and EC death. CsA (10 μg/ml) led to a 15-fold upregulation of CD46, CD55 and CD9 on EC surface. CsA led to Angpt-2 mediated breakdown of the EC glycoalkyly, which was mitigated by Angpt-1. This EC glycoalkyly breakdown led to decrease in CFH surface binding and surface co-factor activity.

Conclusions: Our findings confirm a role for complement in CsA-induced EC injury, and suggest Angpt-2 mediated glycoalkyly abolishment, induced by CsA, as a mechanism leading to complement alternative pathway dysregulation via decreased CFH surface binding. Insights into this mechanism may provide a potential therapeutic target that might lead to improved patient outcomes which is subject to further studies. It might also apply to other thrombotic microangiopathies, in which a role for complement has so far not been recognized.

FR-OR49
Epigenome-Wide Microarray Analysis of Pre- and Post-Transplant Methylation Profiles in Kidney Transplant Recipients
Katie Kerr,1 Laura J. Smyth,1 Jill Kilner,1 Alexander P. Maxwell,2,1 Helen Mcaeney,1 A.J. Mcknight.1 Queen’s University Belfast, Belfast, United Kingdom; 2Belfast City Hospital Nephrology Service, Belfast, United Kingdom; 3Belfast City Hospital Nephrology Service, Belfast, United Kingdom.

Background: Kidney transplantation is the optimal treatment for suitable individuals with end-stage kidney disease (ESKD). Serious post-transplant complications include infections, cardiovascular events, malignancy, and new onset of diabetes after transplant (NODAT). Our regional nephrology centre has the highest living donor transplant rate per million population in Europe, and promotes research to improve patient outcomes. We compared pre and post-transplant methylation profiles in samples derived from matched participants.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: Epigenome-wide analysis was conducted using the Illumina Infinium MethylationEPIC array to interrogate 862,987 sites across the genome and identify any differentially methylated regions (DMR) in samples derived from peripheral blood mononuclear cells of age and sex matched pre (n=25) and post (n=25) kidney transplant recipients. DNA was extracted in a uniform manner and stored carefully undergoing minimal freeze thaw cycles. Samples were run on the same instrument and regression calibration was performed in R to estimate leukocyte cell proportions.

Results: Association analysis using Partek® GenomicsSuite® identified 53 DMR (FDR adjusted p<0.1 x 10^6, fold change +/-2). Within the top ranked CpG probes we identified DMR within genes dysregulated in melanoma (e.g. EXOC2, VEPH1), genes encoding extracellular matrix proteins that could influence structural glomerular changes (e.g. SPAM1) and genes with prior chronic kidney disease associations (e.g. FNTA). A DMR was also identified within the long intergenic non-protein coding RNA LINC01544, suggesting a possible regulatory function. Additionally, Partek®Pathway™ identified enrichment of DMR in the mitogen-activated protein kinase (MAPK) signaling pathway, primarily implicated in malignancy but also ESKD and cardiovascular disease. Gene ontology analysis identified enrichment of terms associated with localization and binding within cells.

Conclusions: This analysis provides a novel epigenomic perspective on molecular changes caused by kidney transplantation, and highlights markers that may be of relevance to post-transplant complications. We provide evidence supporting further methylation and transcriptomic analyses in larger cohorts to help identify epigenetic risk factors associated with post-transplant complications.

FR-OR50
Impact of Caspase-1 Deletion on Apoptosis and AKI in a Murine Transplant Model
Swati Jain,1 Robert J. Plentzer,1 Trevor Nydam,1 Alkesh Jain.1,2 University of Colorado, Denver, CO; 2Rocky Mountain Regional VA Medical Center, Aurora, CO.

Background: Prolonged cold ischemia (CI) is a known risk factor for acute kidney injury (AKI) after kidney transplantation. However, the mechanism by which CI leads to AKI is unknown. Caspase-1 knockout mice (Casp1KO) are protected from AKI after warm ischemia/reperfusion injury. We hypothesized that Casp1KO mice would be protected from AKI following transplant.

Methods: Renal tubular cells (RTECs) were subjected to cold storage and rewarming (CS/REW). C57Bl/6J wild type or Casp1KO kidneys were subjected to CI for 30 min and then transplanted into wild type recipients (CI+Txp). The recipients underwent bilateral nephrectomy to assess transplant function. DNA was extracted in a uniform manner and stored carefully undergoing any differentially methylated regions (DMR) in samples derived from peripheral blood mononuclear cells of age and sex matched pre (n=25) and post (n=25) kidney transplant recipients. DNA was extracted in a uniform manner and stored carefully undergoing minimal freeze thaw cycles. Samples were run on the same instrument and regression calibration was performed in R to estimate leukocyte cell proportions.

Results: We observed significantly increased expression of NLRP1 inflammasome protein and Caspase-1 in cells subjected to CS/REW. Using Imagestream in a flow cytometer we observed spatial overlap between two different fluorescent labels of inflammasome protein and Caspase-1 in cells subjected to CS/REW. Using Imagestream in a flow cytometer we observed spatial overlap between two different fluorescent labels of inflammasome protein and Caspase-1 in cells subjected to CS/REW. Using Imagestream in a flow cytometer we observed spatial overlap between two different fluorescent labels of inflammasome protein and Caspase-1 in cells subjected to CS/REW.

Conclusions: Caspase-1 deletion improves tubular cell apoptosis following CI+Txp. Deletion of Caspase-1 improves tubular cell apoptosis following CI+Txp. Deletion of Caspase-1 improves tubular cell apoptosis following CI+Txp. Deletion of Caspase-1 improves tubular cell apoptosis following CI+Txp.

Studying Proteinuria in COVID-19 to Define Markers of Severity and New Treatments
Yask Gupta, Juntao Ke, Jeremiah Martino, Qingxue Liu, Byun hae Kil, Tze Yin Lim, Gina Ying Jin, Dina Ahram, Nicholas J. Steers, Simone Sanna-Cherchi. Columbia University Irving Medical Center, New York, NY.

Background: The recent SARS-CoV-2 pandemic has led to ~375,000 fatalities worldwide as of June 1st. Nearly, 43% of COVID-19 patients have been reported to have proteinuria, which can result from direct podocyte injury, podocytopathy related to cytokine storm, or both. This association between respiratory viruses, proteinuria, and primary kidney disease has also been observed in the context of respiratory syncytial virus (RSV), where patients can develop nephrotic syndrome. Therefore, studying primary and virus-dependent models of proteinuria and podocyte injury is critical to shed light into COVID-19 pathobiology, severity of disease and potential treatments.

Methods: We accessed transcriptomic data (RNA-seq) for lung cell lines (A549) infected with three different viruses and identified differentially expressed genes (DEGs) for SARS-CoV-2, RSV and IAV. In parallel, we also investigated DEGs for FSGS and MCD using LIMMA R package. We investigated the statistical correlation between the log-fold change of DEGs (Nephropathic syndrome and SARS-CoV-2) using R. Pathway analysis was performed using WebGestalt. Possible drugs correcting the skewed gene expression in FSGS and SARS-COV-2 were identified using the Connectivity map (eMAP).

Results: 120 gene signatures were specific to SARS-CoV-2. By using gene expression data from glomeruli of FSGS/MCD we identified 902 DEGs for FSGS and 5 for MCD. Out of these, 6 were overlapping and upregulated in COVID-19 and FSGS/MCD (B2M, EIF2AK2, IFIT1, IFIT2, TC7M and UBE2L6). Strikingly, IFIT27 has been recently reported as a marker of disease severity in COVID-19. We found significant positive correlation between the log2 fold change of 94 FSGS/MCD genes intersecting with the 120 COVID-19. The results were specific to glomeruli and to high proteinuric diseases, supporting a common cellular response in lung and podocytes. We then searched the cramp data and identified 59 drugs significantly inversely associated with SARS-COV-2 and 72 for FSGS. Out of these, 7 drugs were in common, representing novel potential drugs for COVID-19 and podocytopathies.

Conclusions: Overall, our results suggest transcriptional congruency between NS and SARS-COV-2 which can possibly be used to design novel therapies treat these diseases.

SA-OR02
Machine Learning for Prediction of Severe AKI in Hospitalized Patients with COVID-19
Kunnardeep Chandhary, Lili Chan, Aparna Saha, Kinsuk Chauhan, Akhil Vaid, Barbara T. Murphy, John C. He, Steven G. Coca, Girish N. Nadkarni. Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Preliminary reports indicate that acute kidney injury (AKI) is common in coronavirus disease (COVID-19) patients and is associated with worse outcomes. Identification of patients at high risk for developing severe AKI in hospitalized COVID-19 patients in the United States is not well-described.

Methods: This is a retrospective observational study of patients aged ≥18 years with laboratory confirmed COVID-19 admitted to the Mount Sinai Health System between February 27 and April 15, 2020. We trained and tested a machine learning algorithm, extreme gradient boosting (XGBoost), a boosted decision-tree based machine learning (ML) model, with 5-fold cross validation to predict AKI requiring dialysis. Patients from the Mount Sinai (MSS) were randomly split into a training and validation set for the model. To increase model generalizability and help minimize bias, the model’s performance was assessed on a test set composed entirely of patients from the other hospitals in the Mount Sinai Health System (MSSH). Input features for the model included demographics, laboratory values, and vital signs that occurred in the first 48 hours of admission.

Results: Of 3,235 hospitalized patients with COVID-19, AKI occurred in 1406 (46%) patients and 280 (20%) with AKI required dialysis. In the training set (n=1,317 patients), the classifier achieved good performance with an area under the receiver operating characteristic curve (AUROC) of 0.79 and area under the precision recall curve (AUPRC) of 0.38 for predicting AKI requiring dialysis. Performance was similar in the testing set (n=1,918) with 0.79 AUROC and 0.36 AUPRC. The features that had a larger impact on the model included serum creatinine, age, potassium, and heart rate.

Conclusions: A machine-learned model using admission features had good performance for dialysis prediction and could be used for resource allocation.

SARS-CoV-2 Detection in Urine Suggests Infection of Kidneys and Correlates with Risk of AKI and Poor COVID-19 Prognosis

Paulo S. Caceres, Gina Savickas, Junior Udumian, Kausan Umanath, Yuvraj Sharma, Jerry Yee, Shannon Murray, Sarah Sarkar, Jamie Fitzgerald, Dipak Maskey, Adrian Ormsby, Pablo A. Ortiz. Henry Ford Hospital, Detroit, MI

Background: Since the emergence of the novel severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), most of the focus has been on the respiratory failure caused by the resulting disease, COVID-19. However, the effects of COVID-19 in the kidney are increasingly recognized. Acute kidney injury (AKI) has been identified with varying prevalence around the world with higher rates (37-46%) reported in the USA. It is debatable whether AKI is an indirect consequence of systemic inflammation or a consequence of viral renal cell infection and tropism. We hypothesize that SARS-CoV-2 directly infects kidney tissue and increases the risk of developing AKI, worsening prognosis of COVID-19 patients.

Methods: We studied 88 COVID-19 patients admitted to the Henry Ford Hospital, Detroit after April 15, 2020. Demographics were: mean age 60, 71% African American, 55% male. We quantified viral copies by RT-PCR (S and N) in urine samples from 52 PCR-confirmed COVID-19 patients. We performed immunofluorescence for Membrane and Spike viral proteins in two COVID-19 biopsies.

Results: The prevalence of AKI was 72%, with 32% of patients admitted to the ICU. The overall mortality rate was 14%, with no deaths in non-AKI patients. Viral proteins M and S were detected in the glomerulus, parietal cells and tubules of COVID-19 patients. In some tubules, SARS-CoV-2 overlapped with ACE2, the receptor for viral entry. Virus was detected in 61% of urine specimens, with 6-fold greater viral load in AKI patient urines (copies/ng RNA: AKI, 742±1338 vs No-AKI: 1523 ± 404; p<0.05, n=52). The highest viral loads were detected three weeks post-AKI in 11,374±2248 copies/ng RNA (p<0.01). Among COVID-19 AKI-patients who died, the urine viral load exceeded 8000 copies/ng RNA. Above this threshold, the mortality rate was 55%.

Conclusions: Our data support that direct viral renal cell infection occurs in COVID-19 AKI patients with urinary viral genome detection. Greater urinary viral loads portend increased mortality. Urinary viral detection can facilitate management and treatment of COVID-19 and more extensive research should focus on studying whether urine contains infective virus or sheds non-infective genomic fragments.

SARS-CoV-2 Receptor Networks in Diabetic Kidney Disease, BK Virus Nephropathy, and COVID-19 Associated AKI

Rajaseer Menon,1 Edgar A. Otto,1 Rachel S. Sealfon,2 Vijil Nair,2 Aaron Wong,3 Chandra L. Theesfeld,4 Xi Chen,2 Yuan Wang,4 Jennifer A. Schaub,4 Celine C. Berthier,5 Sean Eddy,3 Chrysa C. Lienczewski,1 Brad A. Godfrey,4 Ryann Sohany,1 Helen C. Looker,4 Laura H. Mariani,1 Abhijit S. Naik,1 Robert G. Nelson,1 Olga Troyanskaya,4 Matthias Kretzler,1 University of Michigan, Ann Arbor, MI; 2Flatiron Institute, New York, NY; 3National Institutes of Health, Bethesda, MD; 4Princeton University, Princeton, NJ.

Background: COVID-19 shows increased disease burden in patients with diabetic kidney disease (DKD). SARS-CoV-2 uses angiotensin-converting enzyme 2 (ACE2) for host cell entry, so ACE2 levels may influence SARS-CoV-2 susceptibility. We investigated how pre-existing conditions and drug treatments alter receptor expression for host cell entry, so ACE2 levels may influence SARS-CoV-2 susceptibility. We

Methods: Single cell RNA profiling of 7 healthy living donor kidneys, 44 DKD, 3 BK virus nephropathy (BKVN) and a urine COVID19 patient with acute kidney injury (COV-AKI) revealed ACE2 expression primarily in proximal tubular epithelial cells (PTEC).

Results: ACE2 mRNA expression levels were higher in proximal tubule epithelial cells (PTEC) in DKD versus LD, but unaltered by exposures to renin angiotensin aldosterone system inhibitors. Bayesian integrative analysis of public -omics datasets identified molecular network modules induced in ACE2 positive versus negative PTEC in DKD and BKVN (hb.flatiron institute.org/covid-kidney), that were linked to viral entry, immune activation, endomembrane reorganization, and RNA processing. Similar programs were seen in COV-AKI ACE2-positive PTEC, and overlapped with programs in SARS-CoV-2 infected cells.

Conclusions: A consistent ACE2-correlated expression program in PTEC may interact with SARS-CoV-2 infection processes. These networks can seed further research into developing therapeutic strategies and assessing risk in patients with COVID-19.

Funding: NIDDK Support, Private Foundation Support
Results: Of 5,449 patients admitted with Covid-19, AKI developed in 1,993 (36.6%). The peak stages of AKI were stage 1 in 46.5%, stage 2 in 22.4% and stage 3 in 31.1%. Of these, 14.3% required renal replacement therapy (RRT). AKI was primarily seen in Covid-19 patients with respiratory failure, with 89.7% of patients on mechanical ventilation developing AKI compared to 21.7% of non-ventilated patients. 276/285 (96.8%) of patients requiring RRT were on ventilators. Of patients who required ventilation and developed AKI, 52.2% had the onset of AKI within 24 hours of intubation (Figure and Table). Risk factors for AKI included older age, diabetes mellitus, cardiovascular disease, black race, hypertension and need for ventilation and vasopressor medications. Among patients with AKI, 1,136 died (57%), 519 (26%) were discharged and 338 (17%) were still hospitalized.

Conclusions: AKI occurs frequently among patients with Covid-19 disease. It occurs early and in temporal association with respiratory failure and is associated with a poor prognosis.

SA-OR07
A Multicenter Observational Study of Clinical Features and Outcomes of AKI in Critically Ill Patients with COVID-19
Shruti Gupta, David E. Leaf. STOP-COVID Investigators Brigham and Women’s Hospital Department of Medicine, Boston, MA.

Background: Acute kidney injury (AKI) is emerging as an important sequela of COVID-19 infection. Existing data on the incidence and clinical features of AKI in patients with COVID-19 are mainly limited to single-center studies. Given the high incidence of severe AKI among patients with COVID-19 and its strong association with mortality in other settings, we conducted a multicenter nationally representative cohort study to examine the incidence, clinical features, risk factors, and outcomes of AKI in critically ill patients with COVID-19.

Methods: We used data from a multicenter observational study that collected granular, patient-level data from >3,000 critically ill adults with laboratory-confirmed COVID-19 admitted to participating ICUs from 67 centers across the United States. Using multivariable logistic regression, we examined risk factors for the primary composite outcome, AKI requiring renal replacement therapy or death (RRT/death) in the 14 days following ICU admission.

Results: Among 3099 patients, 1205 (38.9%) developed the primary outcome of RRT/death (n=637 required RRT, n=792 died within 14 days, and n=224 both required RRT/death) in the 14 days following ICU admission. Independent risk factors for RRT/death included chronic kidney disease (odds ratio [OR], 5.02; 95% CI, 3.55-7.10 for eGFR<30 vs. ≥60; OR 1.90; 95% CI, 1.55-2.33 for eGFR 30-59 vs. ≥60), as well as older age, male sex, higher body mass index, and greater severity of hypoxemia on ICU admission (Figure). Patients admitted to hospitals with higher degrees of strain also had a greater risk of RRT/death (OR 1.49; 95% CI, 1.06-2.06 for highest versus lowest quintile of hospital strain). Patients requiring RRT and died within 14 days). Independent risk factors for RRT/death included chronic kidney disease (odds ratio [OR], 5.02; 95% CI, 3.55-7.10 for eGFR<30 vs. ≥60; OR 1.90; 95% CI, 1.55-2.33 for eGFR 30-59 vs. ≥60), as well as older age, male sex, higher body mass index, and greater severity of hypoxemia on ICU admission (Figure). Patients admitted to hospitals with higher degrees of strain also had a greater risk of RRT/death (OR 1.49; 95% CI, 1.06-2.06 for highest versus lowest quintile of hospital strain).

Conclusions: This multicenter study identifies several key insights into the risk factors for RRT/death in critically ill patients with COVID-19.

Screening for SARS-CoV-2 (COVID) Infection in Chronic Dialysis Patients: A Nonprofit Provider’s Experience
Harold J. Manley, Karen M. Majchrzak, Ronald Sanders, Serena Cumber, Gideon N. Aweh, Vladimir Ladik, Carol Stewart, Doug Johnson, Antonia Harford, Eduordo K. Gibson, Dialysis Clinic Inc, Nashville, TN; ’Tufts Medical Center, Boston, MA.

Background: The CDC recommends screening of all patients for COVID exposure history and or signs and symptoms prior to treatment. In order to limit the spread of COVID within our facilities, Dialysis Clinic Inc. screens all patients prior their in-center hemodialysis treatment or peritoneal dialysis visit consistent with recommendations.

Methods: We describe the outpatient screening process of our dialysis patients having a positive screen as patients under investigation (PUI) to activate local protocols for isolation and testing. We determined the frequencies of positive screening parameters and rate of identifying COVID patients.

Results: From 2/17 to 5/20, 2020, facilities screened 15,602 patients over 402,002 in-person visits, identifying 959 PUI’s (6%). Among PUIs, 61 of 351 (17%) COVID+ patients were correctly triaged prior to COVID+ diagnosis. In the subset of 788 PUIs screened prior to 4/11/20 where we were able to catalogue reasons for positive screening, 149 (19%) had exposure only and 639 exhibited symptoms (81%), of which 15 had exposure; 34 resided in group home (GH) and 7 had both exposure and GH residence. It was determined 41 (6.4%) were COVID+. Frequency of symptoms elicited by PUI are shown below.

Conclusions: 959 PUIs were identified and isolated by our screening process, resulting in the successful preemptive triage of 61 COVID+ (6%) patients before testing positive, potentially limiting infection spread in the facility. Cough and fever were the most common reasons for positive screen, and fever was most commonly associated with COVID+ diagnosis. However, the majority (83%) of COVID+ patients were primarily asymptomatic and hence not captured by screening.

Screening for SARS-CoV-2 Infection among Hemodialysis Staff: A Rural Hospital’s Experience
Gwyneth C. Landon,1 J. O. Garrett, 2 M. J. Liles.1 1MUSC, Charleston, SC; 2Tufts Medical Center, Boston, MA.

Background: Staff were encouraged to pursue local or state testing. With limited local and state testing availability, staff needed an alternative rapid method for COVID-19 screening. MUSC conducted an anonymous employee screening program.

Methods: We describe the staff screening experience at MUSC.

Results: From 3/1-5/20, 2936 employees were tested. In the initial testing periods (3/1-4/4), 10% of employees were tested in person and 90% were tested at home. In the later testing periods (4/4-5/20), 30% were tested in person and 70% home. Staff were isolated if COVID+ and paid for 2 weeks. Staff who tested positive were not allowed back to work until negative test results were received. Staff who were asymptomatic were tested after 2 weeks. To date, no COVID+ staff were identified.

Conclusions: Staff screening is feasible. Staff were isolated if COVID+ and paid for 2 weeks. Staff who tested positive were not allowed back to work until negative test results were received. Staff who were asymptomatic were tested after 2 weeks. To date, no COVID+ staff were identified.
SA-OR09
Urgent Peritoneal Dialysis Catheter Placement at a New York City Hospital During the COVID-19 Pandemic
Dhwani Patel,1 Nina J. Caplin, Manish Tandon. NYU Langone Health, New York, NY.

Background: During the COVID-19 pandemic, there has been an unparalleled burden on nephrology services to provide kidney replacement therapy to patients admitted to the hospital with COVID-19, who develop severe AKI. Given the unprecedented surge in COVID-19 admissions, ability to provide inpatient hemodialysis and continuous kidney replacement therapy (CRRT) was quickly saturated. We present data from our acute peritoneal dialysis (PD) program that was quickly assembled to provide kidney replacement therapy due to shortage of hemodialysis and CRRT resources.

Methods: Patients admitted to an academic NYC hospital during COVID-19 pandemic with AKI requiring kidney replacement therapy were evaluated for candidacy for bedside PD catheter placement via cut-down method with the majority having COVID respiratory failure. A dedicated surgery team was assembled to place PD catheters within 12-24 hours of request by the nephrology team. Catheters were placed in patients with BMI up to 51. Patients requiring proning were not excluded. Exclusion criteria were prior lower abdominal surgery, known varices, or imminent death.

Results: Thirty-eight PD catheters were placed during the 4 week period from April 8 to May 8, 2020. Majority of the catheters were placed bedside in an ICU setting (36/38 - 95%), with 2 being placed laparoscopically in the OR. There were no episodes of peritonitis. Three catheters required revision due to poor flows. Six catheters required floseal for bleeding along the catheter tract, which resolved without additional intervention. There were no major bleeding complications during PD catheter placement despite many patients being on systemic anticoagulation. Dwell volumes of up to 2.2L did not appear to have negative effects on the ability to ventilate patients. One patient required transition to hemodialysis due to catheter malfunction.

Conclusions: Acute peritoneal dialysis successfully allowed kidney replacement therapy for patients with severe AKI during the peak phase of the COVID-19 pandemic at our hospital in NYC. There were no major complications with acute PD catheter placements.

SA-OR10
Recovery from AKI and Acute Respiratory Distress Syndrome (ARDS) with the Use of Low-Dose Steroids During COVID-19 Infection in an African American Population: A Retrospective Analysis
Subodh J. Saggi,1 Sridesh Nath,1 Roshini Culas,1 Seema Chittalae,1 Aaliya Burza,1 Patrick Geraghty,1 Jie Ouyang,2 Angelika C. Gruessner,1 Moro O. Salifu.1 1SUNY Downstate Health Sciences University, Brooklyn, NY; 2Saint Barnabas Hospital, Bronx, NY.

Background: Corona Virus Disease-19 (CoVID-19) infection associated with AKI and ARDS results in a mortality of 80%. In AA population COVID 19 presentations and outcomes are worse. NIH and Interim WHO guidelines suggest against steroids use unless in the context of clinical trials. We conducted a retrospective analysis on the impact of 2 different doses of IV steroids in AA adult population.

Methods: 75 patients between March 1 and April 30, 2020 were enrolled. Primary outcomes (21-day mortality) and secondary outcomes (improvement in lung function and renal function) were analyzed. Comparisons between the steroid doses (methylprednisolone 1 mg/kg/day or 2 mg/kg/day) and no-steroid groups were performed with the Wilcoxon, Kruskal-Wallis, and Chi-Square tests. Factors affecting the recovery of AKI or ARDS were analyzed. AKI recovery was defined as 50% increase of GFR, and cessation of RRT; lung function recovery was defined as improved oxygenation by P/F ratio > 200 and extubation.

Results: 38 out 75 patients received steroids. Survival in the steroids group reached 73% at 21 days compared to 36% in the non-steroids group (p=0.0006). Steroids improved the likelihood of renal function improvement by 300% (p=0.06). Lung function was 73% in the steroids group versus 45% in the other (p=0.01). Use of anticoagulants (16% vs 51%, p= 0.001) seemed to be interacting with steroids on outcomes. Low dose steroids had the most beneficial impact.

Conclusions: In patients with COVID-19 infection and ARDS with AKI, low dose IV methylprednisolone was associated with a significantly lower incidence of mortality and higher likelihood of renal and lung function recovery. Further investigation with a randomized control trial consisting of low dose steroids seems warranted.

Mortality in steroids and non-steroids groups

p53/MicroRNA-214/ULK1 Axis Impairs Renal Tubular Autophagy in Diabetic Kidney Disease
Zhengwei Ma,1,2 Lin Li,1 Man J. Livingston,1,3 Changlin Mei,1 Zheng Dong,1,2 1Department of Cellular Biology and Anatomy, Medical College of Georgia at Augusta University, Augusta, Augusta, GA; 2Charlie Norwood VA Medical Center, Augusta, GA; 3Department of Nephrology, Changzheng Hospital, Second Military Medical University, Shanghai, China.

Background: The pathogenesis of diabetic kidney disease (DKD) is unclear. Dysregulation of autophagy in DKD has been reported, but the underlying mechanism and its pathogenic role in DKD remain elusive.

Methods: Autophagy changes in DKD were investigated in high glucose treated renal tubular cells in vitro and in Akita mice and streptozotocin (STZ)-induced diabetic mice in vivo. Autophagy-related gene 7 (Atg7), microRNA-214 (miR-214), or p53 were ablated specifically from kidney proximal tubules to elucidate the pathogenic role and underlying mechanism of autophagy dysregulation in DKD. The expression of autophagy-related proteins, miR-214, and p53 were analyzed in human diabetic kidney tissues along with renal pathologies to determine their correlations.

Results: Autophagy was inhibited in DKD models and in human diabetic kidneys. Ablation of Atg7 from kidney proximal tubules led to autophagy deficiency and worsened renal hypertrophy, tubular damage, inflammation, fibrosis, and albuminuria in diabetic mice, indicating a protective role of autophagy in DKD. Autophagy impairment in DKD was associated with the downregulation of ULK1, a key serine/threonine protein kinase for the initiation of autophagy. ULK1 downregulation in DKD involved miR-214, which was induced in diabetic kidney cells and tissues to repress ULK1 expression. Expression of miR-214 from kidney proximal tubules prevented ULK1 decrease and autophagy impairment in diabetic kidneys, resulting in less renal hypertrophy and albuminuria. Furthermore, blockade of p53 attenuated miR-214 induction in DKD, leading to higher levels of ULK1 and autophagy, accompanied by the amelioration of DKD. Compared to non-diabetic samples, renal biopsies from human diabetic patients showed the induction of p53 and miR-214, associated by the downregulation of ULK1 and autophagy. There was a significant positive correlation between p53/miR-214 and renal fibrosis, whereas a negative correlation between ULK1/miR-214 and renal fibrosis in diabetic patients.

Conclusions: Autophagy dysfunction occurs in renal tubules in DKD, and contributes to renal hypertrophy and related pathologies. Mechanistically, p53 is activated in DKD to induce miR-214, which represses ULK1 resulting in autophagy dysfunction. The results identify the p53/miR-214/ULK1 axis of autophagy impairment for the development and progression of DKD.

Podocyte-Derived Extracellular Vesicles Mediate Renal Proximal Tubule Cell De-differentiation via MicroRNA 221 in Diabetic Nephropathy

Hong Su,1 Jiao Qiao,1 Qun Yu,1 Bing Liu,1,2 Junhui Zhen,3 Zhimei Lv,1,2 Hong Wang,3 Department of Nephrology, Shandong Provincial Hospital, China; 2Department of Nephrology, Shandong Shandong Provincial Hospital Affiliated to Shandong First Medical University, Jinan, China; 3Department of Pathology, School of Medicine, Shandong University, Jinan, China.

Background: Podocyte injury is a key event in the initiation of diabetic nephropathy (DN), and the proximal tubule has been regarded as a target of injury. Evidence suggests that cross-talk between podocytes and tubular epithelium is a key component in the pathogenesis of DN, but the mechanisms are not fully understood.

Methods: The podocytes and proximal tubular epithelial cells (PTECs) were co-cultured in high glucose conditions to detect the intercellular communication. Podocytes-derived extracellular vesicles (EVs) was isolated and identified by specific morphology and surface markers. Immuno-fluorescence, PCR, western blot, electron microscope, and transwell were conducted to assess the de-differentiation of PTECs. The expression level of miRNA in EVs was detected and C3-treated mice was used to demonstrate its direct transfer into target cells. A dual-luciferase reporter system was utilized to confirm the binding of miRNA to its target gene. The roles of miRNA and target gene were assessed using specific miRNA inhibitors, mimics and shRNA. In addition, Streptozotocin-induced diabetic mice and a models mice were construct, and miRNA antagonist were used to explore its role in proximal tubule injury.

Results: Podocytes induced de-differentiation of PTECs in high-glucose conditions and mediated the intercellular interaction. The podocytes-derived EVs were extracted and identified as exosomes, and the EVs treatment induced PTECs injury. miR-221 was remarkably increased in EVs and could be directly transferred into target cells, moreover, this miRNA was shown to play a key role in PTECs de-differentiation. The dual-luciferase reporter assay confirmed that miR-221 target DKK2, and miR-221 positively regulated β-catenin activation. Importantly, inhibition of β-catenin markedly diminished the EVs and miRNA induced PTECs de-differentiation. Furthermore, inhibition of miR-221 in diabetic mice reversed the PTECs injury and relative β-catenin activation.

Conclusions: Podocyte-derived EVs in diabetes acted as key mediators of proximal tubule cell injury and the exosomal miR-221 mediated the cells damage through Wnt/β-catenin signaling. These findings provide unique insights in the mechanisms of proximal tubule cell injury in diabetic nephropathy, and miR-221 can be used as a new target for the treatment of renal fibrosis in DN.

Whole-Genome Sequencing Identifies a Dominant Negative ADIPOQ Mutation in a Type 2 Diabetic Family Enriched for ESRD

Marcus G. Pezzolesi,1 Christopher A. Simeone,1 Joseph L. Wilkerson,1 Jose M. Lazaro-guevara,1 Edgar J. Hernandez,1 Bushra Gorsi,1 Scott G. Froodsham,1 Kristina V.O’Neill,1 Scott Summers,1 Andrzej S. Krolowski,2 William L. Holland,3 University of Utah Health Care, Department of Internal Medicine, Salt Lake City, UT, US; Salt Lake City, UT, 1Joslin Diabetes Center; Harvard Medical School, Boston, MA, US; Boston, MA.

Background: Diabetic nephropathy (DN) is a complex, heterogeneous complication of diabetes. Despite evidence of its strong genetic predisposition, identification of the genetic factors that contribute to DN and the risk of end-stage renal disease (ESRD) has been challenging.

Methods: We performed whole genome sequencing (WGS) in a multi-generational family enriched for both type 2 diabetes and ESRD followed by unified linkage analysis and rare variant association testing using gVAST.

Results: Using WGS to evaluate this family, we identified a rare loss-of-function mutation in adiponectin (ADIPOQ) c.245_247delCTG; seen only once among 56,810 Finnish Europeans included in the gnomAD database) observed among 6 ESRD cases in this family. This 10-nucleotide deletion results in a premature termination codon and a complete loss of adiponectin’s globular domain. We found that carriers of this mutation have low circulating adiponectin (15% of normal levels) and dramatically high ceramide levels (double the level of C16 ceramides as compared with wt diabetic patients). Individuals have low circulating adiponectin (15% of normal levels) and dramatically high ceramide levels (double the level of C16 ceramides as compared with wt diabetic patients). This 10-nucleotide deletion results in a premature termination codon and a ADIPOQ mutation in adiponectin (Gly93GlufsTer73; seen only once among 56,810 non-family members). This family is enriched for both type 2 diabetes and ESRD followed by unified linkage analysis.

Conclusions: This family has been followed for 6 wk. Results: Using WGS to evaluate this family, we identified a rare loss-of-function mutation in adiponectin (ADIPOQ c.245_247delCTG; seen only once among 56,810 Finnish Europeans included in the gnomAD database) observed among 6 ESRD cases in this family. This 10-nucleotide deletion results in a premature termination codon and a complete loss of adiponectin’s globular domain. We found that carriers of this mutation have low circulating adiponectin (15% of normal levels) and dramatically high ceramide levels (double the level of C16 ceramides as compared with wt diabetic patients). Individuals have low circulating adiponectin (15% of normal levels) and dramatically high ceramide levels (double the level of C16 ceramides as compared with wt diabetic patients). This 10-nucleotide deletion results in a premature termination codon and a ADIPOQ mutation in adiponectin (Gly93GlufsTer73; seen only once among 56,810 non-family members). This family is enriched for both type 2 diabetes and ESRD followed by unified linkage analysis.

Conclusions: Podocytes/Derived EVs in diabetes acted as key mediators of proximal tubule cell injury and the exosomal miR-221 mediated the cells damage through Wnt/β-catenin signaling. These findings provide unique insights in the mechanisms of proximal tubule cell injury in diabetic nephropathy, and miR-221 can be used as a new target for the treatment of renal fibrosis in DN.

Enhancing Kidney DDAH-1 Expression by Adenovirus Delivery Reduces Asymmetric Dimethylarginine and Ameliorates Diabetic Nephropathy

Michael Wetzle,1 Ting Gao,2 Kristen Stanley,1 Timothy K. Cooper,4 Sidney M. Morris,1 Aliya S. Awad.1 1University of Texas Health Science Center at San Antonio Department of Medicine, San Antonio, TX; 2University of Pittsburgh School of Medicine, Pittsburgh, PA; 3National Institute of Allergy and Infectious Diseases, Division of Clinical Research, Frederick, MD.

Background: Endothelial dysfunction, characterized by reduced bioavailability of nitric oxide and increased oxidative stress, is a hallmark characteristic in diabetes and diabetic nephropathy (DN). High levels of asymmetric dimethylarginine (ADMA) are observed in several diseases including DN and are a strong prognostic marker for cardiovascular events in patients with diabetes and end-stage renal disease. ADMA, an endogenous endothelial nitric oxide synthase (NOS3) inhibitor, is selectively metabolized by dimethylarginine dimethylaminohydrolase (DDAH). Low DDAH levels have been associated with cardiac and renal dysfunction, but its effects on DN are unknown. We hypothesized that enhanced renal DDAH-1 expression would improve DN by reducing ADMA and restoring NOS3 levels.

Methods: DBA/2J mice injected with multiple low doses of vehicle or streptozotocin were subsequently injected intraretraally with adenovirus expressing DDAH-1 (Ad-h-DDAH-1) or vector control (Ad-green fluorescent protein (GFP)), and mice were followed for 6 wk.

Results: Diabetes was associated with increased kidney ADMA (p<0.05) and reduced kidney DDAH-1 activity (p<0.05) and DDAH-1 expression (p<0.05) compared to normal mice but had no effect on kidney DDAH-2 expression. Ad-GFP-treated diabetic mice showed significant increases in albuminuria (p<0.005), histological changes (p<0.005), glomerular macrophage recruitment (p<0.001), inflammatory cytokine (p<0.01) and fibrinotic markers (p<0.01), kidney ADMA levels (p<0.05), and urinary thiobarbituric acid reactive substances excretion (p<0.005) and fibrotic markers (p<0.01) and inflammatory cytokine (p<0.01) and fibrinotic markers (p<0.01), kidney ADMA levels (p<0.05), and urinary thiobarbituric acid reactive substances excretion (p<0.005) and fibrotic markers (p<0.005). These data indicate, for the first time, that DDAH-1 mediates renal tissue protection in DN via the ADMA-NOS3 interaction. Enhanced renal DDAH-1 activity could be a novel therapeutic tool for treating patients with diabetes.

Cell Type Specificity of Hypoxia Signaling in Early Diabetic Kidney Disease (DKD)

Jennifer A. Schaub,1 Rajasree Menon,1 Viji Nair,2 Edgar A. Otto,2 Joel M. Weinberg,1 Helen C. Looker,2 Robert G. Nelson,2 Matthias Kretzler,4 University of Michigan Health System, Ann Arbor, MI; 1National Institutes of Health, Bethesda, MD.

Background: Chronic hypoxia is considered a driver of kidney disease progression. Given the spatial heterogeneity of hypoxia, we evaluated the cell type specificity of Hypoxia Related Genes (HRG) in DKD along the nephron and the association of HRG with structural parameters.

Methods: Cell-specific expression and normalized gene signatures (Z scores) were calculated for 237 HRG in single cell RNA profiles of 44 kidney biopsies from American Indians with Type 2 Diabetes (T2D) and 7 healthy living donor kidneys (LD), and replicated in 49 independent micro-dissected biopsies of T2D with DKD (DN).

Results: Mean measured glomerular filtration rate was 159 ml/min (SD 54) in T2D and 147 ml/min (SD 45) in DN, and mean urine albumin/creatinine ratio was 304 mg/g (SD 1542) for T2D and 35 mg/g (SD 90) for DN. Average HgA1c was 9.2 for T2D and 9.3 for DN. HRG expression showed highly cell-type specific elements in both LD and T2D (Figure 1). HRG signature in stressed proximal epithelial cells (pSPEC), unique to T2D, was dominated by apoptosis and glycosylation signals, while endothelial cells (EC) signatures expressed more genes involved in fibrosis in T2D compared to LD. In DN, Z score of the EC signature was associated with increased mesangial volume (R 0.33, p-value 0.02) and Z score of SPEC signature was associated with interstitial fibrosis (R 0.35, p-value 0.02), which are strong predictors of long-term outcomes in this cohort.

Conclusions: HRG expression varies by cell type in LD and DKD, suggesting transcriptional regulation changes of HRG in diabetes and DKD. Association of HRG signatures with morphometrics that are associated with progressive GFR loss implicate chronic hypoxia processes in early DKD.

Funding: NIDDK Support
Conclusions: Loss of SCO2 and mutant SCO2 reduced glomerular endothelial injury, oxidative stress, and early diabetic injury in the kidney with improved mice survival in a murine model of DKD.

Reversal of Diabetic Nephropathy After 10 Years of Pancreas Transplantation Occurs Despite Parallel Podocyte Loss

Behzad Najafian,1 Michael Mauer,2 Paola Fioretto,3 University of Washington, Seattle, WA; 2University of Minnesota, Minneapolis, MN; 1University of Padova, Padova, Italy.

Background: Diabetic nephropathy (DN) is associated with podocyte (PC) injury and loss. PC injury is believed to play important role in DN progression. DN reversal following 10 years (10Y) of euglycemia after pancreas transplantation (PTx) is documented (N Engl J Med 2017;376:69-75). We hypothesized that PC loss would continue, DN reversal would be associated with PC regeneration and improvement in PC structure.

Methods: Paired kidney biopsies prior to PTx (BL) and 10Y after PTx were compared for classical DN lesions, PC number and foot process width (FPW) using electron microscopy morphometry in 10 type 1 diabetic (T1D) patients with age 33 (30-54) years [median (range)], diabetes duration 23 (16-33) years and albumin excretion rate (AER) 134 (0-951) μg/min at BL. The results were compared with biopsies from 10 age matched living donor biopsies [controls (C)].

Results: Glomerular basement membrane (GBM) width, fractional volume of mesangium/glomerulus [Vv(Mes/glom)] and fractional volume of mesangial/glomerulus [Vv(MM/glom)] and FPW were all increased at BL compared to C (data not shown). There were significant reductions in GBM width (30%, p=0.0002), Vv(Mes/glom) (21%, p=0.001), Vv(MM/glom) (30%, p=0.002), and glomerular volume (27%; p=0.02) at 10Y compared to BL. However, while PC number density did not change from BL to 10Y, there was a significant decrease in PC number/glomerulus (31%; p=0.049), FPW in T1D patients at BL (p=0.0088) or 10Y (p=0.002) was greater than C with no significant change from BL to 10Y. No relationship was found between change in GBM width, Vv(Mes/glom) or Vv(MM/glom) and PC number density, PC number per glomerulus or FPW. Creatinine clearance was reduced by 25% from BL to 5y post PTx in these calcineurin treated patients, and remained stable between 5 and 10Y. AER did not change significantly.

Conclusions: Substantial reversal of GBM and mesangial extracellular matrix (ECM) accumulation in T1D occurs following long term PTx despite decrease in PC number, persistence of foot process widening and no change in PC density. This study does not support PC loss to be an important mediator of glomerular extracellular dynamics in DN in T1D. Moreover, despite long-term normoglycemia, PC do not regenerate and PC injury does not regress in T1D patients.

Urinary Proteomics Identifies Proteins Associated with Rapid eGFR Decline in Type 1 Diabetes

Christine P. Limongi,1 Lokii Natarajan,1 Erikka A. Valo,2 Manjula Darshi,2 Viktor Drel,3 Henrik Nyberg,1 Karin Schumacher,4 Alexandra R. Leonard,4 Jessica M. Vasquez,4 Sandeep K. Mallipatil,5 Division of Nephrology, Department of Medicine, Stony Brook University, Stony Brook, NY.

Background: Varying rates of eGFR decline have been observed in patients with type 1 diabetes (T1D), the pathophysiologic mechanisms of which remain poorly understood.

Methods: We performed a case-control study nested within four T1D cohorts (EDC, CACTI, STENO, FinnDiame) to identify urinary proteins associated with rapid eGFR loss. Cases and controls were defined by annual eGFR decline ≥3ml/min/1.73m² and <1ml/min/1.73m², respectively. We developed a targeted liquid chromatography-tandem mass spectrometry assay to measure 38 peptides of 20 proteins implicated in diabetic kidney disease. Peptide associations with rapid eGFR loss in discovery and validation sets were compared using logistic regression. Associations of significant peptides with rapid eGFR loss were then evaluated in the Nephroseq transcriptomic database.

Results: 1271 participants (508 cases, 763 controls) with baseline median eGFR 95ml/min/1.73m² and ACR ≥30mg/gCr in 36% were included. Over 8 years mean follow-up, mean eGFR slope was −5.65 and 0.57ml/min/1.73m² per year for cases and controls, respectively. Out of 38 urine peptides, 2 cathespin D (CatD) peptides were associated with rapid eGFR loss adjusting for demographic and clinical variables with a false discovery rate of <5% in the discovery set (fully-adjusted OR per SD 1.52, 95%CI 1.22-1.88; 1.41, 95%CI 1.14-1.74). In the validation set, CatD peptides were associated with rapid eGFR decline adjusting for demographic but not clinical variables (1.26, 95%CI 0.99-1.60; 1.15, 95%CI 0.91-1.46). When stratified by baseline urine albumin creatinine ratio (UACR), CatD peptides were associated with rapid eGFR loss among those with UACR 30-300mg/g in both discovery (2.36, 95%CI 1.39-4.03; 2.28, 95%CI 1.32-3.92) and validation (1.93, 95%CI 1.10-1.39; 1.84, 95%CI 1.08-3.13) sets.

Conclusions: Loss of functional SCO2 attenuates diabetic kidney disease in db/db mice.

Nehaben A. Gujarati,1 Alexandra R. Leonard,2 Jessica M. Vasquez,3 Sandeep K. Mallipatil,4 Division of Nephrology, Department of Medicine, Stony Brook University, Stony Brook, NY.

Background: Synthesis of Cytochrome C Oxidase 2 (SCO2), a Cu2+ metallochaperone located in the inner mitochondrial membrane, is essential for the assembly of Complex IV (COX IV) of the electron transport chain, maintenance of the proton gradient, and redox signaling. Altered COX activity and reduced mitochondrial function have been reported in diabetic kidney disease (DKD), but the mechanism mediating this process remains to be explored.

Methods: db/db mice were bred with Sco2 mutant mice (E129K, most common human missense mutation in the Cu2+ binding domain) to generate Sco2−/−;db/db and Sco2+/-;db/db mice. Sco2+/-, Sco2+/-;db/db, and wildtype mice served as controls. All mice were euthanized at 24 weeks of age and assessed for functional and histological changes in the kidney.

Results: Data mining in Nephroseq showed that SCO2 expression was increased in micro-dissected glomeruli in human DKD kidney biopsies (Ju et al. 2013), which we confirmed by immunostaining in human kidney biopsies with DKD as compared to healthy donor nephrectomies. Since SCO2−/− mice are embryonally lethal, we ascertained the role of mutant and heterozygous knockout SCO2 in DKD (SCO2−/−, SCO2+/−). As compared to db/db mice, SCO2−/−;db/db and SCO2+/−;db/db mice had a significant reduction in albuminuria, serum creatinine, glomerular hypertrophy, glomerular oxidative stress (8-oxoG staining) with an increase in podocyte number (WT 1+ cells per glomerular cross-sectional area), synaptopodin expression, and overall survival. SCO2−/−;db/db and SCO2+/−;db/db mice also exhibited less glomerular endothelial injury with a decrease in glomerular capillary loop dilatation and a trend towards decrease in Fcan and Vcan1 and an increase in Angpt1, Vegfa, Kdr and KIf2 expression as compared to db/db mice.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Conclusions: Among patients with TID and largely normal kidney function, differences in renal lysosomal function as suggested by increased urine CatD may represent a mechanism of rapid eGFR loss early in the course of TID.

Reduction in the Rate of eGFR Decline with Semaglutide vs. Placebo: A Post Hoc Pooled Analysis of SUSTAIN 6 and PIONEER 6

Katherine R. Tuttle,1 David Cherney,2 Samy Haddaji,3 Thomas Idorn,4 Offr Moszenzon,5 Vlado Perkovic,6 Soren Rasmussen,7 Benjamin Wolthers,8 Stephen C. Bain,9 Institute of Translational Health Sciences, Kidney Research Institute, and Nephrology Division, University of Washington, Seattle, WA;9 Division of Nephrology, University Health Network, University of Toronto, Toronto, ON, Canada;10 L’institut du thorax, INSERM, CNRS, University of Nantes, CHU Nantes, Nantes, France;6 Novo Nordisk A/S, Søborg, Denmark;11 Diabetes Unit, Department of Endocrinology and Metabolism, Hadassah Medical Center; Hebrew University of Jerusalem, Jerusalem, Israel;3 University of New South Wales, Sydney, NSW, Australia;2 Diabetes Research Unit, Swansea University Medical School, Swansea, United Kingdom.

Background: The SUSTAIN 6 cardiovascular outcomes trial (CVOT) indicated that once-weekly (OW) subcutaneous (s.c.) semaglutide may have beneficial effects on kidney function in subjects with type 2 diabetes (T2D) at high CV risk. SUSTAIN 6 and the PIONEER 6 CVOT (once-daily [OD] oral semaglutide) had similar designs and populations, and both evaluated the effects of semaglutide vs placebo (PBO) on macro- and microvascular outcomes. This post hoc analysis of pooled data from the two trials evaluated the effects of semaglutide vs PBO on kidney function decline.

Methods: Data for 6,480 subjects with T2D from SUSTAIN 6 (OW s.c. semaglutide 0.5 and 1.0 mg or PBO, N=3,297; median follow-up 2.1 years) and PIONEER 6 (OD oral semaglutide 14 mg or PBO, N=3,183; median follow-up 1.3 years) were pooled into two groups: semaglutide and PBO. Annual change in estimated glomerular filtration rate (eGFR) was compared (semaglutide vs PBO) in the overall population and subgroups by baseline (BL) eGFR (≥45 mL/min/1.73 m²) and at each level of additional risk (baseline eGFR <45 mL/min/1.73 m² or baseline eGFR ≥45 mL/min/1.73 m² and at least one additional CV risk factor). Changes in eGFR from BL during trial were analyzed using a linear random regression model with individual intercept and time slope. The estimated treatment difference (ETD) at 1 year between annual rates of eGFR slope from BL was calculated; an interaction p-value <0.05 indicated difference between subgroups.

Results: In the overall population, the annual rate of eGFR change was 0.60 mL/min/1.73 m² (p<0.0001) lower with semaglutide vs PBO. In the eGFR ≥45 mL/min/1.73 m² and at least one additional CV risk group, the ETDs for semaglutide vs PBO were, respectively, 1.07 and 0.48 mL/min/1.73 m²/year, with a non-significant interaction p-value (Figure).

Conclusions: Semaglutide was associated with a significantly smaller decline in kidney function than PBO in subjects with T2D at high CV risk across tested BL eGFR categories; the data suggest the main benefit might be observed in those with kidney disease.

Patrionomer to Enable Spironolactone in Patients with Resistant Hypertension and CKD (AMBER): Results in the Prespecified Subgroup with Diabetes

Rajiv Agarwal,1 Patrick Rossignol,2 Susan Arthur,3 Ansgar Conrad,4 William B. White,4 Bryan Woodward,5 Indiana University School of Medicine, Indianapolis, IN;1 University of Lorraine and FCRIN INI-CRCT, Nancy, France;2 Relypsia, Inc., a Vifor Pharma Group Company, Redwood City, CA;3 University of Connecticut School of Medicine, Farmington, CT;4 University College London (UCL), London, United Kingdom.

Background: Spironolactone (SPIRO) reduces BP in patients (pts) with resistant hypertension (RHTN); however, its use in pts with advanced chronic kidney disease (CKD) is often limited by hyperkalemia (HK). In AMBER, patrionomer (PAT) enabled more persistent use of SPIRO in pts with RHTN and CKD. As SPIRO is recommended in RHTN and diabetes mellitus (DM) increases HK risk, we report results in prespecified subgroups with Type 1 or 2 DM.

Methods: Randomized, double-blind, placebo (PBO)-controlled trial in adults with RHTN and eGFR 25 to 60 mL/min/1.73 m². Pts were assigned (1:1) to PBO or PAT, and SPIRO 25 mg QD, with dose titrations permitted after 1 wk for PAT/PBO and 3 wks for SPIRO. The primary endpoint, between-group difference at Wk 12 in 45 mL/min/1.73 m² and more persistent use of SPIRO in pts with RHTN and CKD. As SPIRO is recommended for pts with RHTN and CKD, we were assessed prospectively in prespecified DM subgroups.

Results: 295 pts were randomized, 145 (49%) DM+ and 150 (51%) DM-. Baseline mean (SD) serum K+ (mEq/L) was 4.76 (0.34) in DM+ and 4.67 (0.39) in DM-. Significantly more pts treated with PAT than with PBO remained on SPIRO at Wk 12 in both subgroups (Figure). LS Mean (SE) cumulative SPIRO dose was higher with PAT than PBO, by 438.7 (177.7) mg in DM+ and 317.8 (175.0) mg in DM-. Adverse events occurred in 61% (PBO) and 60% (PAT) of DM+ pts and in 46% (PBO) and 51% (PAT) of DM- pts. 4 pts had serum magnesium (Mg2+) <1.4 mg/dL between baseline and Wk 12 (none <1.2 mg/dL), including 3 DM+ (1 PBO, 2 PAT) and 1 DM- (PAT) pt. None of these pts had cardiac arrhythmias temporally associated with low Mg2+ levels, neuromuscular abnormalities, or serum K+ below the LLN (3.5 mEq/L).

Conclusions: PAT enabled more pts with advanced CKD and RHTN to continue treatment with SPIRO, regardless of DM status.
Kidneyomics: From Cysts to Populations
Oral Abstract/Saturday

Single-Cell RNA Sequencing Provides Insights into the Mechanism Through Which Adaptive Immune Cells Promote Injury-Induced Cyst Formation

Kurt Zimmerman,1 Bradley K. Yoder,2 Mitchel Mrug,3 Katharina Hopp,3 The University of Oklahoma Health Sciences Center, Oklahoma City, OK; 2The University of Alabama at Birmingham, Birmingham, AL; 3University of Colorado Denver- Anschutz Medical Campus, Aurora, CO.

Backgrounds: Inducible deletion of cilia related genes in adult mice results in slow progressing cystic disease, which can be greatly accelerated by renal injury. However, cells that promote accelerated cystogenesis following renal injury are poorly understood.

Methods: To identify cells that may be responsible for driving rapid, injury induced cystic disease, we performed single cell RNA sequencing on cells isolated from sham operated control and 48 hour ischemia-reperfusion (IR) injured kidneys. IR injured, cilia mutant mice were 56 days post injury, a time point in which injured cilia mutant mice had mild cystic disease.

Results: Single cell RNA sequencing data from sham- and injured- cilia mutant mice indicate that renal injury in the setting of cilia loss results in alterations in T cells clusters with limited differences in other cell populations. In contrast, single cell RNA sequencing data comparing injured cilia mutant mice and normal cilia mutant mice revealed that loss of primary cilia in the setting of IR injury resulted in major changes in clusters of tubular epithelia and macrophages with minimal effects on T cells. These data suggest that accelerated cystogenesis in cilia mutant mice requires both injury induced changes in T cells as well as cilia-dependent alterations in the injured epithelium and macrophages. Using WicNet to identify ligand-receptor-gene regulatory networks, we show that T cells from injured cilia mutant mice produce ligands that cause alterations in the gene expression signature of the cilia mutant epithelium and macrophages suggesting that these cells are master regulators of injury induced cystic disease. In agreement with this hypothesis, our data indicate that loss of adaptive immune cells (including T cells) significantly reduced injury induced cystic disease. In contrast, loss of adaptive immune cells did not affect cyst progression in the absence of injury in multiple cystic models, even when animals were aged out several months.

Conclusions: Collectively, our data indicate that IR injury creates a unique population of ligand-producing T cells that crosstalk with macrophages and epithelium of cilia mutant mice to drive rapid, injury induced cystogenesis.

Activation of AMP-Activated Protein Kinase In Vivo Leads to a Polycystic Kidney Disease

Laura Wilson,1 David Carling,2 1University College London Institute of Child Health, London, United Kingdom; 2MRC London Institute of Medical Sciences, London, United Kingdom.

Background: Polycystic kidney disease (PKD) is a genetic disorder in which numerous fluid-filled cysts form in the kidney. Despite having identified the causative genetic mutations in PKD1 and PKD2, our understanding of the molecular signalling pathways involved in cystogenesis is limited, hindering PKD drug discovery. In this project, we generated a mouse model of AMP-activated protein kinase (AMPK) activation and observed a polycystic kidney phenotype, reminiscent of PKD. AMPK is known for its role in controlling energy homeostasis and is activated in response to cellular stress. It is currently unknown whether AMPK could play a role in PKD pathogenesis.

Methods: AMPK activation mouse models were generated by expressing the AMPKα1 isofrom with a D316A mutation under the control of β-actin (global) and Ksp (kidney-specific) promoters using the Cre-LoxP system. A constitutively active form of AMPK is produced when AMPKα1-D316A is incorporated into the enzyme complex. Renal function was assessed using metabolic caging, serum and urine samples were collected for analysis. Kidneys were collected and snap-frozen for biochemical studies or were embedded for histological studies.

Results: Global activation of AMPKα1 resulted in a striking polycystic kidney phenotype. Tubule dilations were evident from 11 days of age, which progressed to heavily cystic kidneys by 3 weeks of age. Adult mice showed signs of polyuria associated with increased urine osmolarity, kidney damage and compromised renal function. Cysts were observed in the collecting ducts of these mice, consistent with the distal neobrain being mostly affected in PKD. Mechanistically, the cystic kidneys had increased AMPK levels and ERK activation (a pathway known to be dysregulated in PKD), increased PKD1 expression and altered lysosomal protein expression. Kidney specific activation of AMPKα1 also produced polycystic kidneys in mice, demonstrating that AMPK activation within the kidney was causative.

Conclusions: These results show that activation of AMPK causes polycystic kidneys to form, raising the possibility that AMPK activation could be a contributing factor in PKD pathogenesis. Disregulation of the cAMP-ERK pathway in this model suggests a possible mechanism for how AMPK activation could be implicated in renal cystogenesis. Future studies should investigate whether AMPK has a pathogenic role in other PKD models.

CUB062, the Product of the C2orf62 Gene, Is a Polycystin-1 Ligand

Christine A. Ward1, Steven J. Kleene,2 James P. Calvet3, Wendy A. Lea4 1University of Kansas Medical Center, Kansas City, KS; 2University of Cincinnati, Cincinnati, OH.

Background: The PKD1 gene, encoding the protein polycystin-1 (PC1), is responsible for 85% of cases of mutation positive autosomal dominant polycystic kidney disease (ADPKD) and is the most common genetic cause of renal failure (1:800). CUB062 has been shown to be present on easily accessible urinary exosome-likes (ELVs) and to be decreased in individuals with PKD1 mutations. Label-free mass spectrometry comparison of ELVs from normal and PKD1 urine showed that several other proteins were decreased to a degree similar to PC1, including a small signal peptide bearing protein of unknown function, CUB062, the product of the C2orf62 gene.

Methods: To determine whether this novel protein is involved in cystogenesis, we applied a genetic approach and deleted the entire C2orf62 open reading frame in c57Black6j mice. We also investigated the ability of CUB062 to interact with the entire 4302 aa ORF of PC1 and mapped the interacting domains. Furthermore, we probed its ability to rescue injury induced PC1/PKD1 knock-out (KO) murine cilia mutant phenotype.

Results: A TALEN induced deletion of the entire C2orf62 ORF generated mice that were grossly phenotypically normal, and both sexes were fertile. Close inspection of the kidney showed that about 25% of the homozygous null animals had mild tubular dilation in the loop of Henle and collecting duct. The C2orf62- allele exacerbated the fibrocystic disease phenotype in mice using primary cilia patch clamp.

Conclusions: Our data indicate that CUB062 activated cystogenesis in vivo in cilia mutant mice to drive rapid, injury induced cystogenesis.

Interconnected Cells and the Transmission Factor FOXIN1 Drive the Kidney Cystogenesis in Tuberous Sclerosis Complex

Sharon D. Barong1,2,3, Kamary A. Zahedi,1,2,3 Marybeth A. Brooks,1 Catherine E. Pedersen,1 John D. Brooks,1,2,3,4,6 Jane J. Yu,1,2,3,4,6 J. Michael Sollenbarg1,2,3,4,6 1University of New Mexico Health Sciences Center, Albuquerque, NM; 2Raymond G Murphy Department of Veterans Affairs Medical Center, Albuquerque, NM; 3Brigham and Women’s Hospital, Boston, MA; 4University of Cincinnati College of Medicine, Cincinnati, OH; 5LeBonheur Center for Children in Crisis, Memphis, TN; 6St Jude Children’s Research Hospital, Memphis, TN.

Background: Tuberous sclerosis complex (TSC) is caused by mutations in either the TSC1 or TSC2 gene and affects multiple organs, including the kidney. Patients can present with benign tumors (angiomylipomas) and cysts, which can lead to kidney failure. Factors that promote cyst formation and tumor growth in TSC are poorly understood.

Methods: Mice with principal cell specific inactivation of Tsc1 were generated. In addition, mice with double deletion of Fox1 and Tsc1 (Fox1/Tsc1 double KO) or ERT2+ Ift88 f/f (hereafter referred to as cilia mutant mice), ischemia-reperfusion was performed and renal tissue was analyzed for cyst number and size. RNA-seq studies demonstrated a 3-fold enhanced expression of Fox1, which is critical to the development of IC cells and regulation of V H+-ATPase. RNA-seq studies demonstrated a 3-fold enhanced expression of Fox1, which is critical to the development of IC cells and regulation of V H+-ATPase. The expression of Fox1 was significantly increased in FOXIN1 knock-out mice. FOXIN1 knock-out mice showed significantly reduced cyst burden and increased longevity vs. Tsc1 KO mice.

Conclusions: These data suggest that CUB062 might be a circulating ligand for PC1 and carbonic anhydrase 2 (CAII) and Tsc1 (CAII/Tsc1 double KO) were generated based on RNA-seq and expression studies. Results: Tsc1 KO mice showed numerous kidney cortical cysts, which were overwhelmingly comprised of A-intercalated (A-IC) cells that showed strong expression of apical V H+-ATPase. RNA-seq studies demonstrated a 3-fold enhanced expression of Fox1, which is critical to the development of IC cells and regulation of V H+-ATPase and CAII. The expression of Fox1 in Pkd1 mice remained unchanged vs. WT mice. Deletions Fox1 completely abrogated the cyst burden in Fox1/Tsc1 dko mice (Kidney MRK, p=0.0017) and caused a profound reduction in V H+-ATPase expression in the A-IC cells. Mice with double deletion of Tsc1 and CAII, a regulator of V H+-ATPase, showed significant reductions in cyst burden and increased longevity vs. Tsc1 KO mice.

Genome-wide Analyses Provide Insights into the Architecture of Kidney Function and CKD in African Americans in the Million Veteran Program (MVP)

Bryce E. Brown,1,2 Cassianne Robinson-Cohen,1 Elvis A. Akwo,2 Huei-Chang Chen,2 Ran Tao,2 Cecilia P. Chung,2 Csaba P. Kovetsky,4 Katalin Suszta,1 Christopher J. O'Donnell,3 Edward D. Siew,1,2 Adriana Hung,1,2 1 Nashville VAMC, Nashville, TN; 2VUMC, Nashville, TN; 3Boston VA, Nahsville, MA; 4Memphis VA, Memphis, TN; 5Penna Medicine, Philadelphia, PA.

Background: End-stage kidney disease (ESKD) incidence rates for African Americans are more than 3 times higher than for European-Americans. This disparity has been only partly explained by known determinants of ESKD and the presence of high-risk APOL1 variants. The identification of “second hit” triggers may explain kidney outcome disparities observed in African Americans.

Methods: We performed a GWAS of eGFR among 84,544 African Americans from the MVP at or closest to enrollment. Exclusion criteria were: dialysis, kidney transplant, and BMI>18. We evaluated the association of common (minor allele frequency >1%) SNPs with linear eGFR (by CKD-EPI equation), adjusted for age, sex, BMI, and the top ten principal components of ancestry. Analyses were performed by strata of diabetes and estimates were aggregated with fixed-effects meta-analysis.

Results: We identified 2,275 SNPs in 22 independent loci associated with eGFR (p<5x10^-8). The SNP with the strongest signals replicated previously detected associations at SPTASL1/GATM (rs2486272, p = 1.7 x 10^-10). Of these, 19 were identified previously reported loci from GWAS of kidney function or CKD. Known CKD genes from case-control studies such as APOL1 (rs73885319 p=9.08x10^-28) were included in the known loci. Three were novel loci for the association with kidney function in African Americans. Of the novel variants, we discovered SNPs in ABCA1 (rs10091574 p = 2.97x10^-10) associated with accelerated atherosclerosis and lipid metabolism through PPPAR alpha, PRKCI/ps564767p = 3.1x10^-8 associated with leskocyte count and BLK(rs6964029 p=2.49 10^-8) associated with colorectal adenoma. Some of the strongest signals previously reported for kidney phenotypes included: DAB2 (rs25427131 p=1.5 x 10^-10), OCT2 (rs2279463, p=1.98 10^-10), UNCG (rs62435145 p=1.97 10^-10) and PRKAG2 (rs10253736 p=3.0x10^-10). 70 SNPs were exonic variants overall. SNPs within UMOD/PDILT, the top hits for kidney function GWAS and CKD progression among European-Americans, did not reach genome-wide (p=9.19x10^-10) significance.

Conclusions: In this large GWAS of eGFR among African Americans to date, we replicate over 19 previously identified loci, identify 3 novel loci associate with kidney function.

3D Genome Architecture of Human Renal Cortex and Medulla

Selvaraj Muthusamy, Shreeram Akiles. University of Washington, Seattle, WA.

Background: Genomic DNA is organized in a non-random manner within the mammalian nucleus. How this three-dimensional genome architecture influences cell-type specific phenotypes is poorly understood. Genome-wide methods such as Hi-C or massively sequenced Hi-C architecture maps can only be used if the tissue can be dissociated. We developed a novel machine learning algorithm used in the domain of computer vision to identify significant contacts in our Hi-C data.

Methods: We performed global genome conformation (Hi-C) analysis on macrodissected human renal cortex and medulla from the same individual. Since existing algorithms to identify intra and inter-chromosomal interactions in Hi-C sequencing data are plagued by low concordance, we developed a novel machine learning algorithm used in the domain of computer vision to identify significant contacts in our Hi-C data.

Results: Each kidney Hi-C sample was deep sequenced to >400 million mapped contacts enabling visualization of topologically associated domains (TADs) and contacts at 10kb resolution. Comparing even these highly similar samples, our novel algorithm identified significantly different genome conformation at multiple intra-chromosomal contacts in renal cortex (n=1789) and medulla (n=1841) (figure). Further validation by DNA-FISH and comparison to orthogonal functional genomic data sets (ATAC-seq, RNA-seq) are ongoing.

Conclusions: These high-resolution chromatin conformation maps of intact human kidney tissues will provide a valuable resource for the study of kidney genome regulation. Our novel loop-calling algorithm enabled identification of fine genome architectural differences between renal cortex and medulla. Our data can also be used to link genetic risk loci to target genes in genome-wide association studies.

complement system, also cause aHUS. In the glomeruli, DGKE is expressed in endothelial cells and podocytes. The molecular mechanisms by which DGKs cause aHUS are not known. Phosphatidylinositol bisphosphate [PtdIns(4,5)P2] levels are reduced in Dgke knockout cells. Since the disruption of vascular endothelial factor A (VEGFA) signaling in humans and mice results in glomerular lesions that resemble those in humans with loss-of-function mutations in DGKE, we hypothesized that loss of Dgke may impair VEGFA signaling in endothelial cells due to shortage of PtdIns(4,5)P2.

**Methods:** To test this hypothesis, we performed in vitro studies on Dgke knockdown human umbilical vein endothelial cells (HUVECs) and generated endothelial-specific Dgke2 conditional knockout mice.

**Results:** We found that signaling downstream of VEGFA receptor 2 (VEGFR2) is compromised in Dgke knockdown HUVECs due to decreased activation of Akt, a phenotype that is rescued by supplementation the culture medium with PtdIns(4,5)P2. Endothelial-specific Dgke2 conditional knockout mice spontaneously developed thrombocytopenia, scistocytosis, and renal insufficiency, indicating that the endothelium is the cellular compartment responsible of the DGKE disease. Remarkably, these mice also developed albuminuria at later times, indicating that the impairment of the glomerular barrier, which is characteristic of the DGKE disease, is a later and secondary event.

**Conclusions:** Our data indicate that loss of Dgke compromises signalling downstream of VEGFR2 in endothelial cells by decreasing cellular levels of PtdIns(4,5)P2, inducing aHUS and, secondarily, disruption of the glomerular barrier. These results also implicate that pharmacological manipulation of the VEGFA signaling may be used to modify the clinical course of other forms of aHUS.

**Re-Envisioning the APOL1 Cation Channel Structure**

Russell P. Thompson,1 Cresses M. Schanowitz,2 Penney Lee,1 Nada Terra,1 Jayne Raper,1,2 Hunter College, New York, NY; 1Vanderbilt University, Nashville, TN.

**Background:** Apolipoprotein L-I (APOL1) is a channel forming protein that protects humans and other primates from African trypanosome infection. African Americans have inherited common APOL1 variants with increased trypanolytic potential; however, these variants are responsible for an increased risk of kidney disease compared with other variants. Human APOL1 forms non-selective cation channels in a strictly pH dependent manner: channel formation requires acidic pH, whereas channel opening requires pH neutralization. Current APOL1 structural models rely on tenuous comparisons with neutralization.

**Methods:** We recently identified by high-throughput screening and subsequent medicinal chemistry, small molecule TMEM16A inhibitor TMinh-23 that inhibits TMEM16A current fully, with IC50 ~ 30 nM. Here we tested TMinh-23 pharmacokinetics in rodents and its effects on vascular smooth muscle contraction (via wire myograph) and BP in spontaneously hypertensive rats (SHR) and wild type rodents.

**Results:** TMinh-23 pretreatment blocked maximum in vitro vascular smooth muscle contractions induced by a thromboxane mimetic (U46619) in rat mesenteric arteries by 90%. Intraperitoneal (ip) administration of TMinh-23 to rodents at 10 mg/kg produced sustained systemic effects in concentrations of ~10 μM for >4 hours. BP measurements by tail-cuff and telemetry showed a maximum ~45 mmHg reduction in SBP in spontaneously hypertensive rats (SHR) after a single dose TMinh-23 (~10 mg/kg, ip) compared to vehicle administration, with BP gradually returning to baseline values within 6-8 hours after TMinh-23 pretreatment. Minimal effect on BP (less than 10 mmHg decrease in SBP) was seen in wild-type rats and mice with TMinh-23 treatment (10 mg/kg, ip). Chronic 5-day treatment of SHR with TMinh-23 (~10 mg/kg, ip, twice daily) caused sustained decreases (~25 mmHg) in daily average SBP, DBP and MAP during the treatment period. TMinh-23 action was reversible, with BP returning to baseline (~170/115 mmHg) by 3 days after discontinuation of treatment.

**Conclusions:** These studies provide validation for TMEM16A as a target for hypertension therapy, and demonstrate the proof-of-concept for efficacy of TMinh-23 as an antihypertensive with a novel mechanism of action.

**Intravitral Imaging of Affenter Arteriole Calcium Dynamics and the Role of Connexin 45**

Anne Riquier-brison, Georgina Gyarmati, Janos Peti-Peterdi. University of Southern California, Los Angeles, CA.

**Background:** The glomerular afferent (AA) and efferent (EA) arterioles are the most critical resistance vessels in the autoregulation of renal blood flow and glomerular filtration rate. Calcium dynamics of vascular smooth muscle cells (VSMC), in part mediated by gap junction communication via connexin 45 (Cx45), are important regulators of AA contractility and myogenic tone. We aimed to study the role of Cx45 in renal hemodynamics in vivo.

**Methods:** Intravitreal imaging with multiphoton microscopy (MPM) of renal functional parameters was performed in mice expressing a genetically encoded calcium indicator (GCaMP3 or GCaMP5) in cells of renin lineage with or without connexin 45 knockout (KO). Suramin treatment was used to test the effects of purinergic receptor blockade.

**Results:** Compared to the uniform upstream AA segment, high baseline and A(a-), were observed in a few AA VSMCs at the glomerular entrance, which appeared to function as sphincter cells. The diameter of the AA (25±1.27μm WT, vs. 11.3±0.37μm KO) and EA (7.18±0.36μm WT, vs. 8.58±0.30μm KO) were larger in KO animals, although no difference was found in SBP, snGFR and glomerular diameter. Blood flow in AA was also increased (1.42±0.15μm/min WT, vs. 2.0±0.12μm/min KO). AA myogenic tone was visualized 3-4 weeks after unilateral ureteral obstruction (UUO). In WT animals, regular AA contractions were observed uniformly in all AAs with an average frequency of 0.12±0.01 Hz, with large magnitude A(a-), in VSMCs during every contraction (A(a-)) ~ 556±635 AU). In contrast, KO animals showed highly heterogeneous and irregular vascular activity. In those AAs that did exhibit some myogenic tone-like contractions, a higher frequency was observed (0.28±0.02 Hz), however the magnitude of A(a-)) in AA VSMCs was much lower than in the WT (A(a-)) ~ 395±249 AU). In both WT and KO animals, treatment with suramin rapidly blocked AA VSMC calcium influx and the myogenic contractions, and the AA became dilated.

**Conclusions:** AA sphincter cells have robust effects on AA (Ca(a-)), dynamics and contractility in vivo, and Cx45 and purinergic signaling are essential components of AA calcium signaling and vascular contractility. Cx45 and purinergic signaling in the AA regulate the myogenic response and renal blood flow, and may be culprit and potential target in vascular pathologies.

Inorganic Nitrate Supplementation Improves Endothelial Function with Age: Translational Evidence for Suppression of Mitochondria-Derived Oxidative Stress
Matthew J. Rossman,1 Rachel A. Gioscia-Ryan,1 Jessica R. Santos-Parker,1 Brian P. Ziembka,1 Kara L. Lubieniecki,1 Natalie E. Poliektov,2 Lawrence C. Johnson,1 Erzebet E. Nagy,1 Kayla A. Woodward,1 Amy L. Sinder,1 Michel Chonchoł,2 Douglas R. Seals.1 1University of Colorado Boulder College of Arts and Sciences, Boulder, CO; 2University of Colorado Denver - Anschutz Medical Campus, Aurora, CO.

Background: We previously observed improvements in vascular endothelial function with inorganic nitrate supplementation in old mice, which we translated to older humans in a pilot study of sodium nitrite supplementation. Methods: Here, we sought to confirm the efficacy of sodium nitrite in humans and determine mechanisms of action using: 1) a randomized, placebo-controlled, parallel-group clinical trial with sodium nitrate (80 mg/day, 12 weeks) in older adults (n=49, 68±1 yr) and 2) reverse translation experiments in young (6 mo) and old (27 mo) male C57BL/6 mice.

Results: In humans, sodium nitrite increased plasma nitrite (p<0.05) and was well-tolerated over 12 weeks. Endothelial function (brachial artery flow-mediated dilation) was increased by 28% vs. baseline after nitrite supplementation (p<0.05), but unchanged with placebo. Serum from nitrite-treated subjects reduced whole-cell (CellROX) and mitochondria (mito)-specific (MitoSOX) reactive oxygen species (ROS) in human umbilical vein endothelial cell culture (p<0.05), whereas serum from placebo-treated subjects had no effect. Old mice (OC, n=9) had ~30% lower ex vivo carotid artery endothelium-dependent dilation (EDD) vs. young mice (YC, n=9) due to reduced nitrite oxide (NO) bioavailability (p<0.05). Nitrite supplementation (drinking water, 50±8 mg/L, 8 weeks) restored EDD and NO bioavailability in old mice (ON, n=10). MitoROS suppression of EDD was present in OC (increased EDD with a mito-targeted antioxidant, p<0.05), but not in Y or ON. A mito stressor (rotenone) further impaired EDD in OC (p<0.05), whereas Y and ON were protected.

Conclusions: Nitrite supplementation improves age-related endothelial dysfunction and is associated with increased NO, reduced mito ROS and improved mitochondrial stress resistance. Funding: NIDDK Support, Other NIH Support - NIH RO1 AG103308, NIH/NCCATS Colorado CTSA Grant Number UL1 TR002535

Paracrine FGF-23 Signaling in the Heart Causes Cardiac Hypertrophy
Isaac D. Campos, Beatrice Richter, Christopher Yancul, Brian A. Craya, Kylie Heitman, Dominik Kentrup, David G. Westbrook, Christian Faul.1 The University of Alabama at Birmingham Department of Medicine, Birmingham, AL.

Background: Elevated serum levels of the phosphaturic hormone, fibroblast growth factor (FGF) 23, contribute to cardiac hypertrophy in chronic kidney disease (CKD). FGF23 directly targets cardiac myocytes via FGF receptor (FGFR) 4 to induce hypertrophic growth and FGFR4 blockade not only protects rodent models of CKD from cardiac hypertrophy but also from fibrosis. Our cell culture studies indicate that cardiac fibroblasts do not directly respond to FGF23. It is known that a miscommunication between cardiac myocytes and fibroblasts contributes to pathologic cardiac remodeling. It has been shown that in rodent models and patients with CKD, as well as in mice on high phosphate diet without kidney injury, the heart starts to produce FGF23. Here, we studied if by targeting cardiac myocytes FGF23 promotes paracrine signaling that drives fibrosis. We aimed to determine the cardiac cell type(s) that act as FGF23 source and study if FGF23 serves as a novel paracrine signal mediator between cardiac cell types.

Methods: We treated cultured cardiac myocytes with FGF23 and determined expression levels of established paracrine signal mediators (IL6, LIF, TGFβ, FGF2), or with high phosphate and analyzed FGF23 expression, all by qPCR. We isolated cardiac fibroblasts from wildtype mice on a high phosphate (2%) diet or control chow (0.7%) for 12 weeks. We analyzed paracrine signal mediators by qPCR, as well as FGF23 by qPCR and ELISA. After plating cardiac fibroblasts for 24 and 48 hours, we transferred cell supernatants to myocytes and analyzed hypertrophy.

Results: FGF23 did not increase the expression of paracrine signal mediators in cardiac myocytes, or fibroblasts. Phosphate elevations induced FGF23 expression in cardiac fibroblasts, but not in myocytes. Cardiac fibroblast-derived supernatants showed pro-hypertrophic activity when transferred to myocytes, which could be inhibited by co-administration of blocking antibodies for FGF23 or FGFR4.

Conclusions: FGF23 does not affect cardiac fibroblasts by regulating paracrine signal mediators in myocytes. However, FGF23 acts as a novel fibroblast-derived paracrine signaling mediator that induces hypertrophic growth of cardiac myocytes in an FGFR4-dependent manner in scenarios of hyperphosphatemia, such as CKD.

A Renal Potassium-Switch Prioritizes Dietary Potassium Over Sodium, Driving Salt-Sensitive Hypertension
Paul R. Grimm,1 Robert Little,2 Robert A. Fenton,3 Eric J. Delpirc,2 Paul A. Welling,4 John Hopkins University School of Medicine, Baltimore, MD; 1Vanderbilt University, Nashville, TN; 2Aarhus University, Aarhus, Denmark.

Background: Reducing dietary salt (NaCl) is well appreciated to lower blood pressure, but what a growing body of evidence indicates that increasing dietary potassium (K) intake is equally important. A ‘renal K switch’ that turns on the thiazide-sensitive NaCl cotransporter (NCC) in response to low dietary K intake and off in response to high K intake has been implicated. Here we test this idea in genetically engineered mice (CA-SPAK) in which the K switch is ‘locked on.’

Methods: Kinase-activating mutations were introduced in SPAK, Expression of the constitutively active (CA) SPAK mutant was limited to the early DCT and results in NCC hyperactivation. BP responses to small changes in plasma [K+] in CA-SPAK were compared to control mice. Dietary K content was varied over 4 days to titrate [K+] over a narrow range (3.7 mLK, 4.4mM K, and 5.1mM HK). Blood pressure was monitored by telemetry at each [K+] level in mice consuming control or high salt diet (HNa). At the end of each treatment, the BP response to hydrochlorothiazide (HCTZ) was measured to assess the contribution to BP.

Results: BP decreased by ~10 mmHg when [K+] increased from 3.7 to 5.1 m in control mice, coincident with the inactivation of NCC. When the switch was on (LK and MK groups), HNa significantly elevated BP but had no effect when the switch was inactivated by HK. HCTZ significantly reduced BP in the LK/HNa and MK/HNa groups but had no effect on BP in the HK/HNa group, supporting the low K switch hypothesis. HCTZ activation of NCC exacerbates the effects of Na. Studies in CA-SPAK mice reveal a causal relationship between switch activation and BP responses to Na and HK. In contrast to control mice, increasing [K+] in CA-SPAK mice had no effect on BP under control salt conditions and failed to blunt the significant hypertensive effects of HK. HCTZ significantly decreased BP in all CA-SPAK groups to near control levels, consistent with NCC-driven salt reabsorption. Thus, locking on the K switch prevents the anti-hypertensive effects of HK. No sex differences were found.

Conclusions: In summary, low K consumption, common in modern diets, presses the switch pathway to turn on to conserve K at the expense of increasing Na retention, even in the face of high dietary Na, and this elevates BP. Thus, switch activation can drive salt-sensitive hypertension.

SA-OR36
Risk of Cardiovascular Events Is Higher in Patients with Glomerular Disease Compared with the General Population
Heather M. Cunningham,1,2 Mark Canney,1,3 Heather N. Reich,1 Yuyan Zheng,1 Anahat Sahota,4 Seo Am Hor,4 Arenn S. Jauhal,1 Sean Barbour,1,2 Caren L. Rose.1 1BC Provincial Renal Agency, Vancouver, BC, Canada; 2Division of Nephrology, University of British Columbia, Vancouver, BC, Canada; 3Division of Nephrology, University of Toronto, Toronto, ON, Canada; 4School of Medicine, University of British Columbia, Canada; Vancouver, BC, Canada; 5British Columbia Centre for Disease Control, Vancouver, BC, Canada.

Background: Cardiovascular (CV) disease is a recognized cause of morbidity and mortality in chronic kidney disease; however, understanding of CV risk in patients with glomerular disease (GN) is limited. We sought to define CV risk in GN patients and compare incidence rates to the general population.

Methods: A centralized kidney pathology registry (2000-2012) was used to capture all incident cases of focal segmental glomerulosclerosis (FSGS, n=540), IgA nephropathy (IgAN, n=759), membranous nephropathy (MN, n=387), and minimal change disease (MCD, n=226) in British Columbia, Canada. The primary outcome was a composite of major CV events, ascertained from a hospital discharge registry and evaluated using the Kaplan-Meier method. Hazard ratios (HR, 95% CI) were determined using Cox proportional hazards regression. Event rates were age and sex standardized to the general adult population to generate standardized incidence ratios (SIR, 95% CI).

Results: Over a median follow-up of 6.5years there were 338 CV events; 10-year risk (95% CI) was 16.0% (13.8-18.3) and differed by GN type(Figure): IgAN=7.7% (5.4-10.4), MCD=13.2% (7.6-20.4), MN=19.4% (14.3-25.0), and FSGS=27.0% (21.9-32.4). Compared to IgAN, MN (HR=2.6, 1.7-3.9) and FSGS (HR=3.7, 2.6-5.3) had higher risk, but MCD (HR=1.3, 0.8-2.4) did not. Results were similar when comparing CV events occurring after ESKD. CV risk in GN patients was 2.5-fold higher than the general population (SIR 2.5, 2.1-2.8), and was higher in each GN subtype (IgAN=1.4, 1.0-1.8; MCD=1.8, 1.0-2.8; MN=3.0, 2.2-4.0; FSGS=4.0, 3.2-4.9).

Conclusions: Patients with GN are at high risk of CV disease, both before and after ESKD onset. The CV risk for all GN subtypes was higher than the general population, including MCD and IgAN. This suggests CV preventive strategies should be considered in all patients with GN.

Prediction of Atrial Fibrillation Using Clinical and Cardiac Biomarker Data: The CRIC Study
Leila R. Zelnick,1 Michael Shlipak,2 Elsayed Z. Soliman,3 Amanda H. Anderson,4 Robert Christenson,1 James P. Lash,5 Rajat Deo,5 Panduranga S. Rao,5 Farsad Afshininia,3 Jing Chen,4 Jiang He,4 Stephen L. Seliger,2 Raymond R. Townsend,1 Debbie L. Cohen,6 Alan S. Go,5 Nisha Bansal,7 1University of Washington Department of Medicine, Seattle, WA; 2University of California San Francisco, San Francisco, CA; 3Wake Forest University, Winston-Salem, NC; 4Tulane University, New Orleans, LA; 5University of Maryland School of Medicine, Baltimore, MD; 6University of Illinois at Chicago, Chicago, IL; 7University of Pennsylvania, Philadelphia, PA; 8University of Michigan, Ann Arbor, MI; 9Kaiser Permanente Northern California, Oakland, CA.

Background: Clinically available biomarkers of myocardial injury (high sensitivity troponin T, hsTnT) and hemodynamic stress (N-terminal brain natriuretic peptide, NT-proBNP) are strongly associated with atrial fibrillation (AF) in chronic kidney disease (CKD), and have been included in AF prediction models in community-based populations. We investigated the incremental prognostic value of NT-proBNP and hsTnT for AF prediction compared to standard clinical variables in CKD patients enrolled in the Chronic Renal Insufficiency Cohort (CRIC) using machine learning methods.

Methods: Among 2690 CRIC participants without prior AF with complete cardiac biomarker data, cardiac biomarkers NT-proBNP and hsTnT were added to a previously developed AF prediction model using machine learning techniques. Calibration of the AF prediction model was assessed using 10-fold cross-validation; calibration was evaluated graphically.

Results: Mean (SD) age of participants was 57 (11) years, 55% men, 38% black, and 74% with stage 3 chronic kidney disease (CKD). Mean (SD) eGFR 45 (15) mL/min/1.73m2; 251 incident AF events occurred during 7.3 (2.8) years of follow-up. CHARGE-AF prediction equations using original and re-estimated coefficients to predict AF. Discriminatory ability of each model was assessed using 10-fold cross-validation; calibration was evaluated graphically.

Conclusions: Cardiac biomarkers NT-proBNP and hsTnT can improve AF prediction in CKD, particularly when paired with machine learning algorithms.

Renal Hyperfiltration and the Effect of Intensive vs. Standard Blood Pressure Lowering on Cardiovascular Outcomes
Ayodele Oduatayo,1 Samir M. Issakdar, Fatimah Roble, Peter Jumi, Fahad Razak, Amol Verma.1 University of Toronto, Toronto, ON, Canada.

Background: Using the Action to Control Cardiovascular Risk in Diabetes (ACCORD) trial and Systolic Blood Pressure Intervention Trial (SPRINT), we examined whether the effect of intensive versus standard blood pressure (BP) lowering on cardiovascular outcomes varies by the presence of renal hyperfiltration.

Methods: We pooled data on adults in ACCORD and SPRINT without chronic kidney disease (eGFR>60 and urine albumin-to-creatinine ratio <30 mg/g). RHF was defined as an eGFR above the 95th percentile for healthy adults in the National Health and Nutrition Examination Survey. Outcomes of interest were major adverse cardiovascular events (MACE, as defined in the ACCORD primary outcome): a composite of cardiovascular (CV) mortality, acute myocardial infarction (AMI) and stroke. Secondary outcomes were all-cause mortality, CV mortality and CV events. We used fixed effect cox regression.

Results: There were 17,824 and 17,912 adults with RHF and without RHF, respectively. Intensive BP lowering modified the effect of intensive versus standard BP lowering on MACE (p-interaction=0.002) but not all-cause mortality (p-interaction=0.059). For adults with RHF, intensive BP lowering reduced incidence of MACE compared with standard BP lowering (HR: 0.82, 95%-CI: 0.73-0.92). The risk reduction was smaller in adults with normal filtration (HR: 0.84, 95%-CI: 0.71-0.98). Intensive BP lowering was also associated with a larger reduction in the incidence of CV mortality and stroke among adults with RHF (Figure, p-interaction=0.001) but not MACE or heart failure (p-interaction=0.41). Separate analyses of ACCORD and SPRINT were similar.

Conclusions: RHF modified the effect of intensive versus standard BP lowering on cardiovascular outcomes.

Intensive Versus Standard Blood Pressure Lowering and Cardiovascular Outcomes in Adults With and Without Renal Hyperfiltration (Pooled Analysis)

Pooled Analyses of the Phase 3 Roxadustat Studies: Congestive Heart Failure Hospitalization Rates in Dialysis and Non-Dialysis Patients with Anemia Treated with Roxadustat vs. Comparators
Robert Provenzano,1 Lynda Szczec,2 Ming Zhong,2 Bryan Lai,3 Robert Leong,2 Dustin J. Little,4 Kin-Hung P. Yu,2 Wayne State University, Detroit, MI; 2FibroGen Inc, San Francisco, CA; 3AstraZeneca, Gaithersburg, MD.

Background: Roxadustat is an orally bioavailable hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Phase 3 roxadustat studies were performed to treat anemia of chronic kidney disease (CKD). Congestive heart failure (CHF), a common comorbidity in CKD, is associated with a poor prognosis in CKD patients, with a prevalence that increases with CKD severity; approximately 20% in mild CKD (eGFR ≥65) to 40% in patients on hemodialysis.

Methods: Safety data were pooled from pivotal phase 3 studies comparing roxadustat to placebo in Stage 3-5 non-dialysis-dependent (NDD) CKD patients, and to epoetin alfa in the overall dialysis-dependent (DD) CKD patients, and to epoetin alfa in the overall dialysis-dependent (DD) CKD patients, and to epoetin alfa in the overall dialysis-dependent (DD) CKD patients, and to epoetin alfa in the overall dialysis-dependent (DD) CKD patients. Patients with baseline (BL) moderate to severe CHF were not enrolled. CHF hospitalization events were a component of the MACE-plus endpoints in CKD, was also analyzed. CHF is associated with a poorer prognosis in CKD patients, with a prevalence that increases with CKD severity; approximately 20% in mild CKD (eGFR ≥65) to 40% in patients on hemodialysis.

Results: In the pooled NDD studies, 4270 patients were analyzed (2386 roxadustat; 1884 placebo). BL CHF history was comparable between roxadustat (13.0%) and placebo (13.6%) arms. Using ITT long-term follow-up, the HR (95% CI) of hospitalization for CHF among the NDD pooled population was 0.89 (0.72; 1.22) for roxadustat vs placebo. In the pooled DD studies, 3946 patients were analyzed (1940 roxadustat; 1904 epoetin alfa). BL CHF history was comparable between roxadustat (25.7%) and epoetin alfa.
Racial-Ethnic and Socioeconomic Disparities in Healthcare Utilization in Patients with CKD, Diabetes, and Recent Acute Coronary Syndrome: Results from the BETonMACE Trial

Kamyar Kalantar-Zadeh,1 Gregory G. Schwartz,2 Kevin A. Buhr,3 Henry N. Ginsberg,4 Jan O. Johansson,5 Ewelina Kulikowski,6 Stephen J. Nicholls,7 Peter P. Toth,2 Norman C. Wong,3 Michael Sweeney,3 Kausik K. Ray.2 BETonMACE Investigators 1University of California Irvine, Irvine, CA; 2University of Colorado Denver School of Medicine, Aurora, CO; 3Riverside Group, San Francisco, CA; 4Riverside Group Corp., Calgary, AB, Canada; 5Johns Hopkins University School of Medicine, Baltimore, MD; 6Imperial Centre for Cardiovascular Disease Prevention, Imperial College London, London, United Kingdom; 7Columbia University, New York, NY; 8Statistical Data Analysis Center, University of Wisconsin-Madison, Madison, WI; 9Monash Cardiovascular Research Centre, Monash University, Melbourne, VIC, Australia.

Background: Chronic kidney disease (CKD) in type 2 diabetes mellitus (T2DM) patients (pts) is associated with increased cardiovascular disease (CVD) and heart failure risk. We hypothesized that a maladaptive epigenetic response engaging the bromodomain and extraterminal (BET) protein transcription system contributes to excess CVD risk. Hence, the efficacy of BET inhibition (BETi) treatment with apabetalone (APB) was assessed according to presence of CKD in the phase 3 BETonMACE trial.

Methods: BETonMACE compared APB with placebo in 2425 pts with T2DM and recent acute coronary syndrome. The primary outcome was CV death, non-fatal myocardial infarct or stroke (MACE). Hospitalization for congestive heart failure (CHF) was a secondary endpoint. Both outcomes were evaluated according to the presence of CKD (estimated GFR <60 mL/min/1.73 m2 at baseline).

Results: CKD pts were older (71 vs. 61 years), more likely female (42% vs. 23%) or non-white (18% vs. 12%), had longer duration of diabetes (mean 11.3 vs. 8.2 years) and higher serum alkaline phosphatase (91 vs. 81 U/L), and were less likely to receive metformin (69% vs. 84%) or SGLT2 inhibitors (6% vs. 13%) (P<0.05 for all). Under placebo, risk of endpoints was higher in CKD vs. non-CKD pts (MACE: 35/164 (21.3%) vs. 114/1041 (11.0%), HR=2.40, 95% CI [1.67, 3.44]; HCHF: 14/164 (8.5%) vs. 34/1041 (3.3%), HR=3.19, 95% CI [1.66,6.12]; P=0.001 for both). Under APB treatment, pts with CKD had significant reductions in MACE (HR=0.50, 95% CI [0.26, 0.96]; P=0.034) and HCHF (HR=0.26, 95% CI [0.07,0.94], P=0.028) vs. placebo, see Kaplan-Meier figures.

Conclusions: In patients with CKD, the efficacy of BETi treatment with APB was substantially reduced in CKD compared to non-CKD pts, consistent with a maladaptive epigenetic response engaging the bromodomain and extraterminal (BET) protein transcription system in patients with CKD.

Prevalence of Left Ventricular Hypertrophy in Pediatric Patients on Maintenance Dialysis and After Kidney Transplantation: A NAPRTCS Study

Kyle Merrill,1 Shirley Galbiati,2 Mark Mitsnefes.1,2 on behalf of NAPRTCS Investigators 1Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 2EMMES, Rockville, MD; 3University of Cincinnati, Cincinnati, OH.

Background: Left ventricular hypertrophy (LVH) is recognized as the most common cardiovascular complication in children on maintenance dialysis. There have been small single-center, or cross-sectional multi-center studies but there has been no large multi-center studies looking at prevalence of LVH during long-term maintenance dialysis. Using the NAPRTCS database, we determined the prevalence of LVH at time of initiation of maintenance dialysis and changes during long-term dialysis and post kidney transplantation. We also assessed the risk factors associated with LVH in children initiating maintenance dialysis.

Methods: Echocardiographic data were obtained from the NAPRTCS database which initiated collection of echo data in 2013 with the last data obtained in March 2020. LVH was defined as left ventricular mass index (LVMI, height-indexed)>95th percentile for age and sex. Patients with cardiovascular diagnoses, those younger than 1 year old at the time of echocardiography, LVMI values >200 g/m2.7, and LVMI values based on outputting heights were excluded from analysis. Multivariable logistic regression to assess risk factors for LVH at baseline (within first 3 months after initiation of dialysis) was performed.

Results: The study cohort included 606 patients between 1 and 18 years of age (median 10y (IQR 3.8-15.1), 53% females, 48% whites, 27% African-American, and 25% others/unknown) who had LVH data during time on dialysis. Of 182 patients who had echocardiography within first 3 months after initiation of dialysis (baseline), 67% had LVH. In logistic regression, hypertention (OR 2.9, 95% CI 1.4-6.3), anemia

Racial-Ethnic and Socioeconomic Disparities in Healthcare Utilization Among Children with Glomerular Disease in the CureGN Project

Jill Kriisberg,1 Margaret Helmuth,2 Michelle M. O’Shaughnessy,3 for CureGN Stanford University School of Medicine, Stanford, CA; 2Arbor Research Collaborative for Health, Ann Arbor, MI; 3Cork University Hospital Group, Cork, Ireland.

Background: Inpatient charges for nephrotic syndrome differ across racial-ethnic groups. This study compares rates of ACU (acute care utilization i.e., hospitalization or ED visit) across racial-ethnic groups in children with glomerular disease (GD) and explores demographic, socioeconomic (SE), and disease-related factors that might explain any observed differences.

SA-OR43 Biomarker Panels for Discriminating Risk of CKD Progression in Children

Jason H. Greenberg,1 Yurwen Xu,2 Alison G. Abraham,3 Jeffrey R. Schelling,1 Harold I. Feldman,4 Michael Shlipak,5 Venkata Sabbisetty,6 Bradley A. Warady,7 Steven G. Coca,1 Paul L. Kimmel,8 Joseph V. Bonventre,9 Michelle Denburg,4 Chirag R. Parikh,4 Susan L. Furth,4 CKD Biomarker Consortium Yale University, New Haven, CT; Johns Hopkins University, Baltimore, MD; Case Western Reserve University, Cleveland, OH; University of Pennsylvania, Philadelphia, PA; University of California San Francisco, San Francisco, CA; Brigham and Women’s Hospital, Boston, MA; Children’s Mercy Hospitals and Clinics, Kansas City, MO; Mount Sinai Health System, New York, NY; National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.

Background: We used multivariate survival tree analysis to identify plasma and clinical biomarkers to predict CKD progression in children. Methods: The CKiD study prospectively enrolled children aged 6 months to 16 years old with an eGFR of 30-90 and eGFR was assessed annually. The primary outcome of CKD progression was a composite of 50% decline in eGFR or incident ESKD. We used multivariate survival trees to determine combinations of baseline clinical predictors and plasma biomarkers as well as identify optimal thresholds for predicting the time to the composite event. Results: Of the 651 children included, median age was 11 years [IQR, 8-15], 405(62%) were male, 195(30%) had a glomerular cause of CKD, and baseline eGFR was 53 [IQR, 40-67]. 223(34%) of 651 children reached the primary outcome over a median follow-up time of 5.7 years. The Figure shows the best-sized multivariate survival tree and 4 prognosis groups selected after bootstrapping the sample. Plasma KIM1, TNFR1, TNFR2, and baseline eGFR were used to define branching patterns, while MCP1, YKL40, suPAR and the known risk factors of sex, age, glomerular diagnosis, BMI, hypertension, and proteinuria were not included as they did not reach a level of predictive importance. In the final model, KIM1 was the variable with the highest importance, with a median follow-up time of 5.7 years. The Figure shows the best-sized multivariate survival tree and 4 prognosis groups selected after bootstrapping the sample. Plasma KIM1, TNFR1, TNFR2, and baseline eGFR were used to define branching patterns, while MCP1, YKL40, suPAR and the known risk factors of sex, age, glomerular diagnosis, BMI, hypertension, and proteinuria were not included as they did not reach a level of predictive importance. In the final model, KIM1 was the variable with the highest importance, with a median follow-up time of 5.7 years.

Conclusions: Children who had onset of CKD after pubertal onset were excluded. GFR was estimated annually using the bedside and complete CKD equations. Pubertal onset was defined by three separate definitions: transition to Tanner Stage 2, peak growth velocity, and menarche. A mixed effects model with random intercept and random slope was used to compare the slope of eGFR before and after pubertal onset. The model was adjusted for age, race, glomerular diagnosis, baseline proteinuria, and BMI. Results: 339 girls and 552 boys were included; Median age of pubertal onset for girls was 11.0 years [IQR 9.8, 12.1], 14.1 years [IQR 12.4, 17.0], and 14.4 years [IQR 13.1, 15.7] as defined by Tanner stage 2, peak growth velocity, and menarche, respectively. Median age of pubertal onset for boys was 12.4 years (11.3, 13.3) and 14.6 years (IQR 13.4, 16.6) as defined by Tanner stage 2 and peak growth velocity, respectively. Annual percent change in eGFR declined faster among girls and boys after pubertal onset when defined by all measures, after adjustment. For example, annual percent decrease in eGFR was seen to increase from 2.6% prior to 9.0% after Tanner stage 2 in boys using the complete CKD equation (p=0.001).

Conclusions: Estimated GFR declined faster after the onset of puberty among girls and boys with CKD. Clinicians should be aware that puberty may be an important time of kidney function decline among children with CKD. Funding: NIDDK Support

Results: We identified a rare homozygous variant, CLF5I H310Y, that segregates with disease in a consanguineous family with two affected siblings and a cousin. CLF5I encodes claveslin1, a component of clatherin-mediated endocytosis. This variant was not present in a homoygous state in >200,000 chromosomes and is predicted to be pathogenic by in silico analyses. Morpholino knockdown of the orthologous CLF5I gene in zebrafish resulted in edema phenotypes indicative of loss of glomerular filtration barrier (GFB) integrity. This edema phenotype could be rescued with wildtype human CLF5I mRNA but not the H310Y variant. Knockdown of CLF5I in cultured human podocytes as well as overexpression of the H310Y variant in HEK 293 cells decreased endocytosis of fluorescein labeled dextran and increased susceptibility to apoptosis. These aberrant podocyte phenotypes could be rescued in the presence of glucocorticoid, mimicking the sterile responsive phenotype in patients bearing the CLF5I H310Y variant.

Conclusions: We identified a mutation in CLF5I as a new cause of hereditary SSNS. Our data demonstrates the requirement of functional steroid responsive phenotype in patients bearing the SSNS. Our data demonstrates the requirement of functional steroid responsive phenotype in patients bearing the SSNS.

Cross-Talk Between Neutrophils and Macrophages Dictates the Outcome of Acute Pyelonephritis
Juan de Dios Ruiz-Rosado, Hanna H. Cortado, John D. Spencer, Brian Becknell, Santiago Partida-Sanchez. Abigail Wexner Research Institute at Nationwide Children’s Hospital, Columbus, OH.

Background: Pediatric urinary tract infections (UTIs) account for 1.5 million clinic visits annually in the United States. Uropathogenic Escherichia coli (UPEC) causes over 80% of UTIs. Up to 50% of infants with a UTI develop a kidney infection (acute pyelonephritis, APN). To study cell-type specification of renal epithelial cells, we conducted trajectory analysis and resolved the developmental pseudotime along cell differentiation from nephron progenitors. We show that early differentiation of podocytes from the nephron progenitor pool is associated with sustained Foxl1 expression. Differentiation of renal tubule cells followed a more complex pattern, where Hnf4a expression is associated with a more proximal fate, while Tip2b is coupled to the distal tubule differentiation. After cell specification, terminal differentiation was strongly linked to metabolic nuclear receptors such as Eoxra and Ppara for proximal tubules and Ertb and Ppara-ga in loop of Henle.

Methods: Here we conducted single-nucleus ATAC sequencing (snATAC-seq) and single cell RNA-sequencing (scRNA-seq) of kidneys from developing and adult mice. After quality control, we obtained 66,254 scRNA-seq and 28,316 snATAC-seq profiles.

Results: Through clustering analysis, we identified all major cell types in the kidney. By integrating snATAC-seq and scRNA-seq data, we revealed cell type- and developmental stage-specific cis-regulatory elements and inferred promoter-enhancer regulatory units. We defined key cell identity TFs and their gene targets through co-expression patterns. To study cell-type specification of renal epithelial cells, we conducted trajectory analysis and resolved the developmental pseudotime along cell differentiation from nephron progenitors. We show that early differentiation of podocytes from the nephron progenitor pool is associated with sustained Foxl1 expression. Differentiation of renal tubule cells followed a more complex pattern, where Hnf4a expression is associated with a more proximal fate, while Tip2b is coupled to the distal tubule differentiation. After cell specification, terminal differentiation was strongly linked to metabolic nuclear receptors such as Eoxra and Ppara for proximal tubules and Ertb and Ppara-ga in loop of Henle.

Conclusions: We find that loss of Smad4 participates in the Wnt/b-catenin signaling pathway in renal epithelial cells but not the renal interstitium. Smad4 in interstitial cells was confirmed by single cell genotyping and immunostaining. Our findings point to a novel detrimental function for macrophages during APN, and the potential utility of macrophage targeted therapies to reduce long-term sequelae following APN.

Proliferation Control of Interstitial Cells in the Neonatal Kidney
Leif Oxburg, The Rogozin Institute, New York, NY.

Background: Expansion of interstitial cells in the adult kidney is a hallmark of chronic disease, whereas their proliferation during fetal development is necessary for organ formation. An intriguing difference between adult and neonatal kidneys is that the neonatal kidney has the capacity to control interstitial cell proliferation when the target number has been reached in this study, we determine the consequences of inactivating the TGFβ/Smad response on proliferation control of the renal interstitium in the neonatal mouse.

Methods: Smad4 was inactivated using the FloxIcre mouse strain, which is specifically expressed in interstitial progenitor cells in the developing kidney. Loss of Smad4 in interstitial cells was confirmed by single cell genotyping and immunostaining. Interstitial cell lines with tamoxifen-inducible loss of Smad4 were generated from primary interstitial cell progenitor lines for molecular interaction studies.

Results: We find that loss of Smad4 leads to over-proliferation of interstitial cells regionally in the kidney medulla. Analysis of signaling pathway markers in tissue showed that activation of Smad3 is deficient, whereas activation of Smad1/5 is largely unaffected, indicating an effect specifically on TGFβ signaling. Genetic and molecular interaction studies showed that Smad4 participates in the Wnt/b-catenin signaling pathway in interstitial cells, which is responsible for promoting their proliferation. Specifically, Smad4 is required for the expression of the Wnt feedback inhibitor Apcd1.

Conclusions: Based on these findings, we propose a model for interstitial cell proliferation control in which the Wnt/b-catenin proliferative signal is attenuated by Smad4 in interstitial cells was confirmed by single cell genotyping and immunostaining. Our findings point to a novel detrimental function for macrophages during APN, and the potential utility of macrophage targeted therapies to reduce long-term sequelae following APN.

Single-Cell Resolution Regulatory Landscape of the Kidney Highlights Cellular Differentiation Programs and Renal Disease Targets
Zhen Miao, Michael S. Balzer, Ziyuan Ma, Hongbo Liu, Junnan Wu, Katalin Susztak. Susztak Lab University of Pennsylvania, Philadelphia, PA.

Background: The kidney cells undergo complex differentiation during development, among which the nephron progenitors differentiate to more than 10 different epithelial cells. However, the driver pathways, cell type specific transcription factors and regulatory circuits are not fully understood.

Methods: Here we conducted single-nucleus ATAC sequencing (snATAC-seq) and single cell RNA-sequencing (scRNA-seq) of kidneys from developing and adult mice. After quality control, we obtained 66,254 scRNA-seq and 28,316 snATAC-seq profiles.

Expansion of Human Induced Pluripotent Stem Cell-Derived Ureteric Bud Organoids with Repeated Branching Potential
Makoto Ryosaka, Shin-ichi Mae, Kenji Osafune. Center for iPSC Cell Research and Application (CiRA), Kyoto University, Kyoto, Japan.

Background: The mammalian adult kidney, metanephros, develops by the reciprocal interaction between two embryonic progenitor tissues, metanephric mesenchyme and ureteric bud (UB). UB has epithelial polarity and tubular lumens, consists of two domains, the tip and trunk, and repeats branching morphogenesis. The tip cells produce both new tip and trunk cells that further differentiate into collecting ducts (CDs). Recently, we reported a stepwise protocol to induce human induced pluripotent stem cells (hiPSCs) and embryonic stem cells (hESCs) into UB-like structures through anterior intermediate mesoderm. However, the generation of hiPSC/ESC-derived UB-like tissues that show tubular lumens or sufficient branching has not been achieved.

Methods: We established a novel method to induce hiPSCs to differentiate into induced UB (iUB) organoids. We evaluated our iUB organoids using immunostaining and single cell RNA-sequencing analysis.

Results: Our iUB organoids showed RET+ tip and CK19+ trunk domains, epithelial polarity, tubular lumens and developmental potential to repeat branching morphogenesis. The isolated tip regions from the iUB organoids showed repeated branching to reconstitute iUB organoids. We also succeeded in establishing in vitro monitoring and expansion methods for tip cells that can efficiently reconstitute iUB organoids and differentiate into UB-like structures through anterior intermediate mesoderm. However, the generation of hiPSC/ESC-derived UB-like tissues that show tubular lumens or sufficient branching has not been achieved.

Conclusions: Our induction method for iUB organoids will help elucidate the developmental mechanisms of UB branching and develop a selective differentiation method for CD cells, contributing to the creation of disease models for congenital renal abnormalities.

Cyclin G1/CDK5-Mediated Dedifferentiation of Proximal Tubular Cells Drives AKI-to-CKD Transition
Kentsi Taguchi, Bertha C. Elias, Craig R. Brooks. Vanderbilt University Medical Center, Nashville, TN.

Background: Acute kidney injury (AKI) is associated with increased morbidity and mortality in hospitalized patients and predisposes patients to chronic kidney disease (CKD). While kidney cells, particularly proximal tubule cells (PTCs), can undergo dedifferentiation, proliferation, and regeneration to facilitate kidney repair after injury, maladaptive repair resulting in prolonged dedifferentiation of PTCs drives fibrosis. We have found that cyclin G1 (CG1), an atypical cyclin, not only promotes G2/M cell cycle arrest, but also regulates dedifferentiation of PTCs. The aim of the current study is to determine how regulating these processes through manipulating cyclin expression prevents CKD.

Methods: 1; Aristolochic acid nephropathy (AAN) was induced by administration of three doses of AA in 8 to 12-week-old male wild-type (WT) and CG1 globally knockout mice (CG1KO). 2; Unilateral ureteral obstruction (UUO) was performed and kidneys were harvested on day 9. 3; To determine the interaction partners of CG1, immunoprecipitation (IP) was performed in CG1-overexpressing LLC-PK1 cells treated with AA. 4; To examine the pathological role of CGDK5, LLC-PK1 cells or primary PTCs with or without siRNA or pharmacological inhibitors of CDK5 were treated with AA.

Results: CG1 was rapidly upregulated in PTCs in response to kidney injury and remained high in chronic phase following AAN and UUO. Kidney fibrosis and markers of dedifferentiation, such as SOX9, Vimentin, and Snail, were reduced in CG1KO animals following AAN and UUO injuries, compared to WT. IP demonstrated that CG1 binds to p53, mouse double minute 2 homolog (MDM2), and CDK5. Of these, the interaction of CG1 activates CDK5 and translocates the complex into nuclei. Phosphorylation of CDK5 in response to injury was reduced by genetic ablation of CG1. Genetic or pharmacological inhibition of CDK5 preserved E-cadherin in AA-induced cellular injury with reduction of profibrotic markers; however, it showed no additional effect in CG1KO PTCs.

Conclusions: CG1 partnering with CDK5 drives a maladaptive dedifferentiation of PTCs after kidney injury, resulting in increased secretion of profibrotic cytokines and progression of fibrosis. As CG1 is highly expressed in injured PTCs, it represents a potential therapeutic target for prevention of kidney fibrosis.

Incorporation of Urine-Derived Stem Cells into Kidney Organoids Derived from Human Induced Pluripotent Stem Cells
Julie Bejoy, Richard C. Welch, Lauren E. Woodard. Woodard Lab Vanderbilt University Medical Center, Nashville, TN.

Background: Donor-derived somatic cells or stem cells can be differentiated into renal cell types for disease modeling, drug screening, or therapeutic studies. Modeling of kidney disease with kidney organoids derived from human induced pluripotent stem cells (hiPSCs) has been termed a “kidney in a dish.” The recent advances in stem cell-based therapies have shown great promise for the treatment of kidney injuries. To evaluate the therapeutic properties, we studied the incorporation of urine-derived stem cells (USCs) into a kidney organoid model of acute kidney injury. USCs are viable cells from urine which can be expanded in vitro for more than ten passages. There is evidence suggesting that USCs are most likely cultured glomerular parietal epithelial cells.

Methods: For this project, we cultured kidney organoids from fibroblast-derived hiPSCs by the established protocol from Takasato and Little, following optimization. Co-culturing of USCs labeled with a membrane dye and Day 25 kidney organoids revealed that USCs are indeed incorporated into the organoids efficiently within two days of the co-culture. For injury models, we established nephrotoxicity in the proximal tubule by adding the nephrotoxic drug Cisplatin (5 μm) at Day 21 of kidney organoid culture.

Results: The kidney organoids derived from iPSCs expressed the kidney cell type markers ECAD (distal tube), GATA3 (collecting duct), LTL (proximal tubule) and NEPHRIN (Glomeruli) at Day 21. The organoids were then treated with 5 x 10⁵ USCs at Day 22 for 48 hours and evaluated for the expression of kidney injury molecule-1 (KIM-1). Immunostaining revealed that KIM-1 expression was significantly reduced in the organoids treated with USCs compared to the organoids without USCs, suggesting a positive therapeutic impact of USCs. We are currently performing RNAseq on three sets of whole kidney organoids (Control, +Cisplatin, +Cisplatin+USC) to provide detailed interrogation of cellular apoptosis and related signaling pathways in these three different sets of organoids.

Conclusions: The ability of USCs to reduce KIM-1 expression in human kidney organoids suggests that further investigation into the therapeutic potential of USC for treatment of acute kidney injury is warranted.

Supramolecular Nanofibers Containing Arginine-Glycine-Aspartic Acid (RGD) Boost Therapeutic Efficacy of Extracellular Vesicles in Kidney Repair
Gulshat Zhang,1,2 Jie Wu,1 Lingling Wu,1 Xiangmei Chen,1,2 Chinese PLA General Hospital, Beijing, China; 1Nankai University, Tianjin, China.

Background: Extracellular vesicles (EVs) derived from mesenchymal stem cells (MSC-EVs) have been recognized as a promising cell-free therapy for acute kidney injury (AKI), which avoids safety concerns associated with direct cell engraftment. However,
low stability and retention of MSC-EVs have limited their therapeutic efficacy. RGD peptide binds strongly to integrins, which have been identified on the surface of MSC-EV membranes, yet RGD has not been applied to EV scaffolds to enhance and prolong bioavailability.

Methods: Here, we developed RGD hydrogels, which we hypothesized could augment MSC-EV efficacy against AKI.

Results: In vitro tracking of the EVs revealed that RGD hydrogels increased retention and stability of EVs. Upon intrarenal injection, EV-RGD hydrogels provided superior rescuing effects at functional, histopathological and molecular levels. Further analysis revealed that the presence of microRNA let-7a-5p in MSC-EVs served as a novel mechanism contributing to the reduced cell apoptosis and elevated cell autophagy in AKI.

Conclusions: RGD hydrogels boosted the therapeutic efficacy of let-7a-5p-containing-EVs in AKI repair. This study developed an RGD-scaffold to increase the EV integrin-mediated loading and in-turn improved therapeutic efficacy, therefore this strategy shed light on MSC-EVs application as cell-free treatment for potentiated efficiency.

Conclusions: Our data demonstrate that PANX1 overexpression results in overt renal injury during IRI and that is in part mediated by reduced mitochondrial function and in part by metabolites released via Panx1 channels, which facilitates cell death. These results complement our prior studies demonstrating that Panx1 deficiency protects kidneys from IRI and provide strong rationale for the development of selective strategies to inhibit Panx1 in the prevention or treatment of AKI.

Targeting Angiopoietin-Tie2 Signaling in Kidney Ischemia-Reperfusion Injury

Yanyang Li, Tuncer Onay, Pan Liu, Michael Ryczko, Mohammed Javed Ansari, Jing Jin, Susan E. Quagggin.

1Northwestern University Feinberg School of Medicine, Chicago, IL; 2Mannin Research Inc, Toronto, ON, Canada.

Background: The endothelial angiopoietin (ANG)-Tie2 signaling pathway is required for vascular development and homeostasis. Dysregulation of ang-Tie2 pathway has been implicated in diseases including venous malformation, glaucoma, diabetic nephropathy, and septic acute kidney injury (AKI). The endothelial-specific phosphatase VE-PTP/PTPRB is a negative regulator of Tie2 phosphorylation. Here we investigate the therapeutic roles of Angiopoietin/Tie2 signaling in kidney ischemia-reperfusion injury (IRI).

Methods: A bispecific doxycycline-inducible system (VE-PTP-NLS, Roa26-EtA1, tetO-Cre ) was used to knockout VE-PTP at postnatal day 0 (VE-PTPko). Adult male VE-PTPko and littermate control mice underwent bilateral IRI or sham surgery. Serum creatinine was measured on day 1, day 3 and day 7 after surgery by HPLC method. Data were analyzed using two-way ANOVA. Tissues were harvested on day 7 for histology, immunohistochemistry and RNA/protein analysis. Bulk RNAseq was performed with RNA extracted from whole kidney 5 hours after IRI. Normalization and differential expression were determined using DESeq2. For pharmacological studies, adult male C57BL/6J mice were used. A new soluble ANGPT1 mimetic (C4BP-ANG1) or vehicle were administered by intraperitoneal injection.

Results: Western blot analysis showed VE-PTP protein levels were increased in kidneys post-IRI and following hypoxia-inducible factor stabilization. Genetic deletion of VE-PTP rescued declined Tie2 phosphorylation in kidney after IRI. While serum Creatinine was elevated 1 day post-IRI in control mice, this increase was minimal in VE-PTP iKO mice (p<0.005). Global gene expression analysis indicated minimal kidney transcriptome change at base line whereas in the setting of IRI, VEPTPIKO mice showed a less activated renal endothelium and downregulation of acute stress responsive gene signature. A corresponding decrease in pre-fibrotic genes was observed in VE-PTPko mice on day 7. In the pharmacological study, systemic administration of C4BP-ANG1 activated Tie2 and its downstream AKT/eNOS/NO pathways in mouse kidney in physiological condition. Ongoing studies are analyzing its protective effect in ischemic AKI.

Conclusions: Our data provide evidence for augmenting Tie2 activation-induced vascular protection as a promising therapeutic strategy for renal protection following IR-AKI.

Panx1n 1 Channel Regulates Mitochondrial Function and Cell Survival During AKI

Center for Immunity, Inflammation and Regenerative Medicine (CIIR), University of Virginia 1Division of Nephrology and Center for Immunity, Inflammation, and Regenerative Medicine, University of Virginia, Charlottesville, VA; 2Department of Microbiology, Immunology, and Cancer Biology, University of Virginia, Charlottesville, VA.

Background: Panx1n 1 (Panx1) is a membrane associated non-selective channel that, when activated, serves as a conduit for release of small metabolites that have pro- or anti-inflammatory function. We have previously shown that pharmacological inhibition or genetic deletion of Panx1n 1 in mice prior to injury is protective against renal ischemia-reperfusion injury (IRI). How Panx1n 1 contributes to acute kidney injury (AKI) pathology is unknown. We hypothesized that panx1n 1 induces cell death by mediating both intracellular and extracellular events.

Methods: We subjected a novel human Panx1 overexpressing mouse (APANX1-Tg) to IRI or cisplatin-mediated AKI and assessed plasma creatinine and renal expression of neutrophil gelatin associated lipocalin (Ngal). For in vitro studies, Panx1n1 overexpressing TKPTS cells (OX) were challenged with cisplatin. Cell death was assessed by flow cytometry using Annexin-V/7AAD. Mitochondrial function was assessed by measuring TKPTS cells (OX) were challenged with cisplatin. Cell death was assessed by flow cytometry using Annexin-V/7AAD. Mitochondrial function was assessed by measuring respiration at baseline, a greater reduction in mitochondrial function and a higher increase in mitochondrial ROS production after cisplatin exposure compared to controls.

Results: APANX1-Tg mice had significant rise in plasma creatinine and expression of Ngal in the kidneys in both models of AKI compared to their littermate controls. Cisplatin-induced cell death was greater in OX cells compared to control cells. Moreover, cisplatin induced greater death in OX cells than control cells when cultured together. Among genes involved in the cell death pathway, OX cells had reduced expression of Bcl2 and a greater increase in Ho-1 after cisplatin exposure. Assessment of mitochondria showed that OX cells had reduced mitochondrial DNA, Pgc1a expression, and mitochondrial respiration at baseline, a greater reduction in mitochondrial function and a higher increase in mitochondrial ROS production after cisplatin exposure compared to controls.

Exosome-Based Delivery of Super-Repressor IfxαA Ameliorates Kidney Injury After Ischemia-Reperfusion Injury

Sul A Lee, Seonghun Kim, Jinn Park, Boyoung Nam, Jung Tak Park, Seung Hyek Han, Shin-Wook Kang, Tae-Hyun Yoo.

2Metrowest Medical Center, Framingham, MA; 3Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; 4Yonsei University Dental Hospital, Seoul, Republic of Korea.

Background: Ischemia-reperfusion (IR) injury (IRI) is a major cause of acute kidney injury (AKI). Recent studies on the pathophysiology of IR-induced AKI showed that immunologic responses significantly affect renal IRI and repair. Nuclear factor (NF)-κB signaling, which controls cytokine production and cell survival, is significantly involved in IR-induced AKI; its inhibition can ameliorate ischemic AKI. We assessed whether the systemic delivery of NF-κB inhibitor using exosomes could ameliorate the course of ischemic AKI.

Methods: Using EXPLOR, a novel, optogenetically engineered exosome technology, we successfully delivered the exosomal super-repressor inhibitor of NF-κB (Exo-srIxB) into B6 wildtype mice before after kidney IRI surgery, and compared outcomes with those of the control exosome (Exo-Naïve)-injected group. To better understand the protective mechanism of Exo-srIxB in renal IRI, the expression of pro-inflammatory cytokines/chemokines and adhesion molecules and the level of apoptosis were measured using quantitative real-time PCR (qRT-PCR), enzyme-linked immunosorbent assay, western blot, and immunohistochemical/immunofluorescent (IF) staining. Immune cell populations of post-ischemic kidneys and spleens were analyzed using flow cytometry and IF staining.

Results: Exo-srIxB treatment resulted in lower levels of serum blood urea nitrogen (BUN), creatinine, and neutrophil gelatinase-associated lipocalin (NGAL) in post-ischemic kidneys than in the Exo-Naïve treatment group (24h/48h BUN, creatinine, and NGAL, p < 0.001). Systemic delivery of Exo-srIxB decreased NF-κB activity in post-ischemic kidneys, leading to reduced apoptosis levels. Post-ischemic kidneys showed decreased gene expression of pro-inflammatory cytokines and adhesion molecules with
Exo-srKt treatment as compared with the control. Exo-srKt treatment also significantly affected post-ischemic renal immune cell populations, lowering neutrophil, monocyte/macrophage, and T cell frequencies than those in the control.

Conclusions: Thus, the modulation of NF-κB signaling through exosomal delivery can be used as a novel therapeutic method for IR-induced AKI.

SU-OR08 Enhancer and Super-Enhancer Dynamics in Repair After Ischemic AKI Julia Wilhelmsen,1,2 Michaela Willi,2 Hye Kyung Lee,2 Hannes Olsson,1 Jakub Jankowski,3 Takaharu Ichimura,4 Reinhold Erben,4 M. Todd Valerius,5 Lothar Hennighausen,5 Joseph V. Bonventre,1,2 Brigham and Women’s Hospital, Renal Division, Harvard Medical School, Boston, MA; 2Laboratory of Genetics and Physiology, National Institute of Diabetes, Digestive and Kidney Diseases, US National Institutes of Health, Bethesda, MD; 3Division of Renal Medicine, Department of Clinical Sciences, Intervention and Technology, Stockholm, Sweden; 4University of Veterinary Medicine, Department of Physiology, Pathophysiology and Endocrinology, Vienna, Austria.

Background: The endogenous repair process of the mammalian kidney allows rapid recovery after acute kidney injury (AKI) through robust proliferation of tubular epithelial cells. There is currently limited understanding of which transcriptional regulators activate these repair programs. Here we investigate the existence of enhancer and transcription factor dynamics in the regenerating mouse kidney.

Methods: We performed genome-wide ChIP-seq and RNA-seq on kidneys harvested from mice with sham or ischemia/reperfusion injury 2 days after ischemia/reperfusion injury (IRI) to identify activated genes, transcription factor binding, enhancer and super-enhancers associated with kidney repair.

Results: We identified the role of enhancer sets in kidney repair through pharmacological BET inhibition using the small molecule JQ1 in AKI models in vivo.

Response: To injury leads to genome-wide alteration in enhancer repertoire in vivo. We identified 16,781 enhancer and 380 super-enhancer sites (H3K27ac and BRD4 positive) with dynamic binding in SHAM and IRI samples; 5,151 enhancer, 168 super-enhancer lost and 9,774 enhancer, 214 super-enhancer gained after IRI. The lost and gained enhancer sites can be annotated to 62% and 63% of down- and up-regulated transcripts after AKI, respectively. ChIP-seq profiles of predicted transcription factors show specific binding at corresponding enhancer sites with dynamic binding of HNF4a, GR and STAT3. HNF4a and GR show a reduced binding at enhancer and super-enhancer sites after injury, whereas STAT3 binding can be observed at injury gained enhancer and super-enhancer sites. BET (BRD4) inhibition before IRI leads to suppression of 40% of injury-induced transcripts associated with cell cycle regulation, genome-wide Pol II pausing and significantly increased mortality after AKI.

Conclusions: This is the first demonstration of enhancer and super-enhancer and transcription factor binding dynamics in the repairing kidney. In addition, our data call for the need to develop novel therapeutic strategies for AKI.

SU-OR10 Endothelial-Derived mir-17~92 Promotes Angiogenesis to Protect Against Renal Ischemia-Reperfusion Injury Takuto Chiba, Jacqueline Ho, Sunder Simms-Lucas, University of Pittsburgh Medical Center, Pittsburgh, PA.

Background: Acute kidney injury (AKI), resulting from renal ischemia reperfusion injury (IRI) among others, is an independent predictor of morbidity and mortality, and is identified in as many as 50% of ICU patients. Damage to the renal microvasculature is a hallmark of renal IRI. mir-17~92 encodes 6 polycystic microRNAs that show potent pro-angiogenic capacity by targeting anti-angiogenic factors. The function of mir-17~92 in renal microvasculature after renal IRI remains unknown.

Methods: Antibodies bound to magnetic beads were utilized to selectively enrich for renal endothelial cells from mice. Endothelial-specific mir-17~92 knockout (mir-17~92–/-) mice were generated and a renal IRI model was performed. Mice were monitored for the development of AKI using serum chemistries and tissue analysis, and for renal blood flow using a magnetic resonance imaging (MRI). Mice were treated with miRNA mimics during renal IRI to test its therapeutic efficacies.

Results: We demonstrate that miRs-17, -18a, -20a, and -19b are up-regulated in renal endothelial cells after renal IRI in mice. mir-17~92–/-/– mice were generated and a renal IRI model was performed. Mice were monitored for the development of AKI using serum chemistries and tissue analysis, and for renal blood flow using a magnetic resonance imaging (MRI). Mice were treated with miRNA mimics during renal IRI to test its therapeutic efficacies.

Conclusions: These data suggest that endothelial-derived mir-17~92 stimulates a reparative response in damaged renal vasculature during ischemic AKI by regulating angiogenic pathways.

SU-OR11 Inhibition of Cadherin 11 Improves Outcomes in Murine Models of CKD Tessa Huffman,1,2 Michael A. Raddatz,3 Leslie S. Gewin,2 W. David Merriman,3 1Vanderbilt University, Nashville, TN; 2Vanderbilt University Medical Center, Nashville, TN.

Background: Chronic kidney disease (CKD) represents a massive unmet clinical need, as there are virtually no pharmaceutical options for treatment of renal injury. A recent study identified cadherin-11 (CDH11) as a potential biomarker for CKD, as it is expressed in kidney biopsies of patients with samples of CKD patients and its expression is increased in CKD mouse models. We have investigated the role of CDH11 as both a mediator and therapeutic target of CKD.

Methods: In the current study, we used three mouse models of CKD to evaluate the role of CDH11: cadherin-11 (CDH11) as a potential biomarker for CKD, as it is expressed in kidney biopsies of patients with samples of CKD patients and its expression is increased in CKD mouse models. We have investigated the role of CDH11 as both a mediator and therapeutic target of CKD.

Results: Although CDH11 has been found on immune cells and fibroblasts in other fibrotic diseases, we found that in the kidney CDH11 is exclusively expressed in injured proximal tubules (PTs). PTs play a significant role in CKD, as they are both a target and mediator of chronic injury. In our models of CKD, we found that both genetic and pharmacologic CDH11 inhibition improves renal function (BUN and ACR), diminishes cytokine production (TGFβ and IL-6 expression), and reduces tubular injury (expression of KIM-1 and histological analysis). Using primary PT cells, we found that genetic ablation of CDH11 improves cell survival in vitro. Although the specific mechanisms by which CDH11 mitigates PT injury is still under investigation, preliminary data shows that inhibition of CDH11 increases Wnt1-β-catenin activity in the kidneys of injured mice. Wnt1-β-catenin signaling promotes cell survival, which in this context could result in reduced tubular atrophy, cytokine production, and fibrosis. Such pro-survival signaling could be driving the reduction in renal injury we see when CDH11 is inhibited, as PT death strongly correlates with outcomes in CKD.

Conclusions: These results clearly identify CDH11 inhibition as a novel means of improving outcomes in murine CKD models. The mechanism by which CDH11 inhibition protects against renal injury is likely through CDH11 interactions with the Wnt/β-catenin signaling pathway to enhance PT survival. These results could prove an important step towards developing new therapeutic strategies for the treatment of CKD.

SU-OR12
METTL10: A Kidney Disease Risk Gene by Altering Protein Methylation
Hailong Hu, Katalin Susztak. Renal Electrolyte and Hypertension Division, Department of Medicine and Genetics, University of Pennsylvania, Philadelphia, PA.

Background: Genome-wide association studies (GWAS) have identified more than 300 loci where genetic variants are associated with kidney function, however, the causal variants, genes, cell types and the disease mechanism remain mostly unknown.

Methods: We have generated expression of quantitative trait (eQTL) data from microdissected human kidney tubules and glomeruli. We used Bayesian colocalization of eQTL and GWAS to identify likely causal genes for kidney function. We used single cell RNA and ATACseq data to identify causal cell types. Finally, we generated mice with genetic deletion to study kidney disease mechanism.

Results: Kidney disease associated genetic variants showed a strong association with METTL10 expression. Methytransferase-like protein 10 (METTL10), is a non-histone lysine methyltransferase. Patients with CKD variants showed lower level of METTL10 in their kidneys. METTL10 was relatively broadly expressed in kidney tubule cells by single cell expression analysis. Its expression was markedly reduced in mice and patients with kidney disease. We found that Mettl10 controls methylation and the activity of the eukaryotic translation elongation factor 1 alpha (eEF1A). eEF1A is the alpha subunit of the eukaryotic elongation complex, controlling RNA translation. Methylation of eEF1A was markedly reduced in kidneys of Mettl10 KO mice. The reduction in eEF1A activity lead to lower protein translation and tubule cell proliferation. Mettl10 KO mice was more susceptible to injury, it showed more structural damage and collagen expression in the folic acid induced kidney injury model.

Conclusions: Taken together, GWAS and eQTL studies identified Mettl10 a kidney disease risk gene. METTL10 controls the methylation of eEF1A, downstream RNA translation, cell proliferation altering kidney disease risk, defining a novel mechanism for kidney disease development.

Renal Proximal Tubule Cell Differentiation and Metabolism Are Coupled by Nuclear Receptors
Poonam Diillon,1 Jhwan Park,2 Carmen Hurtado del Pozo,2 Lingzi Li,1 Shizheng Huang,1 Royjesh Shrestha,1 Nuria Montserrat,1 Katalin Susztak,3 Susztak Lab 1University of Pennsylvania, Philadelphia, PA; 2Barcelona Institute of Science and Technology, Barcelona, Spain.

Background: Kidney proximal tubule (PT) cells have high mitochondrial density to perform their high energy demanding function to secrete and reabsorb metabolites and electrolytes. Chronic kidney disease is characterized by tubule epithelial atrophy and dedifferentiation, resulting in a decline in kidney function. In this study, we aimed to define upstream regulators that control PT differentiation.

Methods: We performed scRNA and snATACseq analysis on kidneys of developing and adult mice, kidney organoids, and kidneys from control and folic acid-induced kidney injury model. Bioinformatic methods included dimension reduction, differential expression, cell fraction and cell trajectory analysis. Functional studies included mice and cultured tubule cells with genetic deletion of ESRRAs.

Results: Single cell expression analysis identified PT cells as the key vulnerable cell type in kidney fibrosis. Cell trajectory analysis showed a sequential differentiation path from precursor to differentiated PT cell state in development and in healthy adult and diseased kidneys. But this differentiation path showed more complexity in fibrosis, as such enhanced cell differentiation and a blockade of terminal differentiation. Pathway analysis indicated fatty acid oxidation (FAO) and oxidative phosphorylation (OXPHOS) were key variable genes along the PT cell differentiation path in the adult, and developing mouse PT cells and organoids. Single cell epigenetics data identified the critical role of nuclear receptors, HNF4A, HNF1B, PPARA, and ESRRAs driving the PT cell differentiation program. These transcription factors did not only directly control FAO and OXPHOS but also the expression of PT differentiation genes.

Conclusions: The coupling of cell state and metabolism is established by nuclear receptors such as PPARA and ESRRAs that not only control cellular metabolism but also the expression of PT-specific genes in mice and patient samples.

SU-OR14
COX17-Mediated Abnormal Mitochondrial Copper Metabolism Promotes Renal Fibrosis
Saiya Zhu, Chen Yu. Department of Nephrology, Tongji Hospital, Tongji University, Shanghai, China.

Background: Copper is a trace element essential for almost all living organisms. Previously, we found that elevated intracellular copper contributes a unique role to kidney fibrosis. Furthermore, copper ions in cells were mainly accumulated in mitochondria, which damage the structure and function of mitochondria. However, the mechanisms of the interaction of copper metabolism and how a disturbed copper balance induces mitochondrial dysfunction remain to be identified. Copper chaperone COX17, a protein required for cytochrome c oxidase (COX) assembly, was previously hypothesized to shuttle copper between the cytosol and mitochondria based on its dual localization. We found that in the fibrosis model COX17 was highly expressed and COX activity decreased. Therefore, we speculated that COX17 might be involved in mitochondrial copper overload and renal fibrosis.

Methods: Expression level and pattern of COX17 were examined in ischemia- reperfusion injury (IRI) and recruited rat kidneys. The regulatory mechanisms of COX17 in IRI were investigated in renal tubule epithelium cell line (NRK-52E) and rat fibroblasts(NRK-49F) by treating with copper or copper chelator tetrathiomolydate (copper-chelating agent). ICP-MS, mitoSOX, electron microscopy, realtime-qPCR and western blot analysis were applied in the current study.

Results: Firstly, the expressions of COX 17, Col1 in the kidney of IRI group were extremely upregulated compared with the sham group. Unexpected, we found dysfunction of mitochondria in IRI kidneys evidenced by it’s appearing swollen and ruptured. Secondly, stimulated by TGF-β1, COX activity was declined, and mitochondrial content was increased in IRI kidneys. TGF-β1/smad3 were significantly upregulated. More importantly, mitochondrial copper content and col1, fibronectin expression were reduced and mitochondrial function was improved after transfecting with COX17 shRNA. Meanwhile, treatment with copper chelator tetrathiomolydate also alleviated renal fibrosis both in vivo and in vitro.

Conclusions: COX17 was significantly increased in renal fibrosis and transported excessive intracellular copper ions into the mitochondria. Copper overload inhibits the activity of COX and impairs mitochondria, subsequently leading to renal fibrosis.

SU-OR15
Protective Effect of Prostacyclin in Renal Fibrosis
Jing Li, Chuan-Ming Hao. Division of Nephrology, Huashan Hospital Fudan University, Shanghai, China.

Background: Inadequate repairing process to injury has been reported to play a fundamental role in renal fibrosis. Mounting evidence suggests that prostaglandins are important for the response to physiological changes or pathophysiologic insults to tissues including the kidney. Importantly, under certain conditions such as aging and hypertension, prostacyclin (PGI2), an active production of COX/PGI synthase (PGIS), is reduced. The present study provides data showing that low levels of PGI2 are associated with enhanced renal fibrosis.

Methods: Unilateral ureteral obstruction (UUO) was used as a renal fibrosis model. At days 10 after UUO, the mice were sacrificed. Ischemia-reperfusion (IR) model was induced by clamping the left renal pedicle for 35 minutes on D0. After 4 weeks, the right kidney was removed. The mice were treated with beraprost sodium (300ug/kg body weight per day by twice daily gavage) or vehicle from D32 to D55, and were sacrificed on D56.

Results: The PGIS heterozygous (PGIS+/-) mice had normal body weight, blood pressure and blood urea nitrogen (BUN) level. Lossing one allele of PGIS significantly attenuated the increase of PGIS expression after UUO and aggravates UUO - induced renal fibrosis. 1R model was performed on wild-type mice. Treatment with beraprost sodium (BPS), a analog of PGI2, inhibited the expression of fibronectin, collagen 1 and α-SMA in the kidney and ameliorated extracellular matrix deposition in the kidney tissue. Furthermore, the level of phosphorylated P6KA substrates in the normal obstructed kidney of deficient mice was significantly reduced, suggesting the role of IP receptor. IP agonist treatment reduced the expression of fibronectin, collagen I and α-SMA in rat renal fibroblasts (NRK-49F), which were induced by TGF-β.

Conclusions: PGIS/PGL2 plays an important role in protecting the kidney from fibrosis. Lack of PGIS enhances renal fibrosis, and supplementation with PGI2, analog ameliorates renal fibrosis. PGIS/PGL2, is a potential target for CKD.

SU-OR16
Proteomic Risk Assessment of CKD Progression in the Chronic Renal Insufficiency Cohort
Ruth F. Dubin,1 Rajat Deo,2 Zhe Zheng,2 Haochang Shou,2 Yue Ren,2 Hongzhe Li,2 Mark Segal,1 Harold I. Feldman,3 Peter Ganz.1 1University of California San Francisco, San Francisco, CA; 2University of Pennsylvania, Philadelphia, PA.

Background: Quantification of thousands of plasma proteins simultaneously is now feasible in large cohorts using the SomaScan aptamer assay. In this study, we applied large-scale proteomics to patients with chronic kidney disease (CKD) to discover new biomarkers and risk models of CKD progression.

Methods: We measured 4638 unique plasma proteins among 3249 participants in the Chronic Renal Insufficiency Cohort (CRIC), with follow-up to 13 years. Mean age was 59 years; women 54%, non-Hispanic/Latino 94%, estimated glomerular filtration rate (eGFR) was 24 mL/min/1.73m2, and 50% were diabetic. The study outcome was 10-year risk of 50% decline in eGFR, end-stage renal disease or renal transplant (n=1171 events). Associations of individual proteins with the composite outcome were analyzed in Cox survival models adjusted for demographics, comorbidities, eGFR and proteinuria. Protein-only risk models were constructed using elastic net regression and compared to the 4-variable Kidney Failure Risk Equation (K/FRE) model.
Molecular Mechanisms Underlying Sex-Specific Association of Circulating Transforming Growth Factor β1 with the Risk of Accelerated Kidney Disease in Women

Background: Sex differences in kidney function decline and risk of chronic kidney disease (CKD) have been suggested but remain unexplained. We recently showed a sex-specific association between high circulating TGF-β1 in women and a higher risk of accelerated age-related loss of glomerular filtration rate (GFR) in women. Our aim is to investigate the interaction of TGF-β1 with sex on intrarenal TGF-β1 expression, histopathology and kidney function decline in a sex-specific manner.

Methods: Circulating TGF-β1 was measured in plasma samples from 1,738 participants from the Helsingfors Helsespansk Kapitalstudie. They were followed up for 25 years or until diagnosis of CKD. We used logistic regression to test for interaction of sex with circulating TGF-β1 in association with kidney function decline and kidney function at baseline and follow up. Histopathological data from kidney biopsies were examined.

Results: Significant interaction of sex with circulating TGF-β1 was observed in association with kidney function decline (p<0.001). The risk estimates were 1.79 (1.65-1.94) for men and 2.99 (2.74-3.26) for women. Circulating TGF-β1 was associated with higher risk of accelerated age-related decline in GFR in women (OR = 1.79; p <0.001) and histopathologic changes in women (OR = 1.79; p <0.001). Among women, TGF-β1 was associated with the presence of glomerulosclerosis, tubular atrophy, interstitial fibrosis, and tubulointerstitial fibrosis.

Conclusions: Circulating TGF-β1 is associated with accelerated loss of GFR and histopathologic changes in women, but not in men. These findings suggest that TGF-β1 may play a different role in kidney disease progression in women compared to men.
Methods: A deep learning-based method for direct kidney parenchymal volume (KPV) segmentation was developed and validated (Accuracy: Dice 0.956, R² = 0.95) and applied to UKB MRI. Absolute and relative change with age and associations to body weight, BSA and fat free mass from bioimpedance analysis (BIA-FFM) and lean tissue volume from MRI (MRI-LT) were studied using linear regression. Rate changes were compared between and above group mean ages. MRI-LT values (n=8,524) were inferred for 30,308 additional subjects by MRI-based deep learning regression with validated R² = 0.96 (arXiv:2002.06862).

Results: Results KPV from 37,468 subjects (47.6% males) and age changes are shown in Fig1a and Table 1. Correlations between total KPV and BSA and MRI-LT over age are shown in Fig1b. The associated overall correlations were (males / females): Body weight: 0.568/0.460, BSA: 0.574/0.496, BIA-FFM: 0.597/0.536, MRI-LT: 0.636/0.600.

Conclusions: Both sexes show continuous volume decline in the studied age interval. Males show an increasing rate of decline with age. MRI-LT showed strongest correlations to KPV.

Variation in Peritoneal Dialysis-Related Peritonitis Outcomes and Treatment Practices: Results from the Peritoneal Dialysis Outcomes and Practice Patterns Study

Muthana Al sahlawi,1,2 Keith McCullough,1 Ronald L. Pisoni,1 Douglas S. Fuller,1 Junhui Zhao,1 Neil Boudville,1 Yasuhiko Ito,1 Talergska Kanjanabuch,3 Sharon Jessim,3 Beth M. Piraino,1 Isaac Teitelbaum,1 David W. Johnson,1,11 Graham Woodrow,1 Jeffrey Perl1. Division of Nephrology, St. Michael’s Hospital and the Keenan Research Center in the Li Ka Shing Knowledge Institute, St. Michael’s Hospital, University of Toronto, Toronto, Ontario, Canada; 2Department of Internal Medicine, College of Medicine, King Faisal University, Al-Hasa, Saudi Arabia, Al-Hasa, Saudi Arabia; 1Arbor Research Collaborative for Health, Ann Arbor, MI; 3Medical School, University of Western Australia, Perth, Australia, Perth, WA, Australia; 4Aichi Medical University, Nagakute, Japan, Nagakute, Japan, Japan; 5Center of Excellence in Kidney Metabolic Disorders and Division of Nephrology, Department of Internal Medicine, Chulalongkorn University, Bangkok, Thailand, Bangkok, Thailand; 6Division of Nephrology, Jewish General Hospital, McGill University, Montreal, Canada, Montreal, QC, Canada; 7University of Pittsburgh, Pittsburgh, PA, United States, Pittsburgh, PA; 8University of Colorado, Aurora, CO, United States, Aurora, CO; 9Department of Nephrology, Princess Alexander Hospital, Brisbane, Australia, Brisbane, QLD, Australia; 10Australasian Kidney Trials Network, University of Queensland, Brisbane, Australia, Brisbane, QLD, Australia; 11Renal Unit, St James’s University Hospital, Leeds, United Kingdom, Leeds, United Kingdom.

Background: Peritoneal dialysis (PD)-associated peritonitis is a leading cause of technique failure and transition to hemodialysis. In the Optimizing Peritonitis Prevention in The United States (OPPUS) study, we explored the impact of various patient, facility and treatment factors on the likelihood of cure following a peritonitis episode.

Methods: Using Peritoneal Dialysis Outcomes and Practice Patterns Study phase 1 (2014-2017) data from Australia and New Zealand, Canada, Japan, Thailand, the UK, and the US, we defined as the absence of a peritonitis relapse or recurrence, PD catheter removal, transition to hemodialysis or death during the 30 days following a peritonitis episode. Multivariable logistic regression was used to test associations between cure and patient, facility, and treatment characteristics.

Results: We identified 1677 peritonitis episodes in 1190 patients across 126 facilities. Overall, 63% of episodes resulted in a cure. Cure was associated with APD (OR v. CAPD=1.35, 95% CI 1.02-1.80), higher serum albumin (OR=1.04 per 0.1 g/dl, 95% CI=1.01, 1.06), facility icodextrin use (OR=1.06 per 10% greater icodextrin use, 95% CI – 1.01-1.12), and aminoglycoside use for Gram-negative peritonitis (OR v. ceftazidime=3.10, 95% CI=1.02, 9.36). Prior peritonitis (OR v. no prior peritonitis episodes during follow-up=0.84, 95% CI=0.74, 0.97) and concomitant exit-site infection (OR=0.42, 95% CI=0.28, 0.63) were associated with lower cure odds. Higher odds of peritonitis relapse were seen among patients with greater residual urine volume (OR=1.14 per 200 ml, 95% CI=1.07, 1.22).

Conclusions: Different characteristics and management practices can impact the likelihood of cure following a peritonitis episode. Our findings can inform future guidelines in addressing the effect of different modifiable patient, facility, and treatment factors on reducing morbidity associated with PD peritonitis.

Rate of Decline in Residual Kidney Function Before and After Peritoneal Dialysis Initiation: A Post Hoc Analysis of the IDEAL Study

Isabelle Ethier,1,2 Yeoung Jee Cho,3,5 Carmel Hawley,2,5 Elaine Pascoo,2 Andrea K. Vivecelli,3,2 Scott B. Campbell,2,5 Carolyn L. Van Eps,2,5 Nicole Isbel,2,5 Bruce A. Cooper,4 David Harris,4,6,9 Carol A. Pollock,6,9 Mu H. Geot Wong,6,9,12 David W. Johnson.1,2 Centre Hospitalier de L’Universite de Montreal, Montreal, QC, Canada; 2Princess Alexandra Hospital, Woolloongabba, QLD, Australia; 3The University of Queensland Faculty of Medicine, Herston, QLD, Australia; 4Westmead Institute for Medical Research, Westmead, NSW, Australia; 5The University of Sydney School of Medicine, Sydney, NSW, Australia; 6Royal North Shore Hospital, St Leonards, NSW, Australia; 7George Institute for Global Health, Camperdown, NSW, Australia.

Background: Residual kidney function (RFK) is associated with improved survival and quality of life in dialysis patients. Previous studies have suggested that commencement of peritoneal dialysis (PD) may slow RFK decline compared to the pre-dialysis period. We sought to evaluate the association between PD initiation and RFK decline in the Initiating Dialysis Early And Late (IDEAL) trial.

Methods: In this post hoc analysis of the IDEAL randomized controlled trial, PD participants were included if results from 24-hour urine collections had been recorded within 30 days of dialysis initiation (-30 to +30 days from start), and at least one value pre- and one value post-dialysis commencement were available. The primary outcome was slope of RFK decline, calculated as mean of urinary creatinine and urea clearances. Secondary outcomes included slope of urine volume decline and time from PD initiation to anuria.

Results: The study included 151 participants (79 early-start group, 72 late-start group). The slope of RFK decline was slower after PD commencement (-2.69±0.18 mL/min/1.73m² per year) compared to before PD commencement (-4.09±0.33 mL/min/1.73m² per year) change in slope =±1.19 mL/min/1.73m² per year, 95% CI 0.48±1.90, p<0.001). In contrast, urine volume decline was faster after PD commencement (-0.74±0.05 L/yr) compared to beforehand (-0.57±0.06 L/yr, change in slope =±0.18 L/yr, 95% CI=0.34—0.01, p<0.04). No differences were observed between the early- and late-start groups with respect to RFK decline, urine volume decline or time to anuria.

Conclusions: Commencement of PD was associated with a slower decline of RFK compared to the pre-dialysis period.

Steady Concentration Peritoneal Dialysis Increases Ultrafiltration and Sodium Removal Compared with Continuous Ambulatory Peritoneal Dialysis (CAPD)
Olof Heimburg,1 Giedre Martus,2 Martin E. Wilkie,3 Jorgen B. Hegbrant,4 Ola Carlsson,5 Charlotte De Leon,1 Ann Cathrine Johansson,3 Triomed AB, Lund, Sweden;6 Sheffield Teaching Hospital, NHS Foundation Trust, Sheffield, United Kingdom;7 Department of Nephrology, Skåne University Hospital, Malmö, Sweden;8 Department of Nephrology, Lund University, Lund, Sweden;9 CLINTECH, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden.

Background: Fluid and sodium removal (NaR) may be a challenge during glucose-based PD, leading to increased use of high glucose solutions to maintain sufficient fluid removal. This may lead to increased sodium sieving, resulting in reduced NaR. Carry Life® UF uses steady concentration PD (SCPD), where the intraperitoneal (IP) glucose concentration is maintained by infusion of glucose to provide a continuous ultrafiltration (UF) throughout the dwell. The present study investigated the effect of Carry Life® UF on CAPD regarding UF, NaR and glucose absorption.

Methods: Eight stable PD patients were included in the study. Subjects were treated with 5-hour Carry Life® UF treatments using three different glucose doses (11, 14, 20 g/h). An initial fill with 1.5 l, 1.36% glucose PD solution was used. A small volume of dialysate was drained hourly to avoid overfill. A 4-hour peritoneal equilibration test (PET) (2.01, 2.27% glucose) served as control. Data expressed as mean±SD, statistical analysis using ANOVA.

Results: UF volumes were significantly increased during Carry Life® UF treatments (64±256, 739±312, 863±380 ml for 11, 14, 20 g/h) vs. PET (162±242 ml, p<0.01). NaR increased significantly during Carry Life® UF treatments (86±27, 92±33, 110±37 mmol/dwell for 11, 14, 20 g glucose/h) compared to PET (22±33 mmol/dwell, p<0.001).

Conclusions: SCPD performed with Carry Life® UF maintained a stable IP glucose concentration during the treatment (figure a) which generated significantly higher UF volumes compared to PET. During the Carry Life UF treatments glucose was used more efficiently, particularly for the two lowest doses, in comparison to PET (figure b). In summary, SCPD using Carry Life® UF increases the efficiency of PD compared to standard, glucose-based CAPD with respect to UF and NaR.

Efficacy and Safety of Roxadustat in Patients with Dialysis-Dependent CKD and Anemia on Peritoneal Dialysis
Tak Mao D. Chau,1 Lynda Szeczec,2 Jayant Kumar,2 Anjay Rastogi,3 Carol A. Pollock,1 Gopal Saha,1 Tyson T. Lee,1 MakSYM Pola,1 Kin-Hung P. Yu,5 University of Hong Kong, Queen Mary Hospital, Hong Kong SAR, China; Renal Medicine Associates, Albuquerque, NM; University of California Los Angeles, Los Angeles, CA; The University of Sydney, Sydney, NSW, Australia; FibroGen Inc, San Francisco, CA; AstraZeneca, Warsaw, Poland.

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Dialysis modality in patients with dialysis-dependent (DD) CKD on peritoneal dialysis (PD) is of clinical importance. The population of patients with kidney failure in the United States utilizing home dialysis modalities is growing rapidly. Unlike for in-center hemodialysis, there are no patient-reported experience measures for assessment of the patient experience of care for peritoneal dialysis or home hemodialysis. We sought to develop and establish content validity of a patient-reported experience measure for patients undergoing home dialysis using a mixed-methods multiple stakeholder approach.

Methods: We conducted a systematic literature review, followed by concept elicitation focus groups and interviews among 65 participants, including 21 home dialysis patients, 33 home dialysis nurses, 3 patient care partners, and 8 nephrologists. We generated a list of candidate items for possible measure inclusion, and conducted a national aspects of care prioritization exercise among 91 home dialysis patients and 39 providers using a web-based platform. We drafted the Home Dialysis Care Experience (Home-DCE) instrument and conducted 3 rounds of cognitive debriefing interviews to evaluate item comprehensibility, order, and structure. We iteratively refined the measure based on interview findings.

Results: The literature review and concept elicitation phases supported 15 domains of home dialysis care experience in 6 general areas: communication and education of patients; concern and helpfulness of the care team; proficiency of the care team; patient-centered care; care coordination; and amenities and environment. Focus groups results showed that domains of highest importance for measurement were home dialysis staff education and patient-centered communication, care coordination, and personalization of care (Figure). Aspects of care prioritization exercise results confirmed focus group findings. Cognitive debriefing indicated that the final measure was easily understood and supported content validity.

Conclusions: The Home-DCE instrument is a 26-item patient-reported experience measure for use in peritoneal dialysis and home hemodialysis. Qualitative focus group and prioritization survey data support measure content validity. To our knowledge, the Home-DCE instrument represents the first rigorously developed and content valid English language survey instrument for assessment of patient-reported experience of care in home dialysis.

Cardiovascular Thromboembolic Outcomes by Dialysis Modality Following Primary Total Knee Arthroplasty

Chavely Valdes Sanchez, 1 Matthew R. Lozier, 1 Mauricio Tellez, 1 Alexandra M. Sanchez, 1 Gabriel A. Valle. 2 University of Miami at Holy Cross Hospital, Fort Lauderdale, FL; 2The Kidney and Hypertension Group of South Florida, Fort Lauderdale, FL.

Background: There is a paucity in the literature evaluating the impact of dialysis modalities on cardiovascular thromboembolic outcomes following primary total knee arthroplasty (TKA). Therefore, the purpose of this study was to investigate whether patients treated with hemodialysis (HD) or peritoneal dialysis (PD) have higher rates of 1) medical complications, 2) readmission, and 3) cost of care.

Methods: Patients undergoing primary TKA while receiving HD served as the study group (n = 82,518) and matched 1:1 to a control group of PD patients (n = 82,518) by distribution, age, sex, and Elixhauser-Comorbidity Index (ECI). Outcomes analyzed included rates of 90-day medical complications, readmission rates, and cost of care. Logistic regression analysis was used to calculate odds-ratios (OR) for medical complications and readmission rates. Welch’s t-test was used to test for significance on cost of care and ECI between cohorts. P-value less than 0.05 was considered statistically significant.

Results: Patients undergoing HD prior to primary TKA were found to have a significantly lower incidence and odds of cerebrovascular accidents (PD vs. HD: 0.19 vs. 0.13%; OR: 1.44, p=0.003) and venous thromboemboli (0.15 vs. 0.10%; OR: 1.52, p<0.001), specifically deep vein thromboses (0.13 vs 0.10%; OR 1.75, p<0.001). HD patients did however incur significantly higher 90-day cost of care ($104,341.89 vs. $209,611.67; p<0.001). No statistically significant differences were noted in myocardial infarction, pulmonary embolism, or 90-day readmission rates between the two groups.

Conclusions: While incurring a lower 90-day cost of care, patients treated with PD prior to primary TKA may have a greater odds of developing a cerebrovascular accident or deep vein thrombosis when compared to HD.

Outcome comparisons by dialysis modality following TKA.

Peritoneal Dialysis and Vascular Access: Research Abstracts

SU-OR27

Prognostic Roles of Peritoneal Dialysis Effluent Mitochondrial DNA Level

Win H. Than,1,2 Cheuk-Chun Szeto.1,2 Carol & Richard Yu Peritoneal Dialysis Research Centre, Department of Medicine & Therapeutics, Prince of Wales Hospital, Shatin, New Territories, Hong Kong; 2Li Ka Shing Institute of Health Sciences (LiHS), Faculty of Medicine, The Chinese University of Hong Kong, Shatin, New Territories, Hong Kong.

Background: circulating mitochondrial DNA (mtDNA) level is associated with the systemic inflammatory state and prognosis of peritoneal dialysis (PD) patients. We explore the relation between mtDNA level in PD effluent and peritoneal transport characteristics and outcomes of PD patients.

Methods: We measured PD effluent mtDNA levels by quantitative polymerase chain reaction and the result is expressed as copy per 1000 copies of the housekeeping gene. Both PD effluent sediment and cell-free supernatant mtDNA levels were measured. Peritoneal transport was determined by the peritoneal equilibration test and represented as mass transfer area coefficient (MTAC) of creatinine. All patients were followed for technique and overall survival.

Results: 168 PD patients were followed for 41.3 (IQR: 19.3-52.0) months. Their mean age was 60.4±11.8 years; 99 (58.9%) were men. Median PD effluent (PDE) supernatant mtDNA was 255.4 unit (IQR: 157.5-451.3); median PDE sediment mtDNA was 201.6 unit (IQR: 147.8-267.3). PDE supernatant mtDNA level had a modest but significant correlation with MTAC creatinine (r = -0.364, p<0.001) and the number of previous peritonitis episode (r = -0.235, p=0.002). After adjusting for age, gender, Charlson’s Comorbidity Score, total weekly Kt/V, and residual renal function, PDE sediment mtDNA was a significant predictor of technique survival (adjusted hazards ratio [AHR] 1.002, 95%CI 1.000-1.003, p=0.001). In contrast, PDE sediment mtDNA level did not correlate with technique or patient survival.

Conclusions: PDE supernatant mtDNA level had a significant correlation with peritoneal transport. PDE sediment mtDNA level was a significant predictor of technique survival for PD patients. The mechanism of the differential implications between PDE sediment and supernatant mtDNA levels deserves further investigations.

SU-OR28

Hemodynamics and Geometry of Rat Arteriovenous Fistulas: Effect of Sildenafil Treatment

Hannah M. Northrup, 1 Yan-Ting E. Shiu, 1,2 Isabelle D. Falzon, 1 Maheshika S. Somaratna, 1 Timmy C. Lee. 1 University of Utah, Salt Lake City, UT; 2 Wake Forest School of Medicine, Winston-Salem, NC.

Background: Arteriovenous fistula (AVF) maturation is dependent on hemodynamics and remodeling of the vessel wall to increase the AVF flow rate and lumen area for dialysis. Sildenafil is a phosphodiesterase 5 inhibitor that promotes vasodilation and is used clinically to treat erectile dysfunction and pulmonary hypertension. Here we investigate the effect of sildenafil on lumen geometry and hemodynamics in rat AVFs.

Methods: Femoral AVFs were created in 12-16 week-old male Sprague-Dawley rats. Sildenafil was administered at 90 mg/kg in drinking water starting 14 days prior to AVF creation surgery (n=4). 21 days post creation, animals were subject to non-contrast MRI scans, and the MR images were used for reconstruction of the AVF lumen and computational fluid dynamic simulations of the AVF blood flow. Hemodynamic parameters (flow rate, wall shear stress (WSS), vorticity, and oscillatory shear index (OSI)) and geometrical analysis (cross sectional lumen area, anastomosis angle (AA), tortuosity, and nonplanarity angle (NA)) were calculated.

Results: Sildenafil significantly increased the lumen area and flow rate of both the venous and arterial limbs of the AVFs when compared to no-treatment controls (p<0.0001) (Fig. 1). WSS, vorticity, and OSI of treated rats were also significantly higher than controls (p<0.0001). AA, tortuosity, and OSI were significantly higher in treated rats compared to control, which may be due to the increased flow rate. Sildenafil may have therapeutic potential to enhance AVF maturation by affecting the hemodynamics.

Single-Center Real-World Experience with Endovascular Arteriovenous Fistulas

Kareem Genena, 1 Harold M. Szerlip, 1 Neghate Mawla. 2 Baylor University Medical Center at Dallas, Dallas, TX; 2Dallas Nephrology Associates Vacular Center - Plano, Plano, TX.

Background: Endovascular arteriovenous fistulas (EndoAVFs) are created percutaneously via an anastomosis between the radial artery and the perforator vein (Ellipsys), or between the ulnar artery and vein or radial artery and vein (Wavelink). Flow is directed via the perforator vein to the superficial veins.

Methods: We report partial outcomes for 69 technically successful endoAVF creations for patients on hemodialysis between 5/2019 and 4/2020 using 2 catheter-based devices.

Results: 12/69 endoAVFs failed (17%), all before reaching physiologic usability (ok to use) except for 1 which failed due to failure to cannulate at the dialysis center. The most common reason for failure was thrombosis of the perforator vein. In 49 endoAVFs that reached physiologic usability at time of data review, mean duration from creation to physiologic usability was 92 days and mean number of procedures between endoAVF creation and physiologic usability was 1. At time of data review, 9 endoAVFs were pending physiologic usability. 14/49 (29%) of endoAVFs that reached physiologic usability did so with 0 secondary procedures. Mean postoperative brachial artery flow in this subset was 718 ml/min (range 400-1100 ml/min). Mean flow at 4-6 weeks was 843 ml/min. 35/49 (71%) needed at least 1 procedure. Mean postoperative flow in this subset was 545 ml/min. Mean flow at 4-6 weeks was 721 ml/min. In 44 endoAVFs that had been cannulated at time of data review, mean duration from physiologic usability to cannulation was 9 days. In 33 patients whose dialysis catheters had been removed at time of data review, mean duration from first cannulation to dialysis catheter removal was 57 days.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Conclusions: Successfully created endoAVFs have shorter maturation time than surgical AVFs and require less maturation procedures. Immediate postoperative brachial artery flow is an important predictor of endoAVF behavior/outcome. All endoAVFs that reached physiologic usability with 0 secondary procedures had a postoperative flow above 400 ml/min, and mean postoperative flow was higher than those that needed at least 1 procedure. Time from first cannulation to dialysis catheter removal represents a pragmatic measure for endoAVFs. Cannulation injuries sometimes obligate a period of endoAVF rest. Removal of the dialysis catheter not only indicates functional usability of the endoAVF but also proficiency of the dialysis units in cannulating them.

SU-OR30

Association Between Antimicrobial Barrier Cap Use and Outcomes Among Hemodialysis Patients Using a Central Venous Catheter Scott Sibbel,1 Abigail Hunt,1 David B. Van Wyck,2 Lyssa Jordan,1 Francesca Tentori,1 Allen R. Nissenson,3 Steven M. Brunelli.3 Davita Clinical Research, Minneapolis, MN; 2Davita Inc, Denver, CO.

Background: Bloodstream infections (BSIs) are a common complication of central venous catheter (CVC) use and contribute to hospitalization, mortality, and high costs of care in patients on hemodialysis (HD). In a prior randomized clinical trial, patients using CVCs with antimicrobial barrier caps (AmBC; ClearGuard® HD, Pursuit Vascular Inc, Maple Grove, MN, USA) had significantly lower catheter-related BSI rates compared to patients using CVCs with the historical standard of care. Based on these findings, AmBCs were introduced in May 2019 as standard of care for CVC patients across a large dialysis organization (LDO). This study assessed changes in clinical outcomes in a real-world HD population following implementation of AmBC use.

Methods: Study data were derived from LDO electronic medical records over two 3-month periods: Pre (Jul-Oct 2018) and Post (Jul-Oct 2019) AmBC adoption. Included patients were adults receiving in-center HD treatment 3x/week using a CVC. Crude outcome rates were calculated for individual calendar months and for the pre- and post-periods overall; formal comparisons were made using generalized linear models.

Results: A total of 37,642 patients in the pre-period and 40,498 patients in the post-period met eligibility criteria. Overall BSI rate fell from 0.54/100 CVC days in the pre-periods overall; formal comparisons were made using generalized linear models. The contribution of underlying temporal changes (eg, background year-over-year change) could not be quantified.

Conclusions: Adoption of AmBCs for use in HD patients using a CVC for vascular access was associated with an early 34% reduction in infections assessed on the basis of change (difference in [95% CI]) and a 15% reduction in infections assessed on the basis of baseline versus the pre-period overall and within each calendar period met eligibility criteria. Overall BSI rate fell from 0.54/100 CVC days in the pre-periods overall; formal comparisons were made using generalized linear models. The contribution of underlying temporal changes (eg, background year-over-year change) could not be quantified.

Background: NOBILITY demonstrated a sustained benefit of OBI through week 104, approximately 18 months after the final OBI infusion. There were no unexpected safety findings. OBI use in LN will be further evaluated in the Phase 3 REGISTRY trial.

Table. Week 104 Results

Conclusions: NOBILITY demonstrated a sustained benefit of OBI through week 104, approximately 18 months after the final OBI infusion. There were no unexpected safety findings. OBI use in LN will be further evaluated in the Phase 3 REGISTRY trial.

SU-OR32

Complement C5a Receptor Inhibitor Avacopan Improves Renal Function in ANCA Vasculitis David R. Jayne,1,2 Peter A. Merkel,1 Huibin Yue,3 Catherine L. Kelleher,2 Thomas J. Schall,2 Pirow Bekker.2 1Addenbrooke’s Hospital, Cambridge, United Kingdom; 2ChemoCentryx Inc, Mountain View, CA; 3University of Pennsylvania, Philadelphia, PA.

Background: Renal impairment is common in anti-neutrophil cytoplasmic autoantibody-associated vasculitis. The resulting chronic kidney disease and exacerbation of the toxicity risks of high dose or prolonged glucocorticoid use, a mainstay of ANCA treatment, are major consequences. Avacopan was tested for efficacy and effects on renal endpoints compared to standard prednisone therapy in a randomized double-blind Phase 3 trial in ANCA vasculitis.

Methods: Subjects randomized 1:1 received either prednisone (60 mg tapered to 0 over 20 weeks) or avacopan (30 mg twice daily for 52 weeks), combined with either cyclophosphamide (CYP) or rituximab (RTX). Primary endpoints: Disease remission at week 26 and sustained remission at week 52. Changes in urinary albumin to creatinine ratio (UACR) and estimated glomerular filtration rate (eGFR) were also assessed.

Results: 330 subjects were treated: 166 to avacopan and 164 to prednisone treatment groups. Avacopan remission at week 26 was 72.3% vs. 70.1%, for prednisone (P=0.0001 for non-inferiority); avacopan was superior to prednisone for sustained remission (week 52, 65.7%, avacopan vs. 54.9%, prednisone, P=0.0066). 81% percent of subjects had renal disease. UACR decreased more rapidly with avacopan than prednisone: week 4 avacopan was 40% below baseline vs. no change for prednisone (P=0.0001). Baseline to week 52 eGFR (mL/min/1.73 m²) improvement: avacopan eGFR +7.3 vs. prednisone +4.1 (P=0.029). In subjects with baseline eGFR <30: mean eGFR improved 67% more with avacopan than prednisone to week 52: avacopan eGFR +13.7 vs. prednisone +8.2 (P=0.011).

Conclusions: Treatment with avacopan for ANCA vasculitis compared with standard glucocorticoid therapy (both combined with either CYP or RTX) as is effective for remission induction at 26 weeks, and superior to prednisone for sustained remission after 52 weeks. Avacopan led to faster falls in UACR and greater recovery in eGFR when compared to standard prednisone therapy. These findings have important implications for the long term health of AA V patients through better overall disease control, reduced prednisone exposure and reduced severity of chronic kidney disease.

SU-OR33

Prognostic Value of Persistent Proteinuria and Hematuria After Induction Therapy in ANCA-Associated Vasculitis Charles, M.,1,2,3, April, B.,1,2 Benjamin Lonergan,2,3, Thomas F. Houton,2,3 Rachel B. Jones,4 David R. Jayne,4 Alexandre, S.,1,2 HEGP, Hospital Européen Georges Pompidou, Paris, France; 1Université de Paris, Paris, France; 2Cambridge Clinical Trials Unit, Cambridge, United Kingdom; 3Addenbrooke’s Hospital, Cambridge, United Kingdom; 4Institut Mutualiste Montsouris, Paris, France; 5Hôpital Cochin, Paris, France.

Background: In ANCA-associated vasculitides (AAV), hematuria and proteinuria are biomarkers reflecting renal involvement at diagnosis. Yet, the prognostic value of their persistence after immuno suppressive induction therapy, which may reflect renal damage or persistent disease, remains uncertain.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Belimumab (BEL) Improves Renal Outcomes in Active Lupus Nephritis (LN): A Phase 3 Randomized, Placebo (PBO)-Controlled Trial
Brad H. Rovin, Frederic Houssiau, Richard Furie, Ana Malvar, Yoe Kie Onno Teng, Chi chiu Mok, Gabriel Contreras, Xueqing Yu, Sebastian Dolff, Beulah A. Roth, Christi Kleoudis, Susan Gilbride, Ana Kleoudis, Jennifer Madan, Yulia Green, Division of Nephrology, The Ohio State University, Columbus, OH; Pôle de Pathologies Rhumatismales Inflammatoires et Systémiques, Institut de Recherche Expérimentale et Clinique, Université Catholique de Louvain and Service de Rhumatologie, Cliniques Universitaires Saint-Luc, Brussels, Belgium; Division of Nephrology, Northwell Health, Great Neck, NY; Organización Medica de Investigacion, Buenos Aires, Argentina; Expert Center for Lupus-, Vasculitis- and Complement-mediated Systemic Diseases, Department of Internal Medicine – section Nephrology, Leiden University Medical Center, Leiden, Netherlands; Division of Nephrology, Division of Hypertension, Department of Medicine, University of Miami Miller School of Medicine, Miami, FL; Department of Nephropathy, Guangdong Provincial People’s Hospital, Guangzhou, China; GlaxoSmithKline, Uxbridge, United Kingdom; GlaxoSmithKline, Collegeville, PA; Parexel, Durham, NC; GlaxoSmithKline, Stevenage, United Kingdom; Tuen Mun Hospital Department of Medicine and Geriatrics, Hong Kong, Hong Kong; Department of Infectious Diseases, University Hospital Essen, University of Duisburg-Essen, Essen, Germany.

Background: BEL is approved for patients (pts) with systemic lupus erythematosus (SLE) treatment-resistant active lupus nephritis (LN). Methods: This 104-week trial (GSK Study BEL114054; NCT01639339) randomized adults with active LN (class III, IV, and/or V) 1:1 to monthly BEL 10 mg/kg IV or PBO, plus standard therapy (ST) with high-dose corticosteroids + either cyclophosphamide (CYC) or mycophenolate mofetil (MMF) for induction at the investigator’s discretion. CYC was followed by azathioprine (AZA), and MMF by MMF maintenance. The primary endpoint was Primary Efficacy Renal Response (PERR = urine protein:creatinine ratio [UPCR] ≤0.7, estimated glomerular filtration rate [eGFR] no more than 20% below pre-flare value or ≥60 ml/min/1.73 m²; no rescue therapy) at Week 104. Other endpoints were Complete Renal Response (CRR = UPCR ≤0.5; eGFR no more than 10% below pre-flare value or ≥90 ml/min/1.73 m²; no rescue therapy) at Week 104; time to renal event (end-stage kidney disease, doubling of serum creatinine, increased proteinuria and/or impaired renal function, renal disease-related treatment failure) or death. Endpoints were analyzed using the Kaplan-Meier method. Results: 224 pts were randomized to each arm. At Week 104, there were significantly more PERR and CRR responders on BEL vs PBO (43.0% vs 32.3%, OR [95% CI] 1.7 [1.1-2.7]; p = 0.012), respectively. Risk of renal event or death was lower in BEL pts relative to PBO (HR [95% CI] 0.5 [0.3, 0.8]; p = 0.001). Week 104 PERR response rates in pts on CyCAZA were 33.9% with BEL and 27.1% with PBO, and 46.3% vs 34.1% with PBO in those on MMF. BEL significantly reduced risk of renal event or death on background of CyCAZA (HR [95% CI] 0.5 [0.2-1.0]) and MMF (HR [95% CI] 0.5 [0.3, 0.8]) relative to PBO. Adverse events (AEs; ≥1) occurred in 95.5% of BEL and 94.2% of PBO pts, and 25.9% of BEL and 29.9% of PBO pts had ≥1 serious AE. Conclusions: The addition of BEL to commonly used ST for the treatment of LN significantly improved renal responses with no unexpected safety signals. Funding: Commercial Support - GSK

24-Week Interim Analysis of a Randomized, Double-Blind, Placebo-Controlled Phase 2 Study of Atacicept in Patients with IgA Nephropathy and Persistent Proteinuria
Jonathan Barratt, James A. Tumlin, Yusuke Suzuki, Amy Kao, Aida Aydemir, Yulia Zima, Gerald B. Appel. Emory University School of Medicine, Atlanta, GA; Juntendo University, Tokyo, Japan; University of Leicester, Leicester, United Kingdom; EMD Serono Research Institute Inc. (a business of Merck KGaA, Darmstadt, Germany), Billerica, MA; Columbia University Medical Center, New York, NY.

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis and currently has no approved therapy. Its central pathogenic feature is circulating immune complexes of poorly O-galactosylated polyclonal IgA1 (Gd-IgA1) that often deposit in the kidneys (causing inflammation and scarring) and trigger formation of IgA1 aggregates that deposit in glomeruli. This Phase II study (NCT02808429) examines atacicept safety and efficacy in reducing Gd-IgA1 and renal activity in IgAN.

Methods: Patients with Gd-IgA1 (≥0.5 g/l) or 0.75 mg/m² for 24 hr urine protein:creatinine-ratio (UPCR) despite maximal standard of care (ACE inhibitor and/or ARB) were enrolled. Patients were randomized to subcutaneous placebo, atacicept 25mg or 75mg weekly. Primary endpoint: change in proteinuria at Week 48; secondary endpoints: changes in eGFR, serum IgA, IgG, and IgM. Results: This interim analysis showed that, at Week 24, IgAN patients (placebo=5; atacicept 25mg=6; 75mg=5) had a consistent, dose-dependent reduction in IgA, IgG and IgM, and in Gd-IgA1 (Fig 1A), and a higher median % reduction from baseline in UPCR with atacicept than with placebo (Fig 1B); eGFR remained stable. TEAEs were reported in ≤81% of patients (mild/moderate, none severe), with no serious events related, severe hypogammaglobulinemia, or fatal outcomes.

Conclusions: These results provide proof of concept for the potential treatment of patients with IgA nephropathy with atacicept. Funding: Commercial Support - EMD Serono Research & Development Institute Inc. (a business of Merck KGaA, Darmstadt, Germany).

Figure 1. Median changes from baseline to Week 24 in a) serum Gd-IgA1 and b) 24-hour UPCR

Grading System Utilizing Total Score of Oxford Classification for Predicting Renal Prognosis in IgA Nephropathy
Yoshi Miyabe, Kenichi Akiyama, Kazunori Karasawa, Kosaku Nitta, Takahito Motyama. Department of Nephrology, Tokyo Women’s Medical University, 8-1 Kawada-Cho, Shinjuku-ku, Tokyo, Japan.

Background: The Oxford classification of IgA nephropathy (IgAN) can evaluate each MEST-C score comprehensively. Therefore, we aimed to analyze the usefulness of a new grading system that utilized the total score of each MEST-C score in predicting renal prognosis.

Methods: A total of 871 IgAN patients were classified into three groups using the Oxford classification system (O-grade) that utilized the total score of each MEST-C score (O-grade 1-3; II: 2-4, and III: ≥5 points) according to the renal survival rate (>10%, 10%-30%, >30%, respectively). The 20-year renal prognosis was analyzed, and the O-grade combined with the Japanese clinical classification (C-grade) was also evaluated.

Results: The clinical findings became significantly severer with increasing O-grades, and the renal survival rate by the Kaplan-Meier method was 78.5%, 74.9%, and 42.2% for O-grades I, II, and III, respectively (p=0.001). The hazard ratios (HRs) for O-grades I, II, and III with reference to O-grade I were 1.0 (95% CI 1.0-2.9; p=0.363) and 4.7 (95% CI, 2.6-8.4; P<0.001), respectively. In the multivariate analysis,
mean blood pressure and renal function, proteinuria, and O-grade (HR, 1.35; 95% CI, 1.02-1.90; P=0.036) were the independent factors predicting the renal prognosis of this disease.

Development of a Deep Learning Model to Predict ESKD in Patients with Immunoglobulin A Nephropathy (iAN) at Kidney Biopsy Time 

Francesco P. Schena,1 2 Vito Walter Anelli,1 Joseph Trotta,1 Tommaso Di noia,1 Carlo Manno,1 Giovanni Tripepi,1 Graziella D’Arrigo,1 Maria Luisa Russo,1 Maria J. Stangou,1 Akaterini A. Papagianni,1 Carmine Zoccali,1 Vladimir Tesar,1 Rossanna Coppo,1 Schena Faoudation, Bari, Italy; 2 Università degli Studi di Bari Aldo Moro, Bari, Italy; 3 Policlinico di Bari, Bari, Italy; 4 CNR -IFC, Reggio Calabria, Italy; 5 Fondazione Ricerca Molinette, Torino, Italy; 6 Aristotle University of Thessaloniki School of Medicine, Nephrology, Thessaloniki, Greece; 7 University of Prague, Prague, Czechia.

**Background:** Many prediction models to support clinical decision making have been developed for decades but they are based on traditional statistical linear methods. Another approach is the application of artificial intelligence (AI) that is based on machine learning or deep learning algorithms. We developed an artificial neural network (ANN) tool to predict ESKD in patients at kidney biopsy time.

**Methods:** The classifier model to predict ESKD was composed of 4 hidden layers with 100 neurons in each layer. The regression model to predict the time-to-event endpoint consisted of 3 layers containing 125 neurons each.

**Results:** Our tool, based on these two models, was developed in a cohort of 948 iAN patients of the VALIGA and Greek cohort. Then, the tool was validated in an independent cohort of 167 iAN patients from 6 nephrology units. After Cox’s regression analysis 7 variables (age, sex, blood pressure values, serum creatinine, daily proteinuria, MEST classification for the kidney biopsy and therapy at baseline) were chosen to develop the ANN model. The AUC of the ANN model in the study cohort was 0.80. The performance was 0.82 (precision 0.83, accuracy 0.80) for ESKD prediction at 5 years of follow-up and 0.89 (precision 0.81; accuracy 0.83) for patients with 10 years of follow-up. Stable renal function and ESKD were correctly predicted in 91% of iAN patients in the test cohort.

**Conclusions:** (i) Our ANN is a promising alternative to the mathematical models in solving non-linear and multidimensional problems. (ii) We have developed a new clinical decision support system that provides additional information to identify iAN patients at high risk of ESKD (iii) This tool may straitly patients in the context of a personalized therapy. (iv) This tool will be validated in a clinical prospective study.

Complete Remission of Proteinuria in Patients with Focal Segmental Glomerulosclerosis Treated with Sparsentan, a Dual Endothelin and Angiotensin Receptor Antagonist, in the DUET Trial 

Jonathan Hogian,1 Ulysses Diva,2 Edward Murphy,3 Noah Rosenberg,2 Howard Trachtman,1 Radko Komers,1 Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 2 Retrophin, Inc., San Diego, CA; 3 NYU School of Medicine, NYU Langone Medical Center, New York, NY.

**Background:** In FSGS, partial remission (FSGS partial remission endpoint [FPRP]: 40% reduction in proteinuria) and complete remission (FPRP<1.5 g/day) were more likely in patients who reached CR (proteinuria) of strong predictors of kidney survival. In the DUET trial, sparsentan (SPAR) resulted in greater reductions in proteinuria and higher rate of FPRP vs ibersartan (IRB) over the 8-week double-blind (DB) period. This antiproteinuric effect of SPAR was sustained during the open-label extension (OLE) period of DUET. Here we analyze patients who achieved CR (UP/C <0.3 g/g) during OLE period of DUET. Here we analyze patients who achieved CR (UP/C <0.3 g/g) during OLE period of DUET.

**Methods:** DUET randomized patients age 8-75 years with biopsy-proven FSGS, UP/C >1 g/day, and eGFR<30 mL/min to SPAR or IRB for 8 weeks, followed by OLE with all patients treated with SPAR. Baseline and other proteinuria parameters were measured every 12 weeks during OLE. This post-hoc analysis included all patients on SPAR treatment regardless of original randomization.

**Results:** Median follow-up on SPAR was 42.5 months. Of 108 subjects dosed with SPAR, 39% of patients reached CR (68% of CR patients). CR was achieved by 28 patients within the 1st year on SPAR (Kaplan-Meier estimate: 29%). A history of, or nephrotic syndrome at baseline, was documented in 8 (18%) of CR patients. Of subjects with CR, 14%, 41%, and 45% were originally assigned to 200, 400, and 800 mg/day of SPAR dose cohorts, respectively. No patient achieved CR while on IRB during the DB period. Compared to the overall DUET population, CR patients had similar age, sex, and baseline eGFR, but lower baseline mean UP/C (1.67 g/g vs 2.65 g/g), and higher proportion of baseline immunosuppression (45% vs 35%), in particular with mycophenolate mofetil (18% vs 12%). Achieving CR was associated with better preservation of kidney function compared to not achieving CR. In 6 patients (14%), occurrence of CR followed the initiation of new steroid treatment.

**Conclusions:** In the DUET trial, a high proportion of patients achieved CR on at least one occasion. These observational data support the long-term nephroprotective potential of sparsentan.

Characteristics and Outcomes of Pregnancy-Triggered Atypical Hemolytic-Uremic Syndrome (aHUS): Global aHUS Registry Analysis

Fadi Fakhouri,1 Benjamin Miller,2 Marie Scully,2 Gianluigi Ardissoni,4 Imad Al-Dakak,2 Eric Rondeau,1 1University of Lausanne, Lausanne, Switzerland; 2Alexion Pharmaceuticals Inc., Boston, MA; 3University College London, London, United Kingdom; 4Centre for HUS Control, Prevention and Management, Milan, Italy; 5Hôpital Tenon, Paris, France.

**Background:** Pregnancy-triggered aHUS (P-aHUS) accounts for 10–20% of aHUS diagnoses. Complement-mediated thrombotic microangiopathy (CM-TMA) may be associated with high maternal and fetal morbidity and mortality such as ESRD. The clinical characteristics of P-aHUS and survival probability in patients treated with the complement C5 inhibitor eculizumab are described, using the largest collection of P-aHUS data available in a single study.

**Methods:** Patients with a clinical diagnosis of aHUS were included in the global aHUS registry (NCT01522183). Patients with P-aHUS were selected as those first TMA manifestations during pregnancy or within 60 days postpartum. Patients with other triggers of aHUS were excluded. Survival, based on time to ESRD, was calculated by the Kaplan-Meier method.

**Results:** In the registry, 51/1029 female patients were selected with P-aHUS and 27 received eculizumab. Mean ± SD age at pregnancy onset was 30.7 ± 5.9 years. P-aHUS occurred during pregnancy in 28 (54.9%) patients, with the remainder occurring within 60 days of pregnancy. A diagnosis of pre-eclampsia or HELLP (hemolysis elevated liver enzymes low platelet count) syndrome was reported in 28 (54.9%) and 17 (33.3%) patients, respectively. A complement pathogenic variant was identified in 23 (45.1%) patients, of whom 3 (8.3%) also tested positive for anti-complement factor H antibodies. Mean ± SD eculizumab treatment duration was 1.8 ± 1.1 years. Survival probability was higher in eculizumab-treated patients compared with patients not receiving eculizumab (Figure).

**Conclusions:** Survival probability was higher in patients who received eculizumab compared with patients who did not receive eculizumab. Successful treatment with eculizumab, in addition to a complement pathogenic variant, confirms the appropriate classification of P-aHUS as a CM-TMA.

Differences in Kidney Failure Risk by Race/Ethnicity at the Time of GFR-Based Transplant Eligibility
Chi D. Chu,1,2 Neil R. Powe,3,5 Delphine S. Tuot,1,3 University of California San Francisco, San Francisco, CA; 1OptumLabs Visiting Scholar, Cambridge, MA; 2Zuckerberg San Francisco General Hospital and Trauma Center, San Francisco, CA.

Background: Glomerular filtration rate (GFR) less than 20 ml/min/m² is a criterion for kidney transplant listing, but variation in underlying end-stage kidney disease (ESKD) risk distributions by race/ethnicity has the potential to produce systematic racial disparities due to under recognition of the higher progression risk when a singular eGFR threshold is used as a decision point.

Methods: We compared predicted kidney failure risk by race/ethnicity for patients at the time their eGFR fell below 20 ml/min/m² using the OptumLabs® Data Warehouse (OLDW), a longitudinal, real-world data asset with de-identified administrative claims and electronic health record (EHR) data. We identified patients 18-70 years old from 1/1/2014-6/30/2019 who had at least one eGFR ≥20 ml/min/m², and at least two later eGFR values ≥20 ml/min/m² that were a 90 days separated, who also had a urine albumin/creatinine ratio (UACR) measured within 90 days of the first eGFR ≥20 ml/min/m². We calculated 2-year risk of ESKD for each patient using the 4-variable Kidney Failure Risk Equation and compared the distributions by race/ethnicity.

Results: Of 2926 patients, 2024 were non-Hispanic white (NHW), 649 non-Hispanic black (NHB), and 253 Hispanic. At the time of incident eGFR ≥20 ml/min/m², NHWs were older than NHB or Hispanic patients (mean age 59.2 versus 56.2 or 54.3 years, respectively) and had lower median UACR (0.67 versus 1.36 or 1.72 g/g, respectively). Compared to ESKD risk among NHWs (median predicted risk 38.7%), the risk distribution was skewed toward higher risk for NHB and Hispanic patients, who had median predicted risks of 49.4% and 55.8% respectively (Figure).

Conclusions: At the time of incident eGFR ≥20 ml/min/m², NHB and Hispanic populations had greater risk of ESKD. A racial/ethnic disparity in time from GFR-based transplant eligibility to ESKD may exist even with elimination of disparities in timing of transplant referral and waitlisting. Consideration of kidney failure risk might be given greater attention in access to transplantation.

Do Social Determinants of Health Predict Patient-Reported Outcomes in Transplant-Eligible ESRD Patients?
Samuel L. Swift,1 Shu Wang,2 Chung-Chou H. Chang,1 John R. Pleis,3 Mary amanda Dew,2 Ron Shapiro,4 Mark L. Unruh,1 Emilee J. Crowell,3 Kellee Kendall,4 John D. Peipert,2 Larissa Myaskovsky,1 1University of New Mexico, Albuquerque, NM; 2University of Florida, Gainesville, FL; 3University of Pittsburgh, Pittsburgh, PA; 4Mount Sinai Health System, New York, NY; 1Highmark Inc, Pittsburgh, PA; 2Northwestern University Feinberg School of Medicine, Chicago, IL; 3 Centers for Disease Control and Prevention, Hyattsville, MD.

Background: Measuring and understanding patient reported outcomes [PRO, e.g., health related quality of life (HRQoL) and satisfaction with transplant clinic service] is a critical consideration for the care of kidney transplant (KT) eligible patients with end-stage renal disease (ESRD), because research has demonstrated that pre-transplant HRQol predicts both the receipt of a KT as well as post-KT mortality. Although research demonstrated the importance of social determinates of health (e.g., cultural factors, psychosocial characteristics, transplant knowledge) on clinical outcomes, less is known about how they predict PRO in KT-eligible ESRD patients.

Methods: We examined whether social determinants of health (Time 1, assessed shortly after initiating KT evaluation) are risk or protective factors for PRO (Time 2, assessed after notification of KT evaluation outcome – accepted or not), controlling for evaluation outcome, in a prospective cohort study. Of the initial 1152 adults referred for KT evaluation (2010-2012), 955 completed a Time 2 interview, most within 1 year of completing KT evaluation [n=46 months=70% (669), n=6 months<12 months=9% (76), n=12 months>22% (210)]. We used the Physical Composite Score (PCS), Mental Health Composite Score (MCS), and Kidney Summary Score (KSS), from the Kidney Disease Quality of Life Short Form (KDQoL-SF) to measure HRQol, and the Client Satisfaction Questionnaire to measure satisfaction with KT clinic service.

Results: Participants completed KT evaluation in an average of 11.7 months (range=0-43 months). In adjusted multivariable regression models, a stronger sense of mastery predicted higher PCS (β=4.5, p <0.001), MCS (β=5.4, p=0.001), and KSS (β=5.6, p=0.001). Depression predicted lower MCS (β=4.2, p<0.001), and lower KSS (β=5.1, p=0.002). More medical mistrust predicted lower odds of higher patient satisfaction scores (OR=0.6, 95% CI=0.4, 0.8, p=0.002).

Conclusions: Transplant teams should consider identifying and targeting patients with a low sense of mastery, greater depressive symptoms, or an increased sense of medical mistrust, with additional psychosocial support to improve PRO during the KT evaluation process.

Genetic vs. Self-Reported African Ancestry and Kidney Allograft Outcome: Analysis of Two Large Multietnic Urban Transplant Cohorts

Francesca Zanoni,1 Y. Dana Neugut,1 Sumit Mohan,1 Ali G. Ghavari,1 Brendan Keating,2 Krzysztof Kurylk,1 1University of Miami School of Medicine, Miami, FL; 2Miami Transplant Center, New York, NY; 1University of Pennsylvania, Philadelphia, PA.

Background: African-American (AA) kidney transplant recipients have higher risk of allograft rejection and failure. However, it is unknown to what extent the inferior outcomes in self-reported AA are due to genetic versus environmental effects. Herein, we compared the effects of self-reported race versus genetic African admixture on graft outcomes.

Methods: A discovery multicentric cohort of 1,083 kidney transplant recipients from Columbia University and a replication cohort of 761 kidney transplant recipients from University of Pennsylvania were genotyped with high resolution SNP arrays. African admixture proportions, a genetically-derived quantitative measure of African ancestry, was estimated with ADMIXTURE software. Multivariable Cox models were used to investigate associations between African ancestry measures and time to rejection and time to death-censored graft failure, with adjustments for relevant covariates. Akaike information criterion (AIC) was used to compare the models.

Results: 206 and 346 self-identified AA were included in the discovery and replication cohorts, respectively. Over a median follow-up time of 78 months, 432 patients had rejection and 193 had graft failure in the discovery cohort. Self-reported AA ancestry and African admixture were associated with acute rejection (self-report: HR 1.47, 95% CI: 1.18-1.83, AIC: 5540.1; admixture: HR 1.64, 95% CI: 1.22-2.19, AIC: 5548.1, p=0.0001), and graft failure (self-report: HR 1.42, 95% CI: 1.02-1.97, AIC: 2228.9; admixture: HR 1.48, 95% CI: 0.96-2.29, AIC: 2228.9). In the replication cohort, during a median follow-up time of 49 months, 113 patients had rejection and 121 had failure. Self-reported AA ancestry and African admixture measures confirmed to be associated with both acute rejection (self-report: HR 1.36, 95% CI: 1.96-4.78, AIC: 1289.5; admixture: HR 1.36 95% CI: 2.21-6.16, AIC: 1288.9) and failure (self-report: HR 2.16, 95% CI: 1.43-3.27, AIC: 1113.8; admixture: HR 2.46, 95% CI: 1.54-3.94, AIC: 1113.1). In this cohort, the models including African admixture proportion had a better fit when compared to self-report.

Conclusions: In conclusion, self-reported AA race and a genetically-derived continuous measure of African ancestry predict the risk of allograft rejection and failure in multietnic and genetically diverse cohorts.

Deceased Donor Families and Authorization for Research: Differences Among Ethnic Groups

Mariella O. Goggins,1,2 Giselle Guerra,1,2 Miami Transplant Institute 1University of Miami School of Medicine, Miami, FL; 2Miami Transplant Institute, Miami, FL.

Background: Research in transplantation requires next of kin (NOK) to authorize for participation in research. Aim was to determine the rate of research authorization by the NOK within different ethnic groups: African American (AA), White (W) or Hispanic (H).

Methods: Single center study of all deceased donor kidney transplants referred to our institution during 3/1/2019-10/31/2019 from multiple organ procurement organizations (OPO) across the United States. We looked at the authorization for donation form in DonorNet. We searched for the NOK research authorization agreement at the time of organ donation. Donors were grouped by self-identified ethnic groups as W, AA or H.

Results: We had a total of 297 donors, yielding 401 kidney offers. 71% were from OPOs. Donors were from: 46% of W, 29% of AA and 25% of H. In 13% of the donors, no authorization was found. In 57% of cases, the family did not authorize donation.

Conclusions: In conclusion, family authorization rate was lower in AA donors compared to W donors (43% vs 62%, p=0.0001) and H donors (35%, p=0.0002). Multivariable analysis showed that donors from AA were more likely to decline research authorization, yielding multivariable p=0.0001 for AA donor and p=0.002 for younger donor age. Multivariable percentages who were more likely to decline research authorization, yielding multivariable p=0.0001 for AA donor and p=0.002 for younger donor age. Multivariable percentages who were more likely to decline research authorization, yielding multivariable p=0.0001 for AA donor and p=0.002 for younger donor age.

Minimum Diagnostic Criteria for Thrombotic Microangiopathy in Renal Allograft: The Banff TMA Working Group Phase I Results

Marian Afrozian, Banff TMA Working Group University of Texas Medical Branch at Galveston, Galveston, TX.

Background: Thrombotic Microangiopathy (TMA) is a serious complication of renal transplantation, usually with poor outcome. The Banff TMA Working Group (TMA-WG) was formed to study renal transplant TMA (t-TMA) aiming to: 1- Survey current practices used in the diagnosis of t-TMA; 2- Define minimum diagnostic criteria (MDC); and 3- Develop recommendations for adequate diagnosis integrating morphological, clinical, laboratory and molecular findings, where applicable. The project started with Phase I (pathology phase) and is continuing in Phase II (Nephrology phase).

Methods: Using the Delphi methodology during phase I, 23 nephrologists who had >3 years of experience with t-TMA were asked to list their MDC for t-TMA in the following categories: 1- Light, 2- immunofluorescence, and 3- electron microscopy, 4- clinical history, 5- laboratory findings, 6- genetic testing and 7- raised differential diagnoses. Nine rounds (R) of surveys were designed. At the end of each R, MDC were narrowed down following Delphi rules. R6 and R7 were designated as the validation Rs in which the narrowed criteria were validated on 37 renal biopsies (25 TMA and 12 non-TMA cases) using Aperio Imagescope and whole slide digital images scanned @ X400. For each biopsy, pertinent pathology/history/laboratory/genetic information were provided. Descriptive statistical analysis was performed using SPSS program.

Results: Starting with 338 criteria in R1 and following analysis of total 8,677 data entries, MDC were narrowed down to 35, by the end of R9. The graph illustrates the evolution of the criteria over 9 R. A complete list of 35 MDC will be presented at the meeting.

Conclusions: Applying the Delphi methodology to a cohort of t-TMA biopsies in Phase I of the project, nephropathologists from 4 continents generated histopathologic, clinical and laboratory MDC for renal t-TMA. Phase II (Nephrology consensus) and Phase III (consensus of the consensus groups- Combined Phases I & II) will follow Phase I to generate final MDC for t-TMA.

Does Screening for Coronary Artery Disease Predict Cardiac Outcomes Following Renal Transplantation?

Aliash Nimmo, Dominic M. Taylor, Rommel Ravanat, Southampton Hospital, Bristol, United Kingdom.

Background: Screening for asymptomatic coronary artery disease (CAD) prior to transplantation aims to reduce perioperative cardiac events. There is conflicting evidence as to whether this is achieved.

Methods: Individuals recruited to the Access to Transplant and Transplant Outcome Measures (ATTOM) study in England who received a renal transplant between 2011-2017 were studied. Patient demographics and details of screening investigations from ATTOM were linked to outcome data from the Hospital Episode Statistics dataset. Major Adverse Cardiac Events (MACE) comprised unstable angina, myocardial infarction, coronary bypass graft, coronary angioplasty or cardiac death. The effect of screening on MACE was analysed in propensity score-matched groups, using Cox survival analyses, up to 5 years post-transplant.

Results: 2572 individuals received a renal transplant; 51% underwent CAD screening (Figure 1). Age, ethnicity, ischaemic heart disease and diabetes were independently associated with screening. The incidence of MACE at 90 days, 1 and 5 years was 0.9%, 2.1% and 9.4%. After propensity score matching, 1854 individuals were examined. There was no association between screening and MACE at 90 days (HR 0.68, 95% CI 0.28-1.64), 1 year (HR 1.24, 95% CI 0.60-2.54) or 5 years (HR 1.31, 95% CI 0.95-1.79) (Figure 2).

Conclusions: Screening for CAD did not influence the rate of ischaemic cardiac events up to 5 years post-transplant. Units should review protocols with lengthy cardiac workup processes.
SU-OR48
Albuminuria in Kidney Transplantation Patients Predicts Cardiovascular Morbidity After Two Years
Dana Bielopolski,1,2 Ruth Rahaminov,1 Boris Zingerman,1 Avry Chagnac,1 Limor Azulay gitter,1 Benaya Rozen-zvi.1 1The Rockefeller University, New York, NY; 2Rabin Medical Center, Petah Tikva, Israel.

Background: Moderately Increased Albuminuria (MIA) is a well characterized marker of kidney malfunction, both in diabetic and non-diabetic populations, and is used as a prognostic marker for cardiovascular morbidity and mortality. A few studies implied that it has the same value in kidney transplanted patients, but the information relies on spot or dipstick urine protein evaluations, rather than the gold standard of timed urine collection.

Methods: We revisited a cohort of 286 kidney transplanted patients, several years after completing a meticulously timed urine collection and assessed the prevalence of major cardiovascular adverse events (MACE) in relation to albuminuria.

Results: During a median follow up of 8.3 years (IQR 6.4-9.1) 144 outcome events occurred in 101 patients. By Kaplan-Meier analysis MIA was associated with increased rate of CV outcome or death (p=0.03), and this was still significant after stratification according to propensity score quartiles (p=0.048). Time dependent Cox proportional hazard analysis showed independent association between MIA and CV outcomes over 5 years. Cox regression analysis revealed male gender [HR 2.14], pre-emptive renal transplantation [HR 6.57] and HLA mismatch >4 [5.60] as significant risk factors for renal graft failure in SKHT recipients as compared to DDKT recipients at 4 years. Predominant cause of graft failure in SKHT recipients was primary failure (36%) and in DDKT recipients was acute rejection (26%).

Conclusions: This is the largest analysis of the UNOS database till date to describe risk factors associated with renal allograft loss in SKHT recipients. We also showed that 38% of grafts that fail in SKHT recipients, failed in the first year following transplant and primary failure was the predominant cause. Our analysis provides much needed data to policy makers for future combined organ allocation policies.

SU-OR50
Recurrence of IgA Nephropathy After Kidney Transplantation: TANGO Multicenter Study
Audrey Uffing,1,2 Paolo Cravedi,1 Leonardo V. Riella.1 TANGO-project 1Brigham and Women’s Hospital, Boston, MA; 2Universitair Medisch Centrum Groningen, Groningen, Netherlands; 3Icahn School of Medicine at Mount Sinai, New York, NY.

Background: In patients who received a kidney transplantation for end-stage renal disease (ESRD) due to IgA nephropathy, IgA deposits can recur in the transplanted kidney. The incidence, impact and predictors of these recurrent deposits is unclear.

Methods: As part of The Post-Transplant Glomerular Disease (TANGO) project, we performed a multicenter, international, retrospective study to determine the incidence, predictors and treatment response of recurrent IgA deposits after kidney transplantation. Patients with biopsy-proven IgA nephropathy, transplanted in the period 2005-2015 were selected in 16 TANGO centers in Europe, United States and Brazil.

Results: In a total of 504 patients, recurrent IgA deposits were identified by kidney biopsy in 82 patients (16%; 95%CI: 13-19), with a median time to recurrence of 3.4 years (IQR 1.4-5.7 years). Kaplan-Meier analysis showed similar graft survival between patients with and without recurrence in the first years after kidney transplant, though after 8 years, graft failure rates were higher in patients with recurrence (10 year death-censored graft survival 76% and 89%, respectively). Multivariable Cox-regression revealed a higher risk for IgA recurrence.
in patients with a pre-emptive kidney transplant (HR 2.56, 95%CI: 1.59-4.17), patients with DSA at time of transplant (HR 2.74, 95%CI: 1.22-6.14) and patients with shorter time from diagnosis to ESRD (HR 0.84 per month, 95%CI: 0.74-0.96). The presence of systemic autoimmune diseases associated with IgA nephropathy did not affect recurrence rates, nor did early steroid withdrawal. In multivariate analysis of post-transplant complications, de novo DSA was associated with recurrence of IgA deposits (HR 1.91, 95%CI: 1.04-3.51).

**Conclusions:** In our international cohort, IgA deposits reappeared in 16% of patients and was associated with worse graft outcomes after 8 years of transplant compared to patients without recurrence. A pre-emptive transplant, shorter time from native diagnosis to ESRD, DSA at time of transplant and de novo DSA after kidney transplantation were associated with recurrence of IgA deposits.

**Renin Does Not Associate with Mortality or AKI in Acute Respiratory Distress Syndrome**

Jan Mecoy,1 Michael Matthay,2 Jason Abbott,3 Chi-yuan Hsu,4 Kathleen D. Liu,2 *Stanford University School of Medicine, Palo Alto, CA; University of California San Francisco, San Francisco, CA.*

**Background:** Renin may be a marker of severity of illness and mortality in critically ill patients. Angiotensin II infusions in patients with lower renin levels may increase the rate of renal recovery from dialysis-requiring AKI. Given that most ACE is found in the lungs and an ACE defect would lead to higher renin levels, we tested associations between renin and clinical outcomes in patients with acute respiratory distress syndrome (ARDS).

**Methods:** We studied 63 patients with plasma renin measurements enrolled in a phase 2/3 trial of bone marrow-derived human MSCs for moderate-severe ARDS. We estimated associations between renin levels (as a continuous variable) and ARDS severity (assessed by PaO2/FiO2), mean arterial pressure (MAP), and serum creatinine at randomization. We then examined if renin was associated with subsequent AKI (defined as ≥ 2x SCR or new dialysis) or in-hospital mortality.

**Results:** The median renin was 72 pg/mL (25%-75% percentile 33-181 pg/mL). At randomization, there was no cross-sectional correlation between renin level and PaO2/FiO2 (R = 0.03, 95% CI 0.00-0.14, p = 0.21), between renin level and MAP (R = 0.01, 95% CI 0.00-0.12, p = 0.32), or between renin level and serum creatinine (R2 = 0.003, 95% CI 0.00-0.08, p = 0.68). In longitudinal unadjusted analysis, renin did not significantly associate with AKI (OR 1.006 per 10 pg/mL increase, 95% CI 0.992-1.021, p = 0.41) or 28-day mortality (OR 1.00 per 10 pg/mL, 95% CI 0.987-1.014, p = 0.97). Results were similar in a nested analysis of serum creatinine at randomization was associated with AKI (OR 3.27 per mg/dL, 95% CI 1.47-7.30, p = 0.004).

**Conclusions:** We did not find that renin level is a risk factor for mortality or AKI in moderate-severe ARDS.

**Renal Denervation Alleviates Renal Ischemic-Reperfusion Injury-Induced Acute and Chronic Kidney Injury Partly by Modulating miRNAs in Rats**

Xiangyu Zou, Shanghai Childrens Medical Center Affiliated to Shanghai Jiaotong University School of Medicine, Shanghai, China.

**Background:** Renal denervation (RDN) has been used as a potential medium for kidney injury repair and miRNAs involved in the pathophysiology of renal injury. However, the change of miRNAs after RDN and its proper protective mechanisms has yet to be determined.

Male, but Not Female, Spontaneously Hypertensive Rats (SHR) Have Sustained Renal Injury Following a Single Ischemic Insult Progressing to CKD
Riyaz Mohamed, Jennifer C. Sullivan. Augusta University, Augusta, GA.

Background: Renal ischemia-reperfusion (IR) injury is a major cause of acute kidney injury (AKI), which is an independent risk factor for the development of CKD and all-cause mortality. The goal of the current study was to test the hypothesis that hypertensive males will have greater IR injury than hypertensive females resulting in the development of CKD.

Methods: 13-week old male and female SHR were subjected to sham or 30-minute warm bilateral ischemia followed by reperfusion (n=5-6). Systolic blood pressure (BP) measured weekly by tail-cuff.

Results: Plasma creatinine (Pcr) and urine protein creatinine ratio (UPCR) remained elevated at 1-week post IR in male SHR compared to sham (Pir<0.005); Per and UPCR returned to baseline in SHR females. Histological examination of SHR kidneys 7 days post-IR showed greater increases in vascular congestion (P<0.002) and tubular damage (P<0.001) in males. However, glomerular filtration rate (GFR) and systolic BP were not altered in both male and female SHR at 1-week post IR. To determine if this was sustained dysfunction or simply delayed recovery, additional 13-week old male and female SHR were subjected to sham or 30-minute warm bilateral ischemia followed by 20 weeks of reperfusion (n=4-5). Male SHR showed progressive increases in UPCR (P<0.05) and systolic BP up to 20 weeks post-IR compared to respective sham (P<0.001). Whereas in female SHR, UPCR remained at baseline up to 16-week post IR compared to respective sham. However, at 20 weeks of post IR, both male and female SHR exhibit an increase in UPCR compared to respective sham control; although the increase in UPCR was greater in males (P<0.01; Pir<0.09). Male SHR also exhibited greater decreases in glomerular filtration rate (GFR; P<0.0025; Pir<0.12) and increases in systolic BP (P<0.0001; Pir<0.27) compared to females.

Conclusions: Our data demonstrated that impaired renal recovery following IR in SHR males results in exaggerated progression towards CKD.

High Serum Strontium May Predict AKI After Cardiac Surgery with Cardiopulmonary Bypass
Natsumi Tomita,1 Yuji Hotta,1 Karin Matsuoka,2 Hidekazu Ito,1 Yoko Yamamoto,4 Kazuki Ohashi,2 Masahiro Kondo,2 Tomoaki Hayakawa,2 Tomoyo Kataoka,1,3 Kazuya Sobue,1 Kazunori Kimura.1,2 1Department of Hospital Pharmacy, Graduate School of Pharmaceutical Sciences, Nagoya City University, Nagoya, Japan; 2Department of Pharmacology, Nagoya City University Hospital, Nagoya, Japan; 3Department of Clinical Pharmaceutics, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan; 4Aichi-ken Eisei Kenkyujo, Nagoya, Japan; 5Department of Anesthesiology and Intensive Care Medicine, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan.

Background: The prevalence of acute kidney injury after cardiac surgery under cardiopulmonary bypass (AKI-CPB) is high and it worsens patient prognosis, which renders it a major concern during intensive care. Therefore, a predictable marker of AKI-CPB is required. Because some trace metals have been found to affect renal injury, we investigated their association with AKI-CPB.

Methods: Study 1. We enrolled 30 patients from the Nagoya City University Hospital. Serum concentrations of 19 trace metals were measured before surgery and immediately after CPB withdrawal. We defined AKI according to the KDIGO criteria. Factors associated with AKI-CPB were identified by univariate and multivariate analyses. Study 2. We treated male Wistar-ST rats with 1 mg/kg/day of strontium (Sr) or vehicle orally for 3 days, followed by the application of 30 min of ischemia and reperfusion to cause renal injury. Serum creatinine (Scr) and blood urea nitrogen (BUN) levels were evaluated 24 h later. We also incubated human kidney (HK)-2 cells with Sr (0.25 μM, high-Sr or 0.19 μM, normal-Sr) or PBS for 24 h in vitro. These Sr concentrations were determined according to the average serum Sr concentrations in patients with and without AKI. The cells were incubated under normoxia (20% O2) or hypoxia (1% O2) conditions; then, cell viability and mRNA expression were assessed.

Results: Study 1. The incidence of AKI-CPB was 30% (n = 9). Serum Cr levels before surgery were high in the AKI group. Intraoperative factors did not differ between patients with and without AKI. Univariate analysis revealed significantly higher levels of Sr and arsenic before surgery, and higher Sr, arsenic, and zinc levels after CPB in the AKI group (p < 0.05). Multivariate analysis showed that only Sr levels after CPB withdrawal correlated independently with AKI. Study 2. The Scr and BUN levels were higher in Sr treated rats than vehicle treated rats. Incubating HK-2 cells with Sr did not affect their viability under normoxia and hypoxia conditions. However, NF-kB mRNA levels increased only under hypoxia conditions following exposure to high Sr levels.

Conclusions: High Sr levels before CPB may be a useful predictor of AKI-CPB. This study suggested that high Sr levels enhance ischemia-induced inflammation following CPB.

PO2620
BAM15 and Mitochondrial DNA Form a Drug-Companion Biomarker Pair Working Through Reactive Oxygen Species in Septic AKI

Background: Sepsis is multifactorial, so drug-biomarker co-development is likely necessary for developing effective therapeutics. Administration of BAM15, a mitochondrial uncoupler, improved sepsis AKI mortality, kidney function, and mitochondrial function in kidney tubules (ASN, 2019). We now evaluate if BAM15 and mtDNA form a drug companion biomarker pair and are linked mechanistically.

Methods: Mice with sepsis AKI [cecum ligation/puncture (CLP) in CD-1 mice] were treated with BAM15 (5mg/kg IV) at 0h (early) or 6h (delayed) after surgery. Serial plasma and urinary mtDNA was measured by qPCR. This was mimicked in vitro by incubating mouse primary cultured proximal tubular cells (PTCs) with serum from CLP mice. Mitochondrial superoxide generation was measured by live cell imaging with MitoSox-Red. Mitophagy detected in Mt-Keima mice [transgenic for pH-sensitive ratiometric fluorescent protein] by measuring mitochondrial pH.

Results: Plasma and urinary mtDNA were increased in CLP mice starting at 3 hr after CLP. Delayed treatment with BAM15 (6 hr) decreased mtDNA at 12 hrs (Fig 1).

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
CLP serum stimulated superoxide production and release of mtDNA into cultured PCT media, both were proportionately inhibited by BAM15 (Fig 2A-C). Released mtDNA correlated with superoxide production. BAM15 recovered mitochondrial biogenesis through activation of PGC1α pathway and, inhibited CLP reduction of mitophagy.

**Conclusions:** Sepsis increased kidney mtROS and released mtDNA from PT cells. BAM15 attenuated generation of mtROS and inhibited mtDNA release into urine and also circulating mtDNA even delayed BAM15 treatment. In sepsis AKI, BAM15 changed the trajectory of mitochondrial fate. Our results suggest that BAM15 and mtDNA are mechanistically linked via ROS, and form a drug-companion biomarker pair.

**AKI Identification: Use of Electronic AKI Alerts vs. Electronic Health Records in Hospital Episode Statistics**

**Manuela Saving,1 Anna Casula,1 Esther H. Wong,1 Nitin V. Kolhe,2 James Medical Center,2 Dorothea Nitsch,1 UK Renal Registry, Bristol, United Kingdom; 3 Royal Derby Hospital, Derby; United Kingdom; 4 London School of Hygiene & Tropical Medicine, London, United Kingdom; 5 Leicester General Hospital, Leicester, United Kingdom.

**Background:** Acute Kidney Injury (AKI) refers to an abrupt decline in the glomerular filtration rate (GFR) potentially associated with significant morbidity and mortality. Since April 2015, an automated real-time electronic (e)-alert system for AKI was introduced and progressively implemented in England, with alert data being sent to the UK Renal Registry (UKRR) for collection into a master patient index (MPI). Historically, the only way to routinely measure AKI incidence in hospital was to analyse the Hospital Episode Statistics (HES). This project aims to determine whether episodes of AKI identified in the UKRR MPI correspond to coded diagnoses on the discharge record held in HES.

**Methods:** The UKRR MPI of all AKI e-alerts (stages 1, 2 and 3) identified in AKI (stage 1) and stage 3 (mean 83.3% SD 7.3) (figures 1). Younger adults with AKI e-alerts were less often coded in HES for all three AKI stages (33% people aged 18-29 years versus 64% people aged 85 years).

**Conclusions:** In 2017, earlier stages of AKI e-alerts were poorly coded in HES. There was also high degree of inter-hospital variability, particularly for AKI stage 1, reflecting potentially poor clinical recognition and documentation in medical records and subsequent clinical coding. AKI e-alerts were poorly captured in HES for younger adults in comparison to those of older age. Use of HES to identify cases of AKI is likely to underestimate the incidence of AKI, especially for AKI stage 1, though a high proportion of the most severe cases will be captured.

**Assessment of a Modified Renal Angina Index for the Prediction of AKI in Hospitalized Adult Patients**

Ana A. Mariscal-Campos,1 Roland Clara-Del Grano,2 Clinica Los Olivos, Cochabamba, Bolivia; Plurinational State of, 1BIRMED: Universidad Mayor de San Simon Facultad de Medicina, Cochabamba, Bolivia, Plurinational State of.

**Background:** Risk-stratification tools of incident AKI in hospitalized patients are needed. The renal angina index (RAI) was developed and validated in the pediatric population. The purpose of this study was to evaluate the performance of a modified RAI (mRAI) for the prediction of AKI in hospitalized patients.

**Methods:** We analyzed data from 55 hospitalized patients admitted to our center. Inclusion criteria consisted of age ≥ 18, hospital stay ≥ 3 days, at least 2 serum creatinine (Scr) measures in the first 2 days of hospital stay and one measure at 3-7 days of stay. Exclusion criteria consisted of ESKD, kidney transplant or baseline eGFR <15. At admission, mRAI was calculated using the following formula: **risk level criteria 1** (ICU admission), 2 (mechanical ventilation or vasoactive drug support, and 3) diabetes. **X injury level criteria** of Scr increments of ≥ 0.1 mg/dL, ≥ 0.1 mg/dL, and ≥ 0.4 mg/dL. AKI was defined as an increase of serum creatinine level ≥ 0.3 mg/dL or a 1.5 times within 48 hours or ≥ 1.5 times in contrast to baseline creatinine level. We assessed the performance of the mRAI to predict the subsequent development of AKI using KDIGO Scr criteria.

**Results:** Mean (SD) age was 67.9 (13.3), 47.3% were women and 100% Hispanic. The incidence of AKI at 3-7 days of hospital or ICU stay was 52.7%. Most patients developed AKI stage 1 (61.3%) and 38.7% developed severe AKI (KDIGO-Scr stage 2) at 3-7 days. Performance metrics are reported in Table. The RAI exhibited a good, AUC of 0.87 (95% confidential interval [CI]: 0.77-0.96; p <0.0001) in ROC analysis, with a cutoff of 8.

**Conclusions:** The mRAI have robust predictive capacity to identify hospitalized adults patients at high risk of developing AKI. Incorporation of AKI biomarkers into the RAI may potentially improve prediction. The preliminary data of our ongoing study warrants future studies to validate these findings.

Early Prediction of Hospital-Acquired AKI from Electronic Health Records Using Machine Learning

Gurukeshwara Singh,1 Yirui Hu,1 David Riviello,1 Jason Brown,1 Sara Saunders,2 Andrés García-Arce,3 Kevin Ho,1 H. Lester Kirchner.3

1Geisinger Medical Center, Danville, PA; 2Sanofi Genzyme, Cambridge, MA.

Background: Hospital-acquired acute kidney injury (HA-AKI) leads to increased morbidity and mortality. Early prediction of HA-AKI using Electronic Health Records (EHR) may enable clinicians to modify treatment to minimize risk and AKI severity.

Methods: Inpatient admissions from 7/13/2012 – 7/11/2018 who had serum creatinine measured were included. Patients with end-stage renal disease, length of stay <48 hours and AKI at admission were excluded. A validated algorithm was used to determine baseline renal function. AKI was defined according to KDIGO guidelines. Machine learning algorithms were implemented to predict development of HA-AKI beyond the initial 24-hours of admission. 50 input variables to machine learning algorithms (random forest, XGBoost, regression) included demographics, initial laboratory values taken within the first 24-hours of admission, active medications at time of admission, and prevalent comorbidities. Multiple imputation by chained equations (MICE) was used for missing variables. Univariate Feature Selection was utilized where variables were ranked by evaluating contribution to classification outcome. Randomized search was performed to obtain the optimal hyperparameter set for each algorithm. Models were evaluated using a mean area under the receiver operating characteristic curve (AUC) over 5-fold cross-validation.

Results: Among 209,300 inpatient admissions, 26,410 (12.6%) developed HA-AKI. Using AKI prediction, the AUC of the full model was 0.88 for both random forest and XGBoost, and 0.86 for logistic regression. To balance the tradeoff between model simplicity and performance, 23 variables from univariate feature selection evaluated using random forest were selected in predicting HA-AKI (AUC = 0.67). The probability cutoff-off point of AKI prediction outcome was determined using Youden’s Index based on the balance between false positives and false negatives. A probability cutoff of > 0.23 provided sensitivity and specificity of 78% and 81%, respectively.

Conclusions: Our machine learning algorithm applied at 24 hours of admission identified patients at risk for HA-AKI with excellent accuracy. Significant variables included in this algorithm should be monitored in real-time to allow early identification and preventive interventions in patients at risk for HA-AKI.

A Meta-Analysis of Clinical Predictors for Renal Recovery and Mortality in AKI Requiring Continuous Renal Replacement Therapy

Panupong Hansrivijit,1 Max Puthepun,2 Nasrollah Gharahmani,3 Charat Thongprayoon,2 Wisit Cheungpasitporn.3

1UMPC Pinnacle, Harrisburg, PA; 2MPV Clinic Admissions, Rochester, MN; 3Penn State College of Medicine, Hershey, PA. 1University of Mississippi Medical Center, Jackson, MS; 3Drexel University College of Medicine, Philadelphia, PA.

Background: Acute kidney injury (AKI) is a common complication in critically ill patients and can result in a broad spectrum of severity. It is well-established that severe AKI requiring continuous renal replacement therapy (CRRT) carries a significant risk for increased mortality compared to non-dialysis AKI. However, there are no consensus guidelines describing the discontinuation criteria from CRRT. Thus, we performed this meta-analysis to determine the clinical predictors for CRRT discontinuation and overall mortality in patients with AKI.

Methods: Ovid MEDLINE, EMBASE, and Cochrane Library were searched without language restrictions up to January 2020. Our inclusion criteria included patients ≥ 18 years of age, AKI stage 2+. The area under the curve (AUC) was 0.76 (95% bootstrap confidence interval 0.66-0.84). A probability cutoff of > 0.7 predicted renal recovery with 88% sensitivity and 80% specificity. To balance the tradeoff between model simplicity and performance, 23 variables from univariate feature selection evaluated using random forest were selected in predicting HA-AKI (AUC = 0.67). The probability cutoff-off point of AKI prediction outcome was determined using Youden’s Index based on the balance between false positives and false negatives. A probability cutoff of > 0.23 provided sensitivity and specificity of 78% and 81%, respectively.

Conclusions: Our machine learning algorithm applied at 24 hours of admission identified patients at risk for HA-AKI with excellent accuracy. Significant variables included in this algorithm should be monitored in real-time to allow early identification and preventive interventions in patients at risk for HA-AKI.

Regional Variation in Recovery of Kidney Function in Patients Requiring Maintenance Hemodialysis with Acute Tubular Necrosis

Yuetting D. Kwong,1 Kirsten L. Johansen,2 Charles E. McCulloch,1 Kathleen D. Liu,2 Barbara A. Grimes,3 Elaine Ku.1

1University of California San Francisco, San Francisco, CA; 2Hennepin Healthcare, Minneapolis, MN.

Background: Geographic variations in the likelihood of recovery of kidney function in ESKD attributed to acute tubular necrosis (ATN) has not been well established.

Methods: Using data from United States Renal Data System, we performed a retrospective cohort study of incident maintenance hemodialysis (HD) patients between 1/1/1996-12/31/2015 with ESKD attributed to ATN followed up to 1 year. Recovery of kidney function was defined as discontinuation of HD for at least 90 days and alive without the need for kidney transplantation during this period. We used Fine-Gray models to determine unadjusted and adjusted hazard of recovery while accounting for the competing risk of death.

Results: In 48,771 patients included for analysis, 30% recovered kidney function within 1 year. Most patients received HD within a 10-mile radius of their home. Recovery rates at 1 year were lowest in the northeast and highest in the south; lower in metropolitan compared to micropolitan/rural areas. Recovery of kidney function was less likely to occur with distance between patient and dialysis facilities in adjusted analysis.

Conclusions: Patients living in rural/micropolitan locations and receiving dialysis close to home had higher recovery rates. Studies examining regional differences in practice patterns are warranted.

Adequacy of Kidney Follow-Up Among AKI Survivors After Hospital Discharge

Background: Acute kidney injury (AKI) affects 20% of hospitalized patients and results in long-term adverse outcomes. To limit its complications, post-discharge follow-up is advised. The objective of the study was to evaluate the frequency of appropriate follow-up after discharge among AKI survivors.

Methods: This was a population-based cohort study of adult Olmsted County residents hospitalized at their local hospital (Mayo Clinic in Rochester, MN) with an episode of stage II or III AKI between 2006 and 2014. Those dismissed from the hospital on dialysis or who died within 30 days after discharge were excluded. The cumulative incidence of adequate kidney follow-up defined by a serum creatinine (SCr) level and/or an in-person healthcare visit within 30 days, 90-days, or 1-year after discharge was described.

Results: There were 563 survivors of AKI studied (Stage II: N=360 (64%); Stage III: N=203 (36%)). The 30-day cumulative incidence of follow-up with SCr was 78% (95% confidence interval (CI): 74%, 81%), by provider visit was 80% (95% CI: 77%, 83%), by both SCr assessment and provider visit was 70% (95% CI: 65%, 73%). Within 90-days and 1-year, the cumulative incidences of both SCr assessment and provider visit rose to 81% and 91%, respectively. Within 30-days after discharge, only 13% (95% CI: 10%, 16%) of these stage II or III AKI survivors saw a nephrologist. The statistically significant predictors of receiving both a SCr assessment and provider visit within 30-days included higher body mass index, worse baseline and discharge kidney function, higher comorbidity burden, greater maximum AKI severity, and longer duration of AKI during the hospitalization. Age, sex, race/ethnicity, education status, and socioeconomic status did not predict kidney follow-up.

Conclusions: These data demonstrated that 30% of patients with moderate to severe AKI received insufficient kidney follow-up in the 30-day post-discharge interval. Medical risk factors rather than social/demographic characteristics were the primary determinants of kidney follow-up.

Funding: Other NIH Support - National Institute of Allergy and Infectious Diseases of the National Institutes of Health under Award Number K23AI143882; National Center for Advancing Translational Sciences Grant Number UL1 TR002377; National Institute on Aging of the National Institutes of Health Award Number R01AG034676.

Predicting Intra-ICU Mortality Using Machine Learning Algorithms in Patients Who Require Acute Renal Replacement Therapy in a Critical Care Unit

Hsin-Hsiung Hsin, Kianoush Kianoush, Hsin-Hsiung Adequacy of Kidney Follow-Up Among AKI Survivors After Hospital Discharge

Background: Acute kidney injury (AKI) occurs in over 20% of hospitalized patients and is associated with both long-term morbidity and mortality. The purpose of this study is to identify risk factors for readmission for renal cause and mortality following a hospitalization with AKI in US Veterans.

Methods: AKI was defined as a creatinine increase of ≥0.3 mg/dL or at or after admission in ≥1 VA hospital between 2013 and 2018. The primary outcomes were death and hospital readmission for a renal indication. Proportional hazards frailty model was applied. Variables evaluated included demographics, comorbidities, and laboratory data. The final model was chosen based on clinical relevance and parsimony.

Results: From a cohort of 624,822 Veterans with AKI, 218,839 (35%) met inclusion criteria. Reasons for exclusion were <1 year of prior patient data (35%), missing serum creatinine values (14%), palliative status or metastatic cancer (13%), or death during the hospitalization (4%). AKI was present on admission in 71% of patients and developed after admission in 29%. Overall, 48,202 (22%) died within one year. Between 2013 and 2018, 101,170 (46%) died and 21,116 (9%) experienced a renal readmission. The patient characteristics associated with increased hazard of death included age (HR=1.53 per 10 years, CI 1.52-1.54, p<0.001), male sex (HR=1.27, CI 1.22-1.32, p<0.001), heart failure (HR=1.55, CI 1.53-1.57, p<0.001), prior myocardial infarction (HR=1.14, CI 1.11-1.17, p<0.001), lower eGFR, lower systolic blood pressure, lower serum albumin, and higher serum creatinine. The intra-ICU mortality AUC of machine learning algorithms was calculated using the area under the receiver operating characteristic curve (AUC). The intra-ICU mortality AUC of the Sequential Organ Failure Assessment (SOFA) score using data collected one day prior to RRT initiation was 0.683 (95% CI 0.636-0.729) in MICU and 0.685 (95% CI 0.630-0.729) in IMICU. The intra-ICU mortality AUC of machine learning models using logistic regression (LR), XGBoost, random forest (RF) and multilayer perceptron (MLP) trained in eICU were 0.858 (95% CI 0.850-0.867), 0.858 (95% CI 0.850-0.866), 0.859 (95% CI 0.848-0.870), 0.864 (95% CI 0.851-0.876) and validated in MIMIC were 0.799 (95% CI 0.770-0.824), 0.809 (95% CI 0.780-0.833), 0.814 (95% CI 0.791-0.837), 0.800 (95% CI 0.776-0.825), respectively. When training the models using MIMIC dataset, the intra-ICU mortality AUC of LR, XGBoost, RF and MLP were 0.818 95% CI (0.786-0.852), 0.821 (95% CI 0.787-0.856) 0.822 (95% CI 0.791-0.854), 0.827 (95% CI 0.795-0.858), respectively. Validating these models using eICU dataset, the AUC of LR, XGBoost, RF and MLP were 0.846 95% CI 0.828-0.864, 0.847 95% CI 0.829-0.865, 0.853 (95% CI 0.835-0.870), 0.846 (95% CI 0.828-0.865), respectively.

Conclusions: In this study, we designed machine learning models to make intra-ICU mortality prediction for patients who required RRT. Our models correlated better that those used in the prior mortality prediction of patients requiring RRT in ICU. All of the models almost had excellent performance in both databases.
PO0011

Region-wide Implementation of Best Practice in AKI

Anirudh Rao, Kottarathil A. Abraham. On behalf of the Cheshire & Merseyside Acute Kidney Injury Network (CHAMKIN) Liverpool University Hospitals NHS Foundation Trust, Liverpool, United Kingdom.

Background: The Cheshire & Merseyside Acute Kidney Injury Network, United Kingdom, rolled out best practice guidelines of 13 interventions for Acute Kidney Injury (AKI) in October 2014. The aim was to assess the impact of the guidelines.

Methods: Setting & Population: Hospitals in Cheshire & Merseyside. Predictor: Time period before & after introduction, allowing six-month bedding in period. Outcome: Percentage AKI: Number of AKI per month, divided by total number of admissions/month expressed as %. Percentage AKI deaths: Number of AKI related deaths per month divided by total deaths/month expressed as %. Data analysis: Descriptive & Piecewise Linear Regression.

Results: The region saw a notable increase in the number of admissions/month (31.173 vs 38.443) and AKI episodes (4,871 vs 44,493) in the 8 hospitals in pre and post guideline implementation period. Five hospitals were excluded due to guideline implementation pre-roll out (2), implementation dates not provided (2) & no pre-post implementation data (1). The outcomes in the 2 periods are detailed in the Table. The introduction of E-alert saw an increase in AKI detection across the hospitals. The figure shows longitudinal piecewise regression curves. The most significant reduction was noted in hospital A.

Conclusions: The rollout of interventions caused an increased and sustained recognition of AKI, across the hospitals. The % AKI deaths stayed the same except in hospital A. We theorise that the onsite nephrology team in Hospital A aided implementation of the guidelines and training of wider healthcare staff which made the impact. This study highlights the hurdles faced in implementing AKI improvement strategies across various healthcare settings.

PO0013

Incidence and Impact of AKI on Patients with Implantable Left Ventricular Assist Devices: A Meta-Analysis

Charat Thongprayoon,1 Wisit Cheungpasitporn,2 Panupong Hansrivijit,2 Takayuki Miyashita,1 Swetha Rani Kanduri,3 Michael Jaracz1,4 Klimoussh Kasirajan1
1Mayo Clinic Minnesota, Rochester, MN; 2University of Mississippi Medical Center, Jackson, MS; 3UPMC Pinnacle, Harrisburg, PA; 4Medical University of South Carolina, Charleston, SC; 5Mayo Clinic’s Campus in Florida, Jacksonville, FL.

Background: This systematic review and meta-analysis was performed to evaluate the acute kidney injury (AKI) incidence and its associated risk of mortality in patients with implantable left ventricular assist devices (LVAD).

Methods: A systematic literature search in MEDLINE, EMBASE, and Cochrane Databases was conducted through January 2020 to identify studies that provided data on the AKI incidence, and AKI-associated mortality risk in adult patients with implantable LVADs. Pooled effect estimates were examined using random-effects, generic inverse variance method of DerSimonian-Laird.

Results: 56 cohort studies with 63,663 LVAD patients were enrolled in this meta-analysis of AKI incidence. The pooled incidence of reported AKI was 24.9% (95%CI: 20.1%-30.4%), but rose to 36.9% (95%CI: 31.1%-43.1%) when applying the standard definition of AKI per RIFLE, AKIN, and KDIGO criteria. The pooled incidence of severe AKI requiring renal replacement therapy (RRT) was 12.6% (95%CI: 10.5%-15.0%). AKI incidence did not differ significantly between types of LVAD (p = 0.35) or indication for LVAD use (p = 0.62). While meta-regression analysis did not demonstrate a significant association between study size and overall AKI incidence (P=0.55), the study year was negatively correlated with incidence of severe AKI requiring RRT (slope = -0.068, p <0.001). The pooled odds ratios (ORs) of mortality at 30 days and 1 year in AKI patients were 3.66 (95% CI, 2.00-6.70) and 2.22 (95% CI, 1.62-3.04), respectively. The pooled ORs of mortality at 30 day and 1 year in severe AKI patients requiring RRT were 7.52 (95% CI, 4.58-12.33) and 5.41 (95% CI, 3.63-8.06), respectively.

Conclusions: 37% of LVAD patients developed AKI based on standard definitions and 13% developed severe AKI requiring RRT. There has been potential improvement in the incidence of severe AKI requiring RRT for LVAD patients. AKI in LVAD patients was associated with increased 30-day and 1-year mortality.

PO0014

AKI in the Emergency Department: A Prospective Case-Control Study

Telma H. Ragnarsson1,2, Magret Kristjansdottir1,2, Greilis Glisn1,2, Vicente Sanchez-Brunete1,3, Margret O. Tomasdottrir1,2, Olafur H. Samuelsson1, Runolfur Palsson1,2, Olafur S. Indridsson1,1 Landspitali University Hospital, Reykjavik, Iceland; 2University of Iceland, Faculty of Medicine, Reykjavik, Iceland; 3Primary Health Care of the Capital Area, Reykjavik, Iceland.

Background: Acute kidney injury (AKI) is an abrupt decline in kidney function that occurs in hours or days. AKI has been thoroughly studied in the hospital setting, however data on community-acquired AKI are scarce. The aim of this study was to investigate the incidence, causes and prognosis of patients presenting with AKI to the emergency department (ED).

Methods: This was a prospective case-control study in which serum creatinine (SCr) measurements of all patients presenting to the ED of Landspitali–The National University Hospital in Reykjavik were examined for the presence of AKI. The study started on January 1, 2020, and we present data until March 3, 2020. All patients who met the criteria for AKI were invited to participate. Randomly selected control cases (1:2) were paired according to age, sex and time of ED admission. Participants signed informed consent and were questioned about their medical history, habits and use of medications, including over-the-counter (OTC) medications and supplements, in the week prior to admission. Medical records were also reviewed with regard to prior diseases and medical prescriptions.

Prehospital Systolic Blood Pressure and Lactate Are Early Predictors of AKI After Trauma: A Prospective Validation Study
Toru Nasu,1 Kentaro Ueda,1 Shuji Kawashima,1 Yuko Okishio,1 Kosei Kunitatsu,1 Yasuhiro Iwasaki,2 Seiya Kato.1 1Wakayama Medical University, Wakayama, Japan; 2Wakayama Rosai Hospital, Wakayama, Japan.

Background: We have already reported that prehospital systolic blood pressure and lactate can be predictive factors for acute kidney injury (AKI) after trauma. This study is a prospective validation study to determine whether these risk factors are helpful.

Methods: We evaluated all trauma patients who were admitted from January 2019 to December 2019. Patients who were <10 years of age, patients with burns, and patients with chronic kidney disease were excluded from the present study. AKI was defined according to the risk, injury, failure, loss of the kidney function, and end-stage kidney disease (RIFLE) classification from serum creatinine alone.

Results: Four hundred and three patients were included in the analysis. The prevalence of AKI in the overall population was 14.7% including 11.7% of patients with stage R, 2.0% of patients with stage I and 1.0% with stage F. The incidence of stage I and F AKI in the high-risk group (5 of 38 patients, with the positive predictive value of 13.2%) was significantly higher (P=0.001) than that in the low-risk group (7 of 358 patients, with the negative predictive value of 98.1%).

Conclusions: The prehospital systolic blood pressure and early hospital arterial lactate showed good performance in the early prediction of AKI after trauma. These parameters are associated with the early onset of AKI after trauma and may be an early predictor of the effects of treatment to prevent AKI.

PO0016
Association of Race and Risk of Future Scleroderma Renal Crisis at Systemic Sclerosis Diagnosis
Crystal Forman,1 Stephen W. Olson,2 Sarah M. Gordon,2 James B. Hughes,2 Rodger S. Stitt,3 Wayne Bailey,3 Jess D. Edison,2 Robert Nec.2 1San Antonio Uniformed Services Health Education Consortium, Fort Sam Houston, TX; 2Walter Reed National Military Medical Center, Bethesda, MD.

Background: Scleroderma renal crisis (SRC) is a rare and severe manifestation of systemic sclerosis (SSc). Although it is well documented that Blacks with SSc have worse morbidity and mortality than non-Blacks, racial predilection for SRC is underreported. We examine the association of race and future development of SRC in an SSc cohort.

Methods: Using the electronic medical record of the U.S. Military Health System Databank for Cardiovascular Disease (DDCD) who underwent PCI at Duke between January 1, 2003 and December 31, 2013. AKI was defined as a 1.5-fold increase in serum creatinine from outpatient reference value before PCI to the peak value within 7 days post-PCI or a 0.3 mg/dl increase from the reference value within 48 hours. We used logistic regression adjusted for demographics, comorbidities, predispensing medications (NSAIDS, RAAS inhibitors, diuretics), PCI indication (presenting with vs without acute coronary syndrome), peri-procedural prophylaxis with IV fluids and n-acetylcysteine, urgency of PCI and BP at time of PCI.

Results: Of 9422 patients (median age 63y [IQR 54 to 72]; 33% female; 75% white, 20% black, 5% other race), 9% developed AKI: 14% of blacks, 8% of whites, 10% in other race groups. After adjustment, black race was associated with greater likelihood of AKI: odds ratio (OR) 1.80 in black (vs white) patients (95% confidence interval (CI) 1.49 to 2.18. Compared to white, other race was not associated with AKI: OR 1.31, 95% CI 0.91 to 1.87. Low baseline eGFR was associated with graded, higher likelihood of AKI for trend <0.001. There was no interaction between race and baseline eGFR.

Conclusions: Black patients had nearly twice the likelihood for AKI following PCI than whites despite adjustment for baseline kidney function, prophylaxis and procedural characteristics. Future investigations should identify other factors that predispose black individuals to disparate AKI risk following PCI.

PO0017
Racial Differences in AKI Following Percutaneous Coronary Intervention
Joseph Lunyera,1 Robert M. Clare,2 Karen Chiswell,2 Julia J. Scialla,2 Patrick H. Pun,2,3 Kevin L. Thomas,2,3 Monique Starks,2,3 Clarissa J. Diamantidis.1 1Duke University School of Medicine, Durham, NC; 2Duke Clinical Research Institute, Durham, NC; 3University of Virginia School of Medicine, Charlottesville, VA.

Background: Percutaneous coronary intervention (PCI) is a risk factor for AKI, but few studies have quantified racial differences in AKI incidence following PCI. Methods: We examined the association of self-reported race – black, white, and other – and baseline eGFR with AKI incidence among patients captured in the Duke Databank for Cardiovascular Disease (DDCD) who underwent PCI at Duke between January 1, 2003 and December 31, 2013. AKI was defined as a 1.5-fold increase in serum creatinine from outpatient reference value before PCI to the peak value within 7 days post-PCI or a 0.3 mg/dl increase from the reference value within 48 hours. We used logistic regression adjusted for demographics, comorbidities, predispensing medications (NSAIDS, RAAS inhibitors, diuretics), PCI indication (presenting with vs without acute coronary syndrome), peri-procedural prophylaxis with IV fluids and n-acetylcysteine, urgency of PCI and BP at time of PCI.

Results: Of 9422 patients (median age 63y [IQR 54 to 72]; 33% female; 75% white, 20% black, 5% other race), 9% developed AKI: 14% of blacks, 8% of whites, 10% in other race groups. After adjustment, black race was associated with greater likelihood of AKI: odds ratio (OR) 1.80 in black (vs white) patients (95% confidence interval (CI) 1.49 to 2.18. Compared to white, other race was not associated with AKI: OR 1.31, 95% CI 0.91 to 1.87. Low baseline eGFR was associated with graded, higher likelihood of AKI for trend <0.001. There was no interaction between race and baseline eGFR.

Conclusions: Black patients had nearly twice the likelihood for AKI following PCI than whites despite adjustment for baseline kidney function, prophylaxis and procedural characteristics. Future investigations should identify other factors that predispose black individuals to disparate AKI risk following PCI.

PO0018
The Spectrum of Biopsy-Proven Kidney Diseases in 2027 Patients with AKI
Zuilhumaer Abduwupuer, Shao-shan Liang, Feng Xu, Dandan Liang, Xue Yang, Ying Zhu, Zhihong Liu, Cai-hong Zeng. National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China.

Background: Acute kidney injury (AKI) is a group of highly heterogeneous, complicated clinical syndrome. The kidney biopsy plays an irreplaceable role in the evaluation of patients with unexplained AKI and may offer fresh insights into disease heterogeneity. Hence, in this study we aim to analyze the pathological disease spectrum, etiology, and renal recovery of biopsy-proven AKI patients.

Methods: We retrospectively analyzed the clinical and pathological data of AKI patients who went to a kidney biopsy during the hospitalization at our center from January 2013 to December 2018. We classified included patients into pure AKI and ACKD two groups.

Higher Ambient Level of Nitrogen Dioxide Is Associated with an Increased Risk of AKI
Xin Xu, Yanli Li, Lincou Zhang, Fan Fan Hou. Xin Xu Nantang Hospital, Southern Medical University, Guangzhou, China.

Background: Previous studies have suggested that long-term exposure to air pollution increased the risk of chronic kidney disease and its progression. However, the effect of air pollution on the risk of acute kidney injury (AKI) has not been studied.

Methods: We selected from the Epidemiology of AKI in Chinese Hospitalized Patients (EACH2 study) AKI cases of which the onset date could be unambiguously determined. We obtained city-specific daily averages of the ambient level of PM2.5, CO, NO2, SO2 and O3 from the Ministry of Environmental Protection of China. We used the time-stratified case crossover approach to examine the association between the ambient level of air pollutants and the risk of AKI in the selected cases.

Results: A total of 11,923 AKI cases that met the inclusion and exclusion criteria were selected, of which, 3175 (28.1%) were severe AKI (stage 2 or 3). In unvariable analysis, the ambient levels of NO2 and SO2 were significantly associated with the risk of AKI. In the multivariable analysis that incorporated all six pollutants in the same model, NO2 was the sole pollutant whose level remained to be associated with the risk of AKI (p<0.001). The relationship between level of NO2 and the risk of AKI appeared to be linear, with an estimated odds ratio of 1.072 (95% CI: 1.033, 1.113) for each increment of one standard deviation in the exposure. The association was consistent across the subgroups stratified by age, gender, baseline eGFR, AKI severity, need for intensive care, and season.

Conclusions: Higher ambient level of NO2 was associated with an increased risk of AKI in hospitalized adults in China.
PO0023
Decreased Urinary Uromodulin Is Potentially Associated with AKI: A Systemic Review and Meta-Analysis
You Ruilian, Hua Zheng, Limeng Chen. Peking Union Medical College Hospital, Beijing, China.
Background: Conventional diagnostic criteria based on the serum creatinine isn’t sensitive enough to detect Acute Kidney Injury (AKI) timely. Urinary uromodulin (uUMOD) is one of the novel biomarkers being studied for the value of predicting AKI. However, currently available publications showed inconsistent outcomes. This meta-analysis aimed to evaluate the potential association between uUMOD and AKI.
Methods: We searched research articles in Pubmed-Medline, Web of Science, Cochrane library, Embase, China National Knowledge Infrastructure, and Weipu Database(up to 2020.3). Random-effects models were used to estimate the standardised mean difference (SMD) between AKI and Non-AKI. The sensitivity analysis was conducted using the leave-one-out method. Random-effects meta-regression was performed to evaluate the impact of potential confounders on age and surgery.
Results: The meta-analysis was comprising 2678 subjects of 8 studies, which showed that the uUMOD in the patients with AKI was significantly lower than the Non-AKI patients (SMD = -0.77, P = 0.001, 95% confidence interval -1.07, -0.47). Subgroup analysis indicated a significant difference in different ages and surgery group (Figure1-2). Sensitivity analysis displayed the synthetic outcome always in the 95% CI of the pool SMD suggesting a robust result.
Conclusions: The study suggests a potential negative association between uUMOD and AKI. Further studies are needed to investigate the promising diagnostic values and mechanisms in protecting AKI.

PO0025
Relationship of Loop Diuretic with Hospital-Acquired AKI: A Multicenter, Propensity Score-Matching Analysis
Yanqin Li, Licong Su, Xin Xu. Nanfang Hospital of Southern Medical University, Nephrology Guangzhou, China; National Clinical Research Center for Kidney Disease; State Key Laboratory of Organ Failure Research, Guangzhou, China.
Background: Loop diuretics have been widely used to prevent and treat acute kidney injury (AKI). However, there is no clear consensus on the role of loop diuretics in AKI. Methods: The Epidemiology of AKI in Chinese Hospitalized patients is a multicenter retrospective cohort included 3,044,024 hospitalized patients from 25 tertiary hospitals across China during 2013-2015. Patient data were obtained from the electronic hospitalization information system. We selected 575,895 adult patients who had at least two serum creatinine tests within any 7-day window during their first 30 days of hospitalization and excluded those with end-stage renal disease, community-acquired AKI and without prescription data. AKI was defined using the SCr data by the Kidney Disease Improving Global Outcomes criteria. Exposure to Loop diuretics as any filled prescription within 14 days prior to the detection date of AKI in patients with HA-AKI and within 14 days prior to the last SCr testing date in those without AKI. Propensity scores (PS) were calculated using a logistic regression model with age, gender, hospital, division, baseline SCr, SCr testing times, comorbidities, operation procedures, need for intensive care and exposure to other nephrotoxic drugs. Moreover, the inverse probability of the treatment weighting (IPTW) method and standardized mortality ratio weighting method was also used.
Results: Of 575,895 adult analysed, 20,599 (35.8%) used diuretics, 17,077 (29.7%) used loop diuretics, and 6277 (10.9%) had HA-AKI events during hospitalization. 8,274 pairs matched after nearest-neighbor matching without replacement and within caliper width (0.2*SD of the logit of PS). By IPTW, use of loop diuretics was associated with a significantly increased risk of HA-AKI compared with non-users (OR, 1.39; 95% CI, 1.28-1.52). The associations were consistent across multiple regression models. Conclusions: Loop diuretics were widely used and associated with an increased risk of HA-AKI in hospitalized adult in China.

AKI and Bleeding Risks Associated with Vitamin K Antagonists and Antiplatelet Agents in Patients with CKD

S. M. Laville,1 Marie Metzger,1 Agnès Hamroun,8,6 Oriane Lambert,1 Christian Jacqueminet,1 Maurice Laville,1 Luc Frimat,1 Denis Fouque,1 Christian Combe,1 Roberto Pecotis-Filho,2 Benedicte Stengel,1 Ziad Massry,1 Soroush Labbeif1 (1) INSERM U1026, (2) Université Paris-Saclay University, UVSQ, Villejuif, France; (3) Agence de la biomédecine, France; (4) Arbor Research Collaborative for Health, Ann Arbor, MI; (5) Bordeaux, Bordeaux, France; (6) INSERM, U1026, Univ Bordeaux Segalen, Bordeaux, France; (7) Regional and University Hospital Center of Lille, Nephrology Department, Lille, France; (8) Department of Nephrology, Ambroise Pare University Hospital, APHP, Boulogne-Billancourt, France; (9) Department of Clinical Pharmacology, Amiens University Hospital, Amiens, France; (10) MP3CV Laboratory, EA7517, University of Picardie Jules Verne, Amiens, France; (11) Arber Research Collaborative for Health, Ann Arbor, MI.

Background: Anticoagulation in patients with chronic kidney disease (CKD) is challenging because of altered pharmacodynamics/pharmacokinetics. Patients prescribed vitamin K antagonists (VKA) are at high risk of bleeding, and possibly also acute kidney injury (AKI). We assessed bleeding and AKI risks associated with VKA and/or antiplatelet agents (AP) prescription in patients with moderate or advanced CKD.

Methods: We studied a cohort of 3022 nephrology outpatients with CKD stages 2-5 in 25 academic medical centers. Drug prescriptions and their duration were collected prospectively. We used cause-specific Cox proportional hazard models to estimate hazard ratios (HR) of bleeding (identified through hospitalizations) and AKI (as defined according to KDIGO 2012) associated with VKA only, AP only, or VKA + AP prescriptions treated as a time-dependent variable and adjusted for baseline comorbidities, laboratory data, and medications.

Results: At baseline, 65% of the patients were men, median age was 69 (interquartile range (IQR), 60-76), median eGFR was 32 mL/min/1.73m² (IQR, 23-41), 328 (10%) patients were prescribed VKA only, and 1196 (40%) AP only, and 100 (3%) both VKA and AP. Over a median follow-up of 3.0 years (IQR, 2.6-3.1), 71 (2%) patients were newly prescribed VKA and 187 (6%) AP; 152 patients experienced a bleeding event requiring hospital visit/stay (crude incidence rate (IR): 1.9% person-years [95%CI, 1.6-2.2]) and 414 patients developed AKI (crude IR: 1.3% person-years [95%CI, 1.1-1.5]). Adjusted HRs for bleeding associated with prescriptions of AP only, VKA only and AP+VKA were 0.77 [95% CI, 0.48-1.22], 2.29 [95%CI, 1.41-3.73] and 3.77 [95% CI, 2.06-6.83], respectively. Prescription of VKA was associated with increased AKI risk, adjusted HR, 1.79 [95% CI, 1.39-2.32] but not that of AP, 1.19 [95% CI, 0.94-1.49].

Conclusions: This study confirms the high risk of AKI associated with VKA prescription in CKD patients. It also highlights the potential aggravating effect of combining VKA and AP on the risk of bleeding in this population.

Use of Ibuprofen and the risk of Hospital-Acquired AKI in Children

Liong Su, Yangin Li, Xin Xu. Nanfang Hospital, Southern Medical University, Guangzhou, China.

Background: Ibuprofen is widely used in children worldwide, especially in children with cancer, fever or trauma. However, large and high-quality studies on the association between ibuprofen and acute kidney injury (AKI) in children have been lacking.

Methods: The Epidemiology of AKI in Chinese Hospitalized patients (EACH2 study) is a multicenter, retrospective study of 3,044,023 patients admitted from 1st July 2015 to 30th December 2017 from the largest tertiary hospital and a major public primary care institution in Singapore. Laboratory, hospitalization and medication data from 6 months before until 30 days after enrollment were collected. Individuals prescribed ibuprofen within 30 days of hospitalization were identified as the “ibuprofen group” and the controls were matched to the “ibuprofen group” based on age, gender, and hospital and division. Laboratory, other nephrotoxic drugs use and stratification by hospital and division. We compared the effect sizes of ibuprofen among subgroups stratified by age, gender, chronic kidney disease, need for intensive care and exposure to other nephrotoxic drugs.

Results: Among 50,420 children who met the inclusion and exclusion criteria, 5,526 (11.0%) were ibuprofen users, and 3,476 (6.9%) had AKI during hospitalization. Ibuprofen use was associated with significantly increased risk of AKI (hazard ratios, 1.52 [95% CI, 1.11-2.04]) after adjusting for age, sex, and baseline eGFR. The greatest nephrotoxic potential of ibuprofen was observed in children who had chronic kidney disease, required intensive care, or were of elder age.

Conclusions: Ibuprofen was widely used and associated with an increased risk of HA-AKI in hospitalized children in China.

Nonsteroidal Anti-Inflammatory Drugs and Risk of Acute Adverse Renal Outcomes in Hospitalized Children

Cynthia C. Lim,1 Hanis B. Abdul Kadir,1 Jason Choo Chun Jun,1 Teck W. Ang,2 Yong Mong Bee,2 Nguei chuan Tan,2 Singapore General Hospital, Singapore, SG, Singapore, Singapore; (3) Singapore Health Polyclinics, Singapore, Singapore.

Background: Individuals with diabetes mellitus (DM) may be susceptible to non-steroidal anti-inflammatory drug (NSAID)–induced acute kidney injury (AKI). However, information on their risk of NSAID-related adverse renal events is sparse. We aimed to estimate the risk and factors for acute kidney injury and/or hyperkalemia after NSAID prescription to individuals with DM.

Methods: Retrospective cohort study of individuals a21 years with DM who received prescriptions during 1st July 2015 and 30th December 2017 in the largest tertiary hospital and a major public primary care institution in Singapore. Laboratory, hospitalization and medication data from 6 months before until 30 days after first prescription were collected from electronic medical records. Individuals prescribed ibuprofen >14 days before index date were excluded from the “NSAID group”. We included those with systemic NSAID in the preceding 6 months, missing laboratory values, or had baseline estimated glomerular filtration rate (eGFR) <15 ml/min/1.73 m². The outcome was the incidence of AKI (serum creatinine increased >50%) and/or hyperkalemia (serum potassium >5.5 mmol/L) within 30 days after prescription.

Results: We studied 3896 individuals (mean age 65.4 ± 13.3 years) with incident prescriptions: 138 in the NSAID group and 3758 in the non-NSAID group. 30-day AKI and/or hyperkalemia occurred in 525 individuals (13.5%). After adjusting for age, gender, diabetes, renal baseline eGFR, serum potassium, NSAID, RAAS blocker and diuretic, baseline eGFR (adjusted OR 1.41, 95% CI 1.02-1.93, p=0.03) and RAAS blocker (adjusted OR 1.42, 95% CI 1.15-1.75, p<0.001) were independent predictors for the outcome. NSAID prescription for ≥4 days was associated with a higher risk of AKI (adjusted OR 1.62, 95% CI 1.09-2.65, p=0.05). However, the risk of AKI and/or hyperkalemia was markedly increased if NSAID was prescribed concurrently with RAAS blocker (adjusted OR 4.17, 95% CI 1.74-9.98, p<0.001) or diuretic (adjusted OR 3.31, 95% CI 1.90-9.08, p=0.04). More importantly, ≥4-day NSAID prescription was associated with higher 30-day risk of AKI and/or hyperkalemia, especially with concurrent RAAS blocker or diuretic.

Funding: Private Foundation Support

A Retrospective Cohort Study of Chemotherapy-Related AKI

Xin Kang, Li Yang. Renal Division, Peking University First Hospital, Peking University, Beijing, China.

Background: Chemotherapy-related acute kidney injury (CR-AKI) is increasing with the growing number of cancer patients and the development of chemotherapeutic agent. The systemic inflammatory status in AKI is still underestimation.

Methods: This is a multicenter retrospective cohort study of cancer patients with CR-AKI screened from a cohort of hospital-acquired adult AKI patients based on a nationwide AKI survey in China. The enrolled CR-AKI patients were divided into three groups according to peak AKI stages (1 to 3) during hospitalization. The primary outcome was all-cause death in hospital, and the secondary outcome was AKI recovery.

Results: Of 3,468 adult inpatients with hospital-acquired AKI identified basing on the China nationwide AKI survey, 258 patients with CR-AKI were enrolled in our study, of which 20.1% (52/258) were ≥70 years old. A total of 413 person-time chemotherapeutic agents were related to AKI, of which platinum compounds (24.5%, 101/413) were the most common ones, followed by fluoropyrimidines (13.1%, 54/413), and anthracyclines (9.2%, 38/413). Among the 258 CR-AKI patients, 61 (23.0%) reached AKI stage 3, and 144 (55.7%) received RRT in the hospital mortality (17.9, 48/264). Of 907 surviving patients with a reliable serum creatinine value at discharge, 48.3% (100/207) failed to renal recovery. AKI stage 3 remained the independent risk factor for in-hospital death (OR 2.930, 95% CI 1.156-7.427) after adjustment for age, gender, comorbidities, and medications. It is surprising to note that, although patients of AKI stage 1 had lower levels of SCr both at peak and at discharge compared to patients of AKI stage 2 or 3, there was a higher proportion of patients of AKI stage 1 not achieving renal function significantly improved at discharge (failure to recover) compared to those of AKI stage 2 or 3 (57.1% vs. 41.4% vs. 36.4%, P = 0.032). More importantly, a lot more AKI episodes were not recognized or diagnosed by physicians in charge in patients of AKI stage 1 compared to the other two groups (82.8% vs. 60.0% vs. 36.1%, P < 0.001).

Conclusions: CR-AKI accounted for a considerable proportion of hospital-acquired AKI. Severe CR-AKI increases in-hospital mortality. Mild CR-AKI that overlooked by physicians sustained kidney injury was common in these patients. Recognizing CR-AKI at an early stage and making personalized treatment should be emphasized when offering chemotherapy to patients.
PO0030

Characterizing AKI from Vancomycin-Associated Nephrotoxicity in Adult Non-ICU Patients at an Inner City Hospital: Incidence and Predictors

Gerald Fletcher,1,5 Levard G. Roberts,1,2 Sai S. Achi,1 Sheldon Ferguson,1 Maryam M. Handoo,1 Richard S. Sheppard,2 Aye M. Aung,3 Sudhanshu Jain,4 Sudhanshu Andrali,1 1Harlem Hospital Center, New York, NY; 2Emory University, Atlanta, GA; 3The University of Arizona Health Sciences, Tucson, AZ.

Background: Vancomycin is a widely used antibiotic in the in-patient setting. Concerns of vancomycin-associated nephrotoxicity (VAN) were raised due to impurities associated with the first released parenteral formulations in the 1950s. Nephrotoxicity is reported to have markedly declined with a wide variability in the incidence. There is a dearth of information on the current incidence of VAN as a cause of acute kidney injury (AKI) in adult non-ICU populations. The purpose of this study was to estimate the incidence of VAN AKI and identify risk factors of VAN for this population.

Methods: A cohort of patients admitted between January 2015 and December 2017 with the diagnosis of AKI and who received at least 3 days of parenteral vancomycin were identified through a retrospective chart review. Exclusions were ESRD or CKD history. Our primary outcome was the occurrence of VAN AKI, defined as an increase in serum creatinine by 0.3 mg/dl or 50% above baseline after vancomycin exposure. The incidence of VAN AKI was estimated and we estimated risk factors associated with VAN in a logistic regression model.

Results: 587 adult patients received at least 72 hours of parenteral vancomycin for the treatment of sepsis during the period. Demographics were: male 350 (59.6%), female 237 (40.4%) and mean age of 62.3 years. Distribution by ethnicity: non-Hispanic Blacks 71.2%, Hispanics 12.6%, non-Hispanic white 3.4% and 12.4% were other ethnicities. The incidence of VAN AKI was 15.24%. These patients had a longer hospital stay (26.8 versus 21.3 days for no VAN AKI), higher mean vancomycin trough levels, longer duration of exposure to vancomycin and a higher Charlston Comorbidity Index (3.5 versus 2.6). Independent predictors for VAN were: mean vancomycin trough level, hypertension, COPD, congestive heart failure, liver disease, severe obesity and dementia (all p values <0.05). Previous ICU admission and hypotension status did not predict VAN AKI.

Conclusions: We report an incidence of VAN AKI of 15.24% in non-ICU adult patients with no history of ESRD or CKD. Risk factors associated with the development of VAN include mean vancomycin trough level, hypertension, congestive heart failure, COPD, liver disease, severe obesity and dementia.

PO0031

Baseline Urinary Protein Biomarkers as Predictors of eGFR Decline in Cancer Patients Receiving Cisplatin

Melanie S. Joy,1 Blessey George,1 Yichun Hu,2 Susan L. Hogan,3 Xia Wen,3 Lauren Afekousov.1 1University of Colorado, Skaggs School of Pharmacy, Cancer Center, and Division of Renal Diseases and Hypertension, Denver; CO; 2University of North Carolina, Kidney Center, Chapel Hill, NC; 3Rutgers University, Ernest Mario School of Pharmacy, Piscataway, NJ.

Background: Previous data from our group reported significant changes in urinary biomarkers of sub-clinical kidney injury over 10 days after receiving i.v. cisplatin. The current study evaluated the performance of single and a combination of two urinary biomarkers at the time of cisplatin initiation in predicting a reduction in eGFR.

Methods: Patients (n=57) with solid tumors receiving i.v. cisplatin (25 mg/m²) were enrolled in a study to characterize concentrations of 9 urinary proteins (Table). For the outcome of eGFR decline, the eGFR (MDRD equation) after the first dose and one measure at 5-7 days of stay. Exclusion criteria consisted of ESKD, kidney transplant or baseline eGFR <15 ml/min/1.73m². AKI was defined as an increase of serum creatinine level ≥0.3 mg/dl or 1.5 times in contrast to baseline, or the development of renal tubular abnormalities within 48 hours. We evaluated if the microscopic examination of the urine sediment (score ≥2) could be use as a non-invasive detector of renal damage.

Results: Mean (SD) age was 65.1 (17.2), 38.4% were women and 100% Hispanic. The incidence of AKI at 3-7 days of hospital or ICU stay was 34.9%. From the 30 patients that developed AKI, 20 were on stage 1 (66.6%), 8 were on stage 2 (26.6%) and 2 were on stage 3 (6.6%). Performance metrics of the urinary score used are reported in Table. A urine sediment score ≥2 exhibited a fair, but not good, AUC of 0.681 (95% confidence interval [CI]: 0.554–0.808) in ROC analysis.

Conclusions: Urinary protein biomarkers are emerging as tools to identify overt and sub-clinical kidney injury. However, single and double combinations of urinary proteins are insufficient to reliably predict reductions in eGFR as an ideal model outcome. Future studies must determine an improved outcome benchmark for evaluating urinary protein biomarkers.

Funding: NIDDK Support

Table: Performance of the urinary sediment score for the prediction of AKI in hospitalized patients

PO0032

Urinary Sediment Score Is a Useful Predictor of AKI in Hospitalized Patients

Pablo J. Heredia-Murillo,1 Rolando Claire-Del Granado,2,3 Universidad Mayor de San Simon Facultad de Medicina, Cochabamba, Bolivia, Plurinational State of; 2Clínica Los Olivos, Cochabamba, Bolivia, Plurinational State of.

Background: Risk-stratification tools of incident AKI in hospitalized patients are needed. Early documentation of impaired kidney function through a simple examination like the urinary sediment may provide risk reduction in such patients. The present study aims to explore an association between urinary sediment score described by Perazella et al. and hospital-acquired AKI.

Methods: This study included 86 patients who underwent urinalysis, including scoring the urinary sediment during the first 24 hour of admission. Inclusion criteria consisted of age ≥18, hospital stay ≥3 days, at least 2 serum creatinine (SCr) measures in the first 2 days of hospital stay and one measure at 5-7 days of stay. Exclusion criteria consisted of ESKD, kidney transplant or baseline eGFR <15 ml/min/1.73m². AKI was defined as an increase of serum creatinine level ≥0.3 mg/dl or 1.5 times in contrast to baseline, or the development of renal tubular abnormalities within 48 hours. We evaluated if the microscopic examination of the urine sediment (score ≥2) could be use as a non-invasive detector of renal damage.

Results: Mean (SD) age was 65.1 (17.2), 38.4% were women and 100% Hispanic. The incidence of AKI at 3-7 days of hospital or ICU stay was 34.9%. From the 30 patients that developed AKI, 20 were on stage 1 (66.6%), 8 were on stage 2 (26.6%) and 2 were on stage 3 (6.6%). Performance metrics of the urinary score used are reported in Table. A urine sediment score ≥2 exhibited a fair, but not good, AUC of 0.681 (95% confidence interval [CI]: 0.554–0.808) in ROC analysis.

Conclusions: Cellular casts and granular casts are occasionally observed in hospitalized adult patients with risk factors for AKI. The urinary sediment score proposed by Perazella et al. could be a potentially useful marker for early documentation of hospital-acquired AKI.

Kidney Biopsy Findings in AKI in the Cohort of Patients of Mexico Tertiary Hospital

Background: The study of the epidemiology of biopsy-confirmed renal disease provides useful information about the prevalence of renal disease and its clinical manifestations. Performing a kidney biopsy is necessary to accurately diagnose diseases such as glomerulonephritis and tubulointerstitial nephritis, among other such conditions. Kidney biopsy in acute kidney injury (AKI) of unknown origin provides irreplaceable information for diagnosis, treatment, and prognosis. In this report, we analyze the frequency and clinicopathologic correlations of renal native biopsied AKI in Mexican cohort during the period 2014 to 2019.

Methods: We analyzed the frequency and clinicopathologic correlations of AKI confirmed by native renal biopsy in Mexico tertiary hospital and the distribution of the different clinicopathologic findings. From 2014-2019 period, totally 515 patients first received renal biopsy. AKI was diagnosed based on the Kidney Disease: Improving Global Outcomes criteria.

Results: Of the 515 patients investigated, 200 (38.8%) showed AKI. Of these, 102 (51%), 47 (23.5%), and 51 (25.5%) presented with AKI classified as stages 1, 2, and 3, respectively. The primary indication for performing biopsy was rapidly progressive glomerulonephritis (RPGN) in 70 (35%) and nephrotic syndrome in 47 (23.5%). Dialysis previous kidney biopsy was necessary in 48 patients (24%). Focal segmental glomerulosclerosis was the most prevalent primary disease in 37 (18.5%) and lupus nephritis was the most prevalent secondary disease in 53 (26.5%). In the early patients, the most prevalent disease was pauci-immune rapidly progressive GN Multivariate analysis of risk factors associated with AKI showed hemoglobin levels (OR 0.90, 95% confidence interval [CI] 0.671–0.941, p=0.01), dialysis previous kidney biopsy (OR 3.970, 95% CI 2.949–4.392, p<0.008), and baseline serum creatinine levels (OR 2.402, 95% CI 1.371–4.758, p=0.001) were significantly associated with AKI.

Conclusions: We observed a high prevalence of AKI in patients who underwent kidney biopsy to investigate their renal disease, particularly glomerulonephritis. The prevalence of vasculitis and crescentic GN is high, especially in elderly patients.
Late Presentations of Secondary Oxalate Nephropathy
Muna Hale, Pranay Kathuria. The University of Oklahoma - Tulsa, Tulsa, OK.

Introduction: Secondary Oxalate nephropathy is an important differential diagnosis for acute kidney injury (AKI) in chronic malabsorptive disease. Mean presentation is typically within 1-2 years. The following three cases are example of late, abrupt presentations of secondary oxalate nephropathy.

Case Description: Our first case includes a 69-year-old female, with gastric bypass surgery 14 years prior, who presented to emergency room (ER) with AKI. Six months prior her creatinine (Cr) was 1.6 mg/dL, but abruptly increased to 5.99 mg/dL. Serologic work up was negative. Renal biopsy was obtained that revealed deposition of oxalate crystals within renal tubules (Figure 1). Our second case showed a 59-year-old male with history of recurrent pancreatitis due to bulimia that presented to the ER for nausea and vomiting. In the ER, patient had a serum Cr of 5.79 mg/dL. Two months prior, Cr was 1.1 mg/dL. Renal biopsy showed widespread oxalate crystals in the interstitium. The last case was a 48-year-old male with chronic pancreatitis who presented with AKI with suspect acute tubular necrosis. He had been diagnosed with chronic pancreatitis for at least 6 years with Cr 0.9 mg/dL. Patient’s Cr remained at 4.00 mg/dL one month later. Renal biopsy revealed interstitial fibrosis and calcium oxalate crystals.

Discussion: Secondary oxalate nephropathy is a side effect of malabsorptive gastrointestinal (GI) disorders. According to prior case series, the mean presentation of oxalate nephropathy is 1-2 years. These cases illustrate that secondary oxalate nephropathy can present at a later course with rapid onset. Patients also likely progress to ESRD after diagnosis. A systemic review of 108 cases, with 13 months follow up, showed 55% of patients required hemodialysis. Currently, there is no treatment and lifestyle changes include a low fat, oxalate diet. Secondary oxalate nephropathy should be considered in the differential of all patients with malabsorptive states presenting with AKI.

PO0037

Presentation and Outcome of Oxalate Nephropathy Without Known Genetic or Gastrointestinal Cause
Erin E. Bolen, Mina Abdelmalek, John C. Lieske, Mira T. Keddis. Mayo Clinic Arizona, Scottsdale, AZ; Mayo Clinic Minnesota, Rochester, MN.

Background: Oxalate nephropathy (ON) is a frequent and often unexpected finding on kidney biopsy. This study aimed to characterize causes and outcomes in biopsy-proven ON not due to known enteric cause or primary hyperoxaluria (PH) in a multisite health system.

Methods: Cases were identified based upon diagnosis of ON on kidney biopsy between 2009 to 2020 without known enteric or primary cause.

Results: Thirty-four cases were identified with a median follow-up of 11.9 months. None had known fat malabsorption. Genetic testing for PH was negative in 11, and there was no clinical suspicion of PH in the rest. Likely causes of ON included documented high dietary oxalate (7, 21%), oral and/or IV vitamin C supplementation (7, 21%), ethylene glycol (3, 9%), and orlistat (1, 3%). No cause could be identified in 16 (47%). Table 1 shows variables across three etiologies: unknown cause, diet-related, and vitamin C. All cases except one had diffuse intratubular calcium oxalate deposition on biopsy. End stage kidney disease (ESKD) was present in 53%. AKI stage III at biopsy was predictive of ESKD at last follow-up (p<0.05). Treatments included low oxalate diet (29, 85%), calcium supplementation (18, 53%), pyridoxine (12, 35%), and prednisone taper (12, 35%). Diet-related ON appeared to have lower rates of AKI stage III at diagnosis (5, 67%), ESKD (3, 43%), and mortality (2, 29%) compared to vitamin C-related ON and ON of unknown etiology.

Conclusions: This is the largest study of ON not due to PH or enteric cause. The most common causes were high-oxalate diet and high-dose vitamin C. In 47% of cases no cause was identified. ESKD was common, and AKI severity at presentation predicted ESKD at last follow up. Cases attributed strictly to dietary excess may have better short and long term outcomes.

acquiring ESBL producing bacteria in urine or blood cultures. ESBL producing bacteria after previous antibiotics exposure (OR 2.102; 95% CI 1.014-4.356) were risk factors for APN occurrence after 2015 (OR 1.170; 95% CI 1.057-1.296) and AKI Epidemiology, Risk Factors, and Prevention: Clinical Research. The rate of ESBL producing bacteria has steadily increased over the years, which is consistent with the findings from early studies [1,2]. However, recent studies have shown that the rate of ESBL producing bacteria is now significantly higher, with Klebsiella spp. (0.9%) and Enterobacter spp. (0.5%) being the most common pathogens followed by Pseudomonas aeruginosa (0.9%) or diagnosis of ESRD or kidney transplant (ICD-10 codes) were excluded. Clinical data collected included; admission demographics and past history; UOP; pre-identified medication, laboratory results and order sets; specific consultations; and discharge diagnoses.

Results: A total of 22980 patient visits were evaluated. Of the 2067 patients who were admitted through the ED with a discharge diagnosis of septic shock, 433 (20.9%) received one dose of IVcV 1500mg and were categorized as the IVcV group; 1634 (79.1%) did not receive IVcV. A chi-square analysis can be seen in Table 1.

Conclusions: This retrospective study EMR observed that IVcV in the treatment of septic shock is associated with an increase in the incidence of AKI.

Funding: Clinical Revenue Support

Note. A logistic regression revealed that the odds of AKI were 2.57 times higher for IVcV patients compared to non-IVcV patients (95% CI 2.053, 2.37).
Case Description: A 64 year old female with non-small cell lung cancer stage IV with brain metastasis was initiated on pembrolizumab therapy seven months prior to presentation. Three weeks prior to presentation she started omeprazole 20mg daily. At time of presentation the creatinine was found to be 3.07 mg/dL, up from 0.8 mg/dL eleven days prior, improved with cessation of the PPI, however shortly there after the PPI was restored and creatinine again rose and peaked at 7.6 mg/dL. Renal biopsy was performed and confirmed interstitial nephritis. The patient was started on prednisone 1mg/kg/day with rapid improvement in renal function back to baseline.

Discussion: There has been some research linking both pembrolizumab and pembrolizumab in combination with other chemotherapeutic agents to kidney injury. However, in these trials many patients who suffered kidney injury were also receiving proton pump inhibitors, a class of medications known to provoke acute interstitial nephritis. If synergism can be proven, this combination would be avoided, thus preventing this immune related adverse event. Furthermore, reinitiation of check point inhibitors alone after cessation of the PPI and normalization of kidney function in cases such as these, could be trialed.

PO0043
Zolpidem Mega Dose Resulting in Hemodialysis

Introduction: Depression and hypoventilation syndromes are factors that may be overlooked when prescribing Zolpidem. Although hypnotics are not directly associated with rhabdomyolysis, they can lead to severe intoxication and prolonged immobilization. This can lead to compartment/ crush syndromes and depressed respiratory drive and may cause seizures. As consequence of the above renal failure ensued and hemodialysis was required.

Case Description: This case portrays a 36-year-old law student who tried to end his life with the ingestion of 90 Zolpidem pills. As consequence of his metabolic derangement he had seizures, rhabdomyolysis and renal failure that required hemodialysis. Due to pront intervention, hemodynamic stability and full recovery were achieved.

Discussion: A 36-year-old man with hypertension, insomnia and epilepsy was brought to the emergency room by ambulance. Chief complaint was of disorientation and seizures after the ingestion of 90 Zolpidem pills. He was initially combative, disoriented and with incoherent speech. Once consulted, he presented a Glasgow Coma Scale of 3 for which he was intubated. He was diaphoretic with scattered petechiae and associated incoherent speech. Once consulted, he presented a Glasgow Coma Scale of 3 for which he was intubated. He was diaphoretic with scattered petechiae and associated subconjunctival hemorrhage. On lab work he had central bicarbonate at 4.6 mEq/ L. Arterial pH was at 6.5 and PaCO2 at 24, which represented severe metabolic acidosis which he was intubated. He was diaphoretic with scattered petechiae and associated subconjunctival hemorrhage. On lab work he had central bicarbonate at 4.6 mEq/ L. Arterial pH was at 6.5 and PaCO2 at 24, which represented severe metabolic acidosis.

Postrenal AKI due to a Rarely Seen Neoplastic Phenomenon in an Adolescent

Ana L. Prasad cortex,1 Rasheda Amin,2 Carly R. Varela.1 1Inova, Falls Church, VA; 2Pediatric Specialists of Virginia, Fairfax, VA

Introduction: AKI is an important cause of morbidity & mortality in adult and pediatric patients. Based on a lit review by Ceto-Yamane, et al., the pediatric incidence & mortality of AKI in the USA in 2013 was 0.39% and 15.3%, respectively. In general, a patient’s presentation may provide clues to the etiology of AKI (i.e. prerenal, intrarenal and postrenal). AKI due to postrenal/obstructive causes is less common in children as compared to adults and is usually associated with congenital abnormalities e.g. posterior urethral valves, or acquired due to stones or tumors. We report the case of a 14 yo previously healthy female with a unique clinical presentation due to lower urinary tract obstruction secondary to a tumor.

Case Description: The patient presented with 3 weeks of back pain, R leg swelling, headaches, urinary frequency, n/v and hematuria. In the ED, her BUN and creatinine were 107 mg/dL and 21.1 mg/dL, respectively. A RUS showed enlarged non-echogenic kidneys with mild bilateral hydrenephrosis & a heterogeneous pelvic mass. Further labs revealed anemia, low PTH, normal complement levels, ASO & ANA titers. A LE Doppler study was negative for venous thrombosis. A non-contrast MRI revealed a pelvic mass & possible metastasis. Peds Oncology was consulted, and biopsies of bone marrow & pelvic tumor revealed a small round blue cell tumor with immunohistochemical stains diagnostic for rhabdomyosarcoma. She developed oliguria, hyperkalemia & hyperuricemia (24mg/dL). A RUS revealed a small round blue cell tumor with immunohistochemical stains diagnostic for rhabdomyosarcoma. She developed oliguria, hyperkalemia & hyperuricemia (24mg/dL). Rasburicase was given & CRRT was initiated. She received emergent chemotherapy with cyclophosphamide, doxorubicin & vincristine. Bilateral percutaneous nephrostomy tubes were placed with improvement in UOP & renal function allowing CRRT to be stopped. Labs showed a downward trend of BUN & creatinine to 14 mg/dL and 0.8 mg/dL, respectively.

Discussion: Our patient’s clinical presentation was atypical in that her initial US findings of mild hydrenephrosis were not consistent with the severity of her renal injury. Her AKI was likely a combination of obstructive uropathy from the large pelvic tumor compressing her lower urinary tract & uric acid nephropathy. Decompensation of the urinary system, management of hyperuricemia & initiation of tumor directed chemotherapy resulted in marked improvement of kidney function. Our case highlights the importance of considering an obstructive etiology in older children presenting with AKI.

P00047

Profiling AKI Trajectories: Early Results from the Million AKI Project

Benjamin C. Bowe,1,2 Yan Xie,1,2 Andrew K. Gibson,1 Miao Cai,1,2 Hong Xian,2 Geetha S. Maddukuri,1 Ziyad A. Al-Aly.1 1VA St. Louis Health Care System, St. Louis, MO; 2Saint Louis University, Saint Louis, MO.

Background: Clinical guidelines for risk stratification of acute kidney injury (AKI) patients are based on peak increases in serum creatinine (SC). These definitions do not consider other characteristics of change in SC that may provide information on risk of adverse outcomes. Identification of patient groups that display distinct patterns in trajectory of SC and outcome profiles may lead to more nuanced risk-based definitions of AKI.

Methods: Data from the United States Veterans Health Administration were obtained. A latent class growth model identified patient groups based on similar patterns of trajectory in serum creatinine during a hospitalization with an AKI. Regression models examined associations of trajectory groups with risk factors and in-hospital mortality.

Results: We constructed a cohort of 480,575 veterans with an AKI during an inpatient stay (a subset of the Million AKI Project cohort). Of these, 343,471 (71.5%), 63,665 (13.3%), and 73,439 (15.3%) met KDIGO AKI stages 1, 2, and 3 criteria. 9.4% died during their hospitalization. We identified 9 latent trajectories summarized by 4 phenotypes: a mild increase in SC from low baseline (66%), and varying degrees of increase in SC with no (9%), moderate (17%), and near-full recovery (8%). Higher systolic blood pressure (OR=1.02; 95% CI=1.01-1.02 per 1 mmHg), sepsis (2.24; 2.10-2.39), non-use of ACE/ARB (1.54;1.47-1.61), diuretic use (1.16; 1.12-1.20), albuminuria (1.36; 1.31-1.41), and prior history of AKI (1.27; 1.22-1.32) were associated with trajectories with larger increases in SC, while major surgeries (2.48; 2.37-2.60) were associated with trajectories that recovered. Compared to the mild increase group, those with partial or no recovery had a higher odd of in-hospital mortality (1.64; 1.57-1.71) that increased in magnitude with higher baseline SC and a greater increase in SC (2.73; 2.66-2.80). Groups that experienced near-full recovery showed no evidence of a difference in mortality profile (0.97; 0.90-1.05) despite differences in other aspects of the trajectory.

Conclusions: Leveraging the depth and breadth of a high-quality longitudinal electronic health record system, we characterized nearly half a million cases of AKI; our results suggest that profiling of AKI trajectories informs risk stratification and may guide development of post-AKI care.

Preoperative Urine Alpha 1 Microglobulin Levels Are Associated with AKI and Mortality After Cardiac Surgery

Background: Higher urine alpha-1 microglobulin (a1m) levels are a marker of proximal tubule dysfunction and may improve CKD assessment and risk stratification. We hypothesized that a1m levels would be associated with adverse outcomes after cardiac surgery.

Methods: In 1464 adults undergoing cardiac surgery (CABG and/or valve) and prospectively enrolled in the multicenter TRIBE-AKI study, we measured urine a1m pre- and post-operatively. Outcomes were post-operative AKI during index hospitalization (AKIN stage ≥1) and all-cause mortality (median follow-up (IQR) 6.7 (4.0, 7.9) years). Urine a1m was analyzed as a continuous (log2) predictor in multivariable analyses adjusting for demographics, surgery characteristics, comorbidities, baseline eGFR, urine albumin, and urine creatinine. Results: There were 230 AKI events and 459 deaths. Higher pre-operative a1m was independently associated with AKI (aOR=1.36, 95% CI 1.14-1.62) and all-cause mortality (HR=1.19, 95% CI 1.06-1.33) (see table). We observed a significant interaction (p=0.01), whereby a1m had a stronger association with mortality in the subset without CHF (HR=1.29, 95% CI 1.12-1.47) than among those with CHF (HR=1.06, 95% CI 0.85-1.32). However, post-operative changes in a1m were not associated with AKI or mortality risk.

Conclusions: Even after adjusting for baseline kidney function and comorbidities, preoperative a1m was associated with post-operative AKI and all-cause mortality.

Funding: Other NIH Support - NHLBI; study also supported by NIH grant RO1HL085757 (CRP) to fund the TRIBE-AKI Consortium.

Elevated Serum Tenascin C Predicts All-Cause Mortality in Critically Ill Patients with Multiple Organ Dysfunction

Qionghong Xie, Xu Yunu, Chuan-Ming Hao. Huashan Hospital Fudan University, Shanghai, China.

Background: Tenascin-C (TNC) is a matricellular protein that is rarely expressed in most of adult tissues, but re-induced following injury. This study aimed to evaluate serum TNC in critically ill patients with multiple organ dysfunction.

Methods: Adult critical ill patients who met the criteria of at least two organs dysfunction and acute organ injury with an increase of SOFA ≥2 points within 7 days were prospectively enrolled in one derivation cohort (Medical ward) and one external validation cohort (Emergency ward). Serum TNC was measured within the first 24 hours after enrolment and the association between serum TNC and 28-day all-cause mortality was analyzed.

Results: A total of 113 patients with median age 56 (38, 66) years and male of 65.2% in derivation cohort and 66 (53, 73) male and 67% in validation cohort were included. Serum TNC was 210.2 (96.8, 469.6) ng/ml in derivation cohort and 229.4 (141.6, 472.5) ng/ml in validation cohort, both significantly higher than in that healthy controls (median 80.9 ng/ml, n=46, p<0.01 for both). The TNC level >100 ng/ml was associated with the critical illness scores such as SOFA, APACHE II, and SAPS II, as well as 28-day mortality (p=0.01 for all). Compared to the patients with TNC<300ng/ml, patients with TNC≥300ng/ml had a remarkably higher 28-day mortality (38.6% vs. 14.1%, p=0.003 in derivation cohort; 57.8% vs. 13.8% p<0.001 in validation cohort). In multivariable analysis, serum TNC was independently associated with the mortality after adjustment for age, gender and SOFA in both cohorts. The areas under the Receiver Operating Curve of TNC for 28-day mortality was 0.797 in derivation cohort and 0.803 in validation cohort, not inferior to SOFA (0.844 and 0.808), APACHE II (0.86 and 0.762) and SAPS II (0.872 and 0.797).

Conclusions: Serum TNC was significantly increased in critical ill patients with multiple organ dysfunction and was positively associated with the severity of illness and all-cause mortality. It was a useful prognostic tool for predicting all-cause mortality in critical ill patients.

Urinary Waxy Casts Are Associated with Persistence of AKI Requiring Dialysis

Maria Soledad Rivera,1 Vinip Varghese,2 Akanksh Ramanand,1 Ali A. Alawalan,2 Juan Carlos Q. Vélez,2 Ochsner Nephrology, Ochsner Clinical School - University of Queensland, New Orleans, LA; 1Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA.

Background: Waxy casts (WxCs) can be identified during microscopic examination of the urinary sediment (MicrExUrSed) and they have been classically linked to chronic kidney disease (CKD). We previously showed that WxCs predict severity of acute kidney injury (AKI). Thus, we hypothesized that WxCs may inform about duration and persistence of AKI and AKI requiring renal replacement therapy (AKI-RRT).

Methods: We conducted a retrospective observational study in patients seen in inpatient nephrology consultation with AKI stage 2 (AKIN) over the 2.5 years. On the day of consult, MicrExUrSed was performed to determine the percentage of low power fields with WxCs. The outcome measures were persistence of need for RRT at the time of hospital discharge (AKI-RRT-Persist) and the serum in creatinine (sCr) from baseline at the time of hospital discharge (AKI-Persist).

Results: Urine specimens from 286 patients [median age 60 (20 – 88), 37% women] were assessed. The etiology of AKI (de novo AKI 67%, AKI on CKD 33%) was ischemic ATII (47%), toxic ATII (9%), ischemic/toxic ATII (11%) or other (33%). WxCs were found in 85 patients (30%), 61 (72%) of which had de novo AKI. Median sCr for those with WxCs was 3.5 (0.9 – 22.0)mg/dL and 3.1 (0.9 – 12.5) mg/dL for those without WxCs (p=0.12). AKI-RRT at any point during the course of AKI was seen in 45% (38/85) of those with WxCs compared to 32% (54/201) of those without WxCs (p=0.043). There was a greater risk for AKI-RRT Persist for those with WxCs [15.3% vs 7.5%, odds ratio (OR): 2.2, CI 1.1 – 4.9, p=0.046]. Presence and abundance of WxCs were also associated with a greater risk for Persist AKI with the percentage of WxCs: >10% WxCs and >50% WxCs, respectively; chi-square for trend p<0.01.

Conclusions: In patients with AKI, the presence and abundance of WxCs are associated with a greater risk for persistent need for RRT and persistent increase in sCr at the time of hospital discharge. These findings suggest that WxCs inform about the severity of AKI and the timeline of significant AKI.

PO0045

Retrospective Analysis of the Efficiency of Caplacizumab in the Treatment of Acquired Thrombotic Thrombocytopenic Purpura: Results from the REACT-2020 Study Group

Lucas Kuchne,1 Jessica K. Kaufléid,1 Jan Menne,2 Paul T. Brinkkötter, Linus A. Volker.1 REACT-2020 study group 1University of Hospital Cologne, Köln, Germany; 2Hannover Medical School, Medizinische Hochschule Hannover, Hannover, Germany.

Background: Acquired thrombotic thrombocytopenic purpura (aTTP) is a rare but life-threatening disorder, caused by the formation of inhibitory and occasionally non-inhibitory autoantibodies against ADAMTS13. Despite plasma exchange and immunosuppression, long-term mortality and morbidity associated with acute episodes remain high. Here, caplacizumab – a nanobody approved in Germany in 2018 – has developed a non-favorable outcome comprising disease exacerbation or relapse. In some instances, caplacizumab led to a rapid normalization of the platelet count (median 0.5 (0.05-4.8)) and an improvement of the vWF activity.

Methods: We conducted a retrospective observational study in patients seen in inpatient nephrology consultation with aTTP and aTTP-RRT over the 2.5 years. On the day of consult, MicrExUrSed was performed to determine the percentage of low power fields with WxCs. The outcome measures were presence (n=76) and increase (n=48) in sCr from baseline (n=124) at the time of hospital discharge (AKI-Persist).

Results: Among the more than 40,000 patients admitted to Beth Israel Deaconess Medical Center between 2001 and 2012 in the MIMIC-III database, we selected patients with AKI clinical, outcomes, and trials - 1.

Conclusions: Presence and abundance of WxCs were also associated with a greater risk for Persist AKI with the percentage of WxCs: >10% WxCs and >50% WxCs, respectively; chi-square for trend p<0.01.

PO0054

Erythropoiesis-Stimulating Agents in AKI Requiring Dialysis

Jan Mccoy,1 Kathleen D. Liu,2 Chiyuan Hu.1 Stanford University School of Medicine, Palo Alto, CA; 1University of California San Francisco, San Francisco, CA.

Background: Erythropoiesis-stimulating agents (ESAs) are used in patients with CKD to treat anemia. AKI may also be a state of erythropoietin deficiency, although data on this is conflicting. Few studies have examined ESA use in AKI, including the most severe AKI-RRT patients (AKI-D). It is unknown whether and to what extent clinicians prescribe ESAs in AKI-D.

Methods: Among the more than 40,000 patients admitted to Beth Israel Deaconess Medical Centers between 2001 and 2012 in the MIMIC-III database, we selected 591 AKI-D patients and 276 ESKD patients based on ICD-9 diagnostic codes. In a cross-sectional analysis, we determined the frequency of ESA usage and estimated associations between ESA usage and age, sex, surgical (vs medical) ICU admission, ICU length of stay, admission hemoglobin, admission serum creatinine, history of CKD, and ESKD (versus AKI-D) status using multivariable logistic regression. We also examined the relationship between ESA use and the number of bladder catheters, UF NET prescription and practice.

Results: ESA usage (any time during ICU stay) was 13% in AKI-D (vs 21% in ESKD). Among AKI-D patients (Table 1), CKD (adjusted OR 3.59, 95% CI 2.06-6.25, p<0.0001), length of stay (1.06 [1.04-1.08] per day, p<0.0001), sepsis (2.06 [1.08-3.92], p=0.03), and female sex (0.31 [0.13-1.00], p=0.05) were significantly associated with ESA use. Patients treated with ESAs received six more blood transfusions on average than patients who were not treated with ESAs (6.1 more transfusions, 95% CI 2.6-9.7, p=0.0006), but this difference disappeared when adjusted for the variables significantly associated with ESA usage (AUC 0.76). In a multivariable model, AKI-D patients treated with ESAs had a higher risk of persistent need for RRT (50% rise in serum creatinine (sCr) from baseline, AKI-Persist) at discharge. The difference was significant (p=0.03). In patients with AKI-D, the presence and abundance of WxCs were associated with a greater risk for persistent need for RRT at discharge.

Conclusions: Presence and abundance of WxCs were also associated with a greater risk for Persist AKI with the percentage of WxCs: >10% WxCs and >50% WxCs, respectively; chi-square for trend p<0.01.

PO0056

Survey of US Critical Care Practitioners on Perspectives Toward Net Ultrafiltration Prescription and Practice

Huiwen Chen,1,2 Raghavan Murugan,2 University of Pittsburgh Medical Center, Pittsburgh, PA; 2University of Pittsburgh, Pittsburgh, PA.

Background: Previous studies suggest international practice variation in net ultrafiltration (UF NET) among critically ill patients with acute kidney injury treated with kidney replacement therapy. We examined U.S. critical care practitioner attitudes toward UF NET prescription and practice.

Methods: Secondary analysis of a multinational, cross-sectional, internet-assisted, open survey administered to intensivists, nephrologists, advanced practice providers, ICU and dialysis nurses in the U.S.

Conclusions: Of 1,569 international survey respondents, 465 (29.6%) practitioners were from the U.S. Practitioners were mostly nurses and nurse practitioners (58%) and intensivists (38.2%). Median duration of practice was 8.7 (IQR, 4.2-19.4) years and 63.4% practiced in a university- based hospital. Practitioners reported using continuous kidney replacement therapy (CRRT) as the first modality for UF NET in 60% (ICU 20% vs 40% of their patients with median UF NET rate of 51 mL/h, ICUs 25-100 mL/h) for hemodynamically unstable and a maximal rate of 285 mL/h (ICU 1, 200-341 mL/h) for hemodynamically stable patients. 58.3% (range 28.7%-70.2%) of practitioners assessed net fluid balance hourly. Hemodynamic instability was reported in 25% (ICU 10%-100%) of the patients, and practitioners decreased the rate of fluid removal (71.2%); started or increased dose of a vasopressor (56.8%); completely stopped fluid removal (44.5%); and administered a fluid bolus (28.7%). Most clinicians (79.8%) reported patient intolerance as a major barrier. Other barriers include frequent interruptions (50.1%), under prescription (17.3%), and trained staff (17%), inability to titrate fluid removal (10.1%), and unavailability of dialysis machines (8.6%) and cost (2.4%) (Figure 1). More than 70% of clinicians agreed with early protocelated fluid removal and expressed desire to enroll their patients in a future clinical trial.

Conclusions: This study provides new knowledge on UF NET in practices in the U.S. We also identified barriers and specific targets for quality improvement initiatives. Our data reflect the need for evidence-based practice guidelines for UF NET.

PO0057

A Pilot Trial to Evaluate the Clinical usefulness of Contrast-Enhanced Ultrasound in Predicting Renal Outcomes in Patients with AKI

Suveon Hong,1 Da won Kim,2 Dongryul Kim,2 Seok Joon Shin,1 Hye Eun Yoon,1 Uijeongbu St. Mary's Hospital, Uijeongbu, Republic of Korea; 2Incheon St. Mary's Hospital, Incheon, Republic of Korea.

Background: Contrast-enhanced ultrasound (CEUS) enables the assessment of real-time renal microcirculation. This study investigated CEUS-driven parameters as biomarker predictors for renal outcomes in patients with acute kidney injury (AKI).

Methods: Forty-eight patients who were diagnosed with AKI were prospectively enrolled and underwent CEUS at the occurrence of AKI. Parameters measured were the wash-in slope (WIS, time to peak intensity, peak intensity (PI), area under the time–intensity curve (AUC), mean transit time (MTT), time for full width at half maximum, and rise time (RT). The predictive performance of the CEUS-driven parameters for Kidney Disease Improving Global Outcomes (KDIGO) AKI stage, initiation of renal replacement therapy (RRT), AKI recovery, and chronic kidney disease (CKD) progression was
assessed. Receiver operating characteristic (ROC) analysis was performed to evaluate the diagnostic performance of CEUS.

**Results:**
Cortical MTT (OR = 1.07) and RT (OR = 1.20) predicted the initiation of RRT. Cortical WIS (OR = 1.00) predicted AKI recovery. Medullary PI (OR = 1.25) and WIS (OR = 76.23) and medullary PI (OR = 1.25) predicted AKI recovery. Medullary PI (OR = 1.25) and WIS (OR = 76.23) and medullary PI (OR = 1.25) predicted AKI recovery. The areas under the ROC curves showed reasonable performance for predicting the initiation of RRT and AKI recovery. The sensitivity and specificity of the quantitative CEUS parameters were 60–83% and 62–77%, respectively, with an area under the curve of 0.69–0.75.

**Conclusions:** CEUS may be a supplemental tool in diagnosing the severity of AKI and predicting renal prognosis in patients with AKI.

**Funding:** Government Support - Non-U.S.

**PO0058**

**A Clinical Score to Predict Recovery in ESKD due to AKI**

Silvi Shah,1 Anthony C. Leonard,1 Kathleen Harrison,1 Karthikeyan Meganathan,1 Annette Christianson,1 Samantha M. Kramer,1 Charuhas V. Thakar,1,2 *University of Cincinnati, Cincinnati, OH; 1Cincinnati VA Medical Center, Cincinnati, OH.

**Background:** Acute kidney injury (AKI) is a major contributor to end-stage kidney disease (ESKD). About one-third of patients with ESKD due to AKI recover kidney function. However, there is lack of clinical models to predict kidney recovery in ESKD due to AKI.

**Methods:** Using data from the United States Renal Data System (2005-2014), we developed a clinical score to predict kidney recovery by 90-days post-dialysis initiation in patients with ESKD due to AKI (N=22,922). We used multivariable logistic regressions to model the effects of patient demographics, comorbidities, and laboratory measures on kidney recovery. The resulting logistic parameter estimates were transformed into integer point totals by doubling and rounding the estimates. The predictive accuracy of the score models was compared to the underlying logistic models by comparing areas under the receiver operating characteristic curves (AUROC) and internal validation was performed.

**Results:** In ESKD due to AKI, kidney recovery within 90-days occurred in 24% of patients. Median recovery time for patients who recovered was 2 months; 72% recovered within 90-days. In the logistic models of recovery at 90-days, older age, lower body mass index, hemoglobin < 12 gm/dl, Black and Native American race, Hispanic ethnicity, congestive heart failure, amputation, poor functional status, and pre-dialysis nephropathy care were associated with a lower likelihood of recovery. Eight patient characteristics were included in the final clinical score- age, body mass index, race, congestive heart failure, amputation, functional status, and prior nephropathy care. Recovery scores ranged from zero to 11, with corresponding recovery rates ranging from 6% to 86%. Three risk categories (score range of 0-5, 6-7, and 8-11) exhibited 90-day recovery rates of 11%, 23%, and 45%. The internal validation assessment showed no overfitting of the models. The AUROC of the score was 0.70, similar to the original AUROC of 0.71.

**Conclusions:** A simple clinical risk score derived from information available at incident dialysis can accurately predict kidney recovery at 90 days in ESKD due to AKI. This predictive tool can be utilized by dialysis providers and policymakers to individualize care, and to improve the quality and processes of care.

**PO0059**

**AKI in Hospitalized Patients with Influenza Is Associated with Worse Outcomes: A Study of National Inpatient Sample from 2012 to 2014 in the United States**

Nasha Elavag, Si Li, Ibithala Yusuf, Bojana Milekic. The Wright Center for Graduate Medical Education, Scranton, PA.

**Background:** Influenza causes significant morbidity and mortality every year. Physiologically, kidneys receive only 25% of the cardiac output in an average weight adult and therefore often develop acute kidney injury (AKI). Our study determines outcomes of AKI in adults hospitalized with influenza between 2012 and 2014 in the US.

**Methods:** We analyzed adult patients with a principal diagnosis of influenza from the 2012 to 2014 National Inpatient Sample. ICD-9-CM was used to identify the diagnosis variables. Patients were divided into two cohorts; with and without AKI. Patient characteristics between both groups were compared. Chi-squared analysis for categorical variables and multivariate regression analysis was done using STATA 16.0 to determine the relationship of outcomes. P <0.05 was used as the level of statistical significance.

**Results:** 120,730 hospitalizations with influenza were sampled. 16,270 (13.5%) of these had AKI (image 1). After adjusting for potential confounders, patients with AKI had higher odds of mortality (adjusted odds ratio (aOR): 3.83; 95% confidence interval (CI) 3.00-4.89, p<0.001), developing severe sepsis (aOR: 2.74; 95% CI 2.46-3.07, p<0.001), and septic shock (aOR: 9.53; 95% CI 6.42-14.16), riboflavinemia (aOR: 3.03; 95% CI 2.39-3.84), requiring intubation (aOR 5.57; 95% CI 4.61-7.74, p<0.001), a longer length of stay (1.8 days; 95% CI 1.52-2.08, p<0.001) and higher costs ($5054.9; 95% CI $3981.8-$6190.1, p<0.001).

**Conclusions:** Influenza complicated with AKI in hospitalized patients is associated with a worse outcome in terms of morbidity and mortality along with increased healthcare costs and a longer length of stay.

**Impact of Chloride-Rich Crystalloids on Sepsis-Associated Community-Acquired AKI Recovery in Critically Ill Patients**

Shahzad Tehrani,1 Khaled Shawwa,1 Erin F. Barreto,2 Casey M. Clements,2 Kianoush Kashani.1,4 *Department of Medicine, Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; 1Department of Pharmacy, Robert D. and Patricia E. Kern Center for the Science of Health Care Delivery, Mayo Clinic, Rochester, MN; 2Department of Emergency Medicine, Mayo Clinic, Rochester, MN; 3Department of Medicine, Division of Pulmonary and Critical Care Medicine, Mayo Clinic, Rochester, MN.

**Background:** The use of chloride-rich crystalloids for resuscitation is associated with developing acute kidney injury (AKI). We aimed to explore the impact of resuscitation with chloride-rich crystalloids compared to balanced crystalloids on the recovery of kidney function in patients presenting with established sepsis-associated community-acquired AKI (SACA-AKI).

**Methods:** This was a single-center, historical cohort study of patients admitted to the intensive care unit (ICU) who presented to the emergency department (ED) with SACA-AKI at Mayo Clinic, Rochester, MN, from January 2011 to April 2018. We divided the cohort into two groups based on the primary type of crystalloids received in the ED and the first 48-hours of ICU. The first group received primarily normal saline with <20% balanced solutions, and the second group received at least ≥20% balanced crystalloids during the initial volume resuscitation.

**Results:** We included 736 patients who were resuscitated with crystalloids after SACA-AKI diagnosis (mean age 64±16, n = 463 (63%) males). There were 286 (39%) females in the second group, found to have higher positive fluid balance during the first 48-hours of admission compared to the first group [median 5.7 (IQR: 3.6; 8) vs. 3.8 (IQR: 2.1; 6.1) L, P<.001]. By multivariable logistic regression, the patients in the second group had a higher rate of kidney function recovery after adjustments for known recovery risk factors (OR 1.4; 95% CI: 1.04-2.1, P = 0.027).

**Conclusions:** The use of balanced crystalloids during the initial resuscitation is associated with higher odds of kidney function recovery in patients with SACA-AKI.

**The Effect of Care Bundles for AKI: A Systematic Review and Meta-Analysis**

Yixin Chen, Fangfang Zhou, Qun Luo. HwaMei Hospital, University of Chinese Academy of Sciences, Ningbo, China.

**Background:** Acute kidney injury (AKI) is common and associated with increased rates of morbidity and mortality. Implementation of a set of evidence-based AKI care bundles may have some benefits to patients’ outcomes by reducing variable standards of care. We aimed to systematically review the literature to quantify the effect of AKI care bundles on patient outcomes.

**Methods:** We searched PubMed (Medline), EMBASE and Cochrane databases for studies that compare the effect of AKI care bundles with usual standard care in patients with or at risk of AKI from database inception to December 31, 2019. The quality of included studies was assessed using the Newcastle-Ottawa Scale. Heterogeneity was
assessed using Cochrane Q test and I² test statistics. Data were analyzed by RevMan 5.3 and Comprehensive meta-analysis (CMA 3.0). The primary outcome was in-hospital or longest follow-up mortality. Secondary outcomes included AKI incidence and AKI severity.

Results: A total of 11 studies (23,491 patients) were included in the meta-analysis. The implementation of AKI care bundles significantly reduced mortality in all patients (odds ratio, 0.87; 95% CI, 0.79–0.94; P < 0.001; I² = 0%; Fig 1). And in patients at high risk for AKI (identified by novel biomarker, risk prediction score or electronic alert), care bundles significantly reduced AKI incidence (odds ratio, 0.62; 95% CI, 0.44–0.86; P = 0.005; F = 70%; I² = 0%; Fig 2) and rates of AKI severity (odds ratio, 0.52; 95% CI, 0.35–0.76; P = 0.001; F = 41%; Fig 3). In addition, there was no evidence of publication bias among the included studies.

Conclusions: The introduction of AKI care bundles can effectively improve outcome in patients with or at risk of AKI, especially when combined with novel biomarker, risk prediction score or electronic alert to manage AKI at early stage. However, the evidence so far is limited and not strong enough to make definite conclusions.

PO062
Block Randomized Implementation of a Decision-Making Algorithm for Renal Replacement Therapy Initiation in AKI Compared with Standard Care on AKI-Related Outcomes
Yvelynne P. Kelly,1 Salman Ahmed,1 David E. Leaf,1 Ernest I. Mandel,1 Emily S. Robinson,1 Gearoid M. McMahon,1 Peter G. Czarnecki,1 David M. Charytan,1 Shushrut S. Waikar,2 Mallika L. Mendu,1 Brigham and Women’s Hospital, Boston, MA; 2Boston Medical Center, Boston, MA

Background: Acute kidney injury (AKI) requiring renal replacement therapy (RRT) is associated with high mortality and utilization. Clinical decision-making related to AKI-RRT initiation in the intensive care setting is not standardized.

Methods: We conducted a 12 month single center block randomized controlled trial in the intensive care units (ICUs) of a large academic tertiary medical center; alternating use of an AKI Standardized Clinical Assessment and Management Plan (SCAMP), a decision-making algorithm to guide front-line clinicians, with use of a “sham” control form in 4-6 week randomization blocks. The SCAMP provided recommendations about optimal indications for initiating RRT on the basis of various clinical parameters, whereas the sham control form did not provide any recommendations for management of AKI-RRT.

Results: 122 patients were managed with AKI-SCAMP while 102 patients were managed using the sham control form. There was no significant difference in the primary outcome of odds of inpatient, 30-day or 60-day mortality associated with use of the AKI-SCAMP. With respect to secondary outcomes, use of the AKI-SCAMP resulted in a significantly reduced ICU length of stay (relative risk 0.68; 95% CI 0.66–0.69, p < 0.0001; I² = 0%) and hospital length of stay (relative risk 0.75; 95% CI 0.72–0.79, p < 0.0001), as well as a reduced 30-day hospital readmission rate (odds ratio 0.38; 95% CI 0.15–0.99, p = 0.05).

Conclusions: Use of an AKI-SCAMP clinical decision support tool for assessment and management of AKI-RRT led to reduced ICU and hospital length of stay and 30-day hospital readmission rates. We advocate for increased study and use of this clinical decision support tool.

PO063
The Effect in Renal Function and Vascular Decongestion in Type 1 Cardiorenal Syndrome Treated with Two Strategies of Diuretics: A Randomized Clinical Trial
Jonathan Chavez,1,2 Miguel A. Ibarra-Estrada,1,2 Sergio J. Sánchez Villaseca,1,2 Juan Gómez Fregoso,1,2 Natashia L. Gongora,1,2 Andres Aranda,1,2 Joana S. Robinson,1,2 Salman Ahmed,1 David E. Leaf,1 Ernest I. Mandel,1 Emily S. Robinson,1 Gearoid M. McMahon,1 Peter G. Czarnecki,1 David M. Charytan,1 Shushrut S. Waikar,2 Mallika L. Mendu,1 Brigham and Women’s Hospital, Boston, MA; 2Boston Medical Center, Boston, MA

Background: The main treatment strategy in type 1 cardiorenal syndrome (CRS1) is vascular decongestion, it is probable that sequential blockage of the renal tubule with combined diuretics (CD) will obtain similar benefits when compared with stepped furosemide (SF).

Methods: We conducted a double-blind randomized clinical trial in CRS1 consecutive patients, we randomized in a 1:1 fashion to SF group or CD. The SF group received a continuous infusion of furosemide 100mg during the first day, with daily incremental doses to 200mg, 300mg and 400mg during the second, third and fourth day, respectively. The CD group consist in the combination of diuretics trying to block different tubular segments, including 4 consecutive days of oral chlorothalidone 50mg, spironolactone 50mg and infusion of furosemide 100mg. The objectives were asses renal function recovery, and variables associated with vascular decongestion.

Results: During July 2017 to February 2020, 80 patients were randomized, 40 to the SF and 40 to the CD group, both groups were similar at baseline and had several very high-risk features. Mean age was 59 ± 14.5 years, male gender was 37 (46.2%), the median follow up was 182 days, Primary endpoint occurred in 20% in the SF group and in 15.2% in the DC group (p = 0.49), all secondary and exploratory endpoints were similar between groups with non-significant differences. Adverse events occurred frequently (85%) with no differences between groups (p = 0.53).

Conclusions: In patients with SCR-1 and high risk of resistance to diuretics, the strategy of CD compared to SF, offers the same frequency of renal recovery, diuresis, vascular decongestion and adverse events, so it can be considered as an alternative, especially in cases where it is not considered advisable to increase furosemide.

Renin Levels Are Higher in Patients with AKI and Associate with Mortality and Major Adverse Kidney Events

Victor M. Ortiz-Soriano,1 Fabiola Gianella,2 Alexander H. Flannery,1 Xilong Li1,3 Chirag R. Parikh,4 Sherry Mansour,5 Orson W. Moe,5 Stuart Goldstein,1 Javier A. Neyra,2 University of Kentucky, Lexington, KY; University of Texas Southwestern Medical School, Dallas, TX; Yale University School of Medicine, New Haven, CT; Johns Hopkins University, Baltimore, MD; Cincinnati Children’s Hospital Medical Center, Cincinnati, OH.

Background: Renin is a marker of tissue perfusion and may be useful in predicting mortality in critically ill patients. Renin might also reflect structural kidney damage in heterogeneous AKI settings. We examine if renin levels are different in patients with vs. without AKI and if renin levels associate with adverse outcomes in critically ill patients.

Methods: Multicenter observational study utilizing blood samples of critically ill patients (KLAKI) and patients undergoing cardiac surgery (TRIBE-AKI). Renin was measured by ELISA in serum from 296 critically ill patients at 24-48 h of AKI diagnosis (KDIGO ≥2) or ICU admission (controls), and peroperative in plasma from 105 patients undergoing cardiac surgery (35 with AKI [≥0.3 mg/dL increase or ≥50% increase in serum creatinine from baseline preoperative level to postoperative level] and 70 controls without AKI). The association of renin levels with hospital mortality and major adverse kidney events at hospital discharge (MAKE: composite of death, need of renal replacement therapy or patients to recover more than 75% of baseline eGFR) was evaluated in the critically ill group.

Results: Renin levels were higher in critically ill patients with AKI vs. ICU controls without AKI (median [IQR], 67.9 [21.7-343.7] vs 22.2 [6.4-73.0] pg/mL, p<0.001). Similarly, patients undergoing cardiac surgery who developed postoperative AKI had pre and postoperative renin levels differentially higher than those without AKI, sustained from POD1 to POD3 (157.9 [80.0-390.8] vs. 68.9 [20.6-149.9] pg/mL at POD1 in AKI vs. no AKI, p=0.003). In adjusted models, higher renin levels independently associated with increased risk of hospital mortality (OR: 1.27, 95%CI: 1.02-1.58 for every 1-unit increase in renin vs. no AKI, 3.44, 95%CI: 1.08-11.02 when the highest tertile was compared to the lowest tertile). Further, every 1-unit increase in renin increased the risk of MAKE by 16% (95%CI: 1.33%-18%).

Conclusions: Renin levels are differentially higher in patients with heterogeneous AKI when compared to controls without AKI. Renin levels associate with hospital mortality and MAKE in critically ill patients and therefore its risk-stratification should be further explored in this vulnerable population.

PO0066

Biomarker and Safety Results from a Phase 1b Study of RBT-9 in Healthy Volunteers and Subjects with CKD Stage 3/4

Richard A. Zager,1 Bhupinder Singh,2 Alvaro F. Guillen,3 Stuart Goldstein,2 Fred Hutchinson Cancer Research Center, Seattle, WA; University of Washington Department of Medicine, Seattle, WA; Renibus Therapeutics, Southlake, TX; University of California Irvine, Irvine, CA; Cincinnati Children’s Hospital Medical Center, Cincinnati, OH.

Background: Acute kidney injury (AKI) remains a major unmet medical need without any FDA approved preventive or therapeutic options. Safe administration of pharmacologic agents that can prevent AKI in the hospital setting have great potential given the high rate of AKI-related morbidity and mortality. Organ preconditioning to elicit a state of induced cytoprotection prior to insult, such as cardiac surgery, is a mechanism by which the drug RBT-1 has been shown to be protective in various animal models of AKI including glycercyl-induced rhabdomyolysis, maleate-induced hypoxic/ischemic renal injury, and ischemia reperfusion injury. RBT-1 is composed of proprietary formulations of stauromycin prolymphoprotein (RBT-9) and iron sucrose (RBT-3). We conducted three phase 1 clinical trials to study the effect of RBT-1, RBT-3, and RBT-9 on biomarkers of cytoprotection observed in experimental animals and on clinical safety. Herein, we report results from the Phase 1b study of RBT-9 in both healthy volunteers and subjects with CKD Stage 3/4.

Methods: Forty-two subjects were enrolled and received a single dose of RBT-9 at 9 mg (N=6), 27 mg (N=18), and 90 mg (N=18). None of the subjects in the 9 mg group had CKD; 12 subjects (67%) in each of the 27 and 90 mg groups had CKD. Mean age was 59.5 years.

Results: The highest dose of RBT-9 dose-dependently induced cytoprotective biomarker responses (heme oxygenase-1 [HO-1], ferritin, NADPH dehydrogenase [quinone 1] [NQO1], and interleukin-10 [IL-10]) in both healthy volunteers and CKD subjects. Treatment-emergent adverse events (TEAEs) were reported in 20 subjects (47%), the majority of which were photosensitvity events and largely confined to the 90 mg treatment group. TEAEs were generally mild in severity. Only 3 TEAEs were moderate; no TEAEs were severe. No serious adverse events were reported. All TEAEs resolved during follow-up. There was no evidence of renal injury, as assessed by albuminuria and various biomarkers of renal tubular injury (KIM-1, NGAL, cystatin C, NAG).

Conclusions: We conclude that RBT-9 was safe and well tolerated in healthy volunteers and subjects with CKD. Adverse events were generally mild and related to photosensitivity reactions. Dose-dependent cytoprotective protein responses were observed that have previously corresponded with AKI protection in experimental animals.

Analysis of AKI in Patients with Systemic Lupus Erythematosus

Si Li, Yichen Wang, Nascha Elavia, Bojana Milekic. The Wright Center for Graduate Medical Education, Scranton, PA.

Background: Renal involvement is commonly seen in systemic lupus erythematosus (SLE). The goal of our study is to analyze the impact and burden of acute kidney injury (AKI) on patients with SLE.

Methods: We analyzed the Healthcare Cost and Utilization Project Nationwide Inpatient Sample from the years 2012 to 2014. We included patients aged 18 years or older with either a primary or secondary diagnosis of SLE. Descriptive analyses were performed with a focus on patient characteristics and comorbidities. We used weighted multivariable survey regression methods to assess outcomes. Statistical analysis was performed using STATA 16.0. We considered a P value of <0.05 as statistically significant.

Results: We identified a total of 101,615 hospitalizations with SLE, of which 9,475 (9.3%) had AKI. Patients with a diagnosis of AKI were younger (mean age 39.3 vs. 45.4), more likely to be male (16.5% vs. 8.9%), black (45.5% vs. 33.5%), discharged from a teaching institution (72.2% vs. 65.4%). Patients with AKI had a higher prevalence of chronic kidney disease (53.2% vs. 10.1%), hypertension (74.5% vs. 47.5%). After adjustment with the patient and hospital level of confounder, the presence of AKI was independently associated with increased overall in-hospital mortality in patients with SLE (adjusted odds ratio [aOR] 12.1, 95% confidence interval [CI] 6.5-22.4, p<0.001). Length of stay (LOS) was 5.0 days longer (95% CI 4.5-5.6, p<0.001) in patients with AKI, and total hospital costs were $124,856 more than in patients without AKI (95% CI 106,556-143,152, p<0.001).

Conclusions: Patients with AKI were more likely to die in the hospital, had a longer length of stay, higher inpatient care costs. Thus, the presence of AKI poses a significant burden on patients with SLE. Close monitoring and early treatment are warranted in this population.
Efficacy Evaluation of Neutrophil Gelatinase-Associated Lipocalin and Cystatin C in Urine as Biomarkers in Early Diagnosis of AKI in Preterm

Dong Li. Dalian Municipal women and children’s medical center, Dalian, China.

Background: To investigate the value of neutrophil gelatinase-associated lipocalin (NGAL) and cystatin C in urine in the early diagnosis of acute kidney injury in preterm and the efficacy of these two biomarkers in urine.

Methods: A prospective study was conducted on 98 preterm admitted to the NICU, including 55 males and 43 females. According to the diagnostic criteria for neonatal AKI published by the Acute Kidney Injury Network and the Kidney Disease Improving Global Outcomes (KDIGO), the serum creatinine is 1.5 times of the basic level or the urine volume is less than 1.5 ml/(kg*h) ≥24 h, 10 cases of AKI and 88 cases of non-AKI were confirmed on the first day of inclusion, 3 cases of AKI and 95 cases of non-AKI were confirmed on the seventh day of inclusion. Urine samples were collected on the day1, day7 of inclusion and the day of urine volume significant decrease (urine volume < 1.5 ml/(kg*h)), urine NGAL (uNGAL) and urine cyst-C were measured by ELISA, meanwhile serum creatinine were measured. The study was approved by the ethical community board and written consent was obtained from the kids’ parents.

Results: Among 98 cases, 10 cases were separated in AKI group and 88 in non-AKI group on the admission day, uNGAL and urine cyst-C in the AKI group were significantly higher than those in the non-AKI group (P < 0.05). On day 7, 3 cases were diagnosed AKI and 95 cases in non-AKI group. uNGAL and urine cyst-C in the AKI group were significantly higher compared with those in the non-AKI group (P < 0.05). Receiver operating characteristic curves (ROC) for the diagnosis of AKI on day 1 and day 7 were drawn, the area under the curve(AUC) of urine cyst-C on day1 and day 7 was 0.922 vs. 0.849, the sensitivity was 0.900 on day (when the critical value for AKI as 25.19ng/ml), and the sensitivity on day7 was 1(When the critical value was set 23.16ng/ml), and the specificity of urine cyst-C on day1 vs. day7 was 0.975 vs. 0.737 separately. The area under the curve(AUC) of uNGAL for AKI diagnosis was 0.860(day1) and 0.867(day7). When the critical value for AKI diagnosis was 100.12 g/L, the sensitivity for uNGAL was 1, and the specificity was 0.695. The positive value for uNGAL on day1 and day7 were 96% and 100% separately.

Conclusions: NGAL and cyst-C in urine can be used as biological indicators for the diagnosis of AKI in premature infants.

AKI in Sickle Cell Disease

Si Li, Nasha Elavia, Yichen Wang, Bojana Milekic. The Wright Center for Graduate Medical Education, Scranton, PA.

Background: Sickle cell disease may cause acute injury to the kidney, especially during sickle cell crisis. Which mainly related to underlying stress-induced renal vasculopathy and alterations in glomerular hemodynamics. There is a paucity of national-level evidence showing the effect of acute kidney injury (AKI) on patients hospitalized with sickle cell disease. We aim to quantify the relationship between AKI and mortality and resource utilization in patients with sickle cell disease.

Methods: We analyzed adult patients admitted from 2012 to 2014 with a primary or secondary diagnosis of sickle cell disease using the Nationwide Inpatient Sample (NIS). The NIS is the largest publicly available inpatient database in the United States (U.S.). It contains data from approximately 8 million hospital stays each year, representing a 20% stratified sample of all U.S. non-federal hospitals, and is sponsored by the Agency for Healthcare Research and Quality as part of the Healthcare Cost and Utilization Project (HCUP). The International Classification of Diseases, Ninth Revision, Clinical Modification Coding System (ICD-9-CM) was used to identify comorbidities. Survey multivariate regression analysis was performed using STATA 16.

Results: We included 240,550 admissions with sickle cell disease, majority of them were black patients (93%), 10,825 (4.5%) of sickle cell disease patients had AKI. Patients with AKI were older (mean age 41.3±12.5 vs. 31±10.4, p<0.001), more likely to be male (53.1% vs. 44.4%, p<0.001). Sickle cell disease patients had higher prevalence of hypertension (49.9% vs. 16.8%, p<0.001), coronary artery disease (6.3% vs. 2.1%, p<0.001), congestive heart failure (22.5% vs. 4.4%, p<0.001), diabetes mellitus (9.8% vs. 3.5%, p<0.001). After adjusting for patient and hospital-level confounders, patients with AKI had higher odds of mortality (adjusted odds ratio [aOR] 11.3, 95% confidence interval 7.04–18.34, p<0.001), a longer length of stay (2.6 days, 95% CI: 1.2–2.93 days, p<0.001), higher costs (S6707.2; 95% CI: $5816.2–$7598.3, p<0.001).

Conclusions: The demographic characteristics were significantly different between patients with or without AKI. Sickle cell nephropathy imposes a burden on both individual and health care systems. Randomized controlled trials are needed to investigate the role of vaso-occlusive events on AKI development.

Combining Renal Arrest and Damage Biomarkers to Predict the Progression of AKI in Patients with Sepsis

Xiaobing Yang, Xiaolei Tao, Southern Medical University Nanfang Hospital, Guangzhou, China.

Background: Septic AKI accounts for approximately half of all AKI in ICU, and up to 40% of mild or moderate septic AKI would progress to more severe AKI which is associated with significantly increased risk for in-hospital death and later CKD/ESRD.

Conclusions: NGAL and cyst-C in urine can be used as biological indicators for the diagnosis of AKI in premature infants.

Funding: Government Support - Non-U.S.
Early identifying high risk patients for AKI progression might help physicians to enhance individualized monitoring and personalized management in patients with septic AKI.

Methods: This is a prospective, multicenter cohort study which enrolled adult septic patients who initially developed stage 1 or stage 2 AKI in the ICU from January 2014 to March 2018. Sepsis was diagnosed based on the 2016 Sepsis-3 criteria, and AKI was diagnosed and staged according to 2012 KDIGO-AKI guidelines. Renal arrest biomarkers (urinary TIMP2*IGFBP7 [u TIMP2*IGFBP7]) and renal damage biomarkers (urinary KIM-1 [uKIM-1] and urinary IL-18 [uIL-18]) were measured at a time of AKI clinical diagnosis, and the utility of biomarkers for predicting septic AKI progression alone or in combination were evaluated. The primary outcome was AKI progression defined as worsening of AKI stage. The second outcome was receiving dialysis or death during ICU stay.

Results: A total of 149 septic patients with stage 1 or stage 2 AKI were included, 63 patients developed progressive AKI. 49 patients received dialysis or died during ICU stay. uTIMP2*IGFBP7, uKIM-1 and uIL-18 independently predicted the progression of septic AKI in which uTIMP2*IGFBP7 showed the greatest AUC (0.745; 95%CI, 0.667-0.823) as compared to uKIM-1 (AUC 0.719; 95%CI 0.638-0.800) and uIL-18 (AUC 0.619; 95%CI 0.525-0.731). Combination of uTIMP2*IGFBP7 with uKIM-1/uIL-18 further improved the performance of predicting septic AKI progression with AUCs of 0.752 (uTIMP2*IGFBP7 with uKIM-1) and 0.747 (uTIMP2*IGFBP7 with uIL-18), respectively. uTIMP2*IGFBP7, alone or combined with uKIM-1/uIL-18, improved the risk reclassification over the clinical risk factor model alone both for the primary and secondary outcomes, as evidenced by significant category-free net reclassification index.

Conclusions: Combination of renal arrest and damage biomarkers enhanced the prediction of AKI progression in patient with sepsis and improved risk reclassification over the clinical risk factor model alone.

PO0072
Bicarbonate May Not Be the Best Treatment for Rhabdomyolysis: A Retrospective Cohort Study
Hye Won Kim,1 Yunseo Lee,2 Sejoong Kim.1 1Seoul National University Bundang Hospital, Seongnam, Republic of Korea; 2Seoul National University College of Medicine, Seoul, Republic of Korea.

Background: It is controversial whether the use of bicarbonate solution, which has been traditionally attempted to treat rhabdomyolysis, has the beneficial effect of reducing acute kidney injury (AKI) and mortality, compared with the use of non-bicarbonate solution. The purpose of this study is to analyze whether bicarbonate therapy versus non-bicarbonate therapy may be effective in preventing AKI and death in patients with rhabdomyolysis.

Methods: We collected 4077 hospitalized patients with creatinine kinase (CK) > 1000 U/L and divided them into 2 groups: patients who received fluid with bicarbonate and who received fluid without bicarbonate. Patients were subgrouped into low (<2ml/kg/hr), middle (2-4ml/kg/hr) and high (>4 ml/kg/hr) amounts of fluid to receive in first 72 hours of admission. Cox regression analysis models were used to identify risks for dialysis and mortality. Safety profiles were assessed by volume overload and electrolyte imbalances.

Results: In a total of patients with a mean age of 57.9 years (male 66.7%), bicarbonate-containing solution was used in 61.1% of the participants. The proportion of the subjects were 34.6%, 36.5%, and 28.9% for the low, middle, and high fluid group, respectively. The bicarbonate group showed higher incidence rate of AKI (OR 4.5), higher 1-year mortality (OR 3.1) and longer hospital stay (26.6 ± 54.4 vs. 22.0 ± 22.7 days) than the non-bicarbonate group. Patients high given amount of fluid therapy showed higher incidence rate of AKI (OR 3.1), higher rate of dialysis dependency (OR 2.7) and higher 1-year mortality (OR 1.4), compared with low fluid group, regardless of the use of bicarbonate. The use of bicarbonate (adjusted HR [aHR] 1.55), volume overload (aHR 1.28) were associated with higher mortality while the use of furosemide (aHR 0.8) showed the preventive effect. Baseline CK or peak CK were not related to the risk of dialysis or death. Volume overload was significantly higher in the bicarbonate group compared with the non-bicarbonate group.

Conclusions: We showed bicarbonate therapy or high-volume fluid management in patients with rhabdomyolysis were not beneficial in preventing AKI and death, compared with the non-bicarbonate therapy or low-volume fluid management. It suggests that limited use of bicarbonate and adjustment of fluid volume may improve the short-term and long-term outcome of rhabdomyolysis.

Plasma Metabolites Do Not Change Significantly After 48 Hours in Patients on CRRT
Benjamin R. Griffin,1 Matthew Ray,2 Kristy Roloff,2 John T. Brinton,2 Javier A. Neyra,2 J Pedro Teixeira,4 Kirby Mayer,1 Katja M. Gist,2 Muhammad Aflahi,2 Diana I. Jalal,2,3 Julie Haines,2 Sarah Faubel,2,4 University of Iowa, Iowa City, IA; 2University of Colorado, Denver, CO; 3University of Kentucky, Lexington, KY; 4University of New Mexico, Albuquerque, NM; 5Iowa City VA Medical Center, Iowa City, IA; 6VA Eastern Colorado Health Care System, Aurora, CO.

Background: Continuous renal replacement therapy (CRRT) is used in critically ill patients with hemodynamic instability. One of the primary aims of CRRT is to remove solutes that accumulate due to impaired kidney function. Surprisingly, few studies have assessed plasma solute levels during CRRT, and the duration of CRRT necessary to achieve adequate solute removal is unknown.

Methods: To assess the effect of CRRT on plasma solutes, metabolites were determined via targeted ultra-high pressure liquid chromatography coupled to mass spectrometry (UHPLC-MS) in 13 critically ill patients requiring CRRT. Metabolites were assessed on plasma collected prior to CRRT initiation, and on plasma and effluent collected on days 1, 2, and 3 thereafter.

Results: A total of 101 annotated metabolites were evaluated. Plasma levels of 22 metabolites (21.8%) were significantly reduced by Day 1 of CRRT, and included creatinine, phosphate, lactate, and the amino acids alanine, proline, and cysteine. Only 2 metabolites (2.0%) were significantly reduced between Day 1 and Day 2, and none were reduced between Day 2 and Day 3. Figure 1 demonstrates that marginal changes in solute levels decrease as CRRT progresses. All metabolites were detected in the effluent, and the sieving coefficients for metabolites that were reduced versus not reduced after CRRT were not statistically different.

Conclusions: No further reduction in plasma metabolites occurred after 48 hours of CRRT. Since the median CRRT treatment time is 4-7 days nationwide, with some patients treated substantially longer, these data bring into question the utility of prolonged, uninterrupted CRRT therapy, and have major potential implications for the duration of CRRT in the ICU population.

PO0074
Sustained-Low-Efficiency Dialysis with Regional Citrate Anticoagulation and a Standard Hemodialysis Machine in Critically Ill Patients with AKI Francesco Di Mario,1 Filippo M. Fani,2 Paolo Greco,1 Caterina Maccari,1 Elisabetta Parenti,1 Tommaso Di Motta,1 Maria Teresa Farina,1 Giuseppe Regolisti,1 Enrico Fiacchadori,1 1UO Nefrologia, Azienda Ospedaliera-Universitaria Parma, Parma, Italy, Parma, Italy; 2UO Nefrologia e Dialisi, Ospedale San Giovanni di Dio, USL Toscana centro, Firenze, Italy.

Background: Sustained-Low Efficiency Dialysis (SLED) is an increasingly used Kidney Replacement Therapy (KRT) modality in critically ill patients with Acute Kidney Injury (AKI); in this setting regional citrate anticoagulation (RCA) is a rational approach to avoid extracorporeal circuit clotting. The present study was aimed at evaluating the safety and efficacy of a simplified RCA protocol for SLED with a conventional hemodialysis machine.

Methods: SLED was performed for 8-12 hours (daily or every other day) with a Sutural X Nipro® hemodialysis machine and a cellulose triacetate filter (Sureflex-19L, 1.9 m2, KUF 19 ml/mmHg/h). Blood flow was set at 200 ml/min and dialysis fluid flow at 100 ml/min. Citrate was infused in pre-dilution as ACD-A solution (citrate 2.2%, 112.9 mmol/L) at 200-400 ml/h rates (estimated pre-filter citrate concentration 2.4 mmol/L). Treatment was monitored by serial evaluations of ionized calcium (Ca++) and ACT at the beginning, at the 2nd hour and at the end of SLED session. Blood in the extracorporeal circuit was recalcified by the dialysis fluid itself (Ca++ 1.5 mmol/L) through Ca++ backfiltration; i.e. calcium supplementation was started only if patient Ca++ at the 2nd hour was <0.9 mmol/L.

Results: 41 SLED sessions were performed in 12 critically ill patients with AKI (mean age 69 ± 18 SD, mean APACHE II 22). Average pre- and post-SLED urea values were respectively 94 and 32 mg/dL. Most sessions (38/41, 93%) were completed for elapsed prescribed time. No statistically significant differences were observed between systemic ACT values measured during SLED as compared to baseline values. Ca supplementation
(10% Ca gluconate at fixed rate 5 ml/hour) was needed in 10/44 treatments, with rapid normalization of serum Ca. No new cardiac arrhythmia episode or hemorrhagic events were observed.

Conclusions: Our preliminary data suggests that a simplified RCA protocol for SLED using a conventional dialysis machine is easy and safe, also ensuring a good match between prescribed and actual dialysis dose administered.

PO0075 Prediction of AKI in Inpatient General Medical Ward Units Cassandra Chiao, Rachel Urban, Fauzia Osman, Tripti Singh. University of Wisconsin System, Madison, WI.

Background: Acute kidney injury (AKI) is common in hospitalized patients (A). A few scoring systems have been proposed to predict the risk of developing AKI in certain populations such as cardiac catheterization patients (B, C, D, E, F). However, there is no scoring system for predicting AKI in patients on the general medical wards. Our aim is to predict the development of AKI in acute general medical patients.

Methods: Retrospective single center study of all adult patient admitted to a tertiary care university hospital between July 2016-July 2018. AKI was defined by the KDIGO definition of AKI and all stages of AKI were included. We used chi-squared tests, ANOVA, and Kruskal Wallis to determine statistically significant factors. We calculated odds of AKI using logistic regression models. All analyses were conducted using STATA SE 15.

Results: A total of 10,981 were included in the study, 1,573 (14.3%) with AKI and 9,408 (85.7%) without AKI. Baseline demographics were significantly different between the two groups including age, race, length of hospital stay (p<0.001). In the univariate analysis, history of cancer and diabetes, proteinuria, admission BUN, hemoglobin (HGB), and hypotension during admission were predictive of AKI. After adjustment for significant univariable factors, age (OR 0.97 [0.96–0.99], p<0.001), admission BUN (OR 1.02 [1.01–1.04], p<0.001), and HGB (OR 0.79 [0.73–0.85], p<0.001) were significant in the multivariable analysis (Table 1).

Conclusions: We found that the age, admission BUN, and HGB were predictive of AKI in inpatient general medical units. These criteria can be used in acute general medical patients to create a scoring system to determine the likelihood of developing AKI and therefore prevent AKI and its downstream complications in these patients.

PO0076 Is Procalcitonin a Reliable Marker of Bacterial Infection in Patients with AKI? Mariam Charkviani, Sumit Sohal, Natia Murvelashvili, Maria Yanez Bello, Daniela Trelles, Alisha Sharma. Amita Saint Francis Hospital, Evanston, IL.

Background: Procalcitonin (PCT) is a biomarker that helps to distinguish bacterial infections from other causes of infection or inflammation and can be used as a helpful adjunct to clinical judgment for resolving diagnostic uncertainty. Limited data is available about the diagnostic value of PCT in patients with acute kidney injury (AKI). We aimed to assess the diagnostic usefulness of serum PCT level as a marker of bacterial infection in patients with AKI and assess the correlation of serum creatinine clearance to serum PCT level.

Methods: This retrospective case-control observational study involved patients admitted to the hospital during the study period and had PCT checked. Patients were categorized into proven, possible, and no bacterial infection groups. We compared PCT level in AKI group with proven bacterial infection vs no bacterial infection and PCT level during proven and no bacterial infection groups with AKI vs non-AKI. Patients with end-stage kidney disease and other causes of elevated PCT (pancreatitis, cancer, sepsis, etc.) were excluded.

Results: 379 patients were analyzed, 24 patients were excluded from the study. 66 patients classified into the AKI group and 226 into the non-AKI group. 107 patients were in a proven bacterial infection group and 98 Patients in no bacterial infection group. The mean value of PCT was significantly higher with confirmed bacterial infection compared to no bacterial infection in all patients despite their renal function (4.98±7.75 vs 1.66±4.88, p<0.001). PCT level was higher in the AKI group than in the non-AKI group (10.99±12.24 vs 2.39±2.93, p<0.001) in patients with a proven bacterial infection. Patients with no infection had much higher PCT level in the AKI group as compared to the non-AKI group (5.76±14.67 vs 0.71±1.39, p<0.003). PCT level was also significantly higher during confirmed bacterial infection vs no bacterial infection in patients with AKI (9.2±11.05 vs 0.7±2.17, p<0.04). There was a weak positive correlation between creatinine clearance and PCT level (correlation coefficient 0.125, p<0.15).

Conclusions: Higher cutoff level of PCT is needed in patients with AKI to use it as a marker of infection. The specificity of PCT may decrease in patients in AKI if current reference cutoff values are used to guide clinical decisions.

Background: While multiple studies have used statistical models to predict outcomes after AKI, no studies have compared these models to physician intuition at the time of AKI consult. We studied the accuracy of physicians in predicting outcomes after AKI and compared it to the strength of predictive statistical models.

Methods: Our pilot study focuses on the prediction of 3 outcomes after AKI: Recovery, progression to dialysis and mortality. Postgraduate years 4 and 5 level Nephrology providers were asked, at the time of initial renal consult, to forecast outcomes at 3 timepoints: 24hr, 48hr and 7 days. We compared physician prognosis to a gradient boosted trees model trained using retrospective EHR data. Our primary measure of performance was area under the receiver operating characteristic curve (AUCROC) at each time point.

Results: Data was captured from 56 patients with stage 2 AKI. Nephrology providers (<7) were good at predicting dialysis at all three timepoints and death at 48 hours and 7 days. In contrast, their ability to predict recovery of AKI was relatively poor. The statistical model performed significantly better at predicting death at all timepoints, however was poorer at predicting dialysis (Figure 1.0).

Conclusions: Both physician clinical acumen and our statistical model showed good performance in predicting need for dialysis and death after AKI, however performed poorly when predicting recovery. This highlights the need to conduct further in-depth analysis into this area and implement strategies to enhance prediction of recovery after AKI.

PO0078 Short-Term Prognosis of Patients with Cardiorenal Syndrome Type 1-Induced AKI Requiring Continuous Renal Replacement Therapy Yusuke Watanabe, Kei Sugiyama, Daichi Fukaya, Hiroaki Amano, Tsutomu Inoue, Hirokazu Okada. Saitama Medical University, Iruma-gun, Japan.

Background: Cardio-renal syndrome (CRS) type 1 is a condition wherein an acute heart failure (AHF) leads to the development of acute kidney injury (AKI). Continuous renal replacement therapy (CRRT) is used to remove excess solutes and fluids in CRS type 1 patients who have diuretic resistance. However, little is known about the outcomes of CRS type 1 patients who undergo CRRT.

Methods: We reviewed the clinical data of 74 consecutive CRS type 1 patients treated with CRRT from 2012 to 2015. Patients who underwent cardiovascular surgery and those who had chronic kidney disease stage 5 prior to admission were excluded. The primary outcome examined was in-hospital mortality.

Results: The mean age of patients was 70.6 ± 13.6 years old. The causes of AHF were ischemic heart disease (51.4%), valvular disease (13.5%), and other diseases. At the time of the CRRT initiation, the mean serum creatinine was 2.8 ± 1.0 mg/dL. The in-hospital mortality rate was 77.0%. Compared with non-survivors, the survivors had fewer number of previous hospitalizations for heart failure (50.9% vs. 23.5%, p = 0.046), higher systolic blood pressure (97.7 ± 22.2 mmHg vs. 112.3 ± 21.1 mmHg, p = 0.02), better ejection fraction (31.4 ± 17.9% vs. 42.0 ± 15.7%, p < 0.03), smaller inferior vena cava (IVC) diameter (18.0 ± 5.8 mm vs. 14.8 ± 4.4 mm, p = 0.04), less respiratory variations in the IVC diameter (59.6% vs. 49.9%, p = 0.04), lower serum vasopressor requirement (96.5% vs. 31.9%, p = 0.001), and lower respiratory support (36.1% vs. 23.5%, p = 0.02) at CRRT initiation. The survivors required a shorter CRRT duration over the non-survivors (6.1 ± 6.9 days vs. 11.7 ± 12.4 days, p = 0.03). Through the multiple logistic regression analysis, certain factors were associated with a poor short-term prognosis. These factors were history of previous hospitalizations for heart failure, vasopressor requirement upon start of CRRT, and the need for respirator support at CRRT initiation.

Conclusions: In our single-center experience, the use of CRRT for treating AKI caused by CRS type 1 was associated with a high in-hospital mortality rate. Patients with a history of previous hospitalization for heart failure, those who required vasopressors, and patients needing respirator support at CRRT initiation had an especially poorer prognosis.
PO0079

Roux-en-Y Gastric Bypass Is the Most Common Current Cause of Biopsy-Proven Oxalate Nephropathy

Swetha Reddy,1 John C. Lieske,2 Mira T. Keddis.1 1Mayo Clinic Arizona, Scottsdale, AZ; 2Mayo Clinic Minnesota, Rochester, MN.

Background: The objective of this study was to analyze patient characteristics and outcomes of biopsy-proven oxalate nephropathy likely due to an enteric cause at a single large tertiary health system.

Methods: Cases of oxalate nephropathy were identified based on documented kidney biopsy findings between 2009-2019 in patients with an associated enteric process likely to cause fat malabsorption.

Results: A total of 30 cases were identified (mean age of 65.2±8.56 years; 18(60.0%) female) with a median follow-up of 5 months; Risk factors included hypertension in 21(70%), diabetes in 14 (46.7%), chronic kidney disease (CKD) stage 3A or greater in 16(53.3%) and prior kidney stones in 6(20%). The most common enteric causes were Roux en Y gastric bypass (RYGB) in 17(56.7%), pancreatic insufficiency in 6(20%), inflammatory bowel disease in 4(13.3%), and recurrent C. difficile infection in 3(10%). At the time of diagnosis, acute kidney injury (AKI) stage II and stage III were present in 9 (30%) and 15 (50%) respectively, while 11(36.7%) required dialysis. Urinalysis revealed proteinuria in 16(53.2%), oxalate crystals in 10(33.3%), and hematuria in 9(30%). Median plasma oxalate at the time of biopsy was 18.3 (reference <2.01) μmol/L in 26 patients and median 24 hour urine oxalate excretion was 53 (reference [9.7-40.5]) mg/24 hrs in 17 patients. RYGB patients had a higher plasma oxalate compared to patients with other enteric causes (median 24.6 vs 16.5 μmol/L; p=0.03). Renal biopsy and clinical outcomes are shown in table1. Patients with acute tubular injury had greater number of tubules with calcium oxalate crystals by biopsy (median 19 vs 4), as did patients with CKD5 at last follow-up (20 vs 6). Features at the time of biopsy predictive of CKD5 at follow-up included AKI severity (p=0.002), dialysis at diagnosis (p=0.0008), and the presence of moderate to severe tubulointerstitial atrophy (p=0.001).

Conclusions: In this series RYGB was the most common enteric cause of biopsy-proven oxalate nephropathy. Severity of AKI at presentation and degree of tubulointerstitial fibrosis were both associated with worse renal outcome. The amount of renal crystal deposits at diagnosis associated with the short and long term renal injury.

Renal Histology (A) & Outcome (B)

PO0080

Impact of AKI on In-Hospital Outcomes in Chinese Patients with Community-Acquired Pneumonia

Dawei Chen, Xin Wan. Nanjing First Hospital, Nangjing, China.

Background: Acute kidney injury (AKI) is common in community acquired pneumonia (CAP). However, the impact of AKI on in-hospital outcomes of patients with CAP in the population of Chinese remains largely unknown.

Methods: Multiple Cox regression models were employed to identify the association between AKI and in-hospital mortality and 30-day mortality.

Results: 4213 patients were included, and 950 (22.5%) patients were AKI. The independent risk factors for AKI were age, male, hypertension, cardiac dysfunction, diabetes, chronic kidney disease, acute respiratory failure, diuretic, vasoactive drugs, and CURB-65. After multivariable Cox regression, independent risk factors of in-hospital mortality and 30-day mortality were similar: AKI, ACEI/ARB, hypertension, CURB-65, acute respiratory failure, and using vasoactive drugs. Patients developed AKI had worse in-hospital outcomes. Patients with AKI had increased 1.31-fold (HR 1.31, 95 % CI, 1.04–1.66, p< 0.001), non-invasive mechanical ventilation (25.9% vs. 5.8%; P < 0.001), invasive mechanical ventilation (25.4% vs. 7.1%; P < 0.001), and had a longer length of hospital stay (14 days vs. 10 days; P < 0.001) than those without AKI.

Conclusions: AKI was common in Chinese patients with CAP. Patients with CAP who developed AKI had worse in-hospital outcomes.
PO0082

Mortality Prediction of Serum Neutrophil Gelatinase-Associated Lipocalin in Patients Requiring Continuous Renal Replacement Therapy
Byung ha Chung,1 Yohan Park,1 Hyung Duk Kim,1 Eun jeong Ko,1 Tae Hyun Ban,2 Cheol Whee Park,1 Chul Woo Yang,1 Seoul Saint Mary's Hospital, Seocho-gu, Seoul, Republic of Korea; 2Eunpyeong Saint Mary’s Hospital, Eunpyeong-gu, Seoul, Republic of Korea.

Background: We investigated whether serum neutrophil gelatinase-associated lipocalin (NGAL) can predict mortality in patients with acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT).

Methods: This study enrolled 169 patients who underwent serum NGAL testing at CRRT initiation from June 2017 to January 2019. The predictive power of serum NGAL level for 28-day mortality was compared to the Acute Physiology and Chronic Health Evaluation-II (APACHE-II) score and Sequential Organ Failure Assessment (SOFA) score via area under the receiver operating characteristic curve (AuROC) value.

Results: There were 55 survivors and 114 non-survivors at 28 days post-CRRT initiation. Median serum NGAL level was significantly higher in the non-survivor group than in the survivor group (743.0 vs. 504.0 ng/mL, P=0.003). The AuROC value of serum NGAL level was 0.640, which was lower than APACHE-II score and SOFA score values (0.767 and 0.715, respectively). However, in the low APACHE-II score group (<27.5), AuROC value of serum NGAL was significantly increased (0.698), and it was an independent risk factor of 28-day mortality (hazard ratio 2.405, 95% confidence interval (1.209-4.783), P=0.012).

Conclusions: In patients with AKI requiring CRRT, serum NGAL levels may be useful for predicting short-term mortality in those with low APACHE-II scores.

Funding: Government Support - Non-U.S.

PO0084

Prevalence, Length of Stay, and Hospitalization of AKI in Patients with and Without Sjogren Syndrome
Mohamedanwar M. Ghandour, Yahya M. Osman Malik, Wayne State University School of Medicine, Detroit, MI.

Background: Acute Kidney Injury (AKI) has emerged as a significant cause of morbidity and mortality in patients with autoimmune diseases. However, this has not been examined in patients with Sjogren’s syndrome (SJS). To achieve this, we examined the prevalence, mortality, outcomes, Length of Stay (LOS), and hospital charges in patients with AKI with SJS compared to patients without SJS from a National Inpatient Sample database in the period 2010-2013.

Methods: Data retrieved from the National Inpatient Sample (NIS) for adult patients admitted with a principal diagnosis of acute kidney injury between 2010 and 2013, using the respective ICD-9 codes. The study population divided into two groups, with and without Sjogren’s disease. Multivariate and linear regression analysis conducted to adjust for covariates.

Results: The study population represented 97,055 weighted patient discharges with acute kidney injury. Analysis revealed acute kidney injury patients with Sjogren’s compared to patients without Sjogren’s had statistically significant lower hyperkalemia rates (adjusted Odds ratio (OR)0.65, CI 0.46 to 0.92; p =0.017). There was no statistically significant difference in mortality, length of stay, hospital charges, and other outcomes. Moreover, The charges of hospitalization and length of stay were found to be statistically insignificant by the adjusted linear regression model. In addition, nearly three quarters of patients had Medicare, followed by privately insured patients with the least number being on Medicaid. More than half of the population have received their treatment in a tertiary center hospital. Charlson’s index reported more than two-thirds of study subjects to have two or more co-morbidities.

Conclusions: At present, our study is unique as it has examined the prevalence, mortality, and outcomes of Sjogren’s in patients with acute kidney injury. Patients with Sjogren’s has significantly lower hyperkalemia during the hospitalization. Further research is needed to identify the underlying protective mechanisms associated with Sjogren’s that resulted in lower hyperkalemia.

PO0085

Clinical Characteristics and In-Hospital Outcomes for 1519 Consecutive Patients with AKI
Christina I. Montenegro, Jonas Spak, Marie Evans, Stefan H. Jacobson,1 Karolinska Institutet, Danderyd University Hospital, Department of Clinical Sciences, Division of Nephrology, Stockholm, Sweden; 2Karolinska University Hospital Huddinge Department of Renal Medicine, Stockholm, Sweden; 3Karolinska Institutet, Danderyd University Hospital, Department of Clinical Sciences, division of Cardiology, Stockholm, Sweden.

Background: Acute kidney injury (AKI) occurs in about 15% of hospitalized patients. Patients who recover from AKI have a higher long-term risk of end-stage kidney disease and death. The aim of this large single center study was to report differences in lab testing findings and short-term hospital outcomes in relation to cause of AKI in consecutive patients in a nephrology department.

Methods: We conducted a retrospective chart review of patient data obtained via an electronic database created as part of the MRC’s program in conjunction with the health system’s electronic health record. Descriptive statistics were utilized to describe baseline characteristics. We restricted analyses to participants without end stage kidney disease on admission and those who survived at least 24 hours to allow for development of AKI. Kaplan-Meier plots were utilized to show death free survival by AKI category. All analyses were conducted using the R Statistical Computing Environment.

Results: We obtained data for 116 patients in the time period since 2015. Among the 116 patients, 55 patients had AKI defined as doubling of creatinine within 7 days but did not require RRT. Of the remaining 61 patients, 28 developed AKI requiring RRT. Patients who developed AKI or AKI requiring RRT had a mortality of 70% at 30 days. The remaining 33 patients who did not develop AKI had a mortality of 52% at 30 days. Regarding electrolyte derangements, cooling was associated with hypokalemia and hypophosphatemia with 64% percent of patients with potassium less than 3 mmol/L and 57% of patients with phosphorus less than 2 mg/dL.

Conclusions: AKI is associated with a high rate of mortality in this unique patient population, and additionally there is marked hypokalemia and hypophosphatemia in the setting of therapeutic cooling. Given the high mortality, this study raises questions regarding optimal treatment strategies for patients who develop AKI, including timing and delivery of RRT and the ideal approach to volume and electrolyte management.
Methods: All patients diagnosed with AKI between 2009 and 2018 and admitted to the nephrology department at Danderyd University Hospital, Stockholm, Sweden, were included. Relevant laboratory and physiological measures were registered. Patients on dialysis treatment were excluded. Patients were followed until discharge or death, whichever came first. 

Results: In 1519 AKI patients, the majority (n=687) was of prerenal, followed by combined (defined as chronic kidney disease combined with any type of AKI) (n=536), renal (n=166), and postrenal (n=130) etiology. Patients with renal AKI were younger, had longer duration of stay, and had higher bicarbonate levels on admission. 63.2% of patients had a sCr decrease of at least 30% from admission during their stay. Most of these had prerenal followed by postrenal etiology. There was no statistically significant difference in mortality between the four etiologies of AKI.

Conclusions: This study provides data from a large, contemporary AKI patient cohort under nephrology care. We confirm that patient characteristics as well as short-term outcomes differ substantially in patients of variable AKI etiology. Greatest in-hospital reduction of sCr was seen in patients with prerenal and postrenal AKI, whereas patients with renal combined AKI had poorer renal recovery. These findings have important implications for prognostic evaluation upon admission and further resource planning.

Traditional and Non-Traditional Risk Factors and Their Influence on In-Hospital Mortality in Community- vs. Hospital-Acquired AKI

Maria Isabel Acosta-Ochoa, Armando Coca, Jimmy R. Sanchez Gil, Alicia Mendiluce. Hospital Clinico Universitario de Valladolid, Valladolid, Spain.

Background: Many studies compare hard outcomes in Community Acquired (CA-AKI) vs. Hospital Acquired AKI (HA-AKI), but few works contrast how various risk factors (RF) impact in-hospital mortality risk in both groups.

Methods: Retrospective study of in-patients with AKI. AKI was classified by KDIGO-2012 Stages. CA-AKI occurred in the first 48h, and HA-AKI >48h after admission. We compared clinical and epidemiological features, and the traditional RF (age, Charlson’s Index (ChI), ICU entrance, and AKI severity). We analyzed hyponatremia (Na) should be explored and modifiable factors should be tackled in order to prevent etiologies between cohorts. We conclude that these novel associations (e.g. anemia and AKI type, probably due to diverse baseline characteristics, evolution time, and AKI etiologies between cohorts). We conclude that these novel associations (e.g. anemia and haematocrit (Ht), had longer hospital stay, were less frequently admitted to medical wards, and less HD dependent at discharge. Mortality was significantly higher among HA-AKI vs. CA-AKI (31% vs.18% p<0.001). See Table 1. Traditional RF correlated with higher risk of death in both groups. Hypertension, heart failure and anaemia Max were associated with mortality in CA-AKI but not in HA-AKI. On the other side, HA-AKI had a higher risk of death associated with HtNa, which was not significant among CA-AKI patients. See Figure 2. 

Conclusions: We found that HA-AKI is more deadly than CA-AKI (consistent with previous studies), but shows lesser HD dependence at discharge. The traditional RF: older age, higher ChI, ICU admission, and AKI stage 3 influenced in-hospital mortality in both groups. Non-traditional RF showed an heterogeneous influence on outcomes according to AKI type, probably due to diverse baseline characteristics, evolution time, and AKI etiologies between cohorts. We conclude that these novel associations (e.g. anemia and HtNa) should be explored and modifiable factors should be tackled in order to prevent AKI mortality.

One-Year AKI Stage 3 Outcome in Elderly Patients at a Secondary Care Hospital in the United Kingdom

Jeetendra R. Rathod, Matthew James, Syed A. Shafqat, Jonathan Kwan. Darent Valley Hospital, Dartford, United Kingdom.

Background: Elderly patients are prone to Acute Kidney Injury (AKI) 3 due to multiple co-morbidities and frailty. The short term and long term outcome and mortality in this group of patients is unclear.

Methods: We prospectively collected data on patients aged over 70 years with AKI 3 from the daily e-alert sent by the hospital biochemistry lab. 117 patients attended or admitted to secondary care hospital in West Kent, UK over 6.5 months between 13 December 2018 and 26 May 2019 were analysed and followed up for next 12 months. AKI 3 was defined as per KDIGO Criteria. Data was collected for age, co-morbidities, serum creatinine at admission, peak, discharge and 12 months, cause of AKI 3 and mortality. Exclusion criteria: AKI stage 1, stage 2 and patients on regular dialysis.

Results: 57% patients had community acquired and 43% developed AKI 3 while as in-patient. The mean age was 80.1 ± 6.2 years with co-morbidities of Chronic Kidney Disease (>3) 64.7%, Cardiovascular disease (CVD) 50%, Diabetes Mellitus 42.2% and Malignancy 8.7%. The stable baseline, peak and discharge s. creatinine (mean ± std dev) were 127.7 ± 85.6, 420.9 ± 222.7 and 248.5 ± 184.5 umol/L respectively. 59.5% patients were reviewed by nephrologists and 20.7% were transferred under renal care. 30.4% had oliguria at presentation. The reasons for AKI 3 were classified as pre-renal (59.48%), uraemic obstruction (11.2%) and renal that included sepsis (13.79%), cardio-renal syndrome (3.45%), drug induced nephrotoxicity (2.6%), other including ATN (9.70%). Renal function recovery was complete in 44.8%, Partial in 22.4% whereas 32.8% did not have any recover. 6 (5.17%) patients needed acute haemodialysis, of these 2 died and 4 (66.6%) were discharged off dialysis and were alive at 12 months. 47.4% patients were alive at discharge with s.creatinine of 173.2 ± 143.2 umol/L while only 32% of the overall patients were alive at 12 months with s. creatinine (eGFR) (mean ± std dev) 161.5 ± 172.1 (48 ± 28 ml/min) with mean follow up of 331 ± 112 days. All patients that did not recover from AKI died.

Conclusions: We conclude that short and long term outcome in patients with AKI 3 aged more than 70 years has high mortality at discharge (52%) and 12 months (68%). AKI 3 is common in patients with co-morbidities of CKD, CVD and Diabetes mellitus. Outcome of acute haemodialysis is effective in select group of patients.

PO0088

Urine Analysis and Urine Electrolytes Among Patients with COVID-19 Infection and AKI

Background: Determining intravascular volume status for patients who have COVID-19 infection and AKI is critical for guiding decisions about fluid management and treating AKI. In this study, we present data on urinalysis and urine electrolytes among patients with COVID-19 infection who developed AKI at our hospital.

Methods: This is a consecutive patients with COVID-19 who were diagnosed with AKI at our center in Spring of 2020 and had a urinalysis performed within 48 hours of diagnosis of AKI. When applicable we used Mann-Whitney test to compare groups.
**PO0089**

**Recovery of Renal Function Among Left Ventricular Assist Device Patients with Severe AKI Requiring Renal Replacement Therapy: A Meta-Analysis**

**Swetha Rani Kanduri, Wisit Cheungpasitporn, Karthik Kovvuru, Pradeep Vaitha, Chariat Thongprayoon, Kianoush Kashani**

**University of Mississippi Medical Center, Jackson, MS, Mayo Clinic Rochester, Rochester, MN.**

**Background:** Acute kidney injury (AKI) is a common and severe complication after left ventricular assist devices (LVAD) implantation with an incidence of 37%; 13% of which requiring renal replacement therapy (RRT). Severe AKI requiring RRT in LVAD patients is associated with high short-term and long-term mortality, compared with those without RRT. While recovery of renal function is associated with better outcomes, the rates of recovery of renal function among LVAD patients with severe AKI requiring RRT are unclear.

**Methods:** Ovid MEDLINE, EMBASE, and the Cochrane Databases were systematically searched from database inceptions through January 2020 to identify studies evaluating the rates of recovery from severe AKI requiring RRT after LVAD placement, which is defined by regained kidney function resulting in the discontinuation of RRT. Random-effects and generic inverse variance method of DerSimonian-Laird were used to combine the effect estimates obtained from individual studies.

**Results:** A total of 268 patients from 14 cohort studies with severe AKI requiring RRT after LVAD were enrolled. Follow-up time ranges from hospital discharge up to 12 months. 78.5% of renal recovery occurred at the time of hospital discharge or within 30 days. Majority (85%) of patients used continuous-flow LVAD. Overall, the pooled estimated rates of AKI recovery among patients with severe AKI requiring RRT was 50.5% (95%CI: 34.0%-67.0%), respectively. While the data on pulsatile-flow LVAD were limited, subgroup analysis of continuous-flow LVAD demonstrated the pooled estimated rates of AKI recovery among patients with severe AKI requiring RRT of 52.1% (95%CI: 36.8%-67.0%). Meta-regression analysis did not demonstrate a significant association between study year and AKI recovery rate (p = 0.08). There was no publication bias as assessed by the funnel plot and Egger’s regression asymmetry test in all analyses.

**Conclusions:** Recovery from severe AKI requiring RRT after LVAD occurs approximately 50.5%, and it has not significantly changed over the years despite advances in medicine.

**PO0090**

**Early Nephrologist Interventions to Avoid Kidney Replacement Therapy in AKI**

**Christian P. Flores, Pablo Maggianis, Jonathan Chavez, Jorge J. Font, Joana G. Navarro gallardo, Noel Martinez muriillo, Jose A. Torres, Juan Gómez Fregoso**

**Hospital Civil de Guadalajara Unidad Hospitalaria Fray Antonio Alcalde; Guadalajara, Mexico, Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico.**

**Background:** It is well known that early nephrologist involvement in patients with AKI improve outcomes. Determine which intervention has a greater impact on avoiding the need for KRT will be an important advance.

**Methods:** Our objective was to Identify which nephrologist intervention decrease the need of KRT. We analyze age, gender, comorbid conditions, cause of AKI, pharmacology therapy, cause of KRT, early interventions: fluid, antibiotic and nutritional adjustment, nephrotoxic withdrawal and removal of hyperchloremic solutions and death. Kaplan Meier survival analysis. Multivariable logistic regression model was performed. P< 0.05 which is significant.

**Results:** From 2017 to 2020 288 patients with AKI where analyzed prospectively with a 10 days follow-up, 45 (15%) patients die, overall survival of 84.4% (IC 95%:0.80 – 0.88) (Figure1). Only fluid adjustment decreases the risk of KRT (OR 0.75, 95% CI 0.68-0.81, p < 0.001) while having AKI KDIGO 3 increases the risk (OR 1.12, 95% CI 1.05-1.20, p<0.001)beingbelongtooverloadhemancauseofKRT(OR1.67,95%CI,53-1.82,p<0.001). Between all interventions, just fluid adjustment avoid progression to AKI KDIGO 3 (OR 0.76, 95% CI 0.65-0.89, p < 0.001). (Table1)

**Conclusions:** In AKI, fluid adjustment was the most important nephrologist intervention to avoid KRT.
PO0091

Usefulness of the Neutrophil-to-Lymphocyte and Platelet-to-Lymphocyte Ratios in Community-Acquired AKI

Background: The neutrophil-to-lymphocyte (NLR) and platelet-to-lymphocyte (PLR) ratios have been identified as markers of inflammation and endothelial dysfunction. To date, its usefulness as prognostic markers in community-acquired acute kidney injury (CA-AKI) has not been evaluated.

Methods: We established a cohort of patients with CA-AKI admitted to our Nephrology service from January 2010 to February 2015. NLR and PLR ratios were obtained with the first analysis performed.

Results: We studied 308 patients with CA-AKI, 58% were men, mean age 75.22. Etiology of CA-AKI: prerenal 69.5%; renal 23.1%; obstructive 7.5%. AKI KDIGO stages: I, 14.6%; II, 11%; III 74.4%. CKD was detected in 68.8% 17.15% of cases required hemodialysis and 12.3% died. Mean NLR was 9.14 ± 8.47. Mean PLR was 236.99 ± 228.41. NLR according to etiology was: prerenal 8.55±8; renal 9.73±9.8; obstructive 13.99±14.82 (significant differences between obstructive and prerenal). PLR according to etiology: prerenal 228.31±216.34; renal 236.15±233.77; obstructive 320.37±304.89 (non-significant differences). Within the group prerenal, 79 cases were complicated by acute tubular necrosis (ATN). These cases presented a higher NLR (10.7±10.28 vs NLR 7.8±5.6; p=0.026). There were no significant differences between the PLR of both groups. The NLR showed a significant correlation with the peak creatinine (r=0.186; p=0.001) and the length of hospital stay (multiple linear regression analysis). Through correlations (r=0.134, p=0.018 and r=0.165, p=0.07). The NLR, but not the PLR, was associated with the length of hospital stay (multiple linear regression analysis). Through a multivariate binary logistic regression analysis, the variables that were independently associated with mortality during admission were the Liaño individual severity index and the NLR (OR 1.060; IC 95% 1.014 – 1.108). The best cut-off point of the NLR to predict mortality was 6.68 (AUC 0.584; sensitivity 0.60; specificity 0.58; Youden index 0.178)

Conclusions: In our CA-AKI patients cohort, the NLR was associated with the morbidity and the mortality. More studies are need to confirm this finding, but the easiness of obtaining it and its economic cost make it cost-effective, giving the NLR a leading role in assessing the risk of CA-AKI.

PO0092

Clinical Characteristics and Histologic Descriptions of Acute Tubular Injury: A Systematic Review
Yunmeng Wen,1 Chen Yang,2 Steven Menze,3 Avi Z. Rosenberg,1 Chirag R. Parikh,1 Johns Hopkins Medicine, Baltimore, MD; 1Memorial Sloan Kettering Cancer Center, New York, NY.

Background: The term acute tubular injury (ATI) represents histopathologic renal tubular injury and often manifests clinically as acute kidney injury (AKI). Studies systematically summarizing the clinical presentation and histologic changes in human ATI are limited.

Methods: We comprehensively searched human studies of ATI from 1936 to July 2019. We extracted study characteristics, clinical characteristics and histologic descriptions of ATI by bright field, immunofluorescence or electron microscopy (EM) and by immunohistochemistry. We also compared histology of tubular cell injury as a function of tissue procurement timing and etiologies.

Results: We included 292 studies comprising of 1987 patients. The majority of studies (76%) were single center case reports. The mean age of patients included was 47 years old. 39.3% of patients had hypertension and 24.9% of them had diabetes mellitus. Baseline, peak and lowest creatinine were 1.29 mg/dL, 7.04 mg/dL and 1.86 mg/dL respectively. 48.9% of studies were native kidney biopsy cases, of which 86.7% were performed after serum creatinine peaked. There were significant amount of missing data in these clinical characteristics reported across studies. We identified 16 histologic criteria used to determine ATI. Criteria include the presence of any AKI on day 7 or, if death occurred before 7 days, death without AKI recovery. The Chi-square test was used to compare distributions between groups, if p<0.05 then a pairwise comparison between groups was made using the Chi-square test adjusted with Bonferroni correction.

Results: We found a total of 633 patients with severe AKI (53.6%) within 24h. The rate of severe AKI at 24h was different across phenotypes being highest in the delta and beta phenotypes (80.8% and 73.6% respectively), and lowest in the alpha phenotype (30.1%, overall p<0.0001). Greater CKD was most common in the beta phenotype (52.8%, overall p<0.0001) while in the others was lower (31.4% in alpha, 26.8% in gamma, and 35.0% in delta). The highest prevalence of AKI with CKD was again in the beta phenotype (52.0%, overall p<0.0001). AKD occurred more often in the delta (57.4%) and beta (50.0%) phenotypes compared to alpha (25.0%), gamma (26.6%), or delta (34.8%, p<0.0001). AKD occurred more often in the delta (57.4%) and beta (50.0%) phenotypes compared to alpha (32.7%) and gamma (40.1%, p=0.0002).

Conclusions: Severe AKI was significantly more common among patients with beta and delta phenotypes. However, the beta phenotype had a higher level of underlying CKD that predisposed to new AKI. Alpha and gamma phenotypes not only had lower rates of AKD, but these cases were less likely to progress to AKD.

PO0094
Comparison of Clinical Characteristics of AKI in Patients with Glyphosate and Glufosinate Herbicide Poisoning
In O Sun, A young Cho. Presbyterian Medical Center, Jeonju, Jeollabuk-do, Republic of Korea.

Background: This study aimed to investigate the clinical characteristics of acute kidney injury in patients with glyphosate and glufosinate herbicide poisoning.

Methods: From 2008 to 2019, 230 patients admitted to our hospital after glyphosate or glufosinate intoxication were included in this study. Clinical characteristics, laboratory data, and medical outcomes were analyzed. Patients were divided into two groups: glyphosate and glufosinate groups. The study was limited to patients with acute kidney injury (AKI) and excluded patients with diabetes or chronic kidney disease. Demographic data, laboratory data, and medical outcomes were compared between the two groups.

Results: The study included 230 patients, of which 133 were in the glyphosate group and 97 were in the glufosinate group. The incidence of AKI was 13.9% in the glyphosate group and 10.3% in the glufosinate group. The glufosinate group had a higher prevalence of AKI compared to the glyphosate group (p=0.04). There were significant differences in the levels of serum creatinine, blood urea nitrogen, and serum potassium between the two groups. The glufosinate group had higher levels of serum creatinine and blood urea nitrogen, and lower serum potassium levels compared to the glyphosate group.

Conclusions: Glyphosate and glufosinate herbicide poisoning have different clinical characteristics, and the glufosinate group has a higher incidence of AKI.

PO0095
Clinical Significance of Hypoalbuninemia for AKI in Patients with Scrub Typhus
In O Sun, A young Cho. Presbyterian Medical Center, Jeonju, Jeollabuk-do, Republic of Korea.

Background: The aim of this study is to investigate the clinical significance of hypoalbuninemia for acute kidney injury in patients with scrub typhus.

Methods: From 2009 to 2018, 611 patients were diagnosed with scrub typhus. We divided the patients into two groups (normalalbuminemia vs. hypoalbuninemia) based on the serum albumin level of 3.0 g/dL. We compared the occurrence of AKI, clinical characteristics, and severity of acute kidney injury based on RIFLE classification between the two groups.

Results: Of the total 611 patients, 78 (12.8%) were categorized as hypoalbuminemia group. Compared with patients in normalalbuminemia group, patients in hypoalbuminemia group showed higher incidence of AKI (26.5% vs. 11.5%, p<0.01), and higher total leukocyte counts (10.2 × 10^3/mL vs. 6.7 × 10^3/mL, p<0.01). Hypoalbuminemia group showed significantly longer hospital stay (9.6 ± 6.1 vs. 6.1 ± 3.0, p<0.01) and higher incidence of complications in respiratory system (50% vs. 14%, p<0.01), cardiovascular system (28% vs. 11%, p<0.01), neurologic system. Furthermore, acute kidney injury (58% vs. 18%, p<0.01) was also developed in hypoalbuminemia group. The overall incidence of acute kidney injury was 23.1%; of which, 14.9%, 7.0% and 1.2% were classified as Risk, Injury and Failure, respectively. The serum albumin level correlated with acute kidney injury severity (3.4 ± 0.5 vs. 3.0 ± 0.5 vs. 2.6 ± 0.3, p<0.05). In a multivariate logistic regression analysis for predicting acute kidney injury, age, presence of co-morbidities such as chronic kidney disease, diabetes, or hypertension, total bilirubin, leukocytosis and hypoalbuminemia were significant predictors of acute kidney injury.

Conclusions: Hypoalbuminemia was closely associated with scrub typhus associated with acute kidney injury.

PO0096
Risk Factors for Patient Subgroups with Distinct Health Utility Profiles Following AKI
Yuenting D. Kwong,1 Kathleen D. Liu,1 John A. Kellum,1 Christine Misiaskowski.1
1University of California San Francisco, San Francisco, CA; 2University of Pittsburgh, Pittsburgh, PA.

Background: Health-related quality of life (HRQOL) after dialysis initiation for acute kidney injury (AKI) is low. We sought to determine patient subgroups with distinct health utility profiles at 60 days after diagnosis of AKI and evaluated the potential risk factors associated with subgroup membership.

Methods: The Biologic Markers of Renal Recovery for the Kidney (BioMaRK) study is an observational cohort of patients nested within the Veterans Affairs/National Institutes of Health Acute Renal Failure Trial Network study. Clinical characteristics and biomarkers of inflammation were collected from 817 patients with AKI around the time of hospital admission. The serum bicarbonate level was lower in glufosinate intoxication than in glyphosate intoxication (19.8 ± 4.3 vs. 21.5 ± 3.9, p<0.01). In comparison with patients of glyphosate intoxication, patients with glufosinate poisoning experienced increased inflammation (59.6% vs. 19.7%, p<0.01) and intensive care unit admission (66.8% vs. 38.2%, p<0.01) more frequently. The overall incidence of acute kidney injury was 38.3% in this study, and there was no difference between two groups (35.8% vs. 45.6%, p=0.123).

Results: Patients with glufosinate intoxication showed more severe type of clinical manifestation and intensive care unit admission rates than glyphosate intoxication.

Conclusions: Patients with glufosinate intoxication showed more severe type of clinical manifestation and intensive care unit admission rates than glyphosate intoxication.
PO0099
Design of START: A Phase 2 Study Evaluating the Safety and Efficacy of RBT-1 on Preconditioning Response Biomarkers in Subjects Undergoing Cardiac Surgery
Bluhpinder Singh,1,2 Philip T. Lavin,1 Andreas Orfanos,2 Stacey Ruiz,2 Donald J. Keyser,1 Alvaro F. Guilleum,2 Richard A. Zager,3,4 Navdeep Tangri,3 Jean-Claude Tardif1,5 University of California Irvine, University of California Irvine, Irvine, CA, US, Department of Medicine, Irvine, CA; 1Renibus Therapeutics, Southlake, TX; 2Montreal Health Innovations Coordinating Center, Montreal, QC, Canada; 3Fred Hutchinson Cancer Research Center, Seattle, WA; 4University of Washington Department of Medicine, Seattle, WA; 5University of Manitoba, University of Winnipeg, MB, Winnipeg, MB, Canada; 4Institut De Cardiologie de Montreal, Montreal, QC, Canada; 4Boston Biostatistics Research Foundation, Framingham, MA.

Background: Cardiac surgery is associated with an increased risk of acute kidney injury (AKI). RBT-1 induces non-ischemic tissue preconditioning that has shown organ protective effects in several animal models of AKI. Markers of cytoprotection observed with RBT-1 treatment in animals were also found to be upregulated in a Phase 1 study of RBT-1 in healthy volunteers and subjects with Stages 3 and 4 chronic kidney disease (CKD). Based on these data, we have designed a Phase 2, placebo-controlled, double-blind, randomized, multicenter study that will assess the effect of RBT-1 on preconditioning response biomarkers in subjects scheduled to undergo cardiac surgery.

Methods: Study Design: This study will enroll 126 subjects scheduled to undergo coronary artery bypass graft (CABG) and/or cardiac valve surgery. Eligible subjects will be randomized to receive a single dose of RBT-1 or placebo via intravenous infusion between 24 and 48 hours prior to scheduled cardiac surgery. Subjects will be followed through Day 90. Inclusion/Exclusion Criteria: Subjects eligible for enrollment include adults who are scheduled to undergo non-emergent, on-pump coronary artery and/or cardiac valve surgery. Major exclusion criteria include CKD with eGFR ≤ 20 mL/min/1.73m2 or need for dialysis.

Results: Objectives: The primary objective of this study is to evaluate the efficacy of RBT-1 on preconditioning response biomarkers from baseline through Day 3 post-cardiac surgery. Based on preclinical data, plasma heme oxygenase-1 (HO-1), ferritin, and interleukin-10 (IL-10) have been identified as the relevant biomarkers for this study. Secondary objectives include change in tubular injury biomarkers and incidence of AKI based on KDIGO classification. Exploratory objectives include the occurrence of major adverse kidney events (MAKE) through Days 30 and 90.

Conclusions: The multinational START study will assess the cytoprotective preconditioning response to RBT-1 in subjects undergoing cardiac surgery.

PO0100
Acute Peritoneal Dialysis During the COVID-19 Pandemic in New York City
Nina J. Caplin,1,2 Manish Tandon,1,2 Olga Zhdanova,1 Richard Amerling,3 Nathan Thompson,1 NYU Langone Health, New York, NY; 2Bellevue Hospital Center, New York, NY; 3Saint George’s University, Saint George, Grenada.

Introduction: The dramatic spread of COVID-19 in March 2020 threatened to overwhelm ICU capacity. At the peak we had more than 120 patients in the ICU. About 40% of the ICU patients required RRT due to AKI. Our ability to provide RRT with CVVH and IHD was severely limited by critical shortages of equipment and personnel. We rapidly established an acute PD program at Bellevue Hospital for AKI patients. The acute PD program turned out to be instrumental in the BH response to COVID-19.

Case Description: Patients
All patients who needed RRT in the ICU were eligible for PD. PD was performed manually every 1-2 hours. Eventually we acquired 18 cyclers which greatly improved to 24 hours per day. Exchanges were initially performed manually every 1-2 hours. Eventually we acquired 18 cyclers which greatly eased the workload. Outcomes
As of May 8, 2020 63 patients were evaluated, 38 PD catheters were placed with 35 used for exchanges. 2 patients had catheters placed but recovered renal function prior to starting PD. I/38 was nonfunctioning and changed to IHD. 15/38 survived >30 days; 8 recovered renal function; 20 expired <30 days.

Discussion: Because of the shortage of our typically used dialysis modalities we were compelled to start an acute PD program. No patient on PD required additional dialytic support with BID or CVVH. PD was well tolerated by ventilated patients with hemodynamic instability. Acute PD more than adequately filled the gap in treatment options during this unprecedented crisis.

Novel Prescription of Continuous Venovenous Hemodialysis Dialysate Na+ in a Patient with Cerebral Edema and Severe Hypernatremia
Brian Y. Young, Nasim Wiegley, John Howard. University of California at Davis, Division of Nephrology, Department of Internal Medicine, Sacramento, CA.

Introduction: AKI necessitating dialysis is difficult in patients with traumatic brain injury. Slow clearance and increased dialysate Na+ are recommended. Yet, barriers in adjusting dialysate Na+ may occur with premixed commercial dialysate. We present a unique method of prescribing CVVHD to prevent Na+ overcorrection in a patient with cerebral edema and severe hypernatremia.

Case Description: An 18 year old male presented with polytrauma after a motor vehicle accident. His injuries included multiple intracranial bleeds. On day 13, nephrology was consulted for AKI, BUN > 150 mg/dl, and refractory hypekalemia. Head CT scan showed known bleeds and diffuse cerebral edema. At consult, IV 3% saline had already resulted in plasma Na+ ranging 161-166 meq/L for > 3 days. Our hospitals perform CVVHD via NStage with commercial dialysate bags with Na+ fixed at 140 meq/L. To prevent Na+ overcorrection, a custom commercial bag with 3% saline was in-circuit. Initially, clearance goals were set by dialysate flow rate. Then, separate IV pump for 3% saline was Y connected to the pre-pump dialysate line, and IV pump rate was calculated to adjust final dialysate Na+. Final dialysate flow equal to IV pump flow plus residual draw from commercial bags. Our initial goal dialysate Na+ was 160 meq/L. Dialysis solution bags steadily showed adjusted Na+ of about 158 meq/L at initiation. Changes to other dialysate factors (i.e. K+, HCO3-) were negligible. CVVHD was started with titration of the dialysate-attached 3% saline IV pump to control of Na+. All other 3% saline was discontinued. Though the patient ultimately died from overall injuries, change in plasma Na+ was slow and controlled (10 meq in 7 days).

Discussion: We present a new method for adjusting dialysate Na+ using in-circuit mixing of commercial dialysate and 3% saline. Our method used readily available solutions, was easy to titrate, depended solely on dialysis, and did not require manipulation of commercial bags. We suggest consideration of our method in CVVHD, brain trauma, and hypernatremia.
increased to 60 mg/dl. Kidney function did not improve even after 2 months and re-biopsy revealed ongoing interstitial inflammation in IgAN. Consequently, the patient was given a trial of azathioprine 200 mg daily with reduced prednisolone dose (40 mg/dl). Creatinine levels decreased moderately after 2 weeks to 1.70 mg/dl due to which the prednisolone dose was further tapered to 20 mg/dl.

Discussion: In past, azathioprine has shown promise in treatment of lupus nephritis and IgA nephropathy. To our knowledge, this is the first reported case of successful treatment of steroid resistant severe drug induced AIN with azathioprine. As it has lesser side effects and better compliance than steroids, it is suggested that azathioprine may be considered as initial or alternative form of treatment for AIN. Larger, randomized clinical trials need to be conducted in order to establish optimal dosing and long term effectiveness of azathioprine in treating AIN.

The Successful Treatment of Bile Cast Nephropathy with Plasma Exchange

Sweetha Reddy, Theresa Kinard, Margaret Ryan, Leslie F. Thomas. Mayo Clinic Arizona, Scottsdale, AZ.

Introduction: Bile cast nephropathy is a condition of renal dysfunction in the setting of hyperbilirubinemia. There are very few cases of this condition reported in literature, and there is a lack of established treatment guidelines. We report the successful management of two patients with bile cast nephropathy using therapeutic plasma exchange (TPE).

Case Description: CASE 1: A 59 year old man with stage 3 colon carcinoma on Capecitabine developed chemotherapy-induced liver toxicity resulting in severe cholestasis and biopsy-proven bile cast nephropathy. He underwent TPE. CASE 2: A 69 year old African American woman with PSC and colon cancer post a remote colectomy was admitted with pruritus and acute kidney injury (AKI). CT abdomen without contrast showed a 6 cm liver mass with bile duct dilatation, a biopsy proven metastasis from his previous colon cancer. A kidney biopsy confirmed bile cast nephropathy. The patient was started on hemodialysis (HD), and a biliary stent was placed. He was treated with TPE. He opted for hospice due to cancer CASE 3: A 38 year old man was admitted with severe acute alcoholic hepatitis and AKI. A kidney biopsy confirmed bile cast nephropathy. He underwent TPE and a total of four sessions of HD. The clinical course in our patients with biopsy proven bile cast nephropathy post and after TPE therapy is noted in Table 1.

Conclusion: Bile cast nephropathy is a rare entity, presenting a challenge in management. Thrombocytopenia, hepatic insufficiency, coagulopathy, and antiphospholipid antibodies are common with this condition, posing a challenge in case management. In our series, the patients had acute liver and kidney failure with no underlying chronic liver disease. 1-2 plasma volume exchange was performed with each procedure with a combination of plasma and 5% albumin. A good response to TPE in decreased total bilirubin level and improvement in renal function was noted. There were no serious adverse events and all procedures were tolerated well by the patients. Medical management of bile cast nephropathy such as steroids and cholestyramine have shown limited or no benefit. Renal replacement therapy has also been shown to be of limited benefit and should be mainly instituted for the treatment of AKI. In bile cast nephropathy, TPE may help in the clearance of bile acid crystals and reduction of proinflammatory molecules which contribute to acute liver and kidney injury. In this small case series, institution of TPE appeared to improve the clinical course of patients with bile cast nephropathy.

An Unusual Case of IgA Nephropathy Associated with Parvovirus B19

Laila S. Lakhan, Hashim Abbas, Mohamed G. Atta. Johns Hopkins University, Baltimore, MD.

Introduction: Parvovirus is known to cause upper respiratory infections in children and the immunosuppressed. It's association with kidney disease has been sporadically reported in literature, mostly causing lupus like glomerulonephritis with endocapillary and the immunosuppressed. It's association with kidney disease has been sporadically reported in literature, mostly causing lupus like glomerulonephritis with endocapillary and the immunosuppressed.

Case Description: A 23 year old African American female with a history of Hemoglobinopathy due to maternal sickle cell disease presented with a 1 week of generalized edema and malaise. Initially, she was found to have non-oliguric AKI with Creatinine 2.5 mg/dL (baseline Cr: 0.6 mg/dL). Serologies were notable for normal Complements, negative ANA, anti-cardiolipin-IgM and direct antiglobulin. The serum and urinary Immunofixation and serum cryoglobulinemia tests were all negative, while the serum κ to λ light chain ratio was depressed to 0.231. A renal biopsy conducted on day 9 revealed a diffuse proliferative glomerulonephritis with intracapillary pseudo-thrombi formation with orderly arranged microtubular structures of 20-35 nm in diameter in the subendothelial and mesangial area on electron microscopy. The patient developed on day 13 symmetrical finger-tip numbness and tingling with weaknesses in her hands and legs. She was started on hemodialysis (HD), and a biliary stent was placed. He was treated with TPE.

Conclusion: Parvovirus B19 is an RNA virus and is known to cause conditions such as Parvovirus IgM and detectable Parvovirus DNA. She was started on Pulse dose steroids; azathioprine 200 mg daily with reduced prednisolone dose (40 mg/dl). Creatinine levels decreased moderately after 2 weeks to 1.70 mg/dl due to which the prednisolone dose was further tapered to 20 mg/dl.

Discussion: In past, azathioprine has shown promise in treatment of lupus nephritis and IgA nephropathy. To our knowledge, this is the first reported case of successful treatment of steroid resistant severe drug induced AIN with azathioprine. As it has lesser side effects and better compliance than steroids, it is suggested that azathioprine may be considered as initial or alternative form of treatment for AIN. Larger, randomized clinical trials need to be conducted in order to establish optimal dosing and long term effectiveness of azathioprine in treating AIN.

Discussion: This case provides an example of AKI associated with Parvovirus infection. Parvovirus B19 is present in 3% of American Blacks but only 0.3% of African Americans were included in the cohort on which the Oxford Classification was coined. The improvement in acute kidney injury with a short course of steroids is suggestive of Parvovirus related process more than the typical endocapillary proliferation related to IgAN. The extension of Oxford Classification in the African American population can thus be challenging and potentially misleading as seen in this case. A repeat renal biopsy may be warranted to assess the underlying diagnosis of IgANephropathy and should be treated based on findings.
between an uncommon genetic mutation and a rare diagnosis. In this patient, the fact of him being homozygous for PAI-1 4G allele led to arterial occlusion. The patient was transferred to CCU and started on clevidipine and heparin blood. Creatinine was 1.6 and the baseline was unknown. CTA showed right renal artery occlusion. The patient was transferred to CUC and started on clevidipine and heparin drip. Arteriogram and directed thrombolysis were performed. Despite these interventions, his creatinine trend peaked at 2.85, whereas hemoglobin started dropping substantially. High rate IV fluids, a workup for malignancy, and hypercoagulable were started with subsequent stent placement for reperfusion. After 3 days of directed thrombolysis, he was transferred to wards. Urine output decreased and a Foley catheter was placed. The patient was started on clonidine, amlopidine, and labetalol. After 10 days of hospitalization, all workup was unremarkable. PAI-1 4G/5G study was homozygous for 4G allele. The patient’s medical condition improved. He was discharged and advised to follow up as an outpatient.

Case Description: A 53 years old male with hypertension, presented to the emergency room complaining of abdominal pain and pink urine for 3 days. His BP was 186/120 mmHg and pulse 100/min. Physical exam was consistent with right flank tenderness. Urinalysis showed high gravity, high amount of protein and blood. Creatinine was 1.6 and the baseline was unknown. CTA showed right renal artery occlusion. The patient was transferred to CCU and started on clevidipine and heparin drip. Arteriogram and directed thrombolysis were performed. Despite these interventions, his creatinine trend peaked at 2.85, whereas hemoglobin started dropping substantially. High rate IV fluids, a workup for malignancy, and hypercoagulable were started with subsequent stent placement for reperfusion. After 3 days of directed thrombolysis, he was transferred to wards. Urine output decreased and a Foley catheter was placed. The patient was started on clonidine, amlopidine, and labetalol. After 10 days of hospitalization, all workup was unremarkable. PAI-1 4G/5G study was homozygous for 4G allele. The patient’s medical condition improved. He was discharged and advised to follow up as an outpatient.

Discussion: Studies have proven the link between PAI-1 4G and thrombotic events, however, most of the evidence shows a link between PAI-1 4G and venous thrombosis. In this patient, the fact of him being homozygous for PAI-1 4G allele led to arterial thrombosis. Therefore, it might be prudent to include a PAI-1 workup in prothrombotic studies. In renal artery thrombosis, a cause must be established. Although there are other common causes of arterial thrombosis, PAI-1 4G should be considered as a potential cause in patients with few or no risk factors. This case report glimpses the relationship between an uncommon genetic mutation and a rare diagnosis.

Discussion: Cannabinoids are found in natural marijuana and contain many active compounds, but delta-9 tetrahydrocannabinol (THC) and cannabidiol (CBD) are of most interest. THC is the primary ingredient in marijuana that makes people “high”. Synthetic cannabinoids are analogs of natural occurring cannabinoids that are chemically synthesized. This synthetic compound is added to the natural marijuana or other herbs to appear as a natural product. The clinical effects can be like natural marijuana which include tachycardia, conjunctival injection, slurred speech, and increase appetite due to the partial or full agonistic effect at the cannabinoid receptors. Compared to cannabis, synthetic cannabinoids have a greater risk for serious neuropsychiatric toxicity and severe acute kidney injury. We need more clinical research to identify the specific nephrotoxic agents.

Discussion: Synthetic cannabinoids (SC), “Ganja”, have been used as recreational drugs with increasing frequency among young adults but have significant toxicity. We present a case of acute kidney failure in a relatively healthy young male individual after using marijuana pills.

Case Description: 31-year-old Hispanic male with no known past medical history presented to the emergency room with nausea and vomiting for 2 days. He stated that he has recently started taking “Ganja” pills to help with relaxation after losing work due to the Covid-19 pandemic. Vital signs were within normal limits and physical findings were unremarkable. Laboratory data were significant for serum creatinine of 10.14 mg/dl, blood urea nitrogen of 91 mg/dl, estimated glomerular filtration rate of 8 mL/minute per 1.73m², and serum potassium of 7 meq/l. Urine toxicology was positive for cannabinoids. Complements and serologies were all negative. Renal ultrasound was unremarkable. A renal biopsy showed acute tubular injury with tubular dilatation, cytoplasmic simplification and vacuolization (image). Interstitial hemodilution was initiated but later discontinued after renal recovery. On discharge, serum creatinine was 1.2 mg/dl.

The Emerging Role of Bedside Doppler Ultrasound for Precise Assessment of Venous Congestion in Cardiorenal Syndrome
Abhilash Koratala,1 Saqib Mahmud,1 Olanrewaju A. Olaoye,2 Amir Kazory,2 1Medical College of Wisconsin, Milwaukee, WI; 2University of Florida, Gainesville, FL.

Introduction: Congestion is an integral component of cardiorenal syndrome and the primary reason for hospitalization in patients with heart failure (HF). Making it a key target in the management of these patients. Routinely used parameters to monitor response to decongestive therapy such as physical examination, B-type natriuretic peptide changes in weight and net fluid balance, even inferior vena cava ultrasound (IVC US) are all error prone. Doppler ultrasonography (DUS) of the portal, hepatic and when possible, intrarenal veins is an attractive alternative that can be used at bedside to accurately assess the degree of congestion and guide management strategies.

Case Description: A 55-year-old man with a history of HF with reduced ejection fraction of ~25%, hypertension and chronic kidney disease stage 3 presented with acute kidney injury of uncertain etiology. Serum creatinine (Scr) was 3.5 mg/dL for a baseline of 1.6 mg/dL. He had no symptoms except for his usual dyspnea on exertion. Physical examination was significant for crackles at lung bases and mild pitting pedal edema. Bedside US revealed increased extravascular lung water and a dilated but collapsible IVC. DUS revealed stigmata of severe congestion with a pulsatile portal vein and systolic flow reversal, and a hepatic vein with only diastolic (D) component below the baseline. Therefore, the diagnosis of congestive renal failure due to acute cardiorenal syndrome was made and high dose intravenous diuretics were initiated. The follow up DUS on days 3 and 5 showed remarkable improvement (reversal of waveforms to normal pattern) indicating progressive decongestion [Figure]. His diuretic therapy was titrated based on these findings and Scr improved to 2 mg/dL at discharge.

Discussion: Bedside DUS assessment of hepatic and portal veins aids in management of patients with HF by non-invasively monitoring the efficacy of decongestive therapy, and serves as a valuable adjunct to conventional clinical evaluation.

PO0111

Furosemide: An Unusual Cause of Acute Interstitial Nephritis Requiring Hemodialysis: First Case Report
Hassan Alhalabi, Dallas Nephrology Associates, Irving, TX.

Introduction: Furosemide, a loop diuretic, is widely used for volume control and is a known cause of acute interstitial nephritis. However, AIN due to furosemide is not typically associated with abrupt and severe acute kidney injury (AKI). Here we report a patient who developed severe AKI requiring hemodialysis shortly after receiving furosemide.

Case Description: A 65 year old male with a history of hypertension was started on oral furosemide 20 mg daily for edema in his legs. One week later he presented to the emergency room complaining of oliguria and worsening edema. Laboratory findings were significant for a serum creatinine of 37.8 mg/dl and potassium 7.8 mmol/L. Patient required emergent hemodialysis for volume control, clearance and hyperkalemia, and continued to require HD every other day. Serologic work-up included a normal C3, C4, ANA, ANCA, anti-GMB, and SPEP/UPEP. Urinalysis showed small blood, no protein, 12-15 RBC’s, 10 WBC’s. Renal ultrasound was normal. A kidney biopsy was deferred. After starting levothyroxine, complete renal recovery was seen in 2 patients and partial recovery in one within 8 weeks (Table 1).

Discussion: AIN has been reported in patients with severe hypothyroidism, and most cases were suspected to be due to rhabdomyolysis and had rapid normalization. Few cases of slower and incomplete recovery have been noted in cases with prolonged periods of severe hypothyroidism. In our series, normal urinalysis, absence of myoglobin, and normal or modest elevation of CPK makes rhabdomyolysis unlikely. The AKI could be due to hypothyroidism induced changes in renal hemodynamics. Our study relies on eGFR for renal function, and extent to which this reflects true changes in GFR is unclear. Hypothyroidism is a reversible cause of AKI and should be evaluated in cases with unexplained AKI. These patients can attain normal renal function with prompt initiation of levothyroxine therapy.

PO00112

Hypothyroidism-Induced AKI: A Case Series
Spoonri Ramini, Varun Kumar Bandi. Dr. Pinnamaneni Siddhartha Institute of Medical Sciences & RF, Gannavaram, India.

Introduction: Thyroid hormones affect the development and various functions of the kidney. Such effects are partly mediated by direct renal action and partly by cardiovascular and systemic effects.

Case Description: We present a series of 3 patients who presented with unexplained acute kidney injury (AKI). All patients were male, and one was hypertensive on amlopidine. Investigations showed blood urea levels ranging from 20 to 88 mg/dl, serum creatinine between 1.3 to 3.65 mg/dl with estimated glomerular filtration rate (eGFR) of 17.88 to 63.18 mL/min/1.73m2. Urine routine and ultrasound abdomen did not reveal any abnormalities. The patients had features suggestive of hypothyroidism and thyroid evaluation was done. Thyroid stimulating hormone (TSH) was elevated in all patients and T3 and T4 were decreased. The TSH levels ranged between 88.4 to 100 mIU/L. Creatine phosphokinase (CPK) level was modestly elevated in only one case, with absent urine myoglobin in all cases. A possibility of hypothyroidism induced AKI was considered and renal biopsy was deferred. After starting levothyroxine, complete renal recovery was seen in 2 patients and partial recovery in one within 8 weeks (Table 1).

Discussion: AKI has been reported in patients with severe hypothyroidism, and most cases were suspected to be due to rhabdomyolysis and had rapid normalization. Few cases of slower and incomplete recovery have been noted in cases with prolonged periods of severe hypothyroidism. In our series, normal urinalysis, absence of myoglobin, and normal or modest elevation of CPK makes rhabdomyolysis unlikely. The AKI could be due to hypothyroidism induced changes in renal hemodynamics. Our study relies on eGFR for renal function, and extent to which this reflects true changes in GFR is unclear. Hypothyroidism is a reversible cause of AKI and should be evaluated in cases with unexplained AKI. These patients can attain normal renal function with prompt initiation of levothyroxine therapy.

PO00113

Glomerular Congestion Secondary to Renal Vein Stenosis After Kidney Transplant
Muna Alnimiri. University of California Davis Department of Internal Medicine, Sacramento, CA.

Introduction: Renal vein stenosis (RVS) post kidney transplant is uncommon complication, especially when it causes severe glomerular congestion, and AKI. We present a case of RVS 3 months post kidney transplant with kidney biopsy showing severe glomerular congestion

Case Description: 33 y old male CKD secondary to HTN underwent LKT, smooth post op course discharged with a creatinine of 1.1 mg/dl presented for 3 months protocol biopsy with creatinine of 1.5mg/dl, kidney biopsy showed severe glomerular congestion. No rejection figure1, Doppler US showed suspicion for renal vein stenosis. Renal venogram demonstrated narrowing of the transplant renal vein at the anastomosis with the right common iliac vein figure 2 Successful 10 mm angioplasty balloon was inflated along the narrowed segment follow up creatinine back to 1.1mg/dl

Discussion: Transplant RVS is a rare vascular complication after renal transplantation that may cause graft dysfunction. Correction of RVS with either angioplasty or stent placement is safe and effective approach. Our patient presented with AKI and severe glomerular congestion that warranted doppler US, the finding of RVS and glomerular congestion from back pressure warranted urgent venogram and angioplasty with excellent results. Conclusion: in evaluating AKI post kidney transplant ureteral obstruction, rejection, CNI toxicity and renal artery stenosis should be ruled out if all negative RVS should be evaluated.
AKI Clinical, Outcomes, and Trials - 2

Brain Got Spongy at Angry Kidneys

Ubaldo R. Madera Sanchez, 1 Christian Rodriguez Cintron.  1 Hospital Universitario Ramon Ruiz Arnao, Bayamon, PR; 2 Universidad Central Del Caribe, Bayamon, Puerto Rico; 3 Doctors Center Carolina, Carolina, PR.

Introduction: Brain edema is a rare complication of acute kidney injury in patients who have not received renal replacement therapy. Immunologic and pro-inflammatory cascades mediate brain edema that is not dependent on the uremia, and instead, it is due to crosstalk between the kidneys and brain in the so-called reno-cerebral reflex. We are presenting an 88-year-old female with a history of hypertension and hyperthyroidism with acute colitis that developed acute kidney injury and cerebral edema. We want to raise awareness of the need for early diagnosis and treatment to prevent severe clinical outcomes.

Case Description: 88-year-old female with a past medical history of hypertension, hyperthyroidism came to the ER complaining of green-colored non-bloody diarrhea for 2 days. Examination remarkable for left lower quadrant tenderness, tachycardia, altered, awake, oriented to person only, cooperative and following commands. Labs were remarkable for leukocytosis with neutrophilia, fecal leukocyte positive, and metabolic alkalosis. Abdominal CT showed acute colitis localized to descending colon and sigmoid. The patient was admitted with acute colitis. On day 2 of admission creatinine went up to 2.35 from 1.07. On urine, sediment was evident with renal tubular epithelial cells and oxalate crystal. Renal sonogram with no renal abnormality. On day 3 the creatinine continued increasing doubled to 4.4. The patient’s mental status started declining, and metabolic acidosis was present. Renal replacement therapy was advised, but the patient’s family refused it and signed off DNR. The mental status started declining, and metabolic acidosis was present. Renal replacement therapy was advised, but the patient’s family refused it and signed off DNR. The patient was initiated on hemodialysis. Evaluation of AKI with hepatitis B and C serologies, HIV, complement levels and ANA was unremarkable. Kidney ultrasound showed increased echogenicity without hydronephrosis. An abdominal CT scan with IV contrast done for worsening fever and leukocytosis showed diffuse areas of non-enhancement involving bilateral renal cortices consistent with acute renal cortical necrosis.

To note, throughout his presentation and admission, the patient was not hypotensive. He remained dialysis dependent for three months with oliguria that eventually improved and dialysis was discontinued with a stable eGFR of 1.73ml/min. He has remained off dialysis for the past five months and is undergoing transplant evaluation.

Discussion: RCN is thought to be an irreversible cause of AKI secondary to decreased perfusion, vasoospasm and endothelial injury resulting in sclerosis. It is frequently associated with hypotension but in our case the patient was normotensive. The mechanism leading to RCN associated with pancreatitis remains poorly understood. Acute pancreatitis, on the other hand, has been associated with other vasoocclusive ischemic complications (e.g. Purtscher’s retinopathy). RCN is a devastating complication that often leads to dialysis dependence. Despite our patient showing signs of recovery, his prognosis remains poor. Further study is needed to understand its pathophysiology and potentially mitigate its consequences.

Severe Vancomycin Nephrotoxicity

Jefferson L. Tiziozi, Layth Al Attar, Maryam K. Saeed, Jingyin Yan, Bryan M. Tucker. Baylor College of Medicine, Houston, TX.

Introduction: We report a case of acute kidney injury with biopsy-proven changes related to a vancomycin level of 136.6 mg/L. From our review of the literature, this is the highest vancomycin level ever recorded.

Case Description: A 60-year-old female with type 2 diabetes mellitus, hypertension, Sjogren’s disease not requiring immunosuppression, baseline normal kidney function, and left ankle osteomyelitis on home intravenous vancomycin presented with vertigo. Workup revealed oliguric acute kidney injury with sub-nephrotic range proteinuria (blood urea nitrogen 56 mg/dL, creatinine 6.70 mg/dL, urine protein to creatinine ratio 0.98) and an elevated random vancomycin level (136.6 mg/L). A comprehensive evaluation including physical examination, serologic testing, and renal imaging was unremarkable. Due to high vancomycin levels and minimal improvement in renal function despite resuscitation with intravenous crystalloids, hemodialysis was initiated via a tunneled dialysis catheter. A renal biopsy was then obtained, which demonstrated acute tubuloepithelial injury, morphologically consistent with acute tubular necrosis. There was also mild arterial sclerosis, minimal interstitial fibrosis and tubular atrophy, and no immune-mediated glomerulonephritis.

Discussion: Vancomycin is renally-eliminated by glomerular filtration and, to a lesser degree, excretion in the proximal tubule. Various mechanisms of renal injury are reported, including acute tubular necrosis and interstitial nephritis. Accrual of vancomycin-uromodulin complexes lead to inflammation. In this case, a comprehensive workup and kidney biopsy was important to rule out other causes of renal failure and support the diagnosis of vancomycin-induced nephrotoxicity. Renal recovery often occurs with discontinuation of vancomycin therapy. Severe cases, however, are frequently exacerbated by oliguria and require high-flux hemodialysis for effective drug removal by approximately thirty percent. Prolonged exposure to high levels of vancomycin increases the risk of permanent renal failure. This patient developed vancomycin nephrotoxicity despite drug monitoring, dosing based on creatinine clearance, and using the minimum inhibitory concentration required. Further research to establish precise mechanisms of vancomycin-induced nephrotoxicity is needed.

DRESS Syndrome and Acute Interstitial Nephritis Relapse: A Case for Caution

**Introduction:** The syndrome of drug reaction with eosinophilia and systemic symptoms (DRESS) is a rare but potentially life-threatening drug-induced type IV hypersensitivity reaction that usually occurs 2-6 weeks after drug initiation. Typical findings include skin eruption, fever, hematologic abnormalities, and visceral organ involvement. Prolonged corticosteroid treatment is often required as relapse after initial improvement is not uncommon.

**Case Description:** A 62-year-old woman with a history significant for right total hip arthroplasty complicated by a prosthetic joint infection requiring hardware explantation and antibiotic spacer placement initially presented to the ED with fever, rash, and pruritus. She was treated with cefepime and vancomycin for possible intra-operative bacterial cultures. Urinalysis showed pyuria (51-100/hpf) and eosinophils (1-5%). Skin biopsy showed a drug reaction. She was diagnosed with DRESS syndrome and acute interstitial nephritis (AIN) secondary to the antibiotics, which were then changed to aztreonam and daptomycin. She was treated with systemic and topical steroids and was discharged on oral prednisone (80 mg daily) and had clinical improvement. She was seen again the ED 5 days after discharge with fever and worsening rash and pruritus. Physical examination was notable for mild facial swelling and scattered pink macules coalescing into patches on both upper and lower extremities and on the groin. Laboratory studies revealed leukocytosis with peripheral eosinophilia [7.35x10⁹/L] (on discharge: 0.87), elevated serum creatinine of 4.8 mg/dL, and elevated LFTs, ESR, and CRP. She was diagnosed with DRESS syndrome and AIN relapse secondary to rapid steroid taper. She was started on a higher dose of oral prednisone (80 mg daily) and had clinical improvement. She was then discharged with plan to taper by 10 mg every 2 weeks over 4 months.

**Discussion:** Long-term supra-physiologic doses of steroids are necessary to treat DRESS syndrome even after patients appear to have improved. Relapses do occur and frequently follow treatment discontinuation or rapid steroid taper, leading to increased morbidity and mortality. In such cases, a more prolonged steroid treatment is needed, which can cause well-known adverse events and complications. Close monitoring is thus required.

Rivaroxaban-Induced Anticoagulant-Related Nephropathy

**Introduction:** Anticoagulant-related nephropathy (ARN) is a rare and newly recognized cause of acute renal failure (ARF). A lack of serologic studies and hesitancy to perform high risk biopsies due to concerns for thrombosis or hemorrhage, make ARN a challenging diagnosis. The pathophysiology is believed to be from diffuse glomerular hemorrhage which manifests as numerous RBC casts. These RBC casts obstruct and damage tubular epithelial cells resulting in renal failure. We will examine a case of ARN.

**Case Description:** An 83-year-old Caucasian female presented with complaints of lower extremity weakness and was found to have ARF on laboratory investigation (Cr 5.18mg/dL from 1.1mg/dL one month prior). The patient was recently started on rivaroxaban after being diagnosed with a stroke caused by atrial fibrillation. The patient was admitted for evaluation and management of olugic ARF, requiring the initiation of HD. Initial evaluation was significant for hyperkalemia (5.6 mEq/L), hyperphosphatemia (5.0 mg/dL), hypocalcemia (Ca 8.6 mg/dL) and high LDH in addition to oliguric AKI with serum creatinine (2.5 mg/dL, baseline 0.8 mg/dL). Surprisingly Uric acid level was low (1.8mg/dL) as patient had been on prophylactic Allopurinol. Patient did not have any signs of hypovolemia or post renal obstruction. Urine microscopy was bland. Urgent Hemodialysis (HD) session was provided for malignant hyperkalemia. AKI was assumed to be hyperphosphatemia-induced rather than urate nephropathy in TLS. Renal biopsy was considered but deferred due to high risk of bleeding. Hyperkalemia resolved with one session of HD, but hyperphosphatemia rebounded with worsening of creatinine. So CVH was initiated and carried out for 72 hours. It lowered serum phosphate level to normal range with resolution of AKI.

**Discussion:** With the broad use of heparin agents, calcium phosphate deposition, rather than hyperuricemia is becoming the leading cause of AKI in TLS. Choosing an appropriate dialysis modality is crucial to prevent further phosphate nephrotoxicity. Intermittent HD followed by CVH may be an effective approach. CVH should be considered as a preferred modality to achieve a sustained lowering of phosphate level and prevent rebound hyperphosphatemia. Our case is an excellent example when HD followed by CVH helped in early renal recovery by effectively lowering serum phosphate levels.

Continuous Venousous Hemofiltration for Hypouricemic Tumor Lysis Syndrome and Extreme Hyperphosphatemia Complicated by AKI

Muhammad O. Saleem,1 Ambreen Chughtai.2 Augusta University Medical College of Georgia, Augusta, GA; ‘FMH College of Medicine and Dentistry, Lahore, Pakistan.

**Introduction:** Tumor lysis syndrome (TLS) is an oncological emergency and can cause Acute Kidney Injury (AKI) mostly by acute urate nephropathy. We present a case of hypouricemic TLS and severe hyperphosphatemia leading to AKI, effectively managed by Continuous Veno-Venous Hemofiltration (CVVH).

**Case Description:** 44-year male with newly diagnosed Burkitt’s lymphoma and currently receiving first cycle of da-EPOCH chemotheraphy, was found to have clinical TLS per Cairo-Bishop definition. Laboratory studies were significant for hyperkalemia (K 6.4 mEq/L), hyperphosphatemia (Phosphate 13.0 mg/dL), hypocalcemia (Ca 6.9 mg/dL) and high LDH in addition to oliguric AKI with elevated serum creatinine (2.5 mg/dL, baseline 0.8 mg/dL). Surprisingly Uric acid level was low (1.8mg/dL) as patient had been on prophylactic Allopurinol. Patient did not have any signs of hypovolemia or post renal obstruction. Urine microscopy was bland. Urgent Hemodialysis (HD) session was provided for malignant hyperkalemia. AKI was assumed to be hyperphosphatemia-induced rather than urate nephropathy in TLS. Renal biopsy was considered but deferred due to high risk of bleeding. Hyperkalemia resolved with one session of HD, but hyperphosphatemia rebounded with worsening of creatinine. So CVH was initiated and carried out for 72 hours. It lowered serum phosphate level to normal range with resolution of AKI.

**Discussion:** With the broad use of hypouricemic agents, calcium phosphate deposition, rather than hyperuricemia is becoming the leading cause of AKI in TLS. Choosing an appropriate dialysis modality is crucial to prevent further phosphate nephrotoxicity. Intermittent HD followed by CVH may be an effective approach. CVH should be considered as a preferred modality to achieve a sustained lowering of phosphate level and prevent rebound hyperphosphatemia. Our case is an excellent example when HD followed by CVH helped in early renal recovery by effectively lowering serum phosphate levels.
PO0121

Use of Continuous Venous Hemodialysis and Plasmapheresis to Treat Simultaneous Iron and Acetaminophen Overdose

Tripti Singh, Rebecca Nye. University of Wisconsin School of Medicine and Public Health, Madison, WI.

Introduction: Iron may fatally exacerbate toxicity in polypharmacy overdoses, including acetaminophen overdose. We present a case of intentional acetaminophen and iron overdose and treatment with continuous veno-venous hemofiltration (CVVH) and plasmapheresis.

Case Description: 31-year-old male with history of schizophrenia and previous suicide attempts presented to an outside hospital with abdominal pain and emesis 1.5 hours after ingestion of 100 tablets each of 325 mg acetaminophen and 325 mg ferrous sulfate. Vitals on admission were BP 121/83 mmHg, pulse 93 bpm, RR 18/min, G 2 saturation 98% on RA. Labs showed bicarbonate 23 mEq/L, anion gap (AG) of 14, BUN 16 mg/dL, creatinine 1 mg/dL, total bilirubin 0.7 mg/dL, AST 24 units/mL, ALT 16 units/mL, iron 356 μg/dL, and acetaminophen 269.8 μg/mL. Patient was started on IV acetylcysteine. Repeat labs 12 hours later revealed iron level 4526 μg/dL, total bilirubin 4.8 mg/dL, AST 476 units/mL, ALT 855 units/mL. IV deferoxamine was initiated. Patient became lethargic and hypotensive and required intubation. He was transferred to our hospital for further management. Labs upon arrival showed AG of 16, bicarbonate of 12 mEq/L, creatinine 1.98 mg/dL, ALT 13129 units/mL, AST 476 units/mL, and ALT 855 units/mL. IV deferoxamine was started. Patient was unresponsive, euolemic, and NG tube drain was bloody. CVVH was started via left femoral dialysis catheter with blood flow rate of 250 mL/min and replacement fluid rate of 3500 mL/hour. 6 hours after CVVH, labs revealed an iron level of 362 μg/dL, and an acetaminophen level of 100 μg/mL. Due to continued deterioration including hemodynamic instability and persistent acidoses, plasmapheresis was initiated. Labs 2 hours later showed iron level of 20 μg/dL and acetaminophen level of 91 μg/mL. The patient’s clinical status continued to decline despite removal of iron and acetaminophen and he died after 24 hours due to fulminant liver failure.

Discussion: In this case of simultaneous massive iron and acetaminophen overdose, CVVH was effective in removal of iron (60%) and acetaminophen (44%) over 6 hours. Plasmapheresis may be considered as an additional modality to remove excess free iron from the blood.

PO0122

Severe AKI Associated to Acquired Autoimmune Hemolytic Anemia and Hemophagocytic Syndrome: A Case Report

Abir Santes, Anna Lima, Ana Gaspar, Ana C. Brás, Patricia S. Carrilho, Karina Soto. Nephrology Department, Hospital Professor Doutor Fernando Fonseca, EPE, Lisboa, Portugal.

Introduction: Autoimmune hemolytic anemia (AIHA) is a rare entity with an annual incidence of 1-3/100,000. Secondary AKI is associated to lymphoproliferative disorders (LD), autoimmune diseases, drugs, and less frequently to infections, being an unusual cause of AKI. Hemophagocytic syndrome (HLH) is an uncommon syndrome of excessive immune activation that can be triggered by infection that disrupts immune homeostasis. Herein, we present a very rare case of a patient with AKI requiring RRT associated to severe AIHA and HLH.

Case Description: A 46-year-old Caucasian man was admitted with fever, anuria and severe anemia. Three days prior to admission he had vomiting, diarrhoea and oliguria. Physical examination revealed normal BP, fever and pale skin. Blood tests showed SCr 8.8mg/dL (baseline 0.9mg/dL), metabolic acidosis and urine dipstick Hb3+. He had AIHA with Hb 6.7g/dL, LDH 1194U/L, haptoglobin<30mg/dL, total bilirubin 1.35mg/dL, and positive Coombs test. Blood smear revealed atypical lymphocytes and rare blasts; platelet count was normal. HLH was diagnosed based on clinical (fever, splenomegaly) and laboratory criteria, with high ferritin (46833mg/L), tricylglycerides 308mg/dL, high levels of IL2 receptor (13547pg/mL). Sedimentation rate was 85mm/h and CRP 19mg/dL.

Infection was negative for acute bleed but concerning for cerebral edema. RRT was switched to another. We describe a patient with Pheochromocytoma who developed AKI requiring renal replacement therapy (RRT). Our patient experienced an acute hypertensive crisis followed by cardiovascular collapse likely precipitated by intravenous glucocorticoids given for presumed myocarditis. Glucocorticoids increase catecholamines; the excess causes cardiotoxicity which in turn leads to ischemic AKI. Patient was able to tolerate iHDF therapy. However, as the Phenoxybenzamine was up titrated, the fluctuations included hypertensive episodes and was worsened on dialysis. Given the unpredictable fluctuations in blood pressure and the possibility of associated hypertensive encephalopathy and/or

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
cerebral edema in the setting of Pheochromocytoma, it may be prudent to choose CRRT when RRT is warranted, though there are no guidelines regarding which modality is superior in these patients.

PO0125
Blast from the Past: A Rare Case of AKI from Sulfadiazine-Induced Nephrolithiasis

Introduction: Sulfadiazine has been used for the treatment of neutropenoplasmosis in patients with HIV infection. Nephrolithiasis is a known complication of high dose sulfadiazine therapy. However, this complication is rarely seen in HIV patients due to improved antiretroviral therapy. We present a rare case of sulfadiazine-induced nephrolithiasis in a patient with AIDS.

Case Description: A 55-year-old female with DM and HTN was hospitalized for worsening mental status and CT scan finding of frontal lobe mass. During hospital stay, pt. also found to have HIV infection and a very low CD4 count. Antiretroviral therapy and high dose intravenous sulfadiazine 1,500 mg every 6 hours was initiated for presumed neutropenopathy. On admission, serum creatinine (Scr) was 0.68. Seventeen days after initiation of sulfadiazine therapy, Scr increased to 2.42. Urinalysis revealed microscopic hematuria. Kidney sonogram showed left hydronephrosis and echogenic foci in both kidneys concerning for kidney stones. Sulfadiazine was discontinued and patient was started on sodium bicarbonate infusion to alkalinize her urine but Scr continued to worsen, peaking at 4.73 within few days. Serial kidney sonograms revealed alternating fullness of the collecting systems of both kidneys. Urology team was consulted and patient underwent cystoscopy with bilateral ureteral stent placement. Scr subsequently returned to normal limits within one week of ureteral stent placement.

Discussion: Our patient developed severe but reversible post-obstructive AKI secondary to high-dose sulfadiazine-induced nephrolithiasis. In the modern era of antiretroviral therapy, sulfadiazine-induced nephrolithiasis is a very rare occurrence in clinical practice. Hence, clinical and nephrology care providers should be aware of this rare cause of AKI in patients with HIV infection.

PO0126
Rhabdomyolysis as Initial Presentation of COVID-19
Hugo Andrade paz, Mala Sachdeva, Nupur N. Uppal. Northwell Health, Great Neck, NY.

Introduction: Rhabdomyolysis has infectious etiology including Mycoplasma pneumoniae infection, Legionella, and Influenza. To date, there has been one case report from Wuhan China of a patient who developed rhabdomyolysis from COVID-19 during their hospitalization. We report a case where acute kidney injury and rhabdomyolysis was the initial presentation.

Case Description: A 57 year old African American male with history of HTN for more than 10 years, presented with complaints of decreased urine output for 3 days associated with dark urine that progressed to anuria, fever for 11 days, decreased appetite and oral intake and generalized muscle weakness. Labs on admission were notable for acute kidney injury (creatinine 1.77mg/dL) which progressed rapidly to a peak creatinine of 11.10mg/dL within 72 hours, and other electrolyte abnormalities including mild hyperkalemia and acidosis. His CPK was ~92,000U/L on admission and COVID-19 PCR was positive. Other labs included: peak AST 1692 U/L and ALT 291U/L, ferritin 1436 mg/ml, 4.86mg/dL, DDimmer 2330 DDU, urinalysis specific gravity 1.030 with large blood, 10RBCs, 20WBCs, urine spot protein/creatinine 2.1 and random urine sodium 65. Serologic workup was negative for glomerular etiology. He was presumed to have acute tubular necrosis (ATN). He was treated with initial admission for anuria and worsening of renal function. He was maintained on hemodialysis with minimal ultrafiltration three times a week, intravenous fluid resuscitation along with intermittent doses of bumex. He received total of five hemodialysis treatments until he became normo-oliguric and started showing signs of recovery. He was taken off dialysis approximately three weeks after his initial presentation. His creatinine decreased and is 1.4 mg/dL one month after being taken off of hemodialysis.

Discussion: COVID-19 has its usual presentation of fevers, shortness of breath, dry cough and myalgias. This case highlights the importance that rhabdomyolysis can be one of the presenting features of COVID-19. Chances CPK levels should be an initial part of not only acute kidney injury workup in the COVID-19 patient but also for any COVID-19 newly diagnosed case as this diagnosis requires prompt and specific treatment.

PO0127
Lymphomatous Infiltration of the Kidney: A Sonographic Diagnosis
Bhavana Bhasin, Abhisht Koharala. Medical College of Wisconsin, Milwaukee, WI.

Introduction: The purpose of this case study is to illustrate the sonographic findings seen in kidney infiltration by lymphoma.

Case Description: A 56-year-old man with a history of hypertension, diabetes mellitus type 2 and follicular lymphoma with transformation to diffuse large B-cell lymphoma presented with worsening fatigue, headache and diplopia. MRI of the brain demonstrated central nervous system involvement by the lymphoma. He was also found to have worsening renal function with a serum creatinine of 4.5 mg/dl (baseline: 1.6-2 mg/dL). A renal sonogram (RUS) was performed, which demonstrated bilateral enlarged kidneys (~14.5 cm each) with irregular outlines and multiple parenchymal hypoechogenic to heterosexual lesions. No internal vascularity was noted on color Doppler. These findings are consistent with lymphomatous infiltration of the kidneys, confirmed later by PET (positron emission tomography) scan [Figure]. The renal function continued to worsen despite supportive care, and he required initiation of hemodialysis. Acute kidney injury was initially attributed to poor oral intake and mild hypercalcemia, but lymphomatous infiltration likely contributed to his renal impairment as well. Renal biopsy was not undertaken due to progression of the lymphoma and limited life expectancy.

Discussion: Kidney is the most common extra-renal site of leukemic and lymphomatous infiltration, and tumor-cell infiltrates in the kidney are seen in up to 30% of patients with lymphoma. Rarely, renal involvement may be the first manifestation of lymphoma. The kidneys may appear normal on RUS because of the small size of the nodular infiltrates or with the typical findings described above. Unilateral and perirenal infiltration with lymphoma has also been described. Hemophagocytosis may be noted on RUS if there is compression of the renal hilum or ureters by the lymphomatous tissue. Nephrologists performing point of care ultrasound may be aware of these findings. These patients will require a prompt referral to the Hematology & Oncology team when renal ultrasonography leads to a new diagnosis of lymphoma.

PO0128
Minimal Change Nephrotic Syndrome Superimposed on Anti-Glomerular Basement Membrane Antibody Glomerulonephritis: A Case Report
Yuko Shibata, Kazuhiro Fukuoka, Shinya Kaname. Kyorin university school of medicine Kyrion Daigaku, Mitaka, Japan.

Introduction: Background : The renal prognosis of anti-GBM glomerulonephritis (anti-GBM GN) is extremely poor as renal dysfunction often progresses acutely before the initiation of treatment. It is also known that once the disease activities are controlled by aggressive treatment, its recurrence is rare. Here we experienced a case of anti-GBM GN that improved from severe renal dysfunction but later relapsed. A possible cause was thought to be a rare complication of minimal change nephrotic syndrome (MCNS).

Case Description: A 50-year-old man was admitted to our hospital because of general malaise, fever, oliguria and renal dysfunction. The patient’s laboratory data showed serum creatinine as high as 6.6 mg/dl and severe inflammation (C-reactive protein 20.6mg/dl). Anti-glomerular basement membrane antibody (anti-GBM Ab) was detected in his serum, leading to a diagnosis of anti-GBM GN. Treatment was initiated with high-dose glucocorticoid (GC) and plasma exchange therapy (PE), and the patient’s renal function and oliguria improved rapidly and he was discharged 40 days after admission. Renal biopsy findings showed cellular crescents associated with linear IgG deposits along the glomerular tufts compatible with anti-GBM GN, but only about one-third of the glomeruli was involved, suggesting that it still remained an early stage of the disease. However, two months after discharge, he had a relapse and was re-admitted due to severe proteinuria associated with positive anti-GBM Ab. On the second admission, he was treated with high-dose GC and PE combined by intravenous cyclophosphamide, and complete remission was achieved a few weeks later. Electron microscopy of the renal biopsy that returned later showed significant foot process effacement on podocytes in the apparently normal glomeruli without electron dense deposits.

Discussion: Considering clinical course and renal pathology findings, it is suggested that the present case was a rare complication of an early stage of anti-GBM GN and MCNS. Although the cause of concurrent development of anti-GBM GN and MCNS associated with anti-GBM antibody titers is unclear, it may have been precipitated by influenza infection or some unknown factor.

PO0129
Thrombotic Microangiopathy with Acute Interstitial Nephritis Secondary to Trimethoprim-Sulfamethoxazole

Introduction: Thrombotic Microangiopathy (TMA) and Acute Interstitial Nephritis (AIN) are well recognized entities that individually cause significant morbidity and mortality. The relationships with several medications have been described, but the two conditions coexisting are rare.

Case Description: 28-year-old man with no significant past medical history presented with bilateral lower extremity edema, excoriations, discharge, and weakness for one week. He initially presented to an outpatient clinic and was discharged on trimethoprim-sulfamethoxazole (TMP/SMX). His symptoms progressed leading to admission. Physical
examination revealed an obese man with bilateral lower extremity edema, eczematous rashes, and ascites on both feet. Initial laboratory results were significant for a creatinine of 5.2 mg/dl and oliguria. Urinalysis revealed proteinuria, hematuria, and pyuria. He then developed thrombocytopenia and anemia. Haptoglobin and lactate dehydrogenase were elevated, and schistocytes were identified on peripheral smear consistent with microangiopathic hemolytic anemia. He also had eosinophilia. Work-up for autoimmune inflammatory, and connective tissue diseases was ordered and results were unremarkable. ADAMTS13 activity was decreased to 42%. The patient started hemodialysis and a kidney biopsy was performed with findings of acute tubular necrosis, thrombotic microangiopathy, and acute interstitial nephritis. TMP/SMX was discontinued and he was started on steroids. His renal function improved, and he was discharged home without need for further dialysis.

Discussion: TMA is characterized by endothelial damage causing microangiopathic hemolytic anemia, thrombocytopenia, and end-organ damage. TMA can be attributed to genetic and acquired autocrine causes, or may emerge secondary to medical diseases. AIN is a common cause of kidney injury and is associated with multiple drugs. This case demonstrates the unique coexistence of TMA and AIN in a patient receiving TMP/SMX, which has been related to decreased creatinine clearance, bone marrow suppression, hyperkalemia, and hypersensitivity reactions. This case supports the cessation of the offending drug and the use of steroid treatment as an option for TMA and AIN. In conclusion, TMA and AIN may occur simultaneously as an adverse drug reaction.

PO0130
Rhabdomyolysis in SARS-CoV-2 infection
Zhubiz Solhjou,1 Ignacio A. Portales Castillo,2 Bassem Mikhail,2 Nicholas Chedid,1 Ebrahim Barkoudah,1 Alice M. Sheridan,2 †Brigham and Women’s Hospital, Department of Medicine, Boston, MA; 2 †Brigham and Women’s Hospital, Renal Division, Boston, MA.

Introduction: Acute kidney injury (AKI) is a common complication of SARS-CoV-2 infection. Multiple mechanisms have been proposed including acute tubular necrosis (ATN) due to shock, cytokine release syndrome, hypoxia or vascular injury and thrombosis. Direct viral injury to tubular epithelial cells and podocytes has also been described. Rhabdomyolysis has been reported in infection with SARS-CoV, Respiratory Syncytial Virus and Influenza A. Although muscle CK elevation was reported in cohorts of patients with COVID-19 and there is a single case report of late onset rhabdomyolysis, overt rhabdomyolysis has not been described. To our knowledge this is the first patient with presented with signs and symptoms of severe rhabdomyolysis and AKI that was likely secondary to SARS-CoV-2 infection.

Case Description: A 51 year-old male with hypertension and diabetes, presented with five days of diffuse myalgia and mild dry cough with shortness of breath. He denied trauma, new medications, changes in diet, strenuous exercise or illicit drug use. Physical exam notable for fever and tachypnea, but no hypoxia. Labs were clear and all muscles groups were soft and non-tender. Polymerase chain reaction was positive for SARS-CoV-2. Serum creatinine was 2.4 mg/dl (baseline 1.3 mg/dl), Urinalysis showed 3+ blood, 2+ protein and 1-2 RBC per high power field. Initial serum creatinine kinase was 340,000 U/L and peaked at 464,000 U/L on day 4. Serum and urine myoglobin levels were elevated at 15,175 mg/L and >5000 mg/L, respectively on day 5. He received isotonic intravenous (IV) fluids but developed oliguria on day 2, requiring diuresis to maintain urine output. BUN and creatinine increased to 130 and 19 mg/dl, respectively by day 8 and hemodialysis was initiated. Renal clearance and urine output then slowly improved, and dialysis was discontinued by day 15.

Discussion: Myalgia and fatigue are common symptoms of COVID-19 infection. In addition, diastolic hematuria is reported in up to 10% of patients. Thus diagnosis of rhabdomyolysis and myoglobinuria requires a high index of suspicion. Early consideration and timely diagnosis of rhabdomyolysis and the treatment of myoglobinuria with intravenous fluids is extremely important to prevent ATN. However, administration of IV fluids may be challenging in COVID-19 patients at risk of hypoxia and acute respiratory distress syndrome.
fever and eosinophilia, and is usually a diagnosis of exclusion. On renal biopsy (Bx), DI-AIN usually presents with interstitial inflammation rich with eosinophils and neutrophils cast without glomerular injury. Immunofluorescence with negative IgG, IgA, IgM, C3, C1q, fibrinogen, albumin, kappa and lambda light chains. Electron microscopy was unremarkable. Cr at 3rd day peaked at 4.7mg/dL, then trended down. Upon discharge BUN/Cr 58/3.6. One week after at renal clinic visit her kidney function came back to her baseline. We continued steroids for 3 weeks due to suspicion of AI renal imaging and urine culture remained negative.

Discussion: This is a rare case where Zosyn was promptly stopped and prednisone was initiated early in the course of AIN despite neutrophil infiltration on renal Bx. DI-AIN can present with predominant neutrophilic infiltration; however, this makes the diagnosis more challenging. High suspicion, prompt antibiotic discontinuation and early institution of steroid can prevent further kidney injury or potential chronic kidney disease.

Case of Paraneoplastic Pauci-Immune Glomerulonephritis
Golriz Jafari, Masood Mahmood, Anita Kamarzarian. UCLA Medical Center Olive View, Sylmar, CA.

Introduction: This case highlights the importance of complete systemic evaluation for patients presenting with rapidly progressive glomerulonephritis (RPGN).

Case Description: 58 year old male with history of DM type 2 and hypothyroidism presents with acute kidney injury (AKI). Notable findings include a rash which was biopsied and due to leukocytoclastic vasculitis. Baseline Cr 0.59 mg/dL and continued to increase rapidly leading to patient becoming hemodialysis dependent. Urine showed an active sediment; serology including ANCA and anti-GBM were all negative. Patient was empirically started on steroids for possible Immunoglobulin A glomerulonephritis and also due to diagnosis of adrenal insufficiency. Renal biopsy subsequently showed pauci-immune crescentic glomerulonephritis with 89% og glomeruli with crescents, 74% with fibrinoid necrosis and 52% with segmental necrosis. Patient was started on Cytoxan. However further work up revealed a submass which was biopsied and found to be Hodgkin’s lymphoma. Patient was started on chemotherapy however did not make any renal recovery and remains dialysis dependent.

Discussion: This case highlights the importance of thorough evaluation in patients presenting with rapidly progressive glomerulonephritis. Although oftentimes it is due to a primary renal or renal/pulmonary disorder, paraneoplastic conditions should not be overlooked and need further investigation.

Renal Abnormalities in Patients with e-Cigarette, or Vaping, Product Use-Associated Lung Injury (EVALI)
Josephine Abraham, Miekan A. Stonhill, Martin C. Gregory, Sean J. Callahan.
University of Utah Hospital, Salt Lake City, UT.

Background: The use of electronic cigarettes is linked to the development of lung injury. There are no reports to date of renal injury secondary to vaping. Animal studies suggest that vaping could be associated with renal injury (1,2).

Methods: A retrospective chart review of the first twenty cases of patients with EVALI was performed. We present the urinary abnormalities noted in patients with EVALI.

Results: Twenty patients admitted for EVALI underwent urinalysis as part of their laboratory workup. None of these patients had known pre-existing renal disease. All patients except for one had normal creatinine on admission. Proteinuria was seen in thirteen patients (65%) and microscopic hematuria (~4 RBC/hp) was seen in five patients (20%). All patients with microscopic hematuria also had proteinuria. However further work up revealed a vaginal mass which was biopsied and found to be Hodgkin’s lymphoma. Patient was started on chemotherapy however did not make any renal recovery and remains dialysis dependent.

Conclusions: EVALI can be associated with hematuria and proteinuria. In animal studies, E-cigarette vapor is hypothesized to diminish airway barrier function, release inflammatory protein into the circulation creating systemic inflammation leading to distant organ injury and dysfunction (2). There are several limitations to this study. This is a retrospective chart review and long term outcome is unknown as data is lacking. Nevertheless the high prevalence of urinary abnormalities on admission in patient with EVALI calls for further investigation. While the pathogenesis of vaping-associated renal injury is unclear, urine analysis should be considered in all patients presenting with EVALI (Ref 1). Impact of a cigarette refill liquid exposure on rat kidney Golli NE et al. Regul Toxicol Pharmacol 2016 Jun;77:109-16. 2. Chronic inhalation of e-cigarette vapor containing nicotine disrupts airway barrier function and induces inflammation and multiorgan fibrosis in mice Crotty Alexander et al Am J Physiol Regul Integr Comp Physiol. 2018 Jun 1;314(6):R834-R847.

Kidney Biomarkers and Major Adverse Kidney Events in Critically Ill Patients

Alexander H. Flanerry,1 Victor M. Ortiz-Soriano,2 Fabiola Gianella,3 Victor E. Prado,1 Robert D. Toto,1 Orson W. Moe,1 Javier A. Neyra,1 University of Kentucky College of Pharmacy, Lexington, KY; 2University of Kentucky College of Medicine, Lexington, KY; 3University of Texas Southwestern Medical Center at Dallas, Dallas, TX.

Background: Several biomarkers of acute kidney injury (AKI) have been examined for their ability to predict AKI earlier than serum creatinine. Few studies have focused on using kidney biomarkers to better predict major adverse kidney events (MAKE), an increasingly used composite outcome in critical care nephrology research.

Methods: Single-center prospective study collecting blood and urine samples from critically ill patients with AKI KDIGO stage 2 or above, and matched controls from a single, tertiary care intensive care unit. Samples were collected at 24-48 hours after AKI diagnosis (cases) or ICU admission (controls), 5-7 days later, and 4-6 weeks following discharge for AKI patients. The primary outcome of interest was MAKE at hospital discharge.

Results: Serum/urinary neutrophil gelatinase-associated lipocalin, serum/urinary cystatin C, and urinary kidney injury molecule-1 early in the AKI or ICU course were all significantly higher in patients with MAKE compared to those not experiencing MAKE. Serum cystatin C, and to a lesser extent serum NGAL, significantly improved upon a clinical prediction model of MAKE as assessed by the area under the receiver operating characteristic curve. Patients without MAKE experienced a greater decline in serum NGAL from initial measurement to second measurement than those patients experiencing MAKE.

Conclusions: Early values of kidney biomarkers in critically ill patients are associated with MAKE. This relationship appears to be greatest with serum NGAL and cystatin C, which display additive utility to a clinical prediction model. Trending serum NGAL may also have utility in predicting MAKE.

Urine Biomarkers and Risk of Long-Term Kidney Outcomes After Cardiac Surgery: the TRIBE-AKI Study

Christopher A. Philbrook,1 Victor McArthur,2 Yaqi Jia,3 Wissam Obeid,3 Sherry Obeid,1 Michael Shlipak,2 Steven G. Coca,2 Chirag R. Parikh,1 TRIBE-AKI Consortium, Johns Hopkins University School of Medicine, Baltimore, MD; 2Yale University School of Medicine, New Haven, CT; 3Western University Schulich School of Medicine and Dentistry, London, ON, Canada; 4Institute for Clinical Evaluative Sciences, Toronto, ON, Canada; 5University of California San Francisco, San Francisco, CA; 6Icahn School of Medicine at Mount Sinai, New York, NY.

Background: The urine biomarkers epidermal growth factor (EGF) and monocyte chemotactic protein-1 (MCP-1) show promise as biomarkers of chronic kidney disease (CKD) progression in settings such as diabetes mellitus, but their role in the transition from AKI to CKD remains unclear. EGF is produced specifically by renal tubular epithelium of the thick ascending limb and MCP-1 is extensively studied as a marker of kidney inflammation. We evaluated the associations of urine EGF and MCP-1 with CKD incidence or progression after cardiac surgery.

Methods: In this sub-study of the prospective TRIBE-AKI cohort, we evaluated 865 adult patients who underwent cardiac surgery from 2007–2010 at two sites in Canada and the US. We tested the association of first post-operative urine EGF and MCP-1, and the ratio EGF/MCP-1, with the composite outcome of CKD incidence or progression. We assessed for interaction by peri-operative AKI status.

Results: Over a median (IQR) follow-up of 5.8 (4.2-7.1) years, 266 (30.8%) patients developed the composite outcome at an event rate (95% CI) of 55.4 (49.2-62.5) per 1,000 person-years. Elevated levels of first post-operative urinary EGF and MCP-1 were each independently associated with the composite outcome, in opposing directions (Table 1), and the ratio (EGF/MCP-1) was strongly associated with decreased risk of CKD incidence or progression in both continuous and categorical analysis (aHR 0.50 [0.33-0.74] for T3 compared to T1). There was no interaction by AKI status.

Conclusions: Urine EGF and MCP-1 may be useful for risk prediction of future CKD outcomes after peri-operative injury in cardiac surgery.

Higher Plasma KIM-1 Is Associated with Increased Mortality and Decreased Renal Recovery in Patients with AKI Requiring Renal Replacement Therapy

Yvelynne P. Kelly,1 Finnian R. McCausland,1 Mallika L. Mendu,2 Venkata S. Sabbisetti,3 David E. Leaf,1 Sushrut S. Wairag.2 Brigham and Women’s Hospital, Boston, MA; 2Boston Medical Center, Boston, MA.

Background: Plasma kidney injury molecule-1 (KIM-1), a protein synthesized by renal proximal tubular cells, increases during periods of ischemia and thereby acts as a sensitive marker for AKI severity. We hypothesized that higher plasma KIM-1 levels assessed prior to commencing renal replacement therapy (RRT) would associate with higher mortality and RRT dependence in critically ill patients with severe AKI.

Methods: We measured plasma KIM-1 levels in 806 Day 0 samples from participants in Acute renal failure Trial Network (ATN) trial, a randomized controlled trial of intensive versus less-intensive RRT. For our primary analysis we used a logistic regression model to assess the risk of 28-day mortality and an inverse probability weighted logistic regression model to assess the odds of 28-day renal recovery, per doubling in log-transformed Day 0 KIM-1. Both models were adjusted for components of the ATN trial mortality risk score (age, chronic hypoxemia, CVS disease, malignancy, immunosuppressive therapy, ischemic AKI, post open surgery and vital signs at RRT initiation).

Results: Higher levels of plasma KIM-1 were associated with an increased risk of death within 28 days (adjusted odds ratio 1.15; 95% CI 1.03-1.29; p = 0.02) per doubling in log-transformed plasma KIM-1. Higher levels of Day 0 plasma KIM-1 were also associated with an increased risk of persistent RRT dependence at 28 days (adjusted odds ratio 0.76; 95% CI 0.66-0.87; p = 0.001) per doubling in log-transformed plasma KIM-1.

Conclusions: Higher plasma KIM-1 levels measured prior to initiation of RRT are independently associated with higher 28-day mortality and lower probability of 28-day renal recovery in critically ill patients with severe AKI.

Estimated vs. Measured Glomerular Filtration Rate in Acute Decompensated Heart Failure
Jutta S. Swolinsky,1 Enkhtuvshin Tuuvshinbat,1 Fabian Knebel,2 Niklas P. Nerger,2 Caroline Lemke,1 Daniel Meier,1 Edis Gasanin,1 Veselin Mitrovic,1 Kai-Uwe Eckardt,1 Bruce A. Moltitci,1 Kai M. Schmidt-Ott,1 1Charité Universitätsmedizin Berlin, Department of Nephrology and Medical Intensive Care, Berlin, Germany; 2Charité Universitätsmedizin Berlin, Department of Cardiology and Angiology, Campus Mitte, Berlin, Germany; 1FAST Biomedical, Indianapolis, IN; 2Richard L Roudebush VA Medical Center, Indianapolis, IN

Background: Kidney function is closely monitored in patients with acute decompensated heart failure (ADHF). Recent studies indicate that rise in endogenous filtration markers (serum creatinine (Scr) or cystatin c (Cys)) is neither associated with tubular injury nor with adverse outcomes when accompanied by efficient decompensation. The imperfections of Scr or Cys to estimate GFR in non-steady state could contribute to misjudgment of renal failure in ADHF. In this study we measured GFR (mGFR) in patients treated for ADHF and correlated them with estimated GFR dynamics.

Methods: In a prospective cohort study in 50 hospitalized subjects treated for ADHF, mGFR was measured using a two-component intravenous visible fluorescent injectate (VFI) at two timepoints 48h apart. Serum concentrations of a high molecular weight dextran component of VFI were measured 15 and 60 min after injection to quantify plasma volume (PV) using indicator-dilution principle. Concentrations of a low molecular weight component of VFI were measured to determine mgFR based on PV-normalized plasma pharmacokinetics. Pearson’s r, Bland-Altman plots, precision, accuracy and bias were calculated for 4 established equations (CKD EPI r, CKD EPI c, CKD EPI c+c, sMDRD) and kinetic GFR (kGFR, Chen et al., JASN 2013). 38 subjects had complete serial mGFR data.

Results: GFR calculated by any estimating equation correlated significantly with measured GFR (CKD EPI r, r=0.81; CKD EPI c, r=0.81; CKD EPI c+c, r=0.84; sMDRD, r=0.81; kGFR r=0.81, p<0.0001). CKD EPI c+c had the best overall performance with an accuracy (P30) of 75%. However, changes in mGFR during 48h of ADHF treatment were not adequately reflected in corresponding changes of eGFR. KDIGO SCR-based AKI criteria frequently failed to detect relevant decreases of mGFR (Sensitivity 55%).

Conclusions: In patients hospitalized for ADHF undergoing decompangement, GFR estimates based on Scr and CC display substantial deficits in estimating GFR. In particular, changes of Scr- and CC-based GFR displayed a remarkable disconnect from mGFR dynamics. KDIGO SCR criteria displayed a poor sensitivity in detecting relevant decreases of mGFR, indicating a need for improved diagnostic approaches to identify true worsening renal function in ADHF.

Multiple Beneficial Effects of Renal Exosomes on Ischemic Injury
Katherine J. Kelly,1,2 Jesus H. Dominguez.1 1Indiana University School of Medicine, Indianapolis, IN; 2Richard L Roudesh V4 Medical Center, Indianapolis, IN

Background: Ischemic injury to the kidney and other organs is deadly and expensive. We have demonstrated the effectiveness of adult cell-based therapies in multiple models of renal failure. Given the large benefits of relatively few cells, we hypothesized that exosomes from transplanted cells were the therapeutic effector. We and others have shown benefit with exosomes in renal injury models. To define the mechanisms of benefit from renal exosomes, the effects of exosomes from platelets and dermal epithelia were compared to those of renal exosomes.

Methods: The hypothesis that renal exosomes improve multiple pathways of injury postischemia and contain anti-oxidant and anti-inflammatory cargo was tested in a renal ischemia model. Exosomes from post-ischemic kidneys, platelets or skin were isolated by serial centrifugation. Renal function was estimated from serum creatinine. Oxidative stress and inflammation were assessed by immunostaining for 4-hydroxyneonal and neutrophils, respectively. Anti-inflammatory cytokine levels were measured by enzyme-linked immunoassay.

Results: We found significant improvements in renal function (figure) and structure with renal exosomes, given 24 hours postischemia, when renal failure was present. Exosomes from skin epithelia or platelets were not effective. Renal, but not skin or platelet, exosomes decreased evidence of oxidative stress in post-ischemic kidneys by 67%, with preservation of catalase and superoxide dismutase. Significantly less renal neutrophil infiltration was found in the renal exosome group as compared to postischemia groups that received vehicle or skin or platelet exosomes. Anti-inflammatory IL-10 levels were significantly higher in post-ischemic kidneys in the renal exosome group.

Conclusions: Exosomes derived from kidney cells effect multiple pathways of injury to improve postischemic kidney function.

Point-of-Care Prevention and Treatment of AKI with Adipose-Derived Stem Cells: Efficacy and Cost Advance over Culture-Expanded Bone Marrow-Derived Mesenchymal Stem Cells
Anna Gooch,1 Ping Zhang,1 Zhuma Hu,1 Christof Westenfelder.1,2
1SymbioCellTech, LLC, Salt Lake City, UT; 2University of Utah, Salt Lake City, UT.

Background: Our pre-clinical studies (AJP 2005) and a Phase I Clinical Trial (Nat Rev Neph 2010) show that administration of bone marrow-derived, culture expanded, allogeneic Marrow Stromal Cells (MSC) is effective in the prevention and hastened recovery from experimental AKI, and safe and renoprotective in on-pump cardiac surgery patients at high risk for post-op AKI. Significantly, MSC treated unlike historical control on-pump cardiac surgery patients did not develop Chronic Kidney Disease (CKD) long term (>7 years). Expansion and banking of MSCs is expensive and time consuming. To address these limitations, we compared treatment with syngeneic, culture-expanded MSCs or vehicle to treatment with either syngeneic, minimally manipulated allogeneic Adipose Derived Stem Cells (ASCs) or autologous Stromal Vascular Fraction (SVF) immediately isolated from fat, containing ASCs, endothelial precursor and other cells for efficacy in preventing AKI. ASCs share therapeutically critical activities with MSCs and are in sufficiently high numbers/gm fat to present an alternative to culture-expanded MSCs.

Methods: ASCs and SVFs were isolated by minimal processing from abdominal fat harvested from male Fisher344 (F344) rats. IRI AKI was induced (bilateral renal pedicle clamping x 40 min) in 50% of male F344 rats (~200 g wt; n=7 each). Upon reflow, groups were infused (supraprenal aorta) with either (1) 1x106 ASCs, (2) 1x105 autologous SVF cells, (3) 1x106 syngeneic, cultured MSCs, (4 and 5) vehicle in animals with or without fat harvest.

Results: Outcomes were compared to those of sham treated animals (n=7). Renal function assessed by serum Cr (SCr) in ASC or SVF treated animals was significantly better protected, and recovery more rapidly achieved compared to vehicle and MSC treated rats.

Conclusions: Our data suggest therefore that autologous ASCs and the SVF, obtained by minimal manipulation from a patient’s lipop罗斯ate, have the potential to treat that same patient with an efficient, inexpensive and safe point-of-care protocol to prevent or treat AKI and prevent subsequent progression to CKD. Administration of Exosomes from Mesenchymal Stem Cells Provides Effective Survival Benefits and Functional Rescue from Severe, Progressive Ischemia-Reperfusion Injury-Induced AKI in Rats
Anna Gooch,1 Mikhail Sklair,2 Ping Zhang,1 Zhuma Hu,1 Christof Westenfelder.1,2
1SymbioCellTech, LLC, Salt Lake City, UT; 2University of Utah, Salt Lake City, UT.

Background: While administration of Mesenchymal Stem Cells (MSCs) has been demonstrated clinically to prevent Acute Kidney Injury (AKI) such as that caused by cardiac bypass surgery, administration 48 hrs post-injury was found to be ineffective or potentially damaging, likely because the introduction of large cells (~50μm) into the compromised microvasculature may impair renal function. MSCs’ renoprotection is mediated by their paracrine release of anti-inflammatory and trophic cytokines and their exosomes. Exosomes signal, post uptake by target cells, through the lateral transfer of mRNAs, miRNAs, DNA, proteins, and lipids. Since MSC-derived exosomes can prevent AKI we tested whether their small size and ability to move through the compromised renal microvasculature might allow them to provide effective rescue therapy for late stage AKI.

Methods: Exosomes from Sprague Dawley (SD) rat MSCs were isolated post 24 hr culture, purified using the ExoQuick-TC kit, and characterized for size (nanosize), protein and gene expression of relevant markers. 1/R AKI (52 min bilateral renal pedicle clamp) was induced in female SD rats. If the SCr value on Day 2 was greater than that on Day 1, demonstrating progressive AKI, then rats were infused via left carotid artery either 1 ml of Vehicle (PBS; n=9), Exosomes (200 μg protein-equivalent; ~4x10e10 exosomes; n=6), or MSCs (2x10e6; n=6) on Day 3.

Results: Versus controls, all 3 cell types significantly protected renal function and histology from AKI (SCr levels, tissue injury scores); but within 14 days, each treatment elicited a significant IgG antibody response (57-99%) against the infused cell type. Rats inoculated i.p. with hASCs and confirmed to have positive immunity to hASCs were no longer renoprotected by hASCs when treated with them for IRI AKI.

Conclusions: While xenogeneic use of MSCs/ASCs is renoprotective, the demonstrated induction of an immune response makes such applications unsafe/ineffective in pre-clinical studies. Caution is advised in interpreting results of studies using cell lines containing xenogenic expression vectors for genes meant to enhance MSCs’ clinical efficacy. (Not U of Utah work)

Glomerular Filtration Fails to Increase During Pregnancy After Renal Ischemia-Reperfusion Injury
Ellen E. Gillis, Michael W. Brands, Jennifer C. Sullivan. Augusta University, Augusta, GA.

Background: Renal demands are increased during normal pregnancy due to the large increase in plasma volume and cardiac output, with a corresponding increase in glomerular filtration rate and decreased blood pressure (BP). Recent studies in our laboratory have reported that pregnancy after recovery from ischemia reperfusion (IR) injury results in poor maternal and fetal outcomes, including decreased fetal weight, increased fetal mortality, and tissue damage. The gene encoding KIM-1 (IRI) by enabling TECs to bind and engulf dying neighbouring cells, limiting inflammation and immunogenic contents into the extracellular milieu, exacerbating inflammation. Kidney injury, however, is absent in this model, leading to decreased placental perfusion and poor fetal growth.

Methods: Female Sprague Dawley rats (10 weeks of age, n=3) were implanted with telemetry devices and placed into a flooded fetal and maternal cage during pregnancy. Three groups were studied: control rats that did not undergo ischemia (C), rats that underwent 45 minutes of ischemia (I), and rats that underwent 45 minutes of ischemia followed by 1 month of recovery (IR). Two groups of rats were used for analysis: one group was sacrificed at gestational day 20, and the second group was sacrificed at gestational day 20 after the 1 month recovery period. Glomerular filtration rate was calculated using creatinine clearance (using 24 hour urine collection from gestational days 19-20 and plasma creatinine on gestational day 20).

Results: BP decreased to a similar extent (7±1.2mmHg in control vs 8±1.2mmHg in IR dams) by gestational day 20, however the decrease in BP was delayed in the IR dams, resulting in an overall higher pressure load as determined by the area under the curve analysis (2080±33 vs 2184±16, p<0.05, t-test). Glomerular filtration rate was significantly higher (2080±33 vs 2184±16, p<0.05, t-test) in control rats compared to IR rats. The decrease in BP was delayed in the IR dams, leading to an increased pressure load and poor fetal growth.

Myeloid Lactate Dehydrogenase A (LDHA) Regulates Macrophage Polarization and Promotes Fibrosis in AKI
Gunars Osts, Amie Tryaylor, Hannah Eckenrode, Laurence M. Black, Steven L. Cochran, Anupam Agarwal. University of Alabama at Birmingham, Birmingham, AL.

Background: Renal ischemia/reperfusion injury (IRI), a major cause of AKI, is characterized by an initial decrease in blood flow, followed by its subsequent restoration. IRI facilitates infiltration of proinflammatory macrophages as well as proliferation of intrarenal resident macrophages that, upon activation, undergo glycolytic switch, and can further exacerbate injury by inducing excessive inflammation. LDHA, a key enzyme involved in the glycolytic switch, catalyzes the conversion of pyruvate to lactate, regenerating NAD+ from NADH. Here we investigate the role of LDHA in myeloid cells and its effect on AKI.

Methods: To test the hypothesis that myeloid LDHA expression regulates macrophage polarization, LDHA-expressing bone marrow derived macrophages (BMDM) from wild-type and LDHA knockout (LDHA KO) mice grown in M-CSF for 7 days and then polarized with IFN-γ were used. LDHA deficiency in macrophages attenuates systemic inflammatory response and iRIR. Phenotypic alterations in splenic macrophages might play critical roles in the protection against iRIR.

PO0152
PD-1 Regulates Metabolic Fitness of Tregs in Protection from Kidney Ischemia-Reperfusion Injury
Murat Dogan, Rajkumar Venkatadri, Vikram Sabapathy, Sandhya Xavier, Didier Portilla, Rahul Sharma. University of Virginia, Charlottesville, VA.

Background: Regulatory T cells (Tregs) protect the kidney in models of ischemia reperfusion injury (IRI). Previous studies suggested programmed cell death protein 1 (PD-1) expression by Tregs is required for their protective function in AKI. However downstream mechanisms of PD-1 signaling in Tregs in AKI is not clear. We aimed to investigate the role of PD-1 in Tregs with respect to mitochondrial function in AKI.

Methods: We induced AKI in male C57Bl/6 mice with 26 min bilateral renal IRI. CD4-CD25+ Tregs were isolated from PD-1+/+ and PD-1-/- Foxp3-GFP mice and then injected (100,000 cells/200ul) via tail vein into recipient mice 24h prior to ischemia reperfusion surgery. Kidney function was determined by measuring creatinine and tissue KIM-1 and (100,000 cells/200ul) via tail vein into recipient mice 24h prior to ischemia reperfusion surgery. Kidney function was determined by measuring creatinine and tissue KIM-1 and NAG mRNA expression levels. Histological damage was assessed by light microscopic analysis of H&E stained kidney sections. In different set of experiments to understand the metabolic fitness of Tregs, we treated isolated T-cells from PD-1+/+ and PD-1/- mice and incubated them overnight with anti-CD3/Ab to mimic antigenic stimulation or with high concentration of IL-2, which is critical for Treg survival and function. Mitochondrial membrane potential of Tregs was measured with TMRE to monitor the mitochondrial fitness. FACS-sorted Tregs from PD-1+/+ and PD-1/- mice were also analyzed for the expression of genes involved in mitochondrial dynamics and biogenesis.

Results: In the mouse kidney IRI, PD-1+ Tregs offered no protection from AKI. Compared to PD-1+/+ mice, PD-1-/- Tregs had reduced mitochondrial mass and mitochondrial membrane potential. In FACS-sorted Tregs, expression of markers of mitochondrial function, antioxidant pathways as well as those for mitochondrial dynamics were remarkably attenuated in the Tregs from PD-1-/- mice as compared to PD-1+/+ mice.

Conclusions: Ability of Tregs to protect kidney from IRI-induced AKI is dependent on PD-1 expression by Tregs. Mitotracker green and TMRE experiments suggest that in the absence of PD-1, Tregs have reduced mitochondrial number and/or function. Tregs require mitochondrial fitness for their development and optimal function. Additionally, these genes may regulate cytokine rearrangement and microtubule movement related to cell motility, granule release and cell division.

Toll-Like Receptor 4 Blockade Ameliorates Kidney Ischemia-Reperfusion Injury

Background: Renal ischemia-reperfusion injury (IRI) is a key mechanism in various clinical conditions including sepsis and transplantation, and animal studies have demonstrated that toll-like receptor 4 (TLR4) is a key mediator of IRI. Since few study have tried the pharmacologic inhibition of TLR4 in renal IRI, we investigated the effect of TLR4 blockade on this condition with the goal of pursuing better therapeutic options.

Methods: We subjected C57BL/6 mice to 23 minutes of renal pedicle clamping following an intraperitoneal injection of TLR inhibitory peptide (TIP1), a TLR4 inhibitor, or vehicle. Sham mice underwent only a flank incision. Then, the kidneys were harvested after 24 hours of reperfusion for histology, western blot, RT-PCR, and flow cytometry. We also performed primary mouse renal tubular cell culture to assess the effects of TLR4 inhibition on tubular epithelial cells under hypoxia and subsequent reoxygenation.

Results: TIP1 pretreatment lowered the magnitude of an increase in serum creatinine levels and attenuated tubular injury. In addition, TIP1 administration decreased mRNA expressions of inflammatory cytokines, and apoptotic cells, and lowered oxidative stress in postischemic kidneys. The kidneys pretreated with TIP1 also showed less infiltration of macrophages and T helper 17 cells. In primary mouse tubular cells subjected to hypoxia and reoxygenation, the addition of TIP1 into culture media ameliorated the magnitude of an increase in mRNA levels of KIM1 and inflammatory cytokines.

Conclusions: Our data demonstrated that inhibition of TLR4 with TIP1 reduced tubular injury and an inflammatory and immune response in a mouse model of IRI.

Funding: Government Support - Non-U.S.
we injected adeno-associated viral vector serotype 9 (AAV9)-Six1 into uninjured renal pellets before IR injury, then assessed morphologic and functional parameters and genes expression in injury related tissues.

Results: We demonstrated that Six1 promoted cell proliferation by upregulating cyclin and glycolytic genes, and that cell migration through increasing the expression of matrix metalloproteinases (MMPs) in the cell model. Notably, the overexpression of Six1 could suppress inflammation through NF-κB-mediated pathway. Six1 target the promoters of amino-terminal enhancer of split (AES) and translocated in liposarcoma (TLS), which are cofactors of NF-κB subunit RelA, and then inhibit the transactivation function of RelA in a negative feedback circuit. Six1 overexpression resulted in inhibiting inflammation and promoting cell proliferation to reduce kidney damage of mice from IR injury in vivo.

Conclusions: Our studies suggested that Six1 promoted kidney recovery and regeneration through proliferation/migration and anti-inflammation which might be a potential therapeutic target that can be used to improve kidney repair after IR injury.

IRF8-Dependent Regulation of Kidney Dendritic Cells in Ischemic AKI

Li Na,1,2 Stefanie Steiger,2 Zhihua Zheng,1 Hans J. Anders,1 Julia Lichtnekert,2 1Division of Nephrology, The Seventh Affiliated Hospital, Sun Yat-sen University, Shenzhen, China; 2Division of Nephrology, Department of Medicine IV, Hospital of the LMU Munich, Munich, Germany.

Background: Ischemic acute tubular necrosis is a common cause of acute kidney injury (AKI), which involves a greater functional diversity of mononuclear phagocytes (MPCs) such as dendritic cells (DCs). The deletion of DCs induce more kidney injury and impair the recovery of AKI. The hematopoietic transcription factor IRF8 mediates the phenotype of DC. However, the role of IRF8 dependent mechanism during AKI is not well known. Hence, we hypothesized that the dynamically altered expression of IRF8 in DCs could contribute to AKI.

Methods: AKI was induced by transient renal pedicle clamping in C57BL6/J. Kidneys, lymph nodes and spleens were collected on D1, D3 and D7. MPCs were identified by Flow cytometry. Expression of IRF8 and MHC II were quantified by IHC. The knockdown of IRF8 was performed by transfecting siRNA in bone marrow-derived DCs (BMDCs). BMDCs were stimulated with necrotic supernatant from tubular epithelial cells and histones and analyzed by phagocytosis assay, T-cell differentiation assay, RT-PCR or flow cytometry.

Results: In vivo, we identified four distinct phenotypically MPCs with diverse expression status in response to AKI injury. The phenotypes of MPCs in response to AKI injury implies that selective targeting of IRF8 DCs may provide an effective strategy to induce immune-modulation of the progression of AKI.

PO0157

VNN1 Mediates Renal Maladaptive Repair after AKI by Inducing Premature Senescence of Renal Tubular Cells

Kehong Chen, Daping hospital, Chongqing, China; Daping hospital, Chongqing, China.

Background: Renal maladaptive repair can lead to the failure of acute kidney injury (AKI) to chronic kidney disease. Sustained renal interstitial damage catalyzes accelerated senescence of renal tubular cells leading to renal fibrosis after AKI. VNN1/1 (VNN1) is an extracellular enzyme with panthenthamelaminic activity that indirectly reduces the synthesis of glutathione, causing oxidative stress. This study aimed at investigating the role of VNN1 in senescence of renal tubular cells after renal ischemia reperfusion (IR) injury.

Methods: Thirty male wild BALB/c mice were randomly divided into control group, sham group and I/R group. In the I/R group, bilateral renal pedicles were clamped for 35 min and reperfusion was performed. The expression of VNN1 were detected. Furthermore, the degree of renal damage and the senescence of renal tubular cells were compared in wild type mice and VNN1 knockout mice after I/R injury.

Results: Scr, BUN and renal injury score increased significantly at the early stage (3d) of renal injury after I/R. Renal fibrosis was observed in the advanced stage (28-42d).

The expression of VNN1 in renal tubular cells of I/R group increased after I/R injury. The protein levels in VNN1 KO mice were significantly lower than those in wild type mice at 7-28 d after renal reperfusion. The renal interstitial fibrosis level was significantly higher in VNN1 KO mice than that of wild type mice at 42d after reperfusion. The results suggest that VNN1 KO promotes renal repair of AKI. It is found that 50% of the VNN1 up-regulated genes after IR renal injury were stress-related genes through mRNA microarray analysis. The ratio of P16 positive tubule cells in VNN1 KO mice was significantly higher than that in wild type mice at 7d after renal reperfusion. The expression levels of phosphorylated Rb1 in VNN1 KO renal tubular cells were significantly higher than those in the wild type renal tubular cells after hyposxia/reoxygenation, suggesting that VNN1 could promote the senescence of renal tubule cells through P16-Rb1 pathway during AKI repair.

Conclusions: VNN1 mediates renal maladaptive repair after AKI by inducing premature senescence of renal tubular cells through P16-Rb1 pathway.

Funding: NIDDK Support
The Proximal Tubule Is a Source of De Novo NAD+ Synthesis, the Metabolites of Which Are A Valuable Predictor of AKI

Yujia Wang, Chuan-Ming Hao. Huashan Hospital Fudan University, Shanghai, China.

Background: Reduced NAD+ is reported to increase the susceptibility of AKI. De novo synthesis pathway from tryptophan is an important source of NAD+ in the liver and probably kidney. In the present study, we characterized the expression of the enzymes of de novo NAD+ synthesis pathway in the human kidney. We then examined the association of the urine metabolites in this pathway and AKI development in patients who received high-dose methyltrexate (HDMDTX) chemotherapy or liver transplantation (LT) and analyzed their predictive value for AKI.

Methods: The expression of the enzymes of de novo NAD+ synthesis pathway was examined by immunohistochemistry. To examine the predictive value of urine tryptophan metabolites in AKI, 71 patients who received a total of 191 HDMDTX treatments were prospectively enrolled as a discovery cohort and 49 patients receiving LT were enrolled as a validation cohort. Urine samples were collected within 72 hours before chemotherapy/surgery. AKI was defined by KDIGO criteria. Urine tryptophan metabolites were measured by LC-MS and adjusted by creatinine. The performance of these metabolites to predict AKI after HDMDTX/LT was analyzed.

Results: Enzymes of de novo NAD+ synthesis pathway including KMO, KYNU, HAAO, QPR, and ACMSD were detected in renal tubules that were positive for LTL, but not labeled by AQP2, NCCT, nor THP, consistent with proximal tubule expression. A total of 191 HDMDTX treatments were included in the discovery cohort and AKI developed after 35 HDMDTX treatments (18.5%). In those who developed AKI, the urine level of 3-hydroxyanthranilic acid (3-OH AA) was significantly higher while the level of quinolinic acid (QA) was significantly lower compared with those who did not develop AKI (3-OH AA: 4.42 [2.74-9.32] vs 3.57 [1.86-5.73], p = 0.002; QA: 13.43 [9.69-22.34] vs 20.64 [14.80-32.05], p = 0.004). The area under the receiver operating characteristic curve (AUC) of urine QA/3-OH AA for AKI prediction was 0.748. The discrimination ability of the urine QA/3-OH AA on AKI susceptibility was validated in LT cohort, with the AUC as 0.729.

Conclusions: The proximal tubules are an important source of de novo NAD synthesis. Reduced urine QA/3-OH AA ratio is associated with development of AKI. The present study suggests that urine QA/3-OH AA ratio is a potential biomarker to predict AKI and NAD+ synthesis pathway is a potential therapeutic target.

Dietary Omega-3 Fatty Acids After the Lipid Mediator Profile and the Fatty Acid Composition of Membrane Phospholipids but Is Not Enough to Improve Renal Insufficiency

Ryotaro Shioida,1,2 Airi Jo,1 Yusuke Suzuki,1 Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; Department of Endocrinology, Juntendo University Graduate School of Medicine, Tokyo, Japan.

Background: The efficacy of omega-3 fatty acids on ischemia-induced AKI has been reported, but the underlying mechanisms remain poorly understood. There have been no reports that demonstrated how dietary omega-3 fatty acids influenced the components of membrane phospholipids in the kidney. In this study, we focused on the effect of dietary omega-3 fatty acids on the membrane phospholipids components in the kidney, and examined the disease course of ischemia-induced AKI in the presence of the lipid mediator alterable by dietary omega-3 fatty acids.

Methods: Male 4-week-old wild-type Sprague-Dawley rats were fed for 2 months on AIN-93M, which contains 4% soy oil, or modified AIN-93M, which contains 4% perilla oil instead of soy oil. AKI was induced by unilateral ischemic reperfusion with right nephrectomy. Left renal ischemia was induced by using non-traumatic vascular clamps for 30 min. At 24 h after reperfusion, left kidneys and serum were collected. The fatty acid composition of membrane phospholipids and lipid mediators were quantified by HPLC-tandem mass spectrometry (HPLC/MS/MS).

Results: In the kidney of omega-3 diet fed rats, the levels of arachidonic acid-derived proinflammatory lipid mediators, except for 5-HETE, were not reduced compared with omega-6 fed rats. Eicosapentaenoic acid (EPA) and EPA-derived lipid mediators were significantly increased in the kidney of omega-3 diet fed rats. Furthermore, membrane phospholipids which contained EPA and docosahexaenoic acid (DHA) were significantly increased in the kidney of omega-3-fed diets. However, there was no significant difference in serum creatinine, blood urea nitrogen or histological damage between omega-3 diet fed rats and omega-6 diet fed rats.

Conclusions: Dietary omega-3 fatty acids altered the lipid mediator profile and the fatty acid composition of membrane phospholipids, but was not enough to improve renal insufficiency or histological damage.
PO0164
Kidney Functional Improvements by a Novel Potent and Selective Vasopressin V1a Antagonist After Ischemia-Reperfusion Injury (I/RI) in Rats
Karoline Droehner, Hana Cernecka, Chantal Fuerstner, Marie-Pierre L. Collin, Mira Pavkovic, Peter Hein, Frank Etten, Peter Kolkhof. Bayer AG, Wuppertal, Germany.

**Background:** Alteration in renal perfusion is a key pathologic mechanism implicated in the development of ischemic acute kidney injury (AKI). We have reported that activation of V1a receptor decreases renal blood flow (RBF) and oxygenation in settings of increased vasopressin (AVP) levels. Here we studied the role of BAY 2327949, a recently identified potent and selective V1a antagonist, in a rat renal I/RI model.

**Methods:** In a first setting, rats were infused with BAY 2327949 (100 μg/min/kg i.v.) or vehicle and baseline measurements were determined for 20 min. Unilateral ischemia was induced by clamping of left kidneys for 15 min, followed by 20 min of reperfusion. RBF and intrarenal oxygenation (pO) were continuously measured via Laser Doppler Flowmetry. In a second setting, kidney function (creatinine, cystatin C, urea) was studied 24h after 45 minutes of ischemia in uninephrectomised male rats treated with BAY 2327949 (0.5, 1, and 3 mg/kg BID, i.v.).

**Results:** Unilateral clamping resulted in an immediate drop of RBF and pO, that partially recovered during reperfusion (figure). Treatment with BAY 2327949 significantly ameliorated the severity of ischemic hypoxia and resulted in an improved and almost complete restoration of RBF and pO during reperfusion (figure). In the second setting, preventive treatment with BAY 2327949 resulted in dose-dependent, significant improvements of kidney function parameters 24h post I/RI as compared to placebo treated rats.

**Conclusions:** BAY 2327949 is a novel potent and selective vasopressin V1a receptor antagonist blocking the detrimental effects of elevated vasopressin levels on renal perfusion and oxygenation. For these reasons, BAY 2327949 could become a viable treatment option in conditions of increased AVP levels, such as AKI and CKD.

PO0165
Augmentor of Liver Regeneration Protects Kidney from Ischemia-Reperfusion Injury via Regulation of TLR4 Signaling Pathway
Ying Li,1 Xinjia Li,1,2 Changhong Guan,1,2 Weijian Xiong,1,2 The Second Affiliated Hospital, Chongqing Medical University, Chongqing, China; 1ChongqingTraditional Chinese Medicine Hospital, Chongqing, China.

**Background:** Toll-like receptor 4 (TLR4) expressed within the ischemic kidney is a crucial mediator of innate activation and inflammation. The augmenter of liver regeneration (ALR) is an immunoregulator which is highly expressed in kidney upon induction of renal I/R injury. It has been shown that exogenous ALR can protect kidney against I/R injury. However, whether ALR’s protective effect results from its immune regulatory function has yet to be determined. In this study, we show that treating renal I/R induced-rats with recombinant human ALR (rhALR) protects them from kidney I/R.

**Methods:** Rats were randomized into 4 groups as follows: sham-operated group; I/R group; I/R+rhALR1 group; I/R+rhALR2 group. TLR4, neutrophils and macrophages were detected by immunohistochemistry. ERK, JNK, and p38 proteins were tested by WB. mRNA of HMGB-1, Biglycan, HAS1, HAS2 and HAS3 was detected by real-time PCR. The cytokines and chemokines were measured by ELISA.

**Results:** This result is corroborated by less tubular damage on rhALR treated rats than those on untreated rats. rhALR treated rats have significantly less apoptosis in tubular epithelial cells, less tubulointerstitial infiltration by neutrophils (24 h) and macrophages (72 h), as well as lower levels of inflammatory cytokines compared to the untreated control rats. Furthermore, rhALR downregulated mRNA expression of endogenous ligands for TLR4 and restrain activation of TLR4 and downstream signaling molecules (ERK, JNK, and p38) on rats with renal I/R injury.

**Conclusions:** rhALR protects kidney from I/R injury by regulation of TLR4 signaling pathway

---

PO0166
DPP-4 Inhibitor Attenuated Renal Vasoconstriction Following Ischemia-Reperfusion Injury in Cirrhotic Rats
Chiao-Lin Chiang,1,2 Hui-Chun Huang,1,2 Department of Medicine, Taipei Veterans General Hospital, Taipei City, Taiwan; 1Department of Medicine, National Yang-Ming University School of Medicine, Taipei, Taiwan.

**Background:** Cirrhotic patients may develop esophageal varices to cope with portal hypertension. Variceal bleeding is usually associated with hypotension and ischemia-reperfusion injury (IRI) which may activate endogenous vasoconstrictors, leading to severe renal vasoconstriction and renal failure (so called hepatorenal syndrome). Previous studies reported that dipeptidyl peptidase-4 inhibitor (DPP4i) could attenuate the endothelin-1 (ET-1) induced vasoconstriction and increase vasodilation. The aim of this study is to delineate the effect of DPP4i in renal vascular reactivity of cirrhotic rats following IRI.

**Methods:** Male S-D rats were used for experiments. Biliary cirrhosis was created by common bile duct ligation (CBDL). Control group received sham surgery (SHAM). After surgery, Linagliptin (3 mg/kg/d) or distilled water (DW) was administered for 28 days. On the 29th day, bilateral renal pedicles were clamped with microvascular clamps for 45 minutes in IRI group. The clamps were then removed followed with 60 minutes of reperfusion. Kidneys were perfused in situ via right renal artery for continuous monitoring of renal perfusion pressure.

**Results:** There was no difference in mean arterial pressure, heart rate, portal pressure, and blood sugar between DW and DPP4i treated rats. IRI enhanced renal vascular response to ET-1 in both SHAM (p=0.027) and CBDL (p=0.025) rats, implying renal vasoconstriction. Compared with corresponding DW-treated rats, DPP4i treatment abrogated renal hyperreactivity following IRI in CBDL rats (p=0.036), but not in SHAM rats (p=0.737).

**Conclusions:** We concluded that DPP4i may attenuate the development of renal vasoconstriction following IRI in cirrhotic rats. The potentially mechanisms remained to be elucidated.
Concentration-response curves to ET-1 in perfused kidneys of SHAM (A) and BDL (B) rats.

PTEN Protects Against Ischemia Reperfusion-Induced AKI via Regulating TNF-α Mediated Apoptosis

Huizhen Wang, Aiqing Li. Division of Nephrology, Nanfang Hospital, Southern Medical University, Guangzhou, China.

Background: Recently, PTEN, a vital tumor suppressor, has been raised its role in kidney homeostasis. We previous demonstrated that podocyte-specific knock-in of PTEN alleviated albuminuria and glomerulosclerosis in diabetic kidney disease. However, whether PTEN involves in acute kidney injury (AKI) remains unclear.

Methods: The levels of PTEN in renal tissue and serum were detected in ischemia-reperfusion (IR)-induced AKI mice with different ischemia time. Expression of PTEN was also detected in IR-induced cultured HK-2 injury with different ischemia and reperfusion time using ATP/glucose depletion that concentration of antimycin A mimicked the severity of ischemia. Immunoprecipitation and mass spectrometry were combined to analyze differential PTEN-interacting proteins among control, IRI+LV-NC and IRI+LV-PTEN groups. PTEN intervention including knock-down (si-PTEN) and knock-in (lentivirus-PTEN) was performed in HK-2 to reveal the role and mechanism of PTEN in IRI-AKI.

Results: PTEN was significantly reduced in renal tissue and serum in AKI mice at bilateral renal artery occlusion for 28 min and 35 min, and reperfusion for 1 day compared with sham group (P<0.05). Concentration of serum PTEN was negatively correlated with level of serum creatinine (r=-0.87, 95% CI -0.94 to -0.71). PTEN was also downregulated in IR-induced HK-2 injury in an antimycin A concentration dependent manner (P<0.05). There were 23 upregulated (ACO2, BRCA1, USP30), and 20 downregulated (BIN1, pericentrin, SLC12A5) PTEN-interacting proteins in IRI+LV-PTEN group compared with IRI+LV-NC group. Gene Ontology enrichment analysis showed that overrepresentation of differential PTEN-interacting proteins functionally related to cytoskeleton, and ATPase activity. Pathway analysis showed a great role of differential PTEN-interacting proteins in apoptosis, and necroptosis. Knockdown of PTEN increased the expression of NGAL, Ctgf and TNF-α in IR-induced HK-2 injury (P<0.05), while overexpression of PTEN alleviated IR-induced injury (P<0.05).

Conclusions: PTEN was decreased in renal tissue and serum associated with severity of ischemia injury in IRI-AKI mice, suggesting that PTEN is promising to be a serum biomarker for early prediction and evaluation of AKI. PTEN protected HK-2 from IR-induced injury possibly via regulating cytoskeleton and TNF-α-mediated apoptosis signal.

PO0168

Endothelial Prolyl-Hydroxylase Domain Proteins Regulate Capillary Rarefaction Following Ischemic AKI and Reprogram Endothelial Metabolism

Ratnakar Tiwari, Pinelopi P. Kapitsinou. Northwestern University Feinberg School of Medicine, Chicago, IL.

Background: Endothelial cell (EC) metabolism has emerged as a new regulator of EC behaviour, but its role in capillary rarefaction, a common feature of progressive renal disease, remains unknown. Because EC sense oxygen and metabolic alterations through Prolyl hydroxylases 1 to 3 (PHD1-3), here we wished to define the impact of PHD inactivation on post-ischemic kidney injury outcomes, while in vitro studies focused on metabolic consequences.

Methods: Following the induction of renal ischemia-reperfusion injury (IRI), concurrent deletion of PHD1,2,3 was achieved by the Cdhs5(PACCreER) inducible system. Analysis was performed at day 14 post-IR. Furthermore, we examined the impact of DMOG, a PHD inhibitor on angiogenic capacities and global metabolic profiles of endothelial cells.

Results: Post-ischemic kidneys of PHD1,2,3−/− showed more fibrosis, as indicated by 68% increase in collagen area (P=0.005) and significant upregulation of profibrotic genes Loa12, Tgfβ and Acta2 (n=6-8, P<0.05) compared to controls. Quantitative analysis of endomucin staining showed 50% decrease in peritubular capillary density, associated with reduced endothelial proliferation as indicated by Ki-67 immunostaining (n=4, P=0.005). Notably, biochemical inactivation of PHDs by DMOG reduced EC proliferation in MTT assay (P=0.0001) while cell cycle analysis showed decrease of cells in S (~39%, n=3, P<0.05) and G2/M phases (~28%, n=3, P<0.05). Furthermore, DMOG reduced EC migration (50%, n=3, P<0.005) and tube formation. LC-MS analysis showed a profound effect of DMOG in glycolytic, TCA cycle, lipid and, nucleotide metabolites. Specifically, EC treated with DMOG showed an increase in lactate (1.46-fold, P<0.05) and significant reductions in citrate (2.2 fold, P=0.001), alpha-ketoglutarate (2.5 fold, P<0.001), malate (1.4-fold, P<0.05) and malate (1.3 fold, P=0.01). Supplementation with citrate partially rescued the proliferation defect induced by DMOG, suggesting that PHDs may affect angiogenic responses through alterations in mitochondrial metabolism.

Conclusions: Post-ischemic endothelial inactivation of PHDs promotes peritubular capillary rarefaction and fibrosis following AKI, a response which could involve alterations in mitochondrial metabolism.

Treprostinil Inhibits Mitochondria-Mediated Apoptosis During Renal Ischemia-Reperfusion Injury in Rats

Meeiwen Ding,1 Evelyn Tolbert,2 Mark Birkenbach,2,3 Reginald Y. Goh,2,3 Fatemeh Akhlaghi,1,2 Nisanne S. Ghome91.1 University of Rhode Island, Kingston, RI; 2Lifespan Health System, Providence, RI; 3Brown University, Providence, RI.

Background: Renal ischemia-reperfusion (IR) injury is a major factor that contributes to acute kidney injury, which is associated with high morbidity and mortality. Renal I/R injury compromises mitochondrial structure and function, further exacerbating renal tubular injury. Currently, there is no treatment for I/R injury available. We recently demonstrated the efficacy of treprostinil (Remodulin®), an FDA-approved prostacyclin analog, in reducing acute kidney injury during bilateral rat renal I/R injury. In this study, we investigated the role of treprostinil in reducing mitochondria-mediated apoptosis during rat renal I/R injury.

Methods: Male Sprague Dawley rats were randomly assigned to groups: control, sham, I/R, treprostinil or I/R-treprostinil and subjected to 45 minutes of bilateral renal ischemia followed by 1-72 hours reperfusion. Placebo or treprostinil (100 ng/kg/min) was administered subcutaneously via an osmic minipump. Blood and kidney tissue were collected for analysis.

Results: Treprostinil significantly reduced peak elevated Scr vs. placebo (0.6 ± 0.05 vs. 2.1 ± 0.2 mg/dl, p<0.001) at 24-hour post-reperfusion. Treprostinil also prevented I/R-mediated renal apoptosis at 6-hour post-reperfusion vs. placebo (1.0 ± 0.01 vs. 1.4 ± 0.01, p=0.001) relative to control, determined by TUNEL assay. Mitochondrial DNA (mtDNA) copy number was reduced by 23% in I/R-placebo group (p=0.067) from control, starting, following 1-hour post-reperfusion. In contrast, treprostinil preserved mtDNA content to control levels (p=0.01). In addition, placebo increased cytochrome c release into cytosol by 2.4-fold vs. control (p=0.05) at 1-hour post-reperfusion, which treprostinil prevented. Non-targeted semi-quantitative proteomics data using SWATH-MS showed decreased renal ATP levels in placebo, which were restored by treprostinil to that of control at 6-hour post-reperfusion (p<0.05).

Conclusions: Our results demonstrate that treprostinil reduces mitochondrial-mediated renal apoptosis, evidenced by reduced cytochrome c release, restored mtDNA copy number and ATP protein concentration to that of control kidney levels, thereby accelerating mitochondrial recovery and protecting renal tubules from I/R-induced apoptosis. These results suggest that treprostinil is a viable therapy to reduce renal I/R injury.

DNA Repair Factor KAT5 Acts Against Ischemia-Reperfusion Injury Through Promoted DNA Repair and KCC3-Dependent TGF Regulation in Proximal Tubular Cells

Akihito Hishikawa, Kaori Hayashi, Toshiaki Monkawa, Hiroshi Itoh. Keio University School of Medicine, Tokyo, Japan.

Background: It is known that an episode of ischemia-reperfusion (IR) results in tolerance to subsequent IR, which is so-called “pre-conditioning (PC) effect”. However, the molecular mechanisms of the pre-conditioning effect have not been elucidated. We have recently discovered that DNA double strand break (DSB) repair tolerance factor KAT5 is essential for maintenance of podocyte integrity (Cell Rep. 2019). Here we investigated the role of KAT5 in PC effect.

Methods: Wild-type (WT) mice and proximal tubular epithelial cell (PTEC)-specific KAT5 knockout (KO) mice underwent IR injury by clamping bilateral renal arteries for 30 minutes followed by reperfusion. Ischemic pre-conditioning was performed 1 week prior to IR injury. In vitro studies using cultured human PTECs (HK2 cells) were conducted with ATP depletion by Antymicin A (AMA), an in vitro model of acute tubular cell damage.

Results: Serum UN, Cr, urine NGAL, DNA DSB marker γHAX and KAT5 expression of the PTECs were increased and chloride transporter KCC3 expression was decreased at 24 hours after IR. IR with PC showed an attenuated increase in serum UN, Cr urine NGAL and DNA DSBs with accelerated KAT5 and KCC3 expression. Mass spectrometry imaging of the kidney cortex following the first IR demonstrated elevated glomerular adenensine, which is used as a marker of accelerated tubule-glomerular feedback (TGF), whereas it was decreased after the second IR with PC in WT mice, suggesting attenuated TGF in the second IR. Therefore, increased chloride uptake through KCC3 in PTECs may contribute to the suppression of TGF, which maintained GFR. In KAT5 KO mice, PC effect was attenuated with increased DNA damage and decreased KCC3 expression. In vitro ATP depletion studies showed elevated KAT5 and KCC3 expression following second treatment with AMA. Chromatin accessibility assay showed promoted chromatin accessibility of the KCC3 promoter region after the second treatment with AMA. ChiP analysis revealed that KAT5-binding KCC3 promoter region was significantly increased after the second injury compared with the first injury, indicating that elevated KCC3 expression was caused by increased binding of KAT5 to the KCC3 promoter region.

Conclusions: PTEC KAT5 may act against IR injury through promoted DNA repair and regulation of TGF via KCC3 expression.

Blocking the Histone Lysine 79 Methylation Transfer DTT1 Ameliorates AKI

Yingjie A. Guan, Shouqiang Zhuang. Rhode Island Hospital, Alpert Medical School of Brown University, Providence, RI.

Background: The Disruptor of telomeric silencing 1-like (DOT1L) gene encodes a histone methyltransferase that methylates lysine-79 of histone H3 (H3K79). DOT1L-dependent H3K79 methylation plays an important role in various physiological and pathological processes, including transcriptional regulation, embryonic development and renal fibrosis. However, its role in acute kidney injury (AKI) tissue injury remains unknown.

Methods: AKI was induced in Male C57Bl/6 mice by bilateral ischemia-reperfusion (IR) or intraperitoneal injection with folic acid (FA). EPZ5676, a highly selective inhibitor of DOT1L (20 mg/kg) or an equal volume of vehicle was administered immediately after IR or FA injection and then daily for two days. Renal function and histology were assessed by serum creatinine and HE staining. Immunohistochemistry and Western blotting were performed to identify tubule injury (NGAL), apoptosis (TUNEL and cleaved Caspase 3), proliferation (PCNA and Cyclin D) and Wnt signaling activation (active β-catenin and β-catenin).

Results: Mice developed AKI at 48 h after IR injury or FA administration as shown by the upregulation of serum creatinine and NGAL expression levels. Pharmacologic inhibition of DOT1L with EPZ5676 resulted in less severe tubular injury as evidenced by reduced renal dysfunction, diminished NGAL expression. Furthermore, the administration of EPZ5676 significantly reduced the number of TUNEL-positive and cleaved Caspase-3 positive tubular cells in kidneys. Conversely, renal tubular cell proliferation was enhanced as indicated by increased expression of PCNA and cyclin D. Moreover, DOT1L inhibition by EPZ5676 up-regulated the expression of active β-catenin form and β-catenin.

Conclusions: Our data reveals that blocking DOT1L with EPZ5676 may protect against AKI in mice through inhibition of apoptosis and enhancement of kidney repair by a mechanism involved in the modulation of the canonical Wnt signaling pathway.

Triptolide Treats Renal Tubular Injury Induced by Renal Ischemia-Reperfusion Through Specific Delivery of Kidney-Targeting Nanoplatfrom

Zeng Yao, Aiqing Li. Southern Medical University Nanfang Hospital, Guangzhou, China.

Background: Triptolide (TP) has been proved to be effective in the treatment of a variety of kidney diseases. Unfortunately, its clinical application is limited because of its high toxicity and low specificity. Here, we report a novel and safe kidney-targeting nanoplatfrom for specific delivery of TP.

Methods: Nano-polymer MNPs-TP was synthesized by encapsulating TP in a mesoscale nanoparticles (MNPs) with kidney targeting ability. MNPs-TP was injected into mice via tail vein to evaluate its toxicity to organs and immune system, and compared with free TP. The targeting and mechanisms of MNPs-TP treatment were explored by organ imaging, Transwell and other experimental methods. Finally, the model of renal ischemia-reperfusion injury (IRI) in mice was established, and the protective effects and mechanisms of TP and MNPs-TP on renal tubules in different concentrations were compared.

Results: Toxicity test showed serious pathological changes in liver, testes and the proportion of CD4+/cd8+ in blood of mice in TP group, while MNPs-TP showed no toxic effect on these organs. In vivo study showed that TP and MNPs-TP (5 mg/kg) could protect the renal tubules by down-regulating the expression of kidney injury marker (NGAL), proliferation (PCNA and Cyclin D) and Wnt signaling activation in kidneys of mice with AKI. Western blotting was performed to identify renal tubule injury (NGAL), apoptosis (TUNEL and cleaved Caspase 3), proliferation (PCNA and Cyclin D) and Wnt signaling activation.

Conclusions: MNPs-TP showed superior therapeutic effect on renal ischemia-reperfusion injury in comparison with TP. Furthermore, MNPs-TP conjugated presented much lower hepatotoxicity and no adverse effect on the immune and genetic system. The kidney-targeting MNPs may provide a promising drug delivery platform of hydrophobic drugs for treatment of renal diseases.
of urine NGAL is from the plasma, our next step was to examine the renal handling of plasma NGAL.

Methods: Mice: C57Bl/6J. Interventions: bilateral kidney ischemia reperfusion (IR) - 27 minutes; maleic acid (MA) (400mg/kg pH 7.4 in saline, IPA); furosemide (4mg, IPA); uninvolved vehicle animals served as a control. Recombinant human (rh) NGAL (Sig, IV) was injected to determine the fate of circulating rhNGAL. Measurement: transmural glomerular filtration rate (GFR), rhNGAL and mouse (m) NGAL in the plasma and urine, megalin in the urine. To link proximal tubular (PT) function with plasma and urine NGAL levels, we calculated the fractional excretion of rhNGAL (FE-rhNGAL): FE-rhNGAL = ([urine rhNGAL] / [plasma rhNGAL] x [urine creatinine]) / 100.

Results: Uninvolved vehicle: mice had 100% GFR and low levels of plasma and urine (rh)NGAL. IR (ATI model) and MA (PT injury model): 1% and 29% GFR respectively, increased plasma and urine rhNGAL in both models. Furosemide (PT injury model): GFR – 30%, plasma and urine rhNGAL was slightly elevated, urine rhNGAL was similar to control. FE-rhNGAL was less than 1% in normal and PRA mice, and it was greater than 20% in IR and MA treated mice. mNGAL plasma and urine levels, and FE-mNGAL were similar to rhNGAL levels and FE-rhNGAL respectively. Urine concentration of megalin correlated with FE-rhNGAL in every intervention (see Figure). Megalin is expressed on the brush border of PT and is responsible for the resorption of most filtered proteins, including NGAL.

Conclusions: Our data suggest that normal PT function is required for the clearance of plasma NGAL. Consideration of plasma NGAL with FE-NGAL is important to interpret urine NGAL levels and PT function and effectively distinguishes PRA from ATI.

A Case Report of Vaping-Related Renal Thrombotic Microangiopathy

Introduction: Acute kidney injury (AKI) and hematuria have been reported in patients with e-cigarette use (vaping)-associated lung injury (EVALI) but exact renal pathology is not well understood. We report a case of biopsy proven renal thrombotic microangiopathy (TMA) in a patient with EVALI.

Case Description: A 40-year-old woman with history of vaping tetrahydrocannabinol (THC) and depression presented to emergency room with 2 days of fatigue, body aches, non-productive cough, and dyspnea on exertion. On admission, BP was 157/85 mmHg, hemoglobin 5.9, platelet count 239, serum creatinine (Scr) 1.76 with 10-30/hpf non-dysmorphic RBC and 2+ proteinuria on urinalysis. Patient failed initial treatment with diuretics and on day 3, was intubated for respiratory distress. By this time, Scr had increased to 4.68 and LDH was quite elevated (1456) but platelet count was normal (194), haptoglobin high (551) and peripheral stiichocytes only occasional. Her EVALI improved with standard cares in the next week but renal function further worsened, and hemodialysis was started on day 13. Renal biopsy revealed acute TMA with diffuse endothelial swelling, focal segmental glomerular and arteriolar thrombi and activation. Patient was not taking any medications known to cause TMA. Serologic and infection work up were negative including pneumococcus, HIV, antinuclear, anti-Scl70 and antiphospholipid antibodies. The ADAMTS-13 activity was 48% and serum homocysteine was low (3.8). Imaging studies showed no evidence of malignancy. Functional complement work-up did not reveal increased alternative complement pathway activity or autoantibodies. On day 20, patient was started on plasma exchange (PLEX) for 5 sessions followed by a slow renal recovery - last hemodialysis on day 22 and now, more than 1 month after last PLEX and after approximately 2 months of vaping cessation, most recent Scr is 2.57

Discussion: There is no clear association of kidney disease with marijuana use in large population studies but there are case reports of AKI with synthetic cannabinoid use including one report of biopsy proven TMA. Drug-induced TMA is usually a diagnosis of exclusion and temporal correlation. Given the lack of other evident cause of TMA, the diagnosis was made with renal biopsy. No evidence of malignancy, non-sepsis related infection, drug reaction or vasculitis was seen. The patient also had elevated antithrombin III and decreased factor V. TMA was likely related to vaping.

PO0176
A Rare Case of Obstructive Nephropathy with Intratubular Tamm-Horsfall Polyps Secondary to Acquired Hemophilia
Kyle Meissner, Anil Musa, Vikas J. Reddy, Liye Suo, William F. Glass, Jade M. Teakell. University of Texas Health Science Center at Houston, Houston, TX.

Introduction: Acquired hemophilia has been rarely implicated in obstructive nephropathy. We present a case of gross hematuria, bilateral hydropnephrosis, and biopsy-confirmed tubulointerstitial nephritis with intratubular Tamm-Horsfall Protein (TBP) polyps. These atypical pathological aggregations of urinary glycoproteins were previously described to be located in renal veins or lymphatics. Our case represents a rare etiology of obstructive nephropathy, with unique pathological findings, secondary to an acquired hemophilia.

Case Description: A 64-year-old man with hypertension and tobacco use presented with bilateral flank pain and gross hematuria. On physical examination, the patient had normal vital signs. He denied any recent surgeries. Urinalysis showed hematuria, pyuria, and proteinuria. He had oliguric acute kidney injury (AKI) with creatinine (Cr) of 3.2 mg/dL. Renal ultrasound showed bilateral hydronephrosis. Renal function deteriorated over 3 days to Cr of 7.4 mg/dL with proteinuria of 10 g/day. Serologic markers revealed mildly elevated PR3-ANCA. Pulse steroid therapy was begun and kidney biopsy was performed. Pathology report described acute tubulointerstitial nephritis with TBP polyps and interstitial non-caseating granulomas. Immunohistochemistry assay showed TBP polyps within markedly dilated renal tubules, consistent with obstructive nephropathy. No evidence for vasculitis or other vascular lesions was seen. After biopsy, the patient developed retroperitoneal hemorrhage requiring embolization. Further studies indicated the presence of a factor VIII inhibitor. He improved with transition from steroids to mycophenolate mofetil. A few months later, his renal function returned to normal with a bland urinalysis, proteinuria less than 100 mg/dL and resolution of hydronephrosis.

Discussion: We encountered a rare presentation of acquired hemophilia with macroscopic hematuria and AKI. We suspect that blander clots and associated intraluminal clots resulted in elevated tubular pressures causing obstructive nephropathy and the formation of intratubular TBP polyps. Administration of immunosuppressive therapy resulted in cessation of the polyps as well as factor VIII inhibitor production, reinforcing our hypothesis. Anti-factor VIII antibodies are a rare complication of solid tumors and urologic malignancy work-up is ongoing.

PO0177
Reflex Anuria: A Forgotten Urologic Etiology of AKI
Hassan Mahmoud, Jasvinder S. Bhatia. Boston Medical Center, Boston, MA.

Introduction: Reflex anuria (RA) is a rare entity that can lead to severe acute kidney injury (AKI). It was defined by Hull and colleagues in 1980 as “cessation of urine output from both kidneys in response to irritation or trauma to one kidney or its ureter or severe painful stimului to other pelvic organs”. RA represents a gray area between nephrology and urology and should be considered in the differential diagnosis of AKI. We present a case of AKI and anuria where the prompt recognition and management of RA resulted in full recovery of kidney function and avoidance of renal replacement therapy and unnecessary testing.

Case Description: A 40-year-old male with Crohn’s disease status post prior right and left hemicolectomy was admitted with worsening abdominal pain and hematochezia consistent with Crohn’s flare. He underwent open abdominoperineal resection. Pre-operatively, urology performed cystoscopy and prolabolistic bilateral ureteral stent placement. Stents were removed without complication at the end of the case. On post-op day 1, he developed oliguria that progressed to complete anuria. This was associated with rapid rise in serum creatinine up to 5.5 from baseline of 0.6 (Figure 1). The differential diagnosis was broad, including acute tubular necrosis, vascular thrombosis and obstruction but because of the temporal relationship with recent procedures, RA was suspected as the etiology of AKI. Patient underwent urgent bilateral ureteral stent placement which was followed by brisk urine output (~11 L/24 hours) and normalization of serum creatinine.

Discussion: RA is a rare diagnosis that requires high index of clinical suspicion. It is a functional rather than parenchymal disease that can cause dramatic cessation of urine output and AKI. Neurovascular reflex leading to arteriolar vasocstriction and ureteric spasm is a proposed mechanism. This case illustrates that acute anuria and AKI after bilateral ureteral stent placement.

PO0178
AKI in a Patient with COVID-19, G6PD Deficiency, Acetaminophen Overdose, and Methemoglobinemia: What a Broad Differential!
M. Catalina Morales-Alvarez, Benjamin Benhuri, Michelle Shah, Boram Kim. Mount Sinai Beth Israel Hospital, New York, NY.

Introduction: Acute kidney injury (AKI) is a common complication in hospitalized and critically-ill patients. Prompt evaluation and subsequent management is warranted to avoid long term kidney dysfunction. However, a clear diagnostic pathway is not always possible. We present a case and the diagnostic analysis of intrinsic AKI in an unusual confluence of comorbidities.
Discussion: Our patient presented with significant abnormalities in multiple organ systems, including AKI. An analysis of comorbid conditions and typical AKI diagnostics allowed an expansive differential diagnosis (fig 1). One remaining interrogate was the value of a kidney biopsy. Although the etiology of his AKI would remain uncertain and presumably multifactorial, the lack of a clear therapeutic option and both hemodynamic instability and high risk of complications impeded a kidney biopsy. This case exemplifies the challenging but common scenarios and dilemmas that nephrologists face every day. AKI is a well-described entity, yet its diagnosis is complex and dynamic.

Catch 22: The Vicious Cycle of Malignant Hypertension and Worsening Renal Thrombotic Microangiopathy
Sneha Lakshman,1 Larissa Kruger gomes,2 Jeffrey H. William.2
1North Shore Medical Center, Salem, MA; 2North Shore University School of Medicine, Atlanta, GA

Introduction: Renal Thrombotic microangiopathy (TMA) may arise from multiple distinct etiologies. Malignant hypertension is one of these conditions that can precipitate and worsen renal TMA.

Case Description: 34-year-old woman with a history of gestational hypertension, presented to the ED with complaints of a viral URI and was found to be in an hypertensive emergency with an SBP in the 260's. She was a non-smoker and did not use drugs or alcohol. She denied having any other symptoms or any recent medication use. Her labs were notable for hemolytic anemia and acute kidney injury with a creatinine of 4.0 mg/dL. A peripheral smear confirmed schistocytes, along with a normal serum ADAMTS 13 activity at 89. Extensive work-up for atypical hemolytic uremic syndrome was negative and complement levels were normal. Renal ultrasound showed diffusely increased renal cortical echogenicity. Renal biopsy confirmed the diagnosis of acute on chronic renal function and 62 % of patients with poor outcome had glomerular crescents involving 43–75% of the glomeruli.

Discussion: This is a case of an elderly male patient who developed AKI with kidney biopsy that showed lupus nephritis; however, ANA and anti-dsDNA antibody were negative. Patient's renal function continued to worsen that he eventually required hemodialysis. On 6-month repeat chest CT showed resolution of bibasilar opacities, although with persistent upper lobe ground glass opacities consistent with smoking and vaping-related injury.

Renal Limited Lupus-Like Nephritis in an Elderly Male
Abdulhadi T. Geladan,1 Saud O. Abualkhali,1,2 Sheryl C. Caberto.1 Emory University School of Medicine, Atlanta, GA; 2University of Jeddah, Jeddah, Saudi Arabia; 3Saint Vincent Hospital, Worcester, MA

Introduction: Lupus nephritis is a major cause of morbidity in Systemic Lupus Erythematosus (SLE). 60% of SLE patients develop renal impairment, which is more common in age < 55 years old. SLE has a female predominance with a female-to-male ratio of 8:1. We report a case of an elderly male, who has negative serology and absence of extra-renal manifestations of SLE, diagnosed with renal limited lupus-like nephritis (RLLN).

Case Description: A 76-year-old Caucasian male with no previous history of renal or autoimmune diseases was admitted because of acute kidney injury (AKI). Patient had no history of joint pain and swelling, rash, or oral ulcers. He was not taking NSAID or Hydralazine. Laboratory test showed creatinine 2.7 mg/dL, serum albumin 2.1 g/dL, urine protein creatinine ratio 725mg/g, and urinalysis with dysmorphic RBC of >5 RBC/HPF. Serology showed negative anti-dsDNA, ANA titer <1:40 and undetectable complements C3 and C4. Human immunodeficiency virus, and rapid plasma reagin were also negative. Patient’s renal function continued to worsen that he eventually required hemodialysis. A renal biopsy was performed. Light microscopy revealed diffuse endocapillary hypercellularity and no crescent lesion. There was a full house with global granular mesangial and basement membrane staining for IgG, IgA, IgM, C1q, C3, free kappa and lambda light chains under immunofluorescence microscopy. Electron microscopy revealed mesangial and subendothelial dense deposit and segmental duplication. All these findings are consistent with RLLN.

Discussion: This is a case of an elderly male patient who developed AKI with kidney biopsy that showed lupus nephritis; however, ANA and anti-dsDNA antibody were negative and there were no clinical manifestations of SLE. The patient was treated with Methylprednisolone, which was followed by Prednisone and Mycophenolate Mofetil (MMF). On 6-month follow-up, there was improvement in C3 and C4, and 24-hour CrCl estimated the GFR of 35 ml/min; hence, hemodialysis was discontinued. On 6-month follow-up, serum creatinine 1 mg/dL, BUN 14 mg/dL, and GFR >60 ml/min. Our patient’s kidney function recovered; however, there is no definite prediction of RLLN prognosis due to limited data. 47% had a poor outcome with a permanent decrease of renal function and 62 % of patients with poor outcome had glomerular crescents involving 43–75% of the glomeruli.

Postpartum Thrombotic Microangiopathy of Unknown Etiology: Is It Too Late to Save the Kidneys?
John K. Guirguis, S. J. Sher, Simit Doshi. Indiana University School of Medicine, Indianapolis, IN.

Introduction: Thrombotic microangiopathy (TMA) is a rare (0.004%) but life threatening complication in pregnancy. Differentials include uncontrolled hypertension, Hemolysis elevated liver enzymes low platelet count (HELLP) syndrome, atypical Hemolytic Uremic Syndrome (HUS), Thrombotic Thrombocytopenic Purpura (TTP) among others. Lack of randomized trials and absence of gold standard laboratory tests can make diagnosis and treatment challenging. We present a patient with post-partum TMA confirmed on renal biopsy with no conclusive etiology identified.

Case Description: A 36 years old African American patient, G7P5 with history of Hypertension (HTN) and preeclampsia was noted to have blood pressure elevated to 180/103 mmHg during an antenatal care visit at 36 weeks of gestation. Serum Creatinine (sCr) was 0.5mg/dl with urine protein/Cr ratio (UPCR) of 0.75 g/g. She had an induced labor with persistent HTN postpartum. She left against medical advice and was readmitted 10 days later with acute kidney injury (AKI) with sCr of 6 mg/dl and UPCR was 4g/g. urinalysis showed positive protein but no RBCs. BP was elevated to 143/97 mmHg. Laboratory data showed AST 33 U/L, ALT 24 U/L, Hb 9.5 g/dL, platelet counts 211 X10^9/L, C3 of 74 mg/dL, C4<2 mg/dL, negative ANA, ADAMTS 13 >94. Cryo results was inconclusive although RF was elevated at 160 IU/mL. Blood smear showed no schistocytes. She was started on pulse steroids for clinical suspicion of eclampsia. Her workup during his hospital admission revealed a normal ADAMTS13 activity, negative blood and urine cultures, negative 0157:H7 stool antigen, negative urinary streptococcal antigen, negative autoimmune screen, negative hepatitis and HIV serologies, normal vitamin B12 level, normal bone marrow and pan-imaging without malignancy. A renal biopsy revealed acute and chronic TMA in renal arterioles with fibrinoid necrosis, immunohistochemically-proven hemoglobin casts on kidney biopsy associated with intravascular hemolysis. Below is a case of Rifampin-induced hemolysis associated with acute kidney injury (AKI) by various mechanisms including hemoglobin cast nephropathy. This can resemble other causes of AKI such as acute tubular necrosis, acute interstitial nephritis (AIN) and thrombotic microangiopathy (TMA). Few studies have demonstrated immunohistochemically-proven hemoglobin casts on kidney biopsy associated with intravascular hemolysis. Below is a case of Rifampin-induced hemolysis associated with acute kidney injury (AKI).

Case Description: A 62-year-old man with recent diagnosis of Sweet’s syndrome was started on high dose prednisone and TMP-SMX for prophylaxis. He presented 4 days later with confusion, prolabous diaphoresis and “brown-colored” urine. He was normotensive on exam, without cardiac murmurs, clear lungs, soft non-tender abdomen and no skin rashes. Initial labs showed microangiopathic hemolytic anemia, thrombocytopenia and acute kidney injury with hyperkalemia. Blood smear showed schistocytes. He received emergent hemodialysis followed by plasma exchange for suspected TTP/HUS. Extensive workup during his hospital admission revealed a normal ADAMTS13 activity, negative blood and urine cultures, negative 0157:H7 stool antigen, negative urinary streptococcal antigen, negative autoimmune screen, negative hepatitis and HIV serologies, normal vitamin B12 level, normal bone marrow and pan-imaging without malignancy. A renal biopsy confirmed TMA. He remained anuric and dialysis dependent on discharge.

Discussion: Patients with TMA have symptoms arising from anemia, thrombocytopenia, renal failure, or from underlying diseases like systemic infections, malignancies or drug toxicities. Once TMA is confirmed, elucidating the cause of TMA is important because there are specific treatments available for primary TMA syndromes like TTP and complement-mediated TMA. High suspicion of TTP requires urgent plasma exchange until ADAMTS13 levels return, and if complement-mediated TMA is likely, the terminal-complement inhibitor eculizumab can be used. Drug-induced TMA require prompt discontinuation of the drug and supportive management. Trimethoprim-sulfamethoxazole is a rare cause of thrombotic microangiopathy, and the exact mechanism is not understood. Our case highlights the importance of considering TMP-SMX as a potential cause in patients presenting with TMA.

Hemoglobin Cast Nephropathy in Rifampin-Induced Hemolytic Anemia
Saqib Mahmud, Carl S. Dernell, Navtej Bal, Abrish K. Koratala, Alexander J. Gallan, Daniel A. Sturgill. Medical College of Wisconsin, Milwaukee, WI.

Introduction: Hemoglobin released after intravascular hemolysis causes acute kidney injury (AKI) by various mechanisms including hemoglobin cast nephropathy. This can resemble other causes of AKI such as acute tubular necrosis, acute interstitial nephritis (AIN) and thrombotic microangiopathy (TMA). Few studies have demonstrated immunohistochemically-proven hemoglobin casts on kidney biopsy associated with intravascular hemolysis. Below is a case of Rifampin-induced hemolysis associated with acute kidney injury (AKI).

Case Description: A 64-year-old female with recurrent pulmonary Mycobacterium Avium Complex (MAC) infection treated with Rifampin, Ethambutol and Azithromycin presented with nausea and vomiting two weeks after starting therapy. Physical exam was remarkable for small purpuric lesions on the back. Labs showed a serum creatinine of 0.66 mg/dL, BUN 66 mg/dL, hemoglobin 11.1 g/dL, and platelets 9,000/µL. Haptoglobin was normal. LDH was elevated at 507 units/L. A direct antibody test was negative. Urinalysis showed large blood and microscopy showed 2-5 RBCs per hpf and dark granular casts.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Renal ultrasound was unremarkable. Plasma exchange was initiated for possible TMA but discontinued when ADAMTS13 level returned normal. On day four, serum creatinine was 8.1 mg/dL. She received methylprednisolone 120 mg daily for three days due to concern for possible Rifampin induced AIN. A kidney biopsy was planned and hemodialysis was performed to optimize platelet function. Kidney biopsy demonstrated intratubular pigmented casts that were strongly positive for hemoglobin A immunohistochemical stain confirming the diagnosis of hemoglobin cast nephropathy [Figure 1]. She received supportive care with kidney function gradually improving. Creatinine was 2.87 mg/dL on discharge and 1.18 mg/dL four weeks later.

**Discussion:** Hemoglobin cast nephropathy is a rare diagnosis and requires high index of suspicion in patients with hemolysis and AKI. Diagnosis is multifaceted requiring a clinical history, exam, lab workup and most importantly, a kidney biopsy.

**Case Description:** A 39-year-old woman who underwent laparoscopic hysterectomy presented to ED 4 days following surgery with abdominal pain. Her vitals revealed hypotension and tachycardia. Initial laboratory values were as follows: WBCs 18.0x10^9/L, Na 134 mmol/L, K 4.9 mmol/L, Cl 101 mmol/L, HCO3 17 mmol/L, BUN 45 mg/dL, serum Cr 7.4 mg/dL, lactate 2.4 mmol/L. UA was remarkable for hematuria with 25 RBCs/HPF. Abdominal US revealed moderate ascites. An indwelling bladder catheter was placed, and she underwent diagnostic paracentesis, with WBC noted at 1288/μL (35% neutrophils) and ascites-to-serum Cr ratio of 2.14. CT abdomen with IV contrast confirmed a full-thickness tear of the superior wall of the urinary bladder, with the bulk of the indwelling catheter extending beyond the bladder and an associated urinoma surrounding the catheter (Figure 1). She was diagnosed with bladder perforation and underwent open bladder repair emergently. Her serum Cr improved to 0.5 mg/dL in 24 hours.

**Discussion:** Uropertoneum can result in the reabsorption of urine into the systemic circulation, while sodium and chloride ions move in the opposite direction. This results in hyponatremia, metabolic acidosis, azotemia and rise in serum Cr. Uropertoneum should be expected when ascites to serum Cr ratio is >1.0. It is essential to recognize that the rise in serum BUN and Cr is due to pseudo-azotemia from the reabsorption of urine and not from true kidney dysfunction. Bladder injury is diagnosed by CT cystography, which was deferred in our patient giving the clear evidence of bladder injury in the CT abdomen. Complex extra-peritoneal and all intraperitoneal bladder injuries require surgical repair.

**PO0186**

**Recurrent Stage 3 AKI Resolves with Establishing the Diagnosis of TAFRO Syndrome and Treatment with Anti-IL-6 Antibody**

**Ibrahim Tawhia,1 Yashtpal S. Kanwar, Vikram Aggarwal. Northwestern University Feinberg School of Medicine, Chicago, IL.**

**Introduction:** TAFRO syndrome, a unique variant of idiopathic multicentric Castleman’s disease (MCD), is a syndrome with a constellation of thrombocytopenia, anemia, fever, reticulin myelodysplasia/critical insufficiency, and organomegaly. Its pathogenesis is driven by excessive cytokine storm, most notably from IL-6, causing multiorgan failure. 30% of patients with TAFRO-MCD patients require dialysis. Glomerular thrombotic microangiopathy (TMA) and membranoproliferative glomerulonephritis are the most characteristic lesions. We present a challenging case of recurrent dialysis requiring AKI in whom recognition of TAFRO syndrome and glomerular TMA-like lesion led to successful treatment with anti-IL-6 therapy and subsequent definitive diagnosis of MCD.

**Case Description:** A 35-year-old Hispanic female presented in May 2019 with fever, hypotension, anemia, thrombocytopenia, anasarca, hepatosplenomegaly, generalized lymphadenopathy, and anuric AKI. She was admitted to the intensive care unit, required vasoressors, mechanical ventilation, and initiation of continuous renal replacement therapy (CRRT). A comprehensive workup for infectious and autoimmune etiologies was unrevealing. This puzzling presentation was presumed to be driven by an unidentified viral illness. She received an empiric course of IVIG and steroids with mild improvement in anemia, thrombocytopenia, and complete renal recovery. A month later, she was admitted with a similar presentation and proteinuria. She once again required CRRT. Lab work revealed elevated IL-6. Lymph node and bone marrow biopsy were non-contributory. A renal biopsy revealed glomerular capillary endotheliosis. This time it became clear that she had a TAFRO phenotype and decided to treat her with tocilizumab (anti-IL-6 antibody) every two weeks. She had complete recovery of AKI, anemia, and thrombocytopenia within four weeks. She has been on anti-IL-6 antibody for one year, and the disease is in remission. An excisional lymph node biopsy in May 2020 confirmed the diagnosis of Castleman’s disease.

**Discussion:** TAFRO syndrome-MCD related renal involvement has been reported from Japan and France. This case highlights that knowledge of TAFRO syndrome as a cause of AKI, its diagnostic approach, and renal history is valuable for Nephrologists.

**PO0188**

**Urine Proteomics Among Children Developing AKI After Hematopoietic Stem Cell Transplant (HCT): A Pilot Study**

**Daniella Levy Frier,1 Hossein Fazelinia,2 Hua Ding,1 Lynn Spruce,3 Benjamin L. Laskin,1,2 Kathleen E. Sullivan,3 1Division of Nephrology, Children’s Hospital of Philadelphia, Philadelphia, PA; 2University of Pennsylvania, Philadelphia, PA; 3Proteomics Core, Children’s Hospital of Philadelphia, Philadelphia, PA.**

**Background:** AKI is common after HCT and contributes to high morbidity and mortality. Understanding the mechanisms of injury is essential to develop targeted therapies. Our objective was to examine urinary proteins among children after HCT to provide insights into the pathophysiology of AKI in a population whose immune system is newly developing.

**Methods:** Children (>2 years old) undergoing their first allogeneic HCT and enrolled in a prospective, observational cohort had urine collected at baseline and monthly for the 4 months post HCT. Six patients were selected for pilot proteomic analysis (age 7-19 years, median 10 years, 66% male, 3 with AKI, 3 without AKI). Stored urine samples were tested pre-HCT and at 1 and 4 months post-HCT. Samples were tested with liquid chromatography/tandem mass spectrometry with data-independent acquisition. Proteins were assigned and intensities compared between AKI and controls using t-tests at p<0.05. AKI was defined as a 1.5-fold increase in the monthly serum creatinine value compared to baseline.

**Results:** At 1 month post-HCT, 143 proteins were found distinct among the urine of children with AKI(n=3) compared to those without AKI (n=3). Pathway enrichment analysis linked these proteins to cell cycle and ubiquitous pathways. The 4 month time point resulted in identification of 67 proteins which were differentially expressed between AKI and control groups. These proteins were mostly involved in immune regulation. In both groups, unsupervised hierarchical clustering perfectly segregated the subjects based on AKI or control status (Figure). Protein analysis linked these proteins to cell cycle and ubiquitous pathways. The 4 month time point resulted in identification of 67 proteins which were differentially expressed between AKI and control groups.

**Conclusion:** The urinary proteomic fingerprint is distinct after AKI and are mostly cell cycle proteins in early AKI (first month) and immune mediated at 4 months, when most patients are fully engrafted. Additional studies are needed to define and understand the specific pathways.

**Funding:** Private Foundation Support

**Apparent AKI in a Patient with Ascites Following Laparoscopic Hysterectomy**

**Carmen E. Cervantes,1 Steven Menez,1 Mohamad A. Hanounel,1,2 Johns Hopkins University School of Medicine, Baltimore, MD; 1Nephrology Center of Maryland, Baltimore, MD.**

**Introduction:** Bladder injury occurs following blunt or penetrating trauma. Gynecological and colorectal surgeries are the most common surgeries associated with bladder injury. Bladder injury can be classified as intra versus extra-peritoneal. Clinical manifestations include gross or microscopic hematuria, ascites, and/or difficulty voiding. Peritonitis and sepsis are common complications.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

glomerulosclerosis (FSGS). Anabolic steroids are directly toxic to renal glomeruli. Rates (GFR) and achieve greater muscle mass. However, steroids and high-protein supplements is widespread among athletes and bodybuilders seeking to enhance performance and renal function deteriorated. Renal biopsy showed global and segmental acute renal failure, rhabdomyolysis, and (8-25), Cr 13.4 mg/dL (.3-1.2), months ago. Labs were months. He...comes with a significant risk of renal failure. Unfortunately despite multiple hospitalizations, the patient repeatedly missed dialysis...tunneled dialysis catheter and was discharged with close outpatient follow up.

**PO0190**

Roid Renal Failure

Margaret Mallari, Priyesh T. Thakkar. AtlantiCare Regional Medical Center, Atlantic City, NJ.

**Introduction:** Athletes and bodybuilders often utilize anabolic steroids and high-protein supplements to gain muscle mass, however the use of such performance enhancers comes with a significant risk of renal failure.

**Case Description:** A 34-year-old male weightlifter presented with worsening exertional dyspnea, hemoptysis, and bilateral leg swelling over 2-3 months. He admitted to weekly testosterone injections, testosterone-increasing supplements, and a high-protein diet for the past 5 years. To address his lower leg swelling, the patient started Expel, an over-the-counter potassium-sparing diuretic, 2 months ago. Labs were significant for bicarb 19 mmol/L (21-30), BUN 166 mg/dL (8-25), Cr 13.4 mg/dL (3.1-2), and CPK 2630 U/L (26-308). Chest X-ray showed right lower lobe pneumonia. Urinalysis showed proteinuria. Renal ultrasound revealed cortical echogenicity with no hydronephrosis. The patient was admitted for acute renal failure, rhabdomyolysis, and pneumonia. He was started on Ceftriaxone and Azithromycin and placed on IV fluids. During the hospitalization, the patient’s renal function deteriorated. Renal biopsy showed global and segmental glomerulosclerosis, tubular atrophy, severe interstitial fibrosis, arteriosclerosis, and arteriolar hyalinosis. The patient was counseled at length about long term renal replacement therapy and the gravity of his diagnosis. He underwent placement of a tunneled dialysis catheter and was discharged with close outpatient follow up.

Unfortunately despite multiple hospitalizations, the patient repeatedly missed dialysis treatments and continued to use anabolic steroids and high-protein supplements.

**Discussion:** The utilization of anabolic steroids and high-protein supplements is widespread among athletes and bodybuilders seeking to enhance performance and achieve greater muscle mass. However, steroids and high-protein supplements are not benign and their use comes at the risk of renal failure requiring possible long term renal replacement therapy. High-protein supplements increase glomerular filtration rates (GFR) and are associated with the development of focal segmental glomerulosclerosis (FSGS). Anabolic steroids are directly toxic to renal glomeruli. Anabolic steroids bind to podocyte androgen receptors resulting in the apoptotic destruction of podocytes. The patient’s clinic course highlighted the significant risk of renal failure in young athletes using anabolic steroids and high-protein supplements.

**PO0191**

Crystal Clear: A Case of Oxalate Nephropathy

Deanna N. Jones, James L. Pirkle. Wake Forest University, Winston-Salem, NC.

**Introduction:** Oxalate nephropathy is an uncommon and potentially devastating cause of acute kidney injury that can lead to end-stage kidney disease. Oxalate nephropathy can be hereditary (as in hereditary hyperoxaluria), related to toxins (such as ethylene glycol), medications, like high-dose vitamin C, or enteric malabsorption (such as gastric bypass surgery or malabsorptive disorders). Oxalate nephropathy occurs when calcium oxalate crystals form and deposit in the renal tubules and interstitium, leading to acute tubular necrosis.

**Case Description:** A 71-year-old female with a medical history of pulmonary adenocarcinoma s/p Whipple procedure seven months earlier and chronic kidney disease stage 3 (baseline creatinine 1.0 mg/dL) presented to the hospital with elevated serum creatinine found incidentally on outpatient labs. Initial evaluation was concerning for volume depletion, as she improved with intravenous fluids. Over the next several months, she had repeated hospital admissions with worsening non-oliguric renal failure that seemed to respond to intravenous fluids in the hospital but worsened at outpatient visits. Urinalysis repeatedly showed no microscopic hematuria and low-level proteinuria, and urine microscopy showed coarse granular casts, consistent with acute tubular necrosis. Kidney biopsy was consistent with acute tubular injury and extensive tubular calcium oxalate deposition concerning for oxalate nephropathy.

**Discussion:** Oxalate nephropathy is a rare complication of pancreatic surgery and ascorbic acid use. Vitamin C is metabolized to oxalate and then excreted in the urine. In malabsorptive disorders, a higher concentration of fatty acids are present in the gastrointestinal tract, which bind calcium, leaving less to bind oxalate, and thus more oxalate is absorbed. High urinary oxalate can cause crystallization in tubules, leading to acute renal failure. Treatment is supportive, with removal of offending agents, oral calcium supplementation, and adequate oral hydration. Despite this, our patient progressed to end-stage renal disease requiring dialysis.

**PO0192**

A Novel Flow Cytometry Approach Identifies Kidney Mononuclear Phagocyte Subsets Involved in Mouse Kidney Injury Models

**Background:** Mononuclear phagocytes (MNPs) are heterogeneous in phenotype and function, which reflects their double-edged role as drivers of inflammation and repair after kidney injury. Dissection of this complex network of cells into functional subunits has been challenging and more granular approaches could help to identify relevant subsets in preclinical kidney injury models. Here we used a novel flow cytometric approach to phenotypically and functionally dissect renal MNPs and perform a thorough comparison of MNP dynamics between two different kidney injury models.

**Methods:** The dynamic regulation of MNP subsets was monitored over 10d in two frequently used murine kidney injury models: ischemia reperfusion injury (IRI) and unilateral ureter obstruction (UUO). Using flow cytometric markers F4/80, CD11b and CD11c, kidney MNPs were phenotypically divided into five distinct subsets, which were further subdivided into functional subsets of proinflammatory M1-like (CD16+MHCI+CD206-) and regulatory M2-like (CD206+) cells.

**Results:** Three of the five renal MNP subsets were heavily contributing to both M1- and M2-like cell pools in both IRI and UUO, highlighting their functional multifinality in vivo. Phagocytosis. The F4/80pos MNP subset contributed most M2-like cells as from day 3 with a comparable MNP profile in both models. However, M1-like cells from two CD11b+ subsets spiked 24h after IRI, while this spike was shifted to day 3 in the UUO model, which had a temporary early influx of M1-like F4/80+ cells after 3h in turn. After 10d, total MNP numbers were decreasing in the UUO model, while M2-like F4/80+ cells persisted in IRI kidneys.
Conclusions: Our novel flow cytometric approach unravels functional multimodality among MP subpopulations for an earlier M1 response and a more persistent M2 response in IRI compared to UUO. These results might support preclinical model selection and disease understanding in kidney injury.

Microparticles Containing Monoocyte and Other Inflammatory Markers Are Released in AKI
Begoña Campos,1 Kathleen Harrison,1 Samantha M. Kramer,1 Bassam G. Abu Jawdah,2,3 Charulhas V. Thakar,1,4,5 1University of Cincinnati College of Medicine, Cincinnati, OH; 2Cincinnati VA Medical Center, Cincinnati, OH.

Background: Renal epithelial cell injury in AKI and induces a pleiotropic inflammatory cell response. Monoocyte phenotypes (M1 = CD14+/CD16–; M2 = CD14+ /CD16+), and subsequently derived tissue-resident macrophages play a critical role in inflammation and repair in acute kidney injury (AKI). It is accepted that M1 phenotype serves a pro-inflammatory/phagocytic role, whereas M2 phenotype influences tissue repair and remodeling. We have previously shown that microparticles (MP) derived from renal epithelial cells are released in the setting of kidney injury and can be detected in vitro as well as in human plasma, and can carry the biological activity.

Methods: In this study, we evaluated presence of MP expressing markers of inflammation in AKI (defined by standardized criteria). Human samples were derived from a prospectively collected repository (31 cases of AKI in critically ill patients compared to 22 living kidney donor healthy controls). Samples were prepared to measure MP (standard methods), and flow cytometric analysis was evaluated using antibodies against inflammatory proteins. FlowJo software was used for analysis. Mann-Whitney test was used for comparisons.

Results: The average age was 54 years; mean admission creatinine was 1.8 mg/dL and the time between admission and sample collection was 3-4 days. MP containing M2 Monoocyte markers were significantly higher in AKI patients compared to controls (347.03 vs 273.80 mL/ml; p=0.02). MP containing M1 markers were similar compared to control (177.85 vs 285.40 mL/ml; p=0.19). AKI cases also showed significantly higher levels of MP containing other inflammatory markers: Leukocytes (CD45, p=0.015), eosinophils (CD66b, p=0.001), and also in platelets (CD42b, p=0.05).

Conclusions: MP containing monocye/macrophage markers of M2 phenotype are released in the early phase of AKI, which can influence tissue modelling and repair. Moreover, a pattern of MP representing markers of M2 and other inflammatory cells may have prognostic significance to predict the severity of tissue injury or the prospect of recovery.
Conclusions: Activation of β-catenin signaling in tubular cells reduces apoptosis and necrosis in septic AKI. Tubular β-catenin might play a protective role in AKI by regulating cell death via modulating the p53/Akt signaling pathway. Funding: General Research Fund (HKU 171198/18), RGC Collaborative Research Fund (Ref: C7018-16G) and Hong Kong Society of Nephrology Research Grant (2019).

PO0197
Pulsed Ultrasound Improves Dysregulated Oxygen Metabolism and Reduces Tissue Injury in Sepsis-Associated AKI
Shuqin Zheng, Naidi Sun, Diane L. Rosin, Nabin Poudel, Junlan Yao, Shuyu Tanaka, Jiuru Cai, Song Hu, Mark D. Okusa. University of Virginia Health System, Charlottesville, VA.

Background: Sepsis associated-acute kidney injury (SA-AKI) results in part from oxidative stress in septic and non-septic AKI. Tubular β-catenin might play a protective role in AKI by regulating cell death via modulating the p53/Akt signaling pathway. We showed that pulsed US (PUS) reduces inflammatory conditions and kidney injury in sepsis (PMID: 25644106). Using multi-parametric photoacoustic microscopy (PAM) we demonstrated that the imbalance between oxygen supply and oxygen demand is one of the earliest (10 min) findings in the pathogenesis of SA-AKI. We tested the hypothesis that US attenuates kidney injury and improves early tissue oxygen metabolism and cellular bioenergetics.

Methods: We used PAM imaging to assay the change of renal blood oxygen saturation (sO2), peritubular capillary (PC) blood flow (BF) and the metabolic rate of oxygen (MRO) in saline- and LPS-treated mice and mice pretreated with US 24 hr before LPS (as described PMID: 25644106). Mice received a single injection of LPS (5 mg/kg, i.p.), and oxygen consumption and blood flow were measured 10-80 min later by PAM imaging with an image penetration depth of up to 200 μm, and MRO was calculated. Additional animals were treated with LPS and euthanized at increasing time intervals for measurement of blood creatinine and injury and inflammatory biochemical markers.

Results: PAM imaging revealed heterogeneous cortical regions of LPS-induced markedly enhanced oxygen consumption and MRO. Pretreatment with US reversed the early increase of sO2, decline observed 30-80 min after LPS and reversed the cortical regions of increased MRO. PUS prevented the overall reduction of PCBF. LPS-induced AKI, confirmed by increased plasma creatinine, mRNA expression of kidney injury marker Kim1 and Ngal 12-24 hr after LPS, and acute tubular necrosis (by H&E staining), was attenuated by US pretreatment. PUS reduced Kim1 expression in the brush border membrane of proximal tubules in cortex and medulla. PUS attenuated the increase in IL-6 and TNF-α, mRNA expression.

Conclusions: Our results demonstrate that PUS reverses kidney MRO, improves oxygen metabolism and reduces proinflammatory cytokines in SA-AKI. These results provide insight into the mechanisms of kidney tissue protection by US in AKI.

PO0198
Targeting Gadd34 Upstream Open Reading Frame to Treat Sepsis-Induced Kidney Injury
Ashley N. Kidwell, Bernhard Maier, Pierre C. Dagher, Takashi Hato. Indiana University School of Medicine, Indianapolis, IN.

Background: Sepsis-induced acute kidney injury remains a major clinical problem with no effective therapy to date. We have previously shown that bacterial sepsis causes global translation shutdown via phosphorylation of the eukaryotic translation initiation factor eIF2α (eIF2α2). Under physiological conditions, this eIF2α2 phosphorylation is counter-regulated by two eIF2α2 homolog phosphatases. Of the two homolog phosphatases, Growth Arrest DNA-inducible Gene 34 (Gadd34) is the only stress-inducible regulatory subunit. Using ribo-seq analysis of the kidney from septic mice revealed high ribosomal occupancy of the uORF, but not the main protein coding sequence (CDS), consistent with a model in which the uORF serves as a translational inhibitor of the downstream CDS. To investigate the inhibitory role of the Gadd34 uORF, we designed photosensitive Gadd34 5’UTR where a single nucleotide mutation was introduced to abolish the uORF start codon. We also designed antisense oligonucleotides (ASO) that are complementary to a specific portion of the uORF to modulate ribosomal scanning on the native Gadd34 mRNA.

Results: The uORF point mutation led to a two-fold increase in the readout luciferase signal compared with the wild-type control, confirming the inhibitory property of the Gadd34 uORF. We also found that masking of uORF by ASO resulted in sequence-specific increases in translation of the downstream CDS, possibly due to enhanced leaky ribosomal scanning. Finally, we tested the applicability of antisense approach in vivo using a mouse model of endotoxin-induced kidney injury. Despite late intervention (8 hrs post endotoxin challenge), the administration of uORF-targeted ASOs rescued translation and improved kidney injury.

Conclusions: These findings indicate that translational suppression of Gadd34 in late phase sepsis is a maladaptive response that could be therapeutically modulated by targeting its uORF.

PO0200
Lipopolysaccharide Induces NEAT 1 Expression in AKI via TLR4/NF-κB Signaling
Hui Xue1, Wai Han Yiu, Sarah W.Y. Lok,1 Loretta Y.Y. Chan, Joseph C.K. Leung,1 Kar Neng Lai,1 Hui Y. Lan,1 Sydney C. Tang,1 University of Hong Kong, Hong Kong, Hong Kong; 2The Chinese University of Hong Kong, Hong Kong, Hong Kong.

Background: Toll-like receptor 4 (TLR4) Nuclear factor kappa-light-chain-enhancer of activated B cells (NF-κB) have been implicated in the pathogenesis of acute kidney injury(AKI). Nuclear Paraspeckle Assembly Transcript 1 (NEAT1) is a long non-coding RNA that plays key roles in a variety of biological processes and is involved in many other diseases. Beyond its fundamental role of maintaining function of the nucleus, it remains unknown whether interaction between TLR4/NF-κB signaling and NEAT1 is involved in the process of the development of AKI.

Methods: Septic AKI model was established with injection of LPS into mice. Mouse tubular cells were stimulated with LPS for the study of tubular inflammation. The role and upstream regulatory mechanisms of NEAT1 in the inflammatory processes were studied by using signaling inhibitors.

Results: LPS caused elevation of Scr, BUN level, morphological injury and tubular apoptosis, enhanced NLRP3 and Col I expression, and increased expression of TGF β and STC 1 (P<0.05).

Conclusions: Our study reveals a novel TGF β-STC1 pathway that has homeostatic as well as LPS-induced cytoprotective functions in renal tubular epithelium. STC 1 has protective effects on LPS-induced acute renal tubular injury in mice, possibly by targeting TGF β, enhancing TLR4 expression, regulating the TGF β-STC1 signaling pathway, and inhibiting the expression of downstream inflammatory factors.

Funding: Government Support - Non-U.S.
cytokines including IL-6 and CCL-2, whereas treatment with an inhibitor of TLR4 or NF-κB signaling suppressed LPS-induced NEAT1 expression.

Conclusions: NEAT1 expression was induced in LPS-induced AKI model via TLR4-NF-κB signaling, suggesting its potential role in the inflammatory process. Our findings open the door to exploit NEAT1 expression as a potential novel therapeutic approach for AKI and other inflammatory-mediated renal diseases. 

Xinling Shi, Wei Han, Hsing Yen, Mengxu Wang, Jinghui Liu, Xiaolong Xu, Xiongqiang Zhang, Wei Chen, Wei Liu, Dong Zhang, Guangdong Provincial People’s Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China.

Background: Mitochondrial dysfunction in renal tubular epithelial cells (RTECs) is a hallmark of endotoxin-induced acute kidney injury (AKI). Forkhead box O1 (FOXO1) is responsible for regulating mitochondrial function and is involved in several kidney diseases. Herein, we investigated the effect of FOXO1 on endotoxin-induced AKI and related mechanisms.

Methods: In vivo, the mouse model of endotoxin-induced AKI was induced by intra-abdominal injection of LPS (10 mg/kg). The expression of FOXO1 and PGCI-α in mouse kidney were determined. Then we established a mouse model of renal overexpression of FOXO1 by in situ injection of FOXO1 adenovirus-related virus in renal cortex before intra-abdominal injection of LPS. In vitro, Human proximal tubular epithelial (HK-2) cells were stimulated with LPS (40μg/ml), then infected with FOXO1 overexpression adenovirus. The morphology changes of mitochondria were observed using mitotracker staining. Mitox-SOX was used to detect the changes of mitochondrial superoxide content and the expression of FOXO1.

Results: In vivo, FOXO-1 downregulation in mice RTECs and mitochondrial damage was found in endotoxin-induced AKI. Overexpression of FOXO1 could improve renal function and reduce mitochondrial damage. PGCI-α was reduced in endotoxin-induced AKI and reversed by FOXO-1 overexpression. In vitro, expression to LPS led to HK-2 cell viability decline, mitochondrial fragmentation, and mitochondrial superoxide accumulation, as well as downregulation of the FOXO1, PGCI-α and mitochondrial complex. Moreover, over-expression of FOXO1 in HK-2 cells could increase HK-2 cell viability and PGCI-α expression, and alleviated altered mitochondrial injury and superoxide accumulation induced by LPS. Meanwhile, inhibition of FOXO1 in HK-2 cells by siRNA decreased PGCI-α expression and HK-2 cell viability. Chromatin immunoprecipitation assays and PCR analysis confirmed FOXO1 binding to the PGCI-α promoter in HK-2 cells.

Conclusions: In conclusion, downregulation of RTECs FOXO1 mediated endotoxin-induced AKI and mitochondrial damage. Over-expression of FOXO1 could improve renal function and reduce mitochondrial damage. PGCI-α might be a potential target for the prevention and treatment of endotoxin-induced AKI.

PO0203
Renal Angiotensin (Ang) Receptor Changes Following Cecal Ligation and Puncture (CLP)-Induced AKI
Jake R. Lehman, 1,2 Daniel E. Leisman, 1 Tiago Fernandez, 1 Matthew D. Taylor, 1,3 Mariana R. Brewer, 1,3 Mabel N. Abraham, 1 Clifford S. Deutschman, 1,3 Northwell Health Feinstein Institutes for Medical Research, Manhasset, NY; 1,2,3Department of Surgery and Pediatrics, School of Medicine at Hofstra/Northwell, Hempstead, NY; 1 Cohen Children’s Medical Center, Queens, NY; 1,2Cahn School of Medicine at Mount Sinai, New York, NY.

Background: Angiotensin-II (Ang2) modulates renal function and thus may contribute to sepsis-induced acute kidney injury (SIAKI). We have shown that CLP reduced renal Ang2 type-1 receptors (AT1R), but effects on non-classical Ang receptors are unknown. We hypothesized that CLP altered renal abundance of Ang2 type-2 receptors (AT2R) and Ang-(1-7). Mas receptors (Ang-(1-7)R, Mas8), initiators of signaling axes that oppose AT1R.

Methods: C57BL6 mice were randomized to euthanasia at 6, 24, or 48hrs post-CLP (n=5/group). Unoperated mice (T0) served as controls. Mice were resuscitated (50mL/kg NS SQ) immediately and 25 hrs post-operatively. Prior to sacrifice we removed the kidneys under deep isoflurane anesthesia to minimize tissue ischemia. We obtained blood by cardiac puncture. Kidney Injury Molecule-1 (KIM-1) was measured in whole tissue homogenate (ELISA). AT1R, AT2R, and MasR were measured within specific regions of the kidney using immunofluorescence, (IF). We also used IF to compare kidney sections collected from sepsis patients within an hour of death (n=7) to sections from healthy controls (n=10).

Results: KIM-1 and BUN increased 6th post-CLP. Creatinine increased 48th post-CLP. AT1R and AT2R were both reduced AT1R in arteries, macula densa, and glomeruli. However, CLP did not alter MasR abundance in any region (p>0.05). The ratio of total renal MasR to AT1R more than doubled by 6hrs post-CLP (p<0.001 vs. T0). Renal AT2R intensity was increased in renal mesangium by 24h and in glomeruli by 48h (p<0.01 for both). We previously showed decreased AT1R IF in human sepsis kidney sections. In contrast, human sepsis kidneys did not show any decrease in MasR (p>0.05), again suggesting an increase in the MasR to AT1R ratio.

Conclusions: 1. Data on CLP-induced changes in KIM-1 in tissue and BUN in blood suggest that these are earlier markers of CLP-induced AKI than creatinine. 2. CLP and septic AKI may be associated with a shift from classical to non-classical angiotensin signaling in the kidney. Studies of non-classical angiotensin system modulation in septic AKI may enhance understanding of pathobiology and reveal therapeutic targets in septic AKI.

PO0204
The Fibrogenic Response to Renal Injury Is Epigenetically Regulated Through the Activation of Bivalent Genes
Elizabeth D. Nguyen, 1 Daryl M. Okamura, 2,3 Scott R. Houghtaling, 2 Sarah C. Williams, 1 Andrew E. Timms, 1 David R. Beier, 2 Mark W. Majesky, 2,3 1Seattle Children’s Hospital Department of Pediatric Nephrology, Seattle, WA; 2 Seattle Children’s Research Institute, Seattle, WA.

Background: Bivalent genes are regions of epigenetically modified nucleosomes that carry both enhancer and promoter activity. Bivalent genes are typically enriched for inflammatory, apoptotic and fibrogenic pathways is orchestrated through the epigenetic regulation of bivalent genes that are poised for response in the normal kidney.

Methods: Bivalent genes are regions of epigenetically modified nucleosomes that carry both enhancer and promoter activity. Bivalent genes are typically enriched for inflammatory, apoptotic and fibrogenic pathways is orchestrated through the epigenetic regulation of bivalent genes that are poised for response in the normal kidney.

Results: Through peak annotation of CUT&RUN results, 1546 bivalently marked genes were identified in the normal kidney. With the onset of UUO, 62% of these bivalent genes (951/1546, activated bivalent genes) are activated by the loss of the repressive Tgfbir2 (2.5 fold), Tgif (2.5 fold) and Tgfbir2 (2.5 fold). The activated bivalent genes are associated with upregulation of genes that drive the response to uninjured kidney obstruction (UO) in the mouse.

Methods: CUT&RUN ChIP-seq analysis using antibodies to H3K4me3 and H3K27me3 was carried out on normal kidneys and kidneys of mice 5 days after UUO.

Results: Enriched peaks were identified using SEACR, and HOMER was used to perform peak annotation. To determine fold change gene expression, RNA was collected and analyzed from samples 5 days after they were subjected to sham or UUO surgery.

Conclusions: We provide evidence to suggest that the response to renal injury via inflammatory, apoptotic and fibrogenic pathways is orchestrated through the epigenetic regulation of bivalent genes that are poised for response in the normal kidney.

Changes in NAD and Lipid Metabolism Drive Acidosis-Induced AKI

Milica Bugarski,1 Susan Ghazi,1 Marcello Polesel,1 Joana R. Martins,1,2 Andrew Hall,1,3 Institute of Anatomy, University of Zurich, Zurich, Switzerland; 1Center for Microscopy and Image Analysis, Zurich, Switzerland; 2Department of Nephrology, University Hospital Zurich, Zurich, Switzerland.

Background: The kidney has an important role in maintaining normal blood pH. Mitochondria in the proximal tubule (PT) produce ammonia and bicarbonate from glutamine, and during metabolic acidosis (MA) this pathway (ammoniagenesis) is acutely upregulated. MA is frequently associated with acute kidney injury (AKI); however, to what extent the former causes the latter was unclear.

Methods: Multiphoton imaging of mitochondrial function in mouse kidney cortical slices and in vivo; oxygen consumption rate (OCR) in isolated PTs; histological analysis and electron microscopy (EM) in fixed tissue. MA was induced using an established protocol (gavage with 0.8 g/kg NHCl).

Results: Acutely lowering extracellular pH to 6.5 decreased mitochondrial NADH fluorescence signal specifically in PTs, without changing total NADH content, baseline OCR or mitochondrial membrane potential. However, maximal OCR was decreased and response to rotenone was exaggerated, suggesting a switch to complex I and increased oxidation of NADH to NAD+. This can prevent leakage of bacterial contents from the gut and result in improved renal function and decreased inflammation, as evidenced by decreased plasma cytokines, in IAPtg group.

Conclusions: Improved ZO-1 expression probably due to reduced apoptosis decreases intestinal permeability in transgenic mice subjected to endotoxemia. This can p<0.05 suggesting decreased inflammation in transgenic mice. Intestinal and colon Bax of IAPTG+LPS were lower and Bcl2 higher than C5+LPS suggesting improved intestinal integrity. Expression of tight junction protein (ZO-1), protein phosphatase 2A C (PP2Ac), and electron microscopy (EM) in fixed tissue. MA was induced using an established protocol. Partially reversing MA with intravenous injection of bicarbonate and electron microscopy (EM) in fixed tissue. MA was induced using an established protocol (gavage with 0.8 g/kg NHCl).

Results: Serum urea and creatinine of IAPtg mice were 0.6 mg/dl and 65 mg/dl respectively which were 70% lower suggesting low apoptosis in IAPTg. Plasma TNF α were 70% lower in IAPTg compared to C57Bl6 suggesting low inflammation in IAPTg mice. In IAPTg mice with MA, the expression of intestinal and colon caspase 3 in the IAPtg was 4 fold lower than C57Bl6 (p<0.01). Intestinal and renal Bax of IAPtg/LPS were lower and Bcl2 higher than C57Bl6 (p<0.05). Apoptotic markers of IAPtg/LPS were not significantly different from the control suggesting low inflammation in IAPtg. Plasma TNFα and IL-6 levels of IAPtg/LPS were 70±20 and 95±26 pg/ml respectively which were about 1.5 fold lower than C57Bl6 (p=0.05) suggesting decreased inflammation in transgenic mice.

Conclusions: Improved ZO-1 expression probably due to reduced apoptosis decreases intestinal permeability in transgenic mice subjected to endotoxemia. This can prevent leakage of bacterial contents from the gut and result in improved renal function and decreased inflammation, as evidenced by decreased plasma cytokines, in IAPtg group.

Loss of HDAC8 Leads to hH2AX-Induced Cellular Repair and Decreased Epithelial-Mesenchymal Transition in Renal Tubule Epithelial Cells

Background: Acute kidney injury (AKI) remains a significant worldwide problem. Our previous work has shown that hdac8−/− larval zebrafish model of AKI improved survival and increased repair depleted in AKT3. More importantly, after AKI, some HDAC8 have not been elucidated. AKI is known to induce double stranded DNA breaks (DSB), activating factors including the phosphorylation of the histone variant H2AX producing γH2AX. Damaged cells undergo a complex multifactorial fate determination leading to either DNA repair and cell survival or apoptosis.

Methods: hdac8−/− and hdac8+/− mutant zebrafish were injected with gentamicin to induce AKI. Immunofluorescent microscopy, fluorescently activated cell sorting (FACS) of renal tubule epithelial cells (RTEC) were isolated for RNA-seq. We evaluated the expression of RTEC in wild type (WT) and hdac8−/− in RNA-seq. Following AKI, hH2AX at sites of DNA damage. hdac8−/− mutant zebrafish preferentially uses mechanism of DDR for repair and proliferation, as opposed to apoptosis. In the absence of apoptosis hH2AX tubules can prevent cell death and maintain membranes and maintain their epithelial gene signatures, whereas the WT zebrafish lose their polarization and begin EMT. These data support our hypothesis that the loss of HDAC8 allows cells to repair after injury from AKI.

Protein Phosphatase 2A Ct Expressed in Tubular Cells Decrease Kidney Injury

Mengyu Gu, Chunsun Dai. Nanjing Medical University, Nanjing, China.

Background: Protein phosphatase 2A (PP2A), one of the primary serine-threonine phosphatases in mammalian cells, regulates various biological processes. The role and mechanisms for PP2A in kidney injury remains to be determined.

Methods: Generating the mice with Pp2aaca ablation with Cre-Loxp system. Mice were injected with cisplatin to induce AKI. UO was performed on the mice to induce kidney fibrosis.

Results: In this study, we found that the expression of protein phosphatase 2A Ct (Pp2aaca) in tubular cells could promote cell death and kidney injury. The organic cation transporter 2 (OCT2) and multidrug and toxin extrusion protein 1 (MATE1) regulate the renal secretion of drugs including metformin, norfloxacin, or toxins. In this study, we found that the expression of protein phosphatase 2A Ct (Pp2aaca) in tubular cells could promote cell death and kidney injury. The organic cation transporter 2 (OCT2) and multidrug and toxin extrusion protein 1 (MATE1) regulate the renal secretion of drugs including metformin, norfloxacin, or toxins. In this study, we found that the expression of protein phosphatase 2A Ct (Pp2aaca) in tubular cells could promote cell death and kidney injury. The organic cation transporter 2 (OCT2) and multidrug and toxin extrusion protein 1 (MATE1) regulate the renal secretion of drugs including metformin, norfloxacin, or toxins.

Conclusions: This study reveals the essential role for PP2A in regulating tubular cell energy metabolism and survival, which may shed light on treating patients with kidney injury.

In Vitro Inhibition of Renal OCT2 and MATE1 Secretion by Antiemetnic Drugs

A. B. George,1 Xia Wen,1 Edgar A. James,2 Melanie S. Joy,3 Lauren Aleksunes,1 Rutgers The State University of New Jersey, Piscataway, NJ; 2Memorial Sloan Kettering Cancer Center, New York, NY; 3University of Colorado Denver - Anschutz Medical Campus, Aurora, CO.

Background: The organic cation transporter 2 (OCT2) and multidrug and toxin extrusion protein 1 (MATE1) regulate the renal secretion of drugs including metformin, cisplatin, and etometein. Studies suggest that ondansetron, an antiemetetic drug and 5-HT3 antagonist, can inhibit OCT2- and MATE1-mediated transport. The purpose of this study was to test five structurally similar 5-HT3 antagonist, can inhibit OCT2- and MATE1-mediated transport.
Inhibiton of OCT2-MATE1 Secretion of ASP by Ondansetron in MDCK Cells

PO0211
supPAR Determines Outcomes in Septic AKI
Christian Nussba.1,2 David C. Wei,1 Roman Szuderek,2 Florian Käble,2 Claudia Spree,2 Florian Uhle,2 Jesper Eugen-Olsen,1 Thomas Krarup,4 Markus A. Weigand,2 Martin G. Zeter,2 Christian Morath,1 Thorsten Brenner,2 Jochen Reiser,1 Rush University Medical Center, Chicago, IL; 2Heidelberg University Hospital, Heidelberg, Germany; 3University Hospital Essen, Essen, Germany; 4ViroGates A/S, Birkøer, Denmark; 5Copenhagen university hospital Hvidovre, Hvidovre, Denmark.

Background: Sepsis is the main contributor to the development of acute kidney injury (AKI) in critically ill patients. Plasma soluble urinokinase plasminogen activator receptor (supPAR) is a criculating risk factor for AKI and a prognostic marker for the need of renal replacement therapy (RRT). We analyzed the pathophysiologic role and kinetic properties of supPAR in septic AKI in critically ill patients and in a murine model of septic AKI.

Methods: 200 critically ill patients were enrolled prospectively after meeting Sepsis-3 criteria. Serum supPAR levels were measured at 0, 12, 24, 48, 72, 120 and 168-hour after enrollment and the need for RRT within 7 days was assessed as the primary outcome measure. Polybacterial sepsis was induced by cecal slurry injection in three mouse strains, respectively wild type (WT, N=9), supPAR-knockout (KO, N=13), and supPAR transgenic overexpression (OE, N=11).

Results: No or mild AKI occurred in 62 patients (31.0%), moderate or severe AKI without the need for RRT in 102 patients (51.0%), criteria for RRT were met in 36 patients (18.0%) and 7 patients (3.5%) died within the 7-day period. Compared to all other maximum AKI stages and AKI disease courses within 7 days, patients requiring RRT showed significantly higher supPAR levels at all time-points. Patients with supPAR levels ≥ 12.7 ng/ml (highest quartile) had an adjusted odds ratio of 5.22 (95% confidence interval [CI], 2.16-12.65) for the need for RRT, and 4.44 (95% CI, 1.98-9.97) for RRT or death within 7 days compared to patients with levels < 12.7 ng/ml. Compared to KO mice, WT and OE mice showed a significantly greater impairment of renal function and structure 24 hours after induction of sepsis. Kaplan-Meier analysis revealed a survival benefit of KO mice over OE mice within 24h (84.6% vs. 45.5%, p=0.041).

Conclusions: SupPAR distinguishes between divergent AKI stages/courses and the need for RRT at any time within 7 days after sepsis diagnosis. Our experimental data suggest that supPAR is a pathophysiologial driver of septic AKI and may serve as a target for future interventional strategies.

PO0212
Cardiovascular Effects of the American College of Radiology (ACR) Group II Agent Gadobutrol (Dotarem): Renal Proximal Tubular Mitochondrial Toxicity and Acute Tubular Damage
Brent Wagner,1,2 G. P. Escobar,2 Tamara A. Howard,2 Joshua Deaguro,2 Kidney Institute of New Mexico 1New Mexico VA Health Care System, Albuquerque, NM; 2University of New Mexico Health Sciences Center, Albuquerque, NM.

Background: Patients are concerned about gadolinium (Gd) deposition from magnetic resonance contrast agents. Gd is the known cause of iatrogenic ‘nephrogenic’ systemic fibrosis and long-term gadolinium retention in every organ. Without prospective evidence, the ACR partitions brands of Gd-based contrast agents (GBCAs) into three groups: I, associated with the greatest number of systemic fibrosis cases; II, associated with few, if any, unconfounded cases of iatrogenic systemic fibrosis; and III, data are limited.

Methods: Male and female mice were randomized to GBCA treatment with an increasingly popular, ACR group II macrocyclic agent (Dotarem, 2.5 mmol/kg intraperitoneally, 20 doses over 4 weeks). Echocardiographic parameters were compared at the endpoint, tissues examined with transmission electron microscopy.

Results: Gd reduced cardiac systolic volume (29 ± 6 vs 34 ± 4 μL, mean ± SD, M-mode), increased fractional shortening (30 ± 4 vs 25 ± 2%, M-mode), and increased ejection fraction (57 ± 5 vs 50 ± 4%, M-mode). Renal tissue was characterized by tubular damage, pathologic lipid vacuolization, and diffuse mitochondrial toxicity (Figure). Conclusions: GBCA treatment leads to diffuse and long-term intracellular retention in every vital (and non-vital) organ. These studies demonstrate that the American College of Radiology group II agents are far from clinically inert. Consistent with the first element of the Nuremberg Code, voluntary consent for GBCA administration should be obtained from every patient.

Funding: NIDDK Support, Veterans Affairs Support, Commercial Support - DCI
Conclusion: We found that different biomarkers have variable kinetics after PTEC injury. As KIM-1 concentrations rose the earliest after antibiotic exposure. In RNAseq analyses, we found that pathways of metallothionein and cholesterol biosynthesis were dysregulated after colistin exposure. Finally, we found minimal PTEC injury with tobramycin, suggesting that this antibiotic may be less toxic than previously believed. Future work seeks to test these candidate biomarkers in human urine samples.

PO0214
GTS-21 Attenuates the Inflammation of AKI Independent of α7 Nicotinic Acetylcholine Receptor
Yasuna Nakamura,1 Tatsuyoshi Inoue,2 Rie Unii,1 Daichi Fukaya,1 Sho Hasegawa,1 Masaomi Nangaku,1 Reiko Inagaki,1 1The University of Tokyo Graduate School of Medicine, Bunkyo-ku, Japan; 2Nagasaki University School of Medicine Graduate School of Biomedical Sciences, Nagasaki, Japan.

Background: Vagus nerve stimulation protects from kidney injury by activating the cholinergic inflammatory pathway (CAP). It is considered that α7 nicotinic acetylcholine receptor (α7nAChR) in splenich macrophages are important for CAP activation. To elucidate the mechanism of receptor signaling, we promoted further experiments using macrophage-specific α7nAChR knockout mice.

Methods: We generated macrophage-specific α7nAChR-deficient mice by crosses breeding LysM-Cre and α7nAChR flox mice. In vivo, GTS-21 (an α7nAChR specific agonist) was intraperitoneally injected to either wild type C57BL/6j mice (WT) or macrophage-specific α7nAChR-deficient mice prior to administration of lipopolysaccaride (LPS). 4 hours after LPS administration, the mice were euthanized and plasma TNF-α level, plasma creatinine, BUN were evaluated. In vitro, murine macrophage cell line RAW264.7 and primary peritoneal macrophages from either WT or α7nAChR-deficient mice were used. These cells were stimulated with LPS after nicotine (pan nicotinic acetylcholine receptor agonists) or GTS-21 was administrated, then TNF-α level was evaluated 4 hours later.

Results: GTS-21 protected the kidney and suppressed the increase of plasma TNF-α induced by LPS in WT mice. Surprisingly GTS-21 decreased plasma TNF-α level induced by LPS in not only WT mice but also macrophage-specific α7nAChR-deficient mice. In vitro experiments, GTS-21 or nicotine treatment suppressed TNF-α induction by LPS RAW264.7 cells or primary peritoneal macrophages from WT mice. Furthermore, nicotine also suppressed the induction of TNF-α by LPS even in peritoneal macrophages from α7nAChR-deficient mice.

Conclusions: These results suggest that nicotine or GTS-21 might suppress the inflammation independent of α7nAChR in macrophages in vivo and in vitro.

PO0215
Platelets vs. Neutrophils as Therapeutic Targets in Cholesterol Embolism-Related Arterial Occlusion, Kidney Infarction, and AKI

Background: Cholesterol crystal embolism (CCE), a life-threatening complication, is a consequence of the rupture of atheromatous plaques in patients with advanced atherosclerosis. CCE often mimics as a cause of AKI. We hypothesized that platelet contributes to CCE-related artery occlusion leading to AKI and kidney infarction.

Methods: C57/BL6 mice were injected with various doses of cholesterol crystals (CC) to induce CCE in kidney. Primary endpoint: GFR. Secondary endpoints: infarct size, vascular occlusions. 3D MRI and μCT were performed. In vitro studies CC with neutrophils, platelets, endothelial cells.

Results: At 24h, MRI and μCT showed perifocal edema around ischemic lesion and vascular rarefaction in CCE kidney. CC-induced clots causing a dose-dependent GFR loss and infarct size. Immunostaining revealed crystal clots contained fibrin, platelets, ecDNA, neutrophils. To study the role of platelets in this process, we treated mice with platelet antagonist clopidogrel. At 24h, clopidogrel completely protected mice from intravascular obstructions, GFR loss, and kidney infarction. In contrast, neutrophil depletion significantly decreased kidney infarction but not arterial obstructions or GFR loss. Maybe because mononuclear cells had partially replaced neutrophils within clots and ecDNA was still present. DNase I treatment also significantly reduced the percentage of ecDNA positive clots, occluded arterial, GFR loss, infarct size. In vitro studies show, CC-induced clot formation and enhanced fibrinogen release from platelet granules with promotes clot formation. DNase I can strongly inhibited clot formation, fibrin formation, also normalized collagen-driven platelet aggregation.

Conclusions: In summary, not CC itself but the CC-induced fibrin clots obstructed peripheral arteries causing tissue infarction and organ failure. Platelets and ecDNA are central for crystal clots formation. Hence, crystal clots represent the primary target for therapeutic interventions. Among the possible molecular targets in thrombosis, especially enhancing fibrinolysis or inhibiting platelet purinergic signaling could reduce arterial occlusions, infarction, and organ failure. DNase I could have a synergistic effect on CC-induced clot formation in mice and might be a prophylactic/therapeutic approach in human patients with a risk for procedure-related CC embolism.

Funding: Government Support - Non-U.S.
Characterizing De Novo Lymphangiogenesis During AKI Using 3D Imaging and Tissue Cytometry

Laurence M. Black,1 Seth Winfree,2 Malgorzata Kamocka,3 Suraj Deepak Khochare,2 Amie Traylor,4 Stephanie Esman,5 Shehnaz Khan,5 Abolali Zargari,1 Anupam Agarwal,1,2 Tarek M. El-Achkar.1,2 University of Alabama at Birmingham, Birmingham, AL;1,2Bims, Birmingham V.A Medical Center, Birmingham, AL;1 Indiana University School of Medicine, Indianapolis, IN.

Background: The renal lymphatic system is essential for fluid and electrolyte homeostasis, lipid and cholesterol transport, and immune surveillance with lymphatic vessels (LV) primarily intertwined with the blood vasculature. LV development, or lymphangiogenesis (LA) is regulated by its master transcription factor, prospero-related homeobox-1 (Prox-1), which determines lymphatic cell fate. LA is accentuated during inflammation or injury states such as acute kidney injury (AKI), though mechanisms of LA in AKI remain unclear. Understanding the LA process is essential because it will elucidate potential therapeutic targets in AKI.

Methods: Using 10-week old male Prox1-tdTomato lymphatic reporter mice (ProxTom), we investigated the effect of AKI on the abundance and distribution of Prox-1+ cells at the mesoscale level using large scale three-dimensional (3D) imaging and tissue cytometry. ProxTom mice and their controls were subjected to ischemia-reperfusion (IR) or no surgery and kidneys were fixed on day 3. Large scale 3D imaging with confocal microscopy was done on 50µm thick sections spanning the entire cross section of the kidney, followed by tissue cytometry using the volumetric tissue exploration and analysis (VTEA) software tool.

Results: The average number of cells surveyed per specimen was 347,360 ± 36,647. Using VTEA, a gating strategy was devised to account for autofluorescence in the red channel, which was increased after IR due to cell debris and injury. IR samples displayed a significant increase in Prox-1+ cells compared to baseline controls: 717.2 ± 161.8 vs. 174.4 ± 62.1 Prox-1+ cells/mm², respectively (p=0.05). In baseline controls, Prox-1+ cells were well-organized and predominately localized around large vessels in the hilum. However, after injury, the distribution of Prox-1+ cells shifted to the hilar parenchyma and inner medulla in a consistent pattern. Few cells could also be detected in the outer medulla and cortex.

Conclusions: We demonstrate a scale of analytics that is amenable to characterizing de novo renal LA during AKI, which informs the origin and distribution of renal LVs and the dynamics of LA. Such findings will enhance our understanding of the functional role of LVs during injury and help identify novel therapeutics for intervention in AKI.

Peritubular Transcytosis Enables Mesoscale Nanoparticle Treatment of AKI

Ryan Williams,1 Janki Shah,2 Edgar A. Jaimés,2 Daniel A. Heller.1 City College of New York, New York, NY; 1Memorial Sloan Kettering Cancer Center, New York, NY.

Background: In prior studies we demonstrated that mesoscale nanoparticles (MNP) localize to the kidneys up to 26-fold more than to any other organ and that they specifically target the renal tubular epithelium. In this study we investigated the mechanism of MNP localization to the renal tubules and evaluated this platform’s potential for therapeutic delivery in a model of cisplatin-induced acute kidney injury (AKI).

Methods: We synthesized ~400 nm diameter MNPs from the biocompatible polymers poly(lactic-co-glycolic acid) and polyethylene glycol (PLGA-PEG). MNPs were encapsulated with a fluorescent far-red dye or the reactive oxygen species scavenger edaravone. Male C57BL/6 mice, were sacrificed 30 minutes after injection for immune-efect microscope studies. We also performed intravital microscopy to visualize the transit of MNPs in Cx3cr1-/- C57BL/6 mice with GFP-expressing renal macrophages. We also evaluated their therapeutic potential in a cisplatin-induced AKI (25 mg/kg IP) model, 24 hours following cisplatin, mice received edaravone-loaded MNPs or appropriate controls. Serum creatinine and histology were analyzed 72 hours following cisplatin.

Results: We found that MNPs localize to the proximal tubular epithelium via transcytosis from the peritubular capillaries. We observed MNPs flowing in these capillaries and in transit across the tubular interstitium. We also found that transcytosis of MNPs was not facilitated by macrophage uptake. Finally, we found that therapeutic MNPs use this mechanism to localize to the proximal tubules of mice with cisplatin-induced AKI (Figure).

Conclusions: These studies characterized transcytosis from the peritubular capillaries as the mechanism of particle localization to the kidneys and portend the development of additional therapeutic targeting tools for renal diseases.

Role of the Exocyst, Cilia, and Mitochondria in AKI

Daria Ilatovskaya, Xiaofeng Zuo, Peifeng Deng, Wayne R. Fitzgibbon, Joshua H. Lipschutz. Medical University of South Carolina, Charleston, SC.

Background: AKI has high morbidity and mortality. Management consists of supportive care. Among the critical pathways in AKI are alterations of tubular mitochondrial metabolism, and, as recently suggested, disruption of primary ciliary homeostasis. Mitochondria are also involved in ciliopathies. Here we tested if cilia acting via mitochondria are involved in AKI.

Methods: We previously showed that the exocyst trafficking complex is necessary for ciliogenesis. Overexpression of Exoc5, a central exocyst component, protected renal tubule cells against H2O2-induced injury, whereas Exoc5 knockdown worsened it. In AKI, proximal tubules are most susceptible to injury. To determine the effect of Exoc5 loss, we crossed Exoc5fl/fl mice with mice expressing CreERT2 driven by the proximal tubule sodium-dependent inorganic phosphate transporter (SLC34A4-CreERT2). Proximal tubule-specific Exoc5 knockout (KO) mice and littermate controls were subjected to bilateral ischemia reperfusion (IR) injury by clamping the renal arteries. In order to gain mechanistic insight, we evaluated mitochondrial function in Exoc5 overexpressing (OE), Exoc5 knockdown (KD), Exoc5 ciliary targeting sequence point mutant (cts-mut), and control Madin-Darby canine kidney tubule (MDCK) cells.

Results: Proximal tubule-specific Exoc5 KO mice had worse renal injury, and higher serum creatinine following IR injury compared to control mice (p<0.005). Seahorse assays revealed diminished sparse respiratory capacity in Exoc5 KD and Exoc5 cts-mut cells, which was increased in Exoc5 OE cells, compared to control MDCK cells. Tetramethylrhodamine methyl ester was employed to measure mitochondrial membrane potential and we found mitochondrial uncoupling in Exoc5 KD and Exoc5 cts-mut cells as compared with control cells. Transmission electron microscopic imaging revealed healthy circular-shaped mitochondria with dense matrix in control and Exoc5 OE cells. Exoc5 KD cells exhibited mitochondrial damage and swelling consistent with the observed reduced respiration. Interestingly, Exoc5 cts-mut cells demonstrated formation of elongated mitochondria with pronounced cristae and large intracistal spaces, which could indicate less intensive bioenergetics, and would explain the reduced respiration.

Conclusions: For the first time we show that the exocyst and cilia are centrally involved in AKI and the effect may be mediated through mitochondria.

Ascending Vasa Recta Responsible for Medullary Vascular Congestion

Sarah C. Ray, Paul O’Connor. Augusta University Medical College of Georgia, Augusta, GA.

Background: Vascular congestion of the renal medulla is common in acute kidney injury and has been shown to prolong ischemia and promote injury. We have reported that pretreatment with low dose lipopolysaccharide (LPS) attenuates ischemia reperfusion (IR) induced congestion. The temporal localization of congestion during IR and how LPS prevents congestion remains unknown. We hypothesized that vascular congestion

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
originates in the medullary vasa recta (VR) prior to the peritubular (PT) capillary plexus, and that pretreatment with low dose LPS aids in early VR reperfusion. 

Methods: To test this hypothesis, male WKY rats (100ks) were pretreated (I.p) with 1000ug/kg LPS or saline daily for 3 days and a 45-minute warm, bilateral ischemia was performed. Rats were randomized to 0, 1, 2, 6, 10, or 24 hours (n=4-6/group). Control of the medullary VR and PT capillaries was assessed in histological sections (scale: 0-5, 0=0%, 5=100% congestion).

Results: At time 0 (no reperfusion), congestion of the medullary VR averaged 80% in both saline and LPS treated rats. Following reperfusion for 1, 2, 6, and 10 hours, VR congestion in saline treated rats decreased (VR-[C5aR1]fl/fl mice and FoxD1-C5aR1 KO mice and performed qPCR and luminex analysis. Conclusions: Our findings demonstrate that pericytes and macrophages play important roles in the pathogenesis of renal scarring and implicate C5ar1 as a key mediator. Conditional deletion of C5ar1 in these two interstitial cell types reduces inflammation and extracellular matrix protein formation in pericytes as well as macrophage migration and profibrotic phenotype of kidney macrophages.

Selective Expansion of Kidney Double-Negative T Cells Is Driven by Renal Tubular Epithelial Cells Through Direct Cell-Contact and by Soluble Mediators

Mohanraj Sadasivam, Sanjeev Noel, Somayeh Gharai fathabad, Johanna T. Kurzhagen, Abdel Hamad, Hamid Rabb, Johns Hopkins University, Baltimore, MD.

Background: Kidney TCRβ+ +CD8+CD8+ double negative (DN) lymphocytes are a recently recognized unconventional T cell population with important roles in AKI and possibly other diseases like lupus. DN T cells expand after experimental AKI and confer improved renal recovery. However, mechanisms underlying their regeneration and expansion in the kidney are poorly understood. Here, we demonstrate a direct role for renal tubular epithelial cells (RTET) in regulating homeostasis of kidney DN T cells.

Methods: Age-matched B6 WT, MHC I KO, MHC II KO and DKO (MHC I and II KO) mice were studied. T FACS cell functional assays and an in-vitro co-culture system were used to investigate the functional relationship between RTET and DN T cells. RTETs were isolated, purified and cultured in collagen-coated plates. Lymphocytes from both kidney and periphery were isolated, co-cultured with RTET and analyzed by FACs.

Results: DN T cells were anergic when cultured alone, even after stimulation with anti-CD3/CD28, but spontaneously proliferated when co-cultured with RTET (DCN; 1.2 ± 0.6% vs RTET+DCN; 13.8 ± 3.5%, p≤0.0001). Expansion was due to increased proliferation and decreased apoptosis of DN T cells. RTET mediated expansion of DN T cells occurred by multiple mechanism including direct cell-contact and secretion of IL-7. Although activation of T cells required direct TCR crosslinking, activation of DN T cells were TCR-MHC independent as indicated by the ability of RTET from mice lacking MHC class-4, class-II or DKO mice to induce proliferation of DN T cells (21.2 ± 1.5%, vs RTET (MHC I KO)+DN; 17.1 ± 1.5%, vs RTET (MHC II KO)+DN; 17.9 ± 1.8%, vs RTET (DKO)+DN; 32.8 ± 0.3%, p≤0.0001). Reciprocally, DN T cells increased survival of RTET as demonstrated using in-vitro assays. Our ongoing experiments are focusing on identifying surface molecules involved in mediation interactions between DN T cells and RTET.

TGF-β-Induced CD8+CD103+ Regulatory T Cells but Not Natural Regulatory T Cells Alleviates Acute Renal Injury Induced by Ischemia-Reperfusion

Zhenjian Xu, Tongtong Xu, Anping Xu. Sun Yat-sen Memorial Hospital of Sun Yat-sen University, Guangzhou, China.

Background: Acute kidney injury (AKI) is one of the most common complications in clinical practice, inflammatory response induced by hypoxia-reoxygenation is the key mechanism of ischemia-reperfusion acute kidney injury. Regulatory T cells (Treg) are crucial to maintain homeostasis in the main organs. Our previous studies show that the regulatory T cells (nTreg) tend to transfer into Th17 under conditions of inflammation and hypoxia. On the contrary, Treg-induced CD8+CD103+Treg (CD8+CD103+Treg), a new subgroup of Treg we have identified, maintains stable phenotype and immunomodulatory function. The instability of nTreg under conditions of inflammation and hypoxia suggests that Treg are not suitable for treatment of AKI. Accordingly, we studied the role of CD8+CD103+Treg in alleviating AKI.

Methods: In vitro study, we test the phenotype and immunomodulatory function of Treg-induced CD8+CD103+Treg, and expanded in the kidney, it is found that the efficiency of Treg-induced CD8+CD103+Treg with higher anti-inflammatory function and lower pro-inflammatory function. As a result, nTreg was preadministration into the mice and then transferred into the kidney to test its function, and then the kidney function was measured. The expression of CD103 was found to significantly reduce the expression of pro-inflammatory cytokines, such as TNF-α, IL-6, and IL-1β, and the expression of anti-inflammatory cytokines, such as IL-10, in the kidney. The results show that the expression of CD103 is stable in CD8+Treg in vitro under 1% O2 concentration (Fig 1). Treg transfer into Th17 under hypoxic condition. However, CD8+Treg+CD103+Treg seldom transfer into Th17, remain Foxp3 under hypoxic condition (Fig 2.3). In addition, the suppressive function of CD8+CD103+Treg over T cells proliferation under hypoxia remain steady. In vivo study, we found that CD8+CD103+Treg not only reduce the development of renal fibrosis in the mouse, alleviating acute tubular necrosis (ATN) and reducing the mortality of AKI mice. (Fig 4).

A Novel Renoprotective Strategy: Upregulation of PD-L1 Expression Mitigates Cisplatin-Induced AKI

Jun Zhang, Shwen V. Gu, Sus-Wei Hsu, Ching-Hsien Chen. University of California, Davis, Davis, CA.

**Background:** Cisplatin is an effective chemotherapeutic agent against various types of cancers; however, the use of cisplatin is associated with a major side-effect of nephrotoxicity, resulting in acute kidney injury (AKI). Growing evidence suggests that programmed death-1(PD-1)-programmed death ligand (PD-L1) immune checkpoint signaling plays a critical role in mediating inflammatory responses and immune homeostasis. While PD-L1 has emerged as a promising target for immunotherapy, little is known concerning how PD-L1 is regulated. In this study, we aimed to determine the expression and contribution of PD-L1 in cisplatin-induced AKI.

**Methods:** PD-L1 expression in kidney cells and tissues were determined by immunohistochemistry (IHC), real-time polymerase chain reaction and western blot assays. PD-L1-containing lentiviruses were subcapsularly injected into the kidneys of mice. 7 days after the injection, mice were intraperitoneally treated with cisplatin for 3 days and subjected to kidney function tests. High-dimensional single-cell mass spectrometry was used to reveal immune profiling and discover the underlying immunological mechanisms of PD-L1 in an AKI mouse model.

**Results:** IHC staining of PD-L1 shows a significantly lower intensity of staining and less stained proximal tubule epithelial cells in cisplatin-exposed mice tissues than that in the PBS controls. Next, we demonstrate that cisplatin exposure decreased mRNA expression and protein levels of PD-L1 in primary renal proximal tubular epithelial cells and mouse kidney tissues. Furthermore, we also find a decrease in PD-L1 expression with a concomitant increase in pro-inflammatory cytokines in response to cisplatin. Mass spectrometry analyses reveal cisplatin-induced multiple pro-inflammatory leukocytes infiltration in kidneys. Through genetically engineered kidney tissues in mice, ectopic expression PD-L1 in kidneys was able to suppress leukocytes infiltration and pro-inflammatory cytokines. In addition, both serum creatinine and blood urea nitrogen levels were significantly reduced in cisplatin-treated mice with PD-L1 overexpression.

**Conclusions:** Our data suggest a renoprotective effect of PD-L1 upregulation on cisplatin-induced AKI and also provide an alternative therapeutic strategy against nephrotoxicity.

**Regulation of Renal Calbindin Expression During Cisplatin-Induced Kidney Injury**

Blessy George,1 John T. Szilagyi,1 Melanie S. Joy,1 Lauren Aleksejus,1
1Rutgers The State University of New Jersey, Piscataway, NJ; 2University of Colorado Denver - Anschutz Medical Campus, Aurora, CO.

**Background:** Since the discovery of calbindin release into urine during renal injury, there has been growing interest in the utility of this calcium-binding protein as a biomarker of nephrotoxicity. However, little is known about the intrarenal regulation of calbindin during acute kidney injury. We sought to characterize the time-dependent expression and excitation of the renal proximal tubule protein calbindin in comparison to the proximal tubule protein Kim-1 in a mouse model of cisplatin nephrotoxicity.

**Methods:** Male C57BL/6 mice were administered saline vehicle or 20 mg/kg of cisplatin i.p. Urine was collected in metabolic cages for 24 h periods on days 0 – 4. Blood and kidneys were collected between days 2 and 4. Kim-1 and calbindin proteins were measured in urine, kidneys, and blood. Kim-1 and calbindin (Calb1) mRNAs were quantified in kidneys by qPCR.

**Results:** SCr and BUN levels increased in cisplatin-treated mice by day 3, confirming development of acute kidney injury. Urinary concentrations of calbindin and Kim-1 were elevated by 11.6-fold and 2.5-fold, respectively by day 2. Time-dependent decreases in intrarenal calbindin protein to levels 60% of control were observed on days 3 and 4. A 200-fold up-regulation of Calb1 and Kim-1 mRNAs was seen on day 3. These data suggest that early loss of calbindin protein into the urine along with declines in renal calbindin protein initiates a compensatory induction of mRNA expression at later time points (days 3 and 4).

**Conclusions:** Understanding the regulation of calbindin during cisplatin nephrotoxicity further enhances its utility as a urinary biomarker of kidney damage. The results of the current study support the combined use of a proximal (Kim-1) and distal tubule marker to phenotype acute kidney injury or AKI.

**Neutral Ceramidase and Autophagy Play Diverse Roles in Cisplatin-Induced AKI and Fibrosis**

Sara C. Sears, Tess Dupre, Mark A. Doll, Parag P. Shah, Levi J. Beverly, Leah J. Siskind. University of Louisville School of Medicine, Louisville, KY.

**Background:** Cisplatin (CDDP) is a commonly used chemotherapeutic agent with a dose-limiting nephrotoxicity. 30% of patients given CDDP develop acute kidney injury (AKI), increasing risk of chronic kidney disease (CKD) development and mortality. Currently, there are no agents to treat or prevent CDDP-induced kidney injury. We believe this is due in part to a lack of clinically relevant animal models. In the past, only a single high-dose model has been used to study CDDP-induced AKI. Our lab and others have developed a repeated low dose model to also study CKD development following CDDP treatment. Acute and chronic injuries can both be affected by sphingolipids, a family of bioactive lipids. Metabolism of sphingolipids is carried out in part by neutral ceramidase (nCDase), which hydrolyzes ceramide into sphingosine that can then be phosphorylated to form sphingosine-1-phosphate. The regulation of these sphingolipids affects cellular processes implicated in the pathology of CDDP-induced kidney injury, including cell proliferation, autophagy, and apoptosis. Additionally, our lab has previously observed that nCDase knockout protected mouse embryonic fibroblasts from ER-stress induced apoptosis in vitro by upregulating autophagic flux. We hypothesized that loss of nCDase would confer protection from CDDP-induced kidney injury.

**Methods:** We assessed renal outcomes in nCDase knockout (KO) and wild type (WT) C57BL/6 mice in both the acute and chronic models of cisplatin treatment.

**Results:** We demonstrated that nCDase KO provides protection from AKI in the high-dose model of CDDP-induced kidney injury. This protection was reversed when the autophagy-inhibitor chloroquine was co-administered. In the repeated low dose CDDP model, however, we found nCDase KO does not protect against development of renal fibrosis. We also observed that nCDase KO reduces induction of ER stress in the single high-dose model but not in the repeated low dose model.

Cisplatin-Induced MARCKS Phosphorylation Activates NF-κB Signaling and Contributes to AKI

Shenwen V. Gu, Jun Liu, Kuang-Yu Jen, Ching-Hsien Chen. University of California, Davis, Davis, CA.

Background: Cisplatin is widely used for cancer treatment but is known to induce nephrotoxicity with severe damage to the proximal tubules, leading to acute kidney injury (AKI). Although a major substrate of protein kinase C, MARCKS, was shown to be induced phosphorylation at Ser 159/163 (phospho-MARCKS) in response to cisplatin, the molecular mechanism underlying increased phosphorylation of MARCKS and its functional consequence in AKI remain to be established. Herein, we investigated how phospho-MARCKS is regulated in proximal tubular cells, and its role in the context of cisplatin exposure.

Methods: The clinical relevance of phospho-MARCKS was first confirmed using immunohistochemistry. Next, we examined the effect of cisplatin exposure on phospho-MARCKS levels in kidney tubular epithelium. The MARCKS-interactome was identified by mass spectrometry. We also used genetic and pharmacological approaches to verify the functionality and molecular mechanism of cisplatin-induced phospho-MARCKS.

Results: In a screen of 75 renal biopsies from patients, we found that strong phospho-MARCKS expression was observed in kidney specimens from patients with acute renal tubular necrosis and was positively correlated. Western blot analyses demonstrate that an elevated abundance of phospho-MARCKS in cisplatin-exposed tubular epithelial cells and this increase appeared to be concentration-dependent. Mechanistically, we show that MARCKS protein directly bound to nuclear factor-kappa-B-activating protein (NFKAP). Following cisplatin-induced phosphorylation at Ser159 and Ser163, the interaction of MARCKS with NFKAP was inhibited, contributing to NFκB phosphorylation and NF-κB activation. Surprisingly, an elevation of phospho-MARCKS by cisplatin occurred in parallel with upregulation of inflammatory cytokines and markers of nephrotoxicity. Conversely, targeting of MARCKS phosphorylation with the MPS peptide, a novel MARCKS inhibitor, downregulated NF-κB signaling as well as suppressed levels of serum creatinine and blood urea nitrogen in cisplatin-treated mice.

Conclusions: Our results suggest that MARCKS phosphorylation is a novel NF-κB activator in cisplatin-induced proximal tubule damage and also present a proof of concept for the use of MPS peptide as a renal protection agent for AKI.

PO0230

Apobec1 Limits Cisplatin-Induced AKI by Regulating the Disposal of Pro-Ferroptotic Lipids

Xiaojia Pro,1 Heino Velazquez,1,2 Tian-Min Chen,1 Valerie Blanc,3 Nicholas Davidson,1 Robert L. Safirstein,1,2 Gary V. Desir,1,2 Yale University School of Medicine, New Haven, CT, 1Yale, 2VAMC, West Haven, CT, 3Washington University in Saint Louis, Saint Louis, MO.

Background: Cisplatin (CP) causes proximal tubules to undergo regulated necrosis. We previously reported that the RNA editing-specific cytosine deaminase Apobec1, which regulates mitochondrial metabolism, cell fate and proliferation pathways, plays a crucial role in recovery from this injury. Among the known RNA editing targets for Apobec1 is the lipid transport protein Apob and as the resultant smaller Apob48 is the preferred secretory route of potentially cytotoxic triglycerides (TG), we then ask if Apobec1 limits CP-induced AKI.

Methods: ApoBec1 knockout (ko) mice were given CP 15 mg/kg i.p. and renal function, histology, mRNA, protein and lipid content were analyzed and compared to wild type (WT) mice of similar genetic background. We overexpressed rat Apobec1 in PT cells and assessed cell viability histologically and by WST-1 assay after CP exposure. Apobec1 deletion resulted in more severe AKI, plasma creatinine 2.07 mg/dL vs. 0.59 (n=13) vs 0.23 mg/dL, p<0.01 in WT. Remarkably all Apobec1 ko mice died after 6 days, while WT animals all survived. ApoBec1 KO kidneys showed greater necrosis and neutrophil counts. mRNA and protein levels of RIPK3, MLKL, TLR2, TLR4, and ASC4 were markedly increased in ApoBec1-1 ko compared to WT kidneys (p<0.01). Overexpression of ApoBec1 in mouse PT reduced CP-induced cell death 2.35-fold versus cells transduced with vector alone (n = 4, p<0.05). Overexpression of ApoBec1 increased the activities of kinases associated with survival (ERK, STAT3, Akt) and inhibited those inducing cell death (IRF4, and JNK). Plasma TG increased 2-fold higher in CP-treated ApoBec1 ko mice compared to WT animals (104 ± 12.6 vs. 57.4 ± 9.1, n=4, p<0.05), while renal TG trended upward (437.1 ± 130.0 vs. 223.8 ± 121.7, n=5, p=0.27).

Conclusions: We have identified ApoBec1 as a crucial gene regulating the necrotic response to CP-induced nephrotoxicity. ApoBec1 limits lipid accumulation in the kidney following CP-induced AKI and limiting lipotoxicity. Increasing ApoBec1 activity could be an effective strategy to reduce or prevent CP-induced AKI.

Cisplatin is a chemotherapy drug, but it has notorious nephrotoxicity. Background: Salubrinal is a specific inhibitor of eIF2alpha phosphatase, it promotes eIF2alpha phosphorylation which blocks the formation of the pre-initiation complex and halts global protein translation and protein synthesis. In this study, we examined the effect of salubrinal on cisplatin-induced injury in kidney proximal tubular cells.

Methods: Rat proximal tubular cells (RPTC) were treated with cisplatin or cisplatin with salubrinal for 4, 8, and 24 hrs. Cell lysates were collected for immunoblot analysis to examine the expression of proteins. In addition, other signaling proteins implicated in cisplatin injury were examined, including p53, JNK, p38, and p32delta, and ERK. Apoptosis was determined at 24 hrs of treatment by phase contrast and fluorescence microscopy following nuclear staining with Hoechst. Caspase activities were measured enzymatically by using DEVD-AFC, a fluorogenic peptide substrate. To examine cell survival, the cells were changed to fresh medium for 48 hrs after 24 hrs of cisplatin treatments with or without Salubrinal.

Results: Salubrinal suppressed apoptosis and caspase activation in RPTC during cisplatin treatment. It also promoted long-term cell survival after cisplatin treatment. In immunoblot analysis, during cisplatin treatment salubrinal increased eIF2alpha phosphorylation. It also increased PERK phosphorylation and the expression of GRP78 and CHOP, indicative of ER stress or unfolded protein response. Signaling pathways including MAP kinases, PKCdelta, and p32 are involved in cisplatin-induced kidney injury. Our results indicate that inhibition of global protein synthesis may be a new therapeutic strategy for the side-effects of cisplatin chemotherapeutic drugs.

Quantitative Prediction of Cisplatin-Induced AKI Using RENAsym, a Mechanistic Quantitative Systems Toxicology Model, and Renal Proximal Tubule Epithelial Cell In Vitro Assays

Background: Nephrotoxic drugs like cisplatin cause acute kidney injury (AKI) through complex cellular mechanisms that include mitochondrial dysfunction, oxidative stress, and immune mediated injury pathways. However, quantitative prediction of the underlying toxicity mechanisms in a challenging system is not possible. Quantitative systems toxicology (QST) modeling offers a promise for quantitative description of toxicity mechanisms leading to drug-induced AKI. We developed a QST model of cisplatin induced AKI using in vitro assays to characterize kidney injury pathways.

Methods: RENAsym was used to quantify cisplatin induced AKI. The model represents aspects of renal proximal tubule epithelial cells (RPTC) including cell life cycle and death pathways, bioenergetics, immune signaling pathways and biomarker responses. In vitro data related to cisplatin mitochondrial toxicity and oxidative stress generation were measured using RPTEC assays incubated with cisplatin (Cyprotex Inc.). To quantify cisplatin-induced mitochondrial dysfunction, oxygen consumption rate (OCR) was measured using the Seahorse XF analyzer. Cisplatin-induced oxidative stress was measured using high content imaging (HCI).

Results: The Seahorse study shows that the OCR decline at 24 hours, suggesting cisplatin-induced electron transport chain (ETC) inhibition. Similarly, HCI reveals significant oxidative stress elevation after 9 days. Toxicity parameters for cisplatin-induced mitochondrial dysfunction and oxidative stress mechanisms were determined using the above data. Simulations predict dose-dependent cisplatin toxicity as quantified by elevations in cGST, a biomarker that marks RPTC death. A simulated single high dose of 533 mg/m2 i.v. cisplatin results in 14-fold change in cGST, while a simulated clinical dose of 100 mg/m2 shows 7-fold increase. The 100 mg/m2 result is in qualitative agreement with 3.4-fold change observed in a clinical study where patients administered 100 mg/m2 i.v. cisplatin exhibited 20% incidence of AKI (Ummar. 2012, IJBBB).

Conclusions: RENAsym simulations predicted dose-dependent cisplatin-induced AKI that is in qualitative agreement with clinical data. RENAsym shows promise in providing a unique tool for drug-induced AKI prediction.

Diuretic Resistance: When to Consider Hydralazine?
Mohammed Alshehri, Ramez J. Jabaji, Christopher S. Wilcox. MedStar Georgetown University Hospital, Washington, DC.

Introduction: We present a case of acute cardiac failure complicating hydralazine resistance. Case Description: A 52-Year-old woman with a history of obesity, hypertension, congestive heart failure with New York Heart Association functional class IV (EF60-65%), and alcoholic liver disease presented with a 3-day history of mental status change. Her serum creatinine was 3.6mg/dL, compared to 0.8mg/dL a month prior. She was volume overloaded with distended jugular veins, pulmonary crackles, and 2+ edema to her lower abdomen; she had a 30Kg weight gain over 5 months. Her urine sodium and chloride were both <10mEq/L. Urine analysis had 1+ urine protein and 1+ blood. She was started on torsemide 80 mg twice daily and was escalation progressively to IV furosemide 20 mg/h with IV saline as needed. Diuretic resistance is observed in a subset of patients with congestive heart failure.
chlorothiazide 500 mg twice daily. However, these large doses of intravenous diuretics failed to increase daily urine output above 1000 mL. After 20 hours of stable diuretics, vasodilator therapy was initiated with low dose hydralazine 10 mg thrice daily. Within one day, her urine output more than doubled and, over the next 3 days of the stable therapy, it peaked at 4 liters. Her fraction Na excretion (FeNa) was initially 0.1%; it increased to a maximum of 0.8% on the high IV continuous diuretic therapy but increased further to 3.8%-6.2% over 9 days after hydralazine was added to the diuretic regimen. After addition of hydralazine, her congestion dissipated, she lost 23 Kg and the diuretic regimen was reduced eventually to furosemide 80 mg BID and spironolactone 200 mg daily prior to her discharge with a serum creatinine of 1.3 mg/dL. At follow up after 3 months, her symptoms remained well controlled, her weight was reduced by a further 10 kg and her serum creatinine was 0.9 mg/dL.

Discussion: Hydralazine has been recommended to treat diuretic resistance in HF by increasing cardiac output, renal blood flow and renal diuretic delivery. However, our case suggests that hydralazine greatly improves renal tubular diuretic responsiveness as her FeNa increased 3 fold. This is not likely due to better renal diuretic delivery since the patient received constant IV infusions of two diuretics at doses well above their ceiling. Further clinical trials and mechanistic studies of hydralazine-diuretic interaction are warranted.
how renal biopsy and social history remain vital diagnostic tools in patients presenting a pauci-immune or immune complex pattern as with our patient. The case demonstrates association reported with ANCAs, particularly anti-PR3, which can demonstrate either particularly in the absence of overt clinical endocarditis. There has been a crossover and multiple scratches. Treatment focus shifted from immunosuppression to antibiosis. Broader infectious workup was negative for ASO titters, Borrelia antibody, Quantiferon/ evidence of alveolar hemorrhage, immunosuppression and PLEX were discontinued. glomerulonephritis. With a biopsy suggesting an infectious process and BAL without few distinct subepithelial hump-like deposits by EM, suggestive of an infection related trace granular C1q. EM confirmed mixed mesangial (dominant), subendothelial, and a cultures, assays for hepatitis B/C, HIV and Respiratory panel were negative. Blood/urine ENA, anti-GBM, C-ANCA, P-ANCA, and MPO Ab were negative. However, PR3 Ab treated with immunosuppression and plasma exchange. Serologic tests including ANA/ hypoxia and blood-tinged sputum concerning for pulmonary/renal syndrome and was 120 glomeruli and 12 were sclerosed There was focal organizing arterial nephrostomy was place but creatinine rose to 5mg/dl so renal biopsy was done. The specimen had 2-3 schistocytes per high power field. Lactate dehydrogenase was 449 U/L, hemoglobin 6.7g/dl, platelets 228 K/mcl and Creatinine 2.3mg/dl (baseline 0.6 mg/dl). Renal function improved slightly after Foley placement for newly diagnosed BPH, but SCr remained elevated with negative initial AKI workup. Renal biopsy showed oxalate nephropathy. Further history revealed only occasional consumption of nuts with daily servings of tea and polyethylene glycol. Patient B’s genetic testing was also negative. He remains on hemodialysis and has been referred for transplant.

Discussion:
Oxalate nephropathy can result from primary (genetic) or secondary mechanisms. The most common secondary causes include increased intestinal oxalate availability (“enteric” hyperoxaluria) and increased dietary consumption. A basic medical history can reveal risk factors for enteric hyperoxaluria, while a thorough review of diet and supplements is often deferred, delaying the diagnosis. In some cases a single cause is not identified, and instead a combination of dietary and pharmacologic factors are to blame. We present 1 case of oxalate nephropathy most likely caused by high-dose Vitamin C, and another case with a less clear etiology aside from vague dietary and medication factors.

PO0240

Cat Scratch Kidney
Roy Rajan, Jason R. Pettus, Charles W. Hopley. Dartmouth-Hitchcock Health GraniteOne, Lebanon, NH.

Introduction: Acase of amuric RPGN secondary to post infectious glomerulonephritis in setting of bartonella infection
Case Description: An 84-year-old female presented with creatinine of 7.85mg/dl (baseline 0.81mg/dl) during a workup for painful hematuria. She developed progressive hypoxia and blood-tinged sputum concerning for pulmonary/renal syndrome and was treated with immunosuppression and plasma exchange. Serologic tests including ANA/ENA, anti-GBM, C-ANCA, P-ANCA, and MPO Ab were negative. However, PR3 Ab was elevated at 29.3 Units. Complement C3 and C4 levels were normal. Blood/urine cultures, assays for hepatitis B/C, HIV and Respiratory panel were negative. Bartonella PCR was negative. Both TTE and TEE were negative for valvular lesions. Additional patient history elucidated recent acquisition of a pet cat and multiple scratches. Treatment focus shifted from immunosuppression to antibiotic.

Discussion: Our case highlights an underappreciated entity associated with GN, particularly in the absence of overt clinical endocarditis. There has been a crossover association reported with ANCAs, particularly anti-PR3, which can demonstrate either a pauci-immune or immune complex pattern as with our patient. The case demonstrates how renal biopsy and social history remain vital diagnostic tools in patients presenting with non-specific systemic illness.

PO0241

Two Cases of Oxalate Nephropathy: An Uncommon Disease, Often Missed
Claire F. Schretlen, Michelle Neuman, Vishy Chaudhary. West Virginia University Health Sciences Center, Morgantown, WV.

Introduction: Oxalate nephropathy is a state of excess oxalate availability leading to damaging calcium oxalate crystal deposition in the renal tubules and interstitium. It is an uncommon but severe cause of renal damage and leads to dialysis dependence in the majority of patients; thus, diagnostic index of suspicion must be high.

Case Description: Patient A was a 58 year old male with 2 prior renal stones but no history of gastric bypass, IBD, or other malabsorptive state who presented with vomiting, metallic taste, and behavior changes. Serum creatinine (Scr) on admission was 10.2 mg/dL (baseline 1.1 mg/dL). Basic workup including ANCA, ANA, dsDNA, C3, C4, and Hepatitis B and C was unremarkable. A renal biopsy showed severe interstitial fibrosis and tubular atrophy with abundant calcium oxalate crystals, and dialysis was initiated. Dietary history revealed daily consumption of 1,000 mg Vitamin C, salads, and nuts. Genetic testing for primary hyperoxalosis was negative. After 1.5 months he was no longer dialysis-dependent but only attained partial renal recovery (Scr 2.67 mg/dL, eGFR 25).

Patient B was a 68 year old male with no history of renal or GI disease who presented with anemia, weakness, and urinary retention. Admission Scr was 7.7 mg/dL (baseline 1.4 mg/dL). Renal function improved slightly after Foley placement for newly diagnosed BPH, but Scr remained elevated with negative initial AKI workup. Renal biopsy showed oxalate nephropathy. Further history revealed only occasional consumption of nuts with daily servings of tea and polyethylene glycol. Patient B’s genetic testing was also negative. He remains on hemodialysis and has been referred for transplant.

Discussion: Oxalate nephropathy can result from primary (genetic) or secondary causes. The most common secondary causes include increased intestinal oxalate availability (“enteric” hyperoxaluria) and increased dietary consumption. A basic medical history can reveal risk factors for enteric hyperoxaluria, while a thorough review of diet and supplements is often deferred, delaying the diagnosis. In some cases a single cause is not identified, and instead a combination of dietary and pharmacologic factors are to blame. We present 1 case of oxalate nephropathy most likely caused by high-dose Vitamin C, and another case with a less clear etiology aside from vague dietary and medication factors.

Myeloid-Specific PKM2 Deletion Reduces Kidney Damage in Oxa-
late-Induced AKI

Orestes Foresto-Neto,1,2 Magaia A. Silva,3 Ingrid K. Watanabe,3,4 Tâmisa S. Honda,2 Marcos A. Cenedese,1 Meire I. Hiyama,3 Alvaro Pacheco-Silva,3 Niels O. Camara,3,1 Universidade Federal de Sao Paulo, Sao Paulo, Brazil; 2Universidade de Sao Paulo Instituto de Ciencias Biomedicas, Sao Paulo, Brazil.

Background: Reprogramming of immune cell metabolism have been associated with the development of kidney injury. The M2 isozyme of pyruvate kinase (PKM2) catalyzes a critical stage of glycolysis, which was shown to be a crucial metabolic pathway for pro-
flammatory processes in macrophages. The objective of this study was to investigate whether deletion of PKM2 in myeloid cells exerts renoprotection in calcium oxalate (CaOx)-crystal-induced acute kidney disease (AKI).

Methods: AKI was induced in myeloid-specific PKM2-knockout (PKM22/2+/LysM-Cre+) (p<0.05). FACS analysis indicated that the number of F4/80+ CD11b+ cells in kidneys were similarly elevated by CaOx in both PKM22/2+ and PKM2+LysM-
Crev+ mice with the pro-inflammatory phenotype LysM-Cre+ 2-copy mice were significantly reduced in PKM22/2+/LysM-Cre+ (p<0.05). In addition, PKM2 deletion also reduced renal levels of lactate (p<0.05).

Conclusions: The pro-inflammatory status of macrophages relays on glycolysis in CaOx nephropathy. Therefore, deletion of PKM2 in myeloid cells can reduce CaOx-induced renal inflammation and injury. FAPESP (19/02893-9 and 2017/05264-7), CNPq and CAPES.

High-Content Imaging of Kidney Cell Function to Elucidate Mechanisms of Antiviral Drug Toxicity

Adam Pearson,1 Dominik Haenni,2 Andrew Hall,1,2 Universitat Zurich, Zurich, Switzerland; 1University Hospital Zurich, UniversitätsSpital Zurich, Zurich, Switzerland.

Background: Globally, millions of people live with HIV and hepatitis B virus (HBV). Toxicity from antiviral drugs is a major cause of kidney disease in these individuals. Tenovir disoproxil fumarate (TDF) is a first line therapy for HIV and HBV. TDF induces functional proximal tubule (PT) defects for reasons that are unknown, partly due to a lack of appropriate experimental models. Clinically, TDF toxicity is characterized by two major phenotypes: isolated defects in PT solute transport; and severe tubular damage (Fanconi syndrome/acute kidney injury) associated with grossly enlarged mitochondria. The aim of our study was to establish realistic in vitro models of TDF toxicity, to investigate the underlying mechanisms.

Methods: Experiments were performed on monolayers of differentiated human-derived PT cells (RPTEC/TERT1). A high-content image analysis pipeline was established, using automated microscopy and machine learning, to quantify transport function, using dome formation as a readout. Metabolism was evaluated by antibody staining for mitochondrial morphology and autophagy.

Results: We screened numerous treatment regimens and generated phenotypes matching those observed in patients, including transport inhibition and mitochondrial hypertrophy. Further experiments using these models revealed that TDF caused a dose dependent decrease in ATP content increased glycolysis and mtDNA content. Basal and ATP-linked respiration were decreased but maximal respiration was achieved, suggesting inhibition of complex V (ATP synthase). Metabolomic analysis confirmed that TDF was converted to the active antiviral metabolite Tenovir diphosphate (TFVpp), a structural analogue of ATP. Using an in vitro assay of complex V activity, we observed a dose dependent increase in ATP activity increased glycolysis and mitochondrial mass. Metabolomics revealed no major defects in the TCA cycle or beta-oxidation, but clear evidence of oxidative stress.

Conclusions: In summary, we have developed a high-content image analysis pipeline of human-derived PT cells to generate realistic in vitro models of functional TDF toxicity. Metabolic characterization of these revealed a clear phenotype consistent with ATP dependent inhibition with mitochondrial hypertrophy in patients, and the PT solute transport is highly dependent on aerobic respiration. ATP depletion might trigger compensatory mitochondrial biogenesis, leading to hypertrophy.

Immunological Changes Following Cholineric Anti-Inflammatory Pathway Stimulation

William Nash, Shinji Tanaka, Mark D. Okusa. University of Virginia School of Medicine, Charlottesville, VA.

Background: The cholinergic anti-inflammatory pathway (CAP) protect mice from ischemia reperfusion injury (IRI). The interactions and mechanisms that regulate this effect are of great interest as targets for clinical intervention. Vagus nerve stimulation (VNS) induces neurotransmitter cascades that culminate in release of norepinephrine (NE) in the spleen. NE stimulates CD4+ T cells to produce acetylcholine via the choline acetyltransferase enzyme. Acetylcholine then stimulates anti-inflammatory via splenic immune cells that express the 67 nicotinic acetylcholine receptor (nAChR). Adaptive transfer of splenic cells from VNS-treated mice protects kidneys from IRI. However, the downstream effects on splenic structure and function that lead to protection are still not fully understood. The goal of this study is to profile immune cells following CAP stimulation and identify key downstream mechanisms.

Methods: VNS was performed on mice in vivo and nicotine stimulation on immune cells ex vivo. Vagus nerve stimulation was triggered optogenetically using blue light to target the vagus nerve of mice expressing channelrhodopsin-2 under control of the vasculature glutamate transporter 2 promoter. Cells were collected from the spleens between 24- and 48-hours post-stimulation. A concentration of 50 µM nicotine in culture media was used to stimulate α7nAChR-expressing immune cells collected from the peritoneum of mice. Analysis of immune cell populations was performed with flow cytometry and single cell RNA sequencing.

Results: Overall, optogenetic VNS led to a reduced number of CD4+ cells from the spleen. Within the CD4+ population, B1 cells and macrophages exhibited increased representations of ~30% and 60%, respectively. Monocyte and neutrophil representation remained relatively stable, but eosinophils displayed a marked reduction of ~60%. Single cell RNA sequencing showed increased novel gene expression in subpopulations of macrophages, including cell-cell adhesion genes (Sparc) and granule nitrreceptor exchange factors (Argef5) that could regulate function.

Conclusions: Cholinergic stimulation triggers reorganization of immune cell populations and alters gene expression patterns that are likely important for regulating the inflammatory environment. Additional characterization and functional studies are currently underway to fully identify the importance of observed changes.

Reduced Levels of Cyclic-GMP and Inhibition of cGMP-Dependent Protein Kinase Activate p21Waf1/Cip1 and p27Kip1 and Lead to Renal Fibrosis and Dysfunction

Satyanarayana Das, Kandasamy Neelamgama, Kailash N. Pandey. Tulane University Health Sciences Center School of Medicine, New Orleans, LA.

Background: Targeted-deletion of Npr1 (coding for guanylyl cyclase/natriuretic peptide A, GC-ANP/NPR-A) extends hyperproliferative effects in target organs of Npr1 gene-knockout mice; however, the molecular mechanisms of these pathologies are poorly understood. Fibrosis and hypertrophy are regulated by p21Cip1 and p27Kip1, cell-cycle regulatory proteins that inhibit cyclin and cyclin-dependent kinase (cyclin-CDK) complex.

Methods: We examined the activation of CDK blocker (p21Waf1/Cip1 and p27Kip1) in Npr1 gene-knockout (0-copy); Npr1+/- mice and the GC inhibitor, A71915-treated and cGMP-dependent protein kinase (cGK) inhibitor, Rp-8-Br-cGMPS (Rp)-treated wild-type (Npr1)+/+(138.6 ± 3.1 mmHg; p<0.001) and gene-duplicated 4-copy (Npr1++/++) mice using Western blot and quantitative real-time PCR.

Results: Cyclic-GMP levels and cGK activity were significantly decreased in 0-copy mice compared with controls (138.6 ± 3.1 mmHg; p<0.001) and significantly lower BP in 4-copy mice (86.8 ± 2.8 mmHg; p<0.01) compared to 2-copy mice (102.2 ± 1.7 mmHg). Treatment with A71915 and Rp showed significant increase in BP in 2-copy mice but only a small increase in 4-copy mice compared with untreated control animals. Increased phosphorylation of e-erK1/2 (3-fold), p38MAPK (4-fold), p21Waf1/Cip1 (6-fold), and p27Kip1 (5-fold) occurred in 0-copy, A71915-treated and Rp-treated 2-copy mice, but less in A71915-treated 4-copy mice.

Conclusions: The present results suggest that Npr1 has a pivotal role in inhibiting the renal fibrosis and pathology and exerts renal protective effects through the cGK/cCIP1 axis by repressing the CDK inhibitors, p21Waf1/Cip1 and p27Kip1.

Inhibition of Acetyl-CoA Carboxylase in Acutely Injured Tubular Cells Exacerbates DNA Damage and Mitochondria Fission in Diabetic Nephropathy

Xiaohuan Liu,1,2 Jiahua Li,1 Shen-Yang Cheng,1 Guixia Li,1,3 Joseph V. Bonventre.1 Brigham and Women’s Hospital, Boston, MA; The Second Hospital, Chelou College of Medicine, Shandong University, Jinan, China; Shenzhen Third People’s Hospital, Shenzhen, China.

Background: Both diabetes and acute tubular injury (ATI) alter lipid metabolism of proximal tubules. Inhibiting lipogenesis causes G2M cell cycle arrest, which can cause maladaptive tubular repair. Acetyl-CoA carboxylase (ACC) stimulates lipogenesis and inhibits fatty acid oxidation (FAO). Phosphorylation (p-ACC) inhibits ACC, which inhibits lipogenesis and promotes FAO. We hypothesized that p-ACC exacerbates DNA damage and mitochondria dysfunction in diabetic nephropathy (DN) after ATI.

Methods: Human DN samples were co-stained for p-ACC, KiM-1, and a-SMA. ATI was introduced by a single diphtheria toxin (DT) injection in Akita mice in which the DT receptor (DTR) was introduced genetically into the kidney tubule (AkitaSIX2-DTR). The expression ratio of p-ACC/ACC was determined at 3 days after DT and markers for tubular injury and DNA damage (g-H2AX) were evaluated at 3 days and 4 months. Cisplatin-injured HK2 cells were treated with an ACC inhibitor, PF-05175157 (ACCi) or a carnitine palmitoyltransferase 1 inhibitor, etomoxir (CPT1i) and examined for DNA damage and mitochondria fission.

Results: P-ACC expression was increased and correlated with expression of tubular injury marker KiM-1 and myofibroblast marker a-SMA in human DN specimens. At day 3 after DT, ATI increased the p-ACC/ACC ratio in the Akita (60±20%) mice on HFD and resulted in enhanced expression of g-H2AX in KiM-1 positive tubules and kidney fibrosis at 4 months. When cisplatin-injured HK2 cells were treated with ACCi, which allowed b-oxidation of acyl-CoA, there was an increase in mitochondrial fission factor (MFF) without a further increase of g-H2AX. Etomoxir, which blocked acylcarnitine entry into mitochondria, reduced MFF and g-H2AX expression.

Conclusions: Increased levels of p-ACC were associated with increased tubular injury and fibrosis in human DN. P-ACC in injured renal epithelial cells permitted b-oxidation of acyl-CoA in damaged mitochondria and enhanced mitochondrial fission resulting in DNA damage plausibly from reactive oxygen species. Prevention of mitochondrial overload of acyl-CoA is a potential therapeutic target to mitigate mitochondria damage and DNA damage after ATI in DN.

The Effect of ANG-3777 on In Vitro Cell Proliferation

Background: Hepatocyte growth factor (HGF) regulates tissue growth and development by inducing cell motility, proliferation and morphogenesis in multiple cell types including endothelial and epithelial cells. However, it has no effect on proliferation in fibroblasts. ANG-3777 is a novel molecule that exerts similar cytoprotective and regenerative effects as HGF. This study compared the effect of ANG-3777 with that of HGF in stimulating cell proliferation.

Methods: In vitro cell proliferation assays were conducted in triplicate using human umbilical vein endothelial cells (HUVECs), rat neuronal Schwann cells, and mouse fibroblasts. HUVECs and fibroblasts were exposed to 5 μM ANG-3777 or 25 ng/mL HGF for up to 24 hours. Schwann cells were exposed to increasing doses of ANG-3777 (up to 10 μM) or HGF (up to 100 ng/mL) for 16 to 24 hours to evaluate the effective concentration at 50% proliferative activity (EC50). Radiolabeled [3H]-thymidine incorporation was used to quantify cell proliferation. For the cell-based proliferation assays confirmed that the activity of ANG-3777 and HGF compared with vehicle (p<0.01, Figure 1).

Results: A statistically significant increase in cell proliferation (~3-fold) was observed in HUVECs exposed to ANG-3777 and HGF compared with vehicle (p<0.01, Figure 1). Similarly, Schwann cell proliferation increased in a concentration-dependent manner following exposure to ANG-3777 (EC50 0.012 μM) and HGF (EC50 6.5 ng/mL). In mouse fibroblasts (negative control), neither ANG-3777 nor HGF exposure stimulated cell proliferation compared with vehicle.

Conclusions: In vitro cell-based proliferation assays confirmed that the activity of ANG-3777 is comparable to that of HGF in inducing cell proliferation in HUVECs and rat Schwann cells with neither agent stimulating proliferation in mouse fibroblasts.
was induced in mice after right kidney removal, then IRI mice were treated with 200 kIU for 24 h. We found that IRI resulted in a detectable rise in creatinine level.

Methods: Human kidney proximal tubule cells (PTCs; RPTEC cell line) were exposed to FLCs. Control/treated cells were harvested, and total RNA (mRNA+miRNA) was isolated following standard procedures for whole transcriptome sequencing (Agilent Bioanalyzer 2100). RNA sequencing for whole transcriptome was performed by using Illumina NextSeq 500 to generate ~600 paired-end 75bp reads per sample. After initial data quality checking by FastQC and RSeQC, bioinformatics analysis was performed using TopHat, Samtools, and Picard. Further classified, annotated, and visualized were facilitated by Partek and R statistical packages. RNA sequencing data were validated through qPCR.

Results: Whole transcriptome RNA-Seq data suggested role of several genes involved in innate immunity (VNN1, MX1, OAS2, TLRs, IFI6, IFI27, IFIT1, ISG15, BST2) and region-specific enrichment of FLCs. Control/treated cells were harvested, and total RNA (mRNA+miRNA) was isolated following standard procedures for whole transcriptome sequencing (Agilent Bioanalyzer 2100). RNA sequencing for whole transcriptome was performed by using Illumina NextSeq 500 to generate ~600 paired-end 75bp reads per sample. After initial data quality checking by FastQC and RSeQC, bioinformatics analysis was performed using TopHat, Samtools, and Picard. Further classified, annotated, and visualized were facilitated by Partek and R statistical packages. RNA sequencing data were validated through qPCR.

Conclusions: Our results show differentially expressed genes and a mechanism of injury involving cross-talk between innate immunity and inflammatory pathways in PTCs exposed to FLCs.

PO0254 Long-Term Use of Ferric Citrate in the Treatment of Iron Deficiency Anemia in Patients with Non-Dialysis-Dependent CKD: The COMPASS Trial Pablo E. Pergola,1 Diogo S. Belo,3 Paul W. Crawford,6 Moustafa A. Moustafa,2 Wenli Luo,2 Alex Goldfarb,7 Renal Associates PA, San Antonio, TX, 1Cafeteria Research Institute of the University of Texas, El Paso, TX, 2South Carolina Nephrology & Hypertension Center, Inc, Orangeburg, SC, 3Akemia Therapeutics, Inc, Cambridge, MA, 4Research by Design, Chicago, IL.

Background: Ferric citrate (FC) is an FDA-approved oral iron replacement for adults with iron deficiency anemia (IDA) and non-dialysis-dependent (NDD) CKD and as a phosphate binder in adults with dialysis-dependent CKD. For IDA, the recommended FC starting dose is 1 tablet (1 g, contains 210 mg ferrous iron) 3 times daily (TID) titrated to maintain hemoglobin (Hb) goal. We studied the long-term efficacy and safety of various FC regimens for IDA treatment in adults with NDD-CKD (stages 3-5).

Methods: 48-wk, phase 4, randomized, open-label, multicenter study (NCT03236246). Patients received (1:1) FC 1 g tablet TID (3 g/day) or 2 tablets BID (4 g/day). At Wk 12, if Hb was <10 g/dL or changed <0.5 g/dL from baseline (BL), dose was increased to 2 tablets TID (from 1 TID) or 3 tablets BID (from 2 BID). Primary endpoint was change in Hb from BL to Wk 24. Secondary endpoints included change in transferrin saturation (TSAT), ferritin, and phosphate to Wk 48.

Results: This analysis included 183 of 206 randomised patients. Groups were well matched, with mean age 69±10.3 y and 54% with CKD due to diabetes. Mean BL eGFR was 33.6±10.9 mL/min/1.73 m², and Hb was 10.45±0.74 g/dL. Efficacy measures at 48 wks are presented in the Table. Adverse events (AEs) occurring in ≥5% included diarrhea (13.2%), constipation (12.7%), and constipation (12.2%). Incidence of serious AEs was 13.9% in BID and 17.3% in TID groups. Five deaths were reported, none deemed FC related by investigators.

Conclusions: Both FC regimens studied increased and maintained Hb through 48 wks in patients with NDD-CKD with IDA. Patients with lower baseline Hb and iron parameters had a higher increase in Hb with FC treatment. Serum phosphate remained within normal range over study duration. Mean changes in Hb, TSAT, ferritin, and phosphate were similar in the BID and TID and the 3 and 4 g/day dosing groups. These results support the potential for FC dosing flexibility in the long-term treatment of IDA.

PO0255 Spatial Transcriptomic Signatures in Murine AKI Models Ricardo Melo ferreiro,1 Tarek M. El-Achkar, Kimberly S. Collins, Yinghua Cheng, Seth Winfree, Pierre C. Daghie, Michael T. Eadon. Indiana University School of Medicine, Indianapolis, IN.

Background: The localization of whole transcriptome differential expression in different forms of acute kidney injury (AKI) is incompletely understood. We investigated the distribution of expression across the entire kidney, mapping expression patterns to renal histology in the ischemia-reperfusion injury (IRI) and cecal ligation and puncture (CLP) murine models of AKI.

Results: Single cell RNA-seq analysis of kidney cells revealed differential gene expression that defined patterns of maladaptive proximal tubule repair and characterized important signatures in immune cell composition and activation in regenerating vs. fibrosing kidneys.

Health-Related Quality of Life in Roxadustat-Treated Patients with Anemia and Non-Dialysis-Dependent CKD

Daniel W. Coyne,1 Roberto Manilo-Karin,2 Pablo E. Pergola,3 Carol A. Pollock,4 Roberto Pecetto-Filho,4,5 Tyson T. Lee,6 Elise Hardy,4,6 Kin-Hung P. Yu,4 Washington University in Saint Louis School of Medicine, Saint Louis, MO; 2South Texas Kidney Specialists, P.A., McAllen, TX; 3Renal Associates PA, San Antonio, TX; 4The University of Sydney, Sydney, NSW, Australia; 5Arbor Research Collaborative for Health, Ann Arbor, MI; 6Pontificia Universidade Catolica do Parana Departamento de Medicina, Curitiba, Brazil; 7 Fibrogen Inc, San Francisco, CA; 8AstraZeneca, Gaithersburg, MD.

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Anemia in CKD impacts health-related quality of life (HRQL) by reducing physical capacity and energy levels. Studies have demonstrated a direct relationship between HRQL scores and hemoglobin (Hb) levels in non–dialysis-dependent (NDD) and dialysis-dependent patients with CKD. We assessed the impact of roxadustat on HRQL in patients with NDD-CKD.

Methods: Pooled data from three pivotal, phase 3, randomized, double-blind, placebo-controlled studies of roxadustat for the treatment of anemia in patients with NDD-CKD were assessed. Patients with data up to the time of dialysis treatment and who had pretreatment and a post-treatment HRQL measurement were included. Mean changes from baseline to Week 12 in HRQL scores were compared between the treatment groups.

Results: Least-squares mean treatment differences favored the roxadustat group at Week 12 in all p-values <0.05) in the majority of measures analyzed (Table). Between-group differences were larger in subgroups with lower (ie, worse) baseline scores.

Conclusions: Roxadustat demonstrated improvement in most HRQL measures vs. placebo in patients with NDD-CKD.

Funding: Commercial Support - Fibrogen, Inc.; AstraZeneca plc; Astellas Pharma Inc.

PO0260
Subgroup Analyses of Efficacy of Roxadustat for Treatment of Anemia in Patients with Non-Dialysis-Dependent CKD

Daniel W. Coyne,1 Mohamed A. El-Shahawy,2 Roberto Pecetto-Filho,4,5 Hakim M. Gurcan,9 Cameron S. Liu,6 Elise Hardy,4,6 John Houghton,4 Kin-Hung P. Yu,7 Washington University School of Medicine, St. Louis, MO; 2Keck School of Medicine, University of Southern California, Los Angeles, CA; 3AstraZeneca Inc, San Francisco, CA; 4AstraZeneca, Gaithersburg, MD.

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis and improves iron metabolism. Anemia in CKD impacts health-related quality of life (HRQL) by reducing physical capacity and energy levels. Studies have demonstrated a direct relationship between HRQL scores and hemoglobin (Hb) levels in non–dialysis-dependent (NDD) and dialysis-dependent patients with CKD. We assessed the impact of roxadustat on HRQL in patients with NDD-CKD.

Methods: Pooled data from three pivotal, phase 3, randomized, double-blind, placebo-controlled studies of roxadustat for the treatment of anemia in patients with non-dialysis-dependent (NDD) CKD were assessed. Data from prespecified, clinically relevant patient subgroups were analyzed for: mean change from baseline (CFB) in hemoglobin (Hb) averaged over weeks 28–52 regardless of rescue therapy (primary US efficacy endpoint) and patients (%) that received rescue therapy in the first 52 weeks.

Results: Roxadustat- (n=2391) vs. placebo-treated patients (n=1886) achieved a significantly larger mean (SD) CFB in Hb level (1.85 ± 0.94) vs. 0.13 ± 1.01 (p<0.0001). The effect was consistent in all subgroups and fewer patients that received rescue therapy was consistent across a wide range of prespecified subgroups in the overall population and by age group (18–64), gender (male), race (white), region (US, Europe), baseline iron status (ferritin ≥100 mg/dL & TSAT ≥20%), baseline Hb (<8.0 and ≥10.0 g/dL), and dialysis modality (hemodialysis). HR of MACE and MACE+ were lower in the roxadustat vs. epoetin alfa group: 0.70 (95% CI: 0.51, 0.96) (p=0.03) and 0.66 (95% CI: 0.50, 0.89) (p=0.005).

Conclusions: The efficacy of roxadustat vs. epoetin alfa for improving Hb level and reducing IV iron use was consistent across prespecified subgroups in the ID-DD population. Roxadustat reduced MACE and MACE+ vs. epoetin alfa.

Funding: Commercial Support - Fibrogen, Inc.; AstraZeneca plc; Astellas Pharma Inc.

PO0261
Risk of Transfusion in Patients with Non-Dialysis-Dependent CKD Increases with Hemoglobin Levels <10 g/dL vs. ≥10 g/dL: Pooled Results from Roxadustat Phase 3 Studies
Daniel W. Coyne, Roberto Pecotis-Filho, Anjay Rastogi, Lynda Szczech, Tyson T. Lee, Maksym Pola, Kin-Hung P. Yu. Washington University in Saint Louis School of Medicine, Saint Louis, MO; Arteriovascular Research Center for Health, Ann Arbor, MI; Pontificia Universidad Catolica de Parana Departamento de Medicina, Curitiba, Brazil; University of California Los Angeles, Los Angeles, CA; FibroGen Inc, San Francisco, CA; AstraZeneca, Warsaw, Poland.

Background: Roxadustat is a novel, orally bioavailable, heterocyclic small molecule that reversibly inhibits hypoxia-inducible factor (HIF) prolyl hydroxylase enzymes and activates HIF and transcription of HIF-responsive genes, including erythropoietin. In patients with ESRD, the risk for blood/RBC transfusion is higher in patients with hemoglobin (Hb) levels <10 g/dL vs. those with Hb ≥10 g/dL. We evaluated the efficacy of roxadustat vs. placebo on blood/RBC transfusion by Hb level in US-based patients with non-dialysis-dependent (NDD) CKD.

Methods: Data from three pivotal phase 3 randomized, placebo-controlled studies of roxadustat for the treatment of anemia in NDD patients were assessed. Patients were randomized to receive roxadustat or placebo with periodic dose evaluation/titration. Transfusion was allowed at any time if it was deemed a medical necessity by the Investigator. The incidence rate of transfusion was calculated based on Hb level categories as: <9.0, 8.0 to <9.0, and ≥9.0 g/dL. Data were evaluated for the on-treatment period ≥28 days after the last dose of study drug.

Results: In the overall pooled population of patients with NDD-CKD, roxadustat reduced the risk of transfusion by 74% (HR, 0.26; 95% CI, 0.21, 0.32; p<0.0001) vs. placebo. When patient-exposure data were stratified by achieved Hb levels, the risk for transfusion increased as Hb levels decreased (Table). The incidence rate of transfusion increased approximately 4-fold in patients with Hb between 8.0 and <10.0 g/dL vs. those with Hb ≥10 g/dL regardless of treatment arm.

Conclusions: In US-based patients with NDD-CKD and anemia treated with roxadustat, the risk of transfusion was approximately 4 times higher in patients with Hb between 8.0 g/dL and <10.0 g/dL vs. those with Hb ≥10 g/dL.

Funding: Commercial Support - Fibrogen, Inc.; AstraZeneca plc; Astellas Pharma Inc.

Table: Incidence rate of transfusion (events/100 PEY) based on Hb level and treatment group

PO0262
Roxadustat Favorably Modifies Iron Indices in Patients with Non-Dialysis-Dependent CKD-Related Anemia
Daniel W. Coyne, Simon D. Roger, Willis Chou, Anatole Besarab, Robert Leong, Tyson T. Lee, Lynda Szczech, Dustin J. Little, Kin-Hung P. Yu. Washington University in Saint Louis School of Medicine, Saint Louis, MO; Renal Research, Gosford, NSW, Australia; FibroGen Inc, San Francisco, CA; Stanford University School of Medicine Center for Neuroscience in Women’s Health, Palo Alto, CA.

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor that stimulates erythropoiesis by increasing endogenous erythropoietin and improving iron metabolism.

Methods: We analyzed data from a Phase 3, randomized, double-blind study (ANDES) comparing roxadustat to placebo for the treatment of anemia in NDD-CKD patients. 922 patients were randomized (2:1) to receive roxadustat (n=616) or placebo (n=306) thrice weekly with monthly dose titrations. Patients were encouraged to receive oral iron daily unless not tolerated. Change in Hb was compared to changes in key iron and red blood cell (RBC) parameters.

Results: All baseline (BL) parameters were comparable between the study arms. Roxadustat was superior to placebo in increasing mean Hb from BL over weeks (wks) 28-52: +2.00 vs. +0.16 g/dL (p<0.0001), respectively. Iron parameters were unchanged over time in the placebo arm. In the roxadustat arm, significant erythropoiesis was noted with mean Hb increases of 1.52 and 1.89 g/dL at wks 4 and 24; mean decrease in hepcidin was 54.6 μg/L at wk 4 and DTBIC was +0.3 μg/dL at wk 4. An initial decline in mean ferritin and TSAT was noted primarily in the higher BL quartiles, with little change in the 2 lower BL quartiles. Serum iron increased by 13.6 μg/mL at wk 20 from baseline. All initial changes in iron parameters plateaued by wks 16-20, and remained unchanged thereafter. Reticulocyte Hb content at wk 20 were at baseline level, and it was slightly increased by 1-4 fL at wk 4 before plateauing and stabilizing, while mean MCHC was unchanged.

Conclusions: Roxadustat lowered serum hepcidin, accompanied with initial decline in ferritin and TSAT in patients with high BL levels but little change in ferritin and TSAT in patients with low-normal BL levels despite active erythropoiesis. Maintenance of reticulocyte Hb content level during treatment reassures sufficient iron availability during erythropoiesis with roxadustat. These findings in iron parameters suggest that iron is efficiently absorbed and mobilized for erythropoiesis during anemia correction and Hb maintenance with roxadustat in NDD-CKD patients.

similar across all hsCRP quintiles in roxadustat-treated patients (Figure). Mean weekly roxadustat doses at Week 24 for baseline hsCRP quintiles 1 through to 5 were comparable at 3.2, 2.9, 2.5, 3.0, and 3.0 mg/kg, respectively.

Conclusions: Roxadustat increased Hb in anemic NDD-CKD patients independent of inflammation.

Roxadustat Increases Hemoglobin in Anemic Dialysis-Dependent (DD) CKD Patients Independent of Inflammation
Mohamed A. El-Shahawy,1 Simon D. Roger,2 Roberto Manillo-Karin,3 Maksym Pola,4 Stefan Tham,5 Lynda Szczez,5 Carol A. Pollock,5 Keck-USC School of Medicine, Los Angeles, CA; 2Renal Research, Gosford, NSW, Australia; 3Gamma Medical Research, McAllen, TX; 4Clinical Research, AstraZeneca, Warsaw, Poland; 5Clinical Research, AstraZeneca, Gothenburg, Sweden; 6FibroGen Inc., San Francisco, CA; 7The University of Sydney, Sydney, NSW, Australia.

Background: Inflammation is a common cause of decreased responsiveness to erythropoiesis-stimulating agents. Roxadustat, an oral hypoxia-inducible factor prolyl hydroxylase inhibitor, treats anemia by inducing endogenous erythropoietin production and increasing iron utilization via reducing hepcidin. Roxadustat efficacy has been shown in those with inflammation, as defined by baseline (BL) elevation of high sensitivity C-reactive protein (hsCRP). This pooled analysis explored the efficacy of roxadustat in correcting Hb in DD-CKD patients across the spectrum of baseline hsCRP values.

Methods: Data from three randomized Phase 3 pivotal trials in anemic patients with DD-CKD were pooled, and the efficacy of roxadustat in increasing hemoglobin (Hb) from BL was assessed. hsCRP concentration was used as a marker of inflammation; patients with hsCRP >5 mg/L were considered to have inflammation at BL. Mean Hb change from BL (CBF) to Weeks 28–52 was summarized by BL hsCRP quintiles 1 through to 5.

Results: Over all, 1538 roxadustat-treated DD-CKD patients were assessed and had a mean BL hsCRP of 10.5 mg/L. Mean BL Hb measures were similar across the hsCRP quintiles (range 9.5–9.7 g/dL). In patients with BL inflammation (n=723), mean Hb CFB to Weeks 28–52 was 1.29 g/dL with roxadustat. Mean Hb CBF to Weeks 28–52 was similar across all hsCRP quintiles in roxadustat-treated patients (Figure). Mean weekly roxadustat doses at Week 24 for BL hsCRP quintiles 1 through to 5 were comparable at 3.9, 3.4, 3.5, 3.3, and 3.6 mg/kg, respectively.

Conclusions: Roxadustat increased Hb in anemic DD-CKD patients independent of inflammation.

PO0266
Effects of Roxadustat Treatment on Serum Parathyroid Hormone (PTH) in Hemodialysis Patients with Erythropoiesis-Stimulating Agent (ESA) Resistant Anemia
Iwamichi Hashiguchi,1 Satoshi Funakoshi,1,2 Kenji Sawase,1 Tayo Kawazu,1 Kanako Hayashi,1 Kosi Yamaguchi,1 Mineaki Kitamura,1 Takashi Harada,1 Tomoya Nishino,1 Nagasaki Kidney Center, Nagasaki, Japan; 2Nagasaki University Hospital, Nagasaki, Japan.

Background: Roxadustat, an oral HIF-prolyl hydroxylase inhibitor, is shown to stimulate erythropoiesis thereby improving iron metabolism. Of note, recent research suggests that iron utilization plays an important role in bone turnover in hemodialysis patients.

Methods: A total of 64 hemodialysis patients with ESA-resistant anemia despite high-dose epoetin α (3000 units 3 times weekly) therapy participated in the study after giving informed consent. Patients were switched from intravenous epoetin α to oral roxadustat therapy (100 mg 3 times weekly), with no dose change in any of the iron supplements, calcimimetics or vitamin D formulations being used, and were assessed after 8 weeks of roxadustat therapy for improvements in anemia, as well as for changes in parameters related to iron metabolism and bone turnover.

Results: The study included 39 men and 25 women (age, 70.8 ± 11.8 years; Hb concentration, 10.3 ± 1.2 g/dL). After 8 weeks, the Hb concentration tended to be increased (P = 0.06). As shown in Figure, the serum iron, ferritin concentration and TSAT significantly decreased (P < 0.05), suggesting increased iron utilization. Again, the serum calcium concentration was significantly decreased from 8.54 to 8.36 mg/dL, while the intact-PTH (i-PTH) concentration was significantly decreased from 98.6 to 75.80 pg/mL (P < 0.001).

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: Switching hemodialysis patients with ESA-resistant anemia from intravenous ESA to oral roxadustat therapy may result in a decrease in their serum PTH concentrations presumably through improved iron utilization, thus potentially improving their bone mineral metabolism.

Effects of Roxadustat Treatment on HD Patients with ESA-resistant Anemia

PO0267

Ophthalmological Effects of Roxadustat in the Treatment of Anemia in Dialysis-Dependent and Non-Dialysis-Dependent CKD Patients: Findings from Two Phase 3 Studies

Quan D. Nguyen,1 Yasir J. Sepah,2 Yussuke Yamaguchi,3 Tetsuro Otsuka,3 Yoshikatsu Majikawa,3 Michael Reusch,4 Tadao Akizawa,5 Byers Eye Institute, Stanford School of Medicine, Stanford, CA; 3Oclaric Imaging Research and Reading Center, Sunnyvale, CA; 4Astellas Pharma Europe B.V., Leiden, Netherlands; 5Showa University School of Medicine, Tokyo, Japan.

Background: Roxadustat is an orally active hypoxia-inducible factor prolyl hydroxylase inhibitor in late-stage development for the treatment of chronic kidney disease (CKD) anemia. Nonclinical data had suggested that hypoxia-inducible factor stabilization promotes angiogenesis, increasing the risk of retinal pathologies. We herein report the 24-week ophthalmological findings from two phase 3 studies of roxadustat in Japan.

Methods: Dialysis-dependent (DD) and non-dialysis-dependent (NDD) CKD patients (pts) with anemia were randomized to roxadustat (three times weekly) or darbeopoeitin alfa (DA; once weekly [DD]; once every two weeks [NDD]). Darbeopoeitin levels were titrated to maintain target hemoglobin. Ophthalmological assessments (funduscopic photograph, optical coherence tomography) were performed by centralized grading; visit-specific data were presented.

Results: A total of 302 DD pts (150, roxadustat; 152, DA) and 262 NDD pts (131, roxadustat; 131, DA) were randomized and received at least one dose of study drug. Results from the ophthalmological funduscopic photograph assessments are reported in Table 1. No meaningful changes occurred in visual acuity or retinal thickness in the treatment groups of either study.

Conclusions: In DD and NDD CKD pts with anemia, the risk of developing ophthalmic abnormalities was comparable between roxadustat and DA.

Funding: Commercial Support - Astellas Pharma, Inc.

* Any evidence of retinal hemorrhage, from “No” at baseline to “Yes,” and/or an increase in hemoglobin (Hb) levels >10 g/dL vs. those with Hb >10 g/dL. We evaluated the efficacy of roxadustat vs. epoetin alfa on blood/RBC transfusion by Hb level in US-based patients with dialysis-dependent (DD) CKD.

Methods: Data from three pivotal phase 3, randomized, active-controlled studies of roxadustat for the treatment of anemia in DD patients were assessed. Patients were randomized to receive roxadustat or epoetin alfa with periodic dose evaluation/titration. Transfusion was allowed at any time if it was deemed a medical necessity by the Investigator. The incidence rate of transfusion was calculated based on Hb level categorized as: <8.0, 8 to <10, and ≥10 g/dL. Data were evaluated for the on-treatment period + 28 days after the last dose of study drug.

Results: In the overall pooled population of patients with DD-CKD, roxadustat vs. epoetin alfa reduced the risk for transfusion by 18% (HR, 0.82 [95% CI: 0.68, 1.00]; p=0.046). Among patients who were patient-exposed for ≥1 dose of study drug were stratified by achieved Hb level, the risk for transfusion increased as Hb levels decreased (Table). The incidence rate of transfusion increased approximately 5-fold in patients with Hb <10 g/dL vs. those with Hb ≥10 g/dL.

Conclusions: In US-based patients with DD-CKD and anemia treated with roxadustat, the risk for transfusion was approximately 5 times higher in patients with Hb <10 g/dL vs. those with Hb ≥10 g/dL, regardless of treatment arm.

PO0269

A Phase 3, Multicenter, Randomized, Open-Label, Active Comparator Conversion Study of Roxadustat in Non-Dialysis-Dependent (NDD) Patients with Anemia in CKD

Tadao Akizawa,1 Manabu Iwasaki,2 Tetsuro Otsuka,3 Yussuke Yamaguchi,3 Michael Reusch.2 1Showa University School of Medicine, Tokyo, Japan; 2Yokohama City University, Yokohama, Japan; 3Astellas Pharma, Inc., Tokyo, Japan; 4Astellas Pharma Europe B.V., Leiden, Netherlands.

Background: Roxadustat is an orally active hypoxia-inducible factor-prolyl hydroxylase inhibitor for the treatment of anemia in CKD. Efficacy and long-term safety of roxadustat was assessed, following conversion from darbepoeitin alfa (DA), recombinant human erythropoietin (rHuEPO), or epoetin beta pegol (EBP) to roxadustat, in NDD-CKD patients (pts) with anemia. Noninferiority of roxadustat efficacy against DA was evaluated.

Methods: This study enrolled adult Japanese NDD-CKD pts receiving DA, rHuEPO, or EBP for ≥8 weeks before prescreening. Patients who had used rHuEPO or DA were randomized to receive roxadustat or DA (comparative group [CG]). EBP-using pts were allocated to receive roxadustat (referential group [RG]). The primary endpoint was change in average hemoglobin (Hb) from baseline (BL) at Weeks 18-24. Roxadustat efficacy was confirmed if the 95% CI of average Hb at Weeks 18-24 was within 10-12 g/dL; noninferiority of roxadustat efficacy against DA was evaluated.

Results: This study enrolled 134 JAPANAKI patients (n=131) or DA (n=131); 70 pts were allocated to RG and received ≥1 dose of study drug (n=69). The mean (95% CI) of average Hb at Weeks 18-24 in roxadustat was 11.14 (11.01, 11.28) g/dL, confirming the noninferiority of roxadustat. The difference between roxadustat and DA (CGs) in the change in average Hb from BL at Weeks 18-24 was -0.75 g/dL. Treatment-emergent adverse events (TEAEs) were assessed.

Results: A total of 262 pts were randomized to CGs and received at least one dose of roxadustat (n=131) or DA (n=131); 70 pts were allocated to RG and received at least one dose. The mean (95% CI) of average Hb at Weeks 18-24 in roxadustat (CG) was 11.14 (11.01, 11.27) g/dL, confirming the noninferiority of roxadustat. The difference between roxadustat and DA (CGs) in the change in average Hb from BL at Weeks 18-24 was -0.75 g/dL. Treatment-emergent adverse events (TEAEs) were assessed.

Conclusions: This study confirmed the efficacy of roxadustat after conversion from DA, rHuEPO, or EBP, as well as its noninferiority to DA, in NDD-CKD pts with anemia. The safety profile of roxadustat was consistent with previous reports. A final analysis of this study (including 52-week data) will be presented at the congress.

PO0270

HIF Prolyl Hydroxylase Inhibitor Improves Exercise Endurance and Hardly Affects Instantaneous Force in Mice

Background: Erythropoietin (EPO) and hypoxia-inducible factor (HIF) stabilizers (PH inhibitors) are efficient therapeutic modalities against anemia in CKD. Compared to EPO and EPO receptor system, extra-renal action of PH inhibitors has still been subtly unclear. Previous reports caution us about the actual misuse of PH inhibitors in doped athletes, but nonhematopoietic effects of PH inhibitors on skeletal muscles remain controversial. Metabolic shift from oxidative phosphorylation toward glycolysis in myotubes in vitro was previously reported. Direct pharmacological effects of PH inhibitors on skeletal muscles and exercise performance were assessed in vivo.

Methods: Roxadustat, one of PH inhibitors, was administered via oral gavage to 8-week-old C57BL6 mice. Plasma EPO levels and HIF-targeted gene expression were measured.
Temporal Trends in Anemia Management and Major Clinical Outcomes in Incident Dialysis Patients in Canada

Methods: The Canadian Organ Replacement Register was used to identify 35,945 adult patients who initiated hemodialysis or peritoneal dialysis from Jan 1 2007 to Dec 31 2015. Time at risk started on day 90 of dialysis and continued for a minimum of 12 months to capture outcomes via data linkage with hospital discharge diagnoses. Patients were categorized into 3 time periods anchored to landmark target hemoglobin trials and publications of anemia guidelines: Era 1 (Jan 2007-Dec 2009); Era 2 (Jan 2010-Dec 2012); Era 3 (Jan 2013-Dec 2015). Cox proportional hazards regression models were used to investigate the association between era and the primary composite outcome (acute myocardial infarction (AMI), stroke or mortality).

Results: The mean hemoglobin at dialysis initiation decreased from 102.9g/L in 2007 to 95.5g/L in 2015, corresponding with a doubling in the prevalence of hemoglobin <80g/L, which represents a substantial shift in practice and merits further investigation in terms of patient-centered outcomes.

Conclusions: There have been modest declines in average hemoglobin values and ESA use among incident dialysis patients in Canada. Unlike the US, there has been no temporal reduction in stroke. Patient survival has improved over time, likely for reasons other than anemia management. An increasing number of patients are starting dialysis with a hemoglobin <90g/L, which represents a substantial shift in practice and merits further investigation in terms of patient-centered outcomes.

Reported Caregiver Burden in CKD with and Without Anemia: A US-Based Survey

Methods: The survey was administered in January-February 2020 to adult participants recruited from the American Association of Kidney Patients (AAKP) and a third-party recruitment firm. Eligible participants provided care to an adult with CKD within the last 4 weeks. The 15-20 minute survey included questions related to caregiver and patient demographics, clinical characteristics, preferences on anemia treatment, caregiver quality of life (Burden Scale for Family Caregivers [BSFC-S]), and work productivity (Work Productivity Activity Impairment-Caregiver). Outcome was summarized descriptively for caregivers of patients with anemia (A+) and without anemia (A-).

Results: Among 258 caregivers who completed the survey, 42.6% cared for a patient with anemia (A+); non-dialysis dependent (NDD), 38.2%, dialysis dependent (DD), 61.8%). Male caregivers were older (A+: 64 years, A-: 54 years) and more likely to report a high burden (BSFC-S:A+: 69.1%, A-: 58.8%) and work impairment (absenteeism: A+, 19.0%; A-, 14.8%; presenteeism: A+, 37.9%; A-, 32.3%). In the A+ group, >75% of caregivers described anemia as being moderate or severe, and >90% of caregivers had received anemia treatment in the past month (oral iron, 45.5%; intravenous iron, 33.6%; erythropoiesis-stimulating agents, 22.7%; red blood cell transfusion, 20.9%). If a patient was to initiate a new anemia treatment, 46.4% of caregivers would prefer an oral agent, of which 41.2% prefer a once daily formulation.

Conclusions: There is significant caregiver experience by caregivers of patients with CKD, especially when anemia is present. Further studies are needed to better understand its full extent and explore support strategies for caregivers.

Cost and Healthcare Resource Use in Patients with Anemia in CKD

Methods: This retrospective analysis of the integrated Limited Claims and Electronic Health Record (IBM Health, Armonk, NY) spanned Jan 1, 2012 to Sept 30, 2018. Patients were aged ≥18 years with a eGFR measures <60 mL/min/1.73 m² ≥90 days apart. Anemia was defined as any hemoglobin (Hb) value <10 g/dL observed within 6 months of a confirmatory eGFR (baseline period). Total and site-specific costs and selected healthcare resource utilization were analyzed and stratified by presence of baseline anemia, Hb range, CKD stage, sex, and insurance type.

Results: 21.7% of patients (mean age, 72% in the 12 months post-index period.

Conclusions: This descriptive examination of treatment by CKD stage for NDD patients with anemia found that anemia was oftentimes left untreated, especially in the stage 3-4 CKD patients. After NDD CKD patients were diagnosed with anemia, it was almost 1.5 months before treatment was initiated. In NDD CKD patients with anemia, as stage increased, HCRU increased, highlighting the importance of care coordination as CKD progresses.

Modelling the Clinical and Economic Burden of Anemia in Patients with CKD
Oliver T. Darlington,1 David Booth,2 Peter D. Gabb,3 Mylene Sanon,2 Efthathios N. Michalopoulos,2 Youssef M. Farag,2 Xinyu Wang2, Philip McEwan,1,3 Health Economics and Outcomes Research Ltd., Cardiff, United Kingdom; 2Otsuka Pharmaceutical Development and Commercialization, Inc., Princeton, NJ; 3Akebia Therapeutics, Inc., Cambridge, MA; 4Otsuka Pharmaceutical Europe Ltd., Slough, United Kingdom; 5Centre for Health Economics, Swansea University, Swansea, United Kingdom.

Background: Chronic Kidney Disease (CKD) imposes a significant societal burden. Anemia is a common complication of CKD and is independently associated with poorer patient outcomes, including CKD progression, cardiovascular (CV) events and death. The objective of this study was to develop a natural history model to characterize the consequences of anemia in patients with CKD.

Methods: A lifetime Markov model was developed to estimate the economic impact of anemia. Two cohorts aged 58 years with CKD stage 3b were modelled with and without anemia (Hb 9-10 g/dL and Hb > 12 g/dL) to estimate differences in life expectancy (LE) and quality-adjusted life expectancy (QALYs), and event incidence. Hb level was linked to CKD progression, CV hospitalization and mortality using published data. Published direct costs and utility estimates associated with CKD and event incidence were incorporated, and costs were inflated to 2019 US dollars. Costs associated with anemia treatment such as erythropoiesis-stimulating agents or supplemental iron were not considered. Future costs and benefits were discounted at 3.0% per annum.

Results: Predicted LE was 10.21 years in patients with anemia compared to 12.16 years in patients without anemia, or a reduction of 2.15 years. Decreased patient LE and reduced quality of life with anemia resulted in 2.18 fewer QALYs. Time to end stage renal disease was 10.4 years with anemia and 12.5 years without anemia. Patients with anemia experienced 25 additional CV-related hospitalizations per 1,000 patients. Total lifetime costs were higher in the non-anemic cohort due to improved LE ($342,867 vs. $316,510), however annual costs were lower in anemic patients with an undisclosed loss of $2,628 per year due to reduced CV event incidence and CKD management costs.

Conclusions: This analysis supports that those without anemia have increased LE and QALYs, and account for less costs to the healthcare system. Therefore, anemia management, aligned with clinical guidelines, has the potential for better outcomes for both the patient and the healthcare system.

PO0276
Prevalence of Severe Anemia and Transfusion Risk in Medicare and Non-Medicare Populations with CKD Stages 3 and 4
Jill Davis1, Robert M. Perkins,2 Allison A. Petrella,2 Scott B. Robinson,2 Dakota C. Powell2, Anne Murunga,3 Shamkhali Kumar,4 Kevin Dietz,4 Avaleere Health, Washington, DC; 2AstraZeneca, Wilmington, DE.

Background: While 30 million people in the United States have chronic kidney disease (CKD), real-world clinical burden of anemia in non-dialysis dependent (NDD) CKD patients is poorly documented, which we seek to address.

Methods: A retrospective cohort analysis was conducted using the 100% sample of Medicare Fee-For-Service (FFS) beneficiaries (parts A/B/D) and a convenience sample of Commercial (Com), Medicare Advantage (MA), and Managed Medicaid (MM) lives of Commercial (Com), Medicare Advantage (MA), and Managed Medicaid (MM) lives (136,163 from MORE 1999-2016) was conducted. Estimated glomerular filtration rate (eGFR) was calculated using the CKD-EPI formula. Participants were classified as no CKD, CKD stage 1-2, and CKD stage 3-5 using KDIGO criteria. Anemia was defined as WHO criteria. ADL impairments were defined as “some difficulty” or “a lot of difficulty” in activities. Results: Mean age of participants was 46.7 years; 51.0% were female. The percentage of participants with no CKD, CKD stage 1-2, and CKD stage 3-5 was 86.4%, 7.6%, and 6.0%, respectively. Anemia prevalence in each CKD category was 4.9%, 8.7%, and 18.6%, respectively. Multivariable-adjusted prevalence of impairment in ≥1 ADL, by CKD and anemia status, is presented along with covariates in the Table. Compared to participants with no anemia, the adjusted prevalence ratio for impairment in ≥1 ADL was 1.06 (95% CI: 0.98-1.14; p = 0.13) in no CKD, 1.14 (0.99-1.28; p = 0.06) in CKD stage 1-2, and 1.20 (1.05-1.35; p = 0.01) in CKD stage 3-5. The clinical implications of this association should be investigated further.

Adjusted prevalence (95%CI) of impairment in ≥1 ADL by CKD and anemia category

Table reports percentages. Marginally-adjusted prevalence derived using logistic regression models (age, sex, race, education, marital status, income, health insurance, employment, smoking, alcohol use, comorbidities, heart failure, coronary heart disease, angina pectoris, heart attack, stroke, arthritis, chronic obstructive pulmonary disease, body mass index, hypertension, diabetes, and hyperlipidemia).

P-values compare anemia vs. no anemia.

PO0278
Clinical Outcomes in Patients with Anemia in CKD Using Linked US Claims and Electronic Health Records
Eric T. Wittbrodt1,2 Glen James3, Supriya R. Kumar,4 Juan Jose Garcia Sanchez,2 Hungta (tony) Chen,5 James A. Sloan3, Kamyar Kalantar-Zadeh6,7 AstraZeneca, Wilmington, DE; 2AstraZeneca, Cambridge, United Kingdom; 3AstraZeneca, Gaithersburg, MD; 4University of California - Irvine, Irvine, CA.

Background: Anemia is common in pts with CKD, yet contemporary outcome data to understand the long-term clinical burden are scarce. This analysis describes selected cardiovascular and renal outcomes in non-dialysis CKD pts with and without anemia at baseline (BL) in US real-world practice.

Methods: This retrospective observational study evaluated the integrated Limited Claims and Electronic Health Record data (IBM Health, Armonk, NY). Pts were aged ≥18 y with ≥2 eGFR measures <60 mL/min/1.73 m2 ≥90 days apart. A total of 13,692 pts with available BL ≥1 eGFR measures were included. BL pt characteristics and clinical outcomes during follow-up were analyzed for the period from Jan 1, 2012 to Sep 30, 2017. Descriptive data were summarized; no inferential statistics were performed.

Results: A total of 1,305,354 patients were identified from Medicare FFS and 154,163 from MORE. Prevalence of severe anemia in the Medicare FFS cohort was 3.1% and 3.3% in the MORE cohort (Table 1). Severe anemia was highest among stage 4 CKD patients at 11.3% in the FFS cohort and 15.4% in MORE cohort, with prevalence among Medicare FFS beneficiaries at 17.1%. High value, cancer, diabetes, liver disease, and hospitalizations were risk factors for RBCT. Within the MORE cohort, the odds of receiving RBCT increased by 47% for each 1 g/dL decrease in hemoglobin.

Conclusions: The proportion of severe anemia increases with worsening CKD stage in US pts primarily in Medicare FFS. Many clinical factors influence the odds of severely anemic NDD CKD patients receiving RBCT.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Results: Of the total study cohort (N=22,720), 23% (n=5,283) had BL Hb <10 g/dL. The following results are for pts with and without anemia at BL, respectively. Females accounted for 60% and 57% and mean ages (± SD) were 70 (±14) and 71 (±12) y. Proportions by BL CKD stage were: 3a, 50% and 68%; 3b, 27% and 24%; 4, 15% and 7%; 5, 9% and 1%. Median follow-up times were 2.9 and 3.8 y. Acute coronary syndrome (ACS) events during follow-up occurred in 2.2% of pts with BL anemia and 2.3% of pts without BL anemia, heart failure hospitalizations (HFH) occurred in 5.9% and 3.7%, and stroke hospitalizations and emergency visits (S) occurred in 2.8% and 3.0% of pts. Incidence rates/100 pt-yr were 0.8 and 0.7 for ACS, 1.6 and 0.8 for HFH, respectively, and 0.7 in both groups for S. ESRD occurred in 4% and 1%, 40% eGFR decrease in 44% and 25%, and CKD stage progression in 67% and 59% of pts. Median change in eGFR slope was −0.6 and −0.3 mL/min/1.73 m².

Conclusions: This analysis highlights worsened outcomes associated with anemia in CKD, particularly ifH and eGFR decline, in pts of a large US cohort.

PO0279
Prevalence of Anemia and Associated Erythropoiesis-Stimulating Agent Use in 5.9 Million Non-Dialysis CKD Patients
Danielle K. Farrington, Yingying Sang, Morgan Grans, Shoshana Ballew, Stephan C. Dunning, Nikita Stempienwicz, Josef Coresh, Johns Hopkins Medicine, Baltimore, MD; Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; OptumLabs Visiting Fellow, Cambridge, MA; American Medical Group Association, Alexandria, VA; OptumLabs, Cambridge, MA.

Background: Chronic kidney disease (CKD) leads to anemia through erythropoietin deficiency and resistance, and a heightened inflammatory state. Characterizing the burden and factors associated with severe anemia (hemoglobin <9 g/dL) is of particular interest since treatment with erythropoiesis-stimulating agents (ESAs) or other therapies is often considered at this level.

Methods: We analyzed patients in the OptumLabs® Data Warehouse, which contains de-identified claims and electronic health record data, with a complete blood count and serum creatinine measured within 30 days of each other in 2016. Patients requiring dialysis were excluded. We examined the association between low hemoglobin (Hb) categories (<9 g/dL, 9-10 g/dL, 10-11 g/dL) and age, sex, diabetes, history of cardiovascular disease (CVD), and categories of eGFR using polychotomous logistic regression to estimate adjusted relative risk ratios (RRR). Results: Among 5,875,383 patients in 52 centers, mean age was 56 years (SD 17), and 42% were male. The prevalence of Hb <10 g/dL in CKD stages G1-G2, G3a, G3b, G4 and G5 was 2.0%, 4.2%, 9.2%, 20.3% and 36.1%, respectively. Lower eGFR categories were strongly associated with increased risk of anemia, even after adjustment for female sex (RRR 2.6-3.9), diabetes (RRR 1.4-1.8), history of CVD (RRR 1.7-1.9), and age (RRR 2.2-2.4 for age 75+). The frequency of ESA use in patients with hemoglobin <10 g/dL was 0.2%-4%, 0.4%-1.0% and 1.0% in CKD stage G3a, 3b, 4, and 5.

Conclusions: Severe anemia is common and strongly associated with low GFR, female sex, older age, diabetes and history of CVD in a wide range of health care systems. ESA use in non-dialysis CKD patients was very uncommon.

PO0280
Lower Transferrin Saturation (TSAT) Index Is Associated with Anemia-Independent Risk of Increased Mortality in Non-Dialysis (ND) CKD Patients
Murilo H. Guedes, Daniel G. Muenz, Jarcy Zee, Brian Bieber, Sandra Wachter, Benedicte Stengel, Ziad Massy, Helmut Rechel, David M. Charytan, Michelle M. Wong, Ronald L. Pisoni, Bruce M. Robinson, Roberto Pecocis-Filho, Pontificia Universidade Catolica do Parana, Curitiba, Brazil; Arbor Research Collaborative for Health, Ann Arbor, MI; Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; Division of Nephrology, Ambroise Paré University Hospital, APHP, Boulogne-Billancourt, France; The University of British Columbia, Vancouver, BC, Canada; NYU Langone Health, New York, NY; Nephrological Center, Villingen-Schwenningen, Germany; Vifor Pharma Ltd, Glattbrugg, Switzerland.

Background: Iron Deficiency (ID), defined by a TSAT index <20%, is present in approximately half of ND-CKD patients, varying little by CKD stage. Distinct from approaches in conditions such as heart failure, the importance of iron reserves and the basis for iron therapy in CKD has focused primarily on supporting effective erythropoiesis. A comprehensive approach and design to estimate the impact of ID, independently from hemoglobin (Hb) levels, on mortality risk has not been explored in ND-CKD until the present.

Methods: 5144 patients from Brazil (N=294), France (N=2227), the US (N=494), and Germany (N=2129) enrolled in the Chronic Kidney Disease Outcomes and Practice Patterns Study (CKDopps) from 2013-2019 with available TSAT were included in the analysis. We categorized patients by first available TSAT at enrollment. Hb measurements at same time as TSAT were used. Cox models were used to estimate hazard ratios (HR) of TSAT on mortality, censored at start of dialysis or kidney transplantation. Models were progressively adjusted including demographics, comorbidities, inflammation surrogates, treatment with erythropoietin stimulating-agents and Hb.

Results: Sample characteristics were: 59% male; 45% diabetes; and mean (SD) age 69 (13) years, eGFR 28 (11) mL/min, Hb 12 (2) g/dL, TSAT 24 (2) %, ferritin 196 (214) ng/dL. TSAT levels below 25% were progressively associated with higher mortality risk, while patients with TSAT greater than 45% tended to have higher risks for mortality (Figure).

Conclusions: ID, as measured by the TSAT index, is associated with higher risk of all-cause mortality in ND-CKD patients, even after extensive adjustments for clinical, demographic and biochemical confounders, including Hb levels. Interventional studies evaluating the impact of iron supplementation and alternative targets on clinical outcomes in ND-CKD patients are needed to better inform ID management strategies.

Lower Transferrin Saturation (TSAT) Index Is Associated with Worse Health-Related Quality of Life (HRQOL) in Non-Dialysis CKD (ND-CKD) Patients Independently from Hemoglobin (Hb) Levels
Murilo H. Guedes, Daniel G. Muenz, Jarcy Zee, Marcelo Lopes, Sandra Wachter, Benedicte Stengel, Ziad Massy, Elodie Speyer, Fredric O. Finkelstein, Ricardo Sesso, Ronald L. Pisoni, Bruce M. Robinson, Roberto Pecocis-Filho, Pontificia Universidade Catolica do Parana, Curitiba, Brazil; Arbor Research Collaborative for Health, Ann Arbor, MI; Universidade de Sao Paulo, Sao Paulo, Brazil; Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; Yale University, New Haven, CT; Division of Nephrology, Ambroise Paré University Hospital, APHP, Boulogne-Billancourt, France; The University of British Columbia, Vancouver, BC, Canada; NYU Langone Health, New York, NY; Nephrological Center, Villingen-Schwenningen, Germany; Vifor Pharma Ltd, Glattbrugg, Switzerland.

Background: Iron Deficiency (ID) is a common condition in NDD-CKD patients that is associated with poorer outcomes. However, the effect of ID on HRQOL in this population is unknown. We analyzed real world data from a multinational cohort of ND-CKD stage 3 to 5 patients to test the association between TSAT and ferritin with HRQOL.

Methods: Patients from Brazil (N=205), France (N=2,015), the US (N=494), and Germany (N=2129) enrolled in the Chronic Kidney Disease Outcomes and Practice Patterns Study (CKDopps) from 2013-2019 with available TSAT were included. We grouped patients according to TSAT and ferritin levels closest to the HRQOL measurement. Our primary analyses evaluated the associations of TSAT and ferritin with mean differences in physical component summary (PCS) and mental component summary (MCS). Secondary analyses evaluated joint TSAT and ferritin categories, as well as additional pre-specified HRQOL measures. Linear mixed models were adjusted for potential confounders including Hb level.
Results: 2313 patients were included. In the primary analyses, TSAT ≤15% and both ferritin >300 ng/mL and <300 ng/mL were associated with worse PCS scores, while M-CSF was not directionally associated with iron parameters (Figure). Patients with the composite TSAT ≤15%/ferritin ≥300 ng/mL had lower functionality scores and worse PCS, compared to those with TSAT between 20-30% and ferritin 50-299 ng/mL. Adjustment for Hb only slightly attenuated the effects, and the results were similar for subgroups of patients with Hb <11.5 vs ≥11.5 g/dL.

Conclusions: Low TSAT levels, and both low and high ferritin levels, are associated with poorer physical HRQOL in ND-CKD patients, even after adjustment or stratification by Hb level. Intervention studies of iron therapy on HRQOL among ND-CKD individuals are needed to confirm these findings.

PO0283
A Novel, Fast-Acting Iron Sucrose Formulation for CKD Patients with Iron Deficiency Anemia
Charles M. Cook,1 Bhupinder Singh,2,1 Stacey Ruiz,1 Alvaro F. Guilmel.1
1Renibus Therapeutics, Southlake, TX; 2University of California Irvine, University of California Irvine, Irvine, CA, US, Department of Medicine, Irvine, CA; 3CMC SQUARED, Southlake, TX.

Background: Intravenous (IV) iron is commonly used to treat iron deficiency anemia in patients with chronic kidney disease (CKD). However, the report of the physicochemical and safety profile of RBT-3, a novel iron sucrose formulation, which was assessed in a Phase 1b study conducted in healthy volunteers and subjects with chronic kidney disease (CKD) Stage 3 or 4.

Methods: Analytical testing was conducted to examine the physicochemical profile of RBT-3. Safety of RBT-3 was assessed in a Phase 1b study in healthy volunteers and subjects with CKD. RBT-3 was administered IV as a single dose of 120, 240, or 360 mg. Plasma and urine ferritin were measured at baseline, then 2 h (plasma) or 24 h (urine) through 168 h post-treatment to assess clinical response.

Results: RBT-3 particle size is similar to commercially available iron sucrose. However, RBT-3 has a lower molecular weight and higher water content than similar IV iron formulations, suggesting faster uptake and greater solubility, respectively. RBT-3 also has a negative Zeta potential, demonstrating low cytotoxic potential. The quantity of labile iron in RBT-3 is 1.48%, suggesting very low availability of free inorganic iron hydroxide, with a low cytotoxic potential. Furthermore, Fe2+, which is associated with oxidative stress, is present in much lower quantities in RBT-3 (3.4%) compared to commercially available iron sucrose (15.8%). In this Phase 1b study of RBT-3, 18 subjects were enrolled; 6 subjects (3 healthy volunteers and 3 subjects with CKD) randomized to 3 cohorts received a single dose of RBT-3 at 120, 240, or 360 mg. Mean age was 60.3 years; 66.7% of the subjects were female. Dose-dependent increases in plasma ferritin were observed in all subjects within 2 h of treatment and reached statistical significance by 8-12 h. Urine levels were increased at 24 h. Both plasma and urine ferritin levels remained elevated through 168 h (7 days). No treatment-related adverse events (AEs) were observed, and no serious AEs (SAEs) were reported.

Conclusions: RBT-3 represents a novel iron sucrose formulation with desirable physicochemical characteristics that makes it a fast-acting mediator of iron hemodynamics. This is the first report of ferritin level increases within only 2 h by an iron formulation. RBT-3 is safe and well tolerated in healthy volunteers and subjects with CKD at a single dose up to 360 mg.

Response to Oral Iron Therapy in Children with Anemia of CKD
Sharmi Biswas,1 Kelly Meza,1 Haneen Alajyassy,1 Dmitry V. Sannosov,2 Sonia Solomon,2,3 Eduardo M. Peresstein,4 Jibi Kumar,4 Oleh M. Akhurin,4 Pediatric Nephrology 1Well Cornell Medicine, New York, NY; 2Westchester Medical Center, Valhalla, NY; 3Boston Children’s Hospital, Boston, MA; 4NewYork-Presbyterian Hospital/Well Cornell Medical Center, New York, NY.

Background: Anemia is a common complication of chronic kidney disease (CKD). Current guidelines recommend oral iron therapy as the initial treatment of anemia in CKD. However, the efficacy of iron therapy in children with pre-dialysis CKD has not been evaluated. Factors determining the response to oral iron in pediatric CKD remain poorly understood.

Methods: An ongoing retrospective observational study. Data were abstracted from health records of children with pre-dialysis CKD at the time of iron therapy initiation and at the next clinic visit and compared using paired T-test. Children receiving receiving hypoxia-stimulating agents were excluded. Response to iron therapy was defined as improvement in both hemoglobin and hematocrit after iron therapy. Changes of serum ferritin and TSAT levels remained elevated through 168 h (7 days). No treatment-related adverse events (AEs) were observed, and no serious AEs (SAEs) were reported.

Conclusions: RBT-3 represents a novel iron sucrose formulation with desirable physicochemical characteristics that makes it a fast-acting mediator of iron hemodynamics. This is the first report of ferritin level increases within only 2 h by an iron formulation. RBT-3 is safe and well tolerated in healthy volunteers and subjects with CKD at a single dose up to 360 mg.

Improving Knowledge of Nephrologists Regarding an Emerging Class to Treat Anemia Associated with CKD

Background: As emerging therapies hold promise to improve treatment of anemia in patients with CKD, clinicians need to understand mechanisms of action in order to understand the potential place in therapy when available. We sought to determine if online, continuing medical education (CME) could improve the clinical knowledge of nephrologist related to emerging Hypoxia-Inducible Factor Prolyl Hydroxylase Inhibitors (HIF-PHIs).

Methods: The effect of 2 online, 30-minute, CME-certified activities were analyzed. Multiple-choice knowledge and self-efficacy confidence questions were presented both before and immediately after each activity. A repeated pairs pre-/post-assessment study design was used and chi-square test (5% significance level, P < 0.05) assessed educational effect. Cramer’s V was used to calculate the effect size (0.06–0.15 is a noticeable effect, 0.16–0.26 considerable, and >0.26 extensive). The activity launched June 20, 2019 and data were collected through July 11, 2019.

Results: In total, 167 nephrologists were included in the study. Overall improvements were seen for both activities after participation: Activity 1: N=75, P=0.01, V=0.16; Activity 2: N=93, P=0.01, V=0.162. Individual question-level improvement was also demonstrated: 21% of nephrologists (N=75, P<0.05; V=0.169) improved at correctly identifying the mechanism of action of HIF-PHIs 20% of nephrologists (N=75, P<0.05; V=0.197) improved at recognizing clinical trial data for HIF-PHIs 33% of nephrologists (N=92, P<0.05; V=0.315) improved at recognizing clinical trial data for HIF-PHIs 21% of nephrologists (N=93, P<0.05; V=0.103) improved at recognizing CVOTs for HIF-PHIs 45% (N=75) and 47% (N=92) reported increased confidence in understanding HIF PHI clinical trial data Continued educational gaps: 55% (activity 2) and 59% (activity 1) of nephrologists did not recognize the mechanism of action of emerging HIF-PHIs 46% of nephrologists did not recognize clinical trial data for emerging HIF-PHIs 62% of nephrologists did not recognize CVOT data for emerging HIF-PHIs

Conclusions: This study demonstrates the success of online, video-based CME on improving knowledge of nephrologists related to emerging treatments for anemia associated with CKD. Continued knowledge gaps were identified for future educational targets.

Treatment Pathways of Non-Dialysis-Dependent CKD Patients with Anemia: A Report from the DISCOVER CKD Posters
Eric T. Wittbrodt,1 Juan J. Carrero,1 Glen James,1 Steven Fishbane,4 Supriya R. Kumar,2 Roberto Pecotis-Filho,2,6 Juan Jose Garcia Sanchez,1 Carol A. Pollock,3 James A. Sliold,4 Katarina Hedman,4 David C. Wheeler,1 AstraZeneca UK Ltd, Cambridge, United Kingdom; AstraZeneca, Gaithersburg, MD; Karolinska Institutet, Stockholm, Sweden; Northwell, Manhasset, NY; Pontificia Universidade Catolica do Parana, Curitiba, Brazil; Arbor Research Collaborative for Health, Ann Arbor, MI; University of Sydney, Sydney, NSW, Australia; AstraZeneca, Gothenburg, Sweden; University College London, London, United Kingdom.

Background: Anemia is a frequent complication of chronic kidney disease (CKD), yet most patients experiencing this problem remain untreated until the initiation of renal replacement therapy. We describe treatment pathways of key medications prescribed to non-dialysis dependent (NDD) CKD patients with anemia in DISCOVER CKD.

Methods: Patients included in this analysis were extracted from the Limited Claims and EHR (LCED) data. The study cohort included patients aged ≥18 years with 2 estimate glomerular filtration rate (eGFR) measures ≤60 mL/min/1.73m2 >90 days apart between January 2008 and September 2018. The index date was the first Hb measure <12 g/dL (females), <13 g/dL [males] per WHO criteria), or an anemia therapy (iron, ESA or blood transfusion) prescription after the 2nd eGFR measure. Exclusion criteria were: <1-year registration/medical history prior to index, active bleeding in the 30 days preceding and inclusive of index, an Hb value (only) within 30 days from transfusion or bleeding and no Hb measure within a year after CKD diagnosis. Oral iron was incompletely captured in LCED. Sankey Plots were used to visualize chronological treatment pathways (1st to 3rd line) post-index of key medications commonly prescribed to CKD patients with anemia including: oral iron, IV Iron, ESA and blood transfusion.

Results: Preliminarily, 1446 (2.6% of anemia base cohort) patients were prescribed anemia therapies during follow-up, with IV iron (32.5%), transfusions (30.5%), ESA (21.6%), oral iron (12.2%) and ESA-IV Iron (2.7%) used as 1st-line therapies, Figure 1. Median times to 1st-line therapy initiation after index were: 108 days for oral iron, 194 days for ESA, 197 days for IV iron, and 244 days for blood transfusion.

Conclusions: In routine clinical care, anemia in NDD CKD is under treated and rescue therapies are used for anemia more often than preventive therapies.

PO0286
Online CME Successful at Improving Nephrologist Understanding of Emerging Class to Treat Anemia Associated with CKD

Background: As emerging therapies hold promise to improve treatment of anemia in patients with CKD, clinicians need to understand mechanisms of action in order to understand the potential place in therapy when available. We sought to determine if online continuing medical education (CME) could improve the clinical knowledge of nephrologist related to emerging Hypoxia-Inducible Factor Prolyl Hydroxylase Inhibitors (HIF-PHIs).

Methods: The effect of an online, CME-certified, roundtable video discussion was analyzed to determine efficacy of online education. Three multiple-choice knowledge/competence questions and 1 self-efficacy confidence question were presented both before and immediately after each activity. A repeated pairs pre-/post-assessment study design was used and McNemar’s chi-squared test (5% significance level, P < 0.05) assessed educational effect. Cramer’s V was used to calculate the effect size (0.00-0.05 is a noticeable effect, 0.06-0.15 is a noticeable effect, 0.16-0.26 considerable, and >0.26 extensive). The activity launched June 27, 2019 and data were collected through August 27, 2019.

Results: In total, 62 nephrologists answered all pre-/post-assessment questions and were included in the study. Overall improvements were seen after participation in both CME activities: 24% of nephrologists (P<0.05; V=0.216) improved at correctly identifying the mechanism of action of HIF-PHIs 11% of nephrologists (P=0.72; V=0.032) demonstrated improvement at selecting the recommended use of erythropoiesis stimulating agents (ESAs) in the treatment of anemia 21% of nephrologists (P<0.05; V=0.181) improved at recognizing clinical trial data of HIF-PHIs 47% reported increased confidence in understanding HIF PHI clinical trial data Continued educational gaps: 55% of nephrologists did not recognize the mechanism of action of emerging HIF-PHIs 46% of nephrologists did not recognize clinical trial data for emerging HIF-PHIs

Conclusions: This study demonstrates the success of online, video-based roundtable discussion on improving knowledge of nephrologists related to emerging treatments for anemia associated with CKD. Continued knowledge gaps were identified for future educational targets.

PO0288
Physician Attitudes Toward Diagnosis, Treatment Initiation, and Unmet Needs in the Management of Anemia due to CKD: Results from a Real-World Survey in Germany, Italy, and the United Kingdom
Madhusudan Kabra,1 Tim Hammond,2 Allison Fleetwood,2 Lewis Harrison,3 James Jackson,4 Sarah Clayton,1 Adelphi Real World, Bollington, United Kingdom; Osuka Pharmaceutical Europe Limited, Slough, United Kingdom.

Background: Anemia, a complication of chronic kidney disease (CKD), is often defined as serum hemoglobin (Hb) levels of <12 g/dL in women and <13 g/dL in men. Traditionally, primary care physicians (PCPs) have less involvement managing and treating patients with anemia due to CKD while nephrologists play a greater role in treatment decisions. We describe current physician perceptions towards the diagnosis and treatment of anemia due to CKD and unmet needs in anemia management, in a real-world setting

Methods: Data were drawn from the Adelphi CKD Disease Specific Programme, a point-in-time study conducted between November 2019 and April 2020 with nephrologists and PCPs from Germany, Italy, and the United Kingdom. Physicians completed an online survey providing information on their demographics, perceptions on the diagnosis and treatment of anemia, and the current unmet needs they believe exist in the management and treatment of anemia. Results were descriptively analyzed.

Results: A total of 200 physicians (n=140 nephrologists; n=60 PCPs) were included in the analysis. Among those who responded, the majority (98% nephrologists; 80% PCPs) used Hb levels to diagnose anemia in CKD patients. Over two thirds of physicians mentioned using ferritin to diagnose anemia and over half reported using transferrin saturation (TSAT) levels. Approximately 4 in 5 nephrologists and PCPs (78%
PO0291

Amelioration of CKD-Associated Anemia by Vadadustat in Mice Is Not Dependent on Erythropoferone

Mark R. Hanadel, Shirley Wong, Grace Jung, Bo Qiao, Victoria R. Gabayan, Tomas Ganz. University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.

Background: Vadadustat is an investigational hypoxia inducible factor prolyl hydroxylase inhibitor that increases endogenous erythropoietin (EPO) production, and has been shown to decrease increased hepcidin levels, improve iron status, and increase hemoglobin concentrations in anemic chronic kidney disease (CKD) patients. Increased EPO induces erythropoietin secretion of erythropoferone (ERFE), which acts on the liver to suppress serum hepcidin production. To determine whether vadadustat mechanisms of action are dependent on ERFE, we treated wild type (WT) and ERFE knockout (EKO) mice, with and without adenine diet-induced CKD, with vadadustat.

Methods: 6-week-old male C57BL/6 WT and EKO mice were placed on 8-week diets that did or did not contain 0.2% adenine. For the last 3 weeks of the diets, the mice were treated with vadadustat (75 mg/kg/day via oral gavage) or vehicle solution. Mice were euthanized at 14 weeks of age (n=8 mice per group).

Results: Unlike the WT mice, EKO mice had undetectable spleen Erfe mRNA, minimal marrow Erfe mRNA, and no increase in ERFE mRNA or protein in response to vadadustat. However, in both WT and EKO CKD models, vadadustat normalized hemoglobin concentrations (Fig 1a), increased expression of duodenal iron transporters, tended to lower serum hepcidin, and decreased tissue iron concentrations (consistent with increased iron mobilization), suggesting ERFE-independent pro-erythropoietic effects. Vadadustat treatment was also associated with improved kidney function (Fig 1b) and decreased expression of renal fibrosis markers. Lastly, vadadustat affected FGF23 profiles: In non-CKD mice, vadadustat increased plasma total FGF23 out of proportion to intact FGF23, consistent with the known effects of Hf on EPO on FGF23 production and metabolism. However, in the CKD mice, vadadustat markedly decreased both total and intact FGF23 (Fig 1e), effects likely contributed to by improved kidney function.

Conclusions: Vadadustat ameliorates CKD-associated anemia independently of ERFE, and also improves kidney function and lowers FGF23 in this CKD model. How vadadustat affects CKD progression in humans may warrant future studies.

Oxidative Stress and Heme Metabolism in Red Blood Cells of Hemodialysis Patients

Gabriela F. Dias,1,2 Gabriela B. Andrade,2 Nadja Grobe,3 Xia Tao,4 Robertopecoitosilho,2,4 Peter Kotanko,1,5 Andrea N. Morena-Amiral.2 Renal Research Institute, New York, NY; Pontificia Universidade Catolica do Parana, Curitiba, Brazil; Icban School of Medicine at Mount Sinai, New York, NY; Arbor Research Collaborative for Health, Ann Arbor, MI.

Background: We have previously described that indoxyl sulfate promotes red blood cells (RBC) ROS generation in humans (OLM.2018). However, there is little information regarding pathways of antioxidant balance to protect RBC from oxidative stress that occurs during hemodialysis (HD). Intracellular free heme is degraded by Heme Oxygenase (HO-1), which is regarded as the major cytoprotective enzyme (Maines, 1988; Gozzelino et al., 2010). In the current study, we assessed HO-1 activity and ROS production in RBC from healthy subjects and hemodialysis (HD) patients before and after HD.

Conclusions: Blood was drawn from 6 healthy individuals (CON-RBC) and 6 HD patients (HD-RBC) before (pre-HD-RBC) and after high flux HD (post-HD-RBC). Isolated RBC were stained with DCFH-DA (Abcam) for ROS measurements. To quantify HO-1, RBC were incubated with anti-HO-1 antibody (Abcam) and m-IgG BP-CEL 488 (Santa Cruz Biotechnology) as a secondary antibody. Samples were analyzed by flow cytometry.

Results: Our results show a 4-fold increase in ROS levels in pre-HD-RBC compared to CON-RBC. ROS levels were even further increased by 1.65-fold after HD treatment in post-HD-RBC (Figure 1). Both pre-HD-RBC and post-HD-RBC showed a similarly significant increase of 3.36-fold compared to CON-RBC (Figure 1).

Conclusions: High levels of HO-1 may represent a defense against oxidative stress that occurs in ESKD and particularly during the HD session. Further research is needed to evaluate whether HO-1 overexpression could accelerate heme degradation and contribute to renal anemia.

Funding: Private Foundation Support, Government Support - Non-U.S.
Daprodustat Interaction with Phosphate Binders Has Minimal Impact on Hemoglobin Values in Hemodialysis Population

Background: Daprodustat is a hypoxia-inducible factor prolyl hydroxylase inhibitor (PHI) in phase 3 development for the treatment of anemia of chronic kidney disease. Phosphate binders (PB) are widely prescribed for patients on hemodialysis (HD) to control hyperphosphatemia. PB may interfere with medication absorption; thus, coadministration with a PHI may potentially impact the latter’s efficacy on hemoglobin (Hgb). The purpose of this analysis was to determine whether administration of daprodustat in subjects receiving PB has an impact on Hgb values in the HD population.

Methods: The 24-week GSK PHI11033 study (NCT01977482) included 216 subjects on maintenance HD previously treated with recombinant human erythropoietin (Clin Kidney J 2019;12:139–148). Target Hgb range was 10.0 g/dL to 11.5 g/dL. Baseline PB users were defined as a prespecified study subgroup. The difference in mean Hgb values at Week 24 between treatment groups was summarized overall and by subgroup. Comparisons were performed for the Week 24 Hgb (post hoc), as well as the final dose of daprodustat, for those receiving/not receiving PB.

Results: The majority of HD subjects received PB at baseline; 136/177 (77%) of daprodustat and 33/39 (85%) of control subjects were taking PB, with comparable phosphate control at baseline (mean ± SD: phosphate; daprodustat 1.76 mmol/L ± 0.56; control 1.67 mmol/L ± 0.44]). All subjects receiving PB at baseline, except two, continued throughout the study. No meaningful difference in Hgb change from baseline (CFB) at Week 24 was noted between treatment groups. The final median dose for subjects on maintenance HD previously treated with recombinant human erythropoietin was 10 mg (6 mg), with no meaningful difference in the Hgb at Week 24 (mean ± SD: PB use=Yes 10.40 g/dL ± 0.95; PB use=No 10.79 g/dL ± 0.95).

Conclusions: These results suggest that PB use does not have a major impact on Hgb values during the 24-week study. Results of an ongoing, phase 3 dialysis study of daprodustat compared with conventional treatment are awaited to confirm these initial observations.

Prevalence and Severity of Anemia Between Non-Dialysis and Dialysis Outpatients referred to Nephrology Consultation: Epidemiologic Data from 1568 Mexican Patients at a National Reference Hospital L. M. Perez-Navarro1, Samantha Escorza Valdivia1, Alberto Sigfrido Benitez Renteria1, Rafael Valdez-Oroz1, 'Hospital General de Mexico De Eduardo Liceaga, Ciudad de Mexico, Mexico; 2AstraZeneca, Ciudad de Mexico, Mexico.

Background: Anemia is a frequent complication in chronic kidney disease (CKD), and is frequently associated with symptoms such as physical disability, decreased neurocognitive function, and poor quality of life. Our objective is to know the prevalence and severity of anemia between stages of CKD in patients who attended a nephrology clinic for the first time.

Methods: Transversal, descriptive, observational study. Records of adult patients who attended an outpatient nephrology clinic in the period from February 2019 to February 2020 were included. Anemia staging was performed according to the world health organization. Descriptive statistics were performed, with a 95% CI and a p-value ≤0.05.

Results: 1568 patient records were included. Mean age was 56.01 ± 16 years and 51% (804) were women. Distribution of patients by CKD stage: 9% stage 1, 11% stage 2, 12% stage 3a, 16% stage 3b, 23% stage 4, and 27% stage 5. 12% were undergoing renal replacement therapy. 53% of the population had anemia at the cut-off point of Hb<13 for men and <12 for women; stratification of anemia severity between stages of CKD is presented in figure 1. The main comorbidities and risk factors in the subjects with anemia were type 2 diabetes mellitus and hypertension (55%), proteinuria (38%), hypoalbuminemia (34%), hyperkalemia (37%) overweight or obesity (58%), hyperglycemia (45%) hypertriglyceridemia (35%) and hypercholesterolemia (31%).

Conclusions: In patients who attended for the first time an outpatient nephrology clinic, a high prevalence of anemia was found in CKD patients, being more frequent and more severe from stage 3b to stage 5. Identifying these findings will allow establishing public health policies and models of care for patients with CKD.

Funding: Commercial Support - AstraZeneca

Background: Anemia is a common complication in patients with chronic kidney disease (CKD), contributing to reduced quality of life and increased risk of morbidity and mortality. Erythropoiesis-stimulating agents (ESAs) are the established standard of care for anemia management in CKD patients. This review examines hemoglobin (Hb) requirements in randomized controlled trials (RCTs) of ESAs as treatment of anemia in CKD.

Methods: Embase, Medline, and Cochrane Library were searched from 1946 to November 2019 for RCTs evaluating the safety and efficacy of ESAs as treatment for adults with anemia and CKD. Descriptive analyses were performed to assess between-trial differences with respect to baseline Hb and Hb target ranges. Studies were classified by dialysis status (non-dialysis-dependent [NDD] vs dialysis-dependent [DD]) vs renal transplant recipient (RTR), and by treatment goal (correction vs conversion).

Results: Searches retrieved 3,482 records, from which 57 trials met the inclusion criteria. Thirty-seven studies reported a Hb target, including 15 correction studies (NDD, 11; DD, 3; RTR, 1), 19 conversion studies (NDD, 2; DD, 16; RTR, 1) and 3 that were mixed/unclear (DD, 2; NDD/DD, 1). The unweighted means (range) of the mean baseline Hb in correction and conversion studies were 10.1 g/dL (7.0-11.7) and 11.2 g/dL (9.1-13.1), respectively. There were 20 different Hb target ranges used to assess efficacy; 10-12 g/dL was utilized most often (n=8). Three of 37 RCTs used a singular Hb target threshold, whilst the remaining studies used a Hb target range, which varied from narrow (0.5 g/dL) to wide (5.0 g/dL) between the lower and upper limits. Target Hb ranges used an upper limit of >12 g/dL in 21/37 RCTs (correction, 13/15; conversion, 10/19); however, only 3/21 RCTs were published after 2012 (the last update of KDIGO Clinical Practice Guideline).

Conclusions: This systematic review shows that changing Hb requirements over time are a source of difference in RCTs of ESAs for treatment of anemia in CKD. Such differences may introduce bias when using quantitative synthesis methods (e.g. network meta-analysis) to assess the comparative efficacy and safety of ESAs relative to new treatment options.

Excessive Decrease of Hematocrit After Discontinuation of Dapagliflozin Yoshihara Wada1, Yoshiyuki Hamamoto,2 Yoshishia Nakatani,3 Sachiko Honjo,1 Yamato Keida1, Yohei Seno1, Kanako Iwasaki,1 Yorihito Iwasaki,1 Jun Fujikawa,1 Hiroko Nakata,1 Akihiro Hamasaki,1,2 Izuku Kofukai Medical Research Institute Kitano Hospital, Osaka, Japan; 2Kansai Electric Power Hospital, Osaka, Japan; 3Kindai University, Osaka, Japan.

Background: Recently, sodium-glucose cotransporter 2 (SGLT-2) inhibitors were indicated to have hematopoietic effect, but it is still unclear how the effect continues after discontinuation. In this study, we investigated changes in hematocrit, urinary gravity and HbA1c after discontinuation of SGLT-2 inhibitor in patients with type 2 diabetes.
Methods: A total of 8 patients (male: n=4, age: 54.4±11.9 [mean±SD] years, BMI: 27.1±4.4 kg/m², HbA1c: 9.2±1.2 %) with type 2 diabetes who were newly administered 5mg per day of dapagliflozin from March 2015 to September 2019 and discontinued the drug due to adverse events or side effects which did not require admission were retrospectively identified. Changes in HbA1c, hematocrit and urine specific gravity levels before the administration and after the discontinuation of the drugs were evaluated.

Results: The drug was discontinued 8.4±6.6 months after administration due to non-benefit on glycemic control (n=4), polyuria (n=2), weight loss (n=1) and genital infections (n=1). HbA1c was not changed (-0.3±1.1 %; p=0.45) whereas urine specific gravity (0.014±0.009 g/mL; p=0.001) and hematocrit (1.63±1.99 %; p=0.04) were significantly increased at the time of discontinuation. Urine specific gravity (0.005±0.009 g/mL; p=0.12) and hematocrit (0.15±0.14 %; p=0.84) levels were returned to the levels of before drug administration 60 days after the discontinuation. After the 120 days of discontinuation, hematocrit was still decreased during the level of baseline (-1.29±1.70 %; p=0.05) whereas urine specific gravity was not.

Conclusions: Our data demonstrate that the increased urine specific gravity and hematocrit return to original levels within 60 days after the discontinuation of dapagliflozin, and that hematocrit may continue to decrease below the level original even after.

PO0297

Human Mesenchymal Stem Cells Cultured in a Hollow Fiber Bioreactor Maintain Constant Levels of Exosomes in the Perfusion Medium: Relevance to the Simultaneous Production of Two Biotherapeutic Agents

Christof Westenfelder,1,2 Anna Gooch,3 Mikhail Skliar,4 Sabiba Sultana Chowdhury,5 Ping Zhang,3 Zhuha Hu,6 SymbioCellTech, LLC, Salt Lake City, UT;7 University of Utah, Salt Lake City, UT.

Background: We have shown that the administration of allogeneic Mesenchymal Stem Cells (MSC) to patients at high risk for Acute Kidney Injury (AKI) following on-pump cardiac surgery prevents AKI and progression to Chronic Kidney Disease (CKD). Treatment of rats with severe, progressive IRI AKI with MSC-derived exosomes affords significant survival benefits and rescues their renal function (see abstract this meeting). The current study examined the possibility to simultaneously collect MSC-derived exosomes while culturing human MSCs, both used for various therapies in renal and other diseases. This approach, if successful, would be cost saving, efficient and facilitate up-scaling of the production of both MSCs and their exosomes.

Methods: Human MSCs (20x10⁶) were loaded into a hollow fiber Cell Expansion System (Quantum®, TERUMOHeart, pre-conditioned for cell adhesion with Fibronectin) and expanded using cMEM with 5% human Platelet Lysate (hPL). The number of exosomes in aliquots of the perfusion medium were monitored (NanoSight instrument) throughout the course of cell expansion.

Results: MSCs reached ~90% confluence within 12 days, yielding 500x10⁶ MSCs. The number of exosomes/nanoparticles derived from the 5% hPL per se was 4x1x10⁶/ml. Post seeding of MSCs in the bioreactor, exosome numbers in the perfusate decreased and stabilized at 1.1x10⁶/ml. The size of collected exosomes was between 60 and 100 nm.

Conclusions: The data from this pilot study demonstrate that hPL-derived exosomes or nanoparticles are taken up by the expanding MSCs, which lowers their total number in the perfusion medium. However, exosome numbers stabilized during the subsequent cell expansion, indicating that growing MSCs release high numbers of exosomes. This conclusion will be confirmed by quantifying hPL- and MSC-derived exosomes, using specific markers for each type of nanoparticle. Together, these observations show promise for the efficient generation of MSCs and their exosomes to be used for various clinical applications.

Clinical Study Results Confirming a Novel Fluorescent Compound Is a Glomerular Filtration Rate (GFR) Tracer Agent in Humans

Background: A fluorescent GFR tracer agent for use in the clinic would enable a noninvasive transdermal continuous GFR detection method. This would make possible the initial compartment being the vascular to tissue equilibrium, and the terminal compartment (i.e., plasma GFR measurement). The terminal compartment yielded a single GFR value and was unperturbed over the approximate 10 hour time span for which the subjects were eating and taking their usual medications. The comparison of GFR from the MB-102 data to that of GFR from the iohexol data is shown in Figure 1.

Conclusions: The correlation of GFR from plasma MB-102 to that of plasma iohexol is excellent (r-squared = 0.99). Thus MB-102 is a fluorescent GFR tracer agent in humans. This result is the first step in the development of a noninvasive transdermal GFR measurement at the point-of-care.

Dialysate Exposure Does Not Compromise the Function of Bioengineered Proximal Tubules for Bioartificial Kidney

Rosalinde Maseugwu,1 Silvia M. Mhaila,1 Dimitrios Stamatialis,2 Igor R. Middel,1 Marianne C. Verhaar,1 Karin G. Gerritsen,3 Universiteit Utrecht, Utrecht, Netherlands;4 Universiteit Twente, Enschede, Netherlands;5 Universiteit Medisch Centrum Utrecht, Utrecht, Netherlands.

Background: Protein-bound uremic toxins (PBUTs) accumulate in plasma of end-stage kidney disease patients and are associated with a wide range of comorbidities. Their removal by conventional hemodialysis is severely limited, warranting the development of novel renal replacement therapies such as the bioartificial kidney (BAK). Recently, we developed bioengineered kidney tubules as functional BAK units capable of active PBUTs secretion via organic anion transporter-1 (OAT1). To accelerate their application, a comprehensive assessment under clinical-like conditions is essential. Here, we assessed the extent to which exposure to dialysate and uremic plasma would affect the viability and function of the kidney tubules.

Methods: Human conditionally immortalized proximal tubule epithelial cells equipped with OAT1 (cPTEC-OAT1) exposed to plasma (30min) and assessed for PBUTs clearance (indoxyl sulfate (IS), kynurenic acid (KA), L-kynurenine (L-Kyn), hippuric acid (HA) and indole-3-acetic acid (IAA)), determined by LC-MS/MS (n=7). Membrane integrity was evaluated by paracellular FITC-inulin leakage.

Results: Prolonged exposure (240min) of flat monolayers of cPTEC-OAT1 to dialysate slightly reduced the metabolic activity to 80±4% (p=0.001) and OAT1 function to 81±5% (p=0.001) and an increased LDL release (from 10±2% in controls to 15±3%, p=0.05), without inducing the release of IL-6 or IL-8. After 30min, a 3.6±0.1 fold increase in ROS production was noticed. Still, exposure of cPTEC-OAT1-containing hollow fiber membranes to dialysate enabled the concomitant clearance of five PBUTs (IS = 2980±1438; KA = 223±120; L-Kyn = 32±400; HA = 6547±1478 and IAA = 88±1±30 nmol/cm², n=6-7) without compromising the membrane integrity as observed by FITC-inulin leakage (20±4 % vs 25±5%).

Conclusions: The demonstrated functionality of bioengineered kidney tubules in PBUT clearance under clinical-like conditions advances the development of a BAK.

May the (Mechanical) Force Be with You: Modeling Shear Stress on the Glomerulus-On-a-Chip
Stefano Da Sacco,1 Owen Richfield,2 Valentina Villani,3 Geremy Clair,3 Roger E. De Filippo,1 Laura Perin,1 1Children’s Hospital of Los Angeles, Los Angeles, CA; 2Tulane University, New Orleans, LA; 3Pacific Northwest National Laboratory, Richland, WA.

Background: In the glomerulus, mechanical forces generated on glomerular endothelial cells (GEC) by the passage of blood in capillaries and by the flow of ultrafiltrate between adjacent podocytes play a critical role in regulating glomerular filtration. In vivo modeling of shear stress is difficult and traditional in vitro 2D systems are unable to faithfully replicate shear and tensile stress. We have recently developed a barrier-free glomerulus-on-a-chip (GOAC) system that closely mimics architecture, physiology and function of the GFB. In this work we have further modeled shear stress on the chip and assessed how changes in mechanical forces affect the barrier formation and function.

Methods: Mathematical modeling of the shear stress on the GOAC was performed and shear stress was calculated for standard GOAC culture conditions. Using model simulations, angle of inclination and rocking frequency of the GOAC were changed to modify shear stress, and results were assessed after 5 days. Phenotypological analysis by IF were performed and function was measured by albumin-leakage assay. Podocytes and GEC were separated by FACS and transcriptomics and proteomics analysis performed.

Results: Under standard culture conditions, time-averaged shear stress generated by rocking the GOAC is equal to 0.1Pa. By changing angle of the rocking platform, shear stress could be modulated from 0 to ~4Pa exerted on the GEC with each rocking motion. Permeability was not significantly affected by different rocking angles (but was impaired under static conditions) after 5 days. Importantly, Gene and protein expression analysis on podocytes and GEC have identified important changes in cytokines regulation, ECM-cell interaction, proliferation and transcription factors, suggesting that longer-term modification of the shear stress might significantly impact phenotypical and functional cell activity.

Conclusions: The glomerulus-on-a-chip is an ideal system to model architecture and function of the glomerular filtration barrier, including mechanical forces. Changes in shear stress affect cellular gene and protein expression in the GFB and can have long-term effects on phenotype and function. The glomerulus-on-a-chip system can provide an important in vitro tool to study the role of shear stress in physiological and pathologic conditions.

Chronic AMPK Activation Repprograms Glucose Metabolism and Oxygen Respiration in Renal Tubule Epithelial Cells
Kuniko Hunter,1 Rachel C. Evans,2 Harold D. Love,2 William H. Fissell.2 1Vanderbilt University, Nashville, TN; 2Vanderbilt University Medical Center, Nashville, TN.

Background: In vitro human renal tubule epithelial cells (HREC) exhibit a glycolytic, de-differentiated phenotype that limits their use in bioartificial kidney development. We have identified AMP-activated protein kinase (AMPK) and Transforming Growth Factor-β (TGFβ) as critical modulators of HREC differentiation. Here we show that inhibition of TGFβ signaling enhances increased respiration induced by activation of AMPK.

Methods: Primary HREC were seeded on polystyrene tissue culture plates (100,000 cells cm⁻²). After one week, cells were supplemented with AMPK activator Metformin (200μM), TGFβ receptor 1 inhibitor SB431542 (10μM), or both. After five weeks, cell oxygen consumption (OCR) and extracellular acidification rates (ECAR) were assessed using a Seahorse XF96 Analyzer and respiratory inhibitors oligomycin (2μM), CCCP (2μM), Rotenone (0.5μM), Antimycin A (0.5μM) and 2-deoxyglucose (50mM). Statistical differences were estimated by paired, two-tailed Student’s t-test in MatLab.

Results: Metformin and Combination treatments increased cell glycolytic capacity as shown in Fig 1A. Metformin and Combination treatments significantly decreased ATP-coupled respiration, while increasing maximal oxidative phosphorylation capacity and non-mitochondrial respiration capacity as shown by elevated OCR following injections of Oligomycin, CCCP, and Rotenone/Antimycin A, respectively, as shown in Fig 1B.

Conclusions: Concurrent increases in both glycolytic and oxidative phosphorylation capacity suggest AMPK activation and TGFβ inhibition modulate cell mitochondrial and non-mitochondrial metabolic activity.

PO0302

An In Vitro Model of the Glomerular Filtration Barrier Using Tissue-Derived Glomerular Basement Membrane
Dan Wang, Snehal Sani, Nicholas J. Ferrell. Vanderbilt University Medical Center, Nashville, TN.

Background: The glomerular filtration barrier consists of the glomerular basement membrane (GBM), podocytes and endothelial cells that regulate kidney permeability to macromolecules. Damage to podocytes increases albumin permeability, resulting in proteinuria. Interactions between podocytes and the GBM are important for regulating glomerular permeability and are not captured in standard in vitro cell culture systems. This work aims to investigate molecular permeability of the GBM and podocytes using a novel in vitro model that incorporates decellularized GBM.

Methods: GBM substrates were made by pressure compacting decellularized glomeruli from porcine kidneys against a Transwell membrane in a stirred cell. GBM alone provided a stringent barrier to diffusion of both albumin and Ficoll. Podocytes were plated on the GBM at low and high concentrations. Transepithelial electrical resistance (TEER) was measured before molecular permeability measurements. Podocytes on GBM were imaged by staining with phalloidin and DAPI. Permeability of the GBM with and without podocytes were analyzed by measuring FITC-BSA and FITC-Ficoll diffusion through the filtration barrier.

Results: GBM characterization showed that cells are efficiently removed from the glomeruli, and the GBM retains laminin and collagen IV after decellularization. GBM alone provided a stringent barrier to diffusion of both albumin and Ficoll. Podocytes attached and spread on the GBM to further restricted albumin diffusion. TEER showed an increased resistance of GBM with podocyte compared to GBM alone. Podocytes resulted in slightly lower permeability at high seeding concentration than low concentration. Conclusions: Interactions between the GBM and podocytes are important for regulating the permeability of the glomerulus. We developed a new in vitro model of the glomerular filtration barrier that incorporates tissue derived GBM to support podocyte culture. GBM alone restricted albumin and Ficoll diffusion and incorporation of podocytes further restricted albumin diffusion. Future work will focus on the co-culture of podocytes and endothelial cells on both sides of the GBM for evaluating the permeability of the filtration barrier and evaluate how podocyte and endothelial injury regulate permeability.

**Extraction of Escherichia coli in Urine by New Static Electricity Technique In Vitro**

Tokunori Yamamoto,1 Shoichi Maruyama,1 Satoshi Morita,2 Yoshikazu Wakizaka.1,2 1Dept of nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan; 2AFI Corporation, Kyoto, Japan.

**Background:** The treatment results for sepsis are poor due to infectious diseases, and the mortality rate is over 25%. It is clinically significant that the detection identifies patient specimen primary causative organisms as promptly as possible to give appropriate antimicrobial treatment, and to save patients with serious infectious disease. However, it usually takes 2-3 days from the submission of the sample to the identification of the primary causative organism. We newly developed the device (PixeeMoTM approved by AOAC® Performance Tested Certificate No. 012002 in January 14, 2020.) with quick extraction of bacteria in drinking water by static electricity technique. In this report, we evaluated the ability of PixeeMoTM to extract E. coli from urine.

**Methods:** Samples were prepared by adding Ecoli to artificial urine. 27 mL of a dedicated buffer was added to 3 mL of the sample, and after centrifugation (8000 xg, 20 min), 27 mL of the supernatant was removed. This operation was performed 3 times. After the preparation, E. coli was extracted from each sample using PixeeMoTM less than 0.5 hour. The number of bacteria in the sample prepared on the standard agar medium was measured by colony count.

**Results:** The table shows results of the experiments. The components of artificial urine and E. coli were separable and the extraction results by PixeeMo were consistent with the culture method. It was also suggested that the detection limit concentration is 10cells / mL (Table)

**Conclusions:** The new technique could detect clinical pathological conc. of E. coli in short time less than 2.0 hour. Extremely useful possibility is suggested as the new measurement technology of sepsis to reflect a diagnosis and evaluation of treatment, curative effect, very quickly.

**Kidney Segmentation with Deep Learning in MRI of 40,000 UK Biobank Subjects**

Taro Langner,1 Andreas Östling,1 Lukas Maldonis,2 Albin K. Karlsson,1 Daniel Olmo,1 Dag Lindgren,2 Andreas H. Wallin,2 Lowe Lundin,2 Robin Strand,1 Håkan Ahlström,1,2 Joel Kullberg,1,2 1Uppsala Universitet, Uppsala, Sweden; 2Antaros Medical AB, Mölndal, Sweden.

**Background:** Kidney volume and its association to several demographic and physiological parameters are subject of ongoing research. The UK Biobank (UKB) studies over half a million volunteers, examining blood samples, lifestyle, genetics, and body composition, including medical imaging for 100,000 participants, and 10,000 repeat scans. We have developed a system for automated kidney segmentation in 40,000 currently available MRI scans for image-based measurements of parenchymal kidney volume.

**Methods:** UKB neck-to-knee body MRI has been released for 40,264 participants (52% women), aged 44-82 (mean 64) years, with BMI 14-62 (mean 27). The kidneys are imaged in two 17s breath-hold stations with a Siemens 1.5T Aera device at (224 x 174 x 44) voxels of (2.23 x 2.23 x 4.5) mm. In this work, three operators marked cortex and medulla, excluding cysts, in 122 subjects (Fig a, b) for training and validation of a 2.5D U-Net with short skip connections. This neural network learned to segment axial slices.

**Results:** The network predictions matched the references in total kidney volume for a mean error below 4% (or 10 cm³, Dice score 0.956), whereas human repeat segmentation yielded 3% (or 6 cm³, Dice score 0.962). While imaging limitations such as motion may compound this error, similar performance is expected for future UKB releases. After 30 minutes of training, the network can process all scans within two days. Exclusion of anomalies, such as 40 cases of renal fusion, left 37,468 subjects with median voxel count volumes of 277 cm³ for men and 220 cm³ for women.

**Conclusion:** The proposed system may ultimately provide measurements of left and right kidney volume for all imaged UKB subjects which can be analyzed and shared for further large-scale investigation of associations and longitudinal changes in kidney volume.

**Funding:** Other NIH Support - The Swedish Heart-Lung Foundation and Swedish Research Council (2016-01040, 2019-04756) supported this work, which used the UKB, application no. 14237., Government Support - Non-U.S.
Results: KT exposed to CM showed increased OAT1 levels (protein: 2.0±0.3-fold and mRNA: 2.8±0.5-fold). Moreover, EVs mimicked CM effects (2.6±0.4-fold), while CM EV depleted didn’t induce OAT1. EVs were shown to contain OAT1 protein and mRNA as cargo. Visual observations of KT seeded on hollow fibers with CM containing EVs, presented slightly improvement in 3D tubular structure organization with the expression of tight junction protein (ZO-1) and cell polarity (apical cell formation and Na+/K+-ATPase presence at the basolateral side) when compared with the control condition.

Conclusions: KT phenotype can be directed by renal EVs obtained from ciPTEC-OAT1. In addition, renal EVs can support KT to form tight monolayers on hollow fiber membranes. Further research is aimed at a full functional characterization of these bioengineered proximal tubules for application in BAK. PO0308

Nitric Oxide (NO) Based Urinary Catheter Balloon Inflation Solution to Prevent Urinary Tract Infection

Alexander S. Yevzlin, Karthik Ramani, Faroug Suliman. University of Michigan, Ann Arbor, MI.

Background: UTI is the most common hospital acquired infection with indwelling catheters being a major risk factor and are difficult to treat due to the formation of bacterial biofilms which are resistant to systemic antibiotics. NO is an endogenously formed gas molecule known to play a key role in preventing infection by dispersing biofilm formed by a variety of bacterial strains. In this abstract, we describe the effectiveness of a novel urinary catheter balloon inflation fluid to effectively reduce catheter associated urinary tract infections (CAUTI) by providing up to 7 days of bactericidal effect via NO release.

Methods: Our innovative approach to prevent CAUTI involves employing a balloon inflation fluid by using novel NO secreting materials based on using S-nitrosothiol type NO donors like S-nitrosoglutathione (GSNO) within the balloon of urinary catheters that slowly releases NO over a period of up to one week. The advantages of the use of NO in CAUTI prevention is its short half-life with a very low steady-state level immediately adjacent to the surface of the device required to achieve the desired anti-microbial effect with no risk of systemic effects when using NO secreting materials with fluxes that are near physiological levels.

Results: We performed in vitro studies using a Foley catheter placed in a long-necked flask with a shape resembling the urinary bladder and the urethra. (Fig 1) The Foley catheter retention balloon was filled with GSNO solution and the balloon was used to seal the neck of the flask. Then the flask was filled with synthetic urine inoculated with E. coli and incubated for seven days at 37 °C with horizontal shaking at 80 rpm. The results showed a 7-log reduction in planktonic bacterial growth (Fig 2) and a 3-log reduction in biofilm (Fig 3) of the GSNO Foley balloon solution compared to the control.

Conclusions: These data suggest that NO-based urinary catheter balloon fluid results in significant anti-microbial effects in our in vitro model of CAUTI.
dyes for proteins and aldehyde-reactive dyes for carbohydrates. We term this approach FLARE.”

Results: We first showed FLARE’s utilities in freshly fixed mouse kidney tissues (~100 μm) using super-resolution fluorescence microscopy. Within glomeruli, the carbohydrate stain specifically labeled the basement membranes of the capillary loops and the mesangial matrix, while the amine stain revealed interdigitated podocyte epithelial cells that are a major component of the glomerular filtration barrier (Fig. A). In proximal convoluted tubule, the basement membrane was also labeled by the carbohydrate stain, and the amine stain revealed mitochondria and brush border microvilli (Fig. B). Then we stained optically cleared FFPE human kidney tissues (~50 μm) without performing antigen retrieval (Fig C), revealing more general features. Furthermore, FLARE does not perturb antigenicity, where immunolabeling of proteins can be easily integrated afterwards (data not shown).

Conclusions: We have shown that FLARE reveals abundant details in a wide range of kidney tissue processing methods using super-resolution and cleared-tissue microscopy, and is compatible with other staining modalities.

PO0310
Ex Vivo Perfusion and Initial Function of a Recellularized Human-Scale Bioengineered Kidney
Joseph S. Urazasz,1 Emily C. Beck,1 Emily Russell,1 James Jaffe,1 Ron Shapiro,2 Sander Florman,2 Dominique Davidow,2 Thomas Gilbert,1 Jeff Ross.1
1Miromatrix Medical, Inc., Eden Prairie, MN; 2Mount Sinai Health System, New York, NY; 1Recanati/Miller Transplantation Institute at Mount Sinai, New York, NY.

Background: The need for more transplantable kidneys is greater than ever, with nearly 100,000 patients actively waiting for a kidney. To meet this growing demand, our team is developing a fully transplantable bioengineered kidney (BEK) by seeding cells into perfusion-decellularized porcine kidney scaffolds. Previously, orthotopic transplantation of HUVEC-only BEKs in pigs resulted in 83.3% (n=5/6 pigs) renal perfusion at 7 days post in vivo implantation. Building on these results, the focus of the current study was to recellularize the glomerulus of a clinically relevant whole kidney matrix and then assess the preliminary filtration function.

Methods: Adult porcine kidneys were decellularized via detergent perfusion through the vasculature. Primary glomerular cells were isolated from fresh porcine kidneys or rejected human kidneys. The porcine matrix was then seeded with either human umbilical vein endothelial cells (HUVECs), HUVECs and porcine glomerular cells as a model system, or HUVECs and human glomerular cells. Recellularized tissues were then cultured using a custom perfusion recellularization bioreactor until sufficient cellular coverage of the vasculature was obtained through nondestructive metabolic markers. Both HUVEC-only and co-culture BEKs were then implanted in an ex vivo blood loop for 30 minutes, where urine effluent was collected and analyzed for filtration function.

Results: Sufficient histological vascular coverage with endothelial cells and thrombore sistance with vascular patency was found for grafts with a minimum glucose consumption rate of 20 mg/hr. From the ex vivo blood loop test, the ureter effluent hematocrit concentration in the co-culture BEK was found to be undetectable. In comparison, the endothelial-only BEK and the pig’s blood hematocrit levels were both 22%. The addition of glomerular cells in the BEK restored physiological flow rates of ureter effluent.

Conclusions: These results demonstrated human cellular engraftment and growth, long-term vascular patency, sustained hemoperfusion, removal of processed filtrate, and early signs of filtration and waste clearance in BEKs, which moves the field closer to an alternative for kidney transplantation.

PO0311
Stiffening of Decellularized Tubular Basement Membrane Regulates Renal Tubular Epithelial Cell Function
Snehal Sant, Dan Wong, Nicholas J. Ferrell. Vanderbilt University Medical Center, Nashville, TN.

Background: Damage to renal proximal tubule epithelial cells (RPTEC) plays an important role in chronic kidney disease. Epithelial cells are supported by a specialized extracellular matrix called the basement membrane (BM). The structure of the BM is altered in various kidney diseases such as diabetic nephropathy and may result in increased BM stiffness. We have developed a novel cell culture model that utilizes tissue derived tubular basement membrane (TBM) with tunable stiffness as a culture substrate for RPTEC. The aim of this study was to determine if TBM stiffening promotes activation of pro-fibrotic signaling pathways and/or regulates RPTEC differentiation.

Methods: TBM was isolated from decellularized porcine kidneys. TBM cell culture substrates were made by pressure compacting the TBM on Transwell inserts. Conditionally immortalized mouse RPTEC were grown on TBM substrates. To induce stiffening, TBM was treated with the chemical crosslinker genipin. Decellularized TBM was characterized by western blot and immunofluorescence staining. Viability and morphology of RPTEC were evaluated by MTT assay. Real-time PCR was performed on RPTEC to evaluate the effect of stiffness on multiple genes related to kidney fibrosis and RPTEC differentiation.

Results: Western blot analysis of decellularized TBM showed the presence of laminin and collagen IV and absence of lamin B1 showing proper decellularization of TBM. Genipin treatments (0.05% and 0.5%) resulted in average stiffness of 2 kPa and 3.2 kPa respectively, compared to 0.5 kPa for untreated TBM. Neither decellularization nor genipin modification had a significant effect on cell viability. Pro-fibrotic downstream targets of YAP activation (CTGF, AREG, and ANKRDI) were upregulated on stiff TBM substrates. Additionally, stiffness regulated expression of cell-cell junction markers E-cadherin and N-cadherin.

Conclusions: A new cell culture model was developed using tissue derived TBM as a substrate for tubular epithelial cells. Stiffness of the TBM was tuned using genipin. Increased TBM stiffness upregulated pro-fibrotic targets of YAP activation and altered RPTEC cell differentiation. These data show that stiffness significantly affects renal tubal cell function and suggest that TBM stiffening in chronic kidney disease may play a role in disease progression.

HIF-PHI Improves Anemia and Controls Circulating FGF-23 in a CKD Model
Megan L. Noonan, Pu Ni, Rafiou Agoro, Elizabeth A. Swallow, Matthew R. Allen, Kenneth E. White. Indiana University School of Medicine, Indianapolis, IN.

Background: The phosphatase hormone FGF23 is a critical factor in chronic kidney disease-mineral and bone disorder (CKD-MBD), with elevated levels in blood associated with increased odds for patient mortality (>6-fold). Anemia is a potent driver of FGF23 expression, and patients with CKD ultimately develop anemia as the kidneys lose the ability to produce erythropoietin (EPO), in concert with FGF23-mediated alterations in mineral metabolism. Our goal was to investigate a HIF-PHI (hypoxia-inducible factor prolyl hydroxylase inhibitor) for effects on anemia-dependent FGF23 levels and key outcomes in a mouse model of CKD.

Methods: Female C57BL6 mice were fed a casein control or adenine-containing diet to induce CKD, which resulted in markedly elevated iFGF23 and BUN, hyperphosphatemia, and anemia. After 12 weeks of CKD induction, mice were treated with the HIF-PHI Bay 85-3934 (‘Bay’; Molsidurnat) at a human equivalent dose over every other day for 3 weeks.

Results: Compared to saline controls, BAY elevated serum EPO and restored CBCs to normal levels in CKD mice. iFGF23 was significantly elevated in saline-treated CKD mice (120-fold; p<0.01). Importantly, circulating iFGF23 was significantly attenuated (>60%; p=0.05) in BAY-treated mice with CKD, coinciding with downregulated renal Egr-1 expression (p<0.01). Renal 1,25dihydroxyvitamin D3 (1,25D3) was significantly reduced in BAY-treated mice with CKD (p<0.01). The basal activity of bone marker alkaline phosphatase was also reduced (p<0.01). BAY treatment significantly reduced circulating osteocalcin (p<0.01). HIF activation in osteoblasts/osteocytes is associated with increased bone mass, therefore we investigated femur trabecular parameters and cortical porosity, however saw no effect with BAY over this time course. Serum alkaline phosphatase was significantly elevated in CKD-BAY mice compared to CKD controls (p=0.01), suggesting increased osteoblast activity.

Conclusions: Collectively, these results support that resolving anemia using a HIF-PHI may improve kidney function and lower FGF23 during CKD, potentially providing modifiable outcomes beyond improving iron utilization for this patient population.

Second Harmonic Generation and Fluorescence Imaging Reveal Collagen Fibris and Cell Nuclei in Mature Randall Plaque
Victor Hugo Canela,1 Sharon B. Bledsoe,1 Seth Winfree,1 Angela R. Sabo,1 Elaine M. Worcester,2 Tarek M. El-Achkar,1 James C. Williams.1
1Indiana University School of Medicine, Indianapolis, IN; 2University of Chicago, Chicago, IL.

Background: The formation of calcium oxalate (CaOx) stones on Randall’s plaque (RP) is a common phenomenon (perhaps 25% of CaOx stones), yet this mechanism of stones formation is still poorly understood. The objective of the study was to devise novel techniques to study RP structure.

Methods: Micro CT was used to orient RP stones for decalcification and sectioning. Sections were examined for collagen using Second Harmonic Generation (SHG)
signals with multiphoton excitation. Other sections were stained with the DNA marker 7-aminomethylcoumarin D (7-AAD).

**Results:** SHG showed collagen fibrils in the plaque but not in the CaOx overgrowth region. Demineralized RP displayed autofluorescence in the far-blue region, as we have previously described in mineralized RP. Staining of plaque sections with the DNA marker, 7-AAD, confirmed the presence of cell nuclei within mature RP.

**Conclusions:** Our results show that collagen fibrils and cell nuclei are present in RP. The nature of cells and their role in plaque formation are yet to be determined. Our data suggest that these cells contain ordinary nuclear morphology and were well-preserved within the mature plaque. The presence of cell nuclei in the plaque raises critical questions about the role of apoptosis/necrosis and survival in this mineralized environment. Future studies exploring organization of collagen and the nature of cells in plaque will be invaluable in understanding plaque and stone pathogenesis.

**Treatment with β,γ-Methylenedehydrogeno 5'-Triphosphate Prevents Arterial Media Calcification in a Warfarin Rat Model**

Britt Oudebeek,1 Isabel Orriss,2 Jessal J. Patel,2 Geoffrey Van den bergh,1 Patrick D’Haese,1 Anja Verhulst.1 Universiteit Antwerpen Laboratorium voor Pathofysiologie, Wilrijk, Belgium; The Royal Veterinary College Department of Comparative Biomedical Sciences, London, United Kingdom.

**Background:** Arterial media calcification (AMC) is a severe complication in patients with chronic kidney disease, diabetes and osteoporosis. In vitro studies showed that the synthetic P2X receptor agonist β,γ-meATP is a potent inhibitor of vascular smooth muscle cell calcification. We aimed to evaluate whether β,γ-meATP prevents the development of AMC in a rat model of warfarin-induced AMC.

**Methods:** To induce AMC, rats received a diet containing 0.30% warfarin + 0.15% vitK1 throughout the entire study and were subjected to daily i.p. treatments with vehicle (n=10) or 2 mg/kg/day β,γ-meATP (n=10) from start of the study until sacrifice at wk 7. Four rats on a standard chow diet were included as a control group. Serum calcium (Ca) and phosphorus (P) levels were analyzed at sacrifice. To evaluate the bone-like switch of VSMCs, aortic mRNA expression of TNAP and SOX9 were analyzed by qPCR. AMC was evaluated by analysis of total Ca content in the arteries and quantification of the area % calcification on Von Kossa stained aortic sections. To determine arterial stiffness, ultrasound-based pulse wave velocity (PWV) was evaluated in the abdominal aorta.

**Results:** Serum P levels were unchanged in all groups while serum Ca was significantly lower in rats treated with β,γ-meATP vs vehicle group. Exposure to warfarin induced distinct calcification in the aorta and peripheral arteries in vehicle treated rats which led to an increase in PWV score. Interestingly, daily treatment with β,γ-meATP significantly reduced the Ca content in the aorta (mean ± SEM; vehicle 1.49 ± 1.5 mg Ca/g wet tissue vs β,γ-meATP 0.38 ± 0.20 mg Ca/g wet tissue; p<0.05) and peripheral vessels which was further reinforced by a significant (p<0.01) reduction in aortic Von Kossa positive area % vs vehicle group. However, β,γ-meATP did not significantly affect PWV scores. Treatment with β,γ-meATP also did not alter the mRNA expression of bone-like marker genes.

**Conclusions:** β,γ-meATP significantly decreased AMC in the aorta and peripheral vessels of warfarin exposed rats, however, without affecting the bone-like switch of VSMCs suggesting that β,γ-meATP mediates its inhibitory effects on AMC probably by interfering with the formation of Ca-P crystals via its breakdown product methylene β,γ-meATP.

**Efficacy of Oxidative Stress Inhibitor Alone or Combined Therapy with a Calcimimetic in a Rat Model of CKD-MBD**

Neil X. Chen,1 Kalisha O'Neall,2 Shruthi Srinivasan,1 Corinne E. Metzger,1 Alexander J. Stacy,1 James M. Dominguez,1 Annabel Birueto,1 Matthew R. Allen,1 Keith G. Avin,1 Sharon M. Moe,1,2 Indiana University School of Medicine, Indianapolis, IN; Rodenbach Veterans Affairs Medical Center, Indianapolis, IN.

**Background:** We previously demonstrated the role of NADPH oxidase (NOX 1 & 4) and hyperparathyroidism in the pathogenesis of arterial calcification, a component of CKD-MBD. We hypothesized that the combination of reduced NOX activity and lower PTH would have additive benefit on CKD-MBD. To test this hypothesis, we evaluated the efficacy of the NOX 1/4 inhibitor GKT137831 (GKT) alone or combination with the PTH-lowering calcimimetic KP-2326 (KP) on CKD-MBD in a slowly progressing rat model of CKD-MBD, the CP-1 rat.

**Methods:** We compared five groups of animals: 1: Normal (NL); 2: CKD; 3: CKD+GKT (60mg/kg s.q. daily); 4: CKD+ KP (0.6mg/kg i.p., 3x/wk) and 5: CKD+GKT+KP. Treatment began at 18 weeks of age (~60% NL kidney function) and ended at 28 weeks (~25% NL function). Serum biochemistries, aortic calcification and bone architecture were assessed. One Way ANOVA was used for statistical analysis.

**Results:** As expected, there was a decline in kidney function in all CKD groups compared to NL. There was no difference in serum phosphorus or calcium levels between NL and any of the CKD groups. PTH and FGF23 serum levels were elevated by 5 and 2.3 fold, respectively, in CKD rats; only KP treatment reduced PTH levels (p<0.003). Interestingly, GKT alone or combined with KP increased FGF23 levels by 2-fold in

**Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only**

Underline represents presenting author.
CKD rats (p<0.002). Serum 8-OHdG (marker of DNA oxidation) was higher in all CKD animals (p<0.01) and unaffected by treatment. There was increased aorta calcification (by 45%) and heart calcification (by 32%) in all of the CKD animal groups (p<0.01) and only GKT treatment reduced aorta calcification (p<0.03). Compared to NL, trabecular bone volume (BV/TV%) and trabecular number were lower and trabecular separation was higher in all CKD rats (p<0.001). GKT also increased trabecular separation in CKD rats (p<0.04).

Conclusions: In a progressive rat model of CKD-MBD, treatment with a NOX1/4 inhibitor (GTK) early in the course of CKD reduced aorta calcification but did not decrease oxidative stress or increased FGF23 in CKD rats. KP treatment decreased serum PTH levels in CKD, but had no effect on aorta calcification or bone architecture. There were no additive beneficial or adverse effects with the combination of KP and GKT.

Comparison of the Effects of Ferric Citrate and Intravenous Iron on Markers of Mineral and Bone Disorder and Oxidative Stress in a Rat Model of CKD

Annemarie A. Bierig,1 Neil X. Chen,1 Corinne E. Metzger,1 Alexander J. Stacy,1 Shruthi Sinnivan,1 Kalisha O. Neill,1 James M. Dominguez,2 Keith G. Avin,1 Matthew R. Allen,1,2 Sharon M. Moe,1,2 Indiana University School of Medicine, Indianapolis, IN; 2Richard L Roudebush VA Medical Center, Indianapolis, IN.

Background: Anemia and chronic kidney disease-mineral and bone disorder (CKD-MBD) are common in CKD. Ferric citrate is an oral therapy approved as an oral iron replacement product in non-dialysis dependent CKD and as a phosphate binder for dialysis dependent CKD patients. However, studies comparing the effects of ferric citrate vs. IV iron on markers of CKD-MBD and oxidative stress in moderate CKD are limited.

Methods: We compared four groups of male rats (n=11-14 rats/group): 1) Rats with normal kidney function (NL); 2) CKD rats without iron treatment (CKD); 3) CKD rats treated with 35% ferric citrate (FCD); 4) CKD rats treated with 30mg/kg IV ferric iron sucrose (CKD + IV iron). Treatments started at 18 weeks of age (mild CKD) until euthanized at 28 weeks of age (moderate-to-advanced CKD). We determined biochemical markers of CKD-MBD, oxidative stress, bone morphology (by CT), and bone formation rate at 28 weeks. One-way ANOVA was performed with Tukey’s post hoc comparisons.

Results: Untreated and iron-treated CKD rats had higher concentrations of BUN and creatinine than NL rats. Untreated CKD rats had elevated plasma phosphorus and intact FGF23 when compared to NL. CKD+FC rats had lower plasma phosphorus and intact FGF23 while CKD+IV iron rats had lower intact FGF23 compared to CKD rats. However, the C-terminal FGF23 remained high in the untreated CKD and the CKD+IV iron rats compared to NL, but CKD+FC rats tended to be lower than the untreated CKD rats (p<0.07). PTH was elevated in the untreated and iron-treated CKD rats compared to NL. A marker of oxidative stress, 8OHdG, was increased in the untreated and iron-treated CKD rats compared to NL and was not different between iron treatments. At this stage of CKD, there was no cortical porosity in all the CKD rats compared to NL. CKD-induced alterations in trabecular and cortical bone properties and bone formation rate were not changed compared to untreated CKD rats in the iron-treated rats.

Conclusions: Ferric citrate led to more robust reductions in plasma phosphorus and FGF23 than IV iron, while neither source of iron had adverse effects on oxidative stress or bone architecture in a rat model with moderate CKD-MBD.

Upacicalcet, a Novel Non-Peptide Calcimimetic for the Treatment of Secondary Hyperparathyroidism, Has a Low Risk of Hypocalcemia

Upacicalcet also significantly decreased the serum Ca level dose-dependently at 24h and 48h after administration. However, interestingly, it bottomed out without getting too low even with 30 mg/kg of upacicalcet, 100-fold higher than the efficacious dose (0.3 mg/kg) (Table 1).

Conclusions: These findings suggest upacicalcet is a novel non-peptide positive allosteric modulator on human CaSR with a low risk of hypocalcemia for the patients with SHPT.

Influence of Vitamin D and Uremia on Functional Expression of Drug Transporters in Human Proximal Tubule Cells

Stacey M. Tuyo,1 Thomas D. Nolin,2 Melanie S. Joy,1 University of Colorado, Skaggs School of Pharmacy and Pharmaceutical Sciences, Aurora, CO; 2University of Pittsburgh, Department of Pharmacy & Therapeutics, Pittsburgh, PA.

Background: Vitamin D (ViD) deficiency is common in patients with chronic kidney disease (CKD), with prevalence rates as high as 90%. CKD and ViD have independently been shown to modulate the function and expression of various drug transporters, including drug-transport drug interactions and pharmacokinetic alterations. However, the mechanisms remain unclear how the combination of CKD and ViD alters drug transporters. The purpose of this study was to evaluate the function and expression of drug transporters in human proximal tubule cells (hPtCs) following treatment with ViD analogues under in vitro conditions employing human healthy serum (HS) and uremic serum (US) to mimic the CKD environment.

Methods: hPtCs were exposed to 10% HS or 10% US for 24 h, followed by treatment with cholecalciferol (D3) or the active form, calcitriol (1,25D3), at 100 or 440 nM concentrations or 2% ethanol vehicle control (VEH) for 5 days. RT-qPCR and immunoblotting were used to assess effects on gene and protein expression, respectively of P-gp (efflux) and OATP4C1 (uptake) transporters. Apical to basolateral (A>B) and basolateral to apical (B>A) transport was assessed in hPtCs using tranwell inserts and the reporter probe [3H]Doxorubicin (DIO).

Results: Data are shown in the Table. Compared to VEH, 1,25D3 increased P-gp gene expression under HS and US (with exception of the 240 nM concentration). 1,25D3 also increased SLC04C1 protein in HS, but no increase was demonstrated in US. B>A transport was enhanced in HS under treatment with 1,25D3.

Conclusions: These data suggest that uremia decreases OATP4C1 expression and prevents an induction of OATP4C1 expression and function by 1,25D3. Enhanced B>A transport in HS under treatment with 1,25D3, was consistent with the up-regulation of P-gp and SLC04C1. These alterations may help to inform disposition of transporter substrates under ViD treatments.

SNF472 Inhibits Heart Valve Calcification in a Novel In Vitro Method Using Porcine Whole Leaflets

SFN472 inhibits heart valve calcification in a novel in vitro method using porcine whole leaflets.

Aortic valve leaflets from commercial pig hearts were dissected free and randomly assigned to experimental groups. Valve leaflets were cultured in individual wells. Two growth media were used for cultivation: standard growth medium and an antimitroblastic growth medium. The latter was employed to inhibit contraction of the leaflet into a ball-like structure. Calcification was induced in the growth medium by supplementation with 100 μM b-glycerophosphate (control 1) but not CKD media. Leaflets were cultivated for four weeks and medium was changed every third day. To block calcification, SNF472 was used at concentrations between 1 and 100 μM. Calcium amount in leaflets after four weeks was measured by inductively coupled plasma optical emission spectroscopy.

Results: Osteoheterfermentation and calcification accumulation was in principle absent when standard medium was used. However, when the antimitroblastic medium was used, a strong calcium accumulation was induced (p=0.006 compared to controls), and this was blocked in a dose-dependent manner by the calcification inhibitor SNF472 (p<0.001 with EC50 of 3.3 μM).

Conclusions: Cultured whole leaflets of porcine aortic valves are a new in vitro model to study calcification of heart valves. This model will be useful for studying the basic mechanisms of valve calcification and to test pharmacological approaches to inhibit calcification. The latter was shown by SNF472, which strongly inhibited calcification in this model of aortic valve disease.

Anamolization of Uremic Vascular Calcification After Experimental Aortic Transplantation

Maria L. Mac;1 Soren Esgstrand,2 Anders Nordholm,1 Marya Morevati,1 Geert J. Behe,3 Patrick D’Haese,2 Klaus Olgaard,3 Ewa Lewin.3
3Righospitalet, København, Denmark; 1Universiteit Antwerpen, Antwerpen, Belgium; 2Herlev Hospital, Herlev, Denmark.

Background: CKD causes a shift in phenotype of the vascular smooth muscle cell (VSMC) to a bone-like secretory cell and promotes vascular calcification (VC). Our aim was to study whether VC is reversed by transplantation of a uremic calcified aorta into a healthy recipient.

Methods: A novel model of isogenic aorta transplantation in the rat was used (ATx). VC was induced in inbred Dark Agouti rats by 5/6 nephrectomy, high phosphate diet and alfloxurin treatment. The abdominal aorta of the uremic rat was transplanted into a normal rat (uremic ATx, n=16). Control groups: ATx between normal rats (normal ATx, n=9) and age-matched rats (control, n=6). Four weeks after ATx, the aorta was analyzed for genes related to the osteochondrogenic transition by RT-qPCR. Data are presented as mean±SD. mRNA levels are normalized to stabile housekeeping genes and expressed as the ratio to controls.

Results: The uremic donor rat had severe CKD with disturbed mineral and bone metabolism as well as severe aorta calcification with altered expression of genes related to the osteochondrogenic phenotype: ATx mitigated some of these genetic changes as indicated by a significant downregulation of the expression level of mineralization inhibitors and fibrosis matrix proteins. More specifically, mRNA levels of MGP (control 1.0±1.8 vs. uremic ATx 1.74±0.18, p=0.01), Spro (control 1.0±0.2 vs. uremic ATx 13.69±0.47 vs. uremic ATx 2.62±0.84), ANKH (control 1.0±0.15 vs. uremic 10.43±6.90 vs. uremic ATx 4.49±1.72), Postn (control 1.0±0.34 vs. uremic 3.39±0.77 vs. uremic ATx 1.74±0.85), Fntl (control 1.0±0.25 vs. uremic 7.26±2.49 vs. 3.02±1.45), all p<0.01. No difference in expression of these genes between control and normal ATx was noticed. The VSMC markers ACTA2 & Eln were downregulated in uremic VC with no recovery through ATx. The Wnt inhibitor sclerostin showed a trend towards downregulation by ATx. Activin A & TGF-beta were highly upregulated in uremic VC with no reversibility. Plasma biochemistry did not differ between control, normal ATx and uremic ATx.

Conclusions: Our results for the first time show downregulation of genes related to mineralization and fibrosis, indicating amelioration of uremic vasculopathy after experimental aorta transplantation.

effects of Pi versus FGFR23 to determine their contributions towards these CKD-associated pathological phenotypes in vitro models.

Methods: We subject mice with global FGFR4 deletion & wild-type littermates to an increasing dietary Pi load (0.7%, 2.0%, or 3.0%) or an adenine-rich diet (CKD model) to examine systemic inflammation, iron metabolism and skeletal muscle function. Furthermore, mice on a high Pi diet were treated with FGFR23 or Pi to examine activation of downstream signaling events & expression levels of specific target genes. We determine if co-treatment with inhibitors of Pi uptake & of downstream mediators block these observed effects.

Results: A 3% Pi diet as well as an adenine-rich diet promote inflammation, iron dysregulation & skeletal muscle wasting in mice. Outcomes are not alleviated in FGFR4 knockout mice. Furthermore, liver Pi accumulation occurs before hyperphosphatemia, as shown by 2% Pi diet. In cultured hepatocytes, inflammatory cytokine and hepcidin expression are induced by Pi in a dose-dependent manner. Moreover, Pi activates NFκB signaling. Blocking Pi uptake & NFκB attenuates the observed Pi-induced effects.

Conclusions: We postulate in CKD, gradual elevations in serum Pi as well as tissue Pi accumulation, which may occur before detectable changes in systemic Pi, promotes inflammation & anemia by targeting the liver to induce gene programs that regulate inflammation, erythropoiesis & iron metabolism. Our study indicates these Pi effects may be FGFR4-independent. Pharmacological approaches targeting Pi uptake and excretion or Pi’s direct hepatic actions may alleviate various CKD-associated pathologies.

Extrarenal Expression of the Kidney-Related Longevity Gene, α-Klotho, in the Long-Lived Naked Mole Rat (Heterocephalus glaber): A Comparative Biology Study

Marya Morevačić,1 Soren Egstrand,2,4 Anders Nordholm,1,2 Maria L. Mace,2,4 Klaus Olgaard,4 Ewa Lewin,2,4 Righospitalet, Kobenhavn, Denmark;3 Herlev Hospital, Herlev, Denmark.

Background: The naked mole-rat (NMR) is expanding in popularity as a model for studying biomarkers of aging and mineral metabolism. NMR has a lifespan of 30 years, almost ten times longer than the mouse and rat (app. 3-4 years). α-klotho (Kl) is an aging-suppressor gene. Knockout of Kl is associated with decreased lifespan, and overexpression of this gene is linked to extended lifespan in mice. Kl is predominantly expressed in the kidney. We speculated that the expression level of this gene might play a role in the longevity of NMR. The present comparative study aimed to establish the expression level of Kl in long-living NMR vs. normal rats, Rattus norvegicus (RN).

The naked mole-rats (NMR) of Ten NMR's kindly provided by Randers Regnskov (Danish Zoo) (N=5) and Gorburnova and Selavanov laboratory (Aging Research Center, University of Rochester, USA) (N=5) were used and compared to corresponding tissues from RN (N=9).

Methods used were: qPCR, standard PCR, and Sanger sequencing.

Results: In the kidney, similar levels of Kl mRNA were observed between those two species by qPCR (RN: 0.9 ± 0.1 vs. NMR: 1.2 ± 0.2; n.s.). The expression of Kl was further examined in the lung, skin, and liver of NMR, compared to RN. There was no expression of Kl in the lung and skin of NMR. In the liver of NMR, a high expression of Kl mRNA was observed (Cy: 25) by qPCR in contrast to RN, where no expression was detected. Sanger sequencing was performed to confirm that the gene expressed in the liver was Kl. In order to ensure that this was not a truncated form of Kl, which could be a target for mRNA decay, the predicted region for alternative splicing sites for Kl was sequenced in both RN and NMR. These results indicated that this was not the case, neither in the kidney nor in the liver.

Conclusions: This comparative study showed for the first time that α-klotho is significantly expressed in the liver of NMR, while the gene is absent in the liver of RN. Thus, the expression levels of Kl in the kidney are similar in kidneys of NMR and RN. Further downstream experiments are required to clarify whether the hepatic expression of α-klotho might contribute to the longevity of the NMR.

Increased Urinary Leukocyte Esterase Distinguishes Brushite Stone Formers from Patients with Other Stone Types

Background: Compared with calcium oxalate (CaOx) stone formers (SF), patients with brushite (Br) stones have elevated neutrophil infiltration in their renal papillae which may be associated with the observed marked increase in papillary scarring and inflammation. We investigated whether a signal of neutrophil elevation in the kidney could be detected in the urine when not associated with infection.

Methods: We performed urine dipstick analyses for leukocyte esterase (LEU), an enzyme produced by neutrophils and many various forms of infection including nitric (NIT), blood (BLO) and protein (PRO). 24-hr urine specimens were tested using the Siemens Multistix 10SG dipstick read on a Clinitek Status analyzer. We measured urinary ammonia on a Beckman DxC600. We retrospectively analyzed 812 urines from 215 patients; stone type of patients was determined by stone analysis containing >50% apatite (Ap), Br CaOx or uric acid (UA), respectively. BLO, PRO and LEU measurements were on a 5 point scale (negative=0, trace=0.5, small=1, moderate=2, large=3); NIT was yes or no.

Results: In a fully adjusted ANOVA model by stone type and sex with LEU as the dependent variable, crude and BLO, PRO, NIT, sex were independent predictors of urine CaOx vs CaP urine. In turn, these events indicate patients’ urinary chemistry. Brushite SF had significantly higher LEU than CaOx or UA (Table). By chi-square, NIT was not different between the stone types (p = 0.25). Ammonia excretion was not different between stone types. Adjusting for other indicators of infection, such as ammonia, BLO, and PRO as well as the number of stone removal procedures did not abolish this difference. Dipstick LEU may serve as a urine biomarker of the inflammatory activity and neutrophil infiltration that we have observed in the kidneys of Br SF and may improve the papillary histopathology.

Funding: NIDDK Support

Heterogeneity of Mechanisms for Idiopathic Hypercalciuria in Calcium Stone Formers

George A. Helding,1,2 Elaine M. Worcester, Kristin J. Bergsland,1 Fredric L. Coe,1 University of Chicago, Chicago, IL; 2Medical College of Wisconsin, Milwaukee, WI.

Background: In past research, we have found evidence that patterns of segmental nephron tubule calcium reabsorption differ between the sexes in calcium (Ca) stone formers (SF) demonstrating a different underlying mechanism of their hypercalciuria. Whether or not these mechanisms differ between calcium oxalate (CaOx) and calcium phosphates (CaP) SF is not known.

Methods: We studied 18 CaOx SF subjects (12 male), 17 CaP SF subjects (9 male), and 25 normal (N) subjects (13 male) in both the fasted and fed state. Subjects ate a diet consisting of three isocaloric meals with hourly blood and urine samples for 14 hours. We measured endogenous and an exogenous allowance of urinary Ca to determine the calcium (Ca) reabsorption. To account for within-subject correlation due to repeated measures, generalized estimating equations (GEE) were used to estimate and test mean laboratory values between groups. Linear mixed effects models were used to model urine Ca, distally delivered Ca, absolute reabsorption of distally delivered urine Ca and urinary CaOx.

Results: In SF women, distal Ca reabsorption is decreased compared to N women, while in SF men, PT Ca reabsorption is significantly decreased with a more modest reduction in distal Ca reabsorption compared to normal men. Among female CaP SF we found an abnormality of unbound free Ca to PTH that appears to affect post PT Ca reabsorption. Among female CaP and CaOx SF and male CaOx SF we found a clear difference of urine Ca response to ultraltrate Ca concentration. This difference was absent in male CaP SF who had a unique increase in the development of distal Ca delivery on lithium reabsorption in the PT. CaOx male SF also had other PT abnormalities such as modeled urine Ca that was abnormally dependent on the urine-plasma lithium ratio. In addition, CaOx male SF had modeled lithium reabsorption that was abnormally responsive to both urine sodium, an ECF volume marker, and urine Ca concentration, presenting mediated through the Ca receptor (CaR). In contrast, CaP SF showed no abnormalities.

Conclusions: CaP and CaOx SF have differing abnormalities of Ca handling as compared to their same sex normals. In particular, phenotype specific abnormalities related to the CaSR exist in CaOx men and abnormalities related to the PTH receptor exist in CaP women.

Magnesium’s Roles in the Treatment of Hyperphosphatemia of CKD

Background: Hyperphosphatemia is causally related to atherosclerotic cardiovascular disease, the most important cause of death in all stages of renal failure and the single greatest threat to survival among ESRD patients undergoing dialysis. To meet the current K/DOQI guideline, patients use cationic binders to bind phosphate (Pi) in the gastrointestinal tract and prevent its uptake. FDA-approved phosphate binders include calcium acetate, lanthanum salts, sevelamer, and fudeside. Combination therapies of calcium and magnesium salts have the potential both for phosphate binding with reduced calcium load and for reduction in oxidative stress, vascular calcification, and bone dysfunction.

Methods: Recent literature describing treatment of hyperphosphatemia with phosphate binders composed of calcium acetate/magnesium carbonate and calcium citrate/magnesium carbonate was analyzed. The results highlight aspects of magnesium’s roles in the treatment of hyperphosphatemia of Stage 4-5 CKD and illustrate the potential benefits of these combination therapies in treatment of hyperphosphatemia.

Results: Recent clinical data strongly suggest that combinations of calcium and magnesium salts exhibit pleiotropic benefits for hyperphosphatemic Stage 4-5 CKD patients. In addition to reducing the calcium load, magnesium appears to act in the current K/DOQI guideline, patients use cationic binders to bind phosphate (Pi) in the gastrointestinal tract and prevent its uptake. FDA-approved phosphate binders include calcium acetate, lanthanum salts, sevelamer, and fudeside. Combinations of calcium and magnesium salts have the potential both for phosphate binding with reduced calcium load and for reduction in oxidative stress, vascular calcification, and bone dysfunction.

amorphous calcium phosphate to secondary (insoluble) calcite/particles containing needle-like calcium phosphate particles, higher magnesium appeared to beneficially slow the rate of conversion. (4) Analyses of bone turnover parameters suggested that higher magnesium may have supported more normal bone remodeling.

**Conclusions:** Clinical data from several sources suggest that combinations of calcium and magnesium have unique potential for providing pleiotropic benefits to Stage 4-5 CKD patients of all ages. Additional preclinical studies are underway to confirm that calcium magnesium citrates and propionates can be effectively and safely administered to hyperparathyroidic ESRD patients.

**Vitamin D Deficiency, Investigating the Connection Between Osteoporosis and CKD**

**Rafiu Dona,** John M. Greally. Albert Einstein College of Medicine, Bronx, NY.

**Background:** Chronic kidney disease (CKD) is estimated to afflict thirty-seven million people in the United States and leads to drastic alteration in bone and calcium metabolism. Metabolic bone disease is a common complication, resulting in skeletal consequences and CKD-associated osteoporosis. This occurs due to a combination of abnormalities in calcium, phosphorus, parathyroid hormone, vitamin D metabolism, and dysregulation in both bone formation, and bone resorption. One mechanism of the pathophysiology of age-associated osteoporosis is the shift in lineage commitment of mesenchymal stem cells (MSCs) towards adipsogenesis at the expense of osteogenesis. Recent studies have implicated MSCs as mediators of osteoporosis due to the disrupted endogenous stem cell lineage owing individuals, similar to other individuals with CKD.

**Methods:** We performed a re-analysis of a published single cell transcriptomics dataset investigating differentiation of MSCs to osteoblasts and adipocytes. We applied a standard pipeline from the R package “Seurat” to examine transcriptional heterogeneity of undifferentiated mesenchymal stem cells. Additionally, we tested the effects of 1,25D on MSC differentiation towards the osteogenic lineage.

**Results:** Here, we demonstrate heterogeneity of bone-marrow derived MSCs at the transcriptional level, implying potential underlying functional heterogeneity. Using single cell transcriptomics, we characterize the subpopulations of MSCs, multipotent stem cells and cells poised for differentiation. Once we confirmed this heterogeneity, we investigated stem cell priming with the vitamin D metabolite 1α,25-dihydroxyvitamin D3 (1,25D), testing the memory of a prior exposure to stem cells influenced later lineage commitment choices. Vitamin D supplementation is a common therapeutic intervention for osteoporosis, however, the key for patients with CKD-associated osteoporosis is Vitamin D deficiency is prevalent in populations at-risk for developing osteoporosis and patients already diagnosed with CKD.

**Conclusions:** This project supports the commonly used treatment for development and prevention of osteoporosis and demonstrates functional heterogeneity of MSCs. Further steps in this project will explore the response to vitamin D priming at a higher resolution by employing single cell RNA-sequencing.

**PO0330**

**Dissecting Ferric Citrate- and FGF-23-Associated Mineral Metabolism During the Anemia of CKD**

**Nurul A. Donsa,** John M. Greally. Albert Einstein College of Medicine, Bronx, NY.

**Background:** Ferric citrate (FC) is a dual therapy used in patients with chronic kidney disease (CKD). This drug is given as a phosphate (Pi) binder for dialysis-dependent CKD, and for iron deficiency anemia in non-dialysis CKD due to delivery of elemental iron. Elevated Pi and anemia both lead to increased FGF23 during CKD, however, the roles of iron and Pi are unique on CKD pathologies are unclear.

**Methods:** Iron and Pi utilization was tested in a mouse model of CKD receiving FC, with and without osteocyte deletion of FGF23 (flox-Fgf23/Dmp1Cre-). Male mice (n=4-7) with the genotype flox-Fgf23/Dmp1Cre- and -Cre were placed on a customized 0.2% adenine (AD)-containing diet for 6 weeks to induce FGF23 in the presence or absence of 0.5% Pi.

**Results:** After the diet regimen, iFGF23 increased significantly in all CKD mice (p=0.05-0.01), iFGF23 was lower in Cre+ mice fed FC (p=0.01), with Cre+ AD-only mice following a similar trend, demonstrating that the Dmp1-Cre was effective in reducing FGF23. Cre+ mice fed AD-only had higher serum Pi than Cre- controls (p=0.05), and regardless of treatment, the Cre+ mice had higher BUN (p<0.01), showing that FGF23 was required to maintain serum Pi and lessen renal disease. Total serum iron was higher in all mice receiving FC, demonstrating effectiveness of the drug. Consistent with increased serum iron in the FC fed mice, liver Tirc, BMP6, and hepcidin mRNA were increased regardless of genotype (p=0.05-0.01); liver IL6 showed decreased mRNA expression in FC fed mice (p=0.01). Key enzymes that control 1,25D production in kidney were also examined. In Cre+/+ mice fed FC the 1,25D adiabolic enzyme Cyp24a1 was higher (p=0.03-0.01), and calcitobin Cyp24a1 was lower (p=0.01), suggesting that FC may aid in restoring vitamin D metabolism in CKD.

**Conclusions:** In sum, delivery of FC during genetic reductions in FGF23 allowed the identification of FGF23-dependent and -independent actions in CKD. Loss of FGF23 was associated with higher serum Pi and worse renal function, demonstrating that FGF23 was protective of mineral metabolism, an effect independent of FC. In contrast, FGF23-dependent actions in CKD of FC included decreased serum Pi, correcting inflammation markers, and restoring the balance of Cyp24a1 and Cyp27b1 mRNAs, potentially providing beneficial effects on renal 1,25D metabolism.

CKD Decreases Cardiac PGC-1α Through Activin A Disrupting Mitochondrial Function

Matthew J. Williams,1 Kishor B. Devalaraja-Narashimha,2 Keith A. Hruska.1
1Washington University in Saint Louis School of Medicine, Saint Louis, MO; 2Regeneron Pharmaceuticals Inc, Tarrytown, NY.

Background: The CKD-MBD syndrome is a cause of cardiac risk. Our hypothesis was that a new component of the vascular disease, activin A, is responsible for systemic activation of activin receptor (ActRIIA) signaling in kidney disease, and is a mechanism of cardiac disease.

Methods: Two models of CKD were employed, Col4A5 Alport Syndrome mice and ablative CKD in Rosa26 cre ERT/+inhbafl/fl mice. Inhibition of Activin A in CKD was accomplished by either knockdown in Rosa26 cre ERT/+inhbafl/fl CKD mice or by monoclonal antibody in Alport mice. PGC-1α, mitochondrial gene expression and oxidative phosphorylation were measured by PCR and western analysis Cardiac mitochondrial respiration was measured by respirometry.

Results: In two kidney disease models, we show that activin A is the responsible ligand for cardiac and aortic ActRIIA activation in CKD. In untreated CKD mice, cardiac levels of pSmad2 and inhibin βa mRNA and preprotein (activin A monomer) were increased. Activin A inhibition, accomplished by either knockdown in Rosa26 cre ERT/+ inhbafl/fl CKD mice or by monoclonal antibody in Alport mice, prevents CKD-induced cardiac ActRIIA activation and loss of PGC-1α, the master regulator of mitochondrial biogenesis and fatty acid oxidative phosphorylation. Mitochondrial gene expression and oxidative phosphorylation were decreased by CKD but prevented by activin A inhibition in CKD. Cardiac hypertrophy by echocardiography and heart weight was increased by CKD and prevented by activin A inhibition in the absence of vascular stiffness and without change in FGF23 levels.

Conclusions: We conclude that activation of cardiac activin/ActRIIA signaling by CKD induces mitochondrial dysfunction through decreased PGC-1α which contributes to compensated cardiac hypertrophy in the early stages of CKD associated cardiac disease.

Response of Bone to Acid: Effect of Deletion of the Proton Receptor OGR1 in the Osteoblast

Nancy S. Krieger, Luojing Chen, Jennifer Becker, Michaela Chan, David A. Bushinsky. University of Rochester Medical Center Department of Medicine, Rochester, NY.

Background: Metabolic acidosis induces bone resorption by inhibiting osteoblast (OB) bone formation and stimulating osteoclast (OC) bone resorption. Mice generate large amounts of endogenous acid and we have shown that OGR1 is the proton (H+) receptor in bone and is stimulated by this endogenous acid. Mice with a global deletion of OGR1 have increased bone density which appears due to increased bone formation. There is communication between OB and OC and OGR1 is present in both. To determine if the response of OGR1 in the OB is independent of a response in OC, we generated a global deletion of cardiac OGR1 which contributes to compensated cardiac hypertrophy in the early stages of CKD associated cardiac disease.

PO0336
Using a Quantitative Systems Pharmacology Model of CKD-MBD to Guide Therapy Minimizing Calcium Flux from Bone and into Vasculature
Adam E. Gaweda,1 Michael E. Brier,1,2 Eleanor D. Lederer,1,4 1University of Louisville, Louisville, KY; 2Robley Rex VA Medical Center, Louisville, KY; 3University of Texas Southwestern Department of Internal Medicine, Dallas, TX; Dallas VA Medical Center, VA North Texas Health Care System, Dallas, TX.

Background: CKD-MBD is characterized by bone loss and vascular calcification. Pharmacologic treatment of CKD-MBD involves dosing of three agents to minimize these complications through optimal balance of Calcium (Ca), Phosphorus (P), and PTH. Having developed a Quantitative Systems Pharmacology (QSP) model of CKD-MBD, we tested the hypothesis that an AI method called Deep QLearning (DQL) in conjunction with our model can be used to determine the impact of precision therapy on the mineralization defect in patients with End Stage Renal Disease (ESRD).

Methods: Applying a quantitative systems pharmacology (QSP) model of CKD-MBD to mimic disease progression, we trained a Deep Neural Network (virtual physician) to minimize the Ca bone efflux and the Ca vascular tissue influx regardless of achieved serum Ca, P, and PTH predicted by the model. The virtual physician observed Ca, P, PTH and adjusted the doses of P binder, vitamin D, and a calcimimetic. We evaluated a trained virtual physician through simulation of CKD-MBD treatment over 18 months on a population of 100 virtual ESRD patients with varying baseline Ca, P, PTH levels, P intake, and Ca sensing receptor sensitivity.

Results: Simulations produced an average 30% decrease in bone Ca efflux and a 20% decrease in Ca influx to vascular tissue over baseline values. Average P decreased from 7.4 to 5.1 mg/dL, average Ca increased from 8.5 to 9.2 mg/dL, median PTH decreased from 1650 to 315 pg/mL.

Conclusions: Using a QSP model of CKD-MBD, we trained an AI agent to minimize the Ca fluxes from the bone and into the vascular tissue by prioritizing optimization of Ca fluxes over the achievement of specific Ca, P, and PTH levels. Our approach demonstrates beneficial synergy of Systems Biology and AI in modeling complex biological processes.

PO0338
Quantitative Systems Pharmacology Approach to the Treatment of CKD Metabolic Bone Disorder (CKD-MBD) Using Deep Learning
Adam E. Gaweda,1 Michael E. Brier,1,2 Eleanor D. Lederer,1,4 1University of Louisville, Louisville, KY; 2Robley Rex VA Medical Center, Louisville, KY; 3University of Texas Southwestern Department of Internal Medicine, Dallas, TX; 4VA North Texas Health Care System, Dallas, TX.

Background: CKD-MBD is a common comorbidity that leads to serious skeletal and cardiovascular complications. Using a Systems Biology model of CKD-MBD and Artificial Intelligence (AI) - guided precision dosing approach, we tested the hypothesis that this approach can effectively achieve recommendations for Ca, P, and PTH by balancing the administration of vitamin D and a calcimimetic when faced with varying adherence to phosphate binder dosing.

Methods: Using a Quantitative Systems Pharmacology (QSP) approach to model the disease trajectory, we trained a Deep Neural Network AI-agent to adjust doses of a P binder, vitamin D, and a calcimimetic to drive Ca, P, and PTH to recommended targets. We evaluated the agent through treatment simulation in a cohort of 100 virtual patients (defined by dietary P and sensitivity of the Ca receptor) under 3 experimental conditions: 100%, 50%, and 0% adherence to P binder prescription. Using model derived doses of vitamin D and calcimimetic, we analysed the effect of P binder adherence on achieving the recommended Ca, P, and PTH target ranges. Dose adjustments were determined by simultaneously maximizing the percent in range of Ca, P, and PTH while minimizing the changes in bone Ca efflux and vascular Ca influx. Simulations were performed over 18 months.

Results: Results are shown in Table 1.

Conclusions: Using a QSP model of CKD-MBD, we trained an AI agent to guide precision dosing of P binder, vitamin D, and calcimimetic. We validated the agent under three simulated scenarios of P binder adherence. Simulation results show that control of intestinal P absorption is paramount in treatment of CKD-MBD. Failure to control P level severely compromises ability to control vascular tissue calcification even when Ca and PTH are controlled pharmacologically.

PO0339
 Differences in 25-Hydroxyvitamin D Clearance by eGFR and Race: A Pharmacokinetic Study
Simon Hsu, Leila R. Zelnick, Yvonne S. Lin, Cora M. Best, Bryan K. Kestenbaum, Lynn M. Rose, Andrew N. Hoofnagle, Ian H. de Boer. University of Washington, Seattle, WA.

Background: 25-hydroxyvitamin D (25(OH)D) clearance is an essential yet often overlooked determinant of circulating 25(OH)D concentration, the prevailing marker of vitamin D status. Observational studies associate markers of low 25(OH)D clearance with poor clinical outcomes and suggest differences in 25(OH)D clearance by kidney function and race, but these potential variations have not been tested using gold-standard methods.

Methods: We administered intravenous deuterated 25(OH)D (d25(OH)D) in a pharmacokinetic study of 87 adults with a wide range of kidney function, including normal estimated glomerular filtration rate (eGFR ≥ 60 ml/min/1.73m2), non-dialysis chronic kidney disease (CKD; eGFR < 60 ml/min/1.73m2, n=24), and kidney failure treated with hemodialysis (n=20). We measured d25(OH)D and deuterated 24,25-dihydroxyvitamin D, concentrations 5 minutes-12 hours, and 1, 4, 7, 14, 21, 32, 42, and 56 days post-administration. We calculated 25(OH)D clearance using non-compartmental analysis of d25(OH)D concentrations over time. We re-measured 25(OH)D clearance in a subset of participants after 12-16 weeks of 2000 IU/day of oral vitamin D3 (n=18).

Results: We recruited 85 pts in 29 months and included 69 pts in the study. Mean age 50±12.4 years, 48 men, 53 caucasian (78.9%), 53 non-Hispanic black (81.5%), mean BMI 24.5, 53 caucasian (78.9%), 53 non-Hispanic black (81.5%), median dialysis vintage 55 (42 – 84). We observe a significant reduction on P, Mg, PTH, calcitomin, sclerostin, bAP and FGF23. Both Ca and alpha-kloho levels increased, with no significant changes in vitD levels. With restoring renal health (time 1) and comparing with time 0, PTH maintain the negative correlation with sclerostin (p=0.002) and the positive correlation with FGF23 (p=0.002); modify the correlation with P, becoming a negative correlation instead of positive (p=0.001) and gain new correlations with Ca (p=0.001) and vitD levels (p=0.03). Also, PTH correlated with the delta FGF23 (rho=0.4, p=0.003) and sclerostin correlated with delta PTH (p=0.01). FGF23 showed a radical statistical association with P or Ca levels after transplant, contrasting with positive associations in pre transplant (p=0.002, p<0.0001). On the contrary, sclerostin developed a new correlation with P (p=0.0004) and a negative correlation with Ca (p=0.01). We didn’t find correlations between these molecules and alpha-kloho.

Conclusions: It seems that sclerostin influences PTH levels and that PTH is the stimulus for the increase or decrease of FGF23 serum levels. Levels of Ca and P seemed to be directly influenced by the level of PTH in post transplant, and those minerals seemed to be key factors for sclerostin secretion.

Mineral Metabolism Changes in Renal Transplantation
Ana Carina Ferreira,1,2 Marco Mendes,1,2 Cecilia Silva,1 Patricia Cotovio,1 Ines Aires,1,2 David Navarro,1 Fernando C. Pereira,1 Rute M. Salvador,2 Bruna F. Correia,1,2 M. Guadalupe Cabral,2 Fernando E. Nolasco,1,2 Manuel A. Ferreira.1,2 1Hospital Curry Cabral, Lisboa, Portugal; 2Nova Medical School, Lisbon, Portugal.

Background: Successful renal transplant restores many physiological abnormalities. The aim of this study was to analyse the evolution of CKD-MBD patients (alpha-kloho, fibroblast grow factor (FGF) 23, sclerostin, parathyroid hormone (PTH), bone alkaline phosphatase (bAP), calcitomin, vitamin D (vitD), phosphorus (P), Calcium (Ca) and Magnesium (Mg)) pre and post transplantation.

Methods: Prospective cohort study of de novo renal transplant patients (pts). A inclusion and after 12 months (time 0 and 1) pts performed laboratory evaluation. The difference over the achievement of time1 - time 0) is the delta value. Associations between variables were performed by Wilcoxon matched-pairs test and Spearman correlation test. STATA software was used and p < 0.05 was considered statistically significant.

Change in Ca flux distributions over time in the simulated patient cohort.
PO0340
The Vitamin D Metabolite Ratio and Change in Bone Density and Fracture Risk in Older Adults

Charles Ginsberg,1 Ronit Katz,2 Andrew N. Hoofnagle,2 Jan M. Hughes-Austin,1 Lindsay M. Miller,1 Jessica O. Becker,2 Stephen B. Kritchekvsky,1 Michael Shlipak,1 Mark J. Sarnak,1 Joachim H. Is.1 University of California San Diego, La Jolla, CA; 2University of Washington, Seattle, WA; 3University of California San Francisco, San Francisco, CA; 4Tufts Medical Center, Boston, MA; 5Wake Forest University School of Medicine, Winston-Salem, NC.

Background: Recent studies have suggested that 25-hydroxyvitamin D [25(OH)D] may be a poor biomarker of bone health. Higher concentrations of its catabolic product 25,26-dihydroxyvitamin D [25,26(OH)2D3] and a higher ratio of 25,26(OH)2D3 to 25(OH)D (the vitamin D metabolite ratio [VMR]) may provide additional information on vitamin D receptor activity and bone health.

Methods: We measured 24,25(OH)D3, 25(OH)D3, 25(OH)D3 and serial bone densitometry scans over a 9-year period, in 761 community dwelling older adults, that participated in the Health Aging and Body Composition Study. Participants were followed for a median time of 11 years for any fractures. 24,25(OH)D3 and 25(OH)D3 were used to calculate the VMR. We used linear mixed models to assess the relationship between 24,25(OH)D3, 25(OH)D3, 25,26(OH)2D3, and the VMR with annual change in hip, lumbar and thoracic spine bone mineral density (BMD). We used Cox models to assess the relationships between these parameters and fracture risk.

Results: Study participants had mean age 75±3 years, 49% were female, 42% were black, 23% had CKD. 24,25(OH)D3 in participants with normal eGFR (71 ml/min/1.73m2, 95% CI: 16.1 125), but not in those with CKD or kidney failure (p-for-interaction = 0.052). 25(OH)D clearance did not differ after compared with before vitamin D supplementation, although lower 25(OH)D clearance was correlated with a larger increase in serum 25(OH)D concentrations following supplementation (r = 0.31).

Conclusions: Through prospective pharmaco kinetic measurements, these findings confirm impaired 25(OH)D clearance as a feature of disorder mineral metabolism in CKD, and may help understand racial differences in vitamin D metabolism. Surrogate measures of 25(OH)D clearance may allow clinicians to more accurately anticipate individual response to vitamin D supplementation.

PO0341
The Vitamin D Metabolite Ratio Is Independent of Vitamin D Binding Protein Concentration

Charles Ginsberg,1 Andrew N. Hoofnagle,2 Ronit Katz,2 Jessica O. Becker,2 Stephen B. Kritchekvsky,1 Michael Shlipak,1 Mark J. Sarnak,1 Joachim H. Is.1 University of California San Diego, La Jolla, CA; 2University of Washington, Seattle, WA; 3University of California San Francisco, San Francisco, CA; 4Tufts Medical Center, Boston, MA; 5Wake Forest University School of Medicine, Winston-Salem, NC.

Background: 25-hydroxyvitamin D [25(OH)D] may be a poor biomarker of bone health. Higher concentrations of its catabolic product 25,26-dihydroxyvitamin D [25,26(OH)2D3] and a higher ratio of 25,26(OH)2D3 to 25(OH)D (the vitamin D metabolite ratio [VMR]) may provide additional information on vitamin D receptor activity and bone health.

Methods: We measured 24,25(OH)D3, 25(OH)D3, 25,26(OH)2D3, 1,25(OH)2D3, and VDBP in 1,259 participants with normal eGFR, CKD and kidney failure respectively (p = 0.02). 25(OH)D clearance was independent of VDBP concentration, whereas VDBP was strongly directly associated with 25(OH)D concentration following supplementation (r = -0.41).

Conclusions: In diverse cohort of community dwelling older adults, the VMR was independent of vitamin D supplementation whereas VDBP was strongly directly associated with the individual vitamin D metabolite concentrations. The VMR may serve as an important biomarker of vitamin D status and clinical outcomes that can be utilized in populations with a large spectrum of VDBP concentrations.

PO0342
Meta-analysis of the Impacts of Supplementation with Nutritional Vitamin D on Mineral and Bone Markers in Non-Dialysis CKD

Joel Gunnarsson,1 Giuseppe Cianciolo,2 Rosa Lauppe,2 Philipp Csomor,2 Federico Kaisser,3 Marco Rebeco,2 Jordi Bover2 1Quantum AB, Stockholm, Sweden; 2Vifor Pharma Ltd, Glattbrugg, Switzerland; 3Fundacio Puigvert, Barcelona, Spain; 4University of Bologna, Bologna, Italy.

Background: Secondary hyperparathyroidism (SHPT) is a critical component of mineral and bone disorder in chronic kidney disease (CKD-MBD), characterized by excessive parathyroid hormone (PTH) secretion and low levels of vitamin D. Nutritional vitamin D (NVD) supplements are frequently used to treat SHPT, especially in early CKD. The objective of this meta-analysis (MA) was to evaluate the impact of NVD supplements on PTH, vitamin D (25D), calcium (Ca), phosphate (P) and fibroblast growth factor 23 (FGF23).

Methods: Study level results were pooled using a fixed effect model with inverted-variance weighting. The impact of the NVDs was measured in two ways: as change versus placebo or ‘no treatment’ and as change within the NVD study arm (before versus after NVD supplementation).

Results: Overall changes in PTH from NVD supplementation were small when measured within the NVD study arms (pooled reduction of 10.53 pg/ml, 95% confidence interval (CI): -16.33 to -4.73) but larger when compared to placebo/no treatment (reduction of 49.74 pg/ml, 95% CI: -70.17 to -29.3). NVDs tended to increase levels of 25D both within the NVD study arms (increase of 20.62 ng/ml, 95% CI: 19.58 to 21.65) and when compared to placebo/no treatment (increase of 26.87 ng/ml, 95% CI: 24.44 to 29.30). At the end of the study periods, average levels of 25D in the NVD study arms were -30 ng/ml in all but two RCTs and >50 ng/ml in only five of the included RCTs. Ca levels increased statistically significant from supplementation with NVDs versus placebo/no treatment (increase of 0.05 mg/dl, 95% CI: -0.12 to 0.34 mg/dl). Only small and statistically non-significant impacts were observed on levels of P and FGF23.

Conclusions: Our results suggest that the magnitude of 25D increase caused by NVD may be insufficient to effectively and consistently lower PTH. While supplementation with NVDs can be used to correct vitamin D insufficiency, the potential of NVDs to actively reduce PTH in ND-CKD patients with SHPT is limited.

Fibroblast Growth Factor 23 (FGF-23), Calcification Propensity, and Heart Failure with Preserved Ejection Fraction (HFpEF) in Patients with CKD: The CRIC (Chronic Renal Insufficiency Cohort) Study

Alexander S. Leidner,1 Xuan Cai,1 Leila R. Zelnick,2 Nisha Bansal,2 Andreas Pasch,3 Mayank Kansal,3 Jing Chen,3 Amanda H. Anderson,2 James H. Sondheimer,3 James P. Lash,2 Raymond R. Townsend,2 Alan S. Go,4 Frank B. Balk,2 Joel Leidner,1 Myles Wolf,2 Tamara Isakova,5 1Northwestern University Feinberg School of Medicine, Chicago, IL; 2University of Washington, Seattle, WA; 3Calcison, Bern, Switzerland; 4University of Illinois at Chicago, Chicago, IL; 5Tulane University, New Orleans, LA; 6Wayne State University, Detroit, MI; 7University of Pennsylvania, Philadelphia, PA; 8Kaiser Permanente, Oakland, CA; 9Duke University School of Medicine, Durham, NC.

Background: HFpEF represents half of all HF events and is common in patients with CKD. Given lack of treatments, identifying factors that impact HFpEF development is critical. FGF-23 is an osteocyte-derived hormone involved in phosphorous homeostasis and is implicated in HF development. Calcification propensity (TSO) is an in vitro assessment of the time for secondary calciprotein particle formation.

Methods: Multivariable adjusted Cox proportional hazards models, we investigated the associations of FGF23 and TSO with incident HFpEF. FGF23 and TSO were measured at the baseline and Year 1 visits, respectively. Incident HFpEF was
defined as ejection fraction > 50% on echocardiogram at the time of event or by a CRIC Study echocardiogram within 1 year. After excluding individuals with baseline HF and individuals with HF events prior to analyte measurement, we included 3502 and 3029 individuals for our FGF23 and T50 analyses, respectively.

Results: In the FGF23 cohort, 333 incident HFpEF events occurred over a median follow-up of 10.8 years. In the T50 cohort, 259 incident HFpEF events occurred over a median follow-up of 10.2 years. Individuals in the highest FGF23 and lowest T50 quartiles had the highest rates of incident HFpEF (Figure). When adjusted for demographics, cardiovascular risk factors and kidney function, elevated FGF23, but not T50, was independently associated with incident HFpEF (Table).

Conclusions: FGF23, but not T50, was associated with incident HFpEF in patients with CKD. These data are consistent with studies demonstrating cardiac toxicity of FGF23 and may inform future trials of HFpEF development in CKD.

PO0345
Renal Clearance of Intact and C-Terminal FGF-23 in Man
Joachim H. Is,1,2 Afonso J. Houben,1 Abraham A. Kroon,1 Peter W. de Leeuw,2 Andrew N. Hooftvlage,3 Charles Ginsberg,1 Ronit Katz,4 Alexander Bullen,1 Shilpa Sharma,1,4 University of California San Diego, La Jolla, CA; 2VMRF/VA San Diego Healthcare System, San Diego, CA; 3Maastricht Universitair Medisch Centrum+, Maastricht, Netherlands; 4University of Washington, Seattle, WA; 1University of California Los Angeles, Los Angeles, CA.

Background: The ratio of C-terminal (cfGF23) to Intact FGF23 (iGF23) is higher in persons with higher eGFR. Mechanisms are unclear. Differential renal clearance is one possibility.

Methods: Patients were referred for clinically suspected renal artery stenosis (RAS), and maintained off BP meds for 21 days before angiography. This study includes those found without RAS (N=93). Blood was obtained from the aorta (Ao) and bilat. renal veins (RV), and renal blood flow (RBF) was measured using 133Xenon washout. Single pass % reductions of each measure (Ao – RV/Ao) were 100 calculated, left and right was averaged, and multiplied by RBF to provide renal clearance in ml/min/100g kidney tissue. To determine the relative renal clearance, we calculated the cfGF23/iGF23 clearance ratio (C/I ratio) and evaluated its relationship with eGFR.

Results: Mean age was 52±11 years, 22% were women, all were white, eGFR was 77±26 ml/min/1.73m² and directly measured Cr clearance was 72 ± 42 ml/min/100g. Renal clearance of cfGF23 was similar to Cr, while iGF23 was 37% higher (C/I ratio 0.73 ± 0.10). The clearance of cfGF23 and iGF23 were directly correlated to eGFR (r=0.31 and 0.35). However, their relative clearance was similar across the range of eGFR (r=0.01). Results were similar in models adjusted for age, sex, and BMI.

Conclusions: Renal cfGF23 clearances (which measures both iGF23 and c-terminal fragments) is similar to Cr, whereas iGF23 clearance is higher, suggesting that renal clearance of c-terminal fragment clearance is low. While renal cfGF and iGF23 clearance were both reduced in persons with lower eGFR, the relative efficiency of clearance of cfGF23 vs. iGF23 appeared similar across the range of eGFR.

Single Pass Percent Reduction and Renal Clearance of C-terminal and Intact FGF23 in Man (N=93)

PO0346
Association of Changes in Levels of eGFR and Fibroblast Growth Factor 23 from Midlife to Late Life with Risk of Mortality: The ARIC Study
Amy B. Karger,1 Elizabeth Selvin,1 Pam L. Lutesy,1 Yasuyuki Honda,1,2 Kunihiro Shibata,1,2 Charles L. Selvin,3 Josef Coresh,1 Pamela L. Lutesy,1 Kunihiro Matsushita,1 Johns Hopkins University, Baltimore, MD; 3University of Minnesota, Minneapolis, MN.

Background: Aging from midlife to late-life involves the dynamics of levels of eGFR and fibroblast growth factor 23 (FGF23). Whether changes in levels of eGFR and FGF23 from midlife to late-life are independently and jointly associated with subsequent risk of mortality is unknown.

Methods: We included 5639 participants of the Atherosclerosis Risk in Communities Study who had eGFR and serum level of FGF23 measured during midlife (visit 3, 1993-1995, mean age 58 [SD, 5] years, 58% women, 23% black race) and late-life (visit 5, 2011-2013, mean age 76 years). We used Cox regression to examine the associations of past changes in levels of eGFR and FGF23 levels (in quartiles)– separately and jointly– with mortality from visit 5 (2011-2013) through December 31, 2017.

Results: The median eGFR 15-year decline (from visit 3 to 5) was 20.5 ml/min/1.73m² (from median eGFRs 87.8 to 65.7 ml/min/1.73m²). The median FGF23 increase was 17.4 pg/ml (median FGF23s 37.5 to 54.8 pg/ml). During a median follow-up of 5.5 years after visit 5, 868 participants died. Adjusted HRs of mortality were 1.93

**Intact and C-Terminal Fibroblast Growth Factor 23 Assays: Do Kidney Function, Inflammation, and Iron Deficiency Influence Relationships with Clinical Outcomes?**

Shilpa Sharma,1 Ronit Katz,2 Alexander Bullen,2 Alions J. Houwen,4 Michael Shlipak,1 Joachim H. Ix.3 1University of California Los Angeles, Los Angeles, CA; 2University of California San Diego, La Jolla, CA; 3University of California San Francisco, San Francisco, CA; 4Maastricht Universitair Medisch Centrum+ Interne Geneeskunde, Maastricht, Netherlands; 5University of Washington, Seattle, WA.

**Background:** Higher fibroblast growth factor-23 (FGF23) concentrations are associated with heart failure (HF) and mortality, but strengths of associations differ depending upon FGF23 assay type. We investigated whether iron deficiency, inflammation, and kidney function account for these differences.

**Methods:** In 844 Cardiovascular Health Study participants, using a case-cohort design, we examined associations of intact and C-terminal FGF23 with risk of mortality and HF, using modified Cox models to account for case-cohort design, adjusting sequentially by iron status, inflammation, kidney function or their combinations.

**Results:** C-terminal FGF23 more strongly correlated with ferritin (r = -0.26) and CRP (r = 0.21) than intact FGF23 (r = 0.04 & r = 0.07, respectively). The two FGF23 assays moderately correlate with one another (r = 0.47). During follow up, there were 658 deaths, and 220 incident HF events. FGF23 measured by either assay was associated with mortality in unadjusted analysis (intact FGF23 HR per two-fold higher 1.45; 1.25-1.68) to 1.16 (0.97, 1.38). Adjustment for iron deficiency and inflammation completely attenuated the association of intact FGF23 with mortality (β change from 0.99 to 0.76, 1.28) with eGF23 and albuminuria adjustment, whereas C-FGF23 went from 1.45 (1.25, 1.68) to 1.16 (0.97, 1.38). Adjustment for iron deficiency and inflammation did not meaningfully influence the differential associations of the two assays with either endpoint.

**Conclusions:** The associations of biologically active FGF23 with clinical endpoints may be weaker than previously thought.

**Funding:** NIDDK Support

**Factors Associated with Change in Fibroblast Growth Factor 23 Levels from Midlife to Late-Life: The ARIC Study**

Junichi Ishigami,1 Yasuyuki Honda,1 Amy B. Karger,2 Elizabeth Selvin,3 Josef Coresi,3 Pamela L. Lutsey,2 Kunihiro Matsushita,1 Johns Hopkins University, Baltimore, MD; 3University of Minnesota, Minneapolis, MN.

**Background:** Factors associated with change in fibroblast growth factor 23 (FGF23) levels from midlife to late-life are not well-characterized in the general population.

**Methods:** Among 5,981 participants of the Atherosclerosis Risk in Communities Study who had serum level of FGF23 measured during midlife (visit 3, 1993-1995, mean age 58 years, 58% women, 23% black race) and late-life (visit 5, 2011-2013, mean age 76 years), we explored demographic and clinical factors associated with change in FGF23 levels. Change in FGF23 levels was regressed on pre-specified factors assessed at visit 3 (age above vs. below median), sex, race, ever smoke, high BMI (BMI ≥ 30 kg/m²), hypertension, diabetes, history of CVD, and reduced eGFR (HR vs. <60 ml/min/1.73m²) using multivariable linear regression models.

**Results:** The mean FGF23 levels increased by 21.0% (95%CI, 20.3-21.6) pg/mL from 39.7 at visit 3 to 60.6 pg/mL at visit 5. Reduced eGFR, diabetes, hypertension, female, older age, and white race were significantly associated with a greater increase in FGF23 levels (Table). Although history of CVD demonstrated a similar magnitude as race, the β coefficient was not significant. We also did not observe significant associations for BMI or smoking. The associations were strongest for reduced eGFR and diabetes with similar degrees of associations (ΔFGF23, 6.7 [95%CI, 2.7 to 10.6] pg/mL for reduced eGFR and 6.7 [4.4 to 9.0] pg/mL for diabetes) independent of each other.

**Conclusions:** In addition to reduced GFR, we identified diabetes, hypertension, female, older age, and white race as predictors of an increase in FGF23 levels from midlife to late-life. Among these, the strong association of diabetes independent of kidney function deserves future investigations.

**Fibrogenesis Is Induced by Glucocorticoid Stimulation In Vivo and In Vitro: Translational Approach**

Luis Toro, Rodrigo Alzamora, Victor Barrientos, Angela Delucchi, Luis Michea. Universidad de Chile Facultad de Medicina, Santiago, Chile.

**Background:** Previous data have suggested that glucocorticoid (GC) treatment may induce plasma fibroblast growth factor 23 (FGF23). Recently, we have reported that in prepubertal renal transplantation children, chronic GC treatment was associated with increased plasma FGF23 levels, that was related to decreased bone growth in vivo and in vitro. Our objective was to evaluate whether GC treatment modulate FGF23 in adult patients.

**Methods:** Translational approach. This included an observational clinical study of patients who began GC treatment (prednisone 1 mg/kg/day), estimated glomerular filtration rate (eGFR) over 60 ml/min/1.72m². Measurements of intact FGF23 were performed before initiation and 2 months later. Also we performed in vitro and in vivo analysis with cell cultures and experimental rat models which were treated with GC, measurements of plasma and bone FGF23 expression were performed.

**Results:** We recruited 10 patients who began GC treatment. We observed a significant increase in plasma intact FGF23 levels at 2 months (57% increase as compared to baseline values): baseline values: 18.9 +/- 4.2 pg/mL; 2 months: 29.7 +/- 5.2 pg/mL; p<0.001. No significant changes in renal function were detected. Also, rats treated with prednisone had a significant increase in plasma FGF23 and bone FGF23 expression after GC treatment. Finally, pharmacological blockage of glucocorticoid receptor alpha in vitro prevented the increase of FGF23 expression in bone tissue.

**Conclusions:** Sustained glucocorticoid treatment is associated to increased FGF23 expression and plasma levels. This effect should be evaluated in larger groups of patients to evaluate its potential relevance.

PTH 1-84 and Bone Alkaline Phosphatase Are Independently Associated with Mortality, Whereas FGF-23 Predicts Dialysis Initiation in CKD Patients

Silvia M. Titan,1,2 Isabela M. Bensenson,1 Paulo Lotufo,1 Rosa M. Moyzes.1
1Universidade de Sao Paulo, Sao Paulo, Brazil; 2Tufts Medical Center, Boston, MA.

Background: Despite the fact that CKD-MBD is a risk factor for CKD morbidity and mortality, details of its role regarding the role of individual biomarkers are variable. In addition, dimensionality reduction techniques have not been applied in CKD-MBD. The aim of our study was to evaluate a panel of CKD-MBD biomarkers, namely Ca, P, PTH 1-84, FGF-23, 25-vitamin D, 1,25-vitamin D, bone alkaline phosphatase (BAP) and sclerostin, individually and collectively related to death and KRT.

Methods: Events of death and KRT in 454 participants of the Progressor Cohort (Sao Paulo, Brazil) with predominantly CKD G3 and G4 were ascertained after a median follow-up of 6 years. Those with missing values were excluded (n=25) and 4 were lost to follow-up. The association of individual CKD-MBD parameters (DiasSort® assays) and factors derived from factorial analysis was evaluated through Cox and Competitive Risk models (R package “cmpmrk”).

Results: Mean age was 68(12)y, mean eGFR was 38(15) mL/min/1.73m², 63% were male and 56% diabetic. In univariable analysis, sclerostin, BAP, PTH, and factor 1 were associated with death and 1.25vitD, DM, MI, AUC, smoking. After adjustments, BAP, PTH, and factor 1 remained associated with death, and FGF-23 remained associated with death (p<0.01). The addition of PFG-23 with interaction with P significantly improved the model fit for KRT (p=0.0046).

Conclusions: PTH and BAP are positively associated with death and improved its prediction model. This finding suggests that BAP could be reflecting not only bone turnover but also vascular calcification. FGF-23 is associated with the risk of death and improved the model fit for KRT (p=0.0046).

Parathyroid Hormone Serum Levels and Mortality Among Hemodialysis Patients in the Gulf Cooperation Council Countries: Results from the DOPPS (2012-2018)

Iasa Al-Salim,1 Mona Al Rukhaimi,1 Ali AlSalim,2 Faisal As. Shaheen,3 Saeed Al-Ghandi,4 Jamal S. Al Wakee,3 Fadwa M. Al-Ali,5 Ali Alaradi,5 Fayezy F. Alhejali,6 Yaqoob A. Almaimani,7 Essam F. Abdelhamid,8 Brian Bieber,9 Bruce M. Robinson,10 Ronald L. Pisoni.11
On behalf of the GCC-DOPPS Study Group12 1Arbor Research Collaborative for Health, Ann Arbor, MI; 2The Royal Hospital, Ministry of Health, Muscat, Oman; 3Dubai Medical College, Dubai, United Arab Emirates; 4Jahra Hospital, Jahra, Kuwait; 5DSPH, Jeddah, Saudi Arabia; 6King Abdulaziz University, Jeddah, Saudi Arabia; 7Hamad General Hospital, Doha, Qatar; 8Salmaniya Medical Complex, Manama, Bahrain; 9King Saud bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia; 10Amgen UAE, Dubai, United Arab Emirates.

Background: The prospective Dialysis Outcomes and Practice Patterns Study (DOPPS) has collected data since 2012 in all six Gulf cooperation council (GCC) countries (Bahrain, Kuwait, Oman, Qatar, Saudi Arabia, United Arab Emirates). Here, we report the relationship of PTH with mortality in the largest GCC hemodialysis (HD) patient cohort studied to date.

Methods: Data were from randomly-selected national samples of HD facilities in GCC DOPPS phases 5 and 6 (2012-2018). PTH descriptive findings and case-mix adjusted PTH-mortality Cox regression analyses were based on 1825 and 1422 randomly-selected HD patients, respectively.

Results: Mean patient age was 55 years (median dialysis vintage = 2.1 years). Median PTH ranged from 259 pg/mL (UAE) to 437 pg/mL (Kuwait), with 22% having PTH <150 pg/mL, 24% (PTH 150-300), 34% (PTH 301-700), and 20% (PTH >700 pg/mL. Patients with PTH >700 pg/mL, were younger, on dialysis longer, less likely to be diabetic, have urine<200 mL/day, prescribed 3.5 mEq/L dialysate calcium, had higher mean serum creatinine and phosphorus levels, lower white blood cell counts, and more likely to be prescribed cinacalcet, phosphate binders, or IV vitamin D. A U-shaped PTH/mortality relationship was observed with >2-fold and 1.5 fold higher adjusted HR of death at PTH>700 pg/mL and <300 pg/mL, respectively, compared to PTH 301-450 pg/mL.

Conclusions: Secondary hyperparathyroidism is highly prevalent among GCC HD patients, with a strong U-shaped PTH/mortality relationship seen at PTH <300 and >450 pg/mL. Future studies are encouraged for further understanding this PTH/mortality pattern in relation to unique aspects of the GCC HD population.

Effect of PTH Dosing Frequency and Amplitude on Bone Health: From Anabolism to Catabolism

Alhajj Cherif,1,2 Peter Kotanko.1,2 Renal Research Institute, New York, NY; 3Tuoh School of Medicine at Mount Sinai, New York, NY.

Background: In patients with chronic kidney disease or primary hyperparathyroidism, chronically elevated parathyroid hormones (PTH) levels exert catabolic effects on the bone. In contrast, PTH cycling or daily application of teriparatide (TP) promotes bone formation. These responses have important clinical and therapeutic implications. Although the anabolic effects of PTH cycling are widely accepted, the underlying dynamics are not well understood.

Methods: We developed a physiology-based model quantitating the interrelations of osteoclasts, osteoblasts and osteocytes on bone remodeling (Cherif et. al., NDT 33(1), 2018, i165-6). Using the validated model, we explore the effect of altered PTH (TP) dosing (e.g., dosing frequency and amplitude) on bone catabolism and anabolism, respectively.

Results: The model accurately predicts differential responses of anabolic and catabolic effects of continuously and intermittently elevated PTH (TP) levels, respectively. We observe that intermittent dosing of PTH with a high frequency and amplitude induces bone catabolism similar to that seen with chronically elevated PTH. We see a more than 3-fold change from baseline in osteoclastic over osteoblastic activities, resulting in catabolism. Low PTH frequency with high dosing amplitude induces both osteoclastic and osteoblastic activities, but the net result is bone anabolism. Figure 1 shows a region where high osteoclastic activities exceed osteoclastic resorption. These findings suggest the existence of optimal PTH (TP) frequency-amplitude values that enhance anabolic gains, beyond which there can be a detrimental effect on bone.

Conclusions: Our results suggest that both frequency and amplitude of PTH (TP) cycling affect the balance of catabolic and anabolic effects. Understanding the underlying mechanism of differential responses induced by intermittent and continuous levels of PTH, respectively, may provide new therapeutic options for patients and minimize unintended, unforeseen consequences of intervention.

Illustrates regions with high osteoclastic and osteoblastic activities corresponding to anabolic gains and/or catabolic loss in bone health as a function of dosing frequency and amplitude.
PO0353

Chemical Characterization and Quantitation of Circulating Intact Parathyroid Hormone and Parathyroid Hormone Fragments by High-Resolution Mass Spectrometry in Chronic Renal Failure

Kittrawee Kristemetapan, Louis A. Losbanos, Jolaine M. Hines, Katherine O’Grady, Candice Z. Ulmer, Hubert W. Vesper, Felicity T. Enders, Raymond Simms, Rajiv Kritmet, Khon Kaen University, Khon Kaen, Thailand; ‘Centers for Disease Control and Prevention, Atlanta, GA; ‘Mayo Clinic Minnesota, Rochester, MN.

Background: The precise concentrations of full-length parathyroid hormone (PTH 1-84) and the identity and concentrations of PTH fragments in patients with various stages of chronic renal failure (CRF) are unknown.

Methods: We developed a liquid chromatography-high resolution mass spectrometry (LC-HRMS) method to characterize and quantitate PTH 1-84 and PTH fragments in the serum of 221 patients with progressive renal dysfunction. Following capture by matrix-bound amino-terminal or carboxyl-terminal region-specific antibodies and elution from matrix, full-length PTH and PTH fragments were identified and quantitated using LC-HRMS. PTH was simultaneously measured using an intact PTH (iPTH) immunoassay.

Results: Full-length PTH 1-84 and eight PTH fragments (PTH 28-84, 34-77, 34-78, 34-84, and 45-84) were unequivocally identified and were shown to increase significantly when the eGFR declined to less than 17-23 mL/min/1.73 m². Serum concentrations of PTH 1-84 were similar when measured by LC-HRMS following capture by amino-terminal or carboxyl-terminal immunoisolation methods. Serum PTH 1-84 concentrations measured by LC-HRMS were significantly lower compared with PTH measured by an iPTH immunoassay in patients with eGFRs of less than 30 mL/min/1.73 m². PTH 7-84 was below the lower limit of quantitation of the method (<50 pg/mL).

Conclusions: LC-HRMS accurately quantitates full-length PTH, carboxyl-terminal PTH fragments, and mid-region PTH fragments, in the serum of patients with progressive renal failure. Serum concentrations of PTH 1-84 and PTH fragments increase when eGFR declines to less than 17-23 mL/min/1.73 m². Values measured by LC-HRMS are lower than those obtained from an iPTH immunoassay in severe CRF.

PO0354

Management of Secondary Hyperparathyroidism Among Patients Who Transition from Daily At-Home to Three-Times-Weekly Oral Cinacalcet

Steph Karpińska, Scott Sibbel, Adam G. Walker, Gilbert Marlowe, George R. Aronoff, Deborah A. Benner, Steven M. Brunelli, Francine Franks-Tentori.

Background: Results of a small phase 1 clinical trial demonstrated the safety and potential utility of 3X weekly in-center administration of cinacalcet to control secondary hyperparathyroidism (SHPT) in hemodialysis (HD) patients. Moreover, a larger observational study demonstrated comparable control of SHPT among HD patients who initiated 3X weekly cinacalcet in-center to those who initiated cinacalcet at home. The present study assessed the effectiveness of 3X weekly in-center cinacalcet among HD patients who transitioned from cinacalcet administered daily at home in the management of SHPT.

Methods: Patients included in this analysis were ≥18 years of age, receiving standard in-center HD, Medicare beneficiaries, and had 90% compliance to transitioning from daily at-home cinacalcet to cinacalcet given 3X weekly in-center (July 2018 to December 2019). Patients were followed forward in time for up to 9 months after transition to in-center cinacalcet or until loss to follow-up or end of study. Generalized linear models and 95% confidence intervals (CIs) were calculated for parathyroid hormone (PTH), calcium (Ca), and phosphorus (Phos). Hypocalcemia events were defined as Ca <8.4 mg/dL.

Results: We identified 874 qualifying HD patients who transitioned from at-home to in-center cinacalcet administration during the study period. Among patients with baseline PTH <800 pg/mL, PTH levels initially increased but stabilized after transition. Among patients with baseline PTH 800 to 1599 pg/mL and PTH >1600 pg/mL, PTH levels initially decreased but then stabilized following transition. Ca and Phos levels were generally stable for all patients following transition. Hypocalcemia was observed in approximately 25% to 38% of patients during follow-up.

Conclusions: These results suggest that SHPT can be stably maintained by transitioning patients from daily at-home cinacalcet to cinacalcet given in-center 3X per week. We postulate that increased prescription adherence is the likely factor mediating this effect.

PO0355

Real-World Experience with Etecalcitide in an Academic Dialysis Program

Dennis Hu, Benjamin Lobo, Brendan T. Bowman. University of Virginia Health System, Charlottesville, VA.

Background: High parathyroid hormone (PTH) levels may increase fracture risk, vascular calcification, and cardiovascular disease in end-stage kidney disease (ESKD) patients. Treatments include phosphorus binders, Vitamin D analogues, and cinacalcet. However, most ESKD patients persist with high PTH levels. Etecalcitide (ETC) is an injectable calcimimetic recently approved to treat hyperparathyroidism in ESKD. To date, few studies have described the safety and efficacy of ETC on calcium (Ca) and PTH levels in real world usage.

Methods: This retrospective chart review of 195 in-center HD patients describes those who received a stable dose of ETC for at least 12 consecutive weeks. ETC dose, Ca, and PTH levels were obtained monthly x 3 months prior to ETC start and up to 9 months post. 23 patients were included for 2 or more doses of ETC. Overall and severe hypocalcemia were defined as corrected Ca <8.3 and <7.5 mg/dL, respectively.

Results: See Table 1. PTH changed from +3.37% (2.5mg) to -32.57% (10mg) to -3.19% (15mg). As expected, ETC use yielded a statistically significant lower PTH when compared to pre-treatment average of 1 and 2 months pre-drug PTH values versus 3 months post drug average (p<0.0034 via t-test for related samples). Corrected Ca decreased in a dose dependent fashion from 0.22% (2.5mg) to 11.89% (15mg). Overall, hypocalcemia occurred in 36.6% of patients. Severe hypocalcemia ranged between 0% (2.5, 5, 12.5, 15mg) and 1% (7.5, 10mg).

Conclusion: Prior studies have used aggressive PTH lowering targets (>300mg/mL or >30% reduction from baseline) yielding high rates of hypocalcemia (61-68%). Our study is the first to describe results of a typical real world dosing strategy. Our results suggest that PTH levels decrease in a dose dependent fashion and severe hypocalcemia is rare at doses >10mg diminishing PTH reductions which could be due to a preponderance of patients with refractory / tertiary hyperparathyroidism. Rates of overall and severe hypocalcemia were lower here. Limitations of this study include limited adjustment for confounding variables, retrospective nature and small population at higher doses.

Funding: Other NIH Support - IR01DK107870

PO0356

The Cost Effectiveness of Alternate-Day Cinacalcet Therapy for Secondary Hyperparathyroidism (SHPT) in Hemodialysis Patients

Mohammed A. Alhomrany, Muhammed Saeed, Dujanah H. Mousa, Ali Alharbi, Saeed Al-Ghandi, Diaverum AB, Diaverum AB, Riyadh, Saudi Arabia; ‘King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia.

Background: CKD defines as abnormalities of kidney structure or function, present for more than 3 months with implication for health. Secondary hyperparathyroidism (SHPT) is one of implication of CKD, which eventuate with decrease in GFR. The initial treatment starts with incremental approach, constrain of Dietary Phosphorus, use of calcium and non-calcium phosphorus binders and additional Vit D Analogues. Next approach to Secondary hyperparathyroidism (SHPT) after poor response to initial therapy is to use Cinacalcet. Cinacalcet act by activating calcium sensing receptor of parathyroid hormone gland directly and it bypass normal physiological process. It has half-life of 30-40 hours, Cinacalcet is excreted 80% through kidney and 20% through liver.

Methods: We did prospective control study by following Dialysis patients (N=88) who were receiving alternate day Cinacalcet either by physician’s choice or due to noncompliance to home medications. We followed Intact PTH every 3 months, Serum Calcium and serum phosphorus every month after start of alternate day therapy until six months and compared it with 6 months data before start of alternate day Cinacalcet. Data was analyzed by using paired T-Test.

Results: A total of 88 patients were enrolled in the study, who were on hemodialysis for at least one year. The mean age of patients was 49.17±15.80, and 50.8 percent of them were males. The mean duration of dialysis was 6.68 ± 5.27 years and 40.9 percent of patients had diabetic nephropathy as a cause of End stage renal disease. The patients were transferred from once daily dosing to 3 times per week hemodialysis dose. The mean post hemodialysis dose of cinacalcet was 62.73 ± 27.71 mg. The baseline mean PTH value before shifting to alternate dose was 986.69 ± 503.370 mg and after was 798.24 ± 526.92 and the P value was 0.001. The mean serum calcium before was 8.28 ± 2.30 and after it was 8.72 ± 1.42 with a p value of 0.03. Serum phosphorous before and after was, 4.66 ± 1.53, 4.86 ± 1.19 with a P-value of 0.147.

Conclusion: Cinacalcet effectively controls secondary hyperparathyroidism even with modified regimen as used in our study. Cinacalcet showed significant reductions of PTH with intermittent (3/week) dosing and thus is more cost effective and has better directly observed compliance.
A Real-World Observational Study of Calcimetic Use in Hemodialysis (HD) Patients with Secondary Hyperparathyroidism (SHPT) in Europe

Bruno Fouqueray,1 Karly S. Louie,1 Matthias Kohlhe,1,2 Daniel Cezka,1 Giorgia B. Piccoli,1,2 Marianne Rix,1 Corrado Camerini,2 Johannes M. Boots,3 Andreja Marn Pernt,2 Laura Labriola,1 Jose-Vicente Torregrosa,3 Chıldodo M. Ndikumana,4 Kate Floegel,5 Amgen Ltd Uxbridge, Uxbridge, United Kingdom; 2Department of Medicine III, Division of Nephrology and Dialysis, Medical University Vienna, Vienna, Austria; 3Department of Clinical and Biological Sciences, University of Turin, Orbassano, Italy; 4Department of Nephrology, University Hospital Copenhagen, Copenhagen, Denmark; 5Department of Internal Medicine, Nephrology and dialysis, Medical University, the Netherlands, Rotterdam, Netherlands; 6Department of Nephrology, Cliniques Universitaires Saint-Luc, Universite Catholique de Louvain, Brussels, Brussels, Belgium; 7Division of Nephrology, RWTH University of Aachen, Aachen, Germany; 8Amgen GmbH, Rotkreuz, Rotkreuz, Switzerland; 9Nephrologisches Zentrum Mettmen, Gartenstrasse 8, Mettmen, Mettmen, Germany; 10Spedali Civili Brescia, Brescia, Brescia, Italy; 11University Medical Center Ljubljana, Ljubljana, Ljubljana, Slovenia; 12Nephrology and Renal Transplant Department, Hospital Clinic, University of Barcelona, Barcelona, Barcelona, Spain.

Background: Calcimetics, oral calcineal (CIN) and intravenous etelcalcetide (ETEL), are approved for treating SHPT in adult patients on maintenance HD. Data on real-world use of calcimetics are needed to provide guidance in clinical practice.

Methods: In this observational study, Chronic HD patients treated with calcimetics for >3 months were included in analyses conducted within 90 days before and after a calcimetic initiation. Data on demographics, clinical history, laboratory values and calcimetic use were abstracted from medical charts.

Results: Interim data for 503 HD (96 CIN and 407 ETEL) patients from 57 sites across 15 countries are reported. At baseline, values were within normal limits within 90 days before a calcimetic initiation, were included. Data on demographics, clinical history, laboratory values and calcimetic use were abstracted from medical charts. For ETEL, the primary outcomes were: (i) the percent change in PTH from baseline (CIN vs. ETEL); (ii) the proportion of patients achieving >30% reduction in PTH levels from baseline (CIN vs. ETEL).

Conclusions: This is the largest real-world study on calcimetics following 2016 approval of ETEL in Europe. There were marked reductions in PTH, Ca, and P levels. Gastrointestinal events did not differ between ETEL and CIN groups.

Indirect Comparison of Treatments for Secondary Hyperparathyroidism Through a Network Meta-Analysis

Joel Gunnarsson,1 Rosa Lauppe,2 Philipp Csomor,1 Astride Grava,1 Marco Soro,1 1Vifor Pharma Ltd, Glattbrugg, Switzerland; 2Quantify Research AB, Stockholm, Sweden.

Background: Secondary hyperparathyroidism (SHPT) is a complication of chronic kidney disease (CKD) affecting mineral and bone metabolism and characterized by excessive parathyroid hormone (PTH) production and parathyroid hyperplasia. Currently, there is a need for well-tolerated treatment options. The objective of this study was to compare the efficacy and safety of ERC and PCT by assessing their effect on biomarkers PTH, Ca, and phosphate.

Methods: A systematic literature search (SLR) was performed in PubMed to identify randomized controlled trials (RCTs) to be included in a Network Meta-Analysis (NMA). In all articles, the comparator groups were consisting of placebo. A quality assessment was done using the GRADE method. The treatment effects of ERC and PCT were compared using random effects in a frequentist setting, and a sensitivity analysis was performed using a Bayesian approach. The study was registered in the PROSPERO database.

Results: Nine RCTs comprising a total of 1426 patients were included in the analyses. Compared to placebo, treatment with both PCT and ERC lowered levels of PTH in a statistically significant manner. No statistically significant differences in PTH reduction were found between PCT and ERC. Treatment with PCT significantly increased calcium levels compared to placebo (effect size: 0.30 mg/dL; 95% CI: 0.21-0.40 mg/dL), while the estimated effect of ERC on calcium (effect size: 0.10 mg/dL) was not significant (95% CI: -0.43 to 0.23 mg/dL). The calculated difference of effects between treatment with PCT and ERC shows that PCT significantly raises levels of calcium by 0.2 mg/dl (95% CI: -0.37 to -0.04 mg/dl).

Conclusions: This NMA showed that ERC is non inferior in lowering PTH levels vs. PCT. ERC displayed avoidance of clinically relevant increases in serum phosphorus and calcium, offering a new and well-tolerated treatment option for the early management of SHPT in patients with HD CKD.

Parathyrodeectomy Improves Muscular Function but Not Muscle Mass in Hemodialysis Patients with Severe Hyperparathyroidism

Eduardo J. de Sa C. Filho,1 Shirley F. Crispílo,2 Carla M. Avessani,2 Rosa M. Pereira,3 Vanda Jorgetti,4 Peter Stenvingk,4 Bengt Lindholm,2 Rosilene M. Elias,2,3 Rosa M. Moyses,1 1Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil; 2Universidade No de Juho, Sao Paulo, Brazil; 3Karolinska Institutet, Stockholm, Sweden.

Background: Increased levels of parathyroid hormone (PTH) are associated with a negative impact on the bone-muscle axis including sarcopenia and osteoporosis, and it is possible that treating hyperparathyroidism (HPT) could ameliorate these disturbances. However, the effects of parathyrodeectomy (PTX) on muscle mass, strength and performance have not been thoroughly investigated. This study aims to evaluate the impact of PTX on muscle mass, strength, and performance, body fat and resting energy expenditure (REE) in patients with severe HPT.

Methods: We are prospectively evaluating muscle mass, strength and performance of 30 patients before and after 6 months of PTX by using Actigraph GT3X accelerometer, timed-up-and-go (TuG), sit-to-stand-to-sit (STS) and muscle strength tests (dynamometry). Body composition was assessed by bioelectrical impedance x-ray apparatus, and REE was examined by indirect calorimetry. Participants completed the SARC-F questionnaire.

Results: At 6 months after PTX, 20 patients who already completed the protocol, showed a significant drop in PTH ([510(1360-1885) vs. 90(38-260) pg/mL, p<0.01], a significant increase of number of days/steps ([4759(3572-6185) vs. 6343(4123-8540) p 0.01] and improvements of strength tests: IHS(27a14 vs.31±14 kg p 0.01); SP(26±15 vs.31±16 kg p 0.01) and LP[24±23 vs.50±9 kg p 0.01]. In addition, there was an improvement of SARC-F score [1 parathyroid hormone value (PTH) recorded within 90 days before 90 days from parathyroidectomy. Therefore, we strongly feel that there is a need for larger controlled studies to elucidate specific guidelines for treating refractory HPT.

Indications and Justification for Parathyrodeectomy in Secondary Hyperparathyroidism

Aswin Srinivasan,4 Sangeeta Muturi,4 Shabbir Safri,4 Mahendra L. Agraharkar,1,2 University of Texas Medical Branch at Galveston, Galveston, TX; 1Baylor College of Medicine, Houston, TX; 4HCA Gulf Coast Division, Houston, TX; 3University of Houston System, Houston, TX; 2Montefiore Medical Center, Bronx, NY; 4Creighton University, Omaha, NE.

Introduction: Hyperparathyroidism (HPT) is a common complication of CKD, which is treated by diet, medications and surgery. Parathyrodeectomy (PTX) is reserved for patients with refractory HPT. There are no guidelines for the timing or type of surgery. Our findings suggest that PTH-associated sarcopenia is mediated not only by a decrease in muscle mass but also by muscle dysfunction.
Introduction: Secondary hyperparathyroidism (SHPT) is a common complication of end stage kidney disease (ESKD) causing loss of bone density through increased osteoclastic activity. Imbalanced bone resorption and peri-trabecular fibrosis causes formation of hemosiderin-laden giant cell granulomas – brown tumors. Here is a case of palatal brown tumor in an ESKD patient which led to complications of hungry bone syndrome after parathyroidectomy.

Case Description: A 57 yo F with ESKD on HD and SHPT presented with a growing palatal mass. She reported difficulty chewing and shortness of breath. A friable mass was located over the hard palate. Labs showed serum calcium (Ca) 9.5 mg/dL, PTH 4477 pg/mL, phosphate 5.1 mg/dL, and alkaline phosphatase (ALP) 1124 U/L. Parathyroid scan showed a focus of activity in the left thyroid bed. She underwent a mass resection and parathyroidectomy. Pathology revealed an atypical parathyroid adenoma without features of carcinoma. Her postoperative course was complicated by hungry bone syndrome with prolonged hypocalcemia, hypomagnesemia and hypophosphatemia which persisted despite aggressive Ca supplementation and high Ca dialysate. She was also started on teriparatide to stimulate osteoblast activity and bone formation. After a long hospital course, she was discharged on oral supplemental Ca and calcitriol with close follow-up.

Discussion: Despite the advent of effective management strategies for renal osteodystrophy, we must be mindful of brown tumors. Surgical excision with parathyroidectomy is the preferred treatment. Post-operatively, patients must be monitored for hungry bone syndrome. As bone formation increases, rising ALP levels can serve as a biomarker for increasing Ca requirements requiring escalating dosage of supplements. Teriparatide is a recombinant human PTH which can be used to augment bone density.

PO0362

A Case of a Hemodialysis Patient with Secondary Hyperparathyroidism, Effectively Treated with Cinacalcet Hydrochloride but Not with Etelcalcetide

Hironori Nakamura,1 Anayama Mariko,1 Yasushi Makino,1 Masaki Nagasawa,1 Masanori Tokumoto.1 1Department of Nephrology, Shinonoi General Hospital, Nagano, Japan; 2Department of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan.

Introduction: Although both cinacalcet hydrochloride and etelcalcetide are calcimimetics that directly inhibit the parathyroid hormone (PTH) secretion by activating the calcium (Ca)-sensing receptor, their binding sites are different.

Case Description: We report a rare case of a hemodialysis (HD) patient with secondary hyperparathyroidism, in whom cinacalcet was effective to reduce serum intact PTH (i-PTH) level but not etelcalcetide. A HD patient underwent total parathyroidectomy with autotransplantation to his right forearm 19 years ago. His i-PTH level had been almost controlled with 100 mg of cinacalcet. At a month after switching to etelcalcetide, serum i-PTH level increased from 269 pg/ml to 716 pg/ml. Although the dose of etelcalcetide was gradually increased to 45 mg/week, the maximal dose of etelcalcetide, serum i-PTH level increased to 919 pg/ml. Therefore, etelcalcetide was switched to 50 mg/day of cinacalcet, and his i-PTH level decreased to 208 pg/ml.

Discussion: Thus, the present case has resistance to etelcalcetide treatment but not cinacalcet, suggesting that his parathyroid gland might have partial deletion or mutation in the extracellular domain of the Ca-sensing receptor. Therefore, we should consider the possibility of resistance to etelcalcetide treatment while treating secondary hyperparathyroidism.

PO0363

Hypercalcemia Resulting from Spindle Cell Tumor-Induced Calcitriol Production

Tejas Gopal,1,2 Pranu Neclam,1,2 Paul C. Nader.1,3 1University of Texas at Austin, Austin, TX; 2Ascension Texas, Austin, TX; 3Austin Kidney Associates, Austin, TX.

Introduction: Less than 1% of cases of hypercalcemia of malignancy are caused by overproduction and release of 1,25-dihydroxy vitamin D (calcitriol) by tumor cells.1 Calcitriol excess has been identified most often in sarcoidosis, hematologic malignancy, and infection.2 We present a patient who developed severe hypercalcemia from a spindle cell tumor and acute kidney injury as a result of spindle cell neoplasm-mediated calcitriol excess, with normalization of serum calcium and creatinine in response to treatment with prednisone.

Case Description: A 65yo man with a history of a large retroperitoneal mass presented with malaise. He was not taking calcium or vitamin D supplements. Initial labs showed serum calcium 15.7 mg/dL, 1,25-dihydroxy Vit. D 126 pg/mL (elevated), and creatinine 4.5 mg/dL. His PTH 8 pg/mL, PTHrP 0.8 pmol/L, and 25-hydroxy Vit. D 26 ng/mL were suppressed or normal. SPEP, UPEP, serum immunofixation, and serum free light chains were unremarkable. Pathology of the mass revealed a spindle cell neoplasm embedded within fibrous stroma. Prednisone was prescribed to suppress tumor-associated calcitriol production. His serum calcitriol level fell to 33.2 pg/mL, with a serum calcium of 10.9 mg/dL, after taking prednisone 40 mg/day for 2 weeks. His calcitriol 39.2 pg/mL, calcium 8.7 mg/dL, and creatinine 0.81 mg/dL levels were normal while on prednisone 20 mg/day at 76 days after starting corticosteroids and before any anti-tumor therapy or surgical debulking.

Discussion: The conversion of 25-hydroxy Vit. D to calcitriol is catalyzed by 1-alpha hydroxylase, a phenomenon that can occur in extra-renal tissues, such as within macrophages in sarcoid tissue.3,4 We hypothesize that elevated 1-alpha hydroxylase activity in spindle tumor cells or in activated macrophages within tumor stroma was responsible for excess calcitriol production and the resultant hypercalcemia. Corticosteroids inhibit the 1-alpha hydroxylase conversion of 25-hydroxy Vit. D to calcitriol and have been used successfully to reduce malignancy-induced calcitriol production.5,6 This case provides evidence of severe hypercalcemia due to endogenous production of calcitriol associated with a large spindle cell neoplasm, with rapid normalization of both serum calcium and calcitriol levels in response to treatment with prednisone, without anti-tumor therapy or surgical debulking.
Unexplained Persistent Hypercalcemia After Liver Transplantation
Luba Muaddi, Kalathil K. Sureshkumar, Bhavna Chopra. Allegheny General Hospital - Western Pennsylvania Hospital Medical Education Consortium, Pittsburgh, PA.

Introduction: Hypercalcemia has been reported as a sequela of chronic liver disease in association with hyperbilirubinemia. Previous reports of hypercalcemia post liver transplant were thought to be potential rare complication of altered bone metabolism under intense immunosuppression and from prolonged immobilization. However the pathogenesis of this rare phenomenon has not been clarified to this date. We present cases of unexplained severe persistent hypercalcemia in three liver transplant recipients.

Case Description: Hypercalcemia post liver transplant in 3 recipients described in Table 1 and calcium trends shown in Figure 1.

Discussion: Extensive work up for hypercalcemia was negative in our patients. Although immobilization could be contributory, other unrecognized possibilities are plausible. Immunosuppression with steroids and other agents, especially cyclosporine, has been hypothesized to cause calcium imbalance by inhibiting T cell activation and transcription of interleukin-2 which are involved in bone turnover. Depletion of T cells upregulates osteoclastogenesis through prostaglandin production; by interfering with receptor activator of nuclear factor kappa ligand (RANK-L) and osteoprotegerin on osteoblasts. However, only one patient was on cyclosporine. Other, yet unidentified factors modifying calcium metabolism could be involved. We would like to draw attention to this fascinating phenomenon in order to gain more insight. Low dialysate calcium, pharmacotherapy (Calcitonin, Pamidronate and Denusomab) along with improved mobility had successfully lowered serum calcium in these patients. One patient had hypocalcemia after Denusomab administration, hence needed careful monitoring.

Descriptions of hypercalcemia cases post liver transplant.

PO0365

A Rare Case of Hyperthyroidism Presenting with Symptomatic Hypercalcemia
Sameed K. Lodhi, Sranv Sasthi, Hareem Ghazanfar. 1Carle Foundation, Urbana, IL; 2King Edward Medical University, Lahore, Pakistan.

Introduction: Primary hyperparathyroidism and hypercalcemia are by far the most common causes of hypercalcemia in clinical practice. Asymptomatic hypercalcemia with minimally raise calcium levels have been documented in 20% of cases of hyperthyroidism as well and is related to increased bone resorption by osteoclasts and subsequent release of calcium into circulation. We describe a rare case of hypercalcemia with symptomatic hypercalcemia as the first clinical manifestation.

Case Description: A 60 year old male with a history significant for chronic kidney disease, stroke and hypertension was admitted to the hospital following a syncopal event. Physical examination and baseline investigations were normal other than elevated calcium levels of 12.1 mg/dL. PTH levels and PTHp levels were normal ruling out hyperparathyroidism and paraneoplastic related hypercalcemia. Vitamin D levels were also normal. Work up for hyperthyroidism was done which showed extremely low levels of TSH (<0.005 mU/L) with elevated T3 and T4 levels (12.9 ng/dL and 5.52 ng/dL respectively). Thyroid scan was performed which showed significant thyroiditis. Thyrotrphin receptor antibody test also came positive. The patient was diagnosed with Graves’ disease based on the laboratory investigations and subsequently started on 5 mg methimazole TID. He also received one dose of zolendronic acid in the hospital. His calcium levels stabilized, falling from 12.4 to 9-10 mg/dL within 1 month. Patient received methimazole for a total of 7 months after which it was discontinued as his TSH levels (1.38 mU/mL), T3 levels (2.19 ng/dL) and T4 (0.78ng/dL) normalized. Patient further underwent radioiodine ablation for the treatment of Graves’ disease.

Discussion: In past, multiple cases have been reported of concurrent hyperparathyroidism or vitamin D deficiency in hyperthyroid patients. This case is unique as the patient presented with symptomatic hypercalcemia in the absence of other causes and in the absence of other common symptoms of hyperthyroidism. To our knowledge, only 2 cases of hyperthyroidism have been reported previously with hypercalcemia as the first clinical manifestation. Clinicians should be aware of association of hyperparathyroidism with hyperthyroidism as it will facilitate early diagnosis and appropriate intervention.

PO0366

Low Phosphate and Low Calcium Levels Predict Higher Risk for Adverse Events of Maintenance Hemodialysis
Takahiro Kuragano, Takeshi Nakanishi. Hyogo College of Medicine Kidney and dialysis, Nishinomiya, Japan.

Background: It is well known higher serum levels of phosphate (P) and calcium (Ca) associated with higher risk of cardiovascular disease (CVD) and premature death of hemodialysis (HD) patients. However, in the current situation that guidelines penetrated widely, there are few reports which investigated the association CKD-MBD related factors and adverse events of HD patients.

Methods: The study design was the multiple centers, observational study for 3 years. 989 HD patients were enrolled in this study. Hb, ferritin, creatinine, total protein, albumin, total cholesterol, Ca and P levels were measured every 3 months. High-sensitivity C-reactive protein (hsCRP) and intact-parathyroid hormone (int-PTH) were also measured every six months. The correlation between CKD-MBD factors and adverse events were evaluated by the time depended cox hazard model.

Results: 82% (P), 83% (Ca), and 78% (int-PTH) of patients were maintained in a target range. After correlated with age, sex, past history of CVD, Hb, albumin, and hsCRP, compared with the patients with target levels of P, patients with low P levels were significantly higher risk for CVD (P=0.042, HR:2.27), hospitalization (P=0.034, HR:2.44), and all caused mortality (P=0.03, HR:2.29). Compared with the patients who maintain target int-PTH levels, patients with lower (P=0.025, HR:1.46) and higher (P=0.04, HR:1.44) int-PTH were significantly higher risk for hospitalization. Furthermore, compared with the patients who maintain the target levels both of Ca and P, the patients with target Ca and low P levels (P=0.042, HR: 2.75) were significantly higher risk for CVD. And compared with the patients who maintain the target levels both of Ca and P, the patients with low Ca and low P levels (P<0.001, HR: 4.4) and target Ca and low P levels (P=0.22, HR: 2.0) were significantly higher risk for hospitalization.

Conclusions: Although after correlated by several clinical factors, we found that patients who maintain the low serum P levels beared significantly higher risk for CVD and all caused mortality than patients who maintained higher Ca and P levels. Without doubt, extremely higher serum P, Ca, and int-PTH levels should be treated according to guidelines. However, in the current situation that guidelines penetrated widely, CKD-MBD managements which considered the clinical conditions of low P, Ca, and int-PTH are needed.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: Patient level data was collected via an online, HIPAA-compliant form in June 2019 as part of an independent cohort study. A total of 1,615 patient records (789 in-center HD, 200 PD, and 26 home HD) were submitted by 159 nephrologists. Patients had been on dialysis for at least six months (Mean: 26; Median: 15) and most were in LDO-affiliated units.

Results: Patients in the consistently high group had a dialysis vintage longer than those consistently in target or in the target-high variability group (36 months vs. 23 months) and were also younger on average (53 years vs. 61 years). Those in the consistently high and high-target group (CH/HT) had a 37% higher daily pill burden (from binders) than those consistently in target. Patients dialyzing in Fresenius units were the most likely to be consistently in target (27%). Compared to those consistently in target, those in the CH/HT group were significantly more likely to have diabetes, obesity, heart failure and coronary artery disease. They were also six times as likely to have poorly controlled hypertension. Ethically also was correlated with phosphate control with a disproportionate percent of non-white patients in the consistently high and high-target variability groups.

Conclusions: Not only is hyperphosphatemia rampant at any given time, but only a small minority of patients on phosphate binders (19%) are able to achieve consistent control, most patients fluctuate in and out of target. Increased phosphate binder dosing was not associated with better control and suggests that a new approach to the management of hyperphosphatemia is warranted.

PO0368

Hyperphosphatemia with Elevated Serum FGF-23 and PTH, Reduced Calciuretic, and Normal FGF7 Concentrations Characterizes Chronic Renal Failure in Humans

Khitrawee Kritmetak,1,2 Louis A. Losbanos,3 Taylor Berent,1 Susan L. Ashrafzadeh-Kian,1 Alicia Algeciras-Schimnich,1 Jolane M. Hines,1 Ravinder Singh,1 Rajiv Kumar,1 Mayo Clinic Minnesota, Rochester, MN; 1Kohn Kaen University, Khon Kaen, Thailand.

Background: Fibroblast growth factor 23 (FGK23), a phosphatonin produced by osteocytes, regulates phosphate (Pi) homeostasis and is increased in CKD. A recent study showed plasma low serum (s) concentrations of FGF7 may contribute to hyperphosphatemia in patients with hypophosphatemia, and are elevated in some patients with tumor-induced osteomalacia and hypophosphatemia. We hypothesized that FGF7 might play a role in compensating for elevated Pi concentrations in CKD.

Methods: We measured serum concentrations of intact FGF7 (iFGF7, R&D Systems), iFGF23 (Eagle Biosciences), intact parathyroid hormone (iPTH) by enzyme-linked immunosorbent assays and determined s Pi, and 1,25-dihydroxyvitamin D (1,25(OH)2D, by mass spectrometry) among 75 non-kidney transplant patients with varied estimated glomerular filtration rate (eGFR). Relationships between these parameters and eGFR were explored.

Results: For iFGF7 of 60 or more (n=29), 45-59 (n=14), 30-44 (n=9), 25-29 (n=13), and under 15 u/mL 1.73 m2 (n=10), the median (IQR) s FGF7 concentrations were 41.9 (33-147.4), 56.4 (47-458.6), 62.9 (53.2-75.6), 117.5 (87.6-137.2), and 327.5 (195.1-456.3) pg/mL, respectively (P<0.01). At comparable eGFRs, median (IQR) s FGF7 concentrations were 46.1 (40.8-56.1), 43.1 (39.2-49.2), 45.4 (38.5-53.8), 47.7 (38.5-54.6), and 46.1 (40.8-54.6) pg/mL, respectively (P<0.01). Negative correlations between Pi (r = -0.46; P<0.01), iPTH and iFGF7 (r = -0.33; P<0.05), and a positive correlation between 1,25(OH)2D and eGFR (r = 0.51; P<0.01) were demonstrated. Significant increases in iFGF23, iPTH, and Pi were observed at eGFRs of less than 33 (95% CI, 26.40-40.05), 29 (95% CI, 22.51-35.36) and 22 mL/min/1.73 m2 (95% CI, 19.25-25.51), respectively. More significantly, significant decreases in 1,25(OH)2D were observed at eGFRs of less than 35 mL/min/1.73 m2 (95% CI, 36.57-81.43). iFGF7 concentrations did not significantly correlate with eGFR, Pi, iFGF23, iPTH, and 1,25(OH)2D.

Conclusions: Increases in serum concentrations of Pi, iFGF23, iPTH, but not iFGF7, and decreases in 1,25(OH)2D are observed as renal function declines in CKD.

PO0369

Effects of a Reduced Phosphorous Diet on the Circulating Metabolome in Healthy Adults

Shejiut Paul, Orlando M. Gutierrez. University of Alabama at Birmingham, Birmingham, AL.

Background: Excess phosphorus intake is linked to hypertension, heart failure, and disorders of bone and mineral metabolism. The reasons for these associations are unclear. Most prior work on the effects of diet phosphorus have focused on changes in specific endocrine factors in the blood. Less is known about the effects of nutritional phosphorus on the human metabolome, which represents the integrated biologic response to changes in diet.

Methods: In 37 healthy adults, we performed a global metabolomic analysis using untargeted mass spectrometry in plasma samples obtained after consuming a high phosphorus diet (1000 mg/day) for 2 weeks (considered baseline for this study) and after consuming a reduced phosphorus diet (1200 mg/day) fo 6 weeks. Metabolomic profiling was conducted by Metabolon, Inc. using standard protocols. Matched pairs t-tests were used to identify analytes that significantly changed from baseline to six weeks, with each individual serving as his or her own control.

Results: The mean age of study participants was 34±12 years, 36% were black and 49% were men. A total of 222 metabolites significantly changed from baseline to six weeks on a reduced phosphorus diet using a false discovery rate <0.05 to take into account multiple comparisons. Major analytes which differed in six-week vs. baseline samples included metabolites related to tryptophan metabolism, microbiome related biochemicals, urea cycle, bile acids, corticosteroids and androgenic steroids, and acyl carnitines. Changes in specific analytes of note within each of these pathways are depicted in the Figure.

Conclusions: In healthy adults, a reduced phosphorus diet altered metabolites related to the microbiome, urea cycle, steroid hormones, energy and lipid metabolism.

Hospital Admission Rates Among Hemodialysis Patients with Persistent Hyperphosphatemia Who Were Prescribed Changes in Phosphate Binder Treatment: A Retrospective Analysis of Real-World Data

Sagar U. Nigwekar,1 Vidhya Parameswaran,2 Linda Picciocchi,2 Claudia Mullen,2 Michael S. Anger,2 Robert J. Kossmann,1 Massachusetts General Hospital, Boston, MA; 3Fresenius Medical Care Renal Therapies Group, Waltham, MA; 1Fresenius Medical Care North America, Waltham, MA.

Background: Phosphate binders (PB) may have different formulations, potency, and pill burden, however, there is limited data on hard outcomes to support decisions in PB therapy. The goal of this retrospective analysis is to determine the rate of all-cause hospital admissions of patients who, at baseline, remained hyperphosphatemic despite treatment with sevelamer carbonate (SC) and had prescriptions to either (1) switch to monotherapy sucroferic oxihydroxyde (SO) or (2) switched to Non-SO binders [Calcium Acetate, Lanthanum Carbonate, or Ferric Citrate] or added one of these PBs to SC therapy.

Methods: Deidentified clinical and prescription data were retrospectively extracted from the Fresenius Kidney Care database and pharmacy records. All prescription changes were the result of routine clinical care. We aimed to control for selection bias by using Inverse Probability of Treatment Weighting (IPTW). This method was chosen due to its ability to balance baseline characteristics between the two groups and maintain adequate sample size.

Results: We identified 1,076 patients with baseline hyperphosphatemia despite SC prescription who switched PB therapy, including 319 patients with SO therapy and 757 patients with Non-SO therapy. Patients switched to SO had 27 fewer hospital admissions per 100 patient-years compared to patients with Non-SO therapy (Table 1).

Conclusions: In a retrospective database analysis of hemodialysis patients previously treated with sevelamer carbonate and switched to SO or Non-SO phosphate binder therapy, patients switched to SO monotherapy had a lower rate of hospital admissions than patients switched to other, non-SO phosphate binders.

An Observational Analysis of Hospital Admissions and Total Member Costs Associated with the Use of Various Phosphate Binders Used in Dialysis Patients Included in ESRD Seamless Care Organizations
Kristian C. Lindemann,1 Christina Ajala,1 Melissa M. Rosen,2 Claude Mullon,2 Robert J. Kossmann,3 Terry L. Ketchersid,2 Linda Ficciocchi,2 Fresenius Medical Care North America, Waltham, MA; 1Fresenius Medical Care Renal Therapies Group, Waltham, MA; 2Fresenius Medical Care North America, Waltham, MA.

Background: A prior observational study using real world data and estimates of hospitalization costs based on national data, found patients continuing sucralfate oxycodroxide (SO) therapy had fewer hospital admissions and expected lower healthcare costs when compared to patients switching to another phosphate binder (PB). End Stage Renal Disease (ESRD) Seamless Care Organizations (ESCOs) coordinate treatment for patients with chronic kidney disease (CKD). The purpose of this study was to review hospitalization costs and costs associated with various PBs prescribed to dialysis patients in ESCOs.

Methods: Patients included in the analysis had PBs prescribed during 2016-2018 in ESCOs along with parathyroid (PTH) levels <600 pg/ml. Aggregated utilization and cost data from 24 ESCOs were used over 3 years. Total hospital admissions and member months (MM) were used to calculate hospital admission rates and rate ratios. The statements contained in this document are solely those of the authors and do not necessarily reflect the view or policies of CMS. The authors assume responsibility for the accuracy and completeness of the information contained in this document.

Results: Hospital admission rates were found to be lower for SO (Table). Compared to MM treated with SO, an increased hospital admission rate of 11%, 20%, 32%, and 42% was observed for MM treated with SEV, CaAC, FC, and LC, respectively. In addition, the total per member per month (PMPM) healthcare costs were lower for SO ($5670) compared to FC ($5908), LAN ($6104), CaAC ($6303), and SEV ($6354), respectively.

Conclusions: Data from 24 ESCOs showed differences in hospital admission rates with the lowest rate in SO (7.97 per 100-member month (MM)) and the highest in CaAc (11.28 per 100-MM). In addition, total costs of care per MM where SO was prescribed were lower when compared to other PBs.

PO0372
Determining the Value of Pharmaceutical Treatment of Hyperphosphatemia with Phosphate Binders: A Systematic Review
Lindisella Mullon,1 Melissa M. Rosen,1 Michael S. Anger,1 Robert J. Kossmann,2 Claude Mullon,1 Fresenius Medical Care Renal Therapies Group, Waltham, MA; 1Fresenius Medical Care North America, Waltham, MA.

Background: Phosphate binders (PBs) are the primary therapeutic treatment for hyperphosphatemia in ESRD patients receiving dialysis. Medication spending on PBs has been estimated to be over $1.5 billion. There is increased focus on value-based prescribing as a method to control rising healthcare spending in the U.S. However, guidance to support such decisions is limited. The purpose of this study was to review economic evaluations of PBs to understand if specific binders are associated with greater value to patients and payers.

Methods: We conducted a systematic literature review with results restricted to economic evaluations published in English in peer reviewed journals between January 2015 and May 2020. Studies included in the review reported cost-effectiveness outcomes. Studies were included if they reported cost-effectiveness outcomes.

Results: After removing irrelevant articles and duplicates, 8 publications were found that met our inclusion criteria. Four (50%) studies compared either sevelamer carbonate (SEV) or lanthanum carbonate (LC) to calcium-based binders. SEV or LC was cost-effective compared to calcium-based binders. Two studies focused on ferric citrate (FC) with one comparing FC to the standard of care (either calcium acetate, SEV, or LC), and the other to SEV or calcium acetate. The results favored FC based on differences in the use of erythropoiesis-stimulating agents and hospitalization risk. However, these studies did not examine the potential for unsafe levels of iron absorption associated with FC use. The remaining two studies evaluated sucralfate oxycodroxide (SO). One study found SO to be cost-effective relative to SEV based on clinical trial data. The other analysis looked at patients prescribed SO for two years compared to those who discontinued use after 90 days and switched to another binder. This model estimated that SO use had the potential to be cost-saving based on reduced risk of hospitalization. We were unable to find an economic evaluation that compared the two iron-based binders, SO to FC.

Conclusions: This review demonstrates the need for more economic evaluations of phosphate binders. One of the cost-effectiveness analysis was found that compared two non-calcium binders (SO vs SEV) head-to-head. In addition to cost analyses, payers may benefit from reviewing real-world data to examine the clinical benefits of specific phosphate binders.

PO0373
Effect of Lanthanum Carbonate on Blood Pressure in CKD: The COMBINE TRIAL
Mitra Jamshidian,1 Brett Larive,1 Jennifer J. Gassman,1 Kalani L. Raphael,4 Michel Chonchol,2 Joachim H. Ix,1 Charles Ginsberg,1 Cleveland Clinic, Cleveland, OH; 1University of Colorado Denver School of Medicine, Aurora, CO; 2University of California San Diego School of Medicine, La Jolla, CA; 3University of Utah Health, Salt Lake City, UT.

Background: Higher serum phosphate concentrations are associated with vascular calcification, cardiovascular events, and all-cause mortality. Emerging data suggests that higher serum phosphate may also be associated with increased blood pressure (BP). The effect of phosphate-lowering medication on BP has not been studied in a chronic kidney disease (CKD) cohort.

Methods: We evaluated patients from the CKD Optimal Management with Binders and Nicotinamide (COMBINE) Trial, a randomized, double-blind, placebo-controlled trial of phosphate binders and/or nicotinamide in patients with eGFR 20-45 ml/min/1.73m2. Our primary end point for this analysis was 12-month change in systolic BP (SBP). Randomization to lanthanum vs non-lanthanum treatment arms was our primary predictor variable. The secondary predictor variable was 24-hour urine phosphate excretion (a marker of dietary phosphate intake).

Results: 205 participants underwent randomization. The mean ± SD baseline age was 69±12 years, eGFR was 32±7 ml/min per 1.73 m2, and SBP was 129±17 mmHg. Over the 12-month trial, compared to the non-lanthanum arms (N=102), SBP in the lanthanum arms (N=103) rose by 5 mm Hg (P value 0.0497) after adjusting for baseline BP, age, sex, baseline eGFR, clinical center and number of anti-hypertensives over time. Within the lanthanum arms SBP rose by 5 mm Hg (95% CI 1, 9 mm Hg) and diastolic BP rose by 2 mm Hg (95% CI 0.4, 4 mm Hg). BP did not change in the non-lanthanum arms. There was no association between 24-hour urine phosphate excretion and change in BP.

Conclusions: Among trial participants with moderate to severe CKD, randomization to lanthanum carbonate was associated with increased SBP. Future studies should determine whether lanthanum carbonate influences absorption of anti-hypertensive medications.

PO0374
Efficacy of Tenapanor for the Control of Serum Phosphorus in Patients with CKD on Dialysis: Novel Mechanism of Action Allows for Both Monotherapy and Dual-Mechanism Approach
David P. Rosenbaum, Yang Yang, Ardelyx Inc, Fremont, CA.

Background: Tenapanor (TEN) is an investigational, first-in-class, non-binder, phosphate absorption inhibitor being developed to control serum phosphorus (sP) in patients with chronic kidney disease (CKD) on dialysis. It has a unique mechanism of action and acts locally in the gut to inhibit the sodium-hydrogen exchanger 3 (NHE3). This results in the tightening of epithelial cell junctions, reducing paracellular uptake of phosphate, the primary pathway of phosphate absorption, thereby reducing serum phosphorus concentrations.

Methods: Two Phase 3 studies were completed. An 8-week, double-blind (DB), randomized treatment period (RT) with a 4-week placebo (PBO)-controlled randomized withdrawal period (WR) examining the efficacy of TEN as monotherapy to treat hyperphosphatemia (HP) in patients with CKD on dialysis (NCT03427125) and a 4-week, randomized, DB, PBO-controlled study examining the efficacy of TEN administered with phosphate binders (BIND) using a dual mechanism approach to treat patients with uncontrolled HP (≥5.5 mg/dL) in patients with CKD on dialysis (NCT 03824587).

Results: In the monotherapy study, 219 patients were randomized to the RT, 164 patients completed the RT, and of these, 152 (93%) completed the WR. TEN achieved the primary endpoint with a LS mean difference of -0.8% (95% CI: -1.4, -0.2, p=0.01) in sP between TEN and PBO during the WR period. Approximately 50% of the patients treated with TEN achieved a mean sP reduction of 2.56 mg/dl from baseline to the end of the RT period. In the dual mechanism study, 236 patients were randomized to treatment. At week 4, the mean change in sP was significantly greater in the TEN+BIND arm (−0.84 mg/dl v. −0.19 mg/dl in the PBO+BIND arm, p=0.0004). Twice as many patients achieved sP<5.5 mg/dl with TEN+BIND than with PBO+BIND (up to 49.1% v. up to 23.5%, p<0.01). In both studies, the most common adverse event for patients treated with TEN was low stools/diarrhea, leading to discontinuation in 7.8% and 3.4% of patients respectively.

PO0375
Efficacy and Safety of Add-on Tenapanor to Phosphate Binders for Refractory Hyperphosphatemia in Japanese Patients on Hemodialysis: A Phase 2, Double-Blind Study
Tadato Akizawa,1 Yu Sato,2 Masayuki Takamura,3 Hironori Kanda,2 Masafumi Fukakusa4 (Showa University School of Medicine, Tokyo, Japan), 2Kyoyuki Kirin Co., Ltd., Tokyo, Japan; 3Tokai University School of Medicine, Kanagawa, Japan.

Background: Among hemodialysis (HD) patients, some patients have poorly controlled serum phosphorus levels, even while using phosphate binders (PB). Tenapanor is a novel agent, which reduces phosphate uptake by selectively inhibiting sodium/hydrogen exchanger isoform NHE3 on the apical surface of the enterocytes and therefore decreasing paracellular phosphate permeability. The mechanism of action is different from conventional PB used to treat hyperphosphatemia. The additional treatment of tenapanor is expected to reduce serum phosphorus levels in HD patients with poorly managed serum phosphorus levels by PB. Here, we evaluated the efficacy and safety of adding tenapanor to PB for refractory hyperphosphatemia in patients on HD.

Methods: This was a multicenter, randomized, double-blind, placebo (PLA)-controlled, Ph2 study. The study consisted of a screening period, a 2 or 3-week observation period, and a 6-week treatment period. Patients whose serum phosphorus level was ≥6.1 and <10.0 mg/dL with PB were randomized to either tenapanor (TEN) or PB-PLA group in 1:1 ratio. Starting dose of tenapanor was 30 mg BID, which could be reduced in a step-wise manner (30, 20, 10 and 5 mg BID) at the investigator’s discretion, based on GI tolerability. The primary endpoint was the change in serum phosphorus level from baseline value at the end of treatment.

Results: 47 subjects were randomized. Mean change in serum phosphorus level from baseline was 1.99 mg/dL in the tenapanor group and 0.08 mg/dL in the PB group (95% CI: −2.89, 1.26 mg/dL, p<0.001). The achievement ratio of target serum phosphorus level (≤3.5, ≥3.0 mg/dL at the end of treatment was 87.0% in the tenapanor group and 37.5% in the PLA group. Diarrhea was the most frequent adverse event (tenapanor=65.2%; PLA=16.7%), all of which were of mild to moderate severity.

Conclusions: Tenapanor showed a significant decrease in serum phosphorus levels compared with PLA (p<0.001) under PB combination. This result suggests that coadministration of tenapanor with PB could satisfy the unmet needs to better control serum phosphorus in HD patients with refractory hyperphosphatemia.

PO0376
Tolerability of Tenapanor, an Investigational, First-in-Class, Non-Binder Therapy for the Control of Serum Phosphorus in Patients with CKD on Dialysis
David P. Rosenbaum,1 Stuart M. Sprague,2 1Ardelyx Inc, Fremont, CA; 2NorthShore University HealthSystem, Evanston, IL.

Background: Phosphate binders are associated with gastrointestinal (GI) tolerability issues including constipation, diarrhea, nausea, and vomiting. Tenapanor (TEN), a first in class non-binder therapy, blocks the paracellular absorption of phosphate in the GI tract by local inhibition of the sodium-hydrogen exchanger (NHE3), and may have a different GI profile because of its unique mechanism which also reduces dietary sodium absorption, increasing the sodium and water content of stool.

Methods: Data from a 12-week monotherapy study (TEN201), a 52-week monotherapy study (PHREEDOM), and a 4-week combination study (AMPLIFY) were analyzed to evaluate the GI tolerability of TEN. Adverse events were coded to system organ class and preferred term using the Medical Dictionary for Regulatory Activities (MedDRA). A linear mixed model with generalized estimating equations (GEE) was used to compare the primary endpoint of diarrhea incidence between the groups (least square means, 95% CI).

Results: 47 subjects were randomized. Mean change in serum phosphorus level from baseline was −1.99 mg/dL in the tenapanor group and 0.08 mg/dL in the PLA group (95%CI: −2.89, −1.26 mg/dL, p<0.001). The achievement ratio of target serum phosphorus level (≤3.5, ≥3.0 mg/dL at the end of treatment was 87.0% in the tenapanor group and 37.5% in the PLA group. Diarrhea was the most frequent adverse event (tenapanor=65.2%; PLA=16.7%), all of which were of mild to moderate severity.

Conclusions: Tenapanor showed a significant decrease in serum phosphorus levels compared with PLA (p<0.001) under PB combination. This result suggests that coadministration of tenapanor with PB could satisfy the unmet needs to better control serum phosphorus in HD patients with refractory hyperphosphatemia.

PO0377
Changes in Serum Phosphorus Among Patients Who Switch from Sevelamer Carbonate to Sucroferric Oxylolate or Other Phosphate Binders After Persistent Hyperphosphatemia
Vidhya Parameswaran,1 Linda Ficocelli,1 Claude Mullon,1 Robert J. Kossmann,2 Michael S. Anger,1 Sagar U. Nigwekar,3 1Fresenius Medical Care Renal Therapies Group, Waltham, MA; 2Fresenius Medical Care North America, Waltham, MA; 3Massachusetts General Hospital, Boston, MA.

Background: Despite being prescribed phosphate binders (PB), many HD patients have persistent hyperphosphatemia. The current analysis examines serum phosphorus (sP) and pill burden changes among patients who have 3 months of sP > 5.5 mg/dL despite prescription of sevelamer carbonate (SC) and switched to (1) sucroferric oxylolate (SO) monotherapy, or (2) Non-SO binders [Calcitral (Caltrate®) + Calcium Carbonate, or Ferric Citrate] monotherapy or added one of these PBs to SC therapy.

Methods: All deidentified clinical and prescription data were extracted retrospectively from the Fresenius Kidney Care database. Follow-up was divided into quarters (Q1-Q4) to determine mean sP and PB pills/day. We applied Propensity Score Matching (PSM), Coarsened Exact Matching (CEM), and Inverse Probability of Treatment Weighting (IPTW) to address potential confounding/seletion bias. PSM and CEM were used to match patients using overall PSM or agreement with each variable (CEM), and IPTW used weights on all patients.

Results: We identified 1,076 SC patients with baseline hyperphosphatemia who switched to SO (319 patients) and Non-SO (757 patients) PB therapy. Results from IPTW method that allowed retention of the entire sample size (n=1,076) are presented in Table 1. Application of CEM and PB pill burden method identified 197 and 257 matches for SO patients, respectively and noted results comparable to IPTW.

Conclusions: In a retrospective database analysis of HD patients with persistent hyperphosphatemia despite being prescribed SC, patients switched to SO had a mean sP decrease of 1.1 mg/dL compared to 0.79 mg/dL decrease among patients prescribed non-SO PBs. The PB pills/day decreased by 6.3 for SO-treated and 2.2 for Non-SO-treated patients.

Poster 164
Changes in Serum Phosphorus and Pill Burden in Peritoneal Dialysis (PD) Patients Treated with Sucroferric Oxyhydroxide (SO) as Part of Routine Clinical Care: A Contemporary Cohort

Kamary Kalantz-Zadeh,1 Linda Ficociello,2 Meijiao Zhou,2 Vidhya Parameswaran,2,3 Claude Mullon,2 Robert J. Kossmann.4 University of California Irvine, Orange, CA; 2Fresenius Medical Care Renal Therapies Group, Waltham, MA; 3Fresenius Medical Care North America, Waltham, MA.

Background: Previous real-world analyses of SO in PD patients (pts) included pts first prescribed SO within the first 2 years of SO availability in the US (2014 Cohort: Kalantar 2018). A more contemporary cohort of pts prescribed SO may have different patient characteristics or treatment patterns than earlier SO pts. The current retrospective study assessed changes in serum phosphorus (sP) and phosphate binder (PB) pill burden in PD pts recently and previously prescribed SO.

Methods: Included were adult Fresenius Kidney Care PD pts first prescribed SO monotherapy during 5/2018- 5/2019 with PB monotherapy during a 3-month baseline (BL), and sP measured the month before SO initiation (-M1) and 6-months of the follow-up (2108 Cohort). Means were calculated monthly (-M1, M1-M6) for PB pills/day and monthly labs and quarterly for iPTH using mixed-effects linear regression.

Results: At BL, the 2018 Cohort (n=201) included slightly older pts (52.3 vs 50.6 yrs) with shorter dialysis vintage (22 vs 29 months) and different BL PB: sevelamer (42 vs 63%), calcium acetate (35 vs 21%), lanthanum (3 vs 5%), ferric citrate (12 vs 0%), or switched PB (8 vs 11%) compared to 2014 cohort. Lower pill burden (7 vs 10) and sP (6.52 vs 6.59) at BL were observed in 2018 cohort. In the 2018 cohort, pts achieving sP≤5 mg/dL increased from 21.9% at -1M to 40.5-47.3% during follow-up and the pattern was similar in 2014 cohort (25.8% at -1 M to 35.3-44.4% at follow-up). Mean SO pill-day was higher (4.7) in 2018-2019 cohort than the 2014 cohort (4.3).

Conclusions: PD pts prescribed SO as part of routine care in 2018 and 2014 experienced significant reductions in sP, and PB pill burden, and an increase in pts with sP≤5mg/dL.

PO0382

Dose-Response Efficacy and Tolerability of Tenapanor on Hyperphosphatemia in Japanese Hemodialysis Patients: Results of a Randomized Phase 2 Study

Daijo Inaguma,1 Yu Sato,2 Masayuki Takenuma,2 Hironori Kanda,2 Masafumi Fukagawa,1 Tadao Akizawa,1 Fujita Health University School of Medicine, Aichi, Japan; 2Kyowa Kirin Co., Ltd., Tokyo, Japan; 2Tokai University School of Medicine, Kanagawa, Japan; 1Showa University School of Medicine, Tokyo, Japan.

Background: Tenapanor is a novel, non-binder, targeted therapy that reduces paracellular phosphate absorption in the gut by selectively inhibiting the intestinal sodium/hydrogen exchanger isoform NHE3. In a US clinical trial by Ardelyx, Inc., tenapanor significantly reduced serum phosphate level in hemodialysis (HD) patients with hyperphosphatemia as compared to the placebo (PLA). The purpose of this study was to confirm the efficacy, dose-response and tolerability of tenapanor on hyperphosphatemia in Japanese HD patients.

Methods: This was a multicenter, randomized, double-blind, PLA-controlled, parallel-group and dose-finding Ph2 study. The study consisted of a screening, a 2 or 3-week 1st washout (WO) period, a 6-week treatment period, and a 3-week 2nd WO period. Patients were enrolled when screening serum phosphate level was 3.5–6.0 mg/dL and increased by at least 0.1 mg/dL after 1–1.9 mg/dL after 1st WO. Thereafter patients were randomized to one of five groups (PLA, tenapanor 5 mg, 10 mg, 30 mg or 30 mg down titration (DT) twice/day). 30 mg DT group could be down-titrated in a step-wise manner to 10, 5 and 0 mg on the basis of GI tolerability. The primary endpoint was the mean change in serum phosphate level from baseline to end of treatment in each group.

Results: 207 subjects were enrolled (41 or 42 subjects were randomized to each group). The mean change in serum phosphate at the end of treatment from baseline was 0.64 mg/dL in the PLA group, −0.93 mg/dL, in the 10 mg group, −1.36 mg/dL, in the 30 mg group and −1.99 mg/dL in the 30 mg DT group (p<0.001 in all tenapanor groups vs PLA). The major adverse event was diarrhea, which occurred in a dose-dependent manner (PLA: 22.0%, tenapanor 5 mg: 57.1%, 10 mg: 65.9%, 30 mg: 76.2%, 30 mg DT: 70.7%). Most of the events were mild in severity, and, in each tenapanor group, only 1 to 3 subjects were discontinued from the study due to diarrhea.

Conclusions: Tenapanor was well tolerated in Japanese HD patients and significantly decreased serum phosphate level in a dose-dependent manner compared with PLA (p<0.01).

CKD and Vitamin D Status Alter Vitamin D Metabolism

Lauren E. Thompson,1 Stacey M. Tuoey,1 Linda Prebella;2 Raymond E. West,2 Michel Chonchol,2 Nirav A. Shah,3 Thomas D. Nolin,4 Melanie S. Joy,5 1University of Colorado Denver Skaggs School of Pharmacy and Pharmaceutical Sciences, Aurora, CO; 2University of Pittsburgh Department of Pharmacy and Therapeutics, Pittsburgh, PA; 3University of Colorado Denver Division of Renal Diseases and Hypertension, Aurora, CO; 4University of Pittsburgh Renal-Electrolyte Division, Pittsburgh, PA.

Background: Up to 90% of people with chronic kidney disease (CKD) are vitamin D (ViD) deficient. ViD is subsequently prescribed and has documented health benefits, including nephro-protective, cardio-protective and immune-protective. This paired study sought to evaluate and compare ViD metabolism in CKD patients and healthy controls (HC) under both ViD deficiency and repletion.

Results: Compared to the 2014 Cohort, the 2018 cohort (n=208) was larger (vs 424), older (56 vs 51 years with shorter dialysis vintage vs 56 months), more likely prescribed calcium acetate (42 vs 22%) and less likely prescribed sevelamer (41 vs 63%). The 2018 Cohort had better BL sP control (25.7 vs 15.6%) with sP 5.5 mg/dL, yet in both cohorts SO conversion was associated with significant reductions in sP (6.39 to 6.00 vs. 6.86 to 6.41) and PB pills/day (7.6 to 4.4 vs. 9.7 to 4.0). % pts with sP ≤ 5.5 mg/dL increased from 15.6 to 30.4% in 2014 Cohort and 25.7 to 41.3% in Cohort 2018.

Conclusions: Similar to the 2014 Cohort, a contemporary cohort of HD pts converted to SO experienced improved in sP and achieving ≤ 5.5 mg/dL with fewer PB pills/day. Physicians are prescribing SO to a broader patient population with different distributions of baseline PB therapy.

PO0384

Long-Term Safety and Efficacy of Tenapanor for the Control of Serum Phosphorus in Patients with CKD on Dialysis

Glenn M. Chertow,1 Yang Yang,1 David P. Rosenbaum,1 1Ardelyx, Inc., Fremont, CA; 2Stanford Medicine, Stanford, CA.

Background: Tenapanor (TEN) is an investigational, first-in-class, non-binder therapy that targets the primary pathway of phosphate absorption, providing a novel approach to treating hyperphosphatemia. TEN blocks the paracellular absorption of phosphate in the GI tract by local inhibition of the sodium-hydrogen exchanger isoform NHE3 and is dosed as one small pill (<12x7 mm) twice daily. Two previously conducted pivotal trials of TEN met their primary efficacy endpoint.

Methods: A 52-week study consisting of a 26-week, open-label, randomized treatment period (RT) with a 12-week placebo-controlled randomized withdrawal period (RW), followed by a 14-week open label safety extension period (SE). Patients on maintenance dialysis with serum phosphorus (sP) ≥ 6.0 mg/dL and <10 mg/dL and a 1.5 mg/dL increase in sP following washout were randomized 3:1 to receive one 30 mg TEN tablet BID or sevelamer carbonate (SEV; a safety control) dosed per package insert. At end of RT all patients in the TEN arm were re-randomized 1:1 to either TEN or placebo for the RW. Primary endpoint was the mean change in sP from the end of RT to the end of the RW and was compared between TEN and placebo for the efficacy analysis set, defined as patients demonstrating a 1.2 mg/dL decrease in sP at the end of RT.

Results: The study achieved its primary endpoint demonstrating a statistically significant difference in least squares (LS) mean sP change (-1.4 mg/dL, p=0.0001), between TEN and placebo. For the efficacy analysis set (n=131), the mean sP decreased from 7.7 mg/dL at baseline to 5.1 mg/dL at the end of the 26-week TEN treatment, with a mean reduction of 2.6 mg/dL. During the 26-week treatment period, 77% of TEN-treated patients in the intent-to-treat population (n=407) had a decrease in sP, with a mean reduction from baseline of 2.5 mg/dL. TEN was generally well tolerated; the only AE with incidence >5% during RT was loose stools/diarrhea (53.0%), the majority of which were mild-to-moderate and transient in nature. In the RT, 17.4% of tenapanor-treated patients compared to 23.4% of sevelamer-treated patients experienced a serious adverse event.

Conclusions: The trial results suggest that among patients on maintenance dialysis with hyperphosphatemia, TEN dosed one tablet twice daily is safe and efficacious as monotherapy.

Diagnosis of Static Bone Histomorphometry Parameters to Define Low Bone Turnover

Jan M. Hughes-Austin,1 Renata C. Pereira,1 Vanda Jorgetti,1 Isidro B. Salusky,2 Joachim H. Ex.1
1University of California San Diego, La Jolla, CA; 2University of California Los Angeles, Los Angeles, CA

Background: Tetracycline labeling for bone biopsy allows pathologists to measure the pace of new bone production, which is critical to defining bone pathology in CKD. In the setting of clinical fractures, bone tissue is available, but tetracycline labeling is not possible. Therefore, we sought to determine the diagnostic accuracy of static measures of bone turnover relative to that measured by tetracycline in CKD patients undergoing iliac crest biopsy and histomorphometry.

Methods: We evaluated 147 individuals ages 12.4 ± 8.9 who had undergone iliac crest bone biopsy with tetracycline labeling for clinical indications of CKD-MBD. Using the tetracycline labels under fluorescence, we defined bone formation rate relative to bone surface (bFR/BS) as our gold standard to define low bone turnover. A blinded investigator used light microscopy without fluorescence to measure static bone turnover parameters. We then compared the area under the ROC curve (AUC), sensitivity, and specificity of each bone turnover parameter with low turnover based on tetracycline using the Youden J Index, which is the point on the ROC curve farthest from the line of equality that maximizes sensitivity and specificity.

Results: Among the 147 biopsies, 35 (24%) had low bone turnover based on tetracycline. We evaluated 5 parameters available by static bone microscopy, among which Osteoblast Surface relative to Bone Surface (O/S:BS), Osteoclast Surface relative to Bone Surface (Oc/S:BS), Boster Osteoid Volume to Bone Volume (OV/IV) had the highest AUCs for low bone turnover based on tetracycline labeling. Using the best cutoffs from the AUC curves, a 0.5 S:BS of 82% had a sensitivity and specificity of 80% and 75% for low bone turnover.

Conclusions: Static measures of bone turnover have high specificity and sensitivity for identifying low bone turnover defined by tetracycline labeling at the iliac crest in CKD patients. Bone tissue without tetracycline labeling may be useful clinically to define bone turnover.

Acid-Base Status More Than Dietary Acid Intake Determines Urine Citrate Excretion in CKD

Nirmrit Goraya,1,2 Nicolaos E. Madias,3 Abdullah A. Mamun,4 Jan Simon,1 Donald E. Wesson,4,5 Baylor Scott and White Central Texas, Temple, TX; 6Texas A&M University System, College Station, TX; 7Tufts University School of Medicine, Boston, MA; 8Baylor Scott and White Health and Wellness Center, Dallas, TX; 9Surgery, Texas Tech University HSC, Lubbock, TX

Background: Lower urine excretion of the pH-sensitive metabolite citrate (UcitV) might be a clinically useful biomarker of steady-state acid (H+) retention not evident by plasma acid-base parameters in patients with CKD. Ongoing dietary H+ intake might also be an important determinant of UcitV and possibly confound its utility as a biomarker of underlying H+ retention.

Methods: We examined the influence on 8-hour UcitV (UcitV), its plasma citrate concentration (Pcit), and kidney clearance (UcitV/Pcit) components, and 8-hour urinary net acid excretion (8hNAE) of 1) ongoing dietary acid addition assessed by potential renal acid load (PRAL) and 2) steady-state acid-base status assessed by plasma total CO2 (PtcO2) and by H+ retention [estimated by comparing observed to expected PtcO2, increase in response to retained HCO3 (administered minus HUO3CO2H) 2 hours after oral NaHCO3 bolus (0.5 mmol/kg bw), assuming 50% body wt HCO3, apparent space of distribution] in 224 patients with CKD stages 1-3 due to macroalbuminuric, non-diabetic, renal acid load (PRAL) and 2) steady-state acid-base status assessed by plasma total CO2 (PtcO2) and by H+ retention associated inversely with each measure of citrate homeostasis. The data show that steady-state acid-base status is a more important determinant of UcitV than dietary acid intake and support continued exploration of UcitV as a biomarker of underlying H+ retention in CKD.

Calciaphylaxis (Calciﬁc Uremic Arteriopathy) in a Predominantly African-American Urban US Patient Population

Sitarama Arvind Mudunuru, Jose E. Navarrete, Doris J. Armour, Jason Cobb. Emory University, Atlanta, GA

Background: Calciﬁc Uremic Arteriopathy (CUA) which is commonly called calciaphylaxis is a rare and serious condition characterized by painful skin ulcerations due to ischemia with necrosis of the skin. The disorder carries a mortality rate > 50% in the first year, and death is often due to recurrent infections. Risk factors for calciaphylaxis includes end-stage renal disease (ESRD), a history of diabetes, obesity, female gender, Caucasian race, and the use of medications such as warfarin. We present clinical characteristics of CUA patients admitted to a large academic medical center which serves as a CUA referral center due to the presence of a wound center with hyperbaric oxygen therapy available.

Methods: Retrospective chart review of CUA patients from 2001-2019 in our single center academic hospital. Baseline data reported included age, calcium, phosphorus, PT, albumin, hemoglobin, creatinine, BUN, the use of medications such as warfarin or steroids, and treatment options.

Results: There were 110 patients included. Patient identified racial (n=108) make-up included African-American (n=89), Caucasian (n=18), and Asian (n=10). Average age was 56±14 years and 80% of patients were female (n=88). Also, 59% (n=65) of patients were diabetic. Dialysis modalities included hemodialysis (n=82) and peritoneal dialysis (n=24). Also 4 patients with CKD not yet on dialysis at the time of diagnosis. Average calcium levels of 8.9±1.1 mg/dL and phosphorus of 5.1±1.9 mg/dL. The average PTI was 569.6±714.9 pg/mL, albumin 2.5±0.7 g/dL, and hemoglobin 9.8±1.7 g/dL. Approximately 50% of patients received hyperbaric oxygen therapy as inpatient, 25% received sodium thiosulfate therapy, and 20% received a surgical intervention during the admission. Approximately 33% of patients were currently or recently on warfarin therapy, and approximately 25% were currently or recently exposed to high dose steroids.

Conclusions: We reported the largest single center and predominantly African-American (81%) calciaphylaxis case series. In comparison to other reported calciaphylaxis series our average PTI was lower and a high percentage of our patients were using warfarin or steroids. The PTI levels were higher in the African American group compared to others. Also, with a lower than expected parathyroidectomy rate which is likely due to our lower than average PTI.

PO0387

Citraic Acid-Containing Dialyate (CD) Attenuates Vascular Calcification in Hemodialysis Patients (HD)

Kenichi Akiyama, Norio Hanafuso, Yoei Miyabe, Kazunori Karasawa, Takahito Moriyama, Ken Tsuchiya, Kosaku Nitta. Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan

Background: The main causes of death in patients with CKD, especially in HD, are heart failure, cardiovascular, and cerebrovascular disease, which are due to a high degree of systemic vascular calcification. Progression of aortic calcification, simply evaluated by chest radiography, was reported to be significantly associated with overall and cardiovascular mortality in HD. Recently, it was reported that the use of CD reduced blood calciprotein particles (CPPs) associated with arteriosclerosis and inflammation in HD. Therefore, we investigated the effect of using CD on blood CPPs and vascular calcification in HD in a retrospective observational study.

Methods: The subjects were 262 HD who were visiting the Jiban Hospital in Japan. These patients were divided into two groups, those who continued to use acetate-containing dialyate (AD) or switched to CD from October 2017. A one-year retrospective observational study was conducted on the association with blood, laboratory test values, and aOACS (aortic arch calcification score) evaluated by chest X-ray. At baseline, patients with aOACS>50%, bisphosphonate, and warfarin use were excluded. Univariate, multivariate, subgroup analyses were used for statistical analysis. The main outcome was the presence or absence of aOACS exacerbation of 5% or more in one year.

Results: A total of 115 patients with AD and 102 patients with CD matched to the criteria were included. As a result, the use of CD (HR 0.53, 95% confidence interval (CI) 0.30-0.92), P = 0.026, ALP (HR 0.97, 95 %CI 0.94-0.99, P = 0.013), and aOACS (HR 1.36, 95% CI 1.15-1.63, P = 0.0004) were significantly associated with an exacerbation of aOACS. Subgroup analyses showed the characteristics of patients who benefit from using CD are those older than 75 years old, those with non-diabetes as the underlying disease, low nPCR(normalized protein catabolic rate), high blood CRP, and not severe calcification. In other words, patients with MIA syndrome can benefit from the use of CD.

Conclusions: Among patients with mild to moderate vascular calcification, HD with CD had a significantly reduced progression of aOACS compared with AD. The results indicate that the dialysis method using CD in HD may be a useful therapeutic method for suppressing vascular calcification.

PO0389
Vascular Calcifications in Renal Transplantation
Ana Carina Ferreira,1,2 Marco Mendes,1,2 Cecilia Silva,1 Patricia Cotovio,1 Inês Aires,1,2 David Navarro,1 Fernando C. Pereira,1 Rute M. Salvador,2 Bruna F. Correia,2 M. Guadalupe Cabral,2 Fernando E. Nolasco,1,2 Manuel A. Ferreira.1,2,1 Hospital Curry Cabral, Lisboa, Portugal; 2Nova Medical School, Lisbon, Portugal.

Background: The aim of this study was to analyse the progression of vascular calcifications (VC) in a cohort of renal transplanted patients.

Methods: Prospective cohort study of de novo renal transplant patients. All patients were submitted to X-ray of the pelvis and hands (Adragão score); bone biopsy; laboratorial and echocardiographic evaluation at baseline and after 12 months (time 0 and 1). At the end of the study, bone densitometry and non-contrast cardiac CT (Agatston score) were performed. Associations between variables were performed using Wilcoxon rank sum test and Spearman correlation test. STATA software was used and p < 0.05 was considered statistically significant.

Results: We recruited 85 patients during 29 months and 69 were included in the study (6 patients refuse to perform the 2nd evaluation, 5 had primary non-function of the kidney graft, I had no sample on bone biopsy in time 0 and 4 patients died). Mean age 50.1±12.7 years, 59 men (69.4%), 66 caucasian (77.6%), median BMI 25.1±1.34. The median baseline and 12 months Adragão score had no differences. The median coronary artery calcium score (CACS) was 48.5 (0 – 535) and median percentile was 80 (0 – 92.5). Valvular calcifications were present in 15 and 16 patients and baseline and after 1 year (p>0.05). CACS were correlated with age (p=0.001), both Adragão score (p=0.001), presence of valvular calcification in time 1 (p=0.004), baseline calcium (p=0.02), baseline and 12 months sclerostin (p=0.01; p=0.04). CACS were higher in patients with highest values of FGF23 at baseline (p=0.04). Using a pairwise correlation, vitamin D levels (r=0.4, p>0.05) were correlated with the score. Coronary calcium percentile was correlated with Adragão score (p=0.0004), iPTH (r=0.6, p<0.001) and total cholesterol levels (r=-0.3, p=0.01) were correlated with the presence of valvular calcification in time 1 (p=0.02), baseline and 1-year calcium levels (p=0.004; p=0.02) and baseline sclerostin (p=0.01).

Conclusions: VC stabilize after renal transplantation. Adragão score can assess VC in renal transplanted patients. Calcium and sclerostin correlated with Agatston scores.

PO0390
Vascular Calcification and Progression of CKD
Salim Bou Sliman, Harish R. Alappan, W. Charles O’Neill. Emory University, Atlanta, GA.

Background: Vascular calcification, particularly the medial form, is common in advanced chronic kidney disease (CKD) and leads to poor outcomes. However, the extent to which medial calcification affects the kidneys and could exacerbate CKD is unknown.

To this end, progression of CKD was compared in women with and without breast arterial calcification (BAC), a marker of systemic medial arterial calcification, and the prevalence of other calcifications was assessed radiologically and histologically in patients undergoing nephrectomy.

Methods: Women with CKD (eGFR <60 ml/min/1.73m2) were identified from previous studies of breast arterial calcification, and those with a subsequent measurement of serum creatinine at least 1 year later were included. Consecutive patients with CKD and nephrectomies were identified from a computerized search of medical records. Computed tomography (CT) scans were reviewed for aortic and renal artery calcification, and histology (hematoxylin and eosin staining) was reviewed for calcification of main renal arteries and parenchymal arteries. Current or past warfarin use was an exclusion in all cohorts.

Results: Women with (n=51) and without (n=67) breast arterial calcification had similar yearly eGFR declines (1.55 vs. 1.60 ml/min/1.73 m2) despite a greater age (75.4 ± 13.7 vs 70.4 ± 1.5) and lower baseline eGFR (33.8 ± 1.8 vs 39.2 ± 1.6) in women with BAC. There was no correlation between the quantity of BAC and the decline in eGFR (r = 0.10). Of 246 patients with nephrectomies who were screened, 50 had an eGFR < 30. End-stage renal disease was present in 82% and 36% had diabetes. CT scans were available in 34 patients and showed aortic and renal artery calciumization in 59% and 38%, respectively. Prevalences of histologic calcification of renal artery and intraparenchymal arteries were 16% and 15%. When present, calcification of parenchymal arteries was usually very mild, and was severe in only 3 cases and limited to large arteries. In patients with CT scans, only those with renal artery calcification had parenchymal artery calcification (4 of 11 vs. 0 of 17 without, p=0.016).

Conclusions: Vascular calcification does not contribute to the progression of CKD. This is explained by the surprisingly low prevalence and severity of calcification in intrarenal arteries. Patients without renal artery calcification on imaging are at low risk for parenchymal artery calcification.

PO0391
Clinical Outcomes in Patients with Calcinifications on Kidney Biopsy
Anna R. Gaddy,1 Ranjani N. Moorthi,1 Michael T. Eadon,1 Tae-Hwi Schwantes-An,1,2 Carrie L. Phillips,1 Sharon M. Moe,1 Indiana University School of Medicine, Indianapolis, IN; 2Regenstrief Institute Inc, Indianapolis, IN.

Background: Calcification is often noted on kidney biopsies, but the consequences of this finding is not known.

Methods: We searched a biobank for specimens with at least two years of linked clinical data and identified those which had calcification on report. Biopsy specimens were further classified to be described as calcium oxalate (CO), calcium phosphate/dystrophic (DC), or both. Linked clinical data was examined in 3 month intervals before and after index date of kidney biopsy. Cox proportional hazard analysis was performed using a split time model to evaluate relationships between presence of calcification, type of calcification, and clinical endpoints. Linked clinical data was examined in 3 month intervals before and after index date of kidney biopsy. Cox proportional hazard analysis was performed using a split time model to evaluate relationships between presence of calcification, type of calcification, and clinical endpoints.

Results: Patients with any calcification (n=429) vs. without (n=3936) were (p = 0.05) older, more likely to be white, have diabetes, lower eGFR and higher AKI/ATN on kidney biopsy specimen (31 vs. 13%). Patients with COX (n = 126) vs. DC (n = 260) were older, less diabetes, lower eGFR, more likely to have malabsorption or gastric bypass, and used more vitamin D. By univariate analyses, patients with any calcification were more likely to have a decline in the slope of creatinine at 6 months, 1 year, and 2 years; these relationships persisted even after adjustment for baseline eGFR, htn, proteinuria, negative biopsy findings, CAD (for 1 year beta 0.029, p < 0.001). When adjusted for age, diabetes, and baseline eGFR, patients with any calcification were less likely than those without calcification to advance to ESKD (HR 0.59; 95%CI 0.38-0.92; p = 0.05) but not to meet the outcome of death.

Conclusions: The presence of calcification on kidney biopsy specimen is associated with lower progression to ESKD and decrease in rate of decline of eGFR over time at 6 months, 1 year, and 2 years. This paradoxical finding may be due to increased AKI with recovery, rather than progressive chronic disease but requires further analyses.

PO0392
Urinary Phosphate Excretion and Microvascular Function in a Population-Based Cohort
Charles Ginsberg,1,2 Alfons J. Houben,2 Rakesh Malhotra,2 Tos Berendsehot,2 Jeroen Koornman,1,3 Carroll A. Webers,2 Coen Stehouwer,2 Joachim H. Ix,1,2 1University of California San Diego, La Jolla, CA; 2Regenstrief Institute Inc, Indianapolis, IN; 3VA San Diego Healthcare System, San Diego, CA.

Background: Higher serum phosphate is associated with cardiovascular events and all-cause mortality. While these associations have largely been attributed to an increased risk of large vessel calcification, our previous work demonstrated a higher morning serum phosphate level is associated with microvascular dysfunction. However, the relationship between 24-hour urinary phosphate excretion ([UPE]) a surrogate for dietary phosphate] and microvascular function has not been explored.

Methods: We performed a cross-sectional analysis of 3,116 community-living participants that underwent a 24-hour urine collection and skin capillaroscopy, laser-Doppler flowmetry, and flicker-light induced retinal vessel responses as part of the Maastricht Study. The primary outcome was post-occlusive finger skin capillary recruitment. Secondary outcomes included capillary recruitment during venous congestion, heat-induced skin hyperemic response, and flicker-light induced retinal artery and vein dilation.

Results: The mean age of the cohort was 60 years, 48% were women, 7% had an eGFR< 60ml/min/1.73 m2, and the mean serum phosphate concentration was 3.2mg/dl. The mean UPE was 874 ± 315 mg/day. UPE was not associated with any of the microvascular outcomes (Table 1) and there were no significant interactions between UPE and sex, diabetes status or eGFR on any of the outcomes (P>0.43). We found an inverse relationship between UPE and serum phosphate (r=−0.26, p<0.001).

Conclusions: We found no relationship between UPE and microvascular function in community-living individuals predominantly with normal kidney function. Relationships between urine phosphate, serum phosphate and microvascular function require further exploration.

PO0393
Complete Resolution of Calciphylaxis in a Renal Transplant Patient with Calcifediol
Mohankumar Doraiswamy,1 Priyamvada Singh,1 Shumei Meng,2 Todd E. Pesavento.1 1Comprehensive Transplant Center, The Ohio State University Wexner Medical Center, Columbus, OH; 2Division of Endocrinology, The Ohio State University Medical Center, Columbus, OH.

Introduction: Calciphylaxis is a rare but lethal disorder (mortality 60-80%) characterized by occlusion of microvasculature in the subcutaneous adipose tissue and dermis, resulting in excruciating painful, ischemic skin lesions. It commonly occurs in dialysis patients but only few cases in transplants reported. Treatment options are meager, and a multidisciplinary approach (dermatology, nephrology, nutrition, pain, palliative medicine, plastic surgery, and wound care), with surgical debridement, antimicrobial therapy, optimization of calcium-phosphorus product, dialysis adequacy, sodium thiosulfate, and hyperbaric oxygen has been suggested.

Case Description: A 62-year-old female with a LDKT (2008) complicated with CKD II, lupus nephritis, hypothyroidism, presented with painful, bilateral, medial calf ischemic ulcerations, which on punch biopsy revealed calciphylaxis. Her baseline iPTH, calcium, phosphorus, and 25-hydroxy-vitamin D, was 372 pg/mL, 9.4 mg/dL, 3.8 mg/dL, and 17.4 ng/mL, respectively. She was on calcitriol 0.75 mg/daily, ergocalciferol 50,000 units weekly and cinacalcet 30 mcg every other day. We started her on Calcifediol 30 mg, which increased to 60 mg daily. Her calcitriol and ergocalciferol doses were reduced slowly, while cinacalcet remained the same. This led to gradual increase in 25-hydroxyvitamin D and reduction in iPTH levels without effect on the calcium-phosphorus product. Over 1-year follow-up, her ulcers completely resolved as shown in the images with marked improvement in the pain.

Discussion: Treatment of hyperparathyroidism is limited as calcitriol and ergocalciferol worsen the calcium-phosphorus product while calcimimetics cause hypocalcemia, which hinders the attempt to lower calcitriol. Calcifediol is well tolerated and causes a progressive increase in serum 1,25-dihydroxy vitamin D and reductions in plasma iPTH without a significant effect of serum calcium and phosphorus levels. This led to remarkable clinical improvement with resolution of calciphylaxis in this case. Large clinical trials mandated to test these findings.

PO0394
Rapidly Growing “Calcified Cauliflower” in the Lung of an Orthotopic Heart Transplant (OHT) Recipient on Hemodialysis (HD)
Rui Song, Ali Arif, Chandra Dass, Iris J. Lee, Dina Abdelwahab. Lewis Katz School of Medicine at Temple University, Philadelphia, PA.

Introduction: Pulmonary calcinosis is commonly seen in ESRD patients but rarely in OHT recipients. We report a rare case of an OHT recipient who developed AKI requiring RRT. CT chest was noted for rapid progressive calcifications of lungs with both dystrophic and metastatic features.

Case Description: A 48-year old male with non-ischemic cardiomyopathy who underwent OHT. The post-transplant course was complicated by biventricular failure requiring VA-ECMO and IABP support, aortic anastomotic bleeding, multiple surgeries, recurrent bacterial and viral pneumonia dependent on mechanical ventilation, and ischemic acute tubular injury requiring CRRT then switched to HD. The imaging was noted for cardiac calcification, followed by rapidly progressive lung calcification. CT chest showed diffuse ground-glass opacity and “calcified cauliflower” signs with a mixture of dystrophic and metastatic lung calcifications. Work up for hyperparathyroidism, vitamin D toxicity, malignancy was negative. Contributing factors for pulmonary calcinosis included multiple surgeries, infections of the lungs, massive transfusion with subsequent IV calcium repletion, calcium concentration in replacement fluid of CRRT, use of calcium acetate. Subsequently, the patient was put on the lowest calcium bath and longer HD sessions.

CT chest: cauliflower calcification bilaterally

Discussion: Dystrophic pulmonary calcification occurs in the injured lung due to inflammation, infection, or hemorrhage. While metastatic calcification is more common in ESRD patients, primary and secondary hyperparathyroidism, or malignancy. Our case report emphasizes the importance of bone mineral disease as an underlying etiology for pulmonary calcinosis in dialysis-dependent OHT patients. The supportive approach includes avoidance of massive transfusions, IV calcium infusion, and calcium-based phosphorus binder, use of low calcium bath in HD.

PO0395
Calciphylaxis and Ectopic Parathyroid Gland: Chicken or the Egg?
Jonathan Berry, Carissa Wilkins, Tauseef A. Sarguoro, Habeeb S. Amatul. Franciscan Health Inc, Mishawaka, IN.

Introduction: Calciphylaxis is a vascular calcification disorder that is classically seen in patients(pts) with end stage renal disease on hemodialysis. It is most common in caucasian females and risk factors include hypercalcaemia, hyperphosphatemia, hyperparathyroidism, coumarine and iron therapy. This is a case of a patient with severe calciphylaxis, ectopic primary hyperparathyroidism with chronic kidney disease(CKD) not yet on dialysis.

Case Description: 64 year old female with CKD-4, obesity, HTN, pulmonary embolism not on anticoagulation, undiagnosed mediastinal mass came with lower extremity pain and a non-healing ulcer over the left anterior shin. Initial labs showed BUN:68mg/dl, Creatinine:5.4mg/dl, Calcium:11.3mg/dl, PTH:3,059 pg/ml. She underwent punch biopsy of the skin lesion that was consistent with calciphylaxis and was subsequently initiated on hemodialysis and sodium thiosulphate infusion. A nuclear uptake scan showed an anterior mediastinal mass that was consistent with ectopic parathyroid adenoma after surgical excision.

Discussion: This case highlights a rare cause of calciphylaxis in a pt. with undiagnosed ectopic primary hyperparathyroidism and CKD. Our pt. had hypercalcemia and a mediastinal mass which upon work-up was found to be a hypervascular ectopic parathyroid adenoma that likely triggered her calciphylaxis in the setting of concomitant secondary hyperparathyroidism due to chronic kidney disease as evident by hypercellularity of the reamining three parathyroid glands. Only 12 known cases of calciphylaxis are attributed to primary hyperparathyroidism and none due to an ectopic adenoma. Our pt. underwent hemodialysis, parathyroidectomy of the adenomatous gland and sodium thiosulphate infusion after which her PTH and calcium levels significantly improved and her skin lesions healed with no recurrence.
PO0396

Penile Calciphylaxis: Challenges in Its Diagnosis and Management
Isabelle Dominique V. Tomas Cruz, Carl Arenos, Sachiko S. Estreller, Blythe N. Ke, Shahara Abalos-Babaran, Elizabeth Montemayor. Philippine General Hospital, Manila, Philippines.

Introduction: Penile calciphylaxis is an uncommon presentation of a rare systemic disorder.

Case Description: We discuss 2 cases of penile calciphylaxis in patients with end stage kidney disease on hemodialysis presenting with painful ulcerations and eschar formation on their penile shaft. Diabetes mellitus, hyperphosphatemia and vascular calcifications on radiographs were common in both patients. A multidisciplinary approach to management involved wound care with irrigation followed by application of petrolatum-impregnated wet-to-dry dressing, antibiotic therapy, intensification of hemodialysis and use of intravenous sodium thiosulfate. Both patients showed good wound healing on discharge.

Discussion: Skin biopsy may aid in confirmation, but should be weighed against the risks of provoking nonhealing wounds & secondary infection. A high index of suspicion and multidisciplinary management are key components; but, prognosis is poor with survival rates reported to be less than a year upon diagnosis.

Case 1. Penile ulcer

Case 2. A&B. Penile and lower extremity lesions. C. Vascular calcifications on radiograph. D. Punch biopsy of the leg ulcer consistent with calciphylaxis (H&E stain, 40x). E. Thready calcium deposits in the lobular panniculus together with calcification of a medium-sized vessel (H&E stain, 10x)
PO0397
High Turnover Bone Disease After Successful Parathyroidectomy in a Dialysis Patient
Yahya R. Ahmad, Katherine M. Donaldson, Matthew Shea, Florence Lima, Madhumathii Rao. University of Kentucky Department of Nephrology University of Kentucky, Lexington, KY.

Introduction: We report a patient with end stage renal disease (ESRD) on hemodialysis (HD) with history of successful near-total parathyroidectomy (PTX) and normal to low parathyroid hormone (PTH) levels, found to have high-turnover hyperparathyroid (HPT) bone disease on biopsy (tx).

Case Description: 54-year-old female with ESRD on HD for 10 years presented with declining bone density and osteoporosis (left radial T-score of -2.7). She had a near-total PTX in 2014 for secondary hyperparathyroidism and bx proven severe HPT bone disease, complicated by calciphiaxis treated with wound care and sodium thiosulfate. Patient also has history of focal segmental glomerular sclerosis of her native kidneys, gastric bypass, uterine cancer requiring radiation, and psoriatic arthritis and gout requiring steroids. Labs showed corrected calcium 9.4 mg/dL, serum phosphorus 7.9 mg/dL, 25-OH-vitamin D3 16.9 ng/mL, bone specific alkaline phosphatase 12.8 ug/L, intact PTH level 34 pg/mL (consistent with past values), PTH-(1-84)-(7-84) ratio 1.1 (Scantibodies CA). She was started on weekly ergocalciferol. Bone bx showed persistent high-turnover/HPT bone disease with normal mineralization and low bone volume (2019, Figure 1). Relative to her prior bx, however, there was a demonstrably decrease in bone turnover and volume.

Discussion: Bone bx studies showing the evolution of bone disease after PTX in ESRD patients are limited. Development of adynamic bone disease is often presumed, but not established. In this patient, osteoporosis was related to high bone turnover, despite near-total PTX and successful reduction of serum PTH. These observations suggest that more research is needed into mechanisms other than PTH that contribute to bone turnover and loss in ESRD patients.

Figure 1: Anterior iliac crest bone biopsy: 1A – Trichrome stain 10x showing osteoclastic activity with tunneling in trabecular bone and increased osteoid volume and surface 1B – Fluorescent microscopy for tetracycline labeling 10x showing double labels and diffuse uptake in woven bone

PO0398
Successful Treatment of Severe Osteoporosis with Romosozumab in a Patient Undergoing Combined Peritoneal Dialysis and Hemodialysis: A Case Report
Hyeryong Lee, Kazuhiito Fukuoka, Shinya Kaname. Kyorin University School of Medicine, Department of Rheumatology and Nephrology Kyorin Daigaku, Mitaka, Japan.

Introduction: Recently osteoporosis is becoming a bigger problem as aging of population distribution increases. However, the use of anti-osteoporotic drugs is limited because of concerns for increased rates of adverse events associated with decreased drug clearance and comorbidities such as CKD-MBD in dialysis patients. Here we present a case of severe osteoporosis that was successfully treated with romosozumab.

Case Description: A 57-year-old woman ESKD patient due to lupus nephritis had been on peritoneal dialysis (PD) combined with hemodialysis for the last 4 years. She has been suffering from systematic lupus erythematosus and complicated by severe osteoporosis probably due to long-term use of glucocorticoids and renal dysfunction. Although she was treated with vitamin D3 analogues, bisphosphonates, and denosumab, severe pains continued and had pelvic bone and vertebral fractures, followed by repeated pathological bone fractures of the ribs. Thus, we decided to use romosozumab. After administration of romosozumab, bone pains dramatically improved and fragile bone fractures became less frequent, without progression of bone destruction. Four months later levels of tartrate-resistant acid phosphatase-5b decreased, total type 1 procollagen N-terminal propeptide increased, and bone mineral density significantly improved. Serum calcium and inorganic phosphate levels slightly decreased, and intact PTH slightly increased, but no overall adverse effects were noted.

Conclusion: Romosozumab is a humanized anti-sclerostin monoclonal antibody that has recently been introduced for the treatment of osteoporosis. While it demonstrates strong effects on osteogenesis and bone resorption, it also raises concerns about increased cardiovascular events. Our case suggests that romosozumab can be safely and effectively used for the treatment of osteoporosis, at least for a short period, in patients undergoing dialysis, although further study is clearly required to evaluate the efficacy of the agent.

**Ethnic Differences in the Association of Kidney Function and Low Bone Density**

Joshua Chang, Malini Chandra, Jeanne A. Darbinian, Nirmala D. Ramalingam, Joan C. Lao, Sijie Zheng. Kaiser Permanente Oakland Medical Center; Oakland, CA.

**Background:** Chronic kidney disease (CKD) is an important risk factor for bone disease and fracture. Here, we examined the relationship between reduced kidney function (RKF) and bone mineral density (BMD) in women. We also examined PTH and calcium levels among a subset of patients with advanced CKD and low BMD (osteoporosis range).

**Methods:** We examined femoral neck BMD in 118,484 women age 60-79 with an ambulatory creatinine/eGFR within 1 year of the BMD scan and compared the proportion with low BMD (T-score ≤ -2.5) by kidney function. Presence of hyperparathyroidism (PTH > 65) and hypercalcemia (Ca ≥ 10.5 mg/dL) was examined in a subset of 257 patients with low BMD and advanced CKD G3B (eGFR < 45) and G4/G5 (eGFR < 30) who had PTH, calcium, and confirmatory eGFR measured within 2 years of BMD scan.

**Results:** Among 118,484 women, 83% had eGFR ≥ 60, 12% had eGFR 59-45, 4% had eGFR 44-50, and 1% had eGFR < 40. Overall, 12% of women age 60-69 and 21% of women age 70-79 had low BMD, but this varied by race/ethnicity. Asians had the highest burden of low BMD. Within each race/ethnicity group, the burden of low BMD varied by RKF/eGFR (Figure). In the subset with low BMD, advanced CKD, and measured PTH and calcium, 9.7% of G3B (n = 145) and 5.4% of G4/G5 (n = 112) patients were hyperparathyroidic. Of these hyperparathyroidic patients, 57% with G3B had PTH > 65 pg/mL (28.6% had PTH > 130 pg/mL), and all with CKD G4/G5 (n = 6) had PTH > 65 pg/mL (n = 4 > 130 pg/mL). Of the remainder with normal/low calcium, 57% with G3B and 84% with G4/G5 had PTH > 65 pg/mL. (19% of G3B and 53% of G4/G5 had PTH > 130 pg/mL).

**Conclusions:** The burden of low BMD and the association of RKF with low BMD varied by race/ethnicity. The majority of patients with advanced CKD and low BMD also had evidence of hyperparathyroidism when laboratory data were assessed. Our findings support guidelines for PTH and BMD screening in advanced CKD patients to optimize bone health.

**Serum Biomarkers, but Not Dual-Energy X-ray Absorptiometry, Predict Cortical Bone Mineral Density in Children and Young Adults with CKD**

Samira Andromachi Mtsioni,1 Lorenzo Biassoni,2 Amrit Kaur,10 Manish Sinha,2 David C. Wheeler,8 Neil D. Duncan,7 Joyce Popoola,11 David Milford,3 Jin Long,4 Mary B. Leonard,3 Mary Hewett,3 12 Rukshana Shroff.12 Great Ormond Street Hospital For Children NHS Foundation Trust, London, United Kingdom; 2University College London Institute of Child Health, London, United Kingdom; 3Birmingham Women’s and Children’s NHS Foundation Trust, Birmingham, GB, Birmingham, United Kingdom; 4Children’s Hospital “P. & A. Kyriakou”, Athens, Greece; 5Evelina London Children’s Hospital, London, United Kingdom; 6University College London College, London, United Kingdom; 7Imperial College Healthcare NHS Trust, London, London, United Kingdom; 8Stanford University, Stanford, CA, US, Stanford, CA; 9University Hospitals Birmingham NHS Foundation Trust, Birmingham, Birmingham, GB, Birmingham, United Kingdom;10Manchester University NHS Foundation Trust, Manchester, United Kingdom; 11St Georges Healthcare Trust, London, United Kingdom.

**Background:** Currently available serum biomarkers and Dual-energy X-ray Absorptiometry(DXA) are thought to be poor predictors of bone mineral density(BMD). We set out to determine the clinical utility of DXA and routine clinical biomarkers in the young CKD population, by comparing them with tibial cortical BMD measured by peripheral Quantitative Computed Tomography(pQCT).

**Methods:** A multi-centre cross-sectional study with 77 patients on dialysis and 26 in CKD4-5 (n=103 total, ages 5-30 years). Participants underwent hip and lumbar spine (LS) DXA, tibial pQCT [for cortical (cortBMD) and trabecular BMD (trabBMD)] and measurement of routine serum biomarkers. All bone measures were expressed as Z-scores adjusted for age, sex, race and height. Tibial cortical BMD Z-scores was used as the gold standard to evaluate the predictive value of other measures.

**Results:** Bone pain was present in 58%, hindering activities of daily living. 10% had suffered at least one previous low-trauma fracture. DXA LS Z-scores were higher in the CKD compared to the dialysis population, with a corresponding higher trabBMD Z-score on pQCT (p<0.001). CortBMD cortical and mineral content Z-scores were significantly lower in dialysis compared to CKD patients (p<0.01 & p<0.05 respectively). Hip and LS DXA Z-scores did not correlate with any biomarkers or cortBMD. CortBMD Z-scores were negatively associated with PTH (r=-0.44, p<0.001) and alkaline phosphatase (ALP) (r=-0.22, p=0.03) and positively with calcium (r=0.33, p<0.001). None of the patients with PTH levels less than three times the upper limit of normal had a Z-score less than -2 SD (OR 95%CI 7.331 to infinity). Multivariable linear regression analysis showed the independent predictors of cortBMD Z-scores were PTH (β=-0.43, p<0.001), ALP (β=-0.36, p<0.001) and serum calcium (β=0.21, p<0.005), which together predicted 57% of variability in cortBMD. DXA imaging did not improve this model.

**Conclusions:** Routinely used biomarkers are moderate predictors of tibial cortical BMD. DXA is not a clinically useful tool and should not be performed routinely in children and young adults with CKD4-5 and on dialysis.

**Advanced Glycation End Products Are Related with Cortical Bone Quality and Increased Risk for Fractures in CKD Patients**

Noemi A. Roza,1 Keclia Rosana da Silva Quadros,2 André B. Esteves,2 Renata A. Franca,2 Wagner Dominguez, Luzia N. Furukawa,1 Rodrigo B. de Oliveira.1 1Universidade de Sao Paulo, Sao Paulo, Brazil; 2Universidade Estadual de Campinas, Campinas, Brazil.

**Background:** The risk of bone fractures is higher in chronic kidney disease (CKD) patients than general population. We aim to investigate the relationships between advanced glycation end-products (AGEs) and cortical bone in a cohort of CKD patients.

**Methods:** 86 CKD patients (stages 3-4, N=26; hemodialysis, N=32; peritoneal dialysis, N=28) were included. AGEs levels were measured in serum (pentosidine and glycated hemoglobin), in skin (by AGE-Reader device) and in cortical bone by immunohistochemistry; receptor activator of nuclear factor kapp-B (RANK) and its
ligand (RANKL) and SOST mRNA expression were evaluated by real-time PCR. Bone histomorphometry was performed to measure cortical porosity, thickness and volume. Fracture risk was predicted using FRAX tool.

Results: Age was 51±13 years; 48 (56%) were male, 41 (48%) Caucasian and 16 (19%) diabetics; dialysis vintage was 21 (10-44) months. AGEs levels in skin were 3.06 ± 0.7 AU (reference: <2.0 AU), serum pentosidine 71 (44-121) pmol/mL and glycated hemoglobin 5.4 (3-12.1%). Cortical bone volume, thickness and porosity were 22.3 ± 0.7 AU (reference: <2.0 AU), serum pentosidine 71 (44-121) pmol/mL and glycated hemoglobin 5.4 (3-12.1%).

Conclusions: AGEs were detected in cortical bone and skin of CKD patients and correlates with their risk for osteoporotic fractures. Serum pentosidine levels were associated with low thickness of cortical bone. Cortical porosity was associated with serum glycated hemoglobin levels. SOST and RANKL mRNA expression. RANK was positively influenced by serum pentosidine levels. Together these data point to a direct relationship between AGEs and fractures in patients with CKD.

PO0404
Low Bone Turnover and Increasing Calcification with Lower Trabecular Bone Score in Early CKD Patients
Amr E. Mohamed, Mohamed Ahmed, Michael Winkler, Habib Sour, Daniel Devoserop, Marie-Claude M. Faugere, Hartmut H. Mullache, University of Kentucky University of Kentucky, Lexington, KY.

Background: Little information is available on turnover abnormalities early during the development of loss of kidney function. Vascular calcifications may develop in association with bone turnover abnormalities. This study was designed to evaluate bone changes and cardiovascular calcification in early CKD patients without clinically known bone or cardiovascular disease.

Methods: This is a cross-sectional analysis of 32 adult volunteers with CKD stage 2-4. All patients underwent 1) dual energy x-ray absorptionmetry including trabecular bone score (TBS). 2) Non-contrast CT for cardiovascular calcium scoring, and 3) anterior iliac crest bone biopsy after double tetracycline-labelling and mineralized bone histology with histomorphometry.

Results: The mean age of the patients was 61±11 years. Patients tended to be obese (75%), white (72%), and female (59%). The mean eGFR was 44 ± 16 ml/min/1.73 m2. On histomorphometry.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Bone-Derived Hormones, Mineral Metabolism, Cardiovascular Disease, and Patient Survival in ESRD
Ana Carina Ferreira,1,2 Marco Mendes,1,2 Cecilia Silva,1 Patricia Cotovio,1 Ines Aires,1,2 David Navarro,1 Fernando C. Pereira,1,2 Rute M. Salvador,2 Bruna F. Correia,1 M. Guadalupe Cabral,2 Fernando E. Nolasco,1,2 Varvara Mitsioni,4 Lorenzo Biassoni,1 Amrit Kaur,2 Manish Sinha,1 David C. Wheeler,3 Neil D. Duncan,4 Joyce Popoola,1 Simon Mcguirk,2 Kristian H. Mortensen,2 David Milford,1 Jin Long,2 Mary B. Leonard,2 Mary Fewtrell,6,7 Rukshana Shroff,3,8 1Great Ormond Street Hospital For Children NHS Foundation Trust, London, London Kingdom; 5Evelina London Children’s Healthcare, London, United Kingdom; 2University College London Institute of Child Health, London, United Kingdom; 3Birmingham Women’s and Children’s NHS Foundation Trust, Birmingham, United Kingdom; 4University of Glasgow, Glasgow, United Kingdom; 4University College London, London, GB, London, United Kingdom; 9Manchester University NHS Foundation Trust, Manchester, Manchester, United Kingdom; 3University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; 1St Georges HealthCare Trust, London, United Kingdom.

Background: The aim of this study was to analyse the associations between chronic kidney disease-mineral and bone disorder (CKD-MBD) players [alpha-klotho, fibroblast growth factor (FGF) 23, sclerostin, parathyroid hormone (PTH), bone alkaline phosphatase (bAP)] with cardiovascular disease and patient survival in ESRD patients.

Conclusions: Low bone turnover, normal total bone volume and absence of bone formation defects were all associated with normal total bone volume and absence of bone formation defects in these early CKD patients. There were increased vascular calcifications with low TBS pointing to a relationship between bone quality and vascular calcifications.

PO0406
Bone Mineral Density Is Not Associated with Coronary Artery Calcification in Children and Young Adults with CKD
Alexander D. Lalavaniannis,1,2 Nicola J. Crabtree,1 Charles Ferro,1 Varvara Askitis,4 Andromachi Mitiisoni,4 Lorenzo Biassoni,1 Amrit Kaur,2 Manish Sinha,1 David C. Wheeler,3 Neil D. Duncan,4 Joyce Popoola,1 Simon Mcguirk,2 Kristian H. Mortensen,2 David Milford,1 Jin Long,2 Mary B. Leonard,2 Mary Fewtrell,6,7 Rukshana Shroff,3,8

Methods: Patients with CKD4-5 or on dialysis aged 5-30 years underwent tibial pQCT and measurement of vascular health to examine the association between bone demineralization and vascular calcification in a young CKD population.

Results: One hundred participants [median 13.82 years(IQR 10.7 to 16.5), 20% above 18 years, 44% female, 77% on dialysis] underwent tibial pQCT [for cortical/medulla (bMD) and trabecular BMD (tBMD)] and ultrasound for carotid intima-media thickness (cIMT), carotid-femoral pulse wave velocity (cfPWV) and measurement of routine serum biomarkers. All measures were expressed as Z-scores and adjusted for age, height. cIMT was expressed as Agatston score (AS).

Conclusions: Low bone turnover, normal total bone volume and absence of mineralization defect are seen in early stages of CKD. There are increased vascular calcifications with low TBS pointing to a relationship between bone quality and vascular calcifications.
Conclusions: Despite a high prevalence of bone and cardiovascular disease (CVD), there was no increase in bone mineral density (BMD) or serum concentrations of CAC or surrogates of CVD in this cohort of children and young adults with CKD-5D. The skeleton accretes calcium until the third decade of life, perhaps allowing a buffering effect that protects against vascular calcification. Confirmation through longitudinal studies is required.

PO0407
A Randomized, Double-Blind, Placebo-Controlled Trial Assessing Efficacy of Standard and Low-Dose Hydrochlorothiazide Treatment for Prevention of Recurrent Calcareous Nephrolithiasis (NOSTONE Trial)

Nasser Dhayat,1 Olivier Bonny,2 Beat Roth,3 Grazia M. Cereghetti,2 David Schilling,4 Pina Pusztai,5 on behalf of the NOSTONE Investigators6 Inselstippt Universitätsklinik Bern, Bern, Switzerland; 1University of Bern, CTU Bern, Bern, Switzerland; 2Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland.

Background: Nephrolithiasis is a global healthcare problem with a current lifetime risk of up to 18.8% in men and 9.4% in women. Without specific treatment, 5- and 20-year recurrence rates are 40% and 75%, respectively. Given the high cost of medical treatments and surgical interventions as well as the morbidity related to symptomatic stone disease, medical prophylaxis for stone recurrence is an attractive approach. Efficacy of thiazides for kidney stone prevention was tested in 11 trials in the past. However, all these trials had major methodological deficiencies. Nowadays, thiazides are widely used in the treatment of recurrent nephrolithiasis and arterial hypertension, but at significantly lower doses. In the case of recurrent nephrolithiasis, however, this practice is not supported by randomized evidence. Thus, evidence for benefits and harms of thiazides in the prevention of kidney stones remains unclear.

Methods: NOSTONE is a multicenter, randomized, placebo-controlled, double-blind, parallel-group trial with the purpose to assess the dose-response relationship for three different dosages of hydrochlorothiazide (placebo, 12.5mg, 25.0mg, 50.0mg) in kidney stone prevention. The primary outcome is incidence of stone recurrence (a composite of symptomatic or radiologic recurrence) at 3 years, a low-dose CT will be performed at the beginning and the end of the trial. Patients from 12 hospitals throughout Switzerland were included in the trial.

Results: NOSTONE received all necessary approvals by the end of February 2017. Recruitment started in Bern on the 9th of March 2017, all study sites are operative since June 2017. Altogether, 416 patients were randomized in the trial was reached and therefore recruitment stopped (www.nostone.ch). In March 2020 the first patient randomized in the trial completed the treatment phase. All patients are expected to reach end of treatment by the end of August 2021.

Conclusions: The study will provide critical information to physicians for the treatment of kidney stones. The impact of the results of this study will affect many patients currently treated with hydrochlorothiazide for the prevention of recurrent nephrolithiasis.

PO0408
Roux-en-Y Gastric Bypass and Kidney Stones

Background: Roux-en-Y gastric bypass (RYGB) is a bariatric surgical procedure that is highly effective in the management of morbid obesity but also associated with higher risk of stone formation after surgery. It is not known why RYGB is associated with higher kidney stone risk but it may be due to changes in urine composition, such as high urine calcium oxalate supersaturation (CaOx SS) and calcium phosphate supersaturation (CaP SS). It is not known who is at risk for high urine CaOx SS after surgery. We examined 24-hour urine composition in 18 men and women before and after RYGB to look for predictors of urine high CaOx SS and CaP SS.

Methods: Patients were recruited from a bariatric surgery clinic prior to scheduled laparoscopic long-limb RYGB. Three consecutive 24-hour urine collections performed in a Clinical Research Center both before and 1 year after surgery. We performed Welch’s 2-sample and paired t-tests to compare mean urinary values for pre- to post-RYGB collections and to compare men to women in the post-RYGB collections. We used linear regression to evaluate predictors of urine CaOx SS and CaP SS.

Results: Seven men and eleven women completed pre- and post-RYGB urine collections. Post-RYGB, women had a significantly higher urine CaOx SS (13.1 ± 4.6 vs. 12.5 ± 4.0, p = 0.002), CaP SS (5.9 vs. 1.9, p = 0.05), and lower urine volumes (1.7 vs. 2.7L, p = 0.001) compared with men. There were no differences by sex in CaOx SS or urine volume pre-RYGB. Both men and women had high oxalate in the pre- and post-RYGB collections. Urine volume was most strongly associated with urine CaOx SS and a difference in urine CaOx SS of -6.4 (-8.7 to -4.0) for every 1 liter of urine volume excretion. Calcium was also associated with change in -0.01 (-0.01 to -0.002) per mg of citrate. Calcium and oxalate associated with change in -0.01 (-0.01 to -0.002) per mg of citrate. Calcium and oxalate were most strongly associated with urine CaP SS, higher urinary citrate, calcium and pH (1.3 ± 0.7 vs. 1.7 were associated with higher CaP SS (Calcium 0.01mg, 0.008 to 0.12mg; pH 1.3, 0.8 to 1.7). Higher urine volume (-0.4 -0.6 to -0.1) was associated with lower CaP SS and citrate was not significant.

Conclusions: There are important differences in urinary parameters by sex that may contribute to differences in kidney stone risk after RYGB. Women may be at higher risk for kidney stone formation after RYGB compared with men.

PO0409
Nephrocalcinosis at Baseline Did Not Increase the Risk of Nephrocalci- nosis Progression After Long-Term Burosumab Treatment in Adults and Children with X-Linked Hypophosphatemia (XLH)

Farzana Perwad,1 Angel Chen,2 Lin Zhang,3 Mary Scott Roberts,3 Anthony A. Portale,1 1Ultragenyx Pharmaceutical Inc., Novato, CA; 2University of California, San Francisco, San Francisco, CA.

Background: In patients with XLH, excess FGF23 induces hypophosphatemia, leading to musculoskeletal impairments. In two Phase 3 trials (NCT02526160, NCT02015705), burosumab significantly improved serum phosphorus concentrations in adults and children with XLH. We examined subject characteristics and long-term safety of burosumab by the absence or presence of nephrocalcinosis (NC) at baseline (BL) from these trials.

Methods: Adults were randomized (1:1) to burosumab 1.0 mg/kg every 4 weeks or placebo for 24 weeks; after 24 weeks, adults received burosumab through 96 weeks. Children were randomized (1:1) to burosumab 0.8 mg/kg every 2 weeks or oral phosphate and active vitamin D (Pi/D) for 64 weeks. NC was determined at BL and during study by ultrasound and graded by central readers from 0 (normal) to 4 (stone formation).

Results: In adults, NC was found in 73/134 patients (54%) at BL. Age, sex, and duration of treatment with Pi/D as adults did not differ by baseline NC group. Compared with adults within NC at BL, those with NC longer duration of treatment with Pi during childhood (mean [SD] 13.2 [3.2] vs 11.4 [4.0] years) but not with D. After 96 weeks in adults, median 24-hr urine calcium increased by 35% overall but remained within the normal range. NC scores increased by +1 in 5/73 adults with NC at BL and 5/61 adults without NC at BL. In children, NC was found in 14/61 (23%) at BL. Compared with children without NC at BL, children with NC were older (7.6 [2.8] vs 5.7 [3.4] years), more likely to be male (71% vs 36%), treated longer with Pi/D pre-enrollment (4.8 [3.3] vs 3.6 [3.0] years), and had higher 24-hr urine calcium (4.4 [5.4] vs 2.3 [1.9] mg/kg/day [normal <4.9 mg/kg/day]). After 64 weeks in children, median urine calcium decreased by 50% overall. At week 64, NC scores did not increase in any child and decreased by 1 in 8 children. Serum creatinine and estimated GFR did not change in adults or children.

Conclusions: In adults with NC at BL was associated with longer duration of Pi during childhood. In children with NC at BL, NC was associated with longer duration of Pi and D pre-enrollment and with BL hypercalciuria. With long-term burosumab, the presence of NC at BL did not increase the risk of NC progression.

PO0410
Proton-Pump Inhibitors Are Associated with Decreased Urinary Citrate Excretion

Parth M. Patel,1 Alexander Kandabarov,1 Escosa Aiwerioghoiene,1 Enrique Blanco-Martinez,2 Spencer Hart,2 David J. Leehey,2-3 Ahmer Farooq,2 Kristin Baldea,4 Thomas Turk.5 Loyola University Health System, Maywood, IL; 2Edward Hines Junior VA Hospital, Hines, IL.

Background: Proton-pump inhibitors (PPIs) may increase the risk of kidney stone formation, but the mechanism(s) have not been elucidated. PPI-associated hypomagnesaemia is due to impaired intestinal magnesium absorption thought to result from changes in intestinal pH that decrease binding of magnesium to its transporters. Citrate is a tricarboxylic acid with α-ketavalues of 2.9, 4.8, and 5.6. Since citrate is transported primarily in the divalent form (citrate2-) by the intestinal sodium dicarboxylate transporter (NaDC1), changes in intestinal pH by PPIs might decrease the amount of the divalent form, thus reducing intestinal absorption of citrate, thereby decreasing alkaline load and urinary citrate excretion.

Methods: We performed a retrospective review of nephrolithiasis patients treated at our institution and compared patients who were taking PPIs or not at the time of their 24-hour urine collections. Patients taking PPIs were older and more likely to have medical comorbidities associated with metabolic syndrome such as hypertension, diabetes, and dyslipidemia (p<0.01). Controlling for these factors, patients taking PPIs were found to have lower 24-hour urine citrate excretion (p=0.12, ΔF=4.24, n=904). 24-hour urine magnesium excretion was numerically but not significantly lower in patients taking PPIs. There were no other differences in urinary composition between the groups.

Conclusions: Our findings suggest that patients who take PPIs regularly may be at risk for decreased urinary citrate excretion, which is a known risk factor for kidney stone formation. It is possible that the decrease in urinary citrate with PPIs may have clinical significance, particularly in patients with idiopathic hypercalciuria or other conditions associated with hypocitraturia such as genetic polymorphisms of the renal-sodium-citrate (renal-NaDC1) transport system or chronic metabolic acidosis, hypercalcemia, or chronic metaphosphoric acid or anhydride inhibitors, high animal protein diet intake, and incomplete distal RTA.

PO0411
Dietary Intake and Risk of Incident and Recurrent Kidney Stones
Api Chewcharat,1 Eric N. Taylor,2 Charat Thongprayoon,1 Lisa E. Vaughan,1 Ramila A. Mehta,1 Felicity T. Enders,1 John C. Lieske,1 Andrew D. Rule.1
1Mayo Clinic Minnesota, Rochester, MN; 2VA Maine Healthcare System, Augusta, ME.

Background: Dietary factors associated with recurrent kidney stones (KS) may differ from those associated with incident KS.

Methods: We recruited adult incident symptomatic KS formers and controls from local residents surrounding the Mayo Clinics in Minnesota and Florida between 2009 and 2018. Participants were administered a Viocare Food Frequency Questionnaire, a KS survey, and completed a 24h urine chemistry evaluation at a baseline study visit. Medical records of stone formers were reviewed for symptomatic recurrence with a visit lower confirmed stone through May 2019. Analyses compared baseline dietary factors between incident symptomatic stone formers and controls and assessed whether these same dietary factors predicted symptomatic recurrence.

Results: There were 416 incident symptomatic KS formers (74 had a recurrence during follow-up) and 384 controls. Higher dietary potassium, calcium and phytate were associated with lower odds of an incident symptomatic KS adjusting for age, race, BMI, underlying diseases, family history of KS, education status, fluid and energy intake. During median follow-up time of 4.1 years, higher dietary calcium and lower oxalate intake predicted a lower risk of symptomatic KS recurrence (Hazard ratio for highest tertile vs lowest tertile = 0.53, 95%CI [0.28, 0.99] and 2.09, 95%CI [1.18, 3.69], respectively) adjusting for BMI, fluid and energy intake, and Recurrence of Kidney Stone score. (Table)

Conclusions: Certain dietary factors may differ in their association with incident and recurrent KS. In particular, dietary oxalate intake may be more important for preventing recurrence than for preventing a first KS episode.

PO0413
Type 3 Renal Tubular Acidosis in Association with a Pelvic Kidney

Introduction: The association of renal tubular acidosis (RTA) from carbonic anhydrase isoenzyme II (CA II) deficiency, cerebral calcifications and osteopetrosis is now known as marble brain disease

Case Description: 21-year-old woman with a medical history of multiple fractures since childhood, recurrent episodes of nephrolithiasis and, renal tubular acidosis (RTA), presented to establish care at our clinic. Genetic testing had revealed she had CA II gene mutation. Her brother had the same condition but her sisters were healthy. Her medication included potassium citrate and vitamin D3. Laboratory assessment revealed the following: serum Na+ 143 mmol/L, K+ 3.9 mmol/L, Cl- 109 mmol/L, HCO3 21 mmol/L, creatinine 0.73 mg/dl, Ca2+ 9 mg/dl, PO43- 4.4 mg/dl, vitamin D 7.6 mg/dl. Urine pH was 6. CT urogram revealed a normal right kidney and an ectopic left kidney with numerous small stones. (Figure 1). Spine X rays showed osteoporosis of vertebral endplates and MRI brain showed calcifications in basal ganglia. Pyelolithotomy of the pelvic stone was performed and stone analysis revealed 90% calcium phosphate and 10% calcium oxalate. 24-hour urine showed a low urine citrate with low urine volume. Thus the findings were consistent for RTA with low serum bicarbonate, low urine citrate and calcium phosphate predominant stones.

Discussion: CA II deficiency syndrome is a rare autosomal recessive disorder that results in Type 3 RTA (combined proximal and distal RTA). Pelvic kidneys, which result from a failure of mesonephros to ascend normally during early gestation, are prone to urolithiasis due to poor urinary drainage. In our patient RTA, along with altered urine flow due to pelvic kidney predisposed to nephrolithiasis.

PO0412
Cross-Sectional Study of Metabolomic Profiles and the Association with Kidney Stone Disease in the Nurses' Health Studies I and II
Panupat Maprangpho,1 Yukun Li,1 Raji Balasubramaniam,1 Eric N. Taylor,1,2 Gary C. Curhan.1 Bringham and Women’s Hospital Channing Division of Network Medicine, Boston, MA; 1Mahidol University Faculty of Medicine Siriraj Hospital, Bangkok, Thailand; 1VA Maine Healthcare System, Augusta, ME; 2University of Massachusetts Amherst, Amherst, MA.

Background: Kidney stone disease is a painful and expensive health condition with a high recurrence rate and substantial morbidity; however, the mechanisms underlying the disease remain incompletely understood. Metabolomics is one novel approach that might provide important insights into the etiology of stone disease.

Methods: In a subset of participants from the Nurses’ Health Study I and II cohorts (NHSI and NHSII), subjects were divided into stone and non-stone former groups. Data from existing mass-spectrometry based plasma metabolomic profiling that had been performed in multiple case-control studies of other diseases were used. Multivariable logistic regression models were employed to identify metabolites which were associated with kidney stone history after adjusting for multiple comparisons using false detection rate correction.

Results: We included 230 prevalent kidney stone cases among 5380 NHSI participants and 114 cases among 2283 NHSII participants. 277 metabolites were measured and passed the 10% missing threshold. In NHSI, one metabolite was significantly inversely associated with kidney stones (p=0.01) and passed the false-detection rate correction for multiple testing. The identified metabolite was cinnamoylglycine (HMDB0011621), which is a metabolite in the carboxylic acids and derivatives class. There were no significant metabolites in NHSII. When the cohorts were combined, HMDB0011621 was significantly inversely associated with stone history (p<0.01). The odds ratio per standard deviation increase in the metabolite for the combined cohorts was 0.87 (0.81, 0.95).

Conclusions: We identified one plasma metabolite associated with a history of kidney stones. The metabolite has been recently identified as one of the potential biomarkers of proximal tubule function, colonic epithelial resistance and prostate cancer. Larger studies are needed to identify other potential metabolites that may be involved in kidney stone formation.

Ectopic (pelvic) left kidney with multiple stones with a normal looking right kidney

PO0414
Incidence and Characteristics of Kidney Stones in Patients on a Ketogenic Diet: A Meta-Analysis
Prakriti C. Acharya,2 Juan A. Medina,1 Chirag Acharya,3 Charat Thongprayoon,4 Wisit Cheungpasitporn.1 1University of Mississippi Medical Center, Jackson, MS; 2Texas Tech University Health Sciences Center El Paso, El Paso, TX; 3LCCF, Hobbs, NM; 4Mayo Clinic Minnesota, Rochester, MN.

Background: Very-low-carbohydrate diets or ketogenic diets have frequently been used for weight loss in adults and as a therapy for epilepsy in children. The incidence and characteristics of kidney stones in patients on ketogenic diets are not well studied.

Methods: A systematic literature search was performed using MEDLINE, EMBASE, and Cochrane Database of Systematic Reviews from the databases’ inception through April 2020. Observational studies or clinical trials that provide data on the incidence and/or types of kidney stones in patients on ketogenic diets were included. We applied a random-effects model to estimate the incidence of kidney stones.

Results: A total of 36 studies with 2,795 patients on ketogenic diets were enrolled. The estimated pooled incidence of kidney stones was 5.6% (95% CI, 4.4%-7.1%) in patients on ketogenic diets at mean follow-up time 3.7±2.9 years. Subgroup analyses demonstrated the estimated pooled incidence of kidney stones of 5.6% (95% CI, 4.3%-7.2%) in children and 5.6% (95% CI, 2.3%-12.6%) in adults, respectively. Within reported studies, 48.7% (95% CI, 33.2%-64.6%) of kidney stones were uric stones, 36.5% (95% CI, 10.6%-73.6%) were calcium based (CaOx/CaP) stones, and 27.8% (95% CI, 12.1%-51.9%) were mixed uric acid and calcium based stones, respectively.

Conclusions: The estimated incidence of kidney stones in patients on ketogenic diets is 5.6%. Its incidence is comparable among adults and children. Uric acid stones are the most prevalent kidney stones in patients on ketogenic diets followed by calcium based stones. These findings may impact the prevention and clinical management of kidney stones in patients on ketogenic diets.

PO0415
Association of Urine Findings with Metabolic Syndrome (met-s) Traits in Patients with Nephrolithiasis
Yvonne L. Hood,2 Carley Mulligan,1 Deseree de Waal,1 Peter W. Callas,1 Kevan M. Sternberg.1,2 University of Vermont College of Medicine, Burlington, VT; 2University of Vermont Medical Center, Burlington, VT.

Background: Met-s is a health concern related to lifestyle habits including acidicogenic and high protein diets. The odds of nephrolithiasis increases with an increasing number of met-s traits. Prior studies have shown relationships among the number of met-s traits and decreasing urine pH and other acid excretion markers. We evaluated associations of urine factors including acid excretion and stone composition with the number of met-s traits in a large cohort of stone-forming patients.

Methods: A retrospective review was performed of 24-hour urine studies (Litholink, Litholink, Chicago, IL) from patients seen in Urology and Nephrology divisions, UVMCC July 2009 to December 2018. Patients <18 years and those with improper collections based on creatinine/kg were excluded. Patient variables, laboratory values, associated diagnoses, and medications were identified within 6 months of urine collection and 1 year of kidney stone composition. Four groups based on the number (0, 1, 2, 3-4) of met-s traits were calculated using linear contrasts in analysis of variance.

Results: 1250 unique patients, 494 females, 1250 unique patients, 494 females, 703 with stone composition criteria for inclusion. Met-s groups n were 0=509, 1=381, 2=203, 3+4=157. There was no difference or trends among the groups for urine volume, calcium or citrate. There was a significant trend p<0.001 for increasing number of met-s traits with decreasing urine pH and SS calcium phosphate (CaP) and increasing age, weight, protein intake, urine uric acid (UA), SS UA, oxalate, sodium, potassium, phosphorus, urea nitrogen, chloride, estimated net acid excretion and p<0.05 for sulfate (S), ammonium, magnesium. When adjusted for age and protein intake the trend remained significant only for urine pH and a reversed trend for S. There was a significant trend for more UA and fewer predominately CaP stones in those with more met-s traits.

Conclusions: High protein intake accounted for most of the difference in urinary markers of stone risk except low urine pH. The latter facilitates more UA and less CaP contribution to stone composition. Future studies could determine if changing diet can reduce risk for stones in met-s.

PO0416
Primary Hyperoxaluria (PH) Types 1 and 2 with Kidney and/or Liver Transplant Achieve Best Health-Related Quality of Life (HRQoL)
Frank Modersitzki,1 Dawn S. Milliner,2 John C. Lieske,2 David S. Goldfarb.3
1New York University Grossman School of Medicine, New York, NY; 2Mayo Clinic Rochester, Rochester, MN; 3V4 New York Harbor Healthcare-System Manhattan Campus, New York, NY.

Background: Our previous study showed that PH without a transplant (tx) had worse HRQoL compared to the US Standard Population and worsened with increased stone frequency. We now show the first longitudinal HRQoL profiles for PH patients with transplants.

Methods: PH patients were enrolled from the Rare Kidney Stone Consortium registry. HRQoL was measured with a generic non-disease specific instrument (SF-36v2). Results were calculated as norm-based scores (NBS) based on US Standard Population
(Mean domain score = 50). We created three groups based on the time of last stone event (≥30 days, 31–365 days, >366 days). The study compared HRQoL for participants with a kidney and/or liver transplant over 5 different time points.

**Results:** This sub-sample included 100 surveys of 32 PH participants (16 males and 16 females) with a tx. The mean age was 47 years for both males and females. This sub-sample includes 24 participants with liver/kidney tx (75%) and 8 with kidney tx only (25%). Participants with only a kidney tx reported significantly more stone events within a year (26% vs 13%, χ² = 0.028). Two way ANOVA did not find a change in HRQoL profiles over time for PH participants with kidney/liver tx (figure). Most mean domain scores are 50 or above, except for the domain of General Health which was less. Participants with only a kidney tx scored significantly lower in role physical, bodily pain, general health, social function, and physical component score (data not shown) than participants with kidney/liver tx. There was no difference between male and female participants over time.

**Conclusions:** PH participants with kidney/liver tx achieve better HRQoL, measured with a non-disease specific generic instrument, than those with kidney alone; both are better when compared to the US Standard Population. The majority of PH participants with a tx are stone-free, with a direct beneficial impact on their HRQoL.

Assessment of Blood Oxalate Concentrations in Patients with CKD

Anja C. Pfau,1 Monika Wytopil,2 Kinsuk Chauhan,3 Martin Reichel,1 Steven G. Coca,3 Peter S. Aronson,4 Kai-Uwe Eckardt,2 Felix Knaff,1,4 Charite Universitätsmedizin Berlin, Berlin, Germany; 1Universitätsklinikum Erlangen, Erlangen, Germany; 2Lahn School of Medicine at Mount Sinai, New York, NY; 3Yale University Department of Internal Medicine, New Haven, CT.

**Background:** Alterations in oxalate homeostasis are associated with kidney stone disease and progression of chronic kidney disease (CKD). However, accurate measurement of plasma oxalate (Pₐ) concentration is challenging as prompt processing and acidification of samples has been deemed necessary. In the present study we examined the effects of variations in sample handling on Pₐ results. Subsequently, a standardized analytical protocol was established, and Pₐ concentrations were measured in a large cohort of patients with CKD.

**Methods:** We tested the effects on Pₐ results of storage time at room temperature (RT), storage on dry ice and maintenance of samples at -80°C. Pₐ results were calculated using the Student t-test, one-way ANOVA and Pearson's correlation using GraphPadPrism, version 8.0. A P value of <0.05 was considered significant for all analyses.

**Results:** Pₐ concentrations increased rapidly when samples were maintained at RT. This was most relevant for Pₐ < 10 μM as concentrations more than doubled within a few hours. Immediate freezing on dry ice and storage at -80°C provided stable results and allowed postponement of acidification for >1 year. In the GCKD study, mean (SD) eGFR at the time of Pₐ measurement was 44.0 (17.9) ml/min/1.73 m². More than half of the patients had a Pₐ concentration below 2.0 μM. Pₐ correlated positively with urinary albumin to creatinine ratio and inversely with eGFR (P < 0.001). The lowest eGFR quartile, median eGFR was 25.1 ml/min/1.73 m² (IQR 20.3 - 28.1) with a median Pₐ of 2.7 μM (IQR 1.9 – 4.2).

**Conclusions:** We conclude that immediate freezing and maintenance of plasma samples at -80°C facilitates the sample collection process and allows accurate Pₐ assessment in large patient cohorts. Our study presents a critical and useful modification of the complex preanalytical procedure. Moreover, we demonstrate that Pₐ concentrations in patients with CKD are substantially lower than previously reported. The present study may serve as a reference for sample handling to assess Pₐ in clinical trials and to determine its role in CKD progression.

**PO0418**

Safety and Efficacy of Reloxaliase in Enteric Hyperoxaluria (EH): An Aggregate Review of Completed Studies

Christina M. Wyatt,1,2 Alicia Weeks,1 Danica Grujic,1 Annamaria T. Kausz,1 1Allena Pharmaceuticals, Newton, MA; 2Duke University, Durham, NC.

**Background:** EH occurs when excess oxalate is absorbed from the gastrointestinal (GI) tract due to underlying fat malabsorption, increasing renal oxalate load and as a result, risk of both kidney stones and chronic kidney disease. Reloxaliase is a first-in-class enzyme that specifically targets and degrades oxalate within the GI tract to treat EH. An aggregate safety and efficacy assessment of reloxaliase in subjects with EH across completed clinical trials was performed.

**Methods:** There were a total of four Phase 2 and 3 trials that enrolled EH subjects; 2 were single-arm and 2 were randomized, placebo (PBO) controlled. Subjects took reloxaliase orally (7,500 units/dose) to 3 times/day, for 4 days to 12 weeks. The efficacy endpoint in all trials was change in 24-hr urine oxalate (UOx) excretion (mg/d). For this aggregate analysis, percent change from baseline was calculated using the average of all values obtained during treatment.

**Results:** There were a total of 168 randomized subjects with EH (94 reloxaliase and 74 PBO), most with bariatric surgery as the cause of malabsorption. Baseline estimated glomerular filtration rate (eGFR) ranged from normal to as low as 33 ml/min/1.73 m². In subjects with baseline UOx ≥ 50 mg/d, reloxaliase treatment consistently reduced 24-hr UOx by a mean of 23 to 35% across the studies, despite differences in dosing frequency and duration of treatment. Efficacy appeared to be unrelated to baseline eGFR. Adverse events (AEs) were reported in 67% of reloxaliase subjects compared to 51.4% on PBO, with GI AEs most common in both groups. There were no treatment-related serious AEs or deaths, and none of the reloxaliase treated subjects withdrew from the study due to a related AE.

**Conclusions:** Reloxaliase reduces 24-hr UOx excretion and is well tolerated in EH patients independent of eGFR, dosing frequency, or duration of treatment. Further studies are ongoing to assess the long-term benefits of reloxaliase and its potential to decrease kidney stone events and preserve kidney function.

**PO0419**

Trends in Treatment of Secondary Hyperparathyroidism and Association with Post-Transplant Outcomes

**Background:** Secondary hyperparathyroidism (SHPTH) affects nearly all patients with kidney failure on maintenance dialysis and has been independently associated with increased mortality and cardiovascular disorders. Treatment includes vitamin D analogs, calcimimetics, or parathyroidectomy. However, treatment choice for SHPTH on outcomes after kidney transplantation (KT) is not well understood. The primary objectives of our study were to understand treatment trends in SHPTH and their association with post-transplant outcomes.

**Methods:** Using SRTR and Medicare claims data, we identified 12,372 adults (age ≥ 18) who received KT in 2007-2016 and had a diagnosis of SHPTH during dialysis. We examined the association between treatment method for SHPTH and development of tertiary hyperparathyroidism, delayed graft function, graft failure, and death using adjusted Cox proportional hazards models.

**Results:** Of 12,372 patients with a diagnosis of SHPTH, 4,554 (36.8%) received cinacalcet, 205 (1.7%) underwent parathyroidectomy, and 7,613 (61.5%) had no treatment prior to KT. Cinacalcet use increased throughout the duration of the study period with 18.4% of patients receiving it 2007 versus 46.2% in 2017 (p<0.001). Utilization of parathyroidectomy increased from 0.8% in 2007 to 3.1% in 2016 (p=0.005). Compared to patients treated with cinacalcet, those treated with parathyroidectomy had a lower risk of developing tertiary hyperparathyroidism (aHR = 0.49, 95%CI: 0.29-0.82) at 3 years post-KT and those who received no treatment had lower odds of delayed graft function (aOR = 0.87, 95%CI: 0.78-0.96). There was no association between treatment of SHPTH and post-transplant death-censored graft failure, all-cause graft failure or death.

**Conclusions:** The use of calcimimetics and parathyroidectomy to treat SHPTH has been steadily increasing since 2007. Importantly, patients who underwent parathyroidectomy for SHPTH had lower risk of developing tertiary hyperparathyroidism post-transplant. Therefore, patients treated with cinacalcet pre-transplant may need closer surveillance post-transplant for development of tertiary hyperparathyroidism.

A Combined MicroRNA and Target Protein-Based Panel for Predicting the Probability and Severity of Uremic Vascular Calcification

Chia-Ter Chao,1,2 National Taiwan University Hospital Beihu Branch, Taipei, Taiwan; 2Graduate Institute of Toxicology, National Taiwan University, Taipei, Taiwan.

**Background:** Vascular calcification (VC) increases the future risk of cardiovascular events in uremic patients, but effective therapies are still unavailable. Accurate identification of those at risk of developing VC using pathogenesis-based biomarkers is of particular interest and may facilitate individualized risk stratification. We aimed to uncover miRNA-target protein-based biomarker panels for evaluating uremic VC probability and severity.
Methods: We created a 3-tiered in vitro VC model and an in vivo uremic rat model receiving high phosphate diet to mimic uremic VC. RNAs from the in vitro and in vivo models underwent miRNA and mRNA microarray, with results screened for differentially expressed miRNAs and their target genes as biomarkers. Findings were validated in all models and human cells, followed by functional assays of identified miRNAs, and tests of sera from end-stage renal disease (ESRD) and non-diagnosis dependent chronic kidney disease (CKD) patients without and with VC.

Results: Totally 122 down-regulated and 119 up-regulated miRNAs during calcification progression were identified initially; further list-narrowing based on miRNA-mRNA pairing, anti-correlation, and functional enrichment left 16 and 14 differentially expressed miRNAs and mRNAs. Levels of 4 miRNAs (miR-I08-5p, miR-195, miR-125b-2-3p, and miR-378a-3p) were shown to decrease throughout all models tested, while 1 mRNA (SULT1F, a potential target of miR-378a-3p) exhibited the opposite trend concurrently. Among 77 ESRD (88.3% with VC) (Figure A) and 59 CKD patients (61% with VC) (Figure B), serum miR-125b-2-3p and miR-378a-3p decreased with greater VC severity, while serum SULT1F levels increased. Adding serum miR-125b-2-3p, miR-378a-3p, and SULT1F into regression models for VC substantially improved performance compared to using clinical variables alone.

Conclusions: Using a translational approach, we discovered a novel panel of biomarkers for gauging the probability/severity of uremic VC based on miRNAs and their target proteins, which improved the diagnostic accuracy.

PO0422

Tope Olufadé,1 Lois Lamerato,2 Juan Jose Garcia Sanchez,3 Like Jiang,4 Joanna C. Huang,5 Stephen Nolan,2 AstraZeneca, Wilmington, NC; 3Henry Ford Health System, Detroit, MI.

Background: The DAPA-CKD Trial is the first SGLT-2i renal outcome trial to test the efficacy and safety of an SGLT-2i, dapagliflozin, in patients with diagnosed CKD with and without T2D. To appropriately evaluate future results and aid clinical interpretation of the DAPA-CKD trial, the present study assessed the renal and CV outcomes of a “DAPA-CKD-like population” (eGFR 25-75ml/min/1.73m2 and UACR 200-5000mg/g) in a contemporary US healthcare system.

Methods: Administrative data from the Henry Ford Health System was used to identify patients with CKD stages 2 through 4 between 2006 and 2016 based on eGFR lab reading (n=38,376). Exclusions included no confirmatory eGFR > 90 days from index date, death within 30 days, history of renal transplant, and evidence of renal replacement therapy, or progression to CKD stage 5 during the baseline period (6 months prior to post index date). Within that cohort, 17,742 had eGFR (25-75ml/min/1.73m2) and 9,177 had a UACR (0-5000 mg/g) within 12 months of index date. Additional exclusions were type 1 diabetes, lupus nephritis and polycystic kidney disease. Patients were followed through December 31, 2018.

Results: Of the 6,557 patients that met the eligibility criteria and were included in the study cohort, the mean age was 62.9 years and 46.2% were male. The population was stratified by UACR (0–30, 30–199, 200–5000mg/g). Across all outcomes assessed, incidences were highest in the DAPA-CKD-like cohort (UACR 200-5000mg/g) (HF 36.1%, CV 36.1%, Stroke 8.2% (ESKD 18.6%). Mortality 18.5% see Table 1). The greatest increase was observed for renal outcomes particularly ESKD, increasing from 0.9% (UACR 0–30mg/g) to 3.4% (UACR 30-199mg/g) to 18.6% (UACR 200-5000mg/g).

Conclusions: In a contemporary US healthcare system, there remains significant adverse renal, CV and mortality outcomes among patients fitting the DAPA-CKD study inclusion criteria. These results highlight the unmet need existing for additional therapies to delay disease progression and improve outcomes and survival in this high risk population.

NSAID Use Is Not Associated with Kidney Injury or Dysfunction in Ambulatory Older Adults
Jonathan G. Amatrud,1,2 Harini Sarathy,1 Carmen A. Peralta,1,4 Michelle M. Estrella,1,2 Ronit Katz,1 Joachim H. Ix,1 Linda F. Fried,1 Chirag R. Parikh,1 Anne B. Newman,3 Mark J. Sarnak,2 Michael Shlipak,2,4 1University of California San Francisco, San Francisco, CA; 2Kidney Health Research Collaborative, UCSF, San Francisco, CA; 3University of Washington, Seattle, WA; 4Yale Pittsburgh Healthcare System, Pittsburgh, PA; 5University of California San Diego, La Jolla, CA; 6Johns Hopkins University, Baltimore, MD; 7Tufts Medical Center, Boston, MA; 8Cricket Health, San Francisco, CA; 9University of Pittsburgh, Pittsburgh, PA.

Background: NSAIDs cause AKI and may worsen CKD, especially in vulnerable populations such as older adults. We hypothesized that NSAID use would be associated with markers of both tubular and glomerular damage in older adults.

Methods: In the multicenter Health ABC cohort of ambulatory older adults, prescription and OTC NSAID use was self-reported. Estimated GFR by cystatin C, and urine albumin (ACR), KIM-1, and IL-18 were measured in 2,999 participants; urine a1m, NGAL, P1NP, and UMOD were measured in a random subset of 500 participants. We evaluated cross-sectional associations between NSAID use and these biomarkers with separate linear regression models. The association between time-updated NSAID use and eGFR decline over 10 years was estimated with linear mixed models.

Results: Participants had a mean age of 74 years, 51% were female, and 41% African-American. No eGFR differences were detected between NSAID users (n=655) and non-users (n=2344) at baseline (72 mL/min/1.73m2 in both groups). Compared to non-users, NSAID users had 33% (95% CI: 11%-49%) lower adjusted odds of having ACR ≥30 mg/g and 11% (95% CI: 4%-18%) lower mean urine IL-18 concentration at baseline. No significant differences in baseline concentrations of the remaining urine biomarkers were detected. NSAID users and non-users did not differ significantly in the rate of eGFR decline (-2.2% vs. -2.3% per year).

Conclusions: Among ambulatory older adults, NSAID use was not associated with kidney dysfunction or damage upon eight markers of kidney health, and NSAIDs were associated with significantly lower urine albumin and IL-18 concentrations. These findings illustrate the potential for NSAID use without kidney harm, even in a presumably high-risk population.

PO0424
The Prevalence of CKD Among First-Degree Relatives of Saudi Hemodialysis Patients and Associated Factors
Dujanah Alhomrany,1 Imed Alharbi,1 Mohammed A. Alhomrany,1 Imed Helal,1 FayeZ F. Alhejaili,1 Diaverum Saudi Arabia Diaverum Renal Services Group, Riyadh, Saudi Arabia.

Background: In Saudi Arabia, there are currently over 20,000 patients on dialysis and 9810 patients followed up for functioning renal transplantation. The combined prevalence of renal replacement therapy (stage 5 CKD) in Saudi Arabia is estimated to 1294.3 PMP. There are no local data or registry about stages 1 to 4 CKD in the Kingdom. Objective: To assess the prevalence of CKD among first degree relatives of Saudi hemodialysis patients and evaluate the associated characteristics.

Methods: 1st degree relatives of all hemodialysis patients in Diaverum clinics in Saudi Arabia were screened for CKD. Demographic data were collected as well as history of hypertension or diabetes mellitus. Serum creatinine, urinalysis and a single Blood pressure reading were measured. eGFR was calculated using EPI formula. For the index cases, the cause of CKD, age and gender were recorded. The prevalence rates of CKD stages among relatives were calculated and the association between different variables and CKD stages assessed.

Results: Out of 4550 dialysis patients, 20258 1st degree relatives were approached of whom 5177 responded. The cause of CKD among the index cases was DM in 52.5% followed by hypertension (20.6%). The eGFR was < 90 ml/min in 39.6% and < 60 ml/min in 35% of the screened cases. Proteinuria was present in 8%, making the combined prevalence of CKD of 13.8%. In the screened group, the prevalences of glycosuria, hematuria and proteinuria were 9.5%, 17.9% and 26.5% respectively and systolic hypertension (≥130 mmHg) was observed in 28.1% and diastolic hypertension in 8.6%. Serum creatinine values in stage 4 were significantly younger than those in stages 2-5 (p<0.001). The relationship of the screened persons to the index patients among those in stages 2-5 were offspring (35.8%), sibling (41.6%) and parent (50.0%) (p=0.0005). The prevalences of the primary renal diseases in the index cases did not differ between screened relatives in CKD stages 0-1 and those in stage 2-5.

Conclusions: The overall prevalence of CKD was 13.8% and is highest in the Southern region of Saudi Arabia. The presence of CKD in the screened relatives was not associated with identifiable cause of CKD in the index cases or use of analgesics. Many relatives were discovered to have undiagnosed hypertension and undiagnosed diabetes.

Sex Differences in CKD Prevalence in Asia: A Systematic Review and Meta-Analysis
Carrina Hockham,1 Lexia Bao,1 Anushree Tiku,1 Sunil Badve,1,2 Martin P. Gallagher,1,2 Meg J. Jardine,1,2 Vivekanand Jha,1,2 Min Jun.1 The George Institute for Global Health, UNSW Sydney, Sydney, NSW, Australia; 2St. George Hospital, Sydney, NSW, Australia; 3Concord Repatriation General Hospital, Sydney, NSW, Australia; 4The George Institute for Global Health, University of Oxford, Oxford, United Kingdom.

Background: Individual studies reporting sex-specific chronic kidney disease (CKD) prevalence in Asia have shown inconsistent sex differences in CKD prevalence. We sought to synthesize available sex-disaggregated data to better define and compare CKD prevalence in women and men in Asia.

Methods: We systematically searched the literature for observational studies of a≥500 adults reporting sex-disaggregated CKD prevalence data in Asia. We calculated the women-to-men prevalence ratio (PR) for each study and pooled these using random-effects meta-analysis. Subgroup analyses were performed to explore potential sources of heterogeneity in the PR.

Results: Sex-disaggregated CKD prevalence data were available for 12 of the 26 Asian countries (109 studies; 1,452,308 women and 1,391,995 men). Most studies (83%) came from China, Taiwan, Japan and South Korea. Sex-specific CKD prevalence estimates varied substantially between studies (median [IQR] reported prevalence was 16% [9-35%] in women and 17% [8-28%] in men). Overall, CKD prevalence was higher in women compared to men (pooled PR 1.14; 95% CI 1.07-1.21), with evidence of significant heterogeneity (I²=99%). In subgroup analyses, prevalence was higher in women among studies with a younger mean age, a higher proportion of diabetes and that defined CKD using eGFR only (Table 1). The pooled PR varied considerably by country.

Conclusions: Existing sex-disaggregated data suggest a higher overall prevalence of CKD in women compared to men in Asia. However, adequate assessment of sex differences in CKD prevalence is limited by the absence of sex-disaggregated data for a large part of the region. Standardised reporting of sex-disaggregated CKD prevalence data in Asia is needed.

Table 1 Subgroup analyses of the pooled PR.

PO0426
Increased Circulating suPAR Levels in African Patients with HIV
David C. Wei,1 Beata Sameklo,1 Martin G. Zeier,2 Rulan S. Parekh,3 Jochen Reiser,1 Rush University Medical Center, Chicago, IL; 2University Hospital Heidelberg, Heidelberg, Germany; 3University of Toronto, ON, Canada.

Background: Decline in kidney function associated with APOL1 risk alleles is dependent on circulating suPAR levels in African American (AA) patients. Yet, little is known among HIV infected persons in sub-Saharan Africa, and epidemiological data from

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
this region regarding APOL1 risk status is scarce. We aimed to determine APOL1 risk variants, plasma suPAR levels and estimate kidney function in HIV patients in Zambia.

Methods: We performed a cross-sectional study with 480 adult HIV infected persons on anti-retroviral treatment (ART) (women, 64.8%) in Lusaka, Zambia. APOL1 genotyping was done to determine the prevalence of the risk alleles; plasma suPAR levels were assayed and estimated GFR (eGFR) was calculated by CKD-EPI creatinine-based formula.

Results: Plasma suPAR levels were increased and were negatively correlated to eGFR, whether less than 60 or not (r=-0.15, p<0.001). Women while younger (42 vs 46 years old for men, p=0.0003), had higher suPAR than men (3.68 mg/ml vs 3.07 mg/ml, p<0.0001). Ten out of 480 patients (2.1%) had CKD, and their suPAR levels were higher than patients without CKD (5.6 mg/ml vs 3.44 mg/ml, p<0.0001). Fifty patients (10.4%) had 2 APOL1 risk alleles (35 for women vs 15 for men); among those, 3 (6%) developed CKD (p=0.07). No difference in suPAR levels or eGFR was observed between patients who carried 2 APOL1 risk alleles and those with 1 or 0 risk allele.

Conclusions: HIV infected persons in Zambia on ART have increased suPAR levels. The prevalence of two APOL1 risk alleles is similar as with AA HIV patients. A longitudinal study with a bigger cohort should reveal the relationship between suPAR, APOL1 risk alleles and kidney function.

Kidney Tubular Injury and Dysfunction Relate to Frailty and Cognitive Function in Persons with CKD in SPRINT
Lindsay S. Miller,1 Manjula Kurella Tamura,2 Nicholas M. Pajewski,3 Daniel E. Weiner,7 Dena E. Rifkin,1 Michael Shlipak,5,6 Joachim H. Ix,1 1University of California San Diego Division of Nephrology-Hypertension, San Diego, CA; 2Stanford University School of Medicine, Stanford, CA; 3Wake Forest University School of Medicine, Winston-Salem, NC; 4Tufts Medical Center, Boston, MA; 5Kidney Health Research Collaborative, San Francisco, CA; 6VAHCS/UCSF, San Francisco, CA.

Background: The association of markers of kidney disease (eGFR and albuminuria) with frailty and cognition is well established. However, these markers do not specifically evaluate kidney tubule injury or dysfunction.

Methods: We measured 8 biomarkers of kidney tubule dysfunction and injury among 2,882 SPRINT participants with eGFR <60 and evaluated their association with frailty and cognitive function. Frailty was defined with a previously validated frailty index (FI), categorized as fit (FI < 0.10), less fit (0.10 < FI < 0.21), and frail (FI > 0.21). Global cognitive function was measured using the Montreal Cognitive Assessment (MoCA).

Models were adjusted for, demographic, behavioral, and clinical variables including urine creatinine, eGFR, and albuminuria.

Results: Higher urine concentrations of MCP-1 and cT1M were independently associated with frailty (Figure). These associations were independent of demographics, other CKD risk factors, eGFR and albuminuria, and were more strongly associated than associations of albuminuria with frailty (Figure). Higher urine cT1M was associated with lower cognitive function (β -0.09; 95% CI -0.17, -0.01), whereas albuminuria was not (β: -0.09; 95% CI -0.17, -0.01), among those, 3 (6%) developed CKD (p=0.07). No difference in suPAR levels or eGFR was observed between patients who carried 2 APOL1 risk alleles and those with 1 or 0 risk allele.

Conclusions: None of the urine tubule injury markers were associated with MSJE, whereas higher urine NGAL was associated with lower DSST scores. Lower concentrations of sHC03 were associated with lower scores of MSJE but not DSST (Table). These associations were independent of demographics, eGFR, and albuminuria.

Cross-sectional association between tubule injury markers of kidney dysfunction with cognitive function.

PO0428
Association of Kidney Tubule Injury and Dysfunction with Cognitive Function in the Health, Aging and Body Composition Study
Lindsay S. Miller,1 O. Alison Potok,1 Dena E. Rifkin,1 Mark J. Sarnak,2 David A. Drew,2 Linda F. Fried,1 Michael Shlipak,5 Joachim H. Ix,1 University of California San Diego Division of Nephrology-Hypertension, San Diego, CA; 3VA Medical Center, Boston, MA; 4VA Pittsburgh Healthcare System, Pittsburgh, PA; 5Kidney Health Research Collaborative, San Francisco, CA; 6VAHCS/UCSF, San Francisco, CA.

Background: The association of lower levels of eGFR and higher levels of albuminuria with poor cognition is well established. However, these markers do not specifically evaluate kidney tubule injury or dysfunction.

Methods: We measured 5 urinary biomarkers of kidney tubule injury and dysfunction (alpha-1 microglobulin [α1M], kidney injury molecule-1 [KIM-1], interleukin-18 [IL-18], uromodulin [Umod], and neutrophil gelatinase-associated lipocin [NGAL]) among a random sample of 502 participants, and serum bicarbonate [sHC03] among 2,288 community-living elders aged 70-79. We evaluated the cross-sectional associations with cognitive function using the Modified Mini-Mental State Exam (3MSE) and the Digit Symbol Substitution Test (DSST), where higher scores represent better cognitive function.

Results: None of the urine tubule injury markers were associated with MSJE, whereas higher urine NGAL was associated with lower DSST scores. Lower concentrations of sHC03 were associated with lower scores of MSJE but not DSST (Table). These associations were independent of demographics, eGFR, and albuminuria.

Conclusions: None of the urine tubule injury markers were associated with low cognition, only higher NGAL was associated with lower cognitive function testing by DSST. Similarly sHC03 was associated with worse cognitive function by MSJE independent of eGFR, albuminuria, or other risk factors.

Funding: NIDDK Support, Other NIH Support - This research was supported by National Institute on Aging (NIA) contracts #N01-AG-6-2101; N01-AG-6-2103; N01-AG-6-2106; NIA grant R01-AG028805; NINR grant R01-NR012459, Veterans Affairs Support

Cross-sectional association between biomarker of kidney tubule dysfunction with cognitive function.
Conclusions: We observed that elevated TG were associated with higher risk of pneumonia hospitalization in non-CKD and CKD stage 3A-3B patients, but this relationship was not observed in late-stage CKD patients. While use of statins and cholesterol levels have been studied in the context of pneumonia and lung function, future studies are warranted to also investigate the role of triglycerides in pneumonia risk especially among early stage CKD patients.

PO0430

The Reference Interval and Risk Factors of NT-ProBNP in CKD Patients Without Heart Failure

Junzhe Chen, Ying Tang, Zhenjian Xu, Qiuyan Huang, Anping Xu. Department of Nephrology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China.

Background: N-terminal pro-B-type natriuretic peptide (NT-proBNP), a diagnostic marker of heart failure (HF), as well as the specific and sensitive biomarker of HF is been demonstrated to be affected by renal failure. NT-proBNP is significantly associated with the severity of GFR loss. However, the reference interval (RI) of NT-proBNP in nondialysis chronic kidney disease (CKD) patients without HF remains unclear. The aim of our study was to establish the threshold value of NT-proBNP which could help to early recognition, prevention and treatment for HF.

Methods: All patients diagnosed with CKD aged more than 18 years old in our hospital from Jan 01, 2014 to Dec 31, 2019 were recruited into this study. Individuals who diagnosed with HF were excluded. The RI for NT-proBNP was defined by nonparametric method and risk factors were analyzed by linear regression analysis.

Results: A total of 1260 CKD patients without HF were included in this study. Of them, 588(46.67%) were female. NT-proBNP were increased with the advanced stage of kidney function in CKD patients without HF. The median level of NT-proBNP in CKD stage 5 (non-dialysis patients) without HF were the highest, as 610.25 pg/ml. The RIs for NT-proBNP in CKD patients without HF with respect to kidney function stage (ranges of stage 1, stage 2, stage 3, stage 4, stage 5 ND) were 8.15-536.32, 12.38-811.90, 16.62-1411.05, 33.14-2945.05, 88.58-5533.73 pg/ml. We also demonstrated that NT-proBNP was significantly correlated with the serum levels of Hb (β =-0.174, P<0.001), Ca (β =-0.214, P<0.001), P (β =-0.111, P<0.001), hs-CRP (β =-0.140, P<0.001), and eGFR(β =-0.243, P<0.001).

Conclusions: Our study proved that NT-proBNP was increased with the advanced stage of GFR in CKD patients without HF. The RI of NT-proBNP varied among the different stages of CKD without HF and multiple factors contributed to NT-proBNP, which could help clinicians to prevent and take actions against the occurrence of HF.

PO0431

Soluble Urokinase Plasminogen Activation Receptor and Major Adverse Cardiac Event Morbidity in CKD Patients in the German Chronic Kidney Disease (GCKD) Cohort

Claudia Sommerer,1 Sandra Müller-Krebs,1 Jennifer Nadal,2 Matthias Schmid,2 Kai-Uwe Eckardt,1 Jochen Reiser,1 Martin G. Zeier,1 1Department of Nephrology, University Hospital Heidelberg, Heidelberg, Germany; 2Department of Medical Biometry, Informatics, and Epidemiology (IMBI), University Hospital of Bonn, Bonn, Germany; 3Department of Nephrology, Charité, University Medicine Berlin, Berlin, Germany; 4Department of Medicine, Rush University Medical Center, Chicago, IL.

Background: Soluble urokinase plasminogen activation receptor (suPAR) is supposed as risk factor for both chronic kidney disease (CKD) and biomarker for major adverse cardiac events (MACE) disease. A long-term longitudinal analysis in a large cohort of patients suffering from both diseases simultaneously, CKD and cardiovascular (CV) disease including MACE criteria, to analyze suPAR as a predictive biomarker has not been performed, yet.

Methods: SuPAR was studied in the GCKD Study Group with a follow-up time of 4 years. Association of suPAR with CKD (estimated glomerular filtration rate, eGFR) and overall risk of all-cause death, CV death, and MACE (three-point MACE, MACE3; four-point MACE4) was estimated by Cox proportional hazards regression according to quintiles of suPAR.

Results: Altogether, 4994 participants were enrolled (60.1 ± 12.0 years; eGFR of 49.4 ±18.3 mL/min/1.73m²). Median suPAR concentration was 1771 pg/mL (25th-75th percentile, 1447-2254 pg/mL). Hazard ratio for CV mortality was 1.58 (95%CI 0.62-4.00) in the second, 2.15 (95%CI 0.87-5.26) in the third, 3.48 (95%CI 1.53-7.93) in the fourth, and 5.30 (95%CI 2.34-12.0) in the fifth quintile. If additionally adjusted for eGFR, UACR, NT-proBNP, hsCRP results were confirmed.

Conclusions: In the GCKD study cohort suPAR predicts all-cause death, cardiovascular death, and MACE independent of NT-proBNP, renal function and of markers of systemic inflammation.

PO0432

Incidence and Racial Disparities in Cardiovascular Disease and CKD Progression in Young Adults with CKD

Alexander J. Kula,1,2 Nisha Bansal,1 David K. Prince,1 Seattle Children’s Hospital, Seattle, WA; 2University of Washington, Seattle, WA.

Background: Cardiovascular disease (CVD) is a major source of morbidity and mortality in adult CKD patients; yet is not well elucidated in young adults with CKD. Furthermore, racial and ethnic disparities in CVD and CKD progression has been found in research of pediatric and older-adult CKD populations, but has not been investigated specifically in young adults.

Methods: We studied 317 participants aged 21-40yrs of age with mild to moderate CKD enrolled in the Chronic Renal Insufficiency Cohort (CRIC) Study, of whom, 174 were black or Hispanic. We calculated incidence rates for CV events (heart failure [HF], MI, stroke, and death) and CKD progression (50% decline in eGFR or ESRD) for all young adult participants and as stratified by race and ethnicity. Cox proportional hazards regression models were constructed to test the association between race/ethnicity and CV events and CKD progression, adjusting for age, sex, eGFR, UACr, baseline SBP, and APOL1 status.

Results: HF, mortality and CKD progression had the highest incidence rates amongst young adults with CKD (Figure 1). Rates of these events were higher among Black and Hispanic participants: HF (17.5 vs. 5.1/1000 person-years), all-cause mortality (15.2 vs. 7.1/1000 person-years), and CKD progression (125 vs. 59/1000 person-years). Lastly, in adjusted models, black or Hispanic status was significantly associated with higher risk of CV events (HR: 1.25, 95%CI: 1.12-1.41) and CKD progression (HR: 1.38, 95%CI: 1.21-1.57).

Conclusions: Young adults with CKD in the CRIC study experience high incidence rates of cardiovascular disease. The burden of disease is even higher for black and Hispanic participants with CKD. Further research is required to better understand the factors underlying racial disparities in young adults with CKD.

Trends in the Transition to ESRD Among Native Hawaiians and Pacific Islanders Across the United States

Constance Rhee,1 Amy S. You,1 Keith C. Norris,1 Merle R. Kataoka-Yahiro,3 James Davis,4 Glen Hayashi,3 Victoria Page,5 Shiuh-Feng Cheng,4 Roland C. Ng,1 Linda L. Wong,4 Kamyar Kalantar-Zadeh,1 University of California Irvine, Irvine, CA; 2University of California Los Angeles, Los Angeles, CA; 3University of Hawaii Manoa, Honolulu, HI; 4John A. Burns School of Medicine, Honolulu, HI; 5National Kidney Foundation Hawaii, Honolulu, HI.

Background: Census data indicate there are >1.5 million Native Hawaiians and other Pacific Islanders (NHOPIs) in the US. While growing data show NHOPIs have a high prevalence of kidney disease risk factors (diabetes, obesity, hypertension, limited healthcare access), there are major knowledge gaps regarding the burden of end-stage renal disease (ESRD) in this population. We examined trends in the transition to ESRD in NHOPIs.

Methods: Using United States Renal Data System (USRDS) and Census Bureau data, we compared annual incident ESRD rates among NHOPI, African Americans (AA), and other racial subgroups over 2010-16. Rates were calculated as the observed incident ESRD count divided by the race-specific Census population size of that year. Multiple race designations were considered by utilizing Census categorizations that incorporated primary race in combination with one or more other races (alone or combination). We estimated crude rates and rates standardized to the age-sex distribution of 2011 race-specific Census population data.

Results: Over 2010-16, NHOPIs and AAs demonstrated the highest crude incident ESRD rates over time (Fig 1A). A similar pattern was observed for standardized incident ESRD rates (Fig 1B): 918, 638, 308, and 226 incident ESRD patients per million (population/year) in 2016 for NHOPI, AA, Caucasian, Asian, and American Indian/Alaska Native subgroups, respectively. While standardized incident ESRD rates among AAs gradually declined, there was a steady rise in NHOPIs’ incident ESRD rates over time.

Conclusions: NHOPIs demonstrated the highest incident ESRD rates over time. Further studies are needed to determine sociodemographic, biologic/genetic, cultural, and health care related ESRD risk factors among NHOPIs to inform targeted interventions in this population.

PO0436
Defining the Excess Risk of Adverse Kidney Outcomes in CKD Patients with Type 2 Diabetes in the DISCOVER-CKD Cohort
Alyshah Abdul Sultan,1 Stephen Nolan,1 Juan J. Carrero,2 Zhuxin Jiang,3 Supriya R. Kumar,3 Roberto Pecoteis-Filho,4,6 Glen James,7 Juan Jose Garcia Sanchez,8 Lam S. Carolyn,9 Hungta (tony) Chen,9 Eiichi Kanda,4 Naoki Kashihara,4 Mikhail Kasiborod,1 Carol A. Pollock,8 David C. Wheeler,1 Hiddo J. L Heerspink,12 AstraZeneca, Cambridge, United Kingdom; 1Karolinska Institute, Karolinska Institutet, Stockholm, Sweden; 2AstraZeneca, Gaithersburg, MD; 3Arbor Research Collaborative for Health, Ann Arbor, MI; 4Pontificia Universidade Catolica do Parana Escola de Medicina Campus Londrina, Londrina, Brazil; 5National Heart Centre Singapore, Singapore, Singapore; 6Kawasaki Ika Daigaku, Kawasaki, Japan; 7Saint Luke’s Mid America Heart Institute, Kansas City, MO; 8Royal North Shore Hospital, St Leonards, NSW, Australia; 9University College London, London, United Kingdom; 10Rijksuniversiteit Groningen, Groningen, Netherlands.

Background: Chronic Kidney Disease (CKD) patients with type 2 diabetes (T2D) are considered at a high risk of cardiovascular events. However, the excess risk of major kidney events in T2D patients compared to patients without T2D is unknown.

Methods: DISCOVER-CKD is an international observational study of patients with CKD that encompasses large retrospective electronic medical records (EMR) and claims data between 2008 and 2020. Preliminarily, data from US-based Limited Claims and Electronic Health Record (LCED) data (IBM Health, Armonk, NY) and TriNetx (healthcare-based EMR) were analysed. CKD patients (eGFR <60 mL/min/1.73 m²) aged ≥18 years with a 1-year record of urine albumin to creatinine ratio (UACR) were identified. T2D status was ascertained any time before the index date (2nd eGFR measurement). The risk of kidney outcomes (sustained ≥50% eGFR decline or end-stage kidney disease) was compared between patients with and without T2D at ≥5 years’ follow-up.

Results: Compared to non-T2D patients, T2D patients had a slightly higher incidence rate of adverse renal outcomes in LCED (2.7% versus 2.3% per year; TriNetX: 1.8% versus 1.2% per year). After adjusting for all confounding factors (Figure 1) we observed no increased risk of adverse renal outcomes in patients with T2D compared to non-T2D patients in LCED (hazard ratio (HR): 1.08; 95%CI 0.81-1.43) and a 34% increased risk in TriNetX database (HR:1.34; 95%CI 1.11-1.62).

Conclusions: There is an excess risk of renal adverse outcomes in CKD patient with T2D compared to those without T2D. This is explained in part by a large extent by conventional risk markers in LCED but not completely in TriNetX. Both groups (T2D and non-T2D) should be managed proactively to reduce the risk of poor clinical outcomes.

Funding: Commercial Support - AstraZeneca

ESRD (HR, 2.09 95%CI 1.43 to 3.07, I²=37%), all-cause mortality (HR, 1.53 95%CI 1.13 to 2.01, I²=77%) and hospitalization (HR, 1.28, I²=52).

Conclusions: Depressive symptoms in CKD are independent risk factors of poor clinical outcomes, including ESRD, all-cause death, and hospitalization. There is necessary to design high quality studies to assess the effects of treating depressive symptoms in patients with CKD.

PO0438
Association of the Creatinine-to-Cystatin C Ratio with Overall Survival with and Without CKD
Elamn Srija,1 Cachet Wenzinger,1 John Sy,1 Ekamol Tantisattamo,1 Rany M. Hanna,1 Csaba P. Kovesty,2,3 Susan T. Crowley,1 Kamyar Kalantar-Zadeh,1 2Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; 3The University of Tennessee Health Science Center, Memphis, TN; 4VA Long Beach Healthcare System, Long Beach, CA; 5Memphis VA Medical Center, Memphis, TN.

Background: Creatinine and Cystatin C are measured as glomerular filtration markers. Creatinine is highly correlated with skeletal muscle mass, whereas Cystatin C is not. We hypothesized that persons, in whom serum Cystatin C is lower than creatinine level, i.e., creatinine to Cystatin C ratio (CrCCR) >1.00 (regardless of measurement units) have incrementally greater survival chance, likely due to a larger muscle mass.

Methods: We examined a cohort of 7,849 Veterans with baseline measured Cystatin C and creatinine data between 2004-2015. Veterans were divided into 0.25 increments of CrCCR, i.e., <0.75, 0.75–<1.0,1.0–<1.25, ≥1.25. They were further stratified into groups based on normal vs. low eGFR (<60 vs. ≥60 mL/min/1.73 m²), and the associations of CrCCR with survival across two eGFR strata were examined.

Results: The mean age (±SD) in the Veterans’ cohort was 69±12 years. There were 4% female, 77% white, and 15% African American. The median (IQR range) for cystatin C was 1.28 (0.99,1.71) mg/L, for creatinine 1.24 (0.92,1.68) mg/dl, and for the CrCCR was 0.99 (0.81,1.17). Compared to the reference (CrCCR=1.25 and eGFR≥60 mL/ min/1.73 m²) the multivariable adjusted model showed that those with a lower CrCCR >0.75 (regarding lowest mortality strata) had the lowest mortality risk for both eGFR strata, with the normal eGFR group having higher death risk than the low eGFR group (HR=1.05; 1.05-1.32). The in the highest CrCCR group (≥1.25) indicating more muscle mass, the normal eGFR group had the highest overall survival than those with low CrCCR (HR=0.65; 0.65-0.76), respectively. In the highest CrCCR group (≥1.25) indicating more muscle mass, the normal eGFR group had the highest overall survival than those with low CrCCR (HR=0.65; 0.65-0.76), respectively. In the highest CrCCR group (≥1.25) indicating more muscle mass, the normal eGFR group had the highest overall survival than those with low CrCCR (HR=0.65; 0.65-0.76), respectively. In the highest CrCCR group (≥1.25) indicating more muscle mass, the normal eGFR group had the highest overall survival than those with low CrCCR (HR=0.65; 0.65-0.76), respectively. In the highest CrCCR group (≥1.25) indicating more muscle mass, the normal eGFR group had the highest overall survival than those with low CrCCR (HR=0.65; 0.65-0.76), respectively.

Conclusions: A lower CrCCR indicating higher cystatin C relative to creatinine levels are strongly associated with worse overall survival in Veterans regardless of kidney function level. Future studies should examine the clinical utility of this potential surrogate of muscle mass and overall health over creatinine or Cystatin C alone in evaluating risk stratification in patients with and without kidney disease.

PO0437
Increased Risk of Progression to ESRD or Death in CKD Patients with Symptoms of Depression: A Systematic Review and Meta-Analysis of Cohort Studies
Jiahao Zeng,1 Xindong Qin,2,3 Xusheng Liu,2,3 The Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China; Guangdong Provincial Hospital of Chinese Medicine, Guangzhou, China, Guangzhou, China.

Background: Comorbid symptoms of depression are common psychiatric disorder in patients with chronic kidney disease (CKD). It remains unclear whether it is an independent risk factor for progression of patients with CKD not requiring dialysis. We conducted a systematic review to assess the association of depressive symptoms with poor clinical outcomes in patients with CKD not requiring dialysis.

Methods: PubMed, Embase and CINAHL were searched (up to February 15th, 2020) for cohort studies assessing the association of depression with progression to end-stage renal disease (ESRD), defined as requiring maintenance dialysis, or all-cause mortality in patients with CKD not requiring maintenance dialysis. Two independent researchers extracted data, assessed risk of bias and evidence certainty.

Results: Seven cohort studies of 6145 patients were included. Methodological quality of studies was generally low risk of bias. Compared with non-depression or low depressive symptoms, high depressive symptoms increased the risk of progression to

PO0439
CKD by Previous Diabetes or Hypertension: A Longitudinal Outcomes Study in Primary Care
David Vizcaya,1 Belen Salvador-González,2,4 Oriol Cunillera,2 Neus Gil,2,4 Bayer Pharmaceuticals, Sant Joan Despi, Spain; 3Fundació Institut Universitari per a la recerca a l’Atenció Primària de Salut Jordi Gol i Garina (IDAP/IGol), Cornellà, Spain; 4Unitat de Suport a la Recerca Costa de Ponent, Fundació Institut Universitari per a la recerca a l’Atenció Primària de Salut Jordi Gol i Garina (IDAP/IGol), Cornellà, Spain; 5Direcció Atenció Primària Costa de Ponent- Institut Català de la Salut, Cornellà, Spain.

Background: To compare mortality and progression to end-stage-renal-disease (ESRD) in patients with new chronic kidney disease (CKD) by previous occurrence of type 2 diabetes (DM) and/or arterial hypertension (HT) in Catalonia

Methods: We designed a longitudinal retrospective study of adults with new CKD between 2007 and 2017 identified using electronic medical records from primary care
in Catalonia, Spain. New CKD was considered the index event and defined as a first occurrence of an estimated glomerular filtration rate (eGFR) <60 mL/min/1.73 m² or a urine albumin-to-creatinine ratio ≥ 30 mg/g or albuminuria a 20mcg for 90+ days, or a diagnostic code for CKD. Variables were extracted from the SIDIAP research database and the Spanish hospital basic minimum dataset. Patients were classified according to previous occurrence of HT, DM, both or none. The resulting mutually exclusive DM-CKD, HT-CKD, DM-HT/CKD and unspec-CKD, were followed until ESRD and death within the study period. We defined ESRD as an eGFR< 15 mL/min during 90+ days or renal replacement therapy. Fine and Grey regression models were used to assess competing risk of death and Cox regression among the four CKD groups, considering mortality as a competing risk and Cox regression for mortality. Both models were adjusted for multiple confounders.

**Results:** In total, 467,802 persons were included (median age 75 years; 46.8% men). At baseline, 51% had DM, 45% had HT, 33% had HT/DM-CKD and 12% had unspec-CKD. The DM-CKD group were the youngest in average, more likely to be men, had the highest proportion of persons with an eGFR below 60 mL/min/1.73m2 and the highest proportion of altered albuminuria. Comparing unspec-CKD, DM- and HT-CKD had lower risk of ESRD -adjusted subdistribution hazard ratio (SHR) and 95% confidence interval (CI): 0.98 (0.95-0.98) and 0.71 (0.65-0.79), respectively, but HT/DM-CKD had a higher risk: SHR(CI) 1.11 (1.06-1.15). In turn, the risk for death was higher in DM-CKD, HR (CI): 1.19 (1.11-1.27) and lowest in the HT-CKD group, 0.84 (0.79-0.88), as compared to unspec-CKD. For the group HT/DM-HT the HR(CI) was 0.92 (0.87-0.97).

**Conclusions:** According to these results, there are no differences in ESRD risk among CKD patients by prior DM or HT, but there is a synergic effect. Mortality is different in CKD patients with HT vs with DM.

PO0440 Elderly Patients Are Likely to Have Faster CKD Progression if Plasma Brain Natriuretic Peptide (BNP) Is Elevated

Shilo Morimoto, Hiroshi Tanaka. Mihara Red Cross Hospital, Mihara, Japan.

**Background:** Elderly CKD patients have been mostly believed that they have slower decline in eGFR than younger individuals. However, this is not the case, especially when the patient has well-known factor(s) that accelerate(s) CKD progression, such as cardiac dysfunction. Plasma concentration of brain natriuretic peptide (BNP) is often elevated in patients with cardiac dysfunction and is known to be associated with higher mortality. This study was conducted to find out whether plasma BNP level can be used to predict future decline in eGFR.

**Methods:** A hospital-wide study with all the laboratory data for a period of 4 years and 2 months was performed. Non-diaryal CKD patients (median eGFR <60 mL/ min/1.73 m²) with an eGFR slope in whom the eGFR slope was obtained over 731 days or more with BNP measured at least three times were retrieved. An eGFR slope per each patient was calculated and its relationship with plasma BNP level and other factors was assessed. Statistical analysis was done with R 3.6.0 on Ubuntu.

**Results:** A total of 339 patients (M:F = 154:185, age 65-102 (median 84) years) were included whose initial BNP was 130.0±184.2 (0.164.1, median 75.76) pg/mL. A “random forest” analysis, one of the multivariate analyses, was performed using an R package (randomForest), in order to elucidate risk factors associated with faster decline in eGFR, i.e., with the highest change in eGFR. The following factors were found to be initial eGFR, initial BNP and variability of BNP. With linear regression analysis, the eGFR slope was significantly associated with initial eGFR and initial BNP (P<0.001). Patients with higher-than-average initial BNP (>130.0 pg/mL) and initial eGFR had lower rate of decline in eGFR than the rest of the population (3.83±4.62 vs 1.72±3.57, P<0.0001). A combination of initial eGFR and initial BNP correctly differentiated the fastest quartile from the rest in 72.9% of the population.

**Conclusions:** Elevated plasma BNP might predict faster decline in eGFR in the elderly CKD patients.

PO0441 Proton-Pump Inhibitors (PPIs) vs. H2 Blockers (H2B) Users and Overall Risk of CKD Progression

Lili Liu,1 Tarick Ashour,2 Ali Mehdi, Jonathan J. Taliercio,1 Remy Daou,2 Susana Arrigain,1 Jesse D. Schold,3 Nazih L. Nakhoul,2 Georges Nakhoul,2 Cleveland Clinic, Cleveland, OH; 2Universite Saint-Joseph, Beirut, Lebanon; 3Tulane University School of Medicine, New Orleans, LA.

**Background:** PPI use is associated with adverse kidney events. The relationship between PPI use and the development of acute interstitial nephritis (AIN) is well established. However, the relationship between PPI use and CKD progression is less clear. Notably, there is a lack of data concerning renal outcomes in established CKD. The aim of our study is to determine the risk of CKD progression among patients on PPI, H2B, or no anti-acid therapy.

**Methods:** Using our CKD registry, we evaluated the relationship between the use of PPI, H2B, and no treatment among patients with CKD stage 3 and 4 with at least 12 months of PPI visits in the year prior. We evaluated the relationship between medication group and overall mortality using a Cox proportional hazards model while adjusting for demographics and comorbidities, and the relationship between medication group and progression to eGFR<20 or ESKD with death as a competing risk using regression models as described by Fine and Gray.

**Results:** Among 3,930 patients, 1,374 were in PPI group, 119 were in H2 blocker group, and 2,347 had no medication. Average age was 72.8±11.1, and 42.5% male. Among PPI 28% had Coronary Artery Disease compared to 22% among H2B and 19% among no medication (P<0.001). Congestive Heart Failure was 13%, 8% and 7% for each group respectively (P<0.01). Overall mortality was not different amongst the three groups (PPI vs. none HR 0.94, 95% CI: 0.80, 1.10, and PPI vs. H2B HR 0.80, 95% CI: 0.52, 1.24). The cumulative incidence of ESKD/eGFR<20 with death as a competing risk was also not different across groups in univariate (Fig. 1) or adjusted models (PPI vs. none SHR 0.99, 95% CI: 0.74, 1.34, PPI vs. H2B SHR 1.82, 95% CI: 0.91, 3.63). Use of PPI in a CKD population was not associated with increased mortality or CKD progression to ESKD when compared to the use of H2 blockers and to no acid suppressing therapy.

**Conclusion:** Use of PPI in a CKD population was not associated with increased mortality or CKD progression to ESKD when compared to the use of H2 blockers and to no acid suppressing therapy.

PO0442 Renin-Angiotensin-Aldosterone System (RAAS) Blockade Does Not Affect Kidney Progression in Patients with CKD Without Diabetes and Without Proteinuria

Shirley S. Chang,1 Kabir Jalal,1 Andre F. Charest,2 University at Buffalo - The State University of New York, Buffalo, NY; 2 Erie County Medical Center, Buffalo, NY.

**Background:** Non-proteinuric CKD contributes to about 80% of end stage kidney disease and is poorly studied in terms of risk factors & pathogenesis. RAAS blockers such as an angiotensin-converting enzyme inhibitors (ACEI) and angiotensin receptor blockers (ARB) have been shown to be renoprotective in CKD progression in patients with diabetes and proteinuria. There is a paucity of data on effect of ACEI/ARB in non-diabetic non-proteinuric CKD patients.

**Purpose:** This is a retrospective observational study of insurance claim database from 1/07 to 12/31/17 examining the effect of ACEI or ARB use on CKD progression. Inclusion criteria: adults at least 18 years of age, with CKD stage 3 or higher [based on at least 2 serum creatinine (SCr) values 90 days apart] with at least 2 urinalyses with dipstick urine protein with negative or trace, follow-up (FU) period of at least 3 yrs. Patients with diabetes or proteinuria were excluded. Primary outcomes were doubling of SCr, or reaching CKD stage 5. Mortality data was not available. Duration of ACEI/ARB exposure is defined as number of prescribed days. The eGFR was calculated based on CKD-EPI equation. Analysis are performed with 2 models: time varying Cox regression, and mixed model (which included time-period fixed effect and random effects). A greedy 1:1 propensity score matching scheme was applied.

**Results:** Of 20,000 CKD patients, there were 2,853 with CKD stage 3 or higher without proteinuria, with 301 on ACEI/ARB during mean FU 6 yrs. Percentage of patients with hypertension or CHF, mean age, gender, and eGFR did not differ between ACEI/ARB vs. non-ACEI/ARB groups. The eGFR decrease per year was not statistically different between those on ACEI/ARB vs. non-ACEI/ARB group (matched cox model, p = 0.2285; mixed model, p = 0.4546 respectively). Age and ACEI/ARB duration of exposure have no effect. ACEI/ARB patients had lower rate of developing diabetes during the study (OR 0.57, p = 0.0044), and higher rate of proteinuria at the end of study (OR 1.59, p = 0.0048), though these associations were not observed in the matched sample.

**Conclusions:** This study suggests ACEI/ARB does not affect CKD progression in non-diabetic non-proteinuric patients, irrespective of age. Further studies are needed to confirm those findings.

PO0443 Biomarkers of Immune Activation and ESKD: Results from AASK

Teresa K. Chen,1 Michelle M. Estrella,2 Lawrence J. Appel,1 Josef Coresh,1 Shengyuan Luo,1 Jochen Reiser,3 Wassim Obeid,1 Chirag R. Parikh,1 Morgan Grams,1 Johns Hopkins University, Baltimore, MD; 2 University of California San Francisco, San Francisco, CA; 3 Rush University, Chicago, IL.

**Background:** Immune activation is fundamental to the pathogenesis of many kidney diseases, and innate immune molecules such as soluble urokinase-type plasminogen activator receptor (suPAR) have been linked to incidence and progression of CKD.

Novel Fibrosis Biomarker Development and Validation in Human Kidney Disease

Insia M. Schmidt,1,2 Mia Colona,1,2 Bryan R. Kestenbaum,3 Leonidas G. Alexopoulos,1 Ragnar Palsson,1 Anand Srivastava,1 Jing Liu,1 Isaac E. Stillman,1 Helmut G. Rennek,2 Vishal S. Vaidya,2 Haojia Wu,3 Benjamin D. Humphreys,3 Sushrut S. Waikar,1,2 Boston University Medical Center, Boston, MA; 1Brigham and Women’s Hospital, Boston, MA; 3Northwestern University Feinberg School of Medicine, Chicago, IL; 2Washington University in Saint Louis, Saint Louis, MO; 4Beth Israel Deaconess Medical Center, Boston, MA; 5University of Washington School of Medicine, Seattle, WA; 6ProTance LTD, Athens, Greece.

Background: Biomarkers for non-invasive assessment of kidney fibrosis are not available. This study illustrates the characterization of five novel candidate biomarkers of kidney fibrosis—Cadherin-11 (CDH11), Sarcoplasmic reticulum calcium binding-2 (SMOC2), Pigment epithelium-derived factor (PEDF), Matrix-gla protein (MGP), and Thrombospondin-2 (THBS2)—which were selected from transcriptomic findings in animal models of fibrosis.

Methods: We developed Luminex-based assays and measured proteins in plasma and urine samples of two independent prospective cohort studies, the Boston Kidney Biopsy Cohort (BKBC, n=801), a cohort of individuals with biopsy-confirmed semi-quantitative assessment of kidney fibrosis, and the Seattle Kidney Study (SKS, n=252). Ordinal logistic regression and Cox proportional hazards models tested associations of biomarkers with interstitial fibrosis and tubular atrophy (IFTA) in the BKBC and progression to end-stage kidney disease (ESKD) in both cohorts, respectively. sRNA datasets of human kidneys assessed cell-specific gene expression profiles.

Results: In the BKBC, higher levels of urinary PEDF and plasma and urinary SMOC2 and CDH11 were independently associated with more severe IFTA (Figure 1). In both cohort studies, higher levels of plasma and urinary SMOC2 and urinary CDH11 associated with progression to ESKD (HR-range 1.27 to 1.89) after adjustment for age, sex, race, proteinuria, and eGFR. Higher levels of urinary PEDF were associated with ESKD in the SKS (HR=1.29, 95% CI 1.14 to 1.45), with consistent signals in the BKBC, although the latter narrowly missed statistical significance. sRNA-sequencing data demonstrated expression of all biomarkers in human fibroblasts.

Conclusions: Novel plasma and urine biomarkers of kidney fibrosis, developed from animal models, are associated with higher levels of human kidney fibrosis and subsequent progression to ESKD.

PO0445

Urinary Fibrosis Markers and Risk for ESKD: The Chronic Renal Insufficiency Cohort (CRIC) Study

Amanda H. Anderson,1 Robin L. Baulator,1 Wei Yang,2 Katelin Susztak,1 Mircla A. Dobre,1 Hua He,1 Mahboob Rahman,3 Sylvia E. Rosas,4 Anand Srivastava,1 Sushrut S. Waikar,2 Harold I. Feldman,2 The CRIC Study 1Tufts University, New Orleans, LA; 2University of Pennsylvania, Philadelphia, PA; 3Case Western Reserve University, Cleveland, OH; 4Joslin Diabetes and Endocrinology Research Center, Boston, MA; 5Northwestern University, Evanston, IL; 6Boston University, Boston, MA.

Background: Connective tissue growth factor (CCN2) and amino-terminal peptide of procollagen type III (PIIINP) are both correlated with kidney fibrosis. However, it is unclear if these markers are independently associated with the risk for ESKD.

Methods: We measured CCN2 and PIIINP in baseline urine and standardized to urine creatinine (Cr) in a multi-center cohort study of men and women with chronic kidney disease (CKD), the CRIC Study (N=3727). ESKD was defined as initiation of kidney replacement therapy (N=1118 events). Cox proportional hazards models were adjusted hierarchically as indicated (Table).

Results: The mean age of the study population was 58 years; mean eGFR: 45 mL/ min/1.73 m2; and 48% had diabetes. After multivariable adjustment and median follow-up of 10 years, the highest quartiles of CCN2/Cr and PIIINP/Cr were associated with a 1.8-fold and 1.7-fold higher risk for ESKD compared to the lowest quartiles, respectively (Table). The association was no longer statistically significant after adjustment for proteinuria.

Conclusions: Urinary CCN2 and PIIINP are strongly associated with risk for ESKD, an association that may be mediated through proteinuria. Future studies should investigate if these markers add to the identification of those at highest risk for progression to ESKD.

Funding: NIDDK Support

PO0446

Urinary Retinol-Binding Protein Is Associated with the Risk of Kidney Replacement Therapy in CKD

Maria Alice M. Domínguez, Paula Lotufo, Isabela M. Bensenor, Silvia M. Titan, University of Sao Paulo, Universidade de Sao Paulo, Sao Paulo, Brazil.

Background: Retinol-binding protein (RBP), a homolog of the retinol-binding protein (RBP), is used in clinical practice as a risk factor for CKD in tubular diseases, such as Dent’s disease and cystinosis, and in renal transplantation. However, its role as a biomarker of KD progression outside these conditions is less clear. The aim of our study was to evaluate the association of uRBP with the risk of mortality and kidney replacement therapy (KRT) in CKD of multiple etiologies.

Methods: The PROGREDIR cohort is composed of 454 older adults with CKD (predominantly G3 and G4) recruited from the outpatient services of a tertiary hospital in Sao Paulo, Brazil. Baseline uRBP was measured using an immunoenzymatic assay with monoclonal antibody and expressed as mg/g urinary creatinine, and those with missing values were excluded (n=22). Events of death (n=184) and KRT (n=60) were ascertained

Abbreviations: CI: confidence interval; HR: hazard ratio.

Model 1: unadjusted; Model 2: stratified by clinical site and adjusted for age, gender, race/ethnicity, education, BMI, SBP, Hgb, smoking, diabetes, and history of CVD; Model 3: Model 2 + urine Na, urine K, serum phosphate, FGF-23, serum bicarbonate, IL-10, IL-6, TGF-β, hs-TnT, hs-Troponin T, NTproBNP, urine NGAL, eGFR; Model 4: Model 3 + proteinuria.

Underline represents presenting author.
Results: Mean age was 67 (12), y eGFR was 38 (15) mL/min/1.73 m², 64% were male and 58% were diabetic. Median (P25, P75) for uRBp were: 0.29 (0.08, 1.47) in all; 0.24 (0.06, 0.84) vs. 0.46 (0.10, 2.87) in those who remained alive vs. those who died (p = 0.001); and 0.26 (0.08, 0.90) vs. 2.98 (0.21, 17.5) in those without and with KRT, respectively (p = 0.0001). In Cox models, RBP was not related to mortality. However, competing models showed that uRBp was related to the risk of KRT, even after adjustments (Table). This association was also present when only normoalbuminuric participants (CKD A1) were included.

Conclusions: uRBp is significantly associated with the risk of KRT in the setting of CKD, and may be particularly useful as a biomarker in CKD patients with normoalbuminuria (CKD A1).

PO0447 Tubular Secretion of Creatinine and Risk of Kidney Failure: The Modification of Diet in Renal Disease Trial
Pranav S. Garimella,1 Hocine Tighiouart,2 Andrew S. Levey,3 Mark J. Sarnak,4 Joachim H. T.5 University of California San Diego, La Jolla, CA; 5Tufts Medical Center, Boston, MA.

Background: Whether tubular secretion is associated with clinical outcomes beyond glomerular filtrate rate (GFR) or proteinuria is unknown. By using measured GFR and creatinine clearance, we evaluate the association of tubular secretion of creatinine with long-term kidney and mortality outcomes.

Methods: The Modification of Diet in Renal Disease (MDRD) Study was a randomized controlled trial conducted to examine the effects of strict blood pressure control and dietary protein restriction on progression of stages 3 to 4 CKD. This prospective analysis included 838 participants with baseline measures of iothalamate creatinine clearance (CICr), tubular secretion of creatinine (TS cr), and other potential confounding factors (Table). Higher TS cr was associated with a lower risk of ESKD (HR 0.74, 95% CI 0.66–0.84) after adjustments for mGFR, proteinuria, age, sex, body mass index, and GFR slope measurement period occurred in 301 subjects. The GFR slope of the cohort was -0.948 mL/min/1.73 m² per year (95% confidence interval [CI] -1.016, -0.880) in the linear mixed model and -0.982 mL/min/1.73 m² per year (95% CI -1.075, -0.889) according to least squares linear regression. Both calculated GFR slopes were significantly related to the HR of the composite hard endpoints. HR decreased by 0.85 (linear mixed model) and 0.9 (least squares linear regression) times in case of a reduction in slope of GFR decline by 0.75 mL/min/1.73 m² per year. Multiple regression analysis revealed strongly significant associations for GFR slope with urine protein and CKD stage and undetectable relationships for GFR slope with diabetes and age.

Conclusions: This study demonstrated the clinical significance of GFR slope as a surrogate marker for renal prognosis in Japanese CKD patients. In order to reduce slope of eGFR decline, active intervention for proteinuria before the progression to an advanced CKD stage appears to be effective.

PO0448 Clinical Significance and Related Factors of GFR Slope in a Large Multicenter Observational Study in Japan
Yui Kamijo,1,2 Koji Hashimoto,2 Yusuke Yamada,2 Makoto Harada,2 Masatugu Aida,2,3 Shiitomo Yamauchi,2,3 NKEA study group Shishin University School of Medicine, Matsumoto, Japan; 1Nagano Kidney Donation Association, Matsumoto, Japan; 2Ethic Co., Ltd., Chiyoda-ku, Japan.

Background: Recently, GFR slope has attracted attention as an important surrogate marker for the prognosis of CKD, with a reduction in slope of GFR decline by 0.75 mL/min/1.73 m² per year reportedly having clinical significance. This investigation addresses the clinical significance of GFR slope and its related factors on Japanese CKD patients.

Methods: CKD patients in 15 general hospitals between January and March 2014 were surveyed using medical records. The selection criteria were age ≥20 years, eGFR <60 mL/min/1.73 m², and receiving medical treatment for CKD. Baseline patient characteristics, eGFR changes, and hard endpoints (death or ESKD requiring RRT) were analysed. We calculated GFR slope using eGFR data of 2 years by 2 calculation methods, the linear mixed model and least squares linear regression, and examined the relationship of GFR slope with the hazard ratio (HR) of the endpoints. The factors related to GFR slope were also assessed by multiple regression analysis.

Results: Among a total of 11233 patients, we analyzed the data of 7490 CKD G3 and G4 patients (60% male, mean age: 71 years, CKD G3a: 55%, G3b: 30%, G4: 15%, mean eGFR: 44 mL/min/1.73 m², urine protein positive: 51%, diabetes mellitus: 49%, use of RAS-I: 57%). The mean observation period was 1040 days. Hard endpoints after the GFR slope measurement period occurred in 301 subjects. The GFR slope of the cohort was -0.948 mL/min/1.73 m² per year (95% confidence interval [CI] -1.016, -0.880) in the linear mixed model and -0.982 mL/min/1.73 m² per year (95% CI -1.075, -0.889) according to least squares linear regression. Both calculated GFR slopes were significantly related to the HR of the composite hard endpoints. HR decreased by 0.85 (linear mixed model) and 0.9 (least squares linear regression) times in case of a reduction in slope of GFR decline by 0.75 mL/min/1.73 m² per year. Multiple regression analysis revealed strongly significant associations for GFR slope with urine protein and CKD stage and undetectable relationships for GFR slope with diabetes and age.

Conclusions: This study demonstrated the clinical significance of GFR slope as a surrogate marker for renal prognosis in Japanese CKD patients. In order to reduce slope of eGFR decline, active intervention for proteinuria before the progression to an advanced CKD stage appears to be effective.

PO0449 The Kidney Failure Risk Equation: Testing Previous eGFR Slopes, Clinical Variables, and Novel Populations
Morgan Grams, Nigel J. Brunskill, Angela Yee Moon Wang, Navdeep Tangri. CKD Prognosis Consortium CKD Prognosis Consortium, Baltimore, MD.

Background: The 4-variable kidney failure risk equation (KFRE) is a well-validated tool that accurately predicts the 2- and 5-year risk of kidney failure in patients with eGFR <60 mL/min/1.73 m² using baseline eGFR, ACR, age, and sex. The aim of this study was two-fold: to assess whether KFRE can be improved using previous eGFR slope or other variables; and to evaluate whether the KFRE can be used in patients with eGFR ≥60 mL/min/1.73 m².

Methods: We used 36 cohorts in development and 17 cohorts in validation to accomplish these aims; all cohorts participate in the CKD-Prognosis Consortium and had data on the four variables, previous 2-year eGFR slope, and at least 25 ESKD events.

Results: There were 205,004 participants with eGFR <60 mL/min/1.73 m² (12,794 ESKD events) and 441,915 participants with eGFR ≥60 mL/min/1.73 m² (1,220 ESKD events). In the eGFR <60 group, previous 2-year eGFR loss >3 mL/min/1.73 m²/ year was associated with ESKD (meta-analyzed HR 1.36, 95% CI 1.19-1.56) with a small improvement over the 4-variable model (baseline c-statistic in validation cohorts, 0.87-0.89, meta-averaged difference in c-statistic in validation cohorts when adding slope, 0.001, 95% CI: 0.000-0.002). Using previous 5-year slope resulted in slightly better c-statistic compared to the model using 2-year slope (meta-analyzed difference in c-statistic in validation cohorts, 0.003, 95% CI: 0.001-0.005). Other approaches, such as using 1-year average eGFR or 1-year average ACR as inputs in the 4-variable KFRE, or incorporating black race, heart failure, or atrial fibrillation, did not result in meaningful improvements. The KFRE had poor discrimination and calibration in the eGFR ≥60 mL/min/1.73 m² population. In a model that instead predicted 40% decline in eGFR and included age, sex, ACR, diabetes, hypertension, heart failure, and coronary heart disease, previous eGFR loss >3 mL/min/1.73 m²/year over 2- and 5-years were associated with greater risk (HR, 1.43, 95%CI: 1.19-1.70; 1.84, 95%CI: 1.40-2.42).

Conclusions: In summary, the KFRE was improved only slightly by the inclusion of previous eGFR slope. For populations with eGFR >60, a more relevant and predictable outcome may be percent eGFR decline.

Compared of Predicted Risk of Renal Replacement Therapy vs. eGFR for Arteriovenous Fistula Placement in CKD: A Retrospective Analysis

Background: The complexity in predicting which and when patients with chronic kidney disease (CKD) will progress to renal replacement therapy (RRT) contributes to 80% of patients starting hemodialysis without a functioning permanent access. Studies suggest AVF referral at eGFR of 15-20 ml/min increases the likelihood of starting dialysis with an AVF. We were interested in whether a prediction model developed at Kaiser Permanente Northwest better predicted progression to RRT at 1 year compared to eGFR.

Methods: We retrospectively followed 613 patients with stage 4 CKD between ages of 18 to 89 from May 2013 to May 2018 followed by nephrologists who had a nephrology visit with an eGFR and a calculable 2-year risk for RRT around 12 months before end of follow up (defined as death, initiation of RRT, or 2 years from initial enrollment date). We calculated sensitivity, specificity, and area under the curve (AUC) based on a range of 2-year risk for RRT (20%, 40%, 60%, and 80%) and compared them to eGFR threshold of 15 mL/min and 20 mL/min at the 12 month visit prior to end of follow up. We compared 2-year risk for eGFR vs. AVF.

Results: At end of follow up, 12% had died and 14% had progressed to RRT (69% hemodialysis, 22% peritoneal dialysis, 9% transplant). Compared to eGFR threshold of 20 mL/min, specificity and specificity was greater at 2-year risk of 40% (73% and 49% for eGFR threshold of 20 mL/min respectively compared to 83% and 54% respectively for 2-year risk threshold of 40%). Compared to eGFR threshold of 15 mL/min, sensitivity and specificity was greater at 2-year RRT risk of 80% (97% and 11% for eGFR threshold of 15 mL/min respectively compared to 98% and 18% respectively for 2-year RRT risk threshold of 80%). The AUC was greater between 2-year RRT of 20% to 40% (0.73 to 0.70) compared to eGFR between 15 mL/min to 20 mL/min (0.54-0.61). Decision curve analysis showed better net benefit using 2-year risk >40% compared to eGFR of 20 mL/min above a 1 year threshold of 25%.

Conclusions: In patients with CKD stage 4, 2-year risk for RRT better predicted progression to RRT at 1 year compared to eGFR alone. Our study suggests that use of prediction model for RRT may be an important tool for determining optimal timing for AVF referral.

Risk Factors of Renal Replacement Therapy in Hospitalized Patients with CKD Stage 4
Qiaoli Hua, 1 Xusheng Liu, 1 Chuan Zou. 2 Department of Nephrology, the Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China; 3 Department of Dialysis, the Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China; 4 The Second Clinical Medical College, Guangzhou University of Chinese Medicine, Guangzhou, China.

Background: Data on risk factors of renal replacement therapy (RRT) in hospitalized patients with CKD4 may help nephrologists to delay dialysis. The study was designed to describe the risk factors of RRT in CKD4 inpatients.

Methods: Medical records of CKD4 inpatients in Guangdong Provincial Hospital of Chinese medicine during January 2010 - January 2019 were collected. Risk factors such as demographic characteristics, laboratory and echocardiography test results, treatments, comorbidities and primary diseases were collected. Patients were followed up till they reached clinical outcomes (RRT) or the end of the study (January, 2020). Patients who withdrew from the study before 12 years were excluded. Descriptive statistics and survival analysis were performed by Cox regression, with 95% CI, considering a value of P<0.05 as statistically significant.

Results: 222 CKD4 inpatients [age, 60.00(47.75-72.25) years]; female, 55.9% were enrolled. In a multi-follow-up of 2.41 years, 199 inpatients (10.6%) started RRT. Among those patients, the median time progression to RRT was 2.10 (1.20-5.38) years. All patients were divided into two groups according to whether progressed to RRT within 2.41 years. For those received RRT within 2.41 years, they had heavier urine, urine occult blood and account for a higher proportion of inpatients with diabetes mellitus(63.6%), chronic heart failure (43.6%), diabetic kidney disease (55.5%). Their serum albumin and ejection fraction (EF) were lower (P<0.001). The multivariate Cox proportional hazards models showed that age, eGFR ratio (HR: 0.986; 95% confidence interval[CI]: 0.976-0.995); P=0.004, diabetic kidney disease (DKD) (HR: 1.727; 95%CI: (1.274-2.319), P=0.001), urinary protein (HR: 1.148; 95% CI: (1.094-1.205), P=0.001), serum albumin (HR: 0.971; 95% CI: (0.949-0.994), P=0.013), LVMi (HR: 1.010; 95% CI: (1.004-1.016), P=0.002), left ventricular dimension systolic(LVds) (HR: 0.948; 95% CI: (0.910-0.986), P=0.008) and EF (HR: 0.970; 95% CI: (0.950-0.990), P=0.004) were independently associated with factors for progression RRT in CKD4 inpatients.

Conclusions: DKD, urinary protein, LVMi were risk factors that were significantly associated with CKD4 progression to RRT in inpatients. Whereas, serum albumin, LVds, and EF are protective. The urinary protein, serum albumin and echocardiographic parameters need to be taken seriously for patients with CKD.

Indexing Proteinuria to Renal Function Improves Prediction for Renal Events in Individuals with CKD

Afshin Parsa,1 Ivonne H. Schulman,1 Kenneth J. Wilkins,1 Susan R. Mendley,1 Paul L. Kimmel,1 Adan Z. Becerra.2 1Division of Kidney, Urologic, and Hematologic Diseases, National Institute of Diabetes and Digestive and Kidney Diseases, NIH, Bethesda, MD; 2Social & Scientific Systems, Silver Spring, MD.

**Background:** Identifying the optimal measurement of proteinuria in clinical settings has been challenging. To determine the potential consequence of varied measures of proteinuria, we contrasted their clinical significance primarily in relation to renal events and secondarily to cardiovascular (CVD) and mortality events.

**Methods:** We compared the predictive ability of four measures of proteinuria and albuminuria, among 3,992 CKD participants from the Chronic Renal Insufficiency Cohort (CRIC) Study, for incident renal events (halving of glomerular filtration rate [GFR] or end-stage renal disease), CVD events (myocardial infarction, congestive heart failure, stroke and peripheral arterial disease) and mortality over 5 years. The four measures included timed urinal albumin and protein excretion rates (AER, PER), albumin:creatinine ratios (ACR, PCR), albumin:protein: adjusted creatinine (accounting for creatinine production) ratios (eAER, ePER), and lastly albuminuria/proteinuria indexed to GFR (ACR-G, PCR-G), as an estimation of glomerular permeability. We used Harrell’s C-Statistics to measure model discrimination.

**Results:** Predictive performance for renal events was lowest for AER and PER. Results were generally similar for ACR vs eAER and PCR vs ePER. Notably, PCR-G showed significant improvement in predicting renal outcomes and performed better than albuminuria-based measures. C-Statistics for renal events were 0.831, 0.840, 0.841, 0.846 and 0.862 for AER, eAER, ACR, PCR and PCR-G, respectively. Trends were similar for CVD and mortality events, except that ACR performed better than PCR for CVD events, but not as well as PCR-G or ACR-G. Results were overall consistent across diabetes, gender and race strata, and were validated in an additional 1443 participants from the third phase of CRIC.

**Conclusions:** Indexing proteinuria to GFR is a simple and economical measure, compared to albuminuria, that significantly enhances the prediction of CKD progression and associated outcomes.

Evaluate Phosphate Intake and Excretion in CKD Patients

Paul Castaneda,1 Rodrigo López Echeverri,1 Adan Z. Becerra.1 1Division of Kidney, Urologic, and Hematologic Diseases, National Institute of Diabetes and Digestive and Kidney Diseases, NIH, Bethesda, MD; 2Social & Scientific Systems, Silver Spring, MD.

**Phosphate (P) restriction is crucial in CKD patients. Classically, P intake has failed to correlate with 24-h phosphaturia. Organic or inorganic P have different intestinal absorption rates, which might explain the lack of correlation between P intake and phosphaturia. Thus, we aimed to evaluate if the source of dietary P rather than the total P ingested determines phosphaturia, and to what extent inorganic P intake modifies phosphaturia.**

**Methods:** A 3-day dietary survey was performed in 71 stages G2-3 CKD patients to estimate the amount and source of P intake. 24-h urine samples were collected. Total phosphaturia, the FeP(%), and P/UUN, which reflect intestinal absorption of P relative to different intestinal absorption rates, which might explain the lack of correlation between P intake and phosphaturia. Thus, we aimed to evaluate if the source of dietary P rather than the total P ingested determines phosphaturia, and to what extent inorganic P intake modifies phosphaturia.

**Results:** The P intake was 1086.5±361.3 mg/day. P intake was 64.0%, 22.1%, and 14.1% from animal, vegetables, and inorganic sources respectively. Total P intake did not correlate with urinary P (p=0.12), nor FeP. Patients ingesting more P ingested more inorganic P (Fig1). P intake correlated with P/UUN ratio (p=0.008). Patients in the upper P/UUN tertile showed the highest daily P intake (p=0.04) from inorganic sources (p=0.03), and the highest phosphaturia (p=0.04).

**Conclusions:** P/UUN reflects the total P intake and provides information about the amount of inorganic P, and could be used to guide the appropriate nutritional advice for CKD patients.

Hypophosphatemia as a Surrogate Marker of Renal Outcome in Chronic Hepatitis B Patients Receiving Antiviral Therapy

Mee yeon Park,1 Junseok Jeon, Jung eun Lee, Wooseong Huh, Yoon-Goo Kim, Dae joong Kim, Hyun Suk Lee, Hye Ryoun Jung. Division of Nephrology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea; Samsung Medical Center, Gangnam-gu, Seoul, Republic of Korea.

**Background:** Antiviral therapy is crucial for the treatment of chronic hepatitis B (CHB). Although hypophosphatemia has been known to be an important adverse effect of antiviral agents, the clinical significance is yet to be revealed. In this study using a large cohort of CHB patients, the incidence and clinical significant of hypophosphatemia was investigated.

**Methods:** CHB patients who started antiviral therapy between 2005 and 2015, and had received at least one year of therapy, were included after excluding liver cirrhosis, diabetes mellitus, hypertension, concomitant administration of diuretics, and ESRD. Hypophosphatemia was defined as serum phosphorous level ≤ 2.5mg/dL. The primary outcome was changes in renal function. Secondary outcomes included the incidence of infection and changes in serum potassium, uric acid, and total carbon dioxide (tCO2).

---

**Key:** TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Results: Of the 4,335 patients, hypophosphatemia developed in 75 patients (1.7%). When patients were categorized depending on serum phosphate level, median phosphate level of 728 patients (16%) decreased by more than 0.5 mg/dL from the baseline. During the 2-year follow-up period, patients with hypophosphatemia showed lower eGFR compared to the control group. Also, patients whose serum phosphate level decreased by more than 0.5 mg/dL showed significantly lower eGFR compared to the control group at all time points. The incidence of infection and changes in serum potassium, uric acid, and CO2 were similar between groups.

Conclusions: Hypophosphatemia was associated with renal function decline in CHB patients receiving antiviral therapy. 50% of patients who took 12 months of antiviral therapy was relatively low, our results support the clinical significance of hypophosphatemia as a surrogate marker of adverse renal outcome in CHB patients.

PO0457
Dietary Phosphorus Restriction Improves Renal Function, Blood Pressure, FGF-23, and Klotho Levels in CKD Stages 1 and 2

Anita Saxena, Trisha Sachan, Amit Gupta, Anup Kumar, Sachin Sharma.
Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.

Background: To evaluate Impact of dietary education and intervention (phosphorus restriction) on creatinine, eGFR, FGF23, Klotho and blood pressure.

Methods: 105 subjects (CKD stages 1, 2 N 76, 3controls) evaluated for eGFR, creatinine, phosphorus, calcium, FGF-23, soluable o-Klotho iPTH FGF 23, blood pressure and 3 days dietary intake, using standard methodology on first visit, 6 and 12 months. CKD patients were grouped based on dietary phosphorus intake:Group 1 (n=42): phosphorous intake <1000mg/day and Group 2 (n=37; 17 in CKD 1; 20 CKD 2): high phosphorus intake (>1000mg/d). Patients in Group 2 were counselled for low phosphorus diet.

Results: Parameters of controls and CKD patients differed significantly. Dietary, serum and urinary phosphorus (0.001) had significant association. Systolic and diastolic BP, protein intake, dietary phosphorus, iPTH, FGF23 were significantly high (p<0.001) and Klotho significantly low (p<0.001) in Group 2 compared to Group 1. Impact of dietary intervention was seen at 6 and 12 months as reduction in protein intake from 0.64 ± 0.05 to 0.58±0.11 (CKD 1) and 0.71±0.04 to 0.64±0.05 (p<0.012 CKD 2); decline in creatinine from 1.13±0.14 to 1.07±0.14 (CKD 1) and 1.06±0.56 (p<0.009 CKD 1); serum phosphorus from 3.57±0.19 to 3.23±0.58 (CKD 1) and 4.32±0.42 to 3.35±0.85 mg/dL (p<0.001 CKD 2); FGF23 from 55.01±1.65, to 51.27±1.17 (CKD 1); 65.42±4.80 to 56.60±1.23 (p<0.010 CKD 2); systolic BP from 127.95±3.14 to 121.05±4.14 (CKD 1); 134.22±3.54 to 118.38±9.08 (p<0.001 CKD 2) and diastolic BP from 85.14±3.40 to 83.29±8.03 (CKD 1); 89.1±4.74 to 80.33±6.02 (p<0.003 CKD 2) and a significant increase in eGFR mL/min from 95.17±6.50 to 97.75±20.26 (CKD 1); 69.82±8.56 to 74.08±11.07 (p<0.019 CKD 2)) was observed. sKlotho increased from 700.79±27.82 to 879.39±168.37 (p<0.001 CKD 1); from 633.52±6.50 to 823.37±156.67 (p<0.001 CKD 2). Ca x P product declined from 36.10±8.44 to 29.48±7.63 (p<0.001). eGFR can predicted using dietary protein, creatinine systolic BP, haemoglobin, cholesterol (r 0.808).

Conclusions: Dietary counselling had significant effect on all the parameters in early CKD stages. Dietary intervention can prevent in FGF23, reduce blood pressure and prevent decline in renal function as demonstrated by significant increase in eGFR with phosphorus restriction in early stages of CKD.

PO0458
Baseline Serum Magnesium and Risk of CKD Progression in the Chronic Renal Insufficiency Cohort (CRIC) Study

Simon Correa,1,2 Joshua L. Sushrut Walker,3 Finnian R. McCausland,1,2 Brigham and Women's Hospital, Boston, MA; 1Harvard Medical School, Boston, MA; 2Boston Medical Center, Boston, MA.

Background: Serum magnesium (sMg) concentration is regulated by intestinal absorption and renal handling which are impaired in CKD. While Mg has been implicated in absorption and renal handling which are impaired in CKD. While Mg has been implicated in absorp

PO0459
The Effects of Intermittent Fasting on the Progression of CKD

Deepthi Rajasekaran,1,2 Buthayna A. Dinany,1,2 Fairview Hospital, Cleveland, OH; 1University Hospitals, Cleveland, OH; 1Cleveland Clinic, Cleveland, OH.

Background: Intermittent fasting (IF) refers to the practice of restricting food intake to a short period of the day alternating with a prolonged period of fasting. Preclinical studies and clinical trials have shown that IF has broad-spectrum benefits for many health conditions, such as obesity, diabetes mellitus, cardiovascular disease, cancers, and neurologic disorders. There are currently few studies suggesting a decrease in the progression of chronic kidney disease (CKD) with IF.

Methods: Retrospective chart review was done on patients from outpatient nephrology clinic with CKD stage I to IV who were self-reported to practice intermittent fasting. Patients with ESRD on dialysis, hospital admission during the study period, and reported poor compliance with fasting regimens were excluded. The primary outcome was the change in eGFR at the end of the period of intermittent fasting.

Results: Here we report current findings from 16 patients practicing IF regimen with continued ongoing enrollment. 75% of these patients were diabetic. Duration of the IF regimen ranged from 4 months to 12 months. 50% of patients had completed 12 months of IF regimen. 62.5% of patients were found to have an improvement in eGFR at the end of the period of IF. The change in eGFR was found to range from 0.4 ml/min/1.73 m² to 38.8 ml/min/1.73 m² (1.4-76.5%). The median increase in eGFR was 6.5 ml/min/1.73 m² (18.1%) during an average period of 8 months of IF (p-value = 0.04). There was no significant correlation between change in eGFR and change in weight or hemoglobin A1C during this period.

Conclusions: A significant increase in eGFR was seen in a small population of patients with CKD practicing intermittent fasting for four months or more. Previous studies report an average annual decline in GFR of 1.5-2 ml/min/1.73 m² in the general CKD population, with a more rapid decline in certain subsets. Intermittent fasting as a preventive measure for the progression of CKD needs to be studied further.
The Association Between Dietary Fiber Intake and Clinical Outcomes in CKD: A Report from the Chronic Renal Insufficiency Cohort (CRIC)

Sumeet S. Brar, Sarah Delozier, Nishi Pradhan, Mahboob Rahman, Mirela A. Dobre. Case Western Reserve University, Cleveland, OH.

Background: Standard dietary interventions for individuals with chronic kidney disease (CKD) consist of reductions in salt, phosphorus, potassium, and protein intake, with no specific guidance regarding dietary fiber intake. In animal models of kidney disease, a diet high in amylose resistant starch has been found to trigger a reduction in inflammation and CKD progression. It is unclear whether low dietary fiber intake is associated with a higher risk of incident kidney disease progression, cardiovascular disease, and overall mortality in individuals with CKD.

Methods: A total of 3791 participants with chronic kidney disease and information on dietary fiber intake at the baseline visit in the Chronic Renal Insufficiency Cohort (CRIC) Study were included in the analyses. Cox proportional hazards models adjusted for sociodemographic, comorbidities, medications and laboratory data, including eGFR and proteinuria were used to analyze the association between dietary fiber intake and clinical outcomes.

Results: The mean age was 59±11 years, 46% were female, 47% had diabetes, and the average eGFR was 48±17 ml/min/1.73m². The average dietary fiber intake was 17.3±9.6 g. After a median follow-up of 8.8±4.5 years, there was an inverse association between crude death rates and baseline dietary fiber intake: increasing from 3.1 per 100 person-years (PY) for the highest to 3.4 per 100 PY for the lowest fiber tertile. After multivariable adjustments, individuals in the middle and low fiber tertiles were at greater risk of death compared to those in the highest fiber tertile (HR[95%CI], 1.18 [1.01, 1.38], p =0.04 and 1.10 (0.94, 1.29), 0.24, respectively). We found no significant association between dietary fiber intake at the baseline visit in the Chronic Renal Insufficiency Cohort (CRIC) Study with lower risk of ESRD (HR 0.94 [95%CI, 0.89-0.99] per 0.01 g/kg/day per year; p=0.025), but not with mortality risk (P=0.84), Non-linear regression models confirmed these findings (Figure). Compared to patients who had no change in DPI, the hazard ratio (95%CI) of death and ESRD in those with a change of -0.03 g/kg/day per year were 1.12 (0.95-1.47) and 0.71 (0.52-0.98), respectively.

Conclusions: In patients with CKD, DPI showed a relatively small intra-individual temporal variation, but decrease in DPI was significantly associated with lower risk of ESRD, without an association with mortality.
PO0463
Association of Plasma Selenium with Renal Function in Hypertensives: Modification by Folate
Youbou Li, Xinshui Qin, Jing Nie, Mi Liang, Fan Fan Hou. Division of Nephrology, Nanfang Hospital, Southern Medical University; National Clinical Research Center for Kidney Disease; State Key Laboratory of Organ Failure Research, Guangdong Provincial Institute of Nephrology, Guangzhou, China.

Background: We aimed to investigate the association between plasma selenium (Se) and renal function decline in adults with hypertension and to explore the possible modification by folate.

Methods: This was a prospective study, including a total of 935 hypertensive adults from a folate-acid intervention trial (CSPPT) with baseline plasma Se measurements and renal outcome data available. The primary outcome was rapid decline in renal function, defined as an average decline in eGFR ≥5 mL/min/1.73 m^2 per year.

Results: Over a median follow-up of 4.4 years, the primary outcome occurred in 72 participants. After multivariate-adjusted, there was an inverse association between plasma Se and rapid decline in renal function (per 10-unit increment: OR, 0.85; 95% CI: 0.72, 0.99). Consistently, compared to the lowest tertile of baseline plasma Se (<74.5 μg/L), the highest tertile (89.4–150 μg/L) was significantly associated with a 60% (0.40; 0.21, 0.79) reduction in the odds of the outcome. A stronger inverse plasma Se-renal function decline association was observed in those received folic acid treatment (per 10-unit increment: OR, 0.70; 95% CI: 0.54, 0.90; P-interaction=0.036) or with a higher baseline folate concentration (a9 ng/mL: 0.59; 0.43, 0.82; P-interaction=0.004).

Conclusions: In China hypertensives with plasma Se <150 μg/L, there was an inverse relationship of plasma Se with the renal function decline, especially in those with folic-acid supplementation or a higher folate level.

Funding: Government Support - Non-U.S.

Relationship of Serum Triglycerides with Incident Albuminuria Among 114,817 US Veterans
Melissa Soohoo,1 Jui-Ting Hsiung,1,2 Maria V. Marroquin,1,3 Csaba P. Kovedy,1 Kamyr Kalantar-Zadeh,1,2 Elani Streja,1,2 The University of Tennessee Health Science Center, Memphis, TN;1,2VA Long Beach Healthcare System, Long Beach, CA;1,2Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA;1,2Memphis VA Medical Center, Memphis, TN.

Background: The association of metabolic syndrome (MetS) components of impaired glucose, obesity, low high-density lipoprotein, hypertension, and serum triglycerides (TG), with renal endpoints such as incident chronic kidney disease (CKD) have been previously studied individually. Urine albumin to creatinine ratio (UACR) remains an integral part of CKD staging and incidence, yet it remains understudied. Thus, we sought to examine the relationship of TG with incident albuminuria among normal UACR patients with consideration for other MetS components.

Methods: Our cohort comprised 114,817 veterans with albuminuria stage A1 (<30 mg/g) and data on TG and MetS components. Incident albuminuria was defined as at least two UACR measurements of >30 mg/g at 90 days apart. We used Cox proportional hazards models to evaluate the association of TG with incident albuminuria, adjusted for case-mix characteristics, laboratory values and individual MetS components, as well as stratified by s2 and s3 MetS components.

Results: The means±SD age was 65±11, with a median[IQR] of TG, UACR and eGFR of 144[97, 214] mg/dL, 7[4, 13] mg/g, and 75[61, 89] mL/min/1.73 m^2 respectively, and 70% had at least 3 MetS components. We observed a linear association between TG and incident albuminuria, adjusted for case-mix characteristics, laboratory values and individual MetS components, as well as stratified by s2 and s3 MetS components.

Conclusions: Higher TG are associated with incident albuminuria independent of other components of MetS. Further study is needed to understand the drivers of this association, with a specific focus of how to best manage TG levels in addressing albuminuria development.

PO0464
Association Between CKD and New Onset of Dyslipidemia: Results from a Longitudinal Nationwide Survey
Takakii Kosugi,1 Masahiro Eriyuchi,1 Hisako Yoshida,2 Hikari Tasaki,1 Masatoshi Nishimoto,1 Masato Kasahara,3 Kunitoshi Iseki,1 Koichi Asahi,1 Kunihiro Yamagata,4 Tsuneo Konta,2 Shouichi Fujimoto,1 Ichiee Narita,5 Yugo Shiibagaki,10 Toshiki Moriyanma,11 Masahide Suruya,11 Kunihiro Shibagaki,12 Jui-Ting Hsiung,1,2 Maria V. Marroquin,1,3 Csaba P. Kovedy,1 Kamyr Kalantar-Zadeh,1,2 Elani Streja,1,2 Terasaki Institute, Los Angeles, CA;1,2VA Long Beach Healthcare System, Long Beach, CA;1,2Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA;1,2Memphis VA Medical Center, Memphis, TN.

Background: Dyslipidemia is a significant risk factor of CVD and seems to be associated with CKD onset and progression. On the contrary, CKD patients have associated with CKD onset and progression. On the contrary, CKD patients have dyslipidemia more frequently than non-CKD patients, but it is unclear whether CKD affects new onset of dyslipidemia.

Methods: This is a longitudinal study based on data obtained from the Japanese Society of Health Check and Guidance System. Among 664,926 individuals who participated in this program from 2008 to 2014, we excluded participants who met the following criteria: 1) health check only one time, 2) missing values for creatinine or proteinuria, 3) dyslipidemia at baseline, or 4) medication for dyslipidemia at any point. We evaluated new onset of dyslipidemia according to two factor; hypertriglyceridemia (High-TG), hyper-LDL cholesterolemia (High-LDL), or hypo-HDL cholesterolemia (Low-HDL), defined as triglycerides ≥150 mg/dL, LDL cholesterol ≥140 mg/dL, or HDL cholesterol ≤40 mg/dL, respectively, and compared between participants with and without CKD. These associations were analyzed using Kaplan-Meier methods and Cox regression analysis after adjustment for clinically relevant factors.

Results: During a median follow-up period of 3.1 years, the cumulative incidences of High-TG, High-LDL, and Low-HDL were 45,300, 51,940, and 13,313 participants, respectively, among 305,893 participants (non-CKD: 254,884; CKD: 51,009). In the univariable analyses, hazard ratios (HRs) [95% confidence intervals (CIs)] in CKD vs non-CKD participants were 1.31 [1.27-1.34], 1.02 [0.99-1.05], and 1.70 [1.63-1.77] for High-TG, High-LDL, and Low-HDL, respectively. After adjustment for clinically relevant confounders, adjusted HRs [95% CIs] in CKD participants were 1.10 [1.07-1.13], 0.99 [0.96-1.02], and 1.16 [1.11-1.22] for High-TG, High-LDL, and Low-HDL, respectively.

Conclusions: CKD was associated with new onset of High-TG and Low-HDL, but not High-LDL among general population in Japan.
PO0466

Short-Term Associations of Triglycerides with Atherosclerotic and Non-Atherosclerotic Cardiovascular Disease Alleviations Across CKD Stages

Melissa S. Soocho,1,1 Jui-Ting Hsing,1,2 Csaba P. Kovessy,2 Kaymarr Kalantar-Zadeh,1,2 Elain Streja,1,3 Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; 2The University of Tennessee Health Science Center, Memphis, TN; 1VA Long Beach Healthcare System, Long Beach, CA; 2Memphis VA Medical Center, Memphis, TN.

Background: In chronic kidney disease (CKD) patients, we showed that the risk of atherosclerotic cardiovascular disease (ASCVD) and non-ASCVD events with high baseline triglycerides (TG) incrementally attenuated across worse CKD stages, where high TG was associated with lower risk of non-ASCVD events in late-stage CKD. TG levels can change with CKD progression, but associations of time-varying TG with ASCVD or non-ASCVD hospitalizations is unknown.

Methods: We examined time-varying TG with time to first ASCVD or non-ASCVD hospitalization in 2,963,176 US veterans who received care in 2004-2006 (baseline) and were followed to 2014. Events were classified by primary ICD-9 codes. Using time-varying Cox models, we evaluated associations of time-varying TG with first ASCVD or non-ASCVD events stratified by baseline CKD stage, for adjustment for demographics, and time-varying comorbidities and laboratory values.

Results: The cohort was 63±14 years old with a mean [IQR] TG [127, [87, 189]] mg/dL, and 23% had CKD 3A or higher at baseline. TG >80 mg/dL was associated with a lower risk of time to first ASCVD event (ref: TG 120-<160 mg/dL) for all baseline CKD stages (Fig A). There was a linear association between time-varying TG and ASCVD events. High TG (≥240 mg/dL) had the highest risks for ASCVD, for baseline non-CKD, and CKD 3A-3B. Among late-stage CKD patients, the association of high TG and ASCVD was null. We observed an inverse association between time-varying TG with time to first non-ASCVD event (Fig B). Patients with low TG had faster times to first non-ASCVD event for non-CKD and CKD 3A-4, while high TG were associated with slower times in all stages. CKD stage 5 at baseline renal disease patients with TG ≥240 mg/dL had the lowest risk of non-ASCVD event.

Conclusions: Short-term risk of higher TG with ASCVD or non-ASCVD events incrementally decreased across CKD stages, where risk was lower to null in late stage patients. High TG were associated with lower risks of non-ASCVD across all CKD stages. Investigation is needed to evaluate the pathways involving TG and cardiac events as CKD severity progresses in order to best manage health.

PO0467

Metabolic Acidosis and Progression to Renal Replacement Therapy

Vandana S. Mathur,1 Susan E. Funk,2 Nancy L. Reaven,3 Navdeep Tangri.3 1Mathur Consulting, Woodside, CA; 2Strategic Health Resources, La Canada, CA; 3University of Manitoba, Winnipeg, MB, Canada.

Background: Metabolic acidosis is common in advanced chronic kidney disease (CKD) and is associated with its progression (Kraut J, Adv Chronic Kidney Dis. 2017). Methods: De-identified electronic health records (Optum® EHR), 2007 to 2017 were queried to identify patients with non-dialysis CKD Stages 3-5 with ≥1 and normal serum bicarbonate were established based on the index serum bicarbonate (> 22 mEq/L or 22-< 29 mEq/L). Progression to RRT was defined as initiation of dialysis or kidney transplantation, identified in EHR data by diagnosis or procedure codes, or (≤ 22 mEq/L or 22 - < 29 mEq/L). Patients (N = 136,067) were classified with non-dialysis CKD progression, but associations of time-varying TG with ASCVD or non-ASCVD hospitalizations is unknown.

Results: In pts with non-dialysis CKD Stages 3-5, 2 years of post-index data or death within 2 years, and grouped by baseline metabolic acidosis (12 to < 22 mEq/L) vs normal serum bicarbonate (22 to < 30 mEq/L). Patients (N = 136,067) were classified as Asian (N =1,328), Black (N =15,248), Hispanic (N =4,137), White (N=111,953) or Other (N=3,401). The primary endpoint was the composite outcome of death, kidney dialysis or transplant, or 40% decline in eGFR from baseline (DD40). Cox proportional hazards models examined the impact of serum bicarbonate on DD40 within each racial/ethnic group, adjusted for age, sex, eGFR, log albumin-to-creatinine ratio, diabetes, hypertension, heart failure, Charlson Comorbidity Score.

Conclusions: In a large community-dwelling US population, serum bicarbonate was independently associated with adverse kidney outcomes and death in Asians, Blacks, Hispanics and Whites with CKD. Since race and ethnicity are associated with other socioeconomic factors that affect health, further exploration of the potential reasons for the observed range of hazard ratios across groups is warranted.

PO0468

Relationship Between Metabolic Acidosis and CKD Progression Is Evident Across US Racial and Ethnic Groups

Navdeep Tangri,1 Vandana S. Mathur,2 Nancy L. Reaven,1 Susan E. Funk,3 Donald E. Wesson.1 1University of Manitoba, Winnipeg, MB, Canada; 2Mathur Consulting, Woodside, CA; 3Strategic Health Resources, La Canada, CA; 4 Baylor Scott & White Health and Wellness Center, Dallas, TX.

Background: Metabolic acidosis is a known risk factor for CKD progression, but little is known about the impact of race and ethnicity on this relationship. We used a large electronic medical record (EMR) database of >100 million patients from all 50 states and insurance types to evaluate the relationship between metabolic acidosis and adverse renal outcomes and death by race and ethnicity.

Methods: De-identified electronic medical records (Optum® EHR), 2007–2019 were queried to identify patients with non-dialysis CKD Stages 3-5, 2 years of post-index data or death within 2 years, and grouped by baseline metabolic acidosis (12 to < 22 mEq/L) vs normal serum bicarbonate (22 to < 30 mEq/L). Patients (N = 136,067) were classified as Asian (N =1,328), Black (N =15,248), Hispanic (N =4,137), White (N=111,953) or Other (N=3,401). The primary endpoint was the composite outcome of death, kidney dialysis or transplant, or 40% decline in eGFR from baseline (DD40). Cox proportional hazards models examined the impact of serum bicarbonate on DD40 within each racial/ethnic group, adjusted for age, sex, eGFR, log albumin-to-creatinine ratio, diabetes, hypertension, heart failure, Charlson Comorbidity Score.

Results: Overall, 47,032 patients (34.6%) experienced DD40 events within 2 years: Asian, 35%; Black, 44%; Hispanic, 48%; White, 32%; Other, 48%. Serum bicarbonate independent predicted DD40 in all racial/ethnic groups. Adjusted Hazard Ratios for DD40 per 1 mEq/L increase in serum bicarbonate (median 4.2 yrs, max 11.5 yrs follow-up) were as follows: Asian, 0.942 (CI: 0.917- 0.968); Black, 0.976 (CI: 0.969-0.983); Hispanic, 0.970 (CI: 0.956-0.984); White, 0.960 (CI: 0.957-0.963); Pc< 0.0001 for all groups.

Conclusions: In a large community-dwelling US population, serum bicarbonate was independently associated with adverse kidney outcomes and death in Asians, Blacks, Hispanics and Whites with CKD. Since race and ethnicity are associated with other socioeconomic factors that affect health, further exploration of the potential reasons for the observed range of hazard ratios across groups is warranted.

Lower Urine Citrate Excretion Associated with Advanced CKD Stage Is Mediated by Reduced Plasma Citrate and Decreased Kidney Citrate Clearance

Nimrit Goraya,1 Nicolaos E. Madias,2 Abdullah A. Mamun,3 Jan Simon,4 Donald E. Wesson.1 1Texas A&M University College Station, College Station, TX; 2Yale Scott and White Health and Wellness Center, Dallas, TX; 3Tufts University School of Medicine, Boston, MA; 4Surgery, Texas Tech University HSC, Lubbock, TX.

Background: Lower urinary citrate excretion (UcitV) might be a biomarker of covert acid (H+) retention in patients with CKD but without metabolic acidosis and so mechanisms that mediate UcitV differences among patients with CKD would help assessment of its biomarker utility. Because longitudinal eGFR decreases in patients with CKD associated with decreasing UcitV (Goraya, et al. AJP 317:F502, 2019), we examined cross-sectional differences in UcitV across CKD stages and mechanisms that mediate such differences.

Methods: We measured 8-hour UcitV (8h UcitV), plasma citrate concentration (Pcit), and kidney citrate clearance citrate (UcitV/Pcit) in 52 patients with CKD 1 (eGFR=99.5±7.7 ml/min/1.73 m2), 2 (eGFR=73.4±6.1 ml/min/1.73 m2) and 52 with CKD 3 (eGFR=40.1±7.6 ml/min/1.73 m2) with macroalbuminuric, non-diabetic, hypertension-associated nephropathy. We assessed ongoing dietary H+ intake as potential renal acid load (PRAL) and steady-state acid-base status with plasma total CO2 (PTCO2) and H+ retention, the latter estimated by comparing observed to expected PTCO2, increase in response to retained HCO3 (administered minus UHCO3V) 2 hours after oral NaHCO3, bolus (0.5 mmol/kg bw), assuming 50% body weight HCO3, apparent space of distribution.

Results: Although PRAL was not different among CKD 1, CKD 2, and CKD 3 groups (62.4±11.9, 62.9±14.7, and 65.2±7.9 mmol/day, respectively, p=0.47), PTCO2, was progressively lower (26.4±0.7, 25.9±0.6, and 21.6±1.9 mM, respectively, p<0.01) and H+ retention progressively higher (3.9±12.9, 18.2±14.0, and 25.1±13.4 mM, respectively, p<0.01) with advancing CKD stage. 8h UcitV was progressively lower with advancing CKD stage (1.14±0.03, 1.06±0.25, and 0.86±0.10 mmol/1.73m2, respectively, p<0.01) as was Pcit (0.16 ± 0.01, 0.15 ± 0.02, and 0.14 ± 0.01 mM, respectively, p<0.01) and UcitV/Pcit (0.015 ± 0.001, 0.014 ± 0.003, and 0.013 ± 0.001 mmol/1.73 m2, respectively, p<0.01).

Conclusions: Cross-sectional advanced CKD stage was associated with greater H+ retention and lower UcitV, the latter mediated by lower Pcit and lower UcitV/Pcit. The data support that reduced UcitV associated with decreased eGFR reflects underlying H+ retention with reduced body citrate stores and increased citrate conservation through reduced kidney citrate clearance.

Urinary Calcium Excretion and Risk of CKD Progression: The CRIC Study

Jing Liu,1,2 Maria Clarissa Tio,3 Titilayo O. Ilori,3 Ashish Verma,3 Insa M. Schmidt,1,3 Sushrut S. Walkar.1 1Renal Section, Department of Medicine, Boston University Medical Center, Boston, MA; 2Division of Nephrology, Kidney Research Institute, West China Hospital of Sichuan University, Chengdu, China; 3Renal Division, Brigham & Women’s Hospital, Harvard Medical School, Boston, MA.

Background: Hypercalciuria is implicated in nephrolithiasis and nephrocalcinosis, conditions associated with chronic kidney disease (CKD). We aimed to study the determinants of urinary calcium excretion (UCaE) and its association with adverse clinical outcomes in CKD.

Methods: 24-hour UCaE was measured in 3,768 Chronic Renal Insufficiency Cohort (CRIC) participants. We used multivariable linear regression models to determine independent predictors of UCaE in CKD 1-5. Weighted Cox regression analyses tested the associations of UCaE with incident end stage kidney disease (ESKD), CKD progression (50% eGFR decline or incident ESKD), atherosclerotic cardiovascular disease (ASCVD) events, and death.

Results: Estimated glomerular filtration rate (eGFR) correlated most strongly with UCaE (r=0.47, P<0.001). In both males and females, determinants of UCaE included eGFR, African American race, iPTH, 24-hour urine sodium and phosphate, serum albumin and the use of diuretics and angiotensin receptor blockers (Figure 1). Certain predictors of UCaE differed between sexes: systolic blood pressure and alcohol drinker were associated with UCaE in males, while serum calcium and vitamin D intakes were significantly associated with UCaE in females. Higher UCaE was significantly associated with lower risk of ESKD, CKD progression, death and ASCVD events in unadjusted models. These associations were attenuated after adjusting for baseline characteristics, and for most outcomes the associations became insignificant after adjusting for eGFR.

Conclusions: Predictors of UCaE in CKD differed between males and females. eGFR is extremely strongly associated with UCaE and greatly confounds the associations between UCaE and all the outcomes.
Methods: We utilized electronic health record (EHR) data of patients seen at a health care system in the 7-county metropolitan area in Minnesota and linked census tract data. Census tract measures (medium of owner occupied housing units (wealth), percentage of residents >25 years with a Bachelor's degree (education), and median household income (income)) and individual level insurance status (≥65 years: Medicare vs. other insurance; <65 years: Medicare vs. supplemental insurance plan) were obtained from the American Community Survey (2008-2012) and the EHR, respectively. A patient was considered to be living in low and high SES tracts if they belong to the first and fourth quartile of each SES measures. CKD prevalence was defined as having an estimated glomerular filtration rate (eGFR) <60 mL/min/1.73m² or proteinuria. We used a multilevel Poisson regression with robust error variance with a random intercept at the census tract level to estimate the association between tract SES [low (first quartile) vs. high (fourth quartile)], insurance, and CKD.

Results: We included 185,269 patients. Tract SES (wealth and education) and insurance are independently associated with CKD prevalence. After adjusting for demographic and clinical characteristics, patients (<65 and ≥65 years) living in low vs. high SES tracts had higher CKD prevalence (Prevalence Ratio PR, 95%CI of low vs. high tract SES for education among patients <65 years: 1.11 [1.05, 1.18] and 1.08 [1.04, 1.12] for high vs. low SES for education among patients ≥65 years: 1.11 [1.05, 1.18] and 1.08 [1.04, 1.12]) for high vs. low SES for education among patients ≥65 years: 1.11 [1.05, 1.18] and 1.08 [1.04, 1.12]). After adjusting for insurance type, patients on supplemental insurance had higher CKD prevalence (PR, 95%CI: 1.51 [1.43, 1.60]). For patients ≥65 years, insurance type was not associated with prevalence of CKD in the fully adjusted model.

Conclusions: In conclusion, we found that patients from low SES tracts and Medicaid recipients (among patients <65 years) have greater rates of CKD compared to patients from high SES tracts and patients with other insurance. These may be two of several socioeconomic and individual factors influencing the complexity of identification, management, and treatment of CKD.

PO0474

Social Determinants of CKD in the Military Health System

Jenna M. Norton, Lindsay Grunwald, Cara H. Olsen, Eric S. Marks, Tracey L. Koehlimo. Uniformed Services University of the Health Sciences, Bethesda, MD.

Background: A growing body of evidence suggests that negative social determinants of health—or social risks—contribute to socioeconomic and racial disparities in chronic kidney disease (CKD). One mechanism through which social risks appear to produce disease is by impeding access to healthcare. The Military Health System (MHS) provides an opportunity to assess CKD disparities in the context of universal healthcare.

Methods: We identified all MHS beneficiaries aged 18 to 64 who received care through the MHS from October 1, 2015 to September 30, 2018. CKD was identified by ICD-10 code and/or a validated laboratory value-based electronic phenotype for CKD. Directed acyclic graphs were developed to understand potential confounding or mediating roles of covariates. Multivariable logistic regression models were used to compare the prevalence of CKD by race, rank, zip code level median household income, and marital status, controlling separately for suspected confounders (age, sex, active duty status, service branch, and depression) and mediators (hypertension, diabetes, HIV and BMI). For family beneficiaries, the sponsor’s rank and zip code were used.

Conclusions: Racial and socioeconomic disparities persist in CKD under the context of universal healthcare coverage provided by the MHS. While racial disparities may result in part from underlying genetic differences, the presence of disparities by rank and area income suggest social factors remain pertinent despite access to universal healthcare coverage.

PO0475

Low Documentation of Social Determinants of Health Among US Veterans and Medicare Patients with CKD

Yahya Yousif,1 Maggie Flira,2,3 Ayal Wyncott,1 Jennifer L. Bragg-Gresham,1 Kara Zivin,1 NiIka Rios Burrows,4 Carla I. Mercado,4 Delphine S. Tuot,1 Neil R. Powe,1,4,5 Rajiv Saran,1 University of Michigan Division of Nephrology, Ann Arbor, MI; 2University of Michigan, Ann Arbor, MI; 3US Department of Veterans Affairs, Ann Arbor, MI; 4Centers for Disease Control and Prevention, Atlanta, GA; 5University of California San Francisco, San Francisco, CA; 6Zuckerberg San Francisco General Hospital and Trauma Center, San Francisco, CA.

Background: The implementation of ICD-10 codes in 2015 included new codes to identify social determinants of health (SDOH). We sought to identify differences in SDOH-related Z-code (SDOH-ZC) utilization in Veterans Health Administration (VHA) and Medicare patients identifying differences in SDOH-ZC utilization in those with and without chronic kidney disease (CKD).

Methods: We used 5% sample of Medicare claims data (2015-2018) and 100% VA health data (2015-2019). A list of SDOH-ZCs were grouped into 17 categories (education and literacy, employment status, occupational risk factors, housing, economic circumstances, lifestyle factors, etc.). Proportion of claims assigned a SDOH-ZC were measured quarterly across different healthcare encounters and described by patient characteristics including age, sex, race, and hypertension, diabetes, and CKD. Use of SDOH-ZC were compared between those with and without CKD.

Results: SDOH-ZCs appeared more frequently in the VA health system than in Medicare data (Fig 1.a-b). Tobacco use was the most common SDOH-ZC in both the VA and Medicare data. More SDOH-ZCs were evident in the VA employment, housing and economic, and family circumstances. Compared to those without CKD, use of SDOH-ZC was higher in individuals with CKD in outpatient settings but lower among those with inpatient visits, observation stays, and emergency department visits (Fig 1.c-d).

Conclusions: We observed lower recording of SDOH overall and among those with CKD in health care settings. Additional efforts might consider increasing SDOH documentation to help assess need for social services, which could potentially reduce disparities in health outcomes by socioeconomic status.

PO0476

Association of Health-Related Social Needs with Kidney Protective Measures in an Urban Population

Tessa K. Novick,1 Dingfen Han,2 Elizabeth A. Jacobs,1 Michele K. Evans,3 Alan B. Zonderman,1 Deidra C. Crews.2 University of Texas at Austin Dell Medical School, Austin, TX; 3Johns Hopkins University, Baltimore, MD; 2National Institute on Aging, Bethesda, MD.

Background: Health-related social needs are individual-level social determinants of health, such as food insecurity and housing insecurity. Maintaining blood pressure <130/80 mmHg, hemoglobin a1c ~7%, sodium intake <2 g/day, regular physical activity, BMI 20-25 kg/m², and smoking cessation reduce risk of CKD and CKD progression. We evaluated whether having unmet needs was associated with achieving kidney protective measures.

Methods: We performed a cross-sectional analysis of data from the Healthy Aging in Neighborhoods of Diversity Across the Life Span (HANDLS) study (Baltimore, MD) during study visit 4. We used multivariable regression to quantify associations between having and least one unmet social need (food insecurity or housing insecurity), and the number of protective measures taken. Of the 3,330,893 MHS beneficiaries in this analysis, 105,504 (3.2%) had ≥65 years, insurance type was not associated with prevalence of CKD in the fully adjusted model.

Conclusions: In conclusion, we found that patients from low SES tracts and Medicare recipients (among patients <65 years) have greater rates of CKD compared to patients from high SES tracts and patients with other insurance. These may be two of several socioeconomic and individual factors influencing the complexity of identification, management, and treatment of CKD.

Association Between Unmet Health-related Social Needs and Kidney Protective Measures

Methods: Medical records from 1995 to 2019 were reviewed in order to obtain anthropometric measurements, occupation, past medical history and family history. Laboratory data included serum creatinine (Scr), albumin-creatinine ratio (ACR), 24 hour urinary protein-creatinine ratio (PCR), at baseline and at 1,3,5, and 10 years. Time zero kidney biopsies were obtained in a subset of the cohort. eGFR ACR and PCR were used as indicators of kidney function.

Results: 32 patients were included the mean age was 36 ± 10 y and mean eGFR at donation was 95.1 ± 15.5 mL/min. 35% worked in agriculture 50% in household 6% in construction 6% in a storage company 3% unemployed. The mean change in eGFR at 1, 3, 5, and 10 years was -1.82 ± 12.4, -7.5 ± 19.8, -6.9 ± 19.8, -8.1 ± 11.9 ml/min. There was a significant difference between agriculture and domestic workers in eGFR decrease at 5 and 10 years. 50% underwent zero time biopsy and 69% had some evidence of histological damage 62% showed glomerular abnormalities 40% had glomerular sclerosis, tubulointerstitial infiltrates 31% interstitial fibrosis 50% and either medial hypertrophy or intimal fibrosis 69%. These findings were not associated to occupation In multivariate analysis using a lineal model of repetitive measurements, working in agriculture was the most important risk factor associated to eGFR decline (p = .023).

Conclusions: Baseline histological changes were observed in the majority of the kidney donors, Agricultural work was the most important risk factors for eGFR decline.

Association Between Air Pollution and Renal Outcomes: A Systematic Review and Meta-Analysis

Methods: We searched EMBASE, Pubmed, Web of Science, Cochrane library, and CINAHL database, for relevant records using a combination of keywords related to the type of exposure (O3, CO, NO, NO2, SO2, PM10, PM2.5, and PM1) and outcome (CKD, end-stage renal disease -ESRD-, proteinuria/albuminuria, renal function, kidney transplant failure, nephrotic syndrome, and kidney cancer). Using random-effects meta-analyses, we pooled summary statistics (hazard ratios, odds ratios, or beta-coefficients with their respective 95% confidence intervals) associated with a standardized increased level of each pollutant and presented the results by air pollutant and outcome. Heterogeneity was interpreted with caution, due to significant between-studies heterogeneity and risks of methodological bias.

Conclusions: Chronic exposure to particulate matter and nitrite dioxide seems to be associated with poorer renal outcomes. Further studies are warranted to confirm these results.

Prevalence and Severity of Hyperkalemia in Patients Referred to Nephrology Consultation: Epidemiologic Data from 1106 Mexican Patients at a National Reference Hospital

Background: Hyperkalemia (HK, serum K > 5 mEq / L) is an electrolyte disorder that occurs frequently in patients with chronic kidney disease (CKD), heart failure. In CKD, the ability to excrete K+ is reduced, impairing quality of life and increasing morbidity and mortality.

Methods: Cross-sectional retrospective, observational study. Records of adult patients who attended an outpatient Nephrology consultation in the period from February 2019 to February 2020 were included, with laboratory reports from the last 15 days prior to the date of the medical consultation. Descriptive statistics were performed, with a 95% CI and a p-value ≤ 0.05.

Results: 1106 patient records were included. 51% (563) were women. The mean age was 55.8 ± 15.6 years. 47% of the population had Diabetes mellitus and / or hypertension as their main comorbidity and 61% were overweight or obese. HK was identified in 29% of the study population. Figure 1 shows the frequency of HK by stage of CKD. 13% of the patients who entered the study were on renal replacement therapy, of which 54% had HK. 54% of the subjects with HK were diabetic, 56% hypertensive, 25% consumed ACE inhibitors and 13% consumed NSAIDs on a regular basis and 48% had proteinuria.

Conclusions: The presence of HK is a risk factor that increases the risk for cardiovascular complications and accelerates the progression to more advanced stages of CKD. It is important to intentionally search for this alteration in all stages of CKD and implement measures that help correct and mitigate its impact on patients with CKD.

Poster

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Results: Out of the 3008 patients referred, 575 (19.1%) met the inclusion criteria (mean age: 70.4 years; 63.7% male and 94.0% white color). Mean follow-up was 4.1 ± 1.8 years. The prevalence of HK at first consultation was 8.7% and follow up incidence 21.7%. From this cohort, 164 (28.5%) had at least on episode of HK (Group B) and 101 (17.6%) died. During the follow up, RAAS inhibition was removed or not started in 200 (34.8%) and diuretic was initiated in 165 (28.7%). At least one HK episode was associated with Diabetes (65.9 vs 42.3%, p<0.001), Heart failure (36.6 vs 28.0%, p=0.007), Macroalbuminuria (34.1 v 21.2%, p=0.001), CKD progression (33.5 vs 16.3, p=0.001) higher frequency of diuretic initiation (38.4 vs 24.8%, p<0.001) and higher mortality (27.6 vs 13.7%, p<0.001). The independent predictors of mortality were: At least one HK episode (OR 1.82, 95% CI 1.08-3.34); Heart Failure (OR 1.97, 95% CI 1.16-3.35); Older age (OR per 1 year increase 1.04, 95% CI 1.02-1.07); CKD progression (OR 4.18, 95% CI 2.43-7.19); Patients who maintained RAAS inhibition during follow up (OR 0.50, 95% CI 0.26-0.96); Patients who started RAAS inhibition during follow up (OR 0.38, 95% CI 0.16-0.88).

Conclusions: Our study confirms that RAAS Inhibition had and protector and independent impact in mortality when prescribed in CKD early stages. Patients with at least one episode of HK have a higher risk of mortality. All efforts should be made to maintain these therapeutic agents, looking for other ways to control hyperkalemia rather than stop it.

High Serum Alkaline Phosphatase Predicts CKD Progression: Effect Modification by GFR
Francesca Mallamaci,1,2 Graziella D’Arrigo,1 Francesco Marino,2 Graziella Caridi,2 Giovanna Parlongo,2 Daniela Leonardi,1 Patrizia Pizzini,1 Sebastiano Cutrupi,1 Anna Pisano,1 Giovanni Tripepi,1 Carmine Zoccali,1 CNR-IFC, Reggio Calabria, Italy; 2Nephrology, Dialysis and Transplantation Unit, Reggio Calabria, Italy.

Background: In the post-hoc analyses of SUSTAIN/ASSURE trials, Apabetalone, an epigenetic modulator which lowers alkaline phosphatase (AlkPhos), stabilized the GFR in patients with CV disease and GFR <60 ml/min/1.73 m2. Analyzing the relationship between AlkPhos and renal outcomes in patients with CKD is useful to explore the biological hypothesis that AlkPhos is implicated in CKD progression.

Methods: We investigated the relationship between AlkPhos and the risk of a combined end-point (30% GFR loss or dialysis/renal transplantation) in 609 stage 3-5 CKD patients (mean GFR: 34.8±12.1 ml/min/1.73 m2).

Results: Median AlkPhos was 91 IU/L and in the majority of patients had values below 147 IU/L (the upper limit of the normal range). Over a median follow up of 3 yrs, 209 patients had the combined end-point. In an unadjusted analysis, 1 ln increase in AlkPhos entailed a 49% risk excess for the renal end-point (HR:1.49, 95% CI 1.11-2.01, P=0.008). Adjusting for age, gender, smoking, diabetes, cholesterol, BMI, systolic BP, CV comorbidities, hemoglobin, albumin, phosphate, and hs-CRP, did not modify this association (HR:1.48, 95% CI 1.08-2.02, P=0.016). In a fully adjusted analysis testing the GFR as an effect modifier of the AlkPhos - combined renal end point link showed a GFR-BP, CV comorbidities, hemoglobin, albumin, phosphate, and hs-CRP, did not modify this association. Adjusting for age, gender, smoking, diabetes, cholesterol, BMI, systolic BP, CV comorbidities, hemoglobin, albumin, phosphate, and hs-CRP, did not modify this association (HR:1.48, 95% CI 1.08-2.02, P=0.016). In a fully adjusted analysis testing the GFR as an effect modifier of the AlkPhos - combined renal end point link showed a GFR-

Conclusions: This study suggests that AlkPhos is predictive of CKD progression and may modulate CV risk. Further studies are needed to determine whether dietary factors may be a potential mechanistic link underlying these relationships.

The Association Between Fibroblast Growth Factor 23 (FGF-23) and Pulse Pressure (PP) in CKD Stage G5 Patients

Cristian Rodelo-Haad,1,2 Isabel López-López,2 Rafael Santamaría,1,2 Juan R. Munoz-Castaneda,1,2 Sagrario Soriano,1,2 Mariano Rodriguez Portillo,1,2 Alejandro Martin-Malo,1,2 Instituto Maimonides de Investigacion Biomedica de Cordoba, Cordoba, Spain; 1Hospital Universitario Reina Sofia, Cordoba, Spain.

Background: FGF23 is associated with increased cardiovascular events and mortality in CKD patients. Non-classical biological effects of FGF23, such as left ventricular hypertrophy and vascular remodeling, may potentially explain this association. Experimental models suggest that FGF23 stimulates renal tubular sodium reabsorption and volume overload. It is plausible that FGF23 also increases blood pressure. The linking of FGF23 increment with blood pressure control may help identify novel risk factors of mortality in CKD patients. Therefore, we aimed to evaluate the relationship between FGF23, blood pressure control, and indirect signs of arterial stiffness in subjects with CKD G5.

Methods: Clinical and analytical variables were analyzed in 159 CKD G5 patients immediately before starting kidney replacement therapy. The association between these variables and the levels of intact FGF23 (iFGF23) was evaluated with linear regression models. PP was used as an indirect surrogate of arterial stiffness. Statistics were performed using R v3.6.2.

Results: The mean SHP was 158.8±13.3 mmHg, whereas the mean DBP was 87.2±12.3 mmHg, and the mean PP was 76.6±12.3 mmHg. The median iFGF23 was 486.3 (268.8-904.9) pg/ml. iFGF23 was positively correlated with serum phosphate (p<0.001), plasma sodium (p=0.02), C-reactive protein (p<0.01), SBP (p<0.001), DBP (p<0.01) and PP (p=0.02). Linear multivariable analysis (Table 1) showed that iFGF23 was independently associated with the increase in SBP, DBP, and PP, suggesting that for each 10 pg/ml increase in iFGF23, the SBP increased 3.7 mmHg, the PAD increased 3.0 mmHg, and PP increased 2.1 mmHg. By every ten years of increment in age, PP increased 2.4 mmHg (p=0.01).

Conclusions: The increase in iFGF23 is associated with higher SBP, DBP, and PP. These data suggest that iFGF23 may increase the risk of cardiovascular events in patients with CKD G5 through increasing blood pressure and arterial stiffness.

Table 1. Determinants of SBP, DBP, and PP. SBP: Systolic Blood Pressure; DBP: Diastolic Blood Pressure. PP: Pulse Pressure. * Model adjusted by serum phosphate, serum calcium, parathyroid hormone, and C-reactive protein.

Pulse Mass Index and Pulse Mass Pressure Product in CKD Patients

Rina Oba,1,2 Go Kanzaki,1 Kotaro Haruhara,1 Takaya Sasaki,1 Yusuke Okabayashi,1 Kentaro Koike,1 Nobuo Tsuoboi,1 Takashi Yokoo,1 The Jikei University School of Medicine, Division of Nephrology and Hypertension, Department of Internal Medicine, 3-25-8 Nishi-Shimbashi, Minato-ku, Japan.

Background: Recent studies have conflicting findings on the association between obesity and the risk of chronic kidney disease (CKD). The body mass index (BMI) by itself is an imperfect marker of metabolically unhealthy obesity. The pulse mass index (PMI) and the pulse mass pressure product (PMPP) show strong correlations with the risk of cardiovascular disease and may reflect an individual’s metabolic energy state. However, it is still unclear whether PMI and PMPP can be useful parameters for the risk of CKD.

Methods: We retrospectively identified 51 subjects who underwent ambulatory blood pressure monitoring and kidney biopsy simultaneously at the Jikei University Hospital, Tokyo, from 2017 to 2019. All subjects were diagnosed as primary or secondary glomerular diseases or kidney biopsy. The BMI and the PMPP were calculated from the following formula: PMI = BMI × resting heart rate (RHR) /1730. PMPP = BMI × RHR × systolic blood pressure. We evaluated the clinicopathological findings associated with PMI and PMPP.

Results: Of 51 subjects, the age was 50.3 ± 16.1 years (mean ± standard deviation), and 60.8% were male. The eGFR was 44.4 ± 23.5 mL/min/1.73m². The median glomerulosclerosis index (GS) was 18.3 (interquartile range, 4.7-44.4) %, and the tubular injury level was 17.5 (5.0-36.3) %. The PMI was 0.94 ± 0.23, the PMPP was 21.6 ± 7.3 × 10⁶, and the BMI was 22.9 ± 4.7 kg/m². Both PMI and PMPP were positively associated with GS, HbA1c, and triglycerides, whereas negatively associated with eGFR (P = 0.02 and 0.004; respectively), CKD stages (P = 0.04 and 0.02; respectively) and HDL. Of note, each parameter such as BMI, RHR, and blood pressure was not correlated with either eGFR or CKD stages.

Conclusions: We observed correlations between both PMI and PMPP and kidney function. This study indicates that PMI and PMPP may be possible makers of the relative risk of unhealthy obesity with CKD.

PO0485

Thyroid Status and Mortality Among CKD Patients Transitioning to Dialysis

Jia Li,1 Amy S. You,2 Gregory Brent,2 Elani Streja,1 Dorsa F. Maryska,2 Monica Thornhill-Joynes,3 Yoko Narasaki,1,2 Ji-ting Hsiung,3 Cachet Ziemer,2 Christiana Park,1 John J. Sim,1 Danh V. Nguyen,1 Csaba P. Kovessy,1 Kamary Kalantar-Zadeh,2 Connie Rhie,1 University of California Irvine, Irvine, CA; 3University of California Los Angeles, Los Angeles, CA; 1Kidney Specialists Medical Corporation, Los Angeles, CA; 4Kaiser Permanente Southern California, Pasadena, CA; 5The University of Tennessee Health Science Center, Memphis, TN.

Background: Hypothyroidism has been associated with higher death risk in non-dialysis dependent chronic kidney disease (NDD-CKD) and end-stage renal disease (ESRD) patients, presumably due to cardiovascular pathways. We examined whether pre-ESRD thyroid status is a predictor of survival in NDD-CKD patients transitioning to dialysis.

Methods: Among US Veterans with NDD-CKD transitioning to dialysis from 10/2007-3/2015, we examined the association of serum thyrotropin (TSH) levels (TSH) levels averaged over a three-year pre-ESRD transition period (“pre-ESRD prelude period”) with post-ESRD mortality. Patients were followed for the outcome for up to three-years, and HRS for all-cause mortality were estimated using expanded case-mix/laboratory adjusted Cox models. In sensitivity analyses, we examined varying pre-ESRD prelude and post-ESRD mortality intervals.

Results: Among 43,161 patients in the primary cohort (three-year pre-ESRD prelude cohort), increasingly higher TSH levels >3.0mIU/L were associated with incrementally higher mortality (ref: TSH 0.5-3.0mIU/L): adjusted HRs (95%CI): 1.04 (0.95-1.13), 1.04 (1.00-1.07), and 1.16 (1.11-1.22) for TSH levels of <0.5, 3.0-5.0, and >5.0mIU/L, respectively. A similar pattern of findings was observed for patients whose TSH levels were examined over one-year and two-year pre-ESRD prelude periods, with follow-up for the outcome of interest for up to one and two years, respectively.

Conclusions: There was a dose-dependent relationship between higher pre-ESRD TSH levels exceeding 3.0mIU/L and higher post-ESRD mortality in NDD-CKD patients transitioning to dialysis. Further studies are needed to determine the underlying determinants of thyroid dysfunction in CKD, and whether reduction of TSH levels with thyroid hormone supplementation ameliorates mortality in this population.

PO0486
Baseline Characteristics of Non-Dialysis CKD Patients with and Without Anemia: A Report from the Retrospective Cohort from DISCOVER CKD
Eric T. Withbrodt,1 Juan J. Carrero,2 Glen James,3 Steven Fishbane,4 Supriya R. Kumar,1 Roberto Pecotis-Filho,5,6 Juan Jose Garcia Sanchez,7 Carol A. Pollock,7 James A. Sloand,1 Katarina Hedman,1 David C. Wheeler,1 AstraZeneca, Gaithersburg, MD; Karolinska Institutet, Stockholm, Sweden; University of Sydney, Sydney, NSW, Australia; AstraZeneca UK Ltd, Cambridge, United Kingdom; Northwell Health, Manhasset, NY; Pontificia Universidade Catolica do Parana, Curitiba, Brazil; 4Arbor Research Collaborative for Health, Ann Arbor, MI; 2University of Michigan Medical School, Ann Arbor, MI; 1University of California San Francisco, San Francisco, CA

Background: Anemia is a frequent complication of chronic kidney disease (CKD), associated with adverse clinical outcomes and reduced quality of life. This analysis describes baseline characteristics of non-dialysis dependent (NDD) CKD patients with and without anemia in DISCOVER CKD.

Methods: The DISCOVER CKD retrospective cohort of patients in this analysis were extracted from the TruNet health research network, Japan Medical Data Vision (JMDV) and integrated Limited Claims and EHR (LCED) databases. Patients were aged >18 years with 2 estimated glomerular filtration rate (eGFR) measures <60 ml/min/1.73m2 at least 90 days apart between January 2008 and March 2020. The index date was the first Hb measure after the 2nd eGFR measure. Exclusion criteria included: <1-year registration/medical history prior to index, active bleeding, a Hb value (only) within 30 days from transfusion or bleeding and no Hb measure within a year after CKD diagnosis. Anemia was defined as <12 g/dl for females, <13 g/dl for males per WHO criteria. Baseline characteristics were summarized and stratified by presence of anemia.

Results: Preliminarly, of 799183 CKD patients meeting our I/E criteria, 67% were not anemic at baseline. In patients with anemia (33%): 191451 (81%) had a baseline Hb of 10-12 (female) 10-13 (male) g/dl, 36899 (16%) 8-10 g/dl and 9606 (3%) <8 g/dl. Compared to patients without anemia: patients with anemia were older, more likely to be female, to have more advanced CKD, and more likely to have comorbidities.

Conclusions: In routine clinical care, the presence and severity of anemia increases as CKD advances and is associated with a higher comorbidity burden.

PO0487
Incidence of and Risk Factors for Incident eGFR <60 in the Reasons for Geographic and Racial Differences in Stroke Study
Katharine L. Cheung,1 Mary Cushman,1 Deidra C. Crews,3 Suzanne E. Judd,3 David G. Warnock,4 Orlando M. Gutierrez,1 The University of Vermont Larner College of Medicine, Burlington, VT; 2John Hopkins University School of Medicine, Baltimore, MD; 3The University of Alabama at Birmingham School of Public Health, Birmingham, AL

Background: Few contemporary US cohorts examined the incidence of and risk factors for developing a low estimated glomerular filtration rate (eGFR) or whether these factors vary by race, sex or region of US residence.

Methods: We studied 11,814 black or white participants with an eGFR> 60 ml/min/1.73m2 at baseline and who had 10-year follow-up eGFR. Low eGFR was defined as incident eGFR <60 ml/min/1.73m2 at the second visit and a 40% decline from baseline. Incidence rates were calculated overall and by age, sex and race groups. We used Poisson regression to calculate the risk of incident low eGFR, adjusting for demographics, socioeconomic status and clinical factors, and across race, sex and region strata.

Results: At baseline, mean age was 62 (±8.1) years, 54% were female, 36% black and 56% resided in the US stroke belt. The overall incidence of low eGFR was 9% and ranged from 4% in those aged 45-54 to 18% in those 75 years and older. Age, systolic blood pressure, diabetes, heart disease, BMI, smoking, lower income, higher education, and residence in the US stroke belt were independent risk factors for incident low eGFR. Blacks had higher risk, accounting for sociodemographic risk factors, but this was fully attenuated after adjusting for clinical factors. Low eGFR risk factors did not differ substantially by race, sex or region.

Conclusions: The higher incidence of low eGFR in black compared to white participants was accounted for by modifiable clinical risk factors. Residence in the US stroke belt was independently associated with incident low eGFR in REGARDS participants.

Risk factors for incident low eGFR (Relative risk and 95% confidence interval)

PO0488
High Prevalence of CKD Among Individuals Living with HIV in the United States
Jennifer L. Bragg-Gresham,1 Ann Andrews,2 Hal Morgenstern,3 Brenda W. Gillespie, Neil R. Powe,1 Tanushree Banerjee,4 Rajiv Suran,5 1University of Michigan Medical School, Ann Arbor, MI; 2National Kidney Foundation of Michigan, Ann Arbor, MI; 3University of Michigan, Ann Arbor, MI; 4University of California San Francisco, San Francisco, CA

Background: Chronic kidney disease (CKD) is an important comorbidity among people living longer with human immunodeficiency virus (HIV). We report the prevalence, trends and characteristics of individuals with HIV in the US, with the aim of better understanding this understudied, but important risk factor for CKD.

Methods: Data from 22,626 adults aged 20-59 who had consented for HIV testing in the National Health and Nutrition Examination Survey (NHANES; 1999-2014), were analyzed. Those with HIV+ vs. - serology were compared with respect to demographics, comorbidities, and social determinants of health in the full sample and those with CKD, as defined by either eGFR<60 ml/min/1.73m2 or urine albumin to creatinine ratio >30 mg/g. Logistic regression was used to assess the odds of CKD by HIV status. Comparisons were assessed using survey weights for all analyses.

Results: Prevalence of HIV+ remained stable, from 0.4% to 0.6% during this time period. Individuals HIV+ were older than those HIV- in both the full sample and among those with CKD. A higher proportion of HIV+ than HIV- individuals were black, current smokers, had < high school education, with income <$45k, and reported either Medicare or other government insurance (Table). Among individuals with CKD, those HIV+ had almost twice the prevalence of diabetes (30% vs. 19%, p<0.05) and over 4 times higher awareness of their CKD (28% vs. 6%, p<0.002) compared to HIV-. HIV+ vs. HIV- individuals had more than twice the prevalence of CKD (15.3% vs. 7.1%, p<0.002). CKD was associated with HIV+ status [unadjusted odds ratio (OR) = 2.37; 95% CI: 1.36-4.17]. Adjusting for other covariates, attenuated the association only slightly (adjusted OR=2.17; 95% CI: 1.21-3.89).

Conclusions: CKD was associated with HIV+ status among younger adults living with the disease in the United States. However, larger, longitudinal studies among individuals living with HIV and CKD are needed to increase awareness of this complication among survivors of the disease.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: We conducted a cross-sectional analysis using the data from the National Health and Nutrition Examination Survey between 2007 and 2018. We calculated the trend of self-reported illicit drug use (marijuana, cocaine, heroin, methamphetamine, and intravenous drug use) and defined current use if the last use was within 1 year of the survey. We then assessed whether the use of illicit drugs is associated with CKD (defined by estimated glomerular filtration rate ≤ 60 ml/min/1.73 m² and/or urine albumin-creatinine ratio (UACR) ≥ 30 mg/g), microalbuminuria (UACRs 30–300 mg/g) and macroalbuminuria (≥ 300 mg/g). Lastly, we assessed any predictors for drug use in CKD patients.

Results: Between 2007 to 2018, there were 22,214 adult patients between 18-59 years of age. Of these, 2,148 had CKD as defined above. CKD patients were significantly older, more likely to be female, obese, cigarette smoker, alcohol drinker, and to have diabetes, and hypertension. We found that prevalence of marijuana (21.9% vs 21.9%, p=0.23), cocaine (4.9 vs 3.6, p=0.95) and methamphetamine (1.5% vs 1.3%, p=0.52) did not differ between CKD and non-CKD. However, heroin use (0.2% vs 0.5%, p=0.02) were significantly lower in CKD compared to non-CKD. Interestingly, there is a significant trend towards increasing marijuana use in CKD patients overtime as prevalence increase from 17.3% in 2007-2010 to 21.7% in (2011-2014), and up to 26.5% in 2015-2018 (p trend 0.02). Recent illicit drug use was not associated with CKD, microalbuminuria or macroalbuminuria. Age, black race, current smoker and alcohol drinking were significant predictors of drug use within 1 year in CKD patients.

Conclusions: In a national sample, marijuana was the most common illicit drug use among CKD patients and the trend of marijuana use in CKD patients is increasing, likely due to marijuana legalization. Age, black race, current smoker and alcohol drinking increase the odds of illicit drug use in CKD patients.
Ideal cardiovascular health was defined as nonsmoker; body mass index (BMI) <25 kg/m²; ≤150 minutes/week of physical activity; healthy dietary pattern (high in fruits and vegetables, fish, and fiber-rich whole grains; low in sodium and sugar-sweetened beverages); total cholesterol <200 mg/dL; blood pressure <120/80 mm Hg; and fasting blood glucose <100 mg/dL.

At study entry, mean age was 57 years, 71% were male, and 57% had diabetes. The mean baseline eGFR was 47 ml/min/1.73m² and the median protein excretion 633 mg/24 hours. Nine percent met all seven criteria for ideal cardiovascular health. During a median follow-up of 2.9 years, there were 78 CKD progression events. In sex- and age-adjusted analysis, each point higher Life's Simple 7 score was associated with 13% lower risk of CKD progression (HR = 0.89; 95% CI = 0.78-0.96). This association attenuated after adjusting for baseline eGFR and proteinuria (HR = 0.94; 0.83-1.05).

Conclusions: In this cohort of adults with CKD in Mexico, the prevalence of ideal cardiovascular health as measured by Life’s Simple 7 was low. The protective effect of Life’s Simple 7 on CKD progression was explained by baseline kidney function.

PO0495
Patterns of Hospital Admissions Among Patients with CKD
Sarah S. Gray, Dena E. Cohen, Steven M. Brunelli. Davita Clinical Research, Minneapolis, MN.

Background: Although chronic kidney disease (CKD) is relatively common in the United States, an understanding of the frequency, causes, and costs of hospital admissions among patients with CKD at the national level is lacking.

Methods: Study data were derived from the Centers for Medicare & Medicaid Services 100% claims sample (2017-2018). Included patients were adults enrolled in Medicare Parts A and B who had a claim including a diagnosis code for CKD stage 3, 4, or 5 during 2017; exposure was ascribed as the most severe observed stage. Patients with evidence of commercial insurance, diagnosis of end-stage kidney disease, dialysis treatment, or death, prior to 31 Dec 2017 were excluded. Hospital admissions and paid for claims observed from January 1, 2017 through the first of 31 Dec 2018 or censoring for loss of Medicare Part A, dialysis initiation, or death. Hospitalization causes were ascribed on the basis of ICD-10 codes, grouped using Clinical Classification Software Level 1 categories.

Results: A total of 1,352,401 patients with CKD3, 208,963 patients with CKD4, and 16,159 patients with CKD5 met eligibility criteria. Annual hospitalization rates were 0.66, 0.87, and 0.77 admissions/patient-year among patients with each CKD stage, respectively. Across all 3 stages, admissions for “Diseases of the Circulatory System” accounted for approximately 25% of hospitalizations, with “hypertension with complications and secondary hypertension” contributing approximately half of the hospitalizations in this category. Considerable regional variation was observed with respect to annual hospitalization costs among this population, with the Southwest, Northeast, and Mid-Atlantic regions tending to have higher costs than other parts of the country.

Conclusions: Patients with CKD are frequently hospitalized, with associated costs that display marked regional variation. Clinically and regionally targeted programs may result in improved patient outcomes and lower health care costs.

PO0496
Critical Care Resource Use in CKD in the Safety-Net Setting
Jefferson L. Triozzi, Jingbo Niu, Sankar D. Navaneethan. Baylor College of Medicine, Houston, TX.

Background: Chronic kidney disease (CKD) is associated with adverse outcomes among patients with critical illness. There is limited data on the extent of critical care resource use among patients with CKD in safety-net settings.

Methods: We conducted a retrospective cohort study of patients in a safety-net healthcare system with non-dialysis-dependent CKD and critical illness, defined as admission or transfer to the intensive or intermediate care unit. Poison regression was used to identify risk factors for critical illness based on sociodemographic factors, comorbidities, and baseline stage of CKD. Critical care resource use was extracted from the medical record, including dialysis initiation, ventilatory support, blood products, and vasoactive medications. Baseline stage of CKD was included as a baseline stage of CKD.

Results: Out of 1,208 patients with CKD who were hospitalized during a three-year period (stage 3a-43%, stage 3b-35%, stage 4-22%), 495 patients required intermediate or intensive care. In the multi-adjusted model [IRR (95% CI)], critical illness was associated with stage of CKD [stage 3a-1 (referent), stage 3b-1.24 (1.10,1.40), stage 4-1.99 (1.72, 2.30)]. Hypertensive and non-Hypertensive black race, congestive heart failure, and moderate/severe anemia were also associated with risk of receiving critical care (Table 1).

Conclusions: We report a high burden of hospitalizations requiring critical care resources in a safety-net setting. Notably, a third of patients with CKD stage 4 and critical illness required hemodialysis initiation. Further research is needed to prevent critical illness and the need for critical care resources in patients with CKD.

Usual Source of Care and Clinical Outcomes in Adults with CKD: Findings from the Chronic Renal Insufficiency Cohort (CRIC) Study

Stephanie M. Toth-Manikowski,1 Jesse Y. Hsu,1 Michael J. Fischer,1 Jordana B. Cohen,2 Claudia M. Lora,1 Thida C. Tan,1 Jiang He,4 Raquel C. Greer,1 Matthew R. Weir,1 Sarah J. Schrauben,2 Mildra Saunders,2 Ana C. Ricardo,2 James P. Lash.1 1University of Pennsylvania, Philadelphia, PA; 2Kaiser Permanente Northern California, Oakland, CA; 3Tulane School of Public Health and Tropical Medicine, New Orleans, LA; 4Johns Hopkins Medicine, Baltimore, MD; 5University of Maryland School of Medicine, Baltimore, MD; 6University of Chicago, Chicago, IL.

Background: In general populations, having a usual source of care (USOC) increases use of preventive care and is associated with higher survival. However, there are limited data in adults with chronic kidney disease (CKD).

Methods: In the CRIC Study, we categorized participants’ self-reported USOC as follows: 1) clinic/doctor’s office, 2) emergency room (ER)/urgent care, and 3) other. Using multivariable regression analyses, we evaluated the association between USOC and incident end stage renal disease (ESRD), cardiovascular events (myocardial infarction, heart failure, stroke, and peripheral arterial disease), hospitalizations, and all-cause death.

Results: Among 3,140 participants, mean age was 65 years, 45% were non-Hispanic white, 43% non-Hispanic black, 9% Hispanic, and mean estimated glomerular filtration rate (eGFR) was 50 mL/min/1.73m². 90% identified clinic/doctor’s office as USOC, 9% ER/urgent care, and 8% other. Over a median follow-up time of 3.6 years, there were 288 deaths, 181 incident ESRD events, 444 cardiovascular events, and 7,957 hospitalizations. In multivariable analyses, compared to clinic/doctor’s office as USOC, ER/urgent care was associated with higher risk for death and hospitalizations (Table). No significant association was seen with incident ESRD or cardiovascular events.

Conclusions: ER/urgent care as USOC was associated with higher risk for adverse outcomes in this large and diverse adult cohort with CKD. Further studies are needed to identify barriers to accessing appropriate preventive care to reduce negative health outcomes in this population.

PO0498

Healthcare Resource Utilization and Costs of CKD According to the 2012 KDIGO CKD Classification: A Report from the DISCOVER CKD Retrospective Cohort

Juan Jose Garcia Sanchez,2 Juan J. Carrero,2 Supriya R. Kumar,2 Hiddo J. L Heesink,3 Glen James,1 Stephen Nolan,1 Lam S. Carolyn,4 Hungta (Tony) Chiolho,1 Alyshah Abdul Sultan,1 Carol A. Pollock,2 Roberto Dias-Filho,4 AstraZeneca, Cambridge, United Kingdom; 5Karolinska Institutet, Stockholm, Sweden; 6AstraZeneca, Gaithersburg, MD; 7Rijksuniversiteit Groningen, Groningen, Netherlands; 8National Heart Centre Singapore, Singapore, Singapore; 9Duke-NUS Medical School, Singapore, Singapore; 10Royal North Shore Hospital, St Leonards, NSW, Australia; 11Pontificia Universidade Catolica do Parana Escola de Medicina Campus Londrina, Londrina, Brazil; 12Arbor Research Collaborative for Health, Ann Arbor, MI.

Background: The DAPA-CKD trial finished early due to overwhelming efficacy. Real-world data reporting healthcare resource utilization (HCRU) and cost associated with CKD categorized according to the 2012 KDIGO recommendations are scarce. We assessed HCRU and costs in a “DAPA-CKD-like population” (eGFR 25-75/mL/min/1.73m² and UACR 200-5000mg/g) compared to patients categorized according to KDIGO 2012 recommendations.

Methods: DISCOVER CKD is an observational study in patients with CKD, data was extracted using the integrated Limited Claims and Electronic Health Record data. Patients were aged 18 years, with at least 90 days recorded at least 90 days apart between January 2008 and September 2018. Index date was 2nd eGFR. We calculated total and annualized number of encounters and estimated annualized per-patient and total costs. Incidence rates per 100 person-years (PY) were estimated for outpatient and hospitalization events.

Results: Preliminarily, 6270 patients met the KDIGO 2012 definition (mean±SD age 64.0(10.9) years, 51.0% female) and 383 patients met the DAPA-CKD-like criteria (mean±SD age 64.0(11.9) years, 38.9% female). The rate of hospitalizations almost doubled for the DAPA-CKD-like population vs the KDIGO 2012 defined population (Rate 100-PY[95CI] 59.0[53.7-64.8] vs 26.4[25.5-27.3]) and was also higher (Mean±SD 6.5[9.4] vs 5.4[6.6] days). The DAPA-CKD-like population incurred substantially higher annualized per patient hospitalization costs (Mean±SD USD39782[78572] vs USD25717[60019]); Figure 1.

Conclusions: This analysis demonstrated that the DAPA-CKD-like population is associated with a higher HCRU and cost burden. These results highlight the need for innovative therapies to improve patient outcomes in this population.

Tope Oyekanmi,1 Louis Lamerato,2 Juan Jose Garcia Sanchez,2 Like Jiang,1 Joanna C. Huang,1 Stephen Nolan.1 AstraZeneca, Wilmington, NC; 2AstraZeneca UK Ltd, Cambridge, United Kingdom; 1Henry Ford Health System, Detroit, MI.

Background: The DAPA-CKD Trial is the first SGLT-2i renal outcome trial to test the efficacy and safety of an SGLT-2i, dapagliflozin, in patients with diagnosed CKD with and without T2D. The objective of this study is to assess the healthcare resource utilization and cost in a “DAPA-CKD-like population” (eGFR 25-75/mL/min/1.73m² and UACR 200-5000mg/g) using a contemporary US healthcare system.

Methods: Data from the Henry Ford Health System (HFHS) were used to identify patients with CKD stages 2 through 4 between 2006 and 2016 (based on eGFR labs) and patients were followed through 2018. Patients with no confirmatory eGFR > 90 days from index date, death within 30 days, history of renal transplant, and evidence of renal replacement therapy, or progression to CKD stage 5 during the baseline period (6 months pre or post index date) were excluded. Cumulative primary and secondary utilization was evaluated for all patients during the follow-up time. Annual utilization rates are the total observed utilization divided by follow-up time. Billings records with HFHS were used to estimate costs.

Results: 6,557 patients (mean age 62.9 years, 46.2% male) met the eligibility criteria and are included in the study cohort. The population was stratified by UACR (0-<30, 30–189, 190–5,000mg/g) and the DAPA-CKD-like population (200-5000mg/g) was associated with significantly higher annualized per-patient healthcare costs, $39,222/yr (UACR 200-5000mg/g vs UACR 0-<30mg/g).

Understanding Patterns of Medical Spend Informs Design of Upstream Intervention in CKD

**Title**

**University Hospitals, Cleveland, OH.**

**Background:** Despite ease of diagnosis based on laboratory testing, CKD is often unrecognized and comorbid decompensation results in delayed diagnosis in acute care settings. The purpose of our inquiry was to inform the design of systems of care that would prevent escalation of total cost of care (TCOC) of CKD through minimization of acute care spend.

**Methods:** Unrecognized CKD was defined as CKD that was evident by laboratory data in the EHR but not captured by an ICD10 code or DRG for chronic kidney disease. Recognized CKD or ESRD had both ICD10 and DRG data and laboratory evidence of CKD. We then compared inpatient and total medical spends as well as the density of preventive measures such as wellness visits among these groups. The data repository was built on the MS Power BI platform and machine learning and high throughput analyses were conducted using Alteryx utilities.

**Results:** A total of 217,125 patients were included that had eGFR and spend data in 2019. Annual wellness visits occurred on average among 38 percent (n=142,373) of those with unrecognized CKD and only 20.5 %, and 24.3 % of those with undiagnosed CKD stage 3b-5 vs. 46.9 percent of those with recognized CKD/ESRD (p<.0001). A diagnosis of CHF was recorded in 13.1 %, and 10 among those with recognized CKD or ESRD (n= 52,242; P < 0.001). No statistical difference was observed in 2019. Annual wellness visits occurred on average among 38 percent (n=142,373) of those with unrecognized CKD and only 20.5 %, and 24.3 % of those with undiagnosed CKD stage 3b-5 vs. 46.9 percent of those with recognized CKD/ESRD (Chi square for trend <0.001).

**Conclusions:** Our high proportion of time on therapy for key pharmacological treatments during the follow-up period. However, it is well established that a substantial residual risk and unmet need exists with current standard of care.

**Treatment Pathways of CKD Patients Defined by the 2012 KDIGO CKD Classification: A Report from the DISCOVER CKD Retrospective Cohort**

**Juan Jose Garcia Sanchez, 1 Juan J. Carrero, 2 Supriya R. Kumar, 3 Roberto Pecoits-Filho, 4,5 Glen James, 6 Hiddo J. Heerspink, 7 Lam S. Carolyn, 8,9 Hungta (tony) Chen, 2 Eiichiro Kanda, 2 Alyshah Abdul Sultan, 2 Naoki Kashihara, 6 Mikhail Kostoborod, 7 David C. Wheeler, 11 Carol A. Pollock, 12 AstraZeneca, Cambridge, United Kingdom; 7 Karolinska Instituteet, Stockholm, Sweden; 8 AstraZeneca, Gaithersburg, MD; 4 Arbor Research Collaborative for Health, Ann Arbor, MI; 1 Pontificia Universidade Catolica do Parana Escola de Medicina Campus Londrina, Londrina, Brazil; 10 Rijksuniversiteit Groningen, Groningen, Netherlands; 11 National Heart Centre Singapore, Singapore, Singapore; 12 Duke-NUS Medical School, Singapore, Singapore; 9 Kawasaki Ika Daigaku, Kurashiki, Japan; 12 Saint Luke’s Mid America Heart Institute, Kansas City, MO; 13 University College London, London, United Kingdom; 12 Royal North Shore Hospital, St Leonards, NSW, Australia.

**Background:** Treatment strategies to delay the progression of CKD focus on use of RAASI, anti-hypertensive and, for patients with type 2 diabetes, anti-diabetic therapy. Data describing treatment pathways in patients defined according to the 2012 KDIGO classification are scarce.

**Methods:** The DISCOVER CKD retrospective cohort of patients was extracted using the integrated Limited Claims and EHR data. Patients were aged ≥18 years, with ≥1 UACR measure and two measures of eGFR 0-75 mL/min/1.73 m² recorded at least 90 days apart between 2008-2018. Sankey Plots were used to visualize chronological treatment pathways (1st-3rd line) post-index, of key treatments commonly prescribed to these CKD patients including: RAASI, anti-diabetic therapy, beta-blockers and anticoagulants. We also describe median time to 1st line therapy initiation.

**Results:** Preliminarily, 4283 patients were prescribed key treatments during follow-up with anti-hyperglycaemic therapy and RAASI therapy being the most common 1st line therapy. Figure 1. Median time to 1st-line therapy initiation was: 34 days for anti-diabetic therapy, 45 days for beta-blockers, 49 days for RAASI therapy and 50 days for anticoagulants. Anti-diabetic therapy and RAASI therapy accounted for the highest proportion of time in which treated patients remained on therapy during follow-up (68% and 63%, respectively).

**Conclusions:** We observed a high proportion of time on therapy for key pharmacological treatments during the follow-up period. However, it is well established that a substantial residual risk and unmet need exists with current standard of care.

PO0503
Treatment Pathways of Patients with CKD: A Report from the DIS-COVER CKD Retrospective Cohort
Glen James,1 Juan J. Carrero,2 Supriya R. Kumar,3 Steven Fishbane,4 Carol P. Moreno Quinn,4 Hildo J. L. Heerspink,3 Eric T. Wittbrodt,5 Eiichiro Kanda,6 Katarina Hedman,7 Naoki Kashihara,8 Hangta (tony) Chen,9 Mikhail Kosioborod,10 Lam S. Carolyn,11,12 Carol A. Pollock,12 Peter Stenwinkel,13 Roberto Petoecios-Filho,11,12 David C. Wheeler,13 AstraZeneca UK Ltd, Cambridge, United Kingdom; Karolinska Institutet, Stockholm, Sweden; AstraZeneca, Gaithersburg, MD; Northwell, Manhasset, NY; University of Groningen, Groningen, Netherlands; Kawasaki Medical School, Kurashiki, Japan; AstraZeneca, Gothenburg, Sweden; Saint Luke’s Hospital of Kansas City Health Sciences Library, Kansas City, MO; University of Sydney, Sydney, NSW, Australia; Karolinska Universitetssjukhuset, Stockholm, Sweden; Pontificia Universidade Catolica do Parana, Curitiba, Brazil; Arbor Research Collaborative for Health, Ann Arbor, MI; University College London, London, United Kingdom; National Heart Centre Singapore, Singapore, Singapore; Duke-NUS Medical School, Singapore, Singapore.

Background: Chronic kidney disease (CKD) is a global health problem associated with clinical complications. Gaps exist in real-world data to understand treatment pathways of CKD patients. We describe treatment pathways of key medications prescribed to CKD patients in DISCOVER CKD.

Methods: The DISCOVER CKD retrospective cohort of patients were extracted using Japan Medical Data Vision (JMDV) and integrated Limited Claims and EHR (LCED) data. The study included patients aged ≥18 years with a diagnostic CKD code (stage 3A through end stage renal disease or renal replacement therapy) or 2 estimate glomerular filtration rate (eGFR) measures ≥75 mL/min/1.73m2 at least 90 days apart between January 2008 and October 2018. The index date was the date of first diagnostic code or 2nd eGFR. Sankey Plots were used to visualize chronological treatment pathways (1st to 3rd line) post-index of key treatments (including combinations) commonly prescribed at least to 50% CKD patients including: RAAS, statins, diuretics and anti-hypertensives. We also describe median time to first line therapy initiation.

Results: Preliminarily, in the study cohort (N=159849) anti-hypertensives were the most common first-line therapy prescribed. Median time to first-line therapy initiation for LCED and JMDV was: 48 days and 168 days for anti-hypertensives, 39 days and 89 days for diuretics, 51 days and 259 days for RAAS and 56 days and 133 days for statins, respectively. In both databases patients remained on anti-hypertensives the most (33.7%) during treatment.

Conclusions: Patients with CKD have high therapy burden, with varying time to initiation of therapies.

Figure 1 – Treatment Pathways of Key Treatments

PO0504
Increased Urinary Albumin Creatinine Testing in CKD Stage 3 and Effect on Quality Metrics

Background: One of the goals of Advancing American Kidney Health Initiative is “reducing the number of Americans developing End Stage Renal disease by 25% by 2030.” An important part in achieving this goal is increased use of interventions backed by high quality evidence including use of ACE inhibitors or ARBs, control of hypertension, and diabetes (DM) control. Albuminuria has been clearly linked to CKD progression, with cardiovascular and all-cause mortality, dual testing remains limited. We sought to characterize trends in dual testing in all veterans and those seen by nephrologists.

Methods: We used Veterans Health Administration (VA) data (2009–18). VA patients with any inpatient or outpatient visit in a given calendar year were included. Time trend of dual testing and patient characteristics including age, sex, race, hypertension, diabetes, CKD, and cardiovascular diseases (CVD) were noted.

Results: There were 10,335 patients in the CKD registry on 12/5/2017 and 10,315 on 12/5/2019. Average age was 73, 81% had hypertension, 38% had DM, and 44% were male. Automated ACR testing in patients with stage 3 CKD was implemented on 5/23/2018. One and half years after implementation of ACR testing, ACR testing increased from 26% to 61% (p < 0.001). ACE inhibitor or ARB use among patients with renal indication did not increase significantly (79% vs. 81%, p = 0.08). Control of DM increased (78% vs. 81%, p < 0.001) while control of hypertension worsened (76% vs. 74%, p = 0.001). In conclusion: In patients with stage 3 CKD, increased albuminuria testing via automated testing linked with EHR alerts did not result in an overall improvement in CKD quality metrics. However, our study was limited by the cross-sectional design as well as the short follow up.

PO0505
Albuminuria Testing and Prevalence and Incidence of Elevated Albuminuria
Jung-Im Shin, Alex R. Chang, Yingying Sang, Ron T. Gansevoort. CKD Prognosis Consortium CKD Prognosis Consortium, Baltimore, MD.

Background: Guidelines recommend an annual evaluation of urine albumin creatinine ratio (ACR) in patients with diabetes (DM) or hypertension (HTN) for early identification and close monitoring of kidney damage. The aim of this study was to inform ACR testing strategies by 1) evaluating the frequency of ACR testing, 2) determining the prevalence and incidence of ACR≥30 mg/g, and 3) developing and validating a risk prediction model for incident ACR≥30 mg/g.

Methods: We analyzed 28 cohorts from the CKD Prognosis Consortium including 1,909,350 persons with DM or HTN from 5 countries. Analysis was performed separately for persons with DM and those with HTN but without DM. We selected a two-year baseline period for administrative cohorts and used the baseline visit for research cohorts to assess frequency of testing and prevalence of a single ACR≥30 mg/g. Confirmed incident ACR≥30 mg/g (elevated twiced 5 years) assessed 5 years after baseline in those with baseline ACR<30 mg/g. Development of prediction models for incident ACR≥30 mg/g used logistic regression and age, sex, baseline systolic blood pressure, HTN and DM medication use, coronary heart disease, heart failure, BMI, A1c, and eGFR as covariates. Models were validated in 5 DM cohorts and 4 HTN only cohorts.

Results: The median frequency of ACR testing across administrative cohorts was ≥48.8% (95% CI: 32.5-58.3%) and ≥4.3% (95% CI: 3.2-7.1%) in DM and HTN only. Among those tested at baseline, the median prevalence of ACR≥30 mg/g was 32.7% (95% CI: 28.4-37.0%) and 21.9% (95% CI: 18.6-29.6%) in DM and HTN only. Among 107,754 persons with DM and 15,676 persons with HTN only who had baseline ACR≥30 mg/g, the incidence median of ACR≥30 mg/g was 32.7% (95% CI: 28.4-37.0%) at least 5 years was 23.3% (95% CI: 18.6-28.5%) and 21.7% (95% CI: 15.7-26.3%) in DM and HTN only. Risk prediction models for 5 year incidence of ACR≥30 mg/g had only modest accuracy in DM (median C statistic: development cohorts 0.629, IQI: 0.600-0.655, validation cohorts 0.635, IQI: 0.619-0.641) and in HTN only (median C statistic: development cohorts 0.649, IQI: 0.621-0.695; validation cohorts 0.663, IQI: 0.635-0.671).

Conclusions: ACR testing in DM or HTN is low in clinical practice. The risk prediction models for incident ACR≥30 mg/g performed only modestly, suggesting future efforts based on risk stratifications may not improve the table strategy. Universal albuminuria testing for individuals with DM or HTN is likely necessary.

Urine Albumin and Serum Creatinine Dual Testing in US Veterans: Trends and Associations with Subspecialty Care
Nicolë M. Bhaye,1,2,3,4,5 Yoon Ha,1 Diane Steffick,2 Jennifer L. Bragg-Gresham,1 Kara Zivin,1,2 Nilka Rios Burrows,2 Meda E. Pavkovich,2 Delphine S. Tuot,2,3,4 Neil R. Powe,4,5 Rajiv Saran,6 University of Michigan, Ann Arbor, MI; US Department of Veterans Affairs, Ann Arbor, MI; Centers for Disease Control and Prevention, Atlanta, GA; University of California San Francisco, San Francisco, CA; Zuckerberg San Francisco General Hospital and Trauma Center, San Francisco, CA.

Background: Urine albumin and serum creatinine (SCr) help define chronic kidney disease (CKD). Despite the fact that urine albumin and SCr are multiplexed with cardiovascular and all-cause mortality, dual testing remains limited. We sought to characterize trends in dual testing in all veterans and those seen by nephrologists.

Methods: We used Veterans Health Administration (VA) data (2009-18). VA patients with any inpatient or outpatient visit in a given calendar year were included. Time trend of dual testing and patient characteristics including age, sex, race, hypertension, diabetes, CKD, and cardiovascular diseases (CVD) were noted.

Results: Among those tested at baseline, the median prevalence of ACR≥30 mg/g was 32.7% (95% CI: 28.4-37.0%) and 21.9% (95% CI: 18.6-29.6%) in DM and HTN only. Among those tested at baseline, the median prevalence of ACR≥30 mg/g was 32.7% (95% CI: 28.4-37.0%) and 21.9% (95% CI: 18.6-29.6%) in DM and HTN only. Risk prediction models for 5 year incidence of ACR≥30 mg/g had only modest accuracy in DM (median C statistic: development cohorts 0.629, IQI: 0.600-0.655, validation cohorts 0.635, IQI: 0.619-0.641) and in HTN only (median C statistic: development cohorts 0.649, IQI: 0.621-0.695; validation cohorts 0.663, IQI: 0.635-0.671).

Conclusions: ACR testing in DM or HTN is low in clinical practice. The risk prediction models for incident ACR≥30 mg/g performed only modestly, suggesting future efforts based on risk stratifications may not improve the table strategy. Universal albuminuria testing for individuals with DM or HTN is likely necessary.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Results: The study population included 58,508,942 patients (90.3% male). Overall, 12.5% of VA patients had both Scr and urine albumin testing in 2009 as compared with 18.6% in 2018 (Fig A, p<0.001). Among patients seen by nephrologists, 30% had both Scr and urine albumin testing in 2009, increasing to 43.3% in 2018 (Fig B, p<0.001). Compared to VA patients with Scr testing only, those with both Scr and urine albumin testing were older, more likely to be male, and more likely to have diabetes, hypertension, and CKD, but less likely to have CVD (p<0.001).

Conclusions: Dual Scr and urine albumin testing among VA nephrology patients is more common than among all VA patients and has increased over time. However, in a given year, less than half of nephrology patients undergo dual testing. Efforts to encourage screening for albuminuria among patients at high risk for CKD and CVD might be considered.

PO0508

Prevalence of Coded and Uncoded CKD in the Military Health System
Jenna M. Norton, Lindsay Gruenwald, Cara H. Olsen, Eric S. Marks, Tracey L. Koehlmoo. Uniformed Services University of the Health Sciences, Bethesda, MD.

Background: Despite the substantial human and financial costs associated with chronic kidney disease (CKD) and its high prevalence in the general population, little is known about rates of CKD in the nearly 9.5 million beneficiaries of the Military Health System (MHS). Diagnostic codes lack adequate sensitivity and validity for identifying CKD using health system data. Using laboratory-data may enable a more accurate assessment of the burden of CKD in the MHS.

Methods: We identified all MHS beneficiaries aged 18 to 64 who received care through the MHS from October 1, 2015 to September 30, 2018. CKD was identified by ICD-10 code and/or a validated laboratory value-based electronic phenotype for CKD. CKD was considered coded if an ICD-10 code was present and uncoded if no ICD-10 code was present. Characteristics of the coded and uncoded CKD populations were compared using two-tailed t tests (continuous variables) and Pearson’s Chi Square test for independence (categorical variables).

Results: The total study population included 3,330,893 MHS beneficiaries. Of those, 105,504 (3.2%) were identified as having CKD. Of those with CKD, only 37% had an ICD-10 code for CKD. Compared to individuals with coded CKD, those with uncoded CKD had a younger average age (average age 45 vs 52), more likely to be female, and more likely to be active duty, but less likely to be of Black race, to have diabetes or to have hypertension (p<0.0001). Among those with test results recorded in the MHS, those with coded CKD had greater numbers of urine albumin, urine albumin-to-creatinine ratio, urine protein-to-creatinine ratio, serum creatinine, and eGFR results (p<0.0001).

Conclusions: Many MHS beneficiaries with laboratory values indicative of CKD were not coded for CKD, suggesting they may not be receiving appropriate management for this progressive and burdensome disease. Individuals with commonly recognized risk factors for CKD (e.g., older age, male sex, black race, diagnosed diabetes, diagnosed hypertension) were more likely to be coded for CKD, suggesting clinicians may be missing CKD in traditionally lower risk groups—despite available laboratory data to assess disease status.

Funding: Other U.S. Government Support

PO0509

Factors Associated with Screening and Recognition of CKD in the VA Healthcare System
Shweta Bansal, Michael J. Madar. The University of Texas Health Science Center at San Antonio Joe R and Teresa Lozano Long School of Medicine, San Antonio, TX; South Texas Veterans Health Care System, San Antonio, TX.

Background: The successful implementation of interventions to improve kidney disease outcomes requires early identification of CKD which involves screening at-risk population as well as recognizing CKD. We have reported suboptimal detection of proteinuria and documentation of CKD previously and now aim to identify factors associated with these rates.

Methods: We interrogated VISN-17 database for at-risk Veterans with hypertension (HTN) and diabetes seen regularly in primary clinics during 2012-19. The final cohort (N=270,170) charts were analysed for serum creatinine/eGFR, urine protein/albumin, ICD codes for CKD, and nephropathy referral. CKD was defined as eGFR<60ml/min at least twice 90 days apart and/or urine albumin creatinine ratio (uACR) >30 mg/g. Factors were examined which could be associated with screening and recognition.

Results: As shown in table, 94.3% patients had one or other screening procedures done. Urine protein/albumin was present in 56.4% charts, the least in patients with HTN only (40%). CKD by lab evidence was present in 42%; however, only 40% of these had documented ICD-codes for CKD or nephropathy referral. There was no clinically significant difference between screened vs. unscreened or recognized vs. unrecognized groups in age, sex, and BMI. Hispanic race association with decrease screening procedures but no difference in CKD recognition. Patients were more likely to have screening procedures as well documented CKD, if they had heart disease, stroke, lowered frequency of specialty care visits, hospitalizations or ER visits; or elective procedures as vascular and cardiac catheterizations. There was no difference in BP control in screened vs. unscreened group but more patients with documented CKD had BP<140/90mmHg.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

204
Conclusions: Proteinuria was detected and CKD was recognized in half of the at-risk Veterans. Co-morbidities and health care visits other than primary care associated with increased screening and recognition suggest utility of initiatives at primary care level to educate the need for CKD detection and awareness.

PO0510
Spatial Distribution of Newly Detected CKD Among US Veterans, 2009-2018
Jennifer L. Brague-Gresham,1 Brenda W. Gillespie,2 Yun Han,1 Xiaosong Zhang,1 Diane Steffick,3 William Weitzel,4 Susan T. Crowley,4 Rajiv Saran.1 1University of Michigan Medical School, Ann Arbor, MI; 2University of Michigan, Ann Arbor, MI; 3Veterans Health Administration, West Haven, CT; 4Veterans Health Administration, Ann Arbor, MI.

Background: While the rate of new end stage renal disease (ESRD) cases has slowed in recent years, less is known about trends in the incidence of pre-ESRD CKD. Using national data from the Veterans Health Administration (VHA) we examined the rates and spatial distribution of newly detected cases of CKD using laboratory measures.

Methods: Using data from 8.5+ million US Veterans over a decade (2009-18), in the VHA system during the previous 3 years with no indication of kidney disease, rates of newly detected kidney disease were calculated by year. Three measures of kidney disease were assessed by laboratory reports: 1) eGFR < 60 mL/min/1.73m², 2) albuminuria, and 3) either low eGFR or albuminuria. Spatial maps contain 3-year incidence rates (2016-18) by county, based on patient residence.

Results: Rates of newly detected low eGFR were steady from 2011 forward (~30/1,000 PY), after a drop from 55 to 31 cases between 2009 and 2011, a time when standardization of creatinine calibration to IDMS became mandatory and may explain the change in rates. Rates of newly detected albuminuria showed little variability (~10/1,000 PY). Areas of high incidence of low eGFR were present in northern Michigan, northern Indiana, central Illinois, and western North Carolina. Newly detected albuminuria was highest in coastal North Carolina, northern Idaho, northeastern Indiana, and on the border of Washington and Oregon.

Conclusions: Rates of newly detected disease reflect a combination of the true incidence rate as it presents to a health system, but is also influenced by the rate of testing for the disease in question. Despite this limitation, these findings are important for both individual and population health management, early detection, management and prevention.

PO0511
Defining Criteria for CKD Stage 3 Patients Nephrology Referral: An Analysis Focused on CKD Progression and Mortality Risk
Luis F. Goncalves, Adriana Fernandes, Mario R. Raimundo. Hospital Beatriz Angelo, Loures, Portugal.

Background: The high prevalence of CKD and its increasing awareness by primary care clinicians. While the referral of CKD stage 4 and 5 to a nephrology clinic is undisputable, the need for stage 3 patients referral is still subject to debate. Our objective was to investigate baseline characteristics of CKD stage 3 patients associated with subsequent CKD progression, in order to help determine which patients should be referred at this stage.

Methods: Retrospective analysis of all patients referred to a nephrology clinic over 6 years. We included CKD stage 3 patients with at least 36 months of follow-up or 24 of follow up with more than 3 serum creatinine determinations. CKD progression was defined by one of the following: 1) an eGFR decline superior to 5mL/min/year; 2) creatinine duplication; 3) The need for chronic RRT. Baseline covariates included demographics, comorbid conditions and laboratory values. Univariate and multivariate analysis were employed to determine independent predictors of CKD progression and mortality.

Results: Out of the 3008 patients 594 (19.8%) met the inclusion criteria (median age: 71.9 years; 63.8% male). Median follow-up was 4.9 years (IQR 2.2). 133 (22.4%) met the criteria for CKD progression and 110 (18.6%) died. CKD progression was associated with higher proteinuria (405.7 vs 65.5mg/gr, p<0.001), Diabetes (60.9 vs 45.3%, p=0.002), CHF (40.6 vs 28.7%, p=0.009), Anemia (68.0 vs 44.7%, p<0.001), higher diuretic use (48.9 vs 34.1%, p=0.002) and mortality (40.9 vs 12.2%, p=0.001) Albuminuria over 300 mg/gr [Odds ratio (OR) 3.57, 95% CI 2.20 - 5.80] and Anemia (OR 1.97, 95% CI 1.20 – 3.22) were associated with CKD progression. The independent predictors of mortality were: CKD progression (OR 4.49, 95% CI 2.69-7.50), Older age (OR per 1 year increase 1.03, 95% CI 1.01-1.05), presence of CHF (OR 1.75, 95% CI 1.03-2.98), presence of Hyperkalemia at first consultation (OR 2.12, 95% CI 1.00 – 4.52) and Anemia (OR 1.93, 95% CI 1.03 - 3.62).

Conclusions: Patients with macroalbuminuria and anemia at first consultation are at increased risk for rapid CKD stage 3 progression. In this group, patients with CHF, anemia and hyperkalemia (even at first consultation) have a higher risk of mortality. This study may be useful and help us in guiding which CKD stage 3 patients should be referred to a nephrology clinic.
PO0512

Laboratory-Based Potential Indications vs. Risk-Based Triage for Nephrology Referrals in the Veterans Affairs Health System

Vishal Duggal,1,2 Maria E. Montez-Rath,1,3 Chun Thomas,1 Mary K. Goldstein,1 Manjula Kurella Tamura,1,4 VA Palo Alto Health Care System, Palo Alto, CA; 1Stanford University Stanford Health Policy, Stanford, CA; 1Stanford University School of Medicine, Stanford, CA; 4VA Palo Alto Geriatric Research Education and Clinical Center, Palo Alto, CA.

Background: Clinical decision support tools may facilitate identification of chronic kidney disease (CKD) and timely nephrology referral. Little is known about the potential effects they might have on the volume of nephrology referrals. We sought to estimate how the implementation of a CKD decision support tool could affect potential nephrology referral volume based on U.S. Veterans Affairs Health System (VA)/Department of Defense (DoD) guidelines, and the risk profile of referred patients.

Methods: In a retrospective cohort study of 434,735 patients with CKD, we determined the number of patients who met laboratory-based potential indications for nephrology referral based on VA/DoD guidelines. We used the Kidney Failure Risk Equation to estimate end-stage kidney disease (ESKD) risk and to determine how incorporating ESKD risk thresholds would modify referral volume.

Results: Among 70,972 patients meeting potential indications for referral who had not visited a nephrologist in 2013, 12,008 (16.9%) were referred in 2014. The two-year risk of ESKD was low in both groups, 2.9% [9.8-8.6%] in the referred group, compared to 1.3% [0.3-3.9%] in the unreferred group (P < 0.001). The number of patients meeting potential indications for referral was approximately equivalent to the number of patients with a two-year risk of ESKD exceeding 1%, or N=81,132. Among potential indications for referral, rapid eGFR decline accounted for 37.6% of eligible unreferred patients and was associated with the lowest two-year ESKD risk.

Conclusions: Laboratory-based potential indications for referral identify a large number of patients at low risk of ESKD. Further study is needed to determine the value of nephrology care for these populations.

Variation in Kidney Failure Risk Across Health Organizations Among Adults with CKD in Nephrology Ambulatory Care

Chi D. Chu,1,2 Neil R. Powe,1,2 Michael Shlipak,1,3 Rebecca Scherzer,1,3 Sri Lokha Tummalapalli,1 Michelle M. Estrella,1,3 Delphine S. Tuot,1,4 University of California San Francisco, San Francisco, CA; 1OptumLabs Visiting Scholar, Cambridge, MA; 1San Francisco VA Medical Center, San Francisco, CA; 4Zuckerberg San Francisco General Hospital and Trauma Center, San Francisco, CA.

Background: Since most adults with chronic kidney disease (CKD) have low risk for end-stage kidney disease (ESKD) progression, sub specialty nephrology care should focus on patients at highest risk of progression. To optimize utilization of nephrology care, a threshold of 3% risk of ESKD at 5 years based on the Kidney Failure Risk Equation (KFRE) has been proposed for nephrology referral. To understand how application of this threshold in practice could impact CKD care delivery and subspecialty referral, we examined variation in 5-year ESKD risk distributions of patients in nephrology ambulatory care across U.S. healthcare organizations.

Methods: In 22 healthcare organizations, we identified patients age ≥65 years, with eGFR < 60 ml/min/m² and concurrently measured urine albumin/creatinine ratio, who had an ambulatory encounter with a nephrologist from 1/1/2017-12/31/2018 using the OptumLabs® Data Warehouse, a longitudinal, real-world data asset with de-identified administrative claims and electronic health record data. We compared the distribution of patient-derived KFRE 5-year risk across healthcare organizations with ≥500 patients in nephrology care.

Results: Among 45,145 patients with CKD in nephrology care, the overall median 5-year ESKD risk was 2.4%. However, between organizations, the median 5-year ESKD risk varied widely, ranging from 0.8% to 6.7% (Figure). 54.3% of patients were below the 3% recommended referral threshold risk of ESKD.

Conclusions: There is substantial heterogeneity of ESKD risk across healthcare organizations in the population receiving ambulatory nephrology care. A greater understanding of the patient population and delivery system characteristics is needed to explain this heterogeneity, and associated health outcomes could inform recommended risk thresholds for referral and ongoing nephrology care.

Prevalence of Comorbid Conditions at CKD Onset Among US Veterans

Media E. Pavkov,1 Devasmita Choudhury,1 Wei Yu,1 Nilka Rios Burrows,1 Robert Nee2 Alfred K. Cheung,1,3 Keith C. Norris,2 Guofen Yan1 Centers for Disease Control and Prevention, Atlanta, GA; 2Salem VA Medical Center, Salem, VA; 3University of Virginia, Charlottesville, VA; 4Walter Reed National Military Medical Center, Bethesda, MD; 5University of Utah Health, Salt Lake City, UT; 6VA Salt Lake City Health Care System, Salt Lake City, UT; 7University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.

Background: Comorbid conditions such as hypertension (HTN) and diabetes increase risk of adverse outcomes among patients with CKD. It is less clear whether such conditions develop prior to CKD onset or subsequently emerge as the disease progresses. Using a newly constructed national incident CKD cohort, we examined the prevalence of major comorbidities at the time of CKD onset by demographic groups.

Methods: The cohort included 1,074,238 subjects with new-onset CKD between 2002 and 2017 in the U.S. Veterans Health Administration (VHA). CKD onset was defined as the first time when estimated GFR (eGFR; CKD-EPI equation) decreased to a value <60 mL/min/1.73 m² for >3 months. We excluded subjects in VHA for <2 years prior to first eGFR <60, or with CKD stage 4 or 5, or end-stage kidney disease (ESKD) when first identified. Thus, the first time identified was close to the onset of CKD stage 3. Comorbidities at CKD onset were ascertained from ICD-9/ICD-10 codes during any time before onset and through 6 months after onset.

Results: All subgroups (age, gender, race and ethnicity) had similar mean eGFRs at onset (51 ml/min/1.73m²). The percentage with age at onset ≥65 years was greater in males (74%) than females (43%), greater in Black (48%) than in American Indian or Alaska Native (39%), Asian or Pacific Islander (33%), and Hispanic (30%), which in turn were greater than Whites (23%). At CKD onset, HTN was highly prevalent, varying from 83% in females to 96% in Blacks; diabetes ranged from 36% in females to 61% in Hispanics; more than two-thirds had cardiovascular disease (CVD); and 19-28% had cancer across subgroups (Table).

Conclusions: This finding suggests that many veterans at the time of CKD onset had already developed some major comorbidities, which could make them particularly susceptible to death before ESKD.

Classification of Cause of CKD Using ICD-9 and ICD-10 Codes

Jennifer Chen,1 Matthew F. Blum,1 Aditya L. Surapaneni,2 Yingying Sang,2 Alex R. Chang,3 Josef Coresh,1,2 Morgan Grans,1,2 Johns Hopkins University School of Medicine, Baltimore, MD; 3Johns Hopkins School of Public Health, Baltimore, MD; 4Geisinger Health, Danville, PA.

Background: Current KDIGO guidelines classify CKD using three parameters: glomerular filtration rate (GFR), albuminuria, and cause of disease. While prognosis based on estimated GFR and albuminuria have been studied, less is known about the prevalence of disease etiology in CKD patients. We sought to classify various causes of CKD using billing codes for better assessment of the prevalence and risk implications of disease etiology in CKD staging.

Methods: We categorized cause of CKD with 18 potential etiologies and assigned relevant Internal Classification of Diseases (ICD) 9th and 10th revision Clinical Modification codes pertaining to each etiology. We applied the algorithm to two study populations, Johns Hopkins Medicine and Geisinger Health, to assess the prevalence of different etiologies of CKD in large health systems. To validate our CKD classification system, we determined CKD cause among 101 outpatients treated within Johns Hopkins Medicine through internal chart reviews and compared our findings to the classification algorithm generated CKD etiology.

Results: 43.3% and 26.4% of patients with eGFR <60 ml/min/1.73 m² in 2016 in the Geisinger and Johns Hopkins study population, respectively, had a billing code used in our classification algorithm. The most prevalent etiologies of CKD in patients with available billing codes at Geisinger were hypertensive nephrosclerosis (27%), diabetic nephropathy (14.3%), and neoplasm (9.2%). In contrast, the most common causes of CKD in the Johns Hopkins cohort were miscellaneous (12%), obstructive nephropathy (6.3%), and non-PKD hereditary disease (3.2%). Chart review revealed 56% concordance between cause of CKD determined by chart review and that classification algorithm. The most prevalent etiologies of CKD in patients with available billing codes at Johns Hopkins Medicine through internal chart reviews and compared our findings to the classification algorithm generated CKD etiology.

Conclusions: We developed an algorithm for classifying CKD cause by ICD-9 and ICD-10 codes using electronic medical record data; however, validation suggests varying degrees of accuracy across different CKD etiologies.

Epidemiology of Patients with High-Risk CKD: A Demographic Evaluation of Patients Who Had Indications for SGLT2 Inhibitors and GLP-1

Huiwen Chen,1,2 Melanie R. Weltman,1 Manqi Cai,1 Jonathan Yabes,1 Thomas D. Nolin,1 Manisha Jambh,2 Khaled Abdell-Kader,3 University of Pittsburgh, Pittsburgh, PA; 2University of Pittsburgh Medical Center; Pittsburgh, PA; 3Vanderbilt University Medical Center, Nashville, TN.

Background: The emerging evidence of the favorable effects of sodium-glucose co-transporter-2 inhibitors (SGLT2is) and glucagon-like peptide 1 receptor agonists (GLP-1) on renal function has brought hope and excitement to the nephrology communities in the US. However, patients with high risk, CKD and indications for SGLT2is and GLP-1 were not on their medication. We would like to identify the features of these patients and their primary care providers to offer targeted recommendations regarding concerns for initiating SGLT2is and GLP-1.

Methods: This is a preliminary analysis of data obtained from the Kidney Coordinated Health Management Partnership (K-CHAMP) study (NCT03832595), an ongoing, NIH funded pragmatic randomized control trial testing an electronic health record-based registries enable population-based examination of care across racial groups.

Results: Of 2225 African-American patients, 743 (33.4%) would hypothetically be reclassified to a more severe CKD stage if the race multiplier were removed from the eGFR equation. Similarly, 167 of 687 (24.3%) would be reclassified from stage 3B to stage 4. Finally, 64 of 2069 patients (3.1%) would be reassigned from eGFR > 20 ml/min/1.73m² to eGFR ≤ 20 ml/min/1.73m², meeting the criterion for accumulating kidney transplant priority. Zero of 64 African-American patients with an eGFR <20 ml/min/1.73m² after the race multiplier was removed were referred, evaluated or waitlisted for kidney transplant, compared to 19.2% of African-American patients with eGFR<20 ml/min/1.73m² with default CKD-EPI equation.

Conclusions: Our study reveals a meaningful impact of race-adjusted eGFR on the care provided to the African-American CKD patient population.

Disparities in CKD Progression by Medicare Advantage Enrolees

Clarissa J. Diamanditis,1 Lindsay Zepel,2 Virginia Wang,1,2 Valerie A. Smith,1,2 Sarah H. Scholle,4 Lidaa A. Tamayo,1 Matthew L. Maciejewski,1,2 Duke University School of Medicine, Durham, NC; 3HSRD, Durham VA HCS, Durham, NC; 4Optum Labs Visiting Fellow, Minnetonka, MN; 5National Committee for Quality Assurance, Washington, DC; 6Centers for Medicare and Medicaid Services, Baltimore, MD.

Background: The prevalence of chronic kidney disease (CKD) in Medicare beneficiaries has quadrupled in the past two decades, but little is known about risk factors affecting the progression of CKD. This abstract aims to understand the progression of CKD up to five years after study entry in a large cohort of Medicare Advantage (MA) enrollees and whether it differs by provider recognition of CKD, race and ethnicity, or geographic location.

Methods: In a cohort of 1,002,388 MA enrollees with CKD stages 1-4 based on 2013-2018 labs, progression was estimated using a mixed-effects model that adjusted for demographics, urbanicity, comorbidity, urine albumin-to-creatinine ratio, clinical recognition via diagnosis of CKD, and time fixed effects. Race and ethnicity, geographic location, or clinical recognition of CKD were interacted with time in three separate regression models.

Results: Mean (median) follow-up was 3.1 (3.0) years. At study entry, Black and Hispanic MA enrollees had greater kidney function at study entry than other beneficiaries, but their kidney function declined faster compared to non-Hispanic Whites. At study entry, MA enrollees with clinically recognized CKD had estimated glomerular filtration rate levels that were 18.6 units (95% confidence interval (CI): 18.5-18.7) lower than those of unrecognized patients, but kidney function declined more slowly in enrollees with clinical recognition of CKD. There were no differences in CKD progression by metropolitan or non-metropolitan areas.

Conclusions: These results suggest that patients with clinically recognized CKD and racial and ethnic minorities merit closer surveillance and management to reduce their risk of faster progression.

Impact of the Race Multiplier in the Estimated Glomerular Filtration Rate Equation on Care Delivery Among African-American CKD Patients

Salman Ahmed, Mallika L. Mendi. Brigham and Women’s Hospital, Boston, MA.

Background: African-American patients with chronic kidney disease (CKD) have poorer outcomes, including in dialysis access placement and transplantation. Estimated glomerular filtration rate (eGFR) equations, which assign higher eGFR values to African-American patients, may be an inadvertent mechanism for inequitable outcomes. Electronic health record-based registries enable population-based examination of care across racial groups.

Methods: Cross-sectional study at two large academic medical centers and affiliated community primary care and specialty practices.

Results: Of 2225 African-American patients, 743 (33.4%) would hypothetically be reclassified to a more severe CKD stage if the race multiplier were removed from the eGFR equation. Similarly, 167 of 687 (24.3%) would be reclassified from stage 3B to stage 4. Finally, 64 of 2069 patients (3.1%) would be reassigned from eGFR > 20 ml/min/1.73m² to eGFR ≤ 20 ml/min/1.73m², meeting the criterion for accumulating kidney transplant priority. Zero of 64 African-American patients with an eGFR <20 ml/min/1.73m² after the race multiplier was removed were referred, evaluated or waitlisted for kidney transplant, compared to 19.2% of African-American patients with eGFR<20 ml/min/1.73m² with default CKD-EPI equation.

Conclusions: Our study reveals a meaningful impact of race-adjusted eGFR on the care provided to the African-American CKD patient population.

Prevalence of Diabetes, Hypertension, Anemia, and Hyperkalemia as Frequent Comorbidities in Patients with CKD Regardless of their KDIGO Staging
L. M. Perez-Navarro,1 Samantha Escorza Valdivia,1 Alberto Sigfrido Benitez Renteria,1 Rafael Valdez-Ortiz,1 Hospital General de Mexico De Eduardo Lizygua, Ciudad de Mexico, Mexico; 2AstraZeneca, Ciudad de Mexico, Mexico.

Background: Chronic kidney disease (CKD) is a worldwide public health problem. Currently in Mexico, the prevalence of CKD is only an estimate, based primarily on records of advanced stages of the disease. It is necessary to identify comorbidities and thus establish strategies to delay its progression and reduce morbimortality associated with CKD. Objective: To know the prevalence of comorbidities associated with CKD at different stages in an outpatient population who attended a 3rd level hospital.

Methods: This is a cross-sectional retrospective study. Records of adult patients who attended an outpatient nephrology consultation in the period from February 2019 to February 2020 were included, with laboratory reports from 15 days prior to the inclusion date. Descriptive statistics were performed, with a 95% CI and a value of p<0.05.

Results: 1772 patient records were included. 51% (907) were women, the mean age was 42 ± 24.2 years. 12% were on renal replacement therapy, 11% hemodialysis and 1% peritoneal dialysis. 87% (1546) lacked family history of CKD; 11% (192) were smokers. Regarding body mass index, 2% (32) presented low weight, 37% (562) normal weight, 53% (804) overweight and 8% (122) obesity. Figure 1 shows the distribution by CKD stage and main comorbidities. The prevalence of proteinuria was 39% (893), 53% (826) had anemia. The prevalence of hyperkalemia (HK; K>5) was 29% (325). The prevalence of serum albumin <3.5 was 26%; 44% of the population had glucose > 200 mg/dL; 53% with triglyceride >150 mg/dL and 29% with total cholesterol <3.5 was 26%; 44% of the population had glucose >100 mg/dL; 53% had total cholesterol ≥200 mg/dL.

Conclusions: A high prevalence of CKD comorbid risk factors such as diabetes, hypertension, anemia and HK were identified regardless of CKD staging, increasing in proportion in later stages.

PO0520
Cystatin C Use in Clinical Practice
Jennifer Torres,1 Jennifer L. Ennis,2 Rita L. McGill.1 ‘University of Chicago, Chicago, IL; 2Laboratory Corporation of America, Burlington, NC; ’DaVita Inc, Denver, CO.

Background: Cystatin C is a filtration biomarker that can be used as an alternative for serum creatinine. The 2012 KDIGO guidelines advocate for the use of cystatin C to confirm the diagnosis of chronic kidney disease (CKD), but 9 years later it is not clear how this test is being used in clinical practice.

Methods: We examined 87,803 cystatin C levels obtained among 55,360 participants between 11/2011-6/2018 in the database of Laboratory Corporation of America Holdings (LabCorp®). The CKD-EPI cystatin equation was used to calculate the estimated GFR for each level. Descriptive analyses of patient age, sex, and ordering provider were conducted, and relationships between serum cystatin C and creatinine levels were examined with correlation analysis and linear regression.

Results: The mean age was 58 ±17.50% were women. Frequency of orders increased over time, from 6,323 tests in 2012, to 17,822 tests in 2017. Providers ordering cystatin C included: Internal/Family Medicine MDs (64%), radiologists (9%), mid-levels (4%), and 9% unknown. Cystatin C was ordered on patients with a wide range of estimated GFR values (Figure). Linear regression showed that 75% of the variation in cystatin C could be modeled if age, sex, BUN, and creatinine were known. Dispersion between actual and predicted cystatin was minimal at cystatin C levels ≤ 0.5yr and that of eGFR slope 1.5yr (p<0.001 and p=0.001, respectively). In stratified analysis, eGFR slope ≥ 1.5yr had significantly greater C-statistics than that of eGFR slope ≤1yr. eGFR slope ≥1yr had higher prognostic ability of renal events in patients with versus without diabetes, advanced CKD and proteinuria. C-statistics of renal events when considering baseline eGFR alone was 0.853 but combination use of baseline eGFR and eGFR slope ≥1yr significantly increased C-statistics, to 0.913 (p<0.01).

Conclusions: Cystatin C use has increased in recent years and growing evidence has shown the prognostic utility of eGFR slope for the risk of ESRD. Previous observational studies have assessed the association between renal events and eGFR slopes estimated by two measurements of eGFR but had great differences in the interval between two eGFR measurements. In this study, we thus aimed to determine the appropriate interval between two eGFR measurements to evaluate the association of eGFR slope with incidence of renal events.

PO0521
Appropriate Interval Between Two eGFR Measurements for the Evaluation of the Association of eGFR Slope with Incidence of Renal Events
Maiko Kobuki,1 Masaru Matsui,1 Takayuki Uemura,1 Kazuhiro Tsuyama.2 1Nara-ken Sogo Iryo Center, Nara, Japan; 2Nara Koeiitsu Iku Daigaku, Kashihara, Japan.

Background: In recent years, growing evidence has shown the prognostic utility of eGFR slope for the risk of ESRD. Previous observational studies have assessed the association between renal events and eGFR slopes estimated by two measurements of eGFR but had great differences in the interval between two eGFR measurements. In this study, we thus aimed to determine the appropriate interval between two eGFR measurements to evaluate the association of eGFR slope with incidence of renal events.

Methods: This is a retrospective cohort study in 203 CKD patients who visited Nara Prefecture General Medical Center, Japan between 1 January 2013 and 31 December 2016 and in whom two or more than two measurements of eGFR levels were confirmed in medical records. eGFR slopes were estimated by using two measurements of eGFR at baseline and 3, 6, 1.5, 2, or 3 years. We excluded patients with acute kidney injury, urologic malignancies, nephritic syndrome with steroid treatment or collagen diseases. Outcome was renal events defined as a composite of ESRD and eGFR decline of ≥ 30%. C statistics were used to evaluate the association between eGFR slope and incidence of renal events.

Results: The median age of study participants was 67 (56-77) years and 71 (37%) were male. The median levels of baseline eGFR were 34 (21-48) mL/min/1.73m² and diabetes was present in 80 (39%) participants. During the median follow-up period of 38 months, renal events occurred in 52 participants. Median levels of eGFR slopes0.5yr, 1yr, 1.5yr, 2yr and 3yr were -7.8, -3.6, -2.9, -0.9, -1.5 mL/min/1.73m², respectively. C-statistics of eGFR slope ≥0.5yr for renal events were 0.622, 0.691, 0.797, 0.858, 0.806, respectively, and that of eGFR slope ≥1yr was significantly higher than that of eGFR slope ≤0.5yr and eGFR slope ≥1yr (p<0.001 and p=0.001, respectively). In stratified analysis, eGFR slope ≥1yr had higher prognostic ability of renal events in patients with versus without diabetes, advanced CKD and proteinuria. C-statistics of renal events when considering baseline eGFR alone was 0.853 but combination use of baseline eGFR and eGFR slope ≥1yr significantly increased C-statistics, to 0.913 (p<0.01).

Conclusions: eGFR slope for high prognostic ability of renal events may be needed to be calculated by at least 1.5-year interval between two eGFR measurements.

PO0522
Rates of Clinical Events in Patients with CKD: A UK Population-Based Cohort Study
Alyshah Abdul Sultan,1 Ping Sun,1 Katarina Hedman,2 Xia Wang,3 Mark T. Houser,2 Dustin J. Little,2 Glen James.1 ‘AstraZeneca, Cambridge, United Kingdom; 2AstraZeneca, Gothenburg, Sweden; 3AstraZeneca, Gutthersburg, MD.

Background: Epidemiological evidence of clinical event rates in patients with chronic kidney disease (CKD) is limited and can impede the ability of dialysis organizations, government agencies, other institutions, and payers to counsel patients and assess quality of care.

Methods: The Clinical Practice Research Datalink (CPRD) is a large, longitudinal UK-based primary care database that covers 6% (~4 million people) of the population. CPRD is linked to Hospital Episode Statistics (HES), which contains information on all hospital admissions in England. We identified CKD patients with eGFR <60 ml/min/1.73m² in CPRD between 2004 and 2017. Adverse clinical events were identified using ICD-10 and READ codes. Non-dialysis dependent (NDD) patients were staged by eGFR. Dialysis dependent (DD) patients were identified using Classification of Interventions and Procedures (OPCS) and READ codes. Clinical events were identified by ICD10 and READ codes. Incidence rates per 100 person-years (PY) were calculated for selected adverse event stratified by dialysis status and CKD stage.
Results: We identified 310362 NDD and 5248 DD patients with a mean (standard deviation [SD]) age of 75.5 (10.2) years and a median (interquartile range [IQR]) follow-up of 87.5 (46.5-130.9) months. Among NDD patients 96%, 3%, and 1% of patient-years came from CKD 4, and 2, 5, and 5, respectively. Most event rates were consistently higher in DD CKD patients, compared to NDD CKD patients; and higher among CKD 4-5 compared to CKD 1-3 patients (Table 1).

Conclusions: Our results help establish baseline rates of specific clinical events and provide additional evidence of increased morbidity for DD vs. NDD patients, and for NDD patients with more severe vs. less severe kidney disease.

Estimating the Future Burden of CKD Through Microsimulation Methods

Lise Retal,1 Michael Xu,1 Laura Webber,1 Claudia S. Cabrera,2 Elisabeth Strastudis,2 Stephen Nolan,2 Juan Jose Garcia Sanchez,2 HealthLamens, London, United Kingdom; 1AstraZeneca AB, Sodertalje, Sweden; 2AstraZeneca PLC, Cambridge, United Kingdom.

Background: Chronic kidney disease (CKD) is a debilitating and costly condition, impacting over 10% of people globally. Early diagnosis and proactive management could potentially mitigate the rates of progression to end stage renal disease. Understanding the future trajectory of CKD prevalence, progression, outcomes and the related economic burden are important considerations for public health and policy planning. This study explores the epidemiological and cost burden of CKD with an emphasis on high-risk populations with macroalbuminuria, type 2 diabetes (T2D) and/or heart failure (HF), from 2020 to 2025.

Methods: A patient-level microsimulation was developed to estimate the epidemiological and economic burden of CKD in the UK. KDIGO 2012 recommendations were used to categorise patients according to eGFR and albuminuria using the Health Survey of England extrapolated to the UK population. The future prevalence and healthcare costs for the CKD population, as well as for subpopulations – macroalbuminuria, T2D, HF were estimated. Finally, “current practice” management scenario was compared to an early detection and proactive scenario.

Results: By 2025, CKD prevalence in the UK is expected to grow by 11% from ~9.1M to 10.2M corresponding to a £4B (18%) increase in annual cost from £18B, of which, £0.58B is incurred due to macroalbuminuria where prevalence is projected to reach 860,000 by 2025. Within the macroalbuminuria population, costs were comparable between patients with (390,000; £0.31B) and without (465,000; £0.27B) T2D. However, costs for patients with macroalbuminuria were 3-times higher than for CKD patients with HF (£0.11B, 140,000). Early identification and proactive management of patients with CKD and macroalbuminuria resulted in a cumulative £0.65B direct healthcare cost saving by 2025.

Conclusions: This model predicts that CKD poses a serious public health threat. The overall epidemiological burden for patients with macroalbuminuria was comparable with patients with and without T2D. Early detection along with proactive treatment may reduce CKD progression and more directly improve patients’ quality of life while also reducing the long-term economic burden of CKD.

Identifying and Clustering CKD Progression Trajectories Using Machine Learning

Alyshah Abdul Sultan,1 Kirsty Rhodes,2 Michail Doulos,3 Irena Brooks-Shepherd,1 Joshayla S. Faria,1 Jose D. Salazar,1 Glen James,1 Iain MacPhee,2 Robert J. Unwin,1 David Wright,1 Mishal Patel,1 Paul D. Metcalfe,1 Lutz Jermutus,1 1AstraZeneca, Cambridge, United Kingdom; 2AstraZeneca, Gothenburg, Sweden.

Background: There is evidence suggesting that estimated glomerular filtration rate (eGFR) slope can be used as a surrogate clinical endpoint in renal clinical trials. However, there are limited data on the characteristics of fast and slow progressors based on eGFR slope from large population-based studies.

Methods: We identified CKD patients (based on two consecutive eGFRs of ≥75ml/min/1.73m2 recorded more than 90 days apart) aged ≥18 years from the UK Clinical Practice Research Datalink (CPRD) between 2004 and 2019. Estimated GFR measurements over a 5-year observation period post-index date (date of 2nd eGFR measurement) were extracted from their eGFR trajectories using statistical (linear mixed effect models (LMM)) and machine learning techniques (unsupervised machine learning and Bayesian approaches). Association between trajectory clusters and all-cause mortality was assessed using Cox regression analysis.

Results: Preliminary, 407,108 patients with 1.8 million eGFR measurement (median 4 (IQR: 2-6) eGFR measurements per patient) were identified. Using LMM, we found 5% of patients declined rapidly with an average rate of eGFR change per year ~4.78 (95%CI: -9.40 to -3.28) whereas the majority (95%) remain stable or progressed slowly. A distinct fast progressing cluster was also detected using unsupervised machine learning and Bayesian methods which showed broadly linear patterns. Overall, there was an agreement between all three clustering approaches. These findings were replicated in the validation dataset showing consistent findings. Compared to stable/slow progressors, fast progressors were 3 times more likely (HR=2.82; 95%CI 2.75-2.90) to die following the 3-year observation period.

Conclusions: A clear fast progressing cluster was identified with an average eGFR decline of ≥3 ml/min/1.73m2 per year with a higher risk of all-cause mortality compared to other clusters. Whilst Bayesian and unsupervised machine learning methods can detect non-linear patterns, we found broadly linear trajectories.

Using Autoencoders for Imputing Missing Data in eGFR Decline Trajectories of Patients with CKD

Davina J. Zamanizadeh,1 Panayiotis Petousis,1 Tyler A. Davis,1 Anders O. Garlid,2 Xiaoyan Wang,1 Keith C. Norris,1 Obidighwu Duru,1 Katherine R. Tuttle,2 Alex Bui,1 Susanne B. Nicholas.1 CURE-CKD Registry Study Team1 University of California Los Angeles, Los Angeles, CA;2 Providence St Joseph Health, Spokane, WA.

**Background:** Using machine learning (ML) approaches to impute missing data has not been explored in CKD progression. We investigated the utility of a data-driven imputation to improve downstream classifier prediction of rapid eGFR decline in the CURE-CKD registry.

**Methods:** We analyzed CKD patients at UCLA (N=13,206) over a 2-year period. We used: 1) the dataset with missing data; and 2) a censored subset with no missing data. We introduced 33% and 66% missingness by removing values by replacing missing values either missing completely at random (MCAR), missing at random (MAR), or missing not at random (MNAR). We included: eGFR, hemoglobin (HbA1c), systolic blood pressure (SBP), number of ambulatory and inpatient visits, age, sex, ethnicity, rurality status, diagnosis of hypertension, diabetes mellitus (DM), pre-DM, and use of renin angiotensin aldosterone system inhibitors. We introduced missingness on SBP and HbA1c to mirror the original dataset. We imputed missing values using an autoencoder ML model. To predict a 40% eGFR decline over 2 years, we developed random forest models using the full and resultant imputed datasets.

**Results:** On the full subset, the MNAR imputation method achieved a root mean squared error (RMSE) of 0.9. The MAR method achieved RMSE of 3.8 at 33% missingness and 5.4 at 66%. MCAR achieved RMSE of 38.5 at 33% missingness and 56.4 at 66%. Using the random forest model to predict rapid decline on the fully observed subset without removing and imputing data achieved a receiver operating characteristic (ROC) area under the curve (AUC) mean of 80.8±1.1 and precision/recall (PR)-AUC mean of 23.9±1.5; the same as our methodology on MNAR, which is explained by the RMSE of 0, shown in Table 1.

**Conclusions:** Our method accurately imputes clinical data values while accounting for uncertainty caused by missing values.

Machine Learning Prediction of ESKD and Death in CKD Patients: Electronic Medical Record-Based Cohort Study

**Background:** Chronic kidney disease (CKD) is a risk factor for end-stage kidney disease (ESKD) and death. An accurate prediction of those risks is required to improve their prognosis. We developed the new machine learning models for the prediction of CKD progression and death using the electronic-medical-record-based CKD-patient big database in Japan (n=3,714, 66,981 claim data).

**Methods:** We developed 20 risk prediction models with 45 variables for the classification of the patients on the basis of their outcomes (ESKD and death) over 1 to 3 years using random forest (RF), Gradient Boosting Decision Tree (GB), Extreme Gradient Boosting (XG), support vector machine, and multivariate logistic regression models using validation datasets including baseline or time-series datasets. The performance characteristics of the models were compared with those of the laboratory indices, and the kidney failure risk equation (KFRE) using the area under the prediction curves (AUCs) by bootstrapping 1000 times.

**Results:** 53.1% were male; age, 60.1±17.6 years; eGFR, 54.2±30.7 mL/min/1.73 m²; diabetes mellitus, 23.1%. In the validation dataset, 14 models showed statistically significantly higher AUCs for the prediction of outcomes than KFRE 0.782 (0.682, 0.881), and the RF, GB, and XG models based on time-series data showed the highest AUCs: 0.924 (95% CI 0.895, 0.953) (Fig. A). These three models also demonstrated the highest performance in the subgroup analysis that considers eGFR, DM, gender, and age. Moreover, the models' sensitivities were 0.971 (95% CI 0.914, 1.0). Cox proportional hazards models revealed that the probabilities predicted by these models represented the risk of the outcome (p<0.0001) (Fig. B).

**Conclusions:** The machine learning models exhibit better performance than pre-existing models in identifying patients at an increased risk of CKD progression and death. They will enable us to implement effective measures to improve patient's prognosis.

PO0528

Predicting Rapid eGFR Decline Using Electronic Health Record (EHR) Data Despite High Missingness in the CURE-CKD Registry

Tyler A. Davis,1 Panayiotis Petousis,1 Davina J. Zamanizadeh,1 Xiaoyan Wang,1 Keith C. Norris,1 Obidighwu Duru,1 Katherine R. Tuttle,2 Alex Bui,1 Susanne B. Nicholas.1 CURE-CKD Registry Study Team1 University of California Los Angeles, Los Angeles, CA;2 Providence St Joseph Health, Spokane, WA.

**Background:** Patients with rapid eGFR decline tend to progress to kidney failure. Automated tools can identify individuals at risk of severe renal functional decline and facilitate disease mitigation. We describe a deep neural network (DNN) for predicting the risk of rapid eGFR decline (~40% decrease in eGFR over 2 years) and identified populations at higher risk of rapid decline using the CURE-CKD Registry.

**Methods:** Variables include: age, sex, race/ethnicity, ACE inhibitor/ARB use, eGFR, systolic blood pressure (SBP), hemoglobin A1c, and the diagnosis of hypertension, type 2 diabetes (DM), pre-DM or chronic kidney disease (CKD) based on EHR data. We trained and validated our models on patients with CKD (N=93,567) and at-risk for CKD (N=913,289) with eGFR ≥15ml/min/1.73m² over 2 years. We trained and validated a 5-layer DNN, a logistic regression (LR) model, and a gradient boosted tree (GBT) model using a 60/20/20 train/test/validation split. We computed the risk distribution of all 25,475 subpopulations, based on all possible expert defined combinations of the above variables, and compared this risk distribution against the whole population’s risk distribution using the Kolmogorov-Smirnov (KS) test. Subgroups with the highest risk of decline were identified using the KS test (p<0.05) on our highest performing model.

**Results:** The DNN achieved an area under the receiver operating curve (AUC-ROC) of 0.75 on the test set. The LR and GBT achieved an AUC-ROC of 0.72 and 0.73, respectively. The subpopulations with significantly highest average predicted risk across training, validation, and testing were 17,734. We identified the most frequent predictors of rapid eGFR decline across the highest risk populations. Of the top 100 significantly higher risk subpopulations the following variables were the most frequent: CKD (100%), SBP >140 mmHg (72%), age 45-66 years (56%), DM (52%), and AIC >8 (50%).

**Conclusions:** We developed a methodology that uses a risk model for rapid eGFR decline using big data and used its predictions, along with the KS test, to identify subpopulations with significantly high risk for rapid eGFR decline.

PO0529

A Machine Learning-Based Prediction Model for Trajectory of GFR in CKD Patients with Rapid Decline of GFR by Using a Big Database

Daisho Inaguma,1 Akimitsu Kitagawa,1 Ryosuke Yanagiya,1 Akira Koski,2 Takayoshi Furumori,2 Michiharu Kudo,1 Shogo Fukuma,1 Naotake Tsuibo,1 Yukio Yuzawa,1 Fujita Health University School of Medicine, Department of Nephrology, Toyoake, Japan;1 IBM Research, Tokyo, Japan;2 Fujita Health University Bantane Hospital, Department of Nephrology, Nagoya, Japan;2 Fujita Health University, Division of Medical Information System, Toyoake, Japan;3Kyoto University Graduate School of Medicine, Human Health Sciences, Kyoto, Japan.

**Background:** There are various patterns of GFR trajectories in patients with chronic kidney disease (CKD), even among those with rapid declines in GFR. We sought to create a machine learning-based predictive model for extremely rapid decline of GFR in patients with CKD using a single hospital database.

**Methods:** We used a database, which included the electronic medical records of 286,494 patients. We selected patients with CKD and rapid decline in kidney function, which was defined as an estimated GFR (eGFR) decline of 30% or more within two years. We used longitudinal statistics using data extracted from baseline, 90-, 180-, and 360-day windows prior to baseline and exponentially weighted averages (ESAs) where the weight was calculated as 0.9^n (days/decay parameter). The random forest algorithm and python code for the scikit-learn library (https://scikit-learn.org/) were used for model creation.

**Results:** Patients were automatically classified, using machine learning, into three groups according to eGFR at baseline (G1; high GFR, G2; intermediate GFR, G3; low GFR) and nine subgroups according to the slope of eGFR decline. The subgroup with the lowest eGFR decline had the highest risk of declining eGFR.

**Funding:** Other NIH Support - NIMHD

210
fastest GFR decline exhibited the steepest slope (Figure 1). The area under the curves for predicting the steepest (fastest) GFR decline by random forest model among the G1, G2, and G3 were 0.68, 0.72 and 0.81, respectively. Regarding feature importance, in the G1 group, hemoglobin of the 7-day ESAs and measures obtained 90 days prior to baseline ranked within the top five. Meanwhile, serum albumin and CRP at baseline ranked within the top seven in the G3 group.

Conclusions: The random forest model identified patients with extremely rapid GFR decline. Anemia in patients with higher eGFR, and nutritional status in patients with lower eGFR, emerged as strong risk factors.

PO0530

Automation of Renal Blood Flow Analysis from Dynamic Phase-Contrast MRI with Deep Learning

Andrés Martinez Mora,1,3 Dag Lindgren,1 Camilla Englund,1 Lars Johansson,1 Paul Hockings,1 Joel Kullberg.1,2 1Antaros Medical, Malmö, Sweden; 2Uppsala University, Department of Surgical Sciences, Radiology, Uppsala, Sweden; 3Kungliga Tekniska Hogskolan Skolan for kemi bioteknologi och hälsa, Stockholm, Sweden.

Background: Phase-contrast magnetic resonance imaging (PC-MRI) allows to assess renal blood flow (RBF), an important parameter in the development of chronic kidney disease (CKD). RBF assessments require time-consuming and observer-dependent delineations of the renal arteries. Thus, we have developed and evaluated a fully-automated deep learning model for renal artery segmentation.

Methods: PC-MRI data came from 131 subjects, four studies, three MRI vendors and a range of velocity encodings. The deep learning model (DL) was a deep-supervised attention U-Net with residuals with the result re-introduced in a second iteration. Flow was estimated by integrating the flow values in the segmentations. Segmentation and flow results were compared for cross-validation (CV, 73 subjects) against manual delineations and reference flow measurements from external software. The remaining data (Extra) only had reference flow measurements, being only evaluated for flow.

Results: In 4-fold CV, a segmentation accuracy of Dice 0.71 ± 0.21 was obtained. Although most segmentations were relatively accurate, the model failed in ten out of 144 arteries. Flow measurements were relatively highly correlated in CV with no significant deviation from the reference: (r=0.84, DL: 5.8±3.0 ml/s vs Ref: 5.8±3.0 ml/s, p=0.98). The Extra set provided a high correlation and no significant deviation (r=0.94, DL: 6.4±2.8 ml/s vs Ref: 6.7±2.9 ml/s, p=0.11).

Conclusions: The method showed promise to support RBF measurements from PC-MRI. It may save analysis time and increase objectivity in the future. More high quality and representative training data are likely to improve accuracy and generalizability.

Healthcare Engineering to Predict Time and Resource Impact of Integrating a CKD Education Intervention into Primary Care Practice

Julie A. Wright Nune,1 Tammy Ellies,1 Emily P. Chen,1 Audrey Fan,1 Pamela G. Rockwell,1 Angela Fagerlin,2 Luis M. Garcia-Guzman.1 1University of Michigan, Ann Arbor, MI; 2University of Utah Health, Salt Lake City, UT.

Background: This study describes the novel use and application of healthcare engineering and Discrete Event Simulation (DES) to study the impact of adding a physician-led chronic kidney disease (CKD) education review for patients in two primary care settings.

Methods: We developed a computer model to simulate a General Internal Medicine and Family Medicine practice and used it to examine the impact of adding a physician-led CKD education review into routine primary care appointments. To create the computer models we gathered data using real-time process mapping and information from the electronic health record (EHR). The physician-led education review included physicians reviewing a one-page education information sheet, tailored to individual patients. Computer models of each clinic were developed to test the effect on patient flow and time through clinic appointments using different proportions of patients with CKD for which a physician would review the CKD education. We also tested varying amounts of time it would take for physicians to review CKD education within the model.

Results: Adding the physician-led review of CKD education into clinic visits did not significantly increase patient flow or time through clinic. Incrementally increasing potential times for the CKD education review, up to 10 minutes with 50% of all patients, did not reduce patient flow significantly. The estimated resource utilization of physicians increased by about 5%. Similar results were found for Family Medicine.

Conclusions: This research allowed us to perform a "what-if" analysis on the effect of introducing physician-led CKD patient education into routine primary care practice. Results show that it is possible to introduce patient education and support without major disruptions in clinic flow nor patient time through clinic.

Funding: NIDDK Support
or death. Progressive CKD was defined as kidney failure or ≥40% decline in eGFR from the baseline (4 months after surgery). Models were unadjusted, adjusted for %IFTA, and adjusted for %TI.

Results: At surgery mean age was 64 years, 64% male, 66% hypertensive, and 13% diabetic. Samples contained a mean of 349 glomeruli and mean baseline eGFR was 48 ml/min/1.73m². After a mean follow-up of 6.4 years there were 117 CKD progression events and 299 deaths. %IFTA and %TI predicted progressive CKD independent of each other (Table). %TI non-IFTA (not %IFTA) contributed to this risk. After %IFTA adjustment, smaller mean IFTA focus area associated with a higher risk of CKD progression. These findings persisted with adjustment for clinical characteristics including eGFR and proteinuria.

Conclusions: Both total %IFTA and %TI (particularly %I-non IFTA) are important predictors of progressive CKD. At the same %IFTA, a greater number of small IFTA foci are more predictive of progressive CKD than fewer large foci of IFTA.

Modification of the Association Between Dipstick Hematuria and Decline in Kidney Function by Proteinuria: Results from a Longitudinal Nationwide Survey

Hikari Tasaki,1 Masahiro Eriguchi,1 Hisako Yoshida,2 Masatoshi Nishimoto,3 Takakazu Kousui,1 Masato Kasahara,2 Kunitoshi Iseki,4 Koichi Asahi,3 Kunihito Yamagata,5 Tsuneo Konta,6 Shouichi Fujimoto,7 Ichiei Narita,8 Yugo Shibagaki,9 Toshiki Moriyama,10 Masahide Kondo,11 Tsuyoshi Watanabe,11 Kazuhiko Tsuura,1 Nara Medical University, Kashihara, Japan; 2Saint Marianna University School of Medicine, Kawasaki, Japan; 3Osaka City University Graduate School of Medicine, Osaka, Japan; 4Nakamura clinic, Urawa city, Japan; 5Iwate Medical University, Morioka, Japan; 6Yamagata University Faculty of Medicine Graduate School, Yamagata, Japan; 7University of Tsukuba, Tsukuba, Japan; 8Miyazaki University, Miyazaki, Japan; 9Niigata University, Niigata, Japan; 10Osaka University Health Care Center, Suita, Japan; 11University of Tsukuba, Tsukuba, Japan.

Background: We hypothesize that proteinuria has a modification effect on the association of hematuria with decline in kidney function.

Methods: Participants were recruited who have undergone multiple nationwide specific health checks between 2008 and 2014 and have been observed for ≥2 years. We divided the participants into two and three categories according to hematuria and proteinuria, respectively. Using analysis of covariance, changes in eGFR over time (delta-eGFR) were examined in hematuria category stratified by proteinuria category.

Results: Among 253,679 participants, median delta-eGFR was -0.36 mL/min/1.73m² per year (IQR: -2.25-0.54) during a median observation period of 4.0 years (IQR: 3.1-6.4). Among general population, delta-eGFR levels with and without hematuria were comparable in the absence of proteinuria, but proteinuria levels had a gradually increased as the proteinuria category progressed (P for interaction <0.001).

Conclusions: Among general population, delta-eGFR levels with and without hematuria were comparable in the absence of proteinuria, but proteinuria levels had a synergistic effect on eGFR decline rate associated with hematuria.
PO0535

Impact of Variability in Estimated Glomerular Filtration Rate on Major Clinical Outcomes: A Nationwide Population-Based Study

Soojin Lee,1 Yeonhee Lee,1 Schoon Park,1 Yae-rit Kim,2 Min woo Kang,1 Semin Cho,1 Yong Chul Kim,3 Kwon Wook Joo,1 Chun Soo Lim,1 Yon Su Kim,1 Dong Ki Kim.1 1Seoul National University College of Medicine, Seoul, Republic of Korea; 2Keimyung University, Daegu, Republic of Korea; 3Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea.

Background: The estimated glomerular filtration rate (eGFR), commonly estimated using the serum creatinine value, often fluctuates throughout the serial measurement. The clinical significance of GFR variation among the general population with normal renal function has not yet been demonstrated. Thus, we explored the impact of GFR variability on adverse clinical outcomes.

Methods: A nationwide retrospective cohort study using the Korean National Health Insurance System database was performed. National health screening examinees who underwent creatinine measurement at least three times between 2012 and 2016 were considered. Those with eGFR under 60 mL/min/1.73m² were excluded. The fluctuation of eGFR was represented with variability independent of the mean (ViM), which was calculated by the standard deviation divided by the exponent of the regression coefficient of the mean. Then, the risks of myocardial infarction (MI), stroke, and death were assessed according to the quartiles of the ViM.

Results: Of total 3,538,500 participants, 0.29% of myocardial infarction (MI), 0.14% of stroke, and 0.36% of deaths were observed during the median follow-up of 3.27 years. Participants with the highest ViM index, which represents the highest eGFR variability, were significantly associated with an increased risk of MI (hazard ratio [HR]; 1.10, 95% confidence interval [95% CI]; 1.04-1.16), stroke (HR; 1.16; 95% CI 1.09-1.23), and death (HR; 1.18; 95% CI 1.12-1.24). (Figure 1)

Conclusions: Increased eGFR variability exhibited an association with major clinical outcomes, indicating that monitoring eGFR variability might be a useful parameter for predicting the adverse outcomes.

PO0536

Development and Internal Validation of a Mortality Risk Prediction Model in Older Adults with Advanced Non-Dialysis-Dependent CKD

David Y. Li,1 Heather L. Prigmore,2 Thomas G. Stewart,2 Khaled Abdel-Kader,1 Vanderbilt University Medical Center, Nashville, TN; 1Vanderbilt University, Nashville, TN.

Background: Older adults with CKD expect practitioners to share prognostic estimates to inform decision-making regarding future care. The availability of useful mortality prediction models in NDD-CKD could reduce prognostic uncertainty and aid in identifying patients who would benefit from advance care planning (independent of dialysis initiation).

Methods: 699 patients with NDD-CKD stages 4-5 and age ≥60 were enrolled and followed between 2014 and 2019. Cox proportional hazards regression was used to model the risk of 1-year mortality. Candidate predictor variables included age, gender, race, Charlson Comorbidity Index (CCI), common labs and the provider’s response to the Surprise Question (“Would you be surprised if this patient died in the next 12 months?”), SQ, recorded using binary and 5-point Likert response scales). Optimism-corrected measures of model performance were calculated with bootstrap resampling. Model calibration was assessed visually.

Results: In the derivation cohort, age, CCI, hemoglobin levels and the provider’s Likert scale response to the SQ were predictive of 1-year mortality (Table 1). The C-statistic in the derivation sample was 0.76 and the optimism corrected C-statistic obtained by bootstrap resampling was 0.73. Visual examination of model calibration demonstrated good calibration.

Conclusions: A 1-year mortality risk prediction model in older adults with advanced NDD-CKD performed reasonably well and was well calibrated. Studies are needed to understand how to best leverage information on mortality risk to enhance patient-provider communication and ensure that future care delivered to patients is aligned with their priorities.

PO0538
Association of eGFR Index Category and Annual Slope with Adverse Clinical Outcomes in Japan
Ling Zhang,1 Moe H. Kyaw,1 Yasuhiisa Ono,2 Sibylle J. Haaske,1,3 Boehringer Ingelheim USA, Ridgefield, CT; 2Nippon Boehringer Ingelheim, Tokyo, Japan; 1Boehringer Ingelheim Germany, Ingelheim, Germany; 3Tufts Medical Center, Boston, MA

Background: The relationship between the slope of eGFR with adverse clinical events has not been evaluated extensively. The objective of the study was to assess the association between eGFR and clinical outcomes.

Methods: The study population included persons with 3 or more eGFR values in the MDV database between January 1, 2014 and September 30, 2019. Patients were stratified into 5 index eGFR categories (TABLE). Least square regression model was used to examine the association between eGFR and its slope vs. study outcomes. Patients were stratified into 5 index eGFR categories (TABLE). Least square regression model was used to calculate the annual rate of eGFR change to stratify into 6 categories. Cox proportional hazard model was applied to examine the association between eGFR and its slope vs. study outcomes.

Results: 57,692 patients met the study criteria, and were grouped by index eGFR and its slope (TABLE). The mean age ranged from 56.69 to 74.21 in the index eGFR and from 65.3 to 67.2 in the slope categories. The risk of all-cause mortality or hospitalization, CV death, and any CV or renal outcomes were higher among the low and high index eGFR compared to the reference groups (grade 3 eGFR and -1~+1 slope), as well as those with rapidly declining or increasing eGFR.

Conclusions: Our study showed that those with the highest or lowest categories in index eGFR and eGFR slope had a higher risk for adverse clinical outcomes. Further studies are needed to confirm the findings and explore potential reasons why high eGFR and rapid increase are associated with mortality, CV and renal events.

Sex-Specific Differences in Clinical Outcomes Among Patients with CKD: Results from CKDopps
Manfred Hecking,1 Charlotte Tu,1 Jarcy Zee,2 Brian Bieber,2 Sebastian Hödlmoser,3 Benedicte Stengel,4 Helmut Reichel,3 Kunihiro Yamagata,1 Ricardo Sesso,3 Friedrich K. Port,2 Bruce M. Robinson,2 Roberto Pecotto-Filho.1 on behalf of CKDopps and CKD REIN investigators
1Medical University of Vienna, Nephrology & Dialysis, Vienna, Austria; 2Arbor Research Collaborative for Health, Ann Arbor, MI; 3Medical University of Vienna, Department of Epidemiology, Vienna, Austria; 4CESP, Internist U1018, Kidney and Heart Team, Villejuif, France; 5Nephrologisches Zentrum Villingen-Schwenningen, Villingen-Schwenningen, Germany; 6University of Tsukuba, Ibaraki, Japan; 7Escola Paulista De Medicina, Unifesp, Sao Paulo, Brazil

Background: Women have more chronic kidney disease (CKD) than men, but are under-represented in the dialysis population. We aimed to assess sex-specific differences in clinical outcomes among CKD Outcomes and Practice Patterns Study (CKDopps) participants.

Methods: Using data of 5682 CKDopps stage 3-5 patients from Brazil, Germany and the US, we reported cumulative incidence of pre-dialysis death, dialysis, and transplantation, by sex and CKD stage at CKDopps entry. We used Fine & Gray models to assess the effect of sex on the time to events, stratified by CKD stage. Models were adjusted for age and race, and then for eGFR slope in the first 6 months after enrolment, but not for case mix variables as men and women are biologically different.

Results: There were more men than women at baseline (54 vs 46%). Men were more likely on the transplant waitlist (13 vs 10%) and had higher median eGFR at dialysis initiation (11.2 vs 10.6 mL/min/1.73m²). Over a median follow-up of 1.75 years, the crude cumulative incidence of dialysis was higher in men while that of death was similar (Figure). The age- and race-adjusted hazard ratio (HR) (95% CI) between men vs women was 1.59 (1.40-1.82) for dialysis, 1.24 (1.04-1.49) for death and 1.80 (0.83-3.80) for transplantation. After adjustment for eGFR slope, the HR for dialysis was 1.72 (1.46-2.01), but the HR for the other two outcomes remained similar.

Conclusions: Despite higher CKD prevalence in women, more men received treatment at nephrologist-run clinics in our study. Men had a higher chance of commencing dialysis before death, unexplained by CKD progression. This finding helps interpret the preponderance of men in the dialysis population.

PO0540
Predictive Value of Urine Osmolal Gap and Urine Anion Gap in CKD Progression
Hyung Duk Kim, Cheol Whee Park. Division of Nephrology, Department of Internal Medicine, Seoul St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea.

Background: Metabolic acidosis is the major complication of chronic kidney disease (CKD) and associated with poor clinical outcome. Impaired renal ammonium excretion in CKD lead to metabolic acidosis. The urinary anion gap (UAG) and urinary osmolal gap (UOG) have been used to estimate urinary ammonium excretion because of the limitation of clinical application of direct ammonium measurement. We sought to determine whether UAG and UOG predict progression of CKD.

Methods: 185 patients with Stage II-V CKD were prospectively followed up at Catholic Medical College Multicenter Native Kidney Biopsy Cohort. 24-hour urine chemistry was measured at baseline. Routine laboratory test results were obtained at baseline and 1 year after enrollment. UAG and UOG were calculated using 24-hour urine chemistry results. Estimated GFR was calculated with CKD-EPI equation.

Results: Baseline characteristics are shown in Table 1. Positive association between UOG and decline of renal function was observed (Figure 1). The line indicates the regression line for the relation between decline of renal function and urine osmolal gap; R = 0.035, P = 0.003 (P = 0.011).

Conclusions: UAG and UOG predict decline in renal function in CKD patients. Further study is required to determine the direct correlation between UAG and UOG and urinary ammonium excretion.
The overall model fit was excellent ($\chi^2$ = 119.6, p < 0.000). Seven comorbidities were significantly associated with bleeding. Obesity, age, hypertension were not significantly associated with bleeding.

Conclusions: Our results indicate that renal failure, female gender, coagulopathy, and anemia are risk factors for bleeding after renal biopsy, whereas obesity and hypertension are not. A strength of this study is the large sample size. It also suggests that peripheral anemia are risk factors for bleeding, whereas obesity and hypertension were not significantly associated with bleeding.

PO0542
Evaluation of Thromboelastometry and Multiple Electrode Aggregometry in ESRD
Alvna Abdelmaguid,1,2 Lara N. Roberts,3 Jennifer R. Joslin,1 Beverley Hunt,4 Kiran H. Parmar,1 Kate Bramham,1,3 ‘King’s Kidney Care, King’s College Hospital, London, United Kingdom; 2Alexandria University, Medical Research Institute, Alexandria, Egypt; ‘King’s Thrombosis Centre, Department of Haematological Medicine, King’s College Hospital NHS Foundation Trust, London, United Kingdom; ‘Thrombosis and Haemostasis Centre, Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom; ‘Department of Women and Children’s Health, King’s College London, London, United Kingdom.

Background: Bleeding and thrombosis rates are paradoxically increased in chronic kidney disease (CKD), but risk assessment for both is not possible with routine laboratory tests. We aimed to evaluate haemostatic changes in CKD stage 5 patients with modern techniques; using thromboelastometry (TEM), multiple electrode aggregometry (MEA), markers of thrombogenesis, fibrinolysis and endothelial activation.

Methods: TEM, MEA, thrombin anti-thrombin (TAT), alpha-2 antiplasmin, d-dimer and Interferon Adhesion Molecule-1 (ICAM-1) were quantified in 50 CKD Stage 5 patients (including 20 haemodialysis patients) and 30 healthy controls. Patients taking antiplatelet agents were excluded from MEA analysis.

Results: TEM parameters showed hypercoagulability, with increased maximal clot firmness (MCF) & shorter clot formation time (CFT); and D-dimer, TAT and ICAM-concentrations were also increased in CKD Stage 5 patients compared to HC (Table 1). Platelet dysfunction was evident in CKD Stage 5 with lower aggregation in ADPtest and TRAPtest compared to HC.

Conclusions: Our study shows that the prothrombotic changes in CKD Stage 5 are due to increased coagulation and endothelial activation. Bleeding tendency may relate to platelet dysfunction and possibly increased fibrinolytic activation.

Table 1: Comparison of TEM, MEA, alpha-2 Antiplasmin, D-dimer, Thrombin Antithrombin and ICAM-1 between Healthy Controls and CKD Stage 5 (Median and Interquartile Range (IQR))

PO0543
During P2Y12 Antiplatelet Therapy, Treatment of Anemia Was More Frequent Among Peripheral Artery Disease Patients with Lower eGFR: The EUCLID Trial
Judith Hsiu,1,2 Sarah T. Kavanagh,1 Charles W. Hsioyte,2 Marc P. Bonaca,1,3 William R. Hiatt,1,3 CPC Clinical Research, Aurora, CO; 2Dartmouth College, Hanover, NH; 3University of Colorado School of Medicine, Aurora, CO.

Background: Anemia independently predicts amputation and mortality among patients with peripheral artery disease (PAD). In the EUCLID trial, minor bleeding was more frequent among PAD patients with baseline eGFR<60 ml/min/1.73m2 (adjusted HR 1.51, 95% CI 1.07-2.15; p=0.02 for TIMI minor bleeding; HR 1.21, 95% CI 0.89-1.64; p=0.22 for TIMI major bleeding). We evaluated the impact of eGFR on hemoglobin (Hb) levels and anemia treatment.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: EUCLID (NCT01732822) randomized symptomatic PAD patients to monotherapy with ticagrelor or clopidogrel for 30 months (median); treatment groups were combined for analysis. Independent predictors of Hb change from baseline were evaluated in a multivariable model including baseline Hb and eGFR, sex, age, and post-randomization revascularization procedures, myocardial infarction and anemia treatment.

Results: At baseline, 9025, 1870 and 1000 patients had eGFR ≥60, 45-59 and <45 ml/min/1.73m², respectively. Patients with lower eGFR were older, more often male and had higher prevalence of diabetes and hypertension. Mean Hb at baseline was 14.2, 13.5 and 12.7 g/dl for the 3 eGFR categories. Mean fall in Hb during the trial was 0.5±1.7 g/dL and did not differ by baseline eGFR category. On-study treatment with iron, erythropoietin and/or red blood cell transfusion was reported for 479 (5.3%), 163 (8.8%) and 129 (12.9%) patients, respectively (Figure, p < 0.0001 across eGFR categories). In multivariable analysis, even after adjustment for baseline and post-randomization effects, baseline Hb was a significant independent predictor of Hb fall; anemia treatment was a significant independent predictor of Hb rise.

Conclusions: Among patients with PAD taking antiplatelet therapy in the EUCLID trial, those with lower eGFR were more often treated for anemia.

The Ratio and Difference of Urine Protein-to-Creatinine Ratio and Albumin-to-Creatinine Ratio Facilitate Risk Prediction of All-Cause Mortality: A Retrospective Cohort Study

David R. Chang, Hung chieh Yeh, Pei-Lun Chu, Chin-Chi Kuo. Taiwan, China

Background: The difference and ratio of albuminuria (defined by urine albumin-to-creatinine ratio, uACR) and proteinuria (defined by urine protein-to-creatinine ratio, uPCR) has not been systematically evaluated with relevant clinical outcomes. We aimed to assess the prognostic performance between the difference and ratio of uACR and uPCR with all-cause mortality.

Methods: This retrospective cohort study identified 2904 adult patients with concurrently measured uACR and uPCR from the same urine specimen in a tertiary medical center in Central Taiwan between January 2003 and June 2017. Urinary albumin-to-protein ratio (uAPR) was derived by dividing uACR by uPCR. Urinary non-albumin protein (uNAP) was calculated by subtracting uACR from uPCR. Conventional severity categories of uACR and uPCR were used to develop a risk matrix. We evaluated all-cause mortality based on uAPR and uNAP on a continuous scale using the multivariable Cox proportional hazards model.

Results: For each doubling increase in uPCR, uACR, and uNAP, the adjusted hazard ratios (aHRs) of all-cause mortality were 1.29 (95% confidence interval [CI]: 1.24-1.35), 1.12 (1.09-1.16), and 1.41 (1.34-1.49), respectively. Linear dose-response association with all-cause mortality was only observed with uPCR and uNAP. The 3 x 3 risk matrices revealed that patients with severe proteinuria and minimal albuminuria had the highest risk of all-cause mortality (aHR 5.25, 95% CI: 1.88, 14.63). uNAP significantly improved the discriminative performance compared to that of uPCR (c-statistics: 0.834 vs. 0.828, p < 0.05).

Conclusions: uNAP provides better mortality prognostic assessment than uPCR and uACR.

Metformin and the Risk of Lactic Acidosis in Patients with CKD Stage 3

Background: Metformin has become the first-line therapy for the treatment of diabetes in patients with CKD stage 3. The use of metformin in CKD has been debated due to safety concerns related to lactic acidosis.

Methods: We assessed the safety of metformin in a double-blinded trial (NCT02252081). Fifty patients with CKD Stage 3 and metabolic syndrome and/or prediabetes were randomized to either metformin or placebo for 16 weeks. Metformin was started at 500 mg and titrated in 1-2 weeks up to 1500 mg/day in CKD 3a and 1000 mg/day in CKD 3b. Lactic acid (LA) levels were measured at weeks 2, 4, 8, 12, and 16. We compared the effect of metformin on LA between groups and over time using a mixed model and on plasma HCO3 and anion GAP (AG) using ANCOVA of change analysis.

Results: The mean age was 65 ± 10 years old, 80% were male, BMI was 31.4 ± 5.1 kg/m², 16% of patients were CKD Stage 3b. LA levels slightly increased with metformin, but in most patients remained within normal limits (≤ 2.5 mEq/L) [Figure 1, p = 0.05]. The association of metformin and LA remained non-significant in the multivariable-adjusted mixed model (β = 0.15, p = 0.07) and remained steady over time (β = -0.003, p = 0.54). Baseline eGFR had no effect on LA levels (β = 0.01, p = 0.35), whereas higher BMI was associated with higher LA levels (β = 0.02, p = 0.03). Only 3 patients developed LA levels > 3 mEq/L, but no drug discontinuation and 1 at week 12 which was transient. The changes in HCO3 levels and AG were not statistically significant ([HCO3 - Metformin baseline 27 ± 2.1 mEq/L, week 16 26.2 ± 2.8 mEq/L; placebo baseline 26.2 ± 2.1 mEq/L, week 16 26.7 ± 2.8 Eq/L; p = 0.21] (AG: Metformin baseline 10.1 ± 2.2 mEq/L, week 16 10.4 ± 2.1 mEq/L; placebo baseline AG 10.4 ± 2.2 mEq/L, week 16 10.2 ± 2.3 mEq/L, p = 0.42)).

Conclusions: Metformin use in patients with CKD stage 3 appears to be safe. LA levels mildly increased with metformin, but remained within normal limits and stable after week 2. Patients did not develop clinical or laboratory manifestations of acidosis based on HCO3 levels and AG.

PO0546
Magnetic Resonance Imaging-Based Renal Function Estimation Using a Machine Learning Approach
Daichi Fukuya, Tsutomu Inoue, Eito Kozawa, Masahiro Ishikawa, Yusuke Watanabe, Hiroaki Arano, Naoki Kobayashi, Mamoru Niitsu, Hirokazu Okada.

Background: In patients with deterioration of GFR with an unknown clinical course, it is quite difficult to determine whether the renal dysfunction is caused by a hematologic alteration or changes in the renal parenchyma, even when using kidney imaging. Therefore, to estimate renal function quantitatively based on the morphology of the renal parenchyma, we performed an advanced image analysis of renal magnetic resonance imaging (MRI) using machine learning (ML).

Methods: We used coronal Dixon water-dominant images obtained on a 3.0T MR device and a deep ML convolutional neural network (CNN) to evaluate renal function (eGFRcre). K-fold cross-validation (k = 5) was performed for the assessment of accuracy and generalization performance. The study protocol was approved by the IRB of our institute.

Results: A total of 196 patients (age, 57.9 ± 16.9 years; 128 males; CKD stage, G1 (n = 18), G2 (39), G3a (43), G3b (45), G4 (35), and G5 (16)) were included. After optimization of the CNN model, the accuracy, precision, recall, and f-score of the confusing matrix, as well as the AUC of the ROC curve at thresholds of eGFRcre of 60, 45, and 30 were 0.80, 0.83, 0.87, 0.90, 0.87, 0.86, 0.75, 0.71, 0.84, 0.77, 0.83, and 0.76, 0.80, 0.90, 0.85, 0.83, respectively. The output value of the CNN also showed a significant positive correlation with the normalized eGFRcre of the subjects (R² = 0.46, P < 0.01). When the difference in signal intensity between the renal cortex and medulla, as measured based on the region of interest method, was used as a diagnostic index, the accuracy was the same as that of ML if the threshold was eGFRcre 30 (AUC of the ROC curve, 0.84). Conversely, when the threshold was set at eGFRcre 45 or 60, the accuracy deteriorated gradually (AUC = 0.80 and 0.73, respectively).

Conclusions: Compared with the classical method, in which only the signal intensity is used, the ML approach was able to quantitatively evaluate differences in renal morphology regarding a wide range of renal functions. Our results may have clinical applications for assessing the cause of changes in kidney function in the conditions in which renal function and morphology diverge, e.g., in the early stages of acute kidney injury, renovascular hypertensive, and therapeutic interventions that cause hemodynamic alterations.

PO0547
Inflammation Mediates the Association of Depression Severity with Selective Serotonin Reuptake Inhibitor Treatment Response in Patients with CKD
Sanginjoon Torres Rodrigo, L. Parker Gregg, Thomas Carmody, Madhukar Trivedi, Susan Hedaya.

University of Texas Southwestern Medical Center at Dallas, Dallas, TX; V4 North Texas Health Care System, Dallas, TX.

Background: Patients with chronic kidney disease (CKD) are at high risk for depression, which is associated with inflammation in patients with chronic diseases. We investigated whether depression severity is associated with response to treatment with sertraline and whether inflammation mediates this relationship in CKD patients with major depression (MDD).

Methods: We conducted the CKD Antidepressant Sertraline Trial (CAST), a randomized double-blind trial of 193 participants with stage 3-5 CKD and MDD randomized to sertraline or placebo for 12 weeks. Depressive symptoms were assessed using the Quick Inventory of Depressive Symptomatology (QIDS). High sensitivity C-reactive protein (hsCRP) was measured at baseline. Logistic regression determined associations of QIDS and hsCRP with treatment response (≥50% decrease) or improvement (≥3-point decrease) in QIDS. Interaction P < 0.10 was considered significant.

Results: Fifty-nine (30%) participants achieved treatment response. Baseline depression severity by QIDS correlated positively with hsCRP, χ²(1) = 162, P < 0.05. Median (IQR) hsCRP was 5.0 (2.0, 14.6) mg/L in sertraline responders and 2.7 (0.8, 6.0) mg/L in non-responders, P = 0.03. Higher baseline QIDS was associated with increased odds of response in the sertraline group. OR (95% CI) per 1-point increase 1.26 (1.04, 1.53), but lower odds in the placebo group, 0.77 (0.61, 0.97), interaction P = 0.02 (Figure).

Conclusions: Higher depression severity was associated with improvement in depressive symptoms and response to treatment with sertraline in CKD patients. This may be mediated by elevated baseline inflammation. Future studies should test whether sertraline is more effective than placebo in CKD individuals with higher hsCRP.

PO0548
Prospective Study of Patient-Reported Outcomes After Endovascular Renal Ablation in Individuals with Chronic Kidney Pain and Opiate Use
Victor A. Lopez, Ablisheek Deshmjukh, Rajiv Gulati, Paul Novotny, Marie C. Hogan.

Mayo Clinic Minnesota, Rochester, MN; Mayo Clinic Dpt of Nepth & HTN Research, Rochester, MN; Mayo Clinic Biomedical Statistics and Informatics, Rochester, MN; Mayo Clinic Dpt of Cardiovascular Medicine, Rochester, MN.

Background: Endovascular renal ablation (ERA) may be useful for palliating and in some instances relieving refractory kidney pain (RKP) but is not widely available. We report our experience of ERA in 20 patients with RKP.

Methods: We conducted a prospective study of patient-reported outcomes pre and post ERA for RKP. Baseline & subsequent pain questionnaires (McGill Pain (MPQ), Brief Pain Inventory (BPI), Oral and Intravenous morphine milligrams equivalent (MMPE)) & QOL (LASA-6, PHQ-9 & SF-8) were obtained. The Wilcoxon test was used. ERA using an open epidural ablation catheter was performed in a spiral manner distal to proximal the renal arterial ostium. Power was titrated between 5-30 watts guided by change in impedance.

Results: We performed 24 ERA (3 bilateral, 21 unilateral; 4 redo) in 20 patients, 14 male; median age 47yr. 12 patients (60%) had low Pain Hematuria Syndrome (LPHS), 4 (20%) ADPKD, and others 4 (20%). 17 of 20 have completed the baseline questionnaires & 9 of 17 patients have 6mo data. All nine experienced variable or complete reductions in pain & QOL from baseline to 6mo (Table1). A median of 8mo pain relief was reported. After their first ERA, responders (pain relief >6mo) median 8.5mo (n=12) 60% while 4 (20%) reported pain relief <6mo (non-responders) median 2mo. 3 (15%) had no relief, and 1 was lost to FU. In the redo ERA, there was no relief in 2; in 1 pain relief lasted 4mo (non-responder), and in the other, relief was 8mo (responder). Following the first ERA, MME decreased by ≥30% in 6, increased in ≥7 (≥30% in 6:15% in 1:50% in 1). Pain was changed in 3, and no pain was noted in 13. All 17 of 17 patients who completed the procedure had ≥1 renal artery stenosis (5mo later) treated by percutaneous transluminal angioplasty but subsequent reduced kidney function.

Conclusions: Among patients with RKP undergoing ERA, half achieved objective improvement in pain & QOL at 6mo. Prospective randomized studies with careful patient selection are required to assess the role of ERA for palliation of pain.

Assessments of Pain & QOL

PO0549
Clinical Impact of Body Muscle Mass for Kidney Function Evaluation: New eGFR Formula Based on Serum Creatinine and Body Muscle Mass
Kazunori Goto, Yoshiharu Yasuda, Sawako Kato, Shoichi Maruyama, Nagoya University, Nagoya, Japan.

Background: Kidney function is globally evaluated by estimated glomerular filtration ratio (eGFR) based on serum creatinine (C). Since C is influenced by body muscle mass, there is serious concern of overestimation of eGFR among elderly people with low body volume due to frailty. In this study, eGFR based on C (eGFRc) and CxSy (eGFRcSy) were analyzed in association with psao muscle mass index (PMI) by CT image among CKD patients whose kidney function was accurately evaluated by measured GFR (mGFR) computed from inulin clearance (CIn).

Methods: Study design: single-center cross-sectional retrospective study. Study subjects were consecutive 158 CKD patients (123 males) at Nagoya university hospital whose C and abdominal CT were examined within 1 year between 2009 and 2013. New eGFR formula based on C and PMI (eGFRcSy-PMI) were developed in 122 patients and validated in 62 patients, which were randomly determined to each cohort. 20%
accuracy for Cin was analyzed by eGFRcreat and eGFRcrels calculated by eGFR formulae for Japanese. The performance of each eGFRcrel-PMI was assessed by means of bias (eGFRcrel-
mgFR), accuracy (percentage of estimates within 20% of mgFR), root mean squared error, and correlation coefficient. In PMI tertile subgroups and GFR(Cin) subgroups (<30, 30-60, >60%), the performance of each formulae was assessed.

Results: Patients’ characteristics (n=184, mean±SD) or median(IQR) were age: 62 [50, 70], eGFRcrel: 58.5 (25.5), eGFRcrels: 59.4 (25.9), Cin: 55.0 (25.0) and PMI: 7.29 [6.18, 9.11]. Log-PMI was significantly associated with age, gender, log-BMI, log-Cre and logCr in univariate analyses, and with age, gender and log-BMI in multivariate analysis. Next, GFR formula (eGFRcrel-PMI) was well correlated with Cin. 20% accuracy for Cin was the highest in eGFRcrel-PMI (74.5%), compared to eGFRcrels (67.9%) and eGFRcrel (68.5%), which was more prominent among low PMI tertile group (77.4% in eGFRcrel-PMI, 67.7% in eGFRcrels, and 71.0% in eGFRcrel) and high PMI tertile group (75.8% in eGFRcrel-PMI, 59.0% in eGFRcrels, and 67.7% in eGFRcrel).

Conclusions: Body muscle mass seriously influences accuracy of kidney function evaluation, and new GFR formula based on PMI and Cre would be useful for accurate evaluation of kidney function, especially among patients with low and high body muscle mass.

PO0551
Alterations of Gray Matter Volumes and Connectivity in Patients with CKD
Sankar D. Navaneethan,1,2 L. Parker Gregg,1 Peter Richardson,1,2 Baylor College of Medicine, Houston, TX; Michael E DeBakey VAMC, Medical Center, Houston, TX; The University of Texas Southwestern Medical Center, Dallas, TX.

Background: The prevalence of non-alcoholic fatty liver disease (NAFLD) is increasing due to the global epidemics of obesity and diabetes mellitus, which are commonly seen in CKD. We studied the incidence and predictors of NAFLD in those with CKD.

Methods: We conducted a retrospective cohort study of patients with incident CKD (eGFR <60mL/min/1.73 m^2) for 90 days) in the Veterans Health Administration from 2005-2016. Patients with no NAFLD at the time of CKD diagnosis were followed for a primary outcome of NAFLD, defined as development of sustained elevated alanine aminotransferase levels in the absence of hepatitis B or C virus infection or alcoholic liver disease, identified by laboratory values and diagnosis codes. We calculated incidence rates for NAFLD for the entire study population and by CKD stage. Predictors of NAFLD were evaluated using Cox proportional hazards regression, considering death and ESKD as competing risks.

Results: Of 1,155,901 veterans with CKD but no NAFLD, 51,584 (4.4%) developed NAFLD at a rate of 0.86 (0.85-0.87) per 100 person-years during 4.7 years follow-up. A total of 3.9% developed ESKD at a rate of 0.76 (0.75-0.77) per 100 person-years, and 33% died at a rate of 6.5 (6.5-6.5) per 100 person-years during the same time period. In a multivariable model, age >50 (vs. 40-49 years) (HR 0.72, 95% CI 0.67, 0.77), women, blacks and veterans with advanced CKD were less likely to develop NAFLD; however, presence of diabetes, higher BMI, anemia, CHF, and hypertension were associated with higher risk of developing NAFLD (Table).

Conclusions: Patients with CKD have a high incidence of NAFLD, which was associated with diabetes, BMI, and CHF. Future studies should determine if interventions targeting these factors may reduce NAFLD risk.

Factors associated with incident NAFLD in CKD

**Sensitivity of Urinary N-Terminal Osteopontin-to-Creatinine Ratio in Predicting Renal Function Loss**

**Ling Sun,** Satyesh K. Sinha,** Aldons J. Lusis,** Susanne B. Nicholas.

Metabolic Syndrome in Men (METSIM) UCLA, University of California Los Angeles, Los Angeles, CA; Xuzhou City Centre Hospital, Xuzhou, China.

**Background:** Osteopontin (OPN) is a multifunctional protein that gets cleaved to create N-terminal OPN (ntOPN). ntOPN has been reported in urine in kidney disease but little is known about the sensitivity of ntOPN to creatinine ratio (ntOCR) as a urinary biomarker compared to the urinary albumin-to-creatinine ratio (UACR). This study is aimed to explore the prognostic value of ntOCR regarding renal function loss in a subset of the metabolic syndrome in men (METSIM) study with a high incidence of diabetes mellitus.

**Methods:** The METSIM study recruited 10,197 Finnish men between 2005 and 2010 and reexamined participants at two 5-year follow-ups. We performed a prospective observational study of a METSIM cohort of 137 participants, 45-72 years old at entry, with available urine at baseline and the first follow-up period, after 3.8±1.4 year. Serum and urinary levels of the ntOPN were quantified by ELISA. Using estimated glomerular filtration rate (eGFR), UACR and urine albumin excretion (UAEC) of progressors and non-progressors, data were analyzed by paired t-test and Wilcoxon matched-pairs signed-rank test. The area under the receiver-operating characteristics (ROC) curve (AUC) was used to assess the sensitivity/specificity of variables in predicting the progression of CKD.

**Pearson correlation coefficient was performed to detect the relationships between the values of variables.**

**Results:** Compared to the CKD non-progressors, the progressors had significantly higher eGFR at baseline (96.95 vs. 87.75 mL/min/1.73 m², p=0.00) and lower eGFR at follow-up (86.11 vs. 91.40 mL/min/1.73 m², p=0.01). The baseline urine levels of ntOCR were higher in progressors than non-progressors (6.83 vs 3.68 pmol/mg, p=0.05). There were no differences in the UAE, UACR, or serum ntOPN between the two groups. However, baseline urinary ntOCR predicted renal function loss with an AUC of 0.60 (p=0.05), and the change between baseline and follow-up had a higher AUC value of 0.63 (p=0.01).

**Conclusions:** Our study suggests that urinary ntOCR might be a promising predictive biomarker for renal function loss in a population with high rates of metabolic syndrome and diabetes. Measurements at the second METSIM follow-up may confirm this observation. Further studies are needed in females, larger size populations, and long-term follow-up.

**Funding:** Other NIH Support - NCATS

**PO0555**

**Effect of Renin-Angiotensin System Blockade in Immunoglobulin A Nephropathy Only with Persistent Hematuria**

**Hui Xu,** Department of Nephrology, Xiangya Hospital, Central South University, Changsha, China.

**Background:** Recent guideline recommended that long-term renin-angiotensin system blockade (RASB) should be used in immunoglobulin A nephropathy (IgAN) when proteinuria > 1g/d. If proteinuria is 0.5–1g/d, RASB is also suggested. We tried to investigate whether IgAN patients only with persistent hematuria and without proteinuria can benefit from RASB.

**Methods:** IgAN patients only with persistent hematuria initially from January 2013 to December 2018 from four centers were included. We divided patients into treatment and untreated group according to the use of RASB. The primary outcome was the appearance of proteinuria, the secondary outcome was the decreased percentage of hematuria and the rate of estimated glomerular filtration rate (eGFR) decline. Effect of RASB on the outcomes was assessed by multivariate Cox regression models and a propensity score matching.

**Results:** 110 eligible patients were included and 44 (41.9%) received RASB. Patients in the treatment groups had higher diastolic pressure. The unadjusted primary outcome of RASB treated patients was better than the untreated individuals. The multivariate Cox regression revealed that RASB lowered the risk of primary outcome, besides, RASB decreased more percentage of hematuria. No obvious difference was found in the rate of eGFR decline between two groups.

**Conclusions:** RASB decreased the risk of proteinuria appearance and increased the remission of hematuria in IgAN only with persistent hematuria initially, but it did not obviously impact the blood pressure of patients without hypertension and the rate of eGFR decline.

**PO0556**

**Fibrates and CKD Patients: A Controversial Issue**

Aber H. Baki, John Zarif. Ain Shams University Faculty of Medicine, Cairo, Egypt.

**Background:** Fenofibates were not previously known to affect renal function tests until some reports indicated that these drugs may lead to a decrease in renal function. Likewise, the nephrotoxic effect of fibrates remains to be vague and unclear Fenofibrate’s safety in patients with renal insufficiency is an issue because it may increase plasma creatinine. Furthermore, guidelines regarding fenofibrate dosing in renal impairment vary internationally. We investigated fenofibates’ effects on cardiovascular and on advanced CKD, according to eGFR. The multiple incidents of elevated kidney function tests for patients on fibrates have led us to make this study to review our experience as well as literature on this matter.

**Methods:** A prospective cohort study over 6 months with a total of 80 patients on fibrates divided into 2 groups, 40 of which received statins and the other 40 continued on fibrates. All our patients were subjected to full history, clinical examination and complete baseline labs. The kidney function tests including serum creatinine and eGFR were measured at 0.1, 2 and 6 months’ intervals and lipid profile at 0.3,6 months serially in both groups.

**Results:** Out of the baseline values of the kidney function tests that were recorded on previous fibrate therapy, the statin group (n=40) showed a significant decrease in all kidney function values including serum creatinine by (0.9mg/dL, P<0.001) and an increase in the eGFR (8.9 mL/min/1.73 m², P<0.001). Whilst in the other 40 patients who continued to receive fibrates the kidney function tests continued to rise as serum creatinine showed a significant increase in their mean serum Cr levels (by 0.9 mg/dL or 20%, P=0.001), and a significant decrease in their mean eGFR values (by 8.2 mL/min/1.73 m² or 20.55%, P=0.001). On the other hand total and LDL Cholesterol were significantly lower in Statin group at all follow up intervals. Also triglycerides were significantly higher in Statin group at the end of month-6 from baseline.

**Conclusions:** In our study fibrates administration showed a short term state of renal insufficiency. The long term effects of fibrates versus variable renal derangement are yet to be identified. As to lipid profile, shifting from fibrates to statins led to a stastically significant rise in triglycerides but it’s clinical impact is yet to be investigated, so established guidelines might need a revision regarding clinical benefits of fibrates versus it’s renal injury.

**Calciphylaxis: An Uncommon Skin Manifestation in Non-Dialysis CKD Patients**

Rabia Sarwar,1 Ujala Zubair,1 Wanwarat Ananthapanyasut,1 Skagit Regional Health, Mount Vernon, WA; Jinnah Sindh Medical University, Karachi, Pakistan.

**Introduction:** Calciphylaxis is a rare but fatal skin disorder seen in 1-4% of dialysis patients. It is characterized by ischemia and necrosis of the skin tissue due to the deposition of calcium in the arterioles and subcutaneous tissues. The risk of infection is increased, and once ulceration develops, the mortality rate can be above 80%. Risk factors include diabetes, warfarin, vitamin D, obesity, female, white race and mineral-bone disorder. The skin findings ranging from livedo reticularis to nodules, plaques, or deep ulcerations. The treatment is focused on supportive care. To date, there is no strong studies to suggest that sodium thiosulfate (STS), bisphosphonates, or calcimimetics are curative. However, STS is commonly used despite the lack of strong supporting data.
Case Description: We report a case of a 76-year-old Caucasian woman with a history of stage G4/A3 chronic kidney disease, insulin-dependent diabetes, hypertension, secondary hyperparathyroidism, and obesity, who presented with severe pain and redness on both legs. The skin lesions had progressed to the painful ulcerations and eschars on both shins one month after the initial visit. A skin biopsy was performed and histopathology was consistent with calciphylaxis. She was started on STS 25 mg ivq(IV) twice a week and calcitram 30 mg by oral route (PO) thrice a week. The patient showed improvement within one month of the treatment.

Discussion: Calciphylaxis in non-dialysis patients is uncommon; however, it should be considered in those with predilection factors. The skin biopsy is crucial for the diagnosis, which can lead to proper management of such a rare yet lethal disease. STS is the most common drug used to treat calciphylaxis. It acts as a calcium chelator with some antioxidative and vasodilation properties leading to recovery.

PO0558
Calciphylaxis: Clinical Features, Therapeutic Options, and Outcomes
José Agapito Fonseca, Manuela Sanches, Inês C. Duarte, Joana Gameiro, Cristina B. Outelro, Hugo Silva, Sofia C. Jorge, Jose A. Lopes, Estela Nogueira. Hospital de Santa Maria, Centro Hospitalar Universitario Lisboa Norte, Lisboa, Portugal.

Background: Calciphylaxis is characterized by microvascular disease with calcification of the middle layer of the arterioles, intimal hyperplasia and thrombotic occlusion, conditioning areas of ischemia and skin necrosis. Given the rarity of this pathology, there is a lack in literature regarding clinical presentation, diagnostic approach and therapeutic management. We performed a descriptive analysis of clinical, epidemiologic, laboratory characteristics, treatment options and outcomes in a population of patients with calciphylaxis.

Methods: Retrospective analysis of all calciphylaxis diagnosed in a single-center between January 2003 and December 2019.

Results: The diagnosis of calciphylaxis was made in 9 patients, 7 of whom were female, with a mean age of 63.4±10.9 years. Eight patients were on renal replacement therapy (hemodialysis) at the time of diagnosis, with a dialysis vintage of 66.4±22.4 months and one patient had no chronic kidney disease. Six patients were taking warfarin, with a mean of 46 months on anticoagulation. The mean pre-diagnostic serum calcium product was 42 mg2/dL2 with an average of 46 months on anticoagulation. The mean prediagnostic serum calcium product was 42 mg2/dL2 with an average of 46 months on anticoagulation. The mean prediagnostic serum calcium product was 42 mg2/dL2 with an average of 46 months on anticoagulation.

Conclusions: More than 60% of patients were under warfarin, reinforcing the role of vitamin K antagonists in the pathogenesis. Mean time on dialysis was highly variable, from the 1st to the 216th month since the beginning of the technique. The standard of treatment varied according to the drugs available and the clinical evidence that supported its use at the time of diagnosis. The registered deaths corresponded to patients diagnosed later in the course of the disease, reinforcing the importance of a high clinical suspicion regarding the appearance of trophic skin lesions in this population as a form of early diagnosis to prevent mortality.
Pegunigalsidase Alfa, PEGylated α-Galactosidase-A Enzyme in Development for the Treatment of Fabry Disease, Shows a Correlation Between Renal Gb3 Inclusion Clearance and Reduction of Plasma Lyso-Gb3

Ahmad M. Tutfah, Derrynwyn Hughes, Simeon Boyd, Pilar Giraldo, Mia J. Holida, Mohamed G. Atta, Ozbek Gokener-Alpan, Kathleen M. Nicholls, Raphael Schifffman, Gustavo Maegaard, Laura Barisoni, Robert B. Colvin, J. Charles Jennette, Sari Alon, Mali Szafler, Einat Almon, Raul Chertkoff, Kansas University Medical Center; Kansas City, KS; LSDU, Institute of Immunity and Transplantation, Royal Free London NHS Foundation Trust, London, United Kingdom; Hospital de Dia Quiron, Zaragoza, Spain; University of Iowa Hospitals and Clinics, Iowa City, IA; Division of Medical Genetics, Johns Hopkins, Johns Hopkins University School of Medicine, Baltimore, MD; Nephrology Department, the Royal Melbourne Hospital, Melbourne, VIC, Australia; Baylor Institute of Metabolic Diseases, Baylor University Medical Center, Dallas, TX; Duke University, Durham, NC; Massachusetts General Hospital, Harvard Medical School, Department of Pathology, Boston, MA; University of North Carolina, Department of Pathology, Chapel Hill, NC; Protalix Biotherapeutics, Carmiel, Israel; University of Florida, Department of Pediatrics/Genetics & Metabolism, Gainesville, FL; (O&O Alpan LLC, Fairfax, VA; Department of Pediatrics, Section of Genetics, MIND Institute, UC Davis Medical Center, Sacramento, CA.

Background: Fabry disease (FD) is caused by the loss of function of the lysosomal enzyme α-Galactosidase-A leading to the accumulation of globotriaosylceramide (Gb3). Reduction in histological Gb3 burden in renal peritubular capillaries (PTC) is considered an important and objective surrogate endpoint, likely to predict the clinical benefit of treatment in FD. Pegunigalsidase-alfa is a novel PEGylated enzyme in development for the treatment of FD with enhanced pharmacokinetics.

Methods: The phase I/Ii (NCT01678989) dose-ranging studies (0.2 mg/kg; 1 mg/kg; 2 mg/kg) were designed to evaluate the safety (primary objective), pharmacokinetics and efficacy (secondary objective) of pegunigalsidase-alfa administered IV every 2 weeks in adult symptomatic FD treatment naïve male and female patients. The Barisoni Lipid Inclusion Scoring System (BLISS) was adopted to quantitatively assess patients' renal biopsies taken at baseline and at 6 months of treatment. BLISS methodology consists of counting the number of Gb3 inclusions per peritubular capillary; a decrease in the score is indicative of clinical improvement.

Results: Renal biopsies were available and evaluated in 13 out of 16 patients allocated in the three dose groups. Mean BLISS score at baseline was 4.23, proving an important renal involvement, and was reduced to a mean of 0.83 after 6 months (-67.3% ± 3.3 %) with an 86.5% reduction in the 1 mg/kg dose cohort. From the total availability of biopsies (14, including one subject with an FD cardiac variant), 78.6% of patients reached a 50% reduction in BLISS score.

Conclusions: These results show a profound reduction in Gb3 inclusions in PTC after 6 months of pegunigalsidase-alfa treatment. A high correlation (r=0.80) between the reduction in plasma Lyso Gb3 and the reduction of kidney Gb3 inclusions in the kidney biopsies was observed, giving additional support to the potential effectiveness of pegunigalsidase-alfa in treating FD.

Switching from Agalsidase Alfa to Pegunigalsidase Alfa for Treating Fabry Disease: One Year of Treatment Data from Bridge, a Phase 3 Open-Label Study

Camilla Tondel, Ales Linhart, Gabriela Dostalova, Kathleen M. Nicholls, Michael L. West, Ana Jovanovic, Pilar Giraldor, Bojan Vujkovic, Einat Almon, Sari Alon, Mali Szafler, Raul Chertkoff, Derrynwyn Hughes, Haukeland University Hospital, Bergen, Norway; Charles University, Prague, Czechia; The Royal Melbourne Hospital, Melbourne, VIC, Australia; Dallhouse University, Halifax, NS, Canada; Hospital de Dia Quiron, Zaragoza, Spain; General Hospital Slovenc Gradec, Slovenc Gradec, Slovenia; Protalix Biotherapeutics, Carmiel, Israel; LSDU, Institute of Immunity and Transplantation, Royal Free London NHS Foundation Trust, London, United Kingdom; Salford Royal, Dept of Inherited Metabolic Disease, Salford, United Kingdom.

Background: Pegunigalsidase-alfa is a novel, PEGylated α-Galactosidase-A enzyme in development for the treatment of Fabry disease (FD).

Methods: Bridge (PB-102-F30, NCT03018730) is a phase III, open-label, switch-over study, designed to assess the safety and efficacy of pegunigalsidase-alfa (1 mg/Kg EOW) in adult FD patients previously treated with agalsidase alfa for at least 2 years. Results: This is an interim report of 12-months on-treatment data generated from the first 16 patients (9 males and 7 females) out of the 22 adult patients enrolled. Baseline characteristics: age 24-60 years, the mean estimated Glomerular Filtration Rate (eGFR) 75.45 in males and 85.78 mL/min/1.73m² in females, annualized eGFR slope was -0.04 and -0.05 in males and females respectively, mean eGFR at 1.73m² was 90.07 mL/min and 91.57 mL/min, respectively, mean potassium was 3.3% and 3.3 mEq/L, respectively. After one year the mean annualized eGFR slope improved from -5.10 mL/min/1.73m²/year while on agalsidase alfa, to -0.23 mL/min/1.73m²/year on pegunigalsidase alfa. According to Wanner et al. 2018, FD patients with eGFR slope between -5 and -<3 mL/min/1.73m²/year are defined as kidney disease progressing and with eGFR slope < -3 mL/min/1.73m²/year are defined as fast progressing. The therapeutic goal is to reach eGFR slope > 3 mL/min/1.73m²/year for the progressing, and a >5 mL/min/1.73m²/year for the fast progressing. In this interim analysis, 100% of the progressing patients and 66.7% in the fast progressing group achieved the proposed therapeutic goals after switching to pegunigalsidase-alfa. The switch to pegunigalsidase-alfa was safe and well-tolerated. The majority of the patients completed the study fully and the study was well-tolerated.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
by 39.4% (P=0.0049). Triamterene reduced 24-hour urine protein by 33.7% (P=0.0113), UACR by 17.1% (P=0.004) and ACR by 28.6% (P=0.0294). The effect on the 24-hour urine protein is not significantly different between the two drugs. The average change on the eGFR is -2 and -9 ml/min/1.73m2 in the amiloride and triamterene groups, respectively. Average systolic blood pressure reduction is 11 and 3 in amiloride and triamterene groups, respectively. The average change in the weight is -0.5 and -0.7 kg in amiloride and triamterene groups, respectively. Three patients exited the study due to hyperkalemia.

Conclusions: Both amiloride and triamterene showed the effect of proteinuria reduction regardless of the underlying pathology. This effect appears to be independent of the RAAS, given that patients were all on RAAS blockade. Large scale trials are needed to evaluate the antiproteinuric and renoprotection effects of ENaC inhibitors.

PO0565
Comparison of Extended-Release Calcifediol (ERC), Immediate-Release Calcifediol, Cholecalciferol, and Paricalcitol for Treating Secondary Hyperparathyroidism (SHPT) in CKD

Stephen A. Strugnell,1 David M. Spiegel,2 Philipp Csomor,3 Akhtar Ashfaq,1 Charles W. Bishop,1 OPKO Health Inc., Miami, FL; Vifor Pharma Ltd, Zurich, Switzerland.

Background: Serum total 25-hydroxyvitamin D (25D) levels above 50.8 ng/mL are required to produce meaningful and progressive reductions in plasma intact parathyroid hormone (iPTH) in patients with stages 3 or 4 CKD [Strugnell et al 2019]. The current study compared the abilities of four treatment regimens to increase serum 25D to this level and to reduce iPTH in this population.

Methods: Subjects with stage 3 or 4 CKD, SHPT (iPTH >85 and <500 pg/mL) and vitamin D insufficiency (25D <30 ng/mL) underwent an 8-week washout from previous vitamin D therapies and were randomized to 60 days of open-label treatment with: 1) ERC 60 mcg/day; 2) immediate-release calcifediol (IRC) 266 mcg/month; 3) high-dose cholecalciferol (HDC) 300,000 IU/month; or 4) paricalcitol plus low-dose cholecalciferol (PLDC) 0.5 mcg/day and 800 IU/day. Paricalcitol was increased to 2 mcg/day after 30 days if iPTH was not reduced by 30% and safety parameters allowed. Subjects were monitored for changes in serum 25D, calcium (Ca) and phosphorus (P), and plasma iPTH.

Results: Mean (SD) post-washout/pre-treatment baseline levels for 25D and iPTH in the per-protocol population were 20.6 (6.6) ng/mL and 145 (99) pg/mL, respectively. No differences were observed at baseline between treatment groups (14-17 subjects each). At the end of treatment, mean 25D (ng/mL) increased to 82.9 (17.0) with ERC (P<0.05), 30.8 (11.6) with HDC (P<0.05), 26.3 (6.8) with IRC and 24.2 (7.3) with PLDC. All subjects treated with ERC attained 25D levels ≥30 ng/mL vs. only 44% with HDC (P<0.001), 20% with IRC and 14% with PLDC. Most ERC subjects (94%) attained 25D levels ≥50.8 ng/mL. The proportion of subjects who achieved at least a 20% reduction in iPTH were 71% with ERC, 38% with HDC, 20% with IRC and 79% with PLDC. No changes from baseline were observed in mean Ca or P in any treatment group, but one instance of hypercalcemia (≥10.3 mg/dL) was observed with PLDC treatment.

Conclusions: ERC was safe and more effective at increasing serum 25D and decreasing plasma iPTH than IRC, HDC or PLDC in patients with SHPT, vitamin D insufficiency, and stage 3 or 4 CKD.

PO0566
Renoprotective Effects of Febuxostat and Allopurinol in Patients with Hyperuricemia and CKD: A Meta-Analysis

Sherida N. Edding, Monica Therese Cating-Cabral, Brian Michael I. Cabral. St. Luke's Medical Center - Global City, Taguig City, Philippines.

Background: Hyperuricemia is associated with rapid deterioration of renal function in patients with chronic kidney disease (CKD). The two most common urate-lowering drugs available are allopurinol and febuxostat. Randomized controlled trials and observational studies have shown that the individual drugs have potential to slow down deterioration of renal function in CKD patients. However, it is unclear which drug is more effective because of insufficient direct comparison between the two. Hence our study aims to perform a meta-analysis to assess the renoprotective and urate-lowering effects between the two drugs in patients with CKD and hyperuricemia.

Methods: A comprehensive literature search using PubMed was performed with the following search terms: febuxostat, allopurinol, chronic kidney disease, renoprotection. Five relevant studies were selected and analyzed using Cochrane Revman v5.3. Outcomes assessed were changes in estimated glomerular filtration rate, serum creatinine, level of proteinuria and/or albuminuria and change in serum uric acid levels.

Results: Five studies comprising 606 patients were selected – 304 treated with febuxostat and 302 with allopurinol. No significant differences were found in the changes in serum creatinine (mean difference (MD) -0.02; CI -0.07, 0.03; P = 0.39) and eGFR (MD 2.09; CI -0.67, 4.84; P = 0.14) from baseline to 3 months between the two groups. Significant difference in the change in eGFR favoring Febuxostat, was observed after 6 months (MD 4.94; CI 2.25, 7.64; P = 0.003). Significant decrease in proteinuria (MD -0.24; CI -0.42, -0.07; P = 0.007) and albuminuria (MD -80.47; CI -149.29, -11.64, P = 0.02) were observed more in the febuxostat group after 3 months; however these changes were not significant after 6 months. Serum uric acid levels were significantly more reduced in the febuxostat group both after 3 (MD -0.90; CI -1.14, -0.67, P = 0.00001) and 6-months (MD -1.50; CI -1.70, -1.30, P = 0.00001).

Conclusions: Our study showed that febuxostat might be more renoprotective (as measured by eGFR change in 6 months) and offers a better anti-proteinuric and urate-lowering effect. However, more studies are needed to assess its efficacy across the spectrum of CKD, including those requiring hemodialysis and post-transplant patients.

PO0567
CKD Is Associated with Attenuated Plasma Metabolome Response to Oral Glucose Tolerance Testing

Armin Ahmadi,1 Brian J. Bennett,1b Jorge Gamboua,4 Leila R. Zelnick,2 Daniel Rafferty,2 Ian H. de Boer,1,5 Baback Roshanravan,1 Department of Medicine, Division of Nephrology, University of California Davis, Davis, CA; Division of Nephrology and Kidney Research Institute, University of Washington, Seattle, WA; Vanderbilt University School of Medicine, Nashville, TN; Puget Sound Health Care System, Seattle, WA; Obesity and Metabolism Research Unit, Western Human Nutrition Research Center, USDA, ARS, Davis, CA.

Background: Chronic kidney disease (CKD) is associated with decreased anabolic response to insulin contributing to protein-energy wasting. Targeted metabolic profiling of the response to oral glucose tolerance testing (OGTT) may help identify metabolic pathways contributing to disruption in incretin response.

Methods: Using targeted metabolic profiling, we examined the plasma metabolome in 58 moderate to severe non-diabetic CKD patients with estimated glomerular filtration rate (eGFR)-60ml/min per 1.73m2 and 37 healthy controls with normal eGFR before and after 2h of 75g oral glucose challenge. We used linear mixed effect models adjusting for potential confounders of age, sex, race, and body weight to determine the interaction of eGFR and change in metabolites in response to OGTT by CKD status. Pathway analyses were performed using Metaboanalyst.

Results: CKD patients had lower eGFR compared to healthy control (37.3 ± 12.5 Vs. 89.3 ± 17.1 ml/min per 1.73m2). Oral glucose challenge was associated with a marked reduction in a wide array of metabolites, predominantly amino acids, TCA cycle intermediates, and bile acids. CKD status was associated with attenuated OGTT induced prominent changes in pathways of tauurine metabolism, phenylalanine, tyrosine and tryptophan biosynthesis, nicotinamide metabolism, and TCA cycle (Figure 1).

Conclusions: Targeted plasma metabolic profiling in response to OGTT suggests a broad disruption of amino acid and mitochondridal energy metabolism in CKD patients. These findings motivate further investigation into incretin response in patients with CKD and the impact of incretin mimetics such as GLP-1 receptor agonist.

Funding: NIDDK Support

Figure 1: Pathway analysis of OGTT challenge in CKD vs control subjects.
The Effects of Allopurinol on the Progression of CKD According to Baseline Serum Urate Level: Results from Post Hoc Analyses of the CKD-FIX Trial

Background: Allopurinol did not slow decline in estimated glomerular filtration rate (eGFR) over 2 years in patients with chronic kidney disease (CKD) at risk of progression in the CKD-FIX trial. We assessed the effect of allopurinol on eGFR slope by baseline serum urate level.

Methods: In this trial, 369 adults with stage 3 or 4 CKD, without history of gout, and either baseline serum urate ≥265 mg/g or eGFR decrease ≥3.0 mL/min/1.73 m² in the preceding year, were randomized to allopurinol or placebo. The primary outcome was change in eGFR up to 104 weeks using the CKD-EPI creatinine equation. This post hoc subgroup analysis describes outcomes in 352 participants according to baseline serum urate level (normouricemic and hyperuricemic serum urate ≤6 mg/dL in women and >7 mg/dL in men), and tertiles of baseline serum urate level.

Results: At baseline, 65 (18.5%) and 287 (81.5%) participants had normouricemia and hyperuricemia, respectively. The mean serum urate level in the normouricemic group was 5.9 mg/dL (4.8 mg/dL for women, 6.1 mg/dL for men), and mean serum urate in the hyperuricemic group was 8.7 mg/dL (8.3 mg/dL for women and 8.9 mg/dL for men). There were no significant differences in change in eGFR between allopurinol and placebo in normouricemic (mean difference [MD] 0.35, 95%CI -2.72 to 3.42 mL/min/1.73 m²/year) and hyperuricemic (MD -0.06, 95%CI 1.20 to 1.08 mL/min/1.73 m²/year) groups. The mean serum urate levels in the lowest, middle, and highest tertiles were 6.3 mg/L, 8.0 mg/L, and 10.0 mg/L, respectively. The result for the primary outcome was consistent across all tertiles of baseline serum urate level (interaction P value for subgroup analysis = 0.49).

Conclusions: In CKD patients at risk of progression, the effect of allopurinol on eGFR decline was not modified by baseline serum urate level.

CKD Progression End Points as Potential Surrogates for Kidney Failure: Findings from the CKDopps

Jacev Zee,1 Daniel G. Muenz,2 Keith McCullough,3 Brian Bieber,4 Marie Metzger,5 Natalia Alencar de Pinho,6 Antonio A. Lopes,3 Danilo Fliser,1 Bruce M. Robinson,1 Eric W. Young,1 Ronald L. Pisoni,3 Benedicte Stengel,6 Roberto Poon-Chai Filho,2 Arbor Research Collaborative for Health, Ann Arbor, MI; 2 French Institute of Health and Medical Research (INSERM), Villejuif, France; 3 Department of Internal Medicine, Federal University of Bahia, Salvador, Brazil; 4 Universitätsklinikum des Saarlandes and Medizinische Fakultät der Universität des Saarlandes, Homburg, Germany.

Background: Many potential surrogate endpoints for kidney failure (KF) have been used in clinical trials and observational studies of chronic kidney disease (CKD). Individual and composite surrogate endpoints must be compared to ensure accurate research that maximizes power and facilitates harmonization across studies, particularly among an international sample of advanced CKD patients. Methods: Using data from CKD stage 3-5 patients from Brazil, France, Germany, and the US enrolled in the CKD Outcomes and Practice Patterns Study (CKDopps), we defined potential individual and composite KF endpoints based on reaching (1) eGFR<15 mL/min/1.73 m² and (2) eGFR decline of 3.0 mL/min/1.73 m²/year. Potential surrogate endpoints that combine (1) and (2) with and without kidney replacement therapy (KRT, dialysis or transplant). We used each individual and composite endpoint as a time-varying indicator that combine (1) and (2) with and without kidney replacement therapy (KRT, dialysis or transplant). We used each individual and composite endpoint as a time-varying indicator that combine (1) and (2) with and without kidney replacement therapy (KRT, dialysis or transplant).

Results: N=5242 patients had missing IQR (baseline eGFR of 26.8 (20.7-35.5) and 144 (20.7-35.5) follow-up time of a median 2.7 (1.2-3.0) years. Potential surrogate endpoints that included eGFR<15 had higher prediction discrimination compared with those that only included eGFR decline (Figure, AUCs of 0.83-0.84 vs 0.73-0.75). Composite endpoints had higher event counts than non-composite endpoints (Ns of 1622-1878 vs 1144-1556, see Figure x-axis).

Conclusions: A composite KF endpoint defined by the earliest occurrence of either KRT, eGFR<15, or eGFR decline of 40% had the highest prediction discrimination for KRT and the highest number of events among a cohort enrolled at low eGFR. This endpoint should be further evaluated and considered for clinical research studies to optimize power while sufficiently capturing KF.

Treatment for CKD: A Systematic Literature Review and Population Comparison

Juan Jose Garcia Sanchez,1 Juliette C. Thompson,2 David A. Scott,2 Naveen Rao,3 Elisabeth Sörsträðius,4 Glen James,1 Stephen Nolan,3 Eric T. Wittbrodt,8 Alyshah Abdul Sultan,1 Bergur V. Stefansson,1 Dan Jackson,1 Neil S. Hawkins,2 Keith R. Abrams,3 5BioPharmaceuticals Medical, AstraZeneca, Cambridge, United Kingdom; 6Visible Analytics, Oxford, United Kingdom; 7BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; 8BioPharmaceuticals Medical, AstraZeneca, Gaithersburg, MD.

Background: DAPA-CKD is the first renal outcomes trial assessing the efficacy and safety of a sodium–glucose cotransporter-2 inhibitor, dapagliflozin, vs placebo, added to standard of care in patients with chronic kidney disease (CKD) with/without type 2 diabetes (T2D). Several other agents have been or are currently under investigation for their effect on renal and cardiovascular outcomes in CKD; however, comparisons of efficacy are challenging, due to differences in study design, duration, patients and endpoint definitions. We conducted a systematic literature review of randomized controlled trials (RCTs) in CKD, with the aim of assessing inter-study comparability.

Methods: Searches of MEDLINE, Embase, the Cochrane Central Register of Controlled Trials and grey literature sources were conducted to identify phase 3–4 RCTs of adults (≥18 years) with albuminuric CKD with/without T2D, published in English between 1990 and March 25, 2020. Studies of a ≥12 weeks duration that reported clinical outcomes, adverse events, quality of life or patient-reported outcomes for pharmacologic CKD treatments were eligible for inclusion.

Results: Preliminarily, 13,451 unique citations were identified, and 204 full-text manuscripts were included after abstract screening (Figure). Data from 81 RCTs were included: 24, 39 and 18 in patients with CKD with/without T2D, CKD with T2D and CKD without T2D, respectively.

Conclusions: As anticipated, differences in the inclusion of patients with/without T2D between studies make comparisons difficult. Future work will compare additional relevant study characteristics, with further insights available in October 2020.

Funding: Commercial Support - AstraZeneca
A New Vision for Nephrology Trials in Canada

Alicia Murdoch,1 François Madore,1 Dwight Sparkes,1 Karthik K. Tennankore,3 Arris H. Vorster,2 Rita Suri,4 ‘Universite de Montreal, Montreal, QC, Canada; 2Can-SOLVE CKD Network, Vancouver, BC, Canada; 3Dalhousie University, Halifax, NS, Canada; 4McGill University, Montreal, QC, Canada.

Background: The Canadian Nephrology Trials Network (CNTN) was established in 2014 to improve the quantity and quality of clinical trials in nephrology in Canada. With inception of the Canadians Seeking Solutions and Innovations to Overcome Chronic Kidney Disease (Can-SOLVE CKD) Network in 2016, CNTN received additional funding to expand its mandate. We surveyed and assembled a broad cross-section of Canadian kidney patients, nephrology researchers, and other relevant stakeholders in order to establish an expanded new vision for CNTN.

Methods: In July-August 2018, we administered two separate surveys – one to patient members of Can-SOLVE CKD and the second to members of CNTN and other Canadian nephrology investigators. We then conducted a two-day visioning workshop in September 2018 to discuss how best to support nephrology research in Canada. Over 40 stakeholders participated, including 10 patients, 22 researchers, and members of the Can-SOLVE CKD Operations Team.

Results: Through the survey, we identified two issues that were at least moderately challenging: inability to facilitate multi-site trials (81%) and lack of engagement with community sites (74%). Three key themes emerged from the visioning exercise: peer review, training, and engagement. A summary report captured workshop discussions and was used to inform revisions to CNTN’s structure and governance. Three new working committees were created: Capacity Building, Communication and Engagement, and Scientific Operations; as well as a governing Executive Committee. Each committee is co-chaired by a nephrologist and patient, who take turns leading the Executive Committee.

Conclusions: With its new vision and committee structure, CNTN aims to promote a culture of collaboration within the Canadian kidney community and integrate patients into research. The network offers resources to enhance nephrology researchers’ ability to conduct clinical trials, directly involve patients in designing studies, and motivate change in patient care based on patient priorities through increased peer review, engagement, and training.

Implementation of Surprise Question Assessments Using the Electronic Health Record in Older Adults with Advanced CKD

Natalie C. Ennecke1, Khaled Abdel-Kader,2 Manoj Cai,1 Jonathan Yabes,1 Jane O. Schell,1 Manisha Jham1.1University of Pittsburgh School of Medicine, Pittsburgh, PA; 2Vanderbilt University, Nashville, TN.

Background: The Surprise Question (SQ; “Would you be surprised if this patient died in the next 12 months?”) is a validated prognostic tool for mortality and hospitalization among patients with advanced CKD. Yet, barriers in clinical workflow have slowed SQ implementation into practice. We sought (1) To evaluate implementation outcomes following use of electronic health record (EHR) decision support to automate collection of the SQ, and (2) To assess the prognostic utility of the SQ for mortality and hospitalization/emergency room (ER) visit.

Methods: We developed and implemented a synchronous decision support [best practice alert (BPA)] algorithm in the electronic health record (EHR) to identify patients attending an outpatient nephrology follow-up visit who were ≥ 60 years of age with an eGFR<30. At the time of the visit, a ‘pop-up’ BPA was triggered, prompting the physician to answer the SQ (dichotomized). To evaluate implementation, we assessed provider response rate, and efficiency of responses. We assessed the SQ’s prognostic utility in survival and time-to-hospital encounter (hospitalization/ER visit) analyses. We abstracted EHR data on patient sociodemographics and clinical characteristics. Physicians provided their demographic and clinical practice characteristics.

Results: Among 510 unique patients for whom the BPA triggered, 95 had the SQ completed (18.6%) by 16 unique providers. Among those patients with completed SQ, nearly all providers (97.9%) completed the SQ on the clinic appointment day, and 61 (64.2%) the first time the BPA fired. Providers answered “No” for 27 (28.4%) and “Yes” for 68 (71.6%) patients. By 12 months, 6 (6.3%) “No” patients died; 3 (3.2%) “Yes” patients died (age-adjusted hazards ratio [HR] 0.35, CI[0.13, 0.94]). About 40% of “No” patients died (age-adjusted hazards ratio [HR] 0.35, CI[0.13, 0.94]). About 40% of “No” patients died (age-adjusted hazards ratio [HR] 0.35, CI[0.13, 0.94]). About 40% of “Yes” patients died (age-adjusted hazards ratio [HR] 0.35, CI[0.13, 0.94]). About 40% of “No” patients died (age-adjusted hazards ratio [HR] 0.35, CI[0.13, 0.94]). About 40% of “Yes” patients died (age-adjusted hazards ratio [HR] 0.35, CI[0.13, 0.94]). About 40% of “Yes” patients died (age-adjusted hazards ratio [HR] 0.35, CI[0.13, 0.94]).

Conclusions: We successfully integrated the SQ into the EHR for routine collection to aid in clinical practice. Our response rate indicates additional implementation efforts are needed to encourage further integration of the SQ in clinical practice. Consistent with prior research, the SQ has reasonable prognostic utility for mortality and future hospital encounters.

Telehealth for Adults with CKD: A Systematic Review and Meta-Analysis

Li Liao,1 Min Zhang,1 Dingjun Zhang,1 Huifen Chen,1 La Zhang,1 Bingqing Xiu,1 Jiaowang Tan,2 Chendi Dong,1 Yannin Xu,1 Xuosheng Liu,1 Yifan Wu.1 The Second Clinical College, Guangzhou University of Chinese Medicine, Guangzhou, China; 2Renal Division, Beijing University of Chinese Medicine Shenzhen Hospital, Guangzhou, China; 1Renal Division, the Second Affiliated Hospital of Guangzhou University of Chinese Medicine (Guangdong Provincial Hospital of Chinese Medicine), Guangzhou, China.

Background: Evidence has supported improved quality of CKD care when assisted with telehealth, while these results were predominantly based on cohort observation or small-scale randomized controlled trials(RCTs). Moreover, robust findings regarding its effects on endpoints were still limited. This study thus aimed to evaluate impacts of telehealth on dialysis CKD patients.

Methods: This study was conducted and reported according to PRISMA statement. We searched databases including MEDLINE, EMBASE, Cochrane Central Register of Controlled Trials (CENTRAL), Chinese Biomedicine Database (CBM), Chinese National Knowledge Infrastructure (CNKI), Wanfang Database and VIP Database until 2019 April. Relevant studies regarding telehealth for non-dialysis CKD population were screened, reviewed, selected and assessed of quality for systematic review and meta-analysis. The protocol was registered at PROSPERO(CRD42017073665).

Results: Eighteen trials involving 4749 patients were included for systematic review and 4 for further meta-analysis. The qualitative study summarized different study population, telehealth intervention type(consultation, education, monitoring) and variable results of outcomes measured(endpoints, surrogate values, patient-centered outcomes). The quantitative analysis comparing the telehealth and control group detected no significant difference in systolic blood pressure(SBP), diastolic blood pressure(DBP) and serum creatinine(SCr) at 12 months, but found significantly lower SCr level at 6 months, preserved estimated glomerular filtration rate(eGFR) at 6 months and at 12 months in telehealth group.

Conclusions: This study detected advantages of telehealth on delaying CKD progression but uncertain impacts on decreasing endpoint incidence.

Funding: Government Support - Non-U.S.
PO0575
Telenephrology: A Feasible Option for Inmates
Maxwell Butler, Laura J. Maursetter. University of Wisconsin-Madison, Madison, WI.

Background: Socioeconomic and racial disparities are factors that contribute to the disproportionately high burden of chronic disease amongst the incarcerated population in the United States. Access to care can be compromised because of the burden of cost to a facility, lack of staff to transport patients and physical distance from specialists. Telenephrology has been shown to be a feasible option in the correctional setting for specialties such as mental health, infectious disease, cardiology, and primary care, but has not been studied in nephrology. In this quality improvement study, we showed telenephrology is a feasible option that can be implemented for CKD and hypertension management.

Methods: Using quality improvement methodology, data was collected from the electronic medical record for all telenephrology appointments from January 2015 to June 2019. Demographic data, comorbidities, appointment completion, and clinical data including eGFR and blood pressure were tracked for analysis. Data for patients seen over a period of at least 3 years were included in the CKD progression portion and those seen at least 4 times for the blood pressure management.

Results: There were 871 appointments schedule over the 4.3 year period with 86% completed. Technology limited 3.5% of the cancelled appointments. The population was predominantly men (96%) of black race (51.9%) with hypertension (78%) and CKD (75.2%) being the most common comorbidities. There were 214 patients included in the analysis for management of CKD that showed an average annual change in eGFR of -1.57 ml/min/1.73 m² (CI -2.87 to -0.27). There were 79 included in the hypertension analysis with 19.0% achieving a goal BP of 130/80 mm Hg and 63.3% achieving a BP of ≤140/90 mm Hg.

Conclusions: Telenephrology can be successfully carried out in the correctional facility environment with a low number of cancellations due to technology. The study sample showed mild-to-moderate CKD progression consistent with previously reported population rates of eGFR decline suggesting comparable management. The smaller subset in hypertension showed control that was less than the rates achieved in a nationally representative sample of CKD patients (52% and 75%). This marks an area that requires improvement. Continued rising referrals to telenephrology suggest provider acceptance but it is important to study and adjust management to provide at least equal care as in person visits.

PO0576
Nephrology eConsultation: The “Curb Side” Consult for the 21st Century
David Levy, Rickinder Grewal, Scott E. Liebman, Thu H. Le. University of Rochester School of Medicine and Dentistry, Rochester, NY.

Background: The Nephrology Division at the University of Rochester receives on average 120 new outpatient referrals per month. While every effort is made to see new referrals promptly, this demand exceeds the capacity to evaluate these patients in a timely manner. To decrease waiting time and increase efficiency, we developed a Nephrology eConsultation program. Here we report our experience with time and value-based metrics as well as primary care provider (PCP) satisfaction.

Methods: After a year-long pilot phase, in September 2019 we expanded the eConsult program to include remote provider consultation to medical providers across the University health system for renal-related issues such as mild to moderate acute kidney injury, CKD, electrolyte disturbances, and proteinuria.

Results: Within the first 8 months of the expanded program, 110 eConsult requests were received. Of these, 62 were deemed medically appropriate and completed, with 46 (74.2%) related to acute kidney injury, CKD, or azotemia, 6 (9.7%) related to electrolyte imbalances, and 4 (6.5%) related to proteinuria. The mean time for a nephrologist to complete an eConsult was 13.8 minutes (Table 1). Of the 48 deemed inappropriate for eConsults, 36 (75%) were converted to in-person visits due to complexity (Table 2). All eConsults were completed within 67 hours (mean time 15.5 hours). Survey of PCP satisfaction showed that 68% of PCPs were very satisfied and 32% were satisfied with the nephrology eConsult program.

Conclusions: eConsultation in Nephrology has the potential to provide timely, cost effective, and remote guidance to PCPs for more straightforward questions, while prioritizing the limited resource of face-to-face nephrology consultation for patients with more complex diseases. This also offers financial advantages, as the work relative value units (wRVUs) for eConsult is 0.7, or up to 2.8 wRVUs per hour in our model. eConsultation in Nephrology could also be integrated with the rapidly evolving field of telemedicine to improve delivery of care remotely and increase provider and potentially patient satisfaction.

PO0577
Development of a Global CKD Personal Impact Index (CKD-PII) Assessing the Reality of Living with CKD
Mary F. James, Corey Windett, Jillian K. Guiglott. 1W2O, San Francisco, CA; 2AstraZeneca, Wilmington, DE.

Background: CKD affects >700M people globally, but its full burden and personal impact attributes (PIA)—impact on instrumental activities of daily living—are under-recognized. Qualifying of life (QoL) measures fail to show the full patient experience. A Global CKD-PII uncovering the direct and indirect daily impact of CKD on patients may improve understanding of disease burden and secondary complications. The development of the CKD-PII using a geographically diverse cohort of CKD patient-reported aggregate data is described.

Methods: A multiphase approach was used to develop CKD-PII. In Phase 1, social media landscape audit and qualitative interviews determined PIA to understand disease burden. Patient conversations within online communities gauged the social, economic and physical impact of CKD. Each attribute was assigned as high, medium or low impact based on the lexicon, overall sentiment and self-reported impact on patient’s QoL. Qualitative, moderated phone interviews followed an engagement model, whereby key PIA and language and characterization of attributes were further explored. Findings of Phase 1 informed Phase 2, a quantitative survey. Data from both phases will culminate in the development of CKD-PII.

Results: Phase 1: Social media landscape analysis leveraged 12 months of relevant patient dialogues (n=156) and shortlisted 11 key PIA from >200M internet sources. Among the key PIA identified, dietary impacts (19%), time lost to appointments/dialysis (45%) and mental health implications (44%) were rated as high impact. Qualitative interviews (n=15) uncovered key PIA identified consistently. Phase 2: An online survey questionnaire was administered to quantify the extent of patients’ experience of PIA. The CKD-PII synthesizes data from all research phases into an insights and perspectives report evaluating global perspectives.

Conclusions: Uniquely, CKD-PII will use metrics to showcase the real-life impact of CKD, beyond QoL, providing insights into the patient experience that other studies do not typically address. The social media data facilitates understanding of critical issues and prioritized areas of concern on the online landscape. This cohort of global patient-reported data will raise awareness of the deeper impact of CKD and develop tangible and realistic solutions for both patients and doctors to solve the challenges uncovered.

Lowering Mortality in CKD Stage 3B and CKD Stage 4 with Increased Outpatient Nephrology Visits

Stephanie S. Cheung,1 Michael Shen,4 Hui Xue,12 Kaiser Permanente San Diego Medical Center, San Diego, CA;2 Kaiser Permanente Department of Research and Evaluation, Pasadena, CA;3 Kaiser Permanente Orange County, Anaheim, CA;4 Kaiser Permanente Orange County, Business Intelligence & Transformation, Santa Ana, CA.

Background: Management of Chronic Kidney Disease (CKD) is complex requiring comprehensive evaluation of multiple organ systems. We hypothesized that more frequent outpatient nephrology visits is associated with lower mortality in advanced CKD patients.

Methods: CKD Stage 3b & CKD4 patients at Kaiser Permanente Southern California Orange County were followed from 2012 to 2018. Patients were divided into 4 groups based on initial eGFR per MDRD equation; eGFR 30-44, 25-29, 20-24, and 15-19. Each eGFR group was further divided by the number of annual nephrology visits (0, 1, 2, 3, and 4+). Patients who transitioned to dialysis, kidney transplant, or lost to follow up during the 7 years were excluded. Annual all-cause mortality was analyzed based on the number of nephrology visit in each eGFR category using ANOVA.

Results: The cohort consisted of 2943 individuals, 59% female, 41% male, mean age 77.4. 42% of patients were diabetic and 89% had hypertension. Lower starting eGFR had increased mortality over time while renal function stayed fairly stable. Increased outpatient visit was seen with lower eGFR during the follow up period, Figure 1. All CKD3B and CKD4 patients gained a statistically significant reduction in mortality when seen at least twice in nephrology clinic annually, p<0.04, in Figure 2. For eGFR ≤24, the mortality benefit was observed with 1 or more nephrology visit, p<0.005.

Conclusions: CKD stage 3B and 4 patients seen in nephrology clinic at least twice a year had improved survival. More frequent follow up was associated with lower eGFR. The relationship between the lower eGFR and the improved survival warrants further investigation.

PO0579

Uptake of Evidence-Based Recommendations to Improve Care for CKD Patients in the Kidney Coordinated Health Management Partnership (Kidney CHAMP) Study

Melanie R. Weltman,1 Huwein Chen,2 Jonathan Yabes,4 Manqi Cai,4 Khaleed Abdel-Kader,2 Manisha Jhamb,4 Thomas D. Nolan,6 University of Pittsburgh Renal-Electrolyte Division, Pittsburgh, PA; University of Pittsburgh Department of Medicine, Pittsburgh, PA; University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA; Vanderbilt University Division of Nephrology and Hypertension, Nashville, TN.

Background: Medication therapy in patients with chronic kidney disease (CKD) is focused on slowing CKD progression, managing causes of CKD, and preventing cardiovascular morbidity and mortality. The aim of this project was to assess the uptake of evidence-based medication recommendations (recs) provided to primary care providers (PCP) of patients with high-risk CKD by an interdisciplinary nephrology team.

Methods: This project is part of Kidney CHAMP, an ongoing NIH funded, pragmatic randomized controlled trial testing an electronic health record (EHR)-based population health management (PHM) approach to improve CKD care. Eligible patients are 18-85 years with CKD who have a high risk of progression to ESRD and are not being followed by a nephrologist. Patients in the intervention arm receive a nephrologist-led electronic consult and pharmacist-led telephonic medication therapy management (MTM). Recs are provided in the EHR for the PCP to review and order at the upcoming office visit. We focused on medication recs related to the progression of CKD and prevention of cardiovascular disease, which included use of RAAS inhibitors, SGLT2 inhibitors, GLP-1 receptor agonists, and HMG-CoA reductase inhibitors (statins).

Results: From July 1, 2019 to January 31, 2020, 125 patients received an e-consult and 121 patients received MTM. A total of 83 recs were provided to PCPs. Uptake of recs for initiation or dose escalation of RAAS inhibitors was the highest, with 19 of 46 recs (41%) being implemented. Two of eight recs regarding GLP-1 receptor agonists were implemented (25%) and two of 24 recs for SGLT-2 inhibitor initiation were implemented (8%). Five recs for statin initiation were made and none were implemented; however, baseline statin use was high at ≥75%.

Conclusions: Many patients with high risk CKD receive suboptimal care, which can be effectively identified by interdisciplinary nephrology teams using an EHR-based PHM platform. Uptake of RAAS inhibitor recs was highest. However, initiation of medications with recent FDA approved indications for CKD management remained poor. Future research is needed to identify barriers and strategies to increase uptake of evidence-based CKD recs and thereby improve patient care.

PO0580

Interdisciplinary Care Improves Patient Preparedness for ESRD in a High-Risk Patient Population with CKD

Kalvan Prudvil,1 Kaltrina Sedaliu,1,2 Michelle M. Estrella,3, 3 L. Ebony Boulware,4 Michal L. Melamed,1,2 Tanya S. Johns,1,2 Albert Einstein College of Medicine, Bronx, NY; 3Montefiore Medical Center, Bronx, NY; 3San Francisco VA Medical Center, San Francisco, CA; 4Duke University School of Medicine, Durham, NC.

Background: The Kidney Care Choice initiative has made improving the quality of care for patients with late-stage CKD a national priority. Interdisciplinary care (ICD), including nurse practitioner (NP) driven care coordination, is an intervention that may improve health outcomes in patients with CKD. Few studies have evaluated this model of healthcare delivery in racial-ethnic minorities.

Methods: We compared incident ESRD patients who received NP care coordination as part of our ICD clinic (n=84) to a contemporaneous cohort of incident ESRD patients (n=245) who received usual nephrology care alone at Montefiore Medical Center from 10/1/2013—10/31/2017. Clinical data were extracted using Clinical Looking Glass®, and chart reviews were done for validation. Patients included in our study had established care for CKD stage 4.5 and had at least one nephrology clinic visit within 3 months preceding their progression to ESRD. All patients were eligible for ICD, but receipt of ICD was limited by resource availability.

Results: Of the 329 incident ESRD patients included in our study, the mean age was 59.6 years (SD 13.8), 47% were female, and 86% were African American or Hispanic. The baseline characteristics were similar between the groups, except the ICD group had a lower prevalence of hypertension (60% vs 77%). The mean eGFR was 8 ml/min/1.73m² at dialysis initiation. Fifty percent of patients had an arteriovenous (AV) access prior to developing ESRD. However, compared to the usual care group, patients in ICD group were more likely to have a mature AV access at HD initiation (41% vs 33%); start HD as an outpatient (30% vs 19%); receive a preemptive transplant (4% vs 2%); do peritoneal dialysis (7% vs 4%); and be listed for kidney transplant (44% vs 15%) prior to developing ESRD. Receipt of ICD was associated with a higher odds (OR 3.9 [95% CI 2.0 - 7.8]. PC=.0001) of kidney transplant listing compared to usual care alone after adjusting for sociodemographic and clinical factors. Other outcomes also favored ICD but were not statistically significant.

Conclusions: Interdisciplinary care is associated with better ESRD preparedness compared to usual nephrology care alone in racial-ethnic minorities. Larger multicenter randomized studies are needed to determine the effectiveness of ICD among patients with advanced CKD.

Patient Outcomes Following Discharge from a CKD Clinic
Michael Che, Susan J. Thanabalasingam, Eduard A. Illescu, Christine A. White. Queen’s University Department of Medicine, Kingston, ON, Canada.

Background: In Ontario, Canada multidisciplinary care for patients with advanced chronic kidney disease (CKD) is delivered in Multi-Care-Kidney-Clinic (MCKC) operated by Regional Programs funded through a provincial network based on the number of eligible patients. These eligibility criteria were progressively revised between 2016 and 2018 from an absolute estimated glomerular filtration rate (eGFR) less than 30 ml/min/1.73m² to less than 15 ml/min/1.73m² or a two-year risk of end-stage kidney disease, calculated by the Kidney Failure Risk Equation (KFRE), greater than 10%. The objective of this study was to ascertain the outcomes of existing MCKC patients who were discharged as these criteria were implemented.

Methods: This is a retrospective cohort study of prevalent CKD patients in MCKC in 2013 in the region of South Eastern Ontario, followed to January 2020. The outcomes were discharge from MCKC, re-referral, initiation of kidney replacement therapy (KRT), and death. Data were extracted from electronic medical record. Death was ascertained through Ontario’s Office of the Registrar General. Patients’ 2 and 5-year KFRE scores were calculated using the 4-variable KFRE.

Results: Of the 643 MCKC patients in 2013 with available data, 470 (73%) continued follow-up in MCKC, while 142 (22%) and 31 (5%) were discharged to primary care and general nephrology respectively. Of those discharged to primary care, 52 (37%) died, while 15 (11%) were re-referred to nephrology, and 8 (6%) initiated KRT within median (IQR) times of 982 (560) and 850 (1411) days from discharge respectively. Five (63%) of the 8 discharged patients who required KRT did so for unforeseen acute illness rather than progressive CKD.

Conclusions: The results of this study suggest that gradually moving MCKC funding eligibility criteria from absolute eGFR level to one based on both eGFR and the KFRE prediction model resulted in the discharge of a significant number of patients. Notably, few of the discharged patients ultimately required KRT that could have been prevented. This study offers a regional perspective with low loss to follow-up as there is less stringent funding eligibility criteria from absolute eGFR level to one based on both eGFR and the KFRE prediction model.

Association of CKD with Early Heart Failure Readmissions in Adults
Si Li, Yichen Wang, Nasha Elavia, Bojana Mlikic. The Wright Center for Graduate Medical Education, Scranton, PA.

Background: Heart failure is a complex chronic disease with multiple comorbidities that contribute to frequent hospitalization. We aimed to examine the impact of chronic kidney disease on the 30-day readmission rate among patients hospitalized with heart failure.

Methods: We performed a retrospective analysis of the National Readmission Database (NRD) 2016-2017. We identified adult patients with a primary hospital diagnosis of heart failure. We compared baseline demographics and calculated all-cause 30-day readmission rates. Multivariate survey logistic regression was used to identify predictors of readmission.

Results: We identified a total of 865,328 patients admitted with heart failure. 839,625 patients were discharged alive. Among which 181,130 (21.5%) had at least one readmission within 30 days. The in-hospital mortality of index admissions and readmissions was 2.9% and 6.5%, respectively. The 30-day inpatient mortality was 4.0%. The mean length of stay of index admission and readmissions was 5.3 days and 6.4 days, respectively. The most common reasons for all-cause readmissions were acute on chronic heart failure (systolic, diastolic, combined), hypertensive heart and chronic kidney disease with heart failure, sepsis, acute kidney failure. After adjusting for multiple covariates, 30-day readmission was independently associated with chronic kidney disease [adjusted odds ratio (aOR) 1.2, 95% confidence interval (CI) 1.17-1.25, p<0.001], coronary artery disease (aOR 1.01, 95% CI 1.07-1.11), chronic obstructive pulmonary disease (COPD) (aOR 1.20, 95% CI 1.18-1.22). Younger age, lower-income, discharge from larger hospitals were also predictive.

Conclusions: Further prospective studies with focus on multilevel interventions are needed to help reduce early readmission associated significant morbidity and resource utilization for this high-risk population.
A Medication Use Evaluation of Patiromer in a Clinical Practice Setting at a Veteran’s Affairs Medical Center

Danielle N. Cooney,1 Emily M. Fox,2 Mary Beth Low,3 Niraj Desai,2,4 Case Western Reserve University, Cleveland, OH; 2Louis Stokes VA Medical Center, Cleveland, OH.

Background: Patiromer is cation exchange polymer approved for treatment of hyperkalemia. There is limited data regarding the utility, adverse effects, frequency of laboratory monitoring and discontinuation rate of Patiromer in a clinical practice setting.

Methods: We performed a retrospective, observational review of prescriptions written in one or more doses of patiromer between 10/2015 and 11/2019 at the Veterans Affairs Northeast Ohio Health System (VANOHS), to evaluate changes to RAAS inhibitor therapy, adverse effects resulting in patiromer discontinuation, and monitoring of serum potassium level. Patiromer prescription characteristics, concomitant medications, laboratory characteristics and adverse effects were collected for each veteran over the study time period. Baseline characteristics are reported as means; relative frequency of outcomes are reported as percentages.

Results: 69 Veterans with hyperkalemia were included for analysis. Mean age was 70 years, African-American race 29%, diabetes 90%, chronic kidney disease 91%, 17% ESRD on dialysis, and heart failure 36%. The most common patiromer dose was 8.4 g daily (78%), prescribed for a mean 207±159 days. 21% of patients had repeat labs within 2 weeks and 54% within 4 weeks of patiromer initiation. 77% of patients achieved normokalemia (K+<5.0 mEq/L) by the first follow-up lab draw. Amongst 52 veterans with chronic, continuous patiromer use, 22 (41%) were taking RAAS inhibitors at baseline; 15 (29%) of these patients had either increased RAAS inhibitor dose over the study time period. 28 (54%) discontinued patiromer with 7 (25%) veterans doing so due to GI complaints.

Conclusions: In a clinical setting at a Veteran’s Affairs hospital, patiromer therapy preserved RAAS inhibitor use and improved serum potassium levels, but was discontinued at a high rate due to adverse effects.

The Practical Patterns of Medication and the Association Between CKD Stage and Polypharmacy: The Fukuoka Kidney Disease Registry Study

Hagihara Matsumoto,1 Shimizu Torisu,2 Masanori Tokumoto,1 Kazuhiko Tanaka,1 Horioka Ososhi,1 Toshikazu Nakano,1 Takamori Katozono,2 Department of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan; 2Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; 3Department of Nephrology, Nara Medical University, Kashihara, Japan.

Background: Polypharmacy has emerged as one of the important medical and socioeconomic problems in an aging society. Chronic kidney disease (CKD) is also one of the important medical problems for older people. However, the extent to which CKD is involved in polypharmacy still has not been fully explored yet.

Methods: We examined 3,968 Japanese CKD patients using baseline data from a multicenter prospective cohort study in a cross-sectional manner. We used the baseline data of prescribed medicines on medical records. We evaluated the association between CKD stage and polypharmacy (defined as ≥6 medications). The primary end point was polypharmacy (≥6 medications). We used logistic regression analyses with adjustment for potential confounding factors.

Results: At baseline, the prescribed medicines varied between 0 and 17, and the median (interquartile range) was 5 (3–7). Among 3,968 CKD patients, 1,540 (38.8 %) patients showed polypharmacy. The multivariable-adjusted odds ratios for polypharmacy were 1.42 [95% confidence interval, 0.77–2.61] for G3a, 1.44 [0.78–2.65] for G3a, 2.44 [1.34–4.49] for G3b, 4.06 [2.17–7.37] for G4 and 8.46 [4.53–16.5] for G5, respectively, compared to patients in the reference category (G1). The reference value in the higher-gglomerular filtration rate (GFR) category (≥60mL/min/1.73m2), many drugs, including angiotensin-2 receptor blockers, calcium channel blockers, uric acid synthesis inhibitors, proton pump inhibitors, aspirins, loop diuretics, and cation exchange resins were prescribed more frequently, whereas less than less than low GFR category (G5). In addition, aldosterone blockers, biguanides, fbrates, non-steroidal anti-inflammatory drugs, and sulfonylureas were continuously prescribed despite decreased GFR.

Conclusions: The higher GFR categories were independently associated with higher odds of polypharmacy. This might reflect the increasing prescription for managing to control symptoms caused by decreased GFR. We also have to pay more attention to prescribe medicines according to renal function.

A Pilot and Feasibility Randomized Clinical Trial Targeting Sedentary Behavior in CKD: Sit Less, Interact, and Move More (SLIMM) Study

Roberta E. Boucher,1 Guo Wei,1,2 Tom Greene,3 Srinivasan Beddhu,1,2 Division of Nephrology, Hypertension, and Heart Failure, University of Utah School of Medicine, Salt Lake City, UT; 2Medical Service, Veterans Affairs Salt Lake City Health Care System, Salt Lake City, UT; 3Division of Biostatistics, University of Utah School of Medicine, Salt Lake City, UT.

Background: Sedentary behavior (engaging in activities in the seated/lying position) is highly prevalent and associated with mortality in CKD.

Methods: In a 24-week pilot and feasibility RCT, we tested the feasibility of a ‘Sit Less, Interact, Move (SLIMM)’ intervention to replace sedentary activities with casual stepping activities in CKD. Participants wore an accelerometer for 7 days before randomization for increased RAAS inhibitor dose over the study period. Baseline Kidney Function: Prespecified Analyses of the CKD-FIX Trial

Addams,1 Elaine Pascoe,2 Neil Boudville,2 Alan Cass,4 Nicola Dalbeth,2 Richard O. Day,2 Janak de Zoya,2 Bettina Douglass,2 Randall Faulk,2 David Harris,3 Carmel Hawley,2 Graham R. Jones,2 John Kandcillis,2 Sue Pion,3 Vlad Perkovic,3 Gopi Rangan,3 Donna Reindinger,5 Robert J. Walker,3 Giles Walters,7 David W. Johnson,2 Sunil Badve.1 George Institute for Global Health, Sydney, NSW, Australia; 2The University of Queensland, Saint Lucia, QLD, Australia; 3The University of Western Australia, Perth, WA, Australia; 4Menzies School of Health Research, Casuarina, NT, Australia; 5The University of Auckland Faculty of Medical and Health Science, Auckland, New Zealand; 6St Vincent’s Health Australia Ltd, Bondi Junction, NSW, Australia; 7The University of Adelaide Faculty of Health and Medical Sciences, Adelaide, SA, Australia; 8The University of Sydney, Sydney, NSW, Australia; 9University of New South Wales, Sydney, NSW, Australia; 10Monash University, Clayton, VIC, Australia; 11University of Otago, Dunedin, New Zealand; 12Westmead Hospital, Westmead, NSW, Australia; 13Australian National University, Canberra, ACT, Australia.

Background: The CKD-FIX trial showed that allopurinol did not slow the decline of estimated renal function in CKD stage 3 or 4, no history of gout, who were at risk of progression (identified by urine uric acid-to-creatinine ratio ≥ 2.65 mg/g or eGFR decrease ≥ 3.0 mL/min/1.73 m2 in the preceding year) were randomized to receive allopurinol or placebo. Primary outcome was rate of change in eGFR up to 104 weeks using the CKD-EPI creatinine equation. This pre-specified subgroup analysis describes outcomes in patients with CKD stage 3 and stage 4.

Methods: Three hundred and sixty nine adults with CKD stage 3 or 4, no history of gout, who were at risk of progression (identified by urine uric acid-to-creatinine ratio ≥ 2.65 mg/g or eGFR decrease ≥ 3.0 mL/min/1.73 m2 in the preceding year) were randomized to receive allopurinol or placebo. Primary outcome was rate of change in eGFR up to 104 weeks using the CKD-EPI creatinine equation. This pre-specified subgroup analysis describes outcomes in patients with CKD stage 3 and stage 4.

Results: At baseline, 178 (51%) patients had CKD stage 3 (mean eGFR 41 mL/min/1.73 m2, mean serum urate 7.9 mg/dL) and 185 (51%) patients had CKD stage 4 (mean eGFR 23.5 mL/min/1.73 m2, mean serum urate 8.4 mg/dL). In patients with CKD stage 3, change in eGFR did not differ between the allopurinol (-3.4 mL/min/1.73 m2, 95% CI -5.97 to -2.83) and placebo (-3.34 mL/min/1.73 m2, 95% CI -5.49 to -2.09) groups (mean difference [MD], -0.33 mL/min/1.73 m2/year, 95% CI -2.13 to 1.47). In patients with CKD stage 4, there was no difference in change in eGFR between the allopurinol (-2.89 mL/min/1.73 m2/year, 95% CI -3.74 to -2.03) and placebo (-2.89 mL/min/1.73 m2/year, 95% CI -5.79 to -2.04) groups (MD, 0.06 mL/min/1.73 m2/year, 95% CI -1.18 to 1.17). The interaction P value for subgroup analysis was 0.87.
Conclusions: In CKD patients at risk of progression, the effect of allopurinol on eGFR decline was not modified by baseline kidney function.

PO0588
Effects of the SGLT2 Inhibitor Dapagliflozin on Proteinuria in Non-Diabetic Patients with CKD (DIAMOND): A Randomized Double-Blind Cross-Over Trial
Hiddo J. L. Heerspink,1 Claire Dekkers,1 David Cherney,2 Department of Clinical Pharmacy and Pharmacology, University Medical Centre Groningen, Groningen, Netherlands; 2Department of Medicine, Division of Nephrology, University Health Network and University of Toronto, Toronto, ON, Canada.

Background: Sodium glucose co-transporter 2 (SGLT2) inhibition decreases albuminuria and reduces the risk of kidney disease progression in patients with type 2 diabetes. These benefits are unlikely mediated by improvements in glycemic control alone. We therefore examined the renal effects of the SGLT2 inhibitor dapagliflozin in patients with proteinuric kidney disease without diabetes.
Methods: A multicenter double-blind placebo controlled 6-week crossover study was performed in six hospitals in the Netherlands, Canada, and Malaysia. Patients (18-75 years old), without diagnosis of diabetes, 24-h urinary protein excretion >500 mg/24h and estimated glomerular filtration rate (eGFR) >50 ml/min/1.73 m² on stable renin angiotensin system blockade were included. Participants were randomly assigned to one of the two consecutive treatment periods of first placebo and then dapagliflozin 10 mg/day or vice versa. The main secondary outcome was change in iohexol measured GFR (mGFR). The primary outcome was percentage change from baseline in 24-h proteinuria.

Results: A total of 180 patients were screened of whom 53 patients were randomized. Median baseline proteinuria was 1110 mg/24h (IQR 730, 1560) mg/24h; mean mGFR was 58 ml/min/1.73m² (SD 23). The difference in mean proteinuria change from baseline to dapagliflozin and placebo was 0.9% (95% CI: -16.6, 22.1; p=0.93). Compared to placebo, mGFR changed with dapagliflozin treatment by -6.6 ml/min/1.73 m² (95% CI: -9.0, -4.2; p=0.0001) at week 6, which was completely reversible within 6 weeks after discontinuation of dapagliflozin. Differences between dapagliflozin and placebo in body weight, systolic blood pressure and hematocrit were -1.5 kg (95% CI: -3.0, 0.0; p=0.0455), -3.6 mmHg (95% CI: 7.6, -0.4; p=0.0775) and 0.02 L/L (95% CI: 0.01; 0.03; p=0.9001). HbA1c did not change. The number of patients with adverse events during dapagliflozin treatment (n=17; 32.1%) and during placebo treatment (n=13; 25.0%) was similar. No hypoglycemic events were reported.

Conclusions: Six week treatment with dapagliflozin does not affect proteinuria in patients with chronic kidney disease without diabetes, but did induce acute and reversible decreases in mGFR, body weight, and, to a lesser extent, haematocrit, and increased homocœrination.

PO0589
The Impact of Decline in Renal Function on the Clinical and Economic Burden of CKD: An Application of the DAPA-CKD Cost-Effectiveness Model
Philip McEwan,1 Juan Jose Garcia Sanchez,1 Klas Bergenheim,5 Oliver T. Darlington,1 David C. Wheeler,1 Hiddo J. L. Heerspink.2 1AstraZeneca, Cambridge, United Kingdom; 2University of Groningen, Groningen, Netherlands; 3Health Economics and Outcomes Research Ltd, Cardiff, United Kingdom; 4University College London, London, United Kingdom; 5AstraZeneca, Gothenburg, Sweden.

Background: The efficacy of dapagliflozin for the treatment of chronic kidney disease (CKD) has been assessed in DAPA-CKD, which was stopped early for overwhelming efficacy. Cost-effectiveness analysis of new treatments plays an important role in the effective allocation of healthcare resources. The objective of this study was to develop a model for evaluating the cost-effectiveness of dapagliflozin based on the pending results of DAPA-CKD, and to demonstrate its functionality by characterizing the health economic burden of CKD progression from a UK payer perspective.
Methods: A lifetime microsimulation model was developed to estimate health economic outcomes in patients with CKD. Disease progression was modelled based on a historic, prospectively determined renal function curve, with standard eGFR decline (-0.65 ml/min/1.73 m² annually) and one with rapid eGFR decline (-4.20). Published cost and utility estimates were applied and discounted at 3.5%.

Results: DK patients with rapid eGFR decline had a reduced life expectancy of 9.1 years compared with 6.4 years in those with standard rates of eGFR decline. Patients with rapid eGFR decline experienced an additional 326 CV events per 1,000 patients and spent an additional 0.4 years receiving RRT. Reduced life expectancy, increased rates of CKD progression and CV event incidence translated to 2.4 fewer quality adjusted life years annually in patients with eGFR decline (5.5 versus 7.9) and an additional £1937 of direct healthcare expenditure.

Conclusions: The DAPA-CKD cost-effectiveness model is capable of estimating health economic outcomes in patients with CKD, projecting health benefits and costs consistent with published estimates. Our model improved diagnosis flow charts from DAPA-CKD. The economic burden imposed by CKD on both patients and healthcare systems.

Development of a CKD Model in Cynomolgus Monkeys and Its Application to Test Zampilimab, a Monoclonal Antibody (mAb) Specific for Human Transglutaminase 2 (TG2)
Linhong Huang,1 James Z. Song,2 Timothy S. Johnson.1 1UCB Pharma, Slough, United Kingdom; 2Prisys Biotechnology, Shanghai, China.

Background: TG2, a crosslinking enzyme involved in wound healing, is linked to the development of renal fibrosis. TG2 irreversibly crosslinks proteins via ε-glutamyl lysine dipeptide bonds, including extracellular matrix (ECM) proteins. TG2 accelerates ECM deposition and renders the matrix resistant to ECM proteases, forcing ECM homeostasis towards accumulation. TG2 also crosslinks large latent TGFβ1 into the ECM, releasing the active pro-fibrotic TGFβ1 dimer. Zampilimab (IC50 0.2mL, K, 120m) humanized mAb specific for human TG2, is under investigation for the treatment of fibrosis. Application of zampilimab in a primary human cell model of renal fibrosis had positive results; however due to human specificity, zampilimab efficacy cannot be tested in rodent in vivo models.

Methods: A unilateral ureteric obstruction model of CKD was developed in aged cynomolgus monkeys. Zampilimab was applied prophylactically immediately following model induction. TG2 activity was measured using an in-situ activity assay, and zampilimab target occupancy determined by competitive immunofluorescence. Renal fibrosis was measured by computerized image analysis and histopathological scoring of Masson’s trichrome, Picosirius red and H&E stained slides with hydroxyproline measured by amino acid analysis.

Results: Ligation of the left ureter led to development of severe tubulointerstitial fibrosis associated with elevated TG2 activity, leading to end-stage fibrosis in 6 weeks. This primate model has a greater expansion of the tubular basement membrane than similar rodent models, with histology more closely resembling obstructive disease in man. Following zampilimab intervention in a 4-week study, 7 days post final dose, TG2 activity was completely and highly significantly reduced (n=6) at a low dose. However, both zampilimab doses ameliorated the level of renal fibrosis by pathology score, computerized determination of fibrotic index and hydroxyproline.

Conclusions: Our primate model of CKD demonstrated that zampilimab can effectively block TG2 activity and prevent renal fibrosis. A Phase 1/2 study of zampilimab for the treatment of post-renal transplant fibrosis is ongoing (NCT03435578).

Conditional Deletion of Myeloid-Specific Mitofusin 2 Promotes Kidney Fibrosis
Divya Bharia, Allyson M. Capilli, Kiichi Nakahira, Thangamani Muthukumar, Augustine M. Choi, Oleh M. Akchurin, Mary E. Choi. Weill Cornell Medicine, New York, NY.

Background: Mitochondrial dysfunction is implicated in the pathogenesis of CKD. Mitochondrial dynamics regulate macrophage mitochondrial stress responses; we hypothesize that their impairment leads to kidney fibrosis. We determined the role of myeloid-specific mitochondrial fusion proteins (Mfn1) and Mfn2 in Pkn1-mediated mitophagy in experimental and human kidney fibrosis.

Methods: Pkn1-/-, myeloid-specific Mfn1 (LysM-Cre-Mfn1f/f), Mfn2 (LysM-Cre-Mfn2f/f) null mice and corresponding controls were subjected to unilateral ureteral obstruction (UUO,7-days) or adenine diet (AD,28-days). Kidneys, renal macrophages (RMs), bone marrow-derived macrophages (BMDMs), PBMCs, and plasma were analyzed by western blot, qPCR, Mito stress test, ELISA, immunohistochemistry, flow cytomtery, confocal and electron microscopy. Patients with renal biopsy-proven interstitial fibrosis & tubular atrophy (IFTA,e=6) and severe-CKD (GFR<30 ml/min,n=15) were compared to controls (no IFTA,e=9) and mild/moderate-CKD (GFR>30 ml/min,n=8).

Results: Mfn1 and Mfn2 expression decreased in kidneys after UUO or AD, and BMDMacsfer TGF-β1 treatment AD-fed-LysM-Cre-Mfn1f/f but not LysM-Cre-Mfn2f/f mice displayed increased renal expression of CD11b+ F4/80+ macrophages than AD-fed controls. Increased in fibroconnectin, CD206, galectin-3, and TGF-β1 expression in the kidneys and RMs were higher in AD-fed LysM-Cre-Mfn2f/f mice than AD-fed controls. TGF-β1-induced inhibition of mitophagy and increases in mitochondrial mass, size, and superoxide levels were greater in LysM-Cre-Mfn2f/f RMs and BMDMs than LysM-Cre-Mfn1f/f and controls. The reduction in colocalization of Mfn2 but not Mfn1 with renal mitochondria after UUO was higher in Pkn1-/- mice. BMDMs from patients with severe-CKD showed higher superoxide levels and lower Mfn2 expression than mild/moderate-CKD. IFTA was associated with lower renal expression of Mfn1 and Mfn2 and higher circulating CCL2 levels than controls. Decreased Mfn2 and Pkn1 expression in TGF-β1-treated human RMs was associated with increased fibrotic response.

Conclusions: This study is the first to suggest that myeloid-specific Mfn2 but not Mfn1 regulates renal macrophage mitophagy biogenesis and mitophagy prevents fibrosis. Mitophagy inducers may attenuate macrophage superoxide production and progression of kidney fibrosis.

EZH2 Mediates Renal Fibrosis and Links Activation of Notch Signaling and Suppression of Klotho and BMP-7 Expression
Shouyang Zhang,1,2 Shanghai East Hospital, Shanghai, China; ‘Rehace Isand Hospital, Brown University, Providence, RI; ‘Shanghai East Hospital, Shanghai Tongji University, Shanghai, China.

Background: Our previous studies have shown that pharmacological blocking EZH2 (Enhancer of Zeste Homolog 2), a histone H3 lysine 27 methyltransferase, attenuates renal fibrosis in a murine model of renal fibrosis, but the underlying mechanism in this process remain undefined.

Methods: In this study, we used two highly selective EZH2 inhibitors and conditional knockout mouse to evaluate the effect of EZH2 inhibition on renal fibrosis and activation of profibrotic signaling pathways and expression of renoprotective proteins in two in vivo mouse models of chronic kidney disease (CKD) induced by UUO and 5/6 nephrectomy (SNx).

Results: Global inhibition of EZH2 by administration of gamboxic acid or GSK-126 and conditional depletion of EZH2 in pericytes suppressed renal fibroblast activation and fibrogenesis in the kidney with UUO and SNx. Treatment with these inhibitors or EZH2 siRNA also inhibited serum- and TGF-β1-induced activation of renal fibroblasts in culture. Moreover, pharmacological and genetic inhibition of EZH2 suppressed expression of Notch-1, Notch-3, Jagged-1 and HES-1 and HEY-2 in vivo and in vitro. Similarly, inhibition of EZH2 was effective in inhibiting phosphorylation of extracellular signal-regulated kinase 1/2, AKT and NF-kB as well as expression of multiple profibrogenic cytokines/chemokines and renal macropage infiltration. In contrast, EZH2 inhibitors prevented injury-induced downregulation of Klotho and BMP-7, two anti-fibrotic proteins in the kidney.

Conclusions: These results revealed that EZH2 may promote renal fibrosis and activation of renal fibroblasts by activation of Notch signaling, downregulation of Klotho and BMP-7 and induction of inflammation in the injured kidney. Targeting EZH2 may be a novel therapeutic strategy to treat CKD.

Kidney Targeted Renalase Agonist Peptide Rescues Severe Model of Cisplatin-Induced AKI and CKD
Xiaojia Guo1, Leyuan Xu1, Heino Velazquez,1,2 Tian-Min Chen,1,2 Ryan Williams,1,4 Daniel A. Heller,1 Robert L. Saffirstein,1 Gary V. Desir.1,2 Yale University School of Medicine, New Haven, CT; ‘YAMC, West Haven, CT; ‘Sloan-Kettering Institute, New York, NY; ‘The City College of New York Division of Science, New York, NY.

Background: Cisplatin (CP) causes Chronic Kidney Disease (CKD) upon repeated doses and limits its chemotherapeutic use. Renalase (RNLS) is a protein that activates kinases linked to survival and attenuates acute ischemic and CP-induced kidney injury. We now seek to target delivery of RNLS specifically to kidney to prevent CP-induced CKD.

Methods: CKD was induced in RNLS knockout (KO) (severe) and wild type (WT) mice by 2 doses of CP 15 mg/kg 2 weeks apart. The RNLS agonist peptide RP81 was synthesized and encapsulated in mesoscale nanoparticles (MNP) that target the kidney. Its cytoprotective activity was tested in vitro using TKPTS proximal tubule cells and in vivo using RNLS-KO mice. RP81MNP or empty MNP was administered weekly for 4 weeks. RP81MNP was synthesized and encapsulated in mesoscale nanoparticles (MNP) that target the kidney. Its cytoprotective activity was tested in vitro using TKPTS proximal tubule cells and in vivo using RNLS-KO mice. RP81MNP or empty MNP was administered weekly for 4 weeks.

Results: Wild-type type mice showed increased expression of collagen I, collagen IV, vimentin and a-SMA in kidney tissues. The increase of collagen I was significantly attenuated in iRT-PKM2-KO mice, while collagen IV and vimentin induction was marginally inhibited and no inhibition for fibronectin and a-SMA in these mice. Wild-type type and iRT-PKM2-KO kidney tissues had similar levels of Sirius red staining of collagen fibrils. We further examined Lotus Tetragonolobus lectin (LTL) staining of proximal tubules, which detected obviously more intact proximal tubules in iRT-PKM2-KO mice than in wild-type litters.

Conclusions: Together, these results indicate a pathogenic role of glycolysis in maladaptive kidney repair. Importantly, PKM2 and associated metabolism contribute to the regeneration of renal tubules after acute kidney injury.

Pyruvate Kinase M2 in Renal Tubular Cells Is a Key Regulator of Kidney Repair After Ischemic Injury
Qingqing Wei,1 Zheng Dong,1,2 August University, Augusta, GA; ‘Augusta VA Medical Center, Augusta, GA.

Background: Tissue injury and repair is associated with changes of metabolism. In kidneys, metabolic changes including mitochondrial dysfunction and induction of glycolysis have been reported in renal fibrosis and chronic kidney disease. It remains unclear whether and how the metabolic changes contribute to kidney injury and repair. We have examined the effects of glycolysis inhibitors and the ablation of pyruvate kinase M2 (PKM2, an enzyme in glycolysis) in kidney tubules. Glycolysis inhibitors (including PKM2 inhibitor shikonin) suppressed renal fibrosis in the mouse model of unilateral ureter obstruction (UUO). Interestingly, in vitro the inhibitors suppressed fibrotic gene expression (e.g. fibronectin and a-SMA) in fibroblasts, but not in cultured renal tubular cells.

Methods: To further understand the role of glycolysis in renal tubular cells in vivo, we established a mouse model in which PKM2 ablation in renal tubule cells can be induced by doxycycline. To this end, PKM2-floxed mice were bred with Pax8-rtTA/LC1 CRE recombinase mice to create an inducible renal tubule-specific PKM2 knockout (iRT-PKM2-KO) mouse model. Exposure to doxycycline for 5-7 days induced PKM2 ablation in all renal tubules in iRT-PKM2-KO mice, but not in wild-type littersmates. These mice were subjected to 30 minutes of unilateral renal ischemia-reperfusion one day after initial doxycycline treatment, and kidneys were collected at 2 weeks later for histology, immunoblot analysis, and fibrosis staining.

Results: Wild-type type mice showed increased expression of collagen I, collagen IV, vimentin and a-SMA in kidney tissues. The increase of collagen I was significantly attenuated in iRT-PKM2-KO mice, while collagen IV and vimentin induction was marginally inhibited and no inhibition for fibronectin and a-SMA in these mice. Wild-type type and iRT-PKM2-KO kidney tissues had similar levels of Sirius red staining of collagen fibrils. We further examined Lotus Tetragonolobus lectin (LTL) staining of proximal tubules, which detected obviously more intact proximal tubules in iRT-PKM2-KO mice than in wild-type litters.

Conclusions: Together, these results indicate a pathogenic role of glycolysis in maladaptive kidney repair. Importantly, PKM2 and associated metabolism contribute to the regeneration of renal tubules after acute kidney injury.

in vitro studies, Sphk2 deficient perivascular cells expressed less inflammatory cytokines, such as Cxcl1, Itk, Tnf, after LPS stimulation compared with control perivascular cells. Sphk2 deficient and control perivascular cells robustly expressed Smn2, but not Md2h2, and S1pr1-3 among the five S1P receptor subtypes. Among S1pr1-3, only knockdown of S1pr1 resulted in suppressed expression of inflammatory cytokines after LPS stimulation.

Conclusions: Sphk2 deletion in renal perivascular cells was protective against kidney fibrosis. In vitro studies suggested that S1P produced by Sphk2 is exported through Smn2 and reacts with S1PR1 to enhance the inflammatory signal in these cells, leading to immune cell infiltration and subsequent fibrosis in the kidneys.

Histone Demethylase JMJD3 Protects Against Renal Fibrosis by Suppressing TGF-β and Notch Signaling

Chao Yu,1 Shouqiang Zhuang,1,2 Shanghai East Hospital, Shanghai Tongji University; 1Rhode Island Hospital, Brown University; 2Shanghai East Hospital, Shanghai Tongji University, Shanghai, China.

Background: The Jumonji domain containing-3 (JMJD3), a specific histone demethylase for trimethylation on histone H3 lysine 27 (H3K27me3), is associated with the pathogenesis of many diseases, but its role in renal fibrosis remains unexplored. Here, we examined the role of JMJD3 and mechanisms involved in the activation of renal fibroblasts and development of renal fibrosis.

Methods: Murine models of 5/6 nephrectomy (SNx) and ureteral unilateral obstruction (UUO) were used to assess the effect of a specific JMJD3 inhibitor, GSKJ4, and genetic deletion of JMJD3 from FOXD1 stroma-derived renal interstitial cells on the development of renal fibrosis and activation of renal interstitial fibroblasts. Cultured rat renal interstitial fibroblasts (NRK-49F) and mouse renal epithelial (mTECs) cells were also used to examine JMJD3-mediated activation of profibrotic signaling.

Results: JMJD3 and H3K27me3 expression levels were upregulated in the kidney of mice subjected to SNx, 5/6 and UUO. Pharmacological inhibition of JMJD3 with GSKJ4 completely prevented the activation of JMJD3 led to worsening of renal dysfunction as well as increased deposition of extracellular matrix proteins and activation of renal interstitial fibroblasts in the injured kidney. This was coincident with decreased expression of Smad7 and enhanced expression of H3K27me3, transforming growth factor β1 (TGFβ1), Smad3, Notch1, Notch3 and Jagged1. Inhibition of JMJD3 by GSKJ4 or its specific siRNA also resulted in the similar responses in cultured NRK-49F and mTECs exposed to serum or TGFβ1. Moreover, JMJD3 inhibition augmented phosphorylation of AKT and ERK1/2 in vivo and in vitro.

Conclusions: These results indicate that JMJD3 confers anti-fibrotic effects by limiting activation of multiple profibrotic signaling pathways and suggest that JMJD3 modulation may have therapeutic effects for chronic kidney disease.

Induction of CKD by Gene Deletion of Canonical Transient Receptor Potential 1 (TRPC1) Channels Independent of Hypertension and Nephromegaly Despite Diabetes and Metabolic Syndrome

Muhammad Mubeen Arwag, Usman A. Khan, Bonnie Eby, Kai Lau. The University of Oklahoma Health Sciences Center, Oklahoma City, OK.

Background: TRPC1 gene on chromosome 3q22-24 is in the linkage region for diabetic nephropathy. Despite reduced expression in diabetes, no causal relationship has been established. Since null mice are obese, hyperterglycemic and diabetic with fatty liver, we evaluated potential renal phenotypes, testing the hypothesis of impaired Ca signaling, as we found reduced cell free Ca in bone, renal, and parathyroid cells.

Methods: From 3rd to 22nd mon, metabolic, cardiac & abdominal ultrasound (US) & clearance (CL) studies were done in age- & sex-matched littermates of TRPC1 +/-, +/-, & -/- mice. Creatinine (Cr) was analyzed by creatininase or HPLC; glomerular filtration rate (GFR) by inulin Cl. Systolic (S) & diastolic (D) BP was measured by arterial (A) cannulation.

Results: Null mice were hyperglycemic from the 3rd mon & developed diabetes to 6 to 22 mon by standard IP glucose tolerance test. Nephromegaly was absent in null mice since kidney volume by US (0.38 vs 0.46 at 7 mon & 0.4 vs 0.5 cc at 11-20 mon) was 16% smaller & kidney (K) to body (B) weight (Wt) (1.2 vs 1.55 at 7 mon & 1.1 vs 1.5% at 11-20 mon) was lighter by 17-28%. Chronic injury & scarring were suggested by 37% increase in ecchogenicity at 20 mon, though normal at 7 or 11 mon. Urine albumin/cre ratio in null mice rose barely (64-71%). But at 17 mon, CrCl fell by 30% (p<0.01) in null ♀ & by 46% (p<0.01) in null ∆. GFR at 22 mon corroborated stage III CKD as inulin Cl fell by 44%. Whether expressed per mouse, per g Wt, or per 100 g BW, haploid TRPC1 deletion reduced CrCl by 40% (p<0.05) at 16 mon vs 44% by diplodip deletion (p<0.02).

TRPC1 deletion significantly reduced, not raised, mean SBP (113 vs 131 tort), DBP (77 vs 86 tort), & MABP (89 vs 98 tort). Since TRPC1 was implicated in cardiac hypertrophic signaling, smooth muscle proliferation & mesangial cell contraction, we did cardiac US & found 33% reduced cardiac output in -/- mice (14 vs 21 ml/min) & 14% smaller heart mass, corroborated by 20% lower weights measured at 22 mon.

Conclusions: 1. TRPC1 deficiency impairs Ca signaling, retards renal & heart development, compromises hemodynamics and modulates hypothalamic nephropathy. 2. Null mice provide an excellent model to study progressive CKD independent of hypertension and heavy proteinuria.

Sphingosine Kinase 2 in Kidney Perivascular Cells Promotes Inflammation and Fibrosis Through S1PR1 Signaling

Shinji Tanaka,1 Yugesh Kharel,2 Shuqiu Zheng,1 Jonathan E. Lipsey,1 Diane L. Rosin,1 Kevin Lynch,2 Mark D. Okusa.1 Division of Nephrology and Center for Immunity, Inflammation and Regenerative Medicine, University of Virginia, Charlottesville, VA; 2Department of Pharmacology, University of Virginia, Charlottesville, VA.

Background: Sphingosine-1-phosphate (SIP) is a sphingolipid, which is produced by two different kinases, sphingosine kinase (Sphk)1 and 2. SIP is exported through Spn2 or Mfd2h, and then reacts with S1P receptors (SIPR1-5) to affect myriad cell functions. We investigated whether the administration of PAR-1 antagonist vorapaxar, an FDA-approved drug for reducing thrombotic cardiovascular events, has any renoprotective effect in a robust kidney fibrosis murine CKD model following unilateral ischemia reperfusion injury (UIRI), as well as in hypoxia-induced cultured rat proximal tubular epithelial cells (NRK-52E).

Results: Vorapaxar reduced morphological abnormalities and the expression of tubular injury marker Kim-1 in URIIR mice. Mice treated with vorapaxor showed less intrarenal accumulation of ECM proteins including fibronectin, α-smooth muscle actin and collagen 1 via TGF-β-Smaling signaling after URIIR. IR-induced endothelial dysfunction and macrophage infiltration were also decreased by vorapaxar treatment. In NRK-52E cells, PAR-1 expression was activated under a hypoxic milieu associated with upregulation of TGF-β-induced ECM protein accumulation.

Conclusions: Vorapaxor diminishes renal fibrosis through TGF-β-Smaling signaling in URIIR model, and protects against tubular injury during AKI to CKD transition. A PAR-1 targeted strategy by vorapaxor as a therapeutic approach in human CKD warrants further. Funding: Health and Medical Research Fund (HMRF) of Hong Kong (grant no. 05163596), Research Grants Council of Hong Kong (Collaborative Research Fund, grant no. C7081-16A), and Hong Kong Society of Nephrology/ HK Foundation Kidney Research Grant 2018.

The PAR-1 Antagonist Vorapaxor Protects Against AKI to CKD Transition

Sarah W.Y. Lok,1 Wai Han Yiu,1 Loretta Y.Y. Chan,2 Joseph C K Leung,1 Kar Neng Lai,2 Sydney C. Tang.1 The University of Hong Kong, Queen Mary Hospital, Hong Kong, Hong Kong; 2The University of Hong Kong, Hong Kong, Hong Kong.

Background: Protease-activated receptor-1 (PAR-1) has been reported as a coagulation regulator in the pathophysiology of AKI. Beyond its normal function in haemostasis, aberrant PAR-1 signaling may lead to the development of tubulointerstitial fibrosis, and subsequently CKD.

Methods: We investigated whether the administration of PAR-1 antagonist vorapaxor, an FDA-approved drug for reducing thrombotic cardiovascular events, has any renoprotective effect in a robust kidney fibrosis murine CKD model following unilateral ischemia reperfusion injury (UIRI), as well as in hypoxia-induced cultured rat proximal tubular epithelial cells (NRK-52E).

Results: Vorapaxor reduced morphological abnormalities and the expression of tubular injury marker Kim-1 in URIIR mice. Mice treated with vorapaxor showed less intrarenal accumulation of ECM proteins including fibronectin, α-smooth muscle actin and collagen 1 via TGF-β-Smaling signaling after URIIR. IR-induced endothelial dysfunction and macrophage infiltration were also decreased by vorapaxar treatment. In NRK-52E cells, PAR-1 expression was activated under a hypoxic milieu associated with upregulation of TGF-β-induced ECM protein accumulation.

Conclusions: Vorapaxor diminishes renal fibrosis through TGF-β-Smaling signaling in URIIR model, and protects against tubular injury during AKI to CKD transition. A PAR-1 targeted strategy by vorapaxor as a therapeutic approach in human CKD warrants further. Histone Deacetylase 6 Inhibition Mitigates Renal Fibrosis by Suppressing TGF-β/SMAD3 and eGFR Signaling Pathways

Xingying Chen,1 Shougang Zhang,2,1 Shanghai East Hospital / Shanghai East Hospital, Shanghai Tongji University, Shanghai, China; 2Rhe Island Hospital, Brown University, Providence, RI.

Background: We have recently shown that histone deacetylase 6 (HDAC6) is critically involved in the pathogenesis of acute kidney injury, however, its role in renal fibrosis remains unclear.

Methods: In this study, we examined the effect of ricolinostat (ACY-1215), a selective inhibitor of HDAC6, on the development of renal fibrosis in a murine model induced by unilateral ureteral obstruction (UUO).

Results: We found that HDAC6 was highly expressed in the kidney following UUO injury, which was coincident with deposition of collagen fibrils and expression of α-smooth muscle actin, fibronectin, and collagen III. Administration of ACY-1215 reduced these fibrotic changes and inhibited UUO-induced expression of transforming growth factor β1 and profibrotic marker Smad3, and Smad7. ACY-1215 treatment also suppressed phosphorylation of epidermal growth factor receptor and several signaling molecules associated with renal fibrogenesis, including AKT, signal transducer and activator of transcription 3 and NF-kB in the injured kidney. Furthermore, ACY-1215 was effective in inhibiting de novo formation of renal fibroblasts to myofibroblasts in cultured renal interstitial fibroblasts.

Conclusions: Collectively, these results indicate that HDAC6 inhibition can attenuate renal fibrosis development by suppression of TGFβ1 and EGFR signaling.

Inhibition of KIM-1-Mediated Fatty Acid Uptake by a Novel Inhibitor Attenuates Pro-Fibrotic Responses in Multiple Models of Human Primary Kidney Epithelial Cells Including Kidney Tubuloids

Yutaro Mori,1 Amarendra K. Ajay,1 Ankit B. Patel,1 Andrew M. Siedlecki,1 Seiji Kishi,2 Takaharu Ichimura,1 Joseph V. Bonventre.1 Division of Renal Medicine, Department of Medicine, Brigham and Women’s Hospital, Harvard Medical School, Boston, MA; 1Department of Nephrology, Tokushima University Hospital, Tokushima, Japan.

Background: Tubulointerstitial damage is strongly associated with many forms of kidney injury including diabetic kidney disease. Kidney Injury Molecule-1 (KIM-1), a scavenger receptor, is the most upregulated proximal tubule protein with kidney injury. We hypothesized that KIM-1-mediated uptake of fatty acids (FAs) contributes to tubulointerstitial damage.

Methods: Human DKD renal biopsy samples were analyzed. Human primary epithelial cell cultures were established from the non-tumor kidney tissue removed from patients with a renal mass. To grow human renal tubuloids, primary cells were cultured on ultra-low attachment plates for several days. Cells were transferred into media containing multiple growth factors and 5% fetal bovine serum. Cells and tubuloids were treated with palmitate acid with certain groups having siRNA knockdown of KIM-1. Conditioned media from FA-treated human primary cells and tubuloids were applied to mouse primary kidney fibroblasts. An inhibitor for KIM-1-mediated FA-uptake was identified from cell depleted of KIM-1. We confirmed that KIM-1-mediated fatty acid uptake at least in part by inhibiting the direct binding of FA to KIM-1.

Results: KIM-1 expression in DKD patients was positively correlated with tubulointerstitial inflammation and fibrosis. FA-BSA uptake was markedly reduced in cells depleted of KIM-1 indicating the relative importance of KIM-1 to proximal tubule FA uptake. High-dose FA treatment increased cell death. FA treatment increased H2AX expression, a marker for DNA damage response. FA also increased the number of cells in the G2/M phase without an increase of those in S phase by cell cycle analysis, indicating that cells are likely arrested in G2/M phase. Our newly identified inhibitor for KIM-1, JB1, prevented FA uptake at least in part by inhibiting the direct binding of FA to KIM-1.

Conclusions: KIM-1 enhances the proximal tubular uptake of FA, leading to proximal tubule damage, pro-fibrotic responses and increase in cell death. Our findings support JB1 as a novel therapeutic target for chronic kidney disease including DDK and our work introduces a new candidate therapeutic agent.

Results: WT mice fed a HPI diet showed a significant 70% reduction in kidney HNF4α mRNA and protein expression, suggesting that hyperphosphatemia, a hallmark of progressive CKD, contributes to HNF4α downregulation in the kidney. Kidney molecular profiling by RNAseq of Col4a3<sup>−/−</sup> mice showed increased acquired mitochondrial dysfunction and reduced oxidative phosphorylation, suggesting that impaired mitochondrial function strongly contributes to CKD progression. Downstream pathway analyzes showed that the vast majority of these genes (~80%) are regulated by HNF4α. Pharmacological inhibition or HNF4α in Col4a3<sup>−/−</sup> mice led to an accelerated decline in kidney function (200% increase in BUN), demonstrating the crucial role of HNF4α in CKD progression.

Conclusions: These results suggest that HNF4α is a master regulator of mitochondrial function in kidney and might represent a novel therapeutic target to improve outcomes in CKD.

An In Vitro Model to Elucidate the Synthesis of Extracellular Matrix Proteins Involved in Renal Interstitial Fibrosis

Alexandra L. Meiler,1 Alexander L. Reece-Petersen,1 Daniel Guldager Kring,2 Federica Genovese,3 Morten A. Karsdal4 Fibrosis, Renal and Cardiovascular Research 1Nordic Bioscience, Herlev, Denmark; 2Biomedical Sciences, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark.

**Background:** Accumulation of extracellular matrix (ECM) proteins is a hallmark of renal fibrosis, which can lead to altered tissue homeostasis, kidney failure, and ultimately death. Many different cell types are involved in this process, but fibroblasts are the main source of ECM proteins such as fibronectin, collagen type I (COL I), III (COL III), and VI (COL VI). Recently it was suggested that a fragment of COL VI released during collagen maturation is, in fact, a bioactive molecule (endotrophin; ETP) with signaling potential, indicating that collagens are not just passive structural proteins. In this study, we investigated the effect of transforming growth factor (TGF)-β and ETP on the synthesis of different ECM proteins by human renal fibroblasts in the scar-in-a-jar (SiaJ) cell model.

**Methods:** Cells were seeded in 48-well plates at 30,000 cells/well and incubated for 24h in DMEM + 10% FBS for adherence. Cells were starved by incubating them for further 24h in DMEM + 0.4% FBS. Fresh medium was added at day 0 with 250/150 mg/mL Ficol 70/400 and 1% ascorbic acid, containing 0.02 nM TGF-β or either 12 or 30 nM ETP. Medium was changed and collected on days 3, 6, 10, and 13. Biomarkers of ECM formation, could be used to elucidate the mechanisms behind acute and sustained matrix production profiles.

**Results:** Stimulating renal fibroblasts with 0.02 nM TGF-β significantly increased the formation of COL I (P<0.0001), III (P<0.0001), and fibronectin (P<0.0001) compared to unstimulated cells. Interestingly, TGF-β treatment suppressed the formation of COL VI (P<0.0001) and E-cadherin (P<0.0001) in unstimulated cells. Stimulation with 30 nM ETP significantly increased the formation of COL I (P<0.0001) and III (P<0.0001) compared to unstimulated cells. 12 nM ETP significantly increased the synthesis of fibronectin compared to unstimulated cells (P<0.0001).

**Conclusions:** Different growth factors induce different protein expression profiles in fibroblasts. Interestingly, ETP, which originates from the ECM, drives renal fibrosis through increasing COL I and III as well as fibronectin. This SiaJ model, combined with the investigated biomarkers of ECM formation, could be used to elucidate the mechanisms behind acute and sustained matrix production profiles.

FoxM1 Inhibition Ameliorates Renal Interstitial Fibrosis (RIF) by Decreasing Extracellular Matrix and Epithelial-to-Mesenchymal Transition

Wang Y, Hui,1,2 Qiaoling Zhou,1 (Xiayang Hospital, Central South University, Changsha, China; 1Department of Geriatrics, Guangzhou First People’s Hospital, School of Medicine, South China University of Technology, Guangzhou, China).

**Background:** FoxM1 is a transcriptional regulator involved in tumor development, pulmonary fibrosis, and cardiac fibrosis. However, its role in RIF has yet to be elucidated.

**Methods:** We established a TGF-β1-stimulated human proximal tubular epithelial cell (HKT-2) model in vitro and a unilateral ureteral obstruction (UUO)-induced rat RIF model in vivo. FoxM1 inhibition was achieved by siRNA interference in vitro and by injecting thiostrepton into UUO-induced RIF rats in vivo. The degree of renal damage and fibrosis were determined by histological assessment via hematoxylin and eosin staining.

**Results:** Different growth factors induce different protein expression profiles in fibroblasts. Interestingly, ETP, which originates from the ECM, drives renal fibrosis through increasing COL I and III as well as fibronectin. This SiaJ model, combined with the investigated biomarkers of ECM formation, could be used to elucidate the mechanisms behind acute and sustained matrix production profiles.

**Conclusions:** Different growth factors induce different protein expression profiles in fibroblasts. Interestingly, ETP, which originates from the ECM, drives renal fibrosis through increasing COL I and III as well as fibronectin. This SiaJ model, combined with the investigated biomarkers of ECM formation, could be used to elucidate the mechanisms behind acute and sustained matrix production profiles.

The Macrophage Recruitment in the Unilateral Ureteral Obstruction Is Associated with the Raise of MCP-1 and Is Dependent of Lipoclin 2 Expression

Stefany M. Figueroa, Mauricio A. Lozano, Carolina A. Lobos, Javier I. Reyes Osorio, Patricio A. Araos, Cristian A. Amador. Laboratory of Renal Physiopathology Universidad Autonoma de Chile - Campus El Llano Suburbano, Santiago, Chile.

**Background:** The persistent renal inflammation has been proposed as a crucial mechanism at the early stages of renal disease. The macrophages recruitment, as part of the pathogenic events, depends of the monocyte chemoattractant protein-1 (MCP-1) raise. In addition, studies in patients have demonstrated that neutrophil gelatinase-associated lipocalin (NGAL, also called Lipocalin-2), is overexpressed during early stages of renal lesion. However, whether NGAL is relevant for macrophages recruitment at renal level, and if this is related to the increase of MCP-1, remains unknown. Our objective was to determine whether NGAL promotes the pro-inflammatory status during the unilateral ureteral obstruction (UUO), characterized by the macrophage recruitment and the increase of MCP-1.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Methods: Male C57BL/6 Wild type (WT) y Ngal-KO mice (8-12 weeks) were underwent to UUO surgery (control group) or Sham (2, 4, 5, 7 and 10 weeks), in order to determine the associated damage at kidney level and the raise of MCP-1 in peripheral blood mononuclear cells (PBMC).

Results: In WT mice, the UUO induced luminal tubular dilation starting at 3 days (P<0.001 vs Sham), and an induction of plasma area (76.36 ± 3.57 mL/D, P<0.001 vs Sham). In addition, UUO increased NGAL levels in PBMC, plasma and urine (24.1 ± μg/L in Sham vs. 103.8 ± μg/L and 134.5 ± μg/L in UUO, at 3 and 7 days, respectively). This was in accordance with the renal induction of NGAL (mRNA and protein, P<0.001 vs Sham), and increased expression of pro-inflammatory mediators: TGF-β1, CCL5 (RANTES) and MCP-1, with a peak at 7-days. The genetic ablation of NGAL prevented tubular dilation (34.24 ± 6.55 μm) (P<0.01 vs UUO WT) and the rise of MCP-1 induced by UUO in kidney and PBMC (P<0.01 vs WT). This was accompanied with a low grade of macrophagia in kidney of NGAL-KO mice underwent to UUO (15.2% in WT vs 7.3% in NGAL-KO).

Conclusions: The renal overexpression of MCP-1 and the macrophage recruitment induced by UUO is dependent of NGAL presence. Our results suggest that NGAL, by a regulation on MCP-1, may be crucial for macrophage chemotraction during the early stages of renal disease. Acknowledgments. Fondedey #1201251 and Fondedey #3201016

P00608
Enabled Icos + Rte-Tresp Proliferation Is Involved in the Pathogenesis of Active Systemic Lupus Erythematosus (SLE)

Florian Kälble,1 Christian Nischlag,1 Christian Morath,1 Martin G. Zeier,1 Matthias Schaier,1 Andrea Steinborn-Krozeh.2 1Department of Medicine I (Nephrology), University of Heidelberg, Heidelberg, Germany; 2Department of Obstetrics and Gynecology, University of Heidelberg, Heidelberg, Germany.

Background: Dysfunction of CD4+ regulatory T-cells (Tregs) and CD4+ responder T-cells (T-resps) is an important trigger in the development of active systemic lupus erythematosus. By now, underlying mechanisms are not fully understood.

Methods: To determine differences in the differentiation of inducible costimulatory molecule (ICOS)- and ICOS- Tresps/Tregs, their percentages of CD45RA CD31- recent thymic emigrant (RTE)-Tresp differentiation compared to healthy control patients. Hence, the ratio of ICOS -RTE-Tresp differentiation compared to healthy control patients. In contrast, proliferation of ICOS- RTE-Tressps into ICOS CD31-memory-Tregs is inhibited. Similarly, active SLE patients show an impaired proliferation of ICOS -CD31-memory Treg/Tresps within CD4+ Treg/Tresps were calculated. Additionally, subsets were stained for the proliferation marker Ki67. 124 healthy control patients and 117 with a preexist lupus erythematosus (102 patients in remission, 15 patients with a flare) were measured.

Results: SLE patients in remission showed an increased differentiation of ICOS+ RTE-Tregs and ICOS-RTE-Tresps via resting MN-Tregs into CD31-memory-Tregs compared to healthy control patients. In contrast, proliferation of ICOS- RTE-Tressps into ICOS CD31-memory-Tregs is inhibited. Similarly, active SLE patients show an increased differentiation of ICOS- RTE-Tresps and ICOS-RTE-Tresps via resting MN-Tregs. Moreover, proliferation ability of ICOS- RTE-Tresps is not inhibited but enhanced in these patients. Both SLE patients in remission and active SLE patients show an impaired ICOS- RTE-Tresp differentiation compared to healthy control patients. Hence, the ratio of ICOS-Tregs/ICOS-Tresps within CD4+T-cells is significantly increased in both SLE remission and active SLE patients compared to healthy control patients. In contrast, the ratio of ICOS-Tregs/ICOS-Tresps is significantly increased in SLE remission patients, but decreased in active SLE patients compared to healthy control patients.

Conclusions: Proliferation of ICOS- RTE-Tressps is medically inhibited in SLE remission patients. In active SLE patients, proliferation is enabled decreasing the ICOS- Treg/ICOS-Tresp ratio.

Involvement of Calcium-Sensing Receptor in the Development of Interstitial Fibrosis

Akira Kuroawa,1 Kaori Takeyagi,1 Taisuke Shimizu,1 Masaki Terao,1 Hiroaki Hara,1 Takatsugu Iwashita,1 Hajime Hasegawa,1 Department of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawasaki, Japan.

Background: Physiological and pathophysiological role of renal Ca sensing receptor (CaSR) have not been well understood. We have reported the down regulation of CaSR in obstructive chronic renal fibrosis along with the down regulation of Mg transporting molecules, suggesting that CaSR plays an important role in the development of renal damage associated with Mg deficiency. We have reported the down regulation of CaSR expression of claudin-14, 16 and 19, Mg transpirting molecules, seemed to be increased by parathyroid surgery (t), however, it was not statistically significant. However, Cinacalcet partially, but significantly increased the mRNA expression of TRPM6 compared to UUO group (sham: 1.01±0.07, UUO: 0.35±0.01, Cinacalcet: 0.41±0.02).

Conclusions: The expression of claudin-16 and TRPM6 was significantly decreased with development of fibrosis in UUO. The effect of CaSR activation and upregulation by Cinacalcet was limited, however, it restored the progression of fibrosis and impairment of Mg reabsorption. CaSR may play a key role for the Mg loss-related renal fibrosis.

P00610
Fibroblast-Specific LRP-1 Promotes Renal Fibrosis

Ling Lin, Kebin Hu. Penn State University College of Medicine, Hershey, PA.

Background: LRP-1, a scavenger receptor up-regulated during obstructive nephropathy, has been shown to mediate the actions of multiple profibrotic factors including TGF-β1, TGF-β1, and CTGF. However, the in vivo role of LRP-1 in kidney fibrosis remains largely unknown.

Methods: We generated a novel fibroblast-specific LRP-1 knockout mouse (Lrp-1−/−) and induced the unilateral ureteral obstruction (UUO), a classic model of chronic kidney disease (CKD), in these mice to investigate the in vivo role of LRP-1 in kidney fibrosis.

Results: It was found that LRP-1−/− mice had similar phenotype as their littermate controls (Lrp-1+/−). However, after UUO injury, Lrp-1−/− mice displayed significantly decreased fibrosis, as demonstrated by reduced renal collagen content and FSP-1 abundance, in comparison with their littermates. We further found that obstruction-induced epithelial damage was alleviated in Lrp-1−/− mice. After UUO, LRP-1+/− mice displayed decreased E-cadherin and increased vimentin expression, suggesting that epithelio-mesenchymal transition (EMT) was induced in the obstructed kidneys. Intriguingly, Lrp-1−/− mice showed significantly reduced EMT as demonstrated by restoration of E-cadherin and elimination of vimentin induction.

Conclusions: Thus, it is clear that fibroblast LRP-1 promotes kidney fibrosis through EMT.

Essential Renal Tubular Proteins Are Lost by Excretion Within Novel Large Extracellular Vesicles During Chronic Renal Insufficiency

Ryan J. Adam, Brian R. Hoffmann, Alison J. Kriegel. Medical College of Wisconsin, Milwaukee, WI.

Background: Within weeks of surgery, the 5/6 nephrectomy (5/6Nx) rat spontaneously develops renal disease including tubular damage, brush border loss, and the production of very large extracellular vesicles present in the tubule lumen. These large renal tubule extracellular vesicles (LRT-EVs) are too large to be microsomes or exosomes, and lack markers of apoptotic bodies, and thus may represent an undescribed vesicle. We hypothesized that formation and excretion of these vesicles represents a pathological mechanism by which important tubule proteins are lost in chronic renal insufficiency.

Methods: We performed a longitudinal, histologic examination for the presence of LRT-EVs isolated from 5/6Nx rat urine 10 weeks following surgery.

Results: Histologic examination revealed virtually no LRT-EVs in sham-operated rat tubules at any time point. LRT-EVs were present in 5/6Nx rat tubules at all measured time points including 2, 4, 5, 7, and 10 weeks post-surgery, and exhibited a marked increase in percentage of tubule presence between week 5 (7.0 ± 2.7%) and week 7 (51.1 ± 6.5%). This increase temporally corresponds to a time of rapid progression of renal disease. Median LRT-EV diameter upon microscopic image analysis was 2.5 μm. Protemic analysis of isolated LRT-EVs revealed them to contain a wide array of functionally essential tubule proteins including but not limited to basolateral Na+/K+ ATPase subunits, sodium-glucose co-transporters, aquaporin 1, megalin, cubulin, and mitochondrial VDAC.

Conclusions: Loss of important tubule proteins through production and urinary excretion of previously unidentified LRT-EVs may represent a hitherto unappreciated aspect of chronic renal insufficiency.

Indoleamine-2, 3-Dioxygenase Activates Wnt/β-Catenin to Induce Kidney Fibrosis

Binbin Pan1, Changchun Cao,1 Xin Wan2, 3Nanjing Medical University, Sir Run Run Hospital, Nangjing, China; 2Nanjing First Hospital, Nanjing Medical University, Nangjing, China.

Background: Dysorder of tryptophan metabolism catalyzed by indoleamine-2, 3-dioxygenase (IDO) is common in chronic kidney disease which manifests as increased kidney fibrosis. IDO is also reported to be involved in fibrosis of other organs while little is known about correlations of IDO and fibrosis in kidney disease.

Methods: Wild type (WT) mice and IDO− mice were employed. Mice in Sham group underwent exposure of renal artery while mice in AKI group received unique renal artery ischemia-reperfusion injury (IRI) and the contralateral kidney was removed at day 13 after surgery. The IDO markers were analyzed. Prostaglandin E2 (PGE2) was administrated to WT AKI mice. Clinically, a total of 115 CKD patients and 30 non-CKD patients were recruited. IDO was

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
calculated by the ratio of kynurenine and tryptophan. Correlations between indicators were analyzed. The ROC curve was also performed. 

**Results:** WT AKI mice revealed elevated expression of IDO and worse kidney function. PAS staining exhibited less loss of tubular epithelial cells and atrophy tubules in IDO−/− AKI mice. Additionally, fibrosis markers, including α-SMA, fibronectin and vimentin, were more severer in WT AKI mice. GSK-3β and β-catenin were significantly decline in IDO−/− AKI mice. On top of that, PGE2 administration revealed reduced IDO expression and decreased levels of GSK-3β and β-catenin resulting in lower expressions of α-SMA, fibronectin and vimentin in WT AKI mice. In patients, IDO had negative correlations with eGFR (r = -0.742, p = 0.001). Further, the linear regression showed IDO was an independent influence factor of eGFR. ROC curve showed the area under the ROC curve was 0.825 for IDO.

**Conclusions:** IDO could activate Wnt/β-catenin pathway to induce kidney fibrosis. PGE2 could ameliorate kidney fibrosis via inhibiting IDO expression.

**Figure:** Scatter plot of IDO associated with eGFR

**Human Induced Pluripotent Stem Cell-Derived Kidney Micro-Organoids for High Throughput Disease Modeling in Drug Discovery**

Santhosh V. Kumar,1 Anna Jonebring,2 Pernille B. Laerkegaard Hansen,3 Ryan Hicks,2 Kevin Woollard.1 AZ Kidney-organoids 2Bioscience Renal, Research and Early Development Cardiovascular, Renal and Metabolism (CVRM) BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; 3Translational Genomics, Discovery Sciences, R&D, AstraZeneca, Gothenburg, Sweden

**Background:** Human kidney contains around 1 million nephrons, more than 2 dozen different cell types. Reproducing physiological kidney cell types in vitro is limited. Recent advancements in human iPSCs differentiation provide an opportunity to culture and utilize multicellular kidney structures “kidney-organoids”. We have employed a kidney micro-organoid in suspension culture this method eventually accelerates kidney organoids to the industrial scale and differentiates from traditional low throughput transplant organoids. This method involves differentiation of iPSCs to intermediate mesoderm using CHIR and FGF9 and spontaneous aggregation in the swirler culture leads to mature to kidney organoids, this can be used to study kidney disease in a high-throughput manner.

**Methods:** We aimed to model human kidney inflammatory and genetic disease in vitro using kidney micro-organoids, treatment with different insults to reproduce CKD microenvironment eg. IL-1β, TGFβ, Angiotensin-II and prostate sulphate.

**Results:** After 24h of stimulation, we noted significant upregulation of kidney injury biomarkers including KIM1 and inflammatory cytokines. Reproducing genetic diseases like PKD is very challenging in vitro, we show treatment of cultured micro-organoids with forskolin (to elevate intracellular cAMP) altered the transportation of ciliary proteins and promoted cyst formation, resembling human PKD. These observations clearly demonstrate the use of micro-kidney organoids to study renal diseases in vitro for drug discovery applications with human translatable functional biomarkers.

**Conclusions:** Impact statement: Kidney micro-organoids provide a platform for high throughput modeling of human kidney diseases related fibrosis, inflammation and genetic disease like polycystic kidney disease with human translatable biomarkers in drug discovery.

**CKD of Unknown Origin (CKDuo): Is the Problem Dehydration, Water Contamination, or Both?**

Vito M. Campese,1 Alessia Fornoni,2 Yan Zhong,1 Keck School of Medicine of USC, Los Angeles, CA; 2University of Miami, Miami, FL.

**Background:** An increasing number of people of Central America develop CKDuo. The disease is characterized by chronic tubulo-interstitial nephritis. Occasionally, it presents as an acute kidney injury (AKIuo). The cause(s) remain unknown. Some sustain that dehydration is responsible. Others believe the disease is caused by water contaminated with heavy minerals or agrochemicals. To prevent dehydration, workers in these regions ingest 8-12L of water/day. Hence, even if concentrations of toxins are in “acceptable range”, the cumulative intake may reach toxic levels. If this hypothesis is correct, purified water should reduce the incidence of the disease. In 2017 a Nicaraguan sugarcane factory (SER) adhered to the Adelante initiative, consisting of reducing working hours, exposure to heat and dehydration. In 2017-18, these measures had no impact on the incidence of AKIuo.

**Methods:** During the 2019 season, SER adopted the policy of providing highly purified drinking water to > 6000 workers (1L/hour during working hours). The effects on AKIuo were monitored. Comparisons were made of the monthly incidence of AKIuo during years 2017, 2018 and 2019, by One-way ANOVA.

**Results:** With the introduction of purified water, the incidence of AKIuo decreased from 4.0±1.3 cases in 2017 and 3.4±2.1 in 2018 to 2.0±1.5 cases/1000 workers/month in 2019 (P< 0.02). (Fig.1)

**Conclusions:** Although preliminary, these data support the hypothesis that contaminated water may play a major role in AKIuo. This raises enormous public health issues. If dehydration is responsible, the remedies are hydration and less heat exposure. If toxins and agrochemical are responsible, the remedy is providing highly purified water to those at risk. The potential impact of these measures on CKDuo remains to be determined.
Results: Under normoxia, the serum phosphorus (P*) tend to be lower in umod− group compared with WT group (1.9±0.2 vs 2.1±0.2 mmol/L, P=0.064). Under normoxia environment, the α-diversity of gut microbiota decreased in umod− group compared with WT group (Chao1 index, 301.8±55.3 vs 374.3±80.7, P=0.005), and the composition of microbiota was clearly separated between two groups (PCoA, P<0.001). The abundance of g-Lactobacillus (P<0.002) and g-Phascolarctobacterium (P=0.026) increased and g-Ruminococcus (P=0.023) decreased in umod+ group compared with WT group. g-Ruminococcus showed positive relationship with serum phosphorus (R=0.511, P<0.001). Results: Under normoxia, the serum phosphorus (P*) tend to be lower in umod− group compared with WT group (1.9±0.2 vs 2.1±0.2 mmol/L, P=0.064). Under normoxia environment, the α-diversity of gut microbiota decreased in umod− group compared with WT group (Chao1 index, 301.8±55.3 vs 374.3±80.7, P=0.005), and the composition of microbiota was clearly separated between two groups (PCoA, P<0.001). The abundance of g-Lactobacillus (P<0.002) and g-Phascolarctobacterium (P=0.026) increased and g-Ruminococcus (P=0.023) decreased in umod− group compared with WT group. g-Ruminococcus showed positive relationship with serum phosphorus (R=0.511, P<0.001). When CIH was added as an environment condition, the serum phosphorus (P*) increased in umod− group obviously (2.3±0.3 vs 1.8±0.2 mmol/L, P=0.002). Gut composition in umod− were still clearly separated from WT (PCoA, P<0.001). The abundance of g-Lactobacillus, g-Phascolarctobacterium and g-Ruminococcus showed no difference. The abundance of g-Blautia (P=0.008), g-Sutterella (P=0.008), g-Anaerostipes (P=0.008) increased and g-Flavonifractor (P=0.008) and g-Anaerotruncus (P=0.008) decreased in umod− CIH group compared with wild type CIH group. G-Sutterella showed positive relationship with Phosphorus (R=0.831, P<0.001).

Conclusions: Chronic intermittent hypoxia can interact with uromodulin to affect serum phosphorus in umod− rats. These changes were strongly linked to the alterations in gut microbiota.

PO0616
Influence of Colonic Dialysis on the Distribution of Gut Microbiome in CKD Stage 3-5 Patients
Hui Xu, Department of Nephrology, Xiangya Hospital, Central South University, Changsha, China.

Background: Chronic kidney disease (CKD) becomes a major public health challenge given high incidence rates in the world. colonic dialysis (CD) has been used in pre-dialysis CKD patients (CKD3-5) in many hospitals of China because of its advantages of simple operation, low price and few complications. The gut microbiome is a potential cause of CKD progression and serve as a promising therapeutic target. We raise the question that whether CIH improve renal function by affecting intestinal microbiome in CD patients. Improving the imbalance of intestinal microbiome is considered a potential therapeutic target to decline chronic kidney disease (CKD) progression. We aimed to investigate the influence of colonic dialysis (CD) on the distribution of gut microbiome in CKD3-5 patients.

Methods: We studied gut microbiota in 50 patients with CKD, 25 CD patients, 25 outpatients (OP), and compared to 34 healthy subjects (HS). The gut microbiome composition was analyzed by a 16S ribosomal RNA (16S rRNA) gene-based sequencing protocol.

Results: We found that there was no significant difference in the richness of intestinal microbiota between CD and HS, but the richness of bacterial in OP decreased significantly (HS VS. OP p = 0.062). CD can increase the abundance of some short chain fatty acid (SCFA) producing bacteria and decrease the abundance of some uremic toxin producing bacteria. CD also can increase the abundance of some anaerobic bacteria in intestine. Compared with OP, the profile of intestinal microbiota in CD group and HS group was more similarity.

Conclusions: Our study reveals CD treatment alters microbiome profile and increases microbiome richness in CKD3-5.

PO0617
Asymptomatic Hyperuricemia, a Regulator of Innate Immunity in CKD
Stefanie Steiger,1 Qiuyue Ma,1 Paola Romagnani,2 Hans J. Anders,1 1Division of Nephrology, Department of Medicine IV, LMU Hospital, Munich, Germany; 2Department of Biomedical Experimental and Clinical Sciences Maria Serio, University of Florence, Florence, Italy.

Background: Asymptomatic hyperuricemia (HU) is common in patients with chronic kidney disease (CKD) but the causative role of HU on CKD progression remains controversial. Two large multi-center randomized controlled trials, CKD-FIX and PERL study, have now disproven a causal relation. On the other hand, a causative role of HU exists with gout but a rapid correction of HU with urate lowering therapy can also elicit acute gout attacks. This suggests a more complex role of HU in this context. Hence, we hypothesized that soluble uric acid (sUA) has immunomodulatory effects on neutrophil function during the immune response to monosodium urate (MSU) crystals.

Methods: Alb-creERT2;Glut9lox/lox and Glut9lox/lox control mice were injected with tamoxifen and placed either on a chow or acidogenic diet with inosine to induce HU with or without CKD. After 3 weeks, MSU crystals or vehicle were injected into air pouches or postcapillary venules in the cremaster muscle of transgenic mice. Leukocyte infiltration and the extent of inflammation were assessed by flow cytometry, intravital microscopy, and ELISA. Blood neutrophils were isolated from CKD stage G2-4 and G5D patients or healthy individuals and neutrophil transwell migration assays performed.

Results: We found that HU impaired leukocyte recruitment into MSU crystal-injected air pouches of mice with or without CKD. Intravital microscopy revealed that HU specifically reduced leukocyte adhesion, extravasation, and tissue inflammation. The CKD-mediated attenuation of MSU crystal-induced inflammation was fully reversible by treating HU with urate lowering therapy. In neutrophils isolated from healthy individuals, sUA diminished β2 integrin activation and expression, and hence impaired neutrophil migration ex vivo. This process was dependent on the intracellular uptake of sUA via the urate transporter SLC2A9/GLUT9. An impaired migratory capability was also observed in neutrophils from CKD patients.

Conclusions: We identify sUA as an endogenous modulator of innate immunity. HU modulates neutrophil migration by altering efficient β2 integrin activation via SLC2A9 in gouty arthritis related or unrelated to CKD. This process provides a molecular explanation for several previously unexplained clinical phenomena in the context of gout and renal failure.

Serum Lysyl Oxidase Is a Potential Diagnostic Biomarker for Kidney Fibrosis
Xiaojin Zhang, Chen Yu. Department of Nephrology, Tongji Hospital, Tongji University, Shanghai, China, Shanghai, China.

Background: Kidney fibrosis is the ultimate consequence of advanced stages of chronic kidney disease (CKD); however, there are currently no reliable biomarkers or noninvasive diagnostic tests available for the detection of kidney fibrosis. Lysyl oxidase (LOX) promotes collagen crosslinking, and serum LOX levels have been shown to be elevated in patients with fibrosis of the heart, lungs and liver. However, serum LOX levels have not been reported in patients with kidney fibrosis. We explored whether serum LOX levels are associated with kidney fibrosis.

Methods: Overall, 202 patients with kidney disease underwent renal biopsy, scoring of kidney fibrosis and determination of the area of kidney fibrosis. LOX levels were measured in serum and in kidney tissues. We analyzed the association of circulating LOX and tissue LOX levels with the scores and areas of kidney fibrosis. LOX expression was also investigated in vitro and in vivo kidney fibrosis models.

Results: Serum LOX levels were higher in patients with kidney fibrosis than in those without kidney fibrosis (p<0.001) and higher in patients with moderate-severe kidney fibrosis than in patients with mild kidney fibrosis (p=0.001). Both serum LOX and renal tissue LOX levels correlated with the area of kidney fibrosis (r=0.74, p<0.001; r=0.899, p<0.001, respectively). ROC curve analysis of serum LOX levels showed an AUC of 0.80 (95% CI: 0.74 to 0.86). The optimal serum LOX level cutoff point was 235.34 μg/ml for the prediction of kidney fibrosis and 306.56 μg/ml for the prediction of moderate-severe renal fibrosis. LOX expression levels were significantly upregulated (2.3-, 2.6- and 6-fold, respectively) in vitro and in vivo interstitial fibrosis models.

Conclusions: Both serum LOX and tissue LOX levels correlated with the presence and degree of kidney fibrosis in patients with CKD. These results suggest that serum LOX level can be a novel potential diagnostic biomarker for kidney fibrosis and may further potentially serve as a stratified biomarker for the identification of mild and moderate-severe kidney fibrosis.

Proximal Tubule Albumin Uptake: Potential Role for Endothelin System in Sickle Cell Disease Mice
Malgorzata Kasztan, David M. Pollock. University of Alabama at Birmingham, Birmingham, AL.

Background: Elevated plasma endothelin-1 (ET-1) reported in sickle cell disease (SCD) patients correlate with microalbuminuria, a major mortality risk factor in SCD. ET-1 contributes to glomerular and tubular injury in SCD, as evidenced by increased glomerular permeability to albumin and urinary excretion of tubular injury markers. Although selective ET receptor antagonism reduces albuminuria in humanized sickle cell (HbSS) mice, the mechanism of this action remains unclear. The aim of the study was to determine whether selective ET receptor antagonism prevents albuminuria by preserving the expression of tubular albumin-associated transporters in proximal tubule (PT) cells.

Methods: Male C57BL/6 or HbSS and genetic control (HbAA) mice were used to determine the effect of ET-1 on the expression of proximal tubule albumin trafficking mediators, such as megalin and NHE-3.

Results: Exposure of primary mouse PT cells to ET-1 (50μM) for 8h decreased megalin (53% reduction) and doubled NHE-3 expression. Pre-treatment with the ETα antagonist, BQ123 (1 μM), preserved megalin expression and had no effect on NHE-3. Moreover, selective ETα receptor blockade (BQ788, 1 μM) prevented ET-1 mediated increase in NHE-3 expression. Primary PT cells isolated from HbSS mice showed decreased megalin mRNA expression as well as protein abundance relative to HbAA PT controls. Ten-week treatment with selective ETα receptor antagonist (10mg/kg/day) preserved expression of megalin at control levels. There were no differences in NHE-3 mRNA expression in HbSS PT cells regardless the treatment. Interestingly, PT cells from HbSS cultured with HbSS plasma and ET-1 (10μM) had decreased NHE-3 protein abundance compared to non-treated cells.

Conclusions: These results potentially uncover a novel role for ET-1 in PT albumin handling. Our data suggest that PT ET-1 receptor signaling contributes to albuminuria in SCD.

Phosphate and Fibroblast Growth Factor 23 Are Mediators of Lung Injury in CKD
Seth Bollenbeker,1 Brian A. Craya,2 Molly Easter,1 Dominik Krentz,2 Jarrod W. Barnes,2 Christian Faul,2 Stefanie Krick.1 University of Alabama at Birmingham, Division of Pulmonary, Allergy, and Critical Care Medicine, Birmingham, AL; 1University of Alabama at Birmingham, Division of Nephrology, Birmingham, AL.

Background: Although well-documented in chronic kidney disease (CKD), the role of phosphate diet in pulmonary pathology is not widely known. Phosphorus, or phosphate in its oxidized circulating form, is normally removed from the body by healthy kidneys. CKD disrupts this process, leading to hyperphosphatemia in later stages. We have shown that fibroblast growth factor 23 (FGF23), a key regulator of phosphate metabolism, is elevated in inflammatory lung diseases; that increase in FGF23 contributes to unfavorable clinical outcomes. To improve outcomes for patients with concomitant CKD and pulmonary disease, we wanted to examine direct actions of phosphate and FGF23 and their potential underlying mechanisms.

Methods: For in vitro experiments, human lung fibroblasts were treated with 0 to 5 mM sodium phosphate. Expression levels of interleukin (IL)-8 and collagen (COL1)A1 were analyzed by qPCR. Cell counts and viability were quantified with trypan blue staining. In vivo, we placed C57BL/6 mice on a high phosphate (3%) diet to elevate serum phosphate levels in absence of kidney injury and administered bleomycin via oropharyngeal aspiration to generate an acute pulmonary inflammatory response. Serum FGF23 levels were measured by ELISA and serum analysis for phosphate and renal function were obtained. Expression of FGF23 pathway and inflammatory markers were analyzed in murine lung and kidney tissue using qPCR and western blotting.

Results: Augmented phosphate concentrations increased IL-8 and COL1A1 expression from human lung fibroblasts with a concomitant reduction in overall cell number. Serum FGF23 levels were significantly upregulated in mice on a high phosphate diet and further increased in these mice when exposed to bleomycin. Serum phosphate and creatinine levels were significantly elevated. High phosphate and bleomycin increased local FGF23 expression in murine lung tissue.

Conclusions: Upregulation of FGF23 in response to bleomycin during a high phosphate diet suggests that inflammation induced by primary lung injury is worsened by systemic elevation of serum phosphate levels. Our data suggest that in CKD, high serum phosphate levels may increase susceptibility and progression of lung injury. Our results indicate that the existence of a pulmo-renal crosstalk is exaggerating pulmonary injury.

APOL1 Risk Variants Mediate Increased Oxidative Phosphorylation Complexes Biogenesis and Mitochondrial Dysfunction
Mengyuan Ge,1 Gloria Michelle Ducasa,1 Shamroop Kumar Mallela,1 Shaoyi Liu,2 Hazel H. Szeto,2 Jeffrey B. Kopp,1 Flavia Fontanesi,1 Sandra M. Merscher,1 Alesia Fornoni,1 Katz Family Division of Nephrology and Hypertension/ Drug Discovery Center, University of Miami, Miami, FL; 2Social Profit Network Research Lab, Alexandria LaunchLabs, New York, NY; 1Kidney Disease Section, NIDDK, NIH, Bethesda, MD; 2Department of Biochemistry and Molecular Biology, University of Miami, Miami, FL.

Background: Susceptibility to focal segmental glomerulosclerosis (FSGS) in African Americans is associated with genetic variants of the Apolipoprotein L1 gene (APOL1) named G1 and G2. APOL1 risk variants (RV) are a major driver of mitochondrial dysfunction. The mitochondrial specific lipid cardiolipin (CL) interacts with oxidative phosphorylation (OXPHOS) complexes and plays an important role in the biogenesis of OXPHOS complexes. While APOL1 function was assessed in tagged and overexpressed systems, studies evaluating the functions of endogenous APOL1 protein are missing.

Methods: We studied mitochondrial function using human urinary podocyte-like epithelial cells (HUPECs) established from patients with FSGS carrying different APOL1 alleles. Protein and mRNA levels were measured by WB and quantitative PCR respectively. TEM was performed to study mitochondrial morphology. OXPHOS complexes were studied by BN-PAGE analysis followed by WB. To study how APOL1 RV contributes to mitochondrial dysfunction, we purified APOL1-G0/R4 protein using HeLa cells infected with lentivirus carrying the APOL1 G0/G1 under the CMV promoter, followed by protein-lipid overlay assay.

Results: The expression of endogenous APOL1 was decreased in HUPECs carrying RVs (G1/G2 HUPECs) when compared to G0/G0 carrying HUPECs. We observed reduced mitochondrial function in the presence of increased OXPHOS complexes in G1/G2 HUPECs. Using TEM, reduced mitochondrial matrix density and increased mitochondrial area were detected in G1/G2 HUPECs. Hyperbranched mitochondria in G1/G2 HUPECs were validated by the mRNA levels of mitochondrial fission and fusion proteins FIS1 and MFN1. The affinity of APOL1 G1 to CL was significantly higher than the affinity of APOL1 G0 to CL, when normalized to 6His tagged APOL1 expression. We found the mRNA levels of cardiolipin synthase (CRSL1) was significantly increased in G1/G2 HUPECs, which is consistent with the overexpression of OXPHOS complexes in G1/G2 HUPECs.

Conclusions: Our findings indicate that endogenous APOL1 RV expression in human podocytes is associated with mitochondrial dysfunction in the presence of increased OXPHOS complexes, and that APOL1 RVs interact with CL thus interfering with CL function in mitochondria.

Uncovering Genomic Alterations in DOCA-Salt Nephropathy Rats Treated with Finerenone
Junnan Wu,1 Ziyuan Ma,1 Hana Cernecka,2 Ralf Lesche,2 Peter Kolkhof,1 Katalin Susztak,1 University of Pennsylvania, Philadelphia, PA; 2Bayer AG, Leverkusen, Germany.

Background: The aldosterone antagonist spironolactone has antibiotic effects but its clinical use is limited due hyperkalaemia, especially in patients with kidney disease. The mitochondrial specific lipid cardiolipin (CL) interacts with oxidative phosphorylation (OXPHOS) complexes and plays an important role in the biogenesis of OXPHOS complexes. While APOL1 function was assessed in tagged and overexpressed systems, studies evaluating the functions of endogenous APOL1 protein are missing. Our previous work has shown that mitochondrial dysfunction is increased in the presence of endogenous APOL1 RV expression in human podocytes. We have recently developed with pronounced antibiotic activity at doses which have only limited effect on the potassium homeostasis. The exact mitochondrial transcriptional targets of spironolactone and finerenone, however, remain unknown. Since there are more than 20 different members in the ATP synthase, single cell RNA and single cell epigenome (ATAC) profiling can help to define transcriptional targets.

Methods: We treated uninephrectomized, Sprague-Dawley rats injected with DOCA and salt with a high dose of finerenone (10mg/kg/d), spironolactone (50mg/kg/d), or vehicle. Blood pressure parameters included blood pressure, serum and urine electrolytes, albuminuria, renal and cardiac histology. Single nuclei suspensions was prepared from kidneys and hearts for single nuclear RNA and single nuclear open chromatin (ATAC) profiling using the 10X Genomics Chromium platform as well as bulk RNA sequencing.

Results: Fierenone and spironolactone resulted the same degree of blood pressure reduction. DOCA treated rats developed severe myocardial hypertrophy and focal vascuopathy, glomerulosclerosis and tubulointerstitial fibrosis. Fierenone significantly attenuated cardiac and renal histological damage. DOCA-salt rats developed marked albuminuria which was significantly attenuated by spironolactone and finerenone. Serum potassium was elevated in the spironolactone group at weeks 6, but it was unchanged compared to controls in the finerenone group. Bulk RNA-seq results revealed the reduced enrichment of immune response related transcripts in finerenone group compared with DOCA and spironolactone group. Single-cell RNA-seq and single cell epigenome profiling uncovered genomic alterations in different cell types in finerenone-treated kidneys.

Conclusions: Taken together, these findings demonstrated that treatment with finerenone protected from DOCA salt induced cardiac hypertrophy, glomerulosclerosis and tubulointerstitial fibrosis without a significant increase in serum potassium. Single cell epigenome analysis highlighted transcriptional targets of aldosterone, spironolactone and finerenone.

Cell Type-Specific Chromatin Architecture Reveals Target Genes for Kidney Disease Risk Variants
Jingping Yang,1,2 Aiping Duan,1 Zhihong Liu,1 National Clinical Research Center of Kidney Diseases, Jining Hospital, Nanjing, China; 2Nanjing University, Nanjing, China.

Background: Although GWAS studies have identified hundreds of genetic variants associated with kidney diseases, the identification of causal variants and their target genes are rather limited. Most of disease-associated variants locate in non-coding elements. The roles of these elements are cell type-specific. Additionally, due to the non-linear regulation of the elements, the identification of causal variants as well as their target genes is even more challenging.

Methods: In order to understand the genetic risk of kidney diseases, we generated a cell type-specific set of epigenetic landscape including transcription-centered 3D chromatin organization, histone modifications distribution and transcriptome with HiChIP, ChIP-seq and RNA-seq respectively, in kidney tubule cells. We further pinpointed the target genes for the variants and validated two target genes by CRISP techniques in zebrafish, demonstrating that SLC24A1 and MTX1 were indispensable genes to maintain kidney function.

Conclusions: Our results produce valuable multi-omic resource and establish a bioinformatic pipeline in dissecting functions of kidney diseases-associated variants based on cell type-specific epigenetic landscape.

PO0625
A Comprehensive Transcriptome Profiling of Adipocyte Na-K-ATPase Signaling in Uremic Cardiomyopathy by RNA Sequencing Analysis
Komal Sodhi,1 Joan C Edwards School of Medicine at Marshall University, Huntington, WV.

Background: Oxidant stress plays a key role in the development and progression of uremic cardiomyopathy. We have recently demonstrated that adipocyte dysfunction and uremic cardiomyopathy developed in partial nephrectomy mice model, were significantly ameliorated by adipocyte-specific expression of NaKide, an antagonist of Na-K-ATPase signaling. Hence, to better characterize the cellular transcriptome that are involved in various biological pathways associated with adipocyte function, we aim to explore the genomic approach in the present study, through RNAseq analysis.

Methods: For invitro studies, mouse adipocytes were subjected to oxidized LDL (oxLDL) or indexyl sulfate (IS) with or without pNaKide treatments. Partial nephrectomy was performed in C57Bl6 mice in order to produce experimental uremic cardiomyopathy. Specific expression of NaKide in adipocytes was achieved using a lentivirus construct driven by an adiponectin promoter. A complete RNAseq analysis was performed using DESeq2 R package in combination with packages to perform over-representation analysis (ORA) and gene set enrichment analysis (GSEA).

Results: Several gene subsets corresponding to various biological processes and molecular phenotype were differentially expressed in adipocytes in vitro oxLDL/IS treatments and in vivo PNx model. These genes, compared using GSEA analysis, showed that more than 75% of the Kegg pathways were similar among the in vitro treatments and in vivo model. The pathways that were common between in vitro and in vivo treatments, including adipogenesis, ROS signaling, inflammatory response and oxidative phosphorylation pathways, have profound impact on the pathogenesis of uremic cardiomyopathy. The overall analysis showed a widespread normalization of gene expression by pNaKide/adipose specific NaKide treatments that were altered in uremic cardiomyopathy.

Conclusions: The study provides a detailed genome-wide molecular information about adipocyte function in relation to uremic cardiomyopathy pathogenesis. These data provide deeper insight into the activation of pathways associated with adipocyte Na-K-ATPase signaling, which may be a viable clinical target for the prevention and treatment of uremic cardiomyopathy.

Transcriptomic Profiling Identifies Potential Mediators of Tubular Injury Sensitization of Glomeruli to Subsequent Secondary Hits
Janka Babickova,1,2 Xin Li,1 Haichun Yang,1 Agnes B. Fogo,1 Vanderbilt University Medical Center, Nashville, TN; 2Universitetet i Bergen, Bergen, Norway; 3Shanghai Jiao Tong University, Shanghai, China.

Background: Previous studies have shown that even isolated mild tubular injury leads to more severe glomerular damage in response to subsequent injury. The responsible mediators for this sensitization are unknown.

Methods: Double transgenic male mice, Nep25/DTR (- expressing human CD25 receptor on podocytes and Diphtheria toxin receptor on proximal tubular cells) and Nep25/DTR (-5=5 group) were used. Tubular injury was induced by injecting diphtheria toxin, followed by uninurephrectomy (Nx) 4 weeks later and induction of glomerular injury
by LMB2 toxin (CD25 ligand) one week after Nx. Mice were sacrificed 4 weeks after LMB2. Glomeruli and tubules from Nx were separated by sieving technique, RNA was isolated from tubules and next generation RNA sequencing was performed.

**Results:** Histopathological analysis and urinary Kim-1 at Nx and sacrifice confirmed mild tubulointerstitial fibrosis at Nx in Nep25/DTR+ but not Nep25/DTR- mice, and more severe glomerulosclerosis and albuminuria at sacrifice after LMB2 in Nep25/DTR+ vs Nep25/DTR- mice. RNA sequencing revealed 283 differentially expressed genes between the groups, with 93 over-represented and 190 under-represented in Nep25/DTR- mice. STRING analysis of protein-protein interactions (PPI) based on cellular processes detected interactions between the Serpin family members: plasminogen activator inhibitor PAI-1 (Serpinel1), alpha-1-antitrypsin 1-2 (Serpinel1b), protein Z-dependent protease inhibitor (Serpinel1f) and complement C4b (C4b). In addition, members of the non-canonical Wnt signalling pathway Wnt-9a (Wnt9a) and VANG planar cell polarity protein 2 (Vang2) were over-represented and PPI of these genes was found. Quantitative real-time PCR confirmed numerically higher expression of all above-mentioned genes in Nep25/DTR- mice.

**Conclusions:** High-throughput RNA sequencing of isolated tubules with mild injury revealed potential novel mediators of glomerular sensitization to a subsequent injury. Further experimental validation of the effects of the identified molecules on glomerular injury are warranted.

**A Novel Short ACE2 Variant Causes ACE Suppression and Fosters Ang 1-7 Formation in a Murine Model of CKD**

**Gyancta Gulul,1,2 Jan Wysocki,1 Arndt Schulze,1,2 Minghao Ye,1 Chad R. Haney,1 Ming Zhao,1 Zheng J. Zhang,1 Daniel Batlke,1 Northwestern University Feinberg School of Medicine, Chicago, IL; 2Charite Universitätsmedizin Berlin, Berlin, Germany.

**Background:** ACE2 is a monocarboxypeptidase that cleaves Ang II to form Ang-(1-7). It is a large molecule the administration of which leads to increased enzyme activity in plasma, but not in the urine or kidney tissue. We have developed a truncated form of ACE2 that has a longer half-life by fusing it with an Albumin-binding domain (ABD) and is still short enough to be filtered by the kidney. In this study we examined the impact of this novel variant of ACE2 on kidney RAS in a model of CKD.

**Methods:** We used a 5/6 Nephrectomy model in CD-1 mice. The ACE2-ABD was given 3 days post-ablation surgery and thereafter every 3-4 days (3 ug/g BW) for 5 weeks. Afterwards, mice were euthanized and kidneys collected for analyses of RAS components.

**Results:** Administration of ACE2-ABD resulted in increased plasma ACE2 activity (768 vs. 12 RFU/ug/hr, p=0.0001). In kidney lysates there was also an increase in ACE2 activity (32 vs. 22 RFU/ug protein/hr, p=0.03) and a decrease in ACE activity (7187 vs. 4006 RFU/ug protein/hr, p=0.0001). These changes in enzymatic activities were correlated with the highest amount of genes involved in cellular processes, biological regulation and metabolic processes. STRING analysis of protein-protein interactions (PPI) based on cellular processes detected interactions between the Serpin family members: plasminogen activator inhibitor PAI-1 (Serpinel1), alpha-1-antitrypsin 1-2 (Serpinel1b), protein Z-dependent protease inhibitor (Serpinel1f) and complement C4b (C4b). In addition, members of the non-canonical Wnt signalling pathway Wnt-9a (Wnt9a) and VANG planar cell polarity protein 2 (Vang2) were over-represented and PPI of these genes was found. Quantitative real-time PCR confirmed numerically higher expression of all above-mentioned genes in Nep25/DTR- mice.

**Conclusions:** A long-acting form of a short ACE2 variant fused with ABD given every 3-4 days resulted in sustained plasma ACE2 activity and an increase in kidney ACE2 activity associated with suppressed kidney ACE activity. These enzymatic changes provide a favorable kidney RAS profile with increased Ang-(1-7), which overall should be renoprotective.

Transcriptomic Profiling of Thick Ascending Limb Cells In Vivo Reveals the Complex Network of Genes Regulated by Uromodulin
Kaise A. LaFavers, Shehzad Khan, Nida A. Khan, Laura Apple, Radmila Micanovic, Tarek M. El-Achkar. Indiana University School of Medicine, Indianapolis, IN.

Background: Tamm-Horsfall Protein (THP or Uromodulin, gene: Umod) is a protein uniquely made in the kidney by cells of the thick ascending limbs (TAL) of the loop of Henle. We previously established that THP has protective biological functions. Furthermore, THP production is decreased with chronic kidney disease (CKD). It was suggested that the promoter region of the Umod can regulate other genes. THP deficiency itself could alter the expression of other genes. Here, we used an unbiased approach to study the effect of a deletion in the Umod promoter/gene and the resultant THP deficiency on the transcriptomic profile of TAL cells in vivo.

Methods: THP-/- mice resultant from deletion of exons 1-4 and part of the Umod promoter were used, along with THP+/- controls. Immuno-fluorescence guided laser microdissection was performed to isolate TAL cells from the medulla of kidneys of THP+/- and THP-/- mice. After RNA extraction, next generation RNA sequencing and transcriptomic analysis was performed.

Results: The transcriptomic profile of medullary TAL cells was comprehensively defined in vivo. 85% of the top 250 expressed genes were common between THP+/- and THP-/- TAL cells. Overall, 33 protein-coding genes, including Umod, were differentially expressed (FDR<0.05). These encompassed genes with a variety of functions such as immunomodulation (Erk1, Gp2), cytoskeletal/extracellular matrix fibers (Lama1, Ctnnb1) and signal transduction (Camk2b, Pirrn2). One down-regulated gene was a direct neighbor to the Umod locus (Gp2) on chromosome 7. However, many other affected genes were on different chromosomes. Bioinformatic analysis revealed that THP deficiency is associated with significant clustering of genes involved in connective tissue formation and activation or dysfunction of molecular mechanisms that could lead to fibrosis.

Conclusions: We delineated a comprehensive transcriptomic profile of TAL cells in vivo from mouse kidneys. Although highly expressed genes in TAL may not be altered by THP deficiency, many close and distant genes are regulated by the Umod locus or altered by the absence of THP. The absence of THP may also prime the TAL cells towards a fibrosis program. These findings may contribute to understanding the pathogenesis of CKD progression.

Lipid Metabolic Profiling of Ex Vivo Isolated Glomeruli as a Screening Platform for Modelling Glomerular Metabolic Dysfunction During Renal Disease
Simone Romoli,1 Fynn N. Krause,2 Julian L. Griffin,2 Pernille B. Laerkegaard Hansen,1 Kevin Woollard.1 Renal Bioscience ex-vivo glomerular team 1Bioscience Renal, Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; 2University of Cambridge Department of Biochemistry, Cambridge, United Kingdom.

Background: Dysregulated renal metabolism is a hallmark of loss of function in CKD. It is established that changes in tubular metabolism impact tubular functionality during progression of CKD. However, lipid metabolism in the glomerulus during CKD remain poorly described. Here, we use Isolated Glomeruli (IRG) to study lipid metabolism for metabolic drug discovery in kidney diseases.

Methods: Sprague Dawley rat glomeruli were isolated by differential sieving. We used two disease inducers: Adriamycin 1mM (ADR) and AngiotensinII 100nM (AngII) for 24h. To probe metabolic activity, we used an LC-MS approach to quantify uptake and excretion rates of relevant metabolites in culture media, and to measure intracellular metabolites and lipids.

Results: We developed a new cultivation protocol for IRG, using organoids media and shaking platform to maximize the biological activity. Metabolic and lipidomic profiles of IRG were monitored up to 150h. We saw significant metabolic activity for a wide range of metabolites: Uptake and excretion rates rapidly changed during the first 24h of culture, after which they declined. Metabolic rates for glucose, glutamate and alanine were comparatively stable. Following treatment with AngII or ADR glomeruli exhibited metabolic changes after 24h: AngII reduced asparagine uptake, and induced trends towards lower substrate uptake consistent with reduced metabolic activity. Both ADR and AngII perturbated intracellular metabolic levels: glucose nadir (-17%); glucose (17%), increase in NAD+ (209%), which suggest alterations in pentose phosphate pathway. Multivariate analysis revealed differentially responding lipid clusters: specifically, significant abundance and saturation ratio increases of intracellular FFA, including stearate (+34%), oleate (+102%) and arachidonic (+197%), as well as the depletion of several phosphatidylcholine and phosphoethanolamine species following AngII, which have been implicated as renal injury markers and/or relevant to renal injury protection.

Conclusions: Our results show alterations in lipid metabolism after IRG stimulation with AngII and ADR after 24h. We propose IRG/lipid metabolome as a novel platform tool for understanding lipid signalling and improving CKD drug discovery.

Study on the Mechanism of Microinflammation in Uremia Caused by Lactobacillus Activation of Intestinal Macrophages by Mingle Lingshuang Sun, Hongli Jiang. First Affiliated Hospital of Medicine School, Xi’an Jiaotong University, Xi’an, China.

Background: My previous studies have found that Intestinal macrophages in the uremic rats are polarized towards a proinflammatory phenotype and assist bacterial translocation resulting in microinflammation. However, it is still unclear what kind of mechanism activates intestinal macrophages in uremia.

Methods: Male Sprague-Dawley rats were randomly divided into two groups: sham, uremia. Immunohistochemistry was used to analyze the expression of macrophage-inducible C-type lectin (Mincle). RT-PCR and western blot were employed to assess the mRNA and protein expression of toll-like receptor 4 (TLR4).

Results: Our RCT study found that the number of Lactobacilli in the intestines of patients with end-stage diabetic nephropathy was significantly higher than that in non-diabetic patients. The plasma levels of endotoxin, CRP, IL-6, and TNF-a in the uremia group were greater than those in the sham group (p<0.05; Table 1). Compared with the sham group, the uremia group exhibited macrophages with higher staining intensities for Mincle and higher mRNA and protein expression of TLR4(Figure1-2).

Conclusions: The solution to this scientific problem will not only clarify the molecular mechanism of intestinal bacteria in controlling the activation of intestinal macrophages, but also to clarify the micro-inflammation state of uremia.

Angiotensin II Type 1a Receptor Loss Ameliorates Chronic Tubulointerstitial Damage After Renal Ischemia Reperfusion
Yoko Fujita,1 Takeshi Sugaya,1 Daïsuke Ichikawa,1 Jun Tanabe,1 Kenjiro Kimura,2 Yugo Shibaïgaki,3 Atsuko Ikemori,1,3 Division of Nephrology and Hypertension, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan; 2JCHO Tokyo Takanawa Hospital, Tokyo, Japan; 3Department of Anatomy, St. Marianna University School of Medicine, Kawasaki, Japan.

Background: Although angiotensin II (Ang II) type 1 receptor blocker was reported to attenuate chronic tubulointerstitial damage (TID) after renal ischemia reperfusion (IR), its effect is limited. The aim of this study is to reveal whether suppressed activation of angiotensin II type 1a receptor (AT1a) ameliorates severe chronic tubulointerstitial damage (TID) after renal ischemia reperfusion (IR).

Methods: To induce severe chronic TID after IR, unilateral renal ischemia for 45 min was performed via clamping of right renal pedicle using cerebral aneurysm clip in AT1a knockout homo (AT1a−/−) male mice and wild type (AT1a+/+) male mice. Right and left kidneys were removed at 3, 28 and 70 days postischemia. Left kidneys were used as control. Furthermore, another AT1a−/− mice were administered hyalurazeline to maintain the same levels of systolic blood pressure (SBP) as the AT1a+ mice because the SBP levels of the AT1a+ mice were significantly lower compared to the AT1a−/− mice.

Results: Acute tubular necrosis in IR-kidneys of both AT1a+ mice and AT1a−/− mice was observed at 3 days postischemia, and the degree was significantly more severe in the IR-kidneys of AT1a−/− mice than in the IR-kidneys of AT1a+/+ mice. Conversely, the degrees of both interstitial fibrosis at 28 and 70 days postischemia and proximal tubular loss at 70 days postischemia were significantly attenuated in the IR-kidneys of AT1a−/− mice compared to the AT1a+/+ mice. While marked renal atrophy at 70 days postischemia was induced in the AT1a+ mice, such a development was not provoked in the AT1a−/− mice. Although the administration of hyalurazeline in the AT1a−/− mice mildly attenuated the degree of TID at 70 days postischemia, the degree of the AT1a−/− mice was significantly greater compared to the AT1a+ mice. Because renal expression levels of angiotensin (A1/3) protein at 28 days postischemia was significantly higher in the AT1a+ mice compared to the AT1a−/− mice, renat angiotensin-(1-7) may contribute to amelioration of chronic TID after IR in the AT1a+ mice.

Conclusions: Early administration of Ang II type 1 receptor blocker in recovery phase after AKI may be useful for prevention of AKI-to-CKD transition.

Anti-Interleukin 22 Antibody Relieves Angiotensin II-Induced Renal Injury in Mice Through Inhibiting NLRP3 Inflammasome Activation
Rong Tang,1 Xiayu Peng,1 Quanxi Liu,1 Jun Yang,1 Chao Fang,1 Xinwei Guo,1 Junting Wang,2 Changming Hu,2 Anqing Wang,2 and Zengqin Fan,1

1Department of Pathobiology, West China Hospital, Sichuan University, Chengdu, China; 2Institute of Pathology, West China Hospital, Sichuan University, Chengdu, China.

Background: Interleukin-22 (IL-22) is considered as a proinflammatory cytokine and participates in the pathogenesis of autoimmune and inflammatory diseases. Previously, we found that serum IL-22 increased significantly in hypertensive renal damage patients, and IL-22 was positively correlated with renal damage. The aim of this study was to investigate whether anti-IL-22 antibody exerts renoprotective effect by inhibiting NLRP3 inflammasome activation in angiotensin II (Ang II) induced hypertensive renal damage mice.

Methods: Ang II was infused subcutaneously at a rate of 1.5 mg/kg/d to C57BL/6 mice for 28 days to establish the hypertensive model. One day after modeling, mice were randomly divided into five groups: control, Ang II, Ang II+rIL-22, Ang II+anti-IL-22 mAb. After 28 days of treatment, mice were sacrificed, serum, kidney, liver and lung were collected for further analysis. Proteinuria, Serum creatinine (Scr) and renal histopathology were evaluated by western blot. Protein expressions of pro-inflammatory and pro-fibrotic mediators [CXCL9, CXCL10, MCP-1, IL-6, TGF-β] were detected by western blot in kidney and liver. The renal pathological changes were evaluated by H&E staining, Masson's trichrome and elastic van Gieson staining.

Results: Treatment with anti-IL-22 mAb significantly decreased proteinuria excretion, Scr and renal pathological changes. In addition, anti-IL-22 mAb decreased protein expressions of pro-inflammatory and pro-fibrotic mediators in kidney and liver.

Conclusions: Anti-IL-22 mAb therapy ameliorated proteinuria excretion, Scr and renal pathological damage in mice with established hypertensive renal injury. The possible renoprotective mechanism involves anti-IL-22 mAb inhibits IL-22/NLRP3 inflammasome activation and ameliorates renal fibrosis.

PD-1 Regulates Group 3 Innate Lymphoid Cells in Renal Fibrosis
Zhou Liang,1 Hao-Jie Zhong,1 Chang-Jian Zhu,2 Yzu Zhou.1 The first Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; 2Guangdong Medical University, Guangzhou, China.

Background: Group 3 Innate Lymphoid Cells (ILC3) belong to a new family of innate cells, participating in lots of inflammatory and fibrotic diseases. However, limited information exists on the molecular mechanisms regulating these cells. Here, we investigated the expression and function of the immune checkpoint programmed cell death-1 (PD-1) in ILC3 during renal fibrosis.

Methods: Unilateral ureteral obstruction (UIO)-induced renal injury tested subsets of ILC3 activities in immune responses and tissue fibrosis. Kidney and intestine were collected to define the frequency, localization and characterization of PD-1+ ILC3. Loss/gain-of-ILC3 in U/O mice were designed to investigate their roles in renal fibrosis progression. And the fibrogenic effects of ILC3 and the regulatory activity of PD-1 were determined by in vitro co-culture experiments.

Results: ILC3 were accumulated rapidly in fibrotic kidneys, with surrounding by increasing number of active myofibroblasts, and more interestingly, coincided with a robust depletion from the intestines of mouse models, suggesting a functional recruitment of ILC3 after kidney injury. Moreover, fibrosis was associated with an increase of PD-1 expression in ILC3s, and up-expression of PD-1 ligand, PD-L1 was also detected in fibrotic kidney, suggesting a possible involvement of PD-1/PD-L1 pathway. Adoptive transfer of purified intestinal ILC3 into U/O mice significantly enhanced renal fibrosis than those with PBS, whereas PD-1-deficient ILC3 protects kidney from fibrosis. Notably, mice that lacked ILC3 exhibited reduced inflammatory infiltration and decreased fibroblast activation. In vivo studies, direct co-culture of WT-ILC3 with primary renal fibroblasts exacerbates inflammatory response and extracellular matrix production (ECM), which could be blocked by the treatment with neutralizing anti-IL-17A and anti-IL-22 antibodies. Yet co-cultured with PD-1-deficient ILC3 displayed reduced fibrotic activity.

Conclusions: Our findings provided the first evidence that during renal fibrosis, PD-1/PD-L1 axis might play a regulatory role in ILC3 migration and fibrogenesis via producing pro-fibrotic cytokines IL-17A and IL-22.

Interaction Between the Na-K-ATPase and CD40 Signaling in Proximal Tubule Epithelial Cells (PTECs) Contributes to Renal Inflammation and Fibrosis
Steven T. Haller,1 Shungang Zhang,1 Ying Nie,2 Joseph I. Shapiro,2 Jianguo Liu.1
1Department of Medicine University of Toledo College of Medicine and Life Sciences, Toledo, OH; 2Marshall University Joan C. Edwards School of Medicine, Huntington, WV.

Background: We have demonstrated that signaling through the Na-K-ATPase-c1 subunit/c-Src kinase (NKA-c1/c-Src) complex and activation of the pro-inflammatory receptor, CD40 induce renal inflammation and fibrosis in both clinical and experimental models of ischemic and chronic kidney disease (CKD). Circulating cardiotonic steroids (specific ligands of Na-K-ATPase) are significantly elevated in CKD that not only stimulate NKA-c1/c-Src signaling, but also regulate CD40 signaling by upregulation of CD40 expression in PTECs. Furthermore, soluble CD40 ligand (sCD40L)-stimulated CD40 signaling in PTECs is dependent on NKA-c1/c-Src signaling. However, the interplay between Na-K-ATPase and CD40 signaling-induced renal inflammation and fibrosis has not been thoroughly investigated.

Methods: RNA sequencing was performed on pig PTECs with and without a functional NKA-c1/c-Src signaling complex (Ly-22 cells and Ly-22r cells, respectively) following treatment with sCD40L (100ng/ml) for 24hrs. In pig PTECs LCC-PK1 cells treated with the cardiotonic steroid telocinobufagin (TCB), immunoprecipitation was performed to detect protein-protein interaction.

Results: Treatment with sCD40L in Ly-22r cells demonstrated a significant increase in gene expression of pro-inflammatory and pro-fibroictic mediators (CXXCL9, CXXCL10, IL1R1, complement C3, and COL1A2 [all > 5-fold increase]) compared to Ly-22r cells. In LCC-PK1 cells, short-term TCB treatments (up to 1 hr) stimulates interaction between NKA-c1 and CD40 that presents under resting conditions. Long-term TCB treatment (24 hr) still shows the NKA-c1 and CD40 interaction, but reduced NKA-c1 and CD40 interaction was also observed in comparison to control, suggesting a possible endocytosis of NKA-c1 (by the cardiotonic steroid) and CD40.

Conclusions: In renal proximal tubular cells, CD40-induced pro-inflammatory and pro-fibrotic signaling is dependent on the NKA-c1/c-Src complex, and there is an
interaction between NKA-α1 and CD40 that was enhanced by activation of the NKA-α1 (c-Src signaling) A regulation through expression level and/or endocytosis of NKA-α1 and CD40 might be involved to control signaling strength.**

**Soluble Uric Acid, a Negative Regulator of Monocyte Activation in Innate Immunity**

Stefanie Steiges, 1 Qiuyue Ma, 1 Maja Lindenmeyer, 2 Paola Romagnani, 3 Hans J. Anders, 4 Division of Nephrology, Department of Medicine IV, LMU Munich, Munich, Germany; 2Department of Medicine III, University Medical Center Hamburg-Éppendorf, Hamburg, Germany; 3Department of Biomedical Experimental and Clinical Sciences Maria Serio, University of Florence, Florence, Italy.

**Background:** While monosodium urate (MSU) crystals are known to trigger acute inflammatory responses in gouty arthritis, soluble uric acid (sUA) in this context is discrepancy. We hypothesized that diverse sUA preparation methods account for this discrepancy and that a novel animal model with clinically relevant levels of asymptomatic hyperuricemia (HU) and gouty arthritis can ultimately clarify this issue.

**Methods:** Soluble UA was prepared either by pre-warming or solubilized with NaOH. THP-1 cells or CD14+ monocytes from patients with HU and healthy individuals were pre-incubated with sUA prior to stimulation with MSU crystals or LPS. Intracellular sUA uptake via urate transporters was quantified using siRNA technology. In vivo, Alc-aE2/CreERT2/ Glut9 b/c mice were injected with tamoxifen and placed on a chow diet with inosine to induce HU. After 3 weeks, MSU crystals or vehicle were injected into air pouches, and leukocyte infiltration and the extent of inflammation were assessed by flow cytometry, RT-PCR, ELISA.

**Results:** We found that pre-warmed UA created erroneous results because of microcrystal contaminants triggering IL-1β release. Solubilizing UA with NaOH avoided such artifact. This microcrystal-free preparation suppressed LPS- or MSU crystal-induced monocyte activation, a process dependent on the intracellular uptake of sUA via the urate transporter SLC2A9/GLUT9. CD14+ monocytes isolated from HU patients were less responsive to inflammatory stimuli compared to monocytes from healthy individuals. Treatment with plasma from HU patients impaired the inflammatory function of CD14+ monocytes, an effect fully reversible by removing sUA from HU plasma with rasburicase. Moreover, Alc-aE2/CreERT2/ Glut9 b/c mice with HU (serum UA of 9-11mg/dL) showed a suppressed inflammatory response to MSU crystals compared to Glut9 b/c controls without HU.

**Conclusions:** We unraveled a technical explanation for discrepancies in the published literature on the role of sUA and identify HU as an intrinsic suppressor of innate immunity, where sUA modulates the capacity of monocytes to respond to danger signals. Thus, sUA is not only a substrate for the formation of MSU crystals but also an inhibitor of sterile inflammation and may explain several clinical observations in the context of gout and CKD.

**PP2Ac Promotes Macrophage Accumulation and Activation to Accelerate Tubular Cell Death and Kidney Fibrosis Through Regulating Rap1 and TNFα Production**

Yun Liang, Chunsun Dai. Nanjing Medical University, Nanjing, China.

**Background:** Macrophage accumulation and activation play an essential role for kidney fibrosis, the underlying mechanisms remain to be explored.

**Methods:** Analyzing the kidneys of patients and animal models with kidney fibrosis. Generating the mice with macrophage PP2Ac ablation.

**Results:** We observed a significantly increased induction of PP2Ac in macrophages. We then generated mice with macrophage-specific deletion of PP2Ac. These mice developed less renal fibrosis as indicated by less macrophage accumulation, tubular atrophy or extracellular matrix deposition. In cultured cells, the deficiency of PP2Ac in macrophages resulted in decreased cell motility by inhibiting the activity of Rap1. Furthermore, TNFα production was downregulated in macrophages with PP2Ac deficiency and co-culture of PP2Ac-deficient macrophages and renal tubular cells resulted in less tubular cell death, which was due to decreased TNFα production via phosphorylation of STAT3 in macrophages.

**Conclusions:** This study shows that PP2A promotes macrophage accumulation and activation, hence accelerating tubular cell death and kidney fibrosis through regulating Rap1 and TNFα production.

**Funding:** Government Support - Non-U.S.

PO0638

**Investigating LOX and Its Role in AT1R-β-Arrestin Biased Signaling Pathway-Induced Renal Interstitial Fibrosis**

Xiaojin Zhang, Chen Yu. Tongji University, Shanghai, China Department of Nephrology, Tongji Hospital, Tongji University, Shanghai, China, Shanghai, China.

**Background:** We studied the downstream and mechanism of β-arrestin signaling in renal fibrosis process and the role of lysyl oxidase (LOX) in the AT1R-β-arrestin signaling. A regulation through expression level and/or endocytosis of β-arrestin signaling was studied in normal rat kidney tubule epithelial cells (NRK-52E) treated with SII in vitro. BAPN or placebo was administered during ischemia reperfusion (IR)-induced fibrosis progression. Collagen crosslinking and fibrosis progression were assessed histologically and biochemically.

**Results:** The mRNA and protein levels of β-arrestin-1 and β-arrestin-2 were significantly upregulated in renal fibrosis model both in vitro and in vivo. SII activated the ERK-STAT3 PY705 but not STAT3-TR727 in nucleus of NRK-52E cells, which effects were abolished when transfection of siRNA targeting β-arrestin-1 and β-arrestin-2 or pretreated with PD98059 (MEK inhibitor). LOX was strongly induced in fibrotic kidney and NRK-52E cells treated with SII. Active LOX significantly increased collagen crosslinking. In established IR-28d renal fibrosis, LOX inhibition promoted fibrosis progression with a 25% decrease insoluble collagen. Gene silencing of β-arrestin-1 or -2 or STAT3 significantly inhibited SII-induced LOX expression in vitro. Besides, chronatin immunoprecipitation (ChIP) assay clearly demonstrating the interaction between STAT3 and the LOX promoter, which indicated LOX is a direct target gene of β-arrestins-STAT3 signaling.

**Conclusions:** The ERK-STAT3 was downstream of AT1R-β-arrestins, ERK entered the nucleus and activated STAT3-PY705. LOX mediates collagen crosslinking and fibrotic matrix stabilization during renal fibrosis via the AT1R-β-arrestins-ERK-STAT3-PY705 signaling. By blocking this profibrotic pathway, therapeutic LOX inhibition attenuates the fibrosis and suggesting target the LOX has significant potency for the treatment of patients with fibrotic kidney disorders.

**Downregulated Endothelial JMJD3 Accelerates Neointimal Hyperplasia of Arteriovenous Fistula in CKD**

Shaozhen Feng, 1 Quying Guo, 1 Eric K. Peden, 2 William E. Mitch, 1 Luan D. Truong, 2 Zhichong Cheng, 1 Baylor College of Medicine, Houston, TX; 2Houston Methodist Hospital DeBakey Cardiology Associates, Houston, TX; 3Houston Methodist Hospital, Houston, TX.

**Background:** Epigenetic changes are involved in vascular remodeling. The histone demethylase, JMJD3, is a transcriptional co-activator that promotes endothelial regeneration. Despite the importance of JMJD3 in maintaining endothelial function, its role in neointima formation in AVFs remains unknown.

**Methods:** Mice with JMJD3 specific knockout (KO) in ECs was generated. CKD and AVF models were created in Wild type and JMJD3 EC-specific KO mice. Evans blue, immunostaining assays were used to characterize JMJD3 expression and vascular pathology. Mouse primary ECs and VSMCs were isolated to study the signaling pathways that regulate JMJD3 expression and endothelial mesenchymal transition (EndMT). The changes found in mouse AVFs were assessed in AVFs from ESRD patients.

**Results:** JMJD3 expression was downregulated in endothelium of CKD mice. Specific KO of JMJD3 in EC stimulated endothelial barrier dysfunction, EndMT, and inflammatory cells infiltration in AVFs. There were more VSMC proliferation and collagen deposition in AVFs created in JMJD3 KO mice vs. that of in WT mice. Specific KO of JMJD3 in EC accelerated AVF remodeling. EC proliferation was associated with endothelial dysfunction, EndMT, and ECM deposition plus neointimal hyperplasia. Remarkably, endothelial expression of Hes1 in AVFs from ESRD patients was correlated with the decreased JMJD3 level.

**Conclusions:** These findings demonstrate that TGFβ1-Hes1-JMJD3 signaling exist in ECs which epigenetically regulates EC differentiation and barrier function leading to neointimal hyperplasia of AVF in CKD.

Renal Macrophage Infiltration Precedes Macrophage to Myofibroblast Transition and C-T Cell Recruitment Following Repeated Low-Dose Cisplatin Treatment

Sophia M. Sears, Mark A. Doll, Levi J. Beverly, Leah J. Siskind. University of Louisville School of Medicine, Louisville, KY.

Background: Cisplatin is a commonly used chemotherapeutic agent with dose-limiting nephrotoxicity. 30% of patients who receive cisplatin develop acute kidney injury (AKI), which significantly increases the risk of developing renal fibrosis and chronic kidney disease (CKD). There are currently no therapies approved to prevent or treat cisplatin-induced kidney injury (CDDP-KI) and fibrosis. Other models of renal fibrosis have demonstrated that macrophages can play a pro-fibrogenic role by differentiating into myofibroblasts, the main effector of fibrotic development. Macrophage to myofibroblast transition (MMT) is proposed to occur when bone marrow derived M2 macrophages undergo chronic TGFβ stimulation. We hypothesize that cisplatin promotes fibrosis and CKD development through stimulating chronic macrophage activity and MMT in the kidney.

Methods: We used a clinically relevant, repeated low dose model of CDDP-KI to characterize the immune response and MMT in the kidney following cisplatin treatment.

Results: Flow cytometric analysis revealed significantly increased numbers of renal infiltrating macrophages and F4/80+ cells from rats treated with repeated low doses of cisplatin after four doses of cisplatin. These populations remained elevated above vehicle treated controls after a 6-month age-out. At the four dose timepoint, we observed an increase in CD206+ F4/80+ cells and Arg-1 mRNA, indicating M2 polarization. We also identified a population of F4/80+ CD206+ eSMA+ cells present in the kidney, suggesting MMT is occurring. Interestingly, at the 6-month timepoint renal CD4+ and CD8+ T cell populations remained significantly elevated in cisplatin-treated mice compared to vehicle treated controls.

Conclusions: These studies provide insight on how the immune response to CDDP-KI can promote CKD via infiltration of bone marrow derived macrophages and subsequent M2 polarization and MMT. These early events orchestrate an immune response that continues up to 6-months after cisplatin treatment. Therefore, targeting macrophages could be a potential strategy for preventing the AKI to CKD transition triggered by cisplatin.

Microvascular Loss and Remodeling in Human Kidneys Distal to Severe Atherosclerotic Renovascular Disease

Nattawat Klomjit,1 Alfonso Eirin,1 Xiang yang Zhu,1 Aditya S. Pawar,1 Amruthesh S. Puranik,2 Christopher M. Ferguson,1 Seo Rin Kim,1 Kyra L. Jordan,1 Hui Tang,1 Amir Lerman,2 Stephen C. Textor,3 Lilach O. Lerman.1 Division of Nephrology and Hypertension, Department of Medicine, Mayo Clinic, Rochester, MN; 1Longhorn Health, New York University, New York, NY; 2Department of Cardiovascular Disease, Mayo Clinic, Rochester, MN.

Background: Renovascular disease (RVD) may induce hypertension and kidney injury, but its effect on the microcirculation of the post-stenotic human kidney remains unclear.

Methods: Kidneys were collected from patients with RVD undergoing unilateral nephrectomy due to refractory hypertension (n=5) and deceased donor kidneys (DK) (n=5). Injury to the microcirculation was assessed by counting tubules containing small arterioles (PTC), medium-sized arterioles (MSA), and capillaries at 243× magnification. Angiopoietin-1 (Ang-1) expression was analyzed by qRT-PCR and Western Blot. Vascular density of small (0.02-0.2 mm) and large (0.3-0.5 mm) microvessels (MV) was determined by immunofluorescence and optical densities were measured. Vascular tortuosity was measured by the ratio of the arc length to the straight line distance between endpoints of the vessels.

Results: Angiopoietin-1 expression were unchanged. Ang-1 expression was inhibited by atherosclerotic RVD, compared to DK. Ang-1 expression was significantly reduced (p<0.05), whereas VEGF (p=0.9) and FLK-1 (p=0.2) protein or gene expression were unchanged. Angiopoietin-1 expression, whereas VEGF (p=0.9) and FLK-1 (p=0.2) protein or gene expression were unchanged.

Conclusions: Human RVD kidneys develop marked MV remodeling and loss, particularly of PTC and medium-size MV. Angiopoietin-1 upregulation may promote new PTC formation, but fails to offset overwhelming MV loss distal to severe RVD. These findings underscore the major component of microvascular injury in the development of ischemic kidney disease.

Combined Efficacy of the Novel Nonsteroidal and Selective Mineralocorticoid Receptor Antagonist Finerenone and the SGLT2 Inhibitor Empagliflozin in a Non-Diabetic Cardiorenal Rat Model

Peter Kolkhof,1 Mira Pavkovic,2 Elke Hartmann,3 Peter Sandner,1 Ilka Mathar,1 Jörg Hüser,1 Frank Eitner,1 BAYER AG, Pharmaceuticals, Research & Development, Cardiovascular Research, Wuppertal, Germany; 2BAYER AG, Pharmaceuticals, Research & Development, Biomarker Research, Wuppertal, Germany; 3BAYER AG, Pharmaceuticals, Research & Development, Research Pathology, Wuppertal, Germany.

Background: Finerenone and SGLT2 inhibitors have demonstrated clinical benefits in CKD patients with T2D. Efficacy of finerenone and SGLT2i, especially in combination, is unknown in non-diabetic kidney disease.

Methods: Cardiorenal morbidity and mortality was studied in hypertensive and proteinuric L-NAME (20 mg/L) treated renin-angiotensin (mRen2)27 rats. Rats (10-11 weeks old female, n=13-17/group) were treated once daily orally for up to 7 weeks with placebo, finerenone (1 and 3 mg/kg), empagliflozin (3 and 10 mg/kg), or a combination of the respective low doses. Key outcome parameters included mortality, blood pressure, proteinuria, kidney histology and gene expression.

Results: Placebo-treated rats demonstrated a 50% mortality rate over the course of 7 weeks (figure). Drug treatment resulted in variable degrees of survival benefit, most prominent and statistically significant in the low dose combination group (figure). Low dose combination revealed an early, sustained and efficacious proteinuria reduction (~86%, p<0.05) and was highly efficient on renal histology parameters. Monotherapies of finerenone (~27% @ 1 mg/kg, p = n.s.; ~87% @ 3 mg/kg, p<0.05) and empagliflozin (~38% @ 3 mg/kg, p = n.s.; ~64% @ 10 mg/kg, p = n.s.) dose-dependently reduced proteinuria with a comparable protection from renal lesions at higher dosages. Treatment with finerenone and the combination significantly decreased systolic blood pressure while empagliflozin alone and in combination acted strongly glucosoric.

Conclusions: Both, MRA by finerenone and SGLT2i by empagliflozin confer renal protection in preclinical non-diabetic, hypertensive kidney disease. Combination of these two modes of action at low dosages revealed efficacious reduction in proteinuria and mortality indicating a strong potential for combined clinical use in respective cardiorenal patient populations.

**Novel Small Molecule Inducers of ABCA1-Dependent Cholesterol Efflux**

**Preserve Renal Function in Mouse Models of FSGS and Alport Syndrome**

Javier T. Varona Santos,1,2 Matthew B. Wright,1 Christian Kemmer,1 Cyrille Maugue,1 Jean-Philippe Carratol,1 Stephane Roever,1 Judith T. Molina David1,2 Gloria Michelle Ducasa,1,2 Alla Mitrofanova,1,2 Alexa J. Sloan,1,2 Jeffrey D. Pressly,1,2 Christopher Pedigo,1,2 Laura Barisoni,1,2 Armando Mendez,1 Jacopo Sgrignani,1,2 Andrea Cavalli,1,2 Sandra M. Merscher,1,3 Marco Prunotto,1,3 Alessia Fornoni,1,2 University of Miami, Katz Family Division of Nephrology and Hypertension, Miami, FL; 1University of Miami, Peggy and Harold Katz Family Drug Discovery Center; Miller School of Medicine, Miami, FL; 1University of Geneva, School of Pharmaceutical Sciences, Geneva, Switzerland; 2Pharmacy Research and Early Development (pRED), Roche Innovation Center Basel, F. Hoffmann-La Roche Ltd., Basel, Switzerland; 3University of Miami Department of Pathology, Miller School of Medicine, Miami, FL; 4University of Miami, Miller School of Medicine, Diabetes Research Institute, Miami, FL; 5Institute for Research in Biomedicine, Universita della Svizzera Italiana, Bellinzona, Switzerland; 6Swiss Institute of Bioinformatics, Lausanne, Switzerland.

**Background:** Pathological accumulation of cholesterol in podocytes is associated with the progression of kidney disease. Depletion of podocyte cholesterol by non-specific means, with agents such as cycloextrim, or by specific upregulation of ABCA1-mediated cholesterol efflux, have shown promise in renal disease models, but have not progressed in clinical development.

**Results:** The effects of novel compounds (Cpd A and G) that induce ABCA1-mediated cholesterol efflux were evaluated in comparison to LXR agonists in differentiated human podocytes in vitro. In vivo efficacy studies of Cpd A & G were conducted in mouse models of proteinuric kidney disease (Adriamycin-induced nephropathy and Alport Syndrome).

**Results:** ABCA1-mediated cholesterol efflux was significantly increased in podocytes by all agents. While an LXR agonist resulted in accumulation of ABCA1 at the plasma membrane, it also induced significant accumulation in microsomal fractions. In contrast, Cpd A & G induced the redistribution of ABCA1 from intracellular sites to the plasma membrane. In A PRO and podocytes challenged for 6 weeks with Cpd A and G, reduced ACR by 8 and 30-fold, respectively, compared to controls. In CoA3A knockout mice, Cpd G significantly reduced ACR, serum creatinine and blood urea nitrogen, as well as prevented weight loss and mortality vs. control mice. We found that increased accumulation of cholesterol esters in kidney (30% at 4 months) and mRNA for ATG5, an autophagy protein, strongly correlated with albuminuria. In both the FSGS and Alport mouse models, Cpd G significantly reduced lipodropplet formation and cholesterol ester content in kidney cortex.

**Conclusions:** In summary, we describe the effects of novel small molecule drugs in renal disease models that induce ABCA1-mediated cholesterol efflux independently of LXR. This may represent a promising new therapeutic strategy for the treatment of kidney diseases and disorders of cellular cholesterol homeostasis.

**Metformin Therapy Is Able to Halt the Progression of Established CKD in Rats**

Raphaelle Corremans, Ellen Neven, Patrick D’Haeze, Benjamin A. Vervea, Anja Verhulst, Universiteit Antwerpen, Antwerpen, Belgium.

**Background:** Metformin, first-line drug for type-2 diabetes, exerts benign pleiotropic actions beyond its prescribed use and emerging data show protective effects against the development/progression of renal impairment. Current treatment strategies for chronic kidney disease (CKD) mainly focus on controlling important risk factors, while effective treatment directly targeting the kidney is lacking. However, in 2019, the FDA approved the use of the sodium-glucose co-transporter-2 (SGLT2) inhibitor, canagliflozin, to treat diabetic nephropathy. Here, the ability of metformin to attenuate the progression of established, non-diabetic CKD was investigated and compared to canagliflozin.

**Methods:** Adipone-mediated CKD rats (n=86) were assigned to different treatment groups to receive 200 mg/kg metformin, 4 or 5 weeks after the start of the adenine diet (0.25%), i.e. after CKD had developed, or 25 mg/kg canagliflozin 4 weeks after the start of the diet, by daily oral gavage, for 4 weeks. Each treatment group was compared to a vehicle (1% carboxymethylcellulose) group.

**Results:** Serum creatinine levels dramatically rose in vehicle-treated CKD rats: from 0.7 ± 0.1 mg/dL (week 0) to 1.5 ± 0.1 mg/dL (week 4), 2.6 ± 1.2 mg/dL (week 5) and further to 6.2 ± 0.3 mg/dL (week 8) and 4.8 ± 1.1 mg/dL (week 9). Canagliflozin treatment did not alter the increase in serum creatinine as indicated by serum creatinine levels at week 5 (5.8 ± 0.4 mg/dL). In contrast, metformin treatment almost completely prevented the increase from week 4 or 5 on, as indicated by the serum creatinine levels after 8 (2.0 ± 0.5 mg/dL) and 9 (2.9 ± 0.5 mg/dL) weeks (p<0.05 vs. vehicle). Canagliflozin treatment did not alter the tubulointerstitial area percentage, while this parameter was 33% lower at week 8 and 23% lower at week 9 in metformin-treated CKD rats compared to vehicle-treated (p=0.05 vs. vehicle). Further histological examination revealed more tubular proliferation (PCNA positive cells) and less interstitial inflammation (CD45 positive cells) in metformin-treated rats compared to vehicle-treated animals.

**Conclusions:** In conclusion, metformin is able to attenuate the progression of pre-existing, non-diabetic CKD. Our data do not present new evidence for a beneficial effect of canagliflozin on progression of non-diabetic CKD.

**The Novel Soluble Guanylyl Cyclase (sGC) Activator Runcaciguat Attenuates Hypertensive Cardiorenal Rat Diseases**

Aynes M. Benardau, Johannes-Peter Stasch, Michael G. Hahn, Jutta Meyer, Jan R. Kraehling, Frank Eitner, Peter Sandner, Bayer AG, Leverkusen, Germany.

**Background:** Chronic kidney disease (CKD) is often associated with arterial hypertension, leading to the development of hypertensive nephropathy and ultimately kidney failure that is poorly prevented by current treatment options. Hypertension and nephropathy are associated with impaired NO/sGC/cGMP signaling, low cGMP production and increased oxidative stress. Runcaciguat is a novel potent and selective, NO- and cGMP-dependent sGC activator. Here we investigated the therapeutic potential of Runcaciguat in rat models of hypertension associated chronic kidney disease.

**Methods:** Hypertensive rats (Sprague Dawley, 12–13 weeks old, n=15/group, angiotensin II (ANG) minipumps, 450mg/kg/min) were treated orally twice daily for 2 weeks with Runcaciguat (0.3, 1 or 3 mg/kg), losartan (30 mg/kg) or placebo. In a second study, male Renin-transgenic rats (mRen2/27, 8 weeks old, L-NAME 30-50 mg/L, n=18-24/group) were treated twice daily orally for up to 8 weeks with Runcaciguat (1, 3 or 10 mg/kg) or placebo. Key outcome parameters included mortality, blood pressure (BP), proteinuria, kidney histology, kidney and heart biomarkers and kidney gene expression.

**Results:** In the 2-week-treated ANG-rats, Runcaciguat dose-dependently and significantly reduced proteinuria without changing BP. Losartan significantly decreased proteinuria. Runcaciguat reduced kidney LCN2 (NGAL) expression. In the 8-week-treated Renin-transgenic rats, Runcaciguat significantly and dose-dependently improved mortality from 58% (placebo) to 56%, 39% and 28% (@ 1, 3, 10 mg/kg). At all tested doses, Runcaciguat significantly reduced kidney and heart hypertrophy and increased creatinine clearance. At the highest dose, Runcaciguat also significantly reduced BP and proteinuria.

**Conclusions:** The novel oral sGC activator Runcaciguat exhibits cardio-renal protection and improved survival in hypertensive rat models. Our data strongly suggest that Runcaciguat represents a promising treatment option for hypertensive kidney disease patients.

**Funding:** Private Foundation Support

**PO0646**

**The Novel Nonsteroidal and Selective Mineralocorticoid Receptor Antagonist Finerenone Differentiates from SGLT2 Inhibitor Empagliflozin by Anti-Fibrotic Effects in a Progressive Mouse Kidney Fibrosis Model**

Karoline Droebner, Mira Pavkovic, Manuel Grundmann, Elke Hartmann, Laura Goen, Johannes Nordlohne, Frank Eitner, Peter Kolkhof, Bayer AG, Wuppertal, Germany.

**Background:** Finerenone and SGLT2 inhibitors have demonstrated clinical benefits in CKD patients with T2D. Cellular and molecular mechanisms responsible for these benefits are incompletely understood. MR-signaling has been linked to fibrosis in vitro via plasminogen activator inhibitor-1 (PAI-1) modulation. Here we investigated potential drug effects and mechanisms in a relevant preclinical mouse kidney fibrosis model.

**Methods:** Kidney fibrosis was induced in mice via unilateral ureteral obstruction. In a series of experiments, mice (C57/B6J, 8 weeks old male, n=10-12/group) were treated orally for 10 days with the MR antagonist finerenone (3 and 10 mg/kg), the SGLT2 inhibitor strongly increased creatinine clearance. In the 2-week-treated ANG-rats, Runcaciguat dose-dependently and significantly reduced proteinuria without changing BP. Losartan significantly decreased proteinuria. Runcaciguat reduced kidney LCN2 (NGAL) expression. In the 8-week-treated Renin-transgenic rats, Runcaciguat significantly and dose-dependently improved mortality from 58% (placebo) to 56%, 39% and 28% (@ 1, 3, 10 mg/kg). At all tested doses, Runcaciguat significantly reduced kidney and heart hypertrophy and increased creatinine clearance. At the highest dose, Runcaciguat also significantly reduced BP and proteinuria.

**Conclusions:** From the novel oral sGC activator Runcaciguat exhibits cardio-renal protection and improved survival in hypertensive rat models. Our data strongly suggest that Runcaciguat represents a promising treatment option for hypertensive kidney disease patients.

The Novel Potent and Selective Vasopressin V1a Antagonist BAY2372949 Blocks Arginine Vasopressin-Mediated Decline of Renal Blood Flow and Tissue Oxygenation
Hana Cernecka, Karoline Droebner, Hanna Tinel, Elisabeth Pook, Chantal Fuerstner, Marie-Pierre L. Collin, Peter Hein, Frank Eiter, Peter Kolkhof, Bayer AG, Research & Development, Pharmaceuticals, Wuppertal, Germany.

Background: Hypoxia is a major contributor to kidney disease progression. Arginine vasopressin (AVP) potently induces renal medullary vasoconstriction via vascular V1a receptors resulting in reduced renal blood flow (RBF). Here we characterized the kidney-protection properties of a recently identified, potent and selective V1a receptor antagonist.

Methods: BAY 2372949 was characterized in Chinese hamster ovary cells expressing recombinant human and rat V1a and V2 receptors. Vasodilatory effects were investigated on isolated A. renalis rings from male Wistar rats (n=10). RBF and intrarenal tissue oxygenation were studied in isolated perfused rat kidneys and in anesthetized rats (n=5-8 per group) via Laser Doppler Flowmetry.

Results: In vitro receptor profiling showed high potency and selectivity of BAY 2372949 for human V1a receptor (IC50=1.2 nM). BAY 2372949 reduced perfusate-mediated dose-dependent relaxation (IC50=3.1 nM) of isolated rat A. renalis vessel rings precontracted by AVP. BAY 2372949 improved the AVP-mediated reduction of perfusate and venous flow (figure) without affecting urinary volume. In vivo, infusion of AVP significantly increased mean arterial pressure (CON: 97±1, AVP: 135±2, means±SD) which was normalized by BAY 2372949 in a dose-dependent manner (90±5; p<0.0001). Infusion of AVP reduced both renal perfusion (CON: 1060±107; AVP: 17±4) and tissue oxygenation (CON: 27±1; AVP: 17±4). BAY 2372949 dose-dependently restored RBF (960±30; p<0.0001) and increased pO2 (25±1, AVP: 17±4; p<0.0001).

Conclusions: BAY 2372949 is a novel potent and selective vasopressin V1a receptor antagonist blocking the detrimental effects of elevated vasopressin levels on renal perfusion and oxygenation in rats, suggesting potential benefit for patients with cardiorenal diseases.

PO0648
Apabetalone, an Inhibitor of BET Proteins, Downregulates Alkaline Phosphatase and Improves Cardiovascular Risk
Dean Gillihan, Laura Tsujikawa, Li Fu, Sylvia Wasiak, Christopher Halliday, Chris Sarason, Phoebe S. Ho, Stephanie Stotz, Brooke D. Rakai, Kenneth E. Lebioda, Ravi Jahagirdar, Michael Sweeney, Jan O. Johansson, Norman C. Wong, Kamyar Kalantari-Zadeh, Mathias Haarhaus, Ewelina Kulikowska,1 Resverlogix, Calgary, AB, Canada; 2Resverlogix, San Francisco, CA; 3University of California Irvine, Irvine, CA; 4Karolinska University Hospital, Stockholm, Sweden.

Background: Elevated serum alkaline phosphatase (ALP) predicts major adverse cardiac events (MACE). ALP is associated with vascular calcification (VC) & inflammation. We studied apabetalone’s modulating gene expression in pathological VC & inflammation. We studied apabetalone's protective properties of a recently identified, potent and selective V1a receptor antagonist.

Methods: Expression of TNALP (gene symbol ALPL) was measured in primary vascular smooth muscle cells (VSMC) & vascular endothelial cells by q-PCR. TNALP was assessed by immunoblot in four vascular cell types: human aortic smooth muscle cells, human umbilical vein endothelial cells, human microvascular endothelial cells (VMSC) and human umbilical vein endothelial cells by q-PCR. TNALP was assessed by immunoblot & flow cytometry, ALP activity by enzymatic assays. Serum ALP was measured in CVD patients in phase 2 trials (ASSERT, SUSTAIN & ASSURE). Subpopulations had CKD (eGFR<60).

Results: Apabetalone downregulated ALPL expression in liver cells by 60-80%, HepG2s had lower TNALP protein -55%, enzyme activity ~40% & TNALP positive cells 15-30%; renal MCs had >90% decreases in ALPL expression & TNALP enzyme activity (p<0.001). ALPL was suppressed 50-70% in 3 vascular endothelial cell types with apabetalone. In VMSCs, apabetalone lowered ALPL expression, TNALP protein, enzyme activity & extracellular calcium deposition. In ASSERT, apabetalone dose dependently reduced serum ALP (p<0.001). In combined phase 2 analysis, apabetalone lowered ALP (p<0.001). Overall, the apabetalone-mediated decreases in serum ALP in phase 2 correlated with reduced MACE at 12-14 weeks (HR 0.64 per 1-SD in ALP, 95% CI 0.46-0.90; p=0.00 1-SD=13U/L); similar associations were observed at 24-26 weeks (HR 0.66 per 1-SD in ALP 95% CI 0.43-0.99; p=0.045, 1-SD=14U/L).

Conclusions: Apabetalone lowers serum ALP, consistent with reduced hepatic, renal & vascular TNALP production. Modulation of ALP by apabetalone may affect pathogenic processes to lower cardiovascular risk. This study provides insight to MACE reductions in phase 2 clinical trials.

PO0649
Renal Expression of L-Type Fatty Acid Binding Protein in Addition to Angiotensin II Type 1a Receptor Loss Ameliorates Chronic Tubulointerstitial Damage After Renal Ischemia Reperfusion
Yoko Fujita,1 Takeshi Sugaya,1 Daisuke Ichikawa,1 Jun Tanabe,1 Kenjiro Kimura,2 Yugo Shibagaki,3 Atsuko Ikemori.1,2 Division of Nephrology and Hypertension, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan; 3JCHO Tokyo Takanawa Hospital, Tokyo, Japan; 1Department of Anatomy, St. Marianna University School of Medicine, Kawasaki, Japan.

Background: Although angiotensin II (Ang II) type 1 receptor blocker was reported to attenuate chronic tubulointerstitial damage (TID) after renal ischemia reperfusion (IR), its effect is limited. We had revealed the importance of renal L-type fatty acid binding protein (L-FABP) with antioxidative effect in various renal disease models. Therefore, the aim of this study is to elucidate the renoprotective effect of renal L-FABP and Ang II type 1a receptor (AT1a) loss against chronic TID after IR.

Methods: To induce severe chronic TID after renal IR, unilateral renal ischemia for 60 min was performed via clamping of right renal pedicle using 4 types of male mice; wild type mice (h-L-FABP+/+), human L-FABP homosomal transgenic mice (h-L-FABP AT1a-), AT1a knockdown homo mice (hL-FABP AT1a-), and generated h-L-FABP AT1a mice. Right and left kidneys were removed at 10 weeks after IR.

Results: While marked renal atrophy and progressive TID were found in each IR-kidney of h-L-FABP AT1a- and h-L-FABP AT1a- mice, the degrees of both atrophy and TID were significantly ameliorated in the IR-kidneys of the h-L-FABP AT1a- mice. These results suggested that antioxidative effect of L-FABP in addition to AT1a loss may be related to suppression of chronic TID after IR.

Conclusions: Increased expression of renal L-FABP in addition to suppressed activity of AT1a may be a useful strategy for prevention of AKI-to-CKD transition.

Development of a Synthetic Biotic, SYNB8802, for the Treatment of Enteric Hyperoxaluria
Lauren Renaud,1 David Lubkowicz, Pip Reeder, Chris Bergeron, Zhibin C. Chen, Michael J. James, Pasquale Cantarella, Mark Charbonneau, Ron Shmueli, Jr Gao, Vincent Isabella, Mylene Perreault. Synlogic, Cambridge, MA.

Background: Enteric hyperoxaluria (EH) is a metabolic disease that results from excessive absorption of oxalate from dietary sources. Increased oxalate levels can lead to the formation of kidney stones and, ultimately, to kidney failure. EH occurs most frequently in patients with underlying gastrointestinal disorders, including inflammatory bowel disease, short bowel syndrome, or individuals who have undergone bariatric surgery. There is a high unmet need for new EH therapies, as a low oxalate diet is the only option currently available to patients. Synlogic is developing a novel Synthetic Biotic™ medicine for the treatment of EH, designated as SYNB8802.

Methods: SYNB8802 is an engineered bacterium derived from Escherichia coli Nissle 1917 (EcN) that has been engineered to metabolize oxalate to formate and CO2 in the gastrointestinal tract.

Results: Inoculation of SYNB8802 into minimal media showed significant consumption of oxalate and production of formate as compared to un-engineered (EcN) bacterial strain. When administered concomitantly with “C-oxalate to healthy mice, SYNB8802 decreased the urinary recovery of “C-oxalate, indicative of its ability to consume oxalate in vivo. In healthy non-human primates (NHP) administered approximately 400 mg of dietary oxalate, SYNB8802 lowered the urinary recovery of oxalate and “C-oxalate in a dose dependent manner by up to 75% as compared to vehicle. In addition, Synlogic has developed a mathematical model that predicts clinically meaningful reductions in urinary oxalate in EH patients.

Conclusions: Overall, SYNB8802 represents a promising new approach for the treatment of enteric hyperoxaluria.
PO0651
A Novel Small Molecule Modulating the Mitochondrial NEET Proteins Improves Inflammation and Fibrosis in Kidneys of Nonalcoholic Steatohepatitis Mice
Fabiola Terz,2 Stéphanie Le Corre,1 Florence Vasseur,2 Diane Sampson,1 Pauline Radreus,1 Benoit De Chassy,1 Jacky Vonderscher,1 Raphael Darteil,1,2 Eric Meldrum,1,2,3 ENYO Pharma SA, Lyon, France;4 Institut Necker-Enfants Malades, Paris, France.

Background: Non-alcoholic steatohepatitis (NASH) is a disease characterized by excessive fat accumulation, inflammation, and ballooning degeneration of hepatocytes, with or without fibrosis in the liver. It is now reported that NASH not only affects the liver but is also associated with chronic kidney disease (CKD). However, the morphological appearance of NASH kidneys has been poorly characterized. These observations highlight the need for a treatment that targets both conditions. Here, we assessed the effect of a novel chemistry that regulates the function of 3 mitochondrial proteins called the NEET proteins, previously reported to be important in metabolic diseases, on a diet-induced NASH model in mice.

Methods: Mice were fed with a high fat diet for 30 weeks prior treatment with ENYO’s molecule for 8 weeks. The kidneys and livers were collected at sacrifice and sections were stained with H&E, PAS and picrosirius red staining to analyze their morphology. Specific immunostainings and qRT-PCR were performed to quantify the extent of inflammation (CD3, MAC1 and F4/80) and fibrosis (Col1a1, Col3a1, fibronectin).

Results: NASH mice displayed severe renal lesions such as glomerulosclerosis, tubular casts, tubular lipid accumulation and interstitial fibrosis. Mononuclear cell infiltration was also massively increased, in particular in the perivascular areas. Quantitative RT-PCR revealed a significant increase of the expression of several fibrosis and inflammation markers. Therapeutic administration of ENYO’s molecule was shown to resolve these lesions with a return back to normal regarding fibrosis, and a 50% and 35% decrease in lymphocyte and macrophage accumulation, respectively. In the liver, inflammation and fibrosis were also attenuated, specifically in the periporal zone that has been shown to be correlated with the severity of the disease. Interestingly, the most significant responders in the liver were also the best responders in the kidneys.

Conclusions: We have shown that NASH mice developed CKD, recapitulating the phenotypes observed in humans. Moreover, we have identified a new treatment, that by targeting NEET proteins, protects mice from the development of both liver and renal lesions.

PO0652
SIRT3 Deacetylates PDHE1α to Regulated Mitochondria Metabolism in Tubular Epithelial Cells During Renal Fibrosis
Yu Zhang, Yang Zhou, Lei Jiang, Junwei Yang. Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.

Background: Abnormal energy metabolism is considered to be related to renal interstitial fibrosis. Pyruvate dehydrogenase α (PDHE1α) is the main catalytic enzyme of pyruvate dehydrogenase complex (PDHC) linking glycolysis to the TCA cycle. N-lysine acetylation is an important post-translational modification involves in energy metabolism. SIRT3 is a mitochondrial deacetylase that mediates the activity many metabolic enzymes.

Methods: Unilateral ureteral obstruction (UUO) or ischemia-reperfusion (I/R) were used to induce renal fibrosis in C57BL/6j mice or SIRT3 knockout mice. Primary tubular epithelial cells (PTCs) were stimulated by TGF-β1. Protein array and the acetylation array by LC-MS/MS were performed on tubules separated from sham or UUO-operated mice. K149R, K267R, K385R mutations in PDHE1α were transfected into PTCs.

Results: Acetylation showed that the majority of proteins were hyper-acetylation after UUO. GO enrichment analysis revealed that PDH was the mostly enriched GO term. Immunoprecipitation analysis confirmed that PDHE1α acetylation was enhanced after UUO or I/R operation. Activation of SIRT3 by HKL could block the hyper-acetylation of PDHE1α, restored PDH enzyme activity, and inhibited the phosphorylation of PDH in mice with UUO or I/R. On the contrary, Sirt3 KO mice had more acetylated PDHE1α, more phosphorylated PDHE1α and defective PDH enzyme activity. In vitro, increased PDH1 acetylation was accompanied by reduced PDH enzyme activity and increased PDHE1α phosphorylation in PTCs after TGF-β1 stimulation. Activation of SIRT3 by HKL reduced the effect of TGF-β1. Inhibition SIRT3 activity by 3-TYP or SIRT3 siRNA transection have the same effect as TGF-β1. K149, K267, K385 were identified as the main poteintially acetylated sites in PDHE1α. Acetylation of PDHE1α, the activity of PDH and PDHE1α phosphorylation remained unchanged in PTCs with the K385R mutation stimulated with TGF-β1 or SIRT3 siRNA transection.

Conclusions: In summary, we showed that mitochondrial proteins involved in regulating energy metabolism were acetylated and targeted by SIRT3 in PTCs. The deacetylation of PDHE1α at lysine 385 by SIRT3 plays a key role in metabolic reprogramming in renal fibrosis.

Empagliflozin Restores CKD-Induced Impairment of Endothelial Regulation of Cardiomyocyte Relaxation and Contraction
Rio P. Juni, Rushil Al-Shama, Diederik W. Kuster, Jolanda Van der velden, Henrike M. Hamer, Marc G. Vervoelt, Eto C. Eringa, Pieter Koolwijk, Victor van Hinsbergh. Amsterdam University Medical Centres, Amsterdam Universitair Medisch Centra, Amsterdam, Netherlands.

Background: Chronic kidney disease (CKD) promotes development of cardiac abnormalities and is highly prevalent in patients with heart failure (HF), particularly HF with preserved ejection fraction (HFpEF). CKD and HF are associated with endothelial dysfunction and have been shown to benefit from a sodium-glucose co-transporter 2 inhibitor, empagliflozin. We hypothesized that uricemic serum from CKD patients impairs cardiomyocyte (CM) relaxation and contraction by inducing endothelial cell dysfunction and empagliflozin protects against this effect.

Methods: Co-culture system of human cardiac microvascular endothelial cells (CMECs) with adult rat ventricular cardiomyocytes (CMs).

Results: We showed that CMECs promote CM relaxation (return velocity, Fig. A) and contraction (sarcomere shortening, Fig. B). Serum from CKD patients impaired endothelial enhancement of CM function which was rescued by empagliflozin (Fig. A-B). Exposure to uricemic serum reduced nitric oxide (NO) bioavailability in CMECs and increased mitochondrial reactive oxygen species (ROS) and 3-nitrotyrosine level, indicating NO scavenging by ROS. Empagliflozin restored endothelial enhancement of NO level in CMs by restoring endothelial NO bioavailability and reducing endothelial mitochondrial ROS, an effect that was largely independent of sodium-hydrogen exchange.

Conclusions: Serum from CKD patients impairs CM relaxation and contraction through induction of endothelial dysfunction driven by an increase in mitochondrial ROS production. Empagliflozin restores the enhancement effect of CMECs on CM function by reducing mitochondrial oxidative damage, leading to reduced ROS accumulation and increased endothelial NO bioavailability.

246
differences in whole kidney analysis of inflammatory cytokine qPCR between them, renal macrophages isolated from CD148KO mice showed a highly expressed inflammatory cytokine expression (TNF-α, IL-1β, IL-6). Peritoneal macrophages derived from CD148KO mice showed higher inflammatory cytokine expression (TNF-α, IL-1β, IL-6) to LPS, accompanied by higher phosphorylation of Erk. In addition, Erk inhibitor, U0126 diminished the difference between WT and CD148KO macrophages.

Conclusions: Our data suggests that CD148 negatively regulates macrophage M1 polarization through Erk and its deficiency accelerates macrophage inflammation in uUo kidneys, leading to advanced tubular injury and renal fibrosis.

LRG1 Promotes Renal Fibrosis by Enhancing TGF-β-Induced Smad3 Pathway
Quan Hong,1,2 Hong Cai,1,3 Lu Zhang,1,3 Zhouhui Ni,1,2 Guangyun Cai,1 Xiaocihui Chen,2 John C. He,1 Kyung Lee,1 1Icahn School of Medicine at Mount Sinai, New York, NY; 2Chinese PLA General Hospital, Beijing, China; 3Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Shanghai, China; 4James J Peters VA Medical Center, Bronx, NY; 5The First Affiliated Hospital of Xiamen University, Xiamen, China.

Background: Renal fibrosis is a final convergent pathway for CKD progression, but effective fibrosis therapy is lacking. We recently showed that leucine-rich alpha-2 glycoprotein-1 (LRG1), a secreted glycoprotein, is highly upregulated in diabetic kidneys and potentiates the endothelial TGF-β signaling, mediated by ALK1 receptor and Smad1/5 activation, to increase angiogenesis and worsen DKD progression. However, increased LRG1 expression was not limited to the endothelial cells in the diabetic kidneys, but also found in the renal tubular epithelial cells (RTECs). Therefore, we examined whether LRG1 is upregulated in RTECs leading to renal fibrosis progression.

Methods: We examined the expression of LRG1 in the tubulointerstitium RNAseq datasets of human CKD. We explored the potential mechanism in LRG1 upregulation in cultured RTECs and examined the specific TGF-β/Smad signaling pathway mediated by LRG1 using shRNA-knockdown. We examined the effects of LRG1 ablation in unilateral ureteral obstruction (UUO) and aristolochic acid nephropathy (AAN) models of renal fibrosis. We also examined the effects of RTEC-specific overexpression of LRG1 in renal fibrosis in vivo. We further compared the activation of Smad proteins in the RTECs of control, Lrg1-/- and Ren2 LE mice with UUO.

Results: We found that the LRG1 mRNA transcript was markedly increased in the microdissected tubulointerstitial of human CKD. In cultured RTECs, LRG1 expression was upregulated by a pro-inflammatory cytokine TNF-α, and chromatin IP assay confirmed the binding of p65 subunit NF-kB to the LRG1 promoter region. Importantly, LRG1 enhanced the TGF-β-induced Smad3 activation, but not of Smad1/5, and the expression of pro-fibrotic genes in RTECs. The global knockout of Lrsg attenuated renal fibrosis in mice with UUO or AAN. In AAN mice, Lrg1 ablation also improved renal function. In contrast, the RTEC-specific overexpression of LRG1 markedly heightened the renal fibrosis in vivo. The level of Smad3 phosphorylation in RTECs in the obstructed kidneys was directly associated with the loss or gain of LRG1 expression.

Conclusions: Our current study attributes a previously undescribed role of LRG1 as a key modulator of the canonical TGF-β/Smad3 signal transduction in RTECs and suggests that the targeting of LRG1 may be an effective approach against renal fibrosis.

Single-Nucleus RNA Sequencing Identifies New Classes of Renal Proximal Tubular Epithelial Cell in Kidney Fibrosis
Yuehan Luo,1,2 Chia-te Liao,1 Rachel Raybould,1 Bnar Talabani,1 Barbara Szomolay,1 Timothy Bowen,1 Robert Andrews,1 Philip R. Taylor,1 Donald Fraser,1 Wales Kidney Research Unit 1Cardiff University, Cardiff, United Kingdom; 2Chang Gung Memorial Hospital, Taoyuan, Taiwan.

Background: Proximal tubular cells (PTC) play a central role in nephron recovery versus fibrosis following renal injury. PTC heterogeneity is well-documented but poorly-characterized in extant single-cell sequencing data. Here we have determined PTC phenotype in renal fibrosis by single-nucleus RNA sequencing (snRNA-seq).

Methods: Kidneys were harvested from naïve mice and mice with renal fibrosis induced by chronic aristolochic acid administration. Nuclei were isolated using Nuclei EZ Lysis buffer. Libraries were prepared on the 10X platform and snRNA-seq completed using Illumina NextSeq 550. Downstream bioinformatics analyses used Seurat.

Results: A total of 23,885 nuclei were analyzed. PTCs were found in five abundant clusters, mapping to S1, S1-2, S2-cortical S3, and medullary S3 segments. Additional cell clusters were present (“new PTC clusters”) at low abundance in normal kidney and in increased number in kidneys undergoing regeneration/fibrosis following injury. These clusters exhibited clear molecular phenotypes, permitting labeling as, proliferating, differentiated-intermediate, differentiated-regenerating, and (present only following injury) differentiated-senescent. Each of these clusters exhibited a unique gene expression signature, including multiple genes associated with renal injury response and fibrosis progression. Comprehensive pathway analyses revealed metabolic reprogramming, enrichment of cellular communication and cell motility, and various immune signatures in new PTC clusters. In ligand-receptor analysis, new PTC clusters promoted fibrotic signaling to fibroblasts and inflammatory activation to macrophages.

Conclusions: SnRNA-seq permits the dissection of cell-type and cell-subtype-specific responses. We identified previously unknown, injury-associated PTC clusters. These exhibit highly specific and restricted gene signatures, including canonical PTC injury response and fibrosis progression. Comprehensive pathway analyses with compelling novel biology within our renal portfolio.

Artificial Intelligence-Driven Target Identification in CKD
Chanchal Kumar,1 Lisa Buvalli,2 Maria Ryaboshapka,1 Kevin Woolard,9 Julie Williams,2 Natalie Kurbatova,2 Anna Rezmičenko,1 Ian MacPhee,3 Mohammad Bohlooly,4 Dirk S. Paul,4 James Dunbar,2 Andrea Taddei,5 Mark Davies,7 Siobhan McMahon,8,9 Andres Mori,1 Regina Fritsche-Danielson,5 Claire Bendsten,2,6 Pernille B. Laerkgaard Hansen,2 1Translational Science and Experimental Medicine, AstraZeneca, Cambridge, United Kingdom; 2Clinical Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; 3Bioscience Renal, Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; 4Early Clinical Development, Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; 5Centre for Genomic Research, Research and Early Development, Discovery Sciences, BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; 6BenevolentAI, London, United Kingdom; 7Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; 8Bioscience Renal, Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom.

Background: Involvement of multiple pathways and complex pathophysiology are few of the hallmarks of Chronic Kidney Disease (CKD). These reasons contribute to the challenge for drug discovery in CKD, which is a major contributor to global disease burden. Availability of a wealth of CKD omics data has opened avenues for novel insight generation through unbiased integrative analysis. In a pioneering effort AstraZeneca and BenevolentAI initiated a collaboration to leverage the potential of artificial intelligence (AI) to generate novel hypotheses for drug targets in CKD.

Methods: We have created a CKD knowledge graph (CKD-KG) - a knowledge base of biological and chemical entities (genes, small molecules, etc) and their relationships (gene-disease associations, therapeutic drugs, biological processes, etc) and augmented with CKD specific information derived from both public and AstraZeneca proprietary data sets. The CKD-KG was constructed by aggregating information from structured biomedical databases, machine learning (ML)-based extraction from unstructured sources, and patient-centric omics datasets (unstructured: 140M documents, 1B relationships, (ii)-structured: 56M relationships, 3B omics data points, (iii) 35 licensed data sources, and (iv) 53 CKD omics datasets. The CKD-KG was used as input to BenevolentAI’s relational inference and causal reasoning ML models to produce target hypotheses for CKD.

Results: The fleet of models identified 295 potential targets that were triaged down to 69 targets. These 69 targets have been further prioritized based on an in-house human target validation pipeline, and additional criteria such as safety and druggability, in line with AstraZeneca’s 5R framework.

Conclusions: CKD-KG enables a transformative approach to generating novel target hypotheses with the potential of improving health outcomes for CKD patients.

Twist1 in T Lymphocytes Exaggerates Kidney Fibrosis After Ureteral Obstruction
Jiafa Ren, Jamie Privratsky, Steven D. Crowley. Duke University School of Medicine, Durham, NC.

**Background:** T cells play a critical role in directing kidney fibrogenesis. The transcription factor Twist1 limits pro-inflammatory cytokine production in T cells, but the role of T cell-derived cytokine mediators regulated by Twist1 in kidney damage has not been fully elucidated. To explore the role of T cell Twist1 in kidney scar formation, we subjected mice with Twist1 lymphocyte-specific deletion (“TKO”) of Twist1 and controls to the UUO.

**Methods:** 129/SvEv mice with a floxed allele for the gene encoding Twist1 or TNFα were bred with CD4-Cre mice to yield Twist1 TKO or TNFα TKO mice while robust selective deletion of Twist1 mRNA >90% vs. WTs in CD4+ T cells, and >85% vs. WT in CD8+ T cells (p<0.0001) or TNFα mRNA in T cells (published), respectively. Twist1 TKO, TNFα TKO, and WT controls underwent UUO with assessment of kidney fibrosis and T cell phenotype at 14 days.

**Results:** 2 weeks after UUO, Twist1 TKO mice developed less kidney fibrosis compared to WT as quantified by western blot for Colla1 (0.75±0.06 vs 1.0±0.05; p<0.02) and edema (0.56±0.01 vs 1.0±0.08; p<0.001) and by RT-PCR for Colla1 (0.69±0.08 vs 1.0±0.10; p<0.048), fibronectin (0.76±0.07 vs 1.0±0.06; p<0.003), TGFβ1 (0.73±0.08 vs 1.0±0.04; p<0.004) and Pai-1 (0.47±0.05 vs 1.0±0.09; p<0.001). Twist1 TKO mice also showed attenuated kidney injury as indicated by NGAL mRNA expression (0.50±0.06 vs 1.0±0.16; p<0.04). Twist1 can suppress promyelocytic leukemia mediators such as TNFα and IL17A in T cells. In 14d, flow cytometry revealed similar T cell and macrophage numbers in the obstructed WT and Twist1 TKO kidneys. We then used fluorescent cell sorting to isolate CD4+ and CD8+ T cells from obstructed WT and Twist1 TKO kidneys. Sorted CD4+ T cells from Twist1 TKO kidneys expressed similar mRNA levels for TNFα and IL17A compared to WT (p>0.08). CD8+ T cells from obstructed Twist1 TKO kidneys expressed higher mRNA levels for TNFα (1.8±0.39 vs 1.0±0.19; p=0.03), but not IL17A vs WT controls. To further explore the role of TNFα in T cells during fibrogenesis, we subjected TNFα TKO and WT mice to UUO. We found that TNFα deletion in T cells exaggerated kidney fibrosis and injury as quantified by real time PCR for fibronectin (1.4±0.09 vs 1.0±0.13; p=0.03) and NGAL (1.3±0.10 vs 1.0±0.05; p<0.01) mRNA expression, respectively.

**Conclusions:** Twist1 in T cells drives fibrosis in the injured kidney, possibly by limiting TNFα production.

PO0659
Evaluation of the Effects of a Resistant Starch Diet and Metaproteomics Study of Microbiome-Host Interactions in a 5/6 Nephrectomy Murine Model of CKD
Oleg K. Karaduta,1 Galina V. Glazko,2 Zeljko Dvanajscak,3 Yasir Rahmatallah,1 Samuel G. Mackintosh,3 John M. Arthur,1 Boris Zybailov,1 University of Arkansas System, Little Rock, AR; 2Arkana Laboratories, Little Rock, AR.

**Background:** Chronic kidney disease (CKD), a progressive decline in kidney function, is a growing health problem: 13% of all US have CKD. In 40% of cases, CKD leads to irreversible loss of kidney function, end-stage renal disease. Prebiotic resistant starch (RS) changes gut flora and alleviates CKD. However, mechanisms of RS action remain unclear.

**Methods:** Male mice (n=8) were used to reduce renal mass and to induce CKD. 8 mice served as healthy controls. Each of the two groups was further split in two subgroups (n=4, each), either supplemented with RS or regular diet. PEAKS was used to identify peptides via de novo sequencing in cecal content. To better understand the differences between CKD, CKDRS, HRS and H phenotypes we combined all bacteria that were differentially abundant in six comparisons to infer bacterial co-abundance (BCoA) network. Histopathological evaluation was used for kidney damage comparison.

**Results:** Histopathological evaluation showed that CKDRS mice had less kidney damage compared to CKD group. Using metaproteomics we found that the most abundant bacterium in HRS phenotype is indole-producing Oscillibacter sp. 1-3, confirming the result of BlasZEGO that indole metabolism is upregulated in HRS phenotype as compared to CKDRS and CKD. The most connected network hub Firmicutes bacterium ASF500 is significantly overrepresented in CKDRS as compared to CKD and is not significantly different between HRS and H. Firmicutes bacterium ASF500 belongs to 20 bacterial strains from human intestine that can induce Th17 cells in the mouse and rat intestine and have immunostimulatory effects. Experiments to validate effect of butyrate on host immunity in 5/6 nephrectomy model. For the first time we demonstrate decrease in kidney fibrosis and bacteria species responsible for beneficial effects of RS. MST2 analysis allows for understanding fission/fusion cycles, and respiratory performance in mitochondria can affect the onset to many pathologies. Premenopausal females are typically less prone to cardiorenal associated with mortality. The odds of mortality among AKI patients varied significantly among gender.

PO0660
Sex Differences in Renal Mitochondrial Function of Young Healthy Rats
Ryan Schibalski,1 Regina F. Soutanova,2,3 Mark Donndon,1 Allison N. Mccrimmon,1 Kristzian Stadler,2 Darja Ilatovskaya,1 1Medical University of South Carolina, Charleston, SC; 2,3Pennington Biomedical Research Center, Baton Rouge, LA, US.

**Background:** Sex differences in mitochondrial function have been linked to many pathologies. Premenopausal females are typically less prone to cardiovascular damage than males. Differences in the ability to manage oxidative stress, calcium uptake, fission/fusion cycles, and respiratory performance in mitochondria can affect the onset and progression of the diseases. While characteristic sex-related dissimilarities have been reported in renal function, nothing is known with regards to how sex may affect the performance of renal mitochondria. The goal of this study was to compare renal mitochondrial function in young healthy male vs female rats.

**Methods:** Mitochondria were isolated from the kidneys of Sprague Dawley (SD) rats (10-11 weeks). Mitochondrial membrane potential, superoxide and H2O2 levels were measured with luminescent (MCLA) or fluorescent (TMRM, Amplex Red) dyes, and Seahorse analysis was performed. Antioxidant capacity was measured with a Trolox-based assay. Lipid peroxide radicals were detected using with spin resonance spectroscopy (ESR) with in vivo spin trapping.

**Results:** Kidneys from SD male (SDm) and female rats (SDf) were divided into cortex (SDc; 13) and medulla (SDm; 14). First, we report significantly higher membrane potential in SDm compared to SDf (p<0.001). H2O2 levels were elevated in both the cortex and medulla (SDm compared to SDf; p<0.01). Interestingly, mitochondrial superoxide production was increased in the medulla compared to the cortex for both SDm and SDf, while SOD2 expression was lower (p<0.001). Antioxidant capacity was lower in SDm tissues compared to all other groups, which is consistent with higher H2O2 levels (p<0.001). H2O2 levels were higher in the mitochondria of SDf than in SDm, as well as reserve and maximal capacity compared to males. In addition, we report that these parameters were lower in medulla than corticomedulla, independent of sex. ESR analysis showed similar lipid peroxide radical levels in males and females, but detected different reactive adducts – an amine or amino acid-centered radical – in the medulla.

**Conclusions:** We report sex-related differences in mitochondrial function in the kidneys of young healthy rats. Further studies are needed to establish the mechanisms that they may affect the predisposition to kidney disease development later in life.

**Funding:** Other NIH Support - NHLBI, Commercial Support - Dialysis Clinics Inc

PO0661
Renal Involvement in Coronavirus Disease 2019 (COVID-19): A Systematic Review and Meta-Analysis
Kam wa Chan,1 Kam Yn Yu,1 Pak Wing Lee,2 Sydney C. Tang,1 Department of Medicine, The University of Hong Kong, Hong Kong, Hong Kong; 2London School of Hygiene and Tropical Medicine Faculty of Epidemiology and Health, London, United Kingdom.

**Background:** COVID-19 caused substantial casualty worldwide. As the reported renal involvement varied across regions, we sought to review the global prevalence of renal manifestations among COVID-19 patients and determine the risk factors associated with AKI.

**Methods:** We systematically searched 6 databases for peer-reviewed reports and 7 data portals for grey literature for all trials, cohorts, case-control studies and case-series that reported the prevalence of renal manifestations including AKI, RRT, proteinuria and hematuria, and their associated risk factors. All papers were screened, assessed and extracted by at least 2 researchers independently. Quality was assessed according to NIH assessment tools. To avoid duplicate of patient data, we matched the location, institution and time period, and only included the largest data source if studies overlapped. Prevalence of renal manifestations was pooled from studies that consecutively recruited patients from the general population, and with clear definition of outcome. This review was prospectively registered at PROSPERO (CRD42020184621).

**Results:** 36 studies from 8 countries and over 50 cities with a total of 14,712 patients were identified. 34 and 2 were cohorts and case-control studies respectively. 24, 7 and 5 studies reported COVID-19 patients from the general population, severe / critical patients and patients with history of RRT. AKI occurred in 14.3% of all COVID-19 cases and was highest in New York City. 4.7% of hospitalized COVID-19 patients underwent RRT. Proteinuria and hematuria were present in 42.5% and 26.7% of all COVID-19 cases. The odds of mortality among COVID-19 patients who developed AKI was 15 times higher than non-AKI COVID-19 patients (pooled OR=16.85, 95% CI: 10.06 to 28.23, 2 cities, 6 studies, 9,297 patients) and was higher in Hubei. Such effect was not observed among kidney transplant patients (pooled OR=0.95, 95% CI: 0.12 to 7.22, 2 studies, 30 patients). Higher C-reactive protein, leukocyte count, serum lactate dehydrogenase and creatinine levels on admission were associated with AKI.

**Conclusions:** AKI was prevalent among COVID-19 patients and significantly associated with mortality. The odds of mortality among AKI patients varied significantly between cities, which could be associated with differences in healthcare infrastructure and delayed hospitalization and treatment initiation.
PO0660
Forecasting Continuous Renal Replacement Therapy Shortages During the COVID-19 Pandemic in the United States
Yusuke Reddy, Rochelle P. Walensky, Krishna P. Reddy.1,2 Renal Division, Brigham and Women’s Hospital, Boston, MA; 1Medical Practice Evaluation Center, Massachusetts General Hospital, Boston, MA; 1Division of Pulmonary and Critical Care Medicine, Massachusetts General Hospital, Boston, MA.

Background: The coronavirus disease 2019 (COVID-19) pandemic has increased continuous renal replacement therapy (CRRT) demand in the US, however total CRRT demand and capacity remain unclear. Our objective was to project national and statewide CRRT demand and capacity during the COVID-19 pandemic.

Methods: We projected CRRT demand using a model in which 4% of patients admitted with COVID-19 develop acute kidney injury (AKI) requiring CRRT for 12 days. To estimate non-COVID-19 CRRT demand, we applied the prevalence of AKI requiring CRRT among other ICU patients of 8.8%. We assumed capacity would be double this demand and that this demand would decrease to 25% during the pandemic. We compared CRRT demand and capacity to estimate shortage. In sensitivity analysis, we varied parameters influencing CRRT demand and capacity.

Results: We estimated a national CRRT shortage of 1529 (95% uncertainty interval: 1264-3837) machines with a capacity of 9375 machines, and shortages in 8 states during the COVID-19 pandemic (Table 1 and Figure 1).

Conclusions: Several US states are projected to have CRRT shortages during the COVID-19 pandemic. A national strategy, such as the creation of a federal stockpile, is needed to mitigate CRRT shortages during this pandemic and future healthcare crises.

Funding: NIDDK Support

Model-generated results for 8 states with CRRT shortages

PO0663
Acute Tubular Injury in Patients with Severe COVID-19 Infection
Yusuke Fukao, Hajime Nagasawa, Yoshiohito Nihei, Seiji Ueda, Masao Kihara, Tomohito Gohda, Yusuke Suzuki. Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan.

Background: Novel coronavirus, severe acute syndrome coronavirus 2 (SARS-CoV-2), has rapidly spread all over the world. SARS-CoV-2 enters host target via angiotensin-converting enzyme-2 which are ubiquitously expressed in many organs including proximal tubules in kidney. Indeed, autopsy cases with coronavirus disease-2019 (COVID-19) revealed the existence of coronavirus particles in the renal tubular cells. Here, we evaluated tubular injury in patients with severe and non-severe COVID19.

Methods: We investigated the relationship between urinary levels of tubule markers (NAG, β2-MG, L-FABP, and D-dimer) and laboratory markers in 17 COVID-19 patients without chronic kidney disease on admission. We also analyzed the relationship between the laboratory markers and respiratory status in severe (n=7) or non-severe (n=10) COVID-19 patients which were defined by requirements of supplemental oxygen.

Results: Although only 2 patients developed AKI in severe cases, serum Interleukin-6 (IL-6) level significantly increased in all of severe patients and correlated with levels of proteinuria (R2=0.37, p<0.01), NAG (R2=0.41, p<0.006), β2-MG (R2=0.47, p<0.007), L-FABP (R2=0.57, p<0.001) on admission. In addition, severe patients had significantly higher levels of proteinuria (severe: 0.14g/gCr vs non-severe: 0.15g/gCr), NAG (33.3 vs 11.0IU/L), β2MG (17134.4 vs 1168.5g/l), β2-MG (63.6 vs 12.4mg/l), L-FABP (57.9 vs 7.5g/gCr) as compared to non-severe cases. Proteinuria and elevated tubular markers were observed only in 2 and 6 cases respectively in non-severe patients, despite those were found in all severe cases.

Conclusions: We found that acute tubular injury was associated with the severity of COVID-19 infection. Since the pathophysiological hallmark of COVID-19 is severe systemic inflammation, it remains obscure whether progressive damage of tubules in SARS-CoV-2 is the result of direct viral infection, ischemic injury, or exposure of any humoral factors. Further large scaled studies focusing on tubular damage should be needed to elucidate underlying mechanisms of renal complication in COVID-19 infection.

Heat maps demonstrating states with CRRT shortages during the COVID-19 pandemic under scenarios: A) base case, B) highest CRRT capacity estimate and C) lowest CRRT capacity estimate

PO0665
Prolonged Intermittent Renal Replacement Therapy for AKI in COVID-19 Patients with Acute Respiratory Distress Syndrome
Juan Carlos Ramirez-Sandoval, Jorge Gaytan, Mauricio Arvizu-Hernandez, Juan M. Mejia-Villegas, Pedro Xolapa Chavez, Ricardo Corea-Rotter, Olyinka Vega. Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico.

Background: Patients with COVID-19 associated acute respiratory distress syndrome (ARDS) frequently develop severe AKI. Although continuous renal replacement therapy (CRRT) is standard of care for critically ill patients, prolonged intermittent renal replacement therapy (PIRRT) is a feasible option.

Results: Of 142 severe COVID-19 patients, 91 (64%) developed AKI, 42 (29%) Stage 3, and 14 (7%) initiated PIRRT; median age 51 y [IQR 51-59, range 40-73], male 11 [78%], diabetes 5 [36%], median BMI 31 kg/m² [27-51], SOFA score 10 [IQR 9-11], ferritin 790 [158-1374 ng/mL] and D-dimer 3076 [929-8558 ng/mL]. In 81/101 (81%) PIRRT sessions, ultrafiltration (UF) goal was achieved. Duration of PIRRT was 6-8 h in 65/101 (64%) yet in 16/101, procedure was extended 2-4 additional h, to reach UF goal. In subjects with vasoressors, there was a mean norepinephrine dose increase of

COVID-19 AKI: Risk Factors and Markers of Disease from a Large U.K. Cohort

Thomas Phillips,1 Gary Leggett,2 Matt Stammers,1 Kirsty Armstrong,1 Simon D. Fraser,3 Becky Bonfield,1 Kristin Veighy1.1University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom; 2University of Southampton, Southampton, United Kingdom

Background: Acute kidney injury (AKI) is a significant complication of COVID-19 infection. UK NICE guidelines have been developed. Aim: to examine our local patient-level COVID-19 Hospitalisation in England Surveillance System (CHESS) database to elucidate potential risk factors for AKI vs. guidelines.

Methods: 564 COVID positive admissions between 7 March-24 May 2020 at University Hospital Southampton were examined using Python (Anaconda distribution) and SPSS®. AKI was staged by RIFLE and AKIN criteria consistent with NICE guidance. X2-test, Mann-Whitney U-test and logistic regression were used to analyse the data.

Results: AKI was present in 177 patients (31%). At peak, 108 (61%) stage 1; 42 (24%) stage 2; 27 (15%) stage 3. There were no significant differences in cohorts with respect to white vs non-white ethnicity, gender, obesity or anti-COVID-19 treatment. 44% of patients with AKI died vs 19% in the non-AKI group (p<0.001). AKI was associated with ICU admission (27% vs 10% p=0.001), requirement of non-invasive (13% vs 4%) and invasive ventilation (14% vs 4%) (both p<0.001). Prior diabetes (18% vs 8%), hypertension (47% vs 34%), chronic respiratory and cardiac disease (both 25% vs 15%) were more common in the AKI group (p<0.001). Increased age was associated with AKI (p=0.02) and length of stay (LOS) positively correlated to AKI stage (p<0.001). Peak levels of biomarkers: ferritin, D-dimer, C-reactive protein, high sensitivity troponin-I, neutrophil count and total white cell count, were all significantly raised (p<0.001) in the AKI group. Increasing with stage of AKI (p<0.001). However, in multivariable analysis, first clinical observations, neutrophil count, haemoglobin, D-Dimer and albumin came out as the most significant predictors of AKI: Specificity 88.7%, Sensitivity 43.6%.

Conclusions: AKI is a frequent complication of COVID-19 and we identified similar risk factors to those in the NICE guidelines. In addition, we found hypotension and chronic respiratory disease to increase risk of AKI whilst ethnicity, gender, obesity and COVID-19 treatments did not. Furthermore, AKI was associated with increased mortality, ICU admissions and LOS, concordant with previous studies. This data also points to several biomarkers as possible predictors of AKI development and severity. Further analysis of this data is ongoing.

PO0668

Hematuria and Elevated Lactate Dehydrogenase Are Associated with AKI in Hospitalized COVID-19 Patients

George Thomas, Georgees Nahhoul, Jonathan J. Taliercio, Tushar J. Vachharajani, Sevag Demirjian. Cleveland Clinic, Cleveland, OH

Background: Acute kidney injury (AKI) can be a severe complication of COVID-19, particularly in those who require intensive care. Its relationship to the incidence of proteinuria, hematuria, and elevated inflammatory markers has not been well characterized. Our objective is to describe the incidence of AKI in COVID-19, and its association with inflammatory markers.

Methods: Retrospective cohort study of adult patients hospitalized at the Cleveland Clinic with COVID-19. SARS-CoV-2 infection was confirmed by virus detection in respiratory specimens using RT-PCR. AKI was diagnosed per KDIGO serum creatinine-based classification. We selected stage 2 and higher as our primary endpoint for the study. Baseline creatinine was defined as the most recent pre-admission level available within 3 months of presentation. Acute lung injury was defined by the need for mechanical ventilation.

Results: The incidence of AKI was 14% in 621 hospitalized COVID-19 patients, with half requiring kidney replacement therapy (KRT). The incidence of proteinuria and microscopic hematuria were high in these patients (83% and 77% respectively). Seventy-five percent of patients with AKI needed mechanical ventilation, and timing of KRT overlapped with time of mechanical ventilation. Inflammatory markers and acute phase reactants, including LDH, ferritin, and C reactive protein were significantly higher in patients with AKI compared to those without AKI. On adjusted analysis, hematuria and elevated LDH levels were significantly associated with AKI (Figure).

Conclusions: Elevated lactate dehydrogenase levels and microscopic hematuria on presentation are independently associated with 50% probability of moderate to severe AKI. Our findings suggest a possible pathogenetic mechanism of endothelial cell injury and thrombotic microangiopathy as a cause of AKI in COVID-19 patients. Additional studies are needed to explore this potential mechanism of AKI in COVID-19.

PO0669

High C-Reactive Protein and D-Dimer on Admission Predict the Development of AKI in Patients Hospitalized with COVID-19

Sandheep Venkataraman, Zhiying You, Jessica B. Kendrick. University of Colorado Denver School of Medicine, Aurora, CO

Background: COVID-19 infection is characterized by an acute respiratory syndrome that causes severe symptoms in some patients including a high incidence of acute kidney injury (AKI), which is associated with poor prognosis. COVID-19 infection results in a complex host response including a cytokine storm and severe inflammation. We aimed to identify whether high inflammatory markers on admission predict the development of AKI.

Methods: We performed a cohort study utilizing data from 430 patients admitted to the COVID-19 to the University of Colorado Hospital. We excluded patients with a known history of end stage kidney disease or chronic kidney disease or with missing data. A total of 203 patients were included in this analysis. The primary predictors were initial serum C-reactive protein (hsCRP) >100 mg/L and D-dimer >1000 ng/mL, FEU admission to the hospital. The primary outcome was AKI, defined by KDIGO definition of AKI based on serum creatinine levels. AKI diagnosis was confirmed by chart review. Multivariable logistic regression analysis was used to examine the association between CRP and D-dimer on admission and development of AKI.

Results: The mean age and body mass index of patients was 53.7 (16.9) years and 31.5 (8.4) kg/m2 respectively. Fifty-nine percent of patients were male, 40% were Hispanic and 22.7% were Black. 44.3% had hypertension, 35.0% had diabetes and 23% had underlying respiratory disease. Twenty-seven (13.3%) patients developed AKI. After adjustment for age, gender, race/ethnicity, diabetes, hypertension, respiratory disease, cardiovascular disease and ACEi/ARB use, admission CRP level >100 mg/L was associated with nearly a 4-fold increased odds of developing AKI (OR 3.8, 95% CI 1.4-9.8). After full adjustment, admission D-dimer level greater than 1000 ng/mL was associated with a 5-fold increased odds of AKI (OR 5.0, 95% CI 1.8 to 13.5).

Conclusions: High CRP and D-dimer on admission were associated with a significantly higher risk of developing AKI, independent of underlying comorbidities. Thus, high CRP and D-dimer on admission should trigger due deliberation and avoidance of nephroticcy medicines and close monitoring for the development of AKI.

Acute Peritoneal Dialysis in Patients with COVID-19 and AKI: A Single-Center Experience in a Time of Crisis in the United States
Maryanne Sourial,1,2 Mina Sourial,1,2 Rochelle Dalsan,1,2 Jay A. Graham,1,2 Michael J. Ross,1,2 Wei Chen,1,2 Ladan Golestaneh,1,2 Montefiore Medical Center, Bronx, NY; 1Yeshiva University Albert Einstein College of Medicine, Bronx, NY.

Introduction: In developed countries such as the United States, intermittent hemodialysis (IHD) or continuous renal replacement therapy (CRRT) are the primary mode of renal replacement therapy (RRT) for the management of AKI. However, during the COVID-19 pandemic, the ability to provide HD in our hospital system was overwhelmed due to the surge in the number of patients with AKI requiring RRT combined with limited inpatient beds. We present this single-center experience with fluid management on CRRT in relation to respiratory parameters.

Case Description: At Montefiore Medical Center (MMC), in Bronx, NY, the first case of COVID-19 was admitted on March 11, 2020. As the number of patients with COVID-19 rose, we initiated an acute PD program starting on March 25th. As of April 13th, there were 2,015 patients with COVID-19 admitted to the ICU at the University of Michigan between 3/23 and 4/26, with follow-up through 5/12/2020. All patients received post-filter continuous venovenous hemodiafiltration with regional citrate anticoagulation per institutional protocol. Daily cumulative fluid balance and respiratory parameters (P/F and PEEP) were recorded for the first 7 days of CRRT. We assess the relationship between cumulative fluid balance on CRRT and respiratory parameters (P/F and PEEP) with repeated measures modeling adjusted for fluid accumulation at CRRT start, height, weight, and age.

Results: Mean age 54.8, majority black (75%), and comorbidities included hypertension (90.6%), diabetes (56.2%), CKD (53.1%), and organ transplantation (18.8%). Median length of mechanical ventilation was 15.0 (12-25) days. Median cumulative fluid balance from admission to CRRT start was -3.3 (2.0-5.6) liters. There was a trend toward increasingly negative fluid balance on CRRT (figure). When adjusting for age, weight, height and cumulative fluid balance at CRRT start, there was no association between cumulative fluid balance on CRRT and P/F (p=0.21) or PEEP (p=0.47). At end of data collection, 9 (28.1%) patients remained in the hospital, 10 (31.3%) survived to hospital discharge and 13 (40.6%) had died.

Conclusions: Cumulative fluid balance on CRRT did not correlate with change in P/F or PEEP, even after accounting for baseline fluid balance. Nevertheless, it is possible that more aggressive fluid removal is required to demonstrated an effect.

Mean Daily Fluid Balance
Results: The 20 patients initiated early RRT after 6.4±3.6 days from ICU admission. The median hospital length of stay was 42.2 days, the net ultrafiltration rate was 65.5±65.2 ml/h. One patient in control group also received RRT after ICU admission due to AKI. No statistical difference was found in the two subgroups in baseline. 61.3% patients died during hospitalization. The median survival time was 12 days and the average observation time was 19 days. Kaplan-Meier analysis showed that the incidence of AKI, dialysis (HD) and death in ICU patients diagnosed with COVID pneumonia in a Brazilian center. Methods: Analysis from medical records of ICU patients with diagnosis of COVID pneumonia in a brazilian single-center. AKI was defined according to KDIGO criteria. Results: During the period of February 2nd to May 4th, 95 ICU patients diagnosed with COVID were analyzed. There was predominance of male (64.2%), median age of 64.9 years, previous diagnosis of hypertension, diabetes and obesity in 51.6%, 27.4% and 30.5% respectively. AKI was diagnosed in 54 (56.8%) patients and 32 (59.2%) of them required HD. Mortality rate was 17.9%. Patients with AKI, compared to no-AKI patients were statistically significant more frequently hypertensive and diabetic, worse SAPS3 and SOFA scores and need for organ support therapies. Laboratory tests depicted more anemia, lymphopenia, and higher levels of inflammatory markers as well as longer length of stay in ICU, hospital and death. Similar findings were seen in those ones who required HD compared to those with conservator treatment. Comparing patients who undergone death to survivors, they were older, more frequently diabetic, worse SAPS3 and SOFA scores and need for organ support therapies, AKI and dialysis. Multinomial logistic regression predicted that hypertension (p<0.01), mechanical ventilation (p<0.01) and use of hydroxychloroquine (p<0.009) were independent risk factors for AKI, hypertension (p<0.01), mechanical ventilation (p<0.01), use of vasopressor (p=0.04), and use of hydroxychloroquine (p<0.009) for HD patients; and age >65 years (p=0.03) and AKI (p=0.04) for death. Conclusions: In our study, AKI was a common complication of ICU COVID patients, it was associated to hypertension, Mech ventilation and use of hydroxychloroquine. As well as age >65 years, AKI was an independent risk factor to death.

AKI in Patients with COVID-19 Infection: Preliminary Data from AKI COVID-19 Registry of the Spanish Society of Nephrology
Maria Jose Soler,1 Esteban Poch,2 Raquel Diaz Mancebo,3 Rocio E. Echarri,4 Nuria Areste,1 Mercedes Salguero Lazo.1 AKI COVID-19 Registry of the Spanish Society of Nephrology.1 Hospital Vall d Hebron, Barcelona, Spain; 2Hospital Clinic de Barcelona., Barcelona, Spain; 3Hospital Universitario Virgen Macarena., Sevilla, Spain; 4Hospital de la Paz, Madrid, Spain; 5Hospital Universitario Infantia Sofia., San Sebastian de los Reyes, Spain.

Background: SARS-CoV-2 coronavirus pandemic has significant impact on the general population, and chronic hemodialysis patients presented a poor prognosis with a mortality rate around 25%. Data from severe acute kidney injury(AKI) and acute renal replacement therapy(RRT) is scarce. We present the preliminary results of AKI COVID-19 Registry of the Spanish Society of Nephrology.

Methods: The online Registry began operating on May 21th. It collects epidemiological variables, contamination and diagnostic data, signs and symptoms, treatments and outcomes. Patients were diagnosed with SARS-CoV-2 infection based on PCR of the virus.

Results: One week after the AKI COVID registry started, 54 patients with AKI and RRT from 11 Hospitals. Age was 64±9 years and 55% men, 65% hypertension, 31% diabetes mellitus, 14% cardiovascular disease, 26% chronic kidney disease, 6% neoplasms, 29% obesity, 8% chronic obstructive pulmonary disease, and
6% smokers. Previous treatment: 10% immunosuppressive, 20% ACEI, 25% ARBs, 14% antidiabetics, and 16% anticoagulants. Clinical characteristics: 92% common respiratory symptoms, 96% pneumonia, 90% required intensive care unit (ICU) and 87% mechanic ventilation. 32% albuminuria, 18% hematia, and 50% AKI with preserved urine output. Time from COVID-19 symptoms start to AKI 12.3±8days, time ICU 19.8±5days. ACR: CVAE: 15.7: 81.8% lymphopenia. RRT was needed in 91% 13.4±12days: 55% received continuous RRT, and 72% anticoagulation. Kidney biopsy was not performed. Mortality 46.3% (60 patients), and 4% remained under RRT. Time from ICU to renal function recovery 25±14 days. 65.2% death patients had hypercoagulable state. No differences were observed in comorbidities, chronic treatments, renal clinical characteristics, dialysis modality and mortality. Decreased lymphocyte count was associated with worse patient prognosis (dead 495±260 vs. survivors 789±460, p=0.023).

**Conclusions:** The mortality in AKI with RRT and COVID-19 is alarming. Several factors associated with COVID-19 disease is more frequent in males. Interestingly, half of the patients preserved urine output. Severe lymphopenia was associated with mortality. More data from the AKI COVID-19 registry will help us to enlighten the prognosis and risk factors associated to mortality.

**AKI in People Living with HIV Hospitalized with COVID-19**

Molly Fisher,1,2 Melissa Fazzani,2 David B. Hanna,2 Viraj V. Patel,1,2 Uriel R. Felsen,1,2 Mindy Ginsberg,2 Kathryn Anastas,1,2 Michael J. Ross,1,2 Montefiore Medical Center, Bronx, NY; 1Yeshiva University Albert Einstein College of Medicine, Bronx, NY.

**Background:** People living with HIV (PLWH) have an increased burden of kidney disease and interdependence factors as a risk place them at increased risk for acute kidney injury (AKI) in the setting of COVID-19. The aim of our study was to characterize the incidence, risk factors and outcomes of AKI among hospitalized PLWH with COVID-19.

**Methods:** We performed a retrospective study of adult PLWH hospitalized with laboratory confirmed COVID-19 in a large healthcare system in Bronx, New York, from March 10-May 11, 2020. Data collected included demographics, comorbidities, antiretroviral therapy (ART), initial laboratory data, and predmission CD4 count and HIV viral load. AKI was defined and staged using KDIGO criteria. Fisher and Wilcoxon tests were used to determine differences among those with and without AKI.

**Results:** During the study period, 77 PLWH were hospitalized with COVID-19. The majority were Black or Hispanic, 50% were men, 53% had hypertension, 31% diabetes mellitus, 22% chronic kidney disease (CKD) and 14% end-stage kidney disease (ESKD). Mean age count was 470 cells/μL and 85% had a suppressed HIV viral load (<40 copies/μL). After excluding 11 with ESKD, AKI incidence was 50%. Those with AKI were older [63 (SD 9) vs 55 (SD 13) years, p<0.005], more were black (56% vs 37%, p=0.01) and more had CKD (42% vs 9%, p=0.001) compared to those without AKI. There were no significant differences in CD4 count, HIV viral load, or use of tenofovir-containing ART between those with and without AKI. By AKI severity, 11/33 (33%) were stage 1, 4/33 (12%) stage 2 and 18/33 (55%) stage 3. Mechanical ventilation (33% vs 0%, p=0.0004) and in-hospital mortality (42% vs 3%, p=0.0002) were more common in those with AKI. Of 6 patients who required renal replacement therapy, 4 died and 2 remained RRT dependent. Admission white blood cell count, neutrophil/lymphocyte ratio, D-dimer, ferritin, C-reactive protein and lactate dehydrogenase levels were significantly higher in those with AKI.

**Conclusions:** The incidence of AKI in PLWH hospitalized with COVID-19 was high and associated with poor outcomes. We did not identify HIV-specific or COVID-related risk factors for AKI in the setting of COVID-19. Admission inflammatory markers may be predictive of AKI in PLWH with COVID-19.

**AKI Is Related to Mortality in COVID-19 Patients Without Underlying Kidney Disease**

Yue Yu, Huipeng Ge, Xufan Wang, Lijian Tao, Zhangzhe Peng, Xiangcheng Xiao. Xiangya Hospital Central South University, Changsha, China.

**Background:** Due to its high infectivity and mortality, coronavirus disease 2019 (COVID-19) has become a global public health issue. The kidneys act as critical metabolic organs, therefore, whether COVID-19 can induce renal damage is of utmost importance but remains controversial, and the prognosis of COVID-19 encountering acute kidney injury (AKI) is unknown. Moreover, the efficacy of different treatments that COVID-19 patients with AKI (COVID unrelated-AKI (COV-)) are treated with is unknown. The mortality in AKI with RRT and COVID-19 is alarming high. Several factors associated with COVID-19 disease is more frequent in males. Interestingly, half of the patients preserved urine output. Severe lymphopenia was associated with mortality. More data from the AKI COVID-19 registry will help us to enlighten the prognosis and risk factors associated to mortality.

**Funding:** Government Support - Non-U.S.

**Acute Peritoneal Dialysis with Percutaneous Catheter Insertion for COVID-19-Associated AKI in Intensive Care: Experience from a UK Tertiary Centre**

Diansonda B, Braide-Aziwke, Elaine Bowes, Kate Bramham, Caroline Tulley, Eirini Lioudaki, Hugh Cairns, Claire C. Sharpe. King’s College Hospital, London, United Kingdom.

**Background:** During the COVID-19 pandemic in 2020, high rates of acute kidney injury (AKI) in critically unwell patients are being reported, leading to increased demand for renal replacement therapies (RRT). There are considerable challenges providing RRT for large numbers of patients with COVID-19 and alternatives to continuous veno-venous hemodiаlіsіs tہrехnіqұ (CVVHD) in intensive care units (ICU) are needed in both high and low-resource settings. Peritoneal dialysis (PD) can be initiated immediately after percutaneous insertion of the catheter, but there are concerns about impact on ventilation and RRT efficacy. We describe our recent experience of percutaneous catheter insertion and peritoneal dialysis in patients in ICU with COVID-19 infection.

**Methods:** Patients were selected according to local protocol and catheters inserted percutaneously using Soldinger technique by two experienced operators. Sequential Organ Failure Assessment score (SOFA) and ventilation requirements were recorded at time of insertion, and at 24 hours after insertion. Procedure complications, proportion of RRT provided by PD, renal recovery and RRT parameters during PD were assessed.

**Results:** Percutaneous PD catheters were successfully inserted in 32/39 (82.1%) patients after median of 10.0 (IQR 13.0, 19.0) days on ICU. No adverse events following insertion were reported, SOFA scores and ventilation requirements were comparable before and after insertion and adequate RRT parameters were achieved. Median proportion of RRT provided by PD following catheter insertion was 90.2% (IQR 77.5, 100).

**Conclusions:** PD provides a safe and effective alternative to CVVHD in selected patients with AKI and COVID-19 infection requiring ventilation on intensive care.

**Clinical Parameters of Patients Prior to and after Peritoneal Dialysis Catheter Insertion**

The relationship between AKI and outcome of study population

- IQR: interquartile range; PD: Peritoneal Dialysis; PaO2 : FIO2 ratio (arterial oxygen partial pressure (PaO2 in mmHg) to fractional inspired oxygen (FiO2 expressed as a fraction)); SOFA: Sequential Organ Failure Assessment

**PO0680**

**Adding Heparin to Citrate in Continuous Renal Replacement Therapy May Extend Filter Life-span in COVID-Related AKI**

**Background:** COVID may predispose patients to thrombosis and lower filter lifespan. Association between D-dimer level (DD) and filter clotting in Continuous Renal Replacement Therapy (CRRT) has not been described.

**Methods:** All patients who needed CRRT in Hospital das Clinicas (Brazil) during March to May 2020 (COVID related-AKI (COVID+), n=37) and August to September 2019 (COVID unrelated-AKI (COV-), n=18) were studied. Anticoagulation in CRRT in COVID+ was done with citrate 3mmol/L (ACD, n=19), or citrate 4mmol/L plus non-fractioned heparin 10U/Kg/h (ACD/Hep, n=18), while in COV- with citrate 3mmol/L only. Data are expressed in median [IQR]. We performed Spearman’s correlation between DD and time-free of filter clotting (TFC), and Kaplan-Meier curve to study filter survival by anticoagulation method and COVID.

**Results:** ACD/Hep group presented lower filter clotting in 72h when compared to other groups (ACD/Hep: 35% vs ACD: 100% vs COV-: 80%; p< 0.05). Analyzing
filter clotting per patient-day, ACD/Hep also presented less clotting than ACD group (ACD/Hep: 41% vs ACD: 10%; p < 0.05). In COVID patients, median TFC was 33.5 h (17.0; 72.0); ACD: 29.0 h (13.6; 68.5), ACD/Hep: 40.0 h (17.0; 62.0), p = NS. Clotting time from obese patients did not differ from non obese patients (obese: 31.0 h [18.5; 57.2] vs non-obese: 36.0 h [16.8; 72.0], p = ns). Median DD in all COVID patients was 3,519 [1420-13,883]. Patients with DD below median (<3,500) had higher TFC (ACD high DD: 19.0 h [9.0; 27.5], ACD/Hep high DD: 34.0 h [17.0; 62.0], ACD low DD: 57.0 h [27.0; 66.8], ACD/Hep low DD: 67.0 h [26.0; 72.0]; Figure 1). There was statistically significance in correlation between DD and TFC in ACD patients, but not in ACD/Hep group.

Results: We excluded patients with renal failure requiring renal replacement therapy (RRT) (RRRT) or diagnosis of COVID19 as a previous history of thrombosis. We were left with 69 patients, whom we analyzed the first three RRT treatments of each patient. The average age was 59.48 years, 81.2% male, 18.8% female. 15% of patients were African American, 5% Caucasian, 31% Hispanic, and 5% Asian as other. The average BMI was 30.2. 40% of patients had diabetes mellitus, 49% hypertension, and 14% CKD or ESRD. We analyzed a total of 162 RRT treatments. Of these 162 treatments, 49% of patients received bivalirudin, 27% heparin, and 23.4% did not receive AC. We found that 84.5% of patients receiving bivalirudin completed their CRRT treatment, and receiving heparin completed treatment, and 59.3% of patients not on AC completed treatment.

Conclusions: Patients with a confirmed diagnosis of COVID 19 that are critically ill and receive CRRT are more likely to finish their CRRT treatment, and therefore achieved improved clearance, if they were given some form of AC to prevent clotting.

PO0683

Association of Ventilatory Time and AKI in a Bronx Cohort of COVID-19 Patients

Abby M. Baselsey,1 Diane Liu,1 Molly Fisher,2 Laden Golestanneh,2 Eran Y. Bellin,3 Kimberly J. Reidy,4 Children’s Hospital at Montefiore, Bronx, NY; 2 Montefiore Medical Center, Bronx, NY.

Background: The relationship of lung-kidney interactions in COVID-19 has not been well described. AKI has been associated with increased mechanical ventilation times. Recent publications have shown a strong association of COVID-19-AKI with mortality and a high incidence of AKI occurring peri-intubation. We hypothesized that mechanical ventilation (MV) time would be increased in patients with COVID19-AKI and longer in those with severe AKI.

Methods: We analyzed a cohort of incident COVID19 patients who required MV. Patients with end stage renal disease were excluded. AKI was defined using KDIGO criteria (0.3 mg/dL increase or greater than or equal to 50% increase from the baseline Cr) between the start of MV and baseline Cr. AKI stage was defined as per KDIGO. The total MV time was measured in days from date of initial intubation, including subsequent intubation/extubation events, until successful extubation or death. Censored data was not included. Linear regression models were utilized to evaluate associations.

Results: We analyzed 316 patients. 62% were male, 37% were black/African American and 33% were Hispanic/Latino. Hypertension was prevalent in the cohort (N=212) and over 50% were obese. Median MV time was 4.67 days (IQR 1.76, 9.95). AKI occurred in 89% (N=283) of the cohort. Stage 3 AKI developed in over 50% (N=161) of patients. In models adjusted for age, hypertension, diabetes and disease related group weight, patients with AKI had 3.46 more days of MV, however this finding did not reach statistical significance (95%CI 0.92-6.00). This association however was significant and increased linearly with stage of AKI (p for trend <0.001).

Conclusions: This is one of the first studies to evaluate the association of COVID19-AKI and MV time. Even after adjusting for severity of illness, patients with increased stage of AKI had longer MV times. This may be due to pathophysiological kidney-lung interactions seen in non-COVID19 disease and/or direct effect of COVID19 on the kidneys. As few patients in our cohort were spared from kidney injury, inferences comparing those with and without AKI are difficult to discern. We plan to explore this question in a larger cohort to determine whether COVID19-AKI alone is associated with ventilatory time.

PO0684

Can the AKI Alert Staging Tool Help Manage Patients Admitted During the COVID Pandemic?

Barun Mohindra,1 Devendran A. Chatterjee, Gurminder S. Khamra, Georgia W. Wittmer Kidney Medicine, Basildon & Thurrock University Hospital Mid and South Essex University Hospitals Group, Basildon, United Kingdom.

Background: Basildon & Thurrock University Hospital has the second highest rate of hospital admissions with AKI stage 3 in the United Kingdom based on Renal Registry Hospital Episode Submission Data. Acute kidney injury (AKI) is common in hospitalized patients and carries a high risk of mortality. Given the limitations of resources both personnel and equipment, a retrospective study was done to see if the AKI alert staging tool could help predict and direct resources to those patients who would benefit most from specialist intervention.

Methods: Data was reviewed from January - May 2020. This corresponded to the peak of admissions and by the end of the period, the hospital was on course to returning to pre-pandemic activity. Relevant data including admission laboratory tests and imaging was collected. The admission stay was analysed for duration, the need for transfer to an intensive care environment to receive ventilator support and/or renal replacement therapy. Discharge destination was reviewed and whether the patient was discharged home, to another facility or did not survive the admission. For comparison we looked at the same period in the preceding year as this would represent the most matched population.

Results: Over 5000 AKI alerts were generated for this period for 4390 unique admissions. This compares to 3910 AKI alerts for 1098 unique admissions for the identical period in the previous year. The vast majority were for AKI stage one alerts none of which were in COVID positive patients. A significant proportion of patients with AKI Stage 2 and 3 alerts were positive for COVID. Those that were admitted to Intensive Care with Stage 3 AKI almost always required intubation and renal replacement therapy. Mortality was higher in this group.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

254
Conclusions: The AKI alert system helps identify patients who are unwell and can benefit from Nephrologist input at an early stage. The Alert algorithm excludes haemodialysis patients, therefore this population was excluded. During the COVID-19 pandemic there was a clear increase in AKI admissions and alerts creating a substantial demand on renal services. Specialist intervention should be directed to AKI alert stage 2 patients where intervention can help prevent progression into AKI stage 3 and subsequent ICU admission. AKI stage 1 patients who are COVID negative can be managed without specialist input.

PO0685
Characteristics and Outcome of AKI Needing Dialysis with COVID-19

Background: COVID-19 infection has varying grades of mortality worldwide. Multi-organ injury, not uncommonly associated with AKI, portends a poor outcome. We studied AKI needing haemodialysis (HD) in the context of COVID-19 infection.

Methods: From March 15th to May 25th 2020, for consecutive COVID-19 infections AKI needing HD in a large dialysis network age, gender, payer type, days:admission to HD start, urine output, S. Cr, comorbidities, length of stay & outcome, dialysis session details: blood flow rate(BFR), dialysis flow rate(DFR), ultrafiltration volume were reviewed. We compared survivors and non survivors using Mann Whitney/ Wilcoxon 2 sample test for medians and Fisher exact 2 tailed for association.

Results: n = 20. Mean age: 56.7 ± 3.93 years. M:F 17:3, 9 survived, 11 expired. HD sessions=51; CRRT: 4, duration: 22 ± 25.4 hours. 47 sessions: Duration: 4.87 ± 1.11 hours, BFR: 195 ± 43 mL/min, DFR: 389 ±99 mL/min, UF: 437mL/hour. No clotting reported.

Conclusions: AKI needing HD in COVID-19 infection is associated with significant multiorgan injury and high mortality, mostly age and male predominance. No significant clinical characteristics were predictive of survival in a sample size

Comparison of survivors and non survivors of COVID-AKI needing HD

PO0686
Circuit Clotting on Continuous Venovenous Hemofiltration in COVID-19 Patients at New England’s Largest Health Safety-Net Hospital
Claire Avillach, Megan E. Feeeny, Mohamed T. Hassan Kamel, Hassan Mahmoud, Aileen W. Zhen, Natasha Awais, Sandeep Ghai. Boston Medical Center, Boston, MA.

Background: The pandemic of COVID19 led to a surge in critically ill patients with severe kidney failure requiring continuous renal replacement therapy (CRRT). Primary reports rapidly showed a hypercoagulable state associated with cytokine storm representing a challenge to conduct CRRT. We report our experience to face clotting on continuous venovenous hemofiltration (CVVH) with COVID19 patients.

Methods: We reviewed data on all admitted patients with COVID19 diagnosis and requiring CVVH at Boston Medical Center between March, 15th and May 7th, 2020. The study was approved by the institutional IRB.

Results: Twenty six patients were admitted to ICU with COVID19 disease and developed acute kidney injury requiring CRRT. The majority of patients were males (73%), and mean age was 67.6 ± 15.4 (95% CI [62-73]) years. 11 patients (41.2%) had COVID19 diagnosis initiation, patients showed marked inflammatory state with a median CRP of 239mg/dL (IQR 123-391.5), fibrinogen 609mg/dL (431-693), d-dimer 4,036 ng/mL (1,777-15,558). CVVH was conducted in prefiltration mode, with a median therapy rate of 3L/h (2.5-3.1) and a mean blood flow of 280 mL/min. The median cartridge half-life from CVVH initiation was 11.8 hours (3.5-20). Twelve patients (46%) experienced CVVH circuit clotting within the first 2 hours, including 6 patients (23%) with severe recurring clotting. Curative systemic anticoagulation by heparin was used in 12 patients (46%) based on hospital protocol. Its use was associated with mild improvement in cartridge half-life: 13h with curative heparin versus 10.5h with no low dose preventive anticoagulation (non-significant). Of note, heparin was held prior to CRRT initiation for dialysis catheter placement and was reinstituted without bolus, which could lead to early coagulation of the filter in patients with hypercoagulable state. The fatality rate was 76.9% with a median time to outcome of 2.5 days (1-8.7) days.

Conclusions: Conducting CRRT in patients with multiorgan failure secondary to COVID19 is challenging. Our experience suggests only a mild non significant improvement of clotting prevention with heparin anticoagulation at the time of cvvh initiation. Further studies are warranted to determine the optimal anticoagulation regimen.

PO0687
Clinical Characteristics and Short-Term Outcomes of Severe AKI in COVID-19 in Bronx, New York
Milagros Yunes,1 Emad Alahiri,1 Ryan Mocerino,1 Kalyan Prudhvi,1 Ladan Golestaneh,1 Molly Fisher,1 Montefiore Medical Center, Bronx, NY;1 Albert Einstein College of Medicine, Bronx, NY.

Background: After the first reported case of COVID-19 in the U.S., New York City quickly became the epicenter of the pandemic. AKI has been reported in patients with severe COVID-19. The Bronx consists of a predominantly minority population with a high burden of comorbidities that may be at increased risk for AKI in the setting of COVID-19. We aimed to characterize risk factors and short term outcomes in patients hospitalized with COVID-19 and severe AKI.

Methods: We performed a retrospective study of 113 adults hospitalized with COVID-19 in a large healthcare system in the Bronx who required nephrology consultation for AKI from March 11-March 30, 2020. We extracted data on demographics, comorbidities, admission vital signs and labs, need for mechanical ventilation, renal replacement therapy (RRT), in-hospital death and discharge. AKI was defined by KDIGO criteria. Chi-square analyses and Wilcoxon tests were used. Data was censored on April 12, 2020. All patients had ≥14 days of follow up.

Results: Mean age was 63 (SD 12) years old; 69% were men and 33% were Black and 23% were Hispanic. Forty-five patients (39.8%) had chronic kidney disease, 58(51%) had diabetes mellitus and 87(77%) had hypertension. The majority presented with AKI within 24 hours of admission, 75% had Stage 3 AKI. Ninety-two (81%) patients had proteinuria and 53(47%) had hematuria. Intensive care unit (ICU) was required in 62(55%), 64(57%) required mechanical ventilation, 56(49%) required RRT and 18(16%) were not candidates for RRT. In-hospital death occurred in 68(60%) and 22% were discharged. Of those who required RRT, in-hospital death occurred in 35(62.5%) and only 6 patients were discharged, 5 of whom remained RRT dependent. Heavy proteinuria (3+4+) and initial C-reactive protein (CRP) were higher in those with AKI who died [21.1 (IQR 14.3-29.6) versus 6.6 (12.3-16.3), p=0.001].

Conclusions: Severe AKI in the setting of COVID-19 is associated with increased utilization of ICU, mechanical ventilation, and RRT. Outcomes are poor in those with Stage 3 AKI, underscoring the need for palliative care involvement and early goals of care discussions. Elevated initial CRP and heavy proteinuria may be useful to risk stratify patients with COVID-19 and severe AKI at increased risk for mortality.

PO0688
Clinical Factors Associated with AKI in Patients with COVID-19 from a University Hospital in Brazil
Diana Maria Chilado,1 Isabeli S. Maltoni,1 Felipe F. Sanches,1 Mariana R. Coletti,1 Caio C. Delfino,1 Isabelia G. Almeida,1 Letícia C. Albeny,1 Gabriel N. Araujo,2 Renata G. Roizman,1 Giovanna M. Zavadzki,1 Miguel Angelo Goes,1 1Universidade Federal de Sao Paulo, Sao Paulo, Brazil; 2Unisa, Sao Paulo, Brazil.

Background: Critically ill patients with COVID-19 frequently presents Acute kidney Injury (AKI) associated with increased mortality. However, there is paucity of data from Brazil. So, we analyzed factors in associated with COVID-19 hospitalized at Hospital Sao Paulo-Federal University of Sao Paulo. Diagnosis and classification of acute kidney injury (AKI) were by KDIGO. We examined the rates of renal function, mechanical ventilation (MV), renal replacement therapy (RRT), medications and in-hospital mortality.

Methods: We conducted an observation with frequencies and association with binary logistic regression study in patients with COVID-19 hospitalized at Hospital Sao Paulo-Federal University of Sao Paulo. From March 15th to May 7th, 2020. The study was approved by the institutional IRB.

Results: We observed a total of 172 in-patients with COVID-19. Patients were predominantly male (61.5%). We observed hypertension in 55%, diabetes 34%, smokers 27%, obesity (19%). Eighty-nine (52%) patients needed intensive care unit (ICU), 70 (99%) cases of AKI were in ICU (31% of general ward admissions; p<0.001). In the ICU there were 78% needed mechanical ventilation, 36% in RRT, amine vasoactive 65% and mortality in 48%. AKI patients were older (61±15, 55±15; p<0.01), higher creatinine in admission (2.6±1.6, 1.3±0.7; p<0.002), higher RWD (14±7.1, 13±3.1; p<0.08), needed of MV (88%) and vasoactive amine (90%), RRT (88%) and higher mortality (87%). We used creatinine, RWD, in-hospital death and discharge as dependent variables.

Conclusions: AKI is associated with high rates of RRT and death. Higher age and need of mechanical ventilation were associated with AKI in COVID-19 patients.

Funding: Government Support - Non-U.S.
PO0689

Community and Hospital-Acquired AKI in COVID-19

Background: AKI is a frequent complication of COVID-19. We describe characteristics of patients with COVID-19 who developed both, community-acquired AKI (CA-AKI) and hospital-acquired AKI (HA-AKI) in a Mexico City reference COVID-19 center.

Methods: We included data from all consecutive patients hospitalized between March 16th - 29th 2020, with pneumonia and positive SARS-CoV-2 by RT-PCR test. Only data from patients who finished follow-up (n=636) was analyzed. AKI was defined according to KDIGO and ESKD patients (n=6) were excluded. Clinical and demographic characteristics of those with CA-AKI, HA-AKI, and non-AKI were compared by non-parametric ANOVA.

Results: Of 630 COVID-19, AKI was detected in 164 (26%), 81 (49%) CA-AKI, and 83 (51%) HA-AKI. Among AKI, 84 (51%) were Stage 1, 38 (23%) Stage 2, and 42 (26%) Stage 3. Stage 3 was more frequently observed in HA-AKI (p<0.001). RRT was provided to 15 (9.1%) at a median 3 days from diagnosis. Fluid overload was the main indication for RRT initiation. In general, AKI was associated with higher severity of COVID-19 evidenced by several risk scores, ICU admission, mechanical ventilation, and vasopressor therapy. Recovery from AKI was more frequent in the CA-AKI group 66% vs 44% (p<0.001), and often associated to volume depletion and poor fluid management. Among patients with AKI, 92 (56%) died, 49% in the CA-AKI vs. 63% in the HA-AKI group (p<0.001). There were no differences in RAAS inhibitor use between groups.

Conclusions: CA-AKI and HA-AKI are frequent renal manifestations in COVID-19. AKI is associated with more severe COVID-19 and significantly higher mortality. Although more comorbidities were present in CA-AKI, outcomes were better for CA-AKI vs. HA-AKI in spite the latter group being younger, as it represents ICU patients. Although more comorbidities were present in CA-AKI, outcomes were better for non-parametric ANOVA.

PO0691

Kidney Injury in ICU Adults with Severe COVID-19
Jing Qin, Li Ni, Mengjing Wang, Weichen Zhang, Kangjie Wang, Li Yuan, Jie Chen, Huashan Hospital Fudan University, Shanghai, China.

Background: The SARS-CoV-2 infected humans through the angiotensin converting enzyme (ACE-2) receptor. Kidney, which highly expressed ACE-2, became one of the main targets attacked by SARS-CoV-2. In this cross-sectional study, we aimed to explore renal injury in ICU adults with severe coronavirus disease 2019 (COVID-19).

Methods: Fifty-three severe COVID-19 adults, admitted into ICU (Tongji Hospital, Wuhan, China) from Feb-9.2020 to Mar.24.2020, were finally included in analysis. Baseline demographic, clinical characteristics, laboratory examination data and prognosis were all recorded.

Results: Mean age of 53 patients was 67.5±15.2 years, including 34 men and 19 women. The predominant comorbidities were: hypertension in 26 patients (50.0%), diabetes mellitus in 11 patients (21.2%), cardiovascular diseases in 5 patients (9.6%) and chronic kidney disease in 2 patients (3.8%). The mean serum creatinine at admission was 67.2±26.7 μmol/L, while the baseline urine routine before hospitalisation was uninformed. In the period of whole ICU stay, most patients presented abnormal urine routine: 93.2% of patients had proteinuria (+/-9.1%, 1+ 40.9%, 2+ 31.8% and 3+ 11.4%, respectfully) and 97.7% had hematuria. 20 of 53 patients (37.7%) with mean age of 72.9±9.9 years diagnosed as hospital-acquired acute kidney injury, according to KDIGO stage classification. AKI diagnoses were made in 22 (41.5%) patients, of whom 52.5%, 7.35% and 8.4% reached AKI stage I, II and III, respectfully. AKI was diagnosed after 25.0±12.8 days since onset of Covid-19 and after 7.8±5.6 days since ICU admission. The mean duration of AKI course was 7.9±7.1 days. Finally, 16 of 20 patients with AKI (80.0%) died in ICU. The survival time of AKI patients was 32.9±14.6 days since onset of Covid-19 and 15.7±9.4 days since ICU admission. The in-hospital all-cause mortality of AKI patients was higher than non-AKI patients (80.0% vs 29.4%, p<0.001). Only one (5.0%) patient recovered from AKI during ICU stay (serum creatinine reduced ≤50%).

Conclusions: Kidney injury including abnormal urine routine and increased serum creatinine presented in almost all severe Covid-19 patients. AKI event could predict poor prognosis with severe Covid-19. We should increase awareness of kidney injury in patients with severe COVID-19.

PO0692

Association of Antiplatelet and Anticoagulation Therapy with Dialysis-Inducing AKI-D in Critically Ill Patients with COVID-19
Andrew A. Moses, Amer Assal, Paul Asadourian, Anson G. Bautista, Rebekah Boyd, Lyle Dershowitz, Aaron Gans, Catherine Ha, Hannah L. McMullen, Mary Nattakom, Olivia D. Perez, Connor Stonessifer, Wilson W. Stringer, Yuru Xiong, Shayan Shrizarian, Columbus University Irving Medical Center, New York, NY.

Background: Critically ill patients with COVID-19 have a high incidence of thrombotic complications and dialysis-requiring acute kidney injury (AKI-D). COVID-19 hypercoagulability has been implicated as a possible contributor to AKI-D. Our hypothesis is that pre-existing antiplatelet (APT) or anticoagulation therapy (ACT) is associated with a lower incidence of AKI-D in critically ill patients with COVID-19.

Methods: Records of patients with COVID-19 admitted to the ICU from March 13th - April 1st 2020 were reviewed. Exclusion criteria included ESRD status, and ICU discharge or death prior to 14 days of follow-up. Groups were divided based on APT or ACT prior to ICU admission. AKI-D was defined as initiation of renal replacement therapy within 2 weeks of any kind of follow-up day 14. Groups were compared using 2-tailed Fisher’s exact test and unpaired t tests.

Results: A total of 149 records were reviewed, and 98 patients were included (47 died and 4 discharged). Twenty-three patients (23.5%) were on APT or ACT and 39 (40%) required RRT. Table 1 compares characteristics by study group. Hypertension and cardiac conditions were significantly different between groups. Twelve (52%) of patients on APT or ACT required RRT and 27 (36%) not on either required RRT (p=0.22).

Conclusions: Pre-existing APT or ACT was not associated with AKI-D in critically ill patients with COVID-19. 2 weeks of follow-up. Our study confirmed a high incidence of AKI-D but was limited by significant differences in cardiac conditions between study groups. Future larger studies examining this association in groups with comparable cardiac conditions are needed.

COVID-19: AKI and Outcomes

**Background:** Acute Kidney Injury (AKI) occurs in 3-37% of COVID patients; recovery is poorly described.

**Methods:** All patients who recovered from AKI in Clinics Hospital (São Paulo, Brazil) during April 2020 (COVID-related-AKI (COV+), n=35) and September 2019 (COVID-unrelated-AKI (COV-), n=25) were studied for 1.5 month each. Recovery-AKI was represented by spontaneous serum creatinine (sCr) drop in patients not submitted to dialysis, or by withdrawal of dialysis in those who needed the therapy. Serum creatinine, urea (sU), sodium (sNa), bicarbonate (bic), and fluid balance (FB) were analyzed during the first five days of recovery (5-Dr). Data are expressed in mean ± SD. Repeated measures ANOVA was used to compare different days on each parameter, and t test was used to compare groups. Categorical data were analyzed using Fisher’s test.

**Results:** Among 88 COV- patients, 25 recovered from AKI, while 35 in 102 COV+ patients recovered during the time studied (80% COV+ were in KDIGO 3 classification). In COV+ group, COVID-AKI time was predictive of AKI duration: earlier AKI (≤ 4 days from COVID symptoms) lasted 5.6 ± 4.0 days (vs 11.9 ± 9.2 days in later AKI presentation, p<0.01). Both COV+ and COV- patients recovered when sCr was dropped without sU drop. COV+ patients presented negative overall FB during 5-Dr, while COV- patients presented positive FB (p=0.05). COV+ patients had bicarbonate increase in COV+ (from 24.3 ± 3.6 to 27.0 ± 4.9 mmol/L, p<0.05), and in COV- it did not. Among diuretic users, the same pattern of FB was seen between groups (194.9 ± 3163 in COV+ vs 163.5 ± 1080 ml/24h in COV-), and COV- showed increased sNa through 5-Dr (p<0.05), while COV- reduced sNa through 5-Dr (p=0.05). Diuretic users had bicarbonate increase in COV+ (from 24.3 ± 3.6 to 27.0 ± 4.9 mmol/L, p<0.05), but not in COV-. In diuretic non-users, both groups have risen sNa through 5-Dr, but only COV+ reached statistical significance. Diuretic use at AKI-recovery was higher in COV+ patients (57% vs 28%, p=0.05).

**Conclusions:** Later-onset COVID-related AKI seems to be more prolonged. Diuretics should be carefully used in AKI-recovering COV+ patients, once hypernatremia and metabolic alkalosis are more common than in other AKI etiologies.

Impact of Replacement Therapy Modality on Prognosis of SARS-CoV2 Infection
Yannis Lombardi,1,2 Hafedh Fessi,1,2 Hélène François,1,2 Pierre A. Michel,1,2 Camille Petit-Hoang,1,2 Eric Rondeau,1,2 ‘Hôpital Tenon, Paris, France; ‘Sorbonne Université, Paris, France.

Background: Prognosis of SARS-CoV2 infection among patients with Chronic Kidney Disease (CKD) is poorly known. In particular, the impact of replacement therapy (RRT) modality on prognosis is undetermined. Patients with kidney transplant exhibit treatment-induced immunomodulation, while on dialysis are usually older and exhibit higher frailty. We aim to determine the impact of RRT modality on the prognosis of SARS-CoV2 infection among patient with advanced CKD.

Methods: We conducted a retrospective cohort study using our institution’s Clinical Data Warehouse. Health records of all patients with at least one hospitalization or consultation in our nephrology department were screened based on ICD-10 codes. Inclusion criteria were: hospitalization in any of our institution’s hospitals for SARS-CoV2 infection (national Public Health agency criteria). Patients were divided into 3 groups: «active kidney transplants» and «dialysis». A Cox model stratifying on age and medical history of coronary artery disease was used to determine adjusted Hazard Ratio (HR) for death or intensive care unit (ICU) admission.

Results: We included 72 patients: 47 in the «transplant» group and 25 in the «dialysis» group. First hospitalization was on 20/02/28 and last hospitalization on 20/05/19. Median follow-up was 21.5 days. Death or ICU admission occurred in 21 (29%) patients («transplant» group: 15 (32%), «dialysis» group: 6 (24%), p=0.45). In multivariable analysis, adjusted HR of death or ICU admission was 1.70 [95%CI:0.59-4.86] for transplant vs. dialysis (p=0.32).

Conclusions: In our study, among patients hospitalized for SARS-CoV2 infection, no significant difference in risk for ICU hospitalization or death was found between CKD patients on dialysis or with active kidney transplant. A trend for higher risk was noted among patients with active kidney transplant. Further studies are required to confirm these findings.

PO0698
Low-Molecular-Weight Heparin Is a Superior Anticoagulant to Unfractionated Heparin for Renal Replacement Therapy in Patients with AKI due to Coronavirus Disease 2019
Necharik Mereddu, Benjamin German, Casey N. Gashiti, Payal K. Gurmani, Roger A. Rodby, William L. Whittier. Rush University Medical Center, Chicago, IL.

Background: Severe coronavirus disease 2019 (COVID-19) not only causes acute pulmonary pathology leading to acute respiratory distress syndrome needning intubation, but also leads to acute kidney injury (AKI) requiring renal replacement therapy (RRT). Due to hemodynamic instability, these patients (pts) often need either continuous RRT (CRRT) or prolonged intermittent RRT (PIRRT). Accelerated Veno-Venous Hemodialysis (AVVHD), a form of PIRRT with typically 40-50 liter of dialysate used over 8-10 hours has been successfully used to treat hemodynamically unstable pts. In the past, we have published extracorporeal circuit clotting (ECC) to be low (5%) even without anticoagulation. However as hypercoagulability is extreme with COVID-19, we noticed a marked increase in ECC. Unfractionated heparin (UFH) was the initial anticoagulation of choice during the early phase of the pandemic but is currently not considered in preventing ECC, prompting a trial of low molecular weight heparin (LMWH).

Methods: We conducted a single-center retrospective study to evaluate the efficacy and safety of LMWH vs UFH in preventing ECC in pts with AKI due to COVID-19 who received AVVHD from 3/25/20 through 4/30/20 at a large academic medical center. Data collected included pt demographics, type of anticoagulation and thrombolytic use, treatment characteristics including clotting frequency as well as bleeding complications. ECC was defined as any event that required an unexpected interruption in treatment or the use of thrombolytics.

Results: A total of 58 pts received 408 AVVHD treatments. The average pt age was 58 years, 65% were male, 66% were black and 66% were obese with body mass index >30 kg/m2. 188/408 (46%) of AVVHD treatments received anticoagulation with UFH while 165/408 (40%) of treatments received LMWH. ECC occurred in 30% of AVVHD treatments who received UFH vs 15% in the LMWH group, a relative risk reduction of 50% (P = 0.001). 47.1% pts who were on UFH had ECC on the first RRT treatment compared to 13.6% on LMWH (P = 0.01). Only 1 pt experienced a major bleeding event in the UFH group and none with LMWH.

Conclusions: Anticoagulation with LMWH is superior to UFH in reducing ECC in pts receiving AVVHD for AKI due to COVID-19 without an increased risk of bleeding.
COVID-19: AKI and Outcomes

Poster

Patients admitted to KCH from 3/1 to 5/15/2020

Total % of AKI Mortality
COVID-19+ (with HIV) | 43.3% (32/74)
COVID-19+ (without HIV) | 24.4% (19/78)
COVID-19- | 9.1% (9/99)
HIV-uninfected COVID-19 | 9.1% (9/99)

P<0.05 for developed AKI (Mortality Rate) (49.147 359 vs 9.469 24 8.51)

PO0701
Mortality of AKI in Human Immunodeficiency Virus with and without Co-Infection with COVID-19

Ije Oyewo,1 Siddharta D. Rajacharya,1 Ernie Yap,1 Mary C. Mallappallil,1,2 Kings County Hospital Center, Brooklyn, NY; SUNY Downstate Medical Center College of Medicine, Brooklyn, NY.

Background: Since the start of COVID-19 pandemic, concerns have been raised about specific populations being at potential higher risk for developing more severe diseases, and patients living with HIV (PLWH) are among them. SARS-CoV-2, a newly isolated virus from the Corona Virus family, is enveloped, positive-sense single-stranded RNA virus that causes multi-organ failure, especially acute kidney injury (AKI) which is proved to be associated with significantly elevated mortality rate. It dysregulates human immunity especially on T lymphocytes which is shared by HIV as the mechanism of immunity especially on T lymphocytes which is shared by HIV as the mechanism of diseases, and patients living with HIV (PLWH) are among them. SARS-CoV-2, a newly isolated virus from the Corona Virus family, is enveloped, positive-sense single-stranded RNA virus that causes multi-organ failure, especially acute kidney injury (AKI) which is proved to be associated with significantly elevated mortality rate. It dysregulates human immunity especially on T lymphocytes which is shared by HIV as the mechanism of immunity especially on T lymphocytes which is shared by HIV as the mechanism of

Methods: Retrospective chart review of all admitted patients to Kings County Hospital (KCH), a municipal hospital in Brooklyn, New York City between 3/1 to 5/15, 2020, from the electronic medical record. Patients were reviewed in groups of COVID infection without history of HIV, HIV patients admitted without COVID infection and patients with history of HIV who were admitted because of COVID infection. The rate of AKI and mortality were extracted and analyzed using Chi-squared test in SPSS.

Results: A total of 1,092 patients with confirmed COVID-19 diagnosis were admitted in the review time period, out of which 22 were diagnosed with COVID-19 and HIV. In the COVID-19 without HIV diagnosis group, 458 patients developed AKI and 213 patients died, with a mortality rate of 47.3%; in the COVID-19 with HIV group, 9 patients developed AKI and 4 expired, mortality rate is 44.4%. There’s no significant difference between these two groups (p=0.86). Compared to these two groups, 21 out of 93 PLWH without COVID infection had AKI during hospitalization with 2 patients deceased, and a mortality rate of 9.5% which is significantly lower (p=0.03).

Conclusions: Data from our hospital between 3/1 and 5/15/2020 shows the mortality rates of patients with HIV and COVID-19 co-infection with AKI and COVID patients without HIV who developed AKI are not statistically different, but significantly higher than patients with HIV who developed AKI.

PO0702
Phenotype and Outcomes of AKI Associated with COVID-19 in New Orleans

Munir Mohamed,1 Ivo Lukitsch,2 Aldo E. Torres Ortiz,1 Joseph B. Walker,1 Cesar F. Hernandez-Arroyo,1 Muhamed Almasri,2,3 Castauno Caraballo,2,3 1Department of Nephrology, Ochsner Health System, New Orleans, LA; 2Ochsner Clinical School, The University of Queensland, Brisbane, QLD, Australia.

Background: Acute kidney injury (AKI) is a manifestation of COVID-19 (CoV-AKI). However, there is paucity of data from United States, particularly in a predominantly African American (AA) population. We report the phenotype and outcomes of AKI at an academic hospital in New Orleans.

Methods: We conducted an observational study in patients hospitalized at Ochsner Medical Center over 1-month period with COVID-19 and diagnosis of AKI by KDIGO. We examined the rates of renal replacement therapy (RRT) and in-hospital mortality as outcome measures. Adjudication of cause of AKI was independently performed via manual chart review by 3 study team members.

Results: Of 664 admissions with COVID-19, 69 were excluded due to ESRD or kidney transplant. Thus, 575 patients entered the cohort (173 [28%] to an intensive care unit (ICU). Patients were predominantly AA (71%). AKI was diagnosed in 161 patients (28% overall, 61% of ICU admissions), median age 65 [34 – 96], predominantly male (62%) and hypertensive (83%). Median follow up was 25 days. Inhospital mortality rate for those with AKI was 50% (80/161). De novo AKI was diagnosed in 65%, whereas AKI over preexisting chronic kidney disease occurred in 35% of the cohort. Ninety-one (57%) patients arrived with AKI, whereas the remaining 43% acquired AKI during the hospitalization [median hospital day of AKI onset: 4 (2 – 10)]. RRT was required in 89/161 (55%) and 77/105 (73%) patients for all AKI cases and the ICU subset, respectively. The mortality rate for those with AKI-RRT was 72% (64/90). Hemodynamic instability leading to ischemic acute tubular injury (ATI) and rhabdomyolysis accounted for 66% and 7% of the etiology, respectively. Reversible prerenal azotemia occurred in 9%. In 17%, no obvious cause of AKI was identified aside from the COVID-19 diagnosis. Three (1.8%) patients had de novo collapsing glomerulopathy.

Conclusions: CoV-AKI is associated with high rates of RRT, ICU care and death. Hemodynamic instability leading to ischemic ATI is the predominant cause of AKI in this setting, but other etiologies contribute to the overall AKI burden.

PO0703
Presentation on Admission and Outcomes in COVID Patients Admitted with AKI

Richard J. Durrance,1 Payal Ram,1 Paul Catella,2 Demetrios Papademetriou,2 George N. Corissidis,1,2 Icahn School of Medicine at Mount Sinai, Elmhurst Hospital, Elmhurst, NY; Elmhurst Hospital Center Department of Nephrology, Elmhurst, NY.

Background: COVID-19 infection secondary to the SARS-CoV-2 virus was defined by the WHO as a global pandemic. While the disease initially affects the respiratory system, a multi-system organ dysfunction of varying degrees has been described. Renal failure has been recognized as a significant part of the pathophysiology. Elmhurst Hospital Center (EHC) was described as the “epicenter of the epicenter” in New York City. A retrospective chart review was undertaken of COVID positive adult patients (polymers chain reaction testing of a nasopharyngeal sample) admitted to EHC from 3/7/20 - 4/7/20. Demographics, clinical characteristics, biomarkers, and outcomes were examined. AKI was determined by the KDIGO definition. Exclusion criteria: <18 years old, pregnant, ESRD, patients expired within first 5 days.

Results: The average age was 59 years, 77.95% were Male; 55% had hypertension (HTN), 40% had diabetes (DM). Hispanics made up the most significant portion of the demographic with 62.05%, followed by Asians (24.1%). AKI occurred in 44.1% of patients and was associated with HTN (p=0.011) but not DM (p=0.289). AKI was associated with an increased use of mechanical ventilation (p=0.001), and increased mortality (p=0.001). Hypertension (p=0.007), older age (p=0.003), and DM (p=0.018) were significantly associated with mortality. Ethnicity was not associated with mortality (p=0.231). Admission CPK did not have a significant association with AKI (0.065) or death (p=0.19).

Conclusions: Both HTN and DM are associated with increased mortality. AKI is significantly associated with increased respiratory failure requiring mechanical ventilation and mortality. Diabetes and admission CPK were not associated with AKI.
PO0704
Refractoriness of Hyperkalaemia and Hyperphosphatemia in Dialysis-Dependent AKI Associated with COVID-19
Akanksha Ramanand,1 Vinip Varghese,1,2 Yuin Yang,1 Muner Mohamed,2 Juan Carlos Q. Velez,2 Ochsehr Nephrology,3 Ochsehr Clinical School- The University of Queensland, New Orleans, LA; 2Department of Nephrology, Ochsehr Health System, New Orleans, LA.

Background: There have been anecdotal accounts of an unusual incidence of persisting hyperkalaemia (hyperkP) and hyperphosphatemia (hyperSP) in patients with COVID-19 and acute kidney injury (AKI) (CoV-AKI) despite renal replacement therapy (RRT). However, an observation bias could not be discarded. Thus, we examined the rate and severity of hyperkP and hyperSP in patients with CoV-AKI actively treated with RRT.

Methods: Among 161 patients with CoV-AKI, we selected those who underwent RRT by sustained low efficiency dialysis (SLED) for ≥ 2 days (n=64). A database of patients with AKI on SLED who underwent urinary sediment microscopy (Sedi-AKI cohort, 2017-2019, n=60) served as control (non-CoV-AKI). We examined the rate of hyperkP [serum potassium (sK) ≥ 5.5 mmol/L], severe hyperkP [sK ≥ 6.5 mmol/L], hyperSP [serum phosphate (sP) ≥ 4.5 mg/dL], moderate hyperSP [sP > 7.0-10.0 mg/dL] and severe hyperSP [sP > 10.0 mg/dL] as % SLED-days with an event.

Results: Median age were similar: 60 (39-84) and 58 (22-88) years for CoV-AKI and non-CoV-AKI, respectively. Black race (77% vs. 30%, p=0.001) and male sex (78% vs. 61%; p=0.04) were more common in CoV-AKI. Ischemic ATI was the presumed cause of AKI in 85% and 82% of the CoV-AKI and non-CoV-AKI, respectively. Along the duration of SLED, the incidence of hyperkP was greater in CoV-AKI [mean 19 ± 2% vs. 14 ± 0.5% in 5% SLED-days, p=0.002]. The proportion of patients with a 1 event of severe hyperkP was greater in CoV-AKI [33% vs. 7%, p=0.004]. The incidence of hyperSP were similar between groups [mean 56 ± 4% vs. 53 ± 5% SLED-days, p=0.49]. However, the proportion of patients with 1 event of moderate and severe hyperSP were greater in CoV-AKI [86% vs. 60% (p=0.001) and 50% vs. 18% (p=0.002)]. In CoV-AKI, sK and sP correlated with lactate dehydrogenase (LDH) [R=0.305 (p=0.044) and R=0.307 (p=0.043), respectively] but not with creatine kinase; and hyperSP events correlated with shorter SLED runs (hours/run) (R=–0.286, p=0.055).

Conclusions: HyperkP and hyperSP refractory to RRT (by SLED) were more frequent in CoV-AKI compared to other forms of AKI in the pre-COVID-19 era. Because of the correlation of sK and sP with higher LDH and shorter SLED runs, intracellular ion release from cell injury due to cytokine “storm” and RRT interruptions may play a role.

PO0705
Risk Factors for AKI in Patients Hospitalized with COVID-19
Mridula Nadanam, Yu-Lun Liu, Sadaf S. Khan, Shani Shastri, Duwayne L. Willett, Nilum Rajora, Catherine Chen, Susan Hedayati. The University of Texas Southwestern Medical Center, Dallas, TX.

Background: We evaluated risk factors and prevalence associated with AKI in our early experiences with patients hospitalized with COVID-19, 32% of whom required ICU level care, at the University of Texas Southwestern and Parkland Hospitals in Dallas, Texas from 3/13/20-5/07/20.

Methods: Patients admitted with COVID-19 confirmed by SARS-CoV-2 PCR test were screened for AKI. Univariate and multivariate logistic regression was used to perform forward selection and identify independent factors associated with AKI.

Results: COVID-19 was confirmed in 145 patients, of whom 62 (43%) had AKI. Patients with AKI were older, mean (SD) age (17) vs. (54) years without AKI, p=0.03, and were more likely to have hypertension, 74% vs. 47%, p=0.002, and diabetes mellitus, 6% vs. 31%, p=0.001. CKD was present in 42% of those with AKI vs. 7% of those without, p=0.001. Race, ethnicity, and ACEI/ARB use did not differ between groups. Patients with AKI had higher CRP, mean (IQR) 102 (44-161) vs. 59 (21-116) mg/L, p=0.009, and LDH on presentation, 365 (263-493) vs. 317 (228-385) U/L, p=0.04. Ferritin, IL-6, and D-dimer was similar between groups. A higher percent with AKI received steroids, 42% vs. 16%, p=0.001. Tocilizumab was administered in 15% of AKI vs. 5% of non-AKI groups, p=0.08 while rates of hydroxychloroquine and remdesivir use did not differ. Renal replacement therapy was required in 8 patients with AKI, of whom 7 received CVVHD and 1 HD. There were 8 (13%) deaths in those with AKI vs. 5 (6%) in those without. Factors associated with AKI are listed (Table 1).

Conclusions: During the first weeks of COVID-19 outbreak at our hospitals, 43% of patients had AKI. Underlying CKD, diabetes, steroid use and illness severity were independently associated with AKI. Follow-up is needed to determine the long-term impact on kidney function and recovery.

PO0706
The Impact of COVID on CRRT Filter Lifespan
Lewis Mann, Mony Fraer, Sarat C. Kuppachi, Lama A. Noureddine, Lisa M. Antes, Sreedevi koppsieti Jenigiri, Maria T. Story, Meenakshi Sambharia, Jayesh B. Patel, Kandi O’Connor, Benjamin R. Griffin. University of Iowa, Iowa City, IA.

Background: Patients with COVID are more likely to have systemic thrombotic events. Although it has been theorized that those on CRRT also have an increased rate of filter loss due to clotting. If COVID-positive patients are more likely to clot their filter than other patients on CRRT, a more aggressive anticoagulation strategy may be worthwhile. This could result in longer filter lifespan, less circuit down time, which would result in improved clearance, lower costs, less risk of iatrogenic blood loss, and less wasted nursing time. If there is no difference in filter lifespan between COVID positive and negative patients, then more aggressive anticoagulation would result only in added risk without a clear benefit.

Methods: We analyzed COVID data on patients in a related unplanned prospective randomized trial, in which patients are assigned to either pre-filter CVVH or CVVHD. The standard treatment protocol at the University of Iowa is to use citrate anticoagulation with a blood flow rate of 200 mL/min and a dose of 25 mL/kg/hr. The primary outcome is average filter life, and secondary outcomes are mortality, intensive care unit LOS, hospital LOS, and renal recovery.

Results: A total 30 patients using a total of 98 filters from March 25 to May 20, 2020 were evaluated (Table 1). The average filter life in COVID-positive patients was 37.4 +/- 35.8 compared to 33.1 +/- 26.7 in COVID-negative patients (p = 0.55). However, COVID-19 patients were more likely to receive heparin anticoagulation in addition to citrate.

Conclusions: Contrary to other reports, in this retrospective, unadjusted analysis of CRRT patients, the presence of COVID-19 did not decrease average filter life. Further research is needed regarding the appropriate anticoagulation strategy in COVID-19 positive patients.

Table 1: Patient characteristics

PO0707
Single-Center Experience of AKI in COVID-19-Infected Patients in West Kent Hospital, United Kingdom
Matthew James, Tord H. Hogsand, Kieran Jankowski, Jeetendra R. Rathod, Nihal Chitalia, Jonathan Kwan. Darent Valley Hospital, Dartford, United Kingdom.

Background: The outcome of renal function and in COVID-19 positive patients is unclear. We studied the epidemiology of acute kidney injury (AKI) in the COVID-19 positive patients.

Methods: Between 9th March 2020 and 26th April 2020 data was prospectively collected on 253 adult COVID-19 positive inpatients, of whom 71% were male, median age 71 ± 16 years. Common co-morbidities were Hypertension (54%), Cardiovascular Disease (34%), Diabetes Mellitus (12%), Chronic lung disease (8%), and Dementia (6%). CRRT was required in 26% (21/80) patients. The primary outcome was hospital mortality. Secondary outcomes were intensive care unit mortality, hospital mortality, and mortality of patients who were dialysis dependent before admission.

Results: Of the 253 patients, 58.9% were male with (mean ± sdev) age 71.9 ± 16.4 years. Common co-morbidities were Hypertension (54%), Cardiovascular Disease (34%), Diabetes Mellitus (12%), Chronic lung disease (8%), and Dementia (6%). CRRT was required in 26% (21/80) patients. The primary outcome was hospital mortality. Secondary outcomes were intensive care unit mortality, hospital mortality, and mortality of patients who were dialysis dependent before admission.

Conclusions: COVID-19 infected patients have a high mortality rate without a clear benefit.
wise AKI mortality was AKI1 25.7% (27), AKI2 10.4% (11) and AKI3 20% (21). 66.6% had mortality rates of 45% (11) and 20% (21) died with normal creatinine. Mortality in CKD patients as co-morbidity was 64%. All renal transplant patients survived without haemofiltration patients. 23% (25) AKI patients died with normal creatinine. Mortality in patients with COVID-19 infection. AKI was seen in 42.6% patients with COVID-19 infection. More than 60% required mechanical ventilation with 62.5% (15) of these developed AKI with mortality patients. 75% (6) patients with CPAP died. A further 24 (9.75%) of this high mortality.

Conclusions: Elderly patients were most commonly infected with COVID-19 infection. AKI was seen in 42.6% patients with COVID-19 infection. More than 60% COVID-19 infected patients died if they had AKI and were on any form of mechanical ventilatory support or had CKD as co-morbidity.

PO0708
Severe AKI in SARS-COV-19 Patients from a Tertiary Hospital in Rhode Island
Harshitha Kota,1 Kevin Mitchell,1 Jie Tang,1,2 Brown University, Providence, RI; 2University Medicine Foundation Inc, Providence, RI.

Background: The clinical features & outcomes of COVID-19 patients who developed severe AKI are still being elucidated.

Methods: 42 patients with COVID-19 infection who developed KDOQI stage 3 AKI were identified from March 1 to May 15, 2020, at Rhode Island Hospital, a large tertiary teaching hospital. Their clinical presentations and outcomes are presented. The data in table 1 were presented as mean (± SD), median (IQR), or # (%).

Results: The baseline characteristics are outlined in table 1. Among them, 88% were admitted to ICU, 83% were intubated and needed pressor support. 71% received renal replacement therapy (80%) on CVVHDF). The mean duration of RRT and ICU stay were 6 and 14 days, respectively, 33% participants received treatment for COVID-19, among them 14 (33%) received Remdesivir(RDV), 6 (14%) received convalescent plasma(CP), 4 (10%) received hydroxychloroquine(HCQ), and 25 (60%) also received azithromycin. The mortality rates were 15% in the RDV group, 67% in the CP group, and 75% in the HCQ group. The mortality was 67% in those without any treatment. At the 60-day follow-up, 11 (26%) were discharged alive, 21 (50%) died. Those who died were older (mean age 71 vs. 61), having higher Charlson Comorbidity Index (4.7 vs 3.0), more likely to have diabetes (71% vs. 61%) and coronary artery disease (38% vs. 24%).

Conclusions: The mortality rate of SARS-COV-19 patients who developed severe AKI is high in our cohort. Future larger scale studies are needed to elucidate the causes of this high mortality.

PO0709
The Clinical Presentation of AKI Complicating COVID-19: Observations from Elmhurst Hospital, New York City
Nasser M AlNazzari, Demetrios Papademetriou, George N. Cortisidis, Payal Ram, Ellena A. Linden, Aaron S. Stern. Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Early in March, NYC Hospitals became inundated, especially safety net public hospitals. The physicians at Elmhurst Hospital Center (EHC) encountered countless cases of respiratory failure often accompanied by AKI. Autopsy studies from China described an interstitial nephritis, with macrophage infiltrates and complement deposition along with fibrotic changes. We report our experience with COVID-19 and AKI.

Methods: We reviewed the charts of 137 SARS-CoV-2 positive patients (PCR of a nasopharyngeal sample) admitted to EHC 3/7/2020 - 4/7/2020. We categorized patients as having KDOQI defined AKI vs no AKI within the first seven days of admission. Co-morbidities, renal associated markers and inflammatory markers were anaylsed. Clinical outcomes were assessed. Exclusion criteria: <18 years old, pregnant, ESRD, mortality prior to day 7 of hospitalization. Welch T test and Chi square were used for AKI vs non-AKI.

Results: Age was similar in both groups as was gender (male 74% vs 79%) and incidence of diabetes. Early AKI developed in 35% of whom 55% needed RRT; 85% of the AKI patients required mechanical ventilation vs 11.2% of the non-AKI group. Inflammatory markers (WBC, CRP, LDH); urine protein and urine white cells (but not CPK) were significantly higher in the AKI group. Procalcitonin and D-dimers as maximum levels became significant. We found that 20% of those not with early AKI developed late-onset AKI. Mortality was 76.7% in the AKI and 17.9% in the non-AKI group.

Conclusions: Early AKI developing in the first week of hospitalization was associated with overwhelming respiratory failure. The accompanying higher inflammatory markers, elevated urine WBCs and protein could implicate intestinal nephritis as an underlying pathology as described earlier.

PO0710
Incidence of AKI in Hospitalized Patients with COVID-19
Lili Chan, Kumanndep Chaudhary, Aparna Saha, Kinsuk Chauhan, Akhil Vaid, Barbara T. Murphy, John C. He, Girish N. Nadkarni, Steven G. Coca. Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Preliminary reports indicate that acute kidney injury (AKI) is common in coronavirus disease (COVID-19) patients and is associated with worse outcomes. AKI in hospitalized COVID-19 patients in the United States is not well-described.

Methods: This is a retrospective observational study of patients aged ≥18 years with laboratory confirmed COVID-19 admitted to the Mount Sinai Health System between February 27 and April 15, 2020. We describe the frequency of AKI and dialysis requirement, AKI recovery, and adjusted odds ratios (aOR) for mortality while adjusting for age, gender, race, comorbidities, and admission labs and vital signs.

Results: Of 3,235 hospitalized patients with COVID-19, AKI occurred in 1406 (46%) patients and 280 (20%) with AKI required dialysis. The proportion with stages 1, 2, and 3 AKI overall was 35%, 20%, 45%, and 20% received dialysis (Figure 1A). In the 815 patients admitted to the intensive care unit (ICU), 553 (68%) had AKI and 34% required dialysis. The median peak serum creatinine was 2.2 (IQR 1.6-3.7) mg/dL in those that did not receive dialysis and was 8.6 (IQR 6.5-11.4) mg/dL in those that did receive dialysis. Urine studies were available for 581 (18%) patients of whom 338 (60%) patients had AKI. 535 (96%) of all patients had any urinary abnormalities of proteinuria, hematuria, or leukocytoria. Independent predictors of severe AKI were chronic kidney disease, systolic blood pressure, and potassium at baseline. In-hospital mortality in patients with AKI was 41%. The aOR for mortality for AKI was 9.6 (95% CI 7.4-12.3), 56% of patients with AKI who were discharged recovered kidney function back to baseline (Figure 1B).

Conclusions: AKI is common in patients hospitalized with COVID-19, associated with worse mortality, and nearly half of patients do not recover kidney function.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: From 2/17 to 5/29, 2020, Dialysis Clinic Inc. had identified 422 COVID+ patients from 90 clinics in 20 states. We compared their characteristics relative to the uninfected source clinic population (N=6,993) and tracked outcomes over the 15-week period.

Results: Comparative characteristics are shown in the table (*P<0.05). Hospitalization occurred in 295 (70%) with 75 deaths, 159 discharges and 61 still hospitalized. Ten patients died <30 days post-discharge. Another 11 deaths occurred in 116 non-hospitalized patients. Overall, 96 of 422 died (22.7%). While more black patients were infected, death rates were higher in white than black dialysis patients (31.5% vs. 18.8%, p=0.008).

Conclusions: Chronic dialysis patients with COVID have higher death rates than the general population. Infected patients tended to be older, with more comorbidity, particularly DM/CVD, and utilized respiratory inhalers/assistance. Group home residents were overrepresented with COVID while home dialysis patients were disproportionately spared.

PO0712

ESKD Patients Hospitalized with COVID-19: Early Outcomes in Bronx, New York
Molly Fisher,1,2 Milagros Yunis,1 Michele H. Mokrzycki,1,2 Ladan Golestaneh,1,2 Maria Coco,1,2 Montefiore Medical Center, Bronx, NY; 3Yeshiva University Albert Einstein College of Medicine, Bronx, NY.

Background: It is unclear whether end-stage kidney disease (ESKD) patients with COVID-19 are at increased risk for adverse outcomes due to impaired immune responses attributed to uremia. Alternatively, a weakened immune state could mitigate the cytokine surge observed in non-ESKD patients with COVID-19. The aim of our study is to describe the clinical characteristics and short term outcomes in ESKD patients requiring hospitalization for COVID-19.

Methods: We performed a retrospective study of 114 consecutive ESKD patients hospitalized at two major hospitals in the Bronx with COVID-19 from March 9, 2020 to April 12, 2020 in the midst of the coronavirus surge in New York City. Clinical and laboratory data were extracted from the medical record and short term outcomes were reported.

Results: The mean age was 63 years (range 30-87); 61.4% were men and 88.6% were Black or Hispanic. Most had hypertension (89.5%) and diabetes mellitus 66% and 30.7% were nursing home residents. Intensive care unit admission was required in 13(11.4%) patients and 17(14.9%) required mechanical ventilation. In-hospital mortality occurred in 23(20%) patients and was similar to mortality observed in non-ESKD patients. Mortality was 59% in those who required mechanical ventilation. At the time of data censoring, 47% had been discharged and 32% remained hospitalized. Initial procalcitonin, ferritin, lactate dehydrogenase and lymphocyte percentage were significantly higher in those who died.

Conclusions: Short term mortality in Bronx ESKD patients hospitalized with COVID-19 was similar to non-ESKD patients. Mechanical ventilation was associated with high mortality. Initial elevated inflammatory markers may be predictors of mortality in ESKD patients with COVID-19. To date, this is one of the largest studies describing outcomes in hospitalized ESKD patients with COVID-19. Further studies describing long-term outcomes in this population following COVID-19 are needed.
PO0714
Implementation of Strategies for Prevention and Control of SARS-CoV-2 Infection at Dialysis Units in Latin America: Analysis from GlomCon Latin America Working Group (LGlonCon)
Denise Arellano-Mendez,1 Julio A. Gutierrez-Prieto,1 Javier Soto-Vargas,1 Blanca Martinez-Chagollaga,2 Franco H. Cabeza Rivera,1 Desiree Garcia Anton,1 Dolores Negreira,3 Carmen Ayala-Casado,5 GlomCon Latin America Working Group1 Unidad Medica de Atencion Ambulatoria 254, IMSS, Morelia, Mexico; 2Hospital Central del Estado de Chihuahua, Chihuahua, Mexico; 3Hospital General Regional 46, IMSS, Guadalajara, Mexico; 4Hospital General “Dr. Miguel Silva", Morelia, Mexico; 5University of Mississippi Medical Center, Jackson, MS, "Hospital General de Mexicali, Mexicali, Mexico; 6Multi-Organ Transplant Program, University Health Network, Toronto, ON, Canada; 7Pathology Department, University Health Network, Toronto, ON, Canada.

Background: Patients on dialysis belong to the high-risk group to develop severe COVID-19 infection due to their multiple comorbidities. International societies have issued recommendations for the control and prevention of SARS-CoV-2 infection at dialysis units but implementing them may not always be feasible as many healthcare systems in Latin America (LA) have limited resources. This study aims to reflect the experience of nephrologists in LA at taking care of these patients and if the recommendations were adopted in their practices.

Methods: Descriptive analysis extracted from an online survey carried out among nephrologists, renal pathologists and other health workers treating kidney diseases between 1 May 2020 and 31 August 2020. Sixteen Spanish speaking LA countries divided into 6 categories. We present the results for the ESRD category.

Results: 430 responses were obtained, 360 were considered for analysis. 276 (86.5%) of the participants were nephrologists and 178 (64%) of them practiced in dialysis units. 163 (92.6%) already implemented strategies to control and prevent COVID-19 in their units. 125 (71%) received training on it and 128 (72.7%) reported personal protective equipment availability. The most common implemented strategies were: education sessions about COVID-19 for patients and caregivers (68.5%), designated isolation areas or shifts (68.2%) for patients with suspected or confirmed COVID-19 and a 7-feet separation between hemodialysis (HD) machines (61.9%). 49 (28%) of the nephrologists reported an outbreak among patients and 60 (34.2%) among medical staff. Patient absenteeism to their HD sessions due to fear of infection, a decrease in the frequency and the duration of the time of the sessions was reported in 41.7%, 30.2% and 36%, respectively. 29 (16.5%) of the respondents considered that those practices were associated with patient mortality.

Conclusions: Most dialysis units in LA are partially implementing the recommended strategies for control and prevention of COVID-19 but this seems to be insufficient since at least one third of them already faced outbreaks among patients and medical staff.

PO0715
Implementing COVID-19 Infection Control Procedures in Outpatient Dialysis in an Urban US Population
Ibironke W. Apata, Jason Cobb, Jose E. Navarrete, Janice P. Lea. Emory University School of Medicine, Atlanta, GA.

Background: Emerging data reveal disparities in the burden and severity of disease among racial and ethnic minorities in the US. Emory Dialysis consists of 4 outpatient dialysis facilities, serving an older, urban and predominantly African-American population. These facilities are in counties with the highest number of COVID-19 cases in Georgia. We describe infection control measures implemented to prevent COVID-19 transmission, and the clinical characteristics of patients with COVID-19 in the facilities.

Methods: Based on CDC’s recommended guidance, we implemented the following infection control procedure between February and April 2020: 1) screening; triaging all patients, and separating patients with symptoms of COVID-19; 2) monitoring staff for COVID-19 symptoms; 3) limiting healthcare personnel in the facilities; 4) universal masking in the dialysis units; 5) conducting PPE re-trainings; 6) assessing facility preparedness; 7) separating high risk patients (nursing home residents); and 8) cohorting patients with COVID-19 to a dedicated dialysis shift.

Results: Of the 745 patients followed at the Emory dialysis facilities, 18 (2.4%) were diagnosed COVID-19 between March 25—May 7, 2020. Among the 18 patients, 17 were receiving in-center hemodialysis and 1 was on peritoneal dialysis. The median age was 66.8 years (range 43–84) and 11 (61.1%) were female. Nine (50%) were residents of a skilled nursing facility. Sixteen (88.9%) patients had a diagnosis of hypertension, 10 (55.6%) had diabetes, and 10 (55.6%) had cardiac disease. Eight patients (44.4%) required hospitalization and 4 patients (22.2%) died from COVID-19 related complications. Two patients (11%) were dialyzing at adjacent dialysis stations and the timing of their symptoms suggested possible transmission in the dialysis facility. In response, education, infection control audits and PPE re-trainings were conducted to bolster infection control practices.

Conclusions: In a high-risk patient dialysis population, we successfully implemented recommended infection control measures to mitigate the spread of SARS-COV-2 in our facilities. Dialysis facilities must stay vigilant and monitor for possible transmission of COVID-19. Regular audits of infection control practices remains critical.
PO0718
Clinical Characteristics and Outcomes in ESKD Patients with COVID-19 Infection in an Urban Community Hospital in Brooklyn, New York, During the Global Pandemic
Carlos M. Zapata, Yanina E. Rodriguez, Olawale Akande, Laurie Ward, Premila Bhat. Wyckoff Heights Medical Center, Brooklyn, NY.

Background: The impact of coronavirus disease 2019 (COVID-19) on individuals with End Stage Kidney Disease (ESKD) receiving maintenance hemodialysis (MHD) is unknown. This study aims to describe clinical characteristics and outcomes in a cohort of patients with ESDK receiving MHD hospitalized with confirmed COVID-19 infection in an urban community hospital during the New York City peak of the global COVID19 pandemic.

Methods: Cases with a diagnosis of ESKD and COVID-19 based on positive PCR testing results were identified from retrospective review of electronic health records for patients hospitalized between March 4, 2020 and April 30, 2020. Electronic health records were reviewed in order to obtain demographic data, presenting symptoms, laboratory values, medical management, and outcomes.

Results: 29 patients with ESKD on MHD with confirmed COVID-19 infection were identified. 16 (55%) were over age 60 years, 20 (69%) were male and 14 (48%) were Hispanic. 18 (62%) had Diabetes and 26 (89%) were overweight or obese (BMI ≥25). All had hypertension. 68% were on Statin and 40% on ACE inhibitor or ARB at the time of admission. 25 (86%) were dialyzed via arteriovenous fistula or graft. The most common presenting symptoms were dyspnea (85%), cough (60%) and fever (28%). All chest radiographs showed abnormalities, with diffuse infiltrates on 21 (72.4%) and focal infiltrates on the remainder. All patients who required renal replacement therapy during hospitalization received conventional HD. 10 patients required mechanical ventilation during hospitalization (34%); all of these patients died. Overall, 13 patients (45%) died and 16 patients (55%) were discharged after a median of 6 and 7 days hospitalization, respectively. Three patients (10%) were readmitted during the period of observation. No significant associations were found between age, sex, race, or diabetes and mortality. Mechanical ventilation was the most consistent predictor of death.

Conclusions: 45% mortality was observed in a small cohort of patients with ESKD on MHD with confirmed COVID-19 infection hospitalized during the peak of the global COVID-19 infection. This high mortality rate reinforces the need for social distancing and infection control measures to reduce transmission in this high risk population.

PO0719
Clinical Outcomes of Patients with ESKD Hospitalized with COVID-19
Aldo E. Torres Ortiz, Muner Mohamed, Vernelle T. Mitchell, Juan Carlos Q. Velez. Ochsner Nephrology Ochsner Health System, New Orleans, LA.

Background: Patients with end-stage kidney disease (ESKD) comprise a vulnerable population to infections. COVID-19 has been responsible for high mortality worldwide. To-date, there is limited data regarding the impact of COVID-19 in the ESKD population. We report clinical outcomes of ESKD patients with COVID-19 admitted to an academic hospital in New Orleans.

Methods: We conducted an observational study in patients with ESKD and COVID-19 hospitalized at Ochsner Medical Center over a 7-week period. We compared rates of need for mechanical ventilation, shock, need for intensive care (ICU) and in-hospital mortality as outcome measures between patients with and without ESKD.

Results: Among 851 admissions (67% black) with COVID-19, 49 (6%) patients had diagnosis of ESKD. Patients with ESKD were mostly male (61% vs 49% in non-ESKD vs 49% in non-ESKD, p=0.16) were admitted (BMI) were 32 vs 27 kg/m2 (p = 0.11) for those admitted to ICU vs wards, respectively. Thirteen of them (27%) vs 293 (37%) in the non-ESKD group, p=0.16) were admitted (BMI) were 32 vs 27 kg/m2 (p = 0.11) for those admitted to ICU vs wards, respectively. Thirteen of them (27%) vs 293 (37%) in the non-ESKD group, p=0.16) were admitted for COVID19 infection. This high mortality rate reinforces the need for social distancing and infection control measures to reduce transmission in this high risk population.

PO0720
Clinical Symptoms in 44 Hemodialysis Patients Who Survived and Recovered from COVID-19 in Relation to Age and Hospitalization: An International Experience
Mauro Prioz,1 Szymon Brzozko,2 Marta Serwanska-Switew,2 Werner Kleophas,3 Thilo Krueger,4 Joao M. Frazao,5 Fatima Silva,6 Wisam H. Al-Badr,1 Atef Z. Altaher1 Rosnawati Yahya,7 Maciej Drozdz,8 Partha Das,9 Claudio A. Montero,1 Stefan H. Jacobson,9 DaVita Colombia, Bogota, Colombia; DaVita Poland, Wroclaw, Poland; DaVita Germany, Dusseldorf, Germany; DaVita Portugal, Lisbon, Portugal; DaVita Saudi Arabia, Riyadh, Saudi Arabia; DaVita Malaysia, Kuala Lumpur, Malaysia; DaVita International, London, United Kingdom; DaVita Kidney Care Brazil, Brasilia, Brazil; Karolinska Institutet, Stockholm, Sweden.

Background: A novel coronavirus (SARS-CoV-2) is now rapidly spreading throughout the world. Patients undergoing long-term in-center hemodialysis (HD) are highly vulnerable given kidney failure, comorbidities, and the need for frequent visits to a dialysis facility.

Methods: A total of 610 patients on maintenance HD at DaVita clinics in 6 countries were tested for presence of infection with SARS-CoV-2 using polymerase chain reaction (PCR) between March 28 and May 18. Of these, 115 HD patients (19%) were positive. Information up to May 25, 2020, show that 44 patients have recovered. Clinical symptoms during infection with SARS-CoV-2 are reported from these 44 recovering survivors (Germany 13 patients, Poland 12, Portugal 12, Colombia 2, Saudi Arabia 3, and Malaysia 2) to be classified into 4 categories: symptoms, mild, moderate, or severe symptoms. Hospitalizations and time to recovery were also analyzed. Statistical comparisons were made using Chi-2 analysis and Kruskal-Wallis tests.

Results: Of the 44 patients recovering from COVID-19, 22 were ≥70 years and 22 were <70 years. Symptoms in relation to age, hospitalization, and time to recovery are shown below.

Conclusions: The majority of HD patients (66%) who recovered from COVID-19 had no or mild clinical symptoms during the infection. There were no significant differences in the occurrence of symptoms from SARS-CoV-2 in relation to age, hospitalization, or time to recovery. Additionally, old and frail HD patients with confirmed COVID-19 may have mild symptoms of the disease.

Percentage of HD Patients Who Recovered From Clinical Symptoms During Infection With SARS-CoV-2

PO0721
Comparison of Psychological Distress and Demand Induced by COVID-19 During the Lockdown Period in Patients Undergoing Peritoneal Dialysis and Hemodialysis: A Cross-Section Study in a Tertiary Hospital
Zhiyun Zang, Zi Li, Xiaoxiao Xia, Xiaofang Wu, Department of Nephrology, West China Hospital, Sichuan University, Chengdu, China.

Background: Since the outbreak of COVID-19 in December 2019, it has spread rapidly and widely, bringing great psychological pressure to the public. In order to prevent HD and PD patients from being infected by COVID-19, patients were required to stay at home during the lockdown period. In order to prevent the psychological distress and the psychological demand induced by COVID-19 in the patients undergoing dialysis and compare the difference between hemodialysis (HD) and peritoneal (PD) patients during the lockdown period.

Methods: Questionnaires were given to the dialysis patients in West China Hospital of Sichuan University. The Impact of Event Scale (IES) was used to investigate the clinical symptoms in 44 hemodialysis patients who survived and recovered from COVID-19 during the epidemic period of COVID-19. IES scores and the psychological support during the epidemic period of COVID-19.

Results: 232 eligible respondents were enrolled in this cross-section study, consisting of 156 PD patients and 76 HD patients. The median IES score for all the enrolled patients was 8.00 (2.00-19.00), which belonged to the subclinical dimension of post-traumatic stress symptoms. PD patients had a significant higher IES score than PD patients (11.50 vs 8.00) (p<0.05). PD patients already got more psychological support from the medical staff. There was no significant difference in the further demand of psychological support between the two groups. In the multivariate regression analysis, we found that dialysis vintage, the impact of COVID-19 on the severity of illness and daily life, the IES scores and the psychological support during the epidemic period of COVID-19.

Conclusions: HD patients had more severe trauma-related stress symptoms than PD patients. When major public healthy events occurred, careful psychological estimate and sufficient psychological support should be provided to the dialysis patients, especially to the HD patients.

COVID-19: Dialysis Patients

PO0722

COVID-19 Incidence and Outcomes in Hemodialysis Patients in Mexico
Juan M. Ardavin Iturato, Alicia Pineduia, Juan Carlos Rodríguez, Medica Santa Carmen Staff Nephrologists Medica Santa Carmen, Mexico, Mexico.

Background: HD pts are at high risk for COVID-19. High incidence and death rate were reported in China and Europe with more than 20% of asymptomatics. We report incidence, features and outcomes of COVID-19 in HD patients in a network of 8 clinics in Mexico. A protocol was started on Mar 15 with hygiene measures; symptoms triage; separation by age; use of PPE and isolation of suspected cases. We use a more inclusive case definition, different from Mexico Health Ministry’s (SSA). All cases are referred for PCR but most aren’t tested.

Methods: Retrospective analysis of cases (suspect or PCR(+) from mar 15 to may 22 2020 compared to controls. T-test and Chi2 were used. Hospitalization, IMV and deaths were registered. Overall mortality from mar - may 2020 compared to same period of 2019. We compared the number of cases using our case definition with that using the SSA’s. Incidence of COVID-19 in staff was also analyzed.

Results: Total 1267 pts; Of 102 suspects 25 (24%) had PCR and 16 (64%) were (-). 13 (12%) non-tested were discarded based on alternative dx. 2 pts with (-) PCR were cases based on CT. Total 75 cases (10 (+)PCR, 65 w/o test) were analyzed and compared to controls. No differences in HD vintage, DM, CVD, HD session length, VA, BUN or Kt/V. Less age, fem gender, HTN, more sessions/wk, ACEi/ARB and lower Hb were found in the cases. 7 (9%) hospitalized and 2 (3%) required IMV. There were 6 (8%) deaths, only 1 (1.3%) attributed to COVID-19. Overall mortality minimally higher than that of the same period of 2019 (1.5% vs 1.30%). 31% of cases had only 1 symptom. Only 1 PCR(+) and 14 PCR(-) cases fulfilled SSA’s case definition. Among 231 staff members, 31 (13.6%) had tested (+) PCR(+) and 20 non tested.

Conclusions: Incidence of probable or confirmed COVID-19 was 5.9%; probably overestimated suggested by scarce testing and low mortality. ACEi/ARB use more frequent in cases, adjusted for HTN and age. Our protocol helps prevent in-clinic contagion. A more comprehensive probable case definition appears more useful for HD patients.

PO0723

COVID-19 Infection in Patients with ESRD Requiring Hemodialysis
Anna Anisimova, Valeria Ripa, Biruk Almaz, Nirav Mistry, Fariborz Rezai, St. George’s University School of Medicine, True Blue, Grenada; Saint Barnabas Medical Center, Livingston, NJ.

Background: This case series assesses characteristics and outcomes of patients with confirmed novel coronavirus (SARS-CoV-2, COVID-19) infection and end stage renal disease (ESRD) requiring hemodialysis during the COVID-19 pandemic.

Methods: This is a single center retrospective study of 24 ESRD patients on hemodialysis who were admitted to Saint Barnabas Medical Center, a 597-bed acute care hospital in Livingston, New Jersey, and with a confirmed COVID-19 diagnosis between February 1st to April 5th, 2020. The characteristics, clinical course, and outcome were assessed and compared. In addition, a subgroup analysis was made between patients who expired (n=8) versus those who lived (n=16).

Results: The overall mortality rate was 33.3% vs. 21% in the general population with COVID-19. Among the 4 (16%) patients who required ICU admission and prolonged pressor support and invasive mechanical ventilation, 2 (50%) patients were successfully extubated and discharged from the hospital while the other 2 (50%) patients died. There were no statistical differences in laboratory values between patients who survived versus patients who died except C-reactive protein (CRP), p=0.002.

Conclusions: We report a mortality rate of 33.3% in our case series of 24 patients with ESRD on dialysis with concurrent COVID-19 infection. There was a statistical difference in CRP value between patients who died versus survived. Fifty percent of intubated patients were successfully extubated and discharged.

PO0724

COVID-19 Infection Patterns in an Academic Inner City Dialysis Unit
Vipin Synthasam, Sarah M. Ahmad, Sandeep Aggarwal, Ihab M. Wahba, Yonghong Huan, University of Pennsylvania, Philadelphia, PA.

Background: COVID-19 remains a major public health emergency and in-center dialysis provides multiple opportunities for its spread. Elderly immunocompromised host is pose a significant risk for infection as well as poor outcomes. We present a retrospective analysis of COVID-19 cases in our dialysis unit.

Methods: Retrospective analysis was done as a part of a quality improvement project using unidentified patient data including: demographics, distribution of dialysis shift, patient zip code, transportation mode (self, ride share or public transport), residence type (home, long term care facility or homeless shelter), etiology of ESRD and dialysis vintage. T-test and multivariate analysis (including logistic regression for binary and categorical data) were conducted using SPSS v23.

Results: There were 70 patients in the unit and 10 became positive for COVID-19. 65 (92%) of all patients were African American. Between COVID-19 positive and negative patients, there was no significant difference in age (62±15 vs 63±14 years p=0.2), dialysis vintage (7.6±8.7 vs 5.2±4.7 years p=0.31), male gender (7/10 (70%) vs 40/70 (58%) p=0.31). 3/10 (50%) of the positive patients were MWF 2nd shift. On multivariate analysis, this effect approached significance (p=0.05); however, there was no information from the positive patients positive status with demographic characteristics, dialysis vintage, residence type, zip code distribution, or transportation modality. Of note, universal masking and temperature screening were implemented on March 5, 2020 in this unit and no new cases were noted after May 2, 2020.

Conclusions: Our analysis did not show any clear factor associated with COVID-19 infection among our dialysis patients although clustering approached statistical significance. Small sample size and demographic distribution are shortcomings of our study; larger scale epidemiological studies and data analysis are required for better understanding the risk of COVID-19 infection amongst in-center dialysis patients.
COVID-19: Dialysis Patients

Background: Patients on regular dialysis are at an increased risk to COVID-19 due to their multiple comorbidities and exposure in the health care setting. The risk for virus transmission within a dialysis unit is also high emphasizing the importance of implementing infection control measures. The objective of this report is to describe the COVID-19 outbreak in a dialysis unit including interventions done.

Methods: Review of the epidemic course with contact tracing was done from March 14 to May 14, 2020 in the dialysis unit of a tertiary hospital in the Philippines. Results: Of 167 patients, 20 became COVID-19 suspects. Eight were positive -3 were exposed from the first confirmed case, 2 were handled by a COVID-19 infected healthcare worker (HCW) who was asymptomatic at time of contact while 2 asymptomatic patients tested positive during mass testing. Two of 67 HCWs tested positive were exposed to patients. Key interventions are (a) enhanced screening by mass testing using NPS/OPs RT-PCR of patients and HCWs after identifying 6 patients and 2 HCWs infected with COVID-19 (b) instead of cohort, dialysis of COVID-19 confirmed and suspected cases was done in isolation rooms separate from the dialysis unit (d) adequate personal protective equipment for HCWs and masks for all patients and (e) environmental disinfection especially in the waiting area with strict social distancing and daily screening.

Conclusions: The infection control and preventive actions done halted the increase in cases. Maintaining these strategies for the duration of the pandemic allowed further decline in the rate of infection.

COVID-19 Suspects, Cases and Interventions

Effect of COVID-19 on Dialysis Practices on the Ground: Early Results from an International DOPPS Program Survey

Murilo H. Guedes,1,2 Brian Bieber,3 Patricia De Sequeira,2 Pablo A. Urena Torres,1 Giuliano Brunori,1 Xinling Liang,4 Li Zuo,5 Michel Y. Jiaquin,6 Roberto Pecoits-Filho,7 Jeffrey Perl,8 Ronald L. Pisoni,9 Bruce M. Robinson,10
1Pontificia Universidade Catolica do Parana, Curitiba, Brazil; 2Arbor Research Collaborative for Health, Ann Arbor, MI; 3University Hospital Infantia Leonor, Madrid, Spain; 4AURa Nord Saint Ouen, Paris, France; 5Ospedale S. Chiara, Trento, Italy; 6Guangdong Provincial People’s Hospital, Guangzhou, China; 7Peking University People’s Hospital, Beijing, China; 8Cliniques Saint-Luc, University of Louvain Medical School, Brussels, Belgium; 9St. Michael’s Hospital, University of Toronto, Toronto, ON, Canada.

Background: The COVID-19 pandemic caused unprecedented disruption to dialysis patient care globally. Facility surveys were distributed to assess the impact of COVID-19 pandemic on hemodialysis (HD) and peritoneal dialysis (PD) practices.

Methods: Medical Director (MD) and Nurse Manager (NM) Surveys (MDS, NMS) are being distributed in May/June 2020 to 723 clinics enrolled in the Dialysis (in-center HD, PD) or Peritoneal (PDOPPS) Dialysis Outcomes and Practices Study in Canada, China, Japan, the United States, 7 European countries, 5 Gulf Cooperative Council countries, and China metropolitan areas (Beijing, Guangzhou, Shanghai). Surveys content includes the number of COVID-19 cases, testing, and clinical management, screening, infection control, staffing, patient transportation, and psychological support.

Results: As of 27 May 2020, we have 80 MDS (China, Europe, US = 33, 38, 5) and 101 NMS (45, 46, 9) responses from DOPPS sites. The following percentages are presented sequentially for China, Europe, and US. Among MDS, 0%, 6%, 67% reported at least one confirmed COVID-19 case among dialysis patients, and 85% confirmed COVID-19 case among dialysis patients, and 100% of MDS reported being on the late phase of the COVID-19 curve. 19%, 23%, 23% reported in all regions, shortages of human and medical resources were common, as were changes to dialysis delivery/practice including more skipped sessions, greater use of potassium binders, and preferentially recommending home dialysis. Over the next month, we expect hundreds more responses, and will compare approaches in PD and HD clinics. These data will inform guidance for dialysis care as the COVID-19 pandemic ensues.

Demographic and Clinical Characteristics of Patients with CKD and SARS-CoV-2 Undergoing Hemodialysis Treatment

Laura C Fuentes-Mendez, Angela M. Cordoba Hurtado, L. M. Perez-Navarro, Rafael Valdez-Ortiz, Maribel Merino. Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.

Background: Patients on HD or PD are likely to be at increased risk of COVID-19 and its complications because they have multiple comorbid conditions. There is a lack of evidence about the optimal management and even clinical manifestations because clinical presentation is highly variable. The delayed diagnosis is because it’s not recognized by the treating centers and the confusion with patients with fluid overload or uremic syndrome can be fatal in this population.
Factors Associated with SARS-CoV-2 Infection (COVID) Severity and Mortality in Chronic Dialysis Patients

Eduardo K. Lacson,¹,² Gideon N. Aweh,¹ Vladimir Ladik,¹ Harold J. Manley,¹ Carol Stewart,¹ Doug Johnson,¹ Dialysis Clinic Inc, Nashville, TN; Tufts University School of Medicine, Boston, MA.

Background: From 2/17 to 5/29, 2020, Dialysis Clinic Inc. had 422 maintenance dialysis patients diagnosed with COVID from 90 clinics in 20 states. While prognostic factors in the general population have been reported, there is limited information regarding the US dialysis population.

Methods: Over a 15 week period of observation, 96 patients died (22.7%) and 116 (27.5%) were not hospitalized (for up to 30 days post-COVID diagnosis), likely with milder illness. We compiled univariable associations with p<0.1 into stepwise logistic regression models (forcing in age, sex, race) to determine factors associated with 1) Death from COVID; and 2) Moderate/severe illness (hospitalized or died without hospitalization <30 days post-COVID diagnosis).

Results: Candidate variables are listed in the table, with retained significant factors marked (a or b at p<0.05). Notably, 42% of all deaths occurred at age >75 years, increasing to 74% of all deaths at age >65 years. Wheelchair use also associated with higher death risk.

Conclusions: Dialysis patients with low albumin and vintage ≥1 year associated with increased illness severity. It was surprising that a history of pneumonia vaccine associated with more severe illness - whether this reflects “treatment by indication” bias vs. pulmonary immune activation by vaccination vs. chance finding is unclear. PVD also tended to increase illness severity but more importantly, was significantly associated with risk of death, independent of older age.

Impact of Undertaking Safeguards to Limit Exposure and Prevent COVID-19 Infection in Ambulatory Dialysis: A Single-Center Experience

Background: Dialysis patients are considered at high risk to develop serious COVID19 complications. Taking extreme measures are necessary to prevent COVID19 transmission at the dialysis center. We are presenting outcomes of our COVID19 prevention project from our largest dialysis center in Qatar.

Methods: Our project was done at FBJKC (largest dialysis center in Qatar with about 60% of all hemodialysis (HD) and 90% of all peritoneal dialysis (PD patients in Qatar)) between March 1st and May 25th 2020. We gradually implemented a bundle of measures and algorithm (attached) to properly triage and limit COVID19 exposure inside the center. New infection control protocol with specifications to COVID19 were implemented, including a new policy for reusing N95 masks in high risk areas. We tracked number of patients and staff who were infected during that period and source of infection.

Results: Our dialysis census during that period was 480 HD and 170 PD patients. Only 6 HD patients turned positive for COVID19 (0.9%) and 2 PD patients (1.2%) (compared to 1.3% general population in Qatar by May 25th). We had 3 dialysis staff infected out of 114 (2.6%). Our investigation showed that all cases of COVID19 (both in patients and staff) were likely contracted outside the center. All staff and patients exposed to positive cases of COVID19 inside the center turned out negative. Our infection control classified most exposures at low risk, especially after we fully implemented our precautions.

Conclusions: Preventive actions implemented inside a large dialysis center led to prevention of COVID19 transmission. Increase positive COVID19 cases (in staff and patients) were related to countrywide growth of infection.

Outcomes of COVID-19 in ESRD Patients on Hemodialysis

Jia Hwei Ng, Jamie S. Hirsch, Rimda Wanchoo, Mala Sachdeva, Susana Hong, Vipulbhai Sakhia, Kenar D. Jhaveri, Steven Fishbane. on Behalf of Northwell Nephrology Covid-19 Research Consortium Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.

Background: Patients with ESKD have a dysregulated immune system and a higher annual mortality rate compared with the general population. We aimed to describe the clinical characteristics and compare the outcomes of patients with and without ESKD, among those hospitalized with COVID-19 disease.

Methods: We reviewed the health records for all patients hospitalized with Covid-19 between March 1, 2020 and April 27, 2020 from 13 hospitals in New York. Patients < 18 years or admitted to inpatient obstetrics service were excluded. ESKD diagnosis was defined using ICD-10 code and manual adjudication. Patients were followed up through May 27, 2020.

Results: Of 10,482 patients admitted with COVID-19, 419 (4.0%) had ESKD. Among patients with ESKD, 408 (97.4%) were on hemodialysis and 11 (2.6%) were on peritoneal dialysis. When comparing baseline characteristics of the two groups, patients with ESKD were older, were predominately of Black race, and had greater proportions of comorbid conditions. The primary outcome was that patients with ESKD had a higher odds of in-hospital death than those without ESKD (rates, 31.7% vs 25.4%; OR 1.4, 95% CI 1.1 - 1.7). After adjusting for age, sex, race/ethnicity, the odds of
in-hospital death remained higher in the ESKD group (adjusted OR 1.5, 95% CI 1.2 - 1.8). The ESKD group did not have a significantly higher odds of needing mechanical ventilation than the non-ESKD group in both the crude analysis and after adjustment for age, sex, race/ethnicity. The odds of having a length of stay of >7 days was higher in the ESKD group compared to the non-ESKD group, in both the crude analysis and the adjusted analysis (OR 1.62, 95% CI 1.3 - 2.1; adjusted OR 1.6, 95% CI 1.3 - 2.1). The independent predictors for death for non-ESKD patients were age, male gender, cancer, CHF, elevated BUN, low albumin and being on a ventilator. The independent predictors of death for ESKD patients were age, lymphopenia, low albumin and being on a ventilator. Black race was associated with lower risk of death.

Conclusions: ESKD patients had a higher rate of mortality compared to non-ESKD patients hospitalized with COVID-19. Black race was associated with a lower risk of death among ESKD patients compared to white patients.

PO0735
Outcome of Hospitalized ESRD-COVID-19 (C19) Infected Patients
Jose E. Navarrete, Darya Hosen, Harold A. Aranch, Frederic F. Rahbari-Oskoui, Michael J. Connor, Janice P. Lea. Emory University, Atlanta, GA.

Background: Emory University affiliated hospitals serve the metro Atlanta area, where a significant number of C19 cases have occurred. In this report we describe the outcomes of AKI and ESRD patients with confirmed C19 admitted to our health-system.

Methods: All patients seen by Emory Nephrology at 2 tertiary referral and one county hospital were categorized as ESRD if they required dialysis prior to C19 infection, or AKI if they developed acute kidney injury as a result of C19 infection. Outcomes of interest included patient survival and discharge from the hospital. Admission to Intensive Care Unit (ICU) and use of mechanical ventilation were recorded. Comorbid conditions and outpatient use of medications were analyzed.

Results: From 3/1/20 to 5/26/20, 474 consecutive patients were seen in COVID-19 related consultation. 287 patients were considered PUI and eventually tested negative for C19. The remaining 187 patients were C19 positive by nasopharyngeal swab or tracheal aspirate and represent the study population for this report. There were 43 ESRD (23%) and 144 AKI (77%) patients. Age (64 vs 63 years), gender (63 vs 66% males) ethnicity (86 vs 82% African-americans) and comorbid conditions were similar in AKI and ESRD patients. AKI patients were more likely to be admitted to ICU (83 vs 35%) and to require mechanical ventilation (73 vs 20%) compared to ESRD patients (p<0.05). Figure 1 presents the outcomes based on the type of renal disease at presentation. The eGFR of AKI patients at time of admission was 50±34 ml/kg/m². 84 AKI patients required dialysis during their hospitalization (52.5%).

Conclusions: Patients with ESRD C19+ were less likely to require ICU admission or mechanical ventilation. Mortality of ESRD patients was 14% compared with 42% of AKI patients, (p=0.002). ESRD patients with C19 were also more likely to be discharged from the hospital compared to those with AKI. Despite similar demographics and co-morbidities, hospitalized AKI C19 patients had worse mortality than those receiving chronic dialysis.

PO0736
Non-Hospitalized Maintenance Hemodialysis Patients with COVID-19 Have Elevated Inflammatory Markers
Ahkil Hegde, Jennifer E. Flythe, Cynthia J. Denu-Ciocca, Kawan A. Swain, Raven A. Voora, Heather J. Anseede, Gerald A. Hladik, Peter Kotanko, Prabir Roy-Chaudhury, Abhijit V. Kashirsagar. 1UNC Kidney Center, Chapel Hill, NC; 2Renal Research Institute, New York, NY.

Background: In addition to an aggressive pneumonia, patients hospitalized with COVID-19 have marked inflammatory and hypercoagulable states, with downstream cardiovascular and thrombotic events. Hemodialysis patients have baseline increases in inflammatory markers among hemodialysis patients with COVID-19 who were managed as outpatients.

Methods: Patients in our dialysis program with one positive nasopharyngeal swab PCR for SARS-CoV-2 were consecutively admitted to an outpatient COVID-19 hemodialysis shift. While receiving their usual dialysis prescription, the patients also had weekly measurements of D-Dimer, Fibrinogen, C-reactive protein (CRP), and Serum Ferritin, until they tested negative x 2 for SARS-CoV-2.

Results: 16 consecutive patients were admitted to the COVID-19 isolation shift over 30 days. Their average age was 60 yr, 56% were Black, 25% Hispanic, and 44% female. Causes of ESKD included diabetes (75%), glomerular diseases (19%), and hypertension (6%). No patients received intravenous iron supplementation while on the isolation shift. Table 1 displays the inflammatory marker levels in this group. Note, the 4-fold (D-Dimer), 6-fold (Ferritin) and 21-fold (CRP) increase in these biomarkers from normal levels.

Conclusions: Our initial, unique data show an increase in inflammatory markers in a cohort of non-hospitalized COVID-19 hemodialysis patients. Such an increase may be from the pro-inflammatory impact of COVID-19 in a group with pre-existing high levels of inflammation from uremia and oxidative stress. Additional investigation as to whether elevated inflammatory markers with cardiovascular and thrombotic events (dialysis circuit and vascular access clotting, sudden cardiac death) is needed.

Inflammatory Markers among Non-Hospitalized HD Patients with COVID-19

PO0737
Network Analysis of In-Center Spread of COVID-19: A Single Dialysis Center Experience
Lembriz Rivera Fuentes,1 Hanjie Zhang,1 Alhaji Cherif,2 Peter Kotanko.1,2
1Renal Research Institute, New York, NY; 2Icahn School of Medicine at Mount Sinai, New York, NY.

Background: The need to continue in-center hemodialysis (HD) during COVID-19 pandemic presents a risk of transmission for patients and staff members. The present study aimed to determine if the periodic interactions among patients and staff resulted in spread of COVID-19 in a HD center during a period of 2 months

Methods: This is a retrospective analysis on a HD center in New York City (172 patients, 32 staff members, 26 chairs, MWF and TTS schedules, and 4 shifts/day). From March 24th to April 24th we recorded every HD treatment (chair, patient, and staff member involved in care). We kept dated records for positive COVID-19 cases (patients and staff). To estimate the patient-to-patient interaction, we obtained the location coordinates of each dialysis chair, calculated the Euclidian distance between them and weighted the interaction by proximity between chairs. We conducted network analysis to assess these interactions.

Results: During the study period, 16 patients and 2 staff members became COVID-19 positive. As shown in Figure 1(a), there were 3 chairs (2, 24, and 25) that had more than 1 positive patient. Clusters in chairs 2 and 25 were ruled out based on a lack of direct contact between the involved patients (at least 2 shifts separating them at all times; no in-between patients became positive); chair 2 had a nonviable temporal direction of transmission. Based on schedule, shift, and a 14-day incubation period, the cluster in chair 24 was dismissed. This was corroborated by network analysis [Fig. 1(b)] where the purple dots represent the COVID-19 positive patients, the blue dots represent negative patients (same shift/schedule), and the edges represent the weighted patient-to-patient interaction. We reasoned that more exposed patients would have had a higher chance of becoming infected. Similar information was found for staff-to-patient interaction

Conclusions: Based on our analysis we consider that for patient-to-patient, staff-to-patient, and staff-to-staff interactions, in-center spread of COVID-19 was unlikely

Funding: Private Foundation Support

PO0738
Outcomes of Patients on Chronic Dialysis Hospitalized with COVID-19
Lili Chan, Suraj K. Jaladanki, Lewis Kaufman, Shuchita Sharma, Staci A. Leisman, John C. He, Barbara T. Murphy, Steven G. Ceca, Girish N. Nadkarni. Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Preliminary reports find that patients with end stage renal disease (ESRD) on dialysis who test positive for SARS-CoV-2 have fewer symptoms and require less intensive care than expected. However, there are no reports regarding the outcomes of ESRD patients who are hospitalized with coronavirus disease 2019 (COVID-19).

Figure 1(a)infection history; (b)network analysis patient interaction

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: This is a retrospective observational study of patients aged ≥18 years with known COVID-19 admitted to the Mount Sinai Health System between February 27 and May 20, 2020. ESRD patients were identified by International Classification of Disease codes for ESRD. ESRD patients were propensity matched (5:1) to non-ESRD patients by age, gender, race/ethnicity, comorbidities, body mass index, and facility and week of hospital admission. Multivariate analysis was performed to test the association of ESRD with mortality after adjustment for age, diabetes, hypertension, stroke, coronary artery disease, and congestive heart failure.

Results: 122 ESRD patients were admitted during the study period and matched to 610 non-ESRD patients from the same study period. Patients with ESRD were well matched on age, sex, race/ethnicity and most comorbidities except ESRD patients had a higher prevalence of diabetes (55% vs 43%, P=0.02) and hypertension (66% vs 55%, P=0.03). ESRD patients had higher inflammatory markers of ferritin and procalcitonin. There was no significant differences in d-dimer, fibrinogen, C reactive protein, or interleukin-6 (Figure 1A). ESRD patients were significantly less likely to receive mechanical ventilation (3% vs. 10%, P=0.01) or be admitted to the intensive care unit (9% vs. 21%), and had similar in-hospital mortality (9% vs 15%, P=0.5). ESRD status was associated with lower odds of intubation and intensive care admission, but not significantly associated with mortality after adjustments for age and comorbidities (Figure 1B).

Conclusions: While ESRD patients had a higher prevalence of comorbidities and higher inflammatory markers, they had similar in-hospital mortality as matched non-ESRD patients.

PO0739
Outpatient Hemodialysis Unit Preparedness During COVID-19 Pandemic in Several Dialysis Units in New York State
Errol Carter, Duarry R. Sainvilien, Brahim A. Mohamed, Jamrose K. Durrani, John D. Wagner, Angelika C. Gruessner, Subodh J. Saggi. SUNY Downstate Health Sciences University, Brooklyn, NY.

Background: HD units are clustered close contact environments where prolonged and repeated exposure to blood borne pathogens occurs. Weeks into the CoVID-19 pandemic, wide disparities in rates of death and exposure of staff and patients amongst HD units in the same zip code of an epicenter in New York region emerged.

Methods: Random HD units surveyed as to when and what infection control measures they implemented. Direct input into RedCap and SAS 9.0 analysis of the data conducted.

Results: 15 HD units (average census 18-240) responded. Survey compiled exposure rates from 3/1/20 - 4/30/20. The 1st reported case of CoVID-19 by a facility was 3/2/20. Most facilities reported outbreaks (4-30 cases per facility) by 3/21/20. Missed HD sessions due to CoVID varied from 2-100, hospital stays for such patients varied from 2-20 days and death rates from 0-15 per facility. 4 of 15 facilities reported deaths of family members of exposed patients and impediments in logistics of single person transportation forcing carpooling. Home dialysis programs reported minimal deaths and exposures. 20% of facilities had no infection preventionist and 26% no patient educator. Reported waiting area cleaning and hand sanitizer refill rates ranged from 1-5 times per day. 20% of the facilities have < 6 feet distance between patients. Implementation of infection control practices such as wearing of masks by patients varied widely amongst units. Some started March 1st-March 16th some later due to mixed messages of its importance. Lack of personal protective equipment (PPE)(in 13% of facilities), staff, and housekeeping shortages (6.7-13.3%) compounded the problems. Positive CoVID results had 1-10 staff members absent from the facility with sick call rates from 7-30 days, and no staff death. 46% of the HD units don’t belong to the CDC coalition.

Conclusions: Maintenance of strict hand hygiene, proper air flow, repeated environmental surface cleansing, availability of PPE, and patient and staff education remains a cornerstone in preventing infections from spreading. Lack of leadership support and failing to share best practices between dialysis units in the US remains prohibitive but must be encouraged and standardized.

PO0741
Impact of the COVID-19 Pandemic on In-Center Intermittent Hemodialysis Treatment Adherence
Jasmeet Gill,1 Stevan A. Gonzalez,2 Michael R. Wiederkher,3 Harold M. Szerlip,1 Richard C. Fuquay,1 Baylor University Medical Center at Dallas, Dallas, TX; 2Baylor Simmons Transplant Institute, Fortworth, TX; 3Dallas nephrology associates, Dallas, TX.

Background: Studies have shown that 7.9% of patients miss one to two hemodialysis session per month and 35% miss hemodialysis at least once every three months.1 During current COVID-19 pandemic there has been a decrease in utilization of emergency medical services due to fear of contagion. We hypothesized that patients undergoing in-center hemodialysis might have increased compliance with their dialysis prescription to avoid emergency department visits or hospitalizations. We therefore evaluated the effects of the COVID-19 pandemic on patient adherence to their dialysis prescription.

Methods: This is a retrospective analysis of in-center hemodialysis patients treated in the seven American Renal Associates (ARA) dialysis facilities in Dallas, Texas. COVID-19 was declared a pandemic on March 11, 2020 and pandemic related changes were mandated in ARA hemodialysis facilities on March 13, 2020. We used existing clinical data and examined patient compliance with their dialysis prescription between January 1 to March 14, 2020 (pre-COVID) and March 15 to May 18, 2020 (COVID).

Results: The study enrolled 754 eligible patients. Significantly fewer patients missed a single treatment in the COVID vs pre-COVID periods (35.5% vs 49.9%; p<0.001). The percentage of patients who were hospitalized was lower during COVID vs pre-COVID (12.5% vs. 19.6%; p<0.001). The percentage of patients who shortened hemodialysis time was lower during COVID vs pre-COVID (36.2% vs. 40.9%; p=0.06) although not statistically significant. Finally, significantly more patients achieved a weight within 1 kg of their estimated dry weight at the end of the dialysis sessions COVID vs. pre-COVID (28.5% vs. 34.5%, p=0.01).

Conclusions: These data suggest that during current COVID-19 pandemic, hemodialysis patients have become more adherent to their dialysis prescription. Retrospective studies have suggested that patients are avoiding seeking medical care due to fear of contacting the SARS-CoV-2 virus1. Our data suggest that similarly, hemodialysis patients have significantly increased their adherence to hemodialysis prescription in order to avoid hospital visits. Additional studies are ongoing to determine the causes for the observed improved compliance.
PO0742

Accuracy of Lower Temperature Thresholds in Detecting COVID-19 in Hemodialysis Patients

Remi Goupil,1, Annie-Claire Nadeau-Fredette,2 William Beaubien-Souligny,3 Francois Madore,1 Rita Suri,1 for the Réseau Rénal Québécois 1Hôpital du Sacré-Cœur de Montréal, Montreal, QC, Canada; 2Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada; 3Centre Hospitalier de l’Université de Montréal, Montreal, QC, Canada; 4McGill University, Montreal, QC, Canada.

Background: Patients receiving in-center hemodialysis (HD) are uniquely vulnerable to COVID-19 yet identifying infected individuals may be challenging. They may not present with typical symptoms and low basal body temperature may impair detection of fever. We studied the accuracy of temperature thresholds in detecting COVID-19 in HD patients.

Methods: We retrospectively studied all patients between March 24-May 14, 2020 from a single HD unit (Hôpital du Sacré-Cœur) in Montreal, Canada, where COVID-19 is highly prevalent. All patients who presented with symptoms or contact exposure were tested by nasopharyngeal swab. Promoted by an outbreak, systematic testing of all HD patients was started on April 18th. Basal temperature was defined as the average pre-dialysis temperature from weeks -1 to -3 before testing. Diagnostic performance was determined for various temperature thresholds defined a priori.

Results: Of 205 in-center HD patients, 34 developed COVID-19 during the study period. Of those, 21 (61%) were hospitalised, 4 (11%) required intensive care and 9 (26%) died. Baseline characteristics are presented in Table 1. Less than a third had typical clinical circumstance. A substantial proportion of dialysis patients may have had asymptomatic SARS-CoV-2 infection.

PO0743

Assessment of a Laboratory-Based SARS-CoV-2 Antibody Test Among Hemodialysis Patients: A Quality Improvement Initiative

Dena E. Cohen,1 Gilbert Marlowe,1 Gabriel Contreras,2 Marie A. Sosa,2 Jair Munoz Mendoza,2 Oliver Lenza,2 Zain Mithani,2 Jorge L. Posada,2 Julio A. Fernandez-Bombino,2 Luis Garcia-Mayol,1 Michael T. Lemont,1 Anne M. Malloy,1 PO0743,2 Steven Zeng,4 Pura M. Teixeiro,4 Nery Queija,2 Jean S. Jeanty,2 Katie Swanz,4 Misha J.Palecek,4 Mahesh Krishnan,4 Jeffrey A. Giuliani,4 Steven M. Brunelli,1 Davita Clinical Research, Minneapolis, MN; 2University of Miami, Coral Gables, FL; 3Kendall Regional Medical Center, Miami, FL; 4Hialeah Hospital, Hialeah, FL; 5Kidney and Hypertension Specialists, Miami, FL; 6Memorial Healthcare System, Hollywood, FL; 7Davita Inc, Denver, CO.

Background: The coronavirus disease 2019 (COVID-19) pandemic is caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection. Assessment of newly developed anti-SARS-CoV-2 antibody tests in hemodialysis patients is needed.

Methods: As part of a quality improvement (QI) initiative, nasopharyngeal swabs and predialysis blood samples were collected on the same day from adults receiving routine dialysis care at clinics managed by a large dialysis organization in the Miami, Florida, region (April 23-30, 2020). Polymerase chain reaction (PCR) tests for SARS-CoV-2 (Fulgent Genetics, Temple City, California) and chemiluminescence immunoassays (Diazyme Laboratories, Inc, Poway, California) were performed according to manufacturer protocols. For antibody tests (IgM and IgG), a reading of >1 arbitrary unit/ml was scored as positive.

Results: Of 715 participants in the QI initiative, 38 had symptoms consistent with COVID-19 prior to or during the initiative. Among these, COVID-19 was confirmed in 14 and ruled out in 20, with 4 being inconclusive. Among the 34 patients with known COVID-19 status, the sensitivity and specificity of the antibody test were 57.1% and 85.0%, respectively, when both IgM and IgG were considered. The remaining 677 patients had no record of symptoms consistent with COVID-19 or any known exposure. Of these, 38 (5.6%) tested positive for anti-SARS-CoV-2 antibodies; none of the antibody-positive patients with available PCR results (N=33) tested positive for SARS-CoV-2 using PCR.

Conclusions: The operational characteristics of the laboratory-based antibody test make it sufficient to rule in, but not rule out, SARS-CoV-2 infection in the appropriate clinical circumstance. A substantial proportion of dialysis patients may have had asymptomatic SARS-CoV-2 infection.

PO0744

Clinical and Psychosocial Impact in Mexican Hemodialfiltration Population During the COVID-19 Pandemic, Twice Weekly Sessions: Is This Safe?

Jose S. Lopez-Gil, Hector Alejandro P. Garza, Magdalena Madero, Daniela Xavier. Division of Nephrology Instituto Nacional de Cardiologia Dr Ignacio Chavez, Mexico City, Mexico.

Background: There is evidence that in patients with residual kidney function (RKF) could benefit switch thrice versus twice weekly schedule. In patients without RKF, the evidence is limited. We evaluated the clinical and psychosocial impact of the Covid-19 pandemic in Mexico City.

Methods: At the beginning of the Covid-19 pandemic, the on-line postdialiltration hemodiafiltration (OL-HDF) sessions were adjusted from 3 to 2 times per week. 2 months later, we determine hemoglobin, urea, serum creatinine, sodium, potassium, calcium, phosphate, albumin, ferritin and C reactive protein. Likewise psychological evaluation using Hamilton test were carried out and characteristic of sessions were collected. We divide in two groups according to thrice versus twice weekly schedule.

Results: 25 patients were evaluated, 16 (64%) were female, mean age was 42.04±16.02 years, 21 (84%) did not have RKF. The length session between thrice vs twice were 181.74±9.94 vs 196 ± 9.19 (p=0.01). When we analyzed the anuric patients (24.43±10.91 vs 26.5± 12.48 L, p=0.04) and no difference in Kt/V (1.67±0.34, p=0.35). We found significance difference between groups in serum creatine (8.68±3.55 vs 10.04±2.94, p=0.03) in the rest of molecules we did not find difference. 32 and 44% of the patients developed depression and anxiety, respectively. 36% of patients lost their jobs and 80% use public transport. There was a moderate correlation between anxiety episodes and economic limitation due to Covid-19 (r = -0.40 p = 0.04). There was no significant inverse correlation between pharmacological adherence and economic limitation (r = -0.29 p = 0.29).

Conclusions: Change of the schedule in patients without RKF did not show significant differences in terms of biochemical parameters. On the other hand, improvement in replacement volumes. We considered a safe strategy to reduce the risk of transmission among our population. Pharmacological and attending adherence to sessions was not modified despite the psychological findings due to the Covid-19 pandemic.
PO0745
Clothing of Catheters in Patients with Renal Failure with COVID-19
Mary C. Mallappallil,1,2 Jie Ouyang,1,2 Sabu John,1,2 John D. Wagner,1 Mariath W. Thaxton,1 Ernie Yap,1,2 Siddhartha D. Bajracharya.1,2 1Health and hospital corporation New York City - Kings County Hospital, New York, NY; 2State University of New York at Downstate Medical Center, Brooklyn, NY;

Background: We are an inner-city hospital in New York that had a surge of patients diagnosed with COVID-19. Many of these patients had acute kidney injury (AKI) and required renal replacement therapy (RRT). NYC Health + Hospitals/Kings County has 40 adult intensive care unit (ICU) beds. ICU capacity expanded to a potential of 150 beds during the COVID-19 surge. The surge included patients transferred from other NY inner-city hospitals for critical care and RRT. Sequential obstacles were faced in providing hemodialysis (HD) to this expanded pool of AKI patients. Additional machines, supplies, staffing and organization were helpful. Clinicians noted that COVID-19 complications included hypercoagulability and we observed an increased frequency of clotting of hemodialysis catheters (HDC).

Methods: We examined the percentage COVID-19 tested renal failure patients with clotting of HDC access during the period March 1, 2020 to May 15, 2020. We collected data on 146 patients during the above period who had HD. We then compared those who were COVID-19 positive confirmed by testing to those who were not COVID-19 by testing. HDC clotting was identified by the use of alteplase. We compared our findings of the two groups to historical controls during a similar time period prior to the COVID-19 surge, between January 1 to February 29, 2020.

Results: We had 3,665 admissions between March 1 and May 15, 2020, of which 1,075 patients had a confirmed COVID + test during the admission. Of these, 773 patients were noted to have AKI from diagnosis codes in the electronic medical record. Of the 146 patients who needed HD (including patients with AKI and CKD) 97 were COVID-19+ and 49 were negative. HDC clotting identified by the use of alteplase was noted in 27% of those who were COVID-19+ compared to 10% of those who were COVID-19 negative. (P value= 0.02 by Chi-square using SPSS Version 24). The percentage of patients with clotting of catheters in the non-COVID-19 group was comparable to historical controls.

Conclusions: Significantly more COVID-19+ patients had HD catheter clotting compared to non-COVID-19 patients. Increased clotting was noted as a barrier to providing optimal HD therapy. For this and other reasons, we initiated an urgent start acute peritoneal dialysis program to mitigate the challenges in delivering HD to COVID-19 patients.

PO0746
Contingency Planning for COVID-19: Feasibility of Twice Weekly Hemodialysis in a Large Canadian Cohort
David Clark, Kenneth A. West, Karthik K. Tennankore. Dalhousie University Faculty of Medicine, Halifax, NS, Canada;

Background: Reducing hemodialysis treatments from three times weekly to twice weekly is a potential strategy to lessen potential exposure/transmission of COVID-19 while allowing hemodialysis units to operate with fixed/reduced resources. As part of contingency planning at a large Canadian center, all facility-based hemodialysis patients were reviewed in advance for candidacy of a reduced “twice weekly” schedule.

Methods: All prevalent patients receiving at least thrice weekly, facility-based hemodialysis - affiliated with the QEII Halifax, Nova Scotia, Canada - were systematically reviewed in a stepwise manner, using accepted criteria for implementing twice weekly hemodialysis (Fig. 1).

Results: Of 473 patients assessed, only 18 (4%) fulfilled criteria for twice weekly hemodialysis (Fig. 1). Of these patients, average age was 63 ± 12 (SD) years, 61% were diabetic, 95% Caucasian; and at least 67% receiving dialysis for 6+ months prior to assessment. 83% of qualifying patients missed 0 treatments in the preceding month, and none missed >1 treatment. Average for serum albumin was 36 ± 4 g/L, Urea reduction ratio, 72.7, and residual urea clearance, 5.7 ± 2.7 mL/min/1.73m².

Conclusions: Although feasible, a twice weekly hemodialysis strategy applied to a small proportion of our patient population, potentially reflecting an ‘intention to defer’ strategy for initiating dialysis.
PO0749

Mental Health Status During the COVID-19 Pandemic of Hemodialysis Patients
Ernesto Sabath,1,2 Edgar Morales-Montes,1 1Servicios de Salud del Estado de Queretaro, Santiago de Queretaro, Mexico; 2Universidad Autonoma de Queretaro Facultad de Ciencias Naturales, Queretaro, Mexico.

Background: Patients receiving hemodialysis (HD) treatment are a particularly vulnerable population as previous studies have shown that they are at higher risk to develop anxiety, depression, and diminished health-related quality of life. During the COVID-19 pandemic patients and health professionals are under insurmountable psychological pressure which may lead to various psychological problems. The aim of this study was to assess the effect of this pandemic on mental health and quality of life in low-income HD patients.

Methods: Observational, cross-sectional study done in low-income HD patients and matched healthy controls from March-April 2020. The survey collected basic demographic and laboratory data. To assess mental status 3 different scales were used: Generalized Anxiety Disorder (GAD-7), Insomnia Severity Index (ISI), and the Kidney Disease Quality of Life (KDQOL-36). An evaluation of media interest was added.

Results: 152 HD patients and 33 control subjects were included. The median age was similar in both groups (HD 31±17 vs 48±10 yrs p=NS). Literacy was significantly higher in the control group. The control group showed significantly higher interest media (p=0.03); 60.5% of HD patients showed none or low emotional impact with this pandemic (42% in control group p=0.02). Severe anxiety was more prevalent in the control group (22.6 vs 8% p=0.01). The ISI scale showed also significantly higher sleep impairment in control subjects (42.6 vs 20.5%, p=0.04). In the HD group, the prevalence of GAD symptoms was higher in females than men (p=0.005), and one of the most influential factors associated with GAD symptoms was to live in a rented home. Patients ≥50 years had significantly higher GAD symptoms (0.01). Unemployed HD patients showed the lowest K-DQOL scores.

Conclusions: HD patients had less emotional impact, lower GAD-7 and ISI scores, symptoms than healthy controls. To live in a rented home and unemployment were important risk factors associated with a higher prevalence of anxiety and sleep disorders.

Monitoring Trends of COVID-19 Among ESKD Patients in a Large Dialysis Organization
Kristine Kubisiak,1 Eric D. Weinhandl,1 Norma J. Ofsthun,1 Jeffrey L. Hymes,1 Robert J. Kossman,1 Lorien S. Dalrymple,1 Fresenius Medical Care, Waltham, MA; 2Chronic Disease Research Group, Minneapolis, MN.

Background: Monitoring real-time acceleration, plateaus, and deceleration of infection rates is important for healthcare planning during a pandemic. We implemented methodology to continuously monitor daily cases and changes of COVID-19 case rates among individuals with ESKD receiving care in a large dialysis organization.

Methods: We identified patients with ESKD receiving dialysis in a Fresenius Medical Care North America (FMCNA) dialysis facility who tested positive for COVID-19. We fit a loess curve to the daily cumulative number of identified cases and computed the first and second derivative of the fitted curve to assess rate of change and change in rate of change, respectively, over time. We used these visualization techniques to monitor trends in case rates at the national and state levels.

Results: By May 15, 2020, there were 5,513 confirmed COVID-19 cases among patients receiving dialysis in an FMCNA facility. Mean age was 63.6 years, 57% were male, and 71% of confirmed cases had diabetes. Nationally, during the peak infection period in early April, new cases routinely exceeded 150 per day and there was a steady acceleration in growth of cases until the second week of April. As of May 15, 2020, among states with sufficient data, 2 states demonstrated continued acceleration, 10 demonstrated deceleration, and 13 plateaued in rate of growth.

Conclusions: The timing of the acceleration in growth of COVID-19 cases among individuals with ESKD followed national trends in the general population. Varying patterns of plateauing and deceleration of cases at the state level were observed in the ESKD population. Real-time monitoring of disease rates in high-risk populations, such as individuals with ESKD, is needed to plan for continuously changing healthcare demands during a pandemic.

Funding: Commercial Support - Fresenius Medical Care
Results: Of 834 chronic HD patients, 26% (222) were diagnosed with COVID-19. Mean age of those with COVID-19 was 72±9 years old, 86% were Black, 77% had diabetes and all had hypertension. Of these patients, 59% (13/22) required hospitalization and 18% (4/22) died. IgG Ab testing was performed on 19 out of 22 COVID-19 patients. All 19 patients tested positive for IgG Ab with an average Ab titer of 7±1.2. 20 days after the first SARS-CoV-2 RNA test, 68% (13/19) patients remained positive on repeat RNA testing. 3 patients tested positive for SARS-CoV-2 RNA on repeat surveillance testing despite testing negative on 2 prior consecutive nasal or nasopharyngeal specimens (Fig. 1).

None of these 3 patients were symptomatic at the time their repeat swabs were positive for SARS-CoV-2 RNA.

Conclusions: All HD patients with a confirmed diagnosis of COVID-19 developed IgG Ab to the SARS-CoV-2 virus, but the SARS-CoV-2 RNA was detectable in the swab specimen for a prolonged duration of time. In a few cases, the SARS-CoV-2 RNA became detectable after 2 consecutive negative RNA specimens. It is unknown if the IgG antibodies confer immunity against the SARS-CoV-2 virus. Additionally, the significance of persistent viral RNA shedding in patients who have recovered from COVID-19 remains to be elucidated.

PO0754 Rates of Asymptomatic Carriage and Antibody Positivity for SARS-CoV-2 in a Large Haemodialysis Cohort

Background: Haemodialysis patients represent a unique challenge in the COVID-19 pandemic, balancing infection risk while safely providing life-sustaining haemodialysis. Asymptomatic infection rates in haemodialysis patients are unknown. Aims: 1 - To define rates of asymptomatic swab positivity in a cohort of prevalent haemodialysis patients 2 - To define rates of antibody positivity in patients known to have been historically swab positive 3 - To define rates of antibody positivity in patients without prior symptoms or clinical suspicion of COVID-19.

Methods: A programme of COVID-19 screening using a validated nasopharyngeal PCR analysis was carried out across a prevalent cohort of 1253 haemodialysis patients. Concurrently all patients were offered antibody testing for Anti-SARS-CoV-2 IgG/IgM (Roche) and a total of 848 tests were completed.

Results: 1 – Routine screening over a 4 week period from 4/5/20 to 1/6/20 confirmed 7 cases of asymptomatic swab positivity (0.6%). 2 – In our cohort there were 197 confirmed swab positive cases of COVID, and of the 153 survivors 124 were antibody positive (81%). 10 patients were highly clinically suspicious of COVID and managed as such; of those 3 were antibody positive (30%). 3 – Of the remaining swab negative patients who had antibody testing (n=710) 82 were antibody positive (11.5%).

Conclusions: In a large inner-city London haemodialysis where the population prevalence of COVID has been high, we demonstrate 1 – low asymptomatic rates of virus carriage at this later stage in the pandemic 2 – significant proportions of swab positive patients seroconverting to be antibody positive 2 – suggestion that 11.5% of patients had previous been asymptomatic carriers and had seroconverted to be antibody positive.
Figure 1: Example of COVID-19 outbreaks risk map in European dialysis clinics network. Red, yellow, green circles represent respectively high, middle, low risk classes.

PO0758

Distribution of SARS-CoV-2 Positive Tests, Dialysis Stations, and Household Poverty Within Cook County, Illinois

Siddharth Bhatyan1, Ranit Sengupta2, Talar Markossian2, Mohammad samie3, John Larkin1, Caitlin Raimann, Jochen Raimann1, John Larkin3, Len A. Usvyat2, Franklin W. Maddux2, Stefano Garbelli3, Luca Neri3,1 Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany;4 Fresenius Medical Care North America, Waltham, MA;5 Fresenius Medical Care Italia SpA, Palazzo Pignano, Italy.

Background: The frequency of evaluations in hemodialysis (HD) care affords opportunities to assess profiles that may characterize onset of the 2019 coronavirus disease (COVID-19). We aimed to characterize the trajectories of clinical/laboratory assessments before COVID-19 diagnosis in HD patients.

Methods: We assessed data from HD patients with known COVID-19 dialyzed at Fresenius Kidney Care in the United States between 02 Mar and 09 Apr 2020. We trained a model to predict outbreak in each clinic in a 2-week prediction horizon (i.e. two or more COVID-19 cases). In addition to sentinel distance-weighted risk estimates, the model included 73 variables (i.e. regional-level epidemic data from open source datasets and clinical practice data from the EuCliD® database). We generated the training set on data available on 04/01/2020 and tested prediction accuracy at 4/15/2020 and 4/20/2020.

Results: In the training set there were 58 (9.1%) clinics with two or more patients with COVID-19 infection in the two-week prediction window. In the validation samples there were 27 (4.2%) and 12 (1.9%) clinics with two or more patients with COVID-19 infection during the two-week prediction window. The performance of the model was suitable in both testing windows (AUC=0.86 and 0.80 respectively). The model is used to construct risk maps highlighting geographical clusters of clinics at risk (figure).

Conclusions: A sentinel surveillance system together with the wealth of information collected in EuCliD® and state of the art modeling strategies allows prompt risk assessment and timely response to COVID-19 epidemic challenges throughout networked European clinics.

Figure 2: Trajectories 30 Days Before COVID-19 Diagnosis in HD Patients

PO0757

Trajectories of Clinical and Laboratory Characteristics Before COVID-19 Diagnosis in Hemodialysis Patients

Yue Jiao1, John W. Larkin2, Caitlin Monaghan1, Anke Winter3, Jochen G. Raimann4, Luca Neri5, Peter Kotanko6, Jeffrey L. Hymes5, Sangho Lee7, Len A. Usvyat2, Franklin W. Maddux2,8,9 Fresenius Medical Care, Global Medical Office, Waltham, MA; 2Renal Research Institute, New York, NY; 3Fresenius Medical Care Deutschland GmbH, EMEA Medical Office, Bad Homburg, Germany; 4Fresenius Medical Care North America, Waltham, MA; 5Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea; 6Fresenius Medical Care AG & Co. KGaA, Global Medical Office, Bad Homburg, Germany.

Background: The frequency of evaluations in hemodialysis (HD) care affords opportunities to assess profiles that may characterize onset of the 2019 coronavirus disease (COVID-19). We aimed to characterize the trajectories of clinical/laboratory assessments before COVID-19 diagnosis in HD patients.

Methods: We assessed data from HD patients with known COVID-19 dialyzed at Fresenius Kidney Care in the United States between 02 Mar and 09 Apr 2020. We computed mean daily values for 40 variables 90 days before a positive rRT-PCR test (COVID-19+). Nonparametric smoothing splines were used to fit data of individual trajectories and estimate the mean change over time.

Results: There were 1294 HD patients with COVID-19 (mean age 64±14 years, 60% male, 47% white race, 69% had diabetes, and 24% had coronary artery disease). Mean pre-HD body temperature (primarily oral) increased by about 1° Fahrenheit (F) over 10 days before COVID-19+ test and approached 99.5°F at diagnosis (Fig 1A). Mean interdialytic weight gain decreased by about 0.75 kg (Fig 1B) over 14 days before COVID-19+ test, concurrent decreases of about 20 minutes were seen in HD treatment time. Mean neutrophil-to-lymphocyte ratio had mild increases (Fig 1C), while mean platelet counts decreased by about 40x10^3/L over 14 days before COVID-19+ test (Fig 1D). Trajectories of many variables (vitals, heparin, hematology, nutrition, bone, anemia) were observed to change before COVID-19+ test, yet alternations were generally minor.

Conclusions: The trajectories of several clinical/laboratory parameters appeared to change before COVID-19 diagnosis in HD patients. Many changes were small and may not be independently useful in identifying onset of COVID-19. Mean pre-HD body temperature before SARS-CoV-2 infection was 97.4° F and should be considered in screening. Findings may have utility in prediction model development. Further comparisons to patients without COVID-19 are needed.
PO0759
Kidney Patient Mortality due to COVID-19 in Ecuador: The Experience in Guayas Province
Fabian A. Ortiz-Herbener,1,2 Instituto Ecuatoriano de Diálisis y Trasplantes [IEDYT], Guayaquil, Ecuador; 1Unidad de Cuidado Renal Avanzado [UCRA], Guayaquil, Ecuador.

Background: Ecuador is a country of seventeen million population located in the west coast of South America. In late February 2020, Ecuador had its first Covid-19 case in the city of Guayaquil, followed by massive growth of infections in Guayas Province (14,000 of 39,000 cases), the current epicenter. Due to the lack of official information in this population, and the significant impact in mortality saw in other countries, a need for data is warrant.

Methods: There are approximately 15,000 patients on renal replacement therapy in Ecuador, 94% of them on hemodialysis. At Guayas Province, the estimation of 5200 people on hemodialysis accounts for the 34% of the country's patients. A simple telephone-based questionnaire was performed at the first week of May, directed to the owner, medical director, or head of nurses of each center in the Guayas Province.

Results: From the 35 centers in Guayaquil, it was possible to collect data from 29 locations (82.5%) -mostly private centers-, that represents approximately 4719 patients, 89.8% from the total of patients in Guayas Province. Just 2 / 8 public centers provide information. Results are summarized in Table 1.

Conclusions: The 11.91% Covid-19 mortality in Guayas Province was high, especially if the expected monthly mortality is around 0.8-1.1%; the lethality was very high; and this could be explained by the fact that renal patients are considered as high-risk patients in this disease. The low mortality in PD patients could be attributable to the lockdown and stay-in-home measures. It is necessary to implement specific protocols in order to avoid high mortality, if a second peak of Covid-19 is expected.

Results from Guayas Province in Covid-19 pandemic.

PO0760
Clinical Characteristics, Management, and Outcomes in COVID-19-Positive Dialysis Patients from Three London Renal Centres, United Kingdom
Dalvir Kular,1 Irina Chis Ster,4 Dandisona B. Braide-Azikiwe,2 Alexander Sarnowski,1 Eirini Lioudaki,3 Martin L. Ford,1 David Makanguela,1 Alexandra C. Rankin,2 Hugh Cairns,1 Joyce Popoola,1 Nicholas I. Cole,1 Mysoor K. Phansri,1 Richard Hull,1 Pauline A. Swift,1 Debasish Banerjee,1,4 St Helier Hospital, London, United Kingdom; 2King’s College Hospital, London, United Kingdom; 3St George’s University Hospitals NHS Foundation Trust, London, United Kingdom; 4St George’s University of London, London, United Kingdom.

Background: Dialysis patients, with frequent co-morbidities, advanced age and frailty, visiting treatment facilities frequently are perhaps more prone to SARS-CoV-2 infection and related death - the risk-factors and dynamics of which are unknown. The aim of this study was to investigate the hospital outcomes in SARS-CoV-2 infected dialysis patients.

Methods: This prospective, observational, multi-centre study collected data on SARS-CoV-2 infected HD patients between 29/02/2020 and 15/05/2020. Data was collected on demographics, comorbidities, WHO performance status, classical symptoms, laboratory parameters, hospital management and outcomes. Treatment was predominantly supportive, unless patients were part of an approved clinical trial. The study was approved by NHS Research Ethics Committee 20/SW/0077 and Heath Research Authority IRAS 283130.

Results: Of 1737 HD patients at the 3 renal centres, 224 (13%) were COVID-19 positive over the study period. The characteristics of the COVID-19 HD patients were: mean age 65.8; 59% male; 38% Caucasian; 81% hypertension; 54% diabetes; 25% chronic lung disease; 29% ischaemic heart disease and 22% cerebrovascular disease. The most common symptoms at presentation were fever (62%) and cough (53%). About 143 (64%) patients were managed as an inpatient and 81 (36%) as an outpatient. Of 97 patients that required mechanical ventilation: 6 died, 1 patient was discharged and 2 are still under clinical care. Overall 51 patients died (23%), 154 (69%) were discharged alive and 19 (8%) were still under clinical care as of 15/05/2020. Preliminary analyses suggested that those that died were significantly older (p=0.0028), more likely to have ischaemic heart disease (p=0.003), cerebrovascular disease (p=0.019), smoking history (p=0.006), WHO performance status 3-4 (p=0.004), higher neutrophil:lymphocyte ratio at presentation (p=0.0001) and higher CRP at presentation (p=0.0021).

Conclusions: This large cohort of COVID-19 positive haemodialysis demonstrates a high case fatality ratio, which increased significantly with age, cardiovascular disease, smoking history, frailty and markers of inflammation.

Background: The impact of COVID-19 disease on previously healthy children has been minimal, yet there is limited data on the impact of COVID-19 on children and adolescents with kidney transplants.

Methods: We used the existing infrastructure of the Improving Renal Outcomes Collaborative (IROC) learning health system to develop and rapidly implement a web-based registry for collecting clinical and outcomes data about COVID-19 disease in pediatric transplant recipients. We distributed the registry to 32 U.S. pediatric kidney transplant centers and requested clinical and outcomes data from all recipients suspected of having COVID-19 disease. Here, we present an interim analysis of the first 6 weeks of registry data.

Results: Between April 6 and May 27, 2020, 18 IROC centers entered data on 99 pediatric kidney transplant recipients who had PCR based testing for COVID-19. 54 patients were tested due to symptoms of COVID-19 (most commonly fever and cough), 7 asymptomatic patients had a known COVID exposure. 34 patients were tested per hospital policy (e.g. pre-anesthesia), and 4 did not have a reported testing indication. Overall, 10/99 (10%) tested positive for COVID-19, 6 of whom had any symptoms, 3 had a known exposure with a COVID+ individual, and 1 was diagnosed by a pre-anesthesia screen. Thus far, the clinical course and outcomes are known in 8/10 COVID+ patients: 5 received outpatient supportive care alone, 2 were admitted to intensive care and 1 was admitted to a non-COVID ICU, a non-COVID medical ICU, and a non-COVID transplant unit. Transplant outcomes were excellent in all COVID+ patients. There were no cases with respiratory failure, acute kidney injury, or allograft rejection/failure. There were no deaths due to COVID-19 disease.

Conclusions: In this interim analysis of the IROC learning health system, pediatric kidney transplant recipients had a relatively low incidence of COVID-19 disease and excellent short-term outcomes.

PO0764
Clinical Outcomes of Hospitalized Kidney Transplant Recipients with COVID-19 in a Predominantly Minority Population

Background: COVID-19 has been associated with increased morbidity in kidney transplant recipients. We aimed to identify risk factors for mortality in hospitalized kidney transplant recipients with COVID-19.

Methods: We retrospectively reviewed the medical records of 75 kidney transplant recipients admitted for COVID-19 at our institution. Result: Among the 75 patients, 28 (37%) died at a median 8 days (range, 1-36) after admission to the hospital. The Table summarizes the demographics and initial labs values of both groups. Most of our patients were Hispanic (54%) and African American (32%) and 97% had hypertension and 65% had diabetes mellitus. There was no difference between the two groups in terms of sex, type of transplant, time from transplant, immunosuppressive medications, medical comorbidities, presenting symptoms, temperature, or pulse oximetry values on admission. Non-survivors were older and had higher BMI. On admission most patients were lymphopenic, had low CD4/CD8 counts and had higher inflammatory markers (ferritin, d-dimer, CRP, procalcitonin, interleukin-6 levels). Non-survivors had statistically significant higher procalcitonin, IL-6 and pro-BNP levels on admission. More non-survivors required ICU stay (64% vs. 13%, p < 0.001), intubation (57% vs. 11%, p < 0.001) and renal replacement therapy (32% vs. 17%, p=0.17) compared to survivors. There was no difference in secondary bacterial infections, CMV viremia, DVT or stroke between the two groups. In a multivariate analysis, BMI (OR 1.15, CI 1.04-1.30, p = 0.017 per unit increase), higher procalcitonin (OR 4.16, 95% CI 1.09-18.87, p=0.046) and proBNP level (OR 1.017, 1.002-1.034, p=0.039, per 100 unit increase) on admission were associated with increased mortality.

Conclusions: COVID-19 is associated with increased mortality (37%) in our kidney transplant recipients and higher BMI, procalcitonin and proBNP levels at admission are associated with mortality.

PO0763
Living Organ Donor Perspectives on Organ Donation During the COVID-19 Pandemic
Meera N. Harlay,1 Ann C. Klassen,1 Janet Fleetwood,1 Peter P. Reese,2 Krista L. Lentine,1 Michael Mittelman,4 Rebecca L. Bertha,4 Drexel University, Philadelphia, PA; University of Pennsylvania, Philadelphia, PA; St. Louis University, St. Louis, MO; American Living Organ Donor Fund, Philadelphia, PA.

Background: Due to the COVID-19 pandemic, transplant programs across the U.S. postponed living donor surgeries and transplants. We examined perspectives of former and prospective living organ donors on the risks and excess burdens of organ donation during the COVID-19 pandemic.

Methods: In late April 2020, we disseminated an IRB-approved survey to a national online forum of over 1300 living donors and those in workup for donation. Using visual analog scales, respondents rated sources of information about COVID-19, burdens on donors due to the pandemic, and what factors should determine whether living donation should proceed during the pandemic (0=unimportant, 100=very important).

Results: After 4 weeks, there were 101 respondents from 35 U.S. states; 63% were between 31-50 years old, 95% were non-Hispanic white, and 90% were female. Respondents included 68 living donors (72% kidney) and 33 people in work-up to donate (73% kidney). The most and least important sources of information about COVID-19 were personal doctors (median importance 88, IQR 73-100) and social media (median 26, IQR 12-54), respectively. Nearly half (41%) were unsure of their transplant program’s policy for living donation during the pandemic, and 58% reported that the decision to donate during COVID-19 should depend on factors such as transplant candidate health (median 100, IQR 90-100) and availability of COVID-19 tests (median 84, IQR 70-95).

Conclusions: Many living organ donors were uncertain about their transplant program’s approach for donation during the pandemic. Donors were concerned about the health of transplant candidates and financial stressors, and prioritized availability of COVID-19 testing to determine when living donation should proceed during the pandemic.

COVID-19 and Kidney Transplantation: Results from the TANGO International Transplant Consortium

Leonardo V. Riella,1 Suraj Sarvode mothi,4 Enver Akalin,5 Paolo Cravedi,3 TANGO Consortium1,2Massachusetts General Hospital, Boston, MA; 3Montefiore Medical Center, Bronx, NY; 4Mount Sinai Health System, New York, NY; 5B Brigham and Women’s Hospital, Boston, MA.

Background: Chronic immunosuppression and comorbidities may expose kidney transplant recipients to an increased risk of developing critical coronavirus disease 2019 (COVID-19), but data in transplantation have been limited so far to single centers. To determine the clinical presentation, outcomes, and mortality risk factors in transplant patients with COVID-19, we analyzed retrospective data from a large international transplant consortium (TANGO Study).

Methods: Retrospective cohort study included kidney transplant recipients admitted with COVID-19 in 11 centers participating in the international TANGO consortium. We included all adult (≥18 years) kidney transplant recipients with a functioning kidney allograft who were admitted to a hospital between March-April, 2020. Epidemiological, demographic, clinical, laboratory, treatment, and outcome data were extracted from electronic medical records using an ad hoc designed data collection form.

Results: Among 9,697 kidney transplant recipients followed at 11 transplant centers, 145 (1.5%) were hospitalized due to COVID-19. 65% were male and more than half were over 60 years old (55%). Median time since transplant was 5 years (2-10) and 16% were transplanted less than one year from the presentation. Prevalent comorbidities included hypertension (95%), obesity (41%), heart disease (25%) and lung disease (19%). Common symptoms of the onset of illness were fever and dyspnea (71%), followed by myalgia (54%) and diarrhea (33%). Management of anti-rejection therapy varied across centers: antimetabolites were withdrawn in 69% of patients and calcineurin inhibitor in 26%. Other treatments used during hospitalization included hydroxychloroquine (83%), antibiotics (76%), tocilizumab (13%) and antivirals (10%). During a median follow-up of 13 days (IQR: 7 - 21) after diagnosis of COVID-19, mortality was 30% and occurred at a median 10 (5-16) days after admission. Acute kidney injury (AKI) occurred in 46% and respiratory failure requiring intubation in 29% of cases. No rejection events were observed.

Conclusions: Our large international consortium indicates that kidney transplant recipients with COVID-19 have increased mortality (30%) upon hospitalization compared to the general population with a high rate of AKI (46%) and significant respiratory failure (29%).

Atypical Clinical Presentation of COVID-19 in a Kidney Transplant Recipient with Tacrolimus Toxicity

Michael J. Chau,1 Ismail K. Almokyad,3 Ping Li,2 The George Washington University Milken Institute of Public Health, Washington, DC; 1US Department of Veterans Affairs, Washington, DC.

Introduction: Kidney transplant recipients represent a unique challenge to manage amidst the Coronavirus disease 2019 (COVID-19) pandemic as they have reduced innate ability to fight the viral infection due to immunosuppression. However, calcineurin inhibitors such as tacrolimus, may offer an advantage in reducing the effects of cytokine storms in transplant patients with viral pneumonia. We present an atypical case of COVID-19 in a kidney transplant recipient with toxic levels of tacrolimus levels presented with mainly fever and diarrhea.

Case Description: A 76-year old African American male kidney transplant recipient presented to the Emergency Department (ED) after five days of fever (temperature of 101.8°F), nausea, vomiting, diarrhea and urinary frequency on March 27, 2020. His vitals were noted with a temperature of 96.9°F, respiratory rate of 40/ min, and heart rate of 166 beats/min, blood pressure of 110/75 mmHg and pulse oxygen saturation was 85% at ambient air. Admission labs were significant for a rise of serum creatinine to 3.1 mg/dL, from a baseline of 1.5 mg/dL, lactic acid of 4.4 mmol/L, and a tacrolimus level of 26.9 mcg/L. He was transferred to the ICU following increased oxygen demands and elective intubation for impending respiratory failure on hospital day 2. His blood pressure transiently improved with a decrease in lactic acid to 1.4 mmol/L and serum creatinine down to 1.6 mg/dL following IV fluid resuscitation. On hospital day 4, he continued to require high ventilator support and initiated on vasoconstricting agents for hemodynamic support. His serum tacrolimus level continued to increase to 32.9 mcg/L with concordant increase of serum creatinine to 2.1 mg/dL with oliguria. Tacrolimus levels sustained super therapeutic levels >8 mcg/L despite cessation of the drug.

Discussion: It is possible that Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) infection may cause hepatic dysfunction and diarrhea, which reduced drug metabolism and lead to toxic levels of tacrolimus—perpetuating cytokine storm. It is important that in this particular transplant patient population to closely monitor drug levels due to SARS-CoV-2 infection on its metabolism, as well as preventing toxic levels, which further reduces the body’s innate immunity and may indirectly worsen cytokine storm.

Late Rejection of Failed Renal Allograft Precipitated by COVID-19 in a Hemodialysis Patient (HD)

Introduction: We present a case report of an HD patient with a failed allograft that had been stable off immunosuppression who presented with acute allograft rejection in the setting of COVID-19 infection.

Case Description: 50 y/o male with a history of hypertension, living-related kidney transplant in 2005 ESRD after his allograft failed in 2018. The patient’s allograft remained stable off immunosuppression on HD until 3/2020, when the patient presented with severe allograft tenderness with no fever or evidence of urinary tract infection. An abdominal CT was consistent with allograft rejection. Abdominal pain resolved after IV steroids and initiation of low dose tacrolimus. He was discharged but returned 4 days later, with recurrent abdominal pain, fever and shortness of breath. CT chest was consistent with COVID19 pneumonia with a positive swab. His condition was complicated by acute respiratory failure and cytokine storm. Despite receiving Anakinra for COVID-19, our patient died.

Discussion: Failed allograft rejection for patients who initiate HD usually occurs within the first 6-12 months. Unless allograft failure occurs within a year of transplantation, many nephrologists complete withdrawal of immunosuppression in failed grafts after 4 months to decrease the risk of infections. In our case, the development of allograft rejection after stable long-term HD, is very unusual. We propose that the cytokine storm from COVID-19 in our patient provided the appropriate “danger signals” that triggered innate inflammation and augmented effector responses against the allograft's COVID-19 infection triggers a proinflammatory immune response, with IL-6 being a key cytokine that potentially drives T-cell effector responses and inhibits T-regulatory responses to donor allograft.
Results: 31 patients were identified, 30 were admitted. Median age was 58 (IQR 53-68) and 60% were male. 32% Caucasian, 29% African American, 29% multiracial, and 6% Asian. Median time from transplant to COVID-19 testing was 1178 days (IQR 252-2897). The most common symptom was cough, followed by fever, shortness of breath and fatigue. Chest X-ray/CT revealed multifocal patchy opacities. Ten patients required mechanical ventilation. Laboratory markers can be seen in the table. Acute kidney injury occurred in 39% of patients. The majority of patients were on triple immunosuppression (94% on tacrolimus, 90% on mycophenolate, and 74% on prednisone). During the hospital course 87% had the antiviralosibol stopped while 35% had CNI stopped. Treatments utilized included hydroxychloroquine (93%), azithromycin (50%), convalescent plasma (14%), IL-6 inhibitor (10%) and 1 received remdesivir. At a median follow up of 19 days (IQR 8–26) 10 patients died. Risk of death was greater if the patient was admitted to a non-transplant hospital (80% vs 23%, p=0.027), lymphopenic at presentation (47% vs 8%, p=0.013) or had O2 saturation less than 94% (100% vs 57%, p<0.001). During hospitalization mortality was also higher in patients with higher peak serum creatinine (3.2 mg/dl vs 1.5 mg/dl, p=0.013), or if requiring intubation (70% vs 14%, p<0.001). Increase in inflammatory markers including peak D-dimer, peak CRP, ferritin and procalcitonin were also predictive of mortality.

Conclusions: Kidney transplant recipients with COVID-19 should be monitored closely in a transplant center. Mortality is high, particularly in patients presenting with lymphopenia and hypoxemia.

Living Donor Kidney Transplant Practice in the COVID-19 Era: A Survey of US Transplant Programs

Krysta L. Lentine,1 Luke S. Vest,1 Mark Schnitzler, Roslyn B. Mannon,2 Vineeta Kumar,3 Mona D. Doshi,4 Matthew Cooper,5 Didier A. Mandelbrot,6 Meera N. Harhay,7 Michelle A. Josephson,8 Bertram L. Kasiske,9 Yasar Caliskan,10 David Axelrod.11 Saint Louis University, Saint Louis, MO; 2University of Nebraska Omaha, Omaha, NE; 3The University of Alabama at Birmingham, Birmingham, AL; 4University of Michigan, Ann Arbor, MI; 5MedStar Georgetown University Hospital, Washington, DC; 6University of Wisconsin-Madison, Madison, WI; 7Drexel University, Philadelphia, PA; 8University of Chicago, Chicago, IL; 9Hennepin County, Minneapolis, MN; 10University of Iowa, Iowa City, IA.

Background: We surveyed U.S. transplant programs to assess practices, strategies and barriers related to living donor kidney transplantation (LDKT) in the context of the COVID-19 pandemic.

Methods: After IRB approval, the survey was launched 5/20 by email and postings to professional society list-servers, using the Qualtrics platform. Data are reported through 5/27/20, and examined by state COVID-19 prevalence.

Results: Staff at 117 unique centers responded, representing 58% of U.S. living donor recovery centers and 75% of LDKT volume in the year before pandemic declaration. Overall, 66% reported LDKT surgery was on hold (82% in high vs. 50% in low prevalence states). 36% reported that evaluation of new donor candidates had paused, 27% reported evaluations were very decreased (>0% to <50% typical) and 23% reported evaluations were moderately decreased (25% to <50% typical). Barriers to LDKT surgery included program concerns for donor (84%) and recipient (75%) safety, patients concerns (54%), restrictions on elective cases (47%) and hospital administrative restrictions (47%). Programs with higher local COVID-19 prevalence reported more barriers related to staff and resource diversion (Figure). Most centers continuing donor evaluations used remote strategies (video 82%; telephone 43%), 61% of centers plan to continue more telehealth after the pandemic. 32% plan to resume some LDKT within 2 wks and 27% within 1 month. When surgery resumes, all will screen for COVID-19 before donation surgery, although timeframe and modalities vary.

Conclusions: COVID-19 has created many barriers to LDKT, especially in areas of highest prevalence. Transplant centers are planning to restart LDKT cautiously. Consensus-building is needed to reduce barriers, guide optimal practice, and facilitate safe restoration of LDKT across centers.

All data presented in median (IQR) unless otherwise noted

Collapsing/Sclerosing Glomerulopathy (CSG) and Acute Tubular Injury (ATI) in Patients with COVID-19

Sunil Sherchan, Mohamed Kahia, Jamrose K. Durranii, Isna Puri, Ibrahim A. Mohamed, Yohannes Melaku, Ernie Yup, Robert F. Leonardo, Subodh J. Saggi, Moro O. Salifu, Anthony D. Nicastro, SUNY Downstate Health Sciences University, Brooklyn, NY.

Introduction: AKI in patients with COVID-19 may be due to hemodynamic instability or inflammatory responses. We present two cases of CSG and ATI in patients admitted for COVID-19.

Case Description: Case 1: 25-year-old black obese female admitted with fever, cough, dyspea and serum creatinine of 1.4 mg/dl, discharged next day with home quarantine. Re-admitted 26 days later due to nausea, fatigue, and bilateral foot swelling. Serum creatinine 28 mg/dl and urine protein to creatinine ratio (uPCR) of 10.4 g/g. Case 2: 42-year-old black female with hypertension, diabetes mellitus admitted with fever, dyspea, cough, and diarrhea. Patient found to have diabetic ketoacidosis, serum creatinine 12.7 mg/dl. She developed deep vein thrombosis and pulmonary embolism and uPCR 15.4 g/g. She was started on hemodialysis, and died from sepsis and multi-organ dysfunction.

Discussion: Our experience above is part of a growing literature describing the direct visualization of SARS-CoV-2 in causing ATI and CSG. Pathogenetic pathways remain to be elucidated.

Case 1: 25-year-old black obese female admitted with fever, cough, dyspea and serum creatinine of 1.4 mg/dl, discharged next day with home quarantine. Results: Presenting symptoms and hospitalization rates were similar in waitlisted ESKD and kidney transplant patients with Covid-19. Azithromycin and doxycycline use was similar in both groups. Hydroxychloroquine use was more frequent in kidney transplant patients (62% vs 36%), as were other experimental therapies. Mortality was greater in waitlisted ESKD compared to kidney transplant patients (29% vs 13%). Of the waitlisted ESKD patients who died, most were males, Black or Hispanic, and 81% had T2DM and/or HTN as the cause of their ESKD. None of the non-hospitalized patients died in either group.

Conclusions: Waitlisted ESKD patients on dialysis with Covid-19 are comparatively at higher risk for mortality compared to kidney transplant recipients with Covid-19 despite similar demographics and similar burden of comorbidities. Whether the ability of immunosuppressive therapy to prevent the cytokine storm contributed to better survival among kidney transplant recipients remains to be determined.

PO0773
Kidney Transplant Practices in Latin America During the COVID-19 Pandemic: Analysis from GlomCon Latin America Working Group (LGComCon)
Sonia Rodriguez Ramirez,1 Franco H. Cabeza Rivera,2 Julio A. Gutierrez-Prieto,3 Javier Soto-Vargas,4 Blanca Martinez-Chagolla,5 Denisse Arceloi-Mendez,6 Diana Aguirre,7 Desiree Garcia Anton,8 Carmen Avila-Casado.9 GlomCon Latin America Working Group (LGomCon) 1University Health Network, Toronto, ON, Canada; 2University of Mississippi Medical Center, Jackson, MS; 3Hospital Central del Estado de Chihuahua, Chihuahua, Mexico; 4Hospital General Regional 46, Guadalajara, Mexico; 5Hospital General “Dr. Miguel Silva”, Morelia, Mexico; 6Unidad Medica de Atencion Ambulatoria 254, IMSS, Morelia, Mexico; 7Hospital General de Meixcali, Mexicali, Mexico.

Background: Latin America (LA) is the current epicenter of a global pandemic that has never been seen in the era of transplantation and immunotherapy. We aimed to describe their nephrologists’ practices and experience regarding kidney transplant (KT) management in the context of COVID-19 pandemic.

Methods: Descriptive analysis extracted from an online survey conducted among nephrologists, renal pathologists and other health workers treating kidney diseases between May 20-27, 2020 from sixteen Spanish speaking LA countries divided into 6 categories. We present the results for the kidney transplant category.

Results: 430 responses were obtained of which 360 (84%) were considered for analysis. 139 (49%) respondents routinely participate in the care of transplant patients in their centers that perform up to 50 KT per year (70% of them). The transplant activity was suspended in 90% of the centers at the time of the survey. Bigger centers continued their activity but not at full capacity. For transplant recipient who developed COVID-19, 52% of physicians continued the same immunosuppressive treatment for the ones with mild disease (outpatient). For moderate cases (patient but not requiring mechanical ventilation or vasopressors), 72% decreased maintenance therapy starting with the antiproliferative drug. For severe cases (ICU admission for mechanical ventilation or vasopressors), 74% stopped all the immunotherapy with the exception of steroids. ICU admission and need for renal replacement therapy were reported in less than 5% of their cases. Nephrologists from centers that continued their transplant activity during the pandemic reported that only 32% performed routine COVID-19 tests to donors and 51% recipients before KT surgery.

PO0771
What Do Data Tell Us About Patients Receiving Calcineurin Inhibitors (CNIs) and Contracting a Coronavirus
Jung Hoon Son,1 Ollie Fielding,1 Xiaoyang Wang,1 Chris Kipers,1 Jeffrey I. Silberzweig,1 Frank Liu.2 The PEAK team ‘pulseData, New York, NY; 1The Rogosin Institute, New York, NY.

Background: We hypothesized that patients taking CNIs, cyclosporine and tacrolimus would be less susceptible to coronavirus infections because of antiviral and anti-cytokine-storm effects and compared the occurrence of positive coronavirus test rates in a population receiving a CNI and non-CNI treatment population. This is of high importance as CNIs are being trialed as a treatment for severe acute respiratory syndrome coronavirus 2 (COVID-19) immune response (NCT04343108). Transplant nephrologists recommend continuing CNIs through the COVID-19 pandemic.

Methods: We analyzed longitudinal EHR system data from the Rogosin Institute’s nephrology clinic to identify a population of 5,144 patients with a record of respiratory viral panel (RVP) testing for any coronavirus strain between December 2012 and May 2020. We identified 1,195 patients receiving cyclosporine or tacrolimus and compared positive test rates of any coronavirus strain in those receiving CNIs to those not receiving CNIs.

Results: A total of 51 patients tested positive (1.05%) Of the 1,195 CNI recipients, 21 tested positive (1.76%); of 3,949 patients with no record of CNI treatment, 33 tested positive (0.84%). Given an age distribution difference between the two cohorts (CNI cohort median 58; non-CNI cohort median 66), we therefore calculated an age-adjusted positive test rate for both populations, with results of 1.76% for the CNI cohort and 0.83% for the non-CNI cohort. A z-test comparing the population proportions testing positive had a z-value of 2.71 (p-value 0.003), indicating significant difference. 8.47% of positive tests on an RVP for any of coronavirus, rhinovirus or respiratory syncytial were for a coronavirus in the CNI group vs. 6.48% in the non-CNI group (z 2.37, p 0.009). Using a test on an RVP for any of coronavirus, rhinovirus or respiratory syncytial were for a coronavirus in the CNI group vs. 6.48% in the non-CNI group (z 2.37, p 0.009). Using a logistic regression model to examine the probability of testing positive for a coronavirus (features for age, gender, whether the test was conducted in flu season (Dec-Feb) and whether the patient was receiving CNIs) we found that CNIs were statistically significant (p 0.007).

Conclusions: Based on the data, as far as we can tell being on a CNI does not offer protection from a symptomatic coronavirus infection. It remains to be seen if it decreases severity of the illness because of the potential for cytokine storm effects.

Funding: Commercial Support - pulseData
Conclusions: Kidney transplants programs are almost closed throughout LA during the COVID-19 pandemic. The disproportionate resource allocation to COVID-19 will have unintended consequences for those already carrying the burden of health inequality with the potential to disadvantage marginalized patients further. Reported immunosuppression management is in line with transplant societies' recommendations.

PO0774
A Machine Learning-Based Predictive Model for Outcome of COVID-19 in Kidney Transplant Recipients
Ignacio Revuelta, 1,2 Francisco-Javier Santos-Arteaga, 1 Enrique Montagud-Marradi, 1,2 Pedro Ventura-Aguilar, 1,2 Debora Di Caprio, 1,2 David Cucchiari, 1,2 Beatriz Bayés, 1,2 Esteban Poch, 1,2 Federico Oppenheimer, 1 Fritz Diekmann, 1,2
1Department of Nephrology and Kidney Transplant. Hospital Clinic, Barcelona, Spain; 2Institut d’Investigacions Biomediques August Pi i Sunyer, Barcelona, Spain; 3Faculty of Economics and Management. Free University of Bolzano, Bolzano, Italy. 4Department of Economics and Management. University of Trento, Trento, Italy.

Background: Health systems need tools to deal with COVID-19, especially for high-risk population, such as transplant recipients. Predictive models are necessary to improve management of patients and optimize resources.

Methods: A retrospective study of hospitalized transplant patients due to COVID-19 was evaluated (March 3–April 24, 2020). Admission data were integrated to develop a prediction model to evaluate a composite-event defined as Intensive Care Unit admission or intensification treatment with antiinflammatory agents. Predictions were made using a Data Envelopment Analysis (DEA)-Artificial Neural Network (ANN) hybrid, whose accuracy relative to several alternative configurations has been validated through a battery of clustering techniques.

Results: Of 1006 recipients with a planned or an unscheduled visit during the observation period, thirty-eight were admitted due to COVID-19. Twenty-five patients (63.2%) exhibited poor clinical course (mortality rate: 13.2%), within a mean of 12 days of admission stay. Cough as a presenting symptom (P = 0.000), pneumonia (P = 0.011), and levels of LDH (P = 0.031) were admission factors associated with poor outcomes. The prediction hybrid model working with a set of 17 input variables displays an accuracy of 96.3%, outperforming any competing model, such as logistic regression (65.5%) and Random forest (denoted by Bagged Trees, 44.8%). Moreover, the prediction model allows us to categorize the evolution of patients through the values at hospital admission.

Conclusions: The prediction model based in Data Envelopment Analysis-Artificial Neural Network hybrid forecasts the progression towards severe COVID-19 disease with an accuracy of 96.3%, and may help to guide COVID-19 management by identification of key predictors that permit a sustainable distribution of resources in a patient-centered model.

PO0775
Outcomes of COVID-19-Positive Kidney Transplant Recipients

Background: Kidney transplant recipients (KTR) are at increased risk of infections due to immunosuppression (IS). COVID-19 has posed unique challenges due to its evolving symptomatology and lack of effective treatment options. Current data published about the impact of COVID-19 in KTR comes from severely impacted areas. The aim of our study was to review course and outcomes of KTR at our center.

Methods: Retrospective chart review of KTR diagnosed with COVID-19. Descriptive statistics were summarized as absolute numbers for categorical data and as median with interquartile range (IQR) for skewed distribution.

Results: We had 20 KTR diagnosed with COVID-19. Median age of 53.5 years (74-63), 10 males, and 12 blacks. Median time from KT to presentation was 70.7 months (17.25-158.75), with 1 pt in 1st year post KT. Thirteen (65%) pts were obese with BMI≥30 kg/m2, 2 pts had chronic obstructive pulmonary disease, and 5 had cardiac disease. Most common presenting symptom was cough in 14 pts, followed by fever-13 pts, shortness of breath-9, and diarrhea-6pts. During the study, 15 pts were hospitalized, and 9 of them had chest x-ray findings of bilateral opacities consistent with pneumonia. Inflammatory markers were elevated in all pts but did not correlate with disease outcome. Acute kidney injury was seen in 9 pts, with 3 requiring continuous renal replacement therapy. Four pts required mechanical ventilation. Ten pts had reduction of their IS. Hydroxychloroquine was used in 11 pts, and azithromycin in 4. Four hospitalized pts received convalescent plasma as part of an ongoing COVID-19 trial in our center. Donors were 4-6 weeks post recovery from confirmed severe acute respiratory syndrome coronavirus 2 infection. Enrollment was offered to pts at high risk of progression to severe disease. We had 3 deaths, 2 pts remain hospitalized, and the remaining 15 were either discharged or managed as outpatients. Median follow up time from presentation was 25 days (13-38) for the entire cohort.

Conclusions: In our cohort, 45% of patients presented with acute allograft dysfunction highlighting impact of SARS-CoV-2 infection on kidney function. Our center utilized investigational convalescent plasma in 4 pts successfully while the clinical trial outcomes are awaited. Ultimately, the development of a safe and efficacious vaccine targeting SARS-CoV-2 may better equip us to fight this pandemic.

PO0776
COVID-19 in Kidney Transplant Recipients at New England’s Largest Safety-Net Hospital
Hassan Mahmoud, Sandeep Ghai, Jean M. Francis. Boston University, Boston, MA.

Background: The coronavirus disease 2019 (COVID-19) has led to a global pandemic as announced by the World Health Organization. Kidney transplant patients are thought to constitute a unique high risk group for severe COVID19 infection. Furthermore, disparities in health care have led to COVID-19 disproportionately affecting minority groups including African Americans and Hispanics.

Methods: We identified adult kidney transplant recipients who were admitted with COVID-19 between March, 15th and May 1st, 2020. We evaluated the demographic, clinical and laboratory data of all admitted patients. We also evaluated the presence of co-infections as well as decisions regarding immunosuppressant management.

Results: 23 kidney transplant recipients who were hospitalized for COVID-19 were evaluated. 91% of our patients were of minority groups. 35% of patients required ICU admission, and 30% required mechanical ventilation. 40% of patients had associated coinfections in addition to COVID19. 87% of patients had variable degrees of AKI, 26% of patients with AKI required renal replacement therapy. Mortality rate in our population was 22%. Upon admission to the hospital, our immunosuppressant therapeutic approach included stopping the antimitabolites and continuing with the calcineurin inhibitors (targeting trough level of 4 to 6 ng/dl for tacrolimus and 50 ng/dl for cyclosporine), and prednisone if patients were on steroids.

Conclusions: This report demonstrates higher rate of AKI, coinfection and mortality in kidney transplant patients in the setting of COVID19 as compared to general population.

Identifying Scenarios of Benefit or Harm from Kidney Transplantation During the COVID-19 Pandemic: A Simulation Study

Allan Massie,1 Brian J. Boyarsky,1 William A. Werbel,1 Sunjae Bae,1 Eric Chow,2 Robin K. Averey,3 Daniel C. Brennan,1 Jacqueline Garonzik Wang,4 Dorry L. Segev,1 Johns Hopkins University School of Medicine, Baltimore, MD; 2Rosalind Franklin University of Medicine and Science Chicago Medical School, North Chicago, IL.

Background: Clinical decision-making in kidney transplantation (KT) during the COVID-19 pandemic is a challenge: both candidates and recipients may face increased acquisition risks and case fatality rates (CFRs). Given our poor understanding of these risks, many centers have paused or reduced KT activity, yet data to inform such decisions are lacking.

Methods: To quantify the benefit/harm of KT in this context, we conducted a Markov simulation study of immediate-KT vs delay-until-after-pandemic for different patient phenotypes under a variety of potential COVID-19 scenarios (Figure 1), simulating expected life-months gained from transplant over 5 years. A calculator was implemented (http://www.transplantmodels.com/covid_sim), and machine learning approaches were used to evaluate the important aspects of our modeling.

Results: Characteristics of the pandemic (acquisition risk, CFR) and length of delay (length of pandemic, waitlist priority for DDKT) had greatest influence on benefit/harm (Figure 2). In most scenarios of COVID-19 dynamics and patient characteristics, immediate-KT provided survival benefit; KT only began showing evidence of harm in scenarios where CFRs were substantially higher for KT recipients (e.g. ≥50% fatality) than for waitlist registrants.

Conclusions: Our simulations suggest that KT remains beneficial under COVID-19 in many scenarios. Our calculator can help identify patients who would benefit most. As the pandemic evolves, our calculator can update these predictions.

COVID-19 in Patients with CKD in New York City

Oleh M. Akchurin,1,2 Sharmi Biswas,1 Michaela Greenbaum,1,2 Aleksandra Licina,1,2 Justin J. Choi,1,2 Mary E. Choi,1,2 Weill Cornell Medicine, New York, NY; 1NewYork-Presbyterian Healthcare System Inc, New York, NY.

Background: Coronavirus disease 2019 (COVID-19) has affected millions of people, and several chronic medical conditions appeared to increase the risk of severe COVID-19. However, limited data are available about the outcomes of COVID-19 in patients with chronic kidney disease (CKD).

Methods: This was an observational study of patients with CKD at three affiliated hospitals in New York City who were diagnosed with COVID-19 by reverse-transcriptase polymerase chain reaction of nasopharyngeal swab specimens collected in the emergency departments between March 3rd and April 21st, 2020. We stratified patients into three groups: pre-dialysis CKD, dialysis, and transplant. Data are shown as median (interquartile range). Logistic regression was used to identify CKD characteristics associated with non-survival.

Results: Of the 372 confirmed COVID-19 patients with CKD, 182 were pre-dialysis, 149 were on dialysis, and 41 had functional kidney transplant. The median age of the pre-dialysis group was 75 (63-85) years, dialysis group 66 (58-74) years, and transplant group 63 (48-71) years. Men comprised 62.4% of the cohort. Baseline serum creatinine was 1.5 (1.2-2.2) mg/dl in the pre-dialysis group. By the end of the observation period, 78.5% of patients were discharged or had died. Of these patients, mortality was highest in the pre-dialysis group (26.9%), followed by dialysis (24.2%), then transplant (9.8%) groups. Almost half of the cohort was receiving ACE-inhibitors or ARBs pre-COVID-19, which was not associated with non-survival. In the pre-dialysis group, the other group phosphorus was associated with non-survival (OR 1.5 per each 1.0 mg/dl of increase in serum phosphorus). Anemia, defined as hemoglobin <10 g/dl, was also associated with non-survival (OR 3.1) in that group. Body mass index (BMI)>25 kg/m² was paradoxically associated with non-survival (OR 2.7) in patients with pre-dialysis CKD.

Conclusions: Our data demonstrate that mortality in this cohort, particularly in patients with pre-dialysis CKD, was substantially higher than in the general population in New York City. Poorly controlled CKD complications, including CKD-mineral and bone disorder and anemia, as well as low BMI were associated with mortality. Ongoing control of CKD complications may serve as an opportunity to improve outcomes of COVID-19 in patients with CKD.

Kidney Involvement and Outcome of COVID-19 Patients Admitted from a Federal Medical Facility

Yahya R. Ahmad, Matthew Shea, Mohamed M. Abdalbaky, Elijah Kakani, Javier A. Neyra, Amr E. Mohamed. University of Kentucky Medical Center, Lexington, KY; Mansoura University, Mansoura, Egypt.

Background: Correctional facilities face unique challenges with the COVID-19 pandemic. A COVID-19 outbreak was reported in the Federal Medical Center (FMC) in Lexington, Kentucky, a prison for inmates requiring medical and/or mental health care. We aimed to compare clinical characteristics and kidney-related outcomes in inmates from this FMC to other COVID-19 hospitalized patients.

Methods: A total of 86 COVID-19 patients were admitted to our hospital between March 1st and June 1st, 2020. Among those, 37 patients were from the same FMC. We examined demographics, clinical and laboratory characteristics, along with the outcomes of this cohort and compared it to other COVID-19 non-prisoners. AKI was determined by KDIGO criteria.

Results: All inmates were men and their mean age was 59.8±10.6 years. The majority of them were white (60%) and required ICU admission (54%), while 39% of patients required mechanical ventilation. The prevalent comorbidities were hypertension (81%), obesity (62%), diabetes (41%) and coronary artery disease (CAD) (58%). Stage 3 CKD was present in 22% of inmates. The mean eGFR was 58±26 mL/min/1.73m² at time of admission. Significant hematuria and proteinuria were found in 17% and 25% of patients, respectively. Hypertension, heart failure, CAD, COPD, hepatitis C infection, and AKI were more prevalent in the FMC cohort (P = 0.030, 0.001, 0.024, 0.001, 0.017, and 0.011, respectively). The difference in mortality rates was not statistically significant between groups (12% for inmates vs.17% for non-inmates, p=0.520). Incident AKI was higher in inmates vs. non-inmates (68% vs. 38%, p=0.006) and there was no difference in acute groups (12% for inmates vs.17% for non-inmates, p=0.520). AKI was determined by KDIGO criteria.

Conclusions: Incidence of AKI was higher in hospitalized inmates with COVID-19 vs. non-inmates. The need for acute dialysis was strongly associated with mortality in overall COVID-19 hospitalized patients.

Can Urine Biomarkers Predict Severity of COVID-19? A Preliminary Study

Dorukche Katagiri, Eisei Noiri, Masahiro Ishikane, Yuusuke Asai, Noriko Kinoshita, Norio Ohmagara, Fumihiko Hiroshita. National Center for Global Health and Medicine, Shinjuku-ku, Japan.

Background: Early detection of coronavirus disease (COVID-19) in patients likely to develop severe manifestations enables appropriate interventions, including rapid intensive care unit admission. This study was conducted to determine whether non-invasive urine biomarkers can predict the clinical severity of COVID-19.

Methods: Design: A retrospective case series. Setting: Single-center study, national center hospital designated for infectious disease. Patients: Fifty-eight patients who tested positive for SARS-CoV-2 in respiratory specimens through real-time reverse transcription-polymerase chain reaction (RT-PCR) were retrospectively studied. Measurements and main results: Urinary β2-microglobulin (β2MG), liver-type fatty acid binding protein (L-FABP) were serially measured. Serum interferon γ and monocytic chemotactic protein-1 were also evaluated.

Results: The 58 patients were assigned into three groups. Patients requiring intensive care were assigned to the severe group (N = 12). Patients treated with oxygen were assigned to the moderate group (N = 33). Other patients were assigned to the mild group (N = 33). Urine tests revealed that low β2MG and L-FABP levels on admission were associated with mild disease, whereas high levels were associated with severe disease. In severe cases, L-FABP tended to be persistently high. The resulting cutoff values were β2MG; Severe vs. Moderate+Mild: 2.457 μg/dL (Specificity 76.9% and Sensitivity 90.0%, AUC 85.9%), L-FABP; Severe vs. Moderate+Mild: 22.00 μg/gCr (Specificity 84.6% and Sensitivity 90.0%, AUC 91.8%). Urinary β2MG and serum IFN-γ/MCP-1 showed a similar trend.

Conclusions: Evaluating urine biomarkers such as β2MG and L-FABP may allow determination of COVID-19 patients with active cytokines and recognition of patients likely to become critically ill and requiring careful observation and early intervention.

COVID-19 and Kidney Transplant Outcomes

Background: Recent publications report great variations in the clinical course and mortality of COVID-19 in solid organ transplant (SOT) recipients. It is unclear whether these differences are related to study methods, treatment choices, or variables associated with patient populations.

Methods: We reviewed and summarized 9 published articles of COVID-19 in solid organ transplant recipients. We contrasted difference between study design and compared outcomes.

Results: All studies included kidney transplant recipients while study 6 and 8 included non-renal SOT. Four come from the United States. Results can be seen in the attached table. Most studies had a median age in the 50’s, with hypertension and diabetes being common comorbidities. Tacrolimus, mycophenolate analogs and prednisone were the most common immunosuppression regimen. Presenting symptoms were usually fever, cough, dyspnea, and diarrhea. Immunosuppression was either reduced or discontinued in all studies. The majority of patients received hydroxychloroquine. Azithromycin, remdesivir, leronlimab, lopinavir/ritonavir, darunavir, oseltamivir, and tocilizumab were also used. Mortality ranged from 0% to 30%. All studies described hospitalized patients. A third of reports also included outpatients. The median follow-up was approximately 3 weeks for most studies (range of 7 to 29 days). All but one series with reported patient deaths under 20% either did not include or had follow-up periods of less than 10 days.

Conclusions: Presentation of COVID-19 and immunosuppression strategies are similar among transplant centers. Differing outcomes may be related to small number of cases, potentially varying acuities of illness and follow up periods. Given that cytokine storm occurs late in the course of COVID-19, it is plausible that mortality may increase in studies with short follow up. When excluding short or missing follow up, mortality appears to be between 20-30%, which suggests that transplant recipients have a higher mortality than their non-immunocompromised peers.

PO0789
Thrombotic Microangiopathy (TMA) in a Patient with COVID-19
Bessy Suvin Flores Chang, Rushang Parikh, Rinda Wanchao, Vanesa Bijnol, Kenar D. Jhaveri. Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.

Introduction: We describe a patient with COVID-19 and clinically significant kidney biopsy proven TMA

Case Description: 69-year-old Caucasian female with medical history of asthma came to the ED with productive cough, fever and dyspnea for 2 weeks. She was afibrile, tachypneic and hypoxic. Initial laboratories showed a normal WBC, hemoglobin level and platelet count. Inflammatory markers were elevated. SARS-CoV-2 infection was confirmed by PCR assay. CXR showed bilateral diffuse patchy opacities. Treated with hydroxychloroquine, enoxaparin and oxygen was started. Patient received anakinra and tocilizumab. On day 12, the patient developed thrombocytopenia, anemia and worsening kidney function concerning for microangiopathic hemolytic anemia. Due to worsening hypoxemia, patient received convalescent plasma. On day 17, she was intubated due to worsening respiratory failure. Findings suggestive of hemolysis were present. Urinalysis showed hematuria and proteinuria. Patient’s kidney function worsened requiring initiation of CRRT. On day 20, the patient underwent a kidney biopsy that revealed severe acute TMA with cortical necrosis. Beta 2 glycoprotein-1 IgM levels were elevated, anti-phospholipid antibodies were absent. A disintegrin and ADAMTS13 level were not low. C3,C4 were in normal range. Heparin induced antibody testing was negative. Coagulation parameters were normal. Kidney doppler was unremarkable. No other systemic findings of macro thrombi were found. Low factor H complement and plasma SC5b-9 complement levels suggesting an activation of the complement pathway were found. Genetic testing of ADAMTS13 pathway was not done. Plasma exchange was not performed, but received a single dose of eculizumab on day 21. Unfortunately, she died on day 23.

Discussion: Coagulopathy associated with SARS-CoV-2 has been widely reported. Profound hypoxia, inflammation, disseminated intravascular coagulation (DIC) has all been implicated as potential causes, but were not present in our patient. To the best of our knowledge, we report the first case of TMA associated with SARS-CoV-2 with presence of diffuse cortical necrosis and widespread microthrombi in kidney biopsy. It is not clear if the virus played a direct pathogenic role or unmasked a latent complement defect leading to widespread endothelial damage and micro thrombi.

PO0790
Renal Artery Thrombosis with Infarction in a Patient with Mild COVID-19
Ryan Mocerino, Neeja D. Kumar. Montefiore Medical Center, Bronx, NY.

Introduction: There has been increased focus on the microvascular and macrovascular complications of COVID-19. Here we present a case of renal arterial thrombosis in a woman with mild symptoms of COVID-19.

Case Description: A 69 year old female with diabetes, hypertension, coronary artery disease, and acute embolic cerebrovascular event post cardiac catheterization in 2016 presented to the emergency department with acute diffuse intermittent abdominal pain and nonbloody emesis. Prior to this, she had been evaluated for cough, shortness of breath and myalgias which were conservatively managed with improvement. Her medications included aspirin, clopidogrel, furosemide, and insulin. Examination was significant for diffuse nonspecific abdominal tenderness without rebound or guarding. Laboratory assessment revealed preserved renal function with creatinine of 1.10 mg/dL and PCR positive for SARS-CoV-2. A computed tomography of the abdomen and pelvis with intravenous contrast revealed a non-occlusive thrombus in the left renal artery with several large wedge-shaped areas of decreased enhancement consistent with multiple left renal infarctions. On interdisciplinary discussion, the patient was managed conservatively with anticoagulation without acute intervention and was discharged home on apixaban.

Discussion: To our knowledge, this is the first description of renal artery thrombosis with renal infarction in the setting of COVID-19 infection. Patients who present with a COVID-19 infection, regardless of disease severity, should be evaluated for coagulopathy and development of thrombi as these may potentially contribute to infarction and end-organ damage. Although it requires a high index of suspicion, renal infarction should be considered part of the differential when evaluating a patient with COVID-19 infection presenting with abdominal pain or acute kidney injury. Initiation of anticoagulation should be considered with consideration of risks involved.

PO0791
A Case of Severe Thrombocytopenia in a Patient with COVID-19 Receiving Continuous Venovenous Hemodialysis
Hay Me, Zhong Zheng, Jennifer Griffths, Anjani K. Dubey, Savneek S. Chugh. Westchester Medical Center Westchester Medical Center, Valhalla, NY.

Introduction: Thrombocytopenia is a rare complication of renal replacement therapy with most of the cases reported in intermittent hemodialysis patients. There is limited data regarding the incidence of thrombocytopenia caused by continuous renal replacement therapy (CRRT). We report a case of thrombocytopenia in patient treated with CRRT for severe AKI from COVID-19 sepsis unrelated to heparin.

Case Description: A 73-year female with history of type 2 diabetes mellitus was admitted for Coronavirus Disease 2019 (COVID-19) pneumonia. Patient developed acute hypoxic respiratory failure requiring mechanical ventilation despite treatment with hydroxychloroquine, azithromycin and convalescent plasma. Hospital course was complicated by septic shock and acute kidney injury with serum creatinine rising from a baseline of 0.8 mg/dl. Continuous venovenous hemodialysis (CVVHD) without any anticoagulation was initiated due to severe fluid overload. Significant thrombocytopenia below 50,000/mm3 was noted 2 days after CVVHD treatment. Patient received multiple antibiotics and heparin drip before CVVHD and platelet counts were above 150,000/mm3. Heparin induced thrombocytopenia (HIT) was ruled out with negative serotonin release assay and platelet counts remain low despite the discontinuation of all potential agents. Disseminated intravascular coagulopathy was excluded based on coagulation tests. Platelet counts finally went up to 160,000/mm3 on subsequent CVVHD holidays and again dropped to 70,000/mm3 after CVVHD was resumed.
Discussion: The rate of rise in platelet count more than 150,000/mm3 in 2 days after cessation of CVVHD supports the diagnosis of thrombocytopenia caused by CVVHD. Although the exact mechanisms remain unclear, previous studies suggested that the mechanical destruction of platelets by the hemofilter or allergic reaction to dialyzer membrane as some of the reasons. Some studies have found that severe decline (more than 50%) in platelet count was associated with increased mortality and decreased rate of renal recovery. Thrombocytopenia on CVVHD unrelated to HIT is an under-acknowledged complication. Understanding the multiple etiologies of thrombocytopenia will help prevent the excessive use of blood products, fluid overload state and the potential clotting issue of CVVHD due to transfusion.

PO0792
Case Study: Kidney Transplant Patient with COVID-19: Impact of Viral Infection on Background Cell-Free DNA in a Donor-Derived Cell-Free DNA Rejection Assay
Supervisor: Bhumidust,1 Joanna Scheinman,1 Erik L. Lum,1 Philippe M. Gauthier,2 Ebad Ahmed,2 Paul R. Billings.2 University of California Los Angeles, Los Angeles, CA; 1 Natera, In, San Carlos, CA.
Introduction: Donor-derived cell-free DNA (dd-cfDNA) assays are clinically validated to detect kidney transplant injury, reporting the donor fraction as a percentage of the total, or background, cfDNA. Various clinical factors can cause a significant increase in recipient cfDNA, contributing to higher background cfDNA and lower donor fraction, which may result in a false negative test result.
Case Description: A 50+ year old woman with end-stage renal disease secondary to polycystic kidney disease presented with 4 days (d) of diffuse muscle pain at 11 months post-kidney transplant. In the emergency department she had a fever to 101°F, bilateral edema, and a positive COVID-19 (SARS-CoV2) test. She remained febrile for 3d before developing acute respiratory distress requiring oxygen supplementation; her creatinine level was 3 mg/dL. Due to worsening of her respiratory status, she was intubated and started empirically on vancomycin, meropenem, and azithromycin; her mycophenolate mofetil was discontinued. She rapidly progressed to septic shock requiring vasopressor therapy. Her renal function deteriorated, and she was started on continuous renal replacement therapy on hospital d7. She received lenitromib on hospital d7 and d14 and convalescent plasma on hospital d11. Tacrolimus was discontinued on hospital d10 and she continued prednisone at 5 mg/d. Depressed dd-cfDNA testing to assess allograft injury and to rule out active rejection was performed. At hospital d20, her dd-cfDNA was 0.07% with an elevated background cfDNA of 28.569 arbitrary units (AU, 575 median value). At the second blood draw at hospital d25, her dd-cfDNA was 0.25% with a background cfDNA level reduced to 7.503 AU (15X median value).
Discussion: In this case, infection with the SARS-CoV-2 virus was associated with a very elevated background cfDNA level, likely due to cellular apoptosis due to the immune process and/or tissue ischemia due to sepsis-associated hyperperfusion. Although this patient was not known to have active rejection of her allograft, the very high background levels complicate the interpretation of results, especially when donor fraction were reported.

PO0793
COVID-19 AKI to ESRD: A New Cohort of Dialysis-Dependent Patients
Eric J. Chacko,1 Jason Cummings,1 Marc Richards.2 Florida Atlantic University, Boca Raton, FL; 2 Florida Atlantic University, Boca Raton, FL.
Introduction: The Covid-19 pandemic has resulted in a massive number of hospitalizations with widespread effects on the global healthcare system. More research is needed to understand the implications of the disease, particularly its effects on renal function. Although initial studies from China suggested otherwise, there is growing evidence for an association between Covid-19 and AKI.
Case Description: A 66-year-old man with history of CKD IIIb presented to the ED with fever and dry cough for several days. On admission the patient was febrile and tachypneic. Labs were showed elevations in BUN, SCr and inflammatory markers. Chest CT revealed bilateral ground glass opacities and NP swab was positive for SARS-CoV2. The patient was initially treated with hydroxychloroquine, levofloxacin, and IV fluids. Clinical state worsened, eventually requiring intubation and vasopressors. Renal function progressed to anuria. Bicarbonate, potassium binders and loop diuretics with IV fluids. Clinical status worsened, eventually requiring intubation and vasopressors.
Discussion: It is theorized that renal impairment in Covid-19 is due to virus entry into host cells via the ACE-2 receptor present in lungs and kidneys. Post-mortem kidney biopsies suggest that renal damage in Covid-19 is mediated through multiple mechanisms including cytopathic effect, myofibroblastic deposition, and microthrombi-related tubular damage. Although our patient recovered after a prolonged hospital course, he remained anuric requiring RHD far sooner than anticipated with natural progression of CKD, including direct cytotoxicity, immunologic deposition, and microthrombi-related tubular injury. A case report of severe ARF (sCr) was 3.2 mg/dL with an albumin of 2.6 g/dL. A urinalysis showed moderate blood and 3+ protein on dipstick along with granular casts. A urine albumin:Cr (UAC) ratio was 0.19 g/g. Despite volume resuscitation, her sCr continued to rise. Workup included renal ultrasound, hepatitis panel, and parvovirus B19, ANA, ANCA, anti-dsDNA, A, C3, and C4 were neg/nl. On day 5, she was afebrile with resolution of her symptoms, but her sCr was further elevated at 5.3 mg/dL and albumin was 1.1 g/dL. Repeat UAC ratio was elevated over lab measurable range. A biopsy showed FSGS and ATN. She was started on 60mg of prednisone/day. Three weeks later, her sCr was 2.9 mg/dL, albumin 2.4 g/dL and her UAC ratio was 3.0 g/g (Fig 1).
Discussion: The optimal treatment for viral related cFSGS is unknown. Because diffuse foot process effacement typically accompanies this lesion, it is tempting to give steroids. However, there is concern that this may exacerbate the infection, and cFSGS may be driven along with chronicity of the virus. Still, steroids may hasten recovery and reduce morbidity associated with the nephrotic syndrome. The rapid improvement in

PO0794
Rhabdomyolysis as a Complication of COVID-19: A Report of Five Cases
Miguel Maza Moreno,1,2 Vanessa C. Garcia Macas,1,2 Jose L. Herrera,1 Gandhy T. Fonseca,1 Jose H. Cano,1 Juvenal Torres Pastrana.1 CMN 20 de Noviembre Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico; 2 Nephrology and Extracorporeal Membrane Therapy Department, Mexico City, Mexico.
Introduction: COVID-19 virus pandemic has caused more than 5milllion infected and 330 Thousand deaths worldwide. The incidence of acute kidney injury (AKI) is variable, from 0.5% to 32.8%. Rhabdomyolysis (Rb) is a life-threatening emergency, usually manifesting as myalgia, fatigue, pneumonia, and AKI. One of its leading non-traumatic causes are viral infections. We report 5cases of Rb associated with COVID-19.
Case Description: Of a total of 460 positive cases of COVID-19 infection (real-time PCR), at the NationalMedicalCenter20deNoviembre in MexicoCity, 5were diagnosed with Rb and associated AKI(Ck>5,000U/l and KDIGO AKI criteria). Characteristics of patients are presented in (Fig.1). Age range was from 26 to 64 years, only one female, all with BMI: 25-27 kg/m2, time from admission-diagnosis of Rb was on average one week. Most common symptoms were fever, cough, and dyspnea (5/5), as well as abdominal pain (4/5). Only 1/5 was oliguric at diagnosis. Average Ck at diagnosis was 7845 (18165 μg/L) and all cases had high levels of interleukin-6. They were managed with aggressive hydration, 2/5 of them required renal replacement. At the time of this report, 2 had been discharged, 2 remained hospitalized (one still on RRT), and one died.
Discussion: COVID-19 patients can develop AKI primarily due to low oral intake, sepsis, and anaphylaxis. Some patients with COVID-19 have multiple risk factors for Rb development: viral muscle cytotoxicity, continuous hyperthermia, and anaphylaxis storm among others. This shows a high risk of AKI via 3 mechanisms: renal vasoconstriction, tubular obstruction and direct tubular toxicity. Of note, in the described cases, abdominal pain was a common symptom and only one was oliguric. Early identification allowed aggressive treatment, which underscores the importance of having a high index of suspicion. Further observations will be needed to understand the full spectrum of association between COVID-19 and Rb, but is clear that these patients are at high risk for developing AKI by these mechanisms.

PO0795
Corticosteroid Treatment in a Case of COVID-19-Associated Collapsing FSGS
Anna M. Zemke,1 Pravir V. Baxi,2 Roger A. Rodby.2 Department of Internal Medicine, Rush University Medical Center, Chicago, IL; 2 Division of Nephrology, Department of Internal Medicine, Rush University Medical Center, Chicago, IL.
Introduction: Collapsing FSGS (cFSGS) is associated with viral infections including HIV, parvovirus B19 and CMV. Recent reports describe cFSGS in patients infected with coronavirus (COVID-19). While reports on idiopathic cFSGS suggest early response to steroids, there are little data to guide treatment of cFSGS associated with infection. We present a case of AKI with severe abrupt nephrotic syndrome in a COVID-19 patient with cFSGS on biopsy and a rapid response to steroids.
Case Description: A 51 y/o black woman with no known medical history presented with 8 days of fever and SOB COVID-19 testing was positive. Admission serum creatinine (sCr) was 3.2 mg/dL with an albumin of 2.6 g/dL. A urinalysis showed moderate blood and 3+ protein on dipstick along with granular casts. A urine albumin:Cr (UAC) ratio was 0.19 g/g. Despite volume resuscitation, her sCr continued to rise. Workup included renal ultrasound, hepatitis panel, and parvovirus B19, ANA, ANCA, anti-dsDNA, A, C3, and C4 were neg/nl. On day 5, she was afebrile with resolution of her symptoms, but her sCr was further elevated at 5.3 mg/dL and albumin was 1.1 g/dL. Repeat UAC ratio was elevated over lab measurable range. A biopsy showed FSGS and ATN. She was started on 60mg of prednisone/day. Three weeks later, her sCr was 2.9 mg/dL, albumin 2.4 g/dL and her UAC ratio was 3.0 g/g (Fig 1).
Discussion: The optimal treatment for viral related cFSGS is unknown. Because diffuse foot process effacement typically accompanies this lesion, it is tempting to give steroids. However, there is concern that this may exacerbate the infection, and cFSGS may be driven along with chronicity of the virus. Still, steroids may hasten recovery and reduce morbidity associated with the nephrotic syndrome. The rapid improvement in
proteinuria despite an increase in GFR suggests that steroids played a role in the recovery. A randomized trial would be necessary to determine the safety and efficacy of steroids for COVID-19 related fSGS.

PO0796
Remote Peritoneal Dialysis Training in a COVID-19-Positive Patient
Aditya V. Jain, Tina S. Samuel, Leslie A. Jansto, Erwin E. Morales, Cybele Ghosssein. Northwestern University Feinberg School of Medicine, Chicago, IL.

Introduction: Training patients in peritoneal dialysis (PD) traditionally requires up to fourteen in-person clinic visits to cover all aspects of care. The COVID-19 crisis has created an unprecedented challenge in educating patients to perform PD safely while minimizing exposure to staff. Telemedicine has been well-received by staff and patients in other aspects of PD care. We present a case of a COVID-19 positive patient who was fully trained in PD using telemedicine.

Case Description: The patient is a 21-year-old man with VATER Syndrome who progressed to ESRD with uremic symptoms. He chose PD as his dialysis modality while awaiting a kidney transplant. Prior to his PD catheter insertion, he tested positive for COVID-19. He was deemed an ideal candidate for PD training via telemedicine and agreed to proceed. For the first two training sessions, he presented to the PD clinic and was placed in a designated isolation room with his personal computer. His PD nurse was in an adjoining room and trained him via video conferencing with the option to enter his room if needed. The patient quickly mastered the procedure in this monitored environment. He completed the remainder of the required education remotely in his home via telemedicine.

Discussion: There are several advantages of telehealth in COVID-19 patients. The risk of viral exposure to healthcare staff and other patients is reduced by limiting trips to the PD clinic. Additionally, reducing the burden of travel saves time and expense for the patient. Patient selection for telehealth learning is critical: the ideal patient must be motivated and technologically savvy. The patient, PD nurse, and nephrologist must jointly determine whether proceeding with tele-learning is feasible and safe. Although remote videoconferencing is not the conventional or optimal method for PD education, it can be used successfully to train patients while minimizing exposure of COVID-19 to staff.

PO0797
Calciphylaxis and COVID-19-Associated Thrombotic Retiform Purpura in a Peritoneal Dialysis Patient
Elly Varma,1 Cynthia M. Magro,1 Jerry Nuovo,1 Frank Liu,1 Vesh Srivatava.2
1Weill Cornell Medicine, New York, NY; 2Rogosin Institute, New York, NY.

Case Description: A 62-year-old female presented to the emergency room with leg pain and edema for 4 weeks. She had recently been started on peritoneal dialysis. Examination revealed tender, indurated retiform dusky plaques on thighs and bilateral leg pain and edema for 4 weeks. She had recently been started on peritoneal dialysis. She was transferred to interventional hemodialysis and started on intravenous sodium thiosulfate 25 grams three times weekly.

Discussion: In COVID-19 era, coagulation abnormalities are becoming increasingly evident. Management of calciphylaxis in PD patients is difficult under current circumstances due to limitations in the ability to provide regular infusions and multi-interventional care. We hypothesize that our patient had an underlying predisposition for calciphylaxis given risk factors of secondary hyperparathyroidism and an additional insult (COVID-19) caused a so-called “second hit” resulting in clinically apparent disease. Atypical presentations of COVID-19 due to a combination of procoagulant state, as well as any preexisting risk factors for calciphylaxis, must be kept in mind.
PO0799
Severe Hypernatremia as an Unintended Consequence of COVID-19-Related Social Distancing
Mahmoud M. Mohamed,1 Stacy A. Johnson,1 Barry M. Wall.12 The University of Tennessee Health Science Center, Memphis, TN; 2Memphis VA Medical Center, Memphis, TN.

Introduction: COVID-19 is primarily a respiratory infection which can have adverse effects on multiple organ systems. There is limited information concerning the harmful effects of social distancing in patients with COVID-19 who are at risk of undernutrition due to avoidance of medical attention due to fear of contracting the novel COVID-19 disease.

Case Description: A 64-year-old African American female with a past history of HIV-related dementia and seizure disorder was residing with family members, requiring assistance for daily living. She was not able to attend to her hygiene and meals. The family reported that over the past 7-10 days, she had become less interactive, remaining bedbound and resistant oral intake. There was an initial reluctance to bring her to the Medical Center due to the fear of contracting COVID-19 infection, given her status. Despite her condition, the family requested to provide social services, home care, mental status progressively worsened, prompting presentation to the emergency department. The patient had a GCS of 10. The patient was nonresponsive, did not follow commands, and only withdrew from noxious stimuli. Vital signs were prominent for fever 37.7°C and blood pressure was 94/64 mmHg. Pertinent laboratory results included: serum sodium 201 mEq/L, plasma osmolality, 431 mOsm/kg, BUN 107 mg/dL, and creatinine of 4.8 mg/dL. CT head showed no acute intracranial pathology. Her condition required ICU care, including mechanical ventilation. COVID-19 screening was negative to 37 % of cases. Here we report a case of a woman with COVID-19 presenting with rhabdomyolysis and AKI.

Case Description: A 48 y/o Hispanic woman with history of HTN, hyperlipidemia and DM type 2 who presented to the ED complaining of shortness of breath, fever, cough, and myalgias four days before presentation she had been diagnosed with COVID-19 and was self-isolating at home. Her symptoms worsened prompting her visit to the ED. Vital signs showed fever of 103.1 F, pulse 86, respirations 37, blood pressure 106/58 and O2 Sat 85% at room air, 95% with nasal canula at 4 L. PE was normal except for tachycardia. Course was initially uneventful on lung with COVID-19. Admission labs were remarkable for AKI and rhabdomyolysis. Serum creatinine was 3.61, BUN, and total CK 106,193. U/A with blood, 5-10 RBC, 5-10 WBC and many bacteria. FeNa was 0.3%. Toxicology panel was negative. Respiratory viral panel was negative. Inflammation A and B markers were initially elevated 2 L bolus of IV NS then continued with balanced crystalloid solutions for volume expansion over the next 3 days. She received treatment with hydroxychloroquine, azithromycin and ceftriaxone for COVID-19 pneumonia. Her symptoms improved and serum creatinine and CK gradually decreased until back to normal levels.

Discussion: Rhabdomyolysis can be seen associated with viral infections. We presented a patient with COVID-19 and rhabdomyolysis. There are no studies establishing a mechanism for COVID-19 induced rhabdomyolysis. Patients with COVID-19 pneumonia are generally kept with negative fluid balance to avoid overload and worsening of ARDS. On the other hand, volume expansion is mainstay management for rhabdomyolysis. Clinicians should have a high suspicion for rhabdomyolysis in patients with COVID-19 presenting with myalgias and AKI. Early recognition of and appropriate treatment is crucial to improve outcomes.
PO0804
Extracorporeal Cytokine Reduction Using Oxiris Blood Purification in COVID-19
Spencer Hodges,1 Marat Abdullah,2 Mark A. Tidwell,1 Daniel L. Landry,1 1Baystate Medical Center, Springfield, MA; 2Kidney Care and Transplant Services of New England, Springfield, MA.

Introduction: Severe COVID-19 infection can cause "cytokine storm" and end-organ dysfunction. Oxiris, a blood-purification filter, was recently approved by the FDA under emergency use authorization for this indication due to its ability to remove cytokines and endotoxin through its AN-69ST membrane. We describe our experience with the first two cases treated at our institution.

Case Description: Case 1: 58-year-old female patient with a baseline creatinine of 0.8 mg/dL. & history of hemoglobin SC disease was admitted with respiratory failure due to COVID-19 infection. She deteriorated on hospital day (HD) 6 and was intubated. She received broad-spectrum antibiotics and convalescent plasma. On HD 15 she had increasing vasopressor requirement, anuric AKI and was started on continuous renal replacement therapy (CRRT). Due to worsening clinical status on HD18 she was started on the Oxiris hemofilter through the CRRT circuit for 48 hours. Oxygenation improved and there was some improvement in inflammatory markers (IM) (table 1), however, the family withdrew care on HD 20.

Case 2: 29-year-old male with no prior past medical history apart from morbid obesity presented with fever and dry cough in the setting of recent COVID-19 exposure. He was found to be COVID-19 positive and rapidly deteriorated with resultant intubation on HD4. He received hydroxychloroquine, doxycycline, remdesivir and convalescent plasma. Oxiris hemoperfusion was initiated on HD8 due to worsening hyponatremia despite high fluid flow of 250 ml/min and dialysate flow of 25 ml/kg/hour with either systemic heparin or the patients for 48 hours with a scheduled filter exchange at 24 hours. We used a blood-purification filter, was recently approved by the FDA under emergency use authorization for this indication due to its ability to remove cytokines and endotoxin through its AN-69ST membrane. We describe our experience with the first two cases treated at our institution.

Discussion: We present our first 2 cases using the Oxiris hemofilter. We treated the patients for 48 hours with a scheduled filter exchange at 24 hours. We used a blood-purification filter, was recently approved by the FDA under emergency use authorization for this indication due to its ability to remove cytokines and endotoxin through its AN-69ST membrane. We describe our experience with the first two cases treated at our institution.

PO0805
Rhabdomyolysis as a Late Complication of COVID-19 Infection
Benjamin Lidgard, Ann M. O’Hare, Sarah F. Sanghavi, Bessie A. Young, University of Washington, Seattle, WA.

Introduction: The 2019 novel Coronavirus (COVID-19) is a betacoronavirus which typically presents with fever, cough, myalgia, and fatigue and can be associated with acute kidney injury (AKI). Recently, several cases of rhabdomyolysis (with and without AKI) have been reported with COVID-19 infection. We present a case of a patient with COVID-19 infection who developed rhabdomyolysis on hospital day 22.

Case Description: A 74-year-old man presented with several weeks of progressive malaise, dyspnea, fatigue, and nausea. He was hypoxic to 87%, febrile (38.8°C) and had diffuse bilateral infiltrates on chest x-ray [Figure 1]. He was intubated on hospital day 1. Testing for COVID-19 by PCR was positive. Creatinine improved from 1.6 to 0.9 mg/dL with 2L of IV fluids. He did not require vasopressors. On hospital day 22, while still intubated, his creatinine increased from 1.4 to 3.8 mg/dL. The level of creatinine phosphokinase (CPK) had was 7393 U/L from 118 U/L on admission, and his plasma free myoglobin was 34,640 mcg/L. Urinalysis was positive for 3+ occult blood, few red blood cells, and many granular casts. His serum creatinine peaked at 6.67 mg/dL on hospital day 26 and subsequently declined to 1.6 by hospital day 33.

Discussion: Rhabdomyolysis is an infrequent complication of COVID-19 infection. While observed, rhabdomyolysis is typically present on admission. This is, to our knowledge, the latest that rhabdomyolysis has been observed in COVID infection. The patient’s inflammatory markers were not re-checked at the time of this event, though worsening inflammation may have provoked this event. Their troponin was mildly elevated, but was not tested. He was not treated with steroids. No bed sores were observed, and the patient had no access to illicit substances. No medications known to cause rhabdomyolysis were given prior to this development. This case report suggests that rhabdomyolysis-related AKI may be a late complication of COVID-19 infection.

Renal Biopsy
Case Description: Case 1, a 28 years old African American female and Case 2, a 58 years old African American male with baseline CKD III, admitted with COVID-19 infection and had acute kidney injury with significant proteinuria with hypalbuminemia. Patients had kidney biopsies. Please see table for all the details.

Discussion: Possible etiologies of acute kidney injury in COVID 19 are tubular injury due to cytokine storm, direct cytotoxic effect and immune mediated glomerulonephritis. Both the patients had collapsing FSGS in addition to tubular injury suggesting injury to the podocytes. Viral particles were not seen on both the biopsies, and hence direct cytotoxic effect was not considered to be the mechanism of renal injury, although viral level below the detection threshold could not be excluded. Collapsing FSGS has been seen with other viral infections including Parvo-virus infection, Cytomegalovirus infection and HIV. Variant of apolipoprotein L1 (APOL1) gene in African Americans have been shown to be associated with FSGS. These two patients had genetic susceptibility due to APOL1 and COVID infection caused interferon surge leading to a second hit. Teaching Points: Renal biopsy should be considered in patients with COVID-19 and Nephrotic range proteinuria. APOL1 testing should be done in patients with African American descent.

Demographic, clinical, laboratory, biopsy findings and follow up.

SARS-CoV-2 infection in the early post-transplant period after a living donor kidney transplant

Case Description: Three LDKT recipients developed COVID-19 in the early post-transplant period and were detected positive for SARS-CoV-2 at day 7, day 19 and 2 months post-transplant. Patients 1 and 2 had received 1 mg/kg of anti-thymocyte globulin (ATG) as induction and patient 3 had received no induction at the time of transplant. Induction agent was reduced in patient 1 and was stopped in patients 2 and 3. Patient 3 developed acute kidney injury with a peak serum creatinine of 2.4 mg/dL, whereas other 2 patients did not develop kidney allograft dysfunction. All 3 patients recovered from SARS-CoV-2 infection with normal renal function at discharge.

Introduction: Coronavirus disease 2019 (COVID-19) pandemic presented multiple challenges for living and deceased donor kidney transplant programs with the likelihood of exposure to severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). We report the course of COVID-19 and immunosuppression in 3 months of living donor kidney transplantation (LDKT) which has not been described previously.

Case Description: Three LDKT recipients developed COVID-19 in the early post-transplant period and were detected positive for SARS-CoV-2 at day 7, day 19 and 2 months post-transplant. Patients 1 and 2 had received 1 mg/kg of anti-thymocyte globulin (ATG) as induction and patient 3 had received no induction at the time of transplant. Induction agent was reduced in patient 1 and was stopped in patients 2 and 3. Patient 3 developed acute kidney injury with a peak serum creatinine of 2.4 mg/dL, whereas other 2 patients did not develop kidney allograft dysfunction. All 3 patients recovered from SARS-CoV-2 infection with normal renal function at discharge.

Discussion: Limited experience of SARS-CoV-2 infection in early post-transplant period is available in deceased donor kidney transplant (DDKT) with serious morbidity and mortality implications. Lymphopenia described in patients with severe illness due to SARS-CoV-2 can be aggravated by recently used higher dose of lymphocyte depleting agent, especially to cover for delayed graft function in DDKT. As compared to previously reported cases of DDKT, our relatively young recipients of LDKT had a milder course, minimal complications and recovered from SARS-CoV-2 infection. We suggest consideration of recipient age, pretransplant isolation and using induction agent basiliximab or lower dose of ATG for a LDKT program during COVID-19 pandemic.

Introduction: During our current pandemic, physicians must exclude COVID-19 in every patient presenting to the hospital with a febrile illness. However, every patient should have a complete work-up done to not miss other disease processes. Here we describe a case of microscopical polyangitis with symptoms succumbing COVID-19 infection.

Case Description: The patient is a 69 yo female with history of HTN who presented with four weeks of polyarthralgia and fevers; this was accompanied by a dry cough and morning stiffness in her shoulders and hips, for which she heavily used ibuprofen. Vital signs were within normal limits. Physical exam showed clear breath sounds with 2+ pitting edema in the lower legs and no rashes. Labs revealed a WBC of 20,000 cells/μL, with four weeks of polyarthralgia and fevers; this was accompanied by a dry cough and morning stiffness in her shoulders and hips, for which she heavily used ibuprofen. Vital signs were within normal limits. Physical exam showed clear breath sounds with 2+ pitting edema in the lower legs and no rashes. Labs revealed a WBC of 20,000 cells/μL, and a platelet count of 25,000. UA showed moderate leukocyte esterase, trace protein, and large granular leukocytes. Microscopic examination of urine revealed no red blood cells or white blood cells. Hemoglobin was 12.0 g/dL, hematocrit was 35%, and mean corpuscular volume was 89.0 fL. Microcytic anemia was present. A complete blood count revealed no leukocytosis. The ESR was 114 mm/hour, and CRP was 23.4 mg/L. UA showed moderate leukocyte esterase, trace protein, and large granular leukocytes. Microscopic examination of urine revealed no red blood cells or white blood cells. Hemoglobin was 12.0 g/dL, hematocrit was 35%, and mean corpuscular volume was 89.0 fL. Microcytic anemia was present. A complete blood count revealed no leukocytosis. The ESR was 114 mm/hour, and CRP was 23.4 mg/L. A diagnosis of rheumatoid arthritis was made, as well as a diagnosis of possible vasculitis. The patient was started on prednisone 40 mg daily and cyclophosphamide 375 mg in 2 weekly for four weeks and was discharged home in stable condition.

Key: TH - Thursday; FR - Friday; SA - Saturday; SU - Sunday; OR - Oral; PO - Poster; PUB - Publication Only

it is 204 mg/L. UA showed moderate leukocyte esterase, trace protein, and large granular leukocytes. Microscopic examination of urine revealed no red blood cells or white blood cells. Hemoglobin was 12.0 g/dL, hematocrit was 35%, and mean corpuscular volume was 89.0 fL. Microcytic anemia was present. A complete blood count revealed no leukocytosis. The ESR was 114 mm/hour, and CRP was 23.4 mg/L. A diagnosis of rheumatoid arthritis was made, as well as a diagnosis of possible vasculitis. The patient was started on prednisone 40 mg daily and cyclophosphamide 375 mg in 2 weekly for four weeks and was discharged home in stable condition.
**Discussion:** Systemic vasculitis remains to be a diagnostic challenge, especially in the era of COVID-19. The overlap in symptoms of COVID-19 and vasculitis is made even more difficult by previous history and histopathological findings coupled with positive ANCA. Despite treatment, almost a quarter of these patients will progress to ESRD. In the era of COVID-19, great care must be taken to diagnose the kidney manifestations of systemic vasculitis.

PO0811
Low-Sodium Disorders and the 2019 Novel Coronavirus Disease (COVID-19)

Jasmee Gill, Xuini S. Guo, Akinwande A. Akinfolarin, Ankit Mehta.

Introduction: COVID-19 have been well characterized with hallmarks of pneumonia and respiratory failure. Hyponatremia is a well reported finding in patients with COVID-19. However only few reports have been directly attributable to the disease. We report three different presentations of hyponatremia in COVID19 patients.

Case Description: 1. 70 year old man with hypertension, diabetes presented with dyspnea. He was clinically septic. Chest X-ray (CXR) showed bilateral interstitial and airspace opacities. Laboratory data revealed, serum sodium 122 meq/L, serum osmolality 264 mosm/kg, urine osmolality 579 mosm/kg and urine sodium 153 mmol/L. A diagnosis of hyponatremia secondary to the Syndrome of Inappropriate Antidiuretic Hormone (SIADH) was made and the patient was treated with oral urea and fluid restriction. 2. 50 year old man with chronic alcohol abuse presented with bilateral calf soreness. CXR revealed increased interstitial markings. Laboratory data showed serum sodium 113 meq/L, serum osmolality 251 mosm/kg, urine osmolality 426 mosm/kg and urine sodium 148 mmol/L. Hyponatremia was attributed to a low solute state. Serum sodium improved with normal saline infusion. 3. 69 year old female with hypertension admitted with vomiting and diarrhea. CXR showed diffuse pulmonary infiltrates. Initial laboratory data revealed serum sodium of 126 meq/L, serum osmolality 260 mosm/kg. Serum sodium recovered as diarrhea resolved. However, eight days after starting therapy with Selinexor, a nuclear transport inhibitor, serum Na declined to 128 meq/L, serum osmolality 260 mosm/kg. SIADH was attributed to Selinexor therapy. Sodium recovered with oral sodium chloride therapy and fluid restriction.

Discussion: Incidence of Hyponatremia due to SIADH in community acquired pneumonia is 8-31% in adult patients. To the best of our knowledge, there have only been two case reports of SIADH in COVID-19 disease from Switzerland. Hence, it is unclear if SIADH is the predominant presentation of hyponatremia with COVID-19. The etiology of hyponatremia in COVID-19 patients is unclear and needs further research.

PO0812
COVID-19 Short-Term Outcomes of AKI and Chronic Hemodialysis

Introduction: Acute kidney injury (AKI), albuminuria and hematuria are common and in some patients in COVID-19 in addition to viral pneumonia, hypercoagulability and hyperinflammation. We present short-term outcomes of 21 COVID-19 patients with AKI and CRRT and the clinical course of 40 chronic hemodialysis (HD) patients with Covid-19.

Case Description: Twenty-one non-CKD Covid-19 infected patients with AKI required mechanical ventilation and CRRT at the ICU, 20 were males, average age was 59.7 years (y), average BMI 29 kg/m2, 33 % had diabetes. The typical scenario was a normal/slightly elevated creatinine level at admission, normalizing after iv fluids, but rising creatinine from day 3-4 and start of CRRT on day 8 (median). Urinary analysis was available in eight patients, of which seven had albuminuria and/or hematuria. So far eight patients (38 %) have died. Dialysis has been discontinued in nine patients (43 %), median time 17 days in dialysis (range 1-35 days), follow up of 1-4 weeks. Patients 3-4 weeks on CRRT and some had a creatinine(Cr) of 7.87mg/dl. Urinalysis revealed active sediment with 55 RBC/hpf, 65 WBC/hpf, and nphretic range proteinuria: 5 gm/gm of creatinine. He was initiated on renal replacement therapy and received convalescent plasma along with Tocilizumab for the treatment of COVID-19. Serologic testing revealed a positive perinuclear (p)-ANCA (1:320), myeloperoxidase (32.5). Kidney biopsy was consistent with a pauci immune glomerulonephritis; cellular crescent present in 40% of glomeruli. He received pulse dose steroids and Rituximab. The patient had a good clinical response and was able to discontinue hemodialysis and serum Cr decreased to 3.5mg/dl. Case Two: 46 year old South Asian male presented with rash from leukocytoclastic vasculitis and was diagnosed with COVID-19. He had an AKI, serum Cr peaked at 4.0mg/dl with proteinuria, leukocyturia, and microhematuria on urinalysis. Cytoplasmic(c)-ANCA and proteinase-3(PR-3) were positive. A kidney biopsy was performed which revealed a necrotizing glomerulonephritis. He was treated with steroids and Rituximab with a positive response, Cr decreased to 2.0mg/dl.

Discussion: It is now well known that SARS-CoV-2 affects organs outside of the respiratory system, with the kidneys being a usual target. The most commonly reported presentation of COVID-19 and the kidneys is AKI, the etiology of which is predominantly acute tubular necrosis (ATN). Collapsing GN is by far the most described glomerular presentation of COVID-19 and the kidneys is AKI, the etiology of which is predominantly acute tubular necrosis (ATN). Collapsing GN is by far the most described glomerular presentation of COVID-19, but collapsing GN can also be seen in the setting of coronavirus disease 2019 (COVID-19). The etiology of collapsing GN in the setting of COVID-19 is unclear and needs further research.

PO0813
ANA-Associated Vasculitis Under a COVID-19 Mask

Rui Song, Srikanth Thiruvuruduoorthy, Jared Hassler, Ziauddin Ahmed, Serban Constantinescu, Avrum Gillespie. Lewis Katz School of Medicine at Temple University, Philadelphia, PA.

Introduction: Ground glass opacities (GGO) on CT scan are the hallmark of COVID-19. GGO can also be seen in ANA-associated lung injury. Additionally, both can present with kidney injury. We report a case of presumed COVID-19 with AKI which was actually severe ANA-associated vasculitis.

Case Description: A 74-year old female with a history of hypertension and diabetes, who presented with a week of chills, cough, dyspnea, and watery diarrhea, and a creatinine of 10.2 mg/dl (baseline creatinine 1.02 mg/dl). A month prior to admission, she was treated for presumed pulmonary eosinophilia, followed by otitis media, and then bacterial sinusitis with oral ciprofloxacin. Despite a negative swab, she was admitted with suspicion of COVID-19 given GGO seen on CT scan and an exposure history at her senior home. She was treated per the COVID-19 protocol: IV methylprednisolone 125mg, azithromycin, ceftriaxone, and furosemide. Serum creatinine went up to 11.5 mg/dl. ANA was suspected as urine microscopy showed granular casts and no dysmorphic RBC or cellular/WBC/RBC casts. After a repeat negative swab and improvement in respiratory symptoms yet worsening renal function requiring hemodialysis, a full serologic workup was performed. Positive results include p-ANCA (1:320), MPO (49), and ANA (1:160 homogenous) without hypocomplementemia. Other autoimmune markers including anti-GBM antibody were negative. A kidney biopsy was performed and showed pauci-immune crescentic glomerulonephritis (GN) with cellular crescents in more than 80% of the glomeruli with minimal interstitial fibrosis and tubular atrophy. Given the frailty of this patient, she was treated with oral prednisone and rituximab instead of cyclophosphamide. She remained on intermittent hemodialysis and tolerated the treatment well.

Discussion: This case emphasizes the importance of detecting pulmonary-renal syndrome in the era of COVID-19. Given the current global pandemic and a high-volume of infected patients coupled with the lack of sensitivity of the SARS-CoV-2 assays, it is possible to miss this relatively rare ANA-associated vasculitis. Patient with rapid proliferative GN feature and lung symptoms should be further worked up to avoid missing an ANA-associated vasculitis. COVID-19 may actually provoke ANA-associated vasculitis and further testing is underway.

PO0814
Antineutrophil Cytoplasmic Antibody (ANCA) Vasculitis with Glomerulonephritis in COVID-19

Yuriy Khain, Vanesa Bjoj, Kenar D. Jhaveri, Nupur N. Uppal. Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.

Introduction: Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) and the disease it inflicts, coronavirus disease 2019 (COVID-19), has become a global pandemic in 2020. To date, only one case of ANCA associated vasculitis (AAV) with COVID-19 has been reported from Iran. We describe the first two cases of AAV and glomerulonephritis in the United States.

Case Description: Case one: 64 year old African American male with a distinct (>10years) history of cryptogenic organizing pneumonia presented to the hospital with hypoxic respiratory failure secondary to COVID-19. He had an acute kidney injury (AKI) with eGFR 9.1 and creatinine(Cr) of 7.87mg/dl. Urinalysis revealed active sediment with 55 RBC/ hpf, 65 WBC/hpf, and nephritic range proteinuria: 5 gm/gm of creatinine. He was initiated on renal replacement therapy and received convalescent plasma along with Tocilizumab for the treatment of COVID-19. Serologic testing revealed a positive perinuclear (p)-ANCA (1:320), myeloperoxidase (32.5). Kidney biopsy was consistent with a pauci immune glomerulonephritis; cellular crescent present in 40% of glomeruli. He received pulse dose steroids and Rituximab. The patient had a good clinical response and was able to discontinue hemodialysis and serum Cr decreased to 3.5mg/dl. Case Two: 46 year old South Asian male presented with rash from leukocytoclastic vasculitis and was diagnosed with COVID-19. He had an AKI, serum Cr peaked at 4.0mg/dl with proteinuria, leukocyturia, and microhematuria on urinalysis. Cytoplasmic(c)-ANCA and proteinase-3(PR-3) were positive. A kidney biopsy was performed which revealed a necrotizing glomerulonephritis. He was treated with steroids and Rituximab with a positive response, Cr decreased to 2.0mg/dl.

Discussion: It is now well known that SARS-CoV-2 affects organs outside of the respiratory system, with the kidneys being a usual target. The most commonly reported presentation of COVID-19 and the kidneys is AKI, the etiology of which is predominantly acute tubular necrosis (ATN). Collapsing GN is by far the most described glomerular presentation of COVID-19, but collapsing GN can also be seen in the setting of coronavirus disease 2019 (COVID-19). The etiology of collapsing GN in the setting of COVID-19 is unclear and needs further research.

Underline represents presenting author.
**Introduction:** Rhabdomyolysis is characterized by the release of intracellular muscle contents into the circulation. Of the 1099 patients affected by Covid-19 in China, only 0.2% had rhabdomyolysis.

**Case Description:** A 52 year old African American female with past medical history of Diabetes and hypertension presented to the ER with 7 days of worsening fever, chills, myalgias, nausea, vomiting, dyspnea, loss of sense of taste and smell. Her home medications included metformin and Candesartan-HCTZ, however, she had been off medications for a week. She was seen with the chief complaints of fever, cough, dyspnea, and headache. Her vital signs on presentation were: BP 100/60 mmHg, HR 104 bpm, and oxygen saturation of 92%. Physical examination was remarkable for diminished and diffuse coarse breath sounds. Lab work-up showed serum creatinine of 2.99 mg/dl (baseline 1.19 mg/dl) with an estimated GFR of 26 ml/min. Urinalysis revealed protein > 500 mg/dl, RBC 25, and presence of coarse granular casts. Urine protein-creatinine ratio was 3.2. Serology was negative for ANA, ANCA, and anti-proteinase antibodies, as well as hepatitis and HIV panels. Serum C3 and C4 levels were within normal limits. Viral PCR of nasopharyngeal aspirate was positive for SARS-CoV-2. Home medications lisinopril and hydrochlorothiazide were held on admission, and he was started on intravenous fluids, azithromycin, and hydroxychloroquine. On day 4, serum creatinine trended up to 3.29 mg/dl and potassium was 4 mmol/L but since the patient was oliguric, hemodialysis (HD) was started. Serum creatinine then trended to a high of 15 mg/dl, urea nitrogen to 102 mg/dl and serum potassium level to 6.9 mmol/L despite multiple HD sessions. Meanwhile, his oxygen requirement also increased to 15L. After 10 days of daily HD sessions, serum potassium came down to 4.3 mmol/L but he ultimately required HD post discharge.

**Discussion:** Previous literature has discussed SARS-CoV-2 association with rhabdomyolysis. ACE2 of RAS and proximal tubular cells causing hypokalemia. To the best of our knowledge this would be the first documented case of hemodialysis refractory hyperkalemia seen with SARS-CoV-2 infection. One of the mechanisms for kidney injury is a direct viral induced cytopathic effect, which we believe held true for our patient. As viremia cleared, the kidney function improved though it did not return to baseline. In our case, development of hyperkalemia despite hemodialysis makes it more interesting, but it remains unclear how.

---

**PO0187**

**The Role of Point-of-Care Ultrasound in the Management of Dialysis Patients with COVID-19**

**Nathanial C. Reisinger:** 1Abhilash Koratula. 1Medical College of Wisconsin, Milwaukee, WI; 2University of Pennsylvania, Philadelphia, PA.

**Introduction:** Much of the burden for management of outpatient dialysis patients with suspected or confirmed Coronavirus Disease 2019 (COVID-19) has fallen to the dialysis units. Symptom recognition is not straightforward as these patients often have multiple putative etiologies for dyspnea especially given concomitant pulmonary congestion due to fluid overload. In this context, point-of-care ultrasonography (POCUS), particularly lung ultrasound (LUS) is a valuable diagnostic tool for nephrologists taking care of these patients. POCUS is free of ionizing radiation, can be performed at the bedside, and has comparable diagnostic accuracy to chest CT scan for most lung pathologies. We present a case study to illustrate the role of POCUS in dialysis patients.

**Case Description:** A 79-year-old woman with a history of ESKD on maintenance hemodialysis was found to be hypoxemic with an oxygen saturation of 90% on room air. Bedside LUS demonstrated patchy areas of pleural thickening and irregularity as well as confluent B-lines and scattered consolidations consistent with viral pneumonia [Figure]. Focused cardiac US did not reveal any overt signs of fluid overload. She tested positive for COVID-19 and improved with supportive care. She continued to receive dialysis on a separate shift for COVID-19 positive patients.

**Discussion:** In addition to aiding in diagnosis, POCUS limits staff exposure to the virus during transportation and avoids the downtime for radiology room decontamination unlike CT. Most handheld US devices can be completely encased in a standard plastic transducer cover that can be discarded after each use. We propose that dialysis units adopt LUS as a bedside tool to diagnose and monitor the extent of pulmonary involvement in patients with COVID-19 and differentiate from other causes of dyspnea. CT scan can be reserved for those with equivocal LUS findings or underlying chronic lung disease that interferes with interpretation.
Continuous renal replacement therapy (CRRT) while better tolerated is a limited resource. Such patients may not tolerate hemodynamic shifts induced by hemodialysis (HD).

Ventilated patients diagnosed with acute respiratory distress syndrome (ARDS) due to COVID-19 have been particularly challenging for Nephrologists managing patients on continuous renal replacement therapies (CRRTs). This has been well documented in numerous articles and has posed to be a difficult obstacle for those caring for Covid-19 positive patients. This has overall high mortality.

CRRT was continued however multiple issues with filter clotting were encountered. One day later they were intubated for tachypnea and worsening acidosis. They were admitted during this period to the ICU with COVID-19 and AKI showed 7 had normal ferritin levels to 73 pg/mL. Case 2: A 55 year old male on CVVHDF with the M150 filter had a serum ferritin level progressively increasing to 2377 ng/mL and multiple clotting events.

The patient was started on CRRT as thrombocytopenia worsened and there was a concern for heparin-induced thrombocytopenia. He was extubated after 15 days and recovered renal function. Data on 9 other patients therefore, clinicians might have low clinical suspicion for rhabdomyolysis.

Acute peritoneal dialysis (PD) remains a feasible RRT modality in patients on mechanical ventilation. Nevertheless, the hesitance to use PD for fear of increasing intrathoracic pressure (IAP) with dwellings leads to altered respiratory mechanics. Our case demonstrates that acute PD has no adverse respiratory outcomes in a COVID-19 patient.

Case Description: A 42 year-old Hispanic male with end stage renal disease newly initiated on urgent start PD for 1 week presented with acute hypoxic respiratory failure secondary to ARDS from COVID-19. Upon presentation, he was intubated and initiated on lung protective ventilator strategies. Due to high ventilatory requirements (PEEP 15, FiO2 100%) with severe volume overload HD was selected in lieu of PD. He underwent PD run with minimal volume removal due to high daily intake. Due to limited availability of CRRT, he was transitioned to continuous PD via cyclic (fill volume 2L, every 4hr). FiO2 reduced to 40%, peak and plateau pressures did not change, and he was able to maintain adequate ventilation with unchanged tidal volumes while on PD. He eventually received a tracheostomy.

Discussion: COVID-19 has challenged providers with managing critically ill patients in the setting of limited resources. In our case of ARDS with ARF, we transitioned from HD to acute PD in order to facilitate fluid removal in lieu of CRRT. The ICU team feared increased IAP from PD would worsen lung compliance and hypoxemia from atelectasis. A prospective study by Almeida et al showed that acute PD in mechanically ventilated patients was associated with increased IAP, but lung compliance, oxygenation, and PaO2/ FiO2 increased. Our case noted similar observations without adverse event. Acute PD was able to meet the demands on his daily intake without any compromise to ARDS lung protective ventilator strategies.
excessive immune response and cytokine storms which often seen in COVID-19 can promote to high catechol and rhabdomyolysis and therefore it will contribute to rapid worsening on renal function. Early detection and promptly supportive treatment with RRT may help to improve the vital prognosis of COVID-19.

**Introduction:** Continuous renal replacement therapy (CRRT) is a therapy used in critically ill patients and is of particular importance with COVID-19. We present a patient with COVID-19 on propofol for sedation with persistent filter clotting issues found to have severe hypertriglyceridaemia (SHT) corrected with lipopheresis. This case highlights the importance of managing all aspects of CRRT, the highly inflammatory state of COVID-19 and supply chain management during high utilization periods.

**Case Description:** A 41-year-old male with severe obesity and TBD presented to the hospital with shortness of breath and fevers found to have COVID-19. The patient was intubated on presentation due to hypoxemic respiratory failure and admitted to the ICU. The patient was placed on Propofol for sedation. The patient presented with normal kidney function but peri-intubation had a rapid rise in creatinine to 4.00 mg/dL and was started on CRRT. It was noted that the CRRT circuit was continuously clotting within 30 minutes of initiation. The patient was also noted to have rising CPK levels and a concern for Propofol Infusion Syndrome (PRIS) was raised. A triglyceride level was checked and found to be 3286 mg/dL. The patient was initiated on insulin and heparin drips however due to CRRT issues and inadequate clearance a decision was made to perform lipopheresis to rapidly correct SHT. Patient underwent lipopheresis and the triglycerides dropped to 426 mg/dL. The heparin drip was continued and filter life greatly improved. The patient was continued on CRRT and adequate clearance was achieved.

**Discussion:** This case highlights important points for CRRT, COVID-19 and supply chain management. This patient was found to have PRIS however COVID-19 infection, possibly associated with a milder form of respiratory disease and high risk APOL1 genotype, emphasizing the need for ongoing vigilance and further investigation into this phenomenon.

Severe Hypertriglyceridaemia Leading to CRRT Malfunction in a COVID-19 Patient

Rashid Parikh, Richard L. Barnett. Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.

**Introduction:** Continuous renal replacement therapy (CRRT) is a therapy used in critically ill patients and is of particular importance with COVID-19. We present a patient with COVID-19 on propofol for sedation with persistent filter clotting issues found to have severe hypertriglyceridaemia (SHT) corrected with lipopheresis. This case highlights the importance of managing all aspects of CRRT, the highly inflammatory state of COVID-19 and supply chain management during high utilization periods.

**Case Description:** A 41-year-old male with severe obesity and TBD presented to the hospital with shortness of breath and fevers found to have COVID-19. The patient was intubated on presentation due to hypoxemic respiratory failure and admitted to the ICU. The patient was placed on Propofol for sedation. The patient presented with normal kidney function but peri-intubation had a rapid rise in creatinine to 4.00 mg/dL and was started on CRRT. It was noted that the CRRT circuit was continuously clotting within 30 minutes of initiation. The patient was also noted to have rising CPK levels and a concern for Propofol Infusion Syndrome (PRIS) was raised. A triglyceride level was checked and found to be 3286 mg/dL. The patient was initiated on insulin and heparin drips however due to CRRT issues and inadequate clearance a decision was made to perform lipopheresis to rapidly correct SHT. Patient underwent lipopheresis and the triglycerides dropped to 426 mg/dL. The heparin drip was continued and filter life greatly improved. The patient was continued on CRRT and adequate clearance was achieved.

**Discussion:** This case highlights important points for CRRT, COVID-19 and supply chain management. This patient was found to have PRIS however COVID-19 infection, possibly associated with a milder form of respiratory disease and high risk APOL1 genotype, emphasizing the need for ongoing vigilance and further investigation into this phenomenon.
and prednisone induction and is on maintenance prednisone. All 3 patients recovered in SLE; ESRD secondary to lupus nephritis. She had been treated with cyclophosphamide typical features of COVID 19 including hypoxia, fever; extensive bilateral interstitial underlying vasculitides who were admitted with respiratory distress due to COVID 19. Excessive and uncontrolled immune response is thought to be one of the important severe manifestations of the disease often associated with high morbidity and mortality. Called SARS-CoV-2. End Stage Renal Disease patients are at high risk for developing outcomes of COVID 19 in patients who had received cyclophosphamide previously. This case illustrates the complexity of dialysis vascular access and some of the potential complications that are associated with it. It also highlights the importance of timely action to rescue any failed access. As outlined by the statement of ASDIN and VASA, dialysis vascular access should always be treated as a priority, and procedures to salvage it ought to be considered essential. This should also be the case in any future unforeseen restrictions to surgical procedures, such as pandemics or natural disasters.

### PO0827

Kevin S. Hsu, Rasha Alawih, Khaled Boubes. The Ohio State University, Columbus, OH.

**Introduction:** Well-functioning dialysis access is of utmost importance as the lifeline of those with end stage kidney disease (ESKD). With the evolution of COVID-19 pandemic, elective procedures were placed on hold. The American Society of Diagnostic and Interventional Nephrology (ASDIN) and Vascular Access Society of the Americas (VASA) issued a joint position statement on March 24, 2020, designating dialysis vascular access procedures to be “essential.” We present a case with a series of complications that could have been prevented had the patient undergone a timely thrombectomy procedure.

**Case Description:** A 62 year old woman with ESKD undergoing hemodialysis through an upper arm arteriovenous fistula (AVF) presented with a thrombosed AVF in early March 2020 (before the ASDIN statement was issued). She was evaluated by the surgical team; however, due to restrictions to surgical procedures at the time, she did not undergo a thrombectomy and had a right internal jugular tunneled dialysis catheter (TDC) inserted instead. This was complicated by a superior vena cava thrombosis a few weeks later. The TDC was then removed and she had a right femoral TDC placed. She was started on anticoagulation. Her right femoral TDC was complicated by tunnel infection, necessitating its removal and subsequent placement of a left femoral TDC.

**Discussion:** This case illustrates the complexity of dialysis vascular access and some of the potential complications that are associated with it. It also highlights the importance of timely action to rescue any failed access. As outlined by the statement of ASDIN and VASA, dialysis vascular access should always be treated as a priority, and procedures to salvage it ought to be considered essential. This should also be the case in any future unforeseen restrictions to surgical procedures, such as pandemics or natural disasters.

### PO0829

**Renal Biopsy Findings in Patients with COVID-19 Infection**

Tuvet Hong T. Tran, Ming Wu, NYU Langone Health, New York, NY.

**Introduction:** COVID-19 infection is caused by severe acute respiratory syndrome-2 (SARS-CoV-2). SARS-CoV-2, using its Spike protein, interacts with angiotensin converting enzyme-II (ACE2) protein expressed in human kidneys. Upon internalization, host cells may go through pyroptosis, a process characterized by membranous pore formation, cytokine storm and cell death. We report light microscopy (LM), immunofluorescence microscopy (IF), and electron microscopy (EM) findings in renal biopsies of patients with COVID-19 to further understand the pathological process.

**Case Description:** 10 patients were biopsied, age range 25-63 years. 7 were confirmed by the real-time chain reaction (PCR) via nasopharyngeal swab. 3 patients were suspected, but PCR-negative. Common comorbidities include hypertension, hyperlipidemia, and obesity. Patients had AKI with elevated creatinine, range 1.2 to 13.48 mg/dL. Kidney ultrasound showed enlargement and increased echogenicity. Biopsies were performed 9-71 days from symptom onset of such as fever, cough, and diarrhea. Tissue was fixed in formalin and processed for LM. Fresh frozen tissue was utilized for IF. Tissue was fixed in parafomaldehyde and processed for EM. All had acute tubular injury and viral particles on EM (Figure). Patients received supportive care. None required ventilation, but 4 required hemodialysis. Survival rate is 100% (8-12 weeks).

**Discussion:** Renal biopsies were evaluated in 7 confirmed and 3 suspected COVID-19 patients. Although PCR is the gold standard, it is known to have a 15% false negative rate. This may be due to low viral loads and antibody testing may be warranted in suspected PCR-negative patients. Coronavirus particles are reported to measure 50-200 nm, and SARS-CoV-2 50-140 nm. Viral particles were seen in all 10 patients. The particles are contained in vesicles or sacs, and can be found in podocytes, endothelial, and tubular epithelial cells. This may contribute to intrinsic injury resulting in AKI seen in patients.

AKI in the Setting of COVID-19: Histopathologic and Ultrastructural Findings in Postmortem Kidney Biopsy

Pouneh Golmai,1 Christopher P. Larsen,2 Maria V. DeVita,1 Samuel J. Wahl,1 Astrid Weins,1 Helmut G. Rennke,1 Vanessa Bijol,1 Jordan L. Rosenstock,1 Lenox Hill Hospital, New York, New York; 2Arkana Laboratories, Little Rock, Arkansas, USA; Little Rock, AR; Brigham and Women’s Hospital, Boston, MA; Hofstra Northwell School of Medicine at Hofstra University, Donald and Barbara Zucker School of Medicine at Hofstra University, Hempstead, NY.

**Background:** COVID-19 has been associated with a very high risk of AKI. The pathophysiology of the AKI is unclear with conflicting reports regarding the presence of direct infection of the kidney with SARS-CoV2.

**Methods:** Postmortem kidney biopsy was performed in adult patients with confirmed COVID-19 and stage 2-5 AKI. Biopsies were examined using light and electron microscopy. Immunohistochecistry and RNA in situ hybridization were performed for SARS-CoV2.

**Results:** 12 patients (83% male) with mean age of 70±13 years underwent biopsy. Mean baseline and peak creatinine were 1.0 and 5.3 mg/dL, respectively. Renal replacement therapy was required in 8 (67%) patients (Table 1). All 12 patients had a pathologic diagnosis of acute tubular injury with focal acute tubular necrosis (Table 2). There was no glomerulitis, vasculitis, or thrombotic microangiopathy. There were no characteristic viral particles on electron microscopy and there was no evidence of SARS-CoV-2 on immunohistochecistry in the renal biopsy specimens.

**Conclusions:** AKI in patients with COVID-19 infection was associated with acute tubular injury and focal epithelial necrosis in all patients. There was no evidence of direct viral infection. It appears unlikely that SARS-CoV-2 causes renal injury by direct infection.
Kidney Injury Molecule 1 Is a Receptor for SARS-CoV-2

**Background:** Acute kidney injury (AKI) is a common feature of Coronavirus disease 2019 (COVID-19) caused by SARS-CoV-2. Kidney Injury Molecule-1 (KIM-1) has been reported to be a receptor for Hepatitis A virus. KIM-1 is a scavenger receptor in kidney epithelial cells, and it has been hypothesized that KIM-1 is a receptor for SARS-CoV-2 and may play an important role in COVID-19-associated AKI.

**Methods:** Liposomal nanoparticles displaying the SARS-CoV-2 spike protein trimmer (S1 and S2) on their surface (virosomes) were generated. We evaluated spike protein and virome uptake by human KIM-1 expressing kidney epithelial cells and human kidney tubuloids, 3D structures of kidney epithelial cells. KIM-1-mediated uptake was compared to uptake by ACE2, a well-known receptor for SARS-CoV-2. Our recently developed specific KIM-1 spike inhibitor, JB-1 was used to further block virome uptake by KIM-1 expressing cells. KIM-1 expression was augmented in the tubuloids by infection with adenovirus vector carrying human KIM-1 cDNA to examine if the virome uptake was enhanced. Protein-protein interaction characteristics between purified SARS-CoV-2 spike protein and S1 binding domain and purified KIM-1 were determined using microscale thermophoresis.

**Results:** KIM-1 expression on kidney epithelial cells markedly enhanced virome uptake, despite no change in ACE2 expression. This KIM-1 specific uptake was inhibited by JB-1. Human kidney tubuloids also endocytosed virosomes, and tubuloids with enhanced KIM-1 expression secondary to infection of KIM-1/adeno virus had increased uptake of virosomes. Using microscale thermophoresis the Kd for interaction between KIM-1 and SARS-CoV-2 spike protein and the receptor binding domain were 56.2+/-28.8 nM and 0.95+/-3.10 nM respectively.

**Conclusions:** KIM-1 is a receptor for SARS-CoV-2. KIM-1 specific uptake of the SARS-CoV-2 virosome suggests that KIM-1 confers efficient SARS-CoV-2 binding in kidney epithelial cells where these cells are expressing KIM-1. The KIM-1 dependent virome uptake by 3D tubuloids indicates this can be a valuable human cell model for studying SARS-CoV-2 interactions and testing for inhibitors. KIM-1 inhibitors, such as JB-1, can be potential therapeutics for SARS-CoV-2 for COVID-19. Kidney tubular intraluminal and systemic circulating levels of KIM-1 ectodomain may be protective by acting as decoy receptor for the virus.

**Serum Induces Major Transcriptional and Epigenetic Changes at COVID-19-Associated Gene Loci in Primary Renal Epithelial Cells**

Kevin Lidberg, Selvaraj Muthusamy, Mohamed Adil, Jonathan Reichel, Jonathan Himmelfarb, Edward J. Kelly, Shreeram Akileshe. University of Washington, Seattle, WA.

**Background:** Tubular epithelial cells express high levels of COVID-19 entry receptors ACE2 and the accessory protease TMPRSS2. High systemic levels of IL-6 and IL-8 may contribute to the “cytokine storm” associated with poor outcome with COVID-19 infection. We sought to understand the regulation of these key genes in a 3D microphysiological system (MPS) containing primary human tubular epithelial cells cultured with human, a surrogate for a disease-state ultratranslate.

**Methods:** Primary human tubular epithelial cells cultured in the 3D MPS were exposed to 0.5 and 2% serum for 48 hours and their transcriptional responses were evaluated by RNA-seq. Observed changes in transcription of secreted proteins were validated by ELISA on MPS effluents. We also orthogonally validated our MPS findings against gene expression and chromatin accessibility (ATAc-seq) data generated from human renal cortex and primary tubular epithelial cells cultured in 2D in the presence of 10% serum.

**Results:** Serum exposure of tubular MPS elicited 535 up and 285 downregulated genes with upregulation of pro-inflammatory and chemotactic cytokines IL6 and IL8 consistently seen across multiple donors. This was associated with increased IL6 and HAVCR1 (KIM-1) protein secretion in MPS effluents. Tubular epithelial cells cultured in 2D with 10% serum expressed higher levels of HAVCR1 (up 4.5x), LCN2 (NAGL, up 6x), IL6 (up 11.2x) and CICL8 (IL8, up 7.6x) compared to renal cortex. In contrast, ACE2 (down 8.6x) and TMPRSS2 (down 4.4x) were significantly downregulated. Analysis of open chromatin regions revealed a stress response signature at these gene loci, indicating active regulation in response to injury.

**Conclusions:** Proteinuria is common in COVID-19 infected patients and we studied serum-exposure, as a model of glomerular dysfunction and subsequent proximal tubule responses in our kidney MPS. Serum induces the expression and secretion of IL6 and IL8, suggesting a localized, pro-inflammatory tubule response. Our epigenetic analysis revealed that COVID-19 associated genes have a stress response signature with implications for inter-individual variability in expression. Our kidney MPS model and data represent a powerful system for studying the complex effects that COVID-19 infection exerts on the kidney.

**Kidney Injury Molecule 1 is a Receptor for SARS-CoV-2**

Takaharu Ichimura,1 Mahmoud L. Nasr,1 Samuel Mon-Wei Yu,1 Yutaro Mori,1 Joseph V. Bonventre.2 Brigham and Women’s Hospital, Boston, MA.

**Background:** Kidney injury molecule-1 (KIM-1), a type-I transmembrane glycoprotein, has been well studied as an specific injury marker for proximal tubules (PT). KIM-1 functions as a receptor for apoptotic fragments through a phagocytic process. KIM-1 (also called TIM-1) serves as a receptor for hepatitis A virus and Ebola virus, and possibly for severe respiratory syndrome-coronavirus (SARS-CoV-1). During the pandemic spread of coronavirus disease 2019 (COVID-19), many patients have suffered from acute kidney injury (AKI) as well as lung damage, Viral uptake has been attributed to interactions with ACE2, a receptor for the virus. The goal of this study was to understand whether there is kidney histological data that KIM-1 may also serve as a receptor for SARS-CoV-2 to infect the PT.

**Methods:** Two patients (one adult and one child) who died of COVID19 and 10 patients with AKI but no COVID19 (control group) were included in the study. All kidney tissue sections were stained for KIM-1 (monoclonal AKGT antibody) and scored from 0 to 3+. Electron microscopy was conducted using kidney tissue of the COVID19+ patients.

**Results:** Both COVID19+ patients had normal pre-mortem levels of serum creatinine (sCr) (adult 0.63 and child 0.17 mg/dl), whereas the control cases all had elevated sCr (1.9-10.7 mg/dl). Control renal biopsies revealed positive KIM-1 staining ranging from 1+ to 3+ along the surface of PT in a patchy pattern involving 20 to 80% of the cortex; no cytoplasmic granular materials were identified. By contrast, the KIM-1 staining in COVID19+ kidneys revealed spotty granular staining in the cytoplasm and diffuse staining in the PT. The staining intensity of 3+ in the COVID19+ kidneys compared to uptake by ACE2, a well-known receptor for SARS-CoV-2. Our recently published kidney tubuloids, 3D structures of kidney epithelial cells. KIM-1-mediated uptake was compared to uptake by ACE2, a well-known receptor for SARS-CoV-2. Our recently developed specific KIM-1 spike inhibitor, JB-1 was used to further block virome uptake by KIM-1 expressing cells. KIM-1 expression was augmented in the tubuloids by infection with adenovirus vector carrying human KIM-1 cDNA to examine if the virome uptake was enhanced. Protein-protein interaction characteristics between purified SARS-CoV-2 spike protein and S1 binding domain and purified KIM-1 were determined using microscale thermophoresis.

**Results:** KIM-1 expression on kidney epithelial cells markedly enhanced virome uptake, despite no change in ACE2 expression. This KIM-1 specific uptake was inhibited by JB-1. Human kidney tubuloids also endocytosed virosomes, and tubuloids with enhanced KIM-1 expression secondary to infection of KIM-1/adeno virus had increased uptake of virosomes. Using microscale thermophoresis the Kd for interaction between KIM-1 and SARS-CoV-2 spike protein and the receptor binding domain were 56.2+/-28.8 nM and 0.95+/-3.10 nM respectively.

**Conclusions:** KIM-1 is a receptor for SARS-CoV-2. KIM-1 specific uptake of the SARS-CoV-2 virosome suggests that KIM-1 confers efficient SARS-CoV-2 binding in kidney epithelial cells where these cells are expressing KIM-1. The KIM-1 dependent virome uptake by 3D tubuloids indicates this can be a valuable human cell model for studying SARS-CoV-2 interactions and testing for inhibitors. KIM-1 inhibitors, such as JB-1, can be potential therapeutics for SARS-CoV-2 for COVID-19. Kidney tubular intraluminal and systemic circulating levels of KIM-1 ectodomain may be protective by acting as decoy receptor for the virus.

**Kidney and Lung ACE2 Expression After an ACE Inhibitor or an Angiotensin II Receptor Blocker: Implications for COVID-19**

Enrique Lopes,1 Jan Wysocki,2 Dinghao Ye,2 Maria Jose Soler,3 Daniel Battle,3 Northwestern University Feinberg School of Medicine, Chicago, IL; 1Northwestern Universit Vall d’Hebron, Hospital Vall d’Hebron, Barcelona, Spain.

**Background:** There have been concerns that ACE inhibitors and Ang II receptor blockers may cause an increase in full length (FL) membrane bound ACE2, the main receptor for SARS-CoV-2, that could enhance the risk and worsen the clinical course of COVID-19. Information on the impact of ACE deficiency and AT1 blockade on ACE2 expression at target sites is required to understand this issue.

**Methods:** Kidneys from two genetic models of ACE ablation and mice treated with captopril or telmisartan were used to examine ACE2 in isolated kidney and lung membranes.

**Results:** In global ACE KO mice, ACE2 protein abundance in kidney membranes was increased by 82% of wild type. In ACE2/ACE KO mice that over-express cardiac ACE protein but has no kidney ACE expression, ACE2 protein in kidney membranes was reduced to 42 % of wild type, p < 0.05. In ACE 8/8 mice that over-express cardiac ACE protein, ACE2 expression was reduced to 27 % of wild type, p < 0.05. ACE2 protein levels in ACE8/8 mice treated with captopril or telmisartan were reduced by 85% and 90%, respectively.

**Conclusions:** Our initial evidence suggests there is an atypical staining pattern of ACE2 in the PT of COVID19+ patients, raising a possibility that KIM-1 may also serve as a receptor for SARS-CoV-2 in the PT.
also decreased (38% of the WT, p<0.01). In kidney membranes from mice that received captopril or telmisartan for 2 weeks there was a reduction in ACE2 protein to the level of 37%, p<0.01 and 76%, p<0.05 of that of vehicle control mice, respectively. In lung membranes the expression of ACE2 was very low and not detected by western blotting but no significant differences in terms of ACE2 activity could be detected in mice treated with captopril (118% of control) or telmisartan (93% of control).

**Conclusions:** Genetic kidney ACE deficiency, suppressed ACE enzyme activity by Captopril or blockade of the AT1 receptor with telmisartan are all associated with a decrease in ACE2 expression in kidney membranes. These findings altogether suggest that ACE2 protein abundance at two potential target sites for SARS-CoV-2 infection is decreased or unaffected by RAS blockers. Since these medications do not increase ACE2 expression in lung or kidney epithelia, we conclude that they likely would not pose a risk for increased susceptibility to COVID-19.

Noninvasive Mapping of the Cellular Response to COVID-19 via Urine Single-Cell RNA Sequencing (scRNAseq)

Jennifer A. Schaubi, Ryann Sohaney, Abhijit S. Naik, Rajasree Menon, Edgar A. Otta, Laura H. Mariani, Celine C. Bertiher, Matthias Ketletser, University of Michigan Health System, Ann Arbor, MI.

**Background:** COVID-19 is associated with a high incidence of AKI. Mapping the transcriptional profiles of kidney and urinary tract derived single cell populations can establish a framework to assess renal molecular response to COVID-19 and emerging treatment strategies.
